Universal Serial Bus Controller (USB)

41.1 Chip-specific USB information

Table 321. Reference links to related information

Topic	Related module	Reference
CM33	Arm Cortex CM33 Platform (CM33)	CM33 Platform
A55	Arm Cortex CA55 Platform (CA55)	CA55 Platform
System memory map		System memory map
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

The chip includes two instances of USB 2.0 Controllers and PHY that can be used as USB OTG port, USB HOST port or USB Device port.

The chip supports the following USB Controller and PHY output signals.

USB Instance	Signal
USB1 Controller	OTG_PWR
USB2 Controller	OTG_OC
USB1 Controller	OTG_OC
USB2 Controller	OTG_PWR
USB1 PHY	OTG_ID
USB2 PHY	OTG_ID

41.2 Overview

USB provides a high-performance functionality that conforms to *Universal Serial Bus Specification Revision 2.0*.

USB comprises two independent USB controller cores (two on-the-go (OTG) controller cores). Each controller core supports UTMI interfaces according to its feature support. Both the controller cores are single-port cores. For the OTG cores, there is only one port, which can be used as either a downstream or an upstream port.

See Features for more information.

NOTE

The term "OTG" is used throughout this document. The USB core hardware does not support the automatic OTG function. It is a dual-role (Host and Device mode) core, which you can implement in software with the hardware assist.

41.2.1 Block diagram

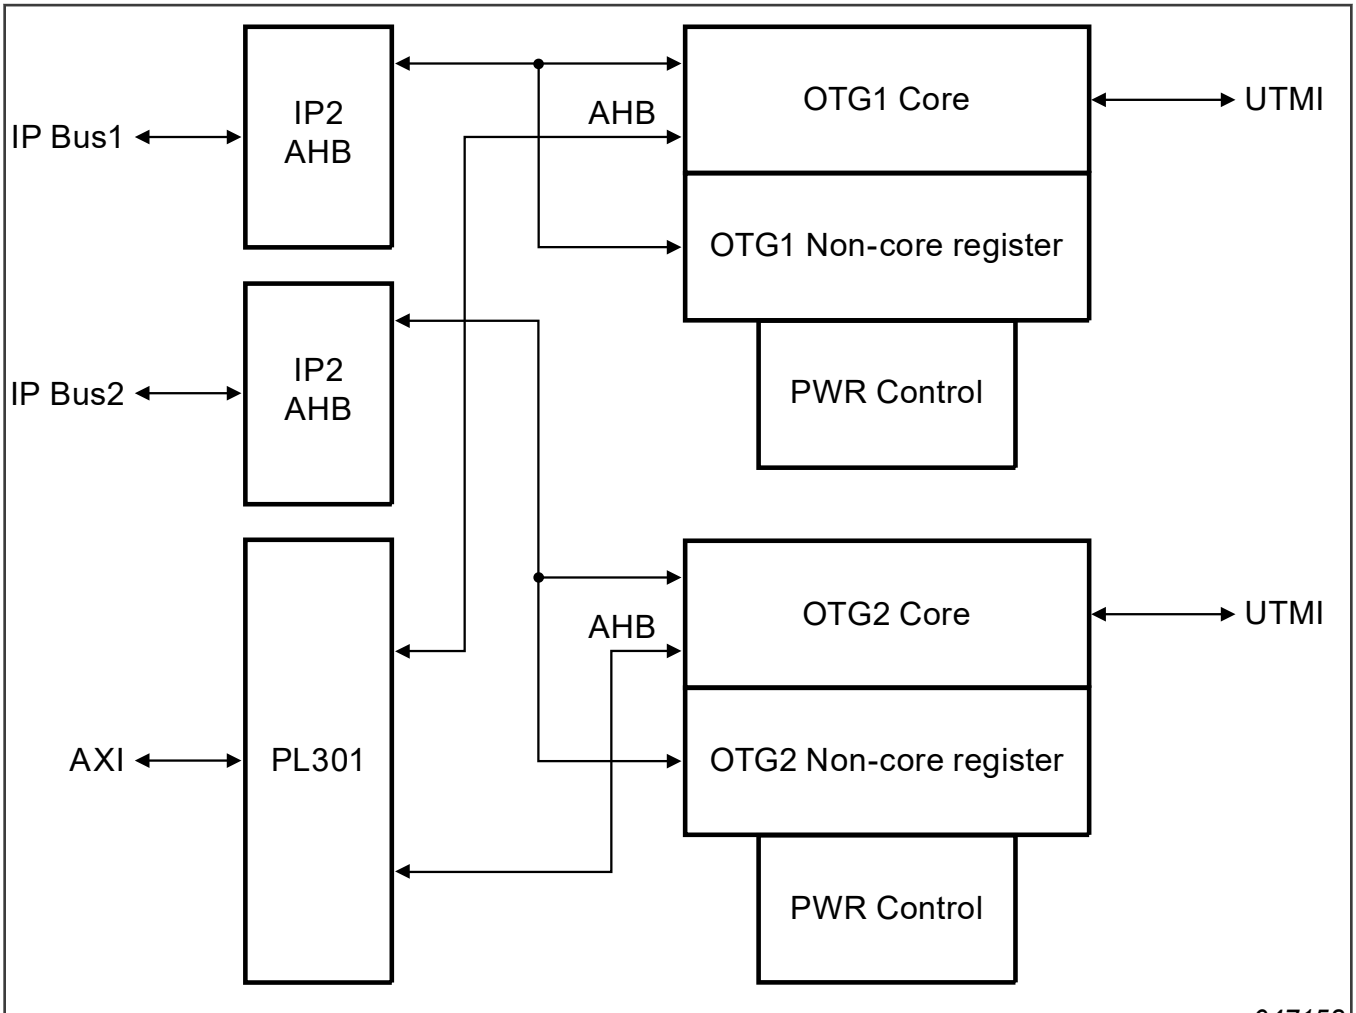

Figure 165. Block diagram

41.2.2 Features

- Includes USB 2.0 controller cores in this chip:
  - Controller core 0 is also named OTG1 core; its connected port is named OTG1 port.
  - Controller core 1 is also named OTG2 core; its connected port is named OTG2 port.
- Support for USB 2.0 controller core 0:
  - High-speed (HS), full-speed (FS), and low-speed (LS) OTG cores
  - HS, FS, and LS UTMI-compliant interface
  - HS, FS, and LS operations in Host mode (with UTMI transceiver)
  - HS and FS operations in Peripheral mode (with UTMI transceiver)
  - OTG signaling, session request protocol, and host negotiation protocol
  - Eight bidirectional endpoints
- USB 2.0 controller core 1:

- HS, FS, and LS OTG core
- HS, FS, and LS UTMI-compliant interface
- HS, FS, and LS operations in Host mode (with UTMI transceiver)
- HS and FS operations in Peripheral mode (with UTMI transceiver)
- Hardware support for OTG signaling, session request protocol, and host negotiation protocol
- Eight bidirectional endpoints

- Low-Power mode with local and remote wake-up capability
- Embedded DMA controller in each core

41.3 Functional description

These sections describe the functionality of the various building blocks of USB.

41.3.1 Submodule sections

41.3.1.1 USB 2.0 controller core 0

USB 2.0 controller 0 is an instantiation of an EHCI-compatible core that supports HS, FS, and LS operations.

In Host mode, this controller core supports HS, FS, and LS operations. In Device mode, it supports HS and FS operations.

41.3.1.1.1 Host mode

The controller supports direct connection of an HS, FS, or LS device with an on-chip UTMI transceiver. The system does not have a separate transaction translator block. The DMA and protocol engine blocks include the transaction translator function, which is normally associated with a USB 2.0 HS hub to support connection to FS and LS devices.

41.3.1.1.2 Peripheral (Device) mode

The following features are supported in this mode:

- Eight bidirectional endpoints
- HS or FS operation
- Support for HNP and SRP
- Remote wake-up capability

41.3.1.2 USB 2.0 controller core 1

The USB 2.0 controller core 1 is an instantiation of the EHCI-compatible core that supports the HS, FS, and LS operations USB 2.0 controller core 1 is identical as core 0.

In Host mode, this controller core supports the HS, FS, and LS operations. In Device mode, it supports HS and FS operations.

41.3.2 Host data structures

For detailed information, see the "Data Structures" chapter in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

41.3.3 Operation references

41.3.3.1 Host operational model

For detailed information, see the "Operational Model" chapter in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

41.3.3.2 Interrupts: host operational model

For detailed information about interrupt capability provided by the EHCI host controller hardware, see the "Interrupts" section in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

41.3.3.3 Host controller initialization

For detailed information, see the "Host Controller Initialization" section in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

41.3.4 EHCI deviations

For the purposes of a dual-role host or device controller with support for On-The-Go (OTG) applications, you must deviate from EHCI specification. Device and OTG operations are not specified in EHCI; therefore, the implementation supported in this core is proprietary.

The Host mode operation of the core is near EHCI compatible, with a few minor differences documented in this section. The following is a summary of these deviations.

Table 322. EHCI deviations

Deviations	Description
Embedded transaction translator	Allows direct attachment of the FS and LS devices in Host mode without the need for a companion controller (see Embedded transaction translator function).
Device operation	Generally disabled; therefore, Device mode is mostly transparent when in Host mode (exceptions are provided in the following sections). See Device operation for more information.
Embedded design interface	Does not have a PCI; therefore, the PCI configuration registers described in the EHCI specification are not applicable (see Embedded design interface for more information).
On-the-Go (OTG) operation	Includes an OTG for port 1.

41.3.4.1 Embedded transaction translator function

The OTG controller supports directly connected FS and LS devices, without requiring a companion controller, by including the capabilities of a USB 2.0 HS hub transaction translator.

Although there is no separate transaction translator block in the system, the transaction translator function that is normally associated with an HS hub is implemented within the DMA and protocol engine blocks. The embedded transaction translator function is an extension of the EHCI interface, but makes use of the standard data structures and operational models that already exist in the EHCI specification to support FS and LS devices.

41.3.4.1.1 Discovery: EHCI deviation

In a standard EHCI controller design, the EHCI host controller driver detects an FS or LS device by analyzing whether PORTSC1[PE] becomes 1 after the port reset operation.

PORTSC1[PE] becomes 1 in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate an HS connection (that is, after chirp completes successfully).

Because this controller has an embedded transaction translator, PORTSC1[PE] always becomes 1 after the port reset operation, regardless of the host device chirp result. PORTSC1[PSPD] indicates the resulting port speed. Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected FS and LS devices or hubs.

Table 323. Summary of EHCI

Standard EHCI	EHCI with embedded transaction translator
After PORTSC1[PE] becomes 1, following a connection and reset sequence, the device or hub is assumed to be in HS.	After PORTSC1[PE] becomes 1, following a connection and reset sequence, PORTSC*n* indicates the device or hub speed.
FS and LS devices are assumed to be downstream from an HS hub; therefore, all port-level controls are performed using the hub class through the nearest hub.	FS and LS devices can either be downstream from an HS hub or directly attached. When an FS or LS device is downstream from an HS hub, the port-level control is performed using the hub class through the nearest hub. When an FS or LS device is directly attached, the port-level control is accomplished using PORTSC*n*.
FS and LS devices are assumed to be downstream from an HS hub with HubAddr = X, where HubAddr > 0 and HubAddr is the address of the hub where the bus transitions from HS to either FS or LS (that is, a split target hub).	FS and LS devices can be either downstream from an HS hub with HubAddr = X [HubAddr > 0] or directly attached, where HubAddr = 0 and HubAddr is the address of the root hub where the bus transitions from HS to either FS or LS (that is, a split target hub is the root hub).

41.3.4.1.2 Operational model

The operational models support the behavior of the transaction translator (see the USB 2.0 specification) and support the EHCI controller moving packets between the system memory and a USB-HS hub. Because the embedded transaction translator exists within the host controller, there is no physical bus between the EHCI host controller driver and the USB FS and LS buses.

The following sections briefly discuss the operational model for how the EHCI and transaction translator operational models are combined without a physical bus existing between them. These sections assume that you are familiar with both the EHCI and USB 2.0 transaction translator operational models.

41.3.4.1.2.1 Microframe pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the host (H) and the bus (B). The embedded transaction translator must use the same pipeline algorithms specified in the USB 2.0 specification for a hub-based transaction translator.

All periodic transfers begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the microframe pipeline implemented in the embedded transaction translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 are ready to execute on the bus in B-frame 0.

When programming the S-mask and C-mask fields in the EHCI data structures to schedule periodic transfers for the embedded transaction translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming those fields for downstream hub-based transaction translators.

After periodic transfers are exhausted, any stored asynchronous transfer is moved. Asynchronous transfers are opportunistic: they must execute whenever possible, and their operation is not tied to H-frame and B-frame boundaries. However, an asynchronous transfer cannot babble through the start of B-frame 0 (SOF).

41.3.4.1.2.2 Split-state machines

The start- and complete-split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded transaction translator.

A start- or complete-split operation occurs by requesting the split to the HS hub. The start-complete split operation is an internal operation to the embedded transaction translator. The following table summarizes the conditions where handshakes are emulated from an internal state instead of actual handshakes to the HS split bus traffic.

Table 324. Summary of handshake conditions

Condition	Emulate TT response
Start-split: All asynchronous buffers full	NAK
Start-split: All periodic buffers full	ERR
Start-split: Success for start of an asynchronous transaction	ACK
Start-split: Start periodic transaction	No handshake (OK)
Complete-split: Failed to find transaction in queue	Bus time out
Complete-split: Transaction in queue is busy	NYET
Complete-split: Transaction in queue is complete	Actual handshake from an LS or FS device

41.3.4.1.2.3 Asynchronous transaction scheduling and buffer management

Table 325. Asynchronous transaction scheduling and buffer management

USB 2.0 specification items	Implementation in the embedded transaction translator
11.17.3	Sequencing is provided and a packet-length estimator ensures that no FS or LS packet babbles exist in the SOF time.
11.17.4	Transaction tracking happens for two data pipes.

41.3.4.1.2.4 Periodic transaction scheduling and buffer management

Table 326. Periodic transaction scheduling and buffer management

USB 2.0 specification items	Implementation in the embedded transaction translator
11.18.6.[1-2]	• Terminate of pending start-split conditions: — End of frame (EOF), and not started in six microframes — Idle for more than four microframes • Terminate of pending complete-split conditions: — EOF — Idle for more than four microframes
11.18.[7-8]	• Transaction tracking for up to 16 data pipes • Complete-split transaction searching

Table continues on the next page...

Table 326. Periodic transaction scheduling and buffer management (continued)

USB 2.0 specification items	Implementation in the embedded transaction translator
	NOTE There is no data schedule mechanism for these transactions other than the microframe pipeline. The embedded TT assumes that the number of packets scheduled in a frame does not exceed the frame duration (1 ms); otherwise, it results in an undefined behavior.

41.3.4.1.2.5 Multiple transaction translators

HCSPARAMS[N_TT] indicates the maximum number of embedded transaction translators that USB currently supports.

41.3.4.2 Device operation

The coexistence of a device operational controller within the host controller has little effect on the EHCI compatibility for host operation, except as discussed in the following sections.

41.3.4.2.1 USBMODE

You cannot initialize the dual-role controller in Host or Device modes. Considering this, you must program USB Device Mode (USBMODE) for a host operation before the EHCI host controller driver can begin EHCI host operations.

41.3.4.2.2 Fields with nonzero values in USB core registers

Some of the reserved fields and reserved addresses in the capability and operational registers are used in Device mode. For Device mode, you must adhere to the following requirements:

- Always write 0 to all EHCI reserved fields (some of which are device fields) in the operational registers. This is an EHCI requirement of the device controller driver.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusively for the device are undefined in Host mode.

41.3.4.2.3 SOF interrupt

The start of frame (SOF) interrupt for Device mode is shared as a free-running 125 µs interrupt for Host mode.

EHCI does not specify this interrupt, but it has been added for convenience and as a potential software time base. See USB Status (USBSTS) and Interrupt Enable (USBINTR) for more information.

41.3.4.3 Embedded design interface

This is an embedded USB host controller, defined by the EHCI specification, and thus does not implement the PCI configuration registers.

41.3.4.3.1 Frame adjust register

Because the optional PCI configuration registers are not included in this implementation, there is no corresponding bit-level timing adjustment (such as the one provided by the Frame Adjust register in the PCI configuration registers). The start of microframes is timed precisely to 125 µs using the transceiver clock as a reference clock. That is, a 60 MHz transceiver clock for 8-bit physical interfaces and full-speed serial interfaces, or a 30 MHz transceiver clock for 16-bit physical interfaces.

41.3.4.4 Miscellaneous variations from EHCI

41.3.4.4.1 Programmable physical interface behavior

This design supports multiple physical interfaces that can operate in different modes if you program the core with software-programmable physical interface modes. Software programmability allows you to select the physical interface part during the board design phase, instead of selection during the chip design phase. Port Status and Control (PORTSC1) provides the control fields for selecting the physical interface operating mode, a capability that EHCI does not define.

41.3.4.4.2 Discovery

41.3.4.4.2.1 Port reset

The port connect methods that EHCI specifies require you to set PORTSC1[PR] for a duration of 10 ms. Because of the complexity involved in supporting the attachment of devices that are not high speed, there are counters already present in the design that can count the 10 ms reset pulse to alleviate the software requirement needed to measure this duration. Perform the following procedure to establish the basic connection.

Table 327. Port reset

Step	Purpose	Programming	Notes
1	Change the port	Wait for the port change interrupt	A port connect change occurs to notify the host controller driver that a device is attached.
2	Reset the device	Write 1 to PORTSC1[PR]	—
3	Reset the device after 10 ms	Write 0 to PORTSC1[PR]	This step, which is necessary in a standard EHCI design, can be omitted with this implementation. If the EHCI host controller driver attempts to write 0 to PORTSC1[PR] when a reset is in progress, the write is ignored and the reset continues until completion.

A port enable change occurs to notify the host controller that the device in now operational, and at this point, the port speed is determined.

41.3.4.4.2.2 Port speed detection

After the port change interrupt indicates that a port is enabled, the EHCI stack must determine the port speed. Unlike the EHCI implementation, which reassigns the port owner for any device that does not connect at HS, this host controller supports direct attachment of non-HS devices.

Consider the following differences for port-speed detection:

- PORTSC1[PO] is read-only and always reads 0.
- PORTSC1[PSPD] provides the current operating speed of the port to the host controller driver.
- PORTSC1[HSP] signifies whether the port is in high speed or in full or low speed. This information is redundant with the aforementioned PORTSC1[PSPD].

41.3.4.4.3 Port Test Control mode

This mode behaves exactly as described in EHCI. An alternate host controller driver procedure is neither necessary nor supported.

41.3.5 Device data structures

This section defines the interface data structures used to communicate control, status, and data between the device controller driver (DCD) software and device controller.

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device queue heads and transfer descriptors.

NOTE

You must ensure that no interface data structure reachable from the device controller spans a 4 KB page boundary.

The data structures defined in this chapter are, from the device controller's perspective, a mix of read-only (RO) and read/write (R/W) fields. The device controller must preserve the RO fields on all data structure writes.

Figure 166 shows the organization of the device endpoint queue head (dQH).

Endpoint queue heads are arranged in an array, in a continuous area of memory indicated by Endpoint List Address (ENDPTLISTADDR). The even-numbered device queue heads in the list support receive endpoints (Out/Setup) and the odd-numbered queue heads in the list are used for transmit endpoints (In/Interrupt). That is, the device queue heads in the list with an even offset support receiver endpoints (Out) and the queue heads in the list with an odd offset are used for the transmit endpoint (In). The device controller indexes into this array based on the endpoint number received from the USB bus. All information necessary to respond to transactions (for all primed transfers) is contained in this list, enabling the device controller to readily respond to incoming requests without having to traverse a linked list.

NOTE

The endpoint queue head list must be aligned to a 2 KB boundary.

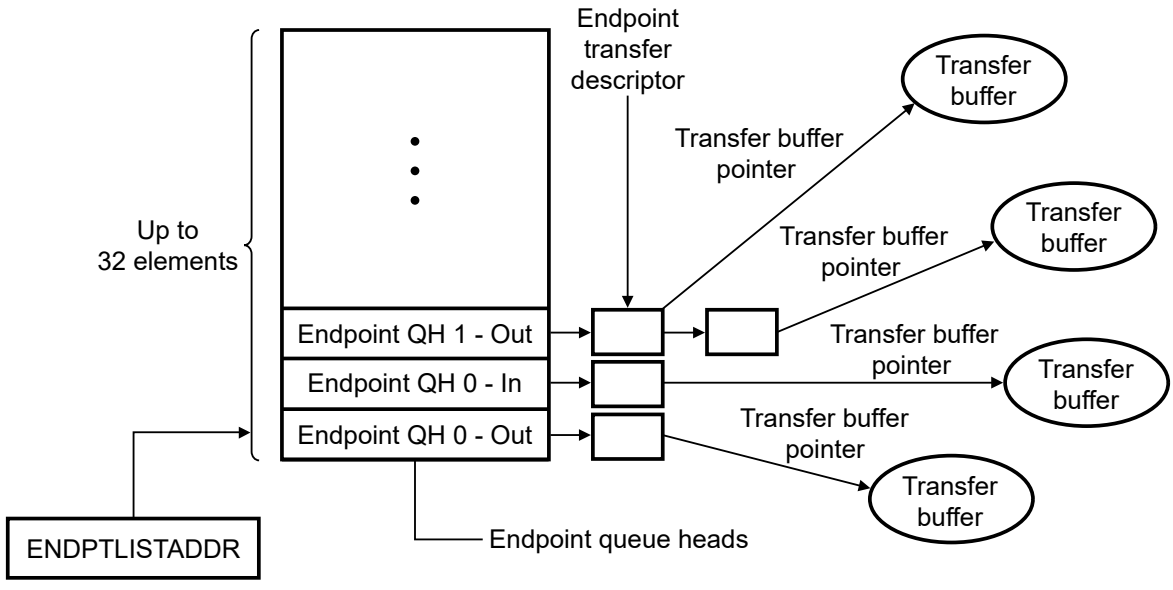

Figure 166. Endpoint queue head organization

41.3.5.1 Device endpoint queue head (dQH)

The dQH is where all transfers for a given endpoint are managed. It is a 48-byte data structure, but must be aligned on 64-byte boundaries.

During priming of an endpoint, the device transfer descriptor (dTD) is copied into the overlay area of the dQH, which starts at the next dTD pointer DWORD and continues through the end of the buffer pointer. After a transfer is complete, the dTD status DWORD is updated in the dTD indicated by the current dTD pointer. When a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the device controller can access the required information with minimal latency.

Table 328. Endpoint queue head (dQH) structure

Host controller read/write Host controller read-only

41.3.5.1.1 Endpoint capabilities and characteristics

This DWORD specifies static information about the endpoint; in other words, this information does not change over the lifetime of the endpoint. The device controller software must not attempt to modify this information when the corresponding endpoint is enabled.

Table 329. Endpoint capabilities and characteristics

Field	Function
31-30 MULT	Multiplier Indicates the number of packets executed per transaction description. • 00 – Execute *n* transactions as demonstrated by the USB variable length packet protocol, where *n* is computed using dQH and dTD. • 01 – Execute one transaction • 10 – Execute two transactions • 11 – Execute three transactions **NOTE** You must write 00b to this field for non-ISO endpoints, and 01b, 10b, or 11b, as needed, for ISO endpoints.
29 ZLT	Zero-Length Termination Select Enables a zero-length packet to terminate transfers, where the total transfer length is a multiple of the maximum packet length. This field is not relevant for isochronous transfer types. • 0 – Enable a zero-length packet to terminate transfers equal to a multiple of the maximum packet length (default) • 1 – Disable the zero-length packet on transfers that are equal in length to a multiple maximum packet length
28-27 Reserved	Reserved for future use; must be 0.
26-16 Maximum Packet Length	Maximum Packet Length Corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field can contain is 400h (1024).
15 IOS	Interrupt On Setup Used for control type endpoints to indicate whether USBSTS[UI] is configured in response to a setup being received.
14-0 Reserved	Reserved for future use; must be 0.

41.3.5.1.2 Transfer overlay-endpoint queue head

The seven DWORDS in the overlay area represent a transaction working space for the device controller.

The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, it does not read the associated endpoint.

After an endpoint is ready, the device controller copies the dTD into the queue head overlay area. Until a transfer is expired, you must not write to the queue head overlay area or the associated transfer descriptor. After the transfer is complete, the device controller writes the results back to the original transfer descriptor and advances the queue.

See Device endpoint transfer descriptor (dTD) for a description of the overlay fields.

41.3.5.1.3 Current dTD pointer

The device controller uses the current dTD pointer to locate the transfer in progress. This word is for device controller (hardware) use only, and the DCD software must not modify it.

The following table describes the dTD pointer.

Table 330. Current dTD pointer

Bit	Description
31-5 Current dTD	Current dTD Points to the dTD that is represented in the transfer overlay area. The device controller modifies this field to the next dTD pointer during endpoint priming or queue advance.
4-0 Reserved	Reserved for future use; must be set to 0.

41.3.5.1.4 Setup buffer

The setup buffer is a dedicated storage for the 8-byte data that follows a setup PID.

NOTE

Each endpoint has a TX and an RX dQH associated with it. Only the RX queue head is used for receiving setup data packets.

Table 331. Multiple mode control (HCCPARAMS)

DWORD	Bits	Description
1	31-0	Setup Buffer 0 Contains bytes 3–0 of an incoming setup buffer packet. The device controller writes to it so you can read it.
2	31-0	Setup Buffer 1 Contains bytes 7–4 of an incoming setup buffer packet. The device controller writes to it so you can read it.

41.3.5.2 Device endpoint transfer descriptor (dTD)

The dTD informs the device controller of the location and quantity of data to be sent and received for a given transfer.

The DCD must not attempt to modify any field in an active dTD except the next like pointer, which you must modify only as described in Managing transfers with transfer descriptors.

Table 332 describes the dTD structure.

Table 332. dTD structure[1]

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

0	Total bytes	IOC	0	MULTO	0	Status
Buffer pointer (page 0)				Current offset		
Buffer pointer (page 1)				0	Frame number	
Buffer pointer (page 2)				Reserved		
Buffer pointer (page 3)				Reserved		
Buffer pointer (page 4)				Reserved		

1. The shaded cells indicate host controller read/write fields and unshaded cells indicate host controller read-only fields.

Table 333 describes the dTD pointer.

Table 333. Next dTD pointer

Field	Function
31-5 Next Transfer Element Pointer	Next Transfer Element Pointer Contains the physical memory address of the next dTD to be processed. This field corresponds to memory address signals [31:5], respectively.
4-1 Reserved	Reserved for future use; must be 0.
0 T	Terminate Indicates to the device controller whether there are valid entries in the queue. • 0 – Pointer is valid (points to a valid transfer element descriptor) • 1 – Pointer is invalid

Table 334 describes the dTD token.

Table 334. dTD token

Field	Function
31 Reserved	Reserved for future use; must be 0.
30-16 Total Bytes	Total Bytes Specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes moved during the transaction, after the successful completion of the transaction.

Table continues on the next page...

Table 334. dTD token (continued)

Field	Function
	The maximum value you can store in the field is 5 × 4 KB (5000h). This is the maximum number of bytes that 5-page pointers can access. Although it is possible to create a transfer up to 20 KB, this assumes that the first offset into the first page is 0. When the offset cannot be predetermined, crossing past the fifth page can be guaranteed by limiting the total bytes to 16 KB. Therefore, the maximum recommended transfer is 16 KB (4000h). If the value of this field is 0 when the host controller fetches this transfer descriptor (and the active bit is 1), the device controller executes a zero-length transaction and retires the transfer descriptor. "In" transfers do not require that dTD be an even multiple of the Maximum Packet Length field in dQH. If you build such a transfer descriptor for an "In" transfer, the last transaction is always less than the value of the Maximum Packet Length field.
15 IOC	Interrupt On Complete Indicates whether USBSTS[UI] will be configured in response to the device controller being finished with this dTD.
14-12 Reserved	Reserved for future use; must be 0.
11-10 MULTO	Multiplier Override Can be used for transmit-ISO (that is, ISO-IN) to override the multiplier in the queue head. This field must be zero for all packet types that are not transmit-ISO. For example, if QH.multiplier = 3, the Maximum Packet Size field = 8, the Total Bytes field = 15, and the MULTO field = 0 (default), then three packets are sent: {Data2(8); Data1(7); Data0(0)}. If QH.multiplier = 3, the Maximum Packet Size field = 8, the Total Bytes field = 15, and the MULTO field = 2, then two packets are sent: {Data1(8); Data0(7)}. For maximum efficiency, you must calculate MULTO = greatest integer of (the Total Bytes field ÷ the Maximum Packet Size field). In cases where the Total Bytes field = 0, the MULTO field must be 1. For non-ISO and non-TX endpoints, you must write 0 to the MULTO field.
9-8 Reserved	Reserved for future use; must be 0.
7-0 Status	Status Used by the device controller to communicate individual command execution states back to the device controller software. This field contains the status of the last transaction performed on this dTD. The following are the bit encodings: • 0, 2, and 4 – Reserved • 3 – Transaction error • 5 – Data buffer error • 6 – Halted • 7 – Active

Table 335 describes the dTD buffer page pointer list.

Table 335. dTD buffer page pointer list

Field	Function
31-12 Buffer Pointer	Selects the page offset in memory for the packet buffer. Nonvirtual memory systems typically set the buffer pointers to a series of incrementing integers.
0, 11-0 Current Offset	Indicates the current offset that offsets into the 4 KB buffer where the packet will begin.
1, 10-0 Frame Number	Indicates the frame number in which a packet finishes. You typically use it to correlate relative completion times of packets on an ISO endpoint. The device controller writes to this field.

41.3.6 Device operational model

The function of the device operation is to transfer a request in the memory image to and from USB.

The device controller performs the data transfers (pointed to by the queue head) using a set of linked list transfer descriptors. The following sections explain the use of the device controller from the point-of-view of the DCD, and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

41.3.6.1 Device controller initialization

After hardware reset, the device is disabled until you write 1 to USBCMD[RS]. In the Disabled state, the pull-up on USB D+ is not active, which prevents an attach event from occurring. The minimum requirement is to have the queue heads setup for endpoint 0 before the device attach occurs.

After you enable the device, a USB reset occurs, followed by a setup packet arriving at endpoint 0. You must prepare a queue head so that the device controller can store the incoming setup packet.

Perform the following procedure to initialize a device:

1. Set Controller mode to Device mode in USB Device Mode (USBMODE).

   NOTE

   Transitioning from Host mode to Device mode requires a device controller reset before modifying USB Device Mode (USBMODE).

2. Allocate and initialize device queue heads in the system memory.

   At a minimum, initialize device queue heads 0 Tx and 0 Rx.

   NOTE

   You must initialize all device queue heads for control endpoints before the endpoint is enabled. Noncontrol device queue heads before the endpoint can be used.

   For information on device queue heads, see Device data structures.

3. Configure the ENDPOINTLISTADDR pointer.
4. Enable the microprocessor interrupt associated with the USB core.

   NXP recommends you to enable all device interrupts including USBSTS[UI], USBSTS[UEI], USBSTS[PCI], USBSTS[URI], and USBSTS[SLI].

   For a list of available interrupts, see Interrupt Enable (USBINTR) and USB Status (USBSTS) register tables.

5. Write 1 to USBCMD[RS]. After this field becomes 1 and the device is connected to a host, the host downstream port issues a bus reset. The DCD must monitor the reset event and adjust the software state as described in Bus reset.

NOTE

Endpoint 0 is designed as a control endpoint only; you do not need to configure it using Endpoint Control 0 (ENDPTCTRL0).

Because the first packet received is always a setup packet, it is not necessary to initially prime endpoint 0. The contents of the first setup packet require a response in accordance with the USB device framework command set.

41.3.6.2 Port state and control

From a chip or system reset, the device controller enters the powered state. A transition from the powered state to the attach state occurs when USBCMD[RS] = 1.

After receiving a reset on the bus, the port enters the defaultFS or defaultHS state in accordance with the reset protocol described in Appendix C.2 of *USB 2.0 Specification Rev. 2.0*.

The following state diagram depicts the state of a USB 2.0 device.

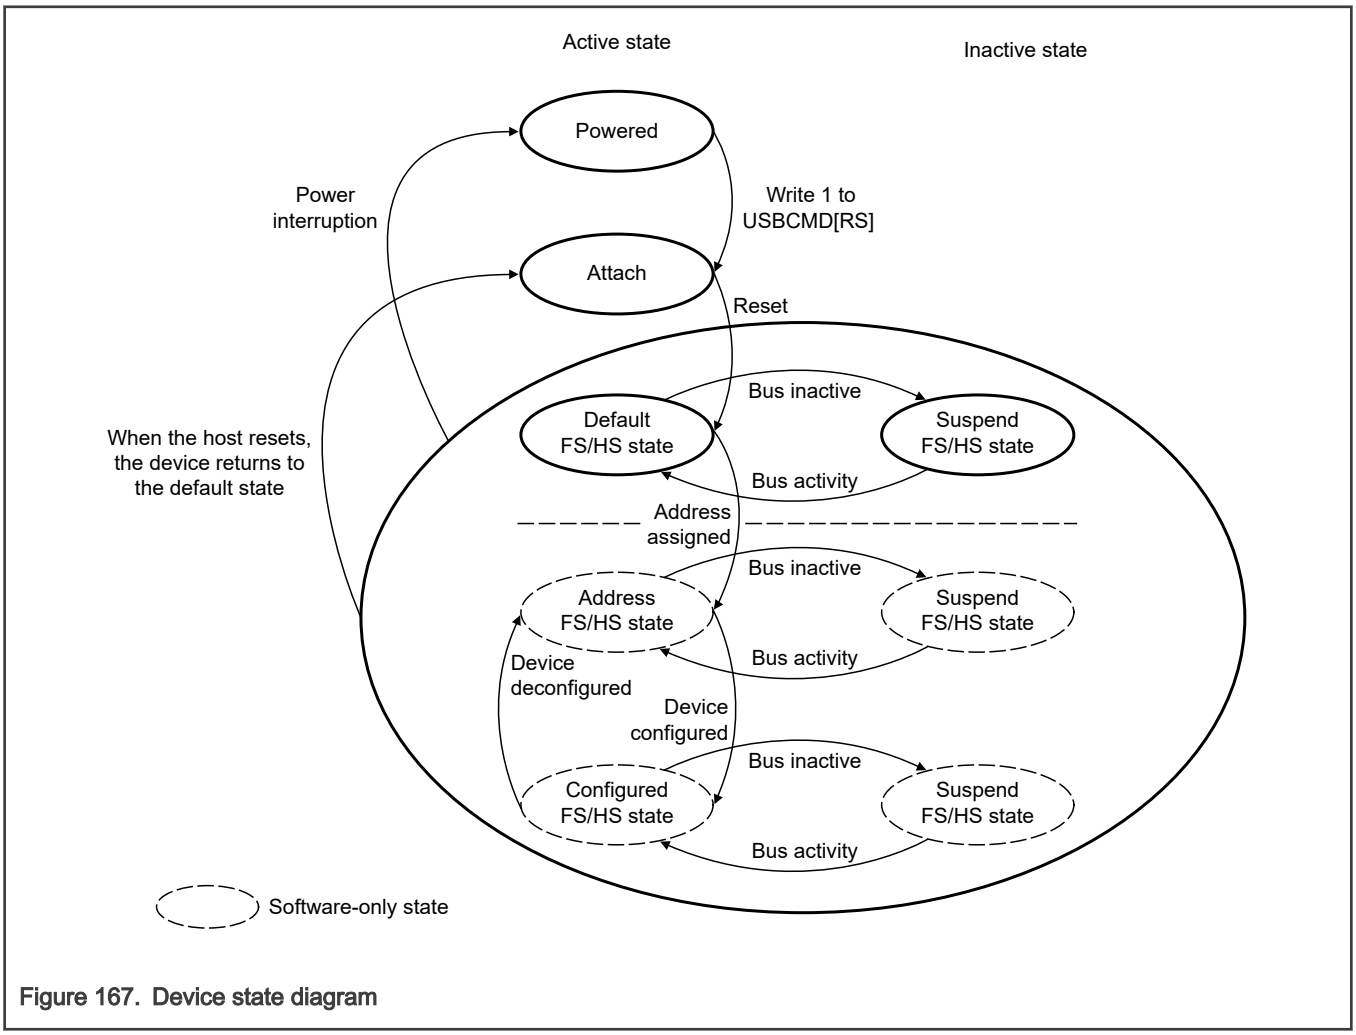

Figure 167. Device state diagram

The powered, attach, defaultFS, defaultHS, suspendFS, and suspendHS states are implemented in the device controller and communicated to the DCD using the following device controller state information fields:

- USBSTS[SLI]
- USBSTS[URI]

- USBSTS[PCI]
- PORTSC1[HSP]

It is the DCD's responsibility to maintain a state variable to differentiate between the defaultFS and defaultHS states, and the Address and Configured states. A change of state from Default to either Address or Configured is part of the enumeration process described in the device framework section of the USB 2.0 specification.

After entering the Address state, the DCD programs Device Address (DEVICEADDR).

Entry into the Configured state indicates that you have properly initialized all endpoints to be used in the operation of the device by programming the ENDPTCTRL*x* registers and initializing the associated queue heads.

41.3.6.2.1 Bus reset

The host uses a bus reset to initialize downstream devices.

When a bus reset is detected, the device controller renegotiates its attachment speed, resets the device address to 0, and notifies the DCD by interrupt (assuming USBINTR[URE] = 1). After a reset is received, all endpoints (except endpoint 0) are disabled, and the device controller cancels any primed transactions. The following table explains the concept of priming, and the tasks that DCD must perform when a reset is received.

Table 336. Bus reset

Step	Purpose	Programming
1	Clear all setup token semaphores	Read Endpoint Status (ENDPTSTAT) and write the same value back to ENDPTSTAT.
2	Clear all the endpoint-complete status fields	Read Endpoint Complete (ENDPTCOMPLETE) and write the same value back to ENDPTCOMPLETE.
3	Cancel primed status	Wait until all fields in Endpoint Prime (ENDPTPRIME) become 0, and then write FFFFFFFFh to Endpoint Flush (ENDPTFLUSH).

Read PORTSC1[PR] and ensure it is still active. A USB reset occurs for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before the end of the reset occurs; otherwise, a hardware reset of the device controller is recommended. This is a rare scenario.

You can perform a hardware reset by writing 1 to USBCMD[RST]. By writing 0 to USBCMD[RS], a hardware reset causes the device to detach from the bus. Thus, the DCD must completely reinitialize the device controller after a hardware reset.

Additionally, you must free up all allocated dTDs because the device controller will no longer execute them. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs are allocated.

At this time, the DCD can release the control back to the OS because no further changes to the device controller are permitted until a port change detect is indicated.

After a port change detect, the device reaches the default state and the DCD can read Port Status and Control (PORTSC1) to determine whether the device is operating in FS or HS mode. At this time, the device controller reaches its normal operating mode and DCD can begin enumeration according to *USB 2.0 specification chapter 9: Device Framework*.

NOTE

The device DCD may use the FS or HS mode information to determine the bandwidth mode of the device.

In some applications, it may not be possible to enable one or more pipes when in FS mode. There is no difference in DCD operations in FS and HS modes, except for the data rate issue.

41.3.6.2.2 Suspended state and Resume signal

Table 337. Operational models for Suspended state and Resume signal

Suspended	Resume
To conserve power, USB devices automatically enter Suspended state when the device observes no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. The attached devices must be prepared to suspend at any time when they are powered, regardless of whether they are assigned a nondefault address, are configured, or neither of the two conditions exist. Bus activity may cease because of the host entering a suspend mode of its own. In addition, a USB device must enter the Suspended state when the attached hub port is disabled. A USB device exits Suspend mode when there is bus activity. It may also request the host to exit Suspend mode or selectively suspend by using electrical signaling to indicate remote wake-up. The ability of a device to signal remote wake-up is optional. If the USB device is capable of remote wake-up signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wake-up signaling must be disabled. The device controller moves into the Suspended state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the Suspended state, an interrupt notifies the DCD (assuming that PORTSC1[SUSP] is 1, meaning the device controller is suspended). The DCD response, when the device controller is suspended, is application-specific and may involve switching to a low-power operation. See the USB 2.0 specification for information about bus power limits in Suspended state.	If the device controller is suspended, its operation is resumed when an active signal is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port by writing 1 to PORTSC1[FPR] when the device is in the Suspended state. Sending resume signal to an upstream port must cause the host to issue resume signaling and bring the suspended bus segment (one more device) back to the active condition. **NOTE** Before using resume signaling, the host must enable it via the set feature command defined in the device framework (chapter 9 of the USB 2.0 specification).

41.3.6.3 Managing endpoints

The USB 2.0 specification defines an endpoint (also called a device endpoint or an address endpoint) as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device.

The combination of the endpoint number and endpoint direction specifies the endpoint address.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a control type data channel used for device discovery and enumeration. Other types of endpoints that USB supports include bulk, interrupt, and isochronous. Each endpoint type has a specific behavior related to packet response and error handling.

The USB device controller hardware supports up to eight endpoint numbers.

Each endpoint direction is essentially independent, and you can configure it with differing behaviors in each direction. For example, the DCD can configure endpoint "1-In" as a bulk endpoint and endpoint "1-Out" as an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, always a control endpoint and uses both directions.

Each endpoint direction requires a queue head allocated in memory. To support the eight endpoint numbers, 16 queue heads are required. The operation of an endpoint and use of queue heads are described later in this document.

See the USB 2.0 specification for more information about endpoint operations.

41.3.6.3.1 Endpoint initialization

After hardware reset, all endpoints except endpoint 0 are uninitialized and disabled. The DCD must configure and enable each endpoint by configuring ENDPTCTRL*x*.

Each 32-bit ENDPTCTRL*x* is split into an upper and a lower half. The lower half of ENDPTCTRL*x* is used to configure the receive or "Out" endpoint, and the upper half is used to configure the corresponding transmit or "In" endpoint. You must configure the control endpoints in the same way for both the upper and lower halves of ENDPTCTRL*x*; otherwise, the behavior is undefined. The following table shows the fields and corresponding values for device controller endpoint initialization.

Table 338. Device controller endpoint initialization: configuration settings

Step	Purpose	Programming
1	Reset the PID sequence.	Write 1 to ENDPTCTRL*x*[TXR] and ENDPTCTRL*x*[RXR].
2	Configure receive data toggle sequencing.	Write 0 to ENDPTCTRL*x*[TXI] and ENDPTCTRL*x*[RXI].
3	Select the endpoint type.	Configure ENDPTCTRL*x*[TXT] and ENDPTCTRL*x*[RXT].
4	Configure the endpoint stall condition.	Write 0 to ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS].

41.3.6.3.2 Stalling

The following are the occasions in which the device controller may need to return a STALL response to the host:

- In case of a functional stall: It is a condition that DCD sets, as described in the USB 2.0 device framework. This kind of a stall is only used on noncontrol endpoints, and can be enabled in the device controller by writing 1 to ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS], associated with the given endpoint and the given direction. In a functional stall condition, the device controller continues to return STALL responses to all transactions occurring on the respective endpoint and direction until DCD writes 0 to ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS].
- In case of a protocol stall: Unlike a function stall, it is used on control endpoints. The device controller automatically clears it at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD must enable ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS] (both directions) as a pair. A single write to ENDPTCTRL*x* can ensure that both ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS] become 1 at the same instant.

NOTE

Any write to ENDPTCTRL*x* in Operational mode must preserve ENDPTCTRL*x*[TXT] and ENDPTCTRL*x*[RXT], which means you must perform a read-modify-write operation.

Table 339. Device controller stall response matrix

USB packet	Value of ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS]	Effect on ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS]	USB response
Setup packet that a noncontrol endpoint receives	N/A	None	STALL
In, Out, or Ping packet that a noncontrol endpoint receives	1	None	STALL
In, Out, or Ping packet that a noncontrol endpoint receives	0	None	ACK, NAK, or NYET
Setup packet that a control endpoint receives	N/A	Cleared	ACK
In, Out, or Ping packet that a control endpoint receives	1	None	STALL
In, Out, or Ping packet that a control endpoint receives	0	None	ACK, NAK, or NYET

41.3.6.3.3 Data toggle

Data toggle is a mechanism to maintain data coherency between the host and device for a given data pipe.

For more information about data toggle, see the USB 2.0 specification.

41.3.6.3.3.1 Data toggle reset

The DCD can reset ENDPTCTRL*x*[TXR] and ENDPTCTRL*x*[RXR] and cause the data toggle sequence to reset in the device controller by writing 1 to ENDPTCTRL*x*[TXR] and ENDPTCTRL*x*[RXR].

This is necessary only when configuring or initializing an endpoint, or returning from a STALL condition.

41.3.6.3.3.2 Data toggle inhibit

Writing 1 to ENDPTCTRL*x*[TXI] and ENDPTCTRL*x*[RXI] causes the device controller to ignore the data toggle pattern that is normally sent, and accepts all incoming data packets regardless of the data toggle state.

During normal operation, the device controller checks the DATA0 and DATA1 fields against the data toggle to determine whether the packet is valid. If the data PID does not match either ENDPTCTRL*x*[TXR] or ENDPTCTRL*x*[RXR] (that the device controller maintains for that endpoint), the data toggle is considered invalid. In this case, the device controller assumes that the packet is already received and discards the packet without reporting it to the DCD. To prevent the host controller from resending the same packet, the device controller responds to the error packet by acknowledging it with either an ACK or NYET response.

NOTE

This feature is for test purposes only; you must never use it during a normal device controller operation.

41.3.6.3.3.3 Priming transmit (TX) endpoints

Priming a transmit endpoint causes the device controller to fetch the device transfer descriptor (dTD) for the transaction that the dQH points to.

After the dTD is fetched, it is stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host, without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint, with the maximum number of endpoints configured at the device synthesis time.

After a priming request is complete, Endpoint Status (ENDPTSTAT) indicates an endpoint state of primed transmit. For this, the device controller can respond to an "In" request from the host and meet the stringent bus turnaround time of HS USB.

Because only the leading data is stored in the device controller FIFO, the device controller must begin filling in leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that the system memory bus can incur.

41.3.6.3.3.4 Priming receive (RX) endpoints

From the point of view of the DCD, priming receive endpoints is identical to priming transmit endpoints. Considering the device controller, the major difference in the operational model is that there is no data movement of the leading packet data because the data will be received from the host.

As part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the receive FIFO does not scale with the number of endpoints.

41.3.6.4 Operational model for packet transfers

The host initiates all transactions on the USB bus, and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 specification.

With USB 1.1 FS and LS rates, this turnaround time was significant and the USB 1.1 device controllers were architected in a way that enabled the device controller to access the main memory or interrupt a host protocol processor in order to respond to the USB 1.1 transaction. The architecture of the USB 2.0 device controller is different because the same methods do not meet the USB 2.0 HS turnaround time requirements from the increased clock rate.

A USB host sends requests to the device controller in an order that cannot be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable if the endpoint number and direction are considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then the host is expected to send "In" requests to that endpoint. This device controller is architected in a way that enables it to prepare packets for each endpoint or direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host-initiated transactions on the bus is referred to as priming the endpoint. This term is used throughout the chapter to describe the device controller operation so you can use priming to appropriately architect the DCD. Furthermore, the term flushing is used to describe the action of clearing a packet that is queued for execution.

41.3.6.4.1 Interrupt and bulk endpoint operational model

The behaviors of the device controller for interrupt and bulk endpoints are identical.

All valid "In" and "Out" transactions to bulk pipes handshake with a NAK unless the endpoint is primed. After the endpoint is primed, data delivery commences.

The device controller retires a dTD after the packets described in the transfer descriptor are completed. Each dTD describes "N" packets to be transferred according to the USB variable length transfer protocol. Equation 38, Table 340, and Table 341 describe how the device controller computes the number and length of packets that USB must send and receive. These vary according to the total number of bytes and maximum packet length. Also, Table 342 describes when TX-dTD and RX-dTD are considered complete.

With ZLT = 0, N = INT (number of bytes ÷ maximum packet length) + 1

With ZLT = 1, N = MAXINT (number of bytes ÷ maximum packet length)

N = MAXINT (number of bytes ÷ maximum packet length)

Equation 38. Formula for N

Table 340. Variable length transfer protocol example (ZLT = 0)

Bytes (dTD)	Maximum packet length (dQH)	N	P1	P2	P3
511	256	2	256	255	—
512	256	3	256	256	0
512	512	2	512	0	—

Table 341. Variable length transfer protocol example (ZLT = 1)

Bytes (dTD)	Maximum packet length (dQH)	N	P1	P2	P3
511	256	2	256	255	—
512	256	2	256	256	—
512	512	1	512	—	—

NOTE

You must write 00 to the MULT field in the dQH (see Device endpoint queue head (dQH)) for bulk, interrupt, and control endpoints.

Table 342. TX-dTD and RX-dTD completion status

TX-dTD is considered complete when:	RX-dTD is considered complete when:
All packets described in dTD are successfully transmitted. When this occurs, the total bytes in dTD become zero.	• All packets described in dTD are successfully received. When this occurs, the total bytes in dTD become zero. • A short packet (number of bytes < maximum packet length) is received. This is a successful transfer completion. DCD must check the total bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received. • A long packet is received: (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). This is an error condition. The device controller discards the remaining packet and sets the Data Buffer Error bit in the Status field of the dTD (see Device endpoint transfer descriptor (dTD)). In addition, the endpoint is flushed and the USBERR interrupt becomes active.

After the successful completion of the packet(s) that dTD describes, the Active bit in the Status field of the dTD is cleared and the next pointer is followed when the Terminate field in dTD is clear. When the Terminate field is set, the device controller flushes the endpoint or direction and ceases operations for that endpoint or direction.

After an unsuccessful completion of a packet (in the case of a long packet), the dQH points to the dTD in error. To recover from this error condition, the DCD must properly reinitialize the dQH by clearing the Active bit and updating the next dTD pointer before attempting to reprime the endpoint.

NOTE

The device controller automatically retires all packet level errors, such as a missing handshake or CRC error. An interaction with the DCD is not required for handling such errors.

41.3.6.4.1.1 Interrupt and bulk endpoint bus response matrix

The following table shows the device controller's response to packets on interrupt and bulk endpoint, according to the device controller's state. In the table:

- Bus error refers to force bit stuff error.
- NYET or ACK: If the transfer descriptor has packets remaining (according to the USB variable length protocol), the response is ACK. Otherwise, the response is NYET.

A system error (SYSERR) should not occur when the latency FIFOs are correctly sized and the DCD is responsive.

Table 343. Interrupt and bulk endpoint bus response matrix

Token type	Stall	Not primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	Bus error	N/A
Out	STALL	NAK	Receive + NYET or ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

41.3.6.4.2 Control endpoint operation model

41.3.6.4.2.1 Setup phase

All requests to a control endpoint begin with a setup phase, followed by an optional data phase and a required status phase. The device controller always accepts the setup phase unless the setup lockout is engaged.

The setup lockout engages so that future setup packets are ignored. Lockout of setup packets ensures that when software is reading the setup packet stored in the queue head, that data is not written at the same time because this can potentially cause an invalid setup packet.

You can disable the setup lockout mechanism only one time at initialization (by writing 1 to USBMODE[SLOM]), and a new tripwire type semaphore ensures that the setup packet payload is extracted from the queue head without being corrupted by an incoming setup packet. Setup lockout is not necessary when using the tripwire. This is the preferred behavior because ignoring repeated setup packets because of long software interrupt latency leads to a compliance issue.

Leaving the Setup Lockout mode as 0 results in pre-2.3 hardware behavior.

After receiving an interrupt and inspecting Endpoint Setup Status (ENDPTSETUPSTAT) to determine that a setup packet is received on a particular pipe, perform the following procedure.

Table 344. Setup phase: associated procedure

Step	Purpose	Programming	Notes
1	Clear the corresponding bit.	Write 1 to ENDPTSETUPSTAT[ENDPTSETUPSTAT].	—
2	—	Write 1 to USBCMD[SUTW].	—
3	Duplicate contents of the Setup Buffer field (in dTD) into a local software byte array.	—	—
4	—	Read USBCMD[SUTW].	If the field is 1, continue to the next step; if the field is 0, go back to step 2.
5	—	Write 0 to USBCMD[SUTW].	—
6	Process the setup packet using a local software byte array copy, and execute the status and handshake phases.	—	After receiving a new setup packet, the status and handshake phases may still be pending from a previous control sequence. These must be flushed and deallocated before linking a new status or handshake dTD for the most recent setup packet.

41.3.6.4.2.2 Data phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must immediately verify (by reading Endpoint Setup Status (ENDPTSETUPSTAT)) that a new setup packet has not been received. A prime completes when the associated field in Endpoint Prime (ENDPTPRIME) is 0 and the associated field in Endpoint Status (ENDPTSTAT) is 1. If the associated field in Endpoint Prime (ENDPTPRIME) becomes 0 and the associated field in Endpoint Status (ENDPTSTAT) has not become 1, prime fails. This is only due to improper setup of the dQH, the dTD, or a setup arriving during the prime operation. If a new setup packet is indicated after the associated field in Endpoint Prime (ENDPTPRIME) becomes 0, then the transfer descriptor is freed and the DCD must reinterpret the setup packet.

If a setup arrives after the data stage is primed, the device controller automatically clears the prime status (Endpoint Status (ENDPTSTAT)) to enforce data coherency with the setup packet.

NOTE

- You must write 00 to the MULT field in the dQH (see Device endpoint queue head (dQH)) for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is performed in the same way as bulk packets.

41.3.6.4.2.3 Status phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal to 0) and prime the endpoint for the status phase.

The DCD must also perform the same checks associated with ENDPTSETUPSTAT[ENDPTSETUPSTAT], as described in the data phase.

NOTE

- You must write 00 to the MULT field in the dQH (see Device endpoint queue head (dQH)) for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is performed in the same way as bulk packets.

41.3.6.4.2.4 Control endpoint bus response matrix

The following table shows the device controller's response to packets on a control endpoint, according to the device controller's state. In the table:

- Bus error refers to force bit stuff error.
- NYET or ACK: If the transfer descriptor has packets remaining (according to the USB variable length protocol), the response is ACK. Otherwise, the response is NYET.
- System error (SYSERR) must never occur when the latency FIFOs are correctly sized and the DCD is responsive.

Table 345. Control endpoint bus response matrix

Token type	Endpoint state					Setup lockout
	Stall	Not primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSERR	—
In	STALL	NAK	Transmit	Bus error	N/A	N/A
Out	STALL	NAK	Receive + NYET or ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

41.3.6.4.3 Isochronous endpoint operational model

Isochronous endpoints are used for real-time scheduled delivery of data, and their operational model is significantly different from the host throttled bulk, interrupt, and control data pipes.

The device controller accomplishes real-time delivery by using the following techniques:

- Exact MULT packets per microframe are transmitted and received. MULT is a two-bit field in the dQH (see Device endpoint queue head (dQH)). The variable length packet protocol is not used for isochronous endpoints.
- NAK responses are not used. Instead, zero-length packets are sent in response to an "In" request for unprimed endpoints. For unprimed RX endpoints, the response to an "Out" transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next microframe. If the ISO-dTD is still active after that frame, then the ISO-dTD is considered ready until the DCD executes or cancels it.

An EHCI-compatible host controller uses the periodic frame list to schedule data exchanges to isochronous endpoints. The operational model for Device mode does not use such a data structure. Instead, the same dTD used for control, bulk, and interrupt endpoints is also used for isochronous endpoints. The difference between bulk and ISO endpoints is in the handling of the dTD:

- Priming an ISO endpoint is a delayed operation so that an endpoint is primed only after an SOF is received. After the DCD writes to the prime bit, the bit is cleared as usual to indicate to software that the device controller completed priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific microframe.
- With isochronous endpoints, the transaction must fully complete within one microframe. After an ISO transaction is started in a microframe, it retires the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

  The Transaction Error bit in the Status field of the dTD indicates a fulfillment error condition. When a fulfillment error occurs on the frame after the transfer fails to complete, the device controller force retires the ISO-dTD and moves to the next ISO-dTD.

NOTE

Partially completed packets cause fulfillment errors. If no activity occurs on a primed ISO-dTD, the transaction stays primed indefinitely. This means it is up to you to discard transmit ISO-dTDs that pile up from a failure of the host or to move the data.

- The data level error handling for ISO packets is different. When a CRC error occurs on a received packet, the packet is not retried in the same way as bulk and control endpoints. Instead, the CRC error is noted by setting the Transaction Error bit in the Status field of the dTD, and the data is stored as usual for the application software to manage. The following table shows how a retired ISO packet is managed.

Table 346. Conditions that cause transmit and receive packets to retire

Conditions for transmit packet retirement (all conditions must be fulfilled)	Conditions for receive packet retirement (all conditions must be fulfilled)
• The MULT counter reaches zero. • A fulfillment error occurs. The Transaction Error bit is set in the Status field of the dTD: number of packets occurred > 0 AND number of packets occurred < MULT. **NOTE** For TX-ISO, the MULT counter can be loaded with a lesser value in the dTD MULTO field in hardware versions 2.3 and later. If MULTO is 0, the MULT counter is initialized to the multiplier in the queue head.	• The MULT counter reaches zero. • A non-MDATA PID is received. The exit criteria is only valid in hardware version 2.3 or later. Before this version, any PID sequence that did not exactly match the MULTO field was flagged as a transaction error because of a PID mismatch or fulfillment error. • An overflow error occurs. This happens when: — The packet received is greater than the maximum packet length (the Data Buffer Error bit is set in the Status field of the dTD). — The packet received exceeds the total bytes allocated in the dTD (the Data Buffer Error bit is set in the Status field of the dTD). • A fulfillment error occurs (the Transaction Error bit is set in the Status field of the dTD): number of packets occurred > 0 AND number of packets occurred < MULT. • A CRC error occurs (the Transaction Error bit is set in the Status field of the dTD).

NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For a continuous microframe-to-microframe operation, the DCD must ensure that the dTD linked-list is ahead of the device controller by at least two microframes.

41.3.6.4.3.1 Isochronous pipe synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the microframe number (specified by USB Frame Index (FRINDEX)) can be used as a marker.

To cause a packet transfer to occur at a specific microframe number ("N"), the DCD must interrupt on SOF during frame N-1. If USB Frame Index (FRINDEX) = N-1, the DCD must write to the prime bit. The device controller primes the isochronous endpoint in microframe N-1 so that the device controller is able to execute delivery during microframe N.

NOTE

Priming an endpoint towards the end of microframe N-1 does not guarantee delivery in microframe N. The delivery may actually occur in microframe N+1 if the device controller does not have enough time to complete the prime before the SOF for packet N is received.

41.3.6.4.3.2 Isochronous endpoint bus response matrix

The following table shows the device controller's response to packets on isochronous endpoints, according to the device controller's state. In the table:

- Bus error refers to force bit stuff error.
- Null packet refers to zero-length packet.

Table 347. Isochronous endpoint bus response matrix

Token type	Stall	Not primed	Primed	Underflow	Overflow
Setup	Stall	Stall	Stall	N/A	N/A
In	Null packet	Null packet	Transmit	Bus error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

41.3.6.5 Managing queue heads

The dQH points to the linked list of transfer tasks; the dTD depicts each of these tasks. An area of memory that Endpoint List Address (ENDPTLISTADDR) points to contains a group of all dQHs in a sequential list, as shown in Figure 168. The even elements in the list of dQHs are used for receive endpoints (Out and Setup) and the odd elements are used for transmit endpoints (In and Interrupt). Device transfer descriptors are linked, head to tail, starting at the queue head and ending at the Terminate bit of the dTD. After the dTD retires, it is no longer a part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers do not exist within the queue head after the dTD is retired (see Software link pointers).

In addition to the current and next pointers, and the dTD overlay examined in Operational model for packet transfers, the dQH also contains the following parameters for the associated endpoint: Multiplier (MULT), Maximum Packet Length, and Interrupt On Setup (IOS). The next section discusses the complete initialization of the dQH, along with these fields.

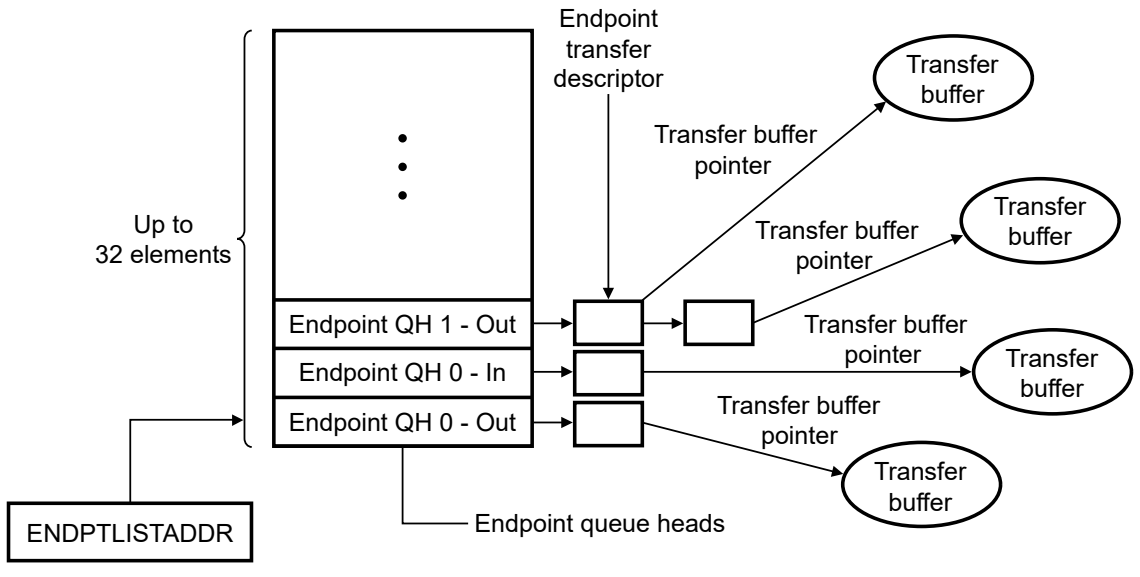

Figure 168. Endpoint queue head diagram

41.3.6.5.1 Queue head initialization

You must initialize a device queue head for each active endpoint. Perform the following procedure to initialize it.

Table 348. Queue head initialization

Step	Programming	Notes
1	Write to the wMaxPacketSize field as either the USB chapter 9 or application-specific protocol requires.	—
2	Write 0 to the MULT field in dQH for control, bulk, and interrupt endpoints.	Set the multiplier to 1, 2, or 3, for ISO endpoints, as the required bandwidth and in conjunction with the USB chapter 9 protocol. In FS mode, the MULT field in dQH can only be 1 for ISO endpoints.
3	Write 1 to the next Terminate field in dTD.	—
4	Write 0 to the Active bit in the Status field of dTD.	—
5	Write 0 to the Halt bit in the Status field of dTD.	—

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTDs.

41.3.6.5.2 Operational model for setup transfers

As discussed in Control endpoint operation model, the DCD gives special treatment to setup transfer. It does not use a dTD, but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

After receiving a notification of the setup packet, the DCD must manage the setup transfer as provided in the following procedure.

Table 349. Setup transfers: associated procedure

Step	Purpose	Programming	Notes
1	Copy setup buffer contents from dQH–RX to software buffer.	—	—
2	Acknowledge setup backup.	Write 1 to the corresponding bit in ENDPTSETUPSTAT[ENDPTSETUPSTAT].	• The acknowledgement must occur before continuing to process the setup packet. • After the acknowledgement has occurred, the DCD must not attempt to access the setup buffer in the dQH–RX. Only the local software copy must be examined.
3	Check for pending data or status dTDs from previous control transfers and flush, if any exist.	See Flushing and de-priming an endpoint.	—
4	—	Decode the setup packet, and prepare data phase (optional) and status phase transfers as required by either the USB chapter 9 or application-specific protocol.	—

NOTE

The device controller can receive setup packets before the completion of previous control transfers. Existing control packets in progress must be flushed and the new control packet must be completed.

41.3.6.6 Managing transfers with transfer descriptors

41.3.6.6.1 Software link pointers

The DCD software must maintain head and tail pointers to the linked list of dTDs for each respective queue head.

This is necessary because the dQH only maintains pointers to the currently working dTD and the next dTD to be executed. The operations described in the next section for managing the dTD assume that the DCD can use the head and tail of the dTD linked list. The following figure shows the software link pointers.

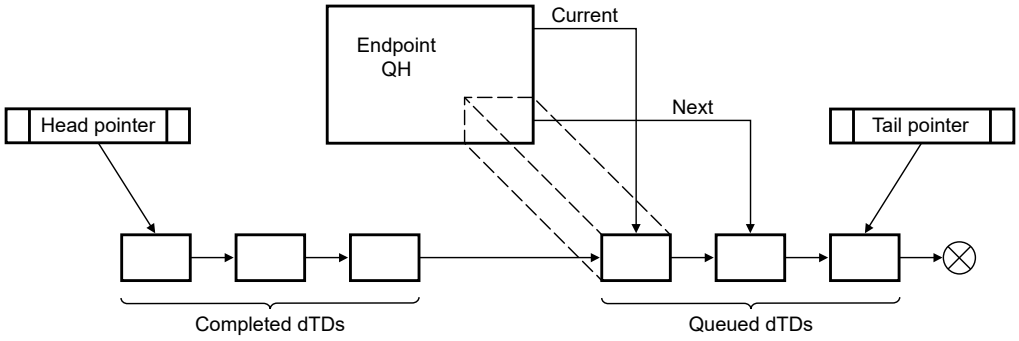

Figure 169. Software link pointers

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the head and tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

41.3.6.6.2 Building a transfer descriptor

Before executing a transfer from the linked list, you must build a dTD to describe the transfer.

As a prerequisite, allocate 8-DWORD dTD block of memory aligned to 8-DWORD boundaries. For example, bit address 4:0 is equal to 00000. Then perform the following procedure to build a dTD.

Table 350. Building a transfer descriptor: associated procedure

Step	Purpose	Programming
1	—	Write 0 to the first seven DWords.
2	—	Write 1 to the Terminate field in dTD.
3	—	Write the transfer size to the Total Bytes field in dQH.
4	—	Write 1 to the Interrupt On Complete (IOC) field in dTD, if desired.
5	Initialize the Status field.	Write 1 to the Active bit of the Status field and write 0 to all remaining Status bits.
6	Point to the start of the data buffer.	Fill in buffer pointer page 0 and the current offset.
7	—	Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointers.

41.3.6.6.3 Executing a transfer descriptor

To safely add a dTD, the DCD must perform the procedures listed in Table 351, based on the case. These procedures manage the event in which the device controller reaches the end of the dTD list at the same time a new dTD is added to the end of the list.

Determine whether the link list is empty by checking the DCD driver. This evaluates whether the pipe is empty (the internal representation of the linked list must indicate whether any packets are outstanding).

Table 351. Executing a transfer descriptor

Step	Case 1: If the link list is empty	Step	Case 2: If the link list is not empty
1	Write to the dQH next pointer and write 0 to the dQH Terminate bit as a single DWORD operation.	1	Add dTD to the end of linked list.
2	Clear the active and halt bits in dQH (in case they are set from a previous error).	2	Read the appropriate field in Endpoint Prime (ENDPTPRIME). If it is 1, it is done; otherwise, continue to read the field.
3	Prime the endpoint by writing 1 to the appropriate field in Endpoint Prime (ENDPTPRIME). You must check that the dTD and dQH content in external memory is updated before writing 1 to the field in Endpoint Prime (ENDPTPRIME).	3	Write 1 to USBCMD[ATDTW].
—	—	4	Read the appropriate status field in Endpoint Status (ENDPTSTAT) (store in a temporary variable for later use).
—	—	5	Read USBCMD[ATDTW]: • If the field is 0, go back to step 3. • If the field is 1, move forward to step 6.
—	—	6	Write 0 to USBCMD[ATDTW]: • If the status field read at step 4 is 1, the procedure is complete. • If the status field read at step 4 is 0, then go to step 1 of case 1.

41.3.6.6.4 Transfer completion

After you initialize a dTD and prime the associated endpoint, the device controller executes the transfer on the host-initiated request. The DCD is notified with a USB interrupt if the Interrupt On Complete (IOC) bit in the dTD is set. Alternately, the DCD can poll Endpoint Complete (ENDPTCOMPLETE) to find when the dTD was executed. After a dTD is executed, the DCD can also check the associated status bits to determine execution success or failure.

NOTE

Multiple dTDs can be completed in a single endpoint-complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that are complete (the Active bit in the dTD Status field is cleared).

By reading the status fields of the completed dTDs, the DCD can determine whether the transfers completed successfully. The following combination of status bits determine the transfer completion success:

- Active = 0
- Halted = 0
- Transaction Error = 0

- Data Buffer Error = 0

If any combination other than the aforementioned one exists, the DCD must take proper action. Device error matrix indicates the transfer failure mechanisms.

In addition to checking the status bit, the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the total bytes transferred is decremented by the actual bytes transferred. For transmit packets, a packet is considered complete only after the actual byte count is zero. For receive packets, the host can send fewer bytes in the transfer according to the USB variable length packet protocol.

41.3.6.6.5 Flushing and de-priming an endpoint

The DCD must flush to de-prime another endpoint on a USB device reset or during a broken control transfer.

Some application-specific requirements may exist to stop transfers in progress. The DCD can perform the following procedure to stop a transfer in progress:

1. Write 1 to the corresponding field(s) in Endpoint Flush (ENDPTFLUSH).
2. Wait until all fields in Endpoint Flush (ENDPTFLUSH) become 0.

   NOTE

   This operation may take quite a long time, depending on the USB bus activity. You must not have this wait loop within an interrupt service routine.

3. Read Endpoint Status (ENDPTSTAT) to ensure that the corresponding fields are now 0 for all endpoints commanded to be flushed. The following is the reason for a flush failure, if the corresponding bits are still 1 after completion of step 2:

   In very rare cases, a packet is already in progress to a particular endpoint when the previous endpoint commands the flush operation by writing to Endpoint Flush (ENDPTFLUSH). A safeguard is in place to refuse the flush, to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush by repeating steps 1–3 until each endpoint is successfully flushed.

41.3.6.6.6 Device error matrix

Table 352 summarizes packet errors that the device controller does not manage automatically.

Table 352. Device error matrix

Error	Direction	Packet type	Data buffer error bit	Transaction error bit
Overflow	RX	Any	1	0
ISO packet error	RX	ISO	0	1
ISO fulfillment error	Both	ISO	0	1

The device controller manages all errors on bulk, control, and interrupt endpoints, except for a data buffer overflow. However, for ISO endpoints, error packets are not retried and errors are tagged as indicated in Table 353.

Table 353. Error descriptions

Error	Description
Overflow	Indicates that the number of bytes received exceeded the maximum packet size or total buffer length.

Table continues on the next page...

Table 353. Error descriptions (continued)

Error	Description
	This error also sets the Halt bit in the dQH, and if there are dTDs remaining in the linked list for the endpoint, then those are not executed.
ISO packet error	Indicates a CRC error on the received ISO packet. Contents are not guaranteed to be correct.
ISO fulfillment error	Indicates that the host failed to complete the number of packets, defined in the dQH MULT field, within the given microframe. For scheduled data delivery, the DCD may need to readjust the data queue because a fulfillment error causes the device controller to cease data transfers on the pipe for one microframe. During the dead microframe, the device controller reports an error on the pipe and primes for the following frame.

41.3.6.7 Servicing interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency, and error operations, and consider the order of interrupts accordingly.

41.3.6.7.1 High-frequency interrupts

You must manage high-frequency interrupts in the order shown in the following table. The most important of these is listed first because the DCD must acknowledge a setup buffer as promptly as possible.

Table 354. High-frequency interrupt events

Execution order	Interrupt	Action
1a	USB interrupt (see Endpoint Setup Status (ENDPTSETUPSTAT))	Copy the contents of the setup buffer and acknowledge the setup packet (as indicated in Figure 168). Process the setup packet according to USB 2.0 chapter 9 or the application-specific protocol.
1b	USB interrupt[1] (see Endpoint Complete (ENDPTCOMPLETE))	Handle the completion of dTD as indicated in Figure 168.
2	SOF interrupt	Perform the action that the application considers necessary. This interrupt may not be used in all applications.

1. It is common for multiple interrupts to stack up on any call to and during the interrupt service routine.

41.3.6.7.2 Low-frequency interrupts

Low-frequency interrupts do not occur often compared to high-frequency interrupts. You can handle low-frequency interrupts in any order.

Table 355. Low-frequency interrupt events

Interrupt	Action
Port change	Change software state information.
Sleep enable (suspend)	Change software state information. Perform low-power handling as necessary.
Reset received	Change software state information. Terminate pending transfers.

41.3.6.7.3 Error interrupts

Error interrupts are infrequent. You must place them last in the interrupt service routine.

Table 356. Error interrupt events

Interrupt	Action
USB error interrupt	This error is redundant because it combines a USB interrupt and an error status in the dTD. The DCD handles packet-level errors more appropriately by checking the dTD status field upon receipt of the USB interrupt (by using Endpoint Complete (ENDPTCOMPLETE)).
System error	Unrecoverable error that requires immediate reset of core; you must free up transfer buffers in progress and restart the DCD.

41.3.7 Modes of operation

USB includes two main modes of operation: Normal mode and Low-Power mode. Each USB OTG controller core can operate at high speed (480 Mbps), full speed (12 Mbps), and low speed (1.5 Mbps).

41.3.7.1 Normal mode

The OTG controller core can operate in Host mode and Device (Peripheral) mode.

Each USB controller core has its corresponding port, which can work in one or more interface modes.

Each controller supports only the interface type listed in this section. Selecting a different interface type in the PORTSC1[PTS] field results in an unpredictable behavior and may cause the system to hang.

- OTG1 port
  - This port supports on-chip UTMI transceiver only.
- OTG2 port
  - This port supports on-chip UTMI transceiver only.

41.3.7.2 Low-Power mode

Each USB controller core has a low-power mode (Suspend mode) to save power.

As the USB 2.0 specification describes, the device can go into the Suspend state after it sees a constant Idle state on the upstream-facing port (UFP). The OTG controller core enters Suspend mode after 3 ms of inactivity on the port when it is in Device Operation mode. The host controller does not suspend automatically; you can place it in Suspend mode.

Either the local Arm platform, the remote USB host, or a peripheral can initiate a wake-up sequence to resume USB communication. For more information on Suspend and Resume states, see Power control.

41.3.7.2.1 Power control

USB supports suspend and wake-up functionalities.

The power control block allows you to place the transceiver in Low-Power mode when the USB bus is in the Idle state, and supports local and remote wake-up to bring the transceiver out of Low-Power mode, when needed. Additionally, the power control block can wake up the Arm platform by generating an interrupt.

41.3.7.2.1.1 Entering low-power Suspend mode

In Host Operation mode, low-power Suspend mode is entered as follows:

1. If needed, set UTMIPHY_CFG1[COMMONONN] to power down most analog blocks and stop clocks during Suspend mode.
2. Write 0 to USBCMD[ASE] and USBCMD[PSE], and wait until USBCMD[AS] and USBCMD[PS] become 0.

3. Write 1 to PORTSC1[SUSP].
4. Write 1 to PORTSC1[PHCD].

NOTE

Step 3 shall be done in atomic operation. That is, interrupt should be disabled during this step.

For Device Operation mode, low-power Suspend mode is entered as follows:

1. If needed, set UTMIPHY_CFG1[COMMONONN] to power down most analog blocks and stop clocks during Suspend mode.
2. After the host drive is in the Idle state for 3 ms, an SLI interrupt is issued (USBSTS[SLI]).
3. Write 1 to PORTSC1[PHCD].

NOTE

Step 2 shall be done in atomic operation. That is, interrupt should be disabled during this step.

41.3.7.2.1.2 Wake-up events

The power control block monitors the USB bus when the USB core is in the USB Suspend state.

Depending on whether the controller is in Host or Device mode, the core monitors a number of wake-up conditions. If the related wake-up interrupt enable field is 1, an interrupt is generated to the Arm platform upon detection of a wake-up condition.

The USB wake-up interrupt also reactivates the Arm platform clocks if they are stopped during the Suspend state.

41.3.7.2.1.2.1 Host mode events

The host controller wakes up after any of the following events:

- Remote wake-up request: A peripheral can request the host to reactivate the bus by driving wake-up signaling on the DM or DP lines. The power control block sends a wake-up request to the USB core when a J-K transition on the DM or DP line is detected.
- Wake-up on overcurrent: If a wake-up on overcurrent is enabled (PORTSC1[WKOC] = 1), the power control block sends a wake-up request to the USB core when an overcurrent event is detected.
- Wake-up on disconnect: If wake-up on disconnect is enabled (PORTSC1[WKDC] = 1), the power control block sends a wake-up request to the USB core when a disconnection event is detected (a J-SE0 or K-SE0 transition on the DM or DP line).
- Wake-up on connect: If a wake-up on connect is enabled (PORTSC1[WKCN] = 1), the power control block sends a wake-up request to the USB core when a connection event is detected (an SE0-J or SE0-K transition on the DM or DP line).

41.3.7.3 Disable mode

To disable the USBPHY analog to achieve low power:

1. Write 0 to UTMIPHY_CFG2[DRVVBUS0] to disable the VBUS valid comparator.
2. Write 1 to UTMIPHY_CFG1[PHY_POR_SW] to reset all test registers and state machines in the PHY.

41.3.8 Clocking

The following are USB clock sources:

- AHB bus clock
- Peripheral access clock
- PL301 peripheral clock

See the "Clock Controller (CLKCTL)" chapter for clock setting, configuration, and gating information.

41.3.9 Reset

Table 357. USB high-speed PHY resets

Reset	Description
Chip reset	Resets the USB controller logic and registers to their default states.
USB controller reset (USBCMD[RST])	Resets the controller. The host or device controller writes 0 to this field after the reset process is complete. You cannot terminate the reset process early by writing 0 to this register.

41.3.10 Interrupts

41.3.10.1 USB core interrupts

The USB core uses a dedicated vector in the interrupt table. In the Interrupt section, you can find the vector numbers for each core.

With the exception of wake-up interrupts, the USB core controls all interrupt sources. See Interrupt Enable (USBINTR) for more information.

41.3.10.2 USB wake-up interrupts

The USB core has an associated wake-up interrupt. These interrupts are generated outside the USB core, but use the same vector as the corresponding USB core interrupt.

The power control blocks generate these interrupts, which run on a low-power, low-speed clock. The wake-up interrupt is designed to work even when the USB and Arm platform clocks are disabled so that a wake-up condition on the USB bus can reactivate the Arm platform clocks.

Because the wake-up interrupt is generated and cleared on a low-power, low-speed clock, this interrupt request responds very slowly to clear actions. For this reason, you must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously because it is clocked by the Arm platform clock. You must wait for at least three low-power clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. Because this interrupt is used only during USB low-power modes, it is sufficient to enable the wake-up interrupt just prior to entering the USB Suspend mode.

41.4 External signals

Table 358. External signals

Signal	Description
OTGn_DN	DN OTG signal
OTGn_DP	DP OTG signal
OTGn_ID	ID signal
OTGn_OC	OTG external input for VBUS overcurrent detection
OTGn_PWR	To control PMIC to supply VBUS voltage
USB2_VBUS	USB 5 V signal
USB2_TXRTUNE	Transmitter resistor tune pin

See the chip-specific USB information for the external signals that this chip supports.

41.5 Initialization

See Host controller initialization and Device controller initialization for information on initializing the USB controller.

41.6 Register interface

USB configuration, control, and status registers are divided into the categories shown in the following table.

EHCI registers are listed along with device registers to show the complementary nature of host and device control.

Table 359. Core register sets

Offset	Register sets	Functional description
000h–07Ch	Identification registers	• Used to declare the target interface presence • Include the complete set of hardware configuration parameters
100h–124h	Static, read-only capability registers	• Define the software limits, restrictions, and capabilities of host and device controller implementation • Used as parameters for the host and device controller driver
080h–0FCh 140h–1FCh	Operational registers	• Dynamic control or status registers that can have read-only, read/write, or read/write-to-clear accesses • Used to control and monitor the operational state of the host and device controller

NOTE

- USB control registers support only DWORD (32-bit) accesses.
- You must not access reserved addresses in the memory map. If you do so, there is no bus error response.

41.6.1 Configuration, control, and status register sets

NOTE

Depending on implementation, "*x*" can have the following values: UOG1, UOG2.

Table 360. Device and host capability registers

Offset (hex)	Size (bytes)	Register name and mnemonic	Device mode	Host mode
000	4	Identification (ID)	O[1]	O
004	4	Hardware General (HWGENERAL)	O	O
008	4	Host Hardware Parameters (HWHOST)	X[2]	O

1B8	4	Endpoint Status (ENDPTSTAT)	O	X
1BC	4	Endpoint Complete (ENDPTCOMPLETE)	O	X
1C0 1C4 1C8 1CC 1D0 1D4 1D8 1DC	64	Endpoint Control 0 (ENDPTCTRL0) Endpoint Control 1 (ENDPTCTRL1) Endpoint Control 2 (ENDPTCTRL2) Endpoint Control 3 (ENDPTCTRL3) Endpoint Control 4 (ENDPTCTRL4) Endpoint Control 5 (ENDPTCTRL5) Endpoint Control 6 (ENDPTCTRL6) Endpoint Control 7 (ENDPTCTRL7)	O	X

1. O means that the register is available in Host and Device operation modes.
2. X means that the register is reserved in Host and Device operation modes.

41.6.2 Identification registers

USB uses identification registers to declare the target interface presence. They include hardware configuration parameters.

41.6.3 OTG operations

41.6.3.1 Register fields used for OTG operations

The behavior descriptions of Device mode and Host mode are provided in Register interface. However, for OTG operations, it is necessary to perform tasks independent of Controller mode.

NOTE

The only way to transit Controller mode out of Host or Device mode is by using USBCMD[RST]. Therefore, it is also necessary for the OTG tasks to be performed independent of a controller reset and Controller mode.

The following figure shows Controller mode.

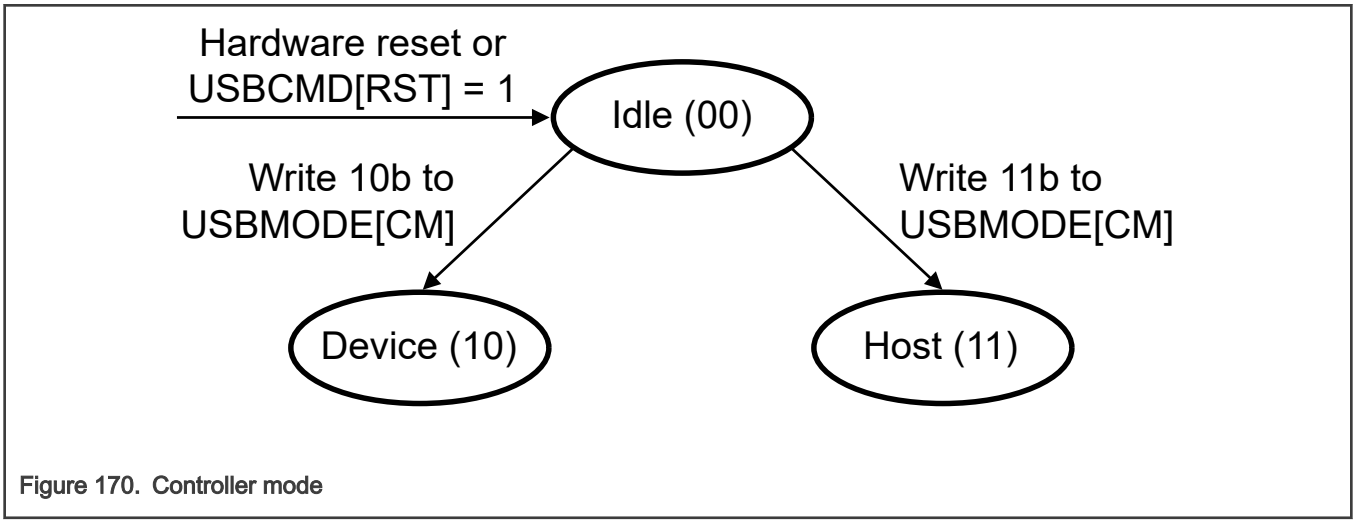

Figure 170. Controller mode

Following are the registers and register fields that are used for OTG operations, which are independent of Controller mode and are also not affected by a write to USBCMD[RST]:

- All identification registers
- All device and host capability registers
- All fields in On-The-Go Status and Control (OTGSC)

Additionally, the following fields of Port Status and Control (PORTSC1) are used:

- Physical interface serial select
- Physical interface data width
- Physical interface low power
- Physical interface wake signals
- Port indicators
- Port power

41.7 Register descriptions

There are two kinds of registers in the USB module: USB core (USBC) registers and USB noncore (USBNC) registers.

USBC registers are used to control USB core functions and are more independent of USB features. Each USB controller core has its own core registers.

USBNC registers are additional to USBC registers and are more dependent on USB features. For detailed descriptions of USBC registers, see Register interface. Section USBNC memory map describes only the USBNC registers.

NOTE

For reserved bits, preserve the value when writing (read the reset value, then write this value back).

41.7.1 USBC memory map

41.7.1.1 USBC register descriptions

41.7.1.1.1 USBC memory map

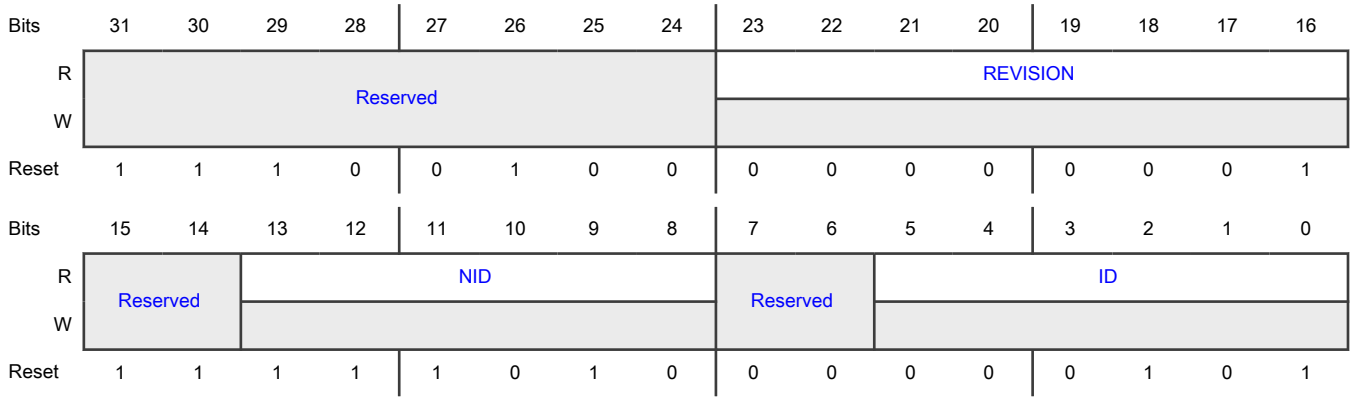
41.7.1.1.2 Identification (ID)

Identifies the USB 2.0 high-speed core and its revision.

Offset

Register	Offset
ID	0h

Diagram



Fields

Field	Description
31-24 —	Reserved
23-16 REVISION	Revision Number Indicates the revision number of the controller core.
15-14 —	Reserved
13-8 NID	Complement Version Indicates the complement version of the ID.
7-6 —	Reserved
5-0 ID	Configuration Number Indicates the configuration number (05h) and signifies that the peripheral is USB 2.0 HS core.

41.7.1.1.3 Hardware General (HWGENERAL)

Indicates general hardware parameters as defined in system-level issues and core configuration.

NOTE

The reset value can vary from instance to instance. Therefore, for more accurate information, see field descriptions and ignore their reset values.

Offset

Register	Offset
HWGENERAL	4h

Reset	0	0	0	0	1	0	1	1	0	0	0	0	1	0	0	0

Fields

Field	Description
31-24 —	Reserved
23-16 TXCHANADD	TX Channel Add Indicates the TX FIFO buffer size.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	The TX FIFO buffer size is (2^TXCHANADD) × 4 bytes. This field becomes 08h, so the buffer size is 256 × 4 bytes. For the OTG controller operating in Device mode, this is the FIFO buffer size per endpoint. As the OTG controller has 8 TX endpoints, there are eight of these buffers. For the OTG controller operating in Host mode, or for host-only controller, the entire buffer memory is used as a single TX buffer. Therefore, there is only one of this buffer.
15-8 —	Reserved
7-0 TXBURST	TX Burst Indicates the default burst size for memory to TX buffer transfer. This is the reset value of fields in BURSTSIZE.

41.7.1.1.7 RX Buffer Hardware Parameters (HWRXBUF)

Indicates RX buffer hardware parameters, such as the default burst size and total buffer size.

Offset

Register	Offset
HWRXBUF	14h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0

Fields

Field	Description
31-16	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
15-8 RXADD	RX Add Indicates the RX FIFO buffer size. The total buffer size for all receive endpoints is (2^RXADD). RX buffer size is (2^RXADD) × 4 bytes. This field becomes 08h, so buffer size is 256 × 4 bytes. There is a single receive FIFO buffer in the USB controller. The buffer is shared for all endpoints for the OTG controller in Device mode.
7-0 RXBURST	RX Burst Indicates the default burst size for memory to RX buffer transfer. This is the reset value of fields in Programmable Burst Size (BURSTSIZE).

41.7.1.1.8 General Purpose Timer 0 Load (GPTIMER0LD)

Controls the load value of the count timer in General Purpose Timer 0 Controller (GPTIMER0CTRL).

Offset

Register	Offset
GPTIMER0LD	80h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Description
31-24	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
23-0 GPTLD	General Purpose Timer Load Value Indicates the general purpose timer load value. This value represents the time in microseconds minus 1 for the timer duration. The value of this field is loaded to GPTIMER0CTRL[GPTCNT], if GPTIMER0CTRL[GPTRST] is 1. For example, for a one millisecond timer, load 1000 - 1 = 999 (or 0003E7h). **NOTE** The maximum value is FFFFFFh or 16.777215 seconds.

41.7.1.1.9 General Purpose Timer 0 Controller (GPTIMER0CTRL)

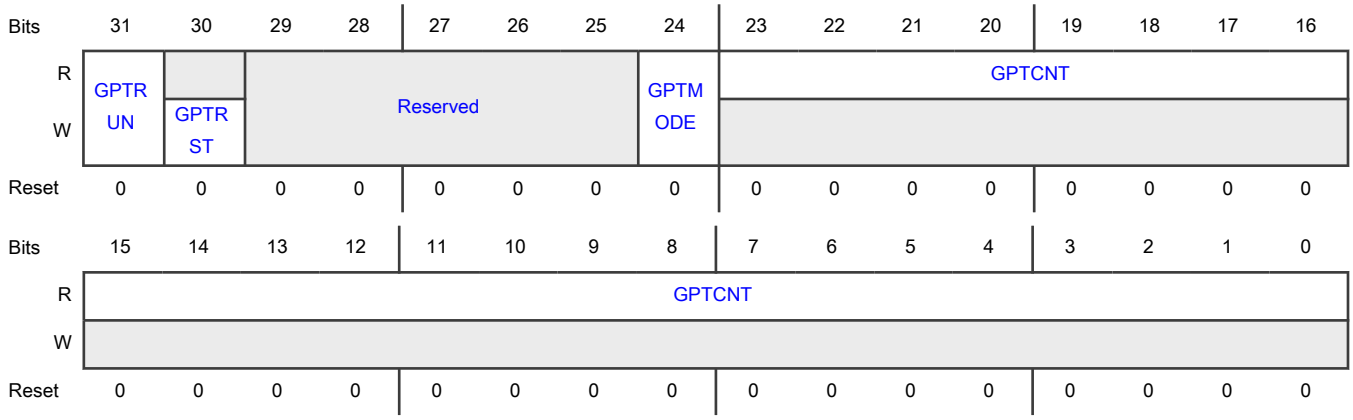
Contains the control for the general purpose countdown timer 0. A data field can be queried to determine the running count value. This timer has granularity on 1 µs and you can program it to a little over 16 seconds. There are two counter modes that are described in the register. When the timer counter value transitions to zero, an interrupt could be generated if enabled.

USBSTS[TI0] is the interrupt status field, and USBINTR[TIE0] is the interrupt enable field.

Offset

Register	Offset
GPTIMER0CTRL	84h

Diagram



Fields

Field	Description
31	General Purpose Timer Run

Table continues on the next page...

Table continued from the previous page...

Field	Description
GPTRUN	Specifies whether the general purpose timer is running or has stopped counting. GPTIMER0CTRL[GPTCNT] is not impacted when writing 1 or 0 to this field. 0 - Stop counting 1 - Run
30 GPTRST	General Purpose Timer Reset Loads the counter value from GPTIMER0LD[GPTLD]. 0 - No action 1 - Load counter value
29-25 —	Reserved
24 GPTMODE	General Purpose Timer Mode Specifies the general purpose timer mode. In One Shot mode, the timer counts down to zero, generates an interrupt, and halts until you reset the counter. In Repeat mode, the timer counts down to zero, generates an interrupt, and automatically reloads the counter value from GPTIMER1LD[GPTLD] to start again. 0 - One Shot mode 1 - Repeat mode
23-0 GPTCNT	General Purpose Timer Counter Indicates the count value of the countdown timer.

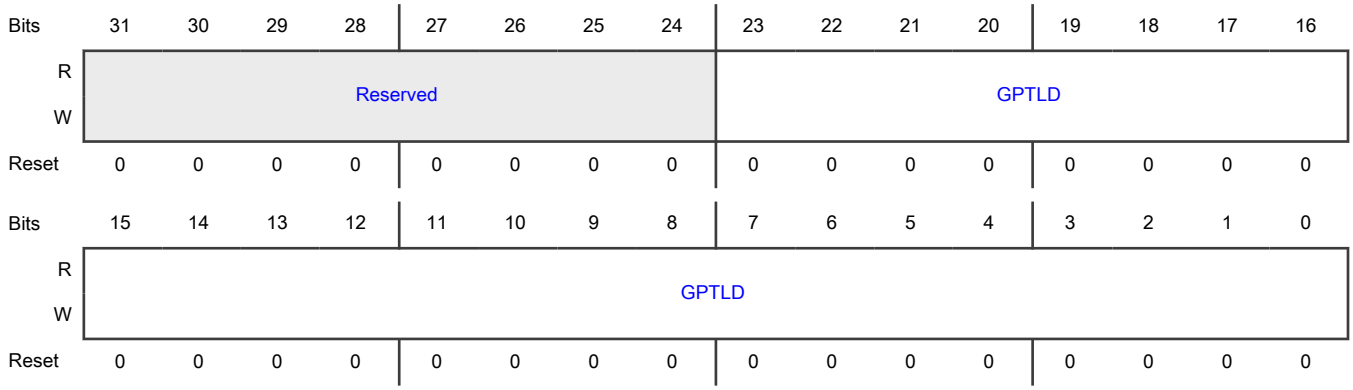
41.7.1.1.10 General Purpose Timer 1 Load (GPTIMER1LD)

Controls the load value of the count timer in General Purpose Timer 1 Controller (GPTIMER1CTRL).

Offset

Register	Offset
GPTIMER1LD	88h

Diagram



Fields

Field	Description
31-24 —	Reserved
23-0 GPTLD	General Purpose Timer Load Value Indicates the general purpose timer load value. This value represents the time in microseconds minus 1 for the timer duration. The value of this field is loaded to GPTIMER0CTRL[GPTCNT] if GPTIMER0CTRL[GPTRST] is 1. For example, for a one millisecond timer, load 1000 - 1 = 999 (or 0003E7h). **NOTE** The maximum value is FFFFFFh or 16.777215 seconds.

41.7.1.1.11 General Purpose Timer 1 Controller (GPTIMER1CTRL)

Contains the control for the general purpose countdown timer 1. A data field can be queried to determine the running count value. This timer has granularity on 1 µs and you can program it to a little over 16 seconds. There are two counter modes that are described in this register. When the timer counter value transitions to zero, an interrupt can be generated if it is enabled.

USBSTS[TI1] is the interrupt status field, and USBINTR[TIE1] is the interrupt enable field.

Field	Description
31 GPTRUN	General Purpose Timer Run Specifies whether the general purpose timer is running or has stopped counting. GPTIMER0CTRL[GPTCNT] is not impacted when writing 1 or 0 to this field. 0 - Stop counting 1 - Run
30 GPTRST	General Purpose Timer Reset Loads counter value from GPTIMER0LD[GPTLD]. 0 - No action 1 - Load counter value
29-25 —	Reserved
24 GPTMODE	General Purpose Timer Mode Indicates the general purpose timer mode. In One Shot mode, the timer counts down to zero, generates an interrupt, and stops until you reset the counter. In Repeat mode, the timer counts down to zero, generates an interrupt, and automatically reloads the counter value from GPTLD bits to start again. 0 - One Shot mode 1 - Repeat mode
23-0 GPTCNT	General Purpose Timer Counter Indicates the count value of the countdown timer.

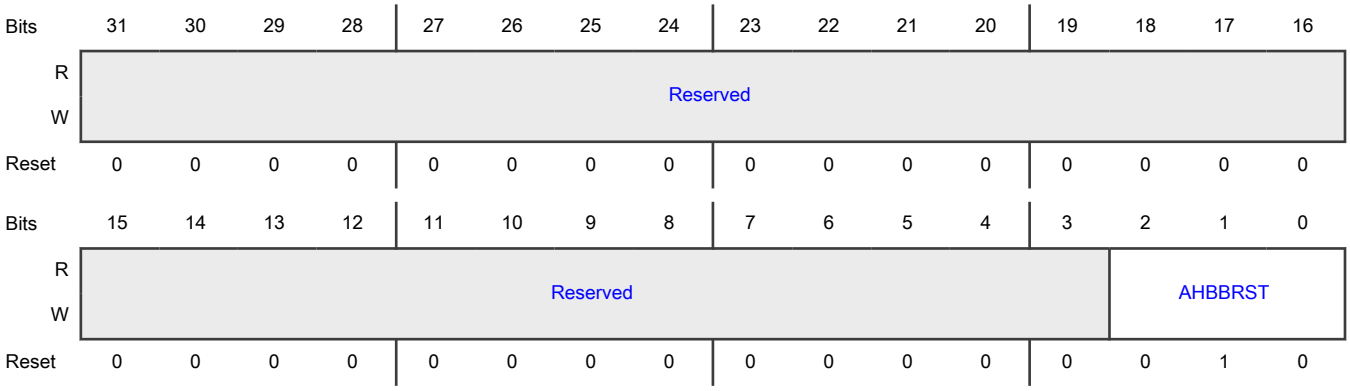
41.7.1.1.12 System Bus Configuration (SBUSCFG)

Defines the system bus configuration.

Offset

Register	Offset
SBUSCFG	90h

Diagram



Fields

Field	Description
31-3 —	Reserved
2-0 AHBBRST	AHB Controller Interface Burst Configuration Controls the AHB controller transfer type sequence (or priority). **NOTE** This register overrides Programmable Burst Size (BURSTSIZE) when the value of AHBBRST is not zero. 000 - Incremental burst of unspecified length only 001 - INCR4 burst, then single transfer 010 - INCR8 burst, INCR4 burst, then single transfer 011 - INCR16 burst, INCR8 burst, INCR4 burst, then single transfer 100 - Reserved; do not use 101 - INCR4 burst, then incremental burst of unspecified length 110 - INCR8 burst, INCR4 burst, then incremental burst of unspecified length 111 - INCR16 burst, INCR8 burst, INCR4 burst, then incremental burst of unspecified length

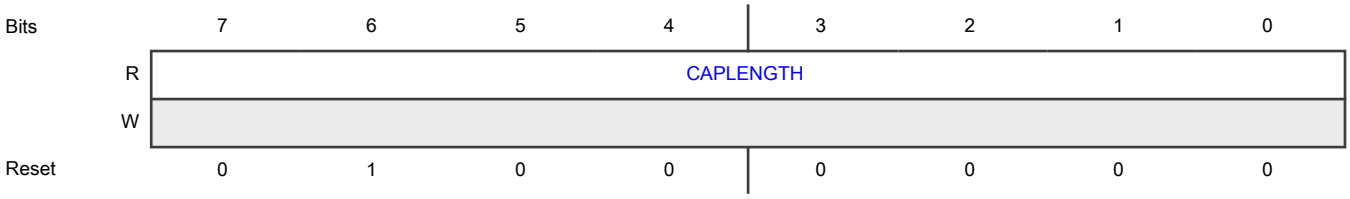
41.7.1.1.13 Capability Registers Length (CAPLENGTH)

Contains the address offset to the operational registers relative to the CAPLENGTH register.

Offset

Register	Offset
CAPLENGTH	100h

Diagram



Fields

Field	Description
7-0 CAPLENGTH	Capability Length Indicates the capability length. This field is used as an offset to add to the register base to find the beginning of the operational register. The default value is 40h.

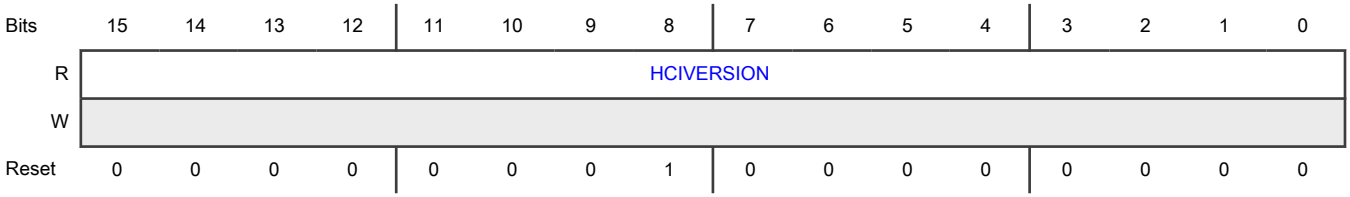
41.7.1.1.14 Host Controller Interface Version (HCIVERSION)

Contains a BCD encoding of the EHCI revision number that this host controller supports. The most significant byte of this register represents a major revision and the least significant byte indicates the minor revision.

Offset

Register	Offset
HCIVERSION	102h

Diagram



Fields

Field	Description
15-0 HCIVERSION	Host Controller Interface Version Number Indicates the host controller interface version number. The default value is 10h, which specifies EHCI rev1.0.

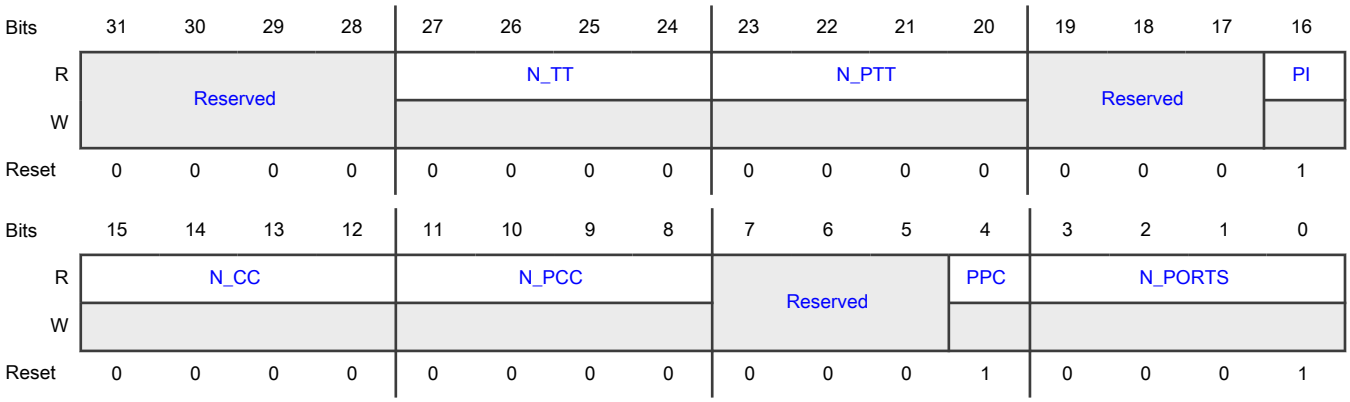
41.7.1.1.15 Host Controller Structural Parameters (HCSPARAMS)

Indicates the port steering logic capabilities of the host control structural parameters (HCSPARAMS).

Offset

Register	Offset
HCSPARAMS	104h

Diagram



Fields

Field	Description
31-28 —	Reserved
27-24 N_TT	Number of Transaction Translators Indicates the number of embedded transaction translators associated with the USB 2.0 host controller. The value of this field is 0001b for multi-port host, and 0000b for single-port host. The default value of this field is 0000b.
23-20 N_PTT	Number of Ports Per Transaction Translator Indicates the number of ports assigned to each transaction translator within the USB 2.0 host controller. The value of this field is equal to that of N_PORTS for a multi-port host, and 0000b for a single-port host. The default value of this field is 0000b.
19-17 —	Reserved
16 PI	Port Indicators (P_INDICATOR) Indicates whether the ports support port indicator control.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	If this field is 1, the port status and control registers include an R/W field for controlling the state of the port indicator. The value of this field is 1b in all controller cores.
15-12 N_CC	Number of Companion Controller Indicates the number of companion controllers associated with this USB 2.0 host controller. The value of this field is 0000b in all controller cores. If this field is 0, there is no internal companion controller and port-ownership hand-off is not supported. If this field is 1, internal companion controllers exist and port-ownership hand-offs are supported. 0000 - No internal companion controller exists 0001 - Internal companion controllers exist
11-8 N_PCC	Number of Ports Per Companion Controller Indicates the number of ports supported per internal companion controller. This field is used to indicate the port routing configuration to the system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2, then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, and so on. In the previous example, N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last 2 are routed to companion controller 2. The value of this field must be consistent with that of N_PORTS and N_CC. The value of this field is 0000b in all controller cores.
7-5 —	Reserved
4 PPC	Port Power Control Indicates whether the host controller implementation includes port power control. The value of this field affects the functionality of PORTSC1[PP] in each port status and control register. 0 - No port power switches 1 - Port power switches exist
3-0 N_PORTS	Number of Ports Indicates the number of downstream ports. This field indicates the number of physical downstream ports implemented on this host controller. The value of this field determines the number of port registers that are addressable in the operational register. The range of valid values is 1h–Fh. A zero in this field is undefined. The value of this field is always 0001b because all controller cores are single-port hosts.

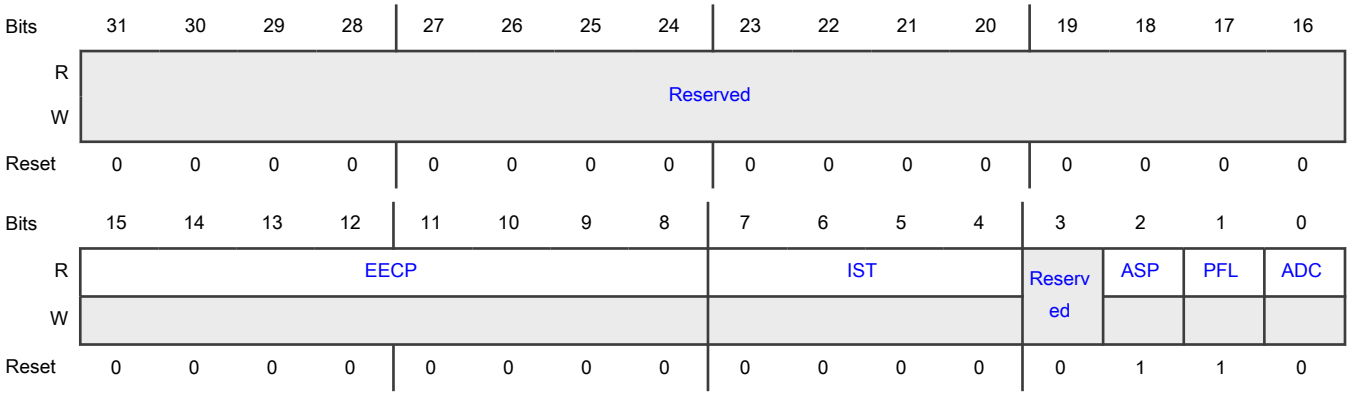
41.7.1.1.16 Host Controller Capability Parameters (HCCPARAMS)

Identifies multiple mode control (time-base bit functionality) and addressing capability.

Offset

Register	Offset
HCCPARAMS	108h

Diagram



Fields

Field	Description
31-16 —	Reserved
15-8 EECP	EHCI Extended Capabilities Pointer Indicates the existence of a capabilities list. A value of 00h indicates that no extended capabilities are implemented. A nonzero value in this field indicates the offset of the first EHCI extended capability in the PCI configuration space. The pointer value must be 40h or greater (if implemented) to maintain the consistency of the PCI header defined for this class of device. **NOTE** The value of this field is 00h in all controller cores.
7-4 IST	Isochronous Scheduling Threshold Indicates, relative to the current position of the executing host controller, where you can reliably update the isochronous schedule. When bit[7] of this field is 0, the value of the least significant three bits indicates the number of microframes during which a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit[7] is 1, then the host software assumes the host controller may cache an isochronous data structure for an entire frame. The value of this field is 00h in all controller cores.
3 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
2 ASP	Asynchronous Schedule Park Capability Indicates whether the park feature for HS queue heads is supported. If this field is 1, then the host controller supports the park feature for high-speed queue heads in the asynchronous schedule. You can enable or disable this feature and set it to a specific level by using USBCMD[ASPE] and USBCMD[ASP]. **NOTE** ASP bit reset value: 00b for OTG controller core; 11b for host-only controller core.
1 PFL	Programmable Frame List Flag Indicates the frame list length. If this flag is 0, you must use a frame list length of 1024 elements with this host controller. You must write 0 to USBCMD[FS_2] and USBCMD[FS_1]. If this flag is 1, you can specify and use a smaller frame list and configure the host controller via USBCMD[FS_2] and USBCMD[FS_1]. The frame list must always be aligned on a 4 KB page boundary. This requirement ensures that the frame list is always physically contiguous. The value of this flag is 1 in all controller cores.
0 ADC	Addressing Capability Indicates 64-bit addressing capability. This field is 0b in all controller cores, and 64-bit addressing capability is not supported.

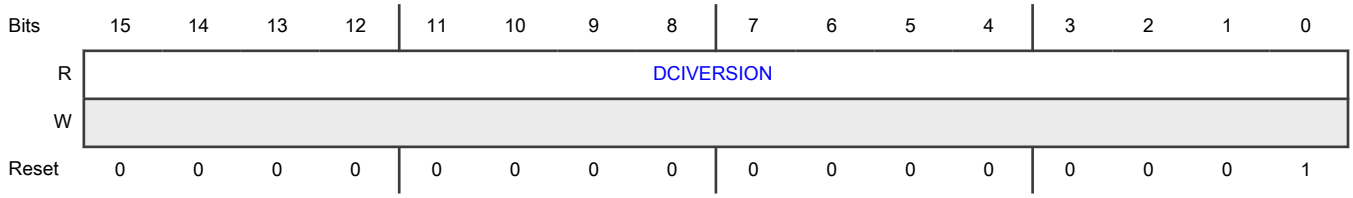
41.7.1.1.17 Device Controller Interface Version (DCIVERSION)

Indicates the 2-byte BCD encoding of the device controller interface version number.

Offset

Register	Offset
DCIVERSION	120h

Diagram



Fields

Field	Description
15-0 DCIVERSION	Device Controller Interface Version Number Indicates the device controller interface version number. The default value of this field is 01h, which specifies rev 0.1.

41.7.1.1.18 Device Controller Capability Parameters (DCCPARAMS)

Indicates the overall device capability of the controller.

NOTE

This register is only available in the OTG controller core.

Offset

Register	Offset
DCCPARAMS	124h

7 DC	Device Capable Indicates whether the controller is capable of operating as a USB 2.0 device. 0 - Not device capable 1 - Device capable
6-5 —	Reserved
4-0 DEN	Device Endpoint Number Indicates the number of endpoints built into the device controller. Valid values are 0–15. 0_0000 - Not device capable 0_0001 - Device capable

41.7.1.1.19 USB Command (USBCMD)

Indicates the command that the serial bus host or device controllers must execute. Writing to the register causes a command to be executed.

Offset

Register	Offset
USBCMD	140h

Fields

Field	Description
31-24 —	Reserved
23-16 ITC	Interrupt Threshold Control Sets the maximum rate at which the host or device controller issues interrupts. ITC contains the maximum interrupt interval, measured in microframes. The following values are the valid maximum interrupt intervals: 0000_0000 - Immediate (no threshold) 0000_0001 - 1 microframe 0000_0010 - 2 microframes 0000_0100 - 4 microframes 0000_1000 - 8 microframes 0001_0000 - 16 microframes 0010_0000 - 32 microframes 0100_0000 - 64 microframes
15 FS_2	Frame List Size 2 (Host mode only) Specifies the size of the frame list that controls which fields in USB Frame Index (FRINDEX) you must use for the frame list current index. This field is both readable and writable only if HCCPARAMS[PFL] is 1; otherwise, it is only readable. **NOTE** This field is made up of USBCMD bits 15, 3, and 2. 0b000 - 1024 elements (4096 bytes) (default value) 0b001 - 512 elements (2048 bytes) 0b010 - 256 elements (1024 bytes) 0b011 - 128 elements (512 bytes) 0b100 - 64 elements (256 bytes) 0b101 - 32 elements (128 bytes) 0b110 - 16 elements (64 bytes) 0b111 - 8 elements (32 bytes)
14 ATDTW	Add dTD TripWire (Device mode only) Works as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. You write 1 and 0 to this field; however, the hardware can also write 0 to the field when the state machine is in the hazard region for which adding a dTD to a primed endpoint may go unrecognized.
13	Setup TripWire (Device mode only)

Table continues on the next page...

Table continued from the previous page...

Field	Description
SUTW	Works as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a queue head by the DCD without being corrupted. If the Setup Lockout mode is off (USBMODE[SLOM] is 1), then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the queue head of a previous setup packet. You write 1 and 0 to this field; however, the hardware can also write 0 to the field if a hazard is detected.
12 —	Reserved
11 ASPE	Asynchronous Schedule Park Mode Enable Enables Park mode. If HCCPARAMS[ASP] is 1, then this field defaults to 1h, with R/W as its access type. Otherwise, the field is 0, with access type RO. **NOTE** ASPE bit reset value: '0b' for OTG controller . 0 - Disable 1 - Enable
10 —	Reserved
9-8 ASP	Asynchronous Schedule Park Mode Count Contains a count of the number of successive transactions that the host controller is allowed to execute from an HS queue head on the asynchronous schedule, before continuing traversal of the asynchronous schedule. If HCCPARAMS[ASP] is 1, then this field defaults to 3h, with R/W as the access type. Otherwise, the field defaults to 0, with access type RO. Valid values are 1h to 3h. You must not write 0 to this field when USBCMD[ASPE] is 1. Doing so leads to undefined behavior. This field is 3h for all controller cores.
7 —	Reserved
6 IAA	Interrupt on Async Advance Doorbell Acts as a doorbell for the host controller to issue an interrupt the next time it advances asynchronous schedule. You must write 1 to this field to ring the doorbell. After the host controller evicts all appropriate cached schedule states, it writes 1 to USBSTS[AAI]. If USBINTR[AAE] is 1, then the host controller asserts an interrupt at the next interrupt threshold.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	The host controller writes 0 to this field after it writes 1 to USBSTS[AAI]. You must not write 1 to this field when the asynchronous schedule is inactive. Doing so yields undefined results. This field is only used in Host mode. Writing 1 to this field in Device mode leads to undefined results.
5 ASE	Asynchronous Schedule Enable Determines whether the host controller skips processing the asynchronous schedule. If this field is 1, Next Asynchronous Address (ASYNCLISTADDR) is used to access the periodic schedule. If this field is 0 (the default value), the asynchronous schedule is not processed. Only the host controller uses this field. 0 - Do not process the asynchronous schedule 1 - Access the asynchronous schedule
4 PSE	Periodic Schedule Enable Determines whether the host controller skips processing the periodic schedule. If this field is 1, Frame List Base Address (PERIODICLISTBASE) is used to access the periodic schedule. If this field is 0 (the default value), the periodic schedule is not processed. Only the host controller uses this field. 0 - Do not process the periodic schedule 1 - Process the periodic schedule
3-2 FS_1	Frame List Size 1 See the description of USBCMD[FS_2].
1 RST	Controller Reset Resets the controller. Use this field to reset the controller. The host or device controller writes 0 to this field after the reset process is complete. You cannot terminate the reset process early by writing 0 to this field. In Host Operation mode, the controller resets its internal pipelines, timers, counters, state machines, and so on, to their initial values when you write 1 to this field. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. You must not write 1 to this field when USBSTS[HCH] is 0. Attempting to reset an actively running host controller results in undefined behavior. In Device Operation mode, the controller resets its internal pipelines, timers, counters, state machines, and so on, to their initial values when you write 1 to this field. Writing 1 to this field when the chip is in the attached state is not recommended because the effect on an attached host is undefined. To ensure that the chip is not in an attached state before initiating a device controller reset, all primed endpoints must be flushed and USBCMD[RS] must be 0.
0 RS	Run/Stop Specifies whether the controller is executing the operation.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	In Host Operation mode, the controller proceeds with the execution of the schedule if the value of this field is 1b. The controller continues the execution as long as this field is 1. If this field becomes 0 (the default value), the host controller completes the current transaction on the USB and then halts. The Halted bit in the Status field of the dTD token indicates when the controller has finished the transaction and has entered the Stopped state. You must not write 1 to this field unless the controller is in the Halted state (that is, USBSTS[HCH] = 1). In Device Operation mode, writing 1 to this field causes the controller to enable a pull-up on D+ and initiate an attach event. This control field is not directly connected to the pull-up enable because the pull-up becomes disabled upon transitioning into high-speed mode. You must use this field to prevent an attach event before the controller is properly initialized. Writing 0 to this field leads to a detach event. 0 - Stop executing 1 - Running

41.7.1.1.20 USB Status (USBSTS)

Indicates various states of the host and device controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus.

Offset

Register	Offset
USBSTS	144h

Fields

Field	Description
31-26 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
25 TI1	General Purpose Timer Interrupt 1 (GPTINT1) Flag Indicates when the counter in General Purpose Timer 1 Controller (GPTIMER1CTRL) transitions to 0. This flag is set when this happens. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Interrupt did not occur 1 - Interrupt occurred When writing 0 - No effect 1 - Clear the flag
24 TI0	General Purpose Timer Interrupt 0 (GPTINT0) Flag Indicates when the counter in General Purpose Timer 0 Controller (GPTIMER0CTRL) transitions to 0. This flag is set when this happens. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Interrupt did not occur 1 - Interrupt occurred When writing 0 - No effect 1 - Clear the flag
23-20 —	Reserved
19 UPI	USB Host Periodic Interrupt Flag Indicates the cause of a periodic interrupt and whether a short packet is detected. The host controller sets this field when the cause of an interrupt is the completion of a USB transaction, where the transfer descriptor (TD) has the IOC field set and the TD is from a periodic schedule. The host controller also sets this field when a short packet (the actual number of bytes received is less than expected) is detected and the packet is on a periodic schedule. The device controller does not use this field; the field is always 0. **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When reading 0 - Interrupt did not occur 1 - Interrupt occurred When writing 0 - No effect 1 - Clear the flag
18 UAI	USB Host Asynchronous Interrupt Flag Indicates the cause of an asynchronous interrupt and whether a short packet is detected. The host controller sets this flag when the cause of an interrupt is the completion of a USB transaction, where the transfer descriptor (TD) has the IOC field set and the TD is from an asynchronous schedule. The host controller also sets this flag when a short packet (the actual number of bytes received is less than expected) is detected and the packet is on an asynchronous schedule. The device controller does not use this field; the field is always 0. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Interrupt did not occur 1 - Interrupt occurred When writing 0 - No effect 1 - Clear the flag
17 —	Reserved
16 NAKI	NAK Interrupt Indicates whether a NAK interrupt is detected. Hardware sets this field, when both ENDPTNAK[EPTN] and ENDPTNAK[EPRN] are set for a particular endpoint, and their corresponding fields (ENDPTNAKEN[EPTNE] and ENDPTNAKEN[EPRNE]) are 1. When all enabled TX and RX endpoint NAK fields are cleared, this field is cleared automatically.
15 AS	Asynchronous Schedule Status Reports the current real status of the asynchronous schedule. If this field is 0, the asynchronous schedule status is disabled, and if this field is 1, the status is enabled. The host controller is not required to immediately disable or enable the asynchronous schedule when you transition USBCMD[ASE]. When this field and USBCMD[ASE] have the same value, the asynchronous schedule is either enabled (1) or disabled (0).

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This field is only used in Host Operation mode. 0 - Disabled 1 - Enabled
14 PS	Periodic Schedule Status Reports the current real status of the periodic schedule. If this field is 0, the periodic schedule is disabled, and if this field is 1, the status is enabled. The host controller is not required to immediately disable or enable the periodic schedule when software transitions USBCMD[PSE]. When this field and USBCMD[PSE] have the same value, the periodic schedule is either enabled (1) or disabled (0). This field is only used in Host Operation mode. 0 - Disabled 1 - Enabled
13 RCL	Reclamation Detects an empty asynchronous schedule. This field is only used in Host Operation mode. 0 - Not detected 1 - Detected
12 HCH	HC Halted Indicates whether the host controller is halted. This field is 0 whenever USBCMD[RS] is 1. The controller writes 1 to this field after it has stopped executing (because of USBCMD[RS] = 0), either by software or by the controller hardware (for example, in case of an internal error). This field is only used in Host Operation mode. The default value is 0b for the OTG core This is because the OTG core is not operating as host by default (see USBMODE[CM]). **NOTE** The reset value of HCH is 0b for the OTG controller core
11 —	Reserved
10 ULPII	ULPI Interrupt Flag Indicates an event completion in the ULPI viewport. Hardware sets this field to 1b when there is an event completion in the ULPI viewport. You can only use this flag if the controller supports UPLI Interface mode.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE This field behaves differently for register reads and writes. When reading 0 - Event completion did not occur 1 - Event completion occurred When writing 0 - No effect 1 - Clear the flag
9 —	Reserved
8 SLI	Device Controller Suspend Flag Indicates whether the device controller entered a suspended state. When a device controller enters a suspended state from an active state, this flag is set to 1. The device controller clears this flag upon exiting from a suspended state. This flag is used only in Device Operation mode. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Did not enter Suspended state 1 - Entered Suspended state When writing 0 - No effect 1 - Clear the flag
7 SRI	SOF Received Flag Indicates whether a start of (micro) frame (SOF) is received. When the device controller detects an SOF, this flag is set to 1. When the SOF is extremely late, the device controller automatically sets this field to indicate that an SOF is expected. Therefore, this flag is set roughly every 1 ms in device FS mode and every 125 ms in HS mode. It is synchronized to the actual SOF that is received. Because the device controller is initialized to FS before connect, this flag sets at an interval of 1 ms during the prelude to connect and chirp. In Host mode, this field sets every 125 µs; the host controller driver can use it as a time base. **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When reading 0 - SOF not received 1 - SOF received When writing 0 - No effect 1 - Clear the flag
6 URI	USB Reset Received Flag Indicates whether a USB reset is received. When the device controller detects a USB reset and enters the default state, this flag is set to 1. This flag is used only in Device Operation mode. **NOTE** This field behaves differently for register reads and writes. When reading 0 - USB reset not received 1 - USB reset received When writing 0 - No effect 1 - Clear the flag
5 AAI	Interrupt on Async Advance Flag Indicates the assertion of the interrupt source. You can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing 1 to USBCMD[IAA]. This flag is used only in Host Operation mode. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Interrupt did not occur 1 - Interrupt occurred When writing 0 - No effect 1 - Clear the flag
4	System Error Flag Indicates an error response to a read on the system interface.

Table continues on the next page...

Table continued from the previous page...

Field	Description
SEI	This flag is set to 1 when an error response is seen to a read on the system interface. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Error response did not occur 1 - Error response occurred When writing 0 - No effect 1 - Clear the flag
3 FRI	Frame List Rollover Flag Indicates whether the frame list index rolled over. The host controller sets this flag to 1 when the frame list index rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. For example, if the frame list size (as programmed in USBCMD[FS_1] and USBCMD[FS_2]) is 1024, USB Frame Index (FRINDEX) rolls over every time FRINDEX[13] toggles. Similarly, if the size is 512, the host controller sets this flag to 1 every time FHINDEX[12] toggles. This field is used only in Host Operation mode. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Frame list index did not roll over 1 - Frame list index rolled over When writing 0 - No effect 1 - Clear the flag
2 PCI	Port Change Detect Flag Indicates port change detection. The host controller sets this flag to 1 when a connect status occurs on any port, a port enable or disable change occurs, or PORTSC1[FPR] becomes 1 as the result of a J-K transition on the suspended port. The device controller sets this flag to 1 when the port controller enters the FS or HS operational state. When the port controller exits the FS or HS operation state because of reset or suspend events, the notification mechanisms are controlled by USBSTS[URI] and PORTSC1[SUSP], respectively. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - Port change not detected 1 - Port change detected When writing 0 - No effect 1 - Clear the flag
1 UEI	USB Error Interrupt (USBERRINT) Flag Indicates an error condition after the completion of a USB transaction. The host or device controller sets this flag after the completion of a USB transaction results in an error condition. This flag is set along with USBSTS[UI], if the TD on which the error interrupt occurred also has its IOC field set in the dTD token. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Interrupt did not occur 1 - Interrupt occurred When writing 0 - No effect 1 - Clear the flag
0 UI	USB Interrupt (USBINT) Flag Indicates the cause of an interrupt. The host or device controller sets this flag when the cause of an interrupt is the completion of a USB transaction where the transfer descriptor (TD) has its interrupt on complete (IOC) field set in the dTD token. The host or device controller also sets this field when a short packet is detected (the actual number of bytes received is less than the expected number of bytes). **NOTE** This field behaves differently for register reads and writes. When reading 0 - Interrupt did not occur 1 - Interrupt occurred When writing 0 - No effect 1 - Clear the flag

41.7.1.1.21 Interrupt Enable (USBINTR)

Enables interrupts to software. An interrupt is generated when a field in this register is 1 and the corresponding interrupt source is active. USB Status (USBSTS) still shows interrupt sources even if they are disabled by USBINTR, allowing you to poll the interrupt events.

Offset

Register	Offset
USBINTR	148h

0 UE	USB Interrupt Enable Enables USB interrupt. When this field is 1 and USBSTS[UI] is 1 too, the controller issues an interrupt. 0 - Disable 1 - Enable

41.7.1.1.22 USB Frame Index (FRINDEX)

Indexes the periodic frame list.

The host controller uses this register to index the periodic frame list. The register updates every 125 microseconds (once per microframe). Bits[*n*:3] are used to select a particular entry in the periodic frame list during periodic schedule execution. The number of bits used for the index depends on the size of the frame list that you define by using USBCMD[FS_2] and USBCMD[FS_1].

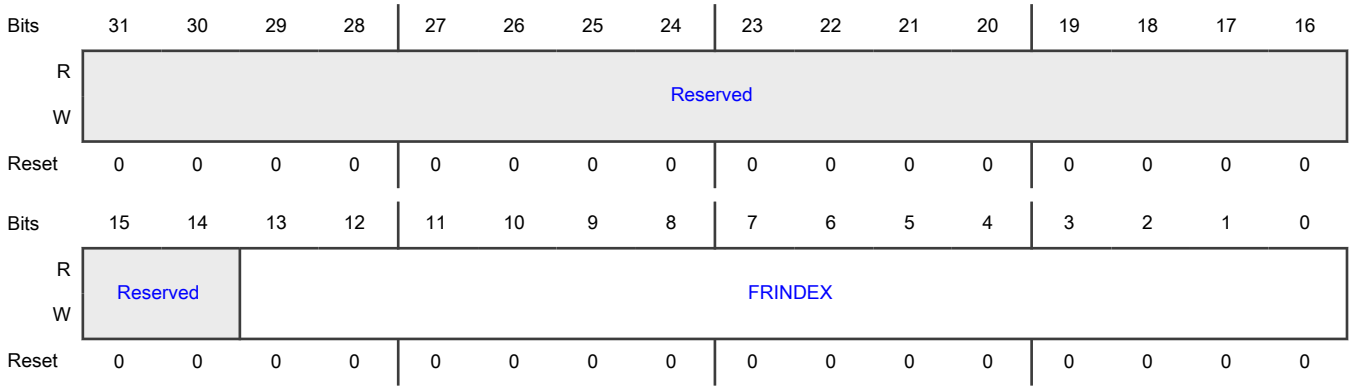
You must write to this register as a DWord. Byte writes produce undefined results. You cannot write to this register unless the host controller is in the Halted state, as indicated by USBSTS[HCH]. A write to this register, when USBCMD[RS] is 1, produces undefined results. Writes to this register also affect the SOF value.

In Device mode, this register is read-only and the device controller updates FRINDEX[13:3] from the frame number indicated by the SOF marker. Whenever the USB bus receives an SOF, FRINDEX[13:3] is checked against the SOF marker. If FRINDEX[13:3] is different from the SOF marker, FRINDEX[13:3] is set to the SOF value and FRINDEX[2:0] is 0 (that is, SOF for 1 ms frame). If FRINDEX[13:3] is equal to the SOF value, FRINDEX[2:0] increments (that is, SOF for 125 µs microframe).

Offset

Register	Offset
FRINDEX	14Ch

Diagram



Fields

Field	Description
31-14 —	Reserved
13-0 FRINDEX	Frame Index Increments at the end of each time frame (microframe). Bits[*n*:3] are used for the frame list current index. This means that each location of the frame list is accessed eight times (frames or microframes) before moving to the next index. In Host mode, the following values of *n* are based on the values of USBCMD[FS_2] and USBCMD[FS_1]. In Device mode, the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode, bits 2:0 indicate the current microframe. The following values are represented as USBCMD (frame list size) number elements *n*. 00_0000_0000_0000 - (1024) 12 00_0000_0000_0001 - (512) 11 00_0000_0000_0010 - (256) 10 00_0000_0000_0011 - (128) 9 00_0000_0000_0100 - (64) 8 00_0000_0000_0101 - (32) 7 00_0000_0000_0110 - (16) 6 00_0000_0000_0111 - (8) 5

41.7.1.1.23 Device Address (DEVICEADDR)

Contains the device address. The upper seven bits of this register represent the device address.

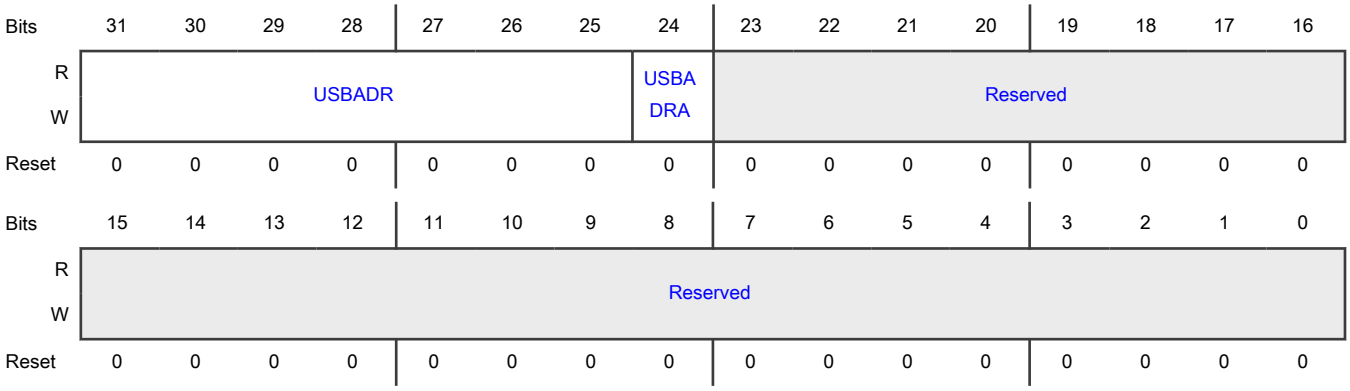
After a controller or USB reset, the device address is set to the default address (0) that matches all incoming addresses. You must reprogram the address after receiving a SET_ADDRESS descriptor.

Only the device controller uses this register.

Offset

Register	Offset
DEVICEADDR	154h

Diagram



Fields

Field	Description
31-25 USBADR	Device Address Represents the USB device address.
24 USBADRA	Device Address Advance Accelerates the SET_ADDRESS sequence by allowing the DCD to preset DEVICEADDR[USBADR] before the status phase of the SET_ADDRESS descriptor. When this field is 0 (the default value), any writes to USBADR are instantaneous. When you write 1 to this field at the same time or before writing to the USBADR field, a write to USBADR is staged and held in a hidden register. After an "In" transaction occurs on endpoint 0 and is ACKed, USBADR loads from the holding register. Hardware automatically writes 0 to this field on the following conditions: • The "In" transaction is ACKed to endpoint 0 (USBADR is updated from the staging register). • "Out" or "Setup" transactions occur to endpoint 0 (USBADR is not updated). • Device reset occurs (USBADR is reset to 0). **NOTE** After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism ensures that this specification is met when the DCD is busy and cannot write to this field within 2 ms from the SET_ADDRESS status phase. If the DCD writes to the USBADR field when USBADRA = 1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR field is programmed instantly at the correct time and meets the 2 ms USB requirement.
23-0 —	Reserved

41.7.1.1.24 Frame List Base Address (PERIODICLISTBASE)

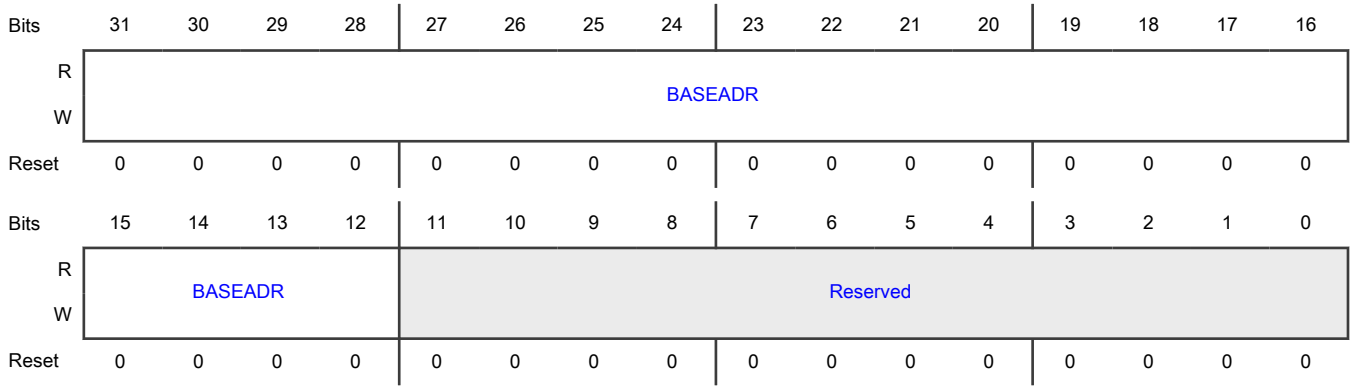
Contains the beginning address of the periodic frame list in the system memory.

The host controller driver (HCD) loads this register before the host controller starts the schedule execution. The memory structure referenced by this physical memory pointer is assumed to be 4-KB aligned. The contents of this register are combined with USB Frame Index (FRINDEX) to enable the host controller to step through the periodic frame list in sequence.

Offset

Register	Offset
PERIODICLISTBASE	154h

Diagram



Fields

Field	Description
31-12 BASEADR	Base Address (Low) Specifies the base address. These bits of this field correspond to memory address signals [31:12], respectively. Only the host controller uses this field.
11-0 —	Reserved

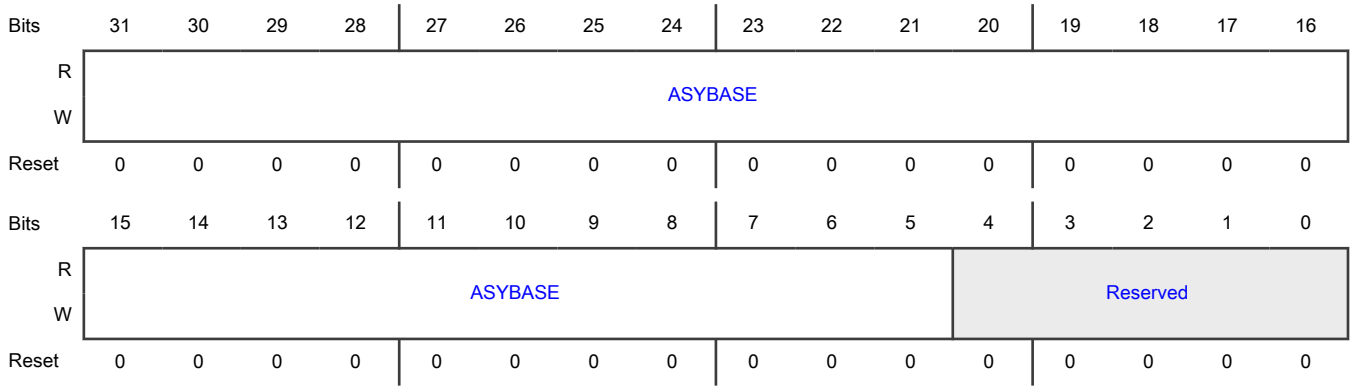
41.7.1.1.25 Next Asynchronous Address (ASYNCLISTADDR)

Contains the address of the next asynchronous queue head to be executed by the host. You cannot modify bits [4:0] of this register; they always return a 0 when read.

Offset

Register	Offset
ASYNCLISTADDR	158h

Diagram



Fields

Field	Description
31-5 ASYBASE	Link Pointer Low (LPL) Specifies the link pointer. The bits of this field correspond to memory address signals [31:5], respectively. This field can only reference a queue head. Only the host controller uses this field.
4-0 —	Reserved

41.7.1.1.26 Endpoint List Address (ENDPTLISTADDR)

Contains the address of the top of the endpoint list in system memory, when in Device mode. You cannot modify bits[10:0] of this register; they always return a 0 when read.

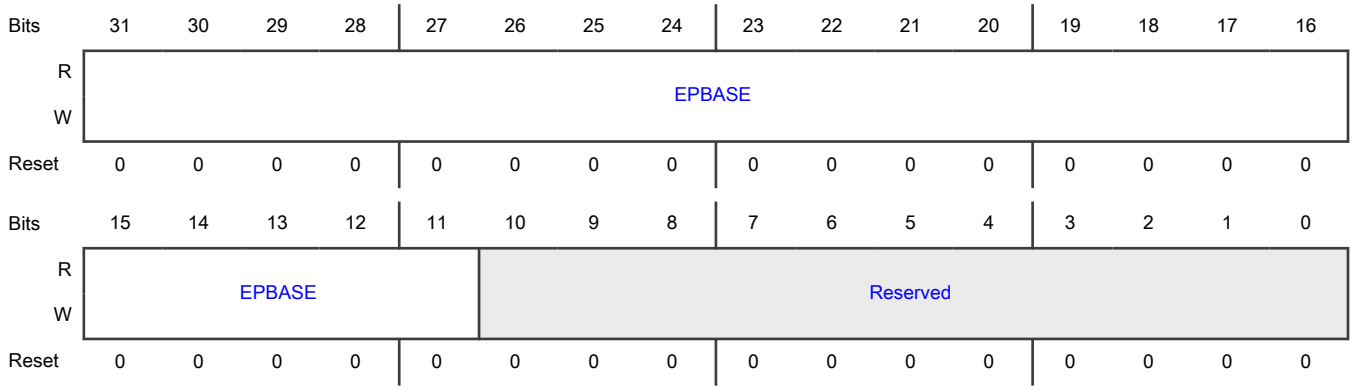
The memory structure referenced by this physical memory pointer is assumed to be 64 bytes.

This is a device-controller-only register.

Offset

Register	Offset
ENDPTLISTADDR	158h

Diagram



Fields

Field	Description
31-11 EPBASE	Endpoint List Pointer (Low) Specifies the endpoint list pointer. These bits of this field correspond to memory address signals [31:11], respectively. This field references a list of up to 32 queue heads (that is, one queue head per endpoint and direction).
10-0 —	Reserved

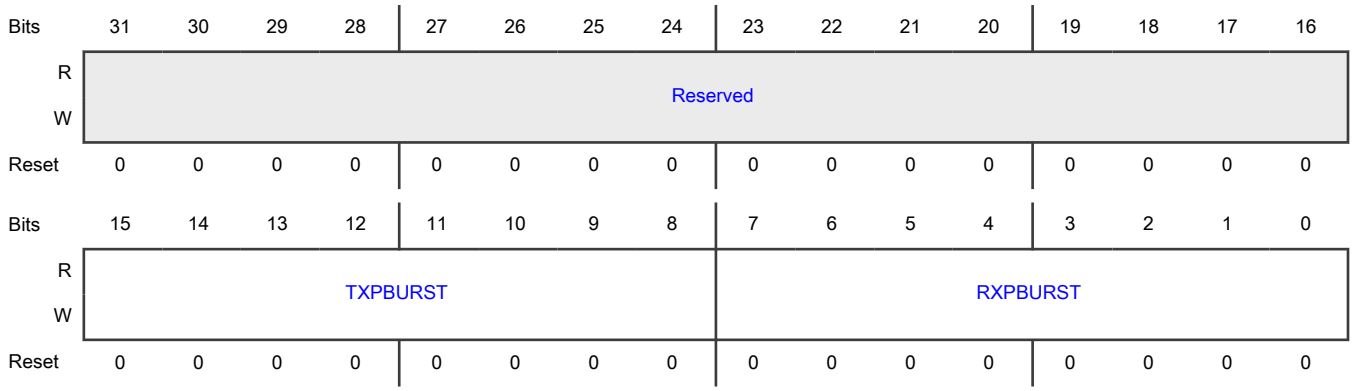
41.7.1.1.27 Programmable Burst Size (BURSTSIZE)

Controls the burst size used during data movement on the AHB controller interface. This register is ignored if SBUSCFG[AHBBRST] has a nonzero value.

Offset

Register	Offset
BURSTSIZE	160h

Diagram



Fields

Field	Description
31-16 —	Reserved
15-8 TXPBURST	Programmable TX Burst Size Represents the maximum length of a burst, in 32-bit words, when moving data from the system memory to the USB bus. HWTXBUF[TXBURST] determines the default value of this field.
7-0 RXPBURST	Programmable RX Burst Size Represents the maximum length of a burst, in 32-bit words, when moving data from the USB bus to the system memory. HWRXBUF[RXBURST] determines the default value of this field.

41.7.1.1.28 TX FIFO Fill Tuning (TXFILLTUNING)

Controls performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus.

The specific areas of performance include how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Following are some related definitions:

T_0 = Standard packet overhead

T_1 = Time to send data payload

T_{ff} = Time to fetch packet into the TX FIFO up to the specified level

T_s = Total packet flight time (send-only) packet

$T_s = T_0 + T_1$

T_p = Total packet time (fetch and send) packet

$T_p = T_{ff} + T_0 + T_1$

After the discovery of a transmit (out or setup) packet in the data structures, the host controller checks to ensure T_p remains before the end of the [micro]frame. If so, it proceeds to prefill the TX FIFO. If the remaining time in the frame of [micro]frame is < T_s at any time during this operation, then the packet attempt ceases and the packet is tried at a later time.

Although this is not an error condition and the host controller eventually recovers, a mark is created in the scheduler health counter to note the occurrence of a back-off event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and should therefore be minimized (not necessarily eliminated). You can minimize back-off events by using TXFILLTUNING[TXSCHHEALTH](T_{ff}).

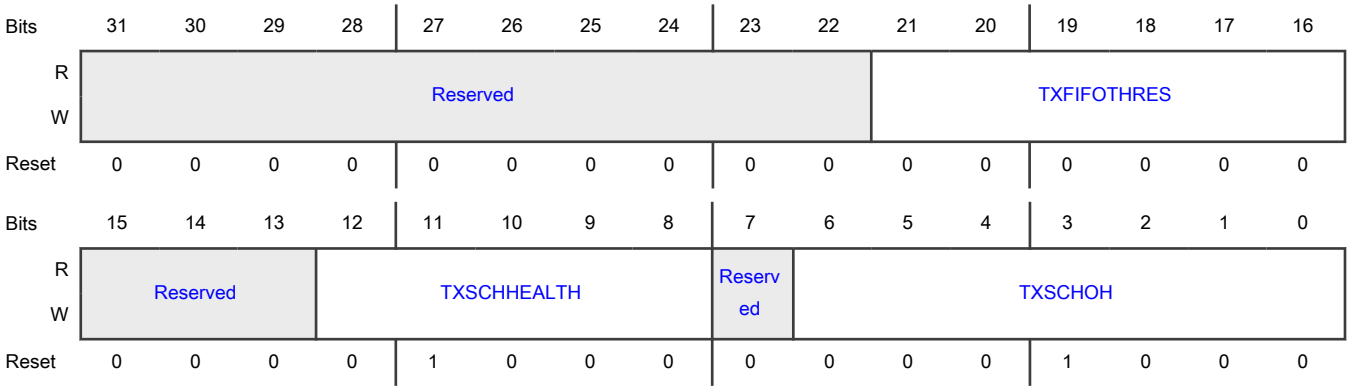
NOTE

The reset value could vary from instance to instance. In that case, see the field descriptions of this register and ignore the reset value in the summary table.

Offset

Register	Offset
TXFILLTUNING	164h

Diagram



Fields

Field	Description
31-22 —	Reserved
21-16 TXFIFOTHRES	FIFO Burst Threshold Controls the number of data bursts that are posted to the TX latency FIFO in Host mode before the packet begins on to the bus. The minimum value is 2 and this value should be as low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth, where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if USBMODE[SDIS] is 1.
15-13 —	Reserved
12-8 TXSCHHEALTH	Scheduler Health Counter Increments when the host controller fails to fill the TX latency FIFO to the level that you program in TXFILLTUNING[TXFIFOTHRES] before running out of time to send the packet before the next SOF. This health counter measures the number of times this occurs to provide feedback for selecting a proper scheduler overhead (TXFILLTUNING[TXSCHOH]). Writing to this register clears the counter that has the maximum value of 31.
7 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
6-0 TXSCHOH	Scheduler Overhead Adds an additional fixed offset to the schedule time estimator described as T_{ff}. As an approximation, the value selected for this register must limit the number of back-off events captured in TXFILLTUNING[TXSCHHEALTH] to less than 10 per second in a highly utilized bus. Selecting a value that is too high for this register is not recommended because it can needlessly reduce USB utilization. The time unit represented in this register is 1.267 µs when a device is connected in High-Speed mode. The time unit represented in this register is 6.333 µs when a device is connected in Low-Speed or Full-Speed mode. The default value is 08h for the OTG controller core .

41.7.1.1.29 Endpoint NAK (ENDPTNAK)

Configures RX and TX endpoint NAKs. Endpoint sends a NAK handshake for the "In", "Out", and "Ping" tokens.

Offset

Register	Offset
ENDPTNAK	178h

Diagram

Field	Description
31-24 —	Reserved
23-16 EPTNE	TX Endpoint NAK Enable Enables transmit endpoint NAK. Each bit in this field enables the corresponding TX endpoint NAK bit. If this bit is set and the corresponding TX endpoint NAK bit is set, the NAK interrupt bit is set. Bit[*n*] - Endpoint #[*n*], where *n* is 0–7.
15-8 —	Reserved
7-0 EPRNE	RX Endpoint NAK Enable Enables receive endpoint NAK. Each bit in this field enables the corresponding RX endpoint NAK bit. If this bit is set and the corresponding RX endpoint NAK bit is set, the NAK interrupt bit is set. Bit[*n*] - Endpoint #[*n*], where *n* is 0–7.

41.7.1.1.31 Configure Flag (CONFIGFLAG)

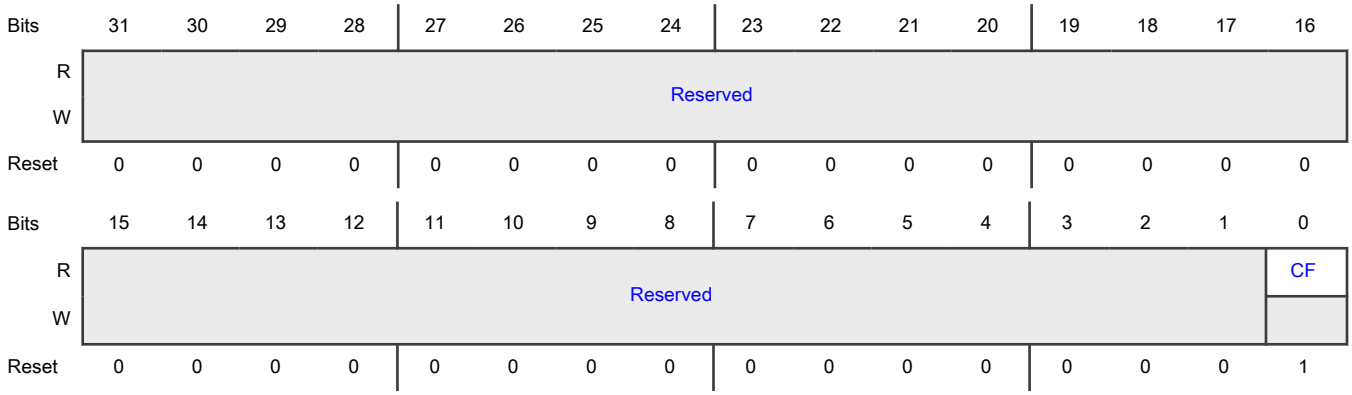
Controls port-routing control logic.

This register is not used in this implementation. A read from this register returns a constant of a 0000_0001h to indicate that all port routings default to this host controller.

Offset

Register	Offset
CONFIGFLAG	180h

Diagram



Fields

Field	Description
31-1 —	Reserved
0 CF	Configure Flag Controls the default port-routing control logic. You must set this flag as the last action in its process of configuring the host controller. If this flag is 0, the port routing control logic routes each port to an implementation dependent on classic host controller by default. If this flag is 1, the port routing control logic routes all ports to this host controller by default. 0 - Port routing to classic host controller 1 - Port routing to this host controller

41.7.1.1.32 Port Status and Control (PORTSC1)

Determines and implements ports that need service.

A host controller can implement one to eight port status and control registers. The number is determined by HCSPARAMS[N_PORTS]. You can read this parameter register to determine how many ports need service.

All controller cores on this product are single-port, so there is only one port status and control register for each controller core.

This register is only reset by POR or controller core reset. The following are the initial conditions of a port:

- No device connected
- Port disabled

If the port supports power control, this state remains until software supplies port power.

A device controller operating in Device mode includes only PORTSC1 and does not support power control in that mode. Port control in Device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate Test mode or force signaling, and allows you to place the PHY into Low-Power Suspend mode and disable the PHY clock.

Offset

Register	Offset
PORTSC1	184h

Fields

Field	Description
31-30 PTS_1	Parallel Transceiver Select 1 Indicates parallel transceiver select 1. Bit field {bit25, bit31, bit30}: 000b - UTMI/UTMI+ 001b - Reserved 010b - ULPI 011b - Serial/USB 1.1 PHY/IC-USB (FS only) 100b - HSIC Parallel Transceiver Select (bit25, bit31, bit30). For the OTG core, it is read-only. For host1, host2, and host3 cores, it is read/write. **NOTE** All USB port interface modes are listed in this field description, but not all are supported. For details related to each controller core, see Features. The behavior is unknown when an unsupported interface mode is selected.
29 STS	Serial Transceiver Select Selects the serial transceiver. The serial interface engine can be used in combination with UTMI+/ULPI physical interface to provide FS and LS signaling instead of the parallel interface signals.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this field is 1, the serial interface engine is used instead of parallel interface signals. This field has no effect unless PORTSC1[PTS_1] is 1 (to select the UTMI+/ULPI interface). The serial/USB1.1 PHY/IC-USB uses the serial interface engine for FS and LS signaling regardless of the value of this field. 0 - Parallel interface signals 1 - Serial interface engine
28 PTW	Parallel Transceiver Width Selects the parallel transceiver width. This field has no effect if the serial interface engine is used. 0 - 8-bit UTMI interface [60 MHz] 1 - 16-bit UTMI interface [30 MHz]
27-26 PSPD	Port Speed Indicates the speed at which the port is operating. 00 - FS 01 - LS 10 - HS 11 - Undefined
25 PTS_2	Parallel Transceiver Select 2 See the description of PORTSC1[PTS_1].
24 PFSC	Port Force Full Speed Connect Specifies the speed at which the port is connected. If this field is 1, the port is forced to connect at FS only. It disables the chirp sequence that allows the port to identify itself as HS. 0 - Normal operation 1 - Forced to full speed
23 PHCD	PHY Low-Power Suspend - Clock Disable (PLPSCD) Disables the PHY clock. Reading this field indicates the status of the PHY clock. **NOTE** You cannot disable the PHY clock if it is being used as the system clock. In Device mode, you can place the PHY into Low-Power Suspend mode when the device is not running (USBCMD[RS] is 0) or the host has signaled suspend (PORTSC1[SUSP] is 1). This field becomes 0

Table continues on the next page...

Table continued from the previous page...

Field	Description
	automatically when the host initials resume. Before forcing a resume from the device, the device controller driver must write 0 to this field. In Host mode, you can place the PHY into Low-Power Suspend mode when the downstream device is placed into Suspend mode or when no downstream device is connected. Low-Power Suspend mode is completely under your control. 0 - Enable 1 - Disable
22 WKOC	Wake on Overcurrent Enable (WKOC_E) Enables wake-up on overcurrent. Writing 1 to this field enables the port to be sensitive to overcurrent conditions as wake-up events. This field is 0 if PORTSC1[PO] is 0.
21 WKDC	Wake on Disconnect Enable (WKDSCNNT_E) Enables wake-up on disconnect. Writing 1 to this field enables the port to be sensitive to device disconnects as wake-up events. This field is 0 if PORTSC1[PO] is 0 or is in Device mode. 0 - Disable 1 - Enable
20 WKCN	Wake on Connect Enable (WKCNNT_E) Enables port sensitivity. Writing 1 to this field enables the port to be sensitive to device connects as wake-up events. This field is 0 if PORTSC1[PO] is 0 or is in Device mode. 0 - Disable 1 - Enable
19-16 PTC	Port Test Control Defines port test control. See Port Test Control mode for the operational model used for these test modes, and chapter 7 of the USB Specification Revision 2.0 for details on each test mode. FORCE_ENABLE_FS and FORCE ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the FORCE_ENABLE_{HS/FS/LS} values to this field forces the port into the connected and enabled states at the selected speed. Writing the TEST_MODE_DISABLE value to this field allows the port state machines to progress normally from that point. **NOTE** *Low-speed operations are not supported as a peripheral device.* Any value other than 0 indicates that the port is operating in Test mode.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Value specific test 0000 - TEST_MODE_DISABLE 0001 - J_STATE 0010 - K_STATE 0011 - SE0 (host) or NAK (device) 0100 - Packet 0101 - FORCE_ENABLE_HS 0110 - FORCE_ENABLE_FS 0111 - FORCE_ENABLE_LS 1000-1111 - Reserved
15-14 PIC	Port Indicator Control Specifies the port indicator. Writing to this field has no effect if HCSPARAMS[PI] is 0. See the USB Specification Revision 2.0 for a description on how these fields must be used. This field is 0 if PORTSC1[PO] is zero. 00 - Port indicators are off 01 - Amber 10 - Green 11 - Undefined
13 PO	Port Owner Indicates port ownership. This field to used to release ownership of the port to a selected host controller (in the event that the attached device is not an HS device). This field unconditionally becomes 0 when the configured field in Configure Flag (CONFIGFLAG) makes a 0 to 1 transition. The field unconditionally becomes 1 whenever the configured field is 0. Write 1 to this field when the attached device is not an HS device. If this field is 1, it means that an internal companion controller owns and controls the port. Port owner handoff is not supported in all controller cores; therefore, this field is always 0.
12 PP	Port Power Works in accordance with HCSPARAMS[PPC]. In other words, the functioning of this field depends on the value of HCSPARAMS[PPC]: • PPC = 0b, PP = 0b (read-only): A controller in Device mode does not have port power control switches. • PPC = 1b, PP = 1b or 0b (read/write): A controller in Host mode requires port power control switches.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	OTG controller requires port power control switches. This field represents the current setting of the switch (0 means off; 1 means on). When power is not available on a port (that is, PP = 0), the port is nonfunctional and does not report attachments, detachments, and so on. When an overcurrent condition is detected on a powered port and PPC is 1, this field, in each affected port, may be transitioned by the controller driver from 1 to 0 (removing power from the port). This feature is implemented in all controller cores (PPC = 1). 0 - Off 1 - On
11-10 LS	Line Status Indicates the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. In Host mode, the host controller driver may not necessarily use LineState (unlike EHCI) because the port controller state machine and port routing manage the connection of LS and FS. In Device mode, the device controller driver may not necessarily use LineState. The following is the encoding of bits [11:10]. 00 - SE0 01 - K-state 10 - J-state 11 - Undefined
9 HSP	High-Speed Port Indicates whether the host or device connected to the port is in HS mode. The field is redundant for PORTSC1[PSPD] but is included for compatibility. 0 - Not in HS mode 1 - In HS mode
8 PR	Port Reset Specifies whether the port is in reset. In Host mode (read/write), the bus-reset sequence (as defined in the USB Specification Revision 2.0) starts when you write 1 to this field. This field automatically changes to zero after the reset sequence is complete. This behavior is different from that of EHCI where the host controller driver is required to write 0 to this field after the reset duration is timed in the driver. In Device mode, this is a read-only status field. Device reset from the USB bus is also indicated in USB Status (USBSTS). This field is 0 if PORTSC1[PP] is 0. 0 - Port not in reset 1 - Port in reset

Table continues on the next page...

Table continued from the previous page...

Field	Description
7 SUSP	Suspend Specifies whether the port is in the Suspended state. In Host mode (read/write), this field works with PORTSC1[PE] to define the port states as follows: In case of {PE, SUSP} port state: 0x - Disable 10 - Enable 11 - Suspend When in the Suspended state, downstream propagation of data is blocked on this port (except for port reset). Blocking occurs at the end of the current transaction if a transaction was in progress when this field was 1. The port is sensitive to resume detection in the Suspended state. The status of the field does not change until the port is suspended; there may be a delay in suspending a port if a transaction is in progress on USB. The host controller unconditionally writes 0 to this field when you write 0 to PORTSC1[FPR]. The host controller ignores a write of zero to this field. If host software writes 1 to this field when the port is not enabled (that is, PORTSC1[PE] is 0), the results are undefined. This field is 0 if PORTSC1[PP] is 0 in Host mode. In Device mode, this is a read-only status field. 0 - Port not in Suspended state 1 - Port in Suspended state
6 FPR	Force Port Resume Specifies whether force resume is detected or driven on the port. In Host mode, write 1 to this field to drive resume signaling. The host controller writes 1 to this field if a J-to-K transition is detected when the port is in the Suspended state. When this field transitions to 1 because a J-to-K transition is detected, USBSTS[PCI] also becomes 1. This field automatically changes to 0 after the resume sequence is complete. This behavior is different from that of EHCI where the host controller driver is required to write 0 to this field after the resume duration is timed in the driver. When the host controller owns the port, the resume sequence follows the defined sequence documented in USB specification revision 2.0. The resume signaling (full-speed "K") is driven on the port until this field remains 1 (that is, until the port has switched to the high-speed idle state). Writing 0 to this field has no effect because the port controller times the resume operation, clears the field, and the port control state switches to HS or FS idle. This field is not-EHCI compatible and remains 0 if PORTSC1[PP] is 0 in Host mode. In Device mode, you must write 1 to this field to drive resume signaling after the device is in the Suspended state for 5 ms or more. The device controller writes 1 to this field if a J-to-K transition is detected when the port is in the Suspended state. The field becomes 0 when the device returns to normal operation. Additionally, when this field becomes 0 because of a K-to-J transition detection, USBSTS[PCI] also becomes 1. 0 - No resume (K-state) detected or driven on port

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Resume detected or driven on port
5 OCC	Overcurrent Change Flag Indicates whether an overcurrent change occurred. Hardware sets this field to 1 when there is a change in an overcurrent active condition. **NOTE** This field behaves differently for register reads and writes. When reading 0 - No change occurred 1 - Change occurred When writing 0 - No effect 1 - Clear the flag
4 OCA	Overcurrent Active Indicates whether the port currently has an overcurrent condition. This field automatically transitions from 1 to 0 when the overcurrent condition is removed. 0 - Overcurrent condition exists 1 - No overcurrent condition exists
3 PEC	Port Enable and Disable Change Flag Indicates whether the port enabled and disabled status has changed. In Host mode (for the root hub), this flag is set to 1 only when a port is disabled because of disconnect on the port or because of appropriate conditions existing at the EOF2 point (see chapter 11 of the USB specification). This field is 0 if PORTSC1[PP] is 0. In Device mode, the device port is always enabled; therefore, this field is always 0. **NOTE** This field behaves differently for register reads and writes. When reading 0 - No change occurred 1 - Change occurred When writing 0 - No effect 1 - Clear the flag
2	Port Enable and Disable

Table continues on the next page...

Table continued from the previous page...

Field	Description
PE	Enables a port. In Host mode, this field is reset to 0b. Only the host controller can enable ports as part of reset and enable. You cannot enable a port by writing 1 to this field, and either a fault condition (such as a disconnect event) or host software can disable a port. The status of this field does not change until the port state actually changes. There may be a delay in disabling or enabling a port because of other host controller and bus events. When this field is 0 (the port is disabled), downstream propagation of data is blocked except for reset. In Host mode, this field is 0 if PORTSC1[PP] is 0. In Device mode, this field is always 1 (the device port is always enabled). 0 - Disable 1 - Enable
1 CSC	Connect Status Change Flag Indicates whether a change has occurred in the port's current connect status. In Host mode, the host or device controller sets this field for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the connect status (PORTSC1[CCS]) changes twice before you clear PORTSC1[CSC]. The hub hardware sets an already-set field (that is, CSC remains set). You can clear this field by writing 1 to it. In Host mode, this field is 0 if PORTSC1[PP] is 0. In Device Controller mode, this field is undefined. **NOTE** This field behaves differently for register reads and writes. When reading 0 - No change occurred 1 - Change occurred When writing 0 - No effect 1 - Clear the flag
0 CCS	Current Connect Status Indicates the current port connection status. In Host mode, if this field is 1, the device is present on port, and if this field is 0 (default), no device is present. This value reflects the current state of the port, and may not correspond directly to the event that causes this field to be set. In Host mode, this field is 0 if PORTSC1[PP] is 0. In Device mode, if this field is 1, it indicates that the device is successfully attached and is operating in either high speed or full speed, as indicated by PORTSC1[HSP]. If this field is 0, it indicates that the device is not

Table continues on the next page...

Table continued from the previous page...

Field	Description
	attached successfully or is forcibly disconnected by writing 0 to USBCMD[RS]. It does not state the device being disconnected or suspended.

41.7.1.1.33 On-The-Go Status and Control (OTGSC)

Provides OTG status and control.

This register is available only in OTG controller core and includes fields for:

- OTG interrupt enables (read/write)
- OTG interrupt status (read/write to clear)
- OTG status inputs (read-only)
- OTG controls (read/write)

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms do not cause an update of the status input register, or cause an OTG interrupt.

See USB Device Mode (USBMODE) for more information.

Offset

Register	Offset
OTGSC	1A4h

Field	Description
31 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
30 DPIE	Data Pulse Interrupt Enable Enables the data pulse interrupt. Writing 1 to the field enables the interrupt.
29 EN_1MS	1 Millisecond Timer Interrupt Enable Enables the 1 ms timer interrupt. Writing 1 to the field enables the interrupt.
28 BSEIE	B Session End Interrupt Enable Enables the B session end interrupt. Writing 1 to the field enables the interrupt.
27 BSVIE	B Session Valid Interrupt Enable Enables the B session valid interrupt. Writing 1 to the field enables the interrupt.
26 ASVIE	A Session Valid Interrupt Enable Enables the A session valid interrupt. Writing 1 to the field enables the interrupt.
25 AVVIE	A VBUS Valid Interrupt Enable Enables the A VBUS valid interrupt. Writing 1 to the field enables the interrupt.
24 IDIE	USB ID Interrupt Enable Enables the USB ID interrupt. Writing 1 to the field enables the interrupt.
23 —	Reserved
22 DPIS	Data Pulse Interrupt Status Flag Indicates the status of the data pulse interrupt. This field becomes 1 when data bus pulsing occurs on a DP or DM line. Data bus pulsing is detected only when USBMODE[CM] = 11b and PORTSC1[PP] = 0b. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Data pulse did not occur 1 - Data pulse occurred When writing 0 - No effect 1 - Clear the flag
21 STATUS_1MS	1 Millisecond Timer Interrupt Status Flag Indicates the status of the timer interrupt. This field becomes 1 once every millisecond.

Table continues on the next page...

Table continued from the previous page...

Field	Description
20 BSEIS	B Session End Interrupt Status Flag Indicates the status of the B session end interrupt. This field becomes 1 when VBUS has fallen below the B session end threshold. **NOTE** This field behaves differently for register reads and writes. When reading 0 - No change 1 - Fallen below the threshold When writing 0 - No effect 1 - Clear the flag
19 BSVIS	B Session Valid Interrupt Status Flag Indicates the status of the B session valid interrupt. This field becomes 1 when VBUS has either risen above or fallen below the B session valid threshold. **NOTE** This field behaves differently for register reads and writes. When reading 0 - No change 1 - Risen above or fallen below the threshold When writing 0 - No effect 1 - Clear the flag
18 ASVIS	A Session Valid Interrupt Status Flag Indicates the status of the A session valid interrupt. This field becomes 1 when VBUS has either risen above or fallen below the A session valid threshold. **NOTE** This field behaves differently for register reads and writes. When reading 0 - No change 1 - Risen above or fallen below the threshold When writing 0 - No effect

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Clear the flag
17 AVVIS	A VBUS Valid Interrupt Status Flag Indicates the status of the A VBUS valid interrupt. This field becomes 1 when VBUS has either risen above or fallen below the VBUS valid threshold on A device. **NOTE** This field behaves differently for register reads and writes. When reading 0 - No change 1 - Risen above or fallen below the threshold When writing 0 - No effect 1 - Clear the flag
16 IDIS	USB ID Interrupt Status Flag Indicates the status of the USB ID interrupt. This field becomes 1 when a change on the ID input is detected. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Change not detected 1 - Change detected When writing 0 - No effect 1 - Clear the flag
15 —	Reserved
14 DPS	Data Bus Pulsing Status Indicates the status of data bus pulsing. If this field is 1, it indicates that data bus pulsing is detected on the port.
13 TOG_1MS	1 Millisecond Timer Toggle Toggles once per millisecond.
12	B Session End

Table continues on the next page...

Table continued from the previous page...

Field	Description
BSE	Indicates that VBUS is below the B session end threshold.
11 BSV	B Session Valid Indicates that VBUS is above the B session valid threshold.
10 ASV	A Session Valid Indicates that VBUS is above the A session valid threshold.
9 AVV	A VBUS Valid Indicates that VBUS is above the A VBUS valid threshold.
8 ID	USB ID Indicates the USB ID. 0 - A device 1 - B device
7-6 —	Reserved
5 IDPU	ID Pullup Provides control over the ID pull-up resistor. If this field is 0, the functionality is off and the ID input is not sampled. If this field is 1 (default), the functionality is on and the ID input is sampled.
4 DP	Data Pulsing Controls pullup on the DP line. Writing 1 to this field causes the pullup on the DP line to be asserted for data pulsing during SRP.
3 OT	OTG Termination Controls pulldown on the DM line. This field must be 1 when the OTG device is in Device mode to control the pulldown on the DM line.
2 —	Reserved
1 VC	VBUS Charge Controls VBUS pulsing during SRP. Writing 1 to this field causes the VBUS line to be charged.
0 VD	VBUS Discharge Discharges VBUS through a resistor.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Writing 1 to this field causes VBUS to discharge through a resistor.

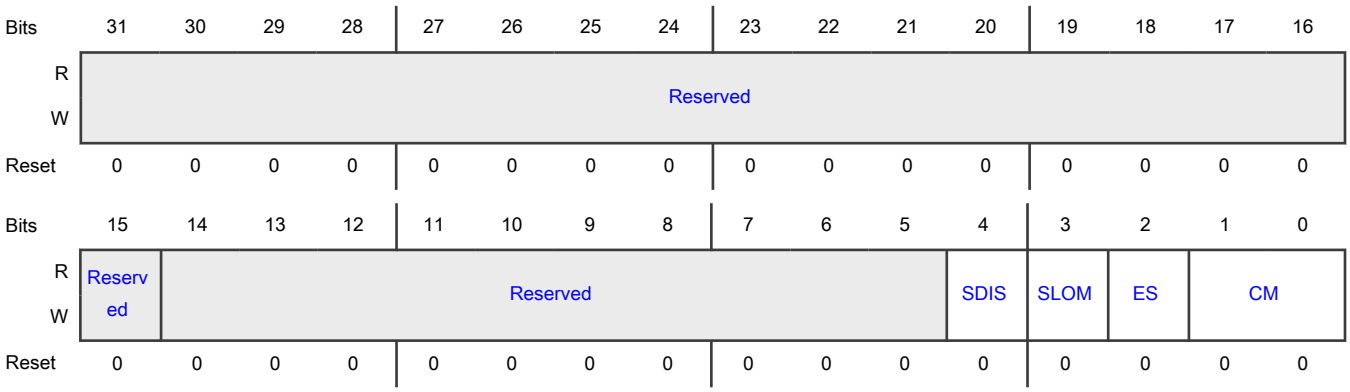
41.7.1.1.34 USB Device Mode (USBMODE)

Selects the USB device mode.

Offset

Register	Offset
USBMODE	1A8h

Diagram



Fields

Field	Description
31-16 —	Reserved
15 —	Reserved
14-5 —	Reserved
4 SDIS	Stream Disable Mode Disables double priming for low-bandwidth systems. In Device mode, writing 1 to this field disables double priming on both RX and TX for low-bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet, the standard double buffering scheme is disabled to prevent overruns and underruns in bandwidth limited systems.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE In High-Speed mode, all packets received are responded to with an NYET handshake when stream disable is active. In Host mode, writing 1 to this field ensures that overruns and underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also ensures that the TX latency is filled to capacity before the packet is launched onto the USB. **NOTE** The time duration to prefill the FIFO becomes significant when stream disable is active. See TX FIFO Fill Tuning (TXFILLTUNING) and TXTTFILLTUNING (MPH only) to characterize the adjustments needed for the scheduler when using this feature. The use of this feature substantially limits the overall USB performance that can be achieved. 0 - Disable 1 - Enable
3 SLOM	Setup Lockout Mode Specifies whether the setup lockouts are on. In Device mode, this field controls the behavior of the setup lock mechanism. See Control endpoint operation model for more information. DCD requires you to use the setup data buffer tripwire in USB Command (USBCMD). 0 - On (default) 1 - Off
2 ES	Endian Select Selects the endianness. You can use this field to change the byte alignment of the transfer buffers to match the host microprocessor. The fields in the microprocessor interface and the data structures are unaffected by the value of this field because they are based on the 32-bit word. 0 - Little endian (default) 1 - Big endian
1-0 CM	Controller Mode Specifies the controller mode. Controller mode is defaulted to the proper mode for host-only and device-only implementations. For those designs that contain both host & device capability, the controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. For combination host and device controllers, you can write to this register only once after reset. If it is necessary to switch modes, you must reset the controller by writing to USBCMD[RST] before reprogramming this register. For the OTG controller core, the reset value is 00b.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	00 - Idle (default for host and device combination) 01 - Reserved 10 - Device controller (default for device-only controller) 11 - Host controller (default for host-only controller)

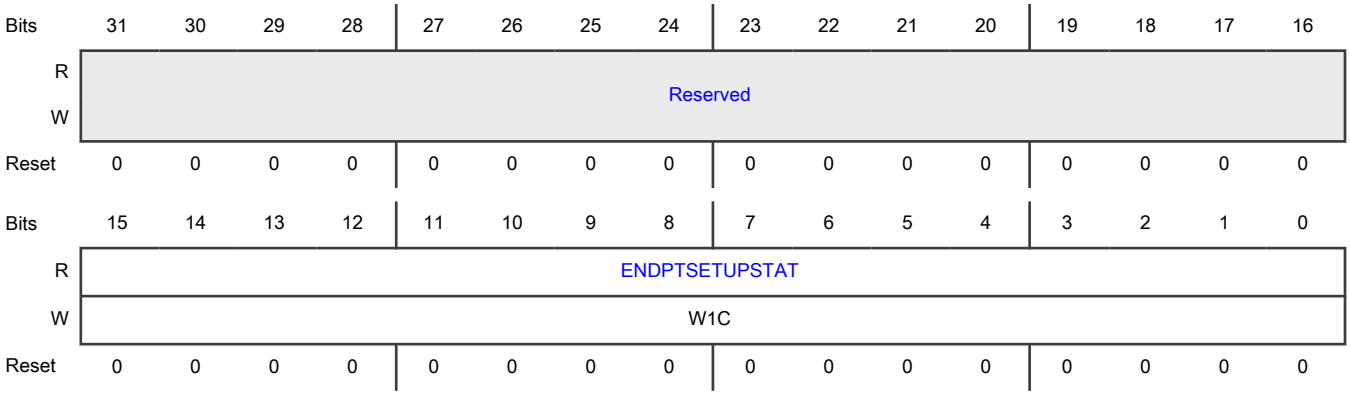
41.7.1.1.35 Endpoint Setup Status (ENDPTSETUPSTAT)

Indicates the endpoint setup status.

Offset

Register	Offset
ENDPTSETUPSTAT	1ACh

Diagram



Fields

Field	Description
31-16 —	Reserved
15-0 ENDPTSETUPSTAT	Endpoint Setup Status Flag Indicates the endpoint setup status and whether the setup transaction is received. For every setup transaction that is received, a corresponding bit in this field becomes 1. You must clear or acknowledge the setup transfer by writing 1 to the respective bit after it has read the setup data from the queue head.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	The response to a setup packet includes many operations in an order. The total response time is crucial to limit bus timeouts if the setup lockout mechanism is engaged. See Managing endpoints in the device operational model. This register is used only in Device mode. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000_0000_0000 - Not received 0000_0000_0000_0001 - Received When writing 0000_0000_0000_0000 - No effect 0000_0000_0000_0001 - Clear the flag

41.7.1.1.36 Endpoint Prime (ENDPTPRIME)

Primes the endpoint.

When you set the prime bit for a given endpoint, the device controller loads the transfer descriptor, pointed to by the queue head, so that the endpoint is ready to transmit or receive when the host sends a request ("In" or "Out" token). The endpoint NAKs all requests from the host until the endpoint is primed. The controller automatically reprimes the endpoint with a new transfer descriptor when one is found via the next_dtd pointer of the current transfer descriptor. Therefore, you must set the prime bit only when a descriptor is added to the queue head.

Offset

Register	Offset
ENDPTPRIME	1B0h

Fields

Field	Description
31-24 —	Reserved
23-16 PETB	Prime Endpoint Transmit Buffer Parses a new transfer descriptor from the queue head and prepares for a transmit buffer. For each endpoint, a corresponding bit is used to request that a buffer is prepared for a transmit operation to respond to a USB "In" or "Interrupt" transaction. You must write 1 to the corresponding bit when posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and preparing a transmit buffer. Hardware writes 0 to this field when the associated endpoint is successfully primed. PETB[*n*] - Endpoint [*n*], *n* is in 0–7 **NOTE** Hardware temporarily writes 1 to this field during hardware repriming operations when a dTD is retired and the dQH is updated.
15-8 —	Reserved
7-0 PERB	Prime Endpoint Receive Buffer Parses a new transfer descriptor from the queue head and prepares for a receive buffer. For each endpoint, a corresponding bit is used to request that a buffer is prepared for a receive operation when a USB host initiates a USB "Out" transaction. You must write 1 to the corresponding bit when posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this field to begin parsing for a new transfer descriptor from the queue head and preparing a receive buffer. Hardware writes 0 to this field when an associated endpoint is successfully primed. PERB[*n*] - Endpoint [*n*], *n* is in 0–7 **NOTE** Hardware temporarily writes 1 to this field during hardware repriming operations when a dTD is retired and the dQH is updated.

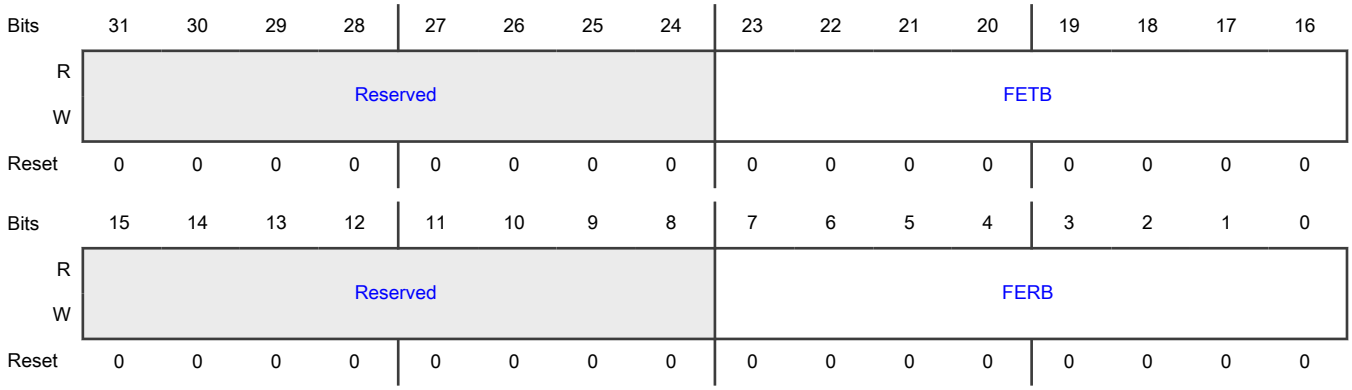
41.7.1.1.37 Endpoint Flush (ENDPTFLUSH)

Flushes the endpoint.

Offset

Register	Offset
ENDPTFLUSH	1B4h

Diagram



Fields

Field	Description
31-24 —	Reserved
23-16 FETB	Flush Endpoint Transmit Buffer Clears any primed transmit buffers. When you write 1 to this field, it causes the associated endpoints to clear any primed transfer buffers. If a packet is in progress for one of the associated endpoints, then that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FETB[*n*]: Endpoint [*n*], *n* is in 0–7
15-8 —	Reserved
7-0 FERB	Flush Endpoint Receive Buffer Clears any primed receive buffers. When you write 1 to this field, it causes the associated endpoints to clear any primed receive buffers. If a packet is in progress for one of the associated endpoints, then that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FERB[*n*]: Endpoint [*n*], *n* is in 0–7

41.7.1.1.38 Endpoint Status (ENDPTSTAT)

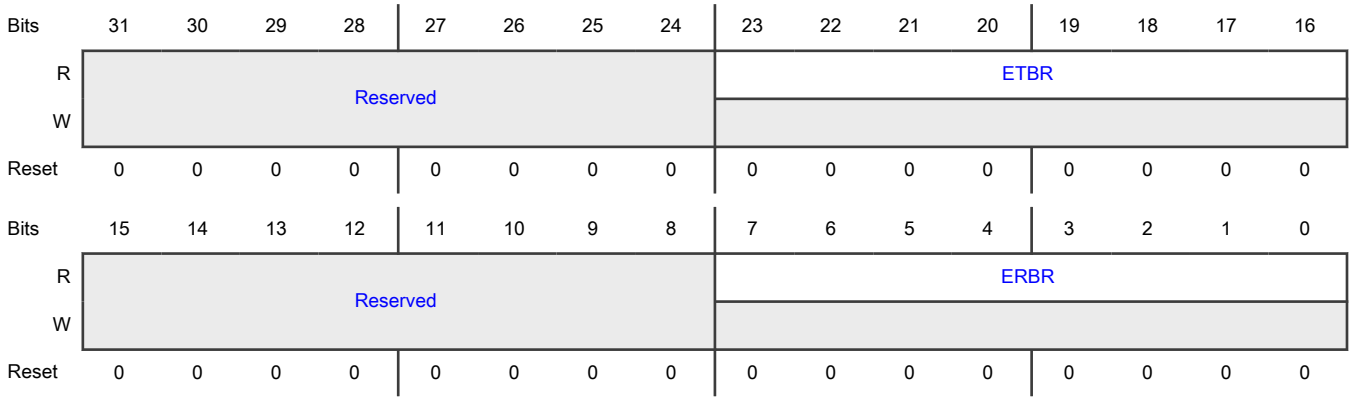
Indicates endpoint transmit and receive buffer ready status.

This register is only used in Device mode.

Offset

Register	Offset
ENDPTSTAT	1B8h

Diagram



Fields

Field	Description
31-24 —	Reserved
23-16 ETBR	Endpoint Transmit Buffer Ready Indicates the endpoint transmit buffer ready status. One bit for each endpoint indicates the status of the respective endpoint buffer. Hardware writes 1 to this field as a response to receiving a command from a corresponding field in Endpoint Prime (ENDPTPRIME). There is always a delay between writing 1 to the corresponding field in Endpoint Prime (ENDPTPRIME) and the endpoint indicating the ready status. This delay time varies based on the current USB traffic and the number of fields with value 1 in Endpoint Prime (ENDPTPRIME). This field becomes 0 via the USB reset, USB DMA system, or through Endpoint Flush (ENDPTFLUSH). ETBR[*n*]: Endpoint [*n*], *n* is in 0–7 **NOTE** Hardware temporarily clears this field during hardware endpoint repriming operations when a dTD is retired and the dQH is updated.
15-8 —	Reserved
7-0 ERBR	Endpoint Receive Buffer Ready Indicates the endpoint receive buffer ready status. One bit for each endpoint indicates status of the respective endpoint buffer. Hardware writes 1 to this field as a response to receiving a command from a corresponding field in Endpoint Prime (ENDPTPRIME). There is always a delay between writing 1 to the corresponding field in Endpoint Prime (ENDPTPRIME) and the endpoint indicating the ready status. This delay time varies based on the current USB traffic and the number of fields with value 1 in Endpoint Prime (ENDPTPRIME). This field becomes 0 via the USB reset, USB DMA system, or through Endpoint Flush (ENDPTFLUSH). ERBR[*n*]: Endpoint [*n*], *n* is in 0–7

Fields

Field	Description
31-24 —	Reserved
23-16 ETCE	Endpoint Transmit Complete Event Flag Indicates whether a transmit event (Out or Setup) occurred. You must read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the transfer descriptor, then this field is set along with USBSTS[UI]. ETCE[*n*]: Endpoint [*n*], *n* is in 0–7 **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When reading 0000_0000 - Transmit did not complete 0000_0001 - Transmit completed When writing 0000_0000 - No effect 0000_0001 - Clear the flag
15-8 —	Reserved
7-0 ERCE	Endpoint Receive Complete Event Flag Indicates whether a received event (Out or Setup) occurred. You must read the corresponding endpoint queue to determine the transfer status. If the corresponding IOC bit is set in the transfer descriptor, then this field is set along with USBSTS[UI]. ERCE[*n*]: Endpoint [*n*], *n* is in 0–7 **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000 - Receive did not complete 0000_0001 - Receive completed When writing 0000_0000 - No effect 0000_0001 - Clear the flag

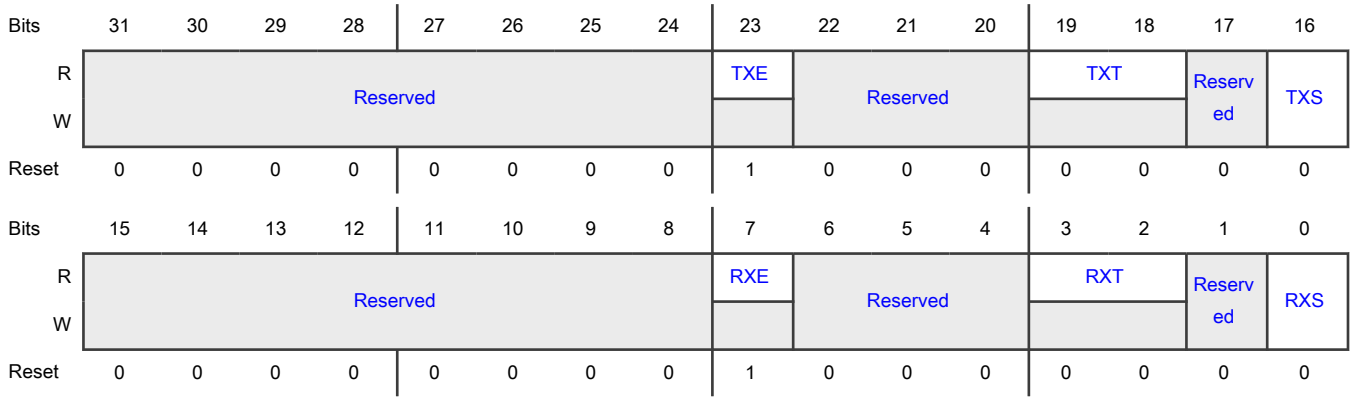
41.7.1.1.40 Endpoint Control 0 (ENDPTCTRL0)

Forces the endpoint to return a STALL handshake to the host. Every device uses this register as a control endpoint.

Offset

Register	Offset
ENDPTCTRL0	1C0h

Diagram



Fields

Field	Description
31-24 —	Reserved
23 TXE	TX Endpoint Enable Enables transmit endpoint. You must enable an endpoint only after it is configured. 0 - Disable 1 - Enable
22-20 —	Reserved
19-18 TXT	TX Endpoint Type Indicates the transmit endpoint type. If this field is 0, endpoint 0 is fixed as a control endpoint.
17 —	Reserved
16 TXS	TX Endpoint Stall Specifies whether the transmit endpoint is stalled. If you write 1 to this field, it forces the endpoint to return a STALL handshake to the host. The field continues returning a STALL response until you write 0 to it or if the field automatically becomes 0 after it receives a new Setup request. After receiving a Setup request, hardware continues to write 0 to this field until the associated endpoint setup status field (ENDPTSETUPSTAT[ENDPTSETUPSTAT]) is cleared.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE There is a slight delay (a maximum of 50 clocks) between clearing ENDPTSETUPSTAT[ENDPTSETUPSTAT] and the hardware continuing to write 0 to this field. In most systems, it is unlikely for the DCD to observe this delay. However, if DCD observes that this field is not becoming 1, you must continually write to this field until it becomes 1 or until a new setup is received (check ENDPTSETUPSTAT[ENDPTSETUPSTAT] for that). 0 - Endpoint OK 1 - Endpoint stalled
15-8 —	Reserved
7 RXE	RX Endpoint Enable Enables the receive endpoint. Endpoint 0 is always enabled. 0 - Disable 1 - Enable
6-4 —	Reserved
3-2 RXT	RX Endpoint Type Indicates the receive endpoint type. If this field is 0, endpoint 0 is fixed as a control endpoint.
1 —	Reserved
0 RXS	RX Endpoint Stall Specifies whether the receive endpoint is stalled. If you write 1 to this field, it forces the endpoint to return a STALL handshake to the host. The field continues returning a STALL response until you write 0 to it or if the field automatically becomes 0 after it receives a new Setup request. After receiving a Setup request, hardware continues to write 0 to this field until the associated endpoint setup status field (ENDPTSETUPSTAT[ENDPTSETUPSTAT]) is cleared.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE There is a slight delay (a maximum of 50 clocks) between clearing ENDPTSETUPSTAT[ENDPTSETUPSTAT] and the hardware continuing to write 0 to this field. In most systems, it is unlikely for the DCD to observe this delay. However, if DCD observes that this field is not becoming 1, you must continually write to this field until it becomes 1, or until a new setup is received (check ENDPTSETUPSTAT[ENDPTSETUPSTAT] for that). 0 - Endpoint OK 1 - Endpoint stalled

41.7.1.1.41 Endpoint Control 1 (ENDPTCTRL1)

Enables endpoint control 1.

This register is used for endpoint 1 in Device Operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of the opposite direction is disabled, then the unused direction type must be changed from the default control type to any other type (bulk type). Leaving an unconfigured endpoint control causes undefined behavior for the data PID tracking on the active endpoint or direction.

16 TXS	TX Endpoint Stall Specifies whether the transmit endpoint is stalled. If this endpoint is configured as a control endpoint, this field automatically becomes 1 after receiving a Setup request. Hardware continues to write 0 to this field until the associated endpoint setup status field (ENDPTSETUPSTAT[ENDPTSETUPSTAT]) becomes 0. You can write 1 to this field to force the endpoint to return a STALL handshake to the host. This control continues to stall until you write 0 to this field or when it becomes 0 automatically for control endpoints. **NOTE** Control endpoint only: There is a slight delay (a maximum of 50 clocks) between clearing ENDPTSETUPSTAT[ENDPTSETUPSTAT] and hardware continuing to write 0 to this field. In most systems, it is unlikely that DCD will observe this delay. However, if DCD observes that this field is not becoming 1, you must continually write to this field until it becomes 1, or until a new setup is received (check ENDPTSETUPSTAT[ENDPTSETUPSTAT] for that). 0 - Endpoint OK 1 - Endpoint stalled
15-8 —	Reserved
7 RXE	RX Endpoint Enable Enables the receive endpoint. You must enable an endpoint only after it is configured. 0 - Disable 1 - Enable
6 RXR	RX Data Toggle Reset Resets receive data toggle. If you write 1 to this field, it resets the PID sequence. When a configuration event is received for this endpoint, you must write 1 to this field to synchronize the data PIDs between the host and device. 0 - Does not reset 1 - Resets
5 RXI	RX Data Toggle Inhibit Inhibits receive data toggle sequencing. This field is used only for testing; you must always write 0 to it. Writing 1 to this field causes this endpoint to ignore the data toggle sequence and always accept data packets regardless of their data PID. 0 - Allow 1 - Inhibit

Table continues on the next page...

Field	Description
4 —	Reserved
3-2 RXT	RX Endpoint Type Specifies the receive endpoint type. 00 - Control 01 - Isochronous 10 - Bulk 11 - Interrupt
1 RXD	RX Endpoint Data Sink Specifies the data sink of the RX endpoint. By default, this field is 0, which refers to dual port memory buffer or DMA engine. You must always write 0 to this field.
0 RXS	RX Endpoint Stall Specifies whether the receive endpoint is stalled. If this endpoint is configured as a control endpoint, this field automatically becomes 1 after receiving a Setup request. Hardware continues to write 0 to this field until the associated endpoint setup status field (ENDPTSETUPSTAT[ENDPTSETUPSTAT]) becomes 0. You can write 1 to this field to force the endpoint to return a STALL handshake to the host. This control continues to stall until you write 0 to this field or when it becomes 0 automatically for control endpoints. **NOTE** Control endpoint only: There is a slight delay (a maximum of 50 clocks) between clearing ENDPTSETUPSTAT[ENDPTSETUPSTAT] and hardware continuing to write 0 to this field. In most systems, it is unlikely that the DCD will observe this delay. However, if DCD observes that this field is not becoming 1, you must continually write to this field until it becomes 1, or until a new setup is received (check ENDPTSETUPSTAT[ENDPTSETUPSTAT] for that). 0 - Endpoint OK 1 - Endpoint stalled

41.7.1.1.44 Endpoint Control 4 (ENDPTCTRL4)

Enables endpoint control 4.

This register is used for endpoint 4 in Device Operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of the opposite direction is disabled, then the unused direction type must be changed from the default control type to any other type (bulk type). Leaving an unconfigured endpoint control causes undefined behavior for the data PID tracking on the active endpoint or direction.

30 TXPREEMPPULSETUNE0	HS Transmitter Pre-Emphasis Duration Control Controls the duration for which the HS pre-emphasis current is sourced onto DP or DM. The HS transmitter pre-emphasis duration is defined in terms of unit amounts. One unit of pre-emphasis duration is approximately 580 ps and is defined as 1X pre-emphasis duration. This signal is valid only if either TXPREEMPAMPTUNE or TXPREEMPAMPTUNE is 1'b1. If TXPREEMPPULSETUNE is not used, set it to the design default. 0 - Design default; long pre-emphasis current duration 1 - Short pre-emphasis current duration
29-28 TXPREEMPAMPTUNE0	HS Transmitter Pre-Emphasis Current Control Controls the amount of current sourced to DP and DM after a J-to-K or K-to-J transition. The HS transmitter pre-emphasis current is defined in terms of unit amounts. One unit amount is approximately 600 µA and is defined as 1X pre-emphasis current. If these signals are not used, set them to the design default (2'b01). 00 - HS transmitter pre-emphasis is disabled 01 - HS transmitter pre-emphasis circuit sources 1x pre-emphasis current 10 - HS transmitter pre-emphasis circuit sources 2x pre-emphasis current 11 - HS transmitter pre-emphasis circuit sources 3x pre-emphasis current
27-26 TXRESTUNE0	USB Source Impedance Adjustment Adjusts the driver source impedance to compensate for added series resistance on the USB (in some applications, there can be significant series resistance on the D+ and D– paths between the transceiver and cable).

Chapter 42
Universal Serial Bus 2.0 PHY (USB2_PHY)

42.1 Overview

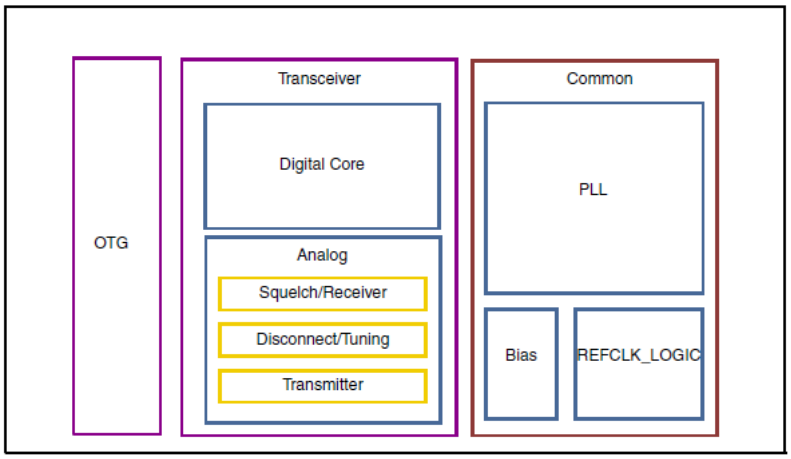
The USB 2.0 PHY, connects a USB controller to a USB system. This chapter provides an introduction to the USB 2.0 PHY and its features.

NOTE

The sections in this chapter are Synopsys Proprietary. Used with permission.

42.1.1 Block Diagram

The following figure shows the USB 2.0 PHY functional block diagram for a one-port macro.



42.1.1.1 System Level Block Diagram

The following figure shows the USB 2.0 PHY and its external interface connections.

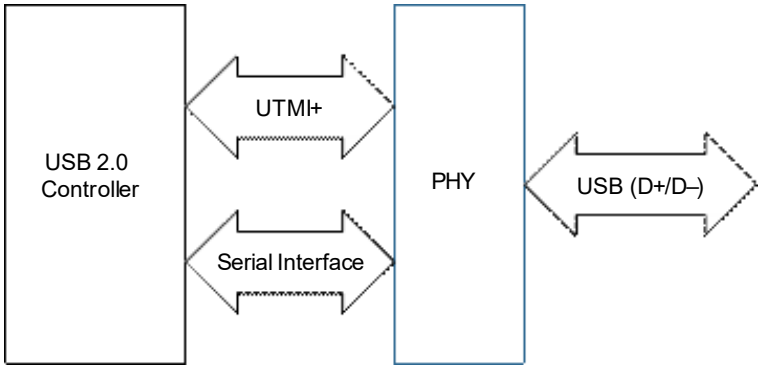


Figure 171. System Level Block Diagram

42.1.2 Features

The USB 2.0 PHY provides the following features.

General Features:

- Implements low power dissipation while active, idle, or on standby
- Fully integrates high-, full-, and low-speed (Host mode only) termination and signal switching
- Implements one parallel data interface and clock for high-, full-, and low-speed (Host mode only) USB data transfers
- Provides on-chip PLL to reduce clock noise and eliminate the need for an external clock generator
- Provides Universal Asynchronous Receiver/Transmitter (UART) support to enable the USB 2.0 PHY to receive and transmit asynchronous, serial data

USB 2.0 Features:

- Supports 480-Mbps high-speed, 12-Mbps full-speed, and 1.5-Mbps low-speed (Host mode only) data transmission rates
- Supports 8/16-bit unidirectional parallel interfaces for HS, FS, and LS (Host mode only) modes of operation, in accordance with the UTMI+ specification
- Provides dual (HS/FS) mode host support
- Implements data recovery from serial data on the USB connector
- Implements SYNC/End-of-Packet (EOP) generation and checking
- Implements Non Return to Zero Invert (NRZI) encoding and decoding Implements logic to support suspend, sleep, resume, and remote wakeup operations
- Supports battery charging to enable devices to draw current in excess of the USB 2.0 specification for charging and/or powering up from dedicated charging ports or charging downstream ports

42.1.3 Interfaces

Each USB 2.0 PHY port has three distinct external interfaces:

- USB Data Plus (D+) and Data Minus (D–) lines: These lines are USB 1.1 and 2.0 specificationcompliant. The USB 2.0 PHY supports high-speed, 480-Mbps transfers, as well as USB 1.1 fullspeed and low-speed transfers through the USB.
- USB 2.0 Transceiver Macrocell Interface (UTMI+): The USB 2.0 PHY supports the following modes through the UTMI+:
  - High-Speed (HS)
  - Full-Speed (FS)
  - Low-Speed Preamble (LS Preamble)

  The UTMI+ contains a receive port, a transmit port, and associated control lines to interface with a USB host controller or device controller. The receive and transmit ports can be configured as 8/16-bit parallel ports for all applicable modes of operation.
- Serial interface: This is the USB 1.1 controller interface that supports full-speed (FS-Serial mode) and low-speed (LS-Serial mode) data transmission rates to and from a USB 1.1 controller.

The USB 2.0 PHY handles low-level USB protocol and signaling. The USB 2.0 PHY supports SYNC detection, data serialization and deserialization, and data recovery.

42.1.4 Standards Compliance

The USB 2.0 PHY complies with the following standards:

- Universal Serial Bus Specification, Revision 2.0, with a High-Speed (HS) Transmit to Receive Inter- Packet Delay requirement of 38 bit-times provided by the UTMI specification version 1.05.
- Embedded Host Supplement to the USB Revision 2.0 Specification, Revision 2.0, USB Implementers Forum, Inc. ADP (Attach Detach Protocol) is not supported.
- UTMI+ Specification, Revision 1.0 (Level 3)

42.2 Clock Generation

The following figure shows the USB 2.0 PHY clock generation and distribution architecture, and the functional behavior of blocks that generate various clocks in the USB 2.0 PHY.

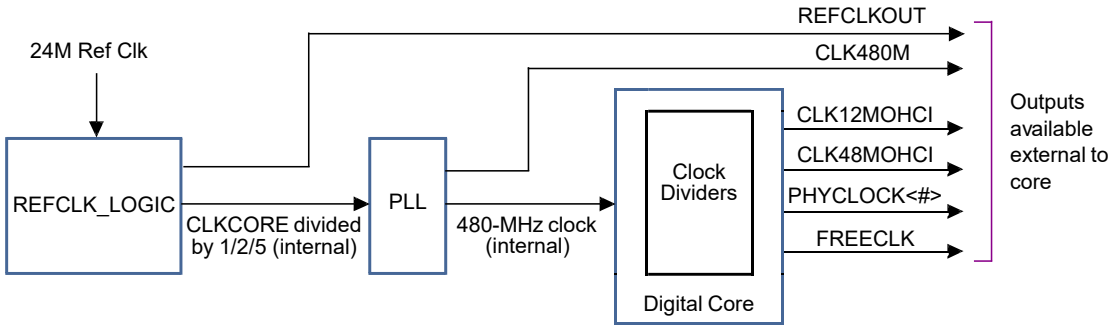

Figure 172. Clock Generation

42.3 Device Initialization

According to the USB 2.0 specification, a host must provide 100 ms between first detecting the D+ line at a high state and initiating a USB reset (SE0). The device pulling up the D+ line is expected to complete initialization within the 100-ms interval and be ready to respond to the host.

If the device requires more than 100 ms to initialize the device might connect the D+ resistance prior to initialization. After the 100-ms interval, the host initiates a USB reset. If the D+ pull-up resistance is enabled and remains enabled after the 100-ms interval, and if the device has not completed initialization, the device does not respond to the host correctly, and the transaction times out.

42.4 Tuning

The USB 2.0 PHY has an internal tuning circuit that ensures that the driver's impedance is within the USB 2.0 specification.

The USB 2.0 PHY performs two types of tuning:

- Incremental tuning: Incremental tuning occurs during an EOP, SOF, or SYNC pattern.
- Full tuning: Full tuning occurs during a power-on reset or after resume operation.

43.3 Overview

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

The EQoS-TSN module supports the 10/100/1000Mbps applications in compliance with IEEE802.3-2015 specifications. It can support advanced applications such as Time-Sensitive Networking (TSN) and Audio Video Bridge (AVB). Other prominent features of the MAC core include a flexible receive parser, media clock recovery and generation, and safety.

43.3.1 Block diagram

The following figure shows the block diagram of this module. The module has four main blocks to perform all functions. The AHB interface is connected to all DMA channels. The DMA arbiter helps in arbitration of all paths (transmit and receive) in channels. Each channel has a separate set of control and status registers (CSR) for managing the transmit and receive functions, descriptor handling, and interrupt handling.

NOTE

In multi queue/channel configurations, enable only Q0/CH0 on Tx and Rx for half-duplex operation. If you want to enable single queue/channel in full-duplex operation, any queue/channel can be enabled.

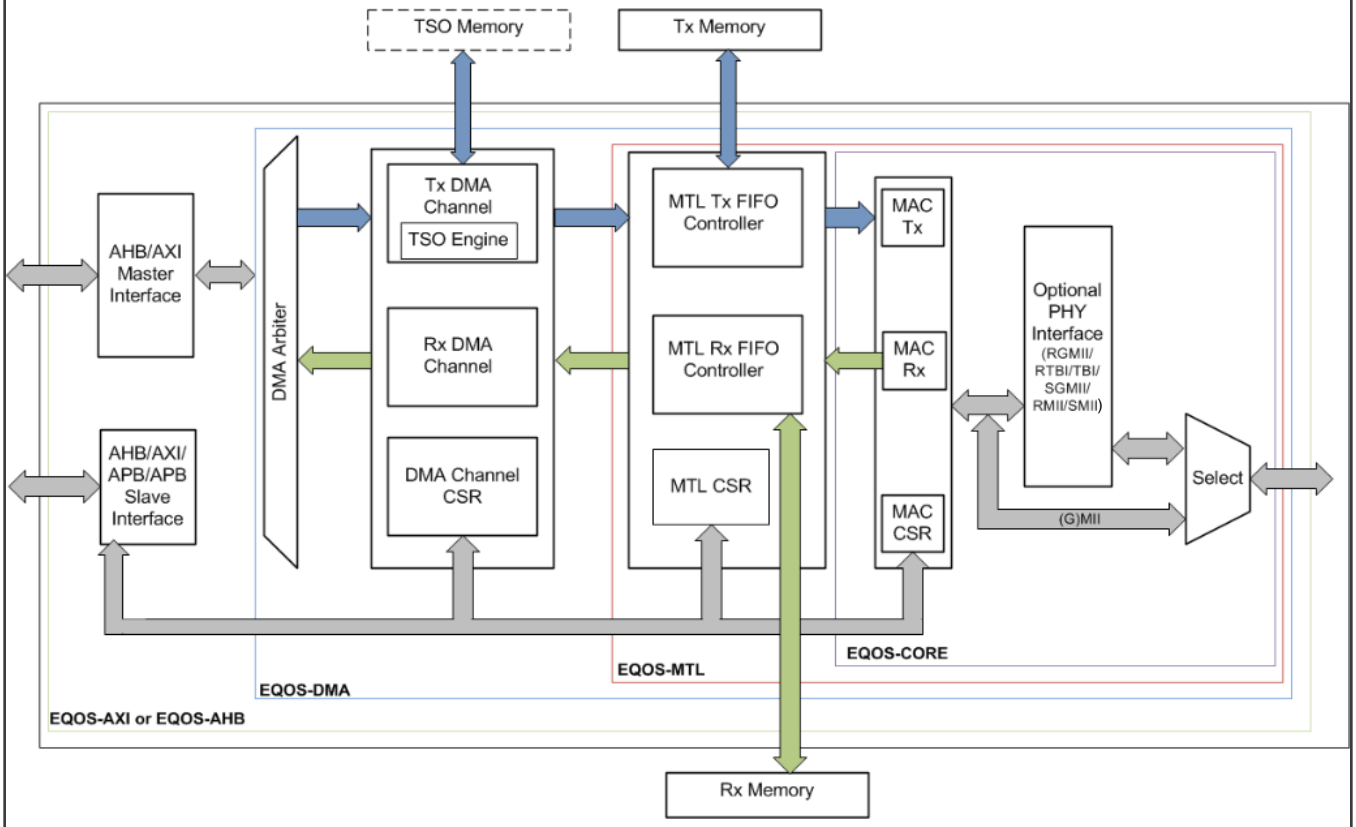

Figure 173. System-Level Block Diagram

43.3.2 Features

This module supports the following features in addition to the default features defined in IEEE802.3 specification

- RMII (10/100Mbps), RGMII (10/100/1000Mbps)
- Time aware shaper (IEEE802.1Qbv), Time synchronization (IEEE1588-2008), and Frame pre-emption (IEEE802.1Qbu) for Time-Sensitive Networking (TSN)
- Media clock recovery and generation for AVB
- RMII specification version 1.2 from RMII consortium
- RGMII specification version 2.6 from HP/Marvell
- Separate interface for Transmit, Receive and Control path
- Broadcast/Multicast Packet duplication
- Full duplex flow control operations (IEEE 802.3x pause packet and priority flow control)
- Network statistics with MAC management (RMON) counters
- Flexibility to control the Pulse per second (PPS) output signal
- MDIO (clause 22 and Clause 45) interface for configuration and management of PHY device
- Preamble and start of packet data (SFD) insertion/deletion

- Automatic CRC and pad generation/stripping option, option to disable CRC checking
- Programmable inter-packet gap
- Source address insertion/replacement
- VLAN insertion, replacement and deletion in transmitted packets with per-packet or static-global control
- Insertion, replacement and deletion of up to two VLAN tags
- Insertion, replacement and deletion of queue/channel based VLAN tags
- IEEE802.1Q VLAN tag detection and option to delete from received packets
- Programmable safety watchdog timeout limits
- Flexible address filtering modes:
  - Up to 2 additional 48-bit perfect (DA) address filters with masks for each byte
  - Up to 2 48-bit SA address comparison check with masks for each byte
  - 64-bit Hash filter for multicast and unicast (DA) addresses
  - Option to pass all multi-cast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Pass all incoming packets (as per filter) with a status report
- Additional packet filtering:
  - VLAN tag-based: Perfect match and Hash-based filtering. Filtering based on either outer or inner VLAN tag is possible
  - Layer 3 and Layer 4-based: TCP or UDP over IPv4 or IPv6
  - Extended VLAN tag based filtering 4 filter selections

43.4 Functional description

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

The following sections describe functional details of the ENET module.

43.4.1 Architecture

This section describes the interfaces, protocols, and functionality. Following are the main blocks of the ENET QOS block.

- DMA Controller
- MAC Transaction Layer (MTL)
- MAC
- Interrupts

43.4.1.1 DMA controller

The DMA has independent Transmit (Tx) and Receive (Rx) engines, and a control and status register (CSR) space. The Tx engine transfers data from the system memory to the MTL interface, whereas the Rx engine transfers data from the MTL interface to the system memory. The DMA engine uses descriptors to efficiently move data from source to destination with minimal Host intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The DMA controller can be programmed to interrupt the Host for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

The DMA and Host communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The DMA supports up to 5 Tx and 5 Rx Descriptor lists (or DMA channels). The base address of each list is written to the respective Tx Descriptor List Address register and Rx Descriptor List Address register. The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. The offset is controlled by the DSL field of DMA_Ch[n]_Control register. The number of descriptors in the list is programmed in the respective Tx (or Rx) Descriptor Ring Length register. Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the List Address register to create a descriptor ring.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers in the system memory. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. Buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when end of packet (EOP) is detected.

This module supports the ring structure for the DMA descriptor. For more information on Descriptor, see the Descriptors .

Following sections describes the operation of DMA Controller.

43.4.1.1.1 DMA Controller Bus Burst Access

The DMA engines attempt to transfer data in a burst of maximum size as programmed in the PBL bit fields of Transmit Control and Receive Control registers of the respective DMA. The Rx and Tx descriptors are always accessed in the maximum possible (limited by PBL or 16 * 8/bus width) burst length for 16 bytes to be read. The burst transfers initiated by the DMA can be split into multiple burst transfers as per the AHB requirements and the settings of DMA_SysBus_Mode register.

The Tx DMA initiates a data transfer only when sufficient space is available in the MTL Tx Queue to accommodate either of the following:

- Bytes corresponding to the configured burst (PBL * bus_width/8)
- Remaining bytes in Tx Buffer without EOP
- Number of bytes till EOP

The Rx DMA initiates a data transfer in the following conditions:

- Sufficient data is available in MTL Rx Queue to accommodate the configured burst
- EOP (when it is less than the configured burst length) is detected in the Rx Queue

43.4.1.1.2 DMA application data buffer alignment

The Tx and Rx data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers with address aligned to the bus width and dummy data (old data) in the invalid byte lanes. This typically happens during the transfer of the beginning or end of an Ethernet packet. For the receiver, the software driver should discard the dummy bytes based on the start address of the buffer and size of the packet.

Table 363. Data buffer alignment examples

Examples	
Buffer Read	If the Tx buffer address is 32'h00000FF2 (for 32-bit data bus), and 15 bytes need to be transferred, the DMA reads five full words from address 32'h00000FF0, but when transferring data to the MTL Tx queue, the extra

Table continues on the next page...

Table 363. Data buffer alignment examples (continued)

	bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the MTL Tx queue, unless it is the end of packet.
Buffer Write	If the Rx buffer address is 32'h0000FF2 (for 64-bit data bus) and 16 bytes of a received packet need to be transferred, the DMA writes 3 full words from address 32'h00000FF0. However, the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data. The DMA considers the offset address only if it is the first Rx buffer of the packet. The DMA ignores the offset address and performs full word writes for the middle and the last Rx buffer of the packet.

43.4.1.1.3 DMA buffer size calculations

The DMA does not update the size fields in the Tx and Rx descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations.

The Tx DMA transfers the exact number of bytes (indicated by buffer size field of TDES2) towards the MAC. If a descriptor is marked as first (FD bit of TDES3 is set), the DMA marks the first transfer from the buffer as SOP. If a descriptor is marked as last (LD bit of TDES3), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The Rx DMA transfers data to a buffer until the buffer is full or the end of packet is received from the MTL. When the FD bit of a descriptor is set, the amount of valid data in a buffer is accurately indicated by the buffer size field (programmed in DMA Channel Receive Control register) minus the data buffer pointer offset. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by the buffer size in Bits [14:1] of Receive Control register). To compute the amount of valid data in this final buffer, the driver must read the packet length (PL bits of RDES3[14:0]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The Rx DMA always transfers the start of next packet with a new descriptor.

43.4.1.2 MAC transaction layer

The MAC Transaction Layer (MTL) provides the FIFO memory Interface to buffer and regulate the packets between system memory and the MAC. It also enables the data to be transferred between the system clock and MAC clock domains. The MTL layer has two data paths: Transmit path and Receive Path. The size of the FIFO is 8 Kb for Tx and Rx. The MTL communicates with the host through Application Transmit Interface (ATI) on the Transmit path and Application Receive Interface (ARI) on the receive path.

43.4.1.2.1 Transmit path

Internal DMA handles all transactions for the transmit path through ATI. Internal DMA pushes the Ethernet packets read from system memory into the corresponding queue. The packet is then popped out and transferred to the MAC when the queue threshold is reached (threshold mode) or complete packet is in the queue (store-and-forward mode). When EOP is transferred, the status of the transmission is taken from the MAC and transferred back to the internal DMA.

43.4.1.2.1.1 Transmit control word

The following control information related to packet transmission is provided as a part of the Control Word through ATI interface:

- Packet Length (if DCB is enabled with WFQ scheduling algorithm)
- CRC Pad Control
- Source Address Insertion Control
- VLAN Insertion and Replacement Control and VLAN Tag for Outer and Inner VLAN Tags
- TCP/IP Checksum Insertion Control
- One-step Timestamping Control Correction
- Transmit Timestamp Enable

43.4.1.2.1.2 Transmit operation

The following two modes of operation triggers reading of the data towards the MAC:

- Threshold mode: In Threshold (or cut-through) mode, as soon as the number of bytes in the Queue cross the configured threshold level (or when the end of packet is written before the threshold is crossed), the data is ready to be popped out and forwarded to the MAC. The threshold level is configured by using the TTC bits of MTL_TxQ0_Operation_Mode register corresponding to an MTL queue.
- Store-and-forward mode:

In store-and-forward mode, the MTL pops out the packet towards the MAC only when one or more of the following conditions are true:

- A complete packet is stored in the Queue
- The Tx FIFO becomes almost full
- The ATI watermark becomes low

The watermark becomes low when the requested queue does not have space to accommodate the requested burst length on the ATI. Therefore, the MTL when operating in the store-and-forward mode allows packet transmission even if the packet length is bigger than the Tx queue size.

The application can flush complete content of the Tx queue by setting Bit 0 (FTQ) of Transmit Operation Mode register corresponding to an MTL queue. This bit is self-clearing and initializes the Queue pointers to the default state. If the FTQ bit is set during a packet transfer from the MTL to the MAC, the MTL stops further transfer because the queue is considered to be empty. Therefore, an underflow event occurs at the MAC transmitter.

43.4.1.2.1.3 Initialization flow

Upon reset, the MTL is ready to manage the flow of data to and from the DMA, and MAC. For configurations with a single Transmit Queue, there are no initialization requirements for enabling the MTL. For configurations with multiple Transmit Queues, initialize the queue size for each of the queues by programming the TQS bits of MTL_TxQ0_Operation_Mode register corresponding to a Transmit queue. Also, initialize the MAC block. Internal DMA controllers must be individually enabled through their respective CSRs.

43.4.1.2.2 Receive path

The MTL Rx module receives the packets from the MAC and pushes them into the Rx Queue. The status (fill level) of the queue is indicated to DMA when it crosses the configured Receive threshold (RTC bits[1:0] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue), or the complete packet is received. The MTL also indicates the fill level of the queue so that the DMA can initiate preconfigured burst transfers towards the AHB interface.

For more information on queues, see Multiple Channels and Queues Support.

43.4.1.2.2.1 Receive Operation

During a Receive operation, the MTL is a slave for the MAC. The general sequence of events is as follows:

1. When the MAC receives a packet, it indicates the availability of receive data.
2. The MAC indicates the SOP and EOP delimiters.
3. The MTL accepts the data and pushes it into corresponding Rx queue.
4. After the EOP is transferred, the MAC drives the status word which is also pushed into the corresponding Rx queue by the MTL.
5. If IEEE 1588 timestamp feature is enabled and the 64-bit timestamp is available along with the packet status, it is pushed into the Rx queue as a part of the status word. Therefore, two additional locations are taken per packet to store the timestamp in the Rx queue.
6. The MTL takes the data out of the queue and sends it to the DMA depending on the following modes:

43.4.1.2.2.1.1 Threshold mode

In the (default) Threshold mode, the MTL reads the data and indicates its availability to the application or DMA when one of the following occurs:

- Data bytes equal to the threshold amount are written to the Rx queue (RTC bits[1:0] of MTL_RxQ0_Operation_Moderegister of corresponding MTL queue)
- A full packet of data is received into the queue

43.4.1.2.2.1.2 Store and forward mode

In the store-and-forward mode (when Bit 5 of MTL_RxQ0_Operation_Mode register of a queue is set to 1), the initial Rx queue locations are reserved for the status words before writing the SOP. A packet is read out only after it is completely written into the Rx queue. In this mode, all error packets are dropped (if configured through Bit 4 of MTL_RxQ0_Operation_Mode register of a queue) such that only valid packets are read and forwarded to the application.

43.4.1.2.2.2 Multi packet receive operation

In Threshold mode, the packet status is available immediately after the packet data. In store-and-forward mode, the packet data is available after the packet status. The MTL is capable of storing any number of packets into the queue as long as it is not full.

If the MAC receives a packet when the corresponding Rx queue is full, the MTL ignores that packet and overflow pulse is generated on the corresponding Rx queue. In addition, the MTL increments the overflow counter in the MTL_RxQ0_Missed_Packet_Overflow_Cnt of corresponding queue.

43.4.1.2.2.3 Error handling in receive operation

Following things would happen, If the MTL Rx queue is full before it receives the EOP data from the MAC.

1. An overflow is declared
2. The whole packet (including the status word) is dropped
3. The overflow counter in the DMA (Overflow Counter register of corresponding MTL queue) is incremented.

This is true even if Bit 4 (FEP) of MTL_RxQ0_Operation_Mode register of corresponding MTL queue is set.

If the start address of such a packet has already been transferred to the Read Controller, the rest of the packet is dropped and a dummy EOP is written to the queue along with the status word with overflow status. The status indicates a partial packet because of overflow. In such packets, the Packet Length field is invalid. If the MTL Receive Queue is configured to operate in the store-and-forward mode and the length of the received packet is more than the queue size, overflow occurs and all such packets are dropped.

The MTL Rx Control logic can filter error and undersized packets, if enabled by using the FEP and FUP bits of MTL_RxQ0_Operation_Mode register of corresponding MTL queue. If the start address of such a packet has already been transferred to the Rx Queue Read Controller, that packet is not filtered. The start address of the packet is transferred to the Read Controller after the packet crosses the receive threshold set by Bits[1:0] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue.

If the MTL Receive Queue is configured to operate in the store-and-forward mode, all error packets can be filtered and dropped. For the application or DMA to flush the error packet being read from the queue, it must assert the flush signal. The MTL then stops transferring data to the application (DMA). It internally reads the rest of the packet and drops it. The MTL then starts the transfer of next packet (if available).

43.4.1.3 MAC

MAC can support RMII or RGMII Phy interface. MAC consists of Mac Transmit interface (MTI), MAC Receive Interface (MRI) and MAC Control Interface (MCI).

43.4.1.3.1 MAC transmission

The MAC transmission process is as follows:

1. Transmission is initiated when the MAC Transaction Layer (MTL) pushes in data with the SOP signal asserted.
2. When the SOP signal is detected, the MAC accepts the data and begins transmitting to the RMII or RGMII.
3. After the EOP is transferred to the MAC, the MAC does one of the following:
   - The MAC completes the normal transmission and gives the transmission status to the MTL.
   - If a normal collision (in half-duplex mode) occurs during transmission, the MAC gives the Transmit Status with retry bit set to the MTL. The MAC gives the Retry request till one of the following is true:
     — Packet is successfully transmitted
     — Maximum retry requests expire
     — When maximum retry requests expire, the MAC aborts the packet transmission with Excessive Collision Transmit Status. The MAC accepts and drops all further data until the next SOP is received. The MTL block should retransmit the same packet from SOP on observing a Retry request (in the Status) from the MAC.
   - If any one of the following happens, the MAC aborts the packet transmission:
     — No carrier (half-duplex mode)
     — Loss of carrier (half-duplex mode)
     — Excessive deferral (half-duplex mode)
     — Late collisions (half-duplex mode)
     — Jabber
     — The MAC accepts and drops all further data until the next SOP is received
4. The MAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. The MAC accepts and drops all further data until the next SOP is received.
5. During the normal transfer of a packet from MTL, if the MAC receives a SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as continuation of the previous packet.

43.4.1.3.2 MAC reception

A receive operation is initiated when the MAC detects an SFD on RMII, RGMII, or MII. The MAC strips the preamble and SFD before proceeding to process the packet. The header fields are checked for filtering and the FCS field used to verify the CRC for the packet. The received packet is stored in a shallow buffer until the address filtering is performed. The packet is dropped in the MAC if it fails the address filter.

43.4.2 Using PHY interfaces

This module support the following modes:

- RMII 10/100 Mbps interface
- RGMII 10/100/1000 Mbps interface

The internal Phy_intf_sel input signal decides which mode has been selected. Phy_intf_sel signal gets sampled at reset. PS and FES bit of MAC configuration register selects the speed of mode.

The module supports the IEEE802.3-2015 specification for RMII (RMII specification version 1.2 from the RMII consortium) and RGMII specification.

NOTE

RMII reference clock (50 MHz) can be fed to IP from an external source or internally from PLL on SoC.

The module supports can access the phy registers through Station Management Agent (SMA) which is a two wire Station management interface (MIM). One wire is management data clock (MDC) and other wire is management data input/output

(MDIO). As per IEEE 802.3 specification, maximum operating frequency of MDC is 2.5 Mhz which can be derived from system clock using a divider. The CR bit of MAC_MDIO_Address register can be programmed to generate different MDC clock frequency.

SMA supports both MDIO clause 45 and clause 22 frame structure as per IEEE802.3 specification. The C45E bit of MAC_MDIO_Address register can be set to enable the clause 45 frame structure.

43.4.3 VLAN and double VLAN insertion, deletion, replacement and tagging

These sections describes the VLAN and Double VLAN features.

43.4.3.1 Double VLAN processing

The module can support processing of two VLAN tags in double VLAN tagging processing. These two VLAN tags can also be named as inner (C-VLAN) and outer (S-VLAN) VLAN tag. If packet is having only one tag then it would be considered as outer tag.

It supports the following function in Double VLAN processing feature using the MAC_VLAN_Incl, MAC_Inner_VLAN_Incl and MAC_VLAN_Tag registers.

- Insertion, replacement, or deletion of up to two VLAN tags in the Transmit path.
- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status.

43.4.3.1.1 Transmit path

Following table describes the features supported by the MAC on the Transmit side.

Table 364. Double VLAN Processing Features in Transmit Path

Feature	Description
Support for C-VLAN and S-VLAN Tag types	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the CSVL bit of MAC_VLAN_INCL and MAC_INNER_VLAN_INCL registers. The module supports processing of any sequence of outer and inner VLAN tags. **NOTE** The module does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN Tag types or the insertion or replacement operation results in invalid sequence of VLAN Tag type. Therefore, the application must provide correct sequence of VLAN Tag types and program the MAC in such a way that it results in correct sequence of VLAN Tag types in the transmitted packet. The application must ensure the following: • The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. • The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. • The inner tag should not be S-VLAN when outer tag should be replaced with C-VLAN. • The outer tag should not be C-VLAN when inner tag should be replaced with S-VLAN.
VLAN Tag deletion	VLAN tag deletion for outer or inner tag can be enabled through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN deletion is enabled, the MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If inner tag deletion is enabled and the packet has only one tag, the MAC does not delete the inner tag.

Table continues on the next page...

Table 364. Double VLAN Processing Features in Transmit Path (continued)

VLAN Tag Insertion or Replacement	VLAN tag insertion or replacement for outer or inner tag can be enabled through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN tag insertion or replacement is enabled, the VLTI bit in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register is used to determine whether the VLAN tag should be taken from the register or the Control Word.

43.4.3.1.2 Receive path

Following table describes the features supported by the MAC on the receive side and the corresponding bits in the MAC_VLAN_Tag register.

Table 365. Double VLAN Processing in Receive Path

Feature	Description
Outer or inner VLAN tag-based filtering	The MAC can filter packets based on the outer or inner VLAN tag through the ERIVLT bit.
C-VLAN or S-VLAN tag-based filtering	The MAC can filter packets based on the C-VLAN or S-VLAN type based on the ERSVLM bit.
Outer and Inner VLAN Tag stripping	The MAC can strip the outer and inner VLAN Tags from received frame based on the EVLS and EIVLS bits.
16-bit outer and inner VLAN Tag and Type in Rx status	The MAC can provide the 16-bit outer and inner VLAN Tag and Type in the Rx status based on the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN Tag type	The MAC can disable or skip checking of outer VLAN Tag type to match C-VLAN or SVLAN based on the DOVLTC bit.

43.4.3.1.3 Source address and VLAN insertion, replacement, or deletion

The module supports the SA and VLAN insertion, replacement and deletion. The source address (SA) and VLAN fields are Tx packet-related control information that are provided as part of the control word through interfaces. IP supports the feature to insert or replace the source address based on the information in the MAC Address Registers, and also the feature to insert, replace or delete the VLAN fields (VLAN Type and VLAN Tag) based on the setting of the VLTI bit in the MAC_VLAN_Incl register. SA insertion or replacement feature can be enabled for all Transmit packets or selective packets. Similarly, VLAN insertion, replacement, or deletion feature can be enabled for all Tx packets or selective packets.

43.4.3.1.4 Programming source address insertion or replacement

The software can use the SA insertion or replacement feature to instruct the MAC to do the following for Tx packets:

- Insert the content of the MAC Address Registers in the SA field
- Replace the content of the SA field with the content of the MAC Address Registers

When SA insertion is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the Transmit packet and it inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC.

The MAC replaces the six bytes following the Destination Address field in the Transmit packet with the content of the MAC Address Registers.

- SARC bit of MAC_Configuration register can be program to enable the SA insertion or replacement for all Tx packets.

- SA insertion for selective packet can be enabled by programming the SA Insertion Control field (bits [25:23] of TDES3) in the first Transmit descriptor of the packet. When Bit 25 of TDES3 is set, the SA Insertion Control field indicates insertion or replacement by MAC Address1 registers. When Bit 25 of TDES3 is reset, it indicates insertion or replacement by MAC Address 0 registers.

If MAC Address1 Registers are not enabled, the MAC Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA Insertion Control field.

43.4.3.1.5 Programming VLAN insertion, replacement, or deletion

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for Tx packets:

- Delete the VLAN Type and VLAN Tag fields
- Insert or replace the VLAN Type and VLAN Tag fields

Insertion or replacement is done based on the setting of VLTI bit in the MAC_VLAN_Incl register as described in the following table:

Table 366. VLAN Insertion or Replacement Based on VLTI Bit

Condition	Description
VLTI bit is set	The MAC inserts or replaces the following: • VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) • VLAN Tag field depending on the Content of the VT field of Transmit context descriptor of the packet
VLTI bit is reset	The MAC inserts or replaces the following: • VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) • VLAN Tag field with the VLT field of MAC_VLAN_Incl register

When VLAN replacement or deletion is enabled, the MAC checks if the VLAN Type field (0x8100 or 0x88a8) is present after the DA and SA fields in the Transmit packet. The replace or delete operation does not occur if the VLAN Type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the Transmit packet and just inserts the VLAN Type and VLAN Tag fields.

VLAN insertion, replacement, or deletion feature can be enabled for all Tx packets by programming the VLC and VLP fields of MAC_VLAN_Incl register.

VLAN insertion, replacement, or deletion for selective packets can be enabled by programming the VTIR field of TDES2 Normal Descriptor.

In addition, the VLP (VLAN Priority control) bit must be reset in MAC_VLAN_Incl register (for outer VLAN) and MAC_Inner_VLAN_Incl register (in inner VLAN) for the MAC to take the control inputs from the host, depending on the configuration.

43.4.3.1.6 Queue/Channel Based VLAN Tag Insertion on Tx

This module supports channel/queue based VLAN tag insertion on all transmitted packets.

43.4.3.1.6.1 Accessing Queue/Channel Specific VLAN Tag Registers

Queue/Channel specific VLAN tag registers are accessed using indirect addressing through the MAC_VLAN_Incl register. VLAN type and tag value can be independently programmed for each queue/channel.

43.4.4 Packet Filtering

There are various packets filtering scheme available in MAC receiver. Filtering sequence in their precedence order of received packet is shown in the following figure.

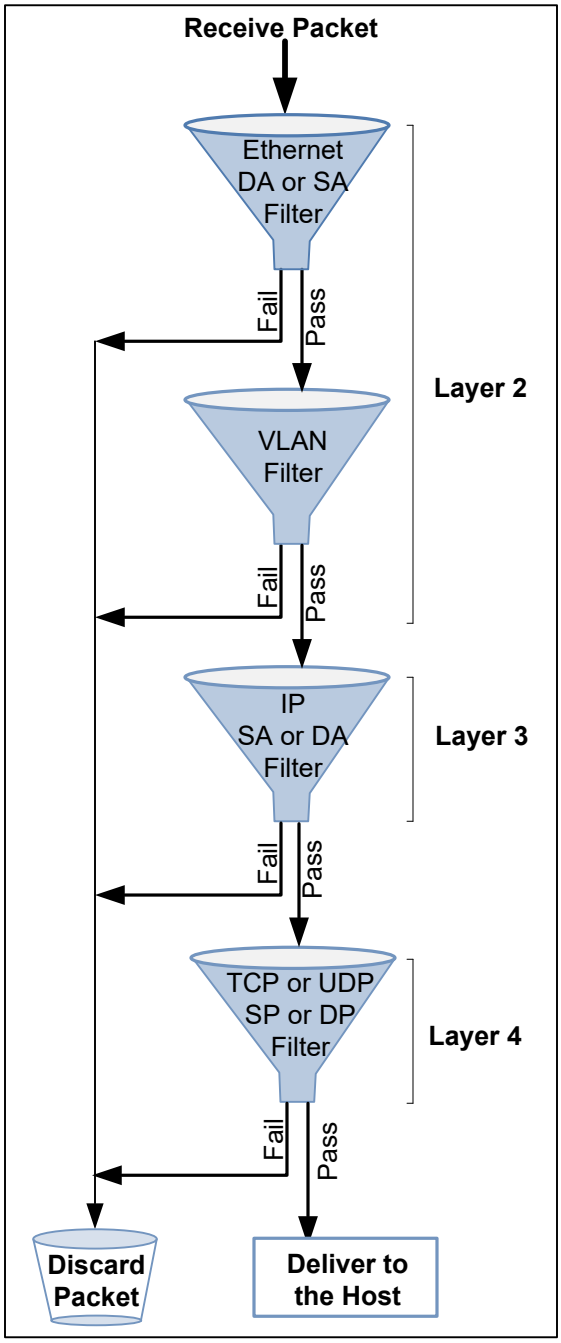

Figure 174. Packet Filtering Sequence

If any of the Layer filters are not enabled, that filter is bypassed and the subsequent filter is applied. A packet that fails any of the filters, is discarded. However, depending on the entry address and the number of parsed entries of the frame offset, discarded packets can be routed to RX_DMA_CH0 and a parser interrupt can be generated.

Even if no parser matched, the frame can be routed into the DMA channel indicated in DMA_CH_NO[2:0].

43.4.4.1 Source address or destination address filtering

The Address Filtering Module of the MAC checks the source address (SA) and destination address (DA) fields of each incoming packet. Programming of different type of address filtering is described in the following sections.

43.4.4.1.1 Unicast destination address filtering

MAC supports up to 64 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of MAC_Packet_Filter register is reset), the MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled. The MacAddr1 to MacAddr63 addresses are selected with an individual enable bit. Each byte of MacAddr1 to MacAddr31 can be masked during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This enables group address filtering for the DA.

In hash filtering mode (when HUC bit is set), the MAC performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the MAC uses the upper 6 bits CRC(by CRC32) of the received destination address to index the content of the Hash table. A value of 000000 selects Bit 0 of selected register, and a value of 111111 selects Bit 63 of Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast packet is considered to have passed the Hash filter; otherwise, the packet is considered to have failed the Hash filter.

43.4.4.1.2 Multicast destination address filtering

PM bit of MAC_Packet_Filter register can be enabled to pass all multicast packets or disabled to do multicast addresses filtering based on HMC bit of MAC_Packet_Filter register. The multicast address is compared with the programmed MAC Destination Address registers (1–31). Also, Group address filtering is supported.

In Hash filtering mode, the MAC performs imperfect filtering using a 64-bit Hash table. The MAC uses the upper 6-bits CRC(by CRC32) of received multicast address to index the content of the Hash table. A value of 000000 selects Bit 0 of selected register and a value of 111111 selects Bit 63 of the Hash Table register. If the corresponding bit is set to 1, the multicast packet is considered to have passed the Hash filter. Otherwise, the packet is considered to have failed the Hash filter.

43.4.4.1.3 Hash or perfect address filtering

HPF bit of MAC_Packet_Filter register must be configured for enabling or disabling the destination address filtering by either Hash filter or Perfect filter. HUC and HMC bit of MAC_Packet_Filter register must be configured to select the Hash filtering or Perfect filtering for Unicast/Multicast packet.

43.4.4.1.4 Broadcast address filtering

The MAC does not filter any broadcast packets by default. DBF bit of MAC_Packet_filter register must be set to reject the broadcast packets.

43.4.4.1.5 Unicast source address filtering

By default, MAC compares the source address field with the value programmed in the source address registers. Bit 30 of MAC address register [1-2] can be configure to use it for source address instead of destination address comparison. The MAC also supports group filtering with source address(SA) . You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in MAC_Packet_Filter register. Otherwise, the result of the SA filter is given as a status bit in the Receive Status word. When the SAF bit is set, the SA filter and DA filter result is AND'ed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

43.4.4.1.6 Inverse filtering

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of MAC_Packet_Filter register. The DAIF bit is applicable for both Unicast and Multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Following two tables summarize the DA and SA filtering based on the type of packets received.

Table 367. Destination Address Filtering

Packet Type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA Filter Operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all packets
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match
	0	X	0	1	X	X	X	Fail on Perfect/Group filter match
	0	0	1	0	X	X	X	Pass on Hash filter match
	0	0	1	1	X	X	X	Fail on Hash filter match
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match
Multicast	1	X	X	X	X	X	X	Pass all packets
	X	X	X	X	X	1	X	Pass all packets
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	X	0	1	0	X	Pass on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	X	1	1	0	X	Fail on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	1	1	0	X	Fail on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x

Table 368. Source Address Filtering

Packet Type	PR	SAIF	SAF	SA Filter Operation
Unicast	1	X	X	Pass all packets.

Table continues on the next page...

Table 368. Source Address Filtering (continued)

Packet Type	PR	SAIF	SAF	SA Filter Operation
	0	0	0	Pass status on Perfect or Group filter match but do not drop packets that fail
	0	1	0	Fail status on Perfect or Group filter match but do not drop packet
	0	0	1	Pass on Perfect or Group filter match and drop packets that fail
	0	1	1	Fail on Perfect or Group filter match and drop packets that fail

NOTE

When the RA bit of MAC_Packet_Filter register is set, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.

43.4.4.2 VLAN Filtering

VLAN tag filter can be done by either perfect match or hash table. Depending upon the configuration, MAC can compare either lower 12 bits or all 16 bits of received VLAN tag for perfect match. MAC forwarded the VLAN tagged packet with match status while it drops all the packets which don't matches.

MAC uses 16-bit VLAN hash table for group address filtering based on the VLAN tag. If hash filtering is enabled then most significant 4-bit of CRC-32 of VLAN tag are used to index the content of the VLAN Hash Table Register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

The MAC also supports the inverse matching for VLAN packets. In the inverse matching mode, when the VLAN tag of a packet matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a packet is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.

Table below shows the different possibilities for VLAN matching and the final VLAN match status. When the RA bit of MAC_Packet_Filter register is set, all packets are received and the VLAN match status is indicated in the VF bit of RDES2 Normal Descriptor (Write-Back Format). When the RA bit is not set and the VTFE bit is set in MAC_Packet_Filter register, the packet is dropped if the final VLAN match status is Fail.

When VLAN VID is programmed to 0 in the VL field of MAC_VLAN_Tag register, all VLAN-tagged packets are considered as perfect matched but the status of the VLAN hash match depends on the VTHM and VTIM bits in MAC_VLAN_Tag register.

Table 369. VLAN Match Status

VID	VLAN Perfect Filter Match Result	VTHM Bit	VLAN Hash Filter Match Result	VTIM Bit	Final VLAN Match Status
VID = 0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID!= 0	Pass	X	X	0	Pass

Table continues on the next page...

Table 369. VLAN Match Status (continued)

VID	VLAN Perfect Filter Match Result	VTHM Bit	VLAN Hash Filter Match Result	VTIM Bit	Final VLAN Match Status
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

In this table, X represents any value.

43.4.4.3 VLAN Filter Fail Packets Queue

When VLAN filtering is enabled, the VLAN Filter Fail Packets can be routed to a programmable Queue (VFFQ) when Bit RA = 1 or VTFE = 0 of MAC_Packet_Filter register and the enable bit (VFFQE of MAC_RXQ_CTRL4) for the queue is set.

The packets that passes the VLAN filtering, are routed to Rx queues based on the VLAN TAG priority field by programming the PSRQ in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. The packets that fail the VLAN filter are discarded if RA=0 or VTFE=1. However, when RA=1 or VTFE=0, the VLAN filter fail packets are still forwarded to the application. In such a scenario, when the VLAN Filter Fail Queue Enable (VFFQE) bit is set, the VLAN filter fail packets are forwarded to the Rx queue number programmed in the VFFQ bit. If VFFQE=0, the Rx queue number is determined by the VLAN priority mapping as per the PSRQ fields.

Table below shows the Rx Queue routing table for Unicast tagged packets, with DA/SA Filter enabled.

Table 370. Rx Queue Routing table for Unicast Tagged Packets

RA	VFTE	SA/DA Filter Result	VLAN Filter Result	VFFQE	Queue Routing
X	X	PASS	PASS	X	PSRQ
0	0	PASS	FAIL	0	PSRQ
0	0	PASS	FAIL	1	VFFQ
0	X	FAIL	X	X	DROPPED
0	1	PASS	FAIL	X	DROPPED
1	X	FAIL	X	0	UFFQ*/PSRQ
1	X	FAIL	X	1	UFFQ*/VFFQ
1	X	PASS	FAIL	0	PSRQ
1	X	PASS	FAIL	1	VFFQ

X : Don't care condition * : When UFFQE is enabled else PSRQ

43.4.4.4 Extended Receive VLAN Filtering and Routing

When Extended Rx VLAN filtering and routing is enabled then both perfect filtering and Hash filtering can be enabled. The overall VLAN filter result is based on the Perfect filter result and Hash filter result (if enabled). Filter result is passed to application/software as part of the status bit. Extended Routing will happen only if VLAN filter has passed. Routing is only based on Perfect filter result. Each Perfect filter has a DMA channel enable and DMA channel number filed which should be programmed for routing.

For more details about routing, see details on 'Extended VLAN Based DMA Selection' in Dynamic (Per Packet) Mapping.

43.4.4.4.1 Comparison mode

Software/Application has following comparison option for each VLAN tag filter

- It can program the MAC to compare the inner or outer VLAN tag with either 12 bits or 16 bits programmed VID.
- It can choose that VID comparison is for SVLAN or CVLAN type frames, if type check is enabled for a filter.

43.4.4.4.2 Filtering

Perfect Filtering is done based on the MAC_VLAN_Tag_Filter registers. For each VLAN Tag Filter, the MAC will compare the relevant VLAN Tag ID and gives a result. If any one of the VLAN Tag Filters gives a match then the frame is considered to have passed the VLAN Tag Filters. If the frame mismatches all the filters, then the frame is considered to have failed the VLAN filter. This behavior is applicable only when the Inverse Filtering is not enabled in MAC_VLAN_Tag_Ctrl Register.

If inverse Filtering is enabled and the frame has mis-matched all the relevant filters then it is considered to have passed the VLAN filter. If the frame matches any one of the relevant filters then it is considered as a fail. If none of the enabled filters can perform a comparison or if none of the filters are enabled, then the frame is bypassed to the application.

The overall filter result and the programming on the VTFE and RA bits of the MAC Filter Register determine if the frame will be dropped or forwarded to the application. If RA = 1 or VTFE = 0, it does not matter if the filter result is a pass or fail. The frame is always forwarded. If RA = 0 and VTFE = 1, only then, if the VLAN Tag Filter result is a pass does the MAC forward the frame. If the frame is forwarded to the application, then the relevant filter result is indicated through the Status bits.

43.4.4.4.3 Filter Status

The Extended Receive VLAN Filtering and Routing feature provides two status bits to indicate the comparison result of the VLAN tags.

By default, the MAC indicates the VLAN Filter Status through one bit in the status – VF field in RDES2. When Extended RX VLAN Filtering and Routing is enabled, two status bits are used to indicate the comparison result of VLAN tags. The Outer VLAN Tag Filter Pass and Inner VLAN Tag Filter Pass bits are defined in the following positions. The status indicated through these bits is highly dependent on the programming as explained below.

In RDES2:

- Bit 15 – Outer VLAN Tag Filter Status
- Bit 14 – Inner VLAN Tag Filter Status

In ARI status: MAC Filter Status:

- Bit 15 – Outer VLAN Tag Filter Status
- Bit 14 – Inner VLAN Tag Filter Status

In MRI Status:

- Bit 47 – Outer VLAN Tag Filter Status
- Bit 46 – Inner VLAN Tag Filter Status

Outer VLAN Tag Filter Status (OTS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Outer VLAN Tag has matched one of the VLAN Tag Filters.
- If this bit is reset, it indicates that the frame's Outer VLAN Tag has either failed the relevant Outer VLAN Tag Filters or bypassed them.
- If none of the filters are enabled for Outer VLAN Tag Comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, then it has failed at least one of or bypassed all the Filters programmed for Outer VLAN Tag Comparison.
- This bit is valid for both Single and Double VLAN Tagged frames.

Inner VLAN Tag Filter Status (ITS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Inner VLAN Tag has matched one of the VLAN Tag Filters.
- If this bit is reset, it indicates that the frame's Inner VLAN Tag has either failed the relevant Inner VLAN Tag Filters or bypassed them.
- If none of the filters are enabled for Inner VLAN Tag Comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, then it has failed at least one of or bypassed all the Filters programmed for Inner VLAN Tag Comparison.
- This bit is valid for only Double VLAN Tagged frames, when Double VLAN Processing is enabled.

The application must look at the status bits and the programming to determine if the Frame has passed or failed the VLAN Filter.

Following two tables 'OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled' and 'OTS and ITS Bit Values with Only VLAN Hash Filter Enabled' show the possible Filter combinations and the corresponding filter results. These tables explain the scenarios when Double VLAN Processing and Hash VLAN filter are enabled in the design.

Legend for the table 'OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled'

- VTIM: VLAN Tag Inverse Match Enable – bit 17 in VLAN_Tag_Ctrl Register.
- HFO: Hash Filter enabled for Outer VLAN Tag Comparison - bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- HFI: Hash Filter enabled for Inner VLAN Tag Comparison – bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- PFO – Perfect Filter comparison enabled for Outer VLAN Tag - Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Outer VLAN Tag comparison (bit 20 is set to 0).
- PFI – Perfect Filter comparison enabled for Inner VLAN Tag - Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Inner VLAN Tag comparison (bit 20 is set to 1).
- OTS – Outer VLAN Tag Filter Status
- ITS – Inner VLAN Tag Filter Status

Following table shows the possible values of status bits (OTS and ITS) when at least one Perfect filter is enabled.

Table 371. OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	0	0	0	1	0	1/0
0	0	0	1	0	1/0	0
0	0	0	1	1	1/0	1/0
0	1	0	1	1	1/0	1/0

Table continues on the next page...

Table 371. OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled (continued)

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	1	0	1	0	1/0	0
0	1	0	0	1	1/0	1/0
0	0	1	1	1	1/0	1/0
0	0	1	1	0	1/0	1/0
0	0	1	0	1	0	1/0
1	0	0	0	1	0	1/0
1	0	0	1	0	1/0	0
1	0	0	1	1	1/0	1/0
1	1	0	1	1	1/0	1/0
1	1	0	1	0	1/0	0
1	1	0	0	1	1/0	1/0
1	0	1	1	1	1/0	1/0
1	0	1	1	0	1/0	1/0
1	0	1	0	1	0	1/0

Following table shows the possible values of status bits (OTS and ITS) when none of the perfect filters are enabled and only the VLAN Hash Filter is enabled.

Table 372. OTS and ITS Bit Values with Only VLAN Hash Filter Enabled

VTIM	HFO	HFI	OTS	ITS
0	0	0	0	0
0	1	0	1/0	0
0	0	1	1/0	1/0
1	0	0	1/0	0
1	1	0	1/0	0
1	0	1	1/0	1/0

With no perfect filters enabled, any VLAN packet is considered to have bypassed the perfect filter. If Hash Filter is enabled for one of the Tags, then the respective Status bit depends on the Filter's result. The Status bits are set to 0 if VLAN Hash Filter is also not enabled.

If the value of ITS/OTS is shown as 1/0; then it indicates that the final result is dependent on the enabled relevant filter's result.

Example 1: The second row of table 'OTS and ITS Bit Values with Only VLAN Hash Filter Enabled' indicates that at least one Perfect Filter is enabled for Outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN Filtering is not enabled. The bit OTS is given as 1/0. If the received frame passes at least one of the enabled Outer VLAN Tag filters then the bit is set to 1. If the frame doesn't pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2: Last Row of table 'OTS and ITS Bit Values with Only VLAN Hash Filter Enabled' indicates that Inverse Filtering is enabled, Hash Filter and at least one perfect filter is enabled for Inner VLAN Tag comparison, then if the received frame's Inner VLAN tag mismatches with both the Hash Filter and all the enabled Perfect filters, then the frame will have the ITS bit set to 1 else it is set to 0. OTS will be set to 0 as no comparison is performed.

43.4.4.4.4 Stripping

Each of the VLAN Tags has individual control over stripping. The programming options of always strip, never strip, strip on pass and strip on fail are available. Inner or Outer VLAN Tag Stripping is based on the pass or fail results of the individual tag. If a tag is bypassed by all the relevant filters, stripping is not applicable for the tag.

- If strip on Pass is enabled for the outer VLAN Tag, then the stripping occurs only if the Outer VLAN tag has passed the relevant filters. The Outer VLAN Tag Filter Result bit will be set.
- If strip on Fail is enabled for the outer VLAN Tag, then stripping occurs only if the Outer VLAN Tag has failed relevant filters. The Outer VLAN Tag Filter Result Bit will be reset.
- If the Outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), then the tag is not stripped, though the Status Bit is still 0.
- As multiple filters are enabled, it is possible that the received VLAN frame could have matched any one or more of the filters. The VLAN Tag's value is not always deterministic from the filter status bits.

If the software/application strips the VLAN Tag based on the filter result, it might lose the VID. So the suggested use is, if stripping is enabled for any of the tags, the tag can be put in the status. For this the software/application will have to enable the respective "VLAN Tag in Status" bit - 24 or 31 in the MAC VLAN Tag Control Register.

See section Programming Guidelines for Extended VLAN Filtering and Routing on Receive

43.4.4.5 Layer 3 and Layer 4 Filtering

IP supports the Layer 3 based packet filtering which is IP Source or Destination Address filtering in the IPv4 or IPv6 packets, and Layer 4 based packet filtering which is Source or Destination Port number filtering in TCP or UDP. When layer 3 and layer 4 packet filtering is enabled then packets are filtered in the following manner.

- Matched Packets: The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the IPC bit of MAC_Configuration register is set and one of the following conditions is true:
  - All enabled Layer 3 and Layer 4 fields match
  - At least one of the enabled field matches and other fields are bypassed or disabled

When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides the status of the lowest filter where Filter 0 is the lowest filter and Filter 3 is the highest filter.

- Unmatched Packets: The MAC drops the packets that do not match any of the enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets.
- Non-TCP or UDP IP Packets: By default, all non-TCP or UDP IP packets are bypassed from the Layer 3 and Layer 4 filters. MAC can optionally be programmed to drop all non-TCP or UDP over IP packets.
- IP has a control register “MAC_L3_L4_Control” to control the Layer L3 and L4 packet filtering along with address registers to program the Layer L3 and L4 fields to be matched.

43.4.4.6 Flexible Receive Parser

When this function is enabled, all incoming packets are parsed as per the programmable instruction stored in memory. It does the following function

- Packet Filter (Accept or Reject)
- DMA Channel Selection

Flexible receive parser block operates over the first 128 bytes data of receive packet based on 64 bytes of instruction on each packet. Following figure shows the functional block diagram of Flexible Receive Parser.

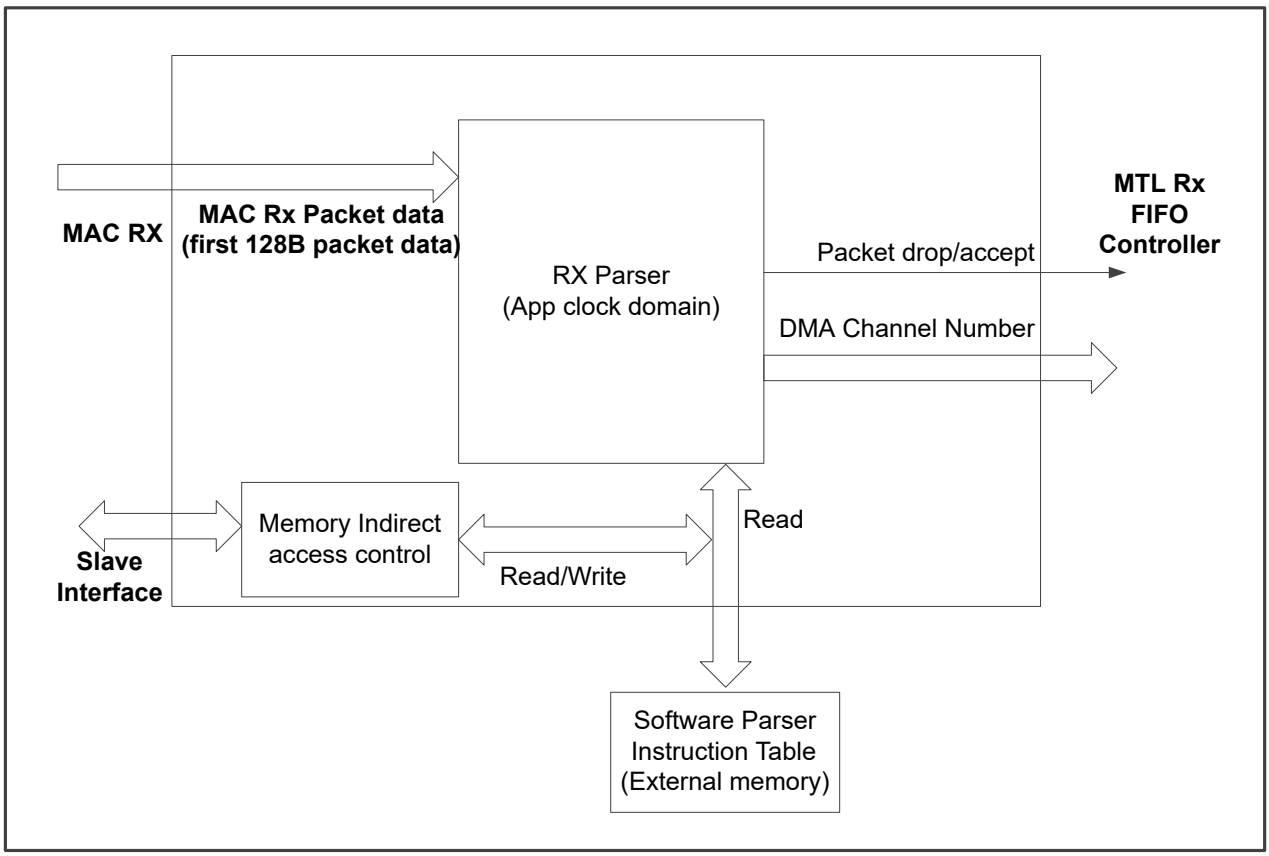

Figure 175. Functional block diagram of flexible recieve parser

43.4.4.6.1 Instruction Table Format of the Flexible Receive Parser

Software must build the 96-bit wide instruction before enabling the receive parser feature. Each instruction is programmed as an entry in the instruction memory.

The format of each entry in the Instruction table is shown in the following table.

Table 373. Rx Parser Instruction Entry Format

Field	Field Name	Description
31:0	MATCH_DATA	The 4-byte data. This data is used for comparing with incoming packet data starts at the frame offset as defined in [79:72] of the entry. The comparison is done only on those bits whose corresponding mask bits are set to 1 (MATCH_EN bits of [63:32]). See the Notes (below this table) on the byte order relative to Ethernet arrival data and endianness supported by QoS IP on the slave interface. The programming of this instruction table should adhere to the same.
62:32	MATCH_EN	When the MATCH_EN is set to 1, the corresponding Packet data bit is used for comparing. Otherwise, corresponding data bit is don't care.
64	AF	Accept frame
65	RF	Reject frame
66	IM	Inverse match
67	NIC	Next instruction control
71:68	Reserved	-
79:72	Frame Offset	[77:72] indicates the frame offset in terms of 4 bytes. (Here [79:78] always 0)Frame offset in the packet data to be compared for Match.This is in terms of 4 bytes. Value Actual Frame offset in bytes 0 01 42 8… ..63 252 The max value programmed in this Instruction Table is 128 B. The 'Actual Frame Offset' should not cross this limit.
87:80	OK Index	If (NIC==0) Memory Index to be used next when ENTRY_MATCH==1 and neither AF or RF is set to 1. If (NIC==1) Memory Index to be used next when ENTRY_MATCH==0 Note: ENTRY_MATCH is a calculated value based on MATCH_DATA, MATCH EN, and IM. It is not a field.
92:88	DMA CH NO	Indicates the DMA Channel Number (1-bit for each). This will be used when ENTRY_MATCH==1 and AF==1 (Accept frame). The encoding is as follows: • bit[0]- DMA Channel Number 0 • bit[1]- DMA Channel Number 1 • bit[2]- DMA Channel Number 2 • bit[3]- DMA Channel Number 3 • bit[4]- DMA Channel Number 4. Note: The DMA Channel number is encoded using bit wise as QoS IP support multicasting/ broadcast across DMA Channels. See section 3.3.12 for more details and proper usage.
128:93	Reserved	0 (This field is only for software view and reserved for future enhancements. The memory width remains as 93-bits for now)

The parser begins parsing from the 0th entry, for each received packet. The subsequent parsing entry location (next entry or OK_INDEX[]) depends on the parser result of the current entry. Following figure shows the detailed flow.

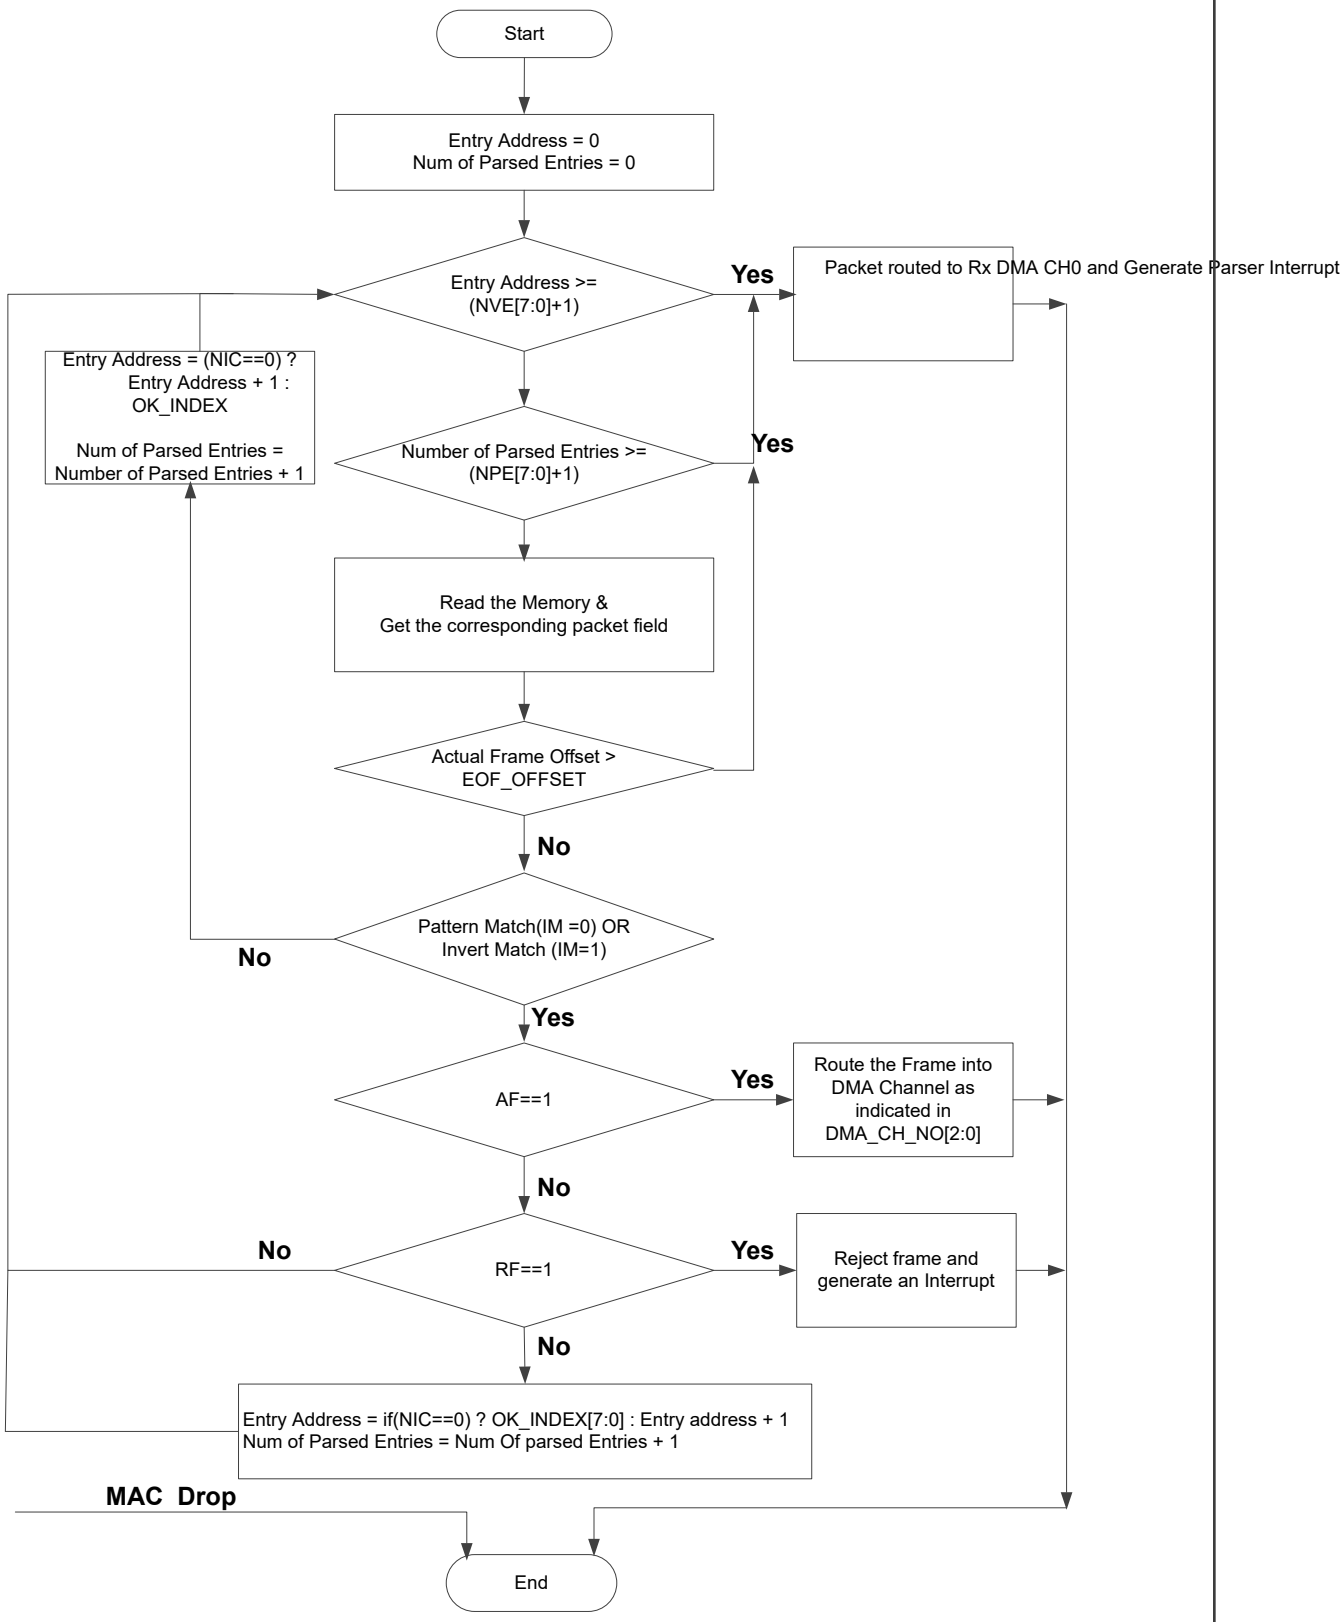

Figure 176. Flexible recieve parser flow chart

In the above figure, MAC Drop means the packet is dropped by the MAC due to another filter condition (for example, DA filter) and will not reach the Flexible Receive Parser.

The EOF_OFFSET shown in the figure is equal to the least among the following:

- Actual Packet size
- 128 Byte when frame pre-emption feature is not enabled/configured
- 128 Byte when frame pre-emption feature is enabled and packet is pre-emptible.
- 64 Byte when frame pre-emption feature is enabled and packet is Express Packet

43.4.4.6.2 Number of Valid Entries (NVE)

NVE indicates the number of valid entries in the instruction table. The default value is 64. Software can change this value by writing into MTL_RXP_Control_Status registers field NVE[7:0].

While parsing, if the Entry address is found to be is greater than NVE[7:0]+1, an error is flagged in the MTL_RXP_Interrupt_Control_Status register bit[0], NVEOVIS (Number of Valid Entries overflow status). IP generates an interrupt status (MTL_Interrupt_Status, bit[23], MTLPIS (MTL Parser Interrupt Status)).

43.4.4.6.3 Number of Parsable Entries (NPE)

NPE indicates the number of entries that can be parsed on an incoming packet. The default value is 64. Software can change this value by writing into MTL_RXP_Control_Status registers field NPE[7:0] (Number of Parsable Entries) bits [21:16].

While parsing, if the number of parsed entries is more than NPE[7:0]+1, an error is flagged in the MTL_RXP_Interrupt_Control_Status register bit[1], NPEOVIS (Number of Parsable Entries overflow status). IP generates an interrupt status (MTL_Interrupt_Status, bit[23], MTLPIS (MTL Parser Interrupt Status).

While NVE[] indicates is the number of valid entries in the Rx parser memory built by software, NPE[] indicates the worstcase parsable entries considering the various possible paths that the parser can take. (NVE[] >= NPE[]).

43.4.4.6.4 Frame Offset

It indicates the frame offset, in terms of 4 bytes which is used while comparing against the current table entry.

In an entry, an error is flagged in the TL_RXP_Interrupt_Control_Status register bit[2], FOOVIS (Frame Offset Overflow Interrupt Status) in any of the following cases:

When Frame Offset is more than

- Packet size
- 128B if pre-emption is disabled
- 128B if pre-emption is enabled and packet is pre-empitble
- 64B if pre-emption is enabled and packet is an Express packet

IP generates an interrupt status (MTL_Interrupt_Status bit[23]) and MTLPIS (MTL Parser Interrupt Status).

NOTE

If the frame ends after the (frame_offset *4) bytes but before ((frame_offset *4)+4) bytes, the Receive parser declares Frame Offset Error if comparison is enabled (via MASK bits) for the non-received bytes; from (frame_offset *4) to ((frame_offset *4)+4).

43.4.4.6.5 Frame Reject

In cases where an Entry matches (considering the Inverse match, IM bit in the instruction table) and Frame Accept bit is not set, and Frame Reject bit (RF) is set, the frame is dropped.

When a frame is dropped due to RF = 1, IP generates an interrupt status (MTL_Interrupt_Status, bit[23], MTLPIS (MTL Parser Interrupt Status).

43.4.4.6.6 Out of Order Processing

The Rx parser flow can be out of order. The decision tree need not be based on the order in which packet arrives. That is, the decision tree can be out of order; the decision tree need not be based on the same order as the packet data arrival (data within one packet). This implies that the next entry and next frame offset (OK_INDEX[]/FRAME_OFFSET[]) can be less than the current entry address and current Frame Offset.

43.4.4.6.7 DMA Channel Selection

When the Rx parser is enabled (FRPE bit[16] is set to 1 in MTL_Operation_Mode register) the Rx parser overrides the DMA selection criteria of the MAC.

When the Rx parser is disabled (FRPE bit[16] is set to 0 in MTL_Operation_Mode register) the MAC/MTL determines the DMA channel number.

43.4.4.6.8 Receive Queue Selection

The Rx Queue is determined by the existing MAC functionality, irrespective of the enabling/disabling of the Rx Parser. This is because the Rx parser is mainly designed for selecting the DMA channel and Rx queuing is decided by the MAC to enable the proper functioning of the Pause/PFC feature.

NOTE

When there are multiple queues and multiple DMA Channels are enabled, a particular DMA channel might receive out of order packets. This is because queue selection is based on MAC criteria (VLAN Priority and other criteria) and Rx DMA channel selection is based on Rx parser.

43.4.4.6.9 MAC Packet Filtering/Drop/Error Handling

The MAC does the packet filtering based on the received packet fields. Disable the Packet Filtering features inside the MAC when the Rx parser is enabled. To disable the Packet Filtering features inside the MAC,

1. Set Promiscuous Mode (PR, bit[0] of MAC_Packet_Filter register)
2. Set all other bits in the MAC_Packet_Filter register to its default values

When MAC decides to drop the packet (due to Rx MAC dependent Error such as GMII Error, Receive Watch Dog Error, CRC Error and Giant Frame Error) the packet is dropped irrespective of the Rx parser decision.

43.4.4.6.10 PAD Strip/CRC Strip Handling

The pad strip and CRC strip are controlled by the software and applicable to all the received packets. When these features are enabled, software must build the Rx parser instructions accordingly.

NOTE

Enable PAD and CRC stripping in real use case.

43.4.4.6.11 VLAN Strip Handling

The MAC supports stripping the VLANs, outer as well as inner VLAN. When MAC is programmed to strip the VLAN, the Rx parser considers those VLAN tags to be part of the incoming packet.

43.4.4.6.12 Multicast and Broadcast Support

IP supports multicast and broadcast packet and the packet is routed to the highest queue number.

When Rx Parser is enabled, the packet routing is decided by the DMA Channel Numbers (DMA CH NO, Bits [95:88]) in the Instruction Table.

When Rx Parser is disabled, the packet routing is determined by DCS (DMA Channel Select) field of the MAC_AddressX_High register. For more details, see Broadcast/Multicast Packet Duplication.

NOTE

DCS/DMA CH NO field is per DMA Channel control and therefore, multiple DMA channels can be selected for routing the packet.

43.4.4.6.13 Pre-emption Support

The MAC supports the frame pre-emption feature when the Flexible Rx parser feature is enabled. The minimum packet size for Frame Preemption is 64 bytes. This means that:

- The Rx parser can operate on 64 bytes of Express traffic.
- The Rx parser can operate on 128 bytes of pre-emptible traffic, as a 64 bytes packet of pre-emptible traffic might be interrupted by Express traffic before that packet is fully received, so the parser needs to have 64 bytes on either side of the express traffic in order to capture the full 64-bytes of a pre-empted packet.

43.4.4.6.14 Software Access to the Flexible Receive Parser Memory

Software can read/write into the Rx parser memory, using the following registers via indirect addressing.

- MTL_RXP_Indirect_Acc_Control_Status
- MTL_RXP_Indirect_Acc_data

For more details, see ENET_QOS register descriptions.

43.4.4.6.15 Statistical Counters

IP supports the following statistics counters for flexible receive parser.

1. MTL_RXP_Drop_Cnt
2. DMA_RXP_Error_Cnt

DMA_CH(#i)_Rxp_Accept_cnt (i=0; i<2)

For more details, see ENET_QOS register descriptions.

43.4.4.6.16 Changing the Instruction Table by Software

Software can update the instruction table in the memory in the following ways

- Disable the MAC Receiver and Receive Parser by setting the RE field of the MAC_Configuration register to 0 and FRPE bit of MTL_Operation_mode register to 0. Wait for Rx Parser to become inactive (RXPIA, MTL_RXP_Control_Status register bit[31]).
- (Optional) Program in the Entry address 0 to unconditionally (all MATCH_EN bit 0) skip to OK_INDEX[] (to certain location in the memory) where it is programmed to reject or accept all packets.

43.4.4.6.17 Receive Cut-Through Functionality

In the case of cut-through mode, the Rx controller attempts to transfer the received packets to DMA just after the cut-through threshold amount of packet data is received (RTC field in the MTL_RxQx_Operation_Mode register).

However due to Rx parser's result worst case arrival time can be more than the programmed cut-through threshold. So, the Rx controller delays the packet transfer to DMA accordingly. So, the cut-through functionality is re-defined as follows

The Rx controller attempts to transfer packet to DMA after at least RTC number of bytes have been received and Rx parser results are available.

43.4.4.6.18 Receive Packet Drop Indication

In most cases, the packet drops internally in the Rx Queue. However, back-to-back packets can arrive for the same queue and first packet's Rx parser result is not available when the second packet arrives. In such cases, the packet cannot be flushed internally and forwarded to DMA or the Application Interface and status is indicated accordingly. For more details, see RDES2, bit 16(RXPD) in Receive Normal Descriptor (Write-Back Format) .

43.4.4.6.19 Runt Packet Handling

The Rx parser can perform the operation with 64B minimum size packet. If the runt packet is received (should be indicated by MAC), the Rx parser assumes that it gets dropped in the MAC. This is because, back-to-back runt packets (< 64B) cannot be handled in the Rx parser.

43.4.4.6.20 Uncorrectable ECC Error Handling

When the parser detects an uncorrectable ECC error while parsing the parser memory, the packet is not dropped. Instead, the packet is sent to the application with an Error Indication. The RXPI (RX Parser Incomplete) is set in the packet status along with Error Summary (ES) bit.

For more details, see Receive Normal Descriptor (Write-Back Format) .

43.4.5 IEEE 1588 Timestamp Support

The MAC supports the IEEE 1588 Precision Time Protocol (PTP). The MAC is able to do precise time stamping and capturing of incoming and outgoing frame to enable support of PTP with its associated software. The MAC supports the all clock types defined in IEEE 1588-2008. Typical frequency of PTP timestamp clock is 125 MHz. The MAC supports:

- Taking a timestamp snapshot of all packets or only PTP type packets.
- Taking a timestamp snapshot of only event messages.
- Identifying the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sending the PTP message type status given by the MAC. The PTP status is finally written back to the Receive Descriptor: RDES1 Normal Descriptor (Write-Back Format).
- Measuring sub-second time in decimal or binary format.

43.4.5.1 Delay Request-Response Mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information. Following figure shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

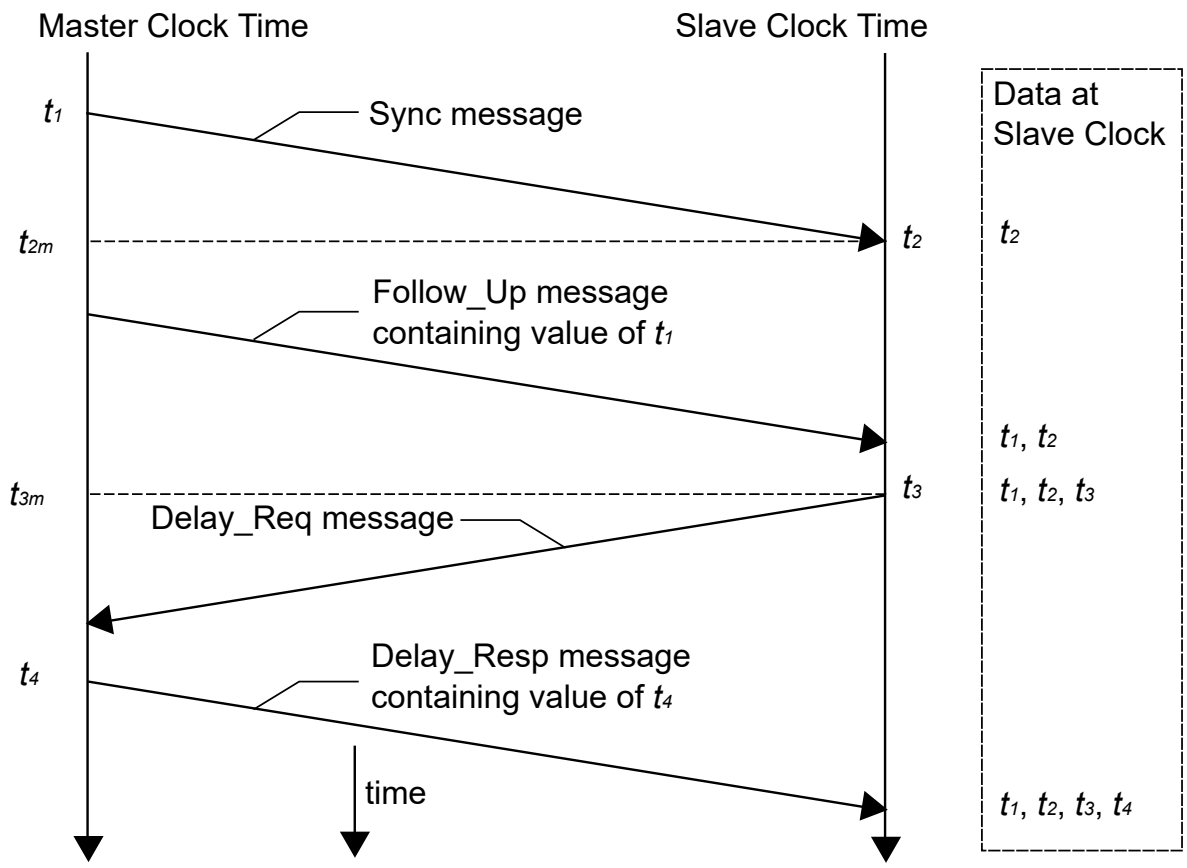

Figure 177. Networked Time Synchronization

As shown in the figure, PTP uses the following process:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the reference time information of the master. This message leaves the system of the master at t1. This time must be captured for Ethernet ports at the internal GMII interface.
2. The slave receives the Sync message and also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master and notes the exact time, t3, at which this packet leaves the internal GMII interface.
5. The master receives the message, capturing the exact time t4, at which the message enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the timing reference of the master.

Most of the PTP implementation is done in the software above the Ethernet layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the internal GMII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

43.4.5.2 Peer-to-Peer PTP Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 supports peer-to-peer PTP (Pdelay) message in addition to the SYNC, Delay Request, Follow-up, and Delay Response messages. Following figure shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

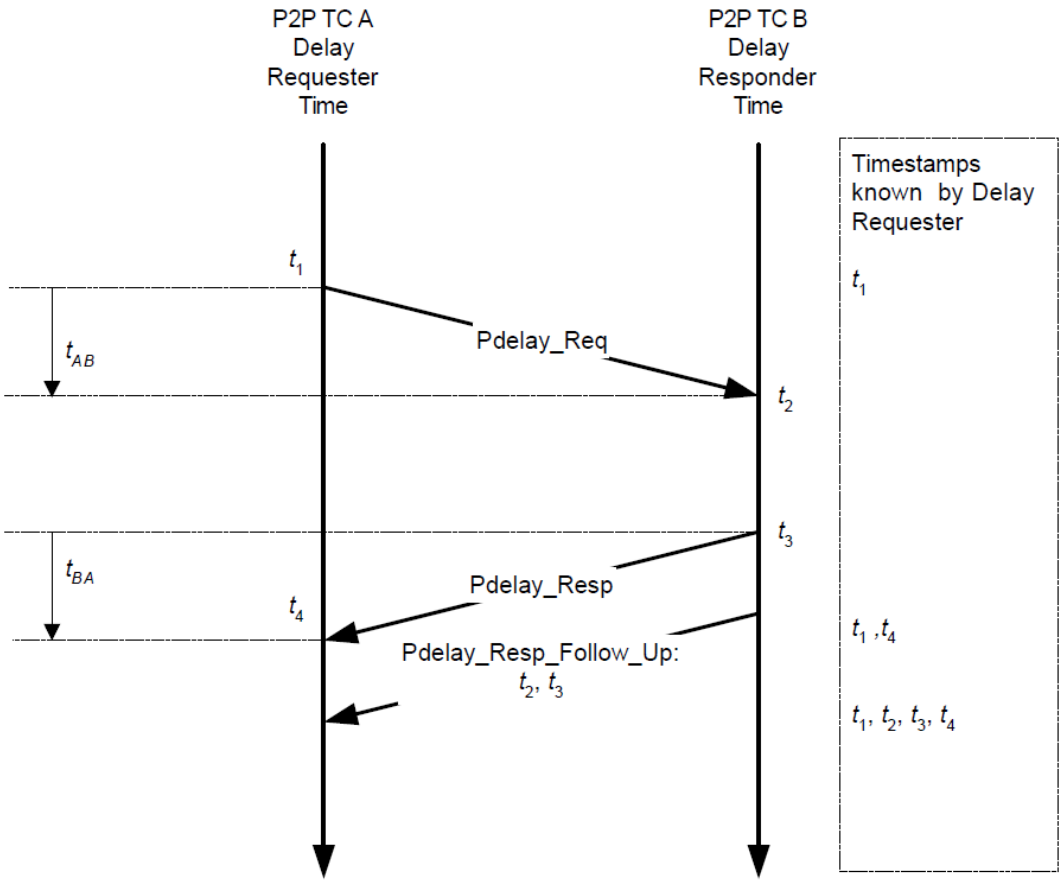

Figure 178. Propagation Delay Calculation in Clocks Supporting Peer-to-Peer Path Correction

As shown in the above figure, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message. To minimize errors because of any frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp message
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
   - Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively
4. Port 1 generates a timestamp (t4) on receiving the Pdelay_Resp message.
5. Port 1 uses all four timestamps to compute the mean link delay.

43.4.5.3 Timestamp Correction

According to the IEEE 1588 specification, a timestamp must be captured when the PTP message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network. As the MAC takes the timestamp at an internal point far from the actual boundary of the node and network, this captured timestamp is corrected/updated for the ingress/egress path latency (including the delay in the PHY layers). Further correction is done for the inaccuracies/errors introduced due to the clock (internal GMII Tx, Rx clock) being different at the capture point as compared to the PTP clock (clk_ptp_ref_i) that is used to generate the time. The resultant CDC (Clock Domain Crossing) circuits add error depending on the clock period of the internal GMII or MII and PTP clocks.

43.4.5.3.1 Ingress Correction

In the Receive side the timestamp captured at the internal snapshot point is delayed (later in time) as compared to the time at which that packet's SFD bit is received at the port's boundary. Therefore, the captured timestamp must be reduced by the ingress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the MAC_Timestamp_Ingress_Corr_* registers.

The correction value consists of the following 3 components:

1. External latency in the PHY layer between boundary point and the input of the core.

   If the PHY is compliant to the IEEE 802.3 Clause 45 MMD registers, it has a register indicating the maximum and minimum ingress latency. The software can read these registers and determine the average ingress latency in the PHY. Alternatively (if the PHY does not support these registers), the ingress latency must be determined from its datasheet or timing characteristics.

2. Internal latency from the input of the core to the internal capture point.

   The internal ingress latency can be read from the MAC_Ingress_Timestamp_Latency register. This is a read-only register and gives the latency in scaled Nanoseconds format defined in IEEE 1588 Clause 5.3.2. The latency differs based on the active PHY interface (for example, RMII) and the operating speed. Therefore, the software must read this register after any speed change in the MAC to determine the current internal latency.

3. CDC Synchronization

   The CDC synchronization error is almost equal to 2 times the clock-period of the PTP clock (clk_ptp_ref_i).

The values determined from these 3 components should be added by the software and must be written into the TSIC and TSICSNS fields of the MAC_Timestamp_Ingress_Corr_* registers.

NOTE

The value written to the register must be negative (two's complement as explained below), because it has to be subtracted from the captured timestamp. The MAC Receiver adds the value in this register to the captured timestamp and then gives the resultant value as the timestamp of the received packet.

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, the nanoseconds field of the captured timestamp is in decimal format with a granularity of 1ns. So the Bit31 of TSIC must be set to 1 (for negative value) and bits[30:0] must be written with "10^9 - total ingress_correction_value[nanosecond part]" represented in binary. For example, if the required correction value is -5 ns, then the value is 0xBB9A_C9FB.

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, the nanoseconds field of the captured timestamp is in binary format with a granularity of ~0.466ns. Therefore, bits[30:0] must be written with "2^31 - total ingress_correction_value" represented in binary with bit[31] = 1.

43.4.5.3.2 Egress Correction

In the Transmit side the timestamp captured at the internal snapshot point is earlier (advanced in time) as compared to the time at which that packet's SFD bit is output at the port's boundary. Therefore, the captured timestamp must be compensated by the egress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the MAC_Timestamp_Egress_Corr_* registers.

The correction value consists of the following 3 components:

1. External latency in the PHY layer between the output of the core and the boundary of the port and the network

   If the PHY is compliant to the IEEE 802.3 Clause 45 MMD registers, it has a register indicating the maximum and minimum egress latency. The software can read these registers and determine the average egress latency in the PHY. Alternatively (if the PHY does not support these registers), the egress latency must be determined from its datasheet or timing characteristics.

2. Internal latency from the internal capture point and the output of the core

   This internal egress latency can be read from the MAC_Egress_Timestamp_Latency register. This is a read-only register and gives the latency in scaledNanoseconds format defined in IEEE 1588 Clause 5.3.2. The latency will differ based on the active PHY interface (for example, RMII) and the operating speed. Hence the software must read this register after any speed change in the MAC to determine the current internal latency.

3. CDC synchronization error

   The CDC synchronization error value for one-step timestamping would be = (1 * period of clk_ptp_ref_i + 4 * period of clk_tx_i). Otherwise (Two-step timestamping mode), the value = -(2 * period of clk_ptp_ref_i).

43.4.5.3.3 Frequency Range of Reference Timing Clock

The timestamp information is transferred across asynchronous clock domains, from the MAC clock domain to the application/system clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is 4 clock cycles of RMII and 3 clock cycles of PTP clocks. If the delay between two timestamp captures is less than this delay, the MAC does not take a timestamp snapshot for the second packet.

43.4.5.3.4 PTP Processing and Control

Following table shows the common message header for the PTP messages. This format is taken from the IEEE 1588-2008.

Table 374. Message Format Defined in IEEE 1588-2008

Bits								Octet	Offset
7	6	5	4	3	2	1	0		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField (*)								1	32
logMessageInterval								1	33

(*) – control Field is used in version 1. In version 2, message Type field is used for detecting different message types.

There are some fields in the Ethernet payload that are being use to detect the PTP packet type and control the snapshot to be taken. These fields are given below in table for PTP packets over Ethernet.

Following table provides information about the fields that are matched to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format.

Table 375. Ethernet PTP Packet Fields Required for Control And Status

Field Matched	Octet Position	Matched Value	Description
MAC Destination Multicast Address[1]	0–5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses[2]: • 01-1B-19-00-00-00 • 01-80-C2-00-00-0E[3]
MAC Packet Type	12, 13	0x88F7	PTP Ethernet packet
PTP Control Field (IEEE 1588 version 1)	46	0x00, 0x01, 0x02, 0x03, or 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management
PTP Message Type Field (IEEE 1588 version 2)	14 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP Version	15 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

1. The unicast address match of destination addresses (DA), programmed in MAC address 0 to 31, is used if the TSENMACADDR bit of MAC_Timestamp_Control register is set.
2. IEEE 1588-2008, Annex F
3. The MAC does not consider the PTP version 1 messages with Peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

43.4.5.4 Transmit Path Functions

The MAC captures a timestamp when the Start Packet Delimiter (SFD) of a packet is sent on the internal GMII interface. The packets, for which the timestamps has to be captured can be controlled on per-packet basis. Each Transmit packet can be marked

to indicate whether a timestamp should be captured for it. The MAC does not process the transmitted packets to identify the PTP packets. You can specify the packets by using the control bits in the Transmit descriptor. The MAC returns the timestamp to the software inside the corresponding Transmit descriptor, thus connecting the time-stamp automatically to the specific PTP packet. The 64-bit timestamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

43.4.5.5 Receive Path Functions

The MAC can be programmed to capture the timestamp of all packets received on the internal GMII interface or to process packets to identify the valid PTP messages. Use the following options of the MAC_Timestamp_Control register to control the snapshot of the time to be sent to the application:

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type

Table 376. Timestamp Snapshot Dependency on Register Bits

SNAPTYPSEL	TSMSTRENA	TSEVNTENA	PTP Messages
00	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
00	0	1	SYNC
00	1	1	Delay_Req
01	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp,Pdelay_Req, Pdelay_Resp,Pdelay_Resp_Follow_Up
01	0	1	SYNC, Pdelay_Req, Pdelay_Resp
01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
10	x	x	SYNC, Delay_Req
11	x	x	Pdelay_Req, Pdelay_Resp

The DMA returns the timestamp to the software inside the corresponding Receive Descriptor. The extended status, containing the timestamp message status and the IPC status, is written in normal descriptor RDES1 and the snapshot of the timestamp is written in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

NOTE

For Programming Guidelines for IEEE 1588 Timestamping (System Time Correction), see System Time Correction

43.4.5.6 IEEE 1588 System Time Source

The ENET QOS block supports both external and internal time source for reference timestamping.

- External Time source uses the 64-bit external time reference and clock as input in IP. The clock input is used to synchronize the external timing reference into MAC clock domain. Upper 32-bit indicates the time in seconds while lower 32-bit indicates the time in nanoseconds.
- Internal time source takes only the reference clock input and uses it to internally generate the Reference time (also called the system time) and capture timestamps.
  - UInteger48 seconds Field: The seconds field is the integer portion of the timestamp in units of seconds. It is 48-bits wide.

    For example, 2.000000001 seconds are represented as seconds Field = 0x0000_0000_0002.
  - UInteger32 nano secondsField The nanoseconds field is the fractional portion of the timestamp in units of nanoseconds.

    For example, 2.000000001 seconds are represented as nanoSeconds = 0x0000_0001. The nanoseconds field supports the following two modes:
    - Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds.
    - Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF_FFFF. Accuracy is ~0.466 ns per bit.

There is a system time register module which is being used when internal time reference is being used. The 80-bit time is maintained in this module and updated using the input reference clock (clk_ptp_ref_i). This time is the source for taking snapshots (timestamps) of Ethernet packets being transmitted or received at the internal GMII interface.

The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, the system time counter is written with the value in the Timestamp Update register. For system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, the frequency offset and/or frequency drift of a slave clock (clk_ptp_ref_i) with respect to the master clock (as defined in IEEE 1588-2002) is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals.

NOTE

For Programming Guidelines for IEEE 1588 Timestamping (For Internal Time-stamp Source Configuration). see Initialization Guidelines for System Time Generation

43.4.5.7 IEEE 1588 Higher Word Register

If system time source is internal, then higher word register can be invoked. MAC timestamp is 64-bit wide. The values of the upper 16-bits of the seconds field can be read from the CSR register.

43.4.5.8 Flexible Pulse-Per-Second Output

The ENET QOS block supports the flexibility of programming the start or stop time, width and interval of pulse generated on pulse per second (PPS) output. IP supports 4 such output signals. By default, the block is in fixed pulse per second output mode with an interval of 1 second.

Initially. the start time should be programmed in target time registers "MAC_PPSx_Target_Time_Seconds and MAC_PPSx_Target_Time_Nanoseconds" for all desired/enabled PPS output. Reprogramming the start or stop time must be done after the synchronization of the earlier programmed value. Bit 31 of the MAC_PPS#_Target_Time_Nanoseconds register indicates that the synchronization is complete. If the application programs a start or stop time that has already elapsed, the MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

The PPS width and interval are programmed in terms of granularity of system time, that is, number of the units of sub-second increment value. For example, to have a PPS pulse width of 40 ns and interval of 100 ns with PTP reference clock of 50 MHz, you

should program the width and interval to values 2 and 5, respectively. You can achieve smaller granularity by using a faster PTP reference clock. Before giving the command to trigger a pulse or pulse train on the PPS output, you should program or update the interval and width of the PPS signal output.

NOTE

See Programming Guidelines for Flexible Pulse-Per-Second Output

43.4.5.9 Media Clock Generation and Recovery

Media clock recovery and generation needs a dedicated hardware and software to complete the operation. IP generates a reference clock with the help of dedicated hardware which is then multiplied to get the desired media clock. Software extracts the presentation time from the incoming PTP 1722 frames and programs these value into CSR registers so IP can read them for media clock recovery.

As shown in the following figure, the timestamp array and the DMA module are external to IP. IP supports a 32-bit presentation time counter in nanoseconds that wraps at the full32 bit value to match up with 1722 presentation time format and an handshake mechanism with external application(such as DMA) to program the presentation time into CSR register.

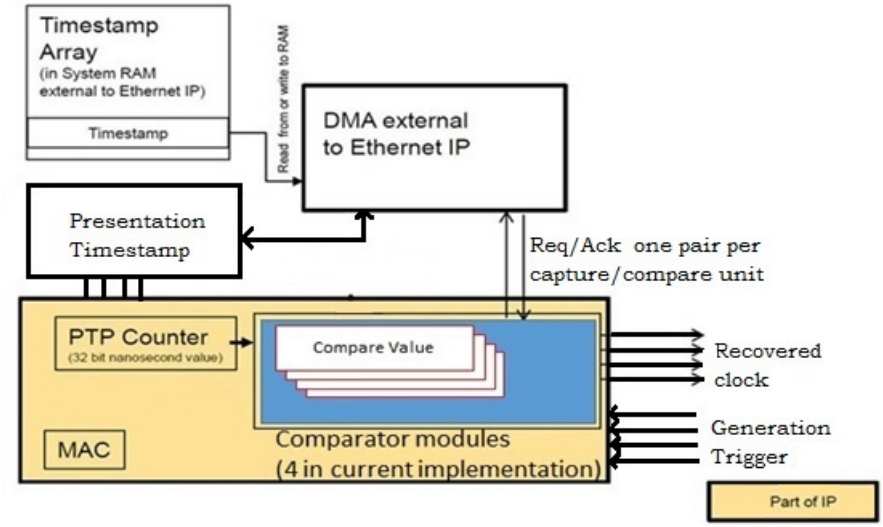

Figure 179. Block Diagram of Media Clock Generation and Recovery

43.4.5.9.1 Presentation Time Counter

Presentation time counter is another view of the PTP System time (1588 timer). For a given PTP System time (PTP[63:32] represents time in seconds and PTP[31:0] represents time in nanoseconds), there exists a corresponding Presentation Time (32-bit value in nanosecond). The Presentation time computed is referred to as Current Presentation Time (CPT).

The Current Presentation Time (CPT) can be viewed as derived from 64bit PTP System Time. PTPNS[63:0] = (PTP[63:32] * 32'd1,000,000,000) + PTP[31:0] where, PTPNS is the PTP system time converted into a 64bit nanosecond value.

Current Presentation Time[31:0] = PTPNS[31:0]

Media Clock Recovery is possible when the System Time is internally generated in IP and CPT is computed in the same way as the Internal PTP System Time generation. Because CPT and System Time values are in nanoseconds, and must be synchronous, the increment cycle of both the timers are same. The timer is updated at the same instance, but the updated value could be different. The software must compute a separate 32-bit update value in nanoseconds for the CPT update. CPT sampled at different edges of a triggering input results in the generation of Media Clock timestamps which are inserted in 1722 based AVBTP packets, to recover the clock at the destination.

43.4.5.9.2 Comparator Modules

As shown in the figure 'Block Diagram of Media Clock Generation and Recovery' the module supports four comparator modules to handle multiple media clocks that might be required. The Comparator modules hand shake with the application to

Program the timestamps into the MAC_PPS(#i)_Target_Time_Seconds register when PTGE field of MAC_Timestamp_Control register is set.

Set the Presentation Time Control bits of the particular instance for recovery mode.

The timestamps received from the application are referred as Target Presentation Time (TPT).

When MCGREN#i field of MAC_PPS_Control register is set to 1, the IP operates in MCGR mode. The comparator module sends up to two requests to the application for TPT write, when PTGE field of MAC_Timestamp_Control register is set and the Presentation time control bits of the particular instance is set for MCGR mode. Subsequent requests are generated each time a Presentation Time match occurs. (CPT transitions from a value less than TPT, to a value greater than or equal to CPT). The first request is asserted when a specific comparator instance is set to MCGR mode with a non-zero Presentation Time Control and an additional request is made when the first data is received into the Comparator. This allows the application to write the next TPT value while IP processes the previous TPT value for a match.

The TPT read from the MAC_PPS(#i)_Target_Time_Second is considered as a future time. A toggle/pulse is generated in the next cycle when a match is detected. When a match is detected, the mcgr_dma_req_o#i request for that comparator is asserted (to obtain next TPT) until the corresponding application acknowledgment is set.

The presentation control bits (PPSCMD#i field of MAC_PPS_Control register) determine the shape of the generated waveform. Also, these bits can be programmed to either toggle or generate a high/low pulse for one PTP clock cycle, upon match.

Media Clock Recovery: A match is when the free-running CPT value matches the received TPT value. A output signal EMAC_TMR signal as shown in the IO mux sheet is asserted (toggle, low pulse, or high pulse) based on the presentation control value programmed.

Media Clock Generation: Based on the presentation control value programmed in MAC_PPS_Control register, the particular comparator captures the presentation time and programs it into MAC_PPS(#i)_Target_Time_Second register. A request is raised to the application to read the captured timestamp. Until the acknowledgment is received from the application, acknowledging that the read operation is complete, no new timestamps are captured.

43.4.5.9.3 Media Clock Generation and Recovery Flow

Following figure shows the media clock generation and recovery flow. For both media clock generation and recovery, set the PTGE field of MAC_Timestamp register for CPT generation and set the MCGREN#i field of MAC_PPS_Control Register for the corresponding instance to be enabled in the MCGR mode.

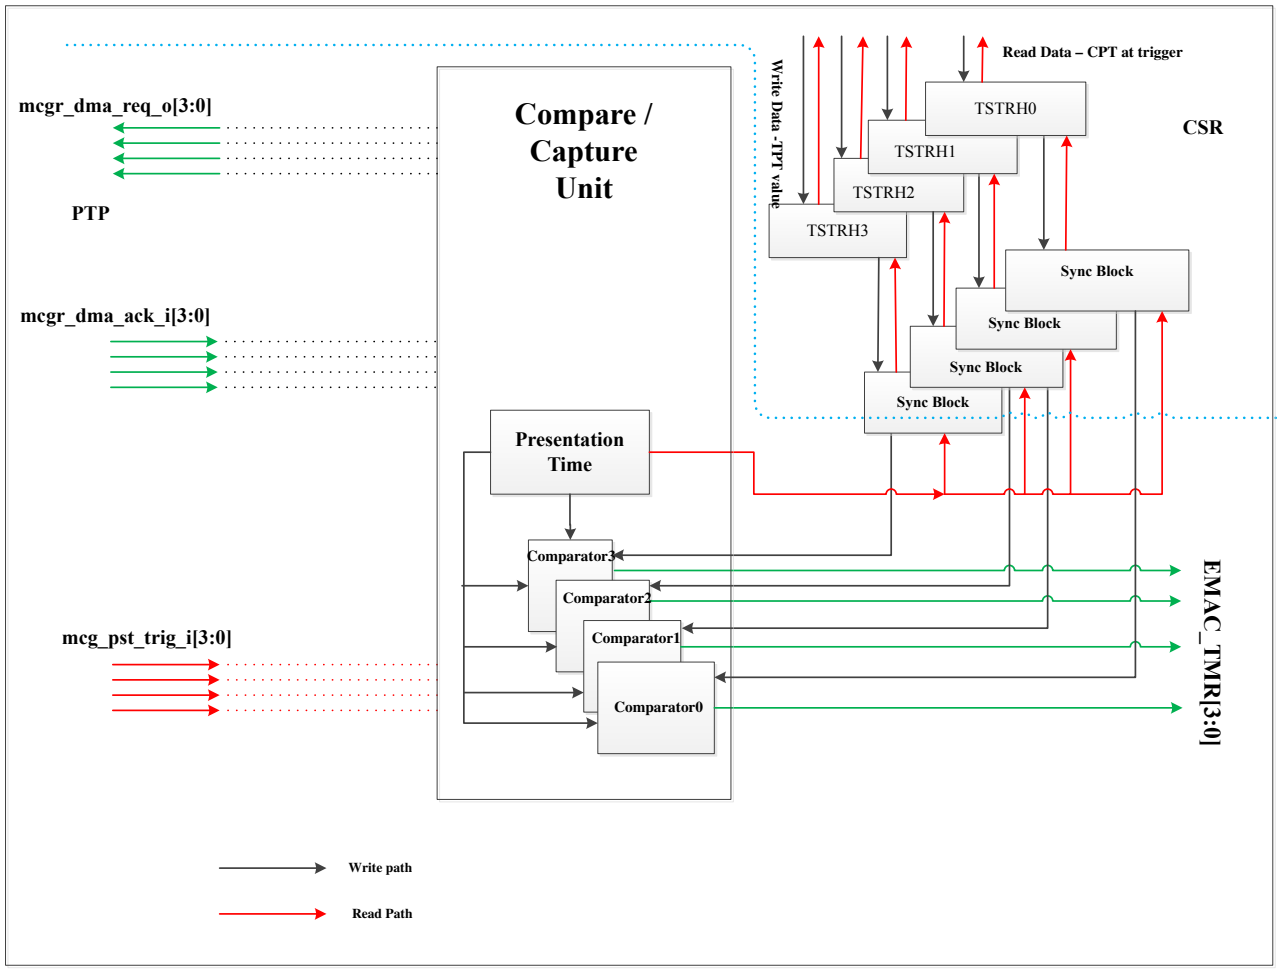

Figure 180. Media Clock Generation and Recovery Flow

NOTE

1. The consecutive triggers to sample the presentation time should always be asserted after a few PTP clock cycles to allow for synchronization delays. (This is not an issue when the input trigger maximum frequency is 8KHz and the PTP clock is running at least at 1MHz)
2. DMA acknowledgment can be both posted as well as non-posted, in the Media Clock Recovery Mode.
3. See "Programming Guidelines for Media Clock Generation and Recovery"

43.4.5.10 One step timestamp

IP supports the one step time stamp feature. It can be enabled for a packet by setting the Bit 20 (OSTC) in the control word.

NOTE

See Programming Guidelines for IEEE 1588 Timestamping .

43.4.5.11 IEEE 1588 Sub Nanoseconds Timestamp

The ENET QOS block supports the ingress and egress correction accuracy in sub-nanoseconds. It is programmed in the TSICSNS and TSECSNS fields of the MAC Timestamp Ingress Correction Subnanosecond and MAC Timestamp Egress

Correction Subnanosecond registers, respectively. In this case, the correction has an unit of nanosecond, multiplied by 2^8. The least significant 8 bits of the value should be programmed in the sub-nanoseconds register.

For example, if the required egress correction is 3.6 nS and TSCTRLSSR bit is set, then TSEC must be 0x3 and TSECSNS must be 0x99 (0.6 * 256). Similarly, if the required ingress correction is -3.6 ns and TSCTRLSSR bit is set, then TSIC must be 0xBB9A_C9FC and TSICSNS must be 0x66 (fractional part of (10^9 - 3.6) * 256).

43.4.6 Multiple Channels and Queues Support

IP supports the five queues and channel on Tx and Rx paths.

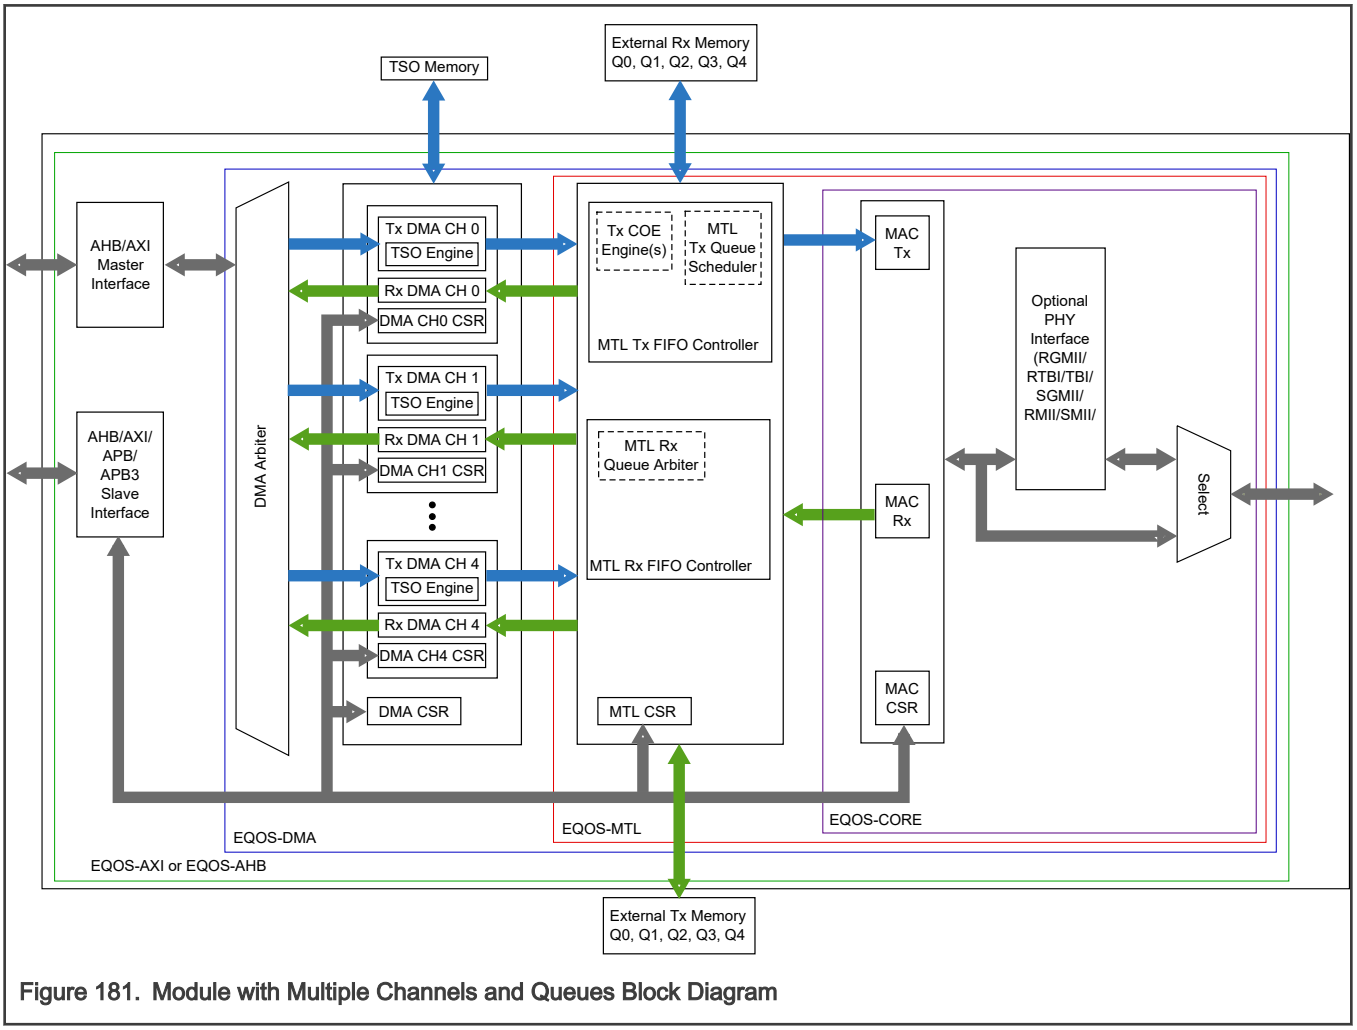

Figure 181. Module with Multiple Channels and Queues Block Diagram

DMA arbiter of IP supports two types of arbitration scheme, fixed priority and weighted round-robin. The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels for accessing descriptors and data buffers. The DA bit of the DMA_Mode register specifies the arbitration scheme (fixed or weighted round-robin) between the Tx and Rx DMA of a channel.

Priority between the corresponding Tx DMA and Rx DMA can be set by using TXPR field of the DMA_Mode register. PR field of the DMA_Mode register can be set to specify the weighted priority between the Tx DMA and Rx DMA in round robin arbitration scheme.

Following table provides information about the priority scheme between Tx DMA and Rx DMA.

Table 377. Priority Scheme for Tx DMA and Rx DMA

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority Schemes
x	x	x	0	1	Rx always has priority over Tx
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests
0	0	1	0	0	Rx has priority over Tx in ratio 2:1
0	1	0	0	0	Rx has priority over Tx in ratio 3:1
0	1	1	0	0	Rx has priority over Tx in ratio 4:1
1	0	0	0	0	Rx has priority over Tx in ratio 5:1
1	0	1	0	0	Rx has priority over Tx in ratio 6:1
1	1	0	0	0	Rx has priority over Tx in ratio 7:1
1	1	1	0	0	Rx has priority over Tx in ratio 8:1
x	x	x	1	1	Tx always has priority over Rx
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests
0	0	1	1	0	Tx has priority over Rx in ratio 2:1
0	1	0	1	0	Tx has priority over Rx in ratio 3:1
0	1	1	1	0	Tx has priority over Rx in ratio 4:1
1	0	0	1	0	Tx has priority over Rx in ratio 5:1
1	0	1	1	0	Tx has priority over Rx in ratio 6:1
1	1	0	1	0	Tx has priority over Rx in ratio 7:1
1	1	1	1	0	Tx has priority over Rx in ratio 8:1

43.4.6.1 Multiple Queues and Channels Support in the Transmit Path

IP supports the five transmit queues and five channels.

NOTE

See Programming Guidelines for Multi-Channel Multi-Queuing

43.4.6.2 Multiple Queues and Channels Support in the Receive Path

IP supports five receive channels and five queues.

In the Receive direction, the MTL Rx Controller selects the Rx DMA for which it is transferring or reading the data from the Rx FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that it has to transfer. The scheduler checks whether sufficient data (of requested burst length) is available to be transferred to these DMAs and then selects the Rx DMA that gets serviced using the programmed priorities.

NOTE

See Programming Guidelines for Multi-Channel Multi-Queuing .

43.4.6.3 Rx Queue to DMA Mapping

The packets in the MTL Rx Queues can be routed to any one of the multiple DMA channels by programming the register MTL_RxQ_DMA_Map0 Register for queues 0 through 3, and MTL_RxQ_DMA_Map1 for queue 4.

The following types of Rx Queue to DMA mapping are possible through programming.

43.4.6.3.1 Static Mapping

In this mode, all of the packets of an Rx Queue are connected to a specific DMA channel. For example, all the packets from Rx Queue 0 can be routed to a DMA channel by programming Q0MDMACH (bit[3:0]) and Q0DDMACH (bit[7] = 0) of the MTL_RxQ_DMA_Map0 Register.

Similarly, packets from other Rx Queues can be routed to any DMA channel by programming register fields corresponding to each Queue.

43.4.6.3.2 Dynamic (Per Packet) Mapping

In this mode, the destination DMA channel of a packet being read from a Rx Queue is not constant but decided independently for each packet. For example, if you set the Q1DDMACH bit of the MTL_RxQ_DMA_Map0 register, the static mapping is disabled for Rx Queue 1 and the value in Q1MDMACH is ignored. The destination DMA channel is decided by the MAC receiver for each packet, depending on the following in decreasing order of priority:

1. L3-L4 filter Based DMA Selection: The TCP/UDP and IP header fields of the received packet are matched against the corresponding values programmed and enabled for comparison in the MAC_L3_L4_Address_Control register. If the match is successful, the DMA channel number programmed in the DMCHN field of the MAC_L3_L4_Ad-dress_Control register is selected as the destination DMA channel number provided DMCHEN bit of the same register is set. If none of the L3-L4 Registers give a comparison match, then the module proceeds to the next step below.
2. Extended VLAN Based DMA Selection: Extended routing is applicable only if the VLAN Filter has passed. Routing is only based on Perfect Filter Result. Each perfect filter has a DMA Channel Enable and a DMA Channel Number field which can be programmed. Routing is applicable for a filter, only if the DMA Channel Enable bit is set. The frame is routed to the smallest Matching Filter's DMA Channel provided it is enabled. If that filter's DMA Channel number is not enabled, the frame gets routed to Channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1. Then the MAC checks if Filter 1's DMA Channel Number is enabled through programming. If yes, the frame gets routed to the programmed value; otherwise it gets routed to DMA. When the inverse filter is enabled; is routed to the least mismatched filter's DMA channel number provided it is enabled. If the DMA Channel enable bit is not set, then the frame is routed based on DA based addressing or to Channel 0.

   If Hash Filter is also enabled, it is used to determine the Filter result only. Routing will still depend on the Perfect Filters enabled. If none of the perfect filters are enabled or if all of them are bypassed, then the VLAN Filter based routing will not take place. The frame will be routed via DA Based addressing or to Channel 0. If all the perfect filters give a fail result and the Hash Filter has passed, then the VLAN Filter result is a pass but routing will be based on DA Based Addressing or to Channel 0. Similar behavior is seen when inverse Filtering is enabled as well.
3. Ethernet DA-Based DMA Selection: The DA address of the received packet is compared against the programmed DA values in MAC Address Registers. If the address matches any of the programmed values, the corresponding DCS field (when enabled) determines the destination DMA channel number.

If none of the previous operations is able to make a successful match/decision, then the packet is routed to DMA Channel 0 by default.

43.4.6.3.2.1 Broadcast/Multicast Packet Duplication

Broadcast/Multicast Packet Duplication feature provides a mechanism to send the received Broadcast/Multicast packets to multiple DMA channels.

The DCS field of the of MAC_Address0_High and other optional MAC_Address(#i)_High (i=1 to 2) registers determines the DMA channel number to which the received packet (that matches the MAC Address present in that register) must be routed.

Packet duplication is not supported in other DMA channel routing mechanisms such as Extended VLAN, or L3-L4 based routing.

The Packet Duplication feature is supported only on the highest MTL Queue configured. Therefore, packet duplication for Broadcast/Multicast packets requires that the MCBCQ field of MAC_RxQ_Ctrl1 register is programmed to the highest RxQ present in the configuration.

43.4.6.4 Selection of Tag Priorities Assigned to Rx Queues

The VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ field in the corresponding MAC_RxQ_Ctrl2 registers. The bit corresponding to the VLAN Tag priority can be set in the PSRQ field for assigning that priority to the Rx Queue. For example, if you want to assign VLAN Tag priority of 3 to Rx Queue 0, set bit [3] in PSRQ field of MAC_RxQ_Ctrl2 register. The VLAN Tag priority assigned to particular Rx Queue must be unique, that is, more than one Rx Queue cannot be assigned the same VLAN Tag priority. However, more than one VLAN Tag priorities can be assigned to same Rx Queue.

The settings in the PSRQ field is used for VLAN Tagged Rx packet routing to Rx Queues as well as for PFC based Tx flow control. The received VLAN Tagged Rx packet is routed to Rx Queue that has the VLAN Tag priority match. In PFC based Tx flow control, PSRQ field corresponding to a particular Rx Queue is used for enabling VLAN Tag priorities in the PFC packet transmitted when corresponding Rx Queue threshold levels are reached.

43.4.6.5 Rx Side Routing from MAC to Queues

IP supports Rx Side Routing from the MAC to Queues. The MAC routes the Rx packets to the Rx Queues based on following packet types in that order

- Unicast/Multicast destination address packets that fail the destination address filter
- Multicast/Broadcast destination address packets that pass the destination address filter
- VLAN Tag Priority field in VLAN Tagged AV data packets
- AV Control packets
- VLAN Tagged IEEE 1588 PTP over Ethernet packets
- Untagged IEEE1588 PTP over Ethernet packets
- VLAN Tag Priority field in VLAN Tagged packets
- Untagged packets

The outer C-VLAN Tagged AV data Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers and the corresponding Rx Queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The AV Control Rx packets can be routed based on the Rx Queue number specified in the AVCPQ field in MAC_RxQ_Ctrl1 register and corresponding Rx Queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The VLAN Tagged Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers and the corresponding Rx Queue is enabled for DCB/generic through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The untagged IEEE 1588 PTP over Ethernet Rx packets can be routed based on the Rx Queue number specified in the PTPQ field in MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. The VLAN tagged IEEE 1588 PTP over Ethernet Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers or the Rx Queue number specified in the PTPQ field in MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This is determined by programming in TPQC field of MAC_RxQ_Ctrl1 register. This type of Rx packet routing is available when IEEE 1588 Timestamp feature support and Multiple Rx Queues are selected in the configuration. The VLAN Tagged IEEE 1588 PTP over Ethernet Rx packets are detected only when 802.1AS mode is disabled (AV8021ASMEN bit in MAC_Timestamp_Control register is set to 0), otherwise this type of Rx packets are routed as generic VLAN Tagged Rx packets.

The multicast/broadcast destination address Rx packets that pass the destination address filter can be routed based on the Rx Queue number specified in the MCBCQ field of MAC_RxQ_Ctrl1 register when enabled through MCBCQEN bit of MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The untagged Rx packets can be routed based on the Rx Queue number specified in the UPQ field of MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The unicast destination address Rx packets that fail the destination address filter can be routed based on the Rx Queue number specified in the UFFQ field of MAC_RxQ_Routing_Ctrl register when enabled through UFFQE bit of MAC_RxQ_Routing_Ctrl register, RA bit of MAC_Packet_Filter register is set to 1 and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The multicast destination address Rx packets that fail the destination address filter can be routed based on the Rx Queue number specified in the MFFQ field of MAC_RxQ_Routing_Ctrl register when enabled through MFFQE bit of MAC_RxQ_Routing_Ctrl register, RA bit of MAC_Packet_Filter register is set to 1 and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

If the Rx packet cannot be classified in any of the defined packet type for routing, it will be routed through Rx Queue 0.

43.4.6.6 Rx Side Arbitration Between DMA and MTL

IP controller supports Rx side arbitration between the DMA and the MTL.

After completing the current packet processing, the DMA Channel Controller fetches the next descriptor. After the descriptor fetching is complete, the DMA Channel Controller evaluates the amount of data to be to be transferred to the Rx Buffer based on the programmed PBL and Rx Buffer Length. Accordingly, it requests the MTL to transfer the data.

After servicing the current request, the MTL Rx Queue arbitration scheme selects Rx Queue based on the arbitration scheme (RAA field of the MTL_Operation_Mode register) and the weights programmed in the Queue <n> Receive Control Register. The arbitration is done among Queues for which DMA is ready to service. After the Rx Queue is selected, PBL (Programmable Burst Length) amount of data is read out from that Queue and is routed to the Rx DMA Channel based on the Rx Channel selection criteria.

The arbitration takes place when every PBL data transfer is completed and descriptors are ready for the processing from at least one DMA Channel.

43.4.6.7 Tx Side Arbitration between DMA and MTL

IP support Tx side arbitration between the DMA and the MTL. Since the number of Tx DMA channels is always equal to the number of Tx Queues in the MTL, they are always mapped directly. For instance, each Tx DMA pushes data into its respective Tx Queue assigned to it.

The data inside each Tx Queue is stored in packets. Hence, if two DMAs are allowed to transfer data into the same queue, when a Tx DMA starts a packet transfer, the other DMA cannot transfer data unless the previous packet is completely pushed-in. This means that the second DMA remains idle until the first packet is transferred. Hence, each DMA is always connected directly to its corresponding Tx Queue.

43.4.6.8 Time-Sensitive Networking (TSN)

The ENET QOS block supports TSN in 100 Mbps or 1000 Mbps mode, which enables the transfer of time-sensitive traffic over a network. The block implements the IEEE 802.1Qbv-2015 (Enhancements to Scheduling Traffic), IEEE 802.3br (Interspersing Traffic) and IEEE 802.1Qbu (Frame Preemption) TSN protocol.

The Transmit path of Queue 0 supports the strict priority algorithm and is used for best-effort traffic while transmit paths of additional queues support traffic management by using the credit-based shaper algorithm. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if the following conditions are true:

- The queue contains one or more packets.
- The credit for the queue is positive as per the algorithm.
- AV traffic can be received on all queues. The block can also receive untagged PTP packets in addition to AV traffic on any queue.

43.4.6.8.1 Enhancements to Scheduled Traffic (EST)

The IEEE 802.1Qbv-2015 defines the schedule for each of the queues on every egress port which makes the implementation aware of traffic arrival schedule. This information can be used to block the lower priority traffic from transmission in this time window/slot. This ensures that scheduled traffic is forwarded from sender to receiver through all the network nodes with a deterministic delay.

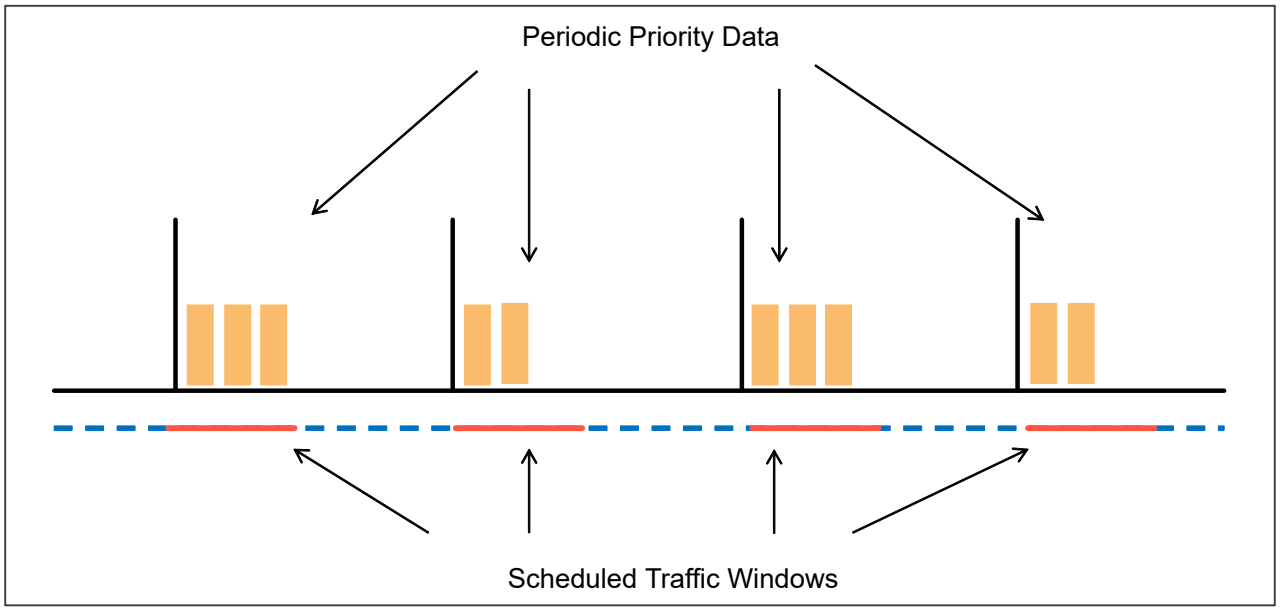

Figure 182. Time Aware Shaper Implementation for Traffic Scheduling

One of the important requirements to achieve a low latency is to ensure there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations while starting a transmission.

As shown in the following figure, if an interfering frame begins transmission just before the start of a reserved time period, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

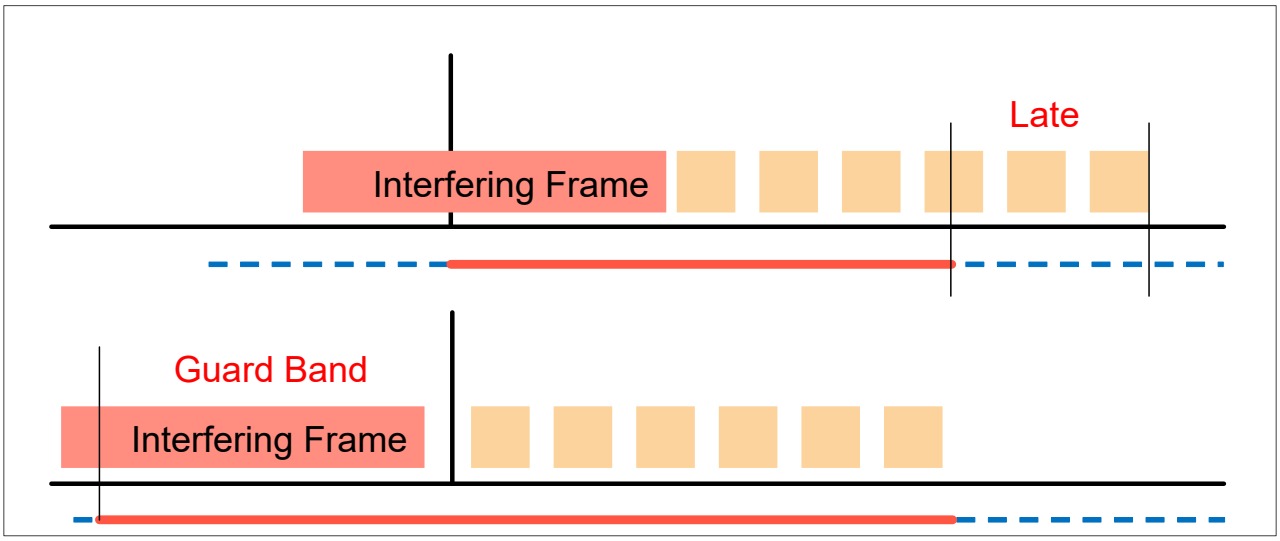

Figure 183. Implementing a Guard Band to Avoid Delays Due to Interfering Frames

A larger guard band equates to a less efficient use of network bandwidth. However, with the implementation of IEEE802.1Qbu (frame preemption), this issue is addressed. Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

43.4.6.8.1.1 Frequently Used Terms in EST

- Gate Control List: The list in the hardware memory that holds the gate controls and the associated time intervals.
- Gate Controls: For a given schedule (row in gate control list) there is a Gate Open (O) and Gate Close (C) state associated with each traffic class. The set of O or C values, whose width is same as configured TCs is called the Gate Controls. Example: CCOCO means TC4=C, TC3=C, TC2=O and so on.
- Time Interval: Time interval (in nanoseconds) is a 16, 20, or 24-bit configurable field in the Gate Control list that indicates the time for which the associated gate controls are valid.
- Base Time Register: Each Gate Control List is associated with a 64-bit Base Time Register that holds the start time (in PTP format) for the list.

43.4.6.8.1.2 Updates to the Transmit Scheduling to Support EST

To support EST, following updates are required to the transmit scheduling:

- Implementation of Gate Control List (GCL)
- Enforcing gate controls in the scheduler
- Accounting for Gate Open (O) duty cycle in the computation of idleSlope (CBS)

43.4.6.8.1.2.1 Implementation of Gate Control List (GCL)

Following figure shows block diagram from the IEEE 802.1Qbv spec that illustrates how the gate control list governs the gate close(C) and open(O) events based on the schedule provided for each event. GCL has the following two parts:

- Time Interval: Defines the time in nano seconds for which the gate controls are valid and should be applied before reading the next gate controls from the list. Configurable width of 16, 20 or 24 to represent a maximum of 64us, 1ms, or 16ms

schedule interval respectively. Supports left shift of the time interval upto 7 bits to be able to apply a multiplication factor from 1 to 128ns (in steps of 2(power)n). The maximum value (post shifting) of this field must be 999,999,999 ns.

- Gate Control: Defines the Open (O) represented by logic 1 or Close (C) represented by logic 0 state for the gate of each TC.

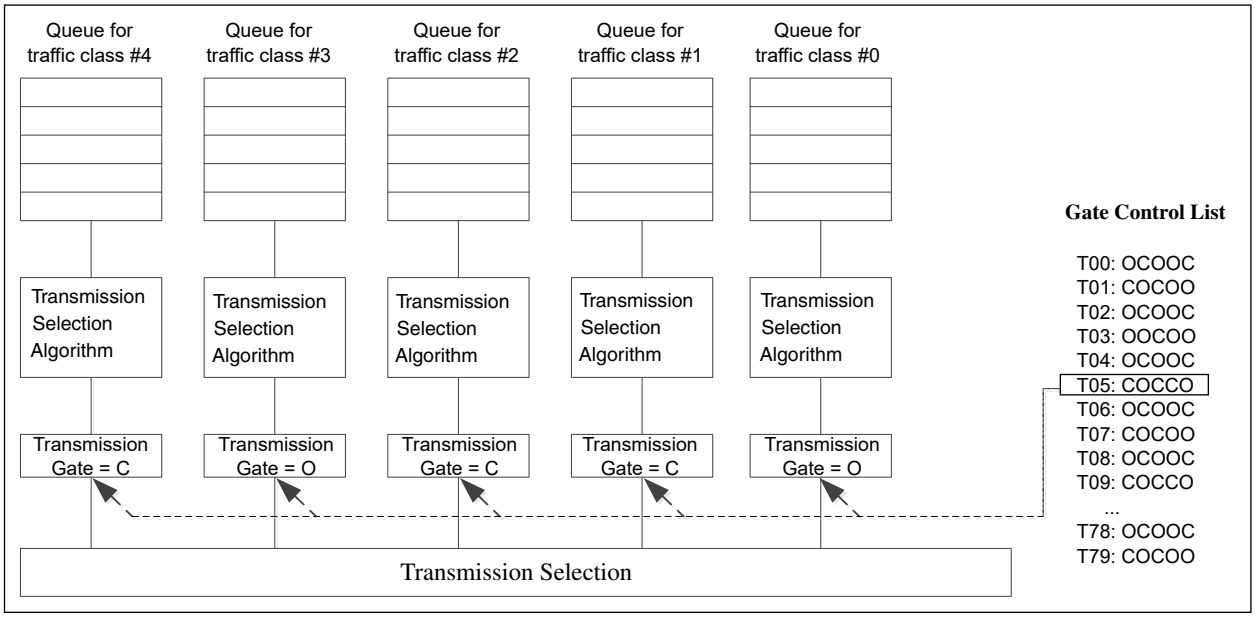

Figure 184. Block Diagram from IEEE 802.1 Qbv Specification - GCL Governing Gate Close and Open Events

The implementation of GCL consists of the following two Gate Control Lists:

- HWOL - Hardware Owned List which is a list for hardware access.
- SWOL - Software Owned List which is a list for software access.

The access to these lists is mutually exclusive. The ownership to the list is set by hardware in the SWOL field of MTL_EST_Status register. Following table provides the implementation details of GCL.

Table 378. External Memory Used for Holding the Two Gate-Control Lists

Gate Control (up to 5 bits)	Time Interval (ns) 16, 20, or 24 bits

43.4.6.8.1.2.2 Registers Related to Gate Control List

Following are the set of 4 registers (one for each GCL) related to GCL. These registers are implemented through Indirect Addressing using the GCL_Control and GCL_Data registers.

1. 64-bit Base Time Register (BTR)

2. 40-bit Cycle Time (CTR)

3. m-bit Time Extension (TER)

4. n-bit [Gate Control] List Length (LLR) (n depends of the configured GCL depth)

43.4.6.8.1.2.2.1 Base Time Register (BTR)

Base Time Registers is a 64-bit register that holds the start time to execute the GCL. The format of the BTR is same as the PTP format (upper 32-bits holds time in seconds and lower 32 bits hold time in nano seconds). Once the execution of a given list begins, the implementation can update the value in BTR to indicate the next list execution begin time.

43.4.6.8.1.2.2.2 Cycle Time Register (CTR)

Cycle Time Register is a 40-bit register that holds the time at which the execution of the GCL should be repeated. The Cycle Time Register consists of an 8-bit value in seconds, and a 32-bit value in nano seconds (similar to the PTP time format with truncated seconds register). For a given Gate Control List the start time is "Base Time" + N * "Cycle Time" where N is an integer value representing the iteration number starting with 0 for first iteration. If the Gate Control List execution takes longer than the Cycle time, then the list is truncated at the Cycle Time and the subsequent loop begins at Cycle Time.

43.4.6.8.1.2.2.3 Time Extension Register (TER)

Time Extension Register (TER) is a m-bit (where m = Configured Time Interval width + 7) register that holds the amount of time (in nano seconds) the current Gate Control List can be extended before switching to the new Gate Control List. This will be useful in avoiding small fragments of the current list being executed before switching to a new list.

43.4.6.8.1.2.2.4 List Length Register (LLR)

List Length Register (LLR) is an n-bit register (when n is 7, 8, 9, 10, or 11 for a GCL configured depth of 64, 128, 256, 512, or 1024 respectively) that holds the integer value of the length of the GCL (that is the number of valid rows in each GCL). The processing of the GCL stops after the number of rows read equals to the LLR value.

43.4.6.8.1.2.3 Transmission Gating Implementation

A Bridge or an end station can be enhanced to allow transmission from each TC that is yet to be scheduled relative to a known timescale. To achieve this, a transmission gate is associated with each TC; the state of the transmission gate determines if the queued frames can be selected for transmission.

For a TC, the transmission gate can be in one of the following two states:

1. OPEN:Queued frames are selected for transmission, in accordance with the definition of the transmission selection algorithm associated with the TC.
2. CLOSED: Queued frames are not selected for transmission.

A frame on a traffic class queue is not available for transmission if the transmission gate is in the closed state or if there is insufficient time available to transmit the entirety of that frame before the next gate-close event associated with that queue.

The implementation has visibility to the current schedule of gate controls and the immediate next schedule of the gate controls. So the maximum Gate Open period does not exceed the sum of the two Time Intervals. This is because, a frame is selected for transmission only if the gate is currently Open and the duration of gate open interval is greater than the time taken to transfer the entire frame.

The implementation must know the frame size before the transmission, so that the transmission overruns can be avoided and only the frames that can complete are scheduled at all times.

The implementation adequately compensates for the implementation delays in the data transfer from the buffer to the line by offsetting the current time with all the relevant delays (provided by the CTOV field of MTL_EST_Control register). This ensures that the schedule provided is always accurately implemented at the line.

43.4.6.8.1.3 Idle Slope Computation Updates

When EST is enabled, credit is accumulated only when the gate is open; therefore, the effective data rate of the idleSlope must be increased to reflect the duty cycle for the transmission gate associated with the queue.

The idleSlope is computed based on the GateOpenTime and OperCycleTime values. Program the idleSlope registers (implemented one per CBS enabled TC) based on the following equation. The existing MTL register has sufficient bit width to accommodate the new values for idleSlope.

idleSlope = (operIdleSlope(N) * OperCycle/GateOpenTime)

43.4.6.8.1.4 Operational Details of GCL

Set the switch to software List, the SSWL field of the MTL_EST_Control Register, so that hardware can access the programmed gate control list. The first set of gate controls are applied when the current time is equal to the value in the Base Time Register (BTR) and is held until the programmed "Time Interval" value.

To avoid transmission overruns, one additional gate control event is always read ahead from the list. This enables the GCL to determine the next gate close events (if any) for the TCs that are open.

The scheduling based on the Gate Open state and Time Interval of only the current and subsequent schedule. An internal accumulator is used to add the time intervals when gate controls are applied. BTR + Accumulator holds the time at which the next set of gate controls are to be applied.

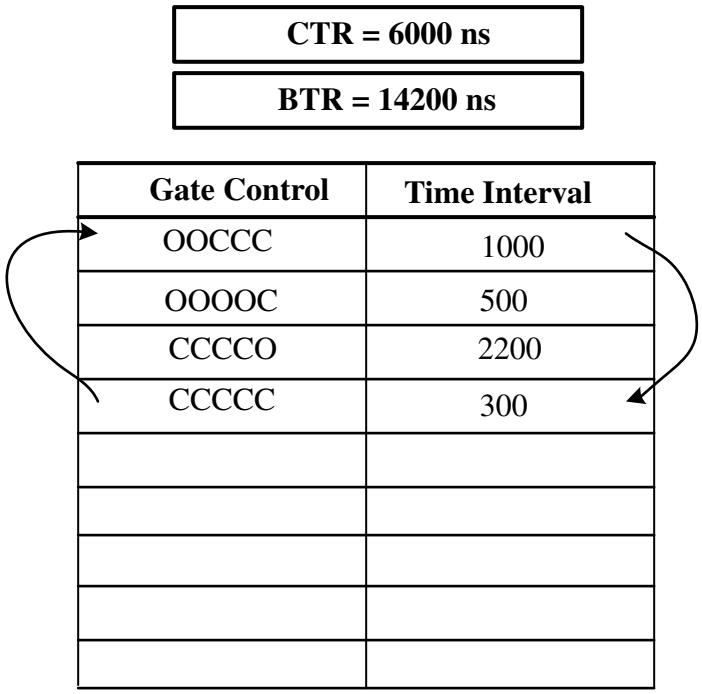

Figure 185. GCL and Associated Registers - BaseTime and CycleTime

The GCL is read progressively from the first row adhering to the schedule. The read operations continue until the List Length (from LLR Register) is reached and the execution of the list restarts at BTR + CTR time. At this point the BTR is incremented by value in CTR to mark the beginning of a new cycle. In the absence of any gate controls, all the gates are deemed to be in Open state, during the execution of the list.

In cases where the execution time of the list is greater than the CycleTime, the list is truncated and the next iteration starts when the current time equals BTR + CTR.

Table 379. GCL and Associated Registers - BTR and CTR

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCC	1000	14200
15200	OOOOC	1500	14200
15700	CCCCO	3700	14200
17900	CCCCC	4000	14200
18200	OOOOO	0	20200
20200	OOCCC	1000	20200
21200	OOOOC	1500	20200

In the example in table, the execution starts at 14200 and the first set of Gate Controls "OOCCC" are applied immediately. As the time interval is 1000ns the next set of gate controls are applied at 14200 (BTR) + 1000 (Accumulator) = 15200 ns . As there are no

gate controls available after the execution of the last gate control and before the next iteration of the loop, the gates are deemed to be in open state during that time period as depicted at time 18200 in the table.

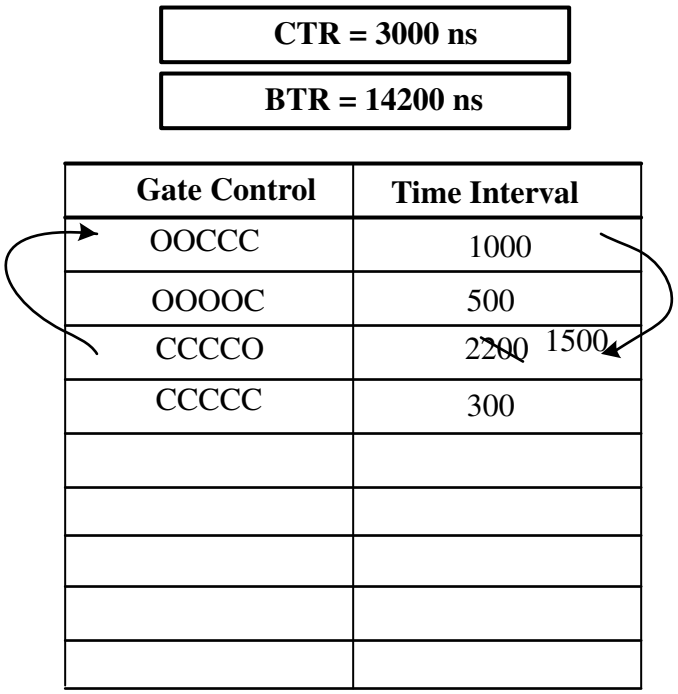

Figure 186. GCL and Associated Registers - BaseTime and CycleTime List Execution Time > CycleTime

As the list execution takes longer than the allocated CycleTime, the list is truncated and the list is started from the BTR+CTR as shown in the following table.

Table 380. GCL and Associated Registers - BTR and CTR, Execution Time > Cycle Time

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCC	1000	14200
15200	OOOOC	1500	14200
15700	CCCCO	3700	14200
17200	OOCCC	1000	17200
18200	OOOOC	1500	17200
18700	CCCCO	3700	17200

While applying the third set of gate controls, the BTR + CycleTime (17200) < BTR + Accumulator (17900), so the list is truncated and execution switches to a new iteration at 17200.

43.4.6.8.1.5 Installing a New GCL

When a new software programmed GCL is available and must be executed at the new BTR value, the switch to the new GCL can happen in one of the following ways.

- New Base Time aligned with current schedule
- New Base Time unaligned with current schedule

43.4.6.8.1.5.1 New Base Time Aligned with Current Schedule

If the choice of cycle time for the new gating cycle is unchanged from the cycle time for the current gating cycle, and if the BTR chosen for the new gating cycle (new BTR) is an integer multiple of the current cycle time (+ current BTR), then the new gating cycle exactly lines up with the old gating cycle, that is, the cycle start times for the new gating cycle is same as they would have been for the old configuration. This could be considered to be the ideal case and allows the new gating cycle to be installed and executed with no timing issues. The implementation completes the execution of an iteration of the current list and switches to the new list at the beginning of the BaseTime listed in the new list.

If (New BaseTime > = Current Time)

ConfigChangeTime = New BaseTime

Else If (New BaseTime < Current Time)

1. Set the BTRError

2. ConfigChangeTime = (New BaseTime + N* New CycleTime)

where N is the smallest integer for which the relation ConfigChangeTime >= CurrentTime and (N =< 8) is TRUE.

When N > 8 the hardware cannot auto recover and the loop count value in BTRError reporting is set to 1111 requiring the software to reprogram the New Base Time.

Following figure illustrates the installation of the new GCL along with the timelines.

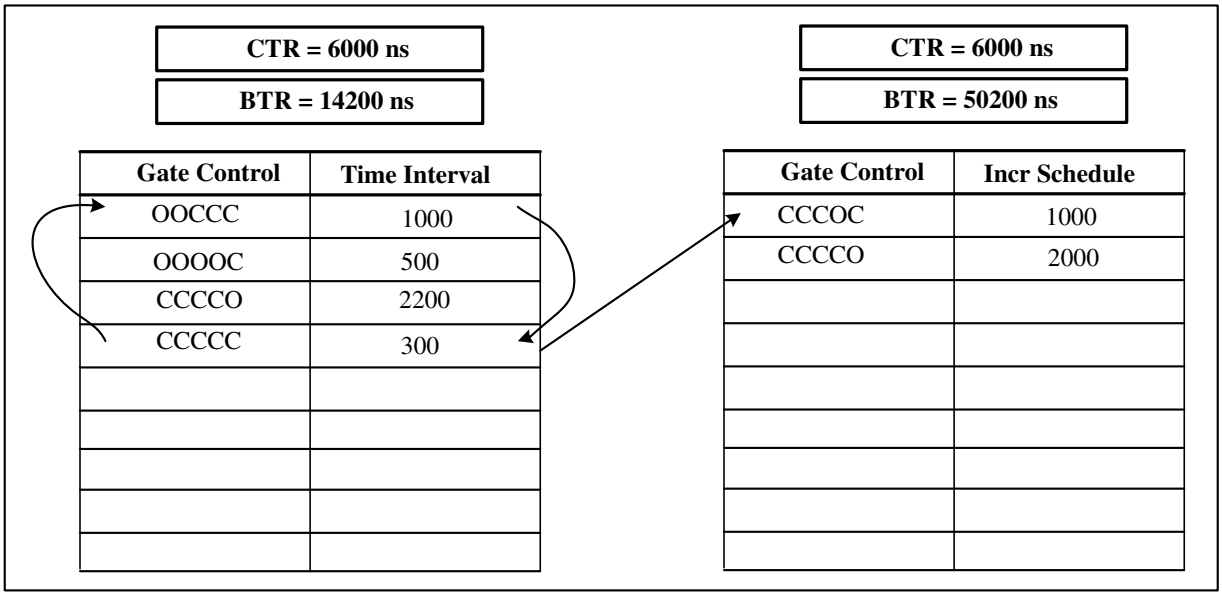

Figure 187. Switching to a New Configuration that is Aligned with the Existing Configuration

In the above example, after the sixth iteration of the first GCL, the BTR values of the old and new GCL are equal. At that point the new GCL is processed as a natural extension to the existing GCL.

Table 381. GCL and Associated Registers - BTR and CTR

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
44200	OOCCC	1000	44200
45200	OOOOC	1500	44200
45700	CCCCO	3700	44200
47900	CCCCC	4000	44200
48200	OOOOO	0	50200
50200	CCCOC	1000	50200
51200	CCCCO	3000	50200
53200	OOOOO	0	56200

43.4.6.8.1.5.2 New Base Time Unaligned with Current Schedule

If new CycleTime differs from current CycleTime or New BaseTime is in the future and is not an integer multiple of current CycleTime, then the old and new cycles do not line up; when new BaseTime is reached (when the new configuration is installed and starts to execute), the last old cycle is normally truncated to start the first new cycle. This could be undesirable if it results in a very short last old cycle; arguably it would be better to simply extend the penultimate old cycle by that small amount, rather than starting a very short cycle. The Cycle Time Extension Register (related to the current config list) allows this extension of the last old cycle to be done in a defined way; if the last complete old cycle ends normally in less than current Cycle Time Extension (TER) ns before the new base time, then the last complete cycle before new BaseTime is reached is extended so that it ends at new BaseTime.

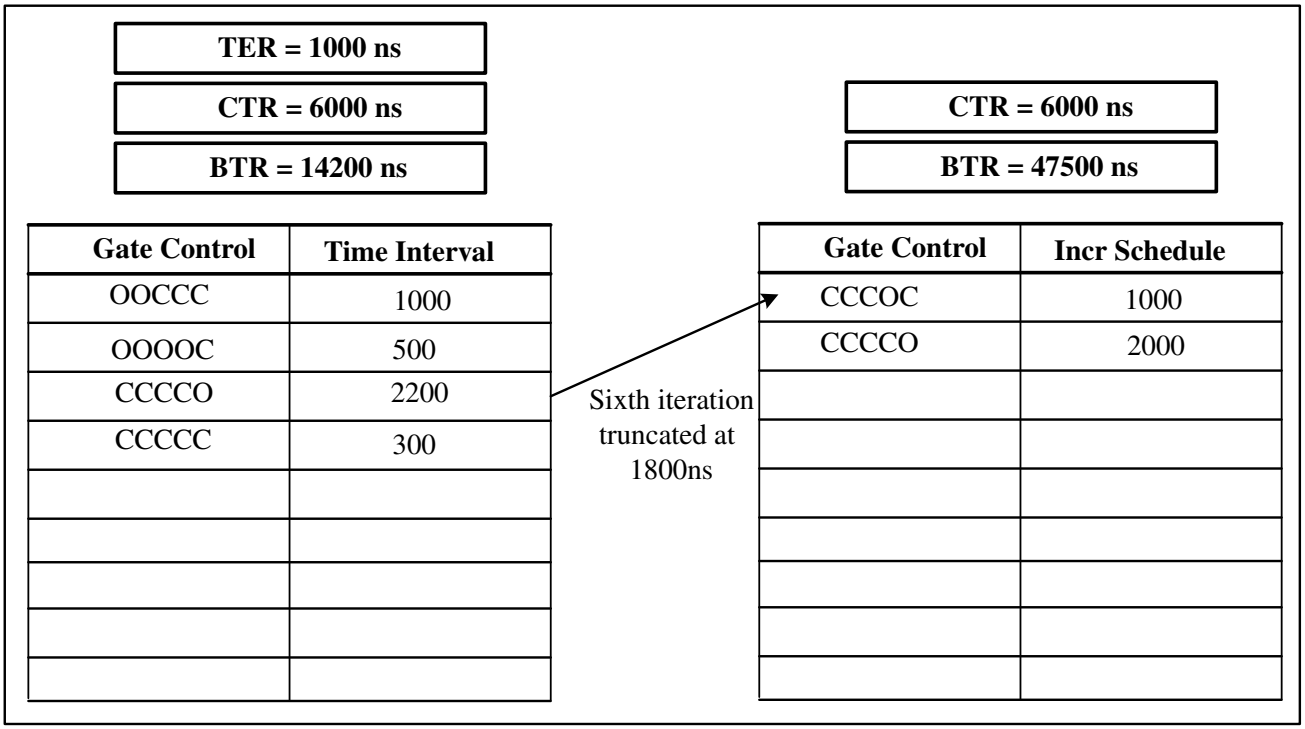

Figure 188. Switching to New List Truncating the Current List

At the end of the fifth iteration the Current time + Cycle time extension (TER) < New BTR so the sixth iteration of current configuration is started. During the sixth iteration of the current list when the new BTR value is smaller than the next schedule in the current list, it switches to the new list.

Table 382. Extending to New List By Truncating the Current List

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
44200	OOCCC	1000	44200
45200	OOOOC	1500	44200
45700	CCCCO	3700	44200
47500	CCCOC	4000	44200
48500	CCCCO	0	50200
50500	OOOOO	1000	50200

Below is an example where the current config list is extended instead of starting a new iteration as the extension time of 800ns is less than the allowed cycle extension time (TER) of 1000ns.

Figure 189. Switching to New List By Extending the Current List

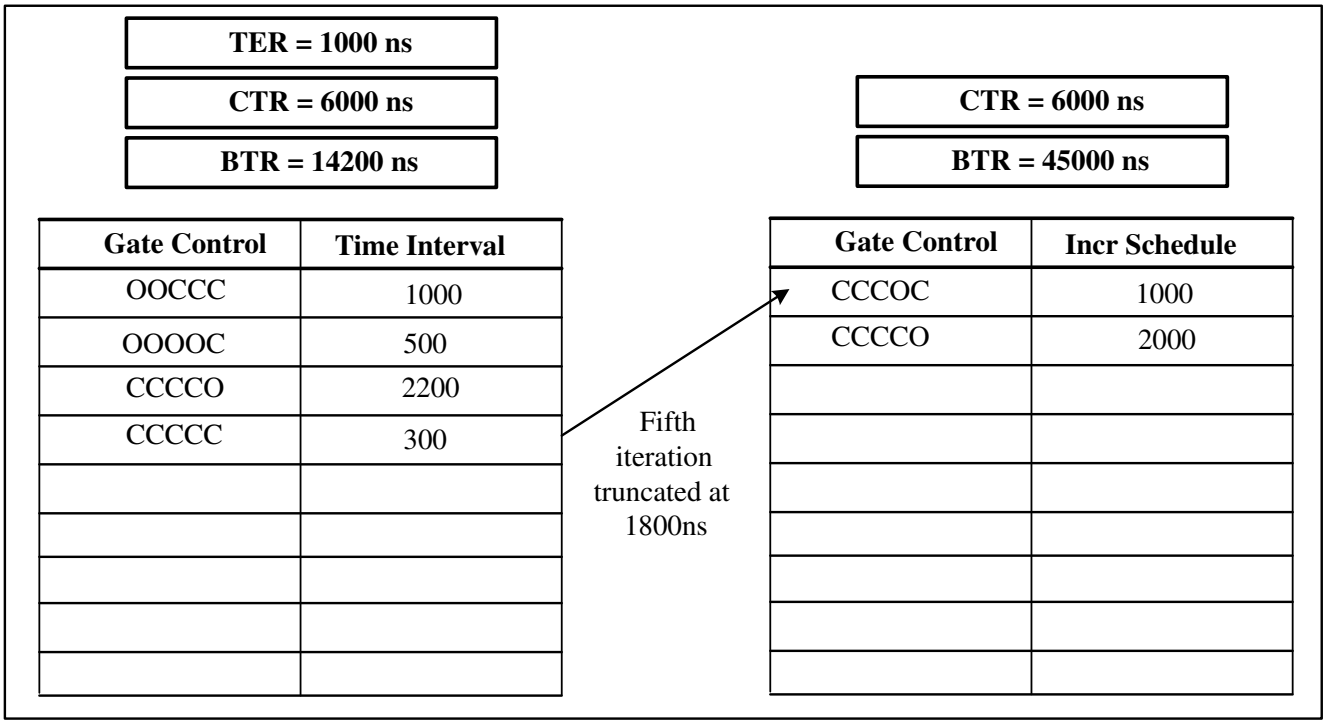

Table 383. Switching to New List By Extending the Current List

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
38200	OOCCC	1000	38200
39200	OOOOC	1500	38200
39700	CCCCO	3700	38200
41900	CCCCC	4000	38200
42200	OOOOO	0	44200
45000	CCCOC	1000	45000
46000	CCCCO	3000	45000
48000	OOOOO	0	51000

43.4.6.8.1.6 Impact of Transmit Scheduling Algorithms on EST

When EST is used in isolation, the Gate Control List manages the final open/close state of the Queues along with the checks carried out by the Transmission Selection Algorithm in MTL. As the Gate Controls operate on a predefined repetitive schedule, it is recommended to use Strict Priority or Credit Based Shaper (CBS) scheduling algorithms.

Other algorithms such as the Weighted Round Robin (WRR), Deficit Weighted Round Robin (DWRR) and Weighted Fair Queuing (WFQ) implement masking of the queues based on the current winning queue. The algorithm is applied only among the group of queues that open simultaneously. To ensure Queues whose gates are "Open" get priority, these algorithms are modified to treat "gate open" queues and "gate closed" queues as separate groups giving priority to gate open queues.

For example, consider 4 queues (Q3, Q2, Q1, Q0) with weights 4:3:2:1; Q3 and Q2 are in Open state in slot one slot, while Q1 and Q0 are in Open state in another slot. In this case, the scheduler works as follows:

1. In the first slot, the Q3 and Q2 are serviced in the ratio of 4:3 for the duration the slot is open.
2. In the second slot, the queues Q1 and Q0 are serviced in the ratio of 2:1.
3. Fresh arbitration is started every time a slot is opened.

In other words, the traffic does not get distributed in the intended ratio of 4:3:2:1; but as two groups with different ratios and only for the duration of the slot when the gates are open continuously

NOTE

See Programming Guidelines for EST

43.4.6.8.2 Frame Preemption (FPE)

Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame. During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower priority (preemptable) frame; the preemptable frame transmission is resumed and completed after the express frame transmission is complete. To support frame preemption, the following two abstractions of the MAC are used:

- A preemptable MAC, called pMAC, which carries the preemptable traffic.
- An express MAC, called eMAC, which carries the express traffic.

In the implementation, only the parts of the MAC that hold the state during preemption are replicated and represented as pMAC and eMAC. The MAC uses the following two ways to put the transmission of the preemtable traffic on hold, in the presence of express traffic:

- The MTL scheduler interrupts the preemptable traffic that is currently being transmitted. When the preemption capability is active, the MAC interrupts the transmission and reception of preemptable frames. A preempted fragment can be followed by zero or more express frames, before the continuation fragments. The preemptable frame can be fragmented any number of times, however, the minimum final and non-final fragment length criterion must be met. However, interleaving of more than 1 preemptable packet is not permitted. This implies that if a preemptable packet is fragmented by an express packet, another preemptable packet cannot be transferred until all the remaining fragments of the first preempted packet are transferred.
- The MTL scheduler prevents starting the transmission of preemptable traffic. When the preemption capability is inactive, the pMAC entity is disabled and only express traffic is transmitted or received. Frame preemption feature can be enabled by setting EFPE field of the MAC_FPE_CTRL_STS register.

43.4.6.8.2.1 GCL Modification to Support FPE

In the EST-only configuration, the GCL entry has up to 24 bits of Time Interval and up to 8 high order bits representing the Gate Open/Close state requirements as shown in the following figure.

Gate Control (up to 5 bits)	Time Interval(ns) 16, 20 , or 24 bits
OOCCC	T0
OOOOC	T1
CCCCO	T2
CCCCC	T3
|	|
|	|
OCOCO	T126
OOOOC	T127

Figure 190. Gate Control List When FPE is Disabled

EST only supports SetGate operation, which implies that the gates are set to either open or close at a given time interval. However, when both Frame Preemption (FPE) and EST are enabled, the GCL also supports Set-and-Hold-MAC and Set-and-Release-MAC operations, in addition to the SetGate operation. To enable the support of hold and release operations, the format of the GCL is slightly changed while configuring and enabling the FPE. The first Queue (Q0) is always programmed to carry preemption traffic and therefore it is always Open. The bit corresponding to Q0 is renamed as Release/Hold MAC control. The TX Queues whose packets are preemptable are indicated by setting the PEC field of the MTL_FPE_CTRL_STS register. The GCL bit of the corresponding Queue are ignored and considered as always "Open". So, even if the software writes a "0" ("C"), it is ignored for such queues.

Gate Control (up to 4 bits)	Release/Hold Indication	Time Interval(ns) 16, 20, or 24 bits
CCCO	0	T0
CCCC	0	T1
OCCC	1	T2
COCC	1	T3
CCOC	1	T4
CCCO	0	T5
CCCC	0	T6

Figure 191. Gate Control List When FPE is Enabled

When the Release/Hold bit transitions from a '0' to '1', a Set-and-Hold-MAC operation is performed. This marks the cease of the preemptable traffic. This is achieved by sending a Hold request to MTL "ha" ns in advance (where ha is the time interval mentioned in the Hold Advance (HADV) field of the MTL_FPE_Advance register). When the Release/Hold bit transitions from a '1' to '0' a Set-and-Release-MAC operation is performed. This marks the resuming of the preemptable traffic. This is achieved by sending a Release request to MTL "ra" ns in advance (where ra is the time interval mentioned in the Release Advance (RADV) field of the MTL_FPE_Advance register). The preemptable traffic is blocked for the time duration the Release/Hold bit is set to a '1' in the Gate Control List.

43.4.6.8.2.2 Impact of Preemption on CBS

In Credit Based Shaper (CBS), the definition of "Transmit" is:

- TRUE for the duration of frame transmission from the queue.
- FALSE when frame transmission from the queue is complete.
- When CBS algorithm is used with frame preemption, the value of "Transmit" is TRUE only while the frame is being transmitted by the MAC. If the frame transmission is delayed or interrupted (for instance, a preemptable frame transmission is interrupted to allow the transmission of an express frame from a different queue, or the start of an express frame is delayed because a preemptable frame is being transmitted) the value of "Transmit" is FALSE until transmission of the frame commences or is resumed.

Also, the value of "Transmit" is FALSE during the transmission of any overhead that is a consequence of frame preemption, (for example, when additional frame overhead, such as mCRC or Fragment Count, is added to the preemptable frame.

At any given time, if there are no frames in the queue, and the value of Transmit is FALSE, and credit is positive value, the credit value is set to zero if there is no preemptable frame from the queue for which transmission is in progress but has been interrupted.

43.4.6.8.2.3 mPacket Format

When the preemption capability is active, MAC sends mPackets to the PHY. An mPacket can be one of the following:

1. A express packet
2. A preemptable packet
3. An initial fragment of a preemptable packet
4. A continuation fragment of a preemptable packet

Start mPacket Delimiter (SMD)

The value of the SMD indicates whether the mPacket contains an express packet, the start of a preemptable packet (initial fragment or complete packet), or any of continuation fragments of a preemptable packet. Following table shows the valid SMD values.

Table 384. Possible SMD Values of mPacket

mPacket Type	Notation	Frame Count	Value
verify packet	SMD-V	-	0x07
respond packet	SMD-R	-	0x19
express packet	SMD-E	-	0xD5
preemptable packet start	SMD-S0	0	0xE6
	SMD-S1	1	0x4C

Table continues on the next page...

Table 384. Possible SMD Values of mPacket (continued)

mPacket Type	Notation	Frame Count	Value
	SMD-S2	2	0x7F
	SMD-S3	3	0xB3
continuation fragment	SMD-C0	0	0x61
	SMD-C1	1	0x52
	SMD-C2	2	0x9E
	SMD-C3	3	0x2A

frag_count

A frag_count is a modulo-4 counter that increments for each continuation fragment of the preemptable packet. The frag_count protects against mPacket reassembly errors by enabling detection of the loss of up to 3 packet fragments.

The frag_count field is present only in mPackets with SMD-C notation (continuation fragment). The frag_count is zero in the first continuation fragment of each preemptable packet.

Table 385. Possible frag_count Values

frag_count	Value
0	0xE6
1	0x4C
2	0x7F
3	0xB3

mData

The contents of the packet from the MAC, starting with the first byte after the SFD to the last byte before the FCS are sent in the mData fields of one or more mPackets for that frame. The minimum size of the mData field is 60 bytes.

CRC The CRC field contains a cyclic redundancy check (CRC) and has an indication of the final mPacket of a frame. In the final mPacket of a frame, the CRC field contains the last 4 octets of the MAC frame (the FCS field).

For other mPackets, the CRC field contains an mCRC value. The mCRC is calculated on the octets of the packet from the first octet of the frame (the octet following the SFD of preemption frames) to the last octet of the packet transmitted in that mPacket by performing an XOR of the calculated 32 bit CRC value of the fragment and a value of 0x0000FFFF.

Summary of Packet Formats

- Express Packet: 7bytes of PREAMBLE, SMD-E, Data, and CRC
- Complete Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, CRC
- Initial Fragment (non-final) of Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, mCRC
- Continuation fragments (non-final) of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, mCRC

- Final fragment of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, CRC

43.4.6.8.2.4 Transmit Preemption

When FPE is enabled (setting EFPE=1 in MAC_FPE_CTRL_STS register), the MTL preempts a preemptable frame, when a "hold" request is asserted (EST/Qbv configured and enabled) express frames are available for transmission, that is, frame is present in MTL FIFO and is qualified for arbitration, after ensuring that the minimum mPacket mData field size is met. Therefore, preemption occurs only if at least 60 bytes of the preemptable frame have been transmitted and at least 64 bytes (including the frame CRC) remain to be transmitted.

The earliest starting position of preemption is controlled by the AFSZ field of the MTL_ FPE_CTRL_STS Register. Preemption does not occur until at least 64 * (1+ AFSZ) - 4 bytes of the preemptable frame have been sent.

When preemption occurs, all the preemptable queues are blocked and only the express queues are allowed to arbitrate (if more than one express queue has traffic) and transmit.

Continuation fragment of the preempted frame is the first frame to be transmitted after "release" request is asserted (EST/Qbv configured and enabled) and all the express traffic transmission completes.

NOTE

PTP packets should be transmitted as express packets.

MTL communicates the following frame-type information to the MAC using a 2-bit preemption control signal on the MTI interface qualified by SoF and EoF.

- Express Frame
- Preemption Frame (Full or Fragment)
- Continuation Fragment (non-Final or Final)

Table 388. Preemption Control Values on MTI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

MTL should wait for the previous fragment status to be received before resuming the continuation fragments of a preempted frame. Fragment status is described in detail in the Tx Fragment Status section.

43.4.6.8.2.4.1 MAC Tx Preemption

MAC supports preemption by implementing the functionality needed to generate the mPackets as described in “mPacket Format”.

Based on the Preemption Control value received on the MTI interface (qualified with SoF and EoF), MAC determines the frame type (shown in the above table 'Preemption Control Values on MTI Interface for Various Frame Types') and generates mPackets accordingly.

When the preemption capability is active, MAC replaces the SFD of a preemption packet with an SMD-S value. A 2-bit rolling frame count is encoded in the SMD-S value.

The SMD-E value is the same as the SFD value so the SFD of an express packet does not need to be replaced.

43.4.6.8.2.4.1.1 Tx Fragment Status

MAC sends Tx fragment status to indicate successful transmission of fragmented mPackets.

In case of a transmission error (underflow, jabber, and so on) the frame status is sent (and not a fragment status) with an error indication along with all other relevant status fields. In case of receiving an error status for a transmitted fragment, the MTL drops the remaining fragments and does not send any more continuation fragments.

43.4.6.8.2.5 Receive Preemption

43.4.6.8.2.5.1 MAC Receive Preemption

When FPE is enabled, the MAC Receiver pases the incoming packets and differentiates between Express packets and preemptable packets. An SMD containing an SMD-E indicates express packet, and SMD containing an SMD-S indicates the first mPacket of a preemptable packet.

If an mPacket containing an SMD-S is received when MAC has not completed receiving the previous preempted packet, MAC sets a CRC Error status for the previously received partial packet.

When an SMD-S is detected, MAC records the frame count indicated by the SMD and then begins sending data on the MRI interface.

The MAC checks the last four bytes of the mPacket . If the last four bytes of the mPacket do not match CRC, that indicates the end of the packet with or without a CRC error as per the CRC check result. If the last four octets of the mPacket match, that indicates that the packet was preempted.

An SMD containing an SMD-C indicates an mPacket that continues the data for a preempted packet. Upon receiving an SMD value of SMD-C, MAC checks the following:

1. A preempted packet is in progress
2. The frame count indicated by the SMD matches the frame count of the packet in progress
3. The frag_count value indicates the next fragment count.

If any of the above check fails, the mPacket is discarded and MAC sets a CRC Error status for the partially received packet.

If all the checks pass, the next fragment count is incremented modulo 4.

When a packet is preempted, the MAC saves the state of the partially received packet (filter check status, timestamp, length fields etc.) and will be able to process any received Express packets before the continuation fragment is received.

The MAC Receiver sends a "dummy status" for all the mPacket fragments successfully received and sends the Rx status with the final fragment. If an error is detected during any of the fragments the Rx status is sent and the fragment is marked as final fragment. All subsequent continuation fragments received for this packet are dropped in the MAC.

The MAC communicates the following frame type information to the MTL using a 2-bit preemption control signal.

1. Express Frame
2. Preemption Frame (Full or Fragment)
3. Continuation Fragment (non-Final or Final)

Table 389. Preemption Control Values on MRI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

43.4.6.8.2.5.1.1 Data Alignment

When a received frame cannot be fragmented on any byte boundary, MAC retains the unaligned bytes of data in the previous fragment and resends them with the next fragment as shown in the following figure.

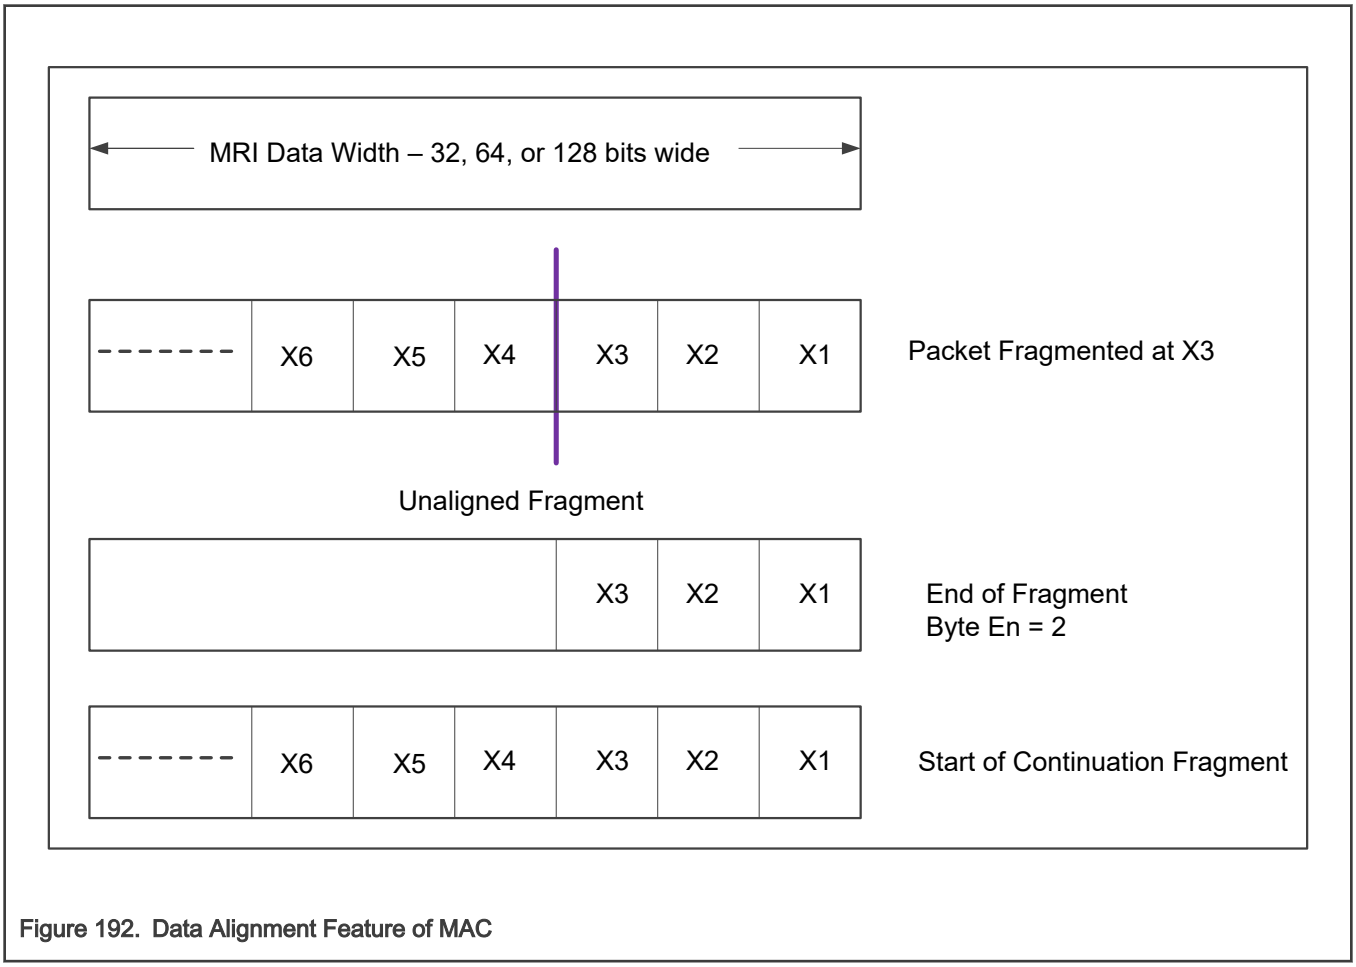

Figure 192. Data Alignment Feature of MAC

43.4.6.8.2.5.1.2 MTL Receive Preemption

The MTL Rx must have at least 2 Rx queues to support FPE function as the preemptable packets and the express packets must be routed to separate Rx queues. The destination Rx queue of a received packet is controlled by MAC_RxQ_Ctrl[n] registers.

Program these registers such that Preemptable traffic and express traffic are not routed to the same Rx queue. As the queue mapping for tagged packets is based on VLAN user-priority field, this implies that priority of preemptable and express packets are mutually exclusive. In other words, packets of a certain priority (traffic class) are either express or preemptable but cannot be both.

For the preemptable frames, in addition to the PSRQ (Priority Selected in Rx queue) based queue routing, a programmable "Frame Preemption Residue Queue" (FPRQ) is supported to route all other Preemption Packets received (Untagged, SA/ DA or VLAN Filter Fails forwarded due to RA being set or VTFE being reset).

Table 390. Preemption Control Values on MRI Interface for Various Frame Types

Preemption Packet Type	Queue Routing
AV Tagged Packets passing the SA/DA and VLAN filters	PSRQ*
DCB/Generic Tagged Packets passing the SA/DA and VLAN filters	PSRQ**
Tagged Packets failing the SA/DA and VLAN filters without setting the Receive All (RA = 0) or setting VTFE = 1	Dropped
All other packets OR when RA = 1	FPRQ

43.4.6.8.2.5.1.3 MTL Receive Arbitration

On the ARI Interface, data is fetched from the MTL Rx FIFO based on the arbitration selected in the MTL_Operation_Mode register. Frame based arbitration can be used only when all the MTL Preemption Queues are operating in Store and Forward mode, else there will be loss of bandwidth on the ARI interface because all the fragments of a preemptable packet is not available. Therefore, any express packets received between the fragments are blocked until all the fragments are received and transferred; this defeats the purpose of express traffic.

When operating in either Threshold (cut through) or Store and forward modes of operation, PBL based arbitration is recommended over Frame based arbitration. In case of PBL based arbitration, the watermark check is always performed and the arbitration/ transfer of data in terms of chunks of "PBL" size of data which is almost similar to the concepts of "fragments". Therefore the express queue packets get blocked for less time as well as the ARI interface transfers the data without loss of efficiency.

43.4.6.8.2.6 Verify and Respond mPackets

When FPE function is present, the MAC can receive and detect the Verify and Respond mPackets, even when FPE is not enabled by software. When MAC detects valid Verify/Respond mPackets, it notifies the software by setting the RVER and RRSP fields of MAC_FPE_CTRL_STS register respectively. Optionally an interrupt can be generated. As such packets have empty (all-zero) data payload, they are dropped inside the MAC and not forwarded to the MRI.

Software can set the SVER and SRSP fields of MAC_FPE_CTRL_STS register to request MAC to transmit Verify and Respond mPackets respectively. Upon successful transmission of these frames, MAC clears the SVER/SRSP bits and sets the TVER & TRSP fields of MAC_FPE_CTRL_STS register. Optionally an interrupt can be generated when these events occur.

43.4.6.8.2.7 Frame Preemption and MMC Counter and Interrupt Registers

The following MMC counters and associated Interrupt registers are instantiated/present in the MAC when Frame Preemption feature is enabled.

Table 391. MMC Counters and Associated Interrupt Registers

Frame Assembly Error Counter	Description	Associated MMC Counter
Frame Assembly Error Counter	A 32-bit counter that provides the number of MAC frames with reassembly errors on the Receiver, due to mismatch in the Fragment Count value.	MMC_Rx_Packet_Assembly_Err_Cntr
Frame SMD Error Counter	A 32-bit counter that provides the number of received MAC frames rejected due to arriving with an SMD-C when there was no preceding preempted frame.	MMC_Rx_Packet_SMD_Err_Cntr
Frame Assembly OK Counter	A 32-bit counter that provides the number of MAC frames that were successfully reassembled.	MMC_Rx_Packet_Assembly_Ok_Cntr
MAC Rx Fragment Counter	A 32-bit counter that provides the number of additional mPackets received due to preemption.	MMC_Rx_FPE_Fragment_Cntr
MAC Tx Fragment Counter	A 32-bit counter that provides the number of additional mPackets transmitted due to preemption.	MMC_Tx_FPE_Fragment_Cntr
Hold Request Counter	A 32-bit counter that maintains the count of number of times a hold request is given to MAC.	MMC_Tx_Hold_Req_Cntr

43.4.6.8.2.7.1 Additional Registers Associated With MMC Interrupts

Following are the additional registers associated with MMC interrupts for the MMC error counters:

- MMC_FPE_Tx_Interrupt
- MMC_FPE_Tx_Interrupt_Mask
- MMC_Rx_Interrupt
- MMC_FPE_Rx_Interrupt_Mask

43.4.6.8.3 Time-Based Scheduling

Time-based scheduling feature is suitable for traffic whose periodicity and rate are predictable. To improve the quality-of-service of such traffic,

- The transmit DMA fetches the packet from the host memory for transmission at designated time. This helps the software to setup the Transmit descriptors in advance even before packet is ready/available. It reduces the overhead on the software and avoids constant monitoring of the time and preparing descriptors just in time when the packet is targeted to be transmitted.
- The MAC transmits the packet only at the designated/pre-determined time even if the packets are fetched in advance. This helps in maintaining a constant transmission rate that can be consumed by the receiver station; therefore avoiding congestion and excessive buffering in the network.

The time-based scheduling feature supports fetching and launching an Ethernet packet at (or after) a pre-determined time. The time-based scheduling is supported only in the following modes/configurations:

- Full duplex mode
- Link speed is 100Mbps or higher

The following figure shows the time-based scheduling flow.

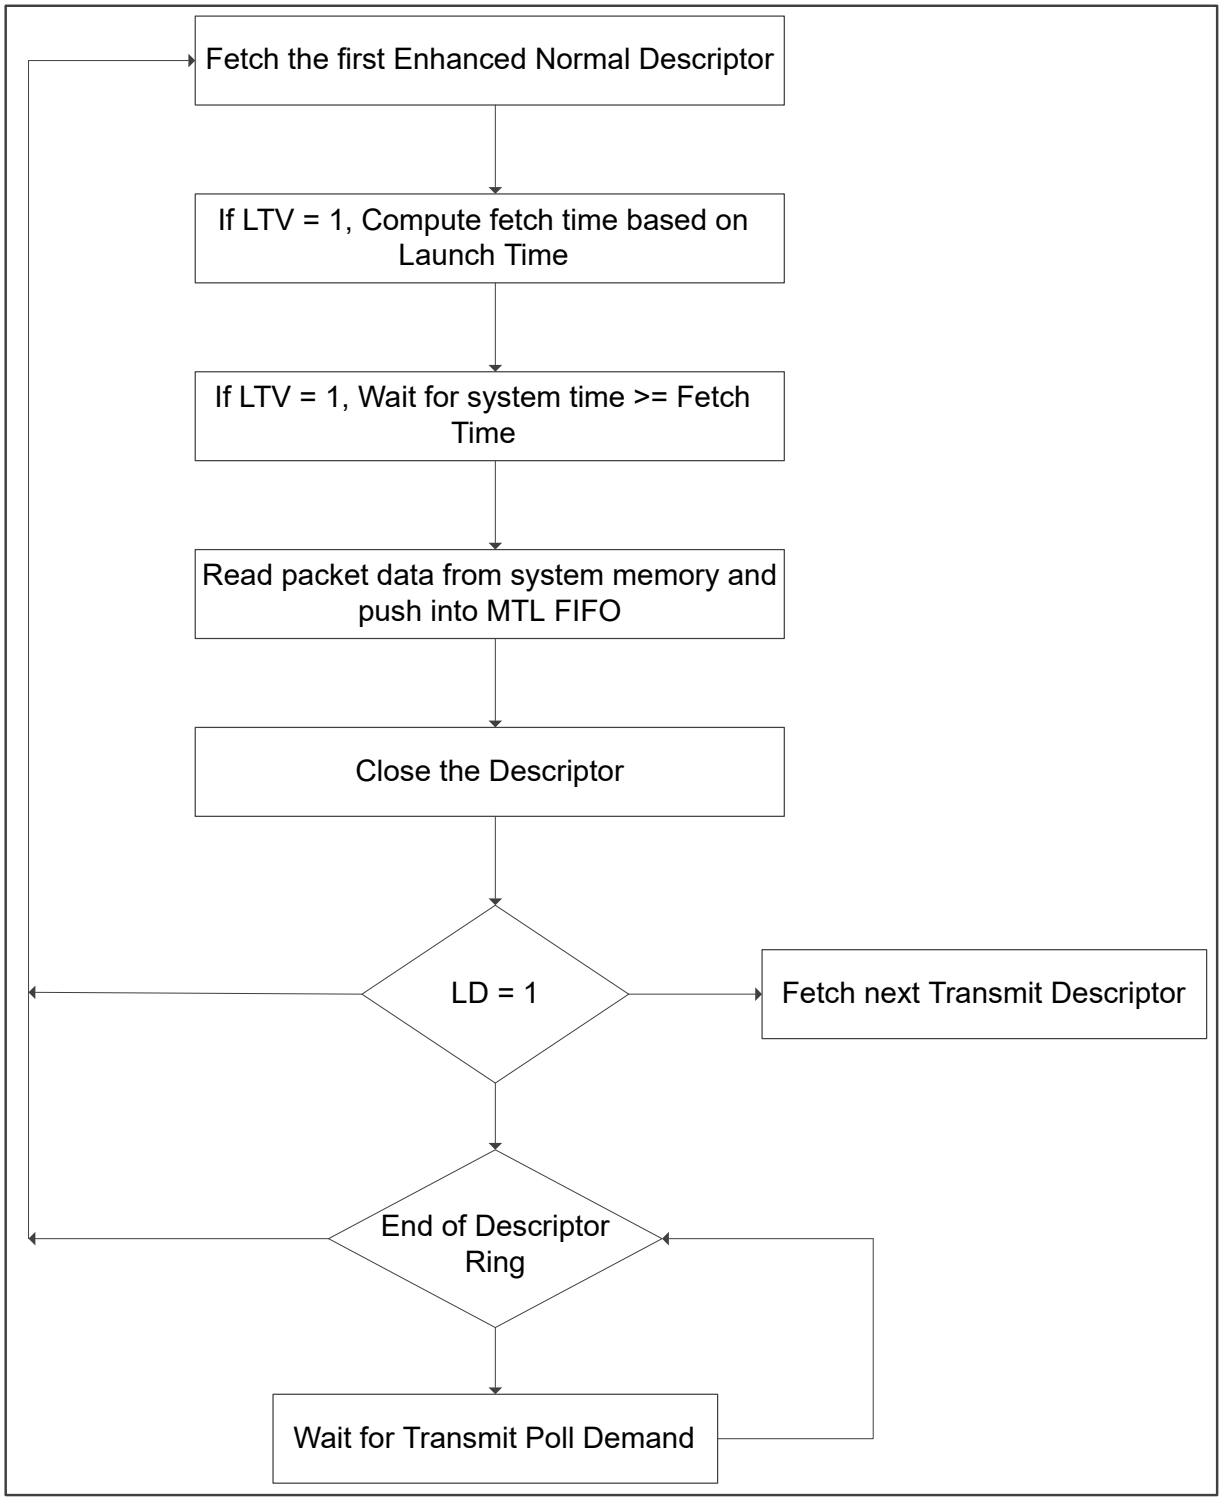

Figure 193. Time-Based Scheduling Flow

Following are the definitions specific to the time-based scheduling feature:

43.4.6.8.3.1 Launch Time

Launch time is the time beyond which the MTL can schedule the packet for transmission. The launch time is reset after the transmission of one frame. Following are the two formats of the launch time.

Normal/Absolute Format:

In this format, the launch time is interpreted in the Normal/Absolute format if the ESTM bit of the MTL_TBS_CTRL register is set to 0.

The launch time is a 32-bit value, where most-significant 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns. The launch time is compared against the IEEE 1588 based System/PTP Time (bits[39:8]) and rolls over after 256 seconds.

The maximum value of the lower 32-bits of System Time is 999,999,999 decimal (0x3B9AC9FF) and it wraps to 0 when reaching this value (representing a full second). Therefore, the maximum value of the lower 24 bits of the Launch Time (after multiplying by 256) must be 0x3B9AC9.

As the maximum value of Launch time is 256 seconds,

- Launch Time is greater than current System Time when its value is between System Time[39:8] and System Time[39:8] + 128 sec
- Launch Time is less than current System Time when its value is between "System Time[39:8] + 128sec" and "System Time[39:8] + 256 sec", because this is a modulo 256 computation.

EST/Offset Format

In this format, the Launch time is an offset value relative to the time indicated by the Base Time Register (BTR) of the GCL list provided in the GCL Slot Number (GSN). The value in the BTR is always updated to the start time of the current loop of the GCL.

For each packet, the GSN value and the Launch Time value are specified in the Enhanced Transmit Descriptor in the DMA configurations, or as Control Word in the MTL configurations.

The launch time offset is a 32-bit value; the upper 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns, which is added to the BTR value corresponding to GCL Slot Number. The value of the Launch Time Offset must be smaller than the value of the Cycle Time (specified in the CTR register that is implemented when EST is enabled). If the CTR is greater than or equal to 1s, the maximum value of the lower-24 bits of Launch Time offset should be 999,999,999 decimal (0x3B9AC9FF).

In this format, the launch time is a 64-bit value, which is interpreted as, Launch Time = Launch GSN BTR[63:0] + (Launch Time Offset[31:0] << 8), which is compared with the System Time [63:0].

GSN BTR is the Base Time value at which the Launch GSN loop started execution.

GCL Slot Number (GSN) A modulo 16 count of the GCL loop count is implemented and known as GSN. The count is incremented for every new GCL loop; installation of new GCL list does not impact the count. The current GCL slot number can be obtained by reading the CGSN field of the MTL_EST_Status register.

The maximum value of GSN is 15. Therefore GSN values between Current GSN (CGSN field of MTL_EST_Status register) and CGSN+8 represent current or future slots; all other GSN values are interpreted as elapsed slots or past slots. So, for the correct interpretation of time, GSN value must be between CGSN and CGSN+8, for correct interpretation of time.

43.4.6.8.3.2 Launch Expiry Time

Normal/Absolute Mode

In the normal mode, when the LEOV (Launch Expiry Offset Valid bit of MTL_TBS_CTRL register) is set, the Launch Expiry Offset (LEOS field of MTL_TBS_CTRL register) determines the maximum amount of time a frame is eligible for launch, starting from the time the frame becomes eligible for launch.

The Launch Expiry Offset is a 24-bit value defined in 256ns units, with a maximum possible value of 999,999,999 ns (0x3B9AC9FF).

Launch Expiry Time = (Launch Time[39:8] + LEOS[32:8]) * 256ns

The packet with a specific Launch time is considered eligible for transmission when the Launch time is less than the System Time and (if LEOV is set) the System Time is less than the Launch Expiry time.

When the System time is greater than the Launch Expiry time the frame is categorized as expired and will be dropped from the MTL FIFO.

NOTE

- For correct interpretation and meaningful operation, the Fetch, Launch, and Launch Expiry time should never be set to a value larger than Current System Time + 128 sec; such a value is interpreted as time that has already elapsed.
- In full duplex mode, the frames dropped from the MTL FIFO have Error Summary (Bit 15) and Excessive Deferral (bit 3) of TxStatus set.

EST/Offset Mode

In the EST mode of operation, when the LEOV field of the MTL_TBS_CTRL register is set, the launch expiry GSN offset (LEGOS field of the MTL_TBS_CTRL register) and Launch Expiry Offset (LEOS field of MTL_TBS_CTRL register) determine the maximum amount of time a frame remains eligible for launch, starting from the time the frame becomes eligible for launch.

Launch Expiry Offset = (LEGOS: LEOS)

LEGOS holds the GSN offset (multiples of CTR time) and LEOS holds maximum value of CTR (sub CTR values) in ns.

Launch Expiry offset is a 24-bit value defined in the units of 256 ns, with a maximum possible value of the smaller of 999,999,999ns or CTR-1 ns.

The Launch Expiry GSN is computed as follows:

Launch Expiry GSN = (Launch GSN + LEGOS + CCMA) Where, CCMA is the CTR Carry due to Modulo addition. This value is 1 if ((Launch Time Offset + LEOS) << 8) is equal to or greater than CTR.

When CCMA = 1, Launch Expiry Offset = (Launch Time Offset+ LEOS) - CTR

When CCMA = 0,

Launch Expiry Offset = (Launch Time Offset + LEOS).

Launch Expiry Time = Launch Expiry GSN BTR[63:0] + Launch Expiry Time Offset.

When LEOV is not set, Launch Expiry Time is not checked.

When LEOV is set, and

- the system time is greater than the Launch Expiry time, the frame is dropped from MTL FIFO. The frame is considered as expired.
- the launch time is smaller than the System Time and Launch Expiry Time is greater than system time, the frame is considered eligible for launch.

NOTE

- Max value of LEGOS is 7. This implies that when LEOV is set, the frame has a maximum life time of <8 GCL loop iterations after it becomes eligible for Launch.
- The slot number of the First GCL List executed each time after EST is enabled, is zero.

43.4.6.8.3.3 Fetch Time

The fetch time accounts for all possible delays in the DMA fetch operation and ensures that the frame is present in the MTL FIFO before the launch time.

If FTOV field of DMA_TBS_CTRL register is set, then fetch time can be indicated for each packet. If the FTOV filed is not set, the Fetch Time Offset is not valid and the DMA fetches packets without any time constraints.

Normal/Absolute Mode

In the Normal mode fetch time derived/calculated by reducing the time specified in the Fetch Time Offset (FTOS) field of DMA_TBS_CTRL register from the given Launch time.

Normal mode of operation, the Fetch Launch Time is computed as:

Fetch Time[39:8] = (Launch Time[39:8] - FTOS[31:8])

The Fetch time is 32-bits and is compared against System Time[39:8] to determine the Eligible for fetching the frame:

- The Fetch time is defined as "greater" than System Time if the Fetch Time is in the range of "System Time[39:8]" and "System Time[39:8] + 128 sec". The frame is considered as not-eligible for fetch.
- The Fetch time is defined as "smaller" than the System Time if the Fetch time is in the range of "System Time[39:8] + 128 sec" and "System Time[39:8] + 256 sec". The frame is considered as eligible for fetch.

This is a modulo 256 computation.

EST/Offset Mode

In the EST/Offset mode, the Fetch GSN Offset (FGOS field of MTL_TBS_CTRL register) provides the Slot Number offset to be deducted from the Launch GSN. In this case the FTOS value should be the smaller of 999,999,999ns or CTR-1 ns.

If (Launch Time Offset >= FTOS):

Fetch Time Offset = ((Launch Time Offset - FTOS) * 256ns)

CBFS(CTR Borrow for Fetch Subtraction) = 0

If (Launch Time Offset < FTOS) Fetch Time Offset = CTR + ((Launch Time Offset - FTOS) * 256ns)

CBFS (CTR Borrow for Fetch Subtraction) = 1

The Fetch GSN is computed as follows:

Fetch GSN = Launch GSN - FGOS - CBFS

Fetch Time = Fetch GSN BTR[63:0] + Fetch Time Offset

The frame is marked eligible for DMA fetch when the fetch time is smaller than the System Time.

DMA Operations Sequence

Following is the sequence of operation when FTOV = 1:

1. Fetch the first Enhanced Normal Descriptor (FD is set)
2. If LTV is set and Fetch enabled, compute the Fetch Time based on the Launch Time Wait for the System Time to be greater than Fetch Time
3. Read the Frame (Data) from the host memory and transfer to MTL FIFO
4. Close the Normal Descriptor
5. Fetch the next Normal Descriptor (if the previous Descriptor was not the Last)
6. Repeat steps 4 to 6, until the last descriptor of the frame (LD is set)

After the Last Descriptor of a frame, the next enhanced normal descriptor should be programmed with a new Launch Time and with LTV bit set. Otherwise, the subsequent frames will be processed without any time restrictions.

NOTE

See Programming the Launch Time in Time-Based Scheduling

43.4.6.8.4 Credit-Based Shaper Algorithm

The MTL Queue Scheduler (shown in Figure 173) uses the credit-based shaper algorithm to arbitrate the AV traffic in all queues and the legacy Ethernet traffic in Queue 0. You can program the additional queues to use the credit-based shaper algorithm.

The following sections provide information about how you can implement the credit-based shaper algorithm:

- Credit Value
- idleSlopeCredit and sendSlopeCredit Values
- Bandwidth Status

43.4.6.8.4.1 Credit Value

The credit value is part of the credit-based sharper algorithm used by the MTL Queue Scheduler.

The credit value is accumulated every transmit clock cycle, that is, 40 ns for 100 Mbps and 8 ns for 1000 Mbps. The credit to be added or subtracted per cycle can be fractional based on the required idleSlope and sendSlope values, as described in the table below.

Table 392. Credit Value Per Transmit Cycle Example

Mode	Values	Description
100 Mbps	• portTransmitRate = 100 Mbps • idleSlope = 70 Mbps (assuming 70% bandwidth reserved for a higher priority traffic class) • sendSlope = 30 Mbps	• credit = 2.8 bits accumulates per cycle (40 ns) for the higher priority traffic class when best-effort packet is being transmitted. • credit = 1.2 bits drains per cycle (40 ns) when higher priority traffic class packet is being transmitted.

The DMA stores the queue traffic in the respective part of the Tx FIFO based on the slot number in the transmit descriptor (if enabled) or the bandwidth availability on the AMBA AHB application bus.

The credit for a queue builds up only when the packet is available but it cannot be transmitted because the MAC is sending a packet from another queue. The module supports another mode in which the credit can build up in advance for a queue in which no packet is available in respective part of the FIFO. This enables sending a burst of high priority traffic in a queue as soon as the data is available. You can enable this mode with Bit 3 of the CBS Control registers of corresponding queues.

When reset, the accumulated credit parameter in the credit-based shaper algorithm is set to zero if there is positive credit, and there is no packet to transmit in a queue. The credit does not accumulate when there is no packet waiting in a queue and other queues are transmitting. When set, the accumulated credit parameter in the credit-based shaper algorithm is not reset to zero if there is positive credit and no packet to transmit in a queue. The credit accumulates even when there is no packet waiting in a queue and other queues are transmitting.

43.4.6.8.4.2 idleSlopeCredit and sendSlopeCredit Values

The idleSlopeCredit and sendSlopeCredit values are programmable.

The software must program the idleSlopeCredit and sendSlopeCredit values. The programmed values should be the credit accumulated or drained per clock cycle scaled by 1024, such as, 2.8 x 1024 = 2867 and 1.2 x 1024 = 1229. In addition, the software must program the hiCredit and loCredit values, scaled by 1024, to adjust for scaling of the idleSlopeCredit and sendSlopeCredit values. This means that if computed hiCredit and loCredit values are 12,000 bits and 3,036 bits respectively, the values to be programmed in the hiCredit and loCredit registers of the corresponding channel are 12000 x 1024 bits and two's complement of 3036 x 1024, respectively.

43.4.6.8.4.3 Bandwidth Status

The hardware maintains the status of the actual bandwidth consumed by each higher priority queue in the CBS status registers. This enables the software to estimate the average bandwidth consumed by numerically higher traffic classes as compared to the reserved bandwidth.

The CBS status register gives the average number of bits transmitted during the previous programmed slot interval (1, 2, 4, 8, or 16 slots of 125 µs) in a queue. The status register is updated even if the credit-based shaper algorithm is not enabled for a queue. The number of slots over which the average bits transmitted per slot are computed is programmed in Bits[6:4] of the CBS control register of the respective queue. For example, if you have programmed two slots, the average bits are computed over slot numbers 0–1, 2–3, 4–5, and so on.

The value programmed in the idleSlopeCredit register of a queue is proportional to the bandwidth reserved for the queue. The software can allocate any bandwidth that is not used by the higher priority queue to the reserved bandwidth of the lower priority queue.

A lower priority queue, which is using the credit-based shaper algorithm, cannot use the unused reserved bandwidth of any higher priority queue that is using the credit-based shaper algorithm. However, a lower priority queue, which is using the strict-priority algorithm, can use the unused reserved bandwidth of any higher priority queue that uses the credit-based shaper algorithm. For example, Queue 1 and Queue 2 use the credit-based shaper algorithm (with reserved bandwidth of 50% and 25%, respectively) and Queue 0 uses the strict-priority algorithm. If Queue 1 uses only 40% of reserved bandwidth, the remaining 10% is used by Queue 0. Queue 2 cannot exceed the reserved bandwidth of 25%.

43.4.6.9 Queue Modes

Both Tx and Rx queues can handle AV traffic.

Queueing is based on WRR (Weighted Round Robin) or WSP (Weighted Strict Priority) algorithm for generic traffic while it is based on CBS (Credit Base Shaper) and SP (Strict Priority) algorithm for AV traffic.

Whether an Rx Queue is configured for generic or AV-based routing depends on the RXQ#EN field of corresponding queue. Queueing is done based on VLAN tag priority. The VLAN tag priority should match the PSRQ field of the MAC_RXQ_CTRL2 registers. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register.

By default, untagged packets in generic traffic are routed to Receive queue specified in UPQ field of MAC_RXQ_CTRL1 register. Queue 0 is the default value of UPQ field. You can override the default value with any other value, for the UPQ field.

AV control packets (tagged or untagged) are routed based on the AVCPQ field of the MAC_RXQ_CTRL1 register. The PTP over Ethernet packets are routed based on the AVPTPQ field of MAC_RXQ_CTRL1 register.

43.4.6.10 Queue Priorities

Priority of an Rx queue can be programmed in corresponding field of MAC_RxQ_Ctrl2 registers. AV queue (high priority) should be programmed as higher priority than the Best-effort queue (low priority).

43.4.7 TCP/IP Offloading Features

43.4.7.1 Transmit Checksum Offload Engine

The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, using which, the software can offload the task of checksum insertion to the hardware. In the transmit path MAC calculates the checksum and inserts it in the Tx packet. This feature helps in reducing the load on the software and can improve the overall throughput of the system. This feature is supported for only Q0 queue.

The checksum offload engine module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 Bits[17:16]).

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if IP is configured for Threshold (cut-through) mode.

43.4.7.1.1 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

NOTE

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (TDES3[0]). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

43.4.7.1.2 TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

NOTE

For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16’h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (TDES3[12]). This engine sets the Payload Checksum Error status bit when:

- It detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO.
- when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received.

When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field. The following table describes the functions supported by

Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as "No" in the table.

NOTE

You should not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Description of Transmit Checksum Offload Engine because it may result in incorrect checksum insertion or unexpected behavior.

Table 393. Transmit Checksum Offload Engine Functions for Different Packet Types

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/ UDPchecksum insertion
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers:		
Hop-by-hop options (in IPv6 main header)	Not Applicable	Yes
Hop-by-hop options (in IPv6 extension header)	Not Applicable	No
Destinations options	Not Applicable	Yes
Routing (with segment left 0)	Not Applicable	No
Routing (with segment left > 0)	Not Applicable	No
TCP, UDP, or ICMP	Not Applicable	Yes
Authentication	Not Applicable	No
Any other next header field in main or extension headers	Not Applicable	No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels:	nbsp;	nbsp;

Table continues on the next page...

Table 393. Transmit Checksum Offload Engine Functions for Different Packet Types (continued)

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/ UDPchecksum insertion
IPv4 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 Tunnels:	nbsp;	nbsp;
IPv4 packet in an IPv6 tunnel	Not applicable	No
IPv6 packet in an IPv6 tunnel	Not applicable	No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

43.4.7.2 Receive Checksum Offload Engine

IP provides the Checksum Offload Engine that is used to detect any error in an IPv4 or IPv6 packet in the receive path. The MAC verifies the checksum field of the received packet with the internally calculated checksum and provides the status.

The Receive Checksum Offload engine is used to detect errors in IP packets by calculating the header checksum and further matching it with the received header checksum. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

Here, the IPv4 or IPv6 packets in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the Enable Double VLAN Processing option is selected and the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Following table describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

NOTE

The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 394. Receive Checksum Offload Engine Functions for Different Packet Types

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
Non-IPv4 or IPv6	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Any other next header field in main or extension headers	• Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable	• Yes • No • Yes • Yes • No • Yes • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels:	• Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	• No • No

Table continues on the next page...

Table 394. Receive Checksum Offload Engine Functions for Different Packet Types (continued)

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
• IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel		
IPv4 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	• Not Applicable • Not Applicable	• No • No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Not Applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not Applicable	No

Set the IPC bit of the MAC_Configuration register for enabling Receive Checksum offload.

43.4.8 MAC Management Counters

IP supports storing the statistics about the received and transmitted packets in registers that are accessible through the application/software. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The MMC counters are free running.

For MMC register details, see registers "MMC_Control" to "MMC_Rx_FPE_Fragment_Cntr" in ENET_QOS register descriptions.

43.4.9 Flow Control

43.4.9.1 Transmit Flow Control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

43.4.9.1.1 Flow control in Full duplex mode

IP supports the IEEE802.3x Pause Packets.

Pause packet structure is shown in the following table.

Table 395. Pause Packet Fields

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC Control opcode	Contains 0001 for IEEE 802.3x Pause Control packets; 0101 for PFC packets
PT	Contains Pause time specified in the PT field of the MAC_Q#_Tx_Flow_Ctrl register

43.4.9.1.2 Pause Packet Control

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

43.4.9.1.3 Flow Control in Half-Duplex Mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

Following table describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EHFC bit of MTL_RxQ0_Operation_Mode register
- TFE bit of MAC_Q0_Tx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Flow control is similar for all queues.

Table 396. Tx MAC Flow Control

EHFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx performs back-pressure when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.
0	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.

Table continues on the next page...

Table 396. Tx MAC Flow Control (continued)

EHFC	TFE	DM	Description
1	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx sends a Pause packet when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.

43.4.9.1.4 Enabling Transmit Flow Control

To independently enable Transmit Flow Control for each Tx queue, set the TFE bit in the MAC_Q#_Tx_Flow_Ctrl register.

43.4.9.2 Receive Flow Control

In the Receive path, the Flow Control is functional only in the full-duplex mode. If any Pause packet is received in the half-duplex mode, the packet is considered as a normal control packet.

NOTE

Receive pause packets should have a frame size of 64 bytes.

The Receive Flow Control is implemented by the MAC based on the bit value of the respective register, and the destination address and different fields of the received packet.

Following table describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of MAC_RX_FLOW_CTRL register
- DM bit of MAC_CONFIGURATION register

Table 397. Rx MAC Flow Control

RFE	DM	Description
0	x	The MAC receiver does not detect the received Pause packets.
1	0	The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets.
1	1	The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

43.4.9.2.1 Enabling Receive Flow Control

To enable Pause Flow Control, set the RFE bit in the MAC_Rx_Flow_Ctrl register.

43.4.10 Loopback Mode

The MAC supports Loopback of transmitted packets to its receiver.

The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result into issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip (for example, in FPGA setup), you should externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets. Big packets (>1522 bytes) may get corrupted in the loopback FIFO.

To enable this feature, program the LM bit of the MAC_Configuration register.

You can enable loopback for all PHY interfaces. The data is always looped back through internal asynchronous FIFO on to the internal Receive GMII interface, irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding transmit PHY interface block, on to the Ethernet line.

43.4.11 Descriptors

43.4.11.1 Overview

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The module supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

NOTE

There is no limit for the number of descriptors that can be used for a single packet.

43.4.11.2 Descriptor Structure

The module supports the ring structure for DMA descriptor as shown in the following figure.

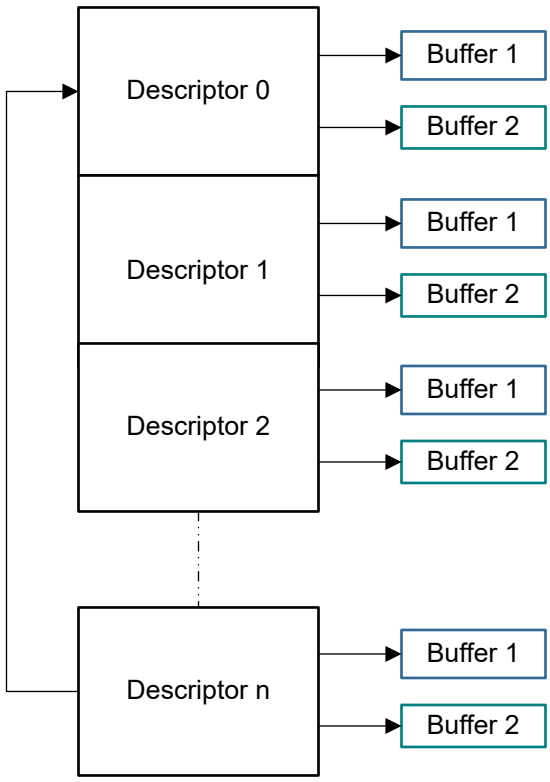

Figure 194. Descriptor Ring Structure

In Ring structure, descriptors are separated by the Word, DWord, or LWord number programmed in the DSL field of the DMA_CH#_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH#_TxDesc_Ring_Length)
- Channel n Receive Control 2 register (DMA_CH#_RX_CONTROL2)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

Current Descriptor Pointer == Descriptor Tail Pointer;

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

Current Descriptor Pointer < Descriptor Tail Pointer;

The DMA automatically wraps around the base address when the end of ring is reached, as shown in the following figure.

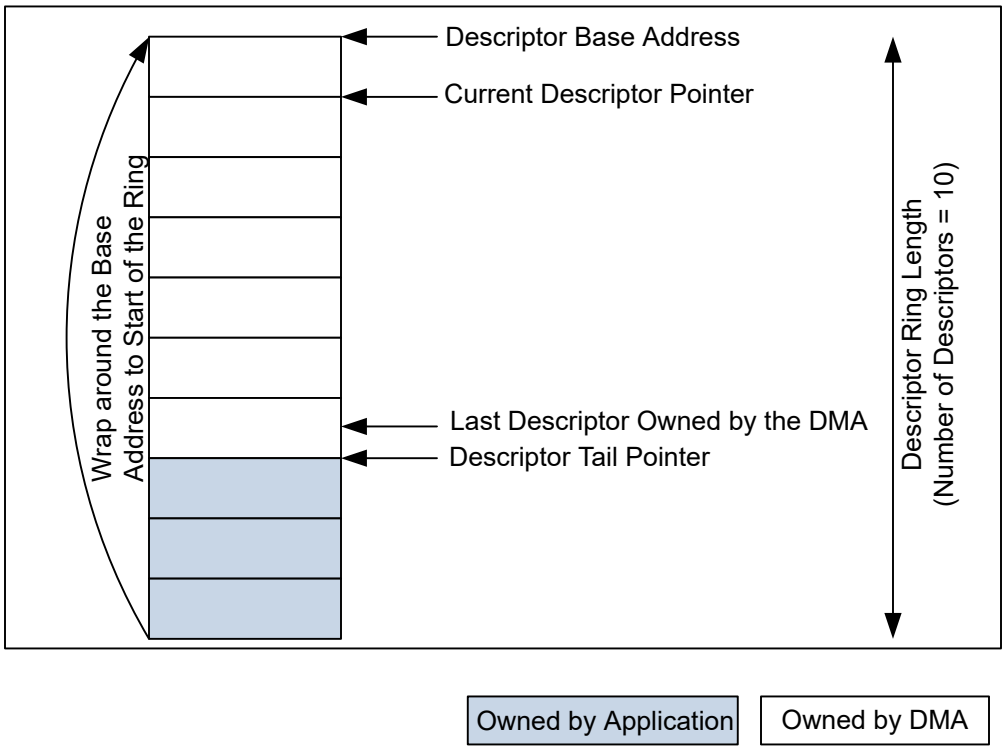

Figure 195. DMA Descriptor Ring

For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

43.4.11.3 Transmit Descriptor

The DMA in the module requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has two formats: Read format and Write-Back format

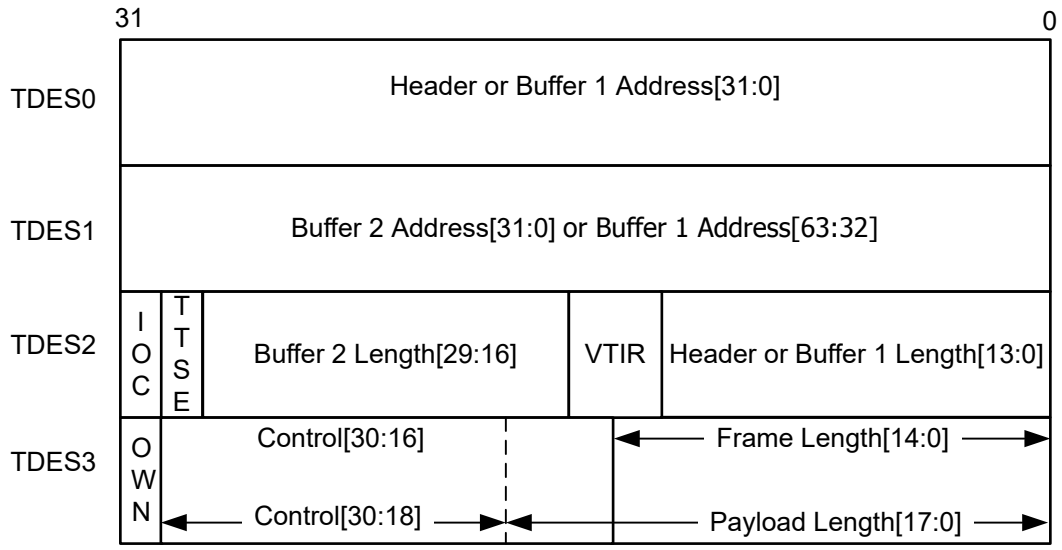
NOTE

TSO Split header is not supported.

43.4.11.3.1 Transmit Normal Descriptor (Read Format)

Following figure shows the Read Format for a Transmit normal descriptor. Table: 'TDES0 Normal Descriptor (Read Format)' through Table: 'TDES3 Normal Descriptor (Read Format)' describe the read format for the Transmit Normal Descriptors: TDES0, TDES1, TDES2, and TDES3.

Figure 196. Transmit Descriptor Read Format



43.4.11.3.1.1 TDES0 Normal Descriptor (Read Format)

Table 398. TDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Buffer 1 Address Pointer or TSO Header Address Pointer These bits indicate the physical address of Buffer 1. These bits indicate the TSO Header Address pointer when the following bits are set: • TSE bit of TDES3 • FD bit of TDES3

43.4.11.3.1.2 TDES1 Normal Descriptor (Read Format)

Table 399. TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 or Buffer 1 Address Pointer

Table continues on the next page...

Table 399. TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
		This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment. In 40- or 48-bit addressing mode, these bits indicate the most-significant 8- or 16- bits of the Buffer 1 Address Pointer.

43.4.11.3.1.3 TDES2 Normal Descriptor (Read Format)

Table 400. TDES2 Normal Descriptor (Read Format)

31	30	29-16	15:14	13:0
IOC	TTSE/ TMWD	B2L	VTIR	HL or B1L

Table 401. TDES2 Normal Descriptor (Read Format)

Bits	Name	Description
31	IOC	Interrupt on Completion This bit controls the setting of TI and ETI status bits in the DMA_CH#_Status register. When ETIC = 1 and TDES2[LD] = 0, this bit sets the ETI bit. When TDES3[LD] = 1, this bit sets the TI status bit.
30	TTSE/ TMWD	Transmit Timestamp Enable or External TSO Memory Write Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor, if TSE bit is not set. If TSE bit is set and external TSO memory is enabled, setting this bit disables external TSO memory writing for this packet.
29:16	B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.
15:14	VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits: • 2'b00: Do not add a VLAN tag. • 2'b01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. • 2'b10: Insert a VLAN tag with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. • 2'b11: Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets. These bits are valid when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core.

Table continues on the next page...

Table 401. TDES2 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
13:0	HL or B1L	Header Length or Buffer 1 Length For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length. If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length in bytes from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes. The maximum header length supported for TSO feature is 1023 bytes. If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length.

43.4.11.3.1.4 TDES3 Normal Descriptor (Read Format)

Table 402. TDES3 Normal Descriptor (Read Format)

31	30	29	28	27:26	25:23	22:19	18	17:16	15	14:0
OWN	CTXT	FD	LD	CPC	SAIC	SLOTNUM or THL	TSE	CIC/TPL	TPL	FL/TPL

Table 403. TDES3 Normal Descriptor (Read Format)

Bits	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
30	CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
29	FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
27:26	CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of Bits[27:26]: • 2'b00: CRC and Pad Insertion The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. • 2'b01: CRC Insertion (Disable Pad Insertion)

Table continues on the next page...

Table 403. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. • 2'b10: Disable CRC Insertion The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. • 2'b11: CRC Replacement The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. This field is valid only for the first descriptor. Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.
25:23	SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 or 1 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet. Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[24:23]: • 2'b00: Do not include the source address • 2'b01: Include the source address. For reliable transmission, the application must provide frames without source addresses. • 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses. • 2'b11: Reserved These bits are valid in the EQOS-DMA, EQOS-AXI, and EQOS-AHB configurations when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core and when the First Segment control bit (TDES3 [29]) is set. This field is valid only for the first descriptor.
22:19	SLOTNUM or THL	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH#_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels. THL: TCP/UDP Header Length

Table continues on the next page...

Table 403. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header. This field is valid only for the first descriptor.
18	TSE	TSO Split header is not supported. The value of this bit is always zero.
17:16	CIC/TPL	Checksum Insertion Control or TCP Payload Length These bits control the checksum calculation and insertion. The following list describes the bit encoding: • 2'b00: Checksum Insertion Disabled. • 2'b01: Only IP header checksum calculation and insertion are enabled. • 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. • 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is valid when the Enable Transmit TCP/IP Checksum Offload option is selected and the TSE bit is reset. When the TSE bit is set, this field contains the upper bits [17:16] of the TCP Payload (or IP Payload for UDP fragmentation). This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support. This field is valid only for the first descriptor.
15	TPL	Reserved or TCP Payload Length When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is Bit 15 of the TCP payload length [17:0]. This field is valid only when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected while configuring the core.
14:0	FL/TPL	Frame Length or TCP Payload Length This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length in case of segmentation and IP payload in case of UDP fragmentation. In case of segmentation, this length does not include Ethernet header or TCP/UDP/IP header length. In case of fragmentation, this length does not include Ethernet header and IP header. When DWRR/WFQ algorithm is NOT enabled, value written into this field is not used when TSE = 0.

43.4.11.3.2 Transmit Normal Descriptor (Write-Back Format)

The write-back format of the Transmit Descriptor includes timestamp low, timestamp high, OWN, and Status bits.

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[28]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet.

Following figure illustrates the write-back format of the Transmit Descriptor.

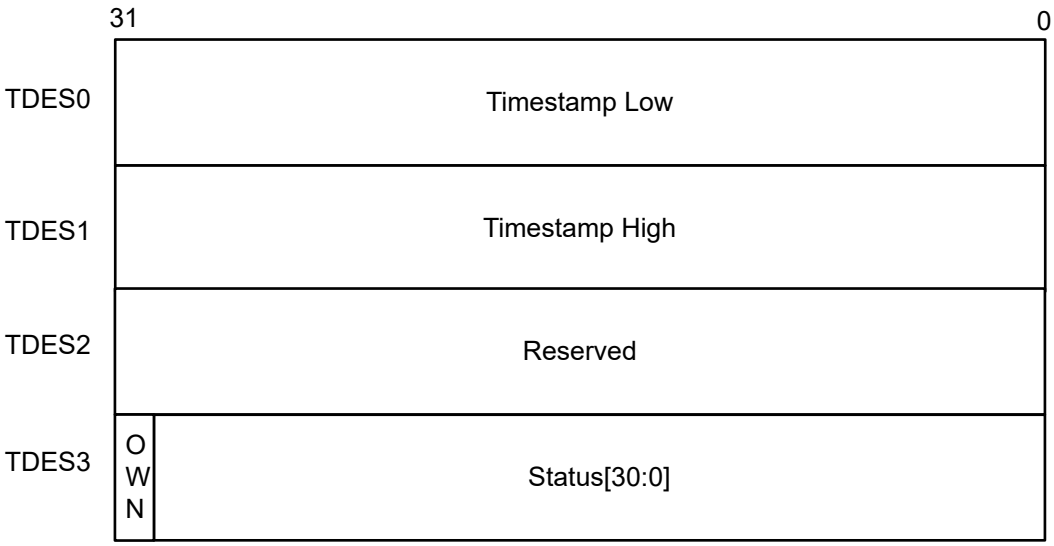


Figure 197. Transmit Descriptor Write-Back Format

TDES0 Normal Descriptor (Write-Back Format)

As described in following table, this format is only applicable to the last descriptor of a packet.

Table 404. TDES0 Normal Descriptor (Write-Back Format)TDES0 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding Transmit packet. The DMA writes the timestamp only if TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Descriptor bit (LD) in the descriptor is set and the Timestamp status (TTSS) bit is set.

TDES1 Normal Descriptor (Write-Back Format)

As mentioned in the following table, this format is only applicable to the last descriptor of a packet.

Table 405. TDES1 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High The DMA updates this field with the most significant 32 bits of the timestamp captured for corresponding transmit packet. The DMA writes the timestamp only if the TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Descriptor bit (LD) in the descriptor is set and Timestamp status (TTSS) bit is set.

TDES2 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 406. TDES2 Normal Descriptor (Write-Back Format)

Bit	Description
31:0	Reserved

TDES3 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 407. TDES3 Normal Descriptor (Write-Back Format)

31	30	29	28	27:24	23	22:18	17	16	15	14	13	12	11	10	9	8	7:4	3	2	1	0
OWN	CTXT	FD	LD	Rsvd	DE	Rsvd	TTSS	EUE	ES	JT	FF	PCE	LoC	NC	LC	EC	CC	ED	UF	DB	IHE

Table 408. TDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the the module DMA owns the descriptor. The DMA clears this bit when it completes the packet transmission. After the write-back is complete, this bit is set to 'b0.
30	CTXT	Context Type This bit should be set to 'b0 for Normal descriptor.
29	FD	First Descriptor This bit indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor This bit is set 'b1 for last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet.
27:24	Rsvd	Reserved
23	DE	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the descriptor. Descriptor Errors can be: • Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet. • All 1s • CTXT, LD, and FD bits set to 1.

Table continues on the next page...

Table 408. TDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		Note 1: When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status register Note 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
22:18	Rsvd	Reserved
17	TTSS	Tx Timestamp Status This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES0 and TDES1 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is set. This bit is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.
16	EUE	ECC Uncorrectable Error Status Indicates the ECC uncorrectable error in the TSO memory. Note: Uncorrectable error in Transmit FIFO memory is reported with (Bit 13) FF = 1. This is because, all such packets are flushed by the module.
15	ES	Error Summary This bit indicates the logical OR of the following bits: • TDES3[0]: IP Header Error • TDES3[14]: Jabber Timeout • TDES3[13]: Packet Flush • TDES3[12]: Payload Checksum Error • TDES3[11]: Loss of Carrier • TDES3[10]: No Carrier • TDES3[9]: Late Collision • TDES3[8]: Excessive Collision • TDES3[3]: Excessive Deferral • TDES3[2]: Underflow Error This bit is also set when EUE (bit 16) is set.
14	JT	Jabber Timeout This bit indicates that the MAC transmitter has experienced a jabber time-out. This bit is set only when the JD bit of the MAC_Configuration register is not set.
13	FF	Packet Flushed This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.

Table continues on the next page...

Table 408. TDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
12	PCE	Payload Checksum Error This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the Payload Length field of the IP Header or the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. This error can also occur when Bus Error is detected during packet transfer. When the Full Checksum Offload engine is not enabled, this bit is reserved.
11	LoC	Loss of Carrier This bit indicates that Loss of Carrier occurred during packet transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.
10	NC	No Carrier This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
9	LC	Late Collision This bit indicates that packet transmission was aborted because a collision occurred after the collision window (512 byte times including Preamble and Carrier Extension in GMII mode). This bit is not valid if Underflow Error is set.
8	EC	Excessive Collision This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after first collision and the transmission of the packet is aborted.
7:4	CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set.
3	ED	Excessive Deferral This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbps mode or Jumbo Packet enabled mode) if DC bit is set in the MAC_Configuration register. When TBS is enabled in full duplex mode and this bit is set, it indicates that the frame has been dropped after the expiry time has reached.
2	UF	Underflow Error This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions:

Table continues on the next page...

Table 408. TDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• The DMA encountered an empty Transmit Buffer while transmitting the packet • The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the suspended state and sets the underflow bit corresponding to a queue in the MTL_Interrupt_Status register.
1	DB	Deferred Bit This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.
0	IHE	IP Header Error When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when Tx Checksum Offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload. In full duplex mode, when EST/Qbv is enabled and this bit is set, it indicates the frame drop status due to Frame Size error or Schedule Error.

43.4.11.3.3 Transmit Context Descriptor

The context descriptor is used to provide the timestamps for one-step timestamp correction, VLAN Tag ID for VLAN insertion feature.

The Transmit Context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction and VLAN Tag ID for VLAN insertion feature. Write back is done on a context descriptor only to reset the OWN bit.

NOTE

The VLAN Tag IDs and MSS values, provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA. When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The Inner VLAN Tag Control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

The following figure shows the format of the Transmit Context descriptor.

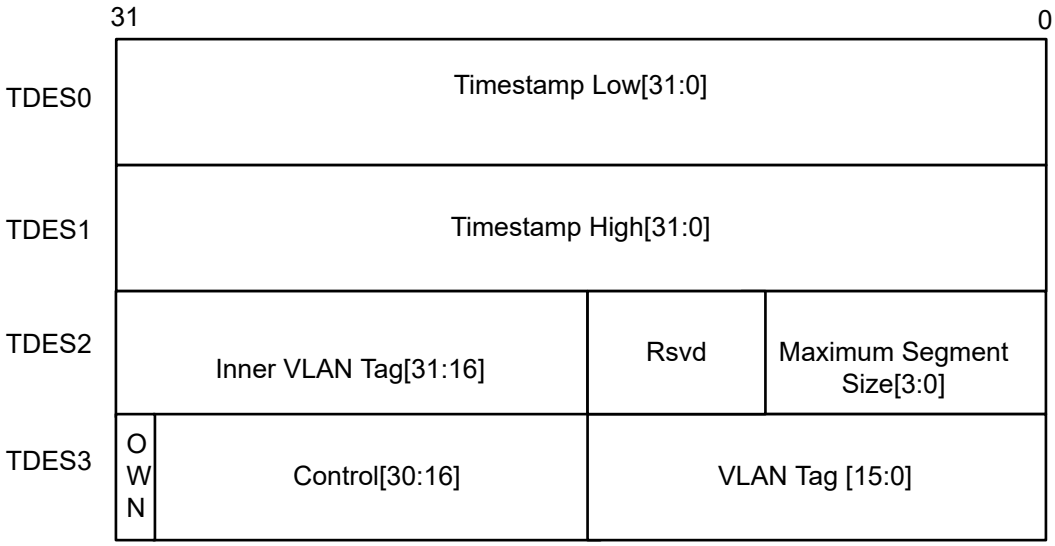

Figure 198. Transmit Context Descriptor Format

43.4.11.3.3.1 TDES0 Context Descriptor

Following table describes the format of the TDES0 Context descriptor.

Table 409. TDES0 Context Descriptor

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. The DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

43.4.11.3.3.2 TDES1 Context Descriptor

Following table describes the format of the TDES1 Context descriptor.

Table 410. TDES1 Context Descriptor

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. The DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

43.4.11.3.3.3 TDES2 Context Descriptor

Following table explains the format of the TDES2 Context descriptor.

Table 411. TDES2 Context Descriptor

Bit	Name	Description
31:16	IVT	Inner VLAN Tag When the IVLTV bit of TDES3 context descriptor is set and the TCMSSV and OSTC bits of TDES3 context descriptor are reset, TDES2[31:16] contains the inner VLAN Tag to be inserted in the subsequent Transmit packets.
15:14	Rsvd	Reserved
13:0	MSS	TSO Split header is not supported. The value of this bit is always zero.

43.4.11.3.3.4 TDES3 Context Descriptor

Table 412. TDES3 Context Descriptor

31	30	29:28	27	26	25:24	23	22:18	17	16	15:0
OWN	CTXT	Rsvd	OSTC	TCMSSV	Rsvd	CDE	Rsvd	IVLTV	VLTV	VT

Follwoing table details the format of the TDES3 Context descriptor.

Table 413. TDES3 Context Descriptor

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit immediately after the read.
30	CTXT	Context Type This bit should be set to 1'b1 for Context descriptor.
29:28	Rsvd	Reserved
27	OSTC	One-Step Timestamp Correction Enable When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
26	TCMSSV	One-Step Timestamp Correction Input or MSS Valid When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid. When the OSTC bit is reset and this bit and the TSE bit of TDES3 are set in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.
25:24	Rsvd	Reserved
23	CDE	Context Descriptor Error

Table continues on the next page...

Table 413. TDES3 Context Descriptor (continued)

Bit	Name	Description
		When this bit is set, it indicates that the descriptor content is incorrect.The DMA sets this bit during write-back while closing the context descriptor. Descriptor Errors can be: • Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet. • All 1s. • CD, LD, and FD bits set to 1. Note 1: When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status register Note 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
22:20	Rsvd	Reserved
19:18	IVTIR	Inner VLAN Tag Insert or Replace When this bit is set, these bits request the MAC to perform Inner VLAN tagging or un-tagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: • 2'b00: Do not add the inner VLAN tag. • 2'b01: Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames. • 2'b10: Insert an inner VLAN tag with the tag value programmed in the MAC_In-ner_VLAN_Incl register or context descriptor. • 2'b11: Replace the inner VLAN tag in packets with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor. This option should be used only with the VLAN frames. These bits are valid when the Enable SA and VLAN Insertion on Tx and Enable Double VLAN Processing options are selected.
17	IVLTV	Inner VLAN Tag Valid When this bit is set, it indicates that the IVT field of TDES2 is valid.
16	VLTV	VLAN Tag Valid When this bit is set, it indicates that the VT field of TDES3 is valid.
15:0	VT	VLAN Tag This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the MAC_VLAN_Incl register is reset.

43.4.11.4 Receive Descriptor

The DMA in the module attempts to read a descriptor only if the Tail Pointer is different from the Base Pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC.

Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following Receive Descriptors are present:

- Normal descriptors
- Context descriptors

All RX descriptors are prepared by the software and given to the DMA as "Normal" Descriptors with the content as shown in Receive Normal Descriptor (Read Format). The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the Rx DMA will close the descriptor with the corresponding packet status. The format of this status is given in the "Receive Normal Descriptor (Write-Back Format)".

For some packets, the normal descriptor bits are not enough to write the complete status. For such packets, the RX DMA writes the extended status to the next descriptor (without processing or using the Buffers/ Pointers embedded in that descriptor). The format and content of the descriptor write back is described in "Receive Context Descriptor".

43.4.11.4.1 Receive Normal Descriptor (Read Format)

The read format for a Receive Normal descriptor is made up of a header or Buffer 1 address, reserved field, payload or Buffer 2 or Next Descriptor address, a 30-bit reserved filed, OWN bit, and an interrupt bit.

Following figure shows the Read Format for a Receive Normal Descriptor.

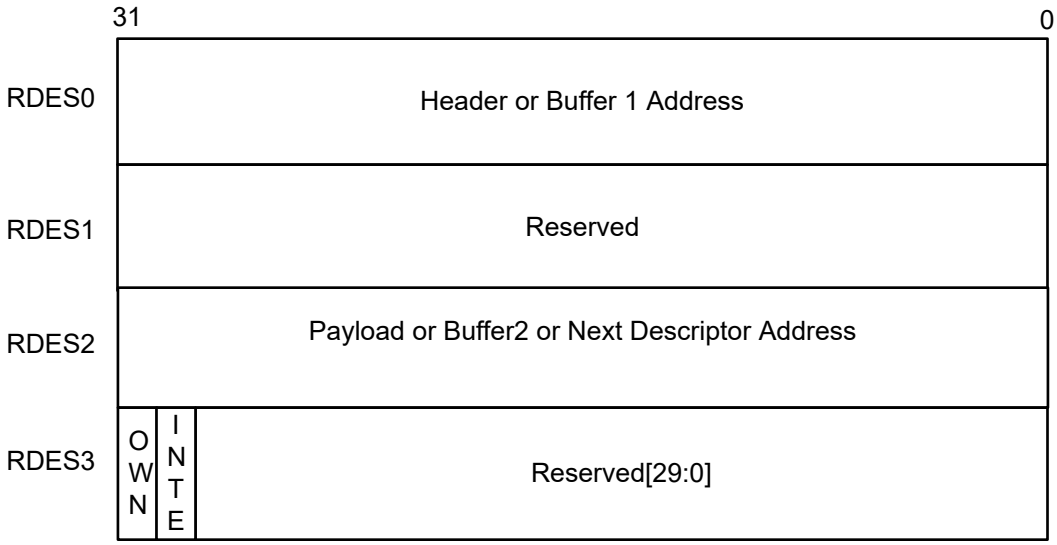

Figure 199. Receive Normal Descriptor Read Format

NOTE

In the Receive Descriptor (Read Format), if the Buffer Address field is all 0s, the module does not transfer data to that buffer and skips to the next buffer or next descriptor.

43.4.11.4.1.1 RDES0 Normal Descriptor (Read Format)

Following table explains the read format of the RDES0 Normal Descriptor.

Table 414. RDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Header or Buffer 1 Address Pointer When the SPH bit of Control register of a channel is reset, these bits indicate the physical address of Buffer 1. When the SPH bit is set, these bits indicate the physical address of Header Buffer where the Rx DMA writes the L2/L3/L4 header bytes of the received packet. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a Write operation with RDES0[1:0] (or RDES0[2:0]/[3:0] in case of 64-/128-bit configuration) as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer. If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.

43.4.11.4.1.2 RDES1 Normal Descriptor (Read Format)

Following table describes the read format of the RDES1 Normal Descriptor.

Table 415. RDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	Reserved or BUF1AP	In 64-bit addressing mode, this field contains the most-significant 32 bits of the Buffer 1 Address Pointer. Otherwise, this field is reserved.

43.4.11.4.1.3 RDES2 Normal Descriptor (Read Format)

Following table provides the read format of the RDES2 Normal Descriptor.

Table 416. RDES2 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 Address Pointer These bits indicate the physical address of Buffer 2. When the SPH bit of the DMA_CH#_Control register is set, the buffer address pointer must be bus width-aligned, that is, RDES2[3:0, 2:0, or 1:0] = 0 corresponding to 128, 64, or 32 bus width. LSBs are ignored internally. When the SPH bit of the DMA_CH#_Control register is reset, there is no limitations on the RDES2 value. However, the RxDMA uses the LS Bits of the pointer address only while transferring the start bytes of a packet. If the BUF2AP is giving the address of a buffer in which the middle or last part of a packet is stored, the DMA ignores BUF2AP[3:0 or 2:0 or 1:0] (corresponding to 128- or 64- or 32-bit data-bus) and writes to the complete location.

43.4.11.4.1.4 RDES3 Normal Descriptor (Read Format)

Following table describes the read format of the RDES3 Normal Descriptor.

31	30	19-26	25	24	23:0
OWN	IOC	Rsvd	BUF2V	BUF1V	Rsvd

Table 417. RDES3 Normal Descriptor (Read Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception • The buffers associated with the descriptor are full
30	IOC	Interrupt Enabled on Completion When this bit is set, an interrupt is issued to the application when the DMA closes this descriptor.
29:26	Rsvd	Reserved
25	BUF2V	Buffer 2 Address Valid When this bit is set, it indicates to the DMA that the buffer 2 address specified in RDES2 is valid. The application must set this bit so that the DMA can use the address, to which the Buffer 2 address in RDES2 is pointing, to write received packet data.
24	BUF1V	Buffer 1 Address Valid When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must set this value if the address pointed to by Buffer 1 address in RDES1 can be used by the DMA to write received packet data.
23:0	Rsvd	Reserved

43.4.11.4.2 Receive Normal Descriptor (Write-Back Format)

The following figure illustrates the write-back format for a Receive Normal descriptor.

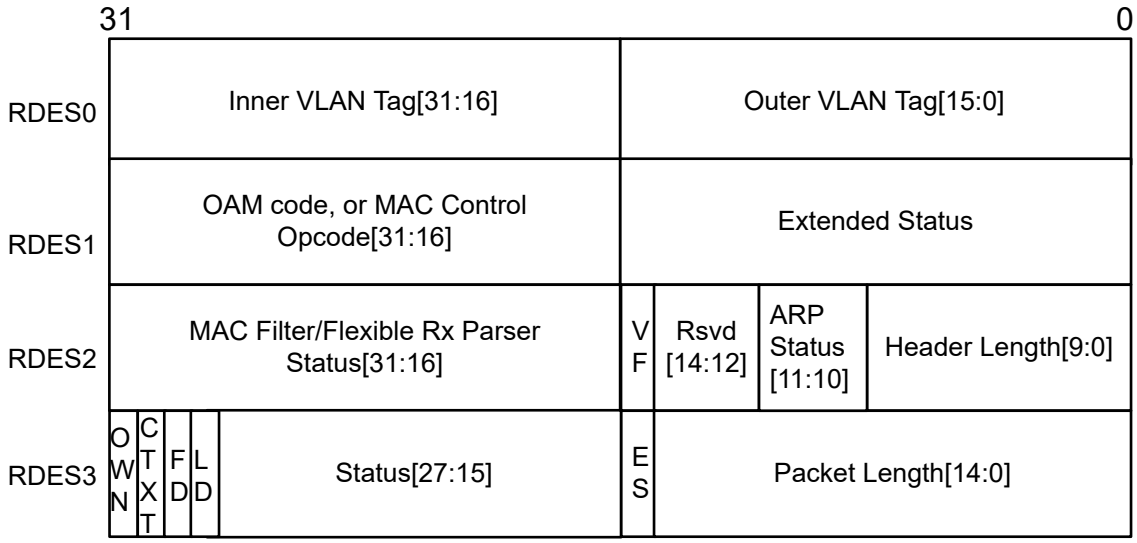

Figure 200. Receive Normal Descriptor (Write-Back Format)

NOTE

When Flexible RX Parser is enabled, RDES2[31:16] indicates Parser status, and not the MAC filter status. MAC filter status is not available when Flexible RX parser is enabled.

43.4.11.4.2.1 RDES0 Normal Descriptor (Write-Back Format)

Following table describes the write-back format for the RDES0 Normal Descriptor.

Table 418. RDES0 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:16	IVT	Inner VLAN Tag This field contains the Inner VLAN tag of the received packet if the RS0V bit of RDES3 is set. This is valid only when Double VLAN tag processing and VLAN tag stripping are enabled.
15:0	OVT	Outer VLAN Tag This field contains the Outer VLAN tag of the received packet if the RS0V bit of RDES3 is set.

43.4.11.4.2.2 RDES1 Normal Descriptor (Write-Back Format)

The Status fields in write-back format are valid only for the last descriptor (RDES3[28] is set). Following table provides the details of the write-back format for RDES1 Normal Descriptor.

31:16	15	14	13	12	11:8	7	6	5	4	3	2:0
OPC	TD	TSA	PV	PFT	PMT	IPCE	IPCB	IPV6	IPV4	IPHE	PT

Table 419. RDES1 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:16	OPC	OAM Sub-Type Code, or MAC Control Packet opcode OAM Sub-Type Code If Bits[18:16] of RDES3 are set to 3'b111, this field contains the OAM sub-type and code fields. MAC Control Packet opcode The bits[15:8] of RDES3 contains the subtype and bits [7:0] contains the code.
15	TD	Timestamp Dropped This bit indicates that the timestamp was captured for this packet but it got dropped in the MTL Rx FIFO because of overflow. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
14	TSA	Timestamp Available When Timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1). This is valid only when the Last Descriptor bit (RDES3 [28]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet.
13	PV	PTP Version This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
12	PFT	PTP Packet Type This bit indicates that the PTP message is sent directly over Ethernet. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
11:8	PMT	PTP Message Type These bits are encoded to give the type of the message received: • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling

Table continues on the next page...

Table 419. RDES1 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• 1011–1110: Reserved • 1111: PTP packet with Reserved message type These bits are available only when you select the Timestamp feature.
7	IPCE	IP Payload Error When this bit is set, it indicates either of the following: • The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment. • The TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. • The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 15 (ES) of RDES3 is not set when this bit is set.
6	IPCB	IP Checksum Bypassed This bit indicates that the checksum offload engine is bypassed. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.
5	IPV6	IPv6 header Present This bit indicates that an IPV6 header is detected. When the Enable Split Header Feature option is selected and the SPH bit of Control Register of a channel is set, the IPV6 header is available in the header buffer area to which RDES0 is pointing.
4	IPV4	IPV4 Header Present This bit indicates that an IPV4 header is detected. When the SPH bit of RDES3 is set, the IPV4 header is available in the header buffer area to which RDES0 is pointing.
3	IPHE	IP Header Error When this bit is set, it indicates either of the following: • The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes. • The IP datagram version is not consistent with the Ethernet Type value. • Ethernet packet does not have the expected number of IP header bytes. This bit is valid when either Bit 5 or Bit 4 is set. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.
2:0	PT	Payload Type These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE): • 3'b000: Unknown type or IP/AV payload not processed • 3'b001: UDP • 3'b010: TCP

Table continues on the next page...

Table 419. RDES1 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• 3'b011: ICMP • 3'b110: AV Tagged Data Packet • 3'b111: AV Tagged Control Packet • 3'b101: AV Untagged Control Packet • 3'b100: IGMP if IPV4 Header Present bit is set else DCB (LLDP) Control Packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 3'b000.

43.4.11.4.2.3 RDES2 Normal Descriptor (Write-Back Format)

31:29	28	27	26:19	18	17	16	15	14	13:11	10	9:0
L3L4FM	L4FM	L3FM	MADRM	HF	DAF	SAF	OTS	ITS	Rsvd	ARPNR	HL

Table 420. RDES2 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:29	L3L4FM	Layer 3 and Layer 4 Filter Number Matched These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet: • 000: Filter 0 • 001: Filter 1 • 010: Filter 2 • 011: Filter 3 • 100: Filter 4 • 101: Filter 5 • 110: Filter 6 • 111: Filter 7 This field is valid only when Bit 28 or Bit 27 is set high. When more than one filter matches, these bits give the number of lowest filter. Note: This status is not available when Flexible RX Parser is enabled.
28	L4FM	Layer 4 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true: • Layer 3 fields are not enabled and all enabled Layer 4 fields match • All enabled Layer 3 and Layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits[31:29].

Table continues on the next page...

Table 420. RDES2 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		Note: This status is not available when Flexible RX Parser is enabled.
27	L3FM	Layer 3 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true: • All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed • All enabled filter fields match When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by Bits[31:29]. Note: This status is not available when Flexible RX Parser is enabled.
26:19	MADRM	MAC Address Match or Hash Value When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset. When the HF bit is set, this field contains the hash value computed by the MAC. A packet passes the hash filter when the bit corresponding to the hash value is set in the hash filter register. Note: This status is not available when Flexible RX Parser is enabled.
18	HF	Hash Filter Status When this bit is set, it indicates that the packet passed the MAC address hash filter. Bits[26:19] indicate the hash value. Note: This status is not available when Flexible RX Parser is enabled.
17	DAF/RXPI	Destination Address Filter Fail When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the DA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet parsing is incomplete (RXPI) due to ECC error. Note: When this bit is set, ES bit of RDES3 is also set.
16	SAF/RXPD	SA Address Filter Fail When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the SA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet is dropped (RXPD) by the parser. Note: When this bit is set, ES bit of RDES3 is also set.
15	OTS	VLAN Filter Status When set, this bit indicates that the VLAN Tag of the received packed passed the VLAN filter. This bit is redefined as Outer VLAN Tag Filter Status (OTS). This bit is valid for both Single and Double VLAN Tagged frames

Table continues on the next page...

Table 420. RDES2 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
14	ITS	Inner VLAN Tag Filter Status (ITS) This bit is valid only for Double VLAN Tagged frames, when Double VLAN Processing is enabled. For more information, see Filter Status.
13:11	Rsvd	Reserved
10	ARPNR	ARP Reply Not Generated When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). This bit is reserved when the Enable IPv4 ARP Offload option is not selected.
9:0	HL	L3/L4 Header Length This field contains the length of the header of the packet split by the MAC at L3 or L4 header boundary as identified by the MAC receiver. This field is valid only when the first descriptor bit is set (FD = 1). The header data is written to the Buffer 1 address of corresponding descriptor. If header length is zero, this field is not valid. It implies that the MAC did not identify and split the header. This field is valid when the Enable Split Header Feature option is selected.

43.4.11.4.2.4 RDES3 Normal Descriptor (Write-Back Format)

Following table describes the write-back format for the RDES3 Normal Descriptor.

31	30	29	28	27	26	25	24	23	22	21	20	19	18:16	15	14:0
OWN	CTXT	FD	LD	RS2V	RS1V	RS0V	CE	GP	RWT	OE	RE	DE	LT	ES	PL

Table 421. RDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception • The buffers associated with the descriptor are full
30	CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 1'b0 to this bit for normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD}

Table continues on the next page...

Table 421. RDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• 2'b00: Intermediate Descriptor • 2'b01: First Descriptor • 2'b10: Reserved • 2'b11: Descriptor Error (due to all 1s) Note: When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	FD	First Descriptor When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet. See the CTXT bit description for details of using the CTXT bit and FD bit together.
28	LD	Last Descriptor When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
27	RS2V	Receive Status RDES2 Valid When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
26	RS1V	Receive Status RDES1 Valid When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
25	RS0V	Receive Status RDES0 Valid When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
24	CE	CRC Error When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set.
23	GP	Giant Packet When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set). Note: Giant packet indicates only the packet length. It does not cause any packet truncation.
22	RWT	Receive Watchdog Timeout

Table continues on the next page...

Table 421. RDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.
21	OE	Overflow Error When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO. Note: This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO.
20	RE	Receive Error When this bit is set, it indicates that the gmii_rxer_i signal is asserted while the gmii_rxdv_i signal is asserted during packet reception. This error also includes carrier extension error in the GMII and half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
19	DE	Dribble Bit Error When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode.
18:16	LT	Length/Type Field This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: • 3'b000: The packet is a length packet • 3'b001: The packet is a type packet. • 3'b011: The packet is a ARP Request packet type • 3'b100: The packet is a type packet with VLAN Tag • 3'b101: The packet is a type packet with Double VLAN Tag • 3'b110: The packet is a MAC Control packet type • 3'b111: The packet is a OAM packet type • 3'b010: Reserved
15	ES	Error Summary When this bit is set, it indicates the logical OR of the following bits: • RDES3[24]: CRC Error • RDES3[19]: Dribble Error • RDES3[20]: Receive Error • RDES3[22]: Watchdog Timeout • RDES3[21]: Overflow Error • RDES3[23]: Giant Packet • RDES2[17]: Destination Address Filter Fail, when Flexible RX Parser is enabled

Table continues on the next page...

Table 421. RDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• RDES2[16]: SA Address Filter Fail, when Flexible RX Parser is enabled • RDES2[13:11]: Receive Parser Overflow Errors (3'b010) This field is valid only when the LD bit of RDES3 is set.
14:0	PL	Packet Length These bits indicate the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 is set and Overflow Error bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current packet.

43.4.11.4.3 Receive Context Descriptor

This descriptor is read-only for the application. Only the DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. The Bit 30 of RDES3 indicates the context type descriptor.

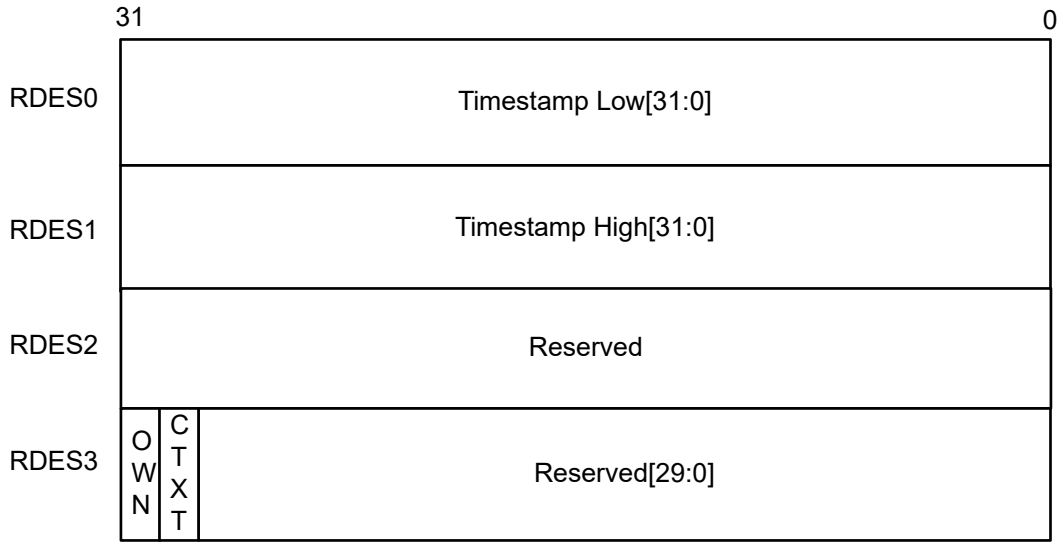

Figure 201. Receive Context Descriptor Format

43.4.11.4.3.1 RDES0 Context Descriptor

Table 422. RDES0 Context Descriptor

Bit	Name	Description
31:0	RTSL	Receive Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for corresponding Receive packet. When this field and the RTSH field of RDES1 show all-ones value, the timestamp must be considered as corrupt.

43.4.11.4.3.2 RDES1 Context Descriptor

Table 423. RDES1 Context Descriptor

Bit	Field	Description
31:0	RTSH	Receive Packet Timestamp High The DMA updates this field with most significant 32 bits of the timestamp captured for corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, the timestamp must be considered as corrupt.

43.4.11.4.3.3 RDES2 Context Descriptor

Table 424. RDES2 Context Descriptor

Bit	Description
31:0	Reserved

43.4.11.4.3.4 RDES3 Context Descriptor

31	30	29	28:0
OWN	CTXT	DE	Rsvd

Table 425. RDES3 Context Descriptor

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception • The buffers associated with the descriptor are full
30	CTXT	Receive Context Descriptor

Table continues on the next page...

Table 425. RDES3 Context Descriptor (continued)

Bit	Name	Description
		When this bit is set, it indicates that the current descriptor is a context descriptor. The DMA writes 1'b1 to this bit for context descriptor. DMA writes 2’b11 to indicate a descriptor error due to all 1s. When CTXT and DE bits are used together, {CTXT, DE} • 2’b00: Reserved • 2’b01: Reserved • 2’b10: Context Descriptor • 2’b11: Descriptor Error Note: When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	DE	Descriptor Error See the CTXT bit description for details of using theDE bit along with CTXT bit.
28:0	Rsvd	Reserved

43.4.11.5 Enhanced Descriptor for Time-Based Scheduling

The time-based scheduling feature needs 32 bytes Enhanced Descriptors to be enabled on all the DMA channels that intend to use the feature (by setting the EDSE bit of DMA_CH(#i)_TX_Control register).

The structure of 32-byte Descriptor for the Context and the Normal Descriptor in Read and Write formats are described in the following sections.

43.4.11.5.1 Enhanced Normal Descriptor - Read (32-Bit Mode)

The fields present in the first 16 bytes of the Enhanced Descriptor format of normal descriptor are as follows:

- LTV

  Launch Time Valid indicates the Launch Time (LT) and GSN fields present in the descriptor are valid. The LTV must be set only if the FD bit of the descriptor is not.

- GSN

  This field indicates the GCL slot number associated with the packet.

- Launch Time (LT)

  This field indicates the Launch Time associated with the packet.

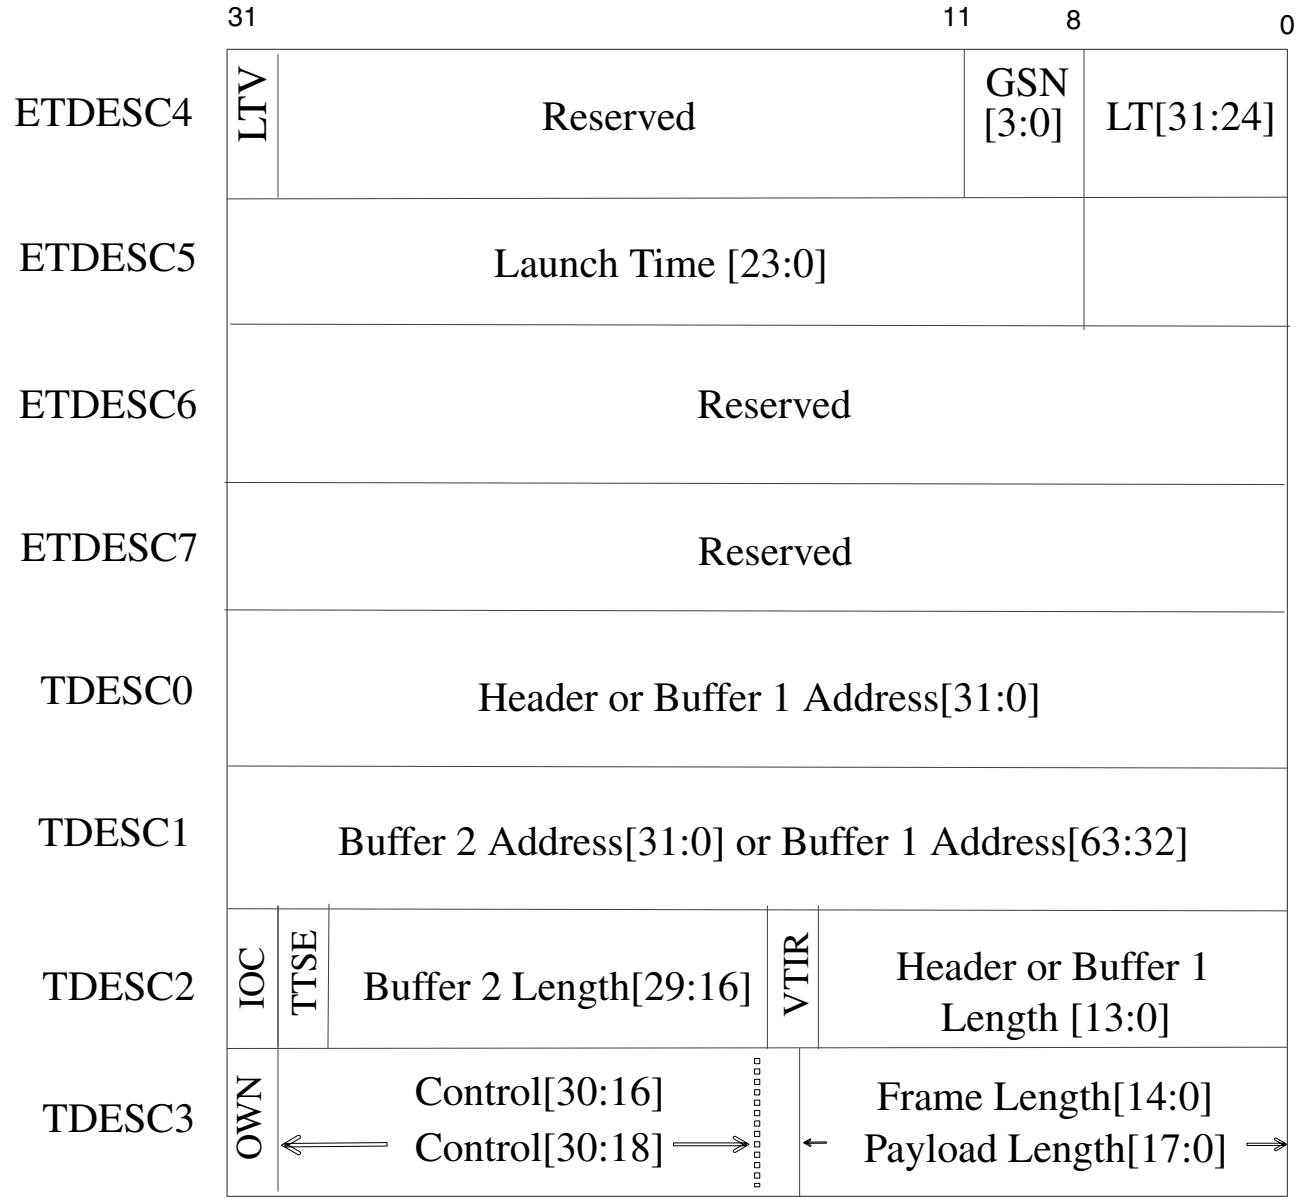

Figure 202. Enhanced Normal Descriptor - Read (32-Bit Mode)

43.4.11.5.2 Enhanced Normal Descriptor (Write, 32-Bit Mode)

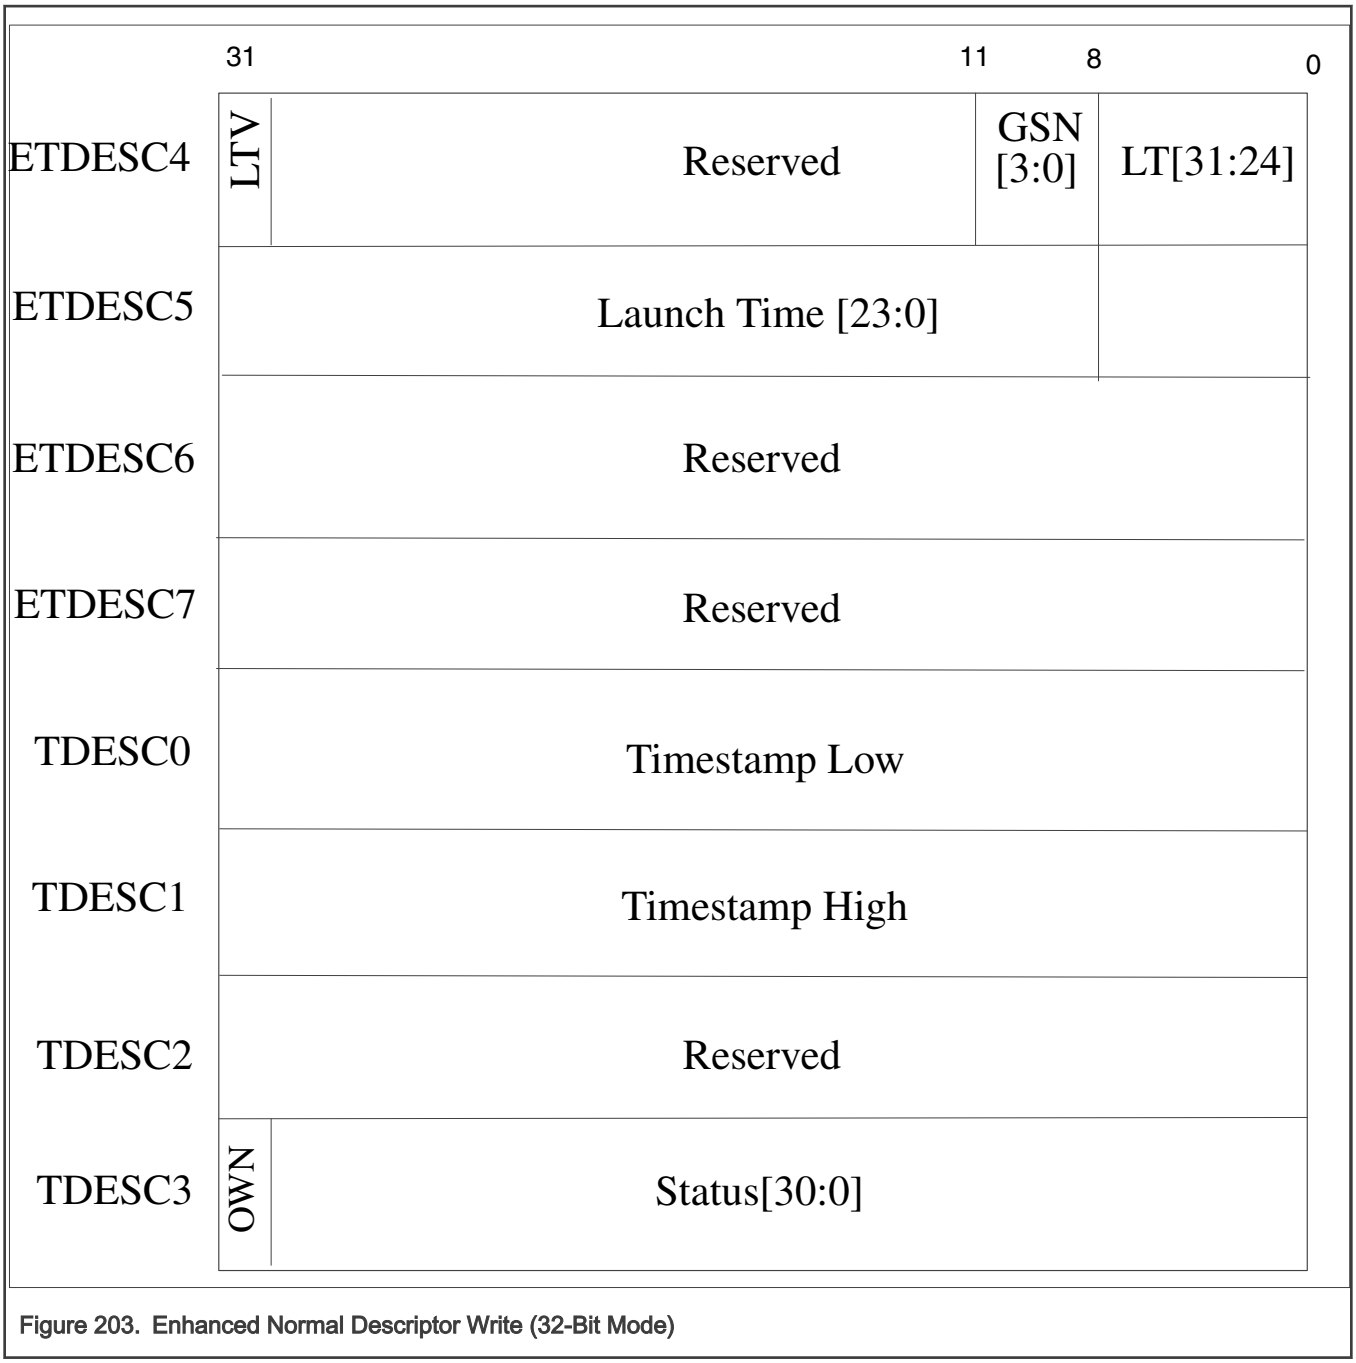

Figure 203. Enhanced Normal Descriptor Write (32-Bit Mode)

NOTE

- All the enhanced descriptor examples, assumes a 32-bit data width configurations. However, the same definitions are valid in 64 and 128 bit configurations.
- In both the write back formats, no modifications can be done to the extended 16 bytes. The rest of the 16 bytes (TDESC0 to TDESC3) are written back as per the previous 16 bytes Descriptor format.
- Fetch time when enabled overrides the AV slot function
- When an unaligned new GCL list (with a different CTR) is installed it is recommended not to have traffic during the installation of the new list. Any traffic during the switching of the lists might have unpredictable behavior regarding Fetch, Launch, and Launch expiry as the CTR and BTR values get updated while the frame is being processed

43.4.11.5.3 Enhanced Context Descriptor (Read, 32-bit Mode)

The first 16 bytes of the Enhanced context descriptor (ETDESC4 to ETDESC7) are reserved and must be zeros. The fields present in last bytes of the Descriptor (TDESC0 to TDESC3) are same as the context descriptor (TDESC0 to TDESC3) in 16 byte format.

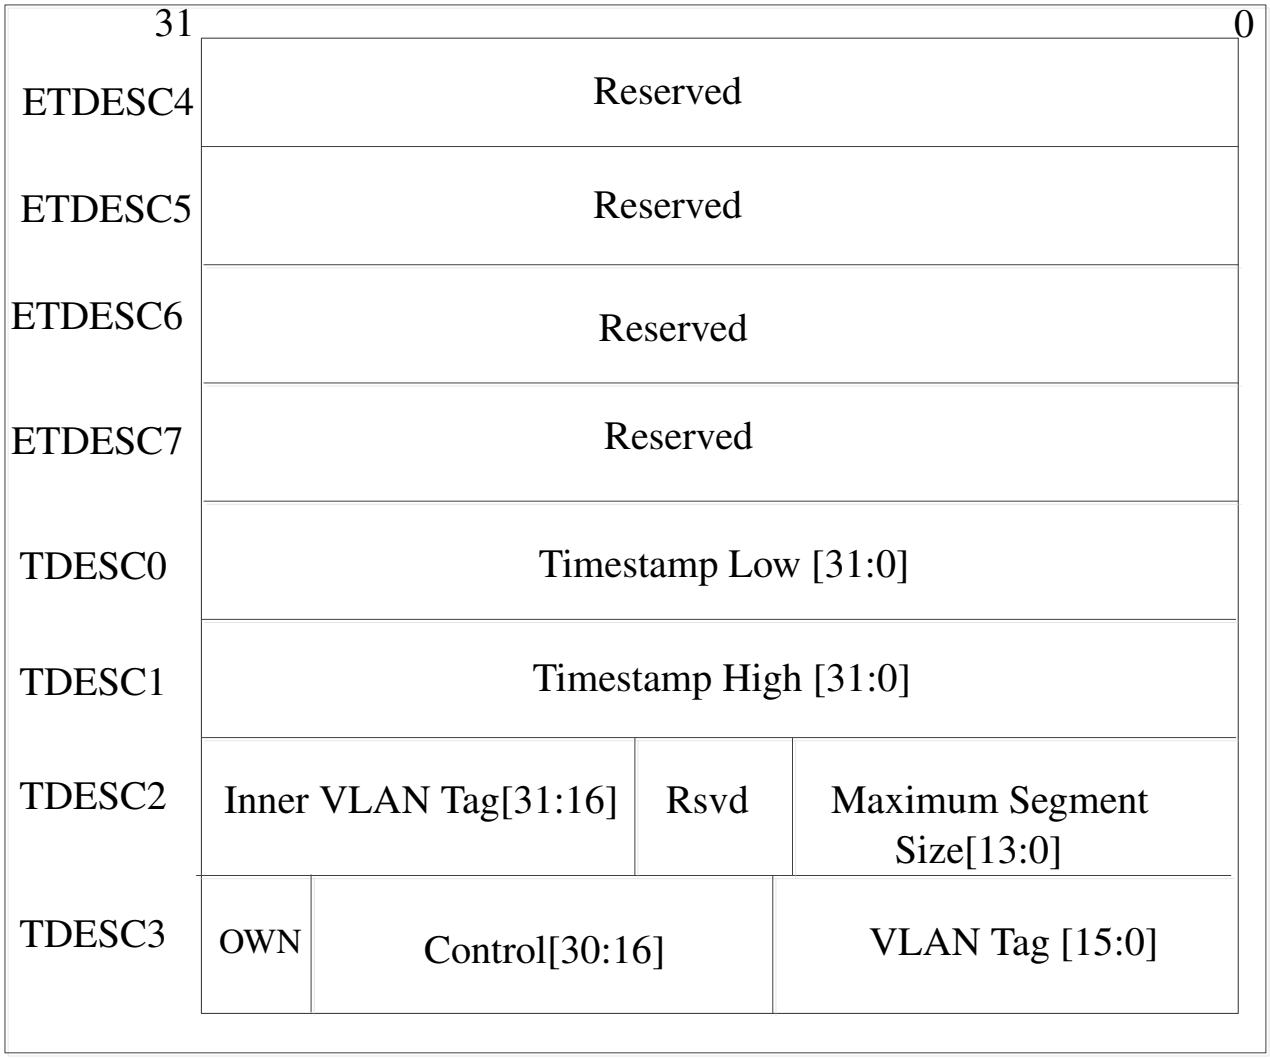

Figure 204. Enhanced Context Descriptor - Read

43.4.11.5.4 Enhanced Context Descriptor (Write, 32 Bit Mode)

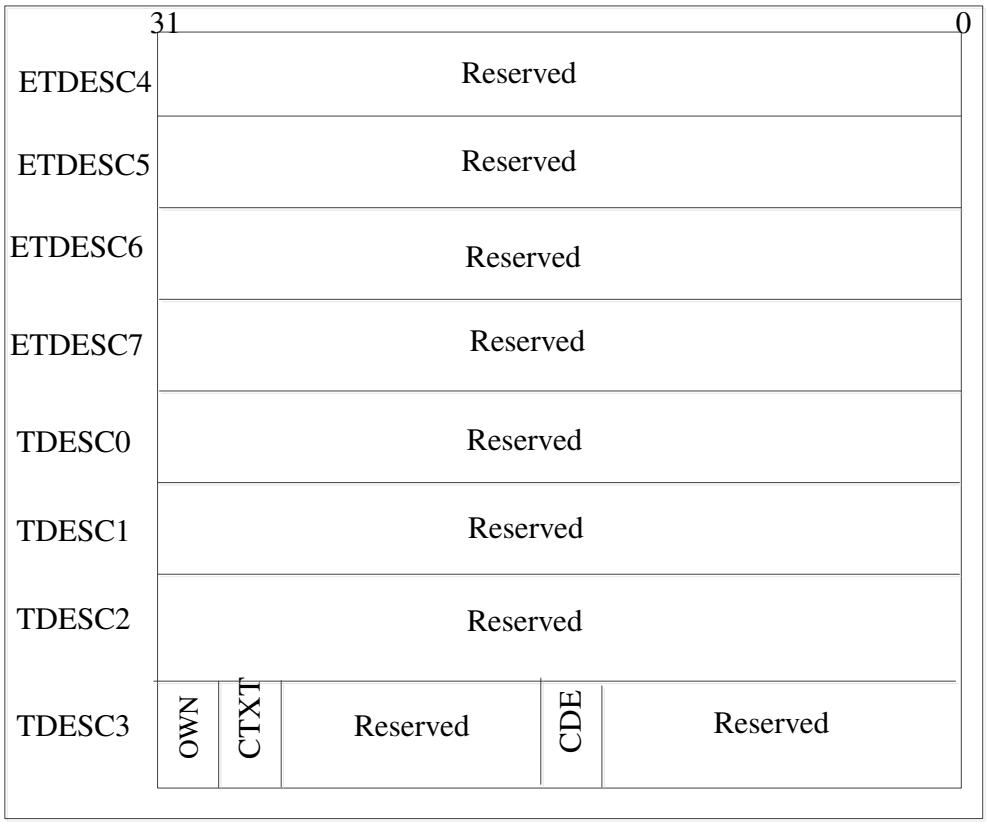

Figure 205. Enhanced Context Descriptor - Write

43.4.12 Power management and low power modes

This section describes the power management (PMT) mechanisms supported by the MAC. PMT supports the reception of network (remote) wake-up frames and magic packet frames. PMT does not perform the clock gate function, but generates interrupts for wake-up frames and magic packets received by the MAC. The PMT block sits on the receiver path of the MAC and is enabled with remote wake-up frame enable and magic packet enable. These enables are in the PMT control and status register and are programmed by the application.

When the power-down mode is enabled in the PMT, then all received frames are dropped by the Ethernet core and they are not forwarded to the application. The Ethernet comes out of the power-down mode only when either a magic packet or a remote wake-up frame is received and the corresponding detection is enabled.

43.4.12.1 Energy Efficient Ethernet

Energy Efficient Ethernet (EEE) is an operational mode that enables the IEEE 802.3 MAC sublayer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps. The Ethernet module supports the IEEE 802.3az-2010 for EEE. The LPI mode allows power saving by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides

of the link can disable some functionality to save power during periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY. The EEE specifies the capabilities negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

43.4.12.1.1 Transmit path functions

In the transmit path, the software must set the LPIEN bit of the MAC LPI control status register to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the LPI LS TIMER(LST) field of MAC LPI timers control register. The PHY link status bit of the LPI control and status register indicates the link status of the PHY.

According to the Energy Efficient Ethernet standard (IEEE 802.3az-2010), the PHY must not stop the transmit clock during the LPI state in the MII (10 or 100) mode.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts transmit enable (TX_EN).
2. Asserts transmit error (TX_ER). Sets TXD[3:0] to 0x1 The MAC maintains the same state of the TX_EN, TX_ER, and TXD signals for the entire duration during which the PHY remains in the LPI state.
3. Updates the status (TLPIEN bit of MAC LPI control status register and generates an interrupt. To bring the PHY out of the LPI state, that is, when the software resets the LPIEN bit, the MAC performs the following tasks:
4. Stops transmitting the LPI pattern and start transmitting the IDLE pattern
5. Starts the LPI TW TIMER
6. Updates the LPI exit status (TLPIEX bit of the MAC LPI control status register and generates an interrupt

The MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programmed in the TWT field of the MAC LPI Timers control register.

43.4.12.1.2 Automated entry/exit of LPI mode in TX path

The MAC transmitter can be programmed to enter and exit LPI IDLE mode automatically based on whether it is IDLE for a specific period or has a packet to transfer. These modes are enabled and controlled by the MAC LPI control status register.

When the LPITXA (bit 19) and LPITXEN (bit 16) of the MAC LPI control status register are set, the MAC transmitter enters the LPI IDLE state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter exits the LPI IDLE state and clears the LPITXEN bit as soon as any of the functions in the TX path (DMA, MTL, or MAC) becomes non-idle due to initiation of a packet transfer. In addition to the above, when bit 20 (LPIATE) is also set, the MAC transmitter enters LPI IDLE state only when the transmit path remains in an idle state (no activity) for the time indicated by the value in MAC LPI Entry Timer. In this mode also, the MAC transmitter exits the LPI IDLE state as soon as any of the functions becomes non-idle. However, the LPITXEN bit is not cleared but remains active so that reentry to LPI IDLE state is possible without any software intervention when the MAC becomes idle again.

When both LPIATE and LPITXA bits are cleared, you can directly control the entry and exit of the LPI IDLE state by programming the LPITXEN bit.

43.4.12.1.3 Receive path functions

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER.
2. The PHY sets RXD[7:0] to 0x01.
3. The PHY de-asserts RX_DV. The PHY maintains the same state of the RX_ER, RXD, and RX_DV signals for the entire duration during which it remains in the LPI state.

4. The MAC updates the RLPIEN bit of the MAC LPI control status register and immediately generates an interrupt.

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER and returns to a normal inter-packet state.
2. The MAC updates the RLPIEX bit of the MAC LPI control status register and generates an interrupt immediately. The sideband signal (synchronous to Rx clock) is also asserted.

43.4.12.1.4 LPI timers

The transmitter maintains the following two timers that are loaded with the respective values from the MAC_LPI_Timers_Control register:

- LPI LS Timer
  - The LPI LS TIMER counts, in milliseconds, the time expired since the link status is up. You can enable the monitoring of the LUD bit of the MAC_PHYIF_Control_Status register by setting the PLSEN bit of the MAC_LPI_Control_Status register. The link status is indicated to the MAC by the LNKSTS bit of the MAC_PHYIF_Control_Status register or the value programmed by the software in the PLS bit of the MAC_LPI_Control_Status register. If the link status is not available in the MAC_PHYIF_Control_Status, the software should get the PHY link status by reading the PHY register and accordingly update the PLS bit. This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. Once the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programmed in bits 25:16 of the MAC_LPI_Timers_Control register. The GMII interface does not assert the LPI pattern unless the terminal count is reached. This ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as 1 second in the IEEE 802.3-az-2010. The LPI LS TIMER is 10-bit wide. Therefore, the software can program up to 1,023 ms.
- LPI TW Timer
  - The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of LPI. The terminal count should be programmed in bits 15:0 of MAC register 53 (LPI timers control register). The terminal count of the timer is the value of resolved transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal operation after the TW timer reaches the terminal count. The MAC supports the LPI TW TIMER in units of a microsecond. The LPI TW TIMER is 16-bits wide. Therefore, the software can program up to 65,535 µs.

43.4.12.1.5 LPI interrupt

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The low-power interrupt is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the MAC LPI control status register.

43.4.12.2 Power management and wake-up

The power management (PMT) block supports the reception of magic packets as wake up packets, as well as the reception of network (remote) wake-up packets as wake up packets.

43.4.12.2.1 Magic packet detection

The magic packet frame is based on a method that uses Advanced Micro Device’s magic packet technology to power up the sleeping device on the network. The MAC receives a specific packet of information, called a magic packet, addressed to the node on the network.

Only magic packets that are addressed to the device or a broadcast address are checked to determine whether they meet the wake-up requirements. Magic packets that pass the address filtering (unicast or broadcast)are checked to determine whether they meet the remote wake-on-LAN data format of 6 bytes of all ones followed by a MAC address appearing 16 times.

The application enables magic packet wake-up by writing a 1 to bit 1 of the PMT control and status register. The PMT block constantly monitors each frame addressed to the node for a specific magic packet pattern. Each frame received is checked for

a 0xFFFF FFFF FFFF pattern following the destination and source address field. The PMT block then checks the frame for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the 0xFFFF FFFF FFFF pattern is scanned for again in the incoming frame. The 16 repetitions can be anywhere in the frame but must be preceded by the synchronization stream (0xFFFF FFFF FFFF). The device also accepts a multicast frame, as long as the 16 duplications of the MAC address are detected.

If the MAC address of a node is 0x0011 2233 4455, then the MAC scans for the data sequence:

- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
- ...CRC

Magic packet detection is updated in the PMT control and status register for magic packet received. A PMT interrupt to the application triggers a read to the PMT CSR to determine whether a magic packet frame is received. When you enable the power-down mode in the PMT block, the MAC drops all received packets and does not forward any packet to the MTL Rx FIFO or the application. The MAC comes out of the power-down mode only when a magic packet is received and the corresponding detection is enabled.

43.4.12.2.2 Remote wake-up detection

The PMT block supports the reception of network (remote) wake-up packets as wake-up packets.

When the MAC is in sleep mode and the remote wake-up bit is enabled in PMT control and status register (0x00C0), normal operation is resumed after receiving a remote wake-up frame. The application writes all eight wake-up filter registers by performing a sequential write to address (0x00C4). The application enables remote wake-up by writing a 1 to bit 2 of the PMT control and status register.

PMT supports 16 programmable filters that allow support of different receive frame patterns. If the incoming frame passes the address filtering of filter command, and if filter CRC-16 matches the incoming examined pattern, then the wake-up frame is received.

Filter_offset (minimum value 12, which refers to the 13th byte of the frame) determines the offset from which the frame is to be examined. Filter byte mask determines which bytes of the frame must be examined. The 31st bit of the byte mask must be set to zero.

The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The wake-up frame is checked only for length error, FCS error, dribble bit error, MII error, collision, and to ensure that it is not a runt frame. Even if the wake-up frame is more than 512 bytes long, if the frame has a valid CRC value, it is considered valid. Wake-up frame detection is updated in the PMT control and status register for every remote wake-up frame received. A PMT interrupt to the application triggers a read to the PMT control and status register to determine the reception of a wake-up frame.

43.4.12.3 System considerations during power-down

MAC neither gates nor stops clocks when power-down mode is enabled. Power saving by clock gating must be done outside the core by the application. The receive data path must be clocked with ENET_RX_CLK during power-down mode because it is involved in magic packet/wake-on-LAN frame detection. However, the transmit path and the application path clocks can be gated off during deep-sleep mode.

The PMT interrupt is asserted when a valid wake-up frame is received. This signal is generated in the receive clock domain.

The recommended power-down and wake-up sequences are as follows.

1. Disable the transmit DMA and wait for any previous frame transmissions to complete. These transmissions can be detected when transmit interrupt (see DMA channel status register bit TI) is received.
2. Disable the MAC transmitter and MAC receiver by clearing the appropriate bits in the MAC configuration register.

3. Wait until the receive DMA empties all the frames from the Rx FIFO. This can be done by reading the appropriate bits of Debug registers in the DMA and MTL CSR space.
4. Enable power-down mode by appropriately configuring the PMT registers.
5. Enable the MAC receiver and enter power-down mode.
6. Gate the application and transmit clock inputs to the core (and other relevant clocks in the system) to reduce power and enter sleep mode.
7. On receiving a valid wake-up frame, the MAC asserts the PMT interrupt signal and exits the power-down mode.
8. On receiving the interrupt, the system must enable the application and transmit clock inputs to the core.
9. Read the PMT status register to clear the interrupt, then enable the other modules in the system and resume normal operation.

43.4.13 Clocks

The table found here describes the clock sources for ENET_QOS. Please see the chip-specific clocking section for clock setting, configuration and gating information.

Table 426. ENET_QOS Clocks

Clock name	Description
aclk_i	Bus clock
clk_csr_i	CSR clock, same source as aclk_i
ptp_ref_i	PTP clock

43.4.14 Interrupts

This module supports interrupt coalescing which reduces the number of interrupts generated by IP and reduces the CPU load. Various interrupt event gets captured in status register. If interrupt enable bit of an interrupt is set then corresponding interrupt will be generated based on event status in status registers. INTM (interrupt mode) bit decides that interrupt signal is a level signal or pulse signal.

Interrupt output signals are shown below which are synchronous to control and Status register (CSR) clock.

- Sbd_intr_o – common interrupt
- Sbd_perch_tx_intr_o[max_dma_ch] – Interrupt per Tx channel
- Sbd_perch_rx_intr_o [max_dma_ch] – Interrupt per Rx channel

NOTE

max_dma_ch is equal to number of Tx/Rx queues which is 2.

The sbd_intr_o common interrupt is level signal. When sbd_intr_o interrupt is asserted, then corresponding interrupt event source can be found in DMA_Interrupt status register. DMA_Interrupt status register is read only register which contains the interrupt event source bits corresponding to each DMA channel (Tx and Rx queue pair), MAC transaction layer and MAC blocks. Software must then read the following registers corresponding to the bits that are set.

- MAC_Interrupt_Status register
- MTL_Interrupt_Status register
- DMA_CH(n)_Status register

sbd_intr_o interrupt gets de-asserted only when all the enabled interrupt events are cleared in their respective status registers and correspondingly all the bits in the DMA_Interrupt_Status register are cleared.

The DMA_CH[n]_Status register captures all the interrupt events of that Tx DMA and Rx DMA channel pair. The DMA_CH[n]_Interrupt_Enable register contains the corresponding enable bits for each of the interrupt event. There are two groups of interrupts in the DMA channel namely Normal and Abnormal interrupts. They are indicated by bits[15:14] of DMA_CH[n]_Status register respectively. The normal group is for events that happen during the normal transfer of packets (TI, RI, TBU) while the abnormal interrupt events are for error events

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated.

The common sbd_intr_o output signal is asserted for the transfer complete interrupts only when the corresponding interrupts are enabled in DMA_CH[n]_Interrupt_Enable register.

This module also supports the following per Channel Transfer Complete interrupt signals.

- sbd_perch_tx_intr_o[max_dma_ch] (Transmit Per Channel Interrupts)
- sbd_perch_rx_intr_o[max_dma_ch] (Receive Per Channel Interrupts)

The behavior of the RI/TI/ sbd_perch_tx_intr_o[]/sbd_perch_rx_intr_o[] changes depending on the settings of INTM field bit[17:16] in DMA_Mode. Following table explains the Transfer Complete Interrupt behavior.

Table 427. Transfer Complete Interrupt Behavior

Interrupt Mode	Behavior of the sbd_perch_tx_intr_o[] and sbd_perch_rx_intr_o[]	Behavior of TI/RI and sbd_intr_o
INTM=1	These signals reflect the value of corresponding TI/RI bits in DMA_CH[n]_Status register when the corresponding interrupt enable is set. Hence they are level signals and are cleared by the application by writing 1’b1 to the RI/TI status bits. This signal will not be asserted when the corresponding interrupt enable bit is not set.	The TI/RI is set as explained above. However, the sbd_intr_o signal and NIS status bit are not asserted for any RI/TI events.
INTM=2	In this mode, RI/TI interrupts are queued. These signals reflect the value of corresponding TI/RI bits inDMA_CH[n]_Status register when the corresponding interrupt enable is set. They are level signals and cleared by software by writing 1’b1 to the RI/TI status bits. However, it is set again if another TI/RI event(s) is detected before the TI/RI bits are cleared for the previous event.	The RI/TI status bits are set whenever the Transfer Complete event is detected and gets reset whenever software driver clears those bits by writing 1. However, if another Transfer Complete event is detected before it is cleared (serviced) by the software, then the module automatically set these status bits again. However, the sbd_intr_o signal is not generated based on TI/RI

43.4.14.1 PMT interrupts

The PMT interrupt signal is asserted when a valid remote wake-up packet is received. When software resets the PWRDWN bit in the remote wake-Up packet detection register, the MAC comes out of the power-down mode, but this event does not generate the PMT interrupt.

When you enable the power-down mode in the PMT block, the MAC drops all received packets and does not forward any packet to the MTL Rx FIFO or the application. The MAC comes out of the power-down mode only when a remote wake-up packet is received and the corresponding detection is enabled. The PMT block is available in the receive path of MAC.

43.5 External signals

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

Table 428. External signals

Port name	Interface	I/O	Description
1588_EVENT_AUX_IN	RMII	I	Auxiliary Timestamp Trigger When this signal goes high (rising edge), a snapshot of the system time is taken and stored in the auxiliary timestamp FIFO.
1588_EVENT_IN	RMII	I	Media Clock Generation Trigger Input Trigger (mcg_pst_trig_i) Input to ENET_QOS to capture presentation time. Based on presentation control value of PPS Control (MAC_PPS_CONTROL), this signal can be pulse or level signal.
1588_EVENT_OUT	RMII	O	Pulse Per Second Output (ptp_pps_o) This signal is high based on the PPS mode selected in PPS Control (MAC_PPS_CONTROL). When PPS is programmed in Media Clock Recovery mode, this port indicates the recovered clock. See Programming Guidelines for Flexible Pulse-Per-Second Output for details.
TX_CLK	RGMII	O for (RGMII)	RGMII: The transmit clock signal is always provided by the MAC on the TX_CLK line. Source-synchronous clocking is used: the clock signal that is output (by either the PHY or the MAC) is synchronous with the data signals.
RX_CLK	RGMII	I	RGMII: Received clock signal (recovered from incoming received data)
REF_CLK1	RMII	I/O	This 50Mhz clock used by the RMII interface. When RMII mode is selected, RX_CLK (25Mhz or 2.5Mhz) should be derived from this clock.
TX_EN	RMII, RGMII	O	The MAC drives this signal. This signal has multiple functions depending on the selected PHY interface. • RMII: When high, indicates that valid data is being transmitted on the phy_txd_o bus. Synchronous to REF_CLK.

Table continues on the next page...

Table 428. External signals (continued)

Port name	Interface	I/O	Description
			• RGMII: Contains TX_EN on the rising edge of TX_CLK, and a logical derivative of TX_EN and TX_ER (TX_EN XOR TX_ER) on the falling edge of TX_CLK.
TX_DATA	RMII, RGMII	O	This is a group of transmit data signals driven by the MAC. It has multiple functions depending on the selected PHY interface. • RMII: Bits[1:0] provide the RMII transmit data. The data is valid only when the TX_EN signal is high. Synchronous to REF_CLK. • RGMII: Bits[3:0] provide serial output Ethernet data
RX_DATA	RMII, RGMII	I	This is a group of data signals received from the PHY. It has multiple functions depending on the selected PHY interface. • RMII: Bits [1:0] provide the RMII receive data. The data is valid only when the RX_EN signal is high. Synchronous to REF_CLK. • RGMII: Bits [3:0] contains the Ethernet input data transferred from the PHY to the media-access controller.
MDC	RMII, RGMII	O	Management Data Clock. The MAC provides timing reference for the MDIO or MII through this periodic clock. This clock is generated from the application clock through a clock divider controlled by MAC_MDIO_ADDRESS[CR].
MDIO	RMII, RGMII	I/O	Transfers control information between the external PHY and the MAC. Data is synchronous to MDC. This signal is an input after reset.
RX_EN	RGMII	I	The PHY drives this signal. It has multiple functions depending on the selected PHY interface. • RMII: Contains the CRS and data valid information of the Receive interface. Synchronous to REF_CLK. In RGMII mode, contains receive data valid on the rising edge of RX_CLK, and a logical derivative of receive data valid and RX_ER (receive data valid XOR RX_ER) on the falling edge of RX_CLK.

43.6 Initialization

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

This section provides the instructions for initializing the DMA or MAC registers in the proper sequence.

43.6.1 Initializing DMA

Complete the following steps to initialize the DMA:

1. Provide a software reset. This resets all of the MAC internal registers and logic (bit-0 of DMA_Mode).

2. Wait for the completion of the reset process (poll bit 0 of the DMA_MODE, which is only cleared after the reset operation is completed).
3. Program the following fields to initialize the DMA_SYSBUS_MODE register:
    a. AAL
    b. Fixed burst or undefined burst
    c. Burst mode values in case of AHB bus interface, OSR_LMT in case of AXI bus interface.
    d. If fixed length value is enabled, select the maximum burst length possible on the AXI Bus (bits [7:1])
4. Create a descriptor list for transmit and receive. In addition, ensure that the descriptors are owned by DMA (set bit 31 of descriptor TDES3/RDES3). For more information about descriptors, see Descriptors
5. Program the Transmit and Receive Ring length registers (DMA_CH(#i)_TXDESC_RING_LENGTH (for i = 0; i <= 1) and DMA_CH#_RX_CONTROL2 (for i = 0; i <= 1)). The ring length programmed must be at least 4.

    NOTE

    The descriptor address from the start to the end of the ring must not cross the 4GB boundary.

6. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_RXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). Also, program transmit and receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CH(#i)_TXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1))

    NOTE

    For 40-bit or 48-bit addressing mode, program the higher address List registers (DMA_CH[n]_TXDESC_LIST_HADDRESS, DMA_CH[n]_RXDESC_LIST_HADDRESS).

    The tailpointer registers must be advanced to the location immediately after the descriptors that are set, for the DMA to know that additional descriptors are available.

7. Program the settings of the following registers for the parameters like maximum burst-length (PBL) initiated by DMA, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
    - DMA_CH(#i)_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
    - DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
    - DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)
8. Enable the interrupts by programming the DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
9. Start the Receive and Transmit DMAs by setting SR (bit 0) of the DMA_CH(#i)_RX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) and ST (bit 0) of the DMA_CH(#i)_TX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
10. Repeat steps 4 to 9 for all the Tx DMA and Rx DMA channels selected in the hardware.

43.6.2 Initializing MTL Registers

The Transaction Layer (MTL) registers must be initialized to establish the transmit and receive operating modes and commands.

Complete the following steps to initialize the MTL registers:

1. Program the Tx Scheduling (SCHALG) and Receive Arbitration Algorithm (RAA) fields in MTL_Operation_Mode to initialize the MTL operation in case of multiple Tx and Rx queues.
2. Program the Receive Queue to DMA mapping in MTL_RxQ_DMA_Map0 and MTL_RxQ_DMA_Map1 registers.
3. Program the following fields to initialize the mode of operation in the MTL_TxQ0_Operation_Mode register.

a. Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) in case of threshold mode
b. Transmit Queue Enable (TXQEN) to value 2'b10 to enable Transmit Queue0
c. Transmit Queue Size (TQS)

4. Program the following fields to initialize the mode of operation in the MTL_RxQ0_Operation_Mode register:
   a. Receive Store and Forward (RSF) or RTC in case of Threshold mode
   b. Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD)
   c. Error Packet and undersized good Packet forwarding enable (FEP and FUP)
   d. Receive Queue Size (RQS)
5. Repeat previous two steps for all MTL Tx and Rx queues selected in the configuration.

43.6.3 Initializing MAC

The MAC configuration registers establish the operating mode of the MAC. These registers must be initialized before initializing the DMA.

The following MAC Initialization operations can be performed after DMA initialization. If the MAC initialization is completed before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: MAC_ADDRESS0_HIGH and MAC_ADDRESS0_LOW. If more than one MAC address is enabled in your configuration, program the MAC addresses appropriately.
2. Program the following fields to set the appropriate filters for the incoming frames in the MAC_PACKET_FILTER register:
   a. Receive All
   b. Promiscuous mode
   c. Hash or Perfect Filter
   d. Unicast, multicast, broadcast, and control frames filter settings
3. Program the following fields for proper flow control in the MAC_Q0_TX_FLOW_CTRL register:
   a. Pause time and other Pause frame control bits
   b. Transmit Flow control bits
   c. Flow Control Busy
4. Program the MAC_INTERRUPT_ENABLE register, as required, and if applicable, for your configuration.
5. Program the appropriate fields in the MAC_CONFIGURATION register. For ex: Inter-packet gap while transmission and jabber disable.
6. Set bit 0 and 1 in MAC_CONFIGURATION register to start the MAC transmitter and receiver.

43.7 Application Information

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

43.7.1 Performing Normal Receive and Transmit Operation

During normal operation of the module, normal and transmit interrupts are read, descriptors polled, the DMA is suspended (if it does not own descriptors), and values of current host transmitter or receiver descriptor pointers are read for debugging.

For normal operation, complete the following steps:

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive).
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register (DMA_CH[n]_TXDESC_TAIL_POINTER and DMA_CH[n]_RXDESC_TAIL_POINTER).
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process (DMA_CH[n]_CURRENT_APP_TXDESC and DMA_CH[n]_CURRENT_APP_RXDESC).
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (Register DMA_CH[n]_CURRENT_APP_TXBUFFER and DMA_CH[n]_CURRENT_APP_RXBUFFER).

43.7.2 Stopping and Starting Transmission

Complete the following steps to pause the transmission.

NOTE

The steps are provided for Channel 0.

1. Disable the Transmit DMA (if applicable) by clearing Bit 0 (ST) of DMA_CH(#i)_TX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) Register.
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of MTL_TXQ0_DEBUG Register (TRCSTS is not 01 and TXQSTS=0).
3. Disable the MAC transmitter and MAC receiver by clearing Bit (RE) and Bit 1(TE) of the MAC_Config-uration Register.
4. Disable the Receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of MTL_TXQ0_DEBUG Register, PRXQ=0 and RXQSTS=00).
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in MTL_TXQ0_DEBUG Register and RXQSTS is 0 in MTL_RXQ0_DEBUG Register).
6. To restart the operation, first start the DMAs, and then enable the MAC Transmitter and Receiver.

NOTE

- Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. These parameters are changed by software only when the MAC transmitter and receiver are not active.
- Similarly, do not change the DMA-related configuration when Transmit and Receive DMA are active.

43.7.3 Programming Guidelines for Switching to New Descriptor List in RxDMA

Switching to a new descriptor list is different in the Rx DMA compared to the Tx DMA. Switching to a new descriptor list is permitted when the RxDMA is in SUSPEND state, as clarified by the following points:

- Generally, RxDMA prepares the descriptors in advance.
- If the RxDMA goes to SUSPEND due to descriptors not being available, a major failure occurs (software is not able to free the filled-up descriptors/buffers). If this issue is not rectified immediately, frames will be lost because of an RxFIFO Overflow. Therefore, the software is allowed to create a new descriptor list and program the RxDMA to start using it immediately, without going into STOP state.

43.7.4 Programming Guidelines for Multi-Channel Multi-Queuing

43.7.4.1 Transmit

1. Program the Transmit queue size in the TQS field of MTL_TXQ[n]_OPERATION_MODE register. Based on the value programmed in the TQS field, the size of the queue is determined.

   In the Transmit operation, the number of channels is equal to the number of the queues. Due to this reason, the Channel-to-Queue mapping is fixed.

2. For a queue to be used, the queue must be enabled in TXQEN in the corresponding MTL_TXQ[n]_OPERATION_MODE Register. In DMA configurations, the ST bit of DMA_CH[n]_TX_CONTROL Register and corresponding TXQEN in MTL_TXQ[n]_OPERATION_MODE Register needs to be enabled.
3. The scheduling method needs to be programmed in SCHALG of MTL_OPERATION_MODE register.
4. Program the MTL_TXQ[n]_Quantum_Weight for DCB queue as per the selected algorithm. In case of CBS algorithm in AVB queues, the MTL_TXQ[n]_ETS_CONTROL, MTL_TXQ[n]_SENDSLOPECREDIT, MTL_TXQ[n]_HICREDIT and MTL_TXQ[n]_LOCREDIT registers also need to be programmed as required.
5. If DCB is enabled and PFC function is required, program MAC_TXQ_PRTY_MAP0 Register to assign a fixed priority to the queue. This priority assigned is used for determining if the corresponding queue should stop transmitting packet based on the received PFC packet.

43.7.4.2 Receive

1. Program the Receive queue size in the RQS field of MTL_RXQ[n]_OPERATION_MODE Register. Based on the value programmed in RQS field, the size of the queue is determined.
2. Enable the Receive Queues 0 to 4 in the fields RXQ0EN to RXQ4EN in MAC_RXQ_CTRL0 Register for AV or DCB. In DMA configurations, SR bit of statically or dynamically mapped DMA_CH[n]_RX_CONTROL Register and corresponding RXQ[n]_EN in MAC_RXQ_CTRL0 Register needs to be enabled.
3. The MAC routes the Rx packets to the Rx Queues based on following packet types:
   a. AV PTP Packets: Based on the programming of AVPTPQ in MAC_RXQ_CTRL1 Register.
   b. AV Untagged Control packets: Based on the programming of AVCPQ in MAC_RXQ_CTRL1 Register.
   c. Data Center Bridging (DCB) related Link Layer Discovery Protocol (LLDP) packets. Program DCBCPQ in MAC_RXQ_CTRL1 Register to indicate to MAC which queue should get the DCB packets.
   d. VLAN Tag Priority field in VLAN Tagged packets: Program PSRQ4-0 of the MAC_RXQ_CTRL2 and MAC_RXQ_CTRL3 Register for the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 4.
   e. The AV tagged control and data packets are also routed based on PSRQ field of the MAC_RXQ_CTRL2 and MAC_RXQ_CTRL3 registers.

   NOTE

   The priorities set in PSRQ4-0 should be unique.

4. If multiple RX DMA channels are enabled, the following programming should be done for proper arbitration and mapping:
   a. Program the RAA field of MTL_OPERATION_MODE register to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.
   b. Program the MTL_RXQ[n]_CONTROL to decide the weights and the packet arbitration for each RxQ.
   c. If static mapping is programmed in MTL_RXQ_DMA_MAP[n] register (RXQ[n]DADMACH is reset to 0), bits RXQx2DMA and others need to be programmed to select the channel for which each queue is mapped.
   d. Set RXQ[n]DADMACH bit in MTL_RXQ_DMA_MAP0 Register to select dynamic mapping of packets in each RxQueue.

e. In dynamic channel mapping, the routing of a packet to a specific RxDMA channel is decided by the value of DCS field in the lowest MAC Address Register.

43.7.4.2.1 Programming Guidelines for Recovering from DMA Channel Failure

When the DMA channel issues a bus error, follow these steps to recover from the failure.

Recovering from the Receive DMA Channel Failure

1. Set the RPF bit to 1. This flushes all the packets one after the other.

   This step is optional. However, setting this bit prevents HOL (head-of-line) blocking in the Rx queues when packets sent to the RXDMA are stopped due to bus error.
2. Reprogram the specific Registers of the DMA channel.
3. Start the DMA channel.

Recovering from the Transmit DMA Channel Failure

1. Stop the specific DMA channel, even if it is in active state.
2. Flush the corresponding MTL queue.
3. Reprogram the specific Registers of the DMA channel.
4. Start the DMA channel.

NOTE

Due to the known limitations in the design, reprogramming the DMA channel registers might not always be successful in recovering from a Bus Error. If the module is not fully functional after reprogramming the DMA, as a workaround, issue a Soft Reset to recover from the Bus Error.

43.7.5 Programming Guidelines for IEEE 1588 Timestamping

43.7.5.1 Initialization Guidelines for System Time Generation

You can enable the timestamp feature by setting Bit 0 of the MAC_TIMESTAMP_CONTROL Register. However, it is essential that the timestamp counter be initialized after this bit is set. Complete the following steps during the module initialization:

1. Mask the Timestamp Trigger interrupt by clearing the bit 16 of MAC_INTERRUPT_ENABLE Register.
2. Set Bit 0 of MAC_TIMESTAMP_CONTROL Register to enable timestamping.
3. Program MAC_SUB_SECOND_INCREMENT Register based on the PTP clock frequency.
4. If you are using the Fine Correction approach, program MAC_Timestamp_Addend and set Bit 5 of MAC_TIMESTAMP_CONTROL Register.
5. Poll the MAC_TIMESTAMP_CONTROL Register until Bit 5 is cleared.
6. Program Bit 1 of MAC_TIMESTAMP_CONTROL Register to select the Fine Update method (if required).
7. Program MAC_SYSTEM_TIME_SECONDS_UPDATE Register and MAC_SYSTEM_TIME_NANOSECONDS_UPDATE Register with the appropriate time value.
8. Set Bit 2 in MAC_TIMESTAMP_CONTROL Register.
9. The timestamp counter starts operation as soon as it is initialized with the value written in the Timestamp Update registers. If one-step timestamping is enabled
   a. To enable one-step timestamping, program Bit 27 of the TDES3 Context Descriptor.
   b. Program registers MAC_TIMESTAMP_INGRESS_ASYM_CORR and MAC_TIMESTAMP_EGRESS_ASYM_CORR to update the correction field in PDelay_Req PTP messages.
10. Enable the MAC receiver and transmitter for proper timestamping.

NOTE

If timestamp operation is disabled by clearing Bit 0 of MAC_TIMESTAMP_CONTROL Register, repeat all these steps to restart the timestamp operation.

43.7.5.2 System Time Correction

43.7.5.2.1 Coarse Correction Method

To synchronize or update the system time in one process (coarse correction method):

1. Set the offset (positive or negative) in the Timestamp Update registers(MAC_SYSTEM_TIME_SECONDS_UPDATE and MAC_SYSTEM_TIME_NANOSECONDS_UPDATE).
2. Set Bit 3 (TSUPDT) of MAC_TIMESTAMP_CONTROL REGISTER.

The value in the Timestamp Update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

43.7.5.2.2 Fine Correction Method

To synchronize or update the system time to reduce system-time jitter (fine correction method):

1. With the help of the algorithm, calculate the rate by which you want to make the system time increments slower or faster.
2. Update the MAC_TIMESTAMP_ADDEND with the new value and set Bit 5 of the MAC_TIMESTAMP_CONTROL Register.
3. Wait for the time for which you want the new value of the Addend register to be active. You can do this by enabling the Timestamp Trigger interrupt after the system time reaches the target value.
4. Program the required target time in MAC_PPS[n]_TARGET_TIME_SECONDS Register and MAC_PPS[n]_TARGET_TIME_NANOSECONDS Register.
5. Enable the Timestamp interrupt in bit 12 of MAC_INTERRUPT_ENABLE register.
6. Set bit 4 in Register MAC_Timestamp_Control.
7. When this trigger causes an interrupt, read MAC_INTERRUPT_STATUS Register.
8. Reprogram MAC_TIMESTAMP_ADDEND Register with the old value and set bit 5 again.

43.7.6 Programming Guidelines for AV Feature

After you enable the AV feature in the module controller, there are several programming tasks to be followed:

- Initializing the DMA for QOS-AHB configurations only
- Enabling slot number checking
- Enabling average bits per slot reporting
- Disabling flow control for AV-enabled queues (transmit and receive flow control)

43.7.6.1 Initializing the DMA in Audio Video Feature

The first step in programming the AV feature in a QOS-AHB configuration is to initialize the DMA.

Use this initialization sequence for QOS-AHB/QOS-AXI configurations with AV feature.

1. Provide a software reset to reset all QOS internal registers and logic (bit 0 in DMA_MODE register).
2. Wait for the completion of the reset process. Poll bit 0 of the DMA_MODE register), which is cleared only after the reset operation is completed.
3. Program the fields to initialize the DMA register by setting the values in DMA_MODE register.

4. Create a proper descriptor list for transmit and receive. In addition, ensure that the DMA owns the Transmit and Receive descriptors. When OSF mode is used, at least two TX descriptors are required.

   For more information about descriptors, see Descriptors .

5. Make sure that your software creates three or more different transmit or receive descriptors in the list before reusing any of the descriptors.
6. Program the Transmit and Receive Ring length registers (DMA_CH(#i)_TXDESC_RING_LENGTH (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH#_RX_CONTROL2 (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). The ring length programmed must be at least 4.
7. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_TXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)). In addition, you must program the Transmit and Receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CH(#i)_TXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_D-MA_TX_CH-1) and DMA_CH(#i)_RXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_D-MA_RX_CH-1)).
8. Program the following fields to initialize the mode of operation in the MTL_TXQ0_OPERATION_MODE register:
   a. Transmit Store And Forward (TSF)
   b. Transmit Threshold Control (TTC)
   c. Transmit Queue Enable (TXQEN) to value 2‘b10 to enable Transmit Queue0
   d. Transmit Queue Size (TQS)
9. Enable the interrupts by programming the DMA_CH(#i)_INTERRUPT_ENABLE (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
10. Repeat steps 4 through 9 for all additional channels of AV feature.
11. Program the CBS control register, idleSlope, sendSlope, hiCredit, and loCredit registers of the AV Queues.
12. Start the Receive and Transmit DMA by setting bit 0 of the DMA_CH(#i)_TX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register and bit 0 of the DMA_CH(#i)_RX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) register.

43.7.6.2 Enabling Slot Number Checking

You can enable slot number checking to specify the intervals at which the DMA channels mapped to AV Queues fetch the frames from the AHB/AXI system bus.

These steps should be completed after step 11 and before step 12 of "Initializing DMA".

You can use the slot number check feature to specify the intervals at which the DMA Channels mapped to AV Queues fetch the frames from the AHB/AXI system bus. This feature is useful for a uniform and periodic transfer of the AV traffic from the host memory. The feature is available only when you enable timestamping and program the MAC_SUB_SECOND_INCREMENT register. To enable the slot number checking:

1. Enable timestamping by following the steps described in "Initialization Guidelines for System Time Generation".
2. Make sure that the SLOTNUM field (bits 22:19) of TDES3 Normal Descriptor (Read Format) contains a valid slot number. You can read the current reference slot number from the DMA_CH(#i)_Slot_Function_Control_Status (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1).
3. Set Bit 0 (ESC) of the Slot Function Control and Status register of a channel to enable the slot number checking.

43.7.6.3 Enabling Average Bits Per Slot Reporting

You can enable the reporting of the average bits that are transmitted in a slot.

The CBS Status register of the additional AV channels provides information about the average bits that are transmitted in a slot. The software can asynchronously read this register to retrieve information about the average bits transmitted per slot. To enable average bits per slot reporting:

1. Enable timestamping by following the steps described in the Initialization Guidelines for System Time Generation .
2. Program Bits [6:4], SLC, of the MTL_TXQ[n]_ETS_CONTROL register of a channel with the number of slots over which the average transmitted bits per slot need to be computed.
3. Enable Bit 9(ABPSSIE) of the MTL_Q[n]_INTERRUPT_CONTROL_STATUS register of a channel to generate the average bits per slot interrupt.

NOTE

- The frequency of this interrupt depends on the value programmed in step 2. For example, when you program value 0 in the SLC field, the interrupt is generated at every 125 microsecond.
- When not required, you can disable this interrupt to stop the interrupt flooding.

4. Read Bits [16:0], ABS, from the MTL_TXQ[n]_ETS_STATUS register of a channel on each interrupt.

NOTE

The software can read the ABS bits in polling mode even if the ABPSIE bit is not enabled. When high, bit 1 (ABPSIS) of the MTL_TXQ[n]_ETS_STATUS register indicates that a new value is updated in the ABS field.

43.7.6.4 Disabling Flow Control for AV Enabled Queues

43.7.6.4.1 Transmit Flow

Program the EHFC (Enable Hardware Flow Control) bit of corresponding Rx Queue's MTL_RXQ[n]_OPERATION_MODE register to 0.

43.7.6.4.2 Receive Flow Control

Program the PSTQ[n] field corresponding to AV enabled Tx Queue in MAC_TXQ_PRTY_MAP0/1 register to 0.

43.7.6.5 Programming Guidelines for Flexible Pulse-Per-Second Output

After you enable the Flexible Pulse-Per-Second Output feature in the module controller, you can perform the following tasks:

- Generating Single Pulse on PPS
- Generating Next Pulse on PPS
- Generating a Pulse Train on PPS
- Generating an Interrupt without Affecting the PPS

43.7.6.5.1 Generating Single Pulse on PPS

To generate single pulse on PPS:

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_CONTROL Register.
   This instructs the MAC to use the Target Time registers (MAC_PPS0_TARGET_TIME_SECONDS and MAC_PPS0_TARGET_TIME_NANOSECONDS) for start time of PPS signal output.
2. Program the start time value in the Target Time registers (MAC_PPS0_TARGET_TIME_SECONDS and MAC_PPS0_TARGET_TIME_NANOSECONDS).
3. Program the width of the PPS signal output in MAC_PPS(#i)_WIDTH (for i = 0; i <= 3) Register.
4. Program Bits [3:0], PPSCMD, of MAC_PPS_CONTROL to 0001. This instructs the MAC to generate single pulse on the PPS signal output at the time programmed in the Target Time registers.

43.7.6.5.2 Generating Next Pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time elapses. You can also program the behavior of the next pulse in advance.

To program the next pulse:

1. Program the start time for the next pulse in the Target Time registers. This time should be more than the time at which the falling edge occurs for the previous pulse.
2. Program the width of the next PPS signal output in MAC_PPS(#i)_WIDTH (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1).
3. Program Bits [3:0], PPSCMD, of MAC_PPS_CONTROL to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs the MAC to generate single pulse on the PPS signal output, at the time programmed in Target Time registers.

   If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the QOS may generate only 1 extended pulse.

43.7.6.5.3 Generating a Pulse Train on PPS

To generate a pulse train on PPS:

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_Control Register. This instructs the MAC to use the Target Time registers for start time of the PPS signal output.
2. Program the start time value in the Target Time registers.
3. Program the interval value between the train of pulses on the PPS signal output in MAC_PPS(#i)_INTERVAL (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) Register.
4. Program the width of the PPS signal output in MAC_PPS(#i)_WIDTH (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) Register.
5. Program Bits[3:0], PPSCMD, of MAC_PPS_CONTROL Register to 0010. This instructs the MAC to generate train of pulses on the PPS signal output with start time programmed in Target Time registers.

   By default, the PPS pulse train is free-running unless stopped by ‘STOP Pulse train at time’ or ‘STOP Pulse Train immediately’ commands.
6. Program the stop value in the Target Time registers. Ensure that Bit 31 (TSTRBUSY) of MAC_PPS(#i)_TARGET_TIME_NANOSECONDS (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) Register is reset before programming the Target Time registers again.
7. Program the PPSCMD field (bit 3:0) of MAC_PPS_CONTROL to 0100. This stops the train of pulses on PPS signal output after the programmed stop time specified in Step 6 elapses.

   You can stop the pulse train at any time by programming 0101 in the PPSCMD field. Similarly, you can cancel the Stop Pulse train command (given in Step 7) by programming 0110 in the PPSCMD field before the time (programmed in Step 6) elapses. You can cancel the pulse train generation by programming 0011 in the PPSCMD field before the programmed start time (in Step 2) elapses.

43.7.6.5.4 Generating an Interrupt without Affecting the PPS

You can use bits[6:5], TRGTMODSEL, of the MAC_PPS_CONTROL Register to program the Target Time registers to do any one of the following:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

To program the Target Time registers to generate only interrupt events:

1. Program 00 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_CONTROL Register. This instructs the MAC to use the Target Time registers for target time interrupt.
2. Program a target time value in the Target Time registers. This instructs the MAC to generate an interrupt when the target time elapses.

   If Bits [6:5], TRGTMODSEL, are changed (for example, to control the PPS), then the interrupt generation is overwritten with the new mode and new programmed Target Time register value.

43.7.6.6 Programming Guidelines for VLAN Filtering on Receive

To program VLAN filtering on receive:

1. Program MAC_VLAN_TAG register for the following bit to select the filtering method:
   a. ETV: Enable 12-Bit VLAN Tag Comparison or 16-bit VLAN Tag comparison.
   b. VTHM: VLAN Tag Hash Table Match Enable.
   c. ERIVLT: Enable inner VLAN Tag or outer VLAN Tag (to enable the inner or outer VLAN Tag filtering, Double VLAN Processing should enabled by setting EDVLP)
   d. ERSVLM: Enable Receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set ESVL)
   e. DOVLTC: Ignores VLAN Type for Tag Match
   f. VTIM: to enable VLAN Tag Inverse Match instead of the normal VLAN Tag matching
2. Program VL of MAC_VLAN_Tag Register for the 12-bit or 16-bit VLAN tag.
3. If Hash filtering of VLAN tag is enabled, program MAC_VLAN_HASH_TABLE Register. When ETV bit is reset, upper 4 bits of the calculated CRC-32 of VLAN Tag are inverted and used to index the content of MAC_VLAN_Hash_Table register. When ETV bit is set, upper 4 bits of calculated CRC-32 of VLAN Tag are used to index the content of MAC_VLAN_HASH_TABLE register. For example, when ETV bit is set, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. When ETV bit is reset a hash value of 4'b1000 selects Bit 7 of the VLAN Hash table.

43.7.6.7 Programming Guidelines for Extended VLAN Filtering and Routing on Receive

For the indirect access of the per VLAN Tag registers, follow these steps.

- Write
  1. Write the required data into the MAC VLAN Tag Data register.
  2. Program the VLAN Tag Control Register's OFS field with the required Filter Register's offset and command type to the CT field. For a write command, set this bit to 0.
  3. Write 1 to the OB field and wait till the OB bit is reset to do the next write. This will guarantee that the appropriate VLAN Tag Filter Register has been programmed.
- Read
  1. Program the VLAN Tag Control Register's OFS Field with the required register's offset and command type to the CT field. For a read command, set this bit to 1.
  2. Write 1 to the OB field and wait till the OB bit is reset. The appropriate VLAN Tag Filter register's value is available in the MAC VLAN Tag Data Register.

43.7.6.8 Programming Sequence for Queue/Channel Based VLAN Inclusion Register

To program the queue/channel-based VLAN inclusion register:

NOTE

Indirect VLAN include registers are not accessed while setting the CBTI bit.

1. Set the CBTI bit of MAC_VLAN_INCL register to 1, to enable queue/channel based VLAN Tag insertion on all transmitted packets. This bit must be set before any indirect access to the queue/channel specific MAC_VLAN_INCL(#i) register.
2. Program the VLAN Tag and VLAN Type to be inserted in packets from a particular queue/channel in VLT and CSVL fields of MAC_VLAN_INCL register; corresponding offset address in ADDR field (0 for queue/channel 0, 1 for queue/channel 1, and so on) must be set. Set the RDWR bit to 0 to indicate write access. The write to byte 0 (byte 3 in Big Endian mode) of MAC_VLAN_INCL register initiates access to indirect access MAC_VLAN_INCL(#i) register.
3. The BUSY bit of MAC_VLAN_INCL register is set by the module to indicate the progress of access to indirect access MAC_VLAN_INCL(#i) register. On completion of the access, the BUSY bit is cleared. The application must not attempt subsequent access to MAC_VLAN_INCL(#i) register when the BUSY bit is 1.
4. Repeat step 2 and step 3 to program VLAN Tag and VLAN Type to be inserted in packets from the remaining queues/channels. The application must ensure that the required VLAN Tag and VLAN Type for all the queues/channels are programmed; otherwise unintended VLAN Tag and VLAN Type might be inserted.

43.7.7 Programming Guidelines for EST

Program the gate control values and time intervals in the Software Owned Gate Control List (SWOL) along with the other EST related registers that are described in ENET_QOS register descriptions to appropriate values. The following sub-sections provide step by step details for programming the GCL and the other EST related registers.

43.7.7.1 Programming the GCL and GCL Linked Registers

To program the Gate Control List (GCL) and the four other registers implemented per GCL:

1. The GCL and the four other GCL-linked registers should be accessed via indirect addressing using the MTL_EST_GCL_CONTROL and MTL_EST_GCL_DATA registers. The SWOL bit of the MTL_EST_STATUS register indicates if GCL0 or GCL1 is owned by software.
2. To program the GCL, write the 32-bit write data to MTL_EST_GCL_DATA register. Then program TL_EST_GCL_CONTROL register to write the write address and other control information.
3. In the MTL_EST_GCL_DATA register, Write Data consists of up to 8 bits (5 configurable, 3 reserved) of Gate Controls and up to 24 bits (configurable) of Time Interval. Gate Close is indicated by programming a '0' and Gate Open is indicated by programming a '1'. For a 4-TC and 20-bit Time Interval Configuration, the data width is 24-bits and the remaining 8-bits are reserved/read-only. The data should be written in the following format.

   {8'h0, TC3, TC2, TC1, TC0, 20-bit Time Interval} where TCx = 0 or 1.
4. MTL_EST_GCL_CONTROL register: Program the SRWO bit to 1 (to start a Write Op) and program the address and R/W fields appropriately.
5. Poll and check for the SRWO bit to be cleared by hardware to indicate the completion of the previous operation before initiating a new R/W operation via the same indirect addressing mode.
6. Repeat steps 3, 4, 5 until the programming of the GCL is completed.
7. Using the same indirect addressing method described above, program the BTR, CTR, TER and LLR registers. Set the GCRR bit in the MTL_EST_GCL_CONTROL register appropriately. The GCRR bit interprets the address field as belonging to these registers (instead of the GCL).

After programming of the GCL and the related registers, program the MTL_EST_CONTROL register to allow hardware to own and process the GCL.When the List Length (as indicated in LLR) is 1, the associated Time Interval should be smaller than the value of the Cycle Time Register. Otherwise, an error is reported (as detailed in the Error handling section) as a single set of gate controls add no value in the TSN context.

NOTE

The time unit in all the GCL related registers is seconds and nanoseconds. In cases where internally generated PTP System Time is used, the nanoseconds field must be programmed to use the Digital Rollover mode. (TSCTRLSSR field of MAC_TIMESTAMP_CONTROL must be set to value '1')

43.7.7.2 Programming the EST Registers

After completing the steps mentioned in "Programming the GCL and GCL Linked Registers" , program the MTL_EST_CONTROL register.

1. Set the Current Time Offset Value and Time Internal Left Shift fields of the MTL_EST_CONTROL register appropriately. Also, set the Enable EST (EEST) and Switch to SWOL (SWOL) bits.

   NOTE

   The CTOV recommendations for GMII for SPRAM configurations are:

   - 96 * Tx clock period, for 32 and 64 bit data width configurations.
   - 128 * Tx clock period for 128 bit data width configurations.

   The CTOV recommendations for GMII for non-SPRAM configurations are:

   - 30 * Tx clock period, when SA/VLAN insertion is enabled.
   - 22 * Tx clock period, when SA/VLAN insertion is not enabled.

2. This will enable the hardware to own and process the new GCL and make a switch to the new GCL at the BTR value. The hardware provides an interrupt (if enabled) when the switch to the new list happens.
3. Appropriate action has to be taken by software to address any other interrupts (explained in the Inter-rupts section) received during the hardware execution of the GCL.

Set the SSWL (Switch to Software Owned List) bit in the MTL_EST_CONTROL register to handoff to hardware. Software is not allowed to write to the GCL and GCL linked registers when the SSWL bit is set, because the new GCL might be in use by the hardware.

The SSWL is reset/cleared by the hardware when it successfully switches to the new list. The hardware also flips the SWOL bit to indicate the new GCL that the software owns.

To install a new GCL, program the GCL it owns (indicated by SWOL bit) as described in "Programming the GCL and GCL Linked Registers" and then program the MTL_EST_CONTROL register as described above. Ensure that the new BTR is set to an appropriate value to avoid BTRError that might need software intervention in some cases.

To avoid transmission overruns, the packet length (frame size) information should be available at all times. Therefore, in the DMA configurations, program the packet length in the first descriptor of every Tx frame. Similarly, in the MTL configuration, provide the packet length in the control word.

NOTE

To avoid transmission overruns, the Packet Length provided in the Transmit Descriptor should account for the SA and VLAN insertion, if applicable, that is, Packet Length should represent the actual packet length on the Ethernet line.

43.7.8 Programming the Launch Time in Time-Based Scheduling

The Launch Time is programmed in the Enhanced Normal Transmit Descriptors in DMA configurations and is driven as a control word in MTL configurations as follows:

The OSTC and Launch Time features are mutually exclusive and should not be used together; in case of a conflict (if OSTC = LTV = 1 in MTL configuration), priority is given to OSTC and the Launch Time is ignored.

In DMA configuration, if a context descriptor is received with a valid OSTC values immediately before receiving a first normal descriptor with LTV bit set, then the LTV is ignored.

43.7.9 Programming Guidelines for Media Clock Generation and Recovery

43.7.9.1 Programming Guidelines for Media Clock Generation

1. To set the PPS instance in Media Clock generation mode, program the appropriate Presentation Time Control (supported generation modes "1001-1011") to PPSCTRL_PPSCMD (for 0th instance)/PPSCMD#i (for 1,2,3 instances) of MAC_PPS_CONTROL register.
2. Based on the selected PPS instance, application must drive the appropriate trigger signal to the corresponding mcg_pst_trig_i[#i].
3. Based on the programmed mode, DUT captures the timestamp and programs it in the MAC_PPS(#i)_TARGET_TIME_SECONDS register. Then, mcgr_dma_req_o[#i] is set.
4. For every request generated by the DUT, the module reads the corresponding MAC_PPS(#i)_TARGET_TIME_SECONDS register and acknowledge the read request by asserting the corresponding mcgr_dma_ack_i[#i].

43.7.9.2 Programming Guidelines for Media Clock Recovery

1. Enable the Current Presentation Time (CPT) Counter by setting the PTGE field of MAC_TIMESTAMP_CONTROL register. In addition to programming the initialization values for the System Time, update the MAC_PRESN_TIME_UPDT register with the equivalent Presentation Time init value. Only then the TSINIT field of MAC_TIMESTAMP_CONTROL register is set.
2. The Increment values used for the System time is also used for the Current Presentation time. This is because, the increment value is in Sub-seconds and Sub-nanoseconds.
3. When an update is needed, along with programming the update values for the System Time, the MAC_PRESN_TIME_UPDT register should be updated with the equivalent Presentation Time update value (32-bit ns). Finally, TSUPDT field of MAC_TIMESTAMP_CONTROL register must be set for the update to happen.
4. Program the MCGREN#i of MAC_PPS_CONTROL register to enable the PPS instance to operate in MCGR mode.
5. To set the PPS instance in Media Clock recovery mode, program the appropriate Presentation Time Control (supported recovery modes "0001 - 0011") to PPSCTRL_PPSCMD (for 0th instance)/PPSCMD#i (for 1,2,3 instances) of MAC_PPS_Control register.
6. After PPS instance is set in recovery mode, corresponding mcgr_dma_req_o[#i] is set by the DUT. For every request generated by the DUT, program the target presentation time into the MAC_PPS(#i)_TARGET_TIME_SECONDS register and acknowledge the request by asserting the corresponding mcgr_d-ma_ack_i[#i]. Acknowledgment can be given before/after programming the Target presentation time.
7. Observe the recovered media clock on the corresponding ptp_pps_o[#i].

43.7.10 Programming Guidelines for ECC Protection for Memories

1. Enable the ECC feature for the respective memory by setting the appropriate bit in MTL_ECC_CONTROL register.
2. A correctable interrupt (sbd_sfty_ce_intr_o) or an uncorrectable interrupt (sbd_sfty_ue_intr_o) are generated to indicate to the application if any correctable/uncorrectable/address errors are detected. Appropriate status is indicated in the DMA/MTL_ECC_INTERRUPT_STATUS register.
3. Debug mode is provided for each memory to specify errors.

NOTE

Enable the ECC feature before the traffic is online (or after the reset), otherwise false interrupts might be triggered.

43.7.10.1 Programming Guidelines for ECC Hardware Error Injection (Debug Mode)

1. Enable the ECC error injection feature for MTL TX/RX and DMA TSO, by setting the appropriate bit in the MTL_DBG_CTL register.

2. Enable the ECC error injection feature for the EST memory by setting the appropriate bit in the EST_GCL_CONTROL register.
3. Enable the ECC error injection for RX Parser memory by setting the appropriate bit in the MTL_RXP_INDIRECT_ACC_CONTROL_STATUS register. To access Rx Parser memory in debug mode, disable the Rx Parser feature by setting the FRPE bit of MTL_OPERATION_MODE register to 0.
4. Where multiple CSR writes are required, for writing single data word into the memory, the application should ensure that all the CSR writes corresponding to one memory write should have the same value for the error injection control word.

43.7.11 Programming Guidelines for On-Chip Datapath Parity Protection

Follow the below steps for on-chip datapath parity protection:

1. Set the EDPP bit of MTL_DPP_CONTROL register to enable the generation of parity and detection of parity Mismatch on datapath.
2. An uncorrectable interrupt (sbd_sfty_ue_intr_o) is generated to indicate to the application whether any parity Mismatches are detected and the appropriate status will be indicated in DMA/MTL_SAFETY_INTERRUPT_STATUS and MAC_DPP_FSM_INTERRUPT_STATUS register.
3. Debug mode is supported for each parity generator, to insert error.

NOTE

To avoid false safety interrupts, enable the datapath parity protection before the start of Rx or Tx traffic.

43.7.12 Programming Guidelines for FSM Parity and Timeout

To program the FSM parity and timeout:

1. Set the PRTYEN and TMOUTEN fields of MAC_FSM_CONTROL register to enable the FSM parity and timeout feature respectively.
2. For parity error detection, force the FSMs to enter into a state with even number of 1s and wait for the safety uncorrectable interrupt to be set with FSMPES of MAC_DPP_FSM_INTERRUPT_STATUS.
3. For Error Injection mode in FSM parity, select the appropriate clock domain for which parity error injection should be set using the [23:16] bits of MAC_FSM_CONTROL register. Wait for the safety uncorrectable interrupt to be set with FSMPES of MAC_DPP_FSM_INTERRUPT_STATUS.
4. For FSM Timeouts, program the large and normal mode values indicated by LTMRMD and NTMRMD of MAC_FSM_ACT_TIMER register.
5. Select large or normal mode tic generation per clock domain by using the [31:24] bits of MAC_FSM_CONTROL Register.
6. Set the TMR field of the MAC_ACT_TIMER field with the appropriate number of CSR clock cycles used to generate 1-microsecond tic.
7. Force the FSM in a particular clock domain to be in an active state for Timeout duration (for example, T-2T). Check for the safety interrupt and the status bit for the corresponding clock domain getting set in [15:8] bits of MAC_DPP_FSM_INTERRUPT_STATUS register.
8. For Error Injection mode in FSM timeout, select the appropriate clock domain for which timeout error injection must be set using the [15:8] bits of MAC_FSM_CONTROL register. Wait for the safety uncorrectable interrupt along with the corresponding error status set in MAC_DPP_FSM_INTERRUPT_STATUS.
9. For application/CSR interface timeout, only normal mode tic generation is used. Based on the timeouts of the configured interface, appropriate fields (MSTTES, SLVTES) of MAC_DPP_FSM_INTERRUPT_STATUS are set along with the safety interrupt.

43.8 Memory Map and register definition

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

This section includes the ENET module memory map and detailed descriptions of all registers.

43.8.1 ENET_QOS register descriptions

43.8.1.1 ENET_QOS memory map

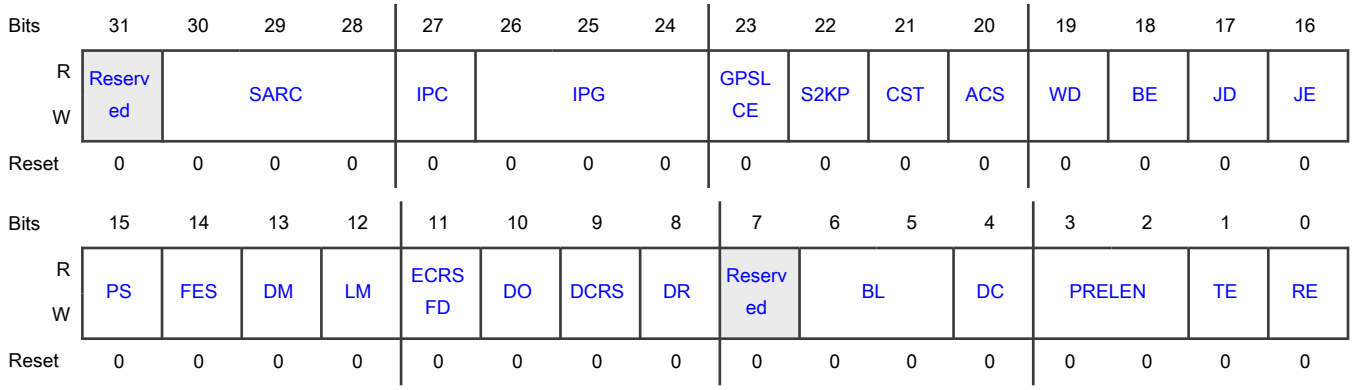
43.8.1.2 MAC Configuration Register (MAC_CONFIGURATION)

The MAC Configuration Register establishes the operating mode of the MAC.

Offset

Register	Offset
MAC_CONFIGURATION	0h

Diagram



Fields

Field	Description
31 —	Reserved
30-28 SARC	Source Address Insertion or Replacement Control This field controls the source address insertion or replacement for all transmitted packets. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[29:28]: 2'b0x: - The mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation. 2'b10:

Table continues on the next page...

Table continued from the previous page...

Field	Description
	- If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the core, the MAC inserts the content of the MAC Address 1 registers in the SA field of all transmitted packets. 2'b11: - If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers in the SA field of all transmitted packets. Note: - Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 000 - mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation 010 - Contents of MAC Addr-0 inserted in SA field 011 - Contents of MAC Addr-0 replaces SA field 110 - Contents of MAC Addr-1 inserted in SA field 111 - Contents of MAC Addr-1 replaces SA field
27 IPC	Checksum Offload When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled. The Layer 3 and Layer 4 Packet Filter and Enable Split Header features automatically selects the IPC Full Checksum Offload Engine on the Receive side. When any of these features are enabled, you must set the IPC bit. 0 - IP header/payload checksum checking is disabled 1 - IP header/payload checksum checking is enabled
26-24 IPG	Inter-Packet Gap These bits control the minimum IPG between packets during transmission. Inter-Packet Gap These bits control the minimum IPG between packets during transmission. This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG. The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_EXT_CONFIGURATION register is reset. When EIPGEN is set, then the minimum IPG

Table continues on the next page...

Table continued from the previous page...

Field	Description
	(greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_EXT_CONFIGURATION register. 000 - 96 bit times IPG 001 - 88 bit times IPG 010 - 80 bit times IPG 011 - 72 bit times IPG 100 - 64 bit times IPG 101 - 56 bit times IPG 110 - 48 bit times IPG 111 - 40 bit times IPG
23 GPSLCE	Giant Packet Size Limit Control Enable When this bit is set, the MAC considers the value in GPSL field in MAC_EXT_CONFIGURATION register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status. 0 - Giant Packet Size Limit Control is disabled 1 - Giant Packet Size Limit Control is enabled
22 S2KP	IEEE 802. IEEE 802.3as Support for 2K Packets When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, see the Table, Gaint Packet Status based on S2KP and JE Bits. Note: When the JE bit is set, setting this bit has no effect on the giant packet status. 0 - Support upto 2K packet is disabled 1 - Support upto 2K packet is Enabled
21 CST	CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. Note: For information about how the settings of the ACS bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bits. 0 - CRC stripping for Type packets is disabled 1 - CRC stripping for Type packets is enabled
20 ACS	Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming packets to the application, without any modification. Note: For information about how the settings of CST bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bit . 0 - Automatic Pad or CRC Stripping is disabled 1 - Automatic Pad or CRC Stripping is enabled
19 WD	Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes. 0 - Watchdog is enabled 1 - Watchdog is disabled
18 BE	Packet Burst Enable When this bit is set, the MAC allows packet bursting during transmission in the GMII half-duplex mode. 0 - Packet Burst is disabled 1 - Packet Burst is enabled
17 JD	Jabber Disable When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes. When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet. 0 - Jabber is enabled 1 - Jabber is disabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
16 JE	Jumbo Packet Enable When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status. 0 - Jumbo packet is disabled 1 - Jumbo packet is enabled
15 PS	Port Select This bit selects the Ethernet line speed. This bit, along with Bit 14, selects the exact line speed. In the 10/100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, this bit is read-only (RO) with appropriate value. In default 10/100/1000 Mbps configurations, this bit is read-write (R/W). The mac_speed_o[1] signal reflects the value of this bit. 0 - For 1000 or 2500 Mbps operations 1 - For 10 or 100 Mbps operations
14 FES	Speed This bit selects the speed mode. The mac_speed_o[0] signal reflects the value of this bit. 0 - 10 Mbps when PS bit is 1 and 1 Gbps when PS bit is 0 1 - 100 Mbps when PS bit is 1 and 2.5 Gbps when PS bit is 0
13 DM	Duplex Mode When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously. This bit is RO with default value of 1'b1 in the full-duplex-only configurations. 0 - Half-duplex mode 1 - Full-duplex mode
12 LM	Loopback Mode When this bit is set, the MAC operates in the loopback mode at GMII. The (G)MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back. 0 - Loopback is disabled 1 - Loopback is enabled
11 ECRSFD	Enable Carrier Sense Before Transmission in Full-Duplex Mode When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal. 0 - ECRSFD is disabled 1 - ECRSFD is enabled
10	Disable Receive Own

Table continues on the next page...

Table continued from the previous page...

Field	Description
DO	When this bit is set, the MAC disables the reception of packets when the gmii_txen_o is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY. This bit is not applicable in the full-duplex mode. 0 - Enable Receive Own 1 - Disable Receive Own
9 DCRS	Disable Carrier Sense During Transmission When this bit is set, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission. 0 - Enable Carrier Sense During Transmission 1 - Disable Carrier Sense During Transmission
8 DR	Disable Retry When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode. 0 - Enable Retry 1 - Disable Retry
7 —	Reserved
6-5 BL	Back-Off Limit The back-off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbps; 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. n = retransmission attempt. The random integer r takes the value in the range 0 <= r < 2^k This bit is applicable only in the half-duplex mode. 00 - k = min(n,10) 01 - k = min(n,8) 10 - k = min(n,4) 11 - k = min(n,1)
4	Deferral Check

Table continues on the next page...

Table continued from the previous page...

Field	Description
DC	When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. If the MAC is configured for 1000/2500 Mbps operation, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode. 0 - Deferral check function is disabled 1 - Deferral check function is enabled
3-2 PRELEN	Preamble Length for Transmit packets These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. 00 - 7 bytes of preamble 01 - 5 bytes of preamble 10 - 3 bytes of preamble 11 - Reserved
1 TE	Transmitter Enable When this bit is set, the Tx state machine of the MAC is enabled for transmission on the GMII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets. 0 - Transmitter is disabled 1 - Transmitter is enabled
0 RE	Receiver Enable When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the GMII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the GMII interface. 0 - Receiver is disabled 1 - Receiver is enabled

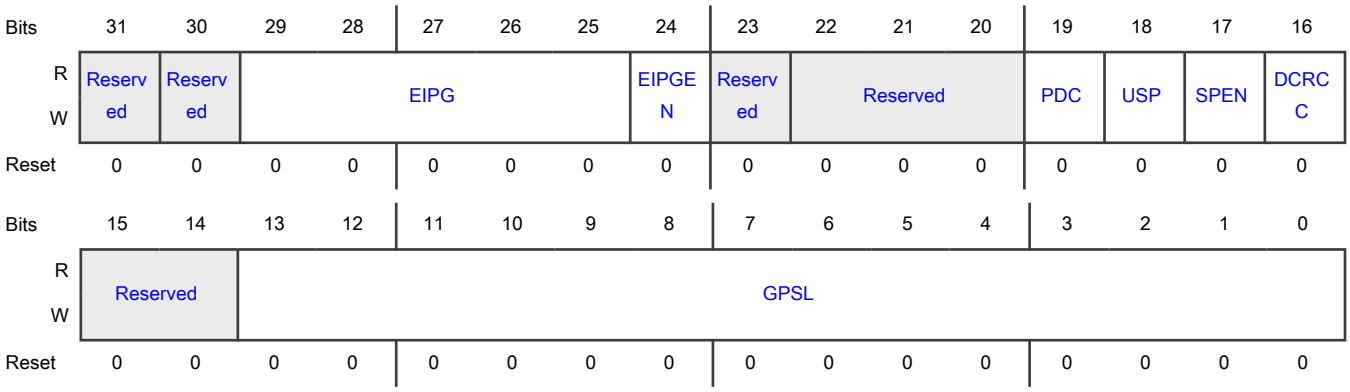
43.8.1.3 MAC Extended Configuration Register (MAC_EXT_CONFIGURATION)

The MAC Extended Configuration Register establishes the operating mode of the MAC.

Offset

Register	Offset
MAC_EXT_CONFIGURATION	4h

Diagram



Fields

Field	Description
31 —	Reserved
30 —	Reserved
29-25 EIPG	Extended Inter-Packet Gap The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits), along with IPG field in CONFIGURATION register, gives the minimum IPG greater than 96 bit times in steps of 8 bit times: {EIPG, IPG} 8'h00 - 104 bit times 8'h01 - 112 bit times 8'h02 - 120 bit times ---------- 8'hFF - 2144 bit times
24 EIPGEN	Extended Inter-Packet Gap Enable When this bit is set, the MAC interprets EIPG field and IPG field in CONFIGURATION register together as minimum IPG greater than 96 bit times in steps of 8 bit times.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is reset, the MAC ignores EIPG field and interprets IPG field in CONFIGURATION register as minimum IPG less than or equal to 96 bit times in steps of 8 bit times. Note: The extended Inter-Packet Gap feature must be enabled when operating in Full-Duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-Duplex mode. 0 - Extended Inter-Packet Gap is disabled 1 - Extended Inter-Packet Gap is enabled
23 —	Reserved
22-20 —	Reserved
19 PDC	Packet Duplication Control When this bit is set, the received packet with Multicast/Broadcast Destination address is routed to multiple Receive DMA Channels. The Receive DMA Channels is identified by the DCS field of MAC_ADDRESS(#i)_HIGH register corresponding to the MAC Address register that matches the Multicast/Broadcast Destination address in the received packet. The DCS field is interpreted to be a one-hot value, each bit corresponding to the Receive DMA Channel. When this bit is reset, the received packet is routed to single Receive DMA Channel. The Receive DMA Channel is identified by the DCS field of ADDRESS(#i)_High register corresponding to the MAC Address register that matches the Destination address in the received packet. The DCS field is interpreted as a binary value. 0 - Packet Duplication Control is disabled 1 - Packet Duplication Control is enabled
18 USP	Unicast Slow Protocol Packet Detect When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_ADDRESS0_HIGH and MAC_ADDRESS0_LOW registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2015, Section 5. 0 - Unicast Slow Protocol Packet Detection is disabled 1 - Unicast Slow Protocol Packet Detection is enabled
17 SPEN	Slow Protocol Detection Enable When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid sub-types. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets. 0 - Slow Protocol Detection is disabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Slow Protocol Detection is enabled
16 DCRCC	Disable CRC Checking for Received Packets When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets. 0 - CRC Checking is enabled 1 - CRC Checking is disabled
15-14 —	Reserved
13-0 GPSL	Giant Packet Size Limit If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_CONFIGURATION register.

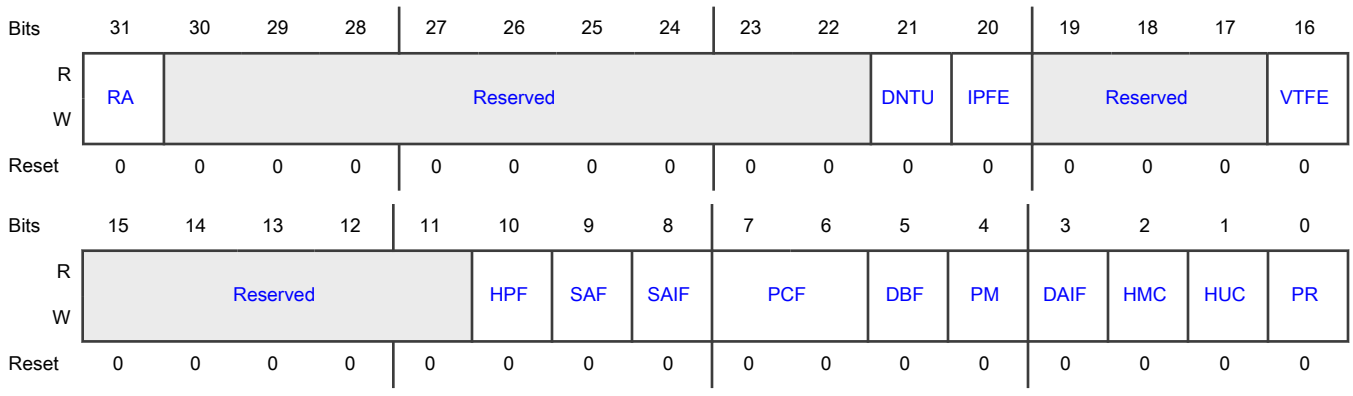
43.8.1.4 MAC Packet Filter (MAC_PACKET_FILTER)

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

Offset

Register	Offset
MAC_PACKET_FILTER	8h

Diagram



Fields

Field	Description
31 RA	Receive All When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter. 0 - Receive All is disabled 1 - Receive All is enabled
30-22 —	Reserved
21 DNTU	Drop Non-TCP/UDP over IP Packets When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forward only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets. 0 - Forward Non-TCP/UDP over IP Packets 1 - Drop Non-TCP/UDP over IP Packets
20 IPFE	Layer 3 and Layer 4 Filter Enable When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields. 0 - Layer 3 and Layer 4 Filters are disabled 1 - Layer 3 and Layer 4 Filters are enabled
19-17 —	Reserved
16 VTFE	VLAN Tag Filter Enable When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag. 0 - VLAN Tag Filter is disabled 1 - VLAN Tag Filter is enabled
15-11 —	Reserved
10 HPF	Hash or Perfect Filter

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is set, the address filter passes a packet if it matches either the perfect filtering or hash filtering as set by the HMC or HUC bit. When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter. 0 - Hash or Perfect Filter is disabled 1 - Hash or Perfect Filter is enabled
9 SAF	Source Address Filter Enable When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet. When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison. Note: According to the IEEE specification, Bit 47 of the SA is reserved. However, in DWC_ether_qos, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA. 0 - SA Filtering is disabled 1 - SA Filtering is enabled
8 SAIF	SA Inverse Filtering When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter. When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter. 0 - SA Inverse Filtering is disabled 1 - SA Inverse Filtering is enabled
7-6 PCF	Pass Control Packets These bits control the forwarding of all control packets (including unicast and multicast Pause packets). 00 - MAC filters all control packets from reaching the application 01 - MAC forwards all control packets except Pause packets to the application even if they fail the Address filter 10 - MAC forwards all control packets to the application even if they fail the Address filter 11 - MAC forwards the control packets that pass the Address filter
5 DBF	Disable Broadcast Packets When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast packets. 0 - Enable Broadcast Packets 1 - Disable Broadcast Packets

Table continues on the next page...

Table continued from the previous page...

Field	Description
4 PM	Pass All Multicast When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is '1') are passed. When this bit is reset, filtering of multicast packet depends on HMC bit. 0 - Pass All Multicast is disabled 1 - Pass All Multicast is enabled
3 DAIF	DA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed. 0 - DA Inverse Filtering is disabled 1 - DA Inverse Filtering is enabled
2 HMC	Hash Multicast When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the hash table. When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers. 0 - Hash Multicast is disabled 1 - Hash Multicast is enabled
1 HUC	Hash Unicast When this bit is set, the MAC performs the destination address filtering of unicast packets according to the hash table. When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programmed in DA registers. 0 - Hash Unicast is disabled 1 - Hash Unicast is enabled
0 PR	Promiscuous Mode When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set. 0 - Promiscuous Mode is disabled 1 - Promiscuous Mode is enabled

43.8.1.5 Watchdog Timeout (MAC_WATCHDOG_TIMEOUT)

The Watchdog Timeout register controls the watchdog timeout for received packets.

43.8.1.6 MAC Hash Table Register 0 (MAC_HASH_TABLE_REG0)

The Hash Table Register 0 contains the first 32 bits of the hash table, when the width of the hash table is 128 or 256 bits.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

- Perform bitwise reversal for the value obtained in Step 1.

- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Fields

Field	Description
31-0 HT31T0	MAC Hash Table First 32 Bits This field contains the first 32 Bits [31:0] of the Hash table.

43.8.1.7 MAC Hash Table Register 1 (MAC_HASH_TABLE_REG1)

The Hash Table Register 1 contains the second 32 bits of the hash table.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

- Perform bitwise reversal for the value obtained in Step 1.

- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Fields

Field	Description
31 EIVLRXS	Enable Inner VLAN Tag in Rx Status When this bit is set, the MAC provides the inner VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the inner VLAN Tag in Rx status. 0 - Inner VLAN Tag in Rx status is disabled 1 - Inner VLAN Tag in Rx status is enabled
30 —	Reserved
29-28 EIVLS	Enable Inner VLAN Tag Stripping on Receive This field indicates the stripping operation on inner VLAN Tag in received packet. 00 - Do not strip 01 - Strip if VLAN filter passes 10 - Strip if VLAN filter fails 11 - Always strip
27 ERIVLT	ERIVLT 0 - Inner VLAN tag is disabled 1 - Inner VLAN tag is enabled
26 EDVLP	Enable Double VLAN Processing When this bit is set, the MAC enables processing of up to two VLAN Tags on Tx and Rx (if present). When this bit is reset, the MAC enables processing of up to one VLAN Tag on Tx and Rx (if present). 0 - Double VLAN Processing is disabled 1 - Double VLAN Processing is enabled
25 VTHM	VLAN Tag Hash Table Match Enable When this bit is set, the most significant four bits of CRC of VLAN Tag (ones-complement of most significant four bits of CRC of VLAN Tag when ETV bit is reset) are used to index the content of the MAC_VLAN_Hash_Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the packet matched the VLAN hash table. When the ETV bit is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison. When the ETV bit is reset, the ones-complement of the CRC of the 16-bit VLAN tag is used for comparison. When this bit is reset, the VLAN Hash Match operation is not performed. 0 - VLAN Tag Hash Table Match is disabled 1 - VLAN Tag Hash Table Match is enabled
24 EVLRXS	Enable VLAN Tag in Rx status When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - VLAN Tag in Rx status is disabled 1 - VLAN Tag in Rx status is enabled
23 —	Reserved
22-21 EVLS	Enable VLAN Tag Stripping on Receive This field indicates the stripping operation on the outer VLAN Tag in received packet. 00 - Do not strip 01 - Strip if VLAN filter passes 10 - Strip if VLAN filter fails 11 - Always strip
20-19 —	Reserved
18 ESVL	Enable S-VLAN When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets. 0 - S-VLAN is disabled 1 - S-VLAN is enabled
17 VTIM	VLAN Tag Inverse Match Enable When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched. 0 - VLAN Tag Inverse Match is disabled 1 - VLAN Tag Inverse Match is enabled
16-7 —	Reserved
6-2 OFS	Offset This field holds the address offset of the MAC VLAN Tag Filter Register which the application is trying to access. The width of the field depends on the number of MAC VLAN Tag Registers enabled.
1 CT	Command Type This bit indicates if the current register access is a read or a write. When set, it indicate a read operation. When reset, it indicates a write operation. 0 - Write operation 1 - Read operation

Table continues on the next page...

Table continued from the previous page...

Field	Description
0 OB	Operation Busy This bit is set along with a read or write command for initiating the indirect access to per VLAN Tag Filter register. This bit is reset when the read or write command to per VLAN Tag Filter indirect access register is complete. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into the Per VLAN Tag register. During a read operation, the data should be read from the VLAN_TAG_DATA register only after this bit is reset. 0 - Operation Busy is disabled 1 - Operation Busy is enabled

43.8.1.9 MAC VLAN Tag Data (MAC_VLAN_TAG_DATA)

This register holds the read/write data for Indirect Access of the Per VLAN Tag registers. During the read access, this field contains valid read data only after the OB bit is reset.

During the write access, this field should be valid prior to setting the OB bit in the MAC_VLAN_Tag_Ctrl Register.

Offset

Field	Description
27-25 DMACHN	DMA Channel Number The DMA Channel number to which the VLAN Tagged Frame is to be routed if it passes this VLAN Tag Filter is programmed in this field. If the Routing based on VLAN Tag Filter is not necessary, this field need not be programmed.
24 DMACHEN	DMA Channel Number Enable This bit is the Enable for the DMA Channel Number value programmed in the field DMACH. When this bit is reset, the Routing does not occur based on VLAN Filter result. The frame is routed based on DA Based DMA Channel Routing. 0 - DMA Channel Number is disabled 1 - DMA Channel Number is enabled
23-21 —	Reserved
20 ERIVLT	Enable Inner VLAN Tag Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). 0 - Inner VLAN tag comparison is disabled 1 - Inner VLAN tag comparison is enabled
19 ERSVLM	Enable S-VLAN Match for received Frames This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets. 0 - Receive S-VLAN Match is disabled 1 - Receive S-VLAN Match is enabled
18 DOVLTC	Disable VLAN Type Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC does not check whether the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit only when VLAN Tag type is similar to the one specified by the Enable S-VLAN Match for received Frames bit. 0 - VLAN type comparison is enabled 1 - VLAN type comparison is disabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
17 ETV	12bits or 16bits VLAN comparison This bit is valid only when VEN of the Filter is set. When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. 0 - 16 bit VLAN comparison 1 - 12 bit VLAN comparison
16 VEN	VLAN Tag Enable This bit is used to enable or disable the VLAN Tag. When this bit is set, the MAC compares the VLAN Tag of received packet with the VLAN Tag ID. When this bit is reset, no comparison is performed irrespective of the programming of the other fields. 0 - VLAN Tag is disabled 1 - VLAN Tag is enabled
15-0 VID	VLAN Tag ID This field holds the VLAN Tag value which is used by the MAC for perfect comparison. It is valid when VLAN Tag Enable is set.

43.8.1.10 MAC VLAN Hash Table (MAC_VLAN_HASH_TABLE)

When VTHM bit of the MAC_VLAN_TAG register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_TAG Register) in the incoming packet is passed through the CRC logic. When ETV bit of MAC_VLAN_TAG register is set, the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. When ETV bit of MAC_VLAN_TAG register is reset, the ones-complement of upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, when ETV bit is set a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table, whereas when ETV bit is reset a hash value of 4b'1000 selects Bit 7 of the VLAN Hash table.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3).

- Perform bitwise reversal for the value obtained in step 1.

- Take the upper four bits from the value obtained in step 2.

If the VLAN hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written.

- If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Field	Description
31 BUSY	Busy This bit indicates the status of the read/write operation of indirect access to the queue/channel specific VLAN inclusion register. For write operation write to a register is complete when this bit is reset. For read operation the read data is valid when the bit is reset. The application must make sure that this bit is reset before attempting subsequent access to this register. 0 - Busy status not detected 1 - Busy status detected
30 RDWR	Read write control This bit controls the read or write operation for indirectly accessing the queue/channel specific VLAN Inclusion register. When set indicates write operation and when reset indicates read operation. This does not have any effect when CBTI is reset. 0 - Read operation of indirect access 1 - Write operation of indirect access
29-27 —	Reserved
26-24 ADDR	Address This field selects one of the queue/channel specific VLAN Inclusion register for read/write access. This does not have any effect when CBTI is reset.
23-22 —	Reserved
21	Channel based tag insertion

Table continues on the next page...

Table continued from the previous page...

Field	Description
CBTI	When this bit is set, outer VLAN tag is inserted for every packets transmitted by the MAC. The tag value is taken from the queue/channel specific VLAN tag register. The VLTI, VLP, VLC, and VLT fields of this register are ignored when this bit is set. When this bit is set, a write operation to byte 3 of this register initiates the read/write access to the indirect register. When reset, outer VLAN operation is based on the setting of VLTI, VLP, VLC and VLT fields of this register. 0 - Channel based tag insertion is disabled 1 - Channel based tag insertion is enabled
20 VLTI	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from: - The Tx descriptor 0 - VLAN Tag Input is disabled 1 - VLAN Tag Input is enabled
19 CSVL	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets. 0 - C-VLAN type (0x8100) is inserted or replaced 1 - S-VLAN type (0x88A8) is inserted or replaced
18 VLP	VLAN Priority Control When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used and bits[17:16] are ignored. 0 - VLAN Priority Control is disabled 1 - VLAN Priority Control is enabled
17-16 VLC	VLAN Tag Control in Transmit Packets - 2'b00: No VLAN tag deletion, insertion, or replacement - 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. VLAN Tag Control in Transmit Packets - 2'b00: No VLAN tag deletion, insertion, or replacement - 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. - 2'b10: VLAN tag insertion The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. - 2'b11: VLAN tag replacement

Table continues on the next page...

Table continued from the previous page...

Field	Description
	The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8). Note: Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 00 - No VLAN tag deletion, insertion, or replacement 01 - VLAN tag deletion 10 - VLAN tag insertion 11 - VLAN tag replacement
15-0 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: - Bits[15:13]: User Priority - Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) - Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

43.8.1.12 MAC Inner VLAN Tag Inclusion or Replacement (MAC_INNER_VLAN_INCL)

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet.

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet. It also contains the inner VLAN tag insertion controls.

43.8.1.13 MAC Q0 Tx Flow Control (MAC_Q0_TX_FLOW_CTRL)

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC.

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

When the PFCE bit in the MAC_Q0_RX_FLOW_CTRL register is enabled, this register controls the generation of Priority Flow Control (PFC) frames with priorities mapped according to PSRQ0 in the MAC_Q0_RXQ_CTRL2 register.

Offset

Register	Offset
MAC_Q0_TX_FLOW_CTRL	70h

If the Pause Time bits are configured to be double-synchronized to the (G)MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.
15-8 —	Reserved
7 DZPQ	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled. 0 - Zero-Quanta Pause packet generation is enabled 1 - Zero-Quanta Pause packet generation is disabled
6-4 PLT	Pause Low Threshold This field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times. 000 - Pause Time minus 4 Slot Times (PT -4 slot times) 001 - Pause Time minus 28 Slot Times (PT -28 slot times)

Table continues on the next page...

Table continued from the previous page...

Field	Description
	010 - Pause Time minus 36 Slot Times (PT -36 slot times) 011 - Pause Time minus 144 Slot Times (PT -144 slot times) 100 - Pause Time minus 256 Slot Times (PT -256 slot times) 101 - Pause Time minus 512 Slot Times (PT -512 slot times) 110 - Reserved
3-2 —	Reserved
1 TFE	Transmit Flow Control Enable Full-Duplex Mode: In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets. Half-Duplex Mode: In the half-duplex mode, when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled. 0 - Transmit Flow Control is disabled 1 - Transmit Flow Control is enabled
0 FCB_BPA	Flow Control Busy or Backpressure Activate This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. Full-Duplex Mode: In the full-duplex mode, this bit should be read as 1'b0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 1'b0. You should not write to this register until this bit is cleared. Half-Duplex Mode: When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Flow Control Busy or Backpressure Activate is disabled 1 - Flow Control Busy or Backpressure Activate is enabled

43.8.1.14 MAC Q1 Tx Flow Control (MAC_Q1_TX_FLOW_CTRL)

This register controls the generation of PFC Control packets of priorities mapped as per the PSRQi field in the MAC_Q1_RXQ_CTRL2/MAC_Q1_RXQ_CTRL3 registers.

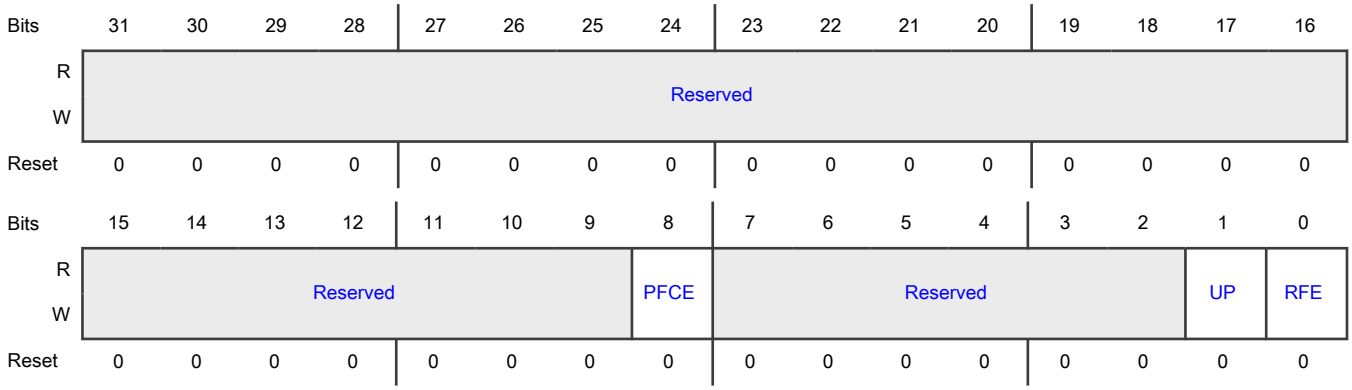
MAC_RX_FLOW_CTRL	90h

Diagram



Fields

Field	Description
31-9 —	Reserved
8 PFCE	Priority Based Flow Control Enable When this bit is set, it enables generation and reception of priority-based flow control (PFC) packets. When this bit is reset, it enables generation and reception of 802.3x Pause control packets. 0 - Priority Based Flow Control is disabled 1 - Priority Based Flow Control is enabled
7-2 —	Reserved
1 UP	Unicast Pause Packet Detect A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in MAC_ADDRESS0_HIGH and MAC_ADDRESS0_LOW. When this bit is reset, the MAC only detects Pause packets with unique multicast address. Note: The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011. 0 - Unicast Pause Packet Detect disabled 1 - Unicast Pause Packet Detect enabled
0 RFE	Receive Flow Control Enable When this bit is set and the MAC is operating in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in half-duplex mode, the decode function of the Pause packet is disabled. When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time.

Fields

Field	Description
31-24 PSRQ3	Priorities Selected in the Receive Queue 3 This field decides the priorities assigned to Rx Queue 3. All packets with priorities that match the values set in this field are routed to Rx Queue 3. For example, if PSRQ3[6, 3] are set, packets with USP field equal to 3 or 6 are routed to Rx Queue 3. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 3 crosses the flow control threshold settings.
23-16 PSRQ2	Priorities Selected in the Receive Queue 2 This field decides the priorities assigned to Rx Queue 2. All packets with priorities that match the values set in this field are routed to Rx Queue 2.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	For example, if PSRQ2[1, 0] are set, packets with USP field equal to 1 or 0 are routed to Rx Queue 2. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 2 crosses the flow control threshold settings.
15-8 PSRQ1	Priorities Selected in the Receive Queue 1 This field decides the priorities assigned to Rx Queue 1. All packets with priorities that match the values set in this field are routed to Rx Queue 1. For example, if PSRQ1[4] is set, packets with USP field equal to 4 are routed to Rx Queue 1. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 1 crosses the flow control threshold settings.
7-0 PSRQ0	Priorities Selected in the Receive Queue 0 This field decides the priorities assigned to Rx Queue 0. All packets with priorities that match the values set in this field are routed to Rx Queue 0. For example, if PSRQ0[5] is set, packets with USP field equal to 5 are routed to Rx Queue 0. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 0 crosses the flow control threshold settings.

43.8.1.25 Receive Queue Control 3 (MAC_RXQ_CTRL3)

This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to Rx Queue 4.

Offset

Register	Offset

Fields

Field	Description
31-24 —	Reserved
23-16 —	Reserved
15-8 —	Reserved
7-0 PSRQ4	Priorities Selected in the Receive Queue 4 This field decides the priorities assigned to Rx Queue 4. All packets with priorities that match the values set in this field are routed to Rx Queue 4. For example, if PSRQ4[7:4] is set, packets with USP field equal to 7, 6, 5, or 4 are routed to Rx Queue 4. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 4 crosses the flow control threshold settings.

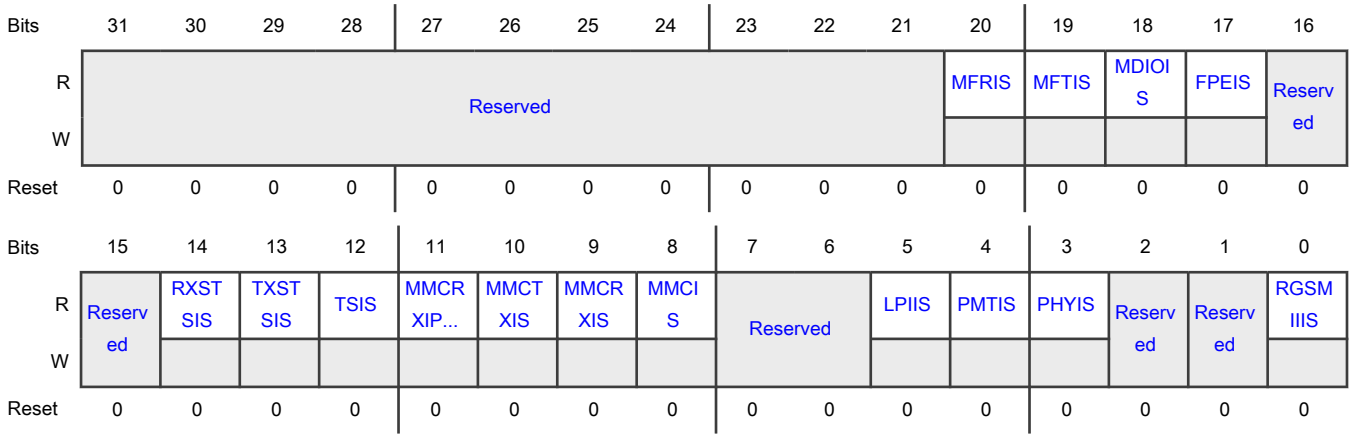
43.8.1.26 Interrupt Status (MAC_INTERRUPT_STATUS)

The Interrupt Status register contains the status of interrupts.

Offset

Register	Offset
MAC_INTERRUPT_STATUS	B0h

Diagram



Fields

Field	Description
31-21 —	Reserved
20 MFRIS	MMC FPE Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC FPE Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option along with FPE support. 0 - MMC FPE Receive Interrupt status not active 1 - MMC FPE Receive Interrupt status active
19 MFTIS	MMC FPE Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC FPE Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option along with FPE support. 0 - MMC FPE Transmit Interrupt status not active 1 - MMC FPE Transmit Interrupt status active
18 MDIOIS	MDIO Interrupt Status This bit indicates an interrupt event after the completion of MDIO operation. To reset this bit, the application has to read this bit/Write 1 to this bit when RCWE bit of CSR_SW_CTRL register is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - MDIO Interrupt status not active 1 - MDIO Interrupt status active
17 FPEIS	Frame Preemption Interrupt Status

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This bit indicates an interrupt event during the operation of Frame Preemption (Bits[19:16] of MAC_FPE_CTRL_STS register is set). To reset this bit, the application must clear the event in MAC_FPE_CTRL_STS that has caused the Interrupt. 0 - Frame Preemption Interrupt status not active 1 - Frame Preemption Interrupt status active
16 —	Reserved
15 —	Reserved
14 RXSTSIS	Receive Status Interrupt This bit indicates the status of received packets. This bit is set when the RWT bit is set in the MAC_RX_TX_STATUS register. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set) in the MAC_RX_TX_STATUS register. 0 - Receive Interrupt status not active 1 - Receive Interrupt status active
13 TXSTSIS	Transmit Status Interrupt This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the MAC_RX_TX_STATUS register: - Excessive Collision (EXCOL) - Late Collision (LCOL) - Excessive Deferral (EXDEF) - Loss of Carrier (LCARR) - No Carrier (NCARR) - Jabber Timeout (TJT) This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set) in the MAC_RX_TX_STATUS register. 0 - Transmit Interrupt status not active 1 - Transmit Interrupt status active
12 TSIS	Timestamp Interrupt Status If the Timestamp feature is enabled, this bit is set when any of the following conditions is true: - The system time value is equal to or exceeds the value specified in the Target Time High and Low registers. - There is an overflow in the Seconds register. - The Target Time Error occurred, that is, programmed target time already elapsed.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	If the Auxiliary Snapshot feature is enabled, this bit is set when the auxiliary snapshot trigger is asserted. In configurations other than EQOS_CORE, when drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_TX_TIMESTAMP_STATUS_NANOSECONDS and MAC_TXTIMESTAMP_STATUS_SECONDS registers. When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the MAC_TX_TIMESTAMP_STATUS_NANOSECONDS and MAC_TX_TIMESTAMP_STATUS_SECONDS registers, for PTO generated Delay Request and Pdelay request packets. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set) in the MAC_TIMESTAMP_STATUS register. 0 - Timestamp Interrupt status not active 1 - Timestamp Interrupt status active
11 MMCRXIPIS	MMC Receive Checksum Offload Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) and Enable Receive TCP/IP Checksum Check options. 0 - MMC Receive Checksum Offload Interrupt status not active 1 - MMC Receive Checksum Offload Interrupt status active
10 MMCTXIS	MMC Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0 - MMC Transmit Interrupt status not active 1 - MMC Transmit Interrupt status active
9 MMCRXIS	MMC Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0 - MMC Receive Interrupt status not active 1 - MMC Receive Interrupt status active
8 MMCIS	MMC Interrupt Status This bit is set high when Bit 11, Bit 10, or Bit 9 is set high. This bit is cleared only when all these bits are low. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0 - MMC Interrupt status not active 1 - MMC Interrupt status active

Table continues on the next page...

Table continued from the previous page...

Field	Description
7-6 —	Reserved
5 LPIIS	LPI Interrupt Status When the Energy Efficient Ethernet feature is enabled, this bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the corresponding interrupt source bit of MAC_LPI_CONTROL_STATUS register is read (or corresponding interrupt source bit of MAC_LPI_CONTROL_STATUS register is written to 1 when RCWE bit of MAC_CSR_SW_CTRL register is set). 0 - LPI Interrupt status not active 1 - LPI Interrupt status active
4 PMTIS	PMT Interrupt Status This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in MAC_PMT_CONTROL_STATUS register). This bit is cleared when corresponding interrupt source bit are cleared because of a Read operation to the MAC_PMT_CONTROL_STATUS register (or corresponding interrupt source bit of MAC_PMT_CONTROL_STATUS register is written to 1 when RCWE bit of CSR_SW_CTRL register is set). This bit is valid only when you select the Enable Power Management option. 0 - PMT Interrupt status not active 1 - PMT Interrupt status active
3 PHYIS	PHY Interrupt This bit is set when rising edge is detected on the phy_intr_i input. This bit is cleared when this register is read (or this bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set). 0 - PHY Interrupt not detected 1 - PHY Interrupt detected
2 —	Reserved
1 —	Reserved
0 RGSMIIIS	RGMII or SMII Interrupt Status This bit is set because of any change in value of the Link Status of RGMII or SMII interface (LNKSTS bit in MAC_PHYIF_CONTROL_STATUS register). This bit is cleared when the PHYIF_CONTROL_STATUS register is read (or LNKSTS bit of MAC_PHYIF_CONTROL_STATUS register is written to 1 when RCWE bit of MAC_CSR_SW_CTRL register is set). This bit is valid only when you select the optional RGMII or SMII PHY interface. 0 - RGMII or SMII Interrupt Status is not active

Table continues on the next page...

Table continued from the previous page...

Field	Description

8 RWT	Receive Watchdog Timeout This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_CONFIGURATION register. Receive Watchdog Timeout This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_CONFIGURATION register. This

Table continues on the next page...

Table continued from the previous page...

Field	Description
	bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the MAC_CONFIGURATION register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No receive watchdog timeout 1 - Receive watchdog timed out
7-6 —	Reserved
5 EXCOL	Excessive Collisions When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. Excessive Collisions When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the CONFIGURATION register, this bit is set after the first collision and the packet transmission is aborted. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No collision 1 - Excessive collision is sensed
4 LCOL	Late Collision When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (512 bytes including Preamble and Carrier Extension in GMII mode). Late Collision When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (512 bytes including Preamble and Carrier Extension in GMII mode). This bit is not valid if the Underflow error occurs. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No collision 1 - Late collision is sensed
3 EXDEF	Excessive Deferral When the DTXSTS bit is set in the MAC_OPERATION_MODE register and the DC bit is set in the MAC_CONFIGURATION register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbps mode or when Jumbo packet is enabled). Excessive Deferral

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When the DTXSTS bit is set in the MAC_OPERATION_MODE register and the DC bit is set in the MAC_CONFIGURATION register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbps mode or when Jumbo packet is enabled). Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No Excessive deferral 1 - Excessive deferral
2 LCARR	Loss of Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. Loss of Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - Carrier is present 1 - Loss of carrier
1 NCARR	No Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. No Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - Carrier is present 1 - No carrier
0 TJT	Transmit Jabber Timeout This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_CONFIGURATION register. Transmit Jabber Timeout This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_CONFIGURATION register. This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the MAC_CONFIGURATION register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event.

Fields

Field	Description
31 RWKFILTRST	Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Remote Wake-Up Packet Filter Register Pointer is not Reset 1 - Remote Wake-Up Packet Filter Register Pointer is Reset
30-29	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
28-24 RWKPTR	Remote Wake-up FIFO Pointer This field gives the current value (0 to 7, 15, or 31 when 4, 8, or 16 Remote Wake-up Packet Filters are selected) of the Remote Wake-up Packet Filter register pointer. Remote Wake-up FIFO Pointer This field gives the current value (0 to 7, 15, or 31 when 4, 8, or 16 Remote Wake-up Packet Filters are selected) of the Remote Wake-up Packet Filter register pointer. When the value of this pointer is equal to maximum for the selected number of Remote Wake-up Packet Filters, the contents of the Remote Wake-up Packet Filter Register are transferred to the clk_rx_i domain when a Write occurs to that register.
23-11 —	Reserved
10 RWKPFE	Remote Wake-up Packet Forwarding Enable When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. Remote Wake-up Packet Forwarding Enable When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. All frames after that event including the received wake-up frame are forwarded to application. This bit is then self-cleared on receiving the wake-up packet. The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high. Note: If Magic Packet Enable and Wake-Up Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Remote Wake-up Packet Forwarding is disabled 1 - Remote Wake-up Packet Forwarding is enabled
9 GLBLUCAST	Global Unicast When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet. 0 - Global unicast is disabled 1 - Global unicast is enabled
8-7 —	Reserved
6 RWKPRCVD	Remote Wake-Up Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. Remote Wake-Up Packet Received

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - Remote wake-up packet is received 1 - Remote wake-up packet is received
5 MGKPRCVD	Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No Magic packet is received 1 - Magic packet is received
4-3 —	Reserved
2 RWKPKTEN	Remote Wake-Up Packet Enable When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet. 0 - Remote wake-up packet is disabled 1 - Remote wake-up packet is enabled
1 MGKPKTEN	Magic Packet Enable When this bit is set, a power management event is generated when the MAC receives a magic packet. 0 - Magic Packet is disabled 1 - Magic Packet is enabled
0 PWRDWN	Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote Wake-Up Packet Enable bit is set high. Note: You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - Power down is disabled 1 - Power down is enabled

43.8.1.30 Remote Wakeup Filter (MAC_RWK_PACKET_FILTER)

The Remote Wakeup Filter registers are implemented as 8, 16, or 32 indirect access registers (wkuppktfilter_reg#i) based on whether 4, 8, or 16 Remote Wakeup Filters are selected in the configuration and accessed by application through MAC_RWK_PACKET_FILTER register.

The Remote Wakeup Filter registers are implemented as 8, 16, or 32 indirect access registers (wkuppktfilter_reg#i) based on whether 4, 8, or 16 Remote Wakeup Filters are selected in the configuration and accessed by application through MAC_RWK_PACKET_FILTER register. When the Remote Wakeup Filters are to be programmed, the entire set of wkuppktfilter_reg registers must be written. The wkuppktfilter_reg register is programmed by sequentially writing the eight, sixteen or thirty-two register values in MAC_RWK_PACKET_FILTER register for wkuppktfilter_REG0, wkuppktfilter_REG1, ..., wkuppktfilter_REG31 respectively. The wkuppktfilter_reg register is read in a similar way. The MAC updates the wkuppktfilter_reg register current pointer value in RWKPTR field of MAC_PMT_CONTROL_STATUS register.

The Remote Wakeup Filters are arranged in blocks of 4 filters each and each such block have eight 32-bit wide registers, viz. wkuppktfilter_REG0-7, wkuppktfilter_reg8-15, wkuppktfilter_REG16-23 and wkuppktfilter_REG24-31. The fields of Remote Wakeup Filter are described as follows:

Filter i Byte Mask: The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2, 3, .., 15) to determine whether or not a packet is a wake-up packet.

- The MSB (31st bit) must be zero.

- Bit j[30:0] is the byte mask.

- If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.

Filter i Command: The 4-bit filter i command controls the filter i operation.

- Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet.

- Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC-16 value. Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2".

- Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. The details are provided below:

-- The And_Previous bit setting is applicable within a set of 4 filters.

-- Setting of And_Previous bit of filter that is not enabled has no effect, that is setting And_Previous bit of lowest number filter in the set of 4 filters has no effect. For example, setting of And_Previous bit of Filter 0 has no effect.

-- If And_Previous bit is set for filter to form AND chained filter, the AND chain breaks at the point any filter is not enabled. For example: If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set) but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 2 is not enabled (bit 0 in Filter 2 command is reset), then since setting of Filter 2 And_Previous bit has no effect only Filter 1 result ORed with Filter 3 result is considered.

-- If filters chained by And_Previous bit setting have complementary programming, then a frame may never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 in Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 in Filter 2 command is reset) indicating unicast detection or vice versa, a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address type.

- Bit 0 is the enable for filter i. If Bit 0 is not set, filter i is disabled.

Filter i Offset: The filter i offset register defines the offset (within the packet) from which the filter i examines the packets.

- This 8-bit pattern-offset is the offset for the filter i first byte to be examined.

- The minimum allowed offset is 12, which refers to the 13th byte of the packet.

- The offset value 0 refers to the first byte of the packet.

Filter i CRC-16: The filter i CRC-16 register contains the CRC-16 value calculated from the pattern and the byte mask programmed in the Remote Wakeup filter register.

- The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1

- Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:

-- 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1, the corresponding byte is taken into the CRC-16 calculation.

-- 8-bit Offset Pointer: Specifies the byte to start the CRC-16 computation. The pointer and the mask are used together to locate the bytes to be used in the CRC-16 calculations.

The structure of the RWK Filter registers is shown in "Figure 10-11 Remote Wake-Up Packet Filter Register".

43.8.1.31 LPI Control and Status (MAC_LPI_CONTROL_STATUS)

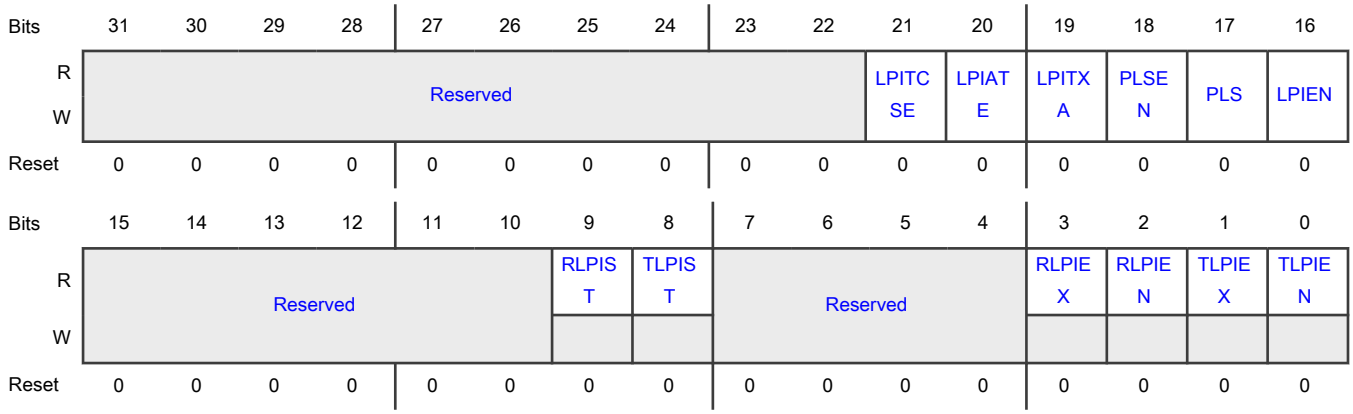
The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status.

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.

Offset

Register	Offset
MAC_LPI_CONTROL_STATUS	D0h

Diagram



Fields

Field	Description
31-22 —	Reserved
21 LPITCSE	LPI Tx Clock Stop Enable When this bit is set, the MAC asserts sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. LPI Tx Clock Stop Enable When this bit is set, the MAC asserts sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is reset, the MAC does not assert sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode. If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern. The Tx Clock cannot be gated and so the LPITCSE bit cannot be programmed. 0 - LPI Tx Clock Stop is disabled 1 - LPI Tx Clock Stop is enabled
20 LPIATE	LPI Timer Enable This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. LPI Timer Enable This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPIATE, LPITXA and LPIEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the MAC_LPI_ENTRY_TIMER register. After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPIEN bit. This enables the re-entry into LPI state when it is IDLE again. When LPIATE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPIEN bit descriptions. 0 - LPI Timer is disabled 1 - LPI Timer is enabled
19 LPITXA	LPI Tx Automate This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. LPI Tx Automate This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. This bit is not functional in the EQOS-CORE configurations in which the Tx clock gating is done during the LPI mode. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the core) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of MAC_TXQ0_OPERATION_MODE register, when the MAC is in the LPI mode, it exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode. 0 - LPI Tx Automate is disabled 1 - LPI Tx Automate is enabled
18	PHY Link Status Enable This bit enables the link status received on the RGMII, SGMII, or SMII Receive paths to be used for activating the LPI LS TIMER.

Table continues on the next page...

Table continued from the previous page...

Field	Description
PLSEN	PHY Link Status Enable This bit enables the link status received on the RGMII, SGMII, or SMII Receive paths to be used for activating the LPI LS TIMER. When this bit is set, the MAC uses the link-status bits of the MAC_PHYIF_CONTROL_STATUS register and the PLS bit for the LPI LS Timer trigger. When this bit is reset, the MAC ignores the link-status bits of the MAC_PHYIF_CONTROL_STATUS register and takes only the PLS bit. 0 - PHY Link Status is disabled 1 - PHY Link Status is enabled
17 PLS	PHY Link Status This bit indicates the link status of the PHY. PHY Link Status This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER. When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down. 0 - link is down 1 - link is okay (UP)
16 LPIEN	LPI Enable When this bit is set, it instructs the MAC Transmitter to enter the LPI state. LPI Enable When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission. 0 - LPI state is disabled 1 - LPI state is enabled
15-10 —	Reserved
9 RLPIST	Receive LPI State When this bit is set, it indicates that the MAC is receiving the LPI pattern on the GMII interface. 0 - Receive LPI state not detected 1 - Receive LPI state detected
8 TLPIST	Transmit LPI State When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the GMII interface. 0 - Transmit LPI state not detected 1 - Transmit LPI state detected
7-4	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
3 RLPIEX	Receive LPI Exit When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII interface, exited the LPI state, and resumed the normal reception. Receive LPI Exit When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). Note: This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0 - Receive LPI exit not detected 1 - Receive LPI exit detected
2 RLPIEN	Receive LPI Entry When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. Receive LPI Entry When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). Note: This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0 - Receive LPI entry not detected 1 - Receive LPI entry detected
1 TLPIEX	Transmit LPI Exit When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. Transmit LPI Exit When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). 0 - Transmit LPI exit not detected 1 - Transmit LPI exit detected
0 TLPIEN	Transmit LPI Entry When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. Transmit LPI Entry When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). 0 - Transmit LPI entry not detected 1 - Transmit LPI entry detected

Table continues on the next page...

Field	Description

43.8.1.32 LPI Timers Control (MAC_LPI_TIMERS_CONTROL)

The LPI Timers Control register controls the timeout values in the LPI states.

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Offset

Register	Offset
MAC_LPI_TIMERS_CONTROL	D4h

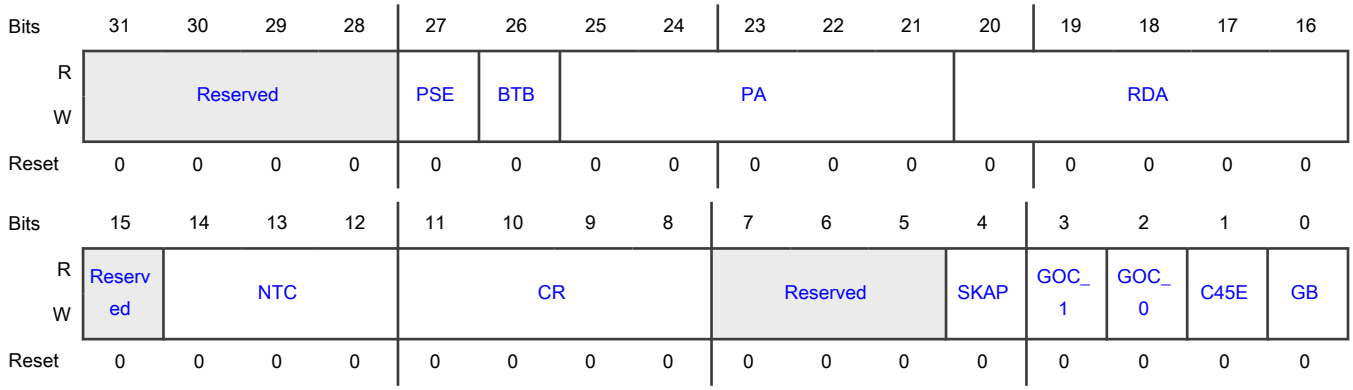
43.8.1.42 MDIO Address (MAC_MDIO_ADDRESS)

The MDIO Address register controls the management cycles to external PHY through a management interface.

Offset

Register	Offset
MAC_MDIO_ADDRESS	200h

Diagram



Fields

Field	Description
31-28 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
27 PSE	Preamble Suppression Enable When this bit is set, the SMA suppresses the 32-bit preamble and transmits MDIO frames with only 1 preamble bit. Preamble Suppression Enable When this bit is set, the SMA suppresses the 32-bit preamble and transmits MDIO frames with only 1 preamble bit. When this bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications. 0 - Preamble Suppression disabled 1 - Preamble Suppression enabled
26 BTB	Back to Back transactions When this bit is set and the NTC has value greater than 0, then the MAC informs the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). Back to Back transactions When this bit is set and the NTC has value greater than 0, then the MAC informs the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which is executed immediately irrespective of the number trailing clocks generated for the previous frame. When this bit is reset, then the read/write command completion (GB is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame. This bit must not be set when NTC=0. 0 - Back to Back transactions disabled 1 - Back to Back transactions enabled
25-21 PA	Physical Layer Address This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. Physical Layer Address This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing.
20-16 RDA	Register/Device Address These bits select the PHY register in selected Clause 22 PHY device. Register/Device Address These bits select the PHY register in selected Clause 22 PHY device. These bits select the Device (MMD) in selected Clause 45 capable PHY.
15	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
14-12 NTC	Number of Trailing Clocks This field controls the number of trailing clock cycles generated on gmii_mdc_o (MDC) after the end of transmission of MDIO frame. Number of Trailing Clocks This field controls the number of trailing clock cycles generated on gmii_mdc_o (MDC) after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.
11-8 CR	CSR Clock Range The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: - 0000: CSR clock = 60-100 MHz; MDC clock = CSR clock/42 - 0001: CSR clock = 100-150 MHz; MDC clock = CSR clock/62 - 0010: CSR clock = 20-35 MHz; MDC clock = CSR clock/16 - 0011: CSR clock = 35-60 MHz; MDC clock = CSR clock/26 - 0100: CSR clock = 150-250 MHz; MDC clock = CSR clock/102 - 0101: CSR clock = 250-300 MHz; MDC clock = CSR clock/124 - 0110: CSR clock = 300-500 MHz; MDC clock = CSR clock/204 - 0111: CSR clock = 500-800 MHz; MDC clock = CSR clock/324 The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1. CSR Clock Range The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: - 0000: CSR clock = 60-100 MHz; MDC clock = CSR clock/42 - 0001: CSR clock = 100-150 MHz; MDC clock = CSR clock/62 - 0010: CSR clock = 20-35 MHz; MDC clock = CSR clock/16 - 0011: CSR clock = 35-60 MHz; MDC clock = CSR clock/26 - 0100: CSR clock = 150-250 MHz; MDC clock = CSR clock/102 - 0101: CSR clock = 250-300 MHz; MDC clock = CSR clock/124 - 0110: CSR clock = 300-500 MHz; MDC clock = CSR clock/204 - 0111: CSR clock = 500-800 MHz; MDC clock = CSR clock/324 The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz freqency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks: - 1000: CSR clock/4 - 1001: CSR clock/6 - 1010: CSR clock/8 - 1011: CSR clock/10 - 1100: CSR clock/12

Table continues on the next page...

Table continued from the previous page...

Field	Description
	- 1101: CSR clock/14 - 1110: CSR clock/16 - 1111: CSR clock/18 These bits are not used for accessing RevMII. These bits are read-only if the RevMII interface is selected as single PHY interface.
7-5 —	Reserved
4 SKAP	Skip Address Packet When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. Skip Address Packet When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set. 0 - Skip Address Packet is disabled 1 - Skip Address Packet is enabled
3 GOC_1	GMII Operation Command 1 This bit is higher bit of the operation command to the PHY or RevMII, GOC_1 and GOC_O is encoded as follows: - 00: Reserved - 01: Write - 10: Post Read Increment Address for Clause 45 PHY - 11: Read When Clause 22 PHY or RevMII is enabled, only Write and Read commands are valid. 0 - GMII Operation Command 1 is disabled 1 - GMII Operation Command 1 is enabled
2 GOC_0	GMII Operation Command 0 This is the lower bit of the operation command to the PHY or RevMII. GMII Operation Command 0 This is the lower bit of the operation command to the PHY or RevMII. When in SMA mode (MDIO master) this bit along with GOC_1 determines the operation to be performed to the PHY. When only RevMII is selected in configuration this bit is read-only and tied to 1. 0 - GMII Operation Command 0 is disabled 1 - GMII Operation Command 0 is enabled
1 C45E	Clause 45 PHY Enable When this bit is set, Clause 45 capable PHY is connected to MDIO. Clause 45 PHY Enable When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO. 0 - Clause 45 PHY is disabled 1 - Clause 45 PHY is enabled
0	GMII Busy The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave.

Table continues on the next page...

Table continued from the previous page...

Field	Description
GB	GMII Busy The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in MAC_MDIO_ADDRESS and MAC_MDIO_DATA registers as long as this bit is set. For write transfers, the application must first write 16-bit data in the GDI field (and also RA field when C45E is set) in MAC_MDIO_DATA register before setting this bit. When C45E is set, it should also write into the RA field of MAC_MDIO_DATA register before initiating a read transfer. When a read transfer is completed (GB=0), the data read from the PHY register is valid in the GD field of the MAC_MDIO_DATA register. Note: Even if the addressed PHY is not present, there is no change in the functionality of this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - GMII Busy is disabled 1 - GMII Busy is enabled

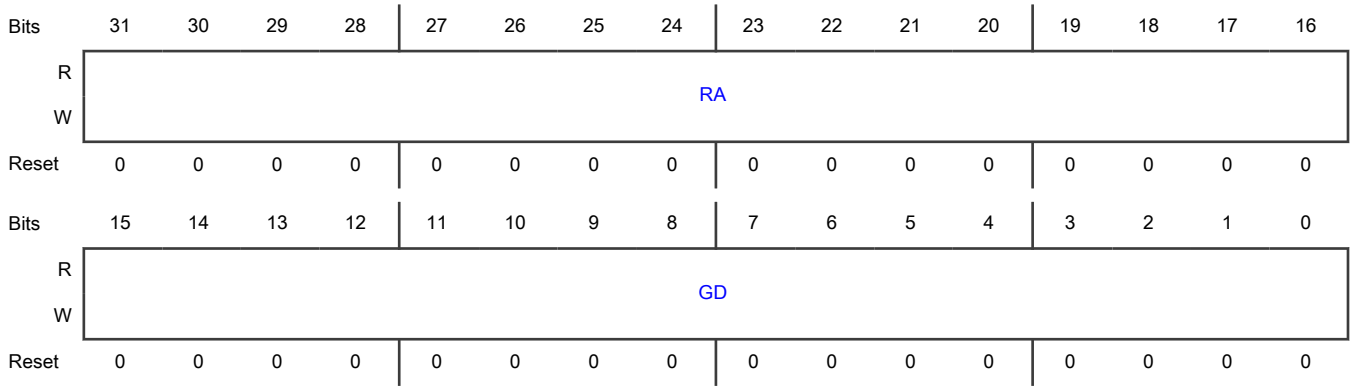
43.8.1.43 MAC MDIO Data (MAC_MDIO_DATA)

The MAC_MDIO_DATA register stores the Write data to be written to the PHY register located at the address specified in MAC_MDIO_ADDRESS. This register also stores the Read data from the PHY register located at the address specified by MAC_MDIO_ADDRESS register.

Offset

Register	Offset
MAC_MDIO_DATA	204h

Diagram



Fields

Field	Description
31-16 RA	Register Address This field is valid only when C45E is set. Register Address This field is valid only when C45E is set. It contains the Register Address in the PHY to which the MDIO frame is intended for.
15-0 GD	GMII Data This field contains the 16-bit data value read from the PHY or RevMII after a Management Read operation or the 16-bit data value to be written to the PHY or RevMII before a Management Write operation.

43.8.1.44 CSR Software Control (MAC_CSR_SW_CTRL)

This register contains SW programmable controls for changing the CSR access response and status bits clearing.

Offset

Register	Offset

Fields

Field	Description
31-0 MPTU	MAC 1722 Presentation Time Update This field holds the init value or the update value for the presentation time. MAC 1722 Presentation Time Update This field holds the init value or the update value for the presentation time. When used for update, this field holds the 32-bit value in ns, that should be added to the Current Presentation Time Counter value. Init happens when TSINIT is set, and update happens when the TSUPDT bit is set (TSINIT and TSINIT defined in MAC_TIMESTAMP_CONTROL register). When ADDSUB field of MAC_SYSTEM_TIME_NANOSECONDS_UPDATE is set, this value is directly used for subtraction

43.8.1.48 MAC Address0 High (MAC_ADDRESS0_HIGH)

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

43.8.1.64 MAC Address8 High (MAC_ADDRESS8_HIGH)

The MAC ADDRESS8 High register holds the upper 16 bits of the ninth 6-byte MAC address of the station.

The MAC ADDRESS8 High register holds the upper 16 bits of the ninth 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC ADDRESS8 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Fields

Field	Description
31 AE	Address Enable When this bit is set, the address filter module uses the 32nd MAC address for perfect filtering. Address Enable When this bit is set, the address filter module uses the 32nd MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering. 0 - Address is ignored 1 - Address is enabled
30 SA	Source Address When this bit is set, the MAC ADDRESS31[47:0] is used to compare with the SA fields of the received packet. Source Address When this bit is set, the MAC ADDRESS31[47:0] is used to compare with the SA fields of the received packet. When this bit is reset, the MAC ADDRESS31[47:0] is used to compare with the DA fields of the received packet. 0 - Compare with Destination Address 1 - Compare with Source Address
29-24 MBC	Mask Byte Control These bits are mask control bits for comparing each of the MAC Address bytes. Mask Byte Control These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC ADDRESS31 registers. Each bit controls the masking of the bytes as follows: - Bit 29: ADDRESS31_High[15:8] - Bit 28: ADDRESS31_High[7:0] - Bit 27: ADDRESS31_Low[31:24] - .. - Bit 24: ADDRESS31_Low[7:0]

Table continues on the next page...

Table continued from the previous page...

Field	Description
	You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.
23-21 —	Reserved
20-16 DCS	DMA Channel Select If the PDC bit of MAC_EXT_CONFIGURATION register is not set: This field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address(#i) content is routed. DMA Channel Select If the PDC bit of MAC_EXT_CONFIGURATION register is not set: This field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address(#i) content is routed. If the PDC bit of MAC_EXT_CONFIGURATION register is set: This field contains the one-hot representation of one or more DMA Channel numbers to which an Rx packet whose DA matches the MAC Address(#i) content is routed.
15-0 ADDRHI	MAC ADDRESS31 [47:32] This field contains the upper 16 bits[47:32] of the 32nd 6-byte MAC address.

43.8.1.111 MAC Address31 Low (MAC_ADDRESS31_LOW)

The MAC ADDRESS31 Low register holds the lower 32 bits of the 32nd 6-byte MAC address of the station.

Offset

Register	Offset

The MAC ADDRESS44 High register holds the upper 16 bits of the 45th 6-byte MAC address of the station.

The MAC ADDRESS44 High register holds the upper 16 bits of the 45th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

31-0 ADDRLO	MAC ADDRESS57 [31:0] This field contains the lower 32 bits of the 58th 6-byte MAC address. MAC ADDRESS57 [31:0] This field contains the lower 32 bits of the 58th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

43.8.1.164 MAC Address58 High (MAC_ADDRESS58_HIGH)

The MAC ADDRESS58 High register holds the upper 16 bits of the 59th 6-byte MAC address of the station.

The MAC ADDRESS58 High register holds the upper 16 bits of the 59th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

Fields

Field	Description
31-9 —	Reserved
8 UCDBC	Update MMC Counters for Dropped Broadcast Packets Note: The CNTRST bit has a higher priority than the CNTPRST bit. Update MMC Counters for Dropped Broadcast Packets Note: The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set. When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of MAC_Packet_Filter register. When reset, the MMC Counters are not updated for dropped Broadcast packets. 0 - Update MMC Counters for Dropped Broadcast Packets is disabled 1 - Update MMC Counters for Dropped Broadcast Packets is enabled
7-6 —	Reserved
5 CNTPRSTLVL	Full-Half Preset When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. Full-Half Preset When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (Half 2KBytes) and all packet-counters gets preset to 0x7FFF_FFF0 (Half 16). When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2KBytes) and all packet-counters gets preset to 0xFFFF_FFF0 (Full 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0. 0 - Full-Half Preset is disabled 1 - Full-Half Preset is enabled
4 CNTPRST	Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle. This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0 - Counters Preset is disabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Counters Preset is enabled
3 CNTFREEZ	MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode. 0 - MMC Counter Freeze is disabled 1 - MMC Counter Freeze is enabled
2 RSTONRD	Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (Bits[7:0]) is read. 0 - Reset on Read is disabled 1 - Reset on Read is enabled
1 CNTSTOPRO	Counter Stop Rollover When this bit is set, the counter does not roll over to zero after reaching the maximum value. 0 - Counter Stop Rollover is disabled 1 - Counter Stop Rollover is enabled
0 CNTRST	Counters Reset When this bit is set, all counters are reset. Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0 - Counters are not reset 1 - All counters are reset

43.8.1.177 MMC Rx Interrupt (MAC_MMC_RX_INTERRUPT)

This register maintains the interrupts generated from all Receive statistics counters.

This register maintains the interrupts generated from all Receive statistics counters.

The MMC Receive Interrupt register maintains the interrupts that are generated when the following occur:

- Receive statistic counters reach half of their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter).

- Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter).

When the Counter Stop Rollover is set, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

Note: R_SS_RC means that this register bit is set internally, and it is cleared when the Counter register is read.

1 RXGBOCTIS	MMC Receive Good Bad Octet Counter Interrupt Status This bit is set when the rxoctetcount_gb counter reaches half of the maximum value or the maximum value. MMC Receive Good Bad Octet Counter Interrupt Status This bit is set when the rxoctetcount_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive Good Bad Octet Counter Interrupt Status not detected 1 - MMC Receive Good Bad Octet Counter Interrupt Status detected
0 RXGBPKTIS	MMC Receive Good Bad Packet Counter Interrupt Status This bit is set when the rxpacketcount_gb counter reaches half of the maximum value or the maximum value. MMC Receive Good Bad Packet Counter Interrupt Status This bit is set when the rxpacketcount_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive Good Bad Packet Counter Interrupt Status not detected 1 - MMC Receive Good Bad Packet Counter Interrupt Status detected

43.8.1.178 MMC Tx Interrupt (MAC_MMC_TX_INTERRUPT)

This register maintains the interrupts generated from all Transmit statistics counters.

This register maintains the interrupts generated from all Transmit statistics counters.

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values

(0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter).

When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.

The MMC Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.

The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

Field	Description
6 RXALGNERPIM	MMC Receive Alignment Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxalignmenterror counter reaches half of the maximum value or the maximum value. 0 - MMC Receive Alignment Error Packet Counter Interrupt Mask is disabled 1 - MMC Receive Alignment Error Packet Counter Interrupt Mask is enabled
5 RXCRCERPIM	MMC Receive CRC Error Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxcrcerror counter reaches half of the maximum value or the maximum value. 0 - MMC Receive CRC Error Packet Counter Interrupt Mask is disabled 1 - MMC Receive CRC Error Packet Counter Interrupt Mask is enabled
4 RXMCGPIM	MMC Receive Multicast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxmulticastpackets_g counter reaches half of the maximum value or the maximum value. 0 - MMC Receive Multicast Good Packet Counter Interrupt Mask is disabled 1 - MMC Receive Multicast Good Packet Counter Interrupt Mask is enabled
3 RXBCGPIM	MMC Receive Broadcast Good Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxbroadcastpackets_g counter reaches half of the maximum value or the maximum value. 0 - MMC Receive Broadcast Good Packet Counter Interrupt Mask is disabled 1 - MMC Receive Broadcast Good Packet Counter Interrupt Mask is enabled
2 RXGOCTIM	MMC Receive Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoctetcount_g counter reaches half of the maximum value or the maximum value. 0 - MMC Receive Good Octet Counter Interrupt Mask is disabled 1 - MMC Receive Good Octet Counter Interrupt Mask is enabled
1 RXGBOCTIM	MMC Receive Good Bad Octet Counter Interrupt Mask Setting this bit masks the interrupt when the rxoctetcount_gb counter reaches half of the maximum value or the maximum value. 0 - MMC Receive Good Bad Octet Counter Interrupt Mask is disabled 1 - MMC Receive Good Bad Octet Counter Interrupt Mask is enabled
0 RXGBPKTIM	MMC Receive Good Bad Packet Counter Interrupt Mask Setting this bit masks the interrupt when the rxpacketcount_gb counter reaches half of the maximum value or the maximum value. 0 - MMC Receive Good Bad Packet Counter Interrupt Mask is disabled 1 - MMC Receive Good Bad Packet Counter Interrupt Mask is enabled

43.8.1.180 MMC Tx Interrupt Mask (MAC_MMC_TX_INTERRUPT_MASK)

This register maintains the masks for interrupts generated from all Transmit statistics counters.

This register maintains the masks for interrupts generated from all Transmit statistics counters.

The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or the maximum values. This register is 32 bit wide.

Fields

Field	Description
31-0 TXLPIUSC	Tx LPI Microseconds Counter This field indicates the number of microseconds Tx LPI is asserted. Tx LPI Microseconds Counter This field indicates the number of microseconds Tx LPI is asserted. For every Tx LPI Entry and Exit, the Timer value can have an error of +/- 1 microsecond.

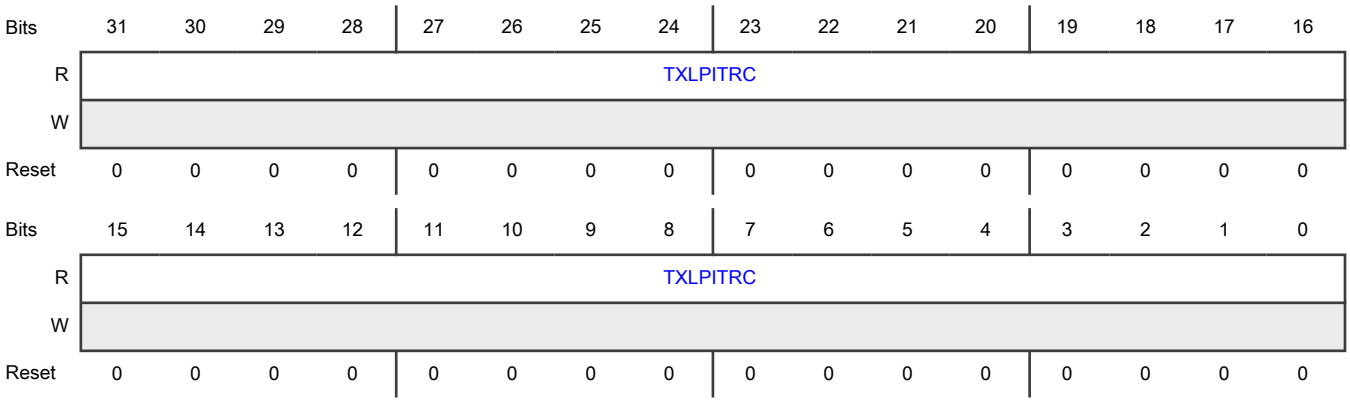
43.8.1.234 Number of Times Tx LPI Asserted (MAC_TX_LPI_TRAN_CNTR)

This register provides the number of times DWC_ether_qos has entered Tx LPI.

Offset

Register	Offset
MAC_TX_LPI_TRAN_CNTR	7F0h

Diagram



Fields

Field	Description
31-0 TXLPITRC	Tx LPI Transition counter This field indicates the number of times Tx LPI Entry has occurred. Tx LPI Transition counter This field indicates the number of times Tx LPI Entry has occurred. Even if Tx LPI Entry occurs in Automate Mode (because of LPITXA bit set in the LPI Control and Status register), the counter will increment.

43.8.1.235 Microseconds Rx LPI Sampled (MAC_RX_LPI_USEC_CNTR)

This register provides the number of microseconds Rx LPI is sampled by DWC_ether_qos.

Offset

Register	Offset
MAC_RX_LPI_USEC_CNTR	7F4h

43.8.1.237 MMC IPC Receive Interrupt Mask (MAC_MMC_IPC_RX_INTERRUPT_MASK)

This register maintains the mask for the interrupt generated from the receive IPC statistic counters.

The MMC Receive Checksum Off load Interrupt Mask register maintains the masks for the interrupts generated when the receive IPC (Checksum Off load) statistic counters reach half their maximum value, and when they reach their maximum values. This register is 32 bits wide.

Offset

Register	Offset
MAC_MMC_IPC_RX_INTERRUPT_MASK	800h

43.8.1.238 MMC IPC Receive Interrupt (MAC_MMC_IPC_RX_INTERRUPT)

This register maintains the interrupt that the receive IPC statistic counters generate.

The MMC Receive Checksum Offload Interrupt register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.

The MMC Receive Checksum Offload Interrupt register is 32 bit wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (Bits[7:0]) must be read to clear the interrupt bit.

43.8.1.267 MMC FPE Transmit Interrupt (MAC_MMC_FPE_TX_INTERRUPT)

This register maintains the interrupts generated from all FPE related Transmit statistics counters.

This register maintains the interrupts generated from all FPE related Transmit statistics counters. The MMC FPE Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC FPE Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

MMC Tx Hold Request Counter Interrupt Status This bit is set when the Tx_Hold_Req_Cntr counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. Exists when any one of the RX/TX MMC counters are enabled during FPE with AV_EST Enabled configuration. 0 - MMC Tx Hold Request Counter Interrupt Status not detected 1 - MMC Tx Hold Request Counter Interrupt Status detected
0 FCIS	MMC Tx FPE Fragment Counter Interrupt status This bit is set when the Tx_FPE_Fragment_Cntr counter reaches half of the maximum value or the maximum value. MMC Tx FPE Fragment Counter Interrupt status This bit is set when the Tx_FPE_Fragment_Cntr counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. Exists when any one of the RX/TX MMC counters are enabled during FPE Enabled configuration. 0 - MMC Tx FPE Fragment Counter Interrupt status not detected 1 - MMC Tx FPE Fragment Counter Interrupt status detected

43.8.1.268 MMC FPE Transmit Mask Interrupt (MAC_MMC_FPE_TX_INTERRUPT_MASK)

This register maintains the masks for interrupts generated from all FPE related Transmit statistics counters.

This register maintains the masks for interrupts generated from all FPE related Transmit statistics counters. The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when FPE related receive statistic counters reach half of their maximum value or the maximum values. This register is 32 bit wide.

43.8.1.271 MMC FPE Receive Interrupt (MAC_MMC_FPE_RX_INTERRUPT)

This register maintains the interrupts generated from all FPE related Receive statistics counters.

This register maintains the interrupts generated from all FPE related Receive statistics counters. The MMC FPE Receive Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones. The MMC FPE Receive Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

43.8.1.278 Layer 4 Address 0 (MAC_LAYER4_ADDRESS0)

The MAC_LAYER4_ADDRESS0, MAC_L3_L4_CONTROL0, MAC_LAYER3_ADDR0_Reg0, MAC_LAYER3_ADDR1_Reg0, MAC_LAYER3_ADDR2_Reg0 and MAC_LAYER3_ADDR3_Reg0 registers are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core.

You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the core. When you select this option, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Field	Description
31-0 L3A20	Layer 3 Address 2 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_CONTROL0 register, this field contains the value to be matched with Bits[95:64] of the IP Source Address field in the IPv6 packets. Layer 3 Address 2 Field When the L3PEN0 and L3SAM0 bits are set in the MAC_L3_L4_CONTROL0 register, this field contains the value to be matched with Bits[95:64] of the IP Source Address field in the IPv6 packets. When the L3PEN0 and L3DAM0 bits are set in the MAC_L3_L4_CONTROL0 register, this field contains the value to be matched with Bits[95:64] of the IP Destination Address field in the IPv6 packets. When the L3PEN0 bit is reset in the MAC_L3_L4_CONTROL0 register, this field is not used.

43.8.1.282 Layer 3 Address 3 Register 0 (MAC_LAYER3_ADDR3_REG0)

The Layer 3 Address 3 Register 0 register is reserved for IPv4 packets.

The Layer 3 Address 3 Register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[127:96] of 128-bit IP Source Address or Destination Address field.

Layer 3 Protocol Enable When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set. 0 - Layer 3 Protocol is disabled 1 - Layer 3 Protocol is enabled

43.8.1.284 Layer 4 Address 0 (MAC_LAYER4_ADDRESS1)

The MAC_LAYER4_ADDRESS1, MAC_L3_L4_CONTROL1, MAC_LAYER3_ADDR0_Reg1, MAC_LAYER3_ADDR1_Reg1, MAC_LAYER3_ADDR2_Reg1 and MAC_LAYER3_ADDR3_Reg1 registers are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core.

You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the core. When you select this option, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set. 0 - Layer 3 Protocol is disabled 1 - Layer 3 Protocol is enabled

43.8.1.290 Layer 4 Address 2 (MAC_LAYER4_ADDRESS2)

The MAC_LAYER4_ADDRESS2, MAC_L3_L4_CONTROL2), MAC_LAYER3_ADDR0_Reg2), MAC_LAYER3_ADDR1_Reg2, MAC_LAYER3_ADDR2_Reg2 and MAC_LAYER3_ADDR3_Reg2 registers are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core.

You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the core. When you select this option, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer 3 Protocol Enable When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set. 0 - Layer 3 Protocol is disabled 1 - Layer 3 Protocol is enabled

43.8.1.314 Layer 4 Address 6 (MAC_LAYER4_ADDRESS6)

The MAC_LAYER4_ADDRESS6), MAC_L3_L4_CONTROL6, MAC_LAYER3_ADDR0_Reg6, MAC_LAYER3_ADDR1_Reg6, MAC_LAYER3_ADDR2_Reg5 and MAC_LAYER3_ADDR3_Reg6 registers are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core.

You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the core. When you select this option, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Field	Description
1 —	Reserved
0 L3PEN7	Layer 3 Protocol Enable When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. Layer 3 Protocol Enable When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set. 0 - Layer 3 Protocol is disabled 1 - Layer 3 Protocol is enabled

43.8.1.320 Layer 4 Address 7 (MAC_LAYER4_ADDRESS7)

The MAC_LAYER4_ADDRESS7, MAC_L3_L4_CONTROL7, MAC_LAYER3_ADDR0_Reg7, MAC_LAYER3_ADDR1_Reg7, MAC_LAYER3_ADDR2_Reg7 and MAC_LAYER3_ADDR3_Reg7 registers are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core.

You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the core. When you select this option, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

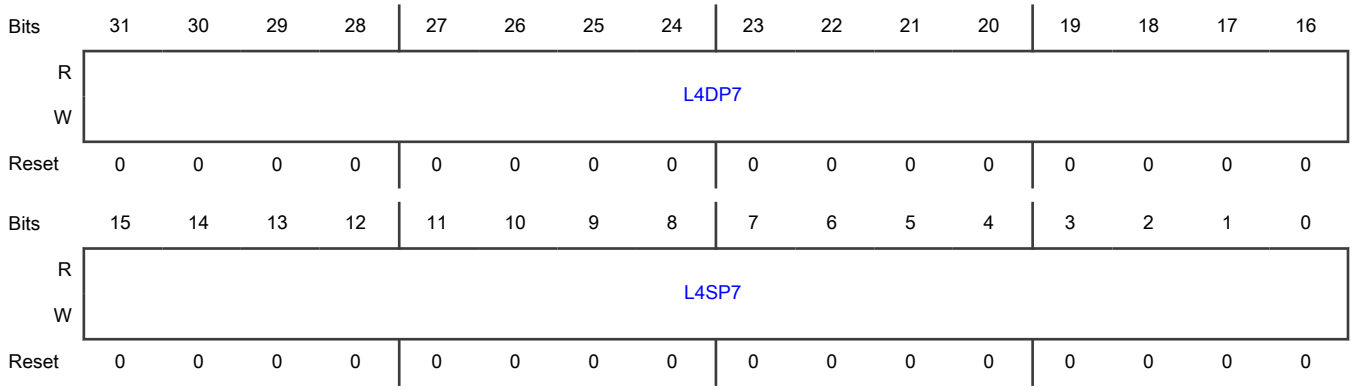
Diagram



Fields

Field	Description
31-16 L4DP7	Layer 4 Destination Port Number Field When the L4PEN7 bit is reset and the L4DPM7 bit is set in the MAC_L3_L4_CONTROL0 register, this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets. Layer 4 Destination Port Number Field When the L4PEN7 bit is reset and the L4DPM7 bit is set in the MAC_L3_L4_CONTROL0 register, this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets. When the L4PEN7 and L4DPM7 bits are set in MAC_L3_L4_CONTROL0 register, this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.
15-0 L4SP7	Layer 4 Source Port Number Field When the L4PEN7 bit is reset and the L4SPM0 bit is set in the MAC_L3_L4_CONTROL0 register, this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets. Layer 4 Source Port Number Field When the L4PEN7 bit is reset and the L4SPM0 bit is set in the MAC_L3_L4_CONTROL0 register, this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets. When the L4PEN7 and L4SPM0 bits are set in MAC_L3_L4_CONTROL0 register, this field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.

43.8.1.321 Layer 3 Address 0 Register 7 (MAC_LAYER3_ADDR0_REG7)

For IPv4 packets, the Layer 3 Address 0 Register 7 register contains the 32-bit IP Source Address field. For IPv6 packets, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Offset

Register	Offset
MAC_LAYER3_ADDR0_REG7	A60h

When the L3PEN0 bit is reset in the MAC_L3_L4_CONTROL0 register, this field is not used.

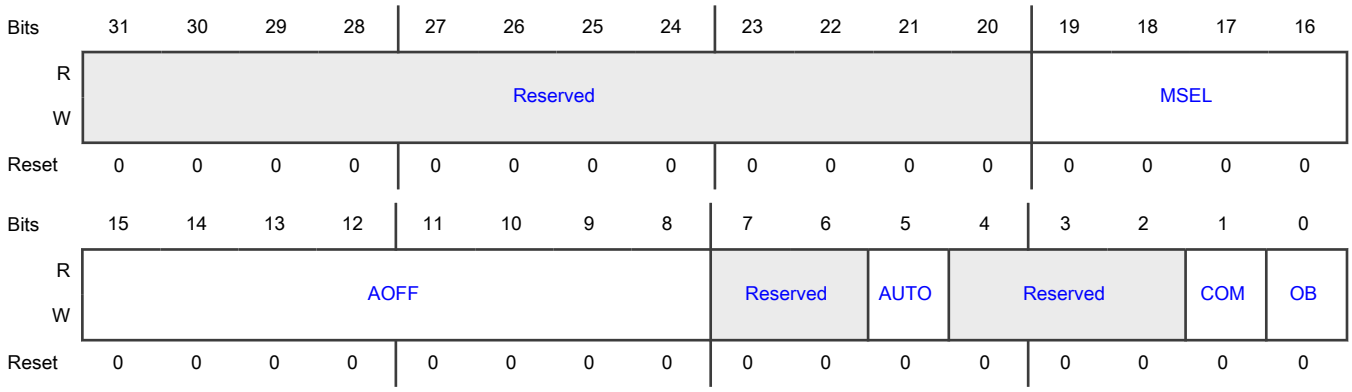
43.8.1.325 MAC_INDIR_ACCESS_CTRL (MAC_INDIR_ACCESS_CTRL)

This register provides the Indirect Access control and status for MAC_<MSEl>_<AOFF> registers.

Offset

Register	Offset
MAC_INDIR_ACCESS_CTRL	A70h

Diagram



Fields

Field	Description
31-20 —	Reserved
19-16 MSEL	Mode Select This field is used in indirect access of MAC_<MSEL>_<AOFF>. This field must be set along with initiation of read/write to MAC_<MSEL>_<AOFF> and should not be changed until the OB is reset. Values: 0000: ESTTyp_RXQ_ (Type based RXQ mappping) 0001-1111: Reserved for future use.
15-8 AOFF	Address Offset This field is used in indirect access of MAC_<MSEL>_<AOFF>. This field must be set along with initiation of read/write to MAC_<MSEL>_<AOFF> and should not be changed until the OB is reset. Values: 00000000: IndReg0(Indirect register 0) 00000001: IndReg1(Indirect register 1) ... 00000111: IndReg7(Indirect register 7) 00001000-11111111: Reserved for future use.
7-6 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
5 AUTO	Auto increment enable 0 - AOFF is not incremented automatically. Software should program the correct Address Offset for each access. 1 - AOFF is incremented by 1. Software should ensure not to cause a wrap condition. Byte wise read/write is not supported when auto increment is enabled.
4-2 —	Reserved
1 COM	Command type. Indicates the register access type. 0 - Indicates a write operation 1 - Indicates a read operation
0 OB	Operation Busy This bit is set along with a read or write command for initiating the indirect access to MAC_<MSEL>_<AOFF> register. This bit is reset when the read or write command to MAC_<MSEL>_<AOFF> register is complete. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into MAC_<MSEL>_<AOFF> register. During a read operation, the data should be read from MAC_INDIR_ACCESS_DATA register only after this bit is reset.

43.8.1.326 MAC_INDIR_ACCESS_DATA (MAC_INDIR_ACCESS_DATA)

This register holds the read/write data for Indirect Access of MAC_<MSEL_<AOFF> registers.

Offset

Register	Offset

28 AV8021ASMEN	AV 802. AV 802.1AS Mode Enable When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS mode of operation. When PTP offload feature is enabled, for the purpose of PTP offload, the transport specific field in the PTP header is generated and checked based on the value of this bit. 0 - AV 802.1AS Mode is disabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - AV 802.1AS Mode is enabled
27-25 —	Reserved
24 TXTSSTSM	Transmit Timestamp Status Mode When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. Transmit Timestamp Status Mode When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the MAC_TX_TIMESTAMP_STATUS_NANOSECONDS register. When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSMIS bit of the MAC_TX_TIMESTAMP_STATUS_NANOSECONDS register. 0 - Transmit Timestamp Status Mode is disabled 1 - Transmit Timestamp Status Mode is enabled
23-21 —	Reserved
20 ESTI	External System Time Input When this bit is set, the MAC uses the external 64-bit reference System Time input for the following: - To take the timestamp provided as status - To insert the timestamp in transmit PTP packets when One-step Timestamp or Timestamp Offload feature is enabled. External System Time Input When this bit is set, the MAC uses the external 64-bit reference System Time input for the following: - To take the timestamp provided as status - To insert the timestamp in transmit PTP packets when One-step Timestamp or Timestamp Offload feature is enabled. When this bit is reset, the MAC uses the internal reference System Time. 0 - External System Time Input is disabled 1 - External System Time Input is enabled
19 CSC	Enable checksum correction during OST for PTP over UDP/IPv4 packets When this bit is set, the last two bytes of PTP message sent over UDP/IPv4 is updated to keep the UDP checksum correct, for changes made to origin timestamp and/or correction field as part of one step timestamp operation. Enable checksum correction during OST for PTP over UDP/IPv4 packets When this bit is set, the last two bytes of PTP message sent over UDP/IPv4 is updated to keep the UDP checksum correct, for changes made to origin timestamp and/or correction field as part of one step timestamp operation. The application shall form the packet with these two dummy bytes. When reset, no updates are done to keep the UDP checksum correct. The application shall form the packet with UDP checksum set to 0.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - checksum correction during OST for PTP over UDP/IPv4 packets is disabled 1 - checksum correction during OST for PTP over UDP/IPv4 packets is enabled
18 TSENMACADDR	Enable MAC Address for PTP Packet Filtering When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet. Enable MAC Address for PTP Packet Filtering When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet. When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in MAC address registers are considered for processing as indicated below, when PTP is directly sent over Ethernet. For normal time stamping operation, MAC address registers 0 to 31 is considered for unicast destination address matching. For PTP offload, only MAC address register 0 is considered for unicast destination address matching. 0 - MAC Address for PTP Packet Filtering is disabled 1 - MAC Address for PTP Packet Filtering is enabled
17-16 SNAPTYPSEL	Select PTP packets for Taking Snapshots These bits, along with Bits 15 and 14, decide the set of PTP packet types for which snapshot needs to be taken. Select PTP packets for Taking Snapshots These bits, along with Bits 15 and 14, decide the set of PTP packet types for which snapshot needs to be taken. The encoding is given in Timestamp Snapshot Dependency on Register Bits Table.
15 TSMSTRENA	Enable Snapshot for Messages Relevant to Master When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Enable Snapshot for Messages Relevant to Master When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node. 0 - Snapshot for Messages Relevant to Master is disabled 1 - Snapshot for Messages Relevant to Master is enabled
14 TSEVNTENA	Enable Timestamp Snapshot for Event Messages When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). Enable Timestamp Snapshot for Event Messages When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, see Timestamp Snapshot Dependency on Register Bits Table. 0 - Timestamp Snapshot for Event Messages is disabled 1 - Timestamp Snapshot for Event Messages is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
13 TSIPV4ENA	Enable Processing of PTP Packets Sent over IPv4-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. Enable Processing of PTP Packets Sent over IPv4-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default. 0 - Processing of PTP Packets Sent over IPv4-UDP is disabled 1 - Processing of PTP Packets Sent over IPv4-UDP is enabled
12 TSIPV6ENA	Enable Processing of PTP Packets Sent over IPv6-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. Enable Processing of PTP Packets Sent over IPv6-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets. 0 - Processing of PTP Packets Sent over IPv6-UDP is disabled 1 - Processing of PTP Packets Sent over IPv6-UDP is enabled
11 TSIPENA	Enable Processing of PTP over Ethernet Packets When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. Enable Processing of PTP over Ethernet Packets When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets. 0 - Processing of PTP over Ethernet Packets is disabled 1 - Processing of PTP over Ethernet Packets is enabled
10 TSVER2ENA	Enable PTP Packet Processing for Version 2 Format When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. Enable PTP Packet Processing for Version 2 Format When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'. 0 - PTP Packet Processing for Version 2 Format is disabled 1 - PTP Packet Processing for Version 2 Format is enabled
9 TSCTRLSSR	Timestamp Digital or Binary Rollover Control When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. Timestamp Digital or Binary Rollover Control When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - Timestamp Digital or Binary Rollover Control is disabled 1 - Timestamp Digital or Binary Rollover Control is enabled
8 TSENALL	Enable Timestamp for All Packets When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC. 0 - Timestamp for All Packets disabled 1 - Timestamp for All Packets enabled
7 —	Reserved
6 PTGE	Presentation Time Generation Enable When this bit is set the Presentation Time generation will be enabled. 0 - Presentation Time Generation is disabled 1 - Presentation Time Generation is enabled
5 TSADDREG	Update Addend Register When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. Update Addend Register When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Addend Register is not updated 1 - Addend Register is updated
4 —	Reserved
3 TSUPDT	Update Timestamp When this bit is set, the system time is updated (added or subtracted) with the value specified in MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update registers. Update Timestamp When this bit is set, the system time is updated (added or subtracted) with the value specified in MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update registers. This bit should be zero before updating it. This bit is reset when the update is complete in hardware. The Timestamp Higher Word register (if enabled during core configuration) is not updated. When Media Clock Generation and Recovery is configured (DWC_EQOS_FLEXI_PPS_OUT_EN) and enabled MAC_Presn_Time_Updt should also be updated before setting this field. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Timestamp is not updated 1 - Timestamp is updated

Table continues on the next page...

Table continued from the previous page...

Field	Description
2 TSINIT	Initialize Timestamp When this bit is set, the system time is initialized (overwritten) with the value specified in the MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update registers. Initialize Timestamp When this bit is set, the system time is initialized (overwritten) with the value specified in the MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update registers. This bit should be zero before it is updated. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled during core configuration) can only be initialized. When Media Clock Generation and Recovery is configured (DWC_EQOS_FLEXI_PPS_OUT_EN) and enabled MAC_Presn_Time_Updt should also be updated before setting this field. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Timestamp is not initialized 1 - Timestamp is initialized
1 TSCFUPDT	Fine or Coarse Timestamp Update When this bit is set, the Fine method is used to update system timestamp. Fine or Coarse Timestamp Update When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp. 0 - Coarse method is used to update system timestamp 1 - Fine method is used to update system timestamp
0 TSENA	Enable Timestamp When this bit is set, the timestamp is added for Transmit and Receive packets. Enable Timestamp When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the Receive side, the MAC processes the 1588 packets only if this bit is set. 0 - Timestamp is disabled 1 - Timestamp is enabled

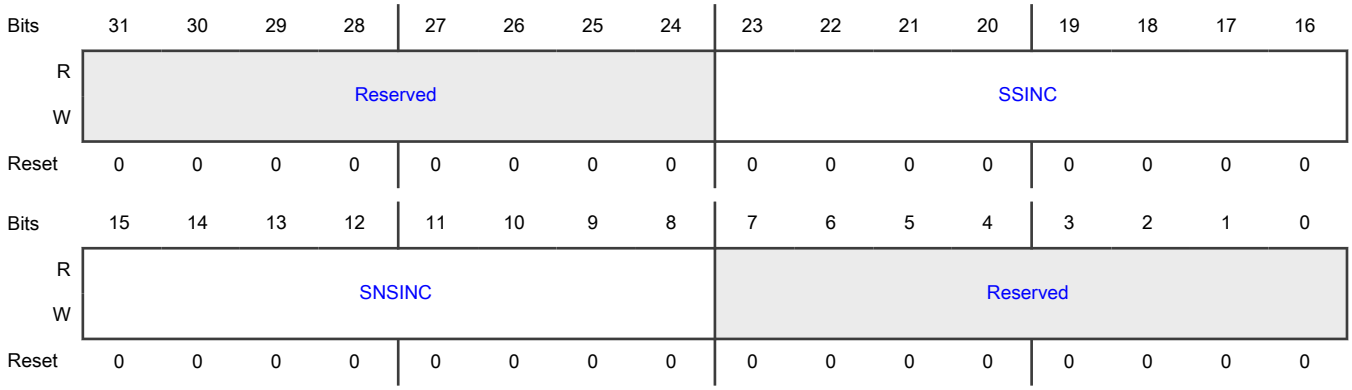
43.8.1.328 Subsecond Increment (MAC_SUB_SECOND_INCREMENT)

This register specifies the value to be added to the internal system time register every cycle of clk_ptp_ref_i clock.

Offset

Register	Offset
MAC_SUB_SECOND_INCREMENT	B04h

Diagram



Fields

Field	Description
31-24 —	Reserved
23-16 SSINC	Sub-second Increment Value The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. Sub-second Increment Value The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [Bit 9 (TSCTRLSSR) is set in TIMESTAMP_CONTROL]. When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465.
15-8 SNSINC	Sub-nanosecond Increment Value This field contains the sub-nanosecond increment value, represented in nanoseconds multiplied by 2^8. Sub-nanosecond Increment Value This field contains the sub-nanosecond increment value, represented in nanoseconds multiplied by 2^8. This value is accumulated with the sub-nanoseconds field of the subsecond register. For example, when TSCTRLSSR field in the TIMESTAMP_CONTROL register is set. and if the required increment is 5.3ns, then SSINC should be 0x05 and SNSINC should be 0x4C.
7-0 —	Reserved

43.8.1.329 System Time Seconds (MAC_SYSTEM_TIME_SECONDS)

The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).

Offset

Register	Offset
MAC_SYSTEM_TIME_SECONDS	B08h

Field	Description
31-0 TSS	Timestamp Second The value in this field indicates the current value in seconds of the System Time maintained by the MAC.

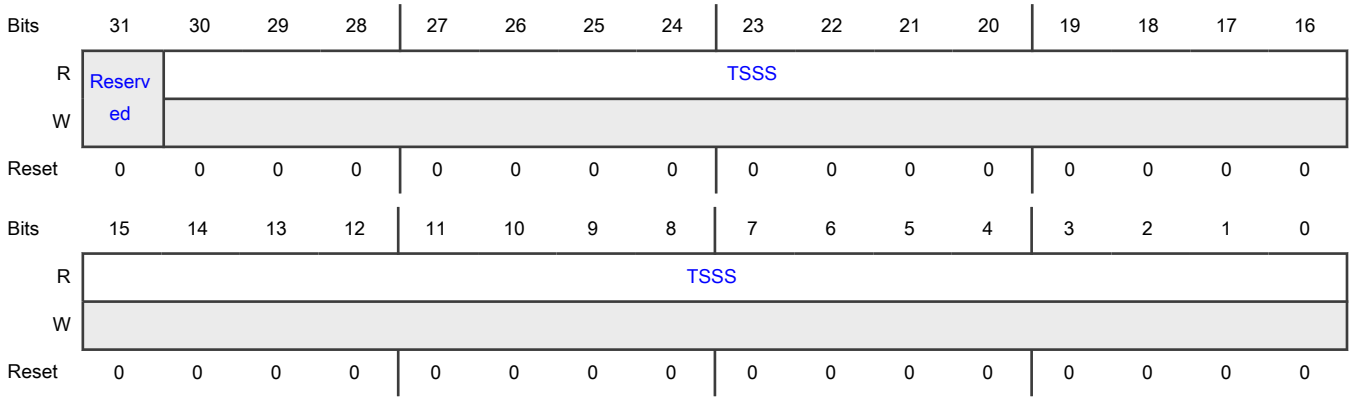
43.8.1.330 System Time Nanoseconds (MAC_SYSTEM_TIME_NANOSECONDS)

The System Time Nanoseconds register, along with System Time Seconds register, indicates the current value of the system time maintained by the MAC.

Offset

Register	Offset
MAC_SYSTEM_TIME_NANOSECONDS	B0Ch

Diagram



Fields

Field	Description
31 —	Reserved
30-0 TSSS	Timestamp Sub Seconds The value in this field has the sub-second representation of time, with an accuracy of 0. Timestamp Sub Seconds The value in this field has the sub-second representation of time, with an accuracy of 0.46 ns. When Bit 9 is set in TIMESTAMP_CONTROL, each bit represents 1 ns. The maximum value is 0x3B9A_C9FF after which it rolls-over to zero.

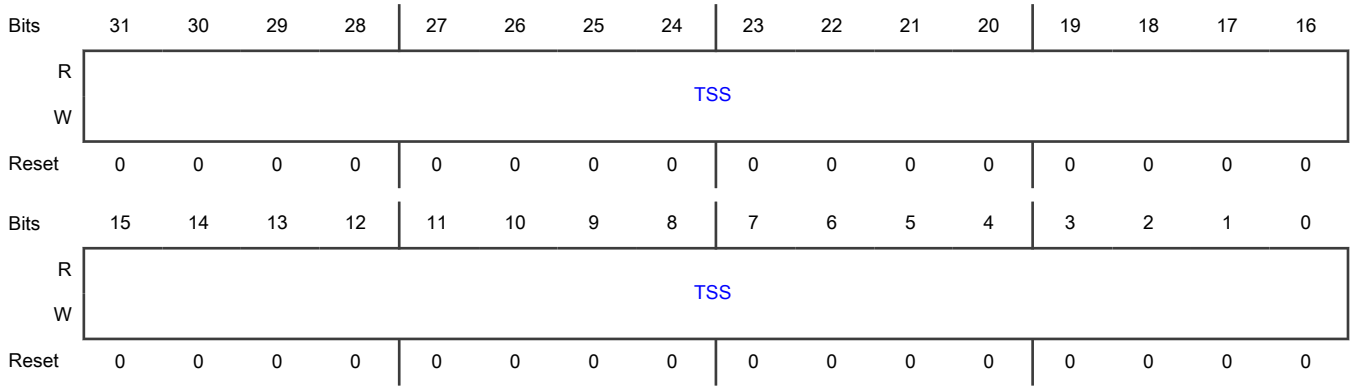
43.8.1.331 System Time Seconds Update (MAC_SYSTEM_TIME_SECONDS_UPDATE)

The System Time Seconds Update register, along with the System Time Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both registers before setting the TSINIT or TSUPDT bits in DWC_eqos_top_map/EQOS_MAC/MAC_TIMESTAMP_CONTROL.

Offset

Register	Offset
MAC_SYSTEM_TIME_SECONDS_UPDATE	B10h

Diagram



Fields

Field	Description
31-0 TSS	Timestamp Seconds The value in this field is the seconds part of the update. Timestamp Seconds The value in this field is the seconds part of the update. When ADDSUB is reset, this field must be programmed with the seconds part of the update value. When ADDSUB is set, this field must be programmed with the complement of the seconds part of the update value. For example, if 2.000000001 seconds need to be subtracted from the system time, the TSS field in the MAC_Timestamp_Seconds_Update register must be 0xFFFF_FFFE (that is, 2^32 - 2).

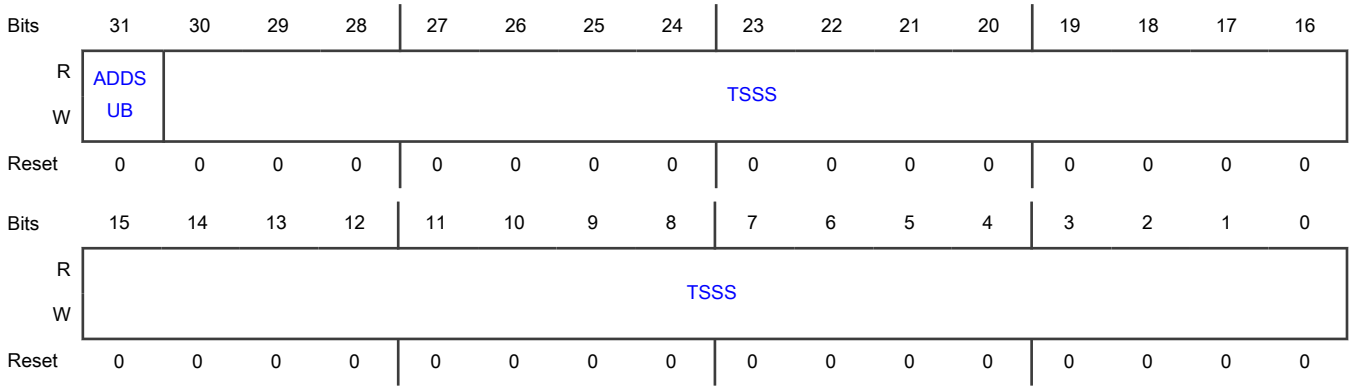
43.8.1.332 System Time Nanoseconds Update (MAC_SYSTEM_TIME_NANOSECONDS_UPDATE)

MAC System Time Nanoseconds Update register.

Offset

Register	Offset
MAC_SYSTEM_TIME_NANOSECONDS_UPDATE	B14h

Diagram



Fields

Field	Description
31 ADDSUB	Add or Subtract Time When this bit is set, the time value is subtracted with the contents of the update register. Add or Subtract Time When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register. 0 - Add time 1 - Subtract time
30-0 TSSS	Timestamp Sub Seconds The value in this field is the sub-seconds part of the update. Timestamp Sub Seconds The value in this field is the sub-seconds part of the update. When ADDSUB is reset, this field must be programmed with the sub-seconds part of the update value, with an accuracy based on the TSCTRLSSR bit of the TIMESTAMP_CONTROL register. When ADDSUB is set, this field must be programmed with the complement of the sub-seconds part of the update value as described below. When TSCTRLSSR bit in MAC_TIMESTAMP_CONTROL is set, the programmed value must be 10^9 - <sub-second value>. When TSCTRLSSR bit in MAC_TIMESTAMP_CONTROL is reset, the programmed value must be 2^31 - <sub-second_value>. When the TSCTRLSSR bit is reset in the TMAC_IMESTAMP_CONTROL register, each bit represents an accuracy of 0.46 ns. When the TSCTRLSSR bit is set in the MAC_TIMESTAMP_CONTROL register, each bit represents 1 ns and the programmed value should not exceed 0x3B9A_C9FF. For example, if 2.000000001 seconds need to be subtracted from the system time, then the TSSS field in the MAC_Timestamp_Nanoseconds_Update register must be 0x7FFF_FFFF (that is, 2^31 - 1), when TSCTRLSSR bit in MAC_TIMESTAMP_CONTROL is reset and 0x3B9A_C9FF (that is, 10^9 - 1), when TSCTRLSSR bit in MAC_TIMESTAMP_CONTROL is set.

43.8.1.333 Timestamp Addend (MAC_TIMESTAMP_ADDEND)

Timestamp Addend register. This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the MAC_TIMESTAMP_CONTROL register). The content of this register is added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i) and the system time is updated whenever the accumulator overflows.

Offset

Register	Offset
MAC_TIMESTAMP_ADDEND	B18h

1 TSTARGT0	Timestamp Target Time Reached When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers. Timestamp Target Time Reached When set, this bit indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS0_TARGET_TIME_SECONDS and MAC_PPS0_TARGET_TIME_NANOSECONDS registers. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - Timestamp Target Time Reached status not detected 1 - Timestamp Target Time Reached status detected
0 TSSOVF	Timestamp Seconds Overflow When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Timestamp Seconds Overflow When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - Timestamp Seconds Overflow status not detected 1 - Timestamp Seconds Overflow status detected

43.8.1.336 Transmit Timestamp Status Nanoseconds (MAC_TX_TIMESTAMP_STATUS_NANOSECONDS)

This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled.

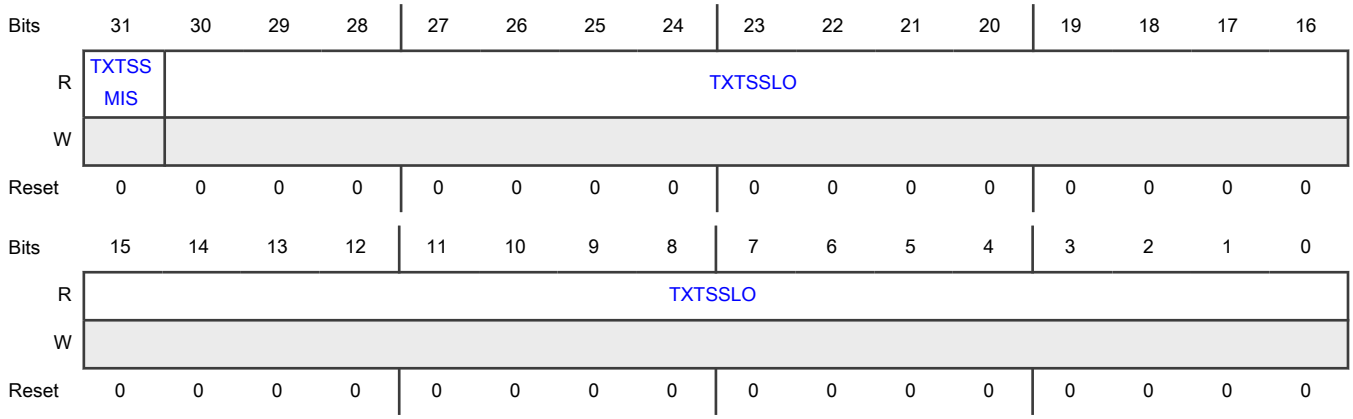
The MAC_TX_TIMESTAMP_STATUS_NANOSECONDS register, along with MAC_TX_TIMESTAMP_STATUS_SECONDS, gives the 64-bit timestamp captured for the PTP packet successfully transmitted by the MAC. This value is considered to be read by the application when the last byte of MAC_TX_TIMESTAMP_STATUS_NANOSECONDS is read. In the little-endian mode, this means when bits[31:24] are read; in big-endian mode, bits[7:0] are read.

If the application does not read these registers and timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the setting of the TXTSSTSM bit of the MAC_TIMESTAMP_CONTROL register. The status bit TXTSC bit [15] in MAC_TIMESTAMP_STATUS register is set whenever the MAC transmitter captures the timestamp.

Offset

Register	Offset
MAC_TX_TIMESTAMP_STATUS_NANOSECONDS	B30h

Diagram



Fields

Field	Description
31 TXTSSMIS	Transmit Timestamp Status Missed When this bit is set, it indicates one of the following: - The timestamp of the current packet is ignored if TXTSSTSM bit of the TIMESTAMP_CONTROL register is reset - The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the MAC_TIMESTAMP_CONTROL register is set. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - Transmit Timestamp Status Missed status not detected 1 - Transmit Timestamp Status Missed status detected
30-0 TXTSSLO	Transmit Timestamp Status Low This field contains the 31 bits of the Nanoseconds field of the Transmit packet's captured timestamp.

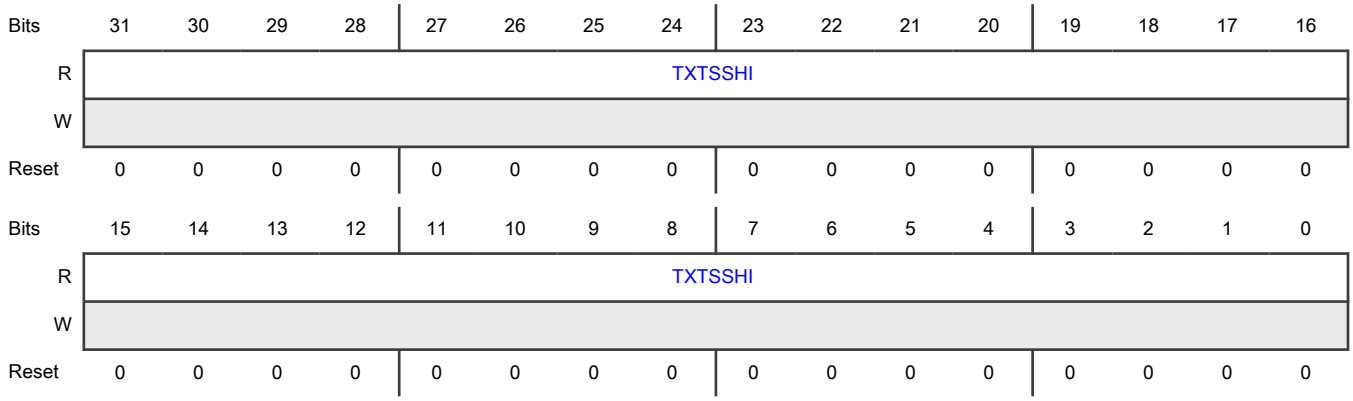
43.8.1.337 Transmit Timestamp Status Seconds (MAC_TX_TIMESTAMP_STATUS_SECONDS)

The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

Offset

Register	Offset
MAC_TX_TIMESTAMP_STATUS_SECONDS	B34h

Diagram



Fields

Field	Description
31-0 TXTSSHI	Transmit Timestamp Status High This field contains the lower 32 bits of the Seconds field of Transmit packet's captured timestamp.

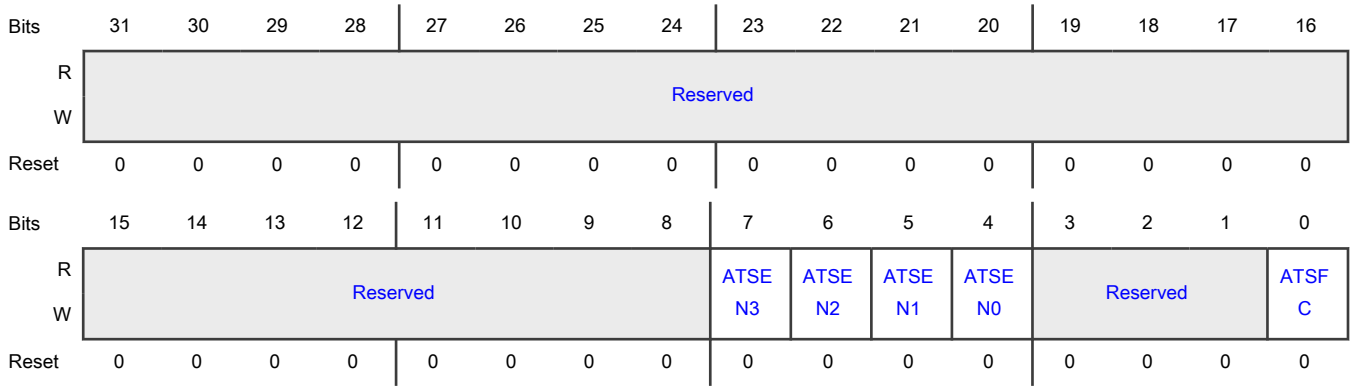
43.8.1.338 Auxiliary Timestamp Control (MAC_AUXILIARY_CONTROL)

The Auxiliary Timestamp Control register controls the Auxiliary Timestamp snapshot.

Offset

Register	Offset
MAC_AUXILIARY_CONTROL	B40h

Diagram



Fields

Field	Description
31-8 —	Reserved
7 ATSEN3	Auxiliary Snapshot 3 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 3. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[3] input is enabled. When this bit is reset, the events on this input are ignored. 0 - Auxiliary Snapshot $i is disabled 1 - Auxiliary Snapshot $i is enabled
6 ATSEN2	Auxiliary Snapshot 2 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 2. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[2] input is enabled. When this bit is reset, the events on this input are ignored. 0 - Auxiliary Snapshot $i is disabled 1 - Auxiliary Snapshot $i is enabled
5 ATSEN1	Auxiliary Snapshot 1 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 1. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[1] input is enabled. When this bit is reset, the events on this input are ignored. 0 - Auxiliary Snapshot $i is disabled 1 - Auxiliary Snapshot $i is enabled
4 ATSEN0	Auxiliary Snapshot 0 Enable This bit controls the capturing of Auxiliary Snapshot Trigger 0. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[0] input is enabled. When this bit is reset, the events on this input are ignored. 0 - Auxiliary Snapshot $i is disabled 1 - Auxiliary Snapshot $i is enabled
3-1 —	Reserved
0 ATSFC	Auxiliary Snapshot FIFO Clear When set, this bit resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, the auxiliary snapshots are stored in the FIFO. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Auxiliary Snapshot FIFO Clear is disabled 1 - Auxiliary Snapshot FIFO Clear is enabled

43.8.1.339 Auxiliary Timestamp Nanoseconds (MAC_AUXILIARY_TIMESTAMP_NANOSECONDS)

The Auxiliary Timestamp Nanoseconds register, along with MAC_Auxiliary_Timestamp_Seconds, gives the 64-bit timestamp stored as auxiliary snapshot. These two registers form the read port of a 64-bit wide FIFO with a depth of 4, 8, or 16 as selected while configuring the core.

You can store multiple snapshots in this FIFO. Bits[29:25] in MAC_TIMESTAMP_STATUS indicate the fill-level of the FIFO. The top of the FIFO is removed only when the last byte of MAC_AUXILIARY_TIMESTAMP_SECONDS register is read. In the little-endian mode, this means when Bits[31:24] are read and in big-endian mode, Bits[7:0] are read.

Offset

Register	Offset
MAC_AUXILIARY_TIMESTAMP_NANOSECONDS	B48h

Field	Description
	11 - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted
20 —	Reserved
19-16 PPSCMD2	Flexible PPS2 Output Control This field controls the flexible PPS2 output (ptp_pps_o[2]) signal. Flexible PPS2 Output Control This field controls the flexible PPS2 output (ptp_pps_o[2]) signal. This field is similar to the PPSCMD0 field. If MCGREN2 is set, then PPSCMD2 indicated by these 4 bits [19:16] are taken as Presentation Time Control bits for media clock generation and recovery for comparator instance 2. This field is similar to the PPSCMD0 Presentation Time Control bits. If MCGREN2 is not set then only 3 bits from [18:16] is used as PPSCMD2 and the 4th bit is to be set as 0. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
15 MCGREN1	MCGR Mode Enable for PPS1 Output This field enables the 1st PPS instance to operate in PPS or MCGR mode. MCGR Mode Enable for PPS1 Output This field enables the 1st PPS instance to operate in PPS or MCGR mode. When set it operates in MCGR mode and on reset it operates in PPS mode. 0 - 1st PPS instance is disabled to operate in PPS or MCGR mode 1 - 1st PPS instance is enabled to operate in PPS or MCGR mode
14-13 TRGTMODSEL1	Target Time Register Mode for PPS1 Output This field indicates the Target Time registers (MAC_PPS1_TARGET_TIME_SECONDS and MAC_PPS1_TARGET_TIME_NANOSECONDS) mode for PPS1 output signal. 00 - Target Time registers are programmed only for generating the interrupt event. The Flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port 01 - Reserved 10 - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation 11 - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted
12 —	Reserved
11-8 PPSCMD1	Flexible PPS1 Output Control This field controls the flexible PPS1 output (ptp_pps_o[1]) signal. Flexible PPS1 Output Control This field controls the flexible PPS1 output (ptp_pps_o[1]) signal. This field is similar to the PPSCMD0 field.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	If MCGREN1 is set, then PPSCMD1 indicated by these 4 bits [11:8] are taken as Presentation Time Control bits for media clock generation and recovery for comparator instance 1. This field is similar to the PPSCMD0 Presentation Time Control bits. If MCGREN1 is not set then only 3 bits from [10:8] is used as PPSCMD1 and the 4th bit is to be set as 0. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
7 MCGREN0	MCGR Mode Enable for PPS0 Output This field enables the 0th PPS instance to operate in PPS or MCGR mode. MCGR Mode Enable for PPS0 Output This field enables the 0th PPS instance to operate in PPS or MCGR mode. When set it operates in MCGR mode and on reset it operates in PPS mode. 0 - 0th PPS instance is enabled to operate in PPS mode 1 - 0th PPS instance is enabled to operate in MCGR mode
6-5 TRGTMODSEL0	Target Time Register Mode for PPS0 Output This field indicates the Target Time registers (MAC_PPS0_TARGET_TIME_SECONDS and MAC_PPS0_TARGET_TIME_NANOSECONDS) mode for PPS0 output signal: 00 - Target Time registers are programmed only for generating the interrupt event. The Flexible PPS function must not be enabled in this mode, otherwise spurious transitions may be observed on the corresponding ptp_pps_o output port 01 - Reserved 10 - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation 11 - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted
4 PPSEN0	Flexible PPS Output Mode Enable When this bit is set, Bits[3:0] function as PPSCMD. Flexible PPS Output Mode Enable When this bit is set, Bits[3:0] function as PPSCMD. When this bit is reset, Bits[3:0] function as PPSCTRL (Fixed PPS mode). 0 - Flexible PPS Output Mode is disabled 1 - Flexible PPS Output Mode is enabled
3-0 PPSCTRL_PPSCMD	PPS Output Frequency Control This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. PPS Output Frequency Control This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: - 0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. - 0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. - 0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	- 0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. - .. - 1111: The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz. Note: In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example: - When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms - When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of One clock of 50 percent duty cycle and 537 ms period Second clock of 463 ms period (268 ms low and 195 ms high) - When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of Three clocks of 50 percent duty cycle and 268 ms period Fourth clock of 195 ms period (134 ms low and 61 ms high) This behavior is because of the non-linear toggling of bits in the digital rollover mode in the MAC_System_Time_Nanoseconds register. or Flexible PPS Output (ptp_pps_o[0]) Control Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programmed only when they are 'all-zero'. The following list describes the values of PPSCMD0: - 0000: No Command - 0001: START Single Pulse This command generates single pulse rising at the start point defined in MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds register and of a duration defined in the PPS0 Width Register. - 0010: START Pulse Train This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by the 'Stop Pulse train at time' or 'Stop Pulse Train immediately' commands. - 0011: Cancel START This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. - 0100: STOP Pulse train at time

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. - 0101: STOP Pulse Train immediately This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010). - 110: Cancel STOP Pulse train This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command. - 0111-1111: Reserved or Presentation Time Control If MCGREN0 is set then these bits are treated as Presentation time control bits. The following list describes the values of PPSCMD0: - 0000: No Operation related to MCGR will be carried out. If set to this value in the mid of clock recovery or generation all the processing inputs will be flushed. - 0001: Capture the Presentation time at rising edge of mcg_pst_trig_i[0] into the MAC_PPS0_Target_Time_Seconds register - 0010: Capture the Presentation time at falling edge of mcg_pst_trig_i[0] into the MAC_PPS0_Target_Time_Seconds register - 0011: Capture the Presentation time at both edges of mcg_pst_trig_i[0] into the MAC_PPS0_Target_Time_Seconds register - 0100-1000: Reserved - 1001: Toggle output on compare - 1010: Pulse output low on compare for one PTP-clock cycle - 1011: Pulse output high on compare for one PTP-clock cycle - 1100-1111: Reserved

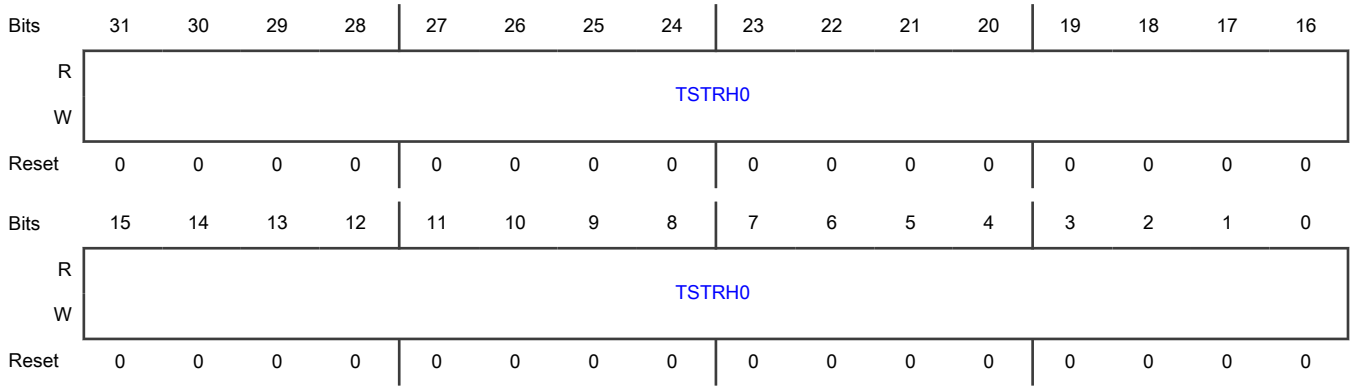
43.8.1.350 PPS0 Target Time Seconds (MAC_PPS0_TARGET_TIME_SECONDS)

The PPS0 Target Time Seconds register, along with PPS0 Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 1 of MAC_TIMESTAMP_STATUS] when the system time exceeds the value programmed in these registers.

Offset

Register	Offset
MAC_PPS0_TARGET_TIME_SECONDS	B80h

Diagram



Fields

Field	Description
31-0 TSTRH0	PPS Target Time Seconds Register This field stores the time in seconds. PPS Target Time Seconds Register This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Target Time mode selected for the corresponding PPS output in the MAC_PPS_CONTROL register.

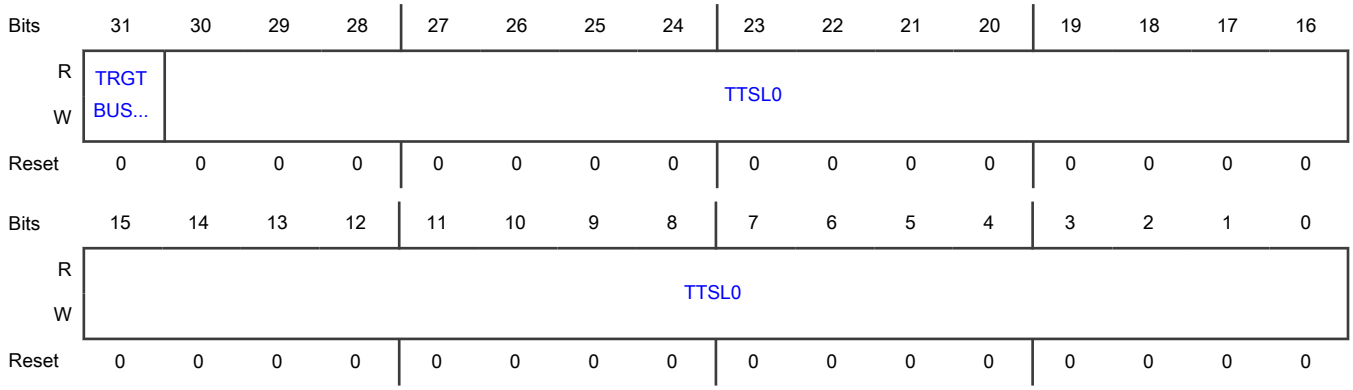
43.8.1.351 PPS0 Target Time Nanoseconds (MAC_PPS0_TARGET_TIME_NANOSECONDS)

PPS0 Target Time Nanoseconds register.

Offset

Register	Offset
MAC_PPS0_TARGET_TIME_NANOSECONDS	B84h

Diagram



Fields

Field	Description
31 TRGTBUSY0	PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the PPS_CONTROL register is programmed to 010 or 011. PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the MAC_PPS_CONTROL register is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. 0 - PPS Target Time Register Busy status is not detected 1 - PPS Target Time Register Busy is detected
30-0 TTSL0	Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in PPS_CONTROL. When the TSCTRLSSR bit is reset in the MAC_TIMESTAMP_CONTROL register, this value should be (time in ns / 0.465). The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. When the TSCTRLSSR bit is set in the MAC_TIMESTAMP_CONTROL register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

43.8.1.352 PPS0 Interval (MAC_PPS0_INTERVAL)

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).

Offset

Register	Offset
MAC_PPS0_INTERVAL	B88h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Description
31-0 PPSINT2	PPS Output Signal Interval These bits store the interval between the rising edges of PPS2 signal output. PPS Output Signal Interval These bits store the interval between the rising edges of PPS2 signal output. The interval is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS2 signal output is 100 ns (that is, 5 units of sub-second increment value), you should program value 4 (5-1) in this register.

43.8.1.361 PPS2 Width (MAC_PPS2_WIDTH)

The PPS2 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of PPS2 signal output (ptp_pps_o[2]).

Offset

Register	Offset
MAC_PPS2_WIDTH	BACh

Diagram

Fields

Field	Description
31-0 PPSWIDTH2	PPS Output Signal Width These bits store the width between the rising edge and corresponding falling edge of PPS0 signal output. PPS Output Signal Width These bits store the width between the rising edge and corresponding falling edge of PPS0 signal output. The width is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS0 signal output is 80 ns (that is, four units of sub-second increment value), you should program value 3 (4-1) in this register. Note: The value programmed in this register must be lesser than the value programmed in MAC_PPS0_Interval.

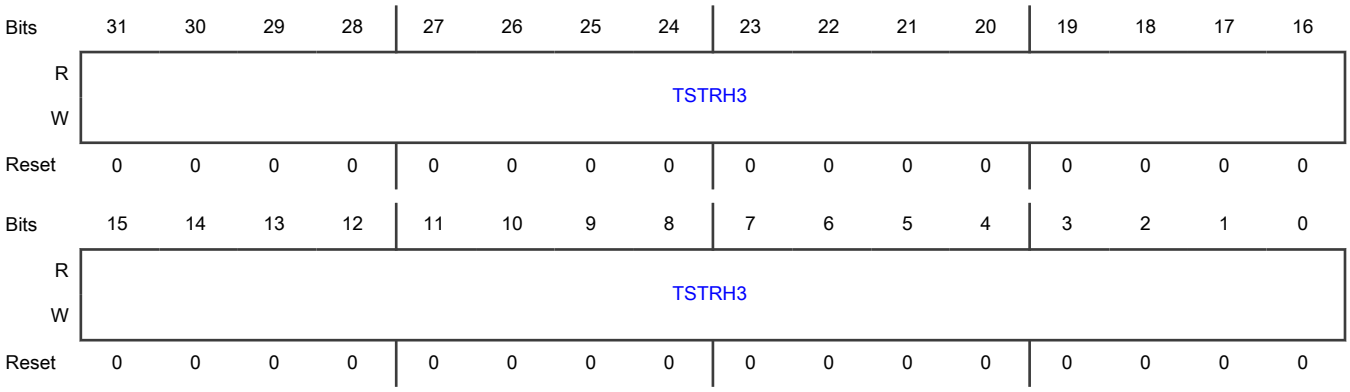
43.8.1.362 PPS3 Target Time Seconds (MAC_PPS3_TARGET_TIME_SECONDS)

The PPS3 Target Time Seconds register, along with PPS3 Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 1 of TIMESTAMP_STATUS] when the system time exceeds the value programmed in these registers.

Offset

Register	Offset
MAC_PPS3_TARGET_TIME_SECONDS	BB0h

Diagram



Fields

Field	Description
31-0 TSTRH3	PPS Target Time Seconds Register This field stores the time in seconds. PPS Target Time Seconds Register This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Target Time mode selected for the corresponding PPS output in the PPS_CONTROL register.

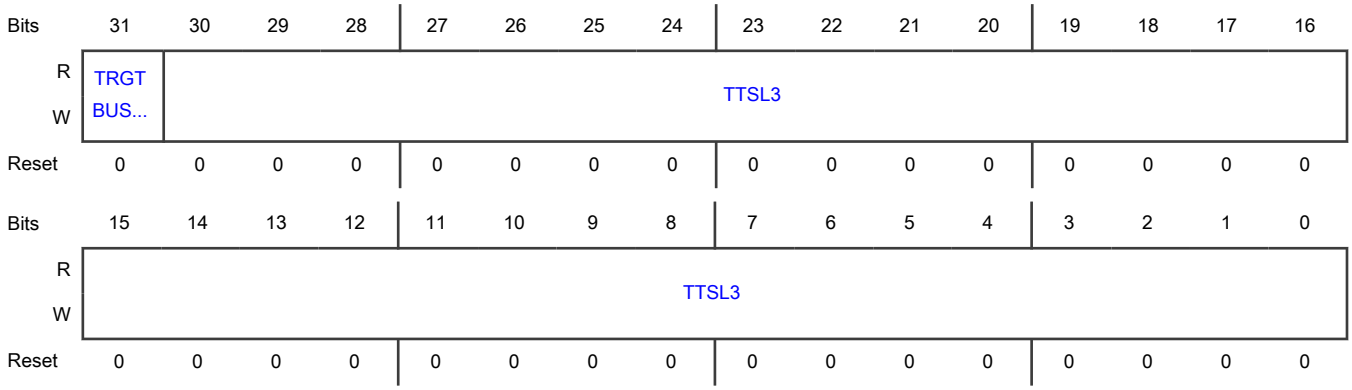
43.8.1.363 PPS3 Target Time Nanoseconds (MAC_PPS3_TARGET_TIME_NANOSECONDS)

PPS3 Target Time Nanoseconds register.

Offset

Register	Offset
MAC_PPS3_TARGET_TIME_NANOSECONDS	BB4h

Diagram



Fields

Field	Description
31 TRGTBUSY3	PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the PPS_CONTROL register is programmed to 010 or 011. PPS Target Time Register Busy The MAC sets this bit when the PPSCMD0 field in the PPS_CONTROL register is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. 0 - PPS Target Time Register Busy status is not detected 1 - PPS Target Time Register Busy is detected
30-0 TTSL3	Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in PPS_CONTROL. When the TSCTRLSSR bit is reset in the TIMESTAMP_CONTROL register, this value should be (time in ns / 0.465). The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. When the TSCTRLSSR bit is set in the TIMESTAMP_CONTROL register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

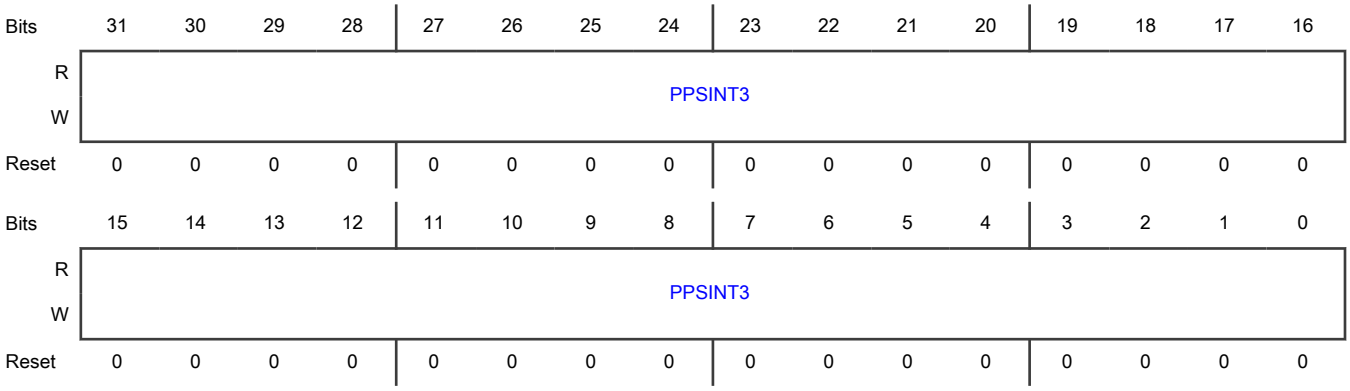
43.8.1.364 PPS3 Interval (MAC_PPS3_INTERVAL)

The PPS3 Interval register contains the number of units of sub-second increment value between the rising edges of PPS3 signal output (ptp_pps_o[3]).

Offset

Register	Offset
MAC_PPS3_INTERVAL	BB8h

Diagram



Fields

Field	Description
31-0 PPSINT3	PPS Output Signal Interval These bits store the interval between the rising edges of PPS3 signal output. Fields

Field	Description
31-24 —	Reserved
23 MTLPIS	MTL Rx Parser Interrupt Status This bit indicates that there is an interrupt from Rx Parser Block. MTL Rx Parser Interrupt Status This bit indicates that there is an interrupt from Rx Parser Block. To reset this bit, the application must read the MTL_RXP_INTERRUPT_STATUS register to get the exact cause of the interrupt and clear its source. 0 - MTL Rx Parser Interrupt status not detected 1 - MTL Rx Parser Interrupt status detected
22-19 —	Reserved
18 ESTIS	EST (TAS- 802. EST (TAS- 802.1Qbv) Interrupt Status This bit indicates an interrupt event during the operation of 802.1Qbv. To reset this bit, the application must clear the error/event that has caused the Interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - EST (TAS- 802.1Qbv) Interrupt status not detected 1 - EST (TAS- 802.1Qbv) Interrupt status detected
17 DBGIS	Debug Interrupt status This bit indicates an interrupt event during the slave access. Debug Interrupt status This bit indicates an interrupt event during the slave access. To reset this bit, the application must read the FIFO Debug Access Status register to get the exact cause of the interrupt and clear its source. 0 - Debug Interrupt status not detected 1 - Debug Interrupt status detected
16 —	Reserved
15-8 —	Reserved
7 —	Reserved
6 —	Reserved
5 —	Reserved
4 Q4IS	Queue 4 Interrupt status This bit indicates that there is an interrupt from Queue 4. Queue 4 Interrupt status This bit indicates that there is an interrupt from Queue 4. To reset this bit, the application must read the MTL_Q4_INTERRUPT_CONTROL_STATUS register to get the exact cause of the interrupt and clear its source. 0 - Queue 4 Interrupt status not detected 1 - Queue 4 Interrupt status detected
3 Q3IS	Queue 3 Interrupt status This bit indicates that there is an interrupt from Queue 3. Queue 3 Interrupt status This bit indicates that there is an interrupt from Queue 3. To reset this bit, the application must read the MTL_Q3_INTERRUPT_CONTROL_STATUS register to get the exact cause of the interrupt and clear its source. 0 - Queue 3 Interrupt status not detected 1 - Queue 3 Interrupt status detected

Table continues on the next page...

Table continued from the previous page...

Field	Description
2 Q2IS	Queue 2 Interrupt status This bit indicates that there is an interrupt from Queue 2. Queue 2 Interrupt status This bit indicates that there is an interrupt from Queue 2. To reset this bit, the application must read the MTL_Q2_INTERRUPT_CONTROL_STATUS register to get the exact cause of the interrupt and clear its source. 0 - Queue 2 Interrupt status not detected 1 - Queue 2 Interrupt status detected
1 Q1IS	Queue 1 Interrupt status This bit indicates that there is an interrupt from Queue 1. Queue 1 Interrupt status This bit indicates that there is an interrupt from Queue 1. To reset this bit, the application must read the MTL_Q1_INTERRUPT_CONTROL_STATUS register to get the exact cause of the interrupt and clear its source. 0 - Queue 1 Interrupt status not detected 1 - Queue 1 Interrupt status detected
0 Q0IS	Queue 0 Interrupt status This bit indicates that there is an interrupt from Queue 0. Queue 0 Interrupt status This bit indicates that there is an interrupt from Queue 0. To reset this bit, the application must read Queue 0 Interrupt Control and Status register to get the exact cause of the interrupt and clear its source. 0 - Queue 0 Interrupt status not detected 1 - Queue 0 Interrupt status detected

43.8.1.376 Receive Queue and DMA Channel Mapping 0 (MTL_RXQ_DMA_MAP0)

The Receive Queue and DMA Channel Mapping 0 register is reserved in EQOS-CORE and EQOS-MTL configurations.

Offset

Register	Offset
MTL_RXQ_DMA_MAP0	C30h

Fields

Field	Description
31-29 —	Reserved
28 Q3DDMACH	Queue 3 Enabled for Dynamic (per packet) DMA Channel Selection When set, this bit indicates that the packets received in Queue 3 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. Queue 3 Enabled for Dynamic (per packet) DMA Channel Selection When set, this bit indicates that the packets received in Queue 3 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 3 are routed to the DMA Channel programmed in the Q3MDMACH field (Bits[26:24]). 0 - Queue 3 disabled for DA-based DMA Channel Selection 1 - Queue 3 enabled for DA-based DMA Channel Selection
27 —	Reserved
26-24 Q3MDMACH	Queue 3 Mapped to DMA Channel This field controls the routing of the received packet in Queue 3 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel 3 - 100: DMA Channel 4 - 101: Reserved - 110: Reserved - 111: Reserved This field is valid when the Q3DDMACH field is reset. Queue 3 Mapped to DMA Channel This field controls the routing of the received packet in Queue 3 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel 3

Table continues on the next page...

Table continued from the previous page...

Field	Description
	- 100: DMA Channel 4 - 101: Reserved - 110: Reserved - 111: Reserved This field is valid when the Q3DDMACH field is reset. Note: The width of this field depends on the number of RX DMA channels and not all the values may be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000 and 001 are valid, the others are reserved
23-21 —	Reserved
20 Q2DDMACH	Queue 2 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 2 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. Queue 2 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 2 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 2 are routed to the DMA Channel programmed in the Q2MDMACH field (Bits[18:16]). 0 - Queue 2 disabled for DA-based DMA Channel Selection 1 - Queue 2 enabled for DA-based DMA Channel Selection
19 —	Reserved
18-16 Q2MDMACH	Queue 2 Mapped to DMA Channel This field controls the routing of the received packet in Queue 2 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel 3 - 100: DMA Channel 4 - 101: Reserved - 110: Reserved - 111: Reserved This field is valid when the Q2DDMACH field is reset.
15-13 —	Reserved
12 Q1DDMACH	Queue 1 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 1 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. Queue 1 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 1 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When reset, this bit indicates that the packets received in Queue 1 are routed to the DMA Channel programmed in the Q1MDMACH field (Bits[10:8]). 0 - Queue 1 disabled for DA-based DMA Channel Selection 1 - Queue 1 enabled for DA-based DMA Channel Selection
11 —	Reserved
10-8 Q1MDMACH	Queue 1 Mapped to DMA Channel This field controls the routing of the received packet in Queue 1 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel 3 - 100: DMA Channel 4 - 101: Reserved - 110: Reserved - 111: Reserved This field is valid when the Q1DDMACH field is reset. Queue 1 Mapped to DMA Channel This field controls the routing of the received packet in Queue 1 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel 3 - 100: DMA Channel 4 - 101: Reserved - 110: Reserved - 111: Reserved This field is valid when the Q1DDMACH field is reset. The width of this field depends on the number of RX DMA channels and not all the values may be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000 and 001 are valid, the other bits are reserved.
7-5 —	Reserved
4 Q0DDMACH	Queue 0 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 0 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. Queue 0 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 0 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 0 are routed to the DMA Channel programmed in the Q0MDMACH field. 0 - Queue 0 disabled for DA-based DMA Channel Selection

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Queue 0 enabled for DA-based DMA Channel Selection
3 —	Reserved
2-0 Q0MDMACH	Queue 0 Mapped to DMA Channel This field controls the routing of the packet received in Queue 0 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel 3 - 100: DMA Channel 4 - 101: Reserved - 110: Reserved - 111: Reserved This field is valid when the Q0DDMACH field is reset. Queue 0 Mapped to DMA Channel This field controls the routing of the packet received in Queue 0 to the DMA channel: - 000: DMA Channel 0 - 001: DMA Channel 1 - 010: DMA Channel 2 - 011: DMA Channel 3 - 100: DMA Channel 4 - 101: Reserved - 110: Reserved - 111: Reserved This field is valid when the Q0DDMACH field is reset. The width of this field depends on the number of RX DMA channels and not all the values may be valid in some configurations. For example, if the number of RX DMA channels selected is 2, only 000 and 001 are valid, the other bits are reserved.

43.8.1.377 Receive Queue and DMA Channel Mapping 1 (MTL_RXQ_DMA_MAP1)

The Receive Queue and DMA Channel Mapping 1 register is reserved in EQOS-CORE and EQOS-MTL configurations.

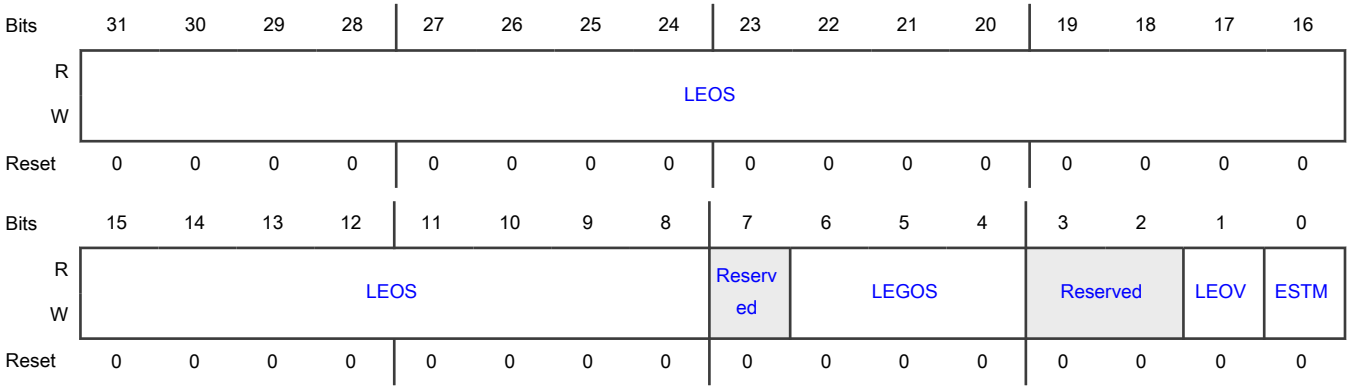
43.8.1.378 Time Based Scheduling Control (MTL_TBS_CTRL)

This register controls the operation of Time Based Scheduling.

Offset

Register	Offset
MTL_TBS_CTRL	C40h

Diagram



Fields

Field	Description
31-8 LEOS	Launch Expiry Offset The value in units of 256 nanoseconds that has to be added to the Launch time to compute the Launch Expiry time. Launch Expiry Offset The value in units of 256 nanoseconds that has to be added to the Launch time to compute the Launch Expiry time. Value valid only when LEOV is set. Max value: 999,999,999 ns, additionally should be smaller than CTR-1 value when ESTM mode is set since this value is a modulo CTR value.
7 —	Reserved
6-4	Launch Expiry GSN Offset The number GSN slots that has to be added to the Launch GSN to compute the Launch Expiry time.

Table continues on the next page...

Table continued from the previous page...

Field	Description
LEGOS	Launch Expiry GSN Offset The number GSN slots that has to be added to the Launch GSN to compute the Launch Expiry time. Value valid only when LEOV is set.
3-2 —	Reserved
1 LEOV	Launch Expiry Offset Valid When set indicates the LEOS field is valid. Launch Expiry Offset Valid When set indicates the LEOS field is valid. When not set, indicates the Launch Expiry Offset is not valid and the MTL must not check for Launch expiry time. 0 - LEOS field is invalid 1 - LEOS field is valid
0 ESTM	EST offset Mode When this bit is set, the Launch Time value used in Time Based Scheduling is interpreted as an EST offset value and is added to the Base Time Register (BTR) of the current list. EST offset Mode When this bit is set, the Launch Time value used in Time Based Scheduling is interpreted as an EST offset value and is added to the Base Time Register (BTR) of the current list. When reset, the Launch Time value is used as an absolute value that should be compared with the System time [39:8]. 0 - EST offset Mode is disabled 1 - EST offset Mode is enabled

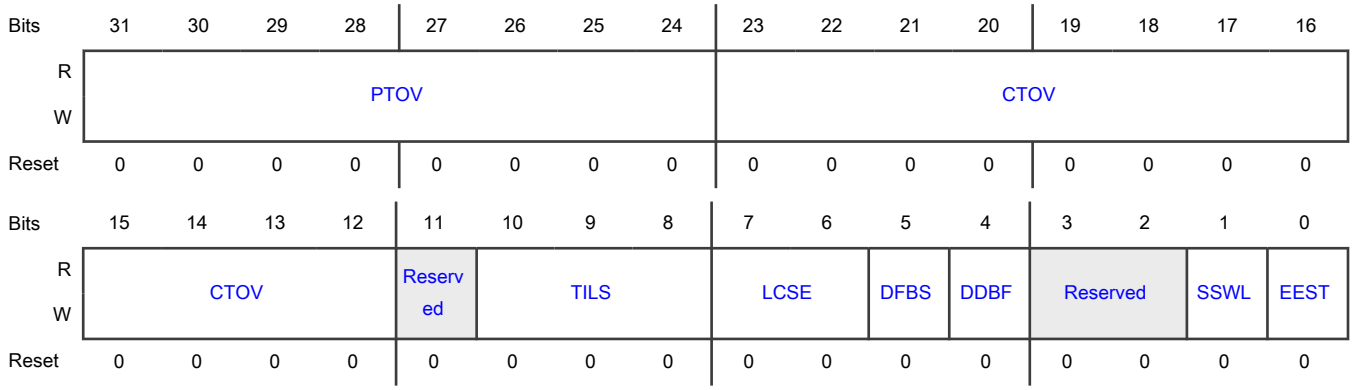
43.8.1.379 Enhancements to Scheduled Transmission Control (MTL_EST_CONTROL)

This register controls the operation of Enhancements to Scheduled Transmission (IEEE802.1Qbv).

Offset

Register	Offset
MTL_EST_CONTROL	C50h

Diagram



Fields

Field	Description
31-24 PTOV	PTP Time Offset Value The value of PTP Clock period multiplied by 6 in nanoseconds. PTP Time Offset Value The value of PTP Clock period multiplied by 6 in nanoseconds. This value is needed to avoid transmission overruns at the beginning of the installation of a new GCL.
23-12 CTOV	Current Time Offset Value Provides a 12 bit time offset value in nano second that is added to the current time to compensate for all the implementation pipeline delays such as the CDC sync delay, buffering delays, data path delays etc. Current Time Offset Value Provides a 12 bit time offset value in nano second that is added to the current time to compensate for all the implementation pipeline delays such as the CDC sync delay, buffering delays, data path delays etc. This offset helps to ensure that the impact of gate controls is visible on the line exactly at the pre-determined schedule (or as close to the schedule as possible).
11 —	Reserved
10-8 TILS	Time Interval Left Shift Amount This field provides the left shift amount for the programmed Time Interval values used in the Gate Control Lists. Time Interval Left Shift Amount This field provides the left shift amount for the programmed Time Interval values used in the Gate Control Lists. - 000: No left shift needed (equal to x1ns) - 001: Left shift TI by 1 bit (equal to x2ns) - 010: Left shift TI by 2 bits (equal to x4ns) - . - . - 100: Left shift TI by 7 bits (equal to x128ns)

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Based on the configuration one or more bits of this field should be treated as Reserved/Read-Only.
7-6 LCSE	Loop Count to report Scheduling Error Programmable number of GCL list iterations before reporting an HLBS error defined in EST_STATUS register. 00 - 4 iterations 01 - 8 iterations 10 - 16 iterations 11 - 32 iterations
5 DFBS	Drop Frames causing Scheduling Error When set frames reported to cause HOL Blocking due to not getting scheduled (HLBS field of EST_STATUS register) after 4,8,16,32 (based on LCSE field of this register) GCL iterations are dropped. 0 - Do not Drop Frames causing Scheduling Error 1 - Drop Frames causing Scheduling Error
4 DDBF	Do not Drop frames during Frame Size Error When set, frames are not be dropped during Head-of-Line blocking due to Frame Size Error (HLBF field of MTL_EST_STATUS register). 0 - Drop frames during Frame Size Error 1 - Do not Drop frames during Frame Size Error
3-2 —	Reserved
1 SSWL	Switch to S/W owned list When set indicates that the software has programmed that list that it currently owns (SWOL) and the hardware should switch to the new list based on the new BTR. Switch to S/W owned list When set indicates that the software has programmed that list that it currently owns (SWOL) and the hardware should switch to the new list based on the new BTR. Hardware clears this bit when the switch to the SWOL happens to indicate the completion of the switch or when an BTR error (BTRE in Status register) is set. When BTRE is set this bit is cleared but SWOL is not updated as the switch was not successful. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Switch to S/W owned list is disabled 1 - Switch to S/W owned list is enabled
0 EEST	Enable EST When reset, the gate control list processing is halted and all gates are assumed to be in Open state. Enable EST When reset, the gate control list processing is halted and all gates are assumed to be in Open state. Should be set for the hardware to start processing the gate control lists. During the toggle from 0 to 1, the gate control list processing starts only after the SSWL bit it set. When DWC_EQOS_ASP_ECC is selected during the configuration, if any uncorrectable error is detected in the EST memory the hardware will reset this bit and disable the EST function.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - EST is disabled 1 - EST is enabled

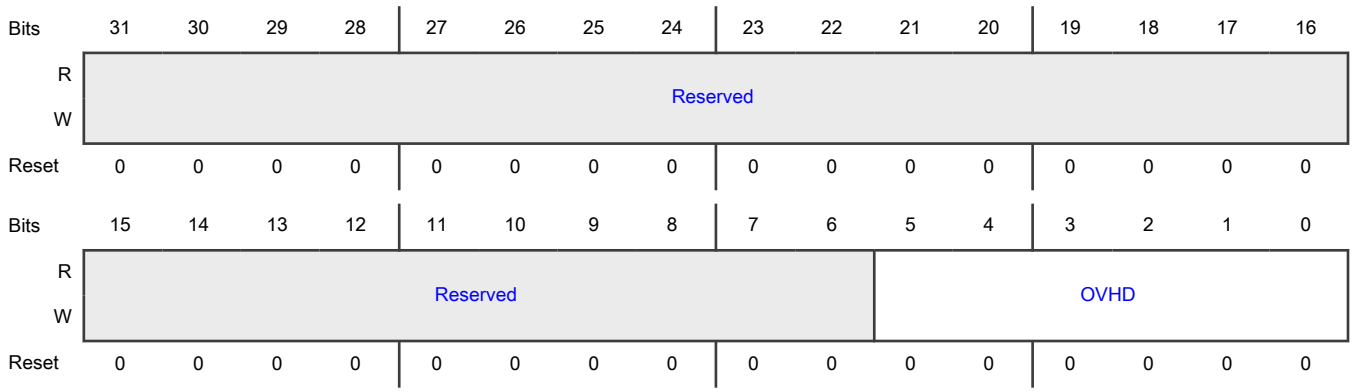
43.8.1.380 MTL_EST_EXT_CONTROL (MTL_EST_EXT_CONTROL)

This register indicates the number of overhead bytes for EST related scheduling.

Offset

Register	Offset
MTL_EST_EXT_CONTROL	C54h

Diagram



Fields

Field	Description
31-6 —	Reserved
5-0 OVHD	Overhead Bytes Value This field indicates the fixed overhead for every packet to account for EST Scheduler Delay, IPG or EIPG, and Preamble bytes.

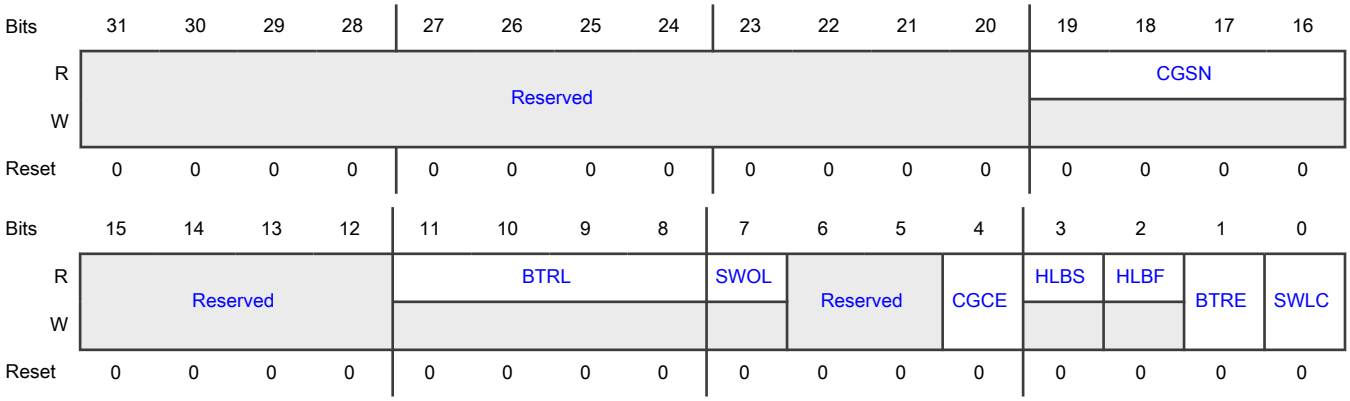
43.8.1.381 Enhancements to Scheduled Transmission Status (MTL_EST_STATUS)

This register provides Status related to Enhancements to Scheduled Transmission (IEEE802.1Qbv).

Offset

Register	Offset
MTL_EST_STATUS	C58h

Diagram



Fields

Field	Description
31-20 —	Reserved
19-16 CGSN	Current GCL Slot Number Indicates the slot number of the GCL list. Current GCL Slot Number Indicates the slot number of the GCL list. Slot number is a modulo 16 count of the GCL List loops executed so far. Even if a new GCL list is installed, the count is incremental.
15-12 —	Reserved
11-8 BTRL	BTR Error Loop Count Provides the minimum count (N) for which the equation Current Time =< New BTR + (N * New Cycle Time) becomes true. BTR Error Loop Count Provides the minimum count (N) for which the equation Current Time =< New BTR + (N * New Cycle Time) becomes true. N = "1111" indicates the iterations exceeded the value of 8 and the hardware was not able to update New BTR to be equal to or greater than Current Time. Software intervention is needed to update the New BTR. Value cleared when BTRE field of this register is cleared.
7 SWOL	S/W owned list When '0' indicates Gate control list number "0" is owned by software and when "1" indicates the Gate Control list "1" is owned by the software. S/W owned list

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When '0' indicates Gate control list number "0" is owned by software and when "1" indicates the Gate Control list "1" is owned by the software. Any reads/writes by the software (using indirect access via GCL_Control) is directed to the list indicated by this value by default. The inverse of this value is treated as HWOL. R/W operations performed by hardware are directed to the list pointed by HWOL by default. 0 - Gate control list number "0" is owned by software 1 - Gate control list number "1" is owned by software
6-5 —	Reserved
4 CGCE	Constant Gate Control Error This error occurs when the list length (LLR) is 1 and the programmed Time Interval (TI) value after the optional Left Shifting is less than or equal to the Cycle Time (CTR). Constant Gate Control Error This error occurs when the list length (LLR) is 1 and the programmed Time Interval (TI) value after the optional Left Shifting is less than or equal to the Cycle Time (CTR). The above programming implies Gates are either always Closed or always Open based on the Gate Control values; the same effect can be achieved by other simpler (non TSN) programming mechanisms. Since the implementation does not support such a programming an error is reported. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Constant Gate Control Error not detected 1 - Constant Gate Control Error detected
3 HLBS	Head-Of-Line Blocking due to Scheduling Set when the frame is not able to win arbitration and get scheduled even after 4 iterations of the GCL. Head-Of-Line Blocking due to Scheduling Set when the frame is not able to win arbitration and get scheduled even after 4 iterations of the GCL. Indicates to software a potential programming error. The one hot encoded values of the Queue Numbers that are not able to make progress are indicated in the MTL_EST_SCH_ERROR register. Bit cleared when MTL_EST_SCH_ERROR register is all zeroes. 0 - Head-Of-Line Blocking due to Scheduling not detected 1 - Head-Of-Line Blocking due to Scheduling detected
2 HLBF	Head-Of-Line Blocking due to Frame Size Set when HOL Blocking is noticed on one or more Queues as a result of none of the Time Intervals of gate open in the GCL being greater than or equal to the duration needed for frame size (or frame fragment size when preemption is enabled) transmission. Head-Of-Line Blocking due to Frame Size Set when HOL Blocking is noticed on one or more Queues as a result of none of the Time Intervals of gate open in the GCL being greater than or equal to the duration needed for frame size (or frame fragment size when preemption is enabled) transmission. The one hot encoded Queue numbers that are experiencing HLBF are indicated in the MTL_EST_FRM_SIZE_ERROR register. Additionally, the first Queue number that experienced HLBF along with the frame size is captured in MTL_EST_FRM_SIZE_CAPTURE register. Bit cleared when MTL_EST_FRAME_SIZE_ ERROR register is all zeros.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - Head-Of-Line Blocking due to Frame Size not detected 1 - Head-Of-Line Blocking due to Frame Size detected
1 BTRE	BTR Error When "1" indicates a programming error in the BTR of SWOL where the programmed value is less than current time. BTR Error When "1" indicates a programming error in the BTR of SWOL where the programmed value is less than current time. If the BTRL = "1111", SWOL is not updated and Software should reprogram the BTR to a value greater than current time and then set SSWL to reinitiate the switch to SWOL. Else if the value of BTRL < "1111", SWOL is updated and this field indicates the number of iterations (of + CycleTime) taken by hardware to update the BTR to a value greater than Current Time. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - BTR Error not detected 1 - BTR Error detected
0 SWLC	Switch to S/W owned list Complete When "1" indicates the hardware has successfully switched to the SWOL, and the SWOL bit has been updated to that effect. Switch to S/W owned list Complete When "1" indicates the hardware has successfully switched to the SWOL, and the SWOL bit has been updated to that effect. Cleared when the SSWL of MTL_EST_CONTROL register transitions from 0 to 1, or on a software write. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Switch to S/W owned list Complete not detected 1 - Switch to S/W owned list Complete detected

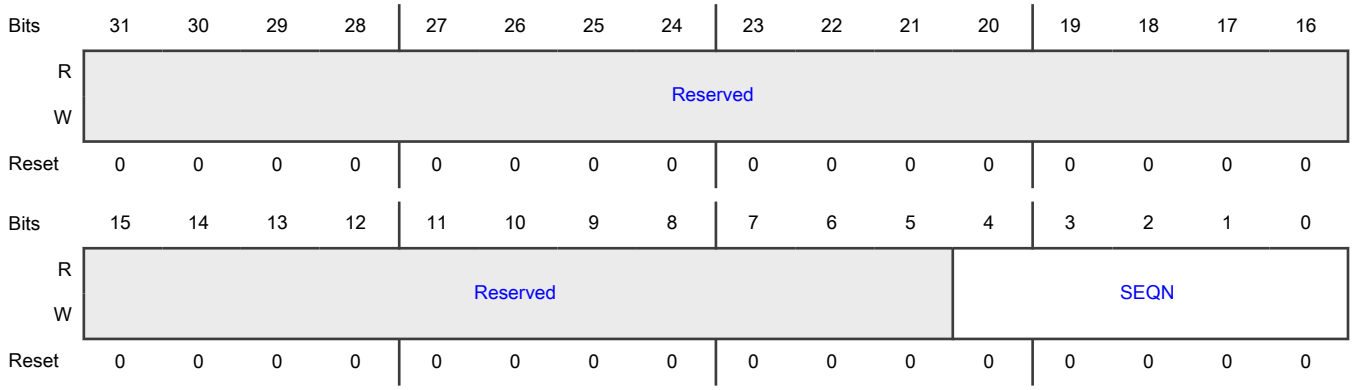
43.8.1.382 EST Scheduling Error (MTL_EST_SCH_ERROR)

This register provides the One Hot encoded Queue Numbers that are having the Scheduling related error (timeout).

Offset

Register	Offset
MTL_EST_SCH_ERROR	C60h

Diagram



Fields

Field	Description
31-5 —	Reserved
4-0 SEQN	Schedule Error Queue Number The One Hot Encoded Queue Numbers that have experienced error/timeout described in HLBS field of status register. Schedule Error Queue Number The One Hot Encoded Queue Numbers that have experienced error/timeout described in HLBS field of status register. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

43.8.1.383 EST Frame Size Error (MTL_EST_FRM_SIZE_ERROR)

This register provides the One Hot encoded Queue Numbers that are having the Frame Size related error.

Offset

Register	Offset
MTL_EST_FRM_SIZE_ERROR	C64h

Field	Description
31-19 —	Reserved
18-16 HBFQ	Queue Number of HLBF Captures the binary value of the of the first Queue (number) experiencing HLBF error (see HLBF field of status register). Queue Number of HLBF Captures the binary value of the of the first Queue (number) experiencing HLBF error (see HLBF field of status register). Value once written is not altered by any subsequent queue errors of similar nature. Once cleared the queue number of the next occurring HLBF error is captured. Width is based on the number of Tx Queues configured; remaining bits are Read-Only. Cleared when MTL_EST_FRM_SIZE_ERROR register is all zeros.
15 —	Reserved
14-0 HBFS	Frame Size of HLBF Captures the Frame Size of the dropped frame related to queue number indicated in HBFQ field of this register. Frame Size of HLBF Captures the Frame Size of the dropped frame related to queue number indicated in HBFQ field of this register. Contents of this register should be considered invalid, if this field is zero. Cleared when MTL_EST_FRM_SIZE_ERROR register is all zeros.

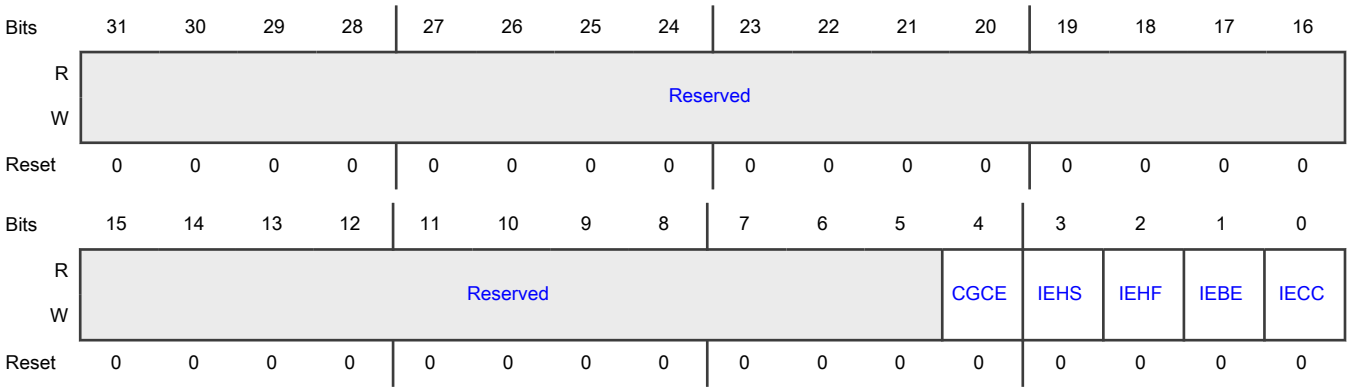
43.8.1.385 EST Interrupt Enable (MTL_EST_INTR_ENABLE)

This register implements the Interrupt Enable bits for the various events that generate an interrupt. Bit positions have a 1 to 1 correlation with the status bit positions in MTL_ETS_STATUS register.

Offset

Register	Offset
MTL_EST_INTR_ENABLE	C70h

Diagram



Fields

Field	Description
31-5 —	Reserved
4 CGCE	Interrupt Enable for CGCE When set, generates interrupt when the Constant Gate Control Error occurs and is indicated in the status. Interrupt Enable for CGCE When set, generates interrupt when the Constant Gate Control Error occurs and is indicated in the status. When reset this event does not generate an interrupt 0 - Interrupt for CGCE is disabled 1 - Interrupt for CGCE is enabled
3 IEHS	Interrupt Enable for HLBS When set, generates interrupt when the Head-of-Line Blocking due to Scheduling issue and is indicated in the status. Interrupt Enable for HLBS When set, generates interrupt when the Head-of-Line Blocking due to Scheduling issue and is indicated in the status. When reset this event does not generate an interrupt. 0 - Interrupt for HLBS is disabled 1 - Interrupt for HLBS is enabled
2 IEHF	Interrupt Enable for HLBF When set, generates interrupt when the Head-of-Line Blocking due to Frame Size error occurs and is indicated in the status. Interrupt Enable for HLBF

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When set, generates interrupt when the Head-of-Line Blocking due to Frame Size error occurs and is indicated in the status. When reset this event does not generate an interrupt. 0 - Interrupt for HLBF is disabled 1 - Interrupt for HLBF is enabled
1 IEBE	Interrupt Enable for BTR Error When set, generates interrupt when the BTR Error occurs and is indicated in the status. Interrupt Enable for BTR Error When set, generates interrupt when the BTR Error occurs and is indicated in the status. When reset this event does not generate an interrupt. 0 - Interrupt for BTR Error is disabled 1 - Interrupt for BTR Error is enabled
0 IECC	Interrupt Enable for Switch List When set, generates interrupt when the configuration change is successful and the hardware has switched to the new list. Interrupt Enable for Switch List When set, generates interrupt when the configuration change is successful and the hardware has switched to the new list. When reset this event does not generate an interrupt. 0 - Interrupt for Switch List is disabled 1 - Interrupt for Switch List is enabled

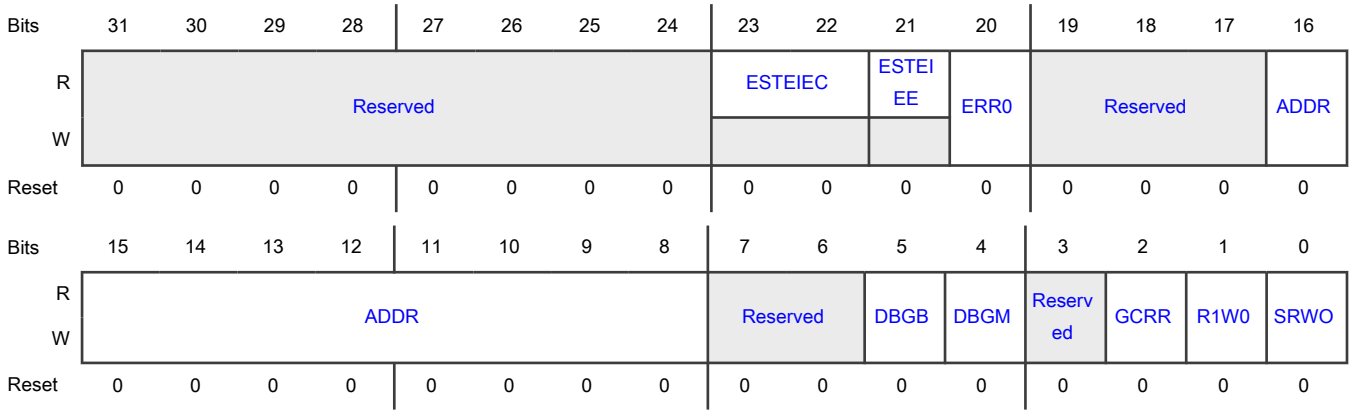
43.8.1.386 EST GCL Control (MTL_EST_GCL_CONTROL)

This register provides the control information for reading/writing to the Gate Control lists.

Offset

Register	Offset
MTL_EST_GCL_CONTROL	C80h

Diagram



Fields

Field	Description
31-24 —	Reserved
23-22 ESTEIEC	ECC Inject Error Control for EST Memory When EIEE bit of this register is set, following are the errors inserted based on the value encoded in this field. ECC Inject Error Control for EST Memory When EIEE bit of this register is set, following are the errors inserted based on the value encoded in this field. This filed will be valid only if DWC_EQOS_ASP_ECC feature is selected during the configuration, else it will be reserved. 00 - Insert 1 bit error 01 - Insert 2 bit errors 10 - Insert 3 bit errors 11 - Insert 1 bit error in address field
21 ESTEIEE	EST ECC Inject Error Enable When set along with EEST bit of MTL_EST_CONTROL register, enables the ECC error injection feature. EST ECC Inject Error Enable When set along with EEST bit of MTL_EST_CONTROL register, enables the ECC error injection feature. When reset, disables the ECC error injection feature. 0 - EST ECC Inject Error is disabled 1 - EST ECC Inject Error is enabled
20 ERR0	When set indicates the last write operation was aborted as software writes to GCL and GCL registers is prohibited when SSWL bit of MTL_EST_CONTROL Register is set. When set indicates the last write operation was aborted as software writes to GCL and GCL registers is prohibited when SSWL bit of MTL_EST_CONTROL Register is set. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table continues on the next page...

Field	Description
	0 - ERR0 is disabled 1 - ERR1 is enabled
19-17 —	Reserved
16-8 ADDR	Gate Control List Address: (GCLA when GCRR is "0"). Gate Control List Address: (GCLA when GCRR is "0"). Provides the address (row number) of the Gate Control List at which the R/W operation has to be performed. By default the Gate Control List pointed by SWOL of MTL_EST_STATUS is selected for R/W, however if the DBGM bit of this register is set, a debug mode access is given to R/W from DBGB. The width of this field is dependent on DWC_EQOS_EST_DEP; unused bits should be treated as read only. Gate Control list Related Registers Address: (GCRA when GCRR is "1"). By default the GCL related register set pointed by SWOL of MTL_EST_STATUS is selected for R/W, however if the DBGM bit of this register is set, a debug mode access is given to R/W from DBGB. Lower 3 bits are only used in this mode, higher order bits are treated as dont cares. - 000: BTR Low (31:0) - 001: BTR High (63:31) - 010: CTR Low (31:0) - 011: CTR High (39:32) - 100: TER (31:0) - 101: LLR (n:0) (where n is (log{DWC_EQOS_EST_DEP} / log2)) - Others: Reserved
7-6 —	Reserved
5 DBGB	Debug Mode Bank Select When set to "0" indicates R/W in debug mode should be directed to Bank 0 (GCL0 and corresponding Time related registers). Debug Mode Bank Select When set to "0" indicates R/W in debug mode should be directed to Bank 0 (GCL0 and corresponding Time related registers). When set to "1" indicates R/W in debug mode should be directed to Bank 1 (GCL1 and corresponding Time related registers). This value is used when DBGM is set and overrides by value of SWOL which is normally used. 0 - R/W in debug mode should be directed to Bank 0 1 - R/W in debug mode should be directed to Bank 1
4 DBGM	Debug Mode When set to "1" indicates R/W in debug mode where the memory bank (for GCL and Time related registers) is explicitly provided by DBGB value, when set to "0" SWOL bit is used to determine which bank to use. 0 - Debug Mode is disabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Debug Mode is enabled
3 —	Reserved
2 GCRR	Gate Control Related Registers When set to "1" indicates the R/W access is for the GCL related registers (BTR, CTR, TER, LLR) whose address is provided by GCRA. Gate Control Related Registers When set to "1" indicates the R/W access is for the GCL related registers (BTR, CTR, TER, LLR) whose address is provided by GCRA. When "0" indicates R/W should be directed to GCL from the address provided by GCLA. 0 - Gate Control Related Registers are disabled 1 - Gate Control Related Registers are enabled
1 R1W0	Read '1', Write '0': When set to '1': Read Operation When set to '0': Write Operation. 0 - Write Operation 1 - Read Operation
0 SRWO	Start Read/Write Op When set indicates a Read/Write Op has started and is in progress. Start Read/Write Op When set indicates a Read/Write Op has started and is in progress. When reset by hardware indicates the R/W Op has completed or an error has occurred (when bit 20 is set) Reads: Data can be read from MTL_EST_GCL_DATA register after this bit is reset Writes: MTL_EST_GCL_DATA should be programmed with write data before setting SRWO. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Start Read/Write Op disabled 1 - Start Read/Write Op enabled

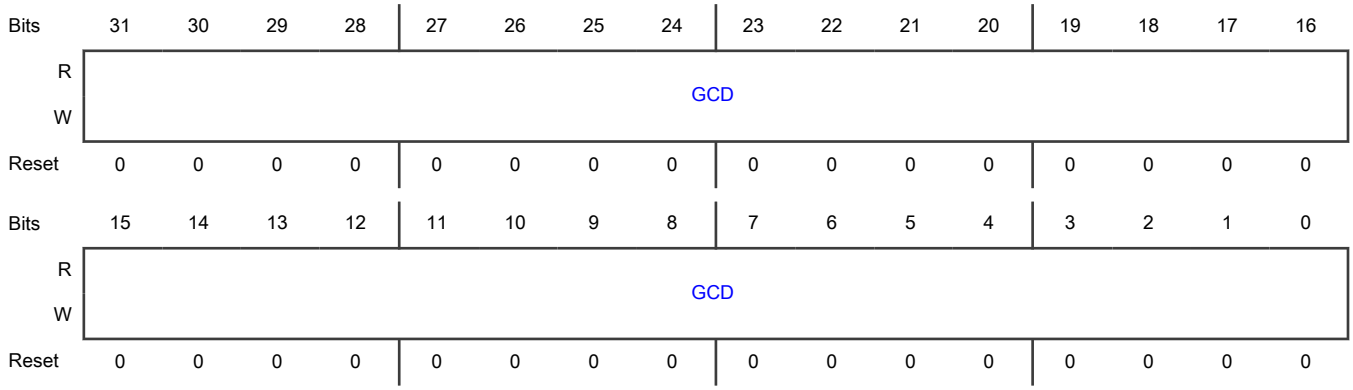
43.8.1.387 EST GCL Data (MTL_EST_GCL_DATA)

This register holds the read data or write data in case of reads and writes respectively.

Offset

Register	Offset
MTL_EST_GCL_DATA	C84h

Diagram



Fields

Field	Description
31-0 GCD	Gate Control Data The data corresponding to the address selected in the MTL_GCL_CONTROL register. Gate Control Data The data corresponding to the address selected in the MTL_GCL_CONTROL register. Used for both Read and Write operations.

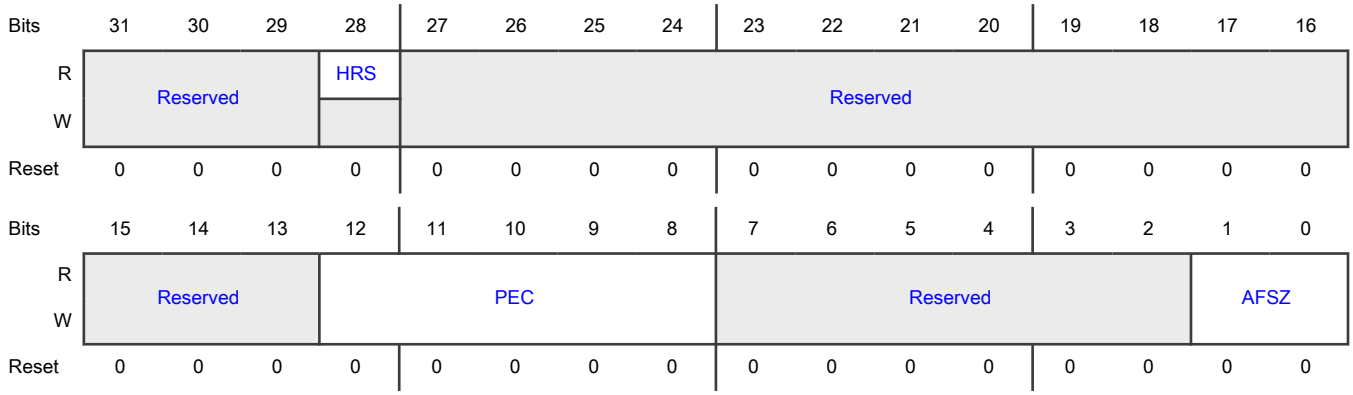
43.8.1.388 Frame Preemption Control and Status (MTL_FPE_CTRL_STS)

This register controls the operation of, and provides status for Frame Preemption (IEEE802.1Qbu/802.3br).

Offset

Register	Offset
MTL_FPE_CTRL_STS	C90h

Diagram



Fields

Field	Description

	1 - Rx Parser Error count overflow occurred
30-0 RXPEC	Rx Parser Error count This 31-bit counter is implemented whenever a Rx Parser encounters following Error scenarios - Entry address >= NVE[] - Number Parsed Entries >= NPE[] - Entry address > EOF data entry address The counter is cleared when the register is read.

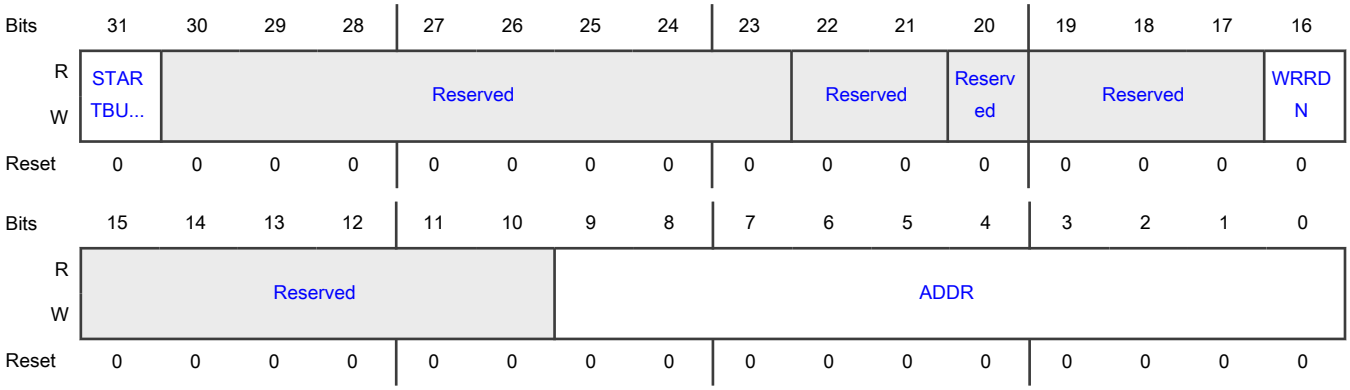
43.8.1.394 RXP Indirect Access Control and Status (MTL_RXP_INDIRECT_ACC_CONTROL_STATUS)

The RXP_INDIRECT_ACC_CONTROL_STATUS register provides the Indirect Access control and status for Rx Parser memory.

Offset

Register	Offset
MTL_RXP_INDIRECT_ACC_CONTROL_STATUS	CB0h

Diagram



Fields

Field	Description
31 STARTBUSY	FRP Instruction Table Access Busy When this bit is set to 1 by the software then it indicates to start the Read/Write operation from/to the Rx Parser Memory. FRP Instruction Table Access Busy When this bit is set to 1 by the software then it indicates to start the Read/Write operation from/to the Rx Parser Memory. Software should read this bit as 0 before issuing read or write request to access the Parser Memory Instructions.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This bit when set to 1 indicates that hardware is busy until its gets cleared by hardware and software should not issue any read or write operation. 0 - hardware not busy 1 - hardware is busy (Read/Write operation from/to the Rx Parser Memory)
30-23 —	Reserved
22-21 —	Reserved
20 —	Reserved
19-17 —	Reserved
16 WRRDN	Read Write Control When this bit is set to 1 indicates the write operation to the Rx Parser Memory. Read Write Control When this bit is set to 1 indicates the write operation to the Rx Parser Memory. When this bit is set to 0 indicates the read operation to the Rx Parser Memory. 0 - Read operation to the Rx Parser Memory 1 - Write operation to the Rx Parser Memory
15-10 —	Reserved
9-0 ADDR	FRP Instruction Table Offset Address This field indicates the ADDR of the 32-bit entry in Rx parser instruction table. FRP Instruction Table Offset Address This field indicates the ADDR of the 32-bit entry in Rx parser instruction table. Each entry has 128-bit (4x32-bit words). The X depends on the configurable DWC_EQOS_FRP_ENTRIES If DWC_EQOS_FRP_ENTRIES == 256 , then X = 9 If DWC_EQOS_FRP_ENTRIES = 128 , then X = 8 IF DWC_EQOS_FRP_ENTRIES = 64, then X = 7 This is can be written by the software before issuing any Read/Write command. The hardware auto-increments this field after the read-write operation gets completed.

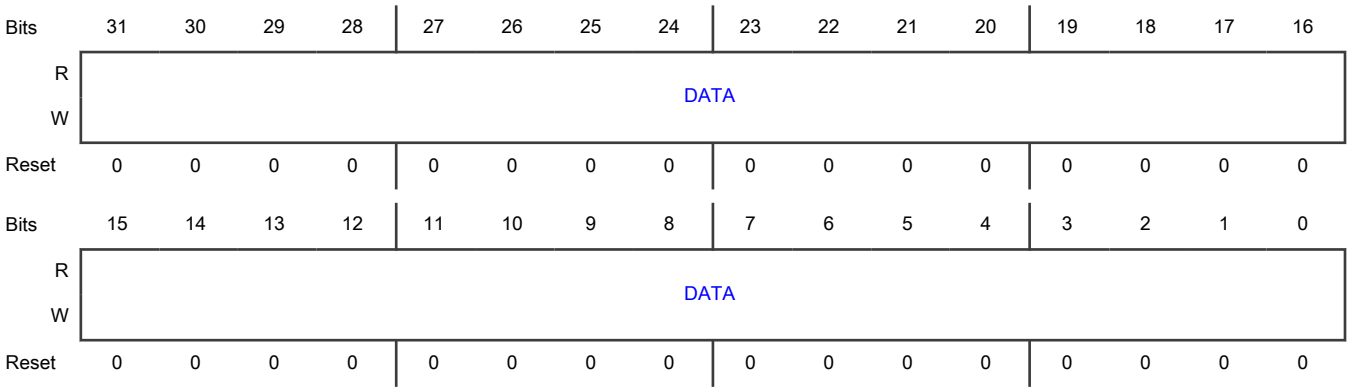
43.8.1.395 RXP Indirect Access Data (MTL_RXP_INDIRECT_ACC_DATA)

The RXP_INDIRECT_ACC_DATA registers holds the data associated to Indirect Access to Rx Parser memory.

Offset

Register	Offset
MTL_RXP_INDIRECT_ACC_DATA	CB4h

Diagram



Fields

Field	Description
31-0 DATA	FRP Instruction Table Write/Read Data Software should write this register before issuing any write command. FRP Instruction Table Write/Read Data Software should write this register before issuing any write command. The hardware provides the read data from the Rx Parser Memory for read operation when STARTBUSY =0 after read command.

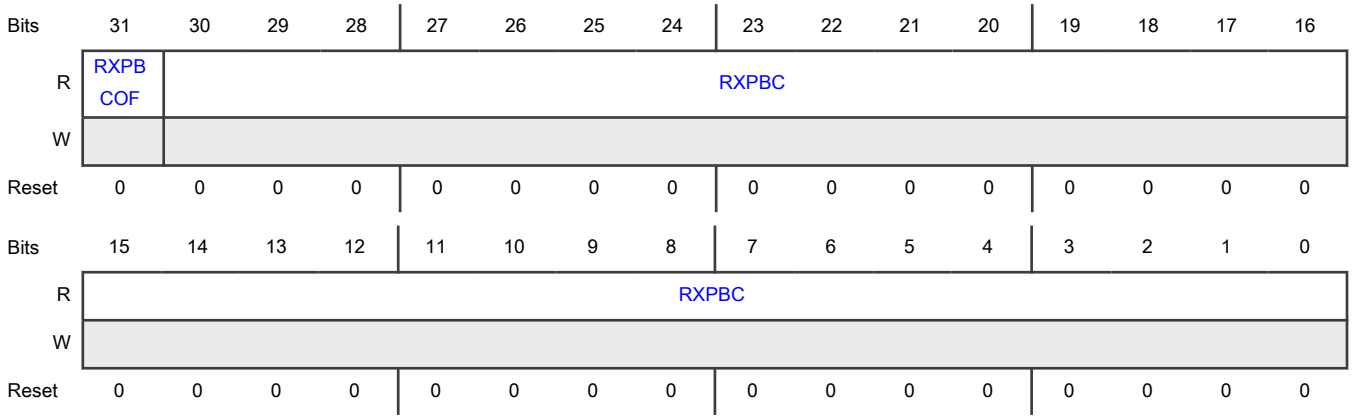
43.8.1.396 MTL_RXP_BYPASS_CNT (MTL_RXP_BYPASS_CNT)

The MTL_RXP_BYPASS_CNT register provides the bypass count of Rx Parser.

Offset

Register	Offset
MTL_RXP_BYPASS_CNT	CB8h

Diagram



Fields

Field	Description
31 RXPBCOF	Rx Parser bypass Counter Overflow Bit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - Indicates that MTL_RXP_BYPASS_CNT[RXPBC] counter field has not crossed the maximum limit 1 - Indicates that MTL_RXP_BYPASS_CNT[RXPBC] counter field has crossed the maximum limit
30-0 RXPBC	Rx Parser Bypass Count This 31-bit counter is implemented when a Rx Parser bypass a packet due to AF=1 and RF=1. The counter is cleared when the register is read.

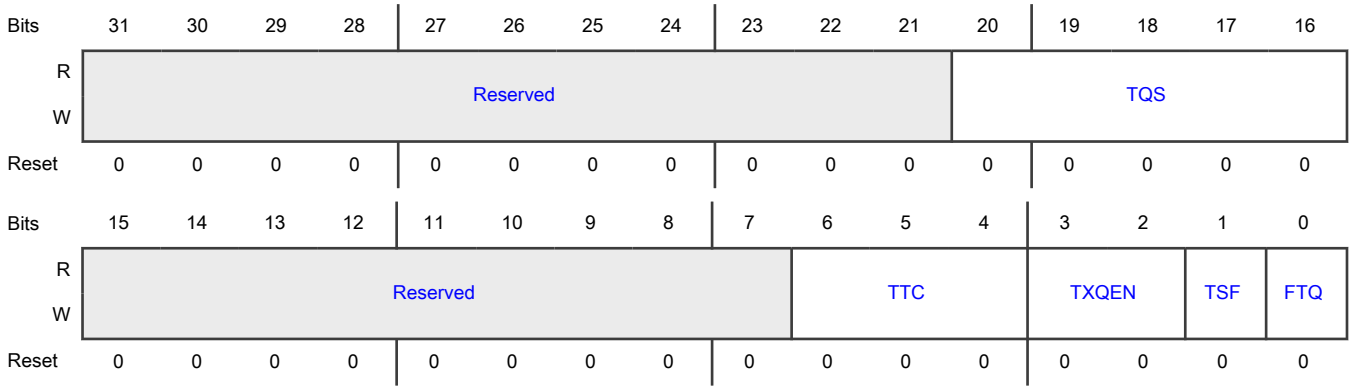
43.8.1.397 Queue 0 Transmit Operation Mode (MTL_TXQ0_OPERATION_MODE)

The Queue 0 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Offset

Register	Offset
MTL_TXQ0_OPERATION_MODE	D00h

Diagram



Fields

Field	Description
31-21 —	Reserved
20-16 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 —	Reserved
6-4 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000 - 32 001 - 64 010 - 96 011 - 128 100 - 192

Table continues on the next page...

Table continued from the previous page...

Field	Description
	101 - 256 110 - 384 111 - 512
3-2 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. Transmit Queue Enable This field is used to enable/disable the transmit queue 0. - 2'b00: Not enabled - 2'b01: Reserved - 2'b10: Enabled - 2'b11: Reserved This field is Read Only in Single Queue configurations and Read Write in Multiple Queue configurations. Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 00 - Not enabled 01 - Enable in AV mode (Reserved in non-AV) 10 - Enabled 11 - Reserved
1 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0 - Transmit Store and Forward is disabled 1 - Transmit Store and Forward is enabled
0 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TXQ0_OPERATION_MODE register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - Flush Transmit Queue is disabled 1 - Flush Transmit Queue is enabled

43.8.1.398 Queue 0 Underflow Counter (MTL_TXQ0_UNDERFLOW)

The Queue 0 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When the DCB operation is enabled with DWRR algorithm for Queue 0 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. When DCB operation is enabled with WFQ algorithm for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. The higher the programmed weights lesser the bandwidth allocated for the particular Transmit Queue. This is because the weights are used to compute the packet finish time (weights*packet_size). Lesser the finish time, higher the probability of the packet getting scheduled first and using more bandwidth. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero.

43.8.1.402 Queue 0 Interrupt Control Status (MTL_Q0_INTERRUPT_CONTROL_STATUS)

This register contains the interrupt enable and status bits for the queue 0 interrupts.

Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Average Bits Per Slot Interrupt Status not detected 1 - Average Bits Per Slot Interrupt Status detected
0 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Queue Underflow Interrupt Status not detected 1 - Transmit Queue Underflow Interrupt Status detected

43.8.1.403 Queue 0 Receive Operation Mode (MTL_RXQ0_OPERATION_MODE)

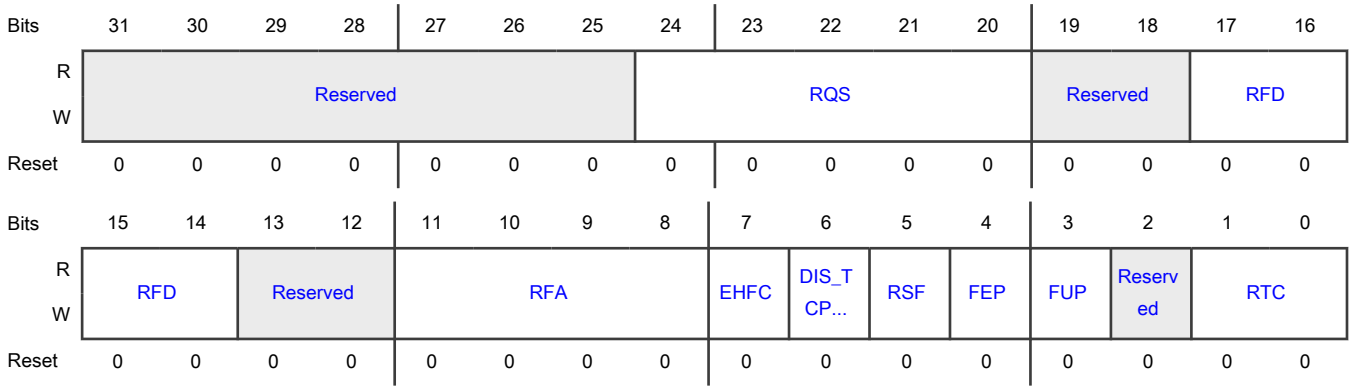
The Queue 0 Receive Operation Mode register establishes the Receive queue operating modes and command.

The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Offset

Register	Offset
MTL_RXQ0_OPERATION_MODE	D30h

Diagram



Fields

Field	Description
31-25 —	Reserved
24-20 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19-18 —	Reserved
17-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1. Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ...

Table continues on the next page...

Table continued from the previous page...

Field	Description
	- 14: Full minus 8 KB, that is, FULL 8 KB - 15: Full minus 8.5 KB, that is, FULL 8.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-12 —	Reserved
11-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
7 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0 - Hardware Flow Control is disabled 1 - Hardware Flow Control is enabled
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0 - Dropping of TCP/IP Checksum Error Packets is enabled 1 - Dropping of TCP/IP Checksum Error Packets is disabled
5 RSF	Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. Receive Queue Store and Forward

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0 - Receive Queue Store and Forward is disabled 1 - Receive Queue Store and Forward is enabled
4 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. 0 - Forward Error Packets is disabled 1 - Forward Error Packets is enabled
3 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0 - Forward Undersized Good Packets is disabled 1 - Forward Undersized Good Packets is enabled
2 —	Reserved
1-0 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.

15-6 —	Reserved
5 TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. 0 - MTL Tx Status FIFO Full status is not detected

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - MTL Tx Status FIFO Full status is detected
4 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission. 0 - MTL Tx Queue Not Empty status is not detected 1 - MTL Tx Queue Not Empty status is detected
3 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue. 0 - MTL Tx Queue Write Controller status is not detected 1 - MTL Tx Queue Write Controller status is detected
2-1 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00 - Idle state 01 - Read state (transferring data to the MAC transmitter) 10 - Waiting for pending Tx Status from the MAC transmitter 11 - Flushing the Tx queue because of the Packet Abort request from the MAC
0 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: - Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled - Reception of 802. Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: - Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled - Reception of 802.3x Pause packet when PFC is disabled 0 - Transmit Queue in Pause status is not detected 1 - Transmit Queue in Pause status is detected

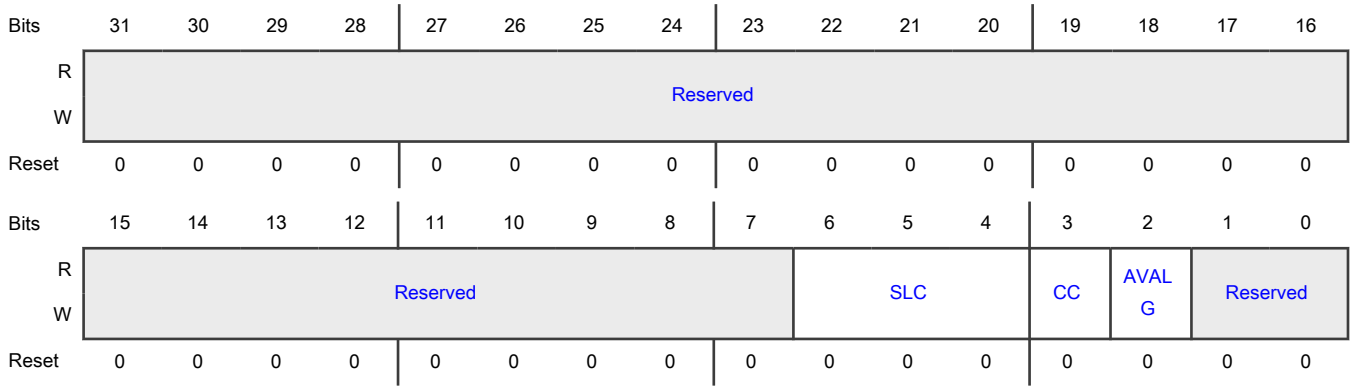
43.8.1.410 Queue 1 ETS Control (MTL_TXQ1_ETS_CONTROL)

The Queue 1 ETS Control register controls the enhanced transmission selection operation.

Offset

Register	Offset
MTL_TXQ1_ETS_CONTROL	D50h

Diagram



Fields

Field	Description
31-7 —	Reserved
6-4 SLC	Slot Count If the credit-based shaper algorithm is enabled, the software can program the number of slots (of duration programmed in DMA_CH1_Slot_Interval register) over which the average transmitted bits per slot, provided in the MTL_TXQ1_ETS_STATUS register, need to be computed for Queue. The encoding is as follows: 000 - 1 slot 001 - 2 slots 010 - 4 slots 011 - 8 slots 100 - 16 slots 101 - Reserved
3 CC	Credit Control When this bit is set, the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero when there is positive credit and no packet to transmit in Channel 1. Credit Control When this bit is set, the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero when there is positive credit and no packet to transmit in Channel 1. The credit accumulates even when there is no packet waiting in Channel 1 and another channel is transmitting. When this bit is reset, the accumulated credit parameter in the credit-based shaper algorithm logic is set to zero when there is positive credit and no packet to transmit in Channel 1. When there is no packet waiting in Channel 1 and other channel is transmitting, no credit is accumulated. 0 - Credit Control is disabled 1 - Credit Control is enabled
2 AVALG	AV Algorithm When Queue 1 is programmed for AV, this field configures the scheduling algorithm for this queue: This bit when set, indicates credit based shaper algorithm (CBS) is selected for Queue 1 traffic.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	AV Algorithm When Queue 1 is programmed for AV, this field configures the scheduling algorithm for this queue: This bit when set, indicates credit based shaper algorithm (CBS) is selected for Queue 1 traffic. When reset, strict priority is selected. 0 - CBS Algorithm is disabled 1 - CBS Algorithm is enabled
1-0 —	Reserved

43.8.1.411 Queue 1 ETS Status (MTL_TXQ1_ETS_STATUS)

The Queue 1 ETS Status register provides the average traffic transmitted in Queue 1.

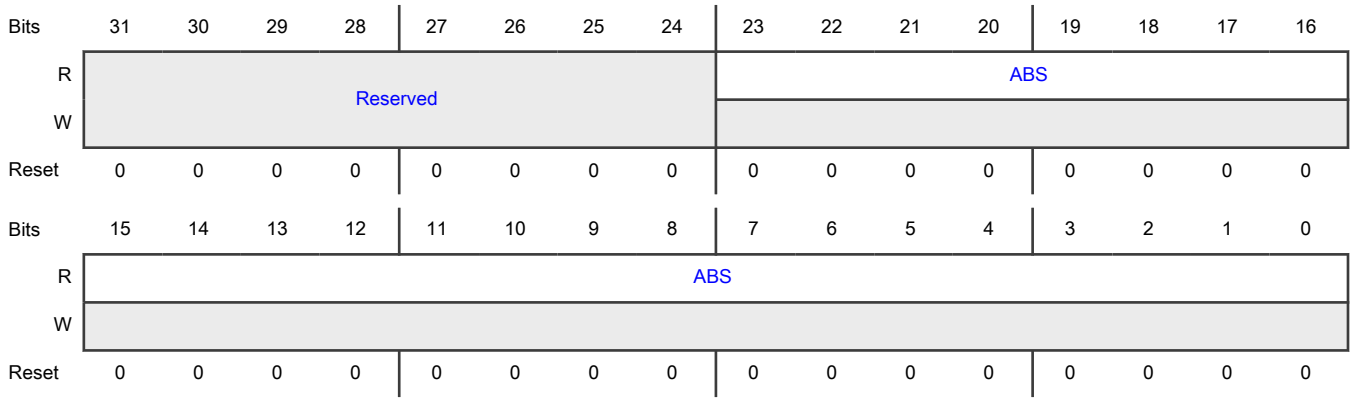
MTL_TXQ1_ETS_STATUS	D54h

Diagram



Fields

Field	Description
31-24 —	Reserved
23-0	Average Bits per Slot This field contains the average transmitted bits per slot.

Table continues on the next page...

Table continued from the previous page...

Field	Description
ABS	Average Bits per Slot This field contains the average transmitted bits per slot. If AV operation is enabled, this field is computed over number of slots, programmed in the SLC field of MTL_TXQ1_ETS_CONTROL register. The maximum value of this field is 0x6_4000 in 100 Mbps, 0x3E_8000 in 1000 Mbps and 9C_4000 in 2500 Mbps mode respectively. When the DCB operation is enabled for Queue, this field is computed over every 10 million bit times slot (4 ms in 2500 Mbps; 10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680.

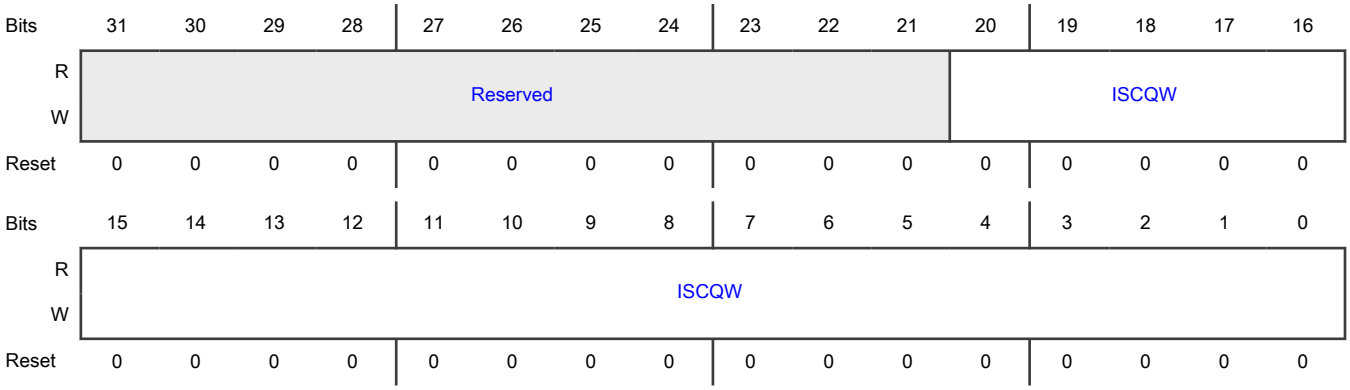
43.8.1.412 Queue 1 idleSlopeCredit, Quantum or Weights (MTL_TXQ1_QUANTUM_WEIGHT)

The Queue 1 idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 1.

Offset

Register	Offset
MTL_TXQ1_QUANTUM_WEIGHT	D58h

Diagram



Fields

Field	Description
31-21 —	Reserved
20-0 ISCQW	idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 1. idleSlopeCredit, Quantum or Weights

Table continues on the next page...

Table continued from the previous page...

Field	Description
	- idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps; 3.2 ns for 2500 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. - Quantum When the DCB operation is enabled with DWRR algorithm for Queue 1 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. - Weights When DCB operation is enabled with WFQ algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero. - Note 1: In multiple Queue configuration this field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. This field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both Receive and Transmit. In Receive, the register is MTL_OPERATION_MODE register. - Note 2: For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that Transmit Queue. The finish time is not a function of particular packet alone but it is as per the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size)) - Note 3: The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time.

43.8.1.413 Queue 1 sendSlopeCredit (MTL_TXQ1_SENDSLOPECREDIT)

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

Offset

Register	Offset
MTL_TXQ1_SENDSLOPECREDIT	D5Ch

1 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Average Bits Per Slot Interrupt Status not detected 1 - Average Bits Per Slot Interrupt Status detected
0 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Queue Underflow Interrupt Status not detected 1 - Transmit Queue Underflow Interrupt Status detected

43.8.1.417 Queue 1 Receive Operation Mode (MTL_RXQ1_OPERATION_MODE)

The Queue 1 Receive Operation Mode register establishes the Receive queue operating modes and command.

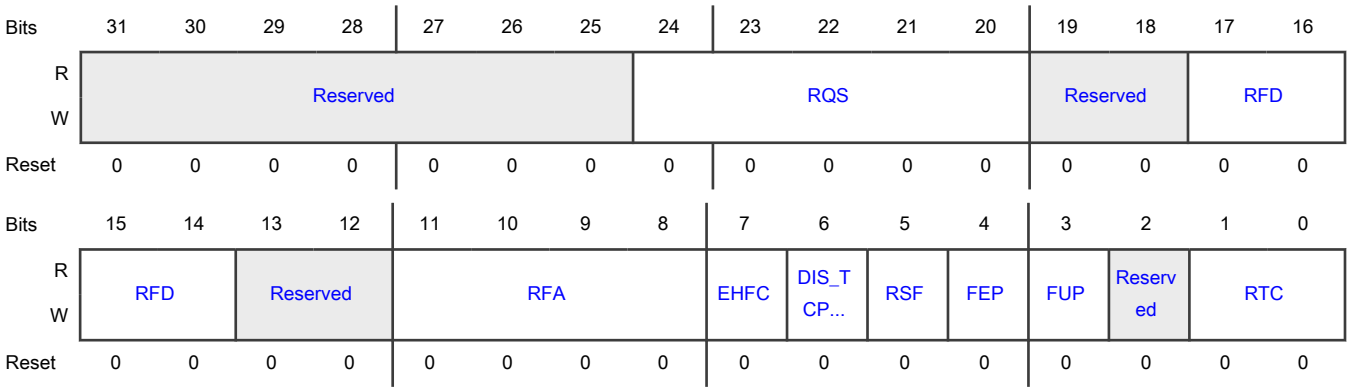
The Queue 1 Receive Operation Mode register establishes the Receive queue operating modes and command.

The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Offset

Register	Offset
MTL_RXQ1_OPERATION_MODE	D70h

Diagram



Fields

Field	Description
31-25 —	Reserved
24-20 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19-18 —	Reserved
17-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1. Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes)

Table continues on the next page...

Table continued from the previous page...

Field	Description
	These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ... - 14: Full minus 8 KB, that is, FULL 8 KB - 15: Full minus 8.5 KB, that is, FULL 8.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-12 —	Reserved
11-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
7 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0 - Hardware Flow Control is disabled 1 - Hardware Flow Control is enabled
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is reset, all error packets are dropped if the FEP bit is reset. 0 - Dropping of TCP/IP Checksum Error Packets is enabled 1 - Dropping of TCP/IP Checksum Error Packets is disabled
5 RSF	Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0 - Receive Queue Store and Forward is disabled 1 - Receive Queue Store and Forward is enabled
4 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. 0 - Forward Error Packets is disabled 1 - Forward Error Packets is enabled
3 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0 - Forward Undersized Good Packets is disabled 1 - Forward Undersized Good Packets is enabled
2 —	Reserved
1-0 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 00 - 64 01 - 32 10 - 96 11 - 128

43.8.1.418 Queue 1 Missed Packet and Overflow Counter (MTL_RXQ1_MISSED_PACKET_OVERFLOW_CNT)

The Queue 1 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Offset

Register	Offset
MTL_RXQ1_MISSED_PACKET_OVERFLOW_CNT	D74h

Diagram

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 00 - Not enabled 01 - Enable in AV mode (Reserved in non-AV) 10 - Enabled 11 - Reserved
1 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0 - Transmit Store and Forward is disabled 1 - Transmit Store and Forward is enabled
0 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TXQ2_OPERATION_MODE register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Flush Transmit Queue is disabled 1 - Flush Transmit Queue is enabled

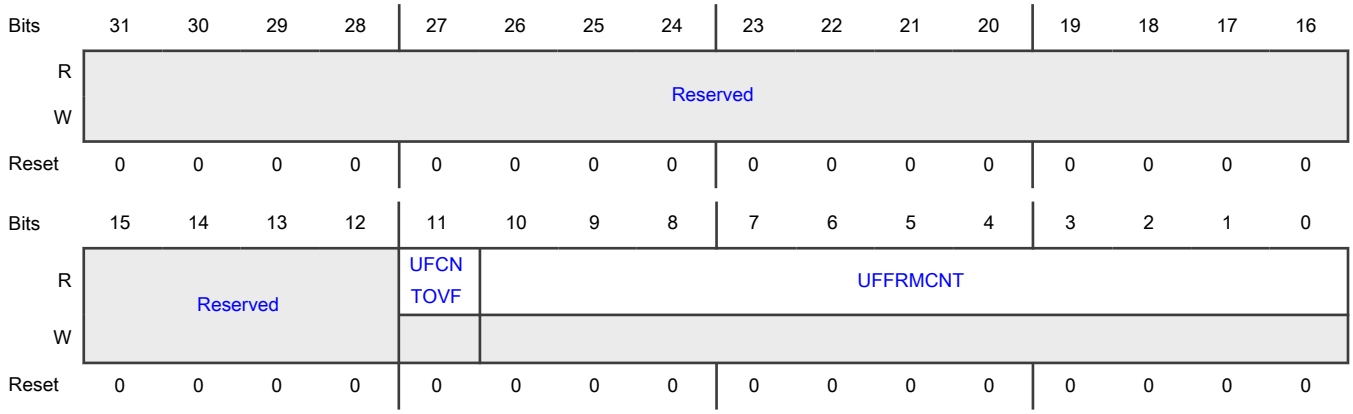
43.8.1.422 Queue 2 Underflow Counter (MTL_TXQ2_UNDERFLOW)

The Queue 2 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

Offset

Register	Offset
MTL_TXQ2_UNDERFLOW	D84h

Diagram



Fields

Field	Description
31-12 —	Reserved
11 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - Overflow not detected for Underflow Packet Counter 1 - Overflow detected for Underflow Packet Counter
10-0 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

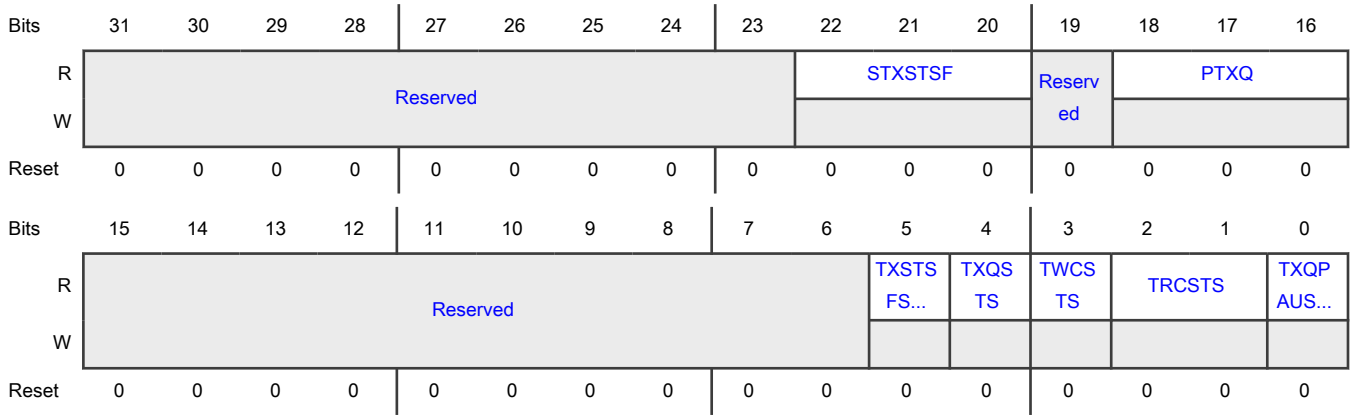
43.8.1.423 Queue 2 Transmit Debug (MTL_TXQ2_DEBUG)

The Queue 2 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Offset

Register	Offset
MTL_TXQ2_DEBUG	D88h

Diagram



Fields

Field	Description
31-23 —	Reserved
22-20 STXSTSF	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_OPERATION_MODE register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
19 —	Reserved
18-16 PTXQ	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_OPERATION_MODE register is set to 1, this field does not reflect the number of packets in the Transmit queue.
15-6 —	Reserved
5 TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. 0 - MTL Tx Status FIFO Full status is not detected

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - MTL Tx Status FIFO Full status is detected
4 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission. 0 - MTL Tx Queue Not Empty status is not detected 1 - MTL Tx Queue Not Empty status is detected
3 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue. 0 - MTL Tx Queue Write Controller status is not detected 1 - MTL Tx Queue Write Controller status is detected
2-1 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00 - Idle state 01 - Read state (transferring data to the MAC transmitter) 10 - Waiting for pending Tx Status from the MAC transmitter 11 - Flushing the Tx queue because of the Packet Abort request from the MAC
0 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: - Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled - Reception of 802. Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: - Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled - Reception of 802.3x Pause packet when PFC is disabled 0 - Transmit Queue in Pause status is not detected 1 - Transmit Queue in Pause status is detected

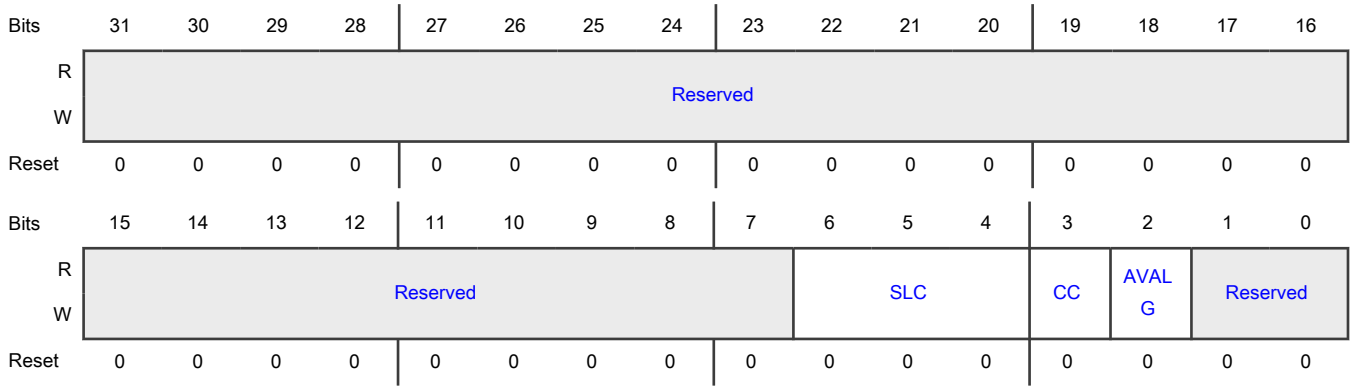
43.8.1.424 Queue 2 ETS Control (MTL_TXQ2_ETS_CONTROL)

The Queue 2 ETS Control register controls the enhanced transmission selection operation.

Offset

Register	Offset
MTL_TXQ2_ETS_CONTROL	D90h

Diagram



Fields

Field	Description
31-21 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
20-0 ISCQW	idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 2. idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 2. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps; 3.2 ns for 2500 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. - Quantum When the DCB operation is enabled with DWRR algorithm for Queue 2 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. - Weights When DCB operation is enabled with WFQ algorithm for Queue 2 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 2 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero. - Note 1: In multiple Queue configuration this field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. This field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both Receive and Transmit. In Receive, the register is MTL_OPERATION_MODE register. - Note 2: For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that Transmit Queue. The finish time is not a function of particular packet alone but it is as per the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size)) - Note 3: The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time.

43.8.1.427 Queue 2 sendSlopeCredit (MTL_TXQ2_SENDSLOPECREDIT)

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

Offset

Register	Offset
MTL_TXQ2_SENDSLOPECREDIT	D9Ch

Fields

Field	Description
31-25 —	Reserved
24-20 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19-18 —	Reserved
17-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1. Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes)

Table continues on the next page...

Table continued from the previous page...

Field	Description
	These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ... - 14: Full minus 8 KB, that is, FULL 8 KB - 15: Full minus 8.5 KB, that is, FULL 8.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-12 —	Reserved
11-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
7 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0 - Hardware Flow Control is disabled 1 - Hardware Flow Control is enabled
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is reset, all error packets are dropped if the FEP bit is reset. 0 - Dropping of TCP/IP Checksum Error Packets is enabled 1 - Dropping of TCP/IP Checksum Error Packets is disabled
5 RSF	Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0 - Receive Queue Store and Forward is disabled 1 - Receive Queue Store and Forward is enabled
4 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. 0 - Forward Error Packets is disabled 1 - Forward Error Packets is enabled
3 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0 - Forward Undersized Good Packets is disabled 1 - Forward Undersized Good Packets is enabled
2 —	Reserved
1-0 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 00 - 64 01 - 32 10 - 96 11 - 128

43.8.1.432 Queue 2 Missed Packet and Overflow Counter (MTL_RXQ2_MISSED_PACKET_OVERFLOW_CNT)

The Queue 2 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. Receive Queue Packet Arbitration

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the DWC_ether_qos drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: - PBL amount of data (indicated by ari_qN_pbl_i[]) or - Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the DWC_ether_qos drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode). 0 - Receive Queue Packet Arbitration is disabled 1 - Receive Queue Packet Arbitration is enabled
2-0 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 2. Receive Queue Weight This field indicates the weight assigned to the Rx Queue 2. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle.

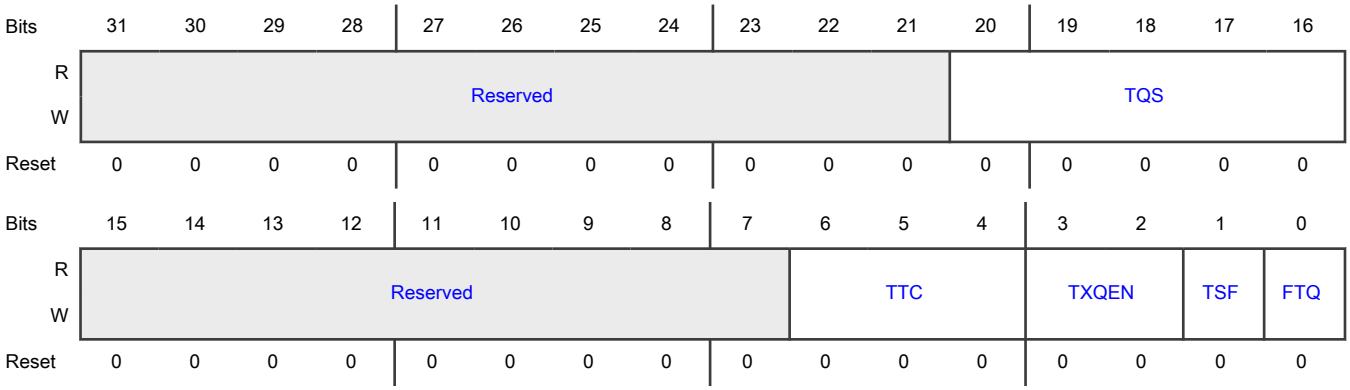
43.8.1.435 Queue 3 Transmit Operation Mode (MTL_TXQ3_OPERATION_MODE)

The Queue 3 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Offset

Register	Offset
MTL_TXQ3_OPERATION_MODE	DC0h

Diagram



Fields

Field	Description
31-21 —	Reserved
20-16 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 —	Reserved
6-4 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000 - 32 001 - 64 010 - 96 011 - 128 100 - 192 101 - 256 110 - 384 111 - 512
3-2 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. Transmit Queue Enable This field is used to enable/disable the transmit queue 0. - 2'b00: Not enabled - 2'b01: Enable in AV mode - 2'b10: Enabled - 2'b11: Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 00 - Not enabled 01 - Enable in AV mode (Reserved in non-AV) 10 - Enabled 11 - Reserved
1 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0 - Transmit Store and Forward is disabled 1 - Transmit Store and Forward is enabled
0 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TXQ3_OPERATION_MODE register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Flush Transmit Queue is disabled 1 - Flush Transmit Queue is enabled

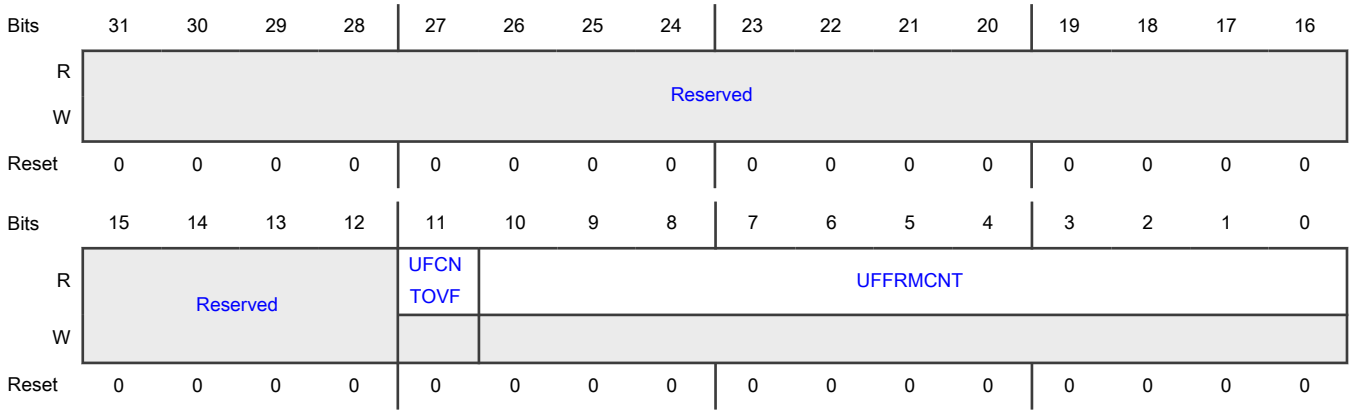
43.8.1.436 Queue 3 Underflow Counter (MTL_TXQ3_UNDERFLOW)

The Queue 3 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

Offset

Register	Offset
MTL_TXQ3_UNDERFLOW	DC4h

Diagram



Fields

Field	Description
31-12 —	Reserved
11 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - Overflow not detected for Underflow Packet Counter 1 - Overflow detected for Underflow Packet Counter
10-0 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

43.8.1.437 Queue 3 Transmit Debug (MTL_TXQ3_DEBUG)

The Queue 3 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Offset

Register	Offset
MTL_TXQ3_DEBUG	DC8h

23-0 ABS	Average Bits per Slot This field contains the average transmitted bits per slot. Average Bits per Slot This field contains the average transmitted bits per slot. If AV operation is enabled, this field is computed over number of slots, programmed in the SLC field of MTL_TXQ3_ETS_CONTROL register. The maximum value of this field is 0x6_4000 in 100 Mbps, 0x3E_8000 in 1000 Mbps and 9C_4000 in 2500 Mbps mode respectively. When the DCB operation is enabled for Queue, this field is computed over every 10 million bit times slot (4 ms in 2500 Mbps; 10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680.

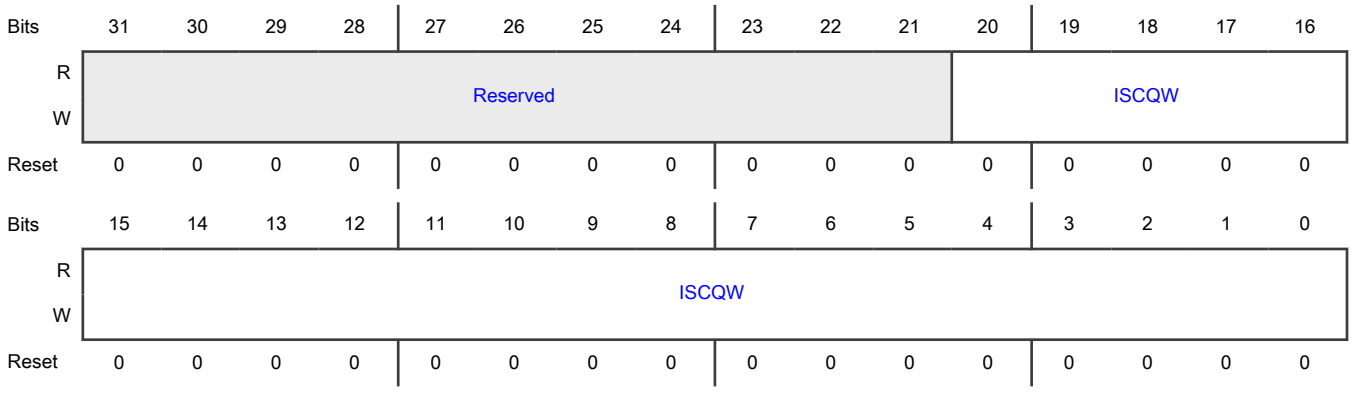
43.8.1.440 Queue 3 idleSlopeCredit, Quantum or Weights (MTL_TXQ3_QUANTUM_WEIGHT)

The Queue 3 idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 3.

Offset

Register	Offset
MTL_TXQ3_QUANTUM_WEIGHT	DD8h

Diagram



Fields

Field	Description
31-21 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
20-0 ISCQW	idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 3. idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 3. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps; 3.2 ns for 2500 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. - Quantum When the DCB operation is enabled with DWRR algorithm for Queue 3 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. - Weights When DCB operation is enabled with WFQ algorithm for Queue 3 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 3 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero. - Note 1: In multiple Queue configuration this field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. This field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both Receive and Transmit. In Receive, the register is OPERATION_MODE register. - Note 2: For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that Transmit Queue. The finish time is not a function of particular packet alone but it is as per the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size)) - Note 3: The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time.

43.8.1.441 Queue 3 sendSlopeCredit (MTL_TXQ3_SENDSLOPECREDIT)

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

Offset

Register	Offset
MTL_TXQ3_SENDSLOPECREDIT	DDCh

24-20 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19-18 —	Reserved
17-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1. Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes)

Table continues on the next page...

Table continued from the previous page...

Field	Description
	These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ... - 14: Full minus 8 KB, that is, FULL 8 KB - 15: Full minus 8.5 KB, that is, FULL 8.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-12 —	Reserved
11-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
7 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0 - Hardware Flow Control is disabled 1 - Hardware Flow Control is enabled
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is reset, all error packets are dropped if the FEP bit is reset. 0 - Dropping of TCP/IP Checksum Error Packets is enabled 1 - Dropping of TCP/IP Checksum Error Packets is disabled
5 RSF	Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0 - Receive Queue Store and Forward is disabled 1 - Receive Queue Store and Forward is enabled
4 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. 0 - Forward Error Packets is disabled 1 - Forward Error Packets is enabled
3 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0 - Forward Undersized Good Packets is disabled 1 - Forward Undersized Good Packets is enabled
2 —	Reserved
1-0 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 00 - 64 01 - 32 10 - 96 11 - 128

43.8.1.446 Queue 3 Missed Packet and Overflow Counter (MTL_RXQ3_MISSED_PACKET_OVERFLOW_CNT)

The Queue 3 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Offset

Register	Offset
MTL_RXQ3_MISSED_PACKET_OVERFLOW_CNT	DF4h

Diagram

Field	Description
31-28 —	Reserved
27 MISCNTOVF	Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - Missed Packet Counter overflow not detected 1 - Missed Packet Counter overflow detected
26-16 MISPKTCNT	Missed Packet Counter This field indicates the number of packets missed by the DWC_ether_qos because the application asserted ari_pkt_flush_i[] for this queue. Missed Packet Counter This field indicates the number of packets missed by the DWC_ether_qos because the application asserted ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.
15-12 —	Reserved
11 OVFCNTOVF	Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - Overflow Counter overflow not detected 1 - Overflow Counter overflow detected
10-0 OVFPKTCNT	Overflow Packet Counter This field indicates the number of packets discarded by the DWC_ether_qos because of Receive queue overflow. Overflow Packet Counter This field indicates the number of packets discarded by the DWC_ether_qos because of Receive queue overflow. This counter is incremented each time the DWC_ether_qos discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

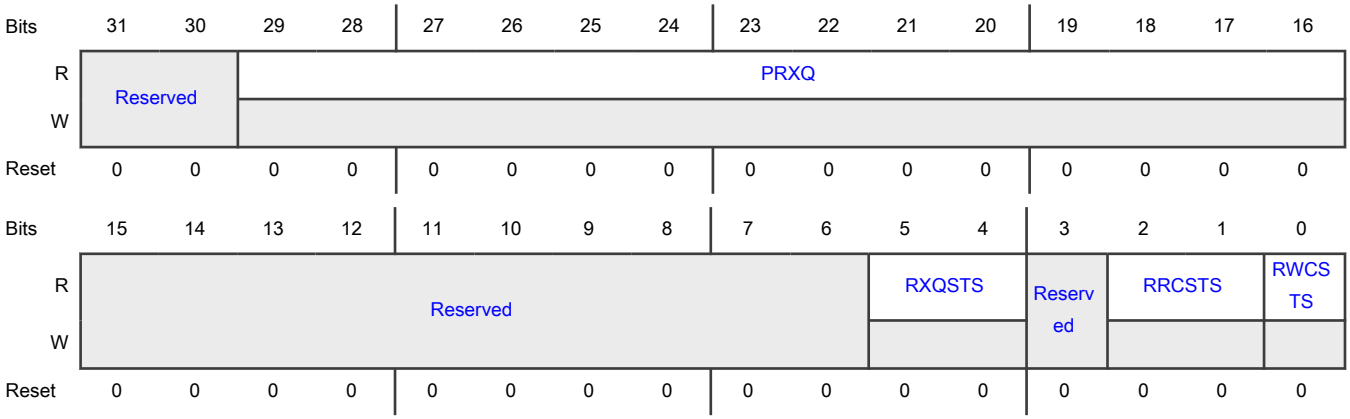
43.8.1.447 Queue 3 Receive Debug (MTL_RXQ3_DEBUG)

The Queue 3 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Offset

Register	Offset
MTL_RXQ3_DEBUG	DF8h

Diagram



Fields

Field	Description
31-30 —	Reserved
29-16 PRXQ	Number of Packets in Receive Queue This field indicates the current number of packets in the Rx Queue. Number of Packets in Receive Queue This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.
15-6 —	Reserved
5-4 RXQSTS	MTL Rx Queue Fill-Level Status This field gives the status of the fill-level of the Rx Queue: 00 - Rx Queue empty 01 - Rx Queue fill-level below flow-control deactivate threshold 10 - Rx Queue fill-level above flow-control activate threshold 11 - Rx Queue full
3 —	Reserved
2-1 RRCSTS	MTL Rx Queue Read Controller State This field gives the state of the Rx queue Read controller: 00 - Idle state

Table continues on the next page...

Table continued from the previous page...

Field	Description
	01 - Reading packet data 10 - Reading packet status (or timestamp) 11 - Flushing the packet data and status
0 RWCSTS	MTL Rx Queue Write Controller Active Status When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue. 0 - MTL Rx Queue Write Controller Active Status not detected 1 - MTL Rx Queue Write Controller Active Status detected

43.8.1.448 Queue 3 Receive Control (MTL_RXQ3_CONTROL)

The Queue 3 Receive Control register controls the receive arbitration and passing of received packets to the application.

Offset

Register	Offset
MTL_RXQ3_CONTROL	DFCh

Fields

Field	Description
31-4 —	Reserved
3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. Receive Queue Packet Arbitration

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the DWC_ether_qos drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: - PBL amount of data (indicated by ari_qN_pbl_i[]) or - Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the DWC_ether_qos drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode). 0 - Receive Queue Packet Arbitration is disabled 1 - Receive Queue Packet Arbitration is enabled
2-0 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 3. Receive Queue Weight This field indicates the weight assigned to the Rx Queue 3. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle.

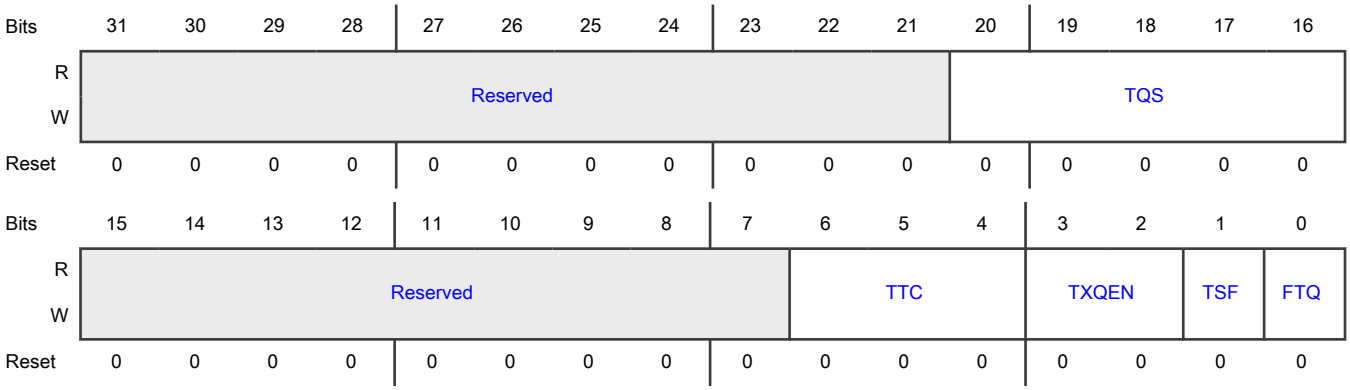
43.8.1.449 Queue 4 Transmit Operation Mode (MTL_TXQ4_OPERATION_MODE)

The Queue 4 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Offset

Register	Offset
MTL_TXQ4_OPERATION_MODE	E00h

Diagram



Fields

Field	Description
31-21 —	Reserved
20-16 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 —	Reserved
6-4 TTC	Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. Transmit Threshold Control These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000 - 32 001 - 64 010 - 96 011 - 128 100 - 192 101 - 256 110 - 384 111 - 512
3-2 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. Transmit Queue Enable This field is used to enable/disable the transmit queue 0. - 2'b00: Not enabled - 2'b01: Enable in AV mode - 2'b10: Enabled - 2'b11: Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 00 - Not enabled 01 - Enable in AV mode (Reserved in non-AV) 10 - Enabled 11 - Reserved
1 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0 - Transmit Store and Forward is disabled 1 - Transmit Store and Forward is enabled
0 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TXQ4_OPERATION_MODE register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Flush Transmit Queue is disabled 1 - Flush Transmit Queue is enabled

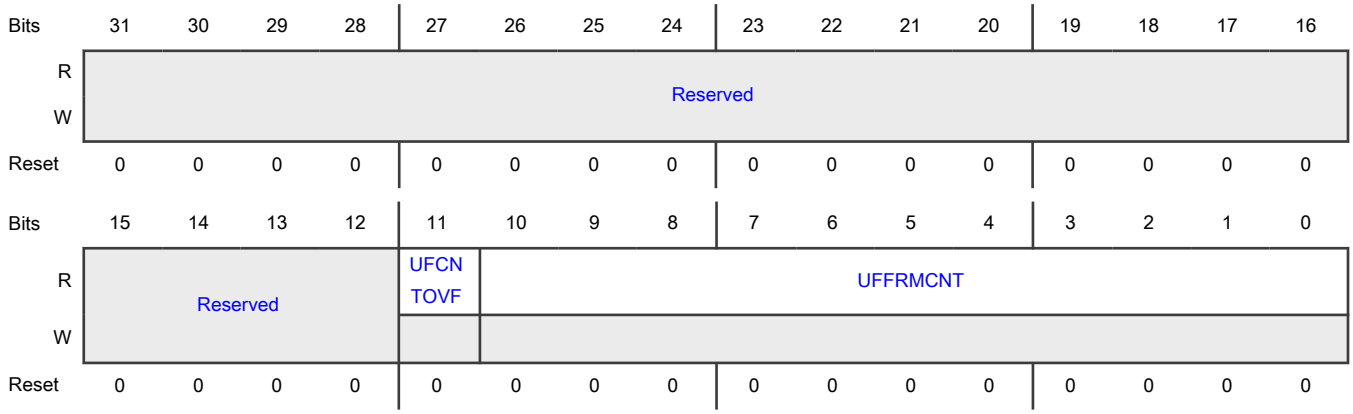
43.8.1.450 Queue 4 Underflow Counter (MTL_TXQ4_UNDERFLOW)

The Queue 4 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

Offset

Register	Offset
MTL_TXQ4_UNDERFLOW	E04h

Diagram



Fields

Field	Description
31-12 —	Reserved
11 UFCNTOVF	Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. Overflow Bit for Underflow Packet Counter This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - Overflow not detected for Underflow Packet Counter 1 - Overflow detected for Underflow Packet Counter
10-0 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

43.8.1.451 Queue 4 Transmit Debug (MTL_TXQ4_DEBUG)

The Queue 4 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Offset

Register	Offset
MTL_TXQ4_DEBUG	E08h

Diagram

Field	Description
2 AVALG	AV Algorithm When Queue 4 is programmed for AV, this field configures the scheduling algorithm for this queue: This bit when set, indicates credit based shaper algorithm (CBS) is selected for Queue 4 traffic. AV Algorithm When Queue 4 is programmed for AV, this field configures the scheduling algorithm for this queue: This bit when set, indicates credit based shaper algorithm (CBS) is selected for Queue 4 traffic. When reset, strict priority is selected. 0 - CBS Algorithm is disabled 1 - CBS Algorithm is enabled
1-0 —	Reserved

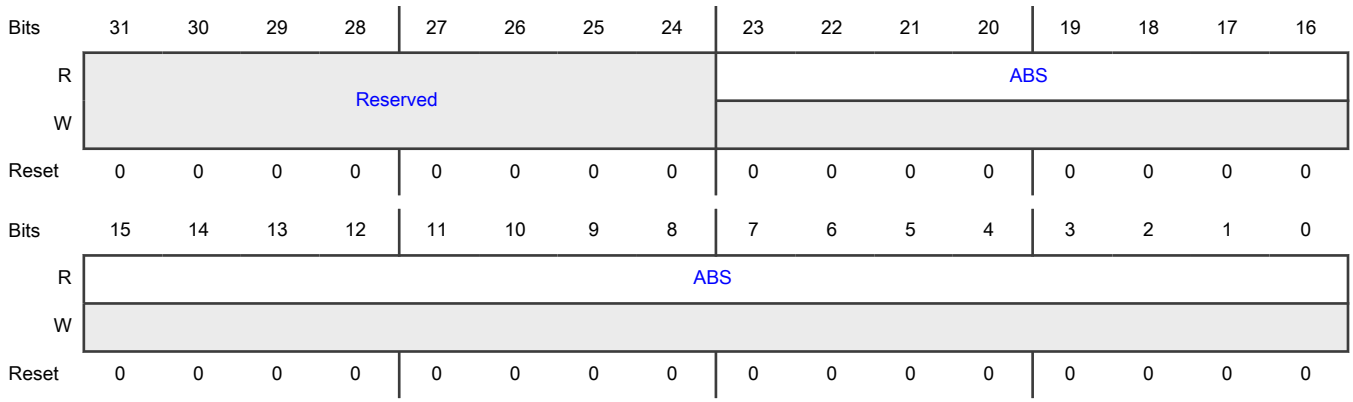
43.8.1.453 Queue 4 ETS Status (MTL_TXQ4_ETS_STATUS)

The Queue 4 ETS Status register provides the average traffic transmitted in Queue 4.

Offset

Register	Offset
MTL_TXQ4_ETS_STATUS	E14h

Diagram



Fields

Field	Description
31-24	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
23-0 ABS	Average Bits per Slot This field contains the average transmitted bits per slot. Average Bits per Slot This field contains the average transmitted bits per slot. If AV operation is enabled, this field is computed over number of slots, programmed in the SLC field of MTL_TXQ4_ETS_CONTROL register. The maximum value of this field is 0x6_4000 in 100 Mbps, 0x3E_8000 in 1000 Mbps and 9C_4000 in 2500 Mbps mode respectively. When the DCB operation is enabled for Queue, this field is computed over every 10 million bit times slot (4 ms in 2500 Mbps; 10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680.

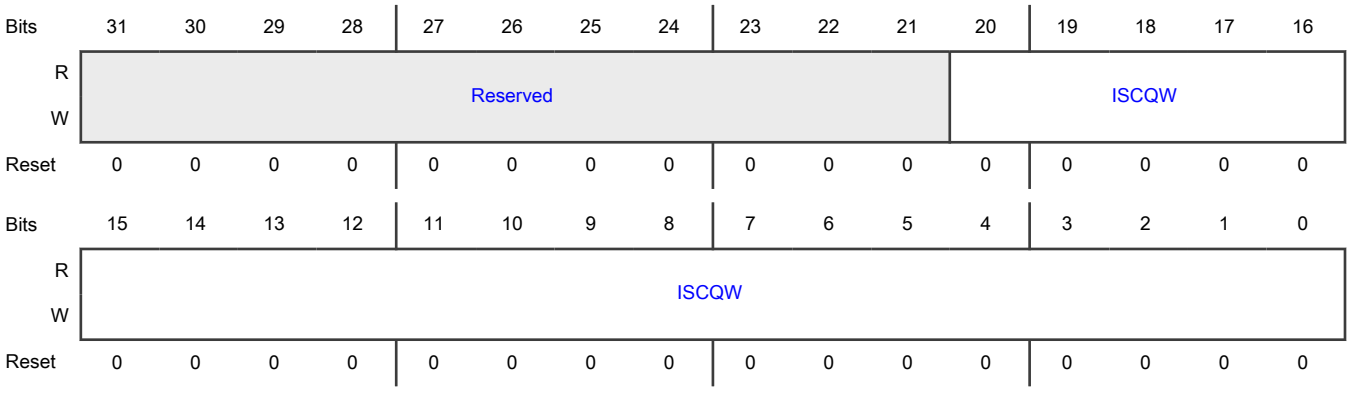
43.8.1.454 Queue 4 idleSlopeCredit, Quantum or Weights (MTL_TXQ4_QUANTUM_WEIGHT)

The Queue 4 idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 4.

Offset

Register	Offset
MTL_TXQ4_QUANTUM_WEIGHT	E18h

Diagram



Fields

Field	Description
31-21 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
20-0 ISCQW	idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 4. idleSlopeCredit, Quantum or Weights - idleSlopeCredit When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 4. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps; 3.2 ns for 2500 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. - Quantum When the DCB operation is enabled with DWRR algorithm for Queue 4 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. - Weights When DCB operation is enabled with WFQ algorithm for Queue 4 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 4 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero. - Note 1: In multiple Queue configuration this field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. This field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both Receive and Transmit. In Receive, the register is OPERATION_MODE register. - Note 2: For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that Transmit Queue. The finish time is not a function of particular packet alone but it is as per the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size)) - Note 3: The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time.

43.8.1.455 Queue 4 sendSlopeCredit (MTL_TXQ4_SENDSLOPECREDIT)

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

Offset

Register	Offset
MTL_TXQ4_SENDSLOPECREDIT	E1Ch

24-20 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19-18 —	Reserved
17-14 RFD	Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes) These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1. Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes)

Table continues on the next page...

Table continued from the previous page...

Field	Description
	These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation: - 0: Full minus 1 KB, that is, FULL 1 KB - 1: Full minus 1.5 KB, that is, FULL 1.5 KB - 2: Full minus 2 KB, that is, FULL 2 KB - 3: Full minus 2.5 KB, that is, FULL 2.5 KB - ... - 14: Full minus 8 KB, that is, FULL 8 KB - 15: Full minus 8.5 KB, that is, FULL 8.5 KB The de-assertion is effective only after flow control is asserted. Note: The value must be programmed in such a way to make sure that the threshold is a positive number. When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 KB. For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register. The width of this field depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only.
13-12 —	Reserved
11-8 RFA	Threshold for Activating Flow Control (in half-duplex and full-duplex These bits control the threshold (fill-level of Rx queue) at which the flow control is activated: For more information on encoding for this field, see RFD.
7 EHFC	Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. Enable Hardware Flow Control When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. 0 - Hardware Flow Control is disabled 1 - Hardware Flow Control is enabled
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is reset, all error packets are dropped if the FEP bit is reset. 0 - Dropping of TCP/IP Checksum Error Packets is enabled 1 - Dropping of TCP/IP Checksum Error Packets is disabled
5 RSF	Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. Receive Queue Store and Forward When this bit is set, the DWC_ether_qos reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0 - Receive Queue Store and Forward is disabled 1 - Receive Queue Store and Forward is enabled
4 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA. 0 - Forward Error Packets is disabled 1 - Forward Error Packets is enabled
3 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0 - Forward Undersized Good Packets is disabled 1 - Forward Undersized Good Packets is enabled
2 —	Reserved
1-0 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 00 - 64 01 - 32 10 - 96 11 - 128

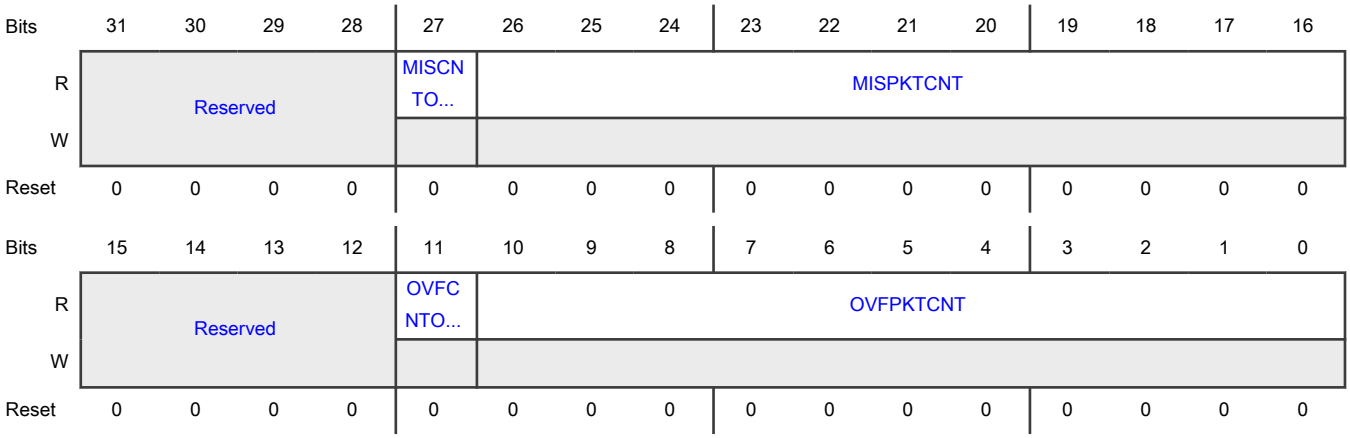
43.8.1.460 Queue 4 Missed Packet and Overflow Counter (MTL_RXQ4_MISSED_PACKET_OVERFLOW_CNT)

The Queue 4 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Offset

Register	Offset
MTL_RXQ4_MISSED_PACKET_OVERFLOW_CNT	E34h

Diagram



Fields

Field	Description
31-28 —	Reserved
27 MISCNTOVF	Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - Missed Packet Counter overflow not detected 1 - Missed Packet Counter overflow detected
26-16 MISPKTCNT	Missed Packet Counter This field indicates the number of packets missed by the DWC_ether_qos because the application asserted ari_pkt_flush_i[] for this queue. Missed Packet Counter This field indicates the number of packets missed by the DWC_ether_qos because the application asserted ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.
15-12 —	Reserved
11 OVFCNTOVF	Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - Overflow Counter overflow not detected 1 - Overflow Counter overflow detected
10-0 OVFPKTCNT	Overflow Packet Counter This field indicates the number of packets discarded by the DWC_ether_qos because of Receive queue overflow. Overflow Packet Counter This field indicates the number of packets discarded by the DWC_ether_qos because of Receive queue overflow. This counter is incremented each time the DWC_ether_qos discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

43.8.1.461 Queue 4 Receive Debug (MTL_RXQ4_DEBUG)

The Queue 4 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Offset

Register	Offset
MTL_RXQ4_DEBUG	E38h

Field	Description
31-4 —	Reserved
3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. Receive Queue Packet Arbitration

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is set, the DWC_ether_qos drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the DWC_ether_qos drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: - PBL amount of data (indicated by ari_qN_pbl_i[]) or - Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the DWC_ether_qos drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode). 0 - Receive Queue Packet Arbitration is disabled 1 - Receive Queue Packet Arbitration is enabled
2-0 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 4. Receive Queue Weight This field indicates the weight assigned to the Rx Queue 4. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle.

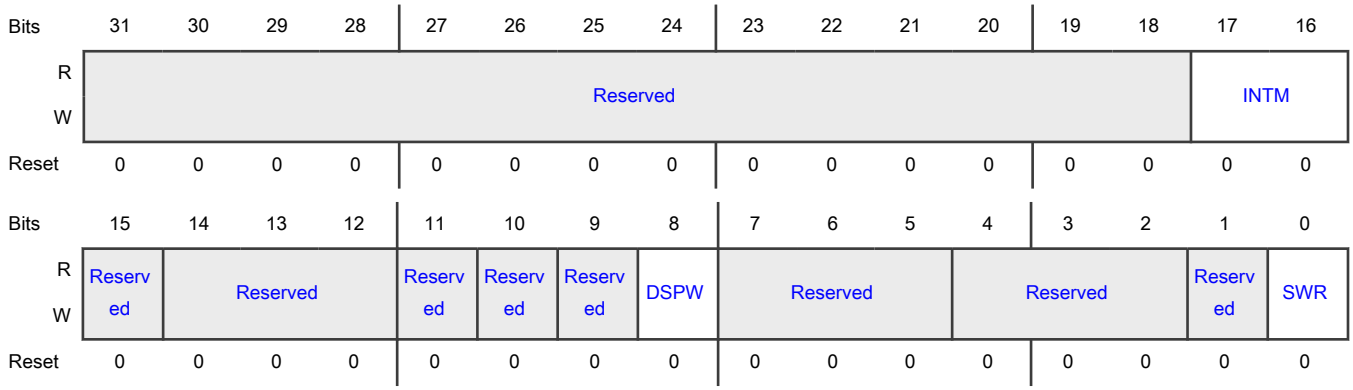
43.8.1.463 DMA Bus Mode (DMA_MODE)

The Bus Mode register establishes the bus operating modes for the DMA.

Offset

Register	Offset
DMA_MODE	1000h

Diagram



Fields

Field	Description
31-18 —	Reserved
17-16 INTM	Interrupt Mode This field defines the interrupt mode of DWC_ether_qos. Interrupt Mode This field defines the interrupt mode of DWC_ether_qos. The behavior of the following outputs changes depending on the following settings: - sbd_perch_tx_intr_o[] (Transmit Per Channel Interrupt) - sbd_perch_rx_intr_o[] (Receive Per Channel Interrupt) - sbd_intr_o (Common Interrupt) It also changes the behavior of the RI/TI bits in the STATUS. - 00: sbd_perch_* are pulse signals for each TX/RX packet transfer completion events (irrespective of whether corresponding interrupts are enabled) for which IOC bits are enabled in descriptor. sbd_intr_o is also asserted when corresponding interrupts are enabled and cleared only when software clears the corresponding RI/TI status bits. - 01: sbd_perch_* are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and de-asserted when the software clears the corresponding RI/TI status bits. The sbd_intr_o is not asserted for these TX/RX packet transfer completion events. - 10: sbd_perch_* are level signals asserted on TX/RX packet transfer completion event when corresponding interrupts are enabled and de-asserted when the software clears the corresponding RI/TI status bits. However, the signal is asserted again if the same event occurred again before it was cleared. The sbd_intr_o is not asserted for these TX/RX packet transfer completion events. - 11: Reserved For more details please refer Table "DWC_ether_qos Transfer Complete Interrupt Behavior". 00 - See above description 01 - See above description 10 - See above description 11 - Reserved

8 DSPW	Descriptor Posted Write When this bit is set to 0, the descriptor writes are always non-posted. Descriptor Posted Write When this bit is set to 0, the descriptor writes are always non-posted. When this bit is set to 1, the descriptor writes are non-posted only when IOC (Interrupt on completion) is set in last descriptor, otherwise the descriptor writes are always posted. 0 - Descriptor Posted Write is disabled 1 - Descriptor Posted Write is enabled
7-5 —	Reserved
4-2 —	Reserved
1 —	Reserved
0 SWR	Software Reset When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. Software Reset When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all DWC_ether_qos clock domains. Before reprogramming any DWC_ether_qos register, a value of zero should be read in this bit. This bit must be read at least 4 CSR clock cycles after it is written to 1. Note: The reset operation is complete only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Software Reset is disabled 1 - Software Reset is enabled

43.8.1.464 DMA System Bus Mode (DMA_SYSBUS_MODE)

The System Bus mode register controls the behavior of the AHB or AXI master. It mainly controls burst splitting and number of outstanding requests.

Offset

Register	Offset
DMA_SYSBUS_MODE	1004h

Field	Description
21-16 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in CONTROL register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of TXQ0_OPERATION_MODE register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 IPBL	Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. If space is not available, the MTL may use handshaking to slow the DMA. Note: This bit/mode must not be used when multiple Transmit DMA Channels are enabled as it may block other Transmit and Receive DMA Channels from accessing the Read Data Channel of AXI bus until space is available in Transmit Queue for current transfer. 0 - Ignore PBL Requirement is disabled 1 - Ignore PBL Requirement is enabled
14-13 —	Reserved
12 —	Reserved
11-5 —	Reserved
4 OSF	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained. 0 - Operate on Second Packet disabled 1 - Operate on Second Packet enabled
3-1	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
0 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TXDESC_LIST_ADDRESS register. - The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the STATUS register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program TXDESC_LIST_ADDRESS register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0 - Stop Transmission Command 1 - Start Transmission Command

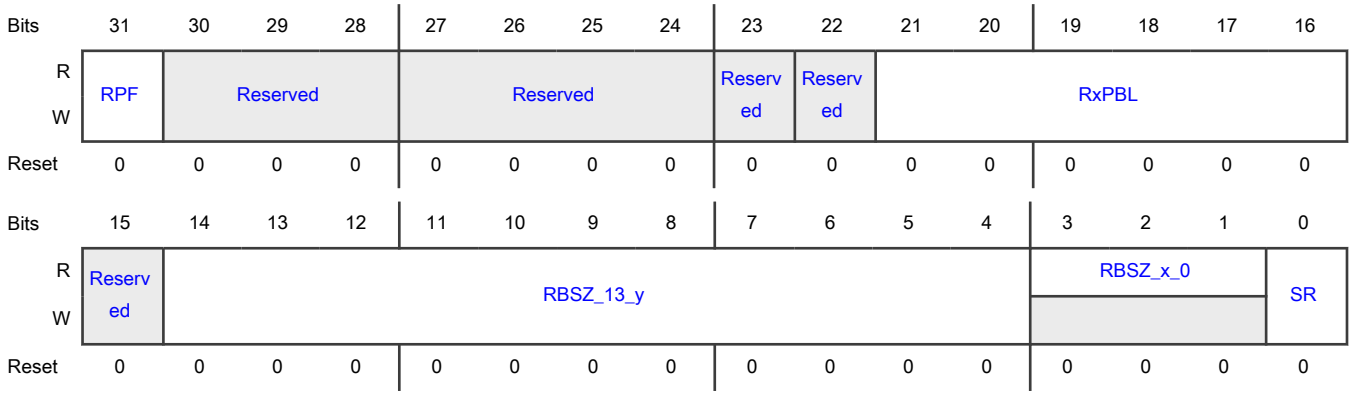
43.8.1.475 DMA Channel 0 Receive Control (DMA_CH0_RX_CONTROL)

The DMA Channel 0 Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Offset

Register	Offset
DMA_CH0_RX_CONTROL	1108h

Diagram



Fields

Field	Description
31 RPF	Rx Packet Flush. Rx Packet Flush. When this bit is set to 1, then DWC_ether_qos automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel, when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, get flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing happens on the Read side of the Rx Queue. When this bit is set to 0, the DWC_ether_qos not flush the packet in the Rx Queue destined to this RxDMA Channel when it is STOP state. This may in turn cause head-of-line blocking in the corresponding RxQueue. 0 - Rx Packet Flush is disabled 1 - Rx Packet Flush is enabled
30-28 —	Reserved
27-24 —	Reserved
23 —	Reserved
22 —	Reserved
21-16 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application

Field	Description
	bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the DMA_CH0_CONTROL register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of RXQ0_OPERATION_MODE register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 —	Reserved
14-4 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
3-1 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the address set by the DMA_CH0_RXDESC_LIST_ADDRESS register. - The position at which the Rx process was previously stopped

Table continues on the next page...

Table continued from the previous page...

Field	Description
	If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH0_STATUS register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH0_RXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0 - Stop Receive 1 - Start Receive

43.8.1.476 Channel 0 Tx Descriptor List Address register (DMA_CH0_TXDESC_LIST_ADDRESS)

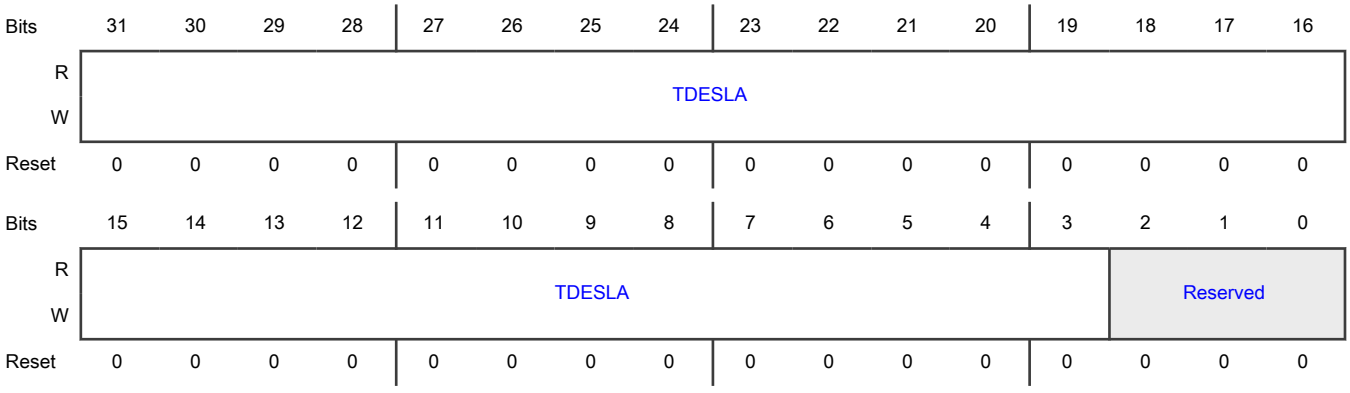
The Channel 0 Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in TX_CONTROL register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Offset

Register	Offset
DMA_CH0_TXDESC_LIST_ADDRESS	1114h

Diagram



Fields

Field	Description
31-3 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 —	Reserved

43.8.1.477 Channel 0 Rx Descriptor List Address register (DMA_CH0_RXDESC_LIST_ADDRESS)

The Channel 0 Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in RX_CONTROL register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Field	Description
	1 - Transmit Interrupt is enabled

43.8.1.483 Channel 0 Receive Interrupt Watchdog Timer (DMA_CH0_RX_INTERRUPT_WATCHDOG_TIMER)

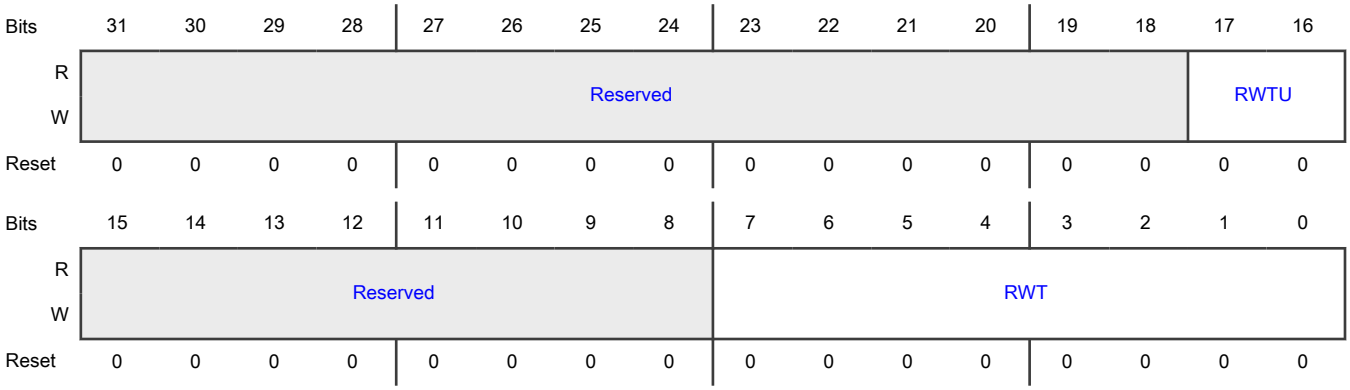
The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA.

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CH0_Status register.

Offset

Register	Offset
DMA_CH0_RX_INTERRUPT_WATCHDOG_TIMER	1138h

Diagram



Fields

Field	Description
31-18 —	Reserved
17-16 RWTU	Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. - 2'b00: 256 - 2'b01: 512

Table continues on the next page...

Table continued from the previous page...

Field	Description
	- 2'b10: 1024 - 2'b11: 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.
15-8 —	Reserved
7-0 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the STATUS register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

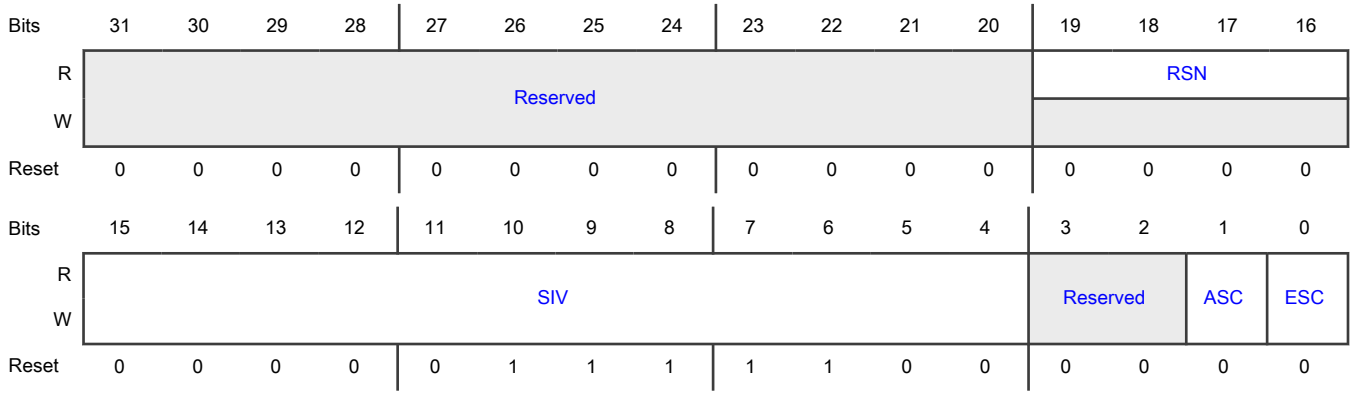
43.8.1.484 Channel 0 Slot Function Control and Status (DMA_CH0_SLOT_FUNCTION_CONTROL_STATUS)

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Offset

Register	Offset
DMA_CH0_SLOT_FUNCTION_CONTROL_STATUS	113Ch

Diagram



Fields

Field	Description
31-20 —	Reserved
19-16 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096us. The default/reset value is 0x07C which corresponds to slot interval of 125us
3-2 —	Reserved
1 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is - equal to the reference slot number given in the RSN field or - ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set. 0 - Advance Slot Check is disabled 1 - Advance Slot Check is enabled
0 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is - equal to the reference slot number or - ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. Note: The UFO (UDP Fragmentation over IPv4)/TSO/USO should not be enabled along with TBS/AVB Slot number check. The UFO/TSO/USO involves multiple packets/segments/fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for software to specify slot number for subsequent packets. 0 - Slot Comparison is disabled 1 - Slot Comparison is enabled

Field	Description
	Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH0_INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Abnormal Interrupt Summary status not detected 1 - Abnormal Interrupt Summary status detected
13 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all ones descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all ones descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Context Descriptor Error status not detected 1 - Context Descriptor Error status detected
12 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Fatal Bus Error status not detected 1 - Fatal Bus Error status detected
11 ERI	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. Early Receive Interrupt

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. In configs supporting ERIC, When ERIC=0, this bit is set only after the Rx DMA has filled up a complete receive buffer with packet data. When ERIC=1, this bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Early Receive Interrupt status not detected 1 - Early Receive Interrupt status detected
10 ETI	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configs supporting ETIC: When ETIC=0, this bit is set only after the Tx DMA has transferred a complete packet to MTL. When ETIC=1, this bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC=1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Early Transmit Interrupt status not detected 1 - Early Transmit Interrupt status detected
9 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0 - Receive Watchdog Timeout status not detected 1 - Receive Watchdog Timeout status detected
8 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Receive Process Stopped status not detected 1 - Receive Process Stopped status detected
7 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode,

Table continues on the next page...

Table continued from the previous page...

Field	Description
	the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Receive Buffer Unavailable status not detected 1 - Receive Buffer Unavailable status detected
6 RI	Receive Interrupt This bit indicates that the packet reception is complete. Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Receive Interrupt status not detected 1 - Receive Interrupt status detected
5-3 —	Reserved
2 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DEBUG_STATUS0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 31 of TDES3. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Buffer Unavailable status not detected 1 - Transmit Buffer Unavailable status detected
1 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Process Stopped status not detected 1 - Transmit Process Stopped status detected

Table continues on the next page...

Table continued from the previous page...

Field	Description
0 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Interrupt status not detected 1 - Transmit Interrupt status detected

43.8.1.490 Channel 0 Missed Frame Counter (DMA_CH0_MISS_FRAME_CNT)

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in RX_CONTROL register.

Offset

Field	Description
21-16 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in CONTROL register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of TXQ1_OPERATION_MODE register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 IPBL	Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. If space is not available, the MTL may use handshaking to slow the DMA. Note: This bit/mode must not be used when multiple Transmit DMA Channels are enabled as it may block other Transmit and Receive DMA Channels from accessing the Read Data Channel of AXI bus until space is available in Transmit Queue for current transfer. 0 - Ignore PBL Requirement is disabled 1 - Ignore PBL Requirement is enabled
14-13 —	Reserved
12 —	Reserved
11-5 —	Reserved
4 OSF	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained. 0 - Operate on Second Packet disabled 1 - Operate on Second Packet enabled
3-1	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
0 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the base address of the Transmit list set by the DMA_CH1_TXDESC_LIST_ADDRESS register. - The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH1_STATUS register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH1_TXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program TXDESC_LIST_ADDRESS register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0 - Stop Transmission Command 1 - Start Transmission Command

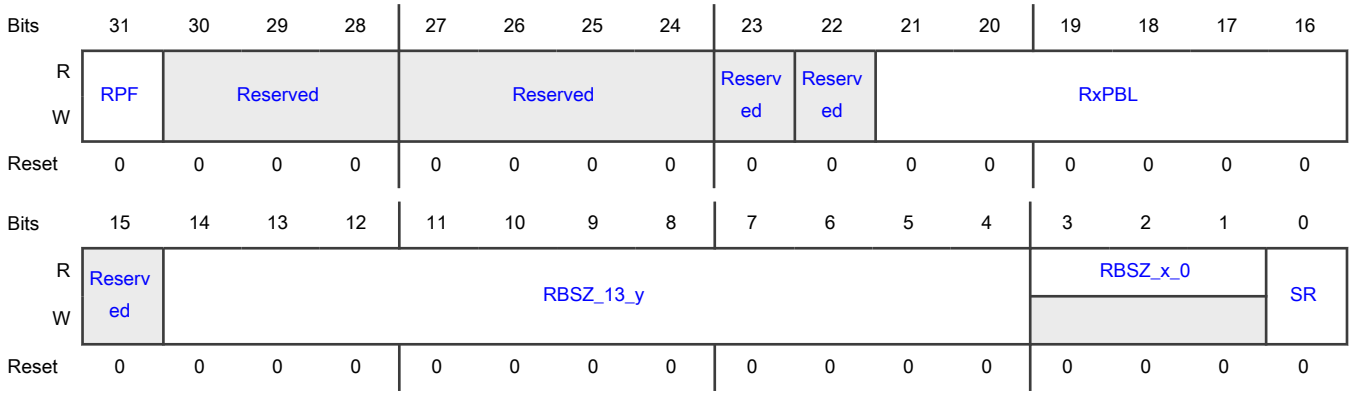
43.8.1.494 DMA Channel 1 Receive Control (DMA_CH1_RX_CONTROL)

The DMA Channel 1 Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Offset

Register	Offset
DMA_CH1_RX_CONTROL	1188h

Diagram



Fields

Field	Description
31 RPF	Rx Packet Flush. Rx Packet Flush. When this bit is set to 1, then DWC_ether_qos automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel, when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, get flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing happens on the Read side of the Rx Queue. When this bit is set to 0, the DWC_ether_qos not flush the packet in the Rx Queue destined to this RxDMA Channel when it is STOP state. This may in turn cause head-of-line blocking in the corresponding RxQueue. 0 - Rx Packet Flush is disabled 1 - Rx Packet Flush is enabled

27-24 —	Reserved
23 —	Reserved
22 —	Reserved
21-16 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application

Table continues on the next page...

Table continued from the previous page...

Field	Description
	bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the CONTROL register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of RXQ1_OPERATION_MODE register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 —	Reserved
14-4 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
3-1 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the address set by the DMA_CH1_RXDESC_LIST_ADDRESS register. - The position at which the Rx process was previously stopped

Table continues on the next page...

Table continued from the previous page...

Field	Description
	If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH1_STATUS register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH1_RXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0 - Stop Receive 1 - Start Receive

43.8.1.495 Channel 1 Tx Descriptor List Address (DMA_CH1_TXDESC_LIST_ADDRESS)

The Channel 1 Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH1_TX_CONTROL register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Offset

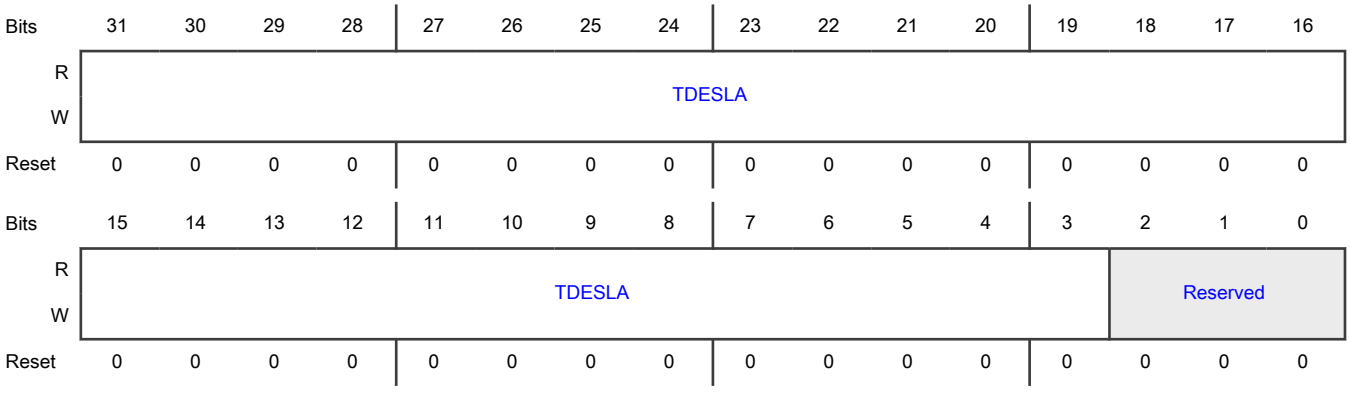
DMA_CH1_TXDESC_LIST_ADDRESS	1194h

Diagram



Fields

Field	Description
31-3 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 —	Reserved

43.8.1.496 Channel 1 Rx Descriptor List Address (DMA_CH1_RXDESC_LIST_ADDRESS)

The Channel 1 Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH1_RX_CONTROL register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

	- 2'b11: 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.
15-8 —	Reserved
7-0 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the STATUS register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

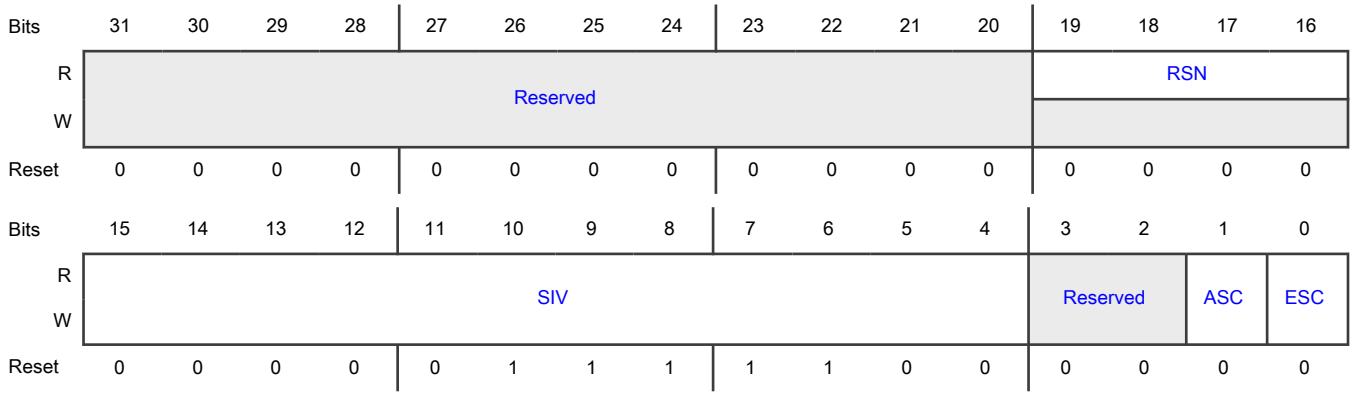
43.8.1.503 Channel 1 Slot Function Control and Status (DMA_CH1_SLOT_FUNCTION_CONTROL_STATUS)

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Offset

Register	Offset
DMA_CH1_SLOT_FUNCTION_CONTROL_STATUS	11BCh

Diagram



Fields

Field	Description
31-20 —	Reserved
19-16 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096us. The default/reset value is 0x07C which corresponds to slot interval of 125us
3-2 —	Reserved
1 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is - equal to the reference slot number given in the RSN field or - ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set. 0 - Advance Slot Check is disabled 1 - Advance Slot Check is enabled
0 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is - equal to the reference slot number or - ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. Note: The UFO (UDP Fragmentation over IPv4)/TSO/USO should not be enabled along with TBS/AVB Slot number check. The UFO/TSO/USO involves multiple packets/segments/fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for software to specify slot number for subsequent packets. 0 - Slot Comparison is disabled 1 - Slot Comparison is enabled

Field	Description
	Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Abnormal Interrupt Summary status not detected 1 - Abnormal Interrupt Summary status detected
13 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Context Descriptor Error status not detected 1 - Context Descriptor Error status detected
12 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Fatal Bus Error status not detected 1 - Fatal Bus Error status detected
11 ERI	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. Early Receive Interrupt

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. In configs supporting ERIC, When ERIC=0, this bit is set only after the Rx DMA has filled up a complete receive buffer with packet data. When ERIC=1, this bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Early Receive Interrupt status not detected 1 - Early Receive Interrupt status detected
10 ETI	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configs supporting ETIC: When ETIC=0, this bit is set only after the Tx DMA has transferred a complete packet to MTL. When ETIC=1, this bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC=1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Early Transmit Interrupt status not detected 1 - Early Transmit Interrupt status detected
9 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0 - Receive Watchdog Timeout status not detected 1 - Receive Watchdog Timeout status detected
8 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Receive Process Stopped status not detected 1 - Receive Process Stopped status detected
7 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode,

Table continues on the next page...

Table continued from the previous page...

Field	Description
	the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Receive Buffer Unavailable status not detected 1 - Receive Buffer Unavailable status detected
6 RI	Receive Interrupt This bit indicates that the packet reception is complete. Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Receive Interrupt status not detected 1 - Receive Interrupt status detected
5-3 —	Reserved
2 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DEBUG_STATUS0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 31 of TDES3. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Buffer Unavailable status not detected 1 - Transmit Buffer Unavailable status detected
1 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Process Stopped status not detected 1 - Transmit Process Stopped status detected

Field	Description
21-16 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in DMA_CH2_CONTROL register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of TXQ2_OPERATION_MODE register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 IPBL	Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. If space is not available, the MTL may use handshaking to slow the DMA. Note: This bit/mode must not be used when multiple Transmit DMA Channels are enabled as it may block other Transmit and Receive DMA Channels from accessing the Read Data Channel of AXI bus until space is available in Transmit Queue for current transfer. 0 - Ignore PBL Requirement is disabled 1 - Ignore PBL Requirement is enabled

Table continued from the previous page...

Field	Description
—	
0 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the base address of the Transmit list set by the DMA_CH2_TXDESC_LIST_ADDRESS register. - The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH2_STATUS register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH2_TXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH2_TXDESC_LIST_ADDRESS register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0 - Stop Transmission Command 1 - Start Transmission Command

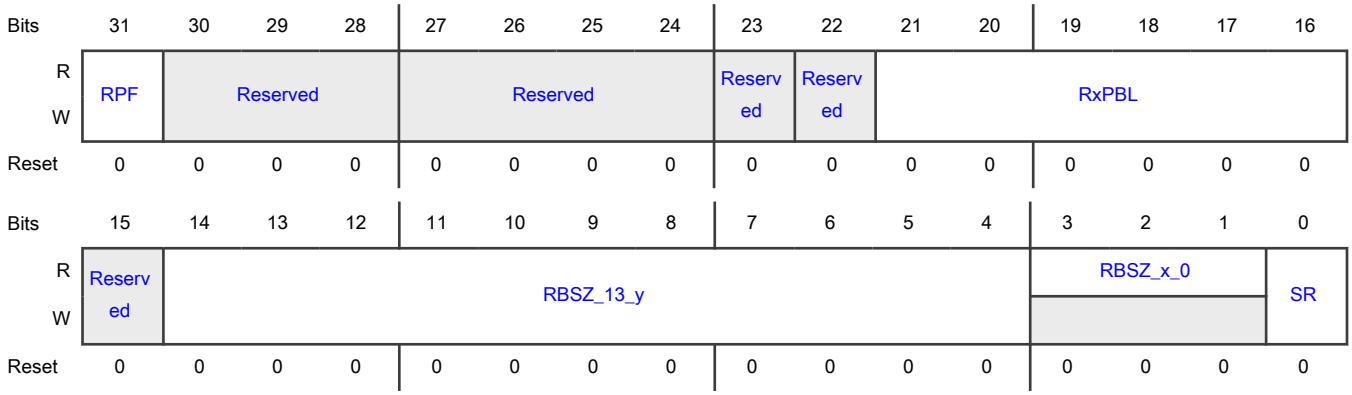
43.8.1.513 DMA Channel 2 Receive Control (DMA_CH2_RX_CONTROL)

The DMA Channel 2 Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Offset

Register	Offset
DMA_CH2_RX_CONTROL	1208h

Diagram



Fields

Field	Description
31 RPF	Rx Packet Flush. Rx Packet Flush. When this bit is set to 1, then DWC_ether_qos automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel, when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, get flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing happens on the Read side of the Rx Queue. When this bit is set to 0, the DWC_ether_qos not flush the packet in the Rx Queue destined to this RxDMA Channel when it is STOP state. This may in turn cause head-of-line blocking in the corresponding RxQueue. 0 - Rx Packet Flush is disabled 1 - Rx Packet Flush is enabled

Field	Description
	bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the DMA_CH2_CONTROL register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of RXQ2_OPERATION_MODE register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 —	Reserved
14-4 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
3-1 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the address set by the DMA_CH2_RXDESC_LIST_ADDRESS register. - The position at which the Rx process was previously stopped

Table continues on the next page...

Table continued from the previous page...

Field	Description
	If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH2_STATUS register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH2_RXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0 - Stop Receive 1 - Start Receive

43.8.1.514 Channel 2 Tx Descriptor List Address (DMA_CH2_TXDESC_LIST_ADDRESS)

The Channel 2 Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in TX_CONTROL register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

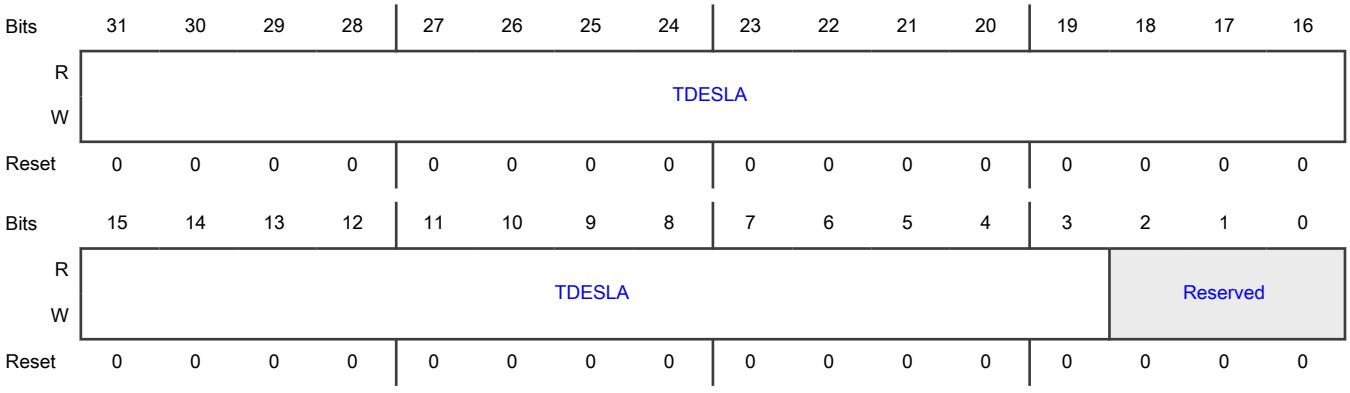
DMA_CH2_TXDESC_LIST_ADDRESS	1214h

Diagram



Fields

Field	Description
31-3 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 —	Reserved

43.8.1.515 Channel 2 Rx Descriptor List Address (DMA_CH2_RXDESC_LIST_ADDRESS)

The Channel 2 Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in RX_CONTROL register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Field	Description
31-24 —	Reserved
23-17 ARBS	Alternate Receive Buffer Size Indicates size in bytes for Buffer 1 when ARBS is programmed to a non-zero value (when split header feature is not enabled). When split header feature is enabled, ARBS indicates the buffer size for header

Table continues on the next page...

Table continued from the previous page...

Field	Description
	data. The maximum alternate buffer is limited to 1020, 1016 or 1008-bytes depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). When ARBS=0, Rx Buffer1 and Rx Buffer2 sizes are based on DMA_CH2_RX_CONTROL[RBSZ]. Width of ARBS field is 8, 7 or 6-bits depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively).
16-10 —	Reserved
9-0 RDRL	Receive Descriptor Ring Length This register sets the maximum number of Rx descriptors in the circular descriptor ring. Receive Descriptor Ring Length This register sets the maximum number of Rx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

43.8.1.520 Channel 2 Interrupt Enable (DMA_CH2_INTERRUPT_ENABLE)

The Channel 2 Interrupt Enable register enables the interrupts reported by the Status register.

Offset

Register	Offset

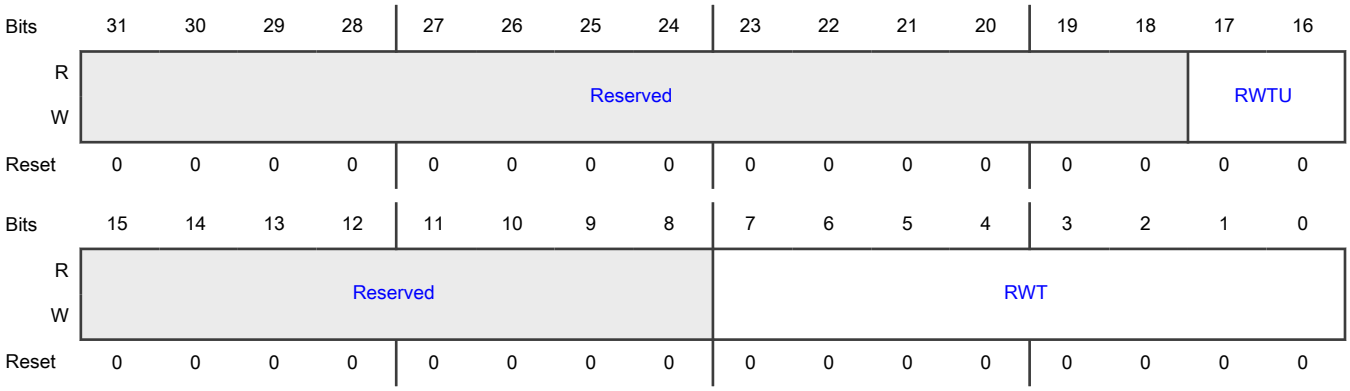
43.8.1.521 Channel 2 Receive Interrupt Watchdog Timer (DMA_CH2_RX_INTERRUPT_WATCHDOG_TIMER)

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CH2_Status register.

Offset

Register	Offset
DMA_CH2_RX_INTERRUPT_WATCHDOG_TIMER	1238h

Diagram



Fields

Field	Description
31-18 —	Reserved
17-16 RWTU	Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. - 2'b00: 256 - 2'b01: 512 - 2'b10: 1024

Table continues on the next page...

Table continued from the previous page...

Field	Description
	- 2'b11: 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.
15-8 —	Reserved
7-0 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the STATUS register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

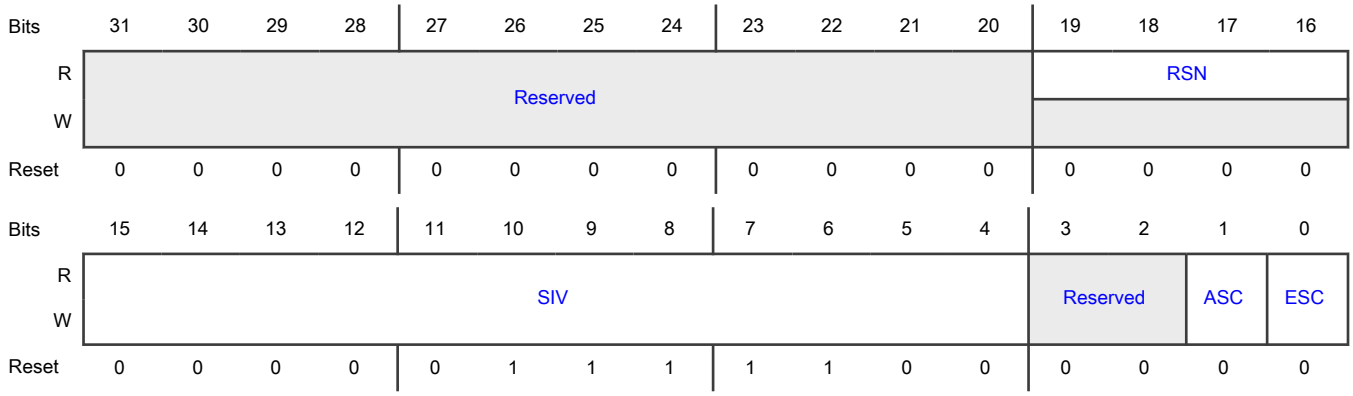
43.8.1.522 Channel 2 Slot Function Control and Status (DMA_CH2_SLOT_FUNCTION_CONTROL_STATUS)

The Channel 2 Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Offset

Register	Offset
DMA_CH2_SLOT_FUNCTION_CONTROL_STATUS	123Ch

Diagram



Fields

Field	Description
31-20 —	Reserved
19-16 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096us. The default/reset value is 0x07C which corresponds to slot interval of 125us
3-2 —	Reserved
1 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is - equal to the reference slot number given in the RSN field or - ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set. 0 - Advance Slot Check is disabled 1 - Advance Slot Check is enabled
0 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is - equal to the reference slot number or - ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. Note: The UFO (UDP Fragmentation over IPv4)/TSO/USO should not be enabled along with TBS/AVB Slot number check. The UFO/TSO/USO involves multiple packets/segments/fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for software to specify slot number for subsequent packets. 0 - Slot Comparison is disabled 1 - Slot Comparison is enabled

43.8.1.523 Channel 2 Current Application Transmit Descriptor (DMA_CH2_CURRENT_APP_TXDESC)

Field	Description
	This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. - Bit 18 -- 1'b1: Error during data transfer by Tx DMA -- 1'b0: No Error during data transfer by Tx DMA - Bit 17 -- 1'b1: Error during descriptor access -- 1'b0: Error during data buffer access - Bit 16 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
15 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH2_INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH2_INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Normal Interrupt Summary status not detected 1 - Normal Interrupt Summary status detected
14 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH2_INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. Abnormal Interrupt Summary

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH2_INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Abnormal Interrupt Summary status not detected 1 - Abnormal Interrupt Summary status detected
13 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Context Descriptor Error status not detected 1 - Context Descriptor Error status detected
12 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Fatal Bus Error status not detected 1 - Fatal Bus Error status detected
11 ERI	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. Early Receive Interrupt

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. In configs supporting ERIC, When ERIC=0, this bit is set only after the Rx DMA has filled up a complete receive buffer with packet data. When ERIC=1, this bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Early Receive Interrupt status not detected 1 - Early Receive Interrupt status detected
10 ETI	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configs supporting ETIC: When ETIC=0, this bit is set only after the Tx DMA has transferred a complete packet to MTL. When ETIC=1, this bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC=1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Early Transmit Interrupt status not detected 1 - Early Transmit Interrupt status detected
9 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0 - Receive Watchdog Timeout status not detected 1 - Receive Watchdog Timeout status detected
8 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Receive Process Stopped status not detected 1 - Receive Process Stopped status detected
7 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode,

Table continues on the next page...

Table continued from the previous page...

Field	Description
	the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Receive Buffer Unavailable status not detected 1 - Receive Buffer Unavailable status detected
6 RI	Receive Interrupt This bit indicates that the packet reception is complete. Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Receive Interrupt status not detected 1 - Receive Interrupt status detected
5-3 —	Reserved
2 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DEBUG_STATUS0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 31 of TDES3. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Buffer Unavailable status not detected 1 - Transmit Buffer Unavailable status detected
1 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Process Stopped status not detected 1 - Transmit Process Stopped status detected

Table continues on the next page...

Table continued from the previous page...

Field	Description
0 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Interrupt status not detected 1 - Transmit Interrupt status detected

43.8.1.528 Channel 2 Missed Frame Counter (DMA_CH2_MISS_FRAME_CNT)

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH2_RX_CONTROL register.

Offset

Register	Offset
DMA_CH2_MISS_FRAME_CNT	1264h

Field	Description
21-16 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in DMA_CH3_CONTROL register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of TXQ3_OPERATION_MODE register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 IPBL	Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. If space is not available, the MTL may use handshaking to slow the DMA. Note: This bit/mode must not be used when multiple Transmit DMA Channels are enabled as it may block other Transmit and Receive DMA Channels from accessing the Read Data Channel of AXI bus until space is available in Transmit Queue for current transfer. 0 - Ignore PBL Requirement is disabled 1 - Ignore PBL Requirement is enabled

Field	Description
—	
0 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the base address of the Transmit list set by the DMA_CH3_TXDESC_LIST_ADDRESS register. - The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH3_STATUS register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH3_TXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH3_TXDESC_LIST_ADDRESS register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0 - Stop Transmission Command 1 - Start Transmission Command

43.8.1.532 DMA Channel 3 Receive Control (DMA_CH3_RX_CONTROL)

Field	Description
	bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the CONTROL register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of RXQ3_OPERATION_MODE register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 —	Reserved
14-4 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
3-1 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the address set by the DMA_CH3_RXDESC_LIST_ADDRESS register. - The position at which the Rx process was previously stopped

Table continues on the next page...

Table continued from the previous page...

Field	Description
	If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH3_STATUS register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH3_RXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0 - Stop Receive 1 - Start Receive

43.8.1.533 Channel 3 Tx Descriptor List Address (DMA_CH3_TXDESC_LIST_ADDRESS)

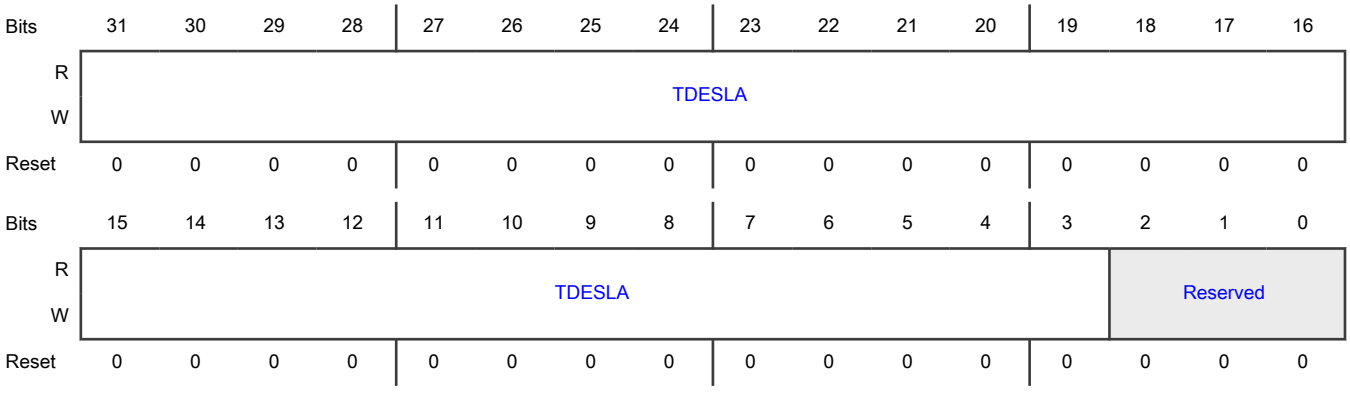
The Channel 3 Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in TX_CONTROL register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Offset

Register	Offset
DMA_CH3_TXDESC_LIST_ADDRESS	1294h

Diagram



Fields

Field	Description
31-3 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 —	Reserved

43.8.1.534 Channel 3 Rx Descriptor List Address (DMA_CH3_RXDESC_LIST_ADDRESS)

The Channel 3 Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in RX_CONTROL register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Field	Description
	- 2'b11: 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.
15-8 —	Reserved
7-0 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the STATUS register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

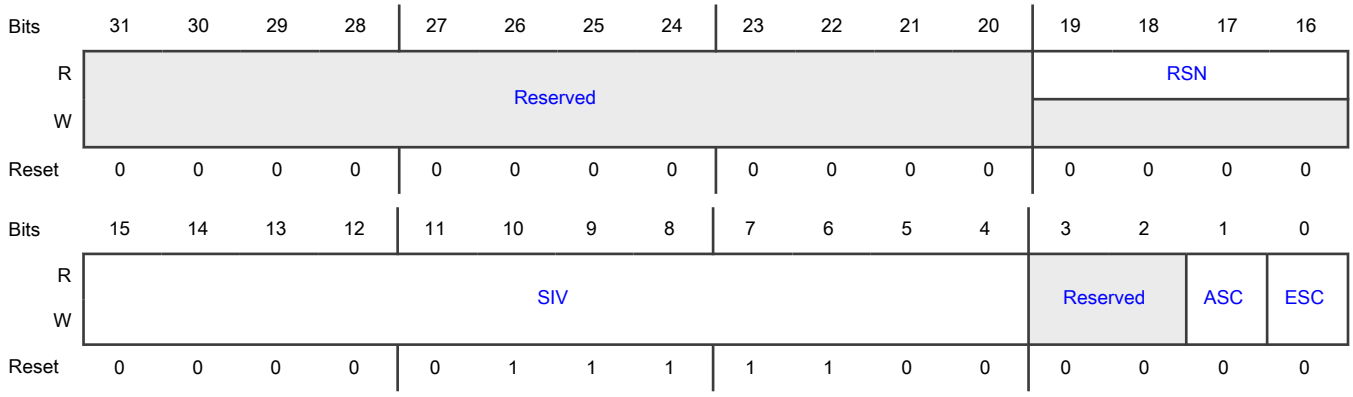
43.8.1.541 Channel 3 Slot Function Control and Status (DMA_CH3_SLOT_FUNCTION_CONTROL_STATUS)

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Offset

Register	Offset
DMA_CH3_SLOT_FUNCTION_CONTROL_STATUS	12BCh

Diagram



Fields

Field	Description
31-20 —	Reserved
19-16 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096us. The default/reset value is 0x07C which corresponds to slot interval of 125us
3-2 —	Reserved
1 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is - equal to the reference slot number given in the RSN field or - ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set. 0 - Advance Slot Check is disabled 1 - Advance Slot Check is enabled
0 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is - equal to the reference slot number or - ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. Note: The UFO (UDP Fragmentation over IPv4)/TSO/USO should not be enabled along with TBS/AVB Slot number check. The UFO/TSO/USO involves multiple packets/segments/fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for software to specify slot number for subsequent packets. 0 - Slot Comparison is disabled 1 - Slot Comparison is enabled

43.8.1.542 Channel 3 Current Application Transmit Descriptor (DMA_CH3_CURRENT_APP_TXDESC)

Field	Description
	This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. - Bit 18 -- 1'b1: Error during data transfer by Tx DMA -- 1'b0: No Error during data transfer by Tx DMA - Bit 17 -- 1'b1: Error during descriptor access -- 1'b0: Error during data buffer access - Bit 16 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
15 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH3_INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH3_INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH3_INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH3_INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Normal Interrupt Summary status not detected 1 - Normal Interrupt Summary status detected
14 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH3_INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. Abnormal Interrupt Summary

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH3_INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Abnormal Interrupt Summary status not detected 1 - Abnormal Interrupt Summary status detected
13 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Context Descriptor Error status not detected 1 - Context Descriptor Error status detected
12 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Fatal Bus Error status not detected 1 - Fatal Bus Error status detected
11 ERI	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. Early Receive Interrupt

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. In configs supporting ERIC, When ERIC=0, this bit is set only after the Rx DMA has filled up a complete receive buffer with packet data. When ERIC=1, this bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Early Receive Interrupt status not detected 1 - Early Receive Interrupt status detected
10 ETI	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configs supporting ETIC: When ETIC=0, this bit is set only after the Tx DMA has transferred a complete packet to MTL. When ETIC=1, this bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC=1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Early Transmit Interrupt status not detected 1 - Early Transmit Interrupt status detected
9 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0 - Receive Watchdog Timeout status not detected 1 - Receive Watchdog Timeout status detected
8 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Receive Process Stopped status not detected 1 - Receive Process Stopped status detected
7 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode,

Table continues on the next page...

Field	Description
	the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Receive Buffer Unavailable status not detected 1 - Receive Buffer Unavailable status detected
6 RI	Receive Interrupt This bit indicates that the packet reception is complete. Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Receive Interrupt status not detected 1 - Receive Interrupt status detected
5-3 —	Reserved
2 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DEBUG_STATUS0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 31 of TDES3. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Buffer Unavailable status not detected 1 - Transmit Buffer Unavailable status detected
1 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Process Stopped status not detected 1 - Transmit Process Stopped status detected

Table continues on the next page...

Table continued from the previous page...

Field	Description
0 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Interrupt status not detected 1 - Transmit Interrupt status detected

43.8.1.547 Channel 3 Missed Frame Counter (DMA_CH3_MISS_FRAME_CNT)

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH3_RX_CONTROL register.

Offset

Field	Description
21-16 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in CONTROL register. 2. Set the TxPBL. Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of TXQ4_OPERATION_MODE register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 IPBL	Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. Ignore PBL Requirement When this bit is set, the DMA does not check for PBL number of locations in the MTL before initiating a transfer. If space is not available, the MTL may use handshaking to slow the DMA. Note: This bit/mode must not be used when multiple Transmit DMA Channels are enabled as it may block other Transmit and Receive DMA Channels from accessing the Read Data Channel of AXI bus until space is available in Transmit Queue for current transfer. 0 - Ignore PBL Requirement is disabled 1 - Ignore PBL Requirement is enabled
14-13 —	Reserved
12 —	Reserved
11-5 —	Reserved
4 OSF	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained. 0 - Operate on Second Packet disabled 1 - Operate on Second Packet enabled
3-1	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
0 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the base address of the Transmit list set by the DMA_CH4_TXDESC_LIST_ADDRESS register. - The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH4_STATUS register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH4_TXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH4_TXDESC_LIST_ADDRESS register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0 - Stop Transmission Command 1 - Start Transmission Command

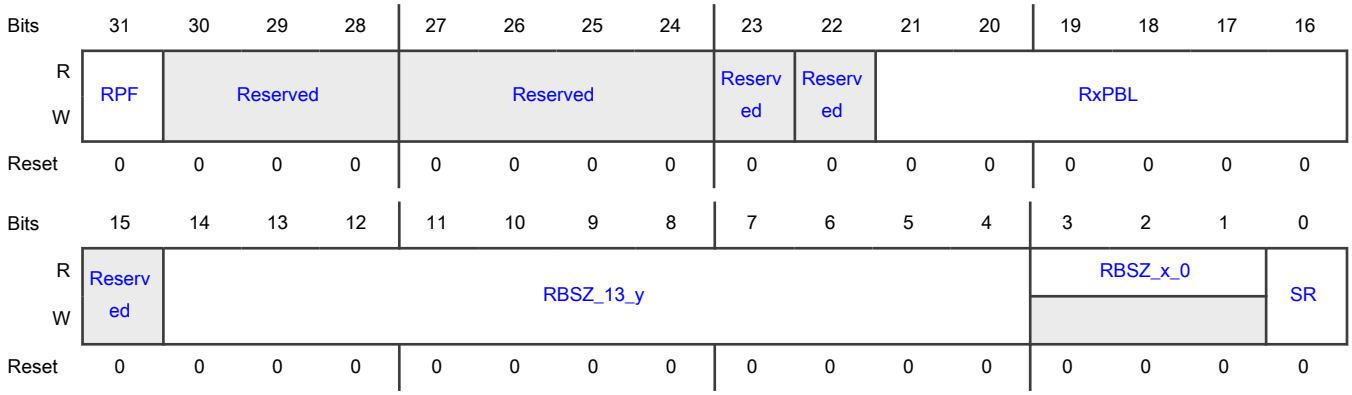
43.8.1.551 DMA Channel 4 Receive Control (DMA_CH4_RX_CONTROL)

The DMA Channel 4 Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Offset

Register	Offset
DMA_CH4_RX_CONTROL	1308h

Diagram



Fields

Field	Description
31 RPF	Rx Packet Flush. Rx Packet Flush. When this bit is set to 1, then DWC_ether_qos automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel, when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, get flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing happens on the Read side of the Rx Queue. When this bit is set to 0, the DWC_ether_qos not flush the packet in the Rx Queue destined to this RxDMA Channel when it is STOP state. This may in turn cause head-of-line blocking in the corresponding RxQueue. 0 - Rx Packet Flush is disabled 1 - Rx Packet Flush is enabled

Table continued from the previous page...

Field	Description
	bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the DMA_CH4_CONTROL register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of RXQ4_OPERATION_MODE register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 —	Reserved
14-4 RBSZ_13_y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_y and lower RBSZ_x_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width).
3-1 RBSZ_x_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: - The current position in the list This is the address set by the DMA_CH4_RXDESC_LIST_ADDRESS register. - The position at which the Rx process was previously stopped

Table continues on the next page...

Table continued from the previous page...

Field	Description
	If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH4_STATUS register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH4_RXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0 - Stop Receive 1 - Start Receive

43.8.1.552 Channel 4 Tx Descriptor List Address (DMA_CH4_TXDESC_LIST_ADDRESS)

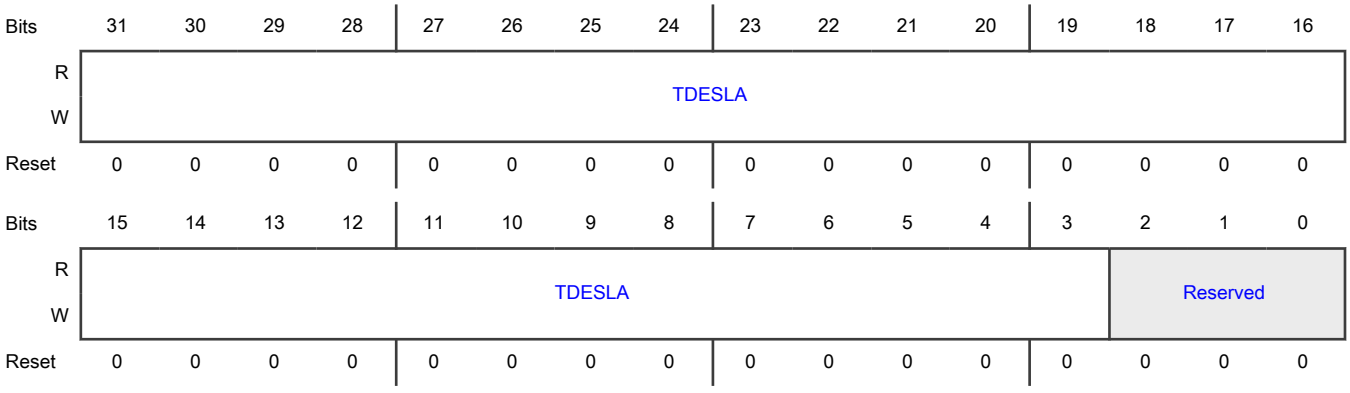
The Channel 4 Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in TX_CONTROL register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Offset

Register	Offset
DMA_CH4_TXDESC_LIST_ADDRESS	1314h

Diagram



Fields

Field	Description
31-3 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 —	Reserved

43.8.1.553 Channel 4 Rx Descriptor List Address (DMA_CH4_RXDESC_LIST_ADDRESS)

The Channel 4 Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

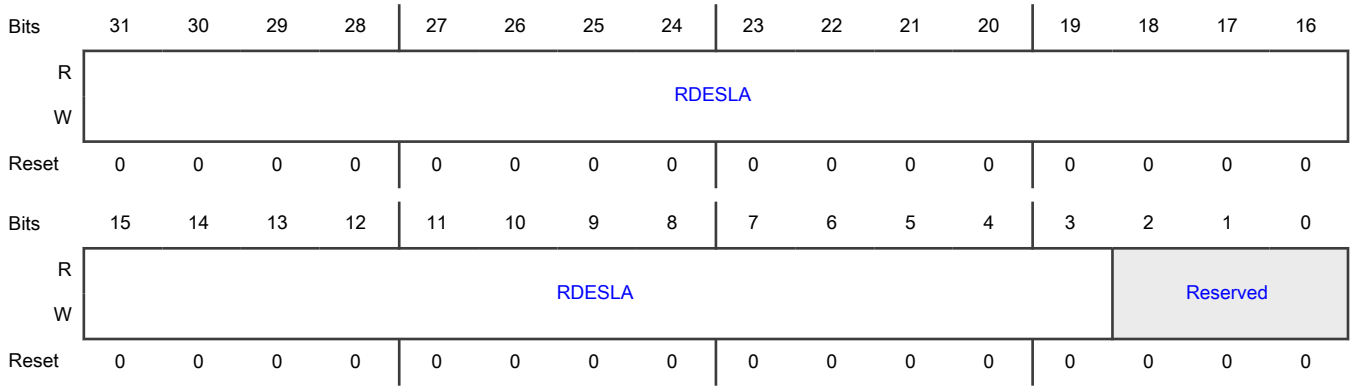
This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in RX_CONTROL register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Offset

Register	Offset
DMA_CH4_RXDESC_LIST_ADDRESS	131Ch

Diagram



Fields

Field	Description
31-3 RDESLA	Start of Receive List This field contains the base address of the first descriptor in the Rx Descriptor list. Start of Receive List This field contains the base address of the first descriptor in the Rx Descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: - 31:2 for 32-bit configuration - 31:3 for 64-bit configuration - 31:4 for 128-bit configuration
2-0 —	Reserved

43.8.1.554 Channel 4 Tx Descriptor Tail Pointer (DMA_CH4_TXDESC_TAIL_POINTER)

The Channel 4 Tx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.

Offset

Register	Offset
DMA_CH4_TXDESC_TAIL_POINTER	1320h

17-16 RWTU	Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. - 2'b00: 256 - 2'b01: 512 - 2'b10: 1024

Table continues on the next page...

Table continued from the previous page...

Field	Description
	- 2'b11: 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.
15-8 —	Reserved
7-0 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the DMA_CH4_STATUS register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

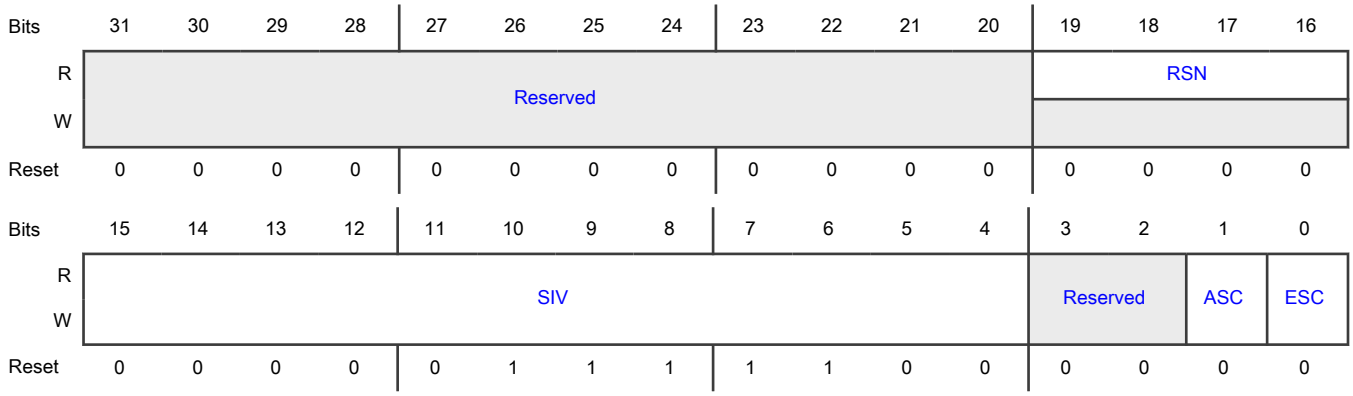
43.8.1.560 Channel 4 Slot Function Control and Status (DMA_CH4_SLOT_FUNCTION_CONTROL_STATUS)

The Channel 4 Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Offset

Register	Offset
DMA_CH4_SLOT_FUNCTION_CONTROL_STATUS	133Ch

Diagram



Fields

Field	Description
31-20 —	Reserved
19-16 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096us. The default/reset value is 0x07C which corresponds to slot interval of 125us
3-2 —	Reserved
1 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is - equal to the reference slot number given in the RSN field or - ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set. 0 - Advance Slot Check is disabled 1 - Advance Slot Check is enabled
0 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is - equal to the reference slot number or - ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. Note: The UFO (UDP Fragmentation over IPv4)/TSO/USO should not be enabled along with TBS/AVB Slot number check. The UFO/TSO/USO involves multiple packets/segments/fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for software to specify slot number for subsequent packets. 0 - Slot Comparison is disabled 1 - Slot Comparison is enabled

43.8.1.561 Channel 4 Current Application Transmit Descriptor (DMA_CH4_CURRENT_APP_TXDESC)

This field does not generate an interrupt.
18-16 TEB	Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. Tx DMA Error Bits

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. - Bit 18 -- 1'b1: Error during data transfer by Tx DMA -- 1'b0: No Error during data transfer by Tx DMA - Bit 17 -- 1'b1: Error during descriptor access -- 1'b0: Error during data buffer access - Bit 16 -- 1'b1: Error during read transfer -- 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
15 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt - Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in INTERRUPT_ENABLE register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Normal Interrupt Summary status not detected 1 - Normal Interrupt Summary status detected
14 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. Abnormal Interrupt Summary

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the INTERRUPT_ENABLE register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 10: Early Transmit Interrupt - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Abnormal Interrupt Summary status not detected 1 - Abnormal Interrupt Summary status detected
13 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Context Descriptor Error status not detected 1 - Context Descriptor Error status detected
12 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Fatal Bus Error status not detected 1 - Fatal Bus Error status detected
11 ERI	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. Early Receive Interrupt

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. In configs supporting ERIC, When ERIC=0, this bit is set only after the Rx DMA has filled up a complete receive buffer with packet data. When ERIC=1, this bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Early Receive Interrupt status not detected 1 - Early Receive Interrupt status detected
10 ETI	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configs supporting ETIC: When ETIC=0, this bit is set only after the Tx DMA has transferred a complete packet to MTL. When ETIC=1, this bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC=1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Early Transmit Interrupt status not detected 1 - Early Transmit Interrupt status detected
9 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0 - Receive Watchdog Timeout status not detected 1 - Receive Watchdog Timeout status detected
8 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Receive Process Stopped status not detected 1 - Receive Process Stopped status detected
7 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode,

Table continues on the next page...

Table continued from the previous page...

Field	Description
	the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Receive Buffer Unavailable status not detected 1 - Receive Buffer Unavailable status detected
6 RI	Receive Interrupt This bit indicates that the packet reception is complete. Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Receive Interrupt status not detected 1 - Receive Interrupt status detected
5-3 —	Reserved
2 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_CH4_DEBUG_STATUS0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: 1. Change the ownership of the descriptor by setting Bit 31 of TDES3. 2. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Buffer Unavailable status not detected 1 - Transmit Buffer Unavailable status detected
1 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Process Stopped status not detected 1 - Transmit Process Stopped status detected

Table continues on the next page...

Table continued from the previous page...

Field	Description
0 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0 - Transmit Interrupt status not detected 1 - Transmit Interrupt status detected

43.8.1.566 Channel 4 Missed Frame Counter (DMA_CH4_MISS_FRAME_CNT)

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH4_RX_CONTROL register.

Offset

Register	Offset
DMA_CH4_MISS_FRAME_CNT	1364h

Diagram

15 MFCO	Overflow status of the MFC Counter When this bit is set then the MFC counter does not get incremented further.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Overflow status of the MFC Counter When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - Miss Frame Counter overflow not occurred 1 - Miss Frame Counter overflow occurred
14-11 —	Reserved
10-0 MFC	Dropped Packet Counters This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programming RPF field in RX_CONTROL register. Dropped Packet Counters This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programming RPF field in RX_CONTROL register. The counter gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.

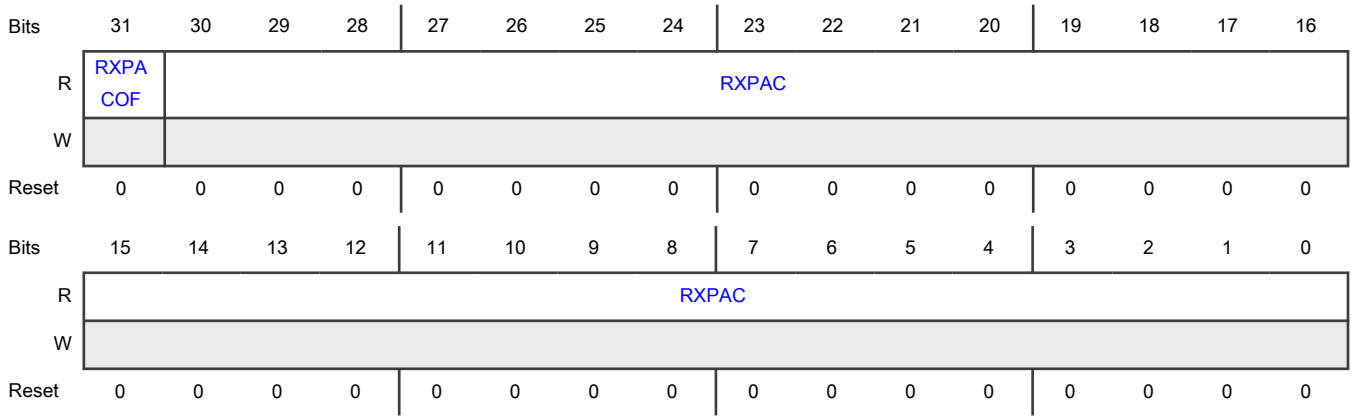
43.8.1.567 Channel 4 RXP Frames Accepted Counter (DMA_CH4_RXP_ACCEPT_CNT)

The DMA_CH4_RXP_Accept_Cnt register provides the count of the number of frames accepted by Rx Parser.

Offset

Register	Offset
DMA_CH4_RXP_ACCEPT_CNT	1368h

Diagram



Fields

Field	Description
31 RXPACOF	Rx Parser Accept Counter Overflow Bit When set, this bit indicates that the RXPAC Counter field crossed the maximum limit. Rx Parser Accept Counter Overflow Bit When set, this bit indicates that the RXPAC Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - Rx Parser Accept Counter overflow not occurred 1 - Rx Parser Accept Counter overflow occurred
30-0 RXPAC	Rx Parser Accept Counter This 31-bit counter is implemented whenever a Rx Parser Accept a packet due to AF =1. Rx Parser Accept Counter This 31-bit counter is implemented whenever a Rx Parser Accept a packet due to AF =1. The counter is cleared when the register is read.

Chapter 44
Ethernet MAC (ENET)

44.1 Overview

The core implements a triple-speed 10/100/1000-Mbit/s ENET compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100-Mbit/s and full-duplex gigabit Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable ENET with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

NOTE

The terminology in this chapter has been updated to align with Annex K (informative) Optional alternative terminology, IEEE 802.3, as shown in the table below.

Table 429. Updated terms

Updated term	Deprecated term
Leader	Master
Follower	Slave

44.1.1 Block diagram

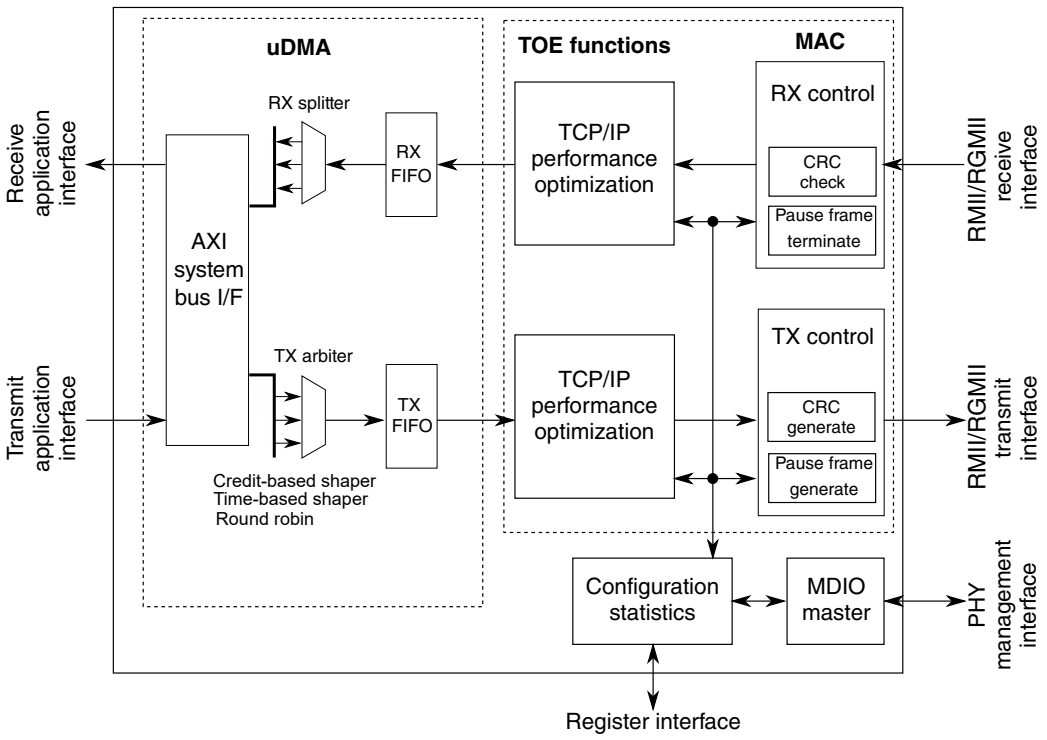


Figure 206. Ethernet MAC-NET core block diagram

44.1.2 Features

The MAC-NET core includes the following features.

44.1.2.1 Ethernet MAC features

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble
- Dynamically configurable to support 10/100-Mbit/s and gigabit operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Supports gigabit full-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial Ethernet PHY devices via one of the following:
  - a 2-bit Reduced MII (RMII) operating at 50 MHz.
  - a (double data rate) 4-bit Reduced GMII (RGMII) operating at 125 MHz.
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
  - Supports Ethernet pause frame (802.3 Annex 31A) providing fully automated flow control without any user application overhead

- Pause quanta used to form pause frames, dynamically programmable
- Pause frame generation additionally controllable by user application offering flexible traffic flow control
- Optional forwarding of received pause frames to the user application
- Implements standard flow-control mechanism

- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive
- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- Supports internal loopback option
- Programmable Clause 22 and Clause 45 MDIO Leader interface for PHY device configuration and management
- Supports legacy FEC buffer descriptors
- Supports interrupt coalescing
- Supports credit-based shaping and round robin QoS scheme for traffic shaping bandwidth distribution. Either policy can be combined with time-based shaping.
- AVB (Audio Video Bridging, IEEE 802.1Qav) features:
  - Credit-based bandwidth distribution policy can be combined with time-based shaping
  - AVB endpoint talker and listener support
  - Support for arbitration between different priority traffic (for example, AVB class A, AVB class B, and non-AVB)

44.1.2.2 IP protocol performance optimization features

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols
- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and insertion on transmit. Configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking
- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodifed/unchecked

- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

44.1.2.3 IEEE 1588 features

- Supports all IEEE 1588 frames.
- Allows reference clock to be chosen independently of network speed.
- Software-programmable precise time-stamping of ingress and egress frames
- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

44.2 Functional description

This section provides a complete functional description of the MAC-NET core.

44.2.1 Ethernet MAC frame formats

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field
- Frame check sequence (CRC value)
- Extension field is defined only for Gigabit Ethernet half-duplex implementations and is not supported by the MAC core

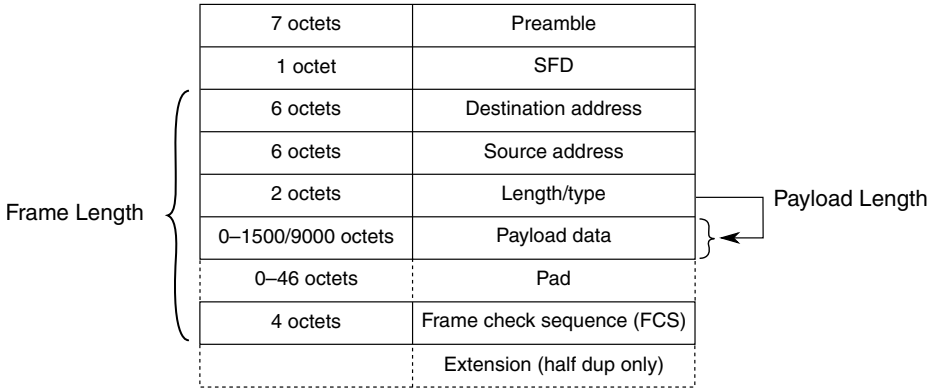

Figure 207. MAC frame format overview

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

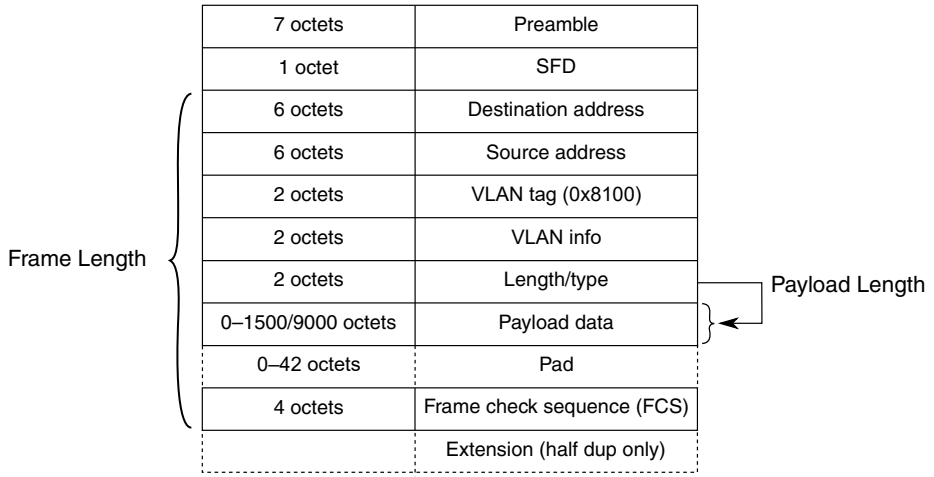

Figure 208. VLAN-tagged MAC frame format overview

Table 430. MAC frame definition

Term	Description
Frame length	Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.
Payload length	The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first. • If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame. • If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.
Destination and source address	48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in MAC address check.

NOTE

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

44.2.1.1 Pause frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

Table 431. Pause Frame Format (Values in Hex)

1	2	3	4	5	6	7	8	9	10	11	12	13	14
55	55	55	55	55	55	55	D5	01	80	C2	00	00	01
Preamble							SFD	Multicast Destination Address					
15	16	17	18	19	20	21	22	23	24	25	26	27 –68	
00	00	00	00	00	00	88	08	00	01	hi	lo	00	
Source Address						Type		Opcode		P1	P2	pad (42)	
69	70	71	72										
26	6B	AE	0A										
CRC-32													

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see Full-duplex flow control operation for details).

44.2.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section. Magic packets are received and inspected only under specific conditions as described in Magic packet detection.

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

44.2.2 IP and higher layers frame format

The following sections use the term datagram to describe the protocol specific data unit that is found within the payload section of its container entity.

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

44.2.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types. The following table lists the types of interest:

Table 432. Ethernet type value examples

Type	Description
0x8100	VLAN-tagged frame. The actual type is found 4 octets later in the frame.
0x0800	IPv4
0x0806	ARP
0x86DD	IPv6

44.2.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

Table 433. IPv4 header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Version	IHL	TOS		Length			
Fragment ID				Flags	Fragment offset		
TTL		Protocol		Header checksum			
Source address							
Destination address							
Options							

Table 434. IPv4 header fields

Field name	Description
Version	4-bit IP version information. 0x4 for IPv4 frames.
IHL	4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5.
TOS	Type of service/DiffServ field.

Table continues on the next page...

Table 434. IPv4 header fields (continued)

Field name	Description
Length	Total length of the datagram in bytes, including all octets of header and payload.
Fragment ID, flags, fragment offset	Fields used for IP fragmentation.
TTL	Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.
Protocol	Identifier of protocol that follows in the datagram.
Header checksum	Checksum of IP header. For computational purposes, this field's value is zero.
Source address	Source IP address.
Destination address	Destination IP address.

44.2.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly. The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or IMCP).

The first byte sent/received is the leftmost byte of the first word (in other words, version/traffic class fields).

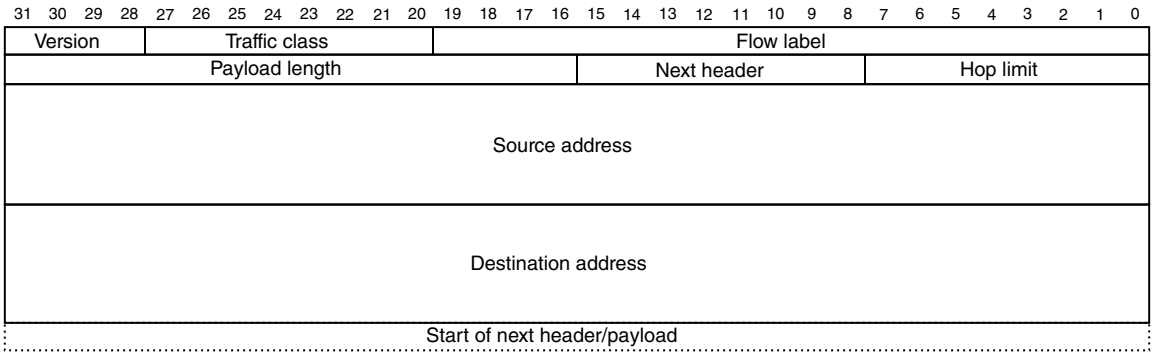

Figure 209. IPv6 header format

Table 435. IPv6 header fields

Field name	Description
Version	4-bit IP version information. 0x6 for all IPv6 frames.
Traffic class	8-bit field defining the traffic class.
Flow label	20-bit flow label identifying frames of the same flow.

Table continues on the next page...

Table 435. IPv6 header fields (continued)

Field name	Description
Payload length	16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.
Next header	Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header.
Hop limit	Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.
Source address	128-bit IPv6 source address.
Destination address	128-bit IPv6 destination address.

44.2.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

Table 436. ICMP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Type		Code		Checksum			
ICMP message data							

Table 437. IP header fields

Field name	Description
Type	8-bit type information
Code	8-bit code that is related to the message type
Checksum	16-bit one's complement checksum over the complete ICMP datagram

44.2.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

Table 438. UDP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source port				Destination port			
Length				Checksum			

Table 439. UDP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Length	Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8)
Checksum	Checksum over the complete datagram and some IP header information

44.2.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6. The TCP payload immediately follows the TCP header.

Table 440. TCP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10	9 8	7 6 5 4	3 2 1 0
Source port				Destination port				
Sequence number								
Acknowledgement number								
Offset	Reserved		Flags	Window				
Checksum				Urgent pointer				
Options								

Table 441. TCP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Sequence number	Transmit sequence number
Ack. number	Receive sequence number
Offset	Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5
Flags	URG, ACK, PSH, RST, SYN, FIN flags
Window	TCP receive window size information

Table continues on the next page...

Table 441. TCP header fields (continued)

Field name	Description
Checksum	Checksum over the complete datagram (TCP header and data) and IP header information
Options	Additional 32-bit words for protocol options

44.2.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

44.2.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2). Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

44.2.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages. The table below shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

Table 442. UDP/IP multicast domains

Name	IP Address	MAC Address mapping
DefaultPTPdomain	224.0.1.129	01-00-5E-00-01-81
AlternatePTPdomain1	224.0.1.130	01-00-5E-00-01-82
AlternatePTPdomain2	224.0.1.131	01-00-5E-00-01-83
AlternatePTPdomain3	224.0.1.132	01-00-5E-00-01-84

Table 443. UDP port numbers

Message type	UDP port	Note
Event	319	Used for SYNC and DELAY_REQUEST messages
General	320	All other messages (for example, follow-up, delay-response)

44.2.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

Table 444. PTPv2 multicast domains

Name	MAC address
Normal messages	01-1B-19-00-00-00
Peer delay messages	01-80-C2-00-00-0E

44.2.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message. All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

44.2.3.2.1 PTPv1 header

Table 445. Common PTPv1 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	2	versionPTP = 0x0001							
2	2	versionNetwork							
4	16	subdomain							
20	1	messageType							
21	1	sourceCommunicationTechnology							
22	6	sourceUuid							
28	2	sourcePortId							
30	2	sequenceId							
32	1	control							
33	1	0x00							
34	2	flags							
36	4	reserved							

The type of message is encoded in the messageType and control fields as shown in Table 446:

Table 446. PTPv1 message type identification

messageType	control	Message Name	Message
0x01	0x0	SYNC	Event message
0x01	0x1	DELAY_REQ	Event message
0x02	0x2	FOLLOW_UP	General message
0x02	0x3	DELAY_RESP	General message
0x02	0x4	MANAGEMENT	General message
other	other	—	Reserved

The field sequenceId is used to non-ambiguously identify a message.

44.2.3.2.2 PTPv2 header

Table 447. Common PTPv2 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	1	transportSpecific				messageId			
1	1	reserved				versionPTP = 0x2			
2	2	messageLength							
4	1	domainNumber							
5	1	reserved							
6	2	flags							
8	8	correctionField							
16	4	reserved							
20	10	sourcePortIdentity							
30	2	sequenceId							
32	1	control							
33	1	logMeanMessageInterval							

The type of message is encoded in the field messageId as follows:

Table 448. PTPv2 message type identification

messageId	Message name	Message
0x0	SYNC	Event message
0x1	DELAY_REQ	Event message
0x2	PATH_DELAY_REQ	Event message
0x3	PATH_DELAY_RESP	Event message
0x4–0x7	—	Reserved
0x8	FOLLOW_UP	General message
0x9	DELAY_RESP	General message
0xa	PATH_DELAY_FOLLOW_UP	General message
0xb	ANNOUNCE	General message
0xc	SIGNALING	General message
0xd	MANAGEMENT	General message

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the TWO_STEP bit in the first octet of the flags field as shown below. Reserved bits are cleared.

Table 449. PTPv2 message flags field definitions

Bit	Name	Description
0	ALTERNATE_MASTER	See IEEE 1588 Clause 17.4
1	TWO_STEP	1 Two-step clock 0 One-step clock
2	UNICAST	1 Transport layer address uses a unicast destination address 0 Multicast is used
3	—	Reserved
4	—	Reserved
5	Profile specific	
6	Profile specific	
7	—	Reserved

44.2.4 MAC receive

The MAC receive engine performs the following tasks:

- Check frame framing
- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

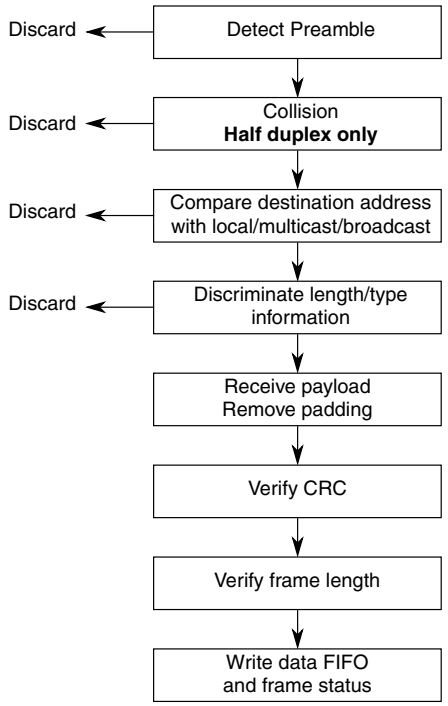

Figure 210. MAC receive flow

44.2.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

44.2.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble. The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100-Mbit/s operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

44.2.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

44.2.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers. If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled (RCR[PROM] = 1) no address checking is performed and all unicast frames are accepted.

44.2.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in ENET*n*_GAUR/GALR (group address hash match) or ENET*n*_IAUR/IALR (individual address hash match).
- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects ENET*n*_GAUR (msb = 1) or ENET*n*_GALR (msb = 0).
- The five least significant bits of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- FCS(x) = x^{32}+ x^{26}+ x^{23}+ x^{22}+ x^{16}+ x^{12}+ x^{11}+ x^{10}+ x^{8}+ x^{7}+ x^{5}+ x^{4}+ x^{2}+ x^{1}+ 1

If Promiscuous mode is enabled (ENET*n*_RCR[PROM] = 1) all unicast and multicast frames are accepted regardless of ENET*n*_GAUR/GALR and ENET*n*_IAUR/IALR settings.

44.2.4.3.3 Broadcast address reject

All broadcast frames are accepted if BC_REJ is cleared or ENET*n*_RCR[PROM] is set. If PROM is cleared when ENET*n*_RCR[BC_REJ] is set, all broadcast frames are rejected.

Table 450. Broadcast address reject programming

PROM	BC_REJ	Broadcast frames
0	0	Accepted
0	1	Rejected
1	0	Accepted
1	1	Accepted

44.2.4.3.4 Miss-bit implementation

For higher layer filtering purposes, RxBD[M] indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled (RCR[PROM] = 1), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when BC_REJ is set
- A unicast is received that does not match either:
  - Node address (PALR[PADDR1] and PAUR[PADDR2])
  - Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])
- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

44.2.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word RCR[NLC] and interrupt bit EIR[PLR].

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

44.2.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET*n*_FTRL[TRUNC_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

44.2.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field. VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxBD[VLAN]) indicates that the current frame is VLAN tagged.

44.2.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Valid pause frames are ignored if ENET*n*_RCR[FCE] is cleared and are forwarded to the client interface when ENET*n*_RCR[PAUFWD] is set.

44.2.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if ENET*n*_RCR[CRCFWD] is cleared and ENET*n*_RCR[PADEN] is cleared. When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- FCS(x) = x^{32}+ x^{26}+ x^{23}+ x^{22}+ x^{16}+ x^{12}+ x^{11}+ x^{10}+ x^{8}+ x^{7}+ x^{5}+ x^{4}+ x^{2}+ x^{1}+ 1

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the x^{31} term as right-most bit of the first octet. The CRC bits are thus received in the following order: x^{31}, x^{30},..., x^{1}, x^{0}.

If a CRC error is detected, the frame is marked invalid and RxBD[CR] is set.

44.2.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of ENET*n*_RCR[PADEN].

NOTE

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

44.2.4.10 Frame classification (AVB)

To support protocols such as Audio Video Bridging (AVB, IEEE 802.1Qav), normal traffic is separated from time-sensitive traffic immediately at the application interface to allow storing them in different queues for further processing. For every frame received, a classification based on VLAN priority can be performed. When a frame is received, and it contains a VLAN tag, the priority is compared against the values set in the classification match registers (see RCMR register and the following figure.

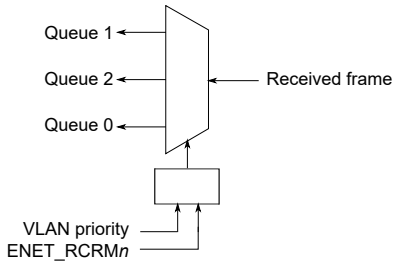

Figure 211. AVB frame classification

44.2.4.11 Receive flushing

RX flushing prevents frames in the RX FIFO from being blocked. Blocking can occur if the frame at the head of the RX FIFO cannot be forwarded because the ring it is associated with cannot accept it. This situation occurs when either the ring's RxBD[EMPTY] is not set or ENET_RDAR*n* is not set. When RX flushing is enabled, via QOS[RX_FLUSHn], the blocking frame will be flushed (discarded).

44.2.5 MAC transmit

Frame transmission starts when the transmit FIFO holds enough data.After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if ENET*n*_TCR[TFC_PAUSE] is set with ENET*n*_OPD[PAUSE_DUR] set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if TFC_PAUSE is set with PAUSE_DUR cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required

- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

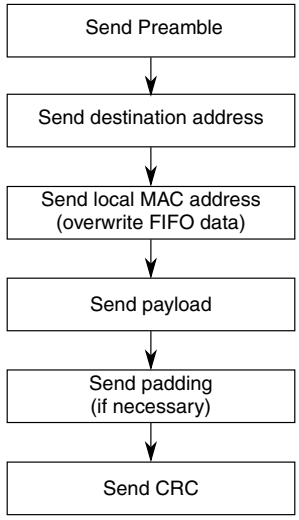

Figure 212. Frame transmit overview

44.2.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes. If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC (TxBD[TC] = 1), the user application is responsible for providing frames with a minimum length of 64 octets.

44.2.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields (ENET*n*_TCR[ADDINS] = 1)
- Transparently forwarded to the Ethernet line (ENET*n*_TCR[ADDINS] = 0)

44.2.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame. The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

The 32 bits of the CRC value are placed in the FCS field so that the x^{31} term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order: x^{31}, x^{30},..., x^{1}, x^{0}.

44.2.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in ENET*n*_TIPG) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS/GMII_CRS de-assertion.

44.2.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets TxBD[LCE].

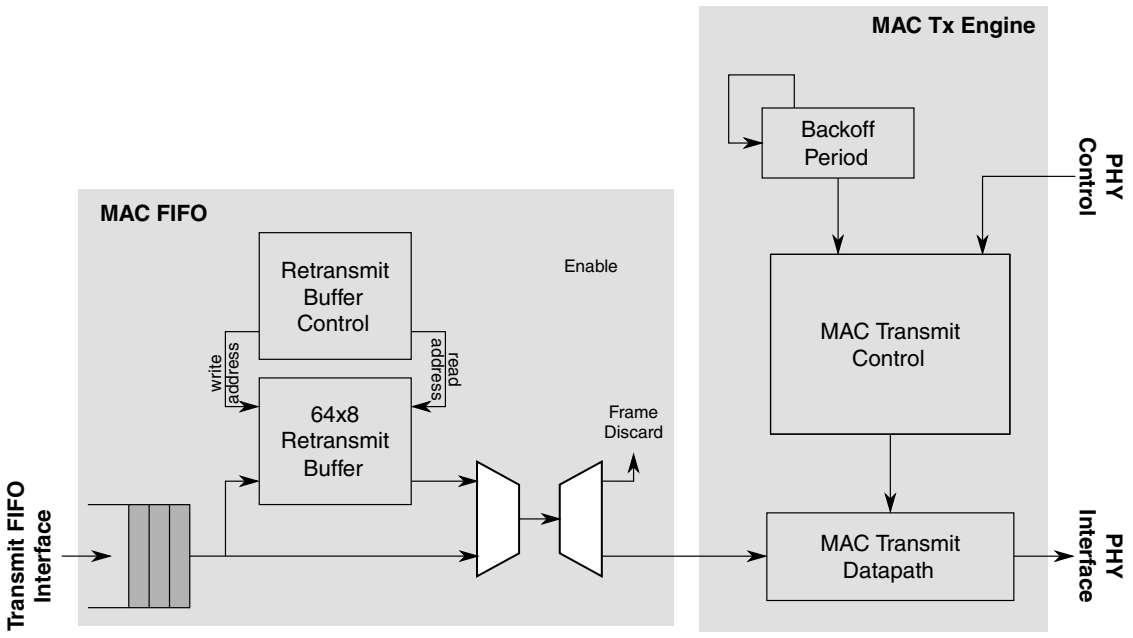

Figure 213. Packet re-transmit overview

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the n^{th} re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- k = min(*n*, N); where *n* is the number of retransmissions and N = 10

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by N = 10 as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET*n*_EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

warning

Ethernet PHYs that support the SQE Test, or "heartbeat," feature must disable this feature. When this feature is enabled, the PHY asserts the collision signal after a frame is transmitted to indicate to the ENET that the PHY's collision logic is working. This may cause data corruption in the next frame from the ENET. This corrupted frame contains up to 21 zero bytes which start somewhere within the MAC destination address field. The ENET, however, will still generate a good FCS (CRC-32) but with corrupted data.

44.2.5.6 Rate limiting / traffic shaping support

The MAC-NET supports two methods to optimize frame traffic for either time-sensitive AVB frames (Class A and Class B) or best-effort non-AVB frames:

- Round-robin scheme
- Credit-based traffic shaping

To ensure that sufficient bandwidth is allocated for the AVB frames, the credit-based shaper must be used. Either method can be combined with a time-based shaper to ensure that a frame is always transmitted in its correct time slot.

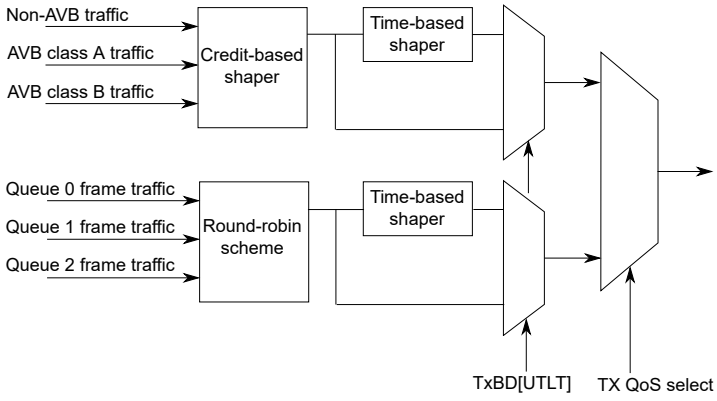

Figure 214. Transmit arbitration schemes

44.2.5.6.1 Round-robin policy

In the round-robin QoS scheme, each queue is given an equal opportunity to transmit one frame. For example, if queue *n* has a frame to transmit, the queue transmits its frame. After queue *n* has transmitted its frame, or if queue *n* does not have a frame to transmit, queue *n*+1 is then allowed to transmit its frame, and so on.

44.2.5.6.2 Credit-based shaper

The AVB credit based shaper acts independently, per class, to control the bandwidth distribution between normal traffic and time-sensitive traffic with respect to the total link bandwidth available. As per the IEEE 802.1Q, the maximum bandwidth distribution that can be allocated for the time-sensitive frames is 75%. The following example uses 70% for AVB frames and 30% for non-AVB frames:

Table 451. Bandwidth allocation example

AVB Class A	50%
AVB Class B	20%

Table continues on the next page...

Table 451. Bandwidth allocation example (continued)

non-AVB frames	30%
Total	100%

See DMACFG register for information on how to allocate bandwidth. The following figure shows how frame traffic is controlled within the MAC-NET core.

44.2.5.6.3 Time-based shaper

The time-based shaper enables the user to specify when a frame can be transmitted. It is always used in combination with either the round-robin scheme or the credit-based shaper. Use of the time-based shaper can ensure that frames are always transmitted in the correct time slot.

44.2.5.6.3.1 Time-based shaper example

Time-based shaping involves the following procedure:

1. Read the current value of the timer. See ATVR register and ATCR register.
2. Calculate the frame launch time and write this value to the TLT field of the frame's TxBD. See Enhanced transmit buffer descriptor.
3. Instruct the ENET to use the TLT by setting TxBD[UTLT].

The frame will be fetched and transmitted only if TxBD[TLT] is less than the current value of the timer. In other words, the timer must be past, that is, be greater than, the transmit launch time before the frame will be fetched and transmitted.

The transmit launch time must not be greater than the current value of ENET_ATVR + (0.5 × ENET_ATPER). This means the application cannot prepare frames with launch times beyond ENET_ATVR + (0.5 × ENET_ATPER). Because ENET_ATVR wraps, calculate TLT using the equation:

(ENET_ATVR + (0.5 × ENET_ATPER)) mod ENET_ATPER

For example, if ENET_ATPER is set to the recommended value of 1,000,000,000 ns (one second), then the user must not prepare future frames with launch times greater than (500,000,000 + ENET_ATVR).

As a specific example, if the current value of ENET_ATVR is 100,000, then you can prepare the following frames:

1. Frame 1 TxBD[TLT] = 100,000ns + 125,000ns
2. Frame 2 TxBD[TLT] = 100,000ns + 250,000ns
3. And so on.

44.2.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.
- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

44.2.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if ENET*n*_RCR[FCE] is set, the MAC transmit logic:

- Completes the transfer of the current frame.

- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets ENET*n*_TCR[RFC_PAUSE].

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets RFC_PAUSE to zero.

If ENET*n*_RCR[FCE] cleared, the MAC ignores received pause frames.

Optionally and independent of ENET*n*_RCR[FCE], pause frames are forwarded to the client interface if PAUFWD is set.

44.2.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets ENET*n*_TCR[TFC_PAUSE]. A single pause frame is generated when the current frame transfer is completed and TFC_PAUSE is automatically cleared. Optionally, an interrupt is generated.
- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in ENET*n*_OPD[PAUSE_DUR].

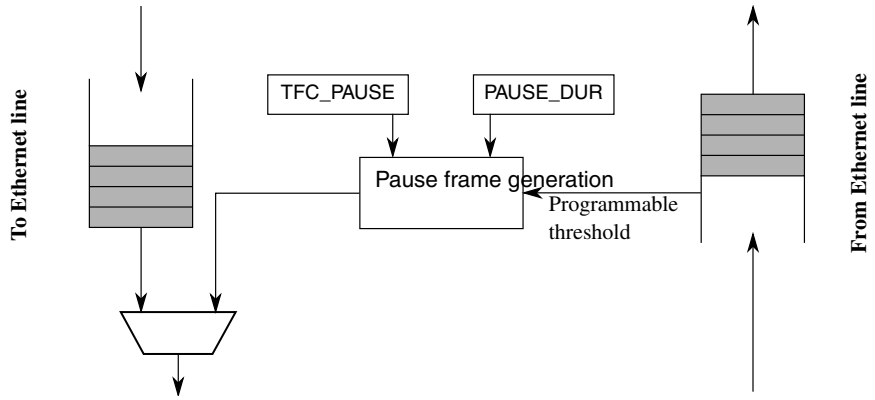

Figure 215. Pause frame generation overview

NOTE

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO, the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

44.2.7 IP accelerator functions

The following sections describe the IP accelerator functions.

44.2.7.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

Table 452. IPv4 pseudo-header for checksum calculation

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10	9 8	7 6 5 4	3 2 1 0
Source address								
Destination address								
Zero		Protocol		TCP/UDP length				

Table 453. IPv6 pseudo-header for checksum calculation

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10	9 8	7 6 5 4	3 2 1 0
Source address								
Destination address								
TCP/UDP length								
Zero							Next header	

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

44.2.7.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets. The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

44.2.7.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENET*n*_TACC and ENET*n*_RACC registers.

When enabled, the valid frame data is arranged as shown in Table 454.

Table 454. 64-bit interface data structure with SHIFT16 enabled

63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	Any value	Any value
Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	Byte 7	Byte 6
...							

44.2.7.3.1 Receive processing

When ENET*n*_RACC[SHIFT16] is set, each frame is received with two additional bytes in front of the frame.The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

NOTE

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

44.2.7.3.2 Transmit processing

When ENET*n*_TACC[SHIFT16] is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic. The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

44.2.7.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (ENET*n*_RSFL cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
  - The frame has an invalid payload length
  - Frame length is greater than MAX_FL
  - Frame received with a CRC-32 error
  - Frame truncated due to receive FIFO overflow
  - Frame is corrupted as PHY signaled an error (RX_ERR asserted during reception)
- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (ENET*n*_RACC), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

44.2.7.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames, as specified above.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBD[FRAG]) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBD[Payload checksum].

NOTE

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

44.2.7.6 IPv6 support

The following sections describe the IPv6 support.

44.2.7.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing (see 32-bit Ethernet payload alignment).

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

44.2.7.6.2 Transmit processing

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

44.2.8 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set ENET*n*_ECR[EN1588] to enable 1588 support.

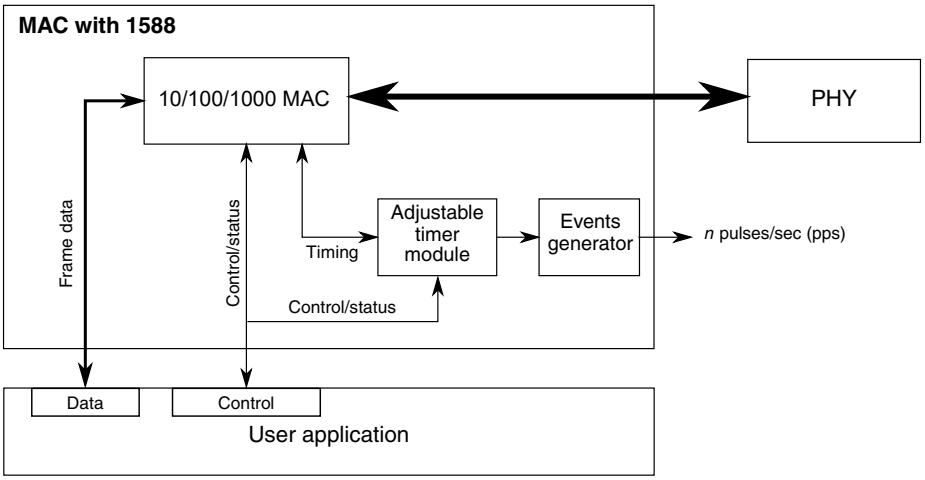

Figure 216. IEEE 1588 functions overview

44.2.8.1 Adjustable timer module

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote leader and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to (1×10^9)-1. The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

44.2.8.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.

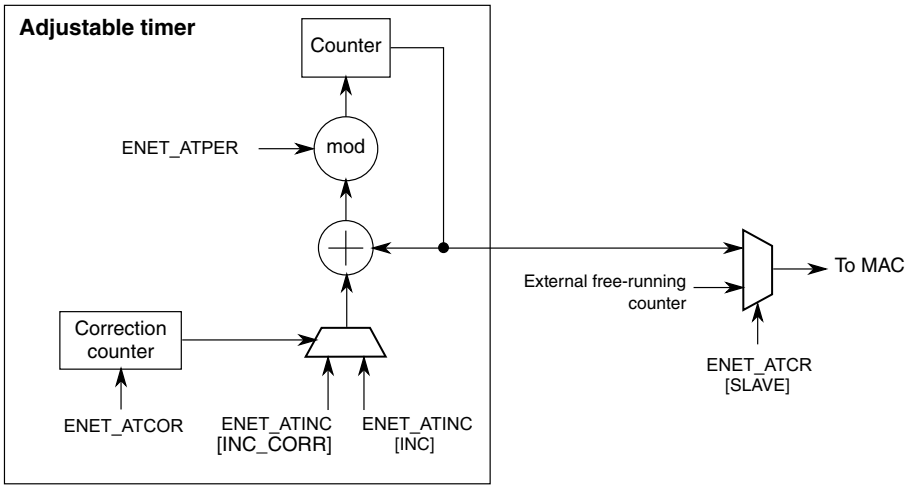

Figure 217. Adjustable timer implementation detail

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in ENET*n*_ATINC. The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in ENET*n*_ATPER, defines the modulo when the counter wraps. In a typical implementation, the period is set to 1×10^9 so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value (Current + Inc $-(1 \times 10^9)$), assuming the period is set to 1×10^9.

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in ENET*n*_ATCOR, it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in ENET*n*_ATINC. To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling follower mode (ENET*n*_ATCR[SLAVE] = 1), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules within the system must operate from a single timer. When follower mode is enabled, you still must set ENET*n*_ATINC[INC] to the value of the leader, since it is used for internal comparisons.

44.2.8.2 Transmit timestamping

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set TxBD[TS] together with the frame.

If TxBD[TS] is set, the MAC records the timestamp for the frame in ENET*n*_ATSTMP. ENET*n*_EIR[TS_AVAIL] is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting TxBD[TS] when it transmits the frame for which a timestamp is needed, and then waits for ENET*n*_EIR[TS_AVAIL] to determine when the timestamp is available. The timestamp is then read from ENET*n*_ATSTMP. This is done for all event frames. Other frames do not use TxBD[TS] and, therefore, do not interfere with the timestamp capture.

44.2.8.3 Receive timestamping

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on RxBD[1588 timestamp]. This is done for all received frames.

44.2.8.4 Time synchronization

The adjustable timer module is available to synchronize the local clock of a node to a remote leader. It implements a free running 32-bit counter, and also contains an additional correction counter.The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a follower scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote leader clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to (1×10^9)–1. In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at 1×10^9.

44.2.8.5 Input capture and output compare

The input capture and output compare block can be used to provide precise hardware timing for input and output events.

44.2.8.5.1 Input capture

The TCCR*n* capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the 1588_TMR*n* signals. An event will cause the corresponding TCSR*n*[TF] timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the TCSR*n*[TIE] field, an interrupt can be generated.

44.2.8.5.2 Output compare

The TCCR*n* compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the TCCR*n* register, the corresponding flag, TCSR*n*[TF], is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by TCSR*n*[TIE], will be generated.The corresponding 1588_TMR*n* output signal will be asserted according to TCSR*n*[TMODE].

NOTE

If TCSR*n*[TMODE] is set to 10X1b or 1010b then the timer output pin toggle-on-overflow will occur only when PINPER, PEREN, and EN bits of the ATCR register are one.

44.2.8.5.3 DMA requests

A DMA request can be enabled by setting TCSR*n*[TDRE]. The corresponding DMA request is generated when the TCSR*n*[TF] timer flag is set. When the DMA has completed, the corresponding TCSRn[TF] flag is cleared.

44.2.9 FIFO thresholds

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 1024 words.

44.2.9.1 Receive FIFO

Four programmable thresholds are available, which can be set to any value to control the core operation as follows.

Table 455. Receive FIFO thresholds definition

Register	Description
ENET*n*_RSFL [RX_SECTION_FULL]	When the FIFO level reaches the ENET*n*_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENET*n*_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again. If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted. To enable store and forward on the receive path, clear ENET*n*_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO. When programming a non-zero value to ENET*n*_RSFL (cut-through operation) it should be greater than ENET*n*_RAEM.
ENET*n*_RAEM [RX_ALMOST_EMPTY]	When the FIFO level reaches the ENET*n*_RAEM value and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. Set ENET*n*_RAEM to a minimum of four.
ENET*n*_RAFL [RX_ALMOST_FULL]	When the FIFO level approaches the maximum and there is no more space remaining for at least ENETn_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow. The corresponding error status is set when the frame is delivered to the application. Set ENET*n*_RAFL to a minimum of 4.
ENET*n*_RSEM [RX_SECTION_EMPTY]	When the FIFO level reaches the ENET*n*_RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client. When the FIFO level goes below the value programmed in ENET*n*_RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client. Clearing ENET*n*_RSEM disables any pause frame generation.

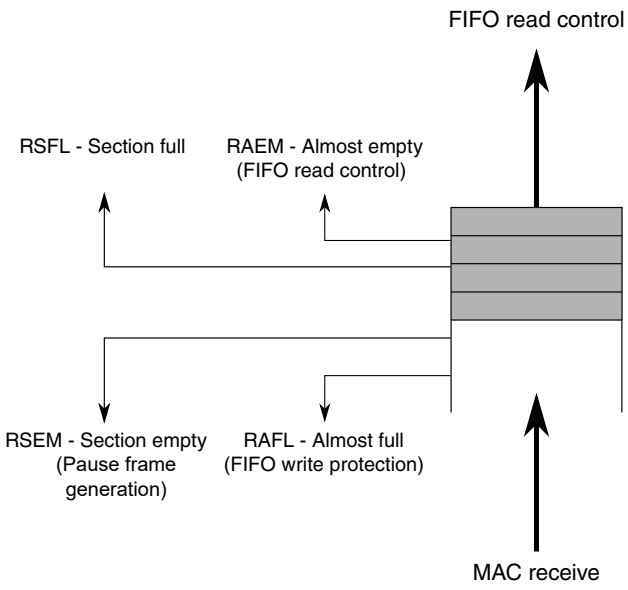

Figure 218. Receive FIFO overview

44.2.9.2 Transmit FIFO

Four programmable thresholds are available which control the core operation as described below.

Table 456. Transmit FIFO thresholds definition

Register	Description
ENET*n*_TAEM [TX_ALMOST _EMPTY]	When the FIFO level reaches the ENET*n*_TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication. Set ENET*n*_TAEM to a minimum of 4.
ENET*n*_TAFL [TX_ALMOST _FULL]	When the FIFO level approaches the maximum, so that there is no more space for at least ENET*n*_TAFL number of words, the MAC deasserts its control signal to the application. If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an GMII/MII error indication. Set ENET*n*_TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion.
ENET*n*_TSEM [TX_SECTION _EMPTY]	When the FIFO level reaches the ENET*n*_TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC. When ENET*n*_TSEM is 0, the signal is never deasserted.
ENET*n*_TFWR	When the FIFO level reaches the ENET*n*_TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation).

Table continues on the next page...

Table 456. Transmit FIFO thresholds definition (continued)

Register	Description
	If a complete frame has a size smaller than the ENET*n*_TFWR threshold, the MAC also transmits the frame to the line. To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO.

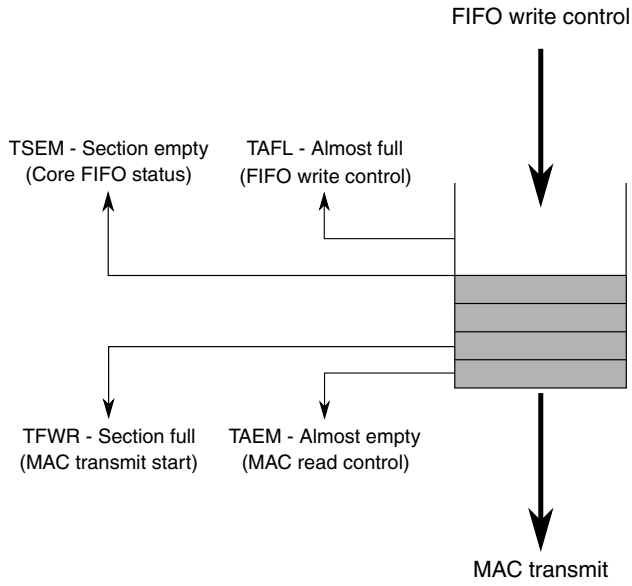

Figure 219. Transmit FIFO overview

44.2.10 Internal loopback option

The core implements internal loopback option. To use internal loopback mode, the RX clock must be provided externally at the RGMII_RCK pin of the PHY interface. The loopback mode is controlled by the following ENET*n*_RCR register field:

Table 457. Loopback option

Register field	Description
LOOP	Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces.

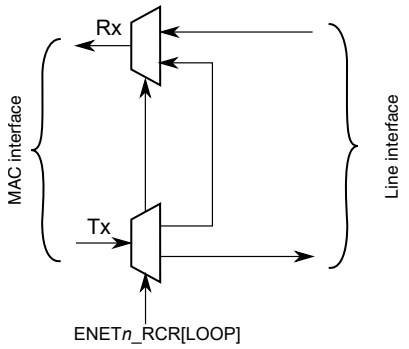

Figure 220. Loopback option

44.2.11 Legacy buffer descriptors

To support the Ethernet controller on previous chips, legacy FEC buffer descriptors are available. To enable legacy support, write 0 to ENET*n*_ECR[1588EN].

NOTE

- Legacy buffer descriptors are used in single-ring mode, that is, when DMA*n*CFG[DMA_CLASS_EN] are zero. In multi-ring mode, legacy TxBDs are used only with the round-robin scheme.
- The legacy buffer descriptor tables show the byte order for little-endian chips. ECR[DBSWP] must be set to 1 after reset to enable little-endian mode.

44.2.11.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. Table 461 contains the descriptions for each field.

Table 458. Legacy FEC receive buffer descriptor (RxBD)

	Byte 1								Byte 0							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset + 0	Data length															
Offset + 2	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset + 4	Rx data buffer pointer — low halfword															
Offset + 6	Rx data buffer pointer — high halfword															

44.2.11.2 Legacy transmit buffer descriptor

The following table shows the legacy FEC transmit buffer descriptor. Table 463 contains the descriptions for each field.

Table 459. Legacy FEC transmit buffer descriptor (TxBD)

	Byte 1								Byte 0							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1. This field is not supported by the uDMA.

44.2.12 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors. It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set ENET*n*_ECR[1588EN].

NOTE

The enhanced buffer descriptor tables show the byte order for little-endian chips. ECR[DBSWP] must be set to 1 after reset to enable little-endian mode.

44.2.12.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. Table 461 contains the descriptions for each field.

Table 460. Enhanced uDMA receive buffer descriptor (RxBD)

	Byte 1								Byte 0

Table 461. Receive buffer descriptor field definitions

Word	Field	Description
Offset + 0	15–0 Data Length	Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed.
Offset + 2	15 E	Empty. Written by the MAC (= 0) and user (= 1). 0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required.
		1 The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 2	14 RO1	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	13 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location.
		1 The next buffer descriptor is found at the location defined in ENET*n*_RDSR.
Offset + 2	12 RO2	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	11 L	Last in frame. Written by the uDMA. 0 The buffer is not the last in a frame.
		1 The buffer is the last in a frame.
Offset + 2	10–9	Reserved, must be cleared.
Offset + 2	8 M	Miss. Written by the MAC. This field is set by the MAC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use the this field to quickly determine whether the frame was destined to this station. This field is valid only if the L and PROM bits are set.

Table continues on the next page...

Table 461. Receive buffer descriptor field definitions (continued)

Word	Field	Description
		0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode.
