NXP Semiconductors
Reference Manual

Document identifier: IMX93RM
Rev. 7, 2026-02-10

i.MX 93 Applications Processor Reference Manual

Contents

Preface About This Manual.....17

Chapter 1 Introduction..... 28
1.1 Overview.....28
1.2 Target Applications.....33
1.3 Endianness Support..... 33

Chapter 2 Memory Maps..... 34
2.1 Memory system overview.....34
2.2 System memory map used by all initiators other than the Cortex-M33 core.....34
2.3 System memory map (Cortex-M33)..... 45
2.4 AIPS Peripheral Bridge 1 Memory Map.....56
2.5 AIPS Peripheral Bridge 2 Memory Map.....68
2.6 AIPS Peripheral Bridge 3 Memory Map.....80
2.7 AIPS Peripheral Bridge 4 Memory Map.....85

Chapter 3 Interrupt and DMA Assignments..... 91
3.1 Overview.....91
3.2 System Interrupts..... 91
3.3 DMA MUX.....105

Chapter 4 Enhanced Direct Memory Access (eDMA3).....111
4.1 Chip-specific eDMA3 information..... 111
4.2 Overview.....111
4.3 Functional description.....114
4.4 External signals..... 119
4.5 Initialization.....119
4.6 Memory map and register definition..... 131
4.7 Glossary..... 166

Chapter 5 Enhanced Direct Memory Access (eDMA4).....167
5.1 Chip-specific eDMA4 information..... 167
5.2 Overview.....167
5.3 eDMA register descriptions..... 170
5.4 Functional description.....213
5.5 External signals..... 218
5.6 Initialization.....218
5.7 Application information..... 221
5.8 Glossary..... 228

Chapter 6 Security Overview..... 229
6.1 Security features.....229
6.2 Edgelock secure enclave.....231

Chapter 7 Fusemap 232
7.1 Overview 232
7.2 Boot Fusemap 232
7.3 Fusemap descriptions table 236
7.4 Programming Fuses 236

Chapter 8 Fuse Status Block 237
8.1 Introduction 237
8.2 Memory map and register definition 237
8.3 Functional description 247
8.4 Acronyms and abbreviations 248

Chapter 9 System Boot 249
9.1 Overview 249
9.2 Boot Types 249
9.3 Boot Modes 251
9.4 Boot Stages 253
9.5 Image Container Set 253
9.6 Boot Flow 264
9.7 Platform Initialization In ROM 275
9.8 Boot Devices 278
9.9 Serial Downloader Boot 293
9.10 Secure boot 295
9.11 ROM API 295

Chapter 10 IOMUXC GPR 298
10.1 Overview 298
10.2 Memory map and register definition 298

Chapter 11 Arm Modules Overview 300
11.1 Overview 300

Chapter 12 ARM Cortex A55 303
12.1 Overview 303
12.2 Functional Description 304
12.3 External Signals 305

Chapter 13 ARM Cortex CM33 TCM MCM and ECC MCM (CM33_CACHE_TCM_ECC_MCM) 306
13.1 Chip-specific CM33 information 306
13.2 Overview 307
13.3 Functional description 308
13.4 External signals 311
13.5 Initialization 312
13.6 Memory map and register definition 312

Chapter 14 ARM Cortex CM33 MCM (CM33_MCM) 362
14.1 Overview 362

14.2 Functional description....362
14.3 External signals....362
14.4 Application information....362
14.5 Memory map and register descriptions....363

Chapter 15 CM33 Cache Memory Controller (XCACHE)....374
15.1 Overview....374
15.2 Functional description....374
15.3 External signals....381
15.4 Initialization....382
15.5 Application information....382
15.6 XCACHE register descriptions....382

Chapter 16 CM33 Performance Monitor (CMX-PERFMON)....390
16.1 Chip-specific CMX-PERFMON information....390
16.2 Overview....390
16.3 Functional description....391
16.4 External signals....392
16.5 Initialization....392
16.6 Memory map and register definition....392

Chapter 17 Neural Processing Unit (NPU)....399
17.1 Overview....399
17.2 Functional descriptions....399
17.3 External signals....403
17.4 Initialization....403
17.5 Application information....403
17.6 Memory map and registers....403

Chapter 18 On-chip RAM (OCRAM)....404
18.1 Overview....404
18.2 Functional description....405
18.3 External signals....407
18.4 Initialization....407
18.5 Application information....407
18.6 Programmable registers....407

Chapter 19 Memory ECC Controller (MECC256)....408
19.1 Overview....408
19.2 Functional description....409
19.3 Signals....411
19.4 Initialization....411
19.5 Application information....411
19.6 Memory Map and register definition....411

Chapter 20 Messaging Unit (MU)....585
20.1 Overview....585
20.2 Functional description....586
20.3 External signals....589

20.4 Initialization....589
20.5 Application information....589
20.6 Register definition....595
20.7 Glossary....639

Chapter 21 Semaphores2 (SEMA42)....640
21.1 Overview....640
21.2 Functional description....641
21.3 External signals....644
21.4 Initialization....644
21.5 Memory map/register definition....644
21.6 Glossary....648

Chapter 22 Trusted Resource Domain Controller (TRDC)....649
22.1 Chip-specific TRDC information....649
22.2 Overview....656
22.3 Functional description....658
22.4 External signals....663
22.5 Initialization....664
22.6 Application information....664
22.7 Register descriptions....665

Chapter 23 System Counter (SYS_CTR)....1253
23.1 Chip-specific SYS_CTR information....1253
23.2 Overview....1253
23.3 Functional description....1254
23.4 External signals....1254
23.5 Initialization....1255
23.6 Application information....1255
23.7 Programming model....1255
23.8 Memory map and register definition....1255

Chapter 24 System Debug....1272
24.1 Overview....1272
24.2 Functional description....1274
24.3 External Signals....1281

Chapter 25 JTAG Controller (JTAGC)....1282
25.1 Chip-specific JTAGC information....1282
25.2 Overview....1282
25.3 Functional description....1283
25.4 External signals....1287
25.5 Initialization....1288
25.6 Application information....1288
25.7 Register description....1288
25.8 Glossary....1290

Chapter 26 External Signals and Pin Multiplexing....1291
26.1 Overview....1291

Chapter 27 IOMUX Controller (IOMUXC)..... 1292
27.1 Overview.....1292
27.2 Functional description.....1294
27.3 Memory Map and register definition..... 1296

Chapter 28 General-Purpose Input/Output (GPIO).....1713
28.1 Chip-specific GPIO information..... 1713
28.2 Overview.....1713
28.3 Functional description.....1714
28.4 External signals 1716
28.5 Initialization.....1717
28.6 Application information..... 1717
28.7 Memory map and register definition..... 1717

Chapter 29 Clock and Power Overview..... 1738
29.1 Overview.....1738
29.2 Components of Clock and Power Management..... 1738
29.3 Power Management..... 1739
29.4 Clocks 1743

Chapter 30 Clock Controller Module (CCM)..... 1747
30.1 Overview.....1747
30.2 System Clocks.....1748
30.3 Functional description.....1760
30.4 Reset..... 1780
30.5 CCM Memory Map and Register definition.....1780

Chapter 31 General Power Controller (GPC)..... 1917
31.1 Overview.....1917
31.2 Functional description.....1918
31.3 External Signals.....1925
31.4 Initialization.....1925
31.5 Memory Map and register definition..... 1926

Chapter 32 System Reset Controller (SRC)..... 1984
32.1 Overview.....1984
32.2 Functional description.....1985
32.3 External Signals.....1993
32.4 Register access permissions.....1993
32.5 Memory Map and register definition..... 1993

Chapter 33 Battery-Backed Non-Secure Module (BBNSM)..... 2073
33.1 Chip-specific BBNSM information..... 2073
33.2 Overview.....2073
33.3 Functional description.....2075
33.4 External Signals.....2078
33.5 Initialization.....2079
33.6 Memory Map and register definition..... 2079

Chapter 34 External Memories..... 2091
34.1 Overview.....2091
34.2 High Performance DRAM Interface (DDR).....2091
34.3 eMMC/SD/SDIO..... 2091
34.4 Flexible Serial Peripheral Interface.....2091

Chapter 35 DDR Memory Controller (DDRC).....2092
35.1 Chip-specific DDR information..... 2092
35.2 Overview.....2093
35.3 Functional description.....2094
35.4 External signals..... 2114
35.5 Initialization.....2116
35.6 DDRC register descriptions..... 2119
35.7 Glossary..... 2246

Chapter 36 Flexible Serial Peripheral Interface (FlexSPI)..... 2247
36.1 Chip-specific FLEXSPI information..... 2247
36.2 Overview.....2248
36.3 Glossary for FlexSPI module.....2250
36.4 Functional description.....2251
36.5 External signals..... 2296
36.6 Initialization.....2297
36.7 Application information..... 2298
36.8 Memory map and register definition..... 2315
36.9 AHB memory map definition.....2364

Chapter 37 FlexSPI Address Remap (AHB_ADDR_REMAP)..... 2366
37.1 Overview.....2366
37.2 Functional description.....2366
37.3 Application Information..... 2366
37.4 Memory map and register definition..... 2367

Chapter 38 Ultra Secured Digital Host Controller (uSDHC).....2369
38.1 Chip-specific USDHC information..... 2369
38.2 Overview.....2369
38.3 Functional description.....2372
38.4 External signals..... 2403
38.5 Application information..... 2404
38.6 uSDHC memory map and register definition.....2423
38.7 Glossary..... 2519

Chapter 39 CAN (FlexCAN).....2521
39.1 Chip-specific FLEXCAN information.....2521
39.2 Overview.....2521
39.3 Functional description.....2524
39.4 External signal descriptions 2578
39.5 Initialization and application information.....2578
39.6 Memory map and register definition..... 2579
39.7 Glossary..... 2688

Chapter 40 Flexible I/O (FlexIO)..... 2690
40.1 Chip-specific FLEXIO information..... 2690
40.2 Overview..... 2690
40.3 Functional description..... 2692
40.4 External signals..... 2702
40.5 Initialization..... 2702
40.6 Application information..... 2702
40.7 Memory map and registers..... 2722
40.8 Glossary..... 2767

Chapter 41 Universal Serial Bus Controller (USB)..... 2768
41.1 Chip-specific USB information..... 2768
41.2 Overview..... 2768
41.3 Functional description..... 2770
41.4 External signals..... 2802
41.5 Initialization..... 2803
41.6 Register interface..... 2803
41.7 Register descriptions..... 2806

Chapter 42 Universal Serial Bus 2.0 PHY (USB2_PHY)..... 2915
42.1 Overview..... 2915
42.2 Clock Generation..... 2917
42.3 Device Initialization..... 2917
42.4 Tuning..... 2917

Chapter 43 Ethernet Controller with TSN (ENET_QoS)..... 2918
43.1 Chip-specific ENET information..... 2918
43.3 Overview..... 2918
43.4 Functional description..... 2920
43.5 External signals..... 3033
43.6 Initialization..... 3034
43.7 Application Information..... 3036
43.8 Memory Map and register definition..... 3049

Chapter 44 Ethernet MAC (ENET)..... 3882
44.1 Overview..... 3882
44.2 Functional description..... 3885
44.3 External signals..... 3936
44.4 Initialization..... 3937
44.5 Memory map/register definition..... 3937

Chapter 45 Audio Overview..... 4051
45.1 Audio Overview..... 4051

Chapter 46 PDM Microphone Interface (PDM)..... 4053
46.1 Chip-specific PDM information..... 4053
46.2 Overview..... 4053
46.3 Functional description..... 4055
46.4 External signals..... 4068

46.5 Initialization....4068
46.6 Application information....4071
46.7 MICFIL register descriptions....4071

Chapter 47 Synchronous Audio Interface (SAI)....4102
47.1 Chip-specific SAI information....4102
47.2 Overview....4103
47.3 Functional description....4105
47.4 External signals....4112
47.5 Initialization....4113
47.6 Memory map and register definition....4113
47.7 Glossary....4164

Chapter 48 Audio Transceiver (SPDIF XCVR)....4165
48.1 Overview....4165
48.2 Functional description....4165
48.3 External signals....4169
48.4 Initialization....4169
48.5 Application information....4170
48.6 Memory Map and register definition....4171
48.7 Glossary....4208

Chapter 49 Medium Quality Sound (MQS)....4209
49.1 Chip-specific MQS information....4209
49.2 Overview....4209
49.3 Functional Description....4210
49.4 External Signals....4211
49.5 Initialization....4212
49.6 Application Information....4212

Chapter 50 Multimedia Overview....4214
50.1 Multimedia Overview....4214

Chapter 51 LCD Interface (LCDIF)....4217
51.1 Chip-specific LCDIF information....4217
51.2 Overview....4217
51.3 Functional description....4218
51.4 Memory Map and register definition....4220

Chapter 52 MIPI-DSI....4246
52.1 Overview....4246
52.2 Functional Description....4247
52.3 External signals....4283
52.4 Memory Map and register definition....4283

Chapter 53 MIPI-DSI DPHY....4371
53.1 Overview....4371
53.2 Functional description....4372

53.3 Initialization....4377

Chapter 54 MIPI-CSI2....4379
54.1 Overview....4379
54.2 Functional Description....4381
54.3 External signals....4414
54.4 Initialization....4414
54.5 Memory Map and register definition....4414

Chapter 55 MIPI-CSI2 DPHY....4480
55.1 Overview....4480
55.2 Functional description....4481
55.3 Initialization....4489

Chapter 56 Pixel Pipeline (PXP)....4491
56.1 Chip-specific PXP information....4491
56.2 Overview....4491
56.3 Functional Description....4492
56.4 External Signals....4525
56.5 Initialization....4525
56.6 PXP Memory Map/Register Definition....4526

Chapter 57 Image Sensing Interface (ISI)....4675
57.1 Chip-specific ISI information....4675
57.2 Overview....4675
57.3 Functional description....4677
57.4 External signals....4683
57.5 Initialization and channel configuration....4683
57.6 Application information....4685
57.7 ISI register descriptions....4687

Chapter 58 Parallel Camera Interface....4744
58.1 Overview....4744
58.2 Functional Description....4744
58.3 External Signals....4747

Chapter 59 LVDS Display Bridge and Pixel Mapper....4749
59.1 Chip-specific LVDS information....4749
59.2 Overview....4749
59.3 Functional Descriptions....4750

Chapter 60 Low Power Inter-Integrated Circuit (LPI2C)....4753
60.1 Chip-specific LPI2C information....4753
60.2 Overview....4753
60.3 Functional description....4755
60.4 External signals....4766
60.5 Initialization....4767
60.6 Application information....4768

60.7 Memory map and registers.....4768
60.8 Glossary..... 4822

Chapter 61 Low Power Serial Peripheral Interface (LPSPI)..... 4823
61.1 Chip-specific LPSPI information.....4823
61.2 Overview.....4823
61.3 Functional description.....4825
61.4 External signals..... 4836
61.5 Initialization.....4836
61.6 Memory map and registers.....4836
61.7 Glossary..... 4870

Chapter 62 Low Power Universal Asynchronous Receiver/Transmitter (LPUART).....4871
62.1 Chip-specific LPUART information.....4871
62.2 Overview.....4871
62.3 Functional description.....4874
62.4 External signals..... 4890
62.5 Initialization.....4891
62.6 LPUART register descriptions..... 4891
62.7 Glossary..... 4940

Chapter 63 Improved Inter-Integrated Circuit (I3C)..... 4941
63.1 Chip-specific I3C information.....4941
63.2 Overview.....4941
63.3 Functional description.....4943
63.4 External signals..... 4957
63.5 Initialization.....4957
63.6 Application information..... 4959
63.7 I3C register descriptions.....4961
63.8 Glossary..... 5069

Chapter 64 Timers Overview..... 5071
64.1 Overview.....5071

Chapter 65 Low-Power Timer (LPTMR)..... 5073
65.1 Chip-specific LPTMR information..... 5073
65.2 Overview.....5074
65.3 Functional description.....5074
65.4 External signals..... 5077
65.5 Initialization.....5077
65.6 Application information..... 5077
65.7 Memory map and register definition..... 5078

Chapter 66 Low Power Periodic Interrupt Timer (LPIT).....5085
66.1 Chip-specific LPIT information.....5085
66.2 Overview.....5085
66.3 Functional description.....5086
66.4 Initialization.....5106

66.5 Memory map and registers.....5107

Chapter 67 Timer/PWM Module (TPM).....5124
67.1 Chip-specific TPM information.....5124
67.2 Overview.....5124
67.3 Functional description.....5126
67.4 External signals.....5146
67.5 Initialization.....5146
67.6 Application information.....5147
67.7 Memory map and register definition.....5148

Chapter 68 Timer (TSTMR).....5173
68.1 Chip-specific TSTMR information.....5173
68.2 Overview.....5173
68.3 Functional description.....5174
68.4 External signals.....5174
68.5 Initialization.....5174
68.6 TSTMR_A memory map and register definition.....5174

Chapter 69 Watchdog timer (WDOG).....5177
69.1 Chip-specific WDOG information.....5177
69.2 Overview.....5179
69.3 Functional description.....5180
69.4 External signals.....5184
69.5 Initialization.....5184
69.6 Application information.....5184
69.7 Memory map and register definition.....5185

Chapter 70 Analog Overview.....5192
70.1 Overview.....5192
70.2 Analog-to-Digital Converter (ADC).....5192
70.3 Temperature Sensor.....5192
70.4 XTAL.....5192
70.5 PLL.....5192
70.6 DIGPROG Device ID.....5193

Chapter 71 Trigger Mux (TRGMUX).....5194
71.1 Chip-specific TRGMUX information.....5194
71.2 Overview.....5194
71.3 Functional description.....5195
71.4 External signals.....5195
71.5 Initialization.....5195
71.6 TRGMUX register descriptions.....5195

Chapter 72 Analog-to-Digital Converter (SAR_ADC).....5198
72.1 Chip-specific ADC information.....5198
72.2 Introduction.....5200
72.3 Functional description.....5201
72.4 External signals.....5225

72.5 Initialization....5225
72.6 SAR_ADC register descriptions....5226

Chapter 73 Thermal Monitoring Unit (TMU)....5337
73.1 Chip-specific TMU information....5337
73.2 Overview....5339
73.3 Functional description....5340
73.4 Initialization....5343
73.5 External signals....5343
73.6 TMU register descriptions....5343
73.7 Glossary....5374

Chapter 74 PLLs....5375
74.1 Overview....5375
74.2 Functional description....5376
74.3 External signals....5379
74.4 Initialization....5379
74.5 Memory map and register definitions....5383

Chapter 75 OSC....5425
75.1 Overview....5425
75.2 Memory map and register definition....5425

Chapter 76 Always-on Domain, Non-secure Block Control (blk_ctrl_ns_aonmix)....5427
76.1 Introduction....5427
76.2 Functional description....5428
76.3 Initialization....5429
76.4 Memory Map and register definition....5429

Chapter 77 Always-on Domain, Secure Block Control (blk_ctrl_s_aonmix)....5453
77.1 Introduction....5453
77.2 Functional description....5454
77.3 Initialization....5455
77.4 Memory Map and register definition....5455

Chapter 78 Wake-up Domain Block Control (blk_ctrl_wakeupmix)....5486
78.1 Introduction....5486
78.2 Functional description....5487
78.3 Initialization....5488
78.4 Memory Map and register definition....5488

Chapter 79 NIC Mix Block Control (blk_ctrl_nicmmix)....5510
79.1 Introduction....5510
79.2 Functional description....5510
79.3 Initialization....5511
79.4 Memory Map and register definition....5511

Chapter 80 ML Mix Domain Block Control (blk_ctrl_mlmix)..... 5523
80.1 Overview.....5523
80.2 Functional description.....5523
80.3 External signals..... 5523
80.4 Memory map and register definition..... 5524

Chapter 81 DDR Mix Domain Block Control (blk_ctrl_ddrmix).....5526
81.1 Overview.....5526
81.2 Functional Description..... 5526
81.3 HWFCC and SWFFC Procedure.....5527
81.4 DDR IO Retention Enter/Exit Procedure..... 5532
81.5 Memory Map and register definition..... 5538

Chapter 82 Media Mix Domain Block Control (blk_ctrl_mediamix)..... 5544
82.1 Overview.....5544
82.2 Functional description.....5545
82.3 External signals..... 5546
82.4 Memory map and register definition..... 5546

Appendix A Release notes.....5585
A.1 About_this_manual changes..... 5585
A.2 Introduction changes.....5585
A.3 Memory Map changes.....5585
A.4 IRQ and DMA assignment changes.....5585
A.5 Enhanced Direct Memory Access (eDMA3).....5585
A.6 Enhanced Direct Memory Access (eDMA4).....5585
A.7 Security Overview changes.....5585
A.8 Fusemap changes.....5586
A.9 FSB module changes 5586
A.10 SystemSecure Boot changes.....5586
A.11 IOMUXC GPR module changes.....5586
A.12 Arm Modules Overview changes..... 5586
A.13 A55 Platform Overview changes.....5586
A.14 ARM Cortex CM33 TCM MCM and ECC MCM (CM33_CACHE_TCM_ECC_MCM).....5586
A.15 MCM module changes..... 5586
A.16 XCACHE module changes.....5586
A.17 CM33 Performance Monitor (CMX-PERFMON)..... 5587
A.18 NPU module changes..... 5587
A.19 OCRAM module changes..... 5587
A.20 MECC256 changes.....5587
A.21 MU module changes..... 5587
A.22 SEMA42 module changes.....5587
A.23 Trusted Resource Domain Controller (TRDC)..... 5587
A.24 System Counter (SYS_CTR).....5588
A.25 System Debug changes.....5588

Preface
About This Manual

Audience

The reference manual is intended for the board-level product designers and product software developers. This manual assumes that the reader has a background in computer engineering and/or software engineering and understands the concepts of the digital system design, microprocessor architecture, input/output (I/O) devices, industry standard communication, and device interface protocols.

Organization

The reference manual describes the chip at a system level and provides an architectural overview. It also describes the system memory map, system-level interrupt events, external pins and pin multiplexing, external memory, system debug, system boot, multimedia subsystem, power management, and system security.

Attachments

This manual includes key information in the files attached to it. For example, memory map and I/O details. Use the content in these attachments in conjunction with this manual's content.

NOTE

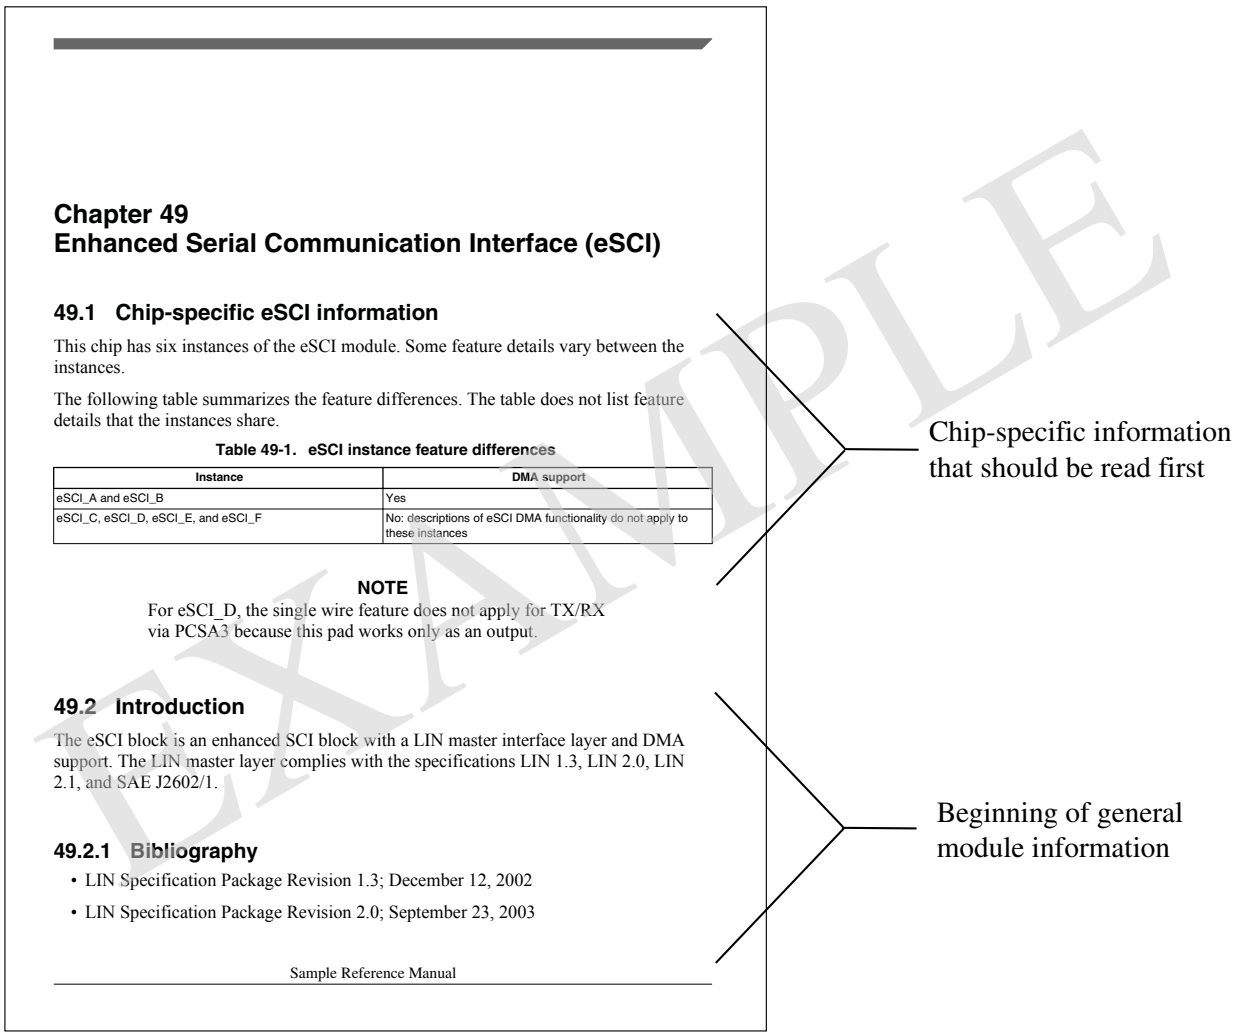
Select the paperclip icon on the left side of the PDF window to see the list of attachments.

Module descriptions

Each module chapter has two main parts:

- The first section, *chip-specific [module name]* information, provides details such as the number of module instances on the chip and connections between that module and the other ones. Read this section *first* because its content is crucial for understanding the information in the other sections of the chapter.
- The subsequent sections provide general information about the module, including its signals, registers, and functional description.

The following figure shows you an example of this demarcation.



Chapter 49
Enhanced Serial Communication Interface (eSCI)

49.1 Chip-specific eSCI information

This chip has six instances of the eSCI module. Some feature details vary between the instances.

The following table summarizes the feature differences. The table does not list feature details that the instances share.

Table 49-1. eSCI instance feature differences

Instance	DMA support
eSCI_A and eSCI_B	Yes
eSCI_C, eSCI_D, eSCI_E, and eSCI_F	No: descriptions of eSCI DMA functionality do not apply to these instances

NOTE
For eSCI_D, the single wire feature does not apply for TX/RX via PCSA3 because this pad works only as an output.

49.2 Introduction

The eSCI block is an enhanced SCI block with a LIN master interface layer and DMA support. The LIN master layer complies with the specifications LIN 1.3, LIN 2.0, LIN 2.1, and SAE J2602/1.

49.2.1 Bibliography

Register Access

Register Diagram Field Access Type Legend

This figure provides the interpretation of the notation used in the register diagrams for a number of common field access types:

Access type	Access description	DITA output	Effect of Write on Value	Readback Value
RW	Read/write	R / W: Mnemonic	Changes to Written Value	Current Value
RO	Read-only	R: Mnemonic / W:	No Effect	Current Value
RU	Reserved, unimplemented	R / W: Reserved	No Effect	Value Undefined
ROZ	Reserved, Read-only zero	R: 0 / W:	No Effect	Returns All Zero
ROO	Reserved, Read-only one	R: 1 / W:	No Effect	Returns All Ones
WO	Write-only	R: / W: Mnemonic	Changed to Written Value	Value Undefined
WOZ	Reserved, Write-only zero	R: / W: 0	Write Value Must Be All 0s.	Value Undefined
WOO	Reserved, Write-only one	R: / W: 1	Write Value Must Be All 1s.	Value Undefined
W0C	Write zero to clear	R: Mnemonic / W: w0c	If a Bit in the Written Value is a 0, the Corresponding Bit in the Field is Set to 0. Otherwise, the Field Bit is Not Affected.	Current Value
W1C	Write one to clear	R: Mnemonic / W: w1c	If a Bit in the Written Value is a 1, the Corresponding Bit in the Field is set to 0. Otherwise, the Field Bit is Not Affected.	Current Value
R2C	Read to clear		Value is cleared following the read operation	Current Value
ROWZ	Read-only, writes zero	R: Mnemonic / W: 0	Write Value Must Be All 0s	Current Value
ROWO	Read-only writes one	R: Mnemonic / W: 1	Write Value Must Be All 1s	Current Value
ROWU	Ready-only writes undefined	R: Mnemonic / W: —	Writes Operation Undefine	Current Value
WORZ	Write-only reads zero	R: 0 / W: Mnemonic	Changes to Written Value	Returns All Zero
WORO	Write-only reads one	R: 1 / W: Mnemonic	Changes to Written Value	Returns All Ones
WORU	Write-only reads undefined	R: — / W: Mnemonic	Changes to Written Value	Value Undefined

Figure 0. Register Field Conventions

NOTE

For reserved register fields, the software should mask off the data in the field after a read (the software can't rely on the contents of data read from a reserved field) and always write all zeros.

Register Macro Usage

A common operation is to update one field without disturbing the contents of the remaining fields in the register. Normally, this requires a read-modify-write (RMW) operation, where the CPU reads the register, modifies the target field, then writes the results back to the register. This is an expensive operation in terms of CPU cycles, because of the initial register read.

To address this issue, some hardware registers are implemented as a group, including registers that can be used to either set, clear, or toggle (SCT) individual bits of the primary register. When writing to an SCT register, all the bits set to 1 perform the associated operation on the primary register, while the bits set to 0 are not affected. The SCT registers always read back 0, and should be considered write-only. The SCT registers are not implemented if the primary register is read-only.

With this architecture, it is possible to update one or more fields using only register writes. First, all bits of the target fields are cleared by a write to the associated clear register, then the desired value of the target fields is written to the set register. This sequence of two writes is referred to as a clear-set (CS) operation.

A CS operation does have one potential drawback. Whenever a field is modified, the hardware sees a value of 0 before the final value is written. For most fields, passing through the 0 state is not a problem. Nonetheless, this behavior is something to consider when using a CS operation.

Also, a CS operation is not required for fields that are one-bit wide. While the CS operation works in this case, it is more efficient to simply set or clear the target bit (that is, one write instead of two). A simple set or clear operation is also atomic, while a CS operation is not.

Note that not all macros for set, clear, or toggle (SCT) are atomic. For registers that do not provide hardware support for this functionality, these macros are implemented as a sequence of read-modify-write operations. When an atomic operation is required, the developer should pay attention to this detail, because unexpected behavior might result if an interrupt occurs in the middle of the critical section comprising the update sequence.

A set of SCT registers is offered for registers in many modules on this device, as described in this manual.
In a module memory map table, the suffix _SET, _CLR, or _TOG is added to the base name of the register.
For example, the CCM_ANALOG_PLL_ARM register has three other registers called CCM_ANALOG_PLL_ARM_SET, CCM_ANALOG_PLL_ARM_CLR, and CCM_ANALOG_PLL_ARM_TOG.

In the sub-section that describes one of these sets of registers, a short-hand convention is used to denote that a register has the SCT register set. There is an italicized *n* appended to the end of the short register name. Using the above example, the name used for this register is CCM_ANALOG_PLL_ARM*n*. When you see this designation, there is a SCT register set associated with the register, and you can verify this by checking it in the memory map table. The address offset for each of these registers is given in the form of the following example:

Address: 20C_8000h base + 0h offset + (4d × i), where i=0d to 3d

In this example, the address for each of the base registers and their three SCT registers can be calculated as:

Register	Address
CCM_ANALOG_PLL_ARM	20C_8000h
CCM_ANALOG_PLL_ARM_SET	20C_8004h
CCM_ANALOG_PLL_ARM_CLR	20C_8008h
CCM_ANALOG_PLL_ARM_TOG	20C_800Ch

Acronyms and Abbreviations

The table below contains acronyms and abbreviations used in this document.

Acronyms and Abbreviated Terms

Term	Meaning
ACMP	Analog Comparator
ADC	Analog-to-Digital Converter
AHB	Advanced High-performance Bus
AIPS	Arm IP Bus
ALU	Arithmetic Logic Unit
AMBA	Advanced Microcontroller Bus Architecture
APB	Advanced Peripheral Bus
ASRC	Asynchronous Sample Rate Converter
AXI	Advanced eXtensible Interface
CA/CM	Arm Cortex-A/Cortex-M
CAAM	Cryptographic Acceleration and Assurance Module
CAN	Controller Area Network
CCM	Clock Controller Module
CM7	Arm Cortex M7 Core
CPU	Central Processing Unit
CSI	CMOS Sensor Interface
CSU	Central Security Unit
CTI	Cross Trigger Interface
D-cache	Data cache
DAP	Debug Access Port
DDR	Double data rate
DMA	Direct memory access
DPLL	Digital phase-locked loop
DRAM	Dynamic random access memory
ECC	Error correcting codes
LPSPI	Low-power SPI
EDMA	Enhanced Direct Memory Access
EIM	External Interface Module
ENET	Ethernet

Table continues on the next page...

Table continued from the previous page...

Term	Meaning
EPIT	Enhanced Periodic Interrupt Timer
EPROM	Erasable Programmable Read-Only Memory
ETF	Embedded Trace FIFO
ETM	Embedded Trace Macrocell
FIFO	First-In-First-Out
GIC	General Interrupt Controller
GPC	General Power Controller
GPIO	General-Purpose I/O
GPR	General-Purpose Register
GPS	Global Positioning System
GPU	Graphics Processing Unit
GPV	Global Programmers View
HAB	High-Assurance Boot
I-cache	Instruction cache
I2C or I^2C	Inter-Integrated Circuit
IC	Integrated Circuit
IEEE	Institute of Electrical and Electronics Engineers
IOMUX	Input-Output Multiplexer
IP	Intellectual Property
IrDA	Infrared Data Association
JTAG	Joint Test Action Group (a serial bus protocol usually used for test purposes)
LCDIF	Liquid Crystal Display Interface
LDO	Low-Dropout
LIFO	Last-In-First-Out
LRU	Least-Recently Used
LPSR	Low-Power State Retention
LSB	Least-Significant Byte

Table continues on the next page...

Table continued from the previous page...

Term	Meaning
LUT	Look-Up Table
LVDS	Low Voltage Differential Signaling
MAC	Medium Access Control
MCM	Miscellaneous Control Module
MMC	Multimedia Card
MSB	Most-Significant Byte
MT/s	Mega Transfers per second
OCRAM	On-Chip Random-Access Memory
OCOTP	On-Chip One-Time Programmable Controller
PCI	Peripheral Component Interconnect
PCIe	PCI express
PCMCIA	Personal Computer Memory Card International Association
BPC	Basic Power Controller
PIC	Programmable Interrupt Controller
PMU	Power Management Unit
POR	Power-On Reset
PSRAM	Pseudo-Static Random Access Memory
PWM	Pulse Width Modulation
PXP	Pixel Pipeline
QoS	Quality of Service
R2D	Radians to Degrees
RISC	Reduced Instruction Set Computing
ROM	Read-Only Memory
RTOS	Real-Time Operating System
Rx	Receive
SAI	Synchronous Audio Interface

Table continues on the next page...

Table continued from the previous page...

Term	Meaning
SCU	Snoop Control Unit
SD	Secure Digital
SDIO	Secure Digital Input/Output
SDLC	Synchronous Data Link Control
SDMA	Smart DMA
SIM	Subscriber Identification Module
SNVS	Secure Non-Volatile Storage
SoC	System-on-Chip
SPBA	Shared Peripheral Bus Arbiter
SPDIF	Sony Philips Digital Interface
SPI	Serial Peripheral Interface
SRAM	Static Random-Access Memory
SRC	System Reset Controller
TFT	Thin-Film Transistor
TPIU	Trace Port Interface Unit
TSGEN	Time Stamp Generator
Tx	Transmit
TZASC	TrustZone Address Space Controller
UART	Universal Asynchronous Receiver/Transmitter
USB	Universal Serial Bus
USDHC	Ultra Secured Digital Host Controller
WDOG	Watchdog
WLAN	Wireless Local Area Network
WXGA	Wide Extended Graphics Array

Conventions

The reference manual uses the following notational conventions:

cleared / set	When a bit has a value of zero, it is said to be cleared; when it has a value of one, it is said to be set.
mnemonics	Instruction mnemonics are shown in lowercase bold.

italics	Italics indicate variable command parameters, for example, **bcctr***x*. The book titles in the text are set in italics.
15	An integer in decimal.
0x	the prefix to denote a hexadecimal number.
0b	The prefix to denote a binary number. Binary values of 0 and 1 are written without a prefix.
n'H4000CA00	The n-bit hexadecimal number.
BLK_REG_NAME	The register names are all uppercase. The block mnemonic is prepended with an underscore delimiter (_).
BLK_REG[FIELD]	The fields within registers appear in brackets. For example, ESR[RLS] refers to the Receive Last Slot field of the ESAI Status Register.
BLK_REG[*n*]	The bit number *n* within the BLK.REG register.
BLK_REG[*l:r*]	The register bit ranges. The ranges are indicated by the left-most bit number *l* and the right-most bit number *r*, separated by a colon (:). For example, ESR[15:0] refers to the lower half word in the ESAI Status Register.
x, U	In some contexts, such as signal encodings, an unitalicized x indicates a "don't care" or "uninitialized". The binary value can be 1 or 0.
x	An italicized *x* indicates an alphanumeric variable.
n, m	Italicized *n or m* represent integer variables.
!	Binary logic operator NOT.
&&	Binary logic operator AND.
||	Binary logic operator OR.
^ or <O+>	Binary logic operator XOR. For example, A <O+> B.
|	Bit-wise OR. For example, 0b0001 | 0b1000 yields the value of 0b1001.
&	Bit-wise AND. For example, 0b0001 & 0b1000 yields the value of 0b0000.
{A,B}	Concatenation, where the *n*-bit value A is prepended to the *m*-bit value B to form an (*n*+*m*)-bit value. For example, {0, REG*m* [14:0]} yeilds a 16-bit value with 0 in the most significant bit.
- or grey fill	Indicates a reserved bit field in a register. Although these bits can be written to with ones or zeros, they always read zeros.
>>	Shift right logical one position.
<<	Shift left logical one position.
<=	Assignment.
==	Compare equal.
!=	Compare not equal.
>	Greater than.
<	Less than.

Notes and cautions

Specific information is provided as part of notes and cautions throughout this manual.

NOTE

Emphasizes information that deserves extra attention.

CAUTION

Informs you of situations that could lead to highly undesirable outcomes—such as damage to the chip or irreversible malfunction.

Numbering systems

The following suffixes identify different numbering systems:

Table 1. Numbering systems

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is mentioned as 101b. In some cases, *0b* is prefixed to binary numbers.
d	Decimal number. Decimal numbers are followed by this suffix only when there is a possibility of confusion. In general, decimal numbers are used without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is mentioned as 3Ch. In some cases, *0x* is prefixed to hexadecimal numbers.

Typographic notation

The following typographic notations are used throughout this document:

Table 2. Typographic notation

Example	Description
x and other italicized text	The italicized, lowercase *x* is used as a placeholder for replaceable numbers. In general, italicized text is used for titles of publications and for emphasis. Additionally, italics could be used for metasymbols in syntax descriptions. Plain lowercase letters are used as placeholders for single letters and numbers.
`code font`	Fixed-width font (such as Courier) used for code. It is used for a letter, word, or phrase that you want the user to type. For example, "Type `Read` and press Enter." This type of font is also used for instruction mnemonics, directives, symbols, subcommands, parameters, operators, computer-language elements, code listings, commands that appear in running text, and for sample code. Instruction mnemonics and directives in text and tables are mentioned in all caps; for example, BSR.
SR[SCM]	A mnemonic in square brackets represents the name of a register field. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets that are separated by a colon represent either: • A subset of a register's named field For example, REVNO[6:4] refers to bits 6-4 that are part of the COREREV field occupying bits 6-0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7-0 of the XAD bus.
MOD.REG	A period separates the elements of a hierarchy: subsystem.module.register. For example:

Table continues on the next page...

Table 2. Typographic notation (continued)

Example	Description
	• SWT.TO means that the TO register is located in the SWT module. • SMU.XRDC.CR means that the CR register is located in the XRDC module within the SMU subsystem.

Special terms

The following terms have special meanings.

Table 3. Special terms

Term	Meaning
Asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
Deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as *negated*.
Reserved	Refers to memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior. You must: • Not modify the default value of a reserved programming setting, such as the reset value of a reserved register field. • Consider undefined locations in memory to be reserved. • Not use the reset values of reserved locations documented in this manual for diagnostic purposes. They are subject to change. **NOTE** BootROM could modify the reserved bit values after reset. Please refer to the BootROM settings attachment.
Write 1 to clear (w1c)	Refers to the access type of a register field that is used to clear the field by writing the value 1 to it.
Undefined (u)	Refers to undefined reset values

Chapter 1
Introduction

1.1 Overview

i.MX 93 applications processors deliver efficient machine learning (ML) acceleration and advanced security with integrated EdgeLock® secure enclave to support energy-efficient edge computing. The i.MX 93 applications processors are the first in the i.MX portfolio to integrate the scalable Arm Cortex®-A55 core, bringing performance and energy efficiency to Linux®-based edge applications and the Arm Ethos®-U65 microNPU, enabling developers to create more capable, cost-effective and energy-efficient ML applications. Optimizing performance and power efficiency for Industrial, IoT and automotive devices, i.MX 93 processors are built with NXP's innovative Energy Flex architecture. The SoCs offer a rich set of peripherals targeting automotive, industrial and consumer IoT market segments. Part of the EdgeVerse™ portfolio of intelligent edge solutions, the i.MX 93 family will be offered in commercial, industrial, extended industrial and automotive level qualification and backed by NXP's product longevity program.

1.1.1 Block Diagram

The functional block diagram is shown in the figure below. This diagram provides a view of the chip's major functional components and core complexes.

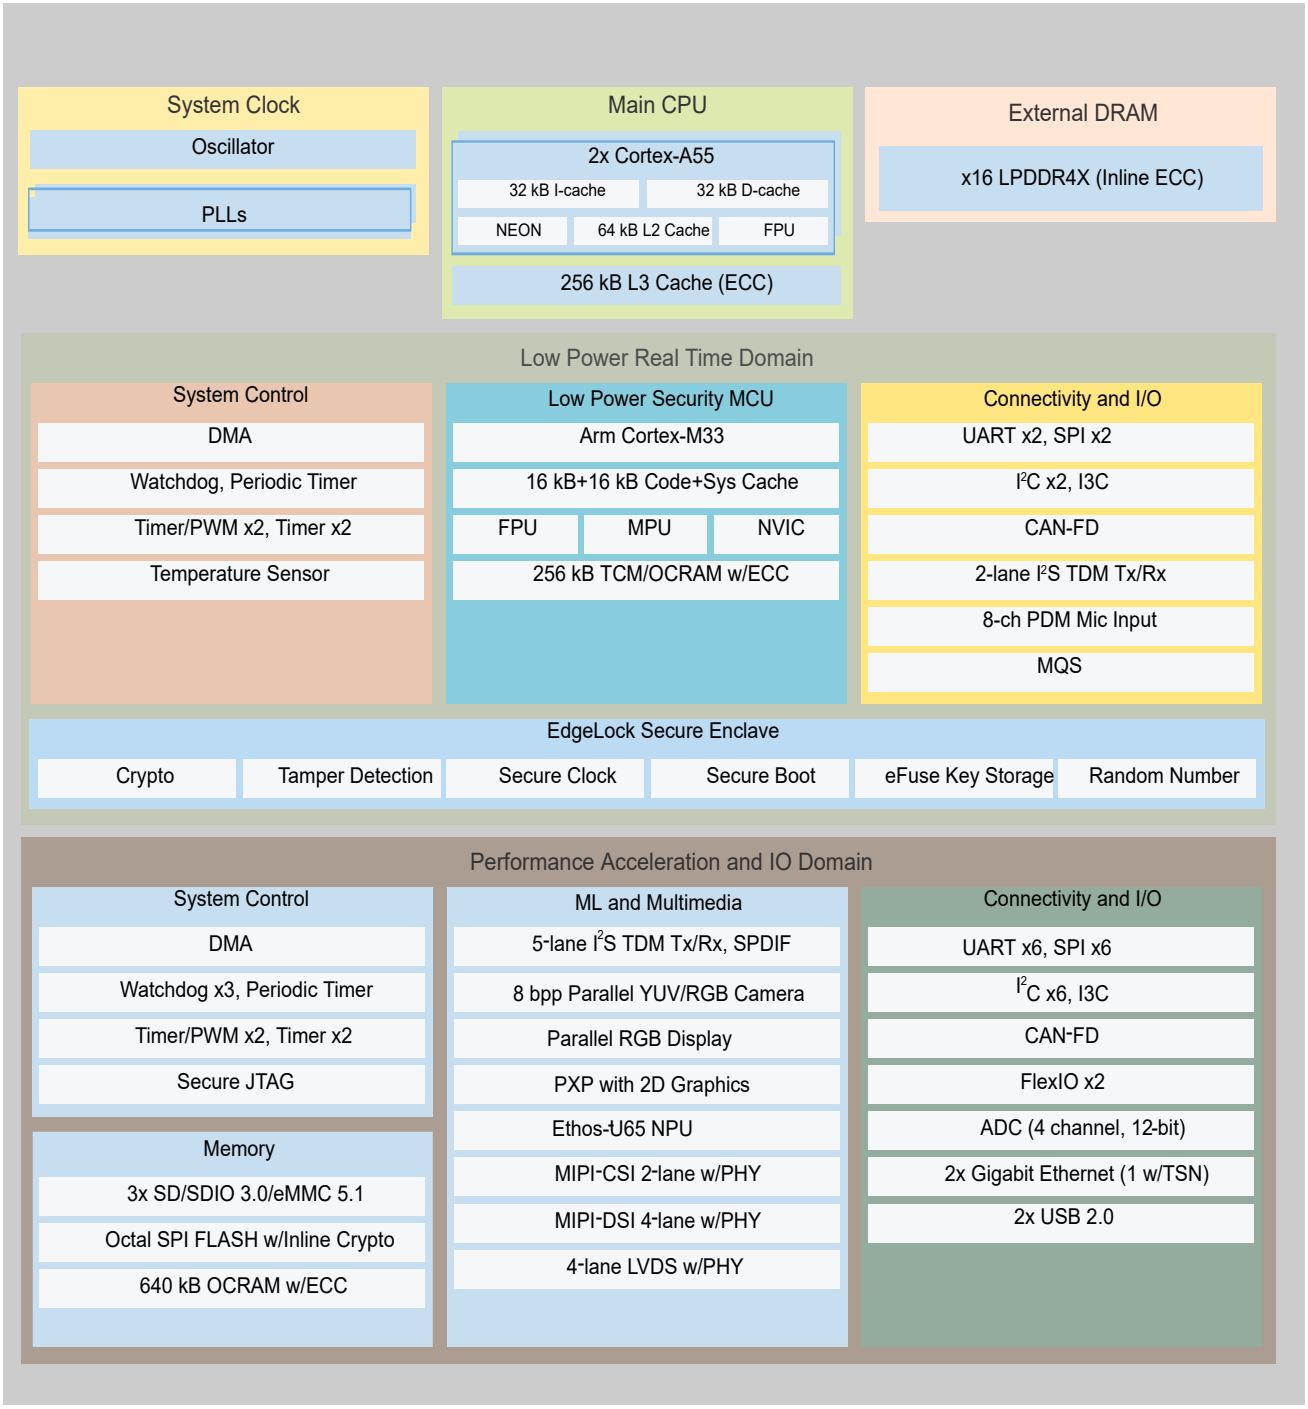

Figure 1. Simplified Block Diagram

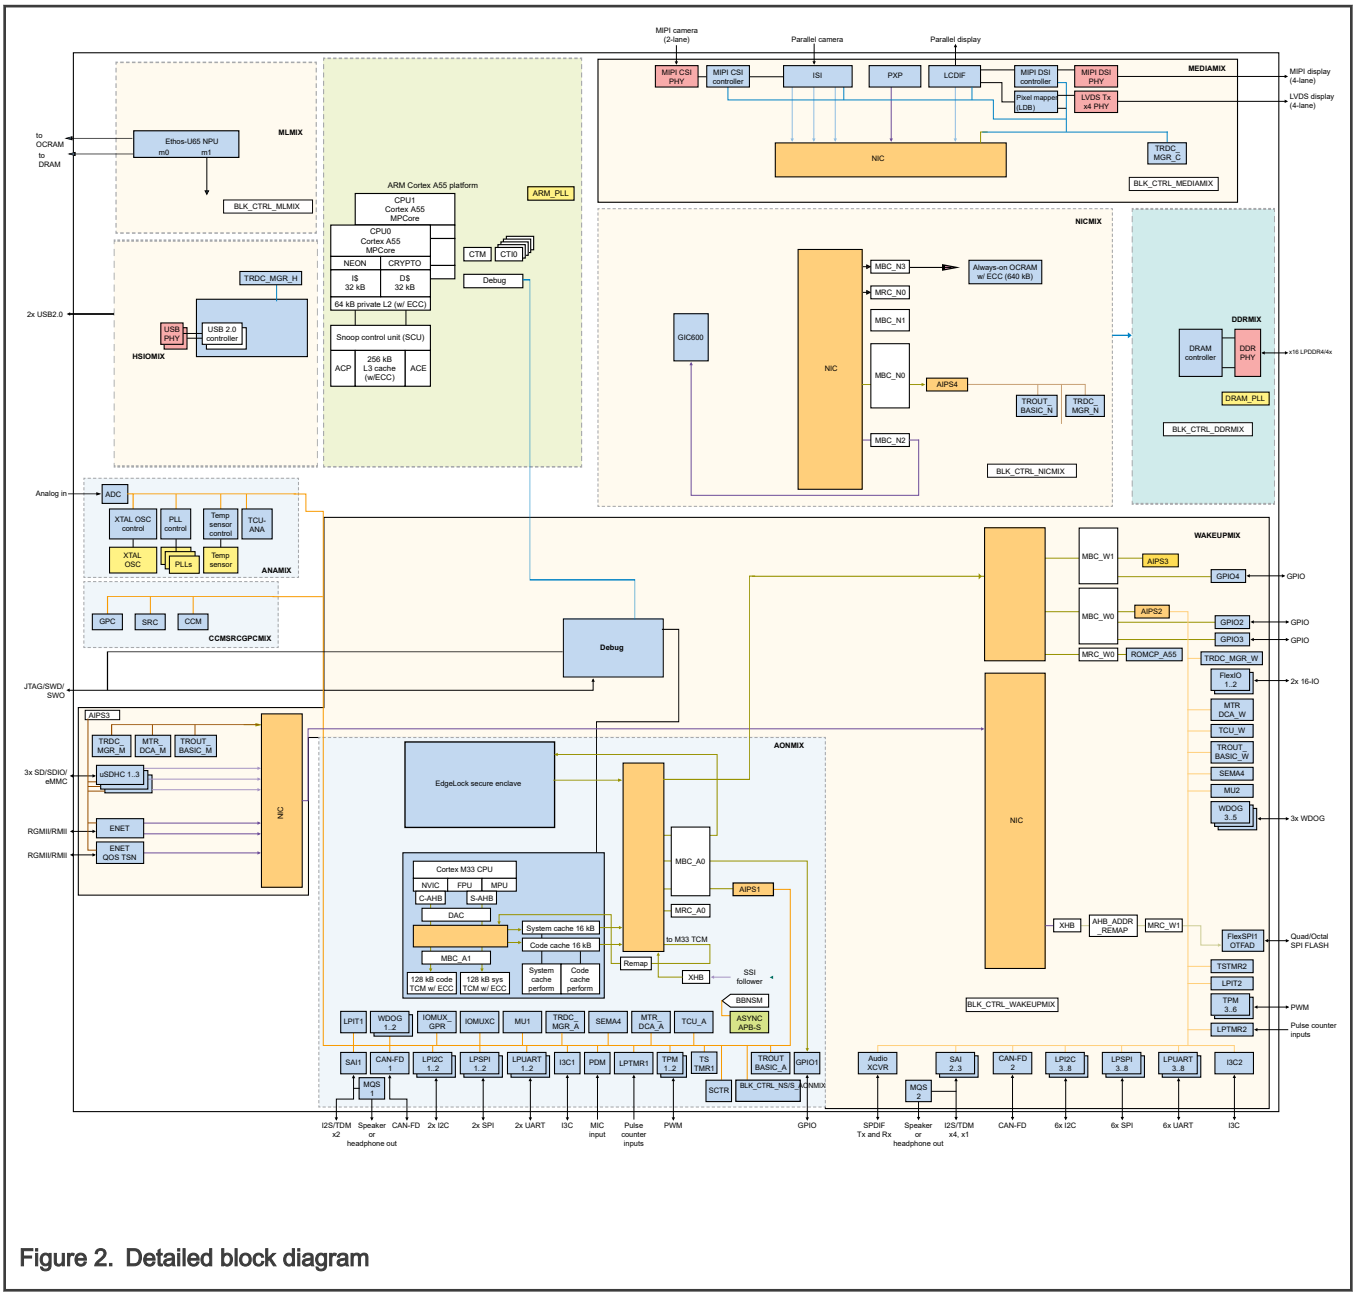

Figure 2. Detailed block diagram

1.1.2 Features

The i.MX93 processor is based on Arm Cortex®-A55 MPCore cluster and Arm Cortex®-M33 which have the following features:

Arm Cortex®-A55 MPCore cluster:

- One cluster of 2x Cortex-A55 cores
- Each core includes 32kB L1-I, 32kB L1-D and 64kB L2 cache per core
- 256kB shared cluster L3 cache
- Core cache protection (parity/ECC) supported

Arm Cortex®-M33 Platform:

- Microcontroller available both for boot and for customer application

- Arm Cortex®-M33 Processor:
  - 16KB L1 Instruction Cache
  - 16KB L1 Data Cache
  - 256 KByte TCM, also accessible as SRAM by the rest of the system
- ECC support for both cache and TCM

On Chip Memory:

- Boot ROM (256KB)
- 256KB Tightly Coupled RAM (TCM) for CM33, with ECC
- 640KB of SoC-specific OCRAM

External Memory Interfaces:

- One 16-bit DRAM controller:
  - Maximum supported capacity is 2GByte
  - LPDDR4X supported.
- FlexSPI FLASH with support for XIP and support for either one Octal SPI, two Quad SPI FLASH devices

Graphics:

- PXP 2D accelerator
- LCDIF display
  - LDB and 4-lane LVDS display (up to 1366x768 or 1280x800)
  - Parallel display (up to 1366x768 or 1280x800)
  - One 4-lane MIPI-DPHY DSI Tx PHY and MIPI-DSI Controller
- ISI camera interface
  - MIPI-DPHY CSI Rx PHY and MIPI-CSI Controller compliant to MIPI-DSI specification v1.2 and MIPI-DPHY specification v1.2
  - Parallel camera
  - Image processing for
    - One processed camera streams at 1080p30, or
  - Image down scaling via decimation and bi-phase filtering
  - Color space conversion
  - Interlaced to progressive conversions

Machine Learning

- High-efficiency Neural-network Processing Unit (NPU)

Audio:

- SPDIF supports raw capture mode that can save all the incoming bits into audio buffer.
- 3x Synchronous Audio Interface (SAI) modules supporting I2S, AC97, TDM, and Codec/DSP interfaces
- Digital microphone input, 8-channel PDM

Connectivity:

- 2x USB 2.0 OTG controller with integrated PHY interfaces
- 3x Ultra Secure Digital Host Controller (uSDHC) interfaces

  - uSDHC1 with boot support for eMMC 5.1 compliance with HS400 DDR signaling to support up to 400 MB/sec
  - uSDHC2 with boot support for SD/SDIO 3.0 compliance with 200 MHz SDR signaling to support up to 100 MB/sec
  - Support for SDXC (extended capacity)
  - USDHC3 to support use cases that need simultaneous support for all three of 1x eMMC, 1x SD Card and 1x SDIO (for WIFI connectivity)
- 8x Universal asynchronous receiver/transmitter (LPUARTs) modules
- 8x LPSPI modules
- 8x I2C modules
- 2x I3C modules
- 2x CAN-FD modules
- 2x 32-pin FlexIO modules
- 1x 1G-bit Ethernet with AVB support (ENET)
- 1x 1G-bit Ethernet QoS with TSN support

Timers and PWMs:

- 2x Low Power Periodical Interrupt Timer (LPIT)
  - 4 channel
  - 4 external trigger source
  - Generic 32-bit resolution timer
  - Periodical interrupt generation
- 6x Timer/PWM module (TPM)
  - Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
  - 16-bit counter, support free-running counter or modulo counter mode, counting up or down
  - Includes 6 channels that can be configured for input capture, output compare, edge-aligned PWM mode, or center-aligned PWM mode
- 2x Low-Power Timer (LPTMR)
- 5x WatchDog modules (WDOG)

GPIO and Pin Multiplexing:

- General-purpose input/output (GPIO) modules with interrupt capability
- Input/output multiplexing controller (IOMUXC) to provide centralized pad control

Analog:

- 1x 12-bit Analog Digital Converter (ADC)

Security:

- TRDC – Resource Domain Controller
  - Supports up to 16 resource domains
- Arm TrustZone® (TZ) architecture
- Secure and trusted access control
- Battery Backed Security Module (BBSM)
  - Monotonic counter - Secure real-time clock (RTC) - Zeroizable Master Key

System Debug:

- Arm CoreSight® debug and trace architecture
- Trace Port Interface Unit (TPIU) to support off-chip real-time trace
- Support for 5-pin (JTAG) and SWD debug interfaces

Power Management:

- One PMIC to supply all power rails.
- Temperature sensor with programmable trim points
- GPC hardware power management controller

1.2 Target Applications

The i.MX93 can be used but not limited to applications such as:

- Industrial
- IoT
- Automotive

1.3 Endianness Support

The chip supports only the Little Endian mode.

Chapter 2
Memory Maps

2.1 Memory system overview

This section introduces the memory architecture of the chip.

NOTE

Accessing the reserved memory regions can result in unpredictable behavior. Write/Read to the Reserved locations may not generate a transfer error.

2.2 System memory map used by all initiators other than the Cortex-M33 core

The following table provides the TrustZone "Non-Secure (NS)" and "Secure (S)" world view of the system (Cortex-A) memory map. Access through the "Secure" memory region can only be performed by code with the appropriate security settings.

NOTE

The System Memory Map (used by Cortex-A cores and all non-Cortex-M initiators in the chip) has TrustZone Non-Secure (NS) and Secure (S) world aliases of the address space below address 8000_0000 (hex). This is done for compatibility with TrustZone-M Cortex-M33 cores, which need these aliases for TrustZone-M Secure World access. Having these aliases in the system memory map allows address pointers to be shared between TrustZone-M Cortex-M33 cores and other initiators using the system memory map.

Table 4. System memory map

Start address (hex)	End address (hex)	Size (KB)	Description
C000_0000 (NS)	FFFF_FFFF (NS)	1048576	DRAM (offset 1GB)
B010_0000 (NS)	BFFF_FFFF (NS)	261120	DRAM (offset continued)
B004_4000 (NS)	B00F_FFFF (NS)	752	DRAM (offset continued)
B000_0000 (NS)	B004_3FFF (NS)	272	DRAM (offset 768 MB)
A000_0000 (NS)	AFFF_FFFF (NS)	262144	DRAM (offset 512 MB)
9000_0000 (NS)	9FFF_FFFF (NS)	262144	DRAM (offset 256 MB)
8000_0000 (NS)	8FFF_FFFF (NS)	262144	DRAM (offset 0 MB)

2.3 System memory map (Cortex-M33)

The following table provides the TrustZone-M "Non-Secure (NS)" and "Secure (S)" world view of the Cortex-M33 memory map. Access through the "Secure" memory region can only be performed by code with the appropriate security settings.

Table 5. System memory map (Cortex-M33)

Start address (hex)	End address (hex)	Size (KB)	Description

2.4 AIPS Peripheral Bridge 1 Memory Map

The following table provides the AIPS-1 memory map. The peripherals have both Secure (S) and Non-Secure (NS) access possibilities. Both, Secure and Non-Secure addresses for each peripheral is provided in the table below.

The start address of AIPS-1 peripherals for the Non-Secure access is 0x4400_0000.

The start address of AIPS-1 peripherals for the Secure access is 0x5400_0000.

NOTE

AIPS1 Peripherals are in the AONMIX domain.

2.5 AIPS Peripheral Bridge 2 Memory Map

The following table provides the AIPS-2 memory map. The peripherals have both Secure (S) and Non-Secure (NS) access possibilities. Both, Secure and Non-Secure addresses for each peripheral is provided in the table below.

The start address of AIPS-2 peripherals for the Non-Secure access is 0x4200_0000.

The start address of AIPS-2 peripherals for the Secure access is 0x5200_0000.

NOTE

AIPS2 Peripherals are in WAKEUPMIX domain.

2.6 AIPS Peripheral Bridge 3 Memory Map

The following table provides the AIPS-3 memory map. The peripherals have both Secure (S) and Non-Secure (NS) access possibilities. Both, Secure and Non-Secure addresses for each peripheral is provided in the table below.

The start address of AIPS-3 peripherals for the Non-Secure access is 0x4280_0000.

The start address of AIPS-3 peripherals for the Secure access is 0x5280_0000.

NOTE

AIPS3 Peripherals are in the MEGAMIX domain.

2.7 AIPS Peripheral Bridge 4 Memory Map

The following table provides the AIPS-4 memory map. The peripherals have both Secure (S) and Non-Secure (NS) access possibilities. Both, Secure and Non-Secure addresses for each peripheral is provided in the table below.

The start address of AIPS-4 peripherals for the Non-Secure access is 0x4900_0000.

The start address of AIPS-4 peripherals for the Secure access is 0x5900_0000.

NOTE

AIPS4 Peripherals are in the NICMIX domain.

Chapter 3
Interrupt and DMA Assignments

3.1 Overview

This section provides information on the assignments of the interrupts and DMA.

3.2 System Interrupts

The system interrupts are routed to both the Cortex-A55 Generic Interrupt Controller (GIC) and the Cortex-M33 Nested Vectored Interrupt Controller (NVIC). The following table describes the interrupt sources.

Table 6. System Interrupt Summary

Module	IRQ	Logic	Description
-	0	-	Reserved
DAP	1	-	DAP Interrupt
-	2	OR	Reserved
-	2	OR	Reserved
CM33	3	OR	CTI trigger outputs from CM33 platform (internal: CTIIRQ[0])
	3	OR	CTI trigger outputs from CM33 platform (internal: CTIIRQ[1])
CA55	4	OR	CTI trigger outputs from CA55 platform (internal: nCTIIRQ[0])
	4	OR	CTI trigger outputs from CA55 platform (internal: nCTIIRQ[1])
	5	OR	Performance Unit Interrupts from CA55 platform (internally: PMUIRQ[0])
	5	OR	Performance Unit Interrupts from CA55 platform (internally: PMUIRQ[1])
	5	OR	Performance Unit Interrupts from CA55 platform (internally: PMUIRQ[2])
	6	OR	ECC error with potential data corruption or loss of coherency from CA55 platform L3 Cache
	6	OR	ECC error with potential data corruption or loss of coherency from CA55 platform Core-0 L1 or L2 Cache
	6	OR	ECC error with potential data corruption or loss of coherency from CA55 platform Core-1 L1 or L2 Cache
	7	OR	1-bit or 2-bit ECC or Parity error from CA55 platform L3 Cache
	7	OR	1-bit or 2-bit ECC or Parity error from CA55 platform Core-0 L1 or L2 Cache

Table continues on the next page...

Table 6. System Interrupt Summary (continued)

Module	IRQ	Logic	Description
	7	OR	1-bit or 2-bit ECC or Parity error from CA55 platform Core-1 L1 or L2 Cache
CAN_FD1	8	OR	AONMIX CAN-FD Interrupt from busoff
	8	OR	AONMIX CAN-FD Interrupt from CAN line error
	8	OR	AONMIX CAN-FD Ored interrupts from ipi_int_MB
	8	OR	AONMIX CAN-FD Rx warning Interrupt
	8	OR	AONMIX CAN-FD Tx warning Interrupt
	8	OR	AONMIX CAN-FD Interrupt from wake up
	8	OR	Reserved
	8	OR	Reserved
	8	OR	AONMIX CAN-FD Busoff done interrupt
	8	OR	AONMIX CAN-FD FD error interrupt
	8	OR	AONMIX CAN-FD FIFO underflow interrupt
	8	OR	AONMIX CAN-FD FIFO overflow interrupt
	8	OR	AONMIX CAN-FD FIFO watermarker interrupt
	8	OR	AONMIX CAN-FD FIFO data available interrupt
	9	OR	AONMIX CAN-FD Correctable error interrupt
	9	OR	AONMIX CAN-FD Non correctable error int host
	9	OR	AONMIX CAN-FD Non correctable error int internal
GPIO1	10	OR	AONMIX GPIO interrupt request 0
	10	OR	AONMIX GPIO async wakeup interrupt request 0
	11	OR	AONMIX GPIO interrupt request 1
	11	OR	AONMIX GPIO async wakeup interrupt request 1
I3C1	12	OR	AONMIX I3C interrupt request
	12	OR	AONMIX I3C interrupt request
LPI2C1	13	OR4[1]	AONMIX LPI2C Master interrupt
	13	OR4[1]	AONMIX LPI2C Master async interrupt
	13	OR4[1]	AONMIX LPI2C Slave interrupt
	13	OR4[1]	AONMIX LPI2C Slave async interrupt
LPI2C2	14	OR4[1]	AONMIX LPI2C Master interrupt
	14	OR4[1]	AONMIX LPI2C Master async interrupt
	14	OR4[1]	AONMIX LPI2C Slave interrupt
	14	OR4[1]	AONMIX LPI2C Slave async interrupt

Table continues on the next page...

Table 6. System Interrupt Summary (continued)

Module	IRQ	Logic	Description
LPIT1	15	OR	AONMIX LPIT global interrupt
LPSPI1	16	OR	AONMIX LPSPI interrupt
	16	OR	AONMIX LPSPI async interrupt
LPSPI2	17	OR	AONMIX LPSPI interrupt
	17	OR	AONMIX LPSPI async interrupt
LPTMR1	18	OR	AONMIX LPTMR async interrupt
LPUART1	19	OR4[1]	AONMIX LPUART TX interrupt
	19	OR4[1]	AONMIX LPUART TX async interrupt
	19	OR4[1]	AONMIX LPUART RX interrupt
	19	OR4[1]	AONMIX LPUART RX async interrupt
LPUART2	20	OR4[1]	AONMIX LPUART TX interrupt
	20	OR4[1]	AONMIX LPUART TX async interrupt
	20	OR4[1]	AONMIX LPUART RX interrupt
	20	OR4[1]	AONMIX LPUART RX async interrupt
MU1	21		AONMIX MU Ored of all (tx,rx,gp,core,murip) interrupt to MUA
	22		AONMIX MU Ored of all (tx,rx,gp,core,murip) interrupt to MUB
MU2	23		WAKEUPMIX MU Ored of all (tx,rx,gp,core,murip) interrupt to MUA
	24		WAKEUPMIX MU Ored of all (tx,rx,gp,core,murip) interrupt to MUB
-	25	-	Reserved
-	26	-	Reserved
-	27	-	Reserved
Edgelock	28		AONMIX Edgelock Trust MUA RX full interrupt
	29		AONMIX Edgelock Trust MUA TX empty interrupt
	30		AONMIX Edgelock Apps Core MUA RX full interrupt
	31		AONMIX Edgelock Apps Core MUA TX empty interrupt
	32		AONMIX Edgelock Realtime Core MUA RX full interrupt
	33		AONMIX Edgelock Realtime Core MUA TX empty interrupt
	34		AONMIX Edgelock secure interrupt

Table continues on the next page...

Table 6. System Interrupt Summary (continued)

Module	IRQ	Logic	Description
	35		AONMIX Edgelock non-secure interrupt
TPM1	36	OR	AONMIX LPTPM global interrupt
	36	OR	AONMIX LPTPM async interrupt
TPM2	37	OR	AONMIX LPTPM global interrupt
	37	OR	AONMIX LPTPM async interrupt
WDOG1	38	OR	AONMIX Watchdog interrupt request. SRC reset source.
	38	OR	AONMIX Watchdog async interrupt request. SRC reset source.
WDOG2	39	OR	AONMIX Watchdog interrupt request. SRC reset source.
	39	OR	AONMIX Watchdog async interrupt request. SRC reset source.
TRDC_MGR_A	40		AONMIX TRDC transfer error interrupt

CM33	212		CM33 MCM interrupt
ANAMIX	213		ANAMIX SFA interrupt
GIC600	214		GIC600 INTERRUPT
	215		GIC600 INTERRUPT
	216		GIC600 INTERRUPT
ADC1	217		ADC interrupt

Table continues on the next page...

Table 6. System Interrupt Summary (continued)

Module	IRQ	Logic	Description
	218		ADC interrupt
	219		ADC interrupt
-	220	-	Reserved
I3C1_RAW_IRQ_GLUE	221		I3C1 wakeup irq after double sync
I3C2_RAW_IRQ_GLUE	222		I3C2 wakeup irq after double sync
-	223 - 267	-	Reserved

1. This interrupt will be asserted if any one of the four interrupts with the same IRQ# are asserted.

3.3 DMA MUX

The table below shows the DMA request signals for the peripherals in the chip. Channel Mux assignments noted as FULL are all channels (0,1,2,3,..), EVEN are even channels only (0,2,4,6,..), ODD are odd channels (1,3,5,7,..), and NONE are 1:1 with the requestor and channel.

NOTE

eDMA3_1 AONMIX supports 31 channels.

Table 7. eDMA3_1 MUX Mapping - AONMIX

DMA	Module	Logic	Channel MUX	Description
0	-	-	NONE	Reserved
1	CAN1	-	NONE	CAN-FD 1 DMA request and response
2	-	-	NONE	Reserved
3	GPIO1	-	NONE	GPIO1 channel 0 DMA request and response
4	GPIO1	-	NONE	GPIO1 channel 1 DMA request and response
5	I3C1	-	NONE	I3C1 "To-bus" DMA request and response
6	I3C1	-	NONE	I3C1 "from-bus" DMA request and response
7	LPI2C1	OR	NONE	LPI2C1 Master TX DMA request
7	LPI2C1	OR	NONE	LPI2C1 Slave TX DMA request
8	LPI2C1	OR	NONE	LPI2C1 Master RX DMA request
8	LPI2C1	OR	NONE	LPI2C1 Slave RX DMA request
9	LPI2C2	OR	NONE	LPI2C2 Master TX DMA request
9	LPI2C2	OR	NONE	LPI2C2 Slave TX DMA request
10	LPI2C2	OR	NONE	LPI2C2 Master RX DMA request
10	LPI2C2	OR	NONE	LPI2C2 Slave RX DMA request
11	LPSPI1	-	NONE	LPSPI1 TX DMA request

System Debug		System Debug Overview

The Enhanced Direct Memory Access Type 3 (eDMA3) is an AHB-based 32-bit-addressing-capable eDMA module. For the rest of the chapter, eDMA refers to the eDMA3 type. There is one instance of eDMA3 in the AON domain. This is called the eDMA3_1 instance.

4.2 Overview

The enhanced direct memory access (eDMA) controller is capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 31 channels

NOTE

The terminology in this chapter has been updated to align with NXP's inclusive language standards, as shown in the table below.

Table 10. Updated terms

4.2.1 Block diagram

Figure 3 illustrates the components of the eDMA system, including the eDMA module (engine).

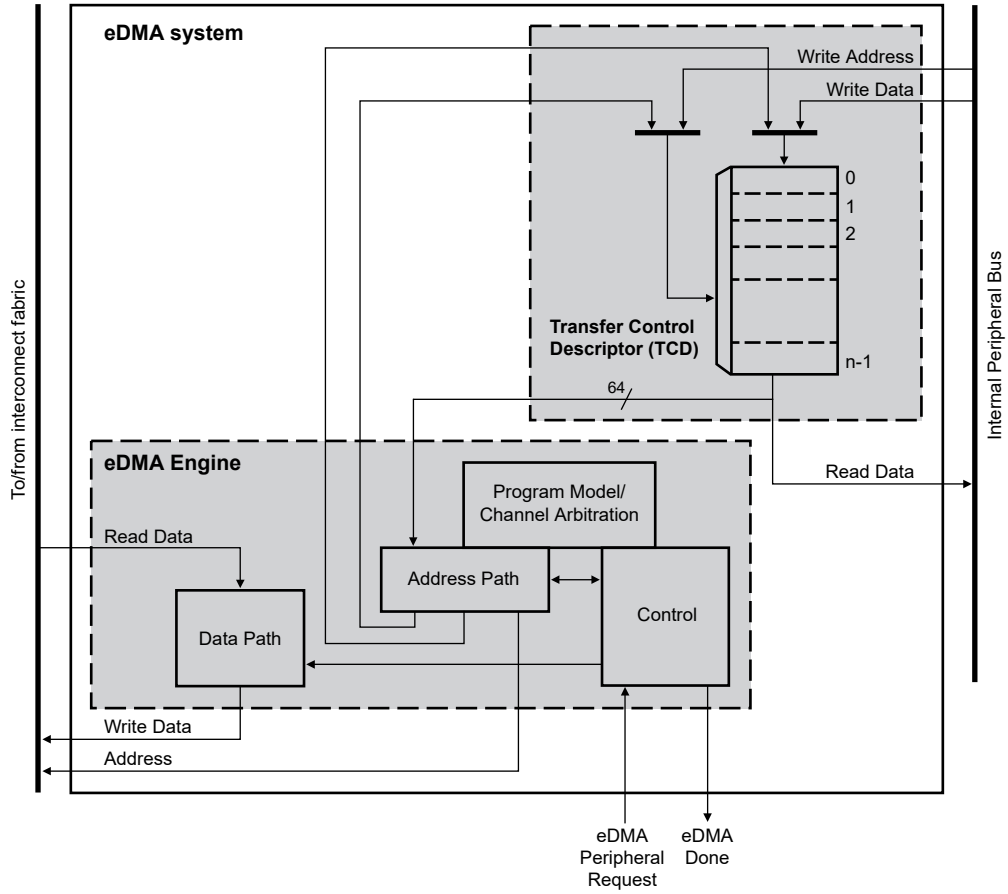

Figure 3. Block diagram

4.2.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 11. eDMA engine submodules

Submodule	Function
Address path	This block: • Implements a primary channel and secondary (preempt) channel • Manages all initiator bus-address calculations All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the primary channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by CH*n*_PRI[ECP]) where a large data transfer can be preempted to minimize the time another channel is blocked from execution.

Table continues on the next page...

Table 11. eDMA engine submodules (continued)

Submodule	Function
	When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of a new TCD*n* from memory as part of a scatter/gather operation. See Dynamic scatter/gather for more details.
Data path	This block implements the bus initiator read/write data path. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), and the data path module implements the second stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has been moved from the source to the destination. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, the eDMA performs two reads, then one 32-bit write.

The transfer control descriptor local memory is further partitioned into:

Table 12. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, and manages accesses from the eDMA engine as well as references from the internal peripheral bus. In simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

4.2.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and is not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for complex address calculations
- 31-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage for all transfers

  - Connections to the crossbar switch for bus driving the data movement
- TCD organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel that are logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module, *n* is used to reference the channel number.

4.3 Functional description

The operation of eDMA is described in the following subsections.

4.3.1 Modes of operation

The eDMA operates in the following modes:

Table 13. Modes of operation

Mode	Description
Normal	In Normal mode, eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the TCD. The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	eDMA operation is configurable in Debug mode via the control register: • If CSR[EDBG] is cleared to 0, eDMA continues to operate. • If CSR[EDBG] is set to 1, eDMA stops transferring data. If Debug mode is entered when a channel is active, eDMA continues operation until the channel retires.

4.3.2 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

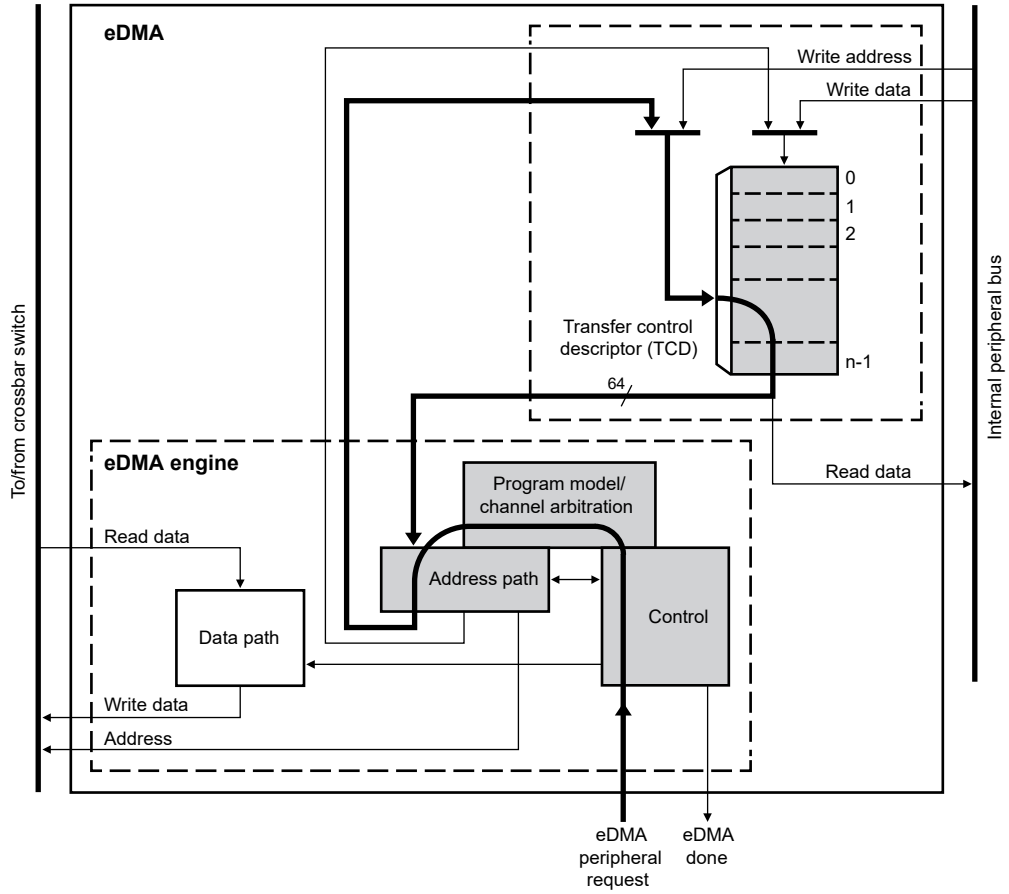

Figure 4. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] field follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration.

In the next cycle, the channel arbitration begins using fixed-priority plus the optional round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor is read from the local memory and then loaded into the eDMA engine address path's primary or secondary channel execution registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path registers.

The following diagram illustrates the second part of the basic data flow:

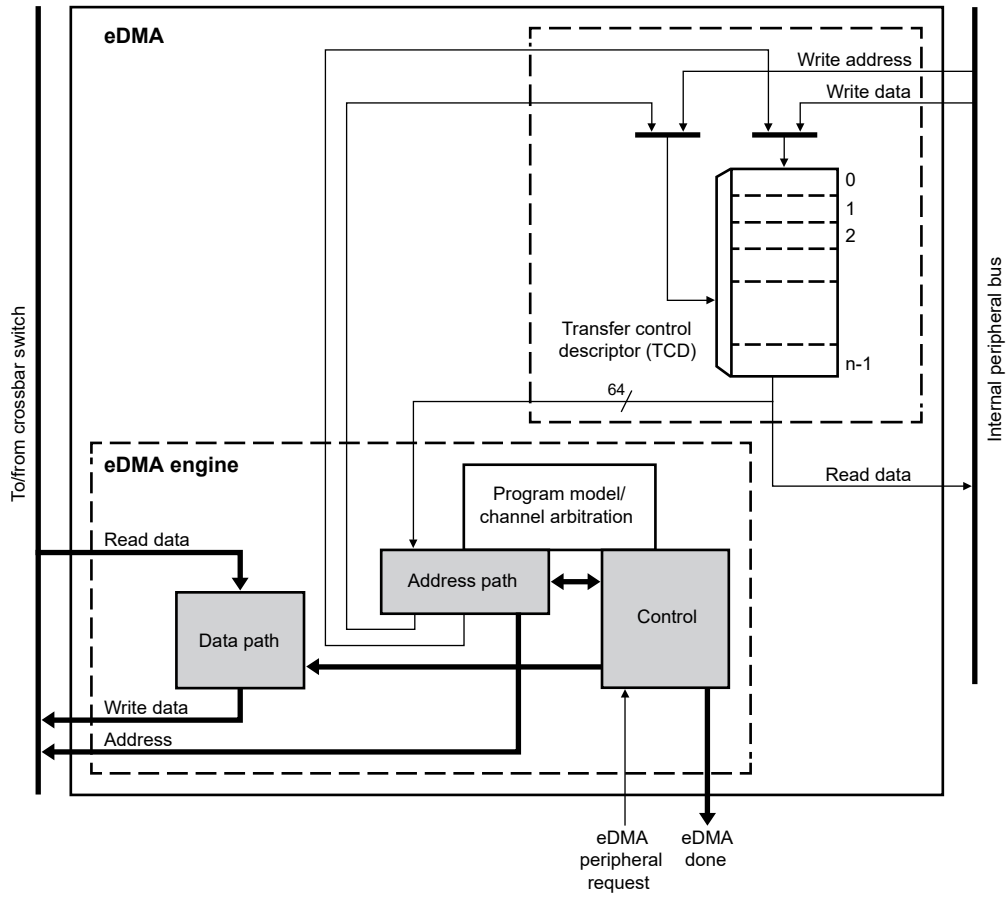

Figure 5. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) go through the required sequence of source reads and destination writes to perform the actual data movement. The source reads are initiated, and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the byte count, NBYTES, has been transferred.

After NBYTES of data has been moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD (for example, SADDR, DADDR, CITER). If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER field. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

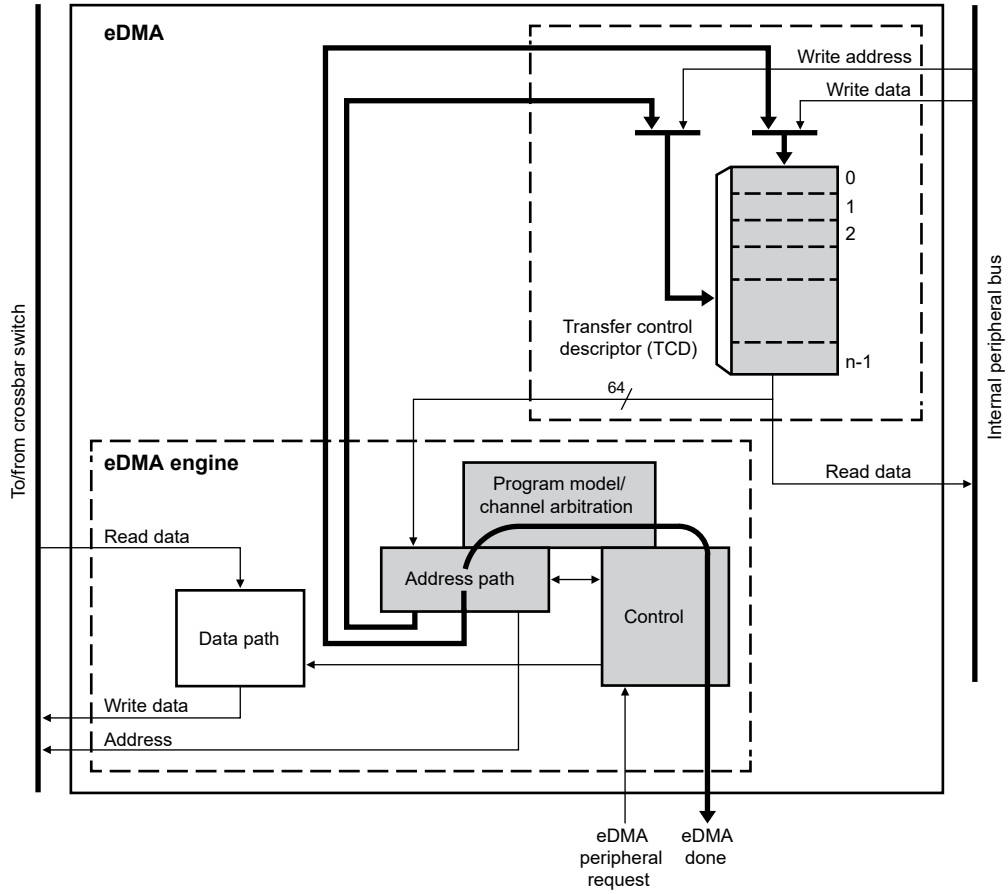

Figure 6. eDMA operation, part 3

4.3.3 Fault reporting and handling

Channel errors are reported in the Error Status register (CHn_ES) and can be caused by any of the following:

- A configuration error, which is an illegal setting in the transfer control descriptor
- An active channel canceled via a "cancel transfer with error" hardware or software request
- An error termination to a bus initiator read or write cycle

A configuration error is reported when an inconsistent state is represented by one of these factors:

- Starting source or destination address
- Source or destination offsets
- Minor loop byte count
- Transfer size

Each of these possible causes is detailed below:

- The addresses and offsets must be aligned on zero-modulo-transfer-sized boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size.

NOTE

To aid in debugging, set the Halt After Error field in the DMA's Control Status register, CSR[HAE]. Upon any error condition, the DMA is halted after the error is recorded. The DMA remains halted and does not process any channel service requests. After the error is fixed, the DMA may be enabled again by clearing the Halt field, CSR[HALT].

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (TCDn_DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[ELINK] field does not equal the TCDn_BITER[ELINK] field.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, are reported as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion if properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel field in the eDMA error register is set to 1. At the same time, the details of the error condition are loaded into the Error Status register (CHn_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag, and the possible assertion of an interrupt request are not affected when an error is detected.

After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

The error status fields are read-only. These error indicators are sticky and cannot be cleared. They show the last recorded error until the DMA is reset. CHn_ES[ERR] is used to determine if a new error condition exists. This field is the logical OR of each channel's error interrupt field (ERR).

After the software has resolved all errors and cleared all of the error interrupt fields, the MP_ES[VLD] is cleared to 0 but the cause of the last error is still indicated.

4.3.4 Channel preemption

The eDMA uses a priority vector value to determine the highest priority channel requesting service.

The priority vector is a combination of:

1. the channel's group priority, CHn_GRPRI
2. the channel's priority level, CHn_PRI[APL]

It can be considered a number composed of these concatenated priority levels: CHn_GRPRI : CHn_PRI[APL]

Priority vector = ((CHn_GRPRI << 8) + (CHn_PRI[APL] << 5) + CH_NUM)

A channel requesting service with the highest priority vector value will receive the next execution slot.

An execution slot is available:

1. immediately if the eDMA is idle
2. when an active channel retires
3. when valid preemption conditions exist

NOTE

Preemption is strictly priority based. Preemption is not bound by a specific group number as defined by CHn_GRPRI.

Channel preemption is enabled on a per-channel basis by setting the CHn_PRI[ECP] field. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher-priority channel. After the preempting channel has completed all of its minor loop data transfers, the preempted channel is restored and resumes execution.

After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended, and the higher-priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted.

A channel's ability to preempt another channel can be disabled by setting CHn_PRI[DPA] to 1. When a channel's preempt ability is disabled, that channel cannot suspend a lower-priority channel's data transfer, regardless of the lower-priority channel's ECP setting. This allows for a pool of low-priority, large-data-moving channels to be defined.

You can configure these low-priority channels to not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true high-priority channel. When you enable round-robin channel arbitration mode (CSR[ERCA] is set to 1), any channel with a priority level equal to 0 (CHn_PRI[APL] = 0) has preemption disabled and cannot preempt another channel.

4.3.5 Clocking

The following table describes the clock sources:

Table 14. Clocks

Clock	Description
hclk	Clock used for the DMA engine
ipg_clk	Clock used for the DMA programming model
dma_ram_clk	Clock used for the TCD RAMs

4.3.6 Interrupts

Software can enable the interrupt for each channel for the following events:

1. The major loop is half complete (INTHALF)
2. The major loop is complete (INTMAJOR)
3. A configuration error occurs (EEI)

4.4 External signals

This module has no external signals.

4.5 Initialization

The following sections discuss initialization of the eDMA and programming considerations.

4.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the MP_CSR if a configuration other than the default is wanted.
2. Write the channel priority levels to the CHn_PRI registers and group priority levels to the CHn_GRPRI registers if a configuration other than the default is wanted.

3. Enable error interrupts in the CHn_CSR[EEI] registers if they are wanted.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the CHn_CSR[ERQ] registers.
6. Request channel service via either:
   - Software: setting TCDn_CSR[START]
   - Hardware: target device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in Table 15, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, defined by TCDn_SADDR, to the destination, defined by TCD_DADDR, continue until the number of bytes specified by TCDn_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCDn_SADDR, TCDn_DADDR, and TCDn_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, then eDMA executes further post-processing, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 15. TCD control and status (TCDn_CSR) fields

TCDn_CSR field name	Description
START	Control field to start the channel explicitly when using a software-initiated DMA service (automatically cleared by hardware)
EEOP	Control field to enable end-of-packet processing
ESDA	Control field to enable storing of the destination address to system memory after the major loop completes
DREQ	Control field to disable hardware-initiated DMA service requests after major loop completion
BWC	Control field for throttling the bandwidth control of a channel
ESG	Control field to enable the scatter-gather feature
INTHALF	Control field to enable interrupt when major loop is half-complete
INTMAJOR	Control field to enable interrupt when major loop completes

Table 16. Channel control and status (CHn_CSR) fields

CHn_CSR field name	Description
ACTIVE	Status field indicating the channel is currently in execution
DONE	Status field indicating major loop completion (cleared by software when a channel begins execution)
EEI	Control field to enable error interrupts
EARQ	Control field to enable external, asynchronous wakeup event in conjunction with the ERQ field
ERQ	Control field to enable hardware service requests

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

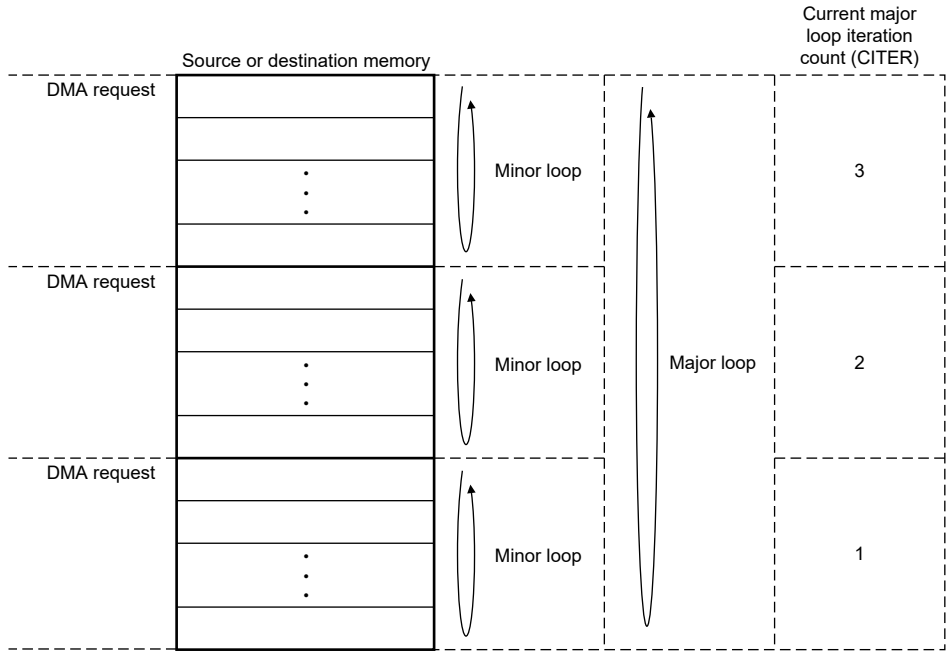

Figure 7. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings are related.

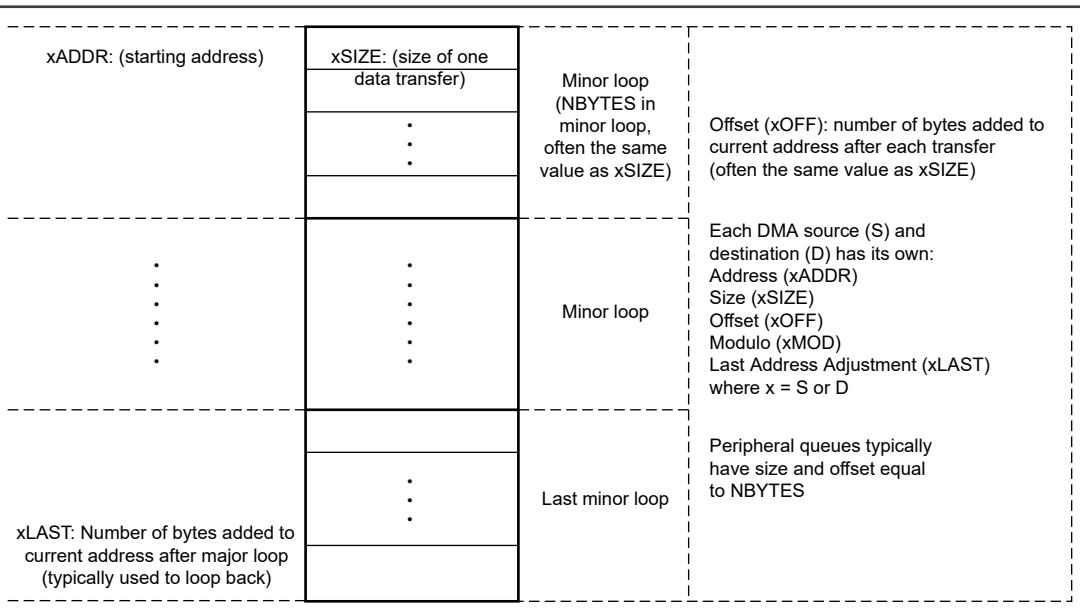

Figure 8. Memory array terms

4.5.2 eDMA arbitration

The eDMA uses a layered arbitration scheme composed of multiple priority levels. The eDMA uses a fixed-priority arbitration scheme with optional round-robin arbitration under specific conditions. The priorities are evaluated in the following order:

Table 17. eDMA arbitration priorities

Priority	Scheme	Description
1 (Highest)	Arbitration group priority	Each channel is assigned an arbitration group via the CHn_GRPRI registers. Priority is given to the highest value (31 being the highest possible value) down to the lowest value (zero, the default).
2	Channel priority	Each channel is assigned a channel priority level via the CHn_PRI registers. The channel priority is a relative priority level within an arbitration group. Priority is given to the highest value (seven being the highest possible value) down to the lowest value (zero, the default). Channel priorities within each arbitration group need not be unique. If multiple channels have the same channel priority level, the channel number will be used to determine priority as defined in row three.
3	Channel number	When two or more channels have the same arbitration group priority and channel priority, the channel number (CHn_NUM) is used to determine the highest priority. Priority is given to the highest channel number. Lowest priority is channel 0. The channel numbers are static and cannot be changed in the programmer's model.
4 (Lowest)	Round-robin	When round-robin is enabled, any channel configured for round-robin operation has lowest priority within an arbitration group. Round-robin is enabled by setting the MP_CSR[ERCA] field to 1. After being enabled, channels with a channel priority of zero (CHn_PRI=0) will use round-robin arbitration. Round-robin arbitration will rotate the channel selection among the channels requesting service with CHn_PRI=0 within the arbitration group. Any non-zero channel within the arbitration group will continue to use fixed-priority arbitration, and if requesting service will be selected over any round-robin channels.

For fixed arbitration, the overall priority can be considered a number composed of three concatenated priority levels: CHn_GRPRI:CHn_PRI:CH_NUM. The largest number has the highest priority and the lowest number has the lowest priority.

For round-robin arbitration, the priority number is CHn_GRPRI:0:X. The module rotates through the CHn_PRI=0 channels requesting service without regard to priority among these channels. Any channel within the arbitration group for which CHn_PRI is greater than 0 will be serviced before the round-robin channels.

4.5.3 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data.

The channel number causing the error is recorded in the Error Status register (CHn_ES). If the error source is not removed before the next activation of the problematic channel, the error is detected and recorded again. Setting the halt after error field, CSR[HAE], will halt the DMA and prevent recurrence of the error.

4.5.4 Arbitration mode considerations

This section discusses arbitration considerations for eDMA.

4.5.4.1 Fixed group arbitration, fixed channel arbitration

In this mode, eDMA selects for execution the channel service request from the highest-priority channel in the highest-priority group. If eDMA is programmed so that the channels within a high-priority group have a high number of requests or large data transfers, that group may consume all the bandwidth of the eDMA controller. That is, no lower-priority groups are serviced if there is always at least one DMA request pending on a channel in the highest-priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly.

4.5.4.2 Fixed group arbitration, round-robin channel arbitration

The highest-priority group with a request is serviced. Lower-priority groups are serviced if no pending requests exist in the higher-priority groups.

Within each group, channels are serviced starting with the highest non-zero channel priority. For all channels with a channel priority programmed to 0, selection begins with the highest channel number requesting service and then rotates through to the lowest channel number requesting service. The round-robin channel arbitration can provide a fairness mechanism to lower-priority channels.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, fixed channel arbitration, but all the channels in the highest-priority group will be serviced. Service latency is short on the highest-priority group, but could potentially be very much longer as the group priority decreases.

4.5.5 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

4.5.5.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the CH*n*_CSR[DONE] field is set to 1 and an interrupt is generated if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte-wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source, and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
```

```
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INTMAJ] = 1
TCDn_CSR[START] = 1 (should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] field requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes:
   - CH*n*_CSR[DONE] = 0
   - TCD*n*_CSR[START] = 0
   - CH*n*_CSR[ACTIVE] = 1
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

4.5.5.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop, transferring 16 bytes per iteration. After the channel's hardware requests are enabled via the CHn_CSR[ERQ] register field, the target device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.

4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
    b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
    c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
    d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
    e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
    f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
    g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
    h. Write 32 bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0.
8. The channel retires, which concludes one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware (eDMA peripheral) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: Channel TCD data from local memory to internal register file.
13. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
    b. Write 32 bits to location 0x2010 → first iteration of the minor loop.
    c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
    d. Write 32 bits to location 0x2014 → second iteration of the minor loop.
    e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
    f. Write 32 bits to location 0x2018 → third iteration of the minor loop.
    g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
    h. Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).
15. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
16. The channel retires, which concludes with the major loop complete. The eDMA goes idle or services the next channel.

4.5.5.3 Using the modulo feature

The modulo feature of the eDMA allows implementation of a circular data queue in which the size of the queue is a power of 2. xMOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature. Modulo addressing applies to cases where the minor loop offset is enabled; that is, the upper address bits remain the same after the minor loop offset is added to the source or destination address.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value but the 28 upper address bits (0x1234567*x*) retain their original value. In this example, the source address is set to 0x12345670, the offset is set to four bytes, and the MOD field is set to four, which allows for a 2^4 byte (16 byte) queue size.

Table 18. Modulo example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

4.5.6 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

4.5.6.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software-initiated service requests.

1. The first method is to read the TCDn_CITER field and test for a change.
2. The second method, extracted from the sequence shown below, is to test the TCDn_CSR[START] field and the CHn_CSR[ACTIVE] field. The minor-loop-complete condition is indicated by both fields reading 0 after TCDn_CSR[START] is set to 1. Polling the CHn_CSR[ACTIVE] field only may be inconclusive because the active status may be missed if the channel execution is short in duration.

The CHn_CSR and TCDn_CSR status fields execute the following sequence for a software-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	1	0	0	Initiate channel service request via software.
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

The best method to test for minor-loop completion when using hardware-initiated (that is, peripheral-initiated) service requests is to read the TCDn_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status fields execute the following sequence for a hardware-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	0	0	0	Initiate channel service request via hardware (peripheral request asserted).
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

For both activation types, the major-loop-complete status is explicitly indicated via the CHn_CSR[DONE] field.

The TCDn_CSR[START] field is cleared to 0 automatically when the channel begins execution, regardless of how the channel activates.

4.5.6.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCDn_SADDR, TCDn_DADDR, and TCDn_NBYTES values if they are read when a channel executes. The true values of SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file, and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES (which decrements to zero as the transfer progresses), can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

4.5.6.3 Checking channel preemption status

A preemptive situation is one in which a preempt-enabled channel is executing and a higher-priority request becomes active. When round-robin channel arbitration mode is enabled, all channels with their channel priority set to 0 lose their preempt ability. Channel priorities of 0 are treated as equal, that is, they are constantly rotating, when round-robin arbitration mode is enabled.

The CHn_CSR[ACTIVE] field for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended when the preempting channel executes one major loop iteration. If two CHn_CSR[ACTIVE] fields are set simultaneously in the global TCD map, a higher-priority channel is actively preempting a lower-priority channel.

4.5.7 Channel linking

Channel linking (or chaining) is a mechanism in which one channel sets the TCDn_CSR[START] field of another channel (or itself), thus initiating a service request for that channel. When properly enabled, the eDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCDn_CITER[ELINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, using an initial field setting of:

```
MP_CSR[GCLC] = 1
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJORELINK] = 1
TCDn_CSR[MAJORLINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] field
2. Minor loop done → set TCD12_CSR[START] field
3. Minor loop done → set TCD12_CSR[START] field
4. Minor loop done, major loop done→ set TCD7_CSR[START] field

When minor loop linking is enabled (TCDn_CITER[ELINK] = 1), the TCDn_CITER[CITER] field uses a nine-bit vector to form the current iteration count. When minor loop linking is disabled (TCDn_CITER[ELINK] = 0), the TCDn_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCDn_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

NOTE

The TCDn_CITER[ELINK] field and the TCDn_BITER[ELINK] field must be equal — if they are not, a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop halfway done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, that is, use another channel's TCD, at the end of a loop.

Table 19. Channel linking parameters

Wanted link behavior	TCD control field name	Description
Link at end of minor loop	TCDn_CITER[ELINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	TCDn_CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of major loop	TCDn_CSR[MAJORELINK]	Enable channel-to-channel linking on major loop completion
	TCDn_CSR[MAJORLINKCH]	Link channel number when linking at end of major loop

4.5.8 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

Steps for channel linking:

1. Set GCLC = 1
2. For linking after major loop complete:
   a. Set MAJORLINKCH = target channel number
   b. Set MAJORELINK = 1, enable the major loop link
   c. Upon major loop completion (CITER decrements to 0), the link will be made.
3. For linking on minor loop completion:
   a. Set LINKCH = target channel number
   b. Set ELINK = 1, enable the minor loop link
   c. Set the beginning iteration count to the same values; LINKCH = target channel and ELINK = 1,
   d. Upon minor loop completion (that is, after each service request except when the major loop is complete) the link will be made.

4.5.8.1 Dynamically changing the channel priority

To change group or channel priority levels:

1. Halt the DMA by writing 1 to the CSR[HALT] field.
2. Change the group or channel priorities as wanted.
3. Enable normal DMA operations by writing 0 to the CSR[HALT] field.

4.5.8.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCDn_CSR[MAJORELINK] field during channel execution (see the diagram in TCD structure). This field is read from the TCD local memory at the end of channel execution, thus allowing you to enable the feature during channel execution.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic channel link by enabling the TCDn_CSR[MAJORELINK] field at the same time the eDMA engine is retiring the channel. TCDn_CSR[MAJORELINK] would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

We recommend that you use the following coherency model when executing a dynamic channel link request.

1. Write 1 to the TCDn_CSR[MAJORELINK] field.
2. Read back the TCDn_CSR[MAJORELINK] field.
3. Test the TCDn_CSR[MAJORELINK] request status:
   - If TCDn_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
   - If TCDn_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCDn_CSR[MAJORELINK] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field is set to 1, indicating the major loop is complete.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing to the TCDn_CSR[MAJORELINK] field. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution.

4.5.8.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in the eDMA programmer's model, thus replacing the current descriptor.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic scatter/gather operation by enabling the TCDn_CSR[ESG] field at the same time the eDMA engine is retiring the channel. The TCDn_CSR[ESG] field would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods are recommended for executing a dynamic scatter/gather request. Whenever the TCDn_CSR is written, the TCD local memory controller forces the TCDn_CSR[ESG] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field has been set to 1, indicating the major loop is complete. If attempting to set the ESG, ensure the DONE field is cleared to 0.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing the TCDn_CSR[MAJORELINK] or TCDn_CSR[ESG] fields. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution and is set to 1 upon major loop completion.

4.5.8.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCDn_CSR[MAJORELINK] field is 0, the TCDn_CSR[MAJORLINKCH] field is not used by the eDMA. In this case, the TCDn_CSR[MAJORLINKCH] bits may be used for other purposes. This method uses the TCDn_CSR[MAJORLINKCH] field as a TCDn_CSR identification (ID).

When the descriptors are built, write a unique TCDn_CSR ID in the TCDn_CSR[MAJORLINKCH] field for each TCDn_CSR associated with a channel using dynamic scatter/gather.

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the TCDn_CSR[DREQ] field to 1 will prevent future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the 16-bit TCDn_CSR control/status field.
5. Test the TCDn_CSR[ESG] request status and TCDn_CSR[MAJORLINKCH] value:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0 and the MAJORLINKCH (ID) did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the MAJORLINKCH (ID) changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

4.5.8.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCDn_DLAST_SGA field as a TCD identification (ID).

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the DREQ field to 1 will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the TCDn_CSR[ESG] field.
5. Test the TCDn_CSR[ESG] request status:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0, read the 32-bit TCDn_DLAST_SGA field.
   - If ESG = 0 and the TCDn_DLAST_SGA did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the TCDn_DLAST_SGA changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

4.5.9 Suspend/resume a DMA channel with active hardware service requests

The DMA allows you to move data from memory or peripheral registers to another location in memory or to peripheral registers without CPU interaction. After the DMA and peripherals are configured and active, it is rare but supported to suspend a peripheral's

service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For coherency, you must follow a specific procedure.

4.5.9.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check the DMA's Hardware Request Status (MP_HRS) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ field to 0 on the appropriate DMA channel.

For example, assume the SPI is set as a initiator for transmitting data via a DMA service request when the TXFIFO has an empty slot. The DMA will transfer the next command and data to the TXFIFO upon the request. If you need to suspend the DMA/SPI transfer loop, perform the following steps:

1. Disable the DMA service request at the SPI.
2. Ensure there is no DMA service request from the SPI by verifying that MP_HRS[HRS] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ field to 0. If a service request is present, wait until the request has been processed and the HRS field reads 0.

4.5.9.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting its ERQ field to 1.
2. Enable the DMA service request at the peripheral.

4.6 Memory map and register definition

The eDMA programming model is partitioned into three parts:

1. The first part defines a number of registers providing overall control functions and is known as the management page.
2. The second part corresponds to the channel (CH) control, status, and configuration.
3. The third part corresponds to the local TCD memory.

TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the data movement operation. Each TCDn definition is presented as 11 registers of 16 or 32 bits. See EDMA_TCD register descriptions for details.

TCD initialization

Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

TCD structure

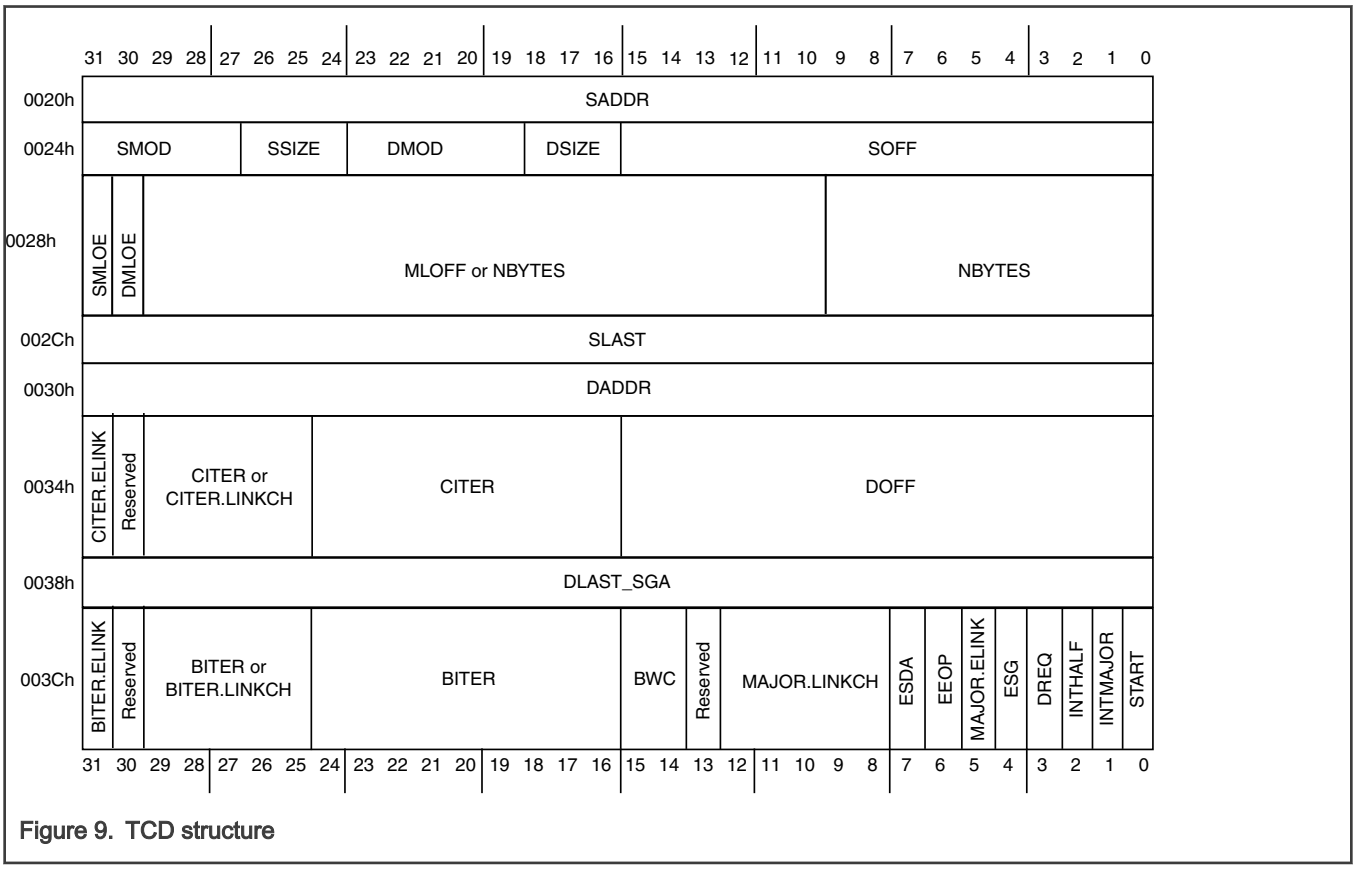

Figure 9. TCD structure

Accesses to reserved memory and fields

- Reading reserved fields in a register returns the value of zero.
- Writes to reserved fields in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

4.6.1 EDMA_MP register descriptions

4.6.1.1 EDMA_MP memory map

EDMA3_1.MP base address: 4400_0000h

NOTE

For registers in the following table with *Protection*, see the REG_PROT details for more information.

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)	Protection
0	Management Page Control (MP_CSR)	32	RW	0031_0000	Yes
4	Management Page Error Status (MP_ES)	32	R	0000_0000	No
8	Management Page Interrupt Request Status (MP_INT)	32	R	0000_0000	No

Table continues on the next page...

Table continued from the previous page...

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)	Protection
C	Management Page Hardware Request Status (MP_HRS)	32	R	0000_0000	No
100 - 178	Channel Arbitration Group (CH0_GRPRI - CH30_GRPRI)	32	RW	0000_0000	Yes

4.6.1.2 Management Page Control (MP_CSR)

The Management Page Control register defines the basic operating configuration of the DMA.

Arbitration uses a two-tier priority system; group and channel priority. The eDMA assigns each channel to a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed priority and may be configured to use a selective round-robin scheme for specified channels within each priority group. For fixed-priority arbitration, eDMA selects for execution the highest priority channel requesting service in the highest priority arbitration group.

The channel priority registers assign the relative priorities within each arbitration group; see CHn_PRI. All channels with a non-zero CHn_PRI value use fixed-priority arbitration.

When you enable round-robin arbitration, all channels with channel priority set to zero do not have a priority and, of those channels requesting service, are cycled through (from high to low channel number) without regard to priority relative to each other within the same priority group. Any channel with a non-zero CHn_PRI value automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH30_GRPRI).

NOTE

For correct operation, changes to the MP_CSR[ERCA, GCLC, GMRC] fields must be performed when the DMA channels are inactive; that is, when the MP_CSR[ACTIVE] field is 0.

Offset

Register	Offset
MP_CSR	0h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Description
31 ACTIVE	DMA Active Status 0 - eDMA is idle 1 - eDMA is executing a channel
30-29 —	Reserved
28-24 ACTIVE_ID	Active Channel ID This field identifies the channel number that is executing when the ACTIVE bit is 1.
23-16 —	Reserved
15-10 —	Reserved
9 CX	Cancel Transfer When set to 1, this field cancels the remaining data transfer, stops the executing channel, and forces the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. CX clears itself to 0 after the cancel has been honored. This cancel retires the channel normally as if the minor loop had been completed. 0 - Normal operation 1 - Cancel the remaining data transfer
8 ECX	Cancel Transfer With Error Cancellation of the remaining data transfer is similar to that of the CX field. Execution of the channel is stopped and the minor loop is forced to finish. The cancellation takes effect after the last write of the current read/write sequence. The ECX field clears itself to 0 after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating Management Page Error Status (MP_ES) and generating an optional error interrupt. 0 - Normal operation 1 - Cancel the remaining data transfer
7 GMRC	Global Initiator ID Replication Control **NOTE** If initiator ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0 - Initiator ID replication disabled for all channels 1 - Initiator ID replication available and controlled by each channel's CHn_SBR[EMI] setting
6	Global Channel Linking Control 0 - Channel linking disabled for all channels

Table continues on the next page...

Table continued from the previous page...

Field	Description
GCLC	1 - Channel linking available and controlled by each channel's link settings
5 HALT	Halt DMA Operations This field stalls the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this field is cleared to 0. 0 - Normal operation 1 - Stall the start of any new channels
4 HAE	Halt After Error When this field is set to 1, any error causes the HALT field to be set to 1. Then all service requests are ignored until the HALT field is cleared to 0. 0 - Normal operation 1 - Any error causes the HALT field to be set to 1
3 —	Reserved
2 ERCA	Enable Round Robin Channel Arbitration 0 - Round-robin channel arbitration disabled. Fixed priority arbitration used for channel selection 1 - Round-robin channel arbitration enabled. Round-robin arbitration used for channel selection
1 EDBG	Enable Debug When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. DMA resumes channel execution when the system exits debug mode or clears the EDBG field to 0. 0 - Debug mode disabled. When in debug mode, the DMA continues to operate 1 - Debug mode is enabled. When in debug mode, the DMA stalls the start of a new channel
0 —	Reserved

4.6.1.3 Management Page Error Status (MP_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus initiator read or write cycle
- An uncorrectable error that occurred when the device was accessing the TCD SRAM
- A "cancel transfer with error" request was made via the corresponding cancel transfer field or input signal

Upon any error condition, the software must initialize the TCD of the channel that contains the error, as it is in an incomplete state after an error. See Fault reporting and handling for more details.

Offset

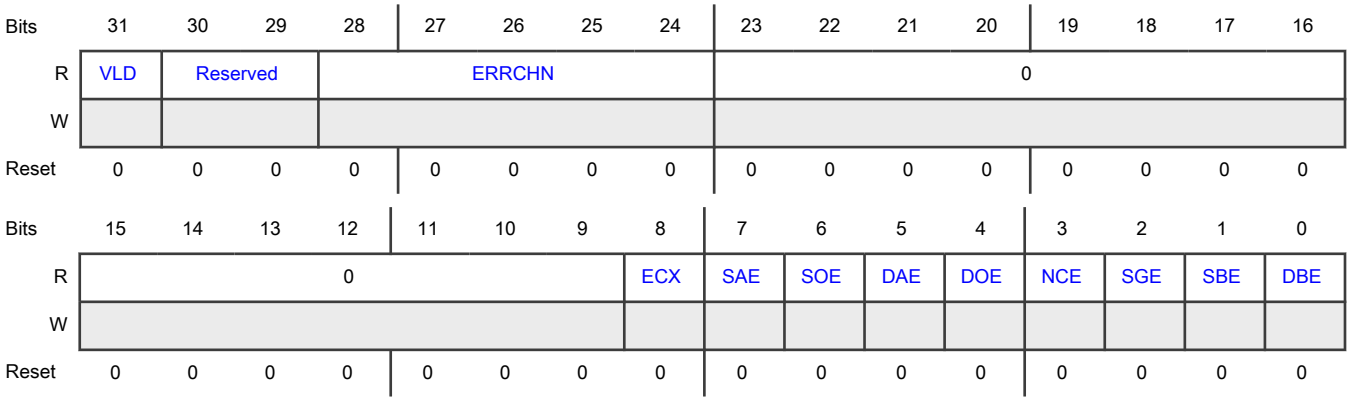
MP_ES	4h

Diagram



Fields

Field	Description
31 VLD	Valid Logical OR of all CHn_ES[ERR] status fields. 0 - No CHn_ES[ERR] fields are set to 1 1 - At least one CHn_ES[ERR] field is set to 1, indicating a valid error exists that software has not cleared
30-29 —	Reserved
28-24 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error or last recorded error-canceled transfer.
23-9 —	Reserved
8 ECX	Transfer Canceled The ECX operation is a management page function. When employed, the targeted channel's CHn_ES register reports an unspecified error; that is, only the CHn_ES[ERR] field is set to 1. The management page has full view of the error condition. 0 - No canceled transfers 1 - Last recorded entry was a canceled transfer by the error cancel transfer input
7	Source Address Error When this field is 1, it indicates that TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].

Table continues on the next page...

Table continued from the previous page...

Field	Description
SAE	0 - No source address configuration error 1 - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error When this field is 1, it indicates that TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0 - No source offset configuration error 1 - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error When this field is 1, it indicates that TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0 - No destination address configuration error 1 - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error When this field is 1, it indicates that TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0 - No destination offset configuration error 1 - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0 - No NBYTES/CITER configuration error 1 - The last recorded error was NBYTES equal to zero or a CITER not equal to BITER error. Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. 0 - No scatter/gather configuration error 1 - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0 - No source bus error 1 - Last recorded error was a bus error on a source read
0	Destination Bus Error

Table continues on the next page...

Table continued from the previous page...

Field	Description
DBE	0 - No destination bus error 1 - Last recorded error was a bus error on a destination write

4.6.1.4 Management Page Interrupt Request Status (MP_INT)

This register shows the current state of the interrupt service requests for all eDMA channels.

Offset

31 —	Reserved
30-0 INT	Interrupt Request Status The INT register presents the interrupt request status for each eDMA channel. Depending on the appropriate field setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion. The eDMA routes channel interrupt requests to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate field in the channel's interrupt request register, CHn_INT, thus negating the interrupt request. 0b - Interrupt request for corresponding channel not present 1b - Interrupt request for corresponding channel present

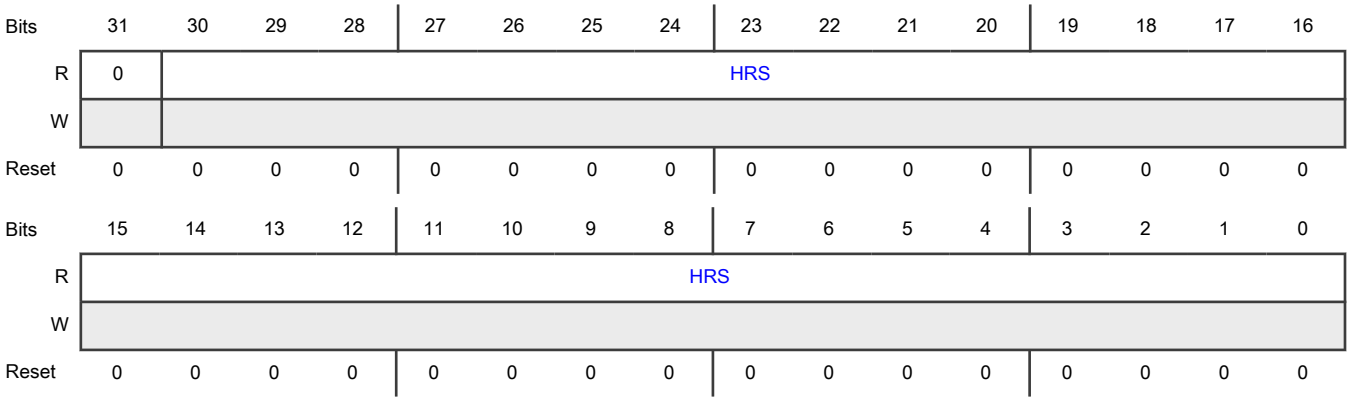
4.6.1.5 Management Page Hardware Request Status (MP_HRS)

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by eDMA's arbitration logic.

Offset

Register	Offset
MP_HRS	Ch

Diagram



Fields

Field	Description
31 —	Reserved
30-0 HRS	Hardware Request Status The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel. 0b - Hardware service request for corresponding channel is not present 1b - Hardware service request for corresponding channel is present

4.6.1.6 Channel Arbitration Group (CH0_GRPRI - CH30_GRPRI)

The contents of this register define the arbitration group associated with each channel. Using a fixed-priority group arbitration scheme, eDMA evaluates the arbitration group priorities by numeric value from highest group number to lowest; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. The range of the group priority values is limited to the values of 0 through 31. Within each arbitration group, the channel priority assignment CH*n*_PRI determines the highest-priority channel.

Offset

For n = 0 to 30:

Register	Offset
CHn_GRPRI	100h + (n × 4h)

4.6.2.2 Channel Control and Status (CH0_CSR - CH30_CSR)

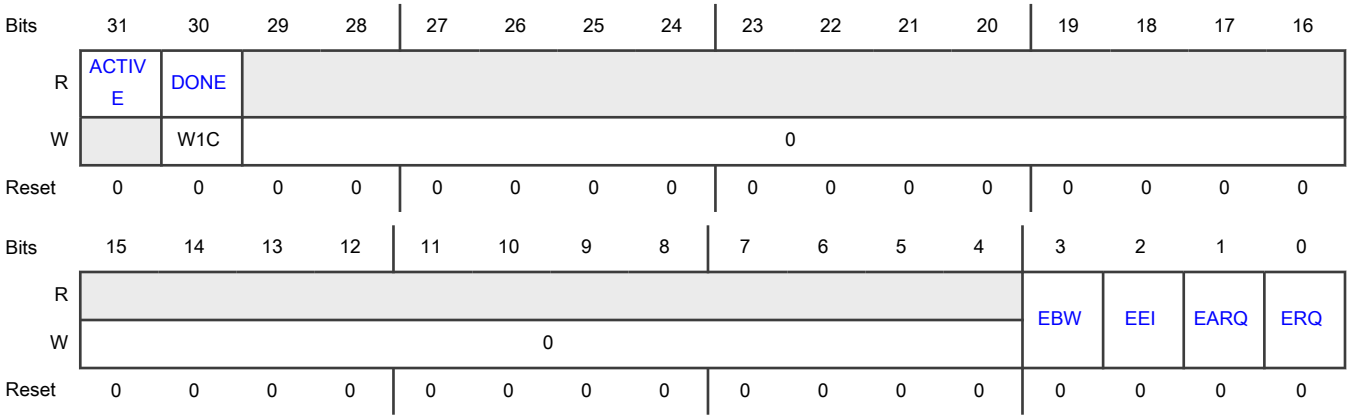
This register contains several fields related to hardware and interrupt requests, configuration, and status for the given channel.

Offset

For n = 0 to 30:

Register	Offset
CHn_CSR	0h + (n × 1_0000h)

Diagram



Fields

Field	Description
31 ACTIVE	Channel Active The ACTIVE field indicates the channel was selected by arbitration and is executing the prescribed transfers. The eDMA sets it to 1 when channel service begins, and clears it to 0 as the minor loop completes or when any error condition is detected. Except for dynamic scatter/gather or dynamic channel linking, you must not modify the transfer control descriptor when a channel is active.
30 DONE	Channel Done The DONE field indicates the eDMA has completed the major loop. The eDMA engine sets this field as the CITER count reaches zero. If enabled, the eDMA generates an interrupt request corresponding to this completed channel. The software clears it, or the hardware clears it when the channel is activated. **NOTE** This field must be cleared to 0 before writing the MAJORELINK or ESG fields.
29-4 —	Reserved
3 EBW	Enable Buffered Writes

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When buffered writes are enabled, all writes except for the last write sequence of the minor loop are signaled by the eDMA as bufferable. 0 - Buffered writes on system bus disabled. Buffered writes on system bus disabled 1 - Buffered writes on system bus enabled. Bufferable write signal asserted on all system bus writes except during last write sequence
2 EEI	Enable Error Interrupt The EEI field enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller. 0 - Error signal for corresponding channel does not generate error interrupt 1 - Assertion of error signal for corresponding channel generates error interrupt request
1 EARQ	Enable Asynchronous DMA Request The enable asynchronous DMA request field (EARQ) does not affect DMA operations. When set to 1, this field allows the hardware service request enable field (ERQ) to propagate out of the DMA to the power controller. When cleared to 0, this field masks the hardware service request enable field to the power controller. 0 - Disable asynchronous DMA request for the channel 1 - Enable asynchronous DMA request for the channel
0 ERQ	Enable DMA Request Disable a channel's hardware service request at the source before clearing the channel's ERQ field. The DMA hardware request input signal and the enable request field (ERQ) must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request field does not affect a channel service request made explicitly through software or channel linking. The state of the ERQ field does not affect the channel's START field. 0 - DMA hardware request signal for corresponding channel disabled 1 - DMA hardware request signal for corresponding channel enabled

4.6.2.3 Channel Error Status (CH0_ES - CH30_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus initiator read or write cycle

The ERR field signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the CHn_CSR[EEI] field, then logically summed across all channels to form an error interrupt request, which may be routed to the interrupt controller.

During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when eDMA detects an error. The contents of this ERR register field can also be polled because a non-zero value indicates the presence of a channel error, regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing a 1 to the ERR field clears the channel's error status, and writing a 0 has no effect.

An unspecified error, where only the ERR field is set to 1, indicates that either a transfer was cancelled with an error. The Management Page Error Status register has full view of the error condition.

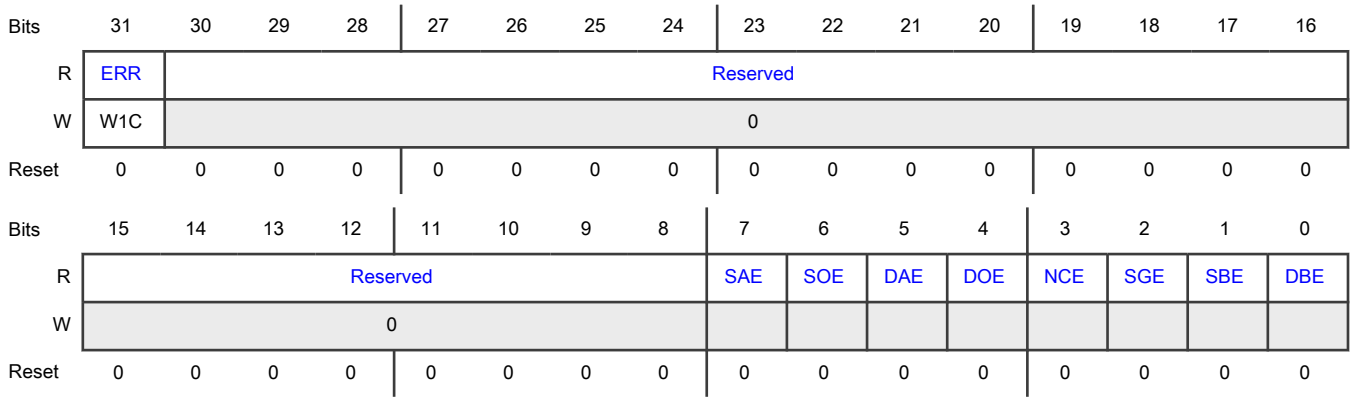
See Fault reporting and handling for more details.

Offset

For n = 0 to 30:

Register	Offset
CHn_ES	4h + (n × 1_0000h)

Diagram



Fields

Field	Description
31 ERR	Error In Channel 0 - An error in this channel has not occurred 1 - An error in this channel has occurred
30-8 —	Reserved
7 SAE	Source Address Error TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0 - No source address configuration error 1 - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0 - No source offset configuration error

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0 - No destination address configuration error 1 - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0 - No destination offset configuration error 1 - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0 - No NBYTES/CITER configuration error 1 - Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG]is enabled. 0 - No scatter/gather configuration error 1 - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0 - No source bus error 1 - Last recorded error was bus error on source read
0 DBE	Destination Bus Error 0 - No destination bus error 1 - Last recorded error was bus error on destination write

4.6.2.4 Channel Interrupt Status (CH0_INT - CH30_INT)

The INT field signals the presence of an interrupt request for the channel. Depending on the appropriate bit setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion.

The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. On writes to INT, a 1 clears the channel's interrupt request. A zero has no effect on the channel's current interrupt status.

Offset

For n = 0 to 30:

Register	Offset
CHn_INT	8h + (n × 1_0000h)

Diagram

4.6.2.5 Channel System Bus (CH0_SBR - CH30_SBR)

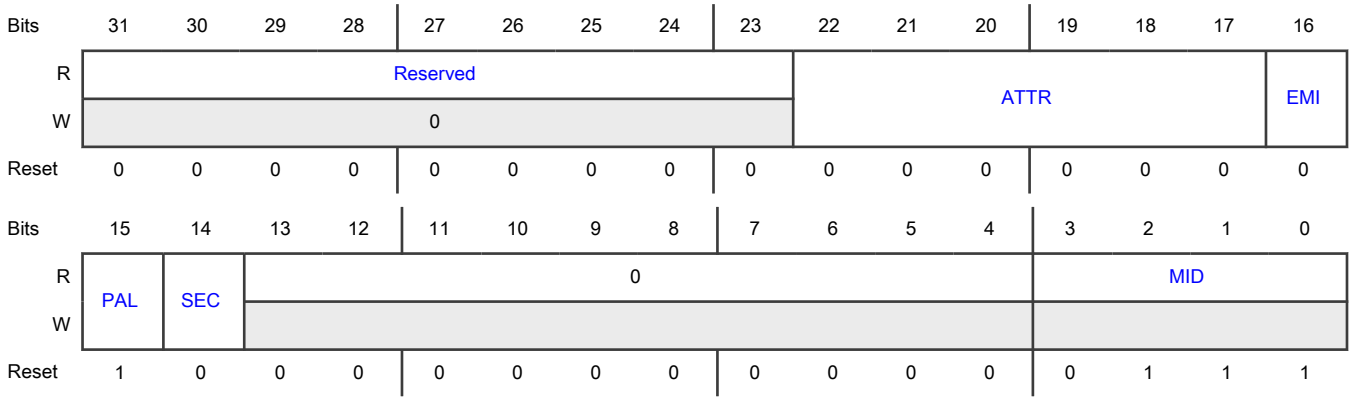
The Channel System Bus register places identification and attribute information on the system bus interface for the eDMA.

Offset

For n = 0 to 30:

Register	Offset
CHn_SBR	Ch + (n × 1_0000h)

Diagram



Fields

Field	Description
31-23 —	Reserved
22-17 ATTR	Attribute Output DMA's system bus attribute output value.
16 EMI	Enable Initiator ID Replication The eDMA initiator ID replication field allows the eDMA to use the same protection level and system bus ID of the initiator programming the eDMA's TCD. When enabled, the eDMA uses the initiator ID and protection level stored in the CHn_SBR registers, instead of the eDMA's default values. When a initiator (for example a core) programs a TCD, its initiator ID is captured when the TCD*n*_CSR control attributes are written. A scatter/gather operation does not affect the CHn_SBR registers. You can write the EMI only if MP_CSR[GMRC] = 1, which means Global Initiator ID Replication Control is enabled; otherwise, the EMI is forced to zero. **NOTE** If initiator ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0 - Initiator ID replication is disabled 1 - Initiator ID replication is enabled
15 PAL	Privileged Access Level This field controls DMA's protection level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other initiator writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0 - User protection level for DMA transfers 1 - Privileged protection level for DMA transfers

Table continues on the next page...

Table continued from the previous page...

Field	Description
14 SEC	Security Level DMA's security level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other initiator writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0 - Nonsecure protection level for DMA transfers 1 - Secure protection level for DMA transfers
13-4 —	Reserved
3-0 MID	Initiator ID This field controls the DMA's initiator ID on the system bus when the channel is active. **NOTE** The ID captured in this register reflects the initiator ID of the core or other initiator writing the channel's security attributes, TCD*n*_SBR[SEC].

4.6.2.6 Channel Priority (CH0_PRI - CH30_PRI)

The contents of these registers define unique priorities associated with each channel within the same channel group. Channel grouping is programmed via Channel Arbitration Group (CH0_GRPRI - CH30_GRPRI).

The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, channel numbers with the same, non-zero value, will be selected based on channel number with the higher channel number having higher priority.

If more than one channel in a group has an arbitration priority level value of zero, then the arbitration mode field MP_CSR[ERCA] is used to determine the arbitration scheme for all channels with APL=0 within a group.

When you enable round-robin channel arbitration (MP_CSR[ERCA] = 1), all channels with APL=0 within a group will use a round-robin arbitration scheme, which rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group.

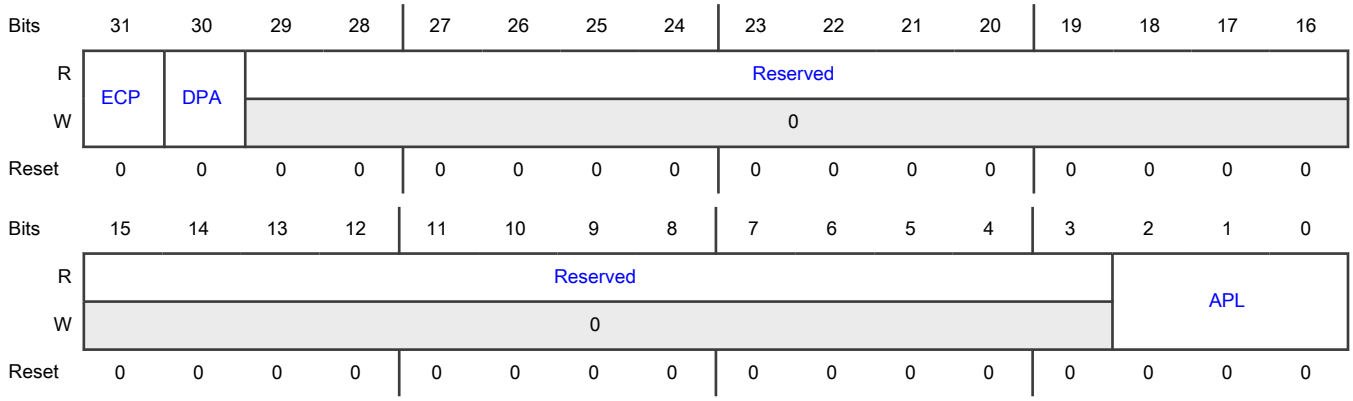
When you enable fixed-priority channel arbitration (MP_CSR[ERCA] = 0), eDMA selects channels with APL=0 based on channel number, with the higher channel number having higher priority.

Offset

For n = 0 to 30:

Register	Offset
CHn_PRI	10h + (n × 1_0000h)

Diagram



Fields

Field	Description
31 ECP	Enable Channel Preemption 0 - Channel cannot be suspended by a higher-priority channel's service request 1 - Channel can be temporarily suspended by a higher-priority channel's service request
30 DPA	Disable Preempt Ability 0 - Channel can suspend a lower-priority channel 1 - Channel cannot suspend any other channel, regardless of channel priority
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Channel priority level for arbitration within the assigned arbitration group.

4.6.2.7 TCD Source Address (TCD0_SADDR - TCD30_SADDR)

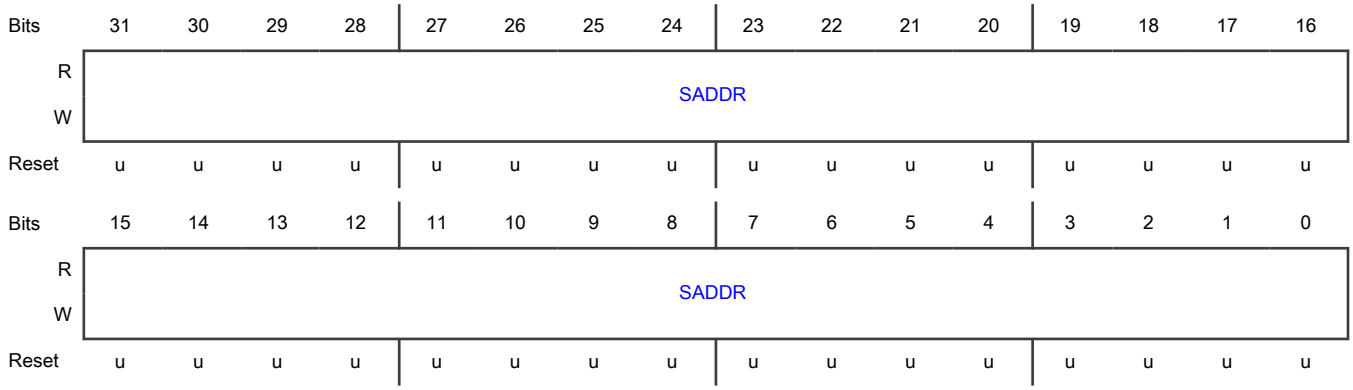
This register contains the address for the read transactions.

Offset

For n = 0 to 30:

Register	Offset
TCDn_SADDR	20h + (n × 1_0000h)

Diagram



Fields

Field	Description
31-0 SADDR	Source Address Memory address pointing to the source data.

4.6.2.8 TCD Signed Source Address Offset (TCD0_SOFF - TCD30_SOFF)

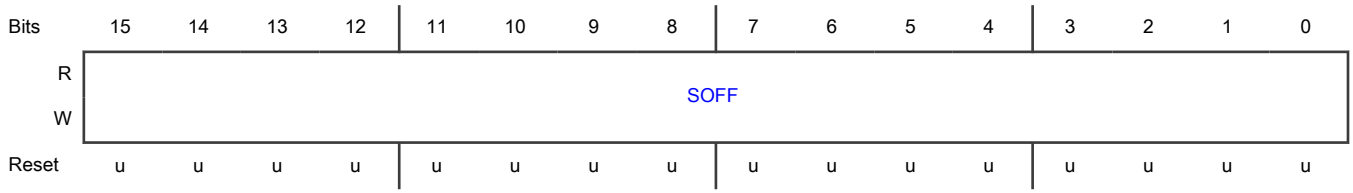
This register contains the sign-extended value added to Source Address register after each read transaction.

Offset

For n = 0 to 30:

Register	Offset
TCDn_SOFF	24h + (n × 1_0000h)

Diagram



Fields

Field	Description
15-0 SOFF	Source Address Signed Offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

4.6.2.9 TCD Transfer Attributes (TCD0_ATTR - TCD30_ATTR)

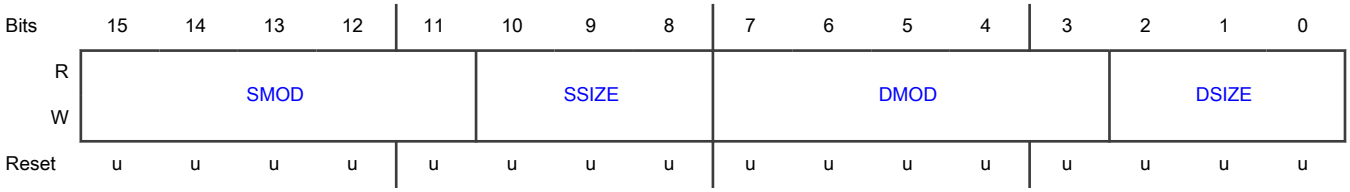
This register contains size and option modulo addressing information for source and destination addresses.

Offset

For n = 0 to 30:

Register	Offset
TCDn_ATTR	26h + (n × 1_0000h)

Diagram



Fields

Field	Description
15-11 SMOD	Source Address Modulo This field defines a specific address range, which is the value after the SADDR + SOFF calculation is performed on the original register value. Setting this field makes it easy to implement a circular data queue. For data queues requiring power-of-2-sized bytes, the queue must start at a 0-modulo-size address and the SMOD field must be set to the appropriate value for the queue, freezing the required number of upper address bits. The value programmed into this field specifies the number of lower address bits that are allowed to change. For a circular queue application, you typically set TCDn_SOFF[SOFF] to the transfer size to implement post-increment addressing, with the SMOD function constraining the addresses to a 0-modulo-size range. 0_0000 - Source address modulo feature disabled
10-8 SSIZE	Source Data Transfer Size 000 - 8-bit 001 - 16-bit 010 - 32-bit 011 - 64-bit 100 - 16-byte 101 - 32-byte 110 - 64-byte 111 - Reserved
7-3	Destination Address Modulo

Table continues on the next page...

Table continued from the previous page...

Field	Description
DMOD	See the SMOD definition.
2-0 DSIZE	Destination Data Transfer Size See the SSIZE definition.

4.6.2.10 TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD30_NBYTES_MLOFFNO)

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR), or destination address (TCDn_DADDR), upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. When minor loop offsets are enabled, the minor loop offset value (TCDn_NBYTES_MLOFFYES[MLOFF]) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both, prior to the addresses being written back to the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (SMLOE or DMLOE is 1), TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is redefined. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is used to specify multiple fields:

- A source enable bit (SMLOE) to specify the minor loop offset must be applied to the source address (TCDn_SADDR) upon minor loop completion
- A destination enable bit (DMLOE) to specify the minor loop offset must be applied to the destination address (TCDn_DADDR) upon minor loop completion
- The sign extended minor loop offset value (MLOFF)

The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is defined as follows:

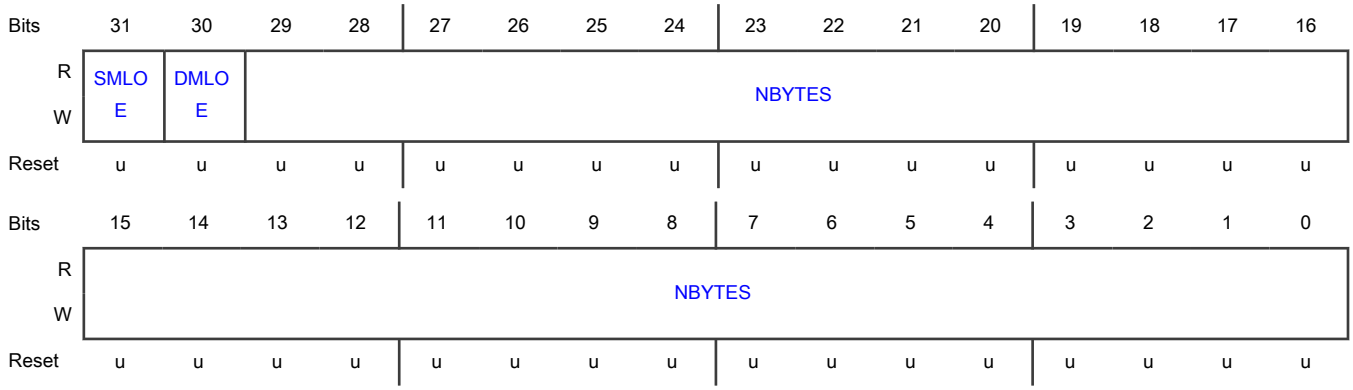
- If SMLOE = 0 and DMLOE = 0, then see the TCDn_NBYTES_MLOFFNO register description.
- If either SMLOE or DMLOE is 1, then see the TCDn_NBYTES_MLOFFYES register description.

Offset

For n = 0 to 30:

Register	Offset
TCDn_NBYTES_MLOFFNO	28h + (n × 1_0000h)

Diagram



Fields

Field	Description
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 - Minor loop offset not applied to SADDR 1 - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 - Minor loop offset not applied to DADDR 1 - Minor loop offset applied to DADDR
29-0 NBYTES	Number of Bytes To Transfer Per Service Request Number of bytes to be transferred for each service request of the channel. When a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the byte transfer count has been reached. This process is normally an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the byte count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is complete, additional processing is performed.

4.6.2.11 TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD30_NBYTES_MLOFFYES)

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offset is an address offset value added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion occurs when the channel has finished the service request and has transferred NBYTES. Minor loop offsets are enabled by setting either the source enable bit (SMLOE) or the destination enable bit (DMLOE).

The source enable bit (SMLOE) specifies the minor loop offset value (MLOFF) that is to be applied to the source address (TCDn_SADDR) upon minor loop completion. The destination enable bit (DMLOE) specifies the minor loop offset (MLOFF) that is to be applied to the destination address (TCDn_DADDR) upon minor loop completion.

If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When you enable the minor loop offset overlay (either SMLOE or DMLOE is 1), eDMA redefines TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES specifies the sign-extended minor loop offset value (MLOFF). The same offset value (MLOFF) applies to both source and destination minor loop offsets. When the minor loop offset is enabled, you must align it to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFNO) defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFYES is defined as follows:

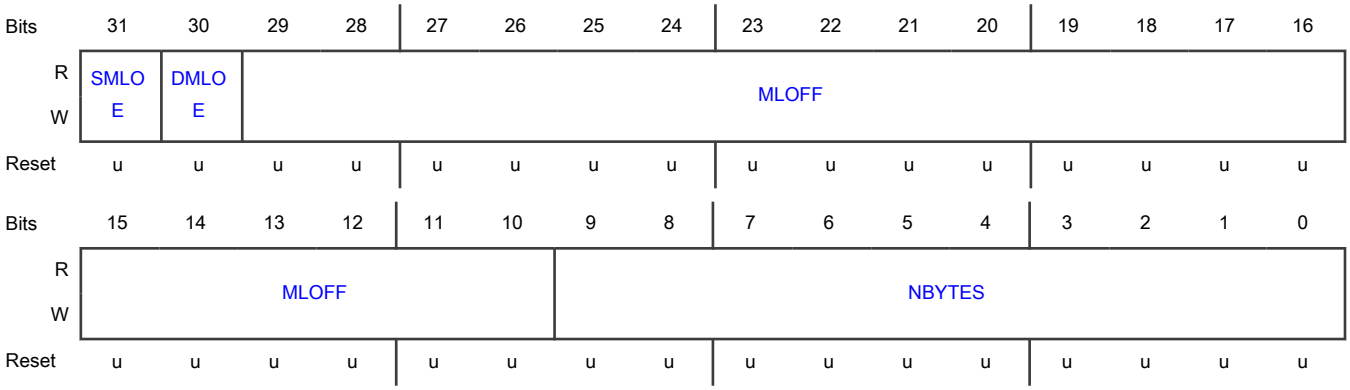
- If either minor loop offset is enabled (SMLOE or DMLOE = 1), then see the TCDn_NBYTES_MLOFFYES register description.
- If SMLOE and DMLOE are both 0, then see the TCDn_NBYTES_MLOFFNO register description.

Offset

For n = 0 to 30:

Register	Offset
TCDn_NBYTES_MLOFFYES	28h + (n × 1_0000h)

Diagram



Fields

Field	Description
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 - Minor loop offset not applied to SADDR

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 - Minor loop offset not applied to DADDR 1 - Minor loop offset applied to DADDR
29-10 MLOFF	Minor Loop Offset If SMLOE or DMLOE is 1, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
9-0 NBYTES	Number of Bytes To Transfer Per Service Request The number of bytes to be transferred in each service request of the channel. As a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the minor byte transfer count has been reached. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is complete, additional processing is performed.

4.6.2.12 TCD Last Source Address Adjustment / Store DADDR Address (TCD0_SLAST_SDA - TCD30_SLAST_SDA)

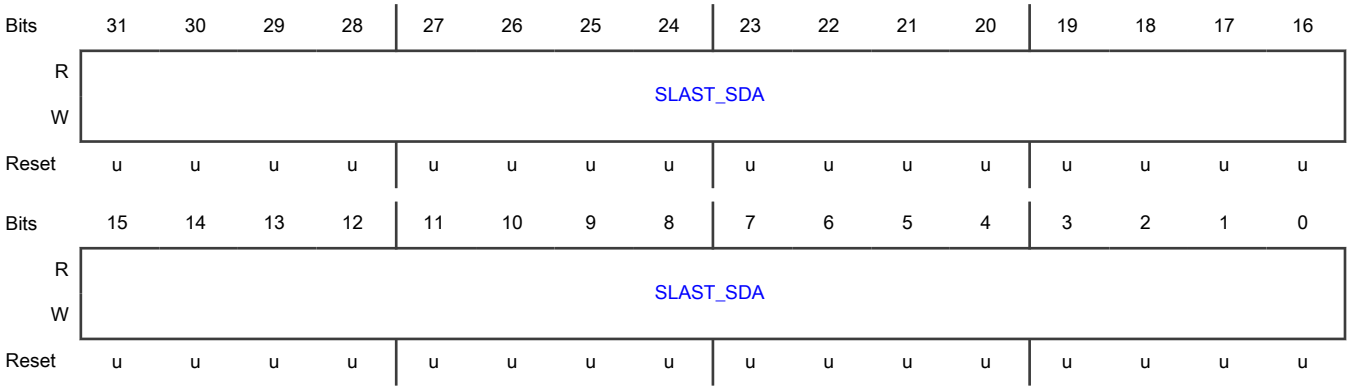
This register contains the value added to the source address when the major loop is complete. When the store destination address option is enabled, this field provides a pointer to memory for storing the final destination address.

Offset

For n = 0 to 30:

Register	Offset
TCDn_SLAST_SDA	2Ch + (n × 1_0000h)

Diagram



Fields

Field	Description
31-0 SLAST_SDA	Last Source Address Adjustment / Store DADDR Address Source last address adjustment or the system memory address for destination address (DADDR) storage. If (TCDn_CSR[ESDA] = 0), then: • Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero.

4.6.2.13 TCD Destination Address (TCD0_DADDR - TCD30_DADDR)

This register contains the address for the write transactions.

Offset

For n = 0 to 30:

Register	Offset
TCDn_DADDR	30h + (n × 1_0000h)

Fields

Field	Description
15-0 DOFF	Destination Address Signed Offset Sign-extended offset that is applied to the current destination address to form the next-state value as each destination write is completed.

4.6.2.15 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD30_CITER_ELINKNO)

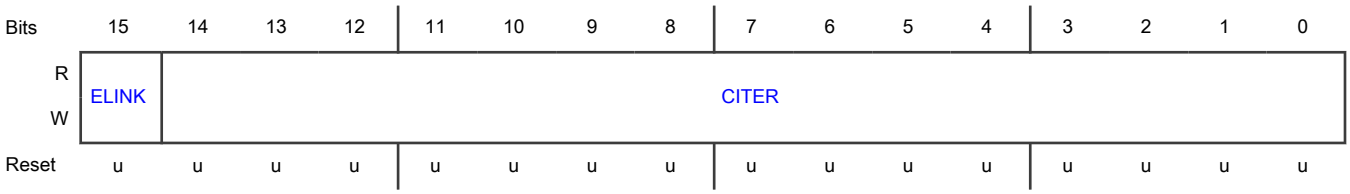
If TCDn_CITER[ELINK] is 0, the TCDn_CITER register is defined as follows.

Offset

For n = 0 to 30:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 1_0000h)

Diagram



Fields

Field	Description
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel to 1. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0 - Channel-to-channel linking disabled 1 - Channel-to-channel linking enabled
14-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

4.6.2.16 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD30_CITER_ELINKYES)

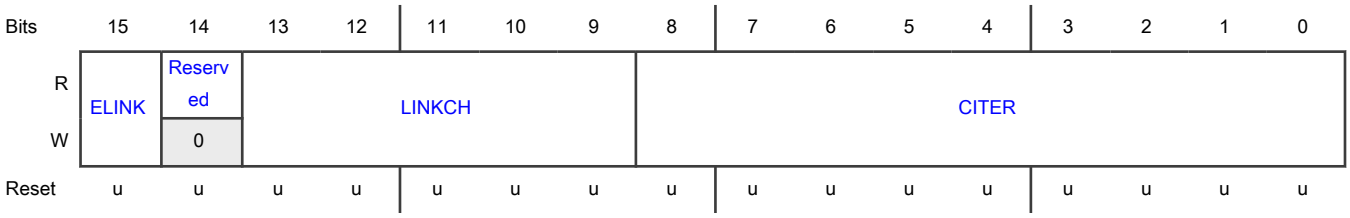
If TCDn_CITER[ELINK] is 1, the TCDn_CITER register is defined as follows.

Offset

For n = 0 to 30:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 1_0000h)

Diagram



Fields

Field	Description
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. When enabled, an internal mechanism sets the TCDn_CSR[START] field of the specified channel (LINKCH) upon minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0 - Channel-to-channel linking disabled 1 - Channel-to-channel linking enabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
14 —	Reserved
13-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted the eDMA engine initiates a channel service request to the channel defined by this field by writing that channel's TCDn_CSR[START] field to 1.
8-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

4.6.2.17 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD30_DLAST_SGA)

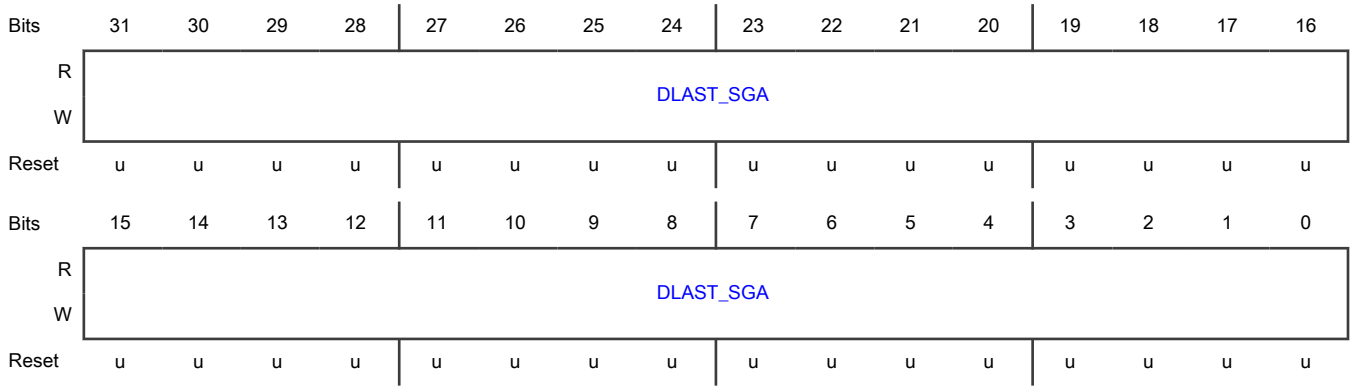
This register contains the value added to the destination address when the major loop is complete. When the Scatter/Gather option is enabled, this field provides a pointer to memory for fetching a transfer control descriptor to reprogram the channel.

Offset

For n = 0 to 30:

Register	Offset
TCDn_DLAST_SGA	38h + (n × 1_0000h)

Diagram



Fields

Field	Description
31-0 DLAST_SGA	Last Destination Address Adjustment / Scatter Gather Address Adjustment of the last destination address or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value is added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo 32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo 32-byte, or else a configuration error is reported.

4.6.2.18 TCD Control and Status (TCD0_CSR - TCD30_CSR)

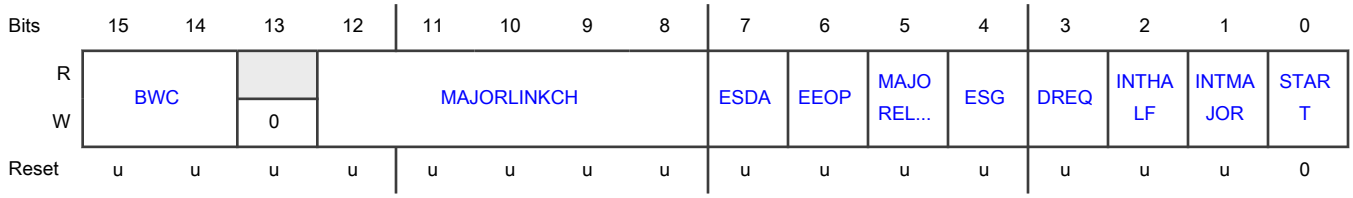
This register is used to enable optional features.

Offset

For n = 0 to 30:

Register	Offset
TCDn_CSR	3Ch + (n × 1_0000h)

Diagram



Fields

Field	Description
15-14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces eDMA to stall after the completion of each read/write access, to control the bus request bandwidth seen by the system bus interconnect. **NOTE** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00 - No eDMA engine stalls 01 - Reserved 10 - eDMA engine stalls for 4 cycles after each R/W 11 - eDMA engine stalls for 8 cycles after each R/W
13 —	Reserved
12-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field to 1.
7 ESDA	Enable Store Destination Address As the channel completes the major loop by either the current iteration counter (CITER) decrementing to 0, or by receiving an enabled end-of-packet signal, this field enables writing the destination address (DADDR) to the address stored in the SLAST_SDA field. The value written to system memory is the next DADDR value prior to the DLAST_SGA offset being applied, or overwritten by an enabled scatter/gather operation. When the ESDA bit is 1, SLAST_SDA contains the write pointer instead of the final source address offset. Because this is a pointer and not a final offset, a last source address offset of zero is applied to SADDR instead of the SLAST_SGA value. 0 - Ability to store destination address to system memory disabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Ability to store destination address to system memory enabled
6 EEOP	Enable End-Of-Packet Processing When enabled by the EEOP field, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel, and to treat the shutdown as the major-loop-completed event. If the EEOP field is 1, the end-of-packet signal from supported peripherals is accepted. If the EEOP field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA-saved destination address), minus the software-saved initial address (DADDR), reflects the total amount of data transferred. 0 - End-of-packet operation disabled 1 - End-of-packet hardware input signal enabled
5 MAJORELINK	Enable Link When Major Loop Complete As the channel completes the major loop, this flag enables linking to another channel defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0 - Channel-to-channel linking disabled 1 - Channel-to-channel linking enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses TCDn_DLAST_SGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure, which is loaded as the transfer control descriptor into local memory. **NOTE** To support the dynamic scatter/gather coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0 - Current channel's TCD is normal format 1 - Current channel's TCD specifies scatter/gather format.
3 DREQ	Disable Request If this flag is 1, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches 0. 0 - No operation. Channel's ERQ field not affected 1 - Clear the ERQ field to 0 upon major loop completion, thus disabling hardware service requests. Channel's ERQ field cleared to 0 when major loop complete
2	Enable Interrupt If Major Counter Half-complete

Table continues on the next page...

Table continued from the previous page...

Field	Description
INTHALF	If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use INTHALF; use INTMAJOR instead. 0 - Halfway point interrupt disabled 1 - Halfway point interrupt enabled
1 INTMAJOR	Enable Interrupt If Major count complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count (CITER) reaches 0. 0 - End-of-major loop interrupt disabled 1 - End-of-major loop interrupt enabled
0 START	Channel Start If this flag is 1, the channel is requesting service. The eDMA hardware automatically clears this flag to 0 after the channel begins execution. 0 - Channel not explicitly started 1 - Channel explicitly started via a software-initiated service request

4.6.2.19 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD30_BITER_ELINKNO)

If the TCDn_BITER[ELINK] field is 0, the TCDn_BITER register is defined as follows.

Offset

For n = 0 to 30:

Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 1_0000h)

Fields

Field	Description
15 ELINK	Enables Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0 - Channel-to-channel linking disabled 1 - Channel-to-channel linking enabled
14-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

4.6.2.20 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD30_BITER_ELINKYES)

If the TCDn_BITER[ELINK] field is set, the TCDn_BITER register is defined as follows.

Offset

For n = 0 to 30:

Register	Offset
TCDn_BITER_ELINKYES	3Eh + (n × 1_0000h)

Diagram

Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

The Enhanced Direct Memory Access Type 4 (eDMA4) is an AXI-based 32-bit-addressing-capable eDMA module. For the rest of the chapter, eDMA refers to the eDMA4 type. There is one instance of eDMA4 in the Wakeup domain. This is called the eDMA4_2 instance.

5.2 Overview

eDMA is a highly programmable data-transfer engine that performs complex data transfers with minimal intervention from a host processor. You can use it in applications where the data size to be transferred is statically known and not defined within the transferred data.

The eDMA microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing TCDs for each of the 64 channels

5.2.1 Block diagram

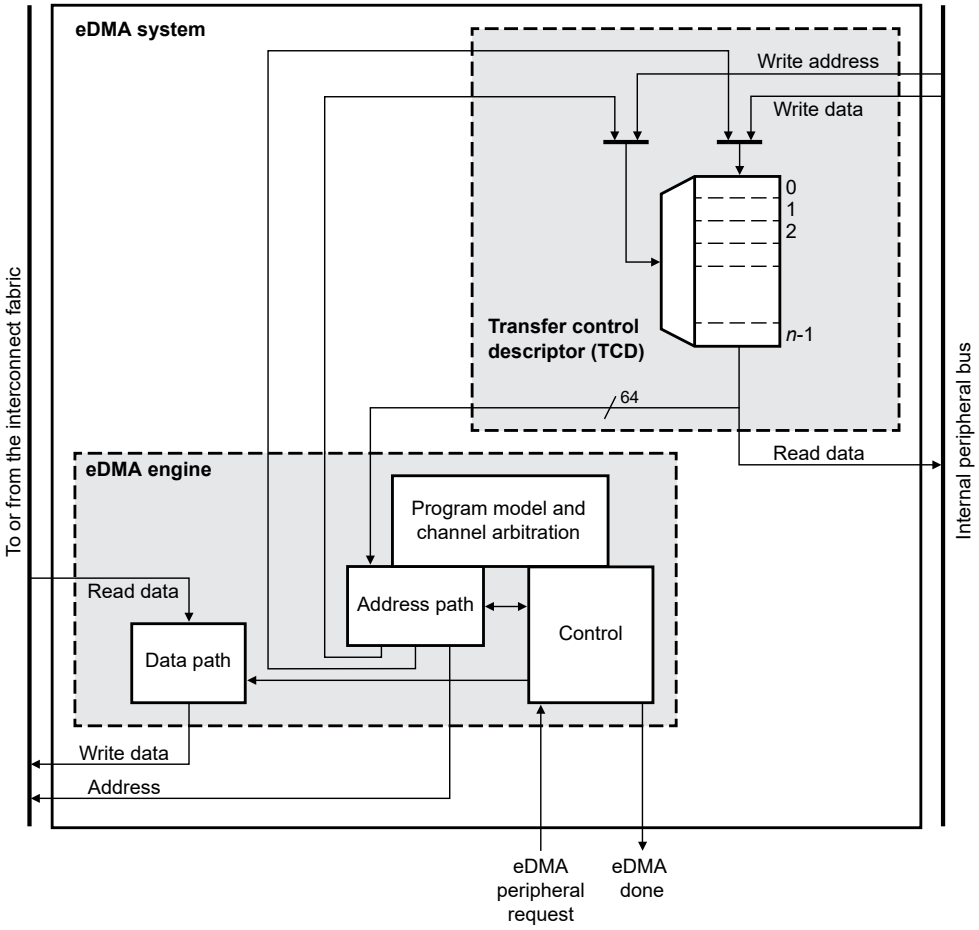

Figure 10. Block diagram

5.2.2 Block parts

eDMA is partitioned into two major modules: the eDMA engine and the TCD local memory.

Table 21 shows the submodules that the eDMA engine is partitioned into.

Table 21. eDMA engine submodules

Submodule	Function
Address path	Implements registered versions of the following channel TCDs: • Primary channel • Secondary (preempt) channel Additionally, this submodule manages all controller bus-address calculations. All channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher-priority channel activation is asserted when the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless a higher-priority channel preempts it. This provides a mechanism (enabled by CH0_PRI[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution.

Table continues on the next page...

Table 21. eDMA engine submodules (continued)

Submodule	Function
	When you select a channel to execute, the contents of its TCD are read from local memory and loaded into the address path channel *x* registers for a normal start and into channel *y* registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for TCD*n*[SADDR], TCD*n*[DADDR], and TCD*n*[CITER] back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading TCD*n*_CITER, and a possible fetch of the next TCD*n* from memory as part of a scatter/gather operation.
Data path	Implements the bus controller read/write datapath. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the two-stage pipelined internal bus. The address path submodule represents the first stage of the bus pipeline (address phase), while the data path module implements the second stage of the pipeline (data phase).
Program model and channel arbitration	Implements the first section of the eDMA programming model and channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via the control logic).
Control	Describes the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the small-size data are required for each reference of the larger size. For example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed followed by a one 32-bit write.

Table 22 shows further partitioning of the TCD local memory.

Table 22. Transfer control descriptor memory

Submodule	Description
Memory controller	Implements the required dual-ported controller, managing accesses from the eDMA engine and references from the internal peripheral bus. If there are simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

5.2.3 Features

- Facilitates data movement through dual-address transfers read from source, write to destination plus a write-only initialization mode:
  - Programmable source and destination addresses and transfer size
  - Support for complex address calculations
- Supports 64-channel implementation that performs complex data transfers with minimal intervention from a host processor:
  - Internal data buffer, used as temporary storage to support large multibyte transfers
  - Connections to the interconnect fabric for bus mastering the data movement
- Supports a TCD that is organized to support two-deep, nested transfer operations:
  - 32-byte TCD stored in local memory for each channel

  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Initializes channel activation through one of the following methods:
  - Explicit software initiation
  - Initiation through channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Supports fixed-priority and round-robin channel arbitration
- Reports channel completion reported through programmable interrupt requests:
  - One interrupt per channel, which can be asserted after the completion of a major iteration count
  - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Provides programmable support for the scatter/gather DMA processing
- Provides support for complex data structures

eDMA uses *n* for reference to the channel number.

5.3 eDMA register descriptions

The eDMA's programming model is partitioned into three parts:

- The first part defines the number of registers providing the overall control functions: the management page.
- The second part corresponds to the channel (CH) control, status, and configuration.
- The third part corresponds to the local TCD memory.

5.3.1 TCD memory

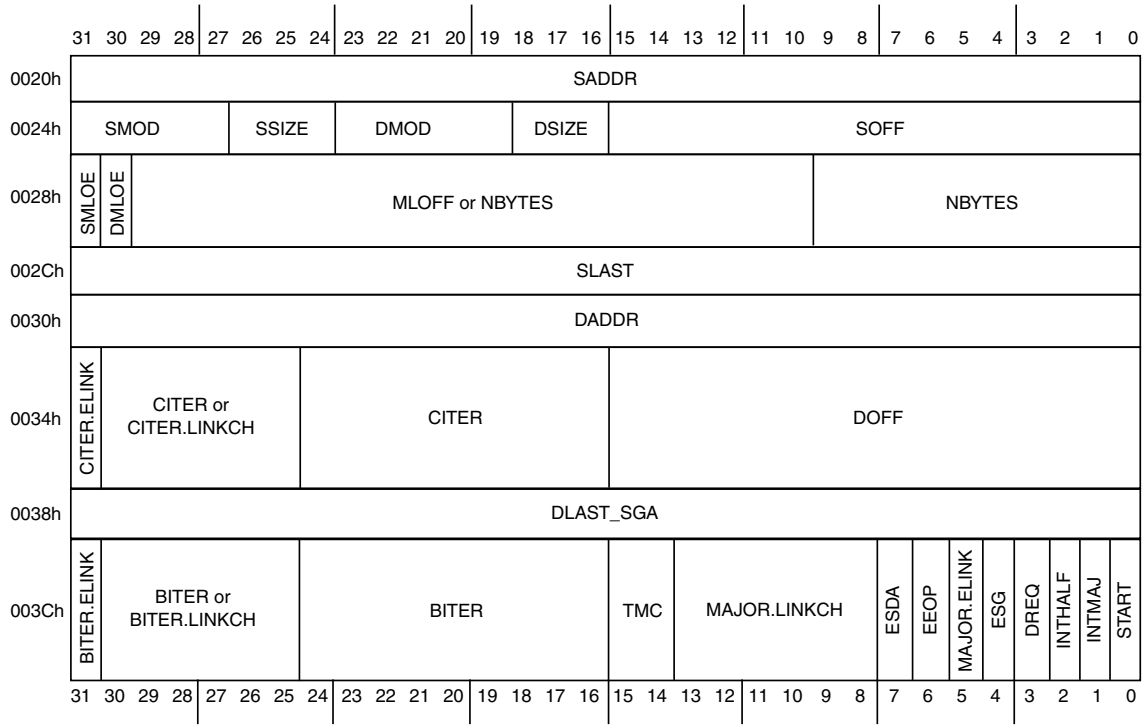
Each channel requires a 32-byte TCD for defining the desired data movement operation. The local memory stores the channel descriptors in a sequential order: channel 0, channel 1, ... channel 63.

This table provides a 32-bit view of the eDMA memory map.

5.3.2 TCD initialization

The TCD memory is in an unknown state after reset. Only the TCD START bit is initialized to 0. Before activating a channel, you must initialize its TCD with the appropriate transfer profile.

5.3.3 TCD structure



5.3.3.1 Reserved memory and bit fields

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading or writing to a reserved memory location generates a bus error.

5.3.4 EDMA4_MP register descriptions

5.3.4.1 EDMA4_MP memory map

EDMA4_2.MP base address: 4200_0000h

NOTE

For registers in the following table with *Protection*, see the REG_PROT details for more information.

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)	Protection
0	Management Page Control (CSR)	32	RW	0040_0000	No
4	Management Page Error Status (ES)	32	R	0000_0000	No
8	Management Page Interrupt Request Status Register - Low (INT_LOW)	32	R	0000_0000	No

Table continues on the next page...

Table continued from the previous page...

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)	Protection
C	Management Page Interrupt Request Status Register-High (INT_HIGH)	32	R	0000_0000	No
10	Management Page Hardware Request Status Register - Low (HRS_LOW)	32	R	0000_0000	No
14	Management Page Hardware Request Status Register - High (HRS_HIGH)	32	R	0000_0000	No
100 - 1FC	Channel Arbitration Group (CH0_GRPRI - CH63_GRPRI)	32	RW	0000_0000	No

5.3.4.2 Management Page Control (CSR)

Defines the basic operating configuration of DMA.

Arbitration uses a two-tier priority system: group and channel priority. Each channel is assigned a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed-priority, and you can configure it to use a selective round-robin scheme for specified channels within each priority group.

For fixed-priority arbitration, select the highest-priority channel requesting service in the highest-priority arbitration group to execute. The channel priority registers assign the relative priorities within each arbitration group (see Channel Priority (CH0_PRI - CH63_PRI)). All channels with a nonzero value in Channel Priority (CH0_PRI - CH63_PRI) use fixed-priority arbitration.

When you enable round-robin arbitration, any channel with its channel priority set to 0 does not have a priority. The channels requesting service are cycled through (from high to low channel number) without considering the relative priority within the same priority group. Any channel with a nonzero value in Channel Priority (CH0_PRI - CH63_PRI) automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH63_GRPRI).

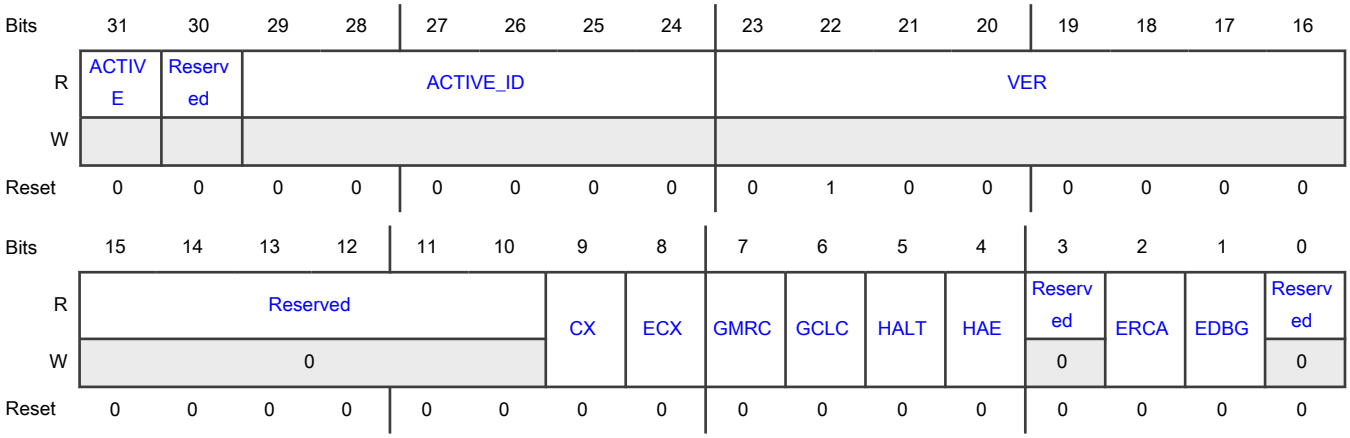
NOTE

For correct operation, perform changes to ERCA, GCLC, and GMRC when the DMA channels are inactive; that is, when ACTIVE is 0.

Offset

Register	Offset
CSR	0h

Diagram



Fields

Field	Description
31 ACTIVE	DMA Active Status Indicates whether eDMA is executing a channel. 0 - Idle 1 - Executing
30 —	Reserved
29-24 ACTIVE_ID	Active Channel ID Indicates the active channel ID.
23-16 VER	eDMA Version Indicates the eDMA version.
15-10 —	Reserved
9 CX	Cancel Transfer Cancels the remaining data transfer. If this field is 1, it stops the executing channel and forces the minor loop to finish. The transfer cancelation takes effect after the last write of the current read/write sequence. The field becomes 0 after the cancel is honored. This cancel retires the channel normally as if the minor loop is completed. 0 - Normal operation 1 - Cancel transfer
8 ECX	Cancel Transfer with Error

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Cancels the remaining data transfer (similar to CX) and treats the transfer cancelation as an error condition, updates the Error Status register (DMA*n*_ES), and generates an optional error interrupt. If this field is 1, it stops the executing channel and forces the minor loop to finish. The transfer cancelation takes effect after the last write of the current read/write sequence. This field becomes 0 after the cancelation is honored. 0 - Normal operation 1 - Cancel transfer
7 GMRC	Global Master ID Replication Control Specifies whether the master ID replication is available. If this field is 1, the master ID replication is available and is controlled by the configuration of CH0_SBR[EMI] for each channel. **NOTE** If master ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0 - Not available 1 - Available
6 GCLC	Global Channel Linking Control Specifies whether channel linking is available and controlled by each channel's link settings. 0 - Disable 1 - Available
5 HALT	Halt DMA Operations Specifies whether DMA operations are halted. If this field is 1, it stalls the start of any new channels. The channels in execution are allowed to complete. Channel execution resumes when you write 0 to this field. 0 - Normal operation 1 - Halt
4 HAE	Halt after Error Specifies whether the operation halts after an error. If this field is 1, an error causes HALT to become 1. Subsequently, all service requests are ignored until HALT becomes 0. 0 - Normal operation 1 - Halt
3 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
2 ERCA	Enable Round-Robin Channel Arbitration Enables round-robin channel arbitration. If this field is 0, round-robin channel arbitration is disabled and fixed-priority arbitration is used for channel selection within each group. If this field is 1, round-robin channel arbitration is enabled and is used for channel selection within each group. 0 - Disable 1 - Enable
1 EDBG	Enable Debug Enables Debug mode. If this field is 0, Debug mode is disabled. When in Debug mode, DMA continues to operate. If this field is 1, Debug mode is enabled. When in Debug mode, DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system exits Debug mode or when this field becomes 0. 0 - Disable 1 - Enable
0 —	Reserved

5.3.4.3 Management Page Error Status (ES)

Provides information concerning the last recorded channel error, which can be caused by:

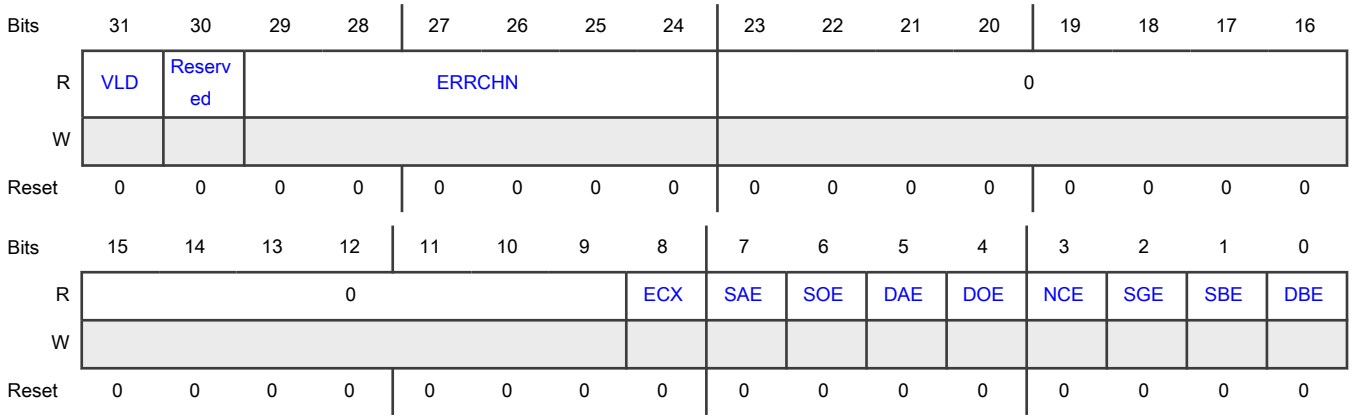
- An illegal setting in TCD.
- An error termination to a bus controller read or write cycle.
- An uncorrectable error occurring when the chip is accessing the TCD SRAM.
- A cancel transfer with error request made through the corresponding cancel transfer bit or input signal.

After an error condition occurs, you must initialize the errant channel's TCD as it is in an incomplete state after an error. See Fault reporting and handling for details.

Offset

Register	Offset
ES	4h

Diagram



Fields

Field	Description
31 VLD	Valid Indicates the logical OR of all ERR status bits. If this field is 1, it indicates that at least one ERR bit is set, indicating an existing valid error that has not been cleared. 0 - No bits are set 1 - At least one bit is set
30 —	Reserved
29-24 ERRCHN	Error Channel Number or Canceled Channel Number Indicates the channel number of the last recorded error or last recorded error canceled transfer.
23-9 —	Reserved
8 ECX	Transfer Canceled Indicates whether the last recorded entry is a canceled transfer by the error cancel transfer input. The ECX operation is a management page function. When this operation is used, the targeted channel's Channel Error Status (CH0_ES - CH63_ES) register reports an unspecified error (only ERR becomes 1). The management page has a complete view of the error condition. 0 - No canceled transfers 1 - Canceled transfers
7 SAE	Source Address Error Indicates whether the last recorded error is a configuration error detected in TCD Source Address (TCD0_SADDR - TCD63_SADDR), which is inconsistent with TCD0_ATTR[SSIZE]. 0 - No error detected

Table continued from the previous page...

Field	Description
	1 - Error detected
6 SOE	Source Offset Error Indicates whether the last recorded error is a configuration error detected in TCD Signed Source Address Offset (TCD0_SOFF - TCD63_SOFF), which is inconsistent with TCD0_ATTR[SSIZE]. 0 - No error detected 1 - Error detected
5 DAE	Destination Address Error Indicates whether the last recorded error is a configuration error detected in TCD Destination Address (TCD0_DADDR - TCD63_DADDR), which is inconsistent with TCD0_ATTR[DSIZE]. 0 - No error detected 1 - Error detected
4 DOE	Destination Offset Error Indicates whether the last recorded error is a configuration error detected in TCD Signed Destination Address Offset (TCD0_DOFF - TCD63_DOFF), which is inconsistent with TCD0_ATTR[DSIZE]. 0 - No error detected 1 - Error detected
3 NCE	NBYTES or CITER Configuration Error Indicates whether NBYTES or CITER configuration error occurred. If this field is 1, the last recorded error is NBYTES equal to zero or a CITER not equal to BITER. Also, the last recorded error is a configuration error detected in TCD*n*_NBYTES or TCD*n*_CITER fields. The configuration error on TCD*n*_NBYTES occurs when TCD*n*_NBYTES is not configured as an integer multiple of TCD0_ATTR[SSIZE] and TCD0_ATTR[DSIZE]. The configuration error on TCD*n*_CITER occurs when TCD*n*_CITER[CITER] is equal to zero or when TCD*n*_CITER[CITER] is not equal to TCD*n*_BITER[ELINK]. 0 - No error detected 1 - Error detected
2 SGE	Scatter/Gather Configuration Error Indicates whether a scatter/gather configuration error is detected. If this field is 1, the last recorded error is a configuration error detected in TCD0_DLAST_SGA[DLAST_SGA]. This field is checked at the beginning of a scatter/gather operation after major loop completion if you enable TCD0_CSR[ESG]. TCD*n*_DLAST_SGA is not on a 32-byte boundary. 0 - No error detected 1 - Error detected
1	Source Bus Error

Table continues on the next page...

Table continued from the previous page...

Field	Description
SBE	Indicates whether the last recorded error is a bus error on a source read. 0 - No error 1 - Error
0 DBE	Destination Bus Error Indicates whether the last recorded error is a bus error on a destination write. 0 - No error 1 - Error

5.3.4.4 Management Page Interrupt Request Status Register - Low (INT_LOW)

This register shows the current state of the interrupt service request for all eDMA channels.

Offset

Register	Offset
INT_LOW	8h

Diagram

Fields

Field	Description
31-0 INT	Interrupt Request Status for channels 31 - 0 The INT register presents the interrupt request status for each eDMA channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion . The eDMA channel interrupt requests are routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit in the channel’s interrupt request register, CHn_INT, thus negating the interrupt request.

Table continues on the next page...

Field	Description
	• 0 - An interrupt request for the corresponding channel is not present. • 1 - An interrupt request for the corresponding channel is present.

5.3.4.5 Management Page Interrupt Request Status Register- High (INT_HIGH)

This register shows the current state of the interrupt service request for all eDMA channels.

Offset

Register	Offset
INT_HIGH	Ch

Fields

Field	Description
31-0 INT	Interrupt Request Status for channels 63-32 The INT register presents the interrupt request status for each eDMA channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion . The eDMA channel interrupt requests are routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit in the channel's interrupt request register, CHn_INT, thus negating the interrupt request. • 0 - An interrupt request for the corresponding channel is not present. • 1 - An interrupt request for the corresponding channel is present.

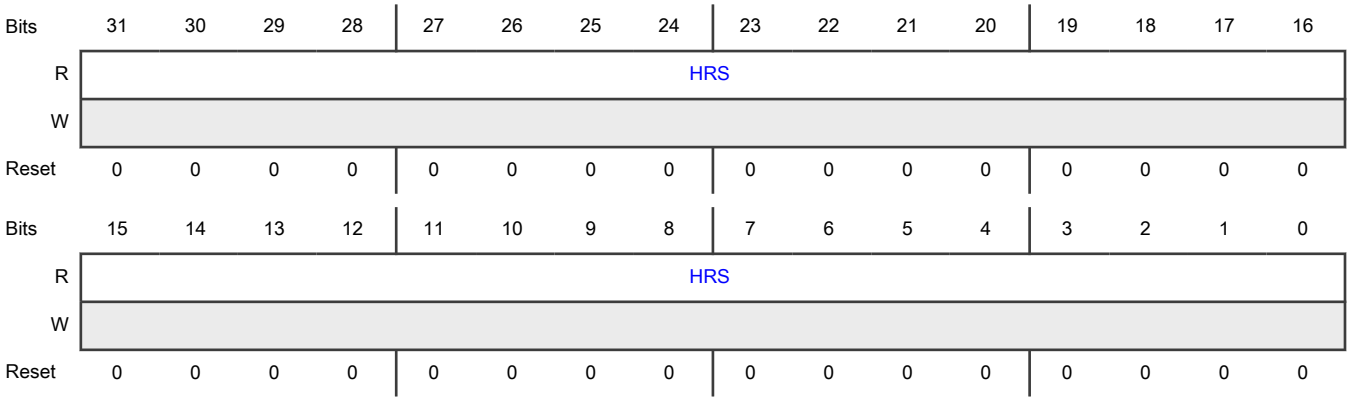
5.3.4.6 Management Page Hardware Request Status Register - Low (HRS_LOW)

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by the eDMA's arbitration logic.

Offset

Register	Offset
HRS_LOW	10h

Diagram



Fields

Field	Description
31-0 HRS	Hardware Request Status for channels 31 - 0 The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel. After the request is completed and channel is free, the HRS bit is automatically cleared by hardware. 0000_0000_0000_0000_0000_0000_0000_0000 - A hardware service request for the channel is not present 0000_0000_0000_0000_0000_0000_0000_0001 - A hardware service request for channel 0 is present

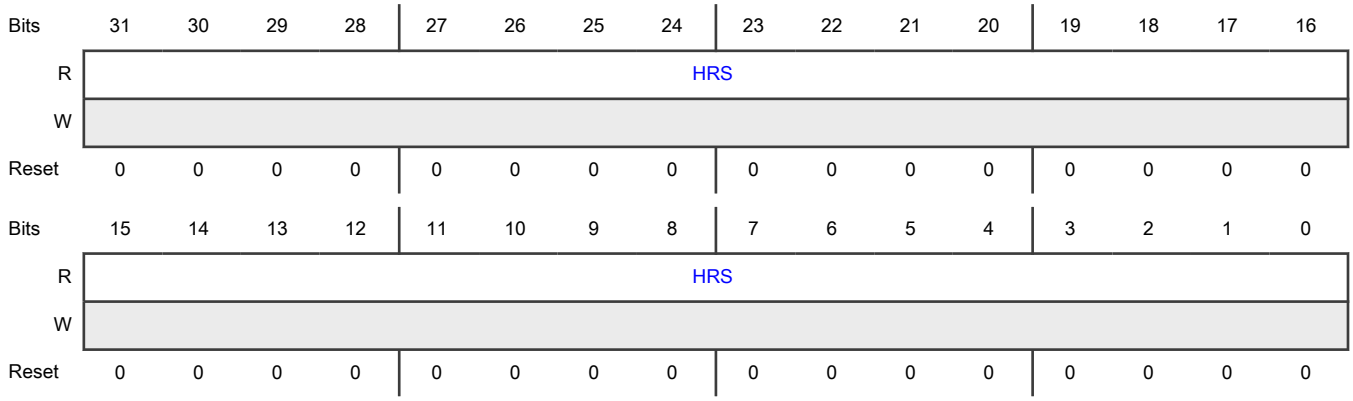
5.3.4.7 Management Page Hardware Request Status Register - High (HRS_HIGH)

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by the eDMA's arbitration logic.

Offset

Register	Offset
HRS_HIGH	14h

Diagram



Fields

Field	Description
31-0 HRS	Hardware Request Status for channels 63-32 The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel. After the request is completed and channel is free, the HRS bit is automatically cleared by hardware. 0000_0000_0000_0000_0000_0000_0000_0000 - A hardware service request for the channel is not present 0000_0000_0000_0000_0000_0000_0000_0001 - A hardware service request for channel 0 is present

5.3.4.8 Channel Arbitration Group (CH0_GRPRI - CH63_GRPRI)

Defines the arbitration group associated with each channel.

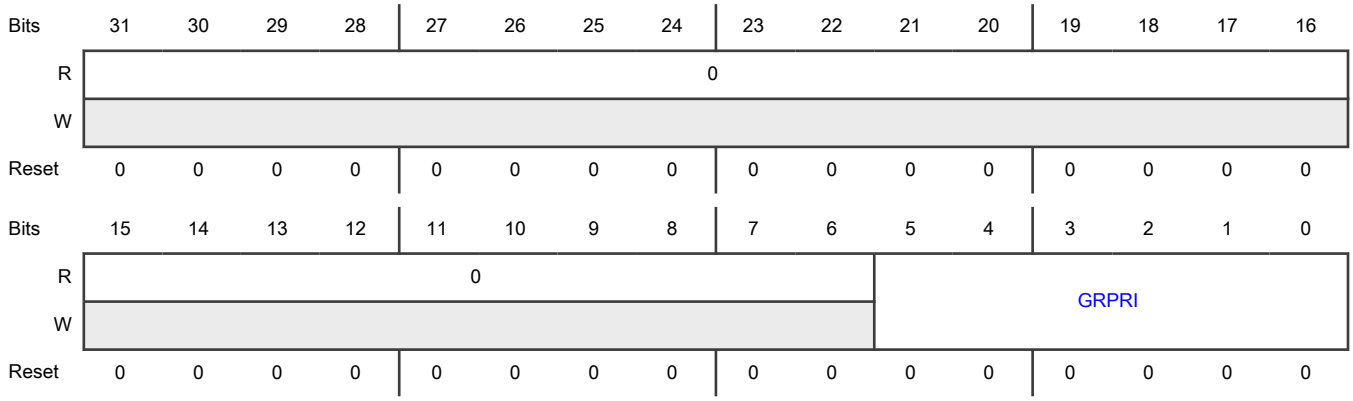
The arbitration group priorities are evaluated by a numeric value from the highest group number to the lowest using the fixed-priority group arbitration scheme; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. The range of the group priority values is limited to the values of 0 through 31. Within each arbitration group, Channel Priority (CH0_PRI - CH63_PRI) determines the highest priority channel.

Offset

For n = 0 to 63:

Register	Offset
CHn_GRPRI	100h + (n × 4h)

Diagram



Fields

Field	Description
31-6 —	Reserved
5-0 GRPRI	Arbitration Group Per Channel Specifies the fixed-priority arbitration group number.

5.3.5 EDMA4_TCD register descriptions

5.3.5.1 EDMA4_TCD memory map

EDMA4_2.TCD base address: 4201_0000h

NOTE

5.3.5.2 Channel Control and Status (CH0_CSR - CH63_CSR)

Provides channel control and status.

The DMA hardware request input signal must be asserted and ERQ must be 1 before a channel's hardware service request is accepted. The state of ERQ does not affect a channel's service request made explicitly through software or channel linking. The state of ERQ does not affect the channel's START field.

EARQ does not affect DMA operations. If this field is 1, this field allows ERQ to propagate out of DMA to the power controller. When 0, this field masks ERQ to the power controller.

EEI enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

DONE indicates whether the channel has completed the major loop. If enabled, eDMA generates an interrupt request corresponding to this completed channel.

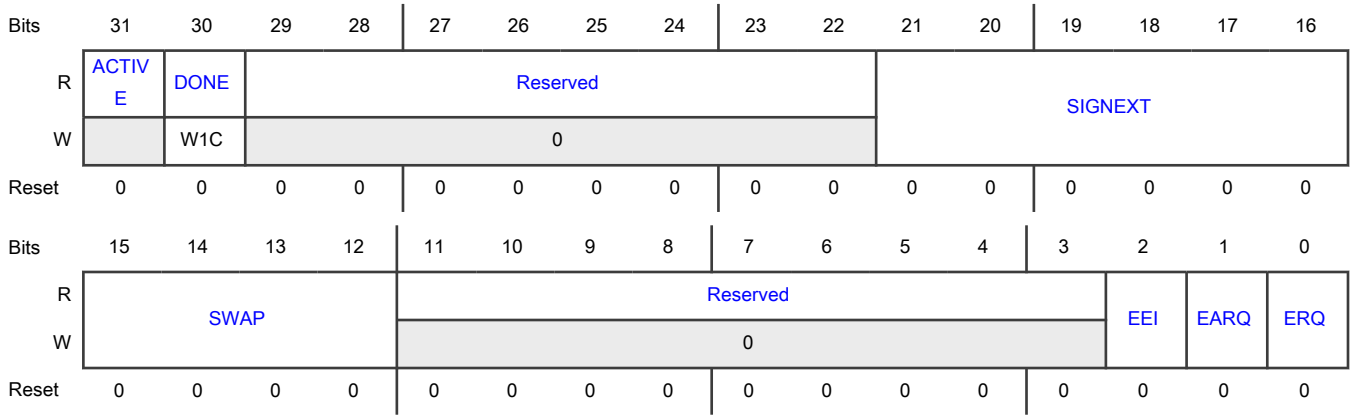
ACTIVE indicates whether the channel is selected by arbitration and is executing the prescribed transfers. Except for dynamic channel linking, you must not modify TCD when a channel is active.

Offset

For n = 0 to 63:

Register	Offset
CHn_CSR	0h + (n × 1000h)

Diagram



Fields

Field	Description
31 ACTIVE	Channel Active Indicates whether the channel is currently in execution. This field becomes 1 when channel service begins; eDMA writes 0 to it when the minor loop completes or when any error condition is detected.
30	Channel Done

Table continues on the next page...

Table continued from the previous page...

Field	Description
DONE	Indicates whether eDMA has completed the major loop. The eDMA engine sets this flag when the CITER count reaches 0. You or hardware can clear the flag when the channel is activated. **NOTE** Clear this flag to write 1 to MAJORELINK. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Not done 1 - Done When writing 0 - No effect 1 - Clear the flag
29-22 —	Reserved
21-16 SIGNEXT	Sign Extension Specifies whether the data written on each transaction is sign extended at the bit specified in this field. 00_0000 - Sign extension disabled 00_0001 - Nonzero value specifying the sign extend bit position
15-12 SWAP	Swap Size Swaps data elements within the specified transfer. The swapping occurs with respect to the specified transfer size (TCD0_ATTR[SSIZE] or TCD0_ATTR[DSIZE]). 0000 - Disabled 0001 - Read with 8-bit swap 0010 - Read with 16-bit swap 0011 - Read with 32-bit swap 0100-1000 - Reserved 1001 - Write with 8-bit swap 1010 - Write with 16-bit swap 1011 - Write with 32-bit swap 1100-1111 - Reserved
11-3	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
2 EEI	Enable Error Interrupt Specifies whether the assertion of the error signal for the corresponding channel generates an error interrupt request. 0 - Do not generate 1 - Generate
1 EARQ	Enable Asynchronous DMA Request Enables asynchronous DMA request for the channel. 0 - Disable 1 - Enable
0 ERQ	Enable DMA Request Enables DMA hardware request for the corresponding channel. Disable the channel's hardware service request at the source prior to writing 0 to this field for the corresponding channel. 0 - Disable 1 - Enable

5.3.5.3 Channel Error Status (CH0_ES - CH63_ES)

Provides information concerning the last recorded channel error. Channel errors can occur because of the following:

- An illegal setting in TCD
- An error termination to a bus master read or write cycle

ERR signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by configuring the appropriate fields in this register. The outputs of this register are enabled by the contents of CH0_CSR[EEI], and then logically summed across all channels to form an error interrupt request, which can be routed to the interrupt controller.

During execution of the interrupt-service routine associated with any DMA errors, it is your responsibility to clear the appropriate field, negating the error-interrupt request. The normal DMA channel completion indicators (setting the TCD DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected. The contents of ERR can also be polled because a nonzero value indicates the presence of a channel error regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing 1 to ERR clears the channel's error status. Writing 0 has no effect on the channel's current error status.

An unspecified error, where only ERR becomes 1 indicates any of the following:

- A transfer is canceled with an error

Management Page Error Status (ES) has a full view of the error condition.

See Fault reporting and handling for details.

Offset

For n = 0 to 63:

Register	Offset
CHn_ES	4h + (n × 1000h)

Fields

Field	Description
31 ERR	Error in Channel Indicates whether an error occurred in this channel. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Not occurred 1 - Occurred When writing 0 - No effect 1 - Clear the flag
30-8 —	Reserved
7 SAE	Source Address Error Indicates whether the last recorded error is a configuration error detected in TCD Source Address (TCD0_SADDR - TCD63_SADDR), which is inconsistent with TCD0_ATTR[SSIZE]. 0 - No error detected 1 - Error detected
6 SOE	Source Offset Error

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Indicates whether the last recorded error is a configuration error detected in TCD Signed Source Address Offset (TCD0_SOFF - TCD63_SOFF), which is inconsistent with TCD0_ATTR[SSIZE]. 0 - No error detected 1 - Error detected
5 DAE	Destination Address Error Indicates whether the last recorded error is a configuration error detected in TCD Destination Address (TCD0_DADDR - TCD63_DADDR), which is inconsistent with TCD0_ATTR[DSIZE]. 0 - No error detected 1 - Error detected
4 DOE	Destination Offset Error Indicates whether the last recorded error is a configuration error detected in TCD Signed Destination Address Offset (TCD0_DOFF - TCD63_DOFF), which is inconsistent with TCD0_ATTR[DSIZE]. 0 - No error detected 1 - Error detected
3 NCE	NBYTES/CITER Configuration Error Indicates whether NBYTES or CITER configuration error occurred. If this field is 1, the last recorded error is a configuration error detected in TCD*n*_NBYTES or TCD*n*_CITER fields. The configuration error on TCD*n*_NBYTES occurs when TCD*n*_NBYTES is not configured as an integer multiple of TCD0_ATTR[SSIZE] and TCD0_ATTR[DSIZE]. The configuration error on TCD*n*_CITER occurs when TCD*n*_CITER[CITER] is equal to zero or when TCD*n*_CITER[CITER] is not equal to TCD*n*_BITER[ELINK]. 0 - No error occurred 1 - Error occurred
2 SGE	Scatter/Gather Configuration Error Indicates whether a scatter/gather configuration error is detected. If this field is 1, the last recorded error is a configuration error detected in TCD0_DLAST_SGA[DLAST_SGA]. This field is checked at the beginning of a scatter/gather operation after major loop completion, if you enable TCD0_CSR[ESG]. TCD*n*_DLASTSGA is not on a 32-byte boundary. 0 - No error detected 1 - Error detected
1 SBE	Source Bus Error Indicates whether the last recorded error is a bus error on a source read. 0 - No error 1 - Error

Table continues on the next page...

Table continued from the previous page...

Field	Description
0 DBE	Destination Bus Error Indicates whether the last recorded error is a bus error on a destination write. 0 - No error 1 - Error

5.3.5.4 Channel Interrupt Status (CH0_INT - CH63_INT)

Indicates the presence of an interrupt request for the channel.

Depending on the appropriate field setting in TCDs, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, you must clear the appropriate bit to negate the interrupt request.

Offset

For n = 0 to 63:

Register	Offset
CHn_INT	8h + (n × 1000h)

Diagram

Fields

Field	Description
31-1 —	Reserved
0 INT	Interrupt Request Indicates whether the interrupt request for the corresponding channel is active.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE This field behaves differently for register reads and writes. When reading 0 - Cleared 1 - Active When writing 0 - No effect 1 - Clear the flag

5.3.5.5 Channel System Bus (CH0_SBR - CH63_SBR)

Places identification and protection information on the system bus interface for eDMA.

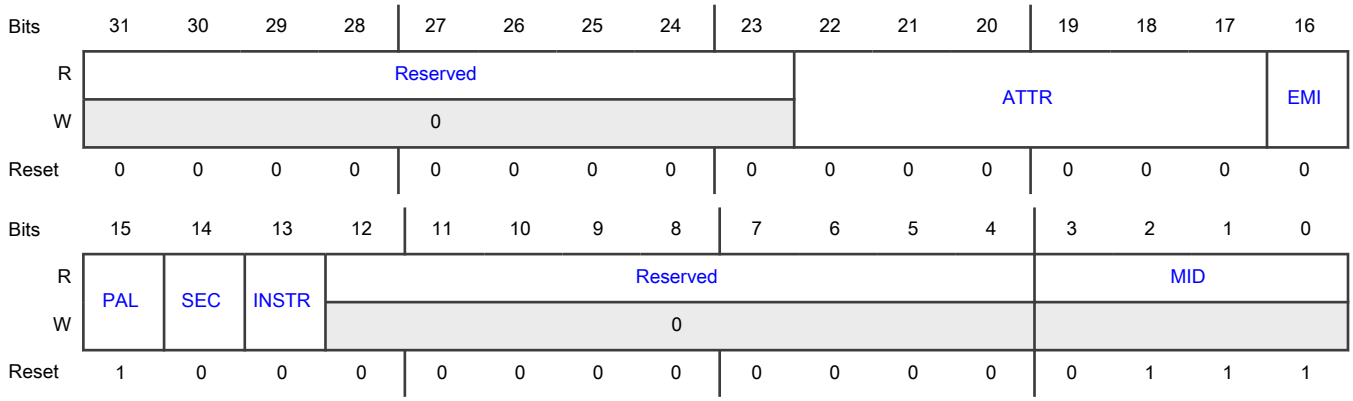
ATTR outputs the register values onto the system bus interface for further decoding by the security system.

Offset

For n = 0 to 63:

Register	Offset
CHn_SBR	Ch + (n × 1000h)

Diagram



Fields

Field	Description
31-23 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
22-17 ATTR	Attribute Output Specifies the DMA's system bus attribute output value.
16 EMI	Enable Master ID Replication Enables master ID replication. This field allows eDMA to use the same protection level and system bus ID of the master programming eDMA's TCD. When you enable this field, eDMA uses the master ID and protection level stored in SBR registers instead of eDMA's default values. When a master, for example a core, programs a TCD, its master ID is captured when TCD*n*_CSR control is written. The protection and security levels are captured when CH*n* _SBR security attributes are written. A scatter/gather operation does not affect Channel System Bus (CH0_SBR - CH63_SBR). You can write to this field only if CSR[GMRC] = 1; otherwise, this field is forced to 0. **NOTE** If you disable master ID replication, the nonsecure, privileged protection level for DMA transfers is used. 0 - Disable 1 - Enable
15 PAL	Privileged Access Level DMA's protection level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH *n* _SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0 - User protection level for DMA transfers 1 - Privileged protection level for DMA transfers
14 SEC	Security Level DMA's security level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH *n* _SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0 - Nonsecure protection level for DMA transfers 1 - Secure protection level for DMA transfers
13 INSTR	Instruction/Data Access DMA's transactions type on the system bus when the channel is active. 0 - Data access for DMA transfers

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Instruction access for DMA transfers
12-4 —	Reserved
3-0 MID	Master ID Indicates the DMA master ID on the system bus when the channel is active. **NOTE** When you enable EMI, the ID captured in this field reflects the master ID of the core or another master writing the channel's control attributes (TCD Control and Status (TCD0_CSR - TCD63_CSR)).

5.3.5.6 Channel Priority (CH0_PRI - CH63_PRI)

Defines the unique priorities associated with each channel within the same channel group.

Channel grouping is programmed through the group priority registers, CH*n*_GRPRI. The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Program the channel priorities with unique values; otherwise, channel numbers with the same nonzero value are selected based on the higher channel number having the higher priority. If more than one channel in a group has an arbitration priority level value of 0, then CSR[ERCA] is used to determine the arbitration scheme for all channels with APL = 0 within a group. When round-robin channel arbitration is enabled (CSR[ERCA] = 1), all channels with APL = 0 within a group use a round-robin arbitration scheme that rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group. When fixed-priority channel arbitration is enabled (CSR[ERCA] = 0), channels with APL = 0 are selected based on the higher channel number having higher priority.

Offset

For n = 0 to 63:

Register	Offset
CHn_PRI	10h + (n × 1000h)

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1. See bit field description.

Fields

Field	Description
31 ECP	Enable Channel Preemption Specifies whether the channel can be temporarily suspended by a service request from a higher priority channel. 0 - Do not suspend 1 - Suspend temporarily
30 DPA	Disable Preempt Ability Specifies whether the channel can suspend any other channel, regardless of channel priority. 0 - Can suspend a lower-priority channel 1 - Cannot suspend any other channel
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Specifies the channel priority level for arbitration within the assigned arbitration group.

5.3.5.7 Channel Multiplexor Configuration (CH0_MUX - CH63_MUX)

Each of the DMA channels can be independently associated with various peripherals in the system. The Channel Multiplexor Configuration register selects the peripheral assigned to each channel. Service requests from the peripheral should be disabled when configuring a channel to a peripheral source.

Each channel must have a unique value when selecting a peripheral slot in the channel mux configuration. The only value that may overlap is source 0. If there is an attempt to write a mux configuration value that is already consumed by another channel, a mux configuration of 0 (SRC = 0) will be written.

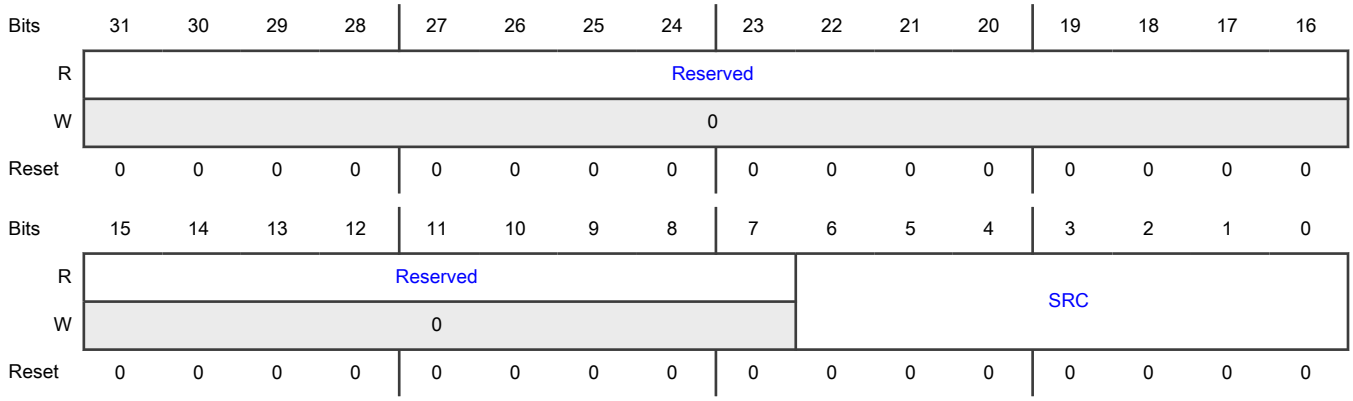
All channels will default to source 0. When a particular peripheral is needed, the channel's mux configuration is set to that source number. When the peripheral is no longer needed, the mux configuration for that channel should be written to 0, thus releasing the resource.

Offset

For n = 0 to 63:

Register	Offset
CHn_MUX	14h + (n × 1000h)

Diagram



Fields

Field	Description
31-7 —	Reserved
6-0 SRC	Service Request Source Hardware service request source for the channel. **NOTE** With the exception of 0, attempts to write a value already in use will be forced to 0.

5.3.5.8 Memory Attributes (CH0_MATTR - CH63_MATTR)

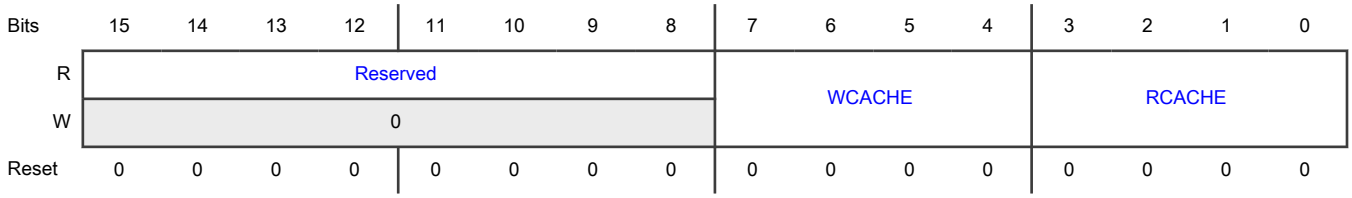
Defines a set of transaction attributes for memory and peripherals. The cache attributes specify how a transaction progresses through the system and how they are handled.

Offset

For n = 0 to 63:

Register	Offset
CHn_MATTR	18h + (n × 1000h)

Diagram



Fields

Field	Description
15-8 —	Reserved
7-4 WCACHE	Write Cache Attributes Defines the attributes associated with a write transaction. • [7] 0b: no write allocate; 1b: write-allocate • [6] 0b: no read allocate; 1b: read-allocate • [5] 0b: non-cacheable; 1b: cacheable • [4] 0b: non-bufferable; 1b: bufferable
3-0 RCACHE	Read Cache Attributes Defines the attributes associated with a read transaction. • [3] 0b: no write allocate; 1b: write-allocate • [2] 0b: no read allocate; 1b: read-allocate • [1] 0b: non-cacheable; 1b: cacheable • [0] 0b: non-bufferable; 1b: bufferable

5.3.5.9 TCD Source Address (TCD0_SADDR - TCD63_SADDR)

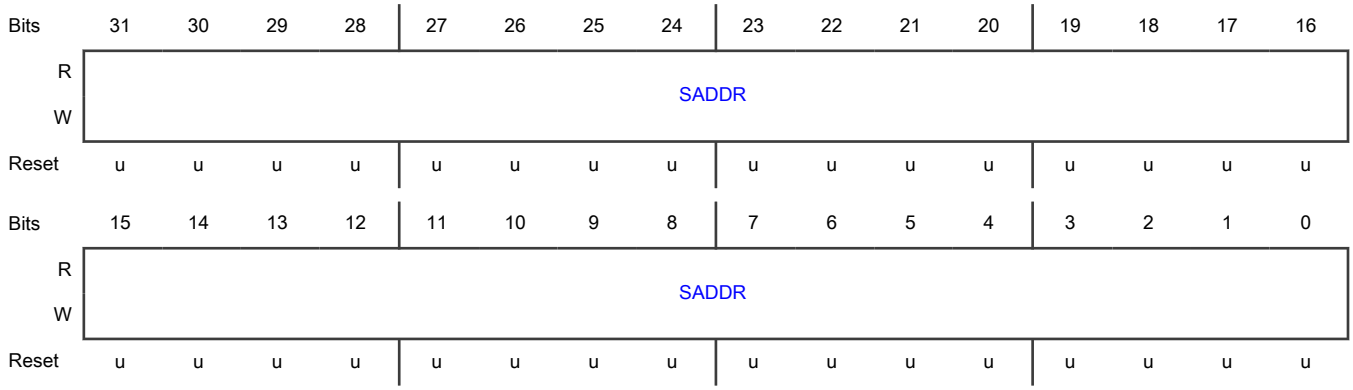
Contains the address for the read transactions.

Offset

For n = 0 to 63:

Register	Offset
TCDn_SADDR	20h + (n × 1000h)

Diagram



Fields

Field	Description
31-0 SADDR	Source Address Specifies the memory address pointing to the source data.

5.3.5.10 TCD Signed Source Address Offset (TCD0_SOFF - TCD63_SOFF)

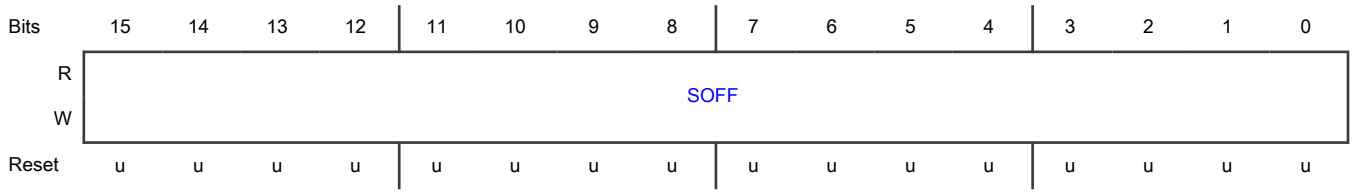
Specifies the sign-extended value added to TCD0_SADDR[SADDR] after each read transaction.

Offset

For n = 0 to 63:

Register	Offset
TCDn_SOFF	24h + (n × 1000h)

Diagram



Fields

Field	Description
15-0 SOFF	Source Address Signed Offset Specifies the sign-extended offset that applies to the current source address to form the next-state value as each source read completes.

5.3.5.11 TCD Transfer Attributes (TCD0_ATTR - TCD63_ATTR)

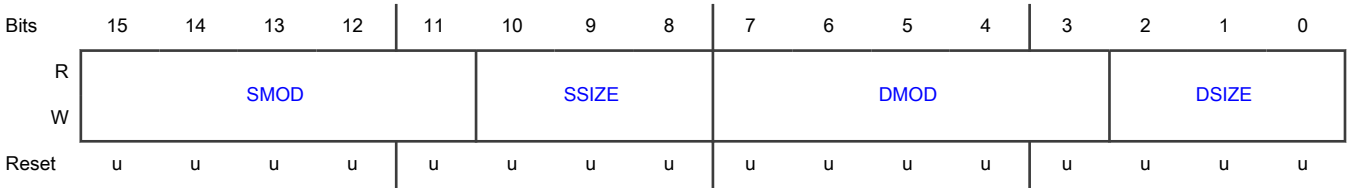
Specifies the size and option modulo addressing information for source and destination addresses.

Offset

For n = 0 to 63:

Register	Offset
TCDn_ATTR	26h + (n × 1000h)

Diagram



Fields

Field	Description
15-11 SMOD	Source Address Modulo Specifies whether the source address modulo feature is enabled for any nonzero value [1-31]. This field defines a specific address range specified to be the value after you perform the TCD0_SADDR[SADDR] + TCD0_SOFF[SOFF] calculation on the original register value. Writing 1 to this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue must start at a 0-modulo-size address and you must set this field to an appropriate value for the queue, freezing the desired number of the upper address bits. The value that you program for this field specifies the number of lower address bits it allows to change. For a circular queue application, TCD0_SOFF[SOFF] is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range. 0_0000 - Disable 0_0001 - Enable
10-8 SSIZE	Source Data Transfer Size Specifies the size of each read transaction on the system bus. **NOTE** NBYTES must be an integer multiple of the source transfer size. 000 - 8-bit 001 - 16-bit 010 - 32-bit 011 - 64-bit 100 - 16-byte

Table continues on the next page...

Table continued from the previous page...

Field	Description
	101 - 32-byte 110 - 64-byte 111 - 128-byte
7-3 DMOD	Destination Address Modulo Specifies the destination address modulo. See SMOD for more information.
2-0 DSIZE	Destination Data Transfer Size Specifies the size of each write transaction on the system bus. **NOTE** NBYTES must be an integer multiple of the destination transfer size. 000 - 8-bit 001 - 16-bit 010 - 32-bit 011 - 64-bit 100 - 16-byte 101 - 32-byte 110 - 64-byte 111 - 128-byte

5.3.5.12 TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD63_NBYTES_MLOFFNO)

Defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCD Source Address (TCD0_SADDR - TCD63_SADDR)) or destination address (TCD Destination Address (TCD0_DADDR - TCD63_DADDR)) upon minor loop completion, which happens when the channel has finished the service request and has transferred NBYTES. When you enable minor loop offsets, the minor loop offset value (MLOFF) is added to the final source address (TCD*n*_SADDR), to the final destination address (TCD*n*_DADDR), or to both prior to the address being written back to TCD. If the major loop is complete, the minor loop offset is ignored, and the major loop address offsets (TCD*n*_SLAST_SDA and TCD*n*_DLAST_SGA) are used to compute the next TCD*n*_SADDR and TCD*n*_DADDR values.

When you enable minor loop mapping (SMLOE or DMLOE = 1), TCD*n* word2 is redefined. A portion of TCD*n* word2 is used to specify following fields:

- A source enable field (SMLOE) must be applied to the source address (TCD*n*_SADDR) after minor loop completion, to specify the minor loop offset.
- A destination enable field (DMLOE) must be applied to the destination address (TCD*n*_DADDR) after minor loop completion, to specify the minor loop offset.
- A sign-extended minor loop offset value (MLOFF)

The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either of the two minor loop offsets are enabled (SMLOE or DMLOE = 1), NBYTES is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE and DMLOE = 0), NBYTES is a 30-bit vector.

One of the two register profiles (TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD63_NBYTES_MLOFFNO) or TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD63_NBYTES_MLOFFYES)) defines the number of bytes to transfer per request. You can select the register depending on whether the source or destination minor loop mapping is enabled.

TCD word 2 is defined when SMLOE and DMLOE are 0. If either SMLOE or DMLOE is 1, see the description of TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD63_NBYTES_MLOFFYES)).

NOTE

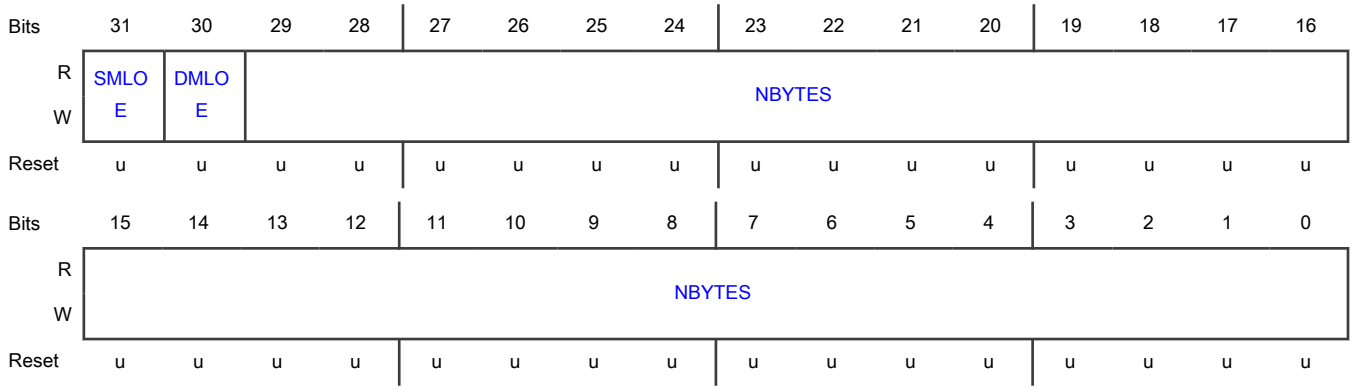
NBYTES must be an integer multiple of the source transfer size and the destination transfer size.

Offset

For n = 0 to 63:

Register	Offset
TCDn_NBYTES_MLOFFNO	28h + (n × 1000h)

Diagram



Fields

Field	Description
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address (SADDR) after minor loop completion. 0 - Do not apply 1 - Apply
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address (DADDR) after minor loop completion. 0 - Do not apply 1 - Apply

Table continues on the next page...

Table continued from the previous page...

Field	Description
29-0 NBYTES	Number of Bytes to Transfer Per Service Request Specifies the number of bytes to be transferred for each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes are performed until the byte transfer count is transferred. This is normally an indivisible operation and you cannot halt the operation. However, you can stall the operation using the bandwidth control field, or through preemption. After the byte count is exhausted, SADDR and DADDR values are written back into the TCD memory, and the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is completed, additional processing is performed.

5.3.5.13 TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD63_NBYTES_MLOFFYES)

Defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCD Source Address (TCD0_SADDR - TCD63_SADDR)) or destination address (TCD Destination Address (TCD0_DADDR - TCD63_DADDR)) upon minor loop completion, which happens when the channel has finished the service request and has transferred NBYTES. You can enable minor loop offsets by either writing 1 to SMLOE or to DMLOE.

SMLOE specifies MLOFF that must be applied to the source address (TCD*n*_SADDR) upon minor loop completion. DMLOE specifies MLOFF that must be applied to the destination address (TCD*n*_DADDR) upon minor loop completion. If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCD*n*_SLAST_SDA and TCD*n*_DLAST_SGA) are used to compute the next TCD*n*_SADDR and TCD*n*_DADDR values.

When the minor loop offset overlay is enabled (either SMLOE or DMLOE = 1), TCD*n*_NBYTES_* is redefined. A portion of TCD*n*_NBYTES_* is used to specify the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When enabled, the minor loop offset must be aligned to the transfer size of the source or destination it is associated with. When either of the two minor loop offsets are enabled (SMLOE or DMLOE is 1), NBYTES is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE and DMLOE are 0), NBYTES is a 30-bit vector.

One of the two register profiles (TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD63_NBYTES_MLOFFYES) or TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD63_NBYTES_MLOFFNO)), defines the number of bytes to transfer per request. You can use the register depending on whether the source or destination minor loop mapping is enabled.

TCD*n*_NBYTES is defined when either of the two minor loop offsets are enabled (SMLOE or DMLOE = 1); see TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD63_NBYTES_MLOFFYES) for more information. If SMLOE and DMLOE = 0, see TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD63_NBYTES_MLOFFNO).

NOTE

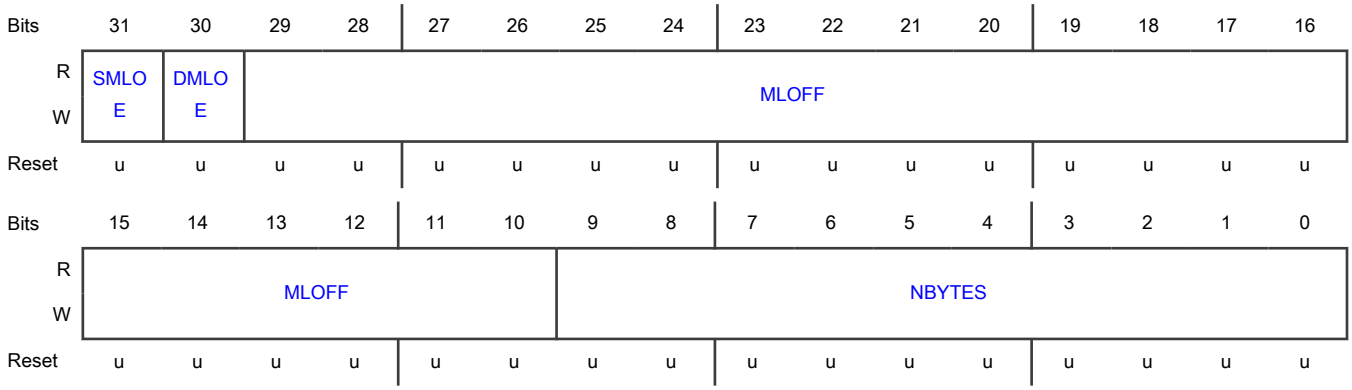
NBYTES must be an integer multiple of the source transfer size and the destination transfer size.

Offset

For n = 0 to 63:

Register	Offset
TCDn_NBYTES_MLOFFYES	28h + (n × 1000h)

Diagram



Fields

Field	Description
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address (SADDR) after minor loop completion. 0 - Do not apply 1 - Apply
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address (DADDR) after minor loop completion. 0 - Do not apply 1 - Apply
29-10 MLOFF	Minor Loop Offset Represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes, if SMLOE or DMLOE = 1.
9-0 NBYTES	Number of Bytes to Transfer Per Service Request Specifies the number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes are performed until the minor byte transfer count is transferred. This is an indivisible operation and you cannot halt the operation. However, you can stall the operation by using the bandwidth control field, or through preemption. After the minor count is exhausted, SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

5.3.5.14 TCD Last Source Address Adjustment and Store DADDR Address (TCD0_SLAST_SDA - TCD63_SLAST_SDA)

Specifies the value added to the source address after the major loop completes.

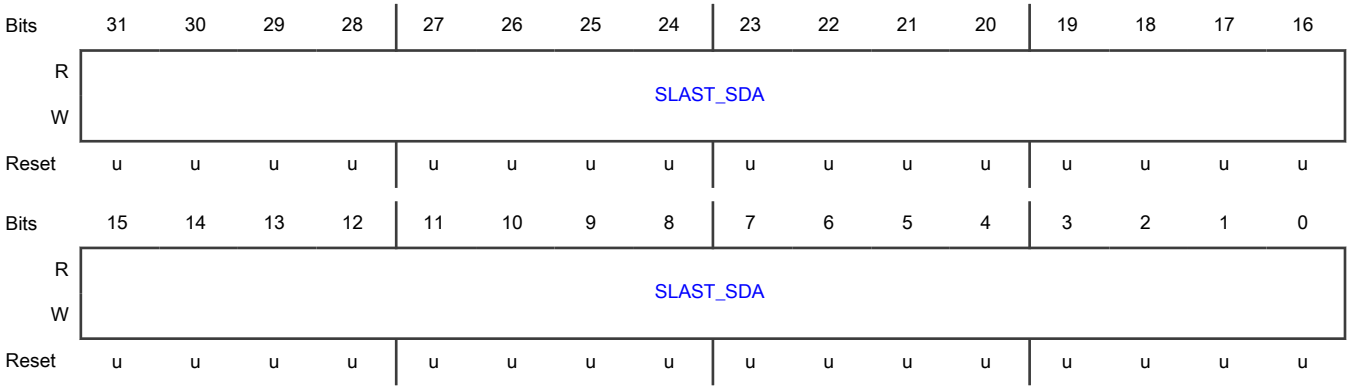
Provides a pointer to memory for storing the final destination address when the store destination address option is enabled.

Offset

For n = 0 to 63:

Register	Offset
TCDn_SLAST_SDA	2Ch + (n × 1000h)

Diagram



Fields

Field	Description
31-0 SLAST_SDA	Last Source Address Adjustment and Store DADDR Address Specifies the last source address adjustment or the system memory address for the destination address (DADDR) storage. When TCD0_CSR[ESDA] = 0, then: • Adjustment value is added to the source address after the completion of the major iteration count. You can use this value to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses the two's-complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is stored in system memory. By saving the final destination address in system memory through the ESDA feature, you can compute the size of a variable destination data buffer by subtracting the beginning DADDR from the final saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. • The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because eDMA forces the lower two address bits of SLAST_SDA to 0 when ESDA is enabled. eDMA performs this write operation when the major loop is complete; that is, when the major iteration count (CITER) decrements to 0.

5.3.5.15 TCD Destination Address (TCD0_DADDR - TCD63_DADDR)

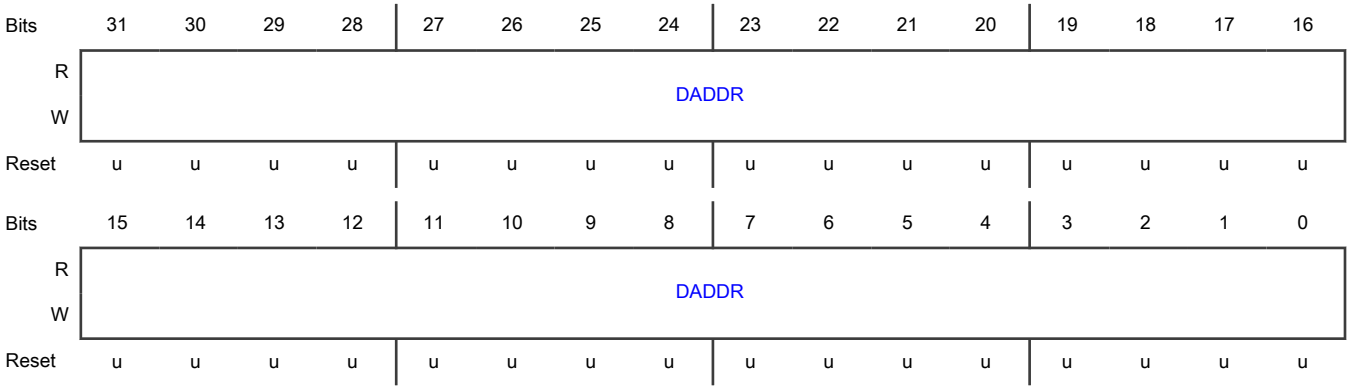
Specifies the address for write transactions.

Offset

For n = 0 to 63:

Register	Offset
TCDn_DADDR	30h + (n × 1000h)

Diagram



Fields

Field	Description
31-0 DADDR	Destination Address Specifies the memory address pointing to the destination data.

5.3.5.16 TCD Signed Destination Address Offset (TCD0_DOFF - TCD63_DOFF)

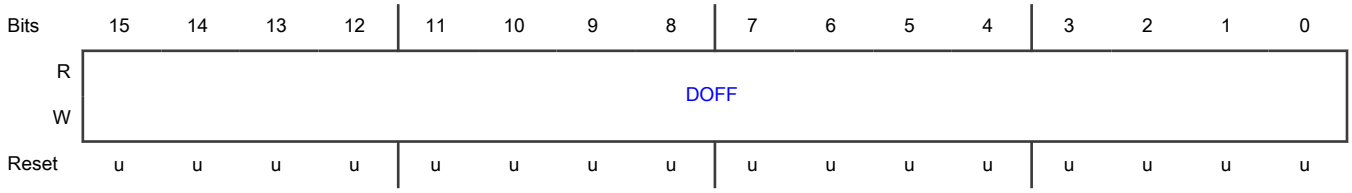
Specifies the sign-extended value added to TCD0_DADDR[DADDR] after each write transaction.

Offset

For n = 0 to 63:

Register	Offset
TCDn_DOFF	34h + (n × 1000h)

Diagram



Fields

Field	Description
15-0 DOFF	Destination Address Signed Offset Specifies the sign-extended offset that is applied to the current destination address to form the next-state value as each destination write is completed.

5.3.5.17 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD63_CITER_ELINKNO)

Allows channel-to-channel linking and specifies the current major iteration count.

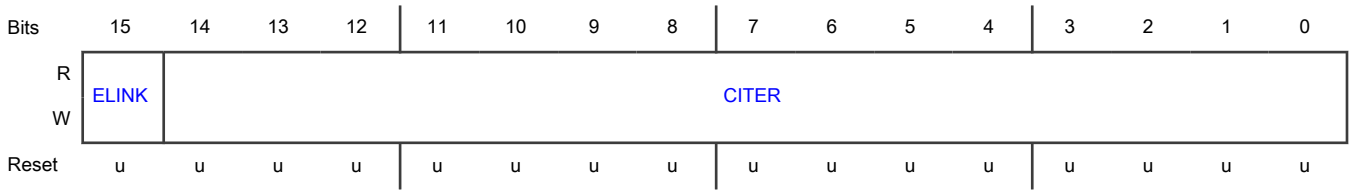
If TCD*n*_CITER[ELINK] is 0, the CITER field is defined as explained in this register.

Offset

For n = 0 to 63:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 1000h)

Diagram



Fields

Field	Description
15 ELINK	Enable Channel-to-Channel Linking after Minor Loop Completion Enables linking to another channel as the channel completes the minor loop, defined by LINKCH. The link target channel initiates a channel service request through an internal mechanism that writes 1 to TCD0_CSR[START] of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed to support MAJORELINK channel linking.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE This field must be equal to BITER[ELINK]; otherwise, a configuration error is reported. 0 - Disable 1 - Enable
14-0 CITER	Current Major Iteration Count Represents the current major loop count (9-bit (ELINK = 1) or 15-bit (ELINK = 0)) for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading CITER from BITER. **NOTE** • When you initially load CITER, you must set this to the same value as that contained in BITER for proper operation of the optional interrupt (see TCD0_CSR[INTHALF]). • If the channel is configured to execute a single service request, the initial values of the BITER and CITER fields must be 0001h.

5.3.5.18 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD63_CITER_ELINKYES)

Allows channel-to-channel linking and specifies the minor loop link channel number and current major iteration count.

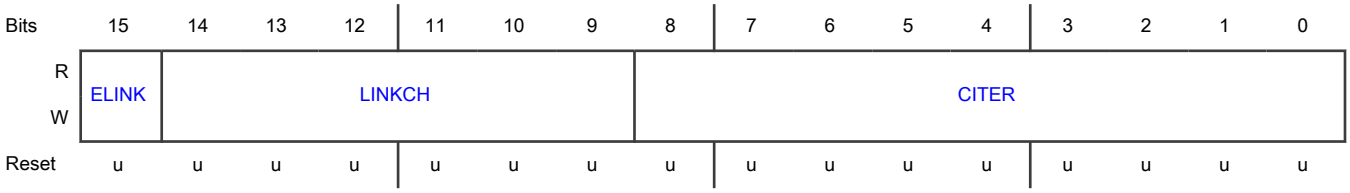
If TCD*n*_CITER[ELINK] is 1, the CITER field is defined as explained in this register.

Offset

For n = 0 to 63:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 1000h)

Diagram



Fields

Field	Description
15 ELINK	Enable Channel-to-Channel Linking on Minor-Loop Complete Enables linking to another channel as the channel completes the minor loop, defined by LINKCH. When enabled, an internal mechanism sets TCD0_CSR[START] of the specified channel (LINKCH) after minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed to support MAJORELINK channel linking. **NOTE** This field must be equal to BITER[ELINK]; otherwise, a configuration error is reported. 0 - Disable 1 - Enable
14-9 LINKCH	Minor Loop Link Channel Number Specifies the minor loop link channel number. When channel-to-channel linking is enabled (ELINK = 1), after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by this field by writing 1 to that channel's TCD0_CSR[START].
8-0 CITER	Current Major Iteration Count Represents the current major loop count (9-bit (ELINK = 1) or 15-bit (ELINK = 0)) for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations (for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading CITER from BITER). **NOTE** • When you initially load CITER, you must set this to the same value as that contained in BITER for proper operation of the optional interrupt (see TCD0_CSR[INTHALF]). • If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0001h.

5.3.5.19 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD63_DLAST_SGA)

Specifies the value added to the destination address when the major loop is complete.

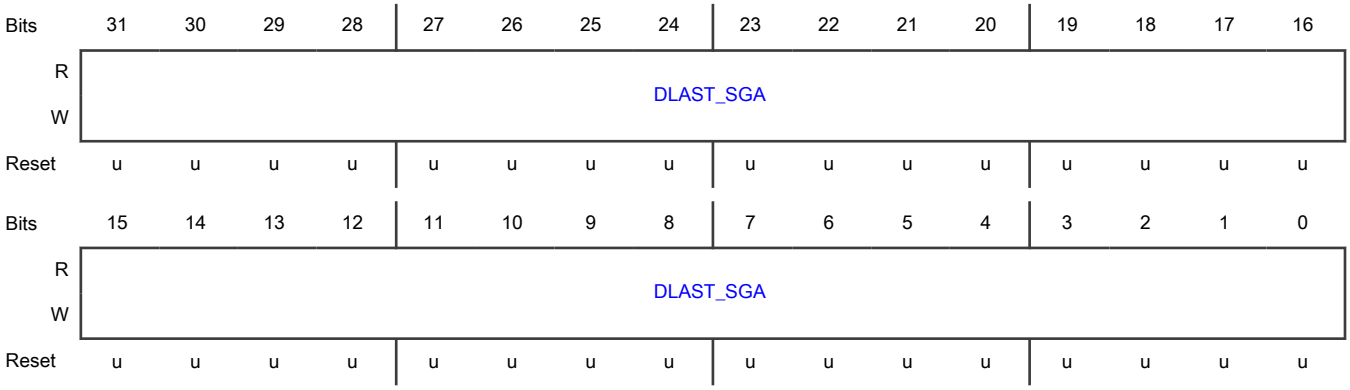
Provides a pointer to memory for fetching a TCD to reprogram the channel, if the scatter/gather option is enabled.

Offset

For n = 0 to 63:

Register	Offset
TCDn_DLAST_SGA	38h + (n × 1000h)

Diagram



Fields

Field	Description
31-0 DLAST_SGA	Final Destination Address Adjustment and Scatter/Gather Address Specifies the destination final address adjustment or the memory address for the next TCD to be loaded into this channel (scatter/gather). If TCD0_CSR[ESG] = 0, then: • Adjustment value is added to the destination address at the completion of the major iteration count. You can use this value to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses the two's-complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo-32-byte region containing the next TCD to be loaded into this channel, which is reloaded after the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, otherwise a configuration error is reported.

5.3.5.20 TCD Control and Status (TCD0_CSR - TCD63_CSR)

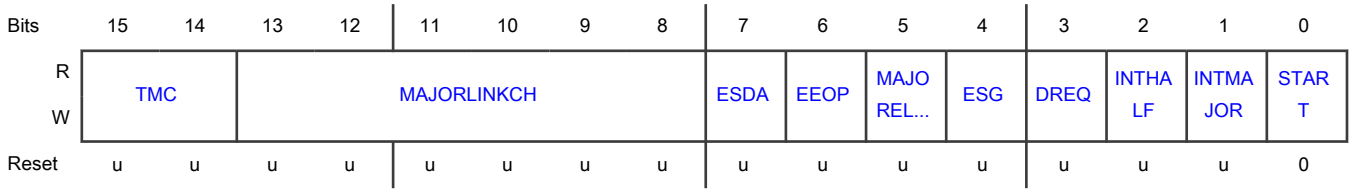
Provides status and control of TCD. It also enables optional features.

Offset

For n = 0 to 63:

Register	Offset
TCDn_CSR	3Ch + (n × 1000h)

Diagram



Fields

Field	Description
15-14 TMC	Transfer Mode Control Specifies the direction in which DMA transfers data. For normal data movement operation, Read/Write mode reads from the source address and writes to the destination address. For Read-Only mode, data is read from the source address and discarded. You can use Read-Only mode for calculating the CRC values on a block of memory. For Write-Only mode, the source address is read once and all subsequent writes to the destination use the data from the first and only read. You may use Write-Only mode to initialize a block of memory to a specific value. 00 - Read/Write 01 - Read-Only 10 - Write-Only 11 - Reserved
13-8 MAJORLINKCH	Major Loop Link Channel Number Specifies the major loop link channel number. If MAJORELINK = 0, you cannot perform any channel-to-channel linking, or chaining after the major loop counter is exhausted. If MAJORELINK is not 0, after the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by writing 1 to that channel's START.
7 ESDA	Enable Store Destination Address Enables the store destination address to system memory operation. This field enables writing the destination address (DADDR) to the address pointed to by TCD0_SLAST_SDA[SLAST_SDA] as the channel completes the major loop through either CITER decrementing to zero or, by receiving an enabled end-of-packet signal. When SDA = 1, TCD0_SLAST_SDA[SLAST_SDA] contains the write pointer instead of the final source address offset. The value written to the system memory specified by SLAST_SDA has the following possibilities: • For a normal successful transfer, the value is the last DADDR value prior to the DLAST_SGA offset that an enabled scatter/gather operation applies or overwrites. You can also compute this value using the TCD information. • For a transfer that EOP ends early, the value written to the memory is the last destination address written with the last good read data before EOP was issued.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - Disable 1 - Enable
6 EEOP	Enable End-of-Packet Processing Enables the end-of-packet hardware input signal. When this field is 1, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel and to treat the shutdown as major loop completed. Additionally, the end-of-packet signal from supported peripherals is accepted. If this field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA saved destination address) minus the software-saved initial address (DADDR) reflects the total amount of data transferred. For this calculation, the destination offset, DOFF, must match the natural boundary of the destination transfer size, DSIZE. For example, if DSIZE = 32-bit, DOFF = 4. 0 - Disable 1 - Enable
5 MAJORELINK	Enable Channel-to-Channel Linking on Major Loop Complete Enables linking to another channel (as the channel completes the major loop), defined by MAJORLINKCH. The link target channel initiates a channel service request through an internal mechanism that writes 1 to START of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to become 0 when you write to it while TCD*n*_CSR[DONE] is 1. Write to this field and MAJORLINKCH at the same time when attempting a dynamic channel link. 0 - Disable 1 - Enable
4 ESG	Enable Scatter/Gather Processing Specifies the current channel's TCD format. This field enables scatter/gather processing in the current channel as the channel completes the major loop. If this field is 1, the eDMA engine uses TCD0_DLAST_SGA[DLAST_SGA] as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as TCD into the local memory. TCD0_DLAST_SGA[DLAST_SGA] provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution. **NOTE** Any changes made to this field while the channel is executing are not recognized until the next time the channel is activated. 0 - Normal format 1 - Scatter/gather format
3	Disable Request

Table continues on the next page...

Table continued from the previous page...

Field	Description
DREQ	Clears CH0_CSR[ERQ] after major loop completion, thus disabling hardware service requests. If this field is 0, no operation is carried out. The channel's ERQ {H,L} bit is not affected. If this field is 1, the channel's ERQ {H,L} bit becomes 0 when the major loop is complete. Also, the eDMA hardware automatically clears the corresponding ERQ field when the current major iteration count reaches 0. 0 - No operation 1 - Clear ERQ
2 INTHALF	Interrupt Enable after Major Counter is Half Complete Enables half-point interrupt. If this field is 1, the channel generates an interrupt request by writing 1 to the appropriate bit in INT when CITER reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use this field. Use INTMAJOR instead. 0 - Disable 1 - Enable
1 INTMAJOR	Interrupt Enable after Major Iteration Count Completion Enables end-of-major loop interrupt. If this field is 1, the channel generates an interrupt request by writing 1 to the appropriate bit in INT when CITER reaches zero. 0 - Disable 1 - Enable
0 START	Channel Start Specifies whether the channel is explicitly started through a software-initiated service request. If this field is 1, it indicates that the channel is requesting service. The eDMA hardware automatically writes 0 to this field after the channel begins execution. 0 - Do not start 1 - Start

5.3.5.21 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD63_BITER_ELINKNO)

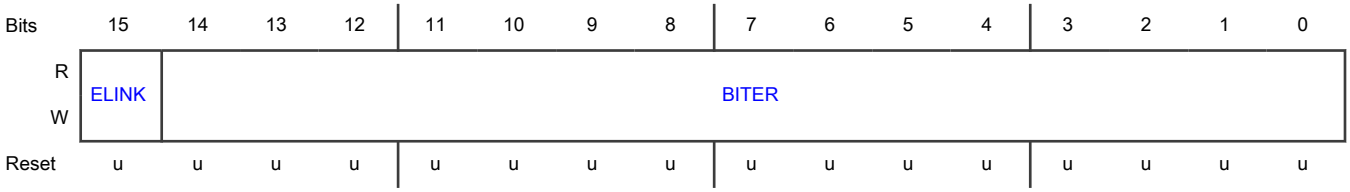
Allows channel-to-channel linking and specifies the major iteration count. If TCD*n*_BITER[ELINK] = 0, TCD*n*_BITER is defined as explained in this register.

Offset

For n = 0 to 63:

Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 1000h)

Diagram



Fields

Field	Description
15 ELINK	Channel-to-Channel Linking after Minor Loop Completion Enables linking to another channel (after the channel completes the minor loop), defined by BITER[LINKCH]. The link target channel initiates a channel service request through an internal mechanism that writes 1 to TCD0_CSR[START] of the specified channel. If you disable the channel linking, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed to support MAJORELINK channel linking. **NOTE** When you load TCD, this field must be set equal to the corresponding CITER; otherwise, a configuration error is reported. When the major iteration count is exhausted, the contents of this field are reloaded into CITER. 0 - Disable 1 - Enable
14-0 BITER	Starting Major Iteration Count Specifies the starting major iteration count. When you first load TCD, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. When the major iteration count is exhausted, the contents of this field are reloaded into CITER. **NOTE** When you load TCD, this field must be set equal to the corresponding CITER field for the proper operation of the optional interrupt (see TCD0_CSR[INTHALF]). When the major iteration count is exhausted, the contents of this field are reloaded into CITER. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0001h.

5.3.5.22 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD63_BITER_ELINKYES)

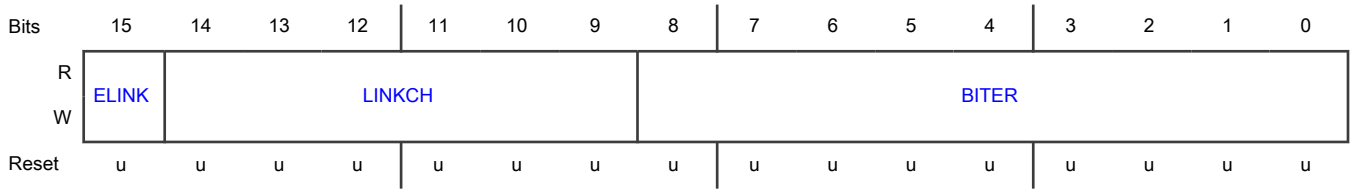
Allows channel-to-channel linking and specifies the link channel number and the starting major iteration count. If TCD*n*_BITER[ELINK] = 1, TCD*n*_BITER is defined as explained in this register.

Offset

For n = 0 to 63:

Register	Offset
TCDn_BITER_ELINKYES	3Eh + (n × 1000h)

Diagram



Fields

Field	Description
15 ELINK	Channel-to-Channel Linking after Minor Loop Completion Enables linking to another channel (as the channel completes the minor loop), defined by BITER[LINKCH]. The link target channel initiates a channel service request through an internal mechanism that writes 1 to TCD0_CSR[START] of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed to support MAJORELINK channel linking. **NOTE** When you load TCD, this field must be equal to the corresponding CITER; otherwise, a configuration error is reported. When the major iteration count is exhausted, the contents of this field are reloaded into CITER. 0 - Disable 1 - Enable
14-9 LINKCH	Link Channel Number Specifies the link channel number. If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field, by writing 1 to that channel's TCD0_CSR[START].

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE When the major iteration count is exhausted, the contents of this field are reloaded into CITER.
8-0 BITER	Starting Major Iteration Count Specifies the starting major iteration count. When you load TCD, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. When the major iteration count is exhausted, the contents of this field are reloaded into CITER. **NOTE** When you load TCD, this field must be set equal to the corresponding CITER for proper operation of the optional interrupt (see TCD0_CSR[INTHALF]). When the major iteration count is exhausted, the contents of this field are reloaded into CITER. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0001h.

5.4 Functional description

The eDMA operation is described in the following subsections.

5.4.1 Modes of operation

Table 23. Modes of operation

Mode	Description
Normal	eDMA transfers data between a source and destination. The source and destination can be a memory block or an I/O block capable of operation with eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in TCD. The minor loop is the sequence of read/write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	eDMA operation is configurable in Debug mode through CSR: • When you write 0 to CSR[EDBG], eDMA continues to operate. • When you write 1 to CSR[EDBG], eDMA stops transferring data. If Debug mode is entered when a channel is active, eDMA continues operating until the channel retires.

5.4.2 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in Figure 11, the first segment involves channel activation. This figure shows the assertion of the eDMA peripheral request signal to request service for channel *n*. When you activate the channel, TCD0_CSR[START] follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, and then into the program model and channel arbitration. In the next cycle, the channel arbitration begins using fixed-priority plus the optional round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD

memory is accessed, and the required descriptor is read from the local memory and loaded into the eDMA engine address path's primary or secondary channel execution registers. The TCD memory is 64-bit wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path registers.

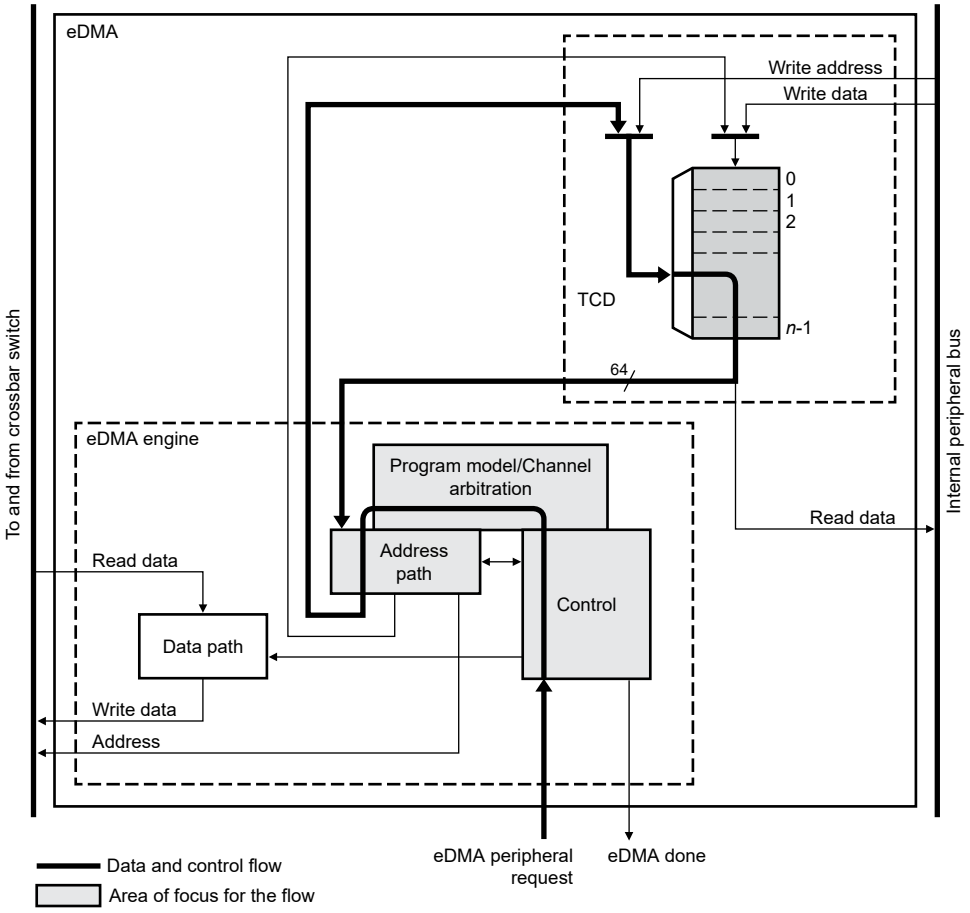


Figure 11. eDMA operation, part 1

Figure 12 illustrates the second part of the data flow to perform the data movement, from the source read to the destination write. The modules associated with the data flow include the address path, data path, and control block.

The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read or destination write processing continues until the byte count, NBYTES, is transferred.

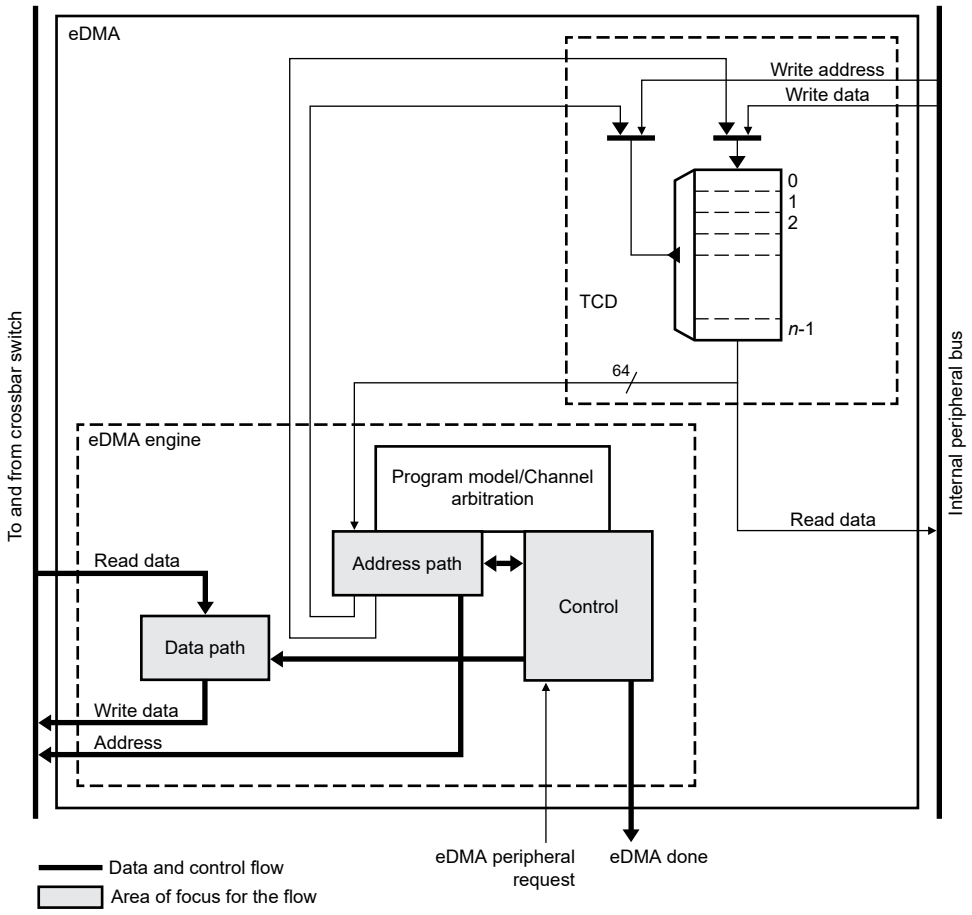

Figure 12. eDMA operation, part 2

After NBYTES of data is moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to some fields in the appropriate TCD, for example, SADDR, DADDR, and CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of BITER into CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). Updates to the TCD memory and the assertion of an interrupt request are shown in Figure 13.

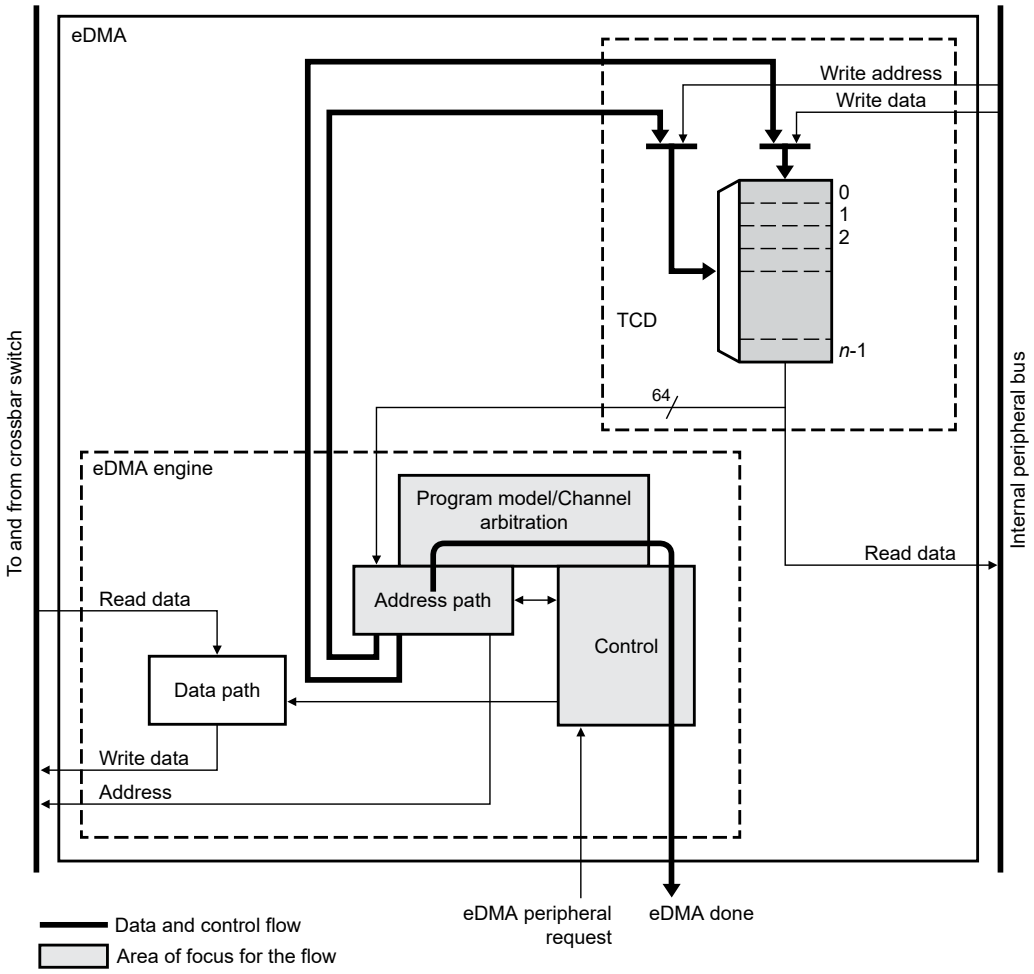

Figure 13. eDMA operation, part 3

5.4.3 Fault reporting and handling

Channel errors are reported in CH0_ES and can be caused by either of the following:

- A configuration error, which is an illegal setting in TCD
- An active channel canceled via a "cancel transfer with error" software request
- An error termination to a bus controller read or write cycle

eDMA reports a configuration error when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represents an inconsistent state. Following are the possible causes of a configuration error:

- The addresses and offsets are aligned on 0-modulo-transfer-size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes are configured to the natural boundary of the programmed transfer size respectively.
- If you enable a scatter/gather operation after the channel completion, a configuration error is reported (if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary).
- If you enable the minor loop channel linking after the channel completion, a configuration error is reported when the link is attempted (if TCD*n*_CITER[ELINK] is not equal to TCD*n*_BITER[ELINK]).

NOTE

To aid in debug, write 1 to CSR[HAE]. After an error condition occurs, eDMA is halted after the error is recorded. eDMA remains halted and does not process any channel service requests. After the error is fixed, you can enable the eDMA by writing 0 to CSR[HALT].

If enabled, all configuration error conditions (except the scatter/gather and minor-loop link errors) report as the channel activates and asserts an error interrupt request, in case it is enabled. A scatter/gather configuration error is reported when the scatter/gather operation begins on major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

When a system bus read or write is terminated with an error, the data transfer is stopped, and the appropriate bus error flag is set. In this case, the eDMA engine updates the state of the channel's TCD with the current source address, destination address, and the current iteration count at the point of the fault. When a system bus error occurs, the channel terminates the processing. Due to the pipeline effect, when eDMA receives a bus error, it does not abort the transfer in progress. Bus errors are imprecise. The source and destination addresses stored in TCD, after a bus error occurs, may not be the addresses that caused the error.

You may cancel a transfer by using CSR[CX]. When a cancel transfer request is recognized, the DMA engine stops processing the channel. Transactions in flight are allowed to complete. If you cancel a transfer on the last sequence of a major or minor loop, the canceled request is discarded, and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except that ES is updated with the canceled channel number, and CSR[ECX] becomes 1. TCD of a canceled channel contains the source and destination addresses of the last transfer saved in TCD. If you want to restart the channel, you must reinitialize TCD because the aforementioned fields no longer represent the original parameters. When the error cancel transfer mechanism cancels a transfer, the channel number is loaded into ES[ERRCHN], and ES[ECX] and ES[VLD] become 1. In addition, it can generate an error interrupt if enabled.

NOTE

The cancel transfer request allows you to stop a large data transfer when you no longer need the full data transfer. CSR[CX] does not abort the channel. It stops the transferring of data and then retires the channel through its normal shutdown sequence. The cancel transfer is an imprecise operation. You must handle the context of the cancel. Depending on whether an interrupt is required or not, you must enable or disable the interrupt before the cancel request. You must clean up TCD because the complete transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states, and the transaction to the system bus has a pipeline effect), and the appropriate channel field in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into ES. When an error is detected the following major loop indicators remain unaffected:

- Setting of CH0_CSR[DONE]
- Possible assertion of an interrupt request

After the error status is updated, the eDMA engine continues to operate by servicing the next appropriate channel. A channel that experiences an error condition is automatically disabled from hardware service requests. If an error terminates a channel, CH0_CSR[ERQ] becomes 0, preventing continuous errors from a peripheral's service request.

The fields in ES represent error indicators that are sticky and cannot be cleared. They show the last recorded error until DMA is reset. You can use ES[VLD] to determine whether a new error condition exists. ES[VLD] is the logical OR of each channel's CH0_ES[ERR]. After you resolve all the errors and clear all the error interrupt bits, ES[VLD] becomes 0, but the cause of the last error is still indicated.

5.4.4 Channel preemption

eDMA uses a priority vector value to determine the highest-priority channel requesting service.

The priority vector is a combination of:

- The channel's group priority, CH0_GRPRI[GRPRI]
- The channel's priority level, CH0_PRI[APL]

- The channel number

Priority vector = ((CH*n*_GRPRI << 8) + (CH*n*_PRI[APL] << 5) + CHn_*)

A channel requesting service with the highest-priority vector value receives the next execution slot, which is available:

- Immediately if eDMA is idle.
- When an active channel retires.
- When valid preemption conditions exist.

NOTE

Preemption is strictly priority based and is not bound by a specific group number as defined by CH*n*_GRPRI.

Write 1 to CH0_PRI[ECP] to enable channel preemption on a per-channel basis. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel completes all its minor loop data transfers, the preempted channel restores and resumes execution. After the restored channel completes one read or write sequence, it is again eligible for preemption. If any higher priority channel requests service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot preempt again.

You can disable the channel's ability to preempt another channel by writing 1 to CH0_PRI[DPA]. When you disable a channel's preempt ability, that channel cannot suspend a lower-priority channel's data transfer, regardless of the lower priority channel's CH*n*_PRI[ECP] being 1. This allows a pool of low priority, large data-moving channels to define. You can configure the low-priority channels not to preempt each other, therefore preventing a low-priority channel from consuming the preempt slot normally available to a true, high-priority channel. When you enable Round-Robin Channel Arbitration mode (CSR[ERCA] = 1), any channel with a priority level equal to zero (CH*n*_PRI[APL] = 0), has the preemption disabled and does not preempt another channel.

5.4.5 Clocking

This module has no clocking considerations.

5.4.6 Interrupts

This module has no interrupts.

5.5 External signals

This module has no external signals.

5.6 Initialization

The following sections discuss eDMA initialization and programming considerations.

5.6.1 Initialization procedure

Table 24. Initialization steps

Step	Purpose	Programming	Notes
1	Specify the configuration other than default.	Write to CSR.	—
2	Specify the priority levels to channel or group for a configuration other than default.	Write the channel priority levels to CH0_PRI and group priority levels to CH0_GRPRI.	—
3	Enable error interrupts if needed.	Write 1 to CH0_CSR[EEI].	—

Table continues on the next page...

Table 24. Initialization steps (continued)

Step	Purpose	Programming	Notes
4	Request service for each channel.	Write the 32-byte TCD for each channel.	—
5	Enable hardware service requests.	Write 1 to CH0_CSR[ERQ].	—
6	Request a channel service through software.	Write 1 to TCD0_CSR[START].	—
7	Request a channel service through hardware.	Target device asserts its eDMA peripheral request signal.	—

5.6.2 Channel selection

After any of the channel requests service, select a channel for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in Table 25, for the selected channel into its internal address path module.

As TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, as defined by TCD0_SADDR, to the destination, as defined by TCD0_DADDR, continue until the number of bytes specified by TCD*n*_NBYTES are transferred.

When the transfer is complete, write the eDMA engine's local TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_CITER back to the main TCD memory and perform any minor loop channel linking, if enabled. If the major loop is exhausted, further postprocessing is performed, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 25. TCD*n*_CSR field descriptions

Field	Description
START	Control field to start channel explicitly when using a software-initiated DMA service (hardware clears it automatically)
EEOP	Control field to enable end-of-packet processing
ESDA	Control field to enable the storing of the destination address to system memory after the major loop completes
DREQ	Control field to disable hardware-initiated DMA service requests after major loop completion
ESG	Control field to enable the scatter-gather feature
INTHALF	Control field to enable the interrupt when the major loop is half complete
INTMAJOR	Control field to enable the interrupt when the major loop completes

Table 26. CH*n*_CSR field description

Field	Description
ACTIVE	Status field indicating the channel is in execution
DONE	Status field indicating major loop completion (you clear it when a channel begins execution)

Table continues on the next page...

Table 26. CH*n*_CSR field description (continued)

Field	Description
EEI	Control field to enable error interrupts
EARQ	Control field to enable an external, asynchronous wake-up event with the ERQ field
ERQ	Control field to enable hardware service requests

5.6.3 Multi-loop iterations

Figure 14 shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, allowing one level of minor loop DMA preemption. The beginning iteration count (BITER) specifies the number of minor loops in a major loop.

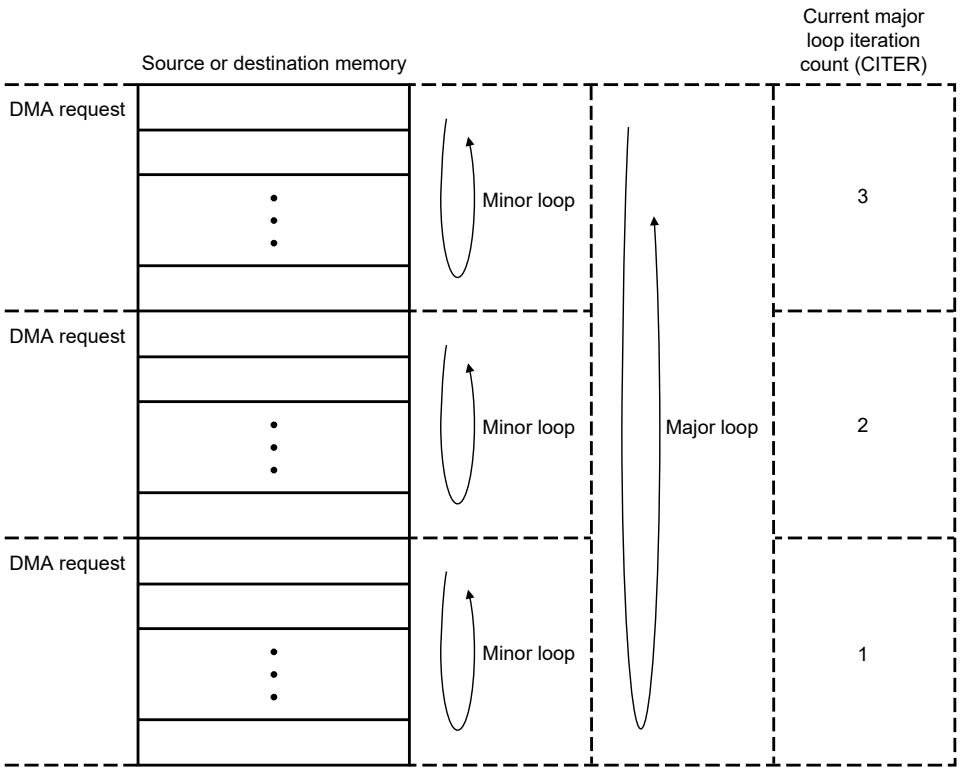

Figure 14. Example of multiple loop iterations

5.6.4 Memory array terms

Figure 15 shows the memory array terms and how the TCD settings interrelate.

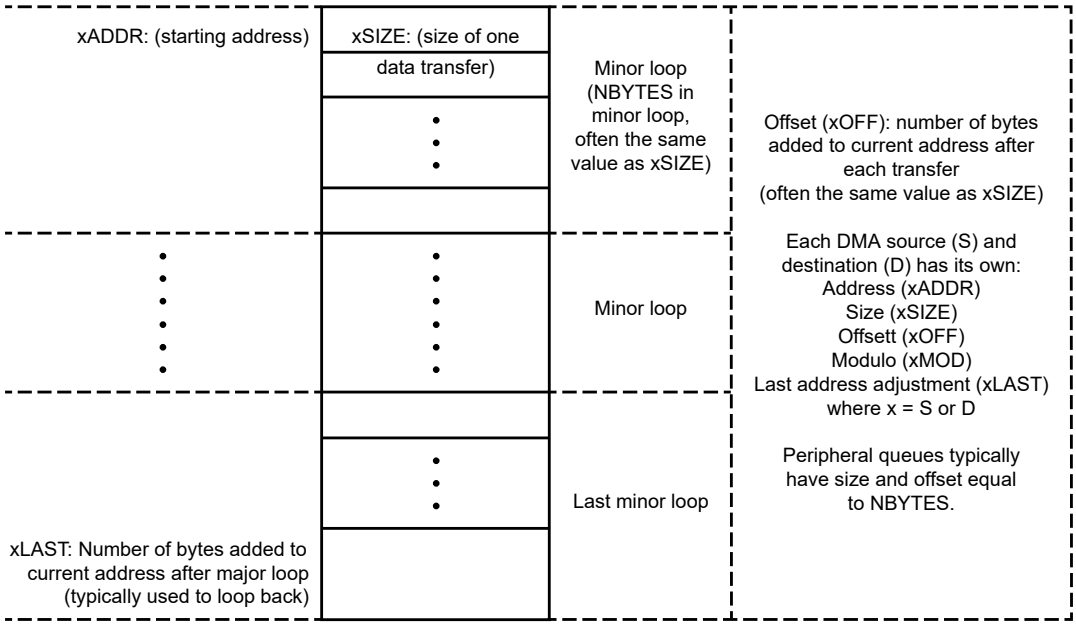

Figure 15. Memory array terms

5.7 Application information

The following sections discuss eDMA application information.

5.7.1 eDMA arbitration

eDMA uses a layered arbitration scheme consisting of multiple priority levels. It uses a fixed-priority arbitration scheme with an optional, round-robin arbitration under specific conditions. The priorities are evaluated in the following order:

1. Highest arbitration group priority: Each channel is assigned an arbitration group through CH0_GRPRI. Priority is given to the highest value (31 is the highest possible value) down to the lowest value (0 being the default).
2. Channel priority: Each channel is assigned a channel priority level through CH0_PRI. The channel priority is a relative priority level within an arbitration group. Priority is given to the highest value (7 being the highest possible value) down to the lowest value (0 being the default). Channel priorities within each arbitration group do not have to be unique. If multiple channels have the same channel priority level, the channel number is used to determine priority as defined in channel number.
3. Channel number: When two or more channels have the same arbitration group and channel priority, the channel number (CH_NUM) is used to determine the highest priority. Priority is given to the highest channel number. The lowest priority is channel 0. The channel numbers are static and you cannot change them in the programmer's model.
4. Lowest: When you enable round-robin, any channel configured for the round-robin operation has the lowest priority within an arbitration group. When you enable round-robin by writing 1 to CSR[ERCA], channels with a channel priority of zero (CH_PRI = 0) use round-robin arbitration, which rotates the channel selection among the channel's requesting service with CH_PRI = 0 within the arbitration group. Any nonzero channel within the arbitration group continues to use fixed-priority arbitration, and if requesting service, selects over any round-robin channels.

For fixed arbitration, you can consider the overall priority as a number composed of three concatenated priority levels (CH_GRPRI:CH_PRI:CH_NUM). The largest number has the highest priority and the lowest number has the lowest priority.

When you enable round-robin arbitration, channels are serviced in an order, per priority group (CH_GRPRI:0:X). Within a priority group, all channels with their channel priority set to zero are cycled through from the highest to lowest channel number.

The round-robin scheme can be overridden by a nonzero channel priority value (any channel with a nonzero CH*n*_PRI value automatically has a higher priority over the round-robin scheme).

5.7.2 Programming errors

eDMA performs various tests on TCD to verify consistency in the descriptor data.

The channel number causing the error is recorded in ES. If you do not remove the error source before the next activation of the problem channel, the error is detected and recorded again. Writing 1 to CSR[HAE] halts the DMA and prevents the recurrence of the error.

5.7.3 Arbitration mode considerations

This section discusses arbitration considerations for eDMA.

5.7.3.1 Fixed-group arbitration, fixed-channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If you program eDMA in a way that the channels with a high-priority group have a high number of requests or large data transfers, that group may consume all the bandwidth of the eDMA controller. That is, no lower priority group is serviced if there is at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that require immediate service.

5.7.3.2 Fixed-group arbitration, round-robin channel arbitration

The highest priority group with a request is serviced. Lower priority groups are serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest nonzero channel priority. For all channels with a channel priority programmed to 0, the highest channel number requesting service is selected, rotating to the lowest channel number requesting service. The round-robin channel arbitration can provide a fairness mechanism to lower priority channels.

This scenario can lead to the same bandwidth consumption problem as indicated in Fixed-group arbitration, fixed-channel arbitration, but all channels in the highest priority group are serviced. Service latency is short on the highest priority group, but can become potentially longer as the group priority decreases.

5.7.4 Performing DMA transfers

This section presents examples on how to perform DMA transfers with eDMA.

5.7.4.1 Single request

To perform a simple transfer of *n* bytes of data with one activation, write 1 to the major loop (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after you acknowledge the channel service request and select the channel to execute. After the transfer is complete, CH0_CSR[DONE] becomes 1 and an interrupt generates, if properly enabled.

The following TCD entry (see Code Listing 1) is configured to transfer 16 bytes of data. eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte-wide memory port at 1000h. The destination memory has a 32-bit port at 2000h. Program the address offsets in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their initial values.

This generates the following event sequence:

1. You must write 1 to TCD0_CSR[START] to request channel service.
2. Arbitration selects the channel for servicing.
3. The eDMA engine writes 0 to CH0_CSR[DONE] and TCD*n*_CSR[START], and 1 to CH0_CSR[ACTIVE].
4. The eDMA engine reads channel TCD data from the local memory to internal register file.
5. The source-to-destination transfers are executed as follows:

a. Data is continuously read from the source addresses by issuing read transactions and adjusting the source address through the source address-offset after each transaction.

b. Data is continuously written to the destination addresses after sufficient data is buffered. Adjust the destination address through the destination address offset after each transaction.

6. The eDMA engine writes 1000h to TCD*n*_SADDR, 2000h to TCD*n*_DADDR, and 1 to TCD*n*_CITER(TCD*n*_BITER).
7. The eDMA engine writes 0 to CH*n*_CSR[ACTIVE], 1 to CH*n*_CSR[DONE], and 1 to CH0_INT[INT].
8. The channel retires and eDMA goes idle or services the next channel.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 1000h
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 2000h
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INTMAJ] = 1
TCDn_CSR[START] = 1 (You must write to this field after all other fields are initialized.)
All other TCDn fields = 0
```

Code Listing 1. Single request

5.7.4.2 Multiple requests

Code Listing 2 shows the transfer of 32 bytes through two hardware requests but is otherwise the same as the previous example (see Single request). The only fields that change are the major loop iteration count and final address offsets. Program eDMA for two iterations of the major loop transferring 16 bytes per iteration. After you enable the channel's hardware requests through CH0_CSR[ERQ], the target device initiates channel service requests.

This generates the following sequence of events:

1. First hardware, that is, eDMA peripheral, requests for channel service.
2. Arbitration selects the channel for servicing.
3. The eDMA engine writes 0 to CH0_CSR[DONE] and TCD0_CSR[START], and 1 to CH0_CSR[ACTIVE].
4. The eDMA engine reads channel TCD*n* data from the local memory to the internal register file.
5. The source to destination transfers are executed as follows:

   a. Data is continuously read from the source addresses by issuing read transactions and adjusting the source address through the source address offset value after each transaction.

   b. Data is continuously written to the destination addresses after sufficient data is buffered. Adjust the destination address through the destination address offset after each transaction.
6. The eDMA engine writes 1010h to TCD*n*_SADDR, 2010h to TCD*n*_DADDR, and 1 to TCD*n*_CITER.
7. The eDMA engine writes 0 to CH*n*_CSR[ACTIVE].
8. The channel retires → one iteration of the major loop. eDMA goes idle or services the next channel.
9. The second hardware, that is, eDMA peripheral, requests channel service.
10. Arbitration selects the channel for servicing.

11. The eDMA engine writes 0 to CH*n*_CSR[DONE] and TCD*n*_CSR[START], and 1 to CH*n*_CSR[ACTIVE].
12. The eDMA engine reads the channel TCD data from the local memory to the internal register file.
13. The source to destination transfers are executed as follows:
    a. Data is continuously read from the source addresses by issuing read transactions and adjusting the source address through the source address offset value after each transaction.
    b. Data is continuously written to the destination addresses after sufficient data is buffered. Adjust the destination address through the destination address offset after each transaction.
14. The eDMA engine writes 1000h to TCD*n*_SADDR, 2000h to TCD*n*_DADDR, and 2 to TCD*n*_CITER(TCD*n*_BITER).
15. The eDMA engine writes 0 to CH*n*_CSR[ACTIVE], and 1 to CH*n*_CSR[DONE] and CH0_INT[INT].
16. The channel retires → major loop complete. eDMA goes idle or services the next channel.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

Code Listing 2. Multiple request

5.7.4.3 Using the modulo feature

The modulo feature of eDMA provides the ability to implement a circular data queue in which the queue's size is a power of 2. MOD is a 5-bit field for the source and destination in TCD, and it specifies which lower address bits increment from their original value after the address plus offset calculation. All upper address bits remain the same as their original value. When you write 0 to this field, it disables the modulo feature. Modulo addressing applies to cases where the minor loop offset is enabled; that is, the upper address bits remain the same after the minor loop offset is added to the source or destination address.

Table 27 shows how to specify the transfer addresses based on the MOD field setting. A circular buffer is created where the address wraps to the original value while the 28 upper address bits (1234_567*x*h) retain their original value. In this example, the source address is set to 1234_5670h, the offset is set to 4 bytes, and MOD is set to 4, allowing for a 2^4 byte (16-byte) size queue.

Table 27. Modulo example

Transfer number	Address
1	1234_5670h
2	1234_5674h
3	1234_5678h
4	1234_567Ch
5	1234_5670h
6	1234_5674h

5.7.5 Monitoring TCD status

This section discusses how to monitor eDMA status.

5.7.5.1 Testing for minor loop completion

There are two methods to test minor loop completion when using software-initiated service requests. First is to read TCD*n*_CITER and test for a change. You may extract another method from Table 28. The second method is to test TCD0_CSR[START] and CH0_CSR[ACTIVE]. The minor-loop-complete condition is indicated by both fields reading zero after you write 1 to TCD*n*_CSR[START]. Only polling CH*n*_CSR[ACTIVE] can be inconclusive because you can miss the active status while the channel execution is of shorter duration.

The CH*n*_CSR and TCD*n*_CSR status fields execute the following sequence (as shown in Table 28) for a software-activated channel.

Table 28. Settings for software-activated channel

Stage	TCD*n*_CSR and CH*n*_CSR			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request through software.
2	0	1	0	Channel is executing.
3a	0	0	0	The channel is idle after completing its minor loop.
3b	0	0	1	The channel is idle after completing its major loop.

The best method to test for minor-loop completion when using eDMA (that is, peripheral, initiated service requests), is to read TCD*n*_CITER and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status fields execute the following sequence (as shown in Table 29) for a hardware-activated channel.

Table 29. Settings for hardware-activated channel

Stage	TCD*n*_CSR and CH*n*_CSR			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request through hardware (peripheral request asserted).
2	0	1	0	Channel is executing.
3a	0	0	0	The channel is idle after completing its minor loop.
3b	0	0	1	The channel is idle after completing its major loop.

For both the activation types, the major-loop-completion status is explicitly indicated through CH0_CSR[DONE].

TCD0_CSR[START] becomes 0 automatically when the channel begins execution regardless of how the channel activates.

5.7.5.2 Checking channel preemption status

A preemptive situation is one in which a preempt-enabled channel is executing and a higher priority request becomes active. When you enable the round-robin channel arbitration mode, all the channels with their channel priority set to zero lose their preempt ability. Channel priorities of zero are treated as equal, that is, constantly rotating, when round-robin arbitration mode is enabled.

CH0_CSR[ACTIVE] remains 1 for the preempted channel throughout the preemption. The preempted channel is temporarily suspended when the preempting channel executes one major loop iteration. If you write 1 to two CH*n*_CSR[ACTIVE] fields simultaneously in the global TCD map, a higher priority channel actively preempts a lower priority channel.

5.7.6 Channel linking

Channel linking (or chaining) is a mechanism where one channel writes 1 to TCD0_CSR[START] of another channel (or itself), initiating a service request for that channel. When properly enabled, the eDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs after the minor loop (or one iteration of the major loop). TCD*n*_CITER[ELINK] determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. After the major loop is exhausted, only the major loop channel link fields are used to determine whether a channel link should be created. For example, the initial fields listed in Code Listing 3 execute as:

1. Minor loop done → write 1 to TCD12_CSR[START]
2. Minor loop done → write 1 to TCD12_CSR[START]
3. Minor loop done → write 1 to TCD12_CSR[START]
4. Minor loop done, major loop done→ write 1 to TCD7_CSR[START]

```
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = Ch
TCDn_CITER[CITER] value = 4h
TCDn_CSR[MAJORELINK] = 1
TCDn_CSR[MAJORLINKCH] = 7h
```

Code Listing 3. Channel linking

After you enable minor loop linking (TCD*n*_CITER[ELINK] = 1), TCD*n*_CITER[CITER] uses a 9-bit vector to form the current iteration count. When you disable minor loop linking (TCD*n*_CITER[ELINK] = 0), TCD*n*_CITER[CITER] uses a 15-bit vector to form the current iteration count. Fields associated with TCD*n*_CITER[LINKCH] are concatenated onto the CITER value to increase the range of CITER.

NOTE

TCD*n*_CITER[ELINK] and TCD*n*_BITER[ELINK] must be equal; else, a configuration error is reported. CITER and BITER vector widths must be equal to calculate the major loop, halfway done interrupt point.

Table 30 summarizes how a DMA channel can link to another DMA channel, that is, use another channel's TCD at the end of a loop.

Table 30. Channel linking parameters

Desired link behavior	TCD control field name	Description
Link at the end of minor loop	TCD*n*_CITER[ELINK]	Enables channel-to-channel linking on minor loop completion (current iteration)
	TCD*n*_CITER[LINKCH]	Links channel number when linking at the end of minor loop (current iteration)
Link at the end of major loop	TCD0_CSR[MAJORELINK]	Enables channel-to-channel linking on major loop completion
	TCD0_CSR[MAJORLINKCH]	Links channel number when linking at the end of major loop

5.7.7 Dynamic channel linking

Dynamic channel linking is the process of writing 1 to TCD0_CSR[MAJORELINK] and TCD0_CSR[MAJORLINKCH] during channel execution. These fields are read from the TCD profile at the end of channel execution. This allows you to enable the feature during channel execution. When attempting a dynamic channel link, you must write to TCD*n*_CSR[MAJORELINK] and TCD*n*_CSR[MAJORLINKCH] in a single write transaction (that being a write size of at least 16 bits to TCD0_CSR).

Because you can change the configuration during execution, it requires a coherency model. Consider a scenario where you attempt to execute a dynamic channel link by writing 1 to TCD*n*_CSR[MAJORELINK] at the same time when the eDMA engine is retiring the channel. TCD*n*_CSR[MAJORELINK] is 1 in the programmer's model, but it is unclear whether the actual link was made before the channel retired.

When you execute a dynamic channel link request, NXP recommends using the following coherency model:

1. Write 1 to TCD*n*_CSR[MAJORELINK].
2. Read TCD*n*_CSR[MAJORELINK].
3. Test the TCD*n*_CSR[MAJORELINK] request status:
   - If TCD*n*_CSR[MAJORELINK] = 1, the dynamic link attempt is successful.
   - If TCD*n*_CSR[MAJORELINK] = 0, the attempted dynamic link does not succeed (the channel is retiring already).

The TCD local memory controller forces TCD*n*_CSR[MAJORELINK] to become 0 on any writes to a channel's TCD*n*_CSR after that channel's CH0_CSR[DONE] becomes 1, indicating that the major loop is complete.

NOTE

Write 0 to CH*n*_CSR[DONE] before writing to TCD*n*_CSR[MAJORELINK]. The eDMA engine automatically writes 0 to CH*n*_CSR[DONE] after a channel begins execution.

5.7.8 Suspend or resume a DMA channel with active hardware service requests

DMA allows you to move data from memory or peripheral registers to another location in memory or peripheral registers without CPU interaction. After you configure DMA and peripherals and they are active, it is rare to suspend a peripheral's service request dynamically. In this scenario, there are restrictions to disable a DMA hardware service request. Follow a specific procedure for coherency. This section provides guidance on how to coherently suspend and resume a DMA channel when a target module triggers the DMA.

5.7.8.1 Suspend an active DMA channel

Perform the following procedure to suspend an active DMA channel:

1. Stop the DMA service request at the peripheral.
2. Read back the appropriate register in the peripheral to confirm that the service request is disabled.
3. Check HRS to ensure that there is no suspended service request to the DMA channel.
4. Write 0 to CH0_CSR[ERQ] on the appropriate DMA channel to disable the hardware service request.

For example, assume the SPI is set as the controller for transmitting data through a DMA service request when DSPI_TXFIFO has an empty slot. DMA transfers the next command and data to the TXFIFO upon the request. If you require to suspend the DMA/SPI transfer loop, perform the following steps:

1. Disable the DMA service request at the source by writing 0 to DSPI_RSER[TFFF_RE]. Confirm that DSPI_RSER[TFFF_RE] is 0.
2. Ensure that there is no DMA service request from the SPI by verifying that HRS[HRS] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by writing 0 to CH0_CSR[ERQ]. If a service request is present, wait until the request is processed and HRS becomes 0.

5.7.8.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by writing 1 to CH0_CSR[ERQ].
2. Enable the DMA service request at the peripheral.

Chapter 6
Security Overview

6.1 Security features

By controlling access to the device as well as providing trusted computing environment, this chip offers various security features and tools that allow customers to protect their assets.

Some of the basic features include:

- Secure boot ensuring that only authentic entity is allowed to access the device or execute code on it.
- Secure debug allowing customers to securely develop and debug software while the device is at manufacturing or deployed in the field.
- Secure lifecycle management guaranteeing that security mechanisms are enforced, and device reaches its highest security level after it has been deployed or returned to NXP for failure analysis.
- Hardware Security Module (HSM) and cryptographic services ensuring that cryptographic keys remain hidden from the application in all circumstances.

This chapter explains the main purpose and features of security-relevant SoC components:

- EdgeLock Secure Enclave (Advanced Profile) (ELE-AP) acts as a Root of Trust for platform security. It manages the SoC lifecycle, enforces secure boot, controls debug access, and provides full key management and key isolation from the rest of SoC.
- Trusted Resource Domain Controller (TRDC) is essential in enabling isolation between various processes running within the SoC. It is used to define and enforce separation between security critical and other processes by introducing the notion of domain IDs, as well as enforcing the trusted execution environment defined by ARM® TrustZone®.
- On-the-Fly AES Decryption (OTFAD) protects the confidentiality of code stored in external memory using AES in CTR mode. The key used for decryption is securely handled by ELE-AP and delivered to OTFAD using a dedicated private bus, ensuring that the key is not observable by any application running on the SoC. OTFAD supports up to four independent memory contexts, each having a unique 128-bit decryption key.
- Battery Backed Secure Memory (BBSM) is used as a non-volatile storage of security parameters including general purpose registers, run-time counter with a wake-up alarm, monotonic counters, as well as tamper detection inputs.

6.1.1 Immutable Root of Trust (RoT)

As defined by Trusted Computing Group, “an Immutable Root of Trust (RoT) is expected to remain identical across all devices within a set of device models based on a defined threat model. It is also expected not to change across time and, therefore, will behave the same during each device’s lifespan.”

Immutable RoT consists of truly immutable hardware logic, including analog and digital logic, read-only memory and one-time programmable memory. It is essential for guaranteeing any security feature, including secure boot, secure debug, life-cycle management, and a number of others. In this device, immutable RoT is embedded in the ELE-AP boot ROM (immutable boot loader) and it relies on the ELE-AP hardware cryptographic accelerators for its function.

6.1.2 Run time root of trust (RRoT)

The processor includes a Run Time Root of Trust (RRoT) Hardware State machine to ensure the Root of Trust is established before Hardware allows access to keys during runtime. The RRoT feature is enabled by the immutable ELE-AP ROM code and is used for features like attestation where keys are stored in memory protected by RRoT based secure access control.

6.1.3 Lifecycle management

During its lifespan, a typical device finds itself in various places around the world. It is manufactured in a semiconductor factory, tested and packaged in silicon manufacturer facilities, sold to various distributors, sold further to the Original Equipment

Manufacturer (OEM), assembled, tested and provisioned by their Contract Manufacturers and, finally, delivered to the end-customer. In the case of failure, a device is returned to OEM or even back to the silicon manufacturer for further failure analysis.

Device life cycle state is used to reflect the actual state of the device, which is further used to instruct the device on how exactly to protect the assets a device hosts during specific time. For example, when a device is being tested at a silicon manufacturer facility and no OEM or end-customer assets have been provisioned, then access to the device, in terms of debug or test, is less restrictive than when a device is with the end-customer.

Life cycle state is monotonic, meaning it can only always be increased. Immutable RoT is in charge of life cycle management and it enforces device access policies accordingly.

6.1.4 Secure boot

Secure boot ensures authenticity, integrity and confidentiality of the device boot loader, firmware, and other software during the boot process and ensures that the intended secure life-cycle state is reached. SHA with ECDSA or RSA with different key lengths are available to guarantee authenticity and integrity of the firmware image. AES-based memory encryption can be used to provide code/data confidentiality while the firmware image is stored in external memory. ELE-AP as an immutable RoT is in charge of enforcing secure boot and it does so according to the policies defined by the life-cycle state.

See i.MX 93 Applications Processor Security Reference Manual for more details about secure boot.

6.1.5 Secure debug

Secure debug is the process used to securely access external jtag debug, following the policy defined by the lifecycle state. When a debugger wants to debug a device, they indicate that through the jtag interface.

NXP provides the asymmetric signed message based mechanism.

6.1.6 IP protection

IP protection is a set of mechanisms used to protect confidentiality and integrity of valuable code and data stored on the device. During secure update, the firmware image is encrypted using AES. While at rest and during secure boot, the firmware image is encrypted and stored in external memory. Up to four independent memory contexts available through OTFAD using a unique 128-bit key per context.

6.1.7 Secure isolation

ELE-AP guarantees run-time key isolation from any process running on the rest of SoC. In addition, Arm® TrustZone® capable Cortex®-M33 and Cortex®-A55, in combination with the Trusted Resource Domain Controller (TRDC), enables secure isolation during run-time.

6.1.8 TrustZone®

Trustzone® (TZ) is a feature on the Cortex®-A55 and Cortex®-M33, which provides segmentation of memory arrays and peripherals into either Secure (S) or Non-Secure (NS). This feature allows the M33 core to execute in either S or NS mode, and provides a secure separation between various application software.

The TrustZone® security architecture is supported. Trustzone®-M is always enabled, as this is an integral feature of the Cortex®-M33 boot ROM and system security. For on-chip RAM, all of OCRAM have TrustZone® access control support. One region with configurable address range of the OCRAM can be set to TZ access only. The Trustzone® memory region protection of DRAM is supported through TRDC.

The majority of system initiators in the SoC do not natively support TrustZone® (and more specifically, do not support a concept of AxPROT[0] indicating controllable privileged vs normal access or AxPROT[1] indicating non-secure vs TrustZone® secure access). Therefore, the TRDC DAC provides controls to override IP initiator’s AxPROT[1:0] inputs to the subsystem NICs. However, initiators which do have concept of these AxPROT[1:0] signals, do not have their signals overridden by the TRDC DAC.

6.1.9 Trusted resource domain control (TRDC)

The chip uses a domain based resource control architecture for the memory/peripheral resource sharing and isolation between the Cortex®-A55 platform, Cortex®-M33 core, and other bus masters. A key feature of this architecture is that it must be possible for either Cortex-A55 platform or the Cortex®-M33 platform to program the resource domain control access lists to implement a customer-defined policy. Another key feature is that any peripheral can be assigned to any domain. The TRDC supports multiple regions with flexible access permission control for each memory space.

A core complex should not rely on TRDC and should use the internal MMU for memory management. In addition, initiators like Cortex®-A55, that implement the DSU architecture, do support AxPROT internally, but do not drive AxPROT[2] and AxPROT[0] on the system bus. For Cortex®-A55, after boot, it is recommended to use the internal MMU for access control.

For more details please refer Chip-specific TRDC information.

6.1.10 Secure key management

Secure key management is a process of securing valuable keys and various key material which are essential in maintaining security of the end-user, OEM and NXP assets. The process strongly relies on the Immutable RoT consisting of ELE-AP, including its logic, ROM as well as OTP fuse. A device-unique master key is only used for further key derivation. Part of the derivation data is supplied by the Immutable RoT, accurately reflecting the device's state, making sure different keys are derived in different states. For example, different life-cycle state will often yield a different derived key. All the platform keys reside within a security subsystem, hidden from the application core at all times.

6.1.11 Block control secure (BLK_CTRL_S_AONMIX)

The chip includes a block called BLK_CTRL_S_AONMIX which contains assorted configuration controls that can potentially have security implications. The BLK_CTRL_S_AONMIX registers are reset only by when ELE-AP is reset. These registers can only be accessed by TrustZone Secure World.

BLK_CTRL_S_AONMIX has the following functions:

- Cortex-M NVIC Interrupt Masking.
- Cortex-A GIC Interrupt Masking.
- WDOG Timer output masking for combined watchdog timer SoC output pin.

6.2 Edgelock secure enclave

The Edgelock Secure Enclave (ELE) supports the following features:

- SoC Life cycle management
- Cryptographic services
- Key Management
- Runtime Root of Trust
- One Time programmable Fuse controller
- Authenticated Debug with multiple debug domains
- Clock Frequency Monitoring

The ELE has a 32-bit bus with access to the SoC. The Edgelock secure enclave has multiple MU instances, and private buses to connect to security components outside EdgeLock Enclave such as BBSM, and FlexSPI's OTFAD.

Chapter 7
Fusemap

7.1 Overview

This section details the various fuses and their associated configuration settings. This chapter also describes various modes and the selection of the required boot devices.

NOTE

The fuses marked as “Reserved” are reserved for NXP internal (and future) use only, or are security related. Customers must not attempt to burn these, because the IC behavior may be unpredictable. The reserved fuses can be read as either '0' or '1'. Security-related fuses are described in the Security Reference Manual (SRM) for this device.

7.1.1 Bank redundancy

Fuses can generally only be set from 0 to 1 and the most common failure is a 1 appearing as a 0. The simplest mechanism to verify these failures is redundancy. Redundancy is when two bits are OR'd together so that if either is set, then the output value is a 1.

In case of fuses protected by redundancy, only 16 of the 32 bits are available (bits 15:0 are automatically copied to 31:16) and checked on read. This allows for multiple programming operations on a word, so bits can be configured at different times.

NOTE

In shadow registers, the inverted version of [15:0] will show in [31:16]. In the fuse array, [31:16] is the same as [15:0].

NOTE

The monotonic array requires redundancy, as it’s programmed individually

7.1.2 Lock bits

There are three kinds of lock bits, write lock, overwrite lock and read lock. If a word attribute of read / write / over-write lock is not set, then it can be read sensed, programmed and the shadow registers can be overwritten.

The write lock bits are used by the controller to control writing/programming of the fuse bits. A set of fuse words used for the same function can be write locked using a single fuse bit. If the fuse write lock is set, it indicates that the associated fuse bits can no longer be updated.

Read lock bits are a specific set of fuses that give you the ability to block bus access to specific words. When a fuse is read locked, it will be loaded to shadow registers during boot, but won't be readable via bus access.

Over-write lock bits are used to disable the feature of allowing SW to write to the shadow registers, enabling emulation of the function without committing to the fuse value.

Refer the attached spreadsheet for the chip fusemap descriptions.

7.1.3 API fuse access

Reading a fuse through an API needs the fuse word index. Fuse word index is calculated by: Fuse index / 32 (interer), or Bank number * 8 + word. Writing a fuse requires bit position, and the number of bits to be written. Please refer to the latest version of *EdgeLock® Secure Enclave (Advanced Profile) (ELE-AP) User Guide* for more details.

7.2 Boot Fusemap

This section describes the various modes and the selection of the required boot devices. The device select is specified by the BOOT_CFG0[3:0] fuses. See i.MX 93 Applications Processor Reference Manual for more details.

Table 31. Boot configuration fuses

7.3 Fusemap descriptions table

Please refer the attached spreadsheet for the chip fusemap descriptions.

7.4 Programming Fuses

This section provides an overview on how to read and program eFuses. The OTP memory is part of the security subsystem and is controlled by the ELE. The ELE Firmware provides API functions which are used to interact with OCOTP CTRL block. Please refer the EdgeLock Enclave (ELE) API Reference Guide for more information.

Chapter 8
Fuse Status Block

8.1 Introduction

The Fuse and Status block (FSB) is an interface to allow the SoC to directly read public fuses and EdgeLock Secure Enclave status information.

FSB also provides SOC with write access to some of the OCOTP registers and shadow SRAM.

8.1.1 Features

The FSB includes the following features:

- Allow the SoC to read certain fuses and status registers
- Fuse values can be read from APB register interface
- FSB provides read/write access to OCOTP registers that hold status of fuse accesses
- FSB does not gate in any way accesses to fuse values and the OCOTP status registers
- FSB implements support for SoC to abort transfers on the FSB APB when accessing fuses
- FSB supports both read and write accesses to OCOTP fuses and status registers

8.2 Memory map and register definition

This section includes the FSB module memory map and detailed descriptions of all registers.

FSB does not by itself generate bus errors on accesses to its register space. However, FSB will return a bus error it might get from OCOTP on accesses to fuse and OCOTP status registers. Unsupported accesses or accesses to reserved space are ignored or return 0.

8.2.1 FSB register descriptions

8.2.1.1 FSB memory map

FSB1 base address: 4751_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	FSB Version ID Register (VERID)	32	R	0202_0001
1C	FSB Status Register (FSB_STATUS)	32	R	0000_0000
64	Access Count Register (ACCESS_COUNT)	32	RW	0000_0000
1000	Fuse Status Register (FUSE_STAT)	32	RW	0000_0000
1004	Fuse Event Register (FUSE_EVNT)	32	RW	0000_0000
1008	Fuse Interrupt Enable Register (FUSE_INT_EN)	32	RW	0000_0000
100C	Fuse Interrupt Register (FUSE_INT)	32	R	0000_0000
1080	Unprogrammed Fuse Counter (UNPROG_CTR)	32	R	0000_0000
8000 - 87FC	Fuse Value Registers (FUSE0 - FUSE511)	32	R	0000_0000

8.2.1.2 FSB Version ID Register (VERID)

This register records the specific version of the FSB module in the chip.

Offset

Register	Offset
VERID	0h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Fields

Field	Description
31-24 MAJOR	Major Version Number This read only field returns the major version number.
23-16 MINOR	Minor Version Number This read only field returns the minor version or revision number. Starting with minor version 2, FSB supports OCOTP status register space in addition to the fuse space and enables write transfers in these areas of the address map.
15-8 ECO	ECO Version Number This read only field returns the ECO version number.
7-0 MISC	Feature Specification This read only field returns the status of various configuration options indicating features present in this instance of FSB. xxxx_xx1x - MU IRQ steering is enabled. xxxx_xxx1 - Support for aborted transfers to OCOTP fuse space on the FSB slave APB is enabled.

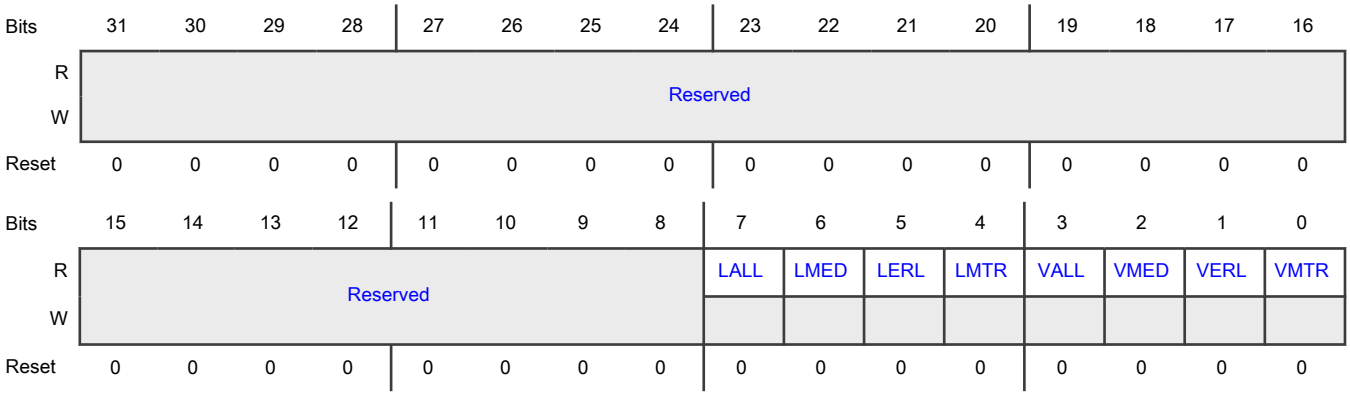
8.2.1.3 FSB Status Register (FSB_STATUS)

FSB status. For now the only status is whether or not fuse values are loaded and valid. At reset, the fuse values will not be valid. FSB does not gate accesses to OCOTP shadow RAM based on the state of these bits.

Offset

Register	Offset
FSB_STATUS	1Ch

Diagram



Fields

Field	Description
31-8 —	Reserved
7 LALL	All fuses loaded. The fuse values are loaded and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.
6 LMED	Medium fuses loaded. The fuse values are loaded and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.
5 LERL	Early fuses loaded. The fuse values are loaded and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.
4 LMTR	MTR Trim fuses loaded. The fuse values are loaded and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.
3 VALL	All fuses valid. The fuse values are valid and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.
2 VMED	Medium fuses valid.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	The fuse values are valid and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.
1 VERL	Early fuses valid. The fuse values are valid and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.
0 VMTR	MTR Trim fuses valid. The fuse values are valid and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.

8.2.1.4 Access Count Register (ACCESS_COUNT)

This register contains a count of the number of times an FSB register has been accessed.

Offset

Register	Offset
ACCESS_COUNT	64h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	COUNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	COUNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-0 COUNT	Access Count Register. Each time an FSB is read or written, this register will increment. Writing a value to this register will set a new starting value. Writing a new value takes precedence over incrementing this register.

8.2.1.5 Fuse Status Register (FUSE_STAT)

Reports the status and address of the last fuse shadow read. Writing to this register will clear the register contents.

If the fuse shadow read reports a RD_ERR or RLD_ERR then the Shadow Loading, Fuse Error, Unprogrammed, Zeroized, ECC and RED status bits will be 0 regardless of the actual fuse status.

Offset

Register	Offset
FUSE_STAT	1000h

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	FUSE_ADDR															
W	0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31 ADDR_ERR	Address error High if the last fuse shadow read used an illegal address, including: • Writing to a fuse shadow • Accessing an address that is not 32-bit aligned • Accessing fuse which does not have a shadow in RAM • The Shadow RAM entry is not accessible from the FSB APB • The `soc_apb_fsb_access_disable` is asserted to disable FSB access • The SRAM controller FSM is in an error state preventing access to the SRAM
30 —	Reserved
29 RD_ERR	Read error High if the last fuse shadow read attempted to read a shadow that was read protected
28 RLD_ERR	Reload error High if the last fuse shadow was read during a Fuse Shadow Reload before it's section (early, mid or late) had finished loading and the Reload Control register setting for that fuse section is set to BLOCK

Table continues on the next page...

Table continued from the previous page...

Field	Description
27 LOADING	Shadow loading High if the last fuse shadow was read while the shadow was still loading from the fusebox. This prevents the ECC and Fuse Errors from being determined
26 FUSE_ERR	Fuse error High if the last fuse shadow read reported a serious error when the shadow was loaded from the fusebox. This includes: • Uncorrected Fuse ECC multi-bit error • Corrected Fuse RED multi-bit error • Transfer error from the fusebox This will also be high if the fuse shadow read reported a multi-bit error
25 SHDW_UNPROG	Shadow unprogrammed High if the last fuse shadow read was unprogrammed
24 SHDW_ZERO	Shadow zeroized High if the last fuse shadow read was zeroized
23-16 —	Reserved
15-0 FUSE_ADDR	Fuse address The address offset of the last fuse shadow read for which the status applies. Note that the 2 lsb will always be zero because the fuse address = fuse number left shifted by 2.

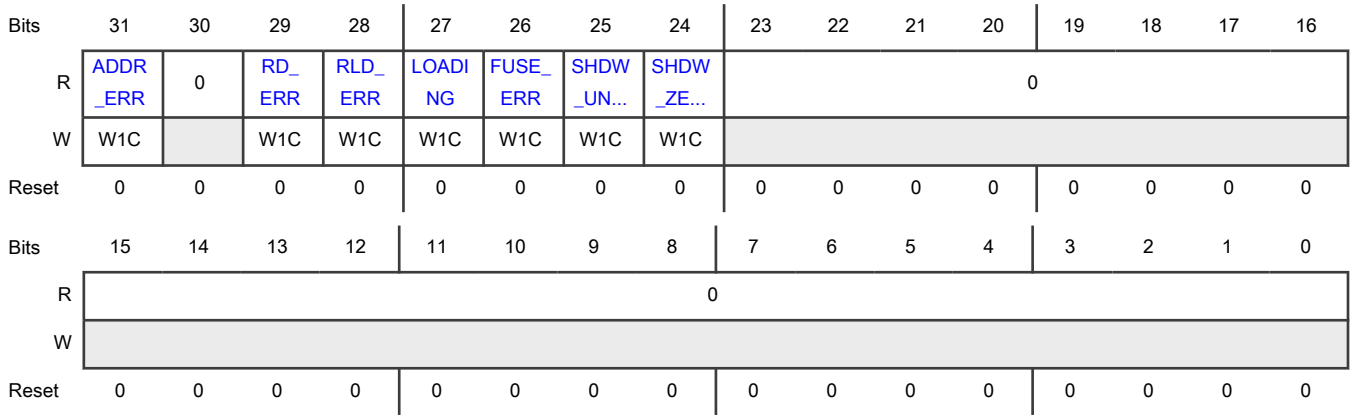
8.2.1.6 Fuse Event Register (FUSE_EVNT)

Accumulates the status from fuse shadow reads. Bits are set when the corresponding status bit is set and cleared by writing a '1' to the event bit.

Offset

Register	Offset
FUSE_EVNT	1004h

Diagram



Fields

Field	Description
31 ADDR_ERR	Address error Set if a shadow read used an illegal address, including: • Writing to a fuse shadow • Accessing an address that is not 32-bit aligned • Accessing fuse which does not have a shadow in RAM • The Shadow RAM entry is not accessible from the FSB APB • The `soc_apb_fsb_access_disable` is asserted to disable FSB access • The SRAM controller FSM is in an error state preventing access to the SRAM Write '1' to clear.
30 —	Reserved
29 RD_ERR	Read error Set if a fuse shadow read attempted to read a shadow that was read protected. Write '1' to clear.
28 RLD_ERR	Reload error Set if a fuse shadow was read during a Fuse Shadow Reload before it's section (early, mid or late) had finished loading and the Reload Control register setting for that fuse section is set to BLOCK. Write '1' to clear.
27 LOADING	Shadow loading Set if a fuse shadow was read while the shadow was still loading from the fusebox. This prevents ECC and Fuse Error from being determined. Write '1' to clear.
26 FUSE_ERR	Fuse error Set if a fuse shadow read reported a serious error when the shadow was being loaded from the fusebox. This includes:

Table continues on the next page...

Table continued from the previous page...

Field	Description
	• Uncorrected Fuse ECC multi-bit error • Corrected Fuse RED multi-bit error • Transfer error from the fusebox This will also be set if a fuse shadow read reported a multi-bit error. Write '1' to clear.
25 SHDW_UNPROG	Shadow unprogrammed Set if a fuse shadow read was unprogrammed. Write '1' to clear.
24 SHDW_ZERO	Shadow zeroized Set if a fuse shadow read was zeroized. Write '1' to clear.
23-0 —	Reserved

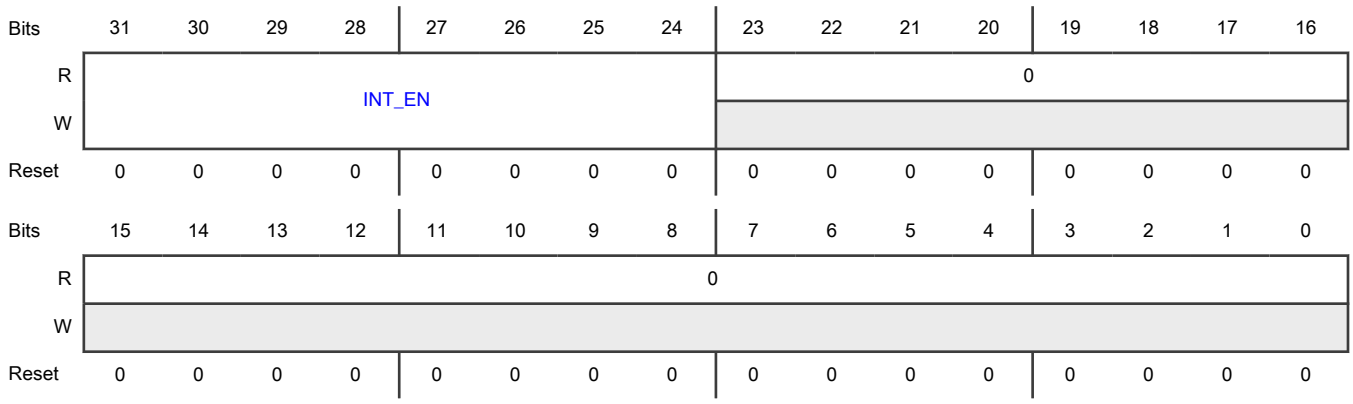
8.2.1.7 Fuse Interrupt Enable Register (FUSE_INT_EN)

Fuse Interrupt Enable Register

Offset

Register	Offset
FUSE_INT_EN	1008h

Diagram



Fields

Field	Description
31-24	Interrupt Enables

Table continues on the next page...

Table continued from the previous page...

Field	Description
INT_EN	AND-ed with the Fuse Event register value to generate the Fuse Interrupt bits. Setting interrupt enable register bits enables the corresponding interrupt bits. See the FUSE_EVNT register for a description of the interrupt signals.
23-0 —	Reserved

8.2.1.8 Fuse Interrupt Register (FUSE_INT)

Set when any of the Fuse Interrupt bits are non-zero. The CSSI ocotp_apb_fsb_irq output is high when this register is non-zero.

Offset

Register	Offset
FUSE_INT	100Ch

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Description
31-24 INT	Interrupts Reports the result of AND-ing the Fuse Event register with the Fuse Interrupt Enable register. See the FUSE_EVNT register for a description of the interrupt signals.
23-0 —	Reserved

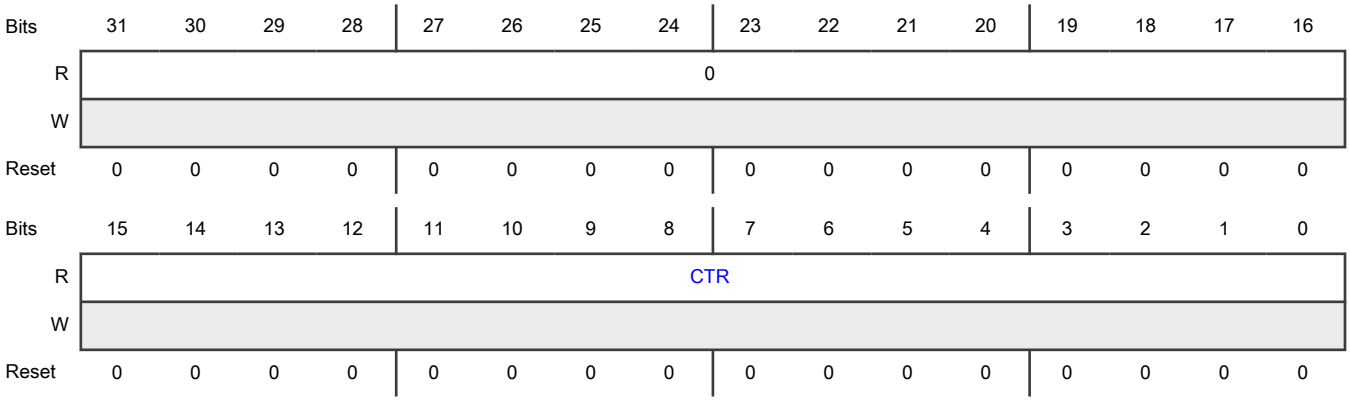
8.2.1.9 Unprogrammed Fuse Counter (UNPROG_CTR)

Reports the number of unprogrammed fuse words read in the last fuse shadow load, fuse shadow reload or CRC All operation.

Offset

Register	Offset
UNPROG_CTR	1080h

Diagram



Fields

Field	Description
31-16 —	Reserved
15-0 CTR	Unprogrammed Fuse Counter The number of fuse words loaded that have not been programmed.

8.2.1.10 Fuse Value Registers (FUSE0 - FUSE511)

The various fuses shadow values can be read from this block of registers. The definition of the fuses is left to the SoC, and not defined here.

NOTE

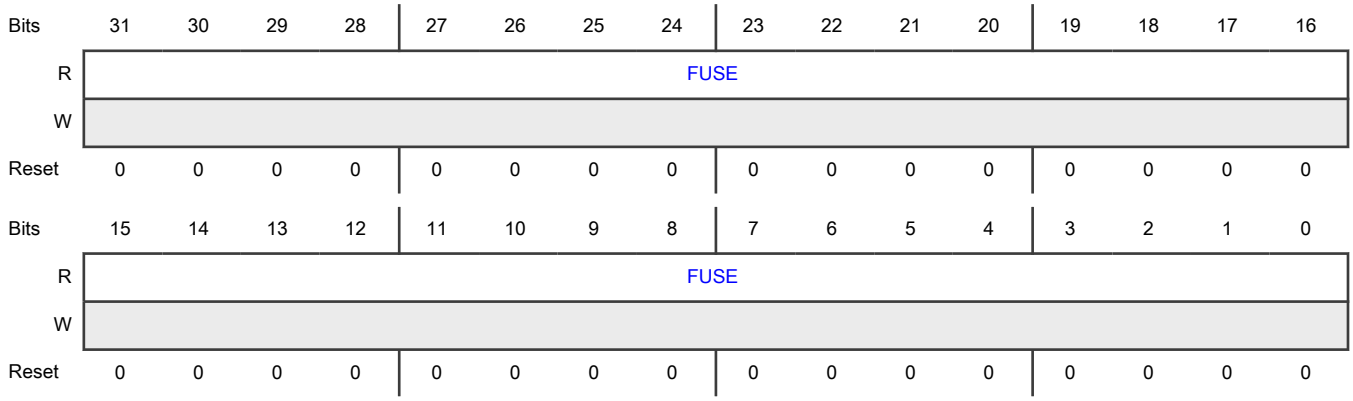
OCOTP will return a bus error if a write access is attempted to a read-only register.

Offset

For a = 0 to 511:

Register	Offset
FUSEa	8000h + (a × 4h)

Diagram



Fields

Field	Description
31-0 FUSE	Fuse Values SoC specific fuse information.

8.3 Functional description

The Fuse Status Block allows the SoC to read EdgeLock Secure Enclave fuse and status values without having to use the Messaging Unit.

Fuse values that are public are accessible via an APB interface between FSB and OCOTP. SoC accesses to fuse registers via FSB slave APB initiate transfers to OCOTP via FSB master APB.

FSB also provides access to OCOTP status registers that contain status of FSB's accesses to fuse values in OCOTP shadow RAM.

The FSB Status register provides state of various OCOTP status flags indicating when different types of fuses are valid and loaded. These flags do not affect behavior of FSB in any way.

FSB implements both read and write transfers to OCOTP status registers and shadow RAM. OCOTP and then FSB can return a bus error if a reserved location is accessed or when writes are not supported.

FSB implements support for SoC to abort transfers on the FSB APB when accessing fuses. This can happen if an access to the fuse area is attempted when OCOTP is not ready and the resulting excessive stall creates a timeout situation. An aborted transfer can be followed by a normal transfer without intervention of any kind. The presence of this feature is indicated via VERID.MISC[0]

The meaning of each fuse value is defined by EdgeLock Secure Enclave and the SoC. The Fuse Status Block does not imply specific meanings to any fuses.

Specific EdgeLock Secure Enclave status signals can also be connected to Fuse Status Block inputs and made available for reading by the SoC. The meaning of any status value is defined by EdgeLock Secure Enclave and the SoC. The Fuse Status Block does not imply specific meanings to any status inputs.

Because all the fuse and status values that are readable from the Fuse Status Block are public, there are no security mechanisms in this block.

8.3.1 Operating modes

Fuse Status registers are public values and can be read by any domain, at any time. There is no access control applied to the reading of any fuse or status registers.

8.3.2 APB errors

FSB asserts the Slave APB Error depending upon the memory region addressed.

8.3.2.1 Fuse Registers

When addressing the memory region containing the FUSE_STAT, FUSE_EVNT, FUSE_INT_EN, FUSE_INT and UNPROG_CTR registers APB bus errors will be reported under the following conditions:

- Reading an address that is not 32-bit aligned or does not match a control register
- Writing to an address that is not 32-bit aligned or does not match a writable control register

8.3.2.2 Fuse Values

When addressing the memory region containing the Fuse Values APB bus errors will be reported under the following conditions:

- Writing to a fuse shadow
- The address is not 32-bit aligned
- There is no fuse shadow RAM at this address
- There is a shadow RAM at this address, but it is not accessible by the FSB APB bus or the OCOTP SRAM Controller FSM is in an error state
- The OCOTP input `soc_apb_fsb_access_disable` is asserted to disable FSB access
- The shadow being read is read protected if the OP_CTRL[FSB_SHDW_ERR_EN] bit is set in OCOTP
- The shadow being accessed is reloading and the RLD_CTRL register in OCOTP is configured to block such accesses.

8.4 Acronyms and abbreviations

Table 32. Acronyms and abbreviated terms

Term	Meaning
FSB	Fuse and Status Block
MU	Messaging Unit - provides asynchronous communications between cores in different (and possibly protected) application domains.
MSC	Managed Security Component - an SoC resident security-related component which operates outside of the EdgeLock Secure Enclave boundary under SoC application core control, and for which EdgeLock Secure Enclave can manage/monitor security state as needed (via TROUT, using a TRIN connection). EdgeLock Secure Enclave can privately provision an MSC with a key information via a special-purpose masked bus (see TrustBus).
OCOTP	Secure On-Chip OTP Controller
TRIN	TRust INside - provides a monitoring interface for sensors or EdgeLock Secure Enclave for action.
Trust Bus	A private bus between EdgeLock Secure Enclave and Managed Security Components
TROUT	TRust OUTside - a logic block associated with a Managed Security Component which is capable of providing alert events to be reported to EdgeLock Secure Enclave for action.

Chapter 9
System Boot

9.1 Overview

The boot process begins at the Power-On Reset (POR) where the hardware reset logic forces the boot core to begin the execution starting from the on-chip boot ROM. The boot core is determined by a combination of boot mode pins and fuses. If the pins indicate boot from fuses, then the fuse value is selected. Boot mode pins and fuses have the same definition. The boot ROM code uses the state of BOOT_MODE[3:0] pins and fuses to determine the boot flow behavior of the device.

The platform boot is performed by the boot ROM and the EdgeLock secure enclave (ELE) ROM, working in concert to ensure that the intended and authorized set of images are loaded and allowed to execute on various processing domains contained by the SoC. The EdgeLock secure enclave ROM manages the secure boot flow based on ELE while the boot ROM mainly handles code fetch and other aspects of functional flow.

Please refer to the latest version of *EdgeLock® Secure Enclave (Advanced Profile) (ELE-AP) User Guide* for more details.

9.1.1 Features

The main features of the ROM include:

- Two boot types
  - Low Power Boot (Cortex-M33 ROM)
  - Single Boot (Cortex-A55 ROM)
- Support for booting from various boot devices
- Serial downloader support

The boot ROM supports the following boot devices:

- Serial NOR Flash via FlexSPI
  - Single (1-1-1 opcode-address-data) fast read
  - Quad (1-4-4 opcode-address-data) fast read
  - Octal (8-8-8 opcode-address-data) fast read
  - Auto probe for MxicOctal, MicronOctal and QuadSPINOR
- Serial NAND Flash via FlexSPI
  - 2K Page NAND
  - 4K Page NAND
- SD/eMMC via uSDHC
- Serial Downloader support on USB 2.0 only
- LPSPI (Recovery boot)

9.2 Boot Types

This chip supports two boot types:

- Single Boot
- Low Power Boot

NOTE

In low power boot mode, only Cortex-M33 core runs after POR. Cortex-A55 core cannot be triggered by Cortex-M33 firmware.

9.2.1 Boot Type Selection

The fuse settings for selecting a boot type is provided in the following table.

Table 33. Boot Type Selection

Boot Mode[3]	Result
0	Single Boot
1	Low Power Boot

9.2.2 Single Boot

In single boot, the Cortex-A55 ROM loads all containers and images, and then jumps to the A55 Firmware (FW).

If the container set has the Cortex-M33 firmware image, the Cortex-A55 ROM will read and place it in the Shared RAM (Cortex-M33 TCM) first, and then request the EdgeLock secure enclave to kick Cortex-M33. Refer to Single Boot Flow (Cortex-A55) for details.

NOTE

If there is a CM33 FW image in OEM container in single boot mode, the CM33 FW image must be prior to CA55 FW image

The EdgeLock secure enclave authenticates both the FW images if Secure Boot is enabled.

The following table provides the boot devices supported for single boot.

Table 34. Boot devices supported for single boot

Boot Stage	Cortex-A55 ROM	Cortex-M33 ROM
Primary and Secondary image set boot	eMMC on USDHC1 SD on USDHC1/2 FlexSPI NAND on FlexSPI1 FlexSPI NOR on FlexSPI1	N/A
Recovery boot	LPSPI 3/4	N/A
USB serial download	USB HID on USB1	N/A

9.2.3 Low Power Boot

In Low Power Boot (LPB), only the Cortex-M33 rom is running after Power-On Reset. Refer to Low Power Boot Flow (Cortex-M33) for the details.

The following table provides the boot devices supported for LP boot.

Table 35. Boot devices supported for LP boot

Boot Stage	Cortex-A55 ROM	Cortex-M33 ROM
Primary and Secondary image set boot	N/A	eMMC on USDHC1

Table continues on the next page...

Table 35. Boot devices supported for LP boot (continued)

Boot Stage	Cortex-A55 ROM	Cortex-M33 ROM
		SD on USDHC1/2 FlexSPI NOR on FlexSPI1 FlexSPI NAND on FlexSPI1
Recovery boot	N/A	LPSPI1/2
USB serial download	N/A	USB HID on USB1

9.3 Boot Modes

There are 3 different boot modes supported on this chip:

- Normal Boot Mode
- Boot from Internal Fuse Mode
- Serial Download Boot Mode

The boot mode can be selected via the Boot Mode pins or overridden by fuses.

9.3.1 Boot Mode pins

There are four boot mode pins used to select boot mode. The boot mode is selected based on the binary value stored in the internal BOOT_MODE register.

The boot mode is initialized by sampling the BOOT_MODE[3:0] inputs on the rising edge of the POR_B. After these inputs are sampled, their subsequent state does not affect the contents of the BOOT_MODE internal register. The state of the internal BOOT_MODE register may be read from the IPP_BOOT_MODE[3:0] field of the SRC Boot Mode Register (SRC_SBMR2).

The available boot modes are detailed in the table below.

Table 36. Boot mode selection

BOOT CODE	BOOT CORE	BOOT_MODE[3:0]	Function
0x0	Cortex-A55	0000	Boot From Internal Fuses
0x1		0001	Serial Download (USB1)
0x2		0010	USDHC1 8-bit eMMC 5.1
0x3		0011	USDHC2 4-bit SD 3.0
0x4		0100	FlexSPI Serial NOR
0x5		0101	FlexSPI Serial NAND 2K
0x8	Cortex-M33	1000	LPB: Boot From Internal Fuses
0x9		1001	LPB: Serial Downloader (USB1)
0xA		1010	LPB: USDHC1 8-bit 1.8V eMMC 5.1

Table continues on the next page...

Table 36. Boot mode selection (continued)

BOOT CODE	BOOT CORE	BOOT_MODE[3:0]	Function
0xB		1011	LPB: USDHC2 4-bit SD 3.0
0xC		1100	LPB: FlexSPI Serial NOR
0xD		1101	LPB: FlexSPI Serial NAND 2K

9.3.2 Normal Boot Mode

In this mode, the boot flow is controlled by the boot type selection, boot device selection, and the boot mode settings.

In this mode, the boot code does the following:

- The Cortex-M33 ROM or/and Cortex-A55 ROM perform hardware initialization, and loads the images from the primary boot device which is selected by the Boot Mode pins or fuses.
- Performs image validation - it requests the EdgeLock secure enclave ROM to do this.
- Then jumps to the Cortex-M33/Cortex-A55 FW entry point specified in the Image Container.

If any error occurs during normal boot, the Cortex-M33/Cortex-A55 ROM will try to boot from the Secondary Image Container Set which is in the same boot device (primary boot device). If this fails, the ROM will try to boot from the Recovery Boot device. If Recovery Boot also fails, the Cortex-M33/Cortex-A55 ROM will jump to the Serial Downloader Mode (see Serial Download Mode).

9.3.3 Boot from Internal Fuses Mode

This mode is similar to the Normal Boot mode but with one difference. In this mode, the Boot Mode pins are ignored. The boot ROM code uses the boot eFUSE settings only. If set to Boot from eFuses, the boot flow is controlled by the BT_FUSE_SEL eFUSE value. If BT_FUSE_SEL = 0, indicating that the boot settings have not been provisioned into the fuse yet, the Cortex-M33 ROM and Cortex-A55 ROM both jump directly to the Serial Downloader. If BT_FUSE_SEL = 1, ROM retrieves the Boot Mode setting from the BT_MODE_FUSES fuse, and then attempts to boot from the selected boot device. The first time a board is used, the default eFUSEs may be configured incorrectly for the hardware on the platform. In such a case, the Boot ROM code may try to boot from a device that does not exist. This may cause an electrical/logic violation on some pads. Using Boot from Fuses mode addresses this problem.

The first time the BT_FUSE_SEL = 0 eFUSE is encountered, it is not blown (thus setting BT_FUSE_SEL). This forces the ROM code to jump directly to the Serial Downloader. This allows a bootloader to be downloaded which can then provision the boot device with a Program Image and blow the BT_FUSE_SEL fuse and other boot configuration eFUSEs.

After reset, the Boot ROM code determines that the BT_FUSE_SEL fuse is blown (BT_FUSE_SEL = 1) and the ROM code performs the internal boot according to the new eFUSE settings. This allows a user to set BOOT_MODE[3:0] =4'b0000 on a production device and burn fuses on the same device (by forcing entry to the Serial Downloader), without pullups/pulldowns on the BOOT_MODE pins.

BT_FUSE_SEL is only an indicator of BOOT_MODE fuse been blown. It has no impact for Internal Boot Mode.

If the fuse, Force_BT_FROM_FUSE, has been blown, the Boot Mode pins will be ignored, and the BootROM will always retrieve the boot mode from the internal fuses.

9.3.4 Serial Download Mode

The Serial Downloader provides a means to download a Program Image to the chip over USB serial connection.

Both, the Cortex-M33 (LP Boot) and Cortex-A55 ROM (Single Boot) support serial download mode on USB 2.0, and only on USB OTG1. This mode can be disabled by fuse.

9.4 Boot Stages

Both the Cortex-M33 and Cortex-A55 ROMs support the following four boot stages.

1. Primary Image Container Set Boot (Primary Boot): Boot from the Primary Image Set Primary Boot Device.
2. Secondary Image Set Boot (Secondary Boot): Boot from the Secondary Image Set in Primary Boot Device.
3. Recovery Boot (if enabled via fuse): Boot from the image set in Recovery Boot Device (only one Image Set supported).
4. Serial Download Boot: load the image set via USB.

9.5 Image Container Set

9.5.1 Image Container Format

The image container format consists of the following parts.

- Container header
- Image array entry
- Signature block
- User program images and data

The high-level view of the container format is shown in the following figure.

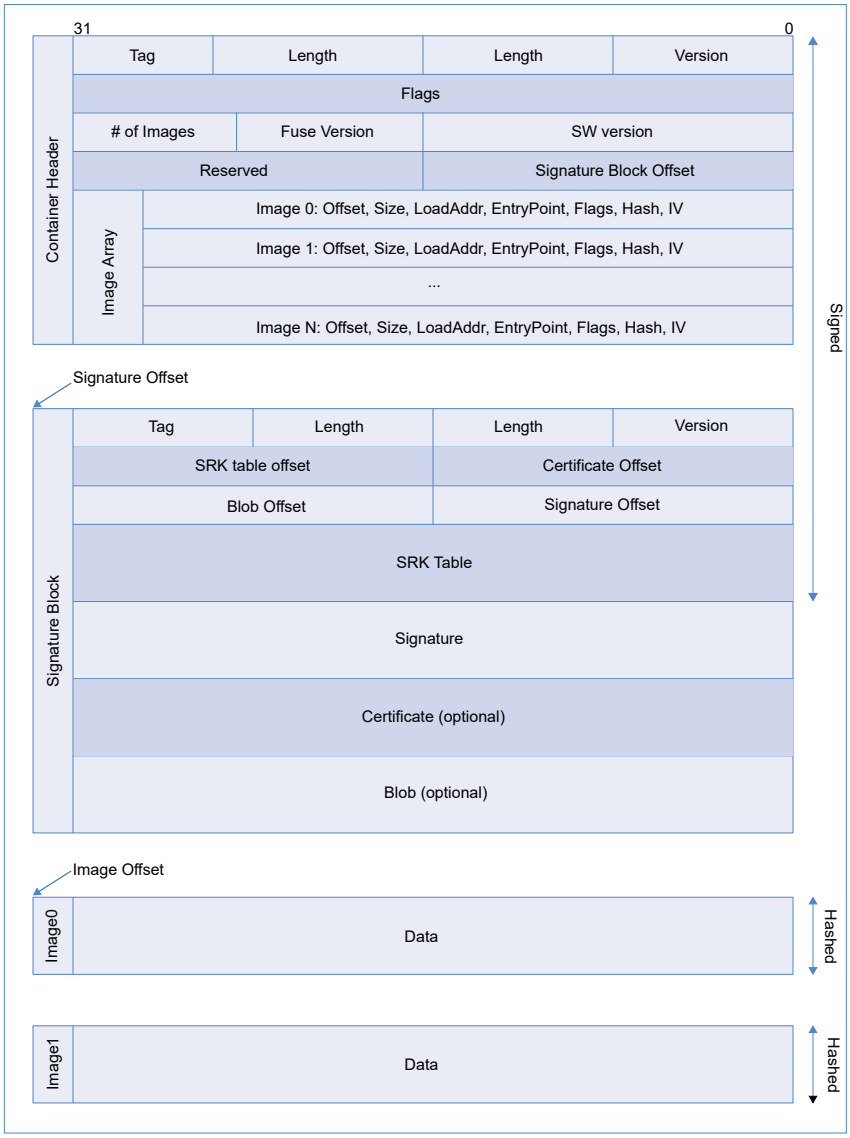


Figure 16. High level view of the container format

ROMs view of the offset/address in the Image container:

- **Blob/Certificate/Signature offset:** Relative to the beginning of Container Header start address, in bytes. 8 bytes alignment.
- **ImageArray.Imagex.Offset:** Relative to the container's start address (beginning of the 1st Container Header start address in the SD card (32KB), for instance), in bytes. Needs to be page aligned.
- **ImgeArray.Imagex.LoadAddr:** The address map is from the Cores view (required to be 4 bytes aligned):
  - For the images booted by Cortex-M33 ROM, the address map is from Cortex-M33 view.
  - For the images booted by Cortex-A55 ROM, the address map is from Cortex-A55 view.
  - 4 bytes aligned
- **ImageArray.Imagex.Entry:** This is from target core's local view. For example,
  - EdgeLock secure enclave FW entry address is from EdgeLock secure enclave view.
  - Cortex-M33 FW entry address is from Cortex-M33 view.

— Cortex-A55 FW entry address is from Cortex-A55 view.

9.5.1.1 Container Header

The container header contains essential information about the entire container image which is used by the ROM.

Table 37. Container header format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Tag	Length (MSB)	Length (LSB)	Version
0x04	Flags			
0x08	# of Images	Fuse Version	SW Version	
0x0c	Reserved		Signature Block Offset	
0x10	Image array (Please see Image Array Entry)			
	Signature Header (Please see Signature Block)			

The container header format fields are defined below.

- **TAG**: Must be 0x87
- **Length**: Size of the container in bytes, from header, up through and including signature block.
- **Version**: Must be 0x00
- **Flags**

Table 38. Flags bitfield description

Bit Field	Description
0-1	SRK Set 0x0 – Container not authenticated 0x1 – NXP SRK 0x2 – OEM SRK 0x3 – Reserved
2-3	Reserved (must be 0)
4-5	SRK Selection 0x0 – SRK1 is used 0x1 – SRK2 is used 0x2 – SRK3 is used 0x3 – SRK4 is used
6-7	Reserved (must be 0)
8-11	SRK Revoke Mask

Table continues on the next page...

Table 38. Flags bitfield description (continued)

Bit Field	Description
	bitmask used to indicate which SRKs to revoke – zero bits set means no SRKs are to be revoked, bit0 – SRK1 is to be revoked, bit1 – SRK2 is to be revoked, bit2 – SRK3 is to be revoked, bit3 – SRK4 is to be revoked,
12-15	Reserved (must be 0)
16-31	Reserved (must be 0)

- **# of images**: Number of images in the image array
- **Fuse Version**: This value must be equal to or greater than the version stored in the fuses to allow loading this container
- **SW Version**: Used to select between multiple images with same Fuse version field.
- **Signature Block Offset**: Offset in bytes from beginning of header to signature block (keys, signature, blob)

9.5.1.2 Container Header Offsets

The following table provides the offset for the 1st image set container header on various boot devices.

Table 39. The offset of the 1st image set

Boot Device	1st Image Container Offset
SD	32KB
eMMC	0 if located in Boot Partition and 32K if in User area
SPI NAND	Right behind FCB/DBBT
FlexSPI NOR	0x1000

The 2nd image set container header and its signature block will be right after the 1st image set container header and it's signature block, with 1KB alignment.

9.5.1.3 Signature Block

Table 40. Signature block format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Tag	Length (MSB)	Length (LSB)	Version
0x04	SRK Table Offset		Certificate Offset	
0x08	Blob Offset		Signature Offset	
0x0C	Reserved (for 64bit alignment purposes)			

Table continues on the next page...

Table 40. Signature block format (continued)

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
	32 bit			
0x10	SRK Table (Please see SRK Table)			
…	Signature (Please see Signature Header)			
…	Certificate (Please see Certificate Header)			
…	Blob (Please see Blob (DEK))			

The signature block format fields are defined below.

- **TAG**: 0x90
- **Version**: 0x00
- **SRK Table Offset**: Offset in bytes from beginning of signature block to SRK table. If 0x0000, then SRK table is not present. This should be the case only if the container is not authenticated, and the SRK key set field in the Container header should be 0.
- **Certificate Offset**: Offset in bytes from beginning of signature block to signing key certificate. If 0x0000, then only a SRK is used in signature verification
- **Signature Offset**: Offset in bytes from beginning of signature block to signature
- **Blob Offset**: Offset in bytes from beginning of signature block to DEK Blob. If 0x0000, then no images are encrypted

NOTE

1. SRK Table, Signature, Certificate and Blob must be in the order shown
2. Certificate and Blob are optional
3. SRK Table, Certificate, Blob, and Signature must start on 64 bit boundaries. Any padding needed to make this happen must be zeros.
4. The container signature is calculated of all data from beginning of container header to the last byte before the signature starts. In other words, most of the signature block itself is included in the signature calculations.

9.5.1.3.1 Certificate Header

The table below provides details about the Certificate Header structure:

Table 41. Certificate format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Tag	Length (MSB)	Length (LSB)	Version
0x04	Permissions	Permissions(inverted)	Signature Offset	
0x08	Public Key			
	Signature			

The certificate format fields are defined below.

- **TAG**: 0xaf

- **Version**: 0x00
- **Permissions**: Bitmask used to indicate what a certificate can be used for
- **Permissions (inverted)**: Must be the same as the Permissions field bitwise inverted
- **Signature Offset**: Offset in bytes from beginning of certificate header to signature
- **Public Key**: Public key. Format matches SRK table “SRK record” entry, for both the RSA as well as ECDSA type keys.
- **Signature**: Signature of certificate. The signature is calculated over all data from the beginning of the certificate up to one byte before the signature itself: from the “Tag” byte through and including the public key SRK record.

9.5.1.3.2 Signature Header

The table below provides details about the Signature Header structure:

Table 42. Signature format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Tag	Length (MSB)	Length (LSB)	Version
0x04	Reserved			
0x08	Signature Data			

The signature format fields are defined below.

- **TAG**: 0xD8
- **Version**: 0x00
- **Signature Data**:Signature.
  - RSA-PSS encoding
  - ECDSA: The r and s components are padded with leading zeros to make them each 8 bit aligned, then concatenated – r|s

9.5.1.3.2.1 SRK Table

The SRK table determines the signature type and length, and consists of 1 to 4 SRK records which contains the public keys. The format of the SRK table is inherited from HAB v4.x

Table 43. SRK table format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Version	Length of SRK Table		Tag
0x04	SRK Record 1			
-	SRK Record 2			
-	SRK Record 3			
-	SRK Record 4			

The SRK table fields are defined below.

- **TAG**: 0xD7
- **Length**: The size of the SRK table in bytes

- **Version**: 0x42

9.5.1.3.2.2 SRK Record

Table 44. SRK record format

Offset	Bits 31-24	Bits 23-16		Bits 15-8	Bits 7-0
0x00	Signing Algorithm	Length of SRK			Tag
0x04	SRK Flags	Reserved	Key Size/Curve		Hash Algorithm
0x08	RSA: Exponent Length (bytes)	RSA: Modulus Length (bytes)			
	ECDSA: Y Length (bytes)	ECDSA: X Length (bytes)			
0x0C	RSA: Modulus (Big endian)				
	ECDSA: X (Big endian)				
-	RSA: Exponent (Big endian)				
	ECDSA: Y (Big endian)				

The SRK record fields are defined below.

- **TAG**: 0xE1
- **Length**: The size of the SRK record
- **Signing Algorithm**:
  - RSA-PSS: 0x22
  - ECDSA: 0x27
- **Hash Algorithm**:
  - SHA-256: 0x00
  - SHA-384: 0x01
  - SHA-512: 0x02
- **Key Size/Curve**:
  - PRIME256V1: 0x1
  - SEC384R1: 0x2
  - SEC521R1: 0x3
  - RSA2048: 0x5
  - RSA3072: 0x6
  - RSA4096: 0x7
- **SRK Flags**:
  - None: 0x00
  - CA Flag: 0x80

NOTE

The keys in the SRK table must match the signing key in algorithm and key length

9.5.1.3.2.3 SRK Revoke

The EdgeLock secure enclave sets fuses based on the fields in the container or a message. If an SRK revoke bit or field return flag is set, the EdgeLock secure enclave will set that fuse. Since the containers are issued by the same entity that owns the SRKs, or is authorized by the SRKs owner, it is expected that the SRK revoke bits will correctly reflect the SRK status registered in the fuses, or revoke additional keys. The EdgeLock secure enclave will check that the SRK revoke bits in a parsed container match what is currently set in the fuses, or will revoke the additional keys corresponding to the revoke bits by updating the fuses.

9.5.1.3.2.4 SRK Fuses

The hash for each of the entire SRK table is stored in the SRK fuses. This allows the boot code to validate the keys in the SRK table from each container. For any of the 4 keys in SRK table that are unused, the corresponding key bits will be set to 0.

NOTE

SHA256 is used to hash the SRK tables

9.5.1.3.3 Image Array Entry

The boot ROM loads images in the order that the images appear in the array.

Table 45. Image Array Entry format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Image Offset			
0x04	Image Size			
0x08	Load Address (64 bits)			
0x0c				
0x10	Entry point (64 bits)			
0x14				
0x18	Flags			
0x1c	Image meta data			
0x20	Hash (512 bits)			
…				
0x60	IV (256 bits)			

The image array entry format fields are defined below.

- **Image Offset**: Offset in bytes from start of container header to beginning of the image
- **Image Size**: Size of the image in bytes
- **Load Address**: Address where the image is copied to in memory (absolute address in system memory map) by the ROM
- **Entry Point**: Entry point of the image (absolute address). Only valid for executable image types.
- **Flags**:

Table 46. Flags bitfield description

Bit Field	Description
0-3	Type of image 0x3 Executable 0x4 Data 0x7 Provisioning image 0x9 Provisioning data All other values reserved (These values extend HAB IVT V1)
4-7	Core ID 0x1 Cortex-M33 0x2 Cortext-A55 All other values reserved
8-10	Hash type (all images in the container have the same HASH size) 0x0 – SHA256 0x1 – SHA384 0x2 – SHA512
11	Encrypted Indicate if this image is encrypted or not
12-31	Reserved

- **Image meta data**: For NXP FW private usage.
- **Hash**: SHA hash of image. Fixed size at 512 bits. Left aligned and padded with zero for hash sizes below 512 bits.
- **IV**: Used only for encrypted images (zero otherwise): SHA256 of the plain text image. Fixed size at 256 bits. The lower 128-bit part of the SHA256 value will be retained as IV in the encryption/decryption process.

9.5.1.3.4 Blob (DEK)

The Blob holds the Wrapped Data Encryption Key (DEK). It is optional if no images are encrypted. The format of the Blob is inherited from HAB v4.x.

Table 47. Blob format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Tag	Length (MSB)	Length (LSB)	Version
0x04	Reserved	Algorithm	Size	Flags
0x08	Wrapped key			

The blob fields are defined below.

- **TAG**: 0x81

- **Length**: Size of the blob in bytes
  - 0x48: 72 bytes, corresponding to a 128 bit AES key blob.
  - 0x50: 80 bytes, corresponding to a 192 bit AES key blob.
  - 0x58: 88 bytes, corresponding to a 256 bit AES key blob.
- **Version**: 0x00
- **Algorithm**: 0x03: AES CBC
- **Size**:
  - 0x10: 128 bit AES key
  - 0x18: 192 bit AES key
  - 0x20: 256 bit AES key
- **Flags**:

  0x80: KEK key flag

  0x01: DEK

9.5.2 Primary Boot Container Set

The images that will be loaded as part of the boot process are stored in containers. A container can contain one or multiple images, as blocks of data specifying the load address, target address, and so on.

9.5.2.1 Secondary Boot Container Set

The Secondary Boot Container Set is a copy of the Primary Container Set. ROM will always try to load the Primary Container Set first and if the Primary Container Set fails, ROM will then attempt to load the Secondary Container Set.

9.5.2.2 Primary Image Set and Secondary Image Set

The Primary Image Set is used in the Primary boot stage while the Secondary Image Set is used in the Secondary boot stage.

If there are two valid image container sets in the primary boot device:

- Primary Image Container Set: The one that has the newer SW Version. If the SW Versions are the same, or for eMMC fast boot Scenario, Image Container Set0 will be the primary one.
- Secondary Image Container Set: The one that has the older SW Version. If the SW Versions are the same, or for eMMC fast boot Scenario, Image Container Set1 will be the secondary one.

If there is only one valid image container set in the primary boot device:

- Both, Primary Image Container Set and Secondary Image Container Set are this only one valid image container set.

Please refer Boot Image Container Sets Selection for information on primary and secondary image sets selection.

9.5.2.3 Typical Boot Image Sets Layout

The typical image layout for the single boot (handled by the Cortex-A55 ROM) is provided in the following table.

Table 48. Typical Cortex-A55 image layout for single boot

Primary Image Container Set	1st Container Header
	1st Signature Block
	Padding for 1KB alignment

Table continues on the next page...

Table 48. Typical Cortex-A55 image layout for single boot (continued)

	2nd Container Header (Optional)
	2nd Signature Block (Optional)
	EdgeLock secure enclave FW (Optional)
	FCB Copy Image (Optional)
	Cortex-M33 Image
	Cortex-A55 Image
…	
Secondary Image Container Set	

The typical image layout for the LP boot (handled by the Cortex-M33 ROM) is provided in the following table.

Table 49. Typical Cortex-M33 image layout for LP boot

Primary Image Container Set	1st Container Header
	1st Signature Block
	Padding for 1KB alignment
	2nd Container Header (Optional)
	2nd Signature Block (Optional)
	EdgeLock secure enclave FW (Optional)
	FCB Copy Image (Optional)
	Cortex-M33 Image
…	
Secondary Image Container Set	

Restrictions to Images:

- The length of all container header(s) in a boot image set is up to 8KB.
- If EdgeLock secure enclave FW exists, it must be in the EdgeLock secure enclave/NXP container, and the EdgeLock secure enclave/NXP container must be the first container in the boot image set.
- The target address of EdgeLock secure enclave FW must be in TCM.
- The target address of Cortex-M33 FW must be in TCM free space or FlexSPI1 NOR space (XIP).
- The target address of Cortex-A55 FW must be in OCRAM free space or FlexSPI1 NOR space (XIP).
- The images cannot overlap with each other.
- The image offset (EdgeLock secure enclave FW, Cortex-M33 FW, and Cortex-A55 FW) must be MAX[1KB, PAGE_SIZE_OF_BOOT_DEVICE] aligned.

- Except EdgeLock secure enclave FW, the target loading address must be MAX[1KB, PAGE_SIZE_OF_BOOT_DEVICE] aligned. For the EdgeLock secure enclave FW, the image size must be 4 bytes aligned.
- For eMMC fast boot or USB boot, images (including container headers) need to be continuous to its former.
- For Single Boot, Cortex-A55 FW is mandatory for the boot image set.
- For Low Power boot, Cortex-M33 FW is mandatory for the boot image set.
- For Low Power boot, Cortex-A55 FW is disallowed to be present in the boot image set.

NOTE

PAGE_SIZE_OF_BOOT_DEVICE value:

- For SPI NAND, it is 2KB/4KB.
- For SD/eMMC, it is 512B.
- For USB, it is 1KB.

9.6 Boot Flow

Although there are two system ROMs (A55 ROM and CM33 ROM), some concepts of ROM boot flow are common:

1. Up to two containers (NXP and OEM containers) are expected to handle by system ROM code while only OEM container is must-have and NXP container is optional.
2. In case NXP container is available in the boot image container set, the NXP container must be the 1st container followed by OEM container. System ROM code always handles the containers one by one based on their container headers order in the header of the boot image container set.
3. If a container has multiple boot images (OEM container may contain multiple images while only EdgeLock secure enclave FW is allowed in NXP container), the images in the container will be handled by ROM code one by one based on the images order in the container header in most cases. The exceptions are the FCB region copy image and the fast boot image, if these two images are available in the OEM container, they will be handled by ROM code prior to other OEM images no matter their orders in OEM container.

9.6.1 High Level Boot Flow for A55 ROM and CM33 ROM

1. System ROM code should initialize all HW/SW resources which system ROM code is needed in ROM boot phase, including stack/data sections, PLLs, clock root/source and peripherals.
2. The boot type (single boot/LP boot) is decided the setting on BT_MODE[3], and it's HW/EdgeLock secure enclave responsibility to release the boot core based on the setting of BT_MODE[3]. The logics of boot type selection are transparent to system ROM code.
3. System ROM code needs to select the one boot image container set based on both the SW versions of NXP/OEM container in the boot image container set and the boot stage.
4. System ROM code needs to address all containers in the selected boot image container set, includes load them into the target (XIP is also supported on XIP device), and request EdgeLock secure enclave to authenticate/verify the containers and their images.
5. If any failure happens, ROM code will go to the error handling, please refer to the Failure Handling in ROM for the details.
6. In case everything goes well, ROM code eventually jumps to the core image: CM33 FW in LP boot mode and CA55 FW in single boot mode.

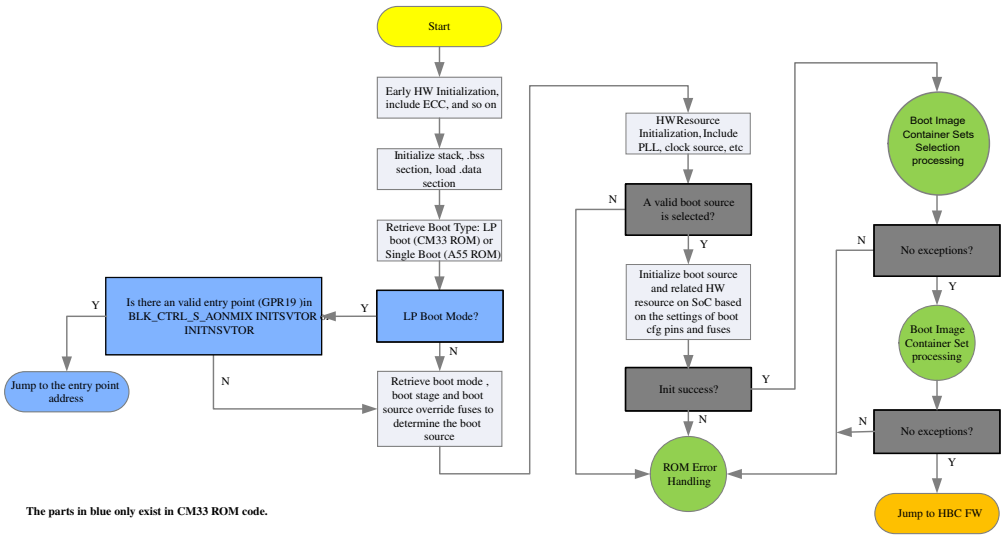

Figure 17. High Level ROM Boot Flow

9.6.2 ROM Early HW Initialization

9.6.2.1 RAM ECC

Because the ECCs of CM33 TCM and NICMIX OCRAM are enabled by default, so CM33 ROM should take care of CM33 TCM initialization while A55 ROM code needs to take care of NIXMIX OCRAM to avoid ECC error which may be caused by accessing to un-initialized RAM space. Please refer to ECC Support section for the details of how ROM code to initialize CM33 TCM/NICMIX OCRAM.

9.6.3 Boot Image Container Sets Selection

For primary boot stage and secondary boot stage, HBC ROM code boots from the selected primary boot device, and it is allowed up to two boot image container sets on primary boot device.

The offset of the 1st boot image container set is fixed on the primary boot device and hard code in ROM code, please refer to The Offsets of the Container Header section for the details. The offset of the 2nd boot image container set on the primary boot device is specified by the fuses “Secondary_boot_offset”:

Offset = 1MB * (2^n)

If Secondary_boot_offset = 0 → n = 2;

If Secondary_boot_offset = 2 → n = 0;

If Secondary_boot_offset = others and Secondary_boot_offset <= 10 → n = Secondary_boot_offset

If Secondary_boot_offset > 10 → Means there is no the 2nd boot image container set

In case there is only one boot image container set on boot source, ROM code regard it as primary boot image container set and will be used in primary boot stage; In case there is two boot image container sets on boot source, ROM code will pick up the one as primary boot image container set which will be used in primary boot stage and another→ one will be the secondary boot image set which will be used in secondary boot stage. It is determined by the SW version of NXP container and OEM container in two boot image container sets, below diagram shows the flow about how ROM code determine the primary and secondary boot image set.

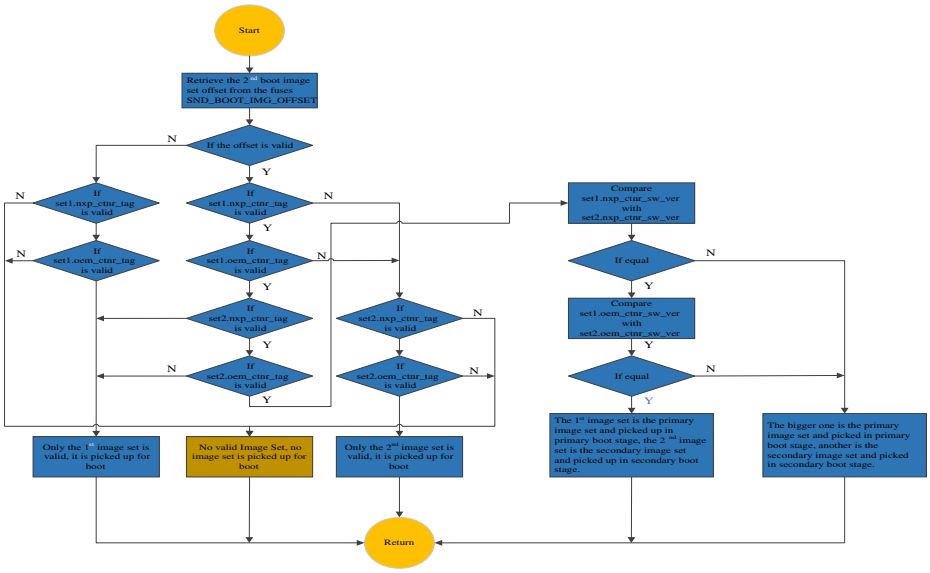

Figure 18. Boot Image Container Sets Selection

9.6.4 Boot Image Container Set Processing

Besides of the legacy regular processing of handling the containers in boot image set, a new AP Fast Boot processing is supported in single boot mode. In order to improve the security level of ROM boot, a FCB check processing is supported in CM33/CA55 ROM code. This processing is used in FlexSPI NOR boot, and to protect the FCB date from the attacks. Please refer to the FCB Check for details.

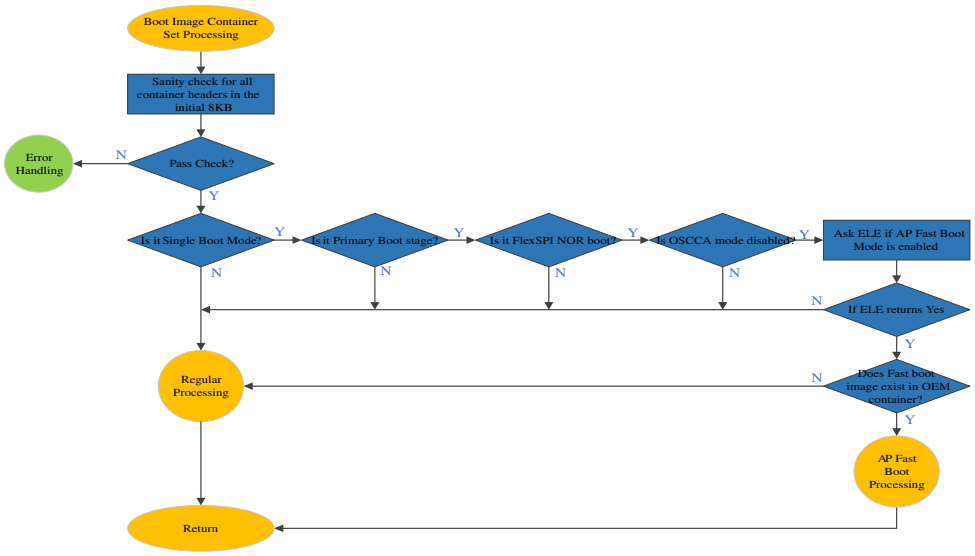

Figure 19. Boot Image Container Sets Selection

9.6.4.1 Regular Processing

- System ROM code loads the headers of the containers in boot image set (the headers are placed in the first 8KB space of the boot image set), the headers are analysed.

- If NXP container exists in boot image container set, system ROM code needs to handle it prior to OEM container. System ROM code loads the NXP container (both header and EdgeLock Enclave FW) and request EdgeLock Enclave to authenticate NXP container via issuing “AUTH_NXP_CTNR” command to EdgeLock Enclave. If EdgeLock Enclave replies failure, break ROM boot flow, update boot stage to next stage then reset system.
- OEM container is must-have, if it doesn’t exist in the boot image container set, system ROM code will break ROM boot flow, update boot stage to next stage then reset system.
- For OEM container, system ROM code requests EdgeLock Enclave to authenticate its container header via issuing “AUTH_OEM_CTNR” command to EdgeLock Enclave, If EdgeLock Enclave replies failure, breaks ROM boot flow, the boot stage is updated to next stage and then the system is reset.
- In the regular boot flow, if boot source is FlexSPI NOR device and FCB is available, the FCB check processing will be executed prior to other OEM images; if FCB check fails, break ROM boot flow, update boot stage to next stage then reset system.
- ROM code will address OEM images one by one based the order in the OEM container (except FCB region copy image since it has been addressed yet), include loading them into target and request EdgeLock Enclave to verify via issuing “Image Verify” command to EdgeLock Enclave. If any failure, break ROM boot flow, update boot stage to next stage then reset system. In single boot mode, if the image is CM33 FW, A55 ROM code needs to requests EdgeLock Enclave to release CM33 TROUT then starts CM33 core after this image pass verify.

9.6.4.2 AP Fast Boot Processing

The performance improvement to meet AP Fast Boot requirement:

1. A55 core hashes the “fast boot image” instead of EdgeLock secure enclave.
2. The hash number calculated by A55 core is passed to EdgeLock secure enclave with command “FAST_VERIFY”, EdgeLock secure enclave takes responsibility to check if the signature is damaged.
3. A new command “Generic Auth” is added in EdgeLock secure enclave ROM, which requests EdgeLock secure enclave to authenticate both NXP container and OEM container header. Correspondingly, A55 ROM code is requested to load both NXP container (includes EdgeLock secure enclave FW) and OEM container header into target before issuing this comman. The information of NXP container and OEM container header should be passed with this command. EdgeLock secure enclave needs to reply twice for this command, the 1st reply means it received the request and starts the processing, and the 2nd reply is to return the result of NXP/OEM container authentication: pass or not pass.

The AP Fast Boot Flow in Single/A55 ROM boot:

1. The AP Fast boot flow will not be executed unless all of the following conditions are met:
    a. The Boot Type is single boot mode (CA55 ROM boot);
    b. The boot stage is primary boot;
    c. The boot source is FlexSPI NOR;
    d. OSCCA mode is disabled;
    e. The AP fast boot mode is enabled: the fuse FASTBOOT_ENABLE[1:0] = 2’b01;
    f. The AP fast boot image exists in OEM container. Although does limit the AP fast boot image must be CM33 FW, normally it should be CM33 image in typical case, and should be running with XIP mode since TCM room is not big enough to place a 3MB image.
2. A55 ROM code loads both NXP container (includes EdgeLock secure enclave FW) and OEM container header, then issues “Generic Auth” command to EdgeLock secure enclave. If EdgeLock secure enclave returns failure, breaks ROM boot flow, the boot stage needs to be updated to next stage. The system must be reset then. If EdgeLock secure enclave returns success, it just means EdgeLock secure enclave received the request and starts to execute Generic Auth processing.
3. A55 ROM code finds out the AP fast boot image, and calculated its hash number;

4. After hash is done, A55 ROM code receives reply from EdgeLock secure enclave to check if both NXP container and OEM container pass authentication (the authentication was requested via “Generic Auth” command). If not pass, update boot stage to next stage then reset system;
5. If pass “Generic Auth” check, if boot source is FlexSPI NOR device and FCB is available, the FCB check processing will be executed prior to other OEM images; if FCB check fails, break ROM boot flow, update boot stage to next stage then reset system. Please refer to the “FCB Check” section for the details;
6. A55 ROM code issues “Fast Verify” command to EdgeLock secure enclave , the hash number of the AP fast boot image will be passed via this command as well, to request EdgeLock secure enclave to check the signature of the AP fast boot image. If not pass check, break ROM boot flow, update boot stage to next stage then reset system;
7. Typically, the AP fast boot image should be CM33 FW, if yes, A55 ROM code needs to requests EdgeLock secure enclave to release CM33 TROUT then starts CM33 core after this image pass verify;
8. A55 ROM addresses other OEM images except the image with fast boot flag set and FCB region copy image, the flow is same with the regular processing.

9.6.4.2.1 FCB Check

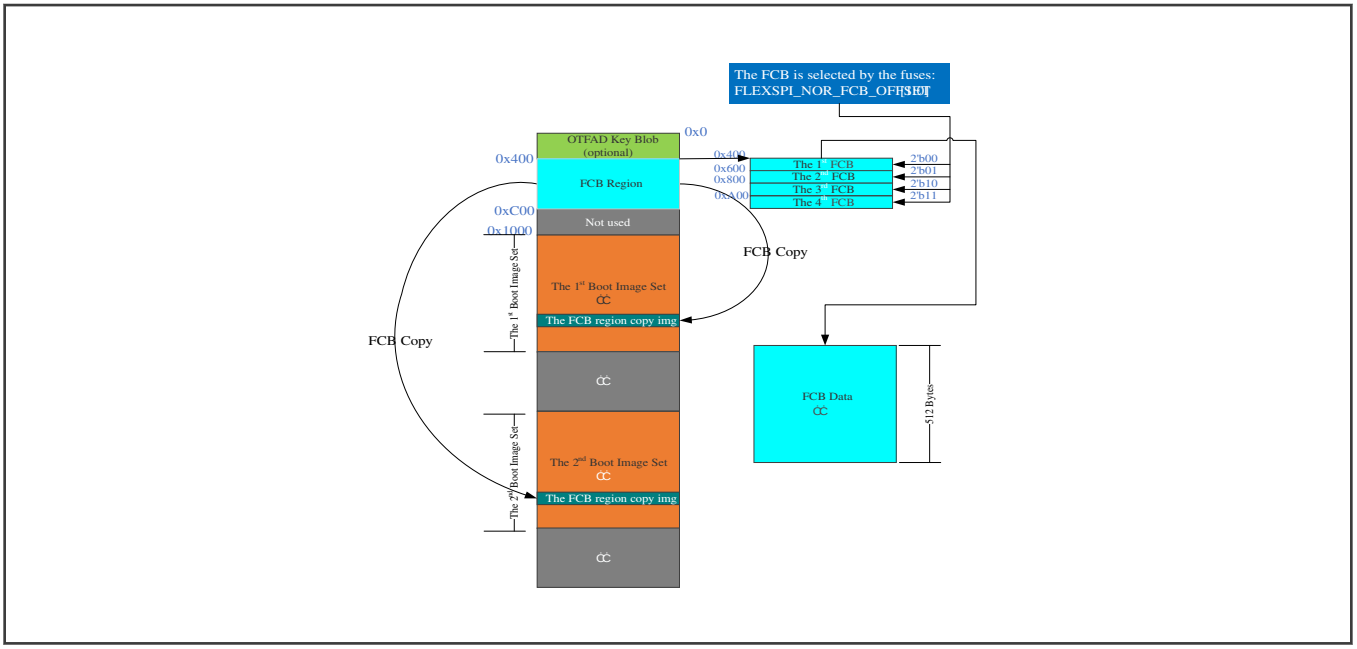
FCB Check processing is to protect FCB content from unexpected modifications because it may introduce the secure issue. For example, if an attacker modifies the FCB on device, then the corrupted FCB data could make the timing marginal, such that the images may pass authentication, but then when we try to execute the code with XIP mode, might not read the correct value from device.

The change request to boot image set:

Needs to build an extra image, names it as FCB region copy image, this image should be placed into OEM container. The content of the FCB region copy image should be exactly same with the content of FCB region at 0x400 on FlexSPI NOR device. Please refer to the “FCB Region” section for the details of FCB region. This FCB region copy image will be packaged into OEM container, and similar with other OEM images, the FCB region copy image should be signed with OEM SRK.

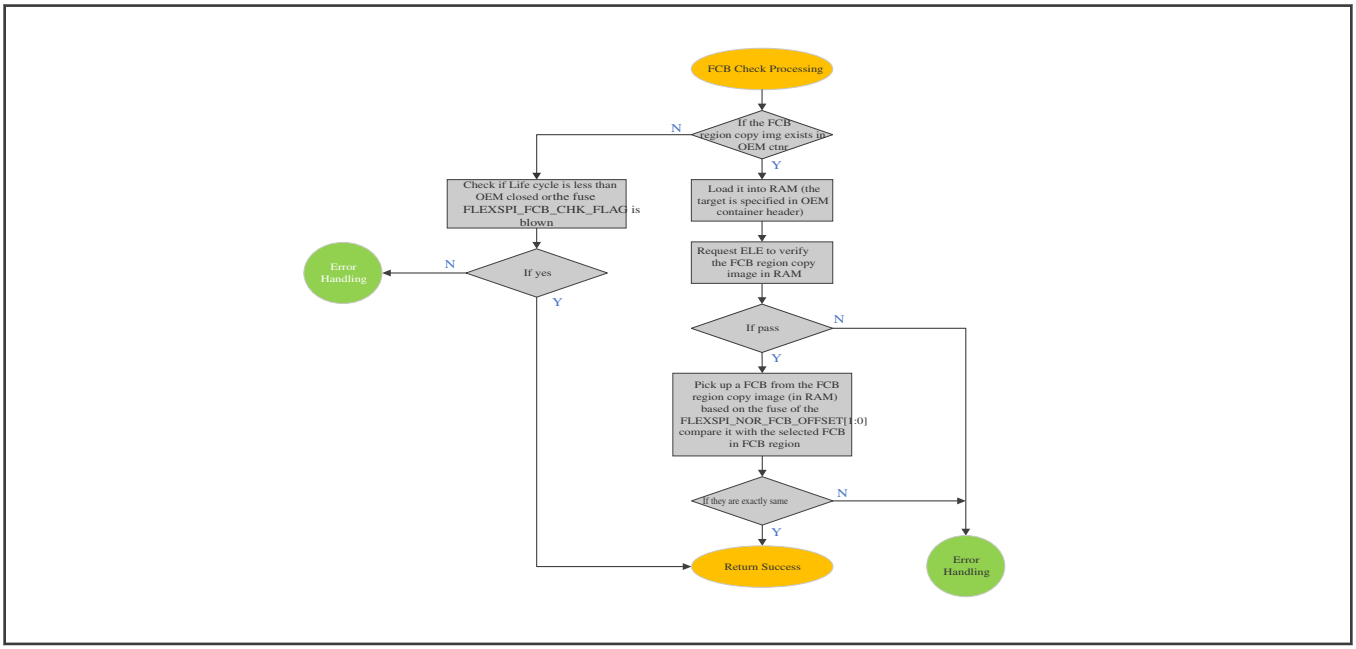
NOTE

The dst of this image must be located in RAM free space (TCM for LP boot and OCRAM for Single boot).



9.6.4.2.2 FCB Check Flow

1. Based on the value of the fuses FLEXSPI_NOR_FCB_OFFSET[1:0], ROM code picks up a FCB from FCB region, then retrieve the configuration parameters from this FCB, and use them to initialize FlexSPI NOR device;
2. Address NXP container;
3. Address OEM container:
    a. Request EdgeLock secure enclave to authenticate OEM container header;
    b. Checks if the FCB region copy image exists in OEM container. If yes, load it to RAM (the dst is specified in OEM container header), then request EdgeLock secure enclave to verify it;
    c. If the FCB region copy image pass the image verify, picks up the FCB from the FCB region copy image based on the value of the fuses FLEXSPI_NOR_FCB_OFFSET[1:0], the compare the content of this FCB with the FCB picked up in step #1. If they are exactly same, continue ROM boot flow; if not, break ROM boot flow, move boot stage then reset system.



The table below shows whether the FCB region copy image is must-have or optional.

Fuse FLEXSPI_FCB_CHK_FLAG	Life Cycle	FCB region copy image
X	Less than OEM Closed	Optional
0	Equal or bigger than OEM Closed	Must-have
1		Optional

NOTE

Once the FCB region copy image exists in OEM container, the FCB check is mandatory and the result of FCB check impacts the ROM boot, means the ROM boot flow will be broken in case any failure in FCB check.

FCB check is needed or not:

1. If the FCB region copy image exists in OEM container, the FCB check processing must be executed, and the result will impact the ROM boot processing; (FCB check is needed)
2. If the FCB region copy image doesn't exists in OEM container,

a. If life cycle is less than OEM closed, it doesn't impact ROM boot; (avoid FCB check)

b. If life cycle is >= OEM closed:

i. In case FLEXSPI_FCB_CHK_FLAG is blown (=1), it doesn't impact ROM boot; (avoid FCB check)

ii. In case FLEXSPI_FCB_CHK_FLAG is not blown (=0), ROM boot flow will be broken and move to next boot stage; (FCB check is needed)

9.6.5 Single Boot Flow (Cortex-A55)

In single boot, up to 2 containers (NXP and OEM containers) are expected to be handled by A55 ROM code.

- NXP container (optional):
  - EdgeLock secure enclave FW only (must-have in case NXP container present)
- OEM container (mandatory), contains:
  - CM33 FW (optional)
  - CA55 FW (must-have)
  - FCB Region Copy Image (optional)

When the CM33 FW is present in the OEM container, A55 ROM loads it, and requests EdgeLock secure enclave to verify image. It then writes the entry point address of the CM33 FW into the SRC GPR19 register then kicks of CM33 core, and continues A55 ROM boot processing. In this case, after CM33 ROM code starts, it is expected to retrieve the entry point from that SRC GPR19 register then directly jumps there.

1. For OTFAD case, A55 ROM needs to initialize FlexSPI controller and device with the safe settings, so that EdgeLock secure enclave can access key blob from FlexSPI NOR device. A55 ROM doesn’t care whether the OTFAD enabled fuse blown, EdgeLock secure enclave needs to take care of this fuse. A55 will always send the message to EdgeLock secure enclave to enable the OTFAD and check the status from EdgeLock secure enclave. From system ROM perspective, the expected behaviors of EdgeLock secure enclave are: IF (OTFAD Enabled fuse set) THEN EdgeLock secure enclave enable the OTFAD and send status to A55 ROM. ELSE EdgeLock secure enclave does not enable OTFAD and always send success to A55 ROM.
2. Before loading EdgeLock secure enclave FW, A55 ROM needs to check the corresponding bits in the GPR register. If the bit set, means the EdgeLock secure enclave FW is in running, A55 ROM skips to load this FW, move to load next image.
3. There is a fuse indicating if EdgeLock secure enclave FW is necessary. System ROMs (both M33 and A55 ROMs) don’t check this fuse. In case the EdgeLock secure enclave/NXP container exists in the boot image set, M33/A55 always load the EdgeLock secure enclave/NXP container and the EdgeLock secure enclave FW, then request EdgeLock secure enclave to authenticate the EdgeLock secure enclave container. EdgeLock secure enclave will decide whether to authenticate it or not. In the MUST NOT NEED EdgeLock secure enclave FW scenario, if M33/A55 ROM find a EdgeLock secure enclave FW container, then send the message to EdgeLock secure enclave. EdgeLock secure enclave should bypass this request and reply success to M33/A55 ROM.

9.6.5.1 Kick Off Cortex-M33 Flow

When the Cortex-A55 finds the Cortex-M33 image in the container.

- The Cortex-A55 ROM sets the SCR bit to release the Cortex-M33 reset to let the TCM accessible.
- After the Cortex-A55 loads the Cortex-M33 image, the Cortex-M33 image is verified.
- The Cortex-A55 ROM sends a request to EdgeLock secure enclave to release the Cortex-M33 TROUT (See BLK_CTRL_S_AONMIX.
- The Cortex-A55 ROM releases the Cortex-M33 CPUWAIT signal. See BLK_CTRL_S_AONMIX[M33_CFG] register.

9.6.5.2 AARCH32 A55 ROM

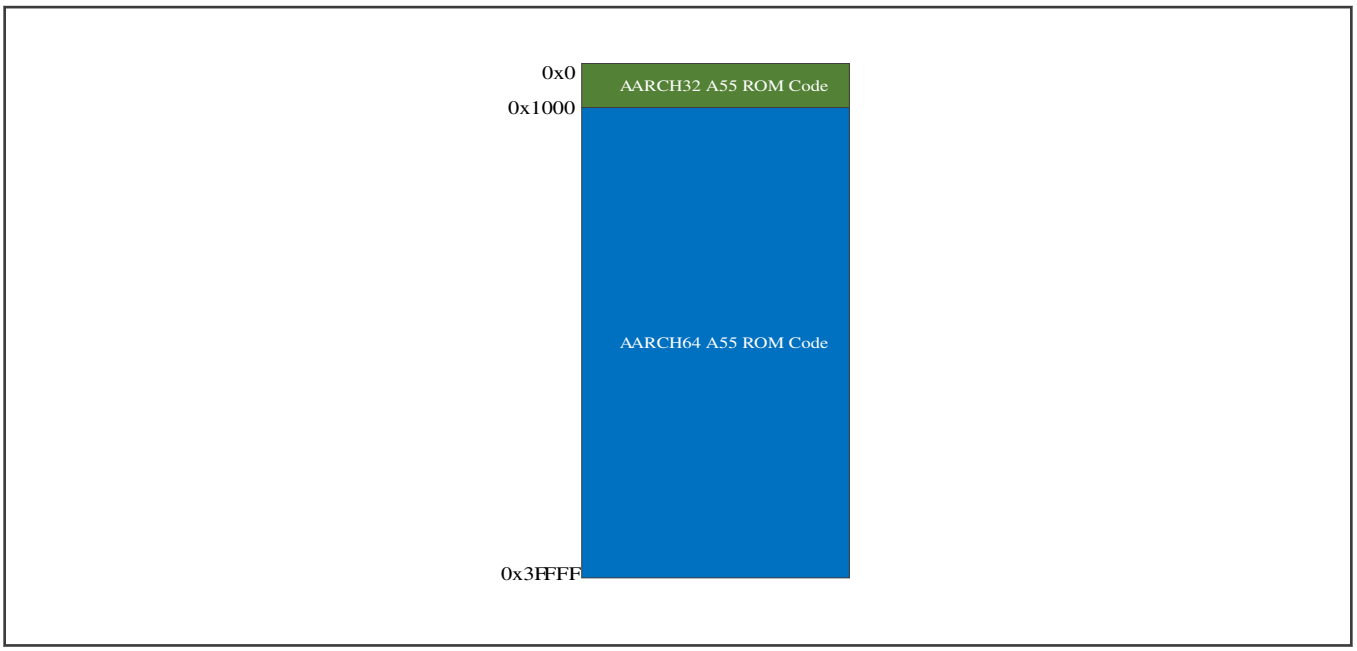
There are two pieces of A55 ROM code:

- AARCH64 A55 ROM code
- AARCH32 A55 ROM code

The purpose to have a AARCH32 CA5 ROM code is to meet the A55 resume usage in AARCH32 mode.

In AARCH64 mode, the start address of CA55 core is decided by RVBAR setting. The reset value of RVBAR is point to 0x1000, means the AARCH64 CA55 ROM code will be executed after reset. And SW is able to update the start address of CA55 core via updating the RVBAR register, for example, place a resume SW in OCRAM space before suspend system, and update the RVBAR register with the entry point of the resume SW in OCRAM, then system is resume, CA55 core starts from OCRAM that the address is specified by RVBAR.

But in AARCH32 mode, CA55 core must starts at 0x0 address, so is not able to update the start address of CA55 core in AARCH32 mode via updating RVBAR. So has to have a AARCH32 CA55 ROM code and place it at 0 address. In AARCH32 mode, after system resume, CA55 core starts from 0 address, it's AARCH32 CA55 ROM code, this AARCH32 CA55 ROM code will retrieve the entry point from RVBAR register, if the entry point is valid, then jumps to it. The entry point reading from RVBAR must be within OCRAM or TCM or DRAM or FlexSPI NOR memory-mapped space, otherwise the entry point will be regarded as invalid, then re-run from 0 address.



9.6.6 Low Power Boot Flow (Cortex-M33)

In LP boot, up to three containers (NXP and OEM containers) are expected to be handled by CM33 ROM code.

- NXP container (optional): EdgeLock Enclave FW only (must-have in case NXP container present)
- OEM container (mandatory), contains:
  - CM33 FW (must-have)
  - FCB Region Copy Image (optional)

When the Cortex-M33 reboots (such as when waking from a low power mode in which Cortex-M33 was off, or if the Cortex-M33 is warm reset without resetting the entire rest of the SoC) in Low Power Boot mode, the Cortex-M33 Boot ROM validates the resume entry point is valid before jumping to the address pointed to by the BLK_CTRL_S_AONMIX INITSVTOR[31:7] and/or INITNSVTOR[31:7] registers.

1. For OTFAD case, M33 ROM needs to initialize FlexSPI controller and device with the safe settings, so that EdgeLock secure enclave can access key blob from FlexSPI NOR device. M33 ROM doesn't care whether the OTFAD enabled fuse blown, EdgeLock secure enclave needs to take care of this fuse. M33 will always send the message to EdgeLock secure

enclave to enable the OTFAD and check the status from EdgeLock secure enclave. From system ROM perspective, the expected behaviors of EdgeLock secure enclave are:

IF (OTFAD Enabled fuse set) THEN EdgeLock secure enclave enable the OTFAD and send status to M33 ROM.

ELSE

EdgeLock secure enclave does not enable OTFAD and always send success to M33 ROM.

2. There is a fuse indicating if EdgeLock secure enclave FW is necessary. System ROMs (both M33 and A55 ROMs) don't check this fuse. In case the EdgeLock secure enclave /NXP container exists in the boot image set, M33/A55 always load the EdgeLock secure enclave /NXP container and the EdgeLock secure enclave FW, then request EdgeLock secure enclave to authenticate the EdgeLock secure enclave container. EdgeLock secure enclave will decide whether to authenticate it or not.
3. In the MUST NOT NEED EdgeLock secure enclave FW scenario, if M33/A55 ROM find a EdgeLock secure enclave FW container, then send the message to EdgeLock secure enclave. EdgeLock secure enclave should bypass this request and reply success to M33/A55 ROM.
4. In LP boot mode, CM33 firstly starts to run while A55 core isn't kicked off by EdgeLock secure enclave during CM33 ROM boot time.

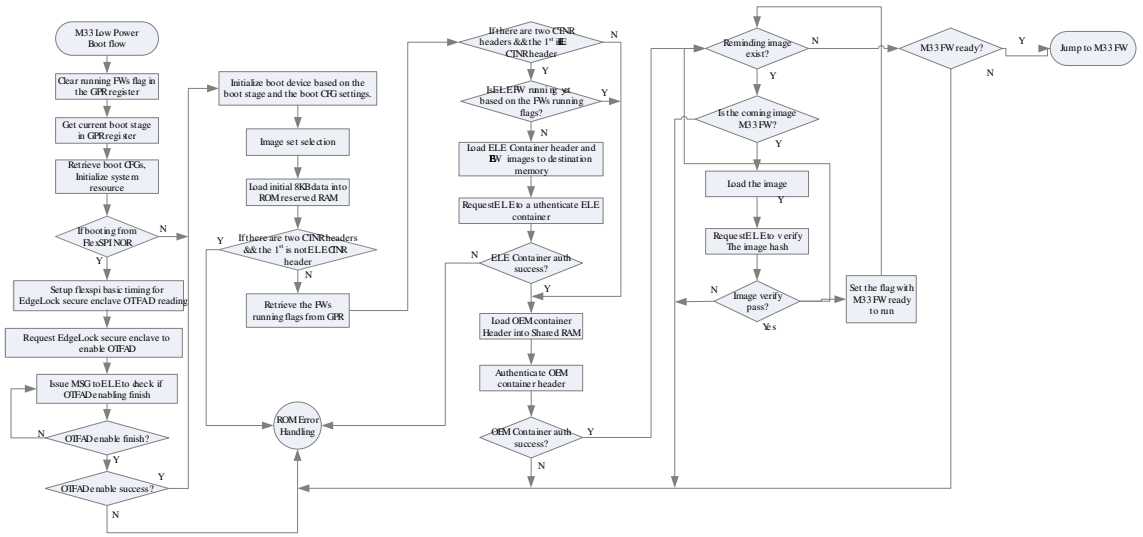


Figure 20. Cortex-M33 ROM Sequence for LP Boot

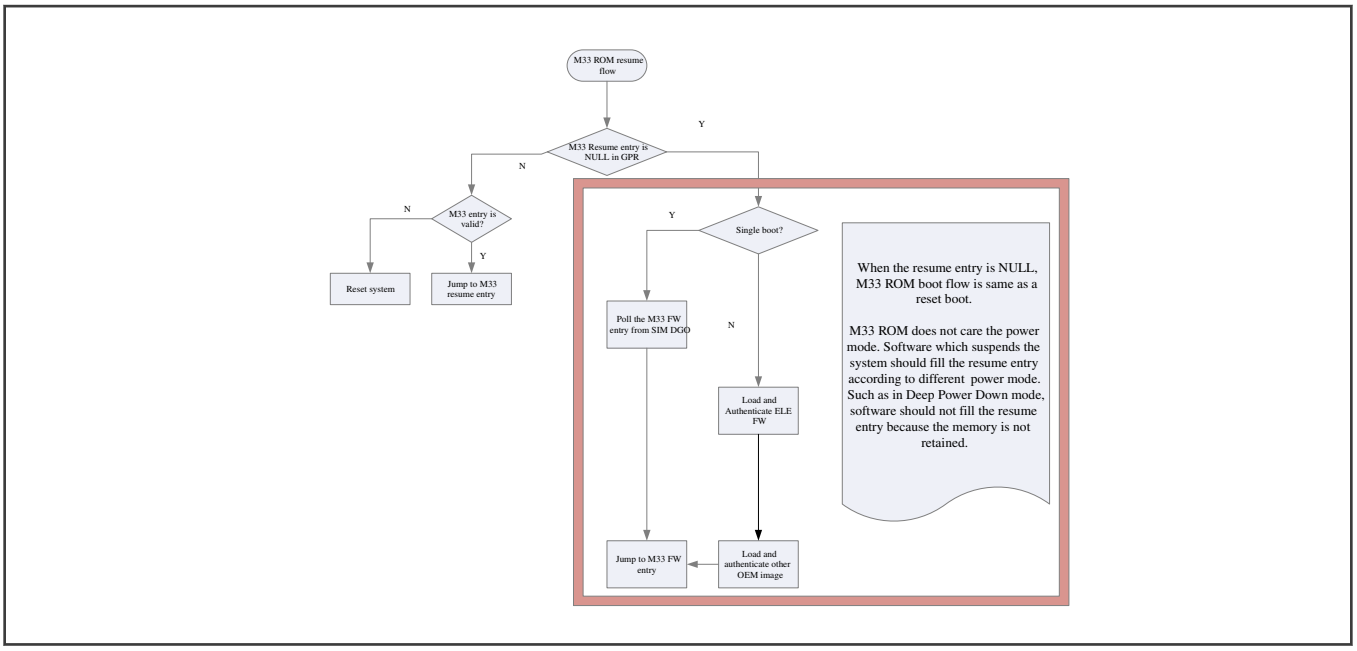
9.6.6.1 M33 ROM Resume Flow



9.6.7 Failure Handling in ROM

There are two categories of failures: Fatal and non-Fatal.

Fatal:

- Attack been detected by HW or Cortex-M33/Cortex-A55 ROM itself (stack cookie, SW secure counter).
- Hard Fault in ROM code.

Non-Fatal:

- Boot device initialization failed.
- Boot device read failure (ECC error, timeout, etc.)
- image failure.

For Fatal failures, ROM trigger a WDOG reset.

For non-fatal failures, ROM sets next boot stage, and then trigger a WDOG reset. After the reset, ROM will try to boot from the secondary image container set. If this fails, it moves to recovery boot. If recovery boot also fails, ROM will move to USB SDP boot. If Booting from the primary boot image set fails, ROM updates the boot stage information stored in the SRC GPR16 register to move to next boot stage, then resets the system. In next boot cycle after system is out of reset, ROM moves to the next boot stage and tries again. The sequence of boot stage moving is Primary image set boot => Secondary Image Set boot => Recovery boot(If enable in fuse) => USB serial download boot;

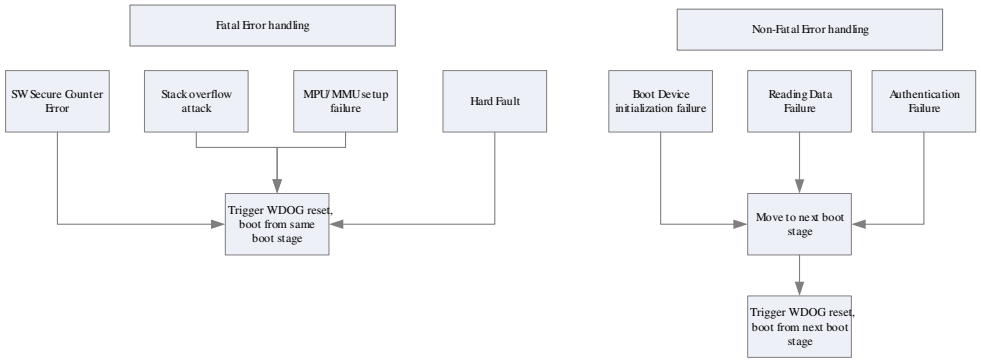


Figure 21. Failure Handling

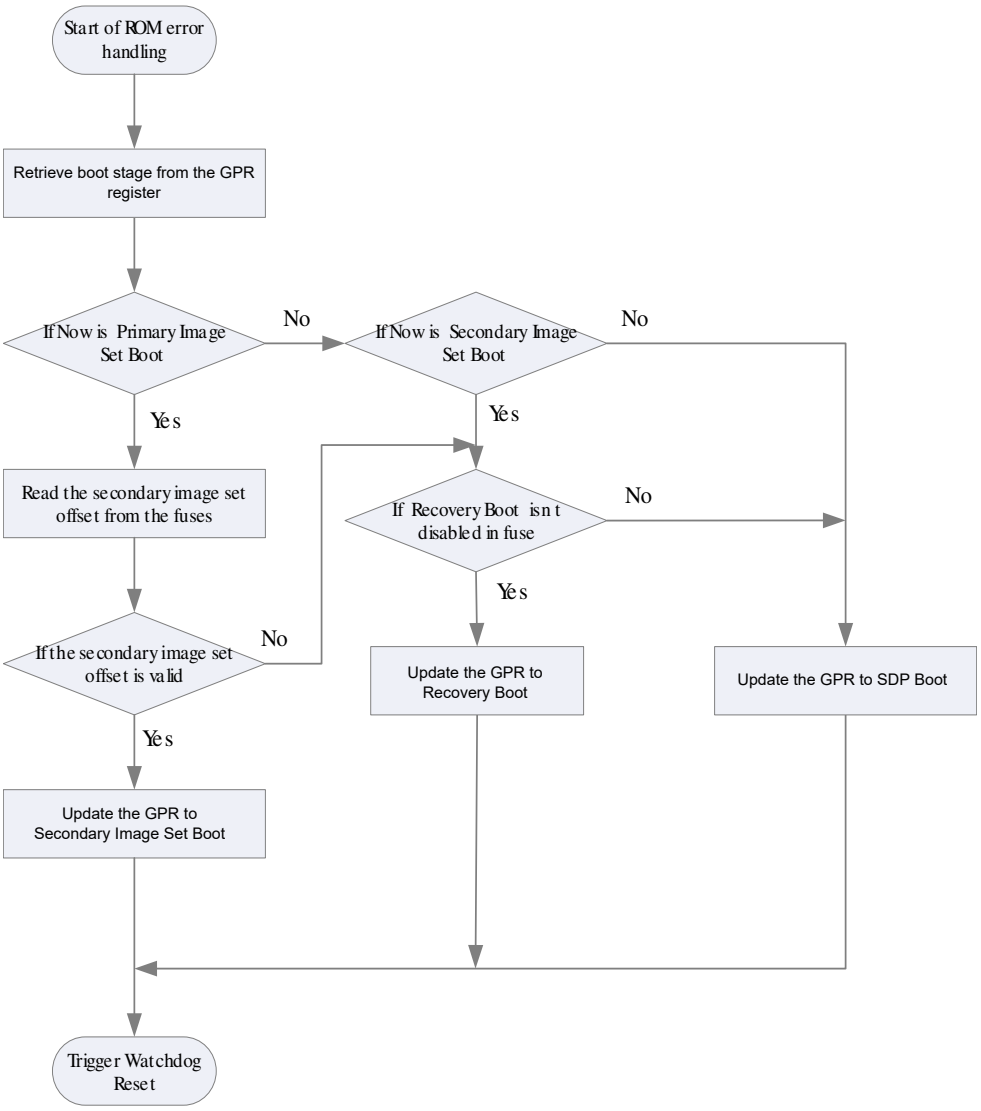

Figure 22. ROM Error Handling

9.7 Platform Initialization In ROM

This section describes the details of the ROM and provides the initialization details. This includes details on:

- ROM memory usage map
- On-chip blocks that the ROM must enable.
- Clock initialization
- Watchdog initialization
- Timer initialization
- Exception handling and interrupt handling
- Failure Handling

9.7.1 Memory Usage

9.7.1.1 Cortex-M33 Memory Usage Map

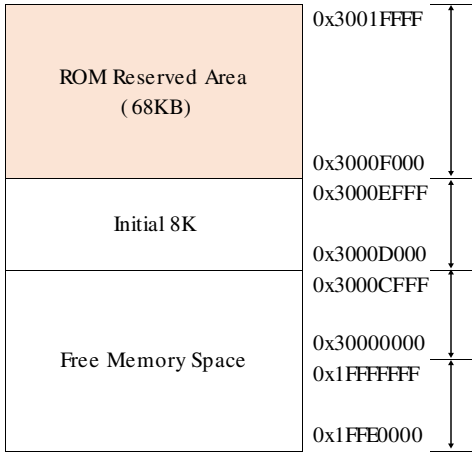

Figure 23. TCM Usage in Cortex-M33 ROM Code (Secure View)

The initial 8KB is used to store the initial image and can be cleared by post boot firmware.

9.7.1.2 Cortex-A55 Memory Usage Map

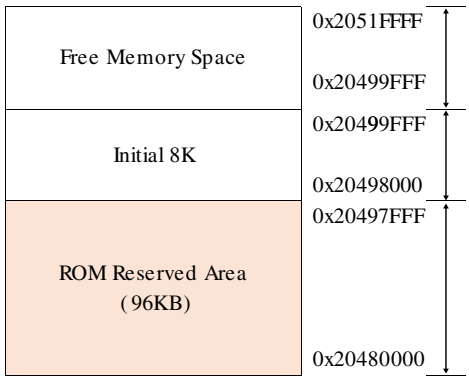

Figure 24. OCRAM Usage in Cortex-A55 ROM Code (Non-secure View)

The initial 8KB is used to store the initial image and can be cleared by post boot firmware.

For single boot, where loads image to Cortex-M33, there is no reserved area on Cortex-M33 TCM.

9.7.2 System HW Settings in ROMs

Table 50. ROM Hardware Usage Overview

Cortex-M33 ROM	Cortex-A55 ROM
EdgeLock secure enclave AHB	EdgeLock secure enclave AHB
CCM/System PLL	CCM/System PLL/ARM PLL
WDOG1	WDOG3
FlexSPI1	FlexSPI1
IOMUXC	IOMUXC
LPSPI1, LPSPI2	LPSPI3, LPSPI4
Cortex-M33 ICache	Cortex-A55 ICache
USDHC1, USDHC2	USDHC1, USDHC2
USB1	USB1
USB1 PHY	USB1 PHY
TCM	OCRAM

9.7.3 Peripheral Clock Enable

The ROM code enables the clocks for the peripherals listed in the following table.

Table 51. Peripheral Clock Enable

Peripheral	Status after ROM exits
WDOG1/3	Enabled
FLEXSPI1	Enabled if FLEXSPI1 NOR/NAND boot
USDHC1/2	Enabled if USDHC1/2 boot
LPSPI1/2/3/4	Enabled if LPSPI1/2/3/4 recovery boot
USB_OTG1	Enabled if SDP boot

9.7.4 Watchdog

By default, the Watchdog (WDOG) hardware is disabled. Unless the fuse WDOGn_ENABLE is blown, ROM will not enable the watchdog. The WDOG timeout can be selected by the fuse 'WDOG Timeout Select'. The fuse setting details are provided below.

'WDOG Timeout Select' configuration options:

- 00 – 1s (Depends on the WDOG reset number)
- 01 – 0.5s

- 10 – 0.25s
- 11 – 0.125s

WDOG1_ENABLE and WDOG3_ENABLE configuration options:

- 0 – Disabled
- 1 – Enabled”

The Cortex-M33 ROM only uses WDOG1 and the Cortex-A55 only uses WDOG3.

9.7.5 Timer

After the necessary internal initialization tasks have been completed, ROM will enable the timer. Once the timer has been enabled, it is in free running mode and ROM will not disable it again.

The Cortex-M33 ROM uses the System Counter, and the Coretx-A55 ROM uses the Generic Timer.

9.7.6 ECC support

There is a HW ECC initialization feature in MECC256. ROM will take advantage of this. This HW engine zeroize all area of OCRAM. ROM polling the register bit until the initialize finishes.

9.7.7 Interrupt and Exception Handling

All interrupts are masked by both the Cortex-M33 and Cortex-A55 ROM.

There are three exception handles in the Cortex-M33 ROM to handle various exceptions:

1. SVC
   - ROM SVC handler
2. NMI
   - Reconfigures NMI_b then return
3. Others
   - Triggers a watchdog reset.

There are two exception handles in the Cortex-A55 ROM to handle various exceptions:

1. SVC
2. Others
   - Trigger a watchdog reset

9.7.8 SRC GPR Registers Usage in System ROM Code

Table 52. SRC GPR Registers Usage in System ROM

GPR16	ROM flags	Bit0: EdgeLock secure enclave FW Loaded flag Bit1: CM33 FW Loaded flag Bit2: CA55 FW Loaded flag Running flag: 0 – The FW is not loaded 1 – The FW is loaded

Table continues on the next page...

Table 52. SRC GPR Registers Usage in System ROM (continued)

		Bit8: SDP on Demand 0 – USB SDP is not on-demand 1 – USB SDP mode is on-demand Bit[27:24]: CM33 ROM Boot Stage Bit[31:28]: CA55 ROM Boot Stage
GPR17	The argument of the CM33 resume FW	Provided by A55 image in Single Boot mode
GPR19	The address of the CM33 resume FW	Provided by A55 image in Single Boot mode. This is optional and can be used a s other purpose if argument is not needed when resuming

9.8 Boot Devices

9.8.1 FlexSPI

The ROM supports auto probe (SFDP (JESD-216) discoverable parameters) feature.

9.8.1.1 IOMUX configuration for FlexSPI devices

The following table shows the FlexSPI IOMUX pin configuration.

Table 53. FlexSPI IOMUX Pin Configuration

Signal Name	PAD Name
FlexSPI_A_DATA0	SD3_DATA0 (ALT1)
FlexSPI_A_DATA1	SD3_DATA1 (ALT1)
FlexSPI_A_DATA2	SD3_DATA2 (ALT1)
FlexSPI_A_DATA3	SD3_DATA3 (ALT1)
FlexSPI_A_DQS	SD1_STROBE (ALT1)
FlexSPI_A_SS0_B	SD3_CMD (ALT1)
FlexSPI_A_SS1_B	SD1_DATA3 (ALT1)
FlexSPI_A_SCLK	SD3_CLK (ALT1)
FlexSPI_A_DATA4	SD1_DATA4 (ALT1)
FlexSPI_A_DATA5	SD1_DATA5 (ALT1)
FlexSPI_A_DATA6	SD1_DATA6 (ALT1)
FlexSPI_A_DATA7	SD1_DATA7 (ALT1)

9.8.1.2 FlexSPI eFUSE Configuration

The boot ROM determines the configuration of external Serial NAND/NOR flash by parameters, either provided by eFUSE, or sampled on GPIO pins during boot. See below table for parameters details.

Table 54. FlexSPI Boot eFUSE Configuration

Fuse	Definition	Settings
BOOT_MODE[3:0]	Boot device selection	Coretx-A55 (Single boot): • 0100 - FlexSPI Serial NOR • 0101 - FlexSPI Serial NAND 2K page Coretx-M33 (LP boot): • 1100 - FlexSPI Serial NOR • 1101 - FlexSPI Serial NAND 2K page
BOOT_CFG0[4]	Override_FlexSPI_NOR_Boot_Selection	0 - Do not override 1 - Override
BOOT_CFG0[6:5]	FlexSPI_NOR_Boot_Override_Selection	00 - Flex SPI (Hyperflash 1.8V) 01 - Flex SPI (Flash with 4B READ(0x13)default supported) 10 - Default Octal mode (Micron) 11 - Default Octal mode (Mxic)
BOOT_CFG0[7]	FlexSPI_NAND_4K_Page_Selection	0 - Not override the default seleciton (2K page) 1 - Override, 4K page is selected
BOOT_CFG2[1:0]	FlexSPI NAND Column Address Width	00 - 12 01 - 13 10 - 14 11 - 15
BOOT_CFG2[3:2]	FlexSPI NAND CS Interval	00 - 100 ns 01 - 200 ns 10 - 400 ns 11 - 50 ns
BOOT_CFG2[5:4]	FlexSPI NAND Search Count	00 - 2 01 - 2 10 - 4 11 - 8
BOOT_CFG2[7:6]	FlexSPI NAND Search Stride	00 - 64 pages 01 - 128 pages 10 - 256 pages 11 - 32 pages

Table continues on the next page...

Table 54. FlexSPI Boot eFUSE Configuration (continued)

Fuse	Definition	Settings
BOOT_CFG2[15:8]	FlexSPI DLL Value	The delay line value only for HyperFlash 00000000 - 11111111
BOOT_CFG2[23]	FlexSPI NAND Busy Bit Offset Override	0 - Do not override 1 - Override

9.8.1.3 FlexSPI Initialization Flow

A reset pin can be selected via the “FlexSPI NOR Reset Pin Port selection” fuses and “FlexSPI NOR Reset Pin selection” fuses. If a valid number has been programmed in these fuses then ROM code will toggle the selected GPIO pin to execute a cold reset to FlexSPI NOR device. The selected GPIO pin should be able to power down the FlexSPI NOR device on low polarity and power up the device on high polarity.

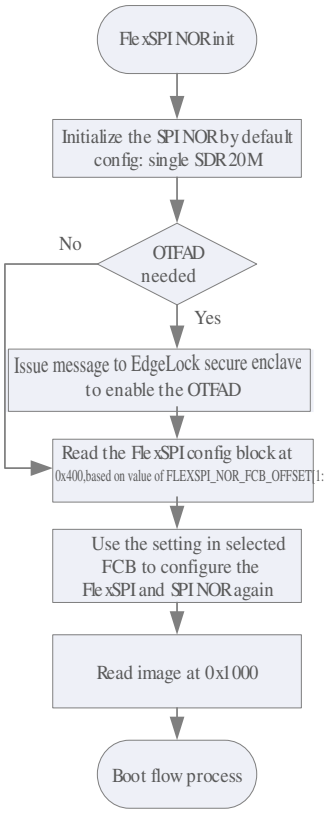

Figure 25. FlexSPI Initialization Flow

9.8.1.4 FlexSPI NOR Memory Map

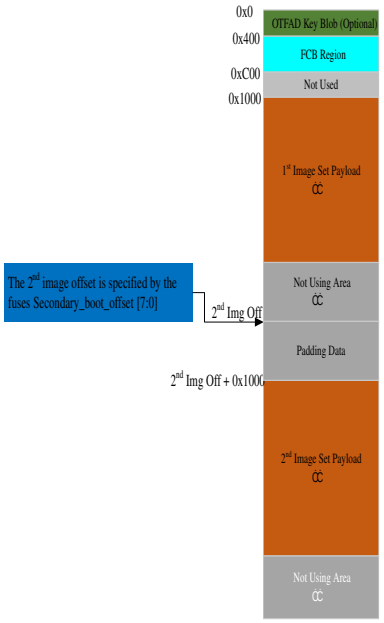

Figure 26. FlexSPI NOR Memory Map

9.8.1.5 FlexSPI NOR FCB region

The FCB region is located at offset 0x400 on FlexSPI NOR device, the size of FCB region is 2KB, so it can have up to 4 FCBs (FlexSPI NOR Configuration Block).

The change request to boot image set:

Two fuses FLEXSPI_NOR_FCB_OFFSET[1:0] are used to select the FCB which will be picked up ROM code to initialize FlexSPI NOR device:

NOTE

the dst of this image must be located in RAM free space (TCM for LP boot and OCRAM for Single boot).

FLEXSPI_NOR_CONFIG_BLOCK_OFFSET[1:0]	The selected FCB
2'b00	The 1st FCB (offset 0x400)
2'b01	The 2nd FCB (offset 0x600)
2'b10	The 3rd FCB (offset 0x800)
2'b11	The 4th FCB (offset 0xA00)

9.8.1.6 FlexSPI NAND

A typical FlexSPI NAND memory map contains two copies of Firmware Config Blocks (FCBs), two copies of discovered bad-block tables (DBBTs) and two image sets. Two image sets share same FCB and DBBT. The first FCB located at the start of the SPI NAND Flash, which is block0, page0. The second FCB located at (0 + page_index * FCB0->searchStride). Using FCB data structure, the DBBT0 and DBBT1 can be found. Normally, ROM use the first FCB and DBBT. If the blocks for FCB and DBBT are corrupted, ROM will search for the next FCB and DBBT using searchCount.

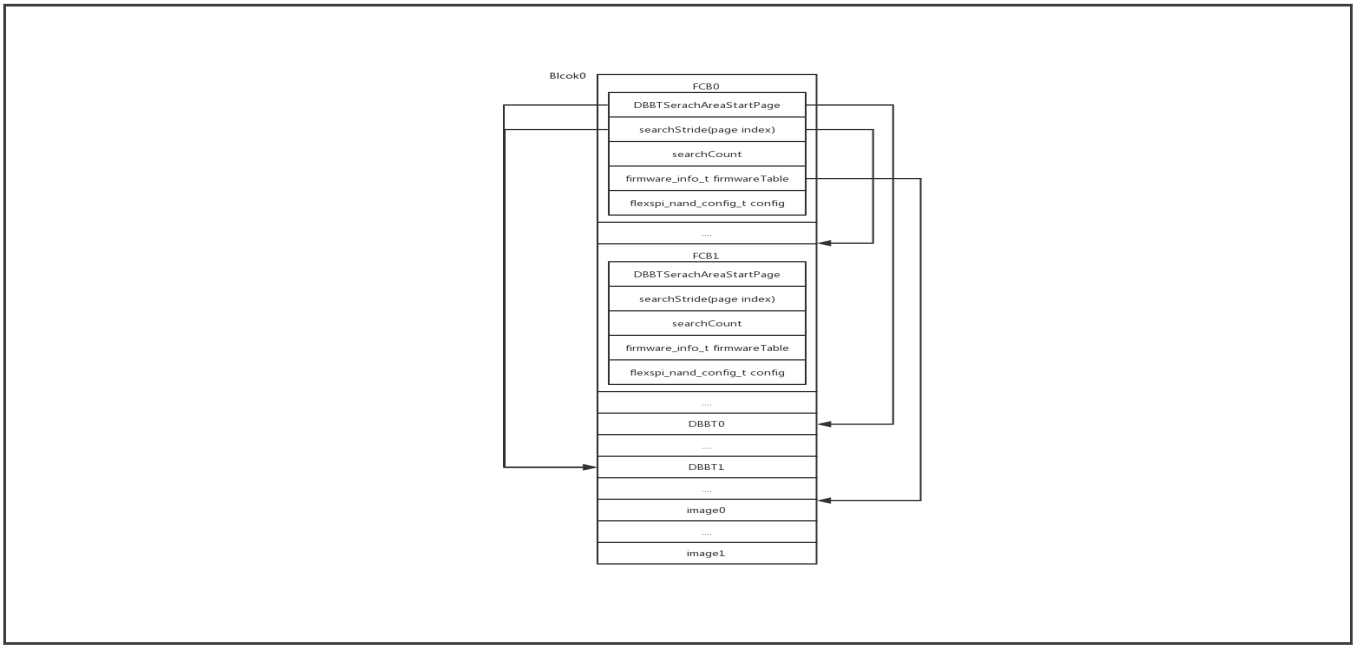

Table 55. FlexSPI NAND Configuration

Name	Offset	Size in bytes	Descriptions
flexspi_mem_config_t memConfig	0x0	448	Generic Memory configuration block over FlexSPI
pageDataSize	0x1c0	4	Data Size in one page, usually it is 2048 or 4096
pageTotalSize	0x1c4	4	Total size in one page, usually, it equals 2 ^ width of column address
pagesPerBlock	0x1c8	4	Pages per block
bypassReadStatus	0x1cc	1	Not used in ROM
bypassEccRead	0x1cd	1	Not used in ROM
hasMultiPlanes	0X1ce	1	Has multiple planes
skipOddBlocks	0x1cf	1	Skip odd blocks
eccCheckCustomEnable	0x1d0	1	Determine if use the customized ECC check related masks
ipCmdSerialClkFreq	0x1d1	1	IP Command Serial Clock Frequency, keep 0
readPageTimeUs	0x1d2	2	Not used in ROM
eccStatusMask	0x1d4	4	ECC status mask
eccFailureMask	0x1d8	4	ECC failure mask
blocksPerDevice	0x1dc	4	Blocks per device, not used in ROM
reserved	0x1e0	32	

Secondary image offset

In the above picture, the image1 offset is decided on the SECONDARY_BOOT_OFFSET fuse bits.

0 = 4MB

1 = 2MB

2 = 1MB

3 = 8MB

4 = 16MB

5 = 32MB

6 = 64MB

7 = 128MB

8 = 256MB

9.8.1.6.1 SPI NAND flash boot flow and Boot Control Blocks(BCB)

There are two BCB data structures:

- FCB
- DDBT

As a part of the SPI NAND media initialization, the ROM driver uses safe SPI NAND timings to search for the Firmware Configuration Block(FCB) that contains the optimum NAND timings, the page address of the Discovered Bad Block Table (DBBT) Search Area, and the start page address of image table. If the FCB is found, the optimum NAND timings are loaded for further reads. If the ECC fails, or the fingerprints do not match, the Block Search state machine increments the page number to the Search Stride number of pages to read for the next BCB until the SearchCount pages have been read. If the search fails to find a valid FCB, the NAND driver responds with an error and the boot ROM enters the serial download mode. The FCB contains the page address of the DBBT Search Area, and the page address for primary and secondary boot images. The DBBT is searched in the DBBT Search Area, just like the FCB is searched. After the FCB is read, the DBBT is loaded, and the primary or secondary boot image is loaded using the starting page address from the FCB.

9.8.1.6.2 Firmware configuration block (FCB) and Discovered Bad Block Table (DBBT)

The FCB is the first sector in the first good block. The FCB must be present at each search stride of the search area. The search area contains copies of the FCB at each stride distance, so, in case the first NAND block becomes corrupted, ROM finds its copy in the next NAND block. The search area must span over at least two NAND blocks. The location information for the DBBT search area, FW1, and FW2 are all specified in the FCB. This table shows the flash control block structure:

Table 56. FLEXSPI NAND FCB

Name	Offset	Size in bytes	Descriptions
reserved	0x0	4	Not used
fingerprint	0x4	4	32-bit word with a value of 0x20424346, in ascii \"FCB\"
version	0x8	4	32-bit version number; this version of FCB is 0x00000001
DBBTSerachAreaStartPage	0xc	4	page index for the first DBBT
searchStride	0x10	2	FCB and DBBT search stride
searchCount	0x12	2	Search time for both FCB and DBBT
firmwareCopies	0x14	4	not used in ROM
reserved	0x18	40	
firmwareTable	0x40	80	Firmware table, each firmware consist two word. - uint32_t startPage - uint32_t pagesInFirmware ROM only use the first firmware to do primary boot. Put this field here is to be compatible with other projects
reserved1	0x80	128	
flexspi_nand_config_t config	0x100	512	Another config structure for flexspi host driver

Table 57. Discovered Bad Block Table

Name	Offset	Size in bytes	Descriptions
reserved	0x0	4	-
fingerprint	0x4	4	32-bit word with a value of 0x44424254,in ascii \"DBBT\"
version	0x8	4	32-bit version number; this version of DBBT is 0x00000001
reserved	0xc	4	
badBlockNumber	0x10	4	Total number of bad blocks
reserved	0x14	12	
badBlockTable	0x20	1024	block number

Bad Block handling in ROM - During the firmware boot, at the block boundary, the Bad Block table is searched for a match to the next block. If no match is found, the next block can be loaded. If a match is found, the block must be skipped and the next block checked.

9.8.2 Expansion Device

The ROM supports booting from the eMMC and SD compliant devices.

9.8.2.1 Clock Settings for SD/eMMC

For USDHC1/2, the clock source is SYS_PLL_PFD1, which is 200MHz.

9.8.2.2 IOMUX Configuration for SD/eMMC

Table 58. SD/eMMC IOMUX pin configuration

Signal Name	USDHC1	USDHC2

PCS0	SAI1_TXFS (ALT2)	UART1_TXD (ALT2)	GPIO_IO08 (ALT1)	GPIO_IO18 (ALT5)

9.8.3.2 Expansion Device LPSPI fuse Configuration

LPSPI boot can be performed based on setting of the BOOT_CFG.

Table 61. Expansion Device LPSPI FUSE Configuration

Fuse	Definition	Settings
BOOT_CFG8[19]	Disable_A55_SPI_Recovery	0 - Disabled 1 - Enabled
BOOT_CFG8[20]	Disable_M33_SPI_Recovery	0 - Disabled

Table continues on the next page...

Table 61. Expansion Device LPSPI FUSE Configuration (continued)

Fuse	Definition	Settings
		1 - Enabled
BOOT_CFG2[16]	SPI Clock/Data Phase Control	0 - Tx on falling, Rx on rising 1 - Tx on rising, Rx on falling
BOOT_CFG2[17]	SPI SCLK Active	0 - Active high 1 - Active low
BOOT_CFG2[18]	SPI SS Active	0 - Active low 1 - Active high
BOOT_CFG2[19]	Recovery SPI Addressing	0 - 3-bytes (24-bit) 1 - 2-bytes (16-bit)
BOOT_CFG2[24]	Recovery CS Select	0 - CS0 1 - CS1
BOOT_CFG2[27:26]	Recovery Port Select	For single boot 0 - LPSPI3 1 - LPSPI4 For LP boot (CM33 ROM boot) 0 - LPSPI1 1 - LPSPI2

9.9 Serial Downloader Boot

9.9.1 USB Serial Download

The Serial Downloader provides a means to download a Program Image to the chip over USB serial connection.

USB serial download boot is supported on USB 2.0 OTG, as HID device. Serial download is only supported via the USB1 instance, for both boot types (LP Boot and Single boot).

USB boot in ROM code works as a HID device. The ROM will view the USB as a normal boot device, similar to the SD card. The difference from the SD card here is that the USB is a 'stream' device. ROM must 'read' it one byte at a time, and it can not specify the offset for the reading. This means that the image for USB boot must be continuous.

The USB boot flow is as follows:

1. ROM gets into USB boot mode and has been enumerated by Host.
2. The Host sends 8KB (initial image header) through USB. ROM reads 8KB from USB connection.
3. ROM parses the header and reads all SPL into OCRAM, per the information provisioned in the IVT header.
4. ROM authenticates the SPL and then jumps to it, if authentication passes.

USB Serial Download boot can be disabled by fuse.

The USB HID device VID/PID and strings are listed in the following table.

Table 62. VID/PID and strings for USB HID device

Descriptor	Value
VID	0x1FC9
PID	0x14E
PID for Azure	0x150
bcdDevice	0x0001

9.9.2 USB Serial Download Descriptor on Chip Lifecycle

ROM provides the current lifecycle (LC) status in the USB String Descriptor 2.

Table 63. USB string descriptor 2 lifecycle values

Lifecycle	USB String Descriptor 2 Value
FAB	FA
INVALID/UNKNOWN	IV
BLANK	BA
NXP_PROV	NP
OEM_OPEN	OO
OEM_SWC	OS
OEM_CLOSED	OC
FR_OEM	FO
FR_NXP	FN
OEM_LOCKED	OL

NOTE

For information on life cycle management of this chip, see the chip's Security Reference Manual.

9.9.3 Serial Downloader eFUSE Configuration

The SDP eFUSE settings are provided in the following table.

Table 64. SDP eFUSE Configuration

Fuse	Definition	Settings
BOOT_MODE[3:0]	Boot device selection	Coretx-A55 (Single boot): • 0001 - Serial Downloader Coretx-M33 (LP boot): • 1001 - Serial Downloader
BOOT_CFG10[2]	SDP_Disable	0 - Enabled 1 - Disabled

Table continues on the next page...

Table 64. SDP eFUSE Configuration (continued)

Fuse	Definition	Settings
BOOT_CFG10[3]	SDP_WO	0 - Enabled 1 - Disabled
BOOT_CFG10[4]	SDP_READ_DISABLE	0 - Enabled 1 - Disabled

9.10 Secure boot

The boot ROM uses the Advanced High Assurance Boot (AHAB) library to provide a secure boot environment for the Cortex-M33 low power boot and Cortex-A55 single boot procedures.

A key feature of the boot ROM is the ability to perform a secure boot. The boot ROM is also called Advanced High-Assurance Boot (AHAB), which protects the system from executing unauthorized program images. Before the AHAB allows the user image to execute, the image must be signed. The signing process is done during the image build process by the private key holder and the signatures are then incuded as a part of the final program image. If configured to do so, the AHAB verifies the signatures using the public keys included in the program image. The corresponding public key hash is embedded in the fuse.

In addition to supporting the digital signature verification to authenticate the program images, encrypted boot is also supported. The encrypted boot can be used to prevent the cloning of the program image directly off the boot device. A secure boot with AHAB can be performed on all boot devices supported on the chip in addition to the serial downloader. The out-of-fab setting for the LIFE_CYLCE is the open configuration, in which the ROM/AHAB performs the image authentication, but all authentication errors are ignored and the image is still allowed to execute.

NOTE

Refer to the chip's Security Reference Manual for additional details on secure boot.

9.11 ROM API

The main purpose is for SPL calling to load/authentication images. The ROM API table is as follows:

Table 65. ROM API Table

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x0	Tag: 0xEA91		Version: 0x0001	
0x4	Reserved as 0x0			
0x8-0xF	Pointer to address of download_image			
0x10 – 0x17	Pointer to address of query_boot_infor			
0x18-0x3F	Reserved as 0x0			

9.11.1 API download_image

The SPL calls this API to load images from the current boot device being active. The definition of this API is as follows.

```
UINT32 load_image(UINT8 *dst, UINT32 offset, UINT32 size, UINT32 xor)
```

The parameters are defined below:

- dst - The physical memory address to be loaded to.

- size - The image size to load. In bytes.
- offset - Where to read from boot device. In bytes. Relative to the beginning of the boot device
- xor - The xor of dst, size, and offset. To address fault injection attack.

The return values are defined below:

- 0xF0 for success others for failure.
- 0x01 – Invalid para. XOR wrong, invalid dest/sizeRead, invalid offset (not page aligned).
- 0x02 – low level device driver read failure (NAND ECC error, SD CRC error, etc.).
- 0x03 – Device not ready (not initialized yet or no valid device at all).
- 0x04 – Out of memory (such as loading data from FlexSPI flash but space is out of FlexSPI NOR device).

NOTE

For USB, the offset will be ignored by ROM.

For eMMC Fast boot, there are two scenarios.

1. Primary boot succeeds, eMMC card in Fast Boot Mode, offset will be ignored by load_image API.
2. Primary boot failed, ROM moves card into normal boot mode, then boots from Secondary Image, offset needs to be provisioned then.

The SPL can call query_boot_infor (BOOT_DEVICE) to check if the card is in Fast Boot Mode. Provisioning "offset" in SPL is recommended since it works for both scenario #1 and #2 above.

NOTE

The API does not need the caller to specify which interface it needs to download.

When booting from SPI NAND and RawNAND, the SPL must pass the good page offset (skip all the bad block) of the NAND device.

9.11.2 API query_boot_infor

```
UINT32 query_boot_infor(UINT32 infor_type, UINT32 *infor, UINT32 xor)
```

The return values are defined below:

- 0xF0 for success and other for failure.
- 1 Invalid para. Invalid Infor type or Invalid Infor type.

The paramaters are defined below:

- infor_type:
  - 01 - BootROM Version
  - 02 - Boot device (see Boot Device Definition).
  - 03 - Device page size (in byte).
  - 04 - The offset (in byte, relative to beginning of the boot image) of the current image's IVT. The intent here is SPL can calculate the physical address (in the boot device) of SW image to be loaded.
  - 05 - Boot Stage (see Boot Stage definition).
  - 06 - The offset (in byte, relative to beginning of the boot device) of the current image. The intent here is SPL can calculate the physical address (in the boot device) of SW image to be loaded.
- Infor - Points to the word to save the infor being queried, valid if returns 0xF0. Must be in TCM/OCRAM free space.
- Xor - The xor of infor_type and Info. To address fault injection attack.

9.11.2.1 Boot Device Definition

Table 66. Boot Device Definition

Bit 31-24	Bit 23-16	Bit 15-8	Bit 7-0
Reserved	Boot Interface	Instance	Device_State

The field definitons are provides below.

- Boot Interface -Indicating the boot interface from which SPL been boot.
  - 0x1 – SD
  - 0x2 – eMMC
  - 0x4 – FlexSPI NOR flash
  - 0x6 – LPSPI EEPROM
  - 0x8 – FlexSPI NAND flash
  - 0xE – USB
- Instance - to specify which port the SPL boots from, from 0 (for example, for SD/eMMC boot, 0 means booting from USDHC1 port).
- Device State - to specify the state of the boot device, if needed. Usually Boot Interface dependent.
  - For eMMC: Bit0 – Card in Fast Boot Mode if set.
  - For other Boot Interfaces, this field shall be 0.

9.11.2.2 Boot Stage definition

The Boot Stage values are as defined below:

- 0x6 – Primary Boot
- 0x9 – Secondary Boot
- 0xA – Recovery Boot
- 0x5 – USB boot

Chapter 10
IOMUXC GPR

10.1 Overview

The IOMUXC GPR module includes a configuration register.

10.2 Memory map and register definition

This section includes the IOMUXC-GPR memory map and detailed description of Configuration register.

10.2.1 IOMUXC GPR register descriptions

10.2.1.1 IOMUXC GPR memory map

IOMUXC_GPR.IOMUXC_GPR base address: 443C_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	IOMUXC GPR Configuration (CONFIG)	32	RW	0000_8920

10.2.1.2 IOMUXC GPR Configuration (CONFIG)

Lower 16 bits [15:0] are data bits and upper 16 bits [31:16] are lock bits. They are one-to-one mapped and control the access of IOMUXC module. Once a lock bit is set, it and its corresponding data bit cannot be cleared unless a reset. Each field can be assigned to any master ID through configuration.

Table 67. Master IDs

Module	4-bit Master ID
Cortex-A55 cores	000n
Reserved	0010 - 0111
Cortex-M33	1000
Reserved	1001
Edgelock	1010

Chapter 11
Arm Modules Overview

11.1 Overview

The following Arm modules are supported in this chip:

- Arm Cortex®-A55 MPCore
- Cortex-M33 Platform
- Neural-network Processing Unit (NPU)
- TrustZone

11.1.1 Arm Cortex®-A55 MPCore

The Cortex®-A55 MPCore has the following features:

- Two Cortex®-A55 processors:
  - 32 kByte L1 Instruction Cache
  - 32 kByte L1 Data Cache
  - 64 kByte per-core L2 cache
  - Media Processing Engine (MPE) with NEONTM technology supporting the Advanced Single Instruction Multiple Data architecture
  - Floating Point Unit (FPU) with support of the VFPv4-D16 architecture
- Support of 64-bit Arm®v8.2-A architecture
- 256 kByte cluster L3 cache

In addition, it also includes various components composing the CoreSightTM debug and trace technology, such as ETM, CTM and CTI.

The Cortex®-A55 platform supports following power gating modes:

Table 68. Cortex-A55 Platform Power Modes

-	CPU0	CPU1	PLATFORM	L3 CACHE Memory array	VDD
ALL_ON	ON	ON	ON	ON	ON
ONE_CPU_ON	ON	OFF	ON	ON	ON
ALL_CPU_OFF	OFF	OFF	ON	ON	ON
L3_RETENTION	OFF	OFF	OFF	RET	ON
ALL_OFF	OFF	OFF	OFF	OFF	ON
POWER_DOWN	OFF	OFF	OFF	OFF	OFF

11.1.2 Cortex-M33 Platform

- Stand by monitoring with Cortex®-A55 and other high-power modules power gated
- IoT device control (for example running uWeave)
- ML applications

- ECC support for both cache and TCM

The Cortex-CM33 core

- 16KB L1 Instruction Cache
- 16KB L1 Data Cache
- 256 KByte TCM, also accessible as SRAM by the rest of the system

.

11.1.3 Neural-network Processing Unit (NPU)/ML (Machine Learning)

This chip includes a Neural-network Processing Unit (NPU)/ML (Machine Learning) module. It supports the following features:

- 256 MACs operating at up to 1.0GHz and 2 OPS/MAC
- 2x 128-bit AXI master interfaces
- 32-bit APB slave interface
  - The 128-bit M0 port is used by the NPU to access OCRAM.
  - The 128-bit M1 port is used by the NPU to access DRAM.
- Q-channel slave port for interaction with the CCM and GPC clock and power control.

11.1.4 GIC-600

GIC-600 is used as the interrupt controller for the Cortex®-A55 processor. It supports a distributed microarchitecture containing several individual blocks that are used to provide a flexible GIC implementation.

- Forward compatibility with ARMv8.2 Cores supporting increased 512 CPU threads/chip and multi-chip capabilities
  - Distributed architecture for reduced power, congestion and improved latency
  - End-to-End credited protocols allows bridging communication to any free-flowing transport layer. Transport layer will be native AXI4 stream.
  - Clock and power control for each block for improved power savings
- QoS improvements
  - Increased ITS caching to reduce memory accesses
  - More flexible use of LPI cache and Pending Tables for reduced memory accesses and improved latency bounding
- Improved trace and debug
  - PMU with full snapshot functionality
  - Full ITS command error logging and reporting via ARMv8.2 RAS error records
  - ECC error logging and containment to allow software recovery
- Improved control over 1-of-N interrupt routing
- SPI collators enabling Q-Channel support on main GIC

11.1.5 TrustZone

The TrustZone architecture provides means to help secure systems, using the TrustZone Security Extensions, and Secure peripherals. TrustZone is a security feature on ARM Cortex M and A series that enables execution separation of trusted (secure) software, and enables access control isolation of trusted resources from non-trusted (non-secure) software and resources, while running on the same CPU. Memory arrays and peripherals are segmented into either Secure (S) or Non-Secure (NS). TrustZone is optimized for energy-efficient, embedded applications that require real-time responsiveness.

More details on TrustZone can be found in “TrustZone® technology can be found at arm.com.

NOTE

"S" = Secure; "NS" = Non-Secure.

Trustzone is always enabled on this chip and is supported through TRDC.

If TrustZone functionality is enabled, then the following restrictions apply to the cores:

- The CPU in a Secure state (CPU-S) can execute instructions from Secure memory (S-memory) only; the CPU cannot execute instructions from Non-Secure memory (NS-memory).
- CPU-S can access data in both S-memory and NS-memory, which means that CPU-S can execute data reads from both S- and NS-memory, and also execute data writes to S or NS-memory.
- CPU-NS can execute instructions only from NS-memory, and cannot execute instructions from S-memory.
- CPU-NS can access data only in NS-memory, which means that CPU-NS can execute data reads from NS-memory only, and can execute data writes to NS-memory only. CPU-NS cannot access data from S-memory.

Chapter 12
ARM Cortex A55

12.1 Overview

The Arm Cortex-A55 implements the Armv8-A architecture. The Cortex-A55 is a high efficiency processor with Media Processing Engine (MPE) with NEON technology supporting Advanced Single Instruction Multiple Data architecture. The Cortex-A55 also includes a floating-point unit (FPU), L1 instruction cache, and L1 data cache, and L2 cache.

There are 2 A55 cores on this chip.

The core also includes various components composing the Arm CoreSight debug and trace technology, such as ETM, CTM and CTI. The debug interface is connected to the DAP and CoreSight debug modules in the SoC to allow debug through JTAG interface.

12.1.1 Block Diagram

The A55 block diagram is shown below.

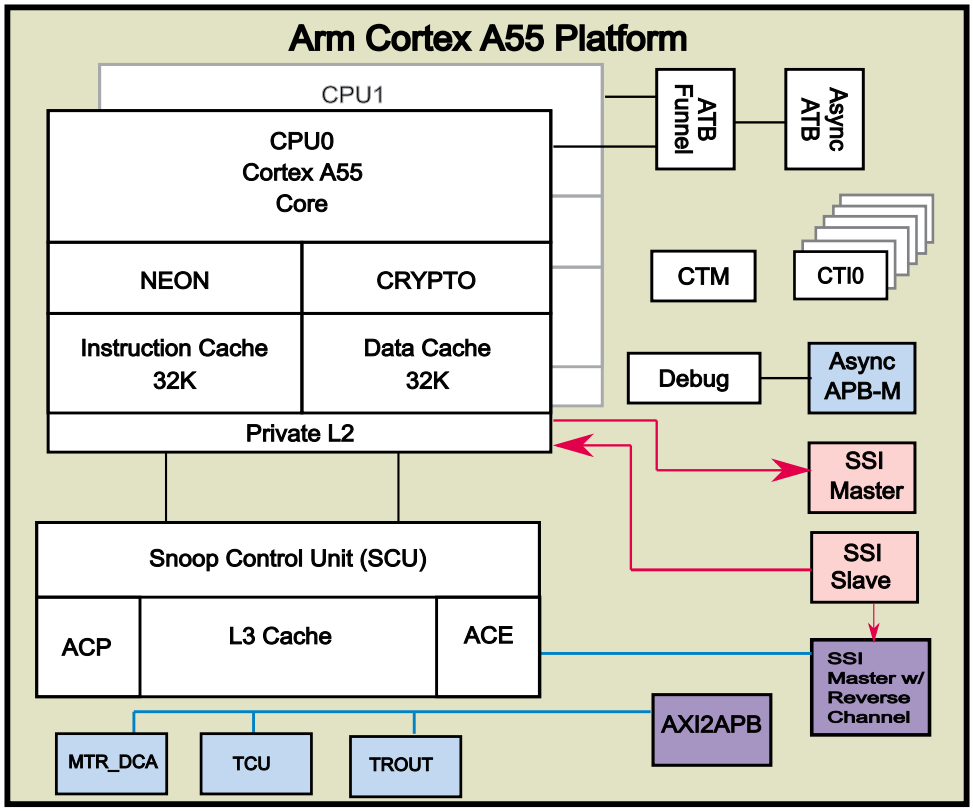

Figure 28. A55 Block Diagram

12.1.2 Features

The Arm Cortex A55 MPCore has the following features:

- Two Cortex-A55 processors:
  - 32 kByte L1 Instruction Cache

  - 32 kByte L1 Data Cache
  - 64 kByte per-core L2 cache
  - Media Processing Engine (MPE) with NEON technology supporting the Advanced Single Instruction Multiple Data architecture
  - Floating Point Unit (FPU) with support of the VFPv4-D16 architecture
- Support of 64-bit Arm v8.2-A architecture
- 256 kByte cluster L3 cache
- Various components composing the CoreSightTM debug and trace technology, such as ETM, CTM and CTI
- The DynamIQ Shared Unit (DSU) shared between cores, includes Snoop Control Unit (SCU), L3 cache, ACE interface, etc.

12.2 Functional Description

The sections below discuss the high-level overview of the Arm Cortex-A55 Platform components.

12.2.1 Arm Cortex-A55 MPCore Processor

The Arm Cortex-A55 processor implements the Armv8-A architecture. the A55 complex has 2. Each core has a 32 kByte L1 Instruction Cache, a 32 kByte L1 Data Cache and a 64 kByte per-core L2 cache. Each core also has a Media Processing Engine (MPE) with NEON technology supporting the Advanced Single Instruction Multiple Data architecture and a Floating Point Unit (FPU) with support of the VFPv4-D16 architecture.

12.2.2 DynamIQ Shared Unit (DSU)

The DynamIQ Shared Unit (DSU) is the portion of the A55 complex that is shared between the cores. The DSU includes the Snoop Control Unit (SCU), L3 cache, etc. The SCU arbitrates between the cores requesting L3 cache access.

12.2.3 Advanced SIMD (NEON)

The Cortex-A55 processor supports the Advanced SIMD and Scalar Floating-point instructions.

See Arm Cortex-A55 documentation for more information.

12.2.4 Atomic Instructions

The Arm Cortex-A55 Core Technical Reference Manual mentions that atomics are supported to cacheable memory but requires a coherent interconnect to support atomics to device or non-cacheable memory. This product does not support such a coherent interconnect. If such an atomic instruction is executed when the interconnect does not support them, it will result in a synchronous Data Abort (for load atomics) or an asynchronous Data Abort (for store atomics)

12.2.5 Debug

The Cortex-A55 platform includes the debug and trace sub-modules. The debug interface is connected to the DAP and CoreSight debug modules in the SoC to allow debug through JTAG interface.

See the System Debug chapter for more information about the A55 Platform debug components, such as ETM, CTI and CTM.

12.2.6 Clocking

The Cortex-A55 platform takes in the following clocks, all of which may be fully asynchronous to each other.

Table 69. A55 Clocks

A55 Platform Clock Name	Source	Frequency (Nominal Voltage)	Description
PERIPHCLK	CCM: Arm_a55_periphclk_root	333MHz	Timers, clock and power management logic in Cortex-A55 platform.
PCLK			Debug Block and DSU Debug APB interfaces.
ATCLK			ATB trace buses output from DSU
GICCLK			GIC AXI-stream interface between DSU and SoC's GIC-600
SCLK	Mux between either Arm_pll_clk or Arm_a55_clk_root	1.4GHz	SCU and L3 subsystem, ACE interface and A55 cores

12.2.7 Interrupts

The Generic Interrupt Controller (GIC) supports and manages interrupts in the cores.

The GIC provides registers for managing:

- Interrupt sources
- Interrupt behavior
- Interrupt routing to one or more cores

GIC-600 is supported

See Arm documentation for more information.

12.3 External Signals

The A55 Platform has no external signals.

Chapter 13
ARM Cortex CM33 TCM MCM and ECC MCM (CM33_CACHE_TCM_ECC_MCM)

13.1 Chip-specific CM33 information

Table 70. Reference links to related information

Topic	Related module	Reference
Full description	Arm Cortex CM33 Platform (CM33)	CM33 Platform
System memory map		System memory map
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

The Cortex-CM33 accesses its Code TCM and Data TCM through its C-AHB and S-AHB buses.

By default, the Code TCM and System TCM are 128KB each. Note that the BLK_CTRL_S_AONMIX register bitfield M33_CFG[TCM_SIZE] is a 2-bit field with 3 valid encodings:

- 00 (default) = REGULAR_TCM: 128kB Code TCM and 128kB Sys TCM
- 01 = DOUBLE_CODE_TCM. 256kB Code TCM and 0 Sys TCM
- 10 = DOUBLE_SYS_TCM. 256kB Sys TCM and 0 Code TCM
- 11 = Reserved

NOTE

To avoid unexpected SW issues, writes to this M33_CFG[TCM_SIZE] register should only be performed when the Cortex-M33 core is in reset.

Code and System TCM are mapped to addresses:

- Code TCM => 0x0FFE_0000 (non-secure) and 0x1FFE_0000 (secure) (plus the additional 128kByte below this if M33_CFG[TCM_SIZE] == DOUBLE_CODE_TCM)
- Data TCM => 0x2000_0000 (non-secure) and 0x3000_0000 (secure) (plus the additional 128kByte above this if M33_CFG[TCM_SIZE] == DOUBLE_DATA_TCM)

The system access to the TCM is mapped to address:

- Code TCM => 0x201E_0000 .. 0x201F_FFFF (plus the additional 128kByte below this if TCM_SIZE == DOUBLE_CODE_TCM)
- System TCM => 0x2020_0000 .. 0x2021_FFFF (plus the additional 128kByte above this if TCM_SIZE == DOUBLE_DATA_TCM)

The valid range of these address ranges depends on the value of M33_CFG[TCM_SIZE].

See the M33_CFG register in the BLK_CTRL_S_AONMIX chapter for more information about CM33 and TCM configuration options.

NOTE

The i.MX93W does not support the Cortex-M33 external NMI pin.

13.2 Overview

CM33 implements the Armv8-M architecture with main extensions. The Arm Cortex-M33 is a high-efficiency processor with security considerations. CM33 includes:

- A single-precision floating-point unit (FPU)
- A nested vectored interrupt controller (NVIC)
- A flash patch breakpoint (FPB)
- The data watchpoint and trace (DWT) unit
- An instrumentation trace macrocell (ITM)

As shown in Figure 29, the CM33 platform also includes:

- Miscellaneous control module CM33_TCM_MCM, which contains programming registers to control the ECC features for CM33 code TCM and system TCM
- Miscellaneous control module CM33_CACHE_ECC_MCM, which contains programming registers to control the ECC features for TAG0, TAG1, DATA0, and DATA1 in the CM33 code cache and system cache

13.2.1 Block diagram

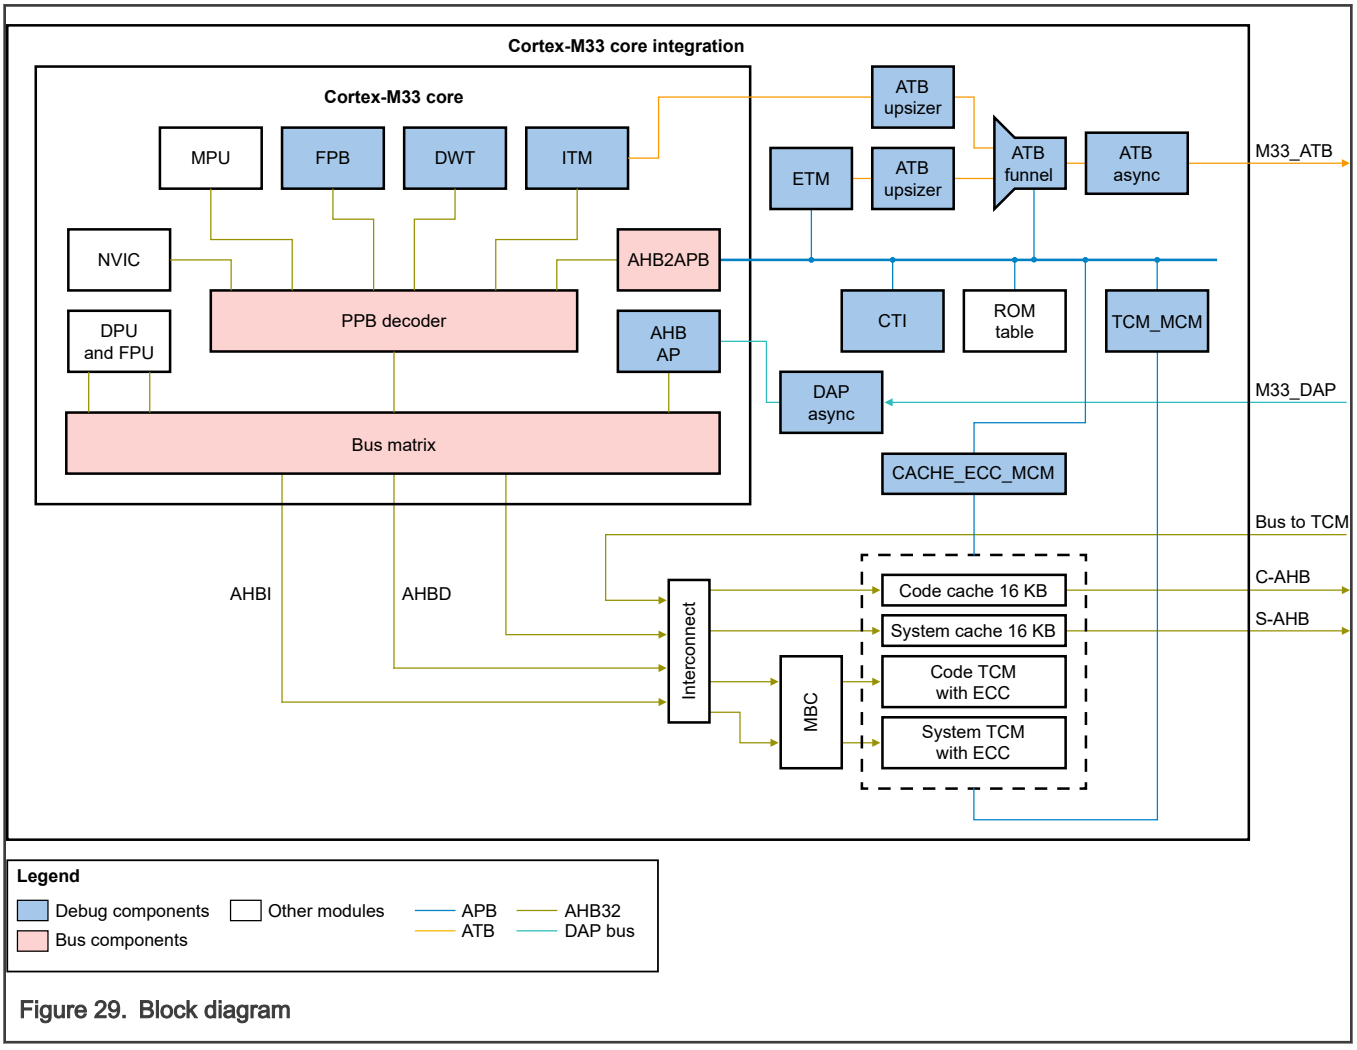

Figure 29. Block diagram

13.2.2 Features

- Cortex-M33 processor
- Single-precision FPU
- NVIC support
- FPB support (does not include patching)
- DWT and ITM support
- ETM support
- Two-way set-associative 16-KB system cache
- Two-way set-associative 16-KB code cache
- Configurable 256-KB tightly coupled memory (TCM):
  - 128-KB system TCM on system bus
  - 128-KB code TCM on code bus
- TCM ECC support
- Cache ECC support
- DSP extensions
- Security extensions
- Wake-up interrupt controller (WIC) support
- Nonsecure memory protection unit (MPU) with 16 regions
- Secure MPU with 16 regions
- Cross trigger interface (CTI) support

The AON domain, which incorporates the Cortex-M33 core, includes one messaging unit (MU) and one hardware semaphore (SEMA42) for inter-core communication with the Cortex-M33 core.

For the Cortex-M33 core, the CM33 platform also supports execution in place (XIP) to facilitate fast power-on wake-up. See the "System Boot" chapter for more details.

The Cortex-M33 debug interface is connected to the DAP and CoreSight debug modules in the chip to allow debugging through the JTAG interface. See the "System Debug" chapter for more details.

13.3 Functional description

The following sections contain a high-level overview of the CM33 components.

13.3.1 Cortex-M33 processor

The Cortex-M33 processor is based on the Armv8-M architecture and has a low gate count and high energy efficiency.

13.3.2 NVIC

NVIC supports 6 priority levels for interrupts. The NVIC IPR registers define 4 bits per IRQ.

13.3.3 FPU

The FPU implements FPv5 floating-point extensions, which support these single-precision operations: add, subtract, multiply, divide, multiply and accumulate, and square root. The FPU also provides conversions between fixed-point and floating point data formats, and it provides floating-point constant instructions.

The FPU is compliant with ANSI/IEEE Std 754-2008.

13.3.4 MPU

The MPU has independent attribute settings for each region and can export memory attributes.

CM33 also supports a secure MPU.

When a core access hits an overlapping memory region, the processor generates a fault.

Instruction accesses and data accesses in a given region have the same region settings.

13.3.5 Debug

See the "System Debug" chapter for more information about the CM33 platform debug components.

13.3.6 Code and system TCM

CM33 accesses its code TCM and system TCM through its C-AHB and S-AHB buses, respectively.

By default, the code TCM and system TCM are 128 KB each. The BLK_CTRL_S_AONMIX register field M33_CFG[TCM_SIZE] is a 2-bit field with three valid encodings:

- 00 (default) = REGULAR_TCM: 50% code TCM and 50% system TCM
- 01 = DOUBLE_CODE_TCM: 100% code TCM and 0% system TCM
- 10 = DOUBLE_SYS_TCM: 100% system TCM and 0% code TCM
- 11 = Reserved

NOTE

To avoid unexpected software issues, perform writes to BLK_CTRL_S_AONMIX.M33_CFG[TCM_SIZE] only when the Cortex-M33 core is in reset.

Code TCM is mapped to 0FFE0000h (nonsecure) and 1FFE0000h (secure) (plus the additional 128 KB below this if M33_CFG[TCM_SIZE] = DOUBLE_CODE_TCM)

System TCM is mapped to 20000000h (nonsecure) and 30000000h (secure) (plus the additional 128 KB above this address if M33_CFG[TCM_SIZE] = DOUBLE_DATA_TCM)

The system bus can access both TCM memories as a continuous address space via their aliases:

- Code TCM is mapped to the aliased code TCM base address (plus the additional 128 KB below this if TCM_SIZE = DOUBLE_CODE_TCM)
- System TCM is mapped to the aliased system base address (plus the additional 128 KB above this address if TCM_SIZE = DOUBLE_DATA_TCM)

See the chip's memory map information for aliased code and system TCM base address details.

The valid range of these address ranges depends on the value of BLK_CTRL_S_AONMIX.M33_CFG[TCM_SIZE].

See the M33_CFG register in the BLK_CTRL_S_AONMIX chapter for more information about the CM33 and TCM configuration options.

13.3.6.1 CM33_TCM_MCM

CM33_TCM_MCM is a miscellaneous control module for the Cortex-M33 core. It contains programming registers to control the ECC features of CM33 TCM.

13.3.6.2 CM33 TCM ECC support

You can use the syndrome value for single-bit ECC to locate the error bit in the CM33 system and code TCM. See the following lookup table for these values.

Table 71. Lookup table for 32-bit data single-bit ECC syndrome

Syndrome value	Error bit
07h	31
7Fh	30
6Eh	29
6Dh	28
6Bh	27
67h	26
5Eh	25
5Dh	24
5Bh	23
57h	22
4Fh	21
7Ch	20
7Ah	19
79h	18
76h	17
75h	16
73h	15
70h	14
68h	13
64h	12
62h	11
61h	10
58h	9
54h	8
52h	7
51h	6
4Ch	5
4Ah	4
49h	3
46h	2
45h	1
43h	0

NOTE

- You cannot use the syndrome value for multibit ECC to locate the error bit in the CM33 system and code TCM.
- You cannot use the syndrome value for single-bit and multibit ECC to locate the error bit in the CM33 system and code cache.

13.3.7 CM33 code and system cache

The following caches are included in the CM33 platform:

- Two-way set-associative 16-KB code cache with ECC and write path error injection support
- Two-way set-associative 16-KB system cache with ECC and write path error injection support

13.3.7.1 CM33_CACHE_ECC_MCM

CM33_CACHE_ECC_MCM is a miscellaneous control module for the Arm Cortex-M33 cache ECC. It contains programming registers to control the ECC features of CM33 TAG0, TAG1, DATA0, and DATA1.

13.3.8 Clocking

See the chip's clocking sections for more information on CM33 clocks.

Table 72. Clocks

Clock name	Description
m33_clk	Main M33 clock
m33_systick_clk	M33 Systick clock

13.3.9 Reset

You can use a CM33 reset to reset the CM33_TCM_MCM and CM33_CACHE_ECC_MCM submodules. Performing a cold or soft reset on the CM33 core also resets the submodules.

13.3.10 Interrupts

Table 73. CM33_TCM_MCM interrupt requests

Interrupt request	Asserted when
tcm_ecc1bit_irq	CM33 detects a single-bit ECC error on TCM (including code and system TCM) and the corresponding interrupt is enabled.
tcm_ecc2bit_irq	CM33 detects a multi-bit ECC error on TCM (including code and system TCM) and the corresponding interrupt is enabled.

Table 74. CM33_CACHE_ECC_MCM interrupt requests

Interrupt request	Asserted when
ecc1bit_irq	CM33 detects a single-bit ECC error on cache (including cache TAG0, cache TAG1, cache DATA0, and cache DATA1) and the corresponding interrupt is enabled.
ecc2bit_irq	CM33 detects a multibit ECC error on cache (including cache TAG0, cache TAG1, cache DATA0, and cache DATA1) and the corresponding interrupt is enabled.

13.4 External signals

The CM33 platform has no external signals.

13.5 Initialization

To initialize CM33:

1. Verify that the clock for CM33 is enabled.
2. Enable the ECC features by writing 0 to the following fields before checking the cache or TCM ECC on read or write data:
   - CACHE_ECCR[RECC_DIS]
   - CACHE_ECCR[WECC_DIS]
   - TCMECCR[RECC_DIS]
   - TCMECCR[WECC_DIS]

13.6 Memory map and register definition

This section includes the memory map and detailed descriptions of all registers.

NOTE

For CM33_TCM_MCM:

- When you configure the code TCM to be double sized (BLK_CTRL_S_AONMIX.M33_CFG[TCM_SIZE] = 01b), all of the TCM is used as code TCM.
- When you configure the system TCM to be double sized (BLK_CTRL_S_AONMIX.M33_CFG[TCM_SIZE] = 10b), all the TCM is used as system TCM.
- However, the code injection and status register always correspond to the TCM space that starts at FFE0000h, and the system injection and status register always correspond to the TCM space that starts at 20000000h.

13.6.1 CM33_CACHE_ECC_MCM register descriptions

13.6.1.1 CM33_CACHE_ECC_MCM memory map

CM33_CACHE_ECC_MCM base address: 4440_1000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)

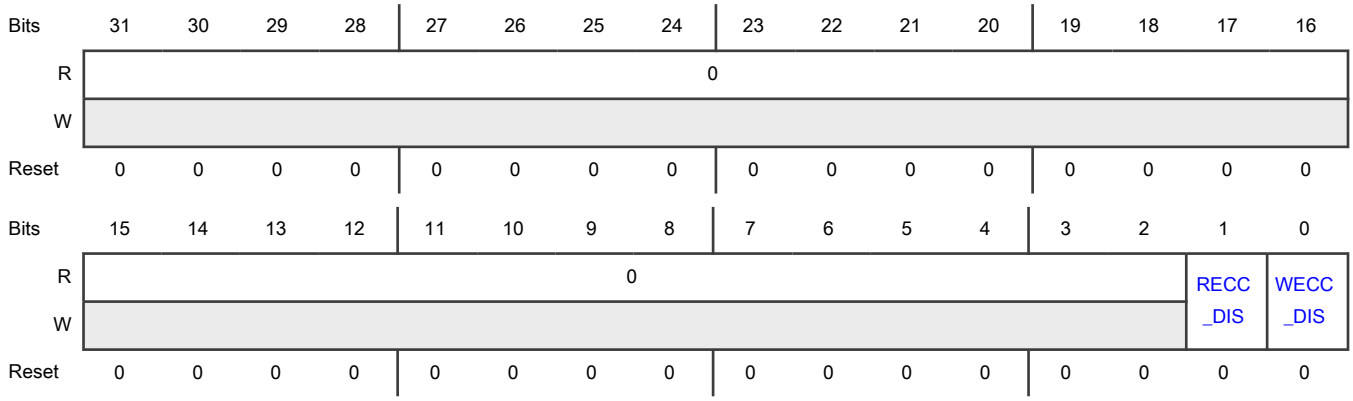
13.6.1.2 CACHE ECC Control (CACHE_ECCR)

Enables the ECC logic for the Cortex-M33 cache. The cache ECC is enabled by default.

Offset

Register	Offset
CACHE_ECCR	0h

Diagram



Fields

Field	Description
31-2 —	Reserved
1 RECC_DIS	Disable Cache ECC Read Check Disables the ECC check on cache read data. 0 - Enable 1 - Disable
0 WECC_DIS	Disable CACHE ECC Write Generation Disables ECC generation on cache write data. 0 - Enable 1 - Disable

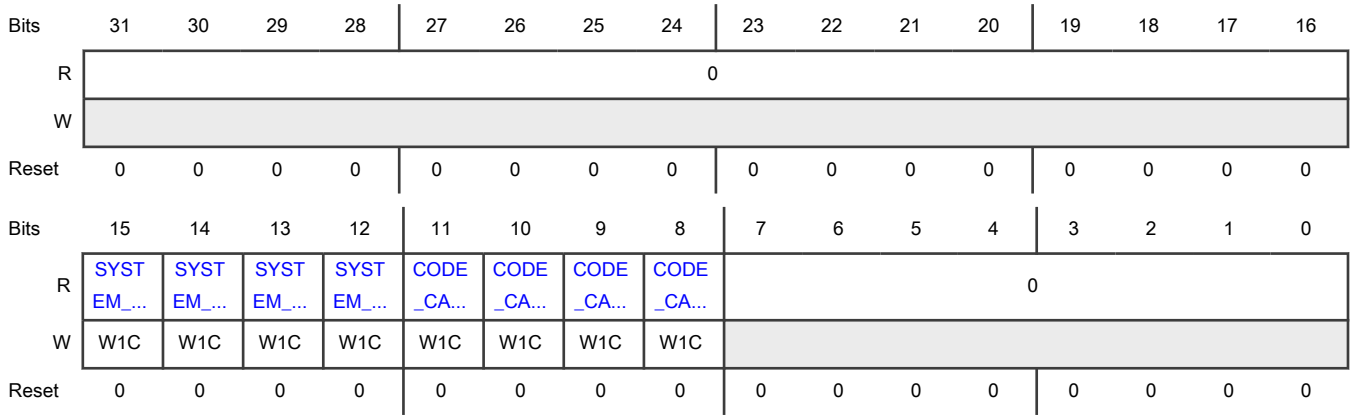
13.6.1.3 Interrupt Status (INT_STATUS)

Contains the ECC interrupt status for the code and system cache.

Offset

Register	Offset
INT_STATUS	20h

Diagram



Fields

Field	Description
31-16 —	Reserved
15 SYSTEM_CACHE_ECC_ERRS_OVER_INT	System Cache Access Multiple Single-Bit ECC Error Interrupt Status Indicates more than one single-bit ECC error in system cache read data when INT_STAT_EN[SYSTEM_CACHE_ECC_ERRS_OVER_INT_EN] = 1. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Not more than one error 1 - Multiple errors When writing 0 - No effect 1 - Clear the flag
14 SYSTEM_CACHE_ECC_ERRM_OVER_INT	System Cache Access Multiple Multibit ECC Error Interrupt Status Indicates more than one multibit ECC error in system cache read data when INT_STAT_EN[SYSTEM_CACHE_ECC_ERRM_OVER_INT_EN] = 1. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Not more than one error 1 - Multiple errors When writing 0 - No effect

7-0 —	Reserved

13.6.1.5 Interrupt Enable (INT_SIG_EN)

Selects which interrupt statuses are available to interrupt the host system. All these status fields share the same interrupt line (that is, all interrupts are combined with a logical OR). Writing 1 to any of these fields enables interrupt generation. The

corresponding field in Interrupt Status (INT_STATUS) generates an interrupt when the corresponding field in Interrupt Status Enable (INT_STAT_EN) is 1.

Offset

Register	Offset
INT_SIG_EN	28h

19 SYS_TCM_FRCNCI	Force Continuous Noncorrectable Data Inversions on System TCM Write Access Injects a multibit ECC error on the bits specified by SYS_TCM_ERR1BIT and SYS_TCM_ERR2BIT into every write access to system TCM that occurs after you write 1 to this field. 0 - Disable injection 1 - Enable injection
18 SYS_TCM_FRC1BI	Force Continuous 1-Bit Data Inversions on System TCM Write Access Injects a single-bit ECC error on the bit specified by SYS_TCM_ERR1BIT into every write access to system TCM that occurs after you write 1 to this field. 0 - Disable injection 1 - Enable injection
17 SYS_TCM_FR1NCI	Force One Noncorrectable Data Inversion on System TCM Write Access Injects a multibit ECC error on the bits specified by SYS_TCM_ERR1BIT and SYS_TCM_ERR2BIT into the first write access to system TCM that occurs after you write 1 to this field. 0 - Disable injection 1 - Enable injection
16 SYS_TCM_FR11BI	Force One 1-Bit Data Inversion on System TCM Write Access Injects a single-bit ECC error on the bit specified by SYS_TCM_ERR1BIT into the first write access to system TCM that occurs after you write 1 to this field. 0 - Disable injection 1 - Enable injection
15-8	Position of Second Bit to Inject ECC Error

Table continues on the next page...

Table continued from the previous page...

Field	Description
SYS_TCM_ERR2BIT	Determines the position of the second bit into which CM33 injects an ECC error. This field is used only for multibit ECC error injection.
7-0 SYS_TCM_ERR1BIT	Position of First Bit to Inject ECC Error Determines the position of the first bit into which CM33 injects an ECC error. This field can be used for both single-bit and multibit ECC error injection.

Chapter 14
ARM Cortex CM33 MCM (CM33_MCM)

14.1 Overview

MCM provides many miscellaneous control functions.

NOTE

The terminology in this chapter has been updated to align with NXP's inclusive language standards, as shown in the table below.

Table 75. Updated terms

Updated term	Deprecated term
Initiator	Master
Target	Slave

14.1.1 Features

- Control and counting logic used when the embedded trace buffer (ETB) is almost full
- Error status and interrupts for the cache write buffer
- Error status and interrupts for the core's floating-point unit (FPU)

14.2 Functional description

14.2.1 Clocking

This module has no clocking considerations.

14.2.2 Interrupts

MCM generates an interrupt if any of the following is true:

- FPU input denormal interrupt is enabled (ISCR[FIDCE] = 1) and an input is denormalized (ISCR[FIDC] = 1).
- FPU inexact interrupt is enabled (ISCR[FIXCE] = 1) and a number is inexact (ISCR[FIXC] = 1).
- FPU underflow interrupt is enabled (ISCR[FUFCE] = 1) and an underflow occurs (ISCR[FUFC] = 1).
- FPU overflow interrupt is enabled (ISCR[FOFCE] = 1) and an overflow occurs (ISCR[FOFC] = 1).
- FPU divide-by-zero interrupt is enabled (ISCR[FDZCE] = 1) and a divide-by-zero occurs (ISCR[FDZC] = 1).
- FPU invalid operation interrupt is enabled (ISCR[FIOCE] = 1) and an invalid operation occurs (ISCR[FIOC] = 1).
- A cache write buffer error occurs.

See Determining the source of the interrupt for more details.

14.3 External signals

This module has no external signals.

14.4 Application information

14.4.1 Determining the source of the interrupt

To determine the exact source of the interrupt, check the interrupt status flags with the corresponding interrupt enable fields.

1. Read the fields located in ISCR[31:16] and in ISCR[15:0].
2. Search the result for asserted flags, which indicate the exact interrupt sources.

14.5 Memory map and register descriptions

The memory map and register descriptions below describe the registers using byte addresses.

NOTE

All MCM registers support only 32-bit writes. Any attempted 8-bit or 16-bit writes will result in undefined behavior.

14.5.1 MCM register descriptions

14.5.1.1 MCM memory map

ppb_mcm2_cm4 base address: E008_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)

24	Store Buffer Fault Attributes (FATR)	32	R	See section
28	Store Buffer Fault Data (FDR)	32	R	See section

14.5.1.2 Interrupt Status and Control (ISCR)

Configures and reports the status of core-related interrupt exception conditions. The individual event indicators are first checked with their exception enables and then logically summed to form an interrupt request sent to the core's NVIC.

The fields in bits 15–8 are indicator flags based on the processor's FPSCR register. Attempted writes to these fields are ignored. After the flags are set, they remain set until you write 0 to the corresponding FPSCR field.

The fields in bits 31–24 control the interrupt enablement. If you write 1 to an interrupt enablement control field, MCM generates an interrupt when the corresponding status field is 1.

25 FDZCE	FPU Divide-by-Zero Interrupt Enable 0 - Disable 1 - Enable
24 FIOCE	FPU Invalid Operation Interrupt Enable 0 - Disable 1 - Enable
23-22	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
21 —	Reserved
20 CWBEE	Cache Write Buffer Error Enable Enables the generation of an interrupt in response to a bus error termination reported on a system bus transfer that has been initiated from the cache's write buffer. 0 - Disable 1 - Enable
19-16 —	Reserved
15 FIDC	FPU Input Denormal Interrupt Status Contains a copy of the core's FPSCR[IDC] and indicates that an input denormalized number has been detected in the processor's FPU. After this field becomes 1, it remains 1 until you write 0 to FPSCR[IDC]. 0 - No interrupt 1 - Interrupt occurred
14-13 —	Reserved
12 FIXC	FPU Inexact Interrupt Status Contains a copy of the core's FPSCR[IXC] and indicates that an inexact number has been detected in the processor's FPU. After this field becomes 1, it remains 1 until you write 0 to FPSCR[IXC]. 0 - No interrupt 1 - Interrupt occurred
11 FUFC	FPU Underflow Interrupt status Contains a copy of the core's FPSCR[UFC] and indicates that an underflow has been detected in the processor's FPU. After this field becomes 1, it remains 1 until you write 0 to FPSCR[UFC]. 0 - No interrupt 1 - Interrupt occurred
10 FOFC	FPU Overflow Interrupt Status Contains a copy of the core's FPSCR[OFC] and indicates that an overflow has been detected in the processor's FPU. After this field becomes 1, it remains 1 until you write 0 to FPSCR[OFC]. 0 - No interrupt 1 - Interrupt occurred

Table continues on the next page...

Table continued from the previous page...

Field	Description
9 FDZC	FPU Divide-by-Zero Interrupt Status Contains a copy of the core's FPSCR[DZC] and indicates that a divide-by-zero has been detected in the processor's FPU. After this field becomes 1, it remains 1 until you write 0 to FPSCR[DZC]. 0 - No interrupt 1 - Interrupt occurred
8 FIOC	FPU Invalid Operation Interrupt Status Contains a copy of the core's FPSCR[IOC] and indicates that an illegal operation has been detected in the processor's FPU. After this field becomes 1, it remains 1 until you write 0 to FPSCR[IOC]. 0 - No interrupt 1 - Interrupt occurred
7-6 —	Reserved
5 —	Reserved
4 CWBER	Cache Write Buffer Error Status Indicates whether a data transfer from the core's cache write buffer was terminated because of a bus error. This field can become 1 only when the corresponding enable field (ISCR[CWBEE]) = 1. The corresponding core fault address, attributes, and write data are typically retrieved from Write Buffer Fault Address (FADR), Store Buffer Fault Attributes (FATR), and Store Buffer Fault Data (FDR) registers during the interrupt handler before clearing the CWBER flag. 0 - No error 1 - Error occurred
3 DHREQ	Debug Halt Request Indicator Indicates whether a debug halt request is initiated because of an ETB counter expiration. This field becomes 1 when: • ETBCC[RSPT] = 11b. • ETBCC[CNTEN] = 1b. • ETBCV[COUNTER] = 0h. This field becomes 0 when the ETB counter disables or reloads. 0 - Not initiated 1 - Initiated
2 NMI	Nonmaskable Interrupt Pending Specifies whether a pending NMI exists. If ETBCC[RSPT] = 10b, this field becomes 1 to indicate a pending NMI when the ETB counter expires.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - No pending NMI 1 - Pending NMI
1 IRQ	ETB-Related Interrupt Pending Specifies whether a pending IRQ exists. If ETBCC[RSPT] = 01b, this field becomes 1 to indicate a pending IRQ when the ETB counter expires. 0 - No pending IRQ 1 - Pending IRQ
0 —	Reserved

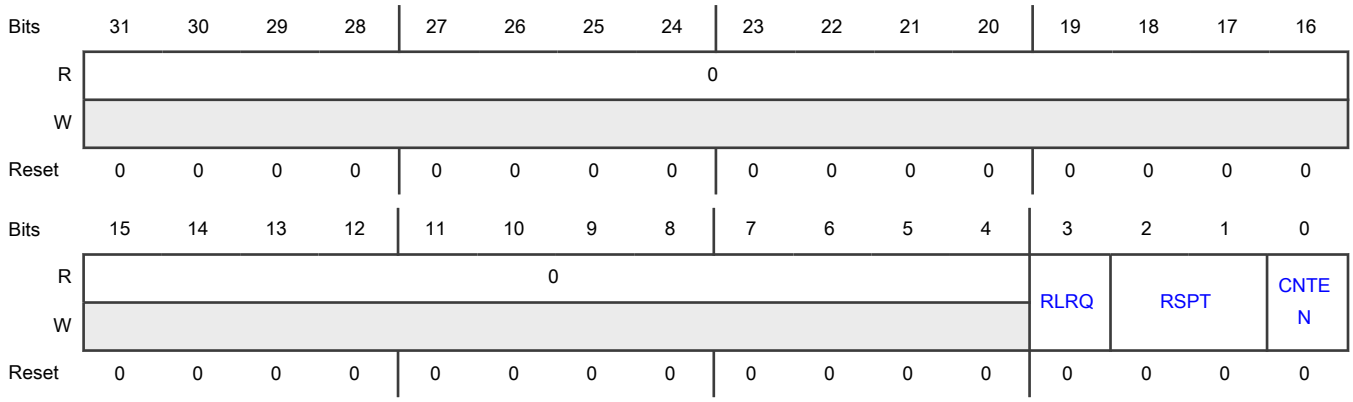
14.5.1.3 ETB Counter Control (ETBCC)

Configures ETB features.

Offset

Register	Offset
ETBCC	14h

Diagram



Fields

Field	Description
31-4 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
3 RLRQ	Reload Request Reloads the ETB packet counter with the value defined in ETBRR[RELOAD]. Writing 1 to this field also clears the pending debug halt, NMI, or IRQ interrupt requests: • Clears the pending NMI or IRQ interrupt request if IRQ or NMI interrupts were enabled and an NMI or IRQ interrupt was generated on counter expiration. • Clears the debug halt request if debug halt was enabled and a debug halt request was asserted on counter expiration. 0 - No effect 1 - Reload the counter (clear pending interrupt requests)
2-1 RSPT	Response Type Specifies the response to the ETB count expiration. 00 - No response 01 - Generate a normal interrupt 10 - Generate an NMI 11 - Generate a debug halt
0 CNTEN	Counter Enable Enables the ETB counter. 0 - Disable 1 - Enable

14.5.1.4 ETB Reload (ETBRR)

Configures the 0-mod-4 value that reloads into the ETB packet counter.

Offset

Register	Offset
ETBRR	18h

14.5.1.6 Write Buffer Fault Address (FADR)

Captures the faulty address if a properly enabled cache write buffer error interrupt event is detected.

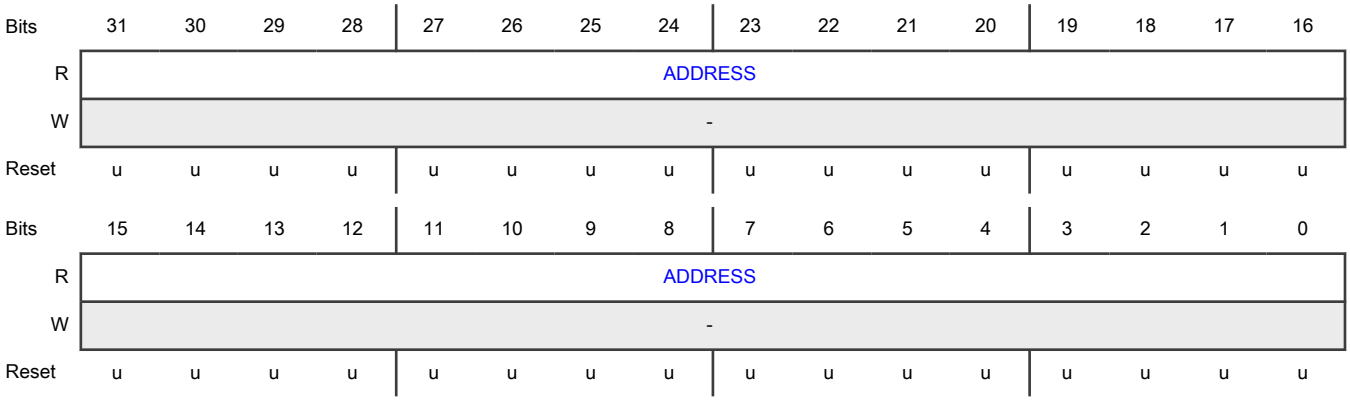
MCM captures a single cache write buffer bus error event. If a subsequent error is detected before the captured error information has been read from the corresponding registers and ISCR[CWBER] is 0, then FATR[BEOVR] becomes 1. However, no additional information is captured.

MCM writes 1 to the field in this register when ISCR[CWBER] is 1. Attempted writes have no effect.

Offset

Register	Offset
FADR	20h

Diagram



Fields

Field	Description
31-0 ADDRESS	Fault Address Contains the faulty address if a properly enabled cache write buffer error interrupt event is detected.

14.5.1.7 Store Buffer Fault Attributes (FATR)

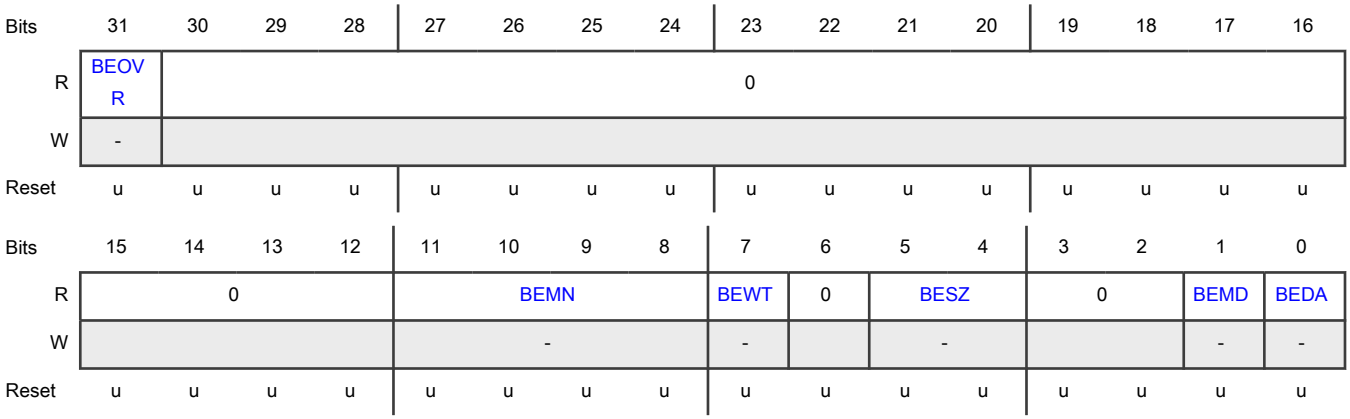
Indicates the faulty attributes if a properly enabled cache write buffer error interrupt event is detected.

MCM writes values to the fields in this register when ISCR[CWBER] is 1b. Your attempted writes have no effect.

Offset

Register	Offset
FATR	24h

Diagram



Fields

Field	Description
31 BEOVR	Bus Error Overrun Indicates if another cache write buffer bus error is detected before system software has retrieved all the error information from the original event. The time window is from the detection of the original cache write buffer error termination to the time when you write 1 to ISCR[CWBER] to clear it and rearm the capture logic. MCM writes 1 to this field and it becomes 0 whenever you write 1 to ISCR[CWBER]. Write Buffer Fault Address (FADR), Store Buffer Fault Data (FDR), and the other FATR fields do not update to reflect this new bus error. 0 - No overrun 1 - Overrun
30-12 —	Reserved
11-8 BEMN	Bus Error Initiator Number Indicates the crossbar switch bus initiator number of the captured cache write buffer bus error.
7 BEWT	Bus Error Write Indicates the type of system bus access when the cache write buffer error was detected. 0 - Read 1 - Write

Table continues on the next page...

Table continued from the previous page...

Field	Description
6 —	Reserved
5-4 BESZ	Bus Error Size Indicates the size of the cache write buffer access when the error was detected. 00 - 8-bit 01 - 16-bit 10 - 32-bit 11 - Reserved
3-2 —	Reserved
1 BEMD	Bus Error Privilege Level Indicates the privilege level of the cache write buffer access when the error was detected. 0 - User mode 1 - Supervisor or privileged mode
0 BEDA	Bus Error Data Access Type Indicates the type of cache write buffer access when the error was detected. 0 - Instruction 1 - Data

14.5.1.8 Store Buffer Fault Data (FDR)

Indicates the captured faulty data, when a properly enabled cache write buffer error interrupt event is detected.

MCM writes 1 to DATA when ISCR[CWBER] is 1. Only the accessed byte lanes contain valid data for byte and halfword writes. Contents of the other bytes are undefined. Attempted writes have no effect.

Chapter 15
CM33 Cache Memory Controller (XCACHE)

15.1 Overview

XCACHE is a general-purpose AMBA AHB bus protocol cache that provides low-latency access to slower memories.

15.1.1 Block diagram

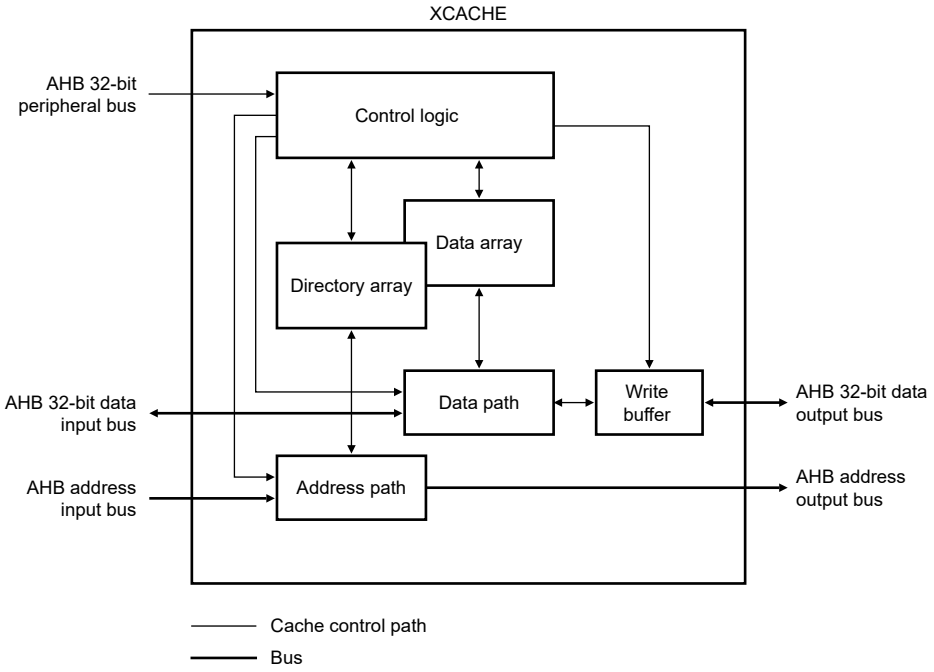

Figure 30. Block diagram

15.1.2 Features

XCACHE is designed to work with AMBA AHB bus systems. It includes:

- An AHB input bus. Accesses have cache mode attributes for cacheable copyback, cacheable write-through, or noncacheable mode operation and for write bufferable mode operation on an access-by-access basis.
- 32-bit data path AHB output bus for downstream cache read miss, cache write-through write, and noncacheable accesses.
- Connections to tag and data RAMs for implementing the cache functions.
- A peripheral interface for accessing the cache's programming model.

XCACHE includes the following AMBA_AHB buses:

- AHB input bus
- AHB output bus

15.2 Functional description

XCACHE is a block of high-speed memory locations that contains address information (commonly known as a tag) and its associated data. It decreases the average time of a memory access.

When data loads into a cache, the access times for subsequent loads and stores are reduced, resulting in overall performance benefits. Access to information already in a cache is known as a cache hit, and other accesses are known as cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the input bus wants to access a cacheable location, the cache is checked. If the access is a cache hit, the access occurs immediately. Otherwise, a location is allocated and the cache line is loaded from memory. Different cache topologies and access policies are possible. However, they must comply with the memory coherency model of the underlying architecture.

15.2.1 Principles of locality

XCACHE operates using the following two principles of locality.

Table 76. Type of locality

Type of locality	Description	Access
Spatial	Groups several locations together under the same tag to minimize the quantity of control information stored. This logical block is commonly known as a cache line.	Access to one location is possibly followed by accesses from adjacent locations (for example, sequential instruction execution or usage of a data structure).
Temporal	Retains recently accessed lines in the cache.	Access to an area of memory possibly repeats within a short period of time (for example, execution of a code loop).

15.2.2 Modes of operation

Table 77. Modes of operation

Mode	Description
Write-Through	Access to address spaces with this cache mode are cacheable: • If all cacheable spaces are read-only spaces, then cache contains read-only data and all writes to the cache cause a fault. See chip-specific cacheable space information. • A read miss on the input bus causes a line read on the output bus of a 16-byte-aligned memory address that contains the desired address. This missed data is loaded into the cache and is marked as valid and not modified. • A read hit to a valid cache location returns data from the cache with no output bus access. • A write miss bypasses the cache and writes to the output bus (no allocation on write-miss policy for Write-Through mode spaces). • A write hit updates the cache hit line with the write data and writes to the output bus. • Caches are input-bus-local and do not support hardware cache coherency. If the input bus accesses write-through regions and an external input bus (such as DMA) need to update these regions, you must first perform explicit cache clears to any needed cache memory range. This ensures all modified cache lines update their associated memories before external inputs modify them, and subsequent cache input bus accesses get the updated memory.
Write-back	Access to address spaces with this cache mode are cacheable:

Table continues on the next page...

Table 77. Modes of operation (continued)

Mode	Description
	• A read miss on the input bus causes a line read on the output bus of a 16-byte-aligned memory address that contains the desired address. This missed data is loaded into the cache and is marked as valid and not modified. • A read hit to a valid cache location returns data from the cache with no output bus access. • A write miss performs a read-to-write (allocate on write miss policy for write-back mode spaces). You perform a line read on the output bus of a 16-byte-aligned memory address containing the desired write address. This missed data is loaded into the cache and marked as valid and modified. Then the write data updates the appropriate cache data locations. • A write hit updates the cache hit line with the write data and marks the line as modified. • Caches do not support hardware cache coherency. If the cache's input bus has written to write-back regions and another input bus that can access the same target memory without going through the cache needs to see these updates, you must perform explicit cache pushes to any needed cache memory range to ensure all modified cache lines update their associated memories before being read by this input. Likewise, if the cache's input bus has accessed write-back or write-through regions and another input bus that can access the same target memory without going through the cache needs to update these regions, you must first perform explicit cache clears to any needed cache memory range. This ensures all modified cache lines update their associated memories before this input modifies them, and subsequent cache input bus accesses get the updated memory.
Non-cacheable	Access to address spaces with this cache mode are not cacheable. These accesses bypass the cache and access the output bus.

There is an optional ECC (Error correcting code) support of the cache tag and data storage RAMs. The optional ECC is SECDED (Single error correct, double error detect).

15.2.3 XCACHE function

XCACHE receives bus requests on the input bus.

You can access the programming model for the cache via XCACHE's AMBA APB bus.

XCACHE then processes the cacheable accesses as needed, when bypassing the noncacheable, cache write-through, cache miss, and cache maintenance accesses to its output bus.

The cache on this chip is structured as follows. It has a 2-way set-associative cache structure with a total size of 16 KB for the cache. The caches have 32-bit addresses and data paths and a 16-byte line size. The cache tags and data storage use single-port, synchronous RAMs.

The tag cache contains the required upper address bits, a modify bit, a valid bit, and up to 8 bits of extended address attributes. The extended address attribute field has information such as the supervisor, user, and/or domain ID of the accesses loading this tag. If any extended address attribute bits are provided, for subsequent accesses that hit a valid tag but have different attributes, the cache coherently forces a miss so that the downstream memory protection logic can check the access.

For this 16 KB cache, each cache tag function uses two 512 x 21-bit RAM arrays or optionally two up to 512 x 29-bit RAM arrays (if all 8 bits of the extended address attribute are used). The cache data function uses two 2048 x 32-bit RAM arrays. The cache

tag entries store 19 bits of upper address as well as a modified and valid bit per cache line, and any optional extended address attribute bits. The cache data entries store four bytes of code or data.

The tag and data RAM ECC codes are stored in RAM arrays with their associated tag and data. The 7Bits tag ECC code word per cache way is stored along side the associated tag way. The 7Bit data ECC code word per cache way is stored along side the associated data way.

All normal cache accesses use physical addresses. This leads to the use of the following cache address:

CACHE - 16 KB size = (512 sets) x (16-byte lines) x (2-way set associative)

Table 78. Tag cache address use

Tag cache address use	Cache
Tag hit address range	Address[31:13]
Tag set select address range	Address[12:4] selects 1 of the512 sets
Not used	Address[3:0]

Table 79. Data cache address use

Data cache address use	System cache
Not used	Address[31:13]
Data set select address range	Address[12:4] used to select one of the 512 sets
32-bit word select	Address[3:2] used to select one of the four 32-bit words within a set
Byte select	Address[1:0] used to select the byte within the 32-bit word

15.2.4 XCACHE control

The cache is disabled at reset. Cache tag and data arrays are not cleared at reset. Therefore, to enable and configure the cache, you must clear the cache commands and initialize the required tag array.

15.2.4.1 XCACHE set commands

XCACHE set commands may operate on:

- All of way 0
- All of way 1
- All of both ways (complete cache)

You can initiate cache set commands by using the upper bits in Cache Control (CCR). Cache set commands perform their operation on the cache independent of CCR[ENCACHE].

You initiate a cache set command by writing 1 to CCR[GO]. This field also acts as a busy bit for set commands and remains 1 when the command is active. XCACHE writes 0 to it after the completion of the set command.

Table 80 shows a list of supported cache set commands:

- Invalidate − Unconditionally clears valid and modify bits of a cache entry.
- Push − Pushes a cache entry if it is valid and modified, and then clears the modify bit. If the entry is not valid or not modified, leave it as is.
- Clear − Pushes a cache entry if it is valid and modified, and then clears the valid and modify bits. If the entry is not valid or not modified, clear the valid bit.

Table 80. Cache set commands

Cache Control (CCR)[27:24] settings				Command
CCR[PUSHW1]	CCR[INVW1]	CCR[PUSHW0]	CCR[INVW0]	
0	0	0	0	NOP
0	0	0	1	Invalidate all way 0
0	0	1	0	Push all way 0
0	0	1	1	Clear all way 0
0	1	0	0	Invalidate all way 1
0	1	0	1	Invalidate all way 1; invalidate all way 0 (invalidate cache)
0	1	1	0	Invalidate all way 1; push all way 0
0	1	1	1	Invalidate all way 1; clear all way 0
1	0	0	0	Push all way 1
1	0	0	1	Push all way 1; invalidate all way 0
1	0	1	0	Push all way 1; push all way 0 (push cache)
1	0	1	1	Push all way 1; clear all way 0
1	1	0	0	Clear all way 1
1	1	0	1	Clear all way 1; invalidate all way 0
1	1	1	0	Clear all way 1; push all way 0
1	1	1	1	Clear all way 1 and way 0 (clear cache)

After a reset, complete an invalidate cache command before using the cache. It is possible to combine the cache invalidate command with the cache enable. That is, writing 8500_0001h to Cache Control (CCR) invalidates the cache and enables the cache.

15.2.4.2 XCACHE line commands

XCACHE line commands operate on a single line in the cache at a time. You can perform cache line commands using a physical or cache address that consists of a set address and a way select. The line command acts on the specified cache line.

Cache line commands with physical addresses first search both ways of the cache set specified by the following physical address bits (see Table 81). If they hit, the commands perform their action on the hit way. For cache-[12:4]

You specify cache line commands using the upper bits in Cache Line Control (CLCR). Cache line commands perform their operation on the cache independent of CCR[ENCACHE]. Using a cache address, the command can be completely specified using Cache Line Control (CLCR). Using a physical address, the command must also use Cache Search Address (CSAR) to specify the physical address.

You can initiate a line cache command by writing 1 to CLCR[LGO] or CSAR[LGO]. These fields also act as busy bits for line commands and remain 1 when the line cache command is active and XCACHE writes 0 to them after the completion of the command.

Table 81. Cache line commands

Cache Line Control (CLCR)[27:24] settings			Command
CLCR[LACC]	CLCR[LADSEL]	CLCR[LCMD]	
0	0	00	Search by cache address and way
0	0	01	Invalidate by cache address and way
0	0	10	Push by cache address and way
0	0	11	Clear by cache address and way
0	1	00	Search by physical address
0	1	01	Invalidate by physical address
0	1	10	Push by physical address
0	1	11	Clear by physical address
1	0	00	Write by cache address and way
1	0	01	Reserved, NOP
1	0	10	Reserved, NOP
1	0	11	Reserved, NOP
1	1	*xx*	Reserved, NOP

15.2.4.2.1 Executing a series of line commands using cache addresses

You can perform a series of line commands with incremental cache addresses by writing to Cache Line Control (CLCR):

1. Place the command in the following fields:
   - CLCR[LACC]
   - CLCR[LADSEL]
   - CLCR[LCMD]
2. Write 1 to CLCR[WSEL] and CLCR[TDSEL] as required.
3. Place the cache address in CLCR[CACHEADDR].
4. Write 1 to CLCR[LGO].

After one line command completes, perform the following procedure to initiate the next command:

1. Increment the cache address (at bit 2 to step through data or at bit 4 to step through lines).
2. Write 1 to CLCR[LGO].

15.2.4.2.2 Executing a series of line commands using physical addresses

You can perform a series of line commands with incremental physical addresses by writing to Cache Line Control (CLCR):

1. Place the command in the following fields:
   - CLCR[LACC]
   - CLCR[LADSEL]
   - CLCR[LCMD]
2. Write 1 to CLCR[TDSEL].
3. Place the physical address in CSAR[PHYADDR] and write 1 to CSAR[LGO].

After one line command completes, perform the following procedure to initiate the next command:

1. Increment the physical address (at bit 2 to step through data or at bit 4 to step through lines).
2. Write 1 to CSAR[LGO].

Cache Line Control (CLCR) and Cache Search Address (CSAR) both contain a field called LGO. Therefore, you can complete the aforementioned steps in a single write to CSAR.

15.2.4.2.3 Line command results

After the completion of a line command, Cache Line Control (CLCR) contains information on the initial state of the line targeted by the command. For line commands with cache addresses, read this information before performing a line command action from the targeted cache line. For line commands with physical addresses, read this information on a hit before performing a line command action from the hit cache line, or, clear the initial valid bit if the command misses. In general, if CLCR[LCIVB] becomes 0, the targeted line is invalid at the start of the line command and no line operation is performed.

Table 82. Line command results

Cache Line Control (CLCR)[22:20] settings			For cache address commands	For physical address commands
CLCR[LCWAY]	CLCR[LCIMB]	CLCR[LCIVB]		
0	0	0	Way 0 line is invalid	No hit
0	0	1	Way 0 valid and not modified	Way 0 valid and not modified
0	1	0	Way 0 line is invalid	No hit
0	1	1	Way 0 valid and modified	Way 0 valid and modified
1	0	0	Way 1 line is invalid	No hit
1	0	1	Way 1 valid and not modified	Way 1 valid and not modified
1	1	0	Way 1 line is invalid	No hit
1	1	1	Way 1 valid and modified	Way 1 valid and modified

After the completion of a line command other than a write, Cache Read/Write Value (CCVR) contains information on the initial state of the line tag or data targeted by the command. For line commands, CLCR[TDSEL] selects between tag and data. If the line command uses a physical address and misses, the data is don't care. For write commands, Cache Read/Write Value (CCVR) holds the write data.

The cache does not have line lock capability.

15.2.4.3 XCACHE ECC enable

There are two ECC control enable inputs - one to enable ECC generation on writes and another to enable ECC checking and correction on reads. These inputs are controlled in an external program model. These signals are:

- ecc_wr_enable - Enable ECC generation on writes.
- ecc_rd_enable - Enable ECC checking and correction on reads.

At reset, the cache is disabled. After reset, to enable the cache with ECC enabled, perform the following:

1. Assert ecc_wr_enable and negate ecc_rd_enabled.
2. Perform the required cache "invalidated all" command. This initializes the TAG ECC.
3. After the invalidate completes, assert both ecc_wr_enable and ecc_rd_enabled.
4. Enable the cache - now the cache is enabled with ECC protection on.

15.2.4.4 XCACHE ECC function

When XCACHE ECC is enabled, for cache tag writes:

- All cache tag write generate the required tag ECC word.
- The cache tag and the associated tag ECC word are written to the tag RAM and tag ECC word RAM simultaneously.

When THE cache ECC is enabled, for cache data writes:

- All cache data writes of less than 32 bits are converted to a 32-bit read-modify-write sequence.
- All cache data writes generate the required data ECC word.
- The cache data and associated data ECC word are written to the data RAM and data ECC word RAM simultaneously.

When cache ECC is enabled, for cache tag reads:

- The cache tag and its ECC word are read in parallel.
- ECC is checked, any single bit error is corrected on-the-fly, any single, or multi-bit error is flagged.

When cache ECC is enabled, for cache data reads:

- For every data 32-bit word read, the data 32-bit word and its ECC word are read in parallel.
- ECC is checked, any single-bit error is corrected on-the-fly. Any single-, or multi-bit error is flagged.

The cache has single- and multi-bit ECC error indicator outputs.

Because all single-bit ECC errors are corrected on-the-fly, cache operations continue as normal when only single-bit ECC errors occur. Note it is possible to get multiple single- or multi-bit ECC errors on one cache access.

Cache read accesses that get multi-bit ECC errors are handled as follows:

- Any access that gets a tag multi-bit error terminates with a bus fault.
- Any access that gets a data multi-bit error on its hit data terminates with a bus fault.
- Data multi-bit error on miss or invalidate ways are ignored.

NOTE

Cache allocate pushes read the cache data arrays and may get ECC errors. Because the cache access that caused the allocate push may have completed before the ECC error, bus errors do not occur on multi-bit ECC errors. Only single or multi-bit ECC error indicators provide indications for an ECC error.

NOTE

Cache commands, which initiate via the cache's program model, may also access the cache tags and cache data RAMs. If these accesses get a multi-bit ECC error, the peripheral bus access that initiated the cache command does not terminate with a bus error. Only single or multi-bit ECC error indicators provide indications for an ECC error.

15.2.5 Clocks

XCACHE uses the AHB input bus clock.

15.2.6 Interrupts

XCACHE has no interrupts.

15.3 External signals

XCACHE has no external signals.

15.4 Initialization

To configure and enable the cache, you must perform XCACHE commands to clear and initialize the required tag array fields.

Table 83. Initialization sequence

Purpose	Programming	Notes
Enable the cache after reset, with the write buffer enabled.	Write 8500_0003h to Cache Control (CCR).	After you write to CCR[GO], it initiates the cache command specified by the following fields: • CCR[INVW1] • CCR[INVW0] The aforementioned fields indicate a command to clear all entries in both cache ways. CCR[ENWRBUF] enables the write buffer and CCR[ENCACHE] enables the cache. See XCACHE control for more information.
Enable the cache after reset, with the write buffer disabled.	Write 8500_0001h to Cache Control (CCR).	After you write to CCR[GO], it initiates the cache command specified by the following fields: • CCR[INVW1] • CCR[INVW0] The aforementioned fields indicate a command to clear all entries in both cache ways, and CCR[ENCACHE] enables the cache. See XCACHE control for more information.

15.5 Application information

XCACHE provides a low-latency access to instructions or data. This decouples processor performance from system memory performance, thereby increasing bus availability for other modules and improving system performance.

15.6 XCACHE register descriptions

The XACHE programming model provides various registers for the following functions:

- Configuring and controlling the cache
- Providing indirect access paths to all cache tag and data storage

NOTE

You can access XCACHE registers only in Supervisor mode.

Fields

Field	Description
31 GO	Initiate Cache Command Initiates the cache command that PUSHW1, INVW1, PUSHW0, and INVW0 indicate if you write 1 to this field. Reading this field indicates whether a command is active. **NOTE** This field remains 1 until the command completes. Writing 0 to it has no effect. 0 - Write: no effect; Read: no cache command active 1 - Write: initiate command; Read: cache command active
30-28	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
27 PUSHW1	Push Way 1 Pushes all modified lines in way 1 when you write 1 to GO. 0 - No operation 1 - Push all modified lines in way 1
26 INVW1	Invalidate Way 1 Invalidates all lines in way 1 when you write 1 to GO. **NOTE** If PUSHW1 and INVW1 are 1, then after you write 1 to GO, this field pushes all modified lines in way 1 and invalidates all lines in way 1 (clear way 1). 0 - No operation 1 - Invalidate all lines in way 1
25 PUSHW0	Push Way 0 Pushes all modified lines in way 0 when you write 1 to GO. 0 - No operation 1 - Pushes all modified lines in way 0
24 INVW0	Invalidate Way 0 Invalidates all lines in way 0 when you write 1 to GO. **NOTE** If PUSHW0 and INVW0 are 1, then after you write 1 to GO, this field pushes all modified lines in way 0 and invalidates all lines in way 0 (clear way 0). 0 - No operation 1 - Invalidate all lines in way 0
23-4 —	Reserved
3 FRCNOALLC	Force No Allocation on Cache Misses Forces no allocation on cache misses when FRCWT is 1. 0 - Allocate on cache misses 1 - Force no allocation on cache misses
2 FRCWT	Force Write Through Mode Specifies whether all cacheable spaces to write through are forced. 0 - Not force

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Force
1 —	Reserved You must always write 0 to this field to maintain compatibility.
0 ENCACHE	Cache Enable Enables the cache. 0 - Disable 1 - Enable

15.6.3 Cache Line Control (CLCR)

Defines the specific line-sized cache operations that you perform using a specific cache line address or physical address.

If you specify a physical address, both ways of the cache are searched, and the command only performs on the way that hits.

Offset

Register	Offset
CLCR	4h

A55	Arm Cortex CA55 Platform (CA55)	CA55 Platform
System memory map		System memory map
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

The chip includes two instances of Performance Monitor (CMX-PERFMON).

16.2 Overview

CMX_PERFMON contains counters that you can configure to count events used to calculate the performance of a CPU, cache, or memory. You can configure CMX_PERFMON to select the events to be counted for each counter. An additional instruction counter is available to count CPU instruction fetches.

Block diagram provides an overview of CMX_PERFMON, which includes three event counters and an instruction counter.

16.2.1 Block diagram

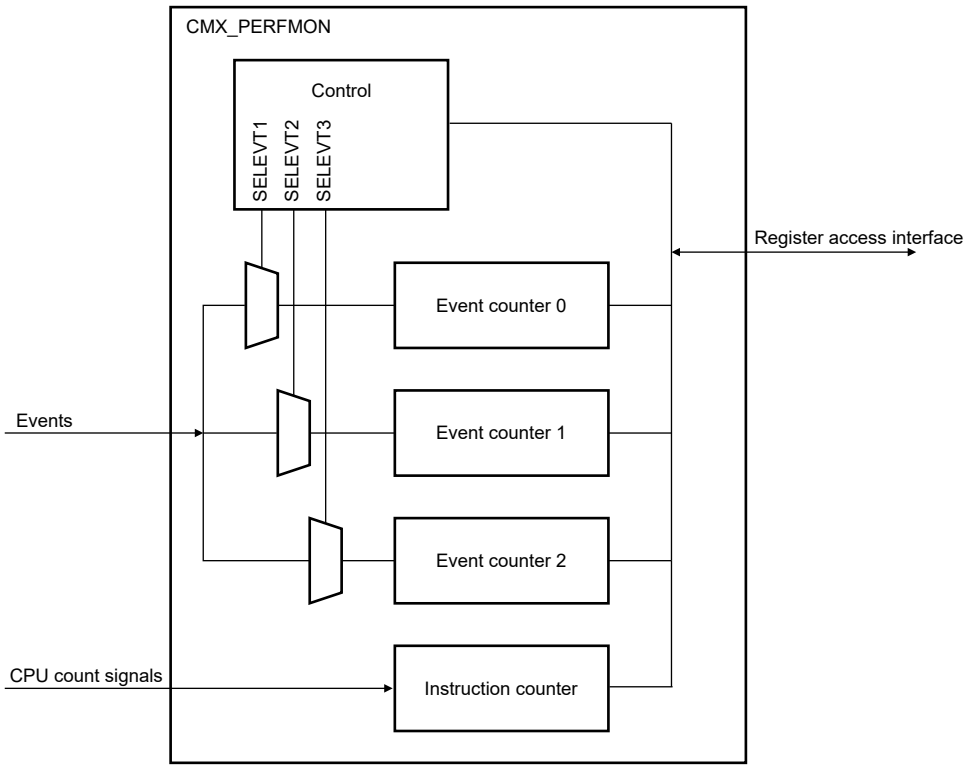

Figure 31. Block diagram

16.2.2 Features

- Three 40-bit event counters
- One 40-bit instruction counter
- Programmable event select
- Countable events that include cache, branch fetches, and stalls
- Memory mapped performance monitor that counts instructions, cache, branch, IPS, and TCM stats
- Count filter based on privilege level

16.3 Functional description

16.3.1 Operations

See the chip-specific CMX_PERFMON information for details about the countable events for the performance counters per CMX_PERFMON instance on this chip.

CMX_PERFMON has 3 programmable counters to count CPU events. The event to be counted is configured using the PMCR*m* register.

Each counter is a 40-bit register that tracks the number of occurrences of the selected event.

The counters can be programmed to take one of the 3 states:

- At idle state, the counters are in idle and do not perform any operation.

- At local start state, the counters are actively listening to CPU and cache and start incrementing when the selected events are observed.
- At local stop state, the counters stop listening to all components. The 3 event counter can be independently cleared by writing to PMCR*m*[RECTR*n*], where *n* denotes the counter instance.

16.3.2 Operating modes

The following table shows:

- The operating modes that you can specify for CMX_PERFMON.
- The PMCR*n*[CMODE] value that you must specify to count events in each mode.

Table 85. Operating modes

Mode	Description	CMODE value (binary)
Privileged	If supported, only counts events in Privilege mode.	11
User	If supported, only counts events in User mode.	10
Both Privileged and User	Counts events in both Privilege and User mode.	00

Use PMCR*n*[SSC] to start and stop the counters.

16.3.3 Clocking

Clock name	Direction	Description
CPU clock (hclk)	Input	Configures the counter logic.
Bus clock (ipg_clk)	Input	Controls the access to the registers.

16.3.4 Interrupts

This module has no interrupts.

16.4 External signals

CMX_PERFMON has no external signals.

16.5 Initialization

To initialize CMX_PERFMON:

1. Program PMCR*m*[SELEVT*n*] to select the specific CPU event to be counted by this counter, where *n* denotes the counter instance.
2. Set PMCR*n*[CMODE] to filter each counter for the selected event while the CPU is in privilege, user, or either mode.
3. Set PMCR*n*[SSC] to program the counter to be in one of idle, local start, or local stop states.
4. Set PMCR*m*[RECTR*n*] to clear the counters independently where *n* denotes the counter instance.

16.6 Memory map and register definition

16.6.1 CMX_PERFMON register descriptions

16.6.1.1 CMX_PERFMON memory map

M33_PCF1 base address: 443E_0000h

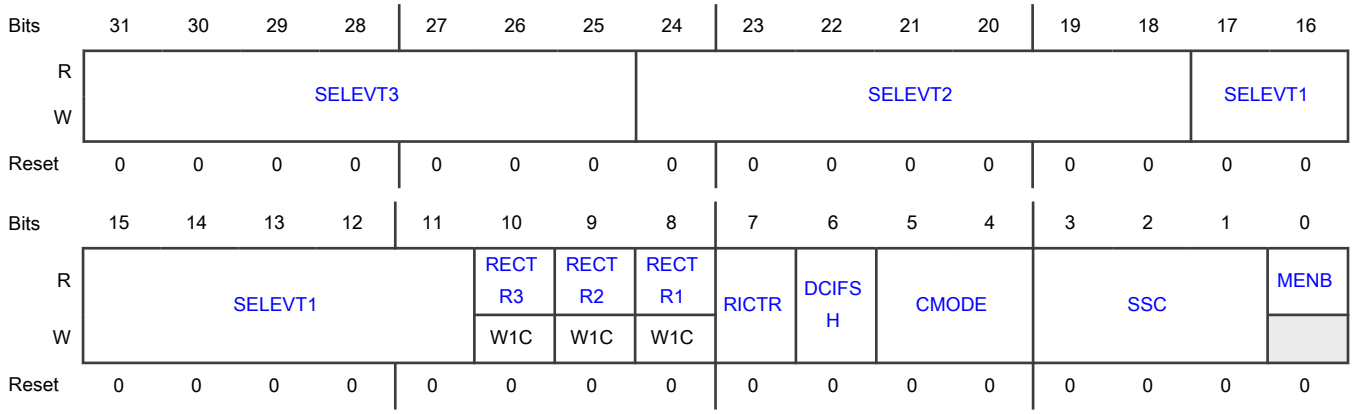
Diagram



Fields

Field	Description
31-25 SELEVT3	Select Event 3 Selects the event to be counted in PMECTR3. See the chip-specific CMX_PERFMON information to select which event PMECTR3 counts.
24-18 SELEVT2	Select Event 2 Selects the event to be counted in PMECTR2. See the chip-specific CMX_PERFMON information to select which event PMECTR2 counts.
17-11 SELEVT1	Select Event 1 Selects the event to be counted in PMECTR1. See the chip-specific CMX_PERFMON information to select which event PMECTR1 counts.
10 RECTR3	Reset Event Counter 3 Writing 1 to this field resets the event counter at the end of the cycle. 0 - Run normally 1 - Reset
9 RECTR2	Reset Event Counter 2 Writing 1 to this field resets the event counter at the end of the cycle. 0 - Run normally 1 - Reset
8 RECTR1	Reset Event Counter 1 Writing 1 to this field resets the event counter at the end of the cycle. 0 - Run normally 1 - Reset

Table continues on the next page...

Table continued from the previous page...

Field	Description
7 RICTR	Reset Instruction Counter Determines whether events reset or clear the instruction counter. Write 1 to clear the instruction counter. This field must be 0 to restart the instruction counter. 0 - Do not reset 1 - Clear
6 DCIFSH	Disable Counters if Stopped or Halted Specifies whether counters continue counting or stop counting when the CPU is halted. 0 - Continue 1 - Stop
5-4 CMODE	Count Mode Determines whether events are counted for Privileged mode, User mode, or both Privileged and User modes. This setting affects the operation of all event counters. 00 - Counted in both User and Privileged modes 01 - Reserved 10 - Reserved 11 - Reserved
3-1 SSC	Start and Stop Control Provides a three-phase mechanism to start and stop the counters. It includes a prioritized scheme with the following relative priorities: local start > local stop The start or stop affects all performance monitor event counters concurrently, so that the counters are coherent. 000 - Idle or no-op 001 - Local stop 010,011 - Local start 100 - Reserved 101 - Reserved 110,111 - Reserved
0 MENB	Module Is Enabled Indicates whether CMX_PERFMON is enabled. Enabling CMX_PERFMON does not start the counters. To start the counters, write a nonzero value to PMCR*n*[SSC]. 0 - Disabled

Fields

Field	Description
31-0 ECTR	Event Counter Specifies the lower 32 bits of the event[*n*] counter. The 40-bit counter value increments each time the event selected in PMCR*m*[SELEVT*n*] occurs.

Chapter 17
Neural Processing Unit (NPU)

17.1 Overview

The Neural Processing Unit (NPU) improves the inference performance of neural networks and is supported with an open-source driver and compiler. The NPU targets quantized Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN).

17.1.1 Block diagram

The following figure shows the main components of NPU.

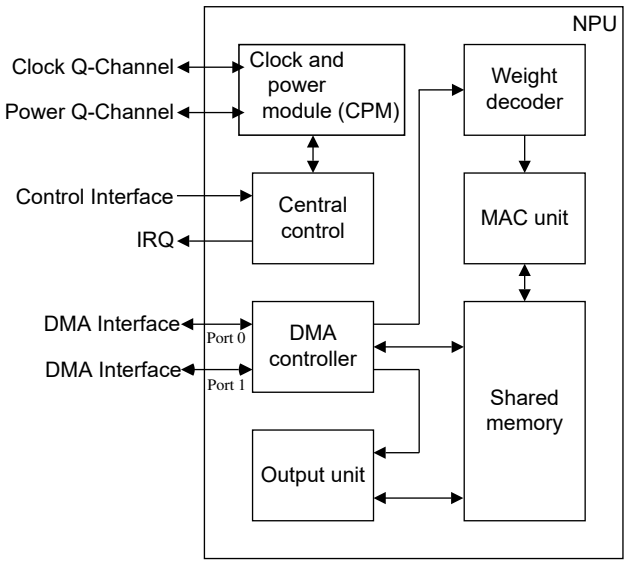

Figure 32. Functional block diagram

17.1.2 Features

- NPU performs 256 8x8 MAC's per cycle.
- NPU targets 8-bit and 16-bit integer RNN
- Handles 8-bit weights

17.2 Functional Description

A neural network must be compiled offline to produce a command stream. The application invokes the driver, which communicates with the NPU to tell it where the command stream is and initiates the network traversal. The command stream describes the steps necessary for the NPU to execute the operators compiled into the command stream autonomously. When complete, the NPU raises an IRQ to the driver. The driver programs the memory location of the command stream and other payloads into registers in the NPU. The Central Control (CC) processes the command stream. The NPU includes a Direct Memory Access (DMA) controller that can read and write to external memory. When the NPU performs inferences, the DMA controller reads the neural network description. This description contains:

- The command stream
- Network weights
- Bias information
- Scale information

The DMA controller also transfers the Input Feature Maps (IFMs) and the Output Feature Maps (OFMs) and NPU-private intermediate data that is also held in system memory.

The NPU consists of the Central Control (CC), a DMA controller, a MAC unit, an Output unit, and the interconnect fabric. The following are descriptions of the units of the NPU:

- The CC receives tasks from the external host application processor. The CC queues and dispatches units of work to the DMA and engines.
- The DMA controller uses its two DMA interfaces to move data between external memory and internal shared memory.
- The MAC unit has various internal units for reading IFMs, performing dot products and accumulations.

17.2.1 External interfaces

The NPU uses two DMA interfaces, a control interface with wake-up signaling, an interrupt interface, two Q-Channel interfaces, clock, and reset to enable access to and from external components.

- **Two DMA interfaces:** These interfaces enable read-access and write-access to external memory for the DMA controller. The NPU has two read/write ports, P0 and P1.
- **Control interface with wake-up signaling:** Enables the device driver that runs on the external host application processor to access the control registers of the NPU.
- **Interrupt interface:** Sends interrupt requests to the external host application processor, usually to signal a completed job.
- **Two Q-Channel interfaces:** These interfaces enable communication with an external clock controller and power controller. This communication enables the system to automatically disable the clock of the NPU or disable the power to it. The clock is otherwise free-running.

17.2.2 Weight Decoder

The Weight Decoder (WD) reads the weight stream from the DMA controller. The decoder decompresses and stores this stream in a double-buffered register, ready for the MAC unit to consume it.

17.2.3 MAC unit

The MAC unit performs multiply-accumulate operations that are required for convolution, depth-wise pooling, vector products, and the max operation required for max pooling.

- **IFM Unit:** The IFM unit inside the MAC unit reads the input feature maps from the shared SRAM and stores them in register slices. These slices are fed into the multipliers in the dot product units. The IFM unit also performs some extra services as part of other operations. The IFM unit handles zero-padding around the outside edge of feature maps and the upscaling that deconvolution requires. Deconvolution upscaling uses nearest neighbor or zero insertion.
- **Dot product units:** The MAC unit contains several dot product units. These dot product units perform the multiply-accumulate operations that are required for convolutions. The dot product units contain a max operator that they use for max pooling.
- **Adder array** The adder array reads a set of accumulators from the shared RAM buffer and updates them with partial accumulations from the dot product units. The adder array then writes the result back. Accuracy is maintained throughout this process. The internal accumulators retain precision so that the output is bit-exact to the software reference, in this case TFL. The compiler selects the accumulator format in the shared buffer. This format can be:
  - 32-bit two's complement
  - 40-bit two's complement

You can also configure the compiler to use 16-bit floating-point format, which improves performance but impacts accuracy.

These formats are only used internally.

17.2.4 Output unit

The Output unit reads finished accumulators from the shared RAM and converts them into output activations. This process includes performing scaling for each OFM, adding the bias to values, and applying the activation function to each point.

Every layer is written to external SRAM, but the activation function and scaling are normally fused. There is no forwarding path from output to input inside the NPU. Although layers can be split into horizontal stripes and run in "cascade" to minimize the SRAM footprint. This means that the external SRAM footprint can be smaller than the largest layer. The activation functions that the Output unit supports are:

- ReLU, ReLU1, ReLU6, and Leaky ReLU
- tanh
- sigmoid
- Configurable Lookup Table (LUT)
- None or bypass

The elementwise operations that the Output unit supports are:

- Elementwise ADD and SUB
- Elementwise Multiplication (MUL)
- Elementwise Min and Max
- Elementwise ABS
- Elementwise Shift Left (SHL) and Elementwise Shift Right (SHR)
- Elementwise Count-leading Zero (CLZ)

When the Output unit has computed output activations, it writes them back into the shared RAM. The output activations are buffered in the shared RAM where they wait for the DMA controller to send them to external memory.

- **Scaling unit:** The Scaling unit in the Output unit performs scaling in convolutions and division in average pooling. The number of scaling operations that are performed per clock depends on the configuration. The number of outputs per clock varies, depending on the operation.
- **ReLU and Leaky ReLU:** Rectified Linear Unit (ReLU) operations are typically performed after scaling and bias addition. The number of ReLU operations that are done in parallel is the same as the number of parallel operations that the Scaling unit performs.

  Leaky ReLU (LReLU) is a variant, a nonzero ReLU with a small positive gradient that targets negative values, unlike standard ReLU functions. Leaky ReLU implements Leaky ReLU as long as the input and output quantization scale are the same. The most recent TensorFlow Lite allows the quantization scale to differ. In that case, we recommend using the LUT for 8-bit activations and element wise operators for 16- bit activations
- **tanh, sigmoid, and LUT:** The Output unit supports tanh and sigmoid functions using a hardwired table combined with bilinear interpolation. The same table is used for both functions, because they are mathematically related. The Output unit can perform one tanh or sigmoid function per cycle.

There is also a Configurable Lookup Table (LUT) that can be used for any point-wise activation or function. For 8-bit activations, the LUT holds up to 256 8-bit values that are directly mapped from IFM to OFM. The LUT size increases to 512 for 16-bit values; however, the outputs are interpolated, bilinear values. The LUT can be configured by setting up a mem2mem transfer.

17.2.5 Clock and Power Module

The Clock and Power Module (CPM) handles hard and soft resets, contains registers for the current security settings, the main clock gate, and the QLPI interface.

- **QLPI for clock:** To enable high-level clock gating, the NPU exposes a Q-Channel slave port. This slave port enables the system to automatically disable the clock of the NPU, that is free-running except during reset. If the entire NPU is in stopped

state, it indicates when the clock can be turned off. You can configure the NPU registers using the control interface, so that it keeps requesting a clock in stopped state.

- **QLPI for power:** For high-level power gating, the NPU exposes a Q-Channel slave port. This slave port permits the system to automatically disable the power of the NPU. If the entire NPU is in stopped state, it indicates when power can be turned off. You can configure the NPU using the control interface, so that it keeps requesting power in stopped state.
- **Clock and power module clock gates:** The CPM contains one main clock gate. Other clock gating is performed inside each of the blocks, which the CPM can override. These clock gates are explicitly instantiated, with the CPM clock gate preceding the block level clock gates.

17.2.6 Clock signals

See SoC Clock Control Module (CCM) Chapter for information on clocking for NPU.

17.2.7 Reset

See SoC System Reset Controller (SRC) Chapter for information on Reset for NPU.

17.2.8 Interrupt signals

See Arm's General Interrupt Controller (GIC) documentation for NPU block interrupts.

17.2.9 Central control

The Central Control (CC) is the main control unit inside the NPU. The CC controls how the NPU processes neural networks, maintains synchronization, and handles data dependencies.

The CC receives tasks from the external host application processor. The CC queues and dispatches units of work to the DMA controller, weight decoder, MAC unit, and Output unit. The DMA controller and MAC unit send events to the CC to signal the completion of work.

The CC contains multiple sets of operation settings to increase efficiency. This enables the CC to set up the next piece of work while the current one is being processed.

After completing scheduling, dispatching, or processing work, the CC checks for any events that have been triggered. If there are no new events, the CC requests underclocking or powerdown, depending on the configuration.

The CC comprises a Traversal unit. The CC instructs this unit to handle commands that require traversal. This unit breaks commands down into smaller commands, performs synchronization as they execute, and implements the different data flows the NPU requires.

The CC comprises a Command unit. This unit receives commands and parses them. Traversal tasks are passed to the traversal unit. Data dependencies can be coded into the NPU command stream by the Offline Compiler, so that data dependencies between commands are not broken. Measuring the data dependency is an NPU internal process.

Other commands can:

- Trigger interrupts.
- Cause the NPU to wait for a data dependency to be cleared.
- Set up internal registers with information relating to the next execution step.

The CC implements a control interface. This interface enables the application processor to control the NPU. This interface also enables performance measurements.

17.2.10 DMA controller

The DMA controller manages all transactions that use the DMA interfaces. The channels that the DMA controller uses are:

- **Command channel:** The NPU uses this channel to read the command stream, normally from external flash. The NPU moves the commands into CC. The application processor activates the command channel when it sets up the location and size of the Command queue. It sets up the Command queue by using the registers that are mapped to the Control Interface.
- **IFM channel:** The NPU uses the IFM channel to read input feature maps and stores them in its shared RAM. Because the shared buffer must store activations from different x,y coordinates in different words, the DMA controller unpacks data which is stored in NHWC format. This might require extra internal buffering, but only for the initial layer of a job. Internal layers can use a more efficient format. The DMA controller considers the kernel stride, because this affects which bank or address the DMA controller requires to store activations. When the DMA controller is in vector-product mode, it supports fetching multiple batches. The IFM channel is triggered once per block for blocks that require input feature maps.
- **OFM channel:** The NPU uses the OFM channel to write output feature maps from shared RAM to external RAM. Because the output is double-buffered in the shared RAM, the DMA requires an interface to synchronize with the output module to notify the DMA which buffer is empty or full. For the last layer of a job, the output must be written out in NHWC format. This may require the DMA to pack the data, depending on the depth of the layer. Since this process reduces the bandwidth, this process is possible in a small register bank inside the DMA. The traversal unit triggers the OFM channel once per output block for blocks that require transfer to external memory.
- **Weight channel:** The weight channel transfers compressed weights from external memory to the weight decoder. The DMA controller uses a read buffer to hide bus latency from the weight decoder and to enable the DMA to handle data arriving out of order. The traversal unit triggers the weight channel for blocks that require the transfer of weights. The weight stream must be quantized to 8 bits or less by an offline tool. When passed through the offline compiler, weights are compressed losslessly and reordered into an NPU-specific weight stream. This process is effective, if the quantizer uses less than 8 bits or if it uses clustering and pruning techniques, it may also employ all three methods. Using lossless compression, an average of ~2 bits is possible in the final weight stream, especially if the weight stream has many zeros.
- **mem2mem channel:** The NPU uses this channel to stream general data from memory to memory. The main purpose of this channel is to read weights from slow, non-volatile memory and store them in the SRAM. This might be performed in preparation for a layer which reads the weights multiple times. Having the weights in SRAM saves power and improves performance compared to reads to nonvolatile memory. The traversal unit triggers mem2mem operations on specific API commands.
- **Bias and scale channel:** This channel streams data to the Output unit. The data that it transmits is the scale and bias necessary for the block that the NPU is processing. Layers that pass through the Output unit are written to the external SRAM. As the layers pass through the Output unit, activation functions can be fused.

NOTE

Only the mem2mem DMA channel is controllable directly by the command stream. The other channels are used to load or store data required by NPU operations. Write DMA channels must always use port 0. Read DMA channels can use port 0 or 1 according to which region is configured for the memory.

17.3 External signals

This module has no external signals.

17.4 Initialization

See Arm's Ethos-U65 NPU documentation for initialization.

17.5 Application information

See Arm's Ethos-U65 NPU documentation for application information.

17.6 Memory map and registers

See Arm's Ethos-U65 NPU documentation for NPU block register description.

Chapter 18
On-chip RAM (OCRAM)

18.1 Overview

The on-chip RAM is implemented as a follower module on the 64-bit system bus. Designed as a simple on-chip memory block, it has one bank of single port SRAM and supports one AXI port with memory banks. For the AXI port, the read and write transactions are handled by two independent modules. The memory banks are organized with the lower two bits of the address which is the AXI bus address and is 64 bits aligned interleaved. This allows a read access and a write access to be processed at the same time if they are targeted to different memory banks.

The OCRAM supports up to 640 Kbytes.

Various options are provided for adding a pipeline or wait-states in a read/write access, in order to ensure flexible timing control at both high and low frequencies.

18.1.1 Block diagram

The OCRAM block diagram is shown in the figure below.

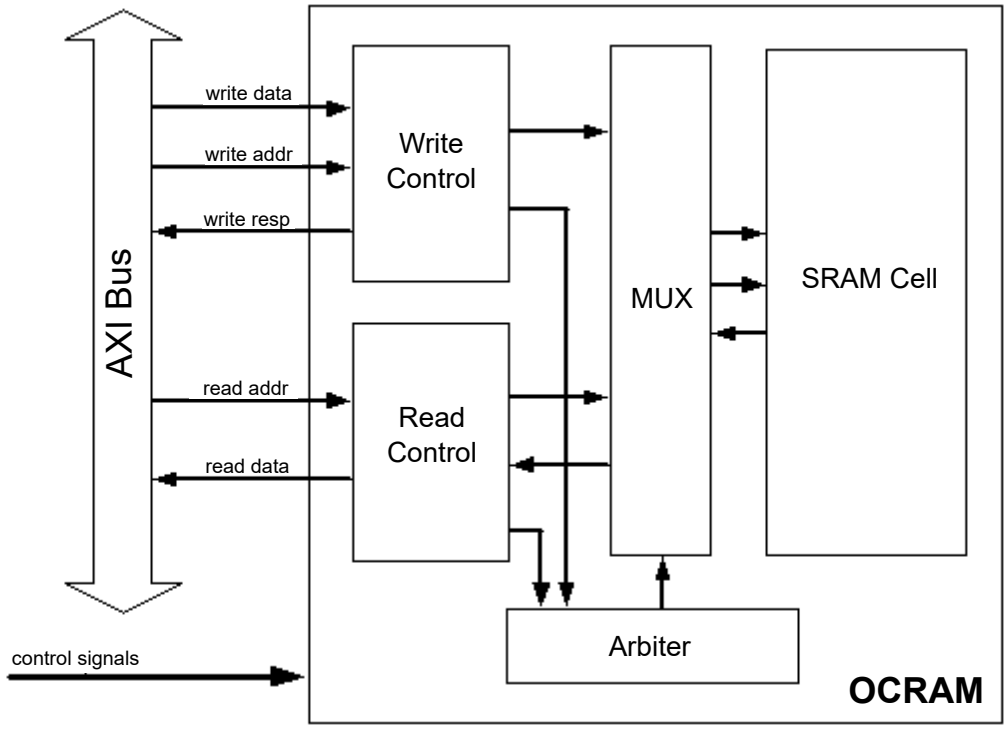

Figure 33. OCRAM block diagram

18.1.2 Features

The OCRAM module provides following features:

- Supports one AXI port with memory banks

- Supports Read/Write arbitration
- Supports TrustZone
- Supports read/write data/address pipeline
- Supports up to four Chip Select (CS)
- Supports up to 640 kBytes

18.2 Functional description

18.2.1 Mode

The following modes are available:

- Read data wait
- Read address pipeline
- Write data pipeline
- Write address pipeline

18.2.2 Memory map

The total on-chip RAM size for the chip is 640 kBytes, organized as 16K x 64 bits. Memory alias is also supported for on-chip RAM, any read/write operation to this area will be mapped back to the 640 kBytes area.

The 32-bit AXI address are arranged as shown in the table below.

Table 86. On-Chip RAM address bits

AXI ADDR bits	Usage	Description
19:7	Memory Address	Selects one of the 160K words in the memory (256-bit word)
6:5	Bank Address	Selects one of the four memory banks (256-bit word)

18.2.3 Read/Write arbitration

The arbiter is used to handle the read/write request from the read control module and write control module. It grants read/write access to the memory cell according to the internal arbitration state and the request/switch signal from the read control module and write control module. Generally, the arbitration is using the round-robin method.

The detailed rules used in arbitration are as follows:

- If there is no granted read or write in the last cycle, and there is only a read request or a write request, the request will be granted.
- If there is no granted read or write in the last cycle, and there are both read or write requests coming in at the same time, the read request will be granted first.
- If a granted read/write transaction has just finished, the write/read request will have the higher priority in the next cycle.
- If the first read/write access request in a transaction is granted, all the data transfer in this burst will be finished before the next arbitration begins, that is, the round-robin arbitration mechanism is based on AXI transaction, not data access.

18.2.4 TrustZone

The OCRAM supports TrustZone. When the SECURE_ENBL bit is set, the STARTADDR and ENDADDR bit-fields in this register establish the region of OCRAM that can only be accessed (both read and write according to the execution mode policy. If this bit is cleared to zero, the entire OCRAM can be accessed in either secure or non-secure mode. The TrustZone bits shows in Programmable registers.

NOTE

The ENDADDR is not configurable and its value is the last address of the OCRAM space. The STARTADDR granularity is 4KB.

18.2.5 Advanced features

This section describes some advanced features designed to avoid timing issues when the OCRAM is working at high frequency.

18.2.5.1 Read data wait state

When the wait state is enabled, it will take 2 cycles for each read access (each beat of a read burst). This can avoid the potential timing problem caused by the longer memory access time at higher frequency. When this feature is disabled, it only takes 1 clock cycle to finish a read transaction. That is, read data is available in the next cycle of read request becomes valid on the bus.

18.2.5.2 Read address pipeline

When this feature is enabled, the read address from the AXI leader is delayed 1 cycle before it can be accepted by the OCRAM. This can avoid setup time issues for the read access on the memory cell at high frequency. Enabling this feature can cost, at most, 1 more clock cycle for each AXI read transaction, that is, at most 1 more clock cycle for each read burst with multiple beats of data.

When this feature is disabled, the read address from the AXI leader can be accepted by the OCRAM without delay, and data can become ready for leader at next clock cycle (if no other access and no read data wait).

18.2.5.3 Write data pipeline

When this feature is enabled, the write data from the AXI leader would be delayed 1 cycle before it can be accepted by the OCRAM. This can avoid setup time issue for the write access on the memory cell at high frequency. Enabling this feature would cost at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write data from the AXI leader can be accepted by the OCRAM without delay, and data can be written to memory at this cycle (if no other access and write address is also ready at this cycle).

18.2.5.4 Write address pipeline

When this feature is enabled, the write address from the AXI leader would be delayed 1 cycle before it can be accepted by the OCRAM. This can avoid setup time issue for the write access on the memory cell at high frequency.

Enabling this feature would take at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data. When this feature is disabled, the write address from the AXI leader can be accepted by the OCRAM without delay, and data can be written to memory at this cycle (if no other access and write data is also ready at this cycle).

18.2.6 Clocks

The following table describes the clock sources for OCRAM. See Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 87. Clocks

Clock name	Description
clk	Synchronized to AXI bus clock

18.2.7 Reset

There is a hardware reset for the OCRAM Controller, which reset all the logic inside it.

18.2.8 Interrupts

There is no interrupt output from the OCRAM controller.

18.3 External signals

The OCRAM has no external pins.

18.4 Initialization

To initialize the block:

- Ensure the clock for the OCRAM controller is enabled.
- Configure corresponding pin MUX for the OCRAM controller external signals.
- Configure registers of the OCRAM Controller properly, according to the applications.

18.5 Application information

- Configure OCRAM Control Registers with valid settings that matches RAM device.
- Write and read operations can be triggered by AXI command.

18.6 Programmable registers

There are no programmable registers in this block. However, OCRAM related programming should be defined in the chip GPRs/CSRs.

Chapter 19
Memory ECC Controller (MECC256)

19.1 Overview

The Memory ECC Controller (MECC256) module supports Single Error Correction and Double Error Detection (SEC-DED) ECC functions to On-Chip RAM (OCRAM) access. It can generate a 8-bit ECC code by Hsiao Hamming algorithm for 64-bit data. Corresponding OCRAM space is available to store ECC code.

19.1.1 Block diagram

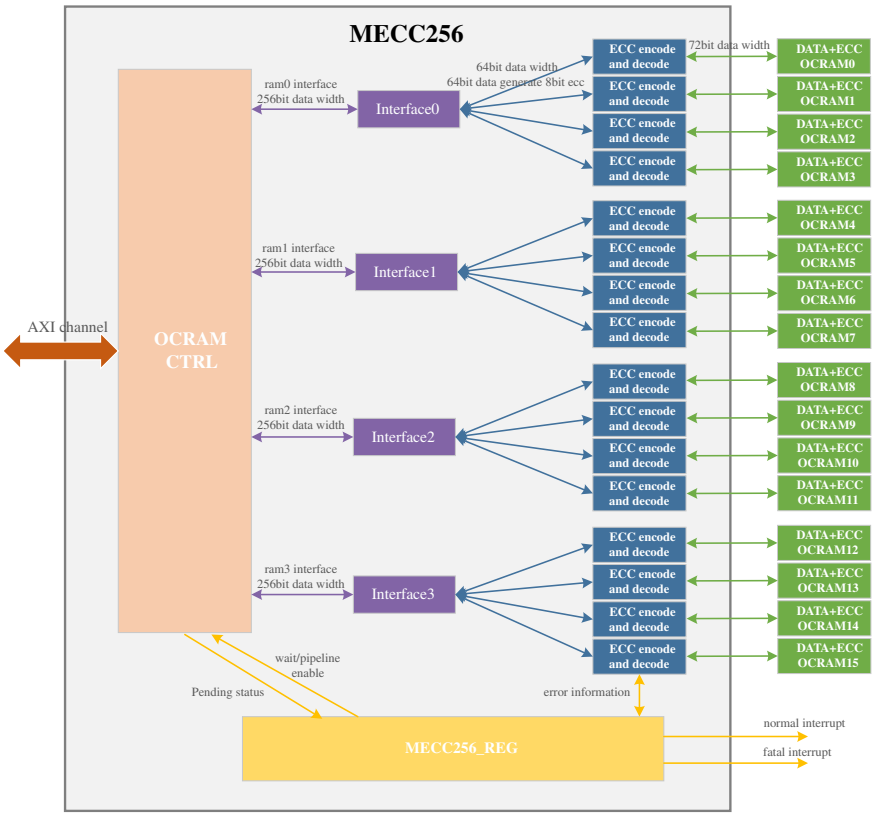

Figure 34. MECC256 block diagram

The following list shows detailed register/bitfield correspondance in the block diagram.

- ecc enable:
  - PIPE_ECC_EN[ECC_EN]
- error injection:
  - ERR_DATA_INJ_LOW/HIGH*n*
  - ERR_ECC_INJ*n*
- error information:

- SINGLE_ERR_ADDR_ECC*n*
- SINGLE_ERR_DATA_LOW/HIGH*n*
- SINGLE_ERR_POS_LOW/HIGH*n*
- MULTI_ERR_ADDR_ECC*n*
- MULTI_ERR_DATA_LOW/HIGH*n*

- pending status:
  - PENDING_STAT
- wait/pipeline enable:
  - PIPE_ECC_EN[READ_DATA_WAIT_EN]
  - PIPE_ECC_EN[READ_ADDR_PIPE_EN]
  - PIPE_ECC_EN[WRITE_DATA_PIPE_EN]
  - PIPE_ECC_EN[WRITE_ADDR_PIPE_EN]

19.1.2 Features

The MECC256 includes the following features:

- Generates a 8-bit ECC code for 64-bit write data. Write data and ECC code are written into seperate OCRAM banks.
- Supports SEC-DED function for 64-bit read data and 8-bit ECC code.
- Integrate 4 banks OCRAM controller and 16 banks memory for converting AXI transaction to RAM interface.
- Error injection on write data and ECC code for debug purpose.
- Two different interrupt types: Normal and Fatal.

19.2 Functional description

The MECC256 converts AXI interface to RAM interface signals, and provides ECC encode/decode function for OCRAM write/read. For each data in OCRAM bank, corresponding space in ECC OCRAM banks is available to store ECC code when ECC function is enabled. When ECC function is disabled, ECC OCRAM banks can also be used to store data.

The OCRAM bank address allocation is as below:

- Bank0: ocram_base_address+0x80*i
- Bank1: ocram_base_address+0x80*i+0x8
- Bank2: ocram_base_address+0x80*i+0x10
- Bank3: ocram_base_address+0x80*i+0x18
- Bank4: ocram_base_address+0x80*i+0x20
- Bank5: ocram_base_address+0x80*i+0x28
- Bank6: ocram_base_address+0x80*i+0x30
- Bank7: ocram_base_address+0x80*i+0x38
- Bank8: ocram_base_address+0x80*i+0x40
- Bank9: ocram_base_address+0x80*i+0x48
- Bank10: ocram_base_address+0x80*i+0x50
- Bank11: ocram_base_address+0x80*i+0x58
- Bank12: ocram_base_address+0x80*i+0x60

- Bank13: ocram_base_address+0x80*i+0x68
- Bank14: ocram_base_address+0x80*i+0x70
- Bank15: ocram_base_address+0x80*i+0x78

where i = 0,1,2,3,4,...

19.2.1 Interface Conversion

The MECC256 integrates 4 banks OCRAM controller which converts AXI master interface signals to 4 groups of OCRAM interface signals (see OCRAM chapter for details). The 4 OCRAM banks are organized with lower 2 bits of address interleaved. This allows a read access and a write access to be processed at the same time if they are targeted to different OCRAM banks. OCRAM controller can support to add pipeline or wait-state in read/write access by register configuration. Each OCRAM bank connects to 4 ECC caluation modules and memory. MECC256 has 16 ECC calculation modules in total. (see block diagram for details)

19.2.2 ECC encode

When ECC is enabled, the 4 groups of OCRAM write access will enter into 16 seperate ECC encode channels. In a ECC encode channel, it will generate 8 bits ECC code for 64 bits OCRAM write data. Then 64 bits OCRAM write access will split into one 64 bits data write and one 8 bits ECC code write. The 64 bits data and 8 bits ecc will be written into one of the OCRAM memory banks according to address.

19.2.3 Error injection

The MECC256 can inject error in write data and ECC code by configuring ERR_DATA_INJ* and ERR_ECC_INJ* registers. The 64 bits write data and 8 bits ECC code can be inverted if corresponding bits in ERR_DATA_INJ* and ERR_ECC_INJ* registers are set. Each OCRAM bank has separate error injection registers. This feature is mainly used for debug.

19.2.4 ECC decode

When ECC is enabled, the 64 bits OCRAM read access will get 64bit read data and 8 bit ECC code from the corresponding OCRAM memory, ECC decode channel can report single bit error or multiple bits error if ECC check is failed. At the same time, the error information will be saved in the module's error registers for debug. When single bit error is detected on read data, the error bit in read data will be corrected. In this case, AXI master will get read data correctly. When multiple bits error is detected on read data, error read data will not be corrected. In this case, master will get read data in error. When single bit error or multiple bits error happens, interrupt will be asserted if the corresponding enable bits are set. Each OCRAM bank has separate error and interrupt registers.

19.2.5 Interrupts

The MECC256 can generate two kinds of interrupts:

- Normal interrupt can be generated for the following cases:
  - Single bit error is corrected for read;
  - AXI access address exceeds OCRAM address range;
  - AXI write access to OCRAM bank is not 64bit/128bit/256bit aligned.
- Fatal interrupt can be generated when 'multiple bits error' is detected for read.

19.2.6 Clocks

There are two clocks in MECC256:

Clock	Description
clk	Main clock
ips_clk	This is for IPS bus, used for register write/read.

There are no special requirements for these two clocks.

19.3 Signals

There are no external signals for MECC.

19.4 Initialization

The steps for initialization process is as below:

1. Enable MECC function (set PIPE_ECC_EN[ECC_EN] = 1).
2. Enable memory initialization (set MEM_INIT[MEM_INIT_ENABLE] = 1).
3. Enable interrupts (set ERR_STAT_EN = 0xFFFF, ERR_SIG_EN = 0xFFFF).

NOTE

- When the MECC function is enabled, the OCRAM memory region can be initialized with 0x00 or 0xFF (initialization data for the first ECC encode), to generate ECC code within OCRAM ECC code region.
  - Initialization is required because the MECC64 needs a complete OCRAM and OCRAM ECC data. When initialized, it generates ECC code depending on initialization data, store data and its ECC code in OCRAM and OCRAM ECC memory.
  - Do such initialization with 64 bits access, with STRD or STMIA instruction. Do not use memset() API, which is STR instruction, in software coding level.
- OCRAM memory with ECC should be non-cacheable, or cacheable with write through, to assure data in OCRAM memory at the write time. It may have different methods to achieve this goal, such as Memory Protection Unit (MPU) or disable cache.

19.5 Application information

There are no application pseudocode examples for MECC256.

19.6 Memory Map and register definition

This section includes the MECC256 module memory map and detailed descriptions of all registers.

19.6.1 MECC256 register descriptions

19.6.1.1 MECC256 memory map

OCRAM_MECC1 base address: 490A_0000h

Field	Description
—	
15 SINGLE_ERR15	Ocram Access Error On Bank3 When OCRAM access unallocated address on bank3, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Ocram access error does not happen on ocram bank3. 1 - Ocram access error happens on ocram bank3.
14 SINGLE_ERR14	Ocram Access Error On Bank2 When OCRAM access unallocated address on bank2, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Ocram access error does not happen on ocram bank2. 1 - Ocram access error happens on ocram bank2.
13 SINGLE_ERR13	Ocram Access Error On Bank1 When OCRAM access unallocated address on bank1, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Ocram access error does not happen on ocram bank1. 1 - Ocram access error happens on ocram bank1.
12 SINGLE_ERR12	Ocram Access Error On Bank0 When OCRAM access unallocated address on bank0, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Ocram access error does not happen on ocram bank0. 1 - Ocram access error happens on ocram bank0.
11 SINGLE_ERR11	AXI Strobe Error On Ocram Bank3 When AXI write access to ocram bank3 is not full size(wstrb=0xff), this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - AXI strobe error does not happen on ocram bank3. 1 - AXI strobe error happens on ocram bank3.
10 SINGLE_ERR10	AXI Strobe Error On Ocram Bank2 When AXI write access to ocram bank2 is not full size(wstrb=0xff), this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - AXI strobe error does not happen on ocram bank2. 1 - AXI strobe error happens on ocram bank2.
9 SINGLE_ERR9	AXI Strobe Error On Ocram Bank1

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When AXI write access to ocram bank1 is not full size(wstrb=0xff), this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - AXI strobe error does not happen on ocram bank1. 1 - AXI strobe error happens on ocram bank1.
8 SINGLE_ERR8	AXI Strobe Error On Ocram Bank0 When AXI write access to ocram bank0 is not full size(wstrb=0xff), this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - AXI strobe error does not happen on ocram bank0. 1 - AXI strobe error happens on ocram bank0.
7 SINGLE_ERR7	Multiple Bits Error On Ocram Bank3 When detect multiple bits error on read data from ocram bank3, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Multiple bits error does not happen on ocram bank3. 1 - Multiple bits error happens on ocram bank3.
6 SINGLE_ERR6	Multiple Bits Error On Ocram Bank2 When detect multiple bits error on read data from ocram bank2, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Multiple bits error does not happen on ocram bank2. 1 - Multiple bits error happens on ocram bank2.
5 SINGLE_ERR5	Multiple Bits Error On Ocram Bank1 When detect multiple bits error on read data from ocram bank1, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Multiple bits error does not happen on ocram bank1. 1 - Multiple bits error happens on ocram bank1.
4 SINGLE_ERR4	Multiple Bits Error On Ocram Bank0 When detect multiple bits error on read data from ocram bank0, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Multiple bits error does not happen on ocram bank0. 1 - Multiple bits error happens on ocram bank0.
3 SINGLE_ERR3	Single Bit Error On Ocram Bank3 When detect single bit error on read data from ocram bank3, this bit will be asserted if corresponding status enable bit in ERR_STAT_EN register is set. 0 - Single bit error does not happen on ocram bank3. 1 - Single bit error happens on ocram bank3.

19.6.1.10 Single Error Interrupt Enable Register (SINGLE_ERR_SIG_EN)

This register is used to select which interrupt status is indicated to the Host System as the interrupt. Setting any of these bits to 1 enables interrupt generation. The corresponding Status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

Offset

Register	Offset
SINGLE_ERR_SIG_EN	20h

Chapter 20
Messaging Unit (MU)

20.1 Overview

MU enables two processors on a chip to communicate and coordinate by passing messages (for example, data, status, and control) through the MU interface. MU also allows one processor to signal the other processor using interrupts.

MU must synchronize the accesses from one side to the other because MU can manage messaging between processors using different clocks. MU accomplishes synchronization using two sets of matching registers: processor A-facing and processor B-facing.

20.1.1 Block diagram

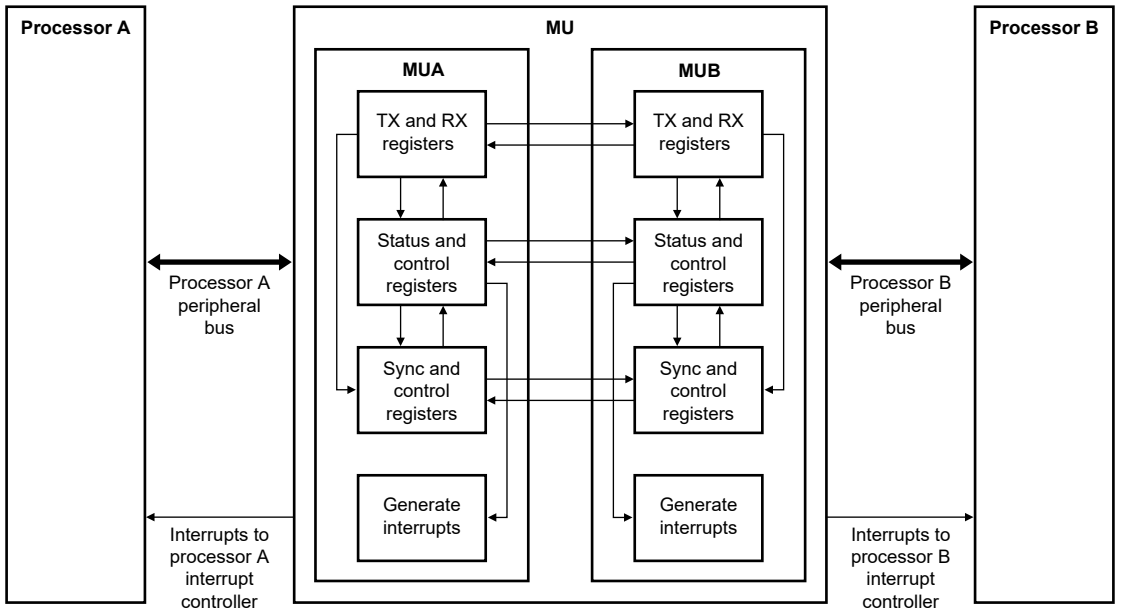

Figure 35. Block diagram

20.1.2 Features

- Memory-mapped registers (MU is connected as a peripheral under the peripheral bus on the processor A-side and processor B-side)
- Synchronized message transfers between cores
  - To send data or messages from one side to the other, MUA provides 4 transmit registers and 4 receive registers. MUB provides 4 transmit registers and 4 receive registers.
  - Transmit empty flags (TSR[TEn]) and receive full flags (RSR[RFn]) facilitate the transfer of data or messages between cores on both sides of MU.
  - A synchronization mechanism updates the transmit and the receive flags. There is an inherent latency between updating the flag on one side and reflecting its status on the other side. See Event update timing.
  - MU has a 3-bit flag data register, which you can use to send flag data between the two MU sides.
- Interprocessor interrupts

  - MU has 12 asynchronous interrupt sources on each side (processor A-side, processor B-side) for signaling the other processor. You can use the interrupts for notification of receive and transmit events and for general-purpose signaling between processors. There are 4 general-purpose interrupt requests available and 8 receive and transmit interrupt sources.
  - Processor A can initiate a non-maskable interrupt (NMI) to processor B.
  - Processor B can initiate a non-maskable interrupt (NMI) to processor A.
- Flexible processor configuration
  - A processor can issue a programmed hardware reset to the other processor by writing 1 to CCR0[HR] .
  - You can configure the boot source for the processor via CCR0[BOOT].
  - You can hold the processor in the reset state by configuring CCR0[RSTH].
  - You can enable the processor platform clock to continue running when the processor enters Stop mode, until the other processor also enters Stop mode. This feature allows the processor to continue accessing peripherals on the bus of the other processor, even when it has entered Stop mode.
- Reset (Each processor can issue a reset to MU via CR[MUR], which is a self-clearing field).

20.2 Functional description

MU enables two cores (processor A and processor B) to communicate with each other:

- By sharing messages and data.
- By enabling one core to wake the other core by using interrupts.

The messaging, control, and status registers of the two cores are mapped to processor A memory and processor B memory as a regular peripheral. The peripheral data bus is 32 bits wide inside MU.

Messaging logic is used with shared memory. Various messaging methods can implement a messaging protocol. For example, a message could mean one of the following:

- A message of *n* words has been written starting at offset *x* in the memory.
- The previous data block that was sent has been read.

The ability to keep messaging logic independent of the shared memory is not restricted to a predefined hardware protocol. The software required to manage the messaging is short and straightforward.

Most of the messaging mechanisms are symmetric. They are duplicated and are available on both the processor A side and processor B side. The messaging mechanisms are:

- 4 32-bit transmit registers, which are each reflected in 4 read-only receive registers on the side of the other processor. These registers can transfer 32-bit word messages or the frame information of the messages written to the shared memory. For example, they can transfer the number of words, initial address, and message type code.
- Writing to a transmitter-side transmit register (TR*n*) clears the Transmitter Empty flag in the transmitter-side Status register (TS*n*[TE*n*]), and sets the Receiver Full flag in the receiver-side Status register (RS*n*[RF*n*]). Setting the flag on the receiver side can trigger an interrupt on the receiver side (a maskable receive interrupt).
- Reading a receiver-side receive register (RR*n*) clears the Receiver Full flag in the receiver-side Status register (RS*n*[RF*n*]), and sets the Transmitter Empty flag in the transmitter-side Status register (TS*n*[TE*n*]). Setting the Transmitter Empty flag can trigger an interrupt on the transmitter side (a maskable transmit interrupt).
- 4 general-purpose interrupt request flags are reflected in General-purpose Status (GSR) on the receiver side.
- 3-bit flag data is transmitted from Flag Control (FCR) to Flag Status (FSR) on the side receiving the flag data. SR[FUP] sets when the flag data is transmitted and clears when the receiving side acknowledges the flag data (the flag is updated).

Writing to a transmit register signals to the receiver side that data is ready for retrieval.

Do not write to the transmit register again without verifying that the data is retrieved. The transmitter side cannot determine the exact time that the receiver attempts to retrieve the data. Before attempting to write to the transmit register again, the transmitter side must wait for the Transmitter Empty interrupt or it must poll TSR[TE*n*].

Reading a receive register signals to the transmitter side that data can be written to that register.

Do not read the receive register again without verifying that the data is written. The receiver side cannot determine the exact time that the transmitter attempts to write the data. Before attempting to read the receive register again, the receiver side must wait for the Receiver Full interrupt or it must poll RSR[RF*n*].

20.2.1 Submodules

20.2.1.1 MUA side

MUA receives its register configuration via the processor A peripheral bus. It sends or receives messages to or from MUB. Processor A can receive messages by reading MUA registers, and MUA can send interrupts to processor A when interrupts are enabled.

NOTE

Processor B should not access MUA registers. Processor C, if exist, should also not access MUA registers. TRDC might be needed to prevent such illegal access of Processor B or C to MUA registers.

20.2.1.2 MUB side

MUB receives its register configuration via the processor B peripheral bus. It sends or receives messages to or from MUA. Processor B can receive messages by reading MUB registers, and MUB can send interrupts to processor B when interrupts are enabled.

NOTE

Processor A should not access MUB registers. Processor C, if exist, should also not access MUB registers. TRDC might be needed to prevent such illegal access of Processor A or C to MUB registers.

20.2.2 Event update timing

The messaging side of each processor has a hardware mechanism to send event update requests to the other processor. An event occurs when the status register of the receiving processor must reflect any information change. The event update latency is the delay between the event being ready at one processor and the resulting update at the status register of the other processor:

- The minimum event latency is (1 clock cycle of the sending side) + (2.5 clock cycles of the receiving side). This minimum case happens when no event is pending when the new event occurs.
- The maximum event latency is (6 clock cycles of the sending side) + (6.5 clock cycles of the receiving side). The maximum case happens when the event occurs just after a previous event is sent to the other side.

The event update latency varies depending on the time at which the subsequent event is triggered.

20.2.3 Clocking

Table 88. MU clocks

Clock name	Description
Bus clock MUA	Used only for bus accesses to MUA control and configuration registers
Bus clock MUB	Used only for bus accesses to MUB control and configuration registers

20.2.4 Resets

The following sections list the reset sources included in MU. Each reset performs a different function for the MU module compared to the function it performs for the system.

20.2.4.1 Asynchronous system reset

When the asynchronous system reset on either side of MU is asserted, SR[MURS] becomes 1 until the asynchronous system reset sequence on both the MUA and MUB sides ends. Verify that SR[MURS] becomes 0 before accessing MU.

The asynchronous system reset on one side of MU resets the other side of MU. The reset forces all control and status registers to return to their default values and clears all internal states. The following table shows the exceptions to this behavior.

Table 89. Exceptions to asynchronous system reset

MUA-side exceptions	MUB-side exceptions
MUB_CCR0[HR]	MUA_CCR0[HR]
MUB_CCR0[HRM]	MUA_CCR0[HRM]
MUB_CCR0[RSTH]	MUA_CCR0[RSTH]
MUB_CCR0[BOOT]	MUA_CCR0[BOOT]
MUB_CR[MURIE]	MUA_CR[MURIE]
MUB_SR[MURIP]	MUA_SR[MURIP]
MUB_SR[MURS]	MUA_SR[MURS]
MUB_CSSR0	MUA_CSSR0

20.2.4.2 Processor hardware reset

Writing 1 to CCR0[HR] generates one hardware reset request to the other processor when CCR0[HRM] on the other MU side is cleared.

Only software asserts and clears CCR0[HR]. Set the required assertion length above the data sheet minimum.

If CCR0[HR] is not masked, MU sends a hardware reset request to the other processor domain reset logic. If CCR0[HR] is masked, MU does not issue the hardware reset request.

20.2.4.3 MU software reset

Writing 1 to CR[MUR] causes most control and status registers to return to their default values and clears all internal states.

The instruction immediately following the assertion of CR[MUR] must not write to the MU registers. The reset sequence may overwrite such a write, with the register retaining the reset value. To know the end of the reset sequence for both processors, monitor the value of SR[MURS]. After the reset sequence on both processors has ended, a write to the MU registers can be attempted.

NOTE

The process of CR[MUR] becoming 1 is delicate because it asynchronously affects the registers on the other side. CR[MUR] becoming 1 may cause unpredictable behavior if, for example, the other processor is concurrently testing an MU register field (TSR[TE*n*] in the other processor). Before writing 1 to CR[MUR], verify that the other processor is not engaged in an MU signaling activity.

20.2.5 Interrupts

MU controls interrupt requests that one processor makes to the other processor. This section describes all the interrupts that the module generates.

MU can generate these interrupt sources individually to send to the processors:

- 4 receive interrupts (asserted when the Receive Full flags are set in Receive Status (RSR) and enabled in Receive Control (RCR)) for each receive register. These interrupts are Ored into a single interrupt for each MUA or MUB, please consult the interrupt map file attached to this document.
- 4 transmit interrupts (asserted when the Transmit Empty flags are set in Transmit Status (TSR) and enabled in Transmit Control (TCR)) for each transmit register. These interrupts are Ored into a single interrupt for each MUA or MUB, please consult the interrupt map file attached to this document.
- 4 general-purpose interrupts (asserted when the GIP flags are set in General-Purpose Interrupt Enable (GIER) and enabled in General-Purpose Interrupt Enable (GIER))
- One non-maskable interrupt (NMI) flag (asserted when the NMI flag is set in Core Control 0 (CCR0))
- MU software and hardware reset (asserted when CR[MUR] and CCR0[HR] are written to and enabled by CR[MURIE] and CIER0[HRIE])

All interrupts except NMI are maskable in the processor control registers: TCR, RCR, GIER, and CR. MU does not assume any internal priority of these interrupts. Multiple interrupts (for example, receive 0 and receive 1, or any transmit or general-purpose interrupts) can be asserted simultaneously. The interrupt controller must resolve the priority of these interrupts at the chip level.

Triggering any enabled interrupt wakes the processor from below mode before servicing the interrupt

The software (as part of the interrupt handler) must clear the general-purpose interrupt pending flags (GSR[GIP*n*]) to deassert the request to the interrupt controller.

The software must also clear the NMI by writing CSSR0[NIMC] (as a part of the interrupt handler) to deassert the NMI request.

When a processor writes to the general-purpose interrupt (GCR[GIR*n*]), MU synchronizes the write event to the other processor to set the general-purpose interrupt request pending flag (GSR[GIP*n*]). When GSR[GIP*n*] is set and the general-purpose interrupt is enabled on the receiving side (GIER[GIE*n*] is 1), the transmitting-side general-purpose interrupt is issued to the receiving processor, which clears this interrupt by writing 1 to GSR[GIP*n*]. The interrupt is deasserted as soon as the write to GSR[GIP*n*] occurs. MU synchronizes the write event of GSR[GIP*n*] to the other processor. The synchronized signal writes 0 to the GIR*n* interrupt.

Before writing 1 to GCR[GIR*n*], verify that the field is 0, which means that a general interrupt is not pending. Generally, MU ignores writing 1 to this field while the field is already 1, but in some cases it may issue a second interrupt.

20.3 External signals

This module has no external signals.

20.4 Initialization

MU does not require initialization.

20.5 Application information

MU facilitates messages between processors. For example, MU passes:

- Short messages. Transmit registers can pass short messages from 1 to 4 words in length for processor A and from 1 to 4 words for processor B. For example, for a four-word message, only one register must have its corresponding interrupt enabled on the receiving side. The first three words of the message are written to the registers with masked interrupts. The fourth word is written to the last register, triggering an interrupt on the receiving side.
- Frame information. Transmit registers can pass frame information for long messages written to the shared system memory. Such frame information normally includes a start address and a number of words. It can include a message type code.
- Event notices and requests. MU can signal events and requests that do not include data words between processors using general-purpose interrupts. For example, one such event is acknowledging that a long message is read from the shared system memory.

- Fixed-length data. Formatted data with a fixed length can be written to predetermined locations in the shared memory. A processor can use general-purpose interrupts to signal to the other processor that the data is ready.
- Announcements. A processor can use the 3 flags to announce its current program state or other billboard messages to the other processor.

20.5.1 Messaging protocols using interrupts

The example below describes a four-word messaging sequence sent between the processor A and processor B.

The transmitting processor writes to the transmit registers sequentially. When *n* = 0, 1, and 2, the interrupts are disabled, so no interrupt goes to the processor (although interrupt conditions occur). For *n* = 3, the interrupt is enabled, and MU generates the last receive interrupt request.

1. Write sequence:
    a. The transmitting processor writes the message information sequentially to its Transmit registers 0, 1, 2.
    b. When the write to Transmit register 3 occurs, RSR[RF3] is set after synchronization. It immediately triggers the receive full 3 interrupt on the receiving processor.
2. Read sequence:
    a. The receiving processor receives the receive full 3 interrupt and starts reading the message transferred from the receive registers.
    b. After the receiving processor reads Receive register 3, MU clears RSR[RF3].

Table 90 and Figure 36 describe the messaging model, using transmit and receive registers and the interrupt messaging protocol.

Table 90. Interrupt messaging protocol (generalized)

Step	Action	Description
1	Processor A writes data.	RR*n* on processor B's side reflects a data write to TR*n* by processor A.
2	Clear the transmitter empty flag and set the receiver full flag.	The data write to TR*n*: • Clears TSR[TE*n*] on the processor A side. • Sets RSR[RF*n*] on the processor B side.
3	Generate the receive interrupt request.	Setting RSR[RF*n*] generates a receive interrupt request to processor B.
4	Processor B reads the data.	After receiving the receive interrupt request, processor B performs a data read of RR*n*.
5	Clear the receiver full flag and set the transmitter empty flag.	Reading the data from the RR*n* register: • Clears RSR[RF*n*] on the processor B side. • Sets TSR[TE*n*] on the processor A side.
6	Generate the transmit interrupt request.	Setting TSR[TE*n*] generates a transmit interrupt request to processor A.

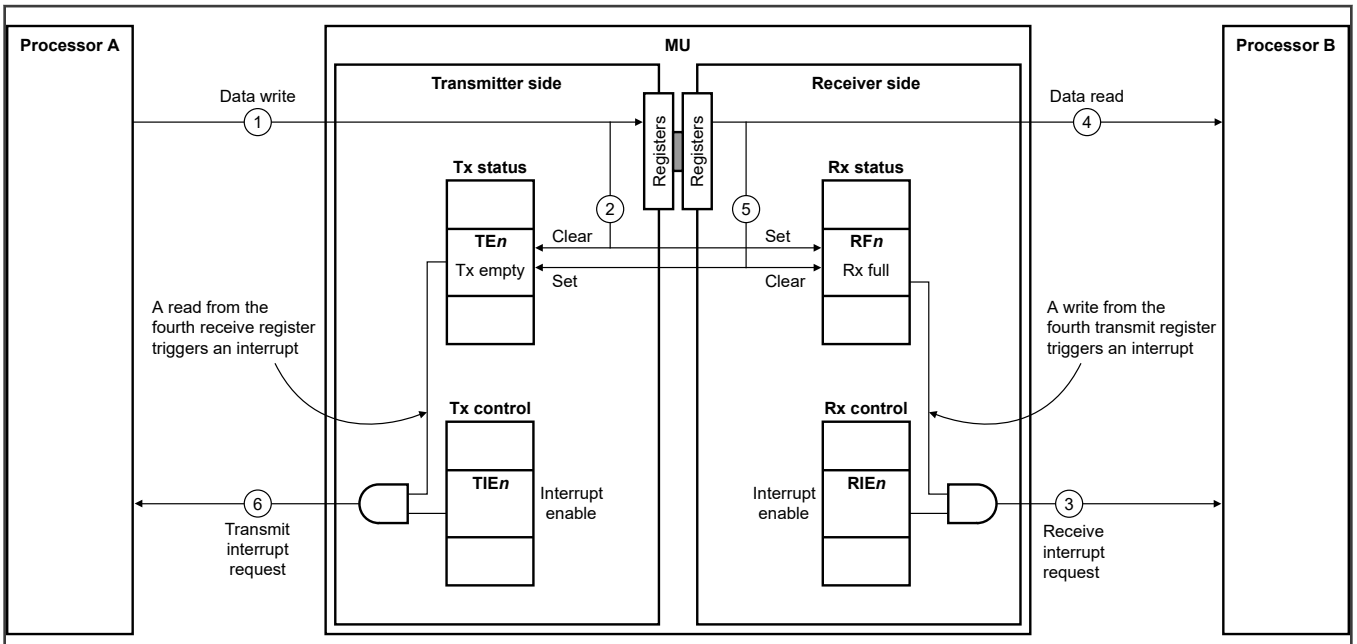

Figure 36. Messaging model using transmit and receive registers

You can use the messaging hardware to implement messaging protocols for an array of message types. MU provides full support for interrupt and polling management schemes.

20.5.2 Messaging protocols using event interrupts

MU can signal events and requests that do not include data words between processors using general-purpose interrupts.

Formatted data with a fixed length can be written to predetermined locations in the shared memory. A processor can use a general-purpose interrupt to signal to the other processor that the data is ready.

A processor can use the 3 flags to announce its current program state (or similar messages) to the other processor.

Table 91 and Figure 37 describe the event steps when the processor triggers a general-purpose interrupt.

Table 91. General-purpose interrupt messaging protocol (generalized)

Step	Action	Description
1	Processor A sets its associated general-purpose interrupt request flag.	Processor A sets GCR[GIR*n*].
2	The general-purpose interrupt request pending status flag is set.	GSR[GIP*n*] is set.
3	MU generates the general-purpose interrupt request to processor B.	Setting GSR[GIP*n*] generates the general-purpose interrupt request to processor B. GIER[GIE*n*] must be set for processor B.
4	Processor B reads the status register.	Processor B reads GSR[GIP*n*].
5	Processor B services the interrupt.	—

Table continues on the next page...

Table 91. General-purpose interrupt messaging protocol (generalized) (continued)

Step	Action	Description
6	Processor B sets GSR[GIP*n*] to clear the interrupt.	Processor B writes 1 to the corresponding GSR[GIP*n*] flag to clear the interrupt.
7	GCR[GIR*n*] is cleared.	Setting GSR[GIP*n*] clears GCR[GIR*n*] on the processor A side.

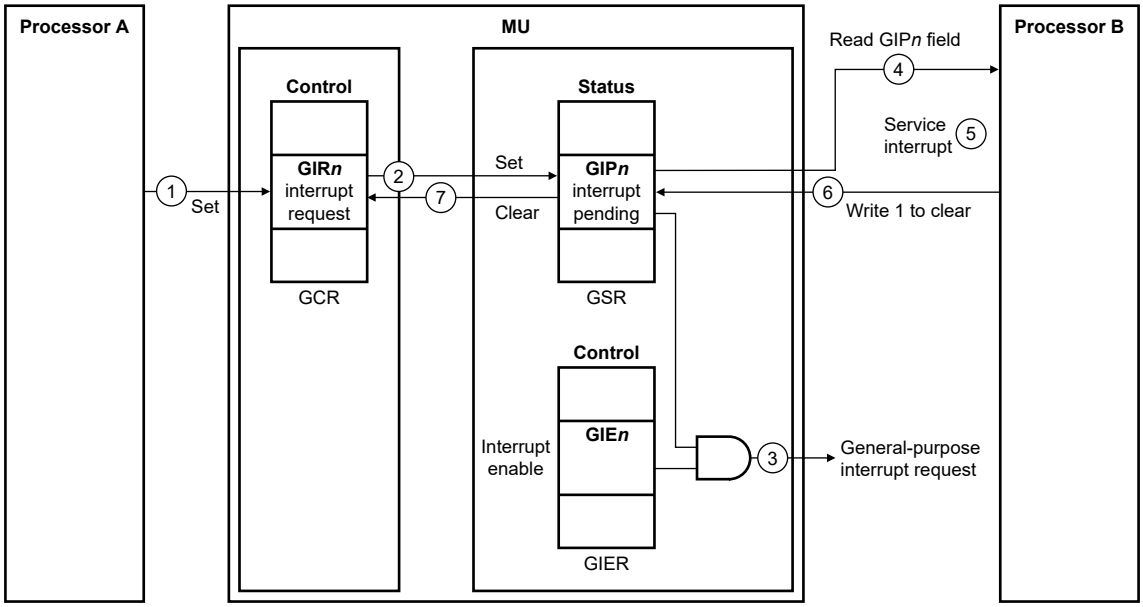

Figure 37. Messaging model using a general-purpose interrupt

20.5.3 Exclusive access to shared memory

MU can signal one processor about its current access to shared memory. This signaling prevents the other processor from overwriting data during the exclusive memory access period.

The following tables describe the signaling protocol that processor A uses to inform processor B about its current access (write) to shared memory:

- Table 92 shows processor A performing an exclusive access to shared memory.
- Table 93 shows processor B scanning for transaction information.
- Table 94 shows processor B accepting exclusive access from processor A.
- Table 95 shows processor B rejecting exclusive access from processor A.

According to the examples shown in the following tables, GCR[GIR*n*], RR*n*, and TR*n* are reserved to support exclusive access to the shared memory protocol.

Table 92. Processor A performs an exclusive access to shared memory

Step	Action	Description
1	Processor A sends the GIR*n* request to processor B using the processor A control register.	Before processor A performs an exclusive access to the shared memory, it sends a GIR*n* request to processor B.
2	Processor A sends an exclusive-access request using a transmit data register (TR*n*).	Processor A sends an exclusive-access request (command, location, and length of target access) to processor B using a selected transmit data register (TR0).
3	Processor A waits for a dedicated interrupt from processor B.	Processor A waits for a dedicated interrupt (as an acknowledgment) triggered by processor B before proceeding.
4	Processor A accesses the shared memory.	After receiving a dedicated interrupt from processor B, processor A proceeds.

Table 93. Processor B scans for transaction information

Step	Action	Description
1	Processor B receives an interrupt from a receive data register (RR*n*).	—
2	Processor B reads the receive data register (RR*n*).	—
3	Processor B scans the receive data register contents.	Processor B scans for transaction information (whether processor A has requested exclusive access).

Table 94. Processor B accepts exclusive access from processor A

Step	Action	Description
1	Processor B triggers a dedicated interrupt.	Processor B acknowledges the request from processor A by triggering a dedicated interrupt (ack) to processor A.
2	Processor B sends a code message to processor A.	With the acknowledge interrupt, processor B sends a code message to processor A through the selected transmit register (TR*n*). The message informs processor A that it can exclusively access the shared memory.

Table 95. Processor B rejects exclusive access from processor A

Step	Action	Description
1	Processor B ignores the request from processor A for exclusive access.	If processor B does not provide permission to processor A, processor B ignores the exclusive-access request.

20.5.4 Packet data transfers

The following table describes an example packet transfer sequence between processor B and processor A subsystems.

Table 96. Packet data transfer sequence

Step	Action	Description
1	Processor B requests DMA.	Processor B sends a DMA request to initiate the packet data transfer.
2	DMA data transfer	DMA acknowledges.
3		DMA starts transferring data from the specified processor B memory location to the specified shared memory.
4		DMA interrupts processor B to signal that the packet transfer has finished.
5	Processor B informs processor A that data is in shared memory.	Using a B-side transmit register, processor B sends a packet information message to processor A about the arrival of new packet data stored in shared memory. The message contains the command, location, and length of packet data.
6	Processor A receives an interrupt.	Processor A receives an interrupt (assuming its corresponding processor A MU-side receive interrupt is enabled). The pending processing task becomes active and processes packet data from memory.
7	Processor A reads data, then writes data.	Processor A reads or processes packet data from shared memory.
8		Processor A writes the result from packet processing to a separate buffer.
9	Processor A informs processor B that the transfer is finished.	After the processing of the packet data finishes, processor A informs processor B (using MU processor A-side transmit register, MUA_TR*n*).
10	Processor A sends an interrupt to processor B (a request for more data).	Processor B receives the next interrupt from processor A, in which processor A requests more packet data.

20.5.5 Freeing a processor from deadlock

During normal operation, one processor may determine that the other processor is not working or is deadlocked. Using Status (SR), the processor can use the methods in the following table to identify and correct the problem.

Table 97. Freeing a processor from deadlock

Processor mode	Technique	Description
—	Processor issues an interrupt.	The other processor can interrupt the processor by issuing one of the 12 (general purpose, receive, or transmit) interrupts.
Normal	Processor issues a non-maskable interrupt.	If a processor is in Normal mode, the other processor can issue a non-maskable interrupt (NMI). You can configure the NMI routine to execute a diagnostic routine that is predefined for such an event.
—	Processor issues a hardware reset.	If the above methods are not helpful, the processor can issue a hardware reset strobe to the other processor.

20.6 Register definition

MU provides transmit and receive data registers (*x*TR0–*n*, *x*RR0–*n*) for communication between processor A and processor B. It also provides control registers (*x*CR) for operations such as interrupts and resets, and status registers (*x*SR) for checking the status of the other MU-side. Figure 38 shows the schematic for MU registers.

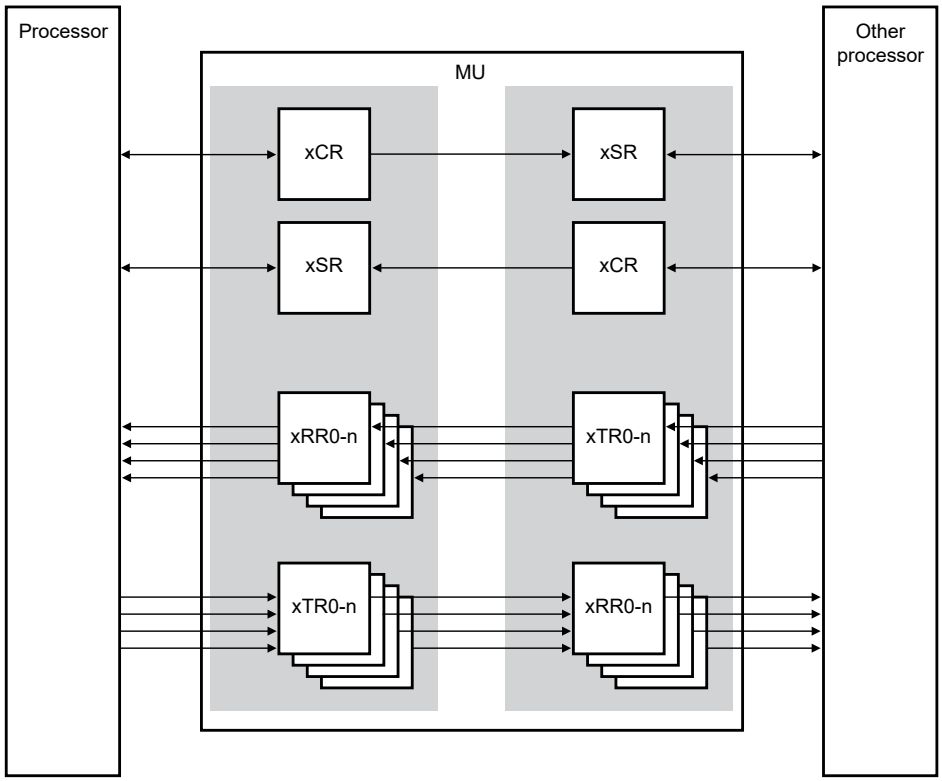

Figure 38. MU registers

20.6.1 MUA register descriptions

This section contains the detailed register descriptions for MUA registers.

NOTE

A module transfer error to processor A or processor B is generated when:

- A read or write access is made to an invalid location.
- A write operation is performed on a read-only register on the processor A side or processor B side of MU.

20.6.1.1 MUA memory map

Fields

Field	Description
31-24 FLAG_WIDTH	Flag Width Specifies the number of flag bits (3) in the Flag Control (FCR) and Flag Status (FSR) registers.
23-16 GIR_NUM	General-Purpose Interrupt Request Number Specifies the number of general-purpose interrupt requests available (4).
15-8 RR_NUM	Receive Register Number Specifies the number of receive registers (4).
7-0 TR_NUM	Transmit Register Number Specifies the number of transmit registers (4).

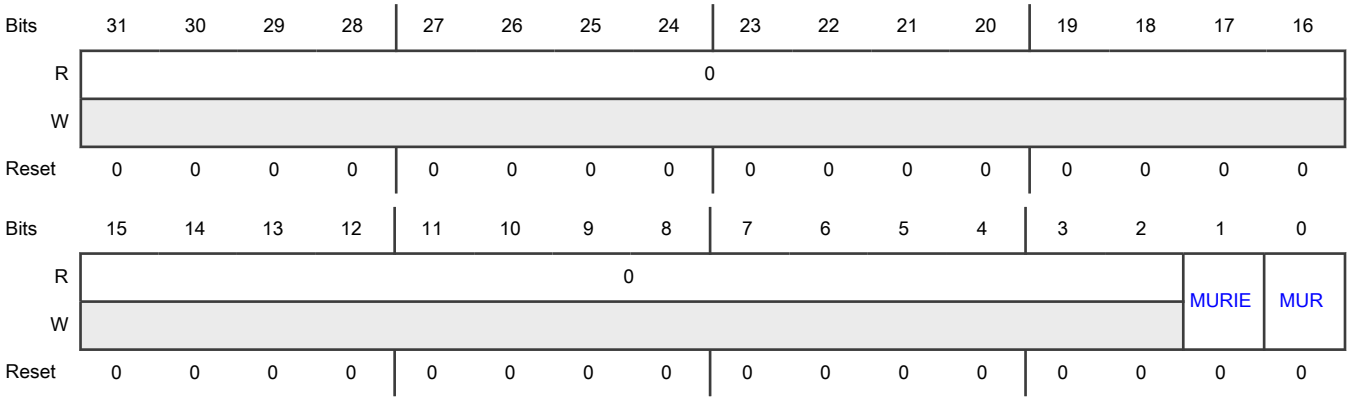
20.6.1.4 Control (CR)

Controls MU reset and reset interrupt enable.

Offset

Register	Offset
CR	8h

Diagram



Fields

Field	Description
31-2 —	Reserved
1 MURIE	MUA Reset Interrupt Enable Enables the processor A-side MU reset interrupt request due to MU reset issued by MUB. If the value of this field is 1, an MU reset interrupt request is issued to processor A when MUA_SR[MURIP] = 1. If the value of this field is 0, MU ignores the value of MURIP and issues no MU reset interrupt request. Only a system reset can reset this field. CR[MUR] cannot reset this field. 0 - Disable 1 - Enable
0 MUR	MU Reset Resets MU. Writing 1 to this field resets the MUA and MUB sides. All internal states are cleared. It forces all control and status registers to return to their default values (except HR, HRM in MUA/B_CCR0 registers; MURIE in MUA/B_CR registers; MURIP and MURS in MUA/B_SR registers). Before writing 1 to this field, interrupt processor B because writing 1 to this field may affect the ongoing processor B program. After writing 1 to this field, monitor the value of MUA_SR[MURS] to know when the reset sequence on the processor B-side has ended. This field always reads 0, and it becomes 0 during the MU reset sequence. 0 - Idle 1 - Reset

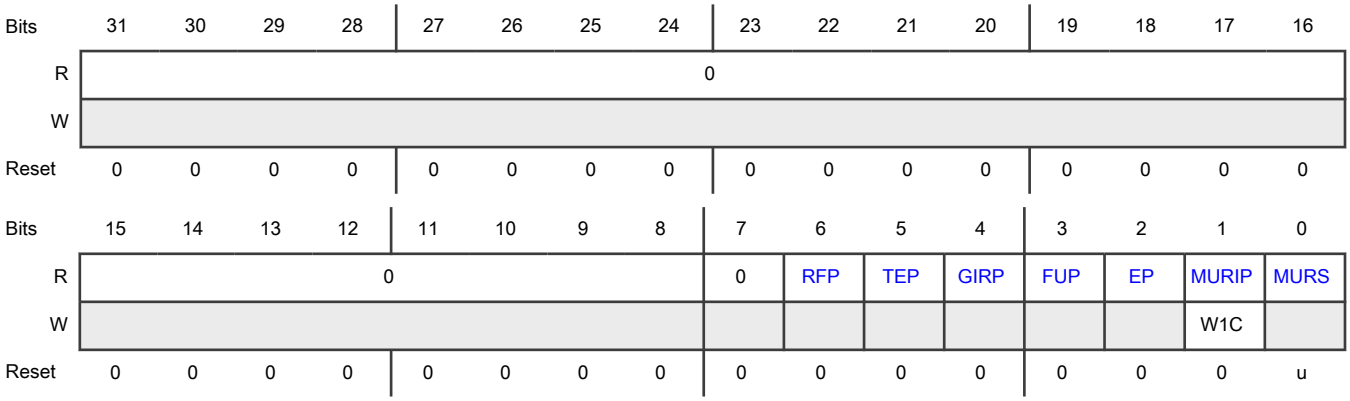
20.6.1.5 Status (SR)

Shows the status of MU resets and the status of pending events and requests.

Offset

Register	Offset
SR	Ch

Diagram



Fields

Field	Description
31-8 —	Reserved
7 —	Reserved
6 RFP	MUA Receive Full Pending Indicates whether a receive full message is pending. This field becomes 1 when MUB writes to a TR*n* register to send data to MUA. After this field becomes 1, MU checks RSR[RF*n*] to determine whether the data in the Receive register is ready for MUA to read it. This field becomes 0 when all MUA RR*n* registers are read, or when MU is reset. 0 - Not pending; MUB is not writing to a Transmit register 1 - Pending; MUB is writing to a Transmit register
5 TEP	MUA Transmit Empty Pending Indicates whether a transmit empty message is pending. This field becomes 1 when any TCR[TIE*n*] field is 1 and TSR[TE*n*] flag is set. After this field becomes 1, MU checks TSR[TE*n*] to determine whether the data in the Transmit (TR*n*) register is ready for MUA to write to it. This field becomes 0 when write operations to all MUA Transmit (TR*n*) registers where TCR[TIE*n*] = 1 (transfer interrupt enabled) are completed, or when MU is reset. 0 - No MUA transmit empty event pending

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Pending; any TCR[TIEn] field is 1 and TSR[TEn] flag is set
4 GIRP	MUA General-Purpose Interrupt Pending Indicates that MUB has sent a general-purpose interrupt request. This field becomes 1 when the MUB side sends a general-purpose interrupt request to the MUA side. GSR[GIP*n*] identifies which general-purpose interrupt request is received. This field becomes 0 when all MUA_GSR[GIP*n*] fields are cleared, or when MU is reset. 0 - No request sent 1 - Request sent
3 FUP	MUA Flag Update Pending Indicates whether a flag update request is pending. MU generates this request when there is a change to the F*n*[2:0] bits of MUA_FCR. This field becomes 1 when the MUA side sends a flag update request to the MUB side. This field becomes 0 when MU acknowledges this flag update request internally (the flag is updated) from the MUB side, or during MU reset. No flag update changes are allowed when this field is 1. When FUP = 1, a write to the F*n*[2:0] bits of MUA_FCR does not generate a flag update event. The F*n*[2:0] bits do not change. If SR[EP] = 1 (event pending), writing to MUA_FCR does not immediately cause this field to become 1. 0 - No pending update flags (initiated by MUA) 1 - Pending update flags (initiated by MUA)
2 EP	MUA Side Event Pending Indicates a pending side event when the MUA side sends an event update request to the MUB side. An event is any hardware message that the Status register on the MUB side reflects. For example, an event occurs when Transmit register 0 is the target of a write operation. During normal operations, the update mechanism for this field operates automatically. MU clears this field automatically when the event update acknowledgment is received, or when MU resets. To ensure that events are posted to MUB, verify that this field is 0. If it is 1, wait and continue to poll this field until it becomes 0. 0 - Not pending 1 - Pending
1 MURIP	MU Reset Interrupt Pending Flag Indicates whether processor B has issued an MU reset. This flag is set after processor B initiates an MU reset by setting MUB_CR[MUR]. If CR[MURIE] = 1, the processor A MU reset interrupt request is issued when processor B writes 1 to MUB_CR[MUR]. Clearing this flag also clears the MU reset interrupt request. Only a system reset can reset this flag. MU reset cannot reset this flag.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE This field behaves differently for register reads and writes. When reading 0 - Reset not issued 1 - Reset issued When writing 0 - No effect 1 - Clear the flag
0 MURS	MUA and MUB Reset State Indicates the reset state of MUA and MUB. This field becomes 1 during any system reset or MU reset from the MUA or MUB side. This field becomes 0 when the reset sequence on both MUA and MUB sides ends. After issuing any of the aforementioned reset events, verify that this field is 0 before starting any access. 0 - Out of reset 1 - In reset

20.6.1.6 Core Control 0 (CCR0)

Allows MUA to control the processor on the MUB side.

Also allows control of the processor A hardware reset mask.

Offset

Register	Offset
CCR0	10h

4 RSTH	Processor B Reset Hold Holds processor B in reset. **NOTE** Writing 1 to this field does not force processor B into reset. It only holds processor B if the processor resets itself. 0 - Release from reset 1 - Hold in reset
3 CLKE	Processor B Clock Enable Enables platform clock for Processor B to continue running when Processor B enters Stop mode until processor A also enters Stop mode. When this field is 0, the Processor B platform clock is gated when Processor B enters Stop mode. 0 - Disable 1 - Enable
2 HRM	Processor A Hardware Reset Mask Disables hardware reset requests to the other processor side. When this field is 1, MUB_CCR0[HR] is masked, and the hardware reset request to processor A is disabled. When this field is 0, MUB_CCR0[HR] is not masked, and the hardware reset to the processor A is enabled. 0 - Enable 1 - Disable
1 HR	Processor B Hardware Reset Initiates hardware reset. Write 1 to this field to start a hardware reset of processor B. Write 0 to this field to deassert the processor B hardware reset input.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Writing 1 to this field does not cause an internal MU reset. It is routed outside MU to the processor B reset logic. Processor B can mask the HR reset issued by processor A to processor B (according to the value of MUB_CCR0[HRM]). This field does not return to the reset value during MU software reset (MUR). 0 - Deassert hardware reset to processor B. 1 - Assert hardware reset to processor B.
0 NMI	MUB Nonmaskable Interrupt Request Indicates whether Processor A has issued a nonmaskable interrupt to Processor B. When this field becomes 1, it initiates a nonmaskable interrupt to processor B. This field becomes 0 after 1 is written to MUB_CSSR0[NMIC] to clear that field. After this field becomes 0, MUA can initiate another nonmaskable interrupt to MUB. This field is cleared when MU resets. 0 - Nonmaskable interrupt not issued 1 - Nonmaskable interrupt issued

1 HRIP	Processor A Hardware Reset Interrupt Pending Flag Indicates whether Processor A had been reset via MUB_CCR0[HR]. This flag is set when Processor B writes 1 to MUB_CCR0[HR] and MUA_CCR0[HRM] = 0. 0 - No hardware reset initiated 1 - Hardware reset initiated
0	Processor A Nonmaskable Interrupt Clear

Table continues on the next page...

Table continued from the previous page...

Field	Description
NMIC	Clears the nonmaskable interrupt (NMI) request from the MUB side. The MUA-side NMI service routine uses this field. Writing 1 to this field clears MUB_CCR0[NMI], deasserting the NMI request and enabling MUB_CCR0[NMI] to trigger another NMI request. This field always reads as 0, so you cannot poll it. You can only use this field as part of the NMI service routine, in which you must write 1 to this field only once. This field is cleared when MU resets. 0 - Default 1 - Clear MUB_CCR0[NMI]

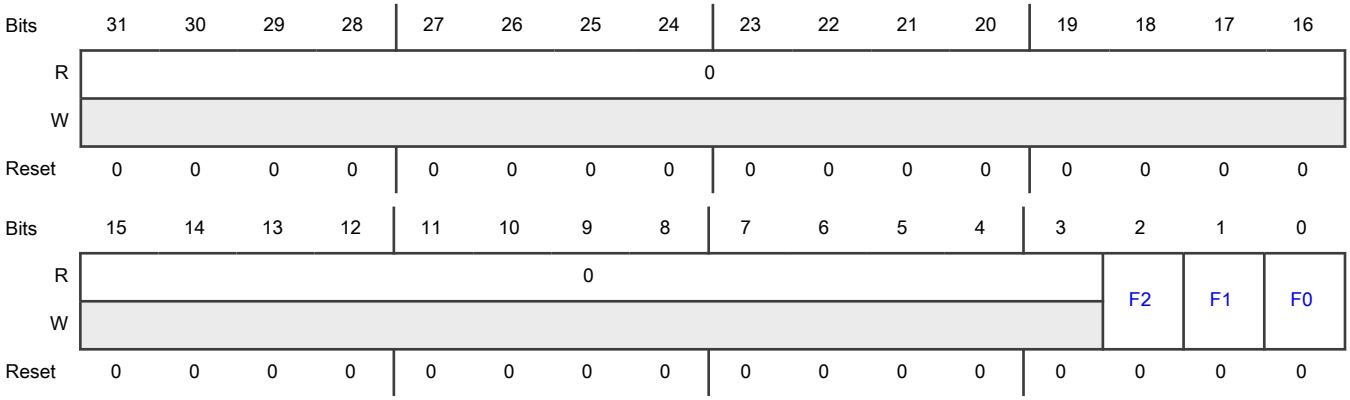
20.6.1.9 Flag Control (FCR)

Configures MUB_FSR[F*n*] flags.

Offset

Register	Offset
FCR	100h

Diagram



Fields

Field	Description
31-3 —	Reserved
2-0	MUA to MUB Flag Configures MUB_FSR[F*n*] flags, where *n* = 0 to 2.

Table continues on the next page...

Table continued from the previous page...

Field	Description
Fn	F*n* configures the corresponding MUB_FSR[F*n*] flag. F*n* becomes 0 when MU resets. 0 - Clear MUB_FSR[Fn] 1 - Set MUB_FSR[Fn]

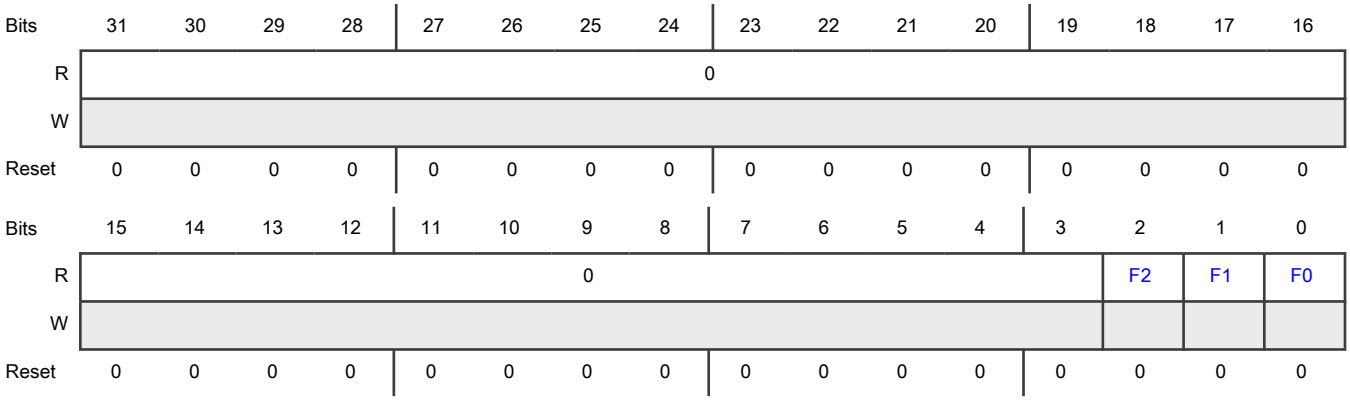
20.6.1.10 Flag Status (FSR)

Contains flags configured by the values written to MUB_FCR[F*n*].

Offset

Register	Offset
FSR	104h

Diagram



Fields

Field	Description
31-3 —	Reserved
2-0 Fn	MUB to MUA-Side Flag Contains flags configured by the values written to MUB_FCR[F*n*], where *n* = 0 to 2. F*n* is the MUA-side flag configured by the values written to MUB_FCR[F*n*]. When MUB_FCR[F*n*] is written to, the write event updates MUA_FSR[F*n*], after the event update latency. 0 - MUB_FCR[Fn] = 0 1 - MUB_FCR[Fn] = 1

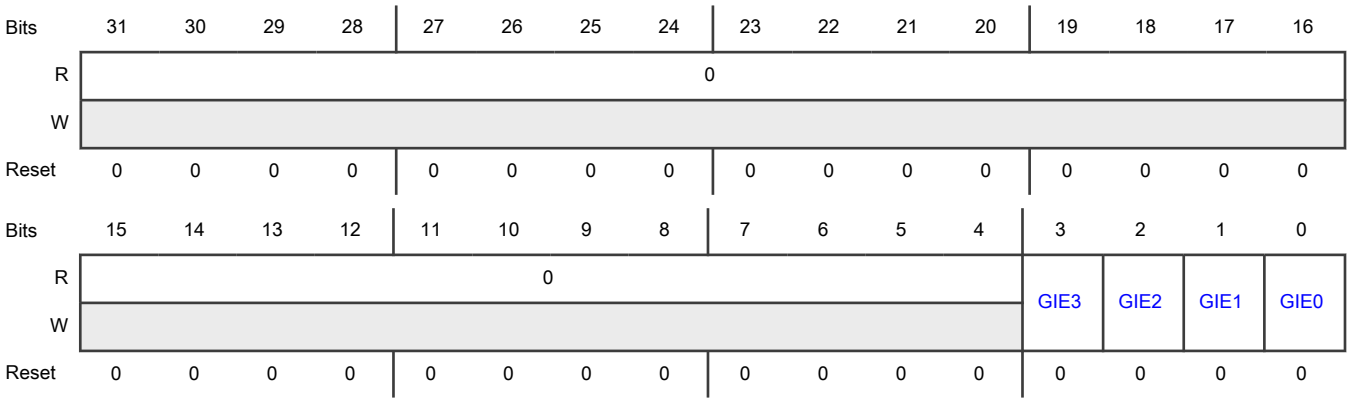
20.6.1.11 General-Purpose Interrupt Enable (GIER)

Contains the MUA general-purpose interrupt enable fields.

Offset

Register	Offset
GIER	110h

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 GIEn	MUA General-purpose Interrupt Enable Enables general-purpose interrupt. There are 4 general-purpose interrupts (*n* = 0 to 3). When GIE*n* = 1, a general-purpose interrupt *n* request is issued to processor A when MUA GSR[GIP*n*] = 1. If GIE*n* = 0, the general-purpose interrupt request pending does not trigger the general-purpose interrupt. GIE*n* becomes 0 when MU resets. 0 - Disable 1 - Enable

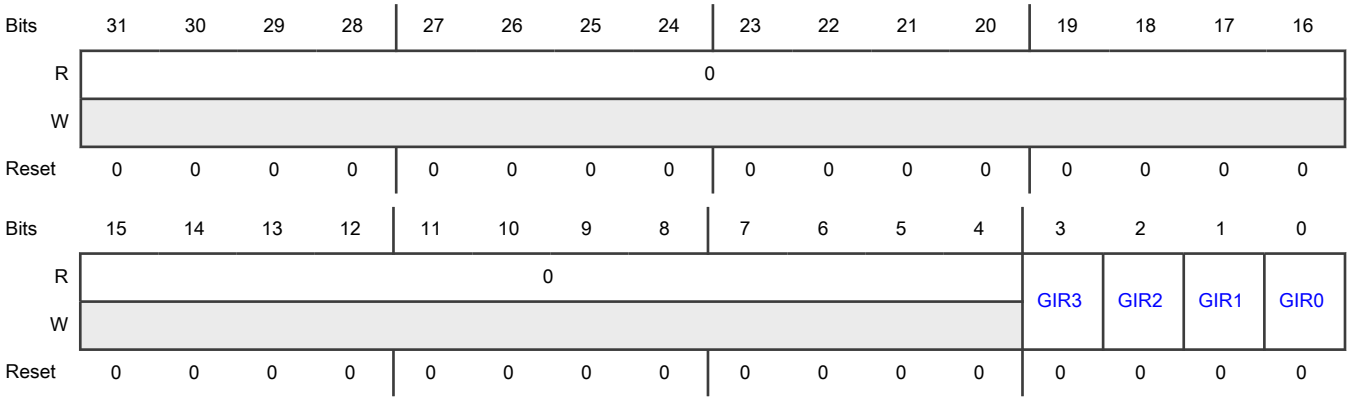
20.6.1.12 General-Purpose Control (GCR)

Contains the MUA general-purpose interrupt request fields.

Offset

Register	Offset
GCR	114h

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 GIRn	MUA General-Purpose Interrupt Request Specifies whether general-purpose interrupts are requested to MUB. There are 4 general-purpose interrupts (*n* = 0 to 3). Writing 1 to GIR*n* sets MUB_GSR[GIP*n*]. If MUB_GIER[GIE*n*] = 1, a general-purpose interrupt request is triggered on processor B. This field becomes 0 when MUB_GSR[GIP*n*] is cleared. This clearing informs MUA that the interrupt is accepted (cleared by software). To ensure proper operations, verify that GIR*n* is 0 (no pending interrupt) before writing 1 to it. This field becomes 0 when MU resets. 0 - Not requested 1 - Requested

20.6.1.13 General-purpose Status (GSR)

Contains the status of the MUA general-purpose interrupt pending requests.

Offset

Register	Offset
GSR	118h

Diagram

Fields

Field	Description
31-4 —	Reserved
3-0 GIPn	MUA General-Purpose Interrupt Request Pending Indicates whether a general-purpose interrupt request is pending. There are 4 general-purpose interrupts (*n* = 0 to 3). GIP*n* informs MUA that MUB_GCR[GIR*n*] changed from 0 to 1. If MUA_GIER[GIE*n*] = 1, a general-purpose interrupt request is issued to processor A. GIP*n* is cleared when MU resets. After GIP*n* is cleared, if MUA_GIER[GIE*n*] = 1, the general-purpose interrupt request is cleared on the MUA side. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Not pending 1 - Pending When writing 0 - No effect 1 - Clear the flag

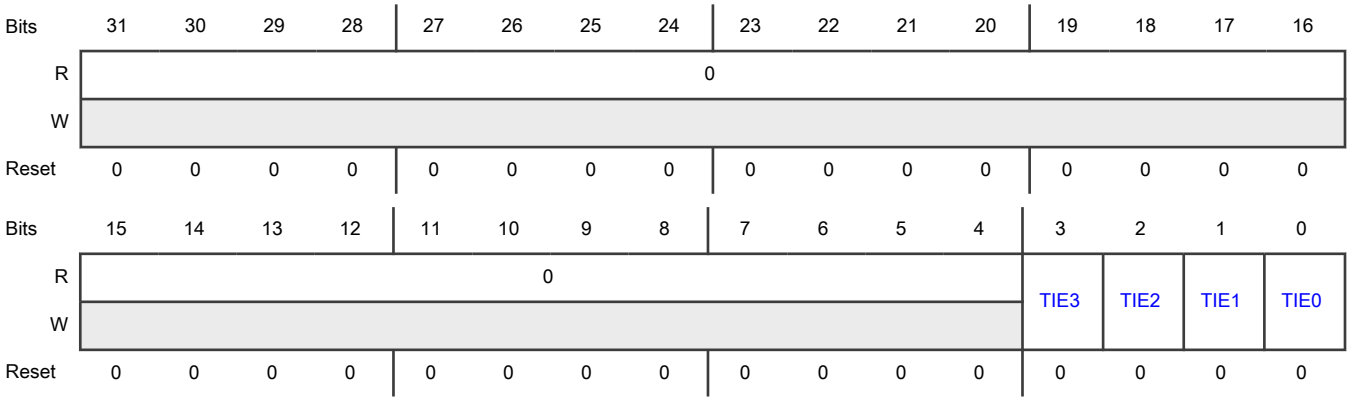
20.6.1.14 Transmit Control (TCR)

Contains the MUA transmit interrupt enable fields.

Offset

Register	Offset
TCR	120h

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 TIEn	MUA Transmit Interrupt Enable Enables MUA transmit interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUA transmit interrupt *n* request is issued when MUA_TSR[TE*n*] is set. If this field is 0, MU ignores the value of MUA_TSR[TE*n*], and no MUA transmit interrupt *n* request is issued. 0 - Disable 1 - Enable

20.6.1.15 Transmit Status (TSR)

Indicates whether the MUA transmit registers are empty.

Offset

Register	Offset
TSR	124h

Fields

Field	Description
31-4 —	Reserved
3-0 TEn	MUA Transmit Empty Indicates whether MUA Transmit (TR*n*) register is empty, where *n* = 0 to 3. This field becomes 1 after the MUB_RR*n* register is read on the MUB side. When TE*n* = 1, it indicates to the MUA side that the MUA_TR*n* register is ready to be written on the MUA side. If MUA_TCR[TIE*n*] = 1, a transmit *n* interrupt is issued on the MUA side. This field becomes 0 after the MUA_TR*n* register is written to on the MUA side. After this field becomes 0, if MUA_TCR[TIE*n*] = 1, the transmit *n* interrupt request is cleared on the MUA side. This field becomes 1 when MU resets. 0 - Not empty 1 - Empty

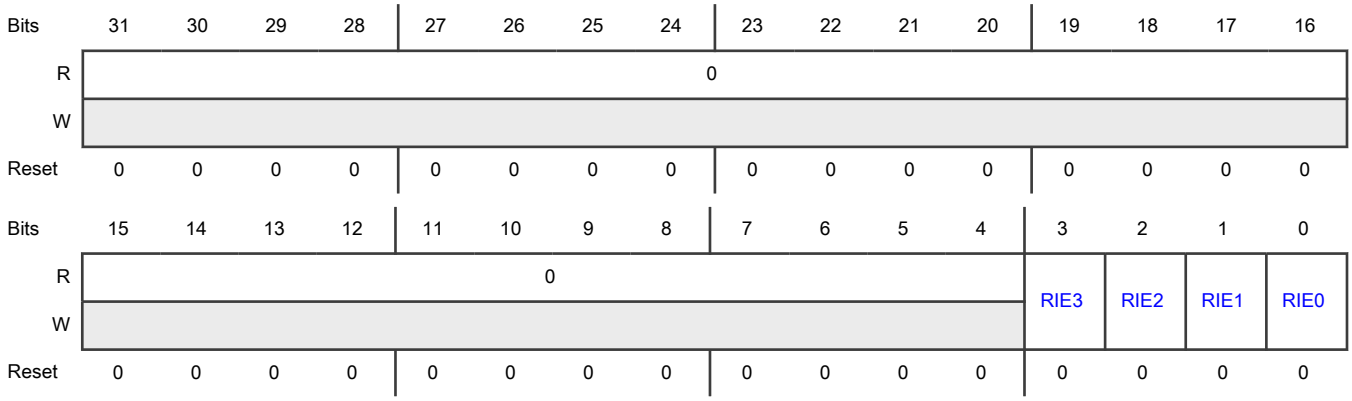
20.6.1.16 Receive Control (RCR)

Contains the MUA receive interrupt enables.

Offset

Register	Offset
RCR	128h

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 RIEn	MUA Receive Interrupt Enable Enables MUA receive interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUA receive interrupt *n* request is issued when MUA_RSR[RF*n*] is set. If this field is 0, MU ignores the value of MUA_RSR[RF*n*], and no MUA receive interrupt request is issued. 0 - Disable 1 - Enable

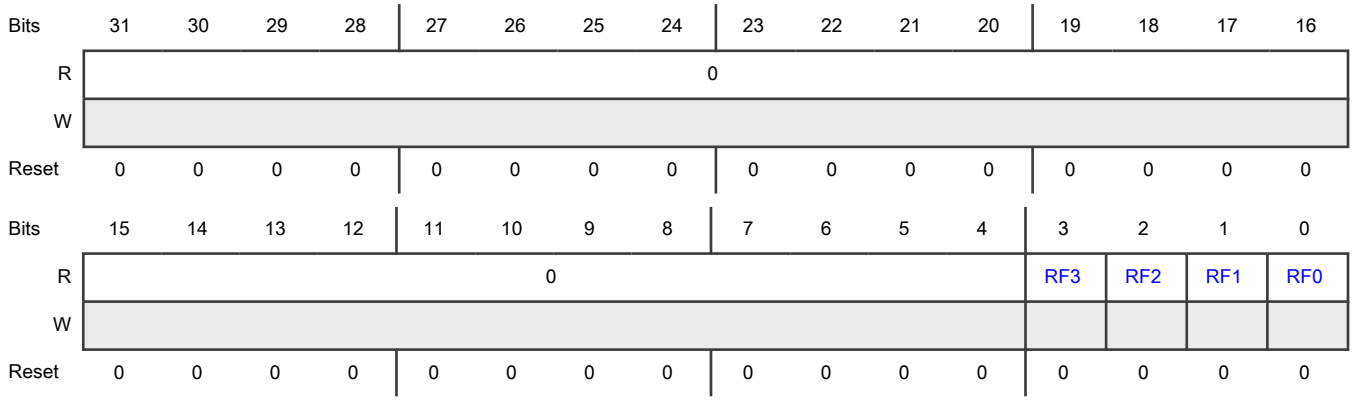
20.6.1.17 Receive Status (RSR)

Indicates whether the MUA receive registers are full.

Offset

Register	Offset
RSR	12Ch

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 RFn	MUA Receive Register Full Indicates whether MUA Receive register (RR*n*) is full, where *n* = 0 to 3. RF*n* becomes 1 when the MUB_TR*n* register is written to on the MUB side. When RF*n* is 1, it indicates to the MUA side that new data in the MUA_RR*n* register is ready for MUA to read it. If MUA_RCR[RIE*n*] = 1, a receive *n* interrupt is issued on the MUA side. RF*n* becomes 0 when the MUA_RR*n* register is read, or when MU is reset. After RF*n* becomes 0, if MUA_RCR[RIE*n*] = 1, the receive *n* interrupt request is cleared on the MUA side. 0 - Not full 1 - Full

20.6.1.18 Transmit (TR0 - TR3)

Contains MUA transmit data.

Offset

Register	Offset
TR0	200h
TR1	204h
TR2	208h
TR3	20Ch

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0															
W	TR_DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-0 TR_DATA	MUA Transmit Data Contains MUA transmit data. MUB_RR*n* reflects the data written to this register. The TR*n* and RR*n* registers are not double-buffered. Writing to MUA_TR*n* overrides the data readable in the MUA_RR*n* register. A write to the Transmit register clears MUA_TSR[TE*n*] on the transmitter side, and sets MUB_RSR[RF*n*] on the receiver side. You can write to this register only when MUA_TSR[TE*n*] = 1. Reading this register returns all zeroes.

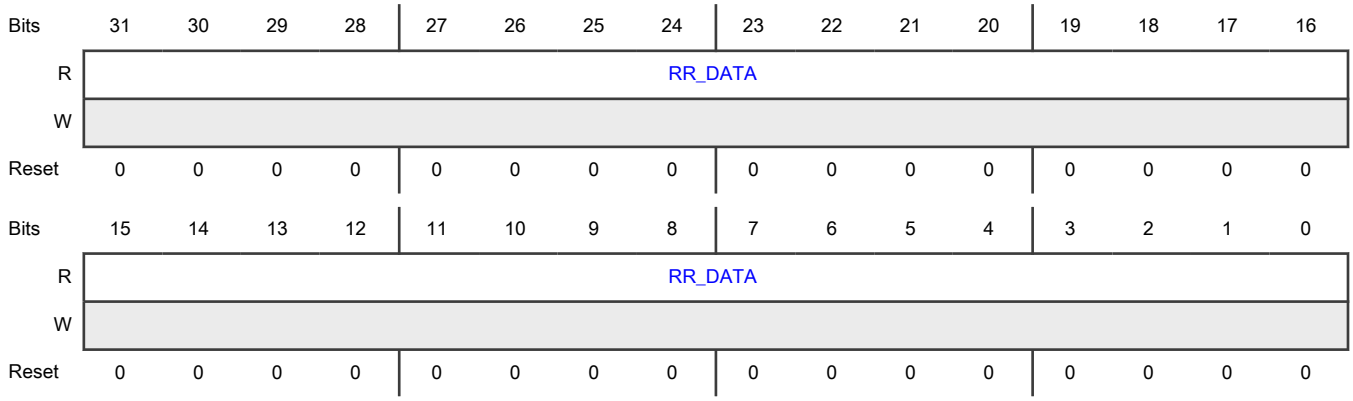
20.6.1.19 Receive (RR0 - RR3)

Contains MUA receive data.

Offset

Register	Offset
RR0	280h
RR1	284h
RR2	288h
RR3	28Ch

Diagram



Fields

Field	Description
31-0 RR_DATA	MUA Receive Data Reflects the data written to MUB TR*n*. Reading this register clears MUA_RSR[RF*n*] on the receiver side, and sets MUB_TSR[TE*n*] on the transmitter side. You can read this register only when MUA_RSR[RF*n*] = 1. Reading it before MUA_RSR[RF*n*] becomes 1 may result in reading incorrect data. Poll MUA_RSR[RF*n*] to confirm it is set before reading RR*n*. Writing to this register generates an error response to MUA.

20.6.2 MUB register descriptions

This section contains the detailed register descriptions for MUB registers.

NOTE

A module transfer error to processor A or processor B is generated when:

- A read or write access is made to an invalid location.
- A write operation is performed on a read-only register on the processor A side or processor B side of MU.

20.6.2.1 MUB memory map

MU1.MUB base address: 4423_0000h

MU2.MUB base address: 4244_0000h

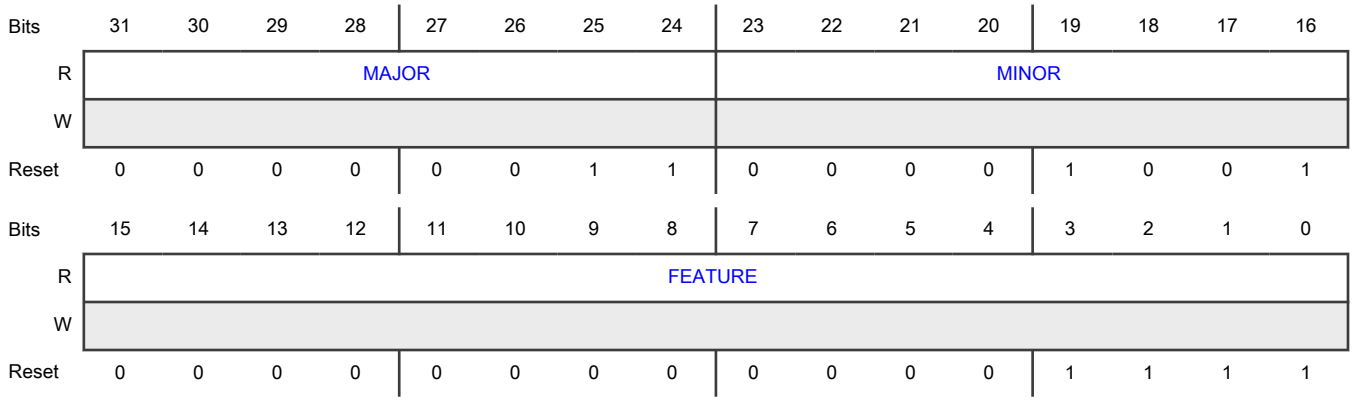
20.6.2.2 Version ID (VER)

Determines the version ID and feature set number of MUB.

Offset

Register	Offset
VER	0h

Diagram



Fields

Field	Description
31-24 MAJOR	Major Version Number
23-16 MINOR	Minor Version Number
15-0 FEATURE	Feature Set Number Indicates the feature set number. MU implements: • Standard features • Expanded number of TR*n*/RR*n* registers

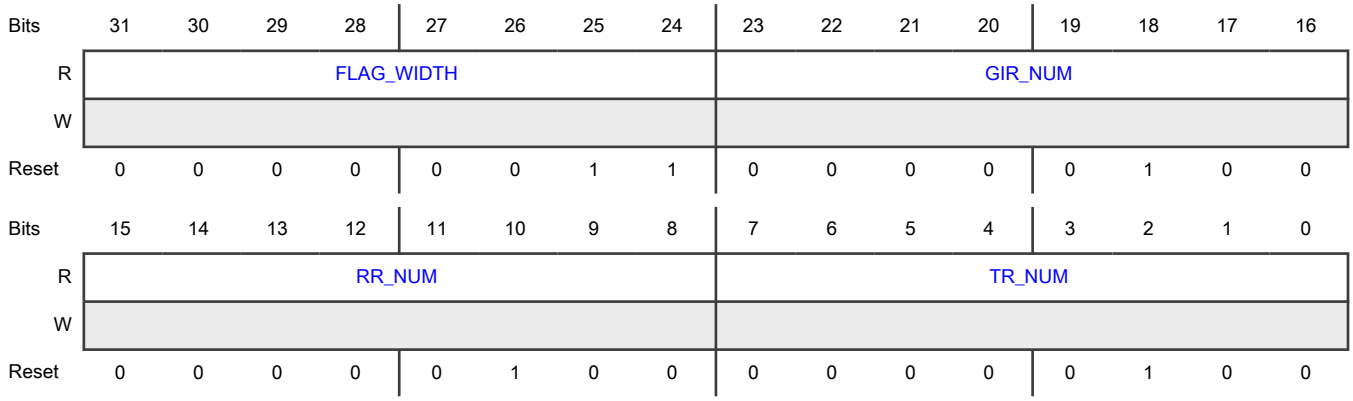
20.6.2.3 Parameter (PAR)

Defines the number of flags, transmit registers, receive registers, and general-purpose interrupt requests available for MU.

Offset

Register	Offset
PAR	4h

Diagram



Fields

Field	Description
31-24 FLAG_WIDTH	Flag Width Specifies the number of flag bits (3) in the Flag Control (FCR) and Flag Status (FSR) registers.

Table continues on the next page...

Table continued from the previous page...

Field	Description
23-16 GIR_NUM	General-Purpose Interrupt Request Number Specifies the number of general-purpose interrupt requests available (4).
15-8 RR_NUM	Receive Register Number Specifies the number of receive registers (4).
7-0 TR_NUM	Transmit Register Number Specifies the number of transmit registers (4).

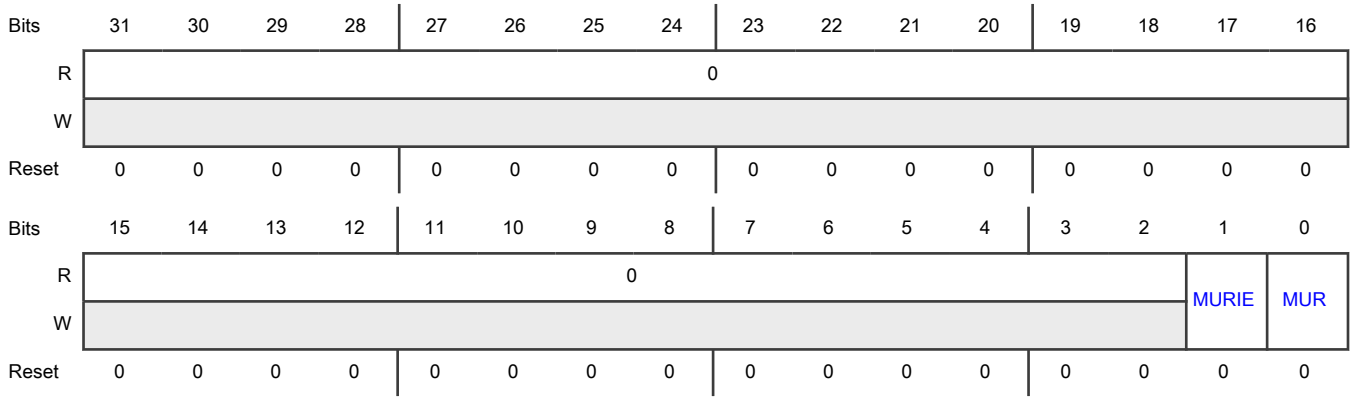
20.6.2.4 Control (CR)

Controls MU reset and reset interrupt enable.

Offset

Register	Offset
CR	8h

Diagram



Fields

Field	Description
31-2 —	Reserved
1 MURIE	MUB Reset Interrupt Enable Enables the processor B-side MU reset interrupt request due to MU reset issued by MUA.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	If the value of this field is 1, an MU reset interrupt request is issued to processor B when MUB_SR[MURIP] = 1. If the value of this field is 0, MU ignores the value of MURIP and issues no MU reset interrupt request. Only a system reset can reset this field. CR[MUR] cannot reset this field. 0 - Disable 1 - Enable
0 MUR	MU Reset Resets MU. Writing 1 to this field resets the MUB and MUA sides. All internal states are cleared. It forces all control and status registers to return to their default values (except HR, HRM in MUB/A_CCR0 registers; MURIE in MUB/A_CR registers; MURIP and MURS in MUB/A_SR registers). Before writing 1 to this field, interrupt processor A because writing 1 to this field may affect the ongoing processor A program. After writing 1 to this field, monitor the value of MUB_SR[MURS] to know when the reset sequence on the processor A-side has ended. This field always reads 0, and it becomes 0 during the MU reset sequence. 0 - Idle 1 - Reset

20.6.2.5 Status (SR)

Shows the status of MU resets and the status of pending events and requests.

Offset

Register	Offset
SR	Ch

W															W1C	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	u

Fields

Field	Description
31-8 —	Reserved
7 —	Reserved
6 RFP	MUB Receive Full Pending Indicates whether a receive full message is pending. This field becomes 1 when MUA writes to a TR*n* register to send data to MUB. After this field becomes 1, MU checks RSR[RF*n*] to determine whether the data in the Receive register is ready for MUB to read it. This field becomes 0 when all MUB RR*n* registers are read, or when MU is reset. 0 - Not pending; MUA is not writing to a Transmit register 1 - Pending; MUA is writing to a Transmit register
5 TEP	MUB Transmit Empty Pending Indicates whether a transmit empty message is pending. This field becomes 1 when any TCR[TIE*n*] field is 1 and TSR[TE*n*] flag is set. After this field becomes 1, MU checks TSR[TE*n*] to determine whether the data in the Transmit (TR*n*) register is ready for MUB to write to it. This field becomes 0 when write operations to all MUB Transmit (TR*n*) registers where TCR[TIE*n*] = 1 (transfer interrupt enabled) are completed, or when MU is reset. 0 - No MUB transmit empty event pending 1 - Pending; any TCR[TIEn] field is 1 and TSR[TEn] flag is set
4 GIRP	MUB General-Purpose Interrupt Pending Indicates that MUA has sent a general-purpose interrupt request. This field becomes 1 when the MUA side sends a general-purpose interrupt request to the MUB side. GSR[GIP*n*] identifies which general-purpose interrupt request is received. This field becomes 0 when all MUB_GSR[GIP*n*] fields are cleared, or when MU is reset. 0 - No request sent 1 - Request sent
3 FUP	MUB Flag Update Pending Indicates whether a flag update request is pending. MU generates this request when there is a change to the F*n*[2:0] bits of MUB_FCR. This field becomes 1 when the MUB side sends a flag update request to the MUA side. This field becomes 0 when MU acknowledges this flag update request internally (the flag is updated) from the MUA side, or during MU reset. No flag update changes are allowed when this field is 1. When FUP = 1, a write to the F*n*[2:0] bits of MUB_FCR does not generate a flag update event. The F*n*[2:0] bits do not change.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	If SR[EP] = 1 (event pending), writing to MUB_FCR does not immediately cause this field to become 1. 0 - No pending update flags (initiated by MUB) 1 - Pending update flags (initiated by MUB)
2 EP	MUB Side Event Pending Indicates a pending side event when the MUB side sends an event update request to the MUA side. An event is any hardware message that the Status register on the MUA side reflects. For example, an event occurs when Transmit register 0 is the target of a write operation. During normal operations, the update mechanism for this field operates automatically. MU clears this field automatically when the event update acknowledgment is received, or when MU resets. To ensure that events are posted to MUA, verify that this field is 0. If it is 1, wait and continue to poll this field until it becomes 0. 0 - Not pending 1 - Pending
1 MURIP	MU Reset Interrupt Pending Flag Indicates whether processor A has issued an MU reset. This flag is set after processor A initiates an MU reset by setting MUB_CR[MUR]. If CR[MURIE] = 1, the processor B MU reset interrupt request is issued when processor A writes 1 to MUA_CR[MUR]. Clearing this flag also clears the MU reset interrupt request. Only a system reset can reset this flag. MU reset cannot reset this flag. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Reset not issued 1 - Reset issued When writing 0 - No effect 1 - Clear the flag
0 MURS	MUA and MUB Reset State Indicates the reset state of MUA and MUB. This field becomes 1 during any system reset or MU reset from the MUA or MUB side. This field becomes 0 when the reset sequence on both MUA and MUB sides ends. After issuing any of the aforementioned reset events, verify that this field is 0 before starting any access. 0 - Out of reset 1 - In reset

20.6.2.6 Core Control 0 (CCR0)

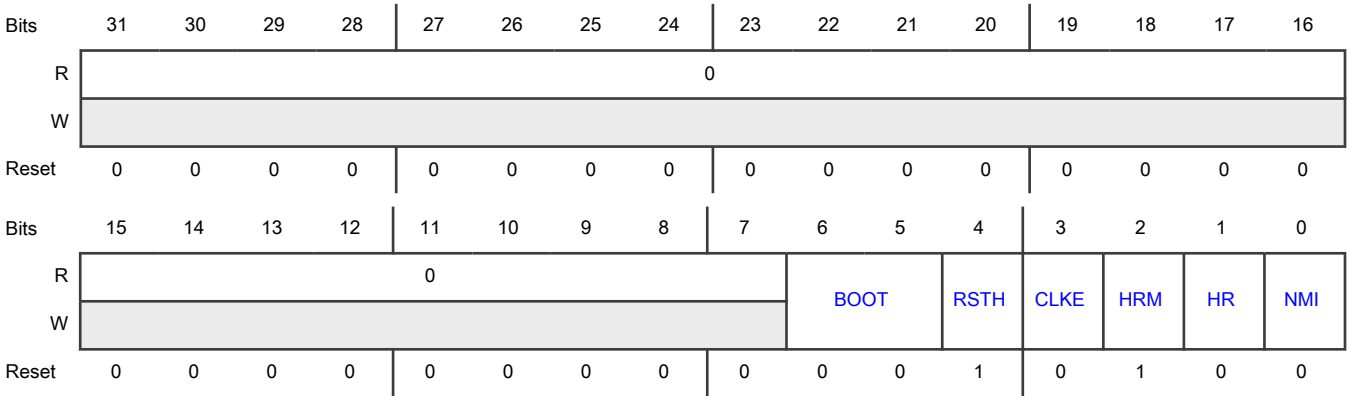
Allows MUB to control the processor on the MUA side.

Also allows control of the processor B hardware reset mask.

Offset

Register	Offset
CCR0	10h

Diagram



Fields

Field	Description
31-7 —	Reserved
6-5 BOOT	Target Processor A Boot Configuration Configures the boot source for processor A when it is the target core. See the chip-specific details for more information on boot options. 00 - Processor Boot option 0 01 - Processor Boot option 1 10 - Processor Boot option 2 11 - Processor Boot option 3
4 RSTH	Processor A Reset Hold Holds processor A in reset. **NOTE** Writing 1 to this field does not force processor A into reset. It only holds processor A if the processor resets itself. 0 - Release from reset

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Hold in reset
3 CLKE	Processor A Clock Enable Enables platform clock for Processor A to continue running when Processor A enters Stop mode until processor B also enters Stop mode. When this field is 0, the Processor A platform clock is gated when Processor A enters Stop mode. 0 - Disable 1 - Enable
2 HRM	Processor B Hardware Reset Mask Disables hardware reset requests to the other processor side. When this field is 1, MUA_CCR0[HR] is masked, and the hardware reset request to processor B is disabled. When this field is 0, MUA_CCR0[HR] is not masked, and the hardware reset to the processor B is enabled. 0 - Enable 1 - Disable
1 HR	Processor A Hardware Reset Initiates hardware reset. Write 1 to this field to start a hardware reset of processor A. Write 0 to this field to deassert the processor A hardware reset input. Writing 1 to this field does not cause an internal MU reset. It is routed outside MU to the processor A reset logic. Processor A can mask the HR reset issued by processor B to processor A (according to the value of MUA_CCR0[HRM]). This field does not return to the reset value during MU software reset (MUR). 0 - Deassert hardware reset to processor A. 1 - Assert hardware reset to processor A.
0 NMI	MUA Nonmaskable Interrupt Request Indicates whether Processor B has issued a nonmaskable interrupt to Processor A. When this field becomes 1, it initiates a nonmaskable interrupt to processor A. This field becomes 0 after 1 is written to MUA_CSSR0[NMIC] to clear that field. After this field becomes 0, MUB can initiate another nonmaskable interrupt to MUA. This field is cleared when MU resets. 0 - Nonmaskable interrupt not issued 1 - Nonmaskable interrupt issued

20.6.2.7 Core Interrupt Enable 0 (CIER0)

Controls interrupt enables.

5 —	Reserved
4 —	Reserved
3 —	Reserved
2 —	Reserved
1 HRIP	Processor B Hardware Reset Interrupt Pending Flag Indicates whether Processor B had been reset via MUA_CCR0[HR]. This flag is set when Processor A writes 1 to MUA_CCR0[HR] and MUB_CCR0[HRM] = 0. 0 - No hardware reset initiated 1 - Hardware reset initiated
0 NMIC	Processor B Nonmaskable Interrupt Clear Clears the nonmaskable interrupt (NMI) request from the MUA side. The MUB-side NMI service routine uses this field. Writing 1 to this field clears MUA_CCR0[NMI], deasserting the NMI request and enabling MUA_CCR0[NMI] to trigger another NMI request. This field always reads as 0, so you cannot poll it. You can only use this field as part of the NMI service routine, in which you must write 1 to this field only once. This field is cleared when MU resets. 0 - Default 1 - Clear MUA_CCR0[NMI]

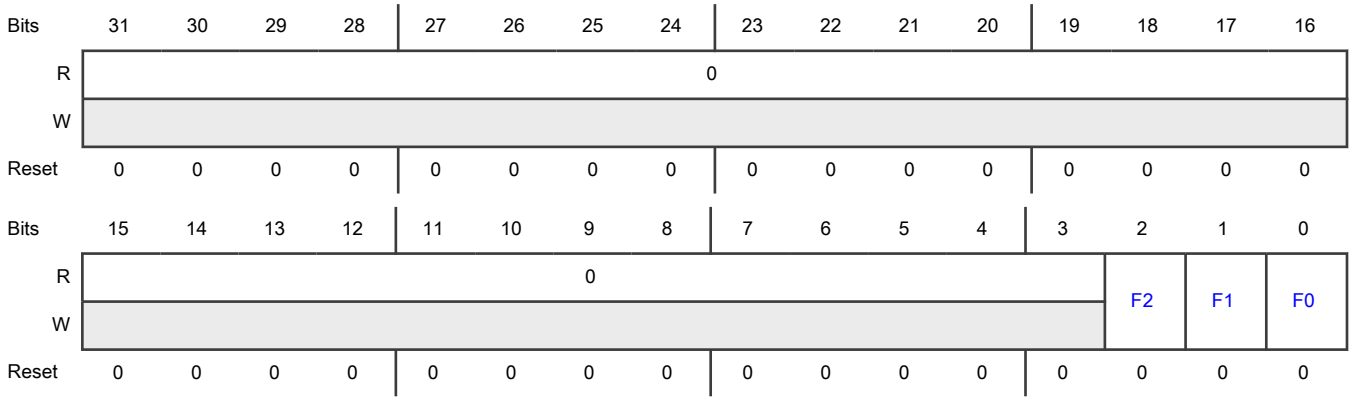
20.6.2.9 Flag Control (FCR)

Configures MUA_FSR[F*n*] flags.

Offset

Register	Offset
FCR	100h

Diagram



Fields

Field	Description
31-3 —	Reserved
2-0 Fn	MUB to MUA Flag Configures MUA_FSR[F*n*] flags, where *n* = 0 to 2. F*n* configures the corresponding MUA_FSR[F*n*] flag. F*n* becomes 0 when MU resets. 0 - Clear MUA_FSR[Fn] 1 - Set MUA_FSR[Fn]

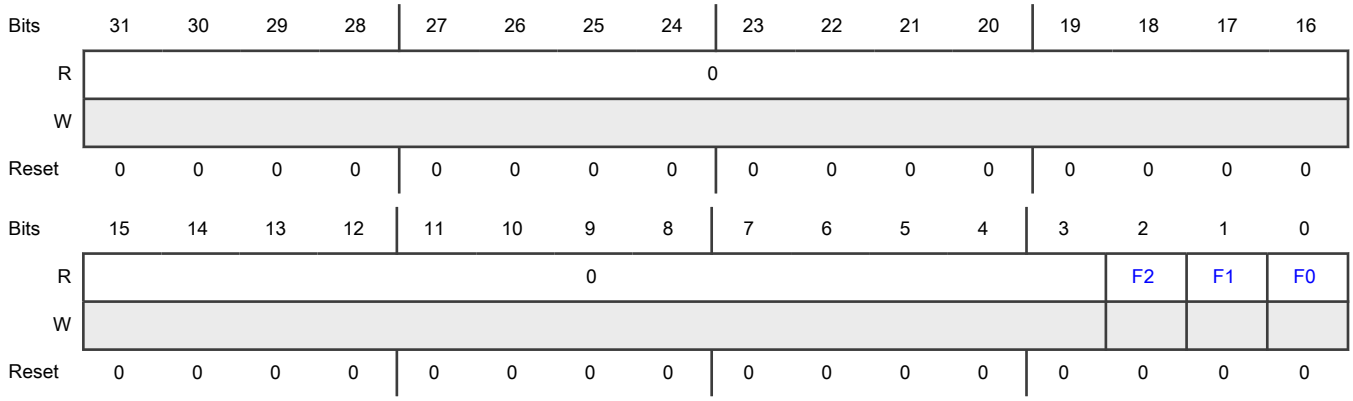
20.6.2.10 Flag Status (FSR)

Contains flags configured by the values written to MUA_FCR[F*n*].

Offset

Register	Offset
FSR	104h

Diagram



Fields

Field	Description
31-3 —	Reserved
2-0 Fn	MUA to MUB-Side Flag Contains flags configured by the values written to MUA_FCR[F*n*], where *n* = 0 to 2. F*n* is the MUB-side flag configured by the values written to MUA_FCR[F*n*]. When MUA_FCR[F*n*] is written to, the write event updates MUB_FSR[F*n*], after the event update latency. 0 - MUA_FCR[Fn] = 0 1 - MUA_FCR[Fn] = 1

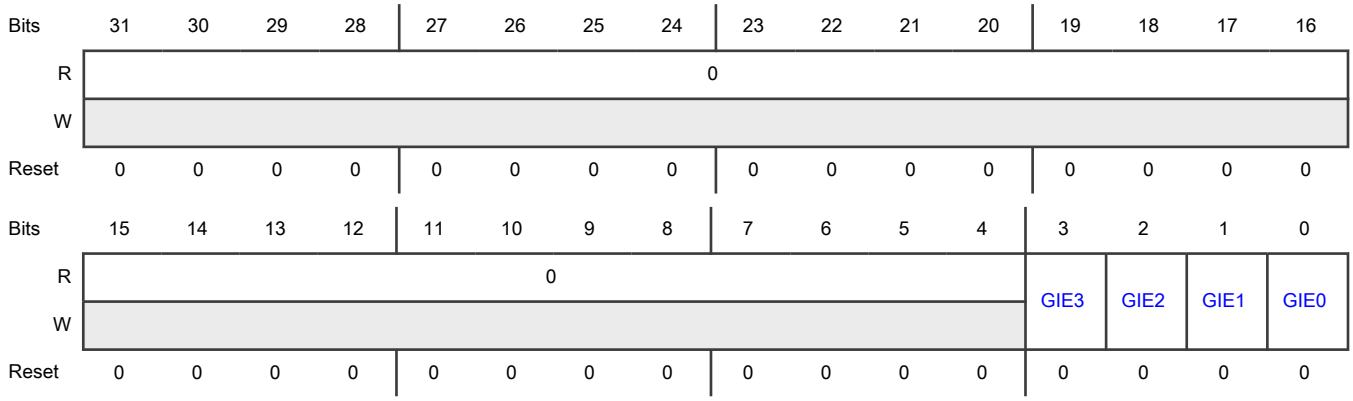
20.6.2.11 General-Purpose Interrupt Enable (GIER)

Contains the MUB general-purpose interrupt enable fields.

Offset

Register	Offset
GIER	110h

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 GIEn	MUB General-purpose Interrupt Enable Enables general-purpose interrupt. There are 4 general-purpose interrupts (*n* = 0 to 3). When GIE*n* = 1, a general-purpose interrupt *n* request is issued to processor B when MUB GSR[GIP*n*] = 1. If GIE*n* = 0, the general-purpose interrupt request pending does not trigger the general-purpose interrupt. GIE*n* becomes 0 when MU resets. 0 - Disable 1 - Enable

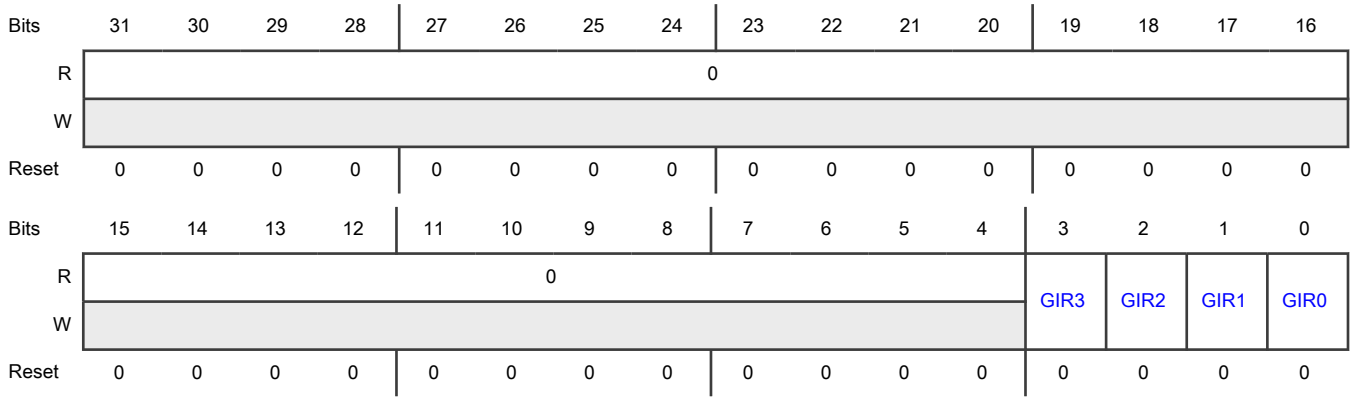
20.6.2.12 General-Purpose Control (GCR)

Contains the MUB general-purpose interrupt request fields.

Offset

Register	Offset
GCR	114h

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 GIRn	MUB General-Purpose Interrupt Request Specifies whether general-purpose interrupts are requested to MUA. There are 4 general-purpose interrupts (*n* = 0 to 3). Writing 1 to GIR*n* sets MUA_GSR[GIP*n*]. If MUA_GIER[GIE*n*] = 1, a general-purpose interrupt request is triggered on processor A. This field becomes 0 when MUA_GSR[GIP*n*] is cleared. This clearing informs MUB that the interrupt is accepted (cleared by software). To ensure proper operations, verify that GIR*n* is 0 (no pending interrupt) before writing 1 to it. This field becomes 0 when MU resets. 0 - Not requested 1 - Requested

20.6.2.13 General-purpose Status (GSR)

Contains the status of the MUB general-purpose interrupt pending requests.

Offset

Register	Offset
GSR	118h

Register	Offset
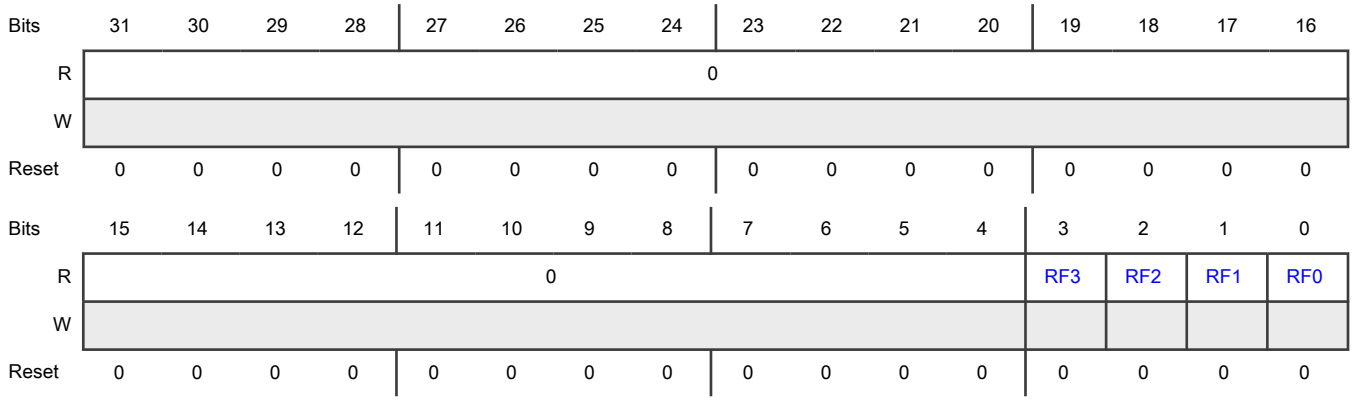
RSR	12Ch

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 RFn	MUB Receive Register Full Indicates whether MUB Receive register (RR*n*) is full, where *n* = 0 to 3. RF*n* becomes 1 when the MUA_TR*n* register is written to on the MUA side. When RF*n* is 1, it indicates to the MUB side that new data in the MUB_RR*n* register is ready for MUB to read it. If MUB_RCR[RIE*n*] = 1, a receive *n* interrupt is issued on the MUB side. RF*n* becomes 0 when the MUB_RR*n* register is read, or when MU is reset. After RF*n* becomes 0, if MUB_RCR[RIE*n*] = 1, the receive *n* interrupt request is cleared on the MUB side. 0 - Not full 1 - Full

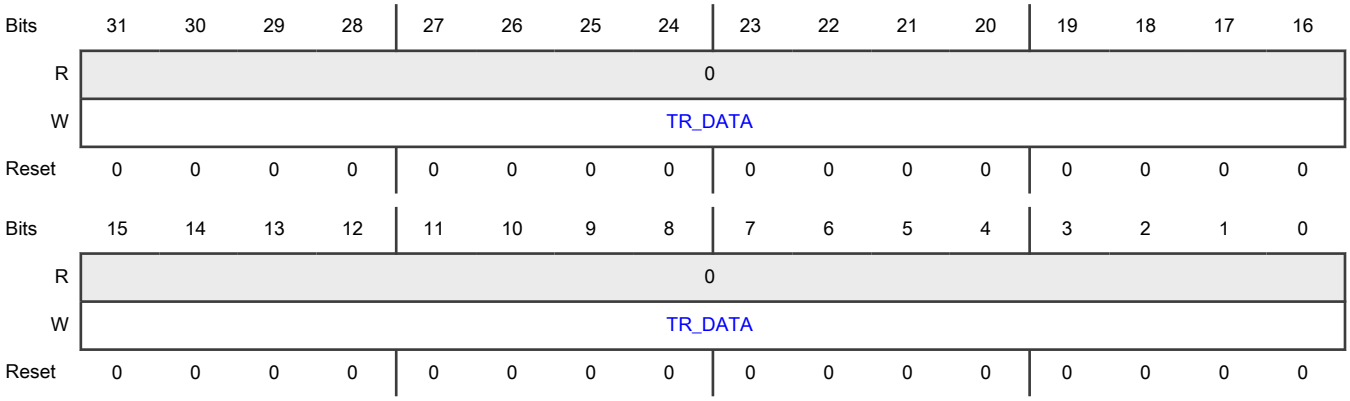
20.6.2.18 Transmit (TR0 - TR3)

Contains MUB transmit data.

Offset

Register	Offset
TR0	200h
TR1	204h
TR2	208h
TR3	20Ch

Diagram



Fields

Field	Description
31-0 TR_DATA	MUB Transmit Data Contains MUB transmit data. MUA_RR*n* reflects the data written to this register. The TR*n* and RR*n* registers are not double-buffered. Writing to MUB_TR*n* overrides the data readable in the MUA_RR*n* register. A write to the Transmit register clears MUB_TSR[TE*n*] on the transmitter side, and sets MUA_RSR[RF*n*] on the receiver side. You can write to this register only when MUB_TSR[TE*n*] = 1. Reading this register returns all zeroes.

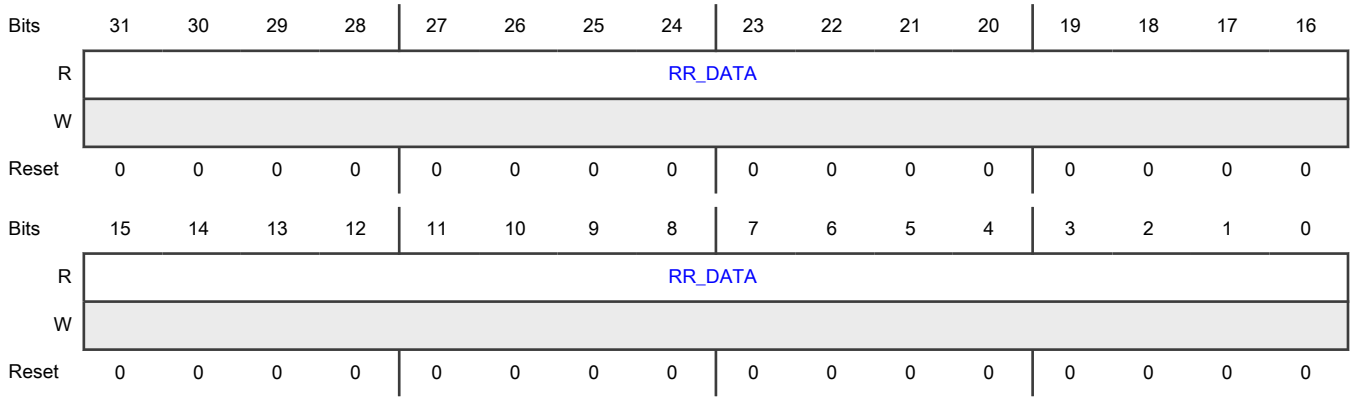
20.6.2.19 Receive (RR0 - RR3)

Contains MUB receive data.

Offset

Register	Offset
RR0	280h
RR1	284h
RR2	288h
RR3	28Ch

Diagram



Fields

Field	Description
31-0 RR_DATA	MUB Receive Data Reflects the data written to MUA TR*n*. Reading this register clears MUB_RSR[RF*n*] on the receiver side, and sets MUA_TSR[TE*n*] on the transmitter side. You can read this register only when MUB_RSR[RF*n*] = 1. Reading it before MUB_RSR[RF*n*] becomes 1 may result in reading incorrect data. Poll MUB_RSR[RF*n*] to confirm it is set before reading RR*n*. Writing to this register generates an error response to MUB.

Chapter 21
Semaphores2 (SEMA42)

21.1 Overview

SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single - write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

NOTE

Terminology in this chapter has been updated as follows:

Table 98. Updated terms

Updated term	Deprecated term
Initiator	Master
Target	Slave
Stop	Abort

21.1.1 Block diagram

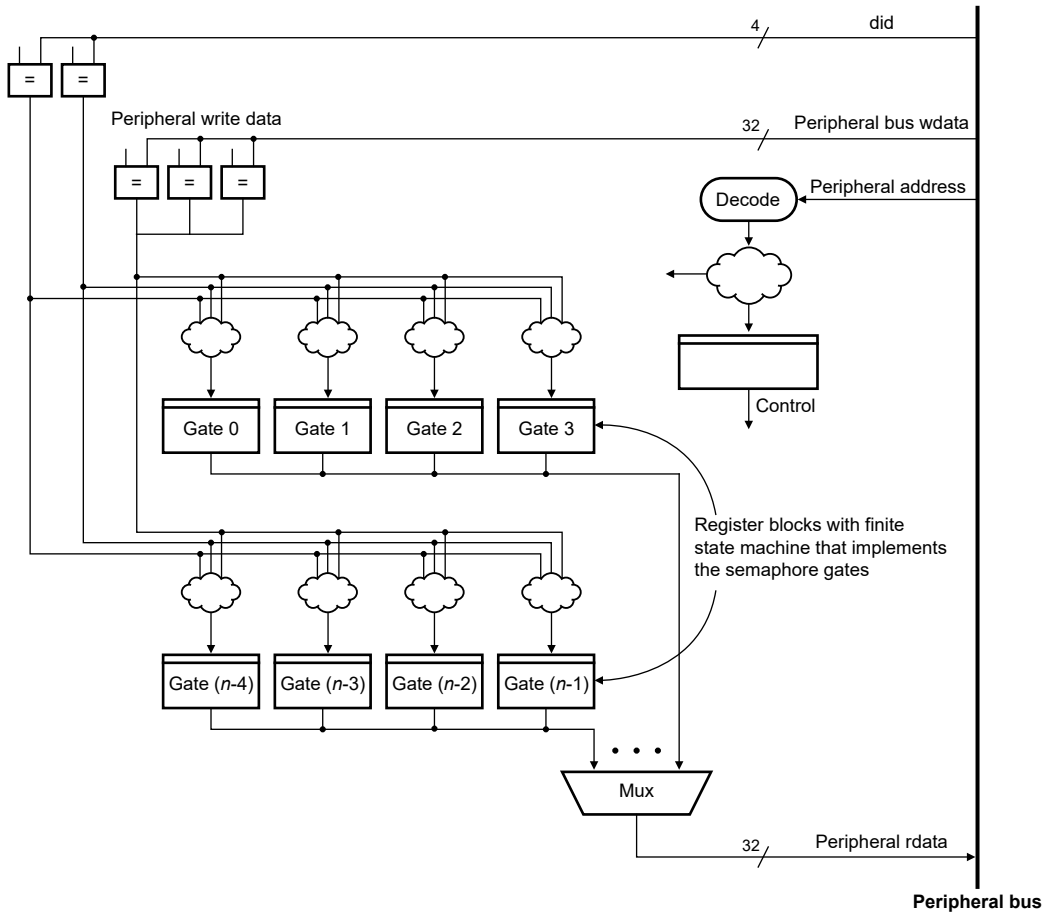

Figure 39. SEMA42 block diagram

21.1.2 Features

SEMA42 implements hardware-enforced semaphores as an IPS-mapped target peripheral device. The feature set includes:

- Support for 64 hardware-enforced gates in a multi-domain configuration that supports up to 15 domains.
- Each hardware gate appears as a 16-state, 4-bit state machine.
- Support for secure reset mechanisms to clear the contents of individual gates, as well as a clear-all capability.
- Memory-mapped target peripheral that offers programming-model accesses.

21.2 Functional description

The intent of the hardware gate implementation is to specify a protocol where the locking domain must unlock the gate. However, some systems may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset. To support this special gate reset requirement, SEMA42 implements a secure reset mechanism that allows you to initialize a hardware gate (or all the gates) by following a specific dual-write access pattern. The secure-gate reset:

- Uses a technique similar to that required for the servicing of a software watchdog timer
- Requires two consecutive writes with pre-defined data patterns from the same domain

You must do this to force the clearing of the specified gate(s). The required access pattern as follows:

1. A domain performs a 16-bit write to the RSTGT memory location. The most significant byte (RSTGT_W[RSTGDP]) must be E2h. The value of least significant byte is irrelevant for this reference and can be anything.
2. The same domain then performs a second 16-bit write to the RSTGT location. For this write, the upper byte (RSTGT_W[RSTGDP]) is the logical complement of the first data pattern (1Dh) and the lower byte (RSTGT_W[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate or all gates to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, SEMA42 stops the special gate reset sequence and does not assert an error signal.
3. Reads of the RSTGT location return information on the 2-bit reset state machine (RSTGT_R[RSTGSM]) that implements these functions:
   - The domain performing the reset (RSTGT_R[RSTGMS])
   - The last-cleared gate number(s) (RSTGT_R[RSTGTN])

   Reads of the RSTGT register do not affect the secure-reset finite state machine in any manner.

21.2.1 Multi-core programming: software gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism for system software to control access to shared data structures, shared hardware resources, and so on. The software uses the gating mechanisms to serialize (and synchronize) accesses to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and domains.

Consider the following description of a typical use-case: dm*X* enters a section of code, where shared data values are to be updated. The domain must first acquire a semaphore. Think of this as the locking (or closing) of a software gate. After the gate locks, a properly-architected software system does not allow other processes (or domains) to execute the same code segment or modify the shared data structure protected by the gate. In other words, the system locks out other processes/domains. Many software implementations include a spin-wait loop within the lock function until the gate locks. After domain X obtains the lock, domain X continues execution and updates the data values protected by the particular lock. After domain X completes the updates, it unlocks (or opens) the software gate, allowing other processes/domains access to the updated data values.

A correctly-implemented system solution must follow these important rules:

- A gate variable must protect all writes to shared data values or shared hardware resources.
- After a domain locks a gate, the system must block other processes/domains from accessing the shared data or resources. Software conventions enforce this.
- The domain that locks a particular gate is the only domain that can open (unlock) that gate.

Information in the hardware gate identifying the locking domain can be extremely useful for system-level debugging.

21.2.2 64 Hardware-enforced gates

Gates appear as a 64-entry byte-size array with read and write accesses.

Domains lock gates by writing "domainID_number+1" to the appropriate gate and must read back the gate value to verify that the lock operation succeeded.

After the gate locks, the locking domain unlocks the gate by writing zeroes.

- 16-state implementation

  If gate = 0h, then state = unlocked

  if gate = 1h, then state = locked by domain (initiator) 0

  if gate = 2h, then state = locked by domain (initiator) 1

  …

  if gate = Fh, then state = locked by domain (initiator) 14

SEMA42 uses the logical domain number and the specified data patterns as reference attributes to validate all write operation.

After a gate locks, the locking domain must unlock the gate by writing zeroes.

21.2.3 State machine of the GATE*n* registers

This section describes more about the SEMA42 functional operation and specific details of the state machines of the GATE*n* registers.

As described previously, each of the GATE*n* registers implements a 4-bit, 16-state machine. The following figure shows a simplified diagram of the state transitions for each gate.

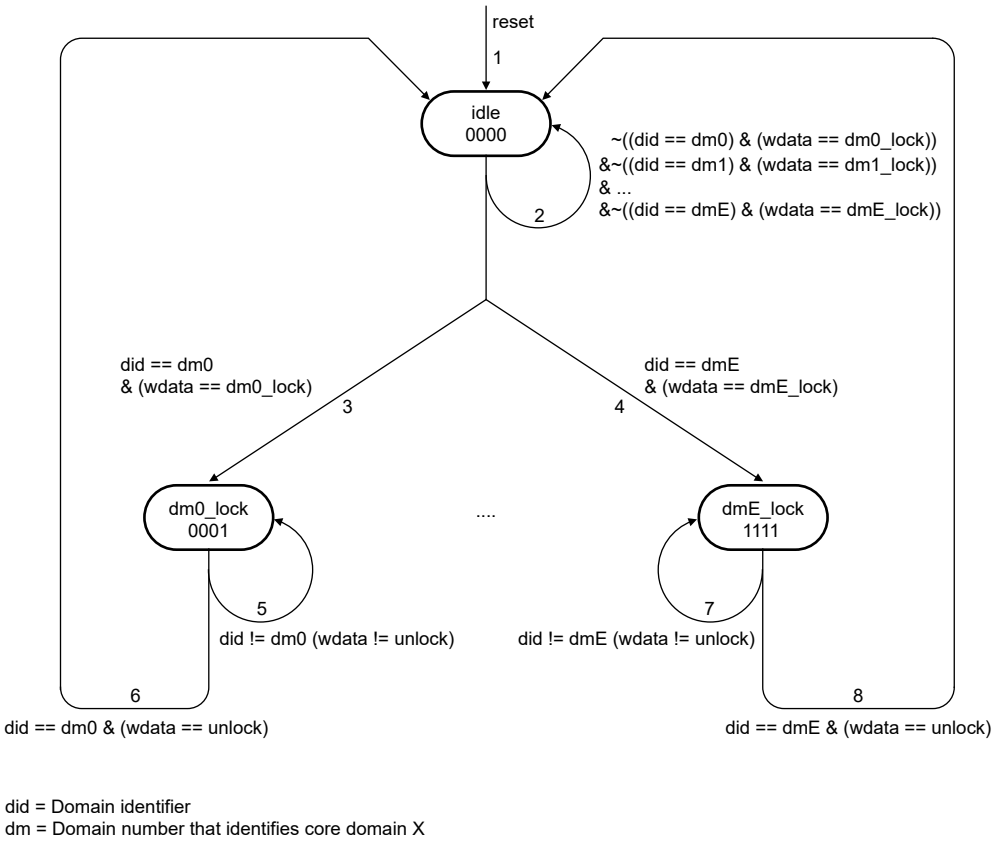

Figure 40. GATE*n* state machine

In the figure above, "dmE" represents domain 14 (E in hexadecimal). The platform passes the domain number to SEMA42.

The following table defines the GATE*n* state transitions.

Table 99. GATE*n* state transitions

Current state	Next state	Transition	Description
–	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding domain occurs, the gate remains in the idle state.
idle	dm0_lock	3	When domain 0h initiates a write of the dm0_lock data value, the gate transitions into the dm0_lock state.

Table continues on the next page...

Table 99. GATE*n* state transitions (continued)

Current state	Next state	Transition	Description
idle	dmE_lock	4	When domain Eh initiates a write of the dmE_lock value, the gate transitions into the dmE_lock state.
dm0_lock	dm0_lock	5	When in this state, the gate remains here if any attempted write is not from domain 0h with the unlock data value.
dm0_lock	idle	6	The gate returns to the idle (unlocked) state after a write from domain 0h with the unlock data value occurs.
dmE_lock	dmE_lock	7	When in this state, the gate remains here if any attempted write is not from domain Eh with the unlock data value.
dmE_lock	idle	8	The gate returns to the idle (unlocked) state after a write from domain Eh with the unlock data value occurs.

SEMA42 uses these gate data values:

- The lock data value is (domain number) + 1.
- The unlock data value is 00h.

21.2.4 Clocking

Type of clock	Description
Module clock (clk)	Functions the module and controls the access to the registers.

21.2.5 Interrupts

This module has no interrupts.

21.3 External signals

This module has no external signals.

21.4 Initialization

This module does not require initialization.

21.5 Memory map/register definition

You can access these registers only in Supervisor mode. User accesses terminate with an error.

21.5.1 SEMA42 register descriptions

21.5.1.1 SEMA42 memory map

SEMA42_1 base address: 4426_0000h

SEMA42_2 base address: 4245_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0 - 3F	Gate (GATE0 - GATE63) [1]	8	RW	00
42	Reset Gate Read (RSTGT_R)	16	R	0000
42	Reset Gate Write (RSTGT_W)	16	W	See section

1. In this array, the index and offset values of the registers do not increment in direct alignment. For details, see the register description.

21.5.1.2 Gate (GATE0 - GATE63)

Implements each semaphore gate in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical domain-identifier number in conjunction with the data patterns to validate all attempted write operations. Only domain initiators can modify the gate registers. After a gate locks, only the locking domain must open (unlock) the gate.

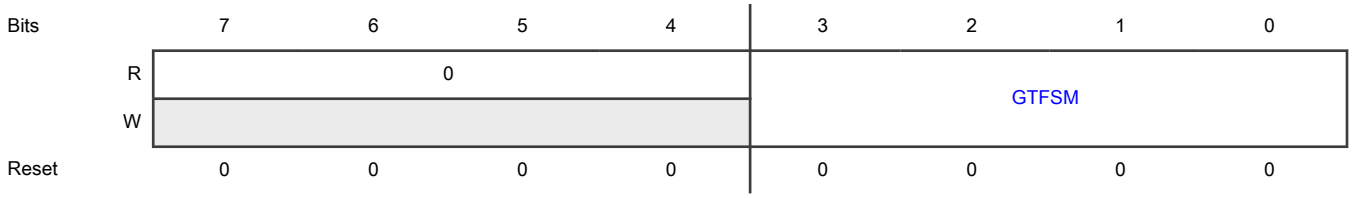
You can read multiple gate values in a single access. However, you can update only a single gate at a time, via a write operation. If you attempt to write a byte-wide value that is neither the unlock value (00h) nor the appropriate lock value (domainID_number + 1), SEMA42 considers this as "no operation" and does not change any gate state. Attempts to write multiple gates in a single-aligned access with a size larger than 8 bits (byte) generate an error termination and do not allow any gate state changes.

Offset

For n = 0 to 63:

Register	Offset
GATEn	0h + (n + 3 - 2 × (n mod 4))

Diagram



Fields

Field	Description
7-4 —	Reserved
3-0 GTFSM	Gate Finite State Machine Indicates the state of the gate for the last domain that locked the gate. This can be useful during system debug. The hardware gate has a 16-state implementation, defined as:

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0000 - The gate is unlocked (free). 0001 - Domain 0 locked the gate. 0010 - Domain 1 locked the gate. 0011 - Domain 2 locked the gate. 0100 - Domain 3 locked the gate. 0101 - Domain 4 locked the gate. 0110 - Domain 5 locked the gate. 0111 - Domain 6 locked the gate. 1000 - Domain 7 locked the gate. 1001 - Domain 8 locked the gate. 1010 - Domain 9 locked the gate. 1011 - Domain 10 locked the gate. 1100 - Domain 11 locked the gate. 1101 - Domain 12 locked the gate. 1110 - Domain 13 locked the gate. 1111 - Domain 14 locked the gate.

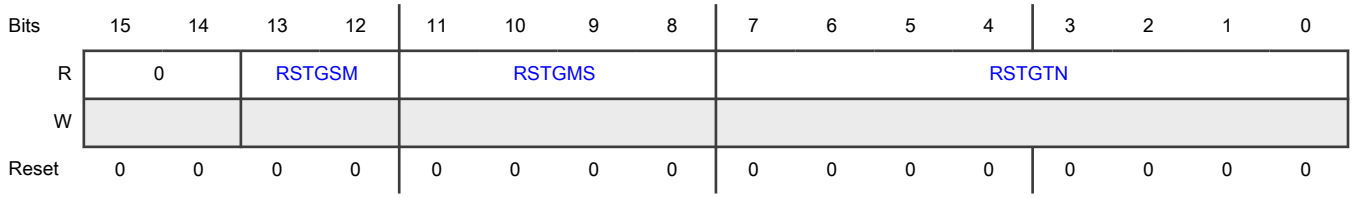
21.5.1.3 Reset Gate Read (RSTGT_R)

Describes the specific hardware gate to be reset and records the logic number of domain. Reset Gate Write (RSTGT_W) also describe the same register showing the fields when you write it.

Offset

Register	Offset
RSTGT_R	42h

Diagram



Fields

Field	Description
15-14 —	Reserved
13-12 RSTGSM	Reset Gate Finite State Machine Indicates the encoded state machine value when you read the register. RSTGSM = 10b is valid for only a single machine cycle, so a read can never return this value. SEMA42 maintains the reset state machine in a 2-bit, 3-state implementation, defined as follows: 00 - Idle, waiting for the first data pattern write. 01 - Waiting for the second data pattern write 10 - The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. 11 - This state encoding is never used and therefore reserved.
11-8 RSTGMS	Reset Gate Domain Records the logical number of the domain performing the gate reset function. To succeed, this function requires that the same domain initiate the two consecutive writes to this register. SEMA42 updates the field each time a write to this register occurs.
7-0 RSTGTN	Reset Gate Number Specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

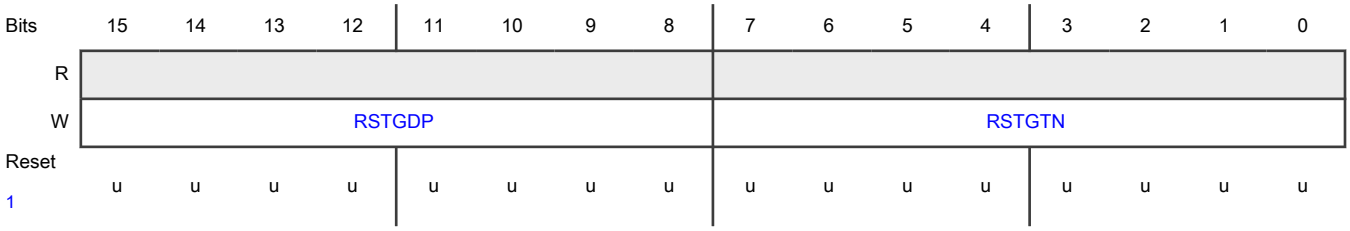
21.5.1.4 Reset Gate Write (RSTGT_W)

Specifies the hardware gate to reset when data patterns are specified.

Offset

Register	Offset
RSTGT_W	42h

Diagram



1. Reset value is not applicable for writes.

Fields

Field	Description
15-8 RSTGDP	Reset Gate Data Pattern You access this field with the specified data patterns on the two consecutive writes to enable the gate-reset mechanism. For the first write, RSTGDP must be E2h. For the second write, RSTGDP must be 1Dh.
7-0 RSTGTN	Reset Gate Number Specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

21.6 Glossary

Chapter 22
Trusted Resource Domain Controller (TRDC)

22.1 Chip-specific TRDC information

Table 100. Related information in i.MX 93 Applications Processor Reference Manual

Topic	Related module
CM33	Arm Cortex CM33 Platform (CM33)
A55	Arm Cortex CA55 Platform (CA55)
Full description	Trusted Resource Domain Controller (TRDC)
System memory map	Memory Maps
Clocking	Clock Controller Module (CCM)
Signal multiplexing	Port control

NOTE

A core complex should not rely on TRDC and should use the internal MMU for memory management. In addition, initiators like Cortex-A55, that implement the DSU architecture, do support AxPROT internally, but do not drive AxPROT[2] and AxPROT[0] on the system bus. For Cortex-A55, after boot, it is recommended to use the internal MMU for access control.

22.1.1 Module instances

This device has six instances of the TRDC module:

- TRDC AONMIX
- TRDC WAKEUPMIX
- TRDC MEGAMIX
- TRDC NICMIX
- TRDC MEDIAMIX
- TRDC HSIOMIX

NOTE

TRDC settings will be lost if the mix power is off.

NOTE

This chip does not support Flash Logical Window (FLW). The registers for FLW exists but have no effect on device operation.

NOTE

TZ-M is enabled on this chip. TRDC components - MGR, MDAC, MRC and MBC cannot be accessed in a non-secure mode.

22.1.2 Chip-specific TRDC information

Table 101. TRDC MGR Configuration

22.1.3 TRDC MDAC Configuration

Table 103. TRDC Configuration

DAC_INST_NUM	This value is the instance number of the MDAC for a give TRDC master.
MASTER	Specifies the master to perform region/domain checking.
Switch/Port	Connect to NIC, NoC system fabric port.
Location	Specifies which subsystem the TRDC master and MRC component is located in.
BUS Type	Specifies the Slave Memories Bus Type to connect to the MRC.
DAC_REG_NUM	For CPU DACs, this typically depends on the number of processing IDs that the connected CPU will generate, or

Table continues on the next page...

Table 103. TRDC Configuration (continued)

	the number of PID values that software will use for context switches. For non-CPU DACs, this is set to 1. Only one register is needed for non-CPU DAC to source the DID/Secure/Priv attributes for the master.
DAC_CPU	Set to 1 for any "CPU" master that could do context switching.
DEFAULT_DID	This is the DID value that is driven out by the MDAC when MDAC_EN_DDID is set and the MDAC is not yet valid/enabled.
DAC_INST_PID_IN	For DACs connected to CPUs, there's an optional PID input and PID registers. If the processor/CPU connected to DAC sources a process-ID, the integrator would connect that bus to the MDAC and enable this parameter. If the CPU does not source a PID, the user can program the PID registers in the MDAC. Software saves and restores this PID with any context switch.
MAX_DOMAIN_MAPPING	Specifies the number of domains.

Table 104. TRDC MDAC Configuration

TRDC location	MDAC	DAC_INST_NUM	MASTER	DAC_REG_NUM	DAC_CPU	DEFAULT_DID	DAC_INST_PID_IN

NOTE

Access on WAKEUPMIX MRC_W2 will not return transfer error.

NOTE

MRCs should be used to check non-contiguous memory space.

22.2 Overview

TRDC provides an integrated and scalable architectural framework for access control, system memory protection, and peripheral isolation. It allows software to assign chip resources including processor cores, non-core bus initiators, memory regions, and peripherals to processing domains to support enforcement of robust operational environments.

- First, each bus initiating resource is assigned to a domain identifier (domainID, DID). Typically, each processor is assigned to a unique domainID and all remaining non-processor bus initiators assigned to a different domainID.

- Next, the access control policies for the individual domains are programmed into any number of registers implemented in the target memory block and region checkers.
- Finally, all accesses throughout the device are monitored concurrently to determine the validity of each access. If a reference from a given domain has sufficient access rights, it is allowed to continue, else the access is aborted and error information captured.

The access control scheme that TRDC defines supports a 4-level model, combining the traditional privileged (also known as supervisor) and user modes with an additional signal defining the secure, nonsecure attributes of each memory reference. The result is a 4-level hierarchical access control mechanism with different access control policies based on read, write, and execute references, where:

SecurePriv > SecureUser > NonsecurePriv > NonsecureUser

Combined with the secure/nonsecure and privileged/user attributes, a domainID is associated with every system bus transaction and forms the hardware basis for the implementation of TRDC's access control mechanisms.

NOTE

The terminology in this chapter has been updated to align with NXP's inclusive language standards, as shown in the table below.

Table 107. Updated terms

Updated term	Deprecated term
Initiator	Master
Target	Slave

22.2.1 Block diagram

As previously noted, the TRDC implementation is distributed across multiple submodules instantiated throughout the device. The TRDC submodules include:

- TRDC_MGR
  - The Manager (MGR) submodule coordinates all programming model reads and writes.
- TRDC_DAC
  - The Domain Assignment Controller (DAC) submodule handles resource assignments and generation of the domain identifiers.
- TRDC_MBC
  - The Memory Block Checker (MBC) submodule implements access controls for on-chip internal memories and peripherals based on a fixed-sized block format.
- TRDC_MRC
  - The Memory Region Checker (MRC) submodule implements the access controls for external off-chip memories and peripherals based on the pre-programmed region descriptor registers.

See Figure 41 for a simplified TRDC block diagram focusing on topology and connections.

NOTE

TRDC typically consists of various submodules like DAC, MGR, MBC, and MRC. However, all the submodules as shown in the block diagram below may not be present for this configuration. For chip-specific implementation details of this module's instances, see the chip-specific information.

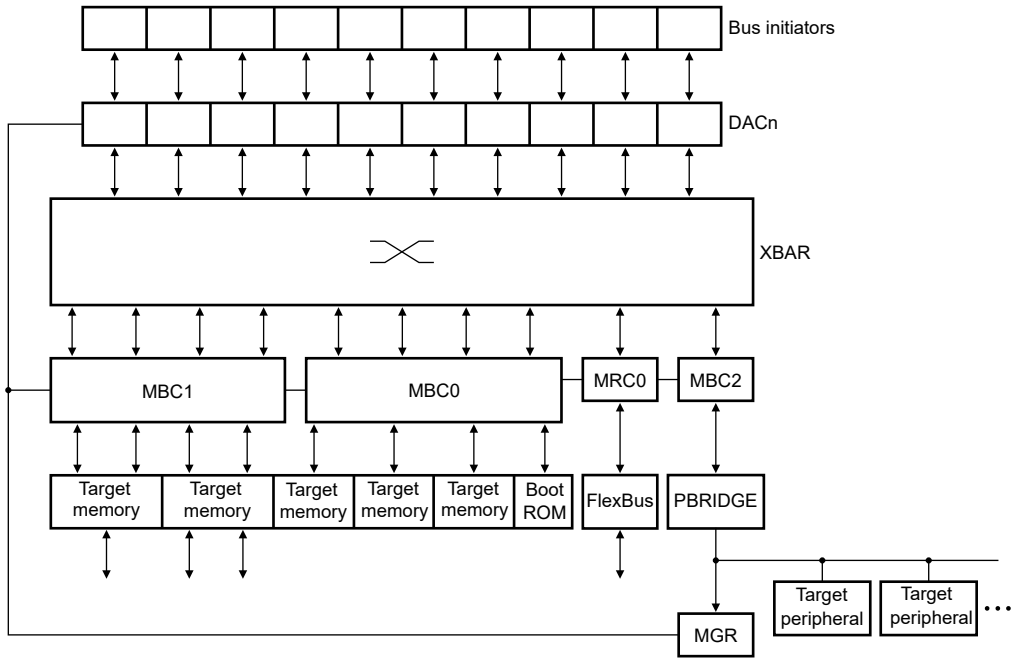

Figure 41. Block diagram

22.2.2 Features

- Ability to assign chip resources to processing "domains":
  - Processor cores, non-core bus initiators, target memories, and target peripherals
  - Each processing domain is assigned a unique domain identifier (domainID, DID)
  - DomainID is an attribute associated with every system bus transaction
  - Used in conjunction with secure/nonsecure, privileged/user attributes
- Defines access rights to targets in MBCs for on-chip memories and peripherals and in MRCs for external memories and peripherals
- Built upon a 4-level hierarchical access control model:
  - SecurePriv > SecureUser > NonsecurePriv > NonsecureUser
  - Defined by multiple sets of user-programmable R/W/X (Read, Write, Execute) flags per access state
- Distributes programming model and hardware implementation across multiple submodules:
  - Supports a broad, highly-configurable architecture definition
  - Supports efficient mechanisms for memory space context switch state changes using nonsecure enables (NSE) for memory blocks and regions

22.3 Functional description

This section provides more details on the operation and implementation of the TRDC submodules.

22.3.1 Modes of operation

TRDC does not support any special modes of operation. As a memory-mapped device located in the core platform's clock domain, it responds strictly on the basis of memory addresses of the connected system buses. TRDC evaluates domain assignment

and access control functions on a reference-by-reference basis using the addresses and attributes connected to the system bus port(s).

22.3.2 Manager (TRDC_MGR)

The MGR submodule is responsible for coordinating TRDC's programming model reads and writes.

The complete programming model is large. Additionally, the programming model is distributed across the various submodule instances (DAC, MBC, MRC).

MGR provides:

- The required hardware management for all programming model accesses.
- Generating and distributing the appropriate address decodes and write data to the DAC, MBC, and MRC submodule instances.
- Collecting and combining all the register read data buses and responses.

MGR implements:

- The Control Register
- All the read-only hardware configuration registers (HWCFG[0-1], DACFGn, MBCm_MEMs_GLBCFG, MRC_GLBCFG)
- The program-visible versions of the domain error capture registers.

To support the domain error reporting functionality, MGR collects the individual captured error indicator output signals from all the submodule instances and remaps them so that they are organized into an instance bitmap by domain that the DERRLOCn register array specifies.

22.3.3 Domain Assignment Controller (TRDC_DAC)

The DAC submodule is responsible for the generation of the domainID on every memory transaction for every bus initiator in the device. The resulting domainID, and {nonsecure, privileged} signals are generated and then treated as address attributes and associated with each transaction as it moves through the system.

DAC modules that drive the domainIDs (DIDs) for processor cores include an option of processor-identifier (PID) matching to select between DIDs. You can accomplish this by first enabling PID checking by writing TRDC_MDA_Wm_n[PE] = [2,3]. With PID matching enabled, a domain hit is determined by matching TRDC_MDA_Wm_n[PID] with the PID input or PID in the TRDC_PID register. The PIDM field can be used to match specific groups of PIDs.

As a simple example, assume a system with two domainIDs.

- domainID 0 is for critical tasks.
- domainID 1 is for non-critical tasks.
- Two domainIDs require two MDA_Wm_n registers, MDA_W0 and MDA_W1.

Further assume the processor’s task identifier defines whether a task is critical or non-critical as defined by system software.

- PIDs [0-15] are assigned to critical tasks.
- PIDs != [0-15] are assigned to noncritical tasks.

During startup, software initializes the MDA_W[0-1] registers. MDA_W0 defines DID = 1 for PIDs [0-15] and MDA_W1 defines DID = 2 for PIDs != [0-15].

1. MDA_W0 = 0x8000_0F81
    - VLD = 1
    - PID = 0x0
    - PIDM = 0xF
    - PE = 2

- DIDS = 0
- DID = 1

2. MDA_W1 = 0x8000_0FC2
   - VLD = 1
   - PID = 0x0
   - PIDM = 0xF
   - PE = 3
   - DIDS = 0
   - DID = 2

As the processor executes, it loads the appropriate task ID into its PID register as the task is started. The processor's PID register value is input to the corresponding DAC module and used by the MDA_Wr_m comparison logic. The system then dynamically generates two domainIDs and the downstream TRDC access check logic can distinguish and enforce different access control rights based on the different domainIDs.

A special mode is provided for driving the DID of non-processor initiators. This is enabled with the DID bypass (DIDB) bit. The DAC has a DID input that can be driven by a initiator and used directly as the DID output. This allows variability in the DID as dictated by the initiator and is intended to be used by DMA initiators that masquerade as, (that is, drive the DID of) the initiator that programmed it.

22.3.4 Access evaluation

Fundamental to the TRDC's operation is the actual access violation check performed by the memory block checker (MBC) and memory region (MRC).

Previous descriptions have detailed the domain assignment mechanisms and the tracking of the domain identifier as an address attribute through the system bus switching fabric(s). As transactions reach the target memory and peripheral controllers, the address is used to select the appropriate memory region descriptor or block configuration register. Once the appropriate register has been selected, the next function is the actual access evaluation.

For this step, the 3-bit M{B,R}ACSEL field of the selected RGD or BLK_CFG register selects the appropriate GLBAC (global access control policy). The GLBAC register defines the access rights for the domain based on the 4-level model combined with the transaction's access attributes (read = 0/write = 1, secure = 0/nonsecure = 1, execute =1/non-execute=0, user = 0/privileged = 1).

The 4-level model is defined by the concatenation of two address attributes: secure/nonsecure and user/privileged attributes. These two attribute signals (nonsecure, privileged) and the resulting access levels are defined as:

```
if {nonsecure, privileged} == 0b00, then level = SecureUser
if {nonsecure, privileged} == 0b01, then level = SecurePriv(ileged)
if {nonsecure, privileged} == 0b10, then level = NonsecureUser
if {nonsecure, privileged} == 0b11, then level = NonsecurePriv(ileged)
```

The resulting hierarchical access control model specifies:

```
SecurePriv , SecureUser , NonsecurePriv , NonsecureUser
```

After the access evaluation is complete and the access error signal generated, the transaction is allowed to continue if it has sufficient access rights, else the access is aborted with the address and attribute information captured in the appropriate error registers.

22.3.5 Memory Block Checker (TRDC_MBC)

The TRDC's Memory Block Checker provides domain-based access control for all system bus references targeted to on-chip internal memories and peripherals. Using programmed block configuration registers which define the access rights per domain and block, the MBC concurrently monitors system bus transactions and evaluates the appropriateness of each transfer. Memory

references that have sufficient access rights are allowed to complete, while references that have insufficient rights are terminated with an access error response.

The TRDC architectural framework supports up to 8 MBC instances where each MBC can support up to 4 sub-regions (MEM[s]). Note monitoring of an AXI memory counts as 2 sub-regions since there are independent read and write channels per AXI memory. Conversely, an AHB connection counts as a single subregion.

Each sub-memory is divided up in equal sized consecutive blocks. Sub-memory 0 (MEM0) can support up to 512 blocks while sub-memory 1-3 (MEM1-MEM3) can each support up to 64 blocks. The number of blocks and size of the block is defined in MBCm_MEMs_GLBCFG[NBLKS,SIZE_LOG2] register fields, where m is the MBC instance number, and s is the sub-memory number. For example, Sub-memory 0 (MEM0) may have 16 consecutive blocks, each of size 64 KB, and corresponding MBCm_DOMd_BLK_CFG_W register to a block will control access to that block.

Each MBCm_DOMd_BLK_CFG_W contains eight access control structures. Each structure is comprised of a 1-bit NSE (NonSecure Enable) plus a 3-bit MBACSEL (Memory Block Access Control Select). The NSE controls secure/nonsecure access to the corresponding block, while the MBACSEL field selects a MBCm_MEMN_GLBACr register which controls the read/write/execute access to the corresponding block. There are 8 programmable MBCm_MEMn_GLBACr registers per block checker, each containing contain read-write-execute control flags for each of the four operating modes:

```
SPR, SPW, SPX - Secure    Privileged {Read, Write, Execute}
SUR, SUW, SUX - Secure    User       {Read, Write, Execute}
NPR, NPW, NPX - Nonsecure Privileged {Read, Write, Execute}
NUR, NUW, NUX - Nonsecure User       {Read, Write, Execute}
```

GLBAC1-7 also have a lock bit MBCm_MEMn_GLBACr[LK]. When LK=1, the GLBACr register is read-only until the next reset. Furthermore, if MBCm_DOMd_BLK_CFG_W[MBACSEL] selects a GLBAC that is locked, the 3-bit MBCACSEL field is also locked until the next reset. GLBAC0 cannot be locked.

The MBC also has MBCm_DOMd_MEMs_BLK_NSE_W registers. These registers are a bit map of the block NSE bits. Each word supports up to 32 blocks.

```
MBCm_DOMd_MEM0_BLK_NSE_W[0-15] has a maximum of 16 words to support 512 blocks
MBCm_DOMd_MEM[1-3]_BLK_NSE_W[0-1] has a maximum of 2 words to support 64 blocks.
```

The block NSE bits can be programmed by writing these registers or by writing the MBCm_MEMN_BLK_{INDEX, SET, CLR, CLR_ALL} registers.

The MBCm_MEMn_NSE_BLK_{INDEX, SET, CLR, CLR_ALL} registers provide a mechanism to efficiently and quickly manipulate the NSE bitmap with bitmasks to set or clear individual blocks within the bitmap and a single operation to perform a clear all across multiple DIDs. The BLK_INDEX register provides the control definition for the BLK_SET and BLK_CLR operations.

22.3.5.1 Memory block hit determination

MBCm_MEMs_GLBCFG[NBLK, SIZE_LOG2] is used to determine which bits of the address correspond to block number.

```
block_n_hit = (addr[MSB:LSB] == n)
where LSB=SIZE_LOG2
MSB=f{NBLKS,LSB}
```

Note that the block hit determination is based only on the address comparison of the first byte being accessed; that is, the MBC does not check the size of the access to make sure it entirely fits within the region.

22.3.5.2 Memory block access evaluation

For a block n hit, the MBC logic evaluates the access rights defined by the MBCm_DOMd_BLK_CFG_Ww registers. The domainID attribute and block number hit selects the appropriate MBCm_DOMd_BLK_CFG_Ww register to use in the access evaluation. The {R,W,X}, nonsecure and privilege attributes of the access are compared with the MBC global access control policy defined in MBCm_DOMd_BLK_CFG_W[MBACSEL, NSE] fields.

While TRDC_CR[GVLDB] = 1, and for each sub-memory being monitored, the MBC performs a reduction-AND of all the individual error terms from each access evaluation.

Unlike the MRC access evaluation and termination, the MBC access evaluation terminates the access with a bus error and reports an access error for only one condition - when the access doesn't have sufficient access rights. By nature, the block checker can only hit in ONE block, and by implementation, there are no "miss" accesses. Accesses outside of the range covered by the MBC are not sent to the MBC. There also aren't any individual block valid bits. When TRDC_CR[GVLDB] = 1, checking on all blocks is always enabled.

22.3.6 Memory Region Checker (TRDC_MRC)

The TRDC's Memory Region Controller provides domain-based, hardware access control for all system bus references targeted at non-peripheral memory spaces. Using pre-programmed *region descriptors* which define memory spaces and their associated access rights per domain identifier, the MRC concurrently monitors system bus transactions and evaluates the appropriateness of each transfer. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

The TRDC architectural framework supports up to 16 MRC instances, where each MRC instance can support [1-16] region descriptors, concurrently monitoring up to 8 target memory ports. Note, monitoring an AXI protocol port counts as two ports since there are independent read address and write address channels. Conversely, an AHB connection counts as a single port.

A partial, simplified one-dimensional block diagram of an instance of the MRC module is shown in Figure 42. In this figure, a single target bus port is shown. When the remaining target ports are considered, the MRC hardware's two-dimensional connection matrix, broadcasting each system bus target port access across the implemented memory region descriptors, is the resulting structure with the basic access evaluation macro shown as the replicated submodule block. In Figure 42, the system bus fabric target port is shown on the left, the memory region descriptor registers are in the middle, and the peripheral bus interface on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and, based on the domainID associated with the reference, access violations.

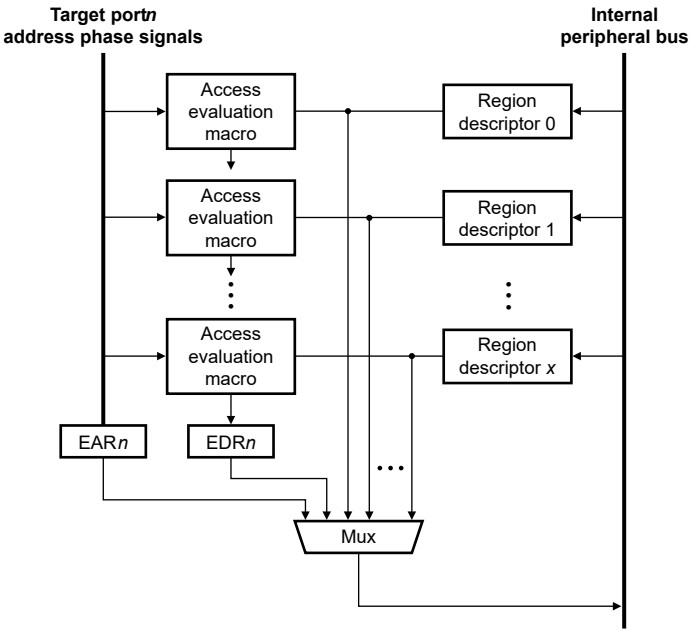

Figure 42. MRC access evaluation macro hardware structure

For each access, the MRC hardware performs a two-step evaluation process. First, the access is compared to all memory region descriptors to determine hit/miss status, and then, using the domainID associated with the reference plus the address attributes {write, nonsecure, privileged}, the access rights are examined using the method detailed in Access evaluation.

22.3.6.1 Memory region descriptor hit determination

To determine if the current reference hits in a given region, two magnitude comparators are used in conjunction with the region's start and end addresses. The boolean equation for this portion of the hit determination is defined as:

```
region_hit_n =
   ((addr >= start_addr) & (addr <= end_addr)) & valid
```

where `addr` is the current system reference address, `start_addr` and `end_addr` are the start and end addresses, and `valid` is the valid bit, all from memory region descriptor n.

Note there are *no hardware checks* to verify that `end_addr ≥ start_addr`, and it is software's responsibility to properly load appropriate values into these fields of the region descriptor.

Also, the region hit determination is based only on an address comparison of the first byte being accessed; that is, the MRC does *not* check the size of the access to make sure it entirely fits within the region.

22.3.6.2 Memory region access evaluation

For each region descriptor hit, the MRC logic evaluates the access rights defined by the MRCm_DOMd_RGDr_Ww registers. Specifically, the domainID attribute selects the appropriate MRCm_DOMd_RGDr_Ww register to use in the access evaluation. The {R,W,X}, nonsecure and privilege attributes of the access are compared with the MRC global access control policy defined in MRCm_DOMd_RGDr_W0[MRACSEL] and MRCm_DOMd_RGDr_W1[NSE] fields. See Access evaluation for additional details on this function.

While TRDC_CR[GVLDR] = 1, and for each bus target port being monitored, the MRC performs a **reduction-AND** of all the individual *(no_hit | error)* terms from each access evaluation macro. Recall as specified in Memory region descriptor hit determination, an *invalid* MRC_DOMd_RGDr_Ww (MRCm_DOMd_RGDr_W1[VLD] = 0) forces the region_hit_n evaluation to be negated.

This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. If the access does not hit in *any* region descriptor, an access error is reported.
2. If the access hits in a single region descriptor and that region signals a domain violation, then an access error is reported.
3. If the access hits in multiple (overlapping) regions and one region signals a violation, then an access error is reported.

The third condition reflects that priority is given to access denying over access allowing for overlapping regions.

Unimplemented domain IDs (DIDs) do not have any associated region descriptors and therefore have no access rights.

22.3.7 Interrupts

This module outputs an interrupt signal which can be connected to the system's interrupt controller. Please check chip-specific interrupt assignment for details. Interrupt is asserted on detection of access violation by any checker, and it remains asserted until DERRLOCn registers are cleared. This interrupt is in addition to interrupt generated by initiator after receiving bus error due to access violation by memory block checker or memory region checker. So, system may receive interrupt through different channels but from the same access violation at checker.

22.4 External signals

The TRDC module does not directly support any external interfaces.

The *internal* interfaces include a standard 32-bit target bus for all programming model accesses, connections to the address phase signals associated with AHB and/or AXI system buses and connections to the target peripheral buses as shown in TRDC block diagram.

22.5 Initialization

Out of reset, TRDC_CR[GVLDR, GVLDB, GVLDM] bits are cleared, TRDC is disabled and in deny by default mode allowing secure privileged startup code to configure the entire programming model. In deny by default mode, only the DIDs that aren't denied by default are allowed to access memory and peripherals. The allowed DIDs are implementation defined. The initialization process typically is performed in 3 steps:

1. Read the various hardware configuration registers (HWCFG{0,1}, DACFGn, MBCm_MEMs_GLBCFG, MRC_GLBCFG) to obtain the implemented hardware capabilities for the device.
2. Using the information retrieved in Step 1 coupled with the desired domain architecture, program all the register data structures for domain assignment (MDA_Wm_n), memory block configuration (MBCm_DOMd_MEMs_BLK_CFG_Ww) and memory region descriptors (MRCm_DOMd_RGDr_Ww). There are individual valid bits included in these registers which typically would be asserted. Additionally, there are also lock mechanisms available if register settings need to be configured and marked as read-only.
3. Once the TRDC programming model is loaded, the TRDC_CR is written with GVLD {R, B, M} asserted. Upon the assertion of the 3 GVLD bits, deny by default mode is exited and at that point, the TRDC is fully operational. The TRDC remains enabled until the next reset.

22.6 Application information

As described in Overview, the TRDC architecture is intended to provide a broad, highly-capable framework for access control, system memory protection and peripheral isolation. The resulting microarchitecture implementation is distributed throughout the core platform, highly configurable via hardware design parameters and software programmability.

22.6.1 Initiator domain assignments

The typical use case related to initiator domain assignments is to include one (or more) processor core(s) in a single domain, possibly coupled with other bus initiator devices like DMA, etc. The definition of a domain may be static, based simply on the combination of a processor and other optional bus initiators. Alternatively, the processor's operation may be configured to dynamically select between a very small number of domains. In particular, the optional inclusion of PID value(s) to be used to create multiple classes of CPU with different domain values.

For example, "critical" tasks, whether safety-critical, performance-critical, etc. can be grouped together in one domain and all other tasks into a second domain. Non-processor bus initiators typically have a single MDA_Wm_n configuration register associated with them. The domainID and {nonsecure, privileged} attributes are usually statically assigned, unless the module can "inherit" attributes from a processor programming it (certain modules like DMAs).

The MDA_Wm_n registers, along with the memory region descriptors and the peripheral domain access control registers all have lock features that allow the register resources to be converted into read-only resources to protect the written configuration.

22.6.2 Memory region descriptor management

There are important concepts to consider in managing the memory region descriptors.

Recall that the association between each MRCn instance and the target memory regions it monitors is SoC-dependent. The device-specific configuration specifies the number of implemented memory region descriptors in a given instance and the specific port numbers associated with the target memories being monitored.

22.6.3 Domain error capture management

Recall when a domain access violation is detected by either a memory region checker or a memory block checker, address and attribute information of the offending access is captured. The DERRLOCn read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_n and DERR_W1_n, the DERRLOCn registers provide the instance number details.

These registers are organized as a word array, *indexed by the faulting domain number*, with the contents of each register providing a bitmap signaling the instance number(s) associated with all submodules containing captured error information for that domain.

It is recommended that the exception handler begin by reading the HWCFG1 register to determine its domainID. Next, it uses the just-retrieved domainID to index into the DERRLOCn array. The resulting DERRLOCn value is then examined to determine the instance number of the reporting MBC and/or MRC submodule.

There may be multiple access violations, across multiple instances, pending for a given domain. It is suggested that exception handler use a "find first one" instruction (alternatively known as "count leading zeroes") to quickly and efficiently find the instance number containing access violation details. Once the instance number has been determined, the captured error address and attribute information can easily be retrieved from the domain error registers. For 32 bits address, the captured error address can be retrieved from DERR_W0_n and the attribute information can be retrieved from DERR_W1_n. For 36 bits address, the captured error address can be retrieved from DERR_W0_n and DERR_W1_n and the attribute information can be retrieved from DERR_W2_n. The 2-bit DERR_W1_n[EST] or DERR_W2_n[EST] field provides information signaling whether one or more errors have been detected by the submodule instance. A special write to DERR_W3_n is required to reset (and rearm) the EST error capture state machine.

This process is repeated until all errors associated with a given domainID have been processed.

A graphical representation of this 2-step retrieval of the domain error address and attributes is shown in Figure 43.

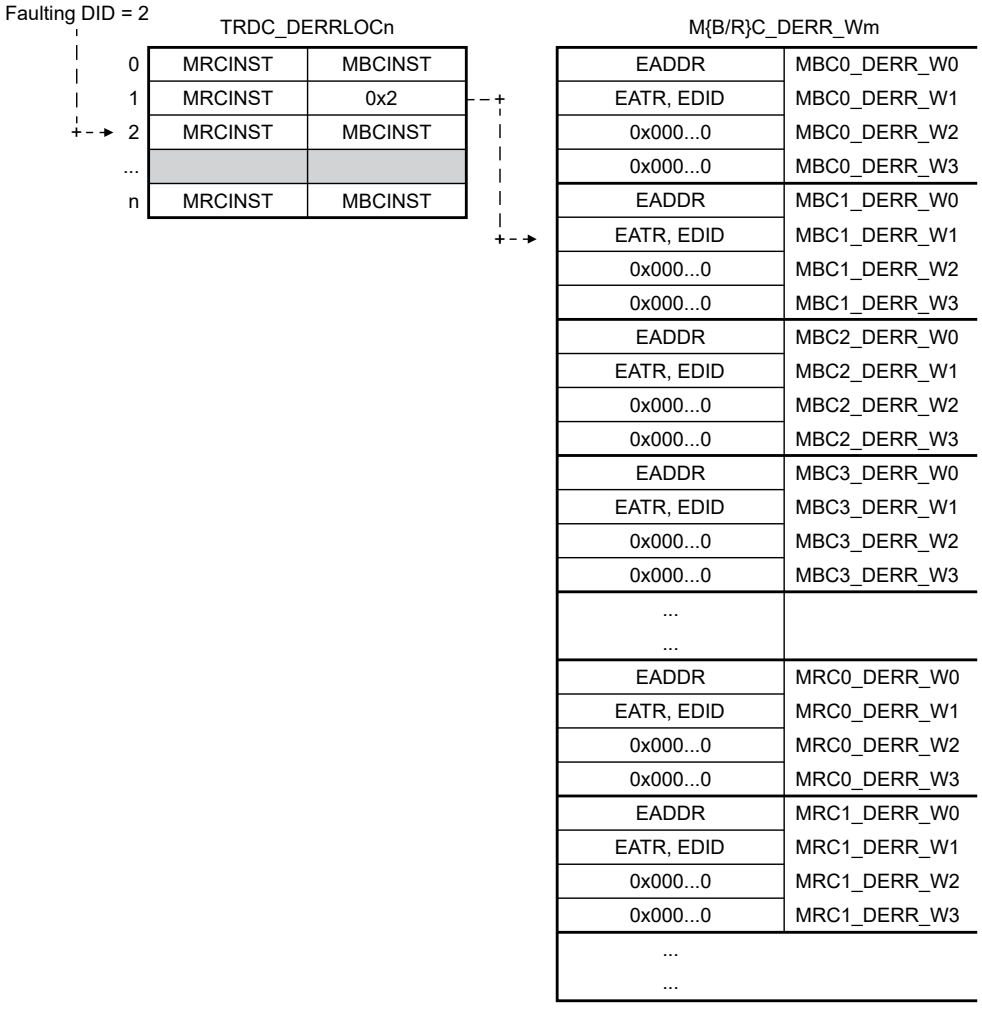

Figure 43. Two-step retrieval of domain error address and attributes

22.7 Register descriptions

The MBCm_NSE_BLK_SET, MBCm_NSE_BLK_CLR and MBCm_NSE_BLK_CLR_ALL registers exist at offset for only domain ID value 0 even when more than 1 domains exist, and address offsets for non-zero domain ID value should be considered reserved space. So, this reserved address space in MBC space does not return transfer error: 0xn14 to 0xn1C where n = (1 to NUM_DID-1) * 2 for each MBC.

If TZ-M is enabled, the TRDC programming model can only be accessed in SecurePrivileged mode. If TZ-M is disabled, it can only be accessed in Privileged mode regardless of Secure or NonSecure; that is it can't be accessed in User mode. Unless noted otherwise, the programming model registers can be accessed via 8-, 16- or 32-bit reads and 32-bit write references. Attempted accesses in a different operating mode, using unsupported write data sizes, writes to read-only resources, or access to reserved spaces are terminated with an error unless noted otherwise. The TRDC programming model is partitioned into these groups of registers:

- Basic hardware control and configuration
- Domain errors: location and details
- Initiator domain assignments
- Memory block and region checkers

It should be noted that many of the programming model registers in TRDC are organized as 2-, 3- or 4- dimensional data structures. For the 2-dimensional structures, the generic arrays contain "m" words representing the "columns" and "n" instances of the structure representing the "rows". These may be described as `structure[n][m]`. They appear in the address space of the programming model memory map in the standard C language row-major layout, that is, the "m" words representing the "column" appear sequentially with the entire row replicated "n" times. The TRDC register structure uses the naming convention of *TRDC_<regname>_Wm_n*, where the column number "m" appears as a numeric suffix on the W (32-bit word) identifier, and the row identifier "n" appears as the final numerical suffix.

For the 4-dimensional structures, the generic arrays contain "m", "d", "s" or "r", and "w" indices corresponding to MBC/MRC instance, domain index, sub-memory or region index and word index. The naming convention for the MBC block configuration and MRC region descriptor word registers are: *MBCm_DOMd_MEMs_BLK_CFG_Ww* and *MRCm_DOMd_RGDr_Ww*

For the reset values in this section, a "*" indicates an initial value determined by the hardware configuration.

22.7.1.2 TRDC Register (TRDC_CR)

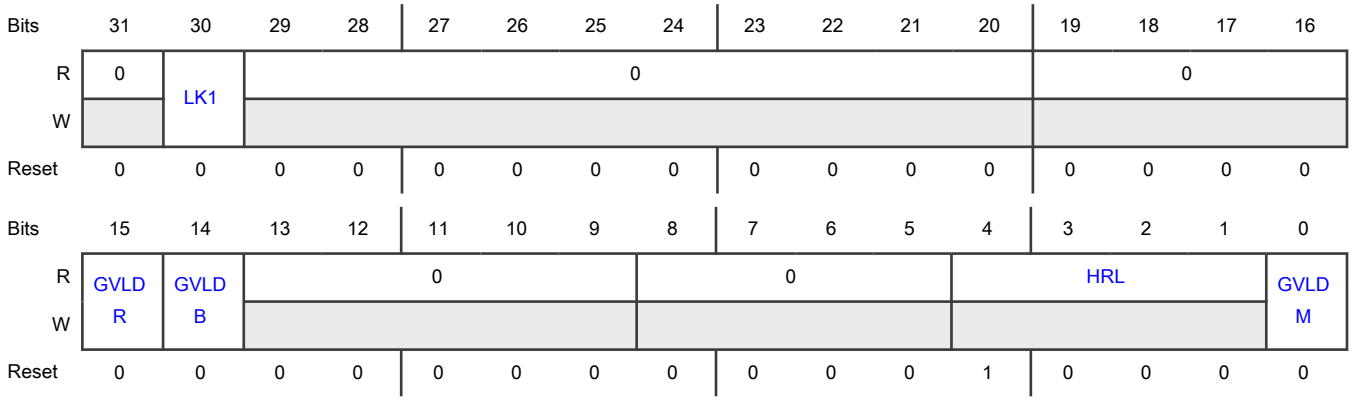
This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_CR	0h

Diagram



Fields

Field	Description
31 —	Reserved
30 LK1	Lock Status This field is the lock status of the TRDC_CR. This field is set when all GVLD bits are set; GVLDR=GVLDB=GVLDM=1b1. Once set, this bit remains asserted until the next reset. 0 - The CR can be written by any secure privileged write. 1 - The CR is locked (read-only) until the next reset.
29-20 —	Reserved
19-16 —	Reserved
15 GVLDR	Global Valid for Memory Region Checkers TRDC global MRC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MRCs are disabled. 1 - TRDC MRCs are enabled.
14 GVLDB	Global Valid for Memory Block Checkers TRDC global MBC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MBCs are disabled. 1 - TRDC MBCs are enabled.
13-9 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
8-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the TRDC's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
0 GVLDM	Global Valid for Domain Assignment Controllers TRDC global DAC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC DACs are disabled. 1 - TRDC DACs are enabled.

22.7.1.3 TRDC Hardware Configuration Register 0 (TRDC_HWCFG0)

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus initiators along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG0	F0h

Fields

Field	Description
31-29 MID	Module ID This field defines major version ID of this module.
28-24 NMRC	Number of MRCs This field defines the number of MRCs on the device [1-16].
23-20 —	Reserved
19-16 NMBC	Number of MBCs This field defines the number of MBCs on the device [1-8].
15-8 NMSTR	Number of bus initiators This read-only field defines the number of bus initiators.
7-5 —	Reserved
4-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-16].

22.7.1.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG1	F4h

Fields

Field	Description
31-4 —	Reserved
3-0 DID	Domain identifier number This field provides the domain number [0-15] of the requesting bus initiator.

22.7.1.5 TRDC Hardware Configuration Register 2 (TRDC_HWCFG2)

This register contains information on the TRDC's hardware configuration. It provides a bitmap signaling the presence of a process identifier (PID) register sourced from the given bus initiator. The HWCFG2 register is associated with bus initiators [31-0]. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG2	F8h

Fields

Field	Description
31-0 PIDPn	Process identifier present Process identifier present from bus initiator n, where n = [31-0]. This field provides a bitmap to signal that bus initiator (where n is defined as bit number) sources a process identifier register to the TRDC_DAC logic. For each bit in this field: • 0 - Bus initiator n does not source a process identifier register. The TRDC_DAC logic provides the needed PID for processor cores. • 1 - Bus initiator n sources a process identifier register.

22.7.1.6 TRDC Hardware Configuration Register 3 (TRDC_HWCFG3)

This register contains information on the TRDC's hardware configuration. Specifically, it provides a bitmap signaling the presence of a process identifier (PID) register sourced from the given bus initiator. The HWCFG3 register is associated with bus initiators [63-32], while the HWCFG2 register covers bus initiators [31-0]. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG3	FCh

Fields

Field	Description
31-0 PIDPn	Process identifier present Process identifier present from bus initiator n, where n = [63-32]. This field provides a bitmap to signal that bus initiator n (where n is defined as 32 + bit number) sources a process identifier register to the TRDC_DAC logic.

Table continues on the next page...

Field	Description
	Process identifier present from bus initiator n, where n = [31-0]. This field provides a bitmap to signal that bus initiator (where n is defined as bit number) sources a process identifier register to the TRDC_DAC logic. For each bit in this field: • 0 - Bus initiator n does not source a process identifier register. The TRDC_DAC logic provides the needed PID for processor cores. • 1 - Bus initiator n sources a process identifier register.

22.7.1.7 Domain Assignment Configuration Register (DACFG1 - DACFG4)

This register defines the number of implemented domain assignment registers for bus initiator m, where m+1 can specify from 1 to 64 bus initiators. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus initiator. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a initiator doesn't exist but it is in the same 32-bit group as DACFG for an existing initiator. For example, when there are only 2 DACFG0-1 registers for 2 initiator, and initiators for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus initiators have one or more domain assignment registers, while non-processor initiators have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
DACFG1	101h
DACFG2	102h
DACFG3	103h
DACFG4	104h

Register reset values

Register	Reset value
DACFG1	03h
DACFG2–DACFG4	81h

Fields

Field	Description
7 NCM	Non-CPU Initiator This read-only field signals that bus initiator m is a non-CPU initiator. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus initiator. 0 - Bus initiator is a processor. 1 - Bus initiator is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of initiator domain assignment registers for bus initiator m This read-only field specifies the number of registers associated with the initiator domain assignment register for a given bus initiator. The value is limited to the range [0-8], where zero indicates a non-existent bus initiator and non-zero values indicate the number of implemented registers associated with this MDAm.

22.7.1.8 TRDC IDAU Control Register (TRDC_IDAU_CR)

This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_IDAU_CR	1C0h

22.7.1.11 TRDC FLW Array Base (TRDC_FLW_ABASE)

This register gives the flash array base address of the Flash Logical Window.

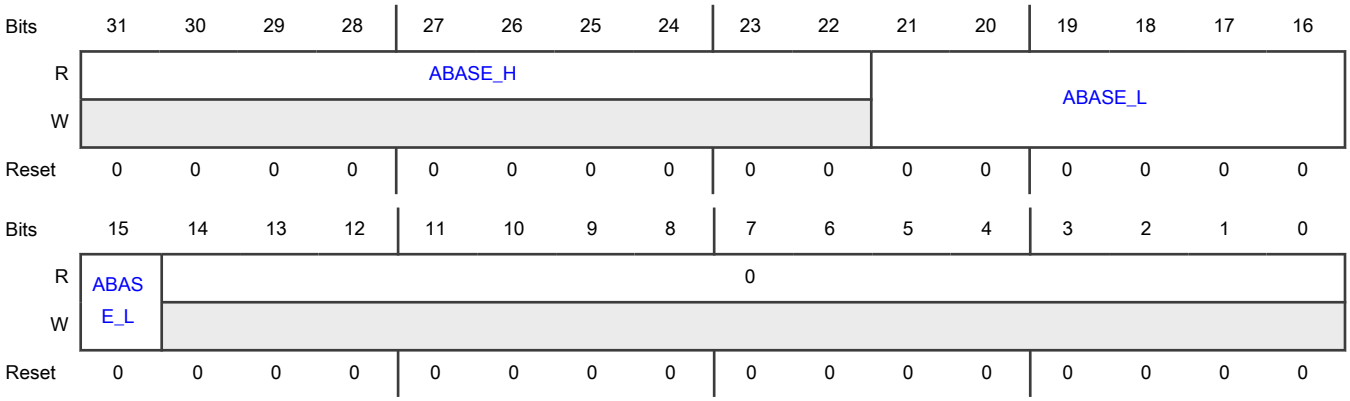
This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Offset

Register	Offset
TRDC_FLW_ABASE	1E8h

Diagram



Fields

Field	Description
31-22 ABASE_H	Array base address high Flash array address upper bits of the base of the FLW (mod 32KBytes).
21-15 ABASE_L	Array base address low Flash array address lower bits of the base of the FLW (mod 32KBytes).
14-0 —	Reserved

22.7.1.12 TRDC FLW Block Count (TRDC_FLW_BCNT)

This register gives the size of the Flash Logic Window in 32KByte blocks.

This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Offset

31-15 —	Reserved
14-0 BCNT	Block Count Size of FLW in number of 32KByte blocks.

22.7.1.13 TRDC Fault Domain ID (TRDC_FDID)

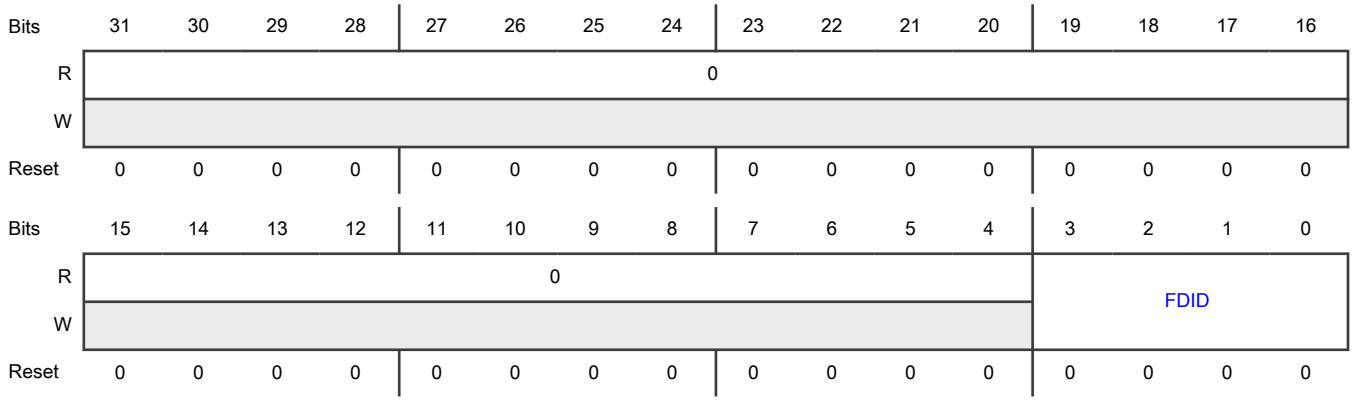
In the event of an access error, this register is used to specify the domainID of the faulting reference before indexing into the Domain Error registers.

If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FDID	1FCh

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

22.7.1.14 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC15)

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

For d = 0 to 15:

Register	Offset
TRDC_DERRLOCd	200h + (d × 4h)

Fields

Field	Description
31-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 31) corresponds to MRC instance 15 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-8 —	Reserved
7-0 MBCINST	MBC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MBC. The least-significant bit of this field (bit 0) corresponds to MBC instance 0. The most-significant bit of this field (bit 7) corresponds to MBC instance 7 Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MBCs. For each bit in this field: • 0 - The memory block checker has not detected an access violation or is not physically present. • 1 - The memory block checker has detected one or more access violations for this domain.

22.7.1.15 MBC Domain Error Word0 Register (MBC0_DERR_W0 - MBC1_DERR_W0)

This read-only register array provides the address of an access violation detected by memory block checker (MBC). These registers are organized as a word array, which is indexed by the MBC instance number. That is, the index, i, of this array is the instance number of MBC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MBC instance that is not physically present.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Fields

Field	Description
31-30 EST	Error state This field signals the state of access violations for this domain in this instance of the block checker or region checker. Once an access violation has been detected and the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. After retrieving the faulting address and attributes, the error capture mechanism must be rearmed by performing a write to DERR_W3_i. 00 - No access violation has been detected. 01 - No access violation has been detected. 10 - A single access violation has been detected. 11 - Multiple access violations for this domain have been detected by this submodule instance. Only the address and attribute information for the first error have been captured in DERR_W0_i and DERR_W1_i.
29-27 —	Reserved
26-24 EPORT	Error port This field identifies the encoded port number of the MBC that detected the access violation. The MBC port number connection is device-specific. See the chip configuration details for more information. This is the MBC target that has the violation. 000 - mbcxslv0 001 - mbcxslv1 010 - mbcxslv2 011 - mbcxslv3
23-12 —	Reserved
11 ERW	Error read/write This field signals whether the captured access violation occurred on a read or write reference. 0 - Read access 1 - Write access
10-8 EATR	Error attributes This field captures attributes of the access violation. 000 - Secure user mode, instruction fetch access. 001 - Secure user mode, data access. 010 - Secure privileged mode, instruction fetch access. 011 - Secure privileged mode, data access. 100 - Nonsecure user mode, instruction fetch access.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	101 - Nonsecure user mode, data access. 110 - Nonsecure privileged mode, instruction fetch access. 111 - Nonsecure privileged mode, data access.
7 SLV_ABORT	Bus protect error This field captures the bus protect error from target which cause access abort.
6 SLV_SA_ERR	Secure attribute check error This field captures the secure attribute check error from target.
5 SLV_PA_ERR	Privilege attribute check error This field captures the privilege attribute check error from target.
4 SLV_DID_ERR	DID check error This field captures the DID check error from target.
3-0 EDID	Error domain identifier This field captures the domain identifier of the access violation.

22.7.1.17 MBC Domain Error Word3 Register (MBC0_DERR_W3 - MBC1_DERR_W3)

This register is used to rearm the error capture logic and clear the DERR_W0_i and DERR_W1_i registers. After the domain access violation error details have been read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

A read of this location returns zeroes. Attempted reads of a Memory Region Checker (MRC) or Memory Block Checker (MBC) instance that is not physically present are error terminated.

See Domain error capture management for more details.

22.7.1.21 Process Identifier (PID1)

In the TRDC's access control definition, each processor has a corresponding process identifier (PID) which performs the important functions: the entire value can be used to group tasks into different domains.

While certain processors include this register in their programming model definitions, others do not. This register is provided for those processors that do *not* include a PID register in their programming models. Secure privileged software saves and restores the PID as part of any context switch.

This data structure defines an array of 32-bit values, one per MDA module, that define the PID. Since this register resource is only applicable to processor cores, the data structure is typically sparsely populated. The HWCFG[2-3] registers provide a bitmap of the implemented PID*n* registers. This data structure is indexed using the corresponding MDA instance number.

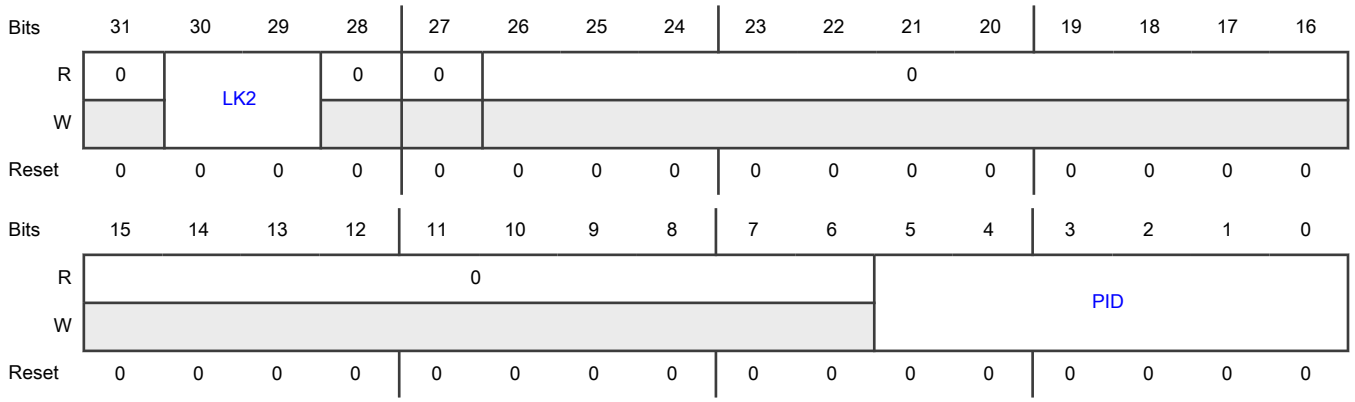
Depending on the operating clock domain of each DAC instance, there may be optional information stored in the corresponding PIDm register to properly implement the LK2 = 2 functionality.

Reads of the PID*n* register return the contents of this register, or the PID*n* value directly sourced from a processor. For non-processor bus initiators, this register does not exist and any attempted read is error terminated.

Offset

Register	Offset
PID1	704h

Diagram



Fields

Field	Description
31 —	Reserved
30-29 LK2	Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, these bits individually remain asserted until the next reset. If the processor sources its PIDm directly, that is, HWCFG{2-3}[PIDPm = 1], then privileged reads of this memory location return zero for this field. 00 - Register can be written by any secure privileged write. 01 - Register can be written by any secure privileged write. 10 - Register can only be written by a secure privileged write from the bus initiator that locked the register. 11 - Register is locked (read-only) until the next reset.
28 —	Reserved
27 —	Reserved
26-6 —	Reserved
5-0 PID	Process identifier This field determines the secure (0) or nonsecure (1) attribute for transactions associated with the corresponding processor. If the processor sources its PID*n* directly, then secure privileged reads of this memory location return the processor register for this field.

22.7.1.22 DAC Initiator Domain Assignment Register (MDA_W0_1_DFMT0 - MDA_W2_1_DFMT0)

The MDA_Wr_m registers provide a 2-dimensional data structure for assigning bus initiators to domains. The number of implemented registers is defined by DACFGm[NMDAR]. This per-initiator domain assignment is then repeated for each bus initiator (MDAm). Thus, m specifies the initiator number and r refers to the specific MDA register for a given bus initiator.

Each Wr within the MDAm structure is a word-sized definition; there are two formats supported, one for processor cores and another for non-processors. Processor initiators typically support one or more Wr domain definitions, while non-processor initiators support a single Wr. Processor initiators Domain Assignment register names use a _DFMT0 suffix. Non-processor initiators Domain Assignment register names use a _DFMT1 suffix.

The DAC submodule is responsible for the generation of domain identifiers for every transaction from every bus initiator. If there is a single Wr for a given initiator, then the specified domain identifier is used directly. If there are multiple Wr values for a given initiator, then the DAC evaluates the conditional terms to determine a “hit”. For all Wr hits, their corresponding domain identifiers are simply logically summed together (boolean OR). Use cases are typically expected to *hit in a single Wr* for a processor initiator. Special care is needed if *none* of the conditional terms hit in any Wr evaluation; for this case, the generated DID = 0 and software needs to be aware of any potential access rights granted for this DID.

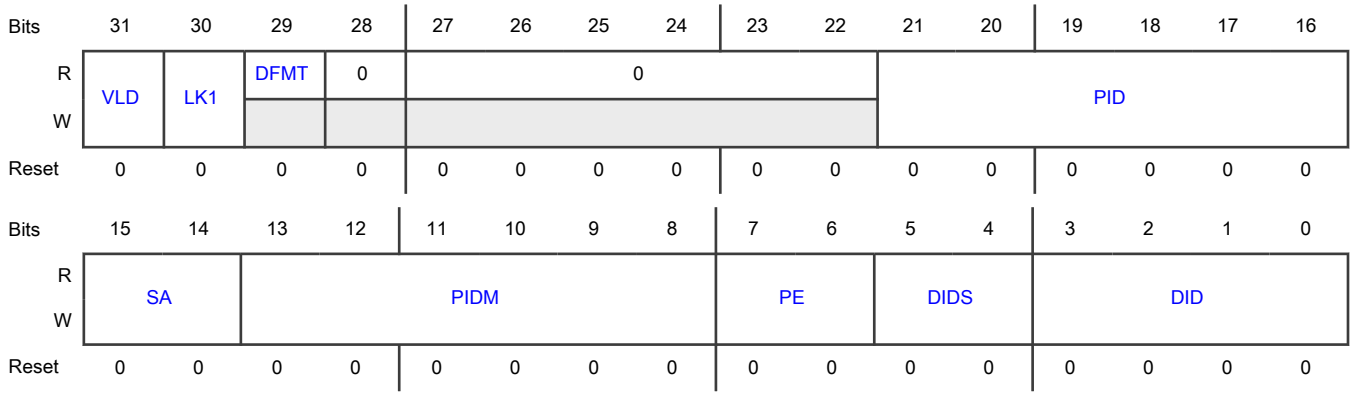
Each MDA_Wr_m register has one of two programming models depending on the state of the domain format field, DFMT. The model described in this section is for DFMT = 0. This definition allows three different specifications of the DID for processors. The DFMT = 1 model is described in Initiator Domain Assignment (MDA_Wr_m_DFMT1) register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Offset

Register	Offset
MDA_W0_1_DFMT0	820h
MDA_W1_1_DFMT0	824h
MDA_W2_1_DFMT0	828h

Diagram



Fields

Field	Description
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by TRDC_CR[GVLDM] = 1. If TRDC_CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and TRDC_CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0 - The Wr domain assignment is invalid. 1 - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0 - Register can be written by any secure privileged write. 1 - Register is locked (read-only) until the next reset.
29	Domain format

Table continues on the next page...

Table continued from the previous page...

Field	Description
DFMT	Identifies this register's domain assignment format. **NOTE** This bitfield access is ROZ 0 - Processor-core domain assignment 1 - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16 PID	Process Identifier This field specifies that the process identifier is to be combined with the PIDM field and included in the domain hit determination. The optional inclusion of the PID and PIDM is controlled by the MDA_Wr_m[PE] field.
15-14 SA	Secure attribute This field defines the secure/nonsecure attribute for processor cores. **NOTE** The bus initiator’s input secure/nonsecure attribute is used if SA = 1X, or this VLD = 0. If TZM_ENB = 0, the initiator attribute is forced to nonsecure. A nonsecure write cannot program this field to 2'b00, which is a security level higher than the mode of the process that is writing it. Reset value of SA: • if TZM_ENB=0, SA reset value = 2'b01 • if TZM_ENB=1, SA reset value = 2'b00 00 - Force the bus attribute for this initiator to secure. 01 - Force the bus attribute for this initiator to nonsecure. 10 - Use the bus initiator’s secure/nonsecure attribute directly. 11 - Use the bus initiator’s secure/nonsecure attribute directly.
13-8 PIDM	Process Identifier Mask This field provides a masking capability so that multiple process identifiers can be included as part of the domain hit determination. If a bit in the PIDM is set, then the corresponding bit of the PID is ignored in the comparison. The optional inclusion of the PID and PIDM is controlled by the MDA_Wr_m[PE] field.
7-6 PE	Process identifier enable Controls the optional inclusion of the PID, qualified by PIDM, into the domain hit evaluation. It provides the ability to include inclusive or exclusive sets of masked PID values.

Table continues on the next page...

Table continued from the previous page...

Field	Description

	00 - No process identifier is included in the domain hit evaluation.
	01 - No process identifier is included in the domain hit evaluation.
	10 - PE = 2. The process identifier is included in the domain hit evaluation as defined by the expression:
	`partial_domain_hit = (PE == 2) && ((PID & ~PIDM) == (TRDC_PIDn[PID] & ~PIDM))`
	11 - PE = 3. The process identifier is included in the domain hit evaluation as defined by the expression:
	`partial_domain_hit = (PE == 3) && ~((PID & ~PIDM) == (TRDC_PIDn[PID] & ~PIDM))`

5-4 DIDS	DID Select This field selects the source of the domain identifier. 00 - Use MDAm[3:0] as the domain identifier. 01 - Use the input DID as the domain identifier. 10 - Use MDAm[3:2] concatenated with the low-order 2 bits of the input DID (DID_in[1:0]) as the domain identifier. 11 - Reserved for future use.
3-0 DID	Domain identifier This 4-bit field is the domain ID attribute that is sent on the accesses from the bus initiator connected to the DAC when DIDS=00b. DID[3:2] is used when DIDS=10b. Write a value greater than the number of DIDs is illegal.

22.7.1.23 DAC Initiator Domain Assignment Register (MDA_W0_2_DFMT1 - MDA_W0_4_DFMT1)

This register is identical to Initiator Domain Assignment (MDA_Wr_m_DFMT0) register except that the domain format field, DFMT, is 1 and the PID field is not used. This format supports two different specifications of the DID for non-core bus initiators.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Offset

31-30 —	Reserved
29-21 —	Reserved
20-16 SIZE_LOG2	Log2 size per block For example SIZE_LOG2=0x0C is 2^12=4 KB blocks.
15-10 —	Reserved
9-0 NBLKS	Number of blocks in this memory

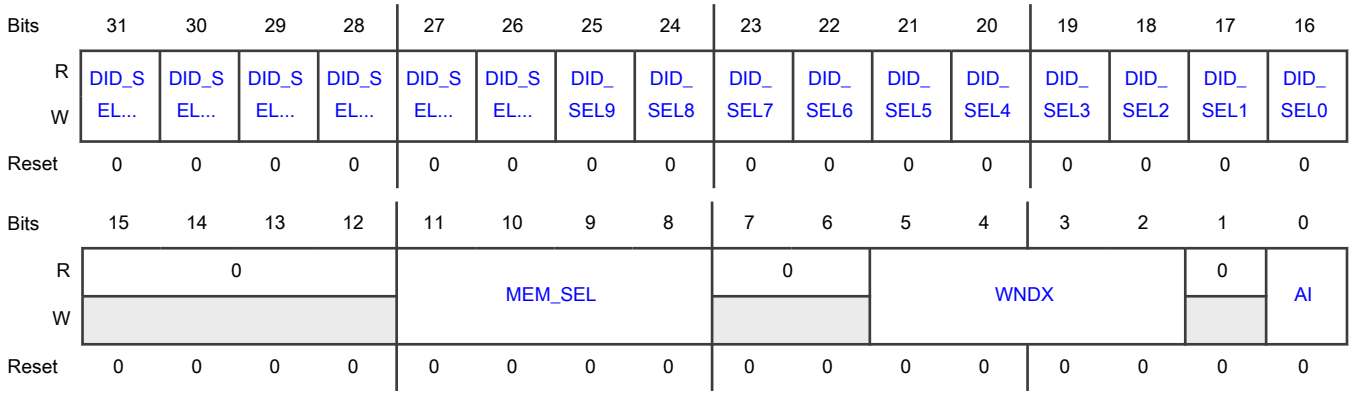
22.7.1.25 MBC NonSecure Enable Block Index (MBC0_NSE_BLK_INDEX - MBC1_NSE_BLK_INDEX)

This R/W register defines the selected memories that are affected by the writes to the NSE_BLK_SET and NSE_BLK_CLR registers.

Offset

Register	Offset
MBC0_NSE_BLK_INDEX	1_0010h
MBC1_NSE_BLK_INDEX	1_2010h

Diagram



Fields

Field	Description
31-16 DID_SELn	DID Select Destination domain bitmap select. 0 - No effect. 1 - Selects NSE bits for this domain.
15-12 —	Reserved
11-8 MEM_SEL	Memory Select Destination memory bitmap select. • Bit [11] - MBC MEM 3 • Bit [10] - MBC MEM 2 • Bit [9] - MBC MEM 1 • Bit [8] - MBC MEM 0
7-6 —	Reserved
5-2 WNDX	Word index into the block NSE bitmap. It selects the BLK_NSE_Wn register, where WNDX determines the value of n.
1 —	Reserved
0 AI	Auto Increment 0 - No effect. 1 - Add 1 to the WNDX field after the register write.

22.7.1.26 MBC NonSecure Enable Block Set (MBC0_NSE_BLK_SET - MBC1_NSE_BLK_SET)

A write to this register sets the appropriate NSE Bits for the selected domains and memories defined at the word location NSE_BLK_INDEX[WDNX]. If NSE_BLK_INDEX[AI] = 1, then the NSE_BLK_INDEX[WDNX] field is incremented by 1 (modulo-16) after the write is completed. This register reads as zero.

22.7.1.30 MBC Global Access Control (MBC0_MEMN_GLBAC1 - MBC0_MEMN_GLBAC7)

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User. The lock bit provides the ability to lock these control access flags and to lock the MBC_BLK_CFG[MBACSEL] field when a locked MBC_MEMN_GLBAC register is selected.

22.7.1.31 MBC Memory Block Configuration Word (MBC0_DOM0_MEM0_BLK_CFG_W0 - MBC0_DOM15_MEM2_BLK_CFG_W0)

MBC[m]_DOM[d]_MEM[s]_BLK_CFG_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

These registers are read/write for both the alternate view of the NSE bit and the 3-bit MBACSEL field. This is an array of 4 bit fields defining the block configuration for the given submemory. Each 4-bit field includes an alternative view of the associated NSE bit plus a 3-bit access control select that selects the global access control value that applies to the referenced memory block.

For a given memory block, B, if the value programmed in the MBACSELn field selects a locked MBC_MEMN_GLBACr register, the MBACSEL field is locked until the next reset. Depending on BLK_CFG_W, the NSEn/MBASELn fields correspond to different blocks. The following table describes the relationship between W (word index) and B (block number).

MEM0 supports up to 512 blocks ; W0 - W63

MEM1-3 supports up to 64 block ; W0 - W7

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

Table 108. Block Config Word to Block Number Relationship

Block Config Word	NSE7/ MBACSEL7	NSE6/ MBACSEL6	NSE5/ MBACSEL5	NSE4/ MBACSEL4	NSE3/ MBACSEL3	NSE2/ MBACSEL2	NSE1/ MBACSEL1	NSE0/ MBACSEL0

Fields

Field	Description
31 NSE7	NonSecure Enable for block B 0 - Secure read and write to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), secure execution and nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
30-28 MBACSEL7	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL7 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
27 NSE6	NonSecure Enable for block B 0 - Secure read and write to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), secure execution and nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
26-24	Memory Block Access Control Select for block B

Table continued from the previous page...

Field	Description
	111 - select MBC_MEMN_GLBAC7 access control policy for block B
3 NSE0	NonSecure Enable for block B 0 - Secure read and write to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), secure execution and nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
2-0 MBACSEL0	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL0 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B

22.7.1.32 MBC Memory Block NonSecure Enable Word (MBC0_DOM0_MEM0_BLK_NSE_W0 - MBC0_DOM15_MEM2_BLK_NSE_W0)

MBC[m]_DOM[d]_MEM[s]_BLK_NSE_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

This is the bitmap of the individual NSE bits for the memory block.

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

The following table describes the relationship between W (word index) and B (block number).

Table 109. Block Config Word to Block Number Relationship

Block NSE Word	BIT31	BIT30-BIT1	BIT0
W0	block 31	block 30 - block 1	block 0
W1	block 63	block 62 - block 33	block 32
For MEM0, block 64 - block 511			
W2	block 95	block 94 - block 65	block 64
. . .			
W15	block 511	block 510 - block 481	block 480

The NSE bitmap can be accessed directly by register reads and writes to these locations, or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and BLK_CFG[NSEn] registers.

Fields

Field	Description
31-0 BITb	Bit b NonSecure Enable [b = 0 - 31]

Table continues on the next page...

Field	Description
	0 - Secure read and write to block B are based on corresponding MBACSEL field in register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), secure execution and nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).

22.7.1.33 MBC Global Access Control (MBC1_MEMN_GLBAC0)

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User.

22.7.1.34 MBC Global Access Control (MBC1_MEMN_GLBAC1 - MBC1_MEMN_GLBAC7)

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User. The lock bit provides the ability to lock these control access flags and to lock the MBC_BLK_CFG[MBACSEL] field when a locked MBC_MEMN_GLBAC register is selected.

22.7.1.35 MBC Memory Block Configuration Word (MBC1_DOM0_MEM0_BLK_CFG_W0 - MBC1_DOM15_MEM1_BLK_CFG_W3)

MBC[m]_DOM[d]_MEM[s]_BLK_CFG_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

These registers are read/write for both the alternate view of the NSE bit and the 3-bit MBACSEL field. This is an array of 4 bit fields defining the block configuration for the given submemory. Each 4-bit field includes an alternative view of the associated NSE bit plus a 3-bit access control select that selects the global access control value that applies to the referenced memory block.

For a given memory block, B, if the value programmed in the MBACSELn field selects a locked MBC_MEMN_GLBACr register, the MBACSEL field is locked until the next reset. Depending on BLK_CFG_W, the NSEn/MBASELn fields correspond to different blocks. The following table describes the relationship between W (word index) and B (block number).

MEM0 supports up to 512 blocks ; W0 - W63

MEM1-3 supports up to 64 block ; W0 - W7

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

Table 110. Block Config Word to Block Number Relationship

Block Config Word	NSE7/ MBACSEL7	NSE6/ MBACSEL6	NSE5/ MBACSEL5	NSE4/ MBACSEL4	NSE3/ MBACSEL3	NSE2/ MBACSEL2	NSE1/ MBACSEL1	NSE0/ MBACSEL0
W0	block 7	block 6	block 5	block 4	block 3	block 2	block 1	block 0
W1	block 15	block 14	block 13	block 12	block 11	block 10	block 9	block 8
W2	block 23	block 22	block 21	block 20	block 19	block 18	block 17	block 16
W3	block 31	block 30	block 29	block 28	block 27	block 26	block 25	block 24
W4	block 39	block 38	block 37	block 36	block 35	block 34	block 33	block 32
W5	block 47	block 46	block 45	block 44	block 43	block 42	block 41	block 40
W6	block 55	block 54	block 53	block 52	block 51	block 50	block 49	block 48
W7	block 63	block 62	block 61	block 60	block 59	block 58	block 57	block 56
For MEM0, block 64 - block 511								
W8	block 71	block 70	block 69	block 68	block 67	block 66	block 65	block 64
. . .								
W63	block 511	block 510	block 509	block 508	block 507	block 506	block 505	block 504

22.7.1.36 MBC Memory Block NonSecure Enable Word (MBC1_DOM0_MEM0_BLK_NSE_W0 - MBC1_DOM15_MEM1_BLK_NSE_W0)

MBC[m]_DOM[d]_MEM[s]_BLK_NSE_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

This is the bitmap of the individual NSE bits for the memory block.

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

The following table describes the relationship between W (word index) and B (block number).

Table 111. Block Config Word to Block Number Relationship

Block NSE Word	BIT31	BIT30-BIT1	BIT0
W0	block 31	block 30 - block 1	block 0
W1	block 63	block 62 - block 33	block 32
For MEM0, block 64 - block 511			
W2	block 95	block 94 - block 65	block 64
.			
.			
.			
W15	block 511	block 510 - block 481	block 480

The NSE bitmap can be accessed directly by register reads and writes to these locations, or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and BLK_CFG[NSEn] registers.

22.7.1.44 MRC Region Descriptor Word 0 (MRC0_DOM0_RGD0_W0 - MRC0_DOM15_RGD7_W0)

MRC[m]_DOM[d]_RGD[r]_W[w], where,

- m - mrc index
- d - domain index
- r - region descriptor index
- w - word index

The MRC[m]_DOM[d]_RGD[r]_W[w] registers provide a 3-dimensional data structure for defining access control policies per domain for each supported memory region.

Memory map/register definition:

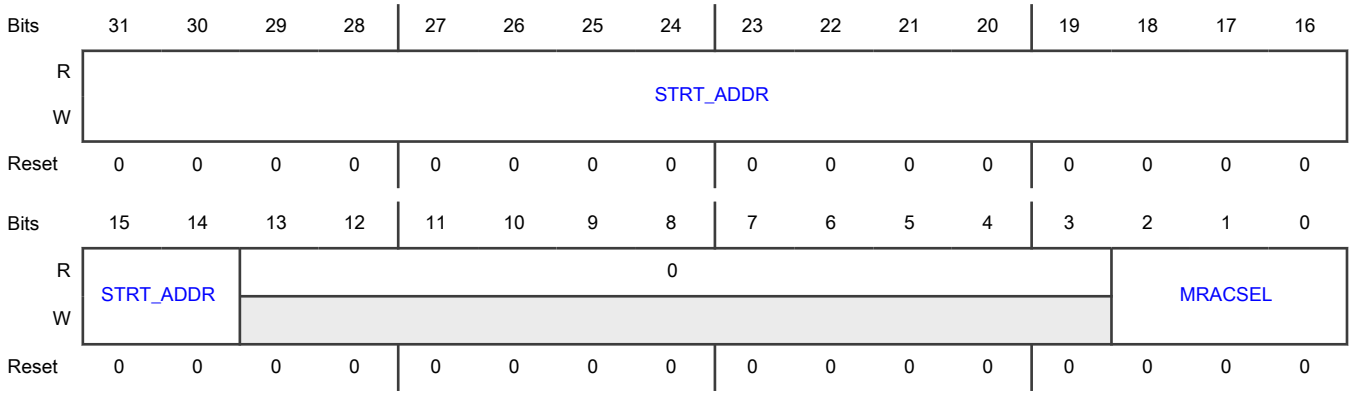
There two word-size registers (W[w]) defined in each memory region. There are up to 16 memory region checkers (MRCs), m, each supporting up to 16 memory region descriptors (RGD), r. The number of MRCs is defined by HWCFG0[NMRC].

Offset

For d = 0 to 15; r = 0 to 7:

Register	Offset
MRC0_DOMd_RGDr_W0	1_4040h + (d × 100h) + (r × 8h)

Diagram



Fields

Field	Description
31-14 STRT_ADDR	Start Address 0-mod-16K physical start address [31:14] of region r. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1.
13-3 —	Reserved
2-0 MRACSEL	Memory Region Access Control Select This field selects the global access control associated with region r. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1. 000 - Select MRC_GLBAC0 access control policy 001 - Select MRC_GLBAC1 access control policy 010 - Select MRC_GLBAC2 access control policy 011 - Select MRC_GLBAC3 access control policy 100 - Select MRC_GLBAC4 access control policy 101 - Select MRC_GLBAC5 access control policy 110 - Select MRC_GLBAC6 access control policy 111 - Select MRC_GLBAC7 access control policy

22.7.1.45 MRC Region Descriptor Word 1 (MRC0_DOM0_RGD0_W1 - MRC0_DOM15_RGD7_W1)

MRC[m]_DOM[d]_RGD[r]_W[w], where,

- m - mrc index
- d - domain index
- r - region descriptor index

- w - word index

The MRC[m]_[d]_rgd[r]_w[w] registers provide a 3-dimensional data structure for defining access control policies per domain for each supported memory region.

Memory map/register definition:

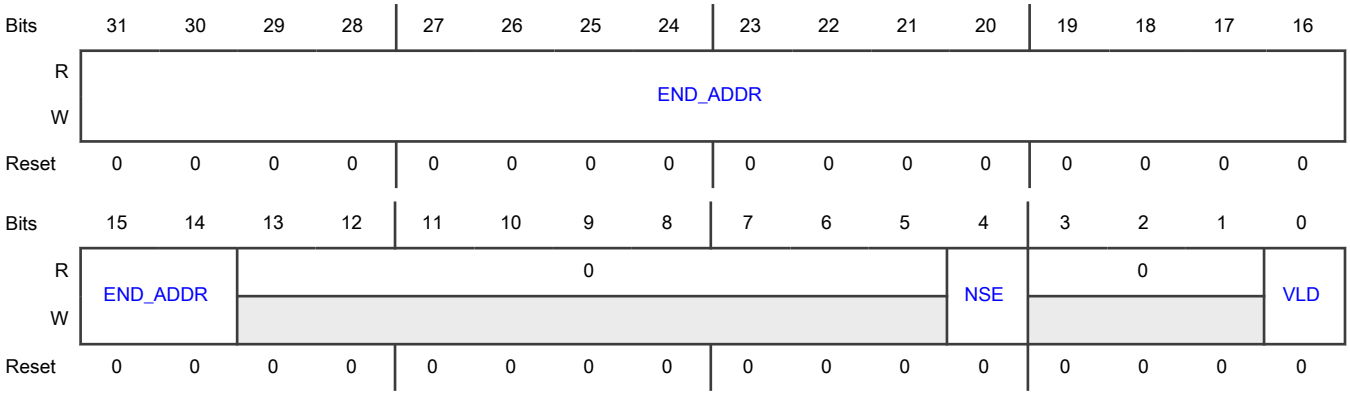
There two word-size registers (W[w]) defined in each memory region. There are up to 16 memory region checkers (MRCs), m, each supporting up to 16 region descriptors (RGD), r. The number of MRCs is defined by HWCFG0[NMRC].

Offset

For d = 0 to 15; r = 0 to 7:

Register	Offset
MRC0_DOMd_RGDr_W1	1_4044h + (d × 100h) + (r × 8h)

Diagram



Fields

Field	Description
31-14 END_ADDR	End Address (16K-1)-mod-16K physical end address [31:14] of region r. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1.
13-5 —	Reserved
4 NSE	NonSecure Enable Alternate view of NSE flag for Region r. 0 - Secure accesses to region r are based on corresponding MRACSEL field in this register (MRCm_DOMd_RGDr_Ww[MRACSEL]), nonsecure accesses to region r are not allowed.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Secure accesses to region r are not allowed, nonsecure accesses to region r are based on corresponding MRACSEL field in this register (MRCm_DOMd_RGDr_Ww[MRACSEL]).
3-1 —	Reserved
0 VLD	Valid If set, this region is valid and accesses are checked for this region. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1.

22.7.1.46 MRC Region Descriptor NonSecure Enable (MRC0_DOM0_RGD_NSE - MRC0_DOM15_RGD_NSE)

This register is the bitmap of the individual NSE bits for the region descriptors. Bit n corresponds to region n.

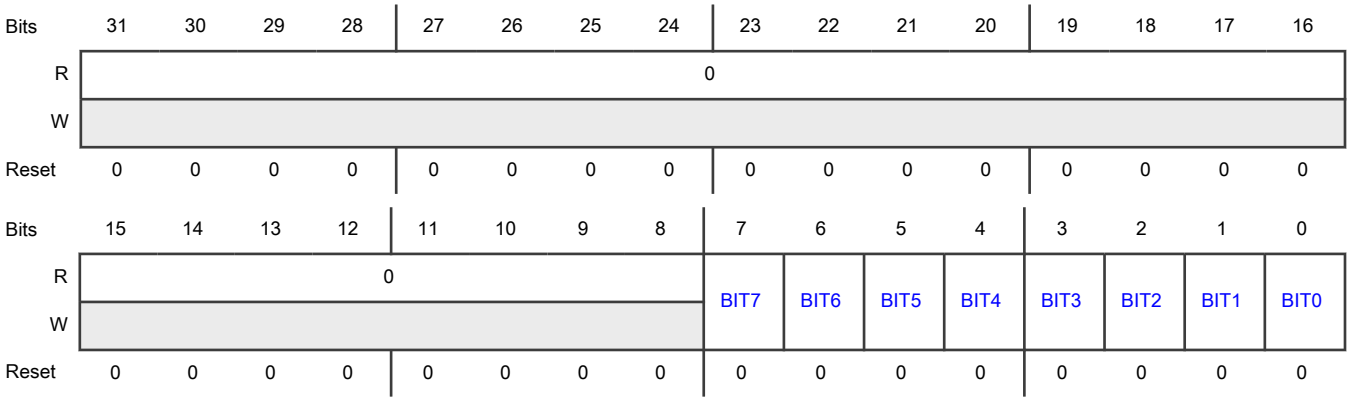
These bits can also be written or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and RGD_W0[NSE] registers.

Offset

For d = 0 to 15:

Register	Offset
MRC0_DOMd_RGD_NSE	1_40C0h + (d × 100h)

Diagram



Fields

Field	Description
31-8 —	Reserved
7-0 BITn	Bit n NonSecure Enable [n = 0 - 15] 0 - Secure accesses to region r are based on corresponding MRACSEL field in this register (MRCm_DOMd_RGDr_Ww[MRACSEL]), nonsecure accesses to region r are not allowed. 1 - Secure accesses to region r are not allowed, nonsecure accesses to region r are based on corresponding MRACSEL field in register (MRCm_DOMd_RGDr_Ww[MRACSEL]).

820	DAC Initiator Domain Assignment Register (MDA_W0_1_DFMT1)	32	RW	2000_0000

22.7.2.2 TRDC Register (TRDC_CR)

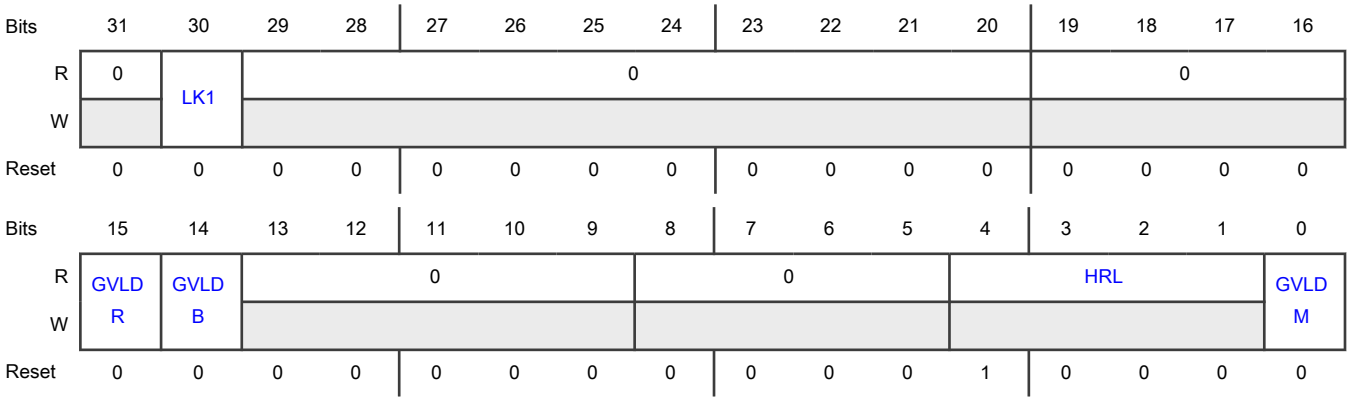
This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_CR	0h

Diagram



Fields

Field	Description
31 —	Reserved
30 LK1	Lock Status This field is the lock status of the TRDC_CR. This field is set when all GVLD bits are set; GVLDR=GVLDB=GVLDM=1b1. Once set, this bit remains asserted until the next reset. 0 - The CR can be written by any secure privileged write. 1 - The CR is locked (read-only) until the next reset.
29-20 —	Reserved
19-16 —	Reserved
15 GVLDR	Global Valid for Memory Region Checkers TRDC global MRC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MRCs are disabled. 1 - TRDC MRCs are enabled.
14 GVLDB	Global Valid for Memory Block Checkers TRDC global MBC enable/disable. Once set, this bit remains set until the next reset.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - TRDC MBCs are disabled. 1 - TRDC MBCs are enabled.
13-9 —	Reserved
8-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the TRDC's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
0 GVLDM	Global Valid for Domain Assignment Controllers TRDC global DAC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC DACs are disabled. 1 - TRDC DACs are enabled.

22.7.2.3 TRDC Hardware Configuration Register 0 (TRDC_HWCFG0)

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus initiators along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG0	F0h

Fields

Field	Description
31-29 MID	Module ID This field defines major version ID of this module.
28-24 NMRC	Number of MRCs This field defines the number of MRCs on the device [1-16].
23-20 —	Reserved
19-16 NMBC	Number of MBCs This field defines the number of MBCs on the device [1-8].
15-8 NMSTR	Number of bus initiators This read-only field defines the number of bus initiators.
7-5 —	Reserved
4-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-16].

22.7.2.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

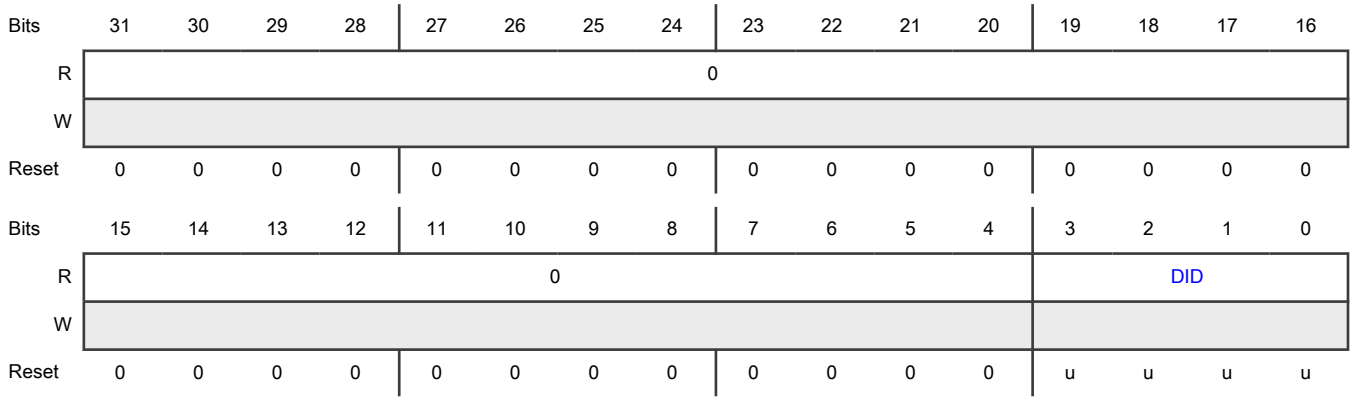
This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG1	F4h

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 DID	Domain identifier number This field provides the domain number [0-15] of the requesting bus initiator.

22.7.2.5 Domain Assignment Configuration Register (DACFG0 - DACFG1)

This register defines the number of implemented domain assignment registers for bus initiator m, where m+1 can specify from 1 to 64 bus initiators. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus initiator. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a initiator doesn't exist but it is in the same 32-bit group as DACFG for an existing initiator. For example, when there are only 2 DACFG0-1 registers for 2 initiator, and initiators for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus initiators have one or more domain assignment registers, while non-processor initiators have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
DACFG0	100h
DACFG1	101h

Diagram

Bits	7	6	5	4	3	2	1	0
R	NCM	0			NMDAR			
W								
Reset	1	0	0	0	0	0	0	1

Fields

Field	Description
7 NCM	Non-CPU Initiator This read-only field signals that bus initiator m is a non-CPU initiator. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus initiator. 0 - Bus initiator is a processor. 1 - Bus initiator is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of initiator domain assignment registers for bus initiator m This read-only field specifies the number of registers associated with the initiator domain assignment register for a given bus initiator. The value is limited to the range [0-8], where zero indicates a non-existent bus initiator and non-zero values indicate the number of implemented registers associated with this MDAm.

22.7.2.6 TRDC IDAU Control Register (TRDC_IDAU_CR)

This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_IDAU_CR	1C0h

22.7.2.11 TRDC Fault Domain ID (TRDC_FDID)

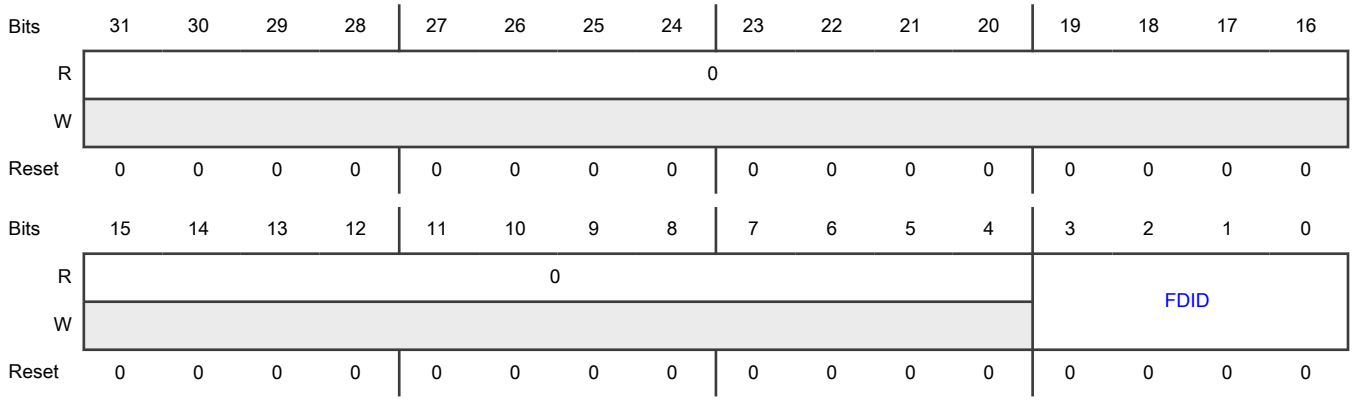
In the event of an access error, this register is used to specify the domainID of the faulting reference before indexing into the Domain Error registers.

If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FDID	1FCh

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

22.7.2.12 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC15)

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap

of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

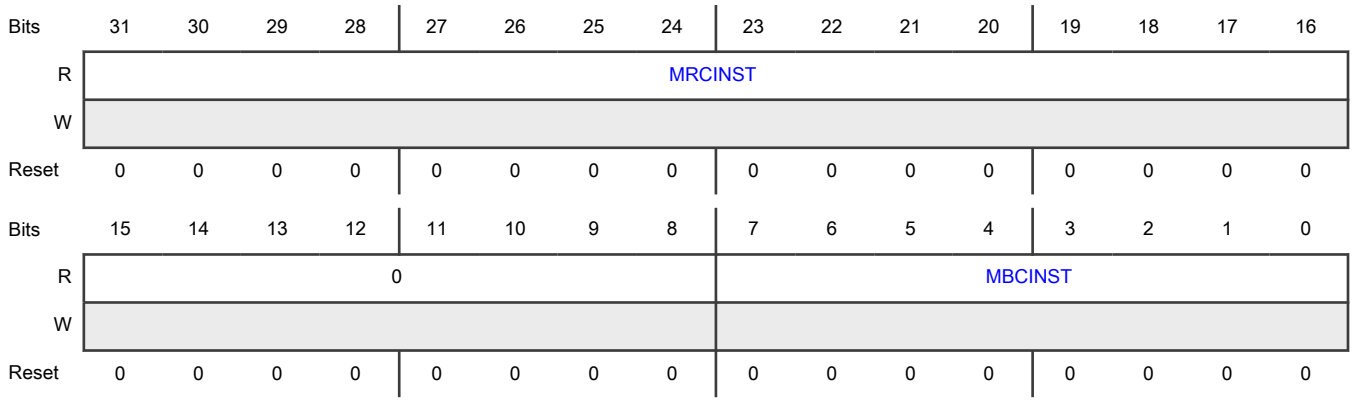
Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

For d = 0 to 15:

Register	Offset
TRDC_DERRLOCd	200h + (d × 4h)

Diagram



Fields

Field	Description
31-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 31) corresponds to MRC instance 15 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-8	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
7-0 MBCINST	MBC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MBC. The least-significant bit of this field (bit 0) corresponds to MBC instance 0. The most-significant bit of this field (bit 7) corresponds to MBC instance 7 Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MBCs. For each bit in this field: • 0 - The memory block checker has not detected an access violation or is not physically present. • 1 - The memory block checker has detected one or more access violations for this domain.

22.7.2.13 DAC Initiator Domain Assignment Register (MDA_W0_0_DFMT1 - MDA_W0_1_DFMT1)

This register is identical to Initiator Domain Assignment (MDA_Wr_m_DFMT0) register except that the domain format field, DFMT, is 1 and the PID field is not used. This format supports two different specifications of the DID for non-core bus initiators.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Fields

Field	Description
31	Valid

Table continues on the next page...

Table continued from the previous page...

Field	Description
VLD	This field indicates the domain assignment is valid. It is further qualified by TRDC_CR[GVLDM] = 1. If TRDC_CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and TRDC_CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0 - The Wr domain assignment is invalid. 1 - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0 - Register can be written by any secure privileged write. 1 - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROO 0 - Processor-core domain assignment 1 - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16 —	Reserved
15-14 —	Reserved
13-9 —	Reserved
8 DIDB	DID Bypass If asserted, this bit enables the bypassing of an input DID value as the domain identifier for this non-processor bus initiator. This capability allows non-processor bus initiators, for example, a DMA to masquerade as a processor. Once set, this field is “sticky” and remains set until the next reset.

This field defines the secure/nonsecure attribute for non-processor cores.
NOTE
The bus initiator’s input secure/nonsecure attribute is used if SA = 1X, or this VLD = 0. If TZM_ENB = 0, the initiator attribute is forced to nonsecure. A nonsecure write cannot program this field to 2'b00, which is a security level higher than the mode of the process that is writing it.
Reset value of SA:
• if TZM_ENB=0, SA reset value = 2'b01
• if TZM_ENB=1, SA reset value = 2'b00
00 - Force the bus attribute for this initiator to secure.
01 - Force the bus attribute for this initiator to nonsecure.
10 - Use the bus initiator’s secure/nonsecure attribute directly.
11 - Use the bus initiator’s secure/nonsecure attribute directly.</td></tr>
<tr><td>5-4
PA</td><td>Privileged attribute
This field defines the privileged/user attribute for non-processor cores.
NOTE
The bus initiator’s input privileged/user attribute is used if PA = 1X, or this VLD = 0.
00 - Force the bus attribute for this initiator to user.
01 - Force the bus attribute for this initiator to privileged.
10 - Use the bus initiator’s privileged/user attribute directly.
11 - Use the bus initiator’s privileged/user attribute directly.</td></tr>
<tr><td>3-0
DID</td><td>Domain identifier
This 4-bit field is the domain ID attribute that is sent on the accesses from the bus initiator connected to the DAC when DIDB=0.
Write a value greater than the number of DIDs is illegal.</td></tr>
</table>

22.7.3.2 TRDC Register (TRDC_CR)

This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_CR	0h

Fields

Field	Description
31 —	Reserved
30 LK1	Lock Status This field is the lock status of the TRDC_CR. This field is set when all GVLD bits are set; GVLDR=GVLDB=GVLDM=1b1. Once set, this bit remains asserted until the next reset. 0 - The CR can be written by any secure privileged write. 1 - The CR is locked (read-only) until the next reset.
29-20 —	Reserved
19-16 —	Reserved
15 GVLDR	Global Valid for Memory Region Checkers TRDC global MRC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MRCs are disabled. 1 - TRDC MRCs are enabled.
14 GVLDB	Global Valid for Memory Block Checkers TRDC global MBC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MBCs are disabled. 1 - TRDC MBCs are enabled.
13-9 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
8-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the TRDC's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
0 GVLDM	Global Valid for Domain Assignment Controllers TRDC global DAC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC DACs are disabled. 1 - TRDC DACs are enabled.

22.7.3.3 TRDC Hardware Configuration Register 0 (TRDC_HWCFG0)

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus initiators along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG0	F0h

Fields

Field	Description
31-29 MID	Module ID This field defines major version ID of this module.
28-24 NMRC	Number of MRCs This field defines the number of MRCs on the device [1-16].
23-20 —	Reserved
19-16 NMBC	Number of MBCs This field defines the number of MBCs on the device [1-8].
15-8 NMSTR	Number of bus initiators This read-only field defines the number of bus initiators.
7-5 —	Reserved
4-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-16].

22.7.3.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

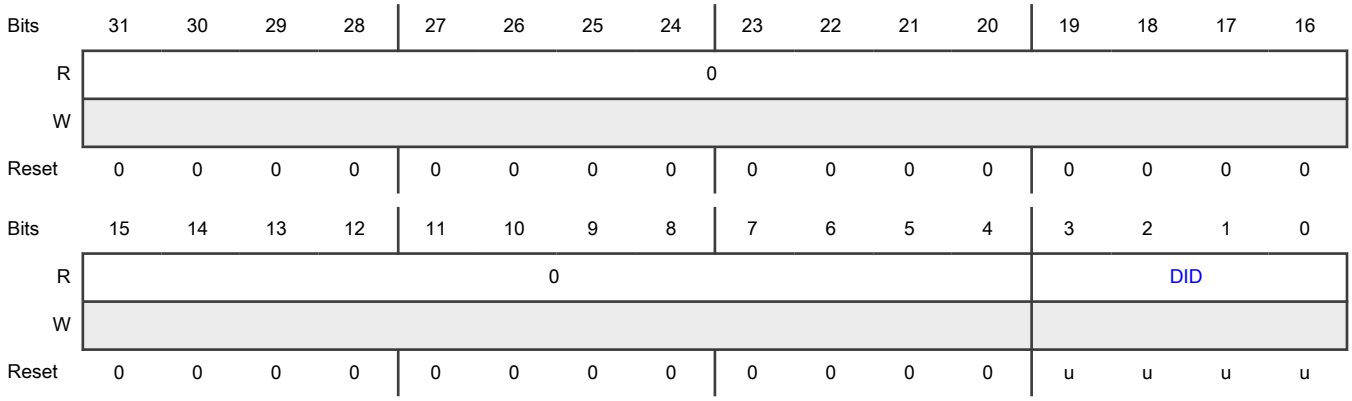
This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG1	F4h

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 DID	Domain identifier number This field provides the domain number [0-15] of the requesting bus initiator.

22.7.3.5 Domain Assignment Configuration Register (DACFG0 - DACFG3)

This register defines the number of implemented domain assignment registers for bus initiator m, where m+1 can specify from 1 to 64 bus initiators. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus initiator. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a initiator doesn't exist but it is in the same 32-bit group as DACFG for an existing initiator. For example, when there are only 2 DACFG0-1 registers for 2 initiator, and initiators for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus initiators have one or more domain assignment registers, while non-processor initiators have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
DACFG0	100h
DACFG1	101h
DACFG2	102h
DACFG3	103h

Reset	1	0	0	0	0	0	0	1

Fields

Field	Description
7 NCM	Non-CPU Initiator This read-only field signals that bus initiator m is a non-CPU initiator. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus initiator. 0 - Bus initiator is a processor. 1 - Bus initiator is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of initiator domain assignment registers for bus initiator m This read-only field specifies the number of registers associated with the initiator domain assignment register for a given bus initiator. The value is limited to the range [0-8], where zero indicates a non-existent bus initiator and non-zero values indicate the number of implemented registers associated with this MDAm.

22.7.3.6 TRDC IDAU Control Register (TRDC_IDAU_CR)

This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_IDAU_CR	1C0h

22.7.3.11 TRDC Fault Domain ID (TRDC_FDID)

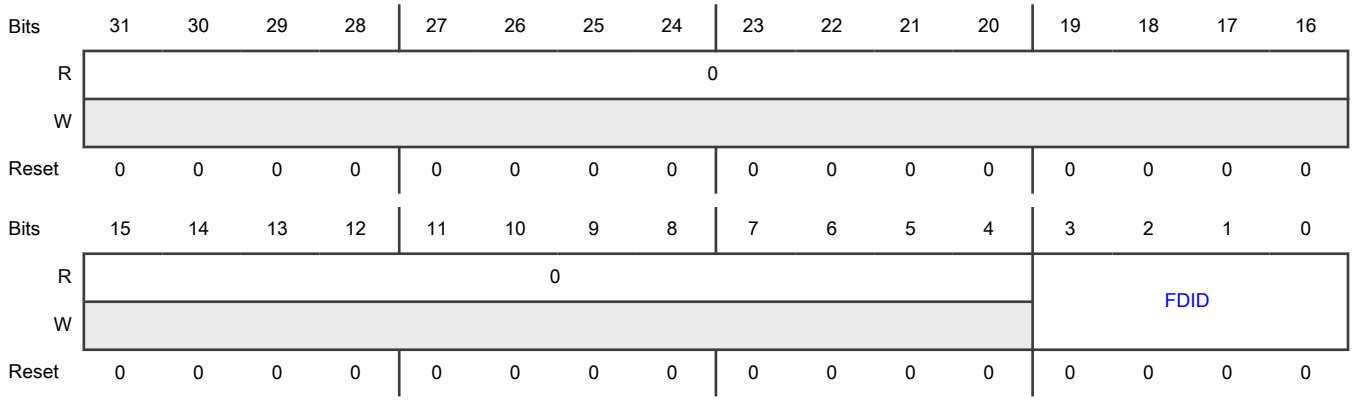
In the event of an access error, this register is used to specify the domainID of the faulting reference before indexing into the Domain Error registers.

If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FDID	1FCh

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

22.7.3.12 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC15)

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap

of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

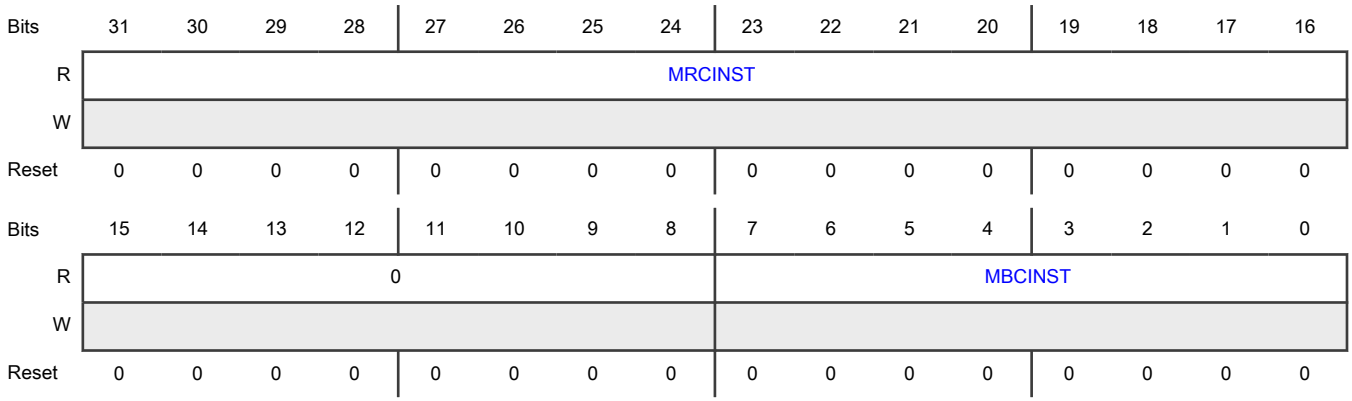
Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

For d = 0 to 15:

Register	Offset
TRDC_DERRLOCd	200h + (d × 4h)

Diagram



Fields

Field	Description
31-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 31) corresponds to MRC instance 15 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-8	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
7-0 MBCINST	MBC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MBC. The least-significant bit of this field (bit 0) corresponds to MBC instance 0. The most-significant bit of this field (bit 7) corresponds to MBC instance 7 Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MBCs. For each bit in this field: • 0 - The memory block checker has not detected an access violation or is not physically present. • 1 - The memory block checker has detected one or more access violations for this domain.

22.7.3.13 DAC Initiator Domain Assignment Register (MDA_W0_0_DFMT1 - MDA_W0_3_DFMT1)

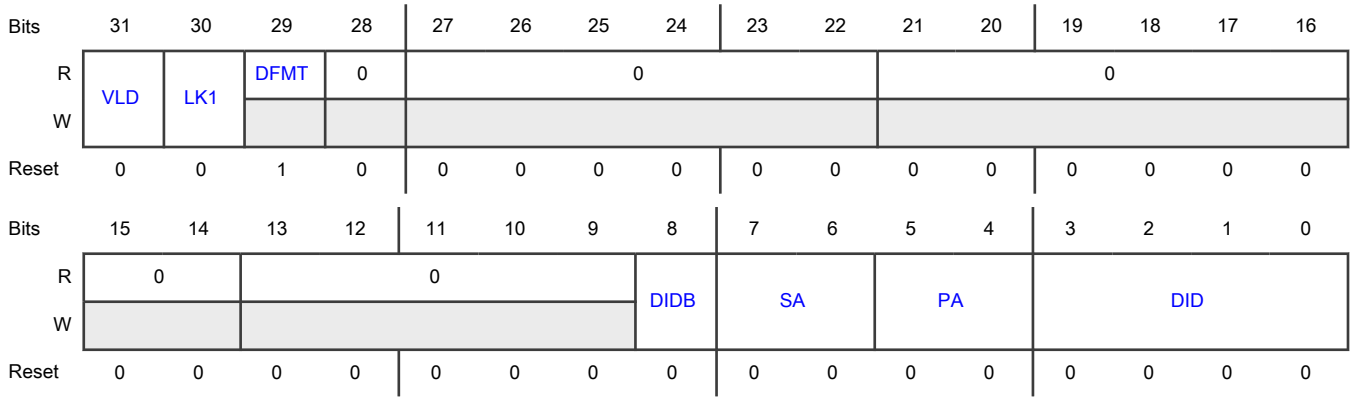
This register is identical to Initiator Domain Assignment (MDA_Wr_m_DFMT0) register except that the domain format field, DFMT, is 1 and the PID field is not used. This format supports two different specifications of the DID for non-core bus initiators.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Offset

Register	Offset
MDA_W0_0_DFMT1	800h
MDA_W0_1_DFMT1	820h
MDA_W0_2_DFMT1	840h
MDA_W0_3_DFMT1	860h

Diagram



Fields

Field	Description
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by TRDC_CR[GVLDM] = 1. If TRDC_CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and TRDC_CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0 - The Wr domain assignment is invalid. 1 - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0 - Register can be written by any secure privileged write. 1 - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROO 0 - Processor-core domain assignment 1 - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16 —	Reserved
15-14 —	Reserved
13-9 —	Reserved
8 DIDB	DID Bypass If asserted, this bit enables the bypassing of an input DID value as the domain identifier for this non-processor bus initiator. This capability allows non-processor bus initiators, for example, a DMA to masquerade as a processor. Once set, this field is “sticky” and remains set until the next reset.

22.7.4.3 TRDC Hardware Configuration Register 0 (TRDC_HWCFG0)

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus initiators along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG0	F0h

Fields

Field	Description
31-29 MID	Module ID This field defines major version ID of this module.
28-24 NMRC	Number of MRCs This field defines the number of MRCs on the device [1-16].
23-20 —	Reserved
19-16 NMBC	Number of MBCs This field defines the number of MBCs on the device [1-8].
15-8 NMSTR	Number of bus initiators This read-only field defines the number of bus initiators.
7-5 —	Reserved
4-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-16].

22.7.4.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

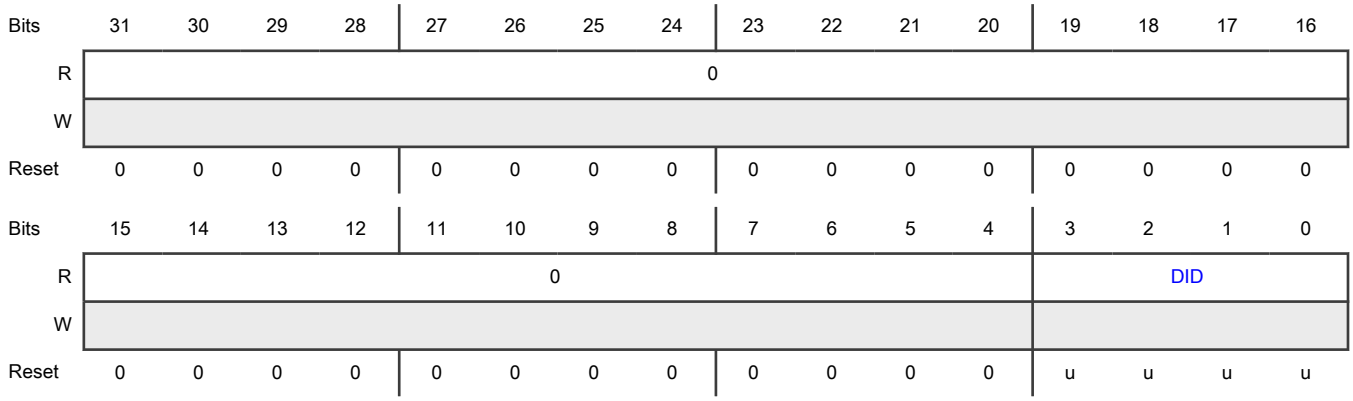
This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG1	F4h

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 DID	Domain identifier number This field provides the domain number [0-15] of the requesting bus initiator.

22.7.4.5 Domain Assignment Configuration Register (DACFG0 - DACFG6)

This register defines the number of implemented domain assignment registers for bus initiator m, where m+1 can specify from 1 to 64 bus initiators. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus initiator. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a initiator doesn't exist but it is in the same 32-bit group as DACFG for an existing initiator. For example, when there are only 2 DACFG0-1 registers for 2 initiator, and initiators for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus initiators have one or more domain assignment registers, while non-processor initiators have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

W								
Reset	1	0	0	0	0	0	0	1

Fields

Field	Description
7 NCM	Non-CPU Initiator This read-only field signals that bus initiator m is a non-CPU initiator. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus initiator. 0 - Bus initiator is a processor. 1 - Bus initiator is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of initiator domain assignment registers for bus initiator m This read-only field specifies the number of registers associated with the initiator domain assignment register for a given bus initiator. The value is limited to the range [0-8], where zero indicates a non-existent bus initiator and non-zero values indicate the number of implemented registers associated with this MDAm.

22.7.4.6 TRDC IDAU Control Register (TRDC_IDAU_CR)

This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_IDAU_CR	1C0h

2-1 —	Reserved
0 VLD	Valid When VLD =0, all address attribute from IDAU is nonSecure. When VLD=1, values in other fields of this register are valid.

22.7.4.7 TRDC FLW Control (TRDC_FLW_CTL)

This register provides control of the FLW = Flash Logical Window operation.

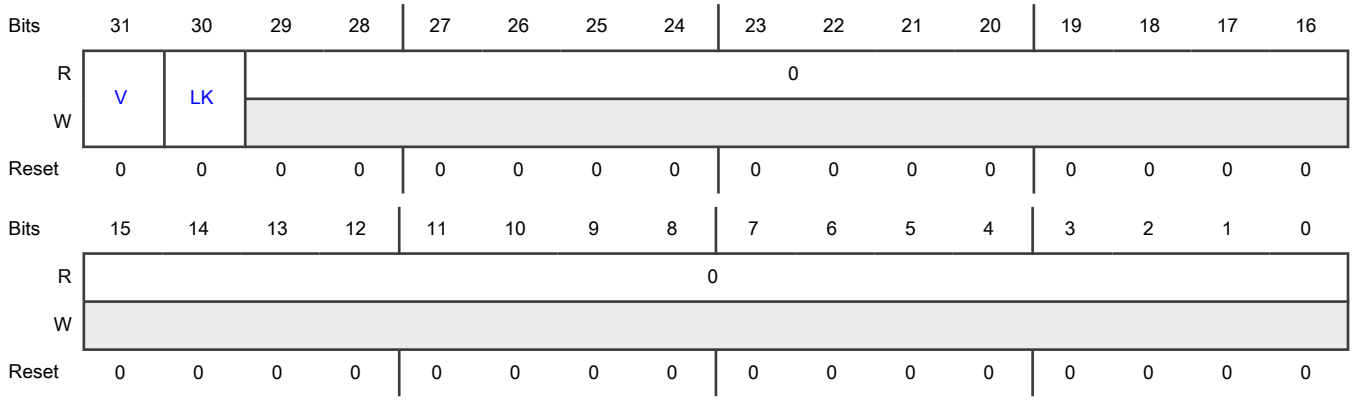
This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FLW_CTL	1E0h

Diagram



Fields

Field	Description
31 V	Valid bit 0 - FLW function is disabled. 1 - FLW function is enabled.
30 LK	Lock bit 0 - FLW registers may be modified. 1 - FLW registers are locked until the next reset.
29-0 —	Reserved

22.7.4.8 TRDC FLW Physical Base (TRDC_FLW_PBASE)

This read-only register gives the physical base address of the Flash Logical Window.

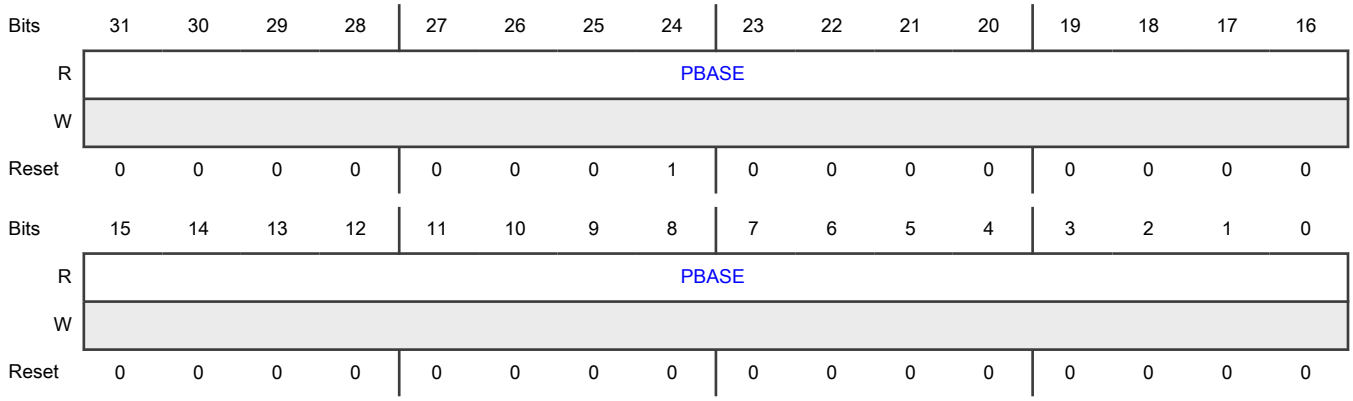
This register exists for this device but has not effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_FLW_PBASE	1E4h

Diagram



Fields

Field	Description
31-0 PBASE	Physical base address Physical address of the base of the FLW (mod 32KBytes).

22.7.4.9 TRDC FLW Array Base (TRDC_FLW_ABASE)

This register gives the flash array base address of the Flash Logical Window.

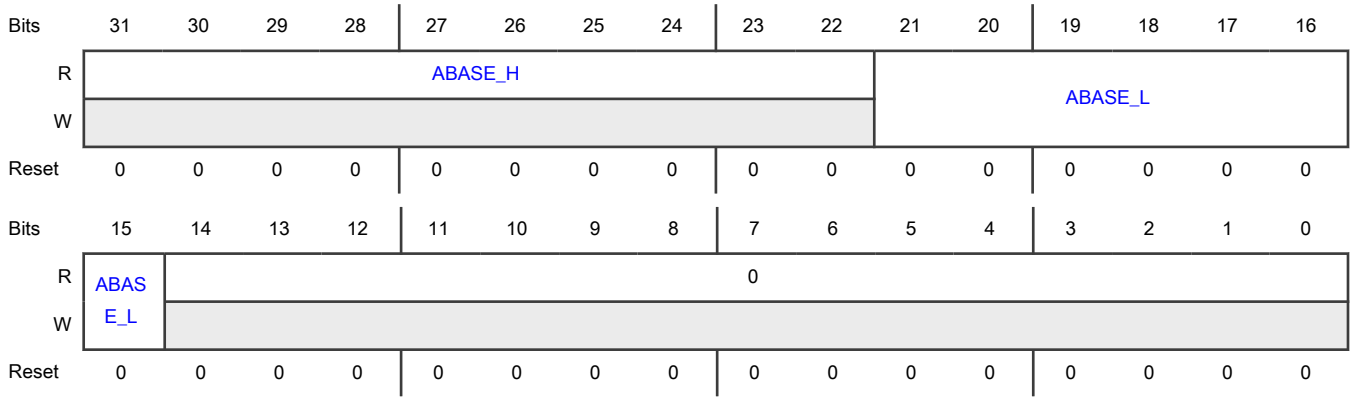
This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Offset

Register	Offset
TRDC_FLW_ABASE	1E8h

Diagram



Fields

Field	Description
31-22 ABASE_H	Array base address high Flash array address upper bits of the base of the FLW (mod 32KBytes).
21-15 ABASE_L	Array base address low Flash array address lower bits of the base of the FLW (mod 32KBytes).
14-0 —	Reserved

22.7.4.10 TRDC FLW Block Count (TRDC_FLW_BCNT)

This register gives the size of the Flash Logic Window in 32KByte blocks.

This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Offset

Register	Offset

Table continues on the next page...

Table continued from the previous page...

Field	Description
14-0 BCNT	Block Count Size of FLW in number of 32KByte blocks.

22.7.4.11 TRDC Fault Domain ID (TRDC_FDID)

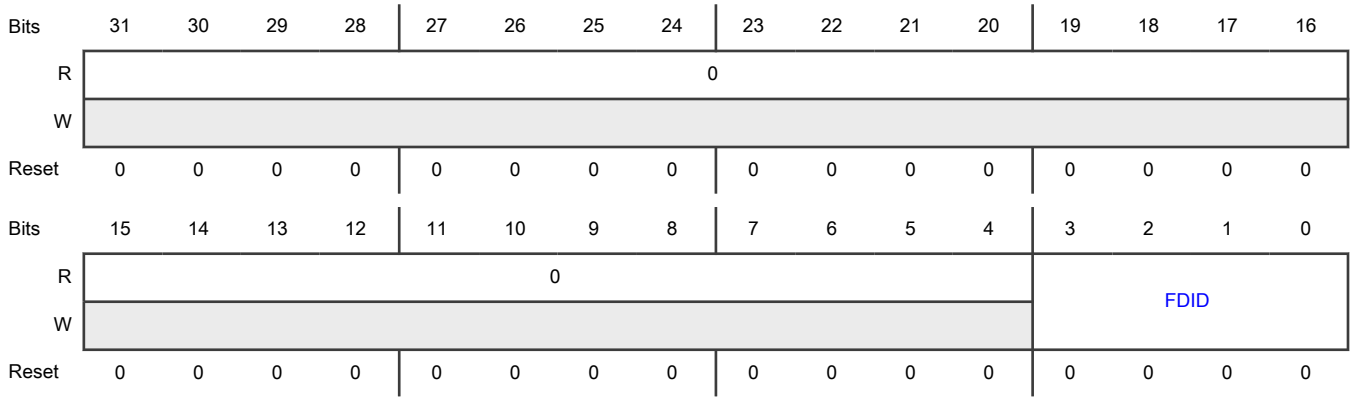
In the event of an access error, this register is used to specify the domainID of the faulting reference before indexing into the Domain Error registers.

If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FDID	1FCh

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

22.7.4.12 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC15)

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap

of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

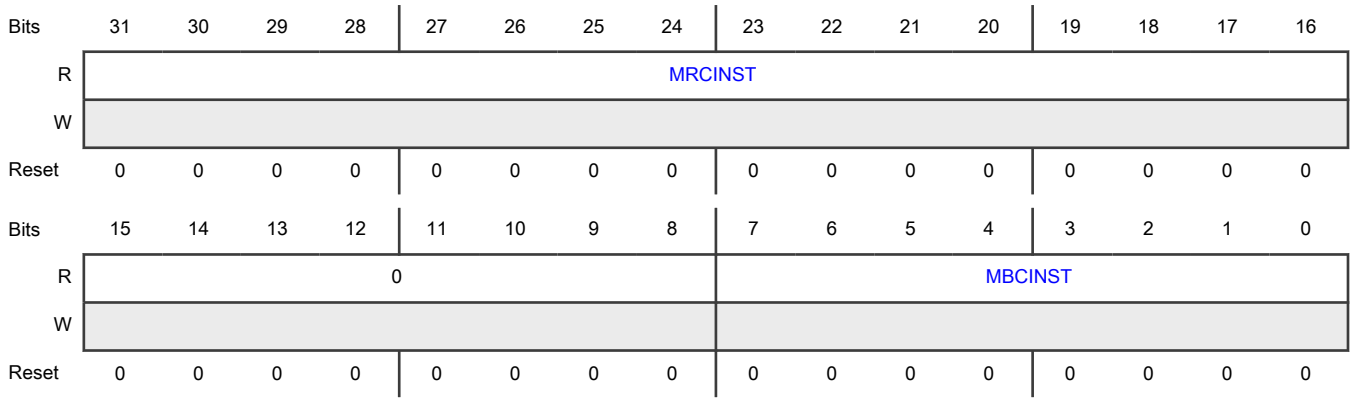
Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

For d = 0 to 15:

Register	Offset
TRDC_DERRLOCd	200h + (d × 4h)

Diagram



Fields

Field	Description
31-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 31) corresponds to MRC instance 15 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-8	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
7-0 MBCINST	MBC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MBC. The least-significant bit of this field (bit 0) corresponds to MBC instance 0. The most-significant bit of this field (bit 7) corresponds to MBC instance 7 Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MBCs. For each bit in this field: • 0 - The memory block checker has not detected an access violation or is not physically present. • 1 - The memory block checker has detected one or more access violations for this domain.

22.7.4.13 DAC Initiator Domain Assignment Register (MDA_W0_0_DFMT1 - MDA_W0_6_DFMT1)

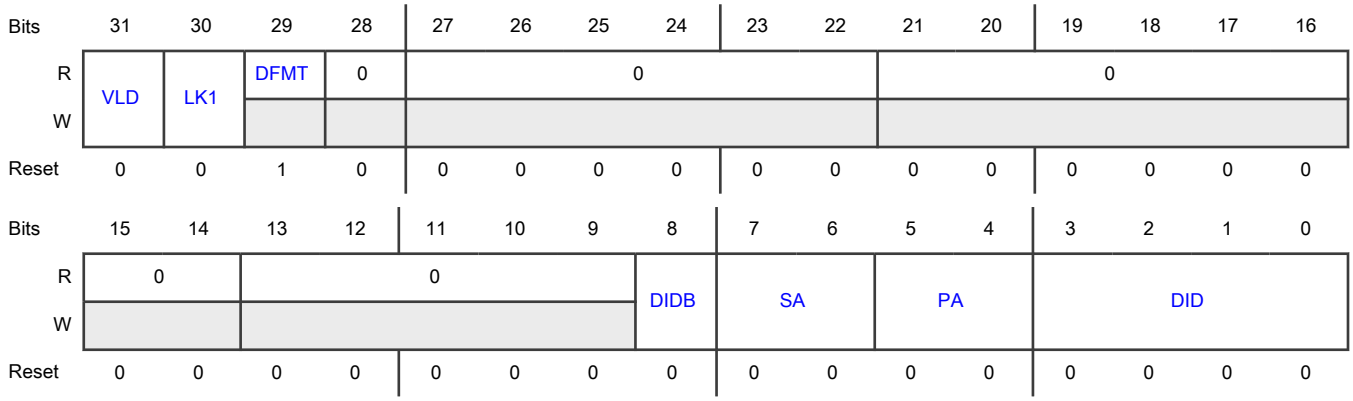
This register is identical to Initiator Domain Assignment (MDA_Wr_m_DFMT0) register except that the domain format field, DFMT, is 1 and the PID field is not used. This format supports two different specifications of the DID for non-core bus initiators.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Offset

Register	Offset
MDA_W0_0_DFMT1	800h
MDA_W0_1_DFMT1	820h
MDA_W0_2_DFMT1	840h
MDA_W0_3_DFMT1	860h
MDA_W0_4_DFMT1	880h
MDA_W0_5_DFMT1	8A0h
MDA_W0_6_DFMT1	8C0h

Diagram



Fields

Field	Description
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by TRDC_CR[GVLDM] = 1. If TRDC_CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and TRDC_CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0 - The Wr domain assignment is invalid. 1 - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0 - Register can be written by any secure privileged write. 1 - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROO 0 - Processor-core domain assignment 1 - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16 —	Reserved
15-14 —	Reserved
13-9 —	Reserved
8 DIDB	DID Bypass If asserted, this bit enables the bypassing of an input DID value as the domain identifier for this non-processor bus initiator. This capability allows non-processor bus initiators, for example, a DMA to masquerade as a processor. Once set, this field is “sticky” and remains set until the next reset.

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>DAC</th><th>DID Input</th></tr>
<tr><td>0</td><td>0</td></tr>
<tr><td>1</td><td>DMA Domain ID</td></tr>
<tr><td>2</td><td>USB Domain ID</td></tr>
</table>
0 - Use MDAn[3:0] as the domain identifier.
1 - Use the DID input as the domain identifier.
</td></tr>
<tr><td>7-6
SA</td><td>Secure attribute
This field defines the secure/nonsecure attribute for non-processor cores.
NOTE
The bus initiator’s input secure/nonsecure attribute is used if SA = 1X, or this VLD = 0. If TZM_ENB = 0, the initiator attribute is forced to nonsecure. A nonsecure write cannot program this field to 2'b00, which is a security level higher than the mode of the process that is writing it.
Reset value of SA:
• if TZM_ENB=0, SA reset value = 2'b01
• if TZM_ENB=1, SA reset value = 2'b00
00 - Force the bus attribute for this initiator to secure.
01 - Force the bus attribute for this initiator to nonsecure.
10 - Use the bus initiator’s secure/nonsecure attribute directly.
11 - Use the bus initiator’s secure/nonsecure attribute directly.</td></tr>
<tr><td>5-4
PA</td><td>Privileged attribute
This field defines the privileged/user attribute for non-processor cores.
NOTE
The bus initiator’s input privileged/user attribute is used if PA = 1X, or this VLD = 0.
00 - Force the bus attribute for this initiator to user.
01 - Force the bus attribute for this initiator to privileged.
10 - Use the bus initiator’s privileged/user attribute directly.
11 - Use the bus initiator’s privileged/user attribute directly.</td></tr>
<tr><td>3-0
DID</td><td>Domain identifier
This 4-bit field is the domain ID attribute that is sent on the accesses from the bus initiator connected to the DAC when DIDB=0.
Write a value greater than the number of DIDs is illegal.</td></tr>
</table>

22.7.5.2 TRDC Register (TRDC_CR)

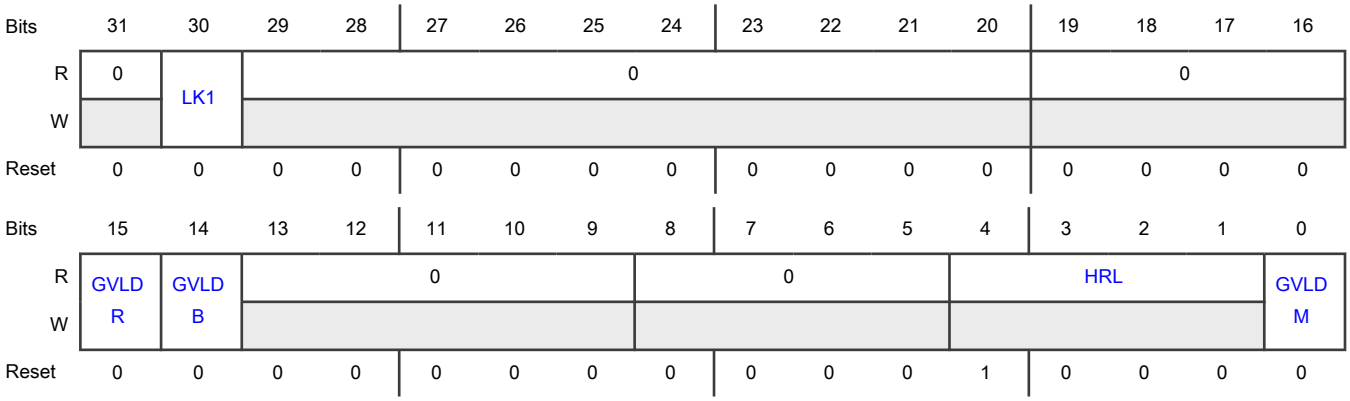
This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_CR	0h

Diagram



Fields

Field	Description
31 —	Reserved
30 LK1	Lock Status This field is the lock status of the TRDC_CR. This field is set when all GVLD bits are set; GVLDR=GVLDB=GVLDM=1b1. Once set, this bit remains asserted until the next reset. 0 - The CR can be written by any secure privileged write. 1 - The CR is locked (read-only) until the next reset.
29-20 —	Reserved
19-16 —	Reserved
15 GVLDR	Global Valid for Memory Region Checkers TRDC global MRC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MRCs are disabled. 1 - TRDC MRCs are enabled.
14 GVLDB	Global Valid for Memory Block Checkers TRDC global MBC enable/disable. Once set, this bit remains set until the next reset.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - TRDC MBCs are disabled. 1 - TRDC MBCs are enabled.
13-9 —	Reserved
8-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the TRDC's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
0 GVLDM	Global Valid for Domain Assignment Controllers TRDC global DAC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC DACs are disabled. 1 - TRDC DACs are enabled.

22.7.5.3 TRDC Hardware Configuration Register 0 (TRDC_HWCFG0)

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus initiators along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG0	F0h

Fields

Field	Description
31-29 MID	Module ID This field defines major version ID of this module.
28-24 NMRC	Number of MRCs This field defines the number of MRCs on the device [1-16].
23-20 —	Reserved
19-16 NMBC	Number of MBCs This field defines the number of MBCs on the device [1-8].
15-8 NMSTR	Number of bus initiators This read-only field defines the number of bus initiators.
7-5 —	Reserved
4-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-16].

22.7.5.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset

Fields

Field	Description
31-0 PIDPn	Process identifier present Process identifier present from bus initiator n, where n = [31-0]. This field provides a bitmap to signal that bus initiator (where n is defined as bit number) sources a process identifier register to the TRDC_DAC logic. For each bit in this field: • 0 - Bus initiator n does not source a process identifier register. The TRDC_DAC logic provides the needed PID for processor cores. • 1 - Bus initiator n sources a process identifier register.

22.7.5.6 TRDC Hardware Configuration Register 3 (TRDC_HWCFG3)

This register contains information on the TRDC's hardware configuration. Specifically, it provides a bitmap signaling the presence of a process identifier (PID) register sourced from the given bus initiator. The HWCFG3 register is associated with bus initiators [63-32], while the HWCFG2 register covers bus initiators [31-0]. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Fields

Field	Description
31-0 PIDPn	Process identifier present Process identifier present from bus initiator n, where n = [63-32]. This field provides a bitmap to signal that bus initiator n (where n is defined as 32 + bit number) sources a process identifier register to the TRDC_DAC logic.

Table continues on the next page...

Field	Description
	Process identifier present from bus initiator n, where n = [31-0]. This field provides a bitmap to signal that bus initiator (where n is defined as bit number) sources a process identifier register to the TRDC_DAC logic. For each bit in this field: • 0 - Bus initiator n does not source a process identifier register. The TRDC_DAC logic provides the needed PID for processor cores. • 1 - Bus initiator n sources a process identifier register.

22.7.5.7 Domain Assignment Configuration Register (DACFG0 - DACFG3)

This register defines the number of implemented domain assignment registers for bus initiator m, where m+1 can specify from 1 to 64 bus initiators. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus initiator. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a initiator doesn't exist but it is in the same 32-bit group as DACFG for an existing initiator. For example, when there are only 2 DACFG0-1 registers for 2 initiator, and initiators for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus initiators have one or more domain assignment registers, while non-processor initiators have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Register reset values

Register	Reset value
DACFG0–DACFG1	04h
DACFG2–DACFG3	81h

Fields

Field	Description
7 NCM	Non-CPU Initiator This read-only field signals that bus initiator m is a non-CPU initiator. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus initiator. 0 - Bus initiator is a processor. 1 - Bus initiator is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of initiator domain assignment registers for bus initiator m This read-only field specifies the number of registers associated with the initiator domain assignment register for a given bus initiator. The value is limited to the range [0-8], where zero indicates a non-existent bus initiator and non-zero values indicate the number of implemented registers associated with this MDAm.

22.7.5.8 TRDC IDAU Control Register (TRDC_IDAU_CR)

This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_IDAU_CR	1C0h

31-15 —	Reserved
14-0 BCNT	Block Count Size of FLW in number of 32KByte blocks.

22.7.5.13 TRDC Fault Domain ID (TRDC_FDID)

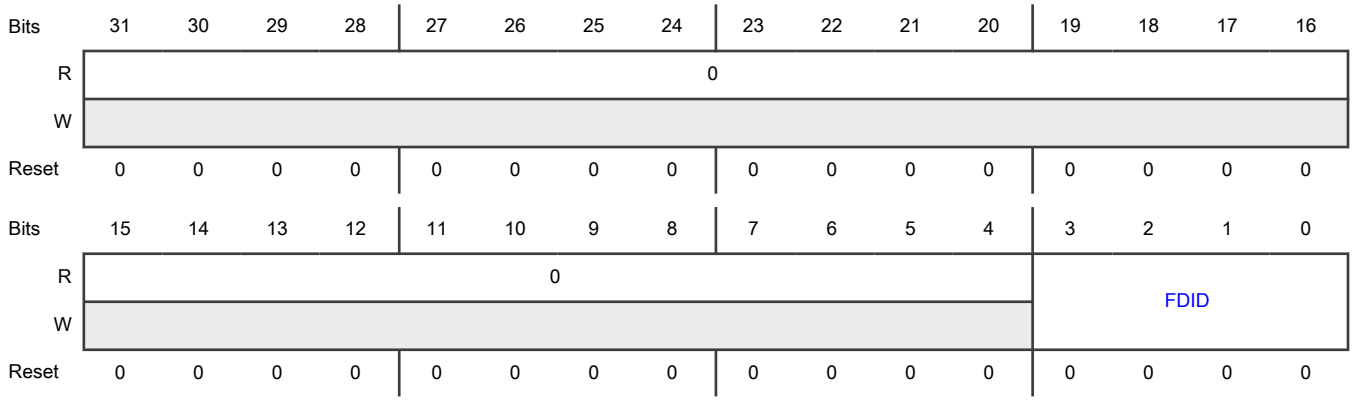
In the event of an access error, this register is used to specify the domainID of the faulting reference before indexing into the Domain Error registers.

If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FDID	1FCh

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

22.7.5.14 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC15)

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

For d = 0 to 15:

Register	Offset
TRDC_DERRLOCd	200h + (d × 4h)

R	0								MBCINST							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 31) corresponds to MRC instance 15 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-8 —	Reserved
7-0 MBCINST	MBC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MBC. The least-significant bit of this field (bit 0) corresponds to MBC instance 0. The most-significant bit of this field (bit 7) corresponds to MBC instance 7 Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MBCs. For each bit in this field: • 0 - The memory block checker has not detected an access violation or is not physically present. • 1 - The memory block checker has detected one or more access violations for this domain.

22.7.5.15 MBC Domain Error Word0 Register (MBC0_DERR_W0 - MBC3_DERR_W0)

This read-only register array provides the address of an access violation detected by memory block checker (MBC). These registers are organized as a word array, which is indexed by the MBC instance number. That is, the index, i, of this array is the instance number of MBC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

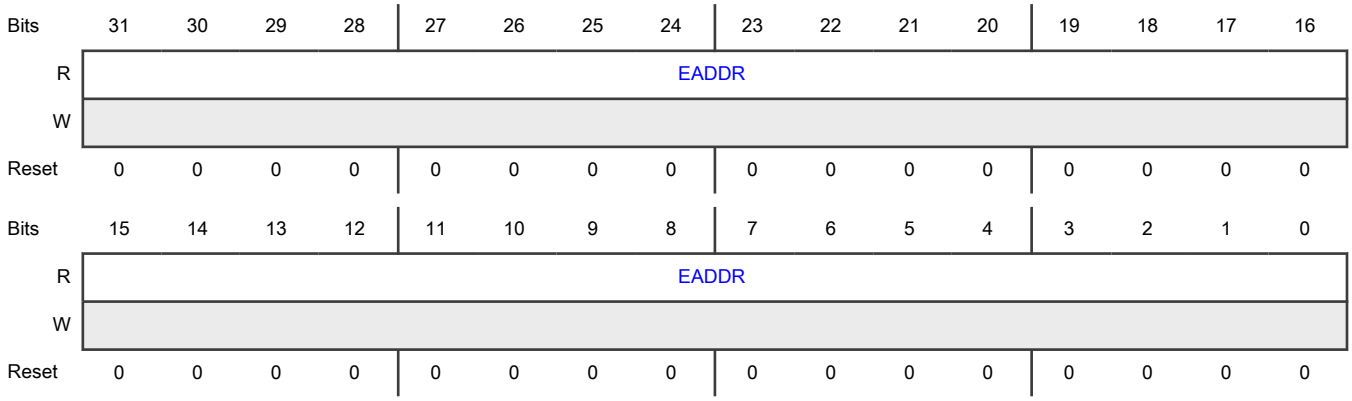
Attempted writes are error terminated as are attempted reads of an MBC instance that is not physically present.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
MBC0_DERR_W0	400h
MBC1_DERR_W0	410h
MBC2_DERR_W0	420h
MBC3_DERR_W0	430h

Diagram



Fields

Field	Description
31-0 EADDR	Error address This is the unaliased virtual address of the access that generated the access violation.

22.7.5.16 MBC Domain Error Word1 Register (MBC0_DERR_W1 - MBC3_DERR_W1)

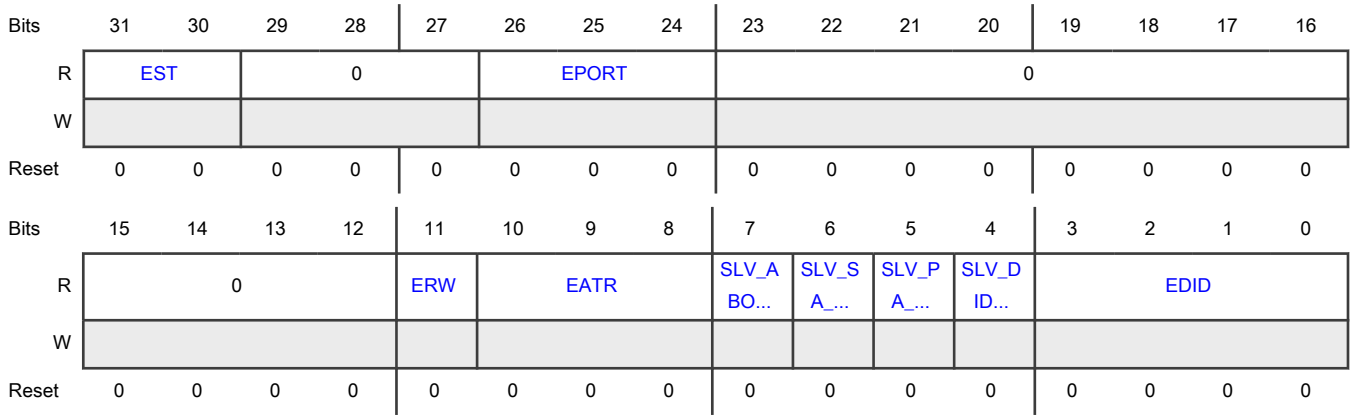
This read-only register array provides the attributes of an access violation detected by Memory Block Checker (MBC). These registers are organized as a word array, which is indexed by the violating submodule instance number. Refer to register Domain Error Location(DERRLOCd), Domain Error Word0 Register(DERR_W0_i), and Domain error capture management for more information.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
MBC0_DERR_W1	404h
MBC1_DERR_W1	414h
MBC2_DERR_W1	424h
MBC3_DERR_W1	434h

Diagram



Fields

Field	Description
31-30 EST	Error state This field signals the state of access violations for this domain in this instance of the block checker or region checker. Once an access violation has been detected and the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. After retrieving the faulting address and attributes, the error capture mechanism must be rearmed by performing a write to DERR_W3_i. 00 - No access violation has been detected. 01 - No access violation has been detected. 10 - A single access violation has been detected. 11 - Multiple access violations for this domain have been detected by this submodule instance. Only the address and attribute information for the first error have been captured in DERR_W0_i and DERR_W1_i.
29-27 —	Reserved
26-24 EPORT	Error port This field identifies the encoded port number of the MBC that detected the access violation. The MBC port number connection is device-specific. See the chip configuration details for more information. This is the MBC target that has the violation. 000 - mbcxslv0 001 - mbcxslv1 010 - mbcxslv2 011 - mbcxslv3
23-12 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
11 ERW	Error read/write This field signals whether the captured access violation occurred on a read or write reference. 0 - Read access 1 - Write access
10-8 EATR	Error attributes This field captures attributes of the access violation. 000 - Secure user mode, instruction fetch access. 001 - Secure user mode, data access. 010 - Secure privileged mode, instruction fetch access. 011 - Secure privileged mode, data access. 100 - Nonsecure user mode, instruction fetch access. 101 - Nonsecure user mode, data access. 110 - Nonsecure privileged mode, instruction fetch access. 111 - Nonsecure privileged mode, data access.
7 SLV_ABORT	Bus protect error This field captures the bus protect error from target which cause access abort.
6 SLV_SA_ERR	Secure attribute check error This field captures the secure attribute check error from target.
5 SLV_PA_ERR	Privilege attribute check error This field captures the privilege attribute check error from target.
4 SLV_DID_ERR	DID check error This field captures the DID check error from target.
3-0 EDID	Error domain identifier This field captures the domain identifier of the access violation.

22.7.5.17 MBC Domain Error Word3 Register (MBC0_DERR_W3 - MBC3_DERR_W3)

This register is used to rearm the error capture logic and clear the DERR_W0_i and DERR_W1_i registers. After the domain access violation error details have been read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

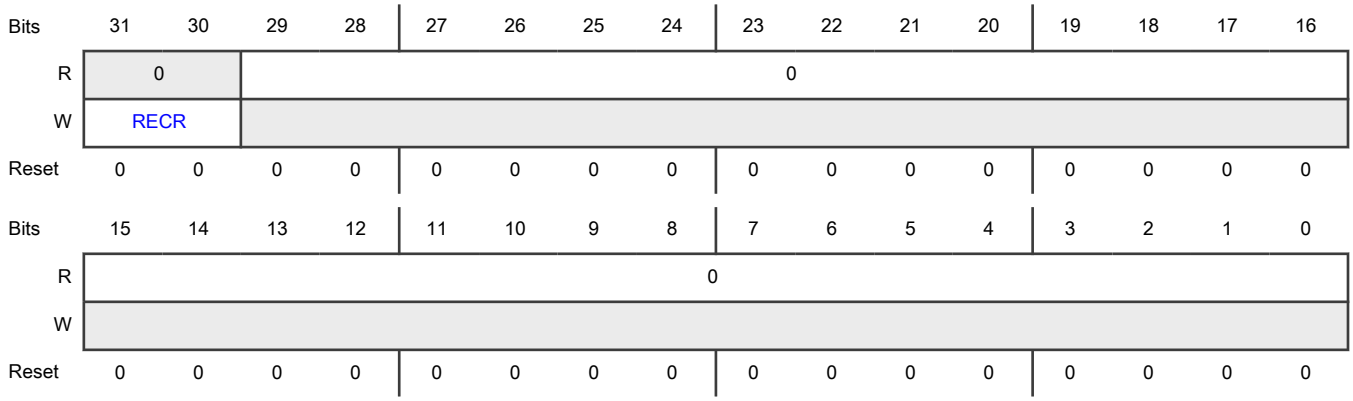
A read of this location returns zeroes. Attempted reads of a Memory Region Checker (MRC) or Memory Block Checker (MBC) instance that is not physically present are error terminated.

See Domain error capture management for more details.

Offset

Register	Offset
MBC0_DERR_W3	40Ch
MBC1_DERR_W3	41Ch
MBC2_DERR_W3	42Ch
MBC3_DERR_W3	43Ch

Diagram



Fields

Field	Description
31-30 RECR	Rearm Error Capture Registers This 2-bit, write-only field controls the rearming of the domain error capture registers. Once an access violation has been detected with the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. Writing 01b to this field rearms the error capture mechanism and clears the DERR_W0_i and DERR_W1_i registers. A write of any value other than 01b has no effect.
29-0 —	Reserved

22.7.5.18 MRC Domain Error Word0 Register (MRC0_DERR_W0)

This read-only register array provides the address of an access violation detected by memory region checker (MRC). These registers are organized as a word array, which is indexed by the MRC instance number. That is, the index, i, of this array is the instance number of MRC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MRC instance that is not physically present.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
MRC0_DERR_W0	480h

Fields

Field	Description
31-0 EADDR	Error address This is the unaliased virtual address of the access that generated the access violation.

22.7.5.19 MRC Domain Error Word1 Register (MRC0_DERR_W1)

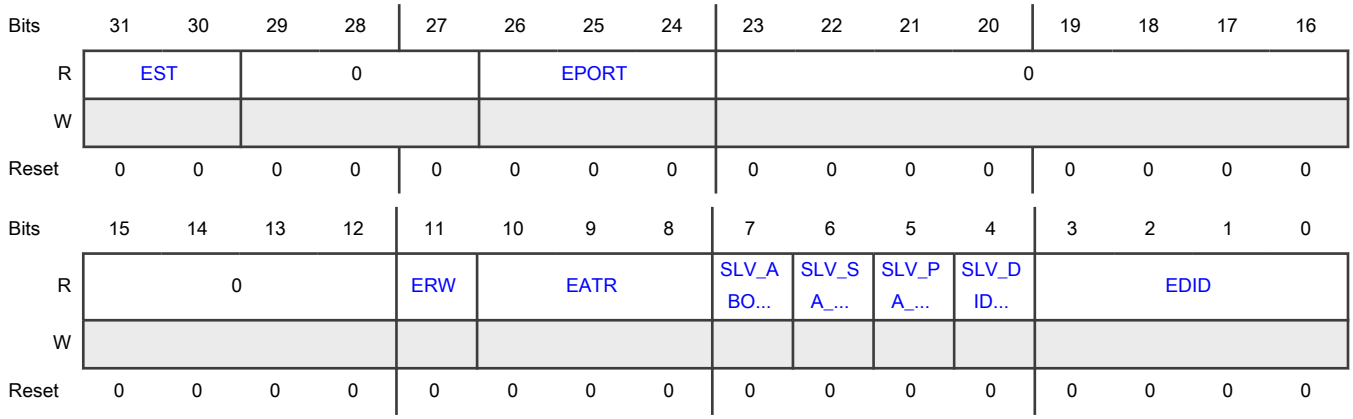
This read-only register array provides the attributes of an access violation detected by memory region checker (MRC). These registers are organized as a word array, which is indexed by the violating submodule instance number. Refer to register Domain Error Location(DERRLOCd), Domain Error Word0 Register(DERR_W0_i), and Domain error capture management for more information.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
MRC0_DERR_W1	484h

Diagram



Fields

Field	Description
31-30 EST	Error state This field signals the state of access violations for this domain in this instance of the block checker or region checker. Once an access violation has been detected and the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. After retrieving the faulting address and attributes, the error capture mechanism must be rearmed by performing a write to DERR_W3_i. 00 - No access violation has been detected. 01 - No access violation has been detected. 10 - A single access violation has been detected. 11 - Multiple access violations for this domain have been detected by this submodule instance. Only the address and attribute information for the first error have been captured in DERR_W0_i and DERR_W1_i.
29-27 —	Reserved
26-24 EPORT	Error port This field identifies the encoded port number of the MRC that detected the access violation. The MRC port number connection is device-specific. See the chip configuration details for more information.
23-12 —	Reserved
11 ERW	Error read/write This field signals whether the captured access violation occurred on a read or write reference. 0 - Read access 1 - Write access
10-8	Error attributes

Table continues on the next page...

Table continued from the previous page...

Field	Description
EATR	This field captures certain attributes of the access violation. 000 - Secure user mode, instruction fetch access. 001 - Secure user mode, data access. 010 - Secure privileged mode, instruction fetch access. 011 - Secure privileged mode, data access. 100 - Nonsecure user mode, instruction fetch access. 101 - Nonsecure user mode, data access. 110 - Nonsecure privileged mode, instruction fetch access. 111 - Nonsecure privileged mode, data access.
7 SLV_ABORT	Bus protect error This field captures the bus protect error from target which cause access abort.
6 SLV_SA_ERR	Secure attribute check error This field captures the secure attribute check error from target.
5 SLV_PA_ERR	Privilege attribute check error This field captures the privilege attribute check error from target.
4 SLV_DID_ERR	DID check error This field captures the DID check error from target.
3-0 EDID	Error domain identifier This field captures the domain identifier of the access violation.

22.7.5.20 MRC Domain Error Word3 Register (MRC0_DERR_W3)

This register is used to rearm the error capture logic and clear the DERR_W0_i and DERR_W1_i registers. After the domain access violation error details have been read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

A read of this location returns zeroes. Attempted reads of a memory region checker (MRC) or Memory Block Checker (MBC) instance that is not physically present are error terminated.

See Domain error capture management for more details.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

22.7.5.21 DAC Initiator Domain Assignment Register (MDA_W0_0_DFMT0 - MDA_W3_1_DFMT0)

The MDA_Wr_m registers provide a 2-dimensional data structure for assigning bus initiators to domains. The number of implemented registers is defined by DACFGm[NMDAR]. This per-initiator domain assignment is then repeated for each bus initiator (MDAm). Thus, m specifies the initiator number and r refers to the specific MDA register for a given bus initiator.

Each Wr within the MDAm structure is a word-sized definition; there are two formats supported, one for processor cores and another for non-processors. Processor initiators typically support one or more Wr domain definitions, while non-processor initiators support a single Wr. Processor initiators Domain Assignment register names use a _DFMT0 suffix. Non-processor initiators Domain Assignment register names use a _DFMT1 suffix.

The DAC submodule is responsible for the generation of domain identifiers for every transaction from every bus initiator. If there is a single Wr for a given initiator, then the specified domain identifier is used directly. If there are multiple Wr values for a given initiator, then the DAC evaluates the conditional terms to determine a “hit”. For all Wr hits, their corresponding domain identifiers are simply logically summed together (boolean OR). Use cases are typically expected to *hit in a single Wr* for a processor initiator. Special care is needed if *none* of the conditional terms hit in any Wr evaluation; for this case, the generated DID = 0 and software needs to be aware of any potential access rights granted for this DID.

Each MDA_Wr_m register has one of two programming models depending on the state of the domain format field, DFMT. The model described in this section is for DFMT = 0. This definition allows three different specifications of the DID for processors. The DFMT = 1 model is described in Initiator Domain Assignment (MDA_Wr_m_DFMT1) register.

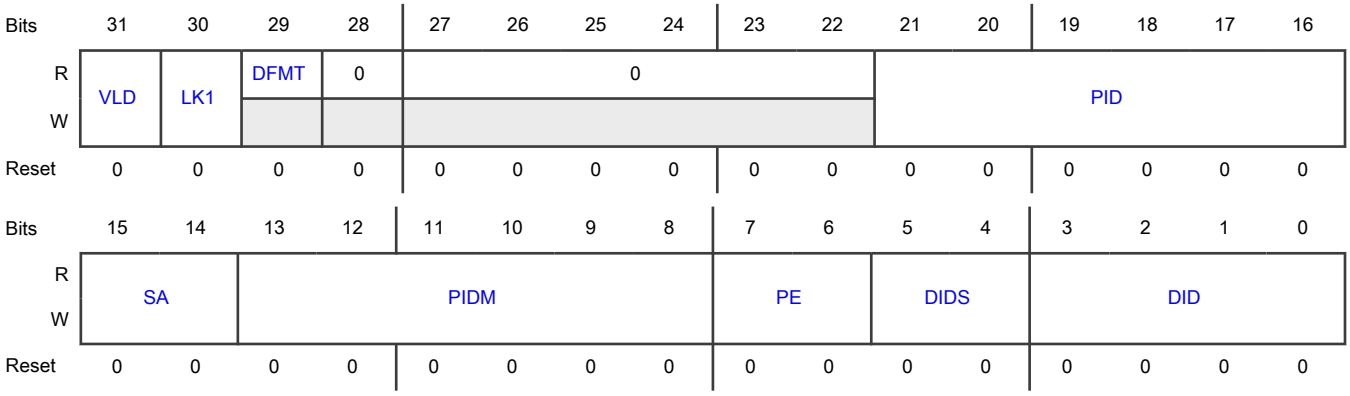
Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Offset

For m = 0 to 1; r = 0 to 3:

Register	Offset
MDA_Wr_m_DFMT0	800h + (m × 20h) + (r × 4h)

Diagram



Fields

Field	Description
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by TRDC_CR[GVLDM] = 1. If TRDC_CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and TRDC_CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0 - The Wr domain assignment is invalid. 1 - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0 - Register can be written by any secure privileged write. 1 - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROZ 0 - Processor-core domain assignment 1 - Non-processor domain assignment

Table continues on the next page...

Table continued from the previous page...

Field	Description
28 —	Reserved
27-22 —	Reserved
21-16 PID	Process Identifier This field specifies that the process identifier is to be combined with the PIDM field and included in the domain hit determination. The optional inclusion of the PID and PIDM is controlled by the MDA_Wr_m[PE] field.
15-14 SA	Secure attribute This field defines the secure/nonsecure attribute for processor cores. **NOTE** The bus initiator's input secure/nonsecure attribute is used if SA = 1X, or this VLD = 0. If TZM_ENB = 0, the initiator attribute is forced to nonsecure. A nonsecure write cannot program this field to 2'b00, which is a security level higher than the mode of the process that is writing it. Reset value of SA: • if TZM_ENB=0, SA reset value = 2'b01 • if TZM_ENB=1, SA reset value = 2'b00 00 - Force the bus attribute for this initiator to secure. 01 - Force the bus attribute for this initiator to nonsecure. 10 - Use the bus initiator's secure/nonsecure attribute directly. 11 - Use the bus initiator's secure/nonsecure attribute directly.
13-8 PIDM	Process Identifier Mask This field provides a masking capability so that multiple process identifiers can be included as part of the domain hit determination. If a bit in the PIDM is set, then the corresponding bit of the PID is ignored in the comparison. The optional inclusion of the PID and PIDM is controlled by the MDA_Wr_m[PE] field.

7-6
PE
	Process identifier enable
	Controls the optional inclusion of the PID, qualified by PIDM, into the domain hit evaluation. It provides the ability to include inclusive or exclusive sets of masked PID values.
	00 - No process identifier is included in the domain hit evaluation.
	01 - No process identifier is included in the domain hit evaluation.
	10 - PE = 2. The process identifier is included in the domain hit evaluation as defined by the expression:
	`partial_domain_hit = (PE == 2) && ((PID & ~PIDM) == (TRDC_PIDn[PID] & ~PIDM))`
	11 - PE = 3. The process identifier is included in the domain hit evaluation as defined by the expression:
	`partial_domain_hit = (PE == 3) && ~((PID & ~PIDM) == (TRDC_PIDn[PID] & ~PIDM))`

Table continues on the next page...

Table continued from the previous page...

Field	Description
5-4 DIDS	DID Select This field selects the source of the domain identifier. 00 - Use MDAm[3:0] as the domain identifier. 01 - Use the input DID as the domain identifier. 10 - Use MDAm[3:2] concatenated with the low-order 2 bits of the input DID (DID_in[1:0]) as the domain identifier. 11 - Reserved for future use.
3-0 DID	Domain identifier This 4-bit field is the domain ID attribute that is sent on the accesses from the bus initiator connected to the DAC when DIDS=00b. DID[3:2] is used when DIDS=10b. Write a value greater than the number of DIDs is illegal.

22.7.5.22 DAC Initiator Domain Assignment Register (MDA_W0_2_DFMT1 - MDA_W0_3_DFMT1)

This register is identical to Initiator Domain Assignment (MDA_Wr_m_DFMT0) register except that the domain format field, DFMT, is 1 and the PID field is not used. This format supports two different specifications of the DID for non-core bus initiators.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Offset

Register	Offset
MDA_W0_2_DFMT1	840h
MDA_W0_3_DFMT1	860h

Field	Description
	0 - Execute access is not allowed in Secure User mode. 1 - Execute access is allowed in Secure User mode.
7 —	Reserved
6 NPR	NonsecurePriv Read NonsecurePriv read access control flag 0 - Read access is not allowed in Nonsecure Privilege mode. 1 - Read access is allowed in Nonsecure Privilege mode.
5 NPW	NonsecurePriv Write NonsecurePriv write access control flag 0 - Write access is not allowed in Nonsecure Privilege mode. 1 - Write access is allowed in Nonsecure Privilege mode.
4 NPX	NonsecurePriv Execute NonsecurePriv execute access control flag 0 - Execute access is not allowed in Nonsecure Privilege mode. 1 - Execute access is allowed in Nonsecure Privilege mode.
3 —	Reserved
2 NUR	NonsecureUser Read NonsecureUser read access control flag 0 - Read access is not allowed in Nonsecure User mode. 1 - Read access is allowed in Nonsecure User mode.
1 NUW	NonsecureUser Write NonsecureUser write access control flag 0 - Write access is not allowed in Nonsecure User mode. 1 - Write access is allowed in Nonsecure User mode.
0 NUX	NonsecureUser Execute NonsecureUser execute access control flag 0 - Execute access is not allowed in Nonsecure User mode. 1 - Execute access is allowed in Nonsecure User mode.

22.7.5.30 MBC Memory Block Configuration Word (MBC0_DOM0_MEM0_BLK_CFG_W0 - MBC1_DOM15_MEM3_BLK_CFG_W2)

MBC[m]_DOM[d]_MEM[s]_BLK_CFG_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

These registers are read/write for both the alternate view of the NSE bit and the 3-bit MBACSEL field. This is an array of 4 bit fields defining the block configuration for the given submemory. Each 4-bit field includes an alternative view of the associated NSE bit plus a 3-bit access control select that selects the global access control value that applies to the referenced memory block.

For a given memory block, B, if the value programmed in the MBACSELn field selects a locked MBC_MEMN_GLBACr register, the MBACSEL field is locked until the next reset. Depending on BLK_CFG_W, the NSEn/MBASELn fields correspond to different blocks. The following table describes the relationship between W (word index) and B (block number).

MEM0 supports up to 512 blocks ; W0 - W63

MEM1-3 supports up to 64 block ; W0 - W7

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

Table 112. Block Config Word to Block Number Relationship

Block Config Word	NSE7/ MBACSEL7	NSE6/ MBACSEL6	NSE5/ MBACSEL5	NSE4/ MBACSEL4	NSE3/ MBACSEL3	NSE2/ MBACSEL2	NSE1/ MBACSEL1	NSE0/ MBACSEL0
W0	block 7	block 6	block 5	block 4	block 3	block 2	block 1	block 0
W1	block 15	block 14	block 13	block 12	block 11	block 10	block 9	block 8
W2	block 23	block 22	block 21	block 20	block 19	block 18	block 17	block 16

Fields

Field	Description
31 NSE7	NonSecure Enable for block B 0 - Secure read and write to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), secure execution and nonsecure accesses to block B are not allowed. 1 - Secure accesses to block B are not allowed, nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
30-28 MBACSEL7	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL7 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
27 NSE6	NonSecure Enable for block B 0 - Secure read and write to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), secure execution and nonsecure accesses to block B are not allowed. 1 - Secure accesses to block B are not allowed, nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
26-24	Memory Block Access Control Select for block B

Table continues on the next page...

Table continued from the previous page...

Field	Description
MBACSEL6	This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL6 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
23 NSE5	NonSecure Enable for block B 0 - Secure read and write to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), secure execution and nonsecure accesses to block B are not allowed. 1 - Secure accesses to block B are not allowed, nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
22-20 MBACSEL5	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL5 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
19 NSE4	NonSecure Enable for block B 0 - Secure read and write to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), secure execution and nonsecure accesses to block B are not allowed.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Secure accesses to block B are not allowed, nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
18-16 MBACSEL4	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL4 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
15 NSE3	NonSecure Enable for block B 0 - Secure read and write to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), secure execution and nonsecure accesses to block B are not allowed. 1 - Secure accesses to block B are not allowed, nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
14-12 MBACSEL3	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL3 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
11	NonSecure Enable for block B

Table continues on the next page...

Table continued from the previous page...

Field	Description
	111 - select MBC_MEMN_GLBAC7 access control policy for block B
3 NSE0	NonSecure Enable for block B 0 - Secure read and write to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), secure execution and nonsecure accesses to block B are not allowed. 1 - Secure accesses to block B are not allowed, nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
2-0 MBACSEL0	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL0 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B

22.7.5.31 MBC Memory Block NonSecure Enable Word (MBC0_DOM0_MEM0_BLK_NSE_W0 - MBC1_DOM15_MEM3_BLK_NSE_W0)

MBC[m]_DOM[d]_MEM[s]_BLK_NSE_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

This is the bitmap of the individual NSE bits for the memory block.

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

The following table describes the relationship between W (word index) and B (block number).

Table 113. Block Config Word to Block Number Relationship

Block NSE Word	BIT31	BIT30-BIT1	BIT0
W0	block 31	block 30 - block 1	block 0
W1	block 63	block 62 - block 33	block 32
For MEM0, block 64 - block 511			
W2	block 95	block 94 - block 65	block 64
. . .			
W15	block 511	block 510 - block 481	block 480

The NSE bitmap can be accessed directly by register reads and writes to these locations, or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and BLK_CFG[NSEn] registers.

22.7.5.33 MBC Global Access Control (MBC1_MEMN_GLBAC1 - MBC1_MEMN_GLBAC7)

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User. The lock bit provides the ability to lock these control access flags and to lock the MBC_BLK_CFG[MBACSEL] field when a locked MBC_MEMN_GLBAC register is selected.

Field	Description
NPR	NonsecurePriv read access control flag 0 - Read access is not allowed in Nonsecure Privilege mode. 1 - Read access is allowed in Nonsecure Privilege mode.
5 NPW	NonsecurePriv Write NonsecurePriv write access control flag 0 - Write access is not allowed in Nonsecure Privilege mode. 1 - Write access is allowed in Nonsecure Privilege mode.
4 NPX	NonsecurePriv Execute NonsecurePriv execute access control flag 0 - Execute access is not allowed in Nonsecure Privilege mode. 1 - Execute access is allowed in Nonsecure Privilege mode.
3 —	Reserved
2 NUR	NonsecureUser Read NonsecureUser read access control flag 0 - Read access is not allowed in Nonsecure User mode. 1 - Read access is allowed in Nonsecure User mode.
1 NUW	NonsecureUser Write NonsecureUser write access control flag 0 - Write access is not allowed in Nonsecure User mode. 1 - Write access is allowed in Nonsecure User mode.
0 NUX	NonsecureUser Execute NonsecureUser execute access control flag 0 - Execute access is not allowed in Nonsecure User mode. 1 - Execute access is allowed in Nonsecure User mode.

22.7.5.35 MBC Global Access Control (MBC2_MEMN_GLBAC1 - MBC2_MEMN_GLBAC7)

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User. The lock bit provides the ability to lock these control access flags and to lock the MBC_BLK_CFG[MBACSEL] field when a locked MBC_MEMN_GLBAC register is selected.

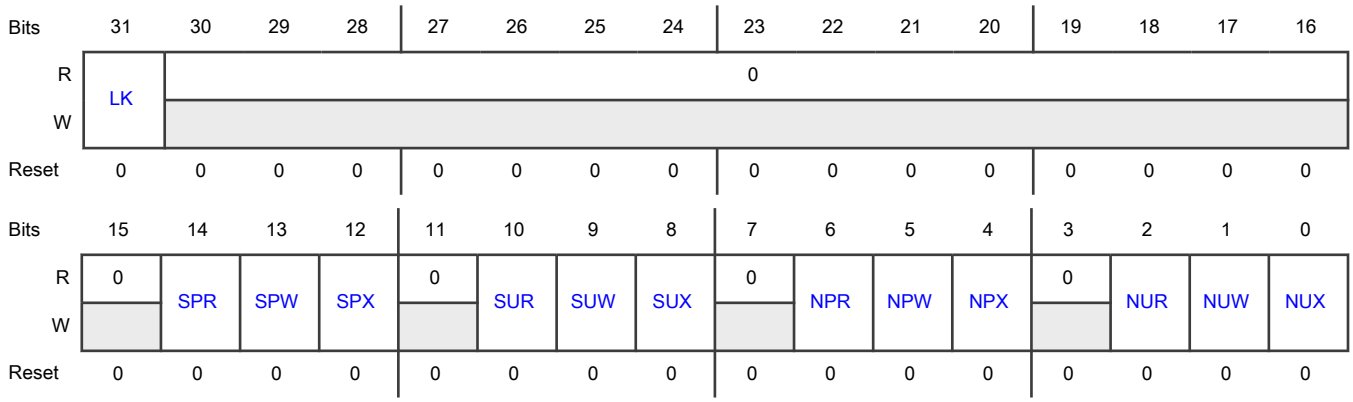
Diagram



Fields

Field	Description
31 LK	LOCK This 1-bit field provides a mechanism to limit writes to the this register to protect its contents. Once set, this bit remains asserted until the next reset. 0 - This register is not locked and can be altered. 1 - This register is locked and cannot be altered.
30-15 —	Reserved
14 SPR	SecurePriv Read SecurePriv read access control flag 0 - Read access is not allowed in Secure Privilege mode. 1 - Read access is allowed in Secure Privilege mode.
13	SecurePriv Write

Table continues on the next page...

Table continued from the previous page...

Field	Description
SPW	SecurePriv write access control flag 0 - Write access is not allowed in Secure Privilege mode. 1 - Write access is allowed in Secure Privilege mode.
12 SPX	SecurePriv Execute SecurePriv execute access control flag 0 - Execute access is not allowed in Secure Privilege mode. 1 - Execute access is allowed in Secure Privilege mode.
11 —	Reserved
10 SUR	SecureUser Read SecureUser read access control flag 0 - Read access is not allowed in Secure User mode. 1 - Read access is allowed in Secure User mode.
9 SUW	SecureUser Write SecureUser write access control flag 0 - Write access is not allowed in Secure User mode. 1 - Write access is allowed in Secure User mode.
8 SUX	SecureUser Execute SecureUser execute access control flag 0 - Execute access is not allowed in Secure User mode. 1 - Execute access is allowed in Secure User mode.
7 —	Reserved
6 NPR	NonsecurePriv Read NonsecurePriv read access control flag 0 - Read access is not allowed in Nonsecure Privilege mode. 1 - Read access is allowed in Nonsecure Privilege mode.
5 NPW	NonsecurePriv Write NonsecurePriv write access control flag 0 - Write access is not allowed in Nonsecure Privilege mode. 1 - Write access is allowed in Nonsecure Privilege mode.

Table continued from the previous page...

Field	Description
4 NPX	NonsecurePriv Execute NonsecurePriv execute access control flag 0 - Execute access is not allowed in Nonsecure Privilege mode. 1 - Execute access is allowed in Nonsecure Privilege mode.
3 —	Reserved
2 NUR	NonsecureUser Read NonsecureUser read access control flag 0 - Read access is not allowed in Nonsecure User mode. 1 - Read access is allowed in Nonsecure User mode.
1 NUW	NonsecureUser Write NonsecureUser write access control flag 0 - Write access is not allowed in Nonsecure User mode. 1 - Write access is allowed in Nonsecure User mode.
0 NUX	NonsecureUser Execute NonsecureUser execute access control flag 0 - Execute access is not allowed in Nonsecure User mode. 1 - Execute access is allowed in Nonsecure User mode.

22.7.5.36 MBC Memory Block Configuration Word (MBC2_DOM0_MEM0_BLK_CFG_W0 - MBC3_DOM15_MEM1_BLK_CFG_W4)

MBC[m]_DOM[d]_MEM[s]_BLK_CFG_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

These registers are read/write for both the alternate view of the NSE bit and the 3-bit MBACSEL field. This is an array of 4 bit fields defining the block configuration for the given submemory. Each 4-bit field includes an alternative view of the associated NSE bit plus a 3-bit access control select that selects the global access control value that applies to the referenced memory block.

For a given memory block, B, if the value programmed in the MBACSELn field selects a locked MBC_MEMN_GLBACr register, the MBACSEL field is locked until the next reset. Depending on BLK_CFG_W, the NSEn/MBASELn fields correspond to different blocks. The following table describes the relationship between W (word index) and B (block number).

MEM0 supports up to 512 blocks ; W0 - W63

MEM1-3 supports up to 64 block ; W0 - W7

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

Table 114. Block Config Word to Block Number Relationship

Block Config Word	NSE7/ MBACSEL7	NSE6/ MBACSEL6	NSE5/ MBACSEL5	NSE4/ MBACSEL4	NSE3/ MBACSEL3	NSE2/ MBACSEL2	NSE1/ MBACSEL1	NSE0/ MBACSEL0
W0	block 7	block 6	block 5	block 4	block 3	block 2	block 1	block 0
W1	block 15	block 14	block 13	block 12	block 11	block 10	block 9	block 8
W2	block 23	block 22	block 21	block 20	block 19	block 18	block 17	block 16
W3	block 31	block 30	block 29	block 28	block 27	block 26	block 25	block 24

7 NSE1	NonSecure Enable for block B 0 - Secure read and write to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), secure execution and nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
6-4 MBACSEL1	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL1 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
3 NSE0	NonSecure Enable for block B 0 - Secure read and write to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), secure execution and nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
2-0 MBACSEL0	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL0 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B

Table continues on the next page...

Table continued from the previous page...

Field	Description
	001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B

22.7.5.37 MBC Memory Block NonSecure Enable Word (MBC2_DOM0_MEM0_BLK_NSE_W0 - MBC3_DOM15_MEM1_BLK_NSE_W1)

MBC[m]_DOM[d]_MEM[s]_BLK_NSE_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

This is the bitmap of the individual NSE bits for the memory block.

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

The following table describes the relationship between W (word index) and B (block number).

Table 115. Block Config Word to Block Number Relationship

Block NSE Word	BIT31	BIT30-BIT1	BIT0
W0	block 31	block 30 - block 1	block 0
W1	block 63	block 62 - block 33	block 32
For MEM0, block 64 - block 511			
W2	block 95	block 94 - block 65	block 64
		.	
		.	
		.	
W15	block 511	block 510 - block 481	block 480

The NSE bitmap can be accessed directly by register reads and writes to these locations, or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and BLK_CFG[NSEn] registers.

22.7.5.39 MBC Global Access Control (MBC3_MEMN_GLBAC1 - MBC3_MEMN_GLBAC7)

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User. The lock bit provides the ability to lock these control access flags and to lock the MBC_BLK_CFG[MBACSEL] field when a locked MBC_MEMN_GLBAC register is selected.

22.7.5.45 MRC Global Access Control (MRC0_GLBAC0)

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, NonsecureUser. The lock bit provides the ability to lock these control access flags, to lock the MRC_BLK_CFG[MRACSEL] field, and to lock the MRC_RGD[STRT_ADDR, END_ADDR, VLD] fields when a locked MRC_GLBAC register is selected.

22.7.5.47 MRC Region Descriptor Word 0 (MRC0_DOM0_RGD0_W0 - MRC0_DOM15_RGD15_W0)

MRC[m]_DOM[d]_RGD[r]_W[w], where,

- m - mrc index
- d - domain index
- r - region descriptor index
- w - word index

The MRC[m]_DOM[d]_RGD[r]_W[w] registers provide a 3-dimensional data structure for defining access control policies per domain for each supported memory region.

Memory map/register definition:

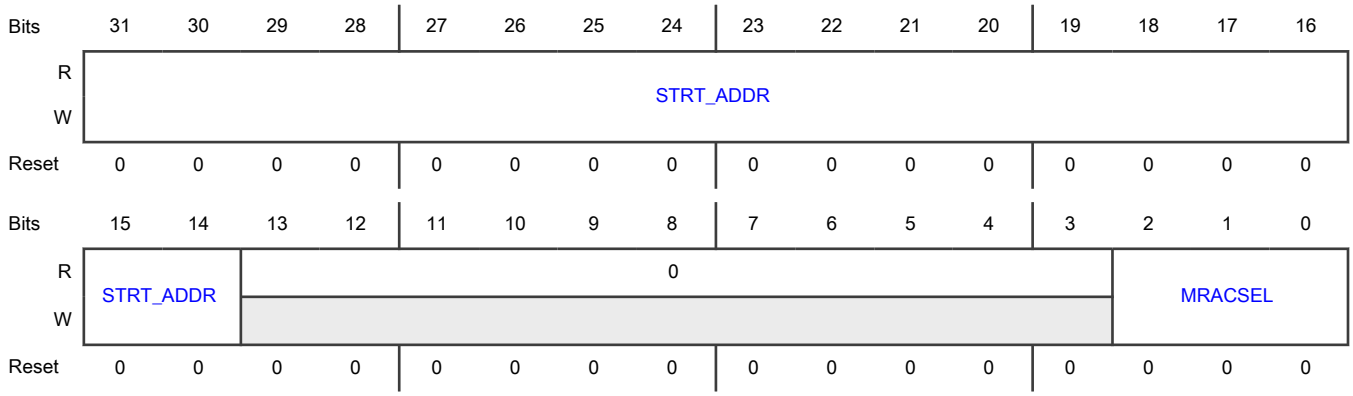
There two word-size registers (W[w]) defined in each memory region. There are up to 16 memory region checkers (MRCs), m, each supporting up to 16 memory region descriptors (RGD), r. The number of MRCs is defined by HWCFG0[NMRC].

Offset

For d = 0 to 15; r = 0 to 15:

Register	Offset
MRC0_DOMd_RGDr_W0	1_8040h + (d × 100h) + (r × 8h)

Diagram



Fields

Field	Description
31-14 END_ADDR	End Address (16K-1)-mod-16K physical end address [31:14] of region r. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1.
13-5 —	Reserved
4 NSE	NonSecure Enable Alternate view of NSE flag for Region r. 0 - Secure accesses to region r are based on corresponding MRACSEL field in this register (MRCm_DOMd_RGDr_Ww[MRACSEL]), nonsecure accesses to region r are not allowed. 1 - Secure and nonsecure accesses to region r are based on corresponding MRACSEL field in this register (MRCm_DOMd_RGDr_Ww[MRACSEL]).
3-1 —	Reserved
0 VLD	Valid If set, this region is valid and accesses are checked for this region. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1.

22.7.5.49 MRC Region Descriptor NonSecure Enable (MRC0_DOM0_RGD_NSE - MRC0_DOM15_RGD_NSE)

This register is the bitmap of the individual NSE bits for the region descriptors. Bit n corresponds to region n.

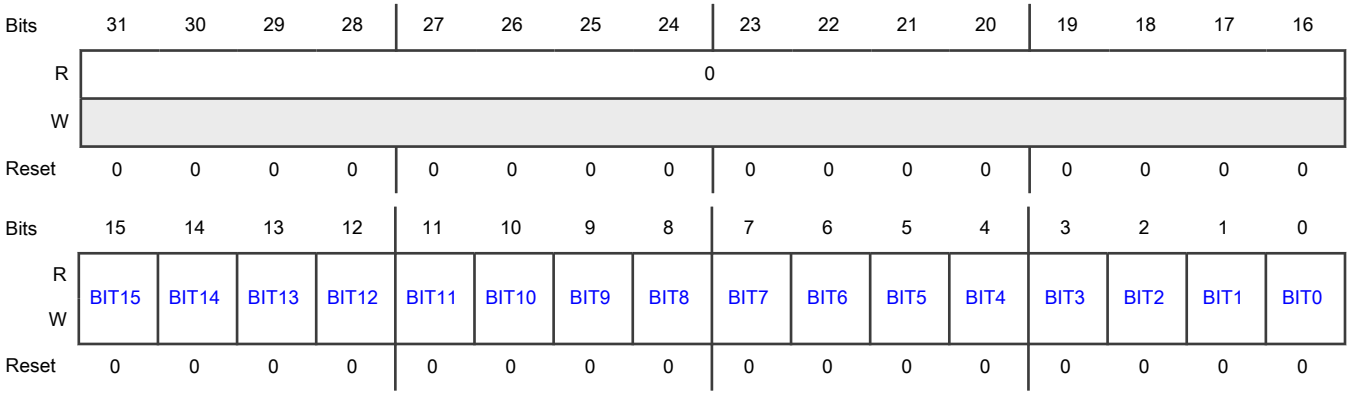
These bits can also be written or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and RGD_W0[NSE] registers.

Offset

For d = 0 to 15:

Register	Offset
MRC0_DOMd_RGD_NSE	1_80C0h + (d × 100h)

Diagram



Fields

Field	Description
31-16 —	Reserved
15-0 BITn	Bit n NonSecure Enable [n = 0 - 15] 0 - Secure accesses to region r are based on corresponding MRACSEL field in this register (MRCm_DOMd_RGDr_Ww[MRACSEL]), nonsecure accesses to region r are not allowed. 1 - Secure and nonsecure accesses to region r are based on corresponding MRACSEL field in register (MRCm_DOMd_RGDr_Ww[MRACSEL]).

22.7.6.2 TRDC Register (TRDC_CR)

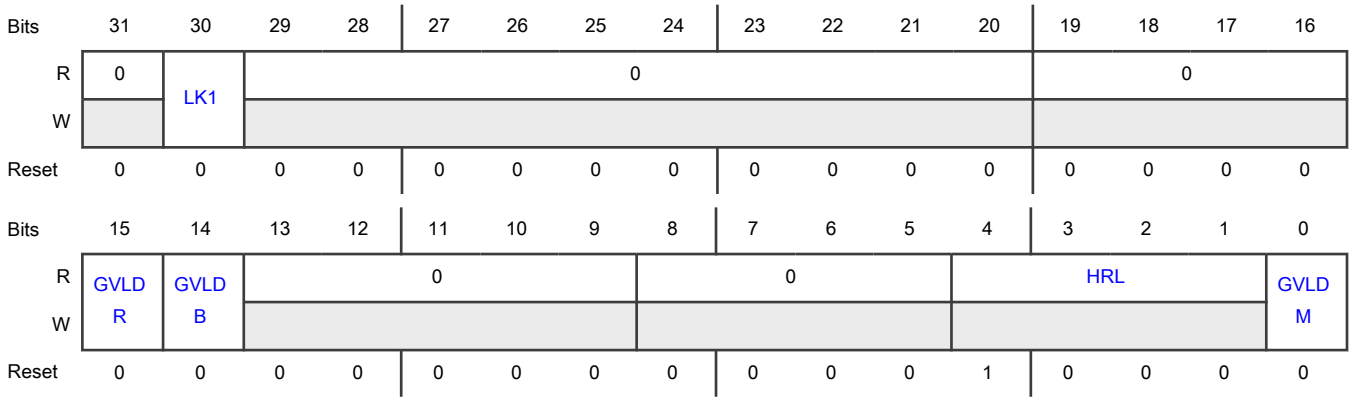
This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_CR	0h

Diagram



Fields

Field	Description
31 —	Reserved
30 LK1	Lock Status This field is the lock status of the TRDC_CR. This field is set when all GVLD bits are set; GVLDR=GVLDB=GVLDM=1b1. Once set, this bit remains asserted until the next reset. 0 - The CR can be written by any secure privileged write. 1 - The CR is locked (read-only) until the next reset.
29-20 —	Reserved
19-16 —	Reserved
15 GVLDR	Global Valid for Memory Region Checkers TRDC global MRC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MRCs are disabled. 1 - TRDC MRCs are enabled.
14 GVLDB	Global Valid for Memory Block Checkers TRDC global MBC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MBCs are disabled. 1 - TRDC MBCs are enabled.
13-9 —	Reserved
8-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the TRDC’s hardware and definition revision level. It can be read by software to determine the functional definition of the module.
0 GVLDM	Global Valid for Domain Assignment Controllers TRDC global DAC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC DACs are disabled. 1 - TRDC DACs are enabled.

22.7.6.3 TRDC Hardware Configuration Register 0 (TRDC_HWCFG0)

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus initiators along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG0	F0h

Fields

Field	Description
31-29 MID	Module ID This field defines major version ID of this module.
28-24 NMRC	Number of MRCs This field defines the number of MRCs on the device [1-16].
23-20 —	Reserved
19-16 NMBC	Number of MBCs This field defines the number of MBCs on the device [1-8].
15-8 NMSTR	Number of bus initiators This read-only field defines the number of bus initiators.
7-5 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
4-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-16].

22.7.6.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

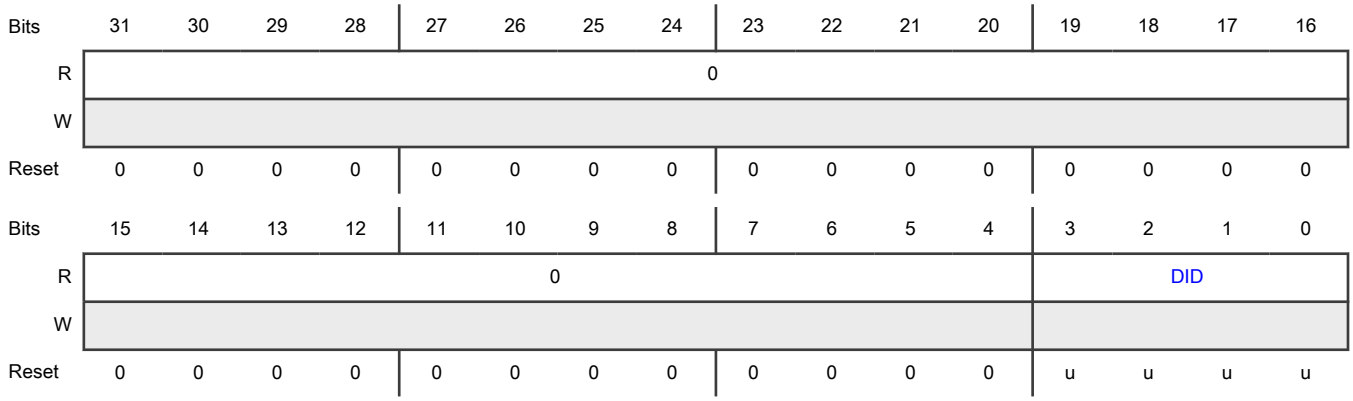
This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG1	F4h

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 DID	Domain identifier number This field provides the domain number [0-15] of the requesting bus initiator.

22.7.6.5 Domain Assignment Configuration Register (DACFG2 - DACFG4)

This register defines the number of implemented domain assignment registers for bus initiator m, where m+1 can specify from 1 to 64 bus initiators. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus initiator. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a initiator doesn't exist but it is in the same 32-bit group as DACFG for an existing initiator. For example, when there are only 2 DACFG0-1 registers for 2 initiator, and initiators for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus initiators have one or more domain assignment registers, while non-processor initiators have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
DACFG2	102h
DACFG3	103h
DACFG4	104h

Diagram

Bits	7	6	5	4	3	2	1	0
R	NCM	0			NMDAR			
W								
Reset	1	0	0	0	0	0	0	1

Fields

Field	Description
7 NCM	Non-CPU Initiator This read-only field signals that bus initiator m is a non-CPU initiator. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus initiator. 0 - Bus initiator is a processor. 1 - Bus initiator is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of initiator domain assignment registers for bus initiator m This read-only field specifies the number of registers associated with the initiator domain assignment register for a given bus initiator. The value is limited to the range [0-8], where zero indicates a non-existent bus initiator and non-zero values indicate the number of implemented registers associated with this MDAm.

22.7.6.6 TRDC IDAU Control Register (TRDC_IDAU_CR)

This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_IDAU_CR	1C0h

Field	Description
18-16 —	Reserved
15-13 —	Reserved
12 LKSAU	Lock SAU Asserting this bit prevents changes to the processor's Secure SAU memory regions already programmed. All processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock these registers 1 - Disable writes to the SAU_CTRL, SAU_RNR, SAU_RBAR and SAU_RLAR registers from software or from a debug agent connected to the processor
11 LKNSMPU	Lock Nonsecure MPU Asserting this bit prevents changes to the processor's Nonsecure MPU memory regions already programmed. All processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock these registers 1 - Disable writes to the MPU_CTRL_NS, MPU_RNR_NS, MPU_RBAR_NS, MPU_RLAR_NS, MPU_RBAR_A_NSn and MPU_RLAR_A_NSn from software or from a debug agent connected to the processor
10 LKSMPU	Lock Secure MPU Asserting this signal prevents changes to the processor's programmed Secure MPU memory regions and all processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock these registers 1 - Disable writes to the MPU_CTRL, MPU_RNR, MPU_RBAR, MPU_RLAR, MPU_RBAR_An and MPU_RLAR_An from software or from a debug agent connected to the processor in Secure state
9 LKNSVTOR	Lock Nonsecure Vector Table Offset Register Asserting this signal prevents changes to the processor's Nonsecure vector table base address. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock this register 1 - Disable writes to the VTOR_NS register
8 LKSVTAIRCR	Lock Secure VTOR, Application interrupt and Reset Control Registers This bit is sticky, once set, it can only be cleared with a reset. Asserting this signal prevents processor changes to: • The Secure vector table base address.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	• Handling of Secure interrupt priority. • BusFault, HardFault, and NMI security target settings in the processor. 0 - Unlock these registers 1 - Disable writes to the VTOR_S, AIRCR[PRIS], and AIRCR[BFHFNMINS] registers
7 —	Reserved
6 SAUDIS	Security Attribution Unit Disable 0 - SAU is enabled 1 - SAU is disabled
5 MPUNSDIS	NonSecure Memory Protection Unit Disabled 0 - Nonsecure MPU is enabled 1 - Nonsecure MPU is disabled
4 MPUSDIS	Secure Memory Protection Unit Disabled 0 - Secure MPU is enabled 1 - Secure MPU is disabled
3 CFGSECEXT	Configure Security Extension 0 - Armv8M Security Extension is disabled 1 - Armv8-M Security Extension is enabled
2-1 —	Reserved
0 VLD	Valid When VLD =0, all address attribute from IDAU is nonSecure. When VLD=1, values in other fields of this register are valid.

22.7.6.7 TRDC FLW Control (TRDC_FLW_CTL)

This register provides control of the FLW = Flash Logical Window operation.

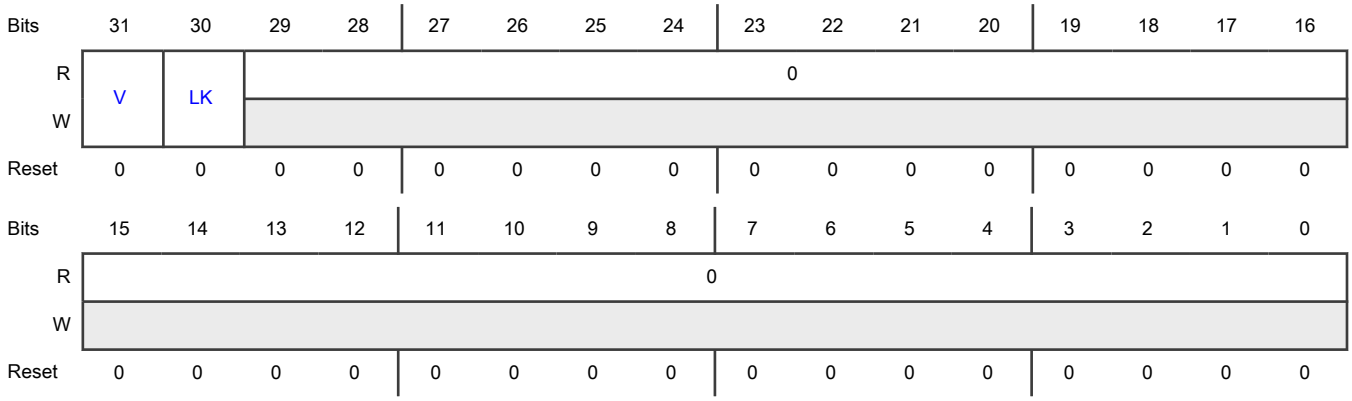
This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FLW_CTL	1E0h

Diagram



Fields

Field	Description
31 V	Valid bit 0 - FLW function is disabled. 1 - FLW function is enabled.
30 LK	Lock bit 0 - FLW registers may be modified. 1 - FLW registers are locked until the next reset.
29-0 —	Reserved

22.7.6.8 TRDC FLW Physical Base (TRDC_FLW_PBASE)

This read-only register gives the physical base address of the Flash Logical Window.

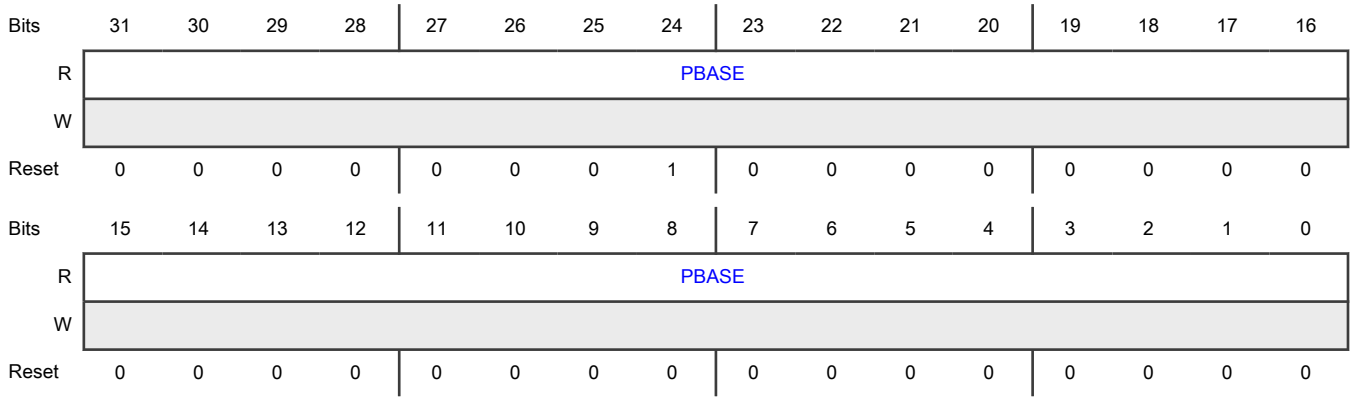
This register exists for this device but has not effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_FLW_PBASE	1E4h

Diagram



Fields

Field	Description
31-0 PBASE	Physical base address Physical address of the base of the FLW (mod 32KBytes).

22.7.6.9 TRDC FLW Array Base (TRDC_FLW_ABASE)

This register gives the flash array base address of the Flash Logical Window.

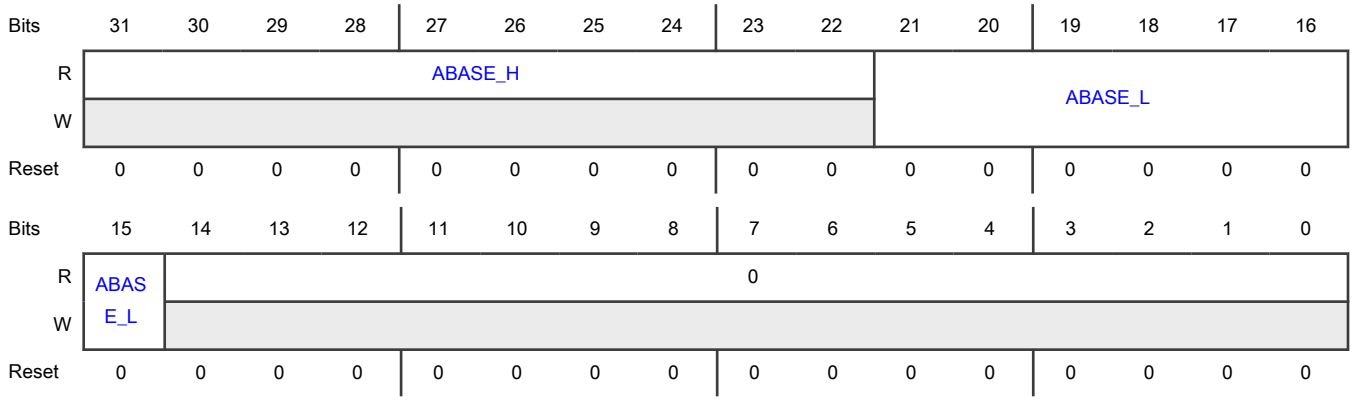
This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Offset

Register	Offset
TRDC_FLW_ABASE	1E8h

Diagram



Fields

Field	Description
31-22 ABASE_H	Array base address high Flash array address upper bits of the base of the FLW (mod 32KBytes).
21-15 ABASE_L	Array base address low Flash array address lower bits of the base of the FLW (mod 32KBytes).
14-0 —	Reserved

22.7.6.10 TRDC FLW Block Count (TRDC_FLW_BCNT)

This register gives the size of the Flash Logic Window in 32KByte blocks.

This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Offset

Register	Offset
TRDC_FLW_BCNT	1ECh

Table continues on the next page...

Table continued from the previous page...

Field	Description
14-0 BCNT	Block Count Size of FLW in number of 32KByte blocks.

22.7.6.11 TRDC Fault Domain ID (TRDC_FDID)

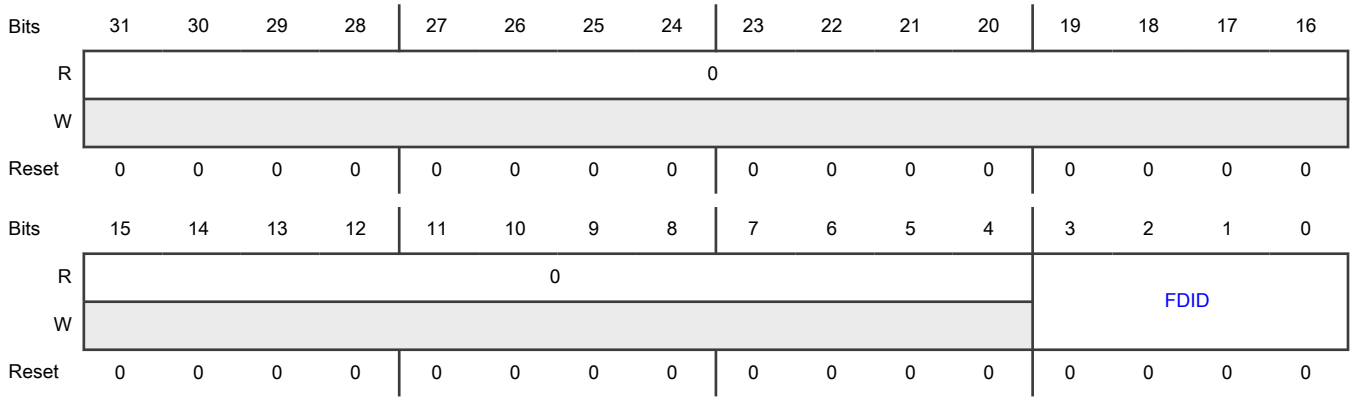
In the event of an access error, this register is used to specify the domainID of the faulting reference before indexing into the Domain Error registers.

If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FDID	1FCh

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

22.7.6.12 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC15)

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap

of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

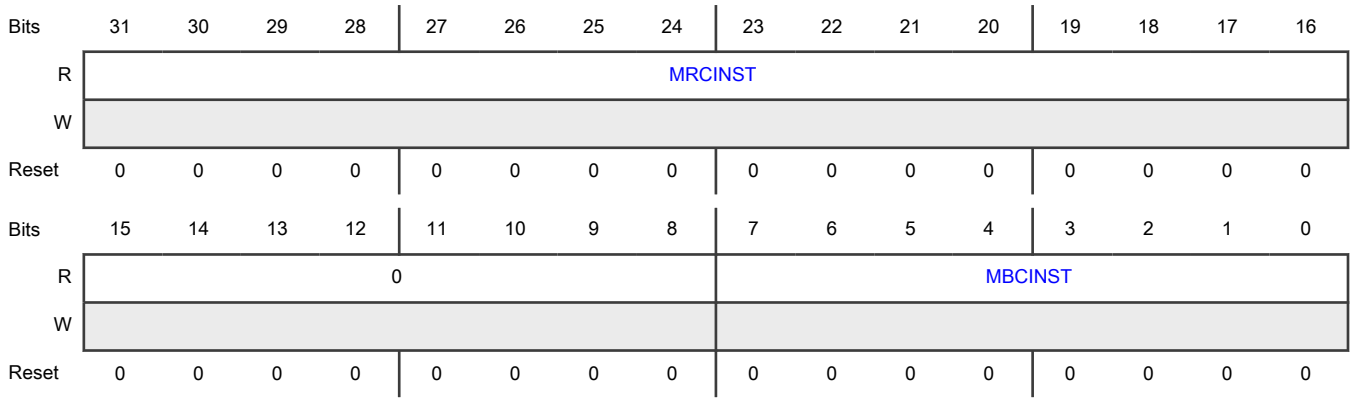
Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

For d = 0 to 15:

Register	Offset
TRDC_DERRLOCd	200h + (d × 4h)

Diagram



Fields

Field	Description
31-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 31) corresponds to MRC instance 15 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-8	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
7-0 MBCINST	MBC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MBC. The least-significant bit of this field (bit 0) corresponds to MBC instance 0. The most-significant bit of this field (bit 7) corresponds to MBC instance 7 Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MBCs. For each bit in this field: • 0 - The memory block checker has not detected an access violation or is not physically present. • 1 - The memory block checker has detected one or more access violations for this domain.

22.7.6.13 MBC Domain Error Word0 Register (MBC0_DERR_W0 - MBC1_DERR_W0)

This read-only register array provides the address of an access violation detected by memory block checker (MBC). These registers are organized as a word array, which is indexed by the MBC instance number. That is, the index, i, of this array is the instance number of MBC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MBC instance that is not physically present.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

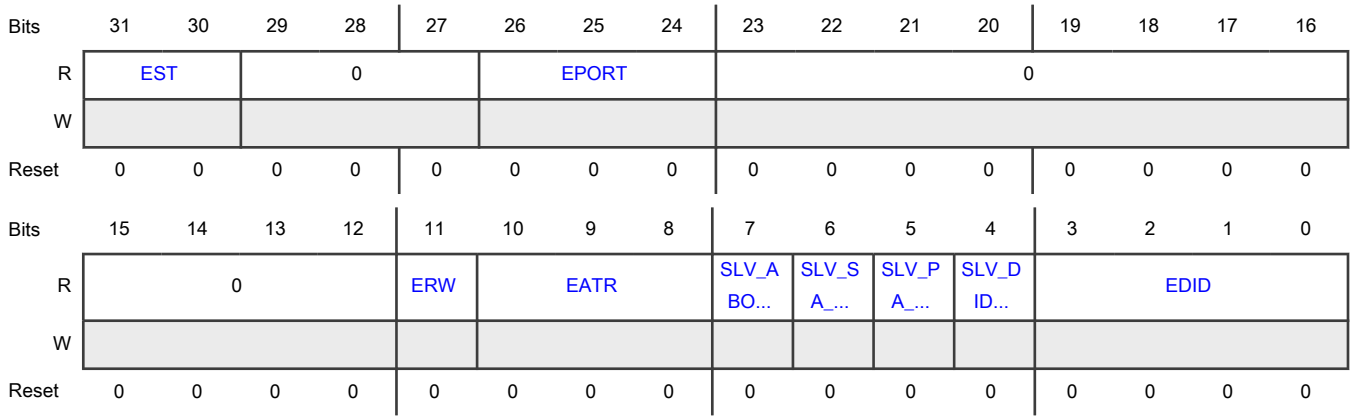
MBC1_DERR_W1	414h

Diagram



Fields

Field	Description
31-30 EST	Error state This field signals the state of access violations for this domain in this instance of the block checker or region checker. Once an access violation has been detected and the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. After retrieving the faulting address and attributes, the error capture mechanism must be rearmed by performing a write to DERR_W3_i.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	00 - No access violation has been detected. 01 - No access violation has been detected. 10 - A single access violation has been detected. 11 - Multiple access violations for this domain have been detected by this submodule instance. Only the address and attribute information for the first error have been captured in DERR_W0_i and DERR_W1_i.
29-27 —	Reserved
26-24 EPORT	Error port This field identifies the encoded port number of the MBC that detected the access violation. The MBC port number connection is device-specific. See the chip configuration details for more information. This is the MBC target that has the violation. 000 - mbcxslv0 001 - mbcxslv1 010 - mbcxslv2 011 - mbcxslv3
23-12 —	Reserved
11 ERW	Error read/write This field signals whether the captured access violation occurred on a read or write reference. 0 - Read access 1 - Write access
10-8 EATR	Error attributes This field captures attributes of the access violation. 000 - Secure user mode, instruction fetch access. 001 - Secure user mode, data access. 010 - Secure privileged mode, instruction fetch access. 011 - Secure privileged mode, data access. 100 - Nonsecure user mode, instruction fetch access. 101 - Nonsecure user mode, data access. 110 - Nonsecure privileged mode, instruction fetch access. 111 - Nonsecure privileged mode, data access.
7	Bus protect error

Table continues on the next page...

Table continued from the previous page...

Field	Description
SLV_ABORT	This field captures the bus protect error from target which cause access abort.
6 SLV_SA_ERR	Secure attribute check error This field captures the secure attribute check error from target.
5 SLV_PA_ERR	Privilege attribute check error This field captures the privilege attribute check error from target.
4 SLV_DID_ERR	DID check error This field captures the DID check error from target.
3-0 EDID	Error domain identifier This field captures the domain identifier of the access violation.

22.7.6.15 MBC Domain Error Word3 Register (MBC0_DERR_W3 - MBC1_DERR_W3)

This register is used to rearm the error capture logic and clear the DERR_W0_i and DERR_W1_i registers. After the domain access violation error details have been read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

A read of this location returns zeroes. Attempted reads of a Memory Region Checker (MRC) or Memory Block Checker (MBC) instance that is not physically present are error terminated.

See Domain error capture management for more details.

Fields

Field	Description
31-30 RECR	Rearm Error Capture Registers This 2-bit, write-only field controls the rearming of the domain error capture registers. Once an access violation has been detected with the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. Writing 01b to this field rearms the error capture mechanism and clears the DERR_W0_i and DERR_W1_i registers. A write of any value other than 01b has no effect.
29-0 —	Reserved

22.7.6.16 MRC Domain Error Word0 Register (MRC0_DERR_W0 - MRC1_DERR_W0)

This read-only register array provides the address of an access violation detected by memory region checker (MRC). These registers are organized as a word array, which is indexed by the MRC instance number. That is, the index, i, of this array is the instance number of MRC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MRC instance that is not physically present.

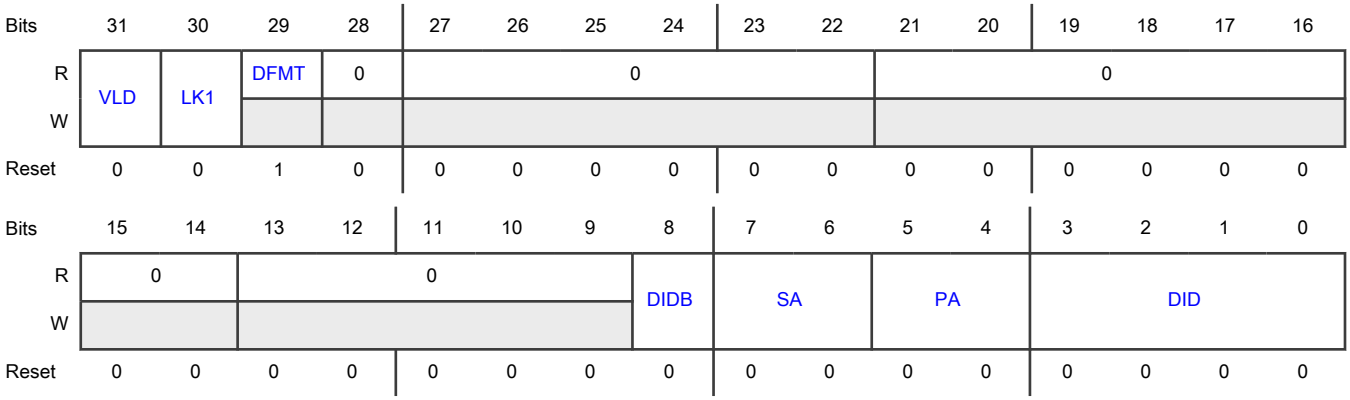
MDA_W0_2_DFMT1	840h
MDA_W0_3_DFMT1	860h
MDA_W0_4_DFMT1	880h

Diagram



Fields

Field	Description
31	Valid

Table continues on the next page...

Table continued from the previous page...

Field	Description
VLD	This field indicates the domain assignment is valid. It is further qualified by TRDC_CR[GVLDM] = 1. If TRDC_CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and TRDC_CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0 - The Wr domain assignment is invalid. 1 - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0 - Register can be written by any secure privileged write. 1 - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROO 0 - Processor-core domain assignment 1 - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16 —	Reserved
15-14 —	Reserved
13-9 —	Reserved
8 DIDB	DID Bypass If asserted, this bit enables the bypassing of an input DID value as the domain identifier for this non-processor bus initiator. This capability allows non-processor bus initiators, for example, a DMA to masquerade as a processor. Once set, this field is “sticky” and remains set until the next reset.

22.7.6.26 MBC Global Access Control (MBC0_MEMN_GLBAC1 - MBC0_MEMN_GLBAC7)

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User. The lock bit provides the ability to lock these control access flags and to lock the MBC_BLK_CFG[MBACSEL] field when a locked MBC_MEMN_GLBAC register is selected.

22.7.6.27 MBC Memory Block Configuration Word (MBC0_DOM0_MEM0_BLK_CFG_W0 - MBC1_DOM15_MEM3_BLK_CFG_W0)

MBC[m]_DOM[d]_MEM[s]_BLK_CFG_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

These registers are read/write for both the alternate view of the NSE bit and the 3-bit MBACSEL field. This is an array of 4 bit fields defining the block configuration for the given submemory. Each 4-bit field includes an alternative view of the associated NSE bit plus a 3-bit access control select that selects the global access control value that applies to the referenced memory block.

For a given memory block, B, if the value programmed in the MBACSELn field selects a locked MBC_MEMN_GLBACr register, the MBACSEL field is locked until the next reset. Depending on BLK_CFG_W, the NSEn/MBASELn fields correspond to different blocks. The following table describes the relationship between W (word index) and B (block number).

MEM0 supports up to 512 blocks ; W0 - W63

MEM1-3 supports up to 64 block ; W0 - W7

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

Table 116. Block Config Word to Block Number Relationship

Block Config Word	NSE7/ MBACSEL7	NSE6/ MBACSEL6	NSE5/ MBACSEL5	NSE4/ MBACSEL4	NSE3/ MBACSEL3	NSE2/ MBACSEL2	NSE1/ MBACSEL1	NSE0/ MBACSEL0
W0	block 7	block 6	block 5	block 4	block 3	block 2	block 1	block 0
W1	block 15	block 14	block 13	block 12	block 11	block 10	block 9	block 8
W2	block 23	block 22	block 21	block 20	block 19	block 18	block 17	block 16
W3	block 31	block 30	block 29	block 28	block 27	block 26	block 25	block 24
W4	block 39	block 38	block 37	block 36	block 35	block 34	block 33	block 32
W5	block 47	block 46	block 45	block 44	block 43	block 42	block 41	block 40

Fields

Field	Description
31 NSE7	NonSecure Enable for block B 0 - Secure read and write to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), secure execution and nonsecure accesses to block B are not allowed.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Secure accesses to block B are not allowed, nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
30-28 MBACSEL7	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL7 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
27 NSE6	NonSecure Enable for block B 0 - Secure read and write to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), secure execution and nonsecure accesses to block B are not allowed. 1 - Secure accesses to block B are not allowed, nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
26-24 MBACSEL6	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL6 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
23	NonSecure Enable for block B

22.7.6.28 MBC Memory Block NonSecure Enable Word (MBC0_DOM0_MEM0_BLK_NSE_W0 - MBC1_DOM15_MEM3_BLK_NSE_W0)

MBC[m]_DOM[d]_MEM[s]_BLK_NSE_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

This is the bitmap of the individual NSE bits for the memory block.

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

The following table describes the relationship between W (word index) and B (block number).

Table 117. Block Config Word to Block Number Relationship

Block NSE Word	BIT31	BIT30-BIT1	BIT0
W0	block 31	block 30 - block 1	block 0
W1	block 63	block 62 - block 33	block 32
For MEM0, block 64 - block 511			
W2	block 95	block 94 - block 65	block 64
.			
.			
.			
W15	block 511	block 510 - block 481	block 480

The NSE bitmap can be accessed directly by register reads and writes to these locations, or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and BLK_CFG[NSEn] registers.

22.7.6.30 MBC Global Access Control (MBC1_MEMN_GLBAC1 - MBC1_MEMN_GLBAC7)

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User. The lock bit provides the ability to lock these control access flags and to lock the MBC_BLK_CFG[MBACSEL] field when a locked MBC_MEMN_GLBAC register is selected.

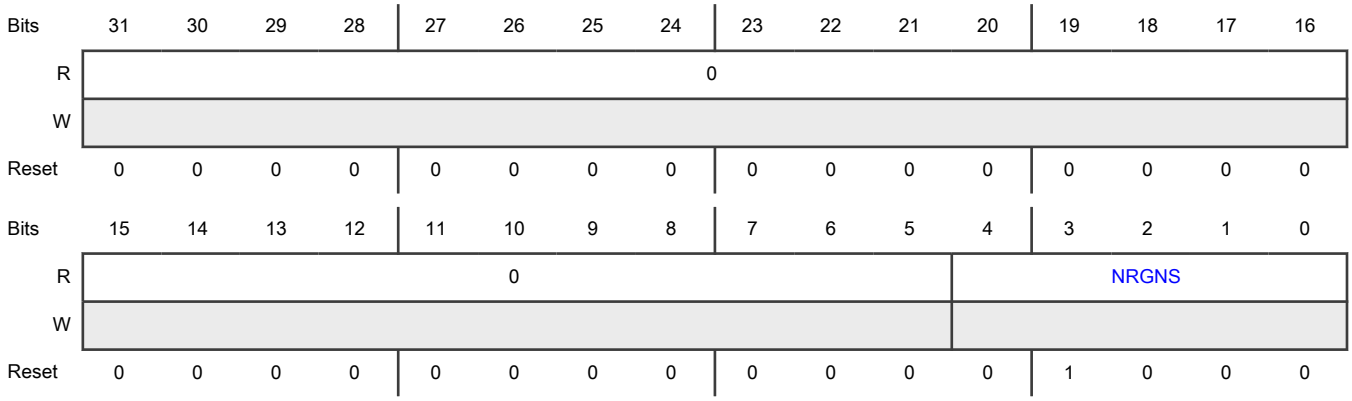
22.7.6.31 MRC Global Configuration Register (MRC0_GLBCFG - MRC1_GLBCFG)

This read-only register describes the number of region descriptors for this memory.

Offset

Register	Offset
MRC0_GLBCFG	1_4000h
MRC1_GLBCFG	1_5000h

Diagram



Fields

Field	Description
31-5 —	Reserved
4-0 NRGNS	Number of regions [1-16]

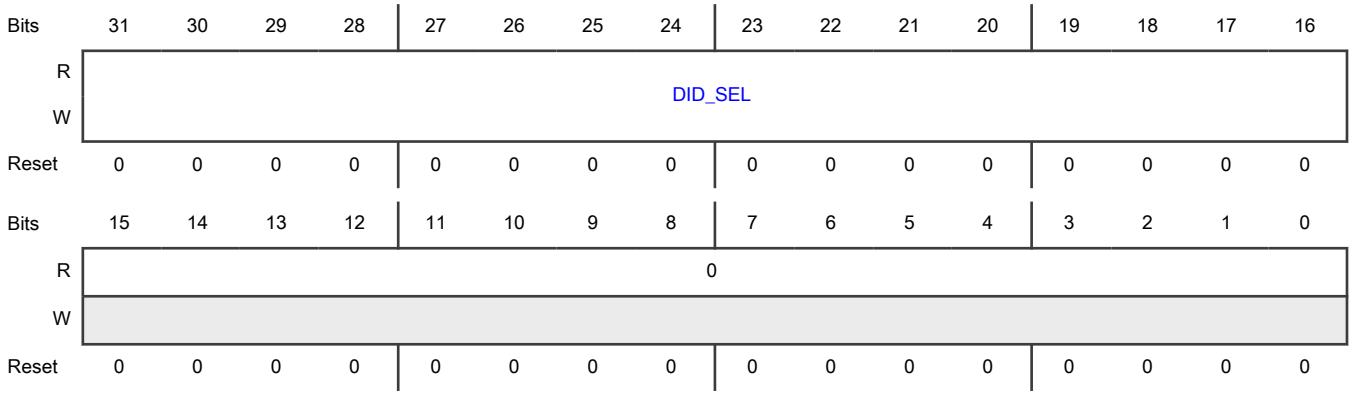
22.7.6.32 MRC NonSecure Enable Region Indirect (MRC0_NSE_RGN_INDIRECT - MRC1_NSE_RGN_INDIRECT)

This R/W register defines the selected domains that are affected by writes to the NSE_RGN_SET and NSE_RGN_CLR registers.

Offset

Register	Offset
MRC0_NSE_RGN_INDIRECT	1_4010h
MRC1_NSE_RGN_INDIRECT	1_5010h

Diagram



Fields

Field	Description
31-16 DID_SEL	DID Select Destination domain bitmap select. • Bit [31] = 1, update domain 15 • Bit [30] = 1, update domain 14 • Bit [29] = 1, update domain 13 • Bit [28] = 1, update domain 12 • Bit [27] = 1, update domain 11 • Bit [26] = 1, update domain 10 • Bit [25] = 1, update domain 9 • Bit [24] = 1, update domain 8 • Bit [23] = 1, update domain 7 • Bit [22] = 1, update domain 6 • Bit [21] = 1, update domain 5 • Bit [20] = 1, update domain 4 • Bit [19] = 1, update domain 3 • Bit [18] = 1, update domain 2 • Bit [17] = 1, update domain 1 • Bit [16] = 1, update domain 0
15-0 —	Reserved

22.7.6.33 MRC NonSecure Enable Region Set (MRC0_NSE_RGN_SET - MRC1_NSE_RGN_SET)

A write to this location sets the appropriate NSE bits in region descriptors for the selected domain in MRC NonSecure Enable Region Indirect register. This register reads as 0.

Offset

Register	Offset
MRC0_NSE_RGN_SET	1_4014h
MRC1_NSE_RGN_SET	1_5014h

Chapter 23
System Counter (SYS_CTR)

23.1 Chip-specific SYS_CTR information

Table 118. Reference links to related information

Topic	Related module	Reference
Full description	Arm Cortex CM33 Platform (CM33)	CM33 Platform
System memory map		System memory map
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

NOTE

Software can read A55 core's generic timer counter value via A55 CP15 to get the SYS_CTR value.

23.1.1 Module instances

This chip has one instance of the SYS_CTR module.

23.2 Overview

SYS_CTR is a programmable system counter that provides you with a shared time base to multiple processors. It is intended for applications in which the counter is always powered on and supports multiple unrelated clocks.

23.2.1 Block diagram

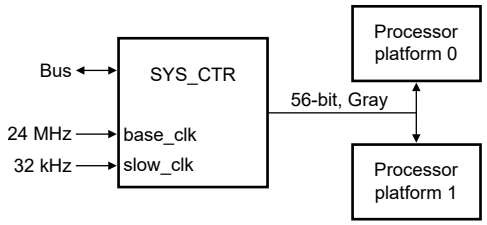

Figure 44. Block diagram

23.2.2 Features

- Two counter clock frequencies:
  - Base clock for normal operation
  - Alternate slow clock for low-power operation
- 56-bit counter width
- Gray-coded counter output for distribution to the processor timers
- Two compare frames, with each frame:

— Containing a 64-bit compare value

— Supporting a programmable interrupt generation

23.3 Functional description

SYS_CTR inputs two counter clock sources and outputs a gray-coded counter value and interrupt signals (one per compare frame) to the platform's interrupt controller.

23.3.1 Modes of operation

Table 119. Modes of operation

Mode	Function
Normal	The counter increments on the rising edge of the selected clock when enabled in Normal mode.
Debug	You can configure the SYS_CTR debug operation via Counter Control (CNTCR): • If CNTCR[HDBG] = 0, SYS_CTR continues to operate. • If CNTCR[HDBG] = 1, SYS_CTR halts when its debug input signal is asserted.

23.3.2 Operation

After reset, SYS_CTR is disabled with the count value reset to 0 and base frequency selected. After the counter is enabled, it increments the appropriate value on each rising edge of the selected clock. Because SYS_CTR handles a 56-bit count value across multiple clock domains, synchronization is necessary. SYS_CTR provides synchronization mechanisms between the various clock domains.

After the system switches the counter's clock source, there is a short pause while the clock multiplexer is handling the clock transition. To maintain an accurate count value, the clock control logic employs two offset counters: one for base-to-slow transition and the other one for slow-to-base transition. These offset counters only operate during the clock transition time to compensate for the idled source clock. Both counters run off the base clock. The transition offset values are added to the system count value at an appropriate time after the counter's clock is restored.

NOTE

Both the base clock and alternate clock must be running when changing frequencies.

23.3.3 Clocks

Table 120. Clocks

Clock	Description
base_clk	Base clock This clock is used during normal operation.
slow_clk	Slow clock This clock is used during low-power mode. It is internally divided by 64 before use.

23.3.4 Interrupts

Each SYS_CTR compare frame (SYS_CTR_COMPARE) is capable of generating one maskable interrupt.

23.4 External signals

This module has no external signals.

23.5 Initialization

To initialize SYS_CTR:

1. Write an initial value to Counter Count Value Low (CNTCV0) and Counter Count Value High (CNTCV1), if a different value is desired.
2. Write 1 to CNTCR[EN] to enable the counter.

23.6 Application information

To use a compare frame:

1. Write the desired count value into Compare Count Value Low (CMPCVL0 - CMPCVL1) and Compare Count Value High (CMPCVH0 - CMPCVH1).
2. Enable interrupts using CMPCR0[IMASK], if required.
3. Write 1 to CMPCR0[EN] to enable the compare function.
4. Read CMPCR0[ISTAT] to check whether the count value is reached.

23.7 Programming model

SYS_CTR contains three programming model sections. Each section has an independent module enable to allow individual secure access control. See the following table for details.

Table 121. Programming model

Programming model	Description
Control	Controls the counter frequency, enable, debug, and count value. This model also contains the frequency-modes table that supplies control and status for the frequency of SYS_CTR.
Read	Allows you to read the count value.
Compare	Controls the compare value frequency, enable, interrupt mask, and interrupt status for each compare frame.

23.8 Memory map and register definition

23.8.1 SYS_CTR_CONTROL register descriptions

NOTE

Write or read access to reserved locations does not generate a transfer error.

NOTE

All 32-bit registers allow only 32-bit wide write operations, and are aligned to 32 bits.

23.8.1.1 SYS_CTR_CONTROL memory map

SYS_CTR_CONTROL base address: 4429_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	Counter Control (CNTCR)	32	RW	0000_0000
4	Counter Status (CNTSR)	32	R	0000_0100
8	Counter Count Value Low (CNTCV0)	32	RW	0000_0000
C	Counter Count Value High (CNTCV1)	32	RW	0000_0000
20	Frequency-Modes Table 0 (CNTFID0)	32	R	016E_3600
24	Frequency-Modes Table 1 (CNTFID1)	32	R	0000_0200
28	Frequency-Modes Table 2 (CNTFID2)	32	R	0000_0000
C0	Counter Control 2 (CNTCR2)	32	RW	0000_0000
FD0	Counter ID (CNTID0)	32	R	0000_0000

23.8.1.2 Counter Control (CNTCR)

Defines the basic operating configuration of SYS_CTR, which operates using a fixed base frequency. However, the counter can increment at a lower alternate frequency than the base frequency, using a correspondingly larger increment. For example, the counter can increment by 46,875 and run at a frequency of 1/46875 of the base frequency, which is the normal operating frequency. The alternate frequency is a significantly lower operating frequency used to reduce power consumption. The frequency-modes table identifies the two available frequencies. These two frequencies are the base frequency (table entry 0) and the lower, alternate frequency (table entry 1). Writing 1 to CNTCR[FCR1] selects the alternate frequency, and writing 1 to CNTCR[FCR0] selects the base frequency. Writing 1 or writing 0 to both FCR0 and FCR1 has no effect and the frequency does not change.

31-24 —	Reserved
23-0 CNTCV1	Counter Count Value Bits [55:32] Specifies the upper 24 bits of the 56-bit system count value.

23.8.1.6 Frequency-Modes Table 0 (CNTFID0)

Indicates the frequency-modes table starting at offset 20h.

Table entries contain 32 bits, and each entry specifies the SYS_CTR update frequency in Hz. The first entry in the table specifies the base frequency of SYS_CTR. To ensure that the overall counter accuracy is maintained, any subsequent entries in the table are exact divisors of the base frequency.

When SYS_CTR is operating at a lower frequency than the base frequency, the increment applied at each counter update is base_frequency ÷ selected_frequency; a 32-bit word of 0 value marks the end of the table. That is, the word of memory immediately after the last entry in the table is 0.

Offset

Register	Offset
CNTFID0	20h

Fields

Field	Description
31-0 CNTFID2	Counter Frequency ID 2 Indicates the end of the frequency-modes table.

23.8.1.9 Counter Control 2 (CNTCR2)

Enables automatic configuration of SYS_CTR via hardware.

SYS_CTR operates using a fixed base frequency. However, the counter can increment at a lower alternate frequency than the base frequency, using a correspondingly larger increment. For example, the counter can increment by 46,875 and run

at a frequency of 1/46875 of the base frequency, which is the normal operating frequency. The alternate frequency is a significantly lower operating frequency used to reduce power consumption. The frequency-modes table identifies the two available frequencies. These two frequencies are the base frequency (table entry 0), and the lower and alternate frequency (table entry 1). Writing 1 to CNTCR2[HWFC_EN] enables hardware to automatically switch to the lower, alternate frequency clock after the chip enters low-power mode. When exiting this mode, hardware automatically switches back to the base frequency. If CNTCR2[HWFC_EN] = 0, frequency changes are fully under software control via Counter Control (CNTCR).

Fields

Field	Description
31-0 CNTID	Counter Identification Specifies counter ID 0, the architectural version of this system counter.

23.8.2 SYS_CTR_READ register descriptions

These read frame registers read the same values as the control frame registers for the count value and counter ID. They are processed via a separate mechanism from the control frame to allow Nonsecure and User mode accesses.

NOTE

Write or read access to reserved locations does not generate a transfer error.

NOTE

All 32-bit registers allow only 32-bit wide write operations, and are aligned to 32 bits.

23.8.2.1 SYS_CTR_READ memory map

SYS_CTR_READ base address: 442B_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
8	Counter Count Value Low (CNTCV0)	32	R	0000_0000
C	Counter Count Value High (CNTCV1)	32	R	0000_0000
FD0	Counter ID (CNTID0)	32	R	0000_0000

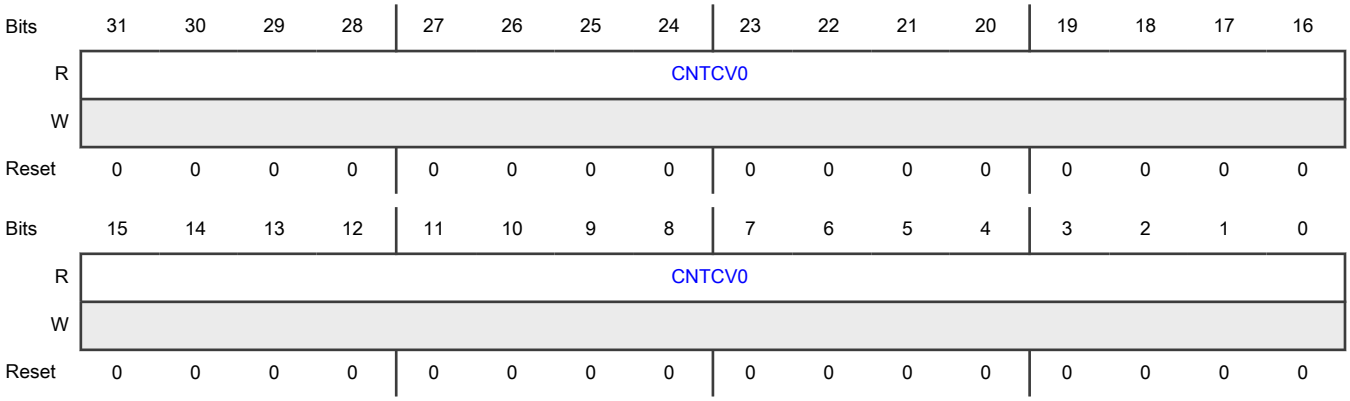
23.8.2.2 Counter Count Value Low (CNTCV0)

Indicates the current count value bits, 31–0.

Offset

Register	Offset
CNTCV0	8h

Diagram



Fields

Field	Description
31-0 CNTCV0	Counter Count Value Bits [31:0] Indicates the lower 32 bits of the 56-bit system count value.

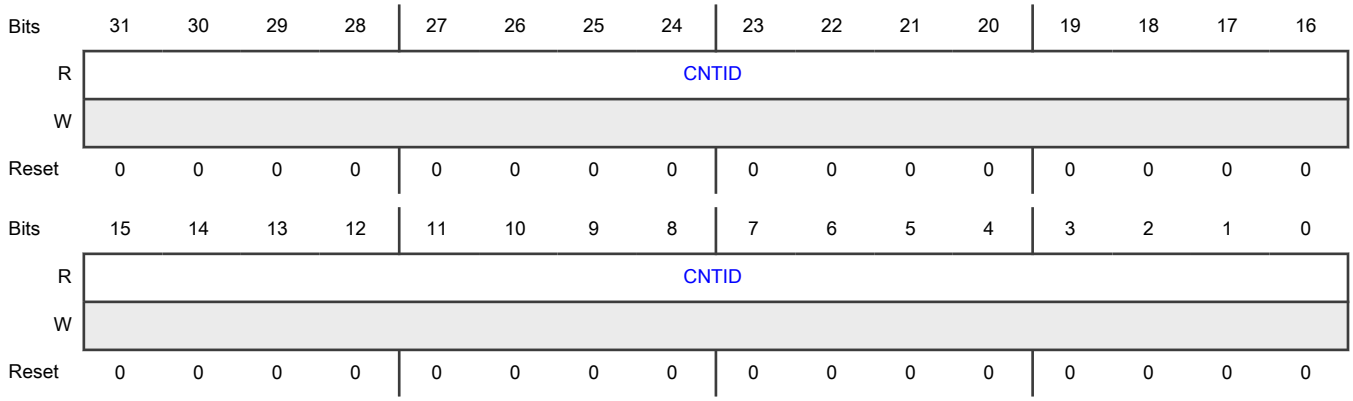
CNTID0	FD0h

Diagram



Fields

Field	Description
31-0 CNTID	Counter Identification Indicates counter ID 0, the architectural version of this system counter.

23.8.3 SYS_CTR_COMPARE register descriptions

Each compare frame:

- Consists of a 256-byte region.
- Has its own compare value and control register.
- Is capable of generating a maskable interrupt.

NOTE

Write or read access to reserved locations does not generate a transfer error.

NOTE

All 32-bit registers allow only 32-bit wide write operations, and are aligned to 32 bits.

23.8.3.1 SYS_CTR_COMPARE memory map

SYS_CTR_COMPARE base address: 442A_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
20	Compare Count Value Low (CMPCVL0)	32	RW	0000_0000
24	Compare Count Value High (CMPCVH0)	32	RW	0000_0000
2C	Compare Control (CMPCR0)	32	RW	0000_0000
120	Compare Count Value Low (CMPCVL1)	32	RW	0000_0000
124	Compare Count Value High (CMPCVH1)	32	RW	0000_0000
12C	Compare Control (CMPCR1)	32	RW	0000_0000
FD0	Counter ID (CNTID0)	32	R	0000_0000

23.8.3.2 Compare Count Value Low (CMPCVL0 - CMPCVL1)

Indicates the current count value bits 31–0.

NOTE

You must write to this set of registers when operating on the base frequency only. Writes to these registers when running on the alternate frequency may have unpredictable results.

Offset

Field	Description
31-24 —	Reserved
23-0 CMPCV1	Compare Count Value Bits [55:32] Specifies the upper 24 bits of the 56-bit compare value. Bits[63:56] are always zero.

23.8.3.4 Compare Control (CMPCR0 - CMPCR1)

Provides control and status of the compare function. When enabled, CMPCR0[ISTAT] indicates whether the counter value is greater than or equal to the value in CMPCV*n*. The ISTAT equation is:

Value of CMPCR0[ISTAT] = CNTCV*n* ≥ CMPCV*n*

CMPCR0[ISTAT] takes no account of the value of CMPCR0[IMASK]. If CMPCR0[ISTAT] = 1 and CMPCR0[IMASK] = 0, the interrupt request is asserted. Writing 0 to CMPCR0[EN] makes CMPCR0[ISTAT] = 0 and negates the interrupt output signal.

Chapter 24
System Debug

24.1 Overview

The chip debug architecture is based on Arm CoreSight technology, with support for the Cortex-A55, Cortex-M33, and EdgeLock Secure Enclave cores.

24.1.1 Block Diagram

The block diagram for the system level debug architecture is provided below.

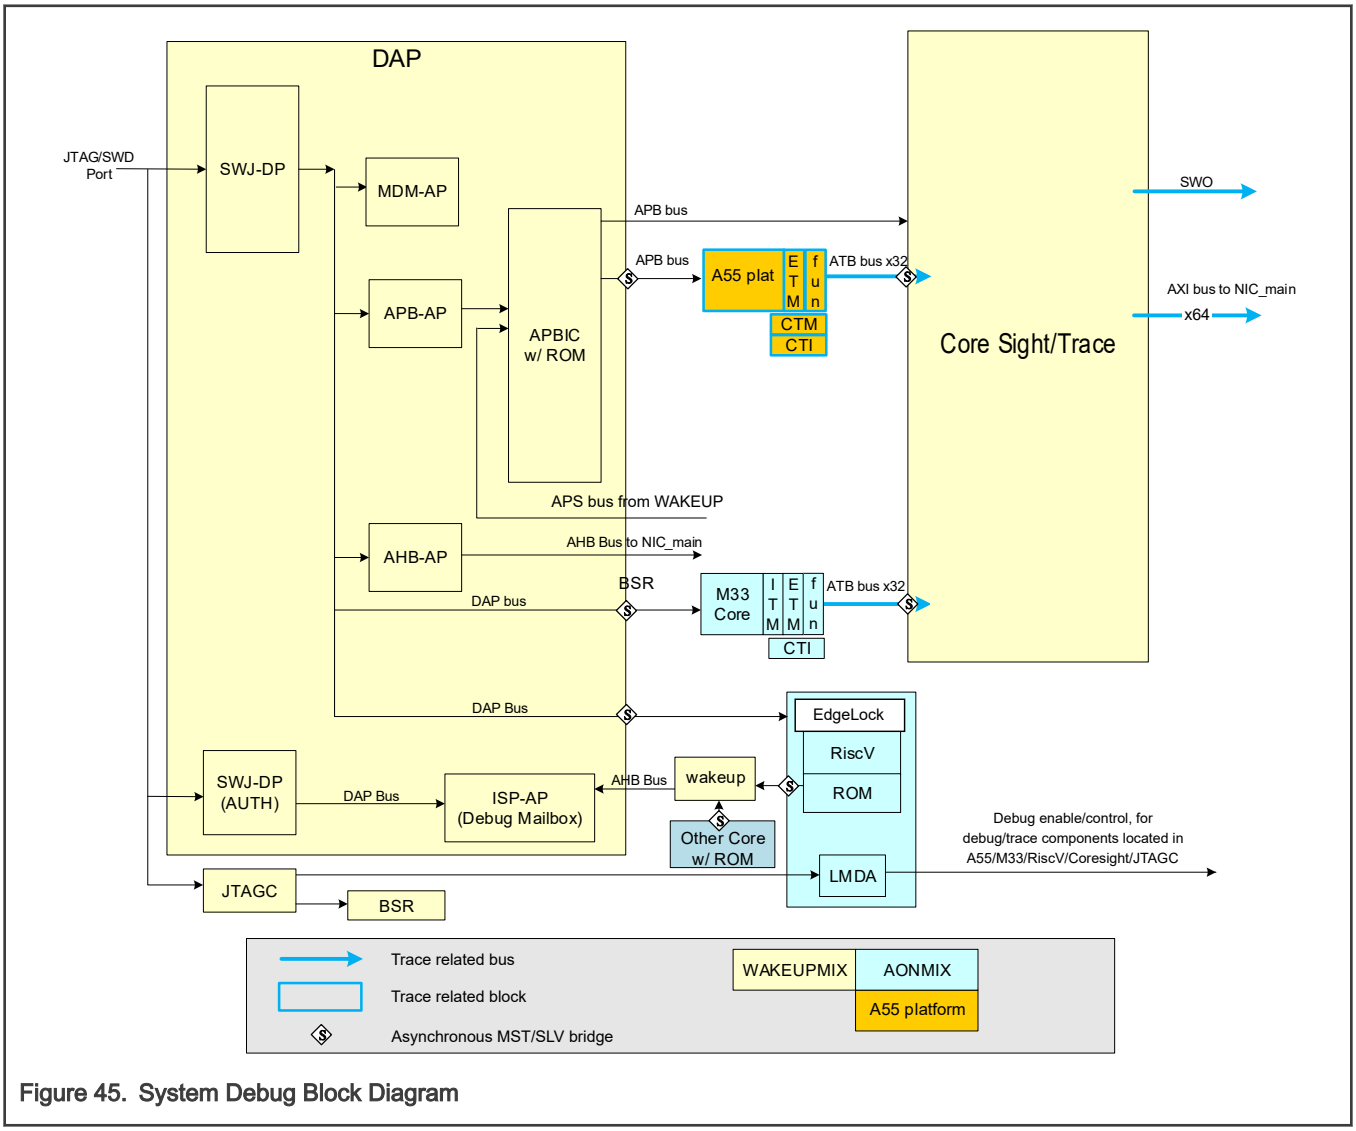

Figure 45. System Debug Block Diagram

The debug/trace components are listed below:

- Debug Access Port (DAP) - Has Serial Wire port (SWJ-DP) which interprets the data coming in and routes to appropriate Access Port (AP).
- Serial Wire port (SWJ-DP) - Consists of a wrapper around the JTAG-DP and SW-DP. It selects JTAG or SWD as the connection mechanism and enables either JTAG-DP or SW-DP as the interface to the various on chip debug/trace components. It is enabled only after debug is authenticated.

- SWJ-DP (AUTH) is another SWJ-DP instance dedicated for ISP-AP. It is enabled only when debug authentication is required, means it will be disabled if debug is authenticated.
- JTAGC
  - JTAGC and DAP/SWJ-DP share the same JTAG interface from PAD.
  - Achieve boundary scan testing, with an external BSR connected.
  - Supports Challenge-response authentication, with LMDA in Edgelock secure enclave.
  - Supports IEEE 1149.6/AC JTAG.
- Debug Access port for Cortex-A55 platform.
- Debug Access port for Coresight.
- Cortex-M33 DAP-AP - Debug Access port for M33 core.
- RISC-V DAP-AP - Debug Access port for RISC-V core in Edgelock secure enclave.
- ISP-AP - Debug Access port for Debug Mailbox, to allow the debugger to communicate with onboard ROM code.
- MDM-AP registers for debugger to control multi-core halt/resume cores.
- Coresight components.
- Cross-Trigger Interface (CTI) and Cross-Trigger Matrix (CTM).

24.1.2 Features

The key features of the debug system include:

- Supports 1149.1/ARM SWD interface. Supports both 5-pins (JTAG) and 2-pins (SWD) interfaces, to make efficient use of package pins, serial wire shares the JTAG pins use an auto-detect mechanism.

NOTE

1149.7 Compact JTAG is NOT supported.

- Supports both non-intrusive and halt-mode trace/debug options
- Supports trace for various cores, including a trace Memory Controller (TMC) to enable capturing trace
  - 4KB ETF in SOC trace block
  - ETR (4G memory range, 64-bit wide) to allow routing trace data to system memory
  - CoreSight Serial Wire Output
- Supports cross trigger between the Cortex-A55 and Cortex-M33
- MDM-AP registers for debugger to control multi-core halt/resume cores
- Supports narrow timestamp for trace components
- Supports ISP-AP (Debug Mailbox), allowing the debugger to communicate with onboard ROM code, providing debug authentication based on messages
- Supports challenge-response authentication

NOTE

Arm ELA-500 and Coresight SoC-600 are not supported.

NOTE

When CM33 core is under software reset (core only and not its debug components), FCLK is cut to the DAP AHB AP of CM33 core. At this time debugger can not configure debug components of CM33. The work around is, after the core comes out of reset it will be gated by TROUT of CM33 CPU WAIT, debugger can configure the debug components while the wait is asserted and once it is done. TROUT can be configured to ungate the core and debug from 1st instruction could be possible.

NOTE

External debugger can access memory inside CM33 through AHBAP when cm33_spiden and cm33_dbgen are enabled by security core.

24.2 Functional description

24.2.1 Debug Access Port (DAP) TAP

DAP is a standard Arm component, comprising of several components. These components are used to access the DAP from an external debugger and Access Ports to access on-chip debug system resources. The DAP supports 1149.1/Arm SW-DP interface, which means that the JTAG interface can be operate in standard 5-pin JTAG-DP interface or in 2-pin SW-DP interface. The following figure shows the connectivity between the DAP and the pads.

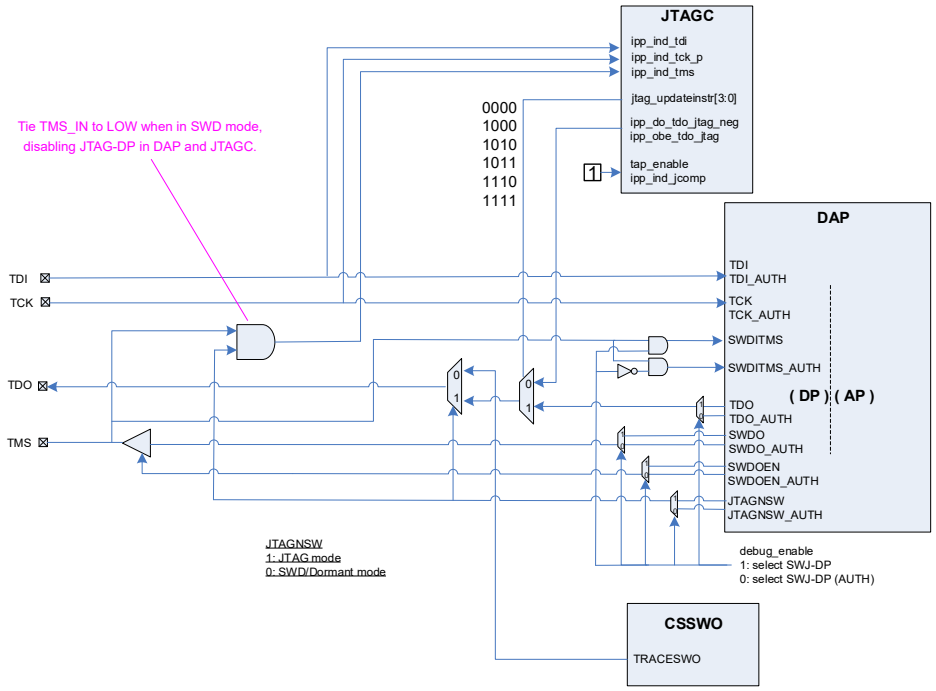

Figure 46. JTAG Pad Connectivity

For PAD descriptions, see External Signals.

24.2.2 JTAGC and JTAG mux

The JTAGC and SWJ-DP/SWJ-DP (AUTH) share the same 5-pin JTAG interface from PAD. SWJ-DP and SWJ-DP (AUTH) will not be enabled at the same time, controlled by the authentication status from LMDA.If debug is authenticated, select SWJ-DP, otherwise select SWJ-DP (AUTH).

SW-DP pins (TCK,TMS) are connected directly from and to SoC pins.

- When SW-DP is enabled, both JTAGC and JTAG-DP will be disabled.

- When SW-DP is disabled, the output to TDO from JTAGC and JTAG-DP will be selected by a mux and that mux is controlled by decode of the IR inside the JTAGC (JTAGC output port jtag_updateinstr[4:0]), and then connected to SoC pins for debug and/or test purposes.

Selection is based on the following table of decodes.

Table 122. Instruction Register

Instruction	Value	Module
EXTEST (Arm)	4'b0000	Arm JTAG-DP
IDCODE (JTAGC)	4'b0001	JTAGC
SAMPLE/PRELOAD	4'b0010	JTAGC
SAMPLE	4'b0011	JTAGC
EXTEST (JTAGC)	4'b0100	JTAGC
TEST_LEAKAGE	4'b0101	JTAGC
ENABLE_TEST_CTRL	4'b0110	JTAGC
ENABLE_CENSOR_CTRL	4'b0111	JTAGC
ABORT (Arm)	4'b1000	Arm JTAG-DP
HIGHZ	4'b1001	JTAGC
DPACC (Arm)	4'b1010	Arm JTAG-DP
APACC (Arm)	4'b1011	Arm JTAG-DP
CLAMP	4'b1100	JTAGC
ENABLE_SOC_DATA1	4'b1101	JTAGC
IDCODE (Arm)	4'b1110	Arm JTAG-DP
BYPASS (Arm)	4'b1111	Arm JTAG-DP

Partial of TARGETID[31:0] input for SWJ-DP should also be connected to JTAGC, for coherence, as below:

Table 123. JTAG TARGETID

JTAGC	SWJ-DP	description
jtagc_pin_plug[9:0]	TARGETID[21:12]	Part Identification Number
jtagc_prn_plug[3:0]	TARGETID[31:28]	Part Revision Number
jtagc_jcomp_plug[0:J-1]	1'b1 (J=1)	JTAG JCOMP value

24.2.3 AP Select Decoding

The recommendation for AP selects decoding is provided in the following table.

NOTE

SWJ-DP (AUTH) has only one DAP slot (the first DAP slot) targeting ISP-AP, so it has no DAPBUSIC decoding logic.

The DAPBUSIC in the table below is only for SWJ-DP rather than SWJ-DP (AUTH).

Table 124. Address Decoding for DAPBUSIC

Destination	DAPBUSIC_AP_SEL[31:24]

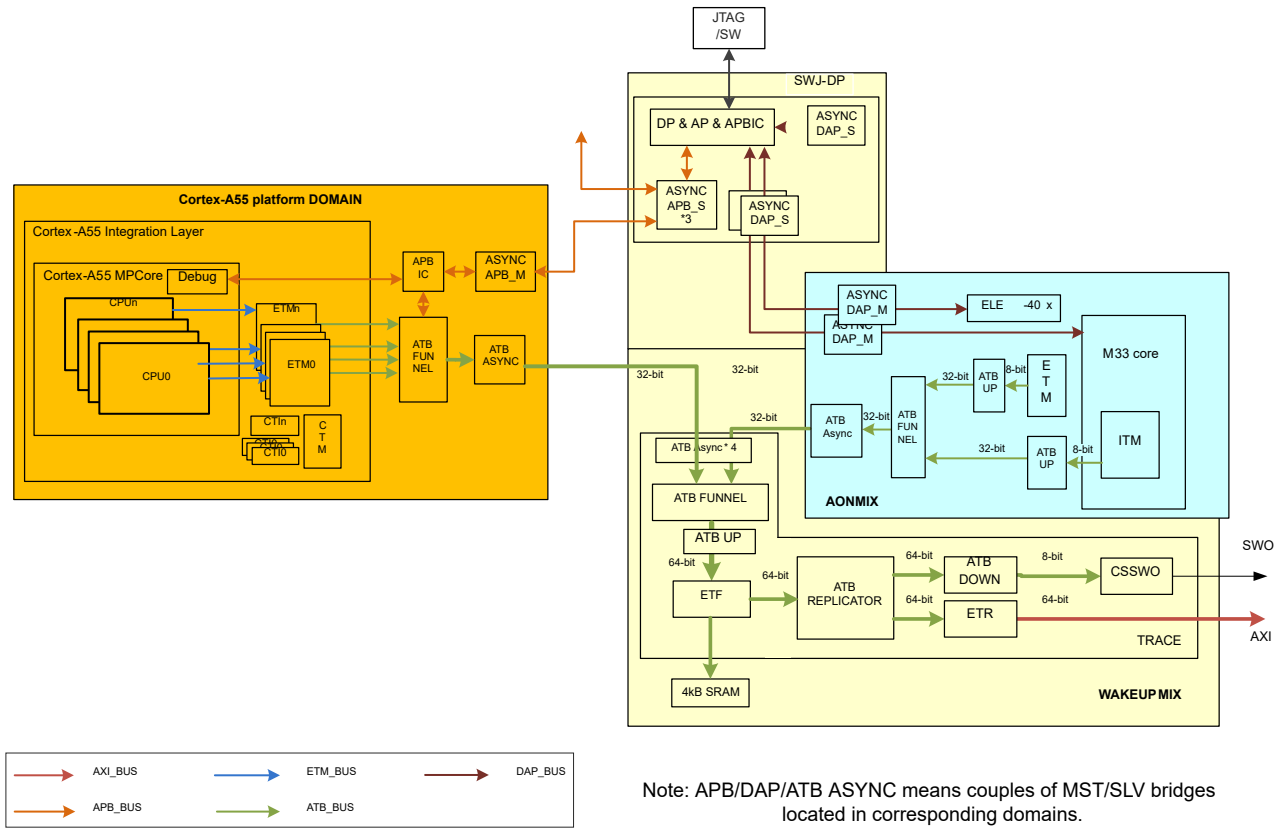
24.2.4 Trace

The debug and trace implementation for the Cortex-A55 and Cortex-M33 is shown in the following figure.



Note: APB/DAP/ATB ASYNC means couples of MST/SLV bridges located in corresponding domains.

Figure 47. Trace Diagram

- Trace sources include ETM in Cortex-A55 and ITM/ETM in Cortex-M33, and ETM for DSP.
- One Embedded Trace FIFO (ETF, can operate as ETB, programmable), 4KB size as 128x256 (width x depth) with single port of SRAM.
- ATB funnel can capture trace data from Cortex-A55, Cortex-M33 ETM and Cortex-M33 ITM.
- ETR - Routing trace to system enabling to reuse SoC resources. (4G memory range, 64-bit wide).

24.2.5 Embedded Cross Trigger (ECT)

The ECT for coreSight consists of a few CTIs and CTM. The diagram below shows the structure of the ECT. The ECT enables subsystems to interact, that is cross trigger with each other. It is used for multiple core run control and trace cross trigger.

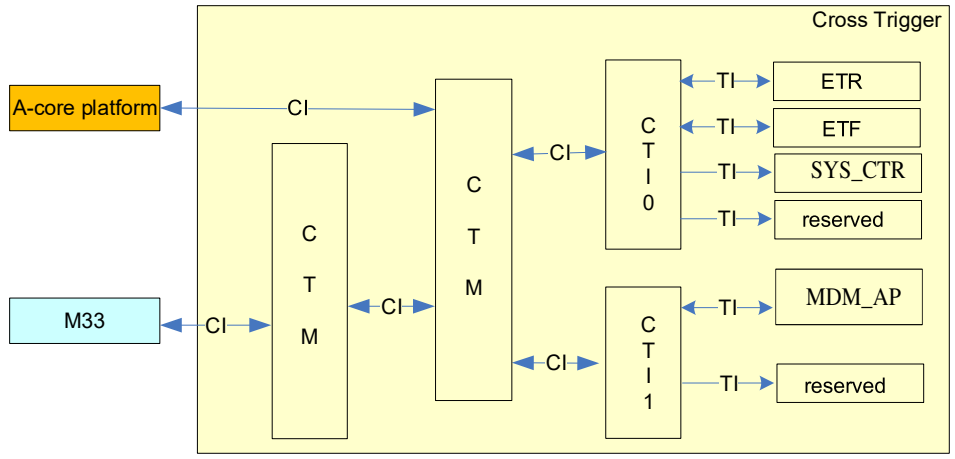


Figure 48. Embedded Cross Trigger Diagram

24.2.6 Timestamp Generation

There is no Arm Coresight Timestamp Generator in the system, and instead the System Counter is the source of the time used by all of the following components:

- System Counter internal counters and comparators.
- Cortex-A55 timestamp value (for trace).
- Cortex-M33 timestamp value (for trace).
- TSTMR1 and TSTMR2 read-only timestamp snapshot registers.
- Cortex-A55 Arm Generic Timer input.

The Cortex-A55 Arm Generic Timer is provided the full width uncompressed timestamp directly from the System Counter, without going through any Coresight Narrow timestamp encoder or decoder blocks. The Coresight Narrow timestamp IP are not used for the Cortex-A Generic Timer inputs in order to provide the maximum accuracy for the Cortex-A functional usage, as recommended by Arm. See the diagram below for details.

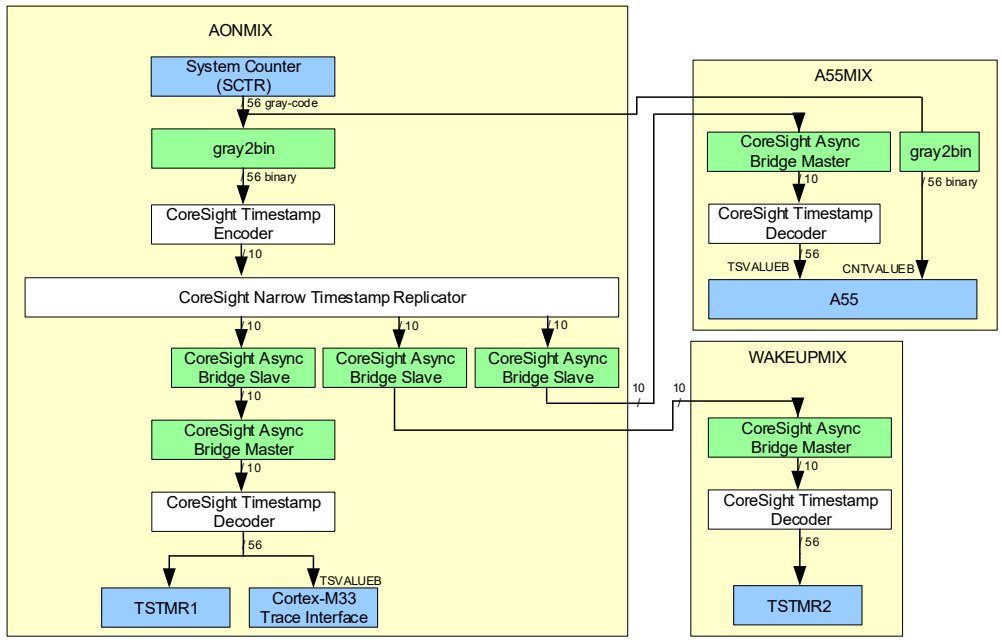

Figure 49. Timestamp Distribution

24.2.7 Debug Access Control from ROM Code

Once debug is authenticated, an external debugger tool may break code execution at any moment. This can potentially be during the boot process, when the ROM code is executing. If this occurs, the normal ROM execution is interrupted. The chip environment is uncertain (for example, the CLOCK initialization status, the interrupt status, the MPU settings).

When the debug tool loads the Flashloader, it will reset the core and halt the core first and then load the Flashloader. In such case, the Cortex-M33 system will be reset, and the ROM execution would be interrupted, and the delay time is not guaranteed before loading the Flashloader. Tasks such as the analog trim and clock initialization may be interrupted.

To address this, the chip allows the ROM code to receive a request whenever a debug request is received, gate the debug request until the ROM code enters a safe state to allow the debugger to continue. This is for reasons purely related to debug ease-of-use, not for reasons related to security.

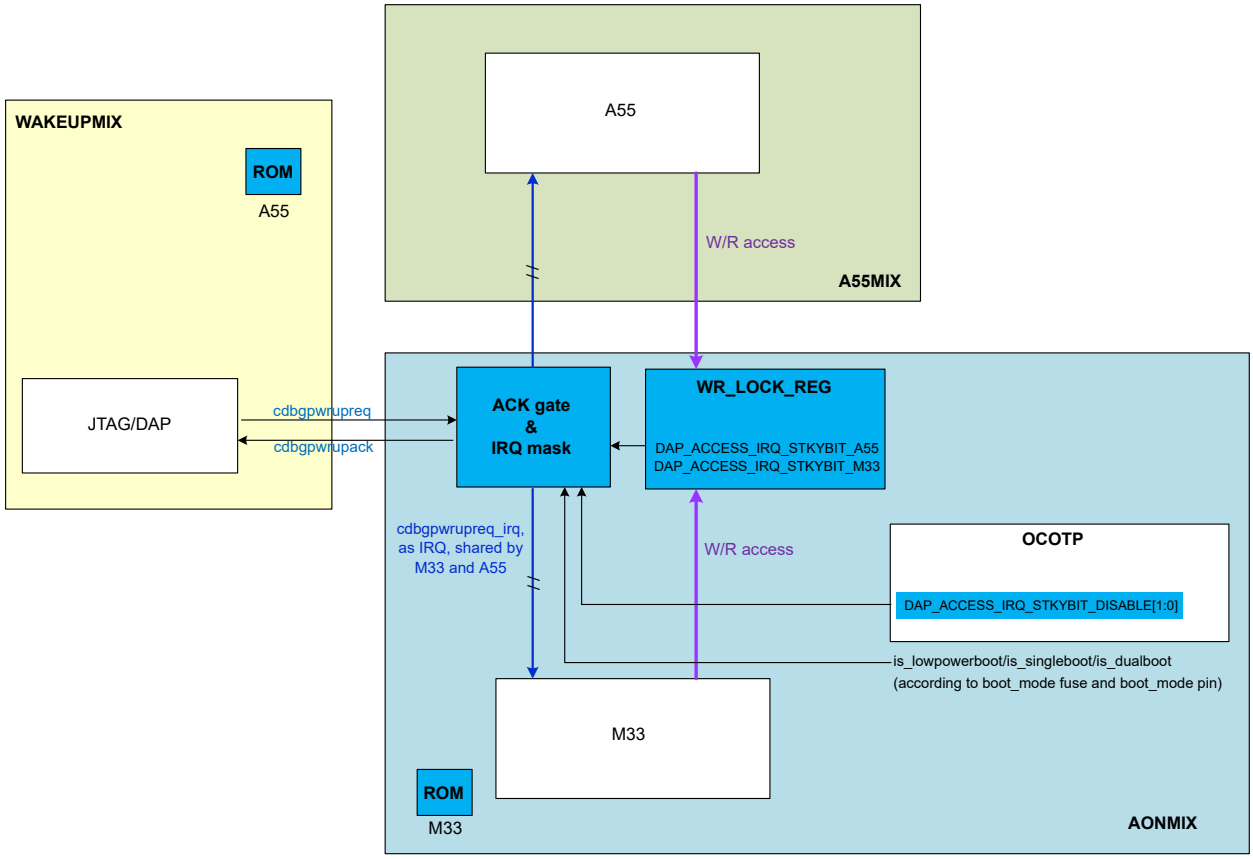

Figure 50. Debug Access Control from ROM Code

Details for the fuse controlling the debug access control from ROM code is provided in the following table.

Table 126. Fuse definition controlling debug access control from ROM code

DAP_ACCESS_IRQ_ STKYBIT_DISABLE[1]	DAP_ACCESS_IRQ_ STKYBIT_DISABLE[0]	Debug Control Logic
0	X	Disable DAP Access qualified by IRQ and sticky-bit logic. Direct DAP Access.
1	0	Enable DAP Access qualified by IRQ and sticky-bit logic.
1	1	Disable DAP Access qualified by IRQ and sticky-bit logic. Direct DAP Access.

DAP_ACCESS_IRQ_STKYBIT_DISABLE supports BootROM control of debug enable, and both fuse bits are in a section of BootROM that may be controlled by either NXP or OEM. By default, this feature is disabled when no fuses are blown.

This feature for the Cortex-M33 and Cortex-A55 will be enabled or disabled at the same time. Therefore, there is no case where one is enabled but another is disabled.

- For low power boot mode (Cortex-M boot), will select Cortex-M33's sticky bit.
- For single boot mode (Cortex-A boot), will select A55's sticky bit.

Pseudo code for the solution is pasted below:

```
      assign dap_access_irq_fuse_disabled =  (DAP_ACCESS_IRQ_STKYBIT_DISABLE[1] == 0) ||
((DAP_ACCESS_IRQ_STKYBIT_DISABLE[1] == 1) && (DAP_ACCESS_IRQ_STKYBIT_DISABLE[0] == 1));

      assign dap_accessible = dap_access_irq_fuse_disabled?  1'b1 :
      (is_lowpowerboot) ?  (DAP_ACCESS_IRQ_STKYBIT_M33) :
      (is_singleboot) ?   (DAP_ACCESS_IRQ_STKYBIT_A55) :
      (is_dualboot)?   (DAP_ACCESS_IRQ_STKYBIT_M33 && DAP_ACCESS_IRQ_STKYBIT_A55) : 1'b1;

      assign cdbgpwrupack = cdbgpwrupreq && fuse_latched && dap_accessible;
      assign cdbgpwrupreq_irq = cdbgpwrupreq && (~cdbgpwrupack);
```

NOTE

- DAP_ACCESS_IRQ_STKYBIT_M33 is a W/R register controlled by the Cortex-M33 ROM. Once set to "1", it will be "1" unless there is a reset.
- DAP_ACCESS_IRQ_STKYBIT_A55 is a W/R register controlled by the Cortex-A55 ROM. Once set to "1", it will be "1" unless there is a reset.
- cdbgpwrupreq_irq will be the final IRQ, shared by the Cortex-M33 and Cortex-A55.

24.3 External Signals

The JTAG signals are outlined in the following table.

Table 127. External signals

Name	I/O	JTAG	SWD	Pullup (PU) / Pulldown (PD)
TMS/SWDIO	I/IO	Mode selection	Data In/Out	PU
TCLK/SWCLK	I	Clock	Clock	PD
TDI	I	Data input	-	PU
TDO	O	Data output	-	NC

25.1.1 Module instances

This device has one instance of the JTAGC module.

25.2 Overview

JTAGC allows you to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from JTAGC is communicated in serial format.

25.2.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. See the chip-specific configuration information within this chapter as well as Register description for more information about the JTAGC registers.

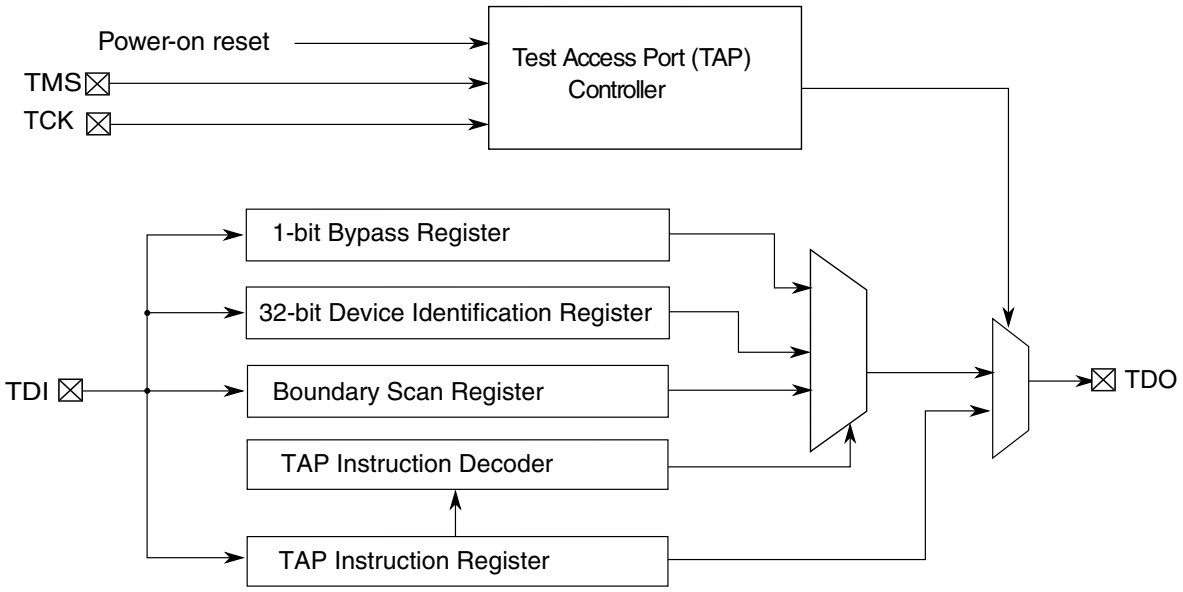

Figure 51. JTAG (IEEE 1149.1) block diagram

25.2.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 TAP interface
  - Four pins (TDI, TMS, TCK, and TDO)
- Instruction register that supports several IEEE 1149.1–2001 defined instructions as well as several public and private device-specific instructions (see JTAGC block instructions for a list of supported instructions).
- Bypass register, boundary scan register, and device identification register
- TAP controller state machine that controls the operation of the data registers, instruction register, and associated circuitry

25.3 Functional description

25.3.1 Modes of operation

The JTAGC block uses a power-on reset indication as its primary reset signals. Several IEEE 1149.1–2001 defined test modes are supported, as well as a bypass mode.

25.3.1.1 IEEE 1149.1–2001 defined test modes

The JTAGC block supports several IEEE 1149.1–2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register when the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, PRELOAD.

Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic when the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ

- CLAMP

The functionality of each test mode is explained in more detail in JTAGC block instructions.

25.3.1.2 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. When in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

25.3.2 IEEE 1149.1-2001 (JTAG) TAP

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction.

Data is shifted between TDI and TDO through the selected register (instruction, test data, or the bypass register) starting with the least significant bit, as illustrated in the following figure.

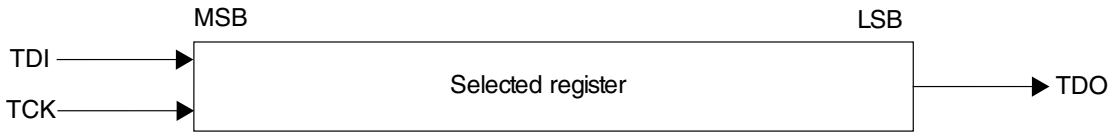

Figure 52. Shifting data through a register

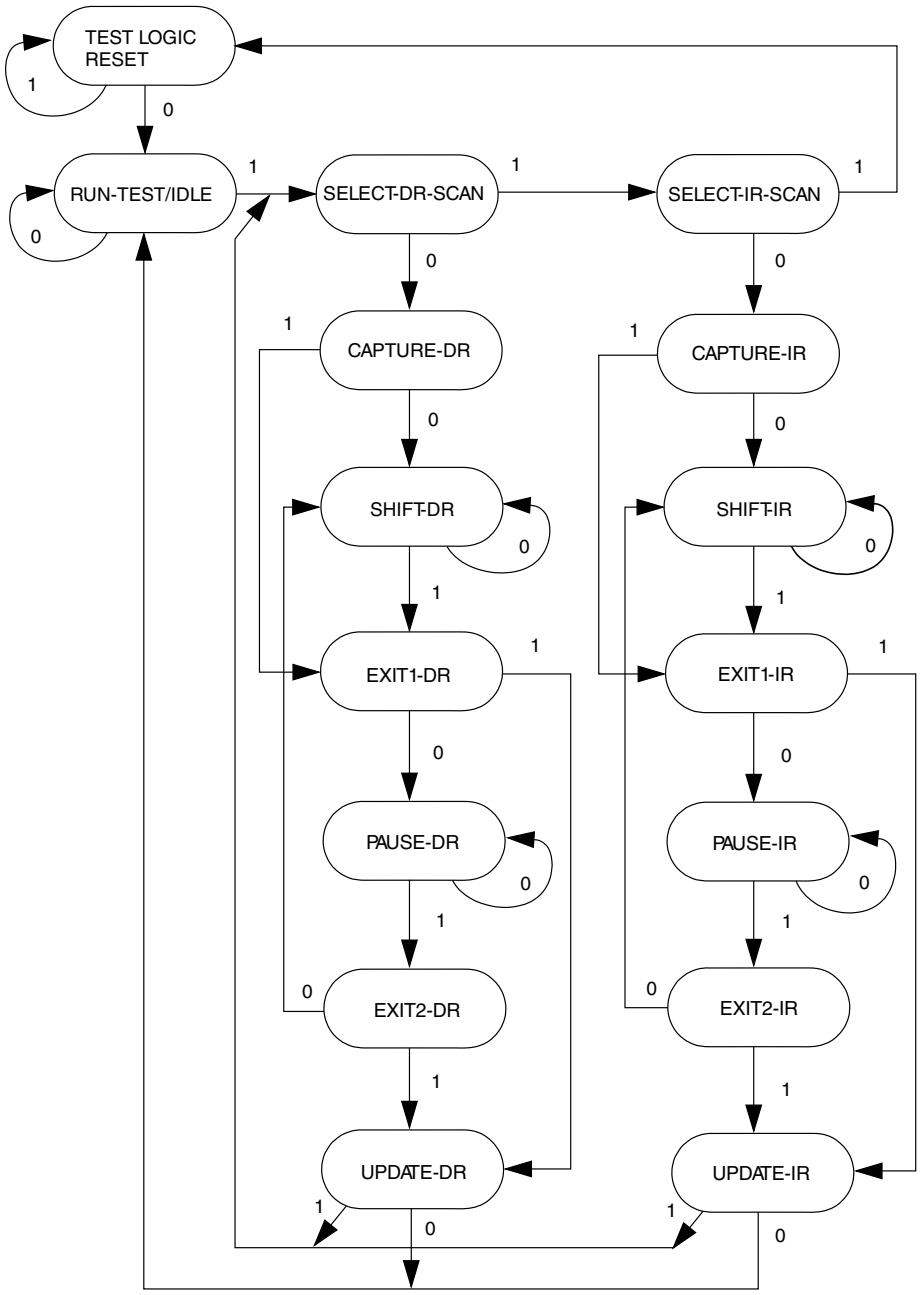
25.3.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin.

The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the figure shows, holding TMS at logic 1 when clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.



The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 53. IEEE 1149.1-2001 TAP controller finite state machine

25.3.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting the JTAGC enable to a logic 1 value.

25.3.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions when the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated after the required number of bits have been acquired.

25.3.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions. See the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

NOTE

See the chip specific information JTAGC block instructions for applicable to your device.

25.3.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

25.3.4.2 PRELOAD instruction

The PRELOAD instruction has two functions:

- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

25.3.4.3 EXTEST external test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the data is loaded into the boundary scan register using the PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state when performing external boundary scan operations.

25.3.4.4 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. When HIGHZ is active all output drivers are placed in an inactive drive state (for example, high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

25.3.4.5 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register when the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) when conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

25.3.4.6 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. When the BYPASS instruction is active the MCU operates normally.

25.3.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

25.3.6 Clocking

There is one clock for this module. For more information See External signals.

25.3.7 Interrupts

This module has no interrupts.

25.3.8 Reset

The JTAGC block is placed in reset when:

- Power-on reset is asserted
- TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state

Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset results in asynchronous entry into the reset state.

When in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the MCU.
- The instruction register is loaded with the IDCODE instruction.

25.4 External signals

JTAGC includes a set of signals that connect to off-chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 130. JTAG signal properties

Name	I/O	Function	Reset state
TCK	Input	Test clock	Weak pulldown
TDI	Input	Test data in	Weak pullup
TDO	Output	Test data out	High Z[1]
TMS	Input	Test mode select	Weak pullup

1. TDO output buffer is disabled when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

25.4.1 Test clock input (TCK)

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

25.4.2 Test data input (TDI)

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

25.4.3 Test data output (TDO)

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is tristateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

25.4.4 Test mode select (TMS)

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

25.5 Initialization

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Place the JTAGC in reset through TAP controller state machine transitions controlled by TMS.
2. Load the appropriate instruction for the test or action to be performed.

25.6 Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

25.7 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

25.7.1 Instruction register

The JTAGC block uses a 4-bit instruction register as shown in the following figure.

The instruction register allows instructions to be loaded into the block to select the test to be performed, or the test data register to be accessed, or both. Instructions are shifted in through TDI when the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states.

Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 0b1, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

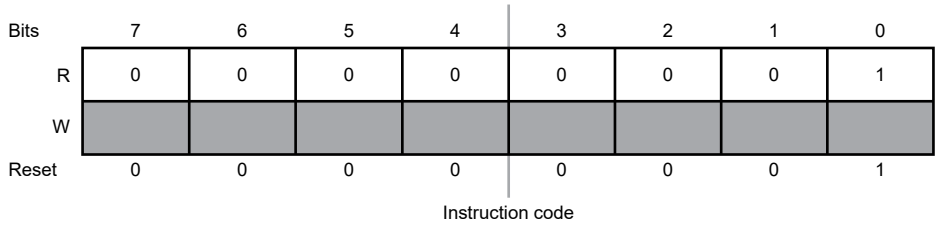


Figure 54. Instruction register

25.7.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

25.7.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP.

The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state when the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

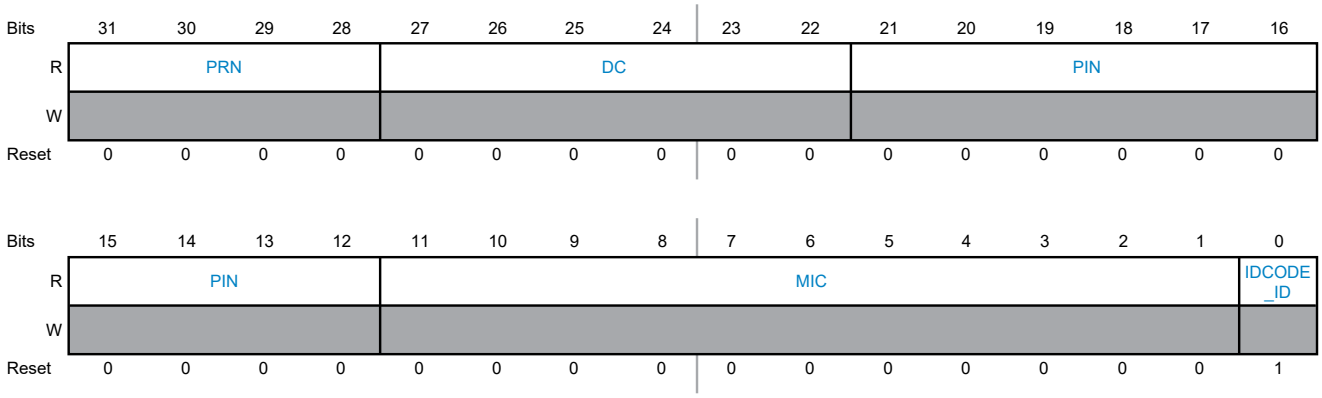

Figure 55. Device identification register

The following table describes the device identification register functions. The device identification register values are described in the chip-specific JTAGC information.

Table 131. Device identification register field descriptions

Field	Function
PRN	Part revision number Contains the revision number of the part.
DC	Design center Indicates the design center.
PIN	Part identification number Contains the part number of the device.
MIC	Manufacturer identity code

Table continues on the next page...

Table 131. Device identification register field descriptions (continued)

Field	Function
	Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID .
IDCODE ID	IDCODE register ID Identifies this register as the device identification register and not the bypass register. Always set to 1.

25.7.4 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, PRELOAD instructions are active. It is used to:

- Capture input pin data
- Force fixed values on output pins
- Select a logic value and direction for bidirectional pins

Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

25.8 Glossary

TAP	Test access port
TCK	Test clock
TDI	Test data in
TDO	Test data out
TMS	Test mode select
JCOMP	JTAG compliance

Chapter 26
External Signals and Pin Multiplexing

26.1 Overview

The chip contains a limited number of pins, most of which have multiple signal options. These signal-to-pin and pin-to-signal options are selected by the input-output multiplexer called IOMUX. The IOMUX is also used to configure other pin characteristics, such as voltage level, drive strength, and hysteresis.

The muxing options table lists the external signals grouped by the module instance, the muxing options for each signal, and the registers used to route the signal to the chosen pad.

26.1.1 Muxing Options

Please refer the Pinlist spreadsheet attached with this RM for more details.

NOTE

ENET1 is Ethernet QoS with TSN and ENET2 is Ethernet MAC.

NOTE

LPUART DCB_B is the same as LPUART DCD_B.

NOTE

Chapter 27
IOMUX Controller (IOMUXC)

27.1 Overview

The IOMUX Controller (IOMUXC), together with the IOMUX, enables the IC to share one pad to several functional blocks. This sharing is done by multiplexing the pad's input and output signals.

Every module requires a specific pad setting (such as pull up or keeper), and for each pad, there are up to 8 muxing options (called ALT modes). The pad settings parameters are controlled by the IOMUXC.

The IOMUX consists only of combinatorial logic combined from several basic IOMUX cells. Each basic IOMUX cell handles only one pad signal's muxing.

27.1.1 Block diagram

The figure below illustrates the IOMUX/IOMUXC connectivity in the system.

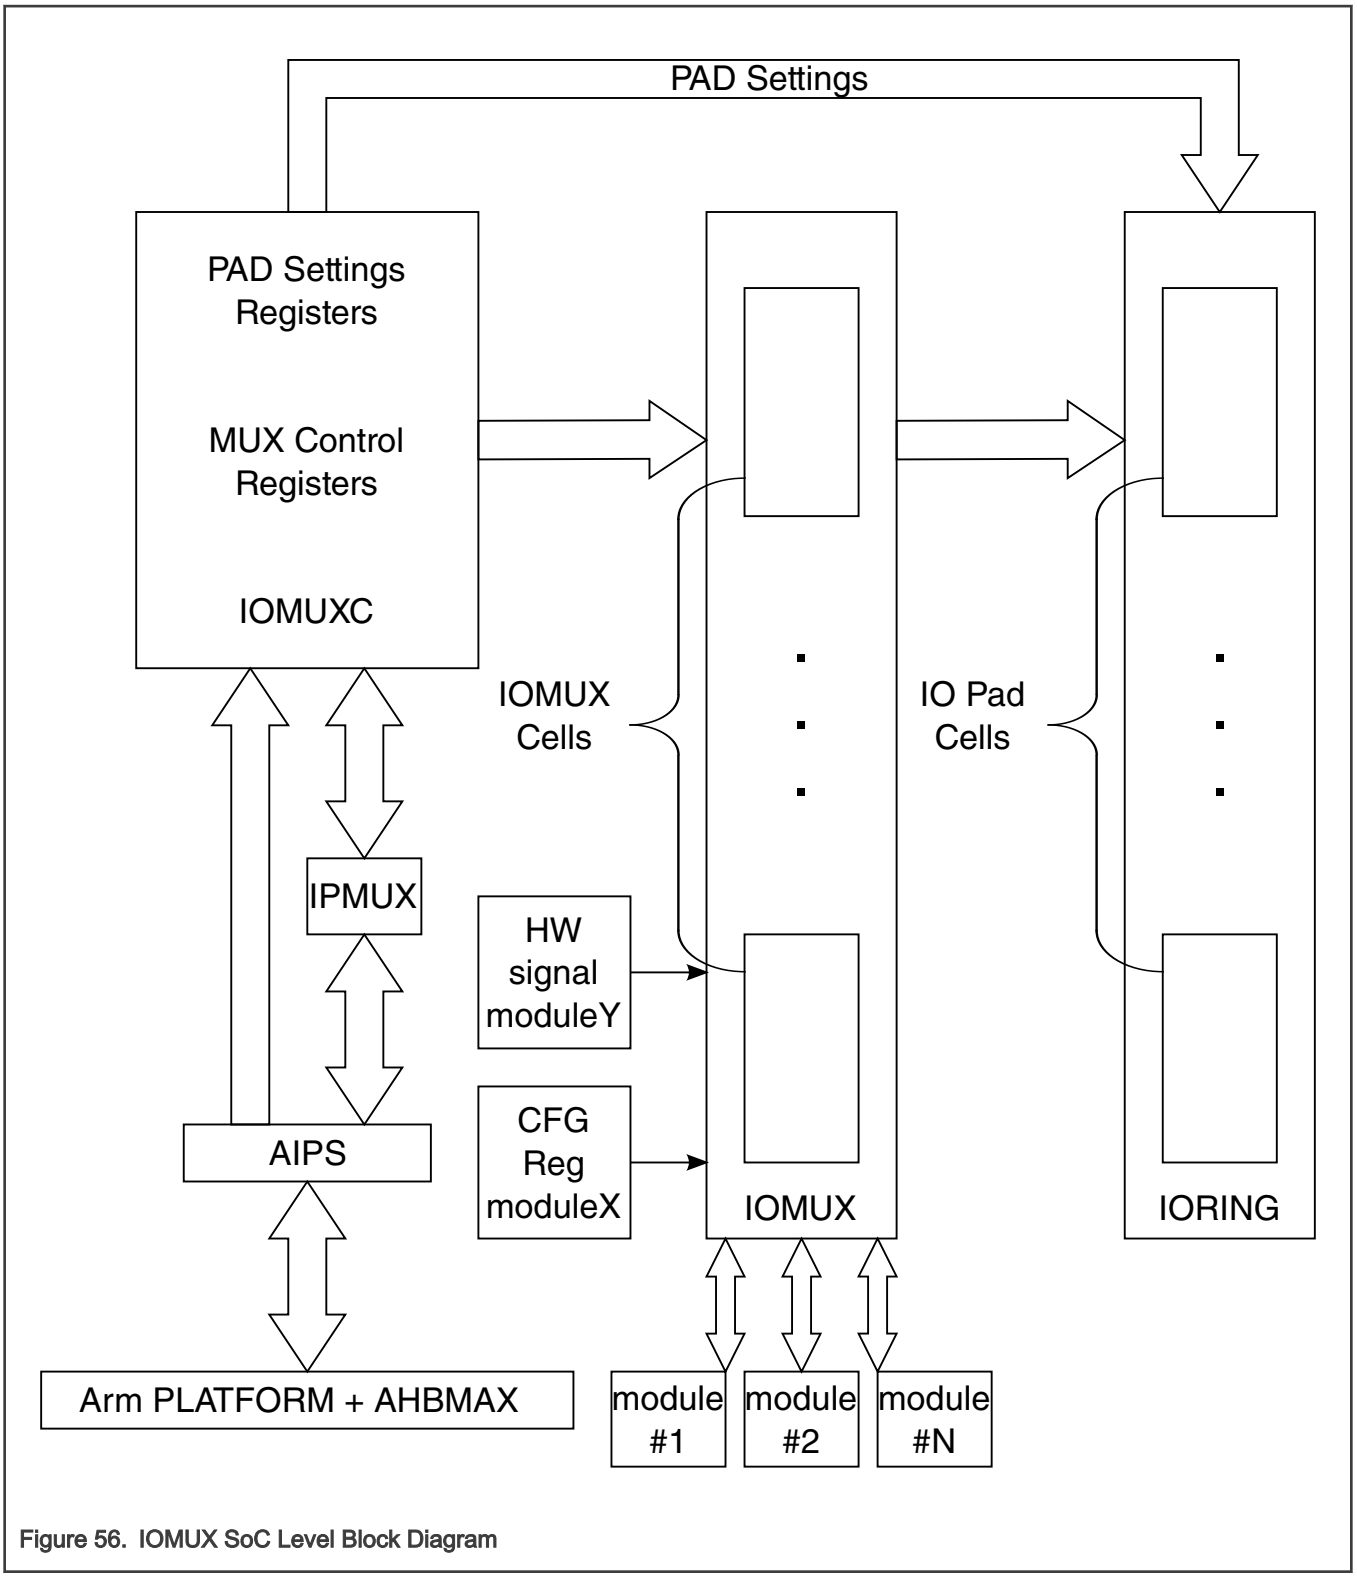

Figure 56. IOMUX SoC Level Block Diagram

27.1.2 Features

The IOMUXC features include:

- 32-bit software mux control registers (SW_MUX_CTL_PAD_<PAD NAME>) to configure 1 of 12 alternate (ALT) MUX_MODE fields of each pad and to enable the forcing of an input path of the pad(s) (SION bit).
- 32-bit software pad control registers (SW_PAD_CTL_PAD_<PAD_NAME>) to configure specific pad settings of each pad.
- 32-bit input select control registers to control the input path to a module when more than one pad drives this module input.

Each SW MUX/PAD CTL IOMUXC register handles only one pad.

Only the minimum number of registers required by software are implemented by hardware. For example, if only ALT0 and ALT1 modes are used on Pad x then only one bit register will be generated as the MUX_MODE control field in the software mux control register of Pad x.

The software mux control registers may allow the forcing of pads to become input (input path enabled) regardless of the functional direction driven. This may be useful for loopback and GPIO data capture.

27.2 Functional description

This section provides a complete functional description of the block.

The IOMUX consists of a number of basic iomux cell units. If only one functional mode is required for a specific pad, it would have been no need for IOMUX and the signals can be connected directly from the module to the I/O. The IOMUX cell is required whenever two or more functional modes are required for a specific pad or when one functional mode and the one test mode are required.

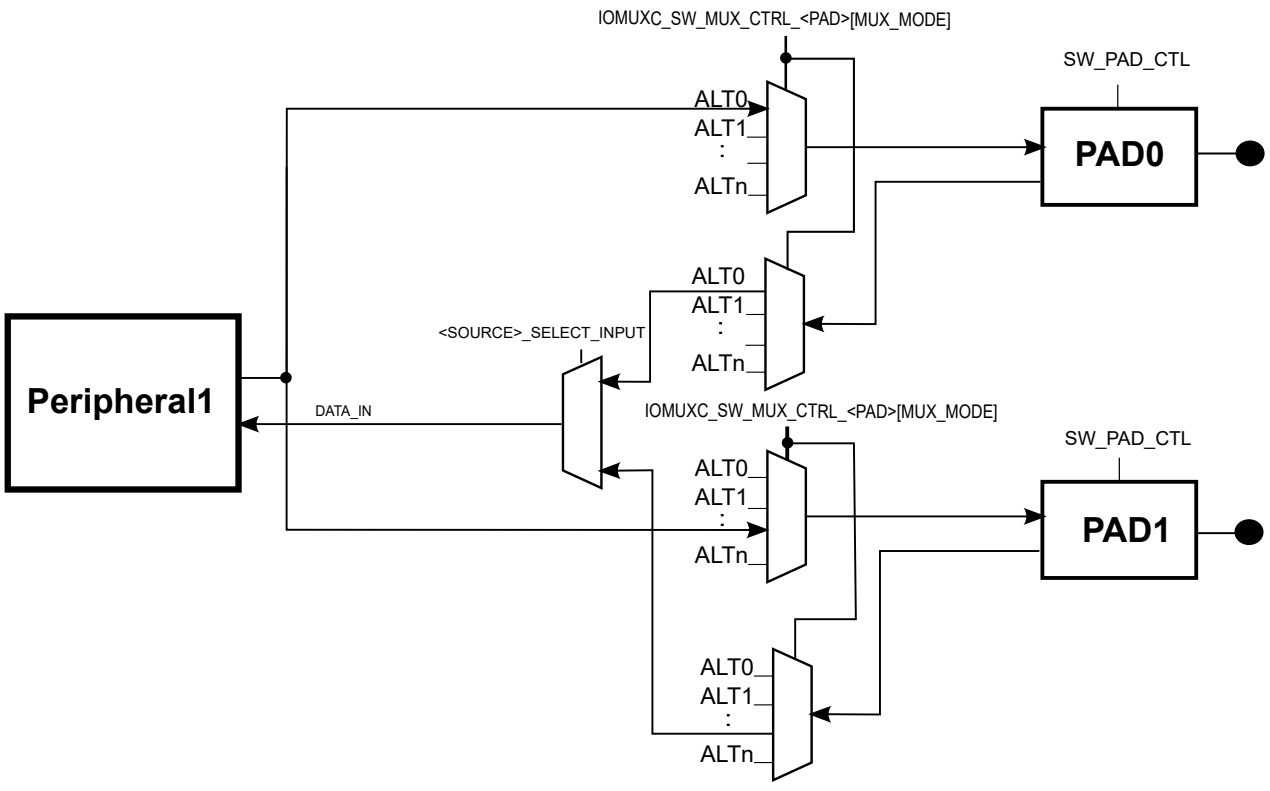

Figure 57. IOMUX Cell Block Diagram

27.2.1 SW Loopback through SION bit

A limited option exists to override the default pad functionality and force the input path to be active regardless of the value driven by the corresponding module. This can be done by setting the SION (Software Input On) bit in the IOMUXC_SW_MUX_CTL register (when available) to "1".

Uses include:

- LoopBack - Module x drives the pad and also receives pad value as an input.

27.2.2 Daisy chain - multi pads driving same module input pin

In some cases, more than one pad may drive a single module input pin. Such cases require the addition of one more level of IOMUXing; all of these input signals are muxed, and a dedicated software controlled register controls the mux in order to select the required input path.

A module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programable via the SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers).

This means that a module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programable via the SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers).

The daisy chain is illustrated in the figure below.

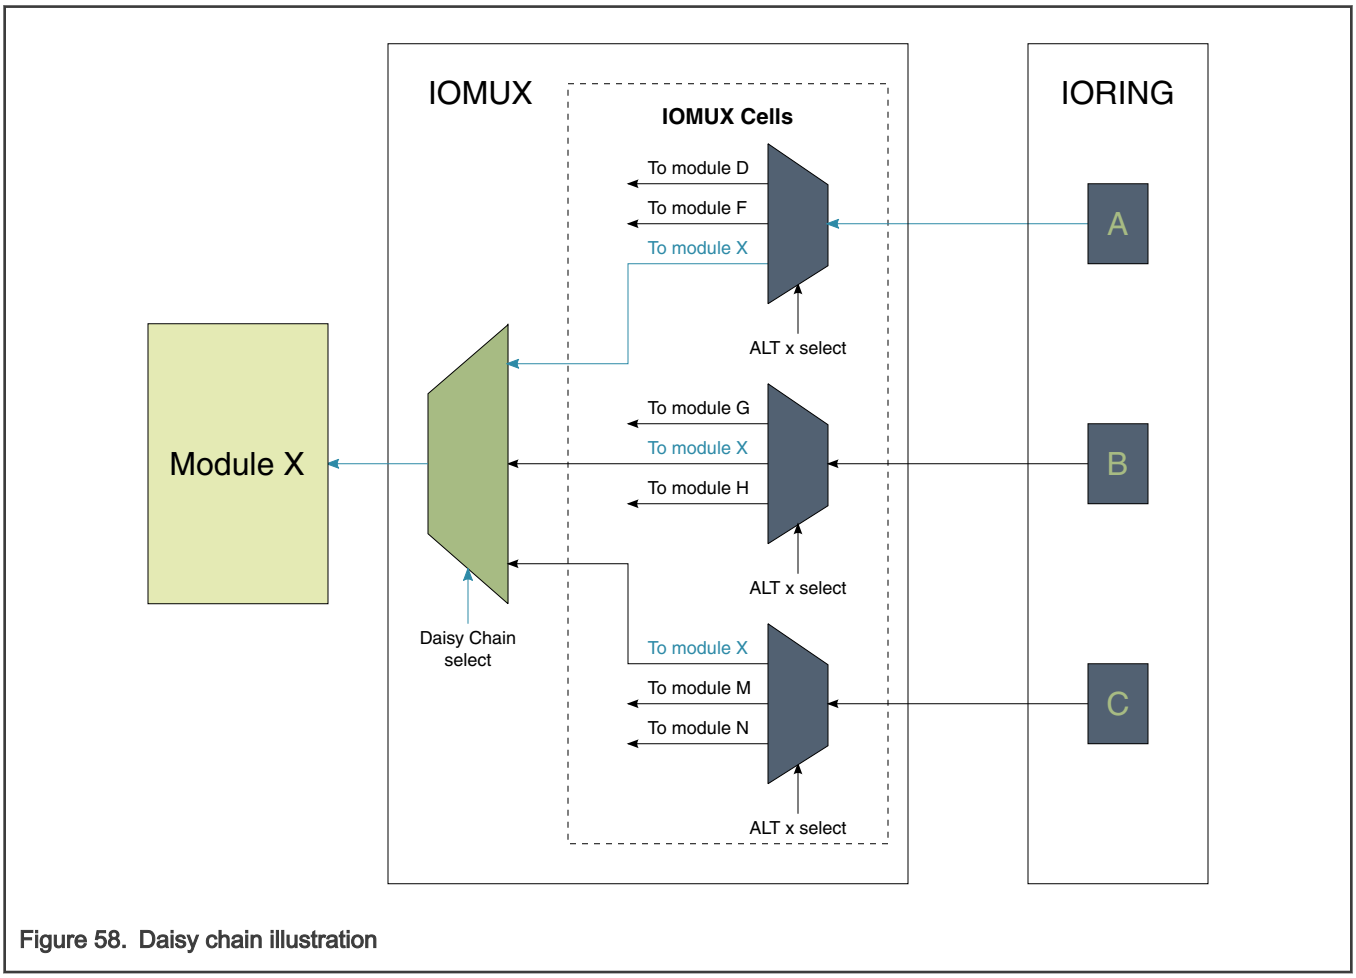

Figure 58. Daisy chain illustration

27.2.3 Clocks

The table found here describes the clock sources for IOMUXC. Please see Clock Controller Module (CCM) chapter for clock setting, configuration and gating information.

Table 132. IOMUXC Clocks

Clock Name	Description
ipg_clk_s	Peripheral access clock

27.3 Memory Map and register definition

This section includes the IOMUXC module memory map and detailed descriptions of all registers.

NOTE

Write/Read to the Reserved locations will not generate a transfer error.

NOTE

ENET1 is Ethernet QoS with TSN and ENET2 is Ethernet MAC in the registers below.
