Fields

Field	Description
31-24 APC	Domain Access Field For APC, the upper 4 bits are lock bits and the lower 4 bits are domain control bits. The higher 4 bits control whether the lower 4 bits can be changed, respectively. If the lock bit is set to 1, the corresponding domain control bit cannot be changed. The higher 4 bits are sticky registers, which means that once they are set to 1, they cannot be set to 0 unless reset. The domain control bits control whether the corresponding domain can access the IOMUX registers. When set to 1, the corresponding domain cannot access the IOMUX register. When set to 0, the corresponding domain can access the IOMUX register. Domain control bit 3 controls access for domain 3, bit 2 controls access for domain 2, and bit 1 controls access for domain 1. Domain control bit 0 controls whether other domains can access the IOMUX register.

Fields

Field	Description
31-24 APC	Domain Access Field For APC, the upper 4 bits are lock bits and the lower 4 bits are domain control bits. The higher 4 bits control whether the lower 4 bits can be changed, respectively. If the lock bit is set to 1, the corresponding domain control bit cannot be changed. The higher 4 bits are sticky registers, which means that once they are set to 1, they cannot be set to 0 unless reset. The domain control bits control whether the corresponding domain can access the IOMUX registers. When set to 1, the corresponding domain cannot access the IOMUX register. When set to 0, the corresponding domain can access the IOMUX register. Domain control bit 3 controls access for domain 3, bit 2 controls access for domain 2, and bit 1 controls access for domain 1. Domain control bit 0 controls whether other domains can access the IOMUX register.

Field	Description
31-24 APC	Domain Access Field For APC, the upper 4 bits are lock bits and the lower 4 bits are domain control bits. The higher 4 bits control whether the lower 4 bits can be changed, respectively. If the lock bit is set to 1, the corresponding domain control bit cannot be changed. The higher 4 bits are sticky registers, which means that once they are set to 1, they cannot be set to 0 unless reset. The domain control bits control whether the corresponding domain can access the IOMUX registers. When set to 1, the corresponding domain cannot access the IOMUX register. When set to 0, the corresponding domain can access the IOMUX register. Domain control bit 3 controls access for domain 3, bit 2 controls access for domain 2, and bit 1 controls access for domain 1. Domain control bit 0 controls whether other domains can access the IOMUX register.

Fields

Field	Description
31-24 APC	Domain Access Field For APC, the upper 4 bits are lock bits and the lower 4 bits are domain control bits. The higher 4 bits control whether the lower 4 bits can be changed, respectively. If the lock bit is set to 1, the corresponding domain control bit cannot be changed. The higher 4 bits are sticky registers, which means that once they are set to 1, they cannot be set to 0 unless reset. The domain control bits control whether the corresponding domain can access the IOMUX registers. When set to 1, the corresponding domain cannot access the IOMUX register. When set to 0, the corresponding domain can access the IOMUX register. Domain control bit 3 controls access for domain 3, bit 2 controls access for domain 2, and bit 1 controls access for domain 1. Domain control bit 0 controls whether other domains can access the IOMUX register.

Field	Description
31-24 APC	Domain Access Field For APC, the upper 4 bits are lock bits and the lower 4 bits are domain control bits. The higher 4 bits control whether the lower 4 bits can be changed, respectively. If the lock bit is set to 1, the corresponding domain control bit cannot be changed. The higher 4 bits are sticky registers, which means that once they are set to 1, they cannot be set to 0 unless reset. The domain control bits control whether the corresponding domain can access the IOMUX registers. When set to 1, the corresponding domain cannot access the IOMUX register. When set to 0, the corresponding domain can access the IOMUX register. Domain control bit 3 controls access for domain 3, bit 2 controls access for domain 2, and bit 1 controls access for domain 1. Domain control bit 0 controls whether other domains can access the IOMUX register.

Field	Description
31-24 APC	Domain Access Field For APC, the upper 4 bits are lock bits and the lower 4 bits are domain control bits. The higher 4 bits control whether the lower 4 bits can be changed, respectively. If the lock bit is set to 1, the corresponding domain control bit cannot be changed. The higher 4 bits are sticky registers, which means that once they are set to 1, they cannot be set to 0 unless reset. The domain control bits control whether the corresponding domain can access the IOMUX registers. When set to 1, the corresponding domain cannot access the IOMUX register. When set to 0, the corresponding domain can access the IOMUX register. Domain control bit 3 controls access for domain 3, bit 2 controls access for domain 2, and bit 1 controls access for domain 1. Domain control bit 0 controls whether other domains can access the IOMUX register.

Fields

Field	Description
31-24 APC	Domain Access Field For APC, the upper 4 bits are lock bits and the lower 4 bits are domain control bits. The higher 4 bits control whether the lower 4 bits can be changed, respectively. If the lock bit is set to 1, the corresponding domain control bit cannot be changed. The higher 4 bits are sticky registers, which means that once they are set to 1, they cannot be set to 0 unless reset. The domain control bits control whether the corresponding domain can access the IOMUX registers. When set to 1, the corresponding domain cannot access the IOMUX register. When set to 0, the corresponding domain can access the IOMUX register. Domain control bit 3 controls access for domain 3, bit 2 controls access for domain 2, and bit 1 controls access for domain 1. Domain control bit 0 controls whether other domains can access the IOMUX register.

If the lock bit is set to 1, the corresponding domain control bit cannot be changed. The higher 4 bits are sticky registers, which means that once they are set to 1, they cannot be set to 0 unless reset. The domain control bits control whether the corresponding domain can access the IOMUX registers. When set to 1, the corresponding domain cannot access the IOMUX register. When set to 0, the corresponding domain can access the IOMUX register. Domain control bit 3 controls access for domain 3, bit 2 controls access for domain 2, and bit 1 controls access for domain 1. Domain control bit 0 controls whether other domains can access the IOMUX register.

Fields

Field	Description
31-24 APC	Domain Access Field For APC, the upper 4 bits are lock bits and the lower 4 bits are domain control bits. The higher 4 bits control whether the lower 4 bits can be changed, respectively. If the lock bit is set to 1, the corresponding domain control bit cannot be changed. The higher 4 bits are sticky registers, which means that once they are set to 1, they cannot be set to 0 unless reset. The domain control bits control whether the corresponding domain can access the IOMUX registers. When set to 1, the corresponding domain cannot access the IOMUX register. When set to 0, the corresponding domain can access the IOMUX register. Domain control bit 3 controls access for domain 3, bit 2 controls access for domain 2, and bit 1 controls access for domain 1. Domain control bit 0 controls whether other domains can access the IOMUX register.

Field	Description
31-24 APC	Domain Access Field For APC, the upper 4 bits are lock bits and the lower 4 bits are domain control bits. The higher 4 bits control whether the lower 4 bits can be changed, respectively. If the lock bit is set to 1, the corresponding domain control bit cannot be changed. The higher 4 bits are sticky registers, which means that once they are set to 1, they cannot be set to 0 unless reset. The domain control bits control whether the corresponding domain can access the IOMUX registers. When set to 1, the corresponding domain cannot access the IOMUX register. When set to 0, the corresponding domain can access the IOMUX register. Domain control bit 3 controls access for domain 3, bit 2 controls access for domain 2, and bit 1 controls access for domain 1. Domain control bit 0 controls whether other domains can access the IOMUX register.

Fields

Field	Description
31-24 APC	Domain Access Field For APC, the upper 4 bits are lock bits and the lower 4 bits are domain control bits. The higher 4 bits control whether the lower 4 bits can be changed, respectively. If the lock bit is set to 1, the corresponding domain control bit cannot be changed. The higher 4 bits are sticky registers, which means that once they are set to 1, they cannot be set to 0 unless reset. The domain control bits control whether the corresponding domain can access the IOMUX registers. When set to 1, the corresponding domain cannot access the IOMUX register. When set to 0, the corresponding domain can access the IOMUX register. Domain control bit 3 controls access for domain 3, bit 2 controls access for domain 2, and bit 1 controls access for domain 1. Domain control bit 0 controls whether other domains can access the IOMUX register.

Chapter 28
General-Purpose Input/Output (GPIO)

28.1 Chip-specific GPIO information

Table 133. Reference links to related information

Topic	Related module	Reference
CM33	Arm Cortex CM33 Platform (CM33)	CM33 Platform
A55	Arm Cortex CA55 Platform (CA55)	CA55 Platform
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

The chip supports four instances of GPIO. GPIO1 is in AONMIX and GPIO2, GPIO3, GPIO4 in WAKEUPMIX. For more details, please refer the Pin Assignments spreadsheet attached with this document.

GPIO1_IO[5], GPIO1_IO[7], GPIO1_IO[11] and GPIO1_IO[13] are output only or tristated.

For the GPIO1,GPIO2 and GPIO4, the following bits are Reserved in the PCNS, PCNP, PCNP, PDOR, PCOR, PTOR, PDIR, PDDR, PIDR, ISFRn registers.

- Bit[31:17] should be Reserved for GPIO1
- Bit[31:30] should be Reserved for GPIO2
- Bit[31:30] should be Reserved for GPIO4

28.2 Overview

GPIO communicates to the processor core via a zero wait-state interface for maximum pin performance.

28.2.1 Block diagram

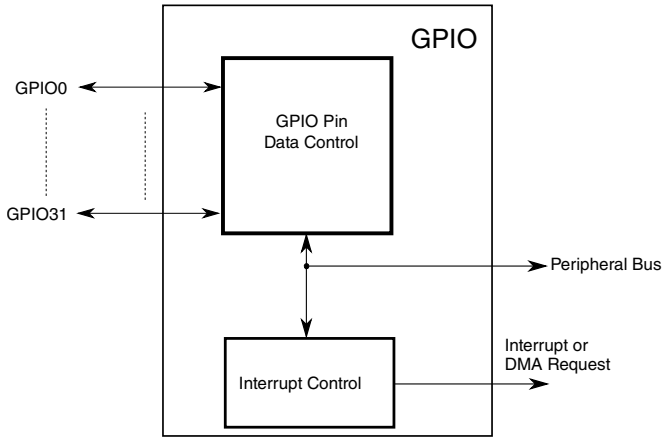

Figure 59. Block diagram

28.2.2 Features

- Port Data Input (PDIR) displays the logic value on each pin when the pin is configured for any digital function, provided the corresponding Port Control and Interrupt modules for that pin are enabled.
- Port Data Output (PDOR), with corresponding set, clear, and toggle registers, controls the output data of each pin when the pin is configured for the GPIO function.
- Port Data Direction (PDDR) controls the direction of each pin when the pin is configured for the GPIO function.
- Port Input Disable (PIDR) controls disabling of the input for each general-purpose pin.
- Pin interrupts:
  - Interrupt flags and enable registers for each pin are functional in all digital pin muxing modes.
  - Support for interrupt or DMA request is configured for each pin.
  - Support for edge-sensitive (rising, falling, or both) or level-sensitive (low, high) interrupts is configured for each pin.
  - Asynchronous wake-up in Low-Power mode.
  - GPIO generates a total of 2 interrupts, and 2 DMA requests.
  - Each pin can be used to generate a single interrupt, or DMA request.
- Protection registers:
  - Each pin is configured for secure or nonsecure and privileged or nonprivileged access.
  - Each interrupt, and DMA request domain is configured for secure or nonsecure and privileged or nonprivileged access.

28.3 Functional description

28.3.1 Low-Power mode

You can configure GPIO to exit Low-Power mode via an asynchronous wake-up signal if an enabled interrupt is detected.

28.3.2 Debug mode

GPIO remains functional in Debug mode.

28.3.3 General-purpose input

The logic state of each pin is available via Port Data Input (PDIR) if:

- The corresponding field in Port Input Disable (PIDR) is 0.
- The pin is configured for a digital function.

28.3.4 General-purpose output

The logic state of each pin is controlled via Port Data Output (PDOR) and Port Data Direction (PDDR), provided the pin is configured for the GPIO function. The following table depicts the conditions for a pin to be configured as input or output.

Table 134. General-purpose output

If	Then
A pin is configured for the GPIO function and the corresponding PDDR field is 0	The pin is configured as an input.
A pin is configured for the GPIO function and the corresponding PDDR field is 1	The pin is configured as an output and the logic state of the pin is equal to the corresponding PDOR field.

For efficient bit manipulation on the general-purpose outputs, pin data set, pin data clear, and pin data toggle registers allow one or more outputs within one port to be set, cleared, or toggled from a single register write, eliminating the need for a read-modify-write operation to prevent changing pins accidentally.

28.3.5 Clocking

GPIO receives a single clock, which is used for register access and synchronization with external pin inputs. There are no special considerations.

28.3.6 Reset

GPIO receives a single reset, which resets the peripheral. There are no special considerations.

28.3.7 External interrupts

The external interrupt capability of GPIO is available in all digital pin muxing modes.

GPIO generates a total of 2 interrupts, and 2 DMA requests. You can configure each pin individually for interrupt, or DMA requests:

- Each output implements a separate interrupt status flag (ISF) register for that domain.
- Each output generates a single interrupt.
- Each output generates a single DMA request.

You can configure each pin individually for any of the external interrupt modes shown in the following table.

Table 135. Available pin configurations for external interrupts

Signal conditions	Software polling using flags	Interrupts	DMA requests
Rising-edge	Yes	Yes	Yes
Falling-edge	Yes	Yes	Yes
Rising- and falling-edge	Yes	Yes	Yes
High-level	—	Yes	—
Low-level	—	Yes	—

The interrupt status flag is set when the configured edge or level is detected on the pin. Unless GPIO is in Low-Power mode, the input is first synchronized to the system clock to detect the configured level or edge transition.

GPIO generates a pin interrupt that asserts when the interrupt status flag is set for any enabled interrupt for that output. The interrupt negates after the interrupt status flags for all enabled interrupts are cleared by writing a logic 1 to either ISFR0[ISF*n*] or ICR0[ISF].

GPIO generates a DMA request that asserts when the interrupt status flag is set for any enabled DMA request in that output. The DMA request negates after the DMA transfer is completed because that clears the interrupt status flags for all enabled DMA requests.

In Low-Power mode, the interrupt status flag for any enabled interrupt is asynchronously set if the required level or edge is detected. This also generates an asynchronous wake-up signal to exit Low-Power mode.

28.3.8 Global interrupt control

The two global interrupt control registers (Global Interrupt Control Low (GICLR) and Global Interrupt Control High (GICHR)) allow a single register write to update the upper 16 bits of Interrupt Control a (ICR0 - ICR31) for up to 16 pins, all with the same value.

These global interrupt control registers allow you to quickly configure multiple pins within the same port with the same interrupt configuration.

The global interrupt control registers are write-only registers and always read 0.

28.3.9 DMA

GPIO generates 2 requests. For each pin, you can configure DMA requests to assert for either rising, falling, or both edge detection. See External interrupts for more information.

28.3.10 Access protection

GPIO implements access protection registers (PCNS and PCNP) for each pin, as shown in Table 136.

Table 136. PCNS and PCNP register access protection implementation

Access	Description
Secure	You can write to or read the pins configured for secure access only in the Secure state.
Nonsecure	You can write to or read the pins configured for nonsecure access only in the Nonsecure state.
Privilege	You can write to the pins configured for privilege access only in the Privilege state.
Nonprivilege	You can write to the pins configured for nonprivilege access in both the Privilege and Nonprivilege states.

GPIO implements access protection registers (ICNS and ICNP) for each interrupt, and DMA request as shown in Table 137.

Table 137. ICNS and ICNP register access protection implementation

Access	Description
Secure	You can configure the outputs programmed for secure access only in the Secure state.
Nonsecure	You can configure the outputs programmed for nonsecure access only in the Nonsecure state.
Privilege	You can configure the outputs programmed for privilege access only in the Privilege state.
Nonprivilege	You can configure the outputs programmed for nonprivilege access in both the Privilege and Nonprivilege states.

You can write to the access protection registers (PCNS, PCNP, ICNS, and ICNP) only in the Secure-Privilege state; you can optionally lock these registers until the next reset.

Configuring a pin interrupt, or DMA request requires the following access permissions:

- Access permission to configure the pin.
- Access permission to either configure to the desired interrupt, or DMA request, or writing 0 to ICR*n*[IRQC].
- Access permission to either configure with the existing interrupt,, or DMA request, or if the current value of ICR*n*[IRQC] is 0.
- The interrupt configuration is not locked.

28.4 External signals

Table 138. External signals

Signal	Description		Direction
GPIO31–GPIO0	General-purpose input/output		I/O
	State meaning	Asserted: The pin is logic 1. Deasserted: The pin is logic 0.	

Table continues on the next page...

Table 138. External signals (continued)

Signal	Description		Direction
	Timing	Assertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock. Deassertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.	

NOTE

Not all pins within each GPIO are implemented on each chip. See the "Signal Multiplexing" chapter for the number of GPIO pins within each port available on this chip.

28.5 Initialization

To initialize GPIO:

1. Initialize the GPIO pins for the output function:
   a. Configure the output logic value for each pin by using Port Data Output (PDOR).
   b. Configure the direction for each pin by using Port Data Direction (PDDR).
2. Initialize the interrupt function by writing to Interrupt Control a (ICR0 - ICR31) for the corresponding pins and desired configuration. If the pin is previously used for a different function, first write 0100_0000h to Interrupt Control a (ICR0 - ICR31) to disable the previous function and clear the flag.

28.6 Application information

GPIO includes the following applications:

- Reading the state of a single pin by performing a byte read of Pin Data (P0DR - P31DR).
- Updating the state of a single pin by performing a byte write to Pin Data (P0DR - P31DR).
- Reading the state of multiple pins by reading Port Data Input (PDIR).
- Updating the state of multiple pins by using the following ways:
  - Writing to Port Data Output (PDOR).
  - Writing to Port Set Output (PSOR) to write 1 to Port Data Output (PDOR).
  - Writing to Port Clear Output (PCOR) to write 0 to Port Data Output (PDOR).
  - Writing to Port Toggle Output (PTOR) to toggle Port Data Output (PDOR).

28.7 Memory map and register definition

The GPIO registers support 8-bit, 16-bit, or 32-bit accesses. Any read or write access to the GPIO memory space that is outside the valid memory map results in a bus error.

NOTE

For simplicity, each GPIO port's register appears with the same width of 32 bits, corresponding to 32 pins. The actual number of pins per port (and therefore the number of usable control bits per port register) is chip-specific. See the "Signal Multiplexing" chapter for the exact control bits of each port.

28.7.1 GPIO register descriptions

28.7.1.1 GPIO memory map

gpio1 base address: 4740_0000h

Fields

Field	Description
31-0 NSEn	Nonsecure Enable Configures secure or nonsecure access protection for each pin. If this field is 0, the pin is configured for secure access. You can read or write to the corresponding pin's registers and fields only in the Secure state. When you access the corresponding pin's registers in the Nonsecure state, all fields in the registers related to that pin are read zero (with writes ignored). If this field is 1, the pin is configured for nonsecure access. You can read or write to the corresponding pin's registers and fields only in the Nonsecure state. When you access the corresponding pin's registers in the Secure state, all fields in the registers related to that pin are read zero (with writes ignored). 0 - Secure access 1 - Nonsecure access

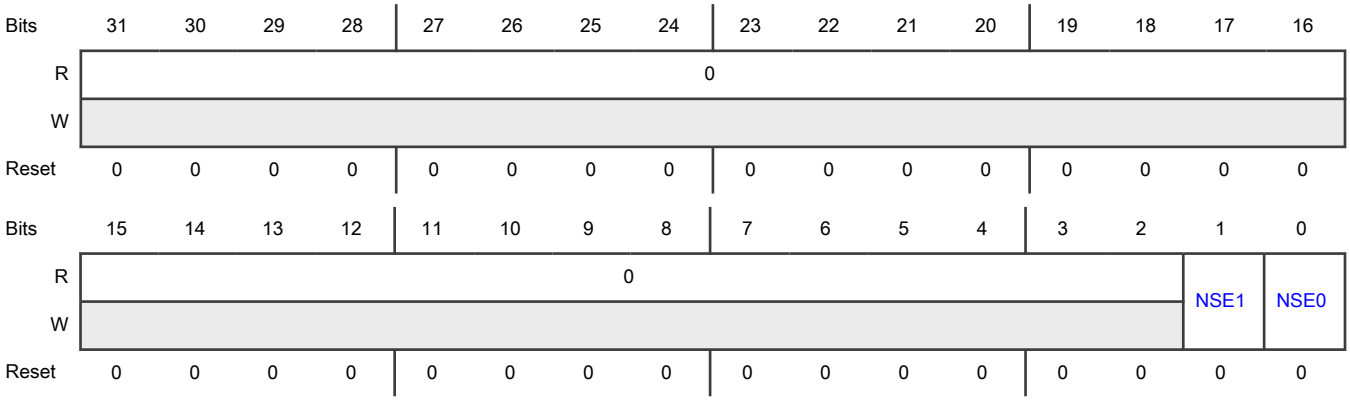
28.7.1.6 Interrupt Control Nonsecure (ICNS)

Configures secure and nonsecure access protection for each interrupt, or DMA request. You can update this register only in the Secure-Privilege state if it is not locked (LOCK[ICNS] = 0).

Offset

Register	Offset
ICNS	14h

Diagram



Fields

Field	Description
31-2 —	Reserved
1-0 NSEn	Nonsecure Enable Configures secure or nonsecure access protection for each interrupt, or DMA request. If this field is 0, the interrupt, or DMA request is configured for secure access. You can configure a pin to use the corresponding interrupt, or DMA request, or reconfigure a pin that is already configured to use the corresponding interrupt, or DMA request only in the Secure state. If this field is 1, the interrupt, or DMA request is configured for nonsecure access. You can configure a pin to use the corresponding interrupt, or DMA request, or reconfigure a pin that is already configured to use the corresponding interrupt, or DMA request only in the Nonsecure state. **NOTE** See the GPIO chip-specific information to determine which GPIO instances support interrupt, DMA request, or trigger capabilities. 0 - Secure access 1 - Nonsecure access

28.7.1.7 Pin Control Nonprivilege (PCNP)

Configures access protection on each pin either for privilege or for both privilege and nonprivilege accesses. You can update this register only in the Secure-Privilege state if it is not locked (LOCK[PCNP] = 0).

Offset

Register	Offset
PCNP	18h

Fields

Field	Description
31-0 NPEn	Nonprivilege Enable Configures privilege or nonprivilege access protection for each pin. If this field is 0, the pin is configured for privilege access. Write access to the corresponding pin's registers and fields is allowed only in the Privilege state. When you access the corresponding pin's registers and fields in the Nonprivilege state, all fields related to that pin in this GPIO are readable (with writes ignored). If this field is 1, the pin is configured for nonprivilege access; read or write access to the corresponding pin's registers is allowed in both Privilege and Nonprivilege states. 0 - Privilege access 1 - Nonprivilege access

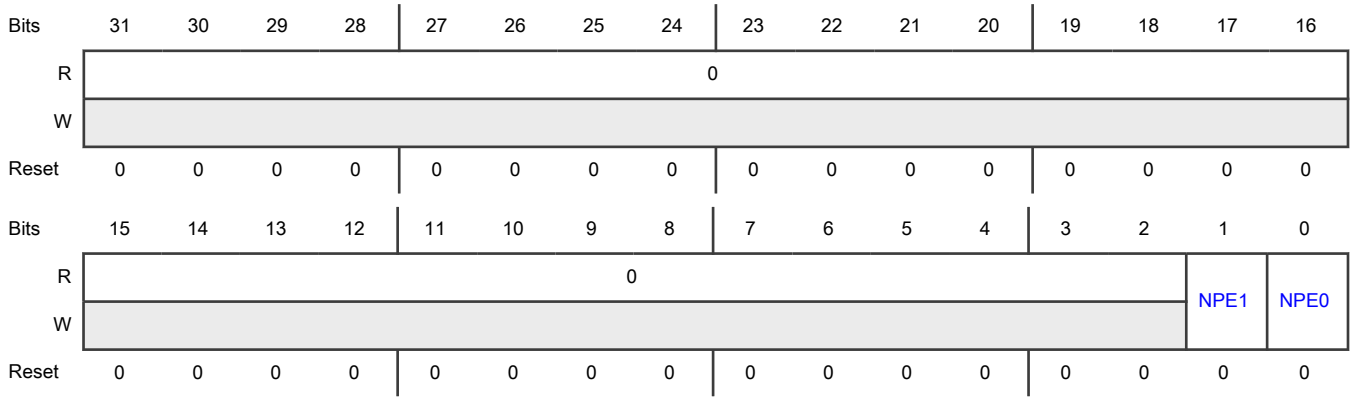
28.7.1.8 Interrupt Control Nonprivilege (ICNP)

Configures privilege and nonprivilege access protection for each interrupt, or DMA request. You can update this register only in the Secure-Privilege state if it is not locked (LOCK[ICNP] = 0).

Offset

Register	Offset
ICNP	1Ch

Diagram



Fields

Field	Description
31-2 —	Reserved
1-0 NPEn	Nonprivilege Enable Configures privilege or nonprivilege access protection for each interrupt, or DMA request. If this field is 0, the pin is configured for privilege access. You can configure a pin to use the corresponding interrupt, or DMA request, or reconfigure a pin that is already configured to use the corresponding interrupt, or DMA request only in the Privilege state. If this field is 1, the pin is configured for nonprivilege access. In either Privilege or Nonprivilege state, you can configure a pin to use the corresponding interrupt, or DMA request, or reconfigure a pin that is already configured to use the corresponding interrupt, or DMA request. **NOTE** See the GPIO chip-specific information to determine which GPIO instances support interrupt, DMA request, or trigger capabilities. 0 - Privilege access 1 - Nonprivilege access

28.7.1.9 Port Data Output (PDOR)

Configures the logic levels that are driven on each general-purpose output pin.

NOTE

Do not modify the pin configuration registers associated with pins that are not available in your selected package. By default, these unbonded pins are set to the Disable state for lowest power consumption.

Offset

Register	Offset
PDOR	40h

Fields

Field	Description
31-0 PDIn	Port Data Input Indicates the logic level of the pin that is configured for use by a digital function. If this field is 0, the pin logic level is logic 0 or is not configured or implemented for use by a digital function. If this field is 1, the pin logic level is logic 1. 0 - Logic 0 1 - Logic 1

28.7.1.14 Port Data Direction (PDDR)

Configures the individual port pins for input or output.

Offset

Register	Offset
PDDR	54h

Fields

Field	Description
31-0 PIDn	Port Input Disable Disables a pin for general-purpose input. If this field is 0, the pin is configured for general-purpose input, provided the pin is configured for a digital function. If this field is 1, the pin is disabled for general-purpose input. 0 - Configured for general-purpose input 1 - Disabled for general-purpose input

28.7.1.16 Pin Data (P0DR - P31DR)

Configures the data feature of a pin. Pins that are unimplemented or not configured for a digital function read zero.

NOTE

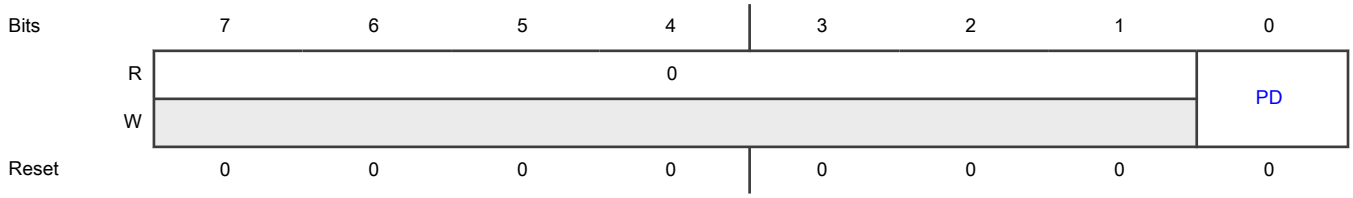
You must not modify Pin Data (P0DR - P31DR) associated with the pins that are not available in your selected package. These unbonded pins are, by default, set to the Disable state for lowest power consumption.

Offset

For a = 0 to 31:

Register	Offset
PaDR	60h + (a × 1h)

Diagram



Fields

Field	Description
7-1 —	Reserved
0 PD	Pin Data (I/O) Specifies the pin logic level. This field updates the corresponding field in Port Data Output (PDOR); reading this field returns the value in the corresponding field of Port Data Input (PDIR). If this field is 0, the pin logic level is logic zero or not configured for use by a digital function. If this field is 1, the pin logic level is logic one. 0 - Logic zero 1 - Logic one

28.7.1.17 Interrupt Control a (ICR0 - ICR31)

Configures interrupt features on each pin.

Offset

For a = 0 to 31:

Register	Offset
ICRa	80h + (a × 4h)

Fields

Field	Description
31-25 —	Reserved
24 ISF	Interrupt Status Flag Indicates whether the configured interrupt is detected. The pin interrupt configuration is valid in all digital pin muxing modes. The fields in Interrupt Status Flag (ISFR0 - ISFR1) have the same function. ISF can be cleared with either register field. If the pin is configured to generate a DMA request, then the corresponding flag is cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level-sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Not detected 1 - Detected

Chapter 29
Clock and Power Overview

29.1 Overview

This chip targets many applications with power requirements that include low power consumption, long battery life, always-on capability, instant-on capability, and doesn't require active cooling. To meet these requirements, the chip design focuses on reducing current consumption, while simultaneously enabling the maximum level of peak performance, and also a balanced level of sustained performance. The chip architecture uses a wide range of power-management techniques, used in combination, for system design flexibility.

This chapter describes these architecture details as a high-level clock and power management overview of the chip.

29.2 Components of Clock and Power Management

The centralized clock generation, power generation and distribution are implemented by the following blocks:

Table 139. Clock and Power Components

Name	Description
PLL	The chip supports Arm PLL, SYSTEM PLL, AUDIO PLL, DRAM PLL and VIDEO PLL.
Crystal OSC (XTALOSC)	The XTALOSC includes a 24 MHz oscillator. The 24MHz crystal oscillator is the primary clock source for all the PLLs, and clock generation for the CPU and high-speed interfaces as well as the low-speed clock source for CCM/SRC/GPC.
PLLs and PFDs	The PLLs and their associated PFDs generate the clocks with various frequencies required to feed the CCM clock generator that supplies the different functional blocks. See the PLL and PFD section in Clock Controller Module (CCM) for information on the PLL and PFD architecture, functional description and programming model.
Clock Control Module (CCM)	The CCM module provides control for clock generation, division, distribution, synchronization, and coarse-level gating. See Clock Controller Module (CCM) for information on the CCM architecture, functional description and programming model.
Low Power Clock Gating (LPCG)	The LPCG distributes the clocks to all blocks in the SoC and handles automated clock gating and block level software-controllable clock gating. See Clock Controller Module (CCM) for information on the LPCG architecture and functional description.
General Power Controller (GPC)	This module controls the power state of the SoC. The GPC handles the power gating under low power modes and also manages the power up / power down sequences. See the General Power Controller (GPC) chapter for information on the GPC architecture, functional description and programming model.
System Reset Controller (SRC)	This module generates the reset signals to all the modules in the SoC. The SRC will appropriately assert reset signals for power transitions, entry, and exit. See the System Reset Controller (SRC) chapter for information on the SRC architecture, functional description and programming model.

Table continues on the next page...

Table 139. Clock and Power Components (continued)

Name	Description
IP Controller (IPC)	The clock roots are delivered to each module through the IPC, which contains the clock gating logic for each clock. The control signals for the clock gating control in the CCM is the source for clock enable signals. Since some of the clocks need to be gated off during reset, the SRC also sends clock gate signals to the IPC.

Together, the modules listed above provide enhanced power-management features with the centralized control for the clock, reset, and power-management signals on the SoC.

29.3 Power Management

The power management design on the chip satisfies many use cases that depend on a key balance of performance and low-power consumption. In order to meet these criteria, the system power management needs to be dynamic and flexible. This is accomplished on a multi-core system by utilizing a power scheme that considers each CPU domain, and arbitrates the appropriate power mode configuration to satisfy the needs of both CPUs, and the system as a whole. The following are additional features supported by the power management architecture:

- Programmable power mode transition rules
- Independent operation mode for individual CPU cores
- Intelligent clock and power management for multi-core architecture
- Unified power management interface (UPI) for all on-chip resources, including clock, power, reset, and peripherals

NOTE

- When switchable MIXes, such as MLMIX/MEDIAMIX/DDRMIX/WKUPMIX, are powered off, corresponding opposite Subsystem sides in NICMIX can generate Slave Error (SLVERR).
- Always-on MIXes, such as HSIOMIX/AONMIX, cannot be powered off, so cannot generate SLVERR by subsystem.
- When clock gating is enabled, subsystem cannot generate SLVERR for both switchable/always-on MIX.

29.3.1 Power Modes

The chip supports the following power modes: -

- RUN: In this mode, the Cortex®-A55 CPU is active and running, some portion can be shut off for power saving.
- Low Power RUN: This mode is defined as a very low power run mode with all external power rails are on. In this mode, all the unnecessary power domain (MIX) can be off, except AONMIX and the internal modules required, such as OSC24M/PLL. Cortex-M33 CPU in AONMIX handles all the computing and data processing. Cortex-A55 is power down and DRAM can be in self-refresh/retention mode. All the modules in the AONMIX, such as SAI/CAN/LPUART, can be used directly. To use modules in other power domain, such as WAKEUPMIX, additional peripherals and related power by Cortex-M33 can be turned on as needed.
- IDLE: The CPU can automatically enter this mode when there is no thread running and all high-speed devices are not active. CPU can be put into power gated state but with L3 data retained, DRAM and bus clock are reduced, most of the internal logic is clock gated but still remain powered. Compared to RUN mode, all the external power from PMIC remains the same, and most of the modules remain their state, so the interrupt response in this mode is very small.
- SUSPEND: It is the most power saving mode where all the clocks are off and all the unnecessary power supplies are off. Cortex®-A55 CPU is fully power gated, all internal digital logic and analog circuit that can be power down will be off, all PHYs are power gated. VDD_SOC (and related digital supply) Voltage is reduced to the “Suspend Mode” voltage. The exit time from this mode will be much longer than IDLE but the power consumption will also be much lower.

- BBSM: This mode is also called RTC mode. In this mode, only the power for the BBSM domain remain on to keep RTC and BBSM logic alive.
- OFF: This mode has all power rails OFF. BBSM, IDLE and SUSPEND are referred as Low Power Mode for the chip, SUSPEND and IDLE are the two typical low power modes defined based on the use case of Linux kernel.

29.3.1.1 Low Power Modes

The state of each module in the IDLE mode, SUSPEND mode are defined in the table below.

	IDLE	SUSPEND[1]
CCM LPM Mode	WAIT	STOP
ARM A55 CPU0	OFF	OFF
ARM A55 CPU1	OFF	OFF
Shared L3 Cache	ON	OFF
DISPLAY	OFF	OFF
DRAM Controller & PHY	ON	OFF
ARM_PLL	OFF	OFF
DRAM_PLL	OFF	OFF
SYSTEM_PLL1	ON	OFF
XTAL	ON	OFF
RTC	ON	ON
External DRAM Device	Self-Refresh [2]	Self-Refresh [3]
DDR clock	266MHz	OFF
AXI clock	133MHz	OFF
Module clocks	ON as needed	OFF
GPIO wakeup	Yes	Yes
RTC wakeup	Yes	Yes
USB remote wakeup	Yes	No [4]
Other wakeup source	Yes	No
WAKEUPMIX	ON	OFF
MLMIX	ON	OFF
NICMIX	ON as needed	OFF

1. In suspend mode, the following modules act as async wakeup sources that can wakeup the chip. These are capable of generating an interrupt without needing to read/write SRAMs.

   GPIO

   UART

   FlexCAN

   ENET QoS

   ENET FEC

LPTMR: count from osc32k

USB(DP/DM Pins)

SDIO

2. Automatic enter self-refresh when there is no DRAM access
3. Put into self-refresh mode by SW before entering low power mode
4. Remote wakeup can be supported if the USB PHY power is on in this mode

29.3.1.2 CPU Power Modes

The Cortex®-A55 and Cortex®-M33 CPU platforms support the power states that are defined as CPU modes. The CPU Modes are detailed below.

Table 140. CPU Modes

CPU Mode	Description
RUN	The Cortex®-A55 CPU is active and running.
WAIT	The Cortex®-A55 and Cortex®-M33 CPU is in the WFI state. The CPU core and L1 cache are clock gated, TCM and peripheral can still be alive. The chip can wakeup from this mode from IRQ with a very short latency.
STOP	The Cortex®-M33 CPU is in the WFI state. The CPU core, L1 cache, TCM, and it's private peripherals are all clock gated. The chip requires a longer time to wakeup from this mode.
SUSPEND	The Cortex®-A55 and Cortex®-M33 CPU core and L1 cache are power gated (except the cache). The TCM is in retention mode. SUSPEND mode consumes the least amount of power, while keeping parts of the system alive. But the chip requires a much longer time to wakeup from this mode.
OFF	The Cortex-A55 core supports a full shutdown mode where power can be removed completely and no state is retained.

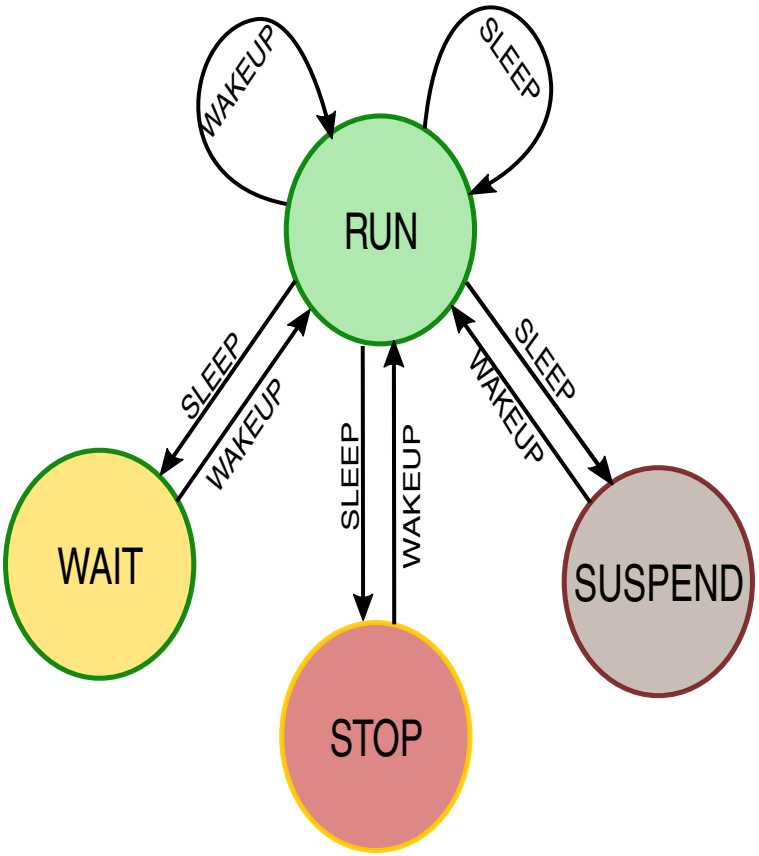

Figure 60. CPU Modes

29.3.2 Power Sequence

The power up and power down sequence in i.MX93 is optimized for use with an external PMIC.

Power Up:

1. NVCC_BBSM_1P8 supply must be turned on. The chip will assert PMIC_ON_REQ at this point in time.
2. VDD_SOC digital voltage supplies should be turned on.
3. VDD analog, PHY and PLL supplies should be turned on.
4. All remaining 1.8V supplies should be turned on including VDD_1P8 analog, PHY and PLL supplies and 1.8V NVCC IO supplies.
5. DDR IO supplies should be turned on.
6. All 3.3V supplies must be turned on, including 3.3V NVCC IO supplies and VDD_USB_3P3.

NOTE

3.3V supply step may be simultaneous with either the 1.8V or the DDR supplies if desired.

7. POR_B should be released. It should be asserted during the entire power up sequence.

Power Down:

- NVCC_BBSM_1P8 supply must be turned off after any other power supply.
- VDD_SOC must be turned off after the other (non-BBSM) power rails or at the same time as other (non-BBSM) rails. No sequence for other power rails during power down.

29.4 Clocks

29.4.1 Clock System Diagram

The overall clock system for the chip is shown in the diagram below.

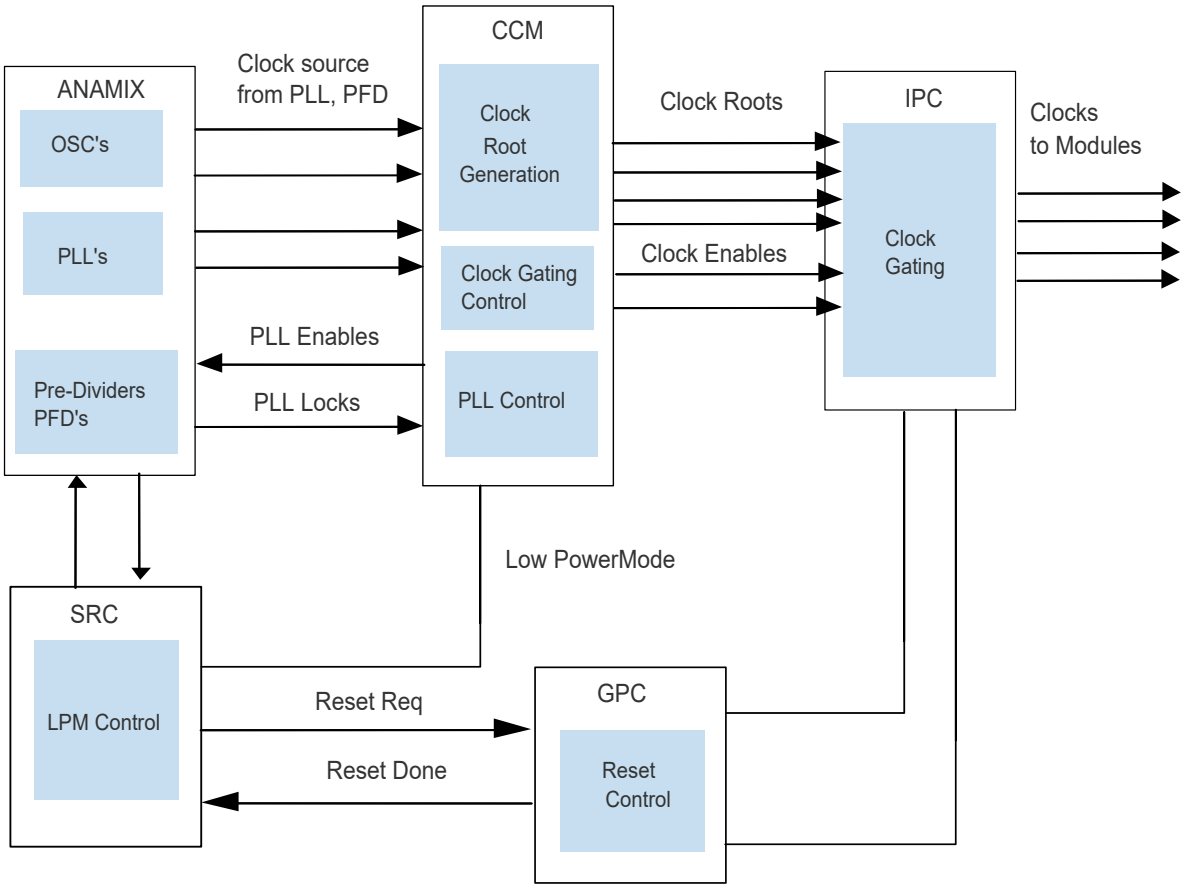

Figure 61. Clock System

The OSCs, PLLs, PFDs and Pre-Dividers generate the clock sources with fixed or variable frequency. The clock sources feed the clock root generation logic inside CCM, which generates numerous clock roots required for core, bus, and peripheral blocks. These clock roots are branched to each module through the LPCG logic, which contains the clock gating cells for each clock. Control signals for the LPCGs are in CCM (clock enable signal). Some of the clocks need to be gated off during reset, because of this, the SRC module will also send clock gate signals to the LPCG.

In low power mode, GPC will drive the low power mode state signal to CCM, then CCM will enable clock gating based on the configuration. At the same time, CCM may also deassert enable signals for PLLs and PFDs, so these modules can power off during low power modes. When the chip enters STOP mode, CCM may deassert the OSC enable signal to shut off the OSC, it may also assert the STOP mode signal to set OSC to low power mode.

The detailed functional description for each block will be described in the following sections.

29.4.2 Oscillators

This chip has two XTAL modules:

- 24MHz XTAL module for system clock
- 32KHz XTAL module for RTC

Each XTAL module includes:

- Crystal oscillator to generate reference clock;
- Digital control logics for the XTAL.

Each XTAL module supports the following mode through register configuration:

- Normal oscillator mode - XTAL generates stable square wave based on the crystal oscillator input.
- Bypass mode - external clock can be input through XTAL pad.

29.4.3 PLL and PFD

The PLLs are used in the chip to generate the high speed clocks required by the modules in SoC. A few PLLs are equipped with Phase Fractional Dividers (PFDs) in order to generate additional frequencies. The following PLLs are used in this chip:

Table 141. PLLs

PLL	Description	Spread Spectrum	Configurable
ARM_PLL	The ARM_PLL/INTEGER PLL is used to generate the clock for the Arm Cortex-A55 platform. It is a programmable integer-frequency multiplier PLL, capable of an output frequency over 1 GHz. This PLL is physically located near the high-speed Cortex-A55 processor.	-	Yes
SYS_PLL1	This is a fractional PLL fixed at a fixed VCO frequency of 4.0GHz. Attached to this integer PLL are 3 PFD (phase frequency detector) circuits, also referred to as DFS (digital frequency synthesis) circuits, which generate Fclkout = FVCO/(MFI+MFN/5)). The PLL PFDs also have a fixed /2 divisor output, so that /2 of each of the 3 clocks are also available for use by the CCM. These clock sources will be used for the majority of AXI/AHB buses in the chip.	Yes[1]	Yes
AUDIO_PLL	An AVPLL used to generate reference clocks, mainly for serial audio interfaces, and external audio codecs. This fractional multiplier PLL provides a low-jitter and high precision audio clock with standardized audio frequencies.	Yes	Yes
VIDEO_PLL	An AVPLL used to generate reference clocks, mainly for display and video interfaces. This fractional multiplier PLL provides a low-jitter and high-precision video clock at standardized video frequencies.	Yes	Yes

1. SYSTEM_PLL1 is also used to generate the 125MHz clocking for Ethernet RGMII. So spread spectrum on SYSTEM_PLL1 can only be enabled when Ethernet is not used.

NOTE

Please see the datasheet for all supported maximum PLL frequencies.

Each PLL can use one of the following clock sources as it's reference clock:

- Primary Option: 24 MHz clock from 24 MHz oscillator (XTAL).

The SYS_PLL, DRAM_PLL, AUDIO_PLL and VIDEO_PLL have the capability to spread spectrum the generated signal. They do not require exact/constant frequency, and can be changed as a part of dynamic frequency scaling procedure and/or can be spread-spectrum modulated.

The main output clocks for the PLLs (PLLx_CLK) are not configurable, but their PFDs are. Each PFD works independently by interpolating the VCO of the PLL to which it is connected. It effectively takes the PLL VCO frequency and produces 18/N x Fvco at it's output where N ranges from 12 to 35. PFD is a completely digital design with no analog components or feedback loops. The frequency switch time is much faster than a PLL because keeping the base PLL locked and changing the integer N only changes the logical combination of the interpolated outputs of the VCO. Note that the PFD not only enables faster frequency changes than a PLL, but also allows the configuration to be safely changed "on-the-fly" without going through the output clock disabling/enabling process.

The basic logical connections for the PLLs, PFDs and Dividers is shown in the diagram below:

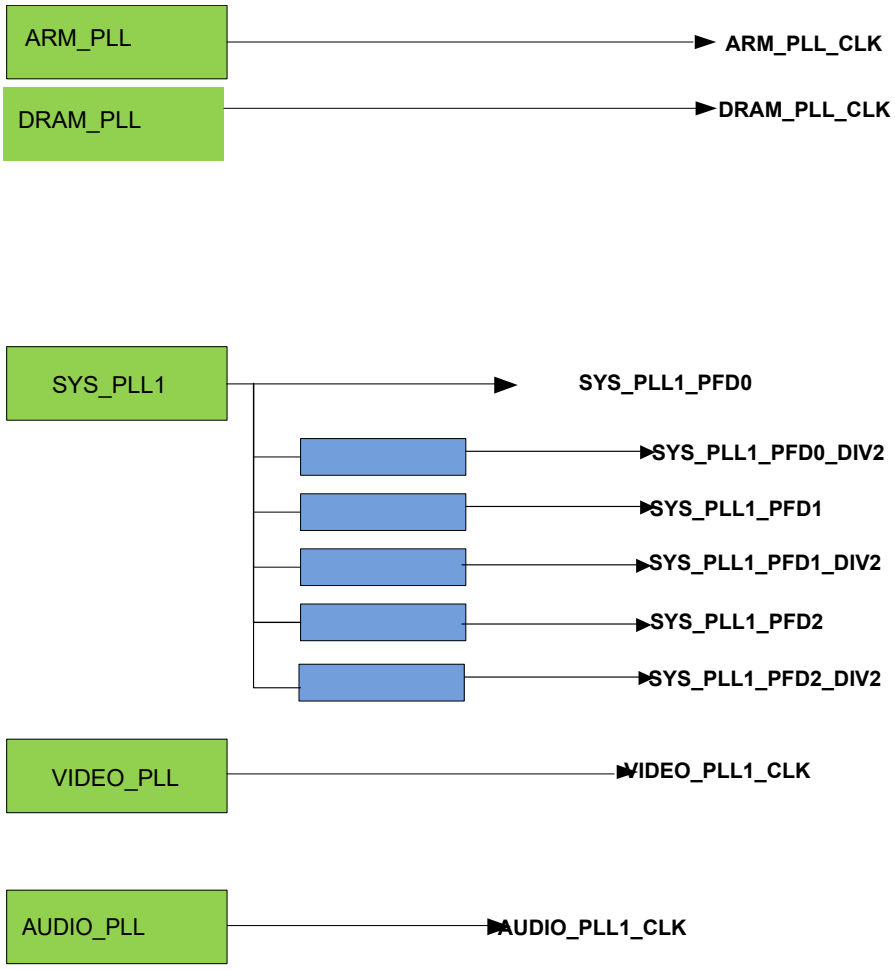

Figure 62. PLL and PFD

PLL configuration and control functions are accessible via configuration and status registers. The CCM block contains the detailed descriptions of the memory mapped registers, and control functions of the clock generation sub-module. Please see CCM for more information.

29.4.4 Clock Root Generation

Clock generation in the CCM creates clock roots for on-chip peripherals. Each clock root will have a dedicated clock slice. It takes the clock source from Oscillators, PLL/PFD or Pre-Dividers, and generate the clock root with required frequency.

The CCM can manage on-chip peripheral clocks by controlling the low power clock gating cells (LPCGs) before the clock roots enter the peripherals.

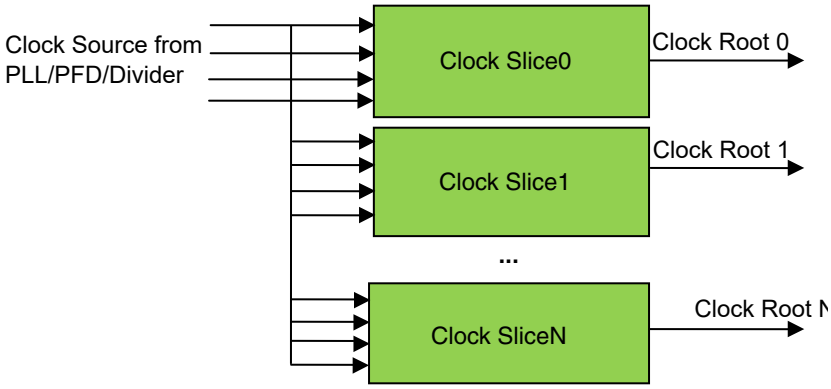

Figure 63. Clock Root Generation from Clock Slice

The LPCGs are implemented to control peripheral functions, and there could be several LPCGs for each functions in a peripheral.

For details on the programming model, please refer to CCM Memory Map/Register Definition.

29.4.5 Low Power Clock Gating (LPCG)

The clock roots generated inside CCM are distributed to the entire SoC through LPCG. The LPCG block receives the root clocks from CCM and splits them to clock branches for each functional block. The clock branches are individually gated clocks.

See the CCM chapter for more information about clock gating.

Chapter 30
Clock Controller Module (CCM)

30.1 Overview

The Clock Control Module (CCM) manages the on-chip module clocks. The oscillators, PLLs, and Phase Fractional Dividers (PFD) will generate clock sources with fixed or variable frequencies.

30.1.1 Block diagram

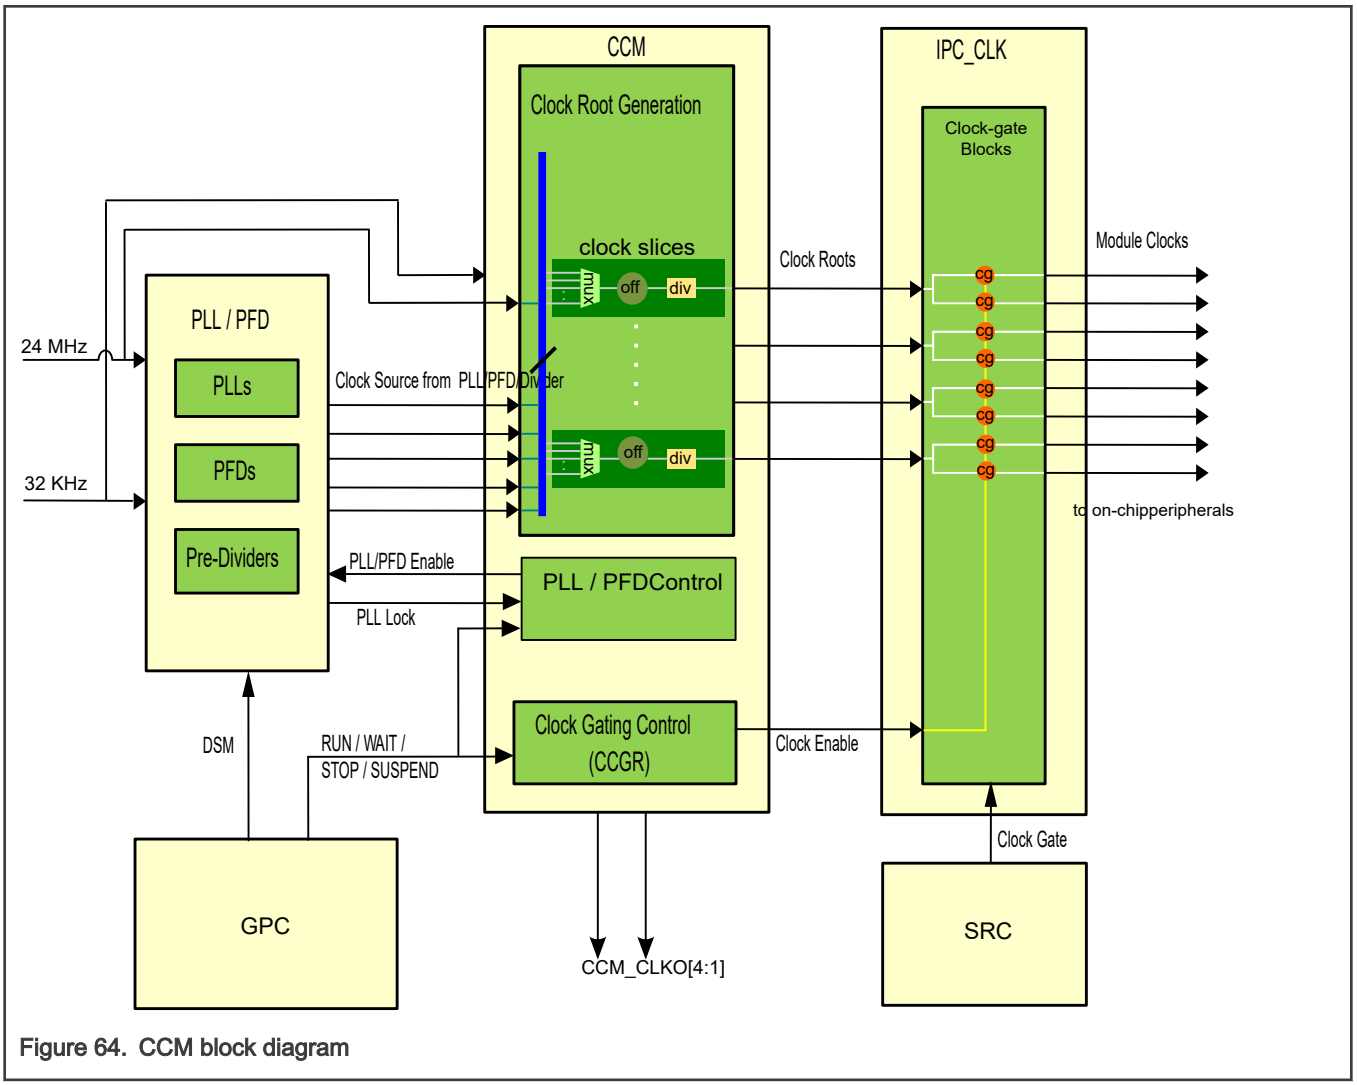

Figure 64. CCM block diagram

The clock root generation logic inside CCM will generate various clock roots required for core, bus, and peripheral blocks. These clock roots will be delivered to each module through IPC_CLK, which contains the clock gating logic for each clock.

The control signal for CCGRs in CCM will be the source for clock enable signals. Since some of the clocks need to be gated off during the reset, the System Reset Controller (SRC) will also send clock gate signals to the IPC_CLK.

In low power mode, the General Power Controller(GPC) will drive the low power mode state signal to CCM, and CCM will enable clock gating based on the configuration. At the same time, CCM may also de-assert enable signals for PLLs/PDFs, so these modules can be powered off during the low power mode.

30.1.2 Features

The CCM includes the following features:

- Clock Root
  - Up to 4 clock sources for each clock root
  - 8-bit divider support up to divide by 256 in each clock root
  - Each clock root can be shutdown by software
- Peripheral clock can be auto gated according to CPU work mode, software configurations, or system work mode
- PLLs and PFDs can be auto shutdown according to CPU work mode, software configurations, or system work mode
- Access Control
  - Two access control schemes: Trustzone, and Domain
  - Write access to each component can be protected independently
  - Independent setting for user, privileged, secure, non-secure
  - Domain mode access can be controlled by whitelist
  - Access control setting can be locked independently

30.2 System Clocks

The table found here shows the CCM output clocks' system-level connectivity.

NOTE

LPIT1 is clocked by AON bus and LPIT2 is clocked by WAKEUP bus. LPIT1 and LPIT2 have their trigger output 0 used as input by CAN1 and CAN2 respectively. Because of this, these LPIT timer instances are clocked by the bus clock - the same clock used to clock the respective CAN IP (bus_aon_clk_root and bus_wakeup_clk_root respectively) in order to ensure that these signals are timed synchronously between these modules.

Table 142. System Clocks Table

Module	Module Clock (instance.clock)	Clock Root Module	Low Power Clock Gating (LPCG)
ipsyncm_anamix	ipsyncm_anamix.ipg_master_clk	bus_aon_clk_root	LPCG7

30.3 Functional description

CCM is comprised of several functional blocks:

- Clock Root
- Clock Gate
- Clock Source
- General Purpose Registers (GPR)

These functions can be configured under various CCM modes. The first section will describe the ways to configure these functions under different CCM modes. And the other sections will describe these functions independently.

30.3.1 Configuration of Functions

CCM functional blocks support the following modes:

- Direct Configuration mode
- CPU Low Power mode
- Auto mode (only for clock sources)

The default CCM mode is Direct Configuration mode.

30.3.2 Clock Sources

Clock roots are generated from various clock sources, which can be either oscillators or PLLs. Clock source is implemented to control PLLs and oscillators, to be automatically turned OFF or ON on system low power actions.

The following table shows the clock sources for the CCM:

Table 143. Clock Sources

Control Channel	Clock Source	Description
OSCPLL0	OSC_24M_CLK	OSC 24MHz CLK

Table continues on the next page...

Table 143. Clock Sources (continued)

Control Channel	Clock Source	Description
OSCPLL1	ARM PLL	ARM PLL VCO (Not connected to the clock tree)
OSCPLL2	ARM PLL CLK	ARM PLL output clock
OSCPLL3	SYSTEM PLL	SYSTEM PLL VCO (Not connected to the clock tree)
OSCPLL4	SYSTEM PLL PFD0	SYSTEM PLL PFD0 (OSCPLL channel can reset SYSTEM PLL PFD. It handles DFS[ENABLE].)
OSCPLL5	SYSTEM PLL PFD0 CLK	SYSTEM PLL PFD0 clock (OSCPLL channel can gate off SYSTEM PLL PFD0 CLK. It handles DFS[CLKOUT_EN].)
OSCPLL6	SYSTEM PLL PFD0 DIV2 CLK	SYSTEM PLL PFD0 divided by 2 clock
OSCPLL7	SYSTEM PLL PFD1	SYSTEM PLL PFD1 (OSCPLL channel can reset SYSTEM PLL PFD. It handles DFS[ENABLE].)
OSCPLL8	SYSTEM PLL PFD1 CLK	SYSTEM PLL PFD1 clock (OSCPLL channel can gate off SYSTEM PLL PFD0 CLK. It handles DFS[CLKOUT_EN].)
OSCPLL9	SYSTEM PLL PFD1 DIV2 CLK	SYSTEM PLL PFD1 divided by 2 clock
OSCPLL10	SYSTEM PLL PFD2	SYSTEM PLL PFD2 (OSCPLL channel can reset SYSTEM PLL PFD. It handles DFS[ENABLE].)
OSCPLL11	SYSTEM PLL PFD2 CLK	SYSTEM PLL PFD2 clock (OSCPLL channel can gate off SYSTEM PLL PFD0 CLK. It handles DFS[CLKOUT_EN].)
OSCPLL12	SYSTEM PLL PFD2 DIV2 CLK	SYSTEM PLL PFD2 divided by 2 clock
OSCPLL13	AUDIO PLL	AUDIO PLL VCO (Not connected to the clock tree)
OSCPLL14	AUDIO PLL CLK	AUDIO PLL output clock
OSCPLL15	DRAM PLL	DRAM PLL VCO (Not connected to the clock tree)
OSCPLL16	DRAM PLL CLK	DRAM PLL output clock
OSCPLL17	VIDEO PLL	VIDEO PLL VCO (Not connected to the clock tree)
OSCPLL18	VIDEO PLL CLK	VIDEO PLL output clock

NOTE

The clock source calculates whether the clock is required for each CPU domain. If clock source is not needed for any domain, clock will be shutdown.

Clock Source blocks have 3 work mode: Direct Control mode, CPULPM mode and Auto mode. Direct Control mode is the default mode. After reset, all Clock Source blocks work in Direct Control mode.

All registers are readable for any domain in any mode, but write access is restricted for protection. Trustzone unauthenticated access will be ignored.

The OSCPLLn_AUTHEN and OSCPLLn_DIRECT registers can be changed in any mode, while the write access should be from the domain granted by OSCPLLn_AUTHEN[WHITE_LIST] and Trustzone authenticated. The default value of OSCPLLn_AUTHEN[WHITE_LIST] is 0xFFFF, which means all 16 domains are granted.

The OSCPLLn_LPM_CUR registers can only be written in CPULPM mode, otherwise the write access will be ignored. And the write access in CPULPM mode should also comply with the Trustzone access control.

In Direct Control mode, the ON/OFF of clock source is determined by OSCPLLn_DIRECT[ON] directly. The default state of OSCPLL is ON.

In CPULPM mode, the ON/OFF of clock source is dependent on the settings in OSCPLLn_LPMs and the current mode every domain is in. There are 3-bit clock dependent level settings for each domain respectively. The bigger the 3-bit value is, the stronger the clock is dependent. Valid values are as follows:

- 0: this clock is not needed in any mode
- 1: this clock is needed in RUN mode, but not needed in WAIT, STOP, SESPEND mode
- 2: this clock is needed in RUN and WAIT mode, but not needed in STOP, SUSPEND mode
- 3: this clock is needed in RUN, WAIT and STOP mode, but not needed in SUSPEND mode
- 4: this clock is needed in RUN, WAIT, STOP and SUSPEND mode

NOTE

The mode above means the mode of domain (CPU platform) instead of CCM mode. There are 4 CPU mode: RUN, WAIT, STOP and SUSPEND. If the CPU is in SUSPEND mode, all clocks are treated as NOT needed.

For PLLs which are used as input to CCM for use as clock roots by the SoC (this in general includes all PLLs in ANAMIX but not SoC-specific PLLs elsewhere in the SoC which are only used by one MIX or PHY), an AUTO_CTRL feature is supported in the CCM. When AUTO_CTRL is enabled, if a PLL is not selected by any CCM clock root, then that PLL will be disabled automatically. Similarly, if a PLL has multiple PFD outputs and a given PFD output is not selected by any CCM clock root, then that PFD output will be disabled automatically.

NOTE

To enable OSCPLL AUTO mode , you need to

1. Enable HW control in OSCPLL by setting CTRL[HW_CTRL_SEL]
2. Enable AUTOMODE in the OSCPLL CCM by setting OSCPLLa_AUTHEN[AUTO_CTRL] to 0x1
3. Set OSCPLLa_DIRECT[ON] to 0x0

30.3.3 Clock Root

CCM clock root generation contains multiple clock root channels. All clock roots are asynchronous each other, even all the clock root setting are the same.

Each clock channel contains an 4-to-1 MUX, and a 8-bit divider. The clock MUX selects 1 clock out of 4 clock inputs. The 8-bit divider can divide selected clock by up to 256. The clock output of the clock channel can be gated off.

The clock root channel setting can be changed from any value to any value, and at any time. It is also possible to change the clock setting when the clock root channel is gating off. If more than one setting is changed at the same time, internal logic will use a

procedure to change the setting. The procedure will make sure the clock output is not faster than the current clock root setting or target clock root setting. If the application does care about the clock during transition, software will need to change the setting one field at a time. This typically happens when a clock must be faster than the given frequency. In this case, the application needs to change each field one at a time and wait for the field to take effect before changing the next field.

Although a clock root channel is designed to be able to switch clocks regardless of clock input status. When the current selected clock input is off, the application needs to avoid changing the clock MUX after the clock input is turned on. This will lead to unstable behavior for the clock root and loading peripherals. To avoid this scenario, the application can either switch the clock MUX before turning on the clock input, or wait until the clock input is stable before changing the MUX option.

The division fractor of the divider is equal to CLOCK_ROOTn_CONTROL[DIV]+1.

All registers are readable for any domain in any mode, but write access are restricted. Unauthenticated write access will be ignored. Only the access from the domains on the whitelist can change the value of CLOCK_ROOTn_CONTROL register, after passing trustzone authentication.

NOTE

LPIT1, TPM1 is clocked by AON bus and LPIT2, TPM3 is clocked by WAKEUP bus. LPIT1, TPM1 and LPIT2, TPM3 have their trigger output 0 used as input by CAN1 and CAN2 respectively. Because of this, these instances are clocked by the bus clock - the same clock used to clock the respective CAN module (bus_aon_clk_root and bus_wakeup_clk_root respectively) in order to ensure that these signals are timed synchronously between these modules.

30.3.4 Clock Gate

Before a clock root goes to on-chip peripherals, the clock roots go through the IPC_CLK. These IPC_CLK are implemented to perform automatic clock gating when a domain enters and leaves low-power states. The IPC_CLKs are mapped to peripherals

so software can be simplified. IPC_CLKs are also implemented to control peripheral functions, and different IPC_CLKs could interface different clocks of the peripheral.

Clock gates have 2 work modes: Direct Control mode and CPULPM mode. Direct Control mode is the implicit mode. After reset, all clock gates work in Direct Control mode.

All registers are readable for any domain in any mode, but write access is restricted for protection. Trustzone unauthenticated access will be ignored.

The LPCGn_AUTHEN and LPCGn_DIRECT registers can be changed in any mode, while the write access should be from the domain granted by LPCGn_AUTHEN[WHITE_LIST] and Trustzone authenticated. The default value of LPCGn_AUTHEN[WHITE_LIST] is 0xFFFF, which means all 16 domains are granted.

The LPCGn_LPM_CUR registers can only be written in CPULPM mode, otherwise the write access will be ignored. And the write access in CPULPM mode should also comply with the Trustzone access control.

In Direct Control mode, the ON/OFF of LPCG is determined by LPCGn_DIRECT[ON] directly. The default state of LPCG is ON.

In CPULPM mode, the ON/OFF of LPCG is dependent on the settings in LPCGn_LPMs and the current mode every domain is in. There are 3-bit clock dependent level settings for each domain respectively. The bigger the 3-bit value is, the stronger the clock is dependent. Valid values are as follows:

- 0: this clock is not needed in any mode
- 1: this clock is needed in RUN mode, but not needed in WAIT, STOP, SUSPEND mode
- 2: this clock is needed in RUN and WAIT mode, but not needed in STOP, SUSPEND mode
- 3: this clock is needed in RUN, WAIT, STOP, SUSPEND mode

NOTE

The mode above means the mode of domain (CPU platform) instead of CCM mode. There are 4 CPU mode: RUN, WAIT, STOP and SUSPEND. If the CPU is in SUSPEND mode, all clocks are treated as NOT needed.

In CPULPM mode, LPCG will calculate whether the clock is required by any CPU domain. If clock is not needed for any domain, the clock will be shutdown.

NOTE

LPCG3 gates ele_clk_root for EdgeLock Secure Enclave.

NOTE

The tstmr1_clk_root, tstmr2_clk_root, mqs1_clk_root, mqs2_clk_root are not used.

30.3.5 General Purpose Registers (GPR)

The general purpose registers provide miscellaneous controls and data saving functions. The GPRs are divided in two regions - shared and private region.

In shared region, all CPU domains access the same registers. If any CPU updates the value in the shared region, all the other CPU domains can read out the new value. The registers have an access control bit field to protect it from being changed unexpectedly.

In private region, each CPU domain has its own register. A CPU domain can only access registers belonging to itself. Since all the registers share the same address, a CPU domain will not have access to registers belonging to another CPU domain.

Shared registers can be read by any domain at any time, while write access to shared registers must be from domains granted by GPR_SHAREDn_AUTHEN[WHITE_LIST] and Trustzone authenticated. Every shared register has independent whitelist.

Private registers can be and only can be read or written by corresponding domain with Trustzone authentication.

GPR_SHAREDn_AUTHEN and GPR_PRIVATEn_AUTHEN registers can be read by any domain at any time, but the write access must be from domains granted by respective whitelist and Trustzone authenticated.

Type	GPR	Position	Width	Description
Shared	0	0	2	EXT_CLK_SEL. Selecting ext_clk from 4 external clocks: • 00b - Select ext1_clk. • 01b - Select ext2_clk. • 10b - Select ext3_clk. • 11b - Select ext4_clk. Changing the value of this field when ext_clk is used is not allowed, otherwise ext_clk will be gated off. **NOTE** Only EXT_CLK1 exists.
Shared	1	32	1	arm_pll_sel.
Shared	2	64	1	dram_pll_sel.

30.4 Reset

The reset of CCM will be released along with system early reset and clocks are provided during system reset. For each power domain, early reset of the power domain in which that clock gate resides, will be fed for correct power up and reset flow.

30.5 CCM Memory Map and Register definition

30.5.1 CCM register descriptions

30.5.1.2 Clock Root Control Register (CLOCK_ROOT0_CONTROL - CLOCK_ROOT94_CONTROL)

This register controls clock root generation, including enable, MUX selection and division factor.

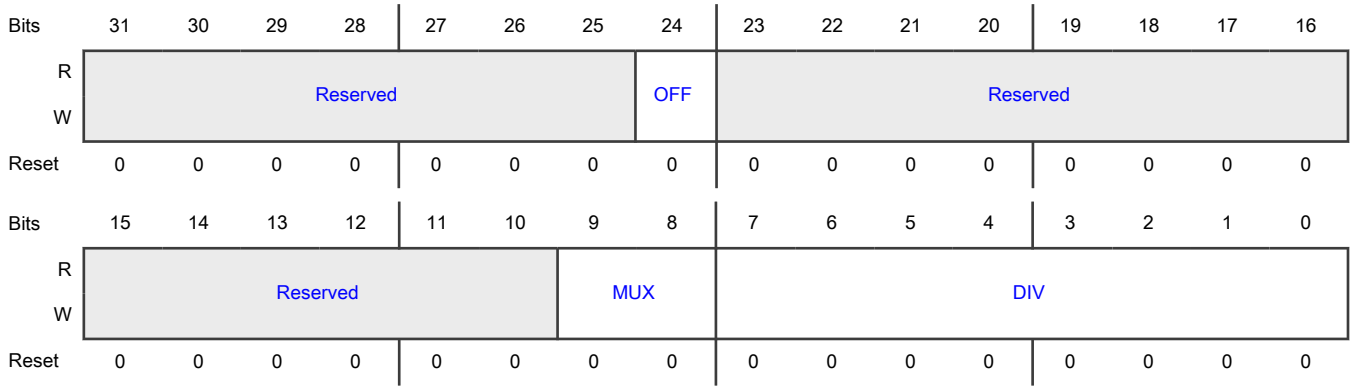
Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

For a = 0 to 94:

Register	Offset	Description
CLOCK_ROOTa_CONTROL	0h + (a × 80h)	Clock Root Control Register
CLOCK_ROOTa_CONTROL_SET	4h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_ROOTa_CONTROL is 1
CLOCK_ROOTa_CONTROL_CLR	8h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_ROOTa_CONTROL is 0
CLOCK_ROOTa_CONTROL_TOG	Ch + (a × 80h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in CLOCK_ROOTa_CONTROL

Diagram



Fields

Field	Description
31-25 —	Reserved
24 OFF	Shutdown clock root. Turn off the generated clock root or not. 0 - Clock is running. 1 - Turn off clock.
23-10 —	Reserved
9-8 MUX	Clock multiplexer. Select clock from 4 clock sources to generate the clock root. 00 - Select clock source 0 01 - Select clock source 1 10 - Select clock source 2 11 - Select clock source 3
7-0 DIV	Clock division fraction. The period of generated clock root is DIV + 1 times longer than selected clock source.

30.5.1.3 Clock root working status (CLOCK_ROOT0_STATUS0 - CLOCK_ROOT94_STATUS0)

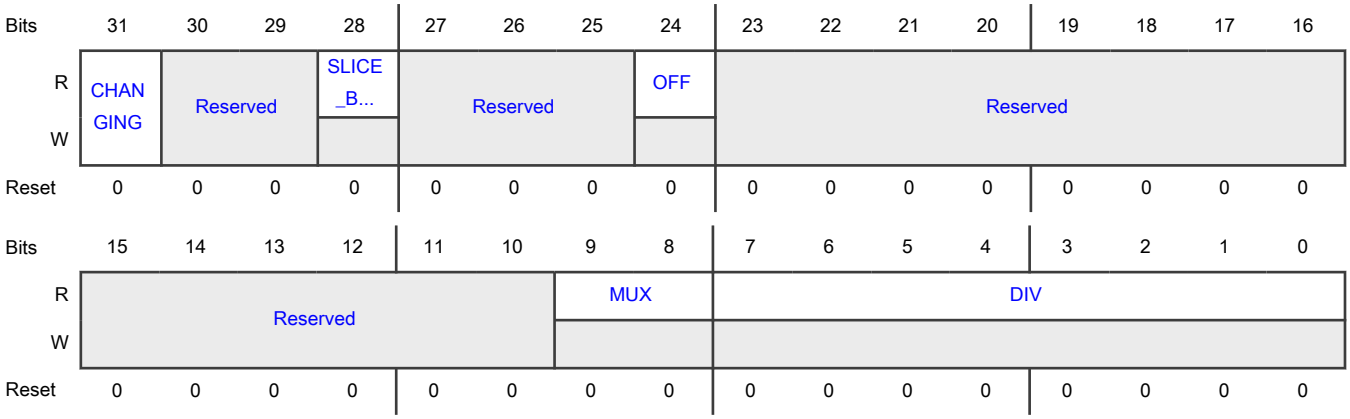
This register shows current clock root running status.

Offset

For a = 0 to 94:

Register	Offset
CLOCK_ROOTa_STATUS0	20h + (a × 80h)

Diagram



Fields

Field	Description
31 CHANGING	Internal updating in clock root This bit indicates the update status of internal clock root logic. 0 - Clock Status is not updating currently 1 - Clock generation logic is updating currently
30-29 —	Reserved
28 SLICE_BUSY	Indication for clock generation logic is applying new setting. 0 - Clock generation logic is not busy. 1 - Clock generation logic is applying new setting.
27-25 —	Reserved
24 OFF	Current clock root OFF setting Current running state of OFF field for clock root. 0 - Clock is running. 1 - Turn off clock.
23-10 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
9-8 MUX	Current clock root MUX setting Current running state of MUX field for clock root.
7-0 DIV	Current clock root DIV setting Current running state of DIV field for clock root. The period of generated clock root is DIV + 1 times longer than selected clock source.

30.5.1.4 Clock root access control (CLOCK_ROOT0_AUTHEN - CLOCK_ROOT94_AUTHEN)

This register controls the access to this Clock Root slice. The access control includes 2 parts: TrustZone control and domain based granting.

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

For a = 0 to 94:

Register	Offset	Description
CLOCK_ROOTa_AUTHEN	30h + (a × 80h)	Clock root access control
CLOCK_ROOTa_AUTHEN_SET	34h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_ROOTa_AUTHEN is 1
CLOCK_ROOTa_AUTHEN_CLR	38h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_ROOTa_AUTHEN is 0
CLOCK_ROOTa_AUTHEN_TOG	3Ch + (a × 80h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in CLOCK_ROOTa_AUTHEN

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	WHITE_LIST															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LOCK_LI...	Reserved			LOCK_TZ	Reserved	TZ_NS	TZ_USER	Reserved							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-16 WHITE_LIST	Whitelist settings Each master(Core or non-Core) can be assigned to any domains among 0-15 through TRDC and through GPC domain assignment register. Once its domains are assigned in TRDC, then its accesses will have its unique domain ID. Each bit in this field represent for one domain. Bit 16-31 represent domains 0-15 respectively. Only the TRDC domains whose corresponding bits are 1 can write to this register. Write violation will fail without any exception or information. Read violation can still get read data. In LPM mode, only the GPC domains whose corresponding bits are 1 can trigger the powering down of the given clock root.
15 LOCK_LIST	Lock white list This bit locks whitelist of this Clock Root. When this bit is set, CLOCK_ROOTn_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - Whitelist is not locked. 1 - Whitelist is locked.
14-12 —	Reserved
11 LOCK_TZ	Lock TrustZone settings This bit locks TrustZone settings. When this bit is set, CLOCK_ROOTn_AUTHEN[TZ_USER] and CLOCK_ROOTn_AUTHEN[TZ_NS] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - TrustZone setting is not locked. 1 - TrustZone setting is locked.
10 —	Reserved
9 TZ_NS	Non-secure access permission Whether the registers of this Clock Root can be changed when CPU is in non-secure mode. The default value is 0, that means only the access from CPU in secure mode can change the registers of this Clock Root. 0 - Cannot be changed in Non-secure mode. 1 - Can be changed in Non-secure mode.
8 TZ_USER	User access permission Whether the registers of this Clock Root can be changed when CPU is in user mode. The default value is 0, that means only the access from CPU in supervisor mode can change the registers of this Clock Root. 0 - Clock Root settings cannot be changed in user mode. 1 - Clock Root settings can be changed in user mode.
7-0	Reserved

30.5.1.5 General Purpose Register (GPR_SHARED0)

These registers are shared general purpose registers.

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED0	4800h	General Purpose Register
GPR_SHARED0_SET	4804h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED0 is 1
GPR_SHARED0_CLR	4808h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED0 is 0
GPR_SHARED0_TOG	480Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED0

30.5.1.6 GPR access control (GPR_SHARED0_AUTHEN)

This register manages GPR access control. The access control includes 2 parts: TrustZone control and domain based granting.

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED0_AUTHEN	4810h	GPR access control
GPR_SHARED0_AUTHEN_SET	4814h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED0_AUTHEN is 1
GPR_SHARED0_AUTHEN_CLR	4818h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED0_AUTHEN is 0
GPR_SHARED0_AUTHEN_TOG	481Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED0_AUTHEN

Fields

Field	Description
31-16 WHITE_LIST	Whitelist settings Each master(Core or non-Core) can be assigned to any domains among 0-15 through TRDC and through GPC domain assignment register. Once its domains are assigned in TRDC, then its accesses will have its unique domain ID. Each bit in this field represent for one domain. Bit 16-31 represent domains 0-15 respectively. Only the TRDC domains whose corresponding bits are 1 can write to this register. Write violation will fail without any exception or information. Read violation can still get read data. In LPM mode, only the GPC domains whose corresponding bits are 1 can trigger the powering down of the shared GPR.
15 LOCK_LIST	Lock white list This bit lock whitelist. When this bit is set, GPR_SHAREDn_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - Whitelist is not locked. 1 - Whitelist is locked.
14-12	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
11 LOCK_TZ	Lock TrustZone settings This bit lock TrustZone settings. When this bit is set, GPR_SHAREDn_AUTHEN[TZ_USER] and GPR_SHAREDn_AUTHEN[TZ_NS] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - TrustZone settings is not locked. 1 - TrustZone settings is locked.
10 —	Reserved
9 TZ_NS	Non-secure access permission Whether the registers of this shared GPR can be changed when CPU is in non-secure mode. The default value is 0, that means only the access from CPU in secure mode can change the registers of this shared GPR. 0 - Cannot be changed in Non-secure mode. 1 - Can be changed in Non-secure mode.
8 TZ_USER	User access permission Whether the registers of this shared GPR can be changed when CPU is in user mode. The default value is 0, that means only the access from CPU in supervisor mode can change the registers of this shared GPR. 0 - Registers of shared GPR slice cannot be changed in user mode. 1 - Registers of shared GPR slice can be changed in user mode.
7-0 —	Reserved

30.5.1.7 General Purpose Register (GPR_SHARED1)

These registers are shared general purpose registers.

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED1	4820h	General Purpose Register
GPR_SHARED1_SET	4824h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED1 is 1

Table continues on the next page...

Table continued from the previous page...

Register	Offset	Description
GPR_SHARED1_CLR	4828h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED1 is 0
GPR_SHARED1_TOG	482Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED1

Fields

Field	Description
31-16 WHITE_LIST	Whitelist settings Each master(Core or non-Core) can be assigned to any domains among 0-15 through TRDC and through GPC domain assignment register. Once its domains are assigned in TRDC, then its accesses will have its unique domain ID. Each bit in this field represent for one domain. Bit 16-31 represent domains 0-15 respectively. Only the TRDC domains whose corresponding bits are 1 can write to this register. Write violation will fail without any exception or information. Read violation can still get read data. In LPM mode, only the GPC domains whose corresponding bits are 1 can trigger the powering down of the shared GPR.
15 LOCK_LIST	Lock white list This bit lock whitelist. When this bit is set, GPR_SHAREDn_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - Whitelist is not locked. 1 - Whitelist is locked.
14-12 —	Reserved
11	Lock TrustZone settings

Table continues on the next page...

Table continued from the previous page...

Field	Description
LOCK_TZ	This bit lock TrustZone settings. When this bit is set, GPR_SHAREDn_AUTHEN[TZ_USER] and GPR_SHAREDn_AUTHEN[TZ_NS] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - TrustZone settings is not locked. 1 - TrustZone settings is locked.
10 —	Reserved
9 TZ_NS	Non-secure access permission Whether the registers of this shared GPR can be changed when CPU is in non-secure mode. The default value is 0, that means only the access from CPU in secure mode can change the registers of this shared GPR. 0 - Cannot be changed in Non-secure mode. 1 - Can be changed in Non-secure mode.
8 TZ_USER	User access permission Whether the registers of this shared GPR can be changed when CPU is in user mode. The default value is 0, that means only the access from CPU in supervisor mode can change the registers of this shared GPR. 0 - Registers of shared GPR slice cannot be changed in user mode. 1 - Registers of shared GPR slice can be changed in user mode.
7-0 —	Reserved

30.5.1.9 General Purpose Register (GPR_SHARED2)

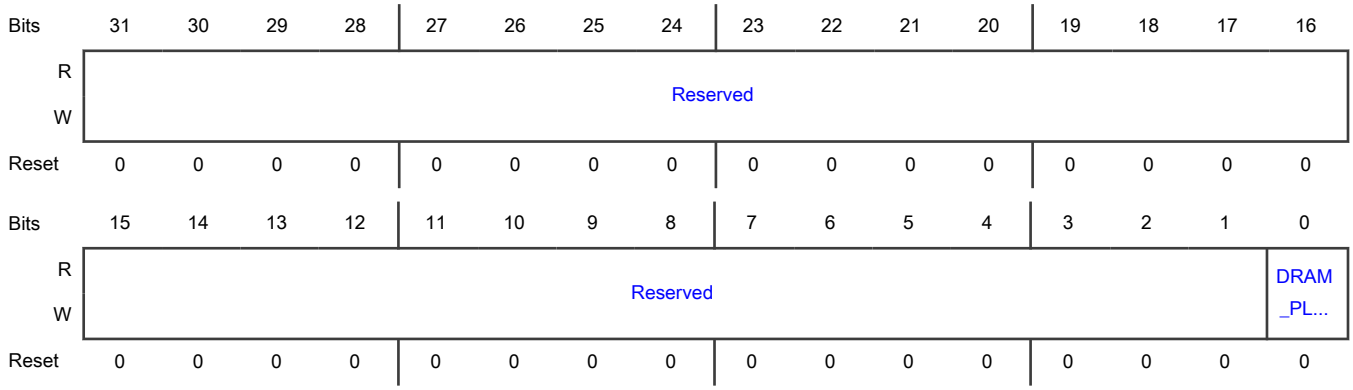
These registers are shared general purpose registers.

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED2	4840h	General Purpose Register
GPR_SHARED2_SET	4844h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED2 is 1
GPR_SHARED2_CLR	4848h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED2 is 0
GPR_SHARED2_TOG	484Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED2

Diagram



Fields

Field	Description
31-1 —	Reserved
0 DRAM_PLL_BYPASS	Clock select signal between ccm clock root and DRAM PLL clock This signal goes to ddrmix, used as clock select signal for DDR PHY. 0 - The clock output of DRAM PLL is selected. 1 - Dram_alt_clk_root is selected.

30.5.1.10 GPR access control (GPR_SHARED2_AUTHEN)

This register manages GPR access control. The access control includes 2 parts: TrustZone control and domain based granting.

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED2_AUTHEN	4850h	GPR access control
GPR_SHARED2_AUTHEN_SET	4854h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED2_AUTHEN is 1
GPR_SHARED2_AUTHEN_CLR	4858h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED2_AUTHEN is 0
GPR_SHARED2_AUTHEN_TOG	485Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED2_AUTHEN

Fields

Field	Description
31-16 WHITE_LIST	Whitelist settings Each master(Core or non-Core) can be assigned to any domains among 0-15 through TRDC and through GPC domain assignment register. Once its domains are assigned in TRDC, then its accesses will have its unique domain ID. Each bit in this field represent for one domain. Bit 16-31 represent domains 0-15 respectively. Only the TRDC domains whose corresponding bits are 1 can write to this register. Write violation will fail without any exception or information. Read violation can still get read data. In LPM mode, only the GPC domains whose corresponding bits are 1 can trigger the powering down of the shared GPR.
15 LOCK_LIST	Lock white list This bit lock whitelist. When this bit is set, GPR_SHAREDn_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - Whitelist is not locked. 1 - Whitelist is locked.
14-12 —	Reserved
11 LOCK_TZ	Lock TrustZone settings This bit lock TrustZone settings. When this bit is set, GPR_SHAREDn_AUTHEN[TZ_USER] and GPR_SHAREDn_AUTHEN[TZ_NS] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - TrustZone settings is not locked. 1 - TrustZone settings is locked.
10 —	Reserved
9 TZ_NS	Non-secure access permission

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Whether the registers of this shared GPR can be changed when CPU is in non-secure mode. The default value is 0, that means only the access from CPU in secure mode can change the registers of this shared GPR. 0 - Cannot be changed in Non-secure mode. 1 - Can be changed in Non-secure mode.
8 TZ_USER	User access permission Whether the registers of this shared GPR can be changed when CPU is in user mode. The default value is 0, that means only the access from CPU in supervisor mode can change the registers of this shared GPR. 0 - Registers of shared GPR slice cannot be changed in user mode. 1 - Registers of shared GPR slice can be changed in user mode.
7-0 —	Reserved

30.5.1.11 General Purpose Register (GPR_SHARED3 - GPR_SHARED7)

These registers are shared general purpose registers.

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

For a = 3 to 7:

Register	Offset	Description
GPR_SHAREDa	4800h + (a × 20h)	General Purpose Register
GPR_SHAREDa_SET	4804h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHAREDa is 1
GPR_SHAREDa_CLR	4808h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHAREDa is 0
GPR_SHAREDa_TOG	480Ch + (a × 20h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHAREDa

Field	Description
	Whether the registers of this shared GPR can be changed when CPU is in non-secure mode. The default value is 0, that means only the access from CPU in secure mode can change the registers of this shared GPR. 0 - Cannot be changed in Non-secure mode. 1 - Can be changed in Non-secure mode.
8 TZ_USER	User access permission Whether the registers of this shared GPR can be changed when CPU is in user mode. The default value is 0, that means only the access from CPU in supervisor mode can change the registers of this shared GPR. 0 - Registers of shared GPR slice cannot be changed in user mode. 1 - Registers of shared GPR slice can be changed in user mode.
7-0 —	Reserved

30.5.1.13 General puspose register (GPR_PRIVATE0 - GPR_PRIVATE7)

These registers is general purpose register.

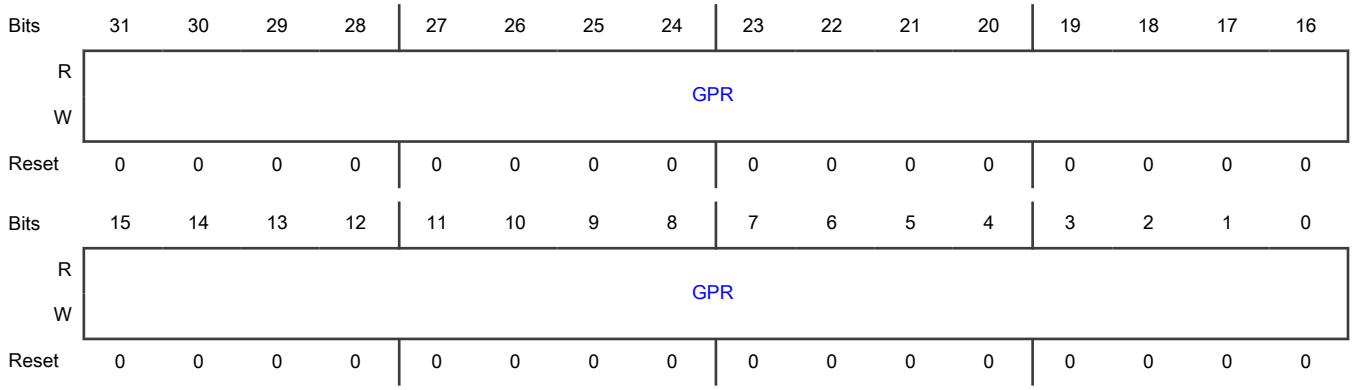
Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

For a = 0 to 7:

Register	Offset	Description
GPR_PRIVATEa	4C00h + (a × 20h)	General puspose register
GPR_PRIVATEa_SET	4C04h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_PRIVATEa is 1
GPR_PRIVATEa_CLR	4C08h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_PRIVATEa is 0
GPR_PRIVATEa_TOG	4C0Ch + (a × 20h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_PRIVATEa

Diagram



Fields

Field	Description
31-0 GPR	GP register General purpose register. This register has dedicated bits for each domain.

30.5.1.14 GPR access control (GPR_PRIVATE0_AUTHEN - GPR_PRIVATE7_AUTHEN)

This register controls the access to this private GPR slice. The access control includes 2 parts: TrustZone control and domain based granting.

NOTE

The domain based granting only influence the access to GPR_PRIVATEn_AUTHEN.

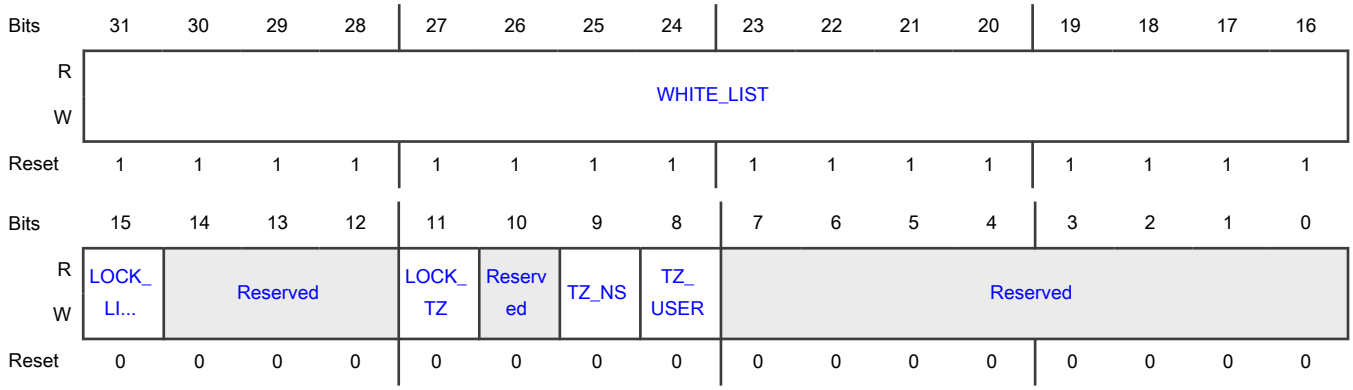
Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

For a = 0 to 7:

Register	Offset	Description
GPR_PRIVATEa_AUTHEN	4C10h + (a × 20h)	GPR access control
GPR_PRIVATEa_AUTHEN_SET	4C14h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_PRIVATEa_AUTHEN is 1
GPR_PRIVATEa_AUTHEN_CLR	4C18h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_PRIVATEa_AUTHEN is 0
GPR_PRIVATEa_AUTHEN_TOG	4C1Ch + (a × 20h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_PRIVATEa_AUTHEN

Diagram



Fields

Field	Description
31-13 —	Reserved
12 IN_USE	This Clock Source is being used or not. This field will be 1, if any Clock Root derived from this Clock Source is enabled. 0 - Clock Source is not being used. 1 - Clock Source is being used.
11-6 —	Reserved
5 STATUS_LATE	Late ready signal sent from PLL. This signal means clock source is ready to be used.
4 STATUS_EARLY	Early ready signal sent from PLL control module. This signal means clock source is going to be used.
3-1 —	Reserved
0 ON	Clock source current state Clock source running status. 0 - Clock source is OFF. 1 - Clock source is ON.

30.5.1.22 Clock source domain status (OSCPLL0_STATUS1 - OSCPLL18_STATUS1)

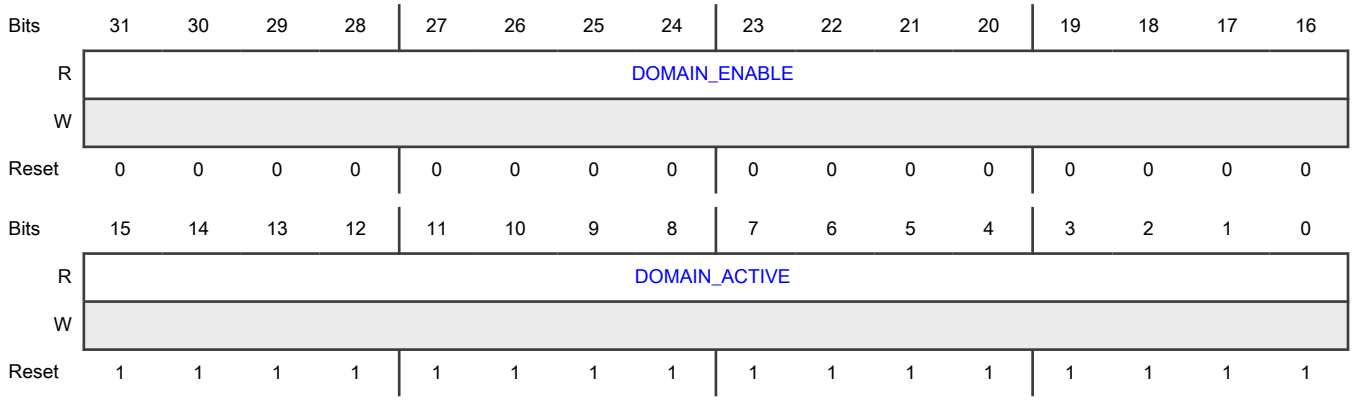
This register shows domain status of clock source.

Offset

For a = 0 to 18:

Register	Offset
OSCPLLa_STATUS1	5024h + (a × 40h)

Diagram



Fields

Field	Description
31-16 DOMAIN_ENABLE	Domain enable Domain x is enabled means that OSCPLLn_LPM_STATUS[CPU_MODE_DOMAINx] is larger than OSCPLLn_LPM[LPM_SETTING_Dx], and this clock source should be ON for DOMAINx. BIT16~BIT31 are corresponding with DOMAIN0~DOMAIN15.
15-0 DOMAIN_ACTIVE	Domain active This field is equal to OSCPLLn_AUTHEN[WHITE_LIST].

30.5.1.23 Clock Source access control (OSCPLL0_AUTHEN - OSCPLL18_AUTHEN)

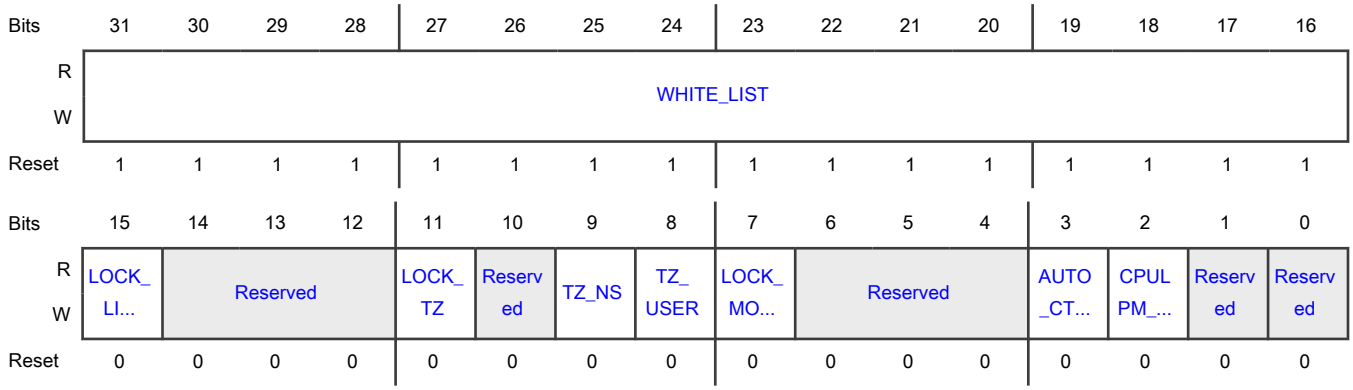
This register controls the access to this Clock Source slice. The access control includes 2 parts: TrustZone control and domain based granting.

Offset

For a = 0 to 18:

Register	Offset
OSCPLLa_AUTHEN	5030h + (a × 40h)

Diagram



Fields

Field	Description
31-16 WHITE_LIST	Whitelist Each master(Core or non-Core) can be assigned to any domains among 0-15 through TRDC and through GPC domain assignment register. Once its domains are assigned in TRDC, then its accesses will have its unique domain ID. Each bit in this field represent for one domain. Bit 16-31 represent domains 0-15 respectively. Only the TRDC domains whose corresponding bits are 1 can write to this register. Write violation will fail without any exception or information. Read violation can still get read data. In LPM mode, only the GPC domains whose corresponding bits are 1 can trigger the enabling/ disabling down of the clock Source.
15 LOCK_LIST	Lock white list This bit lock white list. When this bit is set, OSCPLLn_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - Whitelist is not locked. 1 - Whitelist is locked.
14-12 —	Reserved
11 LOCK_TZ	Lock TrustZone settings This bit locks TrustZone settings. When this bit is set, OSCPLLn_AUTHEN[TZ_USER] and OSCPLLn_AUTHEN[TZ_NS] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - TrustZone settings is not locked. 1 - TrustZone settings is locked.
10 —	Reserved
9 TZ_NS	Non-secure access permission

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Whether the registers of this Clock Source can be changed when CPU is in non-secure mode. The default value is 0, that means only the access from CPU in secure mode can change the registers of this Clock Source. 0 - Cannot be changed in Non-secure mode. 1 - Can be changed in Non-secure mode.
8 TZ_USER	User access permission Whether the registers of this Clock Source can be changed when CPU is in user mode. The default value is 0, that means only the access from CPU in supervisor mode can change the registers of this Clock Source. 0 - Clock Source settings cannot be changed in user mode. 1 - Clock Source settings can be changed in user mode.
7 LOCK_MODE	When this bit is set, CPULPM_MODE and AUTO_CREL cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - CPULPM_MODE and AUTO_CTRL is not locked. 1 - CPULPM_MODE and AUTO_CTRL is locked.
6-4 —	Reserved
3 AUTO_CTRL	Auto mode enable This filed enalbes the Auto mode. **NOTE** The actual working mode of this Clock Source is determined by OSCPLLn_AUTHEN[CPULPM_MODE] and OSCPLLn_AUTHEN[AUTO_CTRL]. 0 - Disable Auto mode 1 - Enable Auto mode
2 CPULPM_MODE	CPULPM mode enable This field enables the CPULPM mode. **NOTE** The actual working mode of this Clock Source is determined by OSCPLLn_AUTHEN[CPULPM_MODE] and OSCPLLn_AUTHEN[AUTO_CTRL]. 0 - Disable CPULPM mode. 1 - Enable CPULPM mode.
1 —	Reserved

Chapter 31
General Power Controller (GPC)

31.1 Overview

The General Power Controller(GPC) is the centralized power controller, which controls the power mode of the processor(s). The GPC takes the Wait For Interrupt (WFI) signal from CPU platforms, and wakeup events from peripherals, to determine the power mode based on the GPC power management policy. The GPC can also control the power mode transition.

31.1.1 Block diagram

The GPC block consists of the following sub-modules:

- CPU Mode Control (CMC): It contains CPU mode controller for the CPU platform. It controls the CPU mode of the CPU platforms and their private resources.
  - CMC for the Cortex-M33 core platform.
  - CMC for the Cortex-A55 core0, referred to as the core0 platform.
  - CMC for the Cortex-A55 core1, referred to as the core1 platform.
  - CMC for the Cortex-A55 cluster (SCU/L3), referred to as the CA55 platform.
- UPI CM Mapping (UPI): The connection between CMC and CPU platform is directly hard-wired, but CPU platform can be assigned to any domain in the system. This block is used to map CPU mode control signals into the correct domain.
- GLOBAL CTRL: It is used to control special resources.

The figure below shows the block diagram of the General Power Controller.

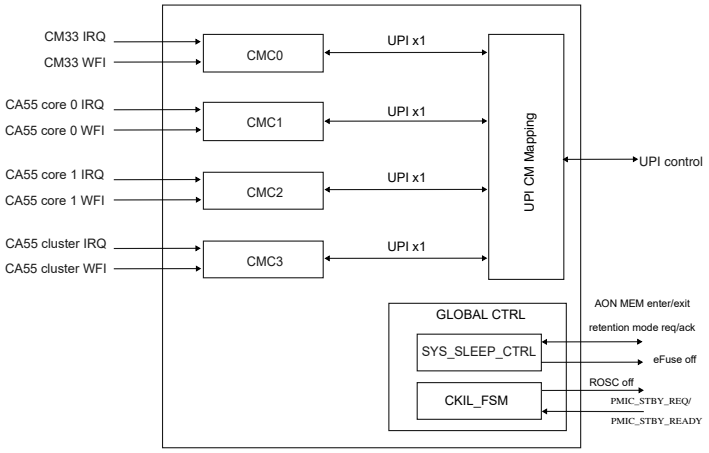

Figure 65. GPC block diagram

31.1.2 Features

The GPC includes the following features:

- Independent CPU modes for each CPU platform
- System sleep management
- Domain access control
- Controllable steps of sleep and wakeup sequence

31.2 Functional description

The following sections describe functional details of the GPC module.

31.2.1 CPU Mode Control (CMC)

The CPU mode is a power mode of the CPU platform. The following are the four CPU modes:

Table 146. CPU Modes

CPU Mode	Description
RUN	The CPU core is active and running under normal operation. All the blocks inside the CPU platform can be accessed when needed. The state of private resources are fully controlled by software configuration.
WAIT	The CPU is in WFI state, but can to get back to RUN mode with very short latency. In typical applications, the CPU will enter WAIT mode whenever there is no active thread running. In WAIT mode, the clock to the CPU core is gated off, the cache is clock gated, and the TCM is still active since there are other modules, such as DMA, that still needs access to it.
STOP	The CPU is in WFI state, and does not require an extremely short exit time. In STOP mode, the clocks to the CPU core, Cache, and TCM are all gated off. The clocks to the bus and peripherals are also gated off. This is the lowest power consumption mode without losing the state of the peripheral. When exiting from STOP mode, there is no need to re-initialize the peripherals.
SUSPEND	Entering SUSPEND mode is for lowest power consumption, and exit time is not critical. In SUSPEND mode, CPU, Cache, and peripherals are all power gated. The biggest difference between SUSPEND and STOP mode is the peripherals will be power gated. Because the peripherals are power gated, entering SUSPEND mode requires the CPU to save the state of the peripherals. When exiting from SUSPEND mode, the CPU needs to restore these states.

CPU Mode transitions happen when the following events occur:

- Sleep Event: CPU enters sleep state with WFI instruction
- Wakeup Event: Any unmasked IRQ wakeup

On a Sleep Event, the CPU has the option to enter WAIT/STOP/SUSPEND mode, or stay in RUN mode. The transition to WAIT/STOP/SUSPEND is called the sleep sequence, and the next state is configured by CM_MODE_CTRL[CPU_MODE_TARGET].

When CPU is in WAIT/STOP/SUSPEND mode, a wakeup request can wake the CPU, and bring it back to RUN mode. This is transition is called the wakeup sequence. The CM_IRQ_WAKEUP_MASK_n register selects which IRQs can wakeup the CPU platform. There are also non-IRQ requests, which can wakeup the CPU. These non-IRQ requests are configured by the CM_NON_IRQ_WAKEUP_MASK register. There is another wakeup event called non-masked interrupt (nmi_in), which can wake the CPU platforms unconditionally.

For the Cortex-A55, there is a special wakeup event called gic_wakeup_req. CM_MISC[IRQ_MUX] can be configured to select if the wakeup is from the IRQs (default selection) or the gic_wakeup_req event.

During a CPU mode transition, the GPC communicates with the system resource controllers by sending the target CPU mode and transition step. Please see the UPI interface for more detials.

If a resource is set as private to a single CPU platform, the resource's power state will change with the CPU platform's mode. If a resource is set as shared by multiple CPU platforms, the resource controller needs to look at all the current modes of the CPU platforms to determine the power state of the resource. For a resource set as shared by multiple CPU platforms, the following rules apply:

- The resource can be power gated, only when all the CPU platforms want to power down the resource.

- The resource can be powered on, when any CPU platform wants to power up the resource.

31.2.2 System Sleep Mode

When a CMC has entered SUSPEND mode, it requests the system to enter system sleep mode.
The mode can be changed by configuring CM_SYS_SLEEP_CTRL[SS_SUSPEND, SS_STOP, SS_WAIT].
The default values are CM_SYS_SLEEP_CTRL[SS_SUSPEND]=1, CM_SYS_SLEEP_CTRL[SS_STOP]=0, and CM_SYS_SLEEP_CTRL[SS_WAIT]=0. If CM_SYS_SLEEP_CTRL[SS_STOP] value is set to 1, when a CMC has entered into STOP mode, the CMC requests the system to enter system sleep mode.

The system is put into system sleep mode only when all the CMCs request the system to enter system sleep mode. If a CPU is disabled by FUSE, the GPC ignores it's CMC system sleep mode requirement. A CPU can also be forced into a system sleep status by configuring GPC_SYS_SLEEP[FORECE_CPU3_DISABLE, FORECE_CPU2_DISABLE, FORECE_CPU1_DISABLE, FORECE_CPU0_DISABLE]. When configured, the GPC will ignore the CMC system sleep mode requirement for the disabled CPU(s).

For details of each system sleep transition step, refer to Table 148.

System sleep mode has the following four functions.

- AON memories (AONMIX memory, HSIO memory, DDR PHY memory) can enter/exit retention mode with configuration of the GPC_AON_MEM_CTRL register.
- eFUSE can be power gated with configuration of the GPC_EFUSE_CTRL register.
- ROSC 24M clock can be turned off with configuration of the GPC_ROSC_CTRL register. Then the GPC works under the 32KHz clock.
- PMIC can be put into standby status with configuration of the PMIC_CTRL, PMIC_PRE_DLY_CTRL, and PMIC_STBY_ACK_CTRL registers.

31.2.3 Unified Power Management Interface (UPI)

GPC does not control the state of the resource directly. During power mode transition, it communicates with the resource controllers through the UPI (Unified Power management Interface) to accomplish the power mode transition.

GPC and resource controllers implement a handshaking mechanism for mode transitions.

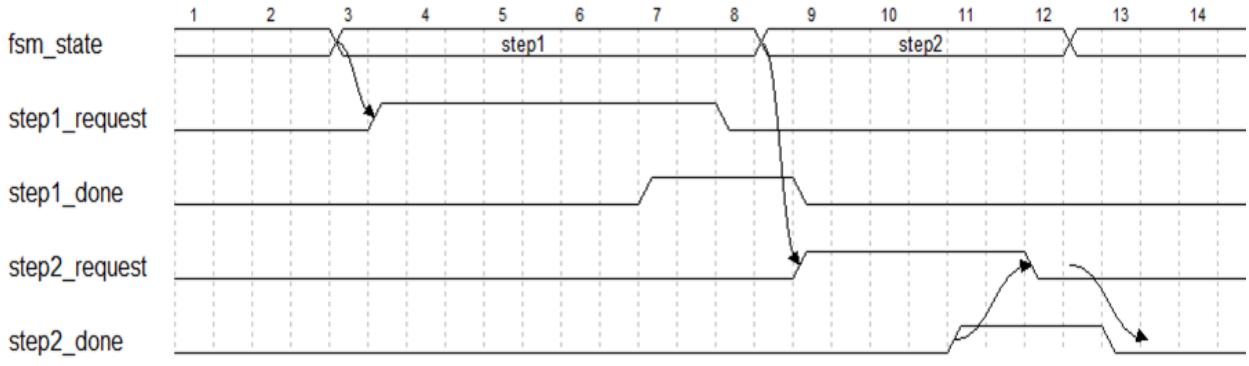

Figure 66. Handshake method

31.2.4 Low Power Sequence

31.2.4.1 CPU mode transition flow

There are four CPU mode control instances:CMC0 for CM33,CMC1 for CA55 Core 0,CMC2 for CA55 Core 1, and CMC3 for CA55 cluster. Each CMC has a state machine to control the sequence of CPU mode transition.

When CMC receives a sleep request from CPU platform, it starts the sleep sequence. The flow cannot be interrupted by a wakeup request until the SLEEP_RSV2 request completes. After the sleep sequence finishes, the CMC stays at IDLE_SLEEP and waits for a wakeup event to start wakeup sequence, which is shown in the left part of the diagram.

Figure 67. CPU mode transition flow

NOTE

SLEEP_RSV2 and WAKEUP_RSV2 are reserved status and don't have a real action.

Table 147. CPU mode transition steps

State	Description
IDLE_RUN	CPU is in RUN mode
SLEEP_A55_HDSK	GPC asserts command to SRC to handshake with CA55
SLEEP_SSAR	GPC asserts command to SRC to send SSAR system save
SLEEP_LPCG	GPC asserts command to CCM to disable LPCGs
SLEEP_PLL	GPC asserts command to CCM to turn PLLs off
SLEEP_ISO	GPC asserts command to SRC to enable isolation signals
SLEEP_RESET	GPC asserts command to SRC to assert reset signals

Table continues on the next page...

Table 147. CPU mode transition steps (continued)

State	Description
SLEEP_POWER	GPC asserts command to SRC to turn off power switch signals
SLEEP_SYS	SSC runs the system sleep transition flow
IDLE_SLEEP	CMC waits for wakeup event to start wakeup sequence
WAKEUP_SYS	SSC runs the wakeup flow
WAKEUP_POWER	GPC asserts command to SRC to de-assert reset signals
WAKEUP_RESET	GPC asserts command to SRC to turn on power switch signals
WAKEUP_ISO	GPC asserts command to SRC to disable isolation signals
WAKEUP_PLL	GPC asserts command to CCM to turn PLLs on
WAKEUP_LPCG	GPC asserts command to CCM to enable LPCGs
WAKEUP_SSAR	GPC asserts command to SRC to send SSAR restore
WAKEUP_A55_HDSK	GPC asserts command to SRC to handshake with CA55

For each step of transition above, there is a control register with the following fields:

- STEP_CNT: This field configures the delay count number.
- CNT_MODE: This field configures the count mode. There are 4 selectable modes available for the delay counter.
- DISABLE: This field disables the step, so that no request is sent out in this transition step.

There is also a read only counter to record the time when the step response is received.

31.2.4.2 System sleep transition flow

There are four transition steps for the system sleep mode. Each step has its own enable register. The system sleep in sequence can be aborted after any step completes because of the wakeup requirement.

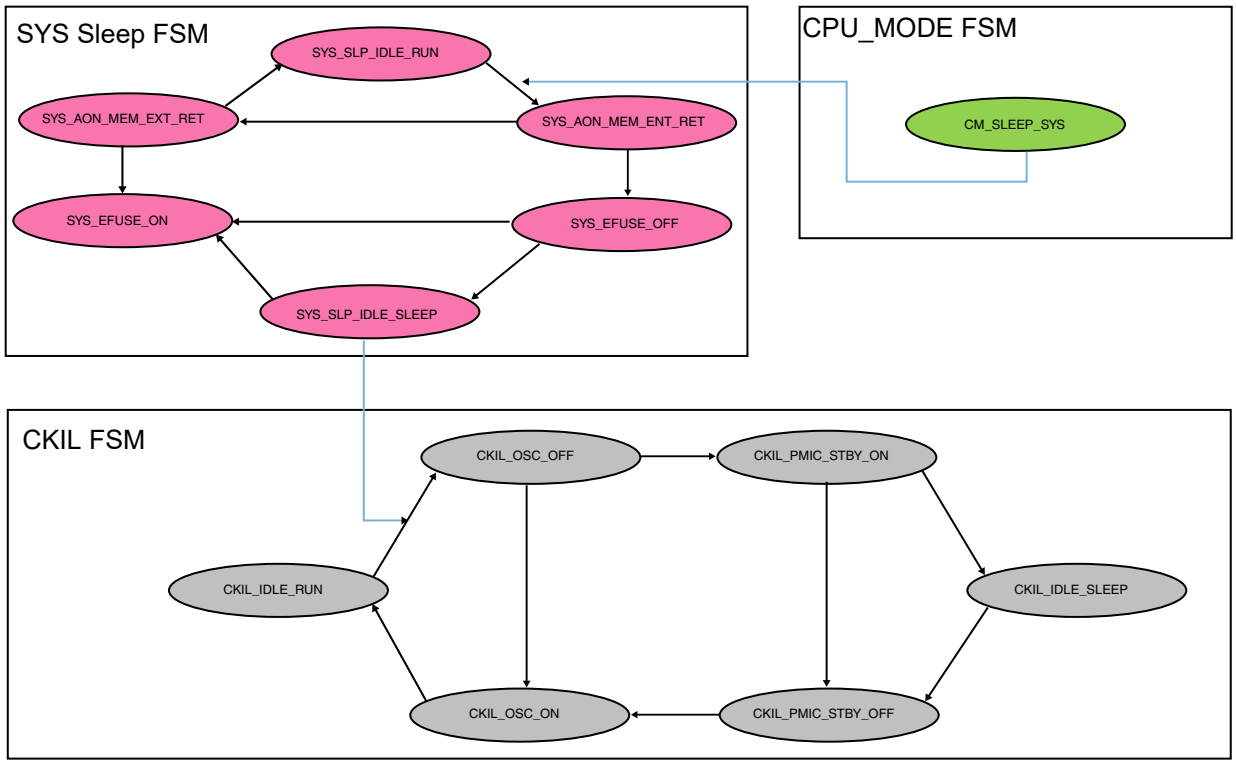

Figure 68. System sleep transition flow

Table 148. System sleep transition steps

State	Description
SYS_SLP_IDLE_RUN	Idle run
SYS_AON_MEM_ENT_RET	AON memories enter retention mode
SYS_EFUSE_OFF	Power off EFUSE
SYS_SLP_IDLE_SLEEP	Idle run
CKIL_OSC_OFF	ROSC 24M clock off
CKIL_PMIC_STBY_ON	Standby on PMIC
CKIL_IDLE_SLEEP	Idle run
CKIL_PMIC_STBY_OFF	Standby off PMIC
CKIL_OSC_ON	ROSC 24M clock on
CKIL_IDLE_RUN	Idle run
SYS_EFUSE_ON	Power on EFUSE
SYS_AON_MEM_EXT_RET	AON memories exit retention mode

31.2.5 Priority of Sleep and Wakeup

IRQs are sent to the GPC, CM33 and GIC.

When CM33 WFI and IRQs occur at the same time, the GPC will not enter the sleep sequence. IRQs can wake up the CM33 from WFI directly.

IRQs are not sent to CA55 directly, but through the GIC. Before the CA55 enters WFI, the GIC distributor register CORE_PWRDN_EN bit is set. Then executing a WFI instruction automatically masks all interrupts and wake_up events in the core. As a result, applying reset is the only way to wake up the core from this WFI. Therefore, when the CA55 CORE0/1 WFI and IRQs happen at the same time, the GPC must enter the sleep sequence.

Wakeup has a higher priority than sleep in CMC0 and CMC3. Sleep has a higher priority than wakeup in CMC1 and CMC2.

31.2.6 System Domain

31.2.6.1 Domain assignment

Each CPU platform and the CMC connected to it can be assigned to the same domain. CPU_DOMAIN[CPUn_DOMAIN] is used to select the domain assignments for CMCn.

Based on the domain assignment, a mapping mechanism between CPU platform and system domain is implemented inside GPC.

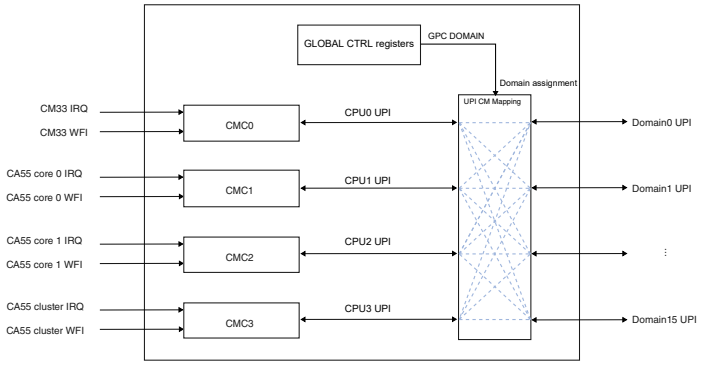

Figure 69. Domain Assignment

When more than one CMCs is assigned to same domain, a two stage priority selects which CMC can control the domain's UPI output. The first stage is CPUn_MASTER flag from GLOBAL which is enabled by register GPC_MASTER[CPUn_MASTER]. Only one CMC with CPUn_MASTER flag owns the domain UPI output. The second stage is for the case when more than one CMC has CPUn_MASTER flag or no CMC has this flag. In this case, the lower indexed CMC has higher priority.

31.2.6.2 Register Access Permissions

The GPC register access is controlled by the following registers and bitfields:

- CM_AUTHEN_CTRL register for CMC access permission
- AUTHEN_CTRL register for GLOBAL registers access permission
- x_AUTHEN_CTRL[WHITE_LIST] field configures which domain IDs can write to the registers
- x_AUTHEN_CTRL[USER] and x_AUTHEN_CTRL[NONSECURE] fields are used to set the privilege and security permission
- x_AUTHEN_CTRL[LOCK_CFG] locks configuration fields and should only be set at initialization
- x_AUTHEN_CTRL[LOCK_LIST] locks WHITE_LIST fields and should only be set at initialization

31.2.7 Resource Low Power Control

31.2.7.1 Hardware Control

The resource behavior under a CPU power mode is configurable. The following is an example of configuring a LPCGn resource under CPU power mode.

1. Configure the CCM register LPCGn_AUTHEN[CPULPM_MODE] to 1.
2. Configure the CCM register LPCGn_LPMn.
3. Configure the CCM register LPCGn_AUTHEN[WHITE_LIST].
4. Configure the GPC CMC register CM_MODE_CTRL[CPU_MODE_TRAGET]. Configure the GPC global register GPC_DOMAIN to assign the CPU control domain, and then execute the "WFI" instruction.
5. The GPC runs the Low Power Sequence up to the WAKEUP_LPCG/SLEEP_LPCG step, then sends the lpcg_request together with cpu_power_mode_n via the UPI.
6. The CCM will turn on or turn off the LPCGn clock based on the LPCGn_LPMn setting in step 2.

31.2.7.2 Resource Domain Assignment

Each resource can be assigned to any (one or multiple) of the 16 domains. This domain assignment is configured in the resource controller's register AUTHEN[WHITE_LIST]. When the resource is controlled by hardware, the WHITE_LIST field indicates which domain UPI request needs to be cared. Take LPCG-n clock gating as an example, which is illustrated below.

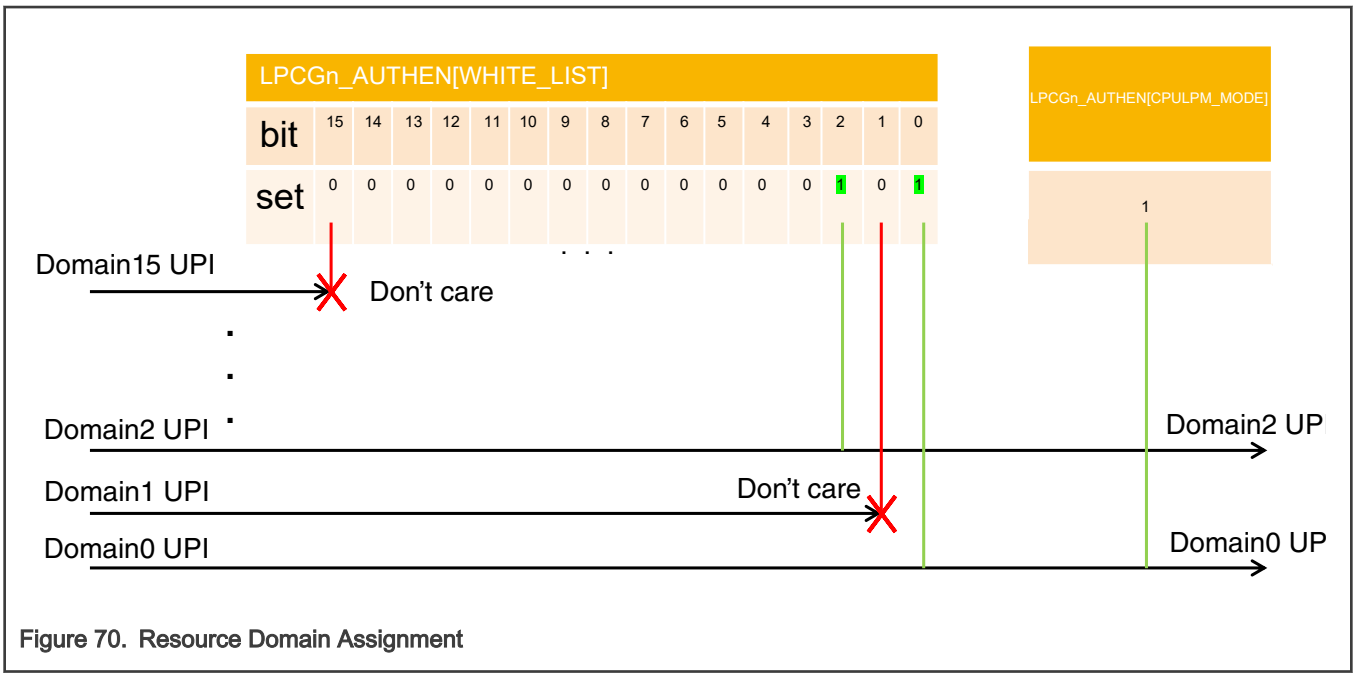

Figure 70. Resource Domain Assignment

The LPCGn_LPMn register provides 16 domain settings (LPM_SETTING_D0 - LPM_SETTING_D15), one for each of the 16 domains. The final resource shut off request is logic AND of all the shared domain requests.

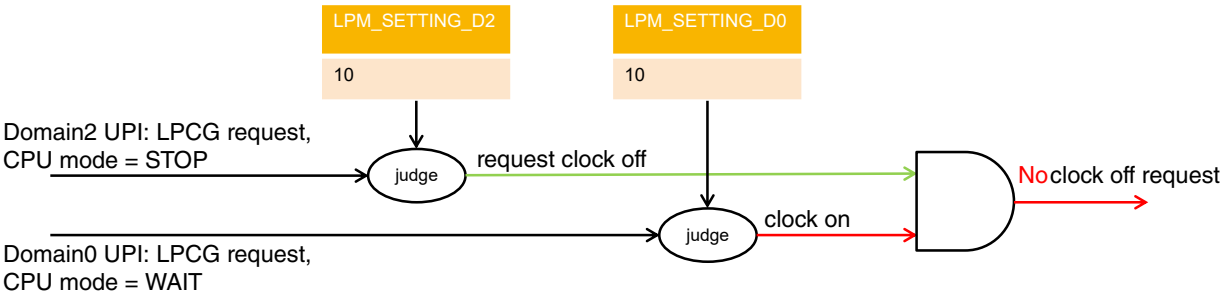

Figure 71. Shared Resource Hardware Control

31.2.7.3 Software Control

The resource behavior can be directly controlled by software. In this mode, the CCM register LPCGn_AUTHEN[CPULPM_MODE] must be set to 0.

31.2.7.4 Switch Between Hardware Control and Software Control

When switching from software control to hardware control, software needs to ensure that the resource is ON. LPCGn_LPMn should be configured to a common value, not always on or always off.

31.2.8 Clocks

This section describes clocks and special clocking requirements of the GPC module.

Table 149. Clocks

Clock	Description
ipg_clk	Main GPC clock. This clock originates from RCOSC 24 MHz and and can be turned off by setting GPC_ROSC_CTRL[ROSC_OFF_EN].
32k_clk	32 kHz clock used to wakeup GPC and RCOSC.

31.2.9 Interrupts

The interrupt inputs of each CMC are independent and the same as the CPU platforms they are connected to. Each CMC has up to 256 IRQ inputs to wake up the core or system.

31.3 External Signals

There are no external signals pinned out for the GPC.

31.4 Initialization

See Low Power Sequence for low power entry and exit flow and considerations.

31.4.1 CPU Sleep Hold (Cortex M-Core Only)

There is a certain delay between the time the core sleeps and when the core clock stops. If a wakeup IRQ appears inside this delay window, the core will process the IRQ and wake up, but the GPC sleep sequence is still shutting off the core clock. Since the sleep sequence is not interruptable, this scenario may lead to unpredictable behavior.

To avoid this scenario, a CPU Sleep Hold is implemented to hold the core in the sleep state until the sleep sequence is finished. The GPC will then send a signal to release the core. The CM_MISC[SLEEP_HOLD_EN] field is used to enable this function.

The core clock can also be gated by a WFI event without any GPC sequence. The GPC uses a signal to clear this gate when a wakeup trigger occurs.

31.5 Memory Map and register definition

This section includes the GPC module memory map and detailed descriptions of all registers.

NOTE

Write/Read to the Reserved locations will not generate a transfer error.

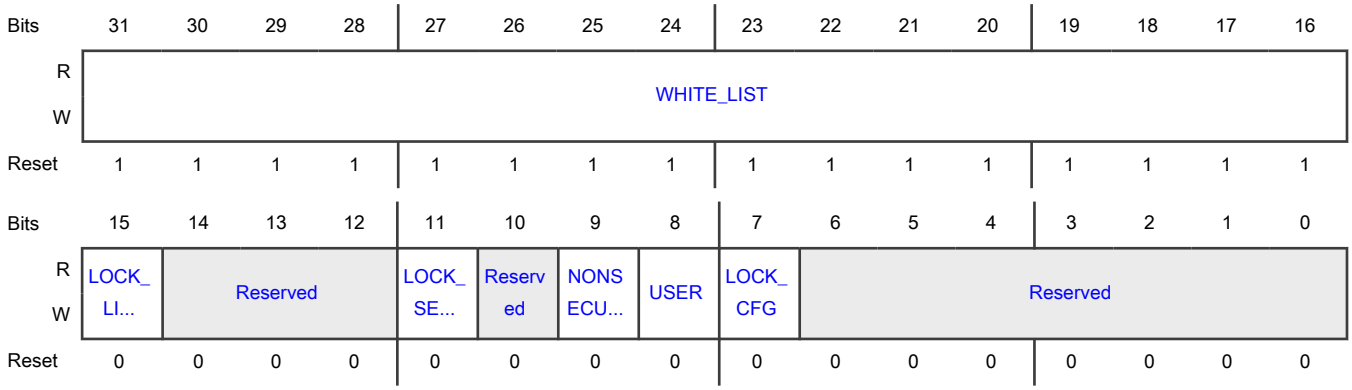
CM_AUTHEN_CTRL	4h

Diagram



Fields

Field	Description
31-16 WHITE_LIST	Domain ID white list When bit is set to 1, the corresponding domain ID can access CPU mode control registers. bit[0] for Domain 0, bit[1] for Domain 1, bit[2] for Domain 2, and bit[3] for Domain 3. Multiple bits with a value of 1 is permitted.
15 LOCK_LIST	White list lock This bit locks the WHITE_LIST. When this bit is set, WHITE_LIST cannot be changed. Once this bit is set, it cannot be cleared until the next system reset. 0 - WHITE_LIST is not locked 1 - WHITE_LIST is locked
14-12 —	Reserved
11 LOCK_SETTING	Lock NONSECURE and USER This bit locks the NONSECURE and USER fields. When this bit is set, LOCK_SETTING cannot be changed. Once this bit is set, it cannot be cleared until the next system reset. 0 - NONSECURE and USER fields are not locked 1 - NONSECURE and USER fields are locked
10 —	Reserved
9 NONSECURE	Allow non-secure mode access 0 - Allow only secure mode to access CPU mode control 1 - Allow both secure and non-secure mode to access CPU mode control registers
8 USER	Allow user mode access 0 - Allow only privilege mode to access CPU mode control registers

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Allow both privilege and user mode to access CPU mode control registers
7 LOCK_CFG	Configuration lock This bit locks the value of low power configuration fields. Once this bit is set, it cannot be cleared until the next system reset. 0 - The value of low power configuration fields are not locked. 1 - The value of low power configuration fields are locked. It locks the CPUx_CM registers which are marked as "Locked by LOCK_CFG field" in the function field.
6-0 —	Reserved

31.5.1.3 Miscellaneous (CM_MISC)

Authentication control for CMC.

Chapter 32
System Reset Controller (SRC)

32.1 Overview

The System Reset Controller (SRC) is responsible for the generation of all the system reset signals and boot argument latching. Its main functions are as follows:

- Deals with all global system reset sources from other modules, and generates global system reset.
- Responsible for power gating of MIXs (Slices) and their memory low power control.

The SRC takes the POR_B from the PAD and fuse bits to complete the boot sequence, and the GPC low power request to complete the power down/up sequence.

32.1.1 Block diagram

The SRC module consists of the following submodules:

- Cold reset control: This submodule is used to process the cold reset source, such as the watchdog, the tempsensor, or the cm33_lockup. These cold reset sources can assert system reset or single mix reset.
- src_signals_driver_ckil: This sub module uses POR_B from the pad and the jtag_rst_b signal to generate the system reset signal (src_system_early_rst_b) and the MIX SLICE reset signal (slice_early_rst_b).
- MIX SLICES: There are 13 MIX SLICES. Each slice corresponds to one resource on the chip. Each slice consists a set of controllers, such as the reset controller and the PG (power gating) controller. See Figure 72 for additional information.
- MEM SLICES: There are 13 MEM SLICES. Each slice corresponds to one memory on the chip.

The figure below shows a high-level block diagram of the SRC.

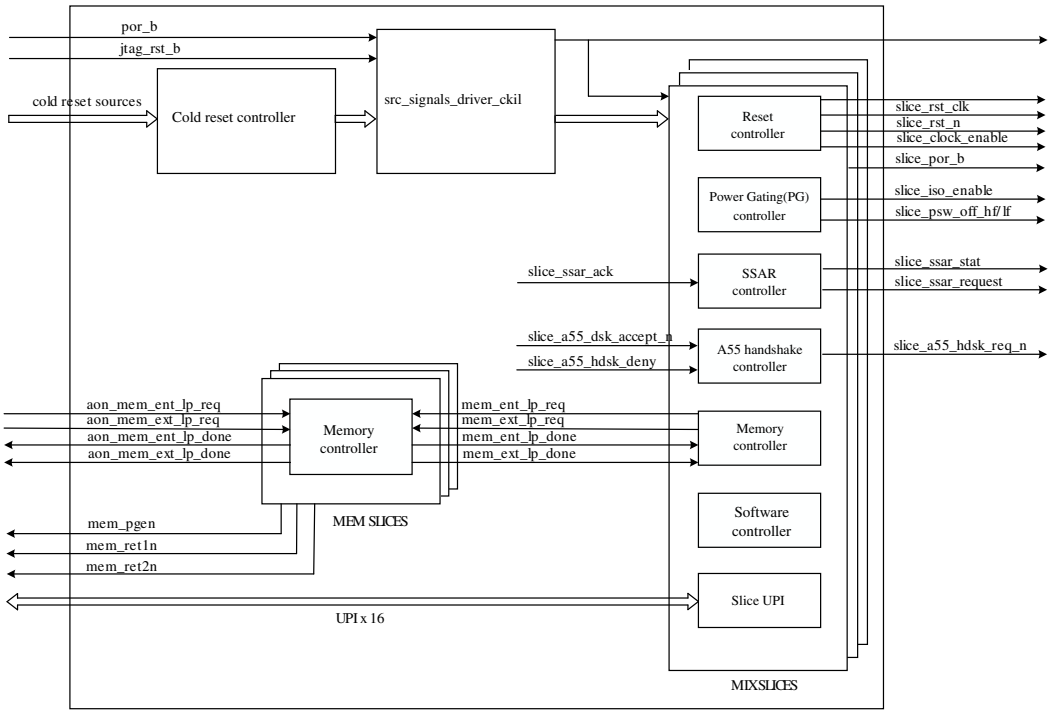

Figure 72. SRC block diagram

32.1.2 Features

The SRC includes the following features:

- Supports two boot modes
- Latches the SRC_BOOT_MODE pins and boot configuration signals from the on-chip Fuse
- Supports system cold reset
- Supports reset control, power control, and memory power control for all MIXs
- Supports handshake with EdgeLock Enclave before a sensitive MIXs reset/power status is changed
- Supports A55 MIX core0/1 and cluster dependency
- Supports A55 MIX power handshake
- Domain access control

32.2 Functional description

The reset control determines the source and type of reset, and performs the necessary reset qualification and stretching sequences. Based on the type of reset, the reset logic generates the reset sequence for the entire chip.

The boot argument latching includes the BOOT_MODE pin, when the system comes out of reset.

32.2.1 MIX and MEM SLICES

There are 13 MIX Slices and 13 MEM Slices. Each slice corresponds to one resource or memory on the chip. The slice and resource assignment is provided below.

Table 150. MIX Slice Assignment

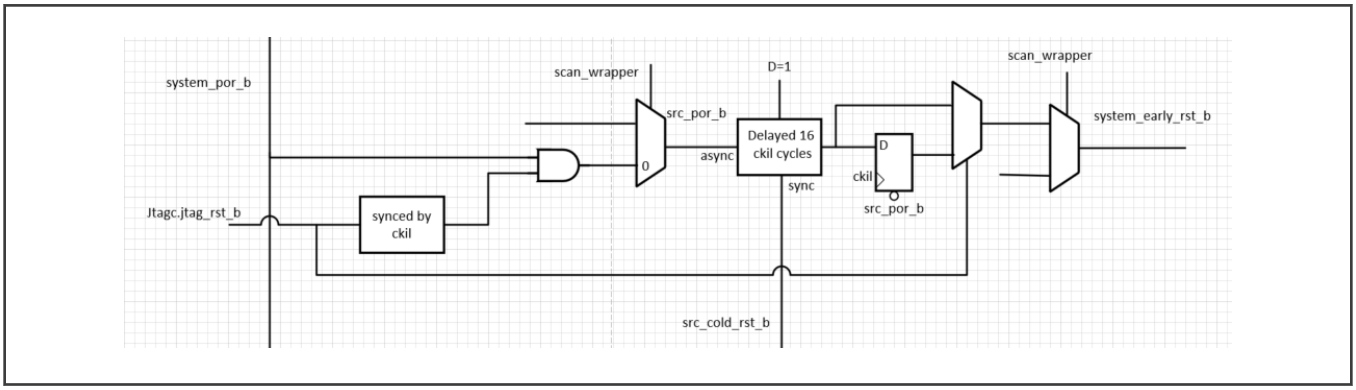
MIX SLICE index	Resource Name
0	EdgeLock Enclave
1	AONMIX
2	WAKEUPMIX
3	DDRMIX
4	DDRPHY
5	MLMIX
6	NICMIX
7	HSIOMIX
8	MEDIAMIX
9	CM33MIX
10	CA55 core 0
11	CA55 core 1
12	CA55 cluster

Table 151. MEM Slice Assignment

MEM SLICE Index	Memory Name
0	AONMIX memory
1	WAKEUPMIX memory
2	DDRMIX memory
3	DDRPHY memory
4	MLMIX
5	NICMIX memory
6	OCRAM
7	HSIOMIX memory
8	MEDIA memory
9	CA55 core 0 memory
10	CA55 core 1 memory
11	CA55 cluster memory
12	L3 cache

32.2.2 src_signals_driver_ckil

This submodule uses POR_B from the pad (system_por_b) and the jtag_rst_b signal to generate the system reset signal (system_early_rst_b).



32.2.3 Reset controller

The reset controller is used to generate reset signals for resources in the chip. It has four reset signals. The signals and the sequence is provided in the following figure.

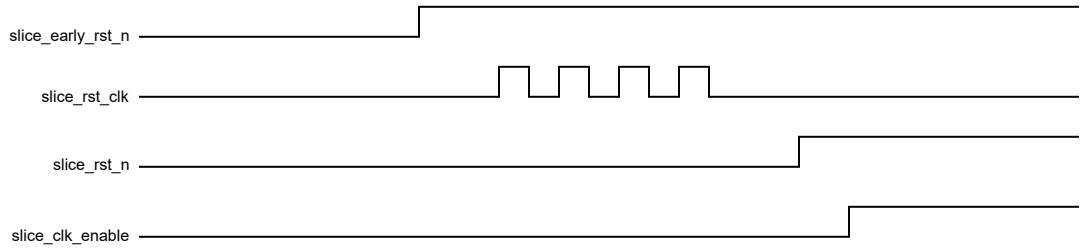


Figure 73. Reset Controller Sequence

Table 152. Reset Controller Signals

Signal	Description
slice_early_rst_n	This signal's release time is earlier than fuse load finished. Active low.
slice_rst_clk	Used for sync-reset logic.
slice_rst_n	Functional reset. Active low.
slice_clk_enable	Used for clock gating. It's release time is later than slice_rst_b, this means that there is no clock when slice_rst_b is releasing.

32.2.4 Power Gating (PG) controller

The power gating controller is used to generate power gating signals and isolation signals. The signals are described in the following table.

Table 153. PG Controller Signals

Signal	Description
slice_iso_enable	When it is high, the mix output signals are clamped to be default value.
slice_psw_off_hf/lf	Power switch gating signal. Active high.
slice_psw_ack_hf/lf	Power switch ack signal. Active high.

32.2.5 SSAR controller

The SRC supports the handshake mechanism with EdgeLock Enclave before executing power off, and after completing power up.

There are 3 signals for each slice. These signals are described in the following table.

Table 154. SSAR Controller Signals

Signal	Direction	Description
ssar_req	Output	Assert to send a notification or request to EdgeLock Enclave.
ssar_stat	Output	Indicates low power status: 0 - indicates power off, 1 - indicates power on
ssar_ack	Input	Assert to indicate that EdgeLock Enclave has gotten the notification or accepted the request.

The Waveform for one slice interface is provided below.

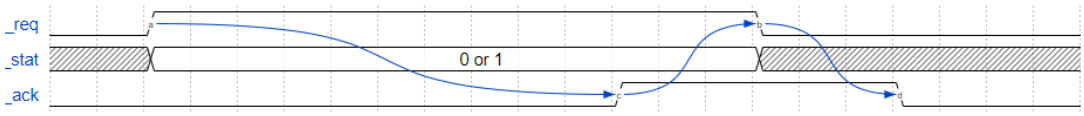

Figure 74. Waveform

32.2.6 A55 handshake controller

The SRC supports the handshake mechanism with A55 before executing A55 power off, and after completing A55 power up.

There are 3 signals for each slice and are described in the following table. These signals can only be sent out by the A55 core0, A55 core1, and A55 cluster slices.

Table 155. SSAR Controller Signals

Signal	Direction	Description
a55_hdsk_qreq_n	Output	Assert to send a notification or request to A55.
a55_hdsk_qaccept_n	Input	Assert to indicate that A55 has accepted the request.
a55_hdsk_qdeny	Input	Assert to indicate that A55 has rejected the request.

32.2.7 Memory controller

Each memory slice can control one memory block on the chip. There are two memory types.

- AON memories (AONMIX memory/ROM, HSIO memory, DDR PHY Memory): these are controlled by the GPC dsm.
- PSW memories: these are controlled by the GPC low power memory step.

32.2.8 Software controller

Software can control each SRC slice controller by configuring the SLICE_SW_CTRL[10:0] bits. SLICE_SW_CTRL[PDN_SOFT] is used for one-key power down/power up.

NOTE

Software access can be active only when AUTHEN_CTRL[LPM_MODE] = 0.

There are two methods to power up and power down a SRC slice.

1. One-key power down/ power up method
2. Step by step power down/ power up method

The one-key power down/power up method is provided below:

- To power off the SRC slice:
    1. Set MEM_CTRL[MEM_LP_EN] = 1, to enable MEM low power control.
    2. SET SLICE_SW_CTRL[PDN_SOFT] = 1, for software power down.
- To power on the SRC slice:
    1. Set MEM_CTRL[MEM_LP_EN] = 1, to enable MEM low power control.

2. Set SLICE_SW_CTRL[PDN_SOFT] = 0, for software power up.

NOTE

1. For initial power up, the register should be configured to an unsensitive value.
2. For initial power up of the CA55, SCR[BT_RELEASE_A55_PLAT] should set to 1.

The step by step power down/power up method is provided below:

- To power off the SRC slice:
  1. Set SLICE_SW_CTRL[ISO_CTRL_SOFT] = 1, for Software isolation on.
  2. Set MEM_CTRL[MEM_LP_EN] = 1, to enable MEM low power control.
  3. Set MEM_CTRL[SW_MEM_CTRL] = 1, for software control MEM to enter low power.
  4. Set SLICE_SW_CTRL[RST_CTRL_SOFT] = 1, reset and clock gate enable.
  5. Set SLICE_SW_CTRL[PSW_CTRL_S OFT] = 1, for software power switch off.
- To power on the SRC slice:
  1. SLICE_SW_CTRL[PSW_CTRL_S OFT] = 0, for software power switch on.
  2. MEM_CTRL[MEM_LP_EN] = 1, to enable MEM low power control.
  3. MEM_CTRL[SW_MEM_CTRL] = 0, for software control MEM to exit low power.
  4. SLICE_SW_CTRL[RST_CTRL_SO FT] = 0, reset release and clock gate disable.
  5. SLICE_SW_CTRL[ISO_CTRL_SO FT] = 0, for software isolation off.

The MIX slice status can be monitored via the Function Status (FUNC_STAT) register. The MEM slice status can be monitored via the MEM Status (MEM_STAT) register. The status must be monitored at each step when using the "step by step power down/power up method" listed above.

Software can control the memories power by configuring the MEM Low Power Control (MEM_CTRL) register.

32.2.9 Switching between hardware control and software control

When switching from software control to hardware control, software needs to ensure that the resource is ON. LPM_SETTING should be configured to common value, not always on or always off.

32.2.10 Cold reset controller

The table below shows the cold reset sources. Each cold reset source can assert system reset or single MIX reset via the SRMRn registers, and can be masked via the SRMASK register. The are two trigger modes available and can be selected through the SRTMR register.

Table 156. Cold Reset Sources

Reset sources	Description
csu_reset_b	Asserts when security violation happens
ipp_user_reset_b	Asserts when the ONOFF pad is pressed down in test mode
wdog1_cm33_rst_b	Asserts when the peripheral WDOG1 timeouts
wdog2_cm33_rst_b	Asserts when the peripheral WDOG2 timeouts
wdog3_wakeupmix_rst_b	Asserts when the peripheral WDOG3 timeouts
wdog4_ca55_rst_b	Asserts when the peripheral WDOG4 timeouts

Table continues on the next page...

Table 156. Cold Reset Sources (continued)

Reset sources	Description
wdog5_ca55_rst_b	Asserts when the peripheral WDOG5 timeouts
tempsense_reset	Asserts when the Temper Sensor requests a reset
m33_lockup	Asserts when CM33 lock up
m33_sysrstreq	Asserts when CM33 system resets
Jtag_sw_rst	Assert when the debugger asserts software reset by JTAG
jtag_rst_b	Asserts when the JTAG requests a reset

32.2.11 Boot sequence

The Boot MODE from the pins can be latched in the SRC SBMR2 register. BOOT_MODE[3] indicates the boot core. If BOOT_MODE[3]=1, CM33 is the boot core. If BOOT_MODE[3]=0, CA55 is the boot core. The MIXs boot status varies depending on the boot core selected. Refer to the table below for details.

MIX SLICE Index	Resource Name	CM33 boot	CA55 boot
0	EdgeLock Enclave	ON	ON
1	AONMIX	ON	ON
2	WAKEUPMIX	ON	ON
3	DDRMIX	OFF	ON
4	DDRPHY	ON	ON
5	MLMIX	OFF	OFF
6	NICMIX	ON	ON
7	HSIOMIX	ON	ON
8	MEDIAMIX	OFF	OFF
9	CM33MIX	ON	ON
10	CA55 Core 0	OFF	ON
11	CA55 Core 1	OFF	ON
12	CA55 Cluster	OFF	ON

All MIXs are by default OFF before the fuse loading is completed. After fuse loading is completed, the MIXs will power up or still be in OFF state depending on the FUSE or BOOT_MODE pin values. The power up sequence is as follows:

1. MIX power on
2. Memory power on
3. Reset release
4. iso_en = 0
5. Clock enable
6. EdgeLock Enclave handshake
7. System boot up

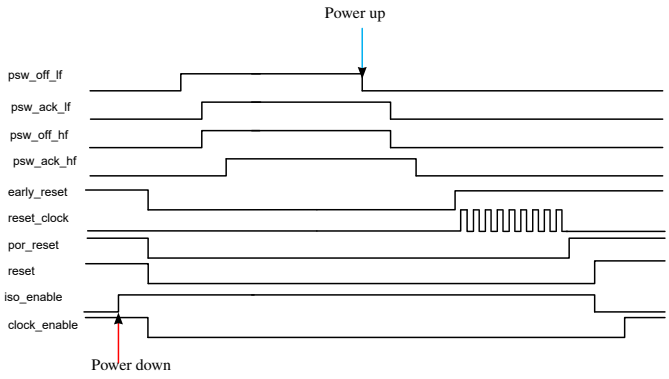

Figure 75. Power Up and Power down Sequence

32.2.12 Reset control

32.2.12.1 CM33 safe reset

There are two CM33 safe reset methods:

- Method 1: Safe reset by HW. The process is as follows.
  1. (SW) Set the M33_CFG[WAIT] bit in blk_ctrl_s_aonmix block. Refer to blk_ctrl_s_aonmix chapter for register details.
  2. (SW) Configure one of the SRC SRMRn register to 'h0100 for CM33
  3. Cold reset occurs
  4. (HW) SRC performs handshake with EgdeLock Enclave through the lp_hdsk_gasket.
  5. (HW) SRC performs safe reset handshake with CM33
  6. (HW) SRC asserts CM33 reset
  7. (CA55 SW) Check CM33 SRC slice FUNC_STAT[RST_STAT] bit for reset state.
  8. (CA55 SW) Load image to the TCM of the CM33
  9. (CA55 SW) Clear M33_CFG[WAIT] bit in the blk_ctrl_s_aonmix block. Refer to blk_ctrl_s_aonmix chapter for register details.
- Method 2: Safe reset by SW access safe reset register. The process is as follows:
  1. (SW) Set the M33_CFG[WAIT] bit in blk_ctrl_s_aonmix block. Refer to blk_ctrl_s_aonmix chapter for register details.
  2. (SW) Configure the SRC SRMRn register to 'h0100 for CM33
  3. (SW) SRC masks cold reset
  4. Cold reset occurs and generates an interrupt to the CA55
  5. (SW) CA55 performs handshake with Edgelock Enclave through the MU
  6. (SW) Set SRC CM_QUIESCE[SAFE_CM33_AHB_REQ] bit to request CM33 platform to be reset at safe state
  7. (SW) Wait for SRC CM_QUIESCE[SAFE_CM33_AHB_ACK_STAT] CM33 safe reset ack
  8. (SW) Set CM33 SRC slice SLICE_SW_CTRL[RST_CTRL_SOFT] bit for software reset assert
  9. (SW) Check CM33 SRC slice FUNC_STAT[RST_STAT] bit for reset state
  10. (SW) Clear SRC CM_QUIESCE[SAFE_CM33_AHB_REQ] bit
  11. (SW) Check SRC CM_QUIESCE[SAFE_CM33_AHB_ACK_STAT] CM33 safe reset state

12. (SW) Clear CM33 SRC slice SLICE_SW_CTRL[RST_CTRL_SOFT] reset bit
13. (SW) Check CM33 SRC slice FUNC_STAT[RST_STAT] bit for reset state
14. (CA55 SW) Load image to the TCM of the CM33
15. (CA55 SW) Clear M33_CFG[WAIT] bit in the blk_ctrl_s_aonmix block. Refer to blk_ctrl_s_aonmix chapter for register details.

32.2.12.2 Reset CA55 except debug component

The CA55 cannot be warm reset. The following power down and power up sequence is required to reset the CA55.

1. Power down CA55.
2. Set CA55_CPUWAIT[CPUn_WAIT] bit to 1 in the blk_ctrl_s_aonmix block. Once the CPUn_WAIT bit is set to 1, the CA55 core stops working.
3. Power up CA55.
4. The CA55 core will continue to stop working, until the WAIT reset is released.
5. Set CA55_CPUWAIT[CPUn_WAIT] bit to 0 in the blk_ctrl_s_aonmix block. Once the CPUn_WAIT bit is set to 0, the CA55 core works normally.

32.2.13 Low-power mode transition

All SRC slices can be powered off. A fixed power off/on sequence is adopted in this chip. Refer to Figure 75 for the power up and power down sequence.

32.2.13.1 Control of slice power-off

There are two ways to power off a slice.

- GPC mode (by setting AUTHEN_CTRL[LPM_MODE] = 1)
- Software (SW) mode (by setting AUTHEN_CTRL[LPM_MODE] = 0). Refer to Software controller for additional details.

NOTE

Do not change AUTHEN_CTRL[LPM_MODE] value, when the slice is in power off/on sequence or is already in power off state.

In the GPC mode, the SRC powers off the slice under the control of the GPC. Each Core can be mapped to any of the 16 domains by the TRDC via GPC_CPUn_DOMAIN_ASSIGNMENT register. In SRC, each slice can be assigned to any of the 16 domains via AUTHEN_CTRL[WHITE_LIST] bits. When the bit is set, the domain's mapped Core's power state transition is considered as a low power trigger, else the transition is ignored.

NOTE

The CPU3_domain cannot assign to CA55 core 0 slice and CA55 core 1 slice domain.

Because a slice can be assigned to 16 domains at most, a unified arbitration rule is defined for each slice.

- The slice enters power-off sequence with the last active Core power state transition, if several cores (of domain's assigned domains' mapping Cores) request the slice to power off.
- The slice enters power-on sequence with the first active Core power state transition, if any one core (of domain's assigned domains' mapping Cores) requests the slice to power on while the slice is in power-off status.

For example, the MLMIX slice can be assigned to the CM33 Core. After CM33 core requests domain to power off/on, CM33 domain enters power off/on sequence with CM33 Core power state transition. For comparison, the NICMIX slice can be assigned to both CM55 Core0 and CM33 Core. If only one Core requests the slice to power off, the NICMIX slice keeps in power on status. If CM55 Core0 requests the slice to power off, and CM33 requests the slice to power off later, then the NICMIX slice enters power-off sequence with CM33 Core's power state transition. When NICMIX slice is already in power-off status, after any Core requests the slice to power on, the NICMIX slice enters power-on sequence with the Core's power state transition.

NOTE

If the slice enters power-off/on sequence, it goes through all the steps[1] and cannot be interrupted. So during the power-off sequence, any Core's power-on request has to be delayed until the completion of slice's power-off sequence. During the power-on sequence, any Core's power-off request has to be delayed until the completion of slice's power-on sequence.

32.2.14 Clocks

The table below describes the relevant SRC clock sources.

Table 157. Clocks

Clock	Description
ipg_clk	Main SRC clock. This clock originates from the 24MHz RCOSC and can be turned off.
32k_clk	32KHz clock.

32.3 External Signals

This table describes the SRC external signals.

Table 158. External Signals

Signal	Direction	Description
POR_B	I	Power on reset input pin, active low.
BOOT_MODE[3:0]	I	Boot mode selection pins. The values are sampled during system reset and can be read in the SBMR2 register. See the boot chapter for specific boot configuration settings, and the pin mux chapter for pin assignments.

32.4 Register access permissions

The SRC uses the AUTHEN_CTRL register to control register access permissions.

- The AUTHEN_CTRL[WHITE_LIST] field is used to configure which domain IDs can write to the registers.
- The AUTHEN_CTRL[TZ_USER] and AUTHEN_CTRL[TZ_NS] fields configure privilege and security permissions.
- The AUTHEN_CTRL[LOCK_CFG] field locks configuration fields which should only be set at initialization.

32.5 Memory Map and register definition

This section includes the SRC module memory map and detailed descriptions of all registers.

32.5.1 SRC GENERAL register descriptions

32.5.1.1 SRC General Registers memory map

SRC General Registers

src_general_reg base address: 4446_0000h

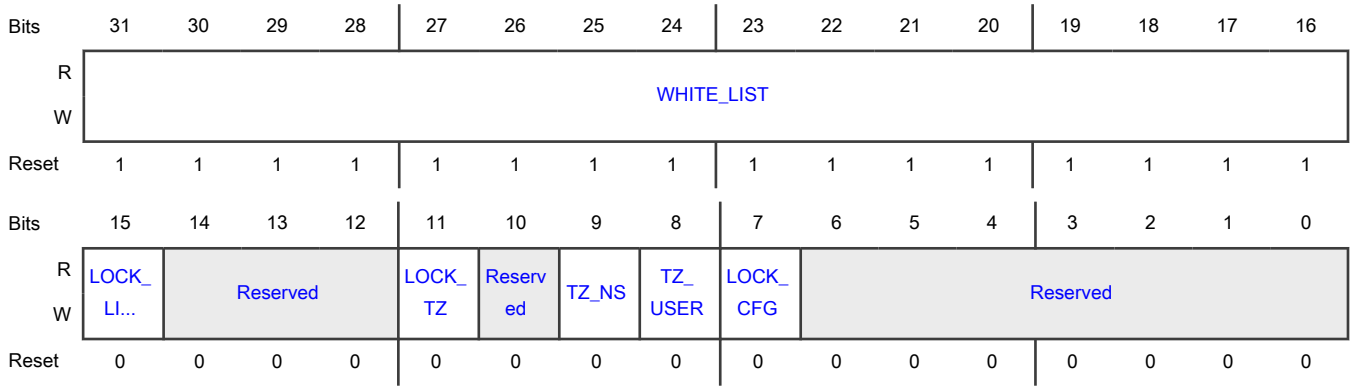
AUTHEN_CTRL	4h

Diagram



Fields

Field	Description
31-16 WHITE_LIST	Domain ID white list Each master(Core or non-Core) can be assigned to any domains among 0-15 through TRDC and through GPC domain assignment register. Once its domains are assigned in TRDC, then its accesses will have its unique domain ID. Each bit in this field represent for one domain. Bit 16-31 represent domains 0-15 respectively. Only the TRDC domains whose corresponding bits are 1 can write to this register. Write violation will fail without any exception or information. Read violation can still get read

Table continues on the next page...

Field	Description
	data. In LPM mode, only the GPC domains whose corresponding bits are 1 can trigger the powering down of the given power slice. 0000_0000_0000_0001 - Core with domain ID=0 can write General registers. 0000_0000_0000_0010 - Core with domain ID=1 can write General registers. 0000_0000_0000_0100 - Core with domain ID=2 can write General registers. 0000_0000_0000_1000 - Core with domain ID=3 can write General registers. 0000_0000_0001_0000 - Core with domain ID=4 can write General registers. 0000_0000_0010_0000 - Core with domain ID=5 can write General registers. 0000_0000_0100_0000 - Core with domain ID=6 can write General registers. 0000_0000_1000_0000 - Core with domain ID=7 can write General registers. 0000_0001_0000_0000 - Core with domain ID=8 can write General registers. 0000_0010_0000_0000 - Core with domain ID=9 can write General registers. 0000_0100_0000_0000 - Core with domain ID=10 can write General registers. 0000_1000_0000_0000 - Core with domain ID=11 can write General registers. 0001_0000_0000_0000 - Core with domain ID=12 can write General registers. 0010_0000_0000_0000 - Core with domain ID=13 can write General registers. 0100_0000_0000_0000 - Core with domain ID=14 can write General registers. 1000_0000_0000_0000 - Core with domain ID=15 can write General registers.
15 LOCK_LIST	White list lock This field can lock itself and WHITE_LIST. 0 - WHITE_LIST value can be changed. 1 - LOCK_LIST and WHITE_LIST value cannot be changed.
14-12 —	Reserved
11 LOCK_TZ	Lock TZ_NS and TZ_USER bits This field can lock itself, TZ_NS and TZ_USER. 0 - TZ_NS and TZ_USER value can be changed. 1 - LOCK_TZ, TZ_NS and TZ_USER value cannot be changed.
10 —	Reserved
9 TZ_NS	Allow non-secure mode access Allow either secure mode or non-secure mode to write general registers.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - General registers can only be written in secure mode. 1 - General registers can be written either in secure mode or non-secure mode.
8 TZ_USER	Allow user mode access Allow either privilege mode or user mode to write general registers. 0 - General registers can only be written in privilege mode. 1 - General registers can be written either in privilege mode or user mode.
7 LOCK_CFG	Configuration lock This field can lock itself and some registers in this General registers. They SRTMR, SRMASK, and SRMRn. 0 - General registers are not locked. 1 - LOCK_CFG and registers in the list are locked.
6-0 —	Reserved

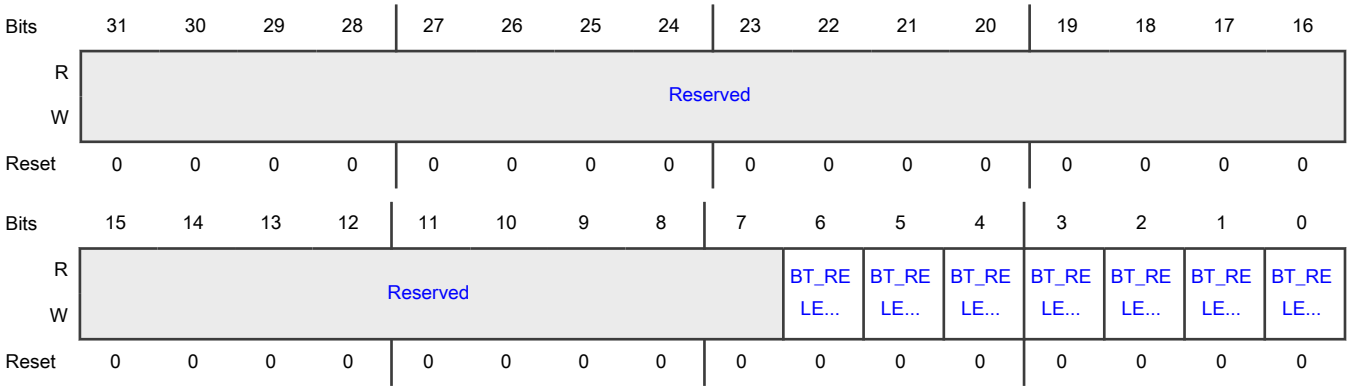
32.5.1.3 SRC Control Register (SCR)

The Reset control register (SCR), contains bits that control operation of the reset controller.

Offset

Register	Offset
SCR	10h

Diagram



Fields

Field	Description
31-7 —	Reserved
6 BT_RELEASE_DDR	If M33 boot, the DDRMIX reset will be held until boot core writes this bit to 1. Once this bit is set to 1, it will be locked. 0 - Hold reset. 1 - Release reset.
5 BT_RELEASE_MEDIA	MEDIAMIX reset will be held until boot core writes this bit to 1. Once this bit is set to 1, it will be locked. 0 - Hold reset. 1 - Release reset.
4 BT_RELEASE_ML	MLMIX reset will be held until boot core writes this bit to 1. Once this bit is set to 1, it will be locked. 0 - Hold reset. 1 - Release reset.
3 BT_RELEASE_A55_PLAT	If M33 boot, the CA55 platform reset will be held until boot core writes this bit to 1. Once this bit is set to 1, it will be locked. 0 - Hold reset. 1 - Release reset.
2 BT_RELEASE_A55_CPU1	If M33 boot, the CA55 CPU1 reset will be held until boot core writes this bit to 1. Once this bit is set to 1, it will be locked. 0 - Hold reset. 1 - Release reset.
1 BT_RELEASE_A55_CPU0	If M33 boot, the CA55 CPU0 reset will be held until boot core writes this bit to 1. Once this bit is set to 1, it will be locked. 0 - Hold reset. 1 - Release reset.
0 BT_RELEASE_M33	If A55 boot, the CM33 reset will be held until boot core writes this bit to 1. Once this bit is set to 1, it will be locked. 0 - Hold reset. 1 - Release reset.

32.5.1.4 SRC RESET TRIGGER MODE REGISTER (SRTMR)

The Reset Trigger Mode Register (SRTMR). Reset by POR not system early reset.

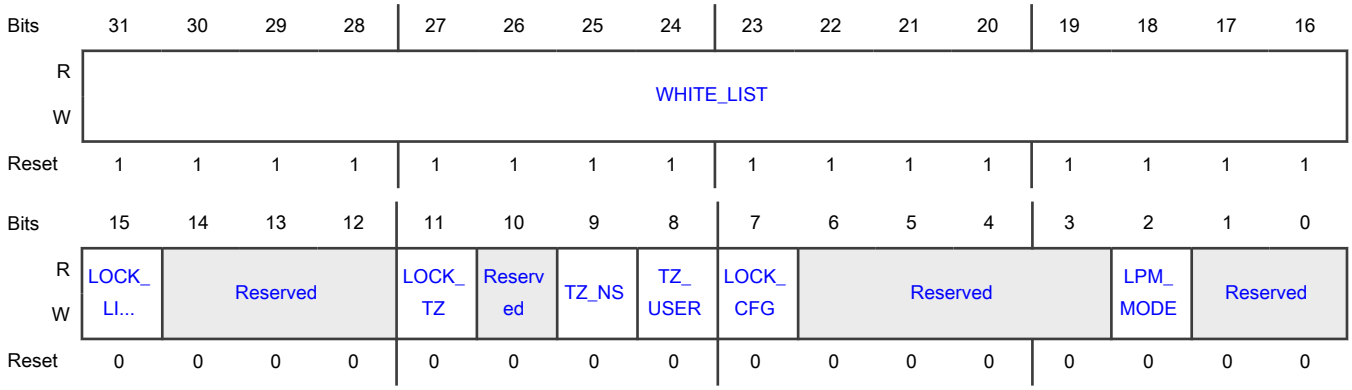
32.5.3.2 Authentication Control (AUTHEN_CTRL)

When GPC_DOMAIN[CPUx_DOMAIN] bit is 1, the MIX SLICE will be power switch with the corresponding CPU.

Offset

Register	Offset
AUTHEN_CTRL	4h

Diagram



Fields

Field	Description
31-16 WHITE_LIST	Domain ID white list Each master(Core or non-Core) can be assigned to any domains among 0-15 through TRDC and through GPC domain assignment register. Once its domains are assigned in TRDC, then its accesses will have its unique domain ID. Each bit in this field represent for one domain. Bit 16-31 represent domains 0-15 respectively. Only the TRDC domains whose corresponding bits are 1 can write this General registers. Write violation will fail without any exception or information. Read violation can still get read data. In LPM mode, only the GPC domains whose corresponding bits are 1 can trigger the powering down of the given power slice. 0000_0000_0000_0001 - Core with domain ID=0 can write SRC MIX SLICE registers. 0000_0000_0000_0010 - Core with domain ID=1 can write SRC MIX SLICE registers. 0000_0000_0000_0100 - Core with domain ID=2 can write SRC MIX SLICE registers. 0000_0000_0000_1000 - Core with domain ID=3 can write SRC MIX SLICE registers. 0000_0000_0001_0000 - Core with domain ID=4 can write SRC MIX SLICE registers. 0000_0000_0010_0000 - Core with domain ID=5 can write SRC MIX SLICE registers. 0000_0000_0100_0000 - Core with domain ID=6 can write SRC MIX SLICE registers. 0000_0000_1000_0000 - Core with domain ID=7 can write SRC MIX SLICE registers. 0000_0001_0000_0000 - Core with domain ID=8 can write SRC MIX SLICE registers. 0000_0010_0000_0000 - Core with domain ID=9 can write SRC MIX SLICE registers. 0000_0100_0000_0000 - Core with domain ID=10 can write SRC MIX SLICE registers. 0000_1000_0000_0000 - Core with domain ID=11 can write SRC MIX SLICE registers. 0001_0000_0000_0000 - Core with domain ID=12 can write SRC MIX SLICE registers. 0010_0000_0000_0000 - Core with domain ID=13 can write SRC MIX SLICE registers. 0100_0000_0000_0000 - Core with domain ID=14 can write SRC MIX SLICE registers. 1000_0000_0000_0000 - Core with domain ID=15 can write SRC MIX SLICE registers.
15	White list lock

Table continues on the next page...

Table continued from the previous page...

Field	Description
LOCK_LIST	This field is write once and can lock the value of the WHITE_LIST field. 0 - WHITE_LIST value can be changed. 1 - WHITE_LIST value cannot be changed.
14-12 —	Reserved
11 LOCK_TZ	Lock NONSECURE and USER This field is write once and can lock the TZ_NS and TZ_USER fields. 0 - TZ_NS and TZ_USER value can be changed. 1 - TZ_NS and TZ_USER value cannot be changed.
10 —	Reserved
9 TZ_NS	Allow non-secure mode access Allow either secure mode or non-secure mode to write this MIX SLICE registers. 0 - This MIX SLICE registers can only be written in secure mode. 1 - This MIX SLICE registers can be written either in secure mode or non-secure mode.
8 TZ_USER	Allow user mode access Allow either privilege mode or user mode to write this MIX SLICE registers. 0 - This MIX SLICE registers can only be written in privilege mode. 1 - This MIX SLICE registers can be written either in privilege mode or user mode.
7 LOCK_CFG	Configuration lock This field is write once and can lock value of the low power configuration fields. 0 - Low power configuration fields are not locked. 1 - Low power configuration fields are locked.
6-3 —	Reserved
2 LPM_MODE	Low power control mode **NOTE** This bit cannot be written for SRC.src_edgelock_slice. 0 - Low power mode controlled by software 1 - Low power mode controlled by GPC hardware
1-0	Reserved

Chapter 33
Battery-Backed Non-Secure Module (BBNSM)

33.1 Chip-specific BBNSM information

Table 159. Reference links to related information

Topic	Related module	Reference
Full description	Arm Cortex CM33 Platform (CM33)	CM33 Platform
System memory map		System memory map
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

The chip includes one instance of BBNSM module.

NOTE

The BBNSM output “pmic_en_b” is active-low, but PMIC_ON_REQ PAD is active-high. There is an inverter between them. PMIC_ON_REQ starts low but is driven high after NVCC_BBSM_1P8 is turned on.

NOTE

Accessing BBNSM registers will block the access of AONMIX peripherals(SAI1, MQS1, CAN1, LPSPI1/LPSPI2, LPI2C1/2, I3C1, TPM1/2) temporarily. For peripherals that need real time, should avoid accessing BBNSM registers when they are working.

33.2 Overview

BBNSM serves as non-volatile logic and storage for the system.

33.2.1 Block diagram

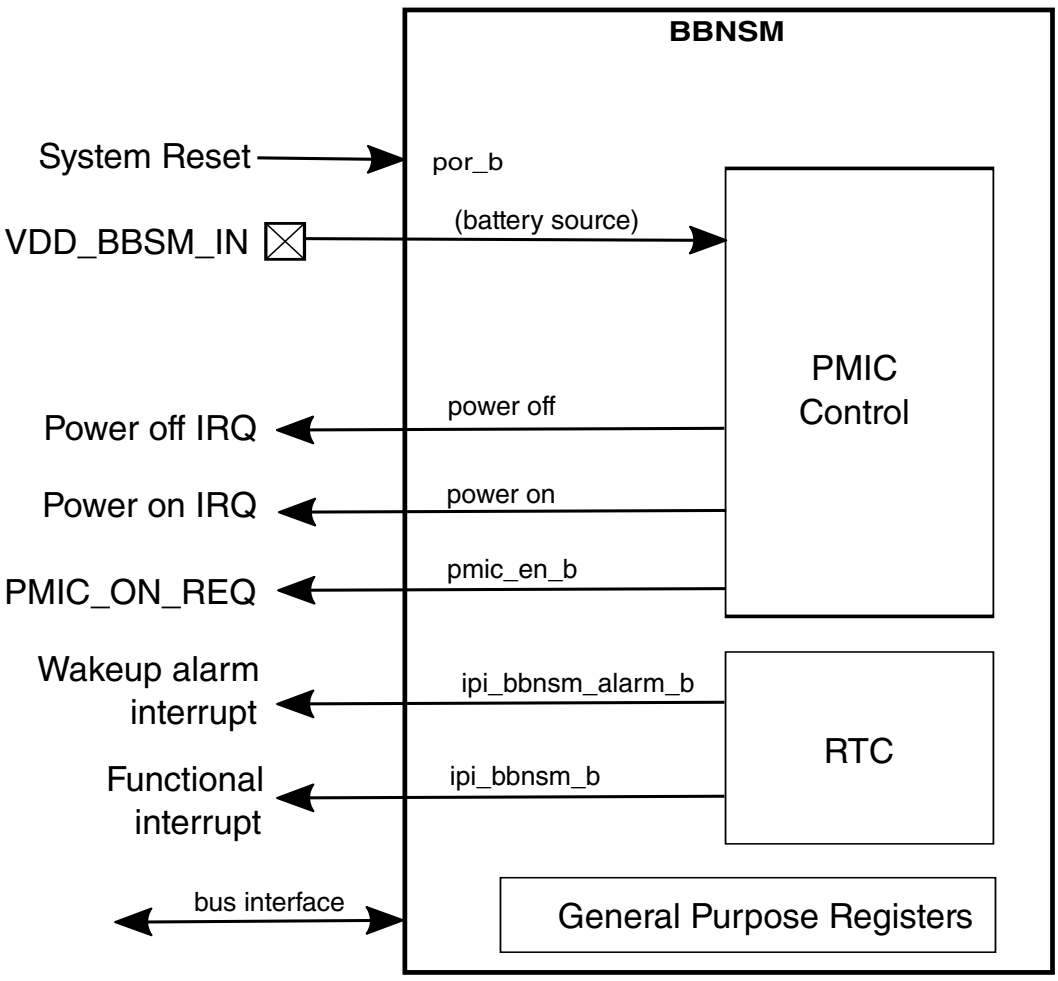

Figure 76. BBNSM block diagram

33.2.2 Features

BBNSM implements the following features:

Table 160. BBNSM feature list

Feature	Description
Non-volatile storage and logic (PMIC logic)	• If the BBNSM power input is connected to an uninterrupted power supply: — BBNSM register values are maintained even when the main SoC is powered off — BBNSM logic continues to operate even when the main SoC is powered off
General-purpose register	• The general-purpose register is available to software to store data. It is 8 registers of 32 bits each by default.

Table continues on the next page...

Table 160. BBNSM feature list (continued)

Feature	Description
Real-time counter (RTC)	• Triggers an interrupt if the RTC reaches its maximum value. • A time alarm can be programmed to generate an interrupt at a specific time.
On/Off Control	• Allows connectivity to a Power Management Integrated Circuit (PMIC) or other voltage regulator devices. • Configurable debounce support for button presses.

33.3 Functional description

The following sections describe functional details of the BBNSM module.

33.3.1 Real-Time Counter (RTC)

BBNSM implements a real-time counter that:

- Retains its state and continues counting even when the main chip is powered down. The BBNSM power input is connected to an uninterrupted power supply
- Generates an interrupt when it reaches the maximum value of all ones. It will then rollover and continue to count
- Generates a functional interrupt request at a particular time by setting the desired time in the Time Alarm register and setting BBNSM_CTRL[TA_EN]
- Can be written at any time
- Can be calibrated so that its count frequency tracks some other time source
- Can be configured to capture the time of a security violation

33.3.1.1 Time Counter Calibration

The real-time counter accuracy may suffer from a drift in the clock, which is used to increment the RTC register. To compensate for this drift, a clock calibration mechanism can adjust the RTC value. It is up to the system processor to decide whether calibration is required or not. If RTC correction is required, enable the mechanism and set the calibration value in the control register. The calibration value (BBNSM_CTRL[CAL_VAL]) includes the sign bit, which is implemented in twos' complement.

If the calibration mechanism is enabled, the calibration value is added or subtracted from the RTC on a periodic basis, once per 32768 cycles of the RTC clock. Positive calibration values will not work with the time alarm feature.

The following table shows the available correction range.

Table 161. Real-time counter calibration settings

Calibration setting (BBNSM_CTRL[CAL_VAL])	Correction in counts per 32768 cycles of the counter clock
01111	+15
...	...
00010	+2
00001	+1
00000	0

Table continues on the next page...

Table 161. Real-time counter calibration settings (continued)

Calibration setting (BBNSM_CTRL[CAL_VAL])	Correction in counts per 32768 cycles of the counter clock
11111	-1
11110	-2
...	...
10001	-15
10000	-16

33.3.1.2 Time Alarm

A time alarm is generated once the most significant 32 bits of the real-time counter match the value in the Time Alarm register. The time alarm can generate interrupts to alert the host processor and can wake up the host processor from one of its low-power modes. This alarm can also wake up the entire system in the power-down mode by asserting the wake-up external output signal.

33.3.2 On/Off Control

The on/off logic inside the BBNSM allows for connecting directly to a PMIC or other voltage regulator device. The module has a button input signal and a wakeup request input signal. It also has two interrupts (power off and power on) and an active-low PMIC enable (pmic_en_b) output. The module can function in two different modes of operation (Dumb PMIC mode and Smart PMIC mode).

33.3.2.1 Smart PMIC Mode

In Smart PMIC mode, BBNSM can generate interrupt outputs (power off and power on) like in Dumb PMIC mode. However, the pmic_en_b signal is a pulse and active-high signal in Smart PMIC mode instead of a level and active-low signal in Dumb PMIC mode. The only configuration option available for this mode is the debounce configuration, which is used for the power off and power on interrupts in the same way as Dumb PMIC mode.

33.3.2.1.1 Smart PMIC Enable Control

The active-high pmic_en_b output asserts if either condition occurs:

- the button input signal asserts
- the wakeup alarm triggers when system power has failed (isolation enable is asserted)

33.3.2.2 Dumb PMIC Mode

In Dumb PMIC mode, BBNSM can generate interrupt outputs (power off and power on) and control the active-low PMIC enable output (pmic_en_b).

33.3.2.2.1 Dumb PMIC Enable Control

The pmic_en_b signal is active (ON state) at reset. In the ON state, the pmic_en_b is deactivated (to OFF state) if either condition occurs:

- the button input signal asserts longer than the BBNSM_CTRL[BTN_TIMEOUT] configuration
- the BBNSM_CTRL[TOSP] bit is set

In the OFF state, the pmic_en_b is activated (to ON state) if either condition occurs:

- the button input signal asserts longer than the BBNSM_CTRL[TURN_ON_TIME] configuration
- the external wakeup request signal asserts

- the wakeup alarm triggers from programming the time alarm and enabling the real-time counter

The behavior of the pmic_en_b signal is described in the state machine below.

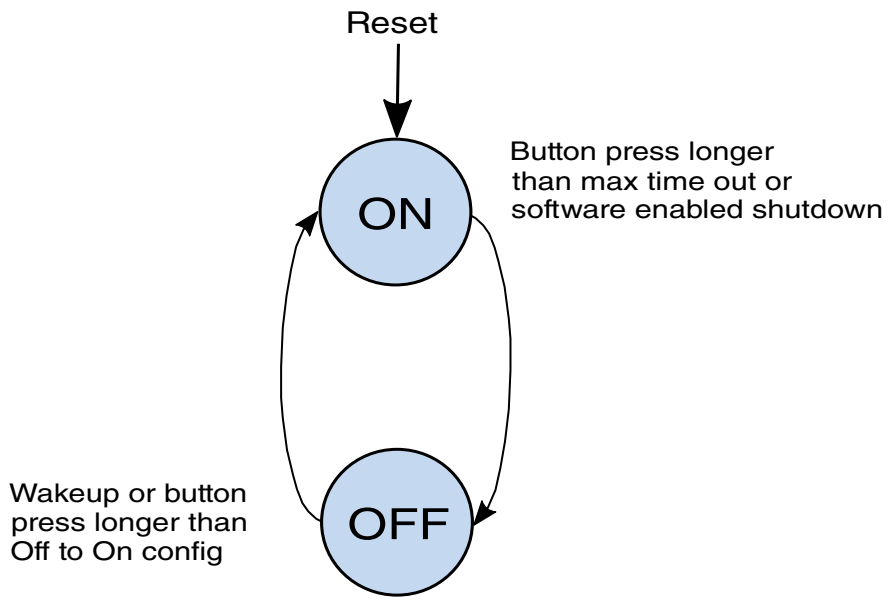

Figure 77. PMIC Enable State Machine (Dumb PMIC Mode)

33.3.3 Clocking

Table 162. BBNSM Clock

Clock	Description
32kHZ RTC clock	Clock is used by BBNSM real-time counter. This clock does not need to be synchronous with other clocks

33.3.4 Reset

Table 163. BBNSM Reset

Reset	Description
por_b	Power-on reset

33.3.5 Interrupts and Alarms

BBNSM provides the following interrupts and alarms:

Table 164. Interrupts and alarms summary

Interrupt/Violation	Event	Default configuration[1]	Configuration options
Functional interrupt (ipi_bbnsm_b)	RTC rollover	Disable	Enable/disable

Table continues on the next page...

Table 164. Interrupts and alarms summary (continued)

Interrupt/Violation	Event	Default configuration[1]	Configuration options
Wakeup alarm interrupt (ipi_bbnsm_alarm_b)	RTC time alarm	Disable	Enable/disable
Power off interrupt	Button input signal	50 msec debounce	Debounce time
Power on interrupt	Button input signal	50 msec debounce	Debounce time

1. Default configuration refers to the state after reset.

33.3.5.1 PMIC Interrupts

The interrupts behave identically in Smart and Dumb PMIC modes.

The power on asserts if:

- system power has failed (isolation enable is asserted), **and**
- the button input signal asserts longer than the BBNSM_CTRL[DEBOUNCE] configuration

The power off asserts if:

- system power has not failed (isolation enable is not asserted), **and**
- the button input signal asserts longer than the BBNSM_CTRL[DEBOUNCE] configuration in the condition of no alarm from BBNSM and tamper event asserted

33.4 External Signals

The table below lists the external signals to the BBNSM.

Table 165. BBNSM external signals

Signal	Description	Direction
ONOFF (btn)	Active-high external on/off button	Input
PMIC_ON_REQ (pmic_en_b)	ONOFF button/PAD has two functions: 1. It can impact the PMIC_ON_REQ value via BBNSM ON-OFF FSM in Dumb PMIC mode or directly pass through the ONOFF button/PAD in Smart PMIC mode. 2. It can generate IRQs which are routed to M33/A55/M7 cores, and also routed to GPC to wake up the system. When PMIC_ON_REQ=1, 1. If ONOFF button was pressed for a "short" time, it can trigger IRQ "set_pwr_off_irq" if it's pressed longer than debounce time the debounce time which is configured in BBNSM_CTRL[19:16]. 2. If you want to toggle PMIC_ON_REQ, then you need to press it longer, the press time length is configured in BBNSM_CTRL[17:16]. When PMIC_ON_REQ=0,	Output

Table continues on the next page...

Table 165. BBNSM external signals (continued)

Signal	Description	Direction
	1. If ONOFF button was pressed for a "short" time, it can trigger IRQ "set_pwr_on_irq" if it's pressed longer than debounce time. The debounce time is configured in BBNSM_CTRL[19:18]. 2. If you want to toggle PMIC_ON_REQ, then you need to press it longer, the press time length is configured in BBNSM_CTRL[21:20].	

33.5 Initialization

There are no initialization steps.

33.6 Memory Map and register definition

This section includes the BBNSM module memory map and detailed descriptions of all registers.

33.6.1 BBNSM register descriptions

33.6.1.1 BBNSM memory map

BBNSM base address: 4444_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	BBNSM Version ID Register (BBNSM_VID)	32	R	0001_013E
4	BBNSM Features Register (BBNSM_FEATURES)	32	R	0000_0020
8	BBNSM Control Register (BBNSM_CTRL)	32	RW	0100_0005
10	BBNSM Interrupt Enable Register (BBNSM_INT_EN)	32	RW	0000_0005
14	BBNSM Events Register (BBNSM_EVENTS)	32	RW	0000_0005
24	BBNSM External Pad Control Register (BBNSM_PAD_CTRL)	32	RW	0000_0000
40	BBNSM Real-Time Counter LS Register (BBNSM_RTC_LS)	32	RW	0000_0000
44	BBNSM Real-Time Counter MS Register (BBNSM_RTC_MS)	32	RW	0000_0000
50	BBNSM Time Alarm Register (BBNSM_TA)	32	RW	0000_0000
300 - 31C	General Purpose Register Word a (GPR0 - GPR7)	32	RW	0000_0000

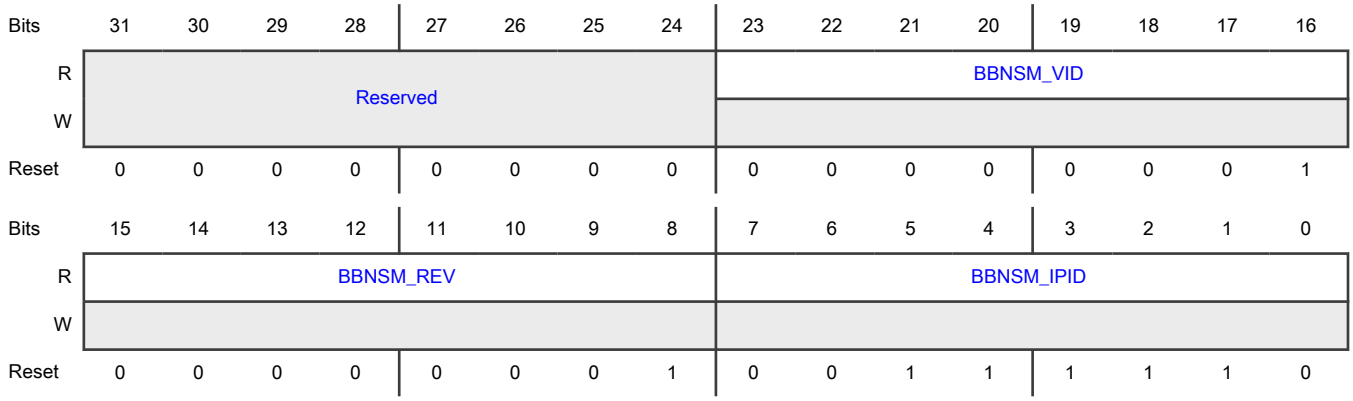
33.6.1.2 BBNSM Version ID Register (BBNSM_VID)

The BBNSM Version ID register can be used by software to differentiate between different versions of the BBNSM and determine what options are implemented in this version of BBNSM. The bit assignments of this register appear below.

Offset

Register	Offset
BBNSM_VID	0h

Diagram



Fields

Field	Description
31-24 —	Reserved
23-16 BBNSM_VID	BBNSM Version ID Version identifier or major version ID of the BBNSM.
15-8 BBNSM_REV	BBNSM Revision Revision number or minor version ID of the BBNSM.
7-0 BBNSM_IPID	BBNSM IP ID Identifier for the Battery-Backed Non-Secure Module.

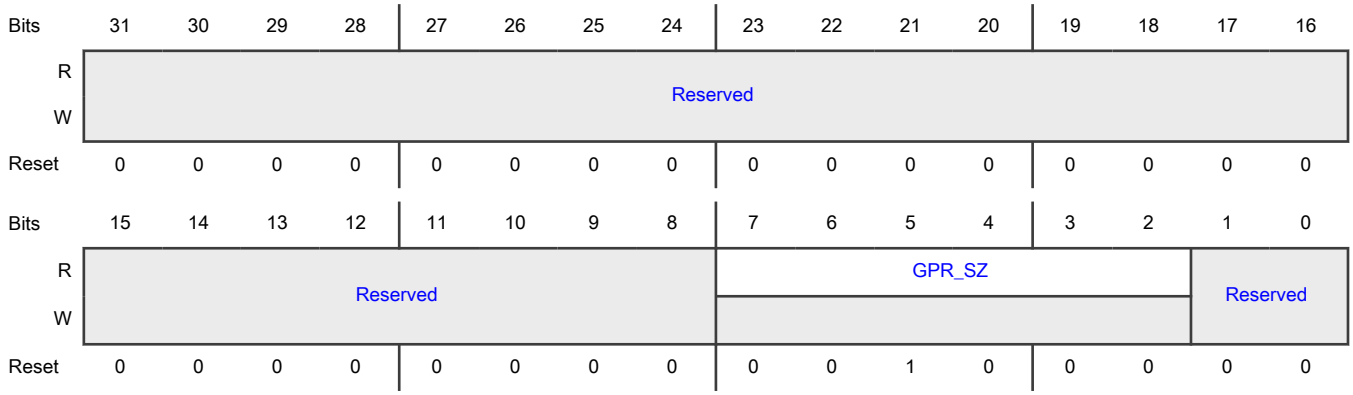
33.6.1.3 BBNSM Features Register (BBNSM_FEATURES)

The BBNSM Features register indicates which optional features are implemented in this version of BBNSM. The bit assignments of this register appear below.

Offset

Register	Offset
BBNSM_FEATURES	4h

Diagram



Fields

Field	Description
31-8 —	Reserved
7-2 GPR_SZ	GPR Register Array Size BBNSM implements a register array of 32-bit words that ELKe firmware can use to retain the GPR values across ELKe power cycles. 00_0000 - This version of BBNSM does not implement a general-purpose register array. All other values - The number of 32-bit words implemented in the general-purpose register array.
1-0 —	Reserved

33.6.1.4 BBNSM Control Register (BBNSM_CTRL)

The BBNSM Control register is used to enable features such as the real-time counter and the time alarm. It can also be used to calibrate the RTC or control the on/off logic for connecting to a PMIC.

Offset

Register	Offset
BBNSM_CTRL	8h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Description
31-29 —	Reserved
28-26 —	Reserved
25 TOSP	Turn Off System Power When set, a signal is sent to the PMIC to turn off the system power. This bit will clear once power is off. This bit is only valid when Dumb PMIC is enabled. 0 - Leave system power on. 1 - Turn off system power when Dumb PMIC is enabled.
24 DP_EN	Dumb PMIC Enable When set, software can control the system power. When cleared, the system requires a Smart PMIC to automatically turn power off. 0 - Smart PMIC is enabled. 1 - Dumb PMIC is enabled.
23 PK_OVR	PMIC On Request Override The value written to PK_OVR will be asserted on output signal bbnsm_pk_override. That signal is used to override the IOMUX control for the PMIC I/O pad. 0 - PMIC On Request Override is disabled. 1 - PMIC On Request Override is enabled.
22 PK_EN	PMIC On Request Enable The value written to PK_EN will be asserted on output signal bbnsm_pk_en. That signal is used to turn off the pullup/pulldown circuitry in the PMIC I/O pad. 0 - PMIC On Request is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - PMIC On Request is enabled.
21-20 TURN_ON_TIME	Turn-On Time Amount of time that button is pressed before pmic_en_b is asserted to turn on the SoC power. 00 - 500 milliseconds. 01 - 50 milliseconds. 10 - 100 milliseconds. 11 - 0 milliseconds.
19-18 DEBOUNCE	Debounce Time Amount of debounce time for the BTN input signal. 00 - 50 milliseconds. 01 - 100 milliseconds. 10 - 500 milliseconds. 11 - 0 milliseconds.
17-16 BTN_TIMEOUT	Button Press Timeout Time it takes to hold the button to request a power down in the condition of no alarm from BBNSM and tamper event asserted. 00 - 5 seconds. 01 - 10 seconds. 10 - 15 seconds. 11 - Timeout disabled. Long button presses will not request a power down.
15-13 —	Reserved
12-8 CAL_VAL	Calibration Value Defines signed calibration value for the RTC. This field can be programmed only when RTC calibration is disabled. This is a 5-bit twos' complement value. Hence, the allowable calibration values are in the range from -16 to +15 counts per 32768 ticks of the counter clock. Positive calibration values will not work with the time alarm feature. 0_0000 - +0 counts per each 32768 ticks of the counter clock. 0_0001 - +1 counts per each 32768 ticks of the counter clock. 0_0010 - +2 counts per each 32768 ticks of the counter clock. 0_1111 - +15 counts per each 32768 ticks of the counter clock. 1_0000 - -16 counts per each 32768 ticks of the counter clock. 1_0001 - -15 counts per each 32768 ticks of the counter clock.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1_1110 - -2 counts per each 32768 ticks of the counter clock. 1_1111 - -1 counts per each 32768 ticks of the counter clock.
7-5 —	Reserved
4 CAL_EN	Calibration Enable Enables the RTC calibration mechanism when set. This bit cannot be changed once set. 0 - RTC Time calibration is disabled. 1 - RTC Time calibration is enabled.
3-2 TA_EN	Time Alarm Enable 01 - Disable the time alarm. 10 - Enable the time alarm. A time alarm event occurs if the value in the real-time counter register is equal to the value in the time alarm register.
1-0 RTC_EN	Real-Time Counter Enable 01 - Disable the real-time counter. 10 - Enable the real-time counter.

33.6.1.5 BBNSM Interrupt Enable Register (BBNSM_INT_EN)

The BBNSM Interrupt Enable Register is used to enable interrupt generation when a status event has occurred in BBNSM. Interrupts supported include RTC rollover and time alarm. The bit assignments of this register appear below.

Offset

Register	Offset
BBNSM_INT_EN	10h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31-0 GPR	32 bits of the GPR.

Chapter 34
External Memories

34.1 Overview

This chip has these external memory interfaces and controllers:

- High Performance DRAM Interface
- SD/eMMC/SDIO Interface
- Flexible Serial Peripheral Interface (FlexSPI)

34.2 High Performance DRAM Interface (DDR)

The chip includes one 16-bit DRAM controller with LPDDR4x memory technology. Maximum supported capacity is 2GByte.

34.3 eMMC/SD/SDIO

This chip has three Ultra Secured Digital Host Controller (uSDHC) modules for SD/eMMC interface with simultaneous support for all three of 1x eMMC, 1x SD Card and 1x SDIO (for WIFI connectivity). It provides the interface between the host system and the SD/SDIO/eMMC cards.

The key features include:

- Support SD/SDIO standard, up to version 3.0
- Support eMMC standard, up to version 5.1
- Support 3.3V and 1.8V

34.4 Flexible Serial Peripheral Interface

The chip has one FlexSPI block that acts as an interface to one external Octal SPI or Quad SPI serial flash device, each with up to four bidirectional data lines. Both Serial NOR flash and Serial NAND flash are supported (both for boot and runtime operation).

The key features include:

- Channel A can be configured as 1/2/4/8-bit operation
- Support both dual-channel or single-channel operation
- Support both SDR mode and DDR mode
- Support up to 166MHz SDR Mode and 166MHz DDR Mode (with external Flash device DQS input)
- Support up to 133MHz SDR Mode and 66MHz DDR Mode (with internal DQS loopback through DQS pad mode)
- Support On-The-Fly AES Decryption (OTFAD) with 4 keys.

Chapter 35
DDR Memory Controller (DDRC)

Table 168. LPDDR4/4X - maximum supported densities

Max Data bus width	Maximum density	Assumed memory organization	Notes
16-bit	16 Gb/2GB	single rank, single channel device with 17-row addresses (R0 - R16)	Byte-mode LPDDR4/4X devices (x16 channel internally split between two dies, x8 each) of any density are not supported therefore, the numbers are applicable only to devices

Table continues on the next page...

Table 168. LPDDR4/4X - maximum supported densities

Max Data bus width	Maximum density	Assumed memory organization	Notes
			with x16 internal organization (referred to as "standard" in the JEDEC specification). The chip also supports dual rank single channel devices therefore, 16Gb/2GB density can be also achieved by using a dual rank single channel device with 16-row addresses (R0 - R15).

35.2 Overview

DDRC includes:

- In-line ECC that detects and corrects single-bit errors for reliable memory operation.
- Dynamic Power Management and Global Auto-Precharge modes that simplify system memory design.
- A large set of special features, including ECC error injection and rapid system debug support.

35.2.1 Block diagram

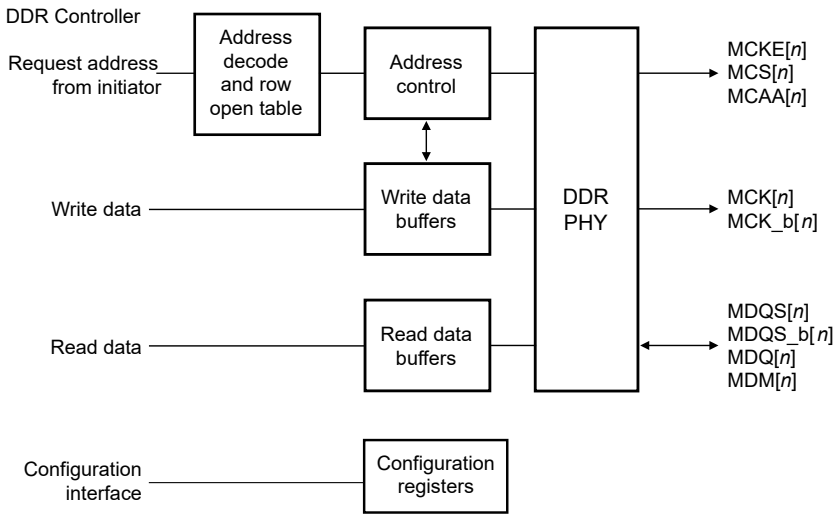

Figure 78. Block diagram

35.2.2 Features

- Support for DDR SDRAM standards:
  - LPDDR4

NOTE

DDRC is designed to support LPDDR4 SDRAMs that are compliant with JESD209-4B as of February 2017.

  - LPDDR4x

NOTE

DDRC is designed to support LPDDR4 SDRAMs that are compliant with JESD209-4B and JESD209-4-1 as of February 2017.

— LPDDR4X

NOTE

DDRC is designed to support LPDDR4X SDRAMs that are compliant with JESD209-4C, January 2020 and JESD209-4-1 as of January 2017.

- Support for the following data-bus widths:
  — 16-bit
- Programmable settings to meet all DDR SDRAM timing parameters
- Support for the following DDR SDRAM configurations:

NOTE

Please refer Chip-specific DDR information section for details on the configurations supported.

  — As many as two ranks, each rank independently addressable. Rank interleaving is also supported.
  — 1-Gbit to 16-Gbit for single channel LPDDR4 devices depending on the internal device configuration
  — 1-Gbit to 16-Gbit for single channel, 32-Gbit for dual channel LPDDR4x devices depending on the internal device configuration
  — x16 data ports
- Data mask signals and read-modify-write operations for subdoubleword writes (a read-modify-write sequence is only necessary when in-line ECC is enabled)
- SECDED in-line ECC
- Open-page management (dedicated entry for each logical bank)
- Automatic DDR SDRAM initialization sequence
- Automatic DDR SDRAM data initialization via the PHY
- Sleep power management
- Error injection
- Performance monitor counters that track the number of occurrences of specific events and generate an interrupt when an event count threshold is exceeded

35.3 Functional description

35.3.1 Overview

DDRC controls processor and I/O interactions with system memory. The memory system allows a wide range of memory devices to be mapped to any arbitrary rank, and provides support for discrete DRAMs .

DDRC receives read and write requests and decodes the transaction address to generate the rank, bank, row, and column addresses. DDRC compares the request's decoded address with values in the row-open table to determine if the address maps to an open page. If the transaction does not map to an open page, DDRC issues an ACTIVATE command.

Programmable parameters allow for a variety of memory organizations and timings.

Optional ECC protection is provided for the DDR SDRAM data bus. DDRC uses ECC to:

- Detect and correct all single-bit errors within the data bus.
- Detect all double-bit errors within the data bus.

DDRC allows you to open a dedicated page for each available DDR SDRAM bank. You can use DDR_SDRAM_INTERVAL[BSTOPRE] to control the amount of time (in clock cycles) that pages remain open.

Error management explains how DDRC handles errors.

35.3.2 Modes of operation

Table 169. Modes of operation

Mode	Description
Dynamic Power Management	In this mode, DDRC can reduce power consumption by negating the DDR SDRAM MCKE signal when no transactions are pending to the DDR SDRAM. This applies to LPDDR4, LPDDR4x only.
Global Auto-Precharge	In this mode, DDRC issues an auto-precharge command with every read or write transaction. To enter this mode: • Write 0 to DDR_SDRAM_INTERVAL[BSTOPRE]. • For separate ranks, write 1 to CS_CONFIG*n*[AP_EN]. See Page-related modes and rank retention for more details.
Open-Page	In this mode, DDRC retains the currently active DDR SDRAM page by not issuing a precharge command. See Page-related modes and rank retention for more details.

35.3.3 Remapping regions

You can use the REMAP_*n*A and REMAP_*n*B registers to remap four regions.

You cannot:

- Overlap regions using REMAP_*n*A and REMAP_*n*B.
- Overlap a mapped region using REMAP_*n*A and REMAP_*n*B with an unmapped region.
- Enable a region for a register if all the regions below that register are enabled as well. This means that:
  - If you write 1 to REMAP_1A[REG_1_REMAP_EN], you must also write 1 to REMAP_0A[REG_0_REMAP_EN].
  - If you write 1 to REMAP_2A[REG_2_REMAP_EN], you must also write 1 to REMAP_0A[REG_0_REMAP_EN] and REMAP_1A[REG_1_REMAP_EN].
  - If you write 1 to REMAP_3A[REG_3_REMAP_EN], you must also write 1 to REMAP_0A[REG_0_REMAP_EN], REMAP_1A[REG_1_REMAP_EN], and REMAP_2A[REG_2_REMAP_EN].

The comparison with Rank n Memory Bounds (CS0_BNDS - CS1_BNDS) occurs after DDRC remaps the AXI addresses mentioned in Remap Region 0B Configuration (REMAP_0B), Remap Region 1B Configuration (REMAP_1B), and Remap Region 2B Configuration (REMAP_2B) to the addresses mentioned in Remap Region 0A Configuration (REMAP_0A), Remap Region 1A Configuration (REMAP_1A) and Remap Region 2A Configuration (REMAP_2A) respectively. You must program Rank n Memory Bounds (CS0_BNDS - CS1_BNDS) to match the addresses after remapping. After remapping, you can access the addresses (programmed in the REMAP_[0-3]A registers) only via the AXI addresses captured in the REMAP_[0-3]B registers. Mapped and nonmapped regions cannot overlap.

ECC is generated based on the AXI address that DDRC receives. DDR_SDRAM_CFG_2[D_INIT] must be 0 so that there is no data initialization in progress, and none scheduled. After writing 1 to DDR_SDRAM_CFG[MEM_EN], execute a write-only memory test on the entire DDR memory region to initialize ECC. If the AXI addresses being remapped are noncontiguous, ensure that the memory test starts from the lowest address range.

For example, if Rank n Memory Bounds (CS0_BNDS - CS1_BNDS) indicates a memory range of 8000_0000h–81FF_FFFFh, program the REMAP registers for mapping 7A00_0000h–7BFF_FFFFh (REMAP_*n*B) to 8000_0000h–81FF_FFFFh (REMAP_*n*A). The ECC calculation uses the AXI address received (7A00_0000h–7BFF_FFFFh).

35.3.4 Timing parameters spanning multiple fields

35.3.4.1 Precharge-to-activate interval (t_{RP})

Calculate t_{RP}, in clock cycles, using this equation:

$$t_{RP} = \text{TIMING_CFG_3[EXT_PRETOACT]} \times 16d + \text{TIMING_CFG_1[PRETOACT]}$$

where TIMING_CFG_1[PRETOACT] must not be 0000

Equation 1. Precharge-to-activate interval (t_{RP})

35.3.4.2 Activate-to-precharge interval (t_{RAS})

Calculate t_{RAS}, in clock cycles, using the following table. The table demonstrates that the minimum value for t_{RAS} is 4.

Table 170. Activate-to-precharge interval (t_{RAS})

When TIMING_CFG_3[EXT_ACTTOPRE] is:	and TIMING_CFG_1[ACTTOPRE] is:	t_{RAS} equals:
000b	0000b	16
	0001b	17
	0010b	18
	0011b	19
	0100b–1111b	TIMING_CFG_1[ACTTOPRE]
001b–111b	0000b–1111b	TIMING_CFG_3[EXT_ACTTOPRE] × 16d + TIMING_CFG_1[ACTTOPRE]

35.3.4.3 Activate-to-read-or-write interval (t_{RCD})

Calculate t_{RCD}, in clock cycles, using this equation:

$$t_{RCD} = \text{TIMING_CFG_3[EXT_ACTTORW]} \times 16d + \text{TIMING_CFG_1[ACTTORW]}$$

where TIMING_CFG_1[ACTTORW] must not be 0

Equation 2. Activate-to-read-or-write interval (t_{RCD})

35.3.4.4 Refresh recovery time (t_{RFC})

Calculate t_{RFC}, in clock cycles, using this equation:

$$t_{RFC} = \text{TIMING_CFG_3[EXT_REFREC]} \times 16d + \text{TIMING_CFG_1[REFREC]} + 8$$

where TIMING_CFG_3[EXT_REFREC] must be less than 11_0000b

Equation 3. Refresh recovery time (t_{RFC})

35.3.4.5 CAS latency

CAS latency is the number of clock cycles between the registration of DDR SDRAM's READ command and the availability of the first output data. For example, if DDRC registers a READ command at clock edge *n* and the latency is *m* clocks, data is available nominally coincident with clock edge *n* + *m*. The largest-possible CAS latency is 44 clock cycles.

Calculate the latency using this equation:

$$\text{CAS latency} = \text{TIMING_CFG_3[EXT_CASLAT]} \times 8d + \text{TIMING_CFG_1[CASLAT]} + 1$$

Equation 4. CAS latency

35.3.4.6 Minimum write recovery interval (n_{WR})

n_{WR} specifies the number of clock cycles from the last data associated with a write command until a precharge command is allowed. Calculate n_{WR} using this equation:

$$n_{WR} = \text{TIMING_CFG_3[EXT_WRREC]} \times 16d + \text{TIMING_CFG_1[WRREC]}$$

Equation 5. Minimum write recovery interval (n_{WR})

35.3.4.7 Minimum MCKE pulse width (t_{CKE})

Calculate t_{CKE}, in clock cycles, using this equation:

$$t_{CKE} = \text{TIMING_CFG_3[EXT_CKE_PLS]} \times 8d + \text{TIMING_CFG_2[CKE_PLS]}$$

Equation 6. Minimum MCKE pulse width (t_{CKE})

35.3.4.8 Four-activate window (t_{FAW})

t_{FAW} is the time during which you can issue no more than four activate commands. Calculate t_{FAW}, in clock cycles, using this equation:

$$t_{FAW} = \text{TIMING_CFG_3[EXT_FOUR_ACT]} \times 64d + \text{TIMING_CFG_2[FOUR_ACT]}$$

where TIMING_CFG_2[FOUR_ACT] must not be 0

Equation 7. Four-activate window (t_{FAW})

35.3.4.9 Precharge power-down exit timing (t_{XP})

t_{XP} defines how long DDRC must wait after exiting precharge power-down before issuing a command to the DDR SDRAM. Calculate t_{XP}, in clock cycles, using this equation:

$$t_{XP} = \text{TIMING_CFG_0[EXT_PRE_PD_EXIT]} \times 16d + \text{TIMING_CFG_0[PRE_PD_EXIT]}$$

where TIMING_CFG_0[PRE_PD_EXIT] must not be 0

Equation 8. Precharge power-down exit timing (t_{XP})

35.3.4.10 Activate-to-activate interval (t_{RRD})

Calculate t_{RRD}, in clock cycles, using this equation:

$$t_{RRD} = \text{TIMING_CFG_3[EXT_ACTTOACT]} \times 16d + \text{TIMING_CFG_1[ACTTOACT]}$$

Equation 9. Activate-to-activate interval (t_{RRD})

where TIMING_CFG_1[ACTTOACT] must not be 0.

35.3.4.11 Write-to-read delay (t_{WTR})

Calculate t_{WTR}, in clock cycles, using this equation:

$$t_{WTR} = \text{TIMING_CFG_3[EXT_WRTORD]} \times 16d + \text{TIMING_CFG_1[WRTORD]}$$

Equation 10. Write-to-read delay (t_{WTR})

where TIMING_CFG_1[WRTORD] must not be 0.

35.3.4.12 Read-to-write turnaround

Calculate the read-to-write turnaround, in clock cycles, using this equation:

$$\text{Read-to-write turnaround} = \text{TIMING_CFG_0[RWT]} + \text{TIMING_CFG_4[EXT_RWT]} \times 4d + CL - WL + (BL \div 2) + 5$$

Equation 11. Read-to-write turnaround

where:

- CL = the CAS latency rounded up to the next integer
- WL = the programmed write latency
- BL = the burst length

35.3.4.13 Write-to-read turnaround

Calculate the write-to-read turnaround, in clock cycles, using this equation:

$$\text{Write-to-read turnaround} = \text{TIMING_CFG_0[WRT]} + \text{TIMING_CFG_4[EXT_RWT]} \times 4d + CL - WL + (BL \div 2) + 1$$

Equation 12. Write-to-read turnaround

where:

- CL = the CAS latency rounded up to the next integer
- WL = the programmed write latency
- BL = the burst length

35.3.4.14 Read-to-read turnaround

Calculate the read-to-read turnaround, in clock cycles, using this equation:

$$\text{Read-to-read turnaround} = \text{TIMING_CFG_0[RRT]} + \text{TIMING_CFG_4[EXT_RRT]} \times 4d + (BL \div 2) + 1$$

Equation 13. Read-to-read turnaround

where BL is the burst length.

35.3.4.15 Write-to-write turnaround

Calculate the write-to-write turnaround, in clock cycles, using this equation:

$$\text{Write-to-write turnaround} = \text{TIMING_CFG_0[WWT]} + \text{TIMING_CFG_4[EXT_WWT]} \times 4d + (BL \div 2)$$

Equation 14. Write-to-write turnaround

where BL is the burst length. The maximum value that can be added to (BL ÷ 2) is 21 clock cycles.

35.3.4.16 Total write latency

Calculate the total write latency, in clock cycles, using this equation:

$$\text{Total write latency} = \text{TIMING_CFG_3[EXT_WR_LAT_2]} \times 32d + \text{TIMING_CFG_2[EXT_WR_LAT]} \times 16d + \text{TIMING_CFG_2[WR_LAT]}$$

Equation 15. Total write latency

Follow these restrictions:

- The total write latency must be:
  - 34 cycles or less.
  - At least four clock cycles.
- Do not write 0b–101b to TIMING_CFG_2[WR_LAT] unless TIMING_CFG_2[EXT_WR_LAT] = 1.

35.3.5 Memory-test address restrictions

DDRC has restrictions for any individual memory test when you use the value of DDR_MTCR[MT_ADDR_EN] to limit the address range to be tested. In this case, neither of the following concatenated values (specified by curly brackets) can be less than the value used during the previous test:

- Starting address {DDR_MT_ST_EXT_ADDR[MT_ST_EXT_ADDR], DDR_MT_ST_ADDR[MT_ST_ADDR]}
- Ending address {DDR_MT_END_EXT_ADDR[MT_END_EXT_ADDR], DDR_MT_END_ADDR[MT_END_ADDR]}

35.3.6 Burst-oriented accesses

Read and write accesses to memory are burst-oriented—accesses start at a selected location and continue for a programmed burst (16 data beats). Accesses to closed pages begin with the registration of an ACTIVATE command, followed by a READ or WRITE command. To access an open page, you do not need an ACTIVATE command.

The address coincident with the ACTIVATE command specifies the logical bank and row to be accessed.

The address coincident with the READ or WRITE command specifies the logical bank and starting column for the burst access.

35.3.7 DDR SDRAM interface operation

DDRC supports the DDR SDRAM configurations shown in Supported DDR SDRAM configurations. The Command Address bus (CA) signals support numerous device densities. The CS signals (see External signals) support up to two ranks of memory. The data path to individual ranks is 16 bits wide.

DDRC supports ranks up to max 16 Gbit per device channel for LPDDR4, LPDDR4X.

The ranks can be constructed using memory devices that are internally organized as x16 memory devices. The MDM signals provide byte selection for memory accesses.

NOTE

A 16-bit DDR SDRAM device has two MDM signals associated with specific halves of the 16 data signals (DQ[0:7] and DQ[8:15]).

When ECC is enabled, DDRC performs all memory accesses on doubleword boundaries (that is, all MDM signals assert simultaneously). However, when ECC is disabled, the memory system uses the MDM signals for byte lane selection when using x16 devices.

35.3.7.1 Relationship of byte lanes to data for x16 devices

Table 171. Relationship of byte lanes to data for x16 devices

Data byte lane	Data bus mask	Data bus strobe	Data bus
0	MDM[0]	MDQS[0] and MDQS_B[0]	MDQ[0:7]
1	MDM[1]	MDQS[1] and MDQS_B[1]	MDQ[8:15]

35.3.7.2 Supported DDR SDRAM configurations

35.3.7.2.1 LPDDR4 LPDDR4x

NOTE

Byte-mode LPDDR4 LPDDR4x devices (x16 channel internally split between two dies, x8 each) of any density are not supported therefore, the numbers are applicable only to devices with x16 internal organization (referred to as "standard" in the JEDEC specification).

NOTE

Dual rank single channel devices are supported therefore, 16Gb/2GB density can be also achieved by using a dual rank single channel device with 16-row addresses (R0 - R15). The tables below always assume single rank configurations.

Table 172. LPDDR4, LPDDR4x x16 device, single 16-bit channel

Device capacity (Gbit)	Device configuration	Row × column × bank bits
1	64 Mbit × 16	13 × 10 × 3
2	128 Mbit × 16	14 × 10 × 3
4	256 Mbit × 16	15 × 10 × 3
8	512 Mbit × 16	16 × 10 × 3
16	1 Gbit × 16	17 × 10 × 3

35.3.7.2.2 Transaction request outside of the programmed address range

If DDRC receives a transaction request and the address does not lie within any of the programmed address ranges for an enabled rank, DDRC reports a memory-select error. See Error management for a detailed description of errors.

35.3.7.2.3 Firmware configures DDRC

System firmware uses the memory-boundary registers to configure DDRC to map the size of each rank in memory.

DDRC uses its bank map to assert the appropriate MCS*n*_b signal for memory accesses according to the provided rank starting and ending addresses. You are not required to map the ranks to a contiguous address space.

35.3.8 DDR SDRAM address multiplexing

This section shows the address bit encodings for the supported DDR SDRAM configurations.

The address and bank address are encoded within the DDR SDRAM command that is presented on the MCAA pins.

NOTE

For LPDDR4, LPDDR4x memories, the DDR SDRAM command includes the MA bits described in this section.

35.3.8.1 LPDDR4 LPDDR4X, 16-bit data bus, no interleaving

Table 173. LPDDR4 LPDDR4X, 16-bit data bus, no interleaving

		High bit	Address from core initiator																														Low bit
Row × col		32	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
17 × 10 × 3	MCAA ROW			16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	MCAA COL																							9	8	7	6	5	4	3	2	1	0	

35.3.9 DDR SDRAM refresh

DDRC supports auto-refresh and self-refresh commands.

Normal operation uses auto-refresh. You control this command by using DDR_SDRAM_INTERVAL[REFINT].

Use self-refresh only when you configure DDRC to enter a sleep power-management state.

The REFINT value:

- Specifies the number of memory bus clock cycles between refresh cycles
- Must accommodate possible outstanding transactions to complete before a refresh request is sent to the memory after the REFINT value is reached

If a memory transaction is in progress when REFINT is reached, the refresh cycle waits for the transaction to complete. In the worst-case scenario, the refresh cycle must wait for the number of bus clock cycles that the longest programmed access requires. Therefore, NXP recommends that the programmed REFINT value be less than what the DDR SDRAM requires. This ensures that a memory transaction does not cause any latency that could violate the device refresh period,

When a refresh cycle is required, DDRC:

1. Completes all current memory requests.
2. Closes all open pages by issuing a PRECHARGE-ALL command to each DDR SDRAM bank with an open page (as indicated by the row open table).
3. Issues one or more auto-refresh commands to each of the DDR SDRAM banks, as identified by their MCS signals, to refresh one row in each bank of the selected rank.

DDRC staggers the auto-refresh commands across the possible banks to reduce the system's instantaneous power requirements. When the memory is populated with two ranks, DDRC issues two sets of auto-refresh commands on consecutive cycles. DDRC also staggers the initial PRECHARGE-ALL commands in two groups for convenience. For this entire refresh sequence, no cycle optimization occurs for the usual case where fewer than two ranks are installed.

When the refresh sequence completes, DDRC initiates any pending memory requests after an inactive period specified by TIMING_CFG_1[REFREC] and TIMING_CFG_3[EXT_REFREC]. DDRC also supports posted refreshes that allow you to use a longer refresh interval.

35.3.9.1 DDR SDRAM refresh timing

You specify the DDR SDRAM refresh timing using TIMING_CFG_1[REFREC].

After reset, you must configure the refresh timing (TIMING_CFG_1[REFREC]) and the extended refresh recovery time (TIMING_CFG_3[EXT_REFREC]) before attempting to access the DDR SDRAM.

35.3.9.2 DDR SDRAM self-refresh and power-saving modes

In normal operation, DDRC issues auto-refresh commands based on the refresh timing (TIMING_CFG_4[EXT_REFINT], DDR_SDRAM_INTERVAL[REFINT]). In low-power modes, DDRC must issue self-refresh commands to preserve the data. You control when DDRC performs a self-refresh by:

- Setting the self-refresh idle threshold (DDR_SR_CNTR[SR_IT]).
- Writing 1 to DDR_SDRAM_CFG_2[FRC_SR].

In the absence of refresh support, you must preserve DDR SDRAM data—for example, by copying the data to disk.

For LPDDR4 LPDDR4x, Dynamic Power Management mode offers tight control of the memory system's power consumption by trading power for performance. This mode uses the MCKE signal to dynamically power down the DDR SDRAM when there is no system memory activity. The MCKE signal deasserts when both of the following conditions are met:

- DDRC has not scheduled any memory refreshes.
- DDRC has not scheduled any memory accesses.

The MCKE signal asserts when a new access or refresh is scheduled. You control this mode by using DDR_SDRAM_CFG[DYN_PWR].

Powering up the DDR SDRAM when a new memory reference is scheduled causes an access latency penalty, depending on:

- Whether you use active or precharge powerdown.
- The settings of TIMING_CFG_0[ACT_PD_EXIT] and TIMING_CFG_0[PRE_PD_EXIT].

35.3.10 DDR SDRAM data beat ordering

DDRC always performs transfers to and from memory in 16-beat bursts. For transfer sizes other than 16 beats, the data transfers still operate as 16-beat bursts. If you enable ECC and either the access is not doubleword aligned or the size is not a multiple of a doubleword (8 byte), DDRC performs a full read-modify-write operation for a write to the DDR SDRAM. If you disable ECC or both accesses are doubleword-aligned with a size that is a multiple of a doubleword, you can use the data-mask signals to prevent the writing of unwanted data to the DDR SDRAM. DDRC also uses data masks to prevent the writing of all unintended full double words to the DDR SDRAM. For example, if you want a one-doubleword (8-byte) write transaction (in 16-bit channel), the remaining 12 beats of data are not written to the DDR SDRAM.

All writes to LPDDR4, LPDDR4x, memory align to beat 0 of the DDR SDRAM.

35.3.11 Page-related modes and rank retention

DDRC manages pages differently in Global Auto-Precharge mode and in Open-Page mode.

In Global Auto-Precharge mode, DDRC uses the DDR SDRAM auto-precharge feature. This feature allows DDRC to indicate that the DDR SDRAM must automatically close the page after the read or write access. This access is performed by using MA[10] of the address during the COMMAND phase of the access to enable auto-precharge. Auto-precharge is nonpersistent—you enable or disable it for each individual READ or WRITE command. You can, however, enable or disable auto-precharge separately for each rank. You disable Global Auto-Precharge mode by either of the following:

- Write 0 to DDR_SDRAM_INTERVAL[BSTOPRE]
- Write 1 to CS_CONFIG[AP_EN]

In Open-Page mode, DDRC allows an open page for each DDR SDRAM rank. In Open-Page mode, DDRC also retains the currently active DDR SDRAM page by not issuing a precharge command. The page remains opens until one of the following conditions occurs:

- The refresh interval completes.
- The time specified in DDR_SDRAM_INTERVAL[BSTOPRE] elapses.
- A bank row collision occurs with another transaction that DDRC just received.

Open-Page mode can dramatically reduce access latencies for page hits. Depending on the memory system design and timing parameters, using Open-Page mode can save several clock cycles for subsequent burst accesses that hit an active page. You can also obtain better performance by using more ranks.

35.3.12 ECC

DDRC supports ECC for the data path between the core and the system memory. The memory detects all double-bit errors and corrects all single-bit errors. It may detect other errors as well but not correct them. Double-bit errors are always reported when error reporting is enabled. When a single-bit error occurs, DDRC:

- Increments ERR_SBE[SBEC].
- Compares ERR_SBE[SBEC] to ERR_SBE[SBET].
- Reports an error if these values are equal.

You can program Single-Bit ECC Memory Error Management (ERR_SBE) in a way that DDRC corrects and ignores minor memory faults, but a catastrophic memory failure generates an interrupt.

For writes that are smaller than 64 bits, DDRC:

1. Performs a double-word read from system memory of the address for the write, checking for errors.
2. Merges the write data with the data read from memory.
3. Generates a new ECC code for the merged double word.
4. Writes the data and ECC code to memory.

If DDRC detects a multi-bit error after the read, the transaction completes the read-modify-write operation to prevent DDRC from hanging. However, the corrupt data is masked on the write, so the original contents in the DDR SDRAM remain unchanged.

35.3.13 Error management

35.3.13.1 Overview

DDRC detects these types of errors:

- Single-bit
- Multi-bit[2]
- Memory-select

This section and its subsections assume that you enabled all the relevant error detection, correction, and reporting functions as described in:

- Memory Error Address Capture (CAPTURE_ADDRESS)
- Memory Error Attributes Capture (CAPTURE_ATTRIBUTES)
- Memory Error Extended Address Capture (CAPTURE_EXT_ADDRESS)
- Memory Data Path Read Capture High (CAPTURE_DATA_HI)
- Memory Data Path Read Capture Low (CAPTURE_DATA_LO)
- Memory Data Path Read Capture ECC (CAPTURE_ECC)
- Memory Error Detect (ERR_DETECT)
- Memory Error Disable (ERR_DISABLE)
- Memory Error Interrupt Enable (ERR_INT_EN)

[2] DDRC uses SECDED ECC, which corrects single-bit errors and detects double-bit errors. Detection of errors of more than two bits is not guaranteed. In this chapter, "multi-bit errors" refers to double-bit errors.

35.3.13.2 Error summary

Table 174. Error summary

Category	Error	Description	Action
Notification	Single-bit ECC threshold	The number of ECC errors has reached the threshold specified in Single-Bit ECC Memory Error Management (ERR_SBE).	If you enable interrupts, DDRC reports the error by generating the appropriate interrupt.
Access error	Multi-bit ECC error	A multi-bit ECC error is detected during a read or read-modify-write memory operation.	
	Memory-select error	Read or write address does not fall within the address range of any of the memory banks.	

35.3.13.3 Single-bit errors

DDRC counts and reports single-bit errors depending on how you program Single-Bit ECC Memory Error Management (ERR_SBE). DDRC does this when it detects a single-bit error:

1. Corrects the data.
2. Increments ERR_SBE[SBEC].
3. Generates a critical interrupt if ERR_SBE[SBEC] = ERR_SBE[SBET].
4. Completes the transaction normally.

35.3.13.4 Multi-bit errors

DDRC does this when it detects a multi-bit error for a read operation:

1. Logs the error in ERR_DETECT[MBE].
2. Optionally generates the machine-check or critical interrupt (if you enable these as described in Memory Error Disable (ERR_DISABLE)).

35.3.13.5 Memory-select errors

These errors occurs when the address from the memory request does not fall into any of the enabled, programmed rank address ranges. DDRC does this when it detects a memory-select error:

1. Logs the error.
2. Optionally generates a critical interrupt (if you enable it as described in Memory Error Detect (ERR_DETECT)).

For all memory-select errors, DDRC does not issue any transactions onto the pins after the first read returns data strobes.Writes are not issued to the ADDR/CMD pins, but reads are issued to the first enabled rank. Write transaction is issued to the DRAM and the read transaction is not issued to the DRAM.

35.3.14 Performance monitoring

Performance monitor counters (PMC0–PMC10) are used to count events specified by the performance monitor local control registers.

- PMC0 (PMC0a and PMC0b) is a 64-bit counter that counts only clock cycles.
- PMC1–PMC10 are 32-bit counters that can monitor 64 counter-specific events in addition to counting 64 reference events.

The following figure shows the performance monitoring components, which consist of:

- One global control register (PMGC0)
- One 64-bit counter (PMC0)

- Ten 32-bit counters (PMC1–PMC10)
- Two local control registers for each counter

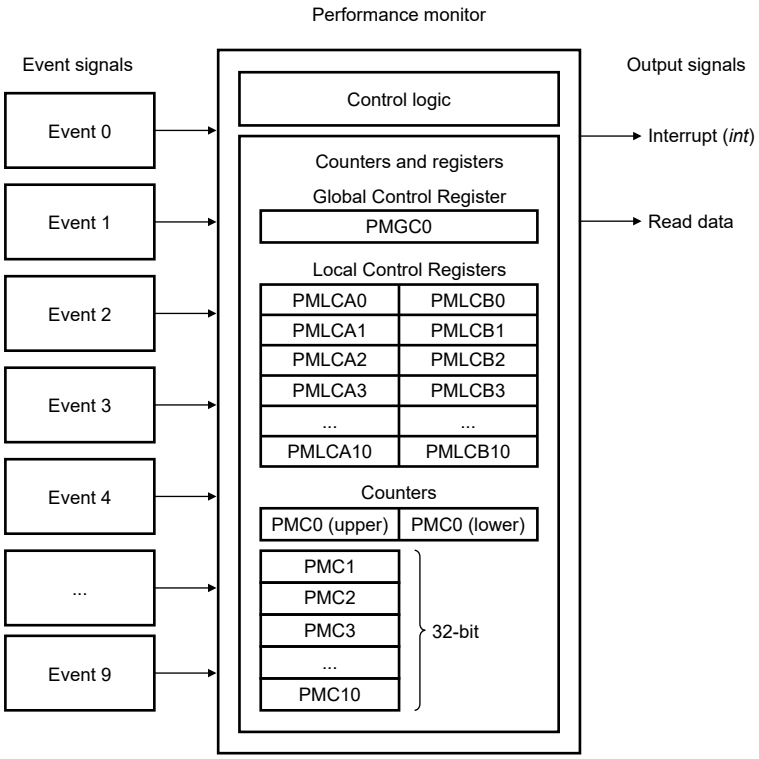

Figure 79. Performance monitor block diagram

The global control register, PMGC0, affects all counters and takes priority over local control registers.

The local control registers are divided into two groups:

- Local control A registers specify:
  - Counter freezing
  - Overflow condition enable
  - Event selection
  - Burstiness

  Local control register PMLCA0, which controls counter PMC0, does not contain event selection because PMC0 counts only cycles.
- Local control B registers:
  - Start and stop triggering
  - Contain the counters' threshold values
  - Contain the threshold multiplier

  Local control register PMLCB0, which controls PMC0, does not contain threshold information because PMC0 only counts cycles.

Performance monitor events are signaled by the functional blocks in DDRC and are selectively recorded in the counters.

- 64 of the events, called reference events, can be counted on any of the ten counters.
- The remaining events, called counter-specific events, can be counted only on the counter where the event is defined.

The performance monitor can generate an interrupt upon a counter overflow. The PMCs can also be programmed to freeze when an interrupt is signaled.

35.3.14.1 Performance monitor interrupt

PMCs can generate an interrupt on an overflow when the most significant bit of a counter transitions to 1. For the interrupt to be signaled, the condition enable field for the counter (PMLCA*n*[CE]) and performance monitor interrupt enable field (PMGC0[PMIE]) must both be 1.

When an interrupt is signaled and the freeze-counters-on-enabled-condition-or-event field (PMGC0[FCECE]) is 1, PMGC0[FAC] is set to 1 by hardware and all of registers are frozen. Software can clear the interrupt condition by resetting the performance monitor and writing 0 to the most significant bit of the counter that generated the overflow.

35.3.14.2 Event counting

PMC1–PMC10 can count the occurrences of specific events. PMC0 is designated to count only clock cycles. However, to provide flexibility, a total of 64 reference events can be counted on any of the 32-bit PMCs (PMC1–PMC10). Additionally, up to 64 unique events can be counted on each 32-bit counter.

You must reset the performance monitor before event-counting sequences. Reset the performance monitor by first freezing one or more counters and then clearing the freeze condition to enable the counters to count according to the register settings. You can freeze counters individually by writing 1 to PMLCA*n*[FC], or simultaneously by writing 1 to PMGC0[FAC]. Writing 0 to these fields enables the performance monitor to begin counting based on the register settings.

Using PMLCA*n*[FC] to reset the performance monitor resets only counter *n*.

35.3.14.3 Threshold events

The threshold feature allows characterization of events that can take a variable number of clock cycles to complete. A threshold event is counted only if the latency is greater than the threshold value specified in PMLCB*n*[THRESHOLD].

There are two types of threshold events:

- Duration threshold events
- Quantity threshold events

35.3.14.3.1 Duration threshold events

For duration threshold events, the 32-bit PMCs increment only when the duration of the event is equal to or greater than the threshold value. The threshold value is scaled by a multiple specified in PMLCB*n*[TBMULT].

A threshold event requires two signals:

- One signal indicates when a threshold event sequence begins.
- A second signal indicates when the event ends.

An internal counter determines when the threshold count is exceeded and when the PMC can increment. This internal counter decrements during a threshold event sequence until it reaches the value of one. A new sequence cannot begin until the current one completes.

Additional threshold start signals are ignored during a sequence until a threshold stop signal occurs. When both a start and stop signal are asserted during the same cycle in a current sequence, the stop terminates the current sequence and the start signals the beginning of a new one. However, if both signals are asserted during the same cycle while not in a current event sequence, both signals are ignored. The following figure is a timing diagram for duration threshold event counting.

Several illegal conditions for threshold counting cause undefined behavior. An illegal condition exists if the threshold value obtained from PMLCB*n*[THRESHOLD] and PMLCB*n*[TBMULT] is less than two. Under these conditions, the intent of threshold counting is ambiguous.

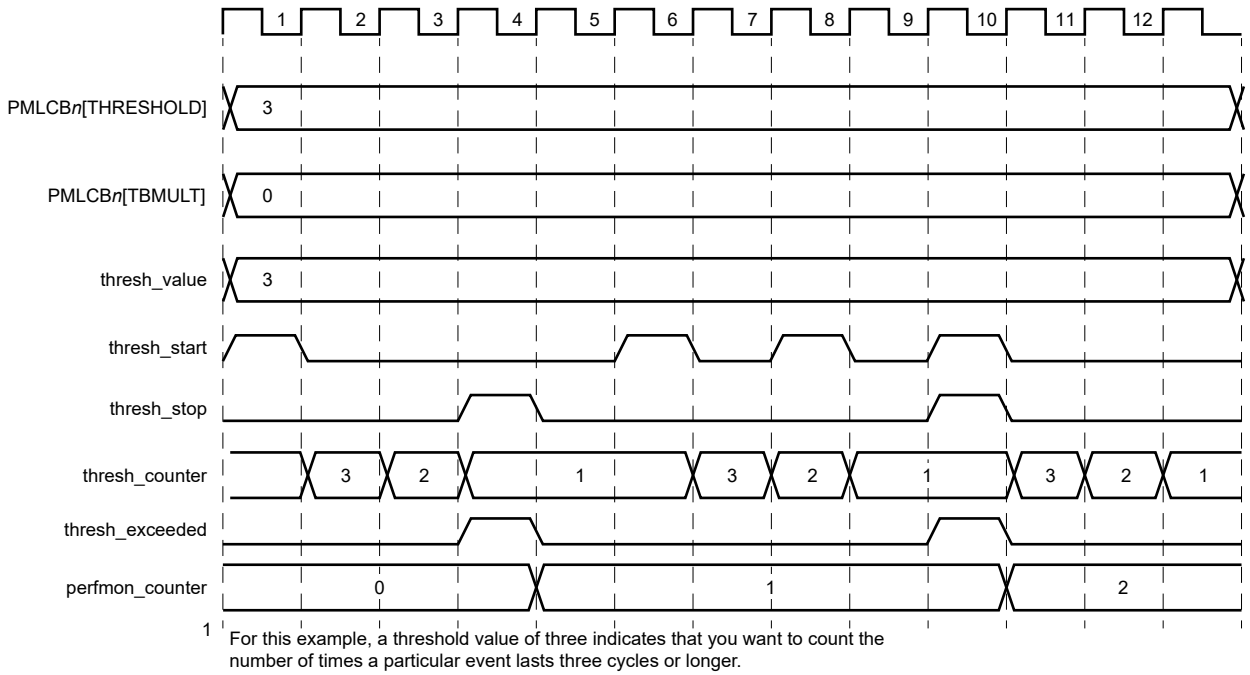

Figure 80. Duration threshold event sequence timing diagram

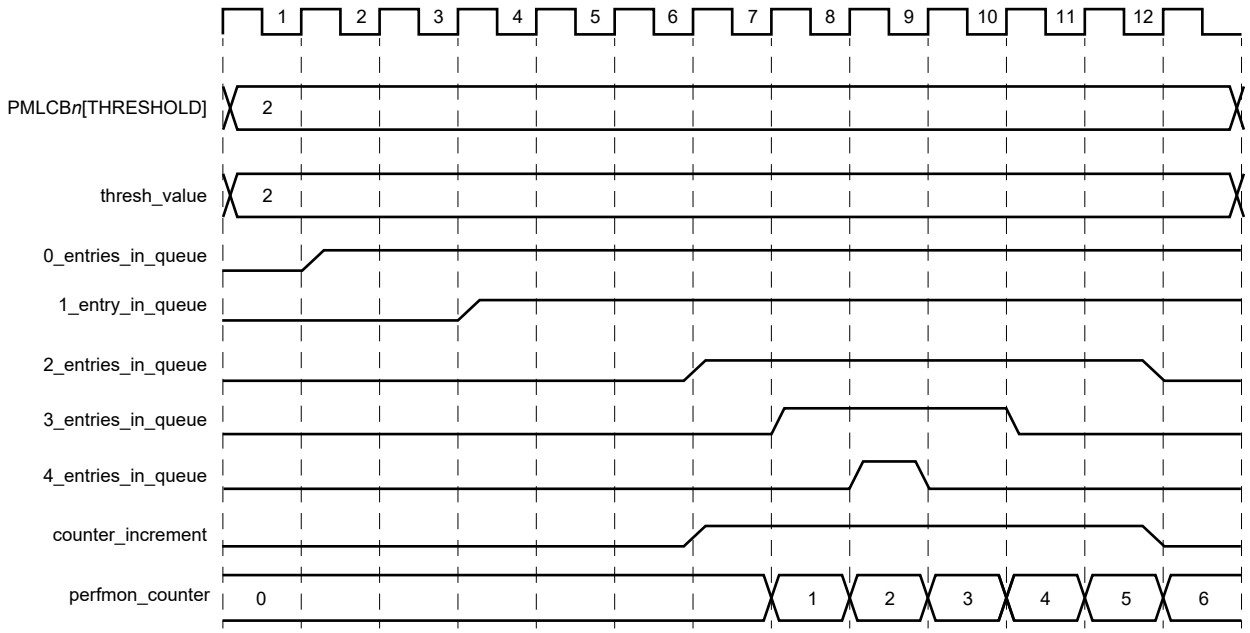
35.3.14.3.2 Quantity threshold events

For quantity threshold events, the performance monitor counter is only incremented when the specified threshold event exceeds the threshold value. These events do not use the multiplier register field (PMLCB*n*[TBMULT]) like the duration threshold events. This type of threshold event is generally used to monitor the usage of buffers and queues. For example, the usage of a specific queue could be characterized by measuring the amount of time the queue is completely full or partially full. For this example, the threshold field would be used to specify how many entries are required to be valid in the queue for that event to be counted. The following figure shows a timing diagram for quantity threshold event counting.



Note: For this example, a threshold value of two indicates that you want to count the number of cycles. There are at least two valid entries in a particular queue.

Figure 81. Quantity threshold event sequence timing diagram

35.3.14.4 Event signals table

Table 175. Event signals

Event ID	Event type	Counter(s)	PMLCA*n*[EVENT] value[1] (h)	Description
REF_12	Reference	C1–C10	0C	Number of read-modify-writes that are required due to ECC
REF_13	Reference	C1–C10	0D	Number of times a read is reordered ahead of another transaction
REF_14	Reference	C1–C10	0E	Number of times a write is reordered ahead of another transaction
REF_15	Reference	C1–C10	0F	Number of internal controller cycles the DDR controller samples data from the DDR PHY for reads
REF_17	Reference	C1–C10	11	Number of pipelined reads that were page misses
REF_18	Reference	C1–C10	12	Number of pipelined reads or writes that were page misses
REF_19	Reference	C1–C10	13	Number of non-pipelined reads that were page misses
REF_22	Reference	C1–C10	16	Number of non-pipelined reads or writes that were page misses
REF_23	Reference	C1–C10	17	Number of pipelined reads that were page hits
REF_24	Reference	C1–C10	18	Number of pipelined reads or writes that were page hits
REF_25	Reference	C1–C10	19	Number of non-pipelined reads that were page hits

Table continues on the next page...

Table 175. Event signals (continued)

Event ID	Event type	Counter(s)	PMLCA*n*[EVENT] value[1] (h)	Description
REF_27	Reference	C1–C10	1B	Number of precharges issued to DRAM that are not caused by a refresh
REF_28	Reference	C1–C10	1C	Number of page misses for oldest transaction
REF_31	Reference	C1–C10	1F	Number of page hits for oldest transaction
REF_59	Reference	C1–C10	3B	Number of precharges including PRE_ALL commands for refreshes
REF_61	Reference	C1–C10	3D	Number of precharges due to bank collision
REF_63	Reference	C1–C10	3F	Number of cycles that commands are stalled due to lack of resources for DRAM access timings
PMC2_72	Counter	C2	48	Number of cycles the scheduler is empty
PMC2_73	Counter	C2	49	Number of filtered write data beats
PMC3_72	Counter	C3	48	Number of cycles the scheduler is full
PMC3_73	Counter	C3	49	Number of filtered read data beats per mask 0
PMC4_72	Counter	C4	48	Number of transactions that load a read for a read-modify-write
PMC4_73	Counter	C4	49	Number filtered read data beats per mask 1
PMC5_72	Counter	C5	48	Number of times medium priority read is loaded to scheduler
PMC5_73	Counter	C5	49	Number of filtered read data beats per mask 2
PMC6_64	Counter	C6	40	Number of cycles interface is blocked for a refresh (only valid for all-bank refresh)
PMC6_72	Counter	C6	48	Number of times low-priority read is loaded to scheduler
PMC7_64	Counter	C7	40	Number of cycles the scheduler is half full
PMC7_65	Counter	C7	41	Number of times a write is loaded to scheduler
PMC8_64	Counter	C8	40	This signal asserts each time the read/write bias is switched for arbitration
PMC8_65	Counter	C8	41	Number of cycles the scheduler is 1/4 full
PMC9_65	Counter	C9	41	Number of cycles the scheduler is 3/4 full
PMC10_65	Counter	C10	41	Number of times high priority read is loaded to scheduler

1. All values not listed are reserved.

35.3.14.5 Chaining

By configuring one counter to increment each time another counter overflows, several counters can be chained together to provide event counts larger than 32 bits. Each counter in a chain adds 32 bits to the maximum count. The register chaining sequence is not arbitrary and is specified indirectly by selecting the register overflow event to be counted. Selecting an event has the effect of selecting a source register because all available chaining events, are dedicated to specific registers.

The chaining overflow event occurs when the counter reaches its maximum value and wraps, not when the register's most significant bit transitions to 1. For this overflow to occur, PMLCA*n*[CE] must be zero to avoid signaling an interrupt when the

counter's most significant bit transitions to 1. Several cycles may be required for the chained counters to reflect the true count because of the internal delay between when an overflow occurs and a counter increments.

35.3.14.6 Triggering

Triggering allows one counter to start or stop counting on the change of another counter or on the overflow of another counter. More specifically, if PMC1 is set to start or stop counting as a result of a change or overflow in counter PMC2, then counter PMC2 must be identified in the local control register of counter PMC1. This is done by appropriately setting the trigger-on select bit or trigger-off select bit (PMLCB1[TRIGONSEL] or PMLCB1[TRIGOFFSEL]). Additionally, the condition that triggers the counter must be selected by configuring the corresponding control bits (PMLCB1[TRIGONCNTL] or PMLCB1[TRIGOFFCNTL]). Assuming the counter is enabled by other control register settings, the counter increments (or freezes) when its specified event occurs after the trigger-on (or off) condition occurs.

When trigger on and trigger off are both selected, the trigger-off condition is ignored until the trigger-on condition has occurred. Furthermore, when a trigger-off condition occurs, the counter state is preserved; it is not restarted by subsequent trigger-on conditions.

Triggering is disabled when the counter's trigger-select bits specify itself as the trigger source. Similarly, triggering is disabled when the trigger control bits are cleared.

35.3.14.7 Burstiness counting

The burstiness counting feature makes it easier to characterize events that occur in rapid succession followed by a relatively long pause. As shown in the table below, event bursts are defined by size, granularity, and distance.

Table 176. Burstiness counting

Parameter	Description	Register field
Size	The minimum number of events constituting a burst	PMLCA*n*[BSIZE]
Granularity	The maximum time between individual events counted as members of the same burst	PMLCA*n*[BGRAN]
Distance	The minimum time between bursts	PMLCA*n*[BDIST] × PMLCB*n*[TBMULT]

The figure below shows the relationships between size, granularity, and distance. Burstiness counting can be performed for all events except threshold events.

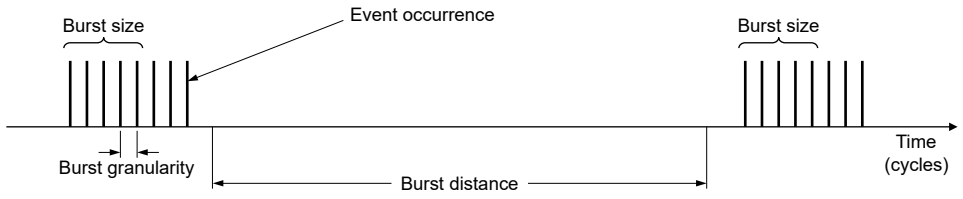

Figure 82. Burst size distance granularity and burstiness counting

The burstiness size field (PMLCA*n*[BSIZE]) specifies the minimum number of event occurrences that constitute a burst. A burst is identified when the number of event occurrences equals or exceeds PMLCA*n*[BSIZE]. Furthermore, these individual event occurrences must be separated by no more clock cycles than the value in the burstiness granularity field (PMLCA*n*[BGRAN]). Although a burst is identified when the minimum number of events occurs, it is not counted until the burst sequence has ended. A burst sequence ends when the specified burstiness granularity is exceeded, at which point the last valid event has occurred for that sequence.

PMLCA*n*[BGRAN] specifies the maximum number of cycles between individual events for them to qualify as members of the same burst sequence.

The burstiness distance field (PMLCA*n*[BDIST]) and threshold/burstiness multiplier field (PMLCB*n*[TBMULT]) specify the acceptable number of cycles between the end of a burst sequence and the beginning of a new sequence for a group of event occurrences to be counted as an individual burst.

The product of the burstiness distance field and the threshold/burstiness multiplier field determine the burstiness distance value used to determine when another burst sequence can begin. Note that the burst distance count begins when a new burst sequence ends and the PMC is incremented. No new burst sequence may begin until the burst distance count has reached zero. After the burst distance count reaches zero, it holds the zero value indicating that a new burst sequence can be counted. The burst distance count begins again when a new burst sequence is identified and counted.

Burstiness counting is disabled when the definition of a burst is ambiguous, that is, when the burst size field is less than two, or the burst distance is zero. When burstiness counting is disabled, regular counting is allowed.

Figure 83 shows that the burst distance is measured from the end of one burst sequence and that a new burst sequence may not begin until the burst distance count expires.

Three internal counters track the different values required for burstiness counting.

- Burstiness size is monitored by a counter. It is loaded with the value specified in the local control register when the burst granularity counter and the burst distance counters reach zero, and no new event is occurring. It always decrements when the following conditions occur: its value is not already zero, an event occurs, and the burst distance count equals zero.
- Burstiness granularity is monitored by a counter that is loaded with the specified value in the local control register on the rising edge of an event occurrence whenever the burst distance count equals zero. The granularity counter is decremented (if it has not already reached zero) when an event is not occurring and burst distance count equals zero.
- Burstiness distance is measured by a counter (burst_dist_ctr) that is loaded with the product of PMLCB*n*[BDIST] and PMLCB*n*[TBMULT] when a burst sequence has been identified and counted. This counter is decremented when burstiness counting is enabled (and the counter has not already reached zero).

A burst is counted at the end of a burst sequence when the three burst parameter counters are all zero. Figure 83 shows a burstiness counting example.

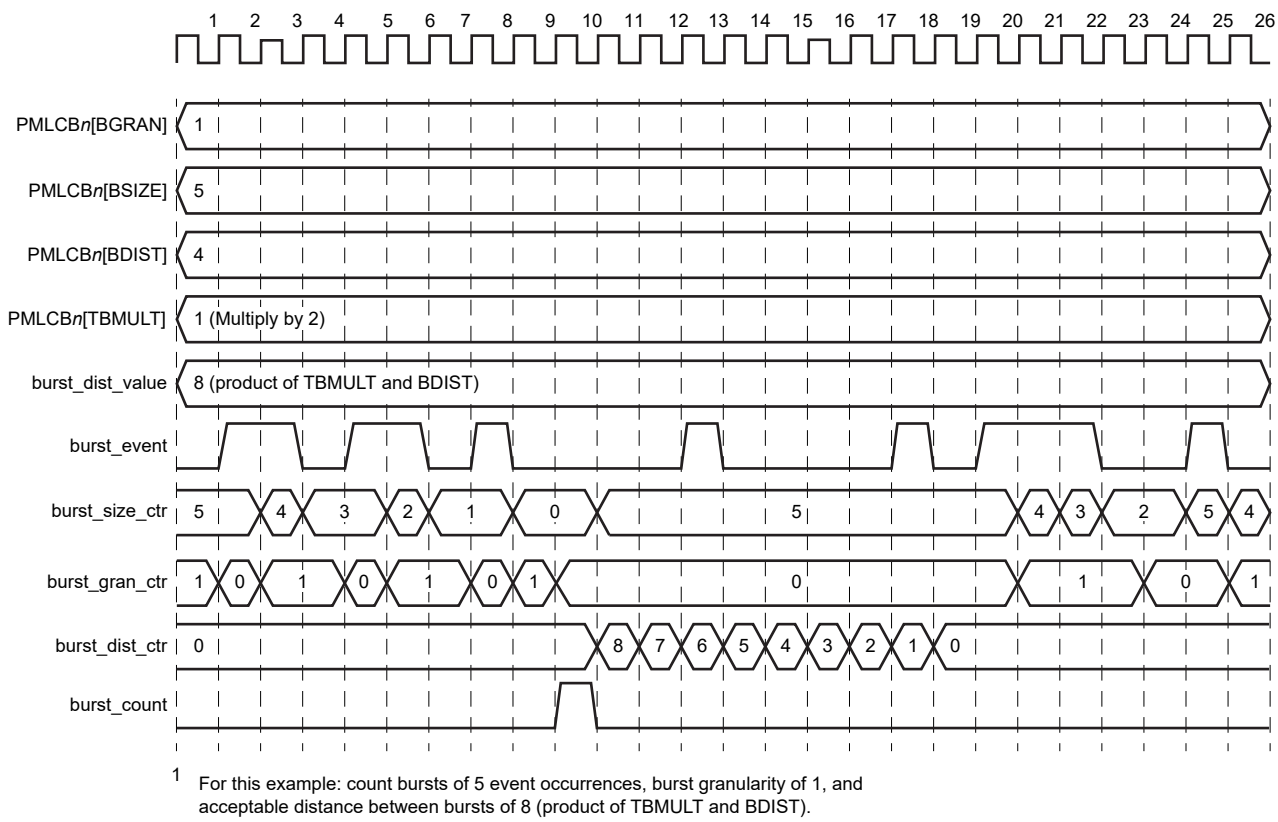

Figure 83. Burstiness counting timing diagram

35.3.15 Clocking

This module has no clocking considerations.

35.3.16 Interrupts

This section describes the interrupts generated by DDR.

Interrupts are generated in the following cases:

- Performance monitor counters generate an interrupt when an event count threshold is exceeded.
- Catastrophic memory failure.
- In case of a single-bit error if ERR_SBE[SBEC] = ERR_SBE[SBET], critical interrupt is generated. See Single-Bit ECC Memory Error Management (ERR_SBE) for details.
- In case of a multi-bit error if ERR_DISABLE[MBED] = 0, ERR_INT_EN[MBEE] and ERR_EN[ECC_EN] = 1, machine-check or critical interrupt is generated. See Memory Error Disable (ERR_DISABLE), Memory Error Interrupt Enable (ERR_INT_EN) and for details.
- In case of Memory-select errors if ERR_DETECT[MBE], ERR_INT_EN[MBEE] and ERR_EN[ECC_EN] = 1
- The performance monitor signals an interrupt when PMGC0[FCECE] = 1
- Writing 1 to PMCn[PMCn] may cause immediate interrupt
- ERR_INT_EN[MSEE, SBEE, MBEE, SSBE12E, REFRATEEE, UPDTMTEE,] enables ECC interrupts or memory-select error interrupts

35.4 External signals

This section provides a summary and details of DDRC external signals.

See the chip data sheet for:

- A pinout diagram showing pin numbers
- Electrical and mechanical specifications

35.4.1 Signal summary LPDDR4 LPDDR4X

Table 177. Signal summary

Name	Description	Reset	Pins	Input or output
MCAA[5:0]	LPDDR4, LPDDR4X address and command	All zeros	6	Output
MCK	DDR SDRAM clock output	0	1	Output
MCK_b	DDR SDRAM clock output (complement)	1	1	Output
MCKE[0:1]	DDR SDRAM clock enable		2	Output
MCS[1:0]_b	CS	All ones	2	Output
MDM[1:0]	Data mask	All zeros	2	Output
MDQ[15:0]	Data bus	All zeros	16	Input or output
MDQS[1:0]	Data strobes	All zeros	2	Input or output

ZN	Driver impedance calibration	See the chip data sheet	1	Input or output

35.4.2 Signal details LPDDR4 LPDDR4X

Table 178. Signal details

Signals	Description	
LPDDR4 LPDDR4X address and command bus MCAA[5:0]	These signals control DDRC outputs for the DDR SDRAM. MA0 is the least-significant bit of the DDRC address output. A is for channel A.	
	Input	—
	Output	These signals represent the address that DDRC drives. They contain different portions of the address depending on the memory size and the DDR SDRAM command that DDRC issues. See DDR SDRAM address multiplexing for a complete mapping of these signals. When DDRC is enabled, it always drives the address, which is valid when a transaction is driven to DDR SDRAM. The signals are in the high-impedance state when DDRC is disabled.
DDR SDRAM clock outputs	These signals comply with the JEDEC DDR SDRAM specifications, which require true and complement clocks. The DDR SDRAM sees a clock edge when the true and complement signal waveforms cross.	

Table continues on the next page...

Table 178. Signal details (continued)

Signals	Description	
• MCK • MCK_b	Input	—
	Output	These signals provide the DDR SDRAM clock output and its complement.
Clock enable MCKEA	This signal enables the clock for the DDR SDRAM. You can deassert it to stop clocking the DDR SDRAM. You must connect this signal for the same memory rank as the corresponding MCK and MCK_b pair.	
	Input	—
	Output	Assertion of this signal indicates that clocking for the DDR SDRAM is enabled. Deassertion of this signal indicates that clocking for the DDR SDRAM is disabled and the DDR SDRAM must ignore MCK or MCK_b signal transitions. MCK and MCK_b become irrelevant during MCKE deassertion. This signal asserts when you write 1 to DDR_SDRAM_CFG[MEM_EN]. DDRC: • Negates this signal when DDRC enters Dynamic Power Management mode or performs a self-refresh. • Asserts this signal again when DDRC exits Dynamic Power Management mode or finishes a self-refresh.
Chip selects MCSA[1:0]_b	These signals select a physical DDR SDRAM rank to perform a memory operation as described in Rank n Memory Bounds (CS0_BNDS - CS1_BNDS) and Rank n Configuration (CS0_CONFIG - CS1_CONFIG).	
	Input	—
	Output	DDRC asserts these signals to begin a memory cycle and negates them when no DDR SDRAM action occurs during the current cycle. The transaction must follow the timing constraints defined in the TIMING_CFG_*n* registers.
DDR SDRAM data output masks MDM[1:0]	These signals mask unwanted bytes of data transferred during a write. You need these signals to support sub-burst-size transactions (such as single-byte writes) on DDR SDRAM where all input and output occurs in multi-byte bursts. MDM0 corresponds to the least-significant byte and MDM1 corresponds to the most-significant byte. Relationship of byte lanes to data for x16 devices shows byte lane encodings. The timing of these signals is the same as that of MDQ*n*.	
	Input	—
	Output	Asserting these signals prevents writing to the DDR SDRAM. Deasserting these signals allows you to read or write the corresponding byte in the DDR SDRAM.
Data bus MDQ[15:0]	These signals provide a bidirectional data bus for DDRC's input and output signals.	

Table continues on the next page...

Table 178. Signal details (continued)

Signals	Description	
	When these signals are in the high-impedance state, no READ or WRITE commands are in progress, and neither DDRC nor the DDR SDRAM drives any data.	
	Input	The signals represent the data that the external DDR SDRAMs drive during a READ transaction.
	Output	The signals represent the data that DDRC drives when writing to the DDR SDRAM.
Data strobes • MDQS[1:0] • MDQS[1:0]_b	These are differential signals that indicate when the MDQ signals convey valid data. See DDR SDRAM interface operation for byte-lane assignments.	
	Input	These signals are driven high when positive capture data is received and driven low when negative capture data is received. If a READ command is registered at clock edge *n*, and you program the latency in TIMING_CFG_1[CASLAT] to be *m* clocks, data strobes at the DDR SDRAM assert coincidentally with the data on clock edge *n*+*m*.
	Output	These signals are driven high when positive capture data is transmitted and driven low when negative capture data is transmitted. If a WRITE command is registered at clock edge *n*, data strobes at the DDR SDRAM assert centered in the data eye on clock edge *n*+1.
Driver impedance calibration ZN	This signal is used for automatic driver calibration. See the chip data sheet for the proper value and connection of the ZN resistor.	
	Input	DDRC drives this signal for four DDR SDRAM cycles at a time when DDRC executes the automatic driver compensation.
	Output	

35.5 Initialization

35.5.1 Fields to initialize at startup

Your boot code must configure the following fields at system reset or startup.

35.6.2 Rank n Memory Bounds (CS0_BNDS - CS1_BNDS)

Defines the starting and ending address of the memory space that corresponds to rank *n*.

When writing to this register, you must ensure that:

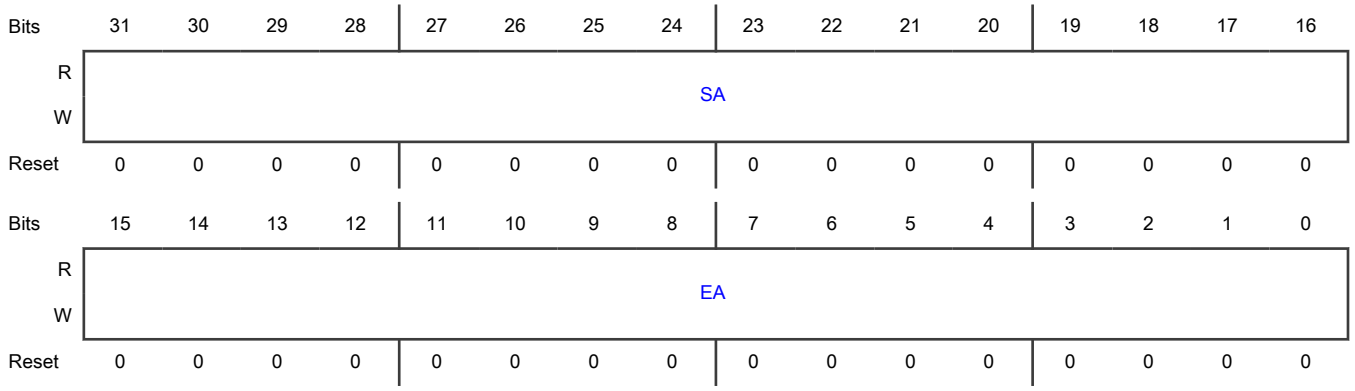
- The memory-space size you specify must equal the size of the physical DDR SDRAM.
- EA is greater than or equal to SA.

When you enable rank interleaving, DDRC uses only the fields in the lower interleaved rank to define the memory space, and does not use the other ranks' CS*n*_BNDS registers. For example, if ranks 0 and 1 are interleaved, DDRC uses CS0_BNDS but does not use CS1_BNDS.

Offset

Register	Offset
CS0_BNDS	0h
CS1_BNDS	8h

Diagram



Fields

Field	Description
31-16 SA	Starting Address Specifies the starting address for rank *n*. DDRC compares the lower 8 bits of this field with the 8 most-significant bits of the 32-bit address. You must write 0b to the upper 8 bits of this field.
15-0 EA	Ending Address Specifies the ending address for rank *n*. DDRC compares the lower 8 bits of this field with the 8 most-significant bits of the 32-bit address. You must write 0b to the upper 8 bits of this field.

35.6.3 Remap Region 0A Configuration (REMAP_0A)

Works with Remap Region 0B Configuration (REMAP_0B) to enable a region that you can remap to a different memory region as DDRC receives the remap address. See Remapping regions for what you can and cannot do when remapping.

The comparison with Rank n Memory Bounds (CS0_BNDS - CS1_BNDS) occurs after DDRC remaps the AXI address mentioned in REMAP_[0-3]B registers on the address mentioned in REMAP_[0-3]A registers. You must program Rank n Memory Bounds (CS0_BNDS - CS1_BNDS) to match the address after remapping. The addresses after remapping (programmed in REMAP_[0-3]A registers) can be accessed only via AXI addresses captured in REMAP_[0-3]B registers. Mapped and nonmapped regions cannot overlap.

35.6.20 DDRC Address Decode 9 (DDR_ADDR_DEC_9)

Defines how the specified bits of the DDR SDRAM address are mapped to the original address of the transaction when you enable address decode overrides via DDR_ADDR_DEC_9[ADDR_DEC_OVRD].

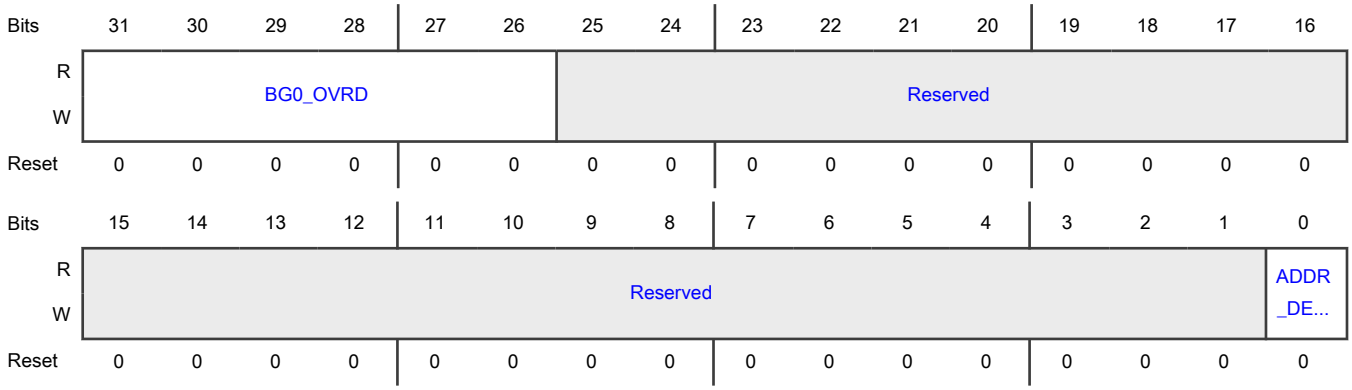
NOTE

When inline ECC is used for LPDDR4, LPDDR4x, we cannot override, lowest 7 Column bits and upper 3 row bits when ECC is enabled.

Offset

Register	Offset
DDR_ADDR_DEC_9	64h

Diagram



Fields

Field	Description
31-26 BG0_OVRD	Bank Group 0 Override Indicates the placement of bank group bit 0 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1.
25-1 —	Reserved
0 ADDR_DEC_OVRD	Address Decode Override Enables the DDR_ADDR_DEC_*n* registers to define the address decode scheme. If this field is enabled, you can implement all the fields of the DDR_ADDR_DEC_*n* registers while leaving a proper field for memory controller interleaving. When using a 16-bit bus, the least-significant bit of the address does not have an override bit mapped to it, and when using a 32-bit bus, the two least-significant bits of the address do not have an override bit mapped to them. When using inline ECC, you cannot alter the lower 7 column bits from their standard placement via the address decode registers.

35.6.21 Rank n Configuration (CS0_CONFIG - CS1_CONFIG)

Enables the DDR SDRAM rank and sets the number of row and column bits used for the rank.

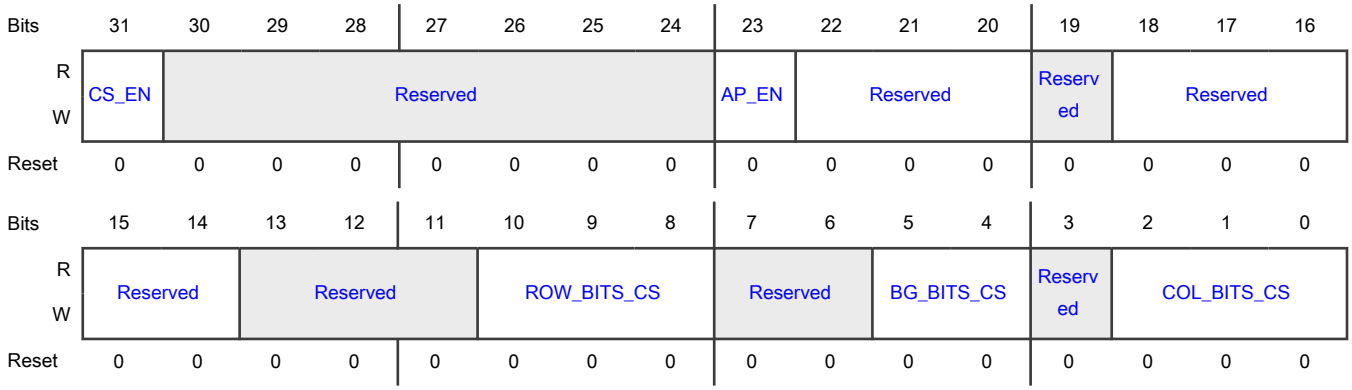
You must write the correct number of row and column bits for each DDR SDRAM to this register.

Because ROW_BITS_CS and COL_BITS_CS establish address multiplexing, you must ensure that you wrote the correct values.

Offset

Register	Offset
CS0_CONFIG	80h
CS1_CONFIG	84h

Diagram



Fields

Field	Description
31 CS_EN	Rank Enable Enables rank *n*. When CS_EN = 1, the rank assumes the state defined in Rank n Memory Bounds (CS0_BNDS - CS1_BNDS). The DDR PHY initialization begins when you write 1 to this field and completes when DDRC changes DDRDSR_2[PHY_INIT_CMPLT] to 1. You must write 1 to DDR_SDRAM_CFG[MEM_EN] after the initialization completes. 0 - Disables 1 - Enables
30-24 —	Reserved
23 AP_EN	Auto-Precharge Enable Enables the auto-precharge command for rank *n*. The rank: • Precharges automatically only if you enabled Global Auto-Precharge mode (DDR_SDRAM_INTERVAL[BSTOPRE] = 0). • Always issues an auto-precharge command for read and write transactions. 0 - Disables 1 - Enables
22-20 —	Reserved
19 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
18-16 —	Reserved
15-14 —	Reserved
13-11 —	Reserved
10-8 ROW_BITS_CS	Row Bits Specifies the number of row bits for the DDR SDRAM on rank *n*. If any rank uses 18 row bits, then all enabled ranks must use 18 row bits. 000 - 12 001 - 13 010 - 14 011 - 15 100 - 16 101 - 17 All other values are reserved.
7-6 —	Reserved
5-4 BG_BITS_CS	Bank Group Bits Specifies the number of bank group bits for DDR SDRAM on rank *n*. When using an LPDDR4, LPDDR4x compliant memory, you must write 1 to this field because the DDRC BG0 functionality controls the BA2 bit of LPDDR4. 00 - 0 01 - Must be set to 1 to enable the 3rd bank address bit for LPDDR4, LPDDR4x memories. 10 - Reserved for LPDDR4 11 - Reserved
3 —	Reserved
2-0 COL_BITS_CS	Column Bits Indicates the number of column bits for the DDR SDRAM on rank *n*. 000 - 8 001 - 9

19-17 CASLAT	CAS Latency Specifies clock cycles that combine with TIMING_CFG_3[EXT_CASLAT] to define the CAS latency (see CAS latency).
16 —	Reserved
15-12 REFREC	Refresh Recovery Specifies clock cycles that combine with TIMING_CFG_3[EXT_REFREC] to define t_{RFC} (see Refresh recovery time (t_{RFC})).
11-8 WRREC	Write Recovery Specifies clock cycles that combine with TIMING_CFG_3[EXT_WRREC] to define n_{WR} (see Minimum write recovery interval (n_{WR})). The value 0b is reserved when TIMING_CFG_3[EXT_WRREC] = 0.
7-4 ACTTOACT	Activate-To-Activate Interval Specifies the number of clock cycles from an activate command until another activate command is allowed for a different logical bank in the same physical bank. This field indicates the activate-to-activate interval (t_{RRD}). 0000 - Reserved All other values - Clock cycles as defined in the description
3-0 WRTORD	Write-To-Read Interval Specifies the number of clock cycles between the last write data pair and the subsequent read command to the same physical bank. This field indicates the last write data pair to read command issue interval (t_{WTR}) for LPDDR4xLPDDR4. 0000 - Reserved All other values - Clock cycles as defined in the description

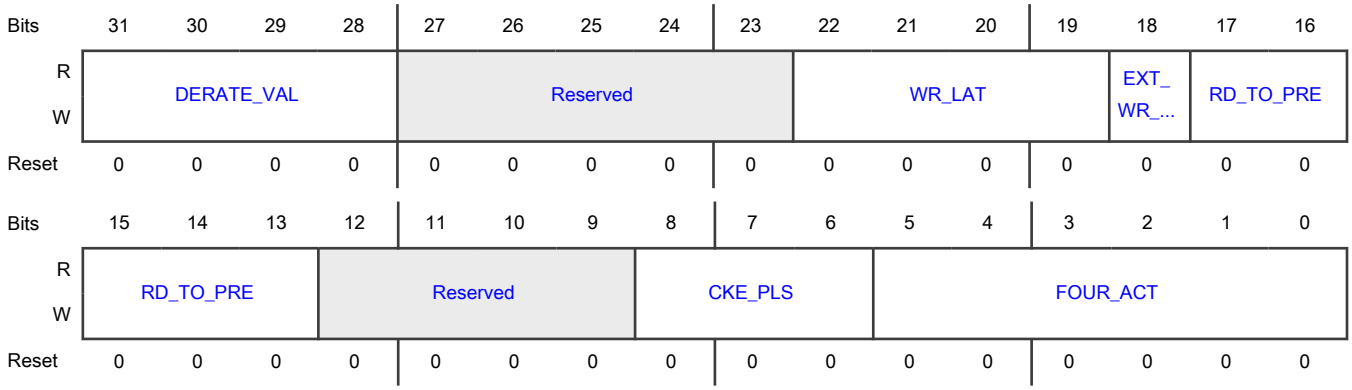
35.6.25 DDR SDRAM Timing Configuration 2 (TIMING_CFG_2)

Sets the clock delay to data for writes.

Offset

Register	Offset
TIMING_CFG_2	10Ch

Diagram



Fields

Field	Description
31-28 DERATE_VAL	Derate Value Enables you to specify the number of cycles used for de-rating DDR SDRAM timing parameters when you set the dynamic refresh rate DDR_SDRAM_CFG_3[DYN_REF_RATE_EN] and the monitored rate requires timing parameter de-rating.
27-23 —	Reserved
22-19 WR_LAT	Write Latency Specifies clock cycles that combine with TIMING_CFG_2[EXT_WR_LAT] and TIMING_CFG_3[EXT_WR_LAT_2] to define the total write latency (see Total write latency).
18 EXT_WR_LAT	Extended Write Latency Enables you to add extra clock cycles that combine with TIMING_CFG_2[WR_LAT] and TIMING_CFG_3[EXT_WR_LAT_2] to define the total write latency (see Total write latency).
17-13 RD_TO_PRE	Read-To-Precharge Time Specifies the read-to-precharge time n_{RTP}) in clock cycles for LPDDR4. Specifies the read-to-precharge time (t_{RTP}) in clock cycles for LPDDR4x. 0_0000 - Reserved All other values - Clock cycles as defined in the description
12-9 —	Reserved
8-6 CKE_PLS	MCKE Pulse Specifies clock cycles that combine with TIMING_CFG_3[EXT_CKE_PLS] to define t_{CKE} (see Minimum MCKE pulse width (t_{CKE})).
5-0	Four Activate

Table continues on the next page...

Table continued from the previous page...

Field	Description
FOUR_ACT	Specifies clock cycles that combine with TIMING_CFG_3[EXT_FOUR_ACT] to define t_{FAW} (see Four-activate window (t_{FAW})).

35.6.26 DDR SDRAM Control Configuration (DDR_SDRAM_CFG)

Enables:

- The DDR SDRAM interface logic.
- Operating features such as self-refresh, error check and correction, and dynamic power management.

Offset

Register	Offset
DDR_SDRAM_CFG	110h

Diagram

R W	NUM_PR				Reserved	Reserved	Reserved	Reserved	Reserved	Reserved		D_INIT	Reserved	Reserved	Reserved	Reserved
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31 FRC_SR	Force Self-Refresh Specifies the mode in which DDRC operates or enters. 0 - Normal mode 1 - Self-Refresh mode
30 —	Reserved
29-28 —	Reserved
27-24 MCK_DIS	MCK Disable Can be used to disable up to 4 MCK clock pairs, if available, according to the following table.

When you have:	MCK_DIS bit 3:	MCK_DIS bit 2:	MCK_DIS bit 1:	MCK_DIS bit 0:
MCK0	Disables or enables the MCK0 clock pair	Does nothing		
MCK0 and MCK1		Disables or enables the MCK1 clock pair	Does nothing	
MCK0, MCK1, and MCK2			Disables or enables the MCK2 clock pair	Does nothing
MCK0, MCK1, MCK2, and MCK3				Disables or enables the MCK3 clock pair

NOTE

- MCK_DIS bit 0 is register bit 24, MCK_DIS bit 1 is register bit 25, and so on.
- In this chip, only MCK0 pair is available, hence only bit 3 is applicable.

0b - Enable the clock pair

1b - Disable the clock pair

7 —	Reserved
6-5 —	Reserved
4 D_INIT	DDR SDRAM Data Initialization Indicates the status of data initialization. You write 1 to this field, and DDRC writes 0 to it. If you write 1 before DDRC is enabled, DDRC automatically initializes the DDR SDRAM after DDRC is enabled. DDRC automatically writes 0 to the field after the initialization is complete. You can only write 1 to this field when DDRC is idle and DDR_MTCR[MT_EN] = 0. This field remains enabled until the initialization is complete. DDR SDRAM Data Initialization (DDR_DATA_INIT) initializes the DDR SDRAM. 0 - No data initialization in progress, and none scheduled 1 - DDRC to initialize the DDR SDRAM after DDRC is enabled
3 —	Reserved
2 —	Reserved
1 —	Reserved. NXP recommends writing 1 to this field.
0 —	Reserved

35.6.28 DDR SDRAM Mode Control (DDR_SDRAM_MD_CNTL)

Enables you to:

- Issue an MRW command to a particular rank.
- Force the MCKE signals to a specific value.

Table 180. DDR_SDRAM_MD_CNTL field settings

Field	MRW	Refresh	Precharge
MD_EN	1	0	0
SET_REF	0	1	0

Table continues on the next page...

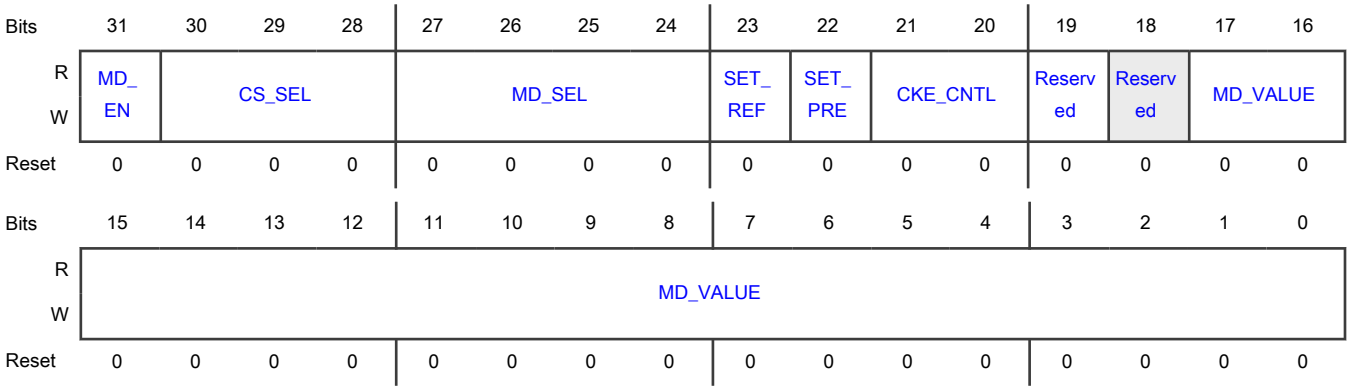
Table 180. DDR_SDRAM_MD_CNTL field settings (continued)

Field	MRW	Refresh	Precharge
SET_PRE	0	0	1
CS_SEL	Chooses rank		
MD_SEL	Selects the mode register	-	Selects a logical bank and bank group
MD_VALUE	Indicates the value written to the mode register	-	Only bit 7 is significant
CKE_CNTL	0	0	0

Offset

Register	Offset
DDR_SDRAM_MD_CNTL	120h

Diagram



Fields

Field	Description
31 MD_EN	Mode Enable This field specifies that valid data in DDR_SDRAM_MD_CNTL[MD_VALUE] is ready to be written to the DDR SDRAM via an MRW command. DDR_SDRAM_MD_CNTL[MD_SEL] selects the specific mode register. Additionally, you must select the rank by writing 1 to DDR_SDRAM_MD_CNTL[CS_SEL]. You write 1 to this field and DDRC writes 0 to it after the selected command is issued. **NOTE** You must not write 1 to this field unless DDR_SDRAM_CFG_3[DYN_REF_RATE_EN] is 0. The following procedure is required when disabling this field.

Table continues on the next page...

Field	Description
	Prior to disabling DDR_SDRAM_CFG_3[DYN_REF_RATE_EN], the following procedure is required to ensure any pending autonomous hardware based mode register operations are complete: 1. Clear DDR_SDRAM_MPR5[MPR_VLD] (set to 0) 2. Poll DDR_SDRAM_MPR5[MPR_VLD] until it is set to 1 which indicates that the latest dynamic refresh MR4 read has completed 3. Immediately clear (disable) DDR_SDRAM_CFG_3[DYN_REF_RATE_EN] Finally, poll DDR_SDRAM_MD_CNTL[MD_EN] to ensure it is 0 to ensure any pending software initiated mode register operations are complete prior to setting to 1. 0 - Does not need to be issued 1 - Valid data contained in the register ready to be issued as an MRW command
30-28 CS_SEL	Select Rank Specifies the rank that is driven active because of a command that you force in this register. 000 - 0 001 - 1 100 - 0 and 1 All other values are reserved.
27-24 MD_SEL	Mode Register Select Selects: • The DDR SDRAM mode register to be changed during a mode select command. • The DDR SDRAM logical bank to be precharged during a precharge command. The precharge-all and refresh commands ignore this field. MD_SEL[0:1] is not used with LPDDR4 LPDDR4x DDR SDRAM. 0000 - MR 0001 - EMR 0010 - EMR2 0011 - EMR3
23 SET_REF	Set Refresh Specifies whether a refresh command must be issued. Forces an immediate refresh to be issued to the rank, as specified by DDR_SDRAM_MD_CNTL[CS_SEL]. You write 1 to this field and DDRC writes 0 to it after the command is issued. LPDDR4 LPDDR4x DDR SDRAM does not support this field. 0 - No 1 - Yes
22 SET_PRE	Set Precharge Specifies whether a precharge command must be issued.

Table continues on the next page...

Field	Description
	Forces a precharge or precharge-all command (depending on the value of DDR_SDRAM_MD_CNTL[MD_VALUE]) to be issued to the rank, as specified by DDR_SDRAM_MD_CNTL[CS_SEL]. You write 1 to this field and DDRC writes 0 to it after the command is issued. LPDDR4 LPDDR4x DDR SDRAM does not support this field. 0 - No 1 - Yes
21-20 CKE_CNTL	Clock Enable Control Specifies the value to which MCKE signals are forced. This field enables you to globally assert or deassert all the MCKE signals issued to the DDR SDRAM. After you force a value to MCKE, DDRC continues to force that value until one of the following occurs: • You write 0 to this field. • Another event (for example, self-refresh entry or exit, or power-down entry or exit) causes the MCKE signals to change. 00 - Not forced 01 - Forced to a lower value 10 - Forced to a higher value 11 - Reserved
19 —	Reserved
18 —	Reserved
17-0 MD_VALUE	Mode Register Value Specifies the value that is presented on the DDRC memory-address pins during an MRW command. This field is significant only when this register is used to issue an MRW, precharge, or precharge-all command. The two most-significant bits do not affect the MRW commands to the DDR SDRAM because A[17:16] of the DDR SDRAM's MR registers are reserved. For an MRW command, this field contains the data to be written to the selected mode register. When using LPDDR4 LPDDR4x DDR SDRAM, the bits of this field, 17:0, map to the DDR SDRAM command as follows:

Table 181. LPDDR4 LPDDR4x MD_VALUE description

MD_VALUE bits	Mapped to
17–14	Unused
13–6	OP7–OP0
5–0	MA5–MA0

Table continues on the next page...

Field	Description
	<table><tr><th>MD_VALUE bits</th><th>Mapped to</th></tr><tr><td colspan="2">For a precharge command, only bit 5 of this field is significant.</td></tr></table>

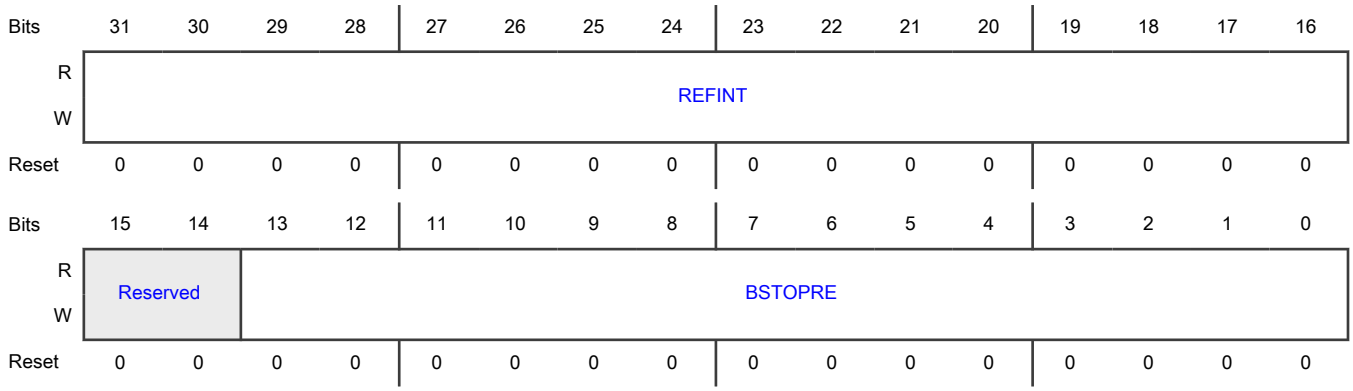
35.6.29 DDR SDRAM Interval Configuration (DDR_SDRAM_INTERVAL)

Specifies the number of DDR SDRAM clock cycles between refreshes issued to the DDR SDRAMs. Additionally, the register provides the number of DDR SDRAM cycles for which a page is retained after being accessed.

Offset

Register	Offset
DDR_SDRAM_INTERVAL	124h

Diagram



Fields

Field	Description
31-16 REFINT	Refresh Interval Represents the number of memory bus clock cycles between refresh cycles. This way, the field controls auto-refresh. Writing 0 to this field turns off auto-refresh. **NOTE** This field should be REFINT*NUM_PR when DDR_SDRAM_CFG2[NUM_PR] is > 1. Depending on DDR_SDRAM_CFG_2[NUM_PR], some quantity of rows is refreshed in each DDR SDRAM rank during each refresh cycle. The value of this field depends on the specific DDR SDRAM used and the interface clock frequency. This field is concatenated with TIMING_CFG_4[EXT_REFINT] to obtain a 17-bit value for the total refresh interval.

Table continues on the next page...

Table continued from the previous page...

Field	Description
15-14 —	Reserved
13-0 BSTOPRE	Precharge Interval Sets the duration (in memory bus clocks) that a page is retained after a DDR SDRAM access. If this field is 0, DDRC: • Leaves Open-Page mode. • Enters Global Auto-Precharge mode. • Uses auto-precharge read and write commands.

35.6.30 DDR SDRAM Data Initialization (DDR_DATA_INIT)

Provides the value that is used to initialize memory when DDR_SDRAM_CFG_2[D_INIT] = 1.

Offset

Register	Offset
DDR_DATA_INIT	128h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-0 INIT_VALUE	Initialization Value Represents the value that DDR SDRAM is initialized with when DDR_SDRAM_CFG_2[D_INIT] = 1.

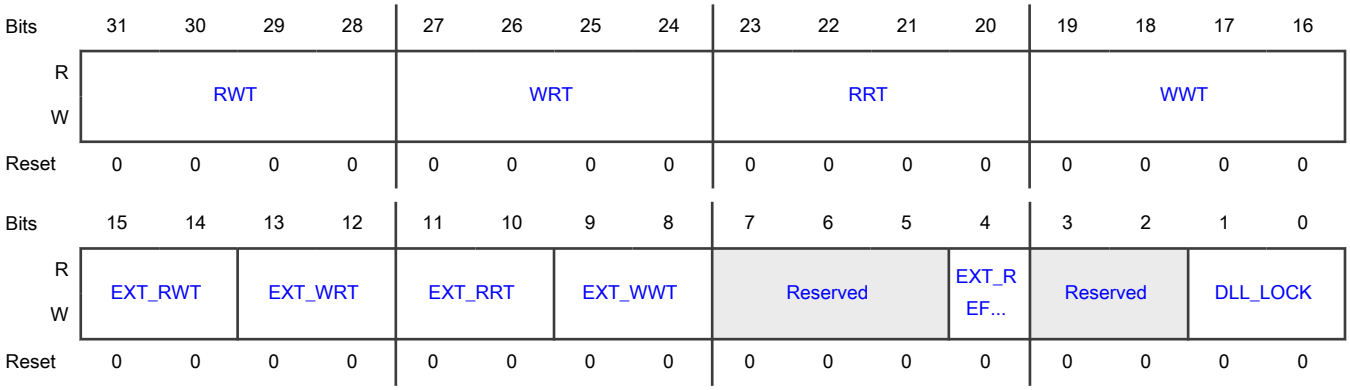
35.6.31 DDR SDRAM Timing Configuration 4 (TIMING_CFG_4)

Provides additional timing fields for turnaround clocks, refresh recovery, and (DLL) lock time.

Offset

Register	Offset
TIMING_CFG_4	160h

Diagram



Fields

Field	Description
31-28 RWT	Read-To-Write Turnaround For Same Rank Specifies the number of clock cycles to be added between a read-to-write turnaround for transactions to the same rank. When you select zero clock cycles, DDRC uses the value used for transactions to different ranks, as defined in TIMING_CFG_0[RWT], for calculating the number of additional clock cycles. Regardless of the value defined in this field, the value that TIMING_CFG_0[RWT] defines is also considered before issuing a write command.
27-24 WRT	Write-To-Read Turnaround For Same Rank Specifies the number of clock cycles to be added between a write-to-read turnaround for transactions to the same rank. When you select zero clock cycles, DDRC uses the value that is used for transactions to different ranks, as defined in TIMING_CFG_0[WRT], for calculating the number of additional clock cycles. TIMING_CFG_0[WRT] provides the minimum number of clock cycles that DDRC uses, regardless of its value.
23-20 RRT	Read-To-Read Turnaround For Same Rank Specifies the number of clock cycles to be added between reads to the same rank as follows: Number of cycles = BL/2 + RRT If you select zero clock cycles, DDRC uses the formula BL/2 to calculate the number of clock cycles required between read commands to the same rank. DDRC must wait for four clock cycles between read-to-read transactions to the same rank.

Table continues on the next page...

Table continued from the previous page...

Field	Description
19-16 WWT	Write-To-Write Turnaround For Same Rank Controls the number of clock cycles to be added between writes to the same rank as follows: Number of cycles = BL/2 + WWT If you select zero clock cycles, DDRC uses the formula BL/2 to calculate the number of clock cycles required between write commands to the same rank. DDRC must wait for four clock cycles between write-to-write transactions to the same rank.
15-14 EXT_RWT	Extended Read-To-Write Turnaround Specifies extra clock cycles that combine with TIMING_CFG_0[RWT] to define the read-to-write turnaround (see Read-to-write turnaround).
13-12 EXT_WRT	Extended Write-To-Read Turnaround Specifies extra clock cycles that combine with TIMING_CFG_0[WRT] to define the write-to-read turnaround (see Write-to-read turnaround).
11-10 EXT_RRT	Extended Read-To-Read Turnaround Specifies extra clock cycles that combine with TIMING_CFG_0[RRT] to define the read-to-read turnaround (see Read-to-read turnaround).
9-8 EXT_WWT	Extended Write-To-Write Turnaround Specifies extra clock cycles that combine with TIMING_CFG_0[WWT] to define the write-to-write turnaround (see Write-to-write turnaround).
7-5 —	Reserved
4 EXT_REFINT	Extended Refresh Interval Specifies the number of memory bus clock cycles between refresh cycles. Depending on the setting of DDR_SDRAM_CFG_2[NUM_PR], some number of rows are refreshed in each DDR SDRAM physical bank during each refresh cycle. EXT_REFINT is concatenated with DDR_SDRAM_INTERVAL[REFINT] to obtain a 17-bit value for the total refresh interval, {EXT_REFINT, REFINT}. This combined refresh interval depends on the specific SDRAMs used and the interface clock frequency. Refreshes are not issued when {EXT_REFINT, EFINT} = 0. 0 - 0 1 - 65,536
3-2 —	Reserved
1-0	DDR SDRAM DLL Lock Time

Table continues on the next page...

Table continued from the previous page...

Field	Description
DLL_LOCK	Specifies the number of clocks that it takes for the DDR SDRAM to be available after exiting Self-Refresh mode. DDRC waits for the number of cycles that this field specifies before issuing any commands after exiting POR or after a self-refresh completes (t_{XSR}). 10 - 1024 clocks 11 - 2048 clocks All other values are reserved.

35.6.32 DDR SDRAM Timing Configuration 7 (TIMING_CFG_7)

Provides required timing fields.

Offset

Register	Offset
TIMING_CFG_7	16Ch

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Description
31-30 —	Reserved
29-28 CKE_RST	MCKE Reset Time Specifies the number of clock cycles for which DDRC must wait after a reset and assertion of MCKE until the first MRW command.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This field indicates MCKE reset time (t_{XPR}), and determines t_{XS} when exiting Self-Refresh mode. Therefore, if t_{XPR} and t_{XS} are different for a particular memory, you must select the greater of these two values and write that value to this field. 00 - 200 01 - 256 10 - 512 11 - 4096
27-24 CKSRE	Clock After Self-Refresh Entry Specifies the number of clock cycles for which DDRC must drive valid MCK and MCK_b values after entering Self-Refresh mode before the clocks are allowed to stop. This field indicates the number of valid clock cycles after entering Self-Refresh mode (t_{CKSRE}). When using an LPDDR4, LPDDR4x memory, you must write t_{ESCKE} to this field. 0000,1010 - 15 0001 - 6 0010 - 7 0011 - 8 0100 - 9 0101 - 10 0110 - 11 0111 - 12 1000 - 13 1001 - 14 1011 - 16 1100 - 17 1101 - 18 1110 - 19 1111 - 32
23-20 CKSRX	Clock After Self-Refresh Exit Specifies the number of clock cycles during which DDRC must drive valid MCK and MCK_b values before exiting Self-Refresh mode and before the clocks are allowed to stop. This field indicates a valid number of clock cycles after exiting Self-Refresh mode (t_{CKSRX}). When using LPDDR4 LPDDR4x DDR SDRAM, you must write t_{SR} to this field. 0000,1010 - 15 0001 - 6

3-0 —	Reserved

35.6.33 DDR SDRAM ZQ Calibration Control (DDR_ZQ_CNTL)

Enables the controls required for ZQ calibration.

When using ZQ calibration, the following define the limitations for DDR SDRAM timing parameters:

- DDR_ZQ_CNTL[ZQOPER]
- DDR_ZQ_CNTL[ZQCS]
- TIMING_CFG_1[PRETOACT]
- TIMING_CFG_1[REFREC]
- DDR_SDRAM_INTERVAL[REFINT]
- Number of enabled ranks

A refresh command can be skipped after a self-refresh completes if this condition is true:

(ZQOPER + ZQCS) × (# of enabled ranks) + PRETOACT + REFREC + $2t_{ck}$ > REFINT

In this scenario, you could use either of these options:

- Posted refreshes to extend the refresh interval
- DDR SDRAM Mode Control (DDR_SDRAM_MD_CNTL) to force an extra refresh to each rank after exiting Self-Refresh mode

However, timing parameters for most chips and frequencies do not allow missed refreshes.

Offset

Register	Offset
DDR_ZQ_CNTL	170h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Description
31 ZQ_EN	ZQ Calibration Enable Determines if ZQ calibration is used. If it is used, DDRC issues a ZQCL command after POR and anytime DDRC completes a self-refresh. A ZQCS command is issued after every 32 refresh sequences to account for VT variations. 0 - Not used 1 - Used
30-28 —	Reserved
27-24 ZQINIT	ZQ Calibration Initialization Time Determines the number of clock cycles allowed for DDR SDRAM ZQ calibration at POR. This field signifies POR ZQ calibration time (t_{ZQinit}).

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Each rank is calibrated separately, and this time must elapse after DDRC issues a ZQCL command to the DDR SDRAM for each rank before a separate command may be issued. When using LPDDR4x DDR SDRAM, you must write t_{ZQCAL} to this field. 0111 - 128 1000 - 256 1001 - 512 1010 - 1024 1011 - 2048
23-20 —	Reserved
19-16 ZQOPER	ZQ Calibration Operation Time Determines the number of clock cycles that DDR SDRAM requires to complete the ZQ calibration when exiting Self-Refresh mode. This field signifies normal operation full calibration time (t_{ZQoper}). Each CS is calibrated separately, and this time must elapse after DDRC issues a ZQCL command to the DDR SDRAM for each CS before a separate command may be issued. When using LPDDR4 ,LPDDR4x memories, you must write t_{ZQCAL} to this field. 0111 - 128 1000 - 256 1001 - 512 1010 - 1024 1011 - 2048
15-12 —	Reserved
11-8 ZQCS	ZQ Calibration Short Time Determines the number of clock cycles allowed for DDR SDRAM ZQ calibration during dynamic calibration, which is issued after every refresh sequence that DDR_ZQ_CNTL[ZQCS_INT] defines. This field signifies normal operation short calibration time (t_{ZQCS}). Each CS is calibrated separately, and this time must elapse after DDRC issues a ZQCS command for each CS before a separate command may be issued. When using LPDDR4 ,LPDDR4x DDR SDRAM, you must write t_{ZQLAT} to this field. 0000 - 1 0001 - 2 0010 - 4

Table continues on the next page...

3-0 ZQCS_INT	ZQCS Interval Determines the number of refresh sequences that are to pass between each ZQCS calibration. 0000 - 32 0001 - 64 0010 - 128 0011 - 256 0100 - 512 0101 - 1024 0110 - 2048 0111 - 4096 1000 - 8192 1001 - 16384 1010 - 32768 1111 - ZQCS calibration disabled All other values are reserved.

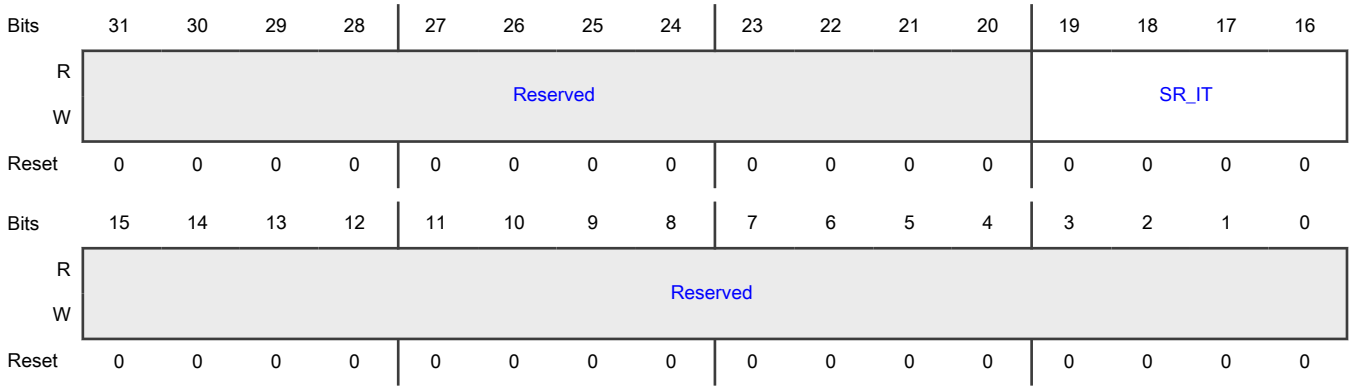
35.6.34 DDR SDRAM Self-Refresh Counter (DDR_SR_CNTR)

Enables you to force DDRC to perform a self-refresh after a predefined period of idle time.

Offset

Register	Offset
DDR_SR_CNTR	17Ch

Diagram



Fields

Field	Description
31-20 —	Reserved
19-16 SR_IT	Self-Refresh Idle Threshold Defines the number of DDR SDRAM clock cycles that must pass when DDRC is idle before it enters Self-Refresh mode, according to the following equation: Number of clock cycles = $2^{(8 + SR_IT \times 2)}$ **NOTE** SR_IT values 1-7 are not supported. Anytime you issue a transaction to DDRC, it exits Self-Refresh mode and resets its internal counter. • When this field is 0, this power-saving feature is disabled. • If you write a non-zero value to this field, DDRC exits Self-Refresh mode anytime a transaction is issued, regardless of the reason it entered this mode. However, when writing a non-zero value to this field, DDR_SDRAM_CFG_3[SR_FAST_WK_EN] must be 1.
15-0 —	Reserved

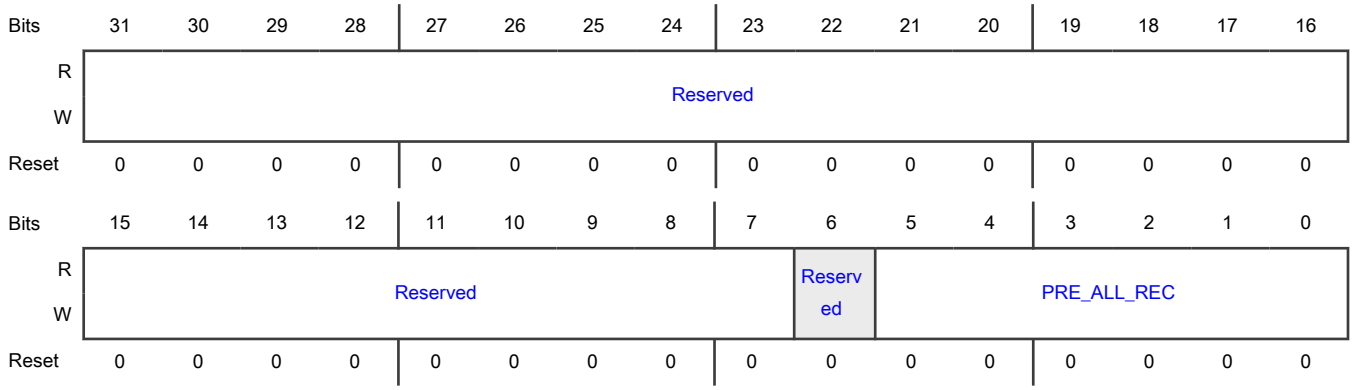
35.6.35 DDR SDRAM Timing Configuration 8 (TIMING_CFG_8)

Provides additional timing fields .

Offset

Register	Offset
TIMING_CFG_8	250h

Diagram



Fields

Field	Description
31-7 —	Reserved
6 —	Reserved
5-0 PRE_ALL_REC	Precharge All-To-Activate Interval Determines the number of clock cycles from a precharge-all command until an activate or refresh command is allowed. When this field is 0, DDRC uses the value of TIMING_CFG_1[PRETOACT] for this interval.

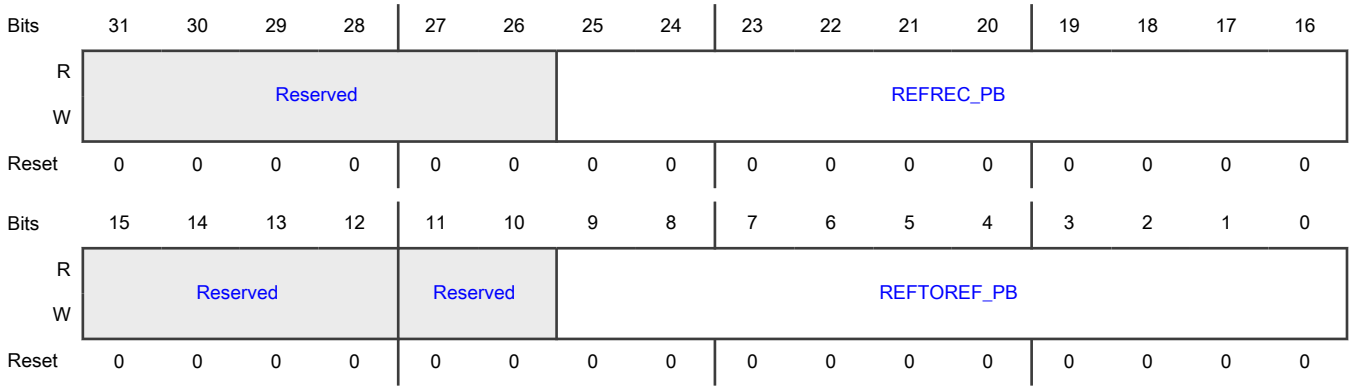
35.6.36 DDR SDRAM timing configuration 9 (TIMING_CFG_9)

The DDR SDRAM timing configuration 9 register provides additional timing fields required to support per-bank refresh.

Offset

Register	Offset
TIMING_CFG_9	254h

Diagram



Fields

Field	Description
31-26 —	Reserved
25-16 REFREC_PB	Refresh Recovery Per-Bank Refresh Refresh recovery time for per-bank refresh. Controls the number of clock cycles from a refresh command to an activate for the same bank. Note that hardware adds an additional 8 clock cycles to the final, 7-bit value of the refresh recovery, such that it (t_{RFCpb}) is calculated as follows: 00_0000_0000 - 8 clocks 00_0000_0001 - 9 clocks 00_0000_0010 - 10 clocks 10_1111_1110 - 774 clocks 10_1111_1111 - 775 clocks
15-12 —	Reserved
11-10 —	Reserved
9-0 REFTOREF_PB	Refresh-to-refresh interval for per-bank refresh. Note that hardware adds an additional 8 clock cycles to the final, 7-bit value of this field, such that it ($t_{pbR2pbR}$) is calculated as follows: 00_0000_0000 - disable PB refresh 00_0000_0001 - 9 clocks 00_0000_0010 - 10 clocks 10_1111_1110 - 774 clocks 10_1111_1111 - 775 clocks

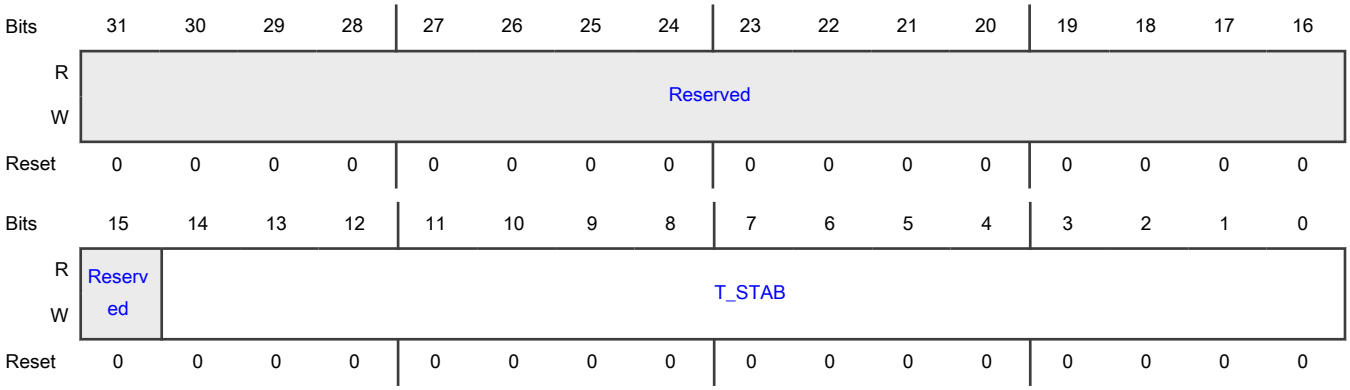
35.6.37 DDR SDRAM Timing Configuration 10 (TIMING_CFG_10)

Provides an additional timing field required to support wake up time for self refresh mode.

Offset

Register	Offset
TIMING_CFG_10	258h

Diagram



Fields

Field	Description
31-15 —	Reserved
14-0 T_STAB	Stabilization Wait Time Defines the stabilization wait time (in MCK clock cycles) when exiting self refresh in slow wakeup mode. If you write 0 to this field, DDRC ignores this constraint. **NOTE** Be aware of a special constraint if you expect the temperature to drift by more than 20 degrees Celsius. In this case, the value you write to this field must be t_{STAB} or 10 µs, whichever is greater, during self-refresh.

35.6.38 DDR SDRAM Timing Configuration 11 (TIMING_CFG_11)

Provides additional timing fields required to support LPDDR4 ,LPDDR4x .

Offset

Register	Offset
TIMING_CFG_11	25Ch

Fields

Field	Description
31 DDRC_RST	DDRC Reset Specifies whether DDRC operates normally or is undergoing reset. You must write 1 to this field if you want to reset DDRC. This resets all state machines and internal FIFOs. The field does not reset DDRC's configuration registers. Before you write 1 to this field, you must write 0 to DDR_SDRAM_CFG[MEM_EN].

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This field returns to 0 by itself. Therefore, you must poll this field and wait until it returns to 0 before re-enabling DDRC. 0 - Operating normally 1 - Undergoing reset
30 —	Reserved
29-28 —	Reserved
27-24 —	Reserved
23-22 —	Reserved
21-20 —	Reserved
19 —	Reserved
18 —	Reserved
17 —	Reserved
16 —	Reserved
15 —	Reserved
14-12 DM_CFG	Data Mask Configuration Determines how DDRC uses the MDM pins. When DM_CFG = 100b, DDRC supports both DBI and data masks. You can use this configuration only with LPDDR4 ,LPDDR4x DDR SDRAM. For more information on value 000b below, see DDR_SDRAM_CFG[SDRAM_TYPE]. 000 - Normal data masks based on the settings defined in DDR_SDRAM_CFG[SDRAM_TYPE] 010 - DBI

Table continues on the next page...

Table continued from the previous page...

Field	Description
	011 - Neither data masks nor DBI 100 - DBI with data masks All other values are reserved.
11 DRAIN_FOR_SR	Drain Queues For Self-Refresh Forces DDRC to drain its main command queue before servicing a self-refresh request. This field is only used for: • Software-initiated, self-refresh requests via DDR_SDRAM_CFG_2[FRC_SR] • Sleep requests • Self-refresh requests enabled in DDR_SR_CNTR[SR_IT] 0 - Do not drain 1 - Drain
10 —	Reserved
9-8 —	Reserved
7 DYN_REF_RATE_EN	Dynamic Refresh Rate Enable Enables only the dynamic refresh rate adjustments for LPDDR4 ,LPDDR4x DDR SDRAM. If you write 1 to this field, DDRC polls the MR4 register every 64 refresh sequences to determine a proper refresh rate. If two ranks are enabled, DDRC alternates between polling rank 0 and rank 1, and uses the lesser of the two refresh intervals. You can find the results of the previous MR4 reads in DDR Refresh Rate (DDR_SDRAM_REF_RATE). This feature cannot be used with rank 2 or rank 3 enabled. 0 - Disables 1 - Enables
6 —	Reserved
5-4 —	Reserved
3 NON_PWR_2	Non Power of 2 Enable This field controls whether a non-power of 2 density DRAM is used. For example, 3Gbit, 6Gbit, and 12Gbit DRAMs are considered non-power of 2 DRAMs. You must program the CSn_BNDS to include the full data available when using a non-power of 2 DRAM. 0 - Disables

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Enables
2 —	Reserved
1 SR_FAST_WK_EN	Self Refresh Fast Wakeup Enable Controls the type of wakeup enable (slow or fast) used after a self-refresh. **NOTE** If you will ever use self refresh with this bit cleared after a given reset, then you must clear this bit during the initial configuration of the DDRC. 0 - Slow 1 - Fast
0 —	Reserved

35.6.40 DDR SDRAM Control Configuration 4 (DDR_SDRAM_CFG_4)

Provides more control configuration for DDRC, along with timings for blocking certain accesses.

Offset

Register	Offset
DDR_SDRAM_CFG_4	264h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Description
31-28 PHY_WAKEUP	PHY Wakeup. This field represents the value used for the phy_wakeup pins to the DDR PHY.
27-26 —	Reserved
25-24 PHY_FREQ_FSP	PHY Frequency FSP. This field represents the bits that will be provided on the phy_freq_fsp pins to the DDR PHY.
23-22 —	Reserved
21-17 PHY_FREQ_HS	PHY Frequency This field represents the bits that will be provided on the phy_freq pins to the DDR PHY.
16-12 PHY_FREQ	Frequency Change and Retention Setup This field represents the bits that will be provided on the phy_freq pins to the DDR PHY. This field needs to be setup prior to changing frequency or entering retention mode. 0_0000 – Frequency State 0 0_0001 – Frequency State 1 0_0010 – Frequency State 2 Prior to entering retention mode, it is necessary to program the values as follows: 1_1111 – Retention mode All other values are reserved.
11-0 —	Reserved

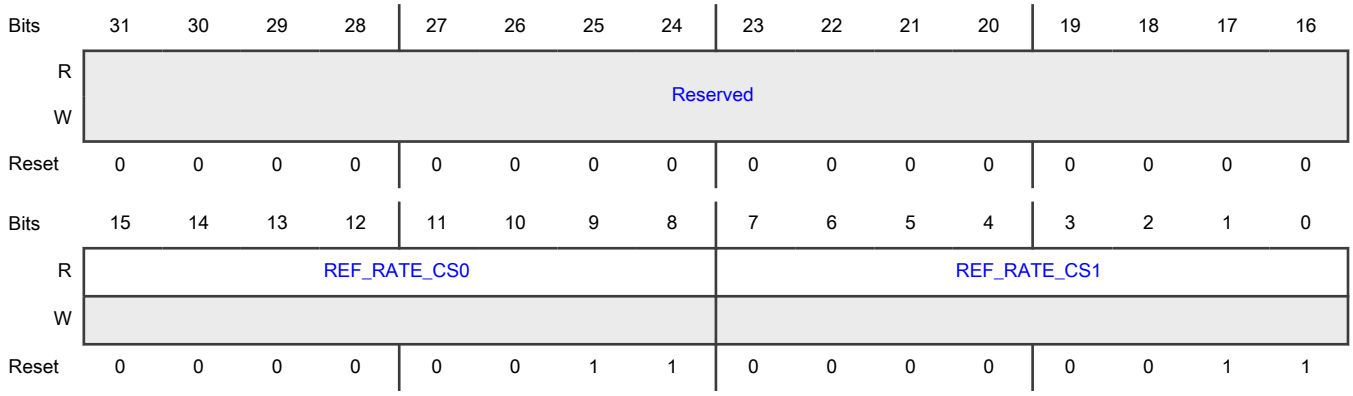
35.6.41 DDR Refresh Rate (DDR_SDRAM_REF_RATE)

Provides the rank-0 and rank-1 status of the last MR4 read to determine the refresh rate.

Offset

Register	Offset
DDR_SDRAM_REF_RATE	2C0h

Diagram



Fields

Field	Description
31-16 —	Reserved
15-8 REF_RATE_CS0	Refresh Rate Rank 0 Represents the value read for the MR4 register on rank 0 during the last dynamic read. This field provides meaningful information only if DDR_SDRAM_CFG_3[DYN_REF_RATE_EN] = 1 and rank 0 is enabled.
7-0 REF_RATE_CS1	Refresh Rate Rank 1 Represents the value read for the MR4 register on rank 1 during the last dynamic read. This field provides meaningful information only if DDR_SDRAM_CFG_3[DYN_REF_RATE_EN] = 1 and rank 1 is enabled.

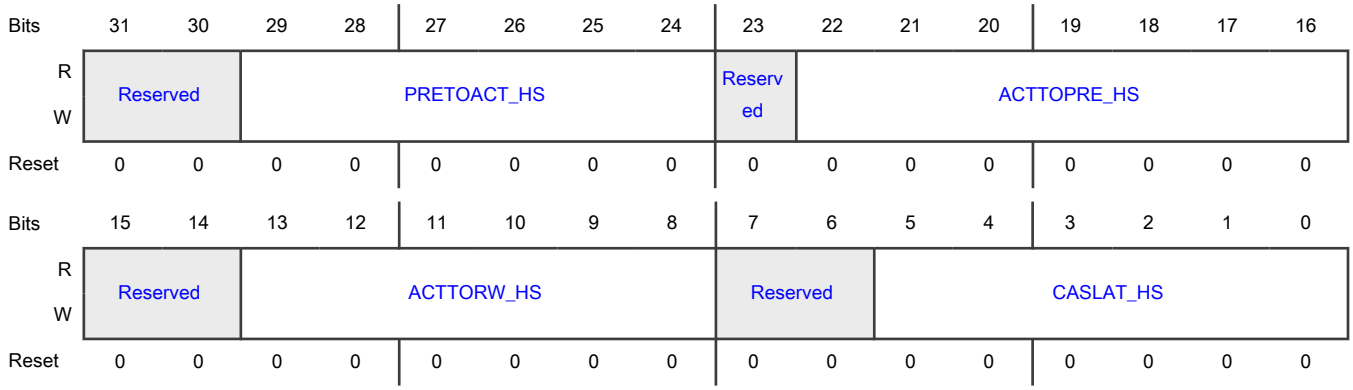
35.6.42 DDR SDRAM Timing Configuration 12 (TIMING_CFG_12)

Provides additional timing fields required to support half-frequency operation when dynamically switching the clock frequency.

Offset

Register	Offset
TIMING_CFG_12	300h

Diagram



Fields

Field	Description
31-30 —	Reserved
29-24 PRETOACT_HS	Precharge-To-Activate Time For Half Speed Defines clock cycles to define t_{RP} when operating at half frequency. 00_0000 - Reserved All other values - Clock cycles as defined in the description
23 —	Reserved
22-16 ACTTOPRE_HS	Activate-To-Precharge Time For Half Speed Defines clock cycles to define t_{RAS} when operating at half frequency.
15-14 —	Reserved
13-8 ACTTORW_HS	Activate To Read Or Write For Half Speed Defines clock cycles that define t_{RCD} when operating at half frequency. 00_0000 - Reserved All other values - Clock cycles as defined in the description
7-6 —	Reserved
5-0 CASLAT_HS	CAS Latency For Half Speed Defines clock cycles that define the CAS latency when operating at half frequency. This field must be programmed to 1 less than the desired CAS latency, similar to {TIMING_CFG_3[EXT_CASLAT], TIMING_CFG_1[CASLAT]}.

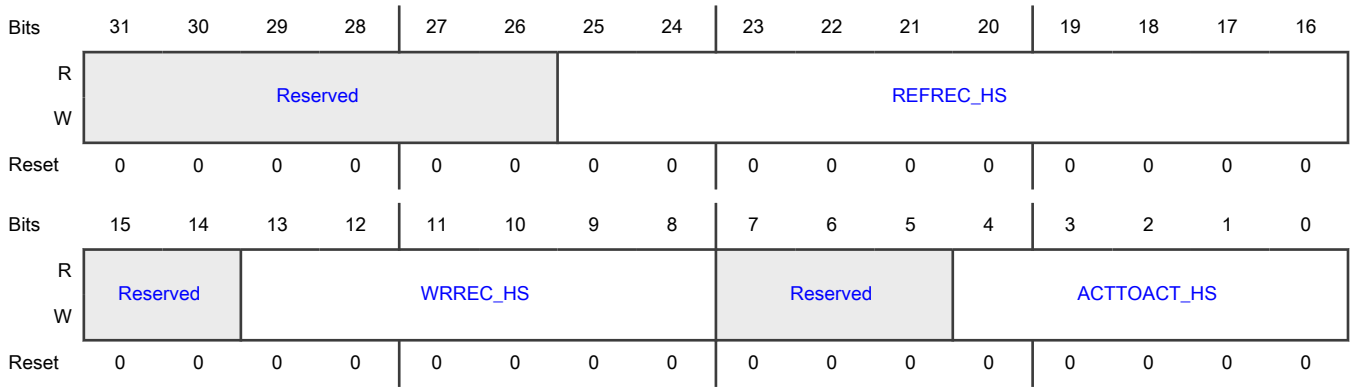
35.6.43 DDR SDRAM Timing Configuration 13 (TIMING_CFG_13)

Provides additional timing fields required to support half-frequency operation when dynamically switching the clock frequency.

Offset

Register	Offset
TIMING_CFG_13	304h

Diagram



Fields

Field	Description
31-26 —	Reserved
25-16 REFREC_HS	Refresh Recovery For Half Speed Defines clock cycles to define t_{RFC} when operating at half frequency. Note that the DDRC adjusts this field by 8 cycles, similar to {TIMING_CFG_3[EXT_REFREC], TIMING_CFG_1[REFREC]}.
15-14 —	Reserved
13-8 WRREC_HS	Write Recovery For Half Speed Defines clock cycles to define n_{WR} when operating at half frequency. The value 0b is reserved. 00_0000 - Reserved All other values - Clock cycles as defined in the description
7-5 —	Reserved
4-0	Activate-To-Activate Interval For Half Speed

Table continues on the next page...

Table continued from the previous page...

Field	Description
ACTTOACT_HS	Specifies the number of clock cycles from an activate command until another activate command is allowed for a different logical bank in the same physical bank when operating at half frequency. This field indicates the activate-to-activate interval (t_{RRD}). 0_0000 - Reserved All other values - Clock cycles as defined in the description

35.6.44 DDR SDRAM Timing Configuration 14 (TIMING_CFG_14)

Provides additional timing fields required to support half-frequency operation when dynamically switching the clock frequency.

Offset

Register	Offset
TIMING_CFG_14	308h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	REFINT_HS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-30 —	Reserved
29-24 WRLAT_HS	Write Latency For Half Speed Indicates the number of clock cycles used to determine the write latency when operating at half frequency. The maximum write latency supported is 34 clocks.
23 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
22-18 RD_TO_PRE_HS	Read-To-Precharge Time For Half Speed Specifies the number of clock cycles indicating read-to-precharge (n_{RTP}) when operating at half frequency. The value 0b is reserved. 0_0000 - Reserved All other values - Clock cycles as defined in the description
17 —	Reserved
16-0 REFINT_HS	Refresh Interval For Half Speed Represents the number of memory bus clock cycles between refresh cycles when operating at half frequency. This way, the field controls auto-refresh. Writing 0 to this field turns off auto-refresh. Depending on DDR_SDRAM_CFG_2[NUM_PR], some quantity of rows is refreshed in each DDR SDRAM physical bank during each refresh cycle. The value of this field depends on the specific DDR SDRAM used and the interface clock frequency.

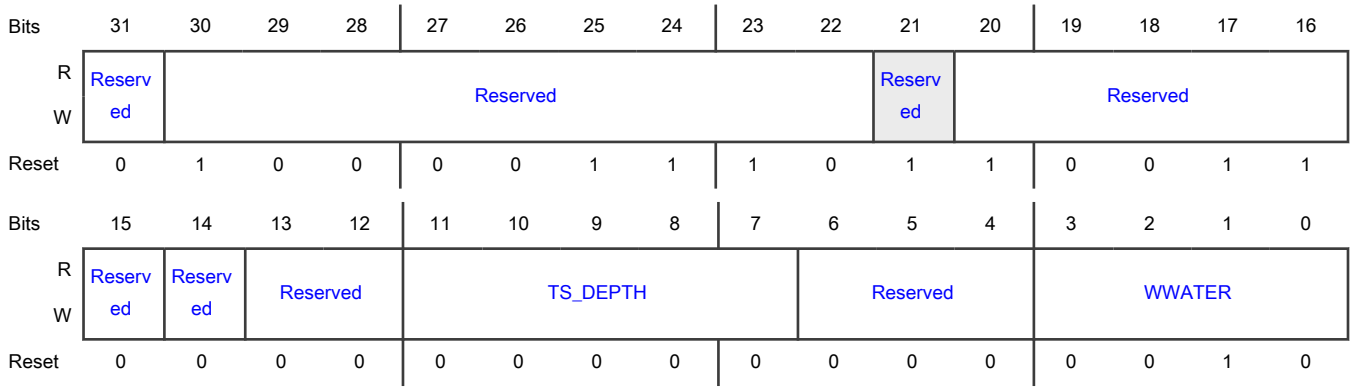
35.6.45 Transaction Configuration Register 1 (TX_CFG_1)

This register contains miscellaneous settings to fine-tune arbitration performance.

Offset

Register	Offset
TX_CFG_1	800h

Diagram



Fields

Field	Description
31 —	Reserved
30-22 —	Reserved
21 —	Reserved
20-15 —	Reserved
14 —	Reserved
13-12 —	Reserved
11-7 TS_DEPTH	Transaction Scheduler Depth This field determines the depth of the Transaction Scheduler. A value of 0b00000 provides the maximum number of entries. You must program the depth to 0b11010 or less if ERR_EN[INLINE_ECC_EN] is set.
6-4 —	Reserved
3-0 WWATER	Write Watermark. Write queue level before writes allowed to arbitrate. This field must be set to 0b0000 if ERR_EN[INLINE_ECC_EN] is set.

35.6.46 DDR SDRAM Debug Status 2 (DDRDSR_2)

Contains the current settings of the driver impedance.

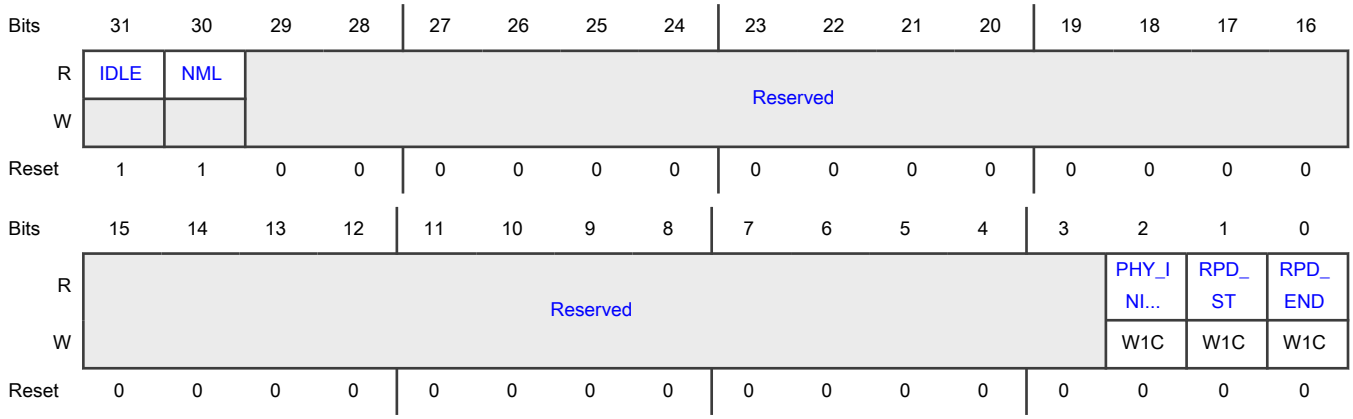
NOTE

Rapid Clear is done only on memory range selected by MTCR register. Address range in MTCR can override rapid clear. Rapid clear is not supported if REMAPing is enabled. Rapid clear will follow similar rules that D_INIT does if REMAP ing is used. Rapid memory status bits must be cleared before accessing memory again.

Offset

Register	Offset
DDRDSR_2	B24h

Diagram



Fields

Field	Description
31 IDLE	Memory controller idle (read only). 0 - Memory controller is busy. 1 - Memory controller is idle.
30 NML	No Modified Lines Indicates whether modified lines exist in the ECC cache. 0 - Exist 1 - Do not exist
29-3 —	Reserved
2 PHY_INIT_CMPLT	DDR PHY Initialization Complete Specifies whether PHY initialization is complete. DDRC changes this field to 1 after the DDR PHY initialization is complete. You must wait until this field becomes 1 before writing 1 to DDR_SDRAM_CFG[MEM_EN]. 0 - Not complete 1 - Complete
1 RPD_ST	Rapid Clear Of Memory Start Specifies whether the rapid clear of memory function has started. If the rapid clear of memory feature is available for DDRC, this field indicates that the sequence has started. After the sequence starts, writes to DDRC's memory-mapped registers do not affect this register's contents. 0 - Not started 1 - Started
0	Rapid Clear Of Memory End

Table continues on the next page...

Table continued from the previous page...

Field	Description
RPD_END	Specifies whether the rapid clear of memory function is complete. If the rapid clear of memory feature is available for DDRC, this field indicates a successful end of the rapid clear sequence. 0 - Not complete 1 - Complete

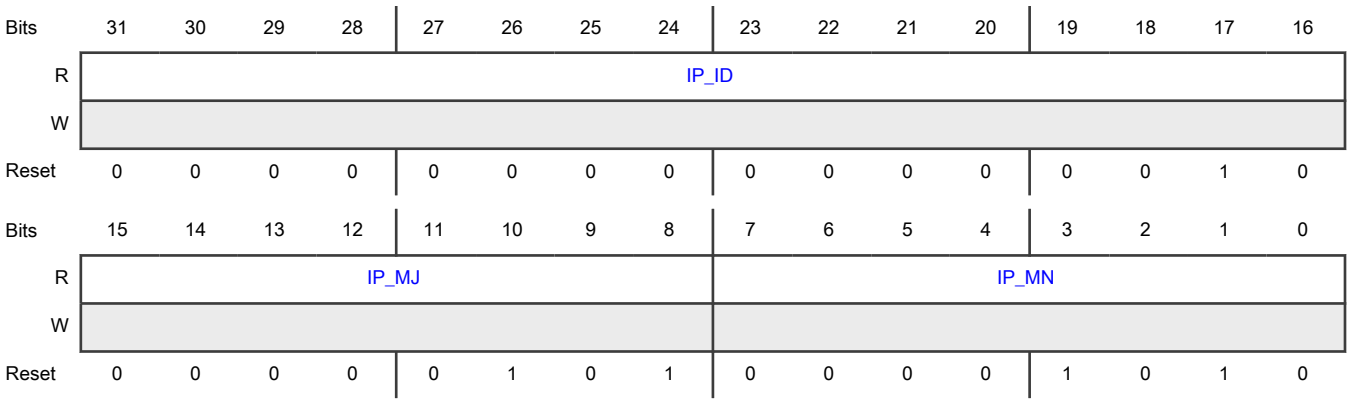
35.6.47 DDRC Revision 1 (DDR_IP_REV1)

Provides the DDRC ID, major revision, and minor revision.

Offset

Register	Offset
DDR_IP_REV1	BF8h

Diagram



Fields

Field	Description
31-16 IP_ID	IP Block ID For DDRC, this value is 2h.
15-8 IP_MJ	Major Revision This is the major revision for DDRC.
7-0 IP_MN	Minor Revision For DDRC, this value is 8'd10h.

35.6.48 DDR SDRAM Memory Test Control (DDR_MTCR)

Enables the controls for an automatic memory test.

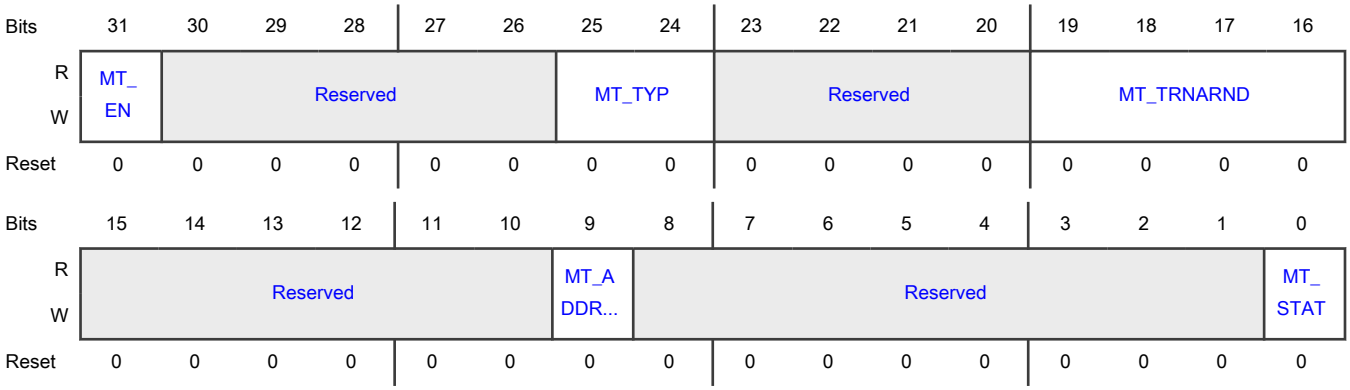
NOTE

You must clear the fields in this register after running a memory test.

Offset

Register	Offset
DDR_MTCR	D00h

Diagram



Fields

Field	Description
31 MT_EN	Memory Test Enable Determines the status of the memory test. You can write 1 to this field to enable the memory test. Depending on the value of DDR_MTCR[MT_TYP], DDRC issues only reads, only writes, or both reads and writes. DDRC writes 0 to this field after the memory test is complete. DDRC: • Issues transactions throughout the memory, as defined by Rank n Configuration (CS0_CONFIG - CS1_CONFIG) and Rank n Memory Bounds (CS0_BNDS - CS1_BNDS). • Checks the data during the memory test. If ECC is enabled, you must read Memory Error Detect (ERR_DETECT) after the memory test to determine whether any ECC errors occurred during the test. Then: • If an ECC error is detected, the error capture registers hold the address, data, and attributes captured for the first fail. • If no ECC errors are detected and the test fails (for a data miscompare), the capture registers hold information for the transaction that caused the first data miscompare.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Transactions that fail with ECC errors are prioritized in capture registers. DDRC writes 0 to this field after the memory test is complete. You can write 1 to this field in either of these conditions: • Before DDR_SDRAM_CFG[MEM_EN] becomes 1 • After the memory controller is enabled and idle You cannot write 1 to this field while the DDRC is processing other transactions. You cannot write 1 to this field when DDR_SDRAM_CFG_2[D_INIT] = 1. 0 - Disables 1 - Enables
30-26 —	Reserved
25-24 MT_TYP	Memory Test Type Determines whether the memory test uses only reads, only writes, or both reads and writes. You must not use the only-read test unless you have already initialized the memory. 00 - Both writes and reads 01 - Only writes 10 - Only reads 11 - Reserved
23-20 —	Reserved
19-16 MT_TRNARND	Memory Test Turnaround Determines the number of writes issued during the memory test before reads to the same addresses are issued. This field allows longer streams of writes and reads, and it can be used to test the write→read and read→write turnarounds. The field is only relevant if DDR_MTCR[MT_TYP] = 0. 0000 - Entire memory is written to before read transactions are issued. 0001 - Total write and read streams are one transaction each. 0010 - Total write and read streams are two transactions each. 0011 - Total write and read streams are four transactions each. All other values are reserved.
15-10 —	Reserved
9	Memory Test Address Range Enable

Table continues on the next page...

Table continued from the previous page...

Field	Description
MT_ADDR_EN	Specifies the memory range used for the memory test. • If this field is 0, the full memory range defined by Rank n Memory Bounds (CS0_BNDS - CS1_BNDS) is used. • If this field is 1, the address range defined by DDR SDRAM Memory Test Start Extended Address (DDR_MT_ST_EXT_ADDR), DDR SDRAM Memory Test Start Address (DDR_MT_ST_ADDR), DDR SDRAM Memory Test End Extended Address (DDR_MT_END_EXT_ADDR), and DDR SDRAM Memory Test End Address (DDR_MT_END_ADDR) is used. To use this field to limit the address range to be tested, for any individual test, the value of neither of the following can be less than that used during the previous test: • The starting address (DDR_MT_ST_EXT_ADDR || DDR_MT_ST_ADDR) • The ending address (DDR_MT_END_EXT_ADDR || DDR_MT_END_ADDR) Additionally, you cannot write 1 to this field if DDR_MTCR[MT_TRNARND] = 0. 0 - Memory range that the CSn_BNDS registers define 1 - Memory range that the DDR_MT_ST_EXT_ADDR, DDR_MT_ST_ADDR, DDR_MT_END_EXT_ADDR, and DDR_MT_END_ADDR registers define
8-1 —	Reserved
0 MT_STAT	Memory Test Status Specifies whether a fail or data miscompare is detected during the memory test. After DDRC writes 0 to DDR_MTCR[MT_EN], this field becomes 1 in case of a data mismatch during a memory test read. In case of a failure during the memory test (that is, a data miscompare), this field becomes 1 at the same time DDR_MTCR[MT_EN] becomes 0. You can write 0 to this field after DDRC writes 1 to it to indicate a data mismatch. **NOTE** You must ignore this status bit if ERR_EN[INLINE_ECC_EN] is set. If you enable inline ECC, then the ERR_DETECT register can be monitored for detected errors during the memory test. 0 - No fail detected 1 - Data miscompare detected

35.6.49 DDR SDRAM Memory Test Pattern n (DDR_MTP0 - DDR_MTP9)

Provides the data pattern that is written during the *n*th set of 32 bits of each 40-byte memory test pattern.

This field works with DDR_MTCR[MT_EN] to enable the memory write and read test.

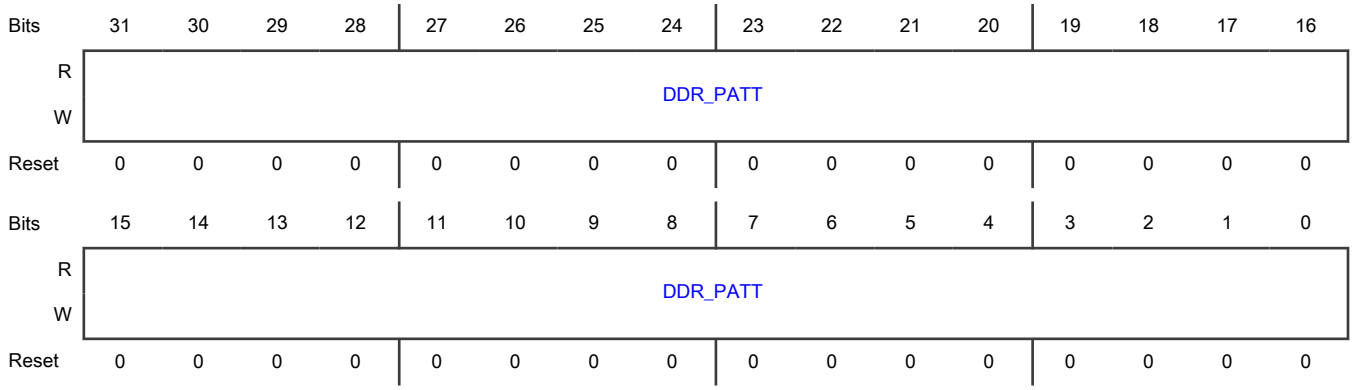
The memory test read compares data that is written to this register.

Offset

For n = 0 to 9:

Register	Offset
DDR_MTPn	D20h + (n × 4h)

Diagram



Fields

Field	Description
31-0 DDR_PATT	DDR SDRAM Pattern Stores the programmable pattern for the memory test.

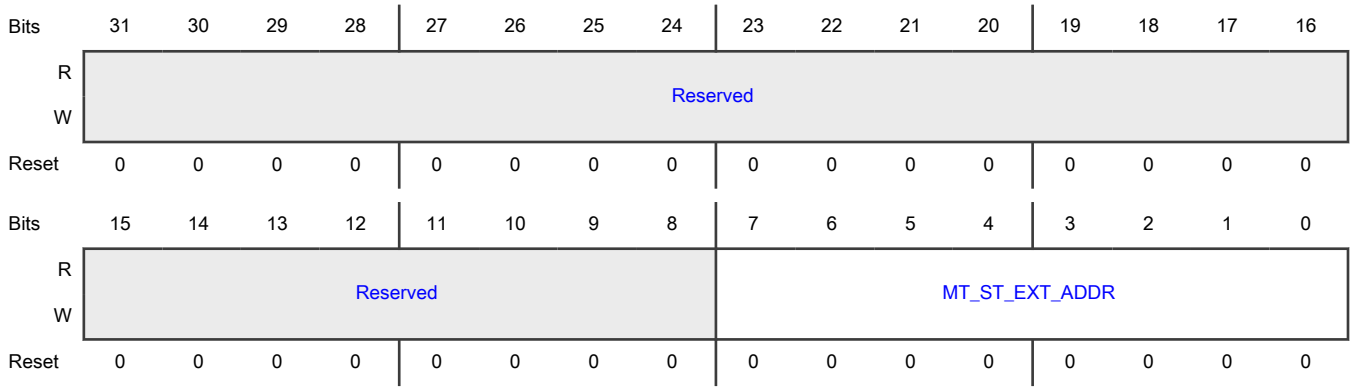
35.6.50 DDR SDRAM Memory Test Start Extended Address (DDR_MT_ST_EXT_ADDR)

Works with DDR_MTCR[MT_ADDR_EN] to specify the extended address for the DDR memory test start.

Offset

Register	Offset
DDR_MT_ST_EXT_ADDR	D60h

Diagram



Fields

Field	Description
31-8 —	Reserved
7-0 MT_ST_EXT_ADDR	Memory Test Start Extended Address Represents the starting extended address that is used for memory testing when DDR_MTCR[MT_ADDR_EN] = 1. See Memory-test address restrictions for restrictions on what you can specify.

35.6.51 DDR SDRAM Memory Test Start Address (DDR_MT_ST_ADDR)

Works with DDR_MTCR[MT_ADDR_EN] to specify the DDR memory test start address.

Offset

Register	Offset
DDR_MT_ST_ADDR	D64h

Fields

Field	Description
31-0 MT_ST_ADDR	Memory Test Start Address Specifies the starting address that is used for memory testing when DDR_MTCR[MT_ADDR_EN] = 1. See Memory-test address restrictions for restrictions on what you can specify.

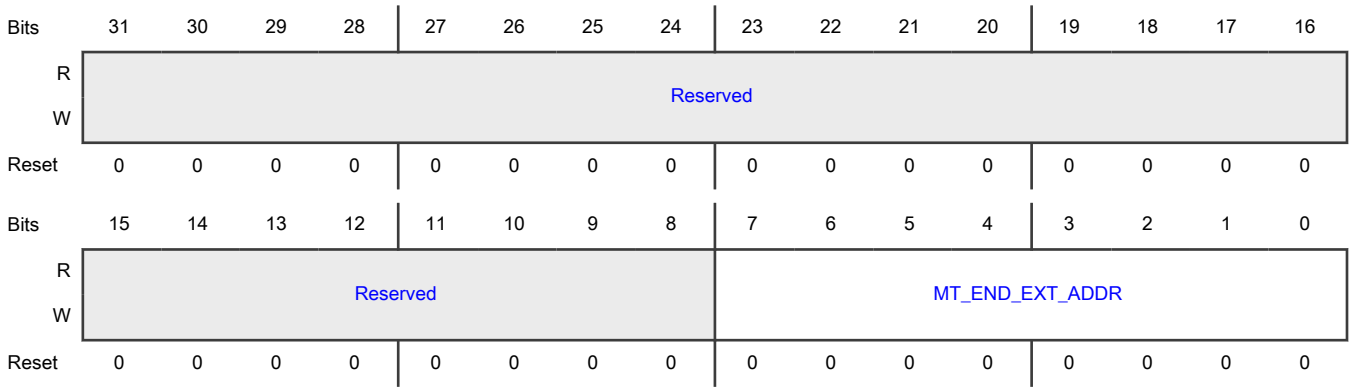
35.6.52 DDR SDRAM Memory Test End Extended Address (DDR_MT_END_EXT_ADDR)

Works with DDR_MTCR[MT_ADDR_EN] to specify the DDR memory test end extended address.

Offset

Register	Offset
DDR_MT_END_EXT_ADDR	D68h

Diagram



Fields

Field	Description
31-8 —	Reserved
7-0 MT_END_EXT_ADDR	Memory Test End Extended Address Specifies the ending extended address that is used when DDR_MTCR[MT_ADDR_EN] = 1. See Memory-test address restrictions for restrictions on what you can specify.

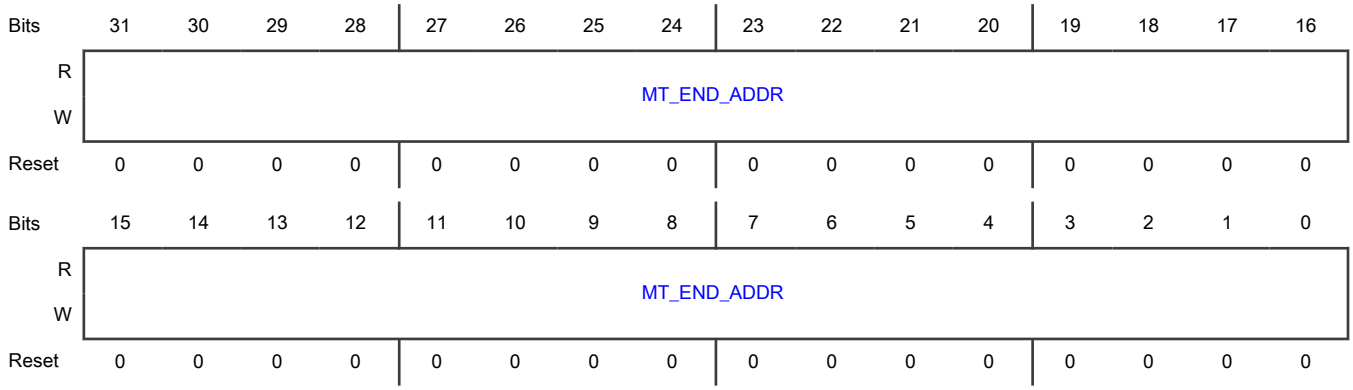
35.6.53 DDR SDRAM Memory Test End Address (DDR_MT_END_ADDR)

Works with DDR_MTCR[MT_ADDR_EN] to specify the DDR memory test end address.

Offset

Register	Offset
DDR_MT_END_ADDR	D6Ch

Diagram



Fields

Field	Description
31-0 MT_END_ADDR	Memory Test End Address Specifies the ending address that is used when DDR_MTCR[MT_ADDR_EN] = 1. See Memory-test address restrictions for restrictions on what you can specify.

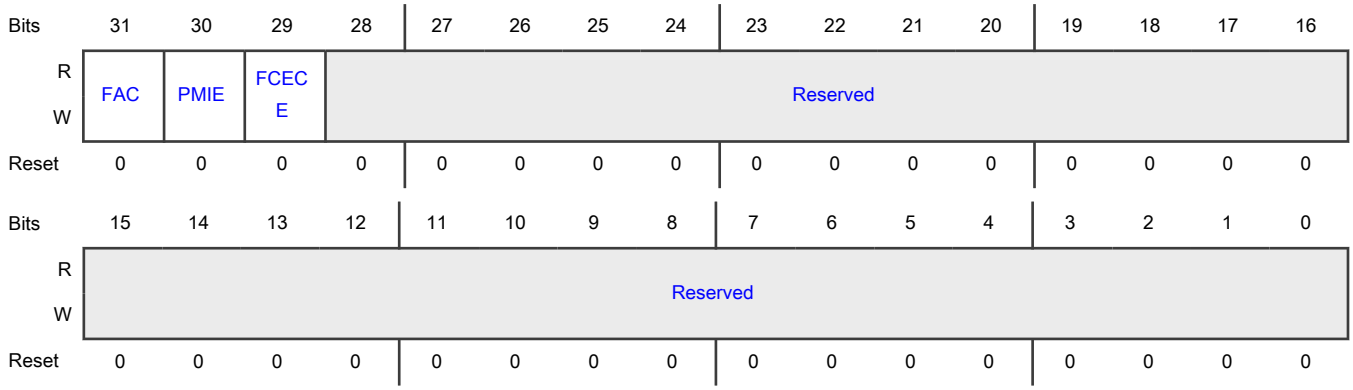
35.6.54 Performance Monitor Global Control (PMGC0)

Controls all PMC's.

Offset

Register	Offset
PMGC0	E00h

Diagram



Fields

Field	Description
31 FAC	Freeze All Counters Specifies whether PMCs are incremented. They are if PMLCA*n*[FC] permits. If PMCs are not incremented, the performance monitor signals an interrupt when PMGC0[FCECE] = 1. 0 - Incremented 1 - Not incremented
30 PMIE	Performance Monitor Interrupt Enable Enables performance monitor interrupts that PMC overflows lead to. Interrupts are enabled and occur when an enabled condition or event occurs. 0 - Disables 1 - Enables
29 FCECE	Freeze Counters On Enabled Condition Or Event Specifies when PMCs can be incremented. These are the conditions: • If PMLCA*n*[CE] is enabled • If the most-significant bit of the counter is 1, that is, when PMC*n* = 1 The use of the trigger and freeze counter conditions depends on the enabled condition. 0 - Enabled if PMLCAn[CE] = 1, until an event or condition occurs. 1 - Enabled if PMLCAn[CE] = 1, until an event or condition occurs. At this point, if PMGC0[FAC] = 1, you must write 0 to it.
28-0 —	Reserved

35.6.55 Performance Monitor Local Control A0 (PMLCA0)

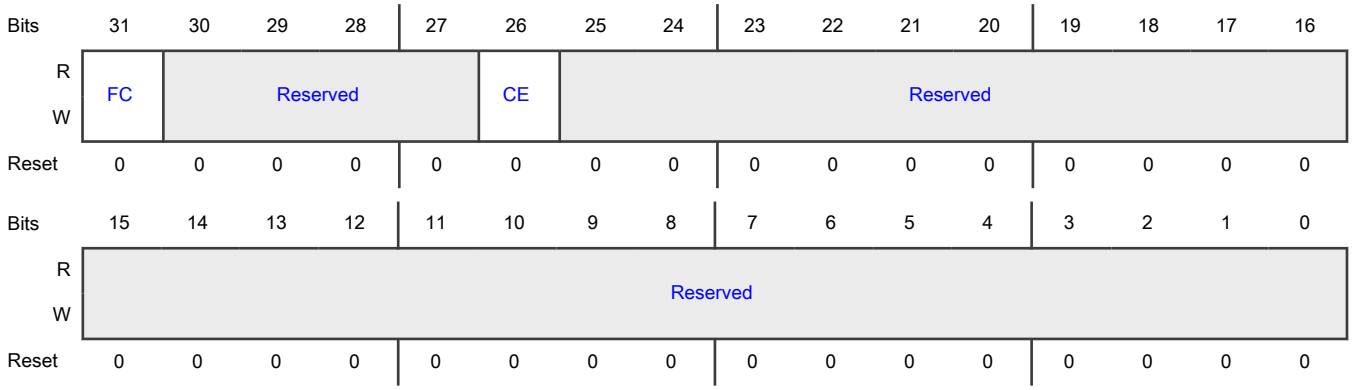
Works with Performance Monitor Local Control B0 (PMLCB0) to associate with an individual counter for specifying the usage of that counter and the event monitored on the counter.

This register controls the operations of the PMC0*n* registers.

Offset

Register	Offset
PMLCA0	E10h

Diagram



Fields

Field	Description
31 FC	Freeze Counter Indicates whether PMCs are enabled and incremented. They are if PMGC0[FAC] permits. This field enables the corresponding PMC*n* register to increment. 0 - Enabled 1 - Disabled
30-27 —	Reserved
26 CE	Condition Enable Controls counter overflow conditions. You must write 0 to this field when PMC0*n* is used as a trigger or is selected for chaining. 0 - Counter overflow conditions for PMC0n cannot occur (PMC0n cannot cause interrupts or freeze counters) 1 - Counter overflow conditions occur when the most-significant bit of PMC0n is 1
25-0 —	Reserved

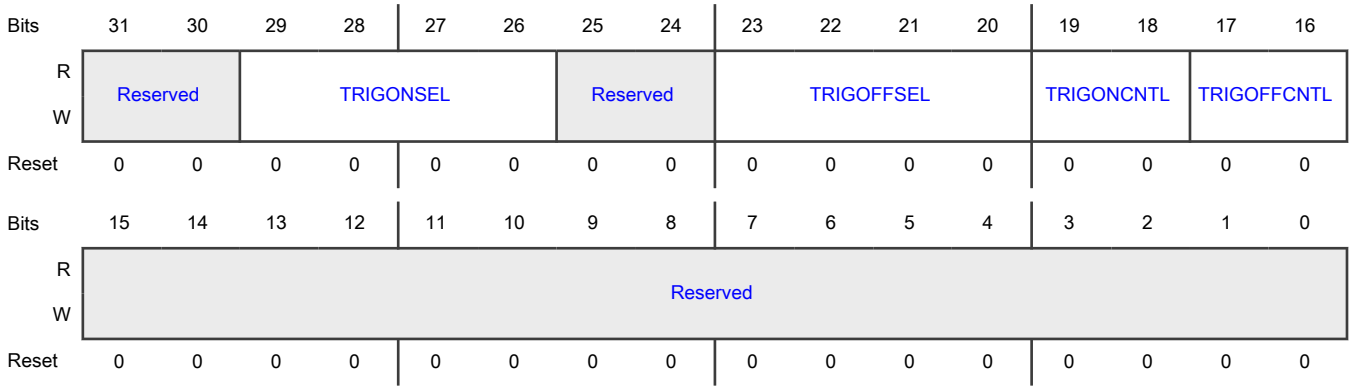
35.6.56 Performance Monitor Local Control B0 (PMLCB0)

Associates with counter 0 to specify how the counter is used and the events monitored on the counter.

Offset

Register	Offset
PMLCB0	E14h

Diagram



Fields

Field	Description
31-30 —	Reserved
29-26 TRIGONSEL	Trigger-On Select Specifies the number of the counter that starts event counting. When the corresponding TRIGONCNTL event overflows, the current counter begins counting. No triggering occurs if the value of this field is self-referential, that is, when the value of this field is set to the current counter number.
25-24 —	Reserved
23-20 TRIGOFFSEL	Trigger-Off Select Specifies the number of the counter that stops event counting. When the corresponding TRIGONCNTL event overflows, the current counter stops counting. No triggering occurs if the value of this field is self-referential, that is, when the value of this field is set to the current counter number.
19-18 TRIGONCNTL	Trigger-On Control Indicates the condition that triggers the counting to start. 00 - Triggering off (no triggering to start) 01 - Trigger on change 10 - Trigger on overflow 11 - Reserved
17-16 TRIGOFFCNTL	Trigger-Off Control Indicates the condition that triggers the counting to stop. 00 - Triggering off (no triggering to start)

Table continues on the next page...

Table continued from the previous page...

Field	Description
	01 - Trigger on change 10 - Trigger on overflow 11 - Reserved
15-0 —	Reserved

35.6.57 PMC 0a (PMC0a)

Holds the lower 32 bits of a 64-bit clock-cycle counter. PMC 0b (PMC0b) holds the upper 32 bits of that counter. This counter counts events that Performance Monitor Local Control A (PMLCA1 - PMLCA10) and Performance Monitor Local Control B (PMLCB1 - PMLCB10) select.

Offset

Register	Offset
PMC0a	E18h

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-0 PMC0	Counter 0 Counts only clock cycles. This field specifies a read-write counter, which you can program with an initial value to count from.

35.6.59 Performance Monitor Local Control A (PMLCA1 - PMLCA10)

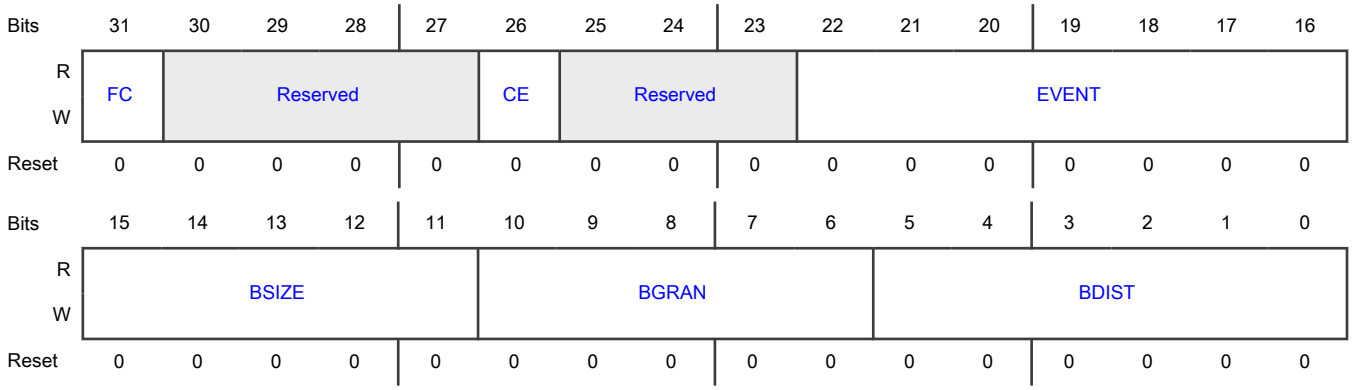
Controls the operation of the PMC*n* registers.

Offset

For a = 1 to 10:

Register	Offset
PMLCAa	E10h + (a × 10h)

Diagram



Fields

Field	Description
31 FC	Freeze Counter Indicates whether PMCs are enabled and incremented. They are if PMGC0[FAC] permits. This field enables the corresponding PMC*n* register to increment. 0 - Enabled 1 - Disabled
30-27 —	Reserved
26 CE	Condition Enable Controls the counter overflow conditions for PMC0. These conditions occur when the most-significant bit of PMC*n* is 1. When the conditions do not occur, they cannot cause interrupts or freeze counters. You must write 0 to this field when PMC0 is used as a trigger or is selected for chaining. 0 - Counter overflow conditions cannot occur 1 - Counter overflow conditions occur
25-23 —	Reserved
22-16 EVENT	Event Selector Selects events to be counted. See Event signals table for a list of events, counters, and the corresponding EVENT field values.
15-11 BSIZE	Burst Size Represents the fewest event occurrences that constitute a burst, which means, a rapid sequence of events followed by a relatively long pause. A value less than two events implies regular event counting. Any non-threshold, regular event may be counted in a bursty fashion.

Table continues on the next page...

Table continued from the previous page...

Field	Description
10-6 BGRAN	Burst Granularity Represents the maximum number of clock cycles between events that are considered part of a single burst.
5-0 BDIST	Burst Distance Specifies the burst distance, which is the number of clock cycles between bursts. This field works with PMLCB*n*[TBMULT] and must have a value greater than PMLCA*n*[BSIZE] for proper burstiness counting behavior. Writing 0 to this field indicates regular counting.

35.6.60 Performance Monitor Local Control B (PMLCB1 - PMLCB10)

Associates with counter 0 to specify how the counter is used and the events monitored on that counter.

Offset

For a = 1 to 10:

Register	Offset
PMLCBa	E14h + (a × 10h)

Diagram

Fields

Field	Description
31-30 —	Reserved
29-26	Trigger-On Select

Table continues on the next page...

Table continued from the previous page...

Field	Description
TRIGONSEL	Specifies the number of the counter that starts event counting. When the corresponding TRIGONCNTL event overflows, the current counter begins counting. No triggering occurs if the value of this field is self-referential, that is, when it is set to the current counter number.
25-24 —	Reserved
23-20 TRIGOFFSEL	Trigger-Off Select Specifies the number of the counter that stops event counting. When the corresponding TRIGONCNTL event overflows, the current counter stops counting. No triggering occurs if the value of this field is self-referential, that is, when it is set to the current counter number.
19-18 TRIGONCNTL	Trigger-On Control Indicates the condition that triggers the counting to start. 00 - Triggering off (no triggering to start) 01 - Trigger on change 10 - Trigger on overflow 11 - Reserved
17-16 TRIGOFFCNTL	Trigger-Off Control Indicates the condition that triggers the counting to stop. 00 - Trigger off (no triggering to start) 01 - Trigger on change 10 - Trigger on overflow 11 - Reserved
15-11 —	Reserved
10-8 TBMULT	Threshold And Burstiness Multiplier Represents threshold and burstiness multiplier. Threshold events are counted when the event duration exceeds a specified threshold value. The threshold is scaled based on the settings of this field, which is also used to scale the burst distance for burstiness counting. For all events that scale the threshold, the threshold field is multiplied from 1 to 128. This field is not used to scale the threshold value for quantity threshold events. 000 - 1 001 - 2 010 - 4 011 - 8

Table continues on the next page...

Table continued from the previous page...

Field	Description
	100 - 16 101 - 32 110 - 64 111 - 128
7-6 —	Reserved
5-0 THRESHOLD	Threshold Specifies a value that is used as an indicator to start counting events. When used, only those events are counted for which the value exceeds this programmed threshold value. For example, if PMC2 counts events for which the duration exceeds the threshold, you can obtain the distribution of those events for a given program by monitoring the program repeatedly, using a different threshold value each time.

35.6.61 Performance Monitor Counter (PMC1)

Specifies counters that can monitor 64 unique events in addition to the 64 reference events that the full set of PMC*n* registers can count.

Offset

Register	Offset
PMC1	E28h

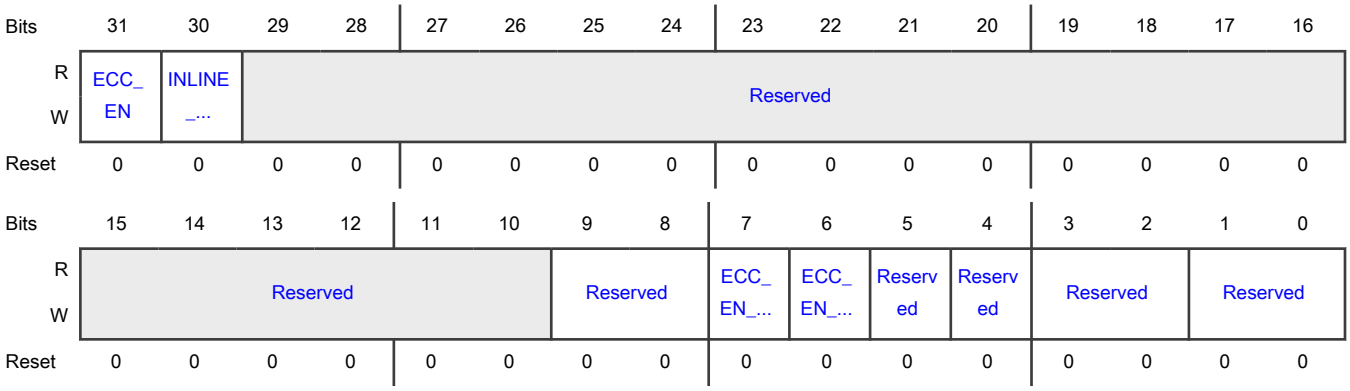
35.6.71 Error Enable (ERR_EN)

Enables controls for many errors that can be reported and injected.

Offset

Register	Offset
ERR_EN	1000h

Diagram



Fields

Field	Description
31 ECC_EN	ECC Enable Enabled global ECC protection for the DDR SDRAM space. This field is the global DDR SDRAM ECC enable. If this field is 0, no ECC errors are reported and no ECC interrupts are generated unless one or more ECC regions are enabled, refer to ECC Region Configuration registers ECC_REG_0 to ECC_REG_7. If this field is 1, the entire DDR SDRAM space is ECC protected. In case protection is enabled only for certain regions, you must program these registers to enable ECC: • ECC Region 0 Configuration (ECC_REG_0) • ECC Region 1 Configuration (ECC_REG_1) • ECC Region 2 Configuration (ECC_REG_2) • ECC Region 3 Configuration (ECC_REG_3) • ECC Region 4 Configuration (ECC_REG_4) • ECC Region 5 Configuration (ECC_REG_5) • ECC Region 6 Configuration (ECC_REG_6) • ECC Region 7 Configuration (ECC_REG_7) Uncorrectable read errors may cause an interrupt. 0 - Disables 1 - Enables
30 INLINE_ECC_EN	Inline ECC Enable Enables inline ECC. You can write 1 to this field only if all of the following conditions are met: • The memory has at least 13 row bits, 10 column bits, and 3 bank bits. • You have enabled data masks (DDR_SDRAM_CFG_3[DM_CFG]) • Either of these conditions is true: — ERR_EN[ECC_EN] = 1. — Certain ECC regions are enabled. When using two ranks of memory, each rank must use the same amount of memory with the same number of row, column, and bank address fields if inline ECC is enabled. When using a 17x10x3 configuration for the DRAM, after DRAM has valid data and ECC, you must read the initial 32k of DRAM, starting with the first defined address. This will load the internal ECC cache with valid data. This is only required for this maximum row/col/bank configuration. **NOTE** Use of inline ECC will reduce overall memory bandwidth. 0 - Disables 1 - Enables

Field	Description
31-0 ECLD	Error Capture Low Data Path Captures the low word of the data path when errors are detected.

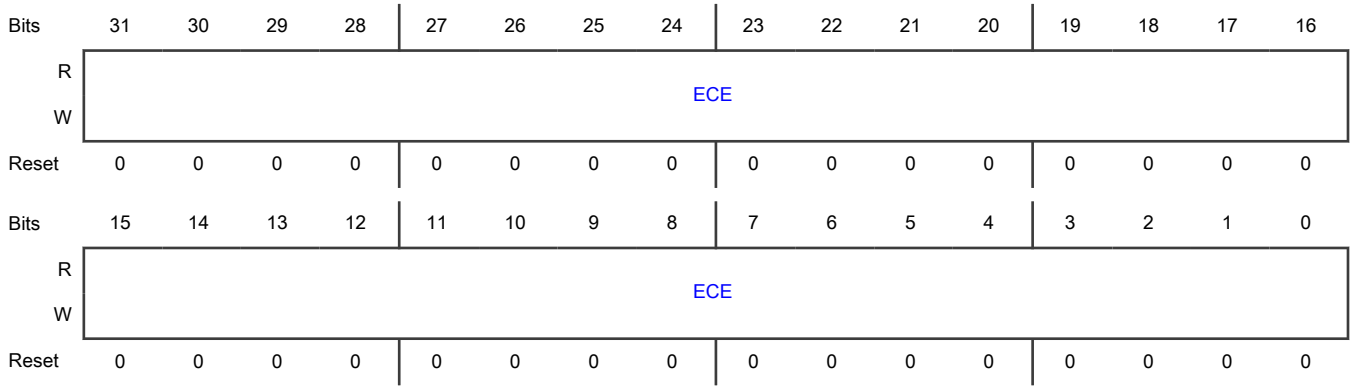
35.6.80 Memory Data Path Read Capture ECC (CAPTURE_ECC)

Stores the ECC syndrome bits that are on the data bus when an error is detected.

Offset

Register	Offset
CAPTURE_ECC	1128h

Diagram



Fields

Field	Description
31-0 ECE	Error Capture ECC Captures the ECC bits on the data path whenever errors are detected. ECC is always generated or checked on 64-bit data chunks. The bits of this field mean the following:

ECE bit numbers	Meaning
0–7	Show the 8-bit ECC for the fourth 64 bits of a 32-byte granule
8–15	Show the 8-bit ECC for the third 64 bits of a 32-byte granule
16–23	Show the 8-bit ECC for the second 64 bits of a 32-byte granule
24–31	Show the 8-bit ECC for the first 64 bits of a 32-byte granule

35.6.81 Memory Error Detect (ERR_DETECT)

Stores the detection fields for multiple-memory errors, single- and multiple-bit ECC errors, and memory-select errors.

You can determine the type of memory error by examining the contents of this register. If an error is disabled using Memory Error Disable (ERR_DISABLE), the corresponding error is never detected or captured in Memory Error Detect (ERR_DETECT).

NOTE

SSBE2, SMBE2 bits are not applicable for LPFLASH.

Offset

Register	Offset
ERR_DETECT	1140h

25 SSBE1	SRAM SBE 1 Indicates whether an SRAM 1 SBE occurred. The receiving multiple SRAM errors do not cause ERR_DETECT[MME] to become 1. 0 - Did not occur 1 - Occurred
24 SSBE2	SRAM SBE 2 Indicates whether an SRAM 2 SBE occurred. The receiving multiple SRAM errors do not cause ERR_DETECT[MME] to become 1. 0 - Did not occur 1 - Occurred
23 SMBE1	SRAM Multi-Bit Error 1 Indicates whether an SRAM 1 multi-bit error occurred. The receiving multiple SRAM errors do not cause ERR_DETECT[MME] to become 1. 0 - Did not occur 1 - Occurred
22 SMBE2	SRAM Multi-Bit Error 2 Indicates whether an SRAM 2 multi-bit error occurred. The receiving multiple SRAM errors do not cause ERR_DETECT[MME] to become 1. 0 - Did not occur 1 - Occurred
21 —	Reserved
20 UPDTMTE	Update Timeout Error Indicates whether a training update timeout is detected. The receiving multiple write configuration errors do not cause ERR_DETECT[MME] to become 1. 0 - Not detected 1 - Detected
19 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
18 —	Reserved
17 —	Reserved
16 PHYE	PHY error. Cleared by software writing a 1. Note that receiving multiple PHY errors will not cause the MME bit to get set. 0 - A DDR PHY error has not been detected. 1 - An error has been detected by the DDR PHY.
15-14 —	Reserved
13 —	Reserved
12 —	Reserved
11 —	Reserved
10 —	Reserved
9-8 —	Reserved
7 REFRATEE	Refresh rate error. Cleared by software writing a 1. 0 - A refresh rate error has not been detected. 1 - A refresh rate error has been detected.
6 —	Reserved
5 —	Reserved
4	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
3 MBE	Multiple-Bit Error Indicates whether DDRC detected a multiple-bit error. 0 - Not detected 1 - Detected
2 SBE	Single-Bit ECC Errors Indicates whether the number of detected single-bit ECC errors crossed the threshold defined in ERR_SBE[SBET]. 0 - Did not cross 1 - Crossed
1 —	Reserved
0 MSE	Memory-Select Error Indicates whether a memory-select error is detected. This error occurs if a transaction arriving at DDRC does not match any valid rank windows. 0 - Not detected 1 - Detected

35.6.82 Memory Error Disable (ERR_DISABLE)

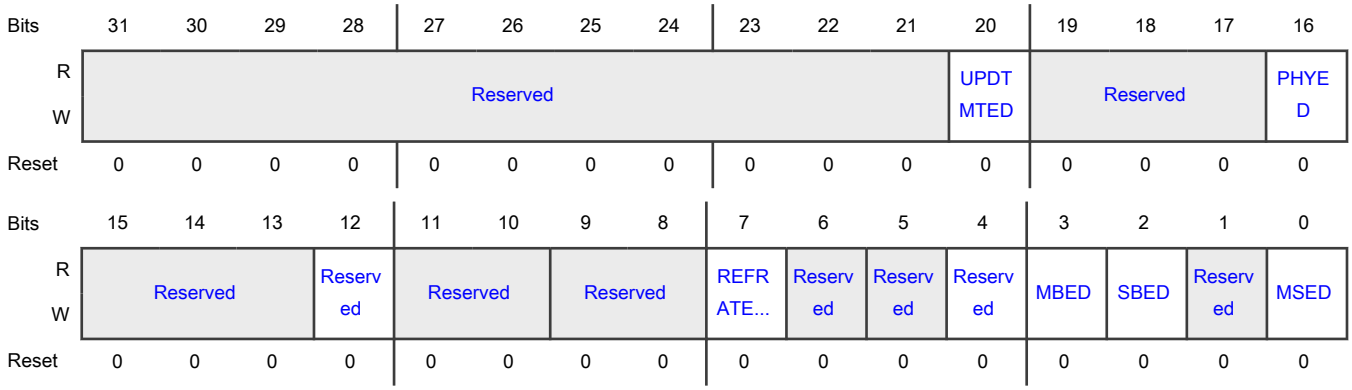
Allows selective disabling of DDRC's error-detection circuitry.

Disabled errors are not detected or reported.

Offset

Register	Offset
ERR_DISABLE	1144h

Diagram



Fields

Field	Description
31-21 —	Reserved
20 UPDTMTED	Update Timeout Error Disable Enables training timeout error checking. 0 - Enables 1 - Disables
19-17 —	Reserved
16 PHYED	PHY Error Disable Enables PHY error checking. 0 - Enables 1 - Disables
15-13 —	Reserved
12 —	Reserved
11-10 —	Reserved
9-8 —	Reserved
7	Refresh Rate Error Disable

Table continues on the next page...

Table continued from the previous page...

Field	Description
REFRATEED	Enables refresh rate error checking. 0 - Enables 1 - Disables
6 —	Reserved
5 —	Reserved
4 —	Reserved
3 MBED	Multiple-Bit ECC Error Disable Indicates if multiple-bit ECC errors are detected or reported. Multiple-bit ECC errors are detected if ERR_EN[ECC_EN] = 1. They are reported if ERR_INT_EN[MBEE] = 1. See Error management for more information. To ensure that an interrupt is generated: • This field must be 0. • ERR_INT_EN[MBEE] and ERR_EN[ECC_EN] must be 1. 0 - Detected 1 - Not detected or reported
2 SBED	Single-Bit ECC Error Disable Enables single-bit ECC errors. 0 - Enables 1 - Disables
1 —	Reserved
0 MSED	Memory-Select Error Disable Enables memory-select errors. 0 - Enables 1 - Disables

35.6.83 Memory Error Interrupt Enable (ERR_INT_EN)

Enables ECC interrupts or memory-select error interrupts.

When an enabled interrupt condition occurs, DDRC generates an interrupt.

Offset

Register	Offset
ERR_INT_EN	1148h

Fields

Field	Description
31-8 —	Reserved
7-0 CEADDR	Captured Extended Address Captures the 8 most-significant bits of the transaction address when an error is detected.

35.6.87 Single-Bit ECC Memory Error Management (ERR_SBE)

Stores:

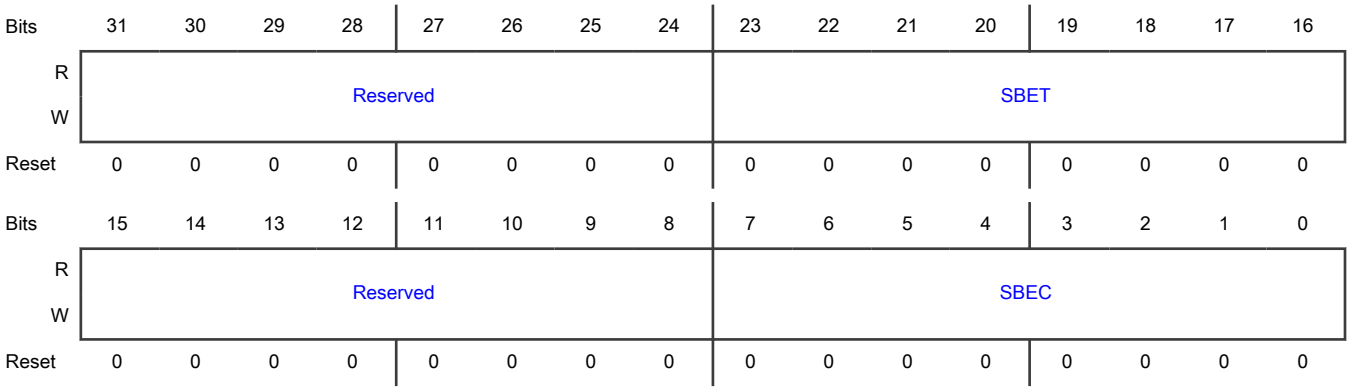
- The threshold value for reporting SBEs.
- The number of SBEs counted since the last error report.

ERR_SBE[SBEC] resets when it reaches the threshold. If necessary, you must reset the counter after it manages the error.

Offset

Register	Offset
ERR_SBE	1158h

Diagram



Fields

Field	Description
31-24 —	Reserved
23-16 SBET	SBE Threshold Establishes the number of SBEs that must be detected before an error condition is reported.

Table continues on the next page...

Table continued from the previous page...

Field	Description
15-8 —	Reserved
7-0 SBEC	SBE Counter Indicates the number of SBEs detected and corrected since the last error report. If you enable SBE reporting, an error is reported and an interrupt is generated when the value of this field equals that of ERR_SBE[SBET]. This field becomes 0 when it reaches its threshold value.

35.6.88 ECC Region 0 Configuration (ECC_REG_0)

Provides bits 31:20 for the starting and ending addresses of a region to be enabled for ECC. The region must be defined only if:

- You enable specific ECC regions.
- ERR_EN[ECC_EN] = 0.

NOTE

ECC region registers should not be programmed without first programming this register. If per region ECC enablement is used for any region, then you must have region 0 enabled.

Offset

Register	Offset
ECC_REG_0	1240h

11-0 REG_7_EA	Region 7 End Address Provides the value to be compared with the upper 12 bits of a 32-bit address when determining if the address is within region 7.

35.7 Glossary

Bank	A collection of memory-cell rows and columns
CS	Chip select
DBI	Data bus inversion
DLL	Delay-locked loop
ECC	Error checking and correction
FFI	Freedom from interference
MRW	Mode register write
ODT	On-die termination
Page	A synonym for row, usually used in the context of Open-Page mode
PIC	Programmable interrupt controller
PMC	Performance monitor counter
POR	Power-on reset
Posted refresh	In a posted refresh, more than one refresh command can be performed at a time. For example if you set the posted refresh to 5, then at each refresh interval 5 consecutive refreshes are issued, keeping the DDR interface blocked until all 5 refreshes are completed. this allows for a longer period of uninterrupted operation in DDR.
SBE	Single-bit error
SECDED	Single-error correcting, double-error detecting

Chapter 36
Flexible Serial Peripheral Interface (FlexSPI)

36.1 Chip-specific FLEXSPI information

Table 182. Reference links to related information

Topic	Related module	Reference
CM33	Arm Cortex CM33 Platform (CM33)	CM33 Platform
A55	Arm Cortex CA55 Platform (CA55)	CA55 Platform
Full description	FLEXSPI	FLEXSPI
System memory map		System memory map
Signal multiplexing	Port control	Signal multiplexing

The chip includes one instance of FLEXSPI with support for one channel.

NOTE

Low power mode entry-exit for FLEXIO is done without CLK gate and without QCHANNEL handshake.

36.1.1 Module instances

This device has one instance of the FLEXSPI module.

36.1.2 Master ID Assignments

To enable FlexSPI to view different IDs from different masters, follow the steps shown below:

- Set AHBCR[HMSTRIDREMAP] =1 to enable master ID mapping
- Configure HMSTRxCR[MSTRID] using the table below (The “n” should be masked by the mask value. Other bits can be selectively masked to group some masters into one AHB buffer region):

Table 183. Master IDs

Module	4-bit Master ID
Cortex-A55 cores	000n
Reserved	0010 - 0111
Cortex-M33	1000
Reserved	1001
Edgelock	1010
eDMA3_1(AHB)	1011
eDMA4_2(AXI)	1100
Reserved	1101 - 1110
All other bus masters	1111

NOTE

After reset, the FlexSPI sees all masters IDs as zero.

36.1.2.1 AHB Memory Map Address Range

The table below shows the address range calculations for the FlexSPI:

Table 184. Memory Map Address Ranges

Description	FlexSPI1
Address range mapped for AHB read access to FLEXSPI RX FIFO	0x4742_0000 – 0x4742_01FF
Address range mapped for AHB write access to FLEXSPI TX FIFO	0x4743_0000 – 0x4743_03FF
AHB Memory for Serial Flash memory access	0x2800_0000 - 0x2FFF_FFFF
AHB RX Buffer size	2 KByte
AHB TX Buffer size	64 Bytes
FLEXSPI RX FIFO	512 KByte
FLEXSPI TX FIFO	1 KByte

NOTE

- FLEXSPI command should be able to access Flash address space which is greater than 128MB.
- AHB command cannot access Flash address space which is greater than 128MB, it can only access within 128MB.
- But for IP command, AHB/IPS BUS both can access IP RX/TX FIFO(different reg configuration will choose IPS or AHB), which means IPS/AHB bus both can access greater than 128MB flash address space indirectly by IP RX/TX FIFO in IP command mode only.

36.2 Overview

FlexSPI supports one SPI channel and up to two external devices. Each channel supports Single/Dual/Quad/Octal mode data transfer (1/2/4/8 bidirectional data lines).

The FlexSPI configuration depends on the chip configuration. See the system-level section for boot information and pinmux for chip-specific information regarding the modes and number of devices supported.

FlexSPI supports communication with both serial flash memory and serial RAM devices. While many of the descriptions, registers, and fields specifically reference flash memory, almost all information can also be applied to serial RAM. Flash memory is used as an example in the tables and figures in this chapter.

NOTE

Terminology in this chapter has been updated to align with JEDEC standard *Expanded Serial Peripheral Interface (xSPI) for Non Volatile Memory Devices, Version 1.0*.

Table 185. Updated terms

Updated term	Deprecated term
Controller	Master
Target	Slave

36.2.1 Block diagram

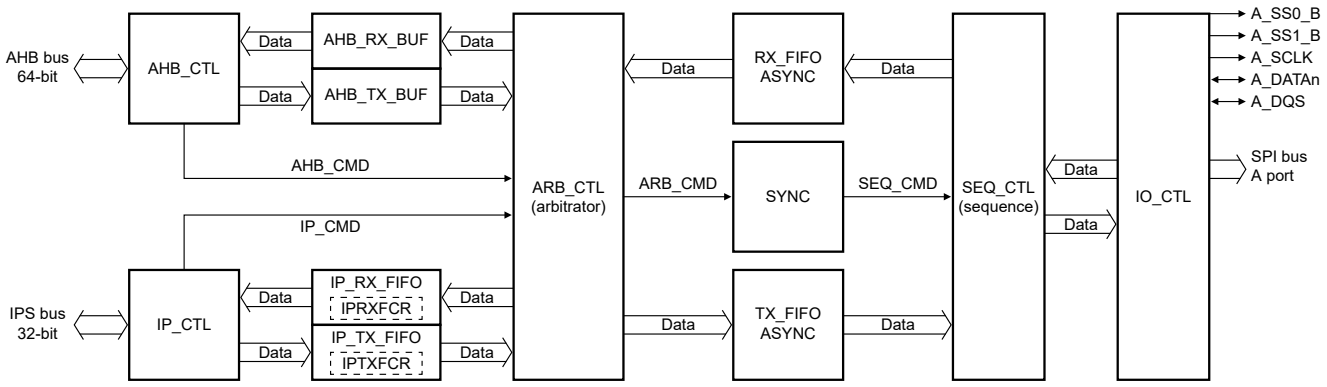

Figure 84. Block diagram

36.2.2 Features

FlexSPI supports:

- Flexible sequence engine (lookup table) to support various vendor devices
  - Serial NOR flash memory and other devices with SPI protocol similar to serial NOR flash memory
  - Serial NAND flash memory
  - HyperBus devices (HyperFlash/HyperRAM)
  - XCCELA devices
  - FPGA devices
- Flash memory access modes
  - Single, Dual, Quad, Octal mode
  - Single Data Transfer Rate (SDR) and Double Data Transfer Rate (DDR) mode
  - Individual mode
- Sampling clock mode
  - Internal dummy read strobe looped back internally
  - Internal dummy read strobe looped back from pad
  - Flash-memory-provided read strobe
- Automatic data learning to select the correct sample clock phase
- Memory mapped read and write access by AHB bus
  - AHB receive buffer implemented to reduce read latency. See the chip-specific section for AHB buffer size.
  - 16 AHB controllers with programmable priority for read access from each
  - 8 flexible and configurable buffers in AHB receive buffer
  - AHB transmit buffer implemented to buffer all write data from one AHB burst. See the chip-specific section for AHB buffer size.

NOTE

All AHB controllers share this AHB transmit buffer. There is no AHB controller number limitation for write access.

- Software-triggered flash memory read and write access by IP bus
  - IP receive FIFO implemented to buffer all read data from external devices. FIFO size: 512 bytes
  - IP transmit FIFO implemented to buffer all write data to external devices. FIFO size: 1024 bytes
  - DMA support to read IP receive FIFO
  - DMA support to fill IP transmit FIFO
  - SCLK stops when IP receive FIFO is full during reading flash memory data
  - SCLK stops when IP transmit FIFO is empty during writing flash memory data

36.3 Glossary for FlexSPI module

Table 186. Glossary

Term	Definition
AHB Command	AHB Command is one or several Serial Flash Memory access command sequences triggered by AHB read/write access to AHB address ranged mapped for Serial Flash Memory.
ASFM_BASE	Base address of AHB address space mapped to Serial Flash Memory.
ARDF_BASE	Base address of AHB address space mapped to IP RX FIFO.
ATDF_BASE	Base address of AHB address space mapped to IP TX FIFO.
Set	Write 1 to register bit to establish logic level one on the bit.
Clear	Write 0 to register bit to establish logic level zero on the bit.
Command Sequence	A command sequence is 4*32 bits sequence code consisting of up to 8 instructions. Command sequence should be programmed in LUT according to Flash command. When a command sequence executed, the chip selection signal becomes asserted. When a command sequence execution finished, the chip selection signal becomes negated.
DDR	Dual data transfer rate for flash access mode Flash receive data on both SCLK rise and fall edge and transmit data on both SCLK rise and fall edge.
Endianness	Byte Ordering scheme.
Field	Two or more register bits grouped together.
Fill	To add entries to a FIFO by software or hardware.
Instruction Code	16 bits code defining the type of command to be executed on FlexSPI interface.
IP Command	IP Command is one or several Serial Flash Memory access command sequences triggered by set register bit IPCMD.TRG.
Negated	A signal that is negated is in its inactive state. An active low signal changes from logic level 0 to logic level 1 when negated, and an active high signal changes from logic level 1 to logic level 0.
SDR	Single data transfer rate for flash access mode

Table continues on the next page...

Table 186. Glossary (continued)

Term	Definition
	Flash receive data on SCLK rise edge and transmit data on SCLK fall edge.
Set	To set a bit or bits means to establish logic level one on the bit or bits.
SFM	Serial Flash Memory
Individual Mode	Access to a single, individual serial flash device at a time.
Memory Command	Serial access Command for reading/programming/configuring. A memory command may consist one or several command sequences, for each command sequence the Chip selection signal will be asserted and deasserted once.
LUT	Look-up table to preserve command sequence. LUT is programmed by software with command sequences which is used to issue memory commands.

36.4 Functional description

36.4.1 Flash connection

There is one FlexSPI interface port (port A) that supports up to two flash devices by providing two chip select outputs.

NOTE

FlexSPI configuration depends on the chip configuration. See the chip-specific FlexSPI information regarding the number of devices supported.

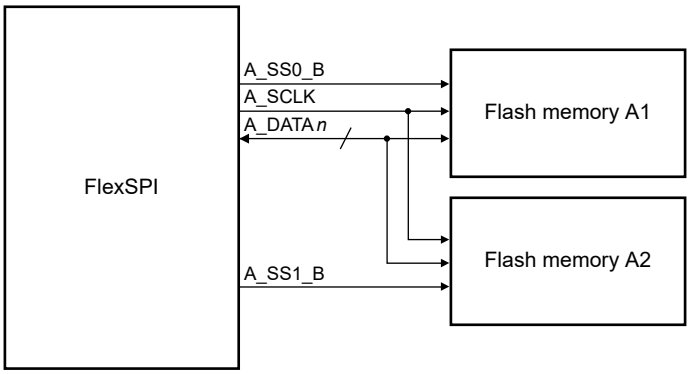

Figure 85. FlexSPI connection diagram with two devices.

NOTE

- Flash A1 and Flash A2 can be two flash chip packages or two flash dies in the same package.
- In individual mode, flash devices cannot be accessed at the same time. But these two devices can be accessed separately.

36.4.2 Flash memory access mode

36.4.2.1 SPI clock mode

FlexSPI only supports SPI clock mode 0: clock polarity (CPOL) = 0 and clock phase (CPHA) = 0. When the SPI bus is idle, SCLK stays at a logic low state.

36.4.2.2 Individual mode

In individual mode, read and write data are received and transmitted on port A or port B.

NOTE

FlexSPI does not support 16-bit read and write for the SPI interface.

36.4.2.3 SDR mode and DDR mode

In SDR mode, flash memory receives data on the rising edge of SCLK and transmits data on the falling edge of SCLK.

In DDR mode, flash memory receives and transmits data on both the rising and falling edges of SCLK.

The instruction (opcode) in the LUT sequence dynamically determines SDR and DDR modes. There is no static configuration register field setting for SDR and DDR modes. See FlexSPI input timing and FlexSPI output timing for details about input and output timing.

36.4.2.4 Single, Dual, Quad, and Octal mode

In Single mode, FlexSPI transmits and receives data on one data pin (DATA0 for transmitting, DATA1 for receiving).

In Dual mode, FlexSPI transmits and receives data on two data pins (DATA0–DATA1 for both transmitting and receiving).

In Quad mode, FlexSPI transmits and receives data on four data pins (DATA0–DATA3 for both transmitting and receiving).

In Octal mode, FlexSPI transmits and receives data on eight data pins (DATA0–DATA7 for both transmitting and receiving).

Instruction (num_pads) in the LUT sequence dynamically determine Single, Dual, Quad, and Octal modes. There is no static configuration register field setting for Single, Dual, Quad, and Octal modes.

36.4.3 Modes of operation

FlexSPI operates with these modes.

Table 187. Operating modes

Mode	Description
Module Disable	This mode is a low-power mode for FlexSPI. In Module Disable mode, the AHB clock and serial clock domains are gated off internally, but the IPS bus clock domain is not gated off. Read and write access to the control and status register are available, but the LUT, IP receive FIFO, and IP transmit FIFO cannot be accessed. Serial memory access is also not available. Write 1 to MCR0[MDIS] to enter this mode. Write 0 to MCR0[MDIS] to exit this mode.
Doze	This mode is a low-power mode for the chip. When the chip requires FlexSPI to enter Doze mode and MCR0[DOZEEN] = 1, FlexSPI enters Doze mode after all transactions are completed (STS0[ARBIDLE] = 1). In Doze mode, the AHB clock and serial clock domains are gated off internally, but the IPS bus clock is not gated off. Read and write access to the control and status register are available, but the LUT, IP receive FIFO, the IP transmit FIFO cannot be accessed. Serial memory access is also not available.

Table continues on the next page...

Table 187. Operating modes (continued)

Mode	Description
	This mode is entered via system request, and exited by deasserting this system request.
Stop	This mode is a low-power mode for the chip. When the chip requires the FlexSPI to enter Stop mode, FlexSPI waits for all transactions to complete (STS0[ARBIDLE] = 1) and return ACK handshake to the system. After the ACK handshake is returned, FlexSPI gates off the AHB clock and serial clock domains internally. The system can gate off the AHB bus clock, IPS bus clock, and serial clock at the system level. This mode is entered via system request. This mode is exited by deasserting this system request, and the ACK handshake message is also deasserted immediately.
Normal	No clock is gated off internally. Normal register access and serial memory access are available.

36.4.4 AHB access memory map

FlexSPI allocates AHB memory space for each memory device starting from the FlexSPI region base address of the system memory map. The FLSHxCR0[FLSHSZ] field determines the amount of memory allocated for each memory device in KB, Fx_SIZE. The memory is then allocated sequentially and contiguously.

NOTE

See the chip-specific section for the maximum flash size supported.

When MCR2[SAMEDEVICEEN] = 1:

- FA1_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB
- FA2_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB
- FB1_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB
- FB2_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB

When MCR2[SAMEDEVICEEN] = 0:

- FA1_SIZE = FLSHSZ × 1 KB
- FA2_SIZE = FLSHA2CR0[FLSHSZ] × 1 KB
- FB1_SIZE = FLSHB1CR0[FLSHSZ] × 1 KB
- FB2_SIZE = FLSHB2CR0[FLSHSZ] × 1 KB

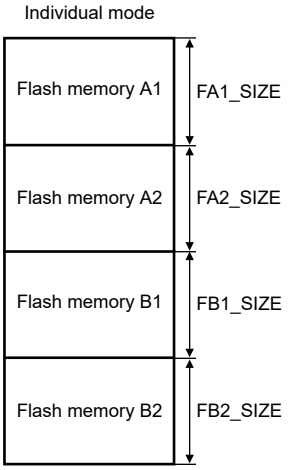

Figure 86. AHB access memory map in individual mode

AHB access memory map in individual mode:

- Flash A1 address range: 0000_0000h to FA1_SIZE
- Flash A2 address range: FA1_SIZE to (FA1_SIZE + FA2_SIZE)
- Flash B1 address range: (FA1_SIZE + FA2_SIZE) to (FA1_SIZE + FA2_SIZE + FB1_SIZE)
- Flash B2 address range: (FA1_SIZE + FA2_SIZE + FB1_SIZE) to (FA1_SIZE + FA2_SIZE + FB1_SIZE + FB2_SIZE)

NOTE

The address used in equations in this topic is the address presented to the memory. The base address for FlexSPI in the system memory map has already been removed, so it not used or shown here.

36.4.4.1 Flash address sent to flash memory devices

The AHB address (AHB command) or IPCR0[SFAR] (IP command) determines the flash memory access start address. See Flash memory access via AHB command and Flash memory access via IP command for more details.

For AHB commands, the FlexSPI controller removes the flash memory base address automatically when sending flash addresses to flash devices. The flash address is sent to devices in two parts: row address and column address. For flash devices that do not support the column address, set FLSHxCR1[CAS] to 0. This setting causes all flash address bits to be sent to flash devices as row addresses.

For word-addressable flash devices, the last bit of the address is not needed, because flash memory is read and programmed in terms of two bytes.

36.4.5 Lookup table (LUT)

The LUT is an internal memory that preserves a number of preprogrammed sequences. Each sequence consists of up to eight instructions which are executed sequentially. When an IP command or an AHB command triggers a flash memory access, the FlexSPI controller:

1. Fetches the sequence from LUT (sequence index or number).
2. Executes the flash memory access to generate a valid flash transaction on the SPI interface.

Figure 87 shows the LUT structures, sequences, and instructions.

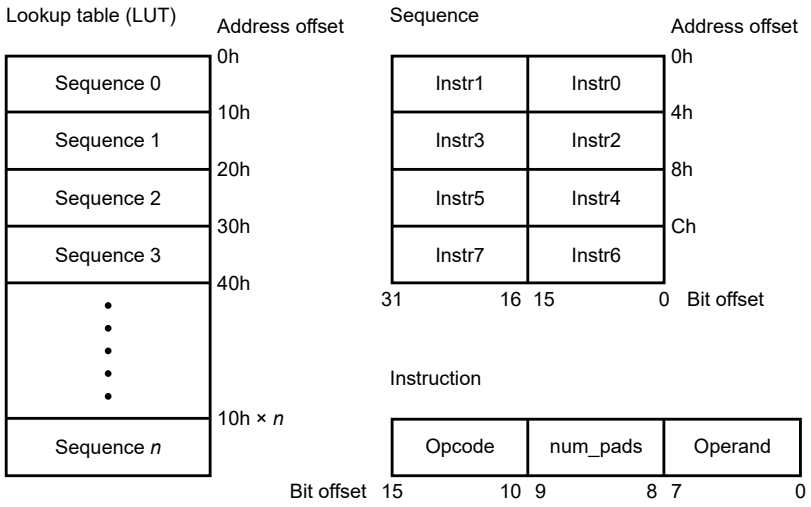

Figure 87. LUT structure, sequences, and instructions

NOTE

If the number of instructions needed for a flash transaction is less than eight, the STOP instruction (code 0000_0000h) must be programmed for unneeded instructions.

For IP and AHB write commands, the FlexSPI controller always executes from instruction pointer 0. For AHB read commands, the FlexSPI controller executes from a saved instruction start pointer. The FlexSPI controller saves the instruction start pointers separately for each flash device. All these saved instruction pointers are zero before the JMP_ON_CS instruction is executed. When the JMP_ON_CS instruction is executed, the operand in the JMP_ON_CS instruction is saved as instruction start pointer. See Execute-In-Place (XIP) enhanced mode.

The reset value of the LUT is unknown because it is implemented as internal memory. The LUT must be programmed according to the connected device. To protect its contents during a code runover, the LUT can be locked or unlocked to prevent unwanted changes after the LUT has been configured. The key to lock or unlock the LUT is **5AF05AF0h**.

To lock the LUT:

1. Write the key (5AF05AF0h) to LUT Key (LUTKEY).
2. Write 1 to LUTCR[LOCK] and write 0 to LUTCR[UNLOCK]. When there is another register write access to FlexSPI between these two write accesses, this LUT is not successfully locked.

To unlock the LUT:

1. Write the key (5AF05AF0h) to the LUT Key Register LUT Key (LUTKEY).
2. Write 0 to LUTCR[LOCK] and write 1 to LUTCR[UNLOCK]. When there is another register write access to FlexSPI between these two write accesses, this LUT is not successfully locked.

The lock status of the LUT can be read from LUTCR[LOCK] and LUTCR[UNLOCK].

36.4.6 Programmable sequence engine

The FlexSPI controller implements a programmable sequence engine that executes the sequence from the LUT. The FlexSPI controller executes the instructions sequentially, and generates flash transactions on the SPI interface accordingly. Table 188 is a complete list of the supported instructions.

Table 188. Instruction set

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
CMD_SDR	00_0001h	00h - one pad (Single mode) 01h - two pads (Dual mode) 02h - four pads (Quad mode) 03h - eight pads (Octal mode)	Transmit command code to flash memory	Command code: Operand[7:0]	Bit number: 8
CMD_DDR	00_0021h				
RADDR_SDR	00_0002h		Transmit row address to flash memory See Flash address sent to flash memory devices	Row_Address[31:0] Row_Address comes from AHB bus (AHB command) or IPCR0[SFAR] (IP command).	Bit number: operand[7:0] Value of operand determines number of bits sent in Row_Address.
RADDR_DDR	00_0022h				
CADDR_SDR	00_0003h		Transmit column address to flash memory. See Flash address sent to flash memory devices.	Column_Address[31:0] Column_Address comes from AHB bus (AHB command) or IPCR0[SFAR] (IP command).	Bit number: operand[7:0] Value of operand determines number of bits sent in Column_Address.
CADDR_DDR	00_0023h				
MODE1_SDR	00_0004h		Transmit mode bits to flash memory	Mode bits: Operand[0]	Bit number: 1
MODE1_DDR	00_0024h				
MODE2_SDR	00_0005h			Mode bits: Operand[1:0]	Bit number: 2
MODE2_DDR	00_0025h				
MODE4_SDR	00_0006h			Mode bits: Operand[3:0]	Bit number: 4
MODE4_DDR	00_0026h				
MODE8_SDR	00_0007h			Mode bits: Operand[7:0]	Bit number: 8
MODE8_DDR	00_0027h				
WRITE_SDR	00_0008h		Transmit program data to flash device	Program data in IP_TX_FIFO or AHB_TX_BUF	AHB burst size and burst type (AHB command) or IPCR1[IDATSZ] (IP command) determines byte number (data size). For details about flash read or program data size, see Flash memory access via AHB command and Flash memory access via IP command.
WRITE_DDR	00_0028h				
READ_SDR	00_0009h		Receive read data from flash device Read data is put into AHB_RX_BUF or IP_RX_FIFO.	-	
READ_DDR	00_0029h				
DATSZ_SDR	00_000Bh		Transmit read or program data size	Internal logic	Bit number: operand[7:0]
DATSZ_DDR	00_002Bh				

Table continues on the next page...

Table 188. Instruction set (continued)

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
			(byte number) to flash device	Read or program data size for current command sequence	Never set operand to zero or greater than 64 for DATSZ instruction.
DUMMY_SDR	00_000Ch		Leave data lines undriven by FlexSPI controller. Turnaround cycles are provided from host driving to device driving. num_pads determines number of pads in input mode.	-	Dummy cycle number (in serial root clock): Operand[7:0] Dummy cycle (N), described in data sheet of flash device, is in number of SCLK cycles. This number may be configurable. In SDR mode, SCLK cycle is same as serial root clock. Operand value must be set to N. In DDR mode, SCLK cycle is double serial root clock cycle. Operand value must be set to 2N, 2N-1 or 2N+1 depending on definition of dummy in data sheet of flash device. See Flash memory access sequence examples and dummy cycle definition in data sheet of external memory.
DUMMY_DDR	00_002Ch				
DUMMY_RWDS_SDR	00_000Dh		Similar to DUMMY_SDR/ DUMMY_DDR instruction. Difference is in dummy cycle number. DQS pin is called RWDS in HyperBus specification. See Dummy instruction for details. **Set operand to "Latency count" for HyperBus devices.**	-	For read command, dummy cycle number (in serial root clock): (operand[7:0] × 4 - 1) if RWDS (DQS pin) is high; (operand[7:0] × 2 - 1) if RWDS (DQS pin) is low; For write command, dummy cycle number (in serial root clock): (operand[7:0] × 4 - 2) if RWDS (DQS pin) is high; (operand[7:0] × 2 - 2) if RWDS (DQS pin) is low;
DUMMY_RWDS_DDR	00_002Dh				

Table continues on the next page...

Table 188. Instruction set (continued)

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
LEARN_SDR	00_000Ah	00h - one pad (Single mode) 01h - two pads (Dual mode) 02h - four pads (Quad mode) 03h - eight pads (Octal mode)	Receive read data or preamble bit from flash device FlexSPI controller compares data line bits with the DLPR register to determine a correct sampling clock phase.	-	Bit number: operand[7:0] Never set operand to zero for LEARN instruction. Value of operand indicates number of bits to receive and compare to DLPR value. For example, 8-bit pattern 5Ah on each data line must set operand to 8.
LEARN_DDR	00_002Ah				
JMP_ON_CS	00_001Fh	Num_pads setting ignored.	Stop execution, deassert CS and save operand[7:0] as instruction start pointer for next sequence. Normally this instruction is used to support Execute-In-Place enhanced mode. See Execute-In-Place (XIP) enhanced mode. This instruction is only allowed for AHB read commands. When using this instruction in IP command or AHB write command, interrupt status flag set (INTR[IPCMDERR] or INTR[AHBCMDERR]).	-	No transaction on SPI interface.
STOP	00_0000h		Stop execution and deassert CS. Next command sequence (to same flash device) starts from instruction pointer 0.	-	

The programmable sequence engine allows configuration of the LUT according to the connected external serial device. The flexible LUT structure easily adapts to new command or protocol changes from different vendors.

The DDR sequence is a flash memory access sequence that contains DDR instructions other than DUMMY_DDR, and may contain SDR instructions. The output and input timing on FlexSPI differs for SDR and DDR sequences. When included as part of a DDR sequence, SDR instructions execute differently from SDR instructions in an SDR sequence. See FlexSPI input timing and FlexSPI output timing.

36.4.6.1 Executing instructions on SPI interface

This section describes the execution of instructions on the SPI interface. For all instructions that receive bits from or transmit bits to flash devices:

- The bit order in one byte is higher on DATA7 than DATA0.
- The bit order is higher on port B than port A.

This order is shown in Figure 88.

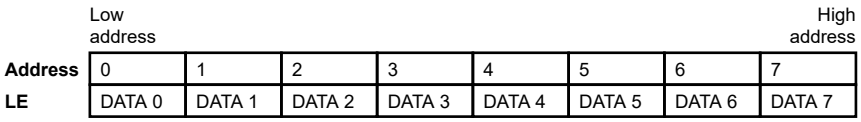

Figure 88. Bus bit order

Figure 89. Bit order precedence in combination mode

Table 189. SPI instructions

Instructions	Description
Command (CMD_SDR, CMD_DDR)	Normally used to transmit a command code to the external device. The command code is the 8-bit operand in the instructions. See Flash memory access sequence examples.
Address (RADDR_SDR, RADDR_DDR, CADDR_SDR, CADDR_DDR)	Normally used to send the flash memory access start address (row address or column address) to an external device. FlexSPI determines the bits of the row address or column address according to the AHB access address or IP command address. See Flash address sent to flash memory devices. The operand value in the instruction code represents the number of address bits to send. For example, when NUM_PADSn = 8, a memory reading the flash memory address on four SCK edges requires the sum of bits in CADDR and RADDR instructions to be 32. Otherwise, FlexSPI does not generate four SCK edges of address phase. See Flash memory access sequence examples.
Mode (MODEx_SDR, MODEx_DDR)	Normally used to send mode bits to external devices. Mode bits are the lower bits of an operand. For example, the bit number is 1 for MODE1_SDR and MODE1_DDR, 2 for MODE2_SDR and MODE2_DDR, 4 for MODE4_SDR and MODE4_DDR, and 8 for MODE8_SDR and MODE8_DDR. The pad number should not be greater than the mode bit number. For example, you cannot set NUM_PADSn to 11b (Octal mode) for MODE4_* instructions. See Flash memory access sequence examples for more details.
Data Size (DATSZ_SDR, DATSZ_DDR)	Used to send the size of program data or read data (byte number) to external devices. This instruction is normally used in FPGA applications where the memory space in external device acts like a FIFO. The external device requires data size information to determine how much

Table continues on the next page...

Table 189. SPI instructions (continued)

Instructions	Description
	data are popped from or pushed into the internal FIFO. The operation value in the data size instructions is the bit number. See Flash memory access sequence examples.
Write (WRITE_SDR, WRITE_DDR)	Normally used to send program data to external device. Programming data is fetched from IP_TX_FIFO (IP Command) or AHB_TX_Buffer (AHB command). For details about flash program data size, see Flash memory access via AHB command and Flash memory access via IP command. The byte order for program data is always from low to high. See Flash memory access sequence examples for more details.
Read (READ_SDR, READ_DDR)	Normally used to receive flash memory data from external devices. Received data is put into IP_RX_FIFO (IP Command) or AHB_RX_Buffer (AHB command). For information about flash memory read data size, see Flash memory access via AHB command and Flash memory access via IP command. The byte order for reading data is always from low to high. See Flash memory access sequence examples.
Dummy (DUMMY_SDR, DUMMY_DDR, DUMMY_RWDS_SDR, DUMMY_RWDS_DDR)	Used to provide turnaround cycles on the SPI interface. During dummy instruction, the FlexSPI controller and external devices do not drive the SPI interface. See Programmable sequence engine for details about dummy cycle number. DUMMY_RWDS_DDR can be used for a HyperBus device that uses RWDS pin to indicate whether extra latency is needed. DUMMY_RWDS_SDR is reserved. The FlexSPI controller checks the DQS pin input level at the fourth cycle after SCLK output toggling is enabled. The DQS pin is called RWDS in HyperBus specification. See Flash memory access sequence examples. **NOTE** FlexSPI releases the bus after at least one cycle. To avoid data contention, the NUM_PADSn value for the dummy commands should be configured to match the number of data lines used for the external memory.
Learn (LEARN_SDR, LEARN_DDR)	Used to determine the correct sample clock phase for flash memory read data sampling. External device drives read data (or data learning pattern) bits on the FlexSPI interface. The FlexSPI controller compares the data line bits to the DLPR register to determine a correct sampling clock phase. Clock phase selection is automatically updated after executing learn instructions. See Data learning for more details. The operand value in learn instructions is the byte number. FlexSPI checks the same data pattern on each data line. The byte order is byte 0, byte 1, byte 2, byte 3, byte0, byte 1, and so on. • Byte 0 is DLPR register bits 7–0. • Byte 1 is DLPR register bits 15–8. • Byte 2 is DLPR register bits 23–16. • Byte 3 is DLPR register bit 31–24. The bit order is from high to low in each byte. See Flash memory access sequence examples.

36.4.6.2 Flash memory access sequence examples

Diagrams below all assume MCR0[SERCLKDIV] = 0.

Figure 90 shows an example SDR single I/O read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.

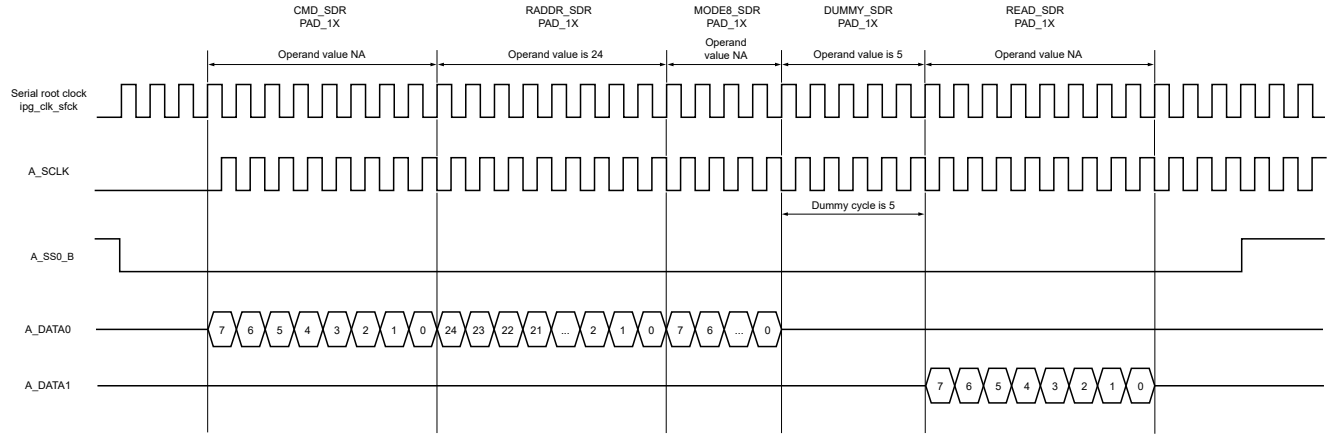

Figure 90. Flash memory access sequence example (SDR single I/O read sequence)

NOTE

- FlexSPI dummy instruction starts and ends at the rising edge of serial root clock.
- Device dummy cycle starts and ends at the falling edge of SCLK (on Cypress S25FS512S data sheet).

Figure 91 shows an example SDR quad I/O read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.

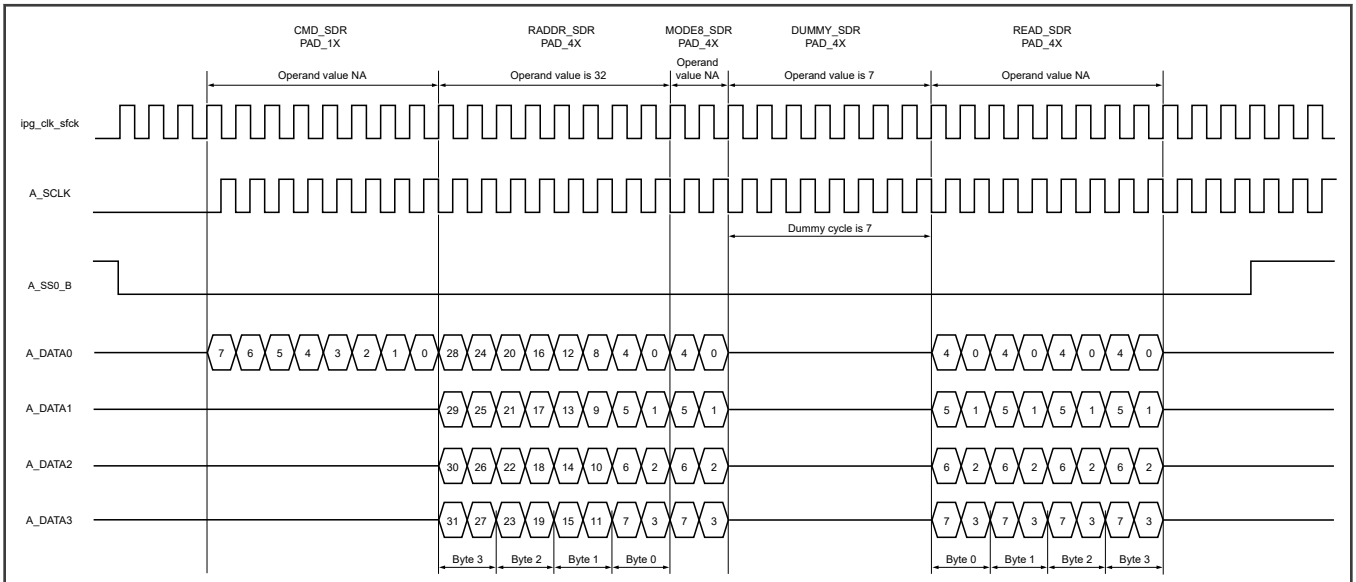

Figure 91. Flash memory access sequence example (SDR quad I/O read sequence)

NOTE

- FlexSPI dummy instruction starts and ends at the rising edge of serial root clock.
- Device dummy cycle starts and ends at the falling edge of SCLK (on Cypress S25FS512S data sheet).

Figure 92 shows an example learn instruction (not for a specified flash device) in individual mode.

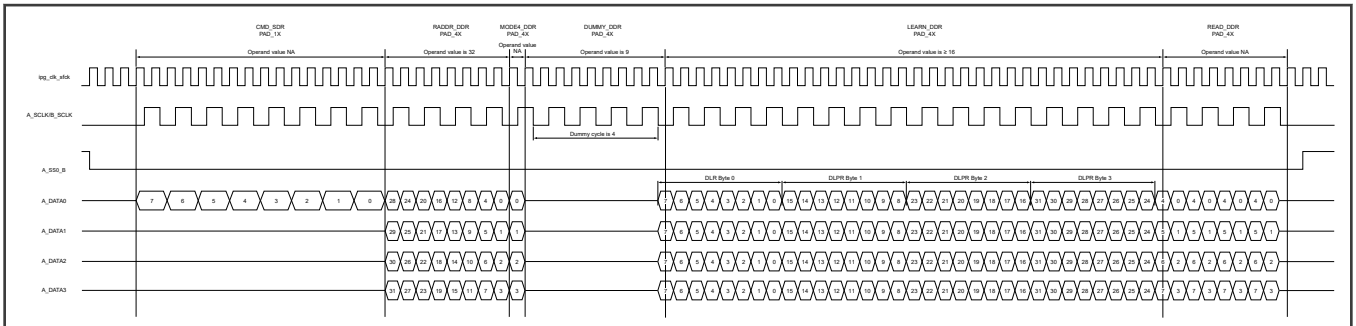

Figure 92. Flash memory access sequence example (data learning)

NOTE

- FlexSPI dummy instruction starts and ends at the rising edge of serial root clock.
- Device dummy cycle starts and ends at the falling edge of SCLK.
- The operand value of DUMMY_DDR instruction is odd because the total cycle number before DUMMY_DDR cycle is odd.

Figure 93 shows an example HyperBus device read transaction (single latency count) in individual mode.

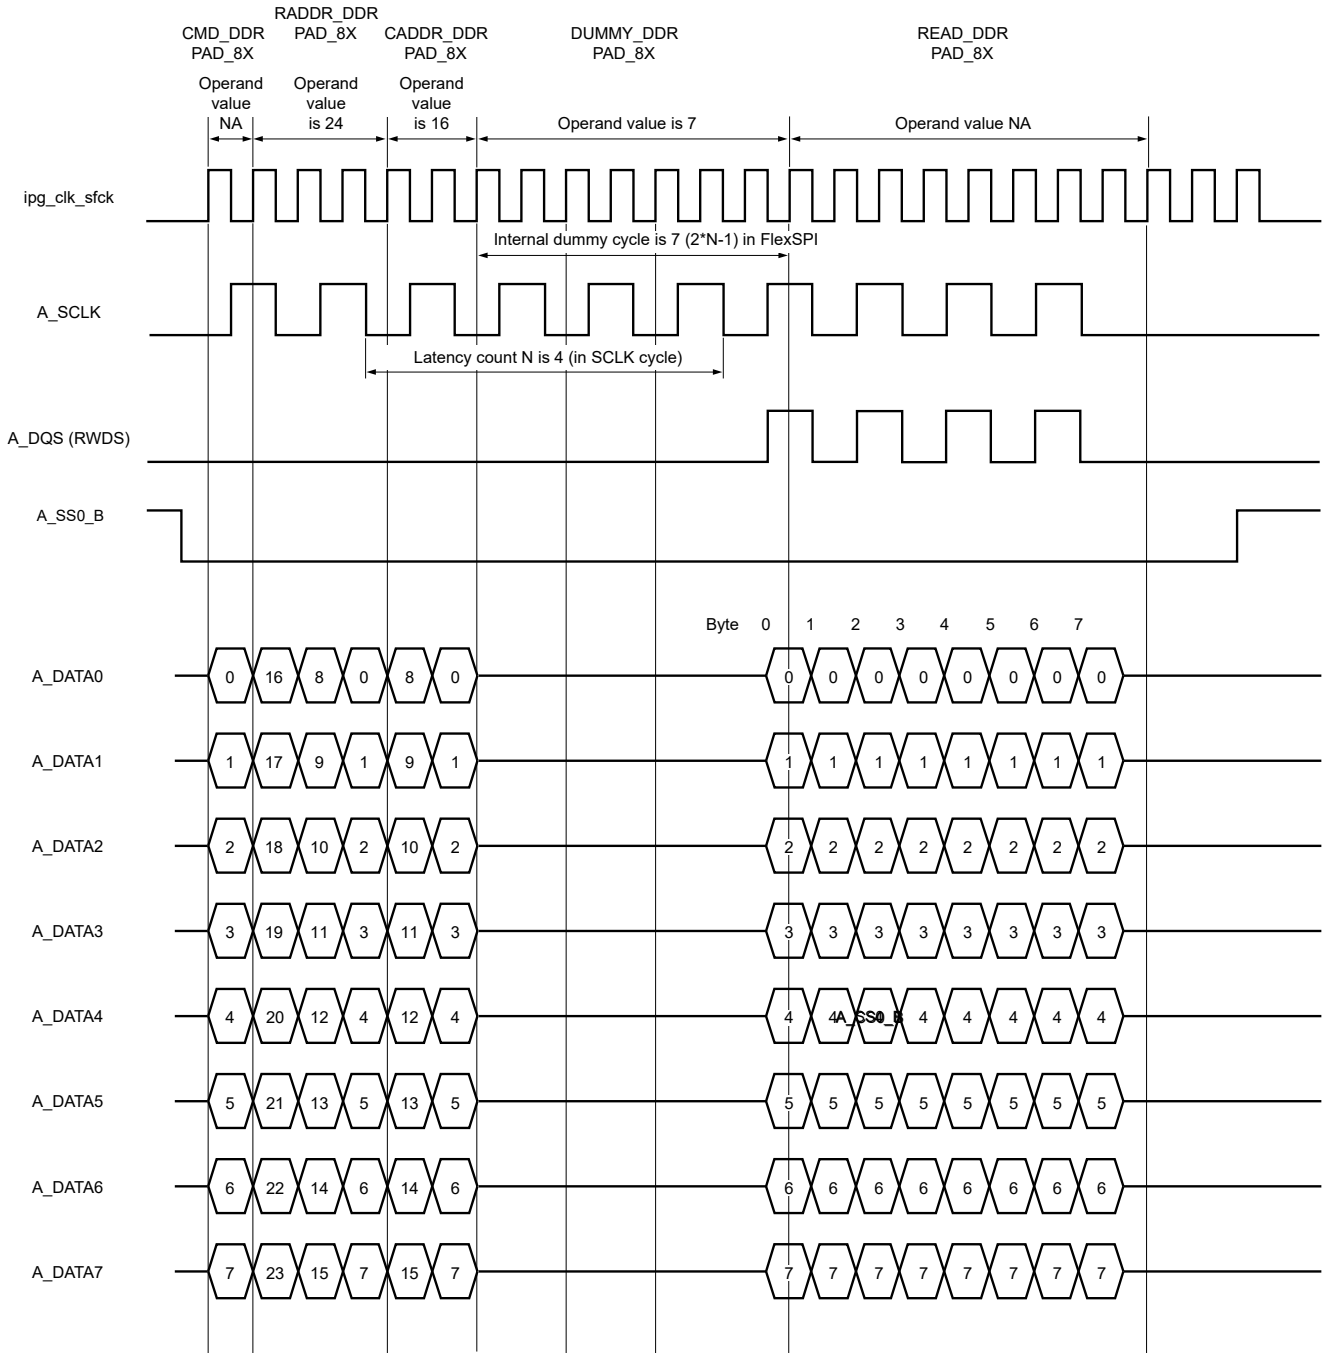

Figure 93. HyperBus device read transaction with single latency count

NOTE

FlexSPI continues to drive the clock until it has latched all of the read data it is expecting. On-chip delay for the data to reach FlexSPI can increase the number of SCK clock pulses.

Figure 94 shows an example HyperBus device read transaction (additional latency count) in individual mode.

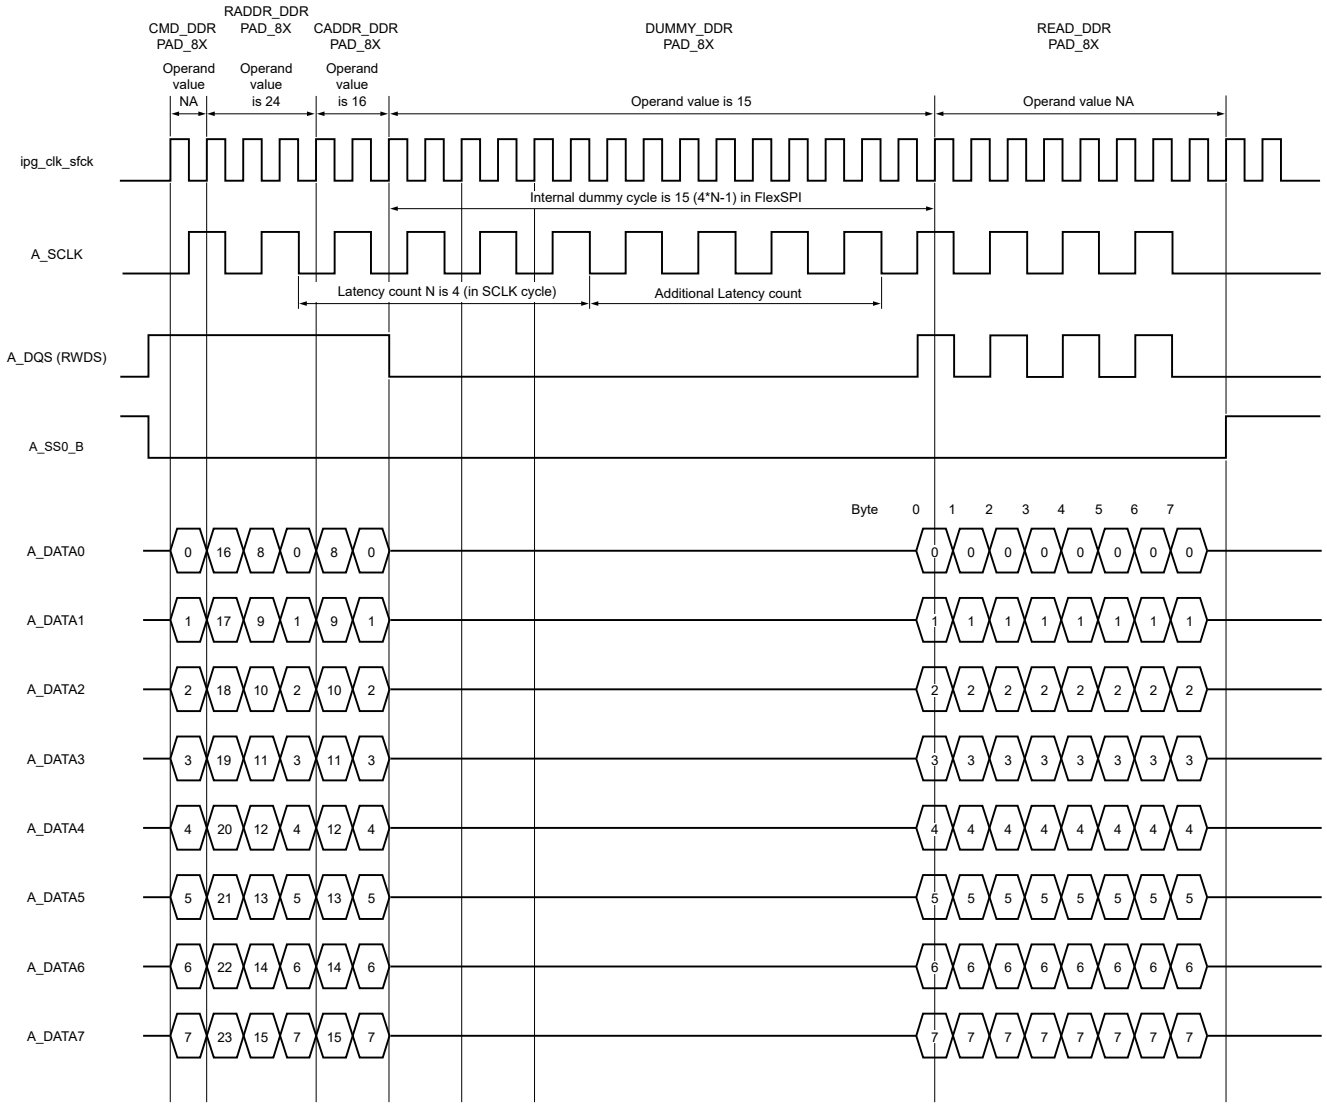

Figure 94. HyperBus device read transaction with additional latency count

Figure 95 shows an example HyperBus device write transaction (single latency count) in individual mode.

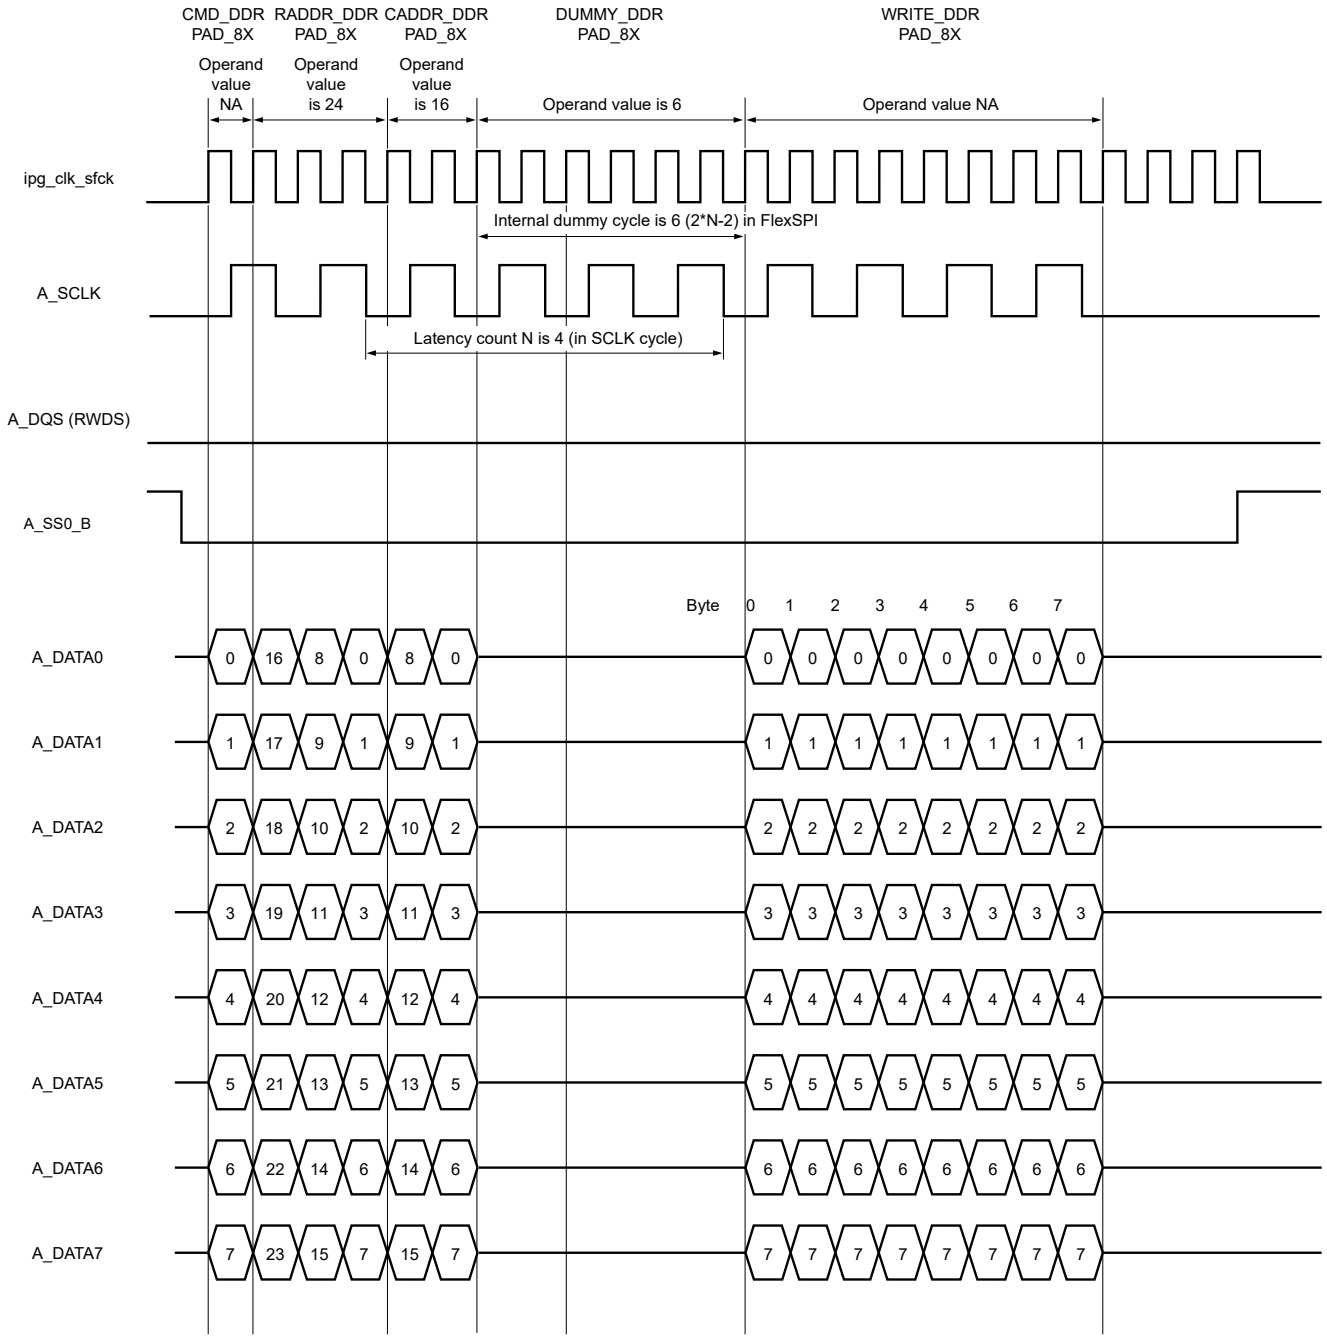

Figure 95. HyperBus device write transaction with single latency count

Figure 96 shows an example HyperBus device write transaction (additional latency count) in individual mode.

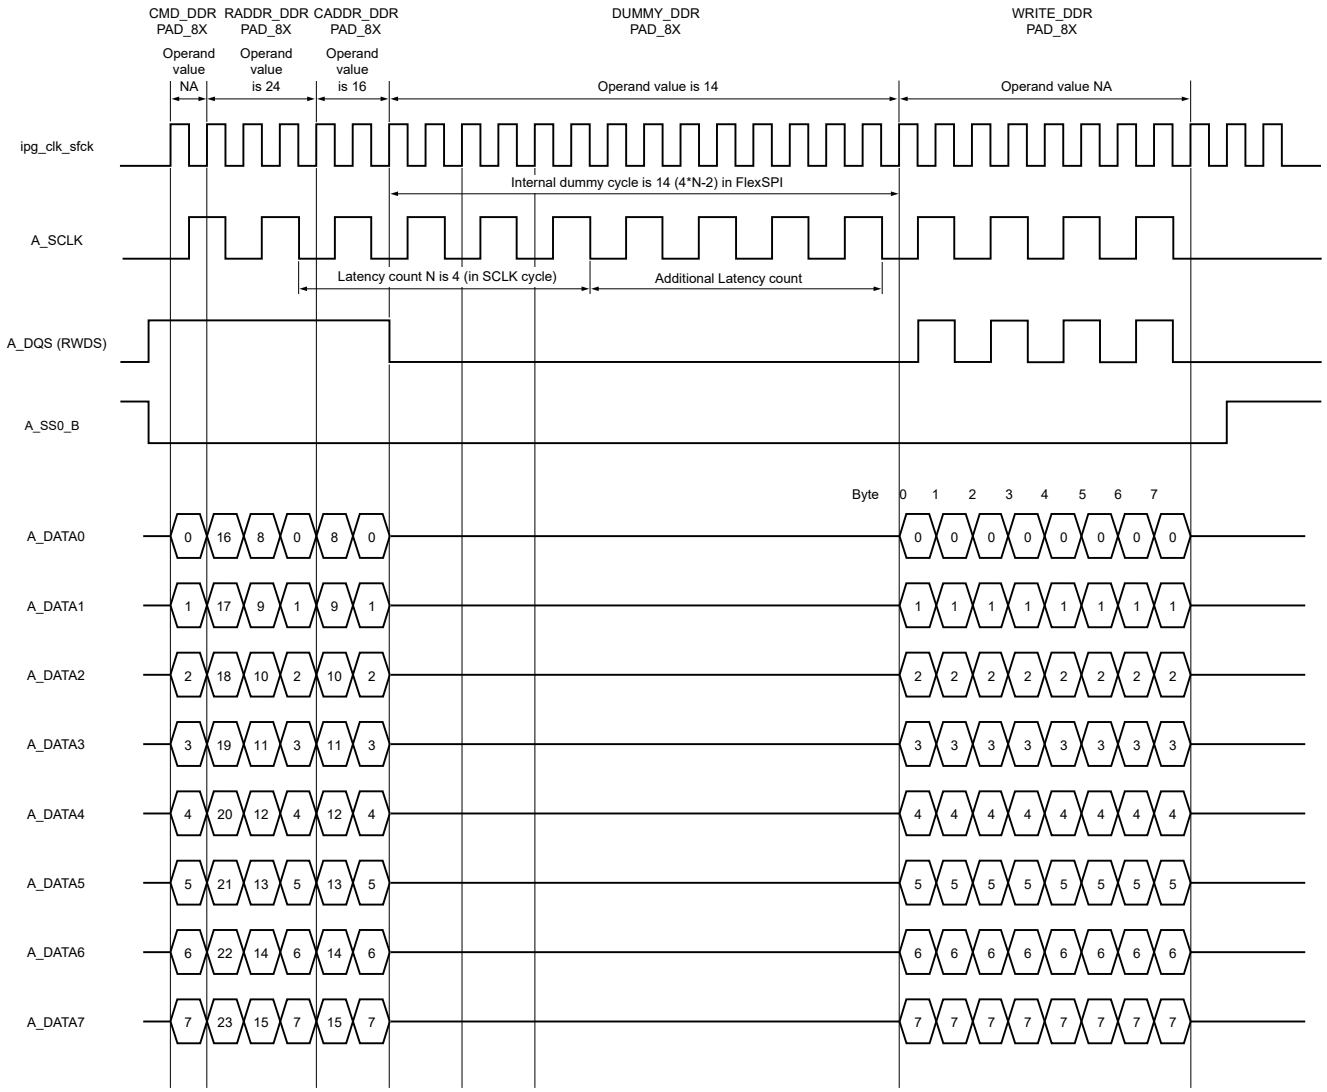

Figure 96. HyperBus device write transaction with additional latency count

36.4.7 Clocking

This section describes FlexSPI clocks and special clocking requirements.

Table 190. Clock usage

Clock name	Description	Comment
serial clock root (ipg_clk_sfck)	Root clock for Serial domain	FlexSPI core clock, used to generate the serial clock output. The clock is optionally divided using MCR0[SERCLKDIV] to obtain the SCLK.

Table continues on the next page...

Table 190. Clock usage (continued)

Clock name	Description	Comment
		Its frequency is same as SPI SCK frequency in SDR mode if MCR0[SERCLKDIV] = 0.
ahb clock (hclk)	AHB bus clock	hclk frequency is higher than 1/4 of serial root clock, so internal async FIFO is never full. This clock is used for internal logic in FlexSPI.
ipg clock (ipg_clk)	IPS bus clock	Register access clock. ipg_clk must be equal to hclk or an integer division of hclk. For example, ipg_clk = hclk/2.
SCLK	FlexSPI serial clock. Output clock on SCLK pin	Half clock frequency of serial clock root in DDR mode, and same frequency as serial clock root in SDR mode. Clock output toggles during the entire flash memory access sequence.
DQS_OUT	Dummy Read Strobe output	Same frequency as SCLK. Clock output toggles during READ and LEARN instructions. The DQS ensures that the data can be strobed correctly. It is only used for data strobe, instead of command or address strobe. The data includes useful read data and data learning patterns.
DQS_IN	Sample clock for receive data	Same frequency as SCLK. Sample clock comes from looped-back dummy read strobe, looped-back SCLK, or flash-memory-provided read strobe.

36.4.8 Interrupts

Table 191 describes all interrupts that FlexSPI generates.

Table 191. Flash memory address, row address, and column address

Interrupt	Enable	Condition
IP command done	INTEN[IPCMDDONEEN]	An IP command is finished.
IP command grant error	INTEN[IPCMDGEEN]	An IP command grant timeout occurs (bus not granted after MCR0[IPGRANTWAIT] × 1024 AHB clock cycles). See Overview of error categories, flags, and triggered sources.
AHB command grant error	INTEN[AHBCMDGEEN]	An AHB command grant timeout occurs (bus not granted after MCR0[AHBGRANTWAIT] × 1024 AHB

Table continues on the next page...

Table 191. Flash memory address, row address, and column address (continued)

		clock cycles). See Overview of error categories, flags, and triggered sources.
IP command error	INTEN[IPCMDERREN]	A command check error or a command execution error for an IP command occurs. See Overview of error categories, flags, and triggered sources.
AHB command error	INTEN[AHBCMDERREN]	A command check error or a command execution error for AHB command occurs. See Overview of error categories, flags, and triggered sources.
IP_RX_FIFO watermark available	INTEN[IPRXWAEN]	The fill level of IP_RX_FIFO reaches the watermark level (IPRXFCR[RXWMRK]).
IP_TX_FIFO watermark empty	INTEN[IPTXWEEN]	The empty level of IP_TX_FIFO reaches the watermark level (IPTXFCR[TXWMRK]).
Data learning failed	INTEN[DATALEARNFAILEN]	No valid sample clock phase found after LEARN instruction is executed. See Overview of error categories, flags, and triggered sources.
Sequence execution timeout	INTEN[SEQTIMEOUTEN]	A sequence execution time exceeds the timeout wait time (MCR1[SEQWAIT]). For example, the following flash memory read command sequence lasts about 800_0000h cycles (ipg_clk_sfck). If SEQWAIT is set to FFFFh, a sequence timeout interrupt is generated. • IP command triggers timeout. • Flash memory read data size is 100_0000h bytes. • Flash memory accesses in single mode and SDR mode.
AHB bus error	INTEN[AHBBUSERROREN]	AHB bus response timeout occurs, or AHB read access occurs while OTFAD is enabled and FlexSPI is still fetching the key blob. For example, AHB read sequence is not configured properly in LUT (such as without a READ instruction). No data is read from the external device. As a result, FlexSPI cannot reach the read data in AHB_RX_Buffers for the AHB read command.
Write command stops SCLK	INTEN[SCKSTOPBYWREN]	IP_TX_FIFO is empty while executing a write command sequence. FlexSPI

Table continues on the next page...

Table 191. Flash memory address, row address, and column address (continued)

		stops SCLK output clock toggling and waits for write data filling.
Read command stops SCLK	INTEN[SCKSTOPBYRDEN]	IP_RX_FIFO is full while executing a read command sequence. FlexSPI stops SCLK output clock toggling and waits to read the data from IP_RX_FIFO.
Key done	INTEN[KEYDONEEN]	OTFAD is enabled and key blob processing is enabled, key blob processing is done, and no error is detected.
Key error	INTEN[KEYERROREN]	OTFAD is enabled and key blob processing is enabled, and an error occurs during key blob processing. Once this interrupt is set, only reset can clear it.

36.4.9 On-The-Fly AES Decryption (OTFAD) support

After power-up, if OTFAD and key fetches are enabled in the system, FlexSPI automatically starts fetching the key blobs from location 0 of flash A1. The key fetches continue until OTFAD receives and processes all key blobs. During the fetch operation, any AHB access causes an error response, and INTR[AHBBUSERROR] is set. No IPS access is allowed during the fetching of key blobs. INTR[KEYDONE] or INTR[KEYERROR] represents the key blob processing result.

After OTFAD processes all key blobs, the OTFAD engine decrypts any reads from FlexSPI and returns them on the AHB bus. When OTFAD is enabled, FlexSPI always enables prefetch; only AHBCR[READSZALIGN] can disable the prefetch. The Read Resume function is also disabled. All read access addresses are eight-byte-aligned automatically, regardless the setting of AHBCR[READADDROPT]. If OTFAD is enabled, the prefetch never crosses the 1 KB boundary.

36.4.10 Flash memory access via IP command

Follow these steps to trigger a flash memory access via IP command.

1. If this command is a programing command, fill the IP transmit FIFO with programming data (for instance, programming flash data and flash memory status registers.)
2. Write the flash memory access start address to IPCR0[SFAR].
3. Write the read or program data size to IPCR1[IDATSZ]. Write the sequence index to IPCR1[ISEQID]. Write the sequence number to IPCR1[ISEQNUM].
4. Write 1 to IPCMD[TRG] to trigger a flash memory access command.
5. Wait for the INTR[IPCMDDONE] flag to set or for the IP command done interrupt to fire, indicating the command has completed on the FlexSPI interface.

NOTE

- The IP transmit FIFO can be filled before or after writing the IPCR0, IPCR1, and IPCMD registers. If the SFM command starts with the IP transmit FIFO empty, FlexSPI stops SCLK toggling to wait for transmit data ready automatically.
- The IPCMD register must be written after writing the IPCR0 and IPCR1 registers.
- One IP command can issue up to eight command sequences.
- You cannot issue another IP command before the previous IP command is finished. Performing this action results in unknown behavior.

If this command is a read command, all read data from flash memory is put into the IP receive FIFO. Software must read data from the IP receive FIFO via AHB bus or IP bus. When the IP receive FIFO is full and the flash device still contains data to read, FlexSPI stops SCLK toggling until the FIFO has free space. See SCLK stop.

A triggered serial flash command contains:

- A flash memory access start address. IPCR0[SFAR] determines this address.
- A flash chip select. The flash memory access address and flash memory size setting (FLSHxCR0[FLSHSZ]) determine the chip select.
- A flash command sequence index and sequence number. FlexSPI sequentially executes the sequences indexed from IPCR1[ISEQID] to (IPCR1[ISEQID] + IPCR1[ISEQNUM]) in LUT.
- Flash individual memory access mode:
- The flash memory read or program data size, in bytes.
  - If the value of IPCR1[IDATSZ] is nonzero, the data size is IPCR1[IDATSZ].
  - If the value of IPCR1[IDATSZ] is zero, the operand value in the read or write instruction determines the data size.

NOTE

- Software must ensure that the last sequence index never exceeds the LUT sequence number. That is, IPCR1[ISEQID] + IPCR1[ISEQNUM] must be less than 32.
- For sequence numbers greater than one, the data size is applied to every command sequence.
- If there is no write or read instruction in the command sequence, the data size is ignored.

The IP command request is sent to the arbitrator after software triggers it. It is not executed on the FlexSPI interface until the arbitrator grants it. See Command arbitration.

36.4.10.1 Reading data from IP receive FIFO

FlexSPI puts read data from the external device into the IP receive FIFO for IP commands.

The data stored in the IP receive FIFO can be read using IPS and register or system and AHB bus transactions:

- Via IP bus
- Via AHB bus

If MCR0[ARDFEN] = 1, only the AHB bus can read the read data in the IP receive FIFO. Read access to the IP receive FIFO using IP bus always returns with data zero, and no bus error occurs.

If MCR0[ARDFEN] = 0, only the IPS bus can read the read data in the IP receive FIFO. Read access to the IP receive FIFO using the AHB bus triggers a bus error.

FlexSPI pushes read data into the IP receive FIFO in sets of 64 bits each time it receives 64 bits of data from an external device. When the number of read data bits is not 64-bit-aligned, FlexSPI pushes additional zero bits into the IP receive FIFO for the last push.

The processor or DMA can read the IP receive FIFO.

36.4.10.1.1 Reading via processor

To read data from the IP receive FIFO via processor, configure the items below.

- Write 0 to IPRXFCR[RXDMAEN].
- Write the watermark level to IPRXFCR[RXWMRK]. The watermark level is (IPRXFCR[RXWMRK] + 1) × 8 bytes.
- Write 1 to INTEN[IPRXWAEN] to enable the IP receive FIFO watermark available interrupt (optional).

The processor must poll INTR[IPRXWA] or wait for the IP receive FIFO watermark available interrupt before reading data from the FIFO. Waiting ensures that a watermark level amount of data is filled in the IP receive FIFO before reading.

After reading a watermark level amount of data from the FIFO, software must set the INTR[IPRXWA] flag to pop that data from the FIFO.

Figure 97 shows the reading flow from the IP receive FIFO via processor.

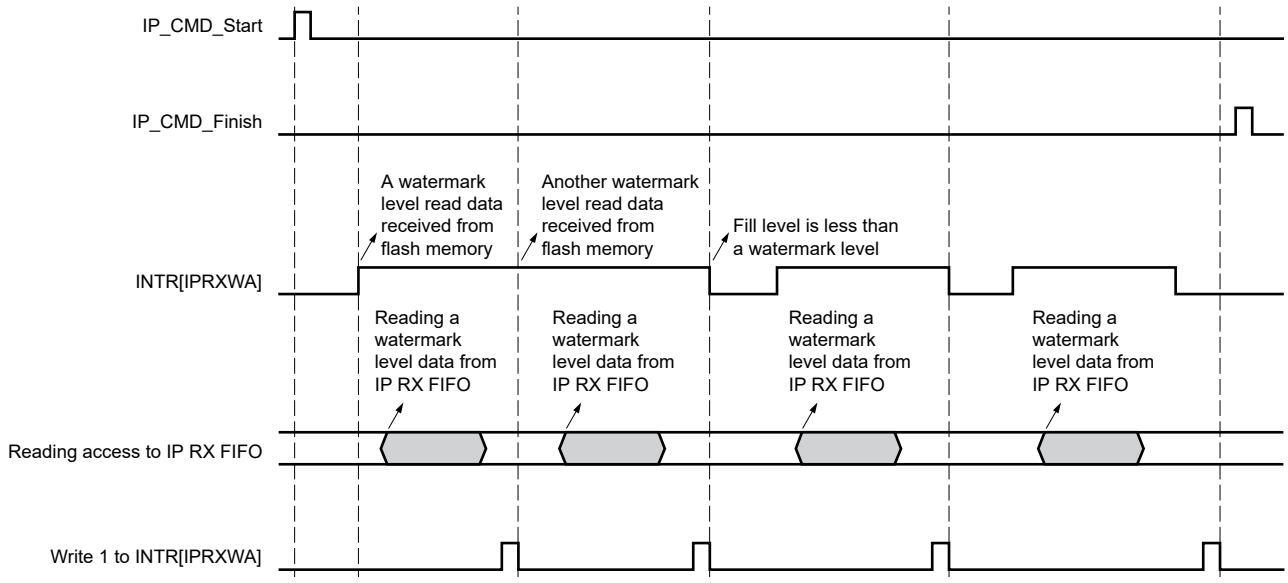

Figure 97. Reading IP receive FIFO via processor

NOTE

- The processor must read a watermark level of data from the IP receive FIFO before setting the INTR[IPRXWA] flag.
- The total flash read or program data size is not required to be a multiple of the watermark level. When the reading data size from the FIFO is less than a watermark level for the last time, software polls IPRXFSTS[FILL], not INTR[IPRXWA]. After all data from the FIFO are copied and all command sequences to flash memory are finished (INTR[IPCMDDONE] = 1), software sets IPRXFCR[CLRIPRXF] to clear the FIFO. If the FIFO is not cleared, the reading data will be incorrect for the next reading command to flash memory.
- Setting the INTR[IPRXWA] flag pops the IP receive FIFO data. Each read access to the FIFO does not pop the data.

36.4.10.1.2 Reading via DMA

To read data from the IP receive FIFO via DMA, configure the items below.

- Write 1 to IPRXFCR[RXDMAEN].
- Write the watermark level to IPRXFCR[RXWMRK]. The watermark level is (IPRXFCR[RXWMRK] + 1) × 8 bytes.

- Configure the DMA transfer minor loop size to match the watermark level.

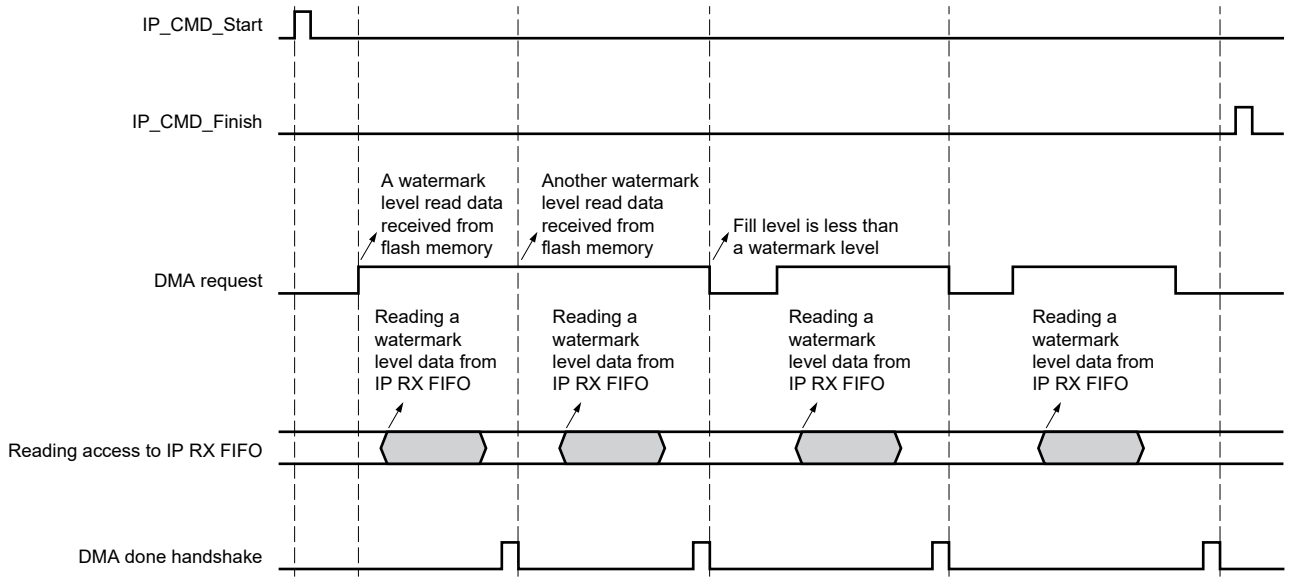

Figure 98. Reading from IP receive FIFO via DMA

NOTE

- When the fill level of the FIFO meets or exceeds the watermark level, a DMA request is generated. This request is level-valid, not pulse-valid.
- DMA reads a watermark level amount of data from the IP receive FIFO each time. (Configure the minor loop size to match the watermark level).
- DMA must return a done handshake (pulse valid) to FlexSPI each time it finishes reading a watermark level amount of data.
- The DMA done handshake (not each read access) pops the IP receive FIFO data.
- The total read and write data size (major loop size) must be a multiple of the watermark level. The DMA does not know when the data is ready for the last reading. When the data size is not a multiple of the watermark level, it is too complex for the DMA driver to poll IPRXFSTS[FILL].

36.4.10.2 Writing data to IP transmit FIFO

The programming data is put into the IP transmit FIFO, then FlexSPI transmits it to the flash memory. IPS or AHB access can write it:

- Via IP bus
- Via AHB bus

To write the programming data into the IP transmit FIFO via AHB bus, write 1 to MCR0[ATDFEN]. The IP bus write access to the FIFO is ignored, but no bus error occurs.

To write the programming data into the IP transmit FIFO via IP bus, write 0 to MCR0[ATDFEN]. The AHB bus write access to the FIFO returns a bus error.

When FlexSPI fetches data to transmit, 64 bits of data from the IP transmit FIFO are popped. If the programming data size is not a multiple of 64 bits, the number of last popped valid bits is less than 64 bits. No error occurs; these invalid bits are not transmitted to the flash memory.

The processor or DMA can fill the IP transmit FIFO with programming data.

36.4.10.2.1 Writing via processor

To write data into the IP transmit FIFO via processor, configure the items below.

- Write 0 to IPTXFCR[TXDMAEN].
- Write the watermark level to IPTXFCR[TXWMRK]. The watermark level is (IPTXFCR[TXWMRK] + 1) × 8 bytes.
- Write 1 to INTEN[IPTXWEEN] to enable the IP transmit FIFO watermark available interrupt (optional).

The processor must poll INTR[IPTXWE] or wait for the IP transmit FIFO watermark empty interrupt before writing data to the FIFO. Waiting ensures that a watermark level amount of data is available in the IP transmit FIFO before writing.

After writing a watermark level amount of data to the FIFO, software must set the INTR[IPTXWE] flag to push that data into the FIFO. (The write pointer is incremented.)

NOTE

Setting the INTR[IPTXWE] flag pushes the IP transmit FIFO data. Each write access to the FIFO does not push the data.

Figure 99 shows the writing flow to the IP transmit FIFO via processor.

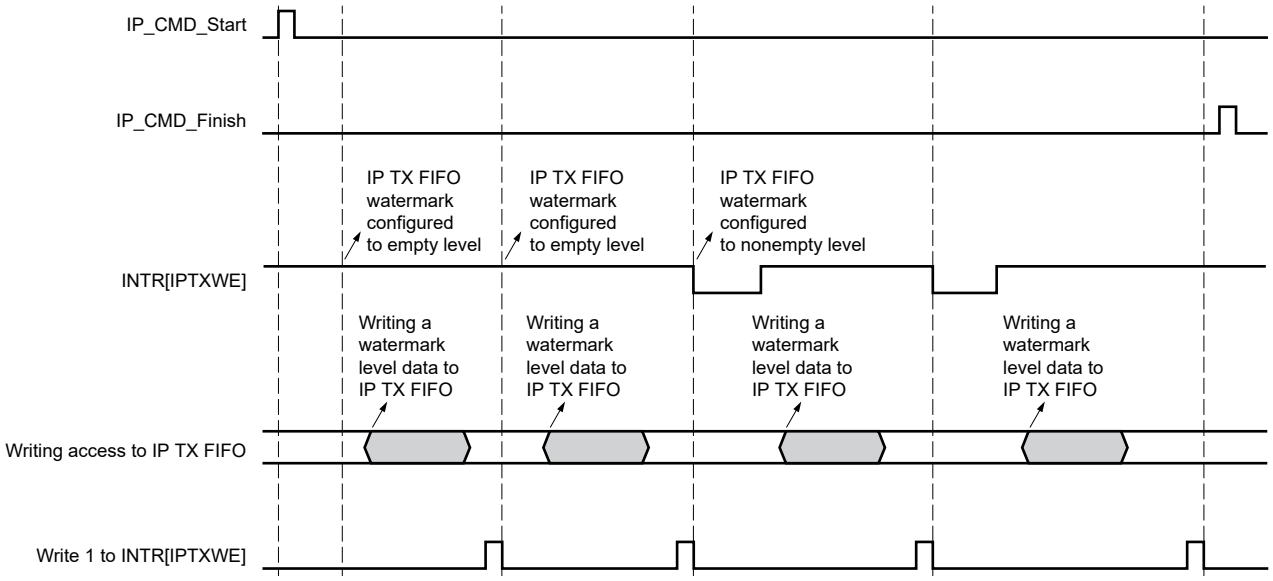

Figure 99. Writing to IP transmit FIFO via processor

NOTE

- The processor must write a watermark level amount of data into the IP transmit FIFO each time.
- The total flash write data size is not required to be a multiple of the watermark level. In this case, the writing data size to the FIFO is less than a watermark level for the last time. After all data to the FIFO are written and all command sequences to flash memory are finished (INTR[IPCMDDONE] = 1), the processor sets IPTXFCR[CLRIPTXF] to clear the FIFO. If the FIFO is not cleared, the programming data will be incorrect for the next programming command to flash memory.

36.4.10.2.2 Writing via DMA

To write data into the IP transmit FIFO via DMA, configure the items below.

- Write 1 to IPTXFCR[TXDMAEN].
- Write the watermark level to IPTXFCR[TXWMRK]. The watermark level is (IPTXFCR[TXWMRK] + 1) × 8 bytes.

- Configure the DMA transfer minor loop size to match the watermark level.

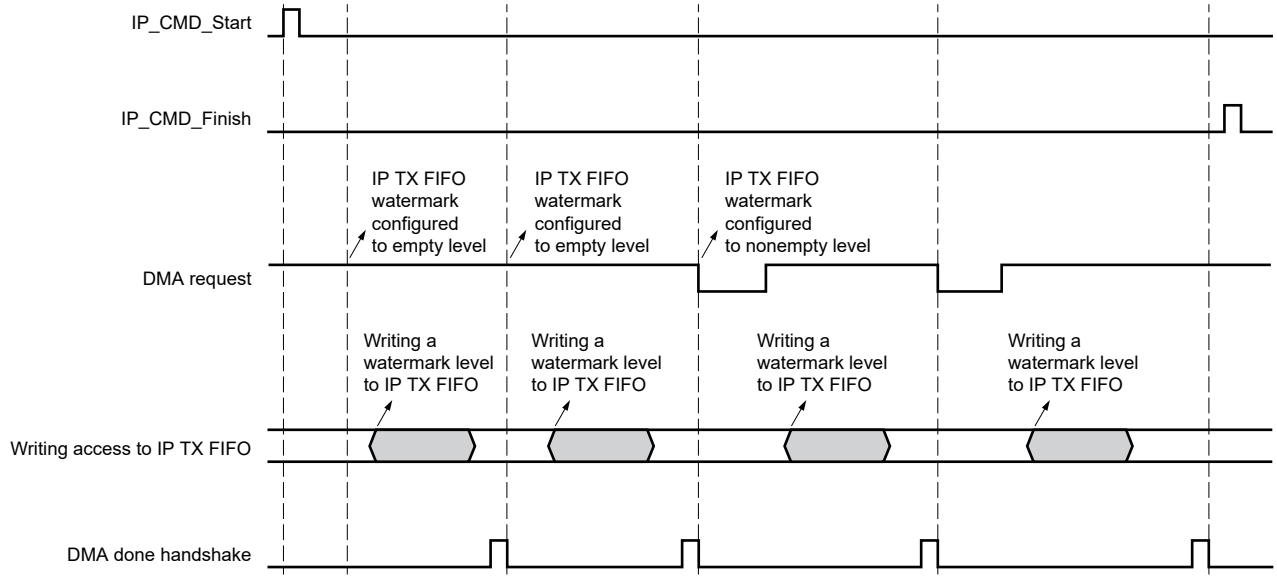

Figure 100. Writing into IP transfer FIFO via DMA

NOTE

- When there is empty space in the IP transmit FIFO greater than the watermark level, a DMA request is generated. This request is level-valid, not pulse-valid.
- DMA writes a watermark level amount of data into the FIFO each time. (Configure the minor loop size to match the watermark level.
- DMA returns a done handshake (pulse valid) to FlexSPI each time it finishes writing a watermark level amount of data.
- The DMA done handshake (not each write access) pushes the IP transmit FIFO data.
- The total program data size (major loop size) is not required to be a multiple of the watermark level. After writing all data into the IP transmit FIFO and all command sequences to flash memory are finished (INTR[IPCMDDONE] = 1), write 1 to IPTXFCR[CLRIPTXF] to clear the FIFO. Failure to clear the FIFO results in incorrect programming data for the next programming command to flash memory.

36.4.11 Flash memory access via AHB command

Flash memory can be accessed via AHB bus directly on the AHB address space. This address space is mapped to serial flash memory in FlexSPI. AHB bus accesses to this address space trigger flash memory access command sequences as needed.

For AHB read access to serial flash memory, FlexSPI fetches data from flash memory into the AHB receive buffer, then returns the data on the AHB bus. For AHB write access to serial flash memory, FlexSPI buffers AHB bus write data into the AHB transmit buffer, then transmits the data to serial flash memory.

No software configuration or polling is needed for AHB commands, except for FlexSPI initialization. As with a normal AHB target, the AHB controller accesses the external flash device transparently.

AHB commands are normally used to access serial flash memory space. IP commands must be used to access the control and status registers or other spaces, such as a one-time programmable (OTP) space in an external flash device.

The AHB commands for read and write access are discussed in detail below.

36.4.11.1 AHB write access to flash memory

For AHB write access to flash memory, FlexSPI buffers the write data from the AHB bus into the internal AHB transmit buffer. FlexSPI then transmits the data to flash memory. FlexSPI only buffers write data for one AHB burst. Figure 101 shows the hardware operation in response to an AHB write access to flash memory.

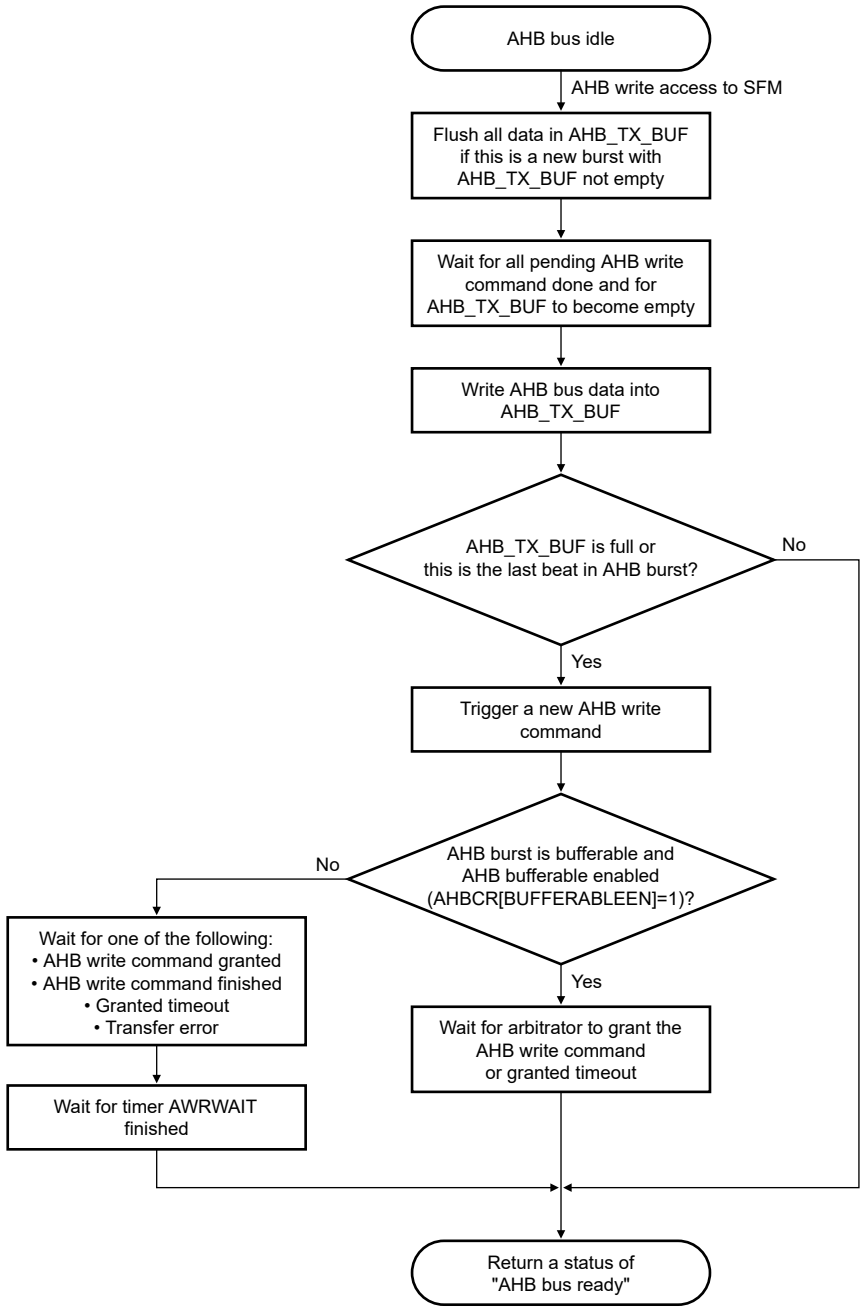

Figure 101. Hardware operation in response to AHB write access to flash memory

NOTE

1. If previous AHB burst is INCR write burst, AHB transmit buffer may not be empty when AHB bus is idle or new burst arrives. A new AHB write command is triggered to flush all data in AHB transmit buffer to external flash device. The new burst is held until this AHB write command finishes.
2. If the current access is bufferable, when the AHB write command is triggered, AHB ready is returned after the write command is granted. If the current access is non-bufferable, AHB ready is returned after the write command finishes.

FlexSPI triggers a new AHB write command in these cases:

- This beat is the last one in the current AHB burst, for any burst type except INCR.
- AHB transmit buffer is full after the current beat data is buffered.
- AHB bus becomes idle or a new burst arrives with the AHB transmit buffer not empty.

Table 192 describes the details of a triggered AHB write command.

Table 192. Triggered AHB write command

Item	Description
Flash memory access start address	Determined by AHB burst address. FlexSPI records the start address for the data in AHB transmit buffer, which is used as flash memory access start address.
Flash memory chip select	FlexSPI uses the settings of the flash memory access start address and flash memory size to determine the chip selection.
Flash memory command sequence index	Determined by FLSHxCR2[AWRSEQID].
Flash memory command sequence number	Determined by FLSHxCR2[AWRSEQNUM]. If AWRSEQNUM is not zero, multiple flash memory access command sequences are triggered every time for an AHB write command. The sequences indexed from AWRSEQID to (AWRSEQID + AWRSEQNUM) in LUT are executed sequentially.
Flash memory access mode (Individual)	
Flash memory data size	Determined by byte number of buffered data in AHB transmit buffer.

The following examples indicate internal logic for AHB write access to flash memory, where AHB_TX_BUF is 64 bytes :

- AHB INCR 64-bit bufferable burst with address sequence 8h, 10h, 18h, 20h, ..., 50h (10 beats total).

  Two AHB write commands are triggered: the first command with flash memory start address 8h and data size 40h; the second command with flash memory start address 48h and data size 10h. See Figure 102.

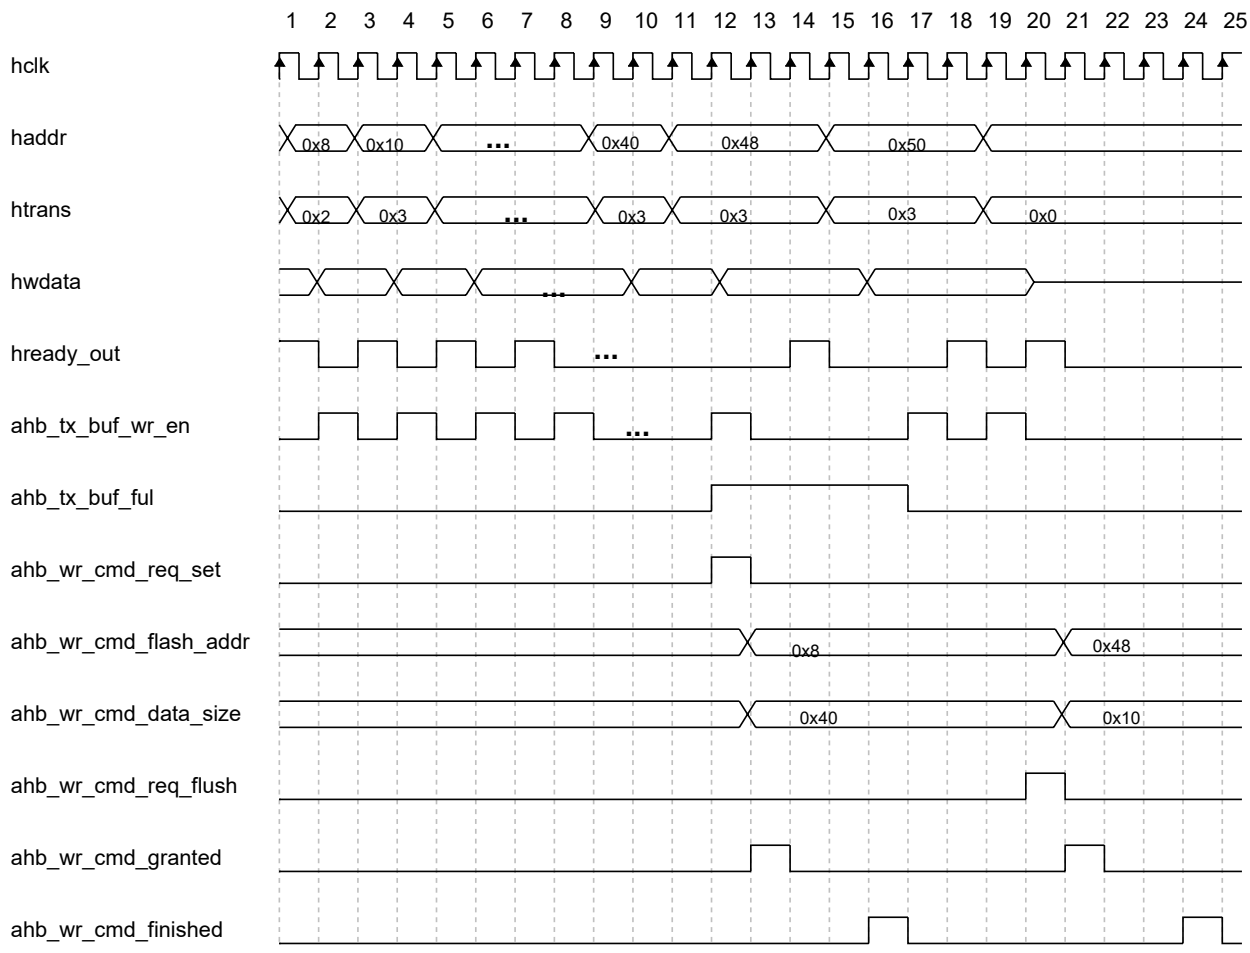

Figure 102. AHB write access (INCR, 64-bit, bufferable)

- AHB WRAP8 64-bit bufferable burst with address sequence 28h, 30h, 38h, 0h, 8h, 10h, 18h, 20h.

  One AHB write command is triggered with flash memory start address 0h and data size 40h. See Figure 103.

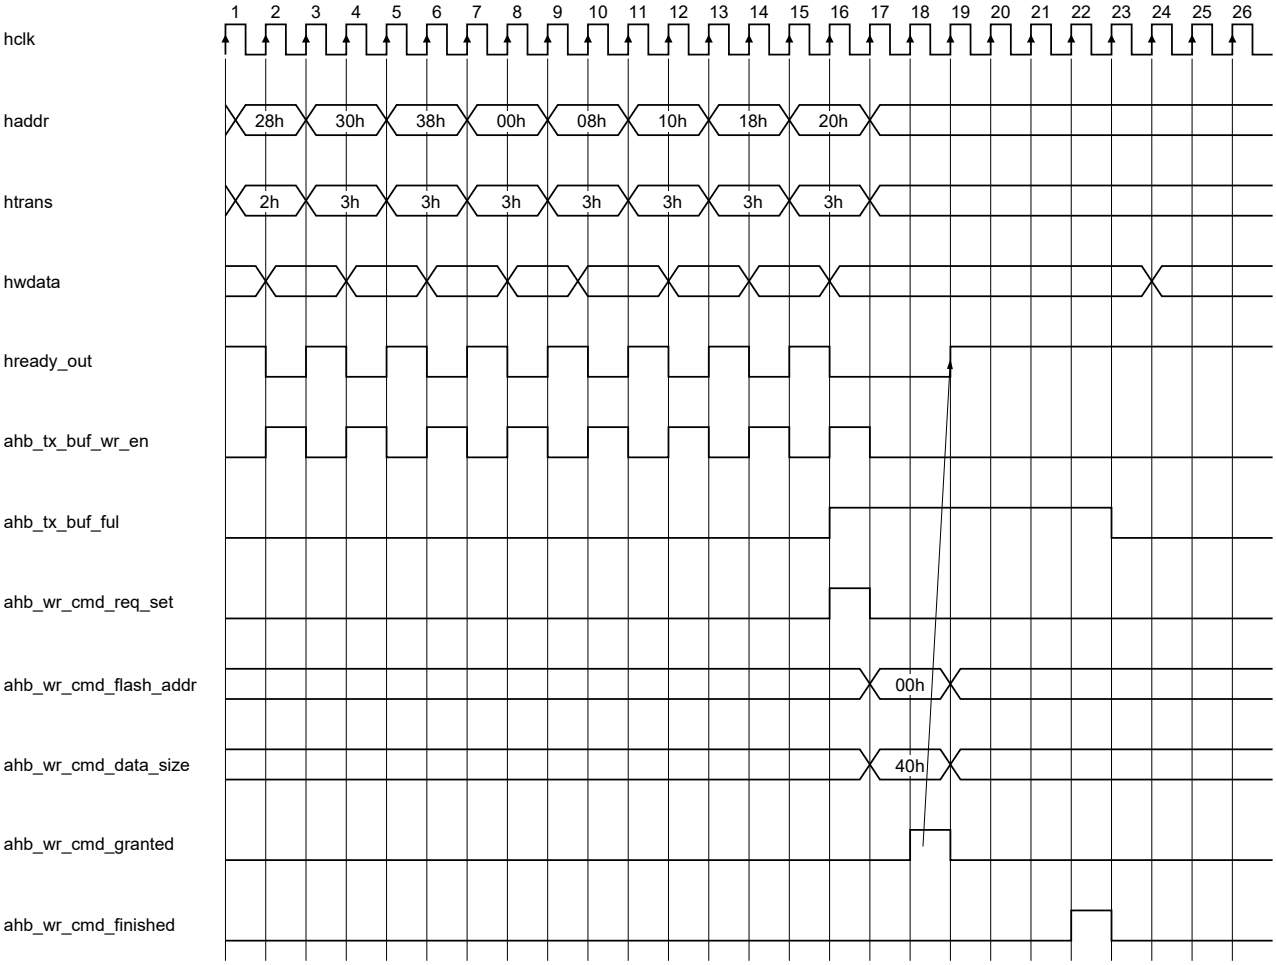

Figure 103. AHB write access (WRAP8, 64-bit, bufferable)

- AHB WRAP8 64-bit non-bufferable burst with address sequence 28h, 30h, 38h, 0h, 8h, 10h, 18h, 20h.

  One AHB write command is triggered with flash memory start address 0h and data size 40h.

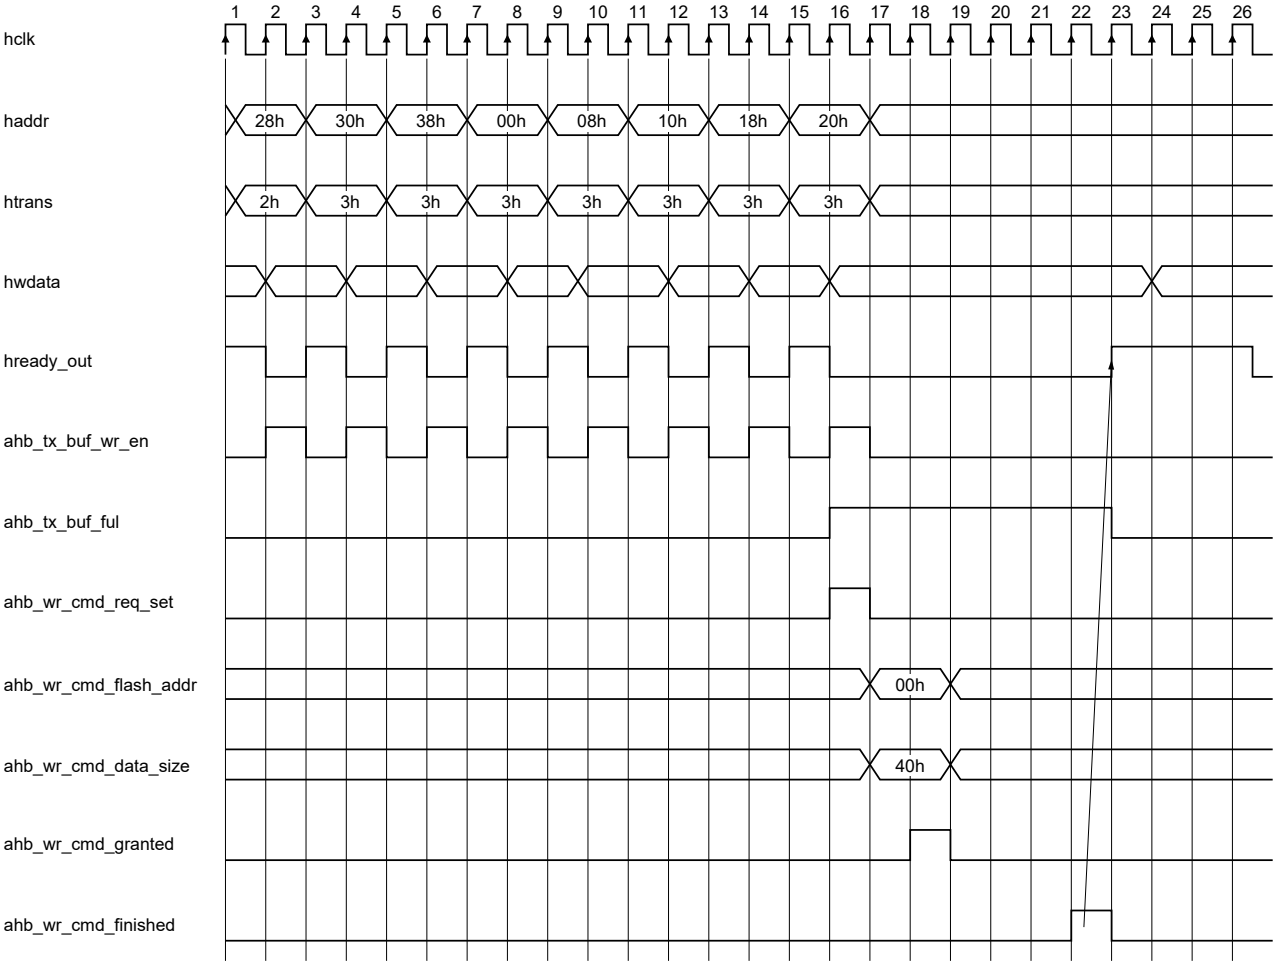

Figure 104. AHB write access (WRAP8, 64-bit, non-bufferable)

NOTE

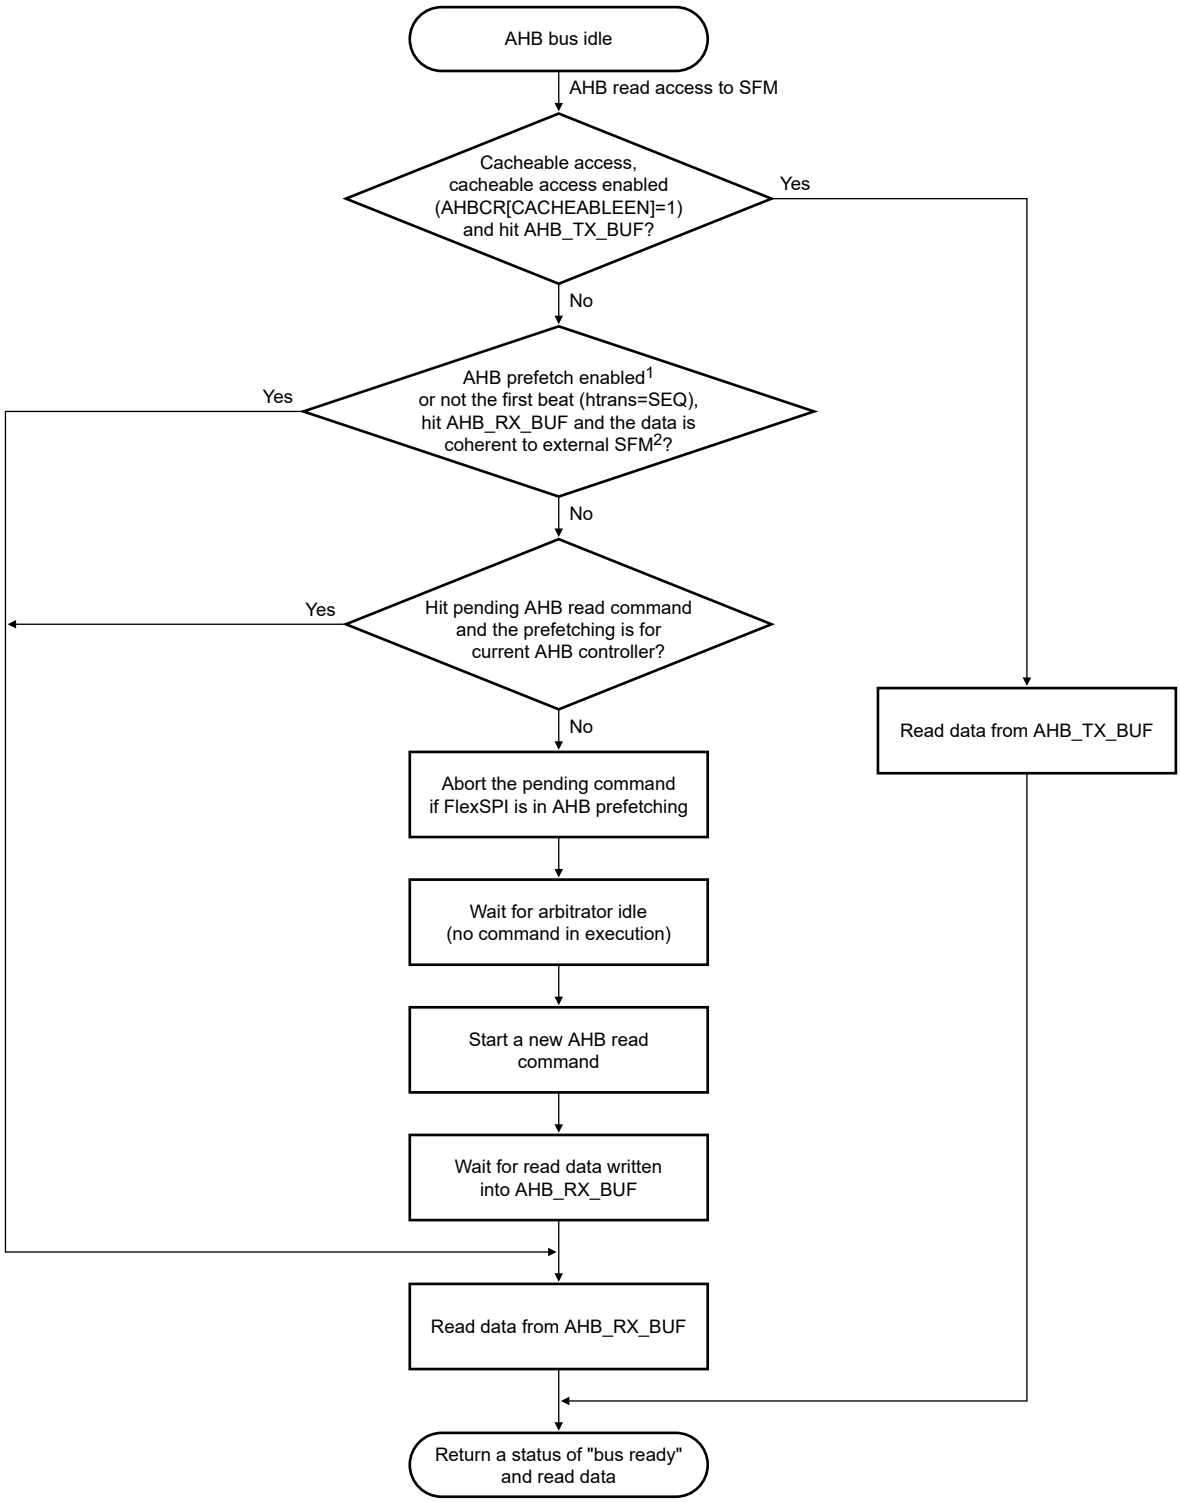
If the burst data size (in bytes) is greater than the AHB transmit buffer size, wrapper burst is not supported. For example, if AHB_TX_BUF is 64 bytes, AHB WRAP16 (16 × 64 bits = 128 bytes) write burst access is not supported.

36.4.11.2 AHB read access to flash memory

For AHB read access to flash memory, FlexSPI checks the burst access type and register setting to determine whether to access these locations:

- The AHB transmit buffer
- The AHB receive buffer
- A pending AHB read command

If all of these options are missed, FlexSPI triggers a new AHB read command to fetch data from flash memory. Figure 105 shows the hardware operation in response to AHB read access to flash memory.



Notes:
1) AHB prefetch is enabled when both AHBCR[PREFETCHEN]=1 and AHBRXBUFxCR0[PREFETCHEN]=1 (x is the AHB RX buffer ID for the current AHB controller) or OTFAD is enabled.
2) The AHB RX buffer holds the data read from flash memory. This data may become incoherent if AHB writes to the same flash-memory address.

Figure 105. Hardware operation in response to AHB read access to flash memory

Table 193 describes the details of a triggered AHB read command.

Table 193. Triggered AHB read command

Item	Description
Flash memory access start address and data size	Determined by AHB address, burst type, and burst size. FlexSPI fetches read data from the start address for the current burst or beat. See Table 194 for details.
Flash memory chip select	FlexSPI uses the settings of the flash memory access start address and flash memory size to determine the chip select.
Flash memory command sequence index	Determined by FLSHxCR2[AWRSEQID].
Flash memory command sequence number	Determined by FLSHxCR2[AWRSEQNUM]. If AWRSEQNUM is not zero, multiple flash memory access command sequences are triggered every time for an AHB read command. The sequences indexed from AWRSEQID to (AWRSEQID + AWRSEQNUM) in LUT are executed sequentially.
Flash memory access mode (Individual)	

NOTE

- FlexSPI automatically determines which ARDSEQNUM and ARDSEQID fields that the flash device uses as sequence ID for chip selection. See MCR2[SAMEDEVICEEN].
- FlexSPI determines which AHB receive buffer to use for the current AHB read access by controller ID. For details about the AHB receive buffer ID and AHB controller ID mapping, see AHB receive buffer management.
- You cannot allocate the size of the AHB receive buffer to be less than the AHB Burst size. This allocation results in unknown behavior.

Table 194. AHB read command flash memory start address and data size

Prefetch enable	Cross flash boundary	Burst type	Flash memory start address [26:0]	Data size
0	Never cross flash boundary, because AHB burst never crosses 1 KB boundary.	SINGLE, INCR4, INCR8, INCR16	hbeat_start_address	(hburst_end_address-hbeat_start_address)
		INCR	hbeat_start_address	byte size of current beat For INCR burst with prefetch disabled, each beat is handled same as SINGLE burst.
		WRAP4, WRAP8, WRAP16	hburst_start_address	(hburst_end_address-hburst_start_address)
1	No	INCR, SINGLE, INCR4, INCR8, INCR16	hbeat_start_address	ahb_rx_buf_sz
	No	WRAP4, WRAP8, WRAP16	hburst_start_address	ahb_rx_buf_sz

Table continues on the next page...

Table 194. AHB read command flash memory start address and data size (continued)

Prefetch enable	Cross flash boundary	Burst type	Flash memory start address [26:0]	Data size
	Yes	INCR, SINGLE, INCR4, INCR8, INCR16	hbeat_start_address	(flash_top_address-hbeat_start_address)
	Yes	WRAP4, WRAP8, WRAP16	hburst_start_address	(flash_top_address-hburst_start_address)

NOTE

- hbeat_start_address is HADDR input from the AHB controller for current beat.
- hburst_start_address (for example 00h) is the lowest address for current burst. hburst_end_address (for example 10h) is the highest address in current burst plus 1. For example, WRAP4 burst with HADDR 8h, Ch, 0h, 4h.
- ahb_rx_buf_sz is the buffer size in bytes of AHB receive buffer that the current AHB controller uses.
- flash_top_address is the top address of currently accessed flash memory.

36.4.11.3 AHB receive buffer management

There are 8 buffers (Buffer 0–7) in the AHB receive buffer. These buffers are transparent to AHB controllers. FlexSPI fetches flash memory data and returns it on the AHB bus automatically. No status register polling is needed for AHB read access to Serial Flash Memory (SFM).

See the chip-specific section for AHB buffer size.Use AHBRXBUF0CR0[BUFSZ]–AHBRXBUFCR7[BUFSZ] to configure the buffer size of each AHB receive buffer. The buffer size for Buffer 0 to Buffer 7 could be set to 0. If the buffer size is set to 0, FlexSPI ignores the related setting of AHBRXBUFxCR0[MSTRID]. Buffer 7 is used for all AHB controllers not assigned to Buffer 0–6. FlexSPI ignores the Buffer 7 size setting field (AHBRXBUF7CR0[BUFSZ]). Its buffer size is: (AHB receive buffer total size) - (the sum of the sizes of Buffer 0–6).

When an AHB read access to serial flash memory occurs, FlexSPI determines which buffer to use via this method:

1. If the controller ID equals AHBRXBUF0CR0[MSTRID] and AHBRXBUF0CR0[BUFSZ] is not zero, Buffer 0 is used.
2. If the controller ID equals AHBRXBUF1CR0[MSTRID] and AHBRXBUF1CR0[BUFSZ] is not zero, Buffer 1 is used.
3. If the controller ID equals AHBRXBUF2CR0[MSTRID] and AHBRXBUF2CR0[BUFSZ] is not zero, Buffer 2 is used.
4. If the controller ID equals AHBRXBUF3CR0[MSTRID] and AHBRXBUF3CR0[BUFSZ] is not zero, Buffer 3 is used.
5. If the controller ID equals AHBRXBUF4CR0[MSTRID] and AHBRXBUF4CR0[BUFSZ] is not zero, Buffer 4 is used.
6. If the controller ID equals AHBRXBUF5CR0[MSTRID] and AHBRXBUF5CR0[BUFSZ] is not zero, Buffer 5 is used.
7. If the controller ID equals AHBRXBUF6CR0[MSTRID] and AHBRXBUF6CR0[BUFSZ] is not zero, Buffer 6 is used.
8. If all the above cases are not met, Buffer 7 is used.

NOTE

- Software must ensure that the size of each buffer is not less than the maximum burst size of an AHB read access from the AHB controller using this buffer. Otherwise, the behavior is undefined. The minimum buffer size request depends on the chip implementation. For example, if the capability of the chip to send out a maximum burst is 64 bytes, the minimum AHB receive buffer is 64 bytes.
- Assigning multiple buffers to a single AHB controller is not supported, unless the prefetch buffer enhancement feature is being used.
- When AHB read prefetch is enabled (AHBCR[PREFETCHEN] = 1), the size of the buffer determines the prefetch data size. If it does not cross the flash boundary, FlexSPI fetches data from the external flash device with that buffer size.
- The priority setting of AHB controller (AHBRXBUFxCR0[PRIORITY] = 1) is used only for suspending control of AHB prefetching. See Command abort and suspend.

36.4.12 Command arbitration

There are four flash memory access command sources:

1. AHB command, that AHB write access to serial flash memory space triggers
2. AHB command, that AHB read access to serial flash memory space triggers
3. IP command, that writing IPCMD[TRG] triggers
4. Suspended command, an AHB read prefetch sequence which is suspended

An AHB bus access never triggers a write command and a read command at the same time.

The AHB prefetch sequence is an AHB command sequence triggered via AHB read access when AHB prefetch is enabled. After all read data is fetched for the current AHB read burst, FlexSPI prefetches more data to reduce read latency for the next AHB read access. An AHB command for a read operation is never aborted while fetching read data for the current AHB read burst. However, a new IP command or AHB command request while prefetching data (not for the current read burst) can abort an AHB read command.

When the arbitrator is idle (STS0[ARBIDLE] = 1), the granted priority of these command sources is:

1. AHB command (read or write)
2. IP command
3. Suspended command

NOTE

When the arbitrator is idle and there is no AHB or IP command request, a suspended command is not granted immediately. The arbitrator waits MCR2[RESUMEWAIT] AHB clock cycle idle states before resuming the suspended command to avoid AHB prefetch sequence being resumed and suspended frequently.

If the arbitrator is busy executing AHB or IP commands (not suspended commands), no new command requests are granted. If the grant times out, an AHB or IP command granted error occurs.

If a new AHB or IP command request comes while arbitrator is executing AHB read prefetch sequence, AHB read prefetch sequence is aborted (but not immediately). Arbitrator grants the AHB or IP command request after AHB read prefetch sequence is aborted on the FlexSPI interface and saved all internal data pointers.

36.4.12.1 Command abort and suspend

Table 195 describes the command abort and suspend mechanism.

Table 195. Command abort and suspend

Action	Description
Aborting a command	As mentioned above, if a new AHB or IP command request arrives, an AHB read prefetch sequence can be aborted.
Suspending a command	When an AHB read prefetch sequence is aborted on the FlexSPI interface, FlexSPI saves this suspended sequence in the cases listed below. FlexSPI resumes this sequence after the arbitrator has been idle for enough time. • There is no valid suspended command (AHBSPNDSTS[ACTIVE] = 0). This condition can occur when no command is suspended or when the suspended command is resumed. • The priority of aborted AHB read prefetch sequence is higher than the active suspend sequence. **NOTE** FlexSPI ignores and never resumes the original suspended sequence.
Activating a suspended command	The suspended command (internal status) becomes active when an AHB prefetch command is aborted and suspended. It becomes inactive in the following cases: • The arbitrator resumes the suspended command. • The AHB controller triggers a new AHB read command request using the same AHB receive buffer (buffer ID).

Figure 106 shows an example of the flow of command abort, suspend, or resume.

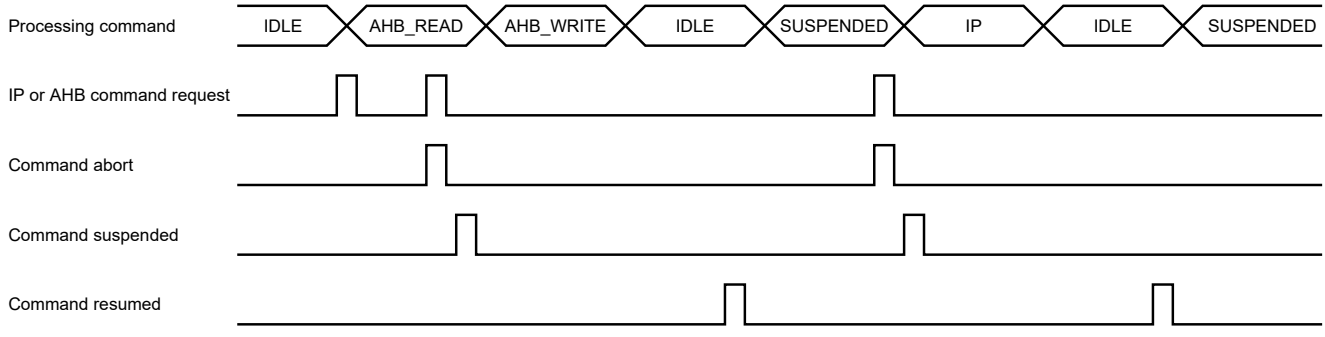


Figure 106. Command instruction execution on FlexSPI interface

NOTE

- The AHB prefetch sequence is aborted, suspended, or resumed twice in Figure 106. A new AHB write command request aborts the sequence the first time, and a new IP command request aborts the sequence the second time.
- The suspended sequence is resumed after a wait time of idle state. If there are frequent IP or AHB command requests and the wait time is not set reasonably, the suspend and resume activities may be triggered frequently.

36.4.13 SCLK stop

FlexSPI stops SCLK output toggling:

- When programming data is not ready for a programming command sequence.
- When an internal FIFO has no space to receive data for reading command sequence.

Certain devices may not support the stopping of SCLK during a command sequence (chip select is valid). SCLK stopping can be avoided via the methods described below.

- For flash memory reading that an IP command triggers:
  - Never trigger a read command with data size larger than IP receive FIFO size.
  - Internal asynchronous FIFO for flash memory reading should never be full.

    FlexSPI pops 64 bits of data per AHB clock cycle from this FIFO, and receives data from FlexSPI interface on the serial root clock. The flash memory access mode (Single, Dual, Quad, or Octal mode and Individual mode) determines the receiving speed. For example, in Octal mode, FlexSPI receives 16 bits per serial root clock cycle. If the AHB clock frequency is faster than 1/4 of the serial root clock, this asynchronous FIFO is never full.
- For flash memory programming that an IP command triggers:
  - Never trigger a program command with data size larger than the IP transmit FIFO size. Write all programming data into the IP transmit FIFO before triggering the IP command.
  - The internal asynchronous FIFO for flash memory programming must never be empty.

    FlexSPI fetches 64 bits of programming data per AHB clock cycle into this FIFO, and transmits data to the FlexSPI interface on the serial root clock. The flash memory access mode (Single, Dual, Quad, or Octal mode and Individual mode) determines the transmitting speed. For example, in Octal mode, FlexSPI transmits 16 bits per serial root clock cycle. If the AHB clock frequency is faster than 1/4 of the serial root clock, this asynchronous FIFO is never empty.
- For flash memory reading or programming that an AHB command triggers:
  - The internal asynchronous FIFO for flash memory reading and programming must never be full or empty. The frequency ratio limitation is same as it is for flash memory reading or flash memory programming that an IP command triggers.

NOTE

- FlexSPI never triggers an AHB read command with data size larger than the internal AHB receive buffer size.
- FlexSPI never triggers an AHB program command with data size larger than the internal AHB transmit buffer size.
- All programming data is buffered into the AHB transmit buffer before triggering an AHB program command in FlexSPI.

36.4.14 FlexSPI output timing

36.4.14.1 Output timing between data and SCLK

This section describes the output timing relationship of data (on A_DATA and B_DATA) and SCLK. There are three cases.

- **SDR instruction in SDR sequence**

  An SDR sequence contains only SDR instructions. In this case, all data bits last one serial root clock cycle on the FlexSPI interface. Figure 107 shows the relationship between the serial root clock, data, and SCLK:

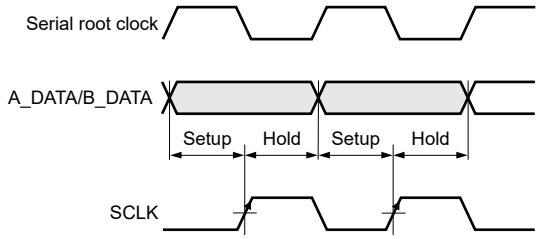

Figure 107. SDR instruction in SDR sequence

- **SDR instructions in a DDR sequence**

  A DDR sequence is a flash memory access command sequence that contains DDR instructions other than DUMMY_DDR. It may contain SDR instructions. If there are SDR instructions in a DDR sequence, all data bits last for two serial root clock cycles on the FlexSPI interface. Figure 108 shows the relationships between the serial root clock, data, and SCLK.

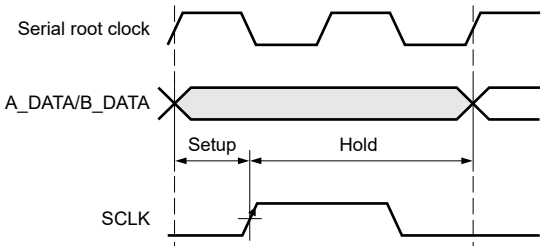

Figure 108. SDR instruction in DDR sequence

- **DDR instructions in a DDR sequence**

  For DDR instructions in a DDR sequence, all data bits last one serial root clock cycle on the FlexSPI interface. Figure 109 shows the relationships between the serial root clock, data, and SCLK.

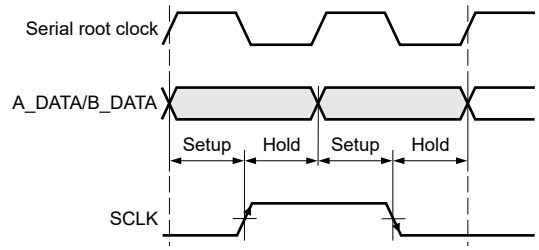

Figure 109. DDR instruction in DDR sequence

36.4.14.2 Output timing between chip select and SCLK

This section describes the output timing relationship between chip select (on A_SS0_B , A_SS1_B, B_SS0_B, and B_SS1_B) and SCLK. The timing relationship for the SDR sequence differs a little from the timing relationship for the DDR sequence.

- **Chip select timing in SDR sequence**

  For an SDR sequence, the delay from chip select assertion to the SCLK rising edge is (FLSHxCR1[TCSS] + 0.5) cycles of the serial root clock. The delay from SCLK falling edge to chip select deassertion is FLSHxCR1[TCSH] cycles of serial root clock. Figure 110 shows the timing relationship between the chip select and SCLK.

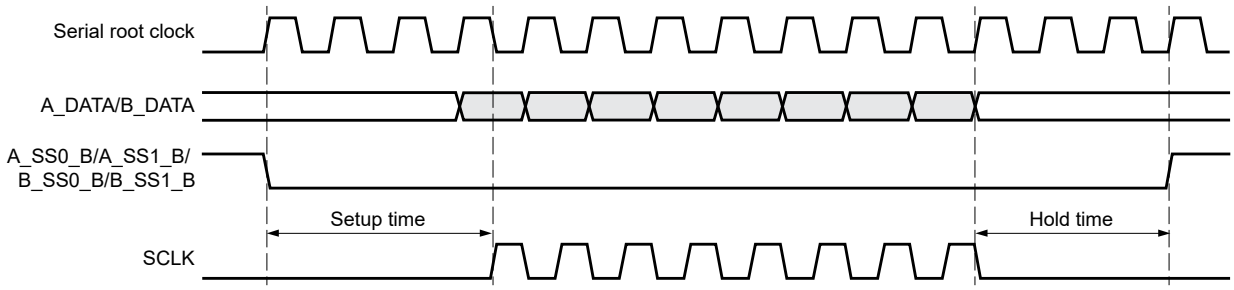

Figure 110. Chip select output timing for SDR sequence

- **Chip select timing in DDR sequence**

  For a DDR sequence, the delay from chip select assertion to the SCLK rising edge is **(FLSHxCR1[TCSS] + 0.5)** cycles of the serial root clock. The delay from the SCLK falling edge to chip select deassertion is **(FLSHxCR1[TCSH] + 0.5)** cycles of serial root clock.

  NOTE

  When AHB receive prefetch is enabled, and prefetch can be aborted, configure TCSH to 1 or greater. Configuring TCSH in this way guarantees a positive chip select hold time after the SCLK falling edge.

  Figure 111 shows the timing relationship between chip select and SCLK.

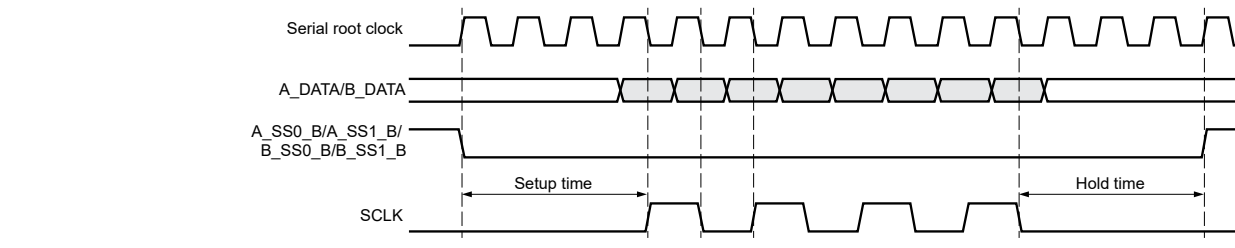

Figure 111. Chip select output timing for DDR sequence

For devices such as an FPGA device, a minimum chip select negation time (time between two chip select assertions) may be required. If the value of FLSHxCR1[CSINTERVAL] is nonzero, FlexSPI ensures a delay between chip select valid assertions. The delay time is CSINTERVAL × 256 cycles of serial root clock for an SDR or DDR sequence. If the external device has no limitation, configure the value of this field to zero. Figure 112 shows the timing of the chip select interval.

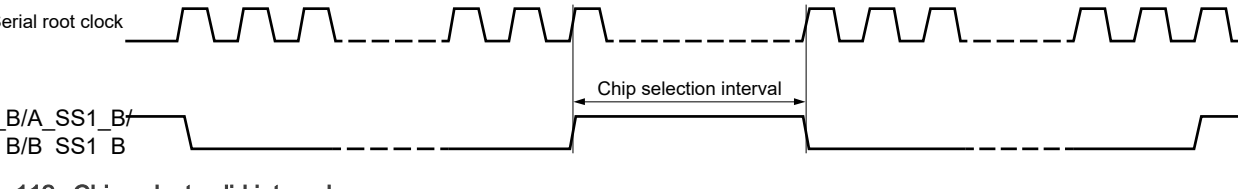

Figure 112. Chip select valid interval

36.4.15 FlexSPI input timing

This section describes the input timing of FlexSPI.

36.4.15.1 Receiving block

This section describes the receiving block in FlexSPI.

FlexSPI decodes instruction code to determine SDR mode or DDR mode. It also determines whether both the rising and falling edges are used for flash data sampling. FlexSPI samples the data line for learn instructions and read instructions.

MCR0[RXCLKSRC] selects the clock source from these four sources for the sampling clock:

- Internal dummy read strobe and looped back internally
- Internal dummy read strobe and looped back from DQS pad
- Flash-memory-provided read strobe

For details about DLL configuration, see DLL configuration for sampling.

Figure 113 shows the sampling block in FlexSPI.

FlexSPI uses both rising and falling edges to sample data from flash_A and flash_B. Two muxes with four clock source inputs generate the signals ipp_ind_io_fa, ipp_ind_io_fb. See Receive clock source features. ipp_ind_io_fa_int and ipp_ind_io_fb_int are reversed from ipp_ind_io_fa and ipp_ind_io_fb. Both sampling flip-flops are used when FlexSPI is in DDR mode. Only the falling edge sampling flip-flop is used in SDR mode.

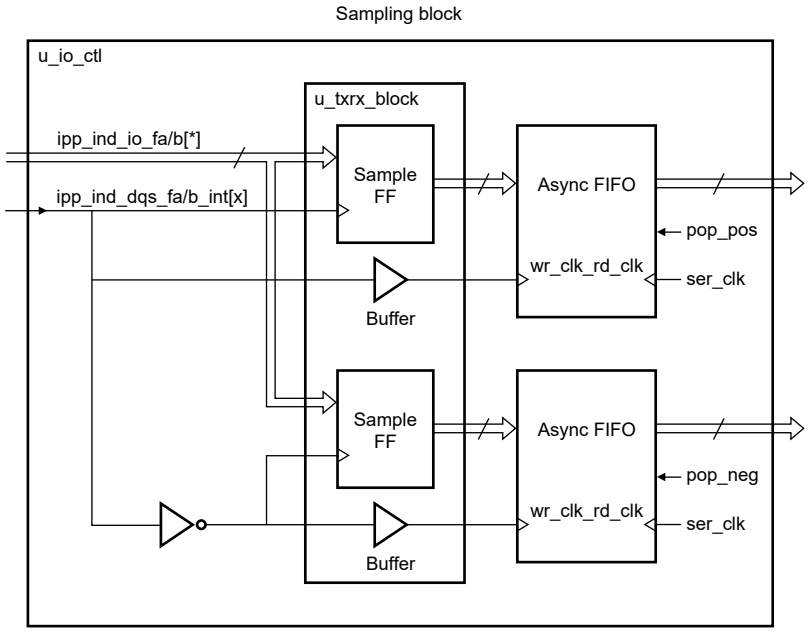

Figure 113. Sampling block in FlexSPI

Figure 114 is the receiving block diagram for data learning.

There are 16 clock phases for sampling data. An internal delay chain delays the clock phases.

See Data learning.

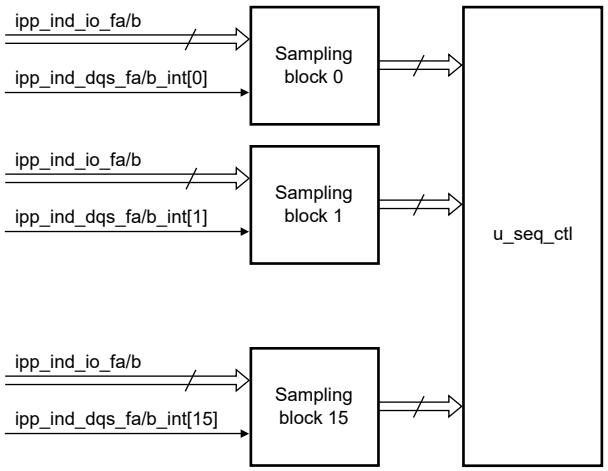

Figure 114. Sampling blocks for data learning

FlexSPI does not support read operations with a zero-turnaround cycle for direction switching on I/O pins. This read operation often occurs in QuadSPI configuration register reads. In Figure 115 and Figure 116, SIO[3:0] is an output from FlexSPI in the CMD phase, and is an input to FlexSPI in the DATA phase. No time remains for FlexSPI to switch the direction. This kind of read is not supported. FlexSPI and flash memory drive the I/O pins at the same time, which may cause a problem. To avoid this behavior on I/O pins, using SPI mode or reading with dummy cycles is required.

NOTE

The cycle numbers are not accurate in the examples below. See the device spec for accurate cycle numbers.

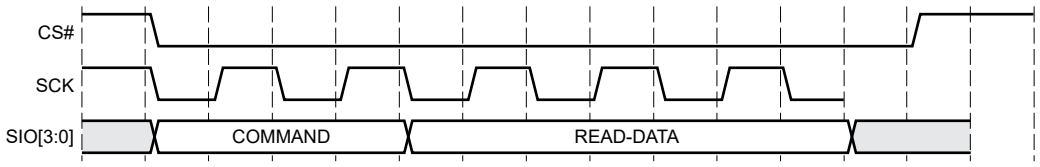

Figure 115. Unsupported read behavior

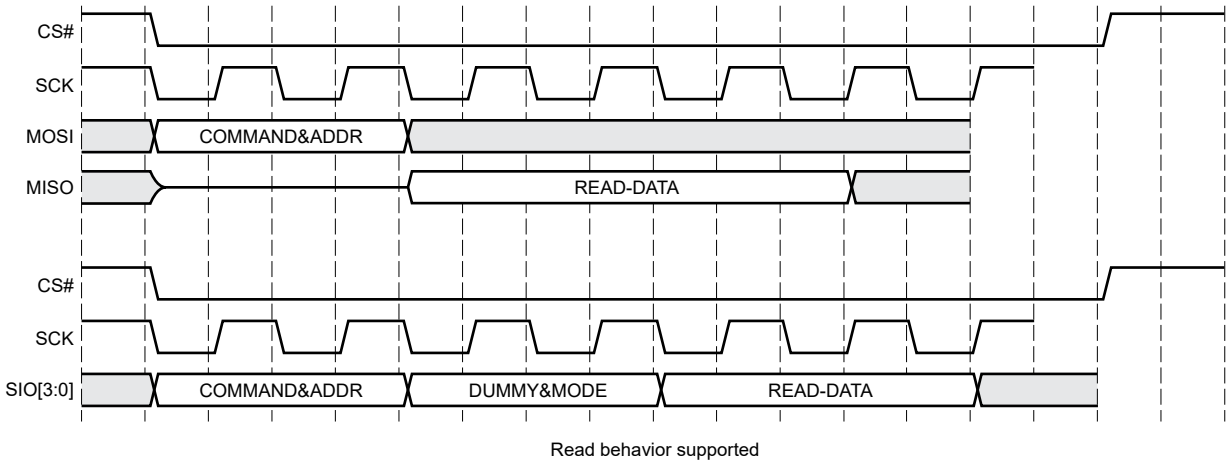

Figure 116. Supported read behavior

36.4.15.2 Receive clock source features

FlexSPI uses a read strobe to sample incoming data. There are several options for generating the read clock strobe that MCR0[RXCLKSRC] selects. Using the receive clock source method has implications for the board connections and can affect the maximum frequency that the interface supports. See the device data sheet for details on the maximum frequency supported for each RXCLKSRC option.

Table 196. RXCLKSRC options

MCR0[RXCLKSRC]	Description	Board connection	Max Frequency
0	Internal dummy read strobe and internal loopback	DQS pin is not used. The DQS pin can be configured for an alternate signal function.	Lowest
1	Internal dummy read strobe and loopback from DQS pad	FlexSPI uses the DQS pin, and it must be configured for its FlexSPI function. The internally generated read strobe is sent to the DQS pin and is sampled at the pin to match more closely the data pin timings. The DQS pin is typically left floating. External capacitance can be added to adjust timing.	Medium
3	Flash-memory-provided read strobe	DQS pin is connected to the DQS or RWDS signal that the memory provides.	Highest

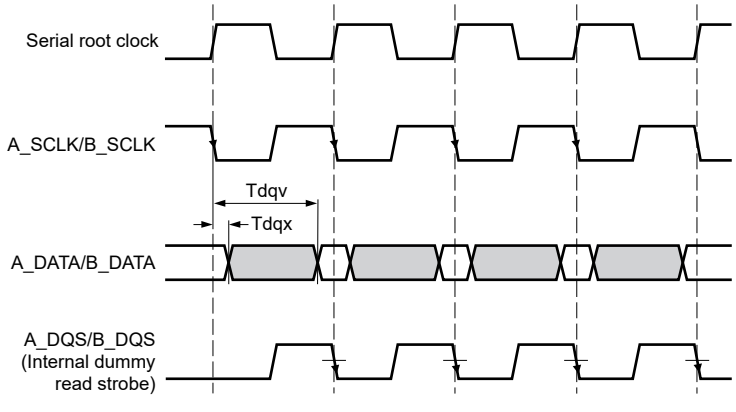
36.4.15.3 Input timing for sampling with dummy read strobe

This section describes the input timing when sampling with the internal dummy read strobe (MCR0[RXCLKSRC] = 0 or 1). The timing for sampling with an internal dummy read strobe loopback is very similar to the timing for loopback from pad. Sampling with a dummy read strobe loopback from the DQS pad can achieve a higher read frequency. It compensates for the delay of the SCLK output path and data pin input path.

The input timing is different for SDR mode and DDR mode.

- **Input timing for sampling with dummy read strobe in SDR mode**

  For SDR read or learn instructions, FlexSPI samples input data pins with the falling edge of the dummy read strobe. Figure 117 shows the input timing for sampling with dummy read strobe in SDR mode.



Tdqv is the setup time from SCLK to the next valid data.
Tdqx is the hold time from SCLK to the current valid data.

Figure 117. Input timing for sampling with dummy read strobe in SDR mode

- **Input timing for sampling with dummy read strobe in DDR mode**

  For DDR read or learn instructions, FlexSPI samples input data pins on rising and falling edges of the dummy read strobe. Figure 118 shows the input timing for sampling with dummy read strobe in DDR mode.

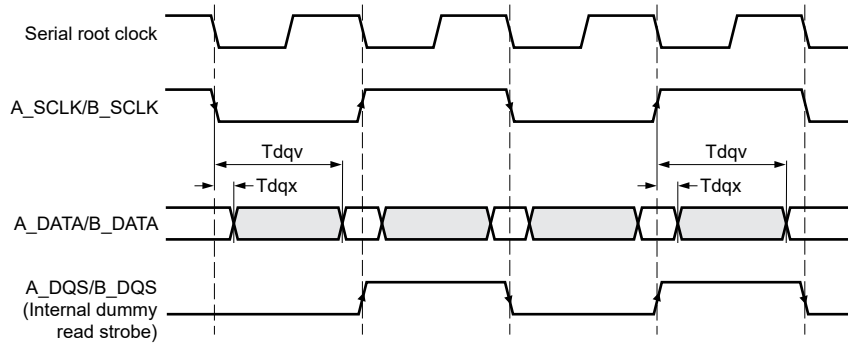


Figure 118. Input timing for sampling with dummy read strobe in DDR mode

36.4.15.4 Input timing for sampling with flash-memory-provided read strobe

This section describes the input timing when sampling with flash-memory-provided read strobe (MCR0[RXCLKSRC] = 3). The input timing is different for SDR mode and DDR mode.

NOTE

There are no known devices that provide a read strobe and support SDR mode operation.

- **Flash-memory-provided read strobe with SCLK**

  Certain flash devices provide both read data and read strobes with SCLK. Then the read strobe edge is aligned with the read data change. The FlexSPI controller delays the read strobe for one half cycle of the serial root clock (with DLL), then samples read data with the delayed strobe. See DLL configuration for sampling. Figure 119 and Figure 120 show the input timing for sampling with flash memory read strobe in SDR mode and DDR mode.

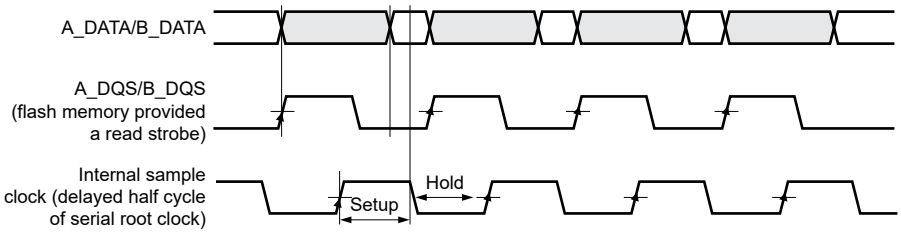

Figure 119. Input timing 2 for flash-memory-provided read strobe in SDR mode

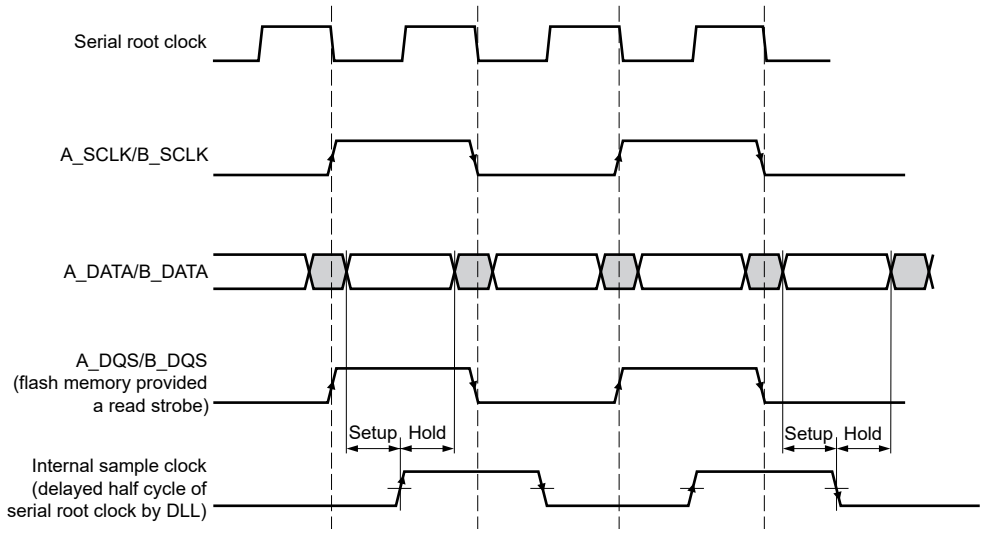

Figure 120. Input timing 2 for flash-memory-provided read strobe in DDR mode

36.4.15.5 DLL configuration for sampling

For the four sampling clock sources described previously, the input timing differs depending on the DLLxCR register configuration, according to the sampling clock source mode. The DLL is a delay-line chain that can be set to a fixed number of delay cells. It can also be auto-adjusted to lock on a certain phase delay to the reference clock.

- DLLxCR must be set to 0000_0100h (one fixed delay cell in DLL delay chain) in the following cases:
  - Sampling data with dummy read strobe looped back internally (MCR0[RXCLKSRC] = 0h)
  - Sampling data with dummy read strobe looped back from DQS pad (MCR0[RXCLKSRC] = 1h)
- When data is sampled with a flash-memory-provided read strobe (MCR0[RXCLKSRC] = 3h) and flash memory provides the read strobe with SCLK, DLL must be configured as follows (when serial root clock is over 100 Mhz. These settings ensure a lock of the reference clock (serial root clock).
  - DLLxCR[SLVDLYTARGET] is up to flash parameters used.
  - DLLxCR[REFPHASEGAP] = 2h
  - DLLxCR[DLLEN] = 1h
  - DLLxCR[OVRDEN] = 0h
  - Other fields in DLLxCR must be kept at their reset values (all zeroes).

    After the register settings above are completed, set the DLL with following steps.

    1. Reset the DLL(DLLxCR[DLLRESET] or MCR0[SWRESET]).
    2. Wait for STS2[xREFLOCK] and STS2[xSLVLOCK] being asserted.
    3. Wait for equal or more than 512 serial root clock cycles.
    4. Start read or write operation.

NOTE

If the serial root clock is slower than 100 MHz, DLL cannot lock on a half cycle of serial root clock. The delay cell number is limited in the delay chain. DLL must be configured as follows instead:

- DLLxCR[OVRDEN] = 1
- DLLxCR[OVRDVAL] = N

  Each delay cell in DLL is about 75 ps to 225 ps. The delay of DLL delay chain is (N × Delay_cell_delay). N is set based on the maximum DDR frequency (N ≤ equation). This value is calculated based on the MAX_DDR_FREQ parameter. N = 21. This value is a recommended value. If a failure occurs, the value might require adjustment in a real application.

  You can calculate the delay of one delay cell and obtain the value of N. If the serial root clock is lower than 100 MHz, the delay chain can't lock with DLLxCR[SLVDLYTARGET] = 0xF (half cycle of root clock delay). You need to set DLLxCR[SLVDLYTARGET] as 0xE (15/32 cycle delay) or less. When DLL is locked (read STS2[AREFLOCK] and STS2[ASLVLOCK]), the delay cell number = STS2[ASLVSEL] +1 and the delay value (one delay cell) = (total delay)/(delay cell number). Based on delay value, the N can be easily calculated.
- Other fields in DLLxCR must be kept at their reset values (all zeroes).

36.4.16 Data learning

The FlexSPI controller generates 16 clock phases (Phase 0–15) via delay cell line (DCL) with the selected sample clock. Clock phase 0 is the selected sample clock (DQS_IN) with no delay cell. 16 sampling blocks are implemented for Port A.

During a learn instruction, FlexSPI compares the sampled data bits with the internal data learn pattern in the Data Learning Pattern (DLPR) register and determines the correct sampling clock phase. The phase selection is automatically updated after a learn instruction and applied to subsequent read instructions or sequences.

When data learning is disabled (MCR0[LEARNEN] = 0), FlexSPI always uses clock phase 0 to sample FlexSPI data lines. Attempting to execute a learn instruction results in an error flag (INTR[IPCMDERR] or INTR[AHBCMDERR]).

FlexSPI supports data learning in both SDR mode and DDR mode. Data learning is not supported if the sampling clock source is a flash-memory-provided read strobe (MCR0[RXCLKSRC] = 3h).

Data learning can achieve high read frequency, but the flash memory input timing still limits the highest frequency. Flash memory must receive the command code and flash address bits.

When data learning is enabled, FlexSPI uses clock phase 0 after reset and before executing a learn instruction. The clock phase selection is updated after FlexSPI executes the learn instruction. The selected sample clock phase can be polled via STS0[DATALEARNPHASEA]. When data learning fails, the INTR[DATALEARNFAIL] interrupt flag is set, and the previous clock phase selection is kept. You can write 1 to MCR2[CLRLEARNPHASE] to reset the internal clock phase selection to clock phase 0.

36.4.16.1 Data learning with flash-memory-provided preamble bit

Certain flash devices support driving with preamble bits before driving read data in each read command sequence. Preamble bits are also called the data-learning pattern (DLP). The DLP is programmable via configuration register in the flash device.

For the specified read command sequence, flash memory returns preamble bits after dummy cycles and before returning read data.

For these flash devices, the operation flow with data learning is:

1. Configure the data learning pattern in Data Learning Pattern (DLPR) register.
2. Configure the same data learning pattern in the flash device by triggering an IP command.
3. Enable data learning in the flash device by triggering an IP command.
4. Configure LUT sequence with valid read command sequence containing the learn instruction.
5. Trigger a flash memory read command via AHB or IP command as normal.

NOTE

The first four steps are executed only once. They are not needed for every flash memory read command.

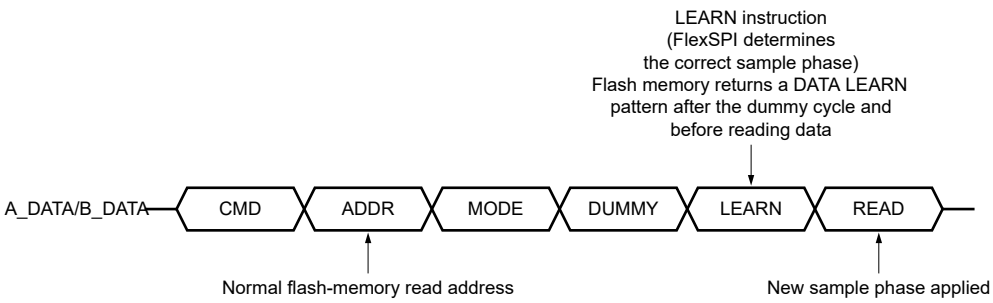

Figure 121. Data learning flow with flash-memory-provided preamble bit

36.4.16.2 Data learning without flash-memory-provided preamble bit

For flash devices that do not provide a preamble bit, the DLP cannot be returned automatically for each read command sequence. For these flash devices, the data learning sequence is:

1. Set data learning pattern in Data Learning Pattern (DLPR) register.
2. Reserve a certain flash memory area and program data (according to data learning pattern and flash memory access mode) to this area via IP command.
3. Configure LUT sequence with read sequence using a learn instruction instead of a read instruction. Trigger the read sequence to the reserved flash memory area via IP command.
4. Trigger the flash memory read command via AHB or IP command as normal. No learn instruction is needed in this read sequence.

NOTE

- The first three steps are executed only once. They are not needed for every flash memory read command.
- Step 4 should be executed with a certain interval to ensure that the internal sampling clock phase is adjusted in time.

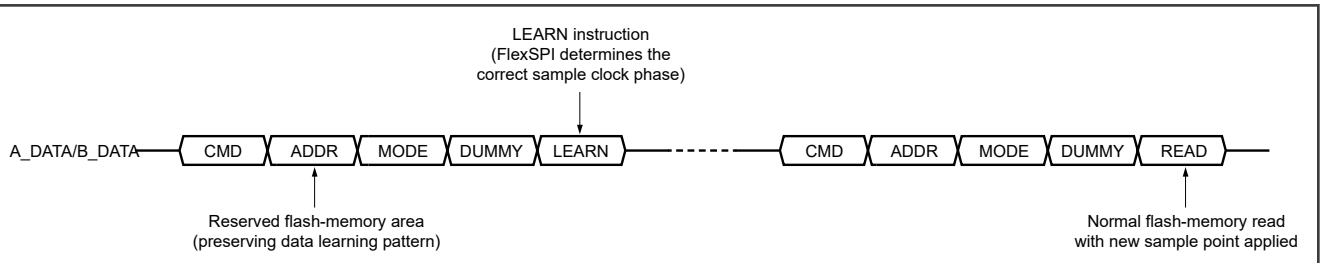

Figure 122. Data learning flow without flash-memory-provided preamble bit

NOTE

- For flash devices that do not provide a preamble bit, software overhead is required to read the reserved flash memory area at the interval.

These items determine the preprogramming data:

- Data Learning Pattern (DLPR register setting)
- DLP bit length

- Individual mode for read command
- Octal, Quad, Dual, or Single mode for read command

Figure 123 shows a preprogramming data example where the DLPR value is 43h, eight bits, and flash memory is read in Quad mode.

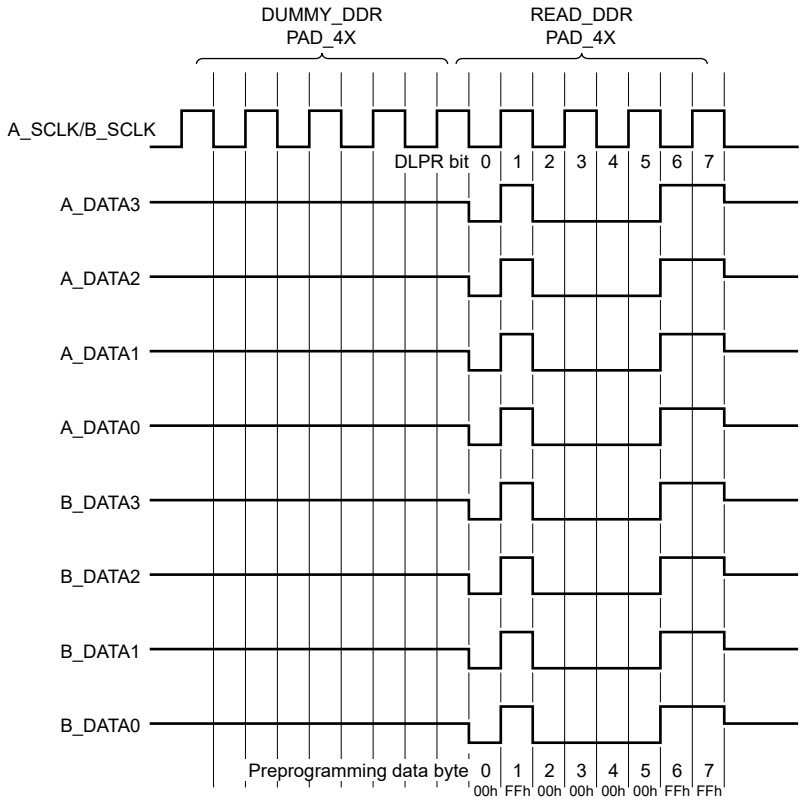

Figure 123. Preprogramming data for data learning

36.4.17 Execute-In-Place (XIP) enhanced mode

FlexSPI always supports XIP, regardless of whether external devices provide XIP enhanced mode. To support XIP, put program codes on an external device, then read or execute these codes directly via AHB read access to serial flash memory space. There is no configuration or status polling needed during AHB read access to the memory of the external device. The AHB receive buffer is fully transparent to software.

Certain devices provide XIP enhanced mode to improve code execution. In this mode, the command code is only sent in the first read instruction. It saves many cycles for command instructions and improves code execution. Devices enter or exit XIP enhanced mode via a special sequence that external devices specify. See the external device data sheet for more details.

Normally, a device enters XIP enhanced mode via this sequence:

1. Enable XIP enhanced mode in external flash device via IP command.
2. Send the first read sequence to external flash device with correct mode bits. Command code is included in this read sequence.
3. Send the subsequent read sequences to external flash device with correct mode bits. Command code is not included in these read sequences. Mode bits must be sent according to the flash specified; otherwise, the flash exits XIP enhanced mode.

The instruction JMP_ON_CS in FlexSPI must be used to support XIP enhanced mode in external devices. This instruction is only allowed in the AHB read command; otherwise, the instruction generates an IPCMDERR or AHBCDMERR interrupt (when the

interrupt is enabled). When external devices do not support XIP enhanced mode, JMP_ON_CS must never be used. To support XIP enhanced mode:

- The first instruction in the read sequence must be the command instruction.
- The last valid instruction must be JMP_ON_CS (with operand 1h).

For the first AHB read command triggered, FlexSPI executes the instructions from the instruction pointer 0 in the sequence (which is the command instruction). After this sequence is executed, FlexSPI saves the operand in the JMP_ON_CS instruction as the start pointer for the next command to current device internally. For the next AHB read command triggered, FlexSPI executes from the instruction pointer 1h, bypassing the command instruction.

After XIP enhanced mode is started, it is possible to access flash via other commands like program commands. You must, however, use a special sequence to exit enhanced XIP mode before you can run a different command. Figure 124 indicates XIP operation with Flash XIP enhanced mode.

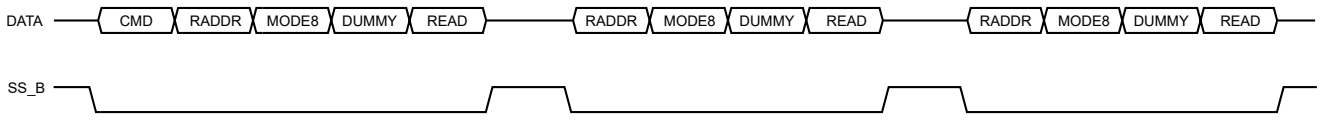

Figure 124. XIP Enhanced Mode Operation

36.4.18 AHB bus blocking

FlexSPI can temporarily block some or all AHB transactions. This feature is useful when IP commands are in progress that could cause a potential conflict with an AHB request. Examples of situations where IP bus blocking would be used are:

- Avoiding RWW (read while write). While programming or erasing flash, reads are not allowed. AHB bus blocking can prevent the AHB bus from requesting a read while IP write commands are in progress.

To block all AHB transactions:

1. Configure blocking for all AHB transactions by writing 1 to IPCR2[IPBLKALLAHB].
2. Request AHB bus blocking by writing 1 to IPCR2[IPBLKAHBREQ].
3. Wait for the AHB bus blocking request to be acknowledged (IPCR2[IPBLKAHBACK] = 1).
4. Perform IP write commands as needed.
5. Request normal operation by writing 0 to IPCR2[IPBLKAHBREQ].
6. Wait for AHB blocking request clear to be acknowledged (IPCR2[IPBLKAHBACK] = 0).

NOTE

AHB bus blocking can only be used to prevent conflicts between AHB and IP transactions. Software must handle conflicts between multiple AHB transactions.

36.5 External signals

This section provides the external signal information for the FlexSPI module.

Table 197. External Signal List

Signal name	Function	Direction	Description
A_SS0_B	Peripheral Chip Select Flash A1	O	Chip select for the serial flash device A1

Table continues on the next page...

Table 197. External Signal List (continued)

Signal name	Function	Direction	Description
A_SCLK	Serial Clock Flash A	O	Serial clock output to the serial flash device A. This clock runs at half the frequency of serial clock root in DDR mode, and at the same frequency as serial clock root in SDR mode. Clock output toggles during the entire flash memory access sequence.
A_DATAn	Serial I/O Flash A	I/O	Data I/O lines to and from the serial flash device A
A_DQS	Data Strobe Signal Flash A	I/O	Data strobe signal for port A. This signal has three functions: • Driven with read strobe by external device. Some flash devices provide the read strobe signal together with read data. In this case, if the external device drives this pad only when reading flash memory data, this pad may require a **pull-down** resistor. • Driven with latency information by external device. Some devices use this pin to indicate the dummy cycles needed (before program or read data transfer) such as HyperRAM or HyperFlash. • Loopback dummy read strobe. The FlexSPI controller provides internal dummy read strobe for flash memory read data. Higher read frequency can be achieved by looping back this dummy read strobe from the pad. This pin can be floated or have some capacitive load added at the board level to compensate for load on DATA or SCLK pins.

36.6 Initialization

The FlexSPI controller initialization sequence is:

1. Enable controller clocks (AHB clock, IP bus clock, or serial root clock) at system level.
2. To enter module stop mode, write 1 to MCR0[MDIS].
3. Configure module control registers: MCR0, MCR1, and MCR2. Do not change MCR0[MDIS].
4. When AHB commands are used, configure AHB Bus Control (AHBCR) and AHB Receive Buffer Control (AHBRXBUFxCR0) registers.
5. Configure flash control registers (FLSHxCR0, FLSHxCR1, or FLSHxCR2) according to external device type.
6. Configure DLL control register (DLLxCR) according to sample clock source selection.
7. To exit module stop mode, write 0 to MCR0[MDIS].
8. Configure LUT as needed for AHB command or IP command.

9. Optionally, to reset controller, write 1 to MCR0[SWRESET].

External devices must be configured via IP command normally after initialization. For example, the WRITE STATUS command performs device configuration for most serial NOR flash memory.

36.7 Application information

This section describes applications that FlexSPI supports.

36.7.1 Application on serial NOR flash device

This section provides the example LUT instruction sequences for serial NOR flash device (Cypress Flash S25FS128S).

36.7.1.1 Write enable command

Table 198 shows the WRITE ENABLE command sequence.

Table 198. WRITE ENABLE command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h	06h	Command name: WREN
1-7	STOP (00h)	0h	00h	

36.7.1.2 Write registers command

Table 199 shows the Write Registers command sequence.

Table 199. Write Registers command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	01h	Command name: WRR
1	WRITE_SDR	0h (Single)	1h or 2h	Data size is 1 byte or 2 bytes. Byte 0 is write data for Status Register 1; Byte 1 is write data for Configuration Register 1. IPCR1[IDATSZ] can override this value.
2-7	STOP (00h)	0h	00h	

36.7.1.3 Page Program command

Table 200 shows Page Program command sequence.

Table 200. PAGE PROGRAM command (Cypress serial NOR flash)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	02h or 12h	Command name: PP or 4PP PP is 3-byte address mode. 4PP is 4-byte address mode.

Table continues on the next page...

Table 200. PAGE PROGRAM command (Cypress serial NOR flash) (continued)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
1	ADDR_SDR	0h (Single)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	WRITE_SDR	0h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default programming data size. This value is ignored for AHB command.
3-7	STOP (00h)	0h	00h	

Table 201 shows Page Program command sequence (QPI mode).

Table 201. PAGE PROGRAM (QPI mode) command (Cypress serial NOR flash)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	2h (Quad)	02h or 12h	Command name: PP or 4PP PP is 3-byte address mode. 4PP is 4-byte address mode.
1	ADDR_SDR	2h (Quad)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	WRITE_SDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default programming data size. This value is ignored for AHB command.
3-7	STOP (00h)	0h	00h	

36.7.1.4 Read Status 1 command

Table 202 shows READ STATUS 1 command sequence.

Table 202. READ STATUS 1 command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	05h	Command name: RDSR1
1	READ_SDR	0h (Single)	1h	1 byte for Status register 1
2-7	STOP (00h)	0h	00h	

36.7.1.5 Read command

Table 203 shows READ command sequence.

Table 203. READ command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	03h or 13h	Command name: READ or 4READ READ is 3-byte address mode. 4READ is 4-byte address mode.
1	ADDR_SDR	0h (Single)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	READ_SDR	0h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
3-7	STOP (00h)	0h	00h	

36.7.1.6 Fast Read command

Table 204 shows Fast Read command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[3:0] = 8h.

Table 204. FAST_READ command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	0Bh or 0Ch	Command name: FAST_READ or 4FAST_READ FAST_READ is 3-byte address mode. 4FAST_READ is 4-byte address mode.
1	ADDR_SDR	0h (Single)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	DUMMY_SDR	0h (Single)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
3	READ_SDR	0h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
4-7	STOP (00h)	0h	00h	

36.7.1.7 Dual IO Fast Read command

Table 205 shows Dual IO FAST_READ command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[3:0] = 8h, Continuous Read mode.

Table 205. Dual IO FAST_READ command (Continuous Read mode)

36.7.1.9 DDR Quad IO Fast Read command

Table 210 shows DDR Quad IO FAST_READ command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[6] = 0, CR2V[3:0] = 8h, Non-QPI mode, Non-continuous read mode.

Table 210. DDR Quad IO FAST_READ command (Non-QPI mode, Noncontinuous read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	EDh or EEh	Command name: QIOR_DDR or 4QIOR_DDR QIOR_DDR is 3-byte address mode. 4QIOR_DDR is 4-byte address mode.

Table continues on the next page...

Table 210. DDR Quad IO FAST_READ command (Non-QPI mode, Noncontinuous read mode) (continued)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
1	ADDR_DDR	2h (Quad)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	MODE8_DDR	2h (Quad)	Any value other than Axh	Exit continuous read mode or keep in noncontinuous read mode.
3	DUMMY_DDR	2h (Quad)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
4	LEARN_DDR	2h (Quad)	1h	DLP is 8 bits.
5	READ_DDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
6-7	STOP (00h)	0h	00h	

Table 211 shows DDR Quad IO FAST_READ command sequence. This table shows Cypress SPI Configuration register bits CR2V[7] = 0, CR2V[6] = 0, CR2V[3:0] = 8h, Non-QPI mode, Continuous read mode.

Table 211. DDR Quad IO FAST_READ command (Non-QPI mode, Continuous read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	EDh or EEh	Command name: QIOR_DDR or 4QIOR_DDR QIOR_DDR is 3-byte address mode. 4QIOR_DDR is 4-byte address mode.
1	ADDR_DDR	2h (Quad)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	MODE8_DDR	2h (Quad)	A0h	Enter continuous read mode or remain in continuous read mode.
3	DUMMY_DDR	2h (Quad)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
4	LEARN_DDR	2h (Quad)	1h	DLP is 8 bits.
5	READ_DDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
6	JMP_ON_CS	0h (or Don't care)	01h	CMD instruction is bypassed after the first read access.
7	STOP (00h)	0h	00h	

Table 212 shows DDR Quad IO FAST_READ command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[6] = 1, CR2V[3:0] = 8h, QPI mode, Continuous read mode.

Table 212. DDR Quad IO FAST_READ command (QPI mode, Continuous read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	2h (Quad)	EDh or EEh	Command name: QIOR_DDR or 4QIOR_DDR QIOR_DDR is 3-byte address mode. 4QIOR_DDR is 4-byte address mode.
1	ADDR_DDR	2h (Quad)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	MODE8_DDR	2h (Quad)	A0h	Enter continuous read mode or remain in continuous read mode.
3	DUMMY_DDR	2h (Quad)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
4	LEARN_DDR	2h (Quad)	1h	DLP is 8 bits.
5	READ_DDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
6	JMP_ON_CS	0h (or Don't care)	01h	CMD instruction is bypassed after the first read access.
7	STOP (00h)	0h	00h	

36.7.2 Application on HyperBus device

This section provides the example LUT instruction sequences for HyperBus device (Cypress RPC flash, HyperRam, or HyperFlash).

36.7.2.1 HyperFlash

This section provides example sequences for HyperFlash devices (Cypress S26KS series).

Table 213 shows the read status command sequence.

Table 213. Read status command

Seq num	Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0 (Write - Addr = 555h, Data = 70h)	0	CMD_DDR	3h (Octal)	20h	CA bit 47: (R/W# = 0h CA bit 46: (Target) = 0h CA bit 45: (Burst Type) = 1h CA bit 44-40: All reserved = 0h
	1	CMD_DDR	3h (Octal)	00h	Row Address: 0000AAh (24 bit)

				data size. This value is ignored for AHB command.
5-7	STOP (00h)	0h	00h	

36.7.3 Application on Serial NAND flash device

This section provides example LUT instruction sequences for serial NAND flash device (Micron Flash MT29 series). The operation of serial NAND flash is similar to serial NOR flash.

The read operation sequence is:

- Page read. Transfer the data from the NAND flash array to the cache register.
- Get feature to read the status.
- Random data read

Table 218 shows the page read command sequence.

Table 218. Page Read command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	13h	Command code: 13h
1	RADDR_SDR	1h (Single)	18h	Row address: 24 bit
2-7	STOP (0h)	0h	00h	

Table 219 shows Get Feature command sequence.

Table 219. Get Feature command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	0Fh	Command code: 0Fh
1	CMD_SDR	1h (Single)	C0h	Status register address (C0h)
2	READ_SDR	0x1 (Single)	02h	2 bytes read data
3-7	STOP (0h)	0h	00h	

Table 220 shows Random Data Read command sequence.

Table 220. Read from Cache x4 command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	6Bh	Command code: 6Bh
1	MODE4_SDR	1h (Single)	0h or 1h	If plane selection is one, software should decode the flash address and write 1h to mode bits. If plane selection

Table continues on the next page...

Table 220. Read from Cache x4 command (continued)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
				is zero, software should write 0h to mode bits. Plane selection bit is 18th bit of flash address. If NAND flash size is less than 4 Gbit, plane selection is always zero.
2	CADDR_SDR	1h (Single)	0Ch	Column address: 12 bit
3	DUMMY_SDR	2h (Quad)	08h	Dummy cycle number: 8 (serial root clock)
4	READ_SDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size.
5-7	STOP (0x0)	0x0	0x00	

The program operation sequence is:

- Write enable
- Program Load. Transfer the write data to the cache register.
- Program Execute
- Get Feature to read the status.

Table 221 shows Program Load command sequence.

Table 221. Program Load command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	02h	Command code: 02h
1	MODE4_SDR	1h (Single)	0h or 1h	If plane selection is one, software should decode the flash address and write 1h to mode bits. If plane selection is zero, software should write 0h to mode bits. Plane selection bit is 18th bit of flash address. If NAND flash size is less than 4 Gbit, plane selection is always zero.
2	CADDR_SDR	1h (Single)	0Ch	Column address: 12 bit
3	WRITE_SDR	1h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default writing data size.
4-7	STOP (0h)	0h	00h	

Table 222 shows Program Execute command sequence.

Table 222. Program Execute command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	10h	Command code: 10h
1	RADDR_SDR	1h (Single)	18h	Row Address: 24 bit
2-7	STOP (0h)	0h	00h	

36.7.4 Application on FPGA device

An FPGA device can be accessed via both AHB and IP commands. All AHB accesses to FPGA are transparent to the software driver (no software intervention). An FPGA device may have some special requirements.

Table 223. Special requirements for FPGA devices

Condition	How to manage the condition
Device type may be different on A1, A2, B1, or B2.	Write 0 to MCR2[SAMEDEVICEEN] and configure the FLSHxCR0 and FLSHxCR1 registers separately for up to four external devices.
Device requires different wait cycle for programming.	The AHB write wait cycle number can be set separately for these four external devices (via FLSHxCR2[AWRWAIT]). Software can configure the sequences in LUT with different dummy instructions (operand determines dummy cycle). FlexSPI holds the AHB bus ready for this wait time; AHB bus performance may decrease when this wait time is very long.
Device requires different wait cycle for reading.	The AHB read sequence index and sequence number can be set separately for these four external devices (via FLSHxCR2[ARDSEQID] and FLSHxCR2[ARDSEQNUM]). Software can configure the sequences in LUT with different dummy instructions (operand determines dummy cycle).
Device may be sensitive to read instruction clock cycle number.	If its internal memory is implemented similar to a FIFO, the device is sensitive to the read instruction clock cycle number. Software can send the data size information to the external device via DATSZ instruction. The FPGA device decodes the data size information and determines how many data bytes must be popped.
Device may require interval time between chip select valid.	This interval can be managed via FLSHxCR1[CSINTERVAL].
Device may use SCLK as reference clock for its internal PLL.	SCLK must be free-running and the clock frequency must be stable. To achieve this configuration, write 1 to MCR0[SCKFREERUNEN] and only use SDR sequences.

36.7.5 Overview of error categories, flags, and triggered sources

Table 224 provides an overview of the categories, flags, and triggered sources of errors in FlexSPI.

Table 224. Error category, triggered sources, and flags

Error Category	Triggered Sources	Description	Error Flags
Command grant error	AHB write command	Command grant timeout	INTR[AHBCMDGE] is set AHB bus error response

Table continues on the next page...

Table 224. Error category, triggered sources, and flags (continued)

Error Category	Triggered Sources	Description	Error Flags
	AHB read command		INTR[AHBCMDGE] is set AHB bus error response
	IP command		INTR[IPCMDGE] is set
Command check error	AHB write command	• AHB write command with JMP_ON_CS instruction used in the sequence • Unknown instruction opcode in the sequence • Instruction DUMMY_SDR or DUMMY_RWDS_SDR used in DDR sequence • Instruction DUMMY_DDR or DUMMY_RWDS_DDR used in SDR sequence	INTR[AHBCMDERR] is set Command is not executed when an error is detected in command check
	AHB read command	• Unknown instruction opcode in the sequence • Instruction DUMMY_SDR or DUMMY_RWDS_SDR used in DDR sequence • Instruction DUMMY_DDR or DUMMY_RWDS_DDR used in SDR sequence	INTR[AHBCMDERR] is set Command is not executed when an error is detected in command check
	IP command	• IP command with JMP_ON_CS instruction used in the sequence • Unknown instruction opcode in the sequence • Instruction DUMMY_SDR or DUMMY_RWDS_SDR used in DDR sequence • Instruction DUMMY_DDR or DUMMY_RWDS_DDR used in SDR sequence • Flash boundary across	INTR[IPCMDERR] is set Command is not executed when an error is detected in command check
Command execution error	AHB write command	Command timeout during execution	INTR[AHBCMDERR] is set INTR[SEQTIMEOUT] is set An AHB bus error response

Table continues on the next page...

Table 224. Error category, triggered sources, and flags (continued)

Error Category	Triggered Sources	Description	Error Flags
			occurs, except in following cases: • Flush triggers AHB write command (INCR burst ended with AHB_TX_BUF not empty) • AHB bufferable write access and bufferable enabled (AHBCR[BUFFERABLEEN] = 1)
	AHB read command		INTR[AHBCMDERR] is set INTR[SEQTIMEOUT] is set AHB bus error response
	IP command		INTR[IPCMDERR] is set INTR[SEQTIMEOUT] is set
AHB bus timeout	AHB write command	AHB bus timeout (no bus ready return)	AHB bus error response
	AHB read command		
Data learning failed	Any command	No valid sample clock phase found after learn instruction is executed	INTR[DATALEARNFAIL] is set

36.8 Memory map and register definition

This section includes the FlexSPI module memory map and detailed descriptions of all registers.

36.8.1 Register access

All registers can be accessed with 8-bit, 16-bit, and 32-bit width operations. Never change the values of reserved fields in control registers. Changing the values of reserved fields may impact the normal functioning of the controller.

NOTE

When FlexSPI can access sensitive memory contents, the FlexSPI controller should protect those contents using resource isolation such as XRDC or TrustZone. Ensure that only trusted software is allowed to access the FlexSPI controller register interface.

36.8.2 FLEXSPI register descriptions

36.8.2.1 FlexSPI memory map

FLEXSPI base address: 425E_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	Module Control 0 (MCR0)	32	RW	FFFF_80C2
4	Module Control 1 (MCR1)	32	RW	FFFF_FFFF

36.8.2.2 Module Control 0 (MCR0)

Controls basic functions of FlexSPI module

Offset

Register	Offset
MCR0	0h

Diagram

Fields

Field	Description
31-24 AHBGRANTWAIT	Timeouts Wait Cycle for AHB command Grant Sets duration of timeout wait cycle for AHB commands. If the arbitrator does not grant the AHB-triggered command, it times out after (AHBGRANTTIMEOUT × 1024) AHB clock cycles. When the pending command sequence is IP-triggered and the read or write data size is too large, this grant timeout may occur. When an AHB command grant timeout occurs, an INTR[AHBCMDGE] interrupt is generated. When INTEN[AHBCMDGEEN] = 1, the arbitrator ignores AHB commands. **NOTE** This field is for debugging only. Do not change the value from its default.
23-16 IPGRANTWAIT	Timeout Wait Cycle for IP Command Grant Sets duration of timeout wait cycle for IP commands. If the arbitrator does not grant the IP-triggered command, it times out after (IPGRANTTIMEOUT × 1024) AHB clock cycles. When the pending command sequence is AHB-triggered and the read or write data size is too large, this grant timeout may occur. When IP command grant timeout occurs, an INTR[IPCMDGE] interrupt is generated. When INTEN[IPCMDGEEN] = 1, the arbitrator ignores IP commands. **NOTE** This field is for debugging only. Do not change the value from its default.
15 LEARNEN	Data Learning Enable Enables data learning feature. When data learning is disabled, the sampling clock phase 0 is always used for receive data sampling, even when a learn instruction is correctly executed. See Data learning. 0 - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Enable
14 SCKFREERUNEN	SCLK Free-running Enable Enables free-running SCLK output. For FPGA applications, the external device may use SCLK as a reference clock to its internal PLL. 0 - Disable 1 - Enable
13 —	Reserved
12 DOZEEN	Doze Mode Enable Enables Doze mode. When enabled, AHB clock and serial clock are gated off when there is a Doze-mode request from the system. 0 - Disable 1 - Enable
11 HSEN	Half Speed Serial Flash Memory Access Enable Enables the clock divider to provide a half-speed clock to external serial flash devices (A_SCLK/B_SCLK) for all commands in SDR and DDR mode. Write 1 to MCR0[MDIS] before changing the value of this field. Failure to do so may cause issues in the internal logic or state machine. 0 - Disable 1 - Enable
10-8 SERCLKDIV	Serial Root Clock Divider Sets divider value for serial root clock. The serial root clock can be divided inside FlexSPI . See Clocking. **NOTE** Do not modify this field while FlexSPI is active (MCR0[MDIS] = 0). 000 - Divided by 1 001 - Divided by 2 010 - Divided by 3 011 - Divided by 4 100 - Divided by 5 101 - Divided by 6 110 - Divided by 7 111 - Divided by 8
7	AHB Write Access to IP Transmit FIFO Enable

Table continues on the next page...

Table continued from the previous page...

Field	Description
ATDFEN	Enables AHB write access to IP transmit FIFO. See Writing data to IP transmit FIFO. 0 - AHB write access disabled. IP bus writes to IP transmit FIFO. AHB bus write access to IP transmit FIFO memory space produces bus error. 1 - AHB write access enabled. AHB bus writes to IP transmit FIFO. IP Bus write access to IP transmit FIFO memory space is ignored and causes no bus error.
6 ARDFEN	AHB Read Access to IP Receive FIFO Enable Enables AHB read access to IP receive FIFO. See Reading data from IP receive FIFO. 0 - AHB read access disabled. IP bus reads IP receive FIFO. AHB Bus read access to IP receive FIFO memory space produces bus error. 1 - AHB read access enabled. AHB bus reads IP receive FIFO. IP Bus read access to IP receive FIFO memory space returns data zero and causes no bus error.
5-4 RXCLKSRC	Sample Clock Source for Flash Reading Selects sampling clock source for flash memory reading. See Receive clock source features. 00 - Dummy Read strobe that FlexSPI generates, looped back internally 01 - Dummy Read strobe that FlexSPI generates, looped back from DQS pad 10 - Reserved 11 - Flash-memory-provided read strobe and input from DQS pad
3-2 —	Reserved
1 MDIS	Module Disable Disables FlexSPI module. When the module is disabled, AHB and serial clock are gated off internally to save power. Only register access is allowed, except for the LUT, IP receive FIFO, and IP transmit FIFO. 0 - No impact 1 - Module disable
0 SWRESET	Software Reset Resets the internal FlexSPI state machine and aborts any transactions in progress. Hardware automatically writes 0 to this field after software reset is done. Configuration registers are not reset. 0 - No impact 1 - Software reset

36.8.2.3 Module Control 1 (MCR1)

Controls basic functions of FlexSPI module

Offset

Register	Offset
MCR1	4h

Diagram

Fields

Field	Description
31-16 SEQWAIT	Command Sequence Wait Sets wait time for command sequence. Command sequence execution times out and aborts after (SEQWAIT × 1024) serial root clock cycles. When this timeout occurs, if the interrupt is enabled (INTEN[SEQTIMEOUTEN] = 1), an INTR[SEQTIMEOUT] interrupt is generated. Also, the arbitrator ignores AHB commands. **NOTE** You cannot write 0 to this field.
15-0 AHBBUSWAIT	AHB Bus Wait Sets wait time for AHB bus. When data is not received from or transmitted to serial flash memory space after (AHBBUSWAIT × 1024) AHB clock cycles, the read or write access times out. When this timeout occurs, the AHB bus receives an error response, and an interrupt is generated (INTEN[AHBBUSERROREN]). When INTR[AHBBUSERROREN] = 1, the arbitrator ignores AHB commands. **NOTE** You cannot write 0 to this field.

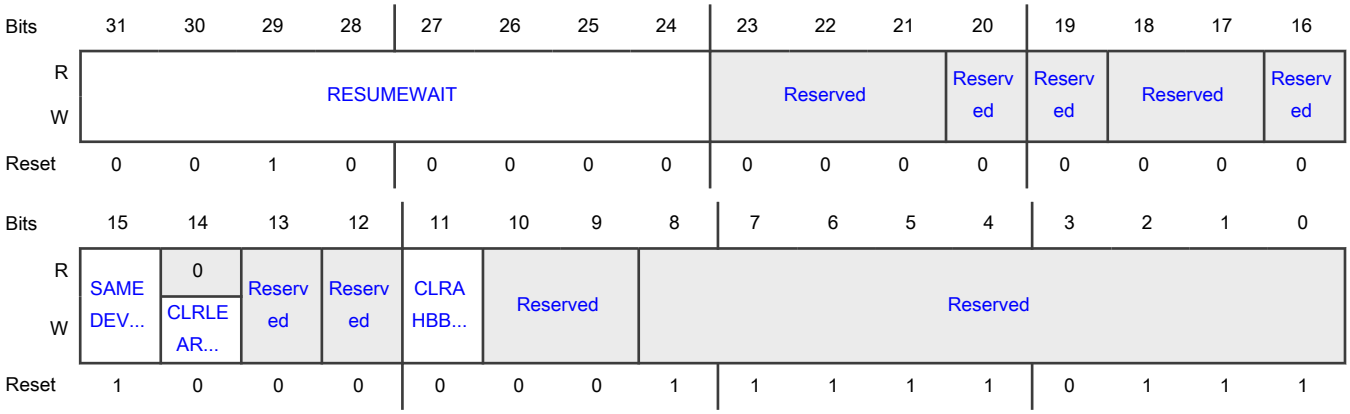
36.8.2.4 Module Control 2 (MCR2)

Controls basic functions of FlexSPI module.

Offset

Register	Offset
MCR2	8h

Diagram



Fields

Field	Description
31-24 RESUMEWAIT	Resume Wait Duration Determines duration (in AHB clock cycles) to remain in idle state before suspended command sequence is resumed. See Command abort and suspend.
23-21 —	Reserved
20 —	Reserved
19 —	Reserved
18-17 —	Reserved
16 —	Reserved
15 SAMEDEVICEEN	Same Device Enable Sets all external devices (A1, A2, B1, and B2) to be the same devices (in type and in size). 0 - In Individual mode, FLSHA1CRx and FLSHA2CRx, FLSHB1CRx and FLSHB2CRx settings are applied to Flash A1, A2, B1, B2 separately.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - FLSHA1CR0, FLSHA1CR1, and FLSHA1CR2 register settings are applied to Flash A1, A2, B1, B2. FLSHA2CRx, FLSHB1CRx, and FLSHB2CRx settings are ignored.
14 CLRLEARNPHASE	Clear Learn Phase Selection Resets the sampling clock phase selection to 0. When 1 is written to this field, it becomes 0 again immediately. 0 - No impact 1 - Reset sample clock phase selection to 0
13 —	Reserved
12 —	Reserved
11 CLRAHBBUFOPT	Clear AHB Buffer Determines whether AHB receive and transmit buffers are cleared automatically when FlexSPI returns Stop mode ACK. If an AHB receive buffer or transmit buffer will be powered off in Stop mode, software should write 1 to this field. Otherwise, an AHB read access after exiting Stop mode may hit either buffer, but their data entries are invalid. 0 - Not cleared automatically 1 - Cleared automatically
10-9 —	Reserved
8-0 —	Reserved

36.8.2.5 AHB Bus Control (AHBCR)

Controls AHB bus interface functions.

Offset

Register	Offset
AHBCR	Ch

Fields

Field	Description
31-27 AFLASHBASE	AHB Memory-Mapped Flash Base Address
26-22 —	Reserved
21-20 ALIGNMENT	AHB Boundary Alignment Configures the size of AHB read and write boundary. All accesses that cross the boundary are divided into smaller sub accesses. 00 - No limit 01 - 1 KB 10 - 512 bytes 11 - 256 bytes
19 —	Reserved
18 —	Reserved
17 —	Reserved
16 —	Reserved
15 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
14-13 —	Reserved
12 —	Reserved
11 —	Reserved
10 READSZALIGN	AHB Read Size Alignment Configures how AHB read size is determined. See Table 194. **NOTE** When 1, data prefetching is disabled regardless of other field settings such as PREFETCH_EN and OTFAD_EN. Read size is rounded up to the nearest eight-byte multiple. For example, if current AHB read size is 12 bytes, it is aligned to 16 bytes. When the fetch size must be eight-byte aligned but no speculative fetching is wanted, write 1 to this field. 0 - Register settings such as PREFETCH_EN and OTFAD_EN determine AHB read size. 1 - AHB read size to up size to 8 bytes aligned, no prefetching
9 —	Reserved
8 —	Reserved
7 RESUMEDISABLE	AHB Read Resume Disable Disables the resumption of AHB read prefetch. **NOTE** When OTFAD is enabled, this field does not affect the resume function; AHB read resume is always disabled. When OTFAD is disabled, suspended AHB read prefetch resumes based on the values of this field and MCR2[RESUMEWAIT]. 0 - Suspended AHB read prefetch resumes when AHB is IDLE. 1 - Suspended AHB read prefetch does not resume once aborted.
6 READADDROPT	AHB Read Address Option Removes AHB burst start address alignment limitation. When the FlexSPI controller is used for FPGA application, this field may be required for FlexSPI to fetch the exact byte number as an AHB burst. In this case, FPGA device should be non-word-addressable and this field must be 0.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE When OTFAD is enabled, FlexSPI functions as it does when READADDROPT = 1 regardless the value of this field. 0 - AHB read burst start address alignment is limited when flash memory is accessed in flash is word-addressable. 1 - AHB read burst start address alignment is not limited. FlexSPI fetches more data than the AHB burst requires for address alignment.
5 PREFETCHEN	AHB Read Prefetch Enable Enables AHB read prefetch. When enabled, FlexSPI fetches more flash read data than the current AHB burst requires. This action reduces the read latency for next AHB read access. **NOTE** When OTFAD is enabled, the AHB prefetch function is enabled regardless of the value of this field. **NOTE** AHB read prefetch is enabled only when both this field and AHBRXBUFnCR0[PREFETCHEN] are 1. 0 - Disable 1 - Enable
4 BUFFERABLEEN	Bufferable Write Access Enable Enables AHB bus bufferable write access. This field affects the last beat of an AHB write access. See AHB write access to flash memory. 0 - Disabled. For all AHB write accesses (bufferable or nonbufferable), FlexSPI returns AHB Bus Ready after transmitting all data and finishing command. 1 - Enabled. For AHB bufferable write access, FlexSPI returns AHB Bus Ready when the arbitrator grants the AHB command. FlexSPI does not wait for the AHB command to finish.
3 CACHABLEEN	Cacheable Read Access Enable Enables AHB bus cacheable read access. 0 - Disabled. When an AHB bus cacheable read access occurs, FlexSPI does not check whether it hit the AHB transmit buffer. 1 - Enabled. When an AHB bus cacheable read access occurs, FlexSPI first checks whether the access hit the AHB transmit buffer.
2 CLRAHBTXBUF	Clear AHB Transmit Buffer Clears status and pointers of AHB transmit buffer. When the clear operation completes, this field clears automatically, so it always reads as 0. 0 - No impact.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Enable clear operation.
1 —	Reserved
0 —	Reserved

36.8.2.6 Interrupt Enable (INTEN)

Includes AHB error response, IPS error response, and ECC error interrupt enables. See Interrupts.

Offset

AHBRXBUF6CR0	8006_0020h
AHBRXBUF7CR0	8007_0020h

Fields

Field	Description
31 PREFETCHEN	AHB Read Prefetch Enable Enables AHB read prefetch for the controller corresponding to the current AHB receive buffer. The prefetch feature is disabled when AHBCR[PREFETCHEN] is 0. You can use this field to enable or disable prefetch separately for each controller. 0 - Disabled 1 - Enabled when AHBCR[PREFETCHEN] is enabled.
30 REGIONEN	AHB Receive Buffer Address Region Enable Enable prefetch buffer enhancement.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE Only AHBRXBUF 0-3 have this function. 0 - Disabled. The buffer hit is based on the value of MSTRID only. 1 - Enabled. The buffer hit is based on the value of MSTRID and the address within AHBBUFREGIONSTARTn and AHBREGIONENDn.
29-27 —	Reserved
26-24 PRIORITY	AHB Controller Read Priority Configure the priority for the AHB Controller Read to which this AHB receive buffer is assigned. 7 is the highest priority, 0 the lowest. See Command abort and suspend.
23-20 —	Reserved
19-16 MSTRID	AHB Controller ID Configures the ID of the AHB controller to which this AHB receive buffer is assigned. See AHB receive buffer management.
15-9 —	Reserved
8-0 BUFSZ	AHB Receive Buffer Size Configures the size of the AHB receive buffer in multiples of 64 bits. See AHB receive buffer management.

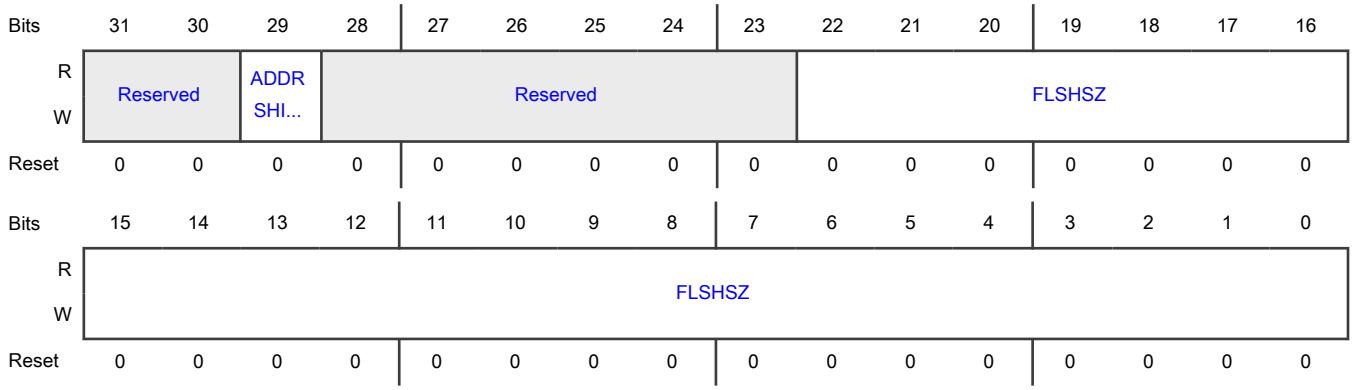
36.8.2.11 Flash Control 0 (FLSHA1CR0 - FLSHB2CR0)

Contains flash memory size setting. FlexSPI determines which device is accessed (Chip Select) via this register.

Offset

Register	Offset
FLSHA1CR0	60h
FLSHA2CR0	64h
FLSHB1CR0	68h
FLSHB2CR0	6Ch

Diagram



Fields

Field	Description
31-30 —	Reserved
29 ADDRSHIFT	AHB Address Shift Function control Used to left-shift five bits for the flash address to support ISSI quad PSRAM. 0 - Disabled 1 - Enabled
28-23 —	Reserved
22-0 FLSHSZ	Flash Size in KB Configures the maximum flash memory size. See the chip-specific section for the maximum flash size supported. When the value of this field is greater than the maximum size, the device flash size is interpreted as the maximum. The maximum flash size is the largest flash size supported for a single device. It is also the maximum total flash size supported for all devices (up to four). If the total flash size is larger than the maximum size, only the maximum flash size address space is accessible. For IPS access, The maximum flash size supported for each device is 4 GB. When the value of this field is greater than 400000h, the device flash size is taken as 4 GB. The max total flash size supported (for all 4 devices) is also 4 GB. If the total flash size is larger than 4 GB, only 4 GB of address space is accessible.

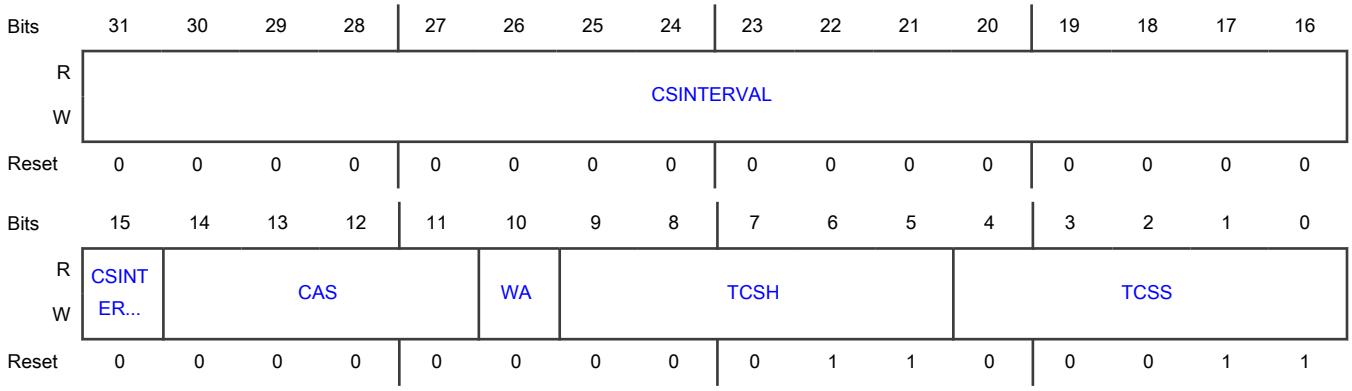
36.8.2.12 Flash Control 1 (FLSHA1CR1 - FLSHB2CR1)

Contains settings for flash device-specific timings and flash internal address space.

Offset

Register	Offset
FLSHA1CR1	70h
FLSHA2CR1	74h
FLSHB1CR1	78h
FLSHB2CR1	7Ch

Diagram



Fields

Field	Description
31-16 CSINTERVAL	Chip Select Interval Configures the minimum interval between flash device chip select deassertion and chip select assertion. If the external flash device has a limitation on the interval between command sequences, configure this field accordingly. If there is no limitation, write 0h to this field. When CSINTERVALUNIT = 0, the chip select invalid interval is: CSINTERVAL × 1 serial clock cycle; When CSINTERVALUNIT = 1, the chip select invalid interval is: CSINTERVAL × 256 serial clock cycles. **NOTE** The minimum chip select interval is 2 cycles, even when the value of CSINTERVAL is less than 2.
15 CSINTERVALUNIT	Chip Select Interval Unit Configures the interval unit for chip select. 0 - 1 serial clock cycle 1 - 256 serial clock cycles
14-11 CAS	Column Address Size When external flash memory has a separate address field for rows and columns, this field configures the flash column address bit width. FlexSPI automatically splits a flash-mapped address into row address and column address according to the values of this field and the WA field.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When the external flash memory does not support column address, write 0 to this field. FlexSPI transmits all flash address bits as Row address. For flash address mapping, see Flash address sent to flash memory devices.
10 WA	Word-Addressable Configures whether external flash memory is word-addressable or byte-addressable. If flash memory is word-addressable, it should be accessed in multiples of 16 bits. Currently, FlexSPI does not transmit flash address bit 0 to external flash memory. For flash address mapping, see Flash address sent to flash memory devices. 0 - Byte-addressable 1 - Word-addressable
9-5 TCSH	Serial Flash CS Hold Time Used to meet flash TCSH timing requirement. Serial flash CS Hold time that FlexSPI promises is: (TCSH + 1/2) serial clock cycles for DDR mode, and TCSH serial clock cycles for SDR mode. See Output timing between chip select and SCLK.
4-0 TCSS	Serial Flash CS Setup Time Used to meet flash TCSS timing requirement. Serial flash CS Setup time that FlexSPI promises is: (TCSS + 1/2) serial root clock cycles for SDR and DDR mode. See Output timing between chip select and SCLK.

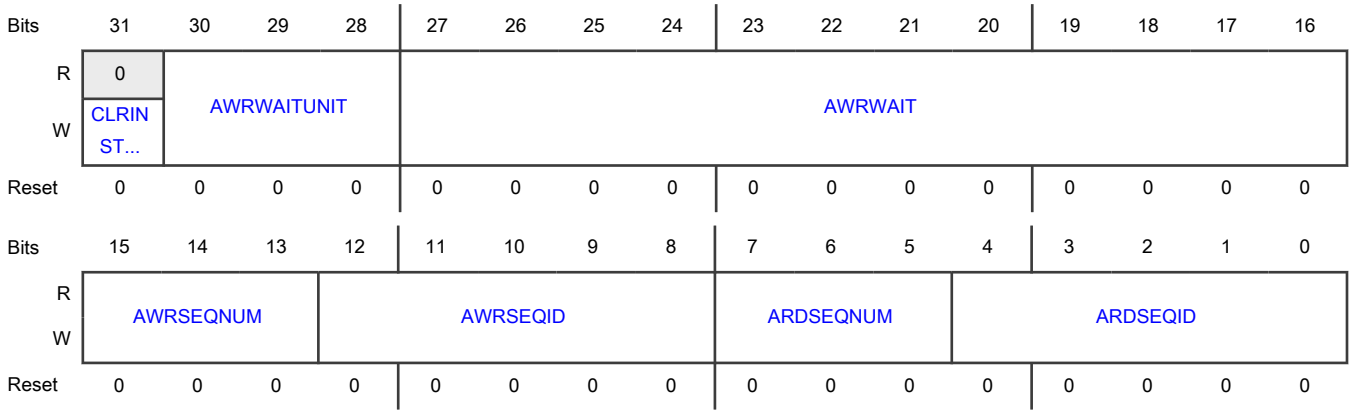
36.8.2.13 Flash Control 2 (FLSHA1CR2 - FLSHB2CR2)

Contains fields to configure AHB bus access. If the four external devices are different types, AHB read and write commands may use different command sequences; AHB bus ready wait time may also differ.

Offset

Register	Offset
FLSHA1CR2	80h
FLSHA2CR2	84h
FLSHB1CR2	88h
FLSHB2CR2	8Ch

Diagram



Fields

Field	Description
31 CLRINSTRPTR	Clear Instruction Pointer Clears the instruction pointer, which is the pointer that JMP_ON_CS saves internally. See Programmable sequence engine. This field is used for AHB read access to external flash memory supporting Execute-In-Place (XIP) mode.
30-28 AWRWAITUNIT	AWRWAIT Unit Configures the unit of AHB write wait time, as the value of AWRWAIT determines, in terms of AHB clock cycles. 000 - 2 001 - 8 010 - 32 011 - 128 100 - 512 101 - 2048 110 - 8192 111 - 32768
27-16 AWRWAIT	AHB Write Wait Configures AHB write wait time, with the AWRWAITUNIT field. Certain devices (such as FPGA) require time to write data into internal memory after the command sequences finished on the FlexSPI interface. If another read command sequence arrives before the current programming finishes internally, the read data may be wrong. This field is used to hold the AHB bus ready for AHB write access, waiting until the programming is finished in the external device. This hold ensures that no AHB read command is triggered before the programming finishes in the external device. The wait cycle between an AHB-triggered command sequence finishing on FlexSPI and the AHB return bus being ready is: AWRWAIT × AWRWAITUNIT.
15-13	Sequence Number for AHB Write-Triggered Command

Table continues on the next page...

Table continued from the previous page...

Field	Description
AWRSEQNUM	Configures the sequence number of an AHB read-triggered command. For certain flash devices (for example, HyperFlash, HyperRam, and Serial NAND flash), a flash programming access is done via several command sequences. An AHB write command triggers (AWRSEQNUM + 1) command sequences to external flash memory each time. FlexSPI executes the sequences in LUT incrementally. **NOTE** • Software should ensure that the last sequence index never exceeds LUT sequence numbers: AWRSEQID + AWRSEQNUM < 32 • Software must ensure that the AWRSEQNUM and LUT fields are configured correctly according to the external device specification. FlexSPI does not check the sequence; it executes the sequences one by one.
12-8 AWRSEQID	Sequence Index for AHB Write-Triggered Command
7-5 ARDSEQNUM	Sequence Number for AHB Read-Triggered Command Configures the sequence number of an AHB read-triggered command in the lookup table. For certain flash devices (for example, HyperFlash, HyperRam, and Serial NAND flash), a flash read access is done via several command sequences. An AHB read command triggers (ARDSEQNUM + 1) command sequences to external flash memory each time. FlexSPI executes the sequences in LUT incrementally. **NOTE** • Software should ensure that the last sequence index never exceeds LUT sequence numbers: ARDSEQID + ARDSEQNUM ≤ 32. • Software must ensure that the ARDSEQNUM and LUT fields are configured correctly according to the external device specification. FlexSPI does not check the sequence; it executes the sequences one by one.
4-0 ARDSEQID	Sequence Index for AHB Read-Triggered Command in LUT

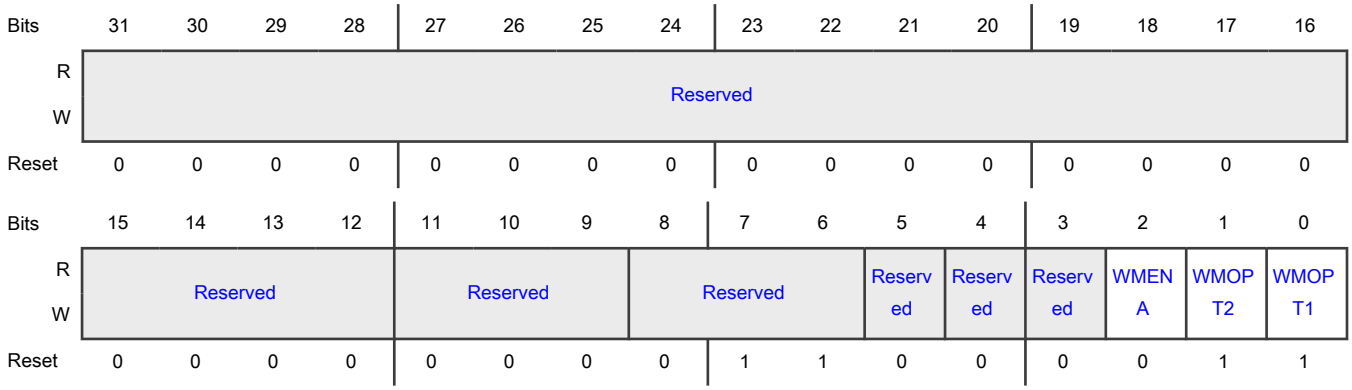
36.8.2.14 Flash Control 4 (FLSHCR4)

Provides configuration for all external devices.

Offset

Register	Offset
FLSHCR4	94h

Diagram



Fields

Field	Description
31-12 —	Reserved
11-9 —	Reserved
8-6 —	Reserved
5 —	Reserved
4 —	Reserved
3 —	Reserved
2 WMENA	Write Mask Enable for Port A Enables write mask for flash device on port A. 0 - Disabled. When writing to external device, DQS(RWDS) pin is not driven. 1 - Enabled. When writing to external device, FlexSPI drives DQS(RWDS) pin as write mask output.
1 WMOPT2	Write Mask Option 2 When using AP memory, used to remove AHB or IP write burst minimum length limitation. When using this field, FLSHCR4[WMOPT1] should be 1. 0 - When writing to an external device, DQS pin is used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst length is not limited.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - When writing to an external device, DQS pin is not used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst length is limited. The minimum write burst length should be 4.
0 WMOPT1	Write Mask Option 1 Used to remove AHB and IP write burst start address alignment limitation. 0 - When writing to an external device, DQS pin is used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst start address alignment is not limited. 1 - When writing to an external device, DQS pin is not used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst start address alignment is limited.

36.8.2.15 IP Control 0 (IPCR0)

Provides all configuration required for IP commands. Provides the start address for the flash device, instead of the chip address, to be accessed for IP command. FlexSPI determines the chip select automatically according to this start address.

NOTE

- You cannot issue an IP command that crosses flash device boundaries. If you do so, it generates an IPCMDERR interrupt.
- Configure this register before an IP command is triggered.
- Do not change the values in this register while an IP command is in progress.

Offset

Register	Offset
IPCR0	A0h

15-0 IDATSZ	Flash Read/Program Data Size (in bytes) for IP command.

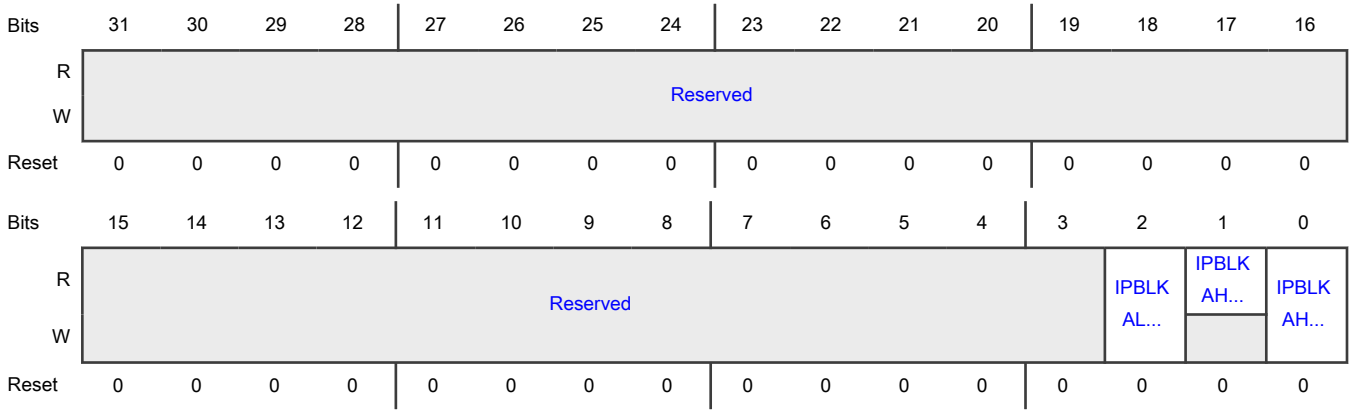
36.8.2.17 IP Control 2 (IPCR2)

Configures whether IP commands can block AHB commands.

Offset

Register	Offset
IPCR2	A8h

Diagram



Fields

Field	Description
31-3 —	Reserved
2	IP Command Blocking All AHB Command Enable 0 - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
IPBLKALLAHB	1 - IP commands block all AHB commands.
1 IPBLKAHBACK	IP Command Blocking AHB Command Acknowledgment Enable 0 - IP commands do not block AHB command acknowledgment. 1 - IP commands block AHB command acknowledgment.
0 IPBLKAHBREQ	IP Command Blocking AHB Command Request Enable 0 - IP commands do not block AHB command requests. 1 - IP commands block AHB command requests.

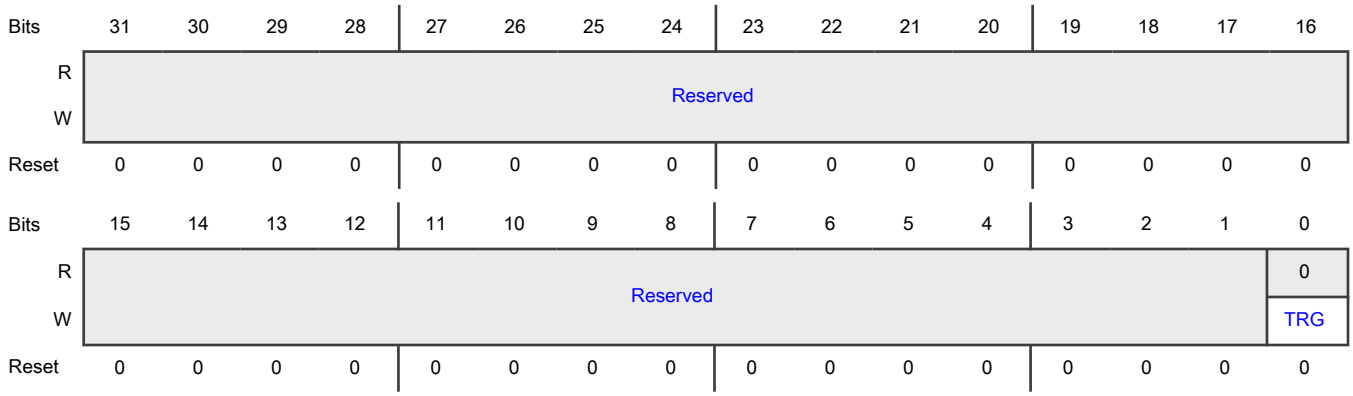
36.8.2.18 IP Command (IPCMD)

Used to trigger an IP command to access external flash device. When the arbitrator grants the IP command, the command is executed on the FlexSPI interface.

Offset

Register	Offset
IPCMD	B0h

Diagram



Fields

Field	Description
31-1 —	Reserved
0 TRG	Command Trigger Triggers an IP command. This field clears automatically after it has been written and always reads as 0.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE You cannot trigger another IP command before the previous IP command finishes on the FlexSPI interface. Software must poll INTR[IPCMDDONE] or wait for this interrupt. 0 - No action 1 - Start the IP command that the IPCR0 and IPCR1 registers define.

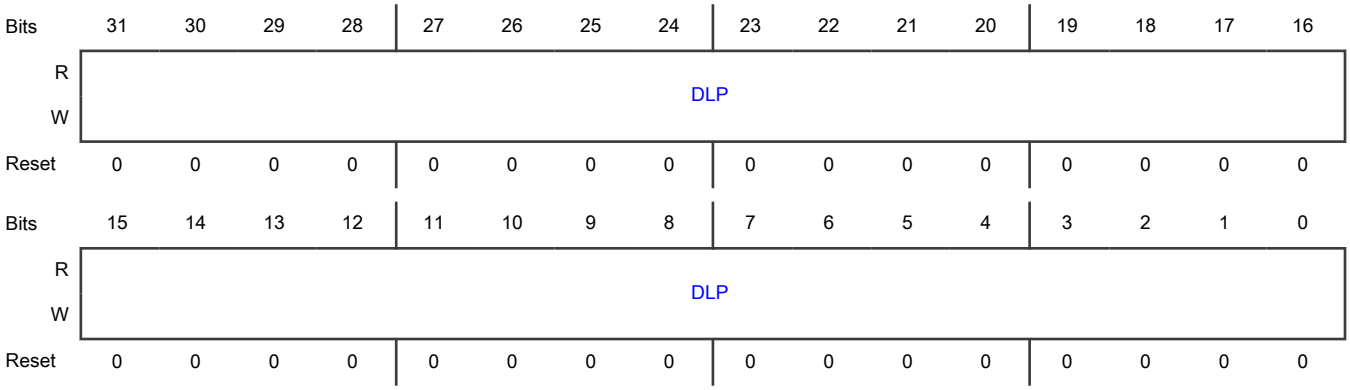
36.8.2.19 Data Learning Pattern (DLPR)

Provides the pattern to be used during Data Learning in FlexSPI.

Offset

Register	Offset
DLPR	B4h

Diagram



Fields

Field	Description
31-0 DLP	Data Learning Pattern The operand in the LEARN_SDR or LEARN_DDR instruction code determines the data learning pattern bit number. This number never exceeds 32 bits. If the operand in the instruction code is greater than 32, a 32-bit pattern is used. See Data learning.

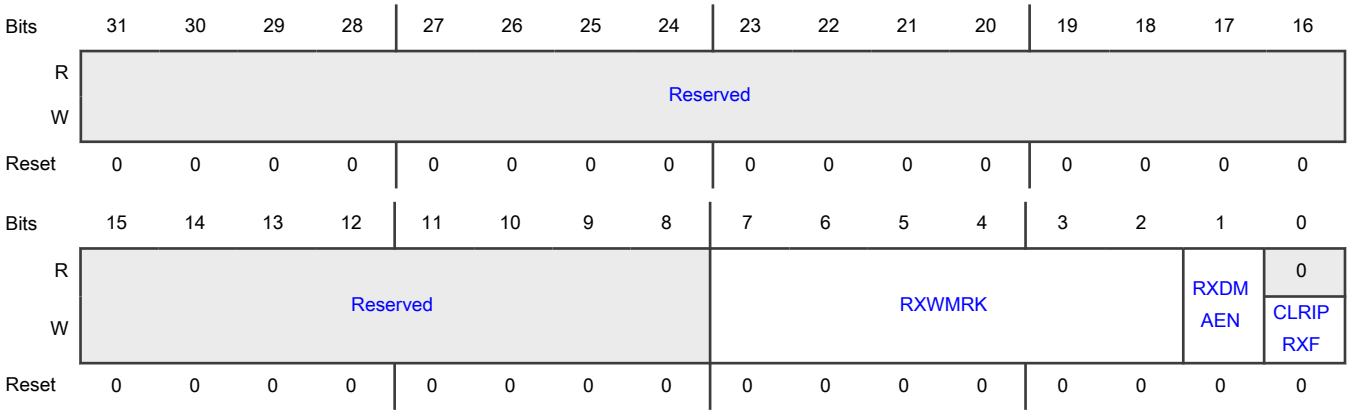
36.8.2.20 IP Receive FIFO Control (IPRXFCR)

Provides the configuration fields for IP receive FIFO management.

Offset

Register	Offset
IPRXFCR	B8h

Diagram



Fields

Field	Description
31-8 —	Reserved
7-2 RXWMRK	IP Receive FIFO Watermark Level Configures the watermark level for the IP receive FIFO. The watermark level is (RXWMRK + 1) × 64 bits. The INTR[IPRXWA] interrupt is set when FlexSPI fills the IP receive FIFO ≥ the watermark level. A DMA request occurs when the fill level is ≥ the watermark level and IPRXFCR[RXDMAEN] = 1. When the fill level is ≥ the watermark level and INTEN[IPRXWAEN] = 1, an INTR[IPRXWA] interrupt is generated. **NOTE** After writing 1 to INTR[IPRXWA] to clear it, the read address should be rolled back to the start address (memory mapped). If the IP bus reads the IP receive FIFO, the read address should roll back to RFDR0. If the AHB bus reads the IP receive FIFO, the read address should roll back to ARDF_BASE.
1 RXDMAEN	IP Receive FIFO Reading by DMA Enable 0 - Disabled. The processor reads the FIFO. 1 - Enabled. DMA reads the FIFO.
0 CLRIPRXF	Clear IP Receive FIFO Clears all valid data entries in IP receive FIFO. Resets the read and write pointers in IP receive FIFO. 0 - No function 1 - A clock cycle pulse clears all valid data entries in IP receive FIFO.

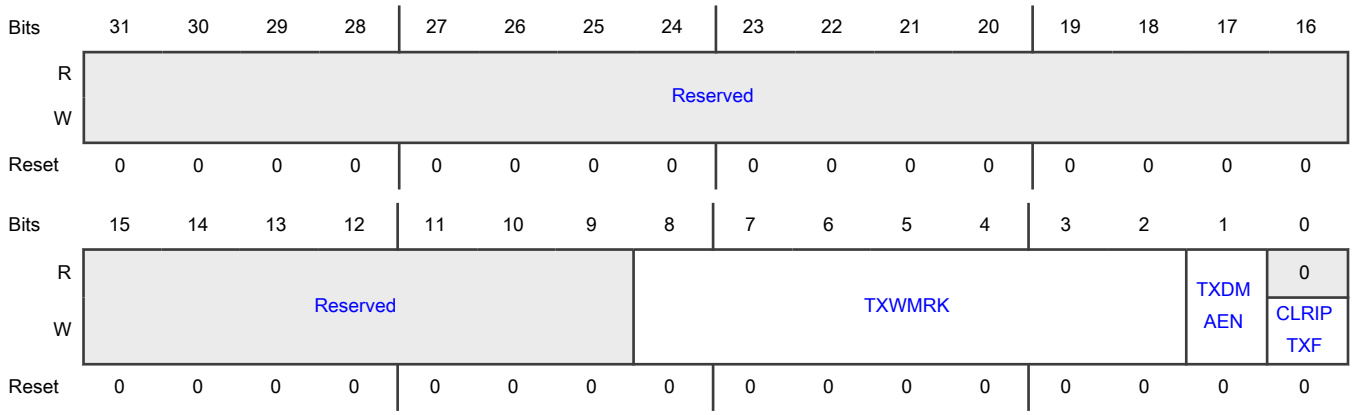
36.8.2.21 IP Transmit FIFO Control (IPTXFCR)

Provides the configuration fields for IP transmit FIFO management.

Offset

Register	Offset
IPTXFCR	BCh

Diagram



Fields

Field	Description
31-9 —	Reserved
8-2 TXWMRK	Transmit Watermark Level Sets the transmit watermark level. The watermark level is (TXWMRK + 1) × 64 bits. INTR[IPTXWE] is set when FlexSPI empties the IP transmit FIFO ≥ the watermark level. When the empty level ≥ the watermark level and IPTXFCR[TXDMAEN] = 1, a DMA request occurs. When the empty level ≥ the watermark level and INTEN[IPTXWEEN] = 1, an INTR[IPTXWE] interrupt is generated. **NOTE** • The watermark level should not be larger than the write window. • The watermark level should not be larger than the IP transmit FIFO size. • The write address to the IP receive FIFO should roll back to the start address of the write window. After pushing the IP transmit fifo, you should write 1 to INTR[IPTXWE] to clear it, which will perform the rollback.
1 TXDMAEN	Transmit FIFO DMA Enable Selects whether DMA or processor fills IP transmit FIFO. 0 - Processor

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - DMA
0 CLRIPTXF	Clear IP Transmit FIFO Clears all valid data entries in IP transmit FIFO. The read and write pointers in IP transmit FIFO are reset. 0 - No function 1 - A clock cycle pulse clears all valid data entries in the IP transmit FIFO.

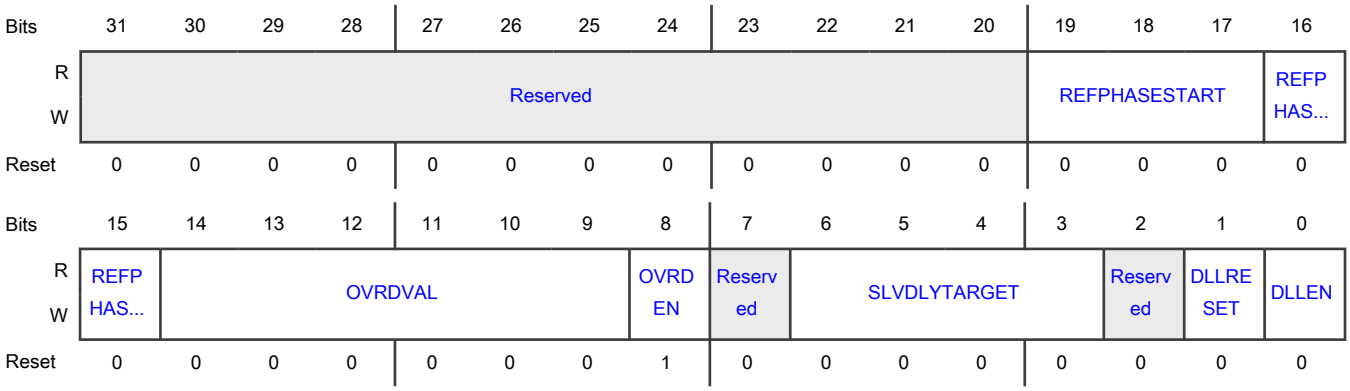
36.8.2.22 DLL Control 0 (DLLACR - DLLBCR)

Configures Flash A and B sample clock DLL.

Offset

Register	Offset
DLLACR	C0h
DLLBCR	C4h

Diagram



Fields

Field	Description
31-20 —	Reserved
19-17 REFPHASESTART	Reference Clock Delay Line Start Phase If the DLL does not lock well when DLLxCR[DLLEN] is enabled, update the register value of REFPHASESTART. 7h is recommended value. Note that DLLxCR[DLLRESET] is required to be triggered after REFPHASESTART is updated.

Table continues on the next page...

Table continued from the previous page...

Field	Description
16-15 REFPHASEGAP	Reference Clock Delay Line Phase Adjust Gap. REFPHASEGAP setting of 2h is recommended if DLLEN is set.
14-9 OVRDVAL	Target Clock Delay Line Override Value Configures the override value for the target clock line delay cell number. When OVRDEN = 1, the delay cell number in DLL is OVRDVAL + 1. See DLL configuration for sampling.
8 OVRDEN	Target Clock Delay Line Override Value Enable Enables the override value for the target clock line delay cell number. 0 - Disable 1 - Enable
7 —	Reserved
6-3 SLVDLYTARGET	Target Delay Line Configures the target delay line for the target. The delay target for target delay line is: ((SLVDLYTARGET+1) × 1/32 × clock cycle of reference clock (serial root clock). If serial root clock is ≥ 100 MHz, DLLEN is set to 1, OVRDEN is set to 0, then SLVDLYTARGET setting is up to flash parameters used.
2 —	Reserved
1 DLLRESET	DLL reset Forces a DLL reset. The forced reset causes the DLL to lose lock and recalibrate to detect a ref_clock half-period phase shift. The reset action is edge-triggered, so software must write 0 to this field after writing 1 to it (no delay limitation). 0 - No function 1 - Force DLL reset.
0 DLLEN	DLL Calibration Enable Enables DLL calibration. When DLL calibration is disabled, the delay cell number in the target delay line is always 1. When DLLxCR[OVRDEN] = 1, the target delay line is overridden and this field is ignored. 0 - Disable 1 - Enable

36.8.2.23 Status 0 (STS0)

Indicates the status of the internal state machine.

Offset

Register	Offset
STS0	E0h

Field	Description
31-12 —	Reserved
11-8 —	Reserved
7-4 DATALEARNPHASEA	Data Learning Phase Selection on Port A Indicates the sampling clock phase selection on Port A after data learning. There are 16 clock phases for the sampling clock that the delay cell line generates. When data learning is not enabled, the default clock phase 0 is used to sample flash read data. When data learning is enabled and a LEARN_SDR or LEARN_DDR instruction has executed correctly, FlexSPI determines the correct clock phase to sample read data. See Data learning.
3-2 ARBCMDSRC	ARB Command Source Indicates the trigger source of current command sequence that the arbitrator has granted. When ARB_CTL is not busy (STS0[ARBIDLE] = 1), the value of this field does not matter. 00 - Trigger source is AHB read command. 01 - Trigger source is AHB write command. 10 - Trigger source is IP command (by writing 1 to IPCMD[TRG]). 11 - Trigger source is a suspended command that has resumed.
1	ARB_CTL State Machine Idle

Table continues on the next page...

Table continued from the previous page...

Field	Description
ARBIDLE	Indicates whether the state machine in ARB_CTL is idle, or a command sequence that the arbitrator granted has not finished on the FlexSPI interface. When idle, no transaction is occurring on the FlexSPI interface (STS0[SEQIDLE] = 1). When waiting for the FlexSPI controller to become idle, poll this field instead of STS0[SEQIDLE]. 0 - Not idle 1 - Idle
0 SEQIDLE	SEQ_CTL State Machine Idle Indicates whether the state machine in SEQ_CTL is idle, or a command sequence is executing on the FlexSPI interface. 0 - Not idle 1 - Idle

36.8.2.24 Status 1 (STS1)

Indicates the error code of the AHB or IPS interface error response.

Offset

Register	Offset
STS1	E4h

7-2 ASLVSEL	Flash A Sample Clock Target Delay Line Delay Cell Number Indicates the sample clock target delay line delay cell number for Flash A. There are 0-63 phases. • 000001b - Indicates lock phase 0. • 100000b - Indicates lock phase 63.
1 AREFLOCK	Flash A Sample Clock Reference Delay Line Locked 0 - Not locked 1 - Locked
0 ASLVLOCK	Flash A Sample Target Delay Line Locked 0 - Not locked 1 - Locked

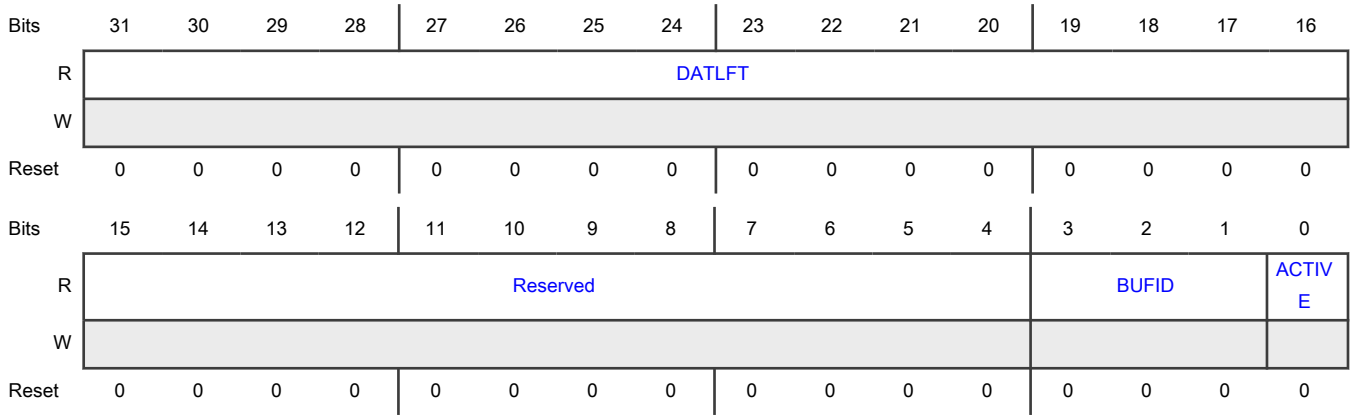
36.8.2.26 AHB Suspend Status (AHBSPNDSTS)

Indicates the status of suspended AHB read prefetch command sequence. When an IP or AHB command is triggered while the arbitrator processes an AHB read sequence (prefetching additional data not for current AHB burst), the prefetch sequence is suspended. When there are no longer transactions on FlexSPI, the prefetch sequence may be resumed. FlexSPI saves only one AHB prefetch sequence. When a new prefetch sequence is suspended with an active sequence already suspended, the previous suspended sequence is removed and never resumed. See Command abort and suspend.

Offset

Register	Offset
AHBSPNDSTS	ECh

Diagram



Fields

Field	Description
31-16 DATLFT	Data Left Contains the data size remaining (in bytes) for a suspended command sequence.
15-4 —	Reserved
3-1 BUFID	AHB Receive Buffer ID for Suspended Command Sequence
0 ACTIVE	Active AHB Read Prefetch Suspended Indicates whether an AHB read prefetch command sequence has been suspended. 0 - No suspended AHB read prefetch command. 1 - An AHB read prefetch command sequence has been suspended.

36.8.2.27 IP Receive FIFO Status (IPRXFSTS)

Indicates the status of IP receive FIFO.

Offset

Register	Offset
IPRXFSTS	F0h

Fields

Field	Description
31-0 RXDATA	Receive Data Contains receive data. See Reading data from IP receive FIFO.

36.8.2.30 IP TX FIFO Data a (TFDR0 - TFDR31)

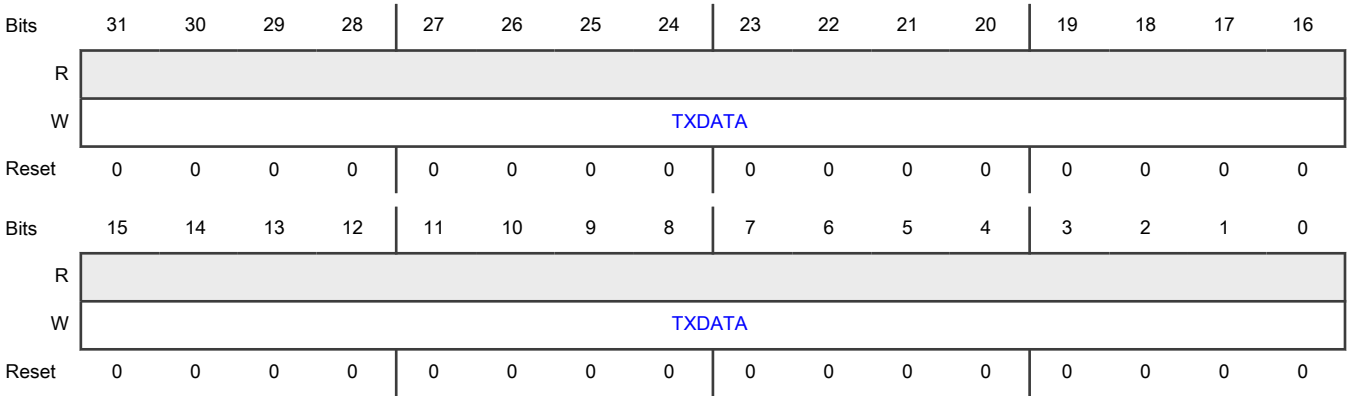
Provides write access to IP transmit FIFO via IPS bus.

Offset

For a = 0 to 31:

Register	Offset
TFDRa	180h + (a × 4h)

Diagram



Fields

Field	Description
31-0 TXDATA	Transmit Data Contains transmit data. See Writing data to IP transmit FIFO.

36.8.2.31 Lookup Table a (LUT0 - LUT127)

Contains a lookup table for command sequences. Software should set the sequence index before triggering an IP command or AHB command. FlexSPI fetches the command sequence from LUT when an IP or AHB command is triggered. There are 32 command sequences in LUT. See Lookup table (LUT) and Programmable sequence engine.

NOTE

LUT is implemented as memory, so the reset value is unknown.

Offset

11-0 —	Reserved

36.9 AHB memory map definition

This section describes FlexSPI module AHB memory map in detail.

36.9.1 AHB memory map for serial flash memory and RAM access

AHB read and write access for serial flash and RAM memory are mapped to a specific address range. See the system memory map for specific address ranges supported.

AHB bus features supported for serial flash and RAM memory reading:

- Cacheable and non-cacheable access
- Prefetch enable and disable
- Burst size: 8, 16, 32, 64 bits
- All burst types: types: SINGLE, INCR, WRAP4, INCR4, WRAP8, INCR8, WRAP16, INCR16

AHB bus features for Serial RAM writing:

- Bufferable and Non-Bufferable access
- Burst size: 8, 16, 32, 64 bits
- All burst types: SINGLE, INCR, WRAP4, INCR4, WRAP8, INCR8, WRAP16, INCR16

See Flash memory access via AHB command for details about AHB access to serial flash memory and RAM.

36.9.2 AHB Memory Map for IP RX FIFO read access

See chip-specific section for the address range mapped for AHB read access.

AHB Bus feature supported for IP RX FIFO reading:

- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer Reading data from IP receive FIFO for more details about IP RX FIFO reading.

36.9.3 AHB Memory Map for IP TX FIFO write access

See chip-specific section for the address range mapped for AHB write access.

AHB Bus feature supported for IP TX FIFO writing:

- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer Writing data to IP transmit FIFO for more details about IP TX FIFO filling.

Chapter 37
FlexSPI Address Remap (AHB_ADDR_REMAP)

37.1 Overview

This module performs a simple address remapping or translation function for system AHB accesses targeted for external SPI memories for Cortex-M33 and EdgeLock secure enclave (ELE). This functionality is provided to simplify the software (SW) creation and build process for systems that support "over the air" (OTA) code updates.

37.2 Functional description

37.2.1 Partition and Connectivity

The AHB_ADDR_REMAP module is located as a system crossbar switch slave module and upstream of the TRDC memory region checker which in turn is upstream from the actual FlexSPI external memory controller. So, the memory access bus connections are:

```
CPU -> Crossbar Slave -> AHB_ADDR_REMAP -> *RDC MRCn -> FlexSPI
```

The AHB_ADDR_REMAP module supports a Control register including the address remap constant. The AHB_ADDR_REMAP slave peripheral space is shared with the FlexSPI's programming model with the remap module controlling and managing the shared IPS address space and bus transactions.

The offset addresses {0x000-0x7FF, 0xC00-0xFFF} are mapped to the FlexSPI while addresses 0x800 - 0xBFF are allocated to the AHB_ADDR_REMAP module.

37.3 Application Information

In the following use case, application code is stored in an external SPI memory. The code typically assumes it is based at address zero so the SW linked memory image reflects this assumption in the resulting binary object file loaded into the memory. For devices that support OTA updates, a significant complication occurs when a new code image is downloaded to the device. Typically, the new code image will be linked into a formerly-unused external memory address space (as the original image is also needed for rollback considerations) and the complication occurs for the application code and how it references the new memory image - the application code must be rewritten as the original "based at address zero" assumption is no longer valid.

The preferred solution with the "based at address zero" assumption can be retained if all addresses are remapped/translated to the new memory image by adding a fixed constant to all access addresses.

Consider the following memory layout example. In the i.MX93, there is a FlexSPI0 external memory controller with the address space mapped to a base address of 0x1400_0000. This is "address zero" for the software application code. At reset, the address remap function is disabled so the addresses generated by the CPU are used directly. Further, assume that the second application code image is mapped to FlexSPI0 address offset of 68 KB, that is, the second "base address" is defined as FlexSPI0 base address + 68KB, 0x1400_0000 + 0x0001_1000 (68K) = 0x1401_1000. When this code image is active, the translated address constant is defined as 0x0001_1000 so the entire code image is remapped by this constant. The result is the application code retains the "based at address zero" concept but the physical addresses sent to the FlexSPI0 control are remapped to the correct physical address:

```
CPU "Virtual" + Remap Address = FlexSPI0 "Physical" // Application SW View
 0x1400_0000     0x0001_1000        0x1401_1000     // offset = 0x0000_0000
 0x1400_1000     0x0001_1000        0x1401_2000     // offset = 0x0000_1000
      ...
 0x1401_0000     0x0001_1000        0x1402_1000     // offset = 0x0001_0000
```

```
      ...
0x1401_0FFF     0x0001_1000        0x1402_1FFF     // offset = 0x0001_0FFF
```

37.4 Memory map and register definition

The AHB_ADDR_REMAP module supports a Control register that contains the remap address constant and control bits. The register can only be accessed by Secure Privileged mode accesses on the IPS slave peripheral bus. Attempted accesses in any other mode are error terminated.

37.4.1 AHB_ADDR_REMAP register descriptions

37.4.1.1 AHB_ADDR_REMAP memory map

AHBRM1 base address: 5E_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
800	Control (CR)	32	RW	0000_0000

37.4.1.2 Control (CR)

Reads of CR depend on the write values; writes of CR update the implemented fields.

NOTE

The CR can only be written while the AHB master bus inputs - Cortex-M33, EdgeLock secure enclave (ELE) are quiescent. Stated differently, writes to the CR register while AHB master bus is processing bus transactions could lead to incoherent and incorrect processing. It is expected the CR register is written once during system startup and remains static until the next reset.

Offset

Register	Offset
CR	800h

Diagram

Fields

Field	Description
31-28 —	Reserved
27-7 RADDR	Remap address It is added to the AHB system virtual address to form the physical address for the external FlexSPI memory. The address remap function is defined in terms of the VADDR (virtual address) and PADDR (physical address): PADDR[31:0] = {VADDR[31:28], (VADDR[27:7] + RADDR[27:7]), VADDR[6:0]} **NOTE** The AMBA-AHB bus specification defines that incrementing burst transfers cannot cross any 1 KB address boundary. Accordingly, the RADDR field must be set to a 0-modulo-1KB (or greater) value so the remap logic does not introduce any illegal boundary crossings.
6-4 —	Reserved
3 LK	Sticky lock bit Once set, it disables any subsequent writes to the CR register until the next reset .
2 —	Reserved
1 —	Reserved
0 ENB	Enable Remap 0 - The module is disabled and all input AHB addresses and attributes are simply routed to the output AHB address and attributes buses. 1 - All AHB addresses from the Cortex-M33 and ELE are remapped using the constant offset defined by the CR[RADDR] field. AHB accesses from other bus masters are simply passed through the module as if it was disabled.

Chapter 38
Ultra Secured Digital Host Controller (uSDHC)

38.1 Chip-specific USDHC information

Table 225. Reference links to related information

Topic	Related module	Reference
Full description	Arm Cortex CM33 Platform (CM33)	CM33 Platform
Full description	Arm Cortex CA55 Platform (CA55)	CA55 Platform
System memory map		System memory map
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing

The chip includes three instances of USDHC that provide simultaneous support for all three of 1x eMMC, 1x SD Card and 1x SDIO (for WIFI connectivity).

NOTE

Write/Read to the Reserved locations will not generate a transfer error.

NOTE

i.MX93 supports mechanical reset to reset eMMC, if uSDHC1 external signal RESET_B is used to reset the eMMC, only 1-bit/4-bit data transfer can be used.

38.2 Overview

uSDHC provides the interface between the host system and the eMMC, SD card, and SDIO as shown in Figure 126. The module acts as a bridge, passing host bus transactions to the eMMC, SD card, and SDIO by sending commands and performing data accesses to/from the cards. It handles the SD card/SDIO/eMMC protocols at the transmission level.

38.2.1 Block diagram

The following figure illustrates the block diagram for uSDHC. Dual port SRAM is FIFO for write/read. For more information, see Data buffer.

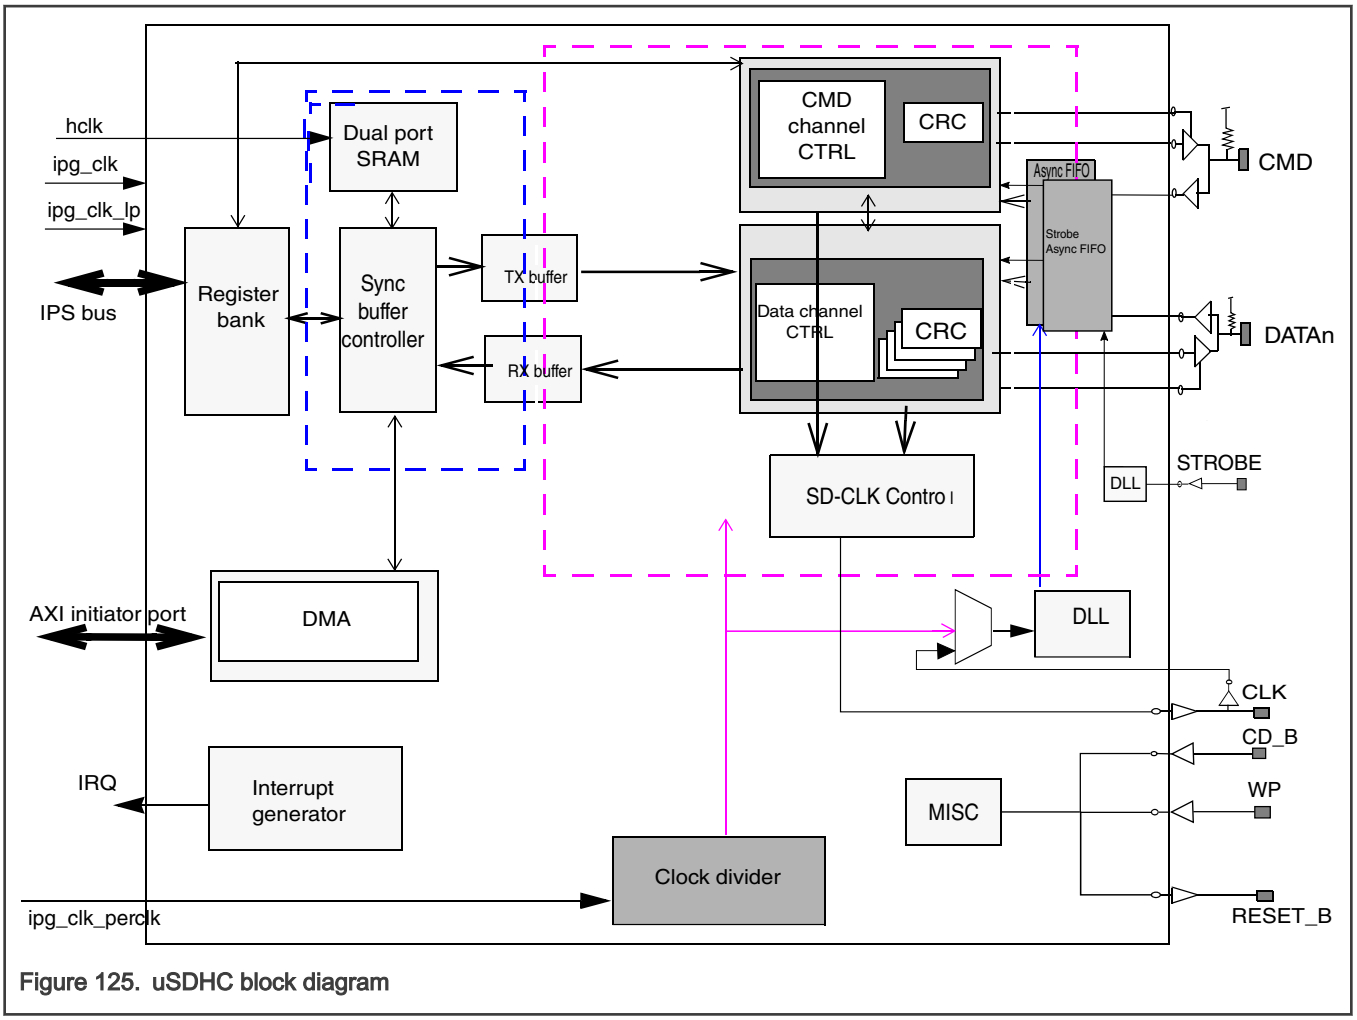

Figure 125. uSDHC block diagram

The figure below shows the System connection of uSDHC:

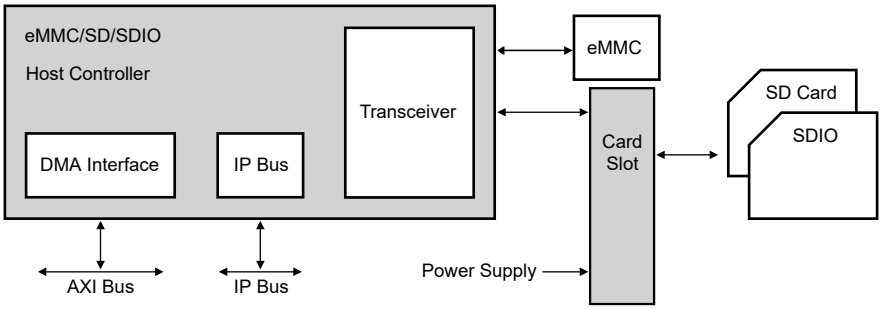

Figure 126. System connection of uSDHC

The following are brief descriptions of the cards supported by uSDHC:

- The Embedded MultiMediaCard (eMMC) is a universal low-cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous eMMC were based on a 7-pin serial bus with a single data pin, while the new high speed eMMC communication is based on an advanced 11-pin serial bus designed to operate in the low-voltage range.
- The Secure Digital Card (SD) is an evolution of the old eMMC technology. It is specifically designed to meet the security, capacity, performance, and environmental requirements inherent in newly emerging audio and video consumer electronic

devices. The physical form factor, pin assignment, and data transfer protocol are backward compatible with the old eMMC (with some additions).

- Under the SD protocol, system connection can be categorized into memory card, I/O card, and combo card, which have both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI (Secure Digital Music Initiative) standard. The I/O card, which is also known as SDIO, provides high-speed data I/O with low-power consumption for mobile electronic devices.

38.2.2 Features

The list given below shows the features of the uSDHC module:

- Conforms to the SD Host Controller Standard Specification version 2.0/3.0
- Compatible with the eMMC System Specification version 4.2/4.3/4.4/4.41/4.5/5.0/5.1
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Specification version 2.0/3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, eMMC, MMC plus, and MMC RS cards
- For card bus clock frequency: See the product Data Sheet for the clock frequency of each supported mode.
- Supports 1-bit/4-bit SD and SDIO modes, and 1-bit/4-bit/8-bit eMMC modes
  - Up to 400 Mbps of data transfer for SDIO using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDIO using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 400 Mbps of data transfer for SDXC cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDXC card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 1600 Mbps of data transfer for eMMC using eight parallel data lines in the Single Data Rate (SDR) mode
  - Up to 3200 Mbps of data transfer for eMMC using eight parallel data lines in the Dual Data Rate (DDR) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer for memory device
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes; also supports interrupt period
- Supports internal DMA capabilities
- Supports voltage selection by configuring vendor-specific register bit VEND_SPEC[VSELECT]
- Supports Advanced DMA to perform linked memory access
- Supports Command Queue mechanism

NOTE

This block can support all the above-listed speed mode and maximum data throughput. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

38.3 Functional description

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA AXI interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock and reset manager, and clock generator.

38.3.1 Modes and operations

38.3.1.1 Data transfer modes

The uSDHC module can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- eMMC 1-bit
- eMMC 4-bit
- eMMC 8-bit
- Identification mode (up to 400 kHz)
- eMMC full-speed mode (up to 26 MHz)
- eMMC high-speed mode (up to 52 MHz)
- eMMC HS200 mode (up to 200 MHz)
- eMMC HS400 mode (200 MHz both edges)
- eMMC DDR mode (52 MHz both edges)
- SD card or SDIO full-speed mode (up to 25 MHz)
- SD card or SDIO high-speed mode (up to 50 MHz)
- SD card or SDIO UHS-I mode (up to 208 or 100 MHz in SDR mode, up to 50 MHz in the DDR mode)

NOTE

This block can support all the above listed speed mode and maximum clock frequency. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

38.3.2 Data buffer

The uSDHC module uses one configurable data buffer to transfer data between the system bus (IP bus or advanced extensible interface (AXI) bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the AXI initiator clock). The buffer is used as a temporary storage for transferring data between the host system and the card. The watermark levels for read and write are both configurable and can range between 1 to 128 words. When using internal DMA mode, The watermark level for read should be configured to 16 and watermark level for write should be configured to integral multiple of 16 to get max AXI bus throughput. The next figure provides the uSDHC buffer scheme as buffer control and buffer RAM wrapper.

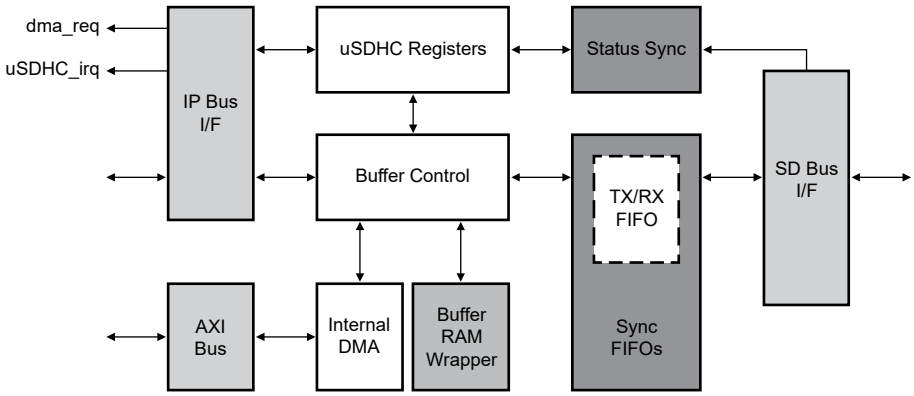

Figure 127. uSDHC buffer scheme

Here are 2 transfer modes to access the data buffer:

- CPU polling mode:
  - For a host-read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, by polling the BRR bit, the host driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar. For more information on the process of writing operation, see Write operation sequence.
- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AXI bus.

For a read operation, when there are more words in the buffer than the amount set in WTMK_LVL[RD_WML], the internal DMA starts fetching data over the AXI bus.

The Write operation functions in a similar manner—sequential and contiguous access is necessary to ensure that the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, the byte order is swapped after the data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, the byte order is swapped before the data is stored in the buffer.

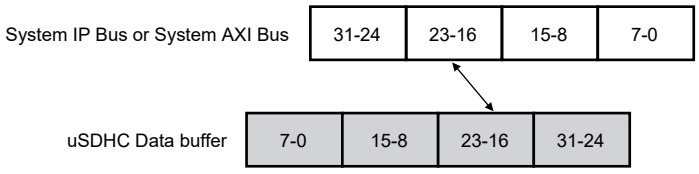

Figure 128. Data swap between system bus and uSDHC data buffer in the byte little endian mode

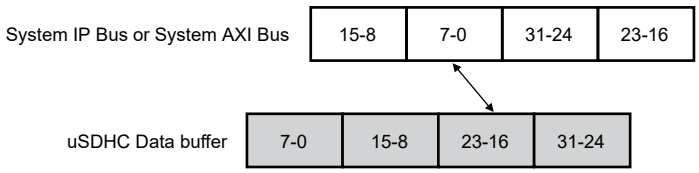

Figure 129. Data swap between system bus and uSDHC data buffer in half word big endian mode

38.3.2.1 Write operation sequence

There are 2 ways to write data into the buffer when the user transfers data to the card:

- Processor core polling through the BWR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, the DMAEN bit in the Transfer Type register is not set when the command is sent, uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in WTMK_LVL[WR_WML] and is ready for receiving new data. At the same time, uSDHC sets the BWR bit. The buffer write ready interrupt is generated if it is enabled by software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC stops the data transfer and abandons the current block. The host driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the write operation from that address. It is recommended that a software reset for Data be applied before the transfer is restarted.

The uSDHC module does not start data transmission until the buffer has been filled with the number of words set in the WR_WML register. If the buffer is empty and the host system does not write data in time, uSDHC stops the CLK to avoid the data buffer underrun situation.

38.3.2.2 Read operation sequence

There are 2 ways to read data from the buffer when the data is received from the card:

- Processor core polling through the BRR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, which is available and ready for system fetching data. At the same time, uSDHC sets the BRR bit. The buffer read ready interrupt is generated if it is enabled by the software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC stops the data transfer and abandons the current block. The host driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the read operation from that address. It is recommended that a software reset (in register RSTD) for data be applied before the transfer is restarted.

For any read transfer mode, uSDHC does not start data transmission until the number of words set in the RD_WML register are in buffer. If the buffer is full and the host system does not read data in time, uSDHC stops the CLK to avoid the data buffer overrun situation.

38.3.2.3 Data buffer and block size

In the uSDHC module, the data buffer can hold up to 256 words (32-bit) and the watermark levels for write and read can be configured accordingly. The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. The host driver may configure the value according to the system and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes). That means, the largest block size is 512 bytes.

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned), stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the software side must write twice for each block. For each block, the ending byte is abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

38.3.2.4 Dividing large data transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in multiples of block size. If the total data length cannot be divided evenly into a multiple of the block size, then there are two options to transfer the data. These two options depend on the function and the card design. Option 1 is for the host driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add placeholder data in the last block to fill the block size. For option 2, the card must manage the removal of the placeholder data. Only for write, uSDHC sends data to the card.

See Figure 130 for an example showing the division of large data transfers, assuming a kind of WLAN SDIO that only supports a block size of up to 64 bytes. Although uSDHC supports a block size of up to 4096 bytes, SDIO can only accept a block size of less than 64 bytes, so the data must be divided (see the example below).

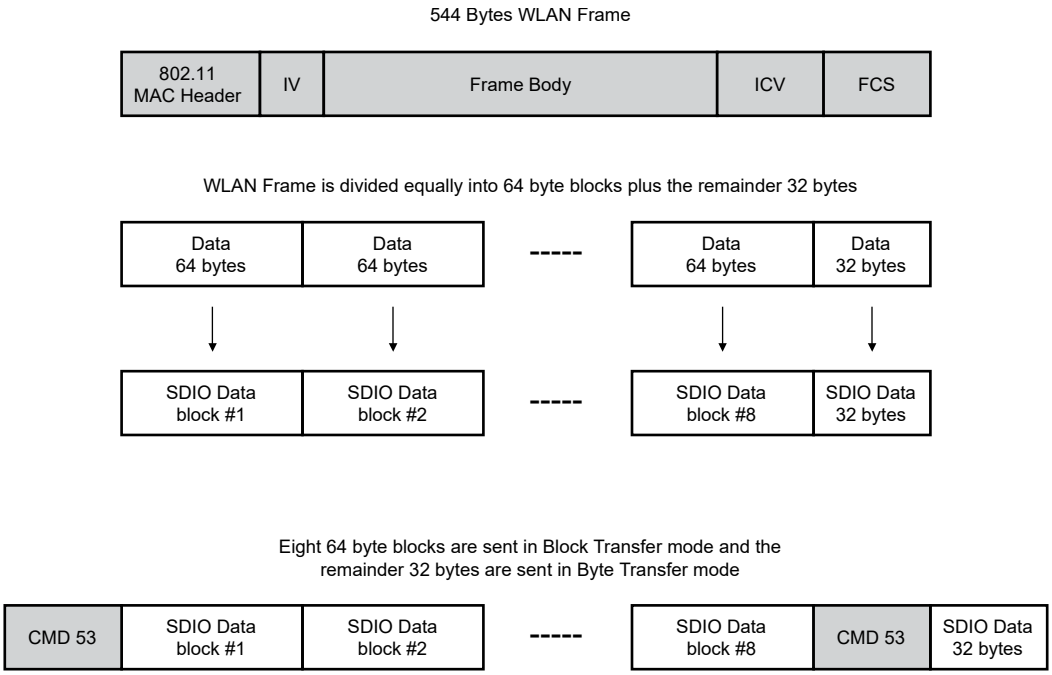

Figure 130. Example for dividing large data transfers

38.3.3 DMA AXI interface

The internal DMA implements a DMA engine and the AXI initiator. When the internal DMA is enabled, but the BWR and BRR bits are set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register. See Figure 131 for an illustration of the DMA AXI interface block.

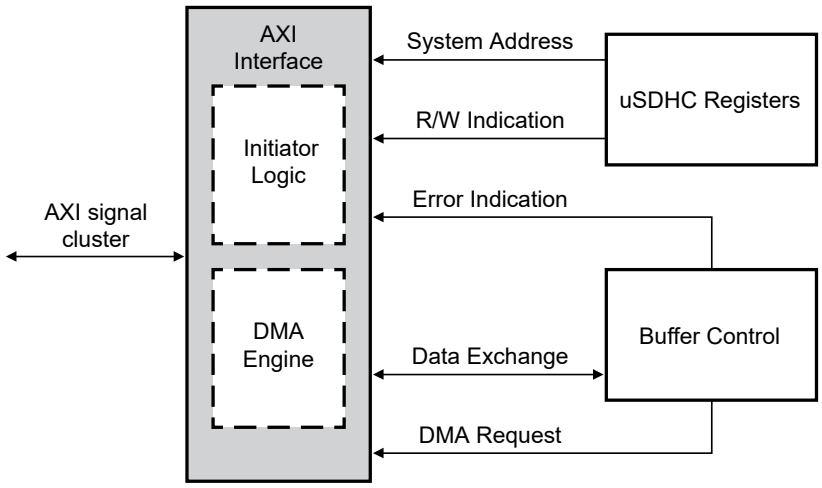

Figure 131. DMA AXI interface block

38.3.3.1 Internal DMA request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the data buffer block sends a DMA request to AXI interface.

The delay in response from the internal DMA engine depends on the system AXI bus loading and the priority assigned to uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The data buffer de-asserts the request if the data buffer space (for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of the current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always automatically set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the watermark level set to six words (24 bytes). After the first burst transfer, if there are greater than or equal to two words in the buffer, which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to transfer for the current block is ceiling((31 - 6 * 4) / 4) = 2. The uSDHC module reads two words out of the buffer, with seven valid bytes and one stuffed byte.

38.3.3.2 AXI initiator interface

It is possible that the internal AXI DMA engine could fail during the data transfer. Upon detection of an AXI bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register is generated to host CPU to report a bus error condition.

After the DMAE interrupt is received, the software sends a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and restart the transfer from this address to recover the corrupted block.

38.3.3.3 ADMA engine

In the SD host controller standard, a new DMA transfer algorithm called the Advanced DMA (ADMA) is defined. For simple DMA, after the page boundary is reached, a DMA interrupt is generated and the new system address is programmed by the host driver. The ADMA defines the programmable descriptor table in the system memory. The host driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized because the host MCU intervention is not be needed during long DMA-based data transfers.

There are two types of ADMA in host controller: ADMA1 and ADMA2. ADMA1 can support data transfer of 4KB aligned data in system memory, and ADMA2 eliminates the restriction so that the data of any location (word aligned) and any size (less than 64 KB) can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors defined in SD host controller Standard, and if the "End" flag is detected in the descriptor, ADMA stops after this descriptor is processed.

38.3.3.3.1 ADMA concept and descriptor format

ADMA1 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Set data length descriptor
- Set data address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA2 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Rsv descriptor (new in ADMA2)
- Set data length and address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA starts read/write operation after it reaches the tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last set type descriptor before the tran type descriptor. Every tran type descriptor triggers a transfer, and the transfer data length is extracted from the most recent set type descriptor. If there is no set type descriptor after the previous Trans descriptor, the data length is the value for previous transfer, or 0 if no set descriptor is ever met.

For ADMA2, the tran type descriptor contains both data length and transfer data address, so the tran type descriptor itself can start a data transfer.

See Figure 132 for the format of the descriptor table for ADMA1.

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 132. Format of the ADMA1 descriptor table

See Figure 133 for the concept and access method of the descriptor table for ADMA1.

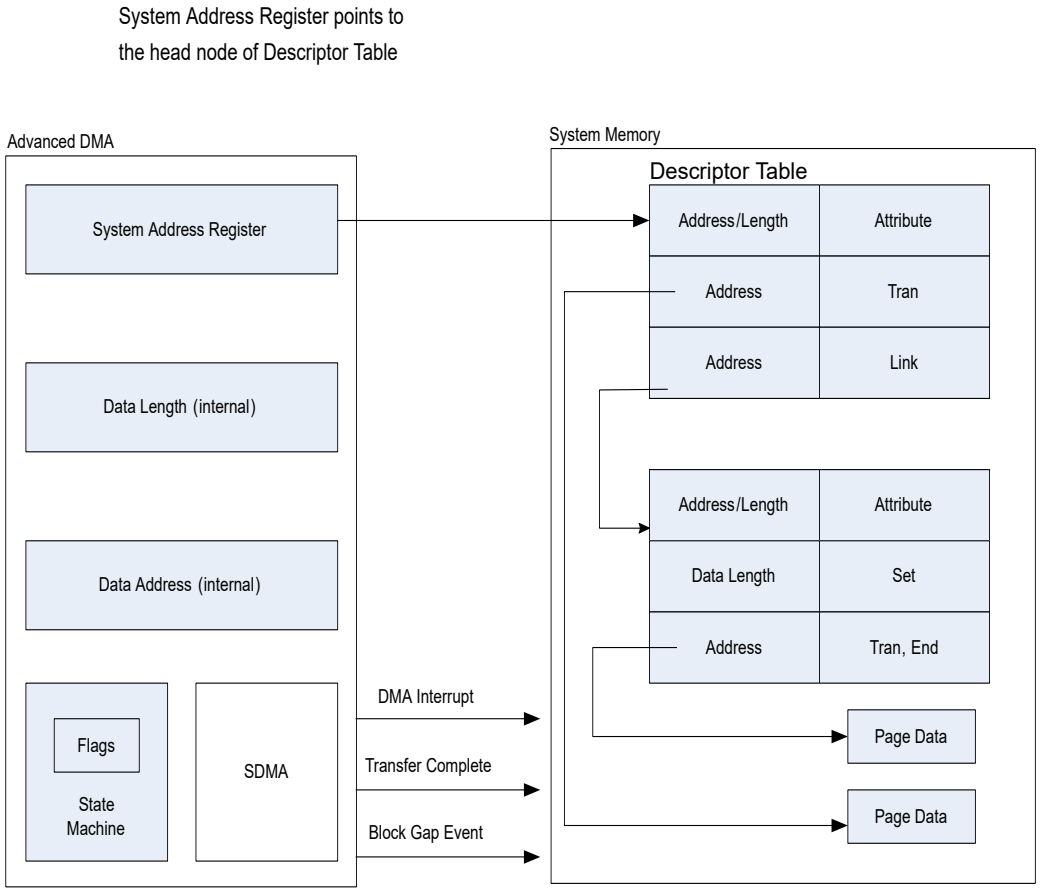

Figure 133. Concept and access method of the ADMA1 descriptor table

The figure below explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it ignores the higher 32-bit. The Address field should be set to word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 134. Format of the ADMA2 descriptor table

See Figure 135 for the concept and access method of the descriptor table for ADMA2.

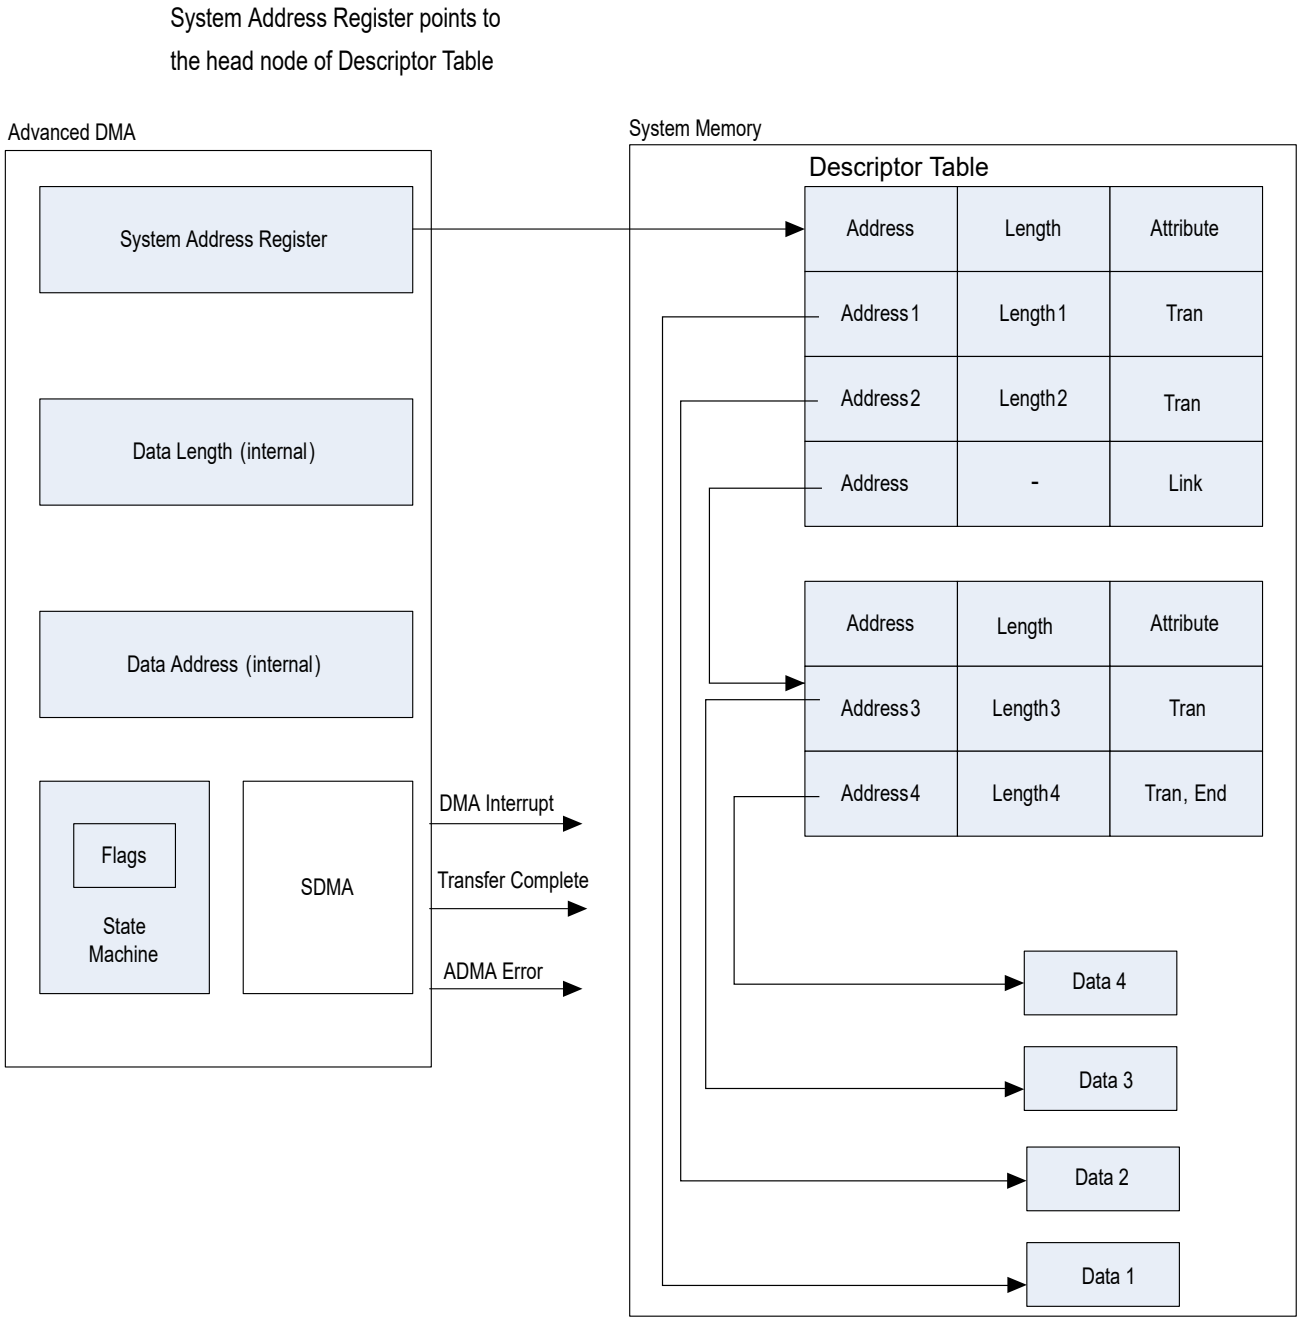

Figure 135. Concept and access method of the ADMA2 descriptor table

38.3.3.3.2 ADMA interrupt

If the interrupt flag descriptor is set, ADMA generates an interrupt according to various types of descriptors.

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer descriptor is complete, which means the data communication between the host system and uSDHC is finished.
- Link type of descriptor: interrupt is generated when new descriptor address is set.

- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer descriptor is complete, which means the data communication between the host system and uSDHC is finished.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

38.3.3.3.3 ADMA error

The ADMA stops whenever an error is encountered. These errors include:

- Fetching descriptor error
- AXI response error
- Data length mismatch error

An ADMA descriptor error is generated when it fails to detect a "valid" flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the "Interrupt" flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in register BLK_ATT must be equal to the whole data length set in descriptor, otherwise data length mismatch error is generated.

When BLKCNTEN bit is not set, then the whole data length set in descriptor is a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors occur.

38.3.4 Register bank with IP bus interface

Register accesses through the IP bus interface are on the register bank. See Figure 136 for the block diagram.

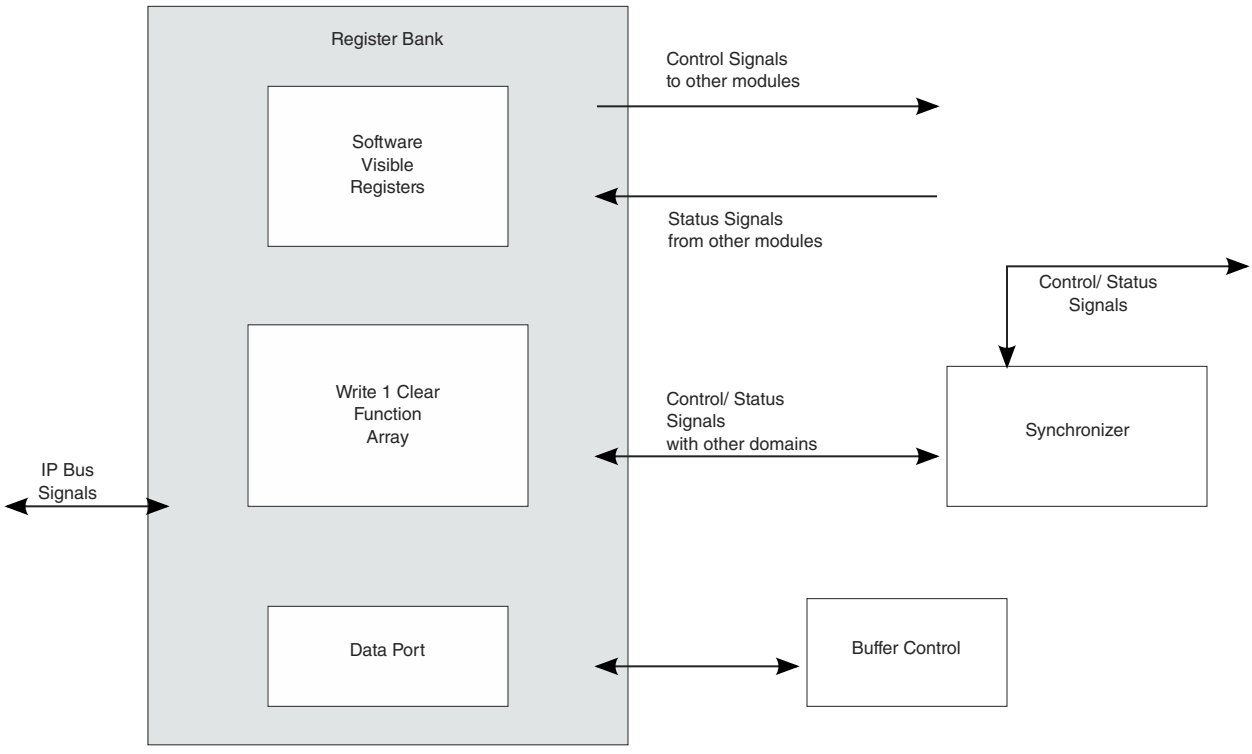

Figure 136. Register bank diagram

Only a 32-bit access is allowed, and no partial read/write is supported; therefore, all accesses are word aligned.

Access to an unimplemented address within the register memory map space does not generate a transfer error.

38.3.4.1 SD protocol unit

The SD protocol unit deals with all SD protocol affairs.

The SD protocol unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from SDIO
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD protocol unit consists of four sub-modules:

- SD control misc
- Command control
- Data control
- Clock control

38.3.4.2 SD control miscellaneous

In the SD control miscellaneous unit:

- The card detection (including CD_B and DATA3 for card detection) and card interrupt are implemented.
- The module monitors the signal level on all the eight data lines and the command lines. It directly routes the level values into the register bank.
- The module also detects the Write Protect (WP) line. If WP is activated as '1', writes to memory and combo cards are ignored by cards. In that case, there is no need to send write command anymore.

38.3.4.3 SD clock control

If the internal data buffer is near full (for read) or near empty (for write), the SD clock must be gated off to avoid buffer over/under-run. This module asserts the gate of the output SD clock to shut the clock off. After the buffer has space (for read) or has data (for write), the clock gate of this module opens, and the SD clock is active again.

38.3.4.4 Command control

The Command Control module deals with the transactions on the CMD line.

See Figure 137 for an illustration of the structure for the Command CRC shift register.

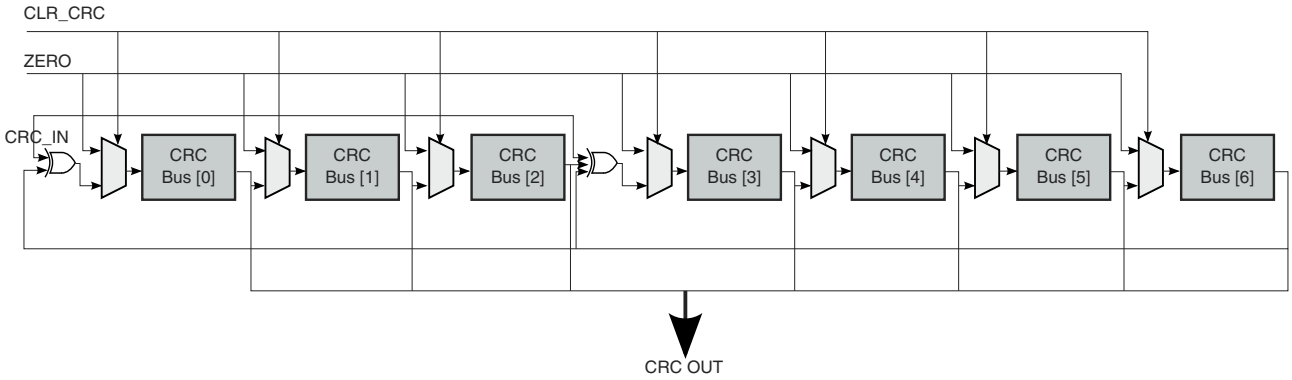

Figure 137. Command CRC shift register

The CRC polynomials for the CMD are as follows:

```
Generator polynomial: G(x) = x^7 + x^3 + 1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[6:0] = Remainder [(M(x) * x^7) / G(x)]
```

38.3.4.5 Data control

The data agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line and generates the read wait state by the request from the transceiver.

The CRC polynomials for the data are as follows:

```
Generator polynomial: G(x) = x^16 + x^12 + x^5 +1

M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0

CRC[15:0] = Remainder [(M(x) * x^16) / G(x)]
```

38.3.5 Card insertion and removal detection

The uSDHC module uses either the DATA3 pin or the CD_B pin to detect card insertion or removal. It is controlled by SoC pad or other logic. When there is no card on the eMMC/SD bus, the DATA3 is pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD_B pin is always a reference for card detection. Whether the DATA3 pin or the CD_B pin is used to detect card insertion, uSDHC sends an interrupt (if enabled) to inform the Host system that a card is inserted.

38.3.6 Power management and wakeup events

When there is no operation between uSDHC and the card through the SD bus, the user can completely disable the peripheral clock and base clock in the chip-level clock control module to save power. When the user needs to use uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to uSDHC are disabled, for instance, when the system is in low-power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC module can generate these interrupts even when there are no clocks enabled. The three interrupts that can be used as wakeup events are these:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from SDIO (not available in multiple block data transfers)

These three wakeup events (or wakeup interrupts) can also be used to wakeup the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to uSDHC are disabled or when the entire system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (PROT_CTRL) for more information on the uSDHC Protocol Control register.

38.3.6.1 Setting wakeup events

For uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters the sleep mode. Before the software disables the host clock, it should ensure that all the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- Internal data buffer is empty

38.3.7 eMMC fast boot

The Embedded MultiMediaCard (eMMC4.3 or later) specification adds a fast boot feature that requires hardware support. There are two types of fast boot modes in the eMMC4.3 or later specification: boot operation and alternative boot operation. Each type also has with-acknowledge and without-acknowledge modes.

In the boot operation mode, the uSDHC controller (eMultiMediaCard host) can read boot data from the target (eMMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for target), before issuing CMD1.

NOTE

For the eMMC4.3 setting, please see the eMMC4.3 specification.

38.3.7.1 Boot operation

If the CMD line is held low for 74 clock cycles and more after power-up before the first command is issued, the target recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after the CMD line goes low, the target starts to send the first boot data to the uSDHC controller on the DATA line(s). The uSDHC controller must keep the CMD line low to read all of the boot data.

NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If boot acknowledge is enabled, the target has to send acknowledge pattern '010' to the uSDHC controller within 50ms after the CMD line goes low. If boot acknowledge is disabled, the target does not send out acknowledge pattern '010'.

The uSDHC controller can terminate the boot mode with the CMD line high.

The boot operation is terminated when all the contents of the enabled boot data are sent to the uSDHC controller. After the boot operation is executed, the target gets ready for the CMD1 operation and the uSDHC controller needs to start a normal eMMC initialization sequence by sending CMD1.

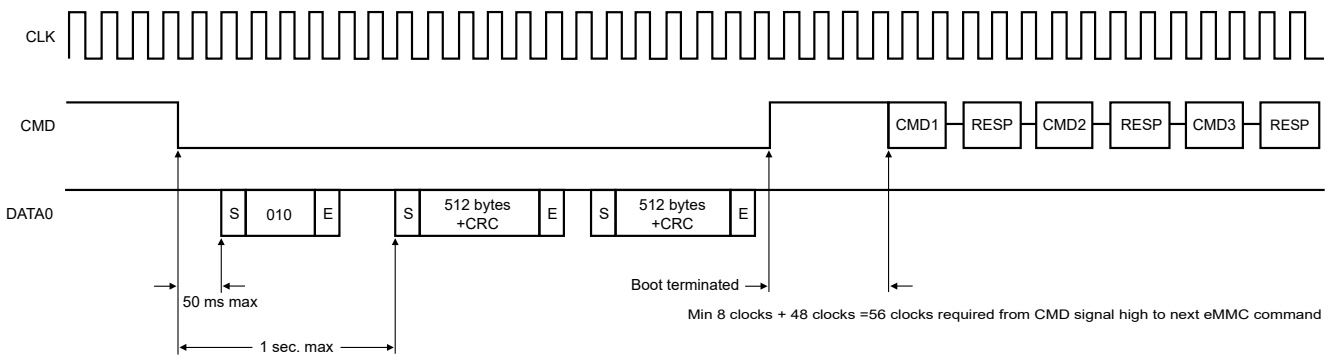

Figure 138. Embedded MultiMediaCard state diagram (normal boot mode)

38.3.7.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the target recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after CMD0 with the argument of 0xFFFFFFFA is issued, the target starts to send the first boot data to the uSDHC controller on the DATA line(s).

If boot acknowledge is enabled, the target must send the acknowledge pattern '010' to the uSDHC controller within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, the target does not send out acknowledge pattern '010'.

The uSDHC controller can terminate the boot mode by issuing CMD0 (Reset).

Boot operation is terminated when all the contents of the enabled boot data are sent to the uSDHC controller. After the boot operation is executed, the target gets ready for the CMD1 operation and the uSDHC controller needs to start a normal eMMC initialization sequence by sending CMD1.

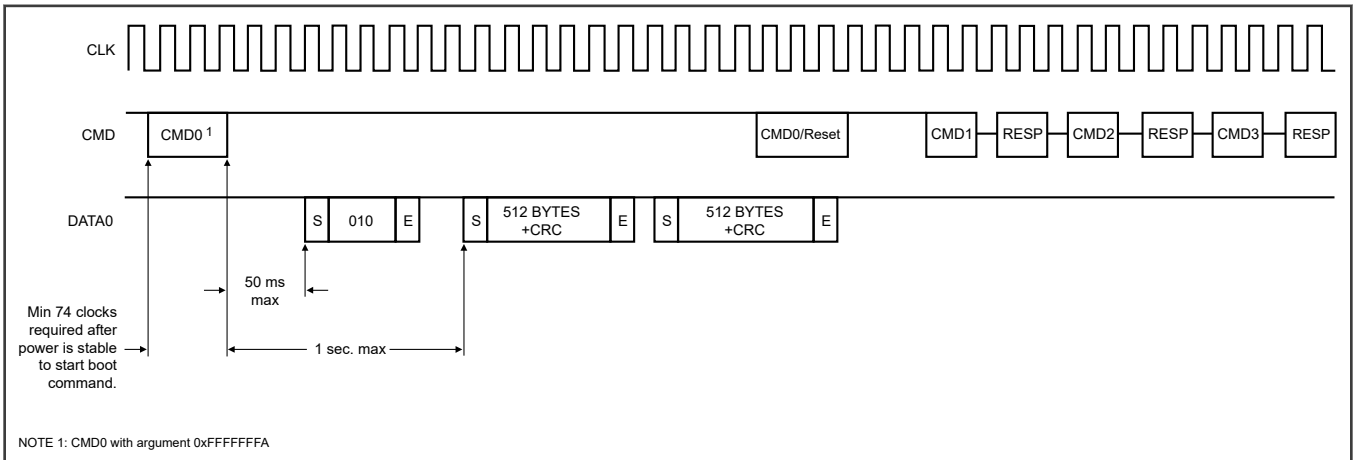

Figure 139. Embedded MultiMediaCard state diagram (alternative boot mode)

38.3.8 Commands for SD card, SDIO, and eMMC

A table containing the list of commands for the eMMC/SD card/SDIO is provided here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the SD card, SDIO, and eMMC:

- Broadcast commands (bc), no response
- Broadcast commands with response (bcr), response from all cards simultaneously
- Addressed (point-to-point) commands (ac), no data transfer on the DATA
- Addressed (point-to-point) data transfer commands (adtc)

Response: A response is a token that is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

Table 227. Commands for eMMC/SD card/SDIO

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all eMMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all eMMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:16] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:16] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO in idle state to send them operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.

Table continues on the next page...

Table 227. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The Embedded MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:16] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:16] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:16] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission. Only supported by memory device.
CMD13	ac	[31:16] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:16] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.

Table continues on the next page...

Table 227. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	adtc	[31:0] reserved bits(all 0)	R1	SEND_TUNING_BLOCK	64 bytes tuning pattern is sent for SDR50 and SDR104.
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21	adtc	[31:0] stuff bits	R1	SEND_TUNING_BLOCK	128 clocks of tuning pattern (64 byte in 4 bit mode or 128 byte in 8 bit mode) is sent for HS200 optimal sampling point detection.
CMD22	Reserved				
CMD23	ac	[31] reliable write request [30:16] set to 0 [15:0] number of blocks	R1	SET_BLOCK_COUNT	Defines the number of blocks (read/write) and the reliable writer parameter (write) for a block read or write command.
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command is issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.

Table continues on the next page...

Table 227. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.

Table continues on the next page...

Table 227. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD39	ac	[31:16] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the eMMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather than a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				

Table continues on the next page...

Table 227. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 is used to read and write these registers. MMC command defined by CE-ATA Digital Protocol.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer. MMC command defined by CE-ATA Digital Protocol.
CMD62-63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block).
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card.

Table continues on the next page...

Table 227. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for eMMC and SD cards. For eMMC, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed eMMC and high-speed SD cards. Command SWITCH_FUNC is for high-speed SD cards.
3. Command SWITCH is for high speed eMMC. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 228.
4. ACMDs is preceded with the APP_CMD command. Commands listed are used for SD only, other SD commands not listed are not supported on this module.

The access bits for the EXT_CSD access modes are listed in the following table.

Table 228. EXT_CSD access modes

Bits	Access name	Operation
00	Command set	The command set is changed according to the Cmd Set field of the argument.
01	Set bits	The bits in the pointed byte are set, according to the bits set to 1 in the Value field.
10	Clear bits	The bits in the pointed byte are cleared, according to the bits set to 1 in the Value field.
11	Write byte	The Value field is written into the pointed byte.

38.3.9 SDIO interrupt

Information on interrupts in 1-bit mode, interrupts in 4-bit mode, and card interrupt handling are detailed in the sections below.

38.3.9.1 Interrupts in 1-bit mode

In this case, the DATA1 pin provides the interrupt function. An interrupt is asserted by pulling the DATA1 low from SDIO, until the interrupt service is finished to clear the interrupt.

38.3.9.2 Interrupt in 4-bit mode

As the interrupt and data line 1 share pin 8 in a 4-bit mode, an interrupt is only sent by the card and recognized by the host during a specific time. This is known as the interrupt period. The uSDHC module only provides samples the level on pin 8 during the interrupt period. At all other times, the host treats it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in a 4-bit mode, there is only a limited period of time that the interrupt period can be active because of the limited period of data line availability between the multiple blocks of data. This requires stricter definition of the interrupt period. For this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line holds low for one clock cycle, then pulls high for the next clock cycle . On completion of the interrupt period, the card releases the DATA1 line into the high Z state. The uSDHC module provides sample of the DATA1 during the interrupt period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Specification v1.10 for further information about the SDIO interrupt.

38.3.9.3 Card interrupt handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, uSDHC clears the interrupt request to the host system. The host driver should clear this bit before servicing the SDIO interrupt, and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from SDIO does not clear, this bit is set again. To clear this bit, it is required to reset the interrupt source from the external card followed by writing 1 to this bit. In a 1-bit mode, uSDHC detects the SDIO interrupt with or without the SD clock (to support wakeup). In a 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from SDIO and the interrupt to the Host System Interrupt Controller. When the SDIO status is set and the host driver needs to service this interrupt, the SDIO bit in the Interrupt Control Register of SDIO is cleared. This is required to clear the SDIO interrupt status latched in uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1 and uSDHC starts sampling the interrupt signal again.

See Figure 140 for an illustration of the SDIO interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

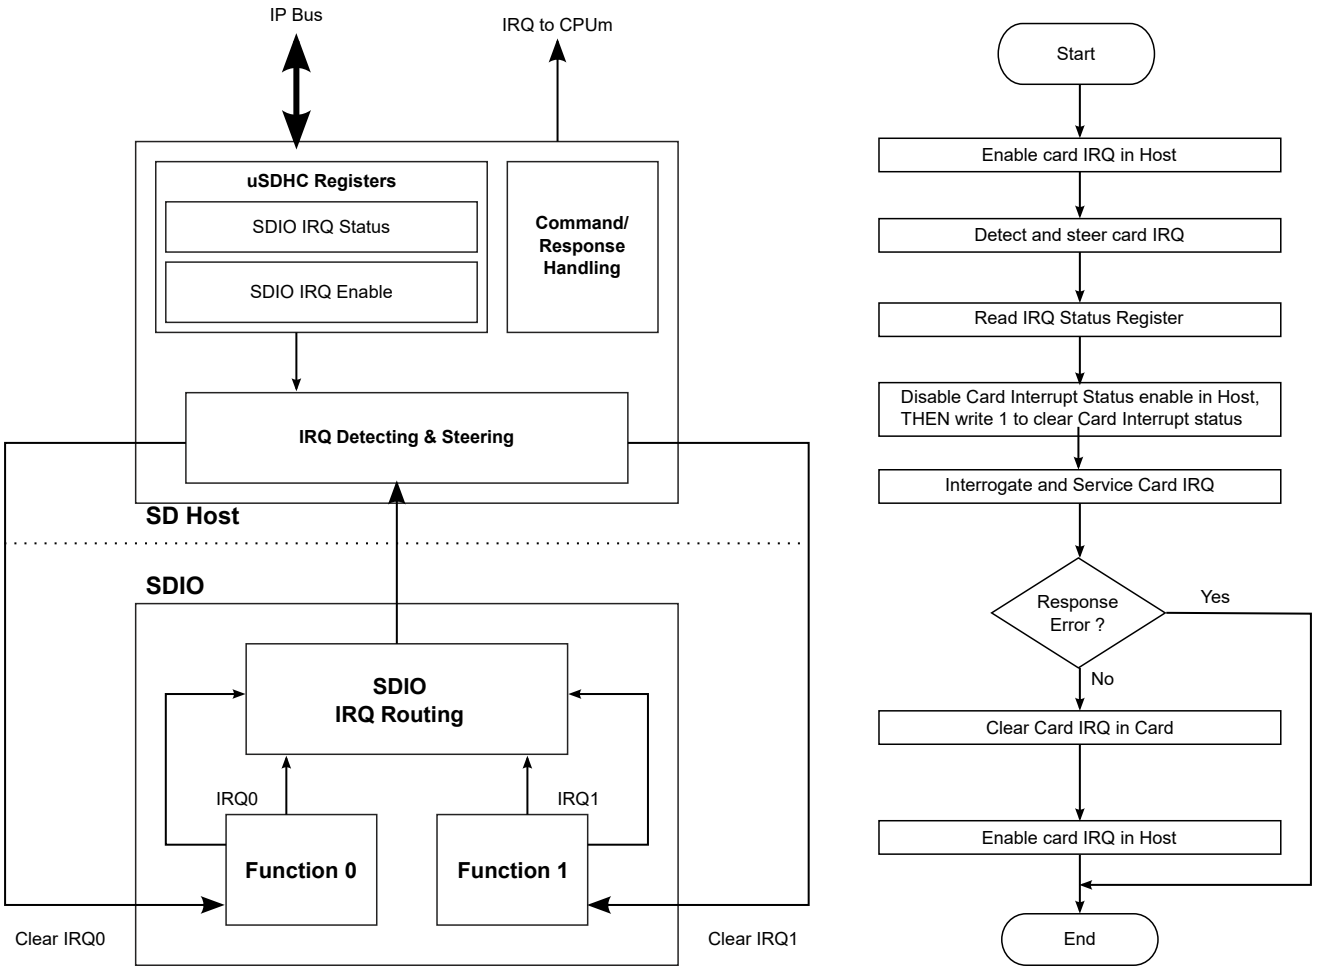

Figure 140. Card interrupt scheme, card interrupt detection, and handling procedure

38.3.10 Speed mode selection

To switch to HS200 or HS400 from High Speed (26 MHz-52 MHz), see the procedure below.

NOTE

While the actual timing change is done, the behavior of any command given (such as CMD13) cannot be guaranteed due to the asynchronous operation. Therefore, you must not use CMD13 to check the busy completion of the timing change indication. In case, CMD13 is used, the host must ignore CRC errors, if appear.

The max frequency for HS200 mode and HS400 mode could be slower than 200 MHz based on the chip implementation, you must set the target frequency for these two speed modes accordingly. Following sections describe the mode selections for HS200 mode and HS400 mode in detail.

38.3.10.1 HS200 mode selection

To switch to HS200, the Driver must perform the following steps:

1. Select the chip (through sending CMD7) and make sure it is unlocked (through CMD42).
2. Read the DEVICE_TYPE [196] field of the Extended CSD register to validate if the chip supports HS200 at the IO voltage appropriate for both host and chip (through CMD8).
3. Read the DRIVER_STRENGTH [197] field of the Extended CSD register to find the supported chip Driver Strengths (through CMD8). The default setting is 50 Ohm. The Host Designer might simulate its specific system, using a device driver models. Host can select the optimal Driver Type that might drive the host system load at the required operating frequency with the minimal noise generated.

   NOTE

   This step can be skipped if changes of Driver strength is not needed.

4. Check the setting of PROT_CTRL[DTW], make sure the data transfer width is set as expected.

   Make sure the I/O pad voltage is 1.8V and corresponding drive strength is set to proper value.

   Set HS200 bit and Driver Strength value in the HS_TIMING [185] field of the Extended CSD register by issuing CMD6. If the host attempts to write an invalid value, the HS_TIMING byte is not changed, the HS200 interface timing is not enabled, the Driver Strength is not changed, and the SWITCH_ERROR field is set. After the chip responds with R1, it might assert Busy signal. Once the busy signal gets de-asserted, the host may send a SEND_STATUS Command (CMD13) using the HS200 timing and after it receives a Trans State indication and No Error it means that the chip is set to HS200 timing and the Driver Strength is set to the selected settings.
5. At this point, the host can set the frequency to ≤ 200 MHz.
6. The host might invoke the HS200 standard tuning procedure, by sending CMD21 to the chip.

NOTE

The host must switch to the required bus width before starting the tuning operation to allow the tuning sequence to be done using the proper bus operating conditions.

38.3.10.2 Standard tuning procedure

By default, lower frequency operation, a fixed sampling clock is used to receive signals on CMD and DAT[3:0]. Before using the HS200, HS400, SDR104, or SDR50 modes, the Host Driver executes the tuning procedure at the mode switch sequence.

1. Issue uSDHC SW reset, set SYS_CTRL[RSTT] to 1.
2. Clear VEND_SPEC[FRC_SDCLK_ON] to 0.
3. Clean the history status by following these steps:
   a. Clear AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] to 0.

b. Read Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS) until AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] reads 0.

c. Write 1 to clear INT_STATUS[BRR].

4. Set TUNING_CTRL to 0x01312880 to enable the standard tuning and disable the CMD line check.
5. Start the tuning procedure by setting AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] to 1.
6. Issue CMD19(SD) / CMD21(eMMC) with the proper Command Transfer Type (CMD_XFR_TYP) and Mixer Control (MIX_CTRL) settings.
7. Wait for uSDHC BRR (Buffer Read Ready) interrupt signal is 1.
8. Check AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]. If AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] = 1, write 1 to clear INT_STATUS[BRR] and then repeat steps 6~7. If AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] = 0, standard tuning has completed, or the tuning has not completed within 40 attempts. The Host Driver might abort this loop if the number of loops exceeds 40 or 150 ms timeout occurs. In this case, a fixed sampling clock should be used (AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] = 0).
9. Sampling Clock Select (AUTOCMD12_ERR_STATUS[SMP_CLK_SEL]) is valid after AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] has changed from 1 to 0.
   AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] = 1, indicates tuning procedure passed.
   AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] = 0, indicates tuning procedure failed. The tuning result is applied to the delay chain, CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) [30:16], upon the successful tuning procedure completion.
10. Set MIX_CTRL[AUTO_TUNE_EN] to 1.

While the tuning sequence is being performed, the Host Controller does not generate interrupts (including Command Complete), except Buffer Read Ready. CMD19 response errors are not indicated.

Writing AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] to 0 forces the Host Controller to use a fixed sampling clock and resets the tuning circuit of the Host Controller.

NOTE

- There could be slight difference on delay cell delay in each project, and this difference can lead to different loop number needed. TUNING_CTRL[TUNING_STEP] can be used to control how may taps are to be added for each step.
- Manual tuning might be required in cases where standard tuning is not able to close passing window with CMD19/21 transfer fail.

38.3.10.3 Manual tuning procedure

Manual tuning controls more details in the tuning procedure, and some corner cases. Manual tuning provides control to tuning start point, tuning steps, and delay chains. To start manual tuning:

1. Clear TUNING_CTRL[STD_TUNING_EN] to 0.
2. Clear VEND_SPEC[FRC_SDCLK_ON] and MIX_CTRL[FBCLK_SEL] to 0, set MIX_CTRL[SMP_CLK_SEL] and MIX_CTRL[EXE_TUNE] to 1 to start tuning.
3. Set SYS_CTRL[RSTA] to 1, and wait for self-clear.
4. Config delay chain, CLK_TUNE_CTRL_STATUS[DLY_CELL_SET_PRE] with the valueA.

NOTE

The valueA must start from 0.

5. Set SYS_CTRL[RST_FIFO] to 1 and wait for self-clear.
6. Send CMD19/21 to card.

7. Poll for CC, CIE, CEBE, CCE and CTOE of Interrupt Status (INT_STATUS) assertion.
8. Poll for TC, DEBE, DCE and DTOE of Interrupt Status (INT_STATUS) assertion.
9. Check TP of Interrupt Status (INT_STATUS); TP = 1 & no command/data error indicates the current CMD19/21 transfer is passed; otherwise, indicates failed.
10. If TP = 0 or command/data error is observed, increase the valueA with the required tuning step(1 to 127) and repeat steps 3~9.
11. If TP = 1 & no command/data error is met after a loop with TP=0 (or command/data error), save the current valueA as value_start. Increase valueA with the required tuning step, and repeat steps 3~9 until TP = 0 (or command/data error) again. Save the current valueA as value_end.
12. Clear MIX_CTRL[EXE_TUNE] to 0.
13. Set SYS_CTRL[RSTA] to 1, and wait for self-clear.
14. Set MIX_CTRL[SMP_CLK_SEL] to 1.
15. Set bit[14:0] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) with the output of expression {[(((value_start+value_end)/2)< < 8)& 0xffffff00] -0x300 } | 0x33.
16. Poll bit[30:16] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) until the value written in the previous step is read.
17. Set MIX_CTRL[AUTO_TUNE_EN] to 1.

The manual tuning procedure defines a passing window, inside which the tuned clock can capture the correct data, and delay chain is to be configured as centered within the passing window.

It is not a fixed flow as the standard tuning. Any step can be changed based on the real case. In cases where passing window is not closed with a tuning fail, the center of the passing region must be applied for the delay chain setting. In cases where two passing windows separated by tuning fail(s) is observed, the center of the first passing window must be applied for the delay chain setting.

NOTE

Both the standard tuning and manual tuning are only for tuning of SD_CLK, cannot be used to tune STROBE clock of HS400 and HS400 enhanced mode.

38.3.10.4 Switch to HS400 mode

The valid IO voltage for HS400 is 1.8 V. The bus width is set to only DDR 8bit in HS400 mode. HS400 supports the same commands as DDR52. To switch to HS400 mode, the host must perform the following steps:

1. Initialize chip with “Backward Compatible Timings", after power-on or software reset (CMD0), the interface timing of the chip is set as the default "Backward Compatible Timing".
2. Select the chip with CMD7.
3. Read the DEVICE_TYPE [196] field of the Extended CSD register to validate whether the chip supports HS400 by sending CMD8.
4. Read the DRIVER_STRENGTH [197] field of the Extended CSD register to find the supported chip's Driver Strengths by sending CMD8.

NOTE

You may skip this step if changes of driver strength is not needed.

5. Set the "Selected Driver Strength" parameter in the HS_TIMING [185] field of the Extended CSD register to the appropriate driver strength for HS400 operation and set the "Timing Interface" parameter to 0x2 to switch to HS200 mode with CMD6. Send CMD13 to make sure mode switch to HS200 mode has been successfully done.

6. Perform the tuning procedure (standard or manual) at the HS400 target operating frequency, save the tuning result (CLK_TUNE_CTRL_STATUS[30:16]), clear TUNING_CTRL[STD_TUNING_EN] to 0, set SYS_CTRL[RSTT] to 1 and wait for self-clear.

   NOTE

   Tuning procedure in HS200 mode is required to synchronize the command response on the CMD line to CLK for HS400 operation.

7. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x1 to switch to High Speed mode with CMD6 and then set the clock frequency to a value not greater than 52 MHz.
8. Set BUS_WIDTH[183] to 0x06 to select the dual data rate x8 bus mode. Check the setting of PROT_CTRL[DTW]. Make sure the data transfer width is set as expected.
9. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x3 to switch to HS400 mode with CMD6. Set the MIX_CTRL[DDR_EN] and MIX_CTRL[HS400_MODE] to 1 to enable HS400 mode in controller.
10. Set bit[14:0] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) with saved tuning result value of 0x68 from standard tuning flow in step 6).
11. Poll bit[30:16] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) until the value written in the step 10 is read.
12. Set MIX_CTRL[SMP_CLK_SEL] to 1’b1 to apply the delay on capture clock of CMD channel, then set the clock frequency to ≤ 200 MHz.

    Ensure that uSDHC function clock source is 2x HS400 mode target frequency, and both SDCLKFS and DVS are configured to 0.
13. Set Strobe DLL control (STROBE_DLL_CTRL) to 0x00400039 to have strobe clock automatically tuned to 1/4 cycle of input ipp_strobe to capture data. Ensure that both STROBE_DLL_STATUS[STROBE_DLL_STS_REF_LOCK] and STROBE_DLL_STATUS[STROBE_DLL_STS_SLV_LOCK] are set before any transfer is started.

    NOTE

    For speed mode switch like from High Speed mode to HS200 mode or HS400(enhanced) mode, you must calibrate the right configuration of slew rate and drive strength for chip pad that are used for uSDHC.

38.3.10.5 Switch to HS400 enhanced mode

This selection flow describes how to initialize the eMMC device in HS400 mode while enabling enhanced strobe without the need for tuning procedure. To switch to HS400 mode with enhanced strobe, the host must perform the following steps:

1. Initialize device with "Backward Compatible Timings", after power-on or software reset (CMD0), the interface timing of the device is set as the default "Backward Compatible Timing".
2. Select the device with CMD7
3. Read the DEVICE_TYPE [196] field of the Extended CSD register to validate whether the device supports HS400 with CMD8.
4. Read the STROBE_SUPPORT[184] field of the Extended CSD register to validate whether the device supports enhanced strobe with CMD8.
5. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x1 to switch to High Speed mode by sending CMD6 and then set the clock frequency to a value not greater than 52 MHz.
6. Set BUS_WIDTH[183] to 0x86 to select the dual data rate x8 bus mode and enable enhanced strobe (this is active only after HS400 mode is selected) with CMD6. Check the setting of PROT_CTRL[DTW]. Make sure the data transfer width is set as expected.
7. Read the DRIVER_STRENGTH [197] field of the Extended CSD register to find the supported device Driver Strengths with CMD8.

NOTE

You may skip this step if changes of driver strength is not needed, if needed host may change the device Driver Strength.

8. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x3 to switch to HS400 mode with CMD6.
9. Set the MIX_CTRL[DDR_EN], MIX_CTRL[HS400_MODE], and MIX_CTRL[EN_HS400_MODE] bits to 1 to enable enhanced HS400 mode in controller.
10. Host may set the clock frequency to a value not greater than 200 MHz. Ensure uSDHC function clock source is 2x HS400 mode target frequency, and both SDCLKFS and DVS are configured to 0 .
11. Set Strobe DLL control (STROBE_DLL_CTRL) to 0x00400039 to have strobe clock automatically delayed 1/4 cycle of input ipp_strobe to capture data. Make sure both STROBE_DLL_STATUS[STROBE_DLL_STS_REF_LOCK] and STROBE_DLL_STATUS[STROBE_DLL_STS_SLV_LOCK] are set before any transfer is started.

NOTE

For speed mode switch like from high speed mode to HS200 mode or HS400(enhanced) mode, you must calibrate the right configuration of slew rate and drive strength for chip pad that are used for uSDHC.

38.3.11 Software restrictions

38.3.11.1 Initialization active

The driver cannot set INITA bit in System Control register when any of the command line or data lines are active, so the driver must ensure both CDIHB and CIHB bits are cleared.

38.3.11.2 Software polling procedure

For polling read or write, after the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in the Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block. For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

38.3.11.3 Suspend operation

To suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by SDIO, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such a 'suspend' command, uSDHC treats the current transfer is stopped and change the BLKCNT register to its original value, instead of retaining the remaining number of blocks.

38.3.11.4 Data length setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

ADMA1 is 4KB aligned.

38.3.11.5 (A)DMA address setting

To configure the ADMA1/ADMA2/DMA address register, when TC bit is set, the register always updates itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring the ADMA1/ADMA2/DMA address register.

38.3.11.6 Data port access

Data port does not support parallel access. For example, during an internal DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or internal DMA. Otherwise the data is corrupted inside the uSDHC buffer.

38.3.11.7 Change clock frequency

The uSDHC module does not automatically gate off the card clock when the host driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing the clock divisor value (SDCLKFS or DVS in System Control Register) or setting the RSTA bit.

Also, before changing the clock divisor value, the host driver should make sure that the SDSTB bit is high.

38.3.11.8 Multi-block read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for eMMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode. In this case, the card may not respond to this extra abort command and uSDHC gets response timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

38.3.12 Clocking

The table found here describes the clock sources for uSDHC. For more information on clocking, see the Clocking chapter.

Table 229. Clocks

Clock name	Description
hclk	Bus clock
ipg_clk	Peripheral clock
ipg_clk_perclk	Base clock
ipg_clk_lp	Low power clock

38.3.12.1 Clock and reset manager

This module controls all four kinds reset signals within uSDHC:

- Hardware reset
- Software reset for all logic
- Software reset for the data logic
- Software reset for the command logic

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

38.3.12.2 Clock generator

The clock generator generates the card CLK by peripheral source clock in two stages. The clock divisor can be configured through register SYS_CTRL[SDCLKFS] for prescaler configuration while the [DVS] for divisor configuration. Details can be found in the register function description. See the following figure for the structure of the divider. The term "Base" represents the frequency of peripheral source clock (see ipg_clk_perclk in Table 229).

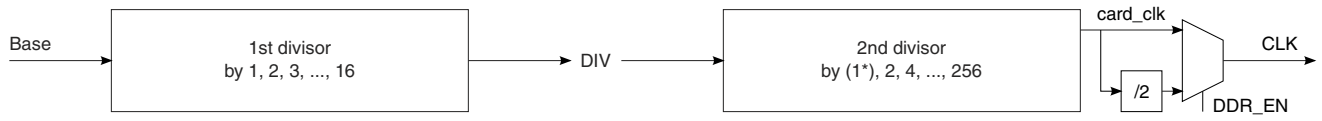

Figure 141. Two stages of the clock divider

The first stage outputs an intermediate clock (DIV) that can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler and outputs the actual internal working clock (card_clk). This clock is the driving clock for all the sub modules of the SD protocol unit, and helps in syncing FIFOs (see Figure 127) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage can be DIV, DIV/2, DIV/4,..., or DIV/256. Therefore, the highest frequency of the card_clk is base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of the base clock is 50%, the duty cycle of card_clk is also 50%, even when the compound divisor is an odd value.

NOTE

CLK is different for the SDR and DDR modes.

- In the SDR mode, CLK is equal to the internal working clock (card_clk).

$$f_{card_clk} = \frac{f_{Base}}{SYS_CTRL[DVS] \times SYS_CTRL[SDCLKFS]}$$

$$f_{CLK} = f_{card_clk}$$

Equation 16. Equation for f_{card_clk} in SDR mode

For HS200 mode, if the source clock f_{Base} = 400 MHz, and the target clock f_{CLK} = 200 MHz, then configuring DVS to 'h00 and SDCLKFS to 'h01, the mapping value of SYS_CTRL[DVS] is 1 and the mapping value of SYS_CTRL[SDCLKFS] is 2.

$$f_{card_clk} = \frac{400MHz}{1x(2)} = 200MHz$$

$$f_{CLK} = f_{card_clk} = 200\ MHz$$

- In the DDR mode, CLK is equal to card_clk/2

$$f_{card_clk} = \frac{f_{Base}}{SYS_CTRL[DVS] \times (SYS_CTRL[SDCLKFS]/2)}$$

$$f_{CLK} = \frac{f_{card_clk}}{2}$$

Equation 17. Equation for f_{card_clk} in DDR mode

For HS400 mode, if the source clock f_{Base} = 400 MHz, and the target clock f_{CLK} = 200 MHz, then configuring DVS to 'h00 and SDCLKFS to 'h00, the mapping value of SYS_CTRL[DVS] is 1 and the mapping value of SYS_CTRL[SDCLKFS] is 2.

$$f_{card_clk} = \frac{400MHz}{1x(2/2)} = 400MHz$$

$$f_{CLK} = \frac{f_{\text{card_clk}}}{2} = \frac{400MHz}{2} = 200MHz$$

38.3.13 Command Queuing (CQE) operation

To facilitate command queuing in eMMC, the device manages an internal task queue that the host can queue data transfer tasks. Initially, the task queue is empty. Every task is issued by the host and initially queued as pending. The device controller works to prepare the pending tasks for execution. The software flow is described below:

1. Read CMDQ_SUPPORT[308] and CMDQ_DEPTH[307] of the extended CSD register (through CMD8) to verify eMMC chip support of command queue.
2. Set CMDQ_MODE_EN in CMD_MODE_EN[15] field of the extended CSD by issuing CMD6.
3. Send CMD13 to ensure a successful mode switch.
4. Define Task Descriptor List (TDL) comprised of task descriptor and transfer descriptor sets.
    a. 0x0010002b,0x00000000,0x20000023,0x34300000, //Write example
    b. 0x0010102b,0x00000000,0x20000023,0x34500000, //Read example
5. Set PROT_CTRL[DMASEL] to 2 to select ADMA2. CMDQ descriptors are in ADMA2 format.
6. Set CQSSC2[SSC2] to RCA.
7. Set Command Queuing Task Descriptor List Base Address (CQTDLBA) and Command Queuing Task Descriptor List Base Address Upper 32 Bits (CQTDLBAU) to TDL start address.
8. Set CQCFG[CQUE] to 1 to enable the command queuing.
9. Set CQTDBR[TDBR] field(s) to trigger the required task(s).
10. Read CQTCN[TCN] field(s) to confirm the task completion(s).
11. Set CQTCN[TCN] field(s) to 1 to clear status.

38.3.14 Abort transaction

Abort command

There are two types of abort command: CMD12 and I/O abort.

- CMD12 is used for memory device: such as eMMC, SD Card, SD Combo Card (Memory portion).
- I/O abort is used for SDIO card, SDCombo (I/O portion). I/O abort stops an infinite block transfer (block count = 0) by writing the ASx bit in CCCR.

If an exact number of blocks are to be transferred, it is recommended that the uSDHC issues a block command with the correct block count, rather than using an infinite count and aborting the data at the correct time.

Asynchronous and synchronous abort

There are two ways to issue an abort command (CMD12 or I/O abort): asynchronous abort and synchronous abort.

- In an asynchronous abort sequence, uSDHC can issue an abort command (CMD12 or I/O abort) at anytime unless Command Inhibit (PRES_STATE[CIHB]) in the Present State register is set to 1.
- In a synchronous abort sequence, uSDHC shall issue an abort command (CMD12 or I/O abort) after data transfer is stopped by using Stop At Block Gap Request (SABGREQ).

Read wait

This function uses DATA2 to allow uSDHC to signal the SDIO or Combo Card to temporarily halt the sending of read data by a card during the block gap.

38.4 External signals

The following table describes the uSDHC external signals:

Table 230. uSDHC external signals

Signal	Description	Direction
CLK	Is an Internally generated clock used to drive the eMMC, SD card, and SDIO.	O
CMD	Is used to send commands and receive responses to and from the card.	I/O
DAT7	DAT7 line in the 8-bit mode — Not used in other modes	I/O
DAT6	DAT6 line in the 8-bit mode — Not used in other modes	I/O
DAT5	DAT5 line in the 8-bit mode — Not used in other modes	I/O
DAT4	DAT4 line in the 8-bit mode — Not used in other modes	I/O
NOTE If uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.		
DAT3	DAT3 line in the 4/8-bit mode or configured as card detection pin. The bit may be configured as card detection pin in the 1-bit mode.	I/O
DAT2	DAT2 line or Read Wait in the 4-bit mode Read Wait in 1-bit mode	I/O
DAT1	DAT1 line in the 4/8-bit mode Also, used to detect interrupt in 1/4-bit mode	I/O
DAT0	DAT0 line in all the modes Also, used to detect busy state	I/O
CD_B	Card detection signal directly routed from the socket. Low value (0) indicates there is a card inserted. In the case the pin is not used (for the embedded memory), tie low. Optional for system implementation.	I
WP	Write protection signals directly routed from the socket. Low value (0) indicates it is not write protected. In the case the pin is not used (for the embedded memory), tie low.	I

Table continues on the next page...

Table 230. uSDHC external signals (continued)

Signal	Description	Direction
	Optional for system implementation.	
RESET_B	Is used to reset the eMMC or control Card power. Active Low. • eMMC: connect eMMC RST_n pin. • Card: instead of hardware reset to enable/disable Card power during warm reset.	O
VSELECT	Is used to change the voltage of the external power supplier. Optional for system implementation.	O
STROBE	Input clock for eMMC HS400 mode. **NOTE** If the uSDHC does not support the HS400 mode, STROBE can also be optional and tied to low.	I

38.5 Application information

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, and ALL_SEND_CID. In the Broadcast mode, eMMC are in the open-drain mode to avoid bus contention. See Commands for SD card, SDIO, and eMMC for the commands of bc and bcr categories.

After the broadcast command CMD3 is issued, the cards enter the standby mode. Addressed type commands are used from this point. In this mode, for eMMC, the CMD/DATA I/O pads turns to the push-pull mode to have the driving capability for maximum frequency operation. See Commands for SD card, SDIO, and eMMC for the commands of ac and adtc categories.

38.5.1 Command send and response receive basic operation

Assuming that the data type WORD is an unsigned 32-bit integer, the flow indicated below presents a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)

{

    WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner

    wCmd = (<cmd_index> & 0x3f) << 24; // set the first 8 bits as '00'+<cmd_index>

    set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL according to the command index;

    if (internal DMA is used) wCmd |= 0x1;

    if (multi-block transfer) {

        set MSBSEL bit;
```

```
        if (finite block number) {

            set BCEN bit;

            if (auto12 command is to use) set AC12EN bit;

        }

    }

    write_reg(CMDARG, <cmd_arg>); // configure the command argument

    write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command

}

wait_for_response(cmd_index)

{

    while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set

    read IRQ Status register and check if any error bits about Command are set

    if (any error bits are set) report error;

    write 1 to clear CC bit and all Command Error bits;

}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure that the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and move to the Standby state no response to the Host when CMD2 is sent. The host driver deals with "fake" errors like this with caution.

38.5.2 Card identification mode

When a card is inserted to the socket or the card is reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for eMMC.

38.5.2.1 Card detect

See Figure 142 for a flow diagram showing the detection of SD card and SDIO using uSDHC.

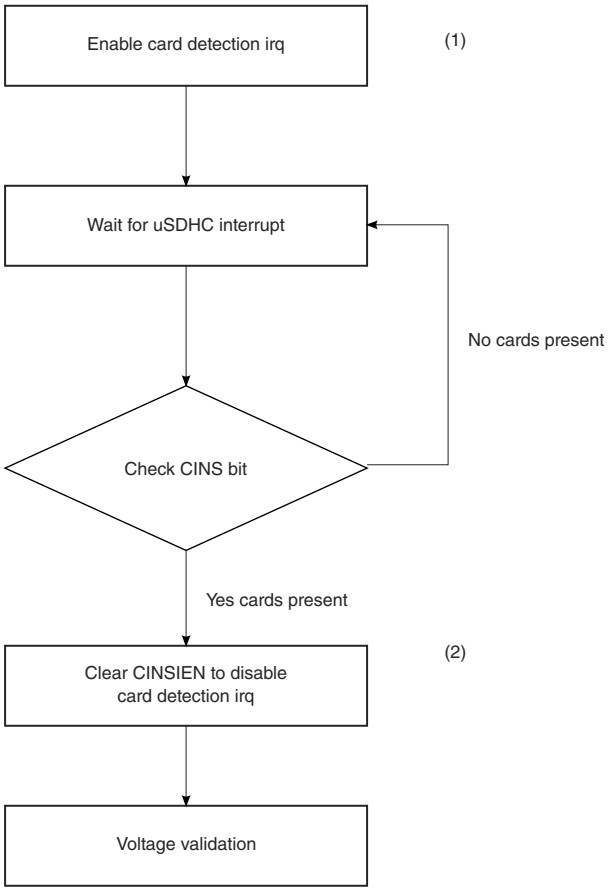

Figure 142. Flow diagram for card detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt.
- When an interrupt from uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion.
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards.

38.5.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) that is driven by Power On Reset (POR).
- Software reset (Host only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the host controller, respectively.
- Card reset (Card only): The command, "Go_Idle_State" (CMD0), is the software reset command for all types of eMMC and SD memory cards. This command sets each card into the idle state regardless of the current card state. For an SDIO, CMD52 is used to write an I/O reset in CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both uSDHC and the card.

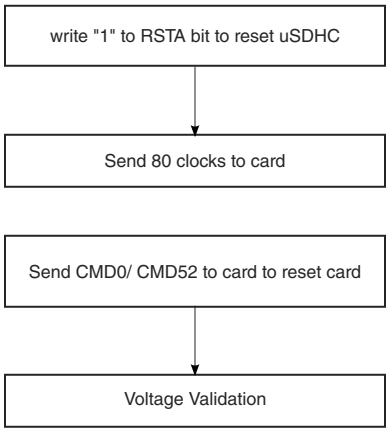

Figure 143. Flow chart for resetting uSDHC and SD card or SDIO

```
software_reset() {
    set_bit(SYSCTRL, RSTA); // software reset the Host set DTOCV and SDCLKFS fields to get the CLK of
    //frequency around 400kHz
    //configure IO pad to set the power voltage of external card to around 3.0V
    //poll bits CIHB and CDIHB
    //bits of PRSSTAT to wait both fields are cleared
    set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
    send_command(CMD_GO_IDLE_STATE, <other parameter>); // reset the card with CMD0 or
    send_command(CMD_IO_RW_DIRECT, <other parameter>);
}
```

38.5.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for VDD are defined in the Operation Conditions Register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer VDD conditions. This means that if the host and card have non-common VDD ranges, the card is neither able to complete the identification cycle nor able to send CSD data.

Therefore, special commands Send_Op_Cont (CMD1 for eMMC), SD_Send_Op_Cont (ACMD41 for SD Memory), and IO_Send_Op_Cont (CMD5 for SD I/O) are used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards that do not match the VDD range(s) desired by the host. This is accomplished when the host sends the desired VDD voltage window as the operand of this command. Cards that cannot perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive state. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive state. This query should be used if the host is able to select a common voltage range or if a notification is sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_argument) {
    label the card as UNKNOWN;
    send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO operation
voltage, command argument is zero
    if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
        if (0 < number of IO functions) {
            label the card as SDIO;
            IORDY = 0;
```

```
            while (!(IORDY in IO OCR response)) { // set voltage range for each IO function
                send_command(IO_SEND_OP_COND, <voltage range>, <other parameter>);
                wait_for_response(IO_SEND_OP_COND);
            } // end of while ...
        } // end of if (0 < ...
        if (memory part is present inside SDIO)
            Label the card as SDCombo; //this is an SD-Combo card
    } // end of if (RESP_TIMEOUT ...
    if (the card is labeled as SDIO)
        return; // card type is identified and voltage range is set, so exit the function;
    send_command(APP_CMD, 0x0, <other parameter>); // CMD55, Application specific CMD prefix
    if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
        send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage range for
memory part or SD card
        wait_for_response(SD_APP_OP_COND); // voltage range is set
        if (card type is UNKNOWN)
           label the card as SD;
        return; //
    } // end of if (no error ...
    else if (errors other than time-out occur) { // command/response pair is corrupted
        deal with it by program specific manner;
    } // of else if (response time-out
    else { // CMD55 is refuse, it must be eMMC
        if (card is already labeled as SDCombo) { // change label
            re-label the card as SDIO;
            ignore the error or report it;
            return; // card is identified as SDIO
        } // end of if (card is ...
        send_command(SEND_OP_COND, <voltage range>, <...>);
        if(RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
            either label the card as UNKNOWN;
            return;
        } // end of if (RESP_TIMEOUT ...
    } // end of else
}
```

38.5.2.4 Card registry

This section briefly describes the registry flow. For details, please refer to the card specifications. Card registry for the eMMC and SD/SDIO/SD combo cards are different. For the SD card, the identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the card spec). Currently, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host requests the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command is sent to all the new cards in the system. Incompatible cards are put into the Inactive state. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready state), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification state.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA is used to address the card for future data transfer operations. After the RCA is received, the card changes its state to the Standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in the system.

For eMMC operation, the host starts the card identification process in the open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line to allow parallel card operation during card identification. After the bus is activated, the host requests the cards to send their valid operation conditions

(CMD1). The response to CMD1 is the "wired AND " operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive state. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in the Ready state) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. As the CID is unique for each card, only one card can be successfully sent its full CID to the host. This card then goes into the Identification state. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign a relative card address (RCA) to the card. After the RCA is received, the state of the card changes to standby, and the card does not react in further identification cycles. Also, its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

The following steps show how to perform an operation using eMMC:

```
card_registry() {
    do { // decide RCA for each card until response time-out
        if(card is labelled as SDCombo or SDIO) { // for SDIO like device
            send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO to publish its RCA
            retrieve RCA from response;
        } // end if (card is labelled as SDCombo ...
        else if (card is labelled as SD) { // for SD card
            send_command(ALL_SEND_CID, <...>);
            if(RESP_TIMEOUT == wait_for_response(ALL_SEND_CID))
                break;
            send_command(SET_RELATIVE_ADDR, <...>);
            retrieve RCA from response;
        } // else if (card is labelled as SD ...
        else if (card is labelled as eMMC) {
            send_command(ALL_SEND_CID, <...>);
            rca = 0x1; //arbitrarily set RCA, 1 here for example
            send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper 16 bits
        } // end of else if (card is labelled as eMMC...
    } while (response is not time-out);
}
```

38.5.3 Card access

Information about Block Write, Block Read, Suspense Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

38.5.3.1 Block write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

38.5.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card indicates that the failure on the DATA line. The transferred data is discarded and not written, and all further transmitted blocks (in multiple block write mode) are ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and stops the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation also stops if the host tries to write over a write-protected area.

For eMMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and does not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO at any time, and the card responds with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby state and release the DATA line without interrupting the write operation. When re-selecting the card, it reactivates the busy indication by pulling data to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card that incorporates the internal DMA and the write operation is a multi-block write. For the other methods (CPU polling status with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Clear INT_SIGNAL_EN[BWRIEN] to 0 to disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer.

   For multi-block write, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, SD Combo Card (memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or any other error that occurred during the auto12 command sending and response receiving, if the device is memory device: such as eMMC, SD Card, SD Combo Card (memory portion).

38.5.3.1.2 DDR write

uSDHC supports the dual data rate mode.

The software flow to write to a card in the DDR mode is described as below:

1. Check the card status and wait until the card is ready for data.

   NOTE

   For eMMC, block length can only be set to 512 Byte.
2. Set the uSDHC number block register (NOB), where nob is 5, for instance.
3. Set the eMMC, SD card to high-speed mode and use SWITCH (CMD6); or set SDIO to high-speed mode and use IO_RW_DIRECT (CMD52).
4. Set the eMMC bus or SD with 4-bit/8-bit DDR mode and use SWITCH (CMD6); or set SDIO to with 4-bit DDR mode and use IO_RW_DIRECT (CMD52).
5. Clear INT_SIGNAL_EN[BWRIEN] to 0 to disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. Set DDR_EN to 1.

   For multi-block write, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, SD Combo Card (Memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
6. Wait for the Transfer Complete interrupt.

7. Check the status bit to see if a write CRC error occurred, or any other error that occurred during the auto12 command sending and response receiving if the device is memory device: such as eMMC, SD Card, SD Combo Card (Memory portion).

38.5.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the Stop At Block Gap Request (SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Similar to the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status and wait until the card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO or the I/O portion of SD Combo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Clear INT_SIGNAL_EN[BWRIEN] to 0 to disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer.

   For multi-block write, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, SD Combo Card (Memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or any other error that occurred during the auto12 command sending and response receiving if the device is memory device: such as eMMC, SD Card, SD Combo Card (Memory portion).

The number of blocks left during the data transfer is accessible by reading the contents of BLK_ATT[BLKCNT]. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The host driver reads the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt (INT_STATUS[TC]) is received.

It is also possible that the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is the end of the transfer. These types of requests are ignored, the driver should treat these as a non-pause transfer, and deal with it as a common write operation.

38.5.3.2 Block read

Information about Normal read, DDR read, Read with Pause, and Delay Line (DLL) in Read Path are detailed in the sections below.

38.5.3.2.1 Normal read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer state. For multi blocks read, data blocks are continuously transferred until a stop command is issued.

The software flow to read from a card that incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other methods (CPU polling status with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status and wait until card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO or the I/O portion of SD Combo Cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Clear INT_SIGNAL_EN[BRRIEN] to 0 to disable the buffer read ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer.

   For multi-block read, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or any other error occurred during the auto12 command sending and response receiving if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion).

38.5.3.2.2 DDR read

The uSDHC module supports dual data rate mode.

The software flow to write to a card in the DDR mode is described below:

1. Check the card status and wait until the card is ready for data.

   NOTE

   For eMMC, block length can only be set to 512 Bytes.
2. Set the uSDHC number block register (NOB) where nob is 5, for instance.
3. Set the eMMC, SD card to high-speed mode and use SWITCH (CMD6); or set SDIO to high-speed mode and use IO_RW_DIRECT (CMD52).
4. Set the eMMC bus or SD with 4-bit/8-bit DDR mode and use SWITCH (CMD6); or set SDIO to with 4-bit DDR mode and use IO_RW_DIRECT (CMD52).
5. Clear INT_SIGNAL_EN[BRRIEN] to 0 to disable the buffer write ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. Set DDR_EN to 1.

   For multi-block read, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
6. Wait for the Transfer Complete interrupt.

7. Check the status bit to see if a write CRC error occurred, or any other error that occurred during the auto12 command sending and response receiving if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion).

38.5.3.2.3 Read with Pause

The read operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the Stop At Block Gap Request (SABGREQ) bit in Control register to pause the transfer between the data blocks.

Only SDIO and SD Combo Card support Read Wait feature while Read with Pause. Read Wait feature means that it uses DATA2 to allow uSDHC to signal the SDIO or SD Combo Card to temporarily halt the sending of read data by a card during the block gap. Before setting SABGREQ to 1, ensure to set the RWCTL bit to 1 after recognizing the read wait capability of SDIO (SRW bit in CCCR register is 1).

Similar to the flow described in Normal read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCCR register on SDIO or SD Combo Card (I/O portion) to confirm that the card supports the Read Wait mode.
2. If SDIO or Combo Card (I/O portion) supports Read Wait, set RWCTL to 1.

   If the device is memory device: such as eMMC, SD Card, or SD Combo Card (Memory portion), set RD_DONE_NO_8CLK to 1.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO or the I/O portion of SD Combo Cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bitfield in the CCCR register (for function 0) or FBR register (for functions 1~7).
5. Set the uSDHC block length register to be the same as the block length set for the card in step 4.
6. Set the uSDHC number block register (NOB), where nob is 5, for instance.
7. Clear INT_SIGNAL_EN[BRRIEN] to 0 to disable the buffer read ready interrupt, configure the DMA setting, and enable the uSDHC DMA when sending the command with data transfer.

   For multi-block read, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or any other error occurred during the auto12 command sending and response receiving if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion).

Similar to the Write operation, it is possible to meet the ending block of the transfer when paused. In this case, uSDHC ignores the Stop At Block Gap Request and treats it as a command read operation.

If the Suspend command is sent and the transfer is later resumed by means of a Resume command, uSDHC takes the command as a normal one accompanied with data transfer. It is left for the host driver to set all the relevant registers before the transfer

is resumed. For memory device, if there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. Then uSDHC automatically sends CMD12 to mark the end of multi-block transfer.

38.5.3.2.4 Delay Line (DLL) in read path

The DLL is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage, and temperature (PVT).

The reasons why DLL is needed for uSDHC are these:

- The path of read data traveling from card to host varies.
- In the eMMC and SD cards DDR mode, the minimum input setup and hold time are both at 2.5 ns.

The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in the override mode. The override value set is the number of delay cells. In the override mode, there is no need to set the DLL_enable. Another DLL mode is target value mode. In this mode, the DLL automatically adjusts the number of delay cells according to the target value set by the user and PVT changes. Be aware that the target value is in units of 1/32 of the clock reference period. If the card_clk is 100Mhz, then the reference clock period is 10ns; setting target value of 16 means 5ns =(16/32)*10ns. The software can disable automatic update by the setting dll_gate_update bit.

As you might change the frequency of card_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card_clk) is changed. If DLL is to be used, make sure SDCLKFS is used (at least be set to divided by 2) so that the REF_CLK generated are the same frequency as card_clk. There are two DLLs, PARTS DLL and STROBE DLL. PARTS DLL controls the SD_CLK loop back delay for which DLL (Delay Line) Control (DLL_CTRL) and DLL Status (DLL_STATUS) are used. STROBE DLL controls the STROBE loop back delay for which Strobe DLL control (STROBE_DLL_CTRL) and Strobe DLL status (STROBE_DLL_STATUS) are used. For PARTS DLL, below flow can be taken as reference. For STROBE DLL, similar register field with prefix STROBE in Strobe DLL control (STROBE_DLL_CTRL) and Strobe DLL status (STROBE_DLL_STATUS) must be used.

Step 1: Set the DLL_CTRL_RESET and DLL_CTRL_ENABLE fields

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: Clear the DLL_CTRL_RESET field

Step 5: Wait until both the DLL_STS_SLV_LOCK and DLL_STS_REF_LOCK are asserted

Step 6: Set the DLL_CTRL_SLV_FORCE_UPD

Step 7: Clear the DLL_CTRL_SLV_FORCE_UPD

NOTE

The software should make sure that the DLL_CTRL_SLV_FORCE_UPD lasts for at least one card_clk. So, the software may need to add some delay between step 6 and step 7.

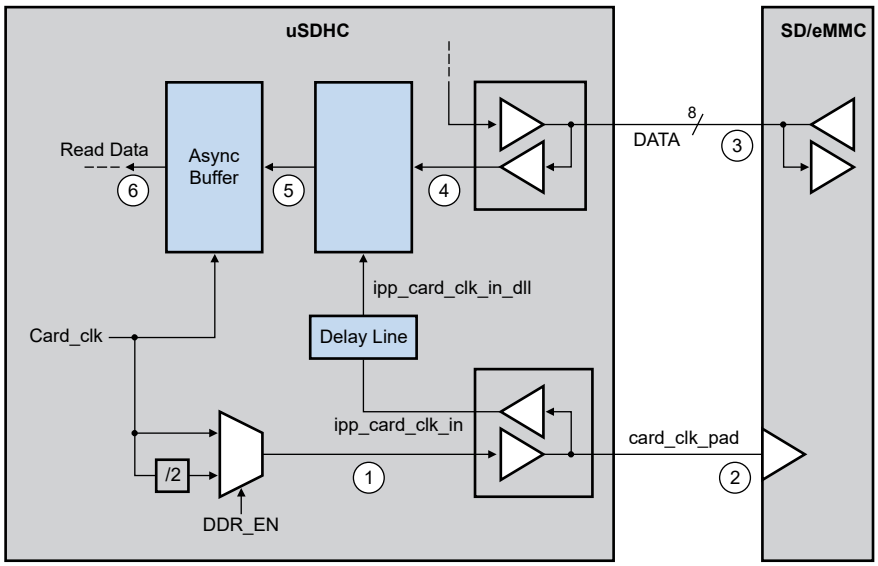

Figure 144. DLL in read path

38.5.3.3 Suspend Resume

The uSDHC module supports the Suspend Resume operations of SDIO and Combo Card, although slightly different than the suggested implementation of Suspend in the SDIO specification. Both Read and Write support Suspend and Resume, however ADMA operation does not support this function.

38.5.3.3.1 Suspend

After setting the SABGREQ bit, the host driver may send a Suspend command to switch to another function of SDIO and Combo Card. The uSDHC module does not monitor the content of the response, so it does not know if the Suspend command succeeded or not. Accordingly, it does not de-assert Read Wait for read pause. To solve this problem, the host driver does not mark the Suspend command as "Suspend", i.e., setting the CMDTYP bits to 01. Instead, the driver sends this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform uSDHC that the current transfer is suspended. Here is the sequence for the Suspend operation:

1. Check CCCR[SRW] on SDIO or SD Combo Card (I/O portion) to confirm that the card supports the Read Wait mode. If SDIO or Combo Card (I/O portion) supports Read Wait, set the RWCTL bit to 1.
2. Set the SABGREQ bit to 1 to pause the current data transfer at block gap. Wait for the BGE bit set as 1, and wait for the Transfer Complete interrupt. Save the context registers in the system memory for later use, including the DMA System Address Register DS_ADDR (for internal DMA operation), and the Block Attribute Register BLK_ATT.
3. Send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.

   The following steps show an example of CMD52 function0 suspend with CMDTYP=2'b00:

   a. Set CMD_ARG to 0x88001802

   b. Set MIX_CTRL to 0x80000000

   c. Set CMD_XFR_TYP to 0x341A0000
4. Check the BS bit of the CCCR in the response (CMD_RSP0[0]). If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
5. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so uSDHC can detect this special setting and be informed that the paused operation has successfully suspended.

The following steps show an example of CMD52 function0 suspend with CMDTYP=2'b01:

a. Set CMD_ARG to 0x00001800

b. Set MIX_CTRL to 0x80000000

c. Set CMD_XFR_TYP to 0x345A0000

6. Clear the BGE bit to 0, and clear the SABGREQ bit to 0. Begin operation for another function on SDIO and Combo Card (I/O portion).

38.5.3.3.2 Resume

To resume the data transfer, a Resume command is issued:

1. To resume the suspended function, restore the context registers (DS_ADDR and BLK_ATT) with the saved value in the step #2 of the Suspend operation.
2. Send the Resume command: In the Transfer Type register, all the bitfields are set to the value as if this were another ordinary data transfer instead of a transfer resume (except the CMDTYP is set to 2'b10).

   The following steps show an example of CMD52 function0 resume with CMDTYP=2'b10:

   a. Set CMD_ARG to 0x88001A01

   b. Set MIX_CTRL either to 0x80000023 (Suspend Write, Host to Card) or to 0x80000033 (Suspend Read, Card to Host)

   c. Set CMD_XFR_TYP to 0x34BA0000

3. If the Resume command (INT_STATUS[CC]) has responded, the data transfer is resumed.

38.5.3.4 ADMA usage

To use the ADMA in a data transfer, the host driver must prepare the correct descriptor chain prior to sending the read/write command. The steps to prepare the correct descriptor chain are as follows:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4KB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors matches the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.
8. Once the ADMA transfer is complete, clear PROT_CTRL[DMASEL] to 00b.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

38.5.3.5 Transfer error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 errors are detailed in the sections below.

38.5.3.5.1 CRC error

It is possible at the end of a block transfer that a write CRC status error or read CRC error occurs. For this type of error, the latest block received is discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one. For a multi-block transfer, the host driver issues a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 is sent by uSDHC. In this case, the host driver re-sends or re-obtains the last block with a single block transfer.

38.5.3.5.2 Internal DMA error

During the data transfer with internal Simple DMA, if the DMA engine encounters an error on the AXI bus, the DMA operation stops, and the DMA error interrupt is sent to the host system. When acknowledged by such an interrupt, the host driver calculates the start address of data block in which the error occurs. The start address can be calculated by either:

- Reading the DMA System Address register: The error occurs during the previous burst. Considering the block size, and the start address of the next burst transfer, it is straight forward to obtain the start address of the corrupted block.
- Reading the BLKCNT field of the Block Attribute register: Considering the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined.To use this method, MIX_CTRL[BCEN] bit has to be set to enable Block Attribute register update.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

38.5.3.5.3 Transfer ADMA error

There are three kinds of possible ADMA errors: The AXI transfer, invalid descriptor, and data-length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the host driver should recover the error as shown below and re-transfer from the place of interruption.

- AXI transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or to the next block if no block is corrupted.
- Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and recreate the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
- Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

38.5.3.5.4 Auto CMD12 error

After the last block of the multi-block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, uSDHC automatically sends a CMD12 to the card to stop the transfer. When errors with this command occur, it is recommended to the host driver to deal with the situations in the following manner:

- Auto CMD12 response time-out: It is not certain whether the command is accepted by the card or not. The host driver clears the auto CMD12 error status bits and re-send CMD12 until it is accepted by the card.
- Auto CMD12 response CRC error: As the card responds to CMD12, it stops the transfer. The host driver may ignore the error and clear the error status bit.
- Auto CMD12 conflict error or not sent: The command is not sent; therefore, the host driver sends a CMD12 manually.

38.5.3.6 Card interrupt

The external cards can inform the host controller by means of some special signals. For SDIO, it can be the low-level on the DATA1 line during some special period. The uSDHC module only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by uSDHC, and the host system is informed by uSDHC asserting the uSDHC interrupt line, the interrupt service from the host driver is called.

As the interrupt source is controlled by the external card, the interrupt from SDIO must be serviced before the CINT bit is cleared. Refer to Card interrupt handling for the card interrupt handling flow.

38.5.4 Switch function

A switch command is issued by the host driver to enable new features added to the eMMC and SD cards. The eMMC and SD cards can transfer data at bus widths other than 1-bit. Different speed modes are also defined. To enable these features, a switch command is issued by the host driver.

For SDIO, the high-speed mode /DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed as high. For SD cards, the high-speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For eMMC, the high-speed mode HS200 or HS400 is queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit, and DDR8-bit width of eMMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO, it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudo-code examples do not show current capability check, which is recommended in the function switch process.

38.5.4.1 Query, enable, and disable SDIO high-speed mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report SDIO does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of the desired value below 25MHz;
(data transactions like normal peers)
}
```

38.5.4.2 Query, enable, and disable SD high-speed mode/DDR50 /SDR50 /SDR104

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;(high speed
mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
```

```
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
      send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of around 50MHz for high speed mode, 100MHz for SDR50, 200MHz for SDR104, 50MHz for DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

38.5.4.3 Query, enable, and disable eMMC high-speed mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of eMMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the eMMC does not support high speed mode and return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of eMMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this eMMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of eMMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report eMMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of eMMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

38.5.4.4 Set eMMC bus width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of eMMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the eMMC does not support multiple bit width and return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-bit,
x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

38.5.5 ADMA operation

Here are the codes for the ADMA1 and ADMA2 operations.

38.5.5.1 ADMA1 operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

38.5.5.2 ADMA2 operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
```

```
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

38.5.6 Fast boot operation

38.5.6.1 Normal fast boot flow

Here are the steps for normal fast boot flow:

1. Software must configure the SYS_CTRL[INITA] bit to make sure that 74 card clocks are finished.
2. Software must configure the eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode. If the data is sent through the DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set Data Transfer Width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN retain the default value, where DPSEL bit is set to 1, DTDSEL is set to 1 and MSBSEL is set to 1.
7. DMAEN should be configured as 0 in the polling mode and if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
8. When step 6 is configured, the boot process begins. The software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt is triggered, and the software must configure eMMC Boot Register to bit 6 to 0 to disable boot. This makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure eMMC Boot Register bit 6 to 0 to disable boot. This render CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin the normal initialization process.
10. You must reset the host and begin the normal process.

38.5.6.2 Alternative fast boot flow

Here are the steps for alternative fast boot flow:

1. Software needs to configure SYS_CTRL[INITA] to make sure 74 card clocks are finished.
2. Software needs to configure eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through the DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in the DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the data transfer width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with the 0xFFFFFFFA argument. In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. Note DMAEN should be configured as 0 in the polling mode, and if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in the DDR fast boot mode, DDR_EN needs to be set to 1.
7. When step 6 is configured, the boot process begins. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host sends out the interrupt and the software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process.
8. If there is no time out, the software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the eMMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the target (card) is ready for the identification step.
9. You must reset the host and begin the normal process.

38.5.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during eMMC fast boot.

In fast boot, the host can use Advanced DMA2 (ADMA2) with two destinations.

The detailed flow is described below:

1. The software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure that 74 card clocks are finished.
2. The software needs to configure the eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the first time, so that the host stops at the block gap when the uSDHC controller gets VAULE1 blocks from the device. Also, configure bits[3-0] to select the ack timeout value according to the SD clock frequency.
3. The software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hffff).
4. The software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
6. The software needs to set at least three pairs of ADMA2 descriptor in boot memory (that is, in IRAM, at least six words). The first pair descriptor defines the start address (that is, IRAM) and data length (that is,512byte*VALUE1) of the first part boot code. The software also needs to set the second pair descriptor, the second start address (any value that

is writable), and data length is suggested to set 1~2word (record as VALUE2). Note that the second couple desc also transfers useful data even at lease 1 word, because our ADMA2 cannot support 0 data_length data transfer descriptor.

7. The software needs to configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot and do not need to be set in normal fast boot.
8. The software needs to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. DMAEN is configured as 1 in the DMA mode. And, if BCEN is configured as 1, then configure blk no in Bock Attributes Register to the max value. And, if in the DDR fast boot mode, DDR_EN needs to be set to 1.
9. When step 8 is configured, boot process begins, the first VALUE1 block number data gets transferred. The software needs to poll the TC bit (bit1 in Interrupt Status Register) to determine first transfer is ended. Also, the software needs to polling the BGE bit (bit2 in Interrupt Status Register) to determine if the first transfer stops at the block gap.
10. When TC and BGE bits are set to 1, the software can analyze the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of the boot code (VALUE3, the remain boot code block). Remember to set the last descriptor with END.
11. The software needs to configure the eMMC Boot Register (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the ack mode or not. In the DMA mode, configure bit 7 to 1 for enabling the automatically stop at block gap feature. Also, configure bit31-bit16 to set the (BLK_CNT - (VALUE1+1+VALUE3)), that host stops at block gap when the uSDHC controller gets (VALUE1+1+VALUE3)) blocks from device totally include the blocks received in step 9. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequency. Note that the software does not need to configure the BLK_CNT again, because it is counted down automatically by the uSDHC controller.
12. The software needs to clear the TC and BGE bits and the software needs to clear SABGREQ (bit 16 in the Protocol control register) and set CREQ (bit17 in the Protocol control register) to 1 to resume the data transfer. Host transfers the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. The software needs to do poll BGE bit to determine if the fast boot is over.

Note:

- When ADMA boot flow starts, for uSDHC, it is like a normal ADMA read operation. So, set ADMA2 descriptor as the normal ADMA2 transfer.
- Need a few words length memory to keep descriptor.
- For the 1~2-word data in second descriptor setting, it is a useful data, so the software needs to deal the data because of the application case.

38.6 uSDHC memory map and register definition

38.6.1 USDHC register descriptions

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map of uSDHC. All these registers only support 32-bit accesses.

NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

38.6.1.1 USDHC memory map

uSDHC1 base address: 4285_0000h

uSDHC2 base address: 4286_0000h

uSDHC3 base address: 428B_0000h

R W	DS_ADDR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-0 DS_ADDR	System address **DMA system address / argument 2** When ACMD23_ARGU2_EN is set to 0, SDMA uses this register as system address and supports only 32-bit addressing mode. Auto CMD23 cannot be used with SDMA. When ACMD23_ARGU2_EN is set to 1, SDMA uses ADMA System Address register (05Fh – 058h) instead of this register to support both ADMA1 and ADMA2. This register is used only for Argument2 and SDMA may use Auto CMD23. 1. **SDMA system address** Because the address must be word (4 bytes) aligned, the least two bits are reserved and always set to 0. When uSDHC stops a DMA transfer, this register points out the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operation during transfers may return an invalid value. The host driver initializes this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The host driver waits until the DLA field in the Present State register is cleared, before writing to this register. The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions. 2. **Argument 2** This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.

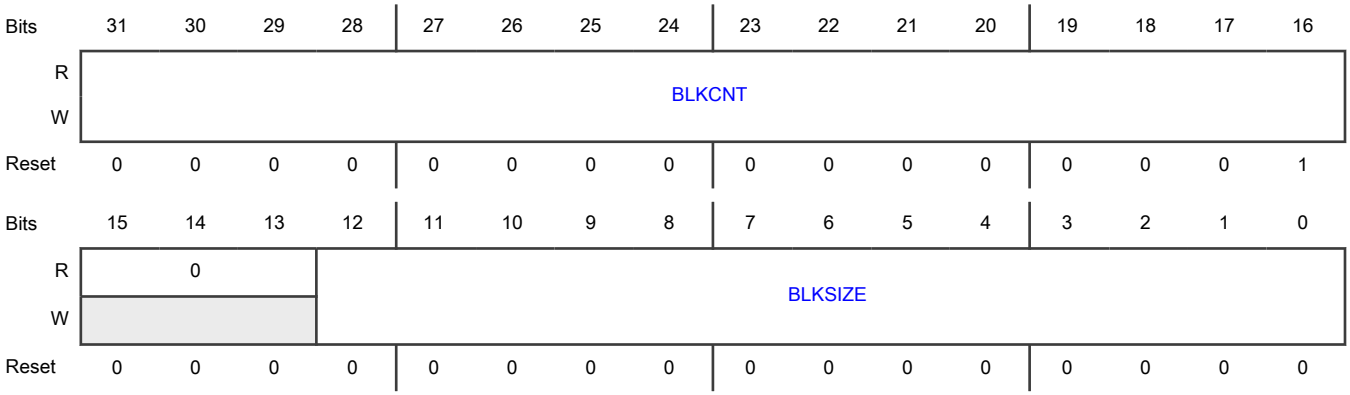
38.6.1.3 Block Attributes (BLK_ATT)

This register is used to configure the number of data blocks and the number of bytes in each block.

Offset

Register	Offset
BLK_ATT	4h

Diagram



Fields

Field	Description
31-16 BLKCNT	Blocks count for current transfer This field is enabled when the Block Count Enable field in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this field always reads as 1. The host driver sets this field to a value between 1 and the maximum block count. The uSDHC module decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to zero results in no data blocks being transferred. This field should be accessed only when no transaction is executing (that is, after transactions are stopped). During data transfer, read operations on this field may return an invalid value and write operations are ignored. When saving transfer content because of a Suspend command, the number of blocks yet to be transferred can be determined by reading this field. The reading of this field should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when the Suspend command is sent out, uSDHC treats the current transfer as stopped and change the BLKCNT field back to its original value instead of keeping the dynamical indicator of the remaining block count. When restoring transfer content prior to issuing a Resume command, the host driver restores the previously saved block count. **NOTE** Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL field is indicating a single block transfer, the read value of BLKCNT is always 1. 0000_0000_0000_0000 - Stop count 0000_0000_0000_0001 - 1 block 0000_0000_0000_0010 - 2 blocks

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1111_1111_1111_1111 - 65535 blocks
15-13 —	Reserved
12-0 BLKSIZE	Transfer block size This field specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations are ignored. 0_0000_0000_0000 - No data transfer 0_0000_0000_0001 - 1 byte 0_0000_0000_0010 - 2 bytes 0_0000_0000_0011 - 3 bytes 0_0000_0000_0100 - 4 bytes 0_0001_1111_1111 - 511 bytes 0_0010_0000_0000 - 512 bytes 0_1000_0000_0000 - 2048 bytes 1_0000_0000_0000 - 4096 bytes

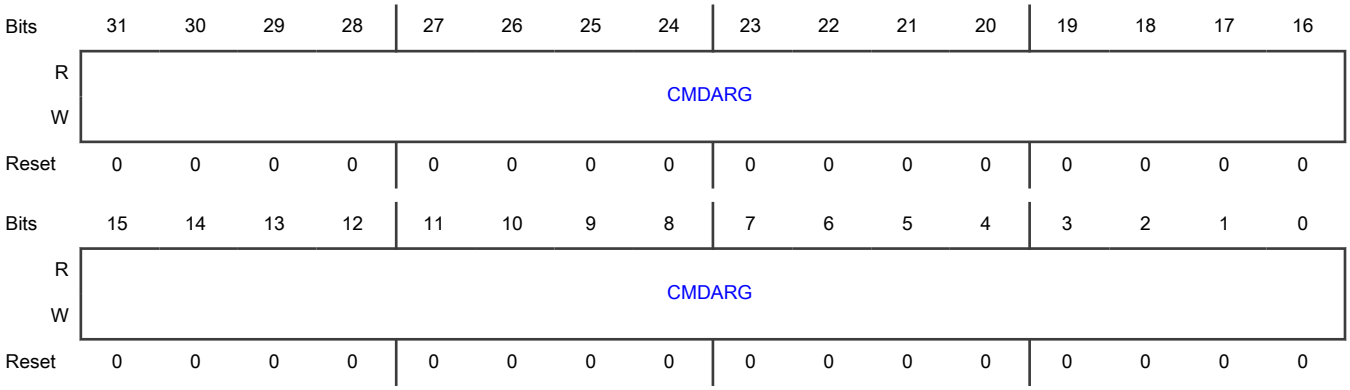
38.6.1.4 Command Argument (CMD_ARG)

This register contains the SD/eMMC command argument.

Offset

Register	Offset
CMD_ARG	8h

Diagram



Fields

Field	Description
31-0 CMDARG	Command argument The SD/eMMC command argument is specified as bits 39-8 of the command format in the SD or eMMC specification. This field is write protected when the Command Inhibit (CMD) field in the Present State register is set.

38.6.1.5 Command Transfer Type (CMD_XFR_TYP)

This register is used to control the operation of data transfers. The host driver sets this register before issuing a command followed by a data transfer or before issuing a Resume command. To prevent data loss, uSDHC prevents writing to the bits, which are involved in the data transfer of this register, when data transfer is active. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver checks the Command Inhibit DAT field (PRES_STATE[CDIHB]) and the Command Inhibit CMD field (PRES_STATE[CIHB]) in the Present State register before writing to this register. When the CDIHB field in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB field is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as a single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC ignores the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (PRES_STATE[WPSPL] field of Present State register is '1'); otherwise, WP is activated as '1', write to memory and combo cards are ignored by cards (in that case, there is no need to send write command anymore).

If the commands with data transfer do not receive the response in 64 clock cycles, that is, if response time-out happens, uSDHC treats the external device, does not accept the command, and stops the data transfer. In this scenario, the driver should issue the command again to retry the transfer. It is also possible that for some reason the card responds to the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

Table 231. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, regarding the Response Type bits as well as the name of the response type.

Table 232. Relationship between parameters and the name of the response type

Response type	Index check enable	CRC check enable	Name of response type
00	0	0	No response
01	0	1	R2
10	0	0	R3, R4
10	1	1	R1, R5, R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification, but R5b is defined in this specification to specify that uSDHC checks the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command is used with R5b.
- The CRC fields for R3 and R4 are expected to be all 1 bits. The CRC check is disabled for these response types.

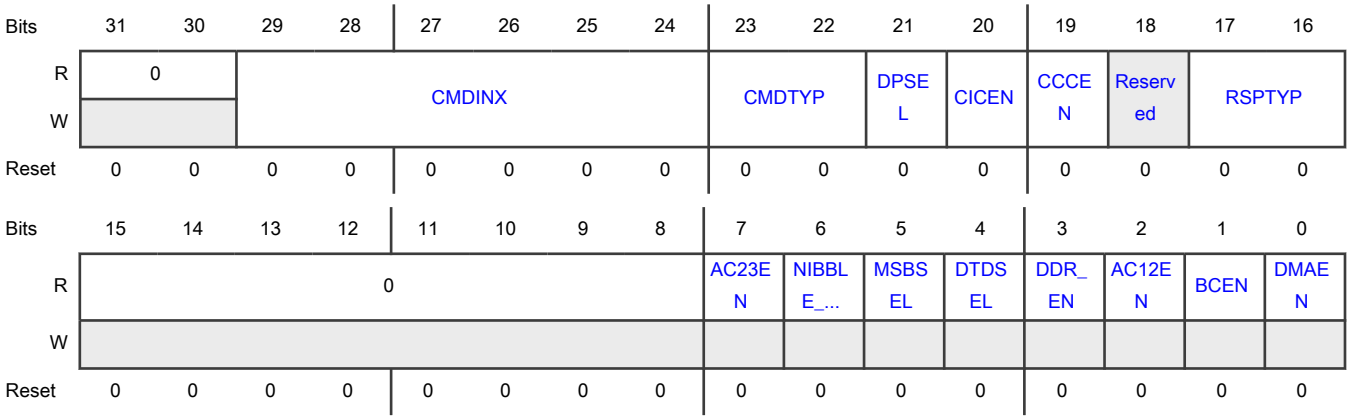
Diagram



Fields

Field	Description
31-30 —	Reserved
29-24 CMDINX	Command index

Table continues on the next page...

Table continued from the previous page...

Field	Description
	These fields are set to the command number that is specified in bits 45-40 of the command-format in the SD Memory Card Physical Layer Specification and SDIO Specification.
23-22 CMDTYP	Command type There are three types of special commands: Suspend, Resume, and Abort. These fields are set to 00b for all other commands. • Suspend command: If the Suspend command succeeds, uSDHC assumes that the card bus has been released and that it is possible to issue the next command that uses the DATA line. Because uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the host driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform uSDHC that a Suspend command was successfully issued. See Suspend Resume for more details. After the end bit of command is sent, uSDHC deasserts Read Wait for read transactions and stops checking busy for write transactions. In a 4-bit mode, the interrupt cycle starts. If the Suspend command fails, uSDHC maintains its current state, and the host driver restarts the transfer by setting the Continue Request field in the Protocol Control register. • Resume command: The host driver re-starts the data transfer by restoring the registers saved before sending the Suspend command and then sends the Resume command. The uSDHC module checks for a pending busy state before starting write transfers. • Abort command: If this command is set when executing a read transfer, uSDHC stops reads to the buffer. If this command is set when executing a write transfer, uSDHC stops driving the DATA line. After issuing the Abort command, the host driver should issue a software reset (Abort Transaction). 00 - Normal other commands 01 - Suspend CMD52 for writing bus suspend in CCCR 10 - Resume CMD52 for writing function select in CCCR 11 - Abort CMD12, CMD52 for writing I/O Abort in CCCR
21 DPSEL	Data present select This field is set to 1 to indicate that data is present and is transferred using the DATA line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52) • Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b (for example, CMD38)) **NOTE** In resume command, this field is set, and other bits in this register is set the same as when the transfer was initially launched. When the write protect switch is on, (that is, the WPSPL field is active as '0'), any command with a write operation ignored. When this field is set, while the DTDSEL field is 0, writes to the register Transfer Type are ignored. 0 - No data present 1 - Data present
20	Command index check enable

Table continues on the next page...

Table continued from the previous page...

Field	Description
CICEN	If this field is set to 1, uSDHC checks the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this field is set to 0, the Index field is not checked. 0 - Disable command index check 1 - Enables command index check
19 CCCEN	Command CRC check enable If this field is set to 1, uSDHC checks the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this field is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. See RSPTYP[1:0] and Command Transfer Type (CMD_XFR_TYP). 0 - Disables command CRC check 1 - Enables command CRC check
18 —	Reserved
17-16 RSPTYP	Response type select 00 - No response 01 - Response length 136 10 - Response length 48 11 - Response length 48, check busy after response
15-8 —	Reserved
7 AC23EN	AC23EN This field is read when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is tied to '0'. When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register. 0 - Disable 1 - Enable
6 NIBBLE_POS	NIBBLE_POS This field indicates the nibble position in the DDR 4-bit mode. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'. 0 - Disable 1 - Enable
5	MSBSEL

Table continues on the next page...

Table continued from the previous page...

Field	Description
MSBSEL	This field enables multiple block DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP). 0 - Disable 1 - Enable
4 DTDSEL	DTDSEL This field defines the direction of DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands. 0 - Disable 1 - Enable
3 DDR_EN	DDR_EN Dual data rate mode selection. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. 0 - Disable 1 - Enable
2 AC12EN	AC12EN Multiple block transfers for memory require a CMD12 to stop the transaction. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0 - Disable 1 - Enable
1 BCEN	BCEN This field is used to enable the Block Count register, which is only relevant for multiple block transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0 - Disable 1 - Enable
0 DMAEN	DMAEN This field enables DMA functionality. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register.

Fields

Field	Description
31-0 CMDRSP2	Command response 2 See Command Response3 (CMD_RSP3) for the mapping of command responses from the SD bus to this field for each response type.

38.6.1.9 Command Response3 (CMD_RSP3)

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD bus to Command Response registers for each response type. In this table, R[ ] refers to a bit range within the response data as transmitted on the SD bus.

Table 233. Response bit definition for each response type

Response type	Meaning of response	Response field	Response register
R1,R1b (normal response)	Card status	R[39:8]	CMDRSP0
R1b (auto CMD12 response)	Card status for auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (publish RCA)	New published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, uSDHC only stores part of the response data in the Command Response registers. This enables the host driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, uSDHC checks R[47:1], and if the response length is 136 the uSDHC checks R[119:1].

Because uSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows uSDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

38.6.1.10 Data Buffer Access Port (DATA_BUFF_ACC_PORT)

The Buffer Data Port register is for 32-bit data access by the Arm platform. When the internal DMA is enabled, any write to this field is ignored, and any read from this field always yields 0s.

Offset

Register	Offset
DATA_BUFF_ACC_PORT	20h

Diagram

Fields

Field	Description
31-0 DATCONT	Data content This field is used to access the internal buffer.

38.6.1.11 Present State (PRES_STATE)

The host driver can get status of uSDHC from this 32-bit read only register.

The host driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands are issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

NOTE

The reset value of Present State register depends on board connectivity.

Offset

Register	Offset
PRES_STATE	24h

Fields

Field	Description
31-24 DLSL	DATA[7:0] line signal level This field is used to check the DATA line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up. 0000_0001 - Data 0 line signal level 0000_0010 - Data 1 line signal level 0000_0100 - Data 2 line signal level 0000_1000 - Data 3 line signal level 0001_0000 - Data 4 line signal level 0010_0000 - Data 5 line signal level 0100_0000 - Data 6 line signal level 1000_0000 - Data 7 line signal level
23 CLSL	CMD line signal level This field is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this field after reset is 1'b1, when the command line is pulled up.
22-21 —	Reserved
20 —	Reserved
19 WPSPL	Write protect switch pin level

Table continues on the next page...

Table continued from the previous page...

Field	Description
	The Write Protect switch is supported for memory and combo cards. This field reflects the inverted value of the WP pin of the card socket. A software reset does not affect this field. The reset value is affected by the external write protect switch. If the WP pin is not used, it should be tied low, so that the reset value of this field is high and write is enabled. 0 - Write protected (WP = 1) 1 - Write enabled (WP = 0)
18 CDPL	Card detect pin level This field reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this field. This field may be valid, but is not guaranteed, because of propagation delay. Use of this field is limited to testing because it must be debounced by software. A software reset does not affect this field. A write to the Force Event Register does not affect this field. The reset value is affected by the external card detection pin. This field shows the value on the CD_B pin (that is, when a card is inserted in the socket, it is 0 on the CD_B input, and consequently, the CDPL reads 1. 0 - No card present (CD_B = 1) 1 - Card present (CD_B = 0)
17 —	Reserved
16 CINST	Card inserted This field indicates whether a card has been inserted. The uSDHC module debounces this signal so that the host driver does not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not affect this field. The Software Reset For All in the System Control register does not affect this field. A software reset does not affect this field. 0 - Power on reset or no card 1 - Card inserted
15 TSCD	Tap select change done This field indicates the delay setting is effective after write CLK_TUNE_CTRL_STATUS register. 0 - Delay cell select change is not finished. 1 - Delay cell select change is finished.
14-13 —	Reserved
12 RTR	Re-Tuning Request (only for SD3.0 SDR104 mode, and eMMC HS200 mode) Host controller may request host driver to execute re-tuning sequence by setting this field when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This field is cleared when a command is issued with setting Execute Tuning field in MIX_CTRL register. Changing of this field from 0 to 1 generates Re-Tuning Event. See Interrupt status registers for more detail. This field isn't set to 1 if Sampling Clock Select in the MIX_CTRL register is set to 0 (using fixed sampling clock). 0 - Fixed or well tuned sampling clock 1 - Sampling clock needs re-tuning
11 BREN	Buffer read enable This status field is used for non-DMA read transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this field is high, valid data greater than the watermark level exist in the buffer. A change of this field from 1 to 0 occurs when some reads from the buffer (read DATPORT (Base + 0x20)) are made and the buffer hasn't valid data greater than the watermark level. A change of this field from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled. 0 - Read disable 1 - Read enable
10 BWEN	Buffer write enable This status field is used for non-DMA write transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this field is 1, valid data greater than the watermark level can be written to the buffer. A change of this field from 1 to 0 occurs when some writes to the buffer (write DATPORT (Base + 0x20)) are made and the buffer hasn't valid space greater than the watermark level. A change of this field from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled. 0 - Write disable 1 - Write enable
9 RTA	Read transfer active This status field is used for detecting completion of a read transfer. This field is set for either of the following conditions: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer A transfer complete interrupt is generated when this field changes to 0. This field is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the System, that is, all data are read away from uSDHC internal buffer. • When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent because of the Stop At Block Gap Request being set to 1. 0 - No valid data

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Transferring data
8 WTA	Write transfer active This status field indicates a write transfer is active. If this field is 0, it means no valid write data exists in uSDHC. This field is set in either of the following cases: • After the end field of the write command • When writing 1 to the Continue Request field in the Protocol Control register to restart a write transfer This field is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple) • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request During a write transaction, a Block Gap Event interrupt is generated when this field is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the host driver in determining when to issue commands during Write Busy state. 0 - No valid data 1 - Transferring data
7-4 —	Reserved
3 SDSTB	SD clock stable This status field indicates that the internal card clock is stable. This field is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON field in System Control register to remove glitches on the card clock when the frequency is changing. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. 0 - Clock is changing frequency and not stable. 1 - Clock is stable.
2 DLA	Data line active This status field indicates whether one of the DATA lines on the SD bus is in use. In the case of read transactions: This status indicates if a read transfer is executing on the SD bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the read command

Table continues on the next page...

Table continued from the previous page...

Field	Description
	• When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer This field is cleared in either of the following cases: • When the end field of the last data block is sent from the SD bus to uSDHC. • When the Read Wait state is stopped by a Suspend command and the DATA2 line is released. The uSDHC module waits at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait to use the suspend / resume function. This field remains 1 during Read Wait. In the case of write transactions: This status indicates that a write transfer is executing on the SD bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the write command • When writing to 1 to the Continue Request field in the Protocol Control register to continue a write transfer This field is cleared in either of the following cases: • When the SD card releases Write Busy of the last data block, uSDHC also detects if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, uSDHC assumes the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and because of a Stop At Block Gap Request. In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This field is cleared when the DATA0 line is released. 0 - DATA line inactive 1 - DATA line active
1 CDIHB	Command Inhibit Data (DATA) This status field is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this field is 0, it indicates that uSDHC can issue the next SD / eMMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register. **NOTE** The SD host driver can save registers for a suspend transaction after this field has changed from 1 to 0. 0 - Can issue command that uses the DATA line 1 - Cannot issue command that uses the DATA line

Table continues on the next page...

Table continued from the previous page...

Field	Description
0 CIHB	Command inhibit (CMD) If this status bit is 0, it indicates that the CMD line is not in use and uSDHC can issue a SD / eMMC command using the CMD line. This field is set also immediately after the Transfer Type register is written. This field is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, commands using only the CMD line can be issued if this field is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If uSDHC cannot issue the command because of a command conflict error (see Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this field remains 1 and the Command Complete is not set. The Status of issuing an auto CMD12 does not show on this field. 0 - Can issue command using only CMD line 1 - Cannot issue command

38.6.1.12 Protocol Control (PROT_CTRL)

This register controls three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether uSDHC issues a Suspend command or the SD card accepts the Suspend command.

- If the host driver does not issue a Suspend command, the Continue request is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card accepts it, a Resume command is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card does not accept it, the Continue request is used to restart the transfer.

Any time stop at block gap request stops the data transfer, the host driver waits for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the host driver clears the Stop At Block Gap Request before or simultaneously.

Offset

Register	Offset
PROT_CTRL	28h

Fields

Field	Description
31 —	Reserved Always write as 0
30 NON_EXACT_BLK_RD	Non-exact block read Current block read is non-exact block read. It is only used for SDIO. 0 - The block read is exact block read. Host driver does not need to issue abort command to terminate this multi-block read. 1 - The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read.
29-27 —	Reserved
26 WECRM	Wakeup event enable on SD card removal This field enables a wakeup event, via a card removal, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Removal Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Removal Status and uSDHC interrupt. 0 - Disables wakeup event enable on SD card removal 1 - Enables wakeup event enable on SD card removal
25 WECINS	Wakeup event enable on SD card insertion This field enables a wakeup event, via a card insertion, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Insertion Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Insertion Status and uSDHC interrupt. 0 - Disable wakeup event enable on SD card insertion 1 - Enable wakeup event enable on SD card insertion
24 WECINT	Wakeup event enable on card interrupt This field enables a wakeup event, via a card interrupt, in the Interrupt Status register. This field can be set to 1 if FN_WUS (Wakeup Support) in CIS is set to 1. When this field is set, the Card Interrupt Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Interrupt Status and uSDHC interrupt. 0 - Disables wakeup event enable on card interrupt 1 - Enables wakeup event enable on card interrupt
23-21 —	Reserved Always write as 3'b100
20	Read performed number 8 clock

Table continues on the next page...

Table continued from the previous page...

Field	Description
RD_DONE_NO_8CLK	According to the SD/eMMC spec, for read data transaction, 8 clocks are needed after the end field of the last data block. So, by default(RD_DONE_NO_8CLK=0), eight clocks are active after the end field of the last read data transaction. However, these 8 clocks should not be active if user wants to use stop at block gap (include the auto stop at block gap in boot mode) feature for read and the RWCTL field (bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid these 8 clocks. Otherwise, the device might send extra data to uSDHC while uSDHC ignores these data. In a summary, this field should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.
19 IABG	Interrupt at block gap This field is valid only in 4-bit mode, of SDIO, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If SDIO cannot signal an interrupt during a multiple block transfer, this field should be set to 0 to avoid an inadvertent interrupt. When the host driver detects an SDIO insertion, it sets this field according to the CCCR of the card. 0 - Disables interrupt at block gap 1 - Enables interrupt at block gap
18 RWCTL	Read wait control The read wait function provided by this field is optional for SDIO. If the card supports read wait, set this field to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise, uSDHC has to stop the SD clock to hold read data, which restricts commands generation. When the host driver detects an SDIO insertion, it sets this field according to the CCCR of the card. If the card does not support read wait, this field should never be set to 1; otherwise, DATA line conflicts might occur. If this field is set to 0, stop at block gap during read operation is also supported, but uSDHC stops the SD clock to pause reading operation. 0 - Disables read wait control and stop SD clock at block gap when SABGREQ field is set 1 - Enables read wait control and assert read wait without stopping SD clock at block gap when SABGREQ field is set
17 CREQ	Continue request This field is used to restart a transaction which was stopped using the stop at block gap request. When a suspend operation is not accepted by the card, it is also by setting this field to restart the paused transfer. To cancel stop at the block gap, set stop at block gap request to 0 and set this field to 1 to restart the transfer. The uSDHC module automatically clears this field, therefore it is not necessary for the host driver to set this field to 0. If both stop at block gap request and this field are 1, the continue request is ignored. 0 - No effect 1 - Restart
16 SABGREQ	Stop at block gap request This field is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the transfer complete is set to 1, indicating a transfer completion, the host driver leaves this field set to 1. Clearing both the stop at block gap request and continue request does not cause the transaction to

Table continues on the next page...

Table continued from the previous page...

Field	Description
	restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC module supports the stop at block gap request for write transfers, but for read transfers it requires that SDIO support read wait. Therefore, the host driver does not set this field during read transfers unless SDIO supports Read Wait and has set the read wait control to 1; otherwise, uSDHC stops the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the host driver writes data to the Data Port register, the host driver sets this field after all block data is written. If this field is set to 1, the host driver does not write data to the Data Port register after a block is sent. Once this field is set, the host driver does not clear this field before the Transfer Complete field in Interrupt Status register is set, otherwise uSDHC's behavior is undefined. This field effects read transfer active, write transfer active, DATA Line Active and Command Inhibit (DATA) in the Present State register. 0 - Transfer 1 - Stop
15-10 —	Reserved
9-8 DMASEL	DMA select This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00 - No DMA or simple DMA is selected. 01 - ADMA1 is selected. 10 - ADMA2 is selected. 11 - Reserved
7 —	Reserved
6 —	Reserved
5-4 EMODE	Endian mode This field supports all three endian modes in data transfer. See Data buffer for more details. 00 - Big endian mode 01 - Half word big endian mode 10 - Little endian mode 11 - Reserved
3 D3CD	DATA3 as card detection pin If this field is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 might set the card into the SPI mode, which uSDHC does not support.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - DATA3 does not monitor card insertion 1 - DATA3 as card detection pin
2-1 DTW	Data transfer width This field selects the data width of the SD bus for a data transfer. The host driver sets it to match the data width of the card. Possible data transfer width is 1-bit, 4-bits or 8-bits. 00 - 1-bit mode 01 - 4-bit mode 10 - 8-bit mode 11 - Reserved
0 —	Reserved

38.6.1.13 System Control (SYS_CTRL)

This register provides control of the system. See detail in the field description.

Offset

Register	Offset
SYS_CTRL	2Ch

Field	Description
—	
28 RSTT	Reset tuning When set this field to 1, it resets tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning field in AUTOCMD12_ERR_STATUS also sets this field to 1 to reset tuning circuit
27 INITA	Initialization active When this field is set, 80 SD-clocks are sent to the card. After the 80 clocks are sent, this field is self cleared. This field is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this field is already 1 has no effect. Writing 0 to this field at any time has no effect. When either of the CIHB and CDIHB fields in the Present State register are set, writing 1 to this field is ignored (that is, when command line or data lines are active, write to this field is not allowed). On the other-hand, when this field is set, that is, during initialization active period, it is allowed to issue command, and the command bit stream appears on the CMD pad after all 80 clock cycles are done. So, when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs to send 80 cycles to the card and does not want to wait till this field is self cleared.
26 RSTD	Software reset for data line Only part of the data circuit is reset. DMA circuit is also reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Data Port register — Buffer is cleared and initialized • Present State register — Buffer read enable — Buffer write enable — Read transfer active — Write transfer active — DATA line active — Command Inhibit (DATA) • Protocol Control register — Continue request • Interrupt Status register — Buffer read ready — Buffer write ready — DMA interrupt — Block gap event — Transfer complete

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0 - No reset 1 - Reset
25 RSTC	Software reset for CMD line Only part of the command circuit is reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Present State Register — Command Inhibit (CMD) • Interrupt Status Register — Command Complete 0 - No reset 1 - Reset
24 RSTA	Software reset for all This reset affects the entire host controller except for the card detection circuit. RSTA resets all the registers that can be reset by RSTC/RSTD. During its initialization, the host driver is set this field to 1 to reset uSDHC. The uSDHC module resets this field to 0 when the capabilities registers are valid and the host driver can read them. Additional use of Software Reset For All does not affect the value of the capabilities registers. After this field is set, it is recommended that the host driver reset the external card and re-initialize it. After this field is set, the software should wait for self-clear. In tuning process, after every CMD19 is finished, this field is set to retest uSDHC. **NOTE** When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0 - No reset 1 - Reset
23 IPP_RST_N	Hardware reset This field has alternative function as below: • eMMC: be used to reset eMMC, through pad directly to eMMC RST_n pin. • Card: be used to control SD Card power enable or disable during warm reset, through pad directly to hardware reset on board.
22 RST_FIFO	Reset the async FIFO Reset the async FIFO between card interface and the internal logic. After this field is set, the software waits for self-clear.

Table continues on the next page...

Table continued from the previous page...

Field	Description
21 —	Reserved
20 —	Reserved
19-16 DTOCV	Data timeout counter value This value determines the interval by which DAT line timeouts are detected. See the Data Timeout Error field in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency is generated by dividing the base clock SDCLK value by this value. The host driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events. 0000 - SDCLK x 2^{32} 0001 - SDCLK x 2^{33} 0010 - SDCLK x 2^{18} 0011 - SDCLK x 2^{19} 1101 - SDCLK x 2^{29}, recommend to use for supported speed modes except HS200, HS400, SDR104 mode 1110 - SDCLK x 2^{30}, recommend to use for HS200 and SDR104 mode 1111 - SDCLK x 2^{31}, recommend to use for HS400 mode
15-8 SDCLKFS	SDCLK frequency select This field is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this field holds the prescaler (of this register) and divisor (next register) of the Base Clock Frequency register. In Single Data Rate mode (DDR_EN field of MIXERCTRL is '0') Only the following settings are allowed: 80h) Base clock divided by 256 40h) Base clock divided by 128 20h) Base clock divided by 64 10h) Base clock divided by 32 08h) Base clock divided by 16 04h) Base clock divided by 8 02h) Base clock divided by 4 01h) Base clock divided by 2 00h) Base clock divided by 1 While in Dual Data Rate mode (DDR_EN field of MIXERCTRL is '1') Only the following settings are allowed:

Table continues on the next page...

Table continued from the previous page...

Field	Description
	80h) Base clock divided by 512 40h) Base clock divided by 256 20h) Base clock divided by 128 10h) Base clock divided by 64 08h) Base clock divided by 32 04h) Base clock divided by 16 02h) Base clock divided by 8 01h) Base clock divided by 4 00h) Base clock divided by 2 When the software changes the DDR_EN field, SDCLKFS might need to be changed also. In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / (prescaler x divisor) For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h yields 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD clock after reset is 375 kHz. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. If setting SDCLKFS and DVS can generate the same clock frequency,(for example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.), SDCLKFS is highly recommended. For HS400 mode, SDCLKFS must be used so that REF_CLK, generated for STROBE DLL, is at the same frequency as STROBE clock. For HS200 mode, if DLL is to be used, make sure SDCLKFS is used so that REF_CLK, generated for PARTS DLL, is at the same frequency as SD_CLK. For SDR104 mode, if DLL is to be used, make sure SDCLKFS is used so that REF_CLK, generated for PARTS DLL, is at the same frequency as SD_CLK.
7-4 DVS	Divisor This field is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle. Before changing clock divisor value (SDCLKFS or DVS), Host driver should make sure the SDSTB field is high. The settings are as follows:

Field	Description
	0000 - Divide-by-1 0001 - Divide-by-2 1110 - Divide-by-15 1111 - Divide-by-16
3-0 —	Reserved Always write as 1.

38.6.1.14 Interrupt Status (INT_STATUS)

An interrupt is generated when the normal interrupt signal enable is enabled and at least one of the status fields is set to 1. For all fields, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For card interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the card driver services the interrupt condition; otherwise, the CINT field is asserted again.

The table below shows the relationship between the command timeout error and the command complete.

Table 234. uSDHC status for command timeout error/command complete bit combinations

Command complete	Command timeout error	Meaning of the status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the transfer complete and the data timeout error.

Table 235. uSDHC status for data timeout error/transfer complete bit combinations

Transfer complete	Data timeout error	Meaning of the status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data transfer complete

The table below shows the relationship between the command CRC error and command timeout error.

Table 236. uSDHC status for command CRC error/command timeout error bit combinations

Command CRC error	Command timeout error	Meaning of the status
0	0	No error
0	1	Response timeout error

Table continues on the next page...

Table 236. uSDHC status for command CRC error/command timeout error bit combinations (continued)

Command CRC error	Command timeout error	Meaning of the status
1	0	Response CRC error
1	1	CMD line conflict

Fields

Field	Description
31 —	Reserved
30-29 —	Reserved
28 DMAE	DMA error Occurs when an Internal DMA transfer has failed. This field is set to 1, when some error occurs in the data transfer. This error can be caused by either simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Because any error corrupts the whole data block, the host driver restarts the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 0 - No error 1 - Error

Table continues on the next page...

Table continued from the previous page...

Field	Description
27 —	Reserved
26 TNE	Tuning error: (only for SD3.0 SDR104 mode and eMMC HS200 mode) This field is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, host driver needs to abort a command executing and perform tuning. This field is relevant in combination with the bus error only and must be cleared prior to all the write and read transactions.
25 —	Reserved
24 AC12E	Auto CMD12 error Occurs when detecting that one of the fields in the Auto CMD12 Error Status register has changed from 0 to 1. This field is set to 1, not only when the errors in Auto CMD12 occur, but also, when the Auto CMD12 is not executed due to the previous command error. 0 - No error 1 - Error
23 —	Reserved
22 DEBE	Data end bit error Occurs either when detecting 0 at the end field position of read data that uses the DATA line, or at the end field position of the CRC. This field is not asserted in tuning process. 0 - No error 1 - Error
21 DCE	Data CRC error Occurs when detecting a CRC error when transferring read data that uses the DATA line, or when detecting the Write CRC status having a value other than 010. This field is not asserted in tuning process. 0 - No error 1 - Error
20 DTOE	Data timeout error Occurs when detecting one of following time-out conditions. • Busy time-out for R1b, R5b type • Busy time-out after Write CRC status • Read Data time-out.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This field is not asserted in tuning process. 0 - No error 1 - Time out
19 CIE	Command index error Occurs if a command index error occurs in the command response. This field is not asserted in tuning process. 0 - No error 1 - Error
18 CEBE	Command end bit error Occurs when detecting that the end field of a command response is 0. This field is not asserted in tuning process. 0 - No error 1 - End bit error generated
17 CCE	Command CRC error Command CRC Error is generated in two cases. • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this field is set when detecting a CRC error in the command response. • The uSDHC module detects a CMD line conflict by monitoring the CMD line when a command is issued. If uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then uSDHC stops the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error should also be set to 1 to distinguish CMD line conflict. This field is not asserted in tuning process. 0 - No error 1 - CRC error generated
16 CTOE	Command timeout error Occurs only if no response is returned within 64 SDCLK cycles from the end field of the command. If uSDHC detects a CMD line conflict, in which case a Command CRC Error is also be set (as shown in Interrupt Status (INT_STATUS)), this field is set without waiting for 64 SDCLK cycles. This is because the command is stopped by uSDHC. This field is not asserted in tuning process. 0 - No error 1 - Time out
15	Error Interrupt Status

Table continues on the next page...

Table continued from the previous page...

Field	Description
ERR_INT_STATUS	This bit is set when any of the error status bit DMAE, AC12E, DEBE, DCE, DTOE, CIE, CEBE, CCE and CTOE is set.
14 CQI	Command queuing interrupt This interrupt is asserted when at least one of the bits in CQIS register is set. This interrupt is cleared only by clearing the source interrupt in CQIS register.
13 TP	Tuning pass:(only for SD3.0 SDR104 mode and eMMC HS200 mode) Current CMD19 transfer is done successfully. That is, current sampling point is correct.
12 RTE	Re-tuning event: (only for SD3.0 SDR104 mode and eMMC HS200 mode) This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. host controller requests host driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning. 0 - Re-tuning is not required. 1 - Re-tuning should be performed.
11 —	Reserved
10-9 —	Reserved
8 CINT	Card interrupt This status field is set when an interrupt signal is detected from the external card. In 1-bit mode, uSDHC detects the Card Interrupt without the SD clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from SDIO and the interrupt to the host system. Writing this field to 1 can clear this field, but as the interrupt source from SDIO does not clear, this field is set again. to clear this field, it is required to reset the interrupt source from the external card followed by a writing 1 to this field. When this status has been set, and the host driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the host system. After completion of the card interrupt service (It should reset the interrupt sources in SDIO and the interrupt signal might not be asserted), write 1 to clear this field, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again. 0 - No card interrupt 1 - Generate card interrupt
7 CRM	Card removal This status field is set if the Card Inserted field in the Present State register changes from 1 to 0. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field

Table continues on the next page...

Table continued from the previous page...

Field	Description
	and the interrupt event might not be generated. When this field is cleared, it is set again if no card is inserted. to leave it cleared, clear the Card Removal Status Enable field in Interrupt Status Enable register. 0 - Card state unstable or inserted 1 - Card removed
6 CINS	Card insertion This status field is set if the Card Inserted field in the Present State register changes from 0 to 1. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if a card is inserted. to leave it cleared, clear the Card Inserted Status Enable field in Interrupt Status Enable register. 0 - Card state unstable or removed 1 - Card inserted
5 BRR	Buffer read ready This status field is set if the Buffer Read Enable field, in the Present State register, changes from 0 to 1. See the Buffer Read Enable field in the Present State register for additional information. This field indicates that cmd19 is finished in tuning process. 0 - Not ready to read buffer 1 - Ready to read buffer
4 BWR	Buffer write ready This status field is set if the Buffer Write Enable field, in the Present State register, changes from 0 to 1. See the Buffer Write Enable field in the Present State register for additional information. 0 - Not ready to write buffer 1 - Ready to write buffer
3 DINT	DMA interrupt Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this field does not be set. Instead, the DMAE field is set. Either Simple DMA or ADMA finishes data transferring, this field is set. 0 - No DMA interrupt 1 - DMA interrupt is generated.
2 BGE	Block gap event If the Stop At Block Gap Request field in the Protocol Control register is set, this field is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this field is not set to 1. In the case of a Read Transaction: This field is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD bus timing). The Read Wait must be supported to use this function.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	In the case of Write Transaction: This field is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). 0 - No block gap event 1 - Transaction stopped at block gap
1 TC	Transfer complete This field is set when a read or write transfer is completed. In the case of a Read Transaction: This field is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the host system). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request field in the Protocol Control register (after valid data has been read to the host system). In the case of a Write Transaction: This field is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request field in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released). In the case of a command with busy, this field is set when busy is deasserted. This field is not asserted in tuning process. 0 - Transfer does not complete 1 - Transfer complete
0 CC	Command complete This field is set when you receive the end field of the command response (except auto CMD12). See the Command Inhibit (CMD) in the Present State register. This field is not asserted in tuning process. 0 - Command not complete 1 - Command complete

38.6.1.15 Interrupt Status Enable (INT_STATUS_EN)

Setting any bit in this register to 1 enables the corresponding interrupt status be requested to the system. If any bit is set to 0, the corresponding interrupt request gets blocked.

- Depending on IABG field setting, uSDHC might be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There are some delays on the Card Interrupt, asserted from the card, to the time the host system is informed.
- To detect a CMD line conflict, the host driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

38.6.1.16 Interrupt Signal Enable (INT_SIGNAL_EN)

This register is used to select which interrupt status is indicated to the host system as the interrupt. These status fields all share the same interrupt lines. Setting any of these fields to 1 enables interrupt generation. The corresponding Status register field generates an interrupt when the corresponding interrupt signal enable field is set.

Offset

Register	Offset
INT_SIGNAL_EN	38h

38.6.1.17 Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS)

When the Auto CMD12 Error Status field in the Status register is set, the host driver checks this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in field 04-01. This register is valid only when the Auto CMD12 Error status field is set.

The table below shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 237. Relationship between command CRC error and command timeout error for auto CMD12

Auto CMD12 CRC error	Auto CMD12 timeout error	Type of error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

- When uSDHC is going to issue an Auto CMD12
  - Set field 0 to 1 if the Auto CMD12 cannot be issued due to an error in the previous command
  - Set field 0 to 0 if the Auto CMD12 is issued

- At the end field of an Auto CMD12 response
  - — Check errors correspond to fields 1-4
  - — Set fields 1-4 corresponding to detected errors
  - — Clear fields 1-4 corresponding to detected errors
- Before reading the Auto CMD12 Error Status field 7
  - — Set field 7 to 1 if there is a command that can't be issued
  - — Clear field 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, field 7 is sampled when the driver is not writing to the Command register. So, it is suggested to read this register only when the AC12E field in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error fields (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

Offset

Register	Offset
AUTOCMD12_ERR_STATUS	3Ch

Field	Description
31-26 —	Reserved
25 —	Reserved
24 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
23 SMP_CLK_SEL	Sample clock select This field is used to select sampling clock to receive CMD and DATA. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is controlled by re-tuning procedure and is valid after the tuning procedure is complete (AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=0). A value of '1' means that tuning has been completed successfully and a value of '0' implies the tuning has failed. Writing '1' to this field is meaningless and ignored when the tuning has failed. The tuning circuit is reset by writing '0' to this field. This field can be cleared by setting AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=1. Once the tuning circuit is reset, it takes time to complete tuning sequence. Therefore, host driver should keep this field as 1 to perform the re-tuning sequence in a short time. This field cannot be changed while the Host controller is receiving response or a read data block. 0 - Fixed clock is used to sample data 1 - Tuned clock is used to sample data
22 EXECUTE_TUNING	Execute tuning This field is used to start the tuning procedure. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is set to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to AUTOCMD12_ERR_STATUS[SMP_CLK_SEL]. 0 - Tuning procedure is stopped 1 - Start tuning procedure
21-19 —	Reserved
18 —	Reserved
17-8 —	Reserved
7 CNIBAC12E	Command not issued by Auto CMD12 error Setting this field to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 error (D04-D01) in this register. 0 - No error 1 - Not issued
6-5 —	Reserved
4 AC12IE	Auto CMD12 / 23 index error Occurs if the command index error occurs in response to a command.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - No error 1 - Error, the CMD index in response is not CMD12/23
3 AC12EBE	Auto CMD12 / 23 end bit error Occurs when detecting that the end field of command response is 0 which should be 1. 0 - No error 1 - End bit error generated
2 AC12CE	Auto CMD12 / 23 CRC error Occurs when detecting a CRC error in the command response. 0 - No CRC error 1 - CRC error met in Auto CMD12/23 response
1 AC12TOE	Auto CMD12 / 23 timeout error Occurs if no response is returned within 64 SDCLK cycles from the end field of the command. If this field is set to1, the other error status fields (2-4) have no meaning. 0 - No error 1 - Time out
0 AC12NE	Auto CMD12 not executed If memory multiple block data transfer is not started, due to a command error, this field is not set because it is not necessary to issue an Auto CMD12. Setting this field to 1 means uSDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this field is set to 1, other error status fields (1-4) have no meaning. 0 - Executed 1 - Not executed

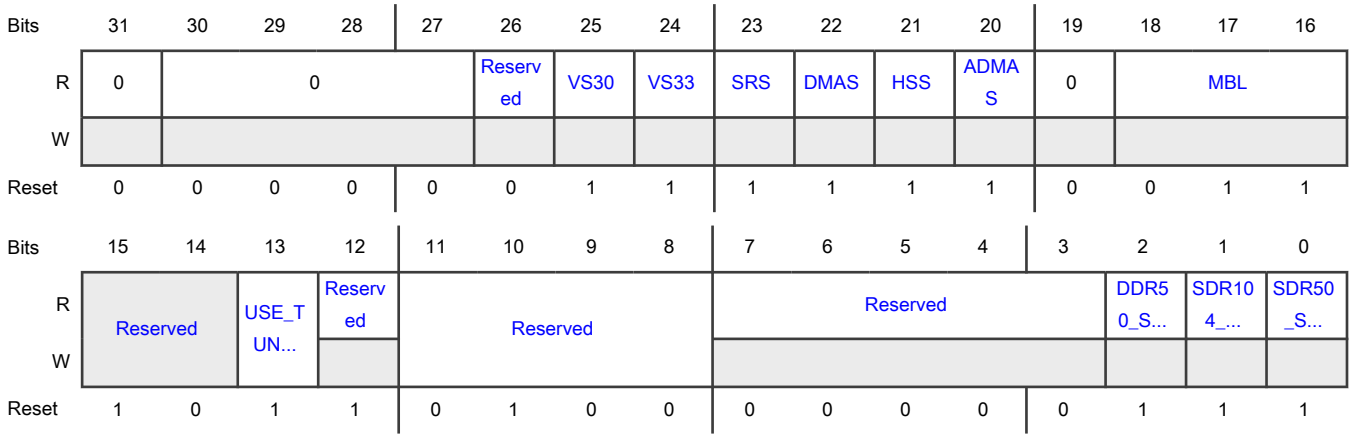
38.6.1.18 Host Controller Capabilities (HOST_CTRL_CAP)

This register provides the host driver with information specific to uSDHC implementation. The value in this register is the power-on-reset value and does not change with a software reset.

Offset

Register	Offset
HOST_CTRL_CAP	40h

Diagram



Fields

26 —	Reserved
25 VS30	Voltage support 3.0 V This field depends on the host system ability. 0 - 3.0 V not supported 1 - 3.0 V supported
24 VS33	Voltage support 3.3 V This field depends on the host system ability. 0 - 3.3 V not supported 1 - 3.3 V supported
23 SRS	Suspend / resume support This field indicates whether uSDHC supports Suspend / Resume functionality. If this field is 0, the Suspend and Resume mechanism, as well as the read wait, are not supported, and the host driver does not issue either Suspend or Resume commands. 0 - Not supported 1 - Supported
22	DMA support

Table continues on the next page...

Table continued from the previous page...

Field	Description
DMAS	This field indicates whether uSDHC can use the internal DMA to transfer data between system memory and the data buffer directly. 0 - DMA not supported 1 - DMA supported
21 HSS	High speed support This field indicates whether uSDHC supports High Speed mode and the host system can supply a SD clock frequency from 25 MHz to 50 MHz. 0 - High speed not supported 1 - High speed supported
20 ADMAS	ADMA support This field indicates whether uSDHC supports the ADMA feature. 0 - Advanced DMA not supported 1 - Advanced DMA supported
19 —	Reserved
18-16 MBL	Max block length This field indicates the maximum block size that the host driver can read and write to the buffer in uSDHC. The buffer transfers block size without wait cycles. 000 - 512 bytes 001 - 1024 bytes 010 - 2048 bytes 011 - 4096 bytes
15-14 —	Reserved
13 USE_TUNING_SDR50	Use Tuning for SDR50 This field is used to enable tuning for SDR50 mode 0 - SDR50 does not support tuning 1 - SDR50 supports tuning
12 —	Reserved
11-8 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
7-3 —	Reserved
2 DDR50_SUPPORT	DDR50 support This field indicates support of DDR50 mode.
1 SDR104_SUPPORT	SDR104 support This field indicates support of SDR104 mode.
0 SDR50_SUPPORT	SDR50 support This field indicates support of SDR50 mode.

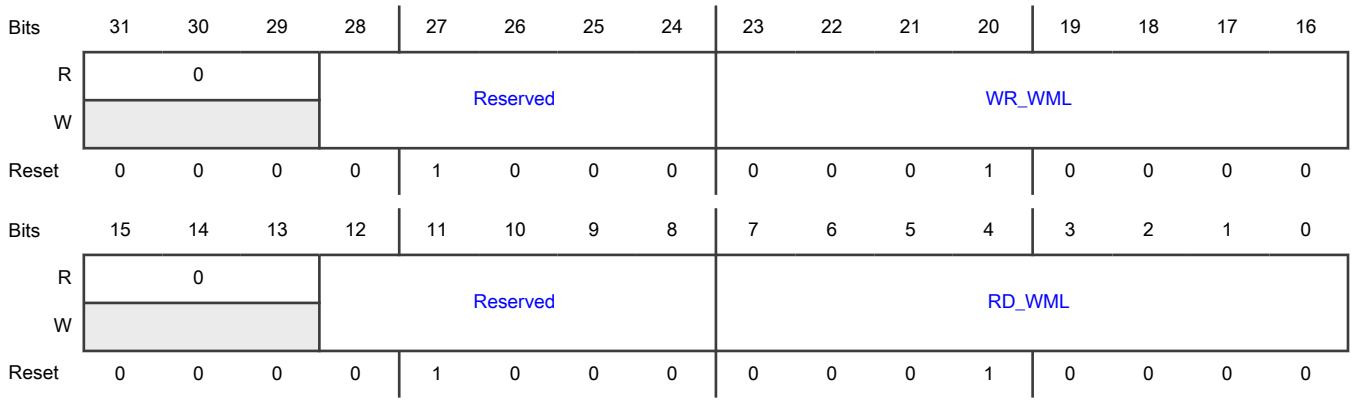
38.6.1.19 Watermark Level (WTMK_LVL)

This register indicates configurability of write and read watermark levels (FIFO threshold). Their value can range from 1 to 128 words.

Offset

Register	Offset
WTMK_LVL	44h

Diagram



Fields

Field	Description
31-29 —	Reserved
28-24 —	Reserved
23-16 WR_WML	Write watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also, the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.When using internal DMA, WR_WML can be set any value between 1 and 128. To get max AXI throughput, we recommend to use integer multiple of 16.
15-13 —	Reserved
12-8 —	Reserved
7-0 RD_WML	Read watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also, the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.When using internal DMA mode, RD_WML must be set to the value less than 16. To get max AXI throughput, recommend to use 16.

38.6.1.20 Mixer Control (MIX_CTRL)

This register is used to DMA and data transfer. To prevent data loss, the software should check if data transfer is active before writing this register. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

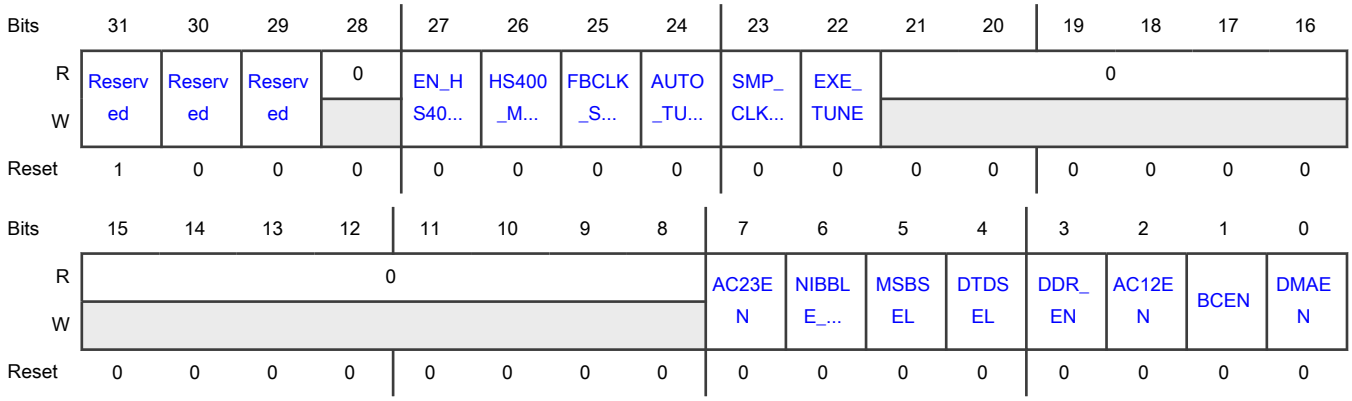
Table 238. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

Offset

Register	Offset
MIX_CTRL	48h

Diagram



Fields

Field	Description
31 —	Reserved Always write as 1.
30 —	Reserved Always write as 0.
29 —	Reserved Always write as 0.
28 —	Reserved
27 EN_HS400_MODE	Enable enhance HS400 mode Enhance HS400 enable
26 HS400_MODE	Enable HS400 mode HS400 Enable
25 FBCLK_SEL	Feedback clock source selection (Only used for SD3.0, SDR104 mode and eMMC HS200 mode) 0 - Feedback clock comes from the loopback CLK 1 - Feedback clock comes from the ipp_card_clk_out
24 AUTO_TUNE_EN	Auto tuning enable (Only used for SD3.0, SDR104 mode and eMMC HS200 mode) 0 - Disable auto tuning 1 - Enable auto tuning
23 SMP_CLK_SEL	Clock selection When TUNING_CTRL[STD_TUNING_EN] is 0, this field is used to select Tuned clock or Fixed clock to sample data / cmd (Only used for SD3.0, SDR104 mode and eMMC HS200 mode)

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - Fixed clock is used to sample data / cmd 1 - Tuned clock is used to sample data / cmd
22 EXE_TUNE	Execute tuning: (Only used for SD3.0, SDR104 mode and eMMC HS200 mode) When TUNING_CTRL[STD_TUNING_EN] is 0, this field is set to 1 to indicate the host driver is starting tuning procedure. Tuning procedure is stopped by writing 0. 0 - Not tuned or tuning completed 1 - Execute tuning
21-8 —	Reserved
7 AC23EN	Auto CMD23 enable This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register.
6 NIBBLE_POS	Nibble position indication This field indicates the nibble position in the DDR 4-bit mode. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single block select This field enables multiple block DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP). 0 - Single block 1 - Multiple blocks
4 DTDSEL	Data transfer direction select This field defines the direction of DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands. 0 - Write (Host to card) 1 - Read (Card to host)
3 DDR_EN	Dual data rate mode selection This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only.
2	Auto CMD12 enable

Table continues on the next page...

Table continued from the previous page...

Field	Description
AC12EN	Multiple block transfers for memory require a CMD12 to stop the transaction. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0 - Disable 1 - Enable
1 BCEN	Block count enable This field is used to enable the Block Count register, which is only relevant for multiple block transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0 - Disable 1 - Enable
0 DMAEN	DMA enable This field enables DMA functionality. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register. 0 - Disable 1 - Enable

38.6.1.21 Force Event (FORCE_EVENT)

This register is not a physically implemented register. Rather, it is an address at which the Interrupt Status register can be written if the corresponding field of the Interrupt Status Enable Register is set. Writing 1 to this register sets the corresponding field of Interrupt Status register, while writing 0 to it has no effect. A read from this register always results in 0's. To change the corresponding status fields in the Interrupt Status register, make sure to set IPGEN field in System Control Register so that peripheral clock is always active.

Forcing a card interrupt generates a short pulse on the DATA1 line, and the driver might treat this interrupt as a normal interrupt. The interrupt service routine might skip polling the card interrupt factor as the interrupt is self cleared.

Offset

Register	Offset
FORCE_EVENT	50h

3 FEVTAC12EBE	Force event Auto Command 12 end bit error Forces the AC12EBE field in the Auto Command12 Error Status register to be set
2 FEVTAC12CE	Force event auto command 12 CRC error Forces the AC12CE field in the Auto Command12 Error Status register to be set
1 FEVTAC12TOE	Force event auto command 12 time out error Forces the AC12TOE field in the Auto Command12 Error Status register to be set
0 FEVTAC12NE	Force event auto command 12 not executed Forces the AC12NE field in the Auto Command12 Error Status register to be set

38.6.1.22 ADMA Error Status (ADMA_ERR_STATUS)

When an ADMA Error Interrupt has occurred, the ADMA error sates field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the host driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.
- ST_CADR: This state is never set because it only increments the descriptor pointer and does not generate an ADMA error.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the host driver should use the ACMD22 to get the number of the written block, rather than using this information, because unwritten data might exist in the host controller.

The host controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The host driver can distinguish this error by reading the Valid field of the error descriptor.

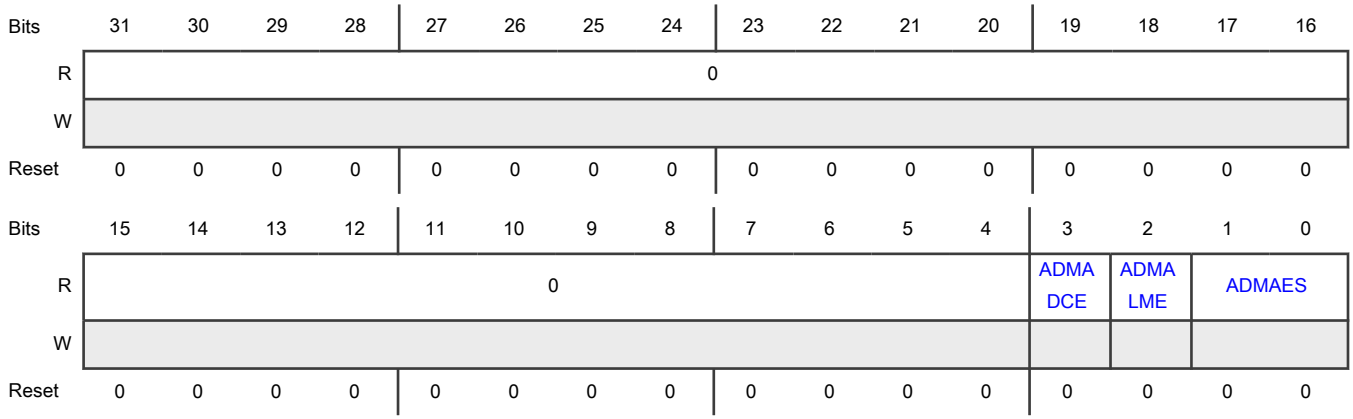
Table 239. ADMA error state coding

D01-D00	ADMA error state (when error has occurred)	Contents of ADMA System Address register
00	ST_STOP (Stop DMA)	Holds the address of the next executable descriptor command
01	ST_FDS (Fetch descriptor)	Holds the valid descriptor address
10	ST_CADR (Change address)	No ADMA error is generated
11	ST_TFR (Transfer data)	Holds the address of the next executable descriptor command

Offset

Register	Offset
ADMA_ERR_STATUS	54h

Diagram



Fields

Field	Description
31-4 —	Reserved
3 ADMADCE	ADMA descriptor error This error occurs when invalid descriptor fetched by ADMA. 0 - No error 1 - Error
2 ADMALME	ADMA length mismatch error This error occurs in the following two cases: • While the block count enable is being set, the total data length specified by the descriptor table is different from that specified by the block count and block length. • Total data length cannot be divided by the block length. 0 - No error 1 - Error
1-0 ADMAES	ADMA error state (when ADMA error is occurred) This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. See ADMA Error Status (ADMA_ERR_STATUS) for more details.

38.6.1.23 ADMA System Address (ADMA_SYS_ADDR)

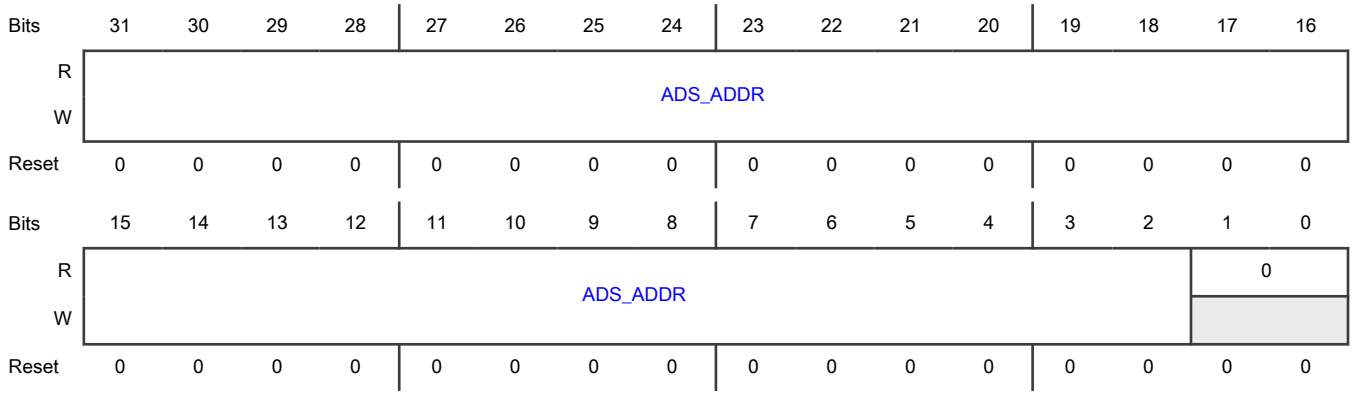
This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the host driver sets the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register holds the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned.

Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions.

Offset

Register	Offset
ADMA_SYS_ADDR	58h

Diagram



Fields

Field	Description
31-2 ADS_ADDR	ADMA system address This field contains the physical system memory address used for ADMA transfers.
1-0 —	Reserved

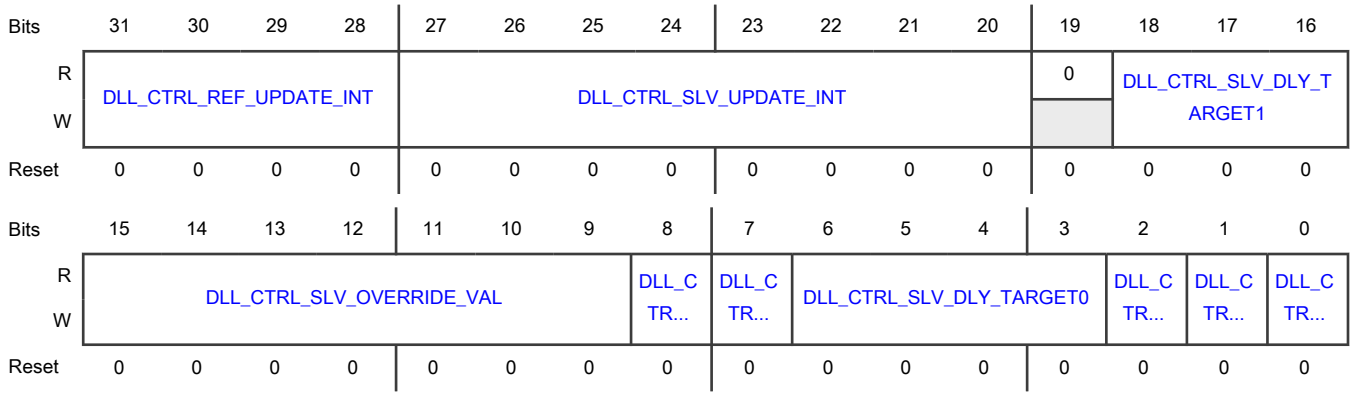
38.6.1.24 DLL (Delay Line) Control (DLL_CTRL)

This register contains control fields for DLL.

Offset

Register	Offset
DLL_CTRL	60h

Diagram



Fields

Field	Description
31-28 DLL_CTRL_REF_UPDATE_INT	DLL control loop update interval The interval cycle is (2 + REF_UPDATE_INT) * REF_CLOCK. By default, the DLL control loop updates every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20 DLL_CTRL_SLV_UPDATE_INT	Target delay line update interval If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the target-delay line using the SLV_FORCE_UPDATE register. Note that the target delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19 —	Reserved
18-16 DLL_CTRL_SLV_DLY_TARGET1	DLL target delay target1 See DLL_CTRL_SLV_DLY_TARGET0 below.
15-9 DLL_CTRL_SLV_OVERRIDE_VAL	DLL target override val When SLV_OVERRIDE = 1, this field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.
8 DLL_CTRL_SLV_OVERRIDE	DLL target override Set this field to 1 to Enable manual override for target delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0
7 DLL_CTRL_GATE_UPDATE	DLL gate update Set this field to 1 to prevent the DLL from updating (because when clock_in exists, glitches might appear during DLL updates). This field might be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6-3 DLL_CTRL_SLV_DLY_TARGET0	DLL target delay target0 The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an REF_CLOCK half-period. The delay is (DLL_CTRL_SLV_DLY_TARGET + 1)* REF_CLOCK_PERIOD[1] / 2) / 16, where DLL_CTRL_SLV_DLY_TARGET is a 7-bit value obtained by concatenating {DLL_CTRL_SLV_DLY_TARGET1, DLL_CTRL_SLV_DLY_TARGET0}. Therefore, the input read-clock can be delayed relative to the input data by (REF_CLOCK_PERIOD / 2) / 16 up to REF_CLOCK_PERIOD * 4.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE For the restrictions of delay cell implementation, the delay target must be set between REF_CLOCK_PERIOD/16 and REF_CLOCK_PERIOD*2 when REF_CLOCK is running at 200 MHz. When REF_CLOCK frequency is slower than 100 MHz, the maximum delay target might not reach REF_CLOCK_PERIOD*2.
2 DLL_CTRL_SLV_FORCE_UPD	DLL target delay line Setting this field to 1, forces the target delay line to update to the DLL calibrated value immediately. The target delay line updates automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the target-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1 DLL_CTRL_RESET	DLL reset Setting this field to 1 force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half-period phase shift. This signal is used by the DLL as edge-sensitive, so to create a subsequent reset, RESET must be taken low and then asserted again.
0 DLL_CTRL_ENABLE	DLL and delay chain Set this field to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the target delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

1. REF_CLOCK_PERIOD is 1/REF_CLOCK.

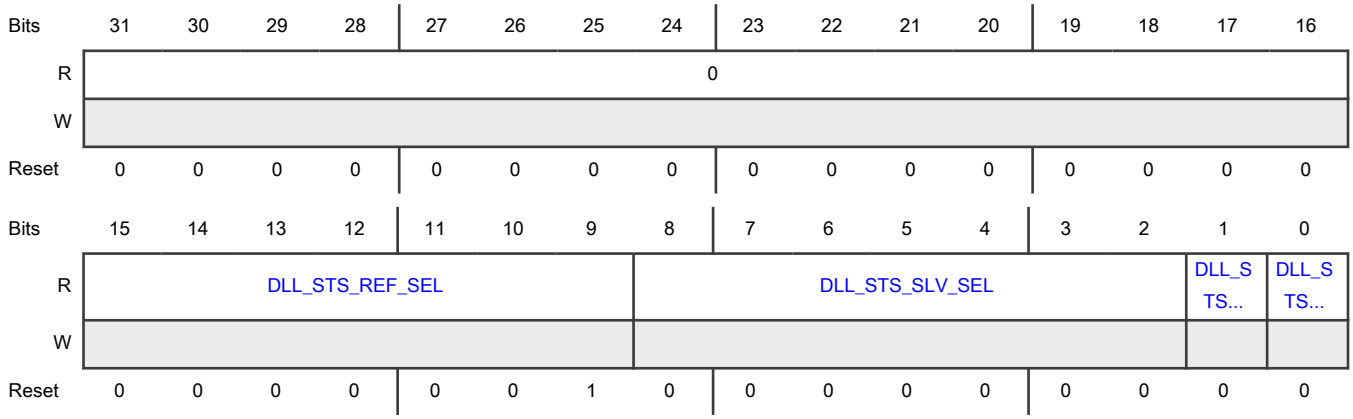
38.6.1.25 DLL Status (DLL_STATUS)

This register contains the DLL status information. All fields are read only and reads the same as the power-reset value.

Offset

Register	Offset
DLL_STATUS	64h

Diagram



Fields

Field	Description
31-16 —	Reserved
15-9 DLL_STS_REF_SEL	Reference delay line select taps This is encoded by 7 fields for 127 taps.
8-2 DLL_STS_SLV_SEL	Target delay line select status This is the instant value generated from reference chain. Because the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status This signifies that the DLL has detected and locked to an REF_CLOCK half-period phase shift , allowing the target delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Target delay-line lock status This signifies that a valid calibration has been set to the target-delay line and that the target-delay line is implementing the programmed delay value

38.6.1.26 CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS)

This register contains the Clock Tuning Control status information. This register is added to support SD3.0 UHS-I SDR104 mode and eMMC HS200 mode.

Offset

Register	Offset
CLK_TUNE_CTRL_STATUS	68h

Diagram

Fields

Field	Description
31 PRE_ERR	PRE error PRE error which means the number of delay cells added on the feedback clock is too small. It is valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
30-24 TAP_SEL_PRE	TAP_SEL_PRE Reflects the number of delay cells added on the feedback clock between the feedback clock and CLK_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is disabled, TAP_SEL_PRE is always equal to DLY_CELL_SET_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is enabled, TAP_SEL_PRE is updated automatically according to the status of the auto tuning circuit to adjust the sample clock phase.
23-20 TAP_SEL_OUT	Delay cells added on the feedback clock between CLK_PRE and CLK_OUT Reflects the number of delay cells added on the feedback clock between CLK_PRE and CLK_OUT.
19-16 TAP_SEL_POST	Delay cells added on the feedback clock between CLK_OUT and CLK_POST Reflects the number of delay cells added on the feedback clock between CLK_OUT and CLK_POST.
15 NXT_ERR	NXT error NXT error which means the number of delay cells added on the feedback clock is too large. It's valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
14-8 DLY_CELL_SET_PRE	delay cells on the feedback clock between the feedback clock and CLK_PRE Set the number of delay cells on the feedback clock between the feedback clock and CLK_PRE.
7-4 DLY_CELL_SET_OUT	Delay cells on the feedback clock between CLK_PRE and CLK_OUT Set the number of delay cells on the feedback clock between CLK_PRE and CLK_OUT.

Table continues on the next page...

Table continued from the previous page...

Field	Description
3-0 DLY_CELL_SET_POST	Delay cells on the feedback clock between CLK_OUT and CLK_POST Set the number of delay cells on the feedback clock between CLK_OUT and CLK_POST.

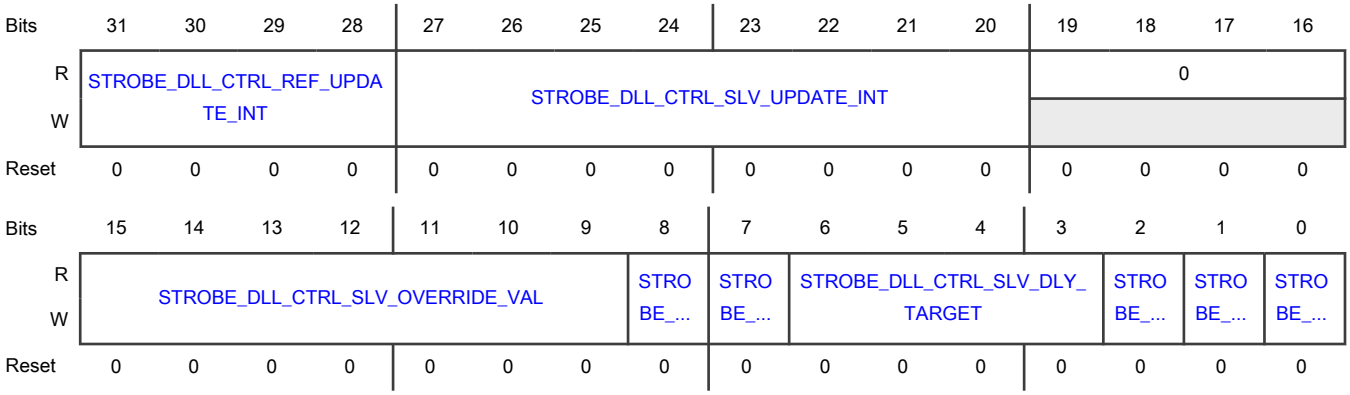
38.6.1.27 Strobe DLL control (STROBE_DLL_CTRL)

This register contains the strobe DLL control information.

Offset

Register	Offset
STROBE_DLL_CTRL	70h

Diagram



Fields

Field	Description
31-28 STROBE_DLL_CTRL_REF_UPDATE_INT	Strobe DLL control reference update interval The interval cycle is (2 + STROBE_REF_UPDATE_INT) * STROBE_REF_CLOCK. By default, the DLL control loop updates every two STROBE_REF_CLOCK cycles. **NOTE** Increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20 STROBE_DLL_CTRL_SLV_UPDATE_INT	Strobe DLL control target update interval Target delay line update interval. If default 0 is used, it means 256 cycles of STROBE_REF_CLOCK. A value of 0x0F results in 15 cycles and so on.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE software can always cause an update of the target-delay line using the STROBE_SLV_FORCE_UPDATE register. The target delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19-16 —	This field is reserved. This read-only field is reserved and always has the value 0.
15-9 STROBE_DLL_CTRL_SLV_OVERRIDE_VAL	Strobe DLL control target Override value When STROBE_SLV_OVERRIDE = 1, this field is used to manually select one of 128 physical taps. A value of 0 selects tap 1, and a value of 0x7F selects tap 128.
8 STROBE_DLL_CTRL_SLV_OVERRIDE	Strobe DLL control target override Set this field to 1 to Enable manual override for target delay chain using STROBE_SLV_OVERRIDE_VAL; set this field to 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if STROBE_SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0.
7 STROBE_DLL_CTRL_GATE_UPDATE	Strobe DLL control gate update Set this field to 1 to prevent the DLL from updating (because when STROBE_CLOCK_IN exists, glitches might appear during DLL updates). This field can be used by software if such a condition occurs. Clear the field to 0 to allow the DLL to update automatically.
6-3 STROBE_DLL_CTRL_SLV_DLY_TARGET	Strobe DLL Control Target Delay Target The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an STROBE_REF_CLOCK half-period. The delay is ((STROBE_DLL_CTRL_SLV_DLY_TARGET + 1) * STROBE_REF_CLOCK_PERIOD[1] / 2) / 16, Therefore, the input read-clock can be delayed relative to the input data by (STROBE_REF_CLOCK_PERIOD / 2) / 16 up to (STROBE_REF_CLOCK_PERIOD *8)/16. **NOTE** For the restrictions of delay cell implementation, the minimum delay target that can be set is REF_CLOCK_PERIOD/16.
2 STROBE_DLL_CTRL_SLV_FORCE_UPD	Strobe DLL control target force updated Setting this field to 1, forces the target delay line to update to the DLL calibrated value immediately. The target delay line should automatically update the STROBE_SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the target-line update can only occur if STROBE_SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1	Strobe DLL control reset

Table continues on the next page...

Table continued from the previous page...

Field	Description
STROBE_DLL_CTRL_RESET	Setting this field to 1 to force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half-period phase shift. This signal is used by the DLL as edge-sensitive, to create a subsequent reset, RESET must be taken low and then asserted again.
0 STROBE_DLL_CTRL_ENABLE	Strobe DLL control enable Set this field to 1 to enable the DLL and delay chain; otherwise, set to 0 to bypasses DLL. **NOTE** Using the target delay line override feature with STROBE_SLV_OVERRIDE and STROBE_SLV_OVERRIDE VAL, the DLL does not need to be enabled.

1. which is 1/STROBE_REF_CLOCK.

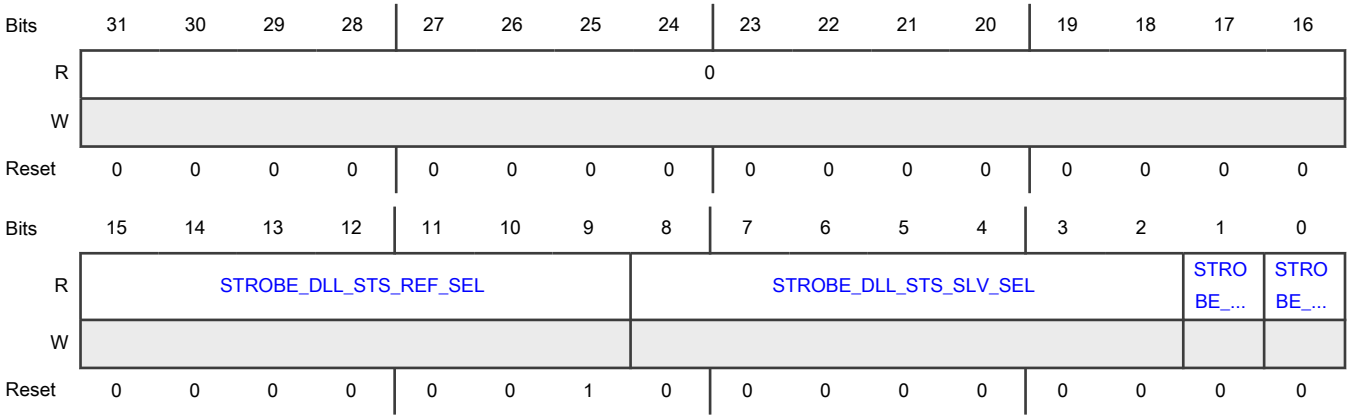
38.6.1.28 Strobe DLL status (STROBE_DLL_STATUS)

This register contains the strobe DLL status information. All fields are read only and read the same as the power-reset value.

Offset

Register	Offset
STROBE_DLL_STATUS	74h

Diagram



Fields

Field	Description
31-16 —	This field is reserved. This read-only field is reserved and always has the value 0.
15-9	Strobe DLL status reference select

Table continues on the next page...

Table continued from the previous page...

Field	Description
STROBE_DLL_STS_REF_SEL	Reference delay line select taps. This is encoded by 7 fields for 127 taps.
8-2 STROBE_DLL_STS_SLV_SEL	Strobe DLL status target select Target delay line select status. This is the instant value generated from reference chain. Because the reference chain can only be updated when STROBE_REF_CLOCK is detected, this value can be updated with the right value when the reference is locked.
1 STROBE_DLL_STS_REF_LOCK	Strobe DLL status reference lock This signifies that the DLL has detected and locked to a half-phase REF_CLOCK shift, it allows the target delay-line to perform programmed clock delays.
0 STROBE_DLL_STS_SLV_LOCK	Strobe DLL status target lock Target delay-line lock status. This signifies that a valid calibration has been set to the target-delay line, and the target-delay line is implementing the programmed delay value.

38.6.1.29 Vendor Specific Register (VEND_SPEC)

This register contains the vendor specific control/status register.

Offset

Register	Offset

Fields

Field	Description
31 CMD_BYTE_EN	Register byte access for CMD_XFR_TYP This field controls the register byte access for Command Transfer Type (CMD_XFR_TYP). If this field is enabled, the register can be configured through byte write enable. IPS_bus can write only one byte once for one write operation. 0 - Disable. MIX_CTRL[7:0] is read/write and CMD_XFR_TYP[7:0] is read-only. 1 - Enable. MIX_CTRL[7:0] is read-only and CMD_XFR_TYP[7:0] is read/write.
30 —	Reserved Always write as 0.
29 —	Reserved Always write as 1
28 —	Reserved Always write as 0.
27-24 —	Reserved Always write as 4'b0000.
23-16 —	Reserved Always write as 8'h00.
15 CRC_CHK_DIS	CRC Check Disable 0 - Check CRC16 for every read data packet and check CRC fields for every write data packet 1 - Ignore CRC16 check for every read data packet and ignore CRC fields check for every write data packet
14-11 —	Reserved Reserved
10 —	Reserved Always write as 0.
9 —	Reserved Always write as 0.
8 FRC_SDCLK_ON	Force CLK Force CLK output active Do not set this bit to 1 unless it is necessary. Also, make sure that this bit is cleared when uSDHC's clock is about to be changed (frequency change, clock source change, or delay chain tuning). 0 - CLK active or inactive is fully controlled by the hardware. 1 - Force CLK active

Table continues on the next page...

Table continued from the previous page...

Field	Description
7 —	Reserved
6 —	Reserved
5 —	Reserved
4 —	Reserved
3 AC12_WR_CHKBUSY_EN	Check busy enable Check busy enable after auto CMD12 for write data packet 0 - Do not check busy after auto CMD12 for write data packet 1 - Check busy after auto CMD12 for write data packet
2 —	Reserved
1 VSELECT	Voltage selection Change the value of output signal VSELECT to control the voltage on pads for external card. There must be a control circuit out of uSDHC to change the voltage on pads. 0 - Change the voltage to high voltage range, around 3.0 V 1 - Change the voltage to low voltage range
0 —	Reserved Always write as 0.

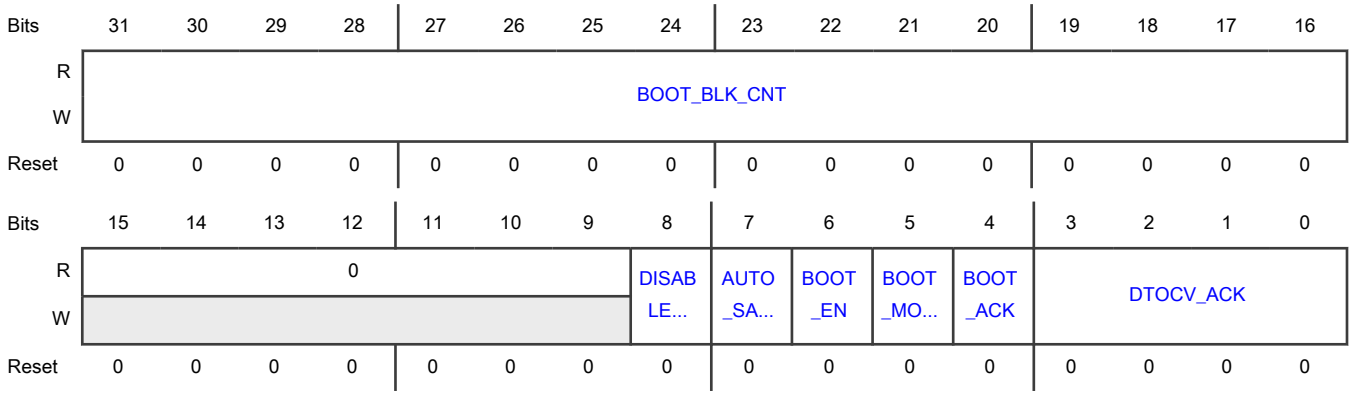
38.6.1.30 eMMC Boot (MMC_BOOT)

This register contains the eMMC Fast Boot control register.

Offset

Register	Offset
MMC_BOOT	C4h

Diagram



Fields

Field	Description
31-16 BOOT_BLK_CNT	Stop At Block Gap value of automatic mode The value defines the Stop At Block Gap value of automatic mode. When received, card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT) and AUTO_SABG_EN is 1, then Stop At Block Gap. Here, BLK_CNT is defined in the Block Attributes Register, field 31 - 16 of 0x04.
15-9 —	Reserved
8 DISABLE_TIME_OUT	Time out **NOTE** When this field is set, there is no timeout check no matter whether BOOT_EN is set or not. 0 - Enable time out 1 - Disable time out
7 AUTO_SABG_EN	Auto stop at block gap During boot, enable auto stop at block gap function. This function is triggered, and host stops at block gap when received card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT).
6 BOOT_EN	Boot enable Boot mode enable 0 - Fast boot disable 1 - Fast boot enable
5 BOOT_MODE	Boot mode Boot mode select 0 - Normal boot 1 - Alternative boot

Table continues on the next page...

Table continued from the previous page...

Field	Description
4 BOOT_ACK	BOOT ACK Boot ACK mode select 0 - No ack 1 - Ack
3-0 DTOCV_ACK	DTOCV_ACK Boot ACK time out counter value 0000 - SDCLK x 2^32 0001 - SDCLK x 2^33 0010 - SDCLK x 2^18 0011 - SDCLK x 2^19 0100 - SDCLK x 2^20 0101 - SDCLK x 2^21 0110 - SDCLK x 2^22 0111 - SDCLK x 2^23 1110 - SDCLK x 2^30 1111 - SDCLK x 2^31

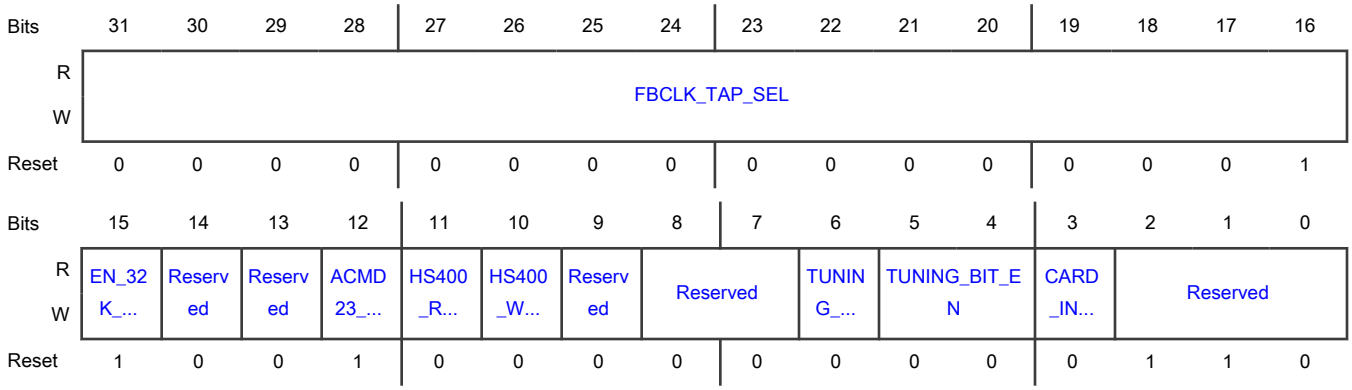
38.6.1.31 Vendor Specific 2 Register (VEND_SPEC2)

This register contains the vendor specific control 2 register.

Offset

Register	Offset
VEND_SPEC2	C8h

Diagram



Fields

Field	Description
31-16 FBCLK_TAP_SEL	Enable extra delay on internal feedback clock It is a hot code. The default value is 16'h0001 that means the length of feedback delay chain is 1. The value of 16'h8000 means the length of feedback delay chain is 16.
15 EN_32K_CLK	Select the clock source for host card detection. It can use low power clock for card detection, by setting this bit to 1. 0 - Use the peripheral clock (ipg_clk) for card detection. 1 - Use the low power clock (ipg_clk_lp) for card detection.
14 —	Reserved
13 —	Reserved
12 ACMD23_ARGU2_EN	Argument2 register enable for ACMD23 0 - Disable 1 - Argument2 register enable for ACMD23 sharing with SDMA system address register. Default is enabled.
11 HS400_RD_CLK_STOP_EN	HS400 read clock stop enable Only stop clock at read block gap.
10 HS400_WR_CLK_STOP_EN	HS400 write clock stop enable Only stop clock at write block gap.
9 —	Reserved
8-7 —	Reserved
6 TUNING_CMD_EN	Tuning command enable Enable the auto tuning circuit to check the CMD line. 0 - Auto tuning circuit does not check the CMD line. 1 - Auto tuning circuit checks the CMD line.
5-4 TUNING_BIT_EN	Tuning bit enable Enable the auto tuning circuit to check the DATA[7:0]. The value option is as the list below. 00 - Enable Tuning circuit for DATA[3:0]

Table continues on the next page...

Table continued from the previous page...

Field	Description
	01 - Enable Tuning circuit for DATA[7:0] 10 - Enable Tuning circuit for DATA[0] 11 - Invalid
3 CARD_INT_D3_TEST	Card interrupt detection test This field is used only for debugging. 0 - Check the card interrupt only when DATA3 is high. 1 - Check the card interrupt by ignoring the status of DATA3.
2-0 —	Reserved

38.6.1.32 Tuning Control (TUNING_CTRL)

The register contains configuration of tuning circuit.

Offset

Register	Offset
TUNING_CTRL	CCh

7-4 MINOR_VN	eMMC minor version number Digit right of decimal point, in BCD format
3-0 VERSION_SUFFIX	eMMC version suffix The second digit right of decimal point, in BCD format

38.6.1.34 Command Queuing Capabilities (CQCAP)

This register indicates hardware capabilities.

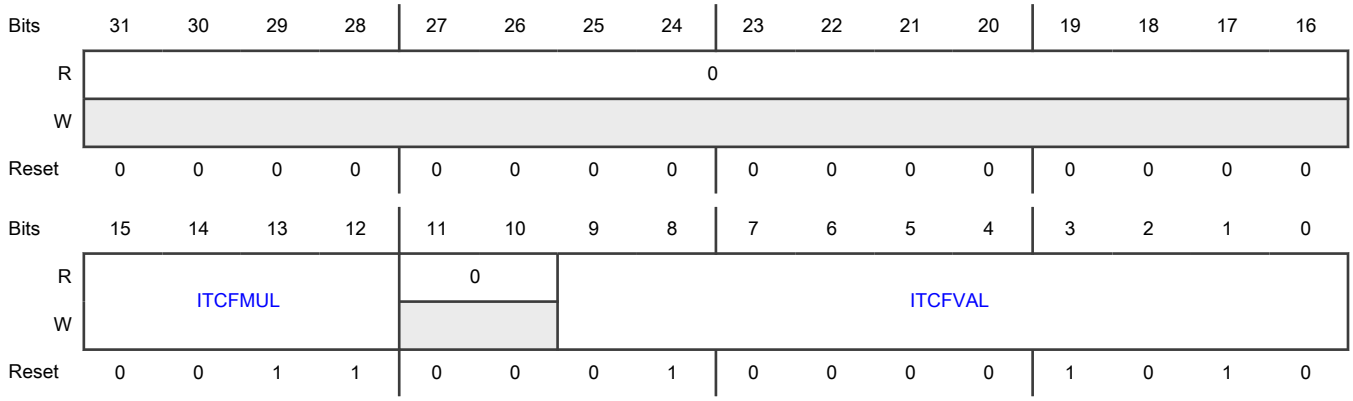
NOTE

This register must not be configured and must be used as a read-only register. Writing to the read-write fields of this register does not affect any functionality. Reset values reflect the correct capability information.

Offset

Register	Offset
CQCAP	104h

Diagram



Fields

Field	Description
31-16 —	Reserved
15-12 ITCFMUL	Internal timer clock frequency multiplier ITCFMUL and ITCFVAL indicate the frequency of the clock used for interrupt coalescing timer and for determining the SQS polling period. See ITCFVAL definition for details. 0001 - 0.001 MHz 0010 - 0.01 MHz 0011 - 0.1 MHz 0100 - 1 MHz 0101 - 10 MHz 0110-1001 - Reserved
11-10 —	Reserved
9-0 ITCFVAL	Internal timer clock frequency value ITCFMUL and ITCFVAL indicate the frequency of the clock used for interrupt coalescing timer and for determining the polling period when using periodic SEND_QUEUE_ STATUS (CMD13) polling. The clock frequency is calculated as ITCFVAL* ITCFMUL. For example, to encode 19.2 MHz, ITCFVAL is C0h (= 192 decimal) and ITCFMUL is 3h (0.1 MHz): 192 * 0.1 MHz = 19.2 MHz.

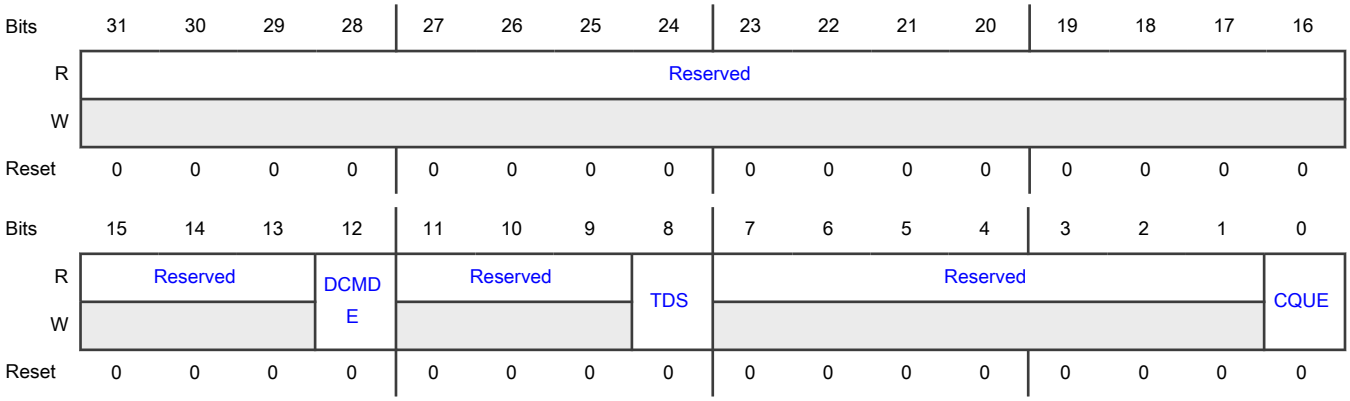
38.6.1.35 Command Queuing Configuration (CQCFG)

This register controls CQE behavior affecting the general operation of command queuing module or operation of multiple tasks in the same time.

Offset

Register	Offset
CQCFG	108h

Diagram



Fields

Field	Description
31-13 —	Reserved
12 DCMDE	Direct command (DCMD) enable This bit indicates to the hardware whether the Task Descriptor in slot #31 of the TDL is a Data Transfer Task Descriptor, or a Direct Command Task Descriptor. CQE uses this bit when a task is issued in slot #31, to determine how to decode the Task Descriptor. 0 - Task descriptor in slot #31 is a Data Transfer Task Descriptor 1 - Task descriptor in slot #31 is a DCMD Task Descriptor
11-9 —	Reserved
8 TDS	Task descriptor size This bit indicates whether the task descriptor size is 128 bits or 64 bits as detailed in Data Structures section. This bit can only be configured when Command Queuing Enable bit is ‘0’ (command queuing is disabled) 0 - Task descriptor size is 64 bits 1 - Task descriptor size is 128 bits
7-1 —	Reserved
0	Command queuing enable

Table continues on the next page...

Table continued from the previous page...

Field	Description
CQUE	Software shall write '1' this bit when in order to enable command queuing mode (for example, enable CQE). When this bit is 0, CQE is disabled and software controls the eMMC bus using the legacy eMMC host controller. Before software writes '1' to this bit, software shall verify that the eMMC host controller is in idle state and there are no commands or data transfers ongoing. When software wants to exit command queuing mode, it shall clear all previous tasks if such exist before setting this bit to 0.

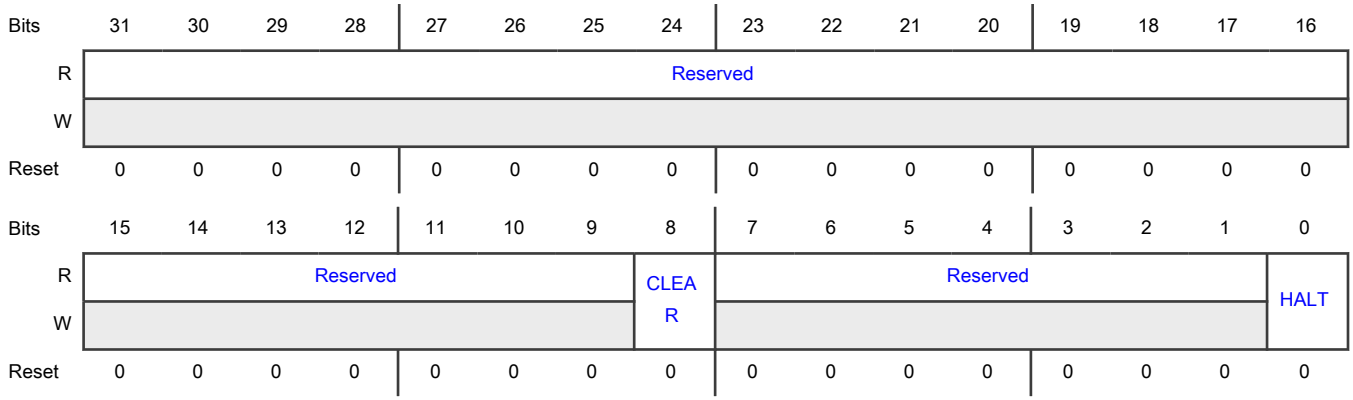
38.6.1.36 Command Queuing Control (CQCTL)

This register controls CQE behavior affecting the general operation of command queuing module or operation of multiple tasks in the same time.

Offset

Register	Offset
CQCTL	10Ch

Diagram



Fields

Field	Description
31-9 —	Reserved
8 CLEAR	Clear all tasks Software shall write '1' this bit when it wants to clear all the tasks sent to the chip. This bit can only be written when CQE is in halt state (for example, Halt bit is 1).

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When software writes 1, the value of the register is updated to '1', and CQE shall reset CQTDBR register and all other context information for all unfinished tasks. Then CQE will clear this bit. Software should poll on this bit until it is set to back 0 and may then resume normal operation, by clearing the Halt bit. CQE does not communicate to the chip that the tasks were cleared. It is software's responsibility to order the chip to discard the tasks in its queue using CMDQ_TASK_MGMT command. Writing '0' to this register shall have no effect.
7-1 —	Reserved
0 HALT	Halt Host software shall write '1' to the bit when it wants to acquire software control over the eMMC bus and disable CQE from issuing commands on the bus. For example, issuing a Discard Task command (CMDQ_TASK_MGMT) When software writes '1', CQE shall complete the ongoing task if such a task is in progress. Once the task is completed and CQE is in idle state, CQE shall not issue new commands and shall indicate so to software by setting this bit to 1. Software may poll on this bit until it is set to 1, and may only then send commands on the eMMC bus. In order to exit halt state (for example, resume CQE activity), software shall clear this bit (write '0'). Writing '0' when the value is already '0' shall have no effect.

38.6.1.37 Command Queuing Interrupt Status (CQIS)

This register indicates pending interrupts that require service. Each bit in this registers is asserted in response a specific event, only if the respective bit is set in CQISTE register.

Offset

Register	Offset
CQIS	110h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	Reserved												TCL	RED	TCC	HAC
W													W1C	W1C	W1C	W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-4 —	Reserved
3 TCL	Task cleared This status bit is asserted (if CQISTE[TCL_STE]=1) when a task clear operation is completed by CQE. The completed task clear operation is either an individual task clear (CQTCLR) or clearing of all tasks (CQCTL).
2 RED	Response error detected interrupt This status bit is asserted (if CQISTE[RED_STE]=1) when a response is received with an error bit set in the device status field. The contents of the device status field are listed in 6.13. Software uses CQRMEM register to configure which device status bit fields may trigger an interrupt, and which are masked.
1 TCC	Task complete interrupt This status bit is asserted (if CQISTE[TCC_STE]=1) when at least one of the following two conditions are met: • A task is completed and the INT bit is set in its Task Descriptor • Interrupt caused by Interrupt Coalescing logic (see 0)
0 HAC	Halt complete interrupt This status bit is asserted (if CQISTE[HAC_STE]=1) when halt bit in CQCTL register transitions from 0 to 1 indicating that host controller has completed its current ongoing task and has entered halt state.

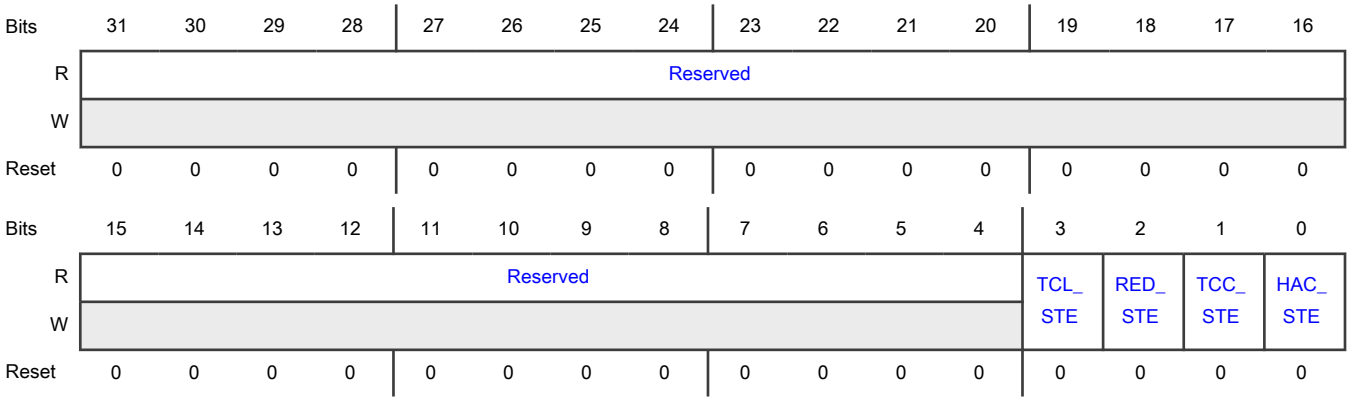
38.6.1.38 Command Queuing Interrupt Status Enable (CQISTE)

This register enables and disables the reporting of the corresponding interrupt to host software in CQIS register. When a bit is set ('1') and the corresponding interrupt condition is active, then the bit is CQIS is asserted. Interrupt sources that are disabled (‘0’) are not indicated in the CQIS register. This register is bit-index matched to CQIS register.

Offset

Register	Offset
CQISTE	114h

Diagram



Fields

Field	Description
31-4 —	Reserved
3 TCL_STE	Task cleared status enable Related to CQIS[TCL] 0 - CQIS[TCL] is disabled 1 - CQIS[TCL] is set when its interrupt condition is active
2 RED_STE	Response error detected status enable Related to CQIS[RED] 0 - CQIS[RED]is disabled 1 - CQIS[RED] is set when its interrupt condition is active
1 TCC_STE	Task complete status enable Related to CQIS[TCC] 0 - CQIS[TCC] is disabled 1 - CQIS[TCC] is set when its interrupt condition is active
0 HAC_STE	Halt complete status enable Related to CQIS[HAC] 0 - CQIS[HAC] is disabled 1 - CQIS[HAC] is set when its interrupt condition is active

38.6.1.39 Command Queuing Interrupt Signal Enable (CQISGE)

This register enables and disables the generation of interrupts to host software. When a bit is set ('1') and the corresponding bit in CQIS is set, then an interrupt is generated. Interrupt sources that are disabled (‘0’) are still indicated in the CQIS register. This register is bit-index matched to CQIS register.

Offset

Register	Offset
CQISGE	118h

R	Reserved												TCL_SGE	RED_SGE	TCC_SGE	HAC_SGE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-4 —	Reserved
3 TCL_SGE	Task cleared signal enable When set and CQIS[TCL] is asserted, the CQE generates an interrupt.
2 RED_SGE	Response error detected signal enable When set and CQIS[RED] is asserted, the CQE generates an interrupt.
1 TCC_SGE	Task complete signal enable When set and CQIS[TCC] is asserted, the CQE generates an interrupt.
0 HAC_SGE	Halt complete signal enable When set and CQIS[HAC] is asserted, the CQE generates an interrupt.

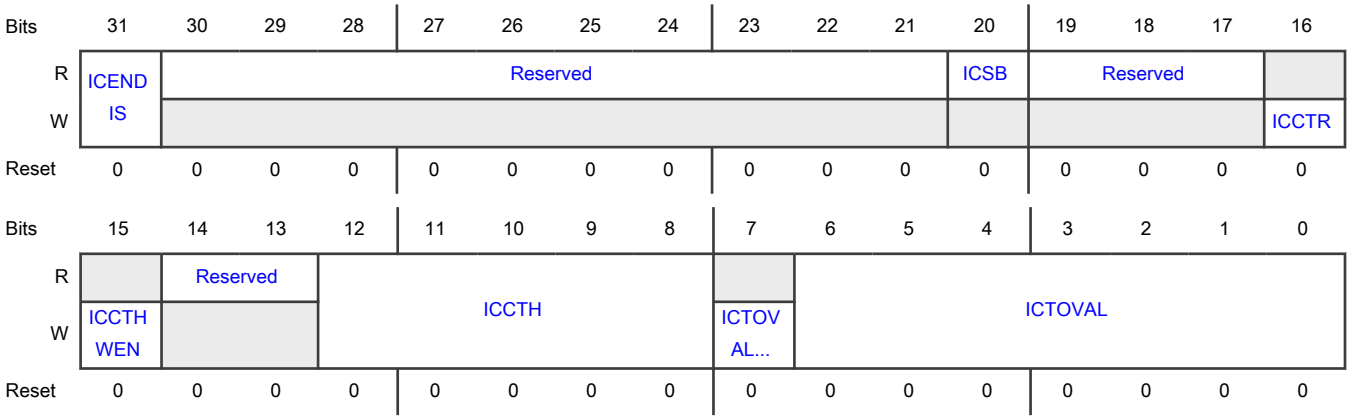
38.6.1.40 Command Queuing Interrupt Coalescing (CQIC)

This register controls the interrupt coalescing feature.

Offset

Register	Offset
CQIC	11Ch

Diagram



Fields

Field	Description
31 ICENDIS	Interrupt coalescing enable/disable When host driver writes ‘1’, the interrupt coalescing timer and counter are reset.
30-21 —	Reserved
20 ICSB	Interrupt coalescing status This bit indicates to software whether any tasks (with INT=0) have completed and counted towards interrupt coalescing (for example, ICSB is set if and only if IC counter > 0). 0 - No task completions have occurred since last counter reset (IC counter =0) 1 - At least one task completion has been counted (IC counter >0)
19-17 —	Reserved
16 ICCTR	Counter and timer reset When host driver writes ‘1’, the interrupt coalescing timer and counter are reset.
15 ICCTHWEN	Interrupt coalescing counter threshold write enable When software writes ‘1’, the value ICCTH is updated with the contents written at the same cycle. When software writes ‘0’, the value in ICCTH is not updated.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE Write operations to ICCTH are only allowed when the task queue is empty.
14-13 —	Reserved
12-8 ICCTH	Interrupt coalescing counter threshold Software uses this field to configure the number of task completions (only tasks with INT=0 in the Task Descriptor) which are required in order to generate an interrupt. Counter Operation: As data transfer tasks with INT=0 complete, they are counted by CQE. The counter is reset by software during the interrupt service routine. The counter stops counting when it reaches the value configured in ICCTH. The maximum allowed value is 31. **NOTE** When ICCTH is 0, task completions are not counted, and counting-based interrupts are not generated. In order to write to this field, the ICCTHWEN field must be set at the same write operation.
7 ICTOVALWEN	Interrupt coalescing timeout value write enable When software writes ‘1’, the value ICTOVAL is updated with the contents written at the same cycle. When software writes ‘0’, the value in ICTOVAL is not updated. **NOTE** Write operations to ICTOVAL are only allowed when the task queue is empty.
6-0 ICTOVAL	Interrupt coalescing timeout value Software uses this field to configure the maximum time allowed between the completion of a task on the bus and the generation of an interrupt. Timer Operation: The timer is reset by software during the interrupt service routine. It starts running when a data transfer task with INT=0 is completed, after the timer was reset. When the timer reaches the value configured in ICTOVAL field it generates an interrupt and stops. The timer’s unit is equal to 1024 clock periods of the clock whose frequency is specified in the Internal Timer Clock Frequency field CQCAP register. The minimum value is 01h (1024 clock periods) and the maximum value is 7Fh (127*1024 clock periods). For example, a CQCAP field value of 0 indicates a 19.2 MHz clock frequency (period = 52.08 ns). If the setting in ICTOVAL is 10h, the calculated polling period is 16*1024*52.08 ns= 853.33 us **NOTE** When ICTOVAL is 0, the timer is not running, and timer-based interrupts are not generated. In order to write to this field, the ICTOVALWEN bit must be set at the same write operation.

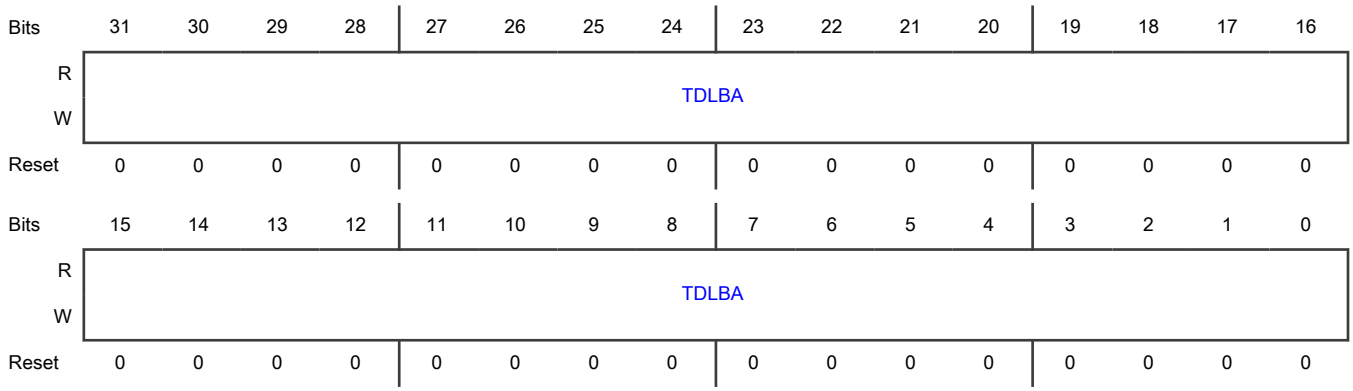
38.6.1.41 Command Queuing Task Descriptor List Base Address (CQTDLBA)

This register is used for configuring the lower 32 bits of the byte address of the head of the Task Descriptor List in the host memory.

Offset

Register	Offset
CQTDLBA	120h

Diagram



Fields

Field	Description
31-0 TDLBA	Task descriptor list base address This register stores the LSB bits (bits 31:0) of the byte address of the head of the Task Descriptor List in system memory. The size of the task descriptor list is 32 * (Task Descriptor size + Transfer Descriptor size) as configured by Host driver. This address shall be set on 1 KByte boundary: The lower 10 bits of this register shall be set to 0 by software and shall be ignored by CQE.

38.6.1.42 Command Queuing Task Descriptor List Base Address Upper 32 Bits (CQTDLBAU)

This register is used for configuring the upper 32 bits of the byte address of the head of the Task Descriptor List in the host memory.

Offset

Register	Offset
CQTDLBAU	124h

Diagram

R W	TDBR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-0 TDBR	Task doorbell Software configures TDLBA and TDLBAU, and enable CQE in CQCFG before using this register. Writing 1 to bit n of this register triggers CQE to start processing the task encoded in slot n of the TDL. CQE always processes tasks in-order according to the order submitted to the list by CQTDBR write transactions. CQE processes Data Transfer tasks by reading the Task Descriptor and sending QUEUED_TASK_PARAMS (CMD44) and QUEUED_TASK_ADDRESS (CMD45) commands to the device. CQE processes DCMD tasks (in slot #31, when enabled) by reading the Task Descriptor, and generating the command encoded by its index and argument. The corresponding bit is cleared to '0' by CQE in one of the following events: 1. When a task execution is completed (with success or error) 2. The task is cleared using CQTCLR register 3. All tasks are cleared using CQCTL register 4. CQE is disabled using CQCFG register Software may initiate multiple tasks at the same time (batch submission) by writing 1 to multiple bits of this register in the same transaction. In the case of batch submission: CQE shall process the tasks in order of the task index, starting with the lowest index. If one or more tasks in the batch are marked with QBR, the ordering of execution will be based on said processing order. Writing 0 by software shall have no impact on the hardware, and will not change the value of the register bit.

38.6.1.44 Command Queuing Task Completion Notification (CQTCN)

This register is used by CQE to notify software about completed tasks.

Offset

Register	Offset
CQTCN	12Ch

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-0 TCN	Task complete notification CQE shall set bit n of this register (at the same time it clears bit n of CQTDBR) when a task execution is completed (with success or error). When receiving interrupt for task completion, software may read this register to know which tasks have finished. After reading this register, software may clear the relevant bit fields by writing 1 to the corresponding bits.

38.6.1.45 Command Queuing Device Queue Status (CQDQS)

This register stores the most recent value of the device's queue status.

Offset

Register	Offset
CQDQS	130h

Fields

Field	Description
31-0 DQS	Device queue status Every time the Host controller receives a queue status register (QSR) from the device, it updates this register with the response of status command (For example, the chip's queue status).

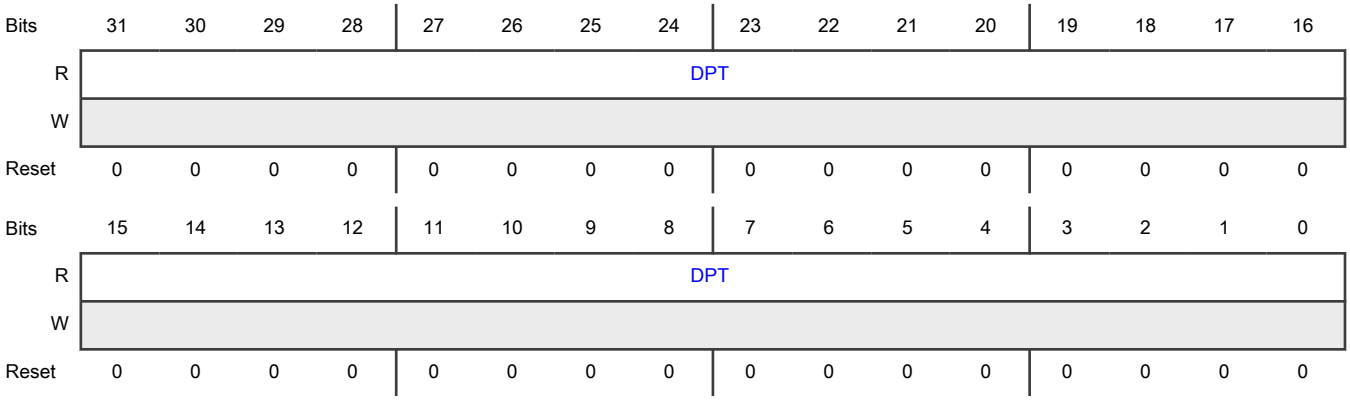
38.6.1.46 Command Queuing Device Pending Tasks (CQDPT)

This register indicates to software which tasks are queued in the device, awaiting execution.

Offset

Register	Offset
CQDPT	134h

Diagram



Fields

Field	Description
31-0 DPT	Device pending tasks Bit n of this register is set if and only if QUEUED_TASK_PARAMS (CMD44) and QUEUED_TASK_ADDRESS (CMD45) were sent for this specific task and if this task hasn't been executed yet. CQE shall set this bit after receiving a successful response for CMD45. CQE shall clear this bit after the task has completed execution. Software needs to read this register in the task-discard procedure, when the controller is halted, to determine if the task is queued in the device. If the task is queued, the driver sends a CMDQ_TASK_MGMT (CMD48) to the device ordering it to discard the task. Then software clears the task in the CQE. Only then the software orders CQE to resume its operation using CQCTL register.

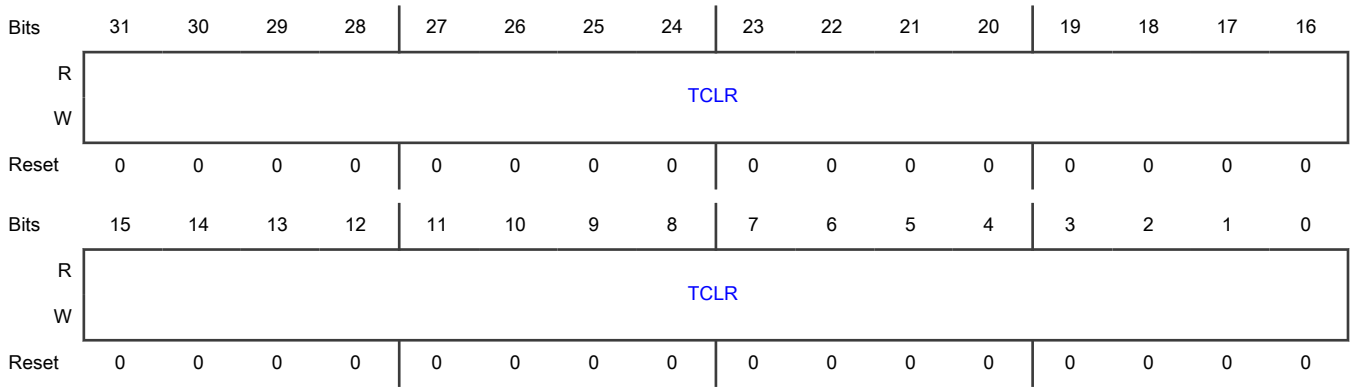
38.6.1.47 Command Queuing Task Clear (CQTCLR)

This register is used for removing an outstanding task in the CQE. The register should be used only when CQE is in Halt state.

Offset

Register	Offset
CQTCLR	138h

Diagram



Fields

Field	Description
31-0 TCLR	Task clear Writing 1 to bit n of this register orders CQE to clear a task which software has previously issued. This bit can only be written when CQE is in Halt state as indicated in CQCFG register Halt bit. When software writes '1' to a bit in this register, CQE updates the value to '1', and starts clearing the data structures related to the task. CQE clears the bit fields (sets a value of 0) in CQTCLR and in CQTDBR once clear operation is complete. Software should poll on the CQTCLR until it is cleared to verify clear operation was complete. Writing to this register only clears the task in the CQE and does not have impact on the device. In order to discard the task in the device, host software shall send CMDQ_TASK _MGMT while CQE is still in Halt state. Host driver is not allowed to use this register to clear multiple tasks at the same time. Clearing multiple tasks can be done using CQCTL register. Writing 0 to a register bit shall have no impact.

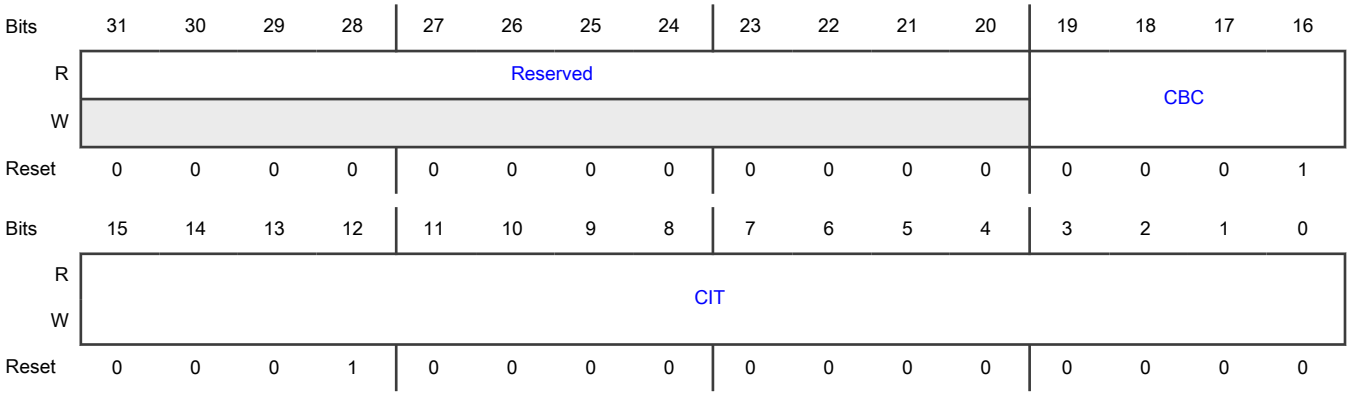
38.6.1.48 Command Queuing Send Status Configuration 1 (CQSSC1)

The register controls the when SEND_QUEUE_STATUS commands are sent.

Offset

Register	Offset
CQSSC1	140h

Diagram



Fields

Field	Description
31-20 —	Reserved
19-16 CBC	Send status command block counter This field indicates to CQE when to send SEND_QUEUE_STATUS (CMD13) command to inquire the status of the device's task queue. A value of *n* means CQE sends status command on the CMD line, during the transfer of data block BLOCK_CNT-n, on the data lines, where BLOCK_CNT is the number of blocks in the current transaction. A value of 0 means that SEND_QUEUE_STATUS (CMD13) command is not sent during the transaction. Instead it will be sent only when the data lines are idle. A value of 1 means that STATUS command is to be sent during the last block of the transaction.
15-0 CIT	Send status command idle timer This field indicates to CQE the polling period to use when using periodic SEND_QUEUE_STATUS (CMD13) polling. Periodic polling is used when tasks are pending in the device, but no data transfer is in progress. When a SEND_QUEUE_STATUS response indicating that no task is ready for execution, CQE counts the configured time until it issues the next SEND_QUEUE_STATUS. Timer units are clock periods of the clock whose frequency is specified in the Internal Timer Clock Frequency field CQCAP register. The minimum value is 0001h (1 clock period) and the maximum value is FFFFh (65535 clock periods). Default interval is: 4096 clock periods. For example, a CQCAP field value of 0 indicates a 19.2 MHz clock frequency (period = 52.08 ns). If the setting in CQSSC1.CIT is 1000h, the calculated polling period is 4096*52.08 ns= 213.33 us

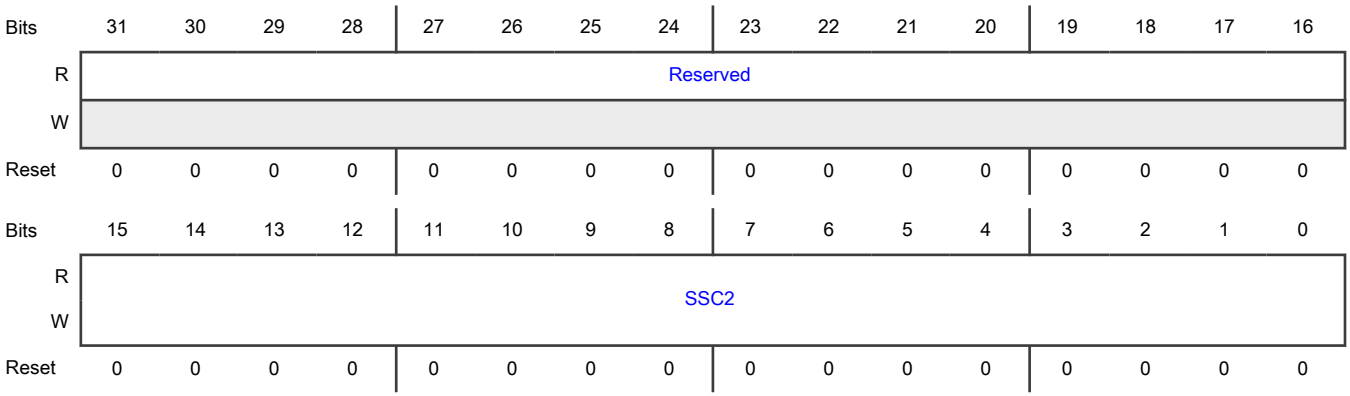
38.6.1.49 Command Queuing Send Status Configuration 2 (CQSSC2)

This register is used for configuring RCA field in SEND_QUEUE_STATUS command argument.

Offset

Register	Offset
CQSSC2	144h

Diagram



Fields

Field	Description
31-16 —	Reserved
15-0 SSC2	Send queue status RCA This field provides CQE with the contents of the 16-bit RCA field in SEND_QUEUE_ STATUS (CMD13) command argument. CQE copies this field to bits 31:16 of the argument when transmitting SEND_ QUEUE_STATUS (CMD13) command.

38.6.1.50 Command Queuing Command Response for Direct-Command Task (CQCRDCT)

This register is used for passing the response of a DCMD task to software.

Offset

Register	Offset
CQCRDCT	148h

Fields

Field	Description
31-0 RMEM	Response mode error mask This bit is used as in interrupt mask on the device status filed which is received in R1/R1b responses. The reset value of this register is set to trigger an interrupt on all “Error” type bits in the device status, as defined in 6.13. **NOTE** Responses to CMD13 (SQS) encode the QSR, so they are ignored by this logic. 0000_0000_0000_0000_0000_0000_0000_0000 - When a R1/R1b response is received, bit i in the device status is ignored 0000_0000_0000_0000_0000_0000_0000_0001 - When a R1/R1b response is received, with bit i in the device status set, a RED interrupt is generated

38.6.1.52 Command Queuing Task Error Information (CQTERRI)

This register is updated by CQE when an error occurs on data or command related to a task activity.

When such error is detected by CQE or indicated by the eMMC controller CQE stores in CQTERRI the task IDs and the command indices of the commands which were executed on the command line and data lines when the error occurred.

Software is expected to use this information in the error recovery procedure. See B.2.8 for more details.

CAN (FlexCAN)

39.1 Chip-specific FLEXCAN information

Table 240. Reference links to related information

Topic	Related module	Reference
CM33	Arm Cortex CM33 Platform (CM33)	CM33 Platform
A55	Arm Cortex CA55 Platform (CA55)	CA55 Platform
System memory map		System memory map
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

The chip includes two instances of CAN-FD Controllers (CAN-FD1 is in AONMIX and CAN-FD2 is in WAKEUPMIX).

CAN1 features a low-pass filter (=glitch filter) on the CAN RX input. This filter is fed by the can1_root_clk, and enabled by the WAKSRC field in the MCR register. If the filter is enabled and can1_clk_root is gated, then the CAN RX input will not reach the FlexCAN logic. This condition must be avoided either by disabling the glitch filter, or by ensuring can1_clk_root is always running when the CAN functionality is required.

CAN2 features a low-pass filter (=glitch filter) on the CAN RX input. This filter is fed by the WAKEUPMIX 24MHz clock and enabled by the WAKSRC field in the MCR register. If the filter is enabled its clock is gated, then the CAN RX input will not reach the FlexCAN logic. This condition must be avoided either by disabling the glitch filter, or by ensuring its clock is always running when the CAN functionality is required.

NOTE

The FlexCAN clock description mentions an "oscillator domain". This domain is connected either to can_clk_root for the CAN module (CAN_CTRL1[CLKSRC] = 0) or to the WAKEUPMIX bus clock (CAN_CTRL1[CLKSRC]=1). It is not directly connected to any oscillator.

39.2 Overview

FlexCAN is a communication controller implementing the CAN protocol according to the ISO 11898-1_2024 standard and CAN 2.0 Part B protocol specifications.

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific real-time processing and reliable operation requirements in the electromagnetic interference (EMI) environment of a vehicle. FlexCAN is a full implementation of the CAN protocol specification, the CAN with flexible data rate (CAN FD) protocol, and the CAN version 2.0 Part B protocol. It supports both standard and extended message frames and long payloads.

NOTE

Legacy Receive (RX) FIFO cannot be used in CAN Flexible Data (FD) mode. In CAN FD mode, use the Enhanced Receive FIFO feature instead of the Legacy Receive FIFO.

NOTE

FD mode is limited to Message Buffer (MB) mode only, the Enhanced Receive FIFO with DMA is supported.

39.2.1 Block diagram

Figure 145 shows the main submodules implemented in FlexCAN.

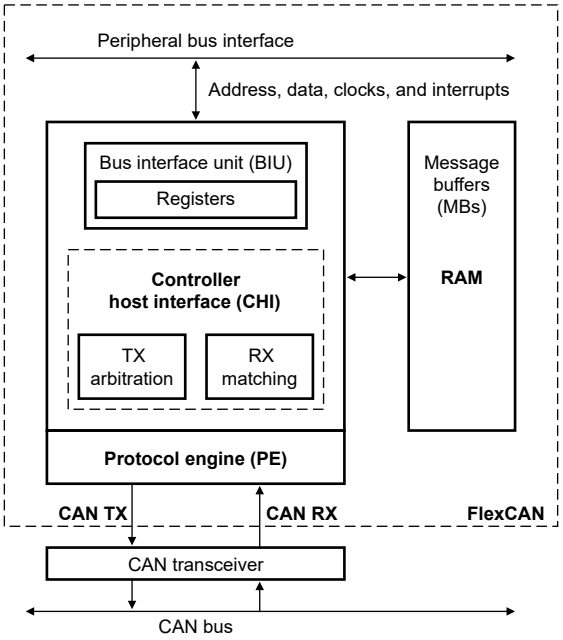

Figure 145. Block diagram

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- RAM access for receiving and transmitting message frames
- Receive message validation
- Error handling
- CAN FD message detection

Controller Host Interface (CHI) manages:

- Message buffer (MB) selection for reception and transmission
- Arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats

Bus Interface Unit (BIU) controls access to and from the internal interface bus to establish connection to the CPU and to other blocks. The BIU manages access to:

- Clocks
- Address and data buses
- Interrupt outputs
- DMA
- Test signals

39.2.2 Features

- Full implementation of *CAN with Flexible data rate (CAN FD) protocol specification* and *CAN Specification Version 2.0, Part B*:
  - Standard data frames
  - Extended data frames

  - Data length of 0–64 bytes
  - Content-related addressing
- Compliance with the ISO 11898-1_2024 standard
- Flexible message buffers that can be configured to store a payload of 0, 8, 16, 32, or 64 bytes
  - Increasing the payload size decreases the number of supported message buffers (see FlexCAN memory partition for CAN FD).
  - Message buffers are configurable as receive or transmit, supporting standard and extended messages.
- Individual Receive Mask registers for each message buffer
- Full-featured Legacy RX FIFO with storage capacity for six frames and automatic internal pointer handling with DMA support
- Full-featured Enhanced RX FIFO with storage capacity of 20 CAN FD frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Programmable clock source to CAN Protocol Interface, either peripheral clock or oscillator clock
- Optional general purpose RAM space, using RAM not used by reception or transmission structures
- Listen-Only mode
- Programmable loopback mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Timestamp based on 32-bit free-running timer, with optional external time tick
- Global network time, synchronized by specific message
- Maskable interrupts
- Independence from transmission medium (external transceiver is assumed)
- Short latency time due to arbitration scheme for high-priority messages
- Low-power modes, with programmable wake-up on bus activity
- Transceiver delay compensation when transmitting CAN FD messages at faster data rates
- Management of remote request frames, automatically or by software
- Restriction only to write CAN bit time settings and configuration bits in Freeze mode
- Transmit message buffer status (lowest-priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- ESR1[SYNCH] to indicate module is synchronous with CAN bus
- CRC status for transmitted message
- Legacy RX FIFO Global Mask register
- Selectable priority between message buffers and receive FIFO during matching process
- Powerful legacy RX FIFO ID filtering, capable of matching incoming IDs against either 128 extended IDs, 256 standard IDs, or 512 partial (8-bit) IDs, with 32 individual masking capability
- Powerful enhanced RX FIFO ID filtering, capable of matching incoming IDs against either 64 extended or 128 standard ID filter elements with three filtering schemes: mask plus filter, range, and two filters without mask
- Complete backward compatibility with previous FlexCAN version
- Detection and correction of errors in memory read accesses:

— Each byte of FlexCAN memory is associated to five parity bits.

— The error correction mechanism ensures that errors in one bit of this 13-bit word can be corrected (correctable errors).

— Errors in two bits can be detected but not corrected (noncorrectable errors).

39.3 Functional description

FlexCAN is a CAN protocol engine with a flexible message buffer system for transmitting and receiving CAN frames. The system is a set of message buffers (MBs) that stores configuration and control data, timestamp, message ID, and data (see Message buffer structure).

For classical CAN frames, FlexCAN supports simultaneous reception through Legacy FIFO and message buffer. For CAN FD frames, FlexCAN supports reception through message buffer and enhanced receive FIFO.

For message buffer reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed in the ID field. A masking scheme makes it possible to match the ID programmed on the message buffer with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of message buffers to be transmitted based on the message ID (optionally augmented by three local priority bits) or the message buffer ordering.

A message buffer is active at a given time if it can participate in both the matching and arbitration processes. A receive message buffer with a 0b code is inactive (see Table 278). A transmit message buffer with a 1000b or 1001b code is also inactive (see Table 279).

FlexCAN can receive and transmit messages in CAN FD format. The message buffers are sized to store the quantity of data bytes selected by FDCTRL[MBDSRn]. The quantity of FD message buffers available for a given quantity of data bytes is described in the CAN FD Control (FDCTRL) register. See also FlexCAN memory partition for CAN FD.

39.3.1 Modes of operation

FlexCAN has these functional modes:

Table 241. Functional modes

Mode	Description
Normal (User or Supervisor)	In Normal mode, FlexCAN receives and transmits message frames, manages errors normally, and enables all CAN Protocol functions. User and Supervisor modes differ in the access to some restricted control registers.
Freeze	Freeze mode is enabled when MCR[FRZ] = 1. If enabled, FlexCAN enters Freeze mode when MCR[HALT] is 1 or when is requested at chip level and FlexCAN writes 1 to MCR[FRZACK]. In this mode, no transmission or reception of frames is done, and synchronicity to the CAN bus is lost. See Freeze mode.
Loopback	FlexCAN enters this mode when CTRL1[LPB] becomes 1. In this mode, FlexCAN performs an internal loopback that can be used for self-test. The bit stream output of the transmitter is internally fed back to the receiver input. The receiving CAN input pin is ignored and the transmitting CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. To ensure proper reception of its own message, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. Both transmit and receive interrupts are generated.
Listen-Only	FlexCAN enters this mode when CTRL1[LOM] becomes 1. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

Table continues on the next page...

Table 241. Functional modes (continued)

Mode	Description
CAN FD Active	In this mode, FlexCAN can transmit and receive all messages formatted according to the CAN FD Standard (2.0) and 2.0B Protocol in an interleaved fashion. The CPU can put FlexCAN into CAN FD Active mode by configuring MCR[FDEN] in Freeze mode.

Some features available in classical CAN are unavailable in CAN FD mode.

Table 242. Differences between classical CAN and CAN FD

Feature	Classical CAN	CAN FD
Legacy RX FIFO DMA	Yes	No
Legacy RX FIFO	Yes	No
Enhanced RX FIFO DMA	Yes	Yes
Enhanced RX FIFO	Yes	Yes

FlexCAN can operate in these low-power modes:

Table 243. Low-power modes

Mode	Description
Module Disable	FlexCAN enters this mode when the CPU writes 1 to MCR[MDIS] and FlexCAN writes 1 to MCR[LPMACK]. After FlexCAN is disabled, it issues a request to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Writing 0 to MCR[MDIS] exits this mode. See Module Disable mode.
Doze	FlexCAN enters this mode when MCR[DOZE] is 1, Doze mode is requested at chip level, and FlexCAN writes 1 to MCR[LPMACK]. When in Doze mode, FlexCAN issues a request to disable the clocks to the CAN Protocol Engine and the CAN Controller-Host Interface submodules. This mode is exited when: • MCR[DOZE] becomes 0 • The chip is removed from Doze mode • Or activity is detected on the CAN bus and the Self-Wake-up mechanism is enabled. See Doze mode.
Stop	FlexCAN enters this mode when Stop mode is requested at chip level and FlexCAN writes 1 to MCR[LPMACK]. When in Stop mode, FlexCAN puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode occurs when the Stop mode request is removed, or when activity is detected on the CAN bus and the Self-Wake-up mechanism is enabled. See Stop mode.

39.3.1.1 Modes of operation details

FlexCAN has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following subsections contain functional details about Freeze mode and low-power modes.

CAUTION

FlexCAN does not support "Permanent Dominant" failure on the CAN bus line. If a Low-Power request or Freeze mode request occurs during a "Permanent Dominant" condition, the corresponding acknowledgment field can never be 1.

39.3.1.1.1 Freeze mode

This mode is requested either by the CPU writing 1 to MCR[HALT] or when the chip is put into Debug mode. MCR[FRZ] must be 1 and the module must not be in a low-power mode.

When MECR[NCEFAFRZ] becomes 1 and a noncorrectable error is detected in a memory read access performed by FlexCAN internal processes (see Error response), FlexCAN also requests Freeze mode. This request occurs via both MCR[HALT] and MCR[FRZ] automatically becoming 1.

To obtain acknowledgment, FlexCAN writes 1 to MCR[FRZACK]. The CPU must only consider FlexCAN to be in Freeze mode when both request and acknowledgment conditions are satisfied.

When Freeze mode is requested, FlexCAN:

1. Waits to be in either Intermission, Error Passive, Bus Off, or Idle state.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent entering Freeze mode.
3. Ignores the receive input pin and drives the transmit pin as recessive.
4. Stops the prescaler, halting all CAN protocol activities.
5. Grants write access to the Error Counters register, which is read-only in other modes.
6. Writes 1 to MCR[NOTRDY] and MCR[FRZACK].

After requesting Freeze mode, you must wait for MCR[FRZACK] to become 1 before executing any other action, otherwise FlexCAN may operate unpredictably. In Freeze mode, all memory-mapped registers are accessible, except for CTRL1[CLKSRC], which can be read but cannot be written.

Freeze mode is exited in one of these conditions:

- CPU writes 0 to MCR[FRZ].
- The chip is removed from Debug mode or the MCR[HALT] becomes 0.

MCR[FRZACK] becomes 0 after the protocol engine recognizes the negation of the freeze request. After leaving Freeze mode, FlexCAN tries to resynchronize to the CAN bus by waiting for 11 consecutive recessive bits.

39.3.1.1.2 Module Disable mode

This low-power mode is normally used to disable a complete FlexCAN block temporarily, with no power consumption. The CPU requests this mode by writing 1 to MCR[MDIS], and FlexCAN acknowledges the request by writing 1 to MCR[LPMACK]. The CPU must only consider FlexCAN to be in Disable mode when both the request and acknowledgment conditions are satisfied.

If FlexCAN is disabled during Freeze mode, the module requests to disable the clocks to the PE and CHI submodules, writes 1 to MCR[LPMACK] and writes 0 to MCR[FRZACK].

If the module is disabled during transmission or reception, FlexCAN:

1. Waits to be in either Idle or Bus Off state, or waits for the third bit of Intermission and then checks that it is recessive.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. FlexCAN does not take a pending move-in into account.
3. Ignores its receive input pin and drives its transmit pin as recessive.
4. Shuts down the clocks to the PE and CHI submodules.
5. Writes 1 to MCR[NOTRDY] and MCR[LPMACK].

In this mode, the Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except for:

- The Receive Message Buffers Global Mask registers
- The Receive Buffer 14 Mask register
- The Receive Buffer 15 Mask register

When in Disable mode, these items may not be accessible:

- The message buffers
- The Receive Individual Mask registers
- The reserved words within RAM

To exit this mode, the CPU writes 0 to MCR[MDIS], causing FlexCAN to request to resume the clocks and write 0 to MCR[LPMACK]. This write occurs after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

39.3.1.1.3 Doze mode

This is a system low-power mode in which the CPU bus is kept alive and a global Doze mode request is sent to all peripherals asking them to enter low-power mode. When Doze mode is globally requested, MCR[DOZE] needs to have been asserted previously for Doze mode to be triggered. The acknowledgement is obtained through the assertion of MCR[LPMACK] by FlexCAN. The CPU must only consider FlexCAN to be in Doze mode when both request and acknowledgement conditions are satisfied.

If Doze mode is triggered during Freeze mode, FlexCAN requests to shut down the clocks to the PE and CHI submodules, sets MCR[LPMACK] and negates MCR[FRZACK]. If Doze mode is triggered during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules.
- Sets MCR[NOTRDY] and MCR[LPMACK].

The Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except the Rx Mailboxes Global Mask registers, the Rx Buffer 14 Mask register, the Rx Buffer 15 Mask register.

Also, the message buffers, the Rx Individual Mask registers, and the reserved words within RAM may not be accessed when the module is in Doze mode.

Exiting Doze mode is done in one of the following ways:

- CPU removing the Doze mode request
- CPU negating MCR [DOZE]
- Self-Wake mechanism

In the Self-Wake mechanism, if MCR[SLFWAK] was set at the time FlexCAN entered Doze mode, then after detection of a recessive to dominant transition on the CAN bus, FlexCAN negates the DOZE bit, requests to resume its clocks and negates the LPMACK after the CAN protocol engine recognizes the negation of the Doze mode request. It also sets ESR [WAKINT] and, if enabled by MCR[WAKMSK], generates a Wake-Up interrupt to the CPU. FlexCAN then waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it does not receive the frame that woke it up. The following table details the effect of SLFWAK and WAKMSK after wakeup from Doze mode.

Table 244. Wakeup from Doze mode

SLFWAK	WAKINT	WAKMSK	FlexCAN clocks enabled	Wakeup interrupt generated
0	—	—	No	No
0	—	—	No	No

Table continues on the next page...

Table 244. Wakeup from Doze mode (continued)

SLFWAK	WAKINT	WAKMSK	FlexCAN clocks enabled	Wakeup interrupt generated
1	0	0	No	No
1	0	1	No	No
1	1	0	Yes	No
1	1	1	Yes	Yes

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the Rx CAN input line when in Doze mode. (See MCR[WAKSRC].) This feature can be used to protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

39.3.1.1.4 Stop mode

In this low-power mode for the system, all chip clocks can be stopped for maximum power savings. Stop mode is globally requested by the CPU and FlexCAN writes 1 to a Stop Acknowledgment signal to indicate acknowledgment. The CPU must only consider FlexCAN to be in Stop mode when both request and acknowledgment conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it shuts down the clocks globally by:

1. Writing 1 to MCR[LPMACK].
2. Writing 0 to MCR[FRZACK].
3. Sending the Stop Acknowledge signal to the CPU.

If Stop mode is requested during transmission or reception, FlexCAN:

1. Waits to be in either Idle or Bus Off state, or waits for the third bit of Intermission and verifies that it is recessive.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. FlexCAN does not take a pending move-in into account.
3. Ignores its receive input pin and drives its transmit pin as recessive.
4. Writes 1 to MCR[NOTRDY] and MCR[LPMACK].
5. Sends a Stop Acknowledge signal to the CPU, so that the CPU can shut down the clocks globally.

FlexCAN exits Stop mode when the CPU resumes the clocks and removes the Stop mode request. This exit can occur as a result of the Self-Wake mechanism.

In Self-Wake, if MCR[SLFWAK] = 1 when FlexCAN enters Stop mode, then upon detecting a recessive-to-dominant transition on the CAN bus, FlexCAN writes 1 to ESR1[WAKINT]. If enabled by MCR[WAKMSK], FlexCAN generates a wake-up interrupt to the CPU. Upon receiving the interrupt, the CPU should resume the clocks and remove the Stop mode request. FlexCAN waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, FlexCAN does not receive the frame that woke it up. Table 245 details the effect of MCR[SLFWAK] and MCR[WAKMSK] upon wakeup from Stop mode. Waking from Stop mode only works when both fields are 1.

After the CAN protocol engine recognizes the negation of the Stop mode request, FlexCAN writes 0 to MCR[LPMACK]. FlexCAN then waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, FlexCAN does not receive the frame that woke it up.

Table 245. Waking from Stop mode

SLFWAK	WAKINT	WAKMSK	Chip clocks enabled	Wake-up interrupt generated
0	—	—	No	No
0	—	—	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	No	No
1	1	1	Yes	Yes

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the receive CAN input line when in Stop mode. (See the description in MCR[WAKSRC].) This feature can protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

NOTE

When FlexCAN is in the Bus Off state and Low-Power mode, FlexCAN may take an extra 128 IDLE cycles to leave the Bus Off state after exiting Low-Power mode.

39.3.2 Transmission process

NOTE

Instances of MB_CS in this topic refer to items in message buffers. See Message buffer structure for details.

To transmit a CAN frame, the CPU must prepare a message buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt flag is set, and clear it if necessary.
2. If the message buffer is active (transmission pending), request an abort of the transmission. Write the ABORT code (1001b) to the CODE field of the Control and Status word.
3. Poll the IFLAG register until the corresponding IFLAG flag is set, or wait for the interrupt request (if enabled by the respective IMASK field).
4. Read the CODE field to identify whether the transmission was aborted or transmitted (see Transmission abort mechanism).
5. Clear the corresponding interrupt flag.
6. Write the ID register (containing the local priority if enabled via MCR[LPRIOEN]).
7. Write payload data bytes.
8. Configure the Control and Status word as needed.
    a. Set ID type via MB_CS[IDE].
    b. Set Remote Transmission Request (if needed) via MB_CS[RTR].
    c. If MCR[FDEN] = 1, configure MB_CS[EDL] and MB_CS[BRS]. For details about the relationship between the written value and transmitted value of MB_CS[ESI], see Table 255.[3]
    d. Configure Data Length Code in bytes via MB_CS[DLC]. See Table 282 for detailed information.

[3] There is no need to write the ESI field; it is automatically transmitted as dominant by error active nodes and as recessive by error passive nodes. If FlexCAN is operating as a network gateway, however, the CPU writes MB_CS[ESI] according to the error status of the node that sent the message.

e. To transmit the CAN frame, activate the message buffer by writing Ch to MB_CS[CODE].

NOTE

To maximize software performance, configure all the fields in the MB_CS word in a single 32-bit write operation. If the fields are configured in separate writes, MB_CS[CODE] must be the last write in the Control and Status word.

When the MB is activated, it participates in the arbitration process and its contents are eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission exceeds the MB payload size, FlexCAN completes the expected DLC by adding a constant CCh pattern.

After a successful transmission:

1. The value of the free-running timer is written into the timestamp field.
2. The CODE field in the Control and Status word is updated.
3. Both Cyclic Redundancy Check (CRCR) and CAN FD CRC (FDCRC) are updated.
4. A status flag is set in the Interrupt Flag register.
5. If allowed by the corresponding Interrupt Mask Register field, an interrupt is generated.

After transmission, the new CODE field depends on the code used to activate the message buffer (see Table 278 and Table 279 in Message buffer structure).

When the Abort feature is enabled (MCR[AEN] is 1), after the Interrupt flag is set for an MB configured as transmit buffer, the message buffer is blocked. The CPU cannot update the message buffer until the Interrupt Flag is cleared by the CPU. The CPU must clear the corresponding IFLAG flag before preparing this MB for a new transmission or reception.

NOTE

For backward compatibility (MCR[AEN] is 0), write the INACTIVE code (1000b) to the CODE field to deactivate the MB. In this case, the pending frame may be transmitted without notification (see Message buffer inactivation).

39.3.3 Arbitration process

The arbitration process scans the message buffers, searching for the transmission MB that holds the message to be sent at the next opportunity. This MB is called the arbitration winner. The scan starts from the lowest number MB and continues to the higher ones.

The arbitration process is triggered when at least one of the following occur:

- CRC field of the CAN frame arrives. The starting point depends on the value of CTRL2[TASD].
- Error Delimiter field of a CAN frame is in progress.
- Overload Delimiter field of a CAN frame is in progress.
- The winner of the arbitration is deactivated, and the CAN bus has not reached the first bit of the Intermission field.
- CPU writes to the Control and Status word of a winner MB, and the CAN bus has not reached the first bit of the Intermission field.
- CHI is in the Idle state and the CPU writes to the Control and Status word of any message buffer.
- FlexCAN exits Bus Off state.
- FlexCAN leaves Freeze mode or a low-power mode.

If the arbitration process does not evaluate all message buffers before the CAN bus reaches the first bit of the Intermission field, the temporary arbitration winner is invalidated. FlexCAN will not compete for the CAN bus at the next opportunity.

The arbitration process selects the winner among the active transmission message buffers at the end of the scan according to the values of CTRL1[LBUF] and MCR[LPRIOEN].

See Arbitration process (continued) for more information about this process.

39.3.3.1 Lowest-number message buffer first

If CTRL1[LBUF] is 1, the first (lowest number) active transmission message buffer found is the arbitration winner. MCR[LPRIOEN] has no effect when CTRL1[LBUF] is 1.

39.3.3.2 Highest-priority message buffer first

If CTRL1[LBUF] is 0, the arbitration process searches for the active transmission message buffer with the highest priority. The frame of this message buffer has a higher probability of winning the arbitration on the CAN bus when multiple external nodes compete for the bus simultaneously.

The sequence of bits considered for this arbitration is called the arbitration value of the message buffer. The transmission message buffer with the lowest arbitration value among all transmission message buffers has the highest priority.

If two or more message buffers have equivalent arbitration values, the message buffer with the lowest number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIOEN].

39.3.3.2.1 Local priority disabled

If MCR[LPRIOEN] = 0, the arbitration value is built using the exact sequence of bits that would be transmitted in a CAN frame where local priority is disabled.

Table 246. Composition of the arbitration value when local priority is disabled

Format	Message buffer arbitration value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	— (18 bits)	— (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

39.3.3.2.2 Local priority enabled

To enable local priority, MCR[LPRIOEN] must be 1. In this case, the message buffer PRIO field (see Message buffer structure) is included at the very left of the arbitration value.

Table 247. Composition of the arbitration value when local priority is enabled

Format	Message buffer arbitration value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	— (18 bits)	— (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

Because the PRIO field is the most significant part of the arbitration value, message buffers with low PRIO values have higher priority than message buffers with high PRIO values. This priority is maintained regardless of the rest of their arbitration values.

The PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

39.3.3.3 Arbitration process (continued)

After the arbitration winner is found (see Arbitration process), its content is copied to a hidden auxiliary message buffer called a transmit serial message buffer (TX SMB). The TX SMB has the same structure as a normal message buffer, but is not user-accessible. This copy operation is called move-out. After it is done, write access to the Control and Status word of the corresponding MB is blocked (if MCR[AEN] = 1). Write access is restored in one of the following events:

- The CPU clears the corresponding IFLAG flag after the message buffer is transmitted.
- FlexCAN enters Freeze mode or Bus Off state.
- FlexCAN loses the bus arbitration, or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the TX SMB is transmitted according to the CAN protocol rules.

The arbitration process can be triggered under the following conditions:

- During RX and TX frames from CAN CRC field to end of frame. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.
- During CAN Bus Off state from TX_ERR_CNT = 124 to 128. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.
- During Control and Status write by CPU in Bus Idle. The first Control and Status write starts the arbitration process, and a second Control and Status write during this same arbitration restarts the process. If other Control and Status writes are performed, the transmission arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and Bus Idle state starts, then an arbitration process is triggered. In this case, the first and second Control and Status writes in Bus Idle do not restart the arbitration process. If there is not enough time to finish arbitration in the Wait for Bus Idle state and the next state is Idle, the scan is not interrupted. That scan is completed during Bus Idle state. During this arbitration, a Control and Status write does not cause an arbitration restart.
- Deactivation of an arbitration winner during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the Wait for Bus Idle state). If a resynchronization occurs during the Wait for Bus Idle state, the arbitration process is restarted.

The arbitration process stops when:

- All message buffers are scanned.
- A transmission message buffer is found (if lowest buffer feature is enabled).
- An arbitration winner deactivates or aborts during any arbitration process.
- There is not enough time to finish the transmission arbitration process (for instance, when a deactivation is performed near the end of frame). In this case, the arbitration process is pending.
- An error or overload flag occurs in the bus.
- A low-power or Freeze mode request occurs in Idle state.

Arbitration is considered pending when:

- It is not possible to finish arbitration process in time.
- A Control and Status write occurs during arbitration, when that write is performed in an MB whose number is lower than the transmission arbitration pointer.
- Any Control and Status write occurs when there is no transmission arbitration process in progress.
- RX Match has updated an RX code to TX code.
- FlexCAN enters the Bus Off state.

If a Control and Status write is performed in the arbitration winner, a new process is restarted immediately.

If a Control and Status write is performed in an MB whose number is higher than the transmission arbitration pointer, the ongoing arbitration process scans this MB as normal.

39.3.4 Receive process

To be able to receive CAN frames into a message buffer, the CPU must prepare it for reception by executing the following steps:

1. If the message buffer is active (either TX or RX), deactivate it (see Message buffer inactivation), preferably with a safe deactivation (see Transmission abort mechanism).

2. Write the ID word into the message buffer.
3. To activate the message buffer, write the EMPTY code (0100b) to the CODE field of the Control and Status word. No setup is required for EDL, BRS, and ESI fields. The respective fields in the received message overwrite these fields.

After the MB is activated, it can receive frames that match the programmed filter. At the end of a successful reception, the move-in process updates the message buffer (see Move-in) as follows:

1. The received data field (up to eight bytes for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.
3. The value of the free-running timer when the second bit of the Identifier field of the frame is written into the Timestamp field of the MB.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 278 and Table 279 in Section Message buffer structure).
6. If allowed by the corresponding Interrupt Mask field, a status flag is set in the Interrupt Flag register and an interrupt is generated.

The recommended way for the CPU to service (read) the frame received in a message buffer is:

1. Read the Control and Status word of that message buffer.
2. Verify that the BUSY bit is 0, indicating that the message buffer is locked. If it is not 0, repeat step 1 until it becomes 0. See Message buffer lock mechanism.
3. Read the contents of the message buffer. After the message buffer is locked, FlexCAN move-in processes do not modify its contents. See Move-in.
4. Acknowledge the proper flag in the IFLAG registers.
5. Unlock the message buffer by reading the free-running timer.

To verify frame reception, the CPU should poll the status flag bit for that specific message buffer in one of the IFLAG registers, not the CODE field of that message buffer. Polling the CODE field does not work in this case. After a frame is received and the CPU services the message buffer (by reading the Control and Status word and unlocking the message buffer), the CODE field does not return to EMPTY. It remains FULL, as explained in Table 278. If the CPU tries to work around this behavior by writing to the Control and Status word to force an EMPTY code after reading the message buffer without a prior safe deactivation, a newly received frame matching the filter of that message buffer may be lost.

CAUTION

In summary: never poll by reading the Control and Status word of the message buffers directly. Instead, read the IFLAG registers.

The Identifier field of the received frame is always stored in the matching message buffer. If the match was due to masking, the contents of the ID field in a message buffer may change. When MCR[SRXDIS] becomes 1, FlexCAN does not store frames transmitted by itself in any MB, even if it contains a matching receive MB. Also, no interrupt flag or interrupt signal is generated. Otherwise, when MCR[SRXDIS] becomes 0, if a matching receive MB exists, FlexCAN can receive frames transmitted by itself.

When MCR[DMA]) becomes 1, upon receiving a frame in the Legacy FIFO, IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see Legacy RX FIFO in DMA operation). The IMASK1 fields in the Legacy RX FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 80h address, optional).
2. Read the ID field (read 84h address, optional).
3. Read all data bytes (start read at 88h address, optional).

39.3.5 Matching process

The matching process scans the message buffer memory for RX MBs programmed with the same ID as the one received from the CAN bus. The matching starts from the lowest number message buffer and continues toward the higher-numbered ones.

For enhanced RX FIFO, see Enhanced RX FIFO.

For legacy RX FIFO, see Legacy RX FIFO.

As the frame is received, it is stored in a hidden auxiliary MB called Receive Serial Message Buffer (RX SMB).

The starting point of the matching process depends on the following conditions:

- If the received frame is a remote frame, the starting point is the CRC field of the frame.
- If the received frame is a data frame with DLC field equal to zero, the starting point is the CRC field of the frame.
- If the received frame is a data frame and the DLC field has a nonzero value, the starting point is the DATA field of the frame.

If a matching ID is found in one of the message buffers, the move-in process transfers the contents of the RX SMB to the matched MB. If any CAN protocol error is detected, no match results are transferred to the matched MB at the end of reception.

The matching process scans all matching elements of the active receive MBs (CODE is EMPTY, FULL, OVERRUN, or RANSWER). The process searches for a successful comparison to the matching elements of the RX SMB that is receiving the frame on the CAN bus. The RX SMB has the same structure as a message buffer. The reception structures (message buffers) associated with the matching elements that had a successful comparison are the matched structures. The matching winner is selected at the end of the scan among those matched structures. The matching winner depends on conditions described in Table 248.

Table 248. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Message buffer	0	—	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY, FULL, or OVERRUN
Message buffer	0	—	1	cmp_msk	cmp_msk	cmp_msk	EMPTY, FULL, or OVERRUN
Message buffer	1	0	—	cmp	no_cmp	cmp	RANSWER
Message buffer	1	1	0	cmp	no_cmp	cmp_msk	EMPTY, FULL, or OVERRUN
Message buffer	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY, FULL, or OVERRUN

1. For message buffer structure, if SMB[IDE] is 1, the ID is 29 bits (ID Standard plus ID Extended). If SMB[IDE] is 0, the ID is 11 bits (ID Standard). For Legacy RX FIFO structure, the ID depends on IDAM.
2. cmp: Compares the RX SMB contents to the MB contents regardless of masks.
3. no_cmp: The RX SMB contents are not compared to the MB contents.
4. cmp_msk: Compares the RX SMB contents to MB contents, accounting for masks.

NOTE

For Enhanced RX FIFO, see Enhanced RX FIFO matching process.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the message buffer is EMPTY.
- The CODE field of the message buffer is either FULL or OVERRUN, and it has already been serviced (the CPU has read the Control and Status word and unlocked it as described in Message buffer lock mechanism).
- The CODE field of the message buffer is either FULL or OVERRUN and an inactivation (see Message buffer inactivation) is performed.

The scan order for message buffers is from the matching element with the lowest number to the higher ones.

39.3.5.1 Matching priority

MCR[IRMQ] affects the matching winner search for MBs. If the field is 0, the matching winner is the first matched MB whether it is free-to-receive or not. If it is 1, the matching winner is selected according to this priority:

1. The first free-to-receive matched message buffer
2. The last non-free-to-receive matched message buffer

39.3.5.2 Special cases

If a non-safe MB inactivation (see Message buffer inactivation) occurs during the matching process and the inactivated MB is the temporary matching winner, the temporary matching winner is invalidated. The matching elements scan is not stopped and not restarted; it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist. In this case, a message may be lost.

Consider an example where:

- MCR[IRMQ] is 1.
- There are two message buffers with the same ID: the second and fifth MBs in the array.
- FlexCAN starts receiving messages with that ID.

When the first message arrives, the matching algorithm finds the first match in message buffer number 2. The code of this message buffer is EMPTY, so the message is stored in that MB. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive." It continues looking, finds MB number 5, and stores the message in that MB. If yet another message with the same ID arrives, the matching algorithm finds no matching free-to-receive MBs, so it overwrites the last matched message buffer (MB number 5). In doing so, it updates the CODE field of the message buffer to OVERRUN.

The ability to match the same ID in more than one MB can be used to implement a reception queue to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the message buffers. The CPU can examine the Timestamp field of the message buffers to determine the order in which the messages arrived.

Matching a range of IDs is possible via ID acceptance masks. FlexCAN supports individual masking per message buffer (see Receive Individual Mask (RXIMR0 - RXIMR95)). During the matching algorithm, if a mask field is 1, the corresponding ID bit is compared. If the mask field is 0, the corresponding ID bit is a "don't care". Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed when the module is in Freeze mode; otherwise, the module blocks them.

FlexCAN also supports an alternate masking scheme with only RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), and Receive 15 Mask (RX15MASK) for backward compatibility with legacy applications. This alternate masking scheme is enabled when the MCR[IRMQ] = 0.

39.3.6 Move process

There are two types of move process: move-in and move-out.

39.3.6.1 Move-in

The move-in process is the copying of a message received by an RX SMB to an RX message buffer that has matched it. Each RX SMB has its own move-in process, but only one is performed at a given time. The move-in starts only when the message held by the RX SMB has a corresponding match (see Matching process) and all of the following conditions are true:

- The CAN bus has reached or already gone past:
  - The second bit of Intermission field next to the frame that carried the message that is in the RX SMB.
  - The first bit of an overload frame next to the frame that carried the message in the RX SMB.
- There is no ongoing matching process.
- The CPU is not locking the destination message buffer.
- No move-in process from another RX SMB is ongoing. If more than one move-in process is to be started at the same time, both are performed and the newest process substitutes for the oldest.

The term "pending move-in" is used throughout the documentation and stands for a move-to-be that does not satisfy all of the above conditions.

If any of the following conditions is satisfied, the move-in is canceled and the RX SMB is able to receive another message:

- The destination message buffer is inactivated after the CAN bus has reached the first bit of the Intermission field next to the frame that carried the message. Also, its matching process has finished.
- There is a previous pending move-in to the same destination message buffer.
- The RX SMB is receiving a frame transmitted by FlexCAN itself and self-reception is disabled (MCR[SRXDIS] = 1).
- Any CAN protocol error is detected.

If the module enters Freeze or Low-Power mode, the pending move-in is not canceled. It remains on hold, waiting for Freeze and Low-Power mode to be exited and for the module to be unlocked. If a message buffer is unlocked during Freeze mode, the move-in occurs immediately.

The move-in process is FlexCAN executing the following steps:

1. Read all data words from the RX SMB in accordance with the selected payload size for the RX storage element.
2. Write all data words to the RX message buffer according to the selected payload size for the RX storage element. If the data size of the storage element is smaller than the original payload size described in the DLC field of the message, the payload is truncated. The high-order bytes that do not fit the destination size are lost.
3. Read the Control and Status and ID words from the RX SMB.
4. Write the Control and Status and ID words to the RX message buffer, and update the CODE field.

The move-in process is not atomic; the inactivation of the destination message buffer immediately cancels it (see Message buffer inactivation). In this case, the message buffer may remain partially updated, and therefore incoherent.

To alert the CPU that the message buffer content is temporarily incoherent, the BUSY Bit (least significant bit of the CODE field) of the destination message buffer becomes 1 during move-in.

39.3.6.2 Move-out

The move-out process is the copying of content from a TX message buffer to the TX SMB when a message for transmission is available (see Arbitration process). The move-out occurs in the following conditions:

- In the first bit of the Intermission field
- During the Bus Off state, when the TX error counter is in the 124 to 128 range
- During the Bus Idle state
- During the Wait for Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently outside the Bus Idle state. In Bus Idle, the move-out has the lowest priority of the concurrent memory accesses.

39.3.7 Data coherence

In order to maintain data coherency and proper FlexCAN operation, the CPU must obey the rules described in Transmission process and Receive process.

39.3.7.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU whether the transmission was aborted or the frame could not be aborted and was transmitted instead.

These primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] must be 1.
- The first CPU action must be the writing of abort code (1001b) into the CODE field of the Control and Status word.

Active message buffers configured for transmission must be aborted before they can be updated. The write operation is blocked and the transmission is not disturbed when the abort code is written to:

- A message buffer currently being transmitted.
- A message buffer that was already loaded into the TX SMB for transmission.

In this case, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration.
- There is an error during the transmission.
- The module is put into Freeze mode.
- The module enters the Bus Off state.
- There is an overload frame.

If none of the conditions above are reached:

1. The message buffer is transmitted correctly.
2. The interrupt flag is set in the proper IFLAG register.
3. If enabled, an interrupt to the CPU is generated.

The abort request is automatically cleared when the interrupt flag is set. If only one of the above conditions is reached, the frame is not transmitted. In this case:

1. The abort code is written into the CODE field.
2. The interrupt flag is set in the proper IFLAG register.
3. Optionally, an interrupt is generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, the write operation is not blocked. The MB is updated and the interrupt flag is set. In this way, the CPU only needs to read the abort code to verify that the active MB was safely inactivated. In this case, although MCR[AEN] = 1 and the CPU wrote the abort code, the MB is inactivated and not aborted, because the transmission did not start yet. A message buffer is aborted only when the abort request is captured and kept pending until one of the previous conditions is satisfied.

39.3.7.2 Message buffer inactivation

Inactivation protects the message buffer against updates by FlexCAN internal processes. It allows the CPU to rely on message buffer data coherence after having updated it, even in Normal mode.

Inactivation of transmission message buffers must be performed only when MCR[AEN] = 0.

If a message buffer is inactivated, it does not participate in the arbitration process or the matching process until it is reactivated. See Transmission process and Receive process for detailed instructions on how to inactivate and reactivate a message buffer.

To inactivate a message buffer, the CPU must update its CODE field to INACTIVE (either 0b or 1000b).

Because you cannot synchronize the CODE field update with FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of an inactivated RX message buffer may be lost without notice. This loss can occur even if there are other message buffers with the same filter.
- A frame containing the message within an inactivated TX message buffer may be transmitted without setting the respective IFLAG flag.

To perform a safe inactivation and avoid the above consequences for TX message buffers, the CPU must use the transmission abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the message buffer (see Message buffer lock mechanism).

39.3.7.3 Message buffer lock mechanism

In addition to message buffer inactivation, FlexCAN uses a message buffer lock mechanism to maintain data coherence for the receive process. When the CPU reads the Control and Status word of an RX message buffer with codes FULL or OVERRUN, FlexCAN is configured to allow the CPU to read the whole message buffer in an atomic operation. FlexCAN sets an internal lock flag for that message buffer.

The lock is released in any of the following events:

- The CPU reads the free-running timer (global unlock operation).
- The CPU reads the Control and Status word of another message buffer, regardless of its code.
- The CPU writes into the Control and Status word. This procedure is not recommended for normal unlocking, because it cancels a pending move and may lose a received message.

The message buffer lock prevents a new frame from being written into the message buffer when the CPU is reading it.

NOTE

The locking mechanism applies only to RX message buffers that have a code other than INACTIVE (0b) or EMPTY[1] (0100b). TX message buffers cannot be locked.

Consider an example where:

- The second and the fifth message buffers of the array are programmed with the same ID.
- FlexCAN has already received and stored messages into these two message buffers.
- The CPU reads message buffer number 5 while another message with the same ID is arriving.

When the CPU reads the Control and Status word of message buffer number 5, this message buffer is locked. The new message arrives and the matching algorithm finds no free-to-receive message buffers, so it overrides message buffer number 5. This message buffer is locked, so the new message cannot be written to it. The message remains in the RX SMB until the message buffer is unlocked, and only then is it written to the message buffer.

If the message buffer remains locked and another new message with the same ID arrives, the new message overwrites the one in the RX SMB. There is no indication of lost messages in the CODE field of the message buffer or in Error and Status 1 (ESR1).

When the message is moved from the RX SMB to the message buffer, the BUSY bit on the CODE field becomes 1. If the CPU reads the Control and Status word and identifies that the BUSY bit is 1, it must wait until the BUSY bit becomes 0 to access the MB.

NOTE

If the BUSY bit is 1 or the message buffer is empty, reading the Control and Status word does not lock the message buffer.

Inactivation takes precedence over locking. If the CPU inactivates a locked receive message buffer, then its lock status is negated and the message buffer is marked as invalid for the current matching round. Any pending message on the RX SMB is not

[1] In previous FlexCAN versions, reading the Control and Status word locked the message buffer even when CODE indicates it is EMPTY. This behavior is maintained when the IRMQ bit is 0.

transferred to the message buffer. A message buffer is unlocked when the CPU reads Free-Running Timer (TIMER) or the Control and Status word of another message buffer.

The lock and unlock mechanisms have the same functionality in Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. If unlocking occurs during a low-power mode, however, the move-in is postponed (see Modes of operation). Move-in takes place only when the module returns to Normal or Freeze mode.

39.3.8 Enhanced RX FIFO

FlexCAN supports an enhanced RX FIFO engine which can store up to 20 CAN FD messages. The region 2000h–204Fh contains the output of the FIFO, which the CPU should read. To enable the enhanced RX FIFO, write 1 to ERFCR[ERFEN]. FlexCAN has two FIFO options, Legacy RX FIFO and Enhanced RX FIFO, but both options cannot be enabled at the same time. See Legacy RX FIFO for additional information.

To configure the enhanced RX FIFO watermark, write a value to ERFCR[ERFWM]. If ERFCR[ERFWM] is configured, the CPU is notified only if a minimum number of messages is stored in the FIFO. When the number of stored messages is greater than the value in ERFCR[ERFWM], the module sets ERFSR[ERFWMI]. Optionally, if MCR[DMA] or ERFIER[ERFWMIIE] are enabled, a DMA transfer or an interrupt can be triggered, respectively.

For the enhanced RX FIFO to receive, the CPU must execute the configuration procedure below. If the CPU must change any configurations of the Enhanced RX FIFO, the same procedure must be followed.

Prerequisites

MCR[RFEN] must be 0.

Procedure

Step	Purpose	Programming	Notes
1	Enter Freeze mode.	See Freeze mode.	—
2	If enhanced RX FIFO is not already enabled, enable it.	Write 1 to ERFCR[ERFEN].	—
3	Reset enhanced RX FIFO engine.	Write 1 to ERFSR[ERFCLR].	—
4	If the enhanced RX FIFO error flags are set, clear them.	Write 1 to these flags: • ERFSR[ERFUFW] • ERFSR[ERFOVF] • ERFSR[ERFWMI] • ERFSR[ERFDA]	—
5	Specify the total number of enhanced RX FIFO filter elements to be used in Enhanced RX FIFO reception.	Write the number to ERFCR[NFE].	—
6	Specify the number of extended ID and standard ID filter elements to be used in Enhanced RX FIFO reception.	Write the number to ERFCR[NEXIF].	ERFCR[NEXIF] ≤ ERFCR[NFE] + 1.
7	If you are using DMA, enable DMA.	Write 1 to MCR[DMA].	—
8	If you are using DMA, specify the number of words to transfer for each Enhanced RX FIFO data element.	Write the number to ERFCR[DMALW].	—

Table continues on the next page...

Table continued from the previous page...

Step	Purpose	Programming	Notes
9	Specify the Enhanced RX FIFO watermark.	Write the number to ERFCR[ERFWM].	If MCR[DMA] = 1, ERFCR[ERFWM] should be 0h.
10	If you are using interrupts, enable the interrupts.	Write 1 to the interrupt enables in Enhanced RX FIFO Interrupt Enable (ERFIER).	—
11	Configure the filter elements.	Write to the ERFFEL*n* registers.	ERFFEL*n* registers are implemented in RAM; you must explicitly initialize them before prior any reception.
12	Exit Freeze mode.	See Freeze mode.	—

There are two types of enhanced RX FIFO filter elements that can be stored in ERFFEL*n* registers: extended-ID filter elements and standard-ID filter elements. Each extended-ID filter element is stored in two ERFFEL*n* registers, and each standard-ID filter element is stored in one ERFFEL*n* register. ERFCR[NFE] defines the total number of Enhanced RX FIFO filter elements.

In addition, the filter memory space can be split into two regions: one for extended-ID filter elements and another for standard-ID filter elements, according to ERFCR[NEXIF]. Figure 146 shows how the enhanced RX filter elements are defined. See Enhanced RX FIFO matching process for information about the Enhanced RX FIFO matching process and filter element formats.

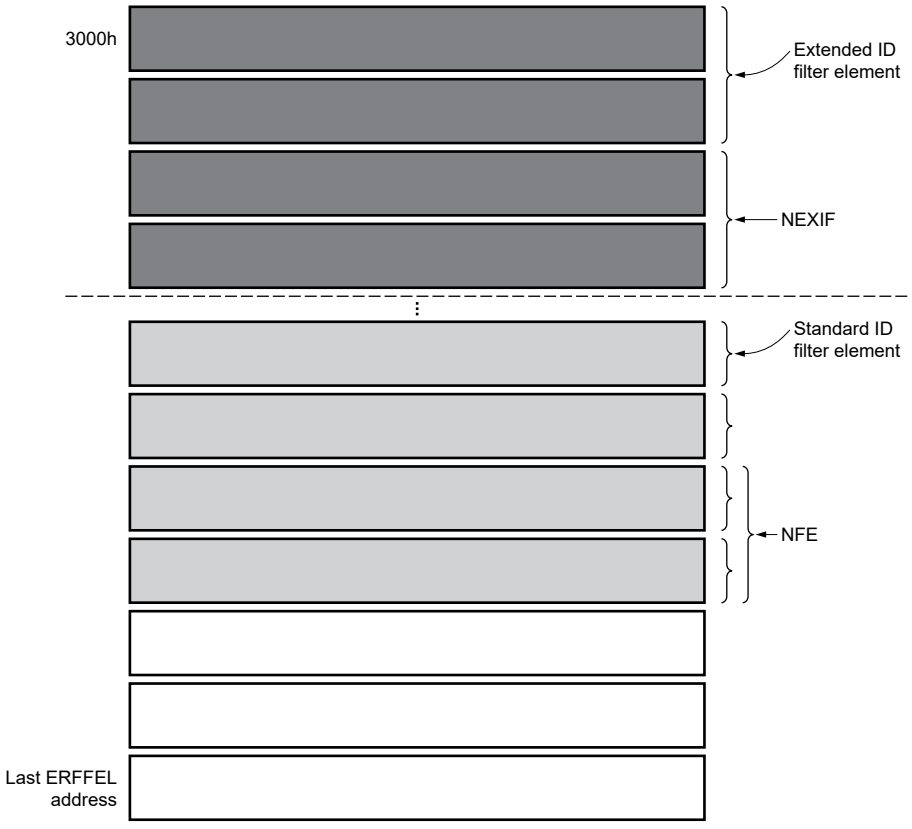

Figure 146. Number of enhanced RX FIFO filter elements

39.3.8.1 Enhanced RX FIFO matching process

When ERFCR[ERFEN] = 1, FlexCAN scans the ERFFEL*n* memory region. If at least one filter element satisfies the matching criteria, the CAN message content is transferred to the enhanced RX FIFO memory. If multiple filters match the incoming message ID, the first matching filter found by the matching process must be indicated in IDHIT.

Each ERFFEL*n* register can store one standard filter element. ERFFEL*n*[FEL][31:30], also called FSCH, determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base-frame format (IDE = 0).
  2. (ID[*n*] = STD ID filter [*n*]) or (STD ID Mask[*n*] = 0) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

In this explanation, RTR and ID are the Remote Transmit Request field and the ID from a CAN message, respectively.

If FSCH = b00, the filters and masks are defined as shown in Table 249.

Table 249. Standard ID filter element with filter and mask scheme (FSCH = b00)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b00		Reserved		RTR Filter	STD ID Filter		Reserved		RTR MASK	STD ID MASK	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. ID ≥ STD ID Filter1.
  3. ID ≤ STD ID Filter2.
  4. (RTR = RTR filter) or (RTR MASK = 0).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b01, the filters and mask are defined as shown in Table 250.

Table 250. Standard ID filter element with range scheme (FSCH = b01)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b01		Reserved		RTR Filter	STD ID Filter2		Reserved		RTR MASK	STD ID Filter1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. (ID[*n*] = STD ID Filter1[*n*]) or (ID[*n*] = STD ID Filter2[*n*]) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b10, the filters are defined as shown in Table 251.

Table 251. Standard ID filter element with two-filter scheme (FSCH = b10)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b10		Reserved		RTR Filter 2	STD ID Filter2		Reserved		RTR Filter 1	STD ID Filter1	

Each pair of ERFFEL*n* registers can store one extended filter element. ERFFEL*n*[FSCH] determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID filter [*n*]) or (EXT ID Mask[*n*] = 0) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b00, the filters and masks are defined as shown in Table 252.

Table 252. Extended ID filter element with filter + mask scheme (FSCH = b00)

31	30	29	28	0
FSCH		RTR Filter	EXT ID Filter	
Reserved		RTR MASK	EXT ID MASK	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches an extended ID filter element only if the following criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. ID ≥ EXT ID Filter1.
  3. ID ≤ EXT ID Filter2.
  4. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b01, the filters and masks are defined as shown in Table 253.

Table 253. Extended ID filter element with range scheme (FSCH = b01)

31	30	29	28	0
FSCH		RTR Filter	EXT ID Filter2	
Reserved		RTR MASK	EXT ID Filter 1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID Filter1[*n*]) or (ID[*n*] = EXT ID Filter2[*n*]) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

If FSCH = b10, the filters are defined as shown in Table 254.

Table 254. Extended ID filter element with two-filter scheme (FSCH = b10)

31	30	29	28	0
FSCH		RTR Filter2	EXT ID Filter2	
Reserved		RTR Filter1	EXT ID Filter 1	

39.3.8.2 Enhanced RX FIFO under DMA operation

You can enable the DMA feature by writing 1 to both ERFCR[ERFEN] and MCR[DMA]. The DMA controller can read the received message by reading a message buffer structure at the enhanced FIFO output port at the address range defined in Enhanced RX FIFO structure.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

For proper FIFO engine operation, the CPU should not access the Enhanced FIFO output port address range during DMA operation. Before writing 1 to MCR[DMA], the CPU must service Enhanced RX FIFO status bits. Otherwise, these bits may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must first clear the ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFWMI], and ERFSR[ERFDA] flags. It must then clear the enhanced RX FIFO engine by writing one to ERFSR[ERFCLR].

When there is one frame available to be read from the Enhanced RX FIFO, FlexCAN sets ERFSR[ERFDA]. Upon receiving the request, the DMA controller can read the message in the Enhanced RX FIFO output. Each message reading process must end by the address defined in ERFCR[DMALW].

Follow these rules for Enhanced RX FIFO DMA operation:

- Because a DMA transfer cannot be changed dynamically, program ERFCR[DMALW] so the enhanced RX FIFO element can store the largest CAN message present on the CAN bus.
- Data bytes are valid according to the DLC field. See Table 282.

Each time the DMA controller reads one message from the FIFO, FlexCAN clears ERFSR[ERFDA]. If there is at least one message stored in the FIFO, FlexCAN sets it again.

Consider an example where the maximum number of bytes in the data field of a CAN frame for a certain application is eight, and high-resolution timestamp is enabled. In that case, the last enhanced RX FIFO address offset can be found in Table 292 and Table 293. Using this address offset, ERFCR[DMALW] can be determined in this way:

- Maximum number of data bytes = 8
- HR_TIME_STAMP enabled
- Last address offset = TS_OFF = 2014h
- DMALW = 5

39.3.8.3 Enhanced RX FIFO clear operation

When ERFCR[ERFEN] is 1, the CPU can clear the Enhanced RX FIFO by writing 1 to ERFSR[ERFCLR]. The clear operation resets the internal FIFO pointers, but the FIFO content stored in RAM is not changed. This operation can only be performed in Freeze mode; the module blocks the operation in other modes. This operation does not clear ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFDA], or ERFSR[ERFWMI]. The CPU must service all these fields before executing the clear FIFO operation.

39.3.9 Legacy RX FIFO

The Legacy RX FIFO is receive-only. To enable it, write 1 to MCR[RFEN]. To maintain software backward compatibility with previous versions of FlexCAN that did not have the Legacy FIFO feature, the reset value of this field is zero.

CAUTION

Do not enable Legacy RX FIFO when the CAN FD feature is enabled.

The Legacy FIFO is six messages deep. The memory region the Legacy FIFO structure occupies (both message buffers and Legacy FIFO engine) is described in Legacy RX FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the Legacy FIFO.

IFLAG1[BUF5I] (Frames Available in Legacy RX FIFO) is set when at least one frame is available to be read from the Legacy FIFO. If the corresponding mask bit enables it, an interrupt is generated. Upon receiving the interrupt, the CPU can read the message (accessing the output of the Legacy FIFO as a message buffer) and Legacy RX FIFO Information (RXFIR), then clear the interrupt. If there are more messages in the Legacy FIFO, clearing the interrupt:

1. Updates the output of the Legacy FIFO with the next message.
2. Updates RXFIR with the attributes of that message.
3. Reissues the interrupt to the CPU.

Otherwise, the flag remains cleared. The output of the Legacy FIFO is valid only when IFLAG1[BUF5I] is set.

IFLAG1[BUF6I] (Legacy RX FIFO Warning) is set when the Legacy RX FIFO receives a new message that increases the number of unread messages from four to five. This change means that the Legacy RX FIFO is almost full. The flag remains set until the CPU clears it.

IFLAG1[BUF7I] (Legacy RX FIFO Overflow) is set when an incoming message is lost because the Legacy RX FIFO is full. The flag is not set when the Legacy RX FIFO is full and a message buffer captures the message. The flag remains set until the CPU clears it.

Clearing one of the three flags above does not affect the state of the other two.

If an IFLAG flag is set and the corresponding mask bit is 1, an interrupt is generated.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria are specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN]. This table can be configured to one of the following formats (see also Legacy RX FIFO structure):

- Format A: 128 Identifier Acceptance Filters (IDAFs) — extended or standard IDs including IDE and RTR
- Format B: 256 IDAFs — standard IDs or extended 14-bit ID slices including IDE and RTR
- Format C: 512 IDAFs — standard or extended 8-bit ID slices

NOTE

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the Legacy RX FIFO has a corresponding Identifier Acceptance Filter Hit Indicator (IDHIT). The IDHIT can be read in the IDHIT field in the Control and Status word, as shown in the Legacy RX FIFO Structure description. The CPU can also obtain this information by accessing Legacy RX FIFO Information (RXFIR). RXFIR[IDHIT] refers to the message at the output of the Legacy FIFO, and is valid when IFLAG1[BUF5I] is set. RXFIR must be read only before clearing the flag, guaranteeing that the information refers to the correct frame within the Legacy FIFO.

The Individual Mask Registers (RXIMR*n*) individually affect up to 32 elements of the filter table, according to the value of CTRL2[RFFN]. This configuration allows very powerful filtering criteria to be defined. If MCR[IRMQ] is 0, the Legacy RX FIFO filter table is affected by Legacy RX FIFO Global Mask (RXFGMASK).

NOTE

See Table 242 for information about the difference between FD and non-FD regarding this feature.

39.3.9.1 Legacy RX FIFO in DMA operation

The receive-only Legacy FIFO can support DMA. To enable this feature, write 1 to both MCR[RFEN] and MCR[DMA]. To maintain backward compatibility with previous versions of the module that did not have the DMA feature, the reset value of MCR[DMA] is zero.

The DMA controller can read the received message by reading a message buffer structure at the Legacy FIFO output port in the 80h–8Ch address range.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

When MCR[DMA] = 1, the CPU must not access the Legacy FIFO output port address range. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. Otherwise, these flags may indicate that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must perform a clear Legacy FIFO operation.

When at least one frame available to be read from the FIFO, IFLAG1[BUF5I] (Frames available in Legacy RX FIFO) is set. A DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the Legacy FIFO as a message buffer). The DMA reading process must end by reading address 8Ch. This read operation:

- Clears IFLAG1[BUF5I].
- Updates the FIFO output with the next message (if the FIFO is not empty).
- Updates Legacy RX FIFO Information (RXFIR) with the attributes of the new message.

If there are more messages stored in the FIFO, IFLAG1[BUF5I] is reasserted and another DMA request is issued. Otherwise, the flag remains cleared.

IFLAG1[BUF6I] and IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Legacy RX FIFO interruption and must not clear the related IFLAG flags. The related IMASK bits are not used to mask the generation of DMA requests.

NOTE

See Table 242 for information about the difference between FD and non-FD regarding this feature.

39.3.9.2 Clear legacy FIFO

When MCR[RFEN] = 1, you can use the clear Legacy FIFO operation to empty Legacy FIFO contents. When the CPU writes 1 to IFLAG1[BUF0I], the clear FIFO operation occurs. This operation can only be performed in Freeze mode; FlexCAN blocks it in other modes. This operation does not clear the FIFO IFLAG flags; the CPU must service all FIFO IFLAG flags before executing the clear FIFO operation.

When Legacy RX FIFO is working with DMA, the clear FIFO operation clears IFLAG1[BUF5I], and the DMA request is canceled.

CAUTION

The clear Legacy FIFO operation does not clear IFLAG flags, except when MCR[DMA] = 1; in this case, only IFLAG1[BUF5I] is cleared.

39.3.10 Fault reaction

This situation is catastrophic, and in response to the fault reaction, FlexCAN goes into a safe state (Freeze) and drives a safe value (recessive bit) on the bus. Either CTRL2[FLT_RXN] or an input "fault reaction" signal from another module can trigger a fault reaction. FlexCAN remains in a safe state as long as CTRL2[FLT_RXN] = 1 or the "fault reaction" signal is asserted and MCR[FRZ] = 1.

A fault can occur at any time, including during frame transmission, reception, and BUS IDLE. If a fault occurs during frame transmission, FlexCAN stops the frame transmission and goes into a safe state.

If a fault occurs during frame reception, FlexCAN stops receiving the frame and goes into a safe state. If FlexCAN is in loopback or self-reception mode, the effect of the fault reaction is the same as described above.

When the fault condition is removed, FlexCAN remains in Freeze mode until the CPU writes 0 to MCR[FRZ].

39.3.11 Retransmission

If a message transmission is unsuccessful due to a reason other than a loss of arbitration or being aborted by the host, FlexCAN attempts to retransmit the message a number of times determined by the value of CTRL2[RETRY].

When a message transmission is unsuccessful, a counter is decremented. When that counter reaches zero, FlexCAN aborts the message. FlexCAN sets the IFLAG for the aborted message and an interrupt is generated (if enabled). FlexCAN sets the IFLAG and updates the CODE field of the control and status word by abort code. The host can read the IFLAG flag and CODE field to identify which message FlexCAN aborted due to retransmission attempts greater than the value of CTRL2[RETRY].

39.3.12 CAN protocol-related features

39.3.12.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure-detection capability that was in the original CAN FD protocol. This original protocol is also called non-ISO CAN FD, by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-ISO CAN FD protocol. FlexCAN still supports non-ISO CAN FD, so it can be used during an intermediate phase, for evaluation and development purposes.

It is recommended that you configure FlexCAN with the ISO CAN FD protocol by writing 1 to CTRL2[ISOCANFDEN].

39.3.12.2 CAN FD frames

ISO 11898-1_2024 specifies the Classical Frame format compliant to ISO 11898-1:2003 (2003) and introduces the CAN Flexible Data Rate Frame format (CAN FD). The Classical Frame format allows bit rates up to one Mbit/s and payloads up to eight bytes per frame. The Flexible Data Rate Frame format allows bit rates faster than one Mbit/s and payloads longer than eight bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

There are additional control bits in the CAN FD frame:

- The Extended Data Length (EDL) bit enables a longer data payload with different data length coding.
- The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame.
- The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes.

There are no Remote Frames (see Remote frames) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in Classical CAN format. When an FD frame is received and matches a message buffer, the RTR bit in the receiving message buffer becomes 0. The RTR bit must be considered in classical frames only.

39.3.12.2.1 CAN FD messages

CAN FD messages may be formatted as long frames where the data field exceeds eight bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching. In this case, the control field, data field, and CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and end of the frame. Messages in the classical CAN format are limited to transport a maximum payload of eight bytes at nominal rate. Figure 147 illustrates the message formats for classical and FD frames with either standard or extended ID.

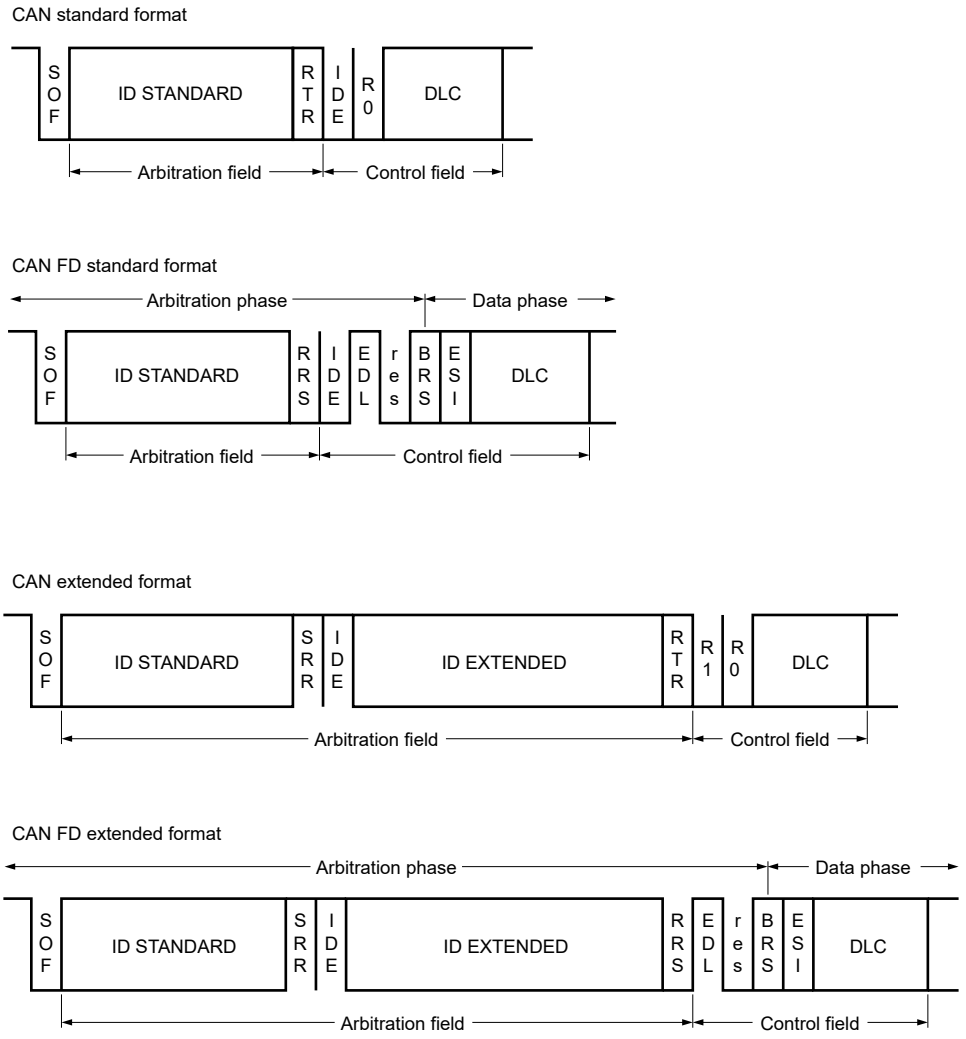

Figure 147. CAN message formats

MCR[FDEN] enables the ability to receive and transmit CAN FD messages. A recessive R0 bit in CAN frames with 11-bit identifiers, or a recessive R1 bit in CAN frames with 29-bit identifiers, is decoded as an EDL bit (not a reserved one). A recessive EDL bit identifies a CAN FD frame, and a dominant EDL bit identifies a Classical CAN frame. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded according to the DLC field value (see DLC definition in Message buffer structure).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start of Frame (SOF) bit until the Bit Rate Switch (BRS) bit is called the arbitration phase. This part is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, is called the data phase. When this second part is transmitted, a second set of CAN data bit timing configuration values determines the data bit rate. Finally, from the CRC delimiter until the Intermission bits, the transmission returns to nominal bit rate.

39.3.12.2.2 BRS in CAN FD

In CAN FD frames with bit rate switching, the bit timing changes inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by CAN Bit Timing (CBT). (Control 1 (CTRL1) also defines this timing for backward compatibility.) Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by CAN FD Bit Timing (FDCBT).

NOTE

If the time quantum length in nominal bit timing and in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase, and it lasts until the next synchronization event. The length of the time quantum should be the same in nominal and data bit timing. This configuration minimizes the chance of error frames on the CAN bus, and optimizes the clock tolerance in networks that use FD frames.

If BRS = 1 in the selected TX MB, FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching. If FDCTRL[FDRATE] = 0, the transmission is performed at nominal rate regardless of the BRS bit value. FDCTRL[FDRATE] can be written at any time but takes effect only for the next message transmitted or received.

Nominal bit timing is resumed at the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. Figure 148 describes the mechanism for entering and leaving the data phase when the BRS bit is recessive.

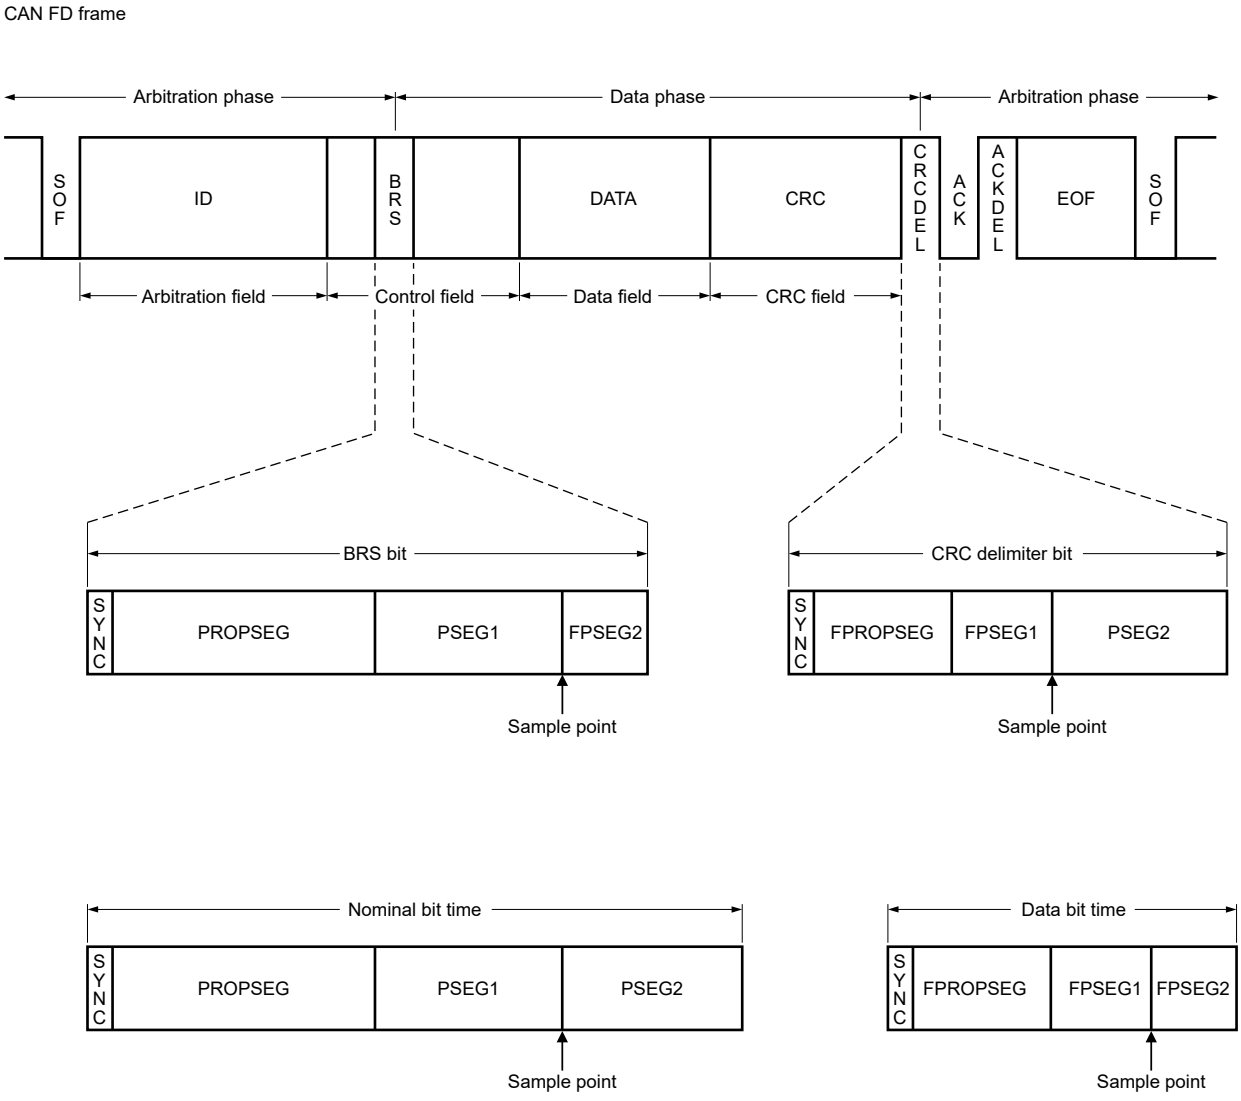

Figure 148. Bit rate switching mechanism for CAN FD messages

NOTE

In Classical CAN frames, the CRC delimiter is one recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter. It accepts two recessive bits before the recessive-to-dominant edge that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of the CAN_PE subblock. For example, for a CAN_PE clock frequency of 40 MHz and the shortest configurable bit time of 5 time quanta, the bit rate in the data phase is 8 Mbit/s.

NOTE

The frequency used in this example may not be supported on this chip. It is shown only to demonstrate how the maximum configurable bit rate is calculated.

39.3.12.2.3 ESI in CAN FD

The value of the ESI field is determined by either of the following:

- The error state of the transmitter at the start of the transmission, if the frame is originated in the FlexCAN node
- The original transmitting node when FlexCAN is acting as a gateway for the message

If the transmitter is error-passive, ESI is transmitted recessive; otherwise, it is transmitted dominant. The permutations of the relationship between the written value and the transmitted value of the ESI are shown in Table 255.

Table 255. Written versus transmitted values of the ESI field

FlexCAN fault confinement status at start of frame	ESI field of TX MB	Transmitted ESI
Error active	0	0 (Error Active)
Error passive	0	1 (Error Passive)
Error active	1	1 (Error Passive)
Error passive	1	1 (Error Passive)

39.3.12.2.4 CRC calculations in CAN FD

Different CAN frame formats have different CRC polynomials. The first polynomial, CRC_15, is used for all frames in Classical CAN format. The second, CRC_17, is used for frames in CAN FD format with a data field up to 16 bytes long. The third, CRC_21, is used for frames in CAN FD format with a data field longer than 16 bytes. Each polynomial results in a Hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The values of the EDL bit and the DLC field select the CRC sequence to be transmitted. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, CAN FD CRC (FDCRC) stores the calculated CRC for the transmitted message. This storage is performed with adequate length for the type of message, for CAN FD and non-FD messages. Cyclic Redundancy Check (CRCR) reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method changes for the CRC sequence, so the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence. This insertion occurs even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN receives a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

39.3.12.2.5 CAN FD errors

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters ECR[RXERRCNT] and ECR[TXERRCNT] accumulate the counts of RX and TX errors, respectively, for both FD and non-FD frames indiscriminately. Two extra error counters, ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST], accumulate RX and TX errors occurring in the data phase of CAN FD frames with BRS = 1 only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see Error Counter (ECR)).

These error flags report errors in both CAN FD and non-FD frames:

- ESR1[BIT1ERR]
- ESR1[BIT0ERR]
- ESR1[ACKERR]
- ESR1[CRCERR]
- ESR1[FRMERR]
- ESR1[STFERR]

If CTRL1[ERRMSK] = 1, they also generate the ERRINT interrupt.

These additional error flags indicate the occurrence of errors in the data phase of CAN FD frames with BRS = 1:

- ESR1[BIT1ERR_FAST]
- ESR1[BIT0ERR_FAST]
- ESR1[CRCERR_FAST]
- ESR1[FRMERR_FAST]
- ESR1[STFERR_FAST]

No ACKERR is detected in the data phase of a CAN FD frame. Fault confinement status reported in ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on ECR[RXERRCNT] and ECR[TXERRCNT] only. Information in ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST] may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN detects an error while transmitting or receiving a CAN FD message in the data phase, it immediately switches:

- Back to the arbitration phase, and
- Back to the nominal rate to start an error flag.

39.3.12.2.6 CAN FD synchronization

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in Classical CAN ones. A hard synchronization is also performed at the recessive-to-dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize when transmitting in the CAN FD data phase.

39.3.12.3 Transceiver delay compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase, when BRS = 1 in the message. This feature enables the use of rates up to 8 Mbit/s.

During the data phase of a CAN FD frame, if the transmitter cannot receive its own latest transmitted bit at the sample point of that bit, it detects a bit error. When bit rate switching is enabled (BRS = 1), the CAN bit time in the data phase can become shorter than the loop delay of the transceiver. This condition impedes the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

The transceiver delay compensation (TDC) process defines a secondary sample point where the transmitted bit is correctly compared to the received bit to check for bit errors.

You can enable the TDC mechanism via FDCTRL[TDCEN] or ETDC[ETDCEN]. The TDC mechanism is effective only during the data phase of FD frames with BRS = 1. It has no effect on either non-FD frames or FD frames transmitted at the normal bit rate. When the transmitted message has BRS = 1, TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit. When TDC is active, the real received bit is compared to the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE

The transmitters using TDC disregard the value of the CRC delimiter bit. A global error at the end of the CRC field causes the receivers to send error frames that the transmitter detects during Acknowledge or End of Frame.

For every transmitted FD frame with BRS = 1, the transition from the recessive EDL bit to the dominant R0 bit triggers the delay measurement (as shown in Figure 149). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see Protocol timing), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The measured loop delay time added to an offset value specified in FDCTRL[TDCOFF] or ETDC[ETDCOFF] determines the position of the secondary sample point. FDCTRL[TDCVAL] or ETDC[ETDCVAL] stores the result of this calculation. The TDCVAL and ETDCVAL value saturates at its maximum value of 63 CANCLK and 255 CANCLK when the delay measurement is too long.

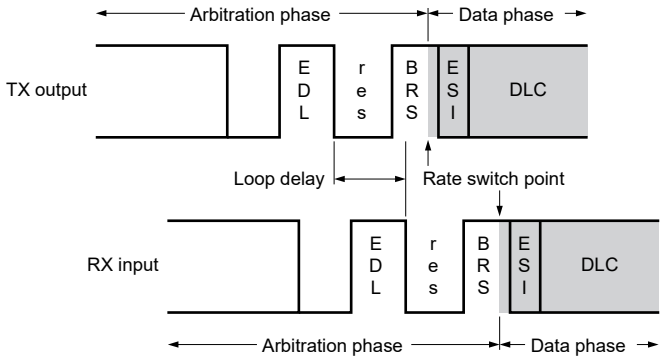

Figure 149. Transceiver loop delay measurement

The measured loop delay is not enough to define the secondary sample point, because it relates to the CAN bit edges. The transceiver delay compensation offset FDCTRL[TDCOFF] or ETDC[ETDCOFF] is used to shift the secondary sample point to an intermediate point inside the bit time, far away from its edges. The value of FDCTRL[TDCOFF] or ETDC[ETDCOFF] cannot be larger than the CAN bit duration in the data phase.

If the secondary sample point is set very near the CAN bit edge (SYNC field), problems may occur during the bit sampling in the data phase. For the TDC to work reliably, the offset must use optimal settings. To ensure that bit sampling is performed in the best region, configure the TDC offset as shown in this equation:

$$Offset = (FPSEG1 + FPROPSEG + 2) \times (FPRESDIV + 1)$$
or
$$Offset = (DTSEG1 + 2) \times (EDPRESDIV + 1), \textit{ if ETDCEN}$$

Equation 18. TDC offset calculation

Figure 150 shows the SSP position when these settings are used.

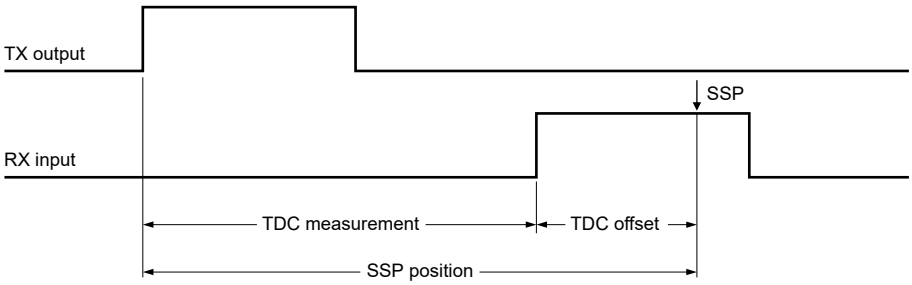

Figure 150. SSP position with optimal values

Alternatively, if CTRL2[BTE] and ETDC[ETDCEN] are 1, you can write 1 to ETDC[TDMDIS] to disable the transceiver delay measurement. In this case, only ETDC[ETDCOFF] defines the SSP position. Figure 151 shows the secondary sample point position when the transceiver delay measurement is disabled.

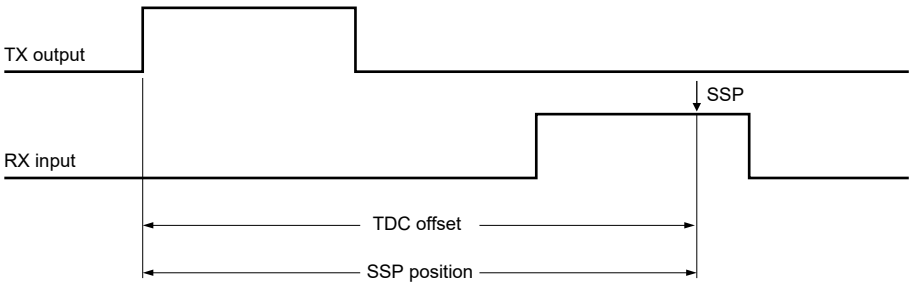

Figure 151. SSP position with TDC measurement disabled by ETDCEN and TDMDIS

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every TX CAN bit:

- The transmitted TX bit value is temporarily stored in a buffer.
- A time countdown based on FDCTRL[TDCVAL] or ETDC[ETDCVAL] is started. This countdown ends with the comparison of the received RX bit (delayed by the external loop delay plus the specified offset) to the stored TX bit.

If a bit error is detected at the secondary sample point, FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase, delay compensation is always disabled. During the data phase, the TDC mechanism of FlexCAN can compensate a maximum delay of 3 CAN bit times − 2 Tq. Beyond this limit, the FDCTRL[TDCFAIL] or ETDC[ETDCFAIL] flag is set. The flag indicates when the TDC mechanism is out of range and is unable to compensate the transceiver loop delay.

39.3.12.4 Remote frames

A remote frame is a special type of frame. You can program a message buffer to be a remote request frame by configuring the message buffer as Transmit with the RTR = 1. After the remote request frame is transmitted successfully, the message buffer becomes a receive message buffer, with the same ID as before.

When FlexCAN receives a remote request frame, the frame can be treated in different ways, depending on remote request storing (CTRL2[RRS]) and RX FIFO Enable (MCR[RFEN]):

- If RRS = 0, the ID of the frame is compared to the IDs of the transmit message buffers with the CODE field 1010b. If a matching ID exists, this message buffer frame is transmitted. If the matching message buffer has the RTR = 1, FlexCAN transmits a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response.

  The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. If a remote request frame is received and matches a message buffer, this message buffer immediately enters the internal arbitration process. However, it is considered a normal TX message buffer, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.

- If CTRL2[RRS] = 1, the ID of the frame is compared to the IDs of the receive message buffers with the CODE field 0100b, 0010b, or 0110b. If a matching ID exists, this message buffer stores the remote frame in the same fashion as a data frame. No automatic remote response frame is generated. The mask registers are used in the matching process.
- If MCR[RFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Legacy FIFO filtering criteria. If the remote frame matches one of the target IDs, it is stored in the Legacy FIFO and presented to the CPU.

  For filtering formats A and B (see Legacy RX FIFO structure), it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted if they match the ID. Remote request frames are considered as normal frames. They generate a Legacy FIFO overflow when a successful reception occurs and the Legacy FIFO is already full.
- If ERFCR[ERFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Enhanced RX FIFO filtering criteria. Remote Request Frames are considered normal frames. They generate an Enhanced RX FIFO overflow when a successful reception occurs and the enhanced RX FIFO is already full.

NOTE

There is no remote frame in the CAN FD format. A fixed dominant RRS bit replaces the RTR bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

39.3.12.5 Overload frames

When a dominant bit is detected on the CAN bus in these locations, FlexCAN transmits overload frames:

- The first or second bit of Intermission.
- The seventh bit (last) of End of Frame field (RX frames).
- The eighth bit (last) of Error Frame Delimiter or Overload Frame Delimiter.

39.3.12.6 Message buffer timestamp

The value of the free-running timer is sampled at the beginning of the Identifier field on the CAN bus. This value is stored at the end of move-in in the TIME_STAMP field of a message buffer, providing network behavior regarding time.

When CTRL2[TIMER_SRC] = 1, an external time tick continuously clocks the free-running timer.

When CTRL2[TIMER_SRC] = 0, the FlexCAN bit clock clocks the free-running timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The free-running timer is not incremented during Disable, Doze, Stop, and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See CTRL1[TSYN].

Alternatively, by configuring CTRL2[MBTSBASE], the timestamp of the message buffer can capture the lower or higher 16 bits of the high-resolution dedicated counter. See the chip-specific FlexCAN timestamp implementation.

39.3.12.7 High-resolution timestamp

The high-resolution timestamp (HR_TIME_STAMP) uses a dedicated timer with a 32-bit counter operating in free-running mode. CTRL2[TSTAMPCAP] enables the high-resolution timestamp. When this field is not zero, the dedicated 32-bit counter value is captured during a valid CAN frame and stored in an HR_TIME_STAMP*n* register.

Each HR_TIME_STAMP*n* corresponds to a specific message buffer. For example, HR_TIME_STAMP0 stores the 32-bit timestamp associated with message buffer 0. HR_TIME_STAMP1 stores the 32-bit timestamp associated with message buffer 1, and so on.

The counter value is captured according to CTRL2[TSTAMPCAP]. For classical CAN frames, the capture points can be the start of frame bit or the point in time a CAN frame is considered valid. This valid point is the seventh bit of end of frame for transmission and the sixth bit of end of frame for reception.

For CAN FD frames, the capture points can be:

- The start of frame

- The point in time a CAN FD frame is considered valid
- The res bit of a CAN FD frame

The 16-bit timestamp of the message buffer can be configured to capture the lower or higher 16 bits of the high-resolution timer. This configuration is made by CTRL2[MBTSBASE]. See the chip-specific FlexCAN timestamp implementation.

39.3.12.8 Protocol timing

Figure 152 shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source field CTRL1[CLKSRC] defines whether the internal clock is connected to the output of a crystal oscillator (oscillator clock) or to the peripheral clock. To guarantee reliable operation, select the clock source when the module is in Disable mode (MCR[MDIS] = 1).

NOTE

To identify the proper clock source, see the clock distribution chapter (module clocks table).

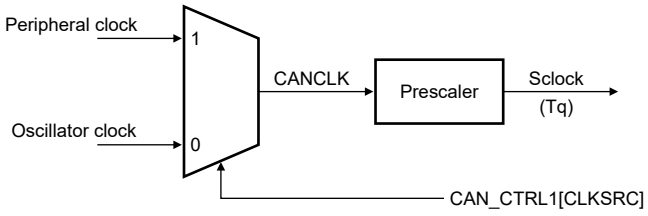

Figure 152. CAN engine clocking scheme

Select the oscillator clock whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The crystal oscillator clock has better jitter performance than the peripheral clock.

39.3.12.8.1 Bit timing configuration

FlexCAN supports various means to configure bit timing parameters required by the CAN protocol. Control 1 (CTRL1) has various fields to control bit timing parameters:

- CTRL1[PRESDIV]
- CTRL1[PROPSEG]
- CTRL1[PSEG1]
- CTRL1[PSEG2]
- CTRL1[RJW]

CAN Bit Timing (CBT) extends the range of the CAN bit timing variables in CTRL1. Enhanced Data Phase CAN Bit Timing (EDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) = 1.

Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in CBT. Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in FDCBT. When using ENCBT and EDCBT, you must program the nominal bit timing and data phase serial clock (Sclock) dividers in Enhanced CAN Bit Timing Prescalers (EPRS).

NOTE

When the CAN FD feature is enabled, always write 1 to CBT[BTF] or CTRL2[BTE] and specify the CAN bit timing variables in CBT or ENCBT. See CAN Bit Timing (CBT) or Enhanced Nominal CAN Bit Timing (ENCBT).

CTRL1[PRESDIV], and its extended range CBT[EPRESDIV] (or EPRS[ENPRESDIV]) and FDCBT[FPRESDIV] (or EPRS[EDPRESDIV]) for the data phase bits of CAN FD messages, defines the prescaler value that generates the serial

clock (Sclock). (See Equation 19.) The period of Sclock defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time managed by the CAN engine. It is the smallest time unit for all configuration values.

$$Tq = \frac{(PRESDIV + 1)}{f_{CANCLK}}$$

Equation 19. Time quantum

The bit rate, which defines the rate the CAN message is received or transmitted, is calculated with the formula:

$$CAN\ bit\ time = (Number\ of\ time\ quanta\ in\ 1\ bit\ time) \times Tq$$

$$Bit\ rate = \frac{1}{CAN\ bit\ time}$$

Equation 20. CAN bit time and baud rate

39.3.12.8.2 Bit time segments

A bit time is subdivided into three segments as shown in Figure 153. See also Figure 154 , Figure 155, and Table 256.

NOTE

For further explanation of the underlying concepts, see ISO 11898-1_2024. See also *CAN Specification Version 2.0, Part A and Part B* for bit timing.

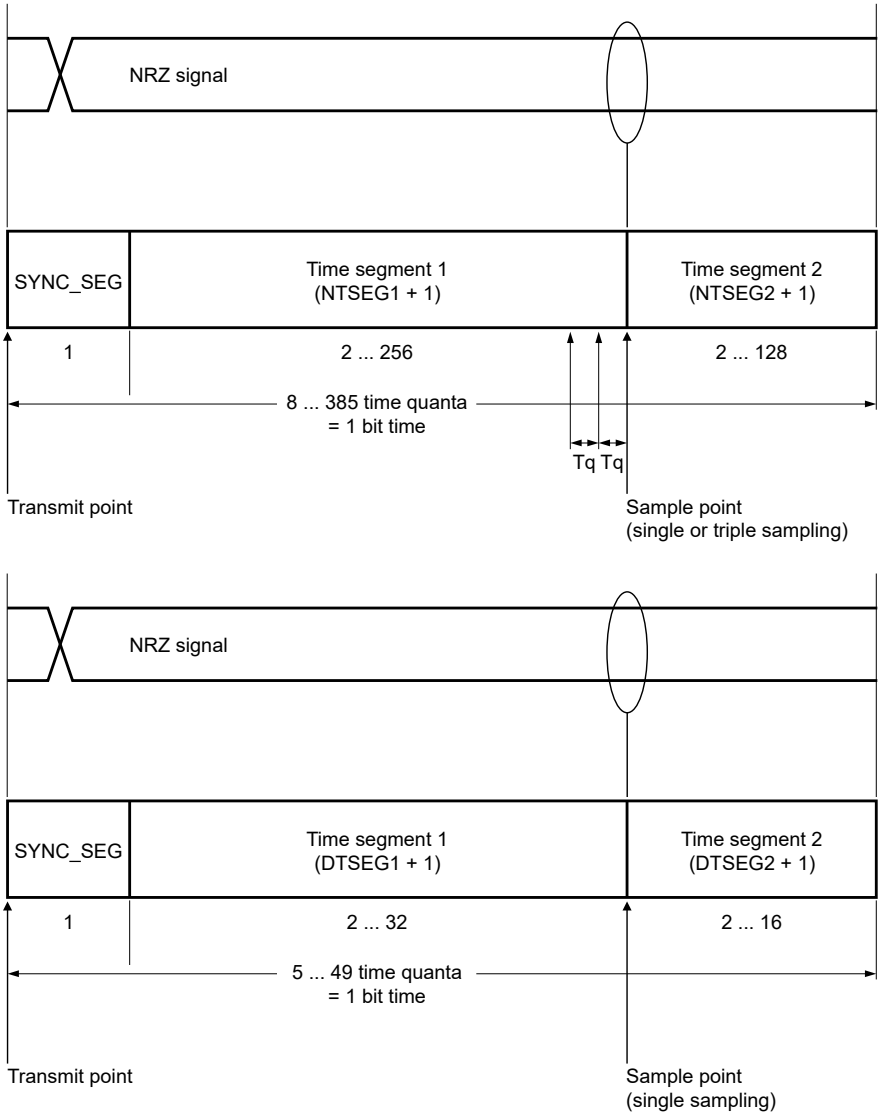

Figure 153. Segments within the bit timing (example using ENCBT and EDCBT bit timing variables)

The three bit time segments are:

- SYNC_SEG—this segment has a fixed length of one time quantum. Signal edges are expected to occur within this section.
- Time Segment 1—this segment includes the propagation segment and the phase segment 1 of the CAN standard.

  It can be programmed by configuring CTRL1[PROPSEG] and CTRL1[PSEG1] so that the sum (plus 2) is 2–16 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPROPSEG] and CBT[EPSEG1] so that the sum (plus 2) is 2–96 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses FDCBT[FPROPSEG] and FDCBT[FPSEG1] so that the sum (plus 1) is 2–39 time quanta.

  If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG1] to configure time segment 1 to 2–256 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG1] must be used for configuring time segment 1 to 2–32 time quanta.
- Time Segment 2—this segment represents the phase segment 2 of the CAN standard.

  It can be programmed by configuring CTRL1[PSEG2] (plus 1) to be 2–8 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPSEG2] so that its value (plus 1) is 2–32 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses

FDCBT[FPSEG2] instead, so that its value (plus 1) is 2–8 time quanta. Time segment 2 cannot be smaller than the Information Processing Time (IPT), which is 2 time quanta in FlexCAN.

If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG2] to configure time segment 2 to 2–128 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG2] must configure time segment 2 to 2–16 time quanta.

NOTE

The bit time defined by the above time segments must not be smaller than five time quanta. For bit time calculations, use an Information Processing Time (IPT) of two, which is the value implemented in the FlexCAN module.

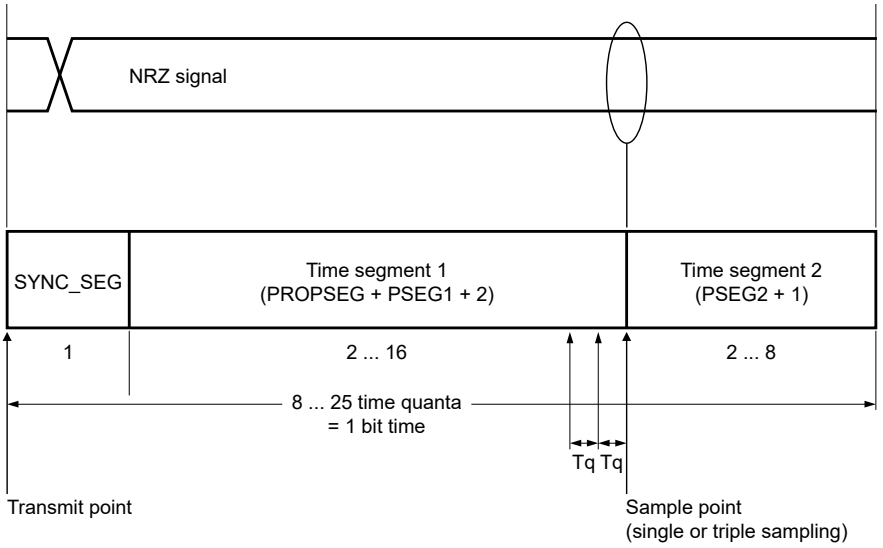

Figure 154. Segments within the bit time (example using CTRL1 bit timing variables for Classical CAN format)

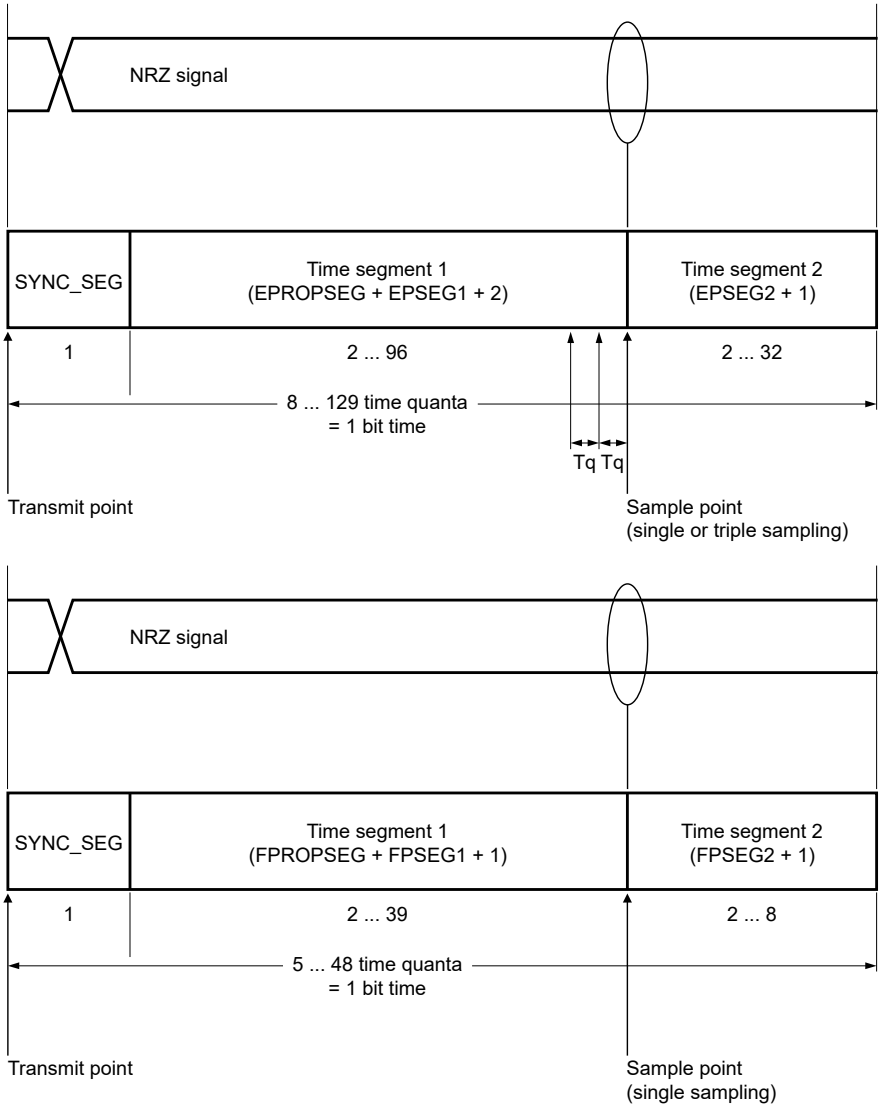

Figure 155. Segments within the bit time (example using CBT and FDCBT bit timing variables for CAN FD format)

Table 256. Time segment syntax

Syntax	Description
SYNC_SEG	Period during which the system expects transitions to occur on the bus
TSEG1	Period corresponding to the sum of PROPSEG and PSEG1
TSEG2	Period corresponding to the PSEG2 value
Transmit point	Point at which a node in Transmit mode transfers a new value to the CAN bus
Sample point	Point at which a node samples the bus. If the option of three samples per bit is selected, this point marks the position of the third sample.

Table 257 gives some examples of the CAN-compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 257. Bosch CAN 2.0B standard compliant bit time segment settings

Time segment 1	Time segment 2	Resynchronization jump width
5 to 10	2	1 to 2
4 to 11	3	1 to 3
5 to 12	4	1 to 4
6 to 13	5	1 to 4
7 to 14	6	1 to 4
8 to 15	7	1 to 4
9 to 16	8	1 to 4

NOTE

You must ensure the bit time settings comply with the CAN Protocol standard ISO 11898-1_2024.

39.3.12.8.3 Calculating peripheral clocks

A CAN bit can be used as a measure of duration (for example, estimating the occurrence of a CAN bit event in a message). When a CAN bit is used in this way, the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

Equation 21. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 0

Or, if CTRL2[BTE] = 1:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (ENPRESDIV + 1) \times (NTSEG1 + NTSEG2 + 3)$$

Equation 22. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 1

Where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure 152), in Hz.
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz.
- PSEG1 is the value of CTRL1[PSEG1].
- PSEG2 is the value of CTRL1[PSEG2].
- PROPSEG is the value of CTRL1[PROPSEG].
- PRESDIV is the value in CTRL1[PRESDIV].
- ENPRESDIV is the value of EPRS[ENPRESDIV].
- NTSEG1 is the value of ENCBT[NTSEG1].
- NTSEG2 is the value of ENCBT[NTSEG2].

The formula above is also applicable to the alternative CAN bit timing variables described in:

- CAN Bit Timing (CBT)

- Enhanced Nominal CAN Bit Timing (ENCBT)
- CAN FD Bit Timing (FDCBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

For example, 180 CAN bits = (180 × NumClkBit) peripheral clock periods.

39.3.12.9 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in, and move-out processes are executed during certain time windows inside the CAN frame. These windows are shown in the following figures.

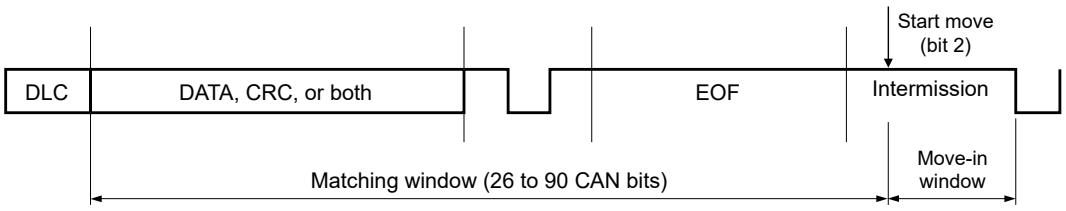

Figure 156. Matching and move-in time windows

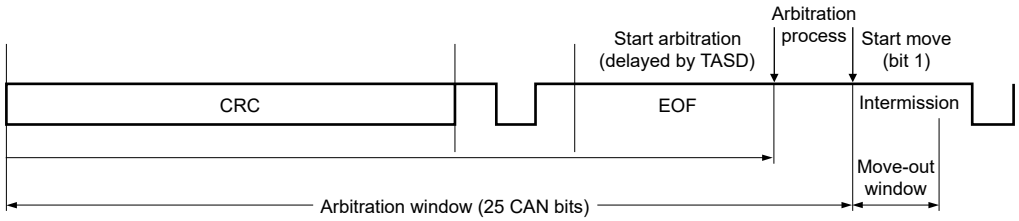

Figure 157. Arbitration and move-out time windows

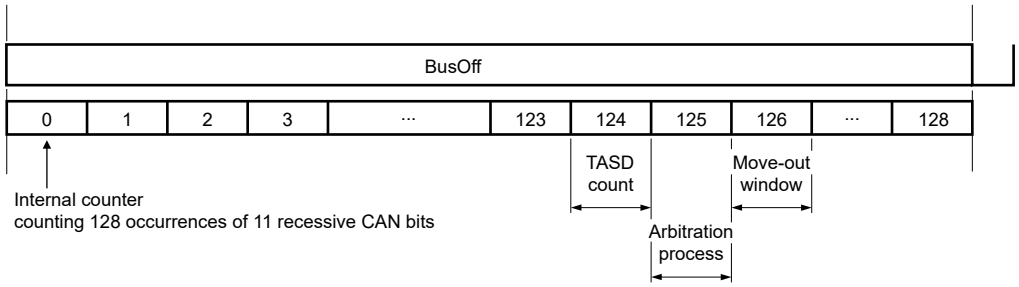

Figure 158. Arbitration at the end of bus off and move-out time windows

NOTE

In these figures, the matching and arbitration timing do not consider delays caused by concurrent memory access due to the CPU or other internal FlexCAN subblocks.

39.3.12.10 TX arbitration start delay

TX Arbitration Start Delay (CTRL2[TASD]) indicates the number of CAN bits that FlexCAN uses to delay the TX arbitration process starting point from the first bit of the CRC field of the current frame. This variable can be written only in Freeze mode; FlexCAN blocks it in other modes.

The ability of the CPU to reconfigure message buffers for transmission after the end of the internal arbitration process impacts transmission performance. In the arbitration process, FlexCAN finds the winner MB for transmission (see Arbitration process). If

the arbitration ends too early (before the first bit of the Intermission field) the CPU may reconfigure some TX message buffers. It is possible that the winning message buffer is no longer the best candidate to be transmitted.

TASD can optimize the transmission performance by defining the arbitration start point, as shown in Figure 159, based on factors such as:

- Peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- Number of message buffers in use by the matching and arbitration processes

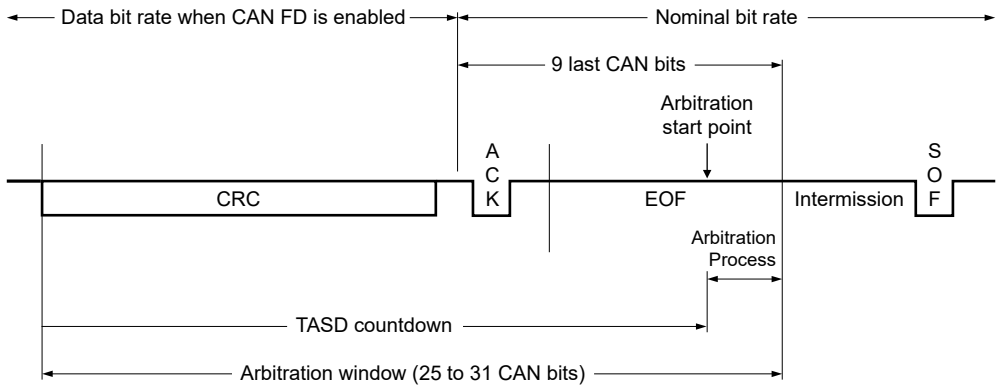

Figure 159. Optimal TX arbitration start point

The duration of an arbitration process, in terms of CAN bits, is:

- Directly proportional to the number of available message buffers
- Directly proportional to the CAN bit rate
- Inversely proportional to the peripheral clock frequency

The optimal arbitration timing occurs when the last message buffer is scanned immediately before the first bit of the Intermission field of a CAN frame. For instance, if the following are true:

- There are few message buffers.
- The peripheral-to-oscillator clock ratio is high.
- The CAN baud rate is low.

Then the arbitration can be placed closer to the end of the frame, adding more delay to its starting point, and vice versa.

If CTRL2[TASD] = 0, the arbitration start is not delayed, and more time is reserved for arbitration. Alternatively, if CTRL2[TASD] is close to 24, the CPU can configure a TX message buffer later, and less time is reserved for arbitration. If too little time is reserved for arbitration, FlexCAN may not be able to find a winner MB in time. The transmitted arbitration winner may not have the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

For CAN FD frames and (MAXMB + 1) ≤ NMB_{END}

$$TASD = 31 - \frac{2 * (MAXMB + 1) + 4}{CPCB_N}$$

For CAN FD frames and (MAXMB + 1) > NMB_{END}

$$TASD = 22 - \frac{2 * (MAXMB + 1) - NMB_{END}}{CPCB_F}$$

For non-FD frames

$$TASD = 25 - \frac{2 * (MAXMB + 1) + 4}{CPCB}$$

Equation 23. Optimal value for TASD

Where:

$$NMB_{END} = \frac{(9 \times CPCB_N) - 4}{2}$$

$$BITRATE_N = \left(\frac{f_{CANCLK}}{[1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] \times (EPRESDIV + 1)} \right)$$

$$BITRATE_F = \left(\frac{f_{CANCLK}}{[1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] \times (FPRESDIV + 1)} \right)$$

$$CPCB_N = \frac{f_{SYS}}{BITRATE_N}$$

$$CPCB_F = \frac{f_{SYS}}{BITRATE_F}$$

$$CPCB = CPCB_N$$

Equation 24. Variables used in TASD calculation

- MAXMB is the value in MCR[MAXMB].
- NMB_{END} is the number of message buffers that the arbitration process can scan during the last nine CAN bits at the end of a frame. (See Equation 24.)
- $BITRATE_N$ is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- $BITRATE_F$ is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- $CPCB_N$ is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- $CPCB_F$ is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- f_{CANCLK} is the oscillator clock, in Hz.
- f_{SYS} is the peripheral clock, in Hz.
- EPSEG1 is the value in CBT[EPSEG1] (CTRL1[PSEG1] can also be used).
- EPSEG2 is the value in CBT[EPSEG2] (CTRL1[PSEG2] can also be used).
- EPROPSEG is the value in CBT[EPROPSEG] (CTRL1[PROPSEG] can also be used).
- EPRESDIV is the value in CBT[EPRESDIV] (CTRL1[PRESDIV] can also be used).
- FPSEG1 is the value in FDCBT[FPSEG1].

- FPSEG2 is the value in FDCBT[FPSEG2].
- FPROPSEG is the value in FDCBT[FPROPSEG].
- FPRESDIV is the value in FDCBT[FPRESDIV].
- NTSEG1 is the value in ENCBT[NTSEG1].
- NTSEG2 is the value in ENCBT[NTSEG2].
- ENPRESDIV is the value in EPRS[ENPRESDIV].
- DTSEG1 is the value in EDCBT[DTSEG1].
- DTSEG2 is the value in EDCBT[DTSEG2].
- EDPRESDIV is the value in EPRS[EDPRESDIV].

If CTRL2[BTE] = 1, then:

$$BITRATE_N = \frac{f_{CANCLK}}{[1 + (NTSEG1 + 1) + (NTSEG2 + 1)] \times (ENPRESDIV + 1)}$$

Equation 25. Nominal baud rate when CTRL2[BTE] = 1

$$BITRATE_F = \frac{f_{CANCLK}}{[1 + (DTSEG1 + 1) + (DTSEG2 + 1)] \times (EDPRESDIV + 1)}$$

Equation 26. Fast baud rate when CTRL2[BTE] = 1

See also Protocol timing for more details.

39.3.12.10.1 TASD configuration examples

The following tables show the TASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (for example, peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 258. TASD values in Case 1

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	24	8.0
64	23	8.0
96	22	8.0

Case 2:

- Clock ratio = 1:1 (for example, peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 259. TASD values in Case 2

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid

Table continues on the next page...

Table 259. TASD values in Case 2 (continued)

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
32	23	6.67
54	22	5.0
64	21	3.33
96	20	1.6

Case 3:

- Clock ratio = 2:1 (for example, peripheral clock 40 MHz and oscillator clock 20 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 260. TASD values in Case 3

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	4.0
54	22	4.0
64	21	3.33
96	20	1.54

39.3.13 Clocks

The following table describes the clock sources for FlexCAN. See the Clock Controller Module (CCM) for clock setting, configuration, and gating information.

Table 261. FlexCAN clocks

Clock name	Description
MODULE_CLK (system_clk)	Peripheral clock
MODULE_CLK_CHI (host_clock)	Control Host Interface (CHI) clock
MODULE_CLK_PE (protocol_engine_clock)	Protocol Engine (PE) clock
MODULE_CLK_PE_NOGATE (protocol_engine_clock_nogate)	Protocol Engine clock (no gating)
MODULE_CLK_S (system_clock_nogate)	Peripheral access clock

39.3.13.1 Clock domains and restrictions

FlexCAN has two clock domains asynchronous to each other:

- The bus domain feeds the Control Host Interface (CHI) submodule.
- The oscillator domain feeds the CAN Protocol Engine (PE) submodule.

When CTRL1[CLKSRC] = 1, synchronous operation occurs because both domains are connected to the peripheral clock. This setting creates a 1:1 ratio between the peripheral and oscillator clocks.

When the two domains are connected to clocks with different frequencies or phases, the frequency relationship between the two clock domains is restricted. In asynchronous operation, the bus domain clock frequency must always be greater than the oscillator domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When performing matching and arbitration, FlexCAN must scan the whole message buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. To provide sufficient time for the scan, observe the following requirements:

- The peripheral clock frequency cannot be less than the oscillator clock frequency.
- There must be a minimum number of peripheral clocks per CAN bit, as specified in Table 262.

Table 262. Minimum number of peripheral clocks per CAN bit for Classical CAN format

Number of message buffers	Value of MCR[RFEN]	Value of ERFCR[ERFEN]	Minimum number of peripheral clocks per CAN bit
16	0	0	16
32	0	0	16
64	0	0	25
96	0	0	37
16	1	0	16
32	1	0	17
64	1	0	30
96	1	0	42
16	0	1	16
32	0	1	19
64	0	1	31
96	0	1	42

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in Table 262 determines the minimum peripheral clock frequency for a given number of message buffers and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit. This number can be defined by adjusting one or more of the bit timing values contained in:

- Control 1 (CTRL1)
- CAN Bit Timing (CBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be eight, so the oscillator clock frequency should be at least eight times the CAN bit rate.

39.3.13.1.1 Clock restrictions for CAN FD

For CAN FD frame format, some constraints must be satisfied. The equation below calculates the number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit).

$$NumClkNomBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

$$= \frac{f_{SYS}}{NomBitRate}$$

Equation 27. Number of peripheral clocks per nominal CAN bit

Where PRESDIV, PSEG1, and PSEG2 are CAN bit time values in Control 1 (CTRL1). Alternatively, EPRESDIV, EPSEG1, and EPSEG2 values in CAN Bit Timing (CBT) or the values of EPRS[ENPRESDIV], ENCBT[NTSEG1], and ENCBT[NTSEG2] can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate), as shown in the equation above.

The number of CAN bits in the data phase of an FD frame with BRS = 1 (fast CAN bits) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in Table 263. Having fewer data bytes means having fewer fast CAN bits. It also means that less time is available for FlexCAN to scan the whole message buffer memory during the internal matching and arbitration processes.

Table 263. Number of fast CAN bits in a CAN FD frame

Minimum number of data bytes	DLC field	NumOfFastBits
0	0h	21
1	1h	29
2	2h	37
3	3h	45
4	4h	53
5	5h	61
6	6h	69
7	7h	77
8	8h	85
12	9h	117
16	Ah	149
20	Bh	186
24	Ch	218
32	Dh	282
48	Eh	410
64	Fh	538

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the message buffer memory during reception and transmission. The equation below calculates this constraint.

$$MinNumClkFastBit_A = \frac{(8.5 \times MaxNumOfMb) + [ERFEN \times (2 \times NFE + 4)] + 64 - (9 \times NumClkNomBit)}{NumOfFastBits}$$

Equation 28. Minimum number of peripheral clocks per fast CAN bit for FlexCAN scan process

Where MaxNumOfMb is the maximum number of available message buffers defined in MCR[MAXMB]. NFE and ERFEN are the fields defined in Enhanced RX FIFO Control (ERFCR).

The clock-domain-crossing circuit between the CHI and PE subblocks also imposes a minimum number of peripheral clocks per fast CAN bit. This minimum is required for the handshake mechanism to work properly without losing status information through the interface, as shown in the equation below.

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{f_{SYS}}{f_{CANCLK}}\right)$$

Equation 29. Minimum number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

Therefore, the larger of the two values calculated above determines the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit).

$$MinNumClkFastBit = Maximum\ (MinNumClkFastBitA, MinNumClkFastBitB)$$

Equation 30. Minimum number of peripheral clocks per fast CAN bit

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) can be calculated as below.

$$DataBitrate_{MAX} = \frac{f_{CANCLK}}{ROUNDUP\left(\frac{MinNumClkFastBit \times f_{CANCLK}}{f_{SYS}}\right)}$$

Equation 31. Maximum achievable baud rate for data phase

These factors affect the maximum data bit rate attainable by FlexCAN in CAN FD mode:

- The peripheral and oscillator clock frequencies
- The maximum number of message buffers
- The expected nominal bit rate

Also, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the configuration of FlexCAN variables affects the CAN FD bit rate, consider this application example:

- The peripheral clock frequency is set to 50 MHz
- The oscillator clock frequency is set to 40 MHz

1. Considering the nominal bit rate as 1 Mbit/s, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

   $$NumClkNomBit = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

   Equation 32. Calculation example for number of peripheral clocks per nominal CAN bit

2. The number of fast CAN bits (NumOfFastBits) is determined in Table 263. For example, if the minimum payload in FD frames is 8 bytes, there are 85 CAN bits in the data phase.
3. Assuming the maximum number of message buffers is 96, and Enhanced RX FIFO is disabled, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated.

$$MinNumClkFastBit_A = \frac{(8.5 \times 96) + 64 - (9 \times 50)}{85} = 5.06$$

Equation 33. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN scan process

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{50}{40}\right) = 6.75$$

Equation 34. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

$$MinNumClkFastBit = Maximum\ (\ 5.06, 6.75\ ) = 6.75$$

Equation 35. Calculation example for number of peripheral clocks per fast CAN bit

4. The maximum CAN bit rate in the data phase can finally be found.

$$DataBitRate_{MAX} = \frac{40 \times 10^6}{ROUNDUP\left(\frac{6.75 \times 40 \times 10^6}{50 \times 10^6}\right)} = 6.667\ Mbps$$

Equation 36. Calculation example for maximum achievable baud rate

Even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbit/s in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbit/s. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

Table 264 shows the maximum data rate for CAN FD with Enhanced RX FIFO disabled according to clock frequencies, payload size, and number of available message buffers. For some cases, if the number of available message buffers is reduced, FlexCAN can then achieve a data rate up to 8 Mbit/s.

Table 264. Maximum CAN bit rate in data phase on CAN FD frames with Enhanced RX FIFO disabled

Peripheral clock frequency (MHz)	Minimum payload size	Number of available message buffers	Maximum data rate (Mbit/s)
40	8	94	6.667
40	8	114	>5.0
40	12	>117	6.667
40	12	128	5.714
50	12–64	128	6.667
60	8	126	8.0
60	12	128	8.0
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

39.3.14 Reset

You can reset FlexCAN in the following ways:

- Chip-level hard reset, which resets all memory-mapped registers asynchronously.
- Soft reset:
  - MCR[SOFTRST], which resets some of the memory-mapped registers synchronously. To see which registers soft reset affects, see Table 267.
  - The chip level soft reset input is not supported, use the MCR[SOFTRST] to trigger a soft reset.

Soft reset is synchronous and must follow an internal request-and-acknowledge procedure across clock domains. Therefore, it may take some time to propagate its effects fully. MCR[SOFTRST] remains 1 when soft reset is pending, so software can poll this field to identify when the reset has completed. Soft reset cannot be applied when clocks are shut down in a low-power mode. The low-power mode should be exited and the clocks resumed before applying soft reset.

The clock source should be selected when the module is in Disable mode (see CTRL1[CLKSRC]). After the clock source is selected and the module is enabled (MCR[MDIS] becomes 0), FlexCAN automatically enters Freeze mode. In Freeze mode:

1. FlexCAN is unsynchronized to the CAN bus.
2. MCR[HALT] and MCR[FRZ] become 1.
3. The internal state machines are disabled.
4. MCR[FRZACK] and MCR[NOTRDY] become 1.

The TX pin is in the recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Reset does not affect the message buffers and the RX Individual Mask registers, so they are not automatically initialized.

39.3.15 Interrupts

FlexCAN has many interrupt sources:

- Interrupts due to message buffers
- Interrupts due to interrupts combined via an OR operator from:
  - Message buffers
  - Bus Off
  - Bus Off Done
  - Error
  - Error Fast (errors detected in the data phase of CAN FD format messages with BRS = 1)
  - Wake Up
  - TX Warning
  - RX Warning

If its corresponding IMASK bit is 1, each message buffer can be an interrupt source. There is no distinction between TX and RX interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each buffer has an assigned flag bit in the IFLAG registers. When the corresponding buffer completes a successful transfer, the flag is set. When the CPU writes 1 to it, the flag is cleared (unless another interrupt is generated at the same time).

NOTE

The CPU must clear only the bit causing the current interrupt. For this reason, do not use bit manipulation instructions (BSET) to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt handler.

If the Legacy RX FIFO is enabled (MCR[RFEN] = 1) and DMA is disabled (MCR[DMA] = 0), the interrupts corresponding to message buffers 0–7 have different meanings.

- Bit 7 of Interrupt Flags 1 (IFLAG1) becomes the Legacy FIFO Overflow flag
- Bit 6 becomes the Legacy FIFO Warning flag

- Bit 5 becomes the Frames Available in Legacy FIFO flag
- Bits 4–0 are unused.

See Interrupt Flags 1 (IFLAG1) for more information.

If both Legacy RX FIFO and DMA are enabled (MCR[RFEN] = 1 and MCR[DMA] = 1), FlexCAN does not generate any Legacy FIFO interrupt. Bit 5 of IFLAG1 still indicates Frames Available in Legacy FIFO and generates a DMA request. Bits 7, 6, and 4–0 are unused.

CAUTION

Legacy FIFO cannot be enabled when CAN FD is enabled.

When multiple message buffer interrupt sources are combined via an OR operator into a single interrupt, the interrupt is generated when any associated message buffer (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which message buffer or FIFO source caused the interrupt.

These interrupt sources generate interrupts like the message buffer interrupt sources, and can be read from Error and Status 1 (ESR1):

- Bus Off
- Bus Off Done
- Error
- Error Fast
- Wake Up
- TX Warning
- RX Warning

The Bus Off, Error, TX Warning, and RX Warning interrupt masks are located in Control 1 (CTRL1); the wake-up interrupt mask is located in Module Configuration (MCR).

39.3.16 Bus interface

CPU access to FlexCAN registers is subject to the following rules:

- Unrestricted read and write access to supervisor registers results in an access error. In Table 267, supervisor registers are registers identified with an S, and registers that are identified with S/U that are in Supervisor Mode
- Read and write access to implemented reserved address space results in an access error.
- Write access to positions whose bits are all currently read-only results in an access error. If at least one of the bits is not read-only, no access error is issued. Write permission to specific positions or some of their bits can change depending on the mode of operation or transitory state. See register and field descriptions for details.
- Read and write access to unimplemented address space results in an access error.
- Read and write access to RAM-located positions during Low-Power mode results in an access error.
- The RXIMR memory region can be considered as general-purpose memory and available for access via these methods:
  - If you write 0 to MCR[IRMQ], the individual masks (RXIMR) are disabled. In this case, the RXIMR memory region is considered general-purpose memory.
  - If MCR[MAXMB] is programmed with a value smaller than the available number of message buffers, the unused memory space can be used as general-purpose RAM space. Reserved words within RAM cannot be used. For example, suppose the RAM in FlexCAN can support up to 16 message buffers, CTRL2[RFFN] = 0h, and MCR[MAXMB] = 0.
    - In this case, the maximum number of message buffers becomes one.
    - The RAM starts at 0080h, and the space 0080h–008Fh is used by the one message buffer.

- The memory space 0090h–017Fh is available.
- The space 0180h–087Fh is reserved.
- The space 0880h–0883h is used by the one individual mask and the available memory in the mask register space is 0884h–08BFh.
- In the space from 08C0h–09DFh, there are reserved words for internal use which cannot be used as general-purpose RAM.

As a rule, free memory space for general purpose depends only on MCR[MAXMB].

— If MCR[FDEN] = 1, general-purpose memory can be used only outside Freeze mode.

1. Access in low power is only possible if RAM_clk and MODULE_CLK are enabled.
2. If MCR[RFEN] = 1, see Legacy FIFO access rules in the rows below.
3. Write operation has no effect.
4. If MCR[RFEN] = 1, do not access Enhanced RX FIFO.

39.3.17 Detection and correction of memory errors

To update the parity bits in memory properly, all FlexCAN memory must be initialized before starting its operation. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization, from 080h–ADFh and from C20h–31FFh. You must also initialize these registers:

- RX Message Buffers Global Mask (RXMGMASK)
- Receive 14 Mask (RX14MASK)
- Receive 15 Mask (RX15MASK)
- Legacy RX FIFO Global Mask (RXFGMASK)

MCR[RFEN] and ERFCR[ERFEN] must not be 1 during memory initialization.

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated with five parity bits that ensure a Hamming distance of 4. The error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors). Errors in two bits can be detected but not corrected (uncorrectable errors). Errors in more than two bits may not be detected. For uncorrectable errors, the error correction logic does not change the corrupted data. When a read access is performed, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

When an all-zeroes or an all-ones read occurs, FlexCAN detects an uncorrectable error. See Error Report Syndrome (RERRSYNR).

Memory errors are indicated to the host via status register (Error Status (ERRSR)) and bus transfer errors. Memory errors are reported via these report registers:

- Error Report Address (RERRAR)
- Error Report Data (RERRDR)
- Error Report Syndrome (RERRSYNR)

MECR[ECCDIS] determines whether the error detection and correction mechanism can be activated. When disabled, updates on indications and reporting registers are stopped. To ensure that memory has consistent parity bits associated with the data, the parity bits are still calculated and written with data in memory write operations.

To avoid accidentally changing the critical error correction configuration, follow this protocol to enable the update of Memory Error Control (MECR):

1. Write 1 to CTRL2[ECRWRE]. (By default, CTRL2[ECRWRE] is 0 and MECR[ECRWRDIS] is 1.)
2. Write 0 to MECR[ECRWRDIS].
3. All writes to Memory Error Control (MECR) must keep MECR[ECRWRDIS] = 0.
4. After configuration is done, lock MECR by writing 1 to MECR[ECRWRDIS] or writing 0 to CTRL2[ECRWRE].

39.3.17.1 Sources of memory access

These major sources (or requestors) can access FlexCAN memory:

- Host (CPU). The largest word accessed is 32-bit.
- FlexCAN internal processes:
  - RX matching
  - TX arbitration
  - Move-in on reception
  - Move-out on transmission

  The largest word accessed is 64-bit.

The source of access determines the way that uncorrectable errors are indicated and reported.

39.3.17.2 Error indication

These flags indicate memory errors:

- ERRSR[HANCEIF]
- ERRSR[FANCEIF]
- ERRSR[CEIF]

Uncorrectable errors detected in memory reads requested by the host are indicated separately from the errors detected in requests by FlexCAN internal processes. When correctable errors are detected, FlexCAN makes no distinction of the source of the access. There are three independent flags for these three cases, and each flag raises an interrupt unless a mask in Memory Error Control (MECR) masks it. If both uncorrectable and correctable errors are found in different bytes in the same read operation, both flags are set.

An uncorrectable error detected in host access is also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If ERRSR[HANCEIF] is not masked, the same uncorrectable error raises a bus transfer error and an interrupt request.

Each indication flag has one overrun flag in Error Status (ERRSR). The overrun flags do not request interrupts. Overrun flags for uncorrectable errors indicate that other errors of the same nature were detected after the current error being treated. Overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated.

The recommended handling sequence for error indication is:

1. Get error report information from report registers.
2. Use this information to take proper measures in the application.
3. Clear the ERRSR[HANCEIF], ERRSR[FANCEIF], and ERRSR[CEIF] flags.
4. If the overrun flag is active:
    a. Alert the application that at least one error could not be managed.
    b. Clear the overrun flag.

FlexCAN internal processes can access memory in transactions larger than 32 bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in two or more 32-bit words, the interrupt and overrun flags are set simultaneously.

39.3.17.3 Error reporting

The error report registers provide detailed information about the address read, raw data, and syndrome read with error. The flags described in Error indication indicate these report registers:

- Error Report Address (RERRAR)
- Error Report Data (RERRDR)
- Error Report Syndrome (RERRSYNR)

The address, data, and syndrome registers are updated simultaneously with the error flags, according to these rules:

1. If either of the uncorrectable error flags is set, the report registers are not updated. The previous uncorrectable error reporting is preserved.
2. Otherwise, either no error flag is set or only the correctable error flag is set. The report registers are updated according to the new error, or according to the most severe new error, if uncorrectable and correctable errors are simultaneously detected.

Reporting of errors detected in accesses larger than 32 bits follows the rules described in Error indication and in the description of Error Report Address (RERRAR).

The addresses reported in RERRAR and defined in ERRIAR are not the same as the addresses listed in the module memory map. The relation between the reported addresses and the respective ones in the module memory map is shown in the description of Error Injection Address (ERRIAR).

Addresses reported when reading memory portions organized as FIFOs refer to the address of the specific entry accessed in the FIFO, not to the FIFO base address. Such memory portions include:

- Legacy RX FIFO Structure
- Enhanced RX FIFO Structure
- Legacy RX FIFO Information (RXFIR)

To ensure coherence of error report registers, disable the report update by writing 1 to MECR[RERRDIS] before reading the report registers.

39.3.17.4 Error response

Correctable errors have no consequence to FlexCAN operation because the host or FlexCAN internal processes corrects affected data before its use.

For host-initiated reads, an uncorrectable error may affect the host, but does not affect FlexCAN operation.

Uncorrectable errors detected on memory read operations requested by FlexCAN internal processes may result in incorrect operation depending on the state of MECR[NCEFAFRZ], as follows:

- During reception (either matching or move-in process), when an uncorrectable error occurs:
  - An incorrect destination may be selected to store the incoming frame.
  - A corrupted frame may be stored in the correct destination.
  - Both of these events may occur.

  If MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode to prevent corrupted data from being treated as valid by FlexCAN internal processes. If MECR[NCEFAFRZ] = 0, FlexCAN continues working, and a corrupted frame is received.
- During arbitration, when an uncorrectable error occurs:
  - A non-highest-priority TX message buffer may be mistakenly selected for transmission.
  - Its data may be corrupted.

  If MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode before starting the move-out. If MECR[NCEFAFRZ] = 0, FlexCAN proceeds to move-out with a corrupted frame that will be transmitted on the CAN bus.
- During move-out, when an uncorrectable error occurs, a corrupted frame is copied from the selected TX MB that won the arbitration to the TX SMB for transmission. If MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode before starting the transmission. When MECR[NCEFAFRZ] = 0, the corrupted frame is transferred from the TX SMB to the Protocol Engine (PE) subblock and is transmitted on the CAN bus.
- An uncorrectable error can also be detected beyond move-out, when TX data is read from TX SMB (buffer located in RAM) to be transferred to the PE subblock for transmission. In this case, a frame with corrupted ID or data is transmitted on the CAN bus.

  To prevent the external nodes from successfully receiving the frame, FlexCAN inverts all bits in the CRC field (CRC sequence plus CRC delimiter). Also, it transmits an error flag just after CRC delimiter due to self-detecting a Bit1 error and a form error due to the CRC field inversion. When MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode just after the error frame. When MECR[NCEFAFRZ] = 0, FlexCAN may attempt to retransmit the same frame, as long as no other higher-priority TX MB is configured for transmission after.

  If the uncorrectable error persists, FlexCAN eventually reaches the Bus Off state due to consecutive error detections. ECR[TXERRCNT] is updated every time FlexCAN inverts the CRC field, causing errors as described above.

When MECR[NCEFAFRZ] = 1 and FlexCAN enters Freeze mode, only the CPU can cause FlexCAN to exit Freeze mode and resume Normal mode. MECR[NCEFAFRZ] becoming 1 is the only way to prevent corrupted frames from being transmitted on the CAN bus to the move-out internal process.

The error report registers can provide information to the application for customized management of these situations.

39.3.17.5 Error injection

These error injection registers are used to inject errors in memory reads to force errors and update the indication and reporting registers:

- Error Injection Address (ERRIAR)
- Error Injection Data Pattern (ERRIDPR)
- Error Injection Parity Pattern (ERRIPPR)

The relation between the error injection addresses and the corresponding addresses in the module memory map is shown in Error Injection Address (ERRIAR).

The injection is done by flipping the data and parity bits corresponding to the bits set to 1 in ERRIDPR and ERRIPPR. You can select injection specifically for memory accesses requested by the host or by FlexCAN internal processes.

For accesses larger than 32 bits, MECR[EXTERRIE] extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

NOTE

It is possible, but very unlikely, for error injection to correct a bit with error. This correction does not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, you must clear MECR[HAERRIE] and MECR[FAERRIE] when configuring the memory injection registers.

39.4 External signal descriptions

FlexCAN has two I/O signals connected to the external chip pins. These signals are summarized in Table 266 and described in the following subsections.

Table 266. FlexCAN signal descriptions

Signal	Description	I/O
CAN RX	CAN receive pin	Input
CAN TX	CAN transmit pin	Output

39.4.1 CAN RX

This pin is the receive pin from the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

39.4.2 CAN TX

This pin is the transmit pin to the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

39.5 Initialization and application information

39.5.1 FlexCAN initialization sequence

For any configuration change or initialization, you must put FlexCAN into Freeze mode (see Freeze mode). The module must be initialized after every reset. FlexCAN memory must be initialized before switching to functional mode.

The following is a generic initialization sequence applicable to FlexCAN:

1. Initialize Module Configuration (MCR).
    a. Enable the individual filtering per message buffer and reception queue features by writing 1 to MCR[IRMQ].
    b. Enable the warning interrupts by writing 1 to MCR[WRNEN].
    c. If required, disable frame self-reception by writing 1 to MCR[SRXDIS].
    d. Enable the Legacy RX FIFO by writing 1 to MCR[RFEN] or enable the Enhanced RX FIFO by writing 1 to ERFCR[ERFEN].
    e. If Legacy RX FIFO or Enhanced RX FIFO is enabled and DMA is required, write 1 to MCR[DMA].
    f. Enable the abort mechanism by writing 1 to MCR[AEN].

g. Enable the local priority feature by writing 1 to MCR[LPRIOEN].

2. Initialize Control 1 (CTRL1) and CAN FD Bit Timing (FDCBT). Optionally initialize CAN Bit Timing (CBT).
   a. Determine the bit timing parameters: CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW].
   b. Optionally determine the bit timing parameters: CBT[EPROPSEG], CBT[EPSEG1], CBT[EPSEG2], and CBT[ERJW].
   c. Determine the CAN FD bit timing parameters: FDCBT[FPROPSEG], FDCBT[FPSEG1], FDCBT[FPSEG2], and FDCBT[FRJW].
   d. Determine the bit rate by programming CTRL1[PRESDIV] and optionally programming CBT[EPRESDIV].
   e. Determine the CAN FD bit rate by programming FDCBT[FPRESDIV].
   f. Determine the internal arbitration mode by programming CTRL1[LBUF].
3. If Error Code Correction (ECC) is enabled, you must initialize all FlexCAN memory. See Detection and correction of memory errors.
4. Initialize the message buffers. (See Message buffer structure for message buffer details.)
   a. The control and status word of all message buffers must be initialized.
   b. If RX FIFO is enabled, the ID filter table must be initialized.
   c. Other entries in each message buffer should be initialized as required.
5. Initialize Receive Individual Mask (RXIMR0 - RXIMR95).
6. Write 1 to required interrupt mask bits in:
   - IMASK registers (for all message buffer interrupts)
   - Module Configuration (MCR) (for wake-up interrupt)
   - Control 1 (CTRL1) and Control 2 (CTRL2) (for Bus Off and Error interrupts)
7. Write 0 to MCR[HALT].

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

39.6 Memory map and register definition

This section describes the registers and data structures in FlexCAN. The base address of the module depends on the particular memory map of the chip.

39.6.1 FlexCAN memory mapping

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0080h.

Each individual register is identified by its complete name and corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most registers can be configured to have either Supervisor or Unrestricted access by programming MCR[SUPV]. These registers are identified as S/U in the Access column of Table 267.

NOTE

An invalid register access results in a bus error. Invalid accesses include reading a write-only register, writing a read-only register, and accessing an invalid address.

NOTE

To update the parity bits in memory properly, all FlexCAN memory must be initialized before reading registers which are implemented in memory. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization, from 080h–ADFh and from C20h–31FFh. You must also initialize RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK) and Legacy RX FIFO Global Mask (RXFGMASK). MCR[RFEN] and ERFCR[ERFEN] must not be 1 during memory initialization.

Table 267. Register access and reset information

Register	Access type	Affected by hard reset	Affected by soft reset
Module Configuration (MCR)	S	Yes	Yes
Control 1 (CTRL1)	S/U	Yes	No
Free-Running Timer (TIMER)	S/U	Yes	Yes
RX Message buffers Global Mask (RXMGMASK)	S/U	No	No
RX Buffer 14 Mask (RX14MASK)	S/U	No	No
RX Buffer 15 Mask (RX15MASK)	S/U	No	No
Error Counter (ECR)	S/U	Yes	Yes
Error and Status 1 (ESR1)	S/U	Yes	Yes
Interrupt Masks 2 (IMASK2)	S/U	Yes	Yes
Interrupt Masks 1 (IMASK1)	S/U	Yes	Yes
Interrupt Flags 2 (IFLAG2)	S/U	Yes	Yes
Interrupt Flags 1 (IFLAG1)	S/U	Yes	Yes
Control 2 (CTRL2)	S/U	Yes	No
Error and Status 2 (ESR2)	S/U	Yes	Yes
Cyclic Redundancy Check (CRCR)	S/U	Yes	Yes
RX FIFO Global Mask (RXFGMASK)	S/U	No	No
RX FIFO Information (RXFIR)	S/U	No	No
CAN Bit Timing (CBT)	S/U	Yes	No
Interrupt Masks 3 (IMASK3)	S/U	Yes	Yes
Interrupt Flags 3 (IFLAG3)	S/U	Yes	Yes
Message buffers	S/U	No	No

Table continues on the next page...

Table 267. Register access and reset information (continued)

Register	Access type	Affected by hard reset	Affected by soft reset
RX Individual Masks	S/U	No	No
Memory Error Control (MECR)	S/U	Yes	Yes
Error Injection Address (ERRIAR)	S/U	Yes	Yes
Error Injection Data Pattern (ERRIDPR)	S/U	Yes	Yes
Error Injection Parity Pattern (ERRIPPR)	S/U	Yes	Yes
Error Report Address (RERRAR)	S/U	Yes	Yes
Error Report Data (RERRDR)	S/U	Yes	Yes
Error Report Syndrome (RERRSYNR)	S/U	Yes	Yes
Error Status (ERRSR)	S/U	Yes	Yes
Enhanced CAN Bit Timing Prescalers (EPRS)	S/U	Yes	No
Enhanced Nominal CAN Bit Timing (ENCBT)	S/U	Yes	No
Enhanced Data Phase CAN bit Timing (EDCBT)	S/U	Yes	No
Enhanced Transceiver Delay Compensation (ETDC)	S/U	Yes	No
CAN FD Control (FDCTRL)	S/U	Yes	No
CAN FD Bit Timing (FDCBT)	S/U	Yes	No
CAN FD CRC (FDCRC)	S/U	Yes	Yes
Enhanced RX FIFO Control (ERFCR)	S/U	Yes	Yes
Enhanced RX FIFO Interrupt Enable (ERFIER)	S/U	Yes	Yes
Enhanced RX FIFO Status (ERFSR)	S/U	Yes	Yes
High-Resolution Timestamp (HR_TIME_STAMP)	S/U	No	No
Enhanced RX FIFO	S/U	No	No
Enhanced RX FIFO Filter Element (ERFFEL)	S/U	No	No

FlexCAN can store CAN messages for transmission and reception using message buffers and RX FIFO structures.

39.6.2 FlexCAN register descriptions

The following table shows the FlexCAN memory map.

The address range from offset 80h–67Fh allocates the ninety-six 128-bit message buffers. The memory maps for the message buffers are in FlexCAN message buffer memory map.

The address range from offset 2000h–204Ch allocates the Enhanced RX FIFO output, and the address range from offset 2050h–263Ch allocates the rest of Enhanced RX FIFO 19 elements. The memory map for the Enhanced RX FIFO is in Enhanced RX FIFO structure.

39.6.2.1 FlexCAN memory map

CAN_FD1 base address: 443A_0000h

CAN_FD2 base address: 425B_0000h

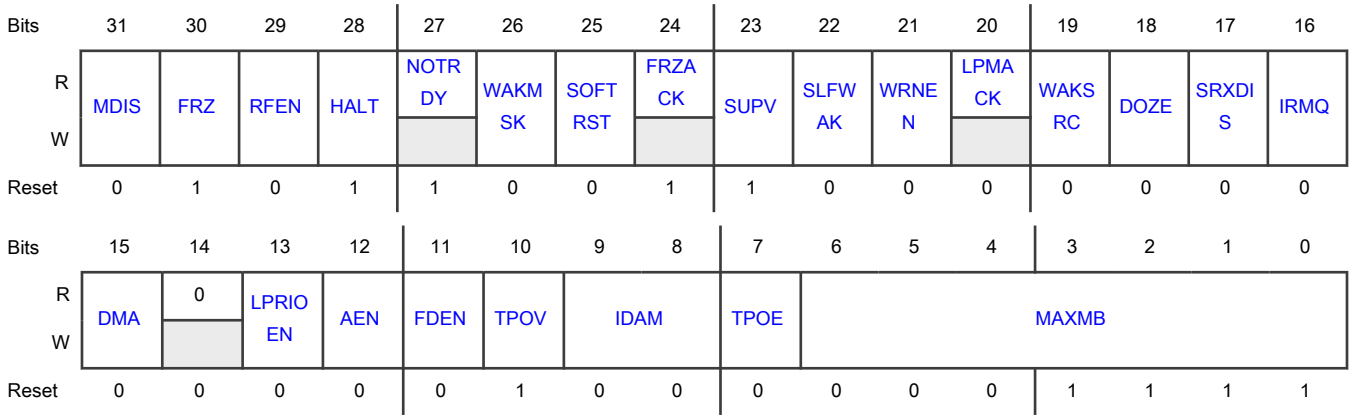
39.6.2.2 Module Configuration (MCR)

Defines global system configurations, including the module operation modes and the maximum message buffer configuration.

Offset

Register	Offset
MCR	0h

Diagram



Fields

Field	Description
31 MDIS	Module Disable Disables FlexCAN. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Soft reset does not affect this field. 0 - Enable 1 - Disable
30 FRZ	Freeze Enable Specifies FlexCAN behavior when MCR[HALT] = 1 or when Debug mode is requested at chip level. When this field becomes 1, FlexCAN can enter Freeze mode. Writing 0 to this field causes FlexCAN to exit from Freeze mode. The chip writes 1 to this field when a noncorrectable error is detected (MECR[NCEFAFRZ] becomes 1). 0 - Disable 1 - Enable
29 RFEN	Legacy RX FIFO Enable Enables the Legacy RX FIFO feature. When this field is 1, message buffers 0–5 cannot be used for normal reception and transmission. The corresponding memory region (80h–DCh) is used by the FIFO engine and additional message buffers (up to 32, depending on CTRL2[RFFN]). These message buffers are used as Legacy RX FIFO ID filter table elements. This field also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 262. This field can be written in Freeze mode only; the module blocks it in other modes. **NOTE** When CAN FD operation is enabled (see MCR[FDEN]), you cannot write 1 to this field. **NOTE** This field must not be 1 if ERFCR[ERFEN] = 1. 0 - Disable 1 - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Description
28 HALT	Halt FlexCAN Puts FlexCAN into Freeze mode. The CPU should write 0 to this field after initializing the message buffers and Control 1 (CTRL1) and Control 2 (CTRL2). FlexCAN performs no reception or transmission before this field becomes 0. Freeze mode cannot be entered when FlexCAN is in a low-power mode. The module writes 1 to this field when a noncorrectable error is detected and MECR[NCEFAFRZ] = 1. 0 - No request 1 - Enter Freeze mode, if MCR[FRZ] = 1.
27 NOTRDY	FlexCAN Not Ready Indicates whether FlexCAN is in Disable mode, Doze mode, Stop mode or Freeze mode. When FlexCAN has exited these modes, this field becomes 0. Soft reset does not affect this field. 0 - FlexCAN is in Normal mode, Listen-Only mode, or Loopback mode. 1 - FlexCAN is in Disable mode, Doze mode, Stop mode, or Freeze mode.
26 WAKMSK	Wake-up Interrupt Mask Enables the wake-up interrupt generation under the Self Wake-Up mechanism. 0 - Disabled 1 - Enabled
25 SOFTRST	Soft Reset Resets internal state machines of FlexCAN and some memory-mapped registers. The CPU can write 1 to this field directly. This field also becomes 1 when global soft reset is requested at the chip level. Because soft reset is synchronous and must follow a request-and-acknowledge procedure across clock domains, it may take some time to propagate its effect fully. When reset is pending, this field remains 1; it automatically becomes 0 when reset completes. You can poll this field to know when the soft reset has completed. Soft reset cannot be applied when clocks are shut down in a low-power mode. Transfer the module out of the low-power mode before applying soft reset. Soft reset does not affect this field. **NOTE** This field becomes 0 within 2 CAN bits after assertion of this bit. 0 - No reset 1 - Soft reset affects reset registers
24 FRZACK	Freeze Mode Acknowledge Indicates whether FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore, you can poll this field to know when FlexCAN has entered Freeze mode. If the Freeze mode request is negated, this field becomes 0 after the FlexCAN prescaler is running again. If Freeze mode is requested when FlexCAN is in a low-power mode, this field becomes 1 only when the low-power mode is exited. See Freeze mode. Soft reset does not affect this field.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE This field becomes 1 within 180 CAN bits if current transmission or reception is ongoing for classical frames and 730 CAN bits if current transmission or reception is ongoing for FD frames after the low-power mode requested by CPU. This field becomes 0 within 2 CAN bits after the Freeze mode request removal (see Protocol timing). 0 - Not in Freeze mode, prescaler running. 1 - In Freeze mode, prescaler stopped.
23 SUPV	Supervisor Mode Configures FlexCAN to be either in Supervisor or User mode. The registers that this field affects are marked as S/U in the Access type column of Table 267. The affected registers start with Supervisor access allowance only. In User mode, affected registers allow both Supervisor and Unrestricted accesses. In Supervisor mode, affected registers allow only Supervisor access. Unrestricted access behaves as though the access is performed on an unimplemented register location. This field can be written only in Freeze mode; the module blocks it in other modes. 0 - User mode 1 - Supervisor mode
22 SLFWAK	Self-Wake-Up Feature Enables the self-wake-up feature when FlexCAN is in a low-power mode other than Disable mode. When this feature is enabled, the FlexCAN module monitors the bus for a wake-up event (that is, a recessive-to-dominant transition). If a wake-up event is detected during Doze mode, FlexCAN requests to resume its clocks. If enabled to do so, it also generates a wake-up interrupt to the CPU. If a wake-up event is detected during Stop mode, FlexCAN generates, if enabled to do so, a wake-up interrupt to the CPU. The CPU can exit Stop mode globally and FlexCAN can request to resume the clocks. When FlexCAN is in a low-power mode other than Disable mode, this field cannot be written, as the module blocks it. 0 - Disable 1 - Enable
21 WRNEN	Warning Interrupt Enable Enables the generation of the flags ESR1[TWRNINT] and ESR1[RWRNINT]. When this field is 1, TWRNINT and RWRNINT flags are set when the respective error counter transitions from less than 96 to greater than or equal to 96. When this field is 0, the TWRNINT and RWRNINT flags are always zero, independent of the values of the error counters. No warning interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes. 0 - Disable 1 - Enable
20	Low-Power Mode Acknowledge

Table continues on the next page...

Table continued from the previous page...

Field	Description
LPMACK	Indicates whether FlexCAN is in a low-power mode (Disable mode, Doze mode, Stop mode). A low-power mode cannot be entered until all current transmission and reception processes have finished. The CPU can poll this field to know when FlexCAN has entered low-power mode. Soft reset does not affect this field. **NOTE** This field becomes 1 within 180 CAN bits if current transmission or reception is ongoing for classical frames and 730 CAN bits if current transmission or reception is ongoing for FD frames after the low-power mode requested by CPU. This field becomes 0 within 2 CAN bits after the low-power mode request removal (see Protocol timing). 0 - Not in a low-power mode 1 - In a low-power mode
19 WAKSRC	Wake-Up Source Determines whether the integrated low-pass filter is applied to the RX input that FlexCAN uses to detect recessive-to-dominant edges on the CAN bus. This filter can protect the RX CAN input from spurious wake-up. This field can be written only in Freeze mode. The module blocks it in other modes. 0 - No filter applied 1 - Filter applied
18 DOZE	Doze Mode Enable Determines whether FlexCAN can enter low-power mode when Doze mode is requested at chip level. This field is automatically reset when FlexCAN wakes from Doze mode upon detecting activity on the CAN bus (self wake-up enabled). 0 - Disable 1 - Enable
17 SRXDIS	Self-Reception Disable Determines whether FlexCAN can receive frames transmitted by itself. If 1, frames transmitted by the module are not stored in any MB, regardless of whether the MB is programmed with an ID that matches the transmitted frame. No interrupt flag or interrupt signal is generated due to the frame reception. This field can be written only in Freeze mode; the module blocks it in other modes. 0 - Enable 1 - Disable
16 IRMQ	Individual RX Masking and Queue Enable Indicates whether RX matching process is based on individual masking and queue, or based on a masking scheme with RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK), and Legacy RX FIFO Global Mask (RXFGMASK). When this field is disabled, for backward compatibility with legacy applications, reading the Control and Status word locks the MB even if it is empty. This field can be written in Freeze mode only. The module blocks it in other modes. 0 - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Enable
15 DMA	DMA Enable Enables DMA. The DMA feature can only be used in Legacy RX FIFO or Enhanced RX FIFO, so MCR[RFEN] or ERFCR[ERFEN] must be 1. When DMA and RFEN are 1, IFLAG1[BUF5I] generates the DMA request, and no RX FIFO interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes. 0 - Disable 1 - Enable
14 —	Reserved
13 LPRIOEN	Local Priority Enable Enables the local priority feature. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word. However, the actual transmitted ID is 11 bits for standard frames and 29 bits for extended frames. This field can be written only in Freeze mode; the module blocks it in other modes. This bit is provided for backward compatibility with legacy applications. 0 - Disable 1 - Enable
12 AEN	Abort Enable Enables the TX abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** When this field is 1, only use the abort mechanism (see Transmission abort mechanism) to update message buffers configured for transmission. **CAUTION** Writing the abort code into RX message buffers can cause unpredictable results when this field is 1. 0 - Disabled 1 - Enabled
11 FDEN	CAN FD Operation Enable Enables the CAN with flexible data rate (CAN FD) operation. This field can be written in Freeze mode only. FlexCAN can receive and transmit messages in CAN 2.0 format. If this field is enabled, FlexCAN can also receive and transmit messages in CAN FD format. FlexCAN can transmit FD frame format according to ISO 11898-1_2024.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE If the value of this field is 1, the Legacy RX FIFO Enable (MCR[RFEN]) field cannot be 1. 0 - Disable 1 - Enable
10 TPOV	TX Pin Override Value Indicates forced value on the TX pin. This bit is affected by soft reset. 0 - TX pin is forced to be dominant 1 - TX pin is forced to be recessive
9-8 IDAM	ID Acceptance Mode Identifies the format of the Legacy RX FIFO ID filter table elements. This field configures all elements of the table at the same time; they are all the same format. See Legacy RX FIFO structure. This field can be written only in Freeze mode; the module blocks it in other modes. 00 - Format A: One full ID (standard and extended) per ID filter table element. 01 - Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element. 10 - Format C: Four partial 8-bit standard IDs per ID filter table element. 11 - Format D: All frames rejected.
7 TPOE	TX Pin Override Enable Enables forcing of the TX pin to recessive or dominant. This bit is affected by soft reset. **NOTE** This bit must not be enabled during the functional mode. 0 - TX pin forcing is disabled 1 - TX pin forcing is enabled
6-0 MAXMB	Number of the Last Message Buffer Defines the number of the last message buffer that takes part in the matching and arbitration processes. The reset value (0Fh) is equivalent to a 16-MB configuration. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** You must write a value smaller than or equal to the number of available message buffers to this field, as described in FlexCAN memory partition for CAN FD. Additionally, the MAXMB value must consider the region of message buffers occupied by Legacy RX FIFO and its ID filters table space defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit, as described in Table 262.

39.6.2.3 Control 1 (CTRL1)

Contains specific FlexCAN control features related to the CAN bus. These features include bit rate, programmable sampling point within an RX bit, Loopback mode, Listen-Only mode, Bus Off recovery behavior, and interrupt enabling (Bus-Off, Error, Warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW]) can also be configured in CAN Bit Timing (CBT), which extends the range of all these variables. If CBT[BTF] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] become read-only.

If CTRL2[BTE] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] are not used by the module. Instead, these fields are read as zero, and a write operation to them has no effect.

NOTE

When the CAN FD feature is enabled, do not use CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] for CAN bit timing. Instead use CBT[EPRESDIV], CBT[ERJW], CBT[EPSEG1], CBT[EPSEG2], and CBT[EPROPSEG].

The CAN bit variables in CTRL1 and in CBT are stored in the same internal register.

Soft reset does not affect the contents of this register.

Fields

Field	Description
31-24 PRESDIV	Prescaler Division Factor Determines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The maximum value of this field is FFh, which gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Sclock frequency = PE clock frequency ÷ (PRESDIV + 1).
23-22 RJW	Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time. One time quantum is equal to one Sclock period. The valid programmable values are 0–3. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = RJW + 1.
21-19 PSEG1	Phase Segment 1 Defines the length of phase segment 1 in the bit time. The valid programmable values are 0–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) × Time Quanta.
18-16 PSEG2	Phase Segment 2 Defines the length of phase segment 2 in the bit time. The valid programmable values are 1–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time Quanta.
15 BOFFMSK	Bus Off Interrupt Mask Provides a mask for the Bus Off interrupt ESR1[BOFFINT]. 0 - Interrupt disabled 1 - Interrupt enabled
14 ERRMSK	Error Interrupt Mask Provides a mask for the Error interrupt ESR1[ERRINT]. 0 - Interrupt disabled 1 - Interrupt enabled
13 CLKSRC	CAN Engine Clock Source Selects the clock source to the CAN Protocol Engine (PE) to be either the peripheral clock or the oscillator clock. When the oscillator clock is selected, the oscillator clock frequency must be lower than the bus clock. The selected clock is fed to the prescaler to generate the serial clock (Sclock). To guarantee reliable operation, this field can be written only in Disable mode. The module blocks it in other modes. See Protocol timing. Ensure the protocol engine clock tolerance according to the CAN Protocol standard ISO 11898-1_2024. To identify the proper clock source, see the clock distribution chapter (module clocks table). If this field is 0, you can further select the peripheral clock source according to the Clock Root section of CCM chapter. 0 - Peripheral clock

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Bus clock
12 LPB	Loopback Mode Configures FlexCAN to operate in Loopback mode. In this mode, FlexCAN performs an internal loopback that can be used for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The RX CAN input pin is ignored and the TX CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. It generates an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** In this mode, MCR[SRXDIS] cannot become 1, because it would impede the self-reception of a transmitted message. **NOTE** FDCTRL[TDCEN] and MCR[ETDCEN] must be 0 when this field is 1. 0 - Disabled 1 - Enabled
11 TWRNMSK	TX Warning Interrupt Mask Provides a mask for the TX Warning interrupt associated with the ESR1[TWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1. 0 - Disabled 1 - Enabled
10 RWRNMSK	RX Warning Interrupt Mask Provides a mask for the RX Warning interrupt associated with the ESR1[RWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1. 0 - Disabled 1 - Enabled
9 —	Reserved
8 ROM	Restricted Operation Mode Enables restricted operation mode. In restricted operation mode, FlexCAN is able to receive and acknowledge CAN messages, but it cannot send error frames and overload frames. If an error or overload condition is detected, FlexCAN treats it as a protocol exception and enters an integrating state. In restricted operation mode, FlexCAN does not increment or decrement the error counters. Besides,

Table continues on the next page...

Table continued from the previous page...

Field	Description
	FlexCAN is able to transmit time reference messages of potential time controllers in a network, but other types of frames must not be configured to be transmitted. **NOTE** This field can be written in freeze mode only. 0 - Restricted operation is disabled 1 - Restricted operation is enabled
7 SMP	CAN Bit Sampling Determines the sampling mode of CAN bits at the RX input. This field can be written in Freeze mode only; the module blocks it in other modes. **NOTE** For proper operation, to write 1 to this field, you must guarantee a minimum value of two time quanta in CTRL1[PSEG1] (or CBT[EPSEG1]).This bit cannot become 1 when CAN FD is enabled (MCR[FDEN] = 1). 0 - One sample is used to determine the bit value. 1 - Three samples are used to determine the value of the received bit: the regular one (sample point) and two preceding samples. A majority rule is used.
6 BOFFREC	Bus Off Recovery Determines how FlexCAN recovers from Bus Off state. If 0, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If 1, automatic recovering from Bus Off is disabled. The module remains in Bus Off state until you write 1 to this field. If this field becomes 0 before 128 sequences of 11 recessive bits are detected on the CAN bus, Bus Off recovery happens as if this field had never become 1. If this field becomes 0 after 128 sequences of 11 recessive bits occurred, FlexCAN resynchronizes to the bus. It waits for 11 recessive bits before joining the bus. After this field becomes 0, it can become 1 again during Bus Off, but it will only be effective the next time the module enters Bus Off. If this field becomes 0 when the module is in Bus Off, writing 1 to this field is not effective for the current Bus Off recovery. **NOTE** See Bus Off in the CAN protocol standard ISO 11898-1_2024 for details. 0 - Enabled 1 - Disabled
5 TSYN	Timer Sync Enables a mechanism that resets the free-running timer each time a message is received in message buffer 0. This feature provides the means to synchronize multiple FlexCAN stations with a special "SYNC" message (that is, global network time). If MCR[RFEN] = 1 (Legacy RX FIFO enabled), the first available message buffer, according to CTRL2[RFFN], is used for timer synchronization instead of MB0. This field can be written in Freeze mode only; the module blocks it in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - Disable 1 - Enable
4 LBUF	Lowest Buffer Transmitted First Determines the ordering mechanism for message buffer transmission. When 1, MCR[LPRIOEN] does not affect the priority arbitration. This field can be written in Freeze mode only; the module blocks it in other modes. 0 - Buffer with highest priority is transmitted first. 1 - Lowest number buffer is transmitted first.
3 LOM	Listen-Only Mode Configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in Error Counter (ECR) are frozen, and the module operates in CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error without changing the receive error counter (ECR[RXERRCNT]), as if it is trying to acknowledge the message. FlexCAN acknowledges Listen-Only mode when ESR1[FLTCONF] = 1, indicating the Error Passive state. There can be some delay between the Listen-Only mode request and its acknowledgment. This field can be written in Freeze mode only; the module blocks it in other modes. 0 - Listen-Only mode is deactivated. 1 - FlexCAN module operates in Listen-Only mode.
2-0 PROPSEG	Propagation Segment Defines the length of the propagation segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation segment time = (PROPSEG + 1) × Time Quanta. One Time Quantum = one Sclock period.

39.6.2.4 Free-Running Timer (TIMER)

Represents a 16-bit free-running counter that the CPU can read and write. The timer starts from 0h after reset, counts linearly to FFFFh, and wraps around.

When CTRL2[TIMER_SRC] = 1, an external time tick continuously increments the timer. The time tick must be synchronous to the peripheral clock, with a minimum pulse width of one clock cycle.

When CTRL2[TIMER_SRC] = 0, the CAN bit clock increments the timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Doze, Stop and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the timestamp entry in a message buffer after a successful reception or transmission of a message.

If CTRL1[TSYN] = 1, the timer is reset whenever a message is received in the first available message buffer, according to CTRL2[RFFN].

The CPU can write to this register anytime. However, if the write occurs simultaneously with the timer being reset by a reception in the first message buffer, the write value is discarded.

Reading this register affects the message buffer unlocking procedure (see Message buffer lock mechanism).

Offset

Register	Offset
TIMER	8h

Fields

Field	Description
31-16 —	Reserved
15-0 TIMER	Timer Value Contains the free-running counter value.

39.6.2.5 RX Message Buffers Global Mask (RXMGMASK)

Masks the filter bits of all RX message buffers, excluding MB14 and MB15, which have individual mask registers.

This register is located in RAM.

RXMGMASK is provided for legacy application support.

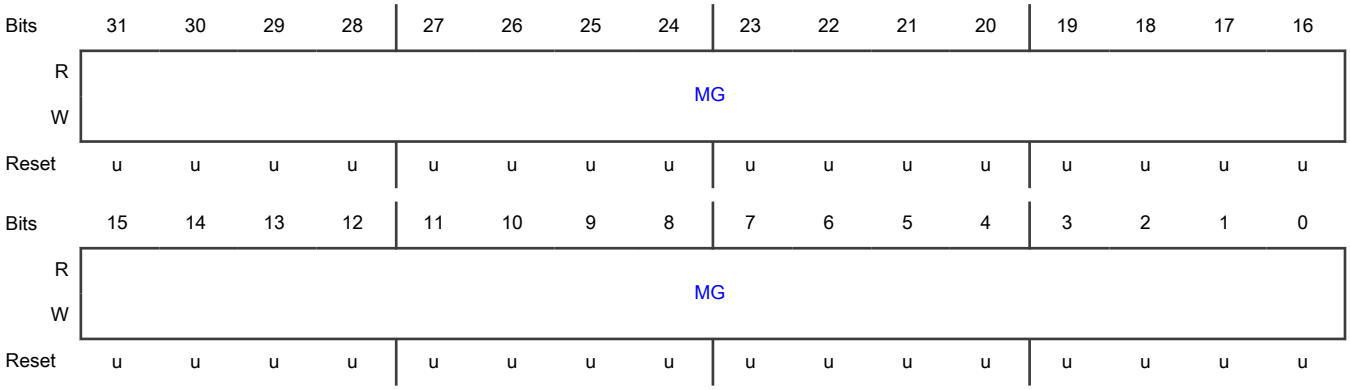
- When MCR[IRMQ] is 0, RXMGMASK is always in effect. The bits in RXMGMASK[MG] mask the MB filter bits.
- When MCR[IRMQ] is 1, RXMGMASK has no effect. The bits in RXMGMASK[MG] do not mask the MB filter bits.

This register can only be written in Freeze mode; the module blocks it in other modes.

Offset

Register	Offset
RXMGMASK	10h

Diagram



Fields

Field	Description
31-0 MG	Global Mask for RX Message Buffers Masks the message buffer filter bits. The alignment with the ID word of the message buffer is imperfect. The two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status word of the MB. The following table shows which MG bits mask each MB filter field.

SMB[RTR] [1]	CTRL2[RRS]	CTRL2[EACEN]	Message buffer filter fields			
			MB[RTR]	MB[IDE]	MB[ID]	Reserved
0	-	0	Note [2]	Note [3]	MG[28:0]	MG[31:29]
0	-	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1	0	-	-	-	-	MG[31:0]
1	1	0	-	-	MG[28:0]	MG[31:29]
1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]

1. RTR bit of the incoming frame. It is saved into an auxiliary MB called RX serial message buffer (RX SMB).
2. If CTRL2[EACEN] is 0, the RTR bit of MB is never compared with the RTR bit of the incoming frame.
3. If CTRL2[EACEN] is 0, the IDE bit of MB is always compared with the IDE bit of the incoming frame.

0b - The corresponding bit in the filter is "don't care."

1b - The corresponding bit in the filter is checked.

39.6.2.6 Receive 14 Mask (RX14MASK)

Masks the filter fields of MB14.

This register is located in RAM.

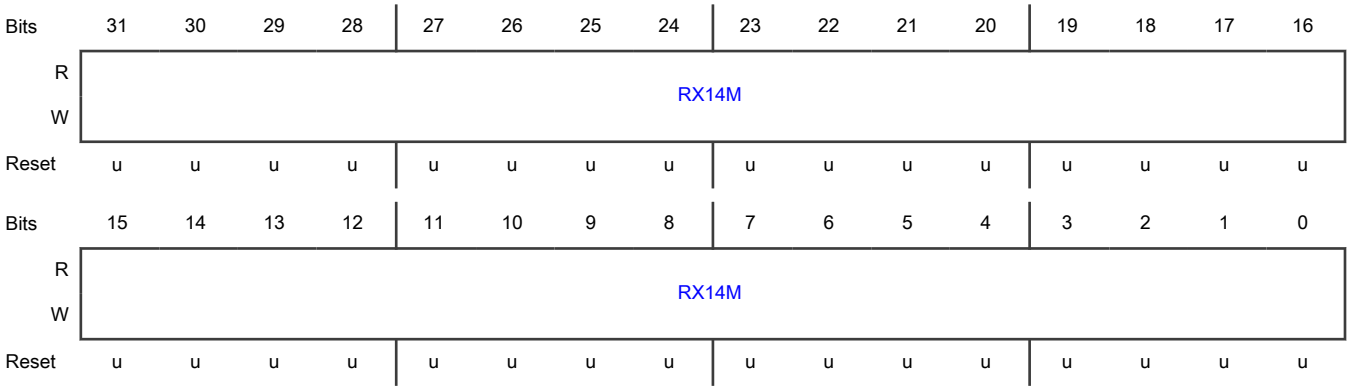
RX14MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX14MASK has no effect.

This register can only be programmed when the module is in Freeze mode; the module blocks it in other modes.

Offset

Register	Offset
RX14MASK	14h

Diagram



Fields

Field	Description
31-0 RX14M	RX Buffer 14 Mask Bits Masks the corresponding MB14 filter field in the same way that RX Message Buffers Global Mask (RXMGMASK) masks the filters of the other message buffers. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

39.6.2.7 Receive 15 Mask (RX15MASK)

Masks the filter fields of MB15.

This register is located in RAM.

RX15MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX15MASK has no effect.

This register can be programmed only when the module is in Freeze mode; the module blocks it in other modes.

Offset

Register	Offset
RX15MASK	18h

Field	Description
31-0 RX15M	RX Buffer 15 Mask Bits Masks the corresponding MB15 filter field in the same way that RX Message Buffers Global Mask (RXMGMASK) masks the filters of other message buffers. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

39.6.2.8 Error Counter (ECR)

Contains error counters for received and transmitted messages.

TXERRCNT and RXERRCNT consider all errors in both CAN FD and non-FD message formats. TXERRCNT_FAST and RXERRCNT_FAST count only the errors that occur in the data phase of CAN FD frames that have BRS = 1.

The Fault Confinement state (ESR1[FLTCONF]) is updated based on TXERRCNT and RXERRCNT counters only. The rules for increasing and decreasing these counters are described in the CAN protocol and are entirely implemented in FlexCAN.

The basic rules for FlexCAN bus state transitions are:

- If the value of TXERRCNT or RXERRCNT becomes greater than or equal to 128, ESR1[FLTCONF] is updated to reflect Error Passive state.
- If the state of FlexCAN is Error Passive, and TXERRCNT or RXERRCNT decrements to a value less than 128 when the other already satisfies this condition, ESR1[FLTCONF] is updated to reflect Error Active state.
- If the value of TXERRCNT becomes greater than 255, ESR1[FLTCONF] is updated to reflect Bus Off state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in Bus Off, TXERRCNT is cascaded with another internal counter to count the occurrences of 11 consecutive recessive bits on the bus. TXERRCNT is reset to zero. It counts in a manner where the internal counter counts 11 such bits and then wraps around when incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, ESR1[FLTCONF] is updated to Error Active, and both error counters are reset to zero. Upon any instance of a dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT_FAST counter is frozen during Bus Off.
- If only one node is operating during system startup, its TXERRCNT increases upon each attempted message transmission, as a result of acknowledge errors (indicated by ESR1[ACKERR]). After the transition to Error Passive state, TXERRCNT no longer increments upon acknowledge errors. The chip never goes into the Bus Off state.

- If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected when being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to return to the Error Active state.
- TXERRCNT_FAST and RXERRCNT_FAST error counter values increment and decrement based on errors detected only in the data phase of CAN FD frames that have BRS = 1. These counters follow the same increment and decrement rules as TXERRCNT and RXERRCNT. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen when FlexCAN is in the Bus Off state. They are reset when FlexCAN leaves the Bus Off state and resume counting after FlexCAN returns to the Error Active state.

NOTE

See Fault confinement in the CAN Protocol standard ISO 11898-1_2024 for details.

Fields

Field	Description
31-24 RXERRCNT_FAST	Receive Error Counter for Fast Bits Counts errors detected in the data phase of received CAN FD messages that have BRS = 1. This field is read-only except in Freeze mode, when the CPU can write an 8-bit zero value only.
23-16 TXERRCNT_FAST	Transmit Error Counter for Fast Bits Counts errors detected in the data phase of transmitted CAN FD messages that have BRS = 1. This field is read-only except in Freeze mode, when the CPU can write an 8-bit zero value only.
15-8 RXERRCNT	Receive Error Counter Counts all errors detected in received messages. This field is read-only except in Freeze mode, when the CPU can write to it.
7-0	Transmit Error Counter

Table continues on the next page...

Table continued from the previous page...

Field	Description
TXERRCNT	Counts all errors detected in transmitted messages. This field is read-only except in Freeze mode, when the CPU can write to it.

39.6.2.9 Error and Status 1 (ESR1)

Reports various error conditions detected in the reception and transmission of a CAN frame. This register provides status information about the chip, and is the source of some interrupts to the CPU. The reported error conditions are:

NOTE

Reading host can clear these fields.

- Errors detected in CAN frames of any format:
  - BIT1ERR
  - BIT0ERR
  - ACKERR
  - CRCERR
  - FRMERR
  - STFERR
- Errors detected in the data phase of CAN FD frames with the BRS bit set only:
  - BIT1ERR_FAST
  - BIT0ERR_FAST
  - CRCERR_FAST
  - FRMERR_FAST
  - STFERR_FAST

One or more error flags may report an error detected in a single CAN frame. To account for more error events occurring in subsequent frames when the CPU does not attempt to read this register, error reporting is cumulative.

Status flags:

- TXWRN
- RXWRN
- IDLE
- TX
- FLTCONF
- RX
- SYNCH

Interrupt flags:

- BOFFINT
- BOFFDONEINT
- ERRINT
- ERRINT_FAST

- WAKINT
- TWRNINT
- RWRNINT

The CPU should follow this procedure when servicing interrupt requests generated by these flags:

1. Read this register to capture all error condition and status flags. This action clears the respective flags that were set since the last read access.
2. Write 1 to clear the interrupt flag that triggered the interrupt request.
3. Write 1 to clear the ERROVR flag, if it is set.

Starting from all error flags cleared, a first error event sets either ERRINT or ERRINT_FAST (provided the corresponding mask bit is 1). If other error events in subsequent frames occur before the CPU serves the interrupt request, the ERROVR flag is set to indicate that errors from different frames have accumulated.

Table 268. CAN bus status

Fields

Field	Description
31 BIT1ERR_FAST	Fast Bit1 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - At least one bit transmitted as recessive is received as dominant.
30 BIT0ERR_FAST	Fast Bit0 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - At least one bit transmitted as dominant is received as recessive.
29 —	Reserved
28 CRCERR_FAST	Fast Cyclic Redundancy Check Error Flag Indicates that the receiver node has detected a CRC error in the CRC field of CAN FD frames that have BRS = 1. This error means that the calculated CRC is different from the received CRC. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - A CRC error occurred since last read of this register.
27 FRMERR_FAST	Fast Form Error Flag Indicates whether the receiver node has detected a form error in the data phase of CAN FD frames that have BRS = 1. This error means that a fixed-form bit field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - A form error occurred since last read of this register.
26 STFERR_FAST	Fast Stuffing Error Flag Indicates that a stuffing error has been detected in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - A stuffing error occurred since last read of this register.
25 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
24 —	Reserved
23 PTA	Passive to Active State If this field is 1, controller is transitioned from passive to active error state. If this field is 0, controller is not transitioned from passive to active error state. Interrupt signals are asserted if enabled from FLTCONF_IE when the controller is transitioned from passive to active error state. 0 - Does not transition 1 - Transitions
22 ATP	Active to Passive State If this field is 1, controller is transitioned from active to passive error state. If this field is 0, controller is not transitioned from active to passive error state. Interrupt signals are asserted if enabled from FLTCONF_IE when the controller is transitioned from active to passive error state. 0 - Does not transition 1 - Transitions
21 ERROVR	Error Overrun Flag Indicates that an error condition occurred when any error flag is already set. 0 - No overrun 1 - Overrun
20 ERRINT_FAST	Fast Error Interrupt Flag Indicates that at least one error flag detected in the data phase of CAN FD frames that have BRS = 1 (BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST, or STFERR_FAST) is set. If CTRL2[ERRMSK_FAST] = 1, an interrupt is generated to the CPU. 0 - No such occurrence. 1 - Error flag set in the data phase of CAN FD frames that have BRS = 1.
19 BOFFDONEINT	Bus Off Done Interrupt Flag Indicates whether ECR[TXERRCNT] has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If CTRL2[BOFFDONEMSK] = 1, an interrupt is generated to the CPU. 0 - No such occurrence 1 - FlexCAN module has completed Bus Off process.
18 SYNCH	CAN Synchronization Status Flag Indicates whether FlexCAN is synchronized to the CAN bus and able to participate in the communication process. FlexCAN sets and clears this flag. See the table in Error and Status 1 (ESR1). 0 - Not synchronized

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Synchronized
17 TWRNINT	TX Warning Interrupt Flag Indicates whether TX error counter changed from less than 96 to greater than or equal to 96. If MCR[WRNEN] = 1, this flag is set when the TXWRN flag transitions from 0 to 1, meaning that the TX error counters reached 96. If CTRL1[TWRNMSK] = 1, an interrupt is sent to the CPU. When MCR[WRNEN] = 0, this flag is masked. The CPU must clear this flag before writing 0 to MCR[WRNEN]. Otherwise, this flag is set when MCR[WRNEN] = 1 again. Writing 0 has no effect. This flag is not generated when in the Bus Off state. This flag is not updated during Freeze mode. 0 - No such occurrence 1 - TX error counter changed from less than 96 to greater than or equal to 96.
16 RWRNINT	RX Warning Interrupt Flag Indicates whether the RX error counter changed from less than 96 to greater than or equal to 96. If MCR[WRNEN] = 1, this flag is set when the RXWRN flag transitions from 0 to 1, meaning that the RX error counters reached 96. If CTRL1[RWRNMSK] = 1, an interrupt is sent to the CPU. When MCR[WRNEN] = 0, this flag is masked. The CPU must clear this flag before writing 0 to MCR[WRNEN]. Otherwise, this flag is set when MCR[WRNEN] = 1 again. Writing 0 has no effect. This flag is not updated during Freeze mode. 0 - No such occurrence 1 - RX error counter changed from less than 96 to greater than or equal to 96.
15 BIT1ERR	Bit1 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. **NOTE** A transmitter does not set this flag for an arbitration field or ACK slot. It is not set for a node sending an error passive flag that detects dominant bits. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - At least one bit sent as recessive is received as dominant.
14 BIT0ERR	Bit0 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - At least one bit sent as dominant is received as recessive.
13	Acknowledge Error Flag

Table continues on the next page...

Table continued from the previous page...

Field	Description
ACKERR	Indicates whether the transmitter node has detected an acknowledge error. This error means that a dominant bit has not been detected during the ACK SLOT. After a read operation, the field's value clears to 0. 0 - No error 1 - Error occurred since last read of this register.
12 CRCERR	Cyclic Redundancy Check Error Flag Indicates whether the receiver node has detected a cyclic redundancy check (CRC) error either in a non-FD message or in the arbitration or data phase of a frame in CAN FD format. This error means that the calculated CRC is different from the received. After a read operation, the field's value clears to 0. 0 - No error 1 - Error occurred since last read of this register.
11 FRMERR	Form Error Flag Indicates whether a form error has been detected in a non-FD message or in the arbitration or data phase of an FD message by the receiver node. This error means that a fixed-form field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0 - No error 1 - Error occurred since last read of this register.
10 STFERR	Stuffing Error Flag Indicates that a stuffing error has been detected in a non-FD message or in the arbitration or data phase of an FD message by the receiver node. After a read operation, the field's value clears to 0. 0 - No error 1 - Error occurred since last read of this register.
9 TXWRN	TX Error Warning Flag Indicates when repetitive errors occur during message transmission. Only the value of ECR[TXERRCNT] affects this flag. This flag is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - TXERRCNT is 96 or greater.
8 RXWRN	RX Error Warning Flag Indicates when repetitive errors occur during message reception. Only the value of ECR[RXERRCNT] affects this flag. This flag is not updated during Freeze mode. After a read operation, the field's value clears to 0.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - No such occurrence. 1 - RXERRCNT is greater than or equal to 96.
7 IDLE	Idle Indicates whether CAN bus is in IDLE state. See Table 268. 0 - Not IDLE 1 - IDLE
6 TX	FlexCAN In Transmission Indicates whether FlexCAN is transmitting a message. See Table 268. 0 - Not transmitting 1 - Transmitting
5-4 FLTCONF	Fault Confinement State Indicates the confinement state of FlexCAN. If CTRL1[LOM] = 1, after a delay that depends on the CAN bit timing, this field indicates Error Passive. The same delay affects the way that this field reflects an update to ECR register by the CPU. It may be necessary to wait up to one CAN bit time for coherence to be restored. Soft reset affects this field, but if CTRL1[LOM] = 1, its reset value lasts for only one CAN bit. After that time, this field reports Error Passive. 00 - Error Active 01 - Error Passive 1x - Bus Off
3 RX	FlexCAN in Reception Flag Indicates whether FlexCAN is receiving a message. See the table in Error and Status 1 (ESR1). 0 - Not receiving 1 - Receiving
2 BOFFINT	Bus Off Interrupt Flag Indicates whether FlexCAN has entered Bus Off state. If CTRL1[BOFFMSK]) = 1, an interrupt is generated to the CPU. Writing 0 to this field has no effect. 0 - No such occurrence. 1 - FlexCAN module entered Bus Off state.
1 ERRINT	Error Interrupt Flag Indicates that at least one of the error flags (ESR1[BIT1ERR], ESR1[BIT0ERR], ESR1[ACKERR], ESR1[CRCERR], ESR1[FRMERR], or ESR1[STFERR]) is set. If the corresponding mask CTRL1[ERRMSK] = 1, an interrupt is generated to the CPU. Writing 0 to this field has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - No such occurrence. 1 - Indicates setting of any error flag in the Error and Status register.
0 WAKINT	Wake-up Interrupt Flag Generates an interrupt to the CPU when a recessive-to-dominant transition is detected on the CAN bus and MCR[WAKMSK] = 1. This field applies when FlexCAN is in low-power mode during Self Wake-up: • Doze mode • Stop mode When MCR[SLFWAK] = 0, this flag is masked. The CPU must clear this flag before disabling the field. Otherwise, it is set when MCR[SLFWAK] becomes 1 again. Writing 0 has no effect. 0 - No such occurrence. 1 - Indicates that a recessive-to-dominant transition was received on the CAN bus.

39.6.2.10 Interrupt Masks 2 (IMASK2)

Masks interrupt flags. This register allows any of the 32 message buffer interrupts to be enabled or disabled for MB63–MB32. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding Interrupt Flags 2 (IFLAG2) flag is set.

Offset

Register	Offset
IMASK2	24h

Fields

Field	Description
31-0 BUF63TO32M	Buffer MBi Mask Masks the corresponding FlexCAN message buffer interrupt for MB63–MB32. **NOTE** If the corresponding Interrupt Flags 2 (IFLAG2) flag is set, writing 1 or 0 to a field in IMASK2 can set or clear an interrupt request. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

39.6.2.11 Interrupt Masks 1 (IMASK1)

Masks interrupt flags. This register allows any of the 32 message buffer interrupts to be enabled or disabled for MB31–MB0. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding Interrupt Flags 1 (IFLAG1) flag is set.

Fields

Field	Description
31-0 BUF31TO0M	Buffer MBi Mask Enables or disables the corresponding FlexCAN message buffer interrupt for MB31–MB0.

Table continues on the next page...

Field	Description
	NOTE If the corresponding Interrupt Flags 1 (IFLAG1) flag is set, writing 1 or 0 to a field in IMASK1 can set or clear an interrupt request. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

39.6.2.12 Interrupt Flags 2 (IFLAG2)

Contains the flags for the 32 message buffer interrupts for MB63–MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective flag in this register. If the corresponding Interrupt Masks 2 (IMASK2) bit is set, an interrupt is generated.

Before updating MCR[MAXMB], the CPU must service the IFLAG2 flags whose MB value is greater than the MAXMB to be updated. Otherwise, those flags remain set and are inconsistent with the number of message buffers available.

Fields

Field	Description
31-0 BUF63TO32I	Buffer MBi Interrupt Flags the corresponding FlexCAN message buffer interrupt for MB63–MB32. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

39.6.2.13 Interrupt Flags 1 (IFLAG1)

Contains the flags for the 32 message buffer interrupts for MB31–MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding Interrupt Masks 1 (IMASK1) bit is set, an interrupt is generated. There is an exception when DMA for Legacy RX FIFO is enabled, as described below.

The BUF7I–BUF5I flags also represent Legacy FIFO interrupts when the Legacy RX FIFO is enabled. When MCR[RFEN] is 1 and MCR[DMA] is 0, the function of the eight least significant interrupt flags changes:

- BUF7I, BUF6I, and BUF5I indicate operating conditions of the Legacy FIFO.
- BUF4I–BUF1I fields are reserved.
- BUF0I empties the Legacy FIFO.

Before writing 1 to MCR[RFEN], the CPU must service the IFLAG flags set in the Legacy RX FIFO region; see Legacy RX FIFO. Otherwise, these IFLAG flags mistakenly show the related message buffers now belonging to Legacy FIFO as having contents to be serviced. When MCR[RFEN] is 0, the Legacy FIFO flags must be cleared. The same care must be taken when a CTRL2[RFFN] value is selected, extending Legacy RX FIFO filters beyond MB7. For example, when RFFN is 8h, Legacy RX FIFO filters occupy the MB23–MB0 range, and related IFLAG flags must be cleared.

When MCR[RFEN] and MCR[DMA] are 1 (DMA feature for Legacy RX FIFO enabled), the function of the eight least significant interrupt flags (BUF7I–BUF0I) changes to support DMA operation. BUF7I, BUF6I, and BUF4I–BUF1I are not used.

BUF5I indicates the operating condition of the Legacy FIFO, and BUF0I empties the Legacy FIFO. Moreover, BUF5I does not generate a CPU interrupt, but it does generate a DMA request. IMASK1 bits in the Legacy RX FIFO region are not considered when bit MCR[DMA] = 1. In addition, the CPU must not clear the BUF5I flag when DMA is enabled. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. When MCR[DMA] is 0, the Legacy FIFO must be empty. Legacy FIFO must be disabled when MCR[FDEN] = 1.

Before updating MCR[MAXMB], the CPU must service the IFLAG1 flags whose MB value is greater than the MCR[MAXMB] to be updated. Otherwise, those flags remain set and are inconsistent with the number of message buffers available.

Fields

Field	Description
31-8 BUF31TO8I	Buffer MBi Interrupt Flags the corresponding FlexCAN message buffer interrupt for MB31–MB8. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
7 BUF7I	Buffer MB7 Interrupt or Legacy RX FIFO Overflow Flags the interrupt for MB7 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, this flag represents a Legacy RX FIFO overflow. In this case, the flag indicates that a message was lost because the Legacy RX FIFO is full. When the Legacy RX FIFO is full and a message buffer captures the message, this flag is not set. 0 - No occurrence of MB7 completing transmission or reception, or no FIFO overflow. 1 - MB7 completed transmission or reception, or FIFO overflow.
6 BUF6I	Buffer MB6 Interrupt or Legacy RX FIFO Warning Flags the interrupt for MB6 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, this flag represents a Legacy RX FIFO warning. In this case, the flag indicates when the number of unread messages within the Legacy RX FIFO is increased to five from four due to the reception of a new message. In other words, the Legacy RX FIFO is almost full. If this flag is cleared when there are more than four unread messages, it does not set again until the number of unread messages in the Legacy RX FIFO decreases to four or fewer. 0 - No occurrence of MB6 completing transmission or reception, or FIFO not almost full. 1 - MB6 completed transmission or reception, or FIFO almost full.
5 BUF5I	Buffer MB5 Interrupt or Frames available in Legacy RX FIFO Flags the interrupt for MB5 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, the BUF5I flag represents frames available in Legacy RX FIFO. In this case, the flag indicates that at least one frame is available to be read from the Legacy RX FIFO. When MCR[DMA] = 1, this flag generates a DMA request. The CPU must not clear this field by writing 1 to BUF5I. 0 - No occurrence of completed transmission or reception, or no frames available

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - MB5 completed transmission or reception, or frames available
4-1 BUF4TO1I	Buffer MBi Interrupt or Reserved Flags the interrupts for MB4–MB1 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears these flags. When MCR[RFEN] = 1, the BUF4TO1I flags are reserved. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
0 BUF0I	Buffer MB0 Interrupt or Clear Legacy FIFO bit Flags the interrupt for MB0 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). If MCR[RFEN] = 1, this field is used to trigger the clear Legacy FIFO operation. This operation empties the Legacy FIFO contents. Before performing this operation, the CPU must service all Legacy FIFO-related IFLAG flags. When MCR[DMA] = 1, this operation also clears the BUF5I flag, aborting the DMA request. The clear Legacy FIFO operation occurs when the CPU writes 1 to BUF0I. This operation is only allowed in Freeze mode; the module blocks it in other conditions. 0 - MB0 has no occurrence of successfully completed transmission or reception. 1 - MB0 has successfully completed transmission or reception.

39.6.2.14 Control 2 (CTRL2)

Complements Control 1 (CTRL1), providing control bits for memory write-access in Freeze mode. This register extends Legacy FIFO filter quantity, and adjusts the operation of internal FlexCAN processes such as matching and arbitration.

Soft reset does not affect the contents of this register.

Table 269 shows how the value of CTRL2[RFFN] determines the Legacy RX FIFO filter structure.

Table 269. Possible Legacy RX FIFO filter structures

RFFN[3:0]	Number of Legacy RX FIFO filter elements	Message buffers occupied by Legacy RX FIFO and ID filter table	Remaining available message buffers	Legacy RX FIFO ID filter table elements affected by RX individual masks	Legacy RX FIFO ID filter table elements affected by Legacy RX FIFO global mask

Fields

Field	Description
31	Error Interrupt Mask for Errors Detected in the Data Phase of Fast CAN FD Frames Enables the ESR1[ERRINT_FAST] interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Description
ERRMSK_FAST	0 - Disable 1 - Enable
30 BOFFDONEMSK	Bus Off Done Interrupt Mask Enables the Bus Off Done interrupt, ESR1[BOFFDONEINT]. 0 - Disable 1 - Enable
29 ECRWRE	Error Correction Configuration Register Write Enable Enables updates for Memory Error Control (MECR). If the protocol described in Detection and correction of memory errors is not followed, this field is automatically 0. 0 - Disable 1 - Enable
28 WRMFRZ	Write Access to Memory in Freeze Mode Enables unrestricted write access to FlexCAN memory in Freeze mode. When this field is 0, write access restrictions are maintained. This field can only be written in Freeze mode, and has no effect out of Freeze mode. **NOTE** Do not write 1 to MCR[RFEN] during FlexCAN memory initialization. 0 - Disable 1 - Enable
27-24 RFFN	Number of Legacy Receive FIFO Filters Defines the number of Receive Legacy FIFO filters, as shown in Table 269. The chip determines the maximum selectable number of filters. Do not program this field with values that cause the number of message buffers occupied by Legacy RX FIFO and Legacy RX FIFO ID Filter to exceed MCR[MAXMB]. MCR[MAXMB] defines the number of message buffers present. This field can only be written in Freeze mode; the module blocks it in other modes. Each group of eight filters occupies a memory space equivalent to two message buffers. The more filters are implemented, the fewer message buffers are available. The Legacy RX FIFO occupies the memory space originally reserved for MB5–MB0. This field should be programmed with a value corresponding to a number of filters less than the number of available memory words. The number of available words can be calculated as follows: (SETUP_MB - 6) × 4 Where SETUP_MB is the smaller of the parameter NUMBER_OF_MB and MCR[MAXMB]. The number of remaining message buffers available is: (SETUP_MB - 8) - (RFFN × 2)

Table continues on the next page...

Table continued from the previous page...

Field	Description
	If the number of Legacy RX FIFO filters programmed through RFFN exceeds the SETUP_MB value (memory space available), the exceeding ones are not functional. **NOTE** • The number of the last remaining available message buffers is the smaller of (NUMBER_OF_MB - 1) and MCR[MAXMB]. • If RX Individual Mask registers are not enabled, the Legacy RX FIFO Global Mask affects all Legacy RX FIFO filters.
23-19 TASD	Transmission Arbitration Start Delay Indicates by how many CAN bits the transmission arbitration process start point can be delayed from the first bit of CRC field on CAN bus. See TX arbitration start delay for details. This field can be written only in Freeze mode; the module blocks it in other modes.
18 MRP	Message Buffers Reception Priority Sets the priority for the matching process. This field can be written only in Freeze mode; the module blocks it in other modes. 0 - Matching starts from Legacy RX FIFO or Enhanced RX FIFO and continues on message buffers. 1 - Matching starts from message buffers and continues on Legacy RX FIFO or Enhanced RX FIFO.
17 RRS	Remote Request Storing Determines what the module does with a remote request. The remote request frame is submitted to a matching process. If this field is 1, the frame is stored in the corresponding message buffer in the same fashion as a data frame. No automatic remote response frame is generated. If this field is 0, an automatic remote response frame is generated if a message buffer with CODE = 1010b is found with the same ID. You can only write to this field in Freeze mode. The module blocks it in other modes. 0 - Generated 1 - Stored
16 EACEN	Entire Frame Arbitration Field Comparison Enable for RX Message Buffers Controls the comparison of IDE and RTR fields within RX message buffer filters with their corresponding bits in the incoming frame by the matching process. If enabled, the IDE and RTR fields of the RX message buffer are compared to their corresponding bits within the incoming frame (mask bits apply). If disabled, the IDE field of the RX message buffer filter is always compared and RTR is never compared despite mask bits. This field does not affect matching for Legacy RX FIFO or Enhanced RX FIFO. You can only write to this field in Freeze mode; the module blocks it in other modes. 0 - Disable 1 - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Description
15 TIMER_SRC	Timer Source Selects the time tick source used for incrementing the free-running timer counter. If CAN bit clock is selected, it defines the baud rate on the CAN bus. If External time tick is selected, the period can be adjusted to match the baud rate on the CAN bus. It can also be adjusted to a different value as required. See the chip-specific section for details about the external time tick. You can only write to this field in Freeze mode. 0 - CAN bit clock 1 - External time tick
14 PREXCEN	Protocol Exception Enable Enables the protocol exception feature. You can only write to this field in Freeze mode. **NOTE** See Protocol exception event in the CAN Protocol standard ISO 11898-1_2024 for details. 0 - Disabled 1 - Enabled
13 BTE	Bit Timing Expansion Enable Enables the use of Enhanced CAN Bit Timing Prescalers (EPRS), Enhanced Data Phase CAN Bit Timing (EDCBT), and Enhanced Nominal CAN Bit Timing (ENCBT) to configure the CAN bit timing segments, instead of using the bit timing fields of CAN Bit Timing (CBT), CAN FD Bit Timing (FDCBT), and Control 1 (CTRL1). If this field is 1: • CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] are read as zero. A write operation to these fields has no effect. • CBT[EPRESDIV], CBT[ERJW], CBT[EPROPSEG], CBT[EPSEG1], and CBT[EPSEG2], and the corresponding fields in CAN FD Bit Timing (FDCBT), are read as zero. A write operation to these fields has no effect. • ETDC[ETDCOFF], ETDC[ETDCEN], ETDC[ETDCFAIL], and ETDC[ETDCVAL] are used by FlexCAN instead of FDCTRL[TDCOFF], FDCTRL[TDCEN], FDCTRL[TDCFAIL], and FDCTRL[TDCVAL]. These fields are read as zero, and a write operation to them has no effect. • ETDC[TDMDIS] can be used to disable transceiver delay measurement. 0 - Disable 1 - Enable
12 ISOCANFDEN	ISO CAN FD Enable Enables the CAN FD protocol according to ISO specification ISO 11898-1_2024 (see CAN FD ISO compliance). When disabled, FlexCAN operates using the non-ISO CAN FD protocol.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	You can only write to this field in Freeze mode. **NOTE** FlexCAN is able to transmit FD frame format according to CAN Protocol standard ISO 11898-1_2024. 0 - Disable 1 - Enable
11 EDFLTDIS	Edge Filter Disable Disables the edge filter used during the Bus Integration state. When the Edge Filter is enabled, two consecutive nominal time quanta with dominant bus states are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of 11 consecutive recessive bits is restarted. The edge filter prevents dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition. You can only write to this field in Freeze mode. **NOTE** See Bus Integration state in the CAN Protocol standard ISO 11898-1_2024 for details. 0 - Enabled 1 - Disabled
10 FLT_RXN	Fault reaction Indicates fault reaction during the functional mode. Setting this bit makes the TX pin to recessive state. 0 - Fault reaction is disabled 1 - Fault reaction is enabled
9-8 MBTSBASE	Message Buffer Timestamp Base Selects the timebase used for capturing the 16-bit TIME_STAMP field of the message buffer register. This field can be written in Freeze Mode only. 00 - TIMER 01 - Lower 16 bits of high-resolution timer 10 - Upper 16 bits of high-resolution timer 11 - Reserved
7-6 TSTAMPCAP	Timestamp Capture Point Configures the point in time when a 32-bit timebase is captured during a CAN frame. This base is stored in the high-resolution timestamp register (HR_TIME_STAMP). For classical CAN frames, capture points can be the start-of-frame bit or the point when CAN frame is considered valid. This point is the seventh bit of the end-of-frame for transmission and the sixth bit of the

Table continues on the next page...

Table continued from the previous page...

Field	Description
	end-of-frame for reception. For CAN FD frames, the high-resolution timestamp can be captured at the start of frame, when a CAN FD frame is considered valid, or the res bit. You can only write to this field in Freeze mode. 00 - Disabled 01 - End of the CAN frame 10 - Start of the CAN frame 11 - Start of frame for classical CAN frames; res bit for CAN FD frames
5 —	Reserved
4-2 RETRY	Number of Retransmission Requests The message is discarded in case of a re-transmission counter exhausted. **NOTE** You can only write to this field in Freeze mode. 000 - No retransmission 001 - Count of re-transmission attempts 010 - Count of re-transmission attempts 011 - Count of re-transmission attempts 100 - Count of re-transmission attempts 101 - Count of re-transmission attempts 110 - Count of re-transmission attempts 111 - Unlimited number of retransmission
1-0 —	Reserved

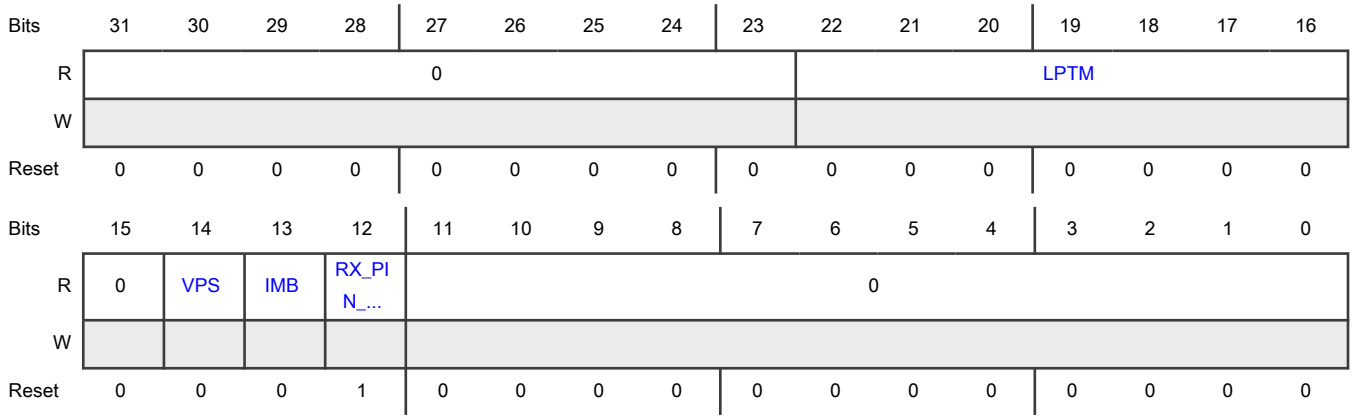
39.6.2.15 Error and Status 2 (ESR2)

Reports general status information.

Offset

Register	Offset
ESR2	38h

Diagram



Fields

Field	Description
31-23 —	Reserved
22-16 LPTM	Lowest Priority TX Message Buffer Indicates the lowest number inactive message buffer when ESR2[VPS] = 1 (see ESR2[IMB]). If no message buffer is inactive, the message buffer indicated depends on the value of CTRL1[LBUF]. If CTRL1[LBUF] = 0, the message buffer indicated is the one with the greatest arbitration value (see Highest-priority message buffer first). If CTRL1[LBUF] = 1, the message buffer indicated is the active TX message buffer with the highest number. If a TX message buffer is being transmitted, it is not considered in the LPTM calculation. If ESR2[IMB] is not 0 and a frame is transmitted successfully, the value of LPTM is updated with its message buffer number.
15 —	Reserved
14 VPS	Valid Priority Status Indicates whether the contents of ESR2[IMB] and ESR2[LPTM] are valid. It becomes 1 upon every complete TX arbitration process, unless the CPU writes to the Control and Status word of a message buffer already scanned. In other words, it is behind the TX Arbitration Pointer, during the TX arbitration process. If there is no inactive message buffer and only one TX message buffer that is being transmitted, this field remains 0. This field becomes 0 upon the start of every TX arbitration process or upon a write to the Control and Status word of any message buffer. **NOTE** No CPU write to the Control and Status of a message buffer that the abort mechanism blocks affects this field. When MCR[AEN] = 1, the abort code write to the Control and Status of an MB being transmitted (pending abort) is blocked. Any write attempt to a TX MB with its IFLAG flag set is also blocked. 0 - Invalid 1 - Valid

Table continues on the next page...

Table continued from the previous page...

Field	Description
13 IMB	Inactive Message Buffer Indicates whether any message buffer is inactive (CODE field is either 1000b or 0b) when ESR2[VPS] = 1. This field becomes 1 when: • A lowest-priority TX message buffer (ESR2[LPTM]) is found and it is inactive during arbitration. • This field is not 1, and a frame is transmitted successfully. This field always becomes 0 at the start of arbitration (see Arbitration process). If a message buffer is successfully transmitted and this field is 0 (no inactive message buffer), ESR2[VPS] and this field both become 1. The index related to the MB transmitted is loaded into ESR2[LPTM]. In this case, the value of ESR2[LPTM] is the number of the first inactive message buffer. 0 - Message buffer indicated by ESR2[LPTM] is not inactive. 1 - At least one message buffer is inactive.
12 RX_PIN_ST	RX Pin Status Indicates the current state of the RX pin. This bit is affected by soft reset. **NOTE** IP takes a few clock cycles to propagate the value of RX pin to this status bit. 0 - RX pin is in the dominant state 1 - RX pin is in a recessive state
11-0 —	Reserved

39.6.2.16 Cyclic Redundancy Check (CRCR)

Provides information about the CRC of transmitted messages for non-FD messages. This register only reports the 15 low-order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, you must use the CAN FD CRC (FDCRC). This register is updated at the same time that the TX interrupt flag is set.

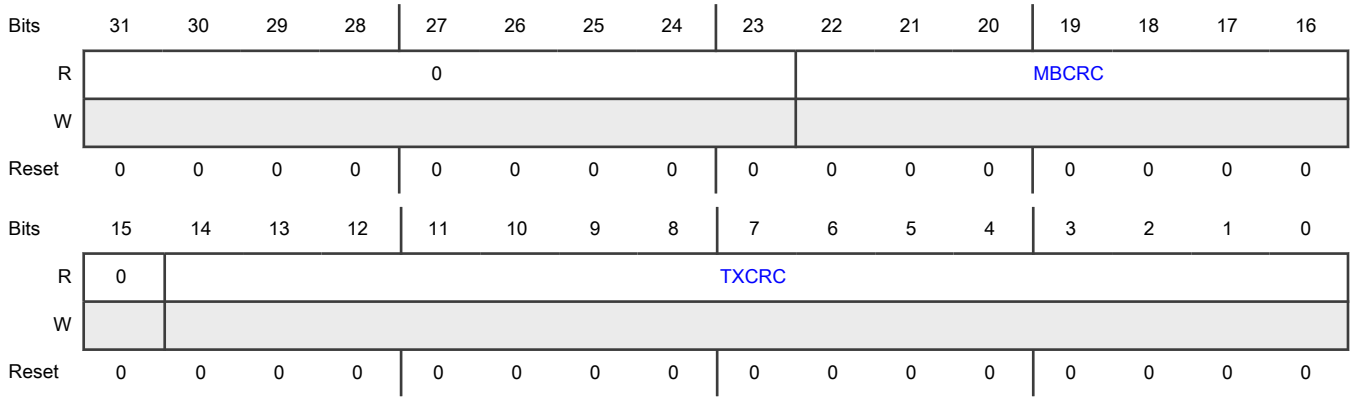
NOTE

See CRC sequence calculation in the CAN Protocol standard ISO 11898-1_2024 for details.

Offset

Register	Offset
CRCR	44h

Diagram



Fields

Field	Description
31-23 —	Reserved
22-16 MBCRC	CRC Message Buffer Indicates the number of the message buffer corresponding to the value in CRCR[TXCRC].
15 —	Reserved
14-0 TXCRC	Transmitted CRC value Indicates the CRC value of the last transmitted message for non-FD frames. For FD frames, CRC value is reported in CAN FD CRC (FDCRC).

39.6.2.17 Legacy RX FIFO Global Mask (RXFGMASK)

Masks the Legacy RX FIFO ID filter table elements that do not have a corresponding RXIMR according to CTRL2[RFFN], when Legacy RX FIFO is enabled.

This register is located in RAM.

You can only write to this register in Freeze mode; the module blocks it in other modes.

The following table shows how the FGM bits correspond to each IDAF field.

Table 270. Correspondence of Legacy RX FIFO global mask bits to IDF fields

Legacy RX FIFO ID filter table elements format (MCR[IDAM])	Identifier acceptance filter fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	—	—	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	—	FGM[29:16], FGM[13:0]		—

Table continues on the next page...

Table 270. Correspondence of Legacy RX FIFO global mask bits to IDF fields (continued)

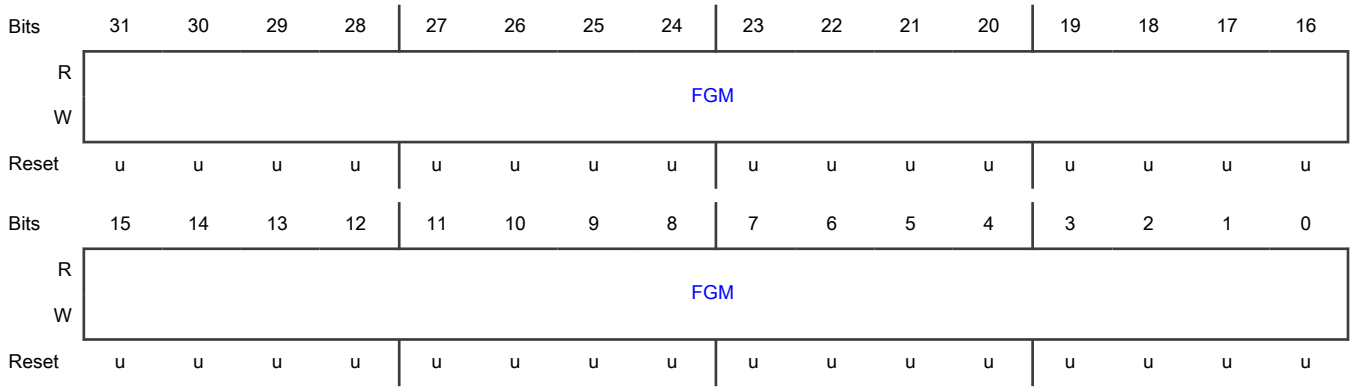
Legacy RX FIFO ID filter table elements format (MCR[IDAM])	Identifier acceptance filter fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
C	—	—		—	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If MCR[IDAM] is equivalent to format B, only the 14 most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.
2. If MCR[IDAM] is equivalent to format C, only the eight most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.

Offset

Register	Offset
RXFGMASK	48h

Diagram



Fields

Field	Description
31-0 FGM	Legacy RX FIFO Global Mask Bits Masks the ID filter table elements bits in a perfect alignment. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

39.6.2.18 Legacy RX FIFO Information (RXFIR)

Provides information about Legacy RX FIFO.

This register is the port through which the CPU accesses the output of the Legacy RXFIR FIFO located in RAM. FlexCAN writes to the Legacy RXFIR FIFO when a new message is moved into the Legacy RX FIFO. Also, its output is updated whenever the output of the Legacy RX FIFO is updated with the next message. See Legacy RX FIFO for instructions on reading this register.

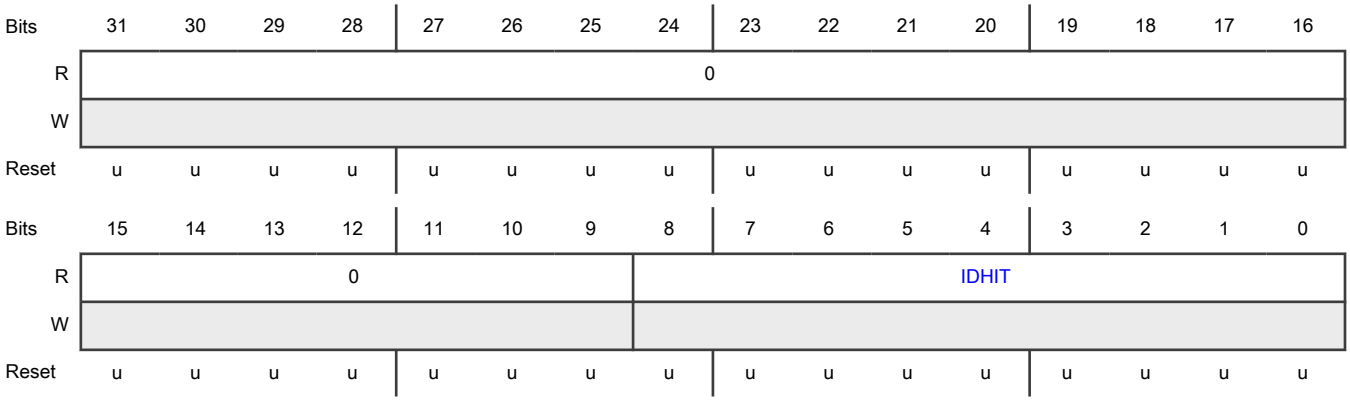
NOTE

RXFIR can be written only during memory initialization, due to the error code correction (ECC) feature. In every other case, this register is read-only.

Offset

Register	Offset
RXFIR	4Ch

Diagram



Fields

Field	Description
31-9 —	Reserved
8-0 IDHIT	Identifier Acceptance Filter Hit Indicator Indicates which Identifier Acceptance filter that the received message hit in the output of the Legacy RX FIFO. If multiple filters match the incoming message ID, the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only when IFLAG1[BUF5I] is set.

39.6.2.19 CAN Bit Timing (CBT)

Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1). EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW are extended versions of CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] respectively.

NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

CBT[BTF] selects the use of the timing variables defined in this register.

When the CAN FD feature is enabled (MCR[FDEN] = 1), always write 1 to CBT[BTF].

Soft reset does not affect the contents of this register.

NOTE

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard ISO 11898-1_2024.

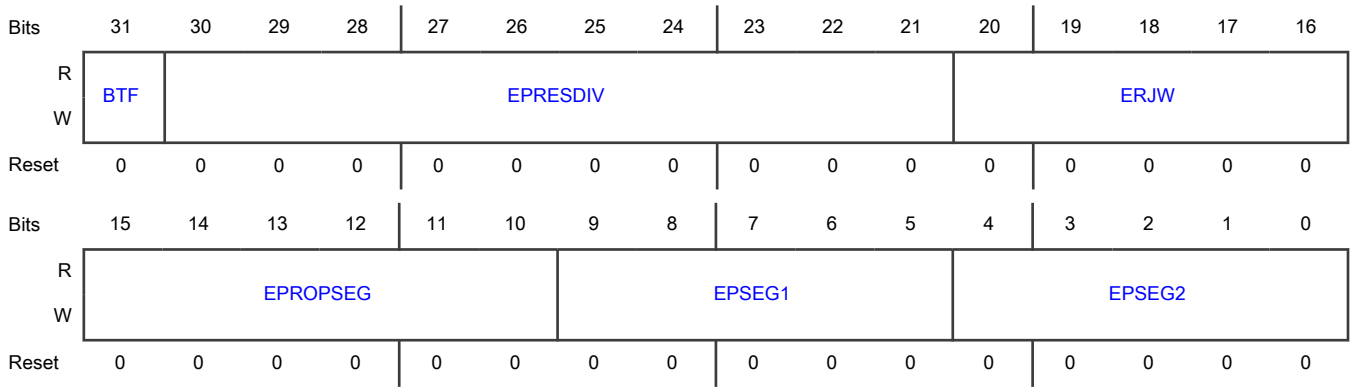
NOTE

If CTRL2[BTE] = 1, EPRESDIV, ERJW, EPROPSEG, EPSEG1, and EPSEG2 are read as zero. A write operation to them has no effect.

Offset

Register	Offset
CBT	50h

Diagram



Fields

Field	Description
31 BTF	Bit Timing Format Enable Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW. These fields replace the CAN bit timing variables defined in Control 1 (CTRL1). This field can be written in Freeze mode only. 0 - Disable 1 - Enable
30-21 EPRESDIV	Extended Prescaler Division Factor Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PRESDIV] value range. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (EPRESDIV + 1)
20-16	Extended Resync Jump Width

Table continues on the next page...

Table continued from the previous page...

Field	Description
ERJW	Defines the maximum number of time quanta that one resynchronization can change a bit time when CBT[BTF] = 1. Otherwise, it has no effect. It extends the CTRL1[RJW] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = ERJW + 1. One Time Quantum = one Sclock period.
15-10 EPROPSEG	Extended Propagation Segment Defines the length of the propagation segment in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PROPSEG] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation Segment Time = (EPROPSEG + 1) × Time Quanta. One Time Quantum = one Sclock period.
9-5 EPSEG1	Extended Phase Segment 1 Defines the length of phase segment 1 in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PSEG1] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (EPSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.
4-0 EPSEG2	Extended Phase Segment 2 Defines the length of phase segment 2 in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PSEG2] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (EPSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.

39.6.2.20 Interrupt Masks 3 (IMASK3)

Enables or disables any number of the 32 message buffer interrupts for MB95–MB64. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding IFLAG3 flag is set.

Offset

Register	Offset
IMASK3	6Ch

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	BUF95TO64M															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-0 BUF95TO64M	Buffer MBi Mask Enables or disables the corresponding FlexCAN message buffer interrupt for MB95–MB64. When CAN FD is enabled, the MB range is defined in accordance with FDCTRL[MBDSRn]. **NOTE** If the corresponding IFLAG3 flag is set, writing 1 or 0 to a field in IMASK3 can set or clear an interrupt request. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

39.6.2.21 Interrupt Flags 3 (IFLAG3)

Defines the flags for the 32 message buffer interrupts for MB95–MB64. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG3 flag. If the corresponding IMASK3 bit is 1, an interrupt is generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB], the CPU must service the IFLAG3 flags whose MB value is greater than the MAXMB to be updated. Otherwise, they remain set and are inconsistent with the number of message buffers available.

39.6.2.24 Receive Individual Mask (RXIMR0 - RXIMR95)

Stores the acceptance masks for ID filtering in RX message buffers and the Legacy RX FIFO.

When the Legacy RX FIFO is disabled (MCR[RFEN] = 0), an individual mask is provided for each available RX message buffer on a one-to-one correspondence. When the Legacy RX FIFO is enabled (MCR[RFEN] = 1), an individual mask is provided for each Legacy RX FIFO ID filter table element on a one-to-one correspondence. This correspondence depends on the setting of CTRL2[RFFN] (see Legacy RX FIFO).

RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0. RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

The CPU can only access the RXIMR registers when the module is in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general-purpose memory. See Bus interface for more information.

Offset

For n = 0 to 95:

Register	Offset
RXIMRn	880h + (n × 4h)

Fields

Field	Description
31-0 MI	Individual Mask Bits

Table continues on the next page...

Field	Description
	Masks the corresponding bit in both the message buffer filter and Legacy RX FIFO ID filter table element in distinct ways. For message buffer filters, see RX Message Buffers Global Mask (RXMGMASK). For Legacy RX FIFO ID filter table elements, see Legacy RX FIFO Global Mask (RXFGMASK). 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

39.6.2.25 Memory Error Control (MECR)

Contains control bits for memory error detection and correction (ECC).

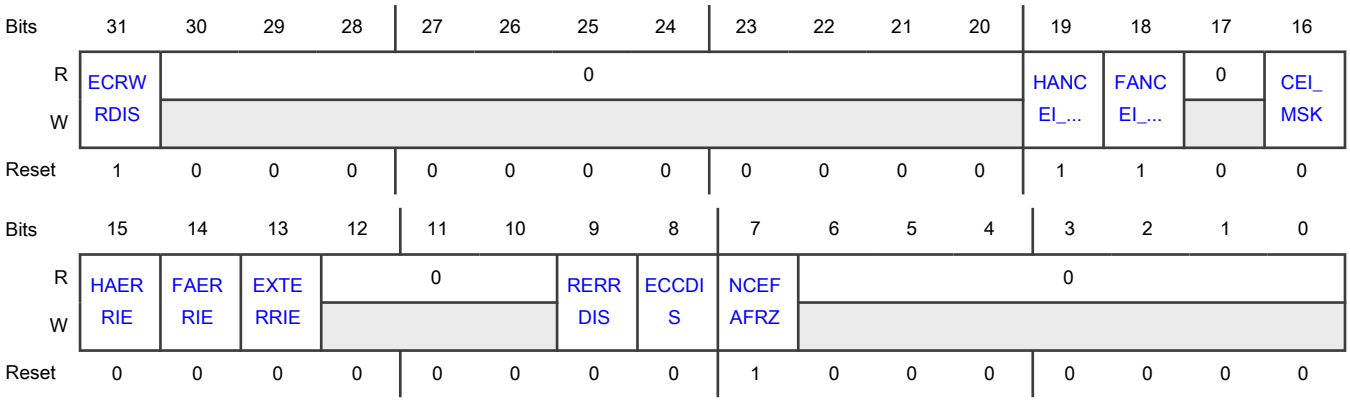
NOTE

When CTRL2[ECRWRE] = 0, writes to this register are blocked, except for MECR[ECRWRDIS].

Offset

Register	Offset
MECR	AE0h

Diagram



Fields

Field	Description
31 ECRWRDIS	Error Configuration Register Write Disable Disables writes on this register. This field automatically becomes 1 (disabled) when CTRL2[ECRWRE] is 1. The protocol described in Detection and correction of memory errors must be followed. 0 - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Disable
30-20 —	Reserved
19 HANCEI_MSK	Host Access with Noncorrectable Errors Interrupt Mask Enables the interrupt for noncorrectable errors detected in memory reads issued by the host (CPU). 0 - Disable 1 - Enable
18 FANCEI_MSK	FlexCAN Access with Noncorrectable Errors Interrupt Mask Enables the interrupt for noncorrectable errors detected in memory reads issued by FlexCAN internal processes. 0 - Disable 1 - Enable
17 —	Reserved
16 CEI_MSK	Correctable Errors Interrupt Mask Enables the interrupt for correctable errors detected in memory reads issued by the host or FlexCAN internal processes. 0 - Disable 1 - Enable
15 HAERRIE	Host Access Error Injection Enable Enables the injection of errors only in memory reads issued by the host (CPU). 0 - Disable 1 - Enable
14 FAERRIE	FlexCAN Access Error Injection Enable Enables the injection of errors only in memory reads issued by FlexCAN internal processes. 0 - Disable 1 - Enable
13 EXTERRIE	Extended Error Injection Enable Extends the error injection on 32-bit memory accesses to the complementary 32-bit word. This feature uses the same 32-bit error injection data and parity words used for 64-bit memory accesses performed by internal FlexCAN processes. See Error Injection Data Pattern (ERRIDPR) and Error Injection Parity Pattern (ERRIPPR). 0 - Disable. Apply error injection only to the 32-bit word.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Enable. Apply error injection to the 64-bit word.
12-10 —	Reserved
9 RERRDIS	Error Report Disable Disables the update of the error report registers. The update of error-related flags and the generation of bus transfer errors are still active. **NOTE** When reading the report registers, this field must be 1 to ensure coherence on the consecutive register reads. 0 - Enable 1 - Disable
8 ECCDIS	Error Correction Disable Completely disables the memory detection and correction mechanism. Besides disabling the error report mechanism, it also stops the update of the error-related flags and the generation of bus transfer errors. The parity bits continue to be calculated and written into memory on write transactions. 0 - Enable 1 - Disable
7 NCEFAFRZ	Noncorrectable Errors in FlexCAN Access Put Chip in Freeze Mode Determines whether to put FlexCAN into Freeze mode when a noncorrectable error is detected in a memory read performed by FlexCAN internal processes. In this case, entering Freeze mode prevents FlexCAN internal processes from treating corrupted data as valid. See Freeze mode for more information. 0 - Normal operation 1 - Freeze mode
6-0 —	Reserved

39.6.2.26 Error Injection Address (ERRIAR)

Contains the address where error is to be injected.

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM. Where pairs of values are provided, the first is the address for MCR[FDEN] = 0, the second is for MCR[FDEN] = 1.

Table 271. Error injection address for classical CAN format

RAM contents	Injection address	Memory map
FlexCAN registers	Not mapped	—

Table continues on the next page...

Table 271. Error injection address for classical CAN format (continued)

RAM contents	Injection address	Memory map
Message buffers	0000h	0080h

Field	Description
31-29 —	Reserved
28-24 PFLIP3	Parity Flip Pattern for Byte 3 (Most Significant) Contains the error injection pattern for Byte 3.
23-21 —	Reserved
20-16 PFLIP2	Parity Flip Pattern for Byte 2 Contains the error injection pattern for Byte 2.
15-13 —	Reserved
12-8 PFLIP1	Parity Flip Pattern for Byte 1 Contains the error injection pattern for Byte 1.
7-5 —	Reserved
4-0 PFLIP0	Parity Flip Pattern for Byte 0 (Least Significant) Contains the error injection pattern for Byte 0.

39.6.2.29 Error Report Address (RERRAR)

Reports the address used for an access operation in which an error (correctable or noncorrectable) was detected. Also reports the identification of the source of that access.

This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] nonzero) are reported with the address aligned, and data is reported in Error Report Data (RERRDR) shifted accordingly. When errors are detected in accesses larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word where the error was detected is reported. For errors detected in more than one 32-bit word, only the least significant address is reported.

Table 272. Source of memory access

SAID[2:0]	Error during...
0	Move-out FlexCAN access
1	Move-in
2	TX arbitration
3	RX matching

Fields

Field	Description
31-0 RDATA	Raw Data Word Read from Memory with Error

39.6.2.31 Error Report Syndrome (RERRSYNR)

Contains the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYND*n* field indicates the type of error and which bit in byte (*n*) the error affects. SYND3 corresponds to the most significant byte in the data word read from memory; SYND0 corresponds to the least significant.

Table 273. Syndrome definition

SYND*n* (hex)	Type	Bit affected
00	—	None (no error)
01	Code	0
02	Code	1
04	Code	2
07	Data	5
08	Code	3
0E	Data	7
10	Code	4
13	Data	2
15	Data	6
16	Data	1
19	Data	3
1A	Data	4
1C	Data	0
06	—	All-zeroes noncorrectable error
1F	—	All-ones noncorrectable error
All others	—	Noncorrectable error

Each BE*n* field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, including the non-read ones. Errors detected in non-read bytes are indicated (see Error indication) and reported (see Error reporting).

19	Host Access with Noncorrectable Error Interrupt Flag

Table continues on the next page...

Table continued from the previous page...

Field	Description
HANCEIF	Indicates that a noncorrectable error was detected in a memory read initiated by host. A bus transfer error is asserted for that access. If MECR[HANCEI_MSK] = 1, the interrupt is 1. 0 - No errors detected 1 - Error detected
18 FANCEIF	FlexCAN Access with Noncorrectable Error Interrupt Flag Indicates that a noncorrectable error was detected in a memory read initiated by FlexCAN internal processes. If MECR[FANCEI_MSK] = 1, the interrupt is 1. 0 - No errors detected 1 - Error detected
17 —	Reserved
16 CEIF	Correctable Error Interrupt Flag Indicates that a correctable error was detected in a memory read. If MECR[CEI_MSK] = 1, the interrupt is 1. 0 - No errors detected 1 - Error detected
15-4 —	Reserved
3 HANCEIOF	Host Access with Noncorrectable Error Interrupt Overrun Flag Indicates that a noncorrectable error was detected in a memory read initiated by host when ERRSR[HANCEIF] was set. No interrupt is associated with this flag. See Error indication. 0 - No errors detected 1 - Error detected
2 FANCEIOF	FlexCAN Access with Noncorrectable Error Interrupt Overrun Flag Indicates that a noncorrectable error was detected in a memory read initiated by FlexCAN internal processes when ERRSR[FANCEIF] was set. No interrupt is associated with this flag. See Error indication. 0 - No errors detected 1 - Error detected
1 —	Reserved
0 CEIOF	Correctable Error Interrupt Overrun Flag Indicates that a correctable error was detected in a memory read when ERRSR[CEIF] was set. No interrupt is associated with this flag. See Error indication. 0 - No errors detected

Field	Description
	1 - Error detected

39.6.2.33 Enhanced CAN Bit Timing Prescalers (EPRS)

Defines the CAN bit timing prescalers for the nominal phase and data phase when CTRL2[BTE] = 1.

Used by the module only if CTRL2[BTE] = 1; otherwise, a write operation has no effect and all fields are read as zero.

This register can be written only in Freeze mode; the module blocks it in other modes.

Soft reset does not affect the contents of this register.

Offset

Register	Offset
EPRS	BF0h

Fields

Field	Description
31-26 —	Reserved
25-16 EDPRESDIV	Extended Data Phase Prescaler Division Factor Defines the ratio between the PE clock frequency and the Sclock frequency in the data phase of a CAN FD message when CTRL2[BTE] = 1. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. Sclock frequency = PE clock frequency ÷ (EDPRESDIV + 1)

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE To minimize errors when processing FD frames, use the same value for this field and for EPRS[ENPRESDIV]. See the first note in CAN FD frames for details.
15-10 —	Reserved
9-0 ENPRESDIV	Extended Nominal Prescaler Division Factor Defines the ratio between the PE clock frequency and the Sclock frequency when CTRL2[BTE] = 1. Otherwise, it reads as 0 and a write operation has no effect. The Sclock period defines the time quantum of the CAN protocol in the nominal phase. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). Sclock frequency = PE clock frequency ÷ (ENPRESDIV + 1)

39.6.2.34 Enhanced Nominal CAN Bit Timing (ENCBT)

Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1) and CAN Bit Timing (CBT), to get higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

Fields

Field	Description
31-29 —	Reserved
28-22 NRJW	Nominal Resynchronization Jump Width Defines the maximum number of time quanta that one resynchronization can change a nominal bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. One time quantum = one Sclock period Nominal Resync Jump Width = NRJW + 1
21-19 —	Reserved
18-12 NTSEG2	Nominal Time Segment 2 Defines the length of Time Segment 2 in the nominal bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Nominal Time Segment 2 = (NTSEG2 + 1) × Time Quanta One time quantum = one Sclock period
11-8 —	Reserved
7-0 NTSEG1	Nominal Time Segment 1 Defines the length of Time Segment 1 in the bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Nominal Time Segment 1 = (NTSEG1 + 1) × Time Quanta One time quantum = one Sclock period

39.6.2.35 Enhanced Data Phase CAN Bit Timing (EDCBT)

Provides an alternative way to store the data phase CAN bit timing variables described in CAN FD Bit Timing (FDCBT) to achieve higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1; otherwise, a write operation has no effect and all fields are read as zero.

Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

NOTE

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard ISO 11898-1_2024.

NOTE

DTSEG1 must be at least two time quanta.

Offset

Fields

Field	Description
31-26 —	Reserved
25-22 DRJW	Data Phase Resynchronization Jump Width Defines the maximum number of time quanta that one resynchronization can change a data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Resync Jump Width = DRJW + 1.
21-16 —	Reserved
15-12 DTSEG2	Data Phase Time Segment 2 Defines the length of time segment 2 in the data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Time Segment 2 = (DTSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.
11-5 —	Reserved
4-0 DTSEG1	Data Phase Segment 1 Defines the length of time segment 1 in the data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Data Phase Time Segment 1 = (NTSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.

39.6.2.36 Enhanced Transceiver Delay Compensation (ETDC)

Contains extended versions of FDCTRL[TDCOFF] and FDCTRL[TDCVAL]. This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

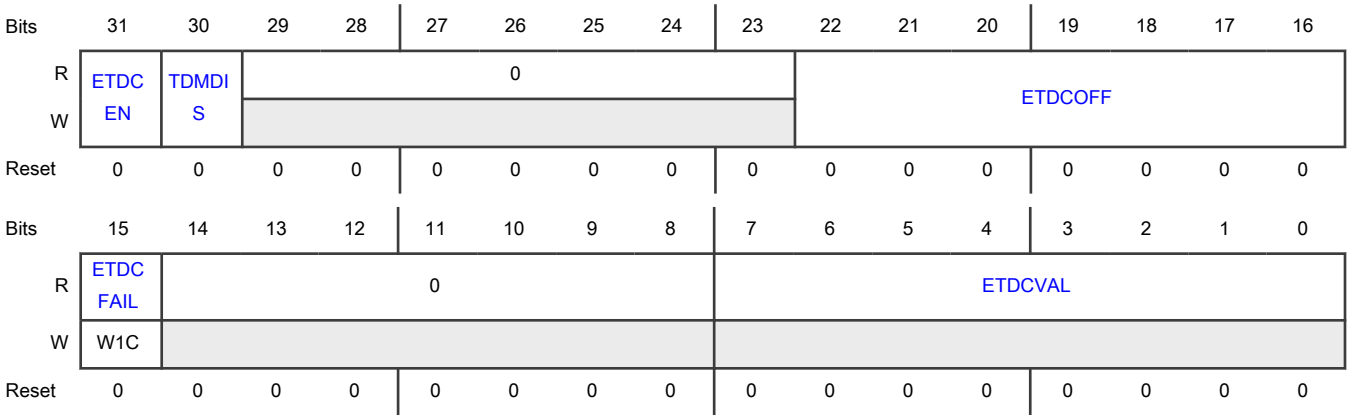
NOTE

See Transmitter delay compensation in the CAN Protocol standard ISO 11898-1_2024 for details.

Offset

Register	Offset
ETDC	BFCh

Diagram



Fields

Field	Description
31 ETDCEN	Transceiver Delay Compensation Enable Enables the TDC feature. It can be written in Freeze mode only. **NOTE** See Transmitter delay compensation in the CAN Protocol standard ISO 11898-1_2024 for details. **NOTE** TDC must be disabled when the Loop Back Mode is enabled. See CTRL1[LPB].

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - Disable 1 - Enable
30 TDMDIS	Transceiver Delay Measurement Disable Disables the transceiver delay measurement. When the TDC measurement is disabled, only ETDC[ETDCOFF] determines the secondary sample point position. If TCD measurement is enabled, the sum of the transceiver delay measurement plus the enhanced TDC offset determines the secondary sample point position. Soft reset does not affect this field. **NOTE** This bit can be enabled only if CTRL2[BTE] = 1. 0 - Enable 1 - Disable
29-23 —	Reserved
22-16 ETDCOFF	Enhanced Transceiver Delay Compensation Offset Contains the offset value to be added to the loop delay of the measured transceiver. This value defines the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for details on how the loop delay measurement is performed. This field can be written in Freeze mode only. Its value can be defined in protocol engine (PE) clock periods (CANCLK, see Protocol timing for more details). It must be smaller than the CAN bit duration in the data bit rate for proper operation. Do not write 0 to this field. **NOTE** If CTRL2[BTE] becomes 1 after a chip-level hard reset, this field is read as 1h.
15 ETDCFAIL	Transceiver Delay Compensation Fail Indicates whether the transceiver delay compensation (TDC) mechanism is out of range. In this case, it is unable to compensate the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones. (See Transceiver delay compensation.) This field becomes 0 the first time FlexCAN detects the out of range condition. 0 - In range 1 - Out of range
14-8 —	Reserved
7-0	Enhanced Transceiver Delay Compensation Value

Table continues on the next page...

Table continued from the previous page...

Field	Description
ETDCVAL	Contains ETDC[ETDCOFF] added to the measured value of the transceiver loop delay in the latest transmitted CAN FD frame, with BRS = 1. The module only updates this field when ETDC[ETDCEN] = 1. Soft reset affects this field. **NOTE** If ETDC[TDMDIS] = 1, this field stores ETDC[ETDCOFF] only.

39.6.2.37 CAN FD Control (FDCTRL)

Contains control bits for CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in Table 274.

When an 8-byte payload is selected:

- Block R0 allocates MB0–MB31.
- Block R1 allocates MB32–MB63.
- Block R2 allocates MB64–MB95.

When a payload larger than eight bytes is selected, the maximum number of message buffers in a block is limited as described below.

Table 274. Number of message buffers

Payload size	Maximum number of message buffers per RAM block
8 bytes	32
16 bytes	21
32 bytes	12
64 bytes	7

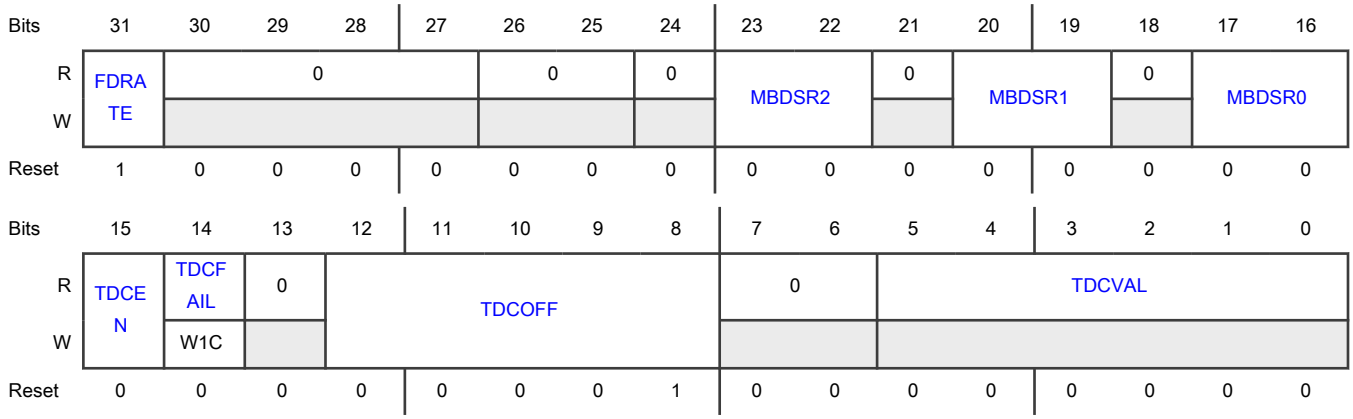
One memory block fits exactly 32 message buffers with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last message buffer in a block and the beginning of the next block. This empty memory corresponds to less than one message buffer, and must not be used.

Soft reset does not affect the contents of this register.

Offset

Register	Offset
FDCTRL	C00h

Diagram



Fields

Field	Description
31 FDRATE	Bit Rate Switch Enable Enables the effect of the Bit Rate Switch (BRS bit) during the data phase of TX messages. When 1, if BRS = 1 in the TX message buffer, frames are transmitted with bit rate switching. When 0, frames are transmitted at a nominal rate, and the BRS bit in the TX MB has no effect. The CPU can write to this field at any time. However, its effect becomes active only under one of these conditions: • The CAN bus is in the Wait for Bus Idle state. • The CAN bus is in the Bus Idle state. • The CAN bus is in the Bus Off state. • The current frame under reception or transmission reaches the interframe space. By writing 0 to FDCTRL[FDRATE], the CPU can force all bits in CAN FD messages to be transmitted at nominal bit rate. This transmission occurs regardless of the value in the BRS bit of the TX message buffers. 0 - Disable 1 - Enable
30-27 —	Reserved
26-25 —	Reserved
24 —	Reserved
23-22 MBDSR2	Message Buffer Data Size for Region 2 Selects the data size per message buffer for region R2 of message buffers allocated in RAM. This field can be written in Freeze mode only.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	00 - 8 bytes 01 - 16 bytes 10 - 32 bytes 11 - 64 bytes
21 —	Reserved
20-19 MBDSR1	Message Buffer Data Size for Region 1 Selects the data size per message buffer for region R1 of message buffers allocated in RAM. This field can be written in Freeze mode only. 00 - 8 bytes 01 - 16 bytes 10 - 32 bytes 11 - 64 bytes
18 —	Reserved
17-16 MBDSR0	Message Buffer Data Size for Region 0 Selects the data size per message buffer for region R0 of message buffers allocated in RAM. This field can be written in Freeze mode only. 00 - 8 bytes 01 - 16 bytes 10 - 32 bytes 11 - 64 bytes
15 TDCEN	Transceiver Delay Compensation Enable Enables the TDC feature. It can be written in Freeze mode only. See Transmitter delay compensation in the CAN Protocol standard ISO 11898-1_2024 for details. TDC must be disabled when Loopback mode is enabled (see CTRL1[LPB]). **NOTE** If CTRL2[BTE] = 1, this field is read as 0 and a write operation has no effect. 0 - Disable 1 - Enable
14	Transceiver Delay Compensation Fail

Table continues on the next page...

Table continued from the previous page...

Field	Description
TDCFAIL	Indicates whether the Transceiver Delay Compensation (TDC) mechanism is out of range. In this case, the mechanism cannot compensate for the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones (see Transceiver delay compensation). The first time that FlexCAN detects the out-of-range condition, this field becomes 1. **NOTE** If CTRL2[BTE] = 1, this field is read as 0 and a write operation has no effect. 0 - In range 1 - Out of range
13 —	Reserved
12-8 TDCOFF	Transceiver Delay Compensation Offset Contains the offset value to be added to the loop delay of the measured transceiver. This value defines the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for details about loop delay measurement. This field can be written in Freeze mode only. Its value can be defined in Protocol Engine Clock periods (CANCLK, see Protocol timing for more details). The value must be smaller than the CAN bit duration in the data bit rate for proper operation. **NOTE** If CTRL2[BTE] = 1, TDCOFF is read as 0 and a write operation has no effect. Do not write 0 to this field.
7-6 —	Reserved
5-0 TDCVAL	Transceiver Delay Compensation Value Contains the value of the transceiver loop delay measured from the transmitted EDL-to-R0 transition edge to the respective received one added to FDCTRL[TDCOFF]. This value is an integer multiple of the Protocol Engine Clock period (CANCLK). If CTRL2[BTE] = 1, this field is read as 0. See Protocol timing for details on the loop delay measurement.

39.6.2.38 CAN FD Bit Timing (FDCBT)

Stores the CAN bit timing variables used in the data phase of CAN FD messages when the FDCTRL[FDRATE] = 1, compatible with the CAN FD specification. Fields in this register define:

- The time quantum duration
- The number of time quanta per CAN bit
- The sample point position for the data bit rate portion of a CAN FD message with BRS = 1

Soft reset does not affect the contents of this register.

The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

Ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard ISO 11898-1_2024.

NOTE

If CTRL2[BTE] = 1, this register is read as zero and a write operation has no effect.

Offset

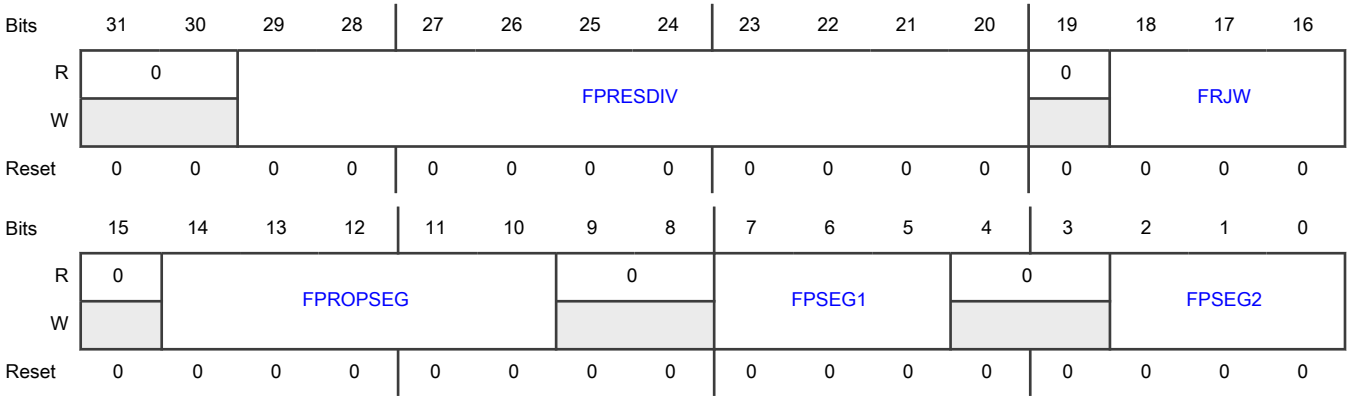
FDCBT	C04h

Diagram



Fields

Field	Description
31-30 —	Reserved
29-20 FPRESDIV	Fast Prescaler Division Factor Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency in the data bit rate portion of a CAN FD message with BRS = 1. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (FPRESDIV + 1). **NOTE** To minimize errors when processing FD frames, use the same value for this field and for CTRL1[PRESDIV] or CBT[EPRESDIV]. See the first note in CAN FD frames for details.
19 —	Reserved
18-16	Fast Resync Jump Width

Table continues on the next page...

Table continued from the previous page...

Field	Description
FRJW	Defines the maximum number of time quanta that one resynchronization can change a bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = FSJW + 1. One Time Quantum = one Sclock period.
15 —	Reserved
14-10 FPROPSEG	Fast Propagation Segment Defines the length of the propagation segment in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation Segment Time = FPROPSEG × Time Quanta. One Time Quantum = one Sclock period.
9-8 —	Reserved
7-5 FPSEG1	Fast Phase Segment 1 Defines the length of phase segment 1 in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Segment 1 = (FPSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.
4-3 —	Reserved
2-0 FPSEG2	Fast Phase Segment 2 Defines the length of phase segment 2 in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Segment 2 = (FPSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.

39.6.2.39 CAN FD CRC (FDCRC)

Provides information about the cyclic redundancy check (CRC) of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats.

- The CRC_15 polynomial is used for all frames in CAN format.
- The CRC_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to 16 bytes.
- The CRC_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than 16 bytes.

Each polynomial shown below results in a Hamming distance of 6. This register is updated at the same time that the TX Interrupt flag is set.

$$CRC_15 = C599h: \ (x^{15} + x^{14} + x^{10} + x^{8} + x^{7} + x^{4} + x^{3} + 1)$$

$$CRC_17 = 3685Bh: \ (x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^{6} + x^{4} + x^{3} + x^{1} + 1)$$

$$CRC_21 = 302899h: \ (x^{21} + x^{20} + x^{13} + x^{11} + x^{7} + x^{4} + x^{3} + 1)$$

Equation 37. CRC polynomial used on CAN frame

NOTE

See CRC sequence calculation in the CAN Protocol standard ISO 11898-1_2024 for details.

Fields

Field	Description
31 —	Reserved
30-24 FD_MBCRC	CRC Message Buffer Number for FD_TXCRC Indicates the number of the message buffer corresponding to the value in FDCRC[FD_TXCRC], for both FD and non-FD frames. It reports the same information as in CRCR[MBCRC].
23-21	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
20-0 FD_TXCRC	Extended Transmitted CRC value Contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. For CRC_15 and CRC_17, the six most significant bits and the four most significant bits are reported as zeroes, respectively. For CRC_15, this field has the same content as Cyclic Redundancy Check (CRCR).

39.6.2.40 Enhanced RX FIFO Control (ERFCR)

Defines the Enhanced RX FIFO configuration.

This register can be written only in Freeze mode.

Soft reset does not affect any of the contents of this register.

Offset

39.6.2.42 Enhanced RX FIFO Status (ERFSR)

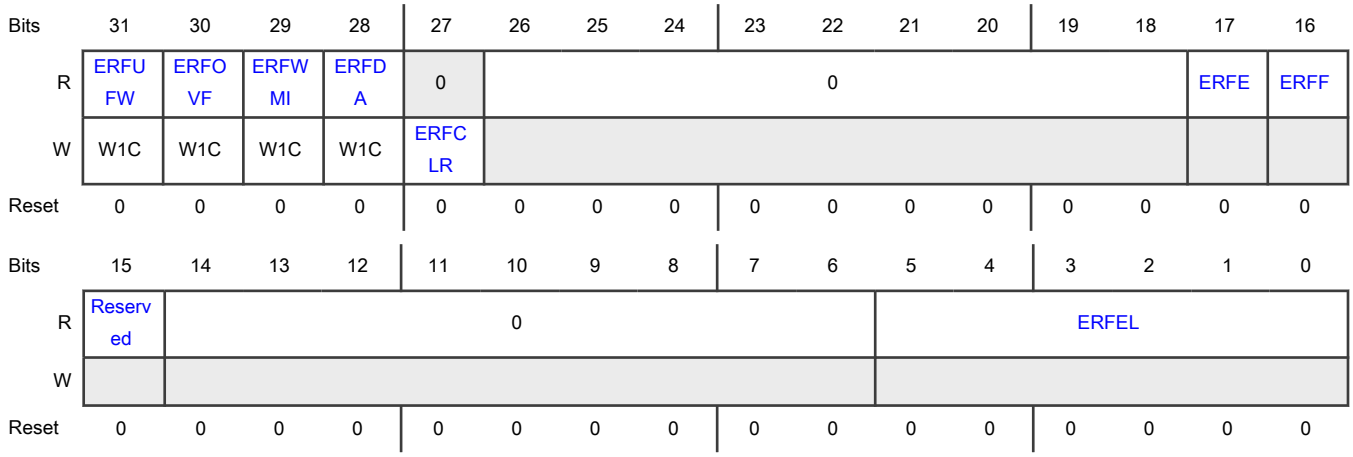
Contains the status fields of the Enhanced RX FIFO including error indications and a clear FIFO field.

Soft reset does not affect this register.

Offset

Register	Offset
ERFSR	C14h

Diagram



Fields

Field	Description
31 ERFUFW	Enhanced RX FIFO Underflow Flag Indicates whether an underflow condition occurred in the enhanced RX FIFO. If ERFIER[ERFUFWIE] = 1, this field generates an interrupt. 0 - No such occurrence 1 - Underflow
30 ERFOVF	Enhanced RX FIFO Overflow Flag Indicates whether an overflow condition occurred in the Enhanced RX FIFO. If ERFIER[ERFOVFIE] = 1, this field generates an interrupt. 0 - No such occurrence 1 - Overflow
29 ERFWMI	Enhanced RX FIFO Watermark Indication Flag Indicates whether the number of messages available in the Enhanced RX FIFO is greater than the watermark defined in ERFCR[ERFWM]. If ERFIER[ERFWMIIE] = 1, this field generates an interrupt. 0 - No such occurrence 1 - Number of messages in FIFO is greater than the watermark
28 ERFDA	Enhanced RX FIFO Data Available Flag Indicates whether there is at least one message stored in the ERX FIFO. If ERFIER[ERFDAIE] = 1, this field generates an interrupt. 0 - No such occurrence 1 - At least one message stored in Enhanced RX FIFO

Table continues on the next page...

Table continued from the previous page...

Field	Description
27 ERFCLR	Enhanced RX FIFO Clear Writing 1 to this field during Freeze mode resets the internal FIFO pointers, but the FIFO content stored in RAM is not changed. Writing to this field outside Freeze mode, or writing 0 to this field, has no effect. 0 - No effect 1 - Clear enhanced RX FIFO content
26-18 —	Reserved
17 ERFE	Enhanced RX FIFO Empty Flag Indicates whether Enhanced RX FIFO is empty. 0 - Not empty 1 - Empty
16 ERFF	Enhanced RX FIFO Full Flag Indicates whether enhanced RX FIFO is full. 0 - Not full 1 - Full
15 —	Reserved
14-6 —	Reserved
5-0 ERFEL	Enhanced RX FIFO Elements Indicates the number of CAN messages stored in the Enhanced RX FIFO.

39.6.2.43 High-Resolution Timestamp (HR_TIME_STAMP0 - HR_TIME_STAMP95)

Stores a copy of a 32-bit timer at the start or end of a CAN frame.

HR_TIME_STAMP0 stores the 32-bit timestamp associated with MB0, HR_TIME_STAMP1 stores the 32-bit timestamp associated with MB1, and so on.

Reset does not affect these registers.

NOTE

Do not write to these registers outside Freeze mode.

Table 275. High-Resolution Timestamp register operation

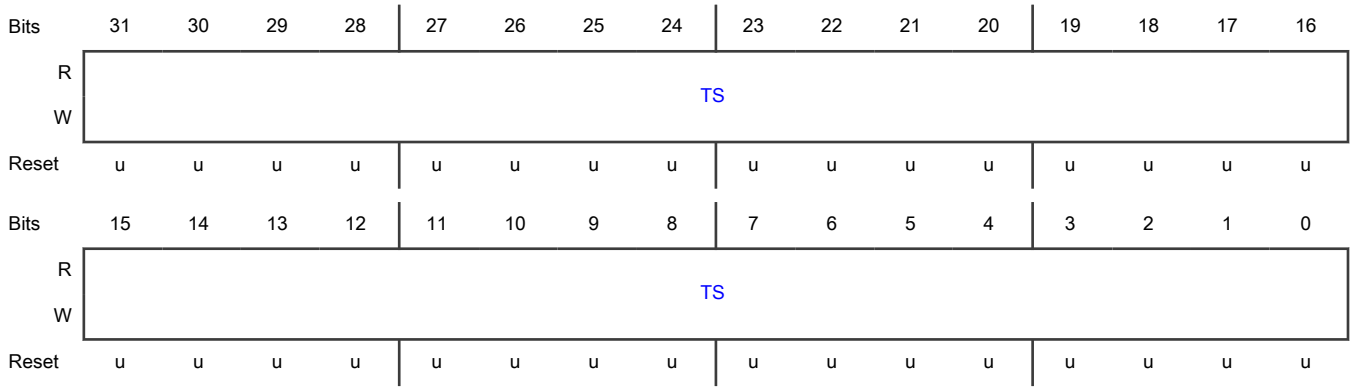
TSTAMPCAP	Captured timebase	Capture point
b00	None	None
b01	32 bits of high-resolution on-chip timer	Seventh bit of the end-of-frame field for transmission and sixth bit of the end-of-frame field for reception.
b10	32 bits of high-resolution on-chip timer	Start of frame
b11	32 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format

Offset

For n = 0 to 95:

Register	Offset
HR_TIME_STAMPn	C30h + (n × 4h)

Diagram



Fields

Field	Description
31-0 TS	High-Resolution Timestamp Captures the copy of the timestamp of corresponding message buffer. This field always captures a 32-bit timer value.

39.6.2.44 Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL127)

Stores the filter elements of the Enhanced RX FIFO.

For standard ID filtering, each ERFFEL register stores one filter element. For extended ID filtering, each pair of ERFFEL registers stores one filter element.

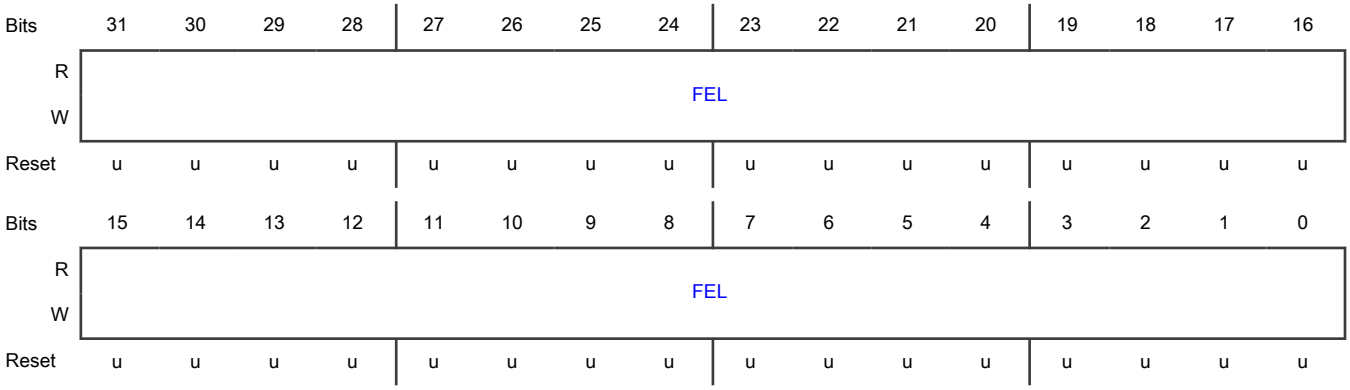
ERFFEL registers can be written only in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

Offset

For n = 0 to 127:

Register	Offset
ERFFELn	3000h + (n × 4h)

Diagram



Fields

Field	Description
31-0 FEL	Filter Element Bits Stores filter elements. Each filter element is used during the match process. If the matching criteria are met, a message is stored in the Enhanced RX FIFO.

39.6.3 Message buffer structure

The message buffer structure used by FlexCAN is represented in the following figure. Both extended (29-bit identifier) and standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual message buffer is 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area 80h–67Fh is used by the message buffers. When CAN FD is enabled, the exact address for each message buffer depends on the size of its payload. See FlexCAN memory partition for CAN FD.

Table 276. Message buffer structure example with 64-byte payload

	31	30	29	28	27 – 24	23	22	21	20	19 – 18	17 – 16	15 – 8	7 – 0

		= Unimplemented or reserved

Table 277. Field descriptions

Mnemonic	Field	Description
EDL	Extended Data Length	Distinguishes between CAN format and CAN FD format frames. EDL must not be 1 for message buffers configured to RANSWER with code field 1010b (see Table 278).
BRS	Bit Rate Switch	Defines whether the bit rate is switched inside a CAN FD format frame.
ESI	Error State Indicator	Indicates whether the transmitting node is error-active or error-passive.
CODE	Message Buffer Code	Can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 278 and Table 279. See Functional description.

Table 278. Message buffer code for RX buffers

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
0000b: INACTIVE. Message buffer is not active.	INACTIVE	—	—	—	Message buffer does not participate in the matching process.
0100b: EMPTY. Message buffer is active and empty.	EMPTY	—	FULL	—	When a frame is received successfully (after Move-in), CODE is automatically updated to FULL.

Table continues on the next page...

Table 278. Message buffer code for RX buffers (continued)

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
0010b: FULL. Message buffer is full.	FULL	Yes	FULL	—	The act of reading the Control and Status word followed by unlocking the message buffer (SRV) does not make CODE return to EMPTY. It remains FULL. If a new frame is moved to the message buffer after the message buffer is serviced, the code remains FULL. See Matching process for matching details related to FULL code.
		No	OVERRUN	—	If the message buffer is FULL and a new frame is moved to this message buffer before the CPU services it, CODE is automatically updated to OVERRUN. See Matching process for details about overrun behavior.
0110b: OVERRUN. Message buffer is being overwritten into a full buffer.	OVERRUN	Yes	FULL	—	If CODE indicates OVERRUN and the CPU has serviced the message buffer, when a new frame is moved to the message buffer, CODE returns to FULL.
		No	OVERRUN	—	If CODE already indicates OVERRUN, and another new frame must be moved, the message buffer is overwritten again, and CODE remains OVERRUN. See Matching process for details about overrun behavior.
1010b: RANSWER[4]. A frame was configured to recognize a Remote	RANSWER	—	TANSWER (1110b)	0	A Remote Answer was configured to recognize a Remote Request

Table continues on the next page...

Table 278. Message buffer code for RX buffers (continued)

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
Request frame and transmit a Response frame in return.[5]					frame received. After that, a message buffer is set to transmit a response frame. CODE is automatically changed to TANSWER (1110b). See Matching process for details. If CTRL2[RRS] = 0, transmit a response frame when a remote request frame with the same ID is received.
		—	—	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0] = 1: BUSY. FlexCAN is updating the contents of the message buffer. The CPU must not access the message buffer.	BUSY[6]	—	FULL	—	Indicates that the message buffer is being updated. It automatically becomes 0 and does not interfere with the next CODE.
		—	OVERRUN	—	

1. SRV: Serviced message buffer. Message buffer was read and unlocked by reading TIMER or another message buffer.
2. A frame is considered a successful reception after the frame is moved to a message buffer (move-in process). See Move-in.
3. Remote Request Stored field. See Control 2 (CTRL2).
4. Code 1010b is not considered TX and a message buffer with this code should not be aborted.
5. Code 1010b must be used in message buffers configured in CAN FD format, with EDL = 1.
6. For TX message buffers, the BUSY bit should be ignored upon read, except when MCR[AEN] = 1. If this field is 1, the corresponding message buffer does not participate in the matching process.

Table 279. Message buffer code for TX buffers

CODE Description	TX Code BEFORE TX frame	MB RTR	TX Code AFTER successful transmission	Comment
1000b: INACTIVE. Message buffer is not active.	INACTIVE	—	—	Message buffer does not participate in arbitration process.
1001b: ABORT. Message buffer is aborted.	ABORT	—	—	Message buffer does not participate in arbitration process.
1100b: DATA. Message buffer is a TX data frame (MB RTR must be 0).	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the message

Table continues on the next page...

Table 279. Message buffer code for TX buffers (continued)

CODE Description	TX Code BEFORE TX frame	MB RTR	TX Code AFTER successful transmission	Comment
				buffer automatically returns to the INACTIVE state.
1100b: REMOTE. Message buffer is a Transmit Remote Request frame (MB RTR must be 1).	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the message buffer automatically becomes an RX Empty message buffer with the same ID.
1110b: TANSWER. Message buffer is a Transmit Response frame from an incoming Remote Request frame.	TANSWER	—	RANSWER	This intermediate code is automatically written to the message buffer by the CHI as a result of a match to a Remote Request frame. The Remote Response frame is transmitted unconditionally once, then the code automatically returns to RANSWER (1010b). The CPU can also write this code with the same effect. The Remote Response frame can be a data frame or another remote request frame, depending on the value of RTR. See Matching process and Arbitration process for details.

Table 280. RX and TX message buffer field descriptions

Mnemonic	Field	Description
SRR	Substitute Remote Request	Fixed recessive bit, used only in extended format. Write 1 to SRR for transmission (TX Buffers). SRR is stored with the value received on the CAN bus for RX receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss. 1: Recessive value is compulsory for transmission in extended format frames. 0: Dominant is not a valid value for transmission in extended format frames.
IDE	ID Extended Bit	Identifies whether the frame format is standard or extended. 1: Frame format is extended 0: Frame format is standard

Table continues on the next page...

Table 280. RX and TX message buffer field descriptions (continued)

Mnemonic	Field	Description
RTR	Remote Transmission Request	Affects the behavior of remote frames and is part of the reception filter. See Table 278, Table 279, and CTRL2[RRS]. If FlexCAN transmits this field as 1 (recessive) and receives it as 0 (dominant), it is interpreted as an arbitration loss. If this field is transmitted as 0 (dominant) and it is received as 1 (recessive), FlexCAN treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission. 1: If message buffer is TX, indicates that the current message buffer may have a Remote Request frame to be transmitted. If the message buffer is RX, incoming remote request frames may be stored. 0: Indicates that the current message buffer has a Data frame to be transmitted. In an RX message buffer, it may be considered in matching processes. **NOTE** When configuring CAN FD frames, this field must be 0.
DLC	Data Length Code	Indicates the length (in bytes) of the RX or TX data, which is located in offset 8h–Fh of the message buffer space (see Table 276). In reception, this field is written by FlexCAN, copied from the DLC field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 282).
TIMESTAMP	Free-Running Counter Timestamp	Provides a copy of the Free-Running Timer, captured for TX and RX frames when the beginning of the Identifier field appears on the CAN bus. See Table 281 for Timestamp operation.
PRIO	Local priority	Used only when MCR[LPRIOEN] = 1, and only makes sense for transmit message buffers. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.
ID	Frame Identifier	In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.
DATA BYTE 0–63	Data Field	Up to 64 bytes can be used for a data frame, depending on the size of payload selected for the message buffers. For RX frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC, as shown in Table 282.

Table 281. Timestamp operation

TSTAMPCAP	MBTSBASE	TIMER_SOURCE	Captured timebase	Capture point
b00	bxx	0	CAN_TIMER incremented by CAN bit clock	Second bit of identifier field
b00	bxx	1	CAN_TIMER incremented by on-chip timer clock	Second bit of identifier field
bxx	b00	0	CAN_TIMER incremented by CAN bit clock	Second bit of identifier field
bxx	b00	1	CAN_TIMER incremented by on-chip timer clock	Second bit of identifier field
b01	b01	x	Lower 16 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception
b01	b10	x	Upper 16 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception
b10	b01	x	Lower 16 bits of high-resolution on-chip timer	Start of frame
b10	b10	x	Upper 16 bits of high-resolution on-chip timer	Start of frame
b11	b01	x	Lower 16 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format
b11	b10	x	Upper 16 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format

14	DATA BYTE 0–47
15	DATA BYTE 0–63

39.6.4 FlexCAN memory partition for CAN FD

When CAN FD is enabled, FlexCAN RAM can be partitioned into blocks of 512 bytes each. Each block can accommodate a number of message buffers depending on the configuration provided by FDCTRL[MBDSR*n*] as shown in Table 283.

Table 283. RAM partition

RAM block	Number of MBs with 8 bytes (default range)	Size control field in FDCTRL	Number of MBs of different sizes, per block
0	0 to 31	MBDSR0	MBDSR0 = 00, 32 MBs with 8-byte payload MBDSR0 = 01, 21 MBs with 16-byte payload MBDSR0 = 10, 12 MBs with 32-byte payload MBDSR0 = 11, 7 MBs with 64-byte payload
1	32 to 63	MBDSR1	MBDSR1 = 00, 32 MBs with 8-byte payload MBDSR1 = 01, 21 MBs with 16-byte payload MBDSR1 = 10, 12 MBs with 32-byte payload MBDSR1 = 11, 7 MBs with 64-byte payload
2	64 to 95	MBDSR2	MBDSR2 = 00, 32 MBs with 8-byte payload MBDSR2 = 01, 21 MBs with 16-byte payload MBDSR2 = 10, 12 MBs with 32-byte payload MBDSR2 = 11, 7 MBs with 64-byte payload

Payload sizes of 16, 32, or 64 bytes may be configured in some or all of RAM blocks. In those cases, the total number of MBs and their respective number order may differ from the default configuration of 8 bytes. Consider an example where:

- Block0 is configured to an 8-byte payload
- Block1 is configured to a 16-byte payload
- Block2 is configured to 32-byte payload

In this case, Table 284 indicates how the message buffers are arranged in RAM.

Table 284. RAM partition example

RAM block	Payload size	Number of MBs in the RAM block	Message buffer range
0	FDCTRL[MBDSR0] = 00, 8-byte payload	32	0 to 31
1	FDCTRL[MBDSR1] = 01, 16-byte payload	21	32 to 52
2	FDCTRL[MBDSR2] = 10, 32-byte payload	12	53 to 64

39.6.5 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

39.6.6 Legacy RX FIFO structure

When MCR[RFEN] = 1, the memory area 80h–DCh (which is normally occupied by MBs 0–5) is used by the reception Legacy FIFO engine.

The region 80h–8Ch contains the output of the Legacy RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read. The region 90h–DCh is reserved for internal use of the Legacy RX FIFO engine.

An additional memory area, which starts at E0h and may extend up to 2DCh (normally occupied by MBs 6–37) depending on the value of CTRL2[RFFN], contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the Legacy RX FIFO.

Out of reset, the ID filter table flexible memory area defaults to E0h and extends only to FCh, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Legacy RX FIFO data structure.

Table 289. Legacy RX FIFO structure

	31 28	24 23	22	21	20	19 18 17 16	15 8	7 0
80h	IDHIT		SRR	IDE	RTR	DLC	TIMESTAMP	
84h		ID standard				ID extended		
88h	Data byte 0		Data byte 1				Data byte 2	Data byte 3
8Ch	Data byte 4		Data byte 5				Data byte 6	Data byte 7
90h–DCh	Reserved							
E0h	ID filter table element 0							
E4h	ID filter table element 1							
E8h–2D4h	ID filter table elements 2 to 125							
2D8h	ID filter table element 126							
2DCh	ID filter table element 127							
		= Unimplemented or reserved						

Each ID filter table element occupies an entire 32-bit word. One, two, or four Identifier Acceptance Filters (IDAFs) can compound each element, depending on MCR[IDAM]. The following tables show the IDAF indexing.

Table 290 shows the three different formats of the ID table elements. All elements of the table must have the same format. See Legacy RX FIFO for more information.

Table 290. ID table structure

Format	31	30	29 24	23 16	15	14	13 8	7 1	0
A	RTR	IDE	RXIDA (standard = 29–19, extended = 29–1)						
B	RTR	IDE	RXIDB_0 (standard = 29–19, extended = 29–16)		RTR	IDE	RXIDB_1 (standard = 13–3, extended = 13–0)		
C	RXIDC_0 (std and ext = 31–24)		RXIDC_1 (std and ext = 23–16)		RXIDC_2 (std and ext = 15–8)		RXIDC_3 (std and ext = 7–0)		
	= Unimplemented or Reserved								

Table 291. Field descriptions

Mnemonic	Field	Description
RTR	Remote Frame	Specifies whether remote frames are accepted into the Legacy FIFO if they match the target ID. 1: Remote frames can be accepted and data frames are rejected.

Table continues on the next page...

Table 291. Field descriptions (continued)

Mnemonic	Field	Description
		0: Remote frames are rejected and data frames can be accepted.
IDE	Extended Frame	Specifies whether extended or standard frames are accepted into the Legacy FIFO if they match the target ID. 1: Extended frames can be accepted and standard frames are rejected. 0: Extended frames are rejected and standard frames can be accepted.
RXIDA	RX Frame Identifier (Format A)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.
RXIDB_0, RXIDB_1	RX Frame Identifier (Format B)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.
RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3	RX Frame Identifier (Format C)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.
IDHIT	Identifier Acceptance Filter Hit Indicator	Indicates which identifier acceptance filter the received message in the output of the Legacy RX FIFO hit. See Legacy RX FIFO for more information.

39.6.7 Enhanced RX FIFO structure

When ERFCR[ERFEN] = 1, the Enhanced RX FIFO is enabled. The region 2000h–204Ch contains the output of the Enhanced RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read.

Table 292. Enhanced RX FIFO structure

	31	30	29	28 … 24	23	22	21	20	19	18	17	16	15 … 8	7	6 … 0

Table 294. Field descriptions

Mnemonic	Field	Description
EDL	Extended Data Length	Distinguishes between classical CAN format and CAN FD format frames. 0: Classical CAN frame format 1: CAN FD frame format

Table continues on the next page...

Table 294. Field descriptions (continued)

Mnemonic	Field	Description
BRS	Bit Rate Switch	Defines whether the bit rate is switched inside a CAN FD format frame. 0: Bit rate is not switched in a CAN FD frame. 1: Bit rate is switched in a CAN FD frame.
ESI	Error State Indicator	Indicates whether the transmitting node is error-active or error-passive. This field is meaningful only if EDL = 1. 0: Error-active 1: Error-passive
SRR	Substitute Remote Request	Fixed recessive bit, used only in extended format. Transmitting nodes always send it as recessive and receiving nodes can receive it as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss.
IDE	ID Extended Bit	Identifies whether the frame format is standard or extended. 0: Standard 1: Extended
RTR	Remote Frame	Identifies whether the current frame is a data frame or a remote request. 0: Data frame 1: Remote request
DLC	Data Length Code	Defines the number of bytes in the data field of a CAN frame (Data byte 0 to Data byte 63). When RTR = 1, the frame is a remote request and does not include the data field, regardless of the DLC field. See Table 282 for more details.
LEGACY TIMESTAMP	16-bit Timestamp	Provides a copy of the Free-Running Timer, captured during the CAN frame. See Table 281 for details about legacy timestamp operation.
ID	Frame Identifier	In base frame format, only the 11 most significant bits are used for frame identification. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification.
DATA BYTE 0–63	Data Field	Up to 64 bytes can be stored in the data field.
IDHIT	Identifier Acceptance Filter Hit Indicator	Indicates which Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL127) the received message in the output of the Enhanced RX FIFO hit. For each filter region, standard-ID filter space, and extended-ID filter space, there is an independent index starting from zero. Table 295 shows how FlexCAN writes IDHIT according to each filter element.
HR TIMESTAMP	High-resolution Timestamp	32-bit timebase captured during the CAN frame. When CTRL2[TSTAMPCAP] is not zero, a 32-bit timebase is captured from a dedicated on-chip timer which operates in free-running mode. See CTRL2[TSTAMPCAP] for details about capture point configuration of the high-resolution timestamp.

Table 295. IDHIT for Enhanced RX FIFO

Enhanced RX FIFO filter element - ERFFEL	IDHIT value	Filter element type
ERFFEL0	0	Extended-ID
ERFFEL1	1	Extended-ID
. . .	. . .	Extended-ID
ERFFEL(m-1)	m-1	Extended-ID
ERFFEL(m)	0	Standard-ID
ERFFEL(m+1)	1	Standard-ID
. . .	. . .	Standard-ID
ERFFEL(2n-m+1)	2x(n-m)+1	Standard-ID

NOTE

Where m = NEXIF and n = NFE. If NEXIF = 0, only standard-ID filter elements exist. If NEXIF > NFE, only extended-ID filter elements exist.

39.7 Glossary

Active message buffer — A message buffer is active if it can participate in the current matching or arbitration process.

Bus interface unit — FlexCAN submodule responsible for the interface to the CPU.

Bus off — See CAN Specification.[4]

CAN — Controller Area Network, a serial communication protocol defined in CAN Specification[4] and ISO International Standard.[5]

CHI — Controller-host interface, a FlexCAN submodule responsible for message buffer matching and arbitration algorithms.

CRC — Cyclic redundancy check

Dominant bit — A dominant bit wins the arbitration on the CAN bus. It is transmitted as 0.

Doze mode — A system low-power mode where the CPU bus remains active and a global Doze mode request is sent to all peripherals asking them to enter low power mode.

Error active — See CAN Specification.[4]

Error frame — See CAN Specification.[4]

Error passive — See CAN Specification.[4]

[4] Controller Area Network - CAN Specification Version 2.0 Part A, Part B, Robert Bosch GmbH, 1991.
[5] ISO International Standard - ISO 11898 First Edition 1993 Road Vehicles - Interchange of Digital Information - Controller Area Network (CAN) for high-speed Communication.

Form error	See CAN Specification.[4]
Hard reset	A reset coming from an external pin and/or following power-on. It resets everything.
Idle	See CAN Specification.[4]
Information processing time	See CAN Specification.[4]
Intermission	See CAN Specification.[4]
Matching elements	Data used in the matching process, such as ID, filter, mask, etc.
MB	See Message buffer.
Message buffer	Internal FlexCAN data structure containing bytes received from, or to be transmitted to, the CAN line, as well as information about this data.
Overload frame	See CAN Specification.[4]
Phase buffer segment	See CAN Specification.[4]
Recessive bit	A recessive bit loses the arbitration on the CAN bus. It is transmitted as 1.
Sclock	Serial clock. Obtained by dividing the clock feeding the CAN engine (oscillator or bus clock) by a prescaler factor. The Sclock period defines the time quantum for CAN protocol timing.
Soft reset	Global reset typically used by peripherals to reinitialize some of its registers, but not all of them.
Stop mode	A system low-power mode in which all chip clocks are stopped for maximum power savings.
Stuffing error	See CAN Specification.[4]
Time quantum	This is equal to the Sclock period. It is the minimum time period used to compose the CAN protocol bit timing.

Chapter 40
Flexible I/O (FlexIO)

40.1 Chip-specific FLEXIO information

Table 296. Reference links to related information

Topic	Related module	Reference
CM33	Arm Cortex CM33 Platform (CM33)	CM33 Platform
A55	Arm Cortex CA55 Platform (CA55)	CA55 Platform
System memory map		System memory map
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

This chip includes two instances of FLEXIO.

FLEXIO_TRIGGER_IN[3:0] are tied to 0.

FLEXIO_TRIGGER_OUT[7:0] are timer trigger outputs. They are routed to ANAMIX TRG_MUX (for controlling ADC triggering). See TRIGMUX for more details.

Table 297. ADC Trigger Inputs - FLEXIO

13	FLEXIO1	Trigger from FlexIO1
14	FLEXIO2	Trigger from FlexIO2

40.2 Overview

FLEXIO is a highly configurable module that provides:

- Emulation of various serial or parallel communication protocols.
- Flexible 16-bit timers with support for various trigger, reset, enable, and disable conditions.
- Programmable logic blocks that allow the implementation of digital logic functions on-chip and configurable interaction of internal and external modules.
- Programmable state machine for offloading basic system control functions from the CPU.

40.2.1 Block diagram

The following diagram provides a high-level overview of the FLEXIO timer and shifter configuration.

FLEXIO uses shifters, timers, and external triggers to shift data into or out of FLEXIO. As shown in the block diagram, timers control the timing of this data shift. You can configure the timers to use generic timer functions, external triggers, or various other conditions to determine the control.

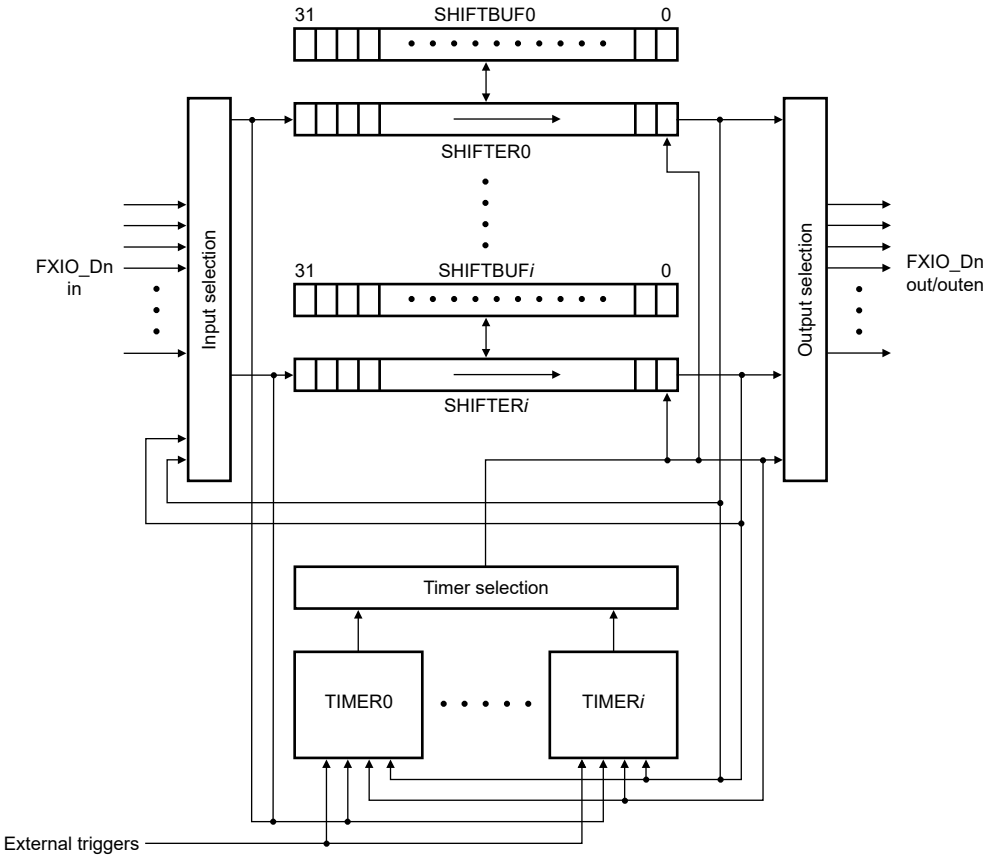

Figure 160. Block diagram

40.2.2 Features

- Array of 32-bit shift registers with transmit, receive, data match, logic, and state modes:
  - Double-buffered shifter operation for continuous data transfer
  - Shifter concatenation to support large transfer sizes
  - Automatic start and stop bit generation
  - 1, 2, 4, 8, 16, or 32 multi-bit shift widths for parallel interface support
  - Interrupt, DMA, or polled transmit and receive operation
- Highly flexible 16-bit timers with support for various internal or external triggers, reset, enable, and disable conditions:
  - Programmable baud rates independent of bus clock frequency, with support for asynchronous operation during Stop mode
  - Programmable logic mode for integrating external digital logic functions on-chip, or combining pin, shifter, or timer functions to generate complex outputs
  - Programmable state machine for offloading basic system control functions from CPU, with support for up to eight states, eight outputs, and three selectable inputs per state
- Integrated general-purpose I/O registers and pin rising or falling edge interrupts to simplify software support
- Support for a wide range of protocols, including but not limited to:
  - UART

— I2C

— SPI

— I2S

— Camera IF

— Motorola 68K or Intel 8080 bus

— PWM or waveform generation

— Input-capture (pulse-edge interval measurement), such as SENT

40.3 Functional description

40.3.1 Shifter operation

Shifters are responsible for buffering and shifting data into or out of FLEXIO. The timer assigned to the shifter controls the timing of shift, load, and store events via SHIFTCTL*n*[TIMSEL]. Shifters are designed to support either DMA, interrupt, or polled operations. The following figure provides a detailed view of the shifter microarchitecture.

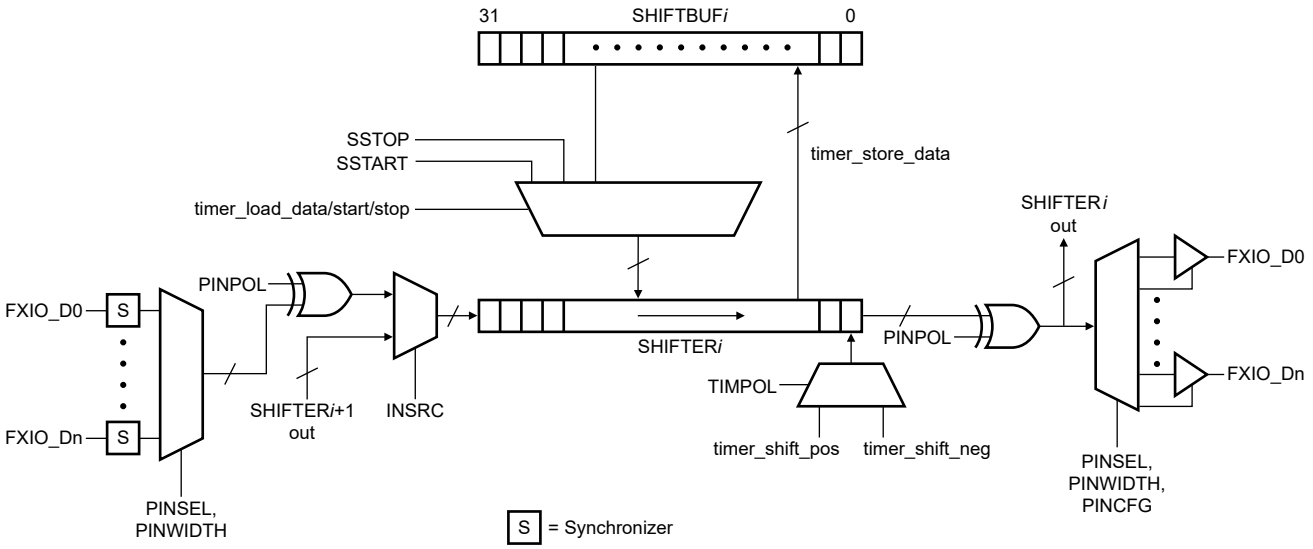

Figure 161. Shifter microarchitecture

40.3.1.1 Transmit mode

In Transmit mode (SHIFTCTL*n*[SMOD] = 010b), the shifter loads data from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) and shifts data out when the assigned timer signals a load event. An optional start and stop bit can be automatically loaded before or after SHIFTBUF register data by configuring either SHIFTCFG[SSTART] and TIMCFG[TSTART], or SHIFTCFG[SSTOP] and TIMCFG[TSTOP] in the shifter and timer.

NOTE

If a stop bit is enabled, the shifter immediately loads a stop bit when it is initially configured for Transmit mode.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has either been loaded from the SHIFTBUF register into the shifter or when the shifter is initially configured for Transmit mode. To clear the flag, write 1 or write new data to SHIFTBUF. In Transmit mode, write any value to the SHIFTBUF register to clear the corresponding shifter status flag, which is cleared regardless of what is writing to the register (DMA or interrupt), or the state of the DMA or interrupt enables. See the functional description of SHIFTSTAT[SSF] for information on how the flag is set and cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). Clear the flag by writing 1.

40.3.1.2 Receive mode

When the assigned timer signals a store event in Receive mode (SHIFTCTL*n*[SMOD] = 001b), the shifter shifts and stores data in Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). You can check for a start and stop bit before or after the shifter data is sampled by configuring either SHIFTCFG[SSTART] and TIMCFG[TSTART], or SHIFTCFG[SSTOP] and TIMCFG[TSTOP] in the shifter and timer.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data is stored in the SHIFTBUF register from the shifter. To clear the flag, write 1 to or read the data from SHIFTBUF. Any read of the SHIFTBUF register clears the corresponding shifter status flag when the shifter is in Receive mode. The flag is cleared regardless of what is reading the register (DMA or interrupt) or the state of the DMA or interrupt enables. See the functional description of SHIFTSTAT[SSF] for information on how the flag is set or cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set either when an attempt to store data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start or stop bit check. Write 1 to clear the flag.

40.3.1.3 Match Store mode

In Match Store mode (SHIFTCTL*n*[SMOD] = 100b), the shifter shifts data in, checks for a match result, and stores matched data in Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) when the assigned timer signals a store event. By configuring either SHIFTCFG[SSTART], TIMCFG[TSTART], and SHIFTCFG[SSTOP], or TIMCFG[TSTOP] in the shifter and timer, you can check for a start and stop bit before or after the shifter data is sampled. You can compare up to 16 bits of data using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs and the matched data is stored in the SHIFTBUF register from the shifter. To clear the flag, read the matched data from the SHIFTBUF register or write 1 to the flag. Any read of the SHIFTBUF register clears the corresponding shifter status flag when the shifter is configured in Match Store mode. The flag is cleared regardless of what is reading the register (DMA or interrupt) or the state of the DMA or interrupt enables. See the functional description for SHIFTSTAT[SSF] to know how the flag is set or cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun), or when a mismatch occurs on a start or stop bit check. Write 1 to clear the flag.

40.3.1.4 Match Continuous mode

In Match Continuous mode (SHIFTCTL*n*[SMOD] = 101b), the shifter shifts data in and continuously checks for a match result whenever a shift event is signaled by the assigned timer. You can compare up to 16 bits of data using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs. The flag clears automatically as soon as no match exists between the shifter data and Shifter Buffer (SHIFTBUF0 - SHIFTBUF7).

You cannot clear the flag by reading the SHIFTBUF register.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when a match occurs. To clear the flag, write 1 or perform a read from the SHIFTBUF register.

40.3.1.5 State mode

State mode enables you to implement any state machine with up to eight states, eight outputs, and three selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU, which can remain in a low-power mode.

In State mode (SHIFTCTL*n*[SMOD] = 110b), when the shifter is selected by the current state pointer (SHIFTSTATE[STATE]), use the SHIFTBUF register to drive the output and compute the next state values. The following figure provides a detailed view of the shifter microarchitecture when configured for State mode.

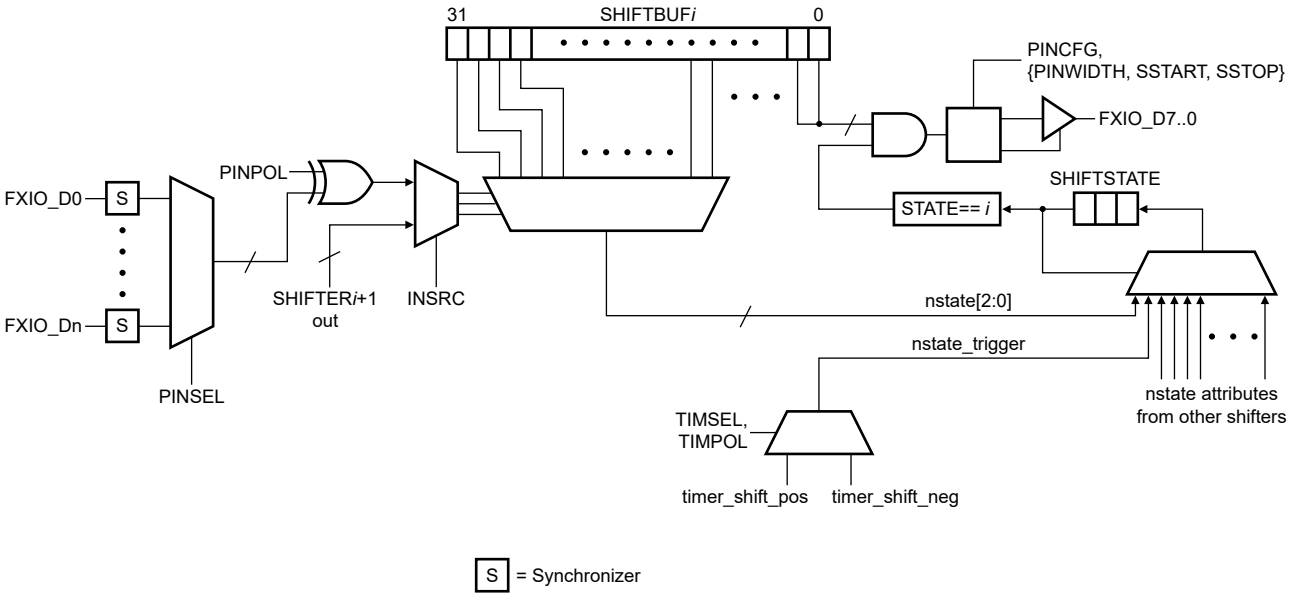

Figure 162. State microarchitecture

When the current state pointer selects a specific shifter (shifter *n*), output pins FXIO_D[7:0] are driven by SHIFTBUF*n*[31:24]; the configuration is defined by SHIFTCTL*n*[PINCFG]. Write 1 to Shifter Configuration (SHIFTCFG0 - SHIFTCFG7) {PWIDTH[3:0],SSTOP[1:0],SSTART[1:0]} to disable the output drive on pins FXIO_D[7:0] for state machine applications that require less than eight output pins.

Use the three input pins selected by SHIFTCTL*n*[PINSEL] and SHIFTBUF*n*[23:0] to compute the next state value.

NOTE

Each state can use a different set of three input pins.

The following table shows how the next state value is computed when the current state pointer is pointing to shifter *n*.

Table 298. Next state computation for SHIFTSTATE[STATE] = *n*

FXIO_D[PINSEL + 2]	FXIO_D[PINSEL + 1]	FXIO_D[PINSEL]	Next state value
0	0	0	SHIFTBUF*n*[2:0]
0	0	1	SHIFTBUF*n*[5:3]
0	1	0	SHIFTBUF*n*[8:6]
0	1	1	SHIFTBUF*n*[11:9]
...	...	...	...
1	1	1	SHIFTBUF*n*[23:21]

NOTE

You can configure other shifters and timers to drive the input pins of a given state, allowing you to create complex combinations of shifters and timers as needed. For example, the output of a shifter configured for Logic mode can be used to drive a state machine input.

The next state transition is triggered using the timer output selected by SHIFTCTL*n*[TIMSEL], with polarity controlled by SHIFTCTL*n*[TIMPOL].

NOTE

Each state can use a different timer to trigger each next state transition, allowing various internal or external trigger sources and clocking configurations to be used. See Timer section for more information.

The current state pointer defaults to shifter 0 at reset; however, you can write to select a different shifter for the initial state. If the current state pointer selects a shifter that is not configured for State mode, then outputs are not driven and the next state transition is never triggered.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when the shifter is selected by the current state pointer. The flag is cleared when the current state pointer is updated to a different shifter.

40.3.1.6 Logic mode

Logic mode enables you to implement a small amount of programmable digital logic within a FLEXIO shifter.

In Logic mode (SHIFTCTL*n*[SMOD] = 111b), use Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) to implement a 5-input, 32-bit programmable logic lookup table. The following figure provides a detailed view of shifter microarchitecture when configured for Logic mode.

Use the SHIFTBUF register to configure the lookup table for the four pin inputs. You can also use SHIFTER*n* to configure a feedback or delayed pin source as the fifth input to the lookup table.

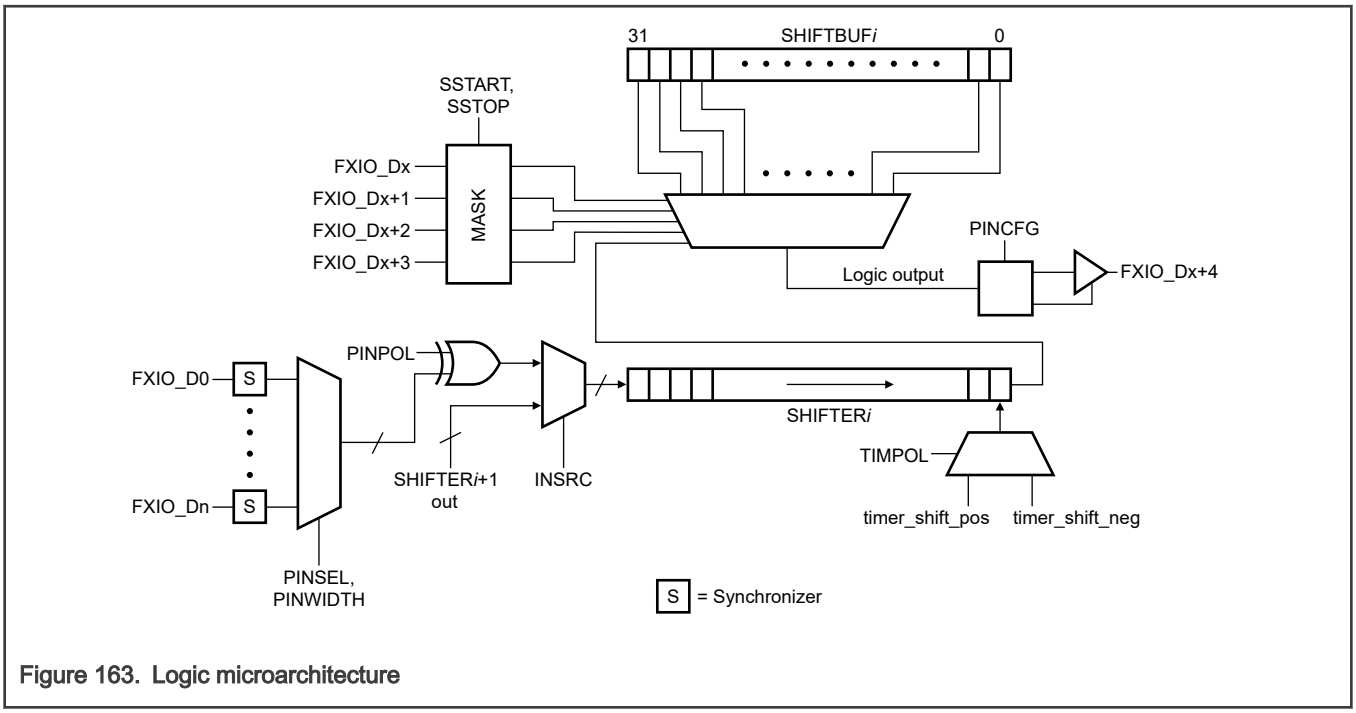

Figure 163. Logic microarchitecture

The lookup table is driven using four pin inputs (maskable using SHIFTCFG[SSTOP] and SHIFTCFG[SSTART]), plus one input from the internal shifter. It can be configured to drive an output pin using SHIFTCTL[PINCFG]. Pin inputs and outputs are fixed for each logic lookup table and are not selectable. The following table lists the logic output value selected by the lookup table for shifter *n*.

Table 299. Logic lookup table for shifter *n*

SHIFTER*n*[0]	FXIO_D[*x* + 3][1]	FXIO_D[*x* + 2]	FXIO_D[*x* + 1]	FXIO_D[*x*]	Logic output to FXIO_D[*x* + 4]
0	0	0	0	0	SHIFTBUF*n*[0]
0	0	0	0	1	SHIFTBUF*n*[1]

Table continues on the next page...

Table 299. Logic lookup table for shifter *n* (continued)

SHIFTER*n*[0]	FXIO_D[*x* + 3][1]	FXIO_D[*x* + 2]	FXIO_D[*x* + 1]	FXIO_D[*x*]	Logic output to FXIO_D[*x* + 4]
0	0	0	1	0	SHIFTBUF*n*[2]
0	0	0	1	1	SHIFTBUF*n*[3]
...	...	...	...	...	...
1	1	1	1	1	SHIFTBUF*n*[31]

1. for shifters *n* = 0...3, *x* = *n*

   for shifter *n* = 4...7, *x* = *n* + 4

To minimize output glitches, use SHIFTCFG*n*[SSTOP] and SHIFTCFG*n*[SSTART] to mask unused input pins. When these fields are 1, {SSTOP[1:0] and SSTART[1:0]} mask FXIO_D[*x* + 3]...FXIO_D[*x*] inputs respectively so that any transitions on these pins do not cause the logic output to glitch.

NOTE

You can configure other shifters and timers to drive the input pins of a given lookup table, allowing you to concatenate lookup tables or create complex combinations of shifters and timers as needed.

SHIFTCFG[PWIDTH] controls the number of delay stages introduced by the internal shifter input (SHIFTER*n*[0]). For example, when configured for a 1-bit shift (SHIFTCFG[PWIDTH] = 0), the internal shifter introduces a 32-shift clock delay before passing its input (selected by SHIFTCTL[PINSEL]) to the lookup table. When configured for a 32-bit shift (SHIFTCFG[PWIDTH] = 16...31), the internal shifter introduces a 1-shift clock delay to its input.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set whenever the output pin allocated to the logic lookup table has a value of 1 after being synchronized with the FLEXIO clock. The flag clears when the output pin has a value of 0. This also allows SHIFTSTAT[SSF] to be used as a trigger to a timer if needed.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when the output pin allocated to the logic lookup table is asserted. Clear the flag by writing 1 to it.

The Logic mode input pins, including pins driven by other shifters and timers, are synchronized with the FLEXIO functional clock before they are input to the programmable logic lookup table.

40.3.2 Timer operation

The FLEXIO 16-bit timers control the loading, shifting, and storing of the shift registers. The counters load the contents of the compare register and decrement down to zero on the FLEXIO clock. The counters can perform generic timer functions such as generating a clock, select output, or a PWM waveform. You can configure these timers to perform any of the following functions:

- Enable in response to a trigger, pin, or shifter condition.
- Decrement always or only on a trigger or pin edge.
- Reset in response to a trigger or pin condition.
- Disable on a trigger or pin condition or on a timer compare.

Timers can optionally include a start condition and a stop condition.

Although each timer operates independently, you can configure a timer to enable or disable at the same time as the previous timer (for example, timer 1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently as a timer output, shifter status flag, pin input, or an external trigger input. The trigger configuration is separate from pin configuration; you can perform it to configure input, output data, or output enable. See the chip-specific FLEXIO information for information on external trigger connections.

You must configure Timer Configuration (TIMCFG0 - TIMCFG7) before writing 1 to TIMCTL*n*[TIMOD].

40.3.2.1 Timer 8-bit Baud Counter mode

In 8-bit Baud Counter mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the baud rate of the shift clock and the upper 8 bits are used to configure the number of shift clock edges in the transfer. When the lower 8 bits decrement to zero, the timer output is toggled and the lower 8 bits reload from the compare register. The upper 8 bits decrement when the lower 8 bits become zero and decrement.

NOTE

A timer reset event in 8-bit Baud Counter mode only resets the lower 8-bit counter. The upper 8-bit counter is not affected and can decrement if the timer reset is configured to update the state of the timer output, which toggles as a result of the timer reset event.

A timer compare event occurs when the upper 8 bits equal zero and decrement. The timer status flag is set on a timer compare event.

40.3.2.2 Timer 8-bit High PWM mode

In 8-bit High PWM mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the timer output high period and the upper 8 bits are used to configure the timer output low period. The lower 8 bits decrement when the output is high. When the lower 8 bits become zero and decrement, the timer output is cleared and the lower 8 bits are reloaded from the compare register. The upper 8 bits decrement when the output is low. When the upper 8 bits become zero and decrement, the timer output is set and the upper 8 bits are reloaded from the compare register.

A timer compare event occurs when the upper 8 bits become zero and decrement. The timer status flag is set on a timer compare event.

40.3.2.3 Timer 16-bit Counter mode

In 16-bit Counter mode, you can use the 16-bit counter to configure either the baud rate of the shift clock (for example, TIMDEC[1:0] ≠ 10 or 11) or the number of shift clock edges in the transfer (for example, TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.

40.3.2.4 Timer 16-bit Counter Disable mode

In 16-bit Counter Disable mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (for example, TIMDEC[1:0] ≠ 10 or 11) or the number of shift clock edges in the transfer (for example, TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer disable event.

40.3.2.5 Timer 8-bit Word Counter mode

In 8-bit Word Counter mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the number of shift clock edges in each word and the upper 8 bits are used to configure the number of words in the transfer. When the lower 8 bits decrement to zero, the timer output is toggled and the lower 8 bits reload from the compare register. The upper 8 bits only decrement when the lower 8 bits become zero and decrement.

A timer compare event occurs when the lower 8 bits become zero and decrement. The timer status flag is set when the upper 8 bits become zero and decrement.

40.3.2.6 Timer 8-bit Low PWM mode

In 8-bit Low PWM mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the timer output low period and the upper 8 bits are used to configure the timer output high period. The lower 8 bits decrement when the output is low. When the lower 8 bits become zero and decrement, the timer output is set and the lower 8 bits are reloaded from the compare

register. The upper 8 bits decrement when the output is high. When the upper 8 bits become zero and decrement, the timer output is cleared and the upper 8 bits are reloaded from the compare register.

A timer compare event occurs when the upper 8 bits become zero and decrement. The timer status flag is set on a timer compare event.

40.3.2.7 Timer enable and start functions

The following events occur when you configure TIMCTL*n*[TIMOD] for the desired mode and the condition configured by the timer enable (TIMCFG*n*[TIMENA]) is detected. When TIMCTL*n*[ONETIM] is 1, the timer status flag must be clear to generate a timer enable event; otherwise, the timer enable event is blocked. You can use this to enforce software intervention after each timer iteration:

- The timer counter loads the current value of the compare register and starts decrementing, as configured by TIMCFG*n*[TIMDEC].
- The timer output may update to its initial state depending on the configuration of TIMCFG*n*[TIMOUT]. Shifters that are controlled by this timer do not see this as a rising edge on the timer shift clock.
- Transmit shifters controlled by this timer either output their start bit value or load the shift register from the shift buffer and output the first bit, as configured by SHIFTCFG*n*[SSTART].

If the timer start bit is enabled, the timer counter reloads with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMCFG*n*[TIMOUT] = 1), a shifter that is configured to shift on the falling edge and load on the first shift does not load correctly.

40.3.2.8 Timer decrement and reset functions

The timer generates the timer output and timer shift clock depending on the fields, TIMCTL*n*[TIMOD] and TIMCFG*n*[TIMDEC]. The shifter clock is either equal to the timer output (when TIMCFG*n*[TIMDEC] ≠ 10 or 11) or equal to the decrement clock (when TIMCFG*n*[TIMDEC] = 10 or 11). If you configure TIMCFG*n*[TIMDEC] to decrement from a pin or trigger, the timer decrements on both rising and falling edges.

If a timer is configured to decrement on the FLEXIO functional clock divided by 16 or 256 (when TIMCFG*n*[TIMDEC] = 100 or 101), then a common prescaler that is shared by all timers is used to generate the two divide ratios. This prescaler is reset when all timers are either idle or configured not to use the prescaler (TIMCFG*n*[TIMDEC] ≠ 100 or 101).

If you configure the timer to reset as determined by TIMCFG*n*[TIMRST], then the timer counter loads the current value of the compare register again. You can configure the timer output and timer shift clock to update on timer reset, as configured by TIMCFG*n*[TIMOUT]. If the time output toggles as a result of the timer reset, this can result in a timer shift clock edge. In 8-bit Baud Counter mode, this also decrements the upper 8 bits of the counter.

In general, when the timer counter decrements to zero, a timer compare event is triggered. The timer compare event causes:

- The timer counter to load the contents of the timer compare register.
- The timer output to toggle.
- Any configured transmit shift registers to load.
- Any configured receive shift registers to store.

Depending on the timer mode, the timer status flag may also be set.

40.3.2.9 Timer disable and stop functions

When the timer is configured to add a stop bit on each compare, the following additional events occur:

- Transmit shifters controlled by this timer output their stop bit value (if configured by SHIFTCFG*n*[SSTOP]).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SHIFTCFG*n*[SSTOP].

- The timer counter reloads the current value of the compare register on the first rising edge of the shifter clock after the compare.

If you configure the timer to insert a stop bit on each compare, you must configure the transmit shifters to load on the first shift.

When the condition configured by timer disable (TIMCFG*n*[TIMDIS]) is detected, the following events occur:

- Timer counter reloads the current value of the compare register and starts decrementing as configured by TIMCFG*n*[TIMDEC].
- Timer output clears. Shifters that are controlled by this timer do not see this as a falling edge on the timer shift clock, but can generate a shift event if the timer shift clock otherwise generates one.
- Transmit shifters controlled by this timer output their stop bit value (if configured by SHIFTCFG*n*[SSTOP]).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SHIFTCFG*n*[SSTOP].

If the timer stop bit is enabled, the timer counter continues decrementing until the next rising edge of the shift clock is detected, at which point it finishes decrementing. Although the timer output is forced low during the stop bit, the timer shift clock can toggle during the stop bit. The timer output does not generate shift events during the stop bit.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). When TIMCTL*n*[ONETIM] is 1, the timer status flag must be clear before the next timer enable condition is detected. When the timer is in the stop state condition, receive shift registers with stop bit enabled store the contents of the shift register into the shift buffer and verify the state of the input data on the configured shift edge. If there is no configured edge between the timer disable and the next rising edge of the shift clock, then the final store and verify do not occur.

40.3.3 Pin operation

The pin configuration for each timer and shifter can be set to use any FLEXIO pin with either polarity. You can configure each timer and shifter as an input, output data, output enable, or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity because the output enable assertion causes logic zero to be output on the pin) or to control the enable on the bidirectional output. You can configure any timer or shifter to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

When more than one shifter or timer is configured to use the same pin for output data, then the output data to the pin is combined using an OR function. This also applies if more than one timer or shifter is configured to use the same pin for output enable.

40.3.3.1 Parallel interface

You can configure shifters to use multiple FLEXIO pins simultaneously by using SHIFTCFG*n*[PWIDTH], which is used to configure the following settings of a shifter:

1. Number of bits shifted per shift clock.
2. Number of pins driven by the shifter per shift clock (only on shifters supporting parallel transmit—that is, SHIFTER0 and SHIFTER4.)
3. Number of pins sampled by the shifter per shift clock (only on shifters supporting parallel receive—that is, SHIFTER3 and SHIFTER7.)

When configured for parallel shift, either 4, 8, 16, or 32 bits can be shifted on every shift clock. If an adjacent shifter is selected as the input source (SHIFTCFG*n*[INSRC] = 1), the least significant 4, 8, 16, or 32 bits from the adjacent shifter are sampled on each shift clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), you can configure the shifter to sample multiple pins (INSRC = 0), with PWIDTH and PINSEL selecting the pins as FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].

NOTE

If PWIDTH is less than the number of bits being shifted on each shift clock, then the most significant bits are masked with 0. For example, if PINSEL = 7 and PWIDTH = 6, then SHIFTER[31:24] samples {0,0,FXIO_D[12:7]} on each shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), you can configure the shifter to drive multiple pins using SHIFTCTL*n*[PINCFG], with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].

NOTE

If PWIDTH is less than the number of bits being shifted on each shift clock, then the most significant pins are not driven. For example, if PINSEL = 7 and PWIDTH = 6, then SHIFTER[5:0] drives only FXIO_D[12:7] on each shift clock.

40.3.3.2 Pin synchronization

When you configure a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized with the FLEXIO clock before a timer or shifter could use the signal. This introduces a small latency of 0.5–1.5 FLEXIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FLEXIO clock cycles.

If an input is used by more than one timer or shifter, then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

NOTE

FLEXIO pins are also connected internally. Configuring a FLEXIO shifter or timer to output data on an unused pin makes an internal connection that allows other shifters and timers to use this pin as an input. This allows a shifter output to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized with the FLEXIO clock and therefore incurs a one-cycle latency.

When using a pin input as a timer trigger, timer clock, or shifter data input, the following synchronization delays occur:

- 0.5–1.5 FLEXIO clock cycles for an external pin
- One FLEXIO clock cycle for an internally driven pin

See Application information for timing considerations such as output valid time and input setup time for specific applications (SPI controller, SPI target, I2C controller, I2S controller, and I2S target).

40.3.3.3 Pin override

You can change the state of any FLEXIO pin at any time. Pin Output Enable (PINOUTE) configures any pin as an output and drives that pin with the value in Pin Output Data (PINOUTD).

Alias registers for PINOUTE and data registers also exist. Writing a logic 1 to an alias register updates the corresponding register fields in both PINOUTE and PINOUTD as follows:

- Pin Output Disable (PINOUTDIS) clears Pin Output Enable (PINOUTE) and Pin Output Data (PINOUTD).
- Pin Output Clear (PINOUTCLR) sets Pin Output Enable (PINOUTE) and clears Pin Output Data (PINOUTD).
- Pin Output Set (PINOUTSET) sets Pin Output Enable (PINOUTE) and Pin Output Data (PINOUTD).
- Pin Output Toggle (PINOUTTOG) sets Pin Output Enable (PINOUTE) and toggles Pin Output Data (PINOUTD).

40.3.3.4 Pin interrupt

You can read the state of any FLEXIO pin at any time and also configure any pin to set a status flag when either a rising or falling edge is detected on that pin. Additionally, you can configure the pin status flag to generate an interrupt.

40.3.4 Low-power modes

FLEXIO remains functional during low-power modes, if CTRL[DOZEN] is 0 and the FLEXIO functional clock remains enabled.

The exception to this is in LLS mode. In this case, CTRL[DOZEN] is ignored and FLEXIO waits for all timers to complete any pending operation before acknowledging LLS mode entry.

40.3.5 Debug mode

FLEXIO remains functional in Debug mode, provided the value of CTRL[DBGE] is 1.

40.3.6 Clocking

Table 300. FLEXIO clocks

Clock	Description
Functional clock	Is asynchronous to the bus clock and can remain enabled in low-power modes. You must enable the FLEXIO functional clock before accessing any of the FLEXIO registers. Provided the FLEXIO functional clock is at least equal to the bus clock, you can configure CTRL[FASTACC] to support fast register accesses.
Bus clock	Is used only for bus accesses to the control and configuration registers.

40.3.7 Reset

Table 301. FLEXIO reset types

Reset	Description
Chip reset	Resets the FLEXIO logic and registers to their default states on chip reset.
Software reset	Resets, using CTRL[SWRST], all logic and registers to their default states, except for the Control register.

40.3.8 Interrupts and DMA requests

The following table shows the status flags that generate the FLEXIO interrupt and DMA requests.

Table 302. FLEXIO interrupts and DMA requests

Flag	Description	Interrupt	DMA request	Low-power wake-up
SHIFTSTAT[SSF]	Shifter status flag	Y	Y	Y
SHIFTERR[SEF]	Shifter error flag	Y	N	Y
TIMSTAT[TSF]	Timer status flag	Y	Y	Y
PINSTAT[PSF]	Pin status flag	Y	N	Y
TRGSTAT[ETSF]	External trigger status flag	Y	N	Y

40.3.9 Peripheral triggers

The connection between FLEXIO peripheral triggers and other peripherals is device-specific.

40.3.9.1 Output triggers

Each FLEXIO timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.

40.3.9.2 Input trigger

FLEXIO supports multiple external trigger inputs that can be used to trigger one or more FLEXIO timers. If a rising edge is detected on an external trigger when FLEXIO is enabled, then the external trigger status flag is set. The external triggers are synchronized to the FLEXIO functional clock and must assert for at least two cycles of the FLEXIO functional clock to be sampled correctly.

40.4 External signals

Table 303. External signals

Signal	Description	Direction
FXIO_D*n* (*n* = 0...31)	Bidirectional FLEXIO shifter and timer pin	Input or output

40.5 Initialization

Perform the following procedure to initialize FLEXIO registers:

1. Enable FLEXIO by writing 1 to CTRL[FLEXEN].
2. Configure shift registers for the given application. It is recommended to write to Shifter Configuration (SHIFTCFG0 - SHIFTCFG7) before writing to the corresponding register, Shifter Control (SHIFTCTL0 - SHIFTCTL7).
3. Configure timer registers for the given application. It is recommended to write to Timer Compare (TIMCMP0 - TIMCMP7) and Timer Configuration (TIMCFG0 - TIMCFG7) before writing to the corresponding register, Timer Control (TIMCTL0 - TIMCTL7).
4. Enable interrupts and/or DMA requests, as appropriate, for the given application.
5. Write transmit data to initiate a transfer (depending on the given application).

40.6 Application information

This section provides examples for a variety of FLEXIO module applications. See FLEXIO register descriptions for more information.

40.6.1 UART transmit

UART transmit can be supported using one timer, one shifter, and one pin (two pins, if supporting CTS). The start and stop bit insertion is handled automatically, and multiple transfers are supported using the DMA controller. The timer status flag is used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention. Before transmitting a break or idle character, you must modify SHIFTCFG*n*[SSTART] and SHIFTCFG*n*[SSTOP] to transmit the required state, and the data to transmit must equal FFh or 00h. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). When performing byte writes to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) (or Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) for transmitting MSB first), the rest of the register remains unaltered. This allows an address mark bit or additional stop bit to remain undisturbed.

NOTE

FLEXIO does not support automatic insertion of parity bits.

Table 304. UART transmit configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.

Table continues on the next page...

Table 304. UART transmit configuration (continued)

Register	Value	Configuration
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with output data on pin 0. You can configure the PINPOL field to invert output data, or support open-drain by writing 1h to the PINPOL and PINCFG fields.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0000_2222h	Configure start bit, stop bit, enable on trigger asserted and disable on compare. You can support CTS by configuring the TIMENA field as 3h.
TIMCTL*n*	01C0_0001h	Configure the dual 8-bit counter using the shifter 0 status flag as an inverted internal trigger source. To support CTS, configure the PINSEL (for pin 1) and PINPOL fields as 1h.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the shifter status flag to indicate when data can be written using an interrupt or a DMA request. Write to SHIFTBUFBBS[7:0] instead to support MSB first transfer.

The following table shows an alternative configuration that supports slower baud rates. This configuration requires two timers.

Table 305. UART transmit configuration for slow baud rate

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with output data on pin 0. Invert output data by writing 1 to the PINPOL field. Support open-drain by configuring the PINPOL and PINCFG fields as 1h.
TIMCMP*n*	0000_000Fh	Configure for 8-bit transfer, and configure TIMCMP[15:0] as (number of bits × 2) - 1.
TIMCFG*n*	0030_2622h	Configure start bit, stop bit, enable on trigger rising edge, decrement on trigger and disable on compare.

Table continues on the next page...

Table 305. UART transmit configuration for slow baud rate (continued)

Register	Value	Configuration
TIMCTL*n*	0740_0003h	Configure the 16-bit counter using the timer 1 output as an internal trigger source.
TIMCMP(*n* + 1)	0000_0001h	Configure baud rate of divide by 4 of the FLEXIO clock, and configure TIMCMP[15:0] as (baud rate divider ÷ 2) - 1.
TIMCFG(*n* + 1)	0000_1200h	Configure enable on trigger asserted and disable on timer 0 disable. You can configure the TIMEN field as 3h to support CTS.
TIMCTL(*n* + 1)	01C0_0003h	Configure the 16-bit counter using the shifter 0 status flag as an inverted internal trigger source. You can support CTS by configuring the PINSEL (for pin 1) and PINPOL fields as 1h.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the shifter status flag to indicate when data can be written using an interrupt or a DMA request. Write to SHIFTBUFBBS[7:0] instead to support MSB first transfer.

40.6.2 UART receive

UART receive can be supported using one timer, one shifter, and one pin (two timers and two pins, if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers are supported using the DMA controller. The timer status flag is used to indicate when the stop bit of each word is received.

FLEXIO does not support triple voting of the received data, which is sampled only once in the middle of each bit. You can use a timer to implement a glitch filter on the incoming data and a different timer to detect an idle line of programmable length. Break characters cause the error flag to set, and the shifter buffer register returns 00h.

NOTE

FLEXIO does not support automatic verification of parity bits.

Table 306. UART receiver configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0080_0001h	Configure receive using timer 0 on the negative edge of clock with input data on pin 0. You can invert input data by writing 1 to the PINPOL field.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set

Table continues on the next page...

Table 306. UART receiver configuration (continued)

Register	Value	Configuration
		TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0204_2422h	Configure start bit, stop bit, enable on pin positive edge and disable on compare. Enable resynchronization to received data with TIMOUT = 2h and TIMRST = 4h.
TIMCTL*n*	0000_0081h	Configure the dual 8-bit counter using the inverted pin 0 input.
SHIFTBUF*n*	Data to receive	You can read received data from SHIFTBUFBYS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from SHIFTBUFBIS[7:0] instead to support MSB first transfer.

The UART receiver with RTS configuration uses a second timer to generate the RTS output. RTS asserts when the start bit is detected and negates when the data is read from the shifter buffer register. If no start bit is detected when the RTS is asserted, the received data is ignored.

Table 307. UART receiver with RTS configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0080_0001h	Configure receive using timer 0 on the negative edge of clock with input data on pin 0. Invert input data by writing 1 to the PINPOL field.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0204_2522h	Configure start bit, stop bit, enable on pin positive edge with trigger asserted and disable on compare. Enable resynchronization to received data with TIMOUT = 2h and TIMRST = 4h.
TIMCTL*n*	02C0_0081h	Configure dual 8-bit counter using the inverted pin 0 input. Trigger is internal using the inverted pin 1 input.
TIMCMP(*n* + 1)	0000_FFFFh	Never compare.

Table continues on the next page...

Table 307. UART receiver with RTS configuration (continued)

Register	Value	Configuration
TIMCFG(*n* + 1)	0030_6100h	Enable on timer *n* enable and disable on the trigger falling edge. Decrement on trigger to ensure no compare.
TIMCTL(*n* + 1)	0143_0003h	Configure 16-bit counter and output on pin 1. Trigger is internal using the shifter 0 flag.
SHIFTBUF*n*	Data to receive	You can read received data using SHIFTBUFBYS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from SHIFTBUFBIS[7:0] instead to support MSB first transfer.

40.6.3 SPI controller

SPI Controller mode can be supported using two timers, two shifters, and four pins. Using the DMA controller, either CPHA = 0 or CPHA = 1 and transfers can be supported. For CPHA = 1, the chip select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of one clock cycle between the target chip select negating and before the next transfer. To initiate each transfer, either the core or DMA writes to the transmit buffer.

NOTE

Because of synchronization delays, the setup time for the serial input data is 1.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 4 of the FLEXIO clock frequency.

Table 308. SPI controller (CPHA = 0) configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0083_0002h	Configure transmit using timer 0 on the negative edge of clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0000_0101h	Configure receive using timer 0 on the positive edge of clock with input data on pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0100_2222h	Configure start bit, stop bit, enable on trigger high and disable on compare; initial clock state is logic 0.

Table 308. SPI controller (CPHA = 0) configuration (continued)

Register	Value	Configuration
TIMCTL*n*	01C3_0201h	Configure dual 8-bit counter using the pin 2 output (shift clock), with shifter 0 flag as the inverted trigger. Write 1 to the PINPOL field to invert the output shift clock.
TIMCMP(*n* + 1)	0000_FFFFh	Never compare.
TIMCFG(*n* + 1)	0000_1100h	Enable when timer 0 is enabled and disable when timer 0 is disabled.
TIMCTL(*n* + 1)	0003_0383h	Configure 16-bit counter (never compare) using the inverted pin 3 output as target select.
SHIFTBUF*n*	Data to transmit	You can write transmit data to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

Table 309. SPI controller (CPHA = 1) configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0021h	Start bit loads data on first shift.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0080_0101h	Configure receive using timer 0 on the negative edge of clock with input data on pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits x 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.

Table continues on the next page...

Table 309. SPI controller (CPHA = 1) configuration (continued)

Register	Value	Configuration
TIMCFG*n*	0100_2222h	Configure start bit, stop bit, enable on trigger high and disable on compare; initial clock state is logic 0.
TIMCTL*n*	01C3_0201h	Configure dual 8-bit counter using pin 2 output (shift clock), with the shifter 0 flag as the inverted trigger. Write 1 to the PINPOL field to invert the output shift clock, and set the TIMDIS field as 3 to keep target select asserted for as long as there is data in the transmit buffer.
TIMCMP(*n* + 1)	0000_FFFFh	Never compare.
TIMCFG(*n* + 1)	0000_1100h	Enable when timer 0 is enabled and disable when timer 0 is disabled.
TIMCTL(*n* + 1)	0003_0383h	Configure 16-bit counter (never compare) using inverted pin 3 output (as target select).
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF. Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

40.6.4 SPI target

SPI Target mode can be supported using one timer, two shifters, and four pins. Either CPHA = 0 or CPHA = 1 can be supported and transfers can be supported using the DMA controller. For CPHA = 1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

You must write the transmit data to the transmit buffer register before the external target select asserts; otherwise, the shifter error flag is set.

NOTE

Because of synchronization delays, the output valid time for the serial output data is 2.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

Table 310. SPI target (CPHA = 0) configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0083_0002h	Configure transmit using timer 0 on the falling edge of shift clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0000_0101h	Configure receive using timer 0 on the rising edge of shift clock with input data on pin 1.
TIMCMP*n*	0000_003Fh	Configure 32-bit transfer. Set TIMCMP[15:0] as (number of bits × 2) - 1.
TIMCFG*n*	0120_0600h	Configure enable on trigger rising edge. Initial clock state is logic 0 and decrements on pin input.
TIMCTL*n*	06C0_0203h	Configure 16-bit counter using pin 2 input (shift clock), with pin 3 input (target select) as the inverted trigger.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

40.6.5 I2C controller

I2C Controller mode can be supported using two timers, two shifters, and two pins. One timer is used to generate the SCL output and another one is used to control the shifters. The two shifters that are used to transmit and receive for every word, when receiving the transmitter, must transmit FFh to 3-state the output. FLEXIO inserts a stop bit after every word to generate and verify the ACK or NACK. FLEXIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (start to repeated start or stop condition), so you must program the compare register with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin is equal to output. However, this increases both the clock high and clock low periods by at least one FLEXIO clock cycle each. The second timer uses the SCL input pin to control the transmit and receive shift registers. This enforces an SDA data hold time by an extra two FLEXIO clock cycles.

Both the transmit and receive shifters must be serviced for each word in the transfer. The transmit shifter must transmit FFh when receiving, and the receive shifter returns the data present on the SDA pin. The transmit shifter loads one additional word on the last falling edge of the SCL pin. When generating a stop condition or a repeated start condition, this word must be 00h and FFh, respectively. During the last word of a controller-receiver transfer, you must set the transmit SHIFTCFG*n*[SSTOP] field to generate a NACK.

The receive shift register asserts an error interrupt if a NACK is detected, but you are responsible for generating the stop or repeated start condition. If a NACK is detected during controller-transmit, the interrupt routine must immediately write 00h (when generating a stop condition) or FFh (when generating a repeated start condition) to the transmit shifter register. You must wait for the next rising edge on SCL before disabling both timers. The transmit shifter must be disabled after the setup delay for a repeated start or stop condition.

NOTE

Because of synchronization delays, the data valid time for the transmit output is two FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

To guarantee SDA hold time, the I2C controller data valid is delayed by two cycles because the clock output is passed through a synchronizer before clocking the transmit or receive shifter. Because the SCL output is synchronous with FLEXIO clock, the synchronization delay is one cycle, and then an additional cycle is involved to generate the output.

Table 312. I2C controller configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Start bit enabled (logic 0) and stop bit enabled (logic 1).
SHIFTCTL*n*	0101_0082h	Configure transmit using timer 1 on the rising edge of clock with inverted output enable (open-drain output) on pin 0.
SHIFTCFG(*n* + 1)	0000_0020h	Start bit disabled and stop bit enabled (logic 0) for ACK or NACK detection.
SHIFTCTL(*n* + 1)	0180_0001h	Configure receive using timer 1 on the falling edge of clock with input data on pin 0.
TIMCMP*n*	0000_2501h	Configure 2 word transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of words × 18) + 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0102_2222h	Configure start bit, stop bit, enable on trigger high, disable on compare, reset if output equals pin. Initial clock state is logic 0 and is not affected by reset.
TIMCTL*n*	01C1_0101h	Configure dual 8-bit counter using pin 1 output enable (SCL open-drain), with the shifter 0 flag as the inverted trigger.
TIMCMP(*n* + 1)	0000_000Fh	Configure 8-bit transfer. Set TIMCMP[15:0] as (number of bits x 2) - 1.
TIMCFG(*n* + 1)	0020_1112h	Enable when timer 0 is enabled; disable when timer 0 is disabled. Enable start bit and stop bit at the end of each word and decrement on pin input.
TIMCTL(*n* + 1)	01C0_0183h	Configure 16-bit counter using inverted pin 1 input (SCL).

Table 312. I2C controller configuration (continued)

Register	Value	Configuration
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUFBBS[7:0]. Use the shifter status flag to indicate when data can be written using interrupt or DMA request.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from SHIFTBUFBIS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request.

40.6.6 I2S controller

I2S Controller mode can be supported using two timers, two shifters, and four pins. One timer is used to generate the bit clock and control the shifters and another timer is used to generate the frame sync. FLEXIO waits for the first write to the transmit data buffer before enabling bit clock and frame sync generation. Data transfers are supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FLEXIO clock frequency. The initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure that the frame sync is generated one clock cycle before the first output data.

NOTE

Because of synchronization delays, the setup time for the receiver input is 1.5 FLEXIO clock cycles. This means that the maximum baud rate is divide by 4 of the FLEXIO clock frequency.

Table 313. I2S controller configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0001h	Load transmit data on first shift and stop bit disabled.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the rising edge of clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0080_0101h	Configure receive using timer 0 on the falling edge of clock with input data on pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0000_0202h	Configure start bit, enable on trigger high and never disable. Initial clock state is logic 1.
TIMCTL*n*	01C3_0281h	Configure dual 8-bit counter using inverted pin 2 output (bit clock), with

Table continues on the next page...

Table 313. I2S controller configuration (continued)

Register	Value	Configuration
		shifter 0 flag as the inverted trigger. Write 0 to the PINPOL field to invert the polarity of the output shift clock.
TIMCMP(*n* + 1)	0000_007Fh	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:0] as (number of bits × baud rate divider) ÷ 1.
TIMCFG(*n* + 1)	0000_0100h	Enable when timer 0 is enabled and never disable.
TIMCTL(*n* + 1)	0003_0383h	Configure 16-bit counter using inverted pin 3 output (as frame sync). Write 0 to the PINPOL field to invert the polarity of the output frame sync.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) instead to support LSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) instead to support LSB first transfer.

40.6.7 I2S target

I2S Target mode can be supported using three timers, two shifters, and four pins. For single transmit and single receive, other combinations of transmit and receive are possible.

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag is set.

NOTE

Because of synchronization delays, the output valid time for the serial output data is 2.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

The output valid time of I2S target is maximum 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization, plus one cycle to output the data.

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until the rising edge of bit clock (when the frame sync is normally sampled). Timer 0 detects the rising edge of bit clock with timer 2 output asserted and asserts output for length of frame. Timer 1 detects the falling edge of bit clock with timer 0 output asserted and controls shift registers for 32-bit transfers.

Table 314. I2S target configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0103_0002h	Configure transmit using timer 1 on the rising edge of shift clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0180_0101h	Configure receive using timer 1 on the falling edge of shift clock with input data on pin 1.
TIMCMP*n*	0000_007Fh	Configure two 32-bit transfers per frame. Set TIMCMP[15:0] as (number of bits × 4) - 1.
TIMCFG*n*	0020_2500h	Configure enable on pin rising edge (inverted bit clock) with trigger high (timer 2) and disable on compare. Initial clock state is logic 1 and decrements on pin input (bit clock).
TIMCTL*n*	0B40_0203h	Configure 16-bit counter using pin 2 input (bit clock), with timer 2 output as the trigger.
TIMCMP(*n* + 1)	0000_003Fh	Configure 32-bit transfers. Set TIMCMP[15:0] as (number of bits × 2) - 1.
TIMCFG(*n* + 1)	0020_2500h	Configure enable on pin (bit clock) rising edge with trigger (timer 0) high and disable on compare. Initial clock state is logic 1 and decrement on pin input (bit clock).
TIMCTL(*n* + 1)	0340_0283h	Configure 16-bit counter using inverted pin 2 input (bit clock), with timer 0 output as the trigger.
TIMCMP(*n* + 2)	0000_0000h	Compare on zero (first edge).
TIMCFG(*n* + 2)	0020_6400h	Configure enable on inverted pin (frame sync) rising edge and disable on trigger falling edge (bit clock). Initial clock state is logic 1 and decrement on inverted pin input (frame sync).
TIMCTL(*n* + 2)	04C0_0383h	Configure 16-bit counter using inverted pin 3 input (frame sync), with pin 2 inverted input (bit clock) as the trigger.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be written

Table continues on the next page...

Table 314. I2S target configuration (continued)

Register	Value	Configuration
		using interrupt or DMA request. Write to the SHIFTBUF register instead to support LSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from the SHIFTBUF register instead to support LSB first transfer.

40.6.8 SENT receiver

The SENT receiver can be supported by using one timer and one pin. The timer is configured as Input-Capture mode, and captures the counter value at the falling edge of the pin input. After the counter value is captured, the counter is automatically restarted from counter value 0. Therefore, the captured value always indicates the period between the previous falling edge and current falling edge. You can configure the CPU interrupt or DMA trigger at each capture of the counter. The CPU software performs the entire SENT frame decoding with the latest tick width adjustment.

Table 315. SENT receiver configuration

Register	Value	Configuration
TIMCMP*n*	—	Stores counter value at the falling edge of the pin.
TIMCFG*n*	0000_6000h	Timer is always enabled. It is disabled on trigger falling edge, decrement counter on FLEXIO clock.
TIMCTL*n*	0040_0007h	Single 16-bit input capture mode. The PINSEL field selects the timer pin input and output. Timer pin output disabled, internal trigger selected, select pin 0 as trigger.

40.6.9 Camera interface

Camera interface can be supported using one timer, one or more shifters, and multiple pins. Multiple transfers can be supported using the DMA controller.

The example configuration shown in the following table describes the FLEXIO configuration for interfacing with an 8-bit CMOS sensor with PCLK, VSYNC, HREF, and D[7:0] outputs. The example uses a 128-bit buffer to capture 16 pixels of image data before an interrupt or DMA transfer. You can use a bigger or smaller buffer depending on system DMA performance and FLEXIO resource usage by other applications.

NOTE

You can use additional timers to track the number of pixels per row and number of rows per frame, or HREF or VSYNC can be assigned as GPIO interrupts for software tracking.

Table 316. Camera interface configuration for 8-bit CMOS sensor

Register	Value	Configuration
SHIFTCFG*n*...*n*+2[1]	0007_0100h	Configure 8-bit parallel shift in from adjacent shifter.
SHIFTCFG*n*+3	0007_0000h	Configure 8-bit parallel shift in from pins FXIO_D[7:0] (D[7:0]).
SHIFTCTL*n*...*n*+3	0080_0001h	Configure receive using timer 0 on the negative edge of clock.
TIMCMP*n*	0000_001Fh	Configure 16 pixel (8 bits/pixel × 16 pixels = 128 bits) transfer. Set TIMCMP[15:0] as (number of pixels × 2) - 1.
TIMCFG*n*	0120_6600h	Configure enable on trigger (HREF) rising edge and disable on trigger falling edge. Initial shift clock state is logic 0 and decrement on PCLK input.
TIMCTL*n*	12C0_0803h	Configure 16-bit counter using FXIO_D[8] input (PCLK), with FXIO_D[9] input (HREF) as the inverted trigger.
SHIFTBUF*n*...*n*+3	Data to receive	Received data can be read from SHIFTBUF*n*...*n*+3. Use the shifter status flag to indicate when data can be read using interrupt or DMA request.

1. *n* = 0 or 4

40.6.10 Motorola 68K and Intel 8080 bus interface

Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by smart and asynchronous LCD controllers. With GPIO, FLEXIO can drive these interfaces using one timer and one shifter. Additional shifters can be used to support large transfers via the DMA controller.

Example configurations are provided for 1-beat and 16-beat transfers. Other lengths are also supported.

The following table provides an example of how to drive a 16-bit 68K or 8080 bus. For an 8080 bus, two GPIOs are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

Table 317. Motorola 68K and Intel 8080 write configuration

Register	Value	Configuration
SHIFTCFG0...7	000F_0100h	Configure 16-bit parallel shift in from adjacent shifter.

Register	Value	Configuration
SHIFTCFG0...6	000F_0100h	Configure 16-bit parallel shift in from the adjacent shifter.
SHIFTCFG7	000F_0000h	Configure 16-bit parallel shift in from pin.
SHIFTCTL0...7	0080_0001h	Configure receive using timer 0 on the negative edge of clock with data input from FXIO_D[15:0].
TIMCMP0	0000_0101h (1 beat) 0000_1F01h (16 beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] = (number of beats × 2) - 1, and set TIMCMP[7:0] = (baud rate divider ÷ 2) - 1.
TIMCFG0	0000_2220h	Configure stop_bit. Enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	1DC3_1001h (Motorola 68K, 1 beat) 01C3_1001h (Motorola 68K, 16 beats) 1DC3_1181h (Intel 8080, 1 beat) 01C3_1181h (Intel 8080, 16 beats)	Configure dual 8-bit counter using either FXIO_D[16] output (EN pin for 68K) or FXIO_D[17] output (nRD pin for 8080), with shifter 7 flag (1-beat) or shifter 0 flag (16 beats) as the inverted trigger.

Table continues on the next page...

Table 318. Motorola 68K and Intel 8080 read configuration (continued)

Register	Value	Configuration
SHIFTBUF0...7	Data received	Received data can be read from SHIFTBUF0 (1 beat) or SHIFTBUF0...7 (16 beats). Use the shifter status flag to indicate when data can be read using interrupt or DMA request.

In general, any operation to a 68K or 8080 bus target begins with a register write cycle followed by one or more data read or write cycles. To accomplish this, perform the following procedure:

1. Configure FLEXIO with 1-beat write configuration.
2. Configure GPIO to assert the nCS and RS pins (and deassert the RDWR pin for 68K).
3. Write register index data to SHIFTBUF0[15:0].
4. Configure GPIO to deassert the RS pin (and assert the RDWR pin for 68K data read).
5. Configure FLEXIO with the desired read or write configuration (1 or 16 beats).
6. Use the shifter status flag to trigger interrupt or DMA driven data transfers to and from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7).
7. Configure GPIO to deassert the nCS pin.

40.6.11 Low-power state machine

Table 319 shows an example of a hypothetical state machine to illustrate the flexibility allowed in Shifter State mode.

In this example, FLEXIO waits for the FXIO_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO_CLK/131072 on the FXIO_D[1:0] pins while the comparator output is asserted. This assumes that the comparator is connected to external trigger 15. See the chip-specific FLEXIO information for actual FLEXIO trigger mappings. Throughout this operation, the CPU can be kept in a stop or VLPS mode by writing 0 to CTRL[DOZEN] and ensuring that FLEXIO_CLK is enabled. Figure 164 shows the states and transitions implemented by this example.

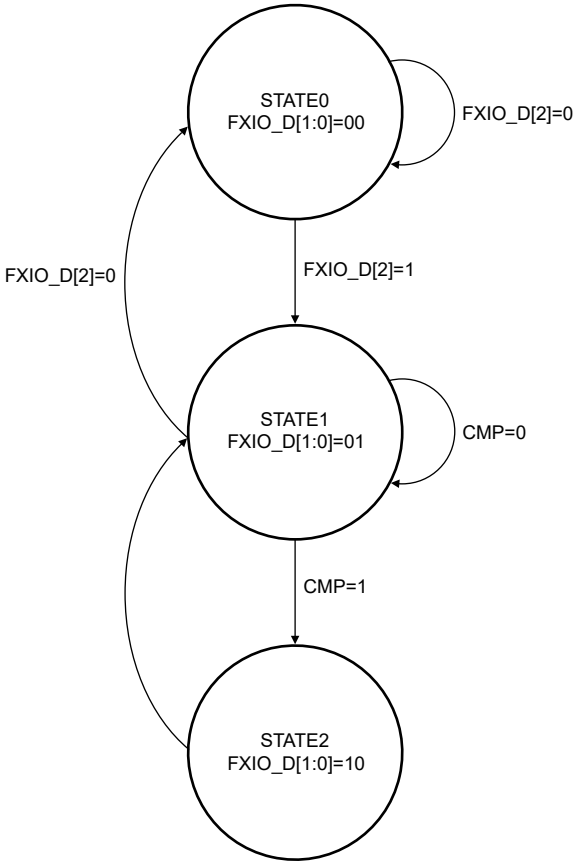

Figure 164. State diagram

Table 319. State machine configuration

Register	Value	Configuration
SHIFTCFG0...2	0000_0003h	Enable FXIO_D[1:0] as outputs.
SHIFTCTL0	0080_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output low to trigger next state.
SHIFTBUF0	0020_8208h	State0: Drive FXIO_D[1:0] = 00; transition to state0 if FXIO_D[2] = 0, state1 if FXIO_D[2] = 1.
SHIFTCTL1	0000_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output high to trigger next state.
SHIFTBUF1	0140_8408h	State1: Drive FXIO_D[1:0]=01; transition to state0 if FXIO_D[2]=0, state1 if CMP = 0, state2 if CMP = 1 (FXIO_D[3]=1).

Table continues on the next page...

Table 319. State machine configuration (continued)

Register	Value	Configuration
SHIFTCTL2	0080_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output low to trigger next state.
SHIFTBUF2	0224_9249h	State2: Drive FXIO_D[1:0] = 10, transition to state1 with timer 0 output low.
TIMCMP0	0000_FFFFh	Configure baud rate of divide by 131072 of the FLEXIO clock. Set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG0	0000_0000h	Configure timer always enabled.
TIMCTL0	0000_0003h	Configure single 16-bit counter.
TIMCFG1	0010_7600h	Configure timer enabled on trigger rising edge, disabled on trigger falling edge, decrement on trigger edge.
TIMCTL1	0F03_0303h	Configure timer output enabled on FXIO_D[3], external trigger 15 (comparator output) selected.

40.6.12 Keypad interface

The keypad interface can support a 3 × 4 keypad matrix using three timers and three shifters, although a larger matrix can be supported using additional shifters. The configuration is designed for four columns configured as active low open-drain pins and three rows configured as input pins with pull-up resistors enabled.

One shifter is configured in Logic mode to assert its output when any of the row inputs are low, indicating a key is pressed. Use a timer to filter the shifter output to ensure that the key is pressed for a minimum amount of time before performing the column scan.

A different shifter is configured for parallel transmit. Use this shifter to scan each column when a keypress is detected. When not scanning, the shifter output is configured to assert all active low open-drain column outputs to detect any keypress. Use a dedicated timer to control the transmit shifter.

The last shifter is configured for parallel receive. Use this shifter to capture the result of the column scanning so that you can decode which key (or keys) was pressed. This configuration captures the state of both row and column pins for each scan, although the row state can also be deduced by the shift order. Use a dedicated timer to control the receive shifter, which shifts at half the frequency of the transmit shifter.

When the result of the key scan is available in the receive shifter register, FLEXIO continues to monitor the row inputs and can trigger multiple scans from a single keypress. To support debouncing, you can decide how many consecutive scans must be considered as a single keypress.

NOTE

Because the pins used in Logic mode are fixed per shifter and the shifters that support parallel shifts are limited, this configuration is restricted to what pins and shifters it can use. Increasing the matrix beyond four-row inputs requires multiple shifters in Logic mode. Increasing beyond four-column outputs requires concatenating transmit shifters to create a larger shift register.

Table 320. Keypad interface configuration

Register	Value	Configuration
SHIFTCFG0	0003_0032h	Start bit enabled (logic 0) and stop bit enabled (logic 1), configured for 4-bit shift.
SHIFTCTL0	0101_0402h	Configure transmit using timer 1 on the rising edge of clock generating open-drain output on pins[7:4] (column outputs).
SHIFTBUF0	0804_0201h	Static data containing the column scan pattern; each column is scanned one-hot with dead time in between.
SHIFTCFG1	0000_0020h	In Logic mode, mask input 3.
SHIFTCTL1	0000_0007h	Configure Logic mode.
SHIFTBUF1	07FF_07FFh	Static data configuring Logic mode LUT. Output asserts if pins [3:1] are logic 0.
SHIFTCFG3	0007_0000h	Configured for 8-bit shift.
SHIFTCTL3	0280_0001h	Configure receive using timer 2 on falling edge of clock with input data on pins [7:0] (both rows and columns; pin 0 is don't care).
TIMCMP0	0000_00ffh	Configure prescanning glitch filter to 256 FLEXIO clock cycles. For different filter cycles, configure TIMCMP[15:0] as (filter cycles) - 1.
TIMCFG0	0103_6600h	Configure enable on trigger rising edge and disable on trigger falling edge. Initial clock state is logic 0 and is not affected by reset.
TIMCTL0	0540_0003h	Configure 16-bit counter using the shifter 1 flag (logic state) as trigger.
TIMCMP1	0000_0F3Fh	Configure eight shifts (twice for each column) at column scan rate of divide by 128. For a different scan frequency, define TIMCMP[7:0] as (scan divider ÷ 2) - 1.
TIMCFG1	0020_2622h	Enable on trigger rising edge, disable on compare. Start and stop bits are enabled.
TIMCTL1	0340_0001h	Configure dual 8-bit counter using timer 0 output as the trigger.
TIMCMP2	0000_0801h	Configure four shifts at half the frequency of the timer 1 trigger.

Table continues on the next page...

Table 320. Keypad interface configuration (continued)

Register	Value	Configuration
TIMCFG2	0110_2100h	Enable on timer 1 enable, disable on compare, decrement on trigger input with output initially negated, and not affected by reset.
TIMCTL2	0740_0001h	Configure dual 8-bit counter using timer 1 output as the trigger.
SHIFTBUF3	Keypad scan result	Keypad scan result can be read from SHIFTBUF3. Each byte is the result of one scan with both row and column pin state from the scan (pin 0 is not used). Use the shifter status flag to indicate when data can be written using interrupt or DMA request.

40.7 Memory map and registers

40.7.1 FLEXIO register descriptions

NOTE

Invalid register accesses, which include reading a write-only register, writing to a read-only register, or accessing an invalid address, result in a bus error.

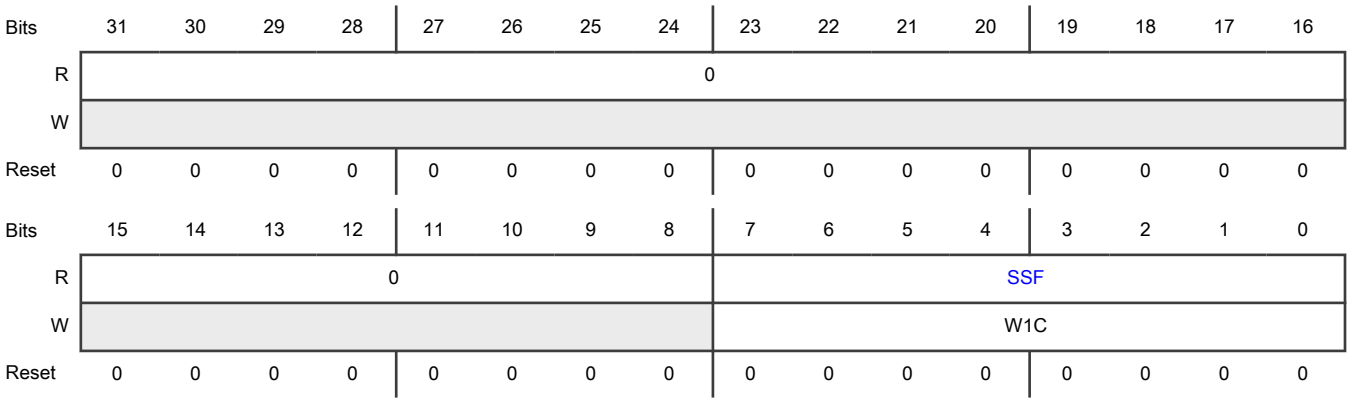
40.7.1.6 Shifter Status (SHIFTSTAT)

Contains shifter status flags.

Offset

Register	Offset
SHIFTSTAT	10h

Diagram



Fields

Field	Description
31-8 —	Reserved
7-0 SSF	Shifter Status Flag Indicates the shifter status. This flag is updated in one of the following cases: • If SHIFTCTL*n*[SMOD] = 001b (Receive mode), the status flag is set when SHIFTBUF is loaded with data from the shifter (SHIFTBUF is full). The status flag is cleared when you read Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). • If SHIFTCTL*n*[SMOD] = 010b (Transmit mode), the status flag is set when SHIFTBUF data is transferred to the shifter (SHIFTBUF is empty) or when SHIFTCTL*n*[SMOD] is initially configured as 010b (Transmit mode). The status flag is cleared when you write to the SHIFTBUF register. • If SHIFTCTL*n*[SMOD] = 100b (Match Store mode), the status flag is set when a match occurs between SHIFTBUF and the shifter. The status flag is cleared when you read the SHIFTBUF register. • If SHIFTCTL*n*[SMOD] = 101b (Match Continuous mode), the status flag returns the current match result between SHIFTBUF and the shifter. You cannot clear the status flag by reading the SHIFTBUF register. • If SHIFTCTL*n*[SMOD] = 110b (State mode), the status flag for a shifter sets when it is selected by the current state pointer. • If SHIFTCTL*n*[SMOD] = 111b (Logic mode), the status flag returns the current value of the programmable logic block output.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	You can clear this status flag by writing a logic one to the flag for all modes except Match Continuous mode, State mode, and Logic mode. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000 - Clear 0000_0001 - Set When writing 0000_0000 - No effect 0000_0001 - Clear the flag

40.7.1.7 Shifter Error (SHIFTERR)

Reports shifter errors.

Offset

Register	Offset
SHIFTERR	14h

Fields

Field	Description
31-8 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
7-0 SEF	Shifter Error Flag Indicates shifter error flag status. This flag is set when one of the following events occurs: • If SHIFTCTL*n*[SMOD] = 001b (Receive mode), it indicates that either the shifter is ready to store new data into SHIFTBUF before the previous data is read from SHIFTBUF (SHIFTBUF overrun), or the received start or stop bit does not match the expected value. • If SHIFTCTL*n*[SMOD] = 010b (Transmit mode), it indicates that the shifter is ready to load new data from SHIFTBUF before new data is written into SHIFTBUF (SHIFTBUF underrun). • If SHIFTCTL*n*[SMOD] = 100b (Match Store mode), it indicates the occurrence of a match event before the previous match data is read from SHIFTBUF (SHIFTBUF overrun). • If SHIFTCTL*n*[SMOD] = 101b (Match Continuous mode), the error flag is set when a match occurs between SHIFTBUF and the shifter. • If SHIFTCTL*n*[SMOD] = 111b (Logic mode), the error flag is set when the output of the programmable logic block is asserted. For SHIFTCTL*n*[SMOD] = 101b (Match Continuous mode), the flag can also be cleared when you read Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000 - Clear 0000_0001 - Set When writing 0000_0000 - No effect 0000_0001 - Clear the flag

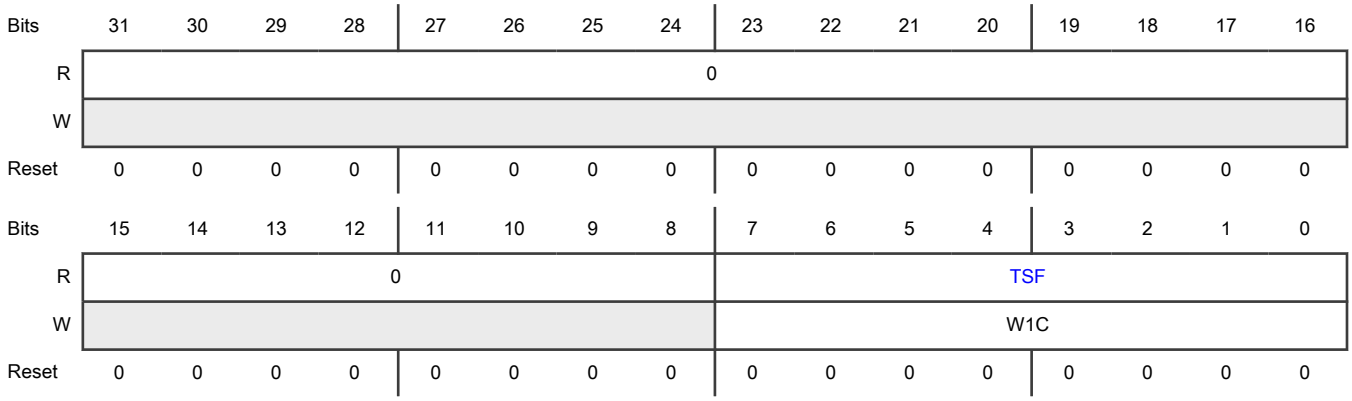
40.7.1.8 Timer Status Flag (TIMSTAT)

Reports timer status.

Offset

Register	Offset
TIMSTAT	18h

Diagram



Fields

Field	Description
31-8 —	Reserved
7-0 TSF	Timer Status Flag Indicates timer status. This flag is set depending on Timer mode: • In 8-bit baud counter mode, this flag is set when the upper 8-bit counter equals zero and decrements. • In 8-bit high PWM mode, this flag is set when the upper 8-bit counter equals zero and decrements. • In 16-bit counter mode, this flag is set when the 16-bit counter equals zero and decrements. • In 16-bit counter disable mode, TSF is set when a timer disable event is detected. • In 8-bit word counter mode, TSF is set when the upper 8-bit counter equals zero and decrements. • In 8-bit low PWM mode, TSF is set when the upper 8-bit counter equals zero and decrements. • In 16-bit input capture mode, TSF is set when a timer disable event is detected and the flag is clear. In this mode, you must read Timer Control (TIMCTL0 - TIMCTL7) only when TSF is set. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000 - Clear 0000_0001 - Set When writing 0000_0000 - No effect 0000_0001 - Clear the flag

Fields

Field	Description
31-0 OUTTOG	Output Toggle Configures the corresponding pins to toggle. If this field is 1, the corresponding field in Pin Output Data (PINOUTD) is inverted and the one in Pin Output Enable (PINOUTE) becomes 1. 0b - No effect 1b - Corresponding field in PINOUTD is inverted; corresponding field in PINOUTE becomes 1

40.7.1.27 Shifter Control (SHIFTCTL0 - SHIFTCTL7)

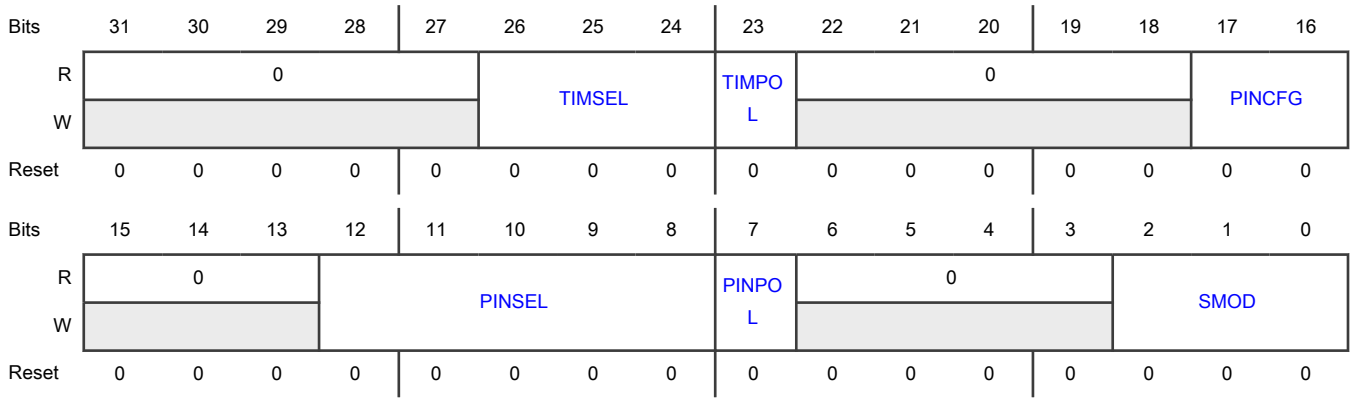
Provides shifter controls.

Offset

For n = 0 to 7:

Register	Offset
SHIFTCTLn	80h + (n × 4h)

Diagram



Fields

Field	Description
31-27 —	Reserved
26-24 TIMSEL	Timer Select Selects which timer is used for controlling the logic or shift register and generating the shift clock. TIMSEL = i selects TIMERi.
23	Timer Polarity

Table continues on the next page...

Table continued from the previous page...

Field	Description
TIMPOL	Determines whether the shift occurs on the positive edge or negative edge of the shift clock. 0 - Positive edge 1 - Negative edge
22-18 —	Reserved
17-16 PINCFG	Shifter Pin Configuration Specifies shifter pin configuration. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register. **NOTE** When initially configuring PINCFG as 11b, FLEXIO may briefly drive the pin low. To avoid this, you can configure PINCFG as 10b along with the rest of the Control register and then perform a subsequent write to set PINCFG as 11b. Likewise, when changing the value of PINCFG from 11b to 00b, you must perform an initial write to set PINCFG as 10b and then perform a subsequent write to update the rest of the Control register with the value of PINCFG as 00b. 00 - Shifter pin output disabled 01 - Shifter pin open-drain or bidirectional output enable 10 - Shifter pin bidirectional output data 11 - Shifter pin output
15-13 —	Reserved
12-8 PINSEL	Shifter Pin Select Selects the pin that is used by the shifter input or output. PINSEL = i selects the FXIO_Di pin. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register.
7 PINPOL	Shifter Pin Polarity Specifies the shifter pin polarity. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to this register. 0 - Active high 1 - Active low
6-3 —	Reserved
2-0 SMOD	Shifter Mode Configures the mode of the shifter.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	000 - Disable 001 - Receive mode; capture the current shifter content into SHIFTBUF on expiration of the timer 010 - Transmit mode; load SHIFTBUF contents into the shifter on expiration of the timer 011 - Reserved 100 - Match Store mode; shifter data is compared to SHIFTBUF content on expiration of the timer 101 - Match Continuous mode; shifter data is continuously compared to SHIFTBUF contents 110 - State mode; SHIFTBUF contents store programmable state attributes 111 - Logic mode; SHIFTBUF contents implement programmable logic lookup table

40.7.1.28 Shifter Configuration (SHIFTCFG0 - SHIFTCFG7)

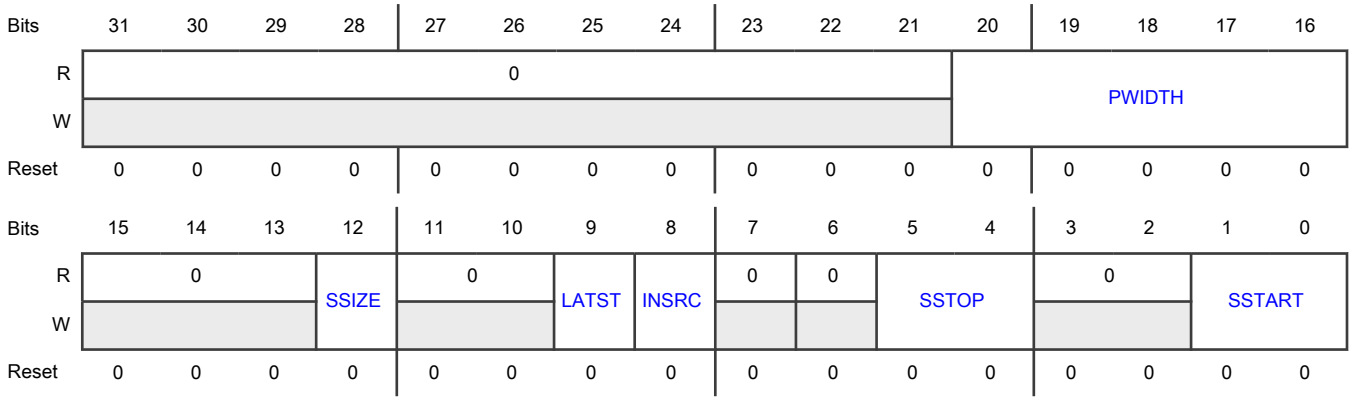
Provides fields for shifter configuration.

Offset

For n = 0 to 7:

Register	Offset
SHIFTCFGn	100h + (n × 4h)

Diagram



Fields

Field	Description
31-21 —	Reserved
20-16	Parallel Width

Table continues on the next page...

Table continued from the previous page...

Field	Description
PWIDTH	Configures the number of bits to be shifted on each shift clock for all shifters: • 1-bit shift for PWIDTH = 0 • 2-bit shift for PWIDTH = 1 • 4-bit shift for PWIDTH = 2...3 • 8-bit shift for PWIDTH = 4...7 • 16-bit shift for PWIDTH = 8...15 • 32-bit shift for PWIDTH = 16...31 For shifters that support parallel transmit (SHIFTER0, SHIFTER4, ...) or parallel receive (SHIFTER3, SHIFTER7, ...), this field, together with PINSEL, also selects the pins to be driven or sampled on each shift clock: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Shifters that do not support parallel transmit or parallel receive only support parallel shift when SHIFTCFG*n*[INSRC] = 1. If SHIFTCTL*n*[SMOD] = 110b (State mode), use this field to disable state outputs (see State mode).
15-13 —	Reserved
12 SSIZE	Shifter Size Configures the size of the Shift registers. A 24-bit Shift register shifts data only into bits [23:0] and does not update bits [31:24] during shift operations. When the Shift register is configured for a 24-bit shift, configuring PWIDTH as 8..15 performs a 12-bit shift and PWIDTH as 16..31 performs a 24-bit shift. 0 - 32-bit 1 - 24-bit
11-10 —	Reserved
9 LATST	Late Store Configures what happens when a receive or match Shift register is configured to both shift and store on the same cycle. 0 - Store the pre-shift register state 1 - Store the post-shift register state
8 INSRC	Input Source Selects the input source for the shifter. Configuring this field as 1 is not supported for the last shifter. 0 - Pin 1 - Shifter n+1 output

Table continues on the next page...

Table continued from the previous page...

Field	Description
7 —	Reserved
6 —	Reserved
5-4 SSTOP	Shifter Stop Allows automatic stop bit insertion, if the selected timer has also enabled a stop bit, when SHIFTCTL*n*[SMOD] is 10b (Transmit mode). If SHIFTCTL*n*[SMOD] is 1b or 100b (Receive mode or Match Store mode), this field allows automatic stop bit checking if the selected timer has also enabled a stop bit. If SHIFTCTL*n*[SMOD] is 110b (State mode), this field disables state outputs (see State mode). If SHIFTCTL*n*[SMOD] is 111b (Logic mode), this field masks logic pin inputs (see Logic mode). 00 - Stop bit disabled for Transmitter, Receiver, and Match Store modes 01 - Stop bit disabled for Transmitter, Receiver, and Match Store modes; when timer is in stop condition, Receiver and Match Store modes store receive data on the configured shift edge 10 - Transmitter mode outputs stop bit value 0 in Match Store mode; if stop bit is not 0, Receiver and Match Store modes set error flag (when timer is in stop condition, these modes also store receive data on the configured shift edge) 11 - Transmitter mode outputs stop bit value 1 in Match Store mode; if stop bit is not 1, Receiver and Match Store modes set error flag (when timer is in stop condition, these modes also store receive data on the configured shift edge)
3-2 —	Reserved
1-0 SSTART	Shifter Start Allows automatic start bit insertion, if the selected timer has also enabled a start bit, when SHIFTCTL*n*[SMOD] is 10b (Transmit mode). If SHIFTCTL*n*[SMOD] = 1b (Receive mode) or 100b (Match Store mode), this field allows automatic start bit checking if the selected timer has also enabled a start bit. If SHIFTCTL*n*[SMOD] is 110b (State mode), this field disables state outputs (see State mode). If SHIFTCTL*n*[SMOD] = 111b (Logic mode), this field masks logic pin inputs (see Logic mode). 00 - Start bit disabled for Transmitter, Receiver, and Match Store modes; Transmitter mode loads data on enable 01 - Start bit disabled for Transmitter, Receiver, and Match Store modes; Transmitter mode loads data on first shift 10 - Transmitter mode outputs start bit value 0 before loading data on first shift; if start bit is not 0, Receiver and Match Store modes set error flag

Table continues on the next page...

Table continued from the previous page...

Field	Description
	11 - Transmitter mode outputs start bit value 1 before loading data on first shift; if start bit is not 1, Receiver and Match Store modes set error flag

40.7.1.29 Shifter Buffer (SHIFTBUF0 - SHIFTBUF7)

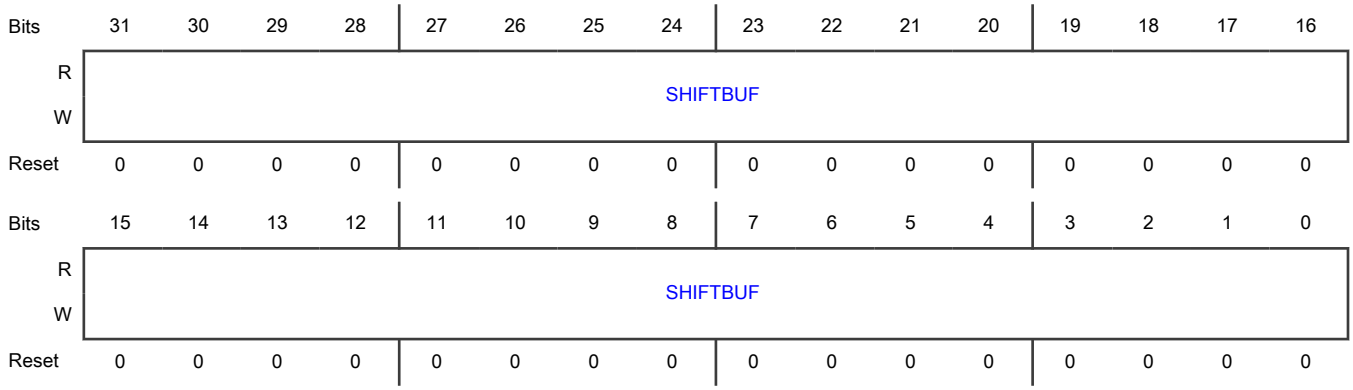
Contains shift buffer data.

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFn	200h + (n × 4h)

Diagram



Fields

Field	Description
31-0 SHIFTBUF	Shift Buffer Contains the data to be matched with the shifter contents and is used for various other functions, depending on the setting of SHIFTCTL*n*[SMOD]: • If SHIFTCTL0[SMOD] is 1b (Receive mode), shifter data is transferred into SHIFTBUF at the expiration of the timer. You must read this register only when the corresponding SHIFTSTAT[SSF] flag is set, indicating that new shifter data is available. • If SHIFTCTL0[SMOD] is 10b (Transmit mode), SHIFTBUF data is transferred into the shifter before the timer begins. • If SHIFTCTL0[SMOD] is 100b (Match Store mode), SHIFTBUF[31:16] contains the data to be matched with the shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1 = mask, 0 = no mask). The match is checked when the timer expires. Shifter data [31:16] is written

Table continues on the next page...

Field	Description
	to SHIFTBUF[31:16] whenever a match event occurs. You must read this register only when the corresponding shifter status flag is set, indicating that new shifter data is available. • If SHIFTCTL0[SMOD] is 101b (Match Continuous mode), SHIFTBUF[31:16] contains the data to be matched with the shifter contents, and SHIFTBUF[15:0] can be used to mask the match result (1 = mask, 0 = no mask). • If SHIFTCTL0[SMOD] is 111b (Logic mode), SHIFTBUF[31:0] implements a 5-input, 32-bit programmable logic lookup table (see Logic mode). • If SHIFTCTL0[SMOD] is 110b (State mode), use SHIFTBUF[31:24] to drive the output value when this shifter is selected by the current state pointer and use SHIFTBUF[23:0] to configure the value of the next state transition (see State mode).

40.7.1.30 Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7)

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is bit-swapped.

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFBISn	280h + (n × 4h)

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-0 SHIFTBUFBIS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register are bit-swapped. Reads return SHIFTBUF[0:31].

40.7.1.31 Shifter Buffer Byte Swapped (SHIFTBUFBYS0 - SHIFTBUFBYS7)

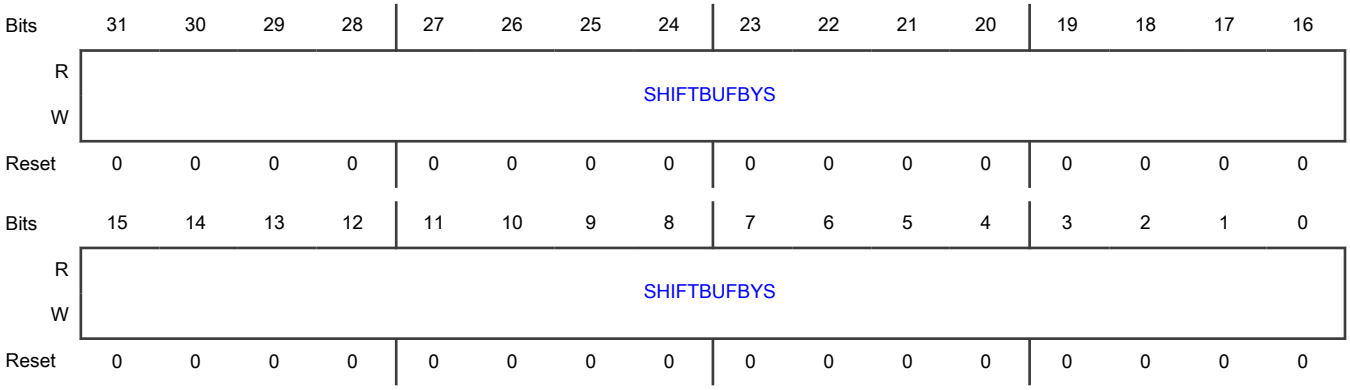
Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is byte-swapped.

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFBYSn	300h + (n × 4h)

Diagram



Fields

Field	Description
31-0 SHIFTBUFBYS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register are byte-swapped. Reads return {SHIFTBUF[7:0], SHIFTBUF[15:8], SHIFTBUF[23:16], SHIFTBUF[31:24]}.

40.7.1.32 Shifter Buffer Bit Byte Swapped (SHIFTBUFBBS0 - SHIFTBUFBBS7)

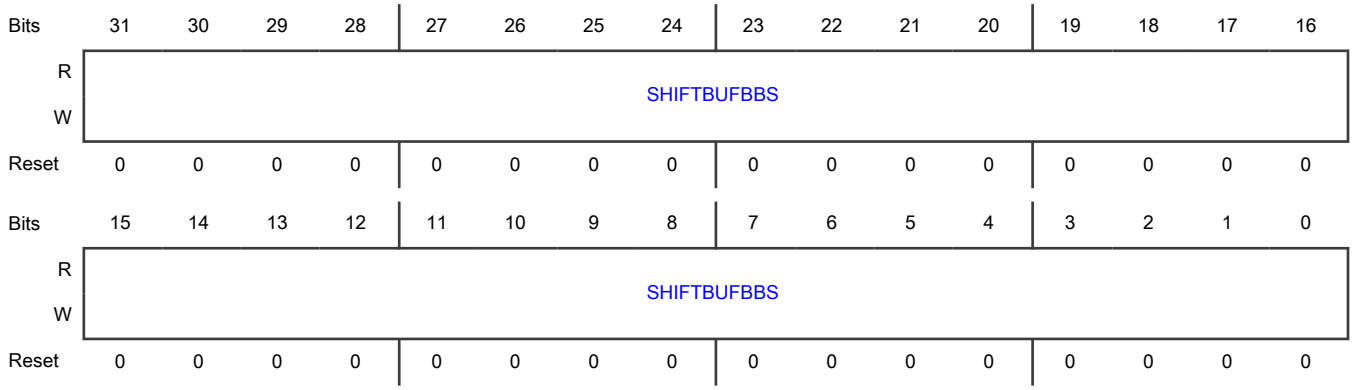
Contains the register data for Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but it is bit-swapped within each byte.

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFBBSn	380h + (n × 4h)

Diagram



Fields

Field	Description
31-0 SHIFTBUFBBS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), except that reads or writes to this register are bit-swapped within each byte. Reads return {SHIFTBUF[24:31], SHIFTBUF[16:23], SHIFTBUF[8:15], SHIFTBUF[0:7]}.

40.7.1.33 Timer Control (TIMCTL0 - TIMCTL7)

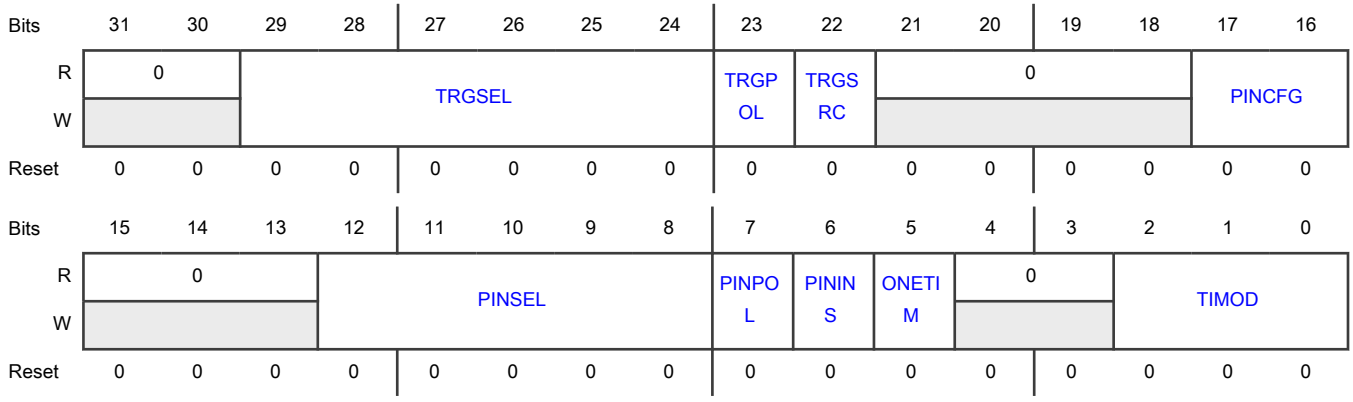
Controls various settings for timer *n*.

Offset

For n = 0 to 7:

Register	Offset
TIMCTLn	400h + (n × 4h)

Diagram



Fields

Field	Description
31-30 —	Reserved
29-24 TRGSEL	Trigger Select Selects the trigger. The valid values for TRGSEL depend on the configuration of Parameter (PARAM): • If TRGSRC = 1, the valid values for *n* depend on the settings of PARAM[PIN], PARAM[TIMER], and PARAM[SHIFTER]. • If TRGSRC = 0, the valid values for *n* depend on PARAM[TRIGGER]. See the chip-specific FLEXIO information for external trigger selection. **NOTE** For a pin, *n* = 0 to 31, for a shifter, *n* = 0 to 7, and for a timer, *n* = 0 to 7. If TRGSRC = 0, configure the trigger selection as *n* = external trigger *n* input. If TRGSRC = 1, you can configure the internal trigger to select an input pin as 2×*n* = pin *n* input. If TRGSRC = 1, you can configure the internal trigger to select a shifter or timer signal as: • 4×*n* + 1 = shifter *n* status flag • 4×*n* + 3 = timer *n* trigger output Following are the values for expanded internal trigger selection (TRGSRC = 1): • 0000 = Pin 0 • 0001 = Shifter 0 flag • 0010 = Pin 1 • 0011 = Timer 0 trigger • 0100 = Pin 2 • 0101 = Shifter 1 flag • 0110 = Pin 3 • 0111 = Timer 1 trigger • ... • This continues up to pin 31, shifter 7, and timer 7.
23 TRGPOL	Trigger Polarity Specifies whether the trigger is active high or active low. 0 - Active high 1 - Active low
22 TRGSRC	Trigger Source Specifies whether the selected trigger source is external or internal.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - External 1 - Internal
21-18 —	Reserved
17-16 PINCFG	Timer Pin Configuration Configures the direction of the timer pin. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register. **NOTE** When you initially configure PINCFG as 11b, FLEXIO may briefly drive the pin low. To avoid this, configure PINCFG as 10b along with the rest of the Control register and then perform a subsequent write to set the value of PINCFG as 11b. Likewise, when changing the value of PINCFG from 11b to 00b, you must perform an initial write to set PINCFG as 10b, and then perform a subsequent write to update the rest of the Control register with PINCFG as 00b. 00 - Timer pin output disabled 01 - Timer pin open-drain or bidirectional output enable 10 - Timer pin bidirectional output data 11 - Timer pin output
15-13 —	Reserved
12-8 PINSEL	Timer Pin Select Selects the pin that is used by the timer input or output. PINSEL = i selects the FXIO_Di pin. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register.
7 PINPOL	Timer Pin Polarity Specifies the timer pin polarity. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register. 0 - Active high 1 - Active low
6 PININS	Timer Pin Input Select Specifies what selects the timer pin input. If this field is 1, the timer input pin is different from the timer output pin. PINSEL must select an even-numbered pin when this field is 1, which means that the output pin is even-numbered and input pin is odd-numbered. 0 - PINSEL selects timer pin input and output 1 - PINSEL + 1 selects the timer pin input; timer pin output remains selected by PINSEL

Table continues on the next page...

Table continued from the previous page...

Field	Description
5 ONETIM	Timer One Time Operation Configures the timer to perform a single enable or disable iteration. Clear the timer status flag for the timer to be enabled again. 0 - Generate the timer enable event as normal 1 - Block the timer enable event unless the timer status flag is clear
4-3 —	Reserved
2-0 TIMOD	Timer Mode Specifies the timer mode: • In 8-bit baud counter mode, the lower 8 bits of the counter and compare register are used to configure the baud rate of the timer shift clock. The upper 8 bits are used to configure the shifter bit count. • In 8-bit PWM high mode, the lower 8 bits of the counter and compare register are used to configure the high period of the timer shift clock. The upper 8 bits are used to configure the low period of the timer shift clock. The shifter bit count is configured using another timer or external signal. • In 16-bit counter mode, the full 16 bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. • In 16-bit counter disable mode, the full 16 bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. • In 8-bit word counter mode, the lower 8 bits of the counter and compare register are used to configure the shifter bit count. The upper 8 bits are used to configure the shifter word count. • In 8-bit PWM low mode, the lower 8 bits of the counter and compare register are used to configure the low period of the timer shift clock. The upper 8 bits are used to configure the high period of the timer shift clock. Use another timer or external signal to configure the shifter bit count. • In 16-bit input capture mode, the inverted value of the 16-bit counter is latched into the compare register when a timer counter disable condition is detected (as configured by TIMCFG*n*[TIMDIS]). This also sets the timer status flag. The timer counter is immediately restarted from FFFFh. 000 - Timer disabled 001 - Dual 8-bit counters baud mode 010 - Dual 8-bit counters PWM high mode 011 - Single 16-bit counter mode 100 - Single 16-bit counter disable mode 101 - Dual 8-bit counters word mode 110 - Dual 8-bit counters PWM low mode 111 - Single 16-bit input capture mode

40.7.1.34 Timer Configuration (TIMCFG0 - TIMCFG7)

Controls various aspects of timer configuration.

The options to enable or disable the timer using the timer *n* - 1 enable or disable are reserved when *n* is evenly divisible by 4 (timer 0, for example).

NOTE

The pin and trigger level and edges specified in this register refer to the signal state after being modified by the settings of TIMCTL*n*[PINPOL] and TIMCTL*n*[TRGPOL]. For example, "trigger low" means that a trigger is actually at logic level 1 if TIMCTL*n*[TRGPOL] is 1 (active low).

Offset

For n = 0 to 7:

Register	Offset
TIMCFGn	480h + (n × 4h)

Diagram

Fields

Field	Description
31-26 —	Reserved
25-24 TIMOUT	Timer Output Configures the initial state of the timer output and whether it is affected by the timer reset. 00 - Logic one when enabled; not affected by timer reset 01 - Logic zero when enabled; not affected by timer reset 10 - Logic one when enabled and on timer reset 11 - Logic zero when enabled and on timer reset
23 —	Reserved
22-20	Timer Decrement

Table continues on the next page...

Table continued from the previous page...

Field	Description
TIMDEC	Configures the source of the timer decrement and that of the shift clock. 000 - Decrement counter on FLEXIO clock; shift clock equals timer output 001 - Decrement counter on trigger input (both edges); shift clock equals timer output 010 - Decrement counter on pin input (both edges); shift clock equals pin input 011 - Decrement counter on trigger input (both edges); shift clock equals trigger input 100 - Decrement counter on FLEXIO clock divided by 16; shift clock equals timer output 101 - Decrement counter on FLEXIO clock divided by 256; shift clock equals timer output 110 - Decrement counter on pin input (rising edge); shift clock equals pin input 111 - Decrement counter on trigger input (rising edge); shift clock equals trigger input
19 —	Reserved
18-16 TIMRST	Timer Reset Configures the condition that causes the timer counter (and optionally the timer output) to be reset. In 8-bit counter mode, the timer reset only resets the lower 8 bits that configure the baud rate. In all other modes, the timer reset resets full 16 bits of the counter. 000 - Never reset timer 001 - Timer reset on timer output high. 010 - Timer reset on timer pin equal to timer output 011 - Timer reset on timer trigger equal to timer output 100 - Timer reset on timer pin rising edge 101 - Reserved 110 - Timer reset on trigger rising edge 111 - Timer reset on trigger rising or falling edge
15 —	Reserved
14-12 TIMDIS	Timer Disable Configures the condition that causes the timer to be disabled and stop decrementing. 000 - Timer never disabled 001 - Timer disabled on timer n-1 disable 010 - Timer disabled on timer compare (upper 8 bits match and decrement) 011 - Timer disabled on timer compare (upper 8 bits match and decrement) and trigger low 100 - Timer disabled on pin rising or falling edge 101 - Timer disabled on pin rising or falling edge provided trigger is high

Table continues on the next page...

Field	Description
	110 - Timer disabled on trigger falling edge 111 - Reserved
11 —	Reserved
10-8 TIMENA	Timer Enable Configures the condition that causes the timer to be enabled and start decrementing. 000 - Timer always enabled 001 - Timer enabled on timer n-1 enable 010 - Timer enabled on trigger high 011 - Timer enabled on trigger high and pin high 100 - Timer enabled on pin rising edge 101 - Timer enabled on pin rising edge and trigger high 110 - Timer enabled on trigger rising edge 111 - Timer enabled on trigger rising or falling edge
7-6 —	Reserved
5-4 TSTOP	Timer Stop Specifies whether the stop bit is enabled. The stop bit can be added on a timer compare (between each word) or on a timer disable. When stop bit is enabled, configured shifters output the contents of the stop bit when the timer is disabled. When stop bit is enabled on timer disable, the timer remains disabled until the next rising edge of the shift clock. If configured for both timer compare and timer disable, only one stop bit is inserted on timer disable. 00 - Disabled 01 - Enabled on timer compare 10 - Enabled on timer disable 11 - Enabled on timer compare and timer disable
3-2 —	Reserved
1 TSTART	Timer Start Specifies whether the start bit is enabled. If it is enabled, configured shifters output the contents of the start bit when the timer is enabled. The timer counter reloads from the compare register on the first rising edge of the shift clock. 0 - Disabled

40.7.1.35 Timer Compare (TIMCMP0 - TIMCMP7)

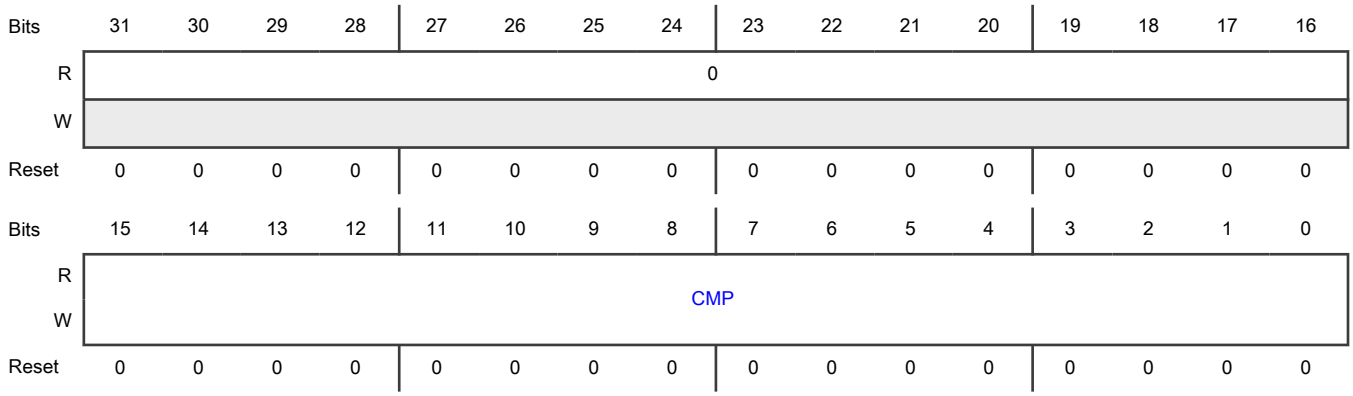
Contains the timer compare value.

Offset

For n = 0 to 7:

Register	Offset
TIMCMPn	500h + (n × 4h)

Diagram



Fields

Field	Description
31-16 —	Reserved
15-0 CMP	Timer Compare Value Loads into the timer counter when the timer is first enabled, when the timer is reset, and when the timer decrements down to zero. In 8-bit baud counter mode, the lower 8 bits configure the baud rate divider as (CMP[7:0] + 1) × 2. The upper 8 bits configure the number of bits in each word as (CMP[15:8] + 1) ÷ 2.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	In 8-bit PWM high mode, the lower 8 bits configure the high period of the output to (CMP[7:0] + 1) and the upper 8 bits configure the low period of the output to (CMP[15:8] + 1). In 16-bit counter mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) as (CMP[15:0] + 1) × 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word as (CMP[15:0] + 1) ÷ 2. In 16-bit counter disable mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) as (CMP[15:0] + 1) × 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word as (CMP[15:0] + 1) ÷ 2. In 8-bit word counter mode, the lower 8 bits configure the number of bits in each word as (CMP[7:0] + 1) ÷ 2. The upper 8 bits configure the number of words to transfer equal to (CMP[15:8] + 1) ÷ 2. In 8-bit PWM low mode, the lower 8 bits configure the low period of the output to (CMP[7:0] + 1) and the upper 8 bits configure the high period of the output to (CMP[15:8] + 1). In 16-bit input capture mode, the compare register is updated with the inverse of the timer counter value whenever the timer status flag is set. You must read this register only when the timer status flag is set.

40.7.1.36 Shifter Buffer Nibble Byte Swapped (SHIFTBUFNBS0 - SHIFTBUFNBS7)
