| ESI | Error State Indicator | Indicates whether the transmitting node is error-active or error-passive. This field is meaningful only if EDL = 1.<br>0: Error-active<br>1: Error-passive |
| SRR | Substitute Remote Request | Fixed recessive bit, used only in extended format. Transmitting nodes always send it as recessive and receiving nodes can receive it as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss. |
| IDE | ID Extended Bit | Identifies whether the frame format is standard or extended.<br>0: Standard<br>1: Extended |
| RTR | Remote Frame | Identifies whether the current frame is a data frame or a remote request.<br>0: Data frame<br>1: Remote request |
| DLC | Data Length Code | Defines the number of bytes in the data field of a CAN frame (Data byte 0 to Data byte 63). When RTR = 1, the frame is a remote request and does not include the data field, regardless of the DLC field. See Table 457 for more details. |
| LEGACY TIMESTAMP | 16-bit Timestamp | Provides a copy of the Free-Running Timer, captured during the CAN frame. See Table 456 for details about legacy timestamp operation. |
| ID | Frame Identifier | In base frame format, only the 11 most significant bits are used for frame identification. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification. |
| DATA BYTE 0–63 | Data Field | Up to 64 bytes can be stored in the data field. |
| IDHIT | Identifier Acceptance Filter Hit Indicator | Indicates which Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL127) the received message in the output of the Enhanced RX FIFO hit. For each filter region, standard-ID filter space, and extended-ID filter space, there is an independent index starting from zero. Table 470 shows how FlexCAN writes IDHIT according to each filter element. |

*Table continues on the next page...*

Table 469. Field descriptions (continued)

| Mnemonic | Field | Description |
|---|---|---|
| HR TIMESTAMP | High-resolution Timestamp | 32-bit timebase captured during the CAN frame. When CTRL2[TSTAMPCAP] is not zero, a 32-bit timebase is captured from a dedicated on-chip timer which operates in free-running mode. See CTRL2[TSTAMPCAP] for details about capture point configuration of the high-resolution timestamp. |

Table 470. IDHIT for Enhanced RX FIFO

| Enhanced RX FIFO filter element - ERFFEL | IDHIT value | Filter element type |
|---|---|---|
| ERFFEL0 | 0 | Extended-ID |
| ERFFEL1 | 1 | Extended-ID |
| . . . | . . . | Extended-ID |
| ERFFEL(m-1) | m-1 | Extended-ID |
| ERFFEL(m) | 0 | Standard-ID |
| ERFFEL(m+1) | 1 | Standard-ID |
| . . . | . . . | Standard-ID |
| ERFFEL(2n-m+1) | 2x(n-m)+1 | Standard-ID |

**NOTE**

Where m = NEXIF and n = NFE. If NEXIF = 0, only standard-ID filter elements exist. If NEXIF > NFE, only extended-ID filter elements exist.

## 70.7 Glossary

**Active message buffer** — A message buffer is active if it can participate in the current matching or arbitration process.

**Bus interface unit** — FlexCAN submodule responsible for the interface to the CPU.

**Bus off** — See CAN Specification.[8]

**CAN** — Controller Area Network, a serial communication protocol defined in CAN Specification[8] and ISO International Standard.[9]

**CHI** — Controller-host interface, a FlexCAN submodule responsible for message buffer matching and arbitration algorithms.

**CRC** — Cyclic redundancy check

[8] Controller Area Network - CAN Specification Version 2.0 Part A, Part B, Robert Bosch GmbH, 1991.
[9] ISO International Standard - ISO 11898 First Edition 1993 Road Vehicles - Interchange of Digital Information - Controller Area Network (CAN) for high-speed Communication.

| | |
|---|---|
| **Dominant bit** | A dominant bit wins the arbitration on the CAN bus. It is transmitted as 0. |
| **Doze mode** | A system low-power mode where the CPU bus remains active and a global Doze mode request is sent to all peripherals asking them to enter low power mode. |
| **Error active** | See CAN Specification.[8] |
| **Error frame** | See CAN Specification.[8] |
| **Error passive** | See CAN Specification.[8] |
| **Form error** | See CAN Specification.[8] |
| **Hard reset** | A reset coming from an external pin and/or following power-on. It resets everything. |
| **Idle** | See CAN Specification.[8] |
| **Information processing time** | See CAN Specification.[8] |
| **Intermission** | See CAN Specification.[8] |
| **Matching elements** | Data used in the matching process, such as ID, filter, mask, etc. |
| **MB** | See Message buffer. |
| **Message buffer** | Internal FlexCAN data structure containing bytes received from, or to be transmitted to, the CAN line, as well as information about this data. |
| **Overload frame** | See CAN Specification.[8] |
| **Phase buffer segment** | See CAN Specification.[8] |
| **Recessive bit** | A recessive bit loses the arbitration on the CAN bus. It is transmitted as 1. |
| **Sclock** | Serial clock. Obtained by dividing the clock feeding the CAN engine (oscillator or bus clock) by a prescaler factor. The Sclock period defines the time quantum for CAN protocol timing. |
| **Soft reset** | Global reset typically used by peripherals to reinitialize some of its registers, but not all of them. |
| **Stop mode** | A system low-power mode in which all chip clocks are stopped for maximum power savings. |
| **Stuffing error** | See CAN Specification.[8] |
| **Time quantum** | This is equal to the Sclock period. It is the minimum time period used to compose the CAN protocol bit timing. |

# Chapter 71
# Synchronous Audio Interface (SAI)

## 71.1 Chip-specific SAI information

### 71.1.1 SAI instances and configuration

**Table 471. SAI instances**

| Instance | MCXE31B | MCXE315/ MCXE316/MCXE317 |
|---|---|---|
| SAI_0 | Yes | No |
| SAI_1 | Yes | No |

**Table 472. SAI configuration**

| Chip | Instances | Synchronous Mode | DMA support | Data Rate/ channel | No. of Channels | Frame Synchronization | Master Clock Frequency | FIFO size(TX/RX)/ Channel | No. of words/ frame |
|---|---|---|---|---|---|---|---|---|---|
| MCXE31B | SAI_0 | No | Yes | 12.288 Mbps | 4 | I2S, AC97, and CODEC/DSP interfaces | 24.576 external audio | 8X32 bit | 8-16 words |
| | SAI_1 | No | Yes | 12.288 Mbps | 1 | I2S, AC97, and CODEC/DSP interfaces | 24.576 external audio | 8x32bit | 8-16 words |

**NOTE**

The SAI_BCLK (SAI_TX_BCLK, SAI_RX_BCLK), SAI_SYNC (SAI_TX_SYNC, SAI_RX_SYNC), and SAI_DATA (SAI_TX_DATA, SAI_RX_DATA) pins are shared between each module instance's (SAI_0, SAI_1) receiver and transmitter. See the IOMUX file attached to this document for details. At any specific time, either the SAI receiver or the SAI transmitter should be active or they should operate synchronously (only one active at a time). The SAI transmitter and SAI receiver should not be configured to operate simultaneously with inconsistent configurations.

**NOTE**

Timing specification of SAI master and SAI slave may limit maximum frequency.

## 71.2 Overview

SAI provides an interface that supports full-duplex serial digital audio interfaces with frame synchronization formats such as $I^2S$, AC97, TDM, and Codec/DSP interfaces.

### 71.2.1 Block diagram

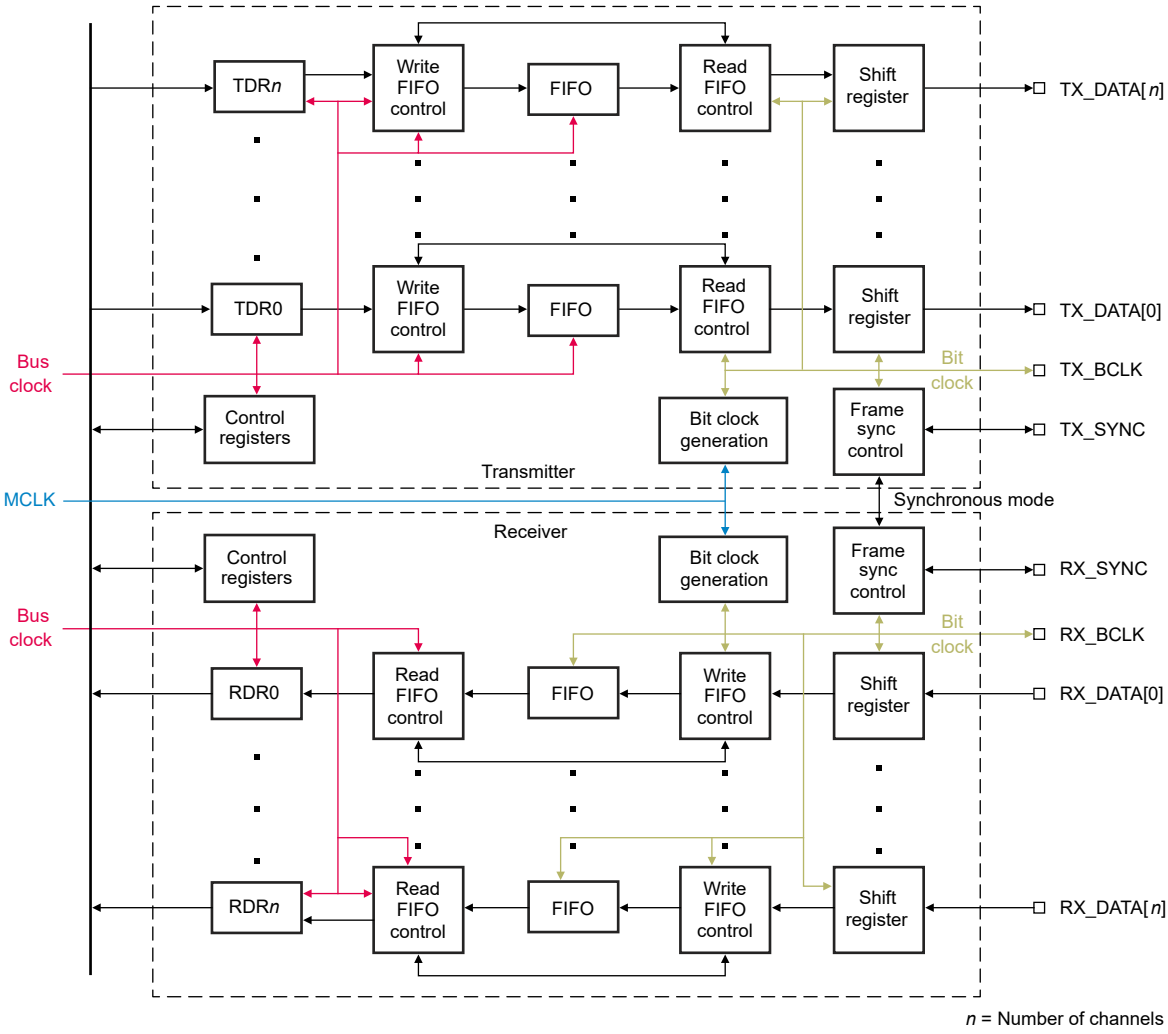

Figure 385. Block diagram

### 71.2.2 Features

Features can vary among chips and among SAI modules on the same chip. See the chip-specific SAI information at the beginning of this chapter.

- Transmitter with independent bit clock and frame synchronization supporting 4 data lines
- Receiver with independent bit clock and frame synchronization supporting 4 data lines
- Maximum frame size of 16 words per data line
- Word length of 8 to 32 bits
- Word length configured separately for the first word and remaining words in a frame
- Asynchronous 8 × 32-bit FIFO for each transmit and receive data line supports:
  - Graceful restart after FIFO error.
  - Automatic restart after FIFO error without software intervention.
  - 8-bit and 16-bit data packing into each 32-bit FIFO word.

— Multiple-data-line FIFOs combining into single-data-line FIFO.

## 71.3 Functional description

This section provides a complete functional description of SAI.

### 71.3.1 Modes of operation

- Run mode
- Debug mode

#### 71.3.1.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

#### 71.3.1.2 Debug mode

You can configure either or both the SAI transmitter and receiver to continue operating in Debug mode:

- Write 1 to TCSR[DBGE] to configure the transmitter to run in Debug mode.
- Write 1 to RCSR[DBGE] to configure the receiver to run in Debug mode.

When TCSR[DBGE] and RCSR[DBGE] are 0 and the chip enters Debug mode, SAI is disabled after completing the current transmit or receive frame. Debug mode does not affect the transmitter and receiver bit clocks.

### 71.3.2 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other. You can configure the SAI transmitter and receiver to operate with a synchronous bit clock and frame sync (see TCR2[SYNC] and RCR2[SYNC]).

If both the transmitter and receiver use the transmitter bit clock and frame sync:

- Configure the transmitter for asynchronous operation and the receiver for synchronous operation.
- Enable the receiver in Synchronous mode only after configuring both the transmitter and receiver.
- Enable the transmitter last and disable the transmitter first.

If both the transmitter and receiver use the receiver bit clock and frame sync:

- Configure the receiver for asynchronous operation and the transmitter for synchronous operation.
- Enable the transmitter in Synchronous mode only after configuring both the receiver and transmitter.
- Enable the receiver last and disable the receiver first.

When operating in Synchronous mode, the transmitter and receiver share only the bit clock, frame sync, and transmitter and receiver enable. Otherwise, the transmitter and receiver operate independently, although the configuration register settings must be consistent across both the transmitter and receiver.

### 71.3.3 Frame sync configuration

When enabled, SAI continuously transmits and receives frames of data. Each frame consists of a fixed number of words, with each word consisting of a fixed number of bits. Within each frame, you can mask any word, causing the receiver to ignore that word and the transmitter to 3-state during that word.

The frame sync signal indicates the start of a frame. A valid frame sync requires the detection of a rising edge (if active high) or falling edge (if active low). The transmitter or receiver cannot be busy with a previous frame. SAI ignores a valid frame sync (in Target mode) or does not generate one (in Controller mode) for the first four bit-clock cycles after enabling the transmitter or receiver.

You can configure the transmitter and receiver frame sync independently by using any of the following options:

- Generate externally or internally
- Configure to be active high or active low
- Assert with the first bit in the frame or one bit early
- Assert for a duration between one bit-clock cycle and the first word length
- Configure the frame length from 1 to 16 words
- Configure the word length from 8 to 32 bits, with separate configurations for the length of the first word and that of the remaining words
- Transmit or receive words MSB first or LSB first

You cannot change these configuration options after enabling the SAI transmitter or receiver.

## 71.3.4 Data FIFO

Each transmit and receive channel includes a 8 × 32-bit FIFO. Use Transmit Data (TDR0 - TDR3) and Receive Data (RDR0 - RDR3) to access FIFO data.

### 71.3.4.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit-wide register via the First Bit Shifted (FBT) configuration field. This field selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required FBT configuration are shown in Figure 386 for LSB-first configurations and Figure 387 for MSB-first configurations.

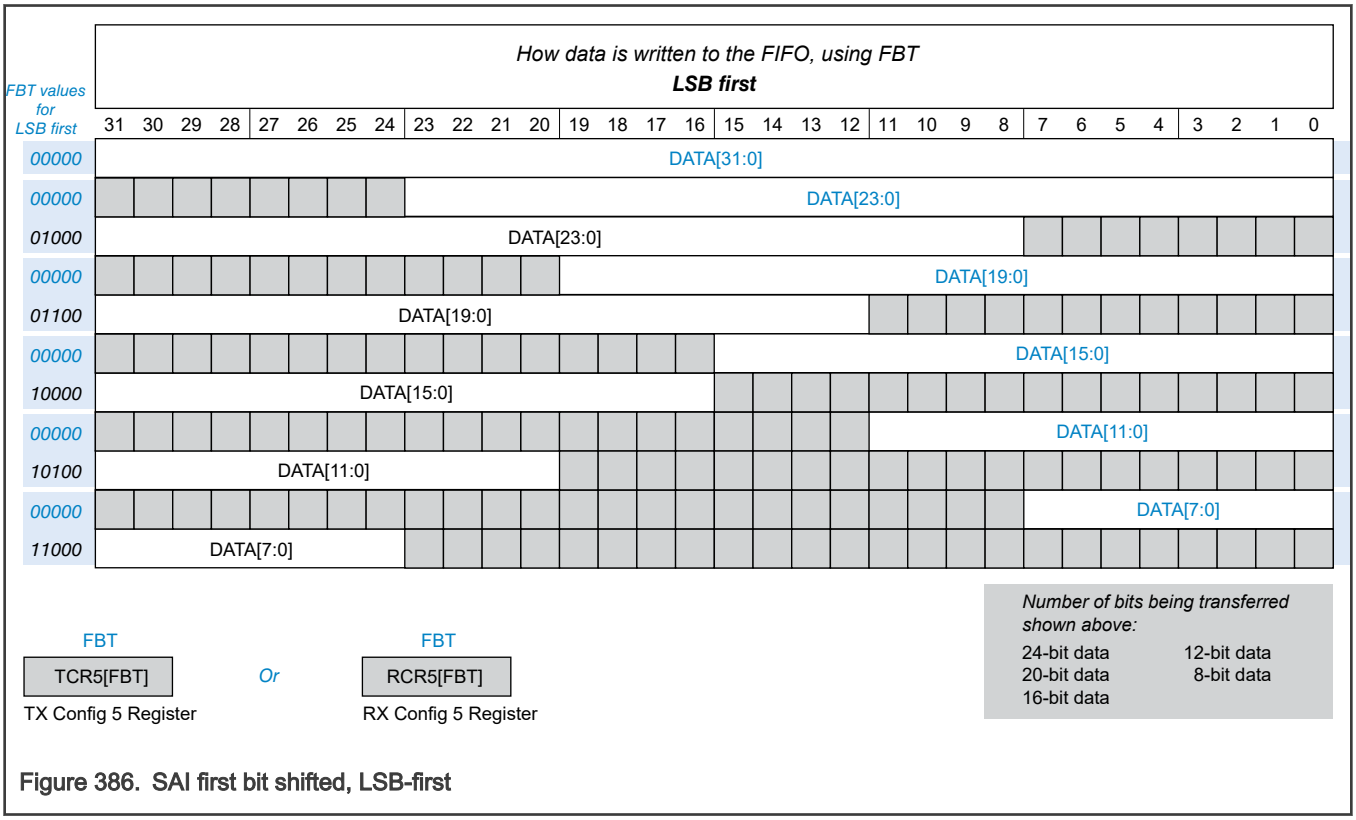

Figure 386. SAI first bit shifted, LSB-first

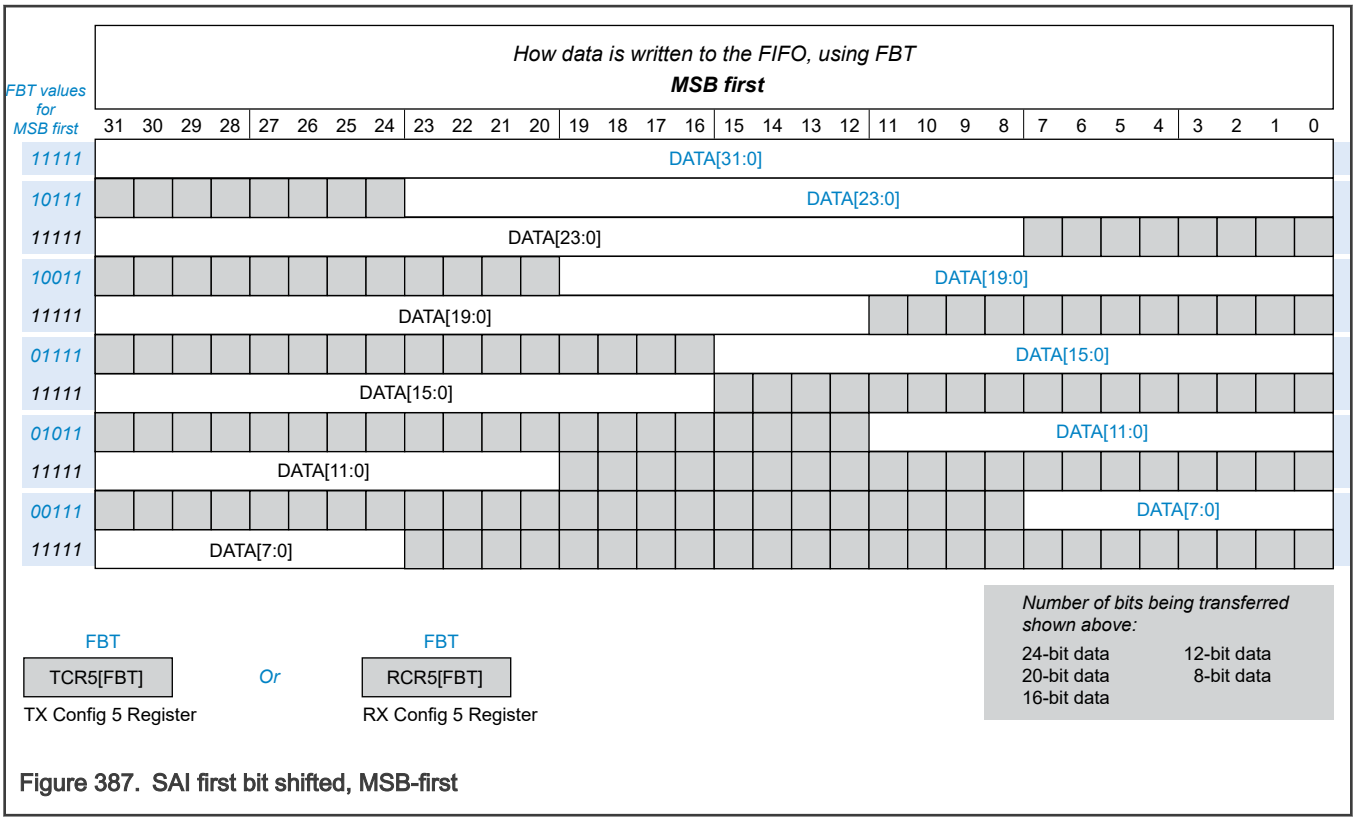

**Figure 387. SAI first bit shifted, MSB-first**

### 71.3.4.2 FIFO pointers

When writing to one of the Transmit Data (TDR0 - TDR3) registers, the write FIFO pointer of the corresponding Transmit FIFO register (TFR*n*[WFP]) increments after each valid write. SAI supports 8-bit, 16-bit, and 32-bit writes to TDR*n*, and the FIFO pointer increments after each individual write. Use only 8-bit writes when transmitting up to 8-bit data, and use only 16-bit writes when transmitting up to 16-bit data:

- If the transmit FIFO is full, SAI ignores writes to TDR*n*.
- If the transmit FIFO is empty, write to TDR*n* at least three bit-clock cycles before the start of the next unmasked word. This write avoids a FIFO underrun.
- Before enabling the transmitter, initialize the transmit FIFO with data. The transmitter starts a new frame after enabling the transmitter. If no data is in the FIFO, the transmitter immediately generates an error.

When reading one of the Receive Data (RDR0 - RDR3) registers, the read FIFO pointer of the corresponding Receive FIFO register (RFR*n*[RFP]) increments after each valid read. SAI supports 8-bit, 16-bit, and 32-bit reads from RDR*n*, and the FIFO pointer increments after each individual read. Use only 8-bit reads when receiving up to 8-bit data, and use only 16-bit reads when receiving up to 16-bit data:

- If the receive FIFO is empty, SAI ignores reads to RDR*n*.
- If the receive FIFO is full, read RDR*n* at least three bit-clock cycles before the end of an unmasked word. This read avoids a FIFO overrun.

### 71.3.4.3 FIFO packing

Using FIFO packing, you can store multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter or receiver. You could emulate this feature by adjusting the number of bits per word and number of words per frame. FIFO packing, however, does not require even multiples of words per frame, and it fully supports word masking.

When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive). In this way, FIFO packing supports scenarios where different words within each frame are stored in different areas of memory.

Using 16-bit FIFO packing for transmitting, the transmit shift register loads at the start of each frame and after every second unmasked transmit word. The first transmitted word is taken from the 16-bit word at byte offset 0h. (The first bit is selected by TCR5[FBT], and you must configure it within this 16-bit word.) The second transmitted word is taken from the 16-bit word at byte offset 2h. (The first bit is selected by TCR5[FBT][3:0].) After the 16-bit word has been transmitted, the transmitter transmits logic zeroes until the start of the next word.

Using 16-bit FIFO packing for receiving, the receive shift register is stored after every second unmasked received word. If there is an odd number of unmasked-received words in each frame, the receive register is also stored, at the end of each frame. The first received word is stored in the 16-bit word at byte offset 0h. (The first bit is selected by RCR5[FBT], and you must configure it within this 16-bit word.) The second received word is stored in the 16-bit word at byte offset 2h. (The first bit is selected by RCR5[FBT][3:0].) The receiver ignores received data until the start of the next word after the 16-bit word has been received.

8-bit FIFO packing is similar to 16-bit packing, except four words are loaded or stored into each 32-bit FIFO word. The first word is stored in byte offset 0h, the second word in byte offset 1h, and so on. You must configure TCR5[FBT], RCR5[FBT], or both within byte offset 0h.

#### 71.3.4.4 FIFO Combining mode

This mode enables separate FIFOs for multiple data channels to be used as a single FIFO for software accesses, as a single data channel, or both. The enabled data channels must be contiguous and data channel 0 must be enabled when using FIFO Combining mode.

You can combine FIFOs for software access by writing to transmit FIFO registers and reading from receive FIFO registers. Doing so enables a DMA controller or software to read or write multiple FIFOs without incrementing the address that is accessed. After FIFO Combining mode is enabled (TCR4[FCOMB] > 00b), the first software access to a FIFO register accesses the first enabled channel FIFO. The second access to a FIFO register accesses the second enabled channel FIFO. This process continues until software accesses the last enabled channel FIFO and the pointer resets to the first enabled channel FIFO. To reset the pointer manually, you can reset the FIFOs or disable FIFO combining on software accesses.

Combining FIFOs for transmit data channels enables one data channel to use the FIFOs of all enabled channel FIFOs. In this case, the data output is identical on each enabled data channel. The transmit shift registers for all enabled data channels load at the start of each frame. The registers also load upon every *n*th unmasked word, where *n* is the number of enabled data channels. The first word transmitted loads from the first enabled channel FIFO; the second word transmitted loads from the second enabled channel FIFO. This loading continues until the end of the frame.

Combining FIFOs for receive data channels enables one data channel to use the FIFOs of all enabled channel FIFOs. In this case, the received data from channel 0 is stored in each enabled data channel. The receive shift registers for all enabled data channels are stored after every *n*th unmasked word, where *n* is the number of enabled data channels. The first word received is stored in the first enabled channel FIFO; the second word received is stored in the second enabled channel FIFO. This storage continues until the end of the frame.

**NOTE**

The first word in each frame is always stored in the first enabled data channel. NXP recommends that the number of unmasked words in each frame be evenly divisible by the number of enabled data channels.

Combining FIFOs for data channels loads or stores each channel FIFO at the same time. As a result, FIFO error conditions are only checked every *n*th word, where *n* is the number of enabled data channels. If any enabled data channel meets the warning flag or request flag conditions, SAI asserts the FIFO warning and request flags.

### 71.3.5 Word mask register

The SAI transmitter and receiver each have a word mask register (Transmit Mask (TMR) and Receive Mask (RMR)) that you can use to mask any word in the frame. The word mask register is double buffered. You can update it before the end of each frame to mask a particular word in the next frame.

TMR causes the transmit data pin to be 3-stated for the length of each selected word; the transmit FIFO is not read for masked words.

RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

## 71.3.6 Clocking

- Audio clock
- Bit clock
- Bus clock

### 71.3.6.1 Audio clock

The audio clock (MCLK) generates the bit clock when you configure the receiver or transmitter for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio clocks to generate the bit clock.

The audio clock generation and selection is chip-specific. See chip-specific clocking information about how the audio clocks are generated.

### 71.3.6.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that an audio clock can generate internally or an external source can supply. SAI can also have synchronous bit clock and frame sync operation between the receiver and transmitter, or between multiple SAI peripherals. The transmitter and receiver configuration affects the bit clock and frame sync in the following ways:

- If you configure both the transmitter and receiver for asynchronous operation, each uses its own bit clock and frame sync.
- If you configure the transmitter for asynchronous operation and the receiver for synchronous operation, both use the transmitter bit clock and frame sync.
- If you configure the receiver for asynchronous operation and the transmitter for synchronous operation, both use the receiver bit clock and frame sync.

Your choice of synchronous or asynchronous operation selects the bit clock and frame sync used.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled.
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames.

In asynchronous operation, a SAI transmitter or receiver can use a bit clock externally generated by a SAI module instance that is disabled in Stop mode. In this case, disable the transmitter or receiver before entering Stop mode. This issue does not apply when the transmitter or receiver is in synchronous operation because all synchronous SAI modules are enabled and disabled simultaneously.

### 71.3.6.3 Bus clock

The control and configuration registers use the bus clock to generate synchronous interrupts and DMA requests.

**NOTE**

Although no minimum bus clock frequency is specified, the frequency must be fast enough (relative to the bit clock frequency) to serve the FIFOs. You must meet this requirement without generating a transmitter FIFO underrun or receiver FIFO overflow condition.

## 71.3.7 Reset

SAI is asynchronously reset on system reset. SAI has a Software reset and a FIFO reset.

#### 71.3.7.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. The SAI receiver includes a software reset that resets all receiver internal logic, including bit clock generation, status flags, and FIFO pointers.

These software resets do not reset the configuration registers. The software resets remain asserted until you clear them via software.

#### 71.3.7.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the value of the FIFO read pointer. This FIFO reset empties the FIFO contents. Use this reset after TCSR[FEF] becomes 1, and before SAI reinitializes the FIFO and TCSR[FEF] becomes 0. SAI asserts the FIFO reset for one cycle only.

The SAI transmitter can also reset the FIFO of individual data channels by writing 1 to the appropriate bit in TCR3[CFR]. Use this reset only when the corresponding bit in TCR3[TCE] is 0.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the value of the FIFO write pointer. This FIFO reset empties the FIFO contents. Use this reset after RCSR[FEF] becomes 1 and SAI reads any remaining data from the FIFO, and before RCSR[FEF] becomes 0. SAI asserts the FIFO reset for one cycle only.

The SAI receiver can also reset the FIFO of individual data channels by writing 1 to the appropriate bit in RCR3[RCE]. Use this reset only when the corresponding bit in RCR3[RCE] is 0.

### 71.3.8 Interrupts and DMA requests

In SAI, the transmitter and receiver generate separate interrupts and DMA requests, but use the same status flags. SAI only generates asynchronous interrupts when the system clock is gated but the corresponding BCLK signal is active.

#### 71.3.8.1 FIFO request flag

SAI sets the transmit FIFO request flag (TCSR[FRF]) when the number of entries in any enabled transmit FIFO is less than or equal to the transmit FIFO watermark configuration (TCR1[TFW]). SAI clears this flag when the number of entries in each enabled transmit FIFO is greater than TCR1[TFW].

SAI sets the receive FIFO request flag (RCSR[FRF]) when the number of entries in any enabled receive FIFO is greater than the receive FIFO watermark configuration (RCR1[RFW]). SAI clears this flag when the number of entries in each enabled receive FIFO is less than or equal to RCR1[RFW].

The FIFO request flag can generate an interrupt when TCSR[FRIE] = 1. It can generate a DMA request when TCSR[FRDE] = 1.

#### 71.3.8.2 FIFO warning flag

SAI sets the transmit FIFO warning flag (TCSR[FWF]) when the number of entries in any of the enabled transmit FIFOs is empty. SAI clears this flag when the number of entries in each enabled transmit FIFO is not empty.

SAI sets the receive FIFO warning flag (RCSR[FWF]) when the number of entries in any of the enabled receive FIFOs is full. SAI clears this flag when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an interrupt when TCSR[FWIE] = 1. The flag can generate a DMA request when TCSR[FWDE] = 1.

#### 71.3.8.3 FIFO error flag

SAI sets the transmit FIFO error flag (TCSR[FEF]) when any enabled transmit FIFOs underrun. After the error flag is set, all enabled transmit channels transmit zero data before SAI clears TCSR[FEF].

When you write 1 to TCR4[FCONT], the FIFO continues transmitting data following an underrun without software intervention. To ensure that data transmits in the correct order, the transmitter continues from the same word number in the frame that caused the FIFO to underrun. It continues only after new data is written to the transmit FIFO. In this case, clear TCSR[FEF] without reinitializing the transmit FIFOs.

SAI sets the receive FIFO error flag (RCSR[FEF]) when any enabled receive FIFO overflows. After the flag is set, all enabled receive channels discard their received data until SAI clears RCSR[FEF] and the next receive frame starts. Empty all enabled receive FIFOs before SAI clears RCSR[FEF].

When you write 1 to RCR4[FCONT], the FIFO continues receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver continues from the same word number in the frame that caused the FIFO to overflow. It continues only after data has been read from the receive FIFO. In this case, clear RCSR[FEF] without emptying the receive FIFOs.

TCSR[FEF] and RSCR[FEF] can only generate an interrupt.

#### 71.3.8.4 Sync error flag

SAI sets a sync error flag (TCSR[SEF] or RCSR[SEF]) when both of these conditions are true:

- The frame sync is generated externally.
- The external frame sync asserts when the transmitter or receiver is busy with the previous frame.

SAI ignores the external frame sync assertion and sets the sync error flag. When this flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

TCSR[SEF] and RCSR[SEF] can only generate an interrupt.

#### 71.3.8.5 Word start flag

SAI sets the word start flag (TCSR[WSF]) at the start of the second bit-clock cycle for the selected word. You can select this word via TCR3[WDFL].

TCSR[WSF] can only generate an interrupt.

## 71.4 External signals

| Name | Function | I/O |
|---|---|---|
| TX_BCLK | Transmit bit clock: the bit clock is an input when externally generated and an output when internally generated. | I/O |
| TX_SYNC | Transmit frame sync: the frame sync is an input sampled synchronously by the bit clock when externally generated. It is an output generated synchronously by the bit clock when internally generated. | I/O |
| TX_DATA[3:0] | Transmit data: the bit clock synchronously generates the transmit data; this signal is 3-stated when not transmitting a word. | O |
| RX_BCLK | Receive bit clock: the bit clock is an input when externally generated and an output when internally generated. | I/O |
| RX_SYNC | Receive frame sync: the frame sync is an input sampled synchronously by the bit clock when externally generated. It is an output generated synchronously by the bit clock when internally generated. | I/O |

*Table continues on the next page...*

*Table continued from the previous page...*

| Name | Function | I/O |
|---|---|---|
| RX_DATA[3:0] | Receive data: the bit clock synchronously samples the receive data. | I |

## 71.5 Initialization

To initialize SAI:

1. Enable the clock to SAI.
2. Reset the internal transmitter logic and receiver logic by writing 1 to TCSR[SR] and RCSR[SR], respectively.

## 71.6 Memory map and register definition

A read or write access to an address from offset 100h and above results in a bus error.

### 71.6.1 SAI register descriptions

SAI provides an interface that supports full-duplex serial digital audio interfaces with frame synchronization formats.

#### 71.6.1.1 SAI memory map

SAI_0 base address: 4036_C000h

SAI_1 base address: 404D_C000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Version ID (VERID) | 32 | R | 0301_0000h |
| 4h | Parameter (PARAM) | 32 | R | See section |
| 8h | Transmit Control (TCSR) | 32 | RW | 0000_0000h |

## 71.6.1.6 Transmit Configuration 2 (TCR2)

### Offset

| Register | Offset |
|---|---|
| TCR2 | 10h |

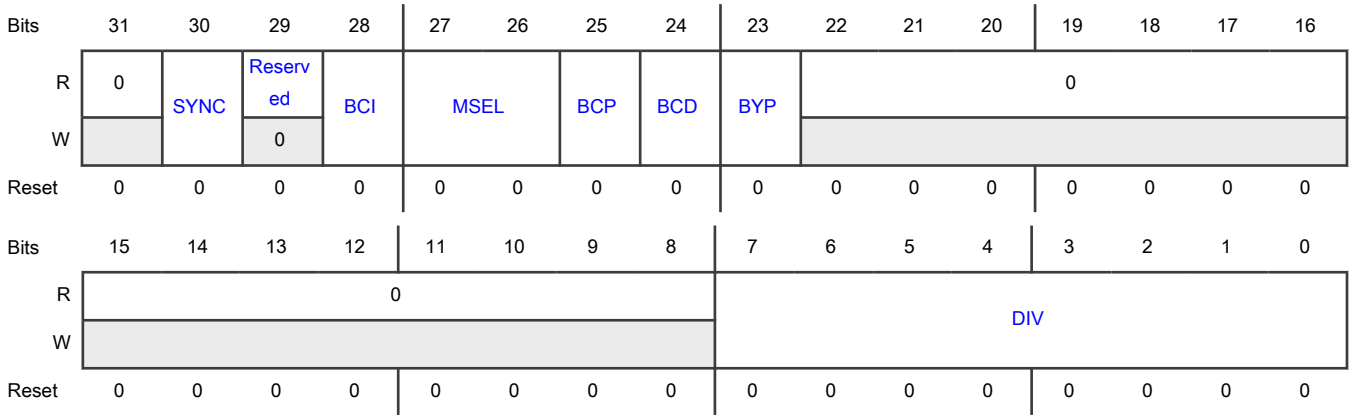
### Function

Contains the SYNC mode and clock setting fields.

**NOTE**

Do not alter this register when TCSR[TE] is 1.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>— | Reserved |
| 30<br>SYNC | Synchronous Mode<br>Configures Asynchronous and Synchronous modes of operation. When configured for Synchronous mode, you must configure the receiver for asynchronous operations.<br>0b - Asynchronous mode<br>1b - Synchronous with receiver |
| 29<br>— | Reserved |
| 28<br>BCI | Bit Clock Input<br>Enables the internal logic to be clocked as if the bit clock is generated externally.<br>When this field is 1 while using an internally generated bit clock in Synchronous or Asynchronous mode, the bit clock used by the transmitter is delayed by the pad output delay. (The pad input clocks the transmitter as if the clock is externally generated.) This setting decreases the data input setup time, but increases the data output valid time.<br>Use the Target mode timing from the data sheet for the transmitter when this field is 1. In Synchronous mode, this field allows the transmitter to use the Target mode timing from the data sheet, while the receiver uses the Controller mode timing. This field has no effect when configured for an externally generated bit clock.<br>**NOTE**<br>When BCI = 1, both the input buffer and output buffer must be enabled for the BCLK pad.<br>0b - Disable<br>1b - Enable |
| 27-26 | MCLK Select |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| MSEL | Selects the audio clock option used to generate an internally generated bit clock. This field has no effect when SAI is configured for an externally generated bit clock.<br>**NOTE**<br>Depending on the chip, some audio clock options might not be available. See the chip-specific information for the meaning of each option.<br>00b - Bus clock<br>01b - Audio clock (MCLK) option 1<br>10b - Audio clock (MCLK) option 2<br>11b - Audio clock (MCLK) option 3 |
| 25<br>BCP | Bit Clock Polarity<br>Configures the polarity of the bit clock. If you write 0 to this field, the bit clock becomes active high with drive outputs on rising edge and sample inputs on falling edge. If you write 1 to this field, the bit clock becomes active low with drive outputs on falling edge and sample inputs on rising edge.<br>0b - Active high<br>1b - Active low |
| 24<br>BCD | Bit Clock Direction<br>Configures the direction of the bit clock.<br>0b - Generate externally in Target mode<br>1b - Generate internally in Controller mode |
| 23<br>BYP | Bit Clock Bypass<br>Bypasses the bit clock divider. When bypassed, the internal bit clock is divide-by-one of the audio clock. When not bypassed, the internal bit clock is generated from the bit clock divider.<br>0b - Disable<br>1b - Enable |
| 22-8<br>— | Reserved |
| 7-0<br>DIV | Bit Clock Divide<br>Determines the value by which SAI divides down the audio clock to generate the bit clock (when configured for an internal bit clock). The division value is (DIV + 1) × 2. |

### 71.6.1.7 Transmit Configuration 3 (TCR3)

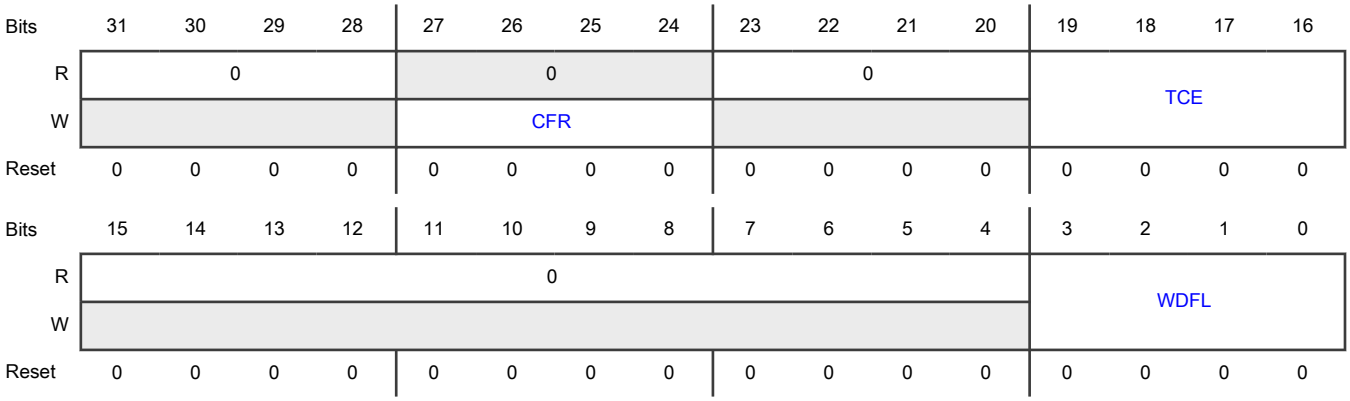
#### Offset

| Register | Offset |
|---|---|
| TCR3 | 14h |

#### Function

Contains the transmit channel settings.

#### Diagram



#### Fields

| Field | Function |
|---|---|
| 31-28<br>— | Reserved |
| 27-24<br>CFR | Channel FIFO Reset<br>Resets the FIFO pointers for a specific channel. Reading this field always returns zero. You must reset FIFO pointers only when a channel is disabled or the FIFO error flag is set.<br>The width of this field = the number of transmit channels (call it *n*). For example, if this field is 2 bits wide, bit position 24 refers to the transmit channel 1 FIFO pointer and bit position 25 refers to the transmit channel 2 FIFO pointer. Writing 1 to bit 24 resets the transmit channel 1 FIFO pointer, and writing 1 to bit 25 resets the transmit channel 2 FIFO pointer. Writing 1 to bit *n* resets the transmit channel *n* FIFO pointer.<br>**NOTE**<br>When there is only one channel, you do not need the individual channel FIFO reset (TCR3[CFR]). For a single channel, use the global FIFO reset (TCSR[FR]).<br>• 0b – No effect<br>• 1b – Reset transmit data channel *n* FIFO |

*Table continued from the previous page...*

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>
NOTE<br>This field is not supported in every instance. The following table includes only supported registers.
<table>
<tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>SAI_0</td><td>TCR3</td><td>—</td></tr>
<tr><td>SAI_1</td><td>—</td><td>TCR3</td></tr>
</table>
</td></tr>
<tr><td>23-20<br>—</td><td>Reserved</td></tr>
<tr><td>19-16<br>TCE</td><td>
Transmit Channel Enable<br>
Enables the corresponding data channel for transmit operations. Changing this field takes effect immediately for generating the FIFO request and warning flags. It takes effect at the end of each frame for transmit operations.<br>
The width of this field = the number of transmit channels (call it n). For example, if this field is two bits wide, bit position 16 refers to transmit channel 1 and bit position 17 refers to transmit channel 2. Writing 1 to bit 16 enables transmit channel 1, and setting bit 17 enables transmit channel 2. Writing 1 to bit n enables transmit channel n. For each transmit data channel:<br>
• 0b – Disable<br>
• 1b – Enable<br>
NOTE<br>This field is not supported in every instance. The following table includes only supported registers.
<table>
<tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>SAI_0</td><td>TCR3</td><td>—</td></tr>
<tr><td>SAI_1</td><td>TCR3[16]</td><td>TCR3[19–17]</td></tr>
</table>
</td></tr>
<tr><td>15-4<br>—</td><td>Reserved</td></tr>
<tr><td>3-0<br>WDFL</td><td>
Word Flag Configuration<br>
Selects the word that sets the word start flag (TCSR[WSF]). The value must be one less than the word number. For example, writing 0 selects the first word in the frame. When you configure this field with a value greater than TCR4[FRSZ], TCSR[WSF] is never set.
</td></tr>
</table>

### 71.6.1.8 Transmit Configuration 4 (TCR4)

#### Offset

| Register | Offset |
|---|---|
| TCR4 | 18h |

#### Function

Contains the transmit fields for FIFO Combine mode, FIFO Packing mode, and frame sync settings.

**NOTE**

Do not alter this register when TCSR[TE] is 1.

#### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | | | FCONT | FCOMB | | FPACK | | 0 | | | | FRSZ | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | | | SYWD | | | | | 0 | | CHMOD | MF | FSE | ONDEM | FSP | FSD |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### Fields

| Field | Function |
|---|---|
| 31-29<br>— | Reserved |
| 28<br>FCONT | FIFO Continue on Error<br>Configures when SAI must continue transmitting after a FIFO error is detected. When this field is 0 and a FIFO error occurs, SAI continues from the start of the next frame after the FIFO error flag clears. When this field is 1 and a FIFO error occurs, SAI continues from the same word that caused the FIFO error after the FIFO warning flag clears.<br>0b - Continue from the start of the next frame<br>1b - Continue from the same word that caused the FIFO error |
| 27-26<br>FCOMB | FIFO Combine Mode<br>Enables FIFO Combine mode for specified operations.<br>When FIFO Combine mode is enabled for FIFO writes, software writing to any FIFO data register alternates the write among the enabled data channel FIFOs. For example, if two data channels are enabled: |

*Table continued from the previous page...*

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>
<ul>
<li>The first write is performed to the first enabled data channel FIFO.</li>
<li>The second write is performed to the second enabled data channel FIFO.</li>
</ul>
Resetting the FIFO or disabling FIFO Combine mode for FIFO writes resets the pointer back to the first enabled data channel.<br><br>
When FIFO Combine mode is enabled for FIFO reads from the transmit shift registers, the transmit data channel output alternates between the enabled data channel FIFOs. For example, if two data channels are enabled:
<ul>
<li>The first unmasked word is transmitted from the first enabled data channel FIFO.</li>
<li>The second unmasked word is transmitted from the second enabled data channel FIFO.</li>
</ul>
Because the first word of the frame is always transmitted from the first enabled data channel FIFO, NXP recommends that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.<br><br>
NOTE<br>
This field is not supported in every instance. The following table includes only supported registers.<br><br>
<table>
<tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>SAI_0</td><td>TCR4</td><td>—</td></tr>
<tr><td>SAI_1</td><td>—</td><td>TCR4</td></tr>
</table>
00b - Disable<br>
01b - Enable on FIFO reads (from transmit shift registers)<br>
10b - Enable on FIFO writes (by software)<br>
11b - Enable on FIFO reads (from transmit shift registers) and writes (by software)
</td></tr>
<tr><td>25-24<br>FPACK</td><td>FIFO Packing Mode<br><br>
Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8 bits or 16 bits, only the first 8 bits or 16 bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer only increments when you write the full 32-bit FIFO word.<br>
00b - Disable FIFO packing<br>
01b - Reserved<br>
10b - Enable 8-bit FIFO packing<br>
11b - Enable 16-bit FIFO packing</td></tr>
<tr><td>23-20<br>—</td><td>Reserved</td></tr>
</table>

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| 19-16<br>FRSZ | Frame Size<br>Configures the number of words in each frame. The value must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 16 words. |
| 15-13<br>— | Reserved |
| 12-8<br>SYWD | Sync Width<br>Configures the length of the frame sync in number of bit-clock cycles. The value must be one less than the number of bit-clock cycles. For example, write 0 for the frame sync to assert for one bit-clock cycle only. You cannot configure the sync width to be longer than the first word of the frame. |
| 7-6<br>— | Reserved |
| 5<br>CHMOD | Channel Mode<br>Specifies the mode of transmit data pins. In TDM mode, transmit data pins are 3-stated when slots are masked or channels are disabled. ### 71.6.1.10 Transmit Data (TDR0 - TDR3)

#### Offset

| Register | Offset |
|---|---|
| TDR0 | 20h |
| TDR1 | 24h |
| TDR2 | 28h |
| TDR3 | 2Ch |

#### Function

Contains transmit data.

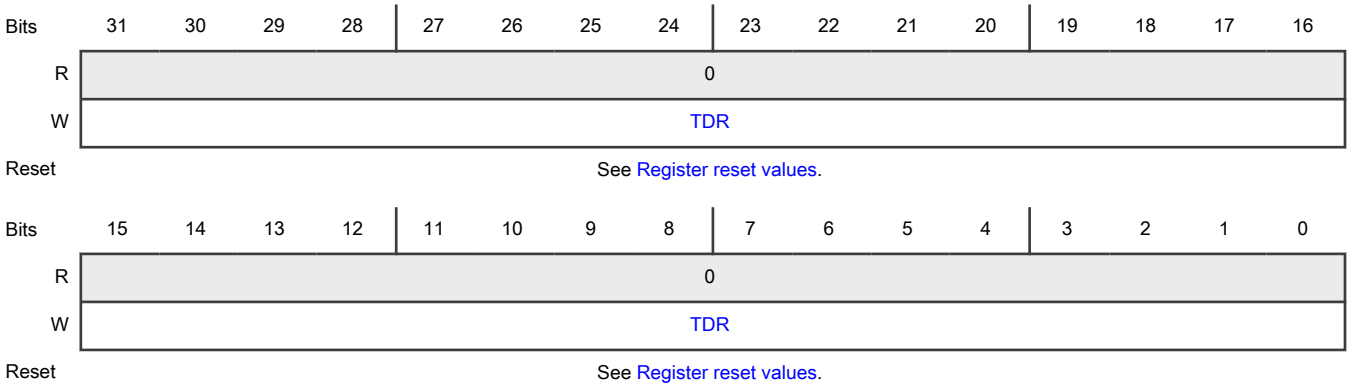
When the transmit FIFO is not full, writes to this register push the data written into the transmit data FIFO. When the transmit FIFO is full, SAI ignores writes to this register.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| SAI_0 | TDR0–TDR3 | — |
| SAI_1 | TDR0 | TDR1–TDR3 |

#### Diagram



#### Register reset values

| Register | Reset value |
|---|---|
| TDR0 | SAI_0,SAI_1: 0000_0000h |
| TDR1–TDR3 | 0000_0000h |

### Fields

| Field | Function |
|---|---|
| 31-0<br>TDR | Transmit Data |

## 71.6.1.11 Transmit FIFO (TFR0 - TFR3)

### Offset

| Register | Offset |
|---|---|
| TFR0 | 40h |
| TFR1 | 44h |
| TFR2 | 48h |
| TFR3 | 4Ch |

### Function

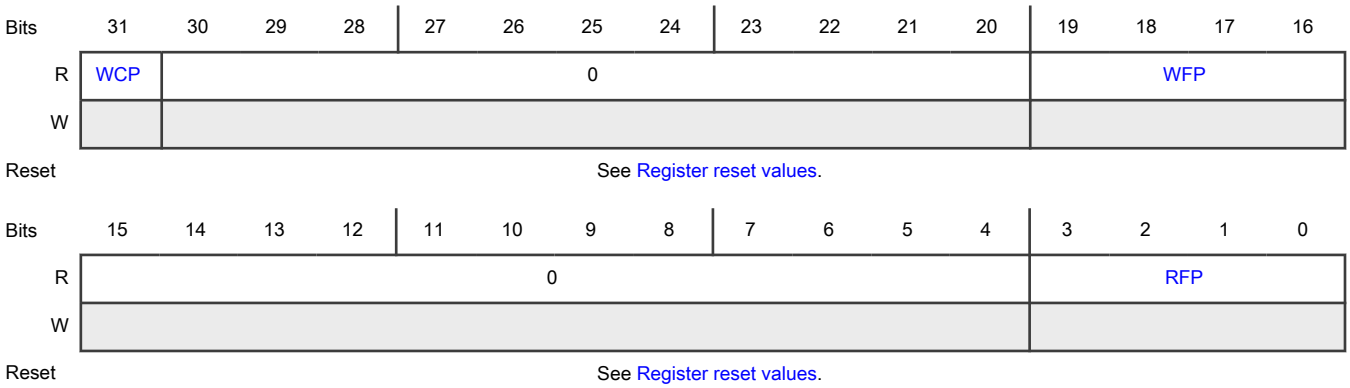
Contains the transmit FIFO pointers. The MSB of the read and write pointers distinguishes between FIFO full and empty conditions. If the read and write pointers are identical, the FIFO is empty. If the read and write pointers are identical except for the MSB, the FIFO is full.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| SAI_0 | TFR0–TFR3 | — |
| SAI_1 | TFR0 | TFR1–TFR3 |

### Diagram



**Register reset values**

| Register | Reset value |
|---|---|
| TFR0 | SAI_0,SAI_1: 0000_0000h |

### 71.6.1.12 Transmit Mask (TMR)

**Offset**

| Register | Offset |
|---|---|
| TMR | 60h |

### Function

Contains the mask for the transmit word. This register is double-buffered and updates:

- When TCSR[TE] first becomes 1.
- At the end of each frame.

This setup allows the masked words in each frame to change from frame to frame.

### Diagram

| 2-0<br>RFW | Receive FIFO Watermark<br>Configures the level of the receive FIFO watermark, in 32-bit FIFO words.<br>000b - 1<br>001b - 2<br>010b-110b - (RFW value + 1)<br>111b - 8 |

## 71.6.1.15 Receive Configuration 2 (RCR2)

### Offset

| Register | Offset |
|---|---|
| RCR2 | 90h |

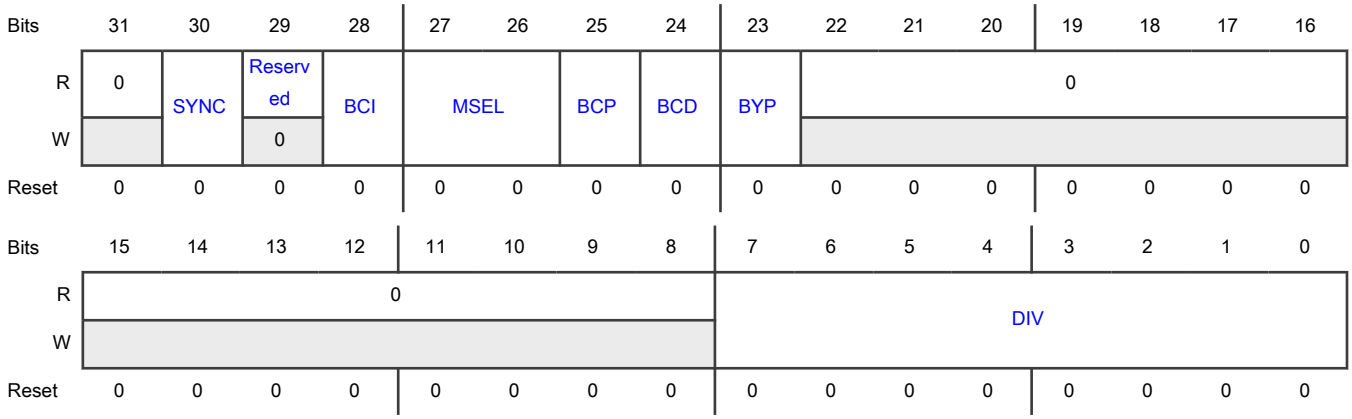
### Function

Contains the SYNC mode and clock setting fields.

**NOTE**

Do not alter this register when RCSR[RE] is 1.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>— | Reserved |
| 30<br>SYNC | Synchronous Mode<br>Configures Asynchronous and Synchronous modes of operation. When configured for a Synchronous mode of operation, you must configure the transmitter for asynchronous operation.<br>0b - Asynchronous mode<br>1b - Synchronous with transmitter |
| 29<br>— | Reserved |
| 28<br>BCI | Bit Clock Input<br>Enables the internal logic to be clocked as if the bit clock is generated externally.<br>When this field is 1 and when using an internally generated bit clock in Synchronous or Asynchronous mode, the bit clock used by the receiver is delayed by the pad output delay. (The pad input clocks the receiver as if the clock is externally generated.) This setting decreases the data input setup time, but increases the data output valid time.<br>Use the Target mode timing from the data sheet for the receiver when this field is 1. In Synchronous mode, this field allows the receiver to use the Target mode timing from the data sheet, while the transmitter uses the Controller mode timing. This field has no effect when configured for an externally generated bit clock.<br>**NOTE**<br>When this field is 1, both the input buffer and output buffer must be enabled for the BCLK pad.<br>0b - Disable<br>1b - Enable |
| 27-26 | MCLK Select |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| MSEL | Selects the audio clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock.<br>**NOTE**<br>Some audio clock options are not available for some chips. See the chip-specific information for the availability and chip-specific meaning of each option.<br>00b - Bus clock<br>01b - Audio clock (MCLK) option 1<br>10b - Audio clock (MCLK) option 2<br>11b - Audio clock (MCLK) option 3 |
| 25<br>BCP | Bit Clock Polarity<br>Configures the polarity of the bit clock. If you write 0 to this field, the bit clock becomes active high with drive outputs on the rising edge and sample inputs on the falling edge. If you write 1 to this field, the bit clock becomes active low with drive outputs on the falling edge and sample inputs on the rising edge.<br>0b - Active high<br>1b - Active low |
| 24<br>BCD | Bit Clock Direction<br>Configures the direction of the bit clock.<br>0b - Generated externally in Target mode<br>1b - Generated internally in Controller mode |
| 23<br>BYP | Bit Clock Bypass<br>Enables the bypass of the bit clock divider. When enabled, the internal bit clock is divide-by-one of the audio clock. When disabled, the internal bit clock is generated from the bit clock divider.<br>0b - Disable<br>1b - Enable |
| 22-8<br>— | Reserved |
| 7-0<br>DIV | Bit Clock Divide<br>Determines the value by which the audio clock is divided to generate the bit clock, when configured for an internal bit clock. The division value is (DIV + 1) × 2. |

### 71.6.1.16 Receive Configuration 3 (RCR3)

#### Offset

| Register | Offset |
|---|---|
| RCR3 | 94h |

#### Function

Contains the receive channel settings.

#### Diagram

### 71.6.1.19 Receive Data (RDR0 - RDR3)

#### Offset

| Register | Offset |
|---|---|
| RDR0 | A0h |
| RDR1 | A4h |
| RDR2 | A8h |
| RDR3 | ACh |

#### Function

Contains receive data.

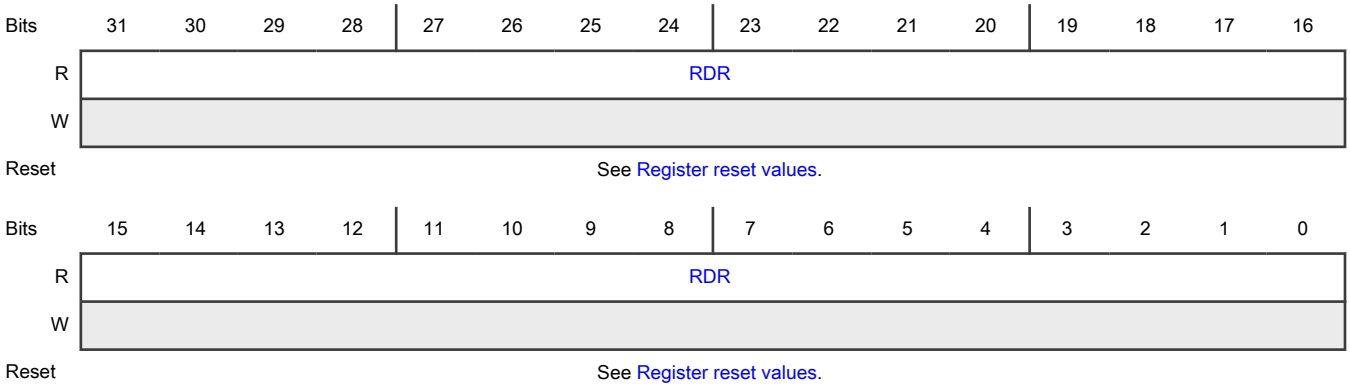
When the receive FIFO is not empty, reads from this register return the data from the top of the receive FIFO. When the receive FIFO is empty, SAI ignores reads from this register.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| SAI_0 | RDR0–RDR3 | — |
| SAI_1 | RDR0 | RDR1–RDR3 |

### Diagram



### Register reset values

| Register | Reset value |
|---|---|
| RDR0 | SAI_0,SAI_1: 0000_0000h |
| RDR1–RDR3 | 0000_0000h |

### Fields

| Field | Function |
|---|---|
| 31-0<br>RDR | Receive Data |

## 71.6.1.20 Receive FIFO (RFR0 - RFR3)

### Offset

| Register | Offset |
|---|---|
| RFR0 | C0h |
| RFR1 | C4h |
| RFR2 | C8h |
| RFR3 | CCh |

### Function

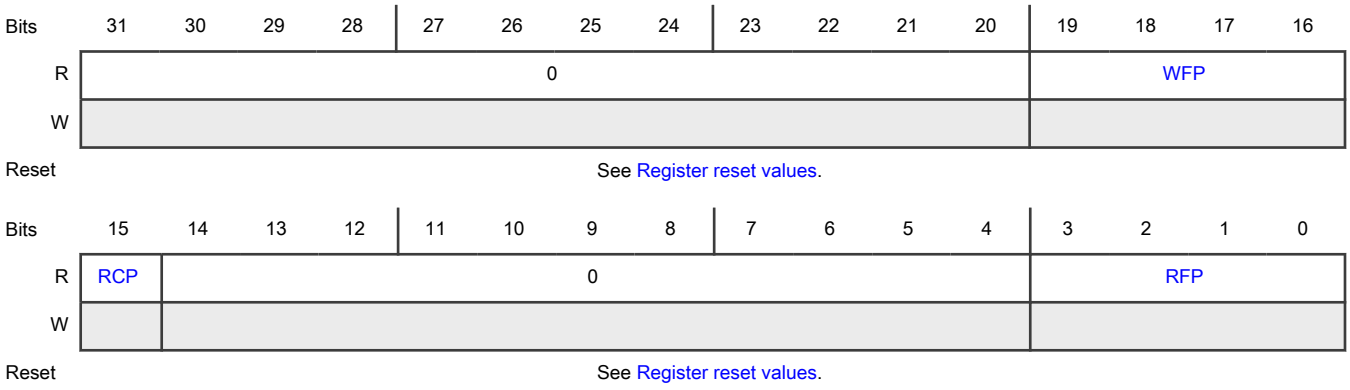
Contains the receive FIFO pointers. The MSB of the read and write pointers distinguishes between FIFO full and empty conditions. If the read and write pointers are identical, the FIFO is empty. If the read and write pointers are identical except for the MSB, the FIFO is full.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| SAI_0 | RFR0–RFR3 | — |
| SAI_1 | RFR0 | RFR1–RFR3 |

### Diagram



### Register reset values

| Register | Reset value |
|---|---|
| RFR0 | SAI_0,SAI_1: 0000_0000h |
| RFR1–RFR3 | 0000_0000h |

### Fields

| Field | Function |
|---|---|
| 31-20<br>— | Reserved |
| 19-16<br>WFP | Write FIFO Pointer<br>Indicates the FIFO write pointer for the receive data channel. |
| 15<br>RCP | Read Channel Pointer<br>Indicates whether this data channel is the next FIFO to be read when FIFO Combine mode is enabled for read operations.<br>**NOTE**<br>This field is not supported in every instance. The following table includes only supported registers. |

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | <table><tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr><tr><td>SAI_0</td><td>RFR0–RFR3</td><td>—</td></tr><tr><td>SAI_1</td><td>—</td><td>RFR0</td></tr></table><br>0b - No effect<br>1b - Next FIFO to be read |
| 14-4<br>— | Reserved |
| 3-0<br>RFP | Read FIFO Pointer<br>Indicates the FIFO read pointer for the receive data channel. |

### 71.6.1.21 Receive Mask (RMR)

#### Offset

| Register | Offset |
|---|---|
| RMR | E0h |

#### Function

Contains the mask for the receive word. This register is double-buffered and updates:

- When RCSR[RE] first becomes 1.
- At the end of each frame.

This setup allows the masked words in each frame to change from frame to frame.

#### Diagram

# Chapter 72
# Ethernet Media Access Controller (EMAC)

## 72.1 Chip-specific EMAC information

### 72.1.1 EMAC instance and configuration

This chip supports up to 1 instance of EMAC IP.

**Table 473. EMAC instance**

| Instance | MCXE31B | MCXE315/MCXE316/ MCXE317 |
|---|---|---|
| EMAC | Yes | No |

**NOTE**

DWC_EQOS refer to the Synopsys Ethernet MAC IP.

**NOTE**

The description for some EMAC registers include references to configurations of the Synopsis Ethernet MAC IP. Refer to MAC_HW_Feature registers for the specific features available in this chip.

**NOTE**

EMAC operates only in Clock options A and B, since the module clock becomes lower than the protocol clock (RMII/MII clocks) in other modes.

Following key features are supported:

- This chip supports only MII/RMII interfaces
- 4 bit MII interface operating at 2.5/25/50Mhz, MII can run at 10/100/200 Mbps.
- 2 bit RMII interface operating at 50Mhz, RMII can run at 10/100Mbps
- 4 bit MII-Lite interface operating at 2.5/25Mhz
- 4 PPS are supported using DMA trigger
- 200Mbps data rate is supported on Ethernet MII interface
- MTL Receive FIFO size 8192bytes
- MTL Transmit FIFO size 8192bytes

**NOTE**

The DMA referred within EMAC chapter refers to the internal EMAC DMA engine and not the device AXBS master DMA.

**NOTE**

Register access beyond 8k address space is not supported and will generate a transfer error.

**NOTE**

Always use store and forward mode if possible. In cut through mode, if multiple masters are active then there is chance (even in round robin arbitration mode) that EMAC DMA may starve for data resulting in insufficient data in TX FIFO leading to Tx underflow. To avoid this, increase MTL_TxQ0_Operation_Mode[TTC] value as needed.

The table below provides the information on the specific configuration utilized for the MCXE31B devices.

Table 474. Specific configuration information

| | | |
|---|---|---|
| **Application Interface** | | |
| | Application interface configuration | EQOS-AHB |
| | Data width | 32 |
| | Endian mode | Little Endian |
| | Address width | 32 |
| | CSR interfcae | APB3 interface |
| **General feature** | | |
| | Mode of operation | 10/100 |
| | Enable double VLAN processing | Yes |
| | Enable Que/channel based VLAN tag inertion on Tx | Yes |
| | Enable SA and VLAN insertion on Tx | Enabled by default |
| **Buffer managemnet** | | |
| | MTL Receive FIFO size in bytes | 8192 |
| | MTL Receive FIFO size in bytes | 8192 |
| | Enable debug memory access | Yes |
| | Use single port memory | Yes |
| **PHY interface** | | |
| | Enable RGMII, RMII only | Enable RMII, GMII/MII default |
| | Enabled signel phy interface | No |
| | Enable MDIO interface | Yes |
| **Filtering** | | |
| | Enable Additional 1-31 MAC address registers | 2 |
| | Enable Address Filter Hash Table | Yes |
| | Hash Table Size | 64 |
| | Enable VLAN Hash table based filtering | Yes |
| | Extended Rx VLAN Filter Enable | Yes |
| | Number of VLAN tag Filters | 4 |
| | Enable Layer3 and Layer4 Packet Filter | Yes |
| | Number of layer3 and Layer 4 packet filters | 4 |
| | Enable Flexible Programmable Receive Parser | Yes |

*Table continues on the next page...*

Table 474. Specific configuration information (continued)

| | | |
|---|---|---|
| | Maximum Packet Header Size for Parsing | 128 |
| | Maximum Entries of Parser Look up table | 64 |
| | Packet duplication support | Yes |
| **IEEE 1588 timestamp** | | |
| | Enable IEEE 1588 Time stamp support | Enabled by default |
| | IEEE 1588 System Time Support | Both option |
| | Add IEEE 1588 Higher word register | Yes |
| | Enable IEEE 1588 sub nanoseconds time stamp support | Yes |
| | Add IEEE 1588 Auxilary snapshot | No |
| | Enable Flexible Pulse Per Seconds Output | Yes |
| | Number of pulse per Second outputs | 4 |
| | Enable PTP Timestamp offload feature | No |
| | Enable One Step timestamp for PTP over UDP/IP feature | No |
| | Enable One Step timestamp feature | Yes |
| **Multiple queue support** | | |
| | Number of transmit Queue | 2 |
| | Number of recieve Queue | 2 |
| | Enable data center Bridging | No |
| | Enable Audo Vedio Bridging | Yes |
| | Enable support for AV in Tx queue 1 | No |
| | Number of DMA Channel on the receive side | 2 |
| **Time sensitive networking** | | |
| | Enable Enhancement to Schedule traffic(EST) | Yes |
| | Width of Time Interval Field in the Gate Control List | 24 |
| | Depth of Gate Control List | 256 |
| | Enable Frame Pre-emption support | Yes |
| **Time based scheduling** | | |
| | Enable time based Scheduling | Yes |
| **TCP/IP offloading features** | | |

*Table continues on the next page...*

Table 474. Specific configuration information (continued)

| | | |
|---|---|---|
| | Enable receive TCP/IP Checksum Check | Enabled by default |
| | Enable transmit TCP/IP Checksum offload | Enabled by default |
| | Enable support for Tx COE in Tx queue 0 | Yes |
| | Enable support for Tx COE in Tx queue 1 | No |
| | Enable TCP Segmentation offloading for TCP/IP | No |
| | Enable Split Header Feature | No |
| | Enable IPv4 ARP offload | No |
| **RMON counters** | | |
| | Enable MAC Management Counters(MMC) | Yes |
| | Enable the MAC Management Counters for Reciever TCP/IP Checksum offload | No |

### 72.1.2 Impact of MAC flush commands on MAC_PPSx_Target_Time_Seconds register

If the software discards the media clock generation request by configuring the PPSCTRL_PPSCMD (or PPSCMD#i) field of MAC_PPS_Control register to 0, the MAC does not flush the captured presentation time, i.e., the MAC_PPSx_Target_Time_Seconds register contents don't get changed.

## 72.2 Overview

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

EMAC:

- Supports the 10/100 Mbps application in compliance with IEEE802.3-2015 specifications
- Can support advanced applications such as time-sensitive networking and AVB
- Supports a MAC core that has prominent features such as a flexible receive parser, media clock recovery and generation, and safety

### 72.2.1 Features

EMAC supports these features in addition to the default feature defined in the IEEE802.3 specification:

- MII (10/100 Mbps), RMII (10/100 Mbps)
- Time-aware shaper (IEEE802.1bv), time synchronization (IEEE802.1AS-rev), and frame preemption (IEEE802.1Qbu) for time-sensitive networking
- Media clock recovery and generation for AVB
- AMBA 2.0 for AHB master and APB3 interface
- RMII specification version 1.2 from RMII consortium
- Separate interface for transmit, receive, and control paths
- Two-buffer ring
- Broadcast and multicast packet duplication
- Full-duplex flow control operations (IEEE 802.3x pause packet and priority flow control)

- Network statistics with MAC management (RMON) counters
- Flexibility to control the pulse per second (PPS) output signal
- MDIO clause 22 and clause 45 interface for configuration and management of the PHY device
- Preamble and SFD insertion and deletion

**NOTE**

Only byte-aligned preamble is supported.

- Automatic CRC and pad generation/stripping option
- Option to disable CRC checking
- Programmable insert packet gap
- Source address insertion or replacement
- VLAN insertion, replacement, and deletion in transmitted packets with per-packet or static-global control, insertion, replacement, and deletion of up to two VLAN tags, insertion, replacement, and deletion of queue or channel-based VLAN tags
- IEEE802.1Q VLAN tag detection and an option to delete the tags in the receive packets
- Programmable safety watchdog timeout limits
- Flexible address filtering modes that allow:
  - Up to two additional 48-bit perfect DA filters with masks for each byte
  - Up to two 48-bit SA comparison checks with masks for each byte
  - 64-bit hash filter for multicast and unicast DA addresses
  - Option to pass all multi-cast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Passing of all incoming packets (according to filter) with a status report
- Additional packet filtering that is based on:
  - Virtual local area network (VLAN) tag—perfect match and hash-based filtering, which is based on either outer or inner VLAN tag, is possible
  - Layer 3 and layer 4—TCP or UDP over IPv4 or IPv6
  - Extended VLAN tag—filtering based on four filter selections

**NOTE**

The DCB feature discussed in the following section(s) is not supported.

### 72.2.2 Block diagram

This figure shows the EMAC block diagram. EMAC has four main blocks to perform all the functions.

- The AHB interface is connected to all DMA channels.
- The DMA arbiter helps in the arbitration of all paths (transmit and receive) in DMA channels.
- Each channel has a separate set of control and status registers (CSRs) for managing the transmit and receive functions, descriptor handling, and interrupt handling.

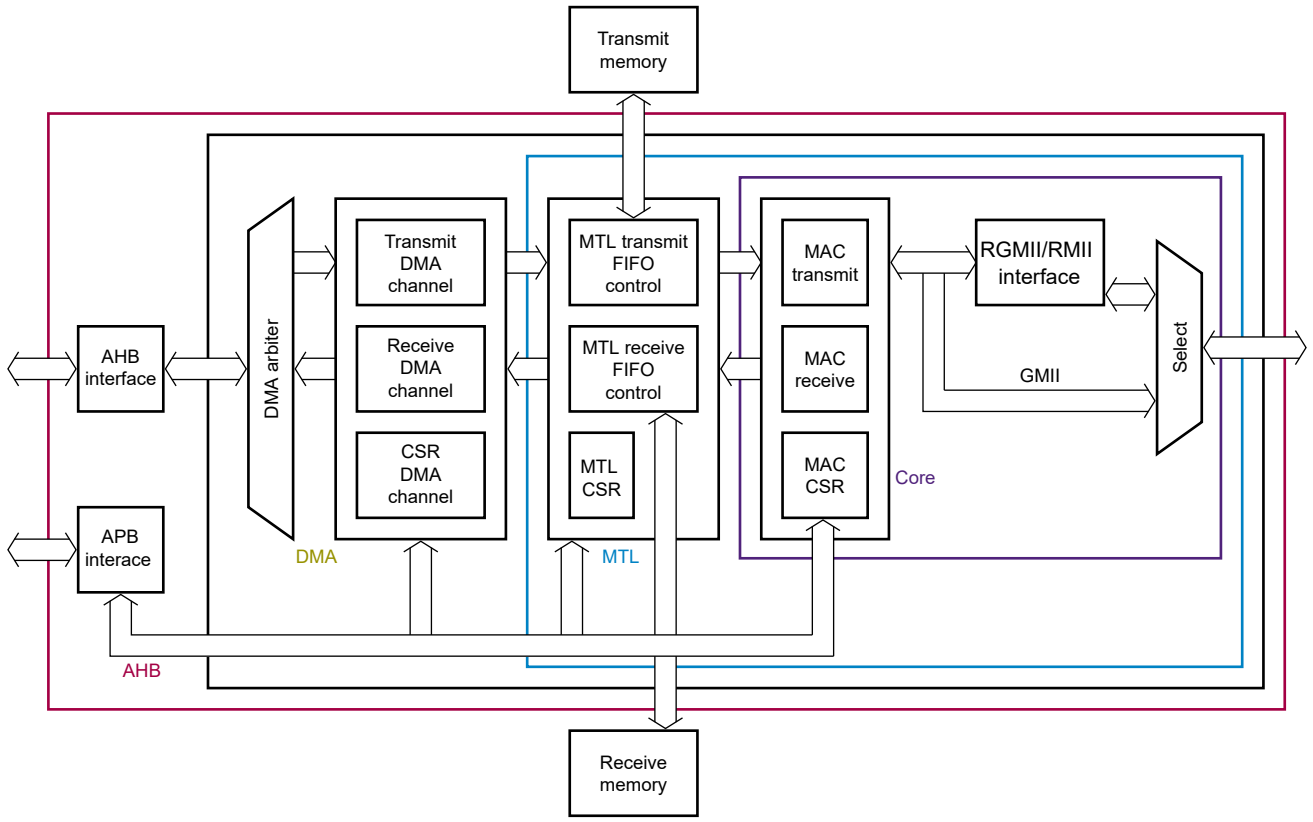

Figure 388. System-level block diagram

## 72.3 Architecture

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

The section describes EMAC interfaces, protocols, and functionality. These are its main blocks:

- AHB master and APB3 slave interface
- DMA controller
- MTL
- MAC
- Interrupts

### 72.3.1 AHB master and CSR slave (APB3) interface

The 32-bit APB3 slave interface:

- Provides access to DMA, MTL, and MAC control and status registers (CSRs)
- Supports the 32-bit write and read transfers to these CSRs
- Supports single- and all-burst transfers, and an OKAY response

The DMA block uses the AHB master interface to interact with the external world. The AHB master interface:

- Controls data transfer
- Is AMBA 2.0-compliant with no restrictions
- Supports 32-bit data transfer

- Supports single and INCR transfers
- Supports burst-length modes such as Fixed, Unspecified, and Mixed

### 72.3.2 DMA inclusions

DMA controller:

- Includes independent transmit (Tx) and receive (Rx) engines, and a CSR space. The transmit engine transfers data from the system memory to the MTL interface, whereas the receive engine transfers data from the MTL interface to the system memory.
- Is designed for packet-oriented data transfers such as packets in Ethernet.
- Communicates with the host through CSR, descriptor lists, and data buffers.

**DMA descriptors**

DMA supports up to two transmit and two receive descriptor lists (or DMA channels). The base address of each list is written to the respective transmit and receive descriptor list address registers. A descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one, and DMA_CH0_Control[DSL] controls the offset. The number of descriptors in the list is programmed using the respective DMA Channel 0 Tx Descriptor Ring Length (DMA_CH0_TxDesc_Ring_Length) and DMA Channel 0 Rx Descriptor Ring Length (DMA_CH0_RxDesc_Ring_Length) registers. After the DMA processes the last descriptor in the list, it automatically jumps to the descriptor in the list address register to create a descriptor ring.

EMAC supports the ring structure for DMA descriptors. For more information, see Descriptors .

The DMA engine uses descriptors to efficiently move data from source to destination with minimal host intervention, and the DMA controller can be programmed to interrupt the host in certain situations. These situations may include packet transmit and receive transfer completion and other normal or error conditions.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers in the system memory, enabling two buffers to be used and physically addressed rather than contiguous buffers in the memory.

**Data buffers**

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. The buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of the next packet when an EOP is detected.

The next few sections discuss DMA controller.

#### 72.3.2.1 DMA controller bus burst access

DMA engines attempt to transfer data in a burst of the maximum size programmed using DMA_CH0_Tx_Control[TxPBL] and DMA_CH0_Rx_Control[RxPBL] of the respective DMAs, which always access the receive and transmit descriptors in the maximum possible (limited by PBL or 16 * 8/bus width) burst length for 16 bytes to be read. The burst transfers that the DMA initiates can be split into multiple burst transfers according to the AHB requirements and settings specified in DMA System Bus Mode (DMA_SysBus_Mode).

The transmit DMA initiates a data transfer only when sufficient space is available in the MTL transmit queue to accommodate either of these:

- Bytes corresponding to the configured burst (PBL * bus_width/8)
- Remaining bytes in the transmit buffer without EOP
- Number of bytes till EOP

The receive DMA initiates a data transfer in these conditions:

- Sufficient data is available in the MTL receive queue to accommodate the configured burst
- EOP (when it is less than the configured burst length) is detected in the receive queue

DMA indicates the start address and the number of transfers required to the AHB master interface. When the interface is configured for fixed-length burst, it transfers data by using the best combination of the INCR4, INCR8, or INCR16 and SINGLE transactions. If EOP is reached before the fixed burst ends on the AHB interface, DMA performs dummy transfers to complete the fixed burst. Otherwise, DMA_SysBus_Mode[FB] becomes 0. The DMA transfers the data using undefined length (INCR) and SINGLE transactions.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first-burst transfer that AHB initiates is less than or equal to the size of the configured PBL value, and the subsequent beats start at an address aligned to this value. The DMA can only align the address for beats up to size 16 (for PBL > 16) for the AHB interface because it does not support more than INCR16.

#### 72.3.2.2 DMA application data buffer alignment

The transmit and receive data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers with an address aligned to the bus width and dummy data (old data) in the invalid byte lanes. The process of write transfer typically happens during the beginning or end of an Ethernet packet transfer. The software driver must discard the dummy bytes based on the start address of the buffer and size of the packet.

**Table 475. Data buffer alignment examples**

| Examples | |
|---|---|
| Buffer read | If the transmit buffer address is FF2h (for a 32-bit data bus) and 15 bytes need to be transferred, the DMA reads five full words from address FF0h. However, when DMA transfers data to the MTL transmit queue, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the MTL transmit queue, unless it is the end of the packet. |
| Buffer write | If the receive buffer address is FF2h (for a 64-bit data bus) and 16 bytes of a received packet need to be transferred, the DMA writes 3 full words from address FF0h. However, the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data. The DMA considers the offset address only if it is the first receive buffer of the packet. It ignores the offset address and performs full-word writes for the middle and last receive buffers of the packet. |

#### 72.3.2.3 DMA buffer size calculations

DMA does not update the size fields in the transmit and receive descriptors. It updates only the status fields (RDES and TDES) of the descriptors. The driver performs the size calculations.

The transmit DMA transfers the exact number of bytes (as the buffer size field of TDES2 indicates) to MAC. If a descriptor is marked as first (TDES3[FD] = 1), the DMA marks the first transfer from the buffer as SOP, and if the descriptor is marked as last (TDES3[LD]), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The receive DMA transfers data to a buffer until the buffer is full or MTL sends the end of packet. When TDES3[FD] = 1, the amount of valid data in a buffer is accurately indicated by the buffer size fields in DMA Channel Rx Control (DMA_CH0_Rx_Control) minus the data buffer pointer offset. The offset is 0 when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by DMA_CH0_Rx_Control[RBSZ_13_y] and DMA_CH0_Rx_Control[RBSZ_x_0]). To compute the amount of valid data in this final buffer, the driver must read the packet length (PL fields of RDES3[14:0]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The receive DMA always transfers the start of the next packet with a new descriptor.

#### 72.3.2.4 DMA arbiter

The arbiter inside the DMA module performs the arbitration between the transmit and receive channel accesses to the AHB master interface. These two types of arbitrations are supported:

- Round-robin: If DMA_Mode[DA] = 0 and both transmit and receive DMAs simultaneously request access, the arbiter allocates the data bus in ratio sets defined in DMA_Mode[PR].
- Fixed-priority: If DMA_Mode[DA] = 1, receive DMA is always prioritized over transmit DMA for data access by default. If DMA_Mode[TXPR] = 1, transmit DMA is prioritized over receive DMA as explained in Table 492.

### 72.3.3 MTL

MTL provides the FIFO memory interface to buffer and regulate the packets between system memory and MAC. It also enables data to be transferred between the system clock and MAC clock domains. The MTL layer has two data paths: transmit path and receive path. MTL communicates with the host through ATI on the transmit path and through ARI on the receive path.

#### 72.3.3.1 Transmit path

The internal DMA:

- Handles all transactions for the transmit path through ATI.
- Pushes the Ethernet packet reads from system memory to the corresponding queue.

The Ethernet packet, then, pops out and is transferred to MAC when the queue reaches its threshold (Threshold mode) or if the complete packet is in the queue (Store-and-Forward mode). When EOP is transferred, the status of the transmission is taken from MAC and transferred back to the internal DMA.

##### 72.3.3.1.1 Transmit control word

This control information related to packet transmission is provided as part of the control word through the ATI interface:

- Packet length (if DCB is enabled with WFQ scheduling algorithm)
- CRC pad control
- Source address insertion control
- VLAN insertion and replacement control and VLAN tag for outer and inner VLAN tags
- TCP/IP checksum insertion control
- One-step timestamping control correction
- Transmit timestamp enable

##### 72.3.3.1.2 Transmit operation

These two modes of operation trigger data read towards MAC:

- Threshold (or cut-through) mode: This is the default mode. In this mode, as soon as the number of bytes in the queue crosses the configured threshold level (or when the end of packet is written before the threshold is crossed), the data is ready to be popped out and forwarded to MAC. The threshold level is configured by using MTL_TxQ0_Operation_Mode[TTC].
- Store-and-Forward mode: In this mode, MTL pops the packet out to MAC only when one or more of the following conditions are true:
  - A complete packet is stored in the queue.
  - The transmit FIFO becomes almost full.
  - The ATI watermark becomes low.

  The watermark becomes low when the requested queue is not spacious enough to accommodate the requested burst length on ATI. Therefore, MTL, when operating in Store-and-Forward mode, allows packet transmission even if the packet length is bigger than the transmit queue size.

You can flush the complete content of the transmit queue by writing 1 to MTL_TxQ0_Operation_Mode[FTQ] or MTL_TxQ1_Operation_Mode[FTQ], depending on the queue. Doing so initializes the queue pointers to the default state. The FTQ

field returns to 0 by itself. If you write 1 to the FTQ field during a packet transfer from MTL to MAC, MTL stops further transfers because MTL considers the queue to be empty. Therefore, an underflow event occurs at the MAC transmitter.

#### 72.3.3.1.3 Initialization flow

After reset, MTL is ready to manage the data flow between DMA and MAC.

- With single-transmit queue configurations, there are no initialization requirements for enabling MTL.
- With multiple-transmit queue configurations, initialize the queue size for each of the queues by programming MTL_TxQ0_Operation_Mode[TQS] corresponding to a transmit queue. Also, initialize the MAC block. Internal DMA controllers must be individually enabled through their respective CSRs.

### 72.3.3.2 Receive path

MAC sends packets to the MTL receive module and pushes them into the receive queue. MTL indicates the status (fill level) of the queue to the application or DMA when it crosses the configured receive threshold (MTL_RxQ0_Operation_Mode[RTC]), or when the MTL receive module receives the complete packet in Store-and-Forward mode. MTL also indicates the fill level of the queue so that DMA can initiate preconfigured burst transfers to the AHB interface.

#### 72.3.3.2.1 Receive operation

During a receive operation, MTL is MAC's slave. This is the general sequence of events:

1. When MAC receives a packet, it indicates the availability of receive data.
2. MAC indicates the SOP and EOP delimiters.
3. MTL accepts the data and pushes it into the corresponding receive queue.
4. When MAC transfers EOP to the MTL receive module, MAC also drives the status word that MTL pushes into the corresponding receive queue.
5. MTL takes the data out of the queue and sends it to DMA depending on these modes:
   - Threshold mode
   - Store-and-Forward mode

   The sections that follow discuss these modes.

##### 72.3.3.2.1.1 Threshold mode

In Threshold (default) mode, MTL reads the data and indicates its availability to the application or DMA when one of these occurs:

- Data bytes equal to the threshold amount are written to the receive queue (to MTL_RxQ0_Operation_Mode[RTC] and MTL_RxQ1_Operation_Mode[RTC]).
- A full packet of data is received into the queue.

##### 72.3.3.2.1.2 Store-and-Forward mode

In this mode (when MTL_RxQ0_Operation_Mode[RSF] = 1), the initial receive queue locations are reserved for the status words before writing the SOP. A packet is read out only after it is completely written into the receive queue. In this mode, all error packets are dropped (if configured through MTL_RxQ0_Operation_Mode[FEP]) in such a way that only valid packets are read and forwarded to the application.

#### 72.3.3.2.2 Multi-packet receive operation

In Threshold mode, the packet status is available immediately after the packet data. In Store-and-Forward mode, the packet data is available after the packet status. MTL is capable of storing any number of packets in the queue as long as it is not full.

If MAC receives a packet when the corresponding receive queue is full, MTL ignores that packet and overflow pulse generates on the corresponding receive queue. In addition, MTL increments the overflow counter in MTL Rx Queue Missed Packet Overflow Count (MTL_RxQ0_Missed_Packet_Overflow_Cnt) for the corresponding queue.

#### 72.3.3.2.3 Error handling in receive operation

MTL performs these actions if the MTL receive queue is full before it receives the EOP data from MAC:

1. Declares an overflow
2. Drops the whole packet (including the status word)
3. Increments the overflow counter in DMA (MTL Rx Queue Missed Packet Overflow Count (MTL_RxQ0_Missed_Packet_Overflow_Cnt))

This is true even if MTL_RxQ0_Operation_Mode[FEP] is 1.

If the start address of such a packet is already transferred to the read controller, the rest of the packet is dropped and a dummy EOP is written to the queue along with the status word with overflow status. The status indicates a partial packet because of overflow. In such packets, the Packet Length field is invalid. If the MTL receive queue is configured to operate in the Store-and-Forward mode and the length of the received packet is more than the queue size, overflow occurs and all such packets are dropped.

The MTL receive control logic can filter errors and undersized packets, if enabled by using MTL_RxQ0_Operation_Mode[FEP] and MTL_RxQ0_Operation_Mode[FUP]. If the start address of one such packet is already transferred to the receive queue read controller, the packet is not filtered. The start address of the packet is transferred to the read controller after the packet crosses the receive threshold defined using MTL_RxQ0_Operation_Mode[RTC].

If the MTL receive queue is configured to operate in Store-and-Forward mode, all error packets can be filtered and dropped. For the application or DMA to flush the error packet being read from the queue, it must assert the flush signal. MTL then stops transferring data to the application (DMA). It internally reads the rest of the packet and drops it. MTL then starts transferring the next packet, if it's available.

### 72.3.4 MAC

MAC can support the MII and RMII PHY interface and it consists of:

- MTI
- MRI
- MCI

#### 72.3.4.1 MAC transmission

The MAC transmission process is as follows:

1. The transmission initiates when MTL pushes in data with the SOP signal asserted.
2. After the SOP signal is detected, MAC accepts the data and begins transmitting to RMII or MII.
3. After the EOP signal is transferred to MAC, it performs one of these steps:
   - Completes normal packet transmission and sends the transmission status to MTL
   - Sends retry requests if a normal collision (in Half-Duplex mode) occurs during transmission, and until one of the following is true:
     - Packet is successfully transmitted.
     - Maximum retry requests have expired. When this happens, MAC aborts the packet transmission with "excessive collision transmit" status. MAC accepts and drops all further data until it receives the next SOP. The MTL block must retransmit the same packet from SOP on observing a retry request (in the status) from MAC.
   - If any one of the following happens, MAC aborts the packet transmission:

- No carrier (Half-Duplex mode)
- Loss of carrier (Half-Duplex mode)
- Excessive deferral (Half-Duplex mode)
- Late collisions (Half-Duplex mode)
- Jabber
- MAC accepts and drops all further data until it receives the next SOP

4. MAC issues an underflow status if MTL is not able to provide data continuously during transmission. Until the next SOP is received, MAC accepts and drops all further data.
5. During the normal transfer of a packet from MTL, if MAC receives an SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as a continuation of the previous packet.

#### 72.3.4.2 MAC reception

The receive operation initiates as follows:

1. MAC detects a state-of-frame data on RMII or MII.
2. MAC strips the preamble and SFD before processing an Ethernet packet.
3. The MAC AFM:
   - Checks the header fields (SA and DA) of an incoming packet for filtering
   - Verifies the CRC contained in the packet's FCS field
4. MAC's AFM checks the header fields (SA and DA) of an incoming packet for filtering.
5. FCS verifies the CRC of the received packet.
6. MAC stores the received packet in a shallow buffer until address filtering is performed.
7. AFM drops the packet if it fails the address filter.

### 72.3.5 Interrupts

EMAC supports interrupt coalescing, which reduces the number of interrupts generated by the module and reduces the CPU load. MAC Interrupt Status (MAC_Interrupt_Status) captures various interrupt events. If the interrupt enable field of an interrupt is 1, the corresponding interrupt generates based on the event status in the Status registers. The Interrupt mode (INTM) field decides whether the interrupt signal is a level signal or pulse signal. See the following table and interrupt map file attached to this document for details.

**Table 476. Interrupt request**

| Interrupt request | Interrupt Enable / Mask Register | Interrupt Flag Register |
|---|---|---|
| Common interrupt | MAC Interrupt Enable (MAC_Interrupt_Enable) | MAC Interrupt Status (MAC_Interrupt_Status) |
| | MMC Receive Interrupt Mask (MMC_Rx_Interrupt_Mask) | MMC Receive Interrupt (MMC_Rx_Interrupt) |
| | MMC Transmit Interrupt Mask (MMC_Tx_Interrupt_Mask) | MMC Transmit Interrupt (MMC_Tx_Interrupt) |
| | MMC FPE Transmit Interrupt Mask (MMC_FPE_Tx_Interrupt_Mask) | MMC Transmit FPE Fragment Counter Interrupt Status (MMC_FPE_Tx_Interrupt) |

*Table continues on the next page...*

Table 476. Interrupt request (continued)

| Interrupt request | Interrupt Enable / Mask Register | Interrupt Flag Register |
|---|---|---|
| | MMC FPE Receive Interrupt Mask (MMC_FPE_Rx_Interrupt_Mask) | MMC Receive Packet Assembly Error Counter Interrupt Status (MMC_FPE_Rx_Interrupt) |
| | MTL Debug Control (MTL_DBG_CTL) | MTL Debug Status (MTL_DBG_STS) |
| | MTL EST Interrupt Enable (MTL_EST_Intr_Enable) | MTL EST Status (MTL_EST_Status) |

| Tx interrupt 0/1 | DMA Channel Tx Control (DMA_CH0_Tx_Control) | DMA Channel 0 Status (DMA_CH0_Status) |
| | DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable) | |
| | DMA Channel 1 Tx Control (DMA_CH1_Tx_Control) | DMA Channel 1 Status (DMA_CH1_Status) |
| | DMA Channel 1 Interrupt Enable (DMA_CH1_Interrupt_Enable) | |
| Rx interrupt 0/1 | DMA Channel Rx Control (DMA_CH0_Rx_Control) | DMA Channel 0 Status (DMA_CH0_Status) |
| | DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable) | |
| | DMA Channel 1 Rx Control (DMA_CH1_Rx_Control) | DMA Channel 1 Status (DMA_CH1_Status) |
| | DMA Channel 1 Interrupt Enable (DMA_CH1_Interrupt_Enable) | |

*Table continues on the next page...*

Table 476. Interrupt request (continued)

| Interrupt request | Interrupt Enable / Mask Register | Interrupt Flag Register |
|---|---|---|
| Safety interrupt | MTL ECC Interrupt Enable (MTL_ECC_Interrupt_Enable) | MTL ECC Interrupt Status (MTL_ECC_Interrupt_Status) |
| | | MTL Safety Interrupt Status (MTL_Safety_Interrupt_Status) |
| | MTL DPP Control (MTL_DPP_Control) | MAC DPP FSM Interrupt Status (MAC_DPP_FSM_Interrupt_Status) |
| | MAC FSM Control (MAC_FSM_Control) | |

These are the interrupt output signals that are synchronous to the CSR clock.

- Sbd_intr_o – common interrupt
- Sbd_perch_tx_intr_o[max_dma_ch] – interrupt per transmit channel
- Sbd_perch_rx_intr_o [max_dma_ch] – interrupt per receive channel

**NOTE**

max_dma_ch = number of transmit/receive queues, which is 2

The sbd_intr_o common interrupt is a level signal. When it is asserted, a corresponding interrupt event source can be found in DMA Interrupt Status (DMA_Interrupt_Status), which is a read-only register that contains the event source fields corresponding to each DMA channel (transmit and receive queue pair), MAC transaction layer, and MAC blocks. You must then read the following registers and look for the fields that are 1:

- MAC Interrupt Status (MAC_Interrupt_Status)
- MTL Interrupt Status (MTL_Interrupt_Status)
- DMA Channel 0 Status (DMA_CH0_Status)

The sbd_intr_o interrupt deasserts only when all the enabled interrupt events are clear in their respective status registers, and correspondingly, all the fields in DMA Interrupt Status (DMA_Interrupt_Status) are 0. DMA Channel 0 Status (DMA_CH0_Status) captures all the interrupt events of that transmit DMA and receive DMA channel pair.

DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable) contains the corresponding enable fields for each of the interrupt events. These are the two groups of interrupts in the DMA channel:

- Normal—DMA_CH0_Status[NIS] indicates this interrupt, which is used for events that occur during the normal transfer of packets (TI, RI, TBU).
- Abnormal—DMA_CH0_Status[AIS] indicates this interrupt, which is used for error events.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts generate.

The common sbd_intr_o output signal asserts for the transfer complete interrupts only when the corresponding interrupts are enabled in DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable).

EMAC also supports these per-channel transfer-complete interrupt signals:

- sbd_perch_tx_intr_o[max_dma_ch] (transmit per channel interrupts)
- sbd_perch_rx_intr_o[max_dma_ch] (receive per channel interrupts)

The behavior of the RI/TI/sbd_perch_tx_intr_o[]/sbd_perch_rx_intr_o[] changes depends on the configuration specified in DMA_Mode[INTM]. This table explains the transfer complete interrupt behavior.

Table 477. Transfer complete interrupt behavior

| Interrupt mode | Behavior of sbd_perch_tx_intr_o[] and sbd_perch_rx_intr_o[] | Behavior of the TI/RI interrupts and sbd_intr_o |
|---|---|---|
| INTM = 1 | In this mode, these signals indicate the values of the corresponding DMA_CH0_Status[RI] and DMA_CH0_Status[TI] fields when DMA_CH0_Status[RI] and DMA_CH0_Status[TI] are 1, respectively. Therefore, they are level signals that you clear by writing 1 to these fields. The signals do not assert when DMA_CH0_Status[RI] or DMA_CH0_Status[TI] is 0. | DMA_CH0_Status[RI] and DMA_CH0_Status[TI] are configured as explained.<br>For any RI/TI events:<br>• The sbd_intr_o signal does not assert.<br>• DMA_CH0_Status[NIS] remains 0. |
| INTM = 2 | In this mode, RI/TI are queued and indicate the values of the corresponding DMA_CH0_Status[RI] and DMA_CH0_Status[TI] fields when any of these fields is 1. RI and TI are level signals that you clear by writing 1 to these fields. However, the fields become 1 again if another TI/RI event is detected before DMA_CH0_Status[RI] and DMA_CH0_Status[TI] become 1 for the previous event. | DMA_CH0_Status[RI] and DMA_CH0_Status[TI] become 1 whenever the transfer complete event is detected and are reset whenever the software driver changes them to 0 by writing 1. However, if another transfer complete event is detected before the software changes it to 0 (services it), EMAC automatically writes 1 to these fields again. The generation of the sbd_intr_o signal; however, is not based on DMA_CH0_Status[RI] or DMA_CH0_Status[TI]. |

## 72.4 External signals

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

### 72.4.1 Module signals

This table provides port/signal names and their descriptions. See the IOMUX file attached to this document for details.

Table 478. Module signals

| Port name (clock/signal) | I/O | Description |
|---|---|---|
| MII_RMII_TXCLK (Clock) | I | MII: The external PHY provides this transmission clock, which operates at a frequency of 25 MHz in 100 Mbps mode and at 2.5 MHz in 10 Mbps mode. All transmission signals that MAC generates are synchronous to this clock, which is required for all PHY interfaces. |

*Table continues on the next page...*

**Table 478. Module signals (continued)**

| Port name (clock/signal) | I/O | Description |
|---|---|---|
| | | RMII: The RMII interface uses this 50 MHz clock. If you select RMII mode, MII_RX_CLK (25 MHz or 2.5 MHz) must be derived from the RMII reference clock. |
| MII_RX_CLK (Clock) | I | The external PHY provides this receive clock for the MII and RMII interfaces. The clock operates at a frequency of 25 MHz in 100 Mbps mode and at 2.5 MHz in 10 Mbps mode. All MII receive signals that MAC receives are synchronous to MII_RX_CLK. The clock's input is required for all PHY interfaces. |
| EMAC_PPS[3:0] (Signals) | I/O | This group of signals is used as pulse per second in Output mode and as media clock generation trigger in Input mode. The signals trigger input to DUT to capture presentation time. Based on the presentation control value of MAC PPS Control (MAC_PPS_Control), the signals can be defined as pulse or level signals. |
| MII_RMII_TX_EN (Signal) | O | MAC drives this signal, which performs multiple functions depending on the selected PHY interface as described in this list:<br>• MII: When high, indicates that valid data is being transmitted to the PHY_TXD_O bus. MII_RMII_TX_EN is synchronous to MII_RMII_TX_CLK.<br>• RMII: When high, indicates that valid data is being transmitted to the PHY_TXD_O bus. MII_RMII_TX_EN is synchronous to MII_RMII_RX_CLK. |
| MII_RMII_TXD[3:0] (Signals) | O | This is a group of transmit data signals driven by MAC. These signals perform multiple functions depending on the selected PHY interface as described in this list:<br>• MII: Bits[3:0] provide the MII transmit data nibble. The data is valid only when the MII_RMII_TX_EN signal is high. MII_RMII_TXD[3:0] is synchronous to MII_MII_TX_CLK. |

*Table continues on the next page...*

**Table 478. Module signals (continued)**

| Port name (clock/signal) | I/O | Description |
|---|---|---|
| | | • RMII: Bits[1:0] provide the RMII transmit data. The data is valid only when the MII_RMII_TX_EN signal is high. MII_RMII_TXD[3:0] is synchronous to MII_RMII_TX_CLK. |
| MII_CRS (Signal) | I | This signal is valid only in MII mode. The PHY drives this signal high when the transmit or receive medium is not idle, and drives the signal low when both these mediums are idle. The signal is not synchronous to any clock. |
| MII_COL (Signal) | I | This signal is valid only in MII mode. The PHY drives this signal high when a collision is detected on the medium. The signal is not synchronous to any clock. |
| MII_RMII_RX_DV (Signal) | I | The PHY drives this signal. It performs multiple functions depending on the selected PHY interface as described in this list:<br>• MII: Indicates that the data on the MII_RXD bus is valid. It remains high continuously from the first recovered byte or nibble of the packet through the final recovered byte or nibble of the packet. MII_RMII_RX_DV is synchronous to MII_RX_CLK.<br>• RMII: Contains the CRS and data valid information of the receive interface. MII_RMII_RX_DV is synchronous to MII_RMII_TX_CLK. |
| MII_RMII_RX_ER (Signal) | I | The PHY drives this signal. It performs multiple functions depending on the selected PHY interface as described in this list:<br>• MII: Indicates an error or carrier extension in the received packet of the MII_RXD[3:0] bus. MII_RMII_RX_ER is synchronous to MII_RX_CLK.<br>• RMII: Is not used. |
| MII_RMII_RXD[3:0] (Signals) | I | This is a group of data signals received from the PHY. These signals perform multiple functions depending on the |

*Table continues on the next page...*

**Table 478. Module signals (continued)**

| Port name (clock/signal) | I/O | Description |
|---|---|---|
| | | selected PHY interface as described in this list:<br>• MII: Bits [3:0] provide the MII receive data nibble. The data is valid only when the MII_RMII_RX_DV signals are high. MII_RMII_RXD[3:0] is synchronous to MII_RX_CLK.<br>• RMII: Bits [1:0] provide the RMII receive data. The data is valid only when the MII_RMII_RX_DV signal is high. MII_RMII_RXD[3:0] is synchronous to MII_RMII_TX_CLK. |
| MII_RMII_MDC | O | MAC provides timing reference for MII_RMII_MDIO or MII through this periodic clock. The application clock generates this clock through a clock divider that MAC_MDIO_Address[CR] controls. |
| MII_RMII_MDIO (Signal) | I/O | MDIO uses this signal to transfer control and data information to PHY. |

## 72.5 Using PHY interfaces

This section is Synopsys Proprietary. Used with permission.

This module support the following modes:

- RMII 10/100 Mbps interface
- MII 10/100 Mbps interface

Phy_intf_sel input signal decides which mode is selected. Samples the Phy_intf_sel signal at reset. See External signals for more information. MAC_Configuration[PS] and MAC_Configuration[FES] selects the mode's speed.

The module supports the IEEE802.3-2015 specification for MII and RMII specification version 1.2 from RMII consortium.

**NOTE**

RMII reference clock (50 MHz) can be fed to IP from an external source or internally from PLL on SoC.

The module supports the access of the phy registers through SMA. It is a two wire Station management interface (MIM):

1. MDC
2. MDIO

According to IEEE 802.3 specification, maximum operating frequency of MDC is 2.5 Mhz which system clock derives using a divider. MAC_MDIO_Address[CR] programs to generate different MDC clock frequency.

SMA supports MDIO clause 45 and clause 22 frame structure per the IEEE802.3 specification. Writing 1 to MAC_MDIO_Address[C45E] enables the clause 45 frame structure.

The MII interface reduces the accuracy of the 1588 timestamp if it is overclocked to run at 200 Mbps. This happens because the MAC logic uses the MII interface speed,to adjust or compensate for the timestamps taken at MII, as compared to the time generated in the PTP clock domain as specified in MAC_Configuration[FES].

## 72.6 VLAN and double VLAN insertion, deletion, replacement and tagging

This section and all its sub-sections are Synopsys proprietary. These are used with permission.

The following sections describe the VLAN and double VLAN features.

### 72.6.1 Double VLAN processing

In the double VLAN tagging processing, the module supports the processing of two VLAN tags. The two VLAN tags are:

1. Inner VLAN tag (C-VLAN)
2. Outer VLAN tag (S-VLAN)

If there is only one tag in a packet then it is considered as an outer tag.

The module uses MAC_VLAN_Incl and MAC_Inner_VLAN_Incl and MAC_VLAN_Tag registers to support the following functions in a double VLAN processing feature.

- Insertion, replacement, or deletion of up to two VLAN tags in the transmit path.
- Packet filtering and stripping on the basis of any one of the two VLAN tags in the receive path. Stripping and providing up to two VLAN tags in the receive path as a part of the receive status.

#### 72.6.1.1 Transmit path

**Table 479. Double VLAN processing features in transmit path**

| Feature | Description |
|---|---|
| Support for C-VLAN and S-VLAN tag types | The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. MAC_VLAN_Incl[CSVL] and MAC_Inner_VLAN_Incl[CSVL] specifies the VLAN type. The module supports the processing of any sequence of outer and inner VLAN tags.<br>**NOTE**<br>The module does not support the C-VLAN and S-VLAN sequence.<br>MAC does not examine whether the packet, which the application provides has a valid sequence of the VLAN tag types or the insertion or replacement operation results in an invalid sequence of VLAN tag type. Therefore, the application must provide a correct sequence of VLAN tag types and program the MAC in such a way that it results in correct sequence of VLAN tag types in the transmitted packet. The application must ensure the following:<br>• The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled.<br>• The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled.<br>• The inner tag should not be S-VLAN when C-VLAN replaces the outer tag.<br>• The outer tag should not be C-VLAN when S-VLAN replaces the inner tag. |
| VLAN tag deletion | MAC_VLAN_Incl[VLC] or MAC_Inner_VLAN_Incl[VLC] respectively enables the VLAN tag deletion for an outer or inner tag. When you enable the VLAN deletion, MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If you enable the inner tag deletion and if there is only one tag in the packet, then the MAC does not delete the tag. |
| VLAN tag insertion or replacement | MAC_VLAN_Incl[VLC] or MAC_Inner_VLAN_Incl[VLC] respectively enables the VLAN tag insertion or replacement for an outer or inner tag. When you enable the VLAN tag insertion or replacement, the MAC_VLAN_Incl[VLTI] or<br>MAC_Inner_VLAN_Incl[VLTI] determines whether the VLAN tag must be fetched from the register or from the control word. |

#### 72.6.1.2 Receive path

Table 480. Double VLAN processing in receive path

| Feature | Description |
|---|---|
| Outer or inner VLAN tag-based filtering | Mac can filter packets through the ERIVLT bit on the basis of the outer or inner VLAN tag. |
| C-VLAN or S-VLAN tag-based filtering | Mac can filter packets through the ERSVLM bit on the basis of the C-VLAN or S-VLAN type. |
| Outer and inner VLAN tag stripping | Mac can strip the outer and inner VLAN tags from received frame on the basis of the EVLS and EIVLS bits. |
| 16-bit outer and inner VLAN tag and type in Rx status | Mac can provide the 16-bit outer and inner VLAN tag and type in the Rx status on the basis of the EVLRXS and EIVLRXS bits, respectively. |
| Disabling or skipping checking of outer VLAN tag type | Mac can disable or skip checking of an outer VLAN tag type to match C-VLAN or S-VLAN on the basis of the DOVLTC bit. |

#### 72.6.1.3 Source address and VLAN insertion, replacement, or deletion

This module supports the SA, and VLAN insertion, replacement and deletion feature. The SA and VLAN fields are Tx packet-related control information that interfaces provide as part of the control word. IP supports the feature to insert or replace the source address on the basis of the information in the MAC address registers, and it also supports the feature to insert, replace, or delete the VLAN fields (VLAN type and VLAN tag) on the basis of the setting of the MAC_VLAN_Incl[VLTI]. SA insertion or replacement feature is enabled for all the transmit packets or selective packets. Similarly, VLAN insertion, replacement, or deletion feature is enabled for all the Tx packets or selective packets.

#### 72.6.1.4 Programming source address insertion or replacement

You can use the SA insertion or replacement feature to instruct MAC to perform the following actions for Tx packets:

- Insert the content of the MAC address registers in the SA field
- Replace the content of the SA field with the content of the MAC address registers

When SA insertion is enabled, the application must ensure that the packets sent to MAC do not have the SA field. The MAC does not check whether the SA field is present in the transmit packet and it inserts the content of MAC address registers in the SA field. Similarly, when the SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC.

MAC replaces the six bytes following the DA field in the transmit packet with the content of the MAC address registers.

- Configure MAC_Configuration[SARC] to enable the SA insertion or replacement for all Tx packets.
- Enable the SA insertion for selective packet by configuring the SA insertion control field (bits [25:23] of TDES3) in the first transmit descriptor of the packet. When you write 1 to bit 25 of TDES3, the SA insertion control field indicates insertion or replacement by MAC Address1 registers. When bit 25 of TDES3 resets, it indicates insertion or replacement by MAC Address 0 registers.

If you do not enable the MAC Address1 registers, then the MAC Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA insertion control field.

#### 72.6.1.5 Programming VLAN insertion, replacement, or deletion

You can use the VLAN insertion, replacement, or deletion feature to instruct MAC to perform the following actions for the Tx packets:

- Delete the VLAN type and VLAN tag fields.
- Insert or replace the VLAN type and VLAN tag fields.

Insertion or replacement is done on the basis of the setting of the MAC_VLAN_Incl[VLTI] as described in theTable 481:

**Table 481. VLAN insertion or replacement based on VLTI bit**

| Condition | Description |
|---|---|
| VLTI bit=1 | MAC inserts or replaces the following:<br>• VLAN type field (C-VLAN or S-VLAN as indicated by the MAC_VLAN_Incl[CSVL])<br>• VLAN tag field depending on the content of the VT field of transmit context descriptor of the packet |
| VLTI bit resets | MAC inserts or replaces the following:<br>• VLAN type field (C-VLAN or S-VLAN as indicated by the MAC_VLAN_Incl[CSVL])<br>• VLAN tag field with the MAC_VLAN_Incl[VLT] |

When the VLAN replacement or deletion is enabled, MAC checks whether the VLAN type field (0x8100 or 0x88a8) is present after the DA and SA fields in the transmit packet. The replace or delete operation does not occur if the VLAN type field is not detected in two bytes following the DA and SA fields. However, when the VLAN insertion is enabled, MAC does not check the presence of VLAN type field in the transmit packet and just inserts the VLAN type and VLAN tag fields.

Configuring MAC_VLAN_Incl[VLC] and MAC_VLAN_Incl[VLP] enables the VLAN insertion, replacement, or deletion feature for all Tx packets.

Configuring the VTIR field of TDES2 normal descriptor enables the VLAN insertion, replacement, or deletion for selective packets.

In addition, the VLP (VLAN Priority control) field must reset in MAC_VLAN_Incl (for outer VLAN) and MAC_Inner_VLAN_Incl register (in inner VLAN) for MAC to take the control inputs from the host, depending on the configuration.

## 72.7 Packet Filtering

This section and all its sub-sections are Synopsys proprietary. Used with permission.

MAC receiver contains various packet filtering scheme. Figure 389 shows the filtering sequence in their precedence order of received packet.

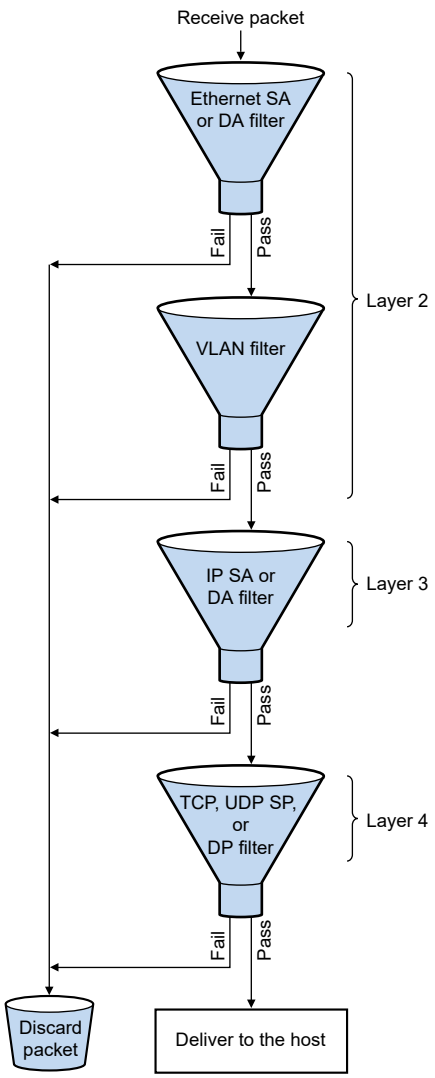

Figure 389. Packet filtering sequence

If you do not enable any of the layer filters, then that filter is bypassed and the subsequent filter is applied. Discard the packet that fails any of the filters. However, you can forward the discarded packet to the host on the basis of the register control.

## 72.7.1 Source address or destination address filtering

The address filtering module of MAC checks the SA and DA fields of each incoming packet. Programming of different types of address filtering is described in the sections that follows.

### 72.7.1.1 Unicast destination address filtering

MAC supports up to three MAC addresses for unicast perfect filtering. If perfect filtering is selected (MAC_Packet_Filter[HUC] resets), MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled. MAC selects the MacAddr1 to MacAddr2 addresses with an individual enable field. Each byte of MacAddr1 to MacAddr2 can be masked when you compare them with corresponding received DA byte by writing 1 to the corresponding Mask byte control field in the register. This enables group address filtering for the DA.

In hash filtering mode (when you write 1 to HUC bit), MAC performs imperfect filtering by using a 64-bit hash table for unicast addresses . For hash filtering, MAC uses the upper 6 bits CRC of the received destination address to index the content of the hash table. A value of 00000 selects bit 0 of selected register, and a value of 11111 selects bit 63 of hash table register. If the value of

the corresponding bit (indicated by the 6-bit CRC) is 1, the unicast packet is considered to have passed the hash filter, otherwise, the packet is considered to have failed the hash filter.

#### 72.7.1.2 Multicast destination address filtering

Enable MAC_Packet_Filter[PM] to pass all the multicast packets or disable to do multicast addresses filtering on the basis of MAC_Packet_Filter[HMC]. Compare the multicast address with the configured MAC destination address registers (1–2), also supports the group address filtering.

In Hash filtering mode, MAC performs imperfect filtering using a 64-bit hash table. MAC uses the upper 6-bits CRC of received multicast address to index the content of the hash table. A value of 000000 selects bit 0 of selected register and a value of 111111 selects bit 63 of the hash table register. The multicast packet is considered to have passed the hash filter if the value of the corresponding bit is equal to 1. Otherwise, the packet is considered to have failed the hash filter.

#### 72.7.1.3 Hash or perfect address filtering

Configure MAC_Packet_Filter[HPF] to enable or disable the destination address filtering either by hash filter or perfect filter. Also configure MAC_Packet_Filter[HUC] and MAC_Packet_Filter[HMC] to select the hash filtering or perfect filtering for unicast or multicast packet.

#### 72.7.1.4 Broadcast address filtering

MAC does not filter any broadcast packets by default. You must write 1 to MAC_Packet_Filter[DBF] to reject the broadcast packets.

#### 72.7.1.5 Unicast source address filtering

MAC by default compares the source address field with the value configured in the source address registers. Configure bit 30 of MAC address register [1-2] to use it for source address instead of destination address comparison. MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. MAC drop the packets that fail the SA filter if you write 1 to MAC_Packet_Filter[SAF] field. Otherwise, the result of the SA filter is given as a status bit in the receive status word. When you write 1 to the SAF field, the SA filter and DA filter results ends to decide whether you can forward the packets. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

#### 72.7.1.6 Inverse filtering

For DA and SA filtering, you can invert the filter-match result at the final output by writing 1 to the DAIF and SAIF fields of MAC_Packet_Filter register. The DAIF field is applicable for both the unicast and multicast DA packets. The unicast or multicast destination address filter result is inverted in this mode. Similarly, writing 1 to the SAIF field reverses the result of unicast SA filter.

Table 482 and Table 483 summarize the DA and SA filtering on the basis of the type of packets received.

**Table 482. Destination address filtering**

| Packet type | PR | HPF | HUC | DAIF | HMC | PM | DBF | DA filter operation |
|---|---|---|---|---|---|---|---|---|
| Broadcast | 1 | X | X | X | X | X | X | Pass |
| | 0 | X | X | X | X | X | 0 | Pass |
| | 0 | X | X | X | X | X | 1 | Fail |
| Unicast | 1 | X | X | X | X | X | X | All packets pass |
| | 0 | X | 0 | 0 | X | X | X | Pass on perfect or group filter match |

*Table continues on the next page...*

Table 482. Destination address filtering (continued)

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | 0 | X | 0 | 1 | X | X | X | Fail on perfect or group filter match |
| | 0 | 0 | 1 | 0 | X | X | X | Pass on hash filter match |
| | 0 | 0 | 1 | 1 | X | X | X | Fail on hash filter match |
| | 0 | 1 | 1 | 0 | X | X | X | Pass on hash or perfect or group filter match |
| | 0 | 1 | 1 | 1 | X | X | X | Fail on hash or perfect or group filter match |
| Multicast | 1 | X | X | X | X | X | X | Pass all packets |
| | X | X | X | X | X | 1 | X | Pass all packets |
| | 0 | X | X | 0 | 0 | 0 | X | Pass on perfect or group filter match and drop pause packets if PCF = 0x |
| | 0 | 0 | X | 0 | 1 | 0 | X | Pass on hash filter match and drop pause packets if PCF = 0x |
| | 0 | 1 | X | 0 | 1 | 0 | X | Pass on hash or perfect or group filter match and drop pause packets if PCF = 0x |
| | 0 | X | X | 1 | 0 | 0 | X | Fail on perfect or group filter match and drop pause packets if PCF = 0x |
| | 0 | 0 | X | 1 | 1 | 0 | X | Fail on hash filter match and drop pause packets if PCF = 0x |
| | 0 | 1 | X | 1 | 1 | 0 | X | Fail on hash or perfect/group filter match and drop pause packets if PCF = 0x |

Table 483. Source address filtering

| Packet type | PR | SAIF | SAF | SA filter operation |
|---|---|---|---|---|
| Unicast | 1 | X | X | Pass all packets. |
| | 0 | 0 | 0 | Pass status on perfect or group filter match but do not drop packets that fail |
| | 0 | 1 | 0 | Fail status on perfect or group filter match but do not drop packet |
| | 0 | 0 | 1 | Pass status on perfect or group filter match and drop packets that fail |
| | 0 | 1 | 1 | Fail status on perfect or group filter match and drop packets that fail |

**NOTE**

When you write 1 to the MAC_Packet_Filter[RA] field, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.

### 72.7.2 VLAN filtering

VLAN tag filter can be done either by perfect match or hash table. Depending upon the configuration, MAC can compare either lower 12 bits or all 16 bits of received VLAN tag for perfect match. MAC forward the VLAN tagged packet with match status when it drop all the packets which do not match.

MAC uses 16-bit VLAN hash table for group address filtering on the basis of the VLAN tag. If MAC enables the hash filtering then the most significant 4-bit of CRC-32 of VLAN tag are used to index the content of the MAC_VLAN_Hash_Table. A value of 1 in the VLAN hash table register, corresponding to the index indicates that the VLAN tag of the packet has matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

MAC supports the inverse matching for VLAN packets. In the Inverse matching mode, the packet must be dropped when the VLAN tag of a packet matches the perfect or hash filter. If MAC enables the VLAN perfect and VLAN hash match, then a packet is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, MAC forwards a packet only when both the perfect and hash filters indicate mismatch.

Table 484 specifies the different possibilities for VLAN matching and the final VLAN match status. When you write 1 to MAC_Packet_Filter[RA] all packets are received and it indicates the VLAN match status in the VF field of RDES2 normal descriptor (write-back format). When the RA field is not set and when you write 1 to MAC_Packet_Filter[VTFE] the packet drops if the final VLAN match status fails

When VLAN VID programs to 0 in the VL field of MAC_VLAN_Tag register, consider that all the VLAN-tagged packets are perfectly matched but the status of the VLAN hash match depends on the VTHM and VTIM fields in MAC_VLAN_Tag register.

**Table 484. VLAN match status**

| VID | VLAN perfect filter match result | VTHM bit | VLAN hash filter match result | VTIM bit | Final VLAN match status |
|---|---|---|---|---|---|
| VID = 0 | Pass | 0 | X | X | Pass |
| | Pass | 1 | X | 0 | Pass |
| | Pass | 1 | Fail | 1 | Pass |
| | Pass | 1 | Pass | 1 | Fail |
| VID1= 0 | Pass | X | X | 0 | Pass |
| | Fail | 0 | X | 0 | Fail |
| | Fail | 1 | Fail | 0 | Fail |
| | Fail | 1 | Pass | 0 | Pass |
| | Fail | 0 | X | 1 | Pass |
| | Pass | X | X | 1 | Fail |
| | Fail | 1 | Pass | 1 | Fail |
| | Fail | 1 | Fail | 1 | Pass |

In Table 484, X represents any value.

### 72.7.3 VLAN filter fail packets queue

When you enable VLAN filtering, route the VLAN filter fail packets to a programmable queue (VFFQ) when the value of MAC_Packet_Filter[RA] = 1 or MAC_Packet_Filter[VTFE] = 0 and write 1 to MAC_RxQ_Ctrl4[VFFQE] for the queue.

Route the packets that passes the VLAN filtering to Rx queues on the basis of the VLAN tag priority field by configuring the PSRQ field in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. Discard the packets that fail the VLAN filter if RA=0 or VTFE=1. However, when RA=1 or VTFE=0, forward the VLAN filter fail packets to the application. In such case, when you write 1 to the VLAN filter fail queue enable (VFFQE) field, the VLAN filter fail packets forward to the Rx queue number programmed in the VFFQ field. If the value of VFFQE=0, the VLAN priority mapping determines the Rx queue number per the PSRQ fields.

Table 485 shows the Rx queue routing table for unicast tagged packets, with DA or SA filter enabled.

**Table 485. Rx queue routing table for unicast tagged packets**

| RA | VFTE | SA or DA filter result | VLAN filter result | VFFQE | Queue routing |
|---|---|---|---|---|---|
| X | X | Pass | Pass | X | PSRQ |
| 0 | 0 | Pass | Fail | 0 | PSRQ |
| 0 | 0 | Pass | Fail | 1 | VFFQ |
| 0 | X | Fail | X | X | Dropped |
| 0 | 1 | Pass | Fail | X | Dropped |
| 1 | X | Fail | X | 0 | UFFQ*/PSRQ |
| 1 | X | Fail | X | 1 | UFFQ*/VFFQ |
| 1 | X | Pass | Fail | 0 | PSRQ |
| 1 | X | Pass | Fail | 1 | VFFQ |

X : Don't care condition * : When UFFQE is enabled else PSRQ.

### 72.7.4 Extended receive VLAN filtering and routing

When the extended Rx VLAN filtering and routing is enabled then both the perfect filtering and hash filtering can be enabled. The overall VLAN filter result is based on the perfect filter result and hash filter result (if enabled). Filter result is passed to application as part of the status bit. Extended routing will take place only if VLAN filter has passed. Routing is only based on perfect filter result. Each perfect filter has a DMA channel enable and DMA channel number filed which must be programmed for routing.

See the extended VLAN based DMA selection in Dynamic (per packet) mapping for more information about routing.

#### 72.7.4.1 Comparison mode

Application has these comparison option for each VLAN tag filter:

- Programs MAC to compare the inner or outer VLAN tag either with 12 bits or 16 bits programmed VID.
- Selects whether the VID comparison is for SVLAN or CVLAN type frames, if type check is enabled for a filter.

#### 72.7.4.2 Filtering

Perfect filtering is done on the basis of the MAC_VLAN_Tag_Filter registers. MAC compares the relevant VLAN tag ID and gives a result for each VLAN tag filter.

The results for each VLAN tag filter are:

- Pass- If any one of the VLAN tag filters gives a match.
- Fail- If the frame mismatches all the filters.

This behavior is applicable only when the inverse filtering is not enabled in MAC_VLAN_Tag_Ctrl.

If inverse filtering is enabled and the frame mis-matches all the relevant filters then it is considered to have passed the VLAN filter. If the frame matches any one of the relevant filters then it is considered to have failed. The frame is bypassed to the application if none of the enabled filters can perform a comparison or if none of the filters are enabled.

The overall filter result and the programming on MAC_Packet_Filter[VTFE] and MAC_Packet_Filter[RA] determines if the frame will drop or it is forwarded to the application. If the value of RA = 1 or VTFE = 0, then the frame is always forwarded whether the filter result is a pass or fail, . If the value of RA = 0 and VTFE = 1, only then, if the VLAN tag filter result is a pass the MAC forwards the frame. If the frame is forwarded to the application, then the relevant filter result is indicated through the status bits.

#### 72.7.4.3 Filter status

The extended receive VLAN filtering and routing feature provides two status fields to show the comparison result of the VLAN tags.

By default, MAC indicates the VLAN filter status through one bit in the status VF field in RDES2. When you enable the extended RX VLAN filtering and routing, two status fields will show the comparison result of the VLAN tags. The outer VLAN tag filter pass and inner VLAN tag filter pass bits are defined in the following positions. The status indicated through these fields depends on the programming as described below.

In RDES2:

- Bit 15 – Outer VLAN tag filter status
- Bit 14 – Inner VLAN tag filter status

In ARI status: MAC filter status:

- Bit 15 – Outer VLAN tag filter status
- Bit 14 – Inner VLAN tag filter status

In MRI status:

- Bit 47 – Outer VLAN tag filter status
- Bit 46 – Inner VLAN tag filter status

Outer VLAN tag filter status (OTS)

- In perfect filtering, without enabling inverse filtering, if you write 1 to this field, it indicates that the frame's outer VLAN tag has matched one of the VLAN tag filters.
- If this field resets, it indicates that the frame's outer VLAN tag has either failed the relevant outer VLAN tag filters or bypassed them.
- This field resets if none of the filters are enabled for outer VLAN tag comparison.
- If inverse filtering is enabled and if you write 1 to this field, then the frame's VLAN tag has passed all the relevant VLAN tag filters. If it is resets, then it has failed at least one filter or bypassed all the filters programmed for outer VLAN tag comparison.
- This bit is valid for both single and double VLAN tagged frames.

Inner VLAN tag filter status (ITS)

- In perfect Filtering, without enabling inverse filtering, if you write 1 to this field, it indicates that the frame's inner VLAN tag has matched one of the VLAN tag filters.
- If this field resets, it indicates that the frame's inner VLAN tag has either failed the relevant inner VLAN tag filters or bypassed them.
- This field resets if none of the filters are enabled for inner VLAN tag comparison.
- If Inverse Filtering is enabled and if you write 1 to this field, then the frame's VLAN tag has passed all the relevant VLAN tag filters. If it resets, then it has failed at least one filter or bypassed all the filters programmed for inner VLAN tag comparison.

- This bit is valid for only double VLAN tagged frames, when double VLAN processing is enabled.

The application must observe the status fields and the program to determine if the frame has passed or failed the VLAN filter.

Table 486 and Table 487 describes the possible filter combinations and the corresponding filter results and they also explain the scenarios when the double VLAN processing and the hash VLAN filter are enabled in the design.

Legend for the table OTS and ITS Bit Values with at least 1 perfect filter enabled

- VTIM: VLAN tag inverse match enable – bit 17 in VLAN_Tag_Ctrl register.
- HFO: Hash filter enabled for outer VLAN tag comparison - bit 25 and bit 27 in VLAN_Tag_Ctrl register.
- HFI: Hash filter enabled for inner VLAN tag comparison – bit 25 and bit 27 in VLAN_Tag_Ctrl register.
- PFO – Perfect filter comparison enabled for outer VLAN tag - Any of the MAC_VLAN_Tag_Filter registers is enabled (write 1 to bit 16) and programmed for outer VLAN tag comparison (write 0 to bit 20).
- PFI – Perfect filter comparison enabled for Inner VLAN Tag - Any of the MAC_VLAN_Tag_Filter registers is enabled (write 1 to bit 16) and programmed for inner VLAN tag comparison (write 1 to bit 20).
- OTS – Outer VLAN tag filter status
- ITS – Inner VLAN tag filter status

Table 486 shows the possible values of status bits (OTS and ITS) when at least one perfect filter is enabled.

**Table 486. OTS and ITS bit values with at least 1 perfect filter enabled**

| VTIM | HFO | HFI | PFO | PFI | OTS | ITS |
|---|---|---|---|---|---|---|
| 0 | 0 | 0 | 0 | 1 | 0 | 1/0 |
| 0 | 0 | 0 | 1 | 0 | 1/0 | 0 |
| 0 | 0 | 0 | 1 | 1 | 1/0 | 1/0 |
| 0 | 1 | 0 | 1 | 1 | 1/0 | 1/0 |
| 0 | 1 | 0 | 1 | 0 | 1/0 | 0 |
| 0 | 1 | 0 | 0 | 1 | 1/0 | 1/0 |
| 0 | 0 | 1 | 1 | 1 | 1/0 | 1/0 |
| 0 | 0 | 1 | 1 | 0 | 1/0 | 1/0 |
| 0 | 0 | 1 | 0 | 1 | 0 | 1/0 |
| 1 | 0 | 0 | 0 | 1 | 0 | 1/0 |
| 1 | 0 | 0 | 1 | 0 | 1/0 | 0 |
| 1 | 0 | 0 | 1 | 1 | 1/0 | 1/0 |
| 1 | 1 | 0 | 1 | 1 | 1/0 | 1/0 |
| 1 | 1 | 0 | 1 | 0 | 1/0 | 0 |
| 1 | 1 | 0 | 0 | 1 | 1/0 | 1/0 |

*Table continues on the next page...*

Table 486. OTS and ITS bit values with at least 1 perfect filter enabled (continued)

| VTIM | HFO | HFI | PFO | PFI | OTS | ITS |
|---|---|---|---|---|---|---|
| 1 | 0 | 1 | 1 | 1 | 1/0 | 1/0 |
| 1 | 0 | 1 | 1 | 0 | 1/0 | 1/0 |
| 1 | 0 | 1 | 0 | 1 | 0 | 1/0 |

Table 487 shows the possible values of status bits (OTS and ITS) when no perfect filters are enabled except the VLAN hash filter is enabled.

Table 487. OTS and ITS bit values with only VLAN hash filter enabled

| VTIM | HFO | HFI | OTS | ITS |
|---|---|---|---|---|
| 0 | 0 | 0 | 0 | 0 |
| 0 | 1 | 0 | 1/0 | 0 |
| 0 | 0 | 1 | 1/0 | 1/0 |
| 1 | 0 | 0 | 1/0 | 0 |
| 1 | 1 | 0 | 1/0 | 0 |
| 1 | 0 | 1 | 1/0 | 1/0 |

With no perfect filters enabled, any VLAN packet is considered to have bypassed the perfect filter. If Hash Filter is enabled for one of the Tags, then the respective Status bit depends on the Filter's result. The Status bits are set to 0 if VLAN Hash Filter is also not enabled.

If the value of ITS/OTS is shown as 1/0; then it indicates that the final result is dependent on the enabled relevant filter's result.

Example 1: The second row of OTS and ITS bit values with only VLAN hash filter enabled indicates that at least one Perfect Filter is enabled for Outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN Filtering is not enabled. The bit OTS is given as 1/0. If the received frame passes at least one of the enabled Outer VLAN Tag filters then the bit is set to 1. If the frame doesn't pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2: The last row of table "OTS and ITS bit values with only VLAN hash filter enabled" indicates that the inverse filtering is enabled, hash filter and at least one perfect filter is enabled for Inner VLAN Tag comparison, then if the received frame's Inner VLAN tag mismatches with both the Hash Filter and all the enabled Perfect filters, then the frame will have the ITS bit set to 1 else it is set to 0. OTS will be set to 0 as no comparison is performed.

#### 72.7.4.4 Stripping

Each VLAN tags has individual control over stripping. The programming options of always strip, never strip, strip on pass and strip on fail are available. Inner or outer VLAN tag stripping is based on the pass or fail results of the individual tag. If all the relevant filters bypasses a tag, stripping is not applicable for the tag.

- If strip on pass is enabled for the outer VLAN tag, then the stripping occurs only if the outer VLAN tag has passed the relevant filters. The outer VLAN tag filter result field will be 1.
- If strip on fail is enabled for the outer VLAN tag, then the stripping occurs only if the outer VLAN tag has failed relevant filters. The outer VLAN tag filter result field will reset.
- If the outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), then the tag is not stripped, though the status bit is 0.

- As multiple filters are enabled, it is possible that the received VLAN frame could have matched any one or more of the filters. The VLAN Tag's value is not always deterministic from the filter status bits.

If an application strips the VLAN tag on the basis of the filter result, it might lose the VID. You can use it, if stripping is enabled for any of the tags, place the tag in the status. For this the software or application will enable the respective VLAN tag in status bit - 24 or 31 in the MAC VLAN tag control register.

See section Programming guidelines for extended VLAN filtering and routing on receive for more information.

### 72.7.5 Layer 3 and layer 4 filtering

IP supports the layer 3 based packet filtering which is an IP source or destination address filtering in the IPv4 or IPv6 packets, and layer 4 based packet filtering which is a source or destination port number filtering in TCP or UDP. When you enable layer 3 and layer 4 packet filtering then packets are filtered in the following manner.

- Matched packets: MAC forward the packets that match all enabled fields to the application along with the status. It gives the matched field status only if MAC_Configuration[IPC] = 1 and if one of the following conditions is true:
  - All enabled layer 3 and layer 4 fields match
  - At least one enabled field matches and other fields are bypassed or disabled

When you enable multiple layer 3 and layer 4 filters, any filter match is considered as a match. If more than one filter matches, MAC provides the status of the lowest filter where filter 0 is the lowest filter and filter 3 is the highest filter.

- Unmatched packets: MAC drop the packets that do not match any enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets.
- Non-TCP or UDP IP packets: By default, all the non-TCP or UDP IP packets bypasses the layer 3 and layer 4 filters. You can optionally program MAC to drop all the non-TCP or UDP packets over IP packets.
- IP has a control register MAC_L3_L4_Control to control the layer L3 and L4 packet filtering along with address registers to program the layer L3 and L4 fields to be matched.

### 72.7.6 Flexible receive parser

When you enable this function, all incoming packets are parsed per the programmable instruction stored in memory. It perform these functions:

- Packet filter (Accept or reject)
- DMA channel selection

Flexible receive parser block operates over the first 128 bytes data of receive packet on the basis of 64 bytes of instruction on each packet. Figure 390 shows the functional block diagram of flexible receive parser.

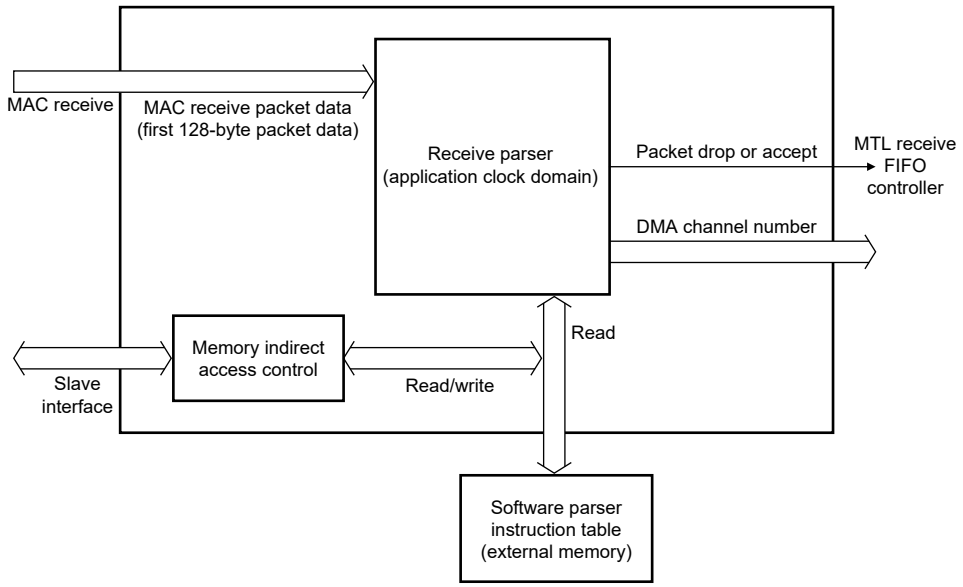

**Figure 390. Functional block diagram of flexible receive parser**

### 72.7.6.1 Instruction table format of the flexible receive parser

You must build the 96-bit wide instruction before enabling the receive parser feature and program each instruction as an entry in the instruction memory.

Table 488 shows the format of each entry in the instruction table .

**Table 488. Rx parser instruction entry format**

| Field | Field Name | Description |
|---|---|---|
| 31:0 | MATCH_DATA | This is a 4-byte data. You can use it to compare with incoming packet data which starts at the frame offset as defined in [79:72] of the entry. The comparison is done only on those bits whose corresponding mask bits are 1 (MATCH_EN bits of [63:32]). See the notes (below this table) on the byte order relative to Ethernet arrival data and endianness which the QoS IP supports on the slave interface. The programming of this instruction table must adhere to the same. |
| 62:32 | MATCH_EN | When the MATCH_EN = 1, you can use the corresponding packet data bit for comparing. Otherwise, corresponding data bit is don’t care. |
| 64 | AF | Accept frame |
| 65 | RF | Reject frame |
| 66 | IM | Inverse match |
| 67 | NC | Next instruction control |
| 71:68 | Reserved | - |

*Table continues on the next page...*

Table 488. Rx parser instruction entry format (continued)

| Field | Field Name | Description |
|---|---|---|
| 79:72 | Frame offset | [77:72] indicates the frame offset in terms of 4 bytes. (Here [79:78] always 0) Compare the frame offset in the packet data for Match. This is in terms of 4 bytes. The value of actual frame offset in bytes are 0 01 42 8… ..63 252<br>The max value programmed in this instruction table is 128 B. The 'Actual frame offset' must not cross this limit. |
| 87:80 | OK index | If (NIC==0) the memory index you can use next when ENTRY_MATCH==1 and neither AF or RF = 1. If (NIC==1) the memory index you can use next when ENTRY_MATCH==0 |
| 95:88 | DMA Ch No | Indicates the DMA channel number (1-bit for each). You can use this when ENTRY_MATCH ==1 and AF = 1 (Accept frame). The following bits give the encoding: bit[0]- DMA channel number o, bit[1]- DMA channel number , 1bit[2]- DMA channel number 2… bit[7]- DMA channel number 7.<br>**NOTE**<br>You can encode the DMA channel number using bit wise as QoS IP support multicasting or broadcast across DMA channels. See section 3.3.12 for more information and proper usage. |
| 128:96 | Reserved | 0 (This field is only for software view and reserved for future enhancements. The memory width remains as 96-bits). |

The parser begins parsing from the 0th entry, for each received packet. The subsequent parsing entry location (next entry or OK_INDEX[]) depends on the current entry parser result. Flexible receive parser flow chart shows the detailed flow.

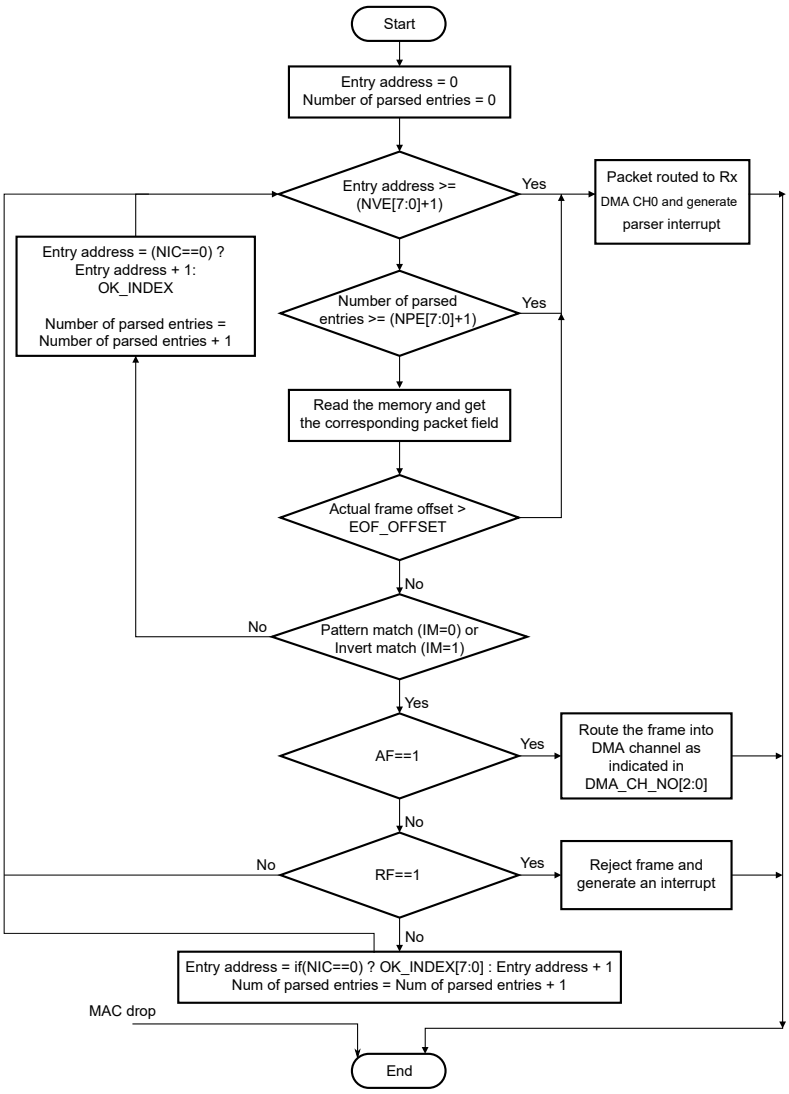

**Figure 391. Flexible receive parser flow chart**

The EOF_OFFSET shown in the figure is the least among the following:

- Actual packet size
- 128 Byte when frame pre-emption feature is not enabled or configured
- 128 Byte when frame pre-emption feature is enabled and packet is pre-emptive
- 64 Byte when frame pre-emption feature is enabled and packet is express packet

### 72.7.6.2 Number of valid entries (NVE)

NVE indicates the number of valid entries in the instruction table. The default value is 64. You can change this value by writing into MTL_RXP_Control_Status[NVE].

When parsing, an error is flagged in MTL_RXP_Interrupt_Control_Status[NVEOVIS], if the entry address is greater than MTL_RXP_Control_Status[NVE] + 1. IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

#### 72.7.6.3 Number of parsable entries (NPE)

NPE indicates the number of entries that you can parse on an incoming packet. The default value is 64. Write into MTL_RXP_Control_Status[NPE] to change this value.

When parsing, an error is flagged in MTL_RXP_Interrupt_Control_Status[NPEOVIS], if the number of parsed of parsed entries is more than MTL_RXP_Control_Status[NPE] + 1. IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

NVE[] indicates the number of valid entries in the receive parser memory which you have built and NPE[] indicates the worstcase parsable entries considering the various possible paths that the parser can take. (NVE[] >= NPE[]).

#### 72.7.6.4 Frame offset

It indicates the frame offset, in terms of 4 bytes which you use when comparing against the current table entry.

In an entry, an error is flagged in MTL_RXP_Interrupt_Control_Status[FOOVIS] in any of the following cases:

When frame offset is more than:

- Packet size
- 128B if pre-emption is disabled
- 128B if pre-emption is enabled and packet is pre-empitble
- 64B if pre-emption is enabled and packet is an express packet

IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

**NOTE**

If the frame ends after the (frame_offset *4) bytes but before ((frame_offset *4)+4) bytes, the receive parser declares a frame offset error if you enable comparison (via MASK bits) for the non-received bytes; from (frame_offset *4) to ((frame_offset *4)+4).

#### 72.7.6.5 Frame reject

You can drop the frame in cases, where an entry matches (considering the inverse match, IM bit in the instruction table) and frame accept bit is not 1, and frame reject bit (RF) = 1.

When a frame drops because RF = 1, IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

#### 72.7.6.6 Out of order processing

The Rx parser flow can be out of order. The decision tree is not based on the order in which packet arrives. This implies that the next entry and next frame offset (OK_INDEX[] and FRAME_OFFSET[]) can be less than the current entry address and current frame offset.

#### 72.7.6.7 DMA channel selection

When you enables the receive parser (MTL_Operation_Mode[FRPE] = 1) it overrides the MAC DMA selection criteria.

When you disables the receive parser (MTL_Operation_Mode[FRPE] = 0) the MAC/MTL determines the DMA channel number.

#### 72.7.6.8 Receive queue selection

The existing MAC functionality determines the receive queue, irrespective of whether the receive parser is enabled or disabled. This is because the receive parser is mainly designed to select the DMA channel and the MAC decides the receive queuing to enable the proper functioning of the pause or PFC feature.

**NOTE**

When there are multiple queues and multiple DMA Channels are enabled, a particular DMA channel might receive out of order packets because queue selection is based on MAC criteria (VLAN Priority and other criteria) and Rx DMA channel selection is based on receive parser.

#### 72.7.6.9 MAC packet filtering/drop/error handling

Packet filtering is done on the basis of the received packet fields. You must disable the packet filtering features inside the MAC when the receive parser is enabled. Follow these steps to disable the packet filtering features inside the MAC :

1. Write 1 to the Promiscuous mode (MAC_Packet_Filter[PR]).
2. Write 1 to all other fields in MAC_Packet_Filter to its default values.

When MAC decides to drop the packet due to the receive MAC dependent error such as:

- GMII error
- Receive watchdog error
- CRC error
- Giant frame error

the packet drops irrespective of the receive parser decision.

#### 72.7.6.10 Pad strip or CRC strip handling

Software controls the pad strip and CRC strip and it is applicable to all the received packets. Also,software must build the receive parser instructions accordingly, when you enable these features.

**NOTE**

Enable pad and CRC stripping in real use case.

#### 72.7.6.11 VLAN strip handling

MAC supports stripping the outer VLAN as well as inner VLAN. When you program MAC to strip the VLAN, the receive parser considers those VLAN tags to be part of the incoming packet.

#### 72.7.6.12 Multicast and broadcast support

IP supports multicast and broadcast packet and the packet route to the highest queue number.

When you enables the receive parser, the DMA channel numbers (DMA CH NO, Bits [95:88]) in the instruction table, decide the packet routing.

When you disables the receive parser, DCS (DMA Channel Select) field of the MAC_AddressX_High register determines the packet routing. See the Broadcast/multicast packet duplication.

**NOTE**

You can select multiple DMA channels for the packet routing because the DCS/DMA CH NO field is per the DMA channel control.

#### 72.7.6.13 Pre-emption support

IP supports the frame preemption feature when the flexible receive parser feature is enabled. It has the following limitations:

- Number of bytes would be 64, so that the receive parser can operate on an express traffic
- Number of bytes would be 128, so that receive parser can operate on a pre-emptive traffic.

#### 72.7.6.14 Software access to the flexible receive parser memory

Software can read and write into the receive parser memory. It uses the following registers via indirect addressing.

- MTL_RXP_Indirect_Acc_Control_Status
- MTL_RXP_Indirect_Acc_Data

For more details, see EMAC register descriptions.

#### 72.7.6.15 Statistical counters

IP supports these statistics counters for flexible receive parser.

1. MTL_RXP_Drop_Cnt
2. DMA_RXP_Error_Cnt

DMA_CH(#i)_Rxp_Accept_cnt (i=0; i<2)

For more details, see EMAC register descriptions.

#### 72.7.6.16 Changing the instruction table by software

Software can update the instruction table in the memory in the following ways:

- Disables the MAC receiver and receive parser by writing 0 to MAC_Configuration[RE] and MTL_Operation_Mode[FRPE]. It waits for receive parser to become inactive (RXPIA, MTL_RXP_Control_Status register bit[31]).
- (Optional) Programs in the entry address 0 to unconditionally (all MATCH_EN bit 0) skip to OK_INDEX[] (to certain location in the memory), where you can program it to reject or accept all the packets.

#### 72.7.6.17 Receive cut-through functionality

In the Cut-Through mode, the receive controller transfer the received packets to DMA just after it receives the cut-through threshold amount of packet data (RTC field in the MTL_RxQx_Operation_Mode register ).

However due to Rx parser's result worst case arrival time can be more than the programmed cut-through threshold. So, the receive controller delays the packet transfer to DMA accordingly, and the cut-through functionality is re-defined as follows:

The receive controller transfers packet to DMA after at least RTC number of bytes have been received and receive parser results are available.

#### 72.7.6.18 Receive packet drop indication

In most cases, the packet drops internally in the receive queue. However, back-to-back packets can arrive for the same queue and the first packet's receive parser result is not available when the second packet arrives. In such cases, the packet cannot be flushed internally and forwarded to DMA or the application interface and indicates the status accordingly. See RDES2, bit 16(RXPD) in Receive normal descriptor (write-back format) for more information.

#### 72.7.6.19 Runt packet handling

The receive parser can performs the operation with 64B minimum size packet. If the runt packet is received (MAC must indicate it), the receive parser assumes that it is dropped in the MAC, this is because, the back-to-back runt packets (< 64B) cannot be handled in the receive parser.

#### 72.7.6.20 Uncorrectable ECC error handling

The packet does not drops when the parser detects an uncorrectable ECC error while parsing the parser memory. The packet is sent to the application with an error indication. The RXPI (RX parser incomplete) sets in the packet status along with error summary (ES) bit.

See the Receive normal descriptor (write-back format) for more information.

## 72.8 IEEE 1588 timestamp support

This section and all its sub-sections are Synopsys proprietary. Used with permission.

IP supports the IEEE 1588 precision time protocol (PTP). It is also able to do precise time stamping and captures incoming and outgoing frame because of the PTP protocol implementation in the IP. It supports all the clock types defined in IEEE 1588-2008. The typical frequency of PTP timestamp clock is 125 MHz.

IP supports these features:

- Provides an option to take snapshot of all packets or only PTP type packets
- Provides an option to take snapshot of only event messages
- Identifies the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status
- Provides an option to measure sub-second time in digital or binary format

### 72.8.1 Delay request-response mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information. Figure 392 shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

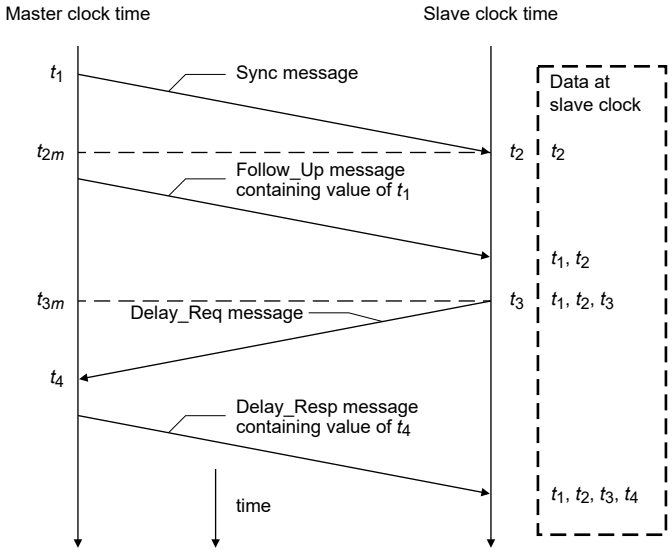

**Figure 392. Networked time synchronization**

As shown in the figure, PTP uses this process:

1. The master broadcast the PTP sync messages to all its nodes. The sync message contains the reference time information of the master. This message leaves the system of the master at t1. You must capture this time for Ethernet ports at GMII or MII.
2. The slave receives the sync message and it also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_Up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master and note the exact time, t3, at which this packet leaves the GMII or MII interface.
5. The master receives the message, capturing the exact time t4, at which the message enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave use the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the master's timing reference.

Most of the PTP implementation is done in the software above the Ethernet layer. However, the hardware captures the exact time when specific PTP packets enter into or leave the Ethernet port at the MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

### 72.8.2 Peer-to-peer PTP transparent clock (P2P TC) message support

The IEEE 1588-2008 supports the peer-to-peer PTP (Pdelay) message in addition to the sync, delay request, follow-up, and delay response messages. Figure 393 shows the method to calculate the propagation delay in clocks supporting the peer-to-peer path correction.

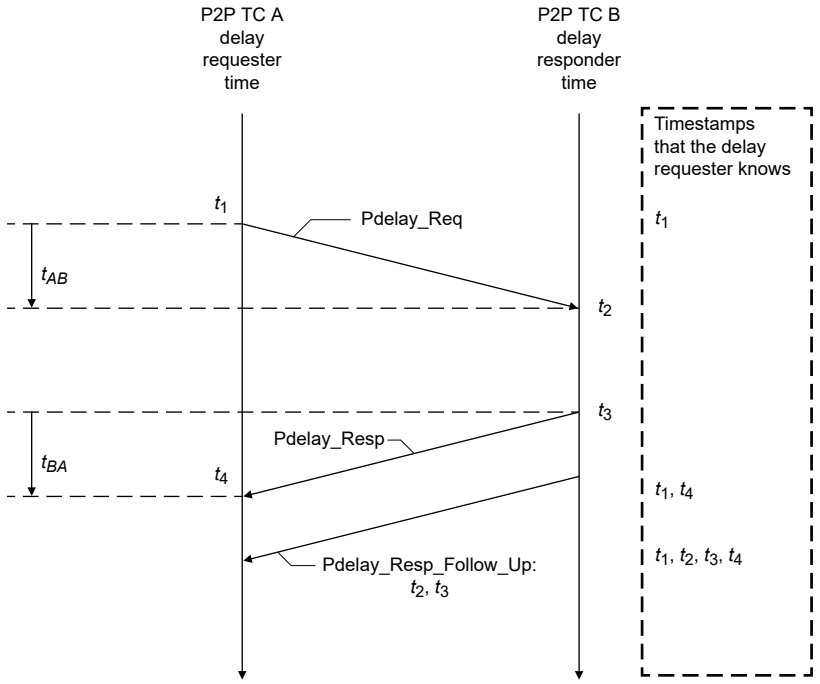

**Figure 393. Propagation delay calculation in clocks supporting peer-to-peer path correction**

As shown in the above figure, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives a Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message. Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message, to minimize the errors because of any frequency offset between the two ports. Port 2 returns any one of the following:
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp message
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
   - Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively
4. Port 1 generates a timestamp (t4) after receiving the Pdelay_Resp message.
5. Port 1 uses all the four timestamps t1, t2, t3, and t4 to compute the mean link delay.

### 72.8.3 Timestamp correction

According to the IEEE 1588 specification, you must capture a timestamp when the PTP message timestamp point (leading edge of the first bit of the octet immediately following the start frame delimiter octet) crosses the boundary between the node and the network. As MAC takes the timestamp at an internal point far from the actual boundary of the node and network, you must correct or update the captured timestamp for the ingress or egress path latency (including the delay in the PHY layers). Further correction

is done for the inaccuracies or errors introduced because the clock (MII Tx, Rx clock) is different at the capture point as compared to the PTP clock (CLK_PTP_REF_I) that generates the time. The resultant CDC (Clock domain crossing) circuits add an error depending on the clock period of the MII and PTP clocks.

#### 72.8.3.1 Ingress correction

The timestamp captured at the internal snapshot point In the receive side is delayed (later in time) as compared to the time at which the packet's SFD bit is received at the port's boundary. Therefore, the ingress latency and the errors in CDC sampling reduces the captured timestamp. You must determine or calculate the correction value and write into the MAC_Timestamp_Ingress_Corr_* registers.

The correction value consists of these three components:

1. External latency in the PHY layer between boundary point and the input of the core.

   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has a register which indicates the maximum and minimum ingress latency. You can read these registers and determines the average ingress latency in the PHY. Alternatively (if the PHY does not support these registers), you must determine the ingress latency from its datasheet or timing characteristics.

2. Internal latency from the core's input to the internal capture point.

   You can read the internal ingress latency from MAC_Timestamp_Ingress_Latency. This is a read-only register and provides the latency in scaled nanoseconds format as defined in IEEE 1588 Clause 5.3.2. The latency differs on the basis of the active PHY interface (MII, RMII, so on) and the operating speed. Therefore, you must read this register after any speed change in MAC, to determine the current internal latency.

3. CDC synchronization

   The CDC synchronization error is almost equal to twice the clock-period of the PTP clock (clk_pt-p_ref_i).

You must add the values that these three components determine and must write into the TSIC and TSICSNS fields of the MAC_Timestamp_Ingress_Corr_* registers.

**NOTE**

The value written into the register must be negative (two's complement as explained below), because it is subtracted from the captured timestamp. The MAC receiver adds the value in this register to the captured timestamp and then gives the resultant value as the timestamp of the received packet.

When MAC_Timestamp_Control[TSCTRLSSR] is 1, it indicates that the nanoseconds field of the captured timestamp is in decimal format with a granularity of 1ns. So the Bit31 of TSIC must be 1 (for negative value) and bits[30:0] must write with "10^9 - total ingress_correction_value[nanosecond part]" represented in binary. For example, if the required correction value is -5 ns, then the value is 0xBB9A_C9FB.

When MAC_Timestamp_Control[TSCTRLSSR] becomes 0, it indicates that the nanoseconds field of the captured timestamp is in binary format with a granularity of ~0.466ns. Therefore, bits[30:0] must write with "2^31 - total ingress_correction_value" represented in binary with bit[31] = 1.

#### 72.8.3.2 Egress correction

The timestamp captured at the internal snapshot point in the transmit side is earlier (advanced in time) as compared to the time at which the packet's SFD bit is output at the port's boundary. Therefore, the egress latency and the errors in CDC sampling must compensate the captured timestamp. You must determine or calculate this correction value and write into the MAC_Timestamp_Egress_Corr_* registers.

The correction value consists of these three components:

1. External latency in the PHY layer between the core output and the port and the network boundary

   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has a register which indicates the maximum and minimum egress latency. You can read these registers and determine the average egress latency in the PHY. Alternatively (if the PHY does not support these registers), you must determine the egress latency from its datasheet or timing characteristics.

2. Internal latency from the internal capture point and the core output of the c

   You can read this internal egress latency from MAC_Timestamp_Egress_Latency. This is a read-only register and gives the latency in scaled nanoseconds format as defined in IEEE 1588 Clause 5.3.2. The latency differs on the basis of the active PHY interface (MII, RMII, so on) and the operating speed. Therefore, you must read this register after any speed change in MAC to determine the current internal latency.

3. CDC synchronization error

   The CDC synchronization error value for one-step timestamping = (1 * period of CLK_PTP_REF_I + 4 * period of CLK_TX_I). Otherwise (Two-step timestamping mode), the value = -(2 * period of CLK_PTP_REF_I).

#### 72.8.3.3 Frequency range of reference timing clock

The timestamp information is transferred across asynchronous clock domains that is from the MAC clock domain to the application/system clock domain. Therefore, a minimum delay is required between the two consecutive timestamp captures. This delay is 4 clock cycles of MII and 3 clock cycles of PTP clocks. If the delay between the two captured timestamp is less than this delay, MAC does not take a timestamp snapshot for the second packet.

#### 72.8.3.4 PTP processing and control

Table 489 shows the common message header for the PTP messages. This format is defined in the IEEE 1588-2008.

**Table 489. Message format defined in IEEE 1588-2008**

| Bits | | | | | | | | Octet | Offset |
|---|---|---|---|---|---|---|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | |
| transportSpecific | | | | messageType | | | | 1 | 0 |
| Reserved | | | | versionPTP | | | | 1 | 1 |
| messageLength | | | | | | | | 2 | 2 |
| domainNumber | | | | | | | | 1 | 4 |
| Reserved | | | | | | | | 1 | 5 |
| flagField | | | | | | | | 2 | 6 |
| correctionField | | | | | | | | 8 | 8 |
| Reserved | | | | | | | | 4 | 16 |
| sourcePortIdentity | | | | | | | | 10 | 20 |
| sequenceId | | | | | | | | 2 | 30 |
| controlField (*) | | | | | | | | 1 | 32 |
| logMessageInterval | | | | | | | | 1 | 33 |

(*) – control Field is used in version 1. In version 2 message type field is used for detecting different message types.

There are some fields in the Ethernet payload that detects the PTP packet type and controls the snapshot to be taken. These fields are specified in Table 490 for PTP packets over Ethernet.

Following table provides the information about the fields that match to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and version 2. The octet positions are offset by 4 for the tagged packets. This is based on the IEEE 1588-2008, Annex D, and the message format.

**Table 490. Ethernet PTP packet fields required for control And status**

| Field matched | Octet position | Matched value | Description |
|---|---|---|---|
| MAC destination multicast address[1] | 0–5 | 01-1B-19-00-00-00<br>01-80-C2-00-00-0E | All PTP messages can use any of the following multicast addresses[2]:<br>• 01-1B-19-00-00-00<br>• 01-80-C2-00-00-0E[3] |
| MAC packet type | 12, 13 | 0x88F7 | PTP Ethernet packet |
| PTP control field<br>(IEEE 1588 version 1) | 46 | 0x00, 0x01, 0x02, 0x03, or 0x04 | • 0x00: SYNC<br>• 0x01: Delay_Req<br>• 0x02: Follow_Up<br>• 0x03: Delay_Resp<br>• 0x04: Management |
| PTP message type field (IEEE 1588 version 2) | 14 (nibble) | 0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD | • 0x0: SYNC<br>• 0x1: Delay_Req<br>• 0x2: Pdelay_Req<br>• 0x3: Pdelay_Resp<br>• 0x8: Follow_Up<br>• 0x9: Delay_Resp<br>• 0xA: Pdelay_Resp_Follow_Up<br>• 0xB: Announce<br>• 0xC: Signaling<br>• 0xD: Management |
| PTP version | 15 (nibble) | 0x1 or 0x2 | • 0x1: Supports PTP version 1<br>• 0x2: Supports PTP version 2 |

1. The unicast address match of destination addresses (DA), which is programmed in MAC address 0 to 31, is used if MAC_Timestamp_Control[TSENMACADDR] = 1.
2. IEEE 1588-2008, Annex F
3. MAC does not consider the PTP version 1 messages with peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

### 72.8.4 Transmit path functions

MAC captures a timestamp when the start packet delimiter (SFD) of a packet is sent on the MII interface. You can control the packets, for which the timestamps are captured on a per-packet basis and mark each transmit packet to indicate whether to capture a timestamp for it. MAC does not process the transmitted packets to identify the PTP packets. You can use the control bits in the transmit descriptor to specify the packets. MAC returns the timestamp to the software inside the corresponding transmit descriptor and therefore connects the timestamp automatically to the specific PTP packet. You must write the 64-bit timestamp information to TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

### 72.8.5 Receive path functions

You can program MAC to capture the timestamp of all packets received on the MII interface or to process the packets to identify the valid PTP messages.

You can use these options of MAC_Timestamp_Control to control the snapshot of the time sent to the application:

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type

**Table 491. Timestamp snapshot dependency on register bits**

| SNAPTYPSEL | TSMSTRENA | TSEVNTENA | PTP messages |
|---|---|---|---|
| 00 | x | 0 | SYNC, Follow_Up, Delay_Req, Delay_Resp |
| 00 | 0 | 1 | SYNC |
| 00 | 1 | 1 | Delay_Req |
| 01 | x | 0 | SYNC, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_Follow_Up |
| 01 | 0 | 1 | SYNC, Pdelay_Req, Pdelay_Resp |
| 01 | 1 | 1 | Delay_Req, Pdelay_Req, Pdelay_Resp |
| 10 | x | x | SYNC, Delay_Req |
| 11 | x | x | Pdelay_Req, Pdelay_Resp |

DMA returns the timestamp to the software inside the corresponding receive descriptor. The extended status, contains the timestamp message status and the IPC status. You must write the extended status in the normal descriptor RDES1 and the snapshot of the timestamp in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

See the System time correction for programming guidelines for IEEE 1588 timestamping (System time correction).

### 72.8.6 IEEE 1588 system time source

IP supports both the external and internal time source for reference timestamping.

- External time source uses the 64-bit external time reference and clock as an input in IP. The clock input synchronizes the external timing reference into the MAC clock domain. Upper 32-bit indicates the time in seconds and the lower 32-bit indicates the time in nanoseconds.
- Internal time source uses the only clock input to generate timing reference internally for snapshot and capture timestamps. Internal time reference has two fields.
  - UInteger48 seconds field: The seconds field is the integer portion of the timestamp in seconds units. It is 48-bit wide.

    For example, 2.000000001 seconds are represented as seconds field = 0x0000_0000_0002.

— UInteger32 nanoseconds field The nanoseconds field is the fractional portion of the timestamp in nanoseconds units.

For example, 2.000000001 seconds are represented as nanoseconds field = 0x0000_0001. The nanoseconds field supports the following two modes:

- Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds.
- Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after 0x7FFF_FFFF value . Accuracy is ~0.466 ns per bit.

There is a system time register module, it is used when you use an internal time reference. The 80-bit time is maintained in this module and updated using the input reference clock (CLK_PTP_REF_I). This time is the source for taking snapshots (timestamps) of Ethernet packets which is transmitted or received at the MII interface.

Initialize or correct the system time counter using the coarse correction method. In this method, write the initial value or the offset value to the timestamp update register. For initialization, write the system time counter with the value in the timestamp update register. For system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, correct the frequency offset and/or frequency drift of a slave clock (CLK_PTP_REF_I) with respect to the master clock (as defined in IEEE 1588-2002) over a period of time instead of in one clock, as in coarse correction. This maintains linear time and does not introduce drastic changes (or a large jitter) in the reference time between the PTP sync message intervals.

See Initialization guidelines for system time generation for programming guidelines for IEEE 1588 timestamping (For internal timestamp source configuration).

### 72.8.7 IEEE 1588 higher word register

You can invoke the higher word register if system time source is internal. MAC timestamp is 64-bit wide. The values of the upper 16-bits of the seconds field are read from the CSR register.

### 72.8.8 Flexible pulse-per-second output

IP supports the flexibility of programming the start or stop time, generates pulse width and interval on pulse-per-second output. It also support four such output signals. By default, IP is in fixed pulse-per-second output mode with interval of 1 second.

Initially you must program the start time in target time registers "MAC_PPSx_Target_Time_Seconds and MAC_PPSx_Target_Time_Nanoseconds" for all desired or enabled pps output. If you re-programs start or stop time then you must do it after the synchronization of earlier programmed value. Bit 31 of MAC_PPS#_Target_Time_Nanoseconds register indicates that the synchronization is complete. If the application programs a start or stop time that has already elapsed, MAC sets an error status bit which indicates the programming error. If enabled, MAC also sets the target time reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

Program the PPS width and interval in terms of granularity of system time, that is, the number of units of sub-second increment value.

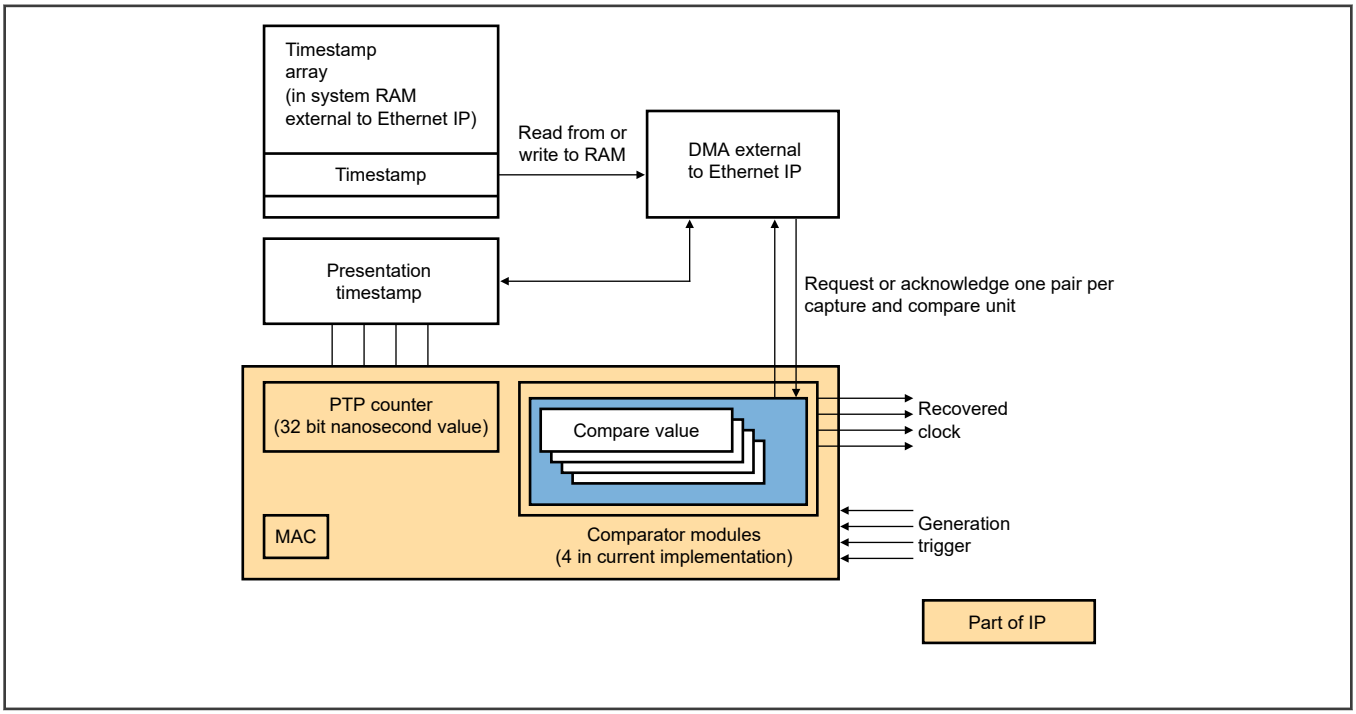
See Programming guidelines for flexible pulse-per-second output for more information.

### 72.8.9 Media clock generation and recovery

Media clock recovery and generation requires a dedicated hardware and software to complete the operation. IP generates a reference clock with the help of a dedicated hardware which multiplies to get the desired media clock. Software extracts the presentation time from the incoming PTP 1722 frames and program these values into CSR registers so that IP can read them for media clock recovery.

Figure 394 shows that the timestamp array and the DMA module are external to IP. IP supports a 32-bit presentation time counter in nanoseconds that completes at the full 32-bit value to match with 1722 presentation time format and an handshake mechanism with an external application (such as DMA) to program the presentation time into CSR register.

**Figure 394. Media clock generation and recovery block diagram**



### 72.8.9.1 Presentation time counter

Presentation time counter provides an another perspective of the PTP system time (1588 timer). For a given PTP system time (PTP[63:32] represents time in seconds Comparator modules and PTP[31:0] represents time in nanoseconds), there exists a corresponding presentation time (32-bit value in nanosecond). The presentation time computed is referred to as current presentation time (CPT).

CPT derives from 64-bit PTP system time. PTPNS[63:0] = (PTP[63:32] * 32'd1,000,000,000) + PTP[31:0] where, PTPNS is the PTP system time converted into a 64-bit nanosecond value.

Current presentation time[31:0] = PTPNS[31:0]

Media clock recovery is possible when the system time is internally generated in IP and compute the CPT in the same way as the internal PTP system time generation. The increment cycle of CPT and system time are same because the values of both the timers are in nanoseconds and they are synchronous. The timer updates at the same instance, but the updated value could be different. You must compute a separate 32-bit update value in nanoseconds for the CPT update. CPT sampled at different edges of a triggering input generates media clock timestamps that are inserted in 1722 based AVBTP packets, to recover the clock at the destination.

### 72.8.9.2 Comparator modules

Figure 394 shows that the module supports four comparator modules to handle multiple media clocks that it may require. When MAC_Timestamp_Control[PTGE] is 1, it indicates that the comparator modules handshake with the application to program the timestamps into the MAC_PPS(#i)_Target_Time_Seconds register.

Write 1 to presentation time control fields of the particular instance for recovery mode.

The timestamps received from the application are referred as target presentation time (TPT).

When MCGREN#i field of MAC_PPS_Control is 1, it indicates that the IP operates in MCGR mode. The comparator module sends up to two requests to the application for TPT write, when MAC_Timestamp_Control[PTGE] and the presentation time control bits of the particular instance are 1 for MCGR mode. Subsequent requests are generated each time a presentation time match occurs. CPT transitions from a value less than TPT, to a value greater than or equal to CPT. The first request asserts when a specific comparator instance sets to MCGR mode with a non-zero presentation time control and an additional request is made when the comparator receives the first data. This allows the application to write the next TPT value when IP processes the previous TPT value for a match.

TPT read from the MAC_PPS(#i)_Target_Time_Second is considered as a future time. A toggle or pulse is generated in the next cycle when a match is detected. Also,the mcgr_dma_req_o#i request for that comparator asserts (to obtain next TPT) until the corresponding application acknowledgment is set, when a match is detected.

The presentation control fields (PPSCMD#i field of MAC_PPS_Control) determine the shape of the generated waveform. You can program these fields to either toggle or generate a high/low pulse for one PTP clock cycle, when matched.

**Media clock recovery:** A match occurs, when the free-running CPT value matches the received TPT value. An output signal, EMAC_TMR signal as shown in the IO mux sheet asserts (toggle, low pulse, or high pulse) on the basis of the programmed presentation control value.

**Media clock generation**: On the basis of the presentation control value programmed in MAC_PPS_Control, the particular comparator captures the presentation time and programs it into MAC_PPS(#i)_Target_Time_Second register. The captured timestamp is read when a request is raised to the application. No new timestamps are captured, until the read operation is complete acknowledgment is received from the application.

### 72.8.9.3 Media clock generation and recovery flow

Figure 395 shows the media clock generation and recovery flow. Write 1 to MAC_Timestamp_Control[PTGE] for CPT generation and write 1 to MAC_PPS_Control MCGREN#i field to enable the corresponding instance in the MCGR mode, for both media clock generation and recovery.

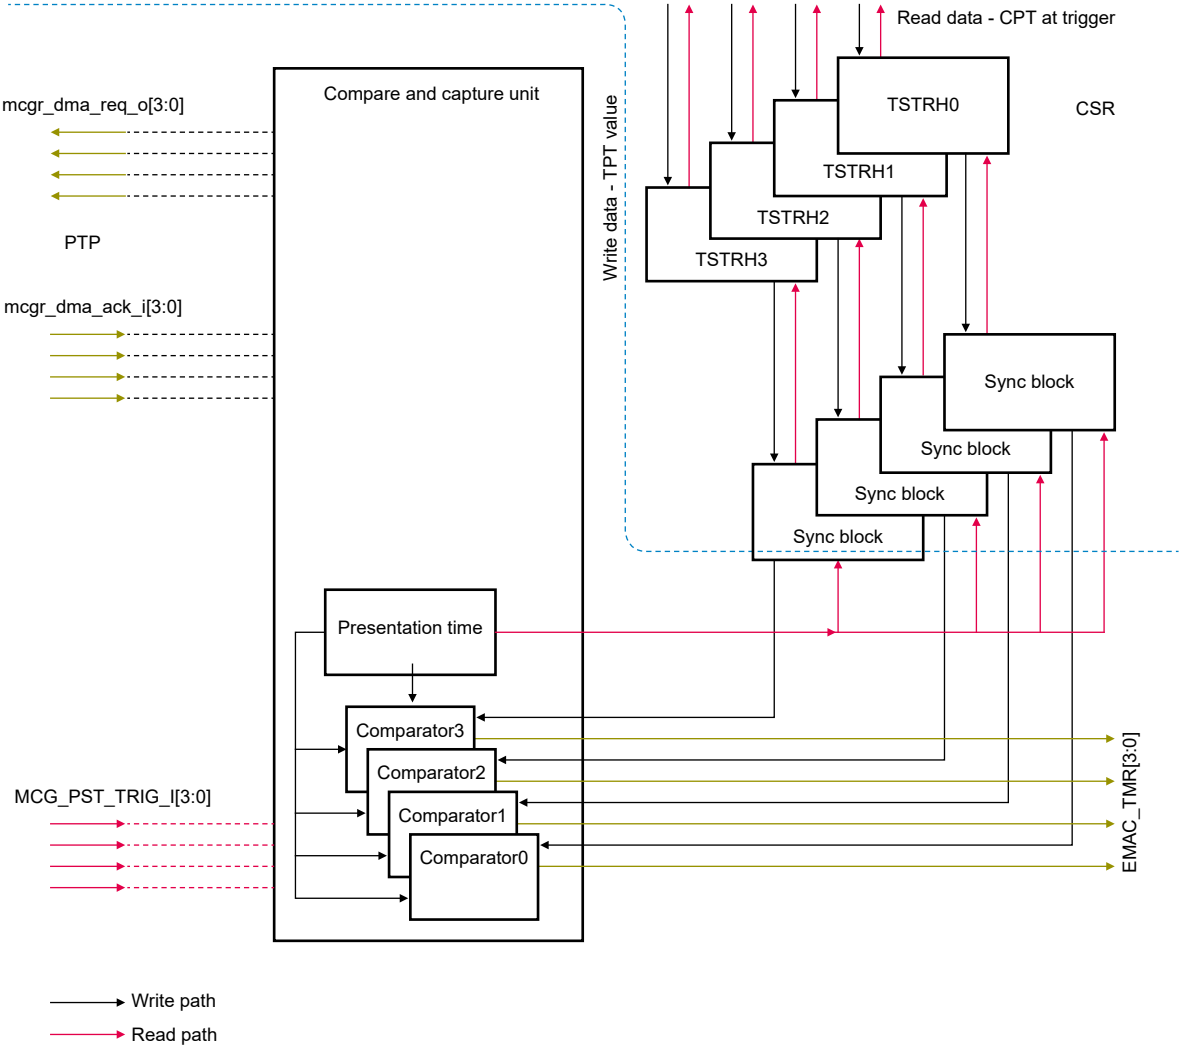


Figure 395. Media clock generation and recovery flow

**NOTE**

1. The consecutive triggers to sample the presentation time must assert after a few PTP clock cycles so as to allow synchronization delays. (There is no such issue when the input trigger maximum frequency is 8 KHz and the PTP clock runs at least at 1MHz)
2. In the Media Clock Recovery mode, the DMA acknowledgment is both posted as well as non-posted.

See Programming guidelines for media clock generation and recovery for more information.

### 72.8.10 One step timestamp

IP supports the one step timestamp feature. Writing 1 to bit 20 (OSTC) in the control word, enables the one step timestamp feature for a packet.

See the Programming guidelines for IEEE 1588 timestamping for more information.

### 72.8.11 IEEE 1588 sub nanoseconds timestamp

IP supports the ingress and egress correction accuracy in sub nanoseconds. It is programmed in MAC_Timestamp_Ingress_Corr_Subnanosec[TSICSNS] and MAC_Timestamp_Egress_Corr_Subnanosec[TSECSNS],

respectively. In this case, the correction has an unit of nanosecond, multiplied by 2^8. You must program the least significant 8 bits of the value in the sub-nanoseconds register.

For example, if the required egress correction is 3.6 nS and MAC_Timestamp_Control[TSCTRLSSR] is 1, then MAC_Timestamp_Egress_Corr_Nanosecond[TSEC] must be 0x3 and MAC_Timestamp_Egress_Corr_Subnanosec[TSECSNS] must be 0x99 (0.6 * 256). Similarly, if the required ingress correction is -3.6 nS and MAC_Timestamp_Control[TSCTRLSSR] is 1, then MAC_Timestamp_Ingress_Corr_Nanosecond[TSIC] must be 0xBB9A_C9FC and MAC_Timestamp_Ingress_Corr_Subnanosec[TSICSNS] must be 0x66 (fractional part of (10^9 - 3.6) * 256).

## 72.9 Multiple channels and queues support

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

IP support two queues and channel on Tx and Rx paths. Figure 396 shows the architecture of IP with two queues and channel.

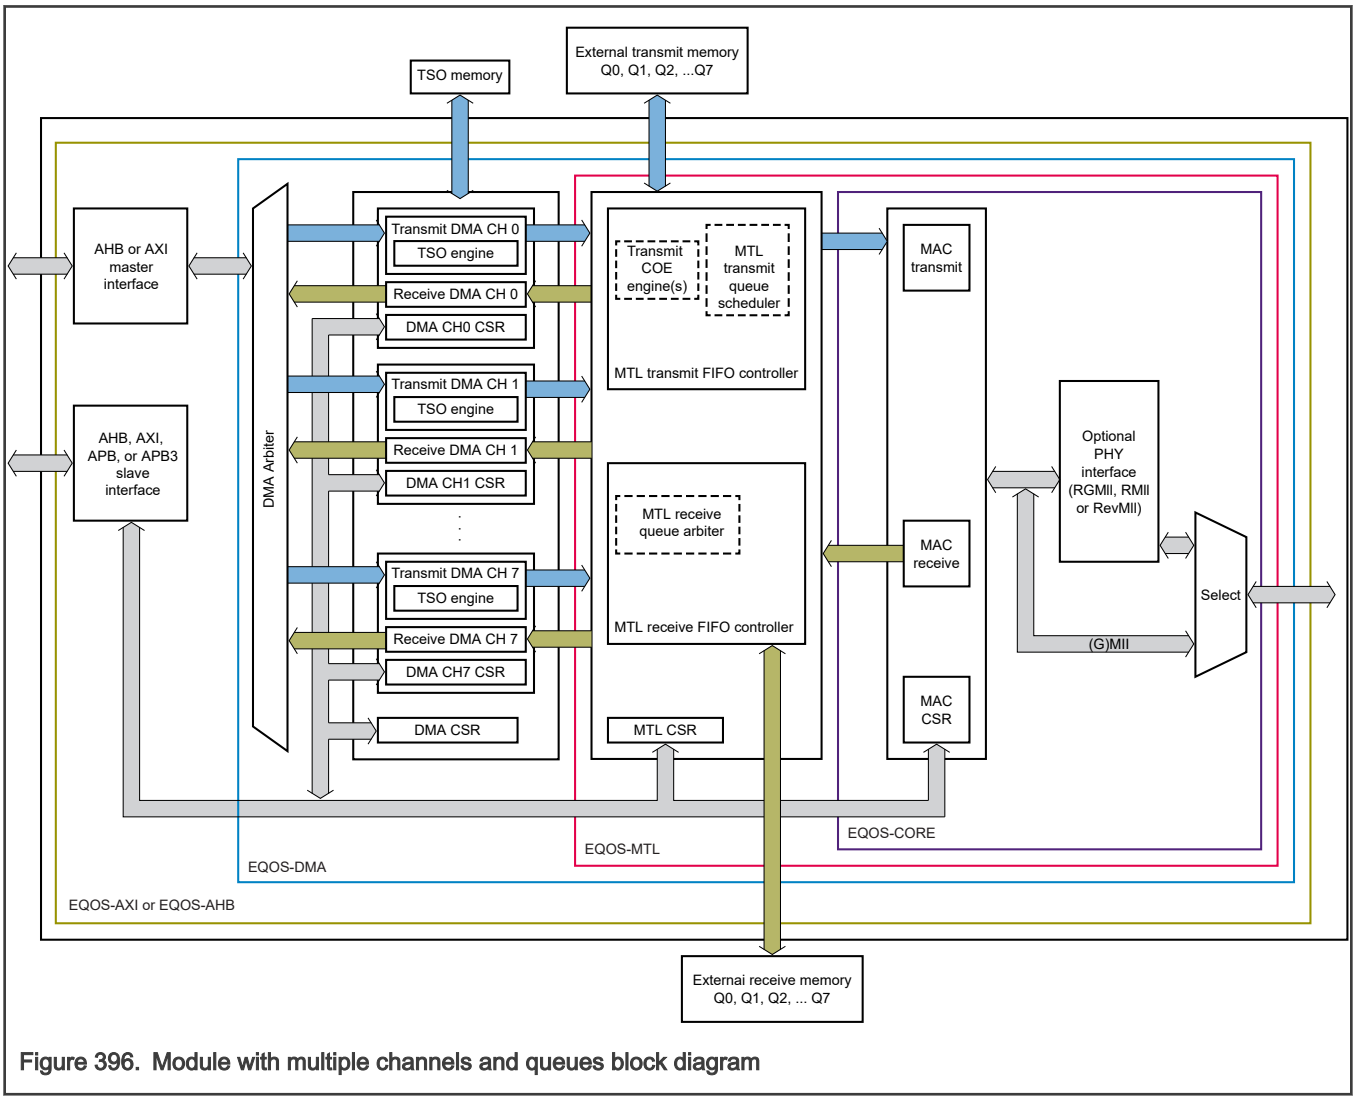

**Figure 396. Module with multiple channels and queues block diagram**

The above block diagram, support only two queues.

IP DMA arbiter support two types of arbitration scheme, fixed priority and weighted round-robin. The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels to access descriptors and data buffers. DMA_Mode[DA] specifies the arbitration scheme (fixed or weighted round-robin) between the channel Tx and Rx DMA.

DMA_Mode[TXPR] sets the priority between the corresponding Tx DMA and Rx DMA. Writing 1 to DMA_Mode[PR] specifies the weighted priority between the Tx DMA and Rx DMA in round robin arbitration scheme.

Table 492 provides an information about the priority scheme between Tx DMA and Rx DMA.

**Table 492. Priority scheme for Tx DMA and Rx DMA**

| Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Priority schemes |
|---|---|---|---|---|---|
| x | x | x | 0 | 1 | Rx always has priority over Tx |
| 0 | 0 | 0 | 0 | 0 | Tx and Rx have equal priority. Rx gets the access first on simultaneous requests |
| 0 | 0 | 1 | 0 | 0 | Rx has priority over Tx in ratio 2:1 |
| 0 | 1 | 0 | 0 | 0 | Rx has priority over Tx in ratio 3:1 |
| 0 | 1 | 1 | 0 | 0 | Rx has priority over Tx in ratio 4:1 |
| 1 | 0 | 0 | 0 | 0 | Rx has priority over Tx in ratio 5:1 |
| 1 | 0 | 1 | 0 | 0 | Rx has priority over Tx in ratio 6:1 |
| 1 | 1 | 0 | 0 | 0 | Rx has priority over Tx in ratio 7:1 |
| 1 | 1 | 1 | 0 | 0 | Rx has priority over Tx in ratio 8:1 |
| x | x | x | 1 | 1 | Tx always has priority over Rx |
| 0 | 0 | 0 | 1 | 0 | Tx and Rx have equal priority. Tx gets the access first on simultaneous requests |
| 0 | 0 | 1 | 1 | 0 | Tx has priority over Rx in ratio 2:1 |
| 0 | 1 | 0 | 1 | 0 | Tx has priority over Rx in ratio 3:1 |
| 0 | 1 | 1 | 1 | 0 | Tx has priority over Rx in ratio 4:1 |
| 1 | 0 | 0 | 1 | 0 | Tx has priority over Rx in ratio 5:1 |
| 1 | 0 | 1 | 1 | 0 | Tx has priority over Rx in ratio 6:1 |
| 1 | 1 | 0 | 1 | 0 | Tx has priority over Rx in ratio 7:1 |
| 1 | 1 | 1 | 1 | 0 | Tx has priority over Rx in ratio 8:1 |

### 72.9.1 Multiple queues and channels support in the transmit path

IP support two transmit queues and two channels.

Fixed priority scheme is the default priority scheme for the DMA channels and channel with highest priority always wins the arbitration when it requests for the bus. Channel 0 is always of lowest priority and channel 1 is always of highest priority.

In weighted strict priority (WSP), the weight corresponds to the number of burst transfers given to a channel in one arbitration cycle. Reallocate the unused burst transfers of one or more channels on the basis of the priority. The channel with highest priority receives the unused burst transfer time before it is allocated to a channel with the next highest priority. You can process the next lower priority, when a channel uses the allocated burst transfers. After processing the allocated bandwidth of all the channels that have packets to transmit, allocate any unused burst transfer time to the channel of the highest priority (if required), and then next highest priority (if required), and so on.

In weighted round robin (WRR) priority scheme, program the weight through TCW field of DMA_CH#_Tx_Control register. IN WRR scheme, service all channels in round-robin order according to the weights settings. Table 493 shows that the TCW field of DMA_CH#_Tx_Control register provides the weight for each transmit channel.

**Table 493. Weight for DMA channels**

| TCW Field | Transmit Channel Weight |
|---|---|
| 000 | 1 |
| 001 | 2 |
| 010 | 3 |
| 011 | 4 |
| 100 | 5 |
| 101 | 6 |
| 110 | 7 |
| 111 | 8 |

The configured weights correspond to the number of burst transfers given to a channel in one arbitration cycle. The unused or excess burst transfers are distributed equally to all channels.

See Programming guidelines for multi-channel multi-queuing for more information.

### 72.9.2 Multiple queues and channels support in the receive path

IP support two receive channels and two queues.

In the receive direction, the MTL Rx controller selects the Rx DMA for which it transfers or reads the data from the receive FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that it will transfer. The scheduler checks whether sufficient data (of requested burst length) is available to transfer to these DMAs and then selects the receive DMA that is serviced using the programmed priorities.

See Programming guidelines for multi-channel multi-queuing for more information.

### 72.9.3 Rx queue to DMA mapping

You can program MTL_RxQ_DMA_Map0 (for queues 0 and 1) to route the packets in the MTL receive queues to any one of the multiple DMA channels.

The following types of receive queue to DMA mapping is possible through programming.

#### 72.9.3.1 Static mapping

In this mode, you can connect all the packets of the receive queue to a specific DMA channel. For example, all the packets from the receive queue 0 program MTL_RxQ_DMA_Map0[Q0MDMACH] (bit[3:0]) and MTL_RxQ_DMA_Map0[Q0DDMACH] (bit[7] = 0) to route to a DMA channel.

Similarly, packets from other receive queues program register fields corresponding to each queue to route to any DMA channel.

#### 72.9.3.2 Dynamic (per packet) mapping

In this mode, the destination DMA channel of a packet read from a Rx queue is not constant but it is decided independently for each packet. For example, if you write 1 to MTL_RxQ_DMA_Map0[Q1DDMACH], it indicates that the static mapping disables for receive queue 1 and ignores the value in MTL_RxQ_DMA_Map0[Q1MDMACH]. The MAC receiver decides the destination DMA channel for each packet, depending on the following in decreasing order of priority:

1. **L3-L4 filter based DMA selection**: The TCP/UDP and IP header fields of the received packet are matched against the corresponding values programmed and enabled for comparison in the MAC_L3_L4_Address_Control register. If the match is successful, the DMA channel number programmed in the DMCHN field of the MAC_L3_L4_Address_Control register is selected as the destination DMA channel number, if DMCHEN field of the same register is 1. If none of the L3-L4 registers give a comparison match, then the module proceeds to the next step below.
2. **Extended VLAN based DMA selection**: Extended routing is applicable only if the VLAN filter has passed. Routing is done only on the basis of the perfect filter result. Each perfect filter has a DMA channel enable and a DMA channel number field which you can program. Routing is applicable for a filter, only if the DMA channel enable field is 1. The frame routes to the smallest matching filter's DMA channel, if it is enabled. If the filter's DMA channel number is not enabled, the frame route to channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1, then the MAC checks if DMA channel number of filter 1 is enabled through programming. If yes, the frame route to the programmed value; otherwise it route to DMA. When the inverse filter is enabled; is routed to the least mismatched filter's DMA channel number provided it is enabled. If the DMA Channel enable bit is not set, then the frame routes on the basis of the DA based addressing or to channel 0.

   If hash filter is also enabled, it is determines the filter result only. Routing will still depends on the enabled perfect filters. Routing based on the VLAN filter will not occur if none of the perfect filters are enabled or if all of them are bypassed. The frame will route via DA based addressing or to channel 0. If all the perfect filters fails and the hash filter has passed, then the VLAN filter result is a pass but routing will be based on DA based addressing or to channel 0. Similar behavior is seen when you enables inverse filtering as well.
3. **Ethernet DA-based DMA selection**: The DA address of the received packet is compared against the programmed DA values in MAC address registers. If the address matches any of the programmed values, the corresponding DCS field (when enabled) determines the destination DMA channel number.

If none of the above operations make a successful match or decision, then the packet routes to the DMA channel 0 by default.

##### 72.9.3.2.1 Broadcast/multicast packet duplication

This feature provides a mechanism to send the received broadcast or multicast packets to multiple DMA channels.

MAC_Address0_High[DCS] and other optional MAC_Address(#i)_High (i=1 to 2) registers determines the DMA channel number to which the received packet (that matches the MAC address present in that register) must route.

DMA channel routing mechanisms such as extended VLAN, or L3-L4 based routing does not support the packet duplication.

The packet duplication feature is supported only on the highest MTL queue configured. Therefore, you must program MAC_RxQ_Ctrl1[MCBCQ] to the highest RxQ present in the configuration for the packet duplication for broadcast or multicast packets.

### 72.9.4 Selection of tag priorities assigned to receive queues

Program the PSRQ field in the corresponding MAC_RxQ_Ctrl2 to assign the VLAN tag priorities to receive queues. The bit corresponding to the VLAN tag priority can be set in the PSRQ field for assigning that priority to the receive queue. For example, if you want to assign VLAN tag priority of 3 to receive queue 0, write 1 to bit [3] in PSRQ field of MAC_RxQ_Ctrl2. The VLAN tag priority assigned to particular receive queue must be unique, that is, you cannot assign more than one receive queue to the same VLAN tag priority. However, more than one VLAN tag priorities can be assigned to same receive queue.

The settings in the PSRQ field is used for VLAN tagged receive packet routing to receive queues as well as for PFC based transit flow control. The received VLAN tagged receive packet route to receive queue that has the VLAN tag priority match. In PFC based transit flow control, PSRQ field corresponding to a particular receive queue enables VLAN tag priorities in the PFC packet transmitted when corresponding receive queue reach the threshold level.

### 72.9.5 Receive side routing from MAC to queues

IP supports receive side routing from MAC to queues. MAC route the receive packets to the receive queues on the basis of the these packet types in that order

- Unicast/Multicast destination address packets that fail the destination address filter
- Multicast/Broadcast destination address packets that pass the destination address filter
- VLAN tag priority field in VLAN tagged AV data packets
- AV control packets
- VLAN tagged IEEE 1588 PTP over Ethernet packets
- Untagged IEEE1588 PTP over Ethernet packets
- VLAN tag priority field in VLAN tagged packets
- Untagged packets

You can route the outer C-VLAN tagged AV data receive packets on the basis of the priorities assigned to receive queues through PSRQ field in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 and the corresponding receive queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0. These packets may be single VLAN tagged with C-VLAN type or double VLAN tagged with outer VLAN tag of C-VLAN type when double VLAN feature enables (MAC_VLAN_Tag_Ctrl[EDVLP] = 1) with an inner C-VLAN tagged or inner S-VLAN tagged when SVLAN processing is enabled (MAC_VLAN_Tag_Ctrl[ESVL] = 1). This type of Rx packet routing is available when you select the AV feature and multiple receive queues in the configuration.

You can route the AV control receive packets on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[AVCPQ] and the corresponding receive queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0. These packets may be single VLAN tagged with C-VLAN type or double VLAN tagged with outer VLAN tag of C-VLAN type when double VLAN feature is enabled (MAC_VLAN_Tag_Ctrl[EDVLP] = 1) with inner C-VLAN tagged or inner S-VLAN tagged when SVLAN processing is enabled (MAC_VLAN_Tag_Ctrl[ESVL] = 1). This type of receive packet routing is available when you select the AV feature and multiple receive queues in the configuration.

You can route the VLAN tagged receive packets on the basis of the priorities assigned to receive queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 and RXQ#EN field in MAC_RxQ_Ctrl0 enables the corresponding receive queue for DCB/generic. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

You can route the untagged IEEE 1588 PTP over Ethernet receive packets on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[PTPQ] and the corresponding receive queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0. Also, you can route the VLAN tagged IEEE 1588 PTP over Ethernet receive packets on the basis of the priorities assigned to receive queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 or the receive queue number specified in the MAC_RxQ_Ctrl1[PTPQ] and RXQ#EN field in MAC_RxQ_Ctrl0 register enables the corresponding Rx queue. Programming MAC_RxQ_Ctrl1[TPQC] determines this. This type of receive packet routing is available when IEEE 1588 timestamp feature supports and the multiple receive queues are selected in the configuration. The VLAN tagged IEEE 1588 PTP over Ethernet receive packets are detected only when you disables 802.1AS mode (MAC_Timestamp_Control[AV8021ASMEN] = 0), otherwise this type of receive packets are routed as generic VLAN tagged Rx packets.

You can route the multicast or broadcast destination address receive packets that passes the destination address filter on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[MCBCQ]the MCBCQ field of MAC_RxQ_Ctrl1 register when enabled through MAC_RxQ_Ctrl1[MCBCQEN] and the corresponding receive queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0. This type of Rx packet routing is available when you select the multiple receive queues in the configuration.

You can route the untagged receive packets on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[UPQ] and RXQ#EN field in MAC_RxQ_Ctrl0 enables the corresponding receive queue. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

The unicast destination address receive packets that fail the destination address filter can be routed based on the receive queue number specified in MAC_RxQ_Ctrl4[UFFQ] when enabled through MAC_RxQ_Ctrl4[UFFQE]UFFQE, MAC_Packet_Filter[RA] = 1 and the corresponding receive queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

You can route the multicast destination address receive packets that fails the destination address filter on the basis of the receive queue number specified in MAC_RxQ_Ctrl4[MFFQ] when MAC_RxQ_Ctrl4[MFFQE] enables it. MAC_Packet_Filter[RA] = 1 and RXQ#EN field in MAC_RxQ_Ctrl0 enables the corresponding receive queue. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

The receive packet will route through the receive queue 0, if it is not classified in any of the defined packet type for routing.

### 72.9.6 Receive side arbitration between DMA and MTL

IP controller supports receive side arbitration between DMA and MTL.

After the current packet processing completes, the DMA channel controller fetches the next descriptor and after the descriptor fetching completes, the DMA channel controller evaluates the amount of data to transfer to the Rx buffer on the basis of the programmed PBL and receive buffer length. Accordingly, it requests the MTL to transfer the data.

After servicing the current request, the MTL receive queue arbitration scheme selects receive queue on the basis of the arbitration scheme (MTL_Operation_Mode[RAA]) and the weights programmed in queue <n> receive control register. The arbitration is done among queues for which DMA is ready to service. After the receive queue is selected, PBL amount of data is read out from that queue and route to the receive DMA channel on the basis of the receive channel selection criteria.

The arbitration occur after every PBL data transfer completes and descriptors are ready for processing from at least one DMA channel.

### 72.9.7 Transit side arbitration between DMA and MTL

IP supports transit side arbitration between DMA and MTL. Transit DMA channels and transit queues are always mapped directly because the number of transit DMA channels are always equal to the number of transit queues in MTL. For instance, each transit DMA pushes data into its respective transit queue assigned to it.

The data inside each transit queue is stored in packets. Therefore, if two DMAs are allowed to transfer data into the same queue, when a transit DMA starts a packet transfer, the other DMA cannot transfer data unless the previous packet is completely pushed-in. This means that the second DMA remains idle until the first packet is transferred. Hence, each DMA is always connected directly to its corresponding transit queue.

### 72.9.8 Audio video bridging

IP supports the audio video bridging in 100 Mbps mode only, which allows the transmission of time sensitive traffic over network. IP implements these protocol for supporting the AVB feature:

- IEEE 802.1Qbv-2015 (Enhancements to scheduling traffic)
- IEEE 802.3br (Interspersing traffic)
- IEEE 802.1Qbu (Frame preemption)

The queue 0 transmit path supports the strict priority algorithm, and it is used for best-effort traffic when transmit paths of additional queues use the credit-based shaper algorithm to support traffic management. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if these conditions are true:

- The queue contains one or more packets.
- The credit for the queue is positive per the algorithm
- AV traffic is received on all queues. IP can also receive untagged PTP packets in addition to AV traffic on any queue.

### 72.9.9 Queue modes

Transit and receive queues both handles the AV traffic.

Queueing is based on WRR (Weighted round robin) or WSP (Weighted strict priority) algorithm for generic traffic. It is based on CBS (Credit Base Shaper) and SP (Strict Priority) algorithm for AV traffic.

The receive queue is configured for generic or AV based routing, which depends on the RXQ#EN field of corresponding queue. Queueing is done on the basis of the VLAN tag priority. The VLAN tag priority must match the PSRQ field of MAC_RxQ_Ctrl2. The receive packets can route to a particular DMA channel on the basis of the DCS field of perfectly-matched MAC address register.

By default, the untagged packets in a generic traffic route to the receive queue specified in MAC_RxQ_Ctrl1[UPQ]. Queue 0 is the default value of MAC_RxQ_Ctrl1[UPQ]. You can override the default value with any other value, for the MAC_RxQ_Ctrl1[UPQ].

The AV control packets (tagged or untagged) route on the basis of MAC_RxQ_Ctrl1[AVCPQ]. The PTP over Ethernet packets route on the basis of MAC_RxQ_Ctrl1[PTPQ].

### 72.9.10 Queue priorities

You can program the priority of an receive queue in the corresponding field of MAC_RxQ_Ctrl2. Also, you must program the AV queue (high priority) as an higher priority than the best-effort queue (low priority).

### 72.9.11 Enhancements to scheduled traffic (EST)

The IEEE 802.1Qbv-2015 defines the schedule for each queues on every egress port which makes the implementation aware of traffic arrival schedule. This information blocks the lower priority traffic from transmission in this time window or slot. This ensures that the sender forward the scheduled traffic to receiver through all the network nodes with a deterministic delay.

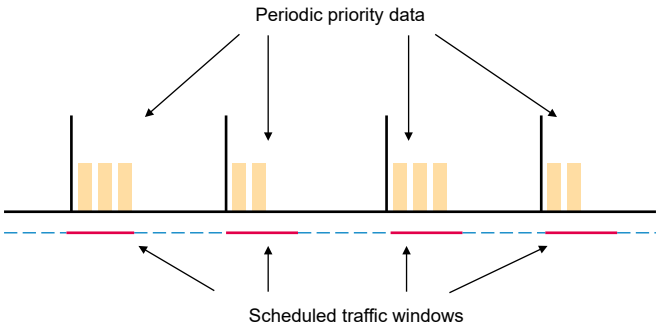

**Figure 397. Time aware shaper implementation for traffic scheduling**

An important requirement to achieve a low latency is to ensure that there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations when a transmission starts.

As shown in Figure 398 , if an interfering frame begins transmission just before the reserved time period starts, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

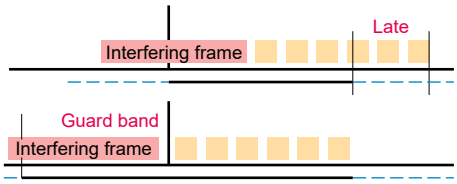

**Figure 398. Implementing a guard band to avoid delays due to interfering frames**

A larger guard band equates to a less efficient use of network bandwidth. However, this issue is addressed with the implementation of IEEE802.1Qbu (frame preemption). Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band must be as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

#### 72.9.11.1 Frequently used terms in EST

These are some of the frequently used terms in the EST support and their definitions.

- Gate control list: The list in the hardware memory that hold the gate controls and the associated time intervals.
- Gate controls: For a given schedule (row in gate control list) there is a gate open (O) and gate close (C) state associated with each TC. The set of O or C values, whose width is same as configured TCs is called the gate controls. Example: CCOCOOCO means TC7=C, TC6=C, TC5=O and so on.
- Time interval: Time interval (in nanoseconds) is a 16, 20, or 24-bit configurable field in the gate control list that indicates the time for which the associated gate controls are valid.
- Base time register: Each gate control list is associated with a 64-bit base time register that holds the start time (in PTP format) for the list.

#### 72.9.11.2 Updates to the transmit scheduling to support EST

To support EST, these updates are required to transmit scheduling:

- Implementation of gate control list (GCL)
- Enforcing gate controls in the scheduler
- Utilizing gate open (O) duty cycle in the computation of idleSlope (CBS)

##### 72.9.11.2.1 Implementation of gate control list (GCL)

Figure 399 shows how the gate control list governs the gate close(C) and open(O) events on the basis of the schedule provided for each event. GCL has two parts:

- Time interval: Defines the time in nanoseconds for which the gate controls are valid and must apply before reading the next gate controls from the list. The configurable width of 16, 20 or 24-bit represents a maximum of 64us, 1ms, or 16ms schedule interval respectively. It supports left shift of the time interval up to 7 bits to be able to apply a multiplication factor from 1 to 128ns (in steps of 2(power)n). The maximum value (post shifting) of this field must be 999,999,999 ns.
- Gate control: Defines the open (O) represented by logic 1 or close (C) represented by logic 0 state for the gate of each TC.

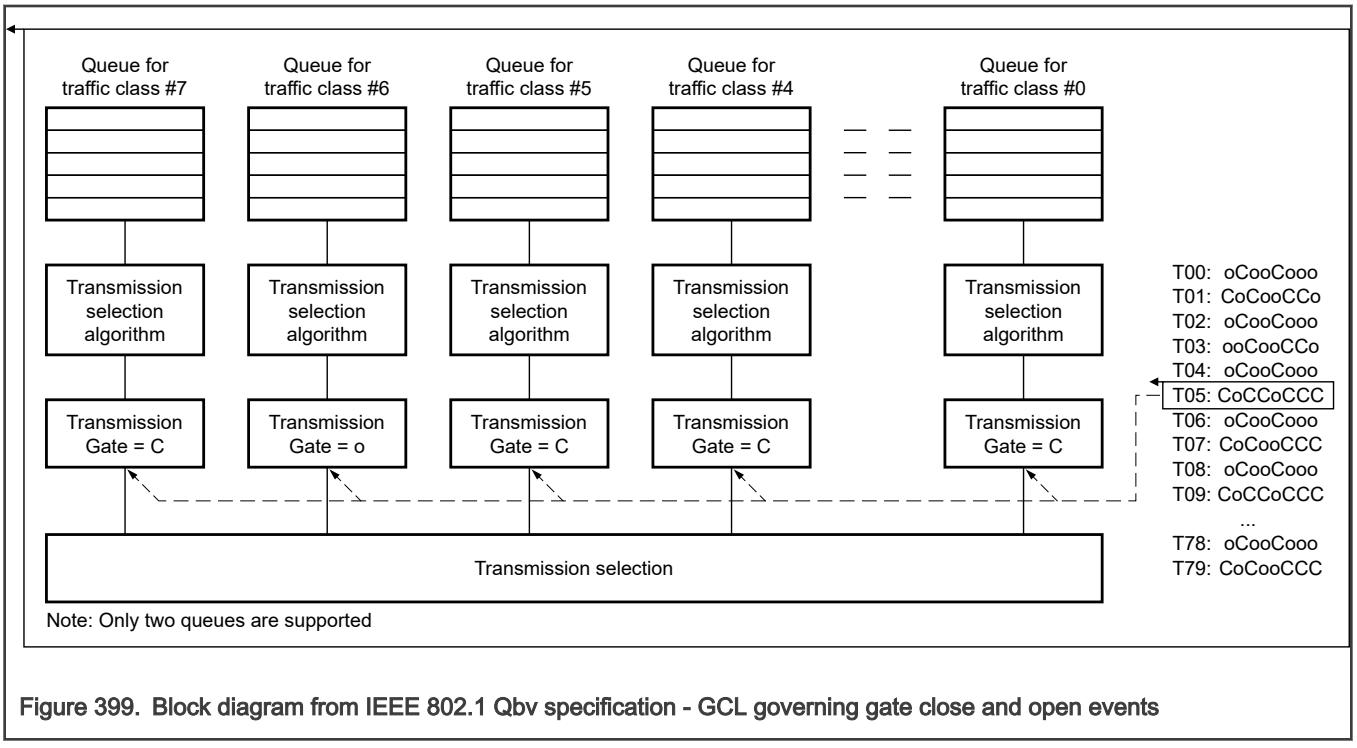

**Figure 399. Block diagram from IEEE 802.1 Qbv specification - GCL governing gate close and open events**

The implementation of GCL consists of these two gate control lists:

- HWOL - Hardware owned list which is a list for hardware access.
- SWOL - Software owned list which is a list for software access.

The access to these lists is mutually exclusive. Hardware sets the ownership to the list in MTL_EST_Status[SWOL]. Table 494 provides the implementation details of GCL.

**Table 494. External memory used for holding the two gate-control lists**

| Gate control (up to 8 bits) | Time interval (ns) 16, 20, or 24 bits | |
|---|---|---|
| OOCCCCCC | T0 | HWOL or SWOL |
| OOOOCCCC | T1 | |
| CCCCOOCC | T2 | |
| CCCCCCOO | T3 | |
| I | I | |
| I | I | |
| OCOCOCOO | | |
| OOOOCCCC | T last | |
| OOOOCCCC | T0 | SWOL or HWOL |
| OOOOCCCC | T1 | |
| OOCCCCCC | T2 | |
| OOOOCCCC | T3 | |
| I | I | |
| I | I | |
| OCOCCCCC | | |
| OOCCCCCC | T last | |

### 72.9.11.2.2 Registers related to gate control list

The following are the set of four registers (one for each GCL) related to GCL. These registers are implemented through Indirect addressing using MTL_EST_GCL_Control and MTL_EST_GCL_Data registers.

1. 64-bit Base time register (BTR)

2. 40-bit Cycle time register (CTR)

3. m-bit Time extension register (TER)

4. n-bit [Gate control] List length register (LLR) (n depends of the configured GCL depth)

#### 72.9.11.2.2.1 Base time register (BTR)

This is a 64-bit register that specifies the start time to execute the GCL. The format of the BTR is same as the PTP format (upper 32-bits holds time in seconds and lower 32 bits hold time in nanoseconds). After the execution of a given list starts, the implementation can update the value in BTR to indicate the next list execution start time.

#### 72.9.11.2.2.2 Cycle time register (CTR)

This is a 40-bit register that specifies the time at which the execution of the GCL must repeat. This register consists of an 8-bit value in seconds, and a 32-bit value in nanoseconds (similar to the PTP time format with truncated seconds register). For a given GCL, the start time is "Base Time" + N * "Cycle Time" where N is an integer value that represents the iteration number starting with 0 for first iteration. If the GCL execution takes longer than the cycle time, then the list is truncated at the cycle time and the subsequent loop begins at cycle time.

#### 72.9.11.2.2.3 Time extension register (TER)

This is a m-bit (where m = Configured time interval width + 7) register that specifies the amount of time (in nano seconds) the current GCL can extend before switching to the new GCL. This helps to avoid the execution of the small fragments of the current list before switching to a new list.

#### 72.9.11.2.2.4 List length register (LLR)

This is an n-bit register (when n is 7, 8, 9, 10, or 11 for a GCL configured depth of 64, 128, 256, 512, or 1024 respectively) that specifies the integer value of the length of the GCL (that is the number of valid rows in each GCL). The processing of the GCL stops after the number of rows read equals to the LLR value.

### 72.9.11.2.3 Transmission gating implementation

A bridge or an end station can enhance to allow transmission from each TC that is yet to be scheduled relative to a known timescale. To achieve this, a transmission gate is associated with each TC; the state of the transmission gate determines if you can select the queued frames for transmission.

For a TC, the transmission gate can be in one of these two states:

1. Open: Select queued frames for transmission, in accordance with the definition of the transmission selection algorithm associated with the TC.
2. Closed: Does not select queued frames for transmission.

A frame on a traffic class queue is not available for transmission if the transmission gate is in the closed state or if there is insufficient time available to transmit the entirety of that frame before the next gate-close event associated with that queue.

The implementation has visibility to the current schedule of gate controls and the immediate next schedule of the gate controls. So the maximum Gate Open period does not exceed the sum of the two Time Intervals. This is because, a frame is selected for transmission only if the gate is currently Open and the duration of gate open interval is greater than the time taken to transfer the entire frame.

The implementation must know the frame size before the transmission, so that you can avoid the transmission overruns and only the frames that can complete are scheduled at all times.

The implementation adequately compensates for the implementation delays in the data transfer from the buffer to the line by offsetting the current time with all the relevant delays (provided by MTL_EST_Control[CTOV]). This ensures that the schedule provided is always accurately implemented at the line.

You must ensure that the GCL slot interval is always greater than the expected packet size and overhead (scheduler delay, inter frame gap (IFG), and preamble, all combined).

### 72.9.11.3 Idle slope computation updates

When EST is enabled, credit accumulates only when the gate is open therefore, the effective data rate of the idleSlope must increase to reflect the duty cycle for the transmission gate associated with the queue.

The idleSlope is computed on the basis of the gate open time and oper cycle time values. Program the idleSlope registers (implemented one per CBS enabled TC) based on the following equation. The existing MTL register has sufficient field width to accommodate the new values for idleSlope.

idleSlope = (operIdleSlope(N) * OperCycle/GateOpenTime)

#### 72.9.11.3.1 Operational details of GCL

Write 1 to MTL_EST_Control[SSWL], so that the hardware can access the programmed gate control list. The first set of gate controls are applied when the current time is equal to the value in the base time register (BTR) and is held until the programmed "time interval" value.

One additional gate control event is always read ahead from the list, to avoid the transmission overruns. This enables the GCL to determine the next gate close events (if any) for the open TCs.

The scheduling is done on the basis of the gate open state and time interval of only the current and subsequent schedule. An internal accumulator adds the time intervals when gate controls are applied. BTR + Accumulator specifies the time at which the next set of gate controls are applied.

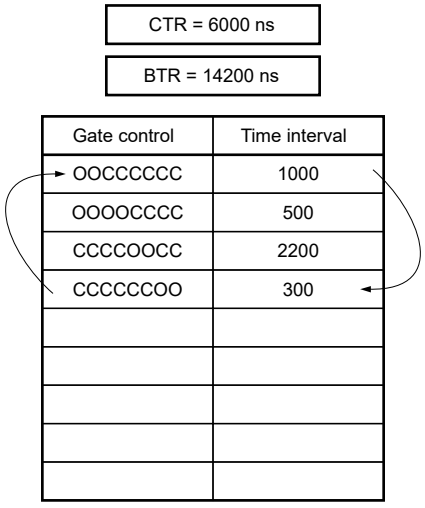

**Figure 400. GCL and associated registers - basetime and cycletime**

GCL is read progressively from the first row adhering to the schedule. The read operations continue until the list length (from LLR register) is reached and the execution of the list restarts at BTR + CTR time. At this point the value in CTR increments BTR to mark the beginning of a new cycle. In the absence of any gate controls, all the gates are in open state, during the execution of the list.

In cases where the execution time of the list is greater than the cycletime, the list is truncated and the next iteration starts when the current time equals BTR + CTR.

**Table 495. GCL and associated registers - BTR and CTR**

| Current time | Gate control applied | Accumulator value | BTR (with updates) |
|---|---|---|---|
| 14200 | OOCCCCCC | 1000 | 14200 |
| 15200 | OOOOCCCC | 1500 | 14200 |
| 15700 | CCCCOOCC | 3700 | 14200 |
| 17900 | CCCCCCOO | 4000 | 14200 |

*Table continues on the next page...*

Table 495. GCL and associated registers - BTR and CTR (continued)

| Current time | Gate control applied | Accumulator value | BTR (with updates) |
|---|---|---|---|
| 18200 | OOOOOOOO | 0 | 20200 |
| 20200 | OOCCCCCC | 1000 | 20200 |
| 21200 | OOOOCCCC | 1500 | 20200 |

Table 495 describes an example in which the execution starts at 14200 and the first set of gate controls "OOCCCCCC" are applied immediately. The time interval is 1000 ns, so the next set of gate controls are applied at 14200 (BTR) + 1000 (Accumulator) = 15200 ns . The above table shows that there are no gate controls available after the execution of the last gate control and before the next iteration of the loop. The gates are deemed in open state during that time period as depicted at 18200 current time.

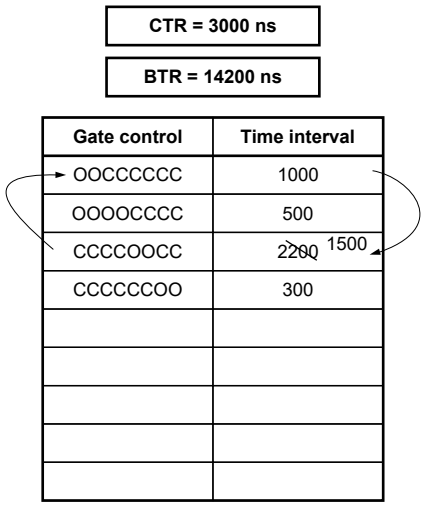

Figure 401. GCL and associated registers - BaseTime and CycleTime list execution time > CycleTime

Table 496 indicates that the list execution takes longer than the allocated CycleTime, so the list is truncated and the list starts from the BTR+CTR.

Table 496. GCL and associated registers - BTR and CTR, execution time > Cycle Time

| Current Time | Gate Control Applied | Accumulator Value | BTR (with updates) |
|---|---|---|---|
| 14200 | OOCCCCCC | 1000 | 14200 |
| 15200 | OOOOCCCC | 1500 | 14200 |
| 15700 | CCCCOOCC | 3700 | 14200 |
| 17200 | OOCCCCCC | 1000 | 17200 |
| 18200 | OOOOCCCC | 1500 | 17200 |
| 18700 | CCCCOOCC | 3700 | 17200 |

When you apply the third set of gate controls, BTR + CycleTime (17200) < BTR + Accumulator (17900), so the list is truncated and execution switches to a new iteration at 17200.

#### 72.9.11.3.2 Installing a new GCL

The switch to the new GCL can happen in one of the following ways when a new software programmed GCL is available and executed at the new BTR value:

- New base time aligned with current schedule
- New base time unaligned with current schedule

##### 72.9.11.3.2.1 New base time aligned with current schedule

If the choice of cycle time for the new gating cycle is unchanged from the cycle time for the current gating cycle, and if the BTR chosen for the new gating cycle (new BTR) is an integer multiple of the current cycle time (+ current BTR), then the new gating cycle exactly lines up with the old gating cycle, that is, the cycle start times for the new gating cycle is same as they would have been for the old configuration. This could be considered to be the ideal case and allows the new gating cycle to be installed and executed with no timing issues. The implementation completes the execution of an iteration of the current list and switches to the new list at the beginning of the BaseTime listed in the new list.

If (New base time > = Current time)

ConfigChangeTime = New BaseTime

Else If (New base time < Current time)

1. Set the BTRError

2. ConfigChangeTime = (New BaseTime + N* New CycleTime)

where N is the smallest integer for which the relation ConfigChangeTime >= CurrentTime and (N =< 8) is true.

When N > 8 the hardware cannot auto recover and the loop count value in BTRError reporting is set to 1111 requires the software to reprogram the new base time.

Figure 402 illustrates the installation of the new GCL along with the timelines.

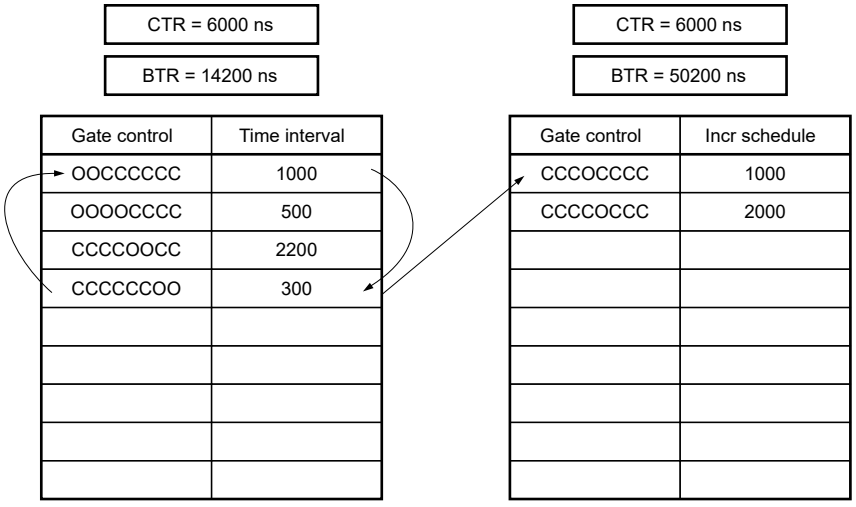

**Figure 402. Switching to a new configuration that is aligned with the existing configuration**

In the above example, after the sixth iteration of the first GCL, the BTR values of the old and new GCL are equal. At that point the new GCL is processed as a natural extension to the existing GCL.

Table 497. GCL and associated registers - BTR and CTR

| Current time | Gate control applied | Accumulator value | BTR (with updates) |
|---|---|---|---|
| 44200 | OOCCCCCC | 1000 | 44200 |
| 45200 | OOOOCCCC | 1500 | 44200 |
| 45700 | CCCCOOCC | 3700 | 44200 |
| 47900 | CCCCCCOO | 4000 | 44200 |
| 48200 | OOOOOOOO | 0 | 50200 |
| 50200 | CCCOCCCC | 1000 | 50200 |
| 51200 | CCCCOCCC | 3000 | 50200 |
| 53200 | OOOOOOOO | 0 | 56200 |

#### 72.9.11.3.2.2 New base time unaligned with current schedule

If the new cycletime differs from the current cycletime or new basetime in the future and is not an integer multiple of current cycletime, then the old and new cycles do not line up. When new basetime is reached ( when the new configuration is installed and starts to execute), the last old cycle is normally truncated to start the first new cycle. This could be undesirable if it results in a very short last old cycle; arguably it would be better to simply extend the penultimate old cycle by that small amount, rather than starting a very short cycle. The Cycle Time Extension Register (related to the current config list) allows this extension of the last old cycle to be done in a defined way; if the last complete old cycle ends normally in less than current Cycle Time Extension (TER) ns before the new base time, then the last complete cycle before new BaseTime is reached is extended so that it ends at new BaseTime.

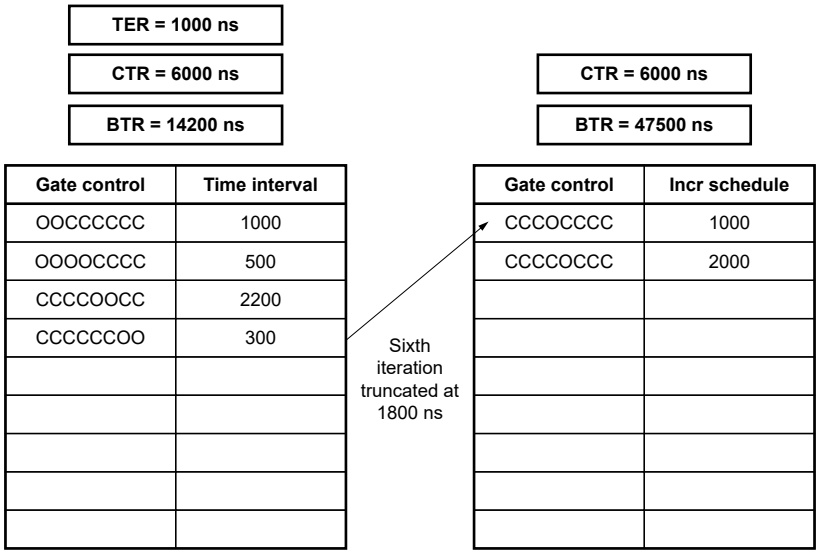

Figure 403. Switching to new list truncating the current list

At the end of the fifth iteration the Current time + Cycle time extension (TER) < New BTR so the sixth iteration of current configuration is started. During the sixth iteration of the current list when the new BTR value is smaller than the next schedule in the current list, it switches to the new list.

Table 498. Extending to new list by truncating the current list

| Current time | Gate control applied | Accumulator value | BTR (with updates) |
|---|---|---|---|
| 44200 | OOCCCCCC | 1000 | 44200 |
| 45200 | OOOOCCCC | 1500 | 44200 |
| 45700 | CCCCOOCC | 3700 | 44200 |
| 47500 | CCCOCCCC | 4000 | 44200 |
| 48500 | CCCCOCCC | 0 | 50200 |
| 50500 | OOOOOOOO | 1000 | 50200 |

Below is an example where the current config list is extended instead of starting a new iteration as the extension time of 800 ns is less than the allowed cycle extension time (TER) of 1000 ns.

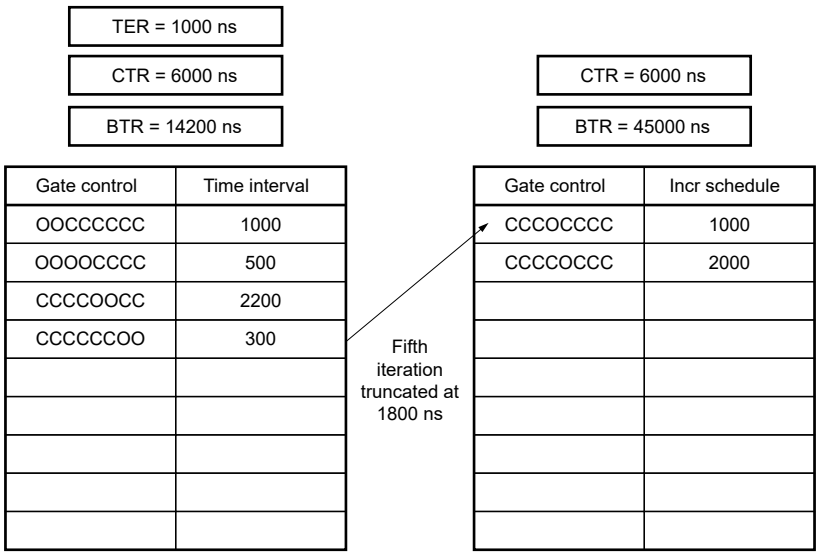

Figure 404. Switching to new list by extending the current list

Table 499. Switching to new list by extending the current list

| Current time | Gate control applied | Accumulator value | BTR (with updates) |
|---|---|---|---|
| 38200 | OOCCCCCC | 1000 | 38200 |
| 39200 | OOOOCCCC | 1500 | 38200 |
| 39700 | CCCCOOCC | 3700 | 38200 |
| 41900 | CCCCCCOO | 4000 | 38200 |
| 42200 | OOOOOOOO | 0 | 44200 |

*Table continues on the next page...*

Table 499. Switching to new list by extending the current list (continued)

| Current time | Gate control applied | Accumulator value | BTR (with updates) |
|---|---|---|---|
| 45000 | CCCOCCCC | 1000 | 45000 |
| 46000 | CCCCOCCC | 3000 | 45000 |
| 48000 | OOOOOOOO | 0 | 51000 |

#### 72.9.11.4 Impact of Transmit Scheduling Algorithms on EST

When EST is used in isolation, the Gate Control List manages the final open/close state of the Queues along with the checks carried out by the Transmission Selection Algorithm in MTL. As the Gate Controls operate on a predefined repetitive schedule, it is recommended to use Strict Priority or Credit Based Shaper (CBS) scheduling algorithms.

Other algorithms such as the Weighted Round Robin (WRR), Deficit Weighted Round Robin (DWRR) and Weighted Fair Queuing (WFQ) implement masking of the queues based on the current winning queue. The algorithm is applied only among the group of queues that open simultaneously. To ensure Queues whose gates are "Open" get priority, these algorithms are modified to treat "gate open" queues and "gate closed" queues as separate groups giving priority to gate open queues.

For example, consider 4 queues (Q3, Q2, Q1, Q0) with weights 4:3:2:1; Q3 and Q2 are in Open state in slot one slot, while Q1 and Q0 are in Open state in another slot. In this case, the scheduler works as follows:

1. In the first slot, the Q3 and Q2 are serviced in the ratio of 4:3 for the duration the slot is open.
2. In the second slot, the queues Q1 and Q0 are serviced in the ratio of 2:1.
3. Fresh arbitration is started every time a slot is opened.

In other words, the traffic does not get distributed in the intended ratio of 4:3:2:1; but as two groups with different ratios and only for the duration of the slot when the gates are open continuously

**NOTE**

See Programming guidelines for EST

### 72.9.12 Frame preemption (FPE)

Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame. During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower priority (preemptable) frame; the preemptable frame transmission is resumed and completed after the express frame transmission is complete. To support frame preemption, the following two abstractions of the MAC are used:

- A preemptable MAC, called pMAC, which carries the preemptable traffic.
- An express MAC, called eMAC, which carries the express traffic.

In the implementation, only parts of the MAC that holds the state during preemption is replicated and represented as pMAC and eMAC. The MAC uses the following two ways to puts on hold, the transmission of the preemtable traffic, in the presence of express traffic:

- The MTL scheduler interrupts the preemptable traffic that is currently being transmitted. When the preemption capability is active, the MAC interrupts the transmission and reception of preemptable frames. A preempted fragment can be followed by zero or more express frames, before the continuation fragments. The preemptable frame can be fragmented any number of times, however, the minimum final and non-final fragment length criterion must be is met. However, interleaving of more than 1 preemptable packet is not permitted. This implies that if a preemptable packet is fragmented by an express

packet, another preemptable packet cannot be transferred until all the remaining fragments of the first preempted packet are transferred.

- The MTL scheduler prevents starting the transmission of preemptable traffic. When the preemption capability is inactive, the pMAC entity is disabled and only express traffic is transmitted or received. Frame preemption feature can be enabled by setting EFPE field of the MAC_FPE_CTRL_STS register.

If you are unable to schedule fragmented packets after a certain number of attempts because of some reason, there is a possibility that the remaining fragmented packets are dropped. For this, software can program MTL_EST_Control[LCSE] to increase number of iterations or MTL_EST_Control[DFBS] to disable dropping of packet.

**NOTE**

EST and FPE cannot be used at the same time.

### 72.9.12.1 GCL Modification to Support FPE

In the EST-only configuration, the GCL entry has up to 24 bits of Time Interval and up to 8 high order bits representing the Gate Open/Close state requirements as shown in the following figure.

| Gate control (up to 8 bits) | Time interval (ns) 16, 20 or 24 bits |
|---|---|
| OOCCCCCC | T0 |
| OOOOCCCC | T1 |
| CCCCOOCC | T2 |
| CCCCCCOO | T3 |
| \| | \| |
| \| | \| |
| OCOCOCOO | T126 |
| OOOOCCCC | T127 |

**Figure 405. Gate Control List When FPE is Disabled**

EST only supports SetGate operation, which implies that the gates are set to either open or close at a given time interval. However, when both Frame Preemption (FPE) and EST are enabled, the GCL also supports Set-and-Hold-MAC and Set-and-Release-MAC operations, in addition to the SetGate operation. To enable the support of hold and release operations, the format of the GCL is slightly changed while configuring and enabling the FPE. The first Queue (Q0) is always programmed to carry preemption traffic and therefore it is always Open. The bit corresponding to Q0 is renamed as Release/Hold MAC control. The TX Queues whose packets are preemptable are indicated by setting the PEC field of the MTL_FPE_CTRL_STS register. The GCL bit of the corresponding Queue are ignored and considered as always "Open". So, even if the software writes a "0" ("C"), it is ignored for such queues.

| Gate control (up to 7 bits) | Release or hold indication | Time interval (ns) 16, 20 or 24 bits |
|---|---|---|
| CCCOOOO | 0 | T0 |
| CCCCOOO | 0 | T1 |
| OCCCOOO | 1 | T2 |
| COCCOOO | 1 | T3 |
| CCOCOOO | 1 | T4 |
| CCCOOOO | 0 | T5 |
| CCCCOOO | 0 | T6 |
| | | |

**Figure 406. Gate Control List When FPE is Enabled**

When the Release/Hold bit transitions from a '0' to '1', a Set-and-Hold-MAC operation is performed. This marks the cease of the preemptable traffic. This is achieved by sending a Hold request to MTL "ha" ns in advance (where ha is the time interval mentioned in the Hold Advance (HADV) field of the MTL_FPE_Advance register). When the Release/Hold bit transitions from a '1' to '0' a Set-and-Release-MAC operation is performed. This marks the resuming of the preemptable traffic. This is achieved by sending a Release request to MTL "ra" ns in advance (where ra is the time interval mentioned in the Release Advance (RADV) field of the MTL_FPE_Advance register). The preemptable traffic is blocked for the time duration the Release/Hold bit is set to a '1' in the Gate Control List.

#### 72.9.12.2 Impact of Preemption on CBS

In Credit Base Shaper(CBS), the definition of "Transmit" is as follows:

- TRUE for the duration of frame transmission from the queue.
- FALSE when frame transmission from the queue is complete.
- When CBS algorithm is used along with frame preemption, the value of "Transmit" is TRUE only while the frame is being transmitted by the MAC. If the frame transmission is delayed or interrupted (for instance, a preemptable frame transmission is interrupted to allow the transmission of an express frame from a different queue, or the start of express frame is delayed because a preemptable frame is being transmitted) the value of "Transmit" is FALSE until transmission of the frame commences or is resumed.

Also, the value of "Transmit" is FALSE during the transmission of any overhead that is a consequence of frame preemption. For example, additional frame overhead (mCRC, Fragment Count) that is added to the preemptable frame.

At any given time, if there are no frames in the queue, and the value of Transmit is FALSE, and credit is positive value, the credit value is set to zero if here is no preemptable frame from the queue for which transmission is in progress but has been interrupted.

#### 72.9.12.3 mPacket Format

When the preemption capability is active, MAC sends mPackets to the PHY. An mPacket can be one of the following:

1. A express packet
2. A preemptable packet
3. An initial fragment of a preemptable packet
4. A continuation fragment of a preemptable packet

**Start mPacket Delimiter (SMD)**

The value of the SMD indicates whether the mPacket contains an express packet, the start of a preemptable packet (initial fragment or complete packet), or any of continuation fragments of a preemptable packet. Following table shows the valid SMD values.

Table 500. Possible SMD Values of mPacket

| mPacket Type | Notation | Frame Count | Value |
|---|---|---|---|
| verify packet | SMD-V | - | 0x07 |
| respond packet | SMD-R | - | 0x19 |
| express packet | SMD-E | - | 0xD5 |
| preemptable packet start | SMD-S0 | 0 | 0xE6 |
| | SMD-S1 | 1 | 0x4C |
| | SMD-S2 | 2 | 0x7F |
| | SMD-S3 | 3 | 0xB3 |
| continuation fragment | SMD-C0 | 0 | 0x61 |
| | SMD-C1 | 1 | 0x52 |
| | SMD-C2 | 2 | 0x9E |
| | SMD-C3 | 3 | 0x2A |

### frag_count

A frag_count is a modulo-4 counter that increments for each continuation fragment of the preemptable packet. The frag_count protects against mPacket reassembly errors by enabling detection of the loss of up to 3 packet fragments.

The frag_count field is present only in mPackets with SMD-C notation (continuation fragment). The frag_count is zero in the first continuation fragment of each preemptable packet.

Table 501. Possible frag_count Values

| frag_count | Value |
|---|---|
| 0 | 0xE6 |
| 1 | 0x4C |
| 2 | 0x7F |
| 3 | 0xB3 |

### mData

The contents of the packet from the MAC, starting with the first byte after the SFD to the last byte before the FCS are sent in the mData fields of one or more mPackets for that frame. The minimum size of the mData field is 60 bytes.

**CRC** The CRC field contains a cyclic redundancy check (CRC) and has an indication of the final mPacket of a frame. In the final mPacket of a frame, the CRC field contains the last 4 octets of the MAC frame (the FCS field).

For other mPackets, the CRC field contains an mCRC value. The mCRC is calculated on the octets of the packet from the first octet of the frame (the octet following the SFD of preemption frames) to the last octet of the packet transmitted in that mPacket by performing an XOR of the calculated 32 bit CRC value of the fragment and a value of 0x0000FFFF.

### Summary of Packet Formats

- Express Packet: 7bytes of PREAMBLE, SMD-E, Data, and CRC
- Complete Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, CRC
- Initial Fragment (non-final) of Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, mCRC
- Continuation fragments (non-final) of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, mCRC
- Final fragment of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, CRC

**Table 502. Current and Previous SMD Values**

| Previous Preemptable packet SMD | Current Preemptable packet SMD |
|---|---|
| SMD-S0 | SMD-S1 |
| SMD-S1 | SMD-S2 |
| SMD-S2 | SMD-S3 |
| SMD-S3 | SMD-S0 |

**Table 503. Current and Previous SMD Values**

| Previous Preemptable fragment SMD | Previous Preemptable fragment FC | Current Preemptable continuation fragment SMD | Current Preemptable continuation fragment FC |
|---|---|---|---|
| SMD-S0 | NA | SMD-C0 | FC0 |
| SMD-S1 | NA | SMD-C1 | FC0 |
| SMD-S2 | NA | SMD-C2 | FC0 |
| SMD-S3 | NA | SMD-C3 | FC0 |
| SMD-C0 | FC0 | SMD-C0 | FC1 |
| SMD-C0 | FC1 | SMD-C0 | FC2 |
| SMD-C0 | FC2 | SMD-C0 | FC3 |
| SMD-C0 | FC3 | SMD-C0 | FC0 |
| SMD-C1 | FC0 | SMD-C1 | FC1 |
| SMD-C1 | FC1 | SMD-C1 | FC2 |
| SMD-C1 | FC2 | SMD-C1 | FC3 |
| SMD-C1 | FC3 | SMD-C1 | FC0 |
| SMD-C2 | FC0 | SMD-C2 | FC1 |

*Table continues on the next page...*

Table 503. Current and Previous SMD Values (continued)

| Previous Preemptable fragment SMD | Previous Preemptable fragment FC | Current Preemptable continuation fragment SMD | Current Preemptable continuation fragment FC |
|---|---|---|---|
| SMD-C2 | FC1 | SMD-C2 | FC2 |
| SMD-C2 | FC2 | SMD-C2 | FC3 |
| SMD-C2 | FC3 | SMD-C2 | FC0 |
| SMD-C3 | FC0 | SMD-C3 | FC1 |
| SMD-C3 | FC1 | SMD-C3 | FC2 |
| SMD-C3 | FC2 | SMD-C3 | FC3 |
| SMD-C3 | FC3 | SMD-C3 | FC0 |

#### 72.9.12.4 Transmit Preemption

When FPE is enabled (setting EFPE=1 in MAC_FPE_CTRL_STS register), the MTL preempts a preemptable frame, when a "hold" request is asserted (EST/Qbv configured and enabled) express frames are available for transmission, that is, frame is present in MTL FIFO and is qualified for arbitration, after ensuring that the minimum mPacket mData field size is met. Therefore, preemption occurs only if at least 60 bytes of the preemptable frame have been transmitted and at least 64 bytes (including the frame CRC) remain to be transmitted.

The earliest starting position of preemption is controlled by the AFSZ field of the MTL_ FPE_CTRL_STS Register. Preemption does not occur until at least 64 * (1+ AFSZ) - 4 bytes of the preemptable frame have been sent.

When preemption occurs, all the preemptable queues are blocked and only the express queues are allowed to arbitrate (if more than one express queue has traffic) and transmit.

Continuation fragment of the preempted frame is the first frame to be transmitted after "release" request is asserted (EST/Qbv configured and enabled) and all the express traffic transmission completes.

**NOTE**

All the PTP packets should be transmitted as express packets

MTL communicates the following frame-type information to the MAC using a 2-bit preemption control signal on the MTI interface qualified by SoF and EoF.

- Express Frame
- Preemption Frame (Full or Fragment)
- Continuation Fragment (non-Final or Final)

Table 504. Preemption Control Values on MTI Interface for Various Frame Types

| Qualifier | Preemption Control Value | Frame Type |
|---|---|---|
| SoF | 00 | Start Express |
| SoF | 01 | Start Preemption |

*Table continues on the next page...*

Table 504. Preemption Control Values on MTI Interface for Various Frame Types (continued)

| Qualifier | Preemption Control Value | Frame Type |
|---|---|---|
| SoF | 10 | Continuation Fragment |
| SoF | 11 | Reserved |
| EoF | 00 | End of Frame |
| EoF | 01 | End of Fragment |

MTL should wait for the previous fragment status to be received before resuming the continuation fragments of a preempted frame. Fragment status is described in detail in the Tx Fragment Status section.

#### 72.9.12.4.1 MAC Tx Preemption

MAC supports preemption by implementing the functionality needed to generate the mPackets as described in “mPacket Format”.

Based on the Preemption Control value received on the MTI interface (qualified with SoF and EoF), MAC determines the frame type (shown in the above table 'Preemption Control Values on MTI Interface for Various Frame Types') and generates mPackets accordingly.

When the preemption capability is active, MAC replaces the SFD of a preemption packet with an SMD-S value. A 2-bit rolling frame count is encoded in the SMD-S value.

The SMD-E value is the same as the SFD value so the SFD of an express packet does not need to be replaced.

##### 72.9.12.4.1.1 Tx Fragment Status

MAC sends Tx fragment status to indicate successful transmission of fragmented mPackets.

In case of a transmission error (underflow, jabber, and so on) the frame status is sent (and not a fragment status) with an error indication along with all other relevant status fields. In case of receiving an error status for a transmitted fragment, the MTL drops the remaining fragments and does not send any more continuation fragments.

### 72.9.12.5 Receive Preemption

#### 72.9.12.5.1 MAC Receive Preemption

When FPE is enabled, the MAC Receiver passes the incoming packets and differentiates between Express packets and preemptable packets. An SMD containing an SMD-E indicates express packet, and SMD containing an SMD-S indicates the first mPacket of a preemptable packet.

If an mPacket containing an SMD-S is received when MAC has not completed receiving the previous preempted packet, MAC sets a CRC Error status for the previously received partial packet.

When an SMD-S is detected, MAC records the frame count indicated by the SMD and then begins sending data on the MRI interface.

The MAC checks the last four bytes of the mPacket . If the last four bytes of the mPacket do not match CRC, that indicates the end of the packet with or without a CRC error as per the CRC check result. If the last four octets of the mPacket match, that indicates that the packet was preempted.

An SMD containing an SMD-C indicates an mPacket that continues the data for a preempted packet. Upon receiving an SMD value of SMD-C, MAC checks the following:

1. A preempted packet is in progress
2. The frame count indicated by the SMD matches the frame count of the packet in progress
3. The frag_count value indicates the next fragment count.

If any of the above check fails, the mPacket is discarded and MAC sets a CRC Error status for the partially received packet.

If all the checks pass, the next fragment count is incremented modulo 4.

When a packet is preempted, the MAC saves the state of the partially received packet (filter check status, timestamp, length fields etc.) and will be able to process any received Express packets before the continuation fragment is received.

The MAC Receiver sends a "dummy status" for all the mPacket fragments successfully received and sends the Rx status with the final fragment. If an error is detected during any of the fragments the Rx status is sent and the fragment is marked as final fragment. All subsequent continuation fragments received for this packet are dropped in the MAC.

The MAC communicates the following frame type information to the MTL using a 2-bit preemption control signal.

1. Express Frame
2. Preemption Frame (Full or Fragment)
3. Continuation Fragment (non-Final or Final)

**Table 505. Preemption Control Values on MRI Interface for Various Frame Types**

| Qualifier | Preemption Control Value | Frame Type |
|---|---|---|
| SoF | 00 | Start Express |
| SoF | 01 | Start Preemption |
| SoF | 10 | Continuation Fragment |
| SoF | 11 | Reserved |
| EoF | 00 | End of Frame |
| EoF | 01 | End of Fragment |

#### 72.9.12.5.1.1 Data Alignment

When a received frame cannot be fragmented on any byte boundary, MAC retains the unaligned bytes of data in the previous fragment and resends them with the next fragment as shown in the following figure.

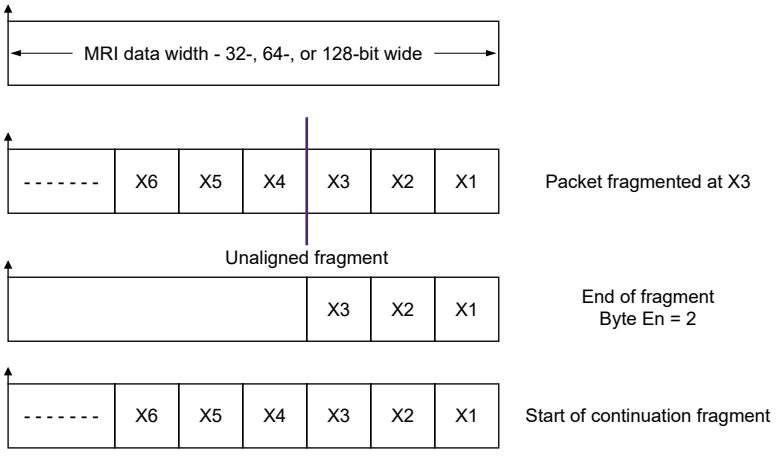

**Figure 407. Data Alignment Feature of MAC**

#### 72.9.12.5.1.2 MTL Receive Preemption

The MTL Rx must have at least 2 Rx queues to support FPE function as the preemptable packets and the express packets must be routed to separate Rx queues. The destination Rx queue of a received packet is controlled by MAC_RxQ_Ctrl[n] registers. Program these registers such that Preemptable traffic and express traffic are not routed to the same Rx queue. As the queue mapping for tagged packets is based on VLAN user-priority field, this implies that priority of preemptable and express packets are mutually exclusive. In other words, packets of a certain priority (traffic class) are either express or preemptable but cannot be both.

For the preemptable frames, in addition to the PSRQ (Priority Selected in Rx queue) based queue routing, a programmable "Frame Preemption Residue Queue" (FPRQ) is supported to route all other Preemption Packets received (Untagged, SA/ DA or VLAN Filter Fails forwarded due to RA being set or VTFE being reset).

**Table 506. Preemption Control Values on MRI Interface for Various Frame Types**

| Preemption Packet Type | Queue Routing |
|---|---|
| AV Tagged Packets passing the SA/DA and VLAN filters | PSRQ* |
| DCB/Generic Tagged Packets passing the SA/DA and VLAN filters | PSRQ** |
| Tagged Packets failing the SA/DA and VLAN filters without setting the Receive All (RA = 0) or setting VTFE = 1 | Dropped |
| All other packets OR when RA = 1 | FPRQ |

#### 72.9.12.5.1.3 MTL Receive Arbitration

On the ARI Interface, data is fetched from the MTL Rx FIFO based on the arbitration selected in the MTL_Operation_Mode register. Frame based arbitration can be used only when all the MTL Preemption Queues are operating in Store and Forward mode, else there will be loss of bandwidth on the ARI interface because all the fragments of a preemptable packet is not available. Therefore, any express packets received between the fragments are blocked until all the fragments are received and transferred; this defeats the purpose of express traffic.

When operating in either Threshold (cut through) or Store and forward modes of operation, PBL based arbitration is recommended over Frame based arbitration. In case of PBL based arbitration, the watermark check is always performed and the arbitration/ transfer of data in terms of chunks of "PBL" size of data which is almost similar to the concepts of "fragments". Therefore the express queue packets get blocked for less time as well as the ARI interface transfers the data without loss of efficiency.

### 72.9.12.6 Verify and Respond mPackets

When FPE function is present, the MAC can receive and detect the Verify and Respond mPackets, even when FPE is not enabled by software. When MAC detects valid Verify/Respond mPackets, it notifies the software by setting the RVER and RRSP fields of MAC_FPE_CTRL_STS register respectively. Optionally an interrupt can be generated. As such packets have empty (all-zero) data payload, they are dropped inside the MAC and not forwarded to the MRI.

Software can set the SVER and SRSP fields of MAC_FPE_CTRL_STS register to request MAC to transmit Verify and Respond mPackets respectively. Upon successful transmission of these frames, MAC clears the SVER/SRSP bits and sets the TVER & TRSP fields of MAC_FPE_CTRL_STS register. Optionally an interrupt can be generated when these events occur.

Software must ensure that frame preemption verify and response packet are not triggered at the same time. Trigger either of the packets and then wait for its completion before triggering another packet.

### 72.9.12.7 Frame Preemption and MMC Counter and Interrupt Registers

The following MMC counters and associated Interrupt registers are instantiated/present in the MAC when Frame Preemption feature is enabled.

Table 507. MMC Counters and Associated Interrupt Registers

| Frame Assembly Error Counter | Description | Associated MMC Counter |
|---|---|---|
| Frame Assembly Error Counter | A 32-bit counter that provides the number of MAC frames with reassembly errors on the Receiver, due to mismatch in the Fragment Count value. | MMC_Rx_Packet_Assembly_Err_Cntr |
| Frame SMD Error Counter | A 32-bit counter that provides the number of received MAC frames rejected due to arriving with an SMD-C when there was no preceding preempted frame. | MMC_Rx_Packet_SMD_Err_Cntr |
| Frame Assembly OK Counter | A 32-bit counter that provides the number of MAC frames that were successfully reassembled. | MMC_Rx_Packet_Assembly_Ok_Cntr |
| MAC Rx Fragment Counter | A 32-bit counter that provides the number of additional mPackets received due to preemption. | MMC_Rx_FPE_Fragment_Cntr |
| MAC Tx Fragment Counter | A 32-bit counter that provides the number of additional mPackets transmitted due to preemption. | MMC_Tx_FPE_Fragment_Cntr |
| Hold Request Counter | A 32-bit counter that maintains the count of number of times a hold request is given to MAC. | MMC_Tx_Hold_Req_Cntr |

#### 72.9.12.7.1 Additional Registers Associated With MMC Interrupts

Following are the additional registers associated with MMC interrupts for the MMC error counters:

- MMC_FPE_Tx_Interrupt
- MMC_FPE_Tx_Interrupt_Mask
- MMC_Rx_Interrupt
- MMC_FPE_Rx_Interrupt_Mask

### 72.9.13 Time-Based Scheduling

Time-based scheduling feature is suitable for traffic whose periodicity and rate are predictable. To improve the quality-of-service of such traffic,

- The transmit DMA fetches the packet from the host memory for transmission at designated time. This helps the software to setup the Transmit descriptors in advance even before packet is ready/available. It reduces the overhead on the software and avoids constant monitoring of the time and preparing descriptors just in time when the packet is targeted to be transmitted.
- The MAC transmits the packet only at the designated/pre-determined time even if the packets are fetched in advance. This helps in maintaining a constant transmission rate that can be consumed by the receiver station; therefore avoiding congestion and excessive buffering in the network.

The time-based scheduling feature supports fetching and launching an Ethernet packet at (or after) a pre-determined time. The time-based scheduling is supported only in the following modes/configurations:

- Full duplex mode
- Link speed is 100Mbps or higher

The following figure shows the time-based scheduling flow.

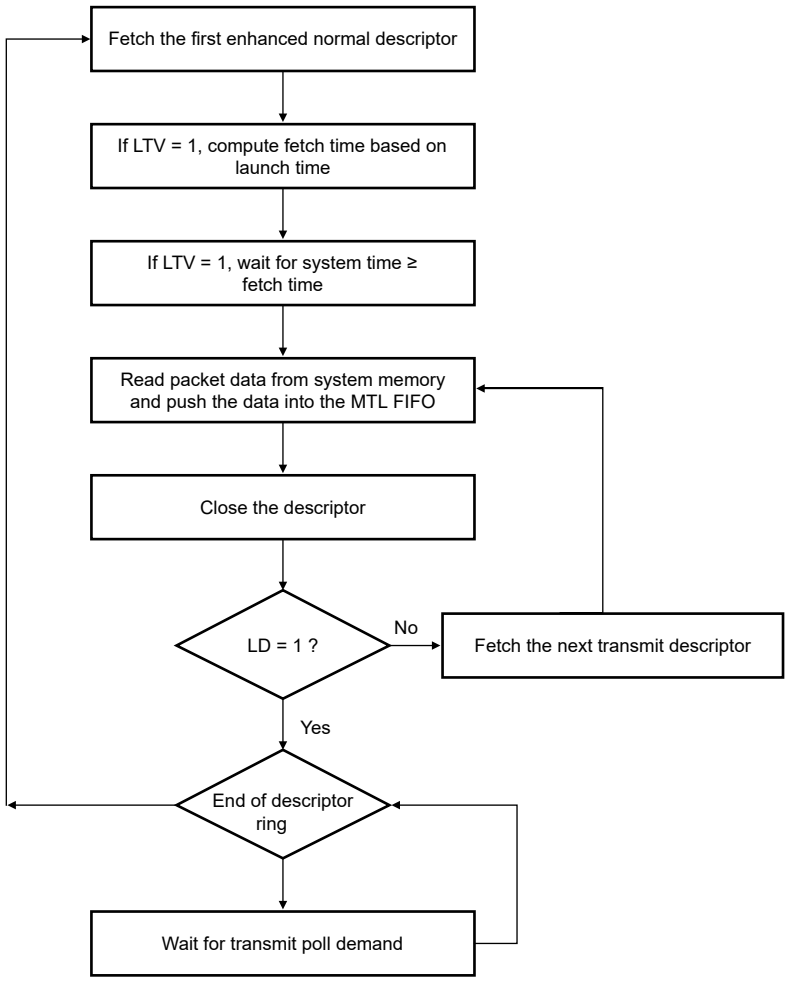

**Figure 408. Time-Based Scheduling Flow**

Following are the definitions specific to the time-based scheduling feature:

### 72.9.13.1 Launch time

The time beyond which MTL can schedule the packet for transmission. The launch time resets after the transmission of one frame. These are the two formats of the launch time.

**Normal or absolute format**:

In this format, the launch time is interpreted in the normal or absolute format if the ESTM bit of the MTL_TBS_CTRL register is set to 0.

The launch time is a 32-bit value, where most-significant 8-bits represent the time in seconds and the rest 24-bits represent the time in 256 ns. The launch time is compared against the IEEE 1588 based system or PTP time (bits[39:8]) and rolls over after 256 seconds.

The maximum value of the lower 32-bits of system time is 999,999,999 decimal (0x3B9AC9FF) and it wraps to 0 when reaching this value (representing a full second). Therefore, the maximum value of the lower 24-bits of the launch time (after multiplying by 256) must be 0x3B9AC9.

As the maximum value of launch time is 256 seconds,

- Launch time is greater than current system time when its value is between system time[39:8] and System time[39:8] + 128 sec.

- Launch time is less than current system time when its value is between System Time[39:8] + 128sec and System Time[39:8] + 256 sec, because this is a modulo 256 computation.

**EST or offset format**

In this format, the launch time is a offset value relative to the time which the BTR of the GCL list provided in the GCL slot number (GSN) indicates. The value in the BTR is always updated to the start time of the current loop of the GCL.

For each packet, the GSN value and the launch time value are specified in the enhanced transmit descriptor in the DMA configurations, or as control word in the MTL configurations.

The launch time offset is a 32-bit value; the upper 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns, which is added to the BTR value corresponding to GCL slot number. The value of the launch time offset must be smaller than the value of the cycle time (specified in the CTR register that is implemented when EST is enabled). If the CTR is greater than or equal to 1s, the maximum value of the lower-24 bits of launch time offset must be 999,999,999 decimal (0x3B9AC9FF).

In this format, the launch time is a 64-bit value, which is interpreted as, Launch time = Launch GSN BTR[63:0] + (Launch time offset[31:0] << 8), which is compared with the system time [63:0].

GSN BTR is the Base Time value at which the Launch GSN loop started execution.

**GCL slot number (GSN)** A modulo 16 count of the GCL loop count is implemented and it is known as GSN. The count is incremented for every new GCL loop. Installation of new GCL list does not impact the count. Read MTL_EST_Status[CGSN] to obtain the current GCL slot number.

The maximum value of GSN is 15. Therefore the GSN values between MTL_EST_Status[CGSN] and MTL_EST_Status[CGSN]+8 represent current or future slots and all other GSN values are interpreted as elapsed slots or past slots. So, for the correct interpretation of time, GSN value must be between MTL_EST_Status[CGSN] and MTL_EST_Status[CGSN]+8.

### 72.9.13.2 Launch expiry time

**Normal or Absolute Mode**

In this mode, when MTL_TBS_CTRL[LEOV] = 1, MTL_TBS_CTRL[LEOS] determines the maximum amount of time a frame is eligible for launch, starting from the time the frame becomes eligible for launch.

The launch expiry offset is a 24-bit value defined in 256 ns units, with a maximum possible value of 999,999,999 ns (0x3B9AC9FF).

Launch expiry time = (Launch time[39:8] + LEOS[32:8]) * 256 ns

The packet with a specific launch time is considered as eligible for transmission when the launch time is less than the system time and (if MTL_TBS_CTRL[LEOV] = 1) the system time is less than the launch expiry time.

When the system time is greater than the launch expiry time, the frame is categorized as expired and it drops from the MTL FIFO.

**NOTE**

- For correct interpretation and meaningful operation, the fetch, launch, and launch expiry time must never set to a value larger than the Current system time + 128 sec; such a value is interpreted as time that has already elapsed.
- In Full Duplex mode, the frames dropped from the MTL FIFO have error summary (Bit 15) and excessive deferral (bit 3) of TxStatus set.

**EST/Offset Mode**

In EST mode, when MTL_TBS_CTRL[LEOV] = 1, MTL_TBS_CTRL[LEGOS] and MTL_TBS_CTRL[LEOS] determines the maximum amount of time a frame remains eligible for launch, starting from the time the frame becomes eligible for launch.

Launch Expiry Offset = (LEGOS: LEOS)

LEGOS holds the GSN offset (multiples of CTR time) and LEOS holds maximum value of CTR (sub CTR values) in ns.

Launch expiry offset is a 24-bit value defined in the units of 256 ns, with a maximum possible value of the smaller of 999,999,999 ns or CTR-1 ns.

The Launch expiry GSN is computed as follows:

Launch expiry GSN = (Launch GSN + LEGOS + CCMA) where, CCMA is the CTR carry due to modulo addition. This value is 1 if ((Launch time offset + LEOS) << 8) is equal to or greater than CTR.

When CCMA = 1, Launch expiry offset = (Launch time offset+ LEOS) - CTR

When CCMA = 0,

Launch expiry offset = (Launch time offset + LEOS).

Launch expiry time = Launch expiry GSN BTR [63:0] + Launch expiry time offset.

When MTL_TBS_CTRL[LEOV] is not 1, the launch expiry time is not checked.

When MTL_TBS_CTRL[LEOV] = 1, and

- the system time is greater than the launch expiry time, the frame drops from MTL FIFO. Then the frame is considered as expired.
- the launch time is smaller than the system time and the launch expiry time is greater than the system time, then the frame is considered eligible for launch.

**NOTE**

- Max value of MTL_TBS_CTRL[LEGOS] is 7. This indicates that when MTL_TBS_CTRL[LEOV] = 1, the frame has a maximum life time of <8 GCL loop iterations after it becomes eligible for launch.
- The slot number of the first GCL list that executes each time after EST is enabled, is zero.

### 72.9.13.3 Fetch time

This accounts for all possible delays in the DMA fetch operation and ensures that the frame is present in the MTL FIFO before the launch time.

If DMA_TBS_CTRL[FTOV] is 1, it indicates the fetch time for each packet. If DMA_TBS_CTRL[FTOV] is not 1, it indicates that the fetch time offset is not valid and DMA fetches packets without any time constraints.

#### Normal/Absolute mode

In this mode fetch time is derived or calculated by reducing the time specified in DMA_TBS_CTRL[FTOS] from the given launch time.

In Normal mode, the fetch launch time is computed as:

Fetch Time[39:8] = (Launch Time[39:8] - FTOS[31:8])

The fetch time is 32-bits and is compared against the system time[39:8] to determine whether it is eligible for fetching the frame:

- The fetch time is defined as greater than system time if the fetch time is in the range of system time[39:8]" and system time[39:8] + 128 sec. The frame is considered as not-eligible for fetch.
- The fetch time is defined as smaller than the system time if the fetch time is in the range of system time[39:8] + 128 sec and system time[39:8] + 256 sec. The frame is considered as eligible for fetch.

This is a modulo 256 computation.

#### EST/Offset mode

In this mode, the fetch GSN offset (DMA_TBS_CTRL[FGOS]) provides the slot number offset to deduct from the launch GSN. In this case the FTOS value must be smaller than 999,999,999 ns or CTR-1 ns.

If (Launch time offset >= FTOS):

Fetch time offset = ((Launch time offset - FTOS) * 256ns)

CBFS(CTR borrow for fetch subtraction) = 0

If (Launch time offset < FTOS) Fetch time offset = CTR + ((Launch time offset - FTOS) * 256ns)

CBFS (CTR borrow for fetch subtraction) = 1

The fetch GSN is computed as follows:

Fetch GSN = Launch GSN - FGOS - CBFS

Fetch time = Fetch GSN BTR[63:0] + Fetch time offset

The frame is eligible for DMA fetch when the fetch time is smaller than the system time.

#### DMA operations sequence

This is the sequence of operation when FTOV = 1:

1. Fetch the first enhanced normal descriptor (FD = 1).
2. Compute the fetch time on the basis of the launch time and wait for the system time to be greater than fetch time, if LTV = 1 and fetch is enabled.
3. Read the frame (data) from the host memory and transfer to MTL FIFO.
4. Close the normal descriptor.
5. Fetch the next normal descriptor (if the previous descriptor was not the last).
6. Repeat steps 4 to 6, until the last descriptor of the frame (LD = 1).

After the last descriptor of a frame, program the next enhanced normal descriptor with a new launch time and with LTV = 1. Otherwise, process the subsequent frames without any time restrictions.

See Programming the launch time in time-based scheduling for more information.

## 72.10 TCP/IP Offloading Features

This section and all other sections, along with respective sub-sections are Synopsys Proprietary. Used with permission.

### 72.10.1 Transmit Checksum Offload Engine

The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, using which, the software can offload the task of checksum insertion to the hardware. In the transmit path MAC calculates the checksum and inserts it in the Tx packet. This feature helps in reducing the load on the software and can improve the overall throughput of the system. This feature is supported for only Q0 queue.

The checksum offload engine module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 Bits[17:16]).

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if IP is configured for Threshold (cut-through) mode.

#### 72.10.1.1 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

**NOTE**

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 0 in Table 19-12 on page 1330). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

#### 72.10.1.2 TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

**NOTE**

For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16'h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (Bit 12 in Table 19-3 on page 1324). This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field. Following table describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as "No" in the table.

**NOTE**

You should not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Description of Transmit Checksum Offload Engine because it may result in incorrect checksum insertion or unexpected behavior.

**Table 508. Transmit Checksum Offload Engine Functions for Different Packet Types**

| Packet Type | Hardware IP headerchecksum insertion | Hardware TCP/ UDPchecksum insertion |
|---|---|---|
| Non-IPv4 or IPv6 packet | No | No |
| IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine. | Yes | Yes |

*Table continues on the next page...*

Table 508. Transmit Checksum Offload Engine Functions for Different Packet Types (continued)

| Packet Type | Hardware IP headerchecksum insertion | Hardware TCP/ UDPchecksum insertion |
|---|---|---|
| IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine. | Not Applicable | Yes |
| IPv4 with TCP, UDP, or ICMP | Yes | Yes |
| IPv4 packet has IP options (IP header is longer than 20 bytes) | Yes | Yes |
| Packet is an IPv4 fragment | Yes | No |
| IPv6 packet with the following next header fields in main or extension headers:<br>• Hop-by-hop options (in IPv6 main header)<br>• Hop-by-hop options (in IPv6 extension header)<br>• Destinations options<br>• Routing (with segment left 0)<br>• Routing (with segment left > 0)<br>• TCP, UDP, or ICMP<br>• Authentication<br>• Any other next header field in main or extension headers | • Not Applicable<br>• Not Applicable<br>• Not Applicable<br>• Not Applicable<br>• Not Applicable<br>• Not Applicable<br>• Not Applicable<br>• Not Applicable | • Yes<br>• No<br>• Yes<br>• No<br>• No<br>• Yes<br>• No<br>• No |
| IPv4 packet has TCP header with Options fields | Yes | Yes |
| IPv4 Tunnels:<br>• IPv4 packet in an IPv4 tunnel<br>• IPv6 packet in an IPv4 tunnel | • Yes (IPv4 tunnel header)<br>• Yes (IPv4 tunnel header) | • No<br>• No |
| IPv6 Tunnels:<br>• IPv4 packet in an IPv6 tunnel<br>• IPv6 packet in an IPv6 tunnel | • Not applicable<br>• Not applicable | • No<br>• No |
| IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled). | Yes | Yes |
| IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled). | Not applicable | Yes |
| IPv4 frames with security features (such as encapsulated security payload) | Yes | No |
| IPv6 frames with security features (such as encapsulated security payload) | Not applicable | No |

### 72.10.2 Receive Checksum Offload Engine

IP provides the Checksum Offload Engine that is used to detect any error in an IPv4 or IPv6 packet in the receive path. The MAC verifies the checksum field of the received packet with the internally calculated checksum and provides the status.

The Receive Checksum Offload engine is used to detect errors in IP packets by calculating the header checksum and further matching it with the received header checksum. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

Here, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the Enable Double VLAN Processing option is selected and the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Following table describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

**NOTE**

The MAC does not append any payload checksum bytes to the received Ethernet packets.

**Table 509. Receive Checksum Offload Engine Functions for Different Packet Types**

| Packet type | Hardware IP header checksum checking | Hardware TCP/UDP/ICMP checksum checking |
|---|---|---|
| Non-IPv4 or IPv6 | No | No |
| IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC) | Yes | Yes |
| IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC) | Not Applicable | Yes |
| IPv4 with TCP, UDP, or ICMP | Yes | Yes |
| IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP | Yes | No |

*Table continues on the next page...*

**Table 509. Receive Checksum Offload Engine Functions for Different Packet Types (continued)**

| Packet type | Hardware IP header checksum checking | Hardware TCP/UDP/ICMP checksum checking |
|---|---|---|
| IPv4 packet has IP options (IP header is longer than 20 bytes) | Yes | Yes |
| Packet is an IPv4 fragment | Yes | No |
| IPv6 packet with the following next header fields in main or extension headers:<br>• Hop-by-hop options (in IPv6 main header)<br>• Hop-by-hop options (in IPv6 extension header)<br>• Destinations options<br>• Routing (with segment left 0)<br>• Routing (with segment left > 0)<br>• TCP, UDP, or ICMP<br>• Any other next header field in main or extension headers | • Not Applicable<br>• Not Applicable<br>• Not Applicable<br>• Not Applicable<br>• Not Applicable<br>• Not Applicable<br>• Not Applicable | • Yes<br>• No<br>• Yes<br>• Yes<br>• No<br>• Yes<br>• No |

| IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled) | Not Applicable | Yes |
| IPv4 frames with security features (such as encapsulated security payload) | Yes | No |

*Table continues on the next page...*

Table 509. Receive Checksum Offload Engine Functions for Different Packet Types (continued)

| Packet type | Hardware IP header checksum checking | Hardware TCP/UDP/ICMP checksum checking |
|---|---|---|
| IPv6 frames with security features (such as encapsulated security payload) | Not Applicable | No |

Set the IPC bit of the MAC_Configuration register for enabling Receive Checksum offload.

## 72.11 MAC Management Counters

This section is Synopsys Proprietary. Used with permission.

IP supports storing the statistics about the received and transmitted packets in registers that are accessible through the application/software. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The MMC counters are free running.

For MMC register details, see registers "MMC_Control" to "MMC_Rx_FPE_Fragment_Cntr" in EMAC register descriptions.

## 72.12 Flow Control

This section and its sub-sections are Synopsys Proprietary. Used with permission.

### 72.12.1 Transmit Flow Control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

#### 72.12.1.1 Flow control in Full duplex mode

IP supports the IEEE802.3x Pause Packets.

Pause packet structure is shown in the following table.

Table 510. Pause Packet Fields

| Field | Description |
|---|---|
| DA | Contains the special multicast address |
| SA | Contains the MAC address 0 |
| Type | Contains 8808 |
| MAC Control opcode | Contains 0001 for IEEE 802.3x Pause Control packets; 0101 for PFC packets |
| PT | Contains Pause time specified in the PT field of the MAC_Q#_Tx_Flow_Ctrl register |

#### 72.12.1.2 Pause Packet Control

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

#### 72.12.1.3 Flow Control in Half-Duplex Mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

Following table describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EHFC bit of MTL_RxQ0_Operation_Mode register
- TFE bit of MAC_Q0_Tx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Flow control is similar for all queues.

**Table 511. Tx MAC Flow Control**

| EHFC | TFE | DM | Description |
|---|---|---|---|
| x | 0 | x | The MAC transmitter does not perform the flow control or backpressure operation. |
| 0 | 1 | 0 | The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. |
| 1 | 1 | 0 | The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx performs back-pressure when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register. |
| 0 | 1 | 1 | The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. |
| 1 | 1 | 1 | The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx sends a Pause packet when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register. |

#### 72.12.1.4 Enabling Transmit Flow Control

To independently enable Transmit Flow Control for each Tx queue, set the TFE bit in the MAC_Q#_Tx_Flow_Ctrl register.

### 72.12.2 Receive Flow Control

In the Receive path, the Flow Control is functional only in the full-duplex mode. If any Pause packet is received in the half-duplex mode, the packet is considered as a normal control packet.

**NOTE**

Receive pause packets should have a frame size of 64 bytes.

The Receive Flow Control is implemented by the MAC based on the bit value of the respective register, and the destination address and different fields of the received packet.

Following table describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of MAC_Rx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Table 512. Rx MAC Flow Control

| RFE | DM | Description |
|---|---|---|
| 0 | x | The MAC receiver does not detect the received Pause packets. |
| 1 | 0 | The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets. |
| 1 | 1 | The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter. |

#### 72.12.2.1 Enabling Receive Flow Control

To enable Pause Flow Control, set the RFE bit in the MAC_Rx_Flow_Ctrl register.

## 72.13 Loopback Mode

This section is Synopsys Proprietary. Used with permission.

The MAC supports Loopback of transmitted packets to its receiver.

The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result into issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip (for example, in FPGA setup), you should externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets. Big packets (>1522 bytes) may get corrupted in the loopback FIFO.

To enable this feature, program the LM bit of the MAC_Configuration register.

You can enable loopback for all PHY interfaces. The data is always looped back through internal asynchronous FIFO on to the internal Receive MII or GMII interface, irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding transmit PHY interface block, on to the Ethernet line.

## 72.14 Automotive Safety Features

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

IP supports the automotive safety feature.

### 72.14.1 Error Correction Code (ECC) Protection for Memories

The Error Correction Code (ECC) block can correct single-bit error and detect double-bit error.

At the write interface, ECC checkbits are generated by computing ECC on the contents of the data bus and respective address is appended with the data that is written to the memory.

At the read interface, ECC checkbits are recomputed on the content of the read data and the respective address is compared with the received checkbits in the memory.

Following figure shows the block diagram of ECC protection for memories

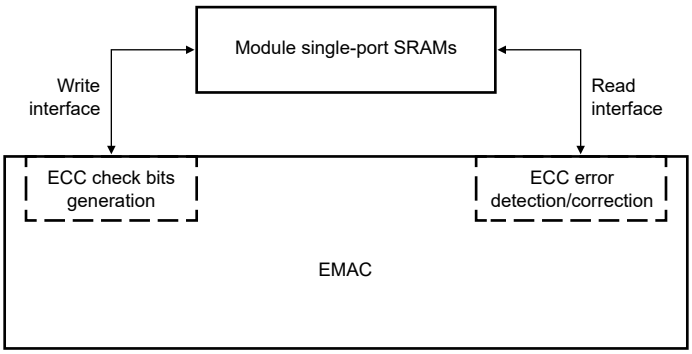

Figure 409. Block Diagram of ECC Protection for Memories

#### 72.14.1.1 Handling the Address Mismatch

The ECC is calculated over the sum of memory data and memory location address. However only data is written in the memory along with the ECC(address is excluded).

On the read interface, the ECC is checked over the sum of memory DATA, memory ECC, and Internally generated address. When an ECC correctable error is detected over the range of the address bit position, it is treated as an uncorrectable error. This is because data might have been read from a different location.

#### 72.14.1.2 Diagnostic Support for the Error Management

Following statistics are provided for monitoring the error behavior on each of the memory blocks.

- Error status provided to management
  - A separate status for correctable, uncorrectable, and address mismatch is specified in the MTL_ECC_Interrupt_Status register.
  - Memory locations at which correctable and uncorrectable errors are detected is specified in the MTL_ECC_Err_Addr_Status register. In addition, a control bit (MEEAO field of MTL_ECC_Control register) decides, whether the first errored memory address is reported or the latest errored memory address is reported.
  - MTL_ECC_Err_Cntr_Status register has separate counters to count the number of correctable and uncorrectable errors
- Interrupts provided to management
  - Separate interrupts are generated for correctable and uncorrectable errors.
  - sbd_sfty_ue_intr_o interrupt is generated when uncorrectable errors are detected and these errors cannot be masked.
  - sbd_sfty_ce_intr_o interrupt is generated when correctable errors are detected. The module sets the respective interrupt enable bits (in the DMA/MTL_ECC_Interrupt_enable register).
  - To find the root cause of the error, read the DMA/MTL_Safety_Interrupt_Status and DMA/MTL_ECC_Interrupt_Status registers.
  - To clear the interrupt, write 1 in the respective interrupt status bit in DMA/MTL_ECC_Interrupt_Status registers.

**NOTE**

- The status/counters/interrupts are generated per memory.
- MTL Tx and Rx memory is logically divided into multiple queues. But, ECC diagnostics (status/counter/interrupts) are common to all queues.

#### 72.14.1.3 ECC Error Injection Capabilities

IP supports error injection capabilities for each memory as a static configuration. The position where the errors are injected in the data word is random. For each memory, 3 control bits are provided to inject errors. The 3 bits are:

- A single bit to enable error injection
- Two bits to indicate the type of error to be injected ❑ 00: 1 bit error
  - 01: 2 bit error
  - 10: 3 bit error
  - 11: 1 bit error in address field

The control bit descriptions for

- MTL Tx/Rx and DMA TSO memory are specified in the MTL_DBG_CTL register, for and for R.
- MTL EST memory are specified in the MTL_EST_GCL_Control register
- Rx parser memory are specified in the MTL_RXP_Indirect_Acc_Control_Status register

**NOTE**

While using debug mode for ECC error injection:

- There should be no traffic in the module
- When multiple CSR writes are required for writing single data word into the memory, the application should ensure that all the CSR writes corresponding to one memory write maintains the same value for the error injection control word.
- See Programming guidelines for ECC protection for memories

### 72.14.2 Finite State Machine(FSM) Parity and Timeout Protection

The FSM protection feature supports FSM parity and time out protection.

#### 72.14.2.1 FSM State Parity Protection

Odd parity is implemented on all the FSM state register bits. Parity is monitored for every clock, after the reset is de-asserted. When a bit flips due to transient errors or permanent faults, the erroneous FSM is set to its default state and an uncorrectable error is indicated.

When the FSM state parity protection is enabled, by setting PRTYEN field of MAC_FSM_Control Register, the FSM state error is indicated by setting the FSMPES field of the MAC_DPP_FSM_Interrupt_Status register. Also, the Safety Interrupt (sbd_sfty_ue_intr_o) is asserted when an FSM Error is detected.

Error Injection mode is also supported for FSM parity error check. Program the Error Injection enable for the respective clock domain denoted by [23:16] bits of MAC_FSM_Control Register.

#### 72.14.2.2 FSM Timeout Protection

The FSM Timeout feature provides a mechanism to ensure that all FSMs in the module can complete a transaction and return to a known completion state (IDLE or any other state that indicates completion of a transaction/transfer) within the programmed timeout value.

Program the TMR field of MAC_FSM_ACT_Timer register with a value that indicates the number of CSR cycles required to generate a 1 microsecond tic. This microsecond tic is internally used to generate the programmed timeout duration. Two timeout tics (normal mode timeout and large mode timeouts) are generated to provide flexibility to choose one per clock domain, by using the bits [31:24] of MAC_FSM_Control Register. Supported values for Timeout duration are 1us, 1.024ms, 16.384ms, 65.5536ms, 262.144ms, 1048.576ms (~1sec), 4194.304ms (~4s), 8.388s, 16.777s, and 33.554s which is based on the programmable bits NTMRMD, LTMRMD fields of MAC_FSM_ACT_Timer register. Interface timeouts are based on the normal mode tic generation; only the FSM timeouts depend on either normal or large tick selection.

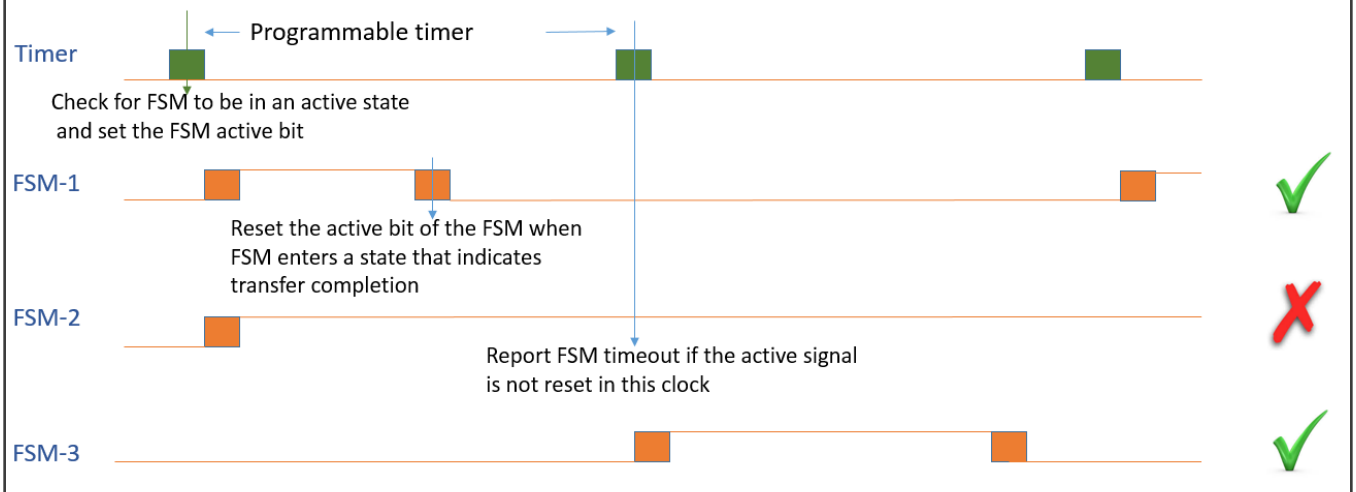

**Figure 410. FSM Timeout Timing Diagram**

In the above figure, the timer ticks are generated based on the programmable timeout value. The timer ticks are synchronized and made available in all the clock domains that have the FSMs.

At every timer tick, all the FSMs are monitored for being in active state (non-IDLE state, which indicates the FSM is actively processing transactions or hand-shakes) and an FSM active flag bit is set. The active flag bit is implemented for every FSM that is monitored for timeout. When the FSM reaches an IDLE or transaction completion state, the active flag bit of that FSM is reset. At the subsequent timer tick, all the FSMs' active flag bits are monitored and any flag that is set indicates a timeout for that FSM. This process of setting the flag and checking at subsequent timer tick is repeated at every tick.

Timeout Error Injection per clock domain is enabled by programming [15:8] fields of MAC_FSM_Control register. When Timeout error injection enable is set for a clock domain, the FSMs in that clock domain automatically timeout and generate an interrupt even without traffic. As error injection is a debug mode, TMR value need not indicate 1us, but can be programmed to a smaller value at which debug mode ticks are needed. FSM Timeout and Parity Error Injection modes can be used for testing at key-on/key-off.

The FSM timeout status is specified in the [15:8] field of MAC_DPP_FSM_Interrupt_Status register as per the respective clock domains. One FSM timeout status bit is made available per clock domain. The safety interrupt (sbd_sfty_ue_intr_o) is asserted when the timeout error is set for any of the clock domains. IP does not attempt to recover from a FSM timeout condition and relies on the application to take the corrective action (resetting IP).

#### 72.14.2.3 Enabling FSM Parity and Timeout Protection

FSM timeout feature is enabled by setting the TMOUTEN field of MAC_FSM_Control register.

**NOTE**

See Programming guidelines for FSM parity and timeout

### 72.14.3 Application/CSR Interface Timeout Protection

This feature provides timeout protection to the application/CSR Interface. All the interfaces which has the handshake mechanism monitored for potential hangs due to the external agent (Master/Slave/Interconnect/Application client) not responding to the requests/transfers initiated by the QoS. After the request is initiated the response arrival interval is monitored. If the response does not arrive within a programmed time (TMR field of MAC_FSM_ACT_Timer) the timeout is triggered, using similar trigger generation as explained in the Section FSM protection.

The timeout is triggered when IP initiates SEQ, NON-SEQ and BUSY transfers on HTRANS[1:0]; and HREADY is not asserted by Slave within the programmed time.

The Timeout status for the AHB master interface is set in the MSTTES field of the MAC_DPP_FSM_Interrupt_Status register. The Safety interrupt (sbd_sfty_ue_intr_o) is asserted when application timeout status is set.

The hardware does not attempt to recover from Application/CSR Interface hangs and relies on software to take appropriate corrective action.

**NOTE**

- Protection is not needed for APB3 Slave interfaces because potential hangs can be only when IP does not respond to the requests. In such cases the IP internal protection logic (FSM timeout) detects such defects.
- Based on the time at which the transfer is initiated relative to the timer ticks, the timeout period could be any value between the programmed timeout and 2x times the programmed timeout.
- When an uncorrectable safety interrupt is issued and the read of the Interrupt status register returns all zeros, it implies that the CSR read is not functional. As soft reset of IP is not possible without the CSR access, and therefore, a hard reset of IP is recommended.
- See Programming guidelines for FSM parity and timeout .

## 72.15 Descriptors

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

### 72.15.1 Overview

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The module supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

**NOTE**

There is no limit for the number of descriptors that can be used for a single packet.

### 72.15.2 Descriptor Structure

The module supports the ring structure for DMA descriptor as shown in the following figure.

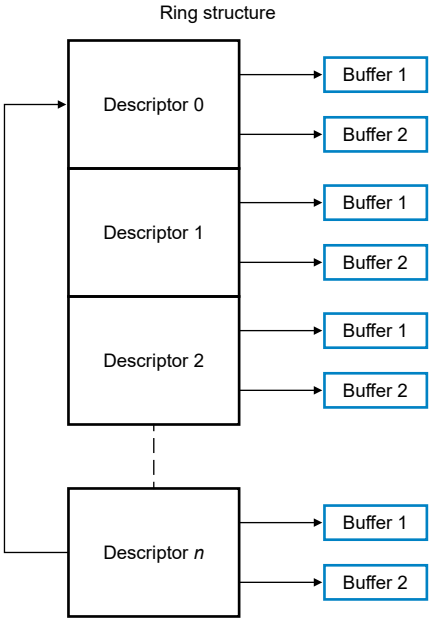

**Figure 411. Descriptor Ring Structure**

In Ring structure, descriptors are separated by the Word, DWord, or LWord number programmed in the DSL field of the DMA_CH#_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH#_TxDesc_Ring_Length)
- Receive Descriptor Ring Length Register (DMA_CH#_RxDesc_Ring_Length)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

Current Descriptor Pointer == Descriptor Tail Pointer;

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

Current Descriptor Pointer < Descriptor Tail Pointer;

The DMA automatically wraps around the base address when the end of ring is reached, as shown in the following figure.

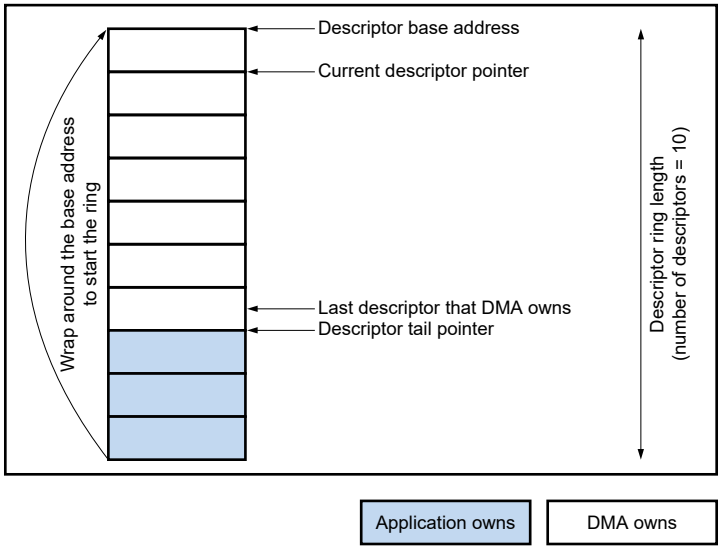

Figure 412. DMA Descriptor Ring

For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

## 72.15.3 Transmit Descriptor

The DMA in the module requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has two formats: Read format and Write-Back format

**NOTE**

TSO Split header is not supported.

Software must not write same tail pointer addresses when DMA is in Suspended state before setting new descriptor(s) for further processing.

### 72.15.3.1 Transmit Normal Descriptor (Read Format)

Following figure shows the Read Format for a Transmit normal descriptor. Table: 'TDES0 Normal Descriptor (Read Format)' through Table: 'TDES3 Normal Descriptor (Read Format)' describe the read format for the Transmit Normal Descriptors: TDES0, TDES1, TDES2, and TDES3.

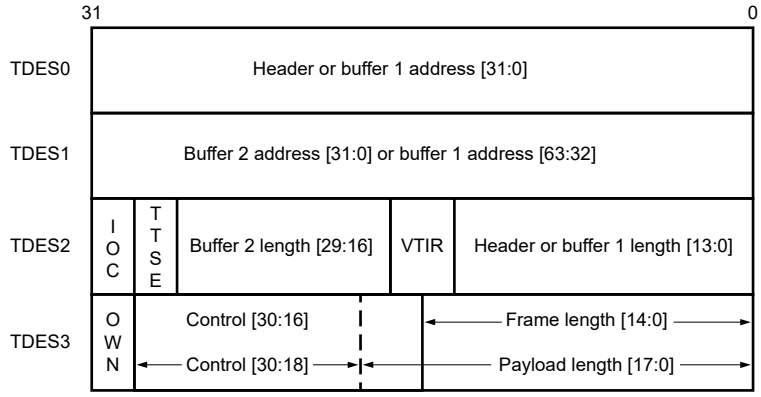

**Figure 413. Transmit Descriptor Read Format**

### 72.15.3.1.1 TDES0 Normal Descriptor (Read Format)

**Table 513. TDES0 Normal Descriptor (Read Format)**

| Bit | Name | Description |
|---|---|---|
| 31:0 | BUF1AP | Buffer 1 Address Pointer or TSO Header Address Pointer<br>These bits indicate the physical address of Buffer 1. These bits indicate the TSO Header Address pointer when the following bits are set:<br>• TSE bit of TDES3<br>• FD bit of TDES3 |

### 72.15.3.1.2 TDES1 Normal Descriptor (Read Format)

**Table 514. TDES1 Normal Descriptor (Read Format)**

| Bit | Name | Description |
|---|---|---|
| 31:0 | BUF2AP | Buffer 2 or Buffer 1 Address Pointer<br>This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment.<br>In 40- or 48-bit addressing mode, these bits indicate the most-significant 8- or 16- bits of the Buffer 1 Address Pointer. |

### 72.15.3.1.3 TDES2 Normal Descriptor (Read Format)

**Table 515. TDES2 Normal Descriptor (Read Format)**

| 31 | 30 | 29-16 | 15:14 | 13:0 |
|---|---|---|---|---|
| IOC | TTSE/ TMWD | B2L | VTIR | HL or B1L |

Table 516. TDES2 Normal Descriptor (Read Format)

| Bits | Name | Description |
|---|---|---|
| 31 | IOC | Interrupt on Completion<br>This bit controls the setting of TI and ETI status bits in the DMA_CH#_Status register. When ETIC = 1 and TDES2[LD] = 0, this bit sets the ETI bit. When TDES3[LD] = 1, this bit sets the TI status bit. |
| 30 | TTSE/ TMWD | Transmit Timestamp Enable or External TSO Memory Write Enable<br>This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor, if TSE bit is not set.<br>If TSE bit is set and external TSO memory is enabled, setting this bit disables external TSO memory writing for this packet. |
| 29:16 | B2L | Buffer 2 Length<br>The driver sets this field. When set, this field indicates Buffer 2 length. |
| 15:14 | VTIR | VLAN Tag Insertion or Replacement<br>These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits:<br>• 2'b00: Do not add a VLAN tag.<br>• 2'b01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets.<br>• 2'b10: Insert a VLAN tag with the tag value programmed in the MAC_VLAN_Incl register or context descriptor.<br>• 2'b11: Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets.<br>These bits are valid when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core. |
| 13:0 | HL or B1L | Header Length or Buffer 1 Length<br>For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length.<br>If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length in bytes from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes. The maximum header length supported for TSO feature is 1023 bytes.<br>If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length. |

#### 72.15.3.1.4 TDES3 Normal Descriptor (Read Format)

Table 517. TDES2 Normal Descriptor (Read Format)

| 31 | 30 | 29 | 28 | 27:26 | 25:23 | 22:19 | 18 | 17:16 | 15 | 14:0 |
|---|---|---|---|---|---|---|---|---|---|---|
| OWN | CTXT | FD | LD | CPC | SAIC | SLOTNUM or THL | TSE | CIC/TPL | TPL | FL/TPL |

Table 518. TDES3 Normal Descriptor (Read Format)

| Bits | Name | Description |
|---|---|---|
| 31 | OWN | Own Bit<br>When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s). |
| 30 | CTXT | Context Type<br>This bit should be set to 1'b0 for normal descriptor. |
| 29 | FD | First Descriptor<br>When this bit is set, it indicates that the buffer contains the first segment of a packet. |
| 28 | LD | Last Descriptor<br>When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value. |
| 27:26 | CPC | CRC Pad Control<br>This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of Bits[27:26]:<br>• 2'b00: CRC and Pad Insertion<br>The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes.<br>• 2'b01: CRC Insertion (Disable Pad Insertion)<br>The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes.<br>• 2'b10: Disable CRC Insertion<br>The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer.<br>• 2'b11: CRC Replacement<br>The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer.<br>This field is valid only for the first descriptor.<br>Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation. |
| 25:23 | SAIC | SA Insertion Control<br>These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet. |

*Table continues on the next page...*

**Table 518. TDES3 Normal Descriptor (Read Format) (continued)**

| Bits | Name | Description |
|---|---|---|
| | | Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement.<br>The following list describes the values of Bits[24:23]:<br>• 2'b00: Do not include the source address<br>• 2'b01: Include or insert the source address. For reliable transmission, the application must provide frames without source addresses.<br>• 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses.<br>• 2'b11: Reserved<br>These bits are valid in the EQOS-DMA, EQOS-AXI, and EQOS-AHB configurations when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core and when the First Segment control bit (TDES3 [29]) is set.<br>This field is valid only for the first descriptor. |
| 22:19 | SLOTNUM or THL | SLOTNUM: Slot Number Control Bits in AV Mode<br>These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1.<br>When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH#_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels.<br>THL: TCP/UDP Header Length<br>If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header.<br>This field is valid only for the first descriptor. |
| 18 | TSE | TSO Split header is not supported. The value of this bit is always zero. |
| 17:16 | CIC/TPL | Checksum Insertion Control or TCP Payload Length<br>These bits control the checksum calculation and insertion. The following list describes the bit encoding:<br>• 2'b00: Checksum Insertion Disabled.<br>• 2'b01: Only IP header checksum calculation and insertion are enabled.<br>• 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware.<br>• 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware.<br>This field is valid when the Enable Transmit TCP/IP Checksum Offload option is selected and the TSE bit is reset.<br>When the TSE bit is set, this field contains the upper bits [17:16] of the TCP Payload (or IP Payload for UDP fragmentation). This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support. |

*Table continues on the next page...*

Table 518. TDES3 Normal Descriptor (Read Format) (continued)

| Bits | Name | Description |
|---|---|---|
| | | This field is valid only for the first descriptor. |
| 15 | TPL | Reserved or TCP Payload Length<br>When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is Bit 15 of the TCP payload length [17:0].<br>This field is valid only when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected while configuring the core. |
| 14:0 | FL/TPL | Frame Length or TCP Payload Length<br>This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted:<br>Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length<br>When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length in case of segmentation and IP payload in case of UDP fragmentation.<br>In case of segmentation, this length does not include Ethernet header or TCP/UDP/IP header length. In case of fragmentation, this length does not include Ethernet header and IP header.<br>When DWRR/WFQ algorithm is NOT enabled, value written into this field is not used when TSE = 0. |

#### 72.15.3.1.5 Transmit normal descriptor (write-back format)

The transmit descriptor write-back format includes timestamp low, timestamp high, OWN, and Status bits.

The write-back format is applicable only for the last descriptor of the corresponding packet. Write 1 to the LD bit (TDES3[28]) in the descriptor where DMA writes back the status and timestamp information for the corresponding transmit packet.

Figure 414 shows the transmit descriptor write-back format.

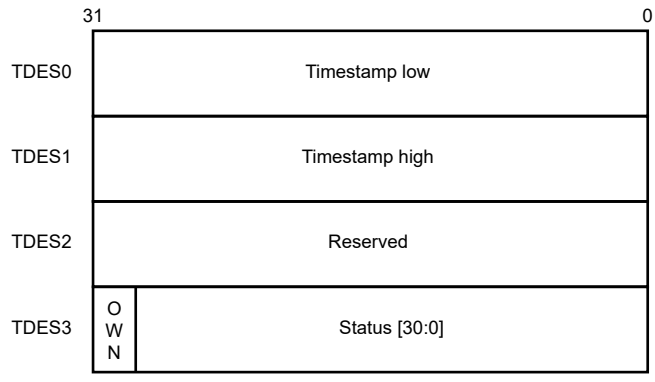

Figure 414. Transmit descriptor write-back format

TDES0 normal descriptor (write-back format)

Table 519 shows that this format is only applicable to the last descriptor of a packet.

**Table 519. TDES0 normal descriptor (write-back format)TDES0 normal descriptor (write-back format)**

| Bit | Name | Description |
|---|---|---|
| 31:0 | TTSL | Transmit Packet Timestamp Low<br>DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding transmit packet. DMA writes the timestamp only if TTSE bit of TDES2 is 1 in the first descriptor of the packet. This field has the timestamp only if you write 1 to the Last Segment bit (LS) in the descriptor and the Timestamp status (TTSS) bit. |

TDES1 normal descriptor (write-back format)

Table 520 shows that this format is only applicable to the last descriptor of a packet.

**Table 520. TDES1 normal descriptor (write-back format)**

| Bit | Name | Description |
|---|---|---|
| 31:0 | TTSH | Transmit Packet Timestamp High<br>DMA updates this field with the most significant 32 bits of the timestamp captured for a corresponding transmit packet. DMA writes the timestamp only if the TTSE bit of TDES2 is 1 in the first descriptor of the packet. This field has the timestamp only if you write 1 to the Last Segment bit (LS) in the descriptor and Timestamp status (TTSS) bit. |

TDES2 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

**Table 521. TDES2 normal descriptor (write-back format)**

| Bit | Description |
|---|---|
| 31:0 | Reserved |

TDES3 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

**Table 522. TDES3 normal descriptor (write-back format)**

| 31 | 30 | 29 | 28 | 27:18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7:4 | 3 | 2 | 1 | 0 |

| OWN | CTXT | FD | LD | Rsvd | TTSS | EUE | ES | JT | FF | PCE | LoC | NC | LC | EC | CC | ED | UF | DB | IHE |

**Table 523. TDES3 normal descriptor (write-back format)**

| Bit | Name | Description |
|---|---|---|
| 31 | OWN | Own Bit<br>When this field is 1, it indicates that the module DMA owns the descriptor. DMA write 0 to this field when it completes the packet transmission. After the write-back is complete, this field is set to 'b0. |
| 30 | CTXT | Context Type |

*Table continues on the next page...*

Table 523. TDES3 normal descriptor (write-back format) (continued)

| Bit | Name | Description |
|---|---|---|
| | | This field must be set to 'b0 for normal descriptor. |
| 29 | FD | First Descriptor<br>This field indicates that the buffer contains the first segment of a packet. |
| 28 | LD | Last Descriptor<br>This field is set to 'b1 for last descriptor of a packet. DMA writes the status fields only in the last descriptor of the packet. |
| 27:24 | Rsvd | Reserved |
| 23 | DE | Descriptor Error<br>When this field is 1, it indicates that the descriptor content is incorrect. DMA writes 1 to this field during write-back when the descriptor is closed.<br>Descriptor errors can be:<br>• Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet.<br>• All 1s<br>• CTXT is 1 along with LD or FD bits as 1.<br>**NOTE**<br>When a descriptor error occurs due to all ones or CTXT, LD, and FD bits are 1, the transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When you write 1 to IOC bit in TDES2 of corresponding first descriptor, the transmit DMA write 1 to TI bit in the DMA_CH#_Status register<br>**NOTE**<br>Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might consider as the first descriptor (even if FD bit is not 1) and partial packet is sent. |
| 22:18 | Rsvd | Reserved |
| 17 | TTSS | Tx Timestamp Status<br>This field indicates that a timestamp has been captured for the corresponding transmit packet. When this field is 1, it indicates that TDES0 and TDES1 have timestamp values that were captured for the transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is 1. This field is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved. |
| 16 | EUE | ECC Uncorrectable Error Status<br>Indicates the ECC uncorrectable error in the TSO memory.<br>**NOTE**<br>An uncorrectable error in the transmit FIFO memory is reported with (Bit 13) FF = 1. This is because the module flushes all such packets. |

*Table continues on the next page...*

Table 523. TDES3 normal descriptor (write-back format) (continued)

| Bit | Name | Description |
|---|---|---|
| 15 | ES | Error Summary<br>This field indicates the logical OR of the following bits:<br>• TDES3[0]: IP header error<br>• TDES3[14]: Jabber timeout<br>• TDES3[13]: Packet flush<br>• TDES3[12]: Payload checksum error<br>• TDES3[11]: Loss of carrier<br>• TDES3[10]: No carrier<br>• TDES3[9]: Late collision<br>• TDES3[8]: Excessive collision<br>• TDES3[3]: Excessive deferral<br>• TDES3[2]: Underflow error<br>This field is 1 when EUE (bit 16) = 1. |
| 14 | JT | Jabber Timeout<br>This field indicates that the MAC transmitter experiences a jabber time-out. This field is 1 only when MAC_Configuration[JD] is not 1. |
| 13 | FF | Packet Flushed<br>This field indicates that DMA or MTL flushes the packet because the CPU gives a software flush command. |
| 12 | PCE | Payload Checksum Error<br>This field indicates that the checksum offload engine had a failure and does not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can either because of insufficient bytes, as the payload length field of the IP header indicates or the MTL starting to forward the packet to the MAC transmitter in Store-and-forward mode without calculating the checksum. This second error condition only occurs when the transmit FIFO depth is less than the length of the Ethernet packet that is transmitted to avoid deadlock. The MTL starts forwarding the packet when the FIFO is full, even in the Store-and-forward mode.<br>This error can also occur when you detects a bus error during packet transfer.<br>When the full checksum offload engine is not enabled, this bit is reserved. |
| 11 | LoC | Loss of Carrier<br>This field indicates that a loss of carrier occurred during packet transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during packet transmission). This field is valid only for the packets transmitted without collision and when MAC operates in the Half-duplex mode. |
| 10 | NC | No Carrier<br>This field indicates that the carrier sense signal from the PHY was not asserted during transmission. |

*Table continues on the next page...*

Table 523. TDES3 normal descriptor (write-back format) (continued)

| Bit | Name | Description |
|---|---|---|
| 9 | LC | Late Collision<br>This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode and 512 byte times including Preamble and Carrier Extension in GMII mode). This bit is not valid if Underflow Error is set. |
| 8 | EC | Excessive Collision<br>This field indicates that the transmission was aborted after 16 successive collisions when you transmits the current packet. If MAC_Configuration[DR] = 1, this field is 1 after first collision and abort the packet transmission. |
| 7:4 | CC | Collision Count<br>This 4-bit counter value indicates the number of collisions occurred before transmitting the packet. The count is not valid when the EC bit = 1. |
| 3 | ED | Excessive Deferral<br>This field indicates that the transmission ends because of an excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbit/s mode or Jumbo packet enabled mode) if MAC_Configuration[DC] = 1.<br>When TBS is enabled in Full duplex mode and this field is 1, it indicates that the frame drops after the expiry time is reached. |
| 2 | UF | Underflow Error<br>This field indicates that MAC aborts the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions:<br>• DMA encounters an empty transmit buffer when it transmits the packet<br>• The application filled the MTL Tx FIFO slower than the MAC transmit rate<br>The transmission process enters the Suspended state and sets the underflow bit corresponding to a queue in MTL_Interrupt_Status. |
| 1 | DB | Deferred Bit<br>This field indicates that MAC defers before transmitting because of presence of carrier. This field is valid only in the Half-Duplex mode. |
| 0 | IHE | IP Header Error<br>When IP Header Error is 1, this field indicates that the checksum offload engine detects an IP header error. This field is valid only when transit checksum offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it inserts an IPv4 header checksum if the Ethernet type field indicates an IPv4 payload.<br>In Full-Duplex mode, when EST/Qbv is enabled and this field is 1, it indicates the frame drop status due to the frame size error or schedule error. |

### 72.15.3.2 Transmit context descriptor

The transmit context descriptor can provide any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor provide the timestamps for one-step timestamp correction and VLAN tag ID for VLAN insertion feature. Write back is done on a context descriptor only to write 0 to OWN bit.

**NOTE**

DMA internally store the VLAN tag IDs and MSS values which the application provides in a context descriptor with their corresponding valid bits set. DMA always passes the last valid VLAN tag to the MTL, when the outer or inner VLAN tag is provided with the valid bit set. The application cannot invalidate the valid VLAN tag which DMA stores. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The inner VLAN tag control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which DMA must use the inner VLAN tag control input.

Figure 415 shows the transmit context descriptor format.

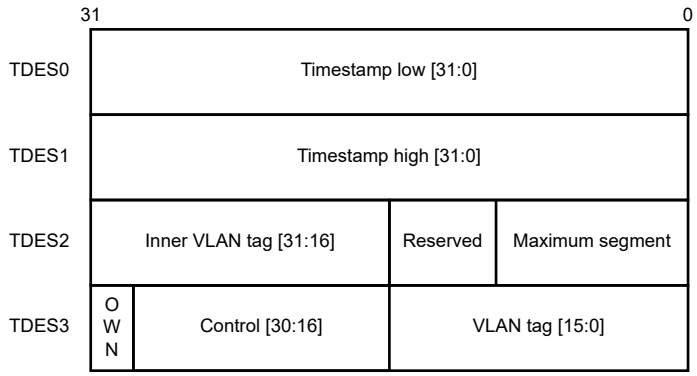

**Figure 415. Transmit context descriptor format**

### 72.15.3.2.1 TDES0 context descriptor

Table 524 describes the TDES0 context descriptor format.

**Table 524. TDES0 context descriptor**

| Bit | Name | Description |
|---|---|---|
| 31:0 | TTSL | Transmit Packet Timestamp Low<br>For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are 1. |

### 72.15.3.2.2 TDES1 context descriptor

Table 525 describes the TDES1 context descriptor format.

**Table 525. TDES1 context descriptor**

| Bit | Name | Description |
|---|---|---|
| 31:0 | TTSH | Transmit Packet Timestamp High<br>For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are 1. |

#### 72.15.3.2.3 TDES2 context descriptor

Table 526 shows the TDES2 context descriptor format.

**Table 526. TDES2 context descriptor**

| Bit | Name | Description |
|---|---|---|
| 31:16 | IVT | Inner VLAN Tag<br>When the IVLTV bit of TDES3 context descriptor is 1 and the TCMSSV and OSTC bits of TDES3 context descriptor becomes 0, it indicates that the TDES2[31:16] contains the inner VLAN tag to insert in the subsequent transmit packets. |
| 15:14 | Rsvd | Reserved |
| 13:0 | MSS | TSO split header is not supported. The value of this bit is always zero. |

#### 72.15.3.2.4 TDES3 context descriptor

**Table 527. TDES3 context descriptor**

| 31 | 30 | 29:28 | 27 | 26 | 25:24 | 23 | 22:18 | 17 | 16 | 15:0 |
|---|---|---|---|---|---|---|---|---|---|---|
| OWN | CTXT | Rsvd | OSTC | TCMSSV | Rsvd | CDE | Rsvd | IVLTV | VLTV | VT |

Table 528 shows the TDES3 context descriptor format.

**Table 528. TDES3 context descriptor**

| Bit | Name | Description |
|---|---|---|
| 31 | OWN | Own Bit<br>When this field is 1, it indicates that the module DMA owns the descriptor. When this field becomes 0, it indicates that the application owns the descriptor. DMA writes 0 to this field immediately after the read. |
| 30 | CTXT | Context Type<br>This field must set to 1'b1 for context descriptor. |
| 29:28 | Rsvd | Reserved |
| 27 | OSTC | One-Step Timestamp Correction Enable<br>When this field is 1, it indicates that DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1. |
| 26 | TCMSSV | One-Step Timestamp Correction Input or MSS Valid<br>When this field and the OSTC field are 1, it indicates that the timestamp correction input provided in TDES0 and TDES1 is valid.<br>When the OSTC field becomes 0 and this field and the TSE bit of TDES3 are 1 in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid. |
| 25:24 | Rsvd | Reserved |

*Table continues on the next page...*

**Table 528. TDES3 context descriptor (continued)**

| Bit | Name | Description |
|---|---|---|
| 23 | DE | Descriptor Error<br>When this field is 1, it indicates that the descriptor content is incorrect. DMA writes 1 to this field during write-back when it closes the context descriptor.<br>Descriptor errors can be:<br>• Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet.<br>• All ones.<br>• CD, LD, and FD bits = 1.<br>**NOTE**<br>When a descriptor error occurs due to all ones or CTXT, LD, and FD bits are 1, the transmit DMA closes the transmit descriptor with DE and LD bits are 1. When you write 1 to IOC bit in TDES2 of corresponding first descriptor, the transmit DMA writes 1 to TI bit in the DMA_CH#_Status register<br>**NOTE**<br>On the basis of CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might considered as the first descriptor (even if FD bit is not 1) and partial packet is sent.<br>**NOTE**<br>This error is categorized as an abnormal event. Recovery from this event is possible by issuing a software reset only. DMA stopping, reconfiguring, and restarting recovery mechanism is not supported. |
| 22:20 | Rsvd | Reserved |
| 19:18 | IVTIR | Inner VLAN Tag Insert or Replace<br>When this field is 1, it requests MAC to perform inner VLAN tagging or un-tagging before transmitting the packets. If the packet is modified for VLAN tags, MAC automatically recalculates and replaces the CRC bytes.<br>The following list describes the values of these bits:<br>• 2'b00: Do not add the inner VLAN tag.<br>• 2'b01: Remove the inner VLAN tag from the packets before transmission. You must use this option only with the VLAN frames.<br>• 2'b10: Insert an inner VLAN tag with the tag value programmed in MAC_Inner_VLAN_Incl or context descriptor.<br>• 2'b11: Replace the inner VLAN tag in packets with the tag value programmed in MAC_Inner_VLAN_Incl or context descriptor. You must use this option only with the VLAN frames..<br>These fields are valid when you select the enable SA and VLAN insertion on transit and enable double VLAN processing options. |
| 17 | IVLTV | Inner VLAN Tag Valid<br>When this field is 1, it indicates that IVT field of TDES2 is valid. |

*Table continues on the next page...*

Table 528. TDES3 context descriptor (continued)

| Bit | Name | Description |
|---|---|---|
| 16 | VLTV | VLAN Tag Valid<br>When this field is 1, it indicates that VT field of TDES3 is valid. |
| 15:0 | VT | VLAN Tag<br>Contains the VLAN tag to insert or replace in the packet. This field is used as VLAN tag only when MAC_VLAN_Incl[VLTI] becomes 0. |

### 72.15.4 Receive descriptor

DMA in the module reads a descriptor only if the tail pointer is different from the base pointer or current pointer. It is recommended to have a descriptor ring with a length that accommodates at least two complete packets which MAC receives. Otherwise, the performance of DMA is impacted because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following receive descriptors are present:

- Normal descriptors
- Context descriptors

You can prepare all the receive descriptors and give to DMA as normal descriptors with the content as shown in receive normal descriptor (read format). DMA reads this descriptor and the receive DMA closes the descriptor with the corresponding packet status after transferring a received packet (or part of) to the buffers indicated by the descriptor. The receive normal descriptor (write-back format) describes the format of this status.

For some packets, only the normal descriptor bits cannot write the complete status. For such packets, the receive DMA writes the extended status to the next descriptor (without processing or using the buffers or pointers embedded in that descriptor). Receive context descriptor describes the descriptor write back format and content.

#### 72.15.4.1 Receive normal descriptor (read format)

The read format for a receive normal descriptor is made up of the following:

- A header or buffer 1 address
- Reserved field
- Payload or buffer 2 or next descriptor address
- A 30-bit reserved field
- OWN bit
- An interrupt field

Figure 416 shows the read format for a receive normal descriptor.

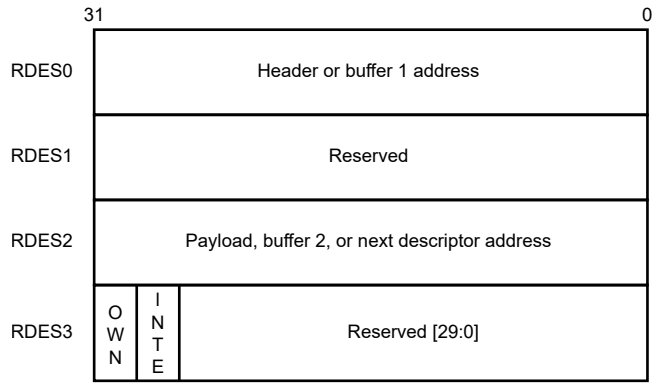

**Figure 416. Receive normal descriptor read format**

**NOTE**

In the receive descriptor (read format), if the buffer address field is all zeros, the module does not transfer data to that buffer and skips to the next buffer or next descriptor.

#### 72.15.4.1.1 RDES0 normal descriptor (read format)

Table 529 shows the RDES0 normal descriptor read format.

**Table 529. RDES0 normal descriptor (read format)**

| Bit | Name | Description |
|---|---|---|
| 31:0 | BUF1AP | Header or Buffer 1 Address Pointer<br>When the SPH field of control register of a channel becomes 0, these field indicates the physical address of buffer 1. When the SPH field is 1, these field indicates the physical address of header buffer where the receive DMA writes the L2/L3/L4 header bytes of the received packet.<br>The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, DMA performs a write operation with RDES0[1:0] (or RDES0[2:0]/[3:0] in case of 64-/128-bit configuration) as zero, when the start of packet is transferred. However, the packet data shifts per the actual offset which the buffer address pointer provides.<br>If the address pointer points to a buffer where the middle or last part of the packet is stored, DMA ignores the offset address and writes to the full location which the data-width indicates . |

#### 72.15.4.1.2 RDES1 normal descriptor (read format)

Table 530 shows the RDES1 normal descriptor read format.

**Table 530. RDES1 normal descriptor (read format)**

| Bit | Name | Description |
|---|---|---|
| 31:0 | Reserved or BUF1AP | Contains the most-significant 32 bits of the buffer 1 address pointer in 64-bit Addressing mode. Otherwise, this field is reserved. |

#### 72.15.4.1.3 RDES2 normal descriptor (read format)

Table 531 shows the RDES2 normal descriptor read format.

Table 531. RDES2 normal descriptor (read format)

| Bit | Name | Description |
|---|---|---|
| 31:0 | BUF2AP | Buffer 2 Address Pointer<br>Indicates the physical address of buffer 2.<br>When the SPH bit of the DMA_CH#_Control register = 1, it indicates that the buffer address pointer must be bus width-aligned, that is, RDES2[3:0, 2:0, or 1:0] = 0 corresponding to 128, 64, or 32 bus width. LSBs are ignored internally.<br>When the SPH bit of the DMA_CH#_Control register becomes 0, it indicates that there is no limitations on the RDES2 value. However, the RxDMA uses the LS fields of the pointer address only when it transfers the start bytes of a packet. If the BUF2AP provides the address of a buffer in which the middle or last part of a packet is stored, DMA ignores BUF2AP[3:0 or 2:0 or 1:0] (corresponding to 128- or 64- or 32-bit data-bus) and writes to the complete location. |

#### 72.15.4.1.4 RDES3 normal descriptor (read format)

Following table describes the RDES3 normal descriptor read format.

| 31 | 30 | 19-26 | 25 | 24 | 23:0 |
|---|---|---|---|---|---|
| OWN | IOC | Rsvd | BUF2V | BUF1V | Rsvd |

Table 532. RDES3 normal descriptor (read format)

| Bit | Name | Description |
|---|---|---|
| 31 | OWN | Own Bit<br>When this field is 1, it indicates that the module DMA owns the descriptor. When this field becomes 0, it indicates that the application owns the descriptor. DMA write 0 this field when either of the following conditions is true:<br>• DMA completes the packet reception.<br>• The buffers associated with the descriptor are full. |
| 30 | IOC | Interrupt Enabled on Completion<br>When this field is 1, it indicates that an interrupt is issued to the application when DMA closes this descriptor. |
| 29:26 | Rsvd | Reserved |
| 25 | BUF2V | Buffer 2 Address Valid<br>When this field is 1, it indicates to the DMA that the buffer 2 address specified in RDES2 is valid.<br>The application must write 1 to this field so that DMA can use the address, to which the buffer 2 address in RDES2 points to write received packet data. |
| 24 | BUF1V | Buffer 1 Address Valid<br>When this field is 1, it indicates to the DMA that the buffer 1 address specified in RDES1 is valid. |

*Table continues on the next page...*

Table 532. RDES3 normal descriptor (read format) (continued)

| Bit | Name | Description |
|---|---|---|
| | | The application must write 1 to this field, if DMA uses the address to which the buffer 1 address in RDES1 points to<br>write the received packet data. |
| 23:0 | Rsvd | Reserved |

### 72.15.4.1.5 Receive normal descriptor (write-back format)

Following figure shows the write-back format for a receive normal descriptor.

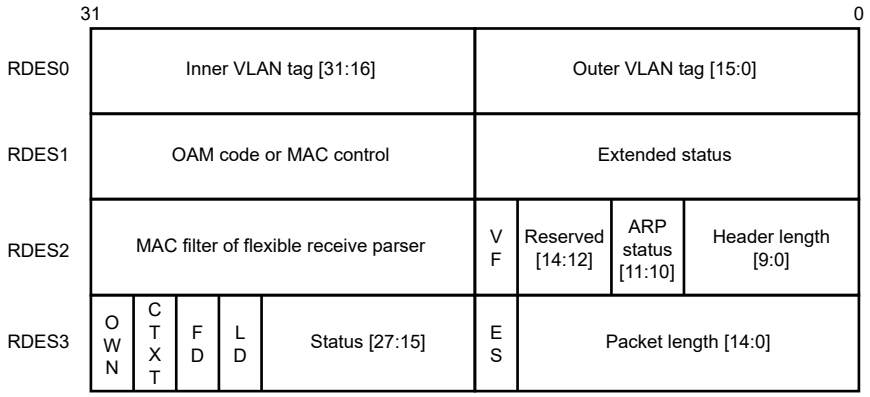

Figure 417. Receive normal descriptor (write-back format)

**NOTE**

When you enables the flexible receive parser, RDES2[31:16] indicates the parser status, and not the MAC filter status. The MAC filter status is not available when flexible receive parser is enabled.

#### 72.15.4.1.5.1 RDES0 normal descriptor (write-back format)

Table 533 shows the write-back format for the RDES0 normal descriptor.

Table 533. RDES0 normal descriptor (write-back format)

| Bit | Name | Description |
|---|---|---|
| 31:16 | IVT | Inner VLAN Tag<br>Contains the inner VLAN tag of the received packet if the RS0V bit of RDES3 = 1.<br>This field is valid only when you enables the double VLAN tag processing and VLAN tag stripping. |
| 15:0 | OVT | Outer VLAN Tag<br>Contains the outer VLAN tag of the received packet if the RS0V bit of RDES3 = 1. |

#### 72.15.4.1.5.2 RDES1 normal descriptor (write-back format)

The status fields in the write-back format are valid only for the last descriptor (RDES3[28] = 1). Following table provide the details of the write-back format for RDES1 normal descriptor.

| 31:16 | 15 | 14 | 13 | 12 | 11:8 | 7 | 6 | 5 | 4 | 3 | 2:0 |
|---|---|---|---|---|---|---|---|---|---|---|---|
| OPC | TD | TSA | PV | PFT | PMT | IPCE | IPCB | IPV6 | IPV4 | IPHE | PT |

**Table 534. RDES1 normal descriptor (write-back format)**

| Bit | Name | Description |
|---|---|---|
| 31:16 | OPC | Indicates any one of the following:<br>• OAM sub-type code: If bits [18:16] of RDES3 as described in RDES3 normal descriptor (read format) are 111b, this field contains the OAM sub-type and code fields.<br>• MAC control packet opcode: Bits 15:8 of RDES3 as described in RDES3 normal descriptor (read format) contain the subtype and bits 7:0 contain the code. |
| 15 | TD | Timestamp Dropped<br>Indicates that the timestamp was captured for this packet but it dropped in the MTL Rx FIFO because of overflow.<br>This field is available only when you select the timestamp feature. Otherwise, this field is reserved. |
| 14 | TSA | Timestamp Available<br>Indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1) when timestamp is present. This is valid only when the last descriptor field (RDES3 [28]) = 1<br>You can write the context descriptor in the next descriptor just after the last normal descriptor for a packet. |
| 13 | PV | PTP Version<br>Indicates that the received PTP message has the IEEE 1588 version 2 format. When this field becomes 0, it indicates the IEEE 1588 version 1 format.<br>This field is available only when you select the timestamp feature. Otherwise, this field is reserved. |
| 12 | PFT | PTP Packet Type<br>Indicates that the PTP message is sent directly over Ethernet. This field is available only when you select the timestamp feature. Otherwise, this field is reserved. |
| 11:8 | PMT | PTP Message Type<br>Encodes to give the type of the message received:<br>• 0000: No PTP message received<br>• 0001: SYNC (all clock types)<br>• 0010: Follow_Up (all clock types)<br>• 0011: Delay_Req (all clock types)<br>• 0100: Delay_Resp (all clock types)<br>• 0101: Pdelay_Req (in peer-to-peer transparent clock)<br>• 0110: Pdelay_Resp (in peer-to-peer transparent clock)<br>• 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) |

*Table continues on the next page...*

Table 534. RDES1 normal descriptor (write-back format) (continued)

| Bit | Name | Description |
|---|---|---|
| | | • 1000: Announce<br>• 1001: Management<br>• 1010: Signaling<br>• 1011–1110: Reserved<br>• 1111: PTP packet with reserved message type<br>These fields are available only when you select the timestamp feature. |
| 7 | IPCE | IP Payload Error<br>When this field is 1, it indicates either of the following:<br>• The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) which MAC calculates does not match the corresponding checksum field in the received segment.<br>• The TCP, UDP, or ICMP segment length does not match the payload length value in the IP header field.<br>• The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP.<br>Bit 15 (ES) of RDES3 is not set when this field is 1. |
| 6 | IPCB | IP Checksum Bypassed<br>Indicates that the checksum offload engine is bypassed. This field is available when you select the enable receive TCP/IP checksum check feature. |
| 5 | IPV6 | IPv6 header Present<br>Indicates that an IPV6 header is detected. When you select the enable split header feature option and the SPH bit of control register of a channel is 1, the IPV6 header is available in the header buffer area to which RDES0 points. |
| 4 | IPV4 | IPV4 Header Present<br>Indicates that an IPV4 header is detected. When the SPH bit of RDES3 is 1, the IPV4 header is available in the header buffer area to which RDES0 points. |
| 3 | IPHE | IP Header Error<br>When this field is 1, it indicates either of the following:<br>• The 16-bit IPv4 header checksum which MAC calculates does not match the received checksum bytes.<br>• The IP datagram version is not consistent with the Ethernet type value.<br>• Ethernet packet does not have the expected number of IP header bytes.<br>This field is valid when either bit 5 or bit 4 is 1. This field is available when you select the enable receive TCP/IP checksum check feature. |
| 2:0 | PT | Payload Type<br>Indicates the type of payload encapsulated in the IP datagram that the receive checksum offload engine (COE) process. |

*Table continues on the next page...*

Table 534. RDES1 normal descriptor (write-back format) (continued)

| Bit | Name | Description |
|---|---|---|
| | | • 3'b000: Unknown type or IP/AV payload not processed<br>• 3'b001: UDP<br>• 3'b010: TCP<br>• 3'b011: ICMP<br>• 3'b110: AV tagged data packet<br>• 3'b111: AV tagged control packet<br>• 3'b101: AV untagged control packet<br>• 3'b100: IGMP, if IPV4 header present field = 1, else DCB (LLDP) control packet<br>If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these fields to 3'b000. |

#### 72.15.4.1.5.3 RDES2 normal descriptor (Write-back format)

| 31:29 | 28 | 27 | 26:19 | 18 | 17 | 16 | 15 | 14 | 13:11 | 10 | 9:0 |
|---|---|---|---|---|---|---|---|---|---|---|---|
| L3L4FM | L4FM | L3FM | MADRM | HF | DAF | SAF | OTS | ITS | Rsvd | ARPNR | HL |

Table 535. RDES2 normal descriptor (Write-back format)

| Bit | Name | Description |
|---|---|---|
| 31:29 | L3L4FM | Layer 3 and Layer 4 Filter Number Matched<br>Indicates the number of the layer 3 and layer 4 filter that matches the received packet:<br>• 000: Filter 0<br>• 001: Filter 1<br>• 010: Filter 2<br>• 011: Filter 3<br>• 100: Filter 4<br>• 101: Filter 5<br>• 110: Filter 6<br>• 111: Filter 7<br>This field is valid only when bit 28 or bit 27 = 1. When more than one filter matches, these fields provide the number of lowest filter.<br>**NOTE**<br>This status is not available when Flexible RX Parser is enabled. |
| 28 | L4FM | Layer 4 Filter Match |

*Table continues on the next page...*

Table 535. RDES2 normal descriptor (Write-back format) (continued)

| Bit | Name | Description |
|---|---|---|
| | | When this field is 1, it indicates that the received packet matches one of the enabled layer 4 port number fields. This status is given only when one of these conditions is true:<br>• Layer 3 fields are not enabled and all enabled layer 4 fields match<br>• All enabled layer 3 and layer 4 filter fields match<br>When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits[31:29].<br>**NOTE**<br>This status is not available when the flexible receive parser is enabled. |
| 27 | L3FM | Layer 3 Filter Match<br>When this field is 1, it indicates that the received packet matches one of the enabled layer 3 IP address fields. This status is given only when one of these conditions is true:<br>• All enabled layer 3 fields match and bypasses all enabled layer 4 fields.<br>• All enabled filter fields match.<br>When more than one filter matches, this field gives the layer 3 filter status of filter which bits[31:29] indicate.<br>**NOTE**<br>This status is not available when the flexible receive parser is enabled. |
| 26:19 | MADRM | MAC Address Match or Hash Value<br>When HF becomes 0, it indicates that this field contains the MAC address register number that matches the received packet destination address. This field is valid only if the DAF field becomes 0.<br>When HF = 1, it indicates that this field contains the hash value that MAC computes. A packet passes the hash filter when the field corresponding to the hash value is 1 in the hash filter register.<br>**NOTE**<br>This status is not available when the flexible receive parser is enabled. |
| 18 | HF | Hash Filter Status<br>When this field is 1, it indicates that the packet passes the MAC address hash filter. Bits[26:19] indicate the hash value.<br>**NOTE**<br>This status is not available when the flexible receive parser is enabled. |
| 17 | DAF/RXPI | Destination Address Filter Fail<br>When flexible receive parser is disabled, and this field is 1, it indicates that the packet fails the DA filter in MAC.<br>When flexible receive parser is enabled, and this field is 1, it indicates that the packet parsing is incomplete (RXPI) due to ECC error. |

*Table continues on the next page...*

Table 535. RDES2 normal descriptor (Write-back format) (continued)

| Bit | Name | Description |
|---|---|---|
| | | **NOTE**<br>When this field is 1, RDES3 ES field is also 1. |
| 16 | SAF/RXPD | SA Address Filter Fail<br>When flexible receive parser is disabled, and this field is 1, it indicates that the packet fails the SA filter in MAC.<br>When flexible receive parser is enabled and this field is 1, it indicates that the parser drops the RXPD packet.<br>**NOTE**<br>When this field is 1, RDES3 ES field is also 1. |
| 15 | OTS | VLAN Filter Status<br>When this field is 1, it indicates that the received packet VLAN tag passes the VLAN filter.<br>This field redefines as an outer VLAN tag filter status (OTS). This field is valid for both single and double VLAN tagged frames. |
| 14 | ITS | Inner VLAN Tag Filter Status (ITS)<br>This field is valid only for double VLAN tagged frames, when double VLAN processing is enabled.<br>See Filter status for more information. |
| 13:11 | Rsvd | Reserved |
| 10 | ARPNR | ARP Reply Not Generated<br>When this field is 1, it indicates that MAC did not generate the ARP reply for the ARP request packet it receives.. This field is 1 when MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time).<br>This field is reserved when you do not select the enable IPv4 ARP offload option. |
| 9:0 | HL | L3/L4 Header Length<br>Contains the length of the packet header which MAC splits at L3 or L4 header boundary which the MAC receiver identifies. This field is valid only when the first descriptor bit = 1 (FD = 1).<br>You can write the header data to the buffer 1 address of corresponding descriptor. If the header length is zero, this field is not valid. It implies that MAC does not identify and split the header.<br>This field is valid when you select the enable split header feature option. |

### 72.15.4.1.5.4 RDES3 normal descriptor (Write-back format)

Following table describes the write-back format for the RDES3 normal descriptor.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18:16 | 15 | 14:0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| OWN | CTXT | FD | LD | RS2V | RS1V | RS0V | CE | GP | RWT | OE | RE | DE | LT | ES | PL |

Table 536. RDES3 normal descriptor (Write-back format)

| Bit | Name | Description |
|---|---|---|
| 31 | OWN | Own Bit<br>When this field is 1, it indicates that the module DMA owns the descriptor. If this field becomes 0, it indicates that the application owns the descriptor. DMA writes 0 to this field when either of these conditions is true:<br>• DMA completes the packet reception.<br>• The buffers associated with the descriptor are full. |
| 30 | CTXT | Receive Context Descriptor<br>When this field is 1, it indicates that the current descriptor is a context type descriptor. DMA writes 1'b0 to this field for a normal receive descriptor.<br>When CTXT and FD bits are used together, {CTXT, FD}<br>• 2’b00: Intermediate descriptor<br>• 2’b01: First descriptor<br>• 2’b10: Reserved<br>• 2’b11: Descriptor error (due to all 1s)<br>**NOTE**<br>When descriptor error occurs, the receive DMA closes the receive descriptor indicating a descriptor error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data. Receive DMA will write 1 to the CDE bit in DMA_CH#_Status register but not to the RI bit even when IOC = 1, as this is not marked as the last receive descriptor for the packet. The subsequent valid receive descriptor writes the packet data. |
| 29 | FD | First Descriptor<br>When this field is 1, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet and if the size of the second buffer is also 0, the next descriptor will contain the beginning of the packet.<br>See the CTXT bit description for more information on how to use the CTXT bit and FD bit together. |
| 28 | LD | Last Descriptor<br>When this field is 1, it indicates that this descriptor buffers points to the last buffers of the packet. |
| 27 | RS2V | Receive Status RDES2 Valid<br>When this field is 1, it indicates that the status in RDES2 is valid and DMA writes it. This field is valid only when the LD bit of RDES3 = 1. |
| 26 | RS1V | Receive Status RDES1 Valid<br>When this field is 1, it indicates that the status in RDES1 is valid and DMA writes it. This field is valid only when the LD bit of RDES3 = 1. |
| 25 | RS0V | Receive Status RDES0 Valid<br>When this field is 1, it indicates that the status in RDES0 is valid and DMA writes it. This field is valid only when the LD bit of RDES3 = 1. |

*Table continues on the next page...*

Table 536. RDES3 normal descriptor (Write-back format) (continued)

| Bit | Name | Description |
|---|---|---|
| 24 | CE | CRC Error<br>When this field is 1, it indicates that a cyclic redundancy check (CRC) error occurs on the received packet. This field is valid only when the LD bit of RDES3 = 1. |
| 23 | GP | Giant Packet<br>When this field is 1, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable = 1).<br>**NOTE**<br>Giant packet indicates only the packet length. It does not cause any packet truncation. |
| 22 | RWT | Receive Watchdog Timeout<br>When this field is 1, it indicates that the receive watchdog timer expires when it receives the current packet. The current packet truncates after watchdog timeout. |
| 21 | OE | Overflow Error<br>When this field is 1, it indicates that the received packet is damaged because of buffer overflow in receive FIFO.<br>**NOTE**<br>This field is 1 only when DMA transfers a partial packet to the application. This happens only when the receive FIFO operates in the Threshold mode. In the Store-and-Forward mode, all the partial packets drops completely in the receive FIFO. |
| 20 | RE | Receive Error<br>When this field is 1, it indicates that the gmii_rxer_i signal asserts when the gmii_rxdv_i signal asserts during the packet reception. This error also includes carrier extension error in the GMII and Half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension. |
| 19 | DE | Dribble Bit Error<br>When this field is 1, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This field is valid only in the MII mode. |
| 18:16 | LT | Length/Type Field<br>Indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows:<br>• 3'b000: The packet is a length packet.<br>• 3'b001: The packet is a type packet.<br>• 3'b011: The packet is a ARP request packet type<br>• 3'b100: The packet is a type packet with VLAN tag<br>• 3'b101: The packet is a type packet with double VLAN tag<br>• 3'b110: The packet is a MAC control packet type<br>• 3'b111: The packet is a OAM packet type |

*Table continues on the next page...*

Table 536. RDES3 normal descriptor (Write-back format) (continued)

| Bit | Name | Description |
|---|---|---|
| | | • 3'b010: Reserved |
| 15 | ES | Error Summary<br>When this field is 1, it indicates the logical OR of these bits, :<br>• RDES3[24]: CRC error<br>• RDES3[19]: Dribble error<br>• RDES3[20]: Receive error<br>• RDES3[22]: Watchdog timeout<br>• RDES3[21]: Overflow error<br>• RDES3[23]: Giant packet<br>• RDES2[17]: Destination address filter fail, when the flexible receive parser is enabled<br>• RDES2[16]: SA address filter fail, when flexible receive parser is enabled<br>This field is valid only when the LD bit of RDES3 = 1. |
| 14:0 | PL | Packet Length<br>Indicates the byte length of the received packet that was transferred to system memory (including CRC).<br>This field is valid when the LD bit of RDES3 = 1 and overflow error bits becomes 0. The packet length also includes the two bytes that appends to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet.<br>This field is valid when the LD bit of RDES3 = 1. When the last descriptor and error summary bits are not 1, this field indicates the accumulated number of bytes that are transferred for the current packet. |

### 72.15.4.1.6 Receive context descriptor

This descriptor is read-only for the application. Only DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. Bit 30 of RDES3 indicates the context type descriptor.

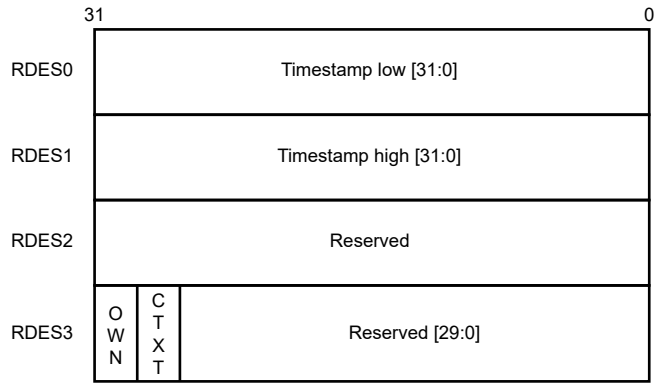

Figure 418. Receive context descriptor format

#### 72.15.4.1.6.1 RDES0 context descriptor

**Table 537. RDES0 context descriptor**

| Bit | Name | Description |
|---|---|---|
| 31:0 | RTSL | Receive Packet Timestamp Low<br>DMA updates this field with least significant 32-bits of the timestamp captured for the corresponding receive packet. When this field and the RTSH field of RDES1 show all-ones value, you must consider the timestamp as corrupt. |

#### 72.15.4.1.6.2 RDES1 context descriptor

**Table 538. RDES1 context descriptor**

| Bit | Field | Description |
|---|---|---|
| 31:0 | RTSH | Receive Packet Timestamp High<br>DMA updates this field with the most significant 32-bits of the timestamp captured for the corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, you must consider the timestamp as corrupt. |

#### 72.15.4.1.6.3 RDES2 context descriptor

| Bit | Name | Description |
|---|---|---|
| 31 | OWN | Own Bit<br>When this field is 1, it indicates that DMA owns the descriptor. When this field becomes 0, it indicates that the application owns the descriptor. DMA clears this field when either of these conditions is true:<br>• DMA completes the packet reception.<br>• The buffers associated with the descriptor are full. |
| 30 | CTXT | Receive Context Descriptor |

*Table continues on the next page...*

Table 540. RDES3 context descriptor (continued)

| Bit | Name | Description |
|---|---|---|
| | | When this field is 1, it indicates that the current descriptor is a context descriptor. DMA writes 1'b1 to this field for context descriptor.<br>DMA writes 2'b11 to indicate a descriptor error due to all = 1.<br>When CTXT and DE bits are used together {CTXT, DE}<br>• 2'b00: Reserved<br>• 2'b01: Reserved<br>• 2'b10: Context descriptor<br>• 2'b11: Descriptor error<br>Note: When descriptor error occurs, the receive DMA closes the receive descriptor indicating descriptor error. This receive descriptor is skipped and the buffer addresses does not write the packet data. The receive DMA writes 1 to the CDE bit in DMA_CH#_Status register but not to the RI bit even when IOC = 1, because this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor writes the packet data. |
| 29 | DE | Descriptor Error<br>See the CTXT bit description for more information about how to use the DE bit along with CTXT bit. |
| 28:0 | Rsvd | Reserved |

## 72.15.5 Enhanced descriptor for time-based scheduling

This feature needs 32 bytes enhanced descriptors to enable on all the DMA channels that uses this feature (write 1 to EDSE bit of DMA_CH(#i)_TX_Control register).

The structure of 32-byte descriptor for the context and the normal descriptor in read and write formats are described in the upcoming sections.

### 72.15.5.1 Enhanced normal descriptor - Read (32-bit mode)

These fields are present in the first 16 bytes of the enhanced descriptor format of normal descriptor:

- LTV- Indicates that the launch time (LT) and GSN fields present in the descriptor are valid. The LTV must be = 1 only if the FD bit of the descriptor is not.
- GSN- Indicates the GCL slot number associated with the packet.
- LT- Indicates the launch time associated with the packet.

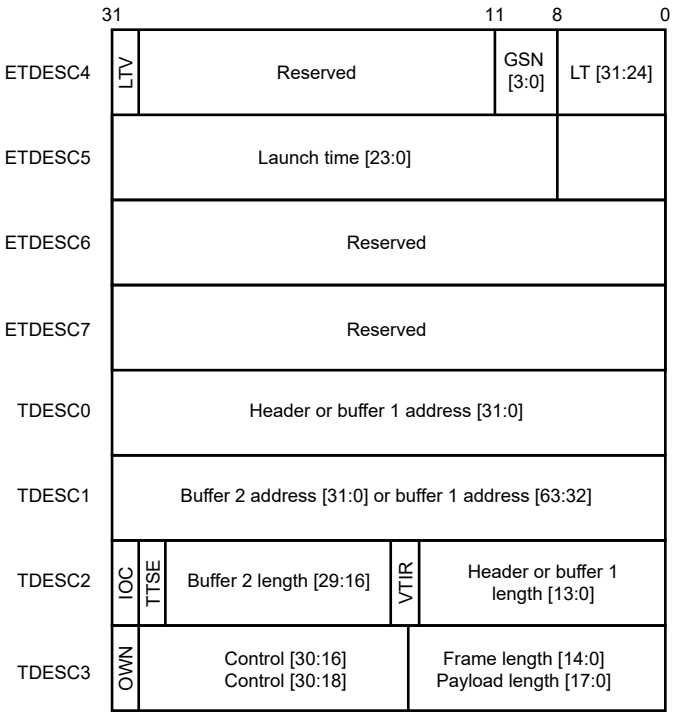

Figure 419. Enhanced normal descriptor - Read (32-bit mode)

### 72.15.5.2 Enhanced normal descriptor (Write, 32-bit mode)

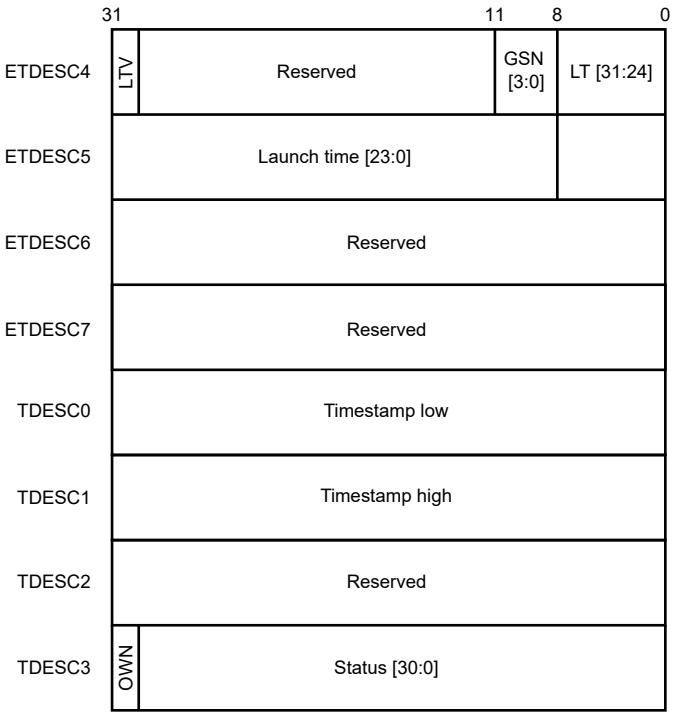

Figure 420. Enhanced normal descriptor write (32-bit mode)

**NOTE**

- All the enhanced descriptors, example, assumes a 32-bit data width configurations. However, the same definitions are valid in 64-bit and 128-bit configurations.
- In both the write back formats, you cannot modify the extended 16 bytes. The remaining 16 bytes (TDESC0 to TDESC3) are written back per the previous 16 bytes descriptor format.
- When you enable the fetch time it overrides the AV slot function
- When an unaligned new GCL list (with a different CTR) is installed it is recommended not to have traffic during the installation of the new list. Any traffic during the switching of the lists might have unpredictable behavior regarding fetch, launch, and launch expiry because the CTR and BTR values get updated when the frame is processed

### 72.15.5.3 Enhanced context descriptor (Read, 32-bit mode)

The first 16 bytes of the enhanced context descriptor (ETDESC4 to ETDESC7) are reserved and must be = 0. The fields present in the last bytes of the descriptor (TDESC0 to TDESC3) are same as the context descriptor (TDESC0 to TDESC3) in 16 byte format.

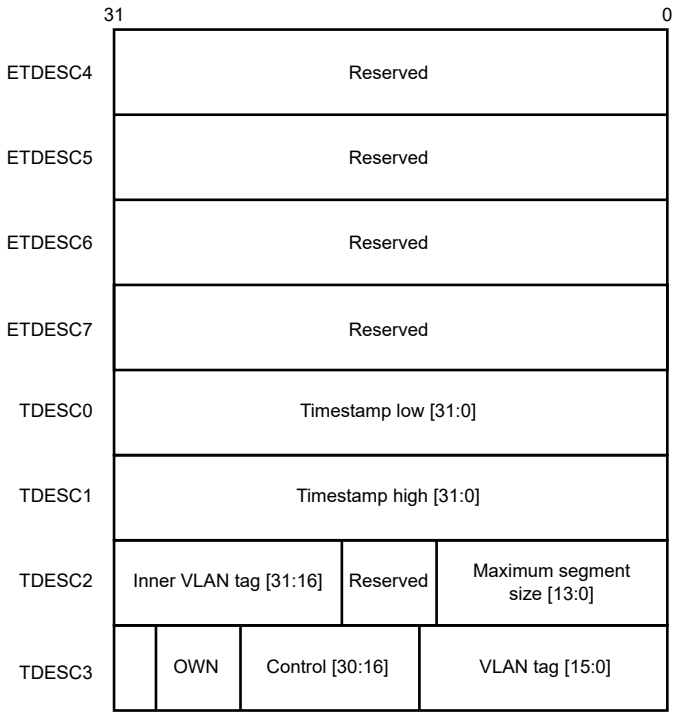

**Figure 421. Enhanced context descriptor - Read**

#### 72.15.5.4 Enhanced context descriptor (Write, 32-bit mode)

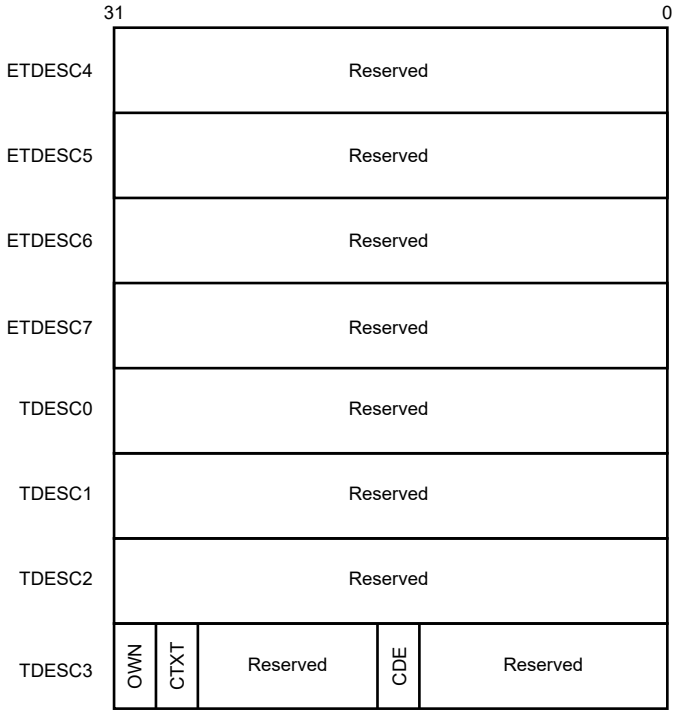

**Figure 422. Enhanced context descriptor - Write**

## 72.16 Programming

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

This section provides the instructions for initializing the DMA or MAC registers in the proper sequence.

### 72.16.1 Initializing DMA

Perform these steps to initialize DMA:

1. Provide a software reset. This resets all the MAC internal registers and logic (bit-0 of DMA_Mode).
2. Wait for the reset process (poll bit 0 of DMA_Mode which is only clears after the reset operation completes) to complete.
3. Program these fields to initialize DMA_SysBus_Mode:
    a. DMA_SysBus_Mode[AAL]
    b. Fixed burst or undefined burst
    c. Burst mode values in case of AHB bus interface, OSR_LMT in case of AXI bus interface.
    d. Select the maximum burst length possible on the AXI bus (bits [7:1]), if fixed length value is enabled.
4. Create a descriptor list for a transmit and receive. Also, ensure that DMA (write 1 to bit 31 of descriptor TDES3/RDES3) owns the descriptors. See Descriptors for more information about descriptors.
5. Program the transmit and receive ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i = 0; i <= 1) and DMA_CH(#i)_RxDesc_Ring_Length (for i = 0; i <= 1)). The programmed ring length must be at least 4.

**NOTE**

The descriptor address from the start to the end of the ring must not cross the 4 GB boundary.

6. Initialize the receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_RxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). Also, program the transmit and receive tail pointer registers that indicates DMA about the available descriptors (DMA_CH(#i)_TxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)).

   **NOTE**

   For 40-bit or 48-bit addressing mode, program the higher address List registers (DMA_CH[n]_TxDesc_List_HAddress, DMA_CH[n]_RxDesc_List_HAddress).

   The tailpointer registers must advance to the location immediately after the descriptors that are set so that DMA is aware that the additional descriptors are available.

7. Program the settings of these registers for the parameters like maximum burst-length (PBL) which DMA initiates, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
   - DMA_CH(#i)_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)
8. Program the DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to enable the interrupts.
9. Write 1 to SR (bit 0) of the DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) and ST (bit 0) of the DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to start the receive and transmit DMAs.
10. Repeat steps 4 to 9 for all the transit DMA and receive DMA channels selected in the hardware.

### 72.16.2 Initializing MTL registers

The transaction layer (MTL) registers must initialize to establish the transmit and receive operating modes and commands.

Perform these steps to initialize the MTL registers:

1. Program MTL_Operation_Mode[SCHALG] and MTL_Operation_Mode[RAA] to initialize the MTL operation in case of multiple transit and receive queues.
2. Program the receive queue to DMA mapping in MTL_RxQ_DMA_Map0.
3. Program these fields to initialize the mode of operation in MTL_TxQ0_Operation_Mode.
   a. MTL_TxQ0_Operation_Mode[TSF] or MTL_TxQ0_Operation_Mode[TTC] in case of Threshold mode.
   b. MTL_TxQ0_Operation_Mode[TXQEN] to value 2'b10 to enable transmit queue0.
   c. MTL_TxQ0_Operation_Mode[TQS]
4. Program these fields to initialize the mode of operation in MTL_RxQ0_Operation_Mode:
   a. MTL_RxQ0_Operation_Mode[RSF] or MTL_RxQ0_Operation_Mode[RTC] in case of Threshold mode.
   b. Flow control activation and de-activation thresholds for MTL receive FIFO (MTL_RxQ0_Operation_Mode[RFA] and MTL_RxQ0_Operation_Mode[RFD]).
   c. Error Packet and undersized good Packet forwarding enable (MTL_RxQ0_Operation_Mode[FEP] and MTL_RxQ0_Operation_Mode[FUP]).
   d. MTL_RxQ0_Operation_Mode[RQS]
5. Repeat previous two steps for all MTL transit and receive queues selected in the configuration.

### 72.16.3 Initializing MAC

The MAC configuration registers establish the operating mode of MAC. These registers must initialize before initializing DMA.

You can perform these MAC initialization operations after DMA initialization. If the MAC initialization completes before DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, the received frames fill the receive FIFO and overflow.

1. Provide the MAC address registers: MAC_Address0_High and MAC_Address0_Low. If more than one MAC address is enabled, , program the MAC addresses appropriately.

2. Program these fields to set the appropriate filters for the incoming frames in MAC_Packet_Filter:

a. Receive all

b. Promiscuous mode

c. Hash or perfect filter

d. Unicast, multicast, broadcast, and control frames filter settings

3. Program these fields for proper flow control in MAC_Q0_Tx_Flow_Ctrl:

a. Pause time and other Pause frame control bits

b. Transmit flow control bits

c. Flow control busy

4. Program MAC_Interrupt_Enable as required, and if applicable, for your configuration.

5. Program the appropriate fields in MAC_Configuration. For example Inter-packet gap when transmission and jabber disable.

6. Write 1 to MAC_Configuration[RE] and MAC_Configuration[TE] to start the MAC transmitter and receiver.

### 72.16.4 Performing normal receive and transmit operation

During normal operation of the module, read the normal and transmit interrupts, poll the descriptors, suspend the DMA (if it does not own descriptors), and read the values of the current host transmitter or receiver descriptor pointers for debugging.

For normal operation, perform these steps:

1. Read the interrupt status for normal transmit and receive interrupts. Then poll the descriptors, read the status of the descriptor which the host owns (either transmit or receive).

2. Set appropriate values for the descriptors, ensure that the DMA owns the transmit and receive descriptors to resume the data transmission and reception.

3. If DMA does not own the descriptors (or no descriptor is available), DMA enters into SUSPEND state. The transmission or reception can resume by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register (DMA_CH[n]_TxDesc_Tail_Pointer and DMA_CH[n]_RxDesc_Tail_Pointer).

4. Read the current host transmitter or receiver descriptor address pointer values for the debug process (DMA_CH[n]_Current_App_TxDesc and DMA_CH[n]_Current_App_RxDesc register).

5. Read the current host transmit buffer address pointer and receive buffer address pointer values for the debug process (Register DMA_CH[n]_Current_App_TxBuffer and DMA_CH[n]_Cur-rent_App_RxBuffer).

### 72.16.5 Stopping and starting transmission

Perform these steps to pause the transmission for some time. The steps are provided for channel 0.

1. Write 0 to bit 0 (ST) of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to disable the transmit DMA (if applicable) .

2. Wait for any previous frame transmissions to complete. Read the appropriate fields of MTL_TxQ0_Debug (MTL_TxQ0_Debug[TRCSTS] is not 01 and MTL_TxQ0_Debug[TXQSTS] = 0) to check this.

3. Write 0 to MAC_Configuration[RE] and MAC_Configuration[TE] to disable the MAC transmitter and MAC receiver.

4. Disable the receive DMA (if applicable), after you ensure that the data in the receive FIFO transfers to the system memory (read the appropriate fields MTL_RxQ0_Debug[PRXQ] = 0 and MTL_RxQ0_Debug[RXQSTS] = 00).

5. Ensure that both the transit queue and receive queue are empty (MTL_TxQ0_Debug[TXQSTS] = 0 and MTL_RxQ0_Debug[RXQSTS] = 0).

6. Restart the operation by first starting the DMAs, and then enable the MAC transmitter and receiver.

**NOTE**

- Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. You can change these parameters only when the MAC transmitter and receiver are not active.
- Similarly, do not change the DMA related configuration when transmit and receive DMA are active.

### 72.16.6 Programming guidelines for switching to new descriptor list in RxDMA

Switching to a new descriptor list is different in the receive DMA as compared to the transit DMA. It is permitted when the RxDMA is in SUSPEND state as described below:

- RxDMA prepares the descriptors in advance.
- If the RxDMA goes to SUSPEND state because the descriptors are not available, a major failure occurs (you are not able to free the filled-up descriptors or buffers). If this issue does not rectify immediately, frames will be lost because of an RxFIFO overflow. Therefore, you can create a new descriptor list and program the RxDMA to start using it immediately, without going into STOP state.

### 72.16.7 Programming guidelines for multi-channel multi-queuing

#### 72.16.7.1 Transmit

1. Program the transmit queue size in TQS field of MTL_TxQ[n]_Operation_Mode register. Based on the value programmed in TQS field, you can determine the queue size.

In the transmit operation, the number of channels is equal to the number of the queues, because of this reason, the channel-to-queue mapping is fixed.

2. Enable the queue in TXQEN in the corresponding MTL_TxQ[n]_Operation_Mode register to use the queue. In DMA configurations, enable the ST field of DMA_CH[n]_Tx_Con-trol register and corresponding TXQEN in MTL_TxQ[n]_Operation Mode register.

3. Program the scheduling method in MTL_Operation_Mode[SCHALG].

4. Program MTL_TxQ[n]_Quantum_Weight register for DCB queue per the selected algorithm. In case of CBS algorithm in AVB queues program the MTL_TxQ[n]_ETS_Control, MTL_TxQ[n]_SendSlopeCredit, MTL_TxQ[n]_HiCredit, and MTL_TxQ[n]_LoCredit registers as required.

5. Program the MAC_TxQ_Prty_Map0 register to assign a fixed priority to the queue, if DCB is enabled and PFC function is required. You can use this assigned priority to determine if the corresponding queue must stop transmitting packet on the basis of the received PFC packet.

#### 72.16.7.2 Receive

1. Program the receive queue size in RQS field of MTL_RxQ[n]_Operation_Mode register. Determine the size of the queue, based on the value programmed in RQS field.
2. Enable the receive queues 0 to 7 in the fields RXQ0EN to RXQ7EN in MAC_RxQ_Ctrl0 for AV or DCB. In DMA configurations, SR bit of statically or dynamically map DMA_CH[n]_Rx_Control register and the corresponding RXQ[n]_EN in MAC_RxQ_Ctrl0 is enabled.

3. Based on these packet types MAC routes the receive packets to the receive queues :
    a. AV PTP packets: Based on the programming of MAC_RxQ_Ctrl1[PTPQ].
    b. AV untagged control packets: Based on the programming of MAC_RxQ_Ctrl1[AVCPQ].
    c. Data center bridging (DCB) related link layer discovery protocol (LLDP) packets. Program DCBCPQ in MAC_RxQ_Ctrl1 to indicate MAC which queue should get the DCB packets.
    d. VLAN tag priority field in VLAN tagged packets: Program PSRQ7-0 of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 register for routing the tagged packets based on the received packets USP (user priority) field to the receive queues 0 to 7.
    e. Route the AV tagged control and data packets based on PSRQ field of MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers.

**NOTE**

The priorities set in PSRQ7-0 must be unique.

4. If multiple receive DMA channels are enabled, you must perform the following programming for proper arbitration and mapping:
    a. Program MTL_Operation_Mode[RAA] to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.
    b. Program the MTL_RxQ[n]_Control register to decide the weights and the packet arbitration for each RxQ.
    c. If you program the static mapping in MTL_RxQ_DMA_Map[n] register (RXQ[n]DADMACH becomes 0), fields RXQx2DMA and others are programmed to select the channel to map each queue.
    d. Write 1 to RXQ[n]DADMACH field in MTL_RxQ_DMA_Map0 to select the dynamic mapping of packets in each receive queue.
    e. In dynamic channel mapping, the value of DCS field in the lowest MAC address register the decides the routing of a packet to a specific RxDMA channel.

#### 72.16.7.2.1 Programming guidelines for recovering from DMA channel failure

When the DMA channel issues a bus error, follow these steps to recover from the failure.

Recovering from the receive DMA channel failure.

Perform these steps if you get bus error in the receive DMA channel:

1. Write 1 to DMA_CH0_Rx_Control[RPF]. This flushes all the packets one after the other.

This step is optional. However, writing 1 to this field prevents head-of-line blocking in the receive queues when packets sent to the RXDMA are stopped due to the bus error.

2. Re-program the specific registers of the DMA channel.

3. Start the DMA channel.

Recovering from the transmit DMA channel failure.

1. Stop the specific DMA channel, even if it is in active state.

2. Flush the corresponding MTL queue.

3. Re-program the specific registers of the DMA channel.

4. Start the DMA channel.

**NOTE**

Due to the known limitations in the design, reprogramming the DMA channel registers might not be always successful in recovering from a bus error. If the module is not fully functional after reprogramming the DMA, you can issue a soft reset to recover from the bus error.

## 72.16.8 Programming guidelines for GMII link state transitions

### 72.16.8.1 Transmit and receive clocks running when link down

Perform these steps when the link is down but the transmit and receive clocks are running:

**NOTE**

The steps are provided for channel 0.

1. Write 0 to bit 0 (ST) of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to disable the transmit DMA (if applicable).

2. Write 0 to MAC_Configuration[RE] to disable the MAC receiver.

3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate fields of MTL_TxQ0_Debug (MTL_TxQ0_Debug[TRCSTS] is not 01) or, flush the Tx FIFO for faster empty operation.

4. Write 0 to MAC_Configuration[TE] to disable the MAC transmitter.

5. Make sure that both the transit queue and receive queue are empty (MTL_TxQ0_Debug[TXQSTS] and MTL_RxQ0_Debug[RXQSTS] are 0).

6. Read the PHY registers to know the latest configuration and accordingly program the MAC registers, after the link is up.

7. Start the transit DMA to restart the operation, and then enable the MAC transmitter and receiver.

You do not disable the receive DMA because the receiver is disabled and the FIFO does not get any data in the receive FIFO.

### 72.16.8.2 Transmit and receive clocks stopped when link down

Perform these steps when the link is down and the transmit and receive clocks are stopped:

**NOTE**

The steps are provided for channel 0.

1. Write 0 to MAC_Configuration[RE] and MAC_Configuration[TE] to disable the MAC transmitter and receiver. This does not take effect immediately as the clocks are absent.

2. Wait until the link is up and the clocks are restored.

3. Wait for the transfer of any partial frame, if any to complete at time of stopping of the transmit or receive clock. To check this, read MAC_Debug (should be all-zero). Some old packets may still remain in the TXFIFO because the MAC transmitter is stopped.

4. Read the PHY registers to know the latest operating mode and accordingly program the MAC registers.

5. Write 1 to MAC_Configuration[RE] and MAC_Configuration[TE] to restart the MAC transmitter and receiver.

## 72.16.9 Programming guidelines for IEEE 1588 timestamping

### 72.16.9.1 Initialization guidelines for system time generation

Write 1 MAC_Timestamp_Control[TSENA] to enable the timestamp feature. However, it is essential to initialize the timestamp counter after MAC_Timestamp_Control[TSENA] = 1. Perform these steps during the module initialization:

1. Write 0 to the bit 16 of MAC_Interrupt_Enable to mask the timestamp trigger interrupt.
2. Write 1 to MAC_Timestamp_Control[TSENA] to enable timestamping.
3. Program MAC_Sub_Second_Increment based on the PTP clock frequency.
4. Program MAC_Timestamp_Addend and write 1 to MAC_Timestamp_Control[TSADDREG], if you are using the fine correction approach.
5. Poll MAC_Timestamp_Control until MAC_Timestamp_Control[TSADDREG] = 0.
6. Program MAC_Timestamp_Control[TSCFUPDT] to select the fine update method (if required).

7. Program MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update with the appropriate time value.
8. Write 1 to MAC_Timestamp_Control[TSINIT].
9. Initialize the timestamp counter with the value written in the timestamp update registers so that the timestamp counter can start operation. If one-step timestamping is enabled
    a. Program Bit 27 of the TDES3 context descriptor, to enable one-step timestamping.
    b. Program MAC_Timestamp_Ingress_Asym_Corr and MAC_Timestamp_Egress_Asym_Corr to update the correction field in PDelay_Req PTP messages.
10. Enable the MAC receiver and transmitter for proper timestamping.

**NOTE**

If the timestamp operation is disabled by writing 0 to MAC_Timestamp_Control[TSENA], repeat all these steps to restart the timestamp operation.

### 72.16.9.2 System time correction

#### 72.16.9.2.1 Coarse correction method

Perform these steps to synchronize or update the system time in one process (coarse correction method):

1. Set the offset (positive or negative) in the timestamp registers that is MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update.

2. Write 1 to MAC_Timestamp_Control[TSUPDT].

The value in the timestamp update registers is added to or subtracted from the system time when MAC_Timestamp_Control[TSUPDT] = 0.

#### 72.16.9.2.2 Fine correction method

Perform these steps to synchronize or update the system time to reduce system-time jitter (fine correction method):

1. Calculate the rate by which you want to increment the system time slower or faster, with the help of the algorithm.

2. Update MAC_Timestamp_Addend with the new value and write 1 to MAC_Timestamp_Control[TSADDREG].

3. Wait for the time for which you want the new value of the addend register to be active. You can do this by enabling the timestamp trigger interrupt after the system time reaches the target value.

4. Program the required target time in MAC_PPS[n]_Target_Time_Seconds register and MAC_PPS[n]_Target_Time_Nanoseconds register.

5. Enable the timestamp interrupt in MAC_Interrupt_Enable[TSIE].

6. Write 1 to bit 4 in MAC_Timestamp_Control.

7. Read MAC_Interrupt_Status when this trigger causes an interrupt.

8. Reprogram MAC_Timestamp_Addend with the old value and write 1 to MAC_Timestamp_Control[TSADDREG] again.

## 72.16.10 Programming guidelines for AV feature

After you enable the AV feature in the module controller, follow these programming tasks:

- Initializing the DMA for QOS-AHB configurations only
- Enabling slot number checking
- Enabling average bits per slot reporting
- Disabling flow control for AV-enabled queues (transmit and receive flow control)

### 72.16.10.1 Initializing the DMA in audio video feature

The first step to program the AV feature in a QOS-AHB configuration is to initialize the DMA.

Use this initialization sequence for QOS-AHB/QOS-AXI/QOS-AXI4 configurations with AV feature.

1. Provide a software reset to reset all the QOS internal registers and logic (DMA_Mode[SWR]).

2. Wait for the reset process to complete. Poll DMA_Mode[SWR], which clears only after the reset operation completes.

3. Set the values in DMA_Mode to program the fields to initialize the DMA register.

4. Create a descriptor list for transmit and receive. In addition, ensure that the DMA owns the transmit and receive descriptors. When you use OSF mode, at least two transmit descriptors are required.

See Descriptors for more information about descriptors.

5. Ensure that you create three or more different transmit or receive descriptors in the list before reusing any descriptors.

6. Program the transmit and receive ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). The ring length programmed must be at least 4.

7. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)). In addition, you must program the transmit and receive tail pointer registers to indicate the DMA about the available descriptors (DMA_CH(#i)_TxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_D-MA_TX_CH-1) and DMA_CH(#i)_RxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_D-MA_RX_CH-1)).

8. Program these fields to initialize the mode of operation in MTL_TxQ0_Operation_Mode:

a. MTL_TxQ0_Operation_Mode[TSF]

b. MTL_TxQ0_Operation_Mode[TTC]

c. MTL_TxQ0_Operation_Mode[TXQEN] to value 2'b10 to enable transmit queue0

d. MTL_TxQ0_Operation_Mode[TQS]

9. Enable the interrupts by programming DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.

10. Repeat steps 4 through 9 for all the additional channels of AV feature.

11. Program the AV queues CBS control register, idleSlope, sendSlope, hiCredit, and loCredit registers.

12. Write 1 to bit 0 of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) register to start the receive and transmit DMA.

### 72.16.10.2 Enabling slot number checking

You can enable slot number checking feature if you specifies the intervals at which the DMA channels map to AV queues fetch the frames from the AHB/AXI system bus.

You must complete these steps after step 11 and before step 12 of Initializing the DMA in audio video feature .

You can use the slot number check feature to specify the intervals at which the DMA channels map to AV queues fetch the frames from the AHB/AXI system bus. This feature is useful for an uniform and periodic transfer of the AV traffic from the host memory and it is available only when you enable timestamping and programs MAC_Sub_Second_Increment. Perform these steps to enable the slot number checking:

1. Follow the steps described in Initialization guidelines for system time generation to enable timestamping.

2. Ensure that the SLOTNUM field (bits 22:19) of TDES3 normal descriptor (Read format) contains a valid slot number. You can read the current reference slot number from the DMA_CH(#i)_Slot_Func-tion_Control_Status (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.

3. Write 1 to bit 0 (ESC) of the slot function control and status register of a channel to enable the slot number checking.

#### 72.16.10.3 Enabling average bits per slot reporting

You can enable the reporting of average bits transmitted in a slot.

The CBS status register of the additional AV channels provide information about the average bits that are transmitted in a slot. You can asynchronously read this register to retrieve information about the average bits transmitted per slot. Perform these steps to enable average bits per slot reporting:

1. Follow the steps as described in the Initialization guidelines for system time generation to enable timestamping.

2. Program SLC bits [6:4], of the MTL_TxQ[n]_ETS_Control register of a channel with the number of slots over which the average transmitted bits per slot are computed.

3. Enable bit 9(ABPSSIE) of the MTL_Q[n]_Interrupt_Control_Status register of a channel to generate the average bits per slot interrupt.

**NOTE**

- The frequency of this interrupt depends on the value programmed in step 2. For example, when you program value 0 in the SLC field, the interrupt generates at every 125 microsecond.
- You can disable this interrupt to stop the interrupt flooding, when it is not required.

4. Read ABS bits [16:0], of the MTL_TxQ[n]_ETS_Status register of a channel on each interrupt.

**NOTE**

You can read the ABS fields in the polling mode even if ABPSIE bit is not enabled. When bit 1 (ABPSIS) of the MTL_TxQ[n]_ETS_Status register is 1, it indicates that a new value is updated in the ABS field.

#### 72.16.10.4 Disabling flow control for AV enabled queues

##### 72.16.10.4.1 Transmit flow

Program the EHFC (Enable Hardware Flow Control) field of the corresponding receive queue's MTL_RxQ[n]_Operation_Mode register to 0.

##### 72.16.10.4.2 Receive flow control

Program PSTQ[n] field, corresponding to AV enabled transit queue in MAC_TxQ_Prty_Map0/1 register to 0.

#### 72.16.10.5 Programming guidelines for flexible pulse-per-second output

After you enable the flexible pulse-per-second output feature in the module controller, you can perform these tasks:

- Generating single pulse on PPS
- Generating next pulse on PPS
- Generating a pulse train on PPS
- Generating an interrupt without affecting the PPS

##### 72.16.10.5.1 Generating single pulse on PPS

Perform these steps to generate single pulse on PPS:

1. Program 11 or 10 (for interrupt) in TRGTMODSEL bits [6:5], of MAC_PPS_Control. This instructs MAC to use the target time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) for a start time of the PPS signal output.
2. Program the start time value in the target time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds).
3. Program the PPS signal output width in MAC_PPS(#i)_Width (for i = 0; i <= 3) register.

4. Program PPSCMD bits [3:0], of MAC_PPS_Control to 0001. This instructs MAC to generate single pulse on the PPS signal output at the time programmed in the target time registers.

#### 72.16.10.5.2 Generating next pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can give the cancel start command (PPSCMD=0011) before the programmed start time elapses to cancel the pulse generation. You can also program the behavior of the next pulse in advance.

Follow these steps to program the next pulse:

1. Program the start time for the next pulse in the target time registers. This time must be more than the time at which the falling edge occurs for the previous pulse.

2. Program the next PPS signal output width in MAC_PPS(#i)_Width (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register.

3. Program PPSCMD bits [3:0], of MAC_PPS_Control to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs MAC to generate single pulse on the PPS signal output, at the time programmed in target time registers.

If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the QOS may generate only 1 extended pulse.

#### 72.16.10.5.3 Generating a pulse train on PPS

Perform these steps to generate a pulse train on PPS:

1. Program 11 or 10 (for interrupt) in TRGTMODSEL bits [6:5] , of MAC_PPS_Control. This instructs MAC to use the target time registers for the start time of the PPS signal output.

2. Program the start time value in the target time registers.

3. Program the interval value between the train of pulses on the PPS signal output in MAC_PPS(#i)_Interval (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register.

4. Program the PPS signal output width in MAC_PPS(#i)_Width (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register.

5. Program PPSCMD bits [3:0], of MAC_PPS_Control to 0010. This instructs MAC to generate train of pulses on the PPS signal output with start time programmed in target time registers.

By default, the PPS pulse train is free-running unless the STOP pulse train at time or STOP pulse train immediately commands stop it.

6. Program the stop value in the target time registers. Ensure that bit 31 (TSTRBUSY) of MAC_PPS(#i)_Target_Time_Nanoseconds (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register becomes 0 before programming the target time registers again.

7. Program PPSCMD field [bit 3:0] of MAC_PPS_Control to 0100. This stops the train of pulses on the PPS signal output after the programmed stop time specified in step 6 elapses.

You can program 0101 in PPSCMD field [bit 3:0] of MAC_PPS_Control to stop the pulse train at any time. Similarly, you can program 0110 in PPSCMD field [bit 3:0] of MAC_PPS_Control before the time (programmed in step 6) elapses to cancel the stop pulse train command (given in Step 7). Also, program 0011 in PPSCMD field [bit 3:0] of MAC_PPS_Control before the programmed start time (in Step 2) elapses to cancel the pulse train generation.

#### 72.16.10.5.4 Generating an interrupt without affecting the PPS

MAC_PPS_Control TRGTMODSEL bits [6:5] enables you to program the target time registers to perform any one of these actions:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

Perform these steps to program the target time registers to generate only interrupt event:

1. Program 00 (for interrupt) in MAC_PPS_Control TRGTMODSEL bits [6:5]. This instructs the MAC to use the target time registers for target time interrupt.

2. Program a target time value in the target time registers. This instructs the MAC to generate an interrupt when the target time elapses.

If TRGTMODSEL bits [6:5], are changed (for example, to control the PPS) then over-write the interrupt generation with the new mode and new programmed target time register value.

### 72.16.10.6 Programming guidelines for VLAN filtering on receive

Perform these steps to program VLAN filtering on receive:

1. Program MAC_VLAN_Tag register for the following fields to select the filtering method:

a. ETV: Enables 12-Bit VLAN tag comparison or 16-bit VLAN tag comparison.

b. VTHM: VLAN tag hash table match enable.

c. ERIVLT: Enables inner VLAN tag or outer VLAN Tag (to enable the inner or outer VLAN tag filtering, writing 1 to MAC_VLAN_Tag_Ctrl[EDVLP] enables the double VLAN processing).

d. ERSVLM: Enables receive S-VLAN match or C-VLAN match (write 1 to MAC_VLAN_Tag_Ctrl[ESVL] to enable S-VLAN processing).

e. DOVLTC: Ignores VLAN type for tag match

f. VTIM: Enables VLAN tag inverse match instead of the normal VLAN tag matching

2. Program VL of MAC_VLAN_Tag register for the 12-bit or 16-bit VLAN tag.

3. Program MAC_VLAN_Hash_Table, if hash filtering of VLAN tag is enabled. When MAC_VLAN_Tag_Ctrl[ETV] becomes 0, it indicates that the upper 4 bits of the calculated CRC-32 of VLAN tag are inverted and index the content of MAC_VLAN_Hash_Table. When MAC_VLAN_Tag_Ctrl[ETV] is 1, it indicates that the upper 4 bits of calculated CRC-32 of VLAN Tag index the content of MAC_VLAN_Hash_Table. For example, when MAC_VLAN_Tag_Ctrl[ETV] is 1, a hash value of 4b'1000 selects bit 8 of MAC_VLAN_Hash_Table. When MAC_VLAN_Tag_Ctrl[ETV] becomes 0 a hash value of 4'b1000 selects bit 7 of MAC_VLAN_Hash_Table.

### 72.16.10.7 Programming guidelines for extended VLAN filtering and routing on receive

Perform these steps, for the indirect access of the per VLAN tag registers:

- Write
  - Write the required data into MAC_VLAN_Tag_Data.
  - Program MAC_VLAN_Tag_Ctrl[OFS] with the required filter register's offset and command type to MAC_VLAN_Tag_Ctrl[CT]. For a write command, set this field to 0.
  - Write 1 to MAC_VLAN_Tag_Ctrl[OB] and wait till it becomes 0 to do the next write. This will guarantee that you have programmed the appropriate VLAN Tag Filter register.
- Read
  - Program MAC_VLAN_Tag_Ctrl[OFS] with the required register's offset and command type to MAC_VLAN_Tag_Ctrl[CT]. For a read command, set this field to 1.
  - Write 1 to MAC_VLAN_Tag_Ctrl[OB] and wait till it becomes 0. The appropriate value of the VLAN Tag Filter register is available in MAC_VLAN_Tag_Data.

### 72.16.10.8 Programming sequence for queue/channel based VLAN inclusion register

Perform these steps to program the queue/channel-based VLAN inclusion register:

**NOTE**

When MAC_VLAN_Incl[CBTI] = 1 you cannot access the indirect VLAN include registers.

1. Write 1 to MAC_VLAN_Incl[CBTI], to enable queue or channel based VLAN tag insertion on all the transmitted packets. This field must be 1 before any indirect access to the queue or channel specific MAC_VLAN_Incl(#i) register.

2. Program the VLAN tag and VLAN type to insert in packets from a particular queue or channel in MAC_VLAN_Incl[VLT] and MAC_VLAN_Incl[CSVL], corresponding offset address in ADDR field (0 for queue/channel 0, 1 for queue/channel 1, and so on) must be set. Write 0 to MAC_VLAN_Incl[RDWR] to indicate write access. The write to byte 0 (byte 3 in Big Endian mode) of MAC_VLAN_Incl initiates access to indirect access MAC_VLAN_Incl(#i) register.

3. Write 1 to MAC_VLAN_Incl[BUSY] via the module to indicate the progress of access to indirect access MAC_VLAN_Incl(#i) register. After the access completes, MAC_VLAN_Incl[BUSY] = 0. The application must not attempt subsequent access to MAC_VLAN_Incl(#i) register when the MAC_VLAN_Incl[BUSY] is 1.

4. Repeat step 2 and step 3 to program VLAN tag and VLAN type to insert in packets from the remaining queues or channels. The application must ensure that the required VLAN tag and VLAN type for all the queues or channels are programmed, otherwise an unintended VLAN tag and VLAN type might be inserted.

## 72.16.11 Programming guidelines for EST

Program the gate control values and time intervals in MTL_EST_Status[SWOL] along with the other EST related registers that are described in EMAC register descriptions to appropriate values. The upcoming sub-sections provide step by step details for programming the GCL and the other EST related registers.

### 72.16.11.1 Programming the GCL and GCL linked registers

Perform these steps to program the GCL and the four other registers implemented per GCL:

1. Access the GCL and the four other GCL-linked registers via indirect addressing using MTL_EST_GCL_Control and MTL_EST_GCL_Data. MTL_EST_Status[SWOL] indicates whether the software owns GCL0 or GCL1.
2. Write the 32-bit write data to MTL_EST_GCL_Data, to program the GCL. Then program MTL_EST_GCL_Control to write the write address and other control information.
3. In MTL_EST_GCL_Data, write data consists of up to 8 bits (configurable) of gate controls and up to 24 bits (configurable) of time interval. Programming a 0 indicates gate close and programming a 1 indicates gate open. For a 4-TC and 20-bit time interval configuration, the data width is 24-bits and the remaining 8-bits are reserved/read-only. You must write the data in the following format.

   {8'h0, TC3, TC2, TC1, TC0, 20-bit Time Interval} where TCx = 0 or 1.
4. Program MTL_EST_GCL_Control[SRWO] to 1 (to start a Write Op) and program the address and R/W fields appropriately.
5. Poll and check that the hardware clears MTL_EST_GCL_Control[SRWO] to indicate that the previous operation completes before initiating a new read-write operation via the same indirect addressing mode.
6. Repeat steps 3, 4, 5 until the programming of the GCL completes.
7. Program the BTR, CTR, TER and LLR registers, using the same indirect addressing method as described above. Write 1 to MTL_EST_GCL_Control[GCRR] appropriately. MTL_EST_GCL_Control[GCRR] interprets the address field as belonging to these registers (instead of the GCL).

After the GCL and the related registers are programmed, program MTL_EST_GCL_Control to allow hardware to own and process the GCL. When the list length (as indicated in LLR) is 1, the associated time interval must be smaller than the cycle time register value. Otherwise, an error is reported (as described in the Error handling section) as a single set of gate controls add no value in the TSN context.

**NOTE**

The time unit in all the GCL related registers is seconds and nanoseconds. In cases where internally generated PTP system time is used, you must program the nanoseconds field to use the Digital Rollover mode. (The value of MAC_Timestamp_Control[TSCTRLSSR]must be 1)

### 72.16.11.2 Programming the EST registers

After the steps mentioned in "Programming the GCL and GCL Linked Registers" completes, program MTL_EST_Control

1. Write 1 to MTL_EST_Control[CTOV] and MTL_EST_Control[TILS]. Also, write 1 to MTL_EST_Control[EEST] and MTL_EST_Control[SWOL].

   **NOTE**

   The CTOV recommendations for GMII for SPRAM configurations are:

   - 96 * Tx clock period, for 32 and 64 bit data width configurations.
   - 128 * Tx clock period for 128 bit data width configurations.

   The CTOV recommendations for GMII for non-SPRAM configurations are:

   - 30 * Tx clock period, when SA/VLAN insertion is enabled.
   - 22 * Tx clock period, when SA/VLAN insertion is not enabled.

2. Enables the hardware to own and process the new GCL and make a switch to the new GCL at the BTR value. The hardware provides an interrupt (if enabled) when the switch to the new list happens.
3. Performs an appropriate action to address any other interrupts (explained in the Interrupts section) received during the hardware execution of the GCL.

Write 1 to MTL_EST_Control[SSWL] to handoff to hardware. Software is not allowed to write to the GCL and GCL linked registers when MTL_EST_Control[SSWL] = 1, because the hardware might be using the new GCL.

The hardware resets or clears MTL_EST_Control[SSWL] when it successfully switches to the new list. The hardware also flips MTL_EST_Status[SWOL] to indicate the new GCL that the software owns.

Program the GCL that software owns (MTL_EST_Status[SWOL] indicates) as described in "Programming the GCL and GCL Linked Registers" and then program MTL_EST_Control as described above, to install a new GCL. Ensure that the new BTR is set to an appropriate value to avoid BTR Error that may require software intervention in some cases.

The packet length (frame size) information must be available at all times, to avoid transmission overruns. Therefore, in the DMA configurations, program the packet length in the first descriptor of every transmit frame. Similarly, in the MTL configuration, provide the packet length in the control word.

**NOTE**

The packet length provided in the transmit descriptor must account for the SA and VLAN insertion, to avoid transmission overruns, if applicable, that is, packet length must represent the actual packet length on the Ethernet line.

## 72.16.12 Programming the launch time in time-based scheduling

Configure the launch time in the enhanced normal transmit descriptors in DMA configurations and is driven as a control word in MTL configurations as follows:

The OSTC and launch time features are mutually exclusive and must not be used together. In case of a conflict (if OSTC = LTV = 1 in MTL configuration), give priority to OSTC and ignore the launch time.

In DMA configuration, if a context descriptor is received with a valid OSTC values immediately before receiving a first normal descriptor with LTV = 1, then the LTV is ignored.

## 72.16.13 Programming guidelines for media clock generation and recovery

### 72.16.13.1 Programming guidelines for media clock generation

These are the guidelines for the media clock generation:

1. Program the appropriate presentation time control (supported generation modes "1001-1011" ) to PPSCTRL_PPSCMD ( for 0th instance)/PPSCMD#i (for 1,2,3 instances) of MAC_PPS_Control, to define the PPS instance in Media clock generation mode.

2. Based on the selected PPS instance, application must drive the appropriate trigger signal to the corresponding MCG_PST_TRIG_I[#i].

3. Based on the programmed mode, DUT captures the timestamp and programs it in the MAC_PPS(#i)_Target_Time_Seconds register. Then, mcgr_dma_req_o[#i] is set.

4. For every request which DUT generates, the module reads the corresponding MAC_PPS(#i)_Target_Time_Seconds register and asserts the corresponding mcgr_d-ma_ack_i[#i] to acknowledge the read request.

### 72.16.13.2 Programming guidelines for media clock recovery

These are the guidelines for the media clock recovery:

- Writing 1 to MAC_Timestamp_Control[PTGE] enables the CPT counter. In addition to configuring the initialization values for the system time, update MAC_Presn_Time_Updt with the equivalent presentation time initialization value, then MAC_Timestamp_Control[TSINIT] = 1.
- Use the increment values for the system time and also for the CPT because the increment value is in sub-seconds and sub-nanoseconds.
- Update MAC_Presn_Time_Updt with the equivalent presentation time update value (32 bit ns), when an update is required, and also configure the updated values for the system time. Finally, MAC_Timestamp_Control[TSUPDT] must be 1 for the update.
- Program the MCGREN#i field of MAC_PPS_Control to enable the PPS instance to operate in MCGR mode.
- Program the appropriate presentation time control (supported recovery modes "0001 - 0011") to PPSCTRL_PPSCMD (for 0th instance) or PPSCMD#i (for 1,2,3 instances) of MAC_PPS_Control register, to set the PPS instance in Media clock recovery mode.
- After the PPS instance is set in Recovery mode, DUT sets the corresponding mcgr_dma_req_o[#i]. For every request which DUT generates, program the target presentation time into the MAC_PPS(#i)_Target_Time_Seconds register and assert the corresponding mcgr_dma_ack_i[#i] to acknowledge the request. Acknowledgment can be given before/after programming the Target presentation time.
- Observe the recovered media clock on the corresponding PTP_PPS_O[#i].

## 72.16.14 Programming guidelines for ECC protection for memories

These are the guidelines for the ECC protection for memories:

- Write 1 to the appropriate field of MTL_ECC_Control to enable the ECC features for the respective memory.
- Generate a correctable interrupt (sbd_sfty_ce_intr_o) or an uncorrectable interrupt (sbd_sfty_ue_intr_o) to indicate the application, if any correctable, uncorrectable, or address errors are detected. DMA_Interrupt_Status or MTL_ECC_Interrupt_Status indicates an appropriate status.
- Provide debug mode for each memory to specify errors.

**NOTE**

Enable the ECC feature before the traffic is online (or after the reset), otherwise the false interrupts may trigger.

### 72.16.14.1 Programming guidelines for ECC hardware error injection (Debug mode)

Follow these steps for ECC hardware error injection:

- Write 1 to the appropriate field in MTL_DBG_CTL to enable the ECC error injection feature for MTL TX/RX and DMA TSO.
- Write 1 to the appropriate field in MTL_EST_GCL_Control to enable the ECC error injection feature for the EST memory.
- Write 1 to the appropriate field in MTL_RXP_Indirect_Acc_Control_Status to enable the ECC error injection for the receive parser memory. To access the receive parser memory in Debug mode, write 0 to MTL_RXP_Indirect_Acc_Control_Status[FRPE] to disable the receive parser feature.
- Ensure that all the CSR writes corresponding to one memory write must have the same value for the error injection control word, where multiple CSR writes are required for writing single data word into the memory.

### 72.16.15 Programming guidelines for on-chip datapath parity protection

Follow these steps for on-chip datapath parity protection:

- Writing 1 to MTL_DPP_Control[EDPP] enables the parity generation and parity detection mismatch on datapath.
- Generates an uncorrectable interrupt (sbd_sfty_ue_intr_o) to indicate the application if any parity mismatch is detected. DMA_Safety_Interrupt_Status or MTL_Safety_Interrupt_Status and MAC_DPP_FSM_Interrupt_Status indicates the appropriate status.
- Supports Debug mode for each parity generator to insert an error.

**NOTE**

Enable the datapath parity protection before the receive or transit traffic starts, to avoid the false safety interrupts.

### 72.16.16 Programming guidelines for FSM parity and timeout

Follow these steps to configure the FSM parity and timeout:

- Write 1 to MAC_FSM_Control[PRTYEN] and MAC_FSM_Control[TMOUTEN] to enable the FSM parity and timeout feature respectively.
- Force the FSMs to enter into a state with even number of 1s and wait for the safety uncorrectable interrupt to define with MAC_DPP_FSM_Interrupt_Status[FSMPES] for a parity error detection.
- Write 1 to the parity error injection using the [23:16] bits of MAC_FSM_Control to select the appropriate clock domain, for Error injection mode in FSM parity. Wait for the safety uncorrectable interrupt to be defined with MAC_DPP_FSM_Interrupt_Status[FSMPES].
- Configure the large and normal mode values which MAC_FSM_ACT_Timer[LTMRMD] and MAC_FSM_ACT_Timer[NTMRMD] indicates , for FSM timeouts.
- Use the [31:24] bits of MAC_FSM_Control to select the large or normal mode tic generation per clock domain.
- Write 1 to MAC_FSM_ACT_Timer[TMR] with the appropriate number of CSR clock cycles to generate 1us tic.
- Force the FSM in a particular clock domain to remain in an active state for timeout duration (for example, T-2T). You can check the safety interrupt and the status field for the corresponding clock domain that sets in the [15:8] bits of the MAC_DPP_FSM_Interrupt_Status .
- Select the appropriate clock domain for which timeout error injection must be set using the [15:8] bits of MAC_FSM_Control, for Error injection mode in FSM timeout. Wait for the safety uncorrectable interrupt to define with the corresponding error status in the MAC_DPP_FSM_Interrupt_Status .
- Use only normal mode tic generation, for application or CSR interface timeout. On the basis of the time-outs of configured interface, appropriate fields (MSTTES, SLVTES) of MAC_DPP_FSM_Interrupt_Status is defined with the safety interrupt.

## 72.17 EMAC register descriptions

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

**NOTE**

This chip has 16 KB allocated per Ethernet controller for configuration space. EMAC uses only 8 KB of this memory and the remaining 8 KB is reserved for future use. Writing to the reserved memory may lead to unintended behavior.

### 72.17.1 EMAC memory map

EMAC base address: 4048_0000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | MAC Configuration (MAC_Configuration) | 32 | RW | 0000_8000h |

### Fields

| Field | Function |
|---|---|
| 31<br>— | Reserved |
| 30-28<br>SARC | Source Address Insertion Or Replacement Control<br>Controls the source address insertion or replacement for all the transmitted packets.<br>Bit 30 of this field specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of bits [29:28]:<br>• 2'b0x: The mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation.<br>• 2'b10: If bit 30 = 0, MAC inserts the content of the MAC Address 0 registers in the SA field of all the transmitted packets. If bit 30 = 1 and the Enable MAC Address Register 1 option is selected while configuring the core, MAC inserts the content of the MAC Address 1 registers in the SA field of all the transmitted packets.<br>• 2'b11: If bit 30 = 0, MAC replaces the content of the MAC Address 0 registers in the SA field of all the transmitted packets. If bit 30 = 1 and the MAC Address Register 1 is enabled, MAC replaces the content of the MAC Address 1 registers in the SA field of all the transmitted packets.<br>**NOTE**<br>Changes to this field take effect only on the start of a packet. If you write to the field when a packet is being transmitted, only the subsequent packet can use the updated value. This means that the current packet does not use the updated value.<br>000b - mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation<br>010b - Contents of are inserted in the SA field<br>011b - Contents of replace the SA field<br>110b - Contents of are inserted in the SA field<br>111b - Contents of replace the SA field |
| 27<br>IPC | Checksum Offload<br>Indicates the status of IP header or payload checksum checking.<br>If this field is 1, the field enables IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When the field becomes 0, the COE function in the receiver is disabled.<br>The Layer 3 and Layer 4 packet filter and enable split header features automatically select the IPC full checksum offload engine on the receive side. When any of these features are enabled, you must write 1 to this field.<br>0b - Disabled<br>1b - Enabled |
| 26-24<br>IPG | Inter-Packet Gap<br>Controls the minimum IPG between packets during transmission.<br>The range of minimum IPG is valid in Full-Duplex mode, and in this mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | When a JAM pattern is being transmitted because of backpressure activation, MAC does not consider the minimum IPG.<br>This function (IPG less than 96-bit times) is valid only when MAC_Ext_Configuration[EIPGEN] is 0. If this field is 1, the minimum IPG (greater than 96-bit times) is controlled according to the field's description.<br>000b - 96-bit times IPG<br>001b - 88-bit times IPG<br>010b - 80-bit times IPG<br>011b - 72-bit times IPG<br>100b - 64-bit times IPG<br>101b - 56-bit times IPG<br>110b - 48-bit times IPG<br>111b - 40-bit times IPG |
| 23<br>GPSLCE | Giant Packet Size Limit Control Enable<br>Enables and disables giant packet size limit control.<br>If this field = 1, MAC considers the value of MAC_Ext_Configuration[GPSL] to declare a received packet as a giant packet. This field must be programmed to have a size of more than 1,518 bytes. Otherwise, MAC considers 1,518 bytes as the giant packet limit.<br>When this field becomes 0, MAC considers the received packet as a giant packet if its size is greater than 1,518 bytes (1522 bytes for a tagged packet).<br>The WD, JE, and S2KP fields have a higher precedence over this field, which means MAC considers a received packet as a giant packet when its size is greater than 9,018 bytes (9,022 bytes for a tagged packet) with JE = 1 and the size of the jumbo packet greater than 2,000 bytes and S2KP = 1. If the WD field is 1, the field terminates the received packet if it reaches the watchdog limit. Therefore, the programmed giant packet limit must be less than the watchdog limit to get the giant packet status.<br>0b - Disabled<br>1b - Enabled |
| 22<br>S2KP | IEEE 802.3 Support For 2K Packets<br>Indicates the status of IEEE 802.3 support for 2K packets.<br>If this field is 1, MAC considers all the packets with up to 2,000-byte length as normal. When the JE field is not 1, MAC considers all the received packets of size more than 2K bytes as giant packets.<br>When this field becomes 0 and the JE field is not 1, MAC considers all the received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this field and the JE field impacts the giant packet status, see this status based on the S2KP and JE fields.<br>If the JE field is 1, writing 1 to the S2KP field has no effect on the giant packet status.<br>0b - Disabled<br>1b - Enabled |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| 21<br>CST | CRC Stripping For Type Packets<br>Indicates the status of CRC stripping for Type packets.<br>If this field is 1, the last four bytes (FCS) of all the Ether-type packets are stripped and dropped before forwarding the packet to the application.<br>This field is valid only when the receive packet size is more than or equal to 1536 bytes.<br>For information about how the settings of this field and the ACS field impact the packet length, see MAC Configuration (MAC_Configuration).<br>0b - Disabled<br>1b - Enabled |
| 20<br>ACS | Automatic Pad Or CRC Stripping<br>Indicates the status of automatic pad or CRC stripping.<br>If this field is 1, MAC strips the pad or the FCS field on the incoming packets only if the size of the packets is less than 1,536 bytes. All the received packets with a size greater than or equal to 1,536 bytes are passed to the application without stripping the pad or the FCS field.<br>When this field becomes 0, MAC passes all the incoming packets to the application, without any modification.<br>For information about how the settings of this field and the CST field impact the packet length, see MAC Configuration (MAC_Configuration).<br>0b - Disabled<br>1b - Enabled |
| 19<br>WD | Watchdog Disable<br>Indicates the status of watchdog.<br>If this field is 1, MAC disables the watchdog timer on the receiver. MAC can receive packets of up to 16,383 bytes.<br>When this field becomes 0, MAC does not allow more than 2,048 bytes (10,240 if the JE field = 1) of the packet being received. MAC cuts off bytes received after 2,048.<br>0b - Enabled<br>1b - Disabled |
| 18<br>— | Reserved |
| 17<br>JD | Jabber Disable<br>Indicates the status of jabber.<br>If this field is 1, MAC disables the jabber timer on the transmitter. It can transfer packets of up to 16,383 bytes. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | If this field is 0 and the application sends more than 2,048 bytes of data (10,240 if the JE field = 1) during transmission, MAC does not send the rest of the bytes in that packet.<br>0b - Enabled<br>1b - Disabled |
| 16<br>JE | Jumbo Packet Enable<br>Indicates the status of jumbo packets.<br>If this field is 1, MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN-tagged packets) without reporting a giant packet error in the receive packet status.<br>0b - Disabled<br>1b - Enabled |
| 15<br>PS | Port Select<br>Selects the Ethernet line speed.<br>This field, along with the FES field, selects the exact line speed. In the 10/100 Mbit/s-only (always 1) or 1000 Mbit/s-only (always 0) configurations, this field is read-only (RO) with an appropriate value. By default, with 10/100/1000 Mbit/s configurations, this field is read-write (R/W). The mac_speed_o[1] signal reflects the value of this field.<br>0b - For 1000 or 2500 Mbit/s operations<br>1b - For 10 or 100 Mbit/s operations |
| 14<br>FES | Speed<br>Indicates the speed.<br>This field selects the speed mode.<br>The mac_speed_o[0] signal indicates the value of this field.<br>0b - 10 Mbit/s if PS = 1 and 1 Gbps if PS = 0<br>1b - 100 Mbit/s if PS = 1 and 2.5 Gbps if PS = 0 |
| 13<br>DM | Duplex Mode<br>Indicates the mode in which MAC operates.<br>If this field is 1, MAC operates in Full-Duplex mode in which it can transmit and receive simultaneously. The field can only be read, with 1 as its default value, in full-duplex-only configurations.<br>0b - Half-duplex mode<br>1b - Full-duplex mode |
| 12<br>LM | Loopback Mode<br>Indicates the status of Loopback mode<br>If this field is 1, MAC operates in Loopback mode at GMII or MII. This mode requires the (G)MII Rx clock input (CLK_RX_I) signal to function properly because the transmit clock is not internally looped back. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 0b - Disabled<br>1b - Enabled |
| 11<br>ECRSFD | Enable Carrier Sense In Full-Duplex Mode<br>Indicates whether ECRSFD is enabled or disabled.<br>If this field is 1, the MAC transmitter checks the CRS signal before packet transmission in Full-Duplex mode. MAC starts transmitting only when the CRS signal is low.<br>If this field becomes 0, the MAC transmitter ignores the status of the CRS signal.<br>0b - Disabled<br>1b - Enabled |
| 10<br>DO | Disable Receive Own<br>Enables or disables receive own.<br>If this field is 1, MAC disables the reception of packets when the gmii_txen_o signal asserts in Half-Duplex mode. When the field is 0, MAC receives all the packets that PHY sent.<br>This field is not applicable in Full-Duplex mode.<br>0b - Enabled<br>1b - Disabled |
| 9<br>DCRS | Disable Carrier Sense During Transmission<br>Enables or disables carrier sense during transmission.<br>If this field is 1, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in Half-Duplex mode. As a result, no errors generate because of loss of carrier or no carrier during transmission.<br>When this field becomes 0, the MAC transmitter generates errors because of carrier sense. MAC can even abort the transmission.<br>0b - Enabled<br>1b - Disabled |
| 8<br>DR | Disable Retry<br>Enables or disables retry attempts.<br>If this field is 1, MAC attempts only one transmission. When a collision occurs on GMII or MII, MAC ignores the current packet transmission and reports a packet abort with excessive collision errors in the transmit packet status.<br>If this field becomes 0, MAC retries based on the settings of the BL field of this register.<br>The settings of this field apply only in Half-Duplex mode.<br>0b - Enabled<br>1b - Disabled |
| 7 | Reserved |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| — | |
| 6-5<br>BL | Back-Off Limit<br>Determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbit/s; 512 bit times for 10/100 Mbit/s) for which MAC waits before rescheduling a transmission attempt during retry attempts after a collision.<br>• *n* = retransmission attempt<br>• *r* = random integer that takes the value in the range 0 <= r < 2^k<br>This field is applicable only in Half-Duplex mode.<br>00b - k = min(n,10)<br>01b - k = min(n,8)<br>10b - k = min(n,4)<br>11b - k = min(n,1) |
| 4<br>DC | Deferral Check<br>Indicates the status of the deferral check function.<br>If this field is 1, the deferral check function is enabled in MAC, which issues a packet abort status, with Tx_Excessive_Deferral_Error[TXEXSDEF] = 1 in the transmit packet status, when the transmit state machine is deferred for more than 24,288 bit times in 10 Mbit/s or 100 Mbit/s mode.<br>If MAC is configured for a 1000/2500 Mbit/s operation, the threshold for deferral is 155,680 bit times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII or MII.<br>The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active, and then the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of this collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer resets to 0 and restarts.<br>When this field becomes 0, the deferral check function disables and MAC defers until the CRS signal becomes inactive.<br>This field is applicable only in Half-Duplex mode.<br>0b - Disabled<br>1b - Enabled |
| 3-2<br>PRELEN | Preamble Length for Transmit Packets<br>Controls the number of preamble bytes that are added to the beginning of every transmit packet.<br>Preamble reduction occurs only when MAC operates in Full-Duplex mode.<br>00b - 7 bytes<br>01b - 5 bytes<br>10b - 3 bytes<br>11b - Reserved |

*Table continues on the next page...*

| 13-0<br>GPSL | Giant Packet Size Limit<br>Declares the status of a packet based on its size.<br>If the received packet size (in bytes) is greater than the value programmed in this field, MAC declares the received packet as a giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Also, any other programmed value is considered as 1,518 bytes.<br>For VLAN-tagged packets, MAC adds 4 bytes to the programmed value. If MAC_VLAN_Tag_Ctrl[EDVLP] = 1, MAC adds 8 bytes to the programmed value for double VLAN-tagged packets.<br>The value of GPSL is valid if MAC_Configuration[GPSLCE] = 1. |

### 72.17.4 MAC Packet Filter (MAC_Packet_Filter)

#### Offset

| Register | Offset |
|---|---|
| MAC_Packet_Filter | 8h |

#### Function

Contains the filter controls for receiving packets.

Some of the controls from this register go to MAC's address check block that performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as pass bad packets and pass control packets.

#### Diagram

### Fields

| Field | Function |
|---|---|
| 31<br>RA | Receive All<br>Indicates whether the received packets are enabled or disabled.<br>• If this field is 1, the MAC Receiver module passes all the received packets to the application, irrespective of their passing the address filter. The result (pass or fail) of the SA or DA filtering is updated in the corresponding field of the receive status word.<br>• If this field is 0, the module passes only those packets to the application that pass the SA or DA address filter.<br>0b - Receive All is disabled<br>1b - Receive All is enabled |
| 30-22<br>— | Reserved |
| 21<br>DNTU | Drop Non-TCP/UDP Over IP Packets<br>Indicates whether MAC drops or forwards non-TCP/UDP protocols over IP packets.<br>• If this field is 1, MAC drops these protocols over IP packets. MAC forwards only those packets that the layer 4 filter processes.<br>• If this field is 0, MAC forwards all these protocols over IP packets.<br>0b - Forwards<br>1b - Drops |
| 20<br>IPFE | Layer 3 and Layer 4 Filter Enable<br>Indicates the status of layer 3 and layer 4 filters.<br>• If this field is 1, MAC drops packets that do not match the enabled layer 3 and layer 4 filters. If these two filters are not enabled for matching, this field does not have any effect.<br>• If this field is 0, MAC forwards all the packets irrespective of the match status of the layer 3 and layer 4 fields.<br>0b - Disabled<br>1b - Enabled |
| 19-17<br>— | Reserved |
| 16<br>VTFE | VLAN Tag Filter Enable<br>Indicates the status of VLAN tag filter.<br>• If this field is 1, MAC drops the VLAN-tagged packets that do not match the VLAN tag.<br>• If this field is 0, MAC forwards all the packets irrespective of the match status of the VLAN tag.<br>0b - Disabled<br>1b - Enabled |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| 15-11<br>— | Reserved |
| 10<br>HPF | Hash Or Perfect Filter<br>Indicates the status of hash or perfect filter.<br>• If this field is 1, the address filter passes a packet if it matches either perfect filtering or hash filtering as defined by the HMC or HUC fields of this register.<br>• If this field is 0 and HUC = 1 or HMC = 1, the packet passes only if it matches the hash filter.<br>0b - Disabled<br>1b - Enabled |
| 9<br>SAF | Source Address Filter Enable<br>Indicates the status of SA filtering.<br>• If this field is 1, MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, MAC drops the packet.<br>• When this field becomes 0, MAC forwards the received packet to the application with an updated field value, depending on the SA address comparison.<br>**NOTE**<br>According to the IEEE specification, bit 47 of the SA field is reserved. However, MAC compares all the 48 bits. You must consider this when programming the MAC address registers for SA.<br>0b - Disabled<br>1b - Enabled |
| 8<br>SAIF | SA Inverse Filtering<br>Indicates the status of SA inverse filtering.<br>• If this field is 1, the address check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA address filter.<br>• If this field becomes 0 and the SA of a packet does not match the values programmed in the SA registers, the SA is marked as failing the SA address filter.<br>0b - Disabled<br>1b - Enabled |
| 7-6<br>PCF | Pass Control Packets<br>Controls the forwarding of all the control packets (including unicast and multicast pause packets).<br>00b - MAC filters all the control packets from reaching the application<br>01b - MAC forwards all the control packets, except pause packets, to the application even if they fail the address filter |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 10b - MAC forwards all the control packets to the application even if they fail the address filter<br>11b - MAC forwards all the control packets that pass the address filter |
| 5<br>DBF | Disable Broadcast Packets<br>Enables or disables broadcast packets.<br>• If this field is 1, AFM blocks all the incoming broadcast packets. In addition, it overrides all the other filter settings.<br>• If this field is 0, AFM passes all the received broadcast packets.<br>0b - Enabled<br>1b - Disabled |
| 4<br>PM | Pass All Multicast<br>Enables or disables the passing of received packets.<br>• If this field is 1, it indicates that all the received packets with a multicast destination address (first bit in the destination address field is 1) are passed.<br>• If this field is 0, filtering of multicast packets depends on the settings of the HMC field.<br>0b - Disabled<br>1b - Enabled |
| 3<br>DAIF | DA Inverse Filtering<br>Indicates the status of DA inverse filtering.<br>• If this field is 1, the Address Check block operates in Inverse Filtering mode for the DA address comparison of both unicast and multicast packets.<br>• If this field is 0, normal filtering of packets is performed.<br>0b - Disabled<br>1b - Enabled |
| 2<br>HMC | Hash Multicast<br>Indicates the status of hast multicast.<br>• If this field is 1, MAC performs the destination address filtering of received multicast packets according to the hash table.<br>• If this field is 0, MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers.<br>0b - Disabled<br>1b - Enabled |
| 1<br>HUC | Hash Unicast<br>Indicates the status of hash unicast. |

*Table continues on the next page...*

## 72.17.6 MAC Hash Table First 32 Bits (MAC_Hash_Table_Reg0)

### Offset

| Register | Offset |
|---|---|
| MAC_Hash_Table_Reg0 | 10h |

### Function

Contains the first 32 bits of the hash table, when the total width of the hash table is 128 bits or 256 bits.

**NOTE**

In this chip, upper 6 bits should be used for 64-bit Hash Table.

The hash table is used for group address filtering, for which the content of the destination address in the incoming packet is passed through the CRC logic and the bits of Receive CRC Error Packets (Rx_CRC_Error_Packets) are used to index the contents of the hash table as follows:

- 6 bits when you have a 64-bit hash
- 7 bits when you have a 128-bit hash
- 8 bits when you have a 256-bit hash

The most-significant bits determine the Hash Table register to be used, and the least-significant 5 bits determine the bit within the register. For example, a hash value of 10_0000b (in 64-bit hash) selects bit 0 of MAC Hash Table Second 32 Bits (MAC_Hash_Table_Reg1).

Perform these steps to calculate the hash value of the destination address:

1. Calculate the 32-bit CRC for DA (see section 3.2.8 in IEEE 802.3 for the steps to calculate CRC32).
2. Perform bit-wise reversal for the value obtained in step 1.
3. Use the upper 6, 7, or 8 bits from the value obtained in step 2.

If this field is 1, the packet is accepted. Otherwise, it is rejected. If MAC_Packet_Filter[PM] = 1, all multicast packets are accepted regardless of the multicast hash values.

If this register is configured to be double-synchronized with the (G)MII clock domain, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the Hash Table registers are written to.

If double-synchronization is enabled, consecutive writes to this register must be performed after at least four clock cycles in the destination clock domain.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### Fields

| Field | Function |
|---|---|
| 31-0<br>HT31T0 | MAC Hash Table First 32 Bits<br>Contains the first 32 bits [31:0] of the hash table. |

## 72.17.7 MAC Hash Table Second 32 Bits (MAC_Hash_Table_Reg1)

### Offset

| Register | Offset |
|---|---|
| MAC_Hash_Table_Reg1 | 14h |

### Function

Contains the second 32 bits of the hash table, when the width of the hash table is 128 or 256 bits.

**NOTE**

In this chip, upper 6 bits should be used for 64-bit Hash Table.

The hash table is used for group address filtering, for which the content of the destination address in the incoming packet is passed through the CRC logic and the bits of Receive CRC Error Packets (Rx_CRC_Error_Packets) are used to index the contents of the hash table as follows:

- 6 bits when you have a 64-bit hash
- 7 bits when you have a 128-bit hash
- 8 bits when you have a 256-bit hash

The most-significant bits determine the Hash Table register to be used, and the least-significant 5 bits determine the bit within the register. For example, a hash value of 10_0000b (in 64-bit hash) selects bit 0 of MAC Hash Table Second 32 Bits (MAC_Hash_Table_Reg1).

Perform these steps to calculate the hash value of the destination address:

1. Calculate the 32-bit CRC for DA (see section 3.2.8 in IEEE 802.3 for the steps to calculate CRC32).
2. Perform bit-wise reversal for the value obtained in step 1.
3. Take the upper 6, 7, or 8 bits from the value obtained in step 2.

If the corresponding bit value of this register is 1'b1, the packet is accepted. Otherwise, it is rejected. If MAC_Packet_Filter[PM] = 1, all multicast packets are accepted regardless of the multicast hash values.

If this register is configured to be double-synchronized with the (G)MII clock domain, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the Hash Table registers are written to.

If double-synchronization is enabled, consecutive writes to this register must be performed after at least four clock cycles in the destination clock domain.

The field enables or disables inner VLAN tag stripping on receive.<br>00b - Do not strip<br>01b - Strip if VLAN filter passes<br>10b - Strip if VLAN filter fails<br>11b - Always strip |
| 27<br>ERIVLT | Enable Inner VLAN Tag Comparison<br>Enables or disables the inner VLAN tag.<br>• If ERIVLT = VTHM = EDVLP = 1, the EMAC receiver enables the VLAN hash filtering operation on the inner VLAN tag (if present).<br>• If ERIVLT = 0 and VTHM = 1, the EMAC receiver enables the VLAN hash filtering operation on the outer VLAN tag (if present). ERSVLM and DOVLTC determine which VLAN type is enabled for filtering.<br>0b - Disabled<br>1b - Enabled |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| 26<br>EDVLP | Enable Double VLAN Processing<br>Enables or disables double VLAN processing.<br>• If this field is 1, MAC enables processing of up to two VLAN tags on transmit and receive (if present).<br>• If this field is 0, MAC enables processing of up to one VLAN tag on transmit and receive (if present).<br>0b - Disabled<br>1b - Enabled |
| 25<br>VTHM | VLAN Tag Hash Table Match<br>Indicates the status of VLAN tag hash table match.<br>• If this field is 1, the most-significant four bits of CRC-32 of VLAN tag are used to index the content of MAC VLAN Hash Table (MAC_VLAN_Hash_Table). See VLAN filtering for details.<br>• If MAC_VLAN_Hash_Table[VLHT] = 1, corresponding to the index, it indicates that the Ethernet packet matches the VLAN hash table. See VLAN filtering for details.<br>• If ETV = 1, the CRC of the 12-bit VLAN identifier (VID) is used for comparison. When the ETV field becomes 0, the CRC of the 16-bit VLAN tag is used for comparison.<br>• If VTHM = 1, the VLAN hash match operation is not performed.<br>0b - Disabled<br>1b - Enabled |
| 24<br>EVLRXS | Enable VLAN Tag In Receive Status<br>Indicates whether the VLAN tag in receive status is enabled.<br>• If this field is 1, MAC provides the outer VLAN tag in the receive status.<br>• If this field is 0, MAC does not provide the outer VLAN tag in receive status.<br>0b - Disabled<br>1b - Enabled |
| 23<br>— | Reserved |
| 22-21<br>EVLS | Enable VLAN Tag Stripping<br>Indicates the stripping operation on the outer VLAN tag in received packets. The field enables or disables VLAN tag stripping on receive.<br>00b - Do not strip<br>01b - Strip if VLAN filter passes<br>10b - Strip if VLAN filter fails<br>11b - Always strip |
| 20 | Disable VLAN Type Check |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| DOVLTC | Enables or disables VLAN type check for VLAN hash filtering.<br>• If this field is 1, the MAC VLAN hash filter matches or filters the VLAN tag that the ERIVLT field specifies only when the VLAN tag type is similar to the one that the ERSVLM field specifies.<br>• If this field is 0, the MAC VLAN hash filter does not check whether the VLAN tag that the ERIVLT field specifies is of type S-VLAN or C-VLAN.<br>0b - Enabled<br>1b - Disabled |
| 19<br>ERSVLM | Enable Receive S-VLAN Match<br>Enables or disables receive S-VLAN match for VLAN hash filtering.<br>• If this field is 1, the MAC receiver enables VLAN hash filtering or S-VLAN matching (type = 88A8h) packets.<br>• If this field is 0, the MAC receiver enables VLAN hash filtering or matching for C-VLAN (type = 8100h) packets.<br>The ERIVLT field determines the VLAN tag position considered for VLAN hash filtering or matching.<br>0b - Disabled<br>1b - Enabled |
| 18<br>ESVL | Enable S-VLAN<br>Enables or disables S-VLAN.<br>If this field is 1, the MAC transmitter and receiver consider the S-VLAN packets (type = 88A8h) as valid VLAN-tagged packets.<br>0b - Disabled<br>1b - Enabled |
| 17<br>VTIM | VLAN Tag Inverse Match Enable<br>Enables or disables VLAN tag inverse matching.<br>• If this field is 1, it enables the VLAN tag inverse matching. The packets without matching VLAN tag are marked as matched.<br>• If this field is 0, it enables the VLAN tag perfect matching. The packets with matched VLAN tag are marked as matched.<br>0b - Disabled<br>1b - Enabled |
| 16<br>ETV | Enable Tag For VLAN<br>Enables or disables 12-bit VLAN tag comparison for VLAN hash filtering.<br>• If this field is 1, a 12-bit VLAN identifier is used for VLAN hash filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of the VLAN tag in the received VLAN-tagged packet are used for hash-based VLAN filtering. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | • When this field becomes 0, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for VLAN hash filtering.<br>0b - Disabled<br>1b - Enabled |
| 15-4<br>— | Reserved |
| 3-2<br>OFS | Offset<br>Holds the address offset of the MAC VLAN Tag Filter register that the application tries to access.<br>The width of this field depends on the number of enabled MAC VLAN Tag registers. |
| 1<br>CT | Command Type<br>Specifies whether the current register access indicates a read or a write operation. It indicates a read operation if this field is 1 and a write operation when the field is 0.<br>0b - Write operation<br>1b - Read operation |
| 0<br>OB | Operation Busy<br>Indicates the operation busy status.<br>• This field becomes 1 to initiate a read or write command for an indirect access to the Per VLAN Tag Filter register.<br>• The field becomes 0 when the read or write command to Per VLAN Tag Filter indirect access register completes. The next indirect register access can be initiated only after the field resets.<br>During a write operation, the field becomes 0 only after the data is written into a MAC_VLAN_Tag_Filter register.<br>During a read operation, the data must be read from MAC VLAN Tag Data (MAC_VLAN_Tag_Data) only after this field becomes 0.<br>0b - Disabled<br>1b - Enabled |

### 72.17.10 MAC VLAN Tag Data (MAC_VLAN_Tag_Data)

#### Offset

| Register | Offset |
|---|---|
| MAC_VLAN_Tag_Data | 54h |

#### Function

Holds the read and write data for indirect access to the Per VLAN Tag registers.

- During read access, this register contains valid read data only after MAC_VLAN_Tag_Ctrl[OB] becomes 0.
- During write access, this register must become valid before you write 1 to MAC_VLAN_Tag_Ctrl[OB].

## 72.17.15 MAC VLAN Hash Table (MAC_VLAN_Hash_Table)

### Offset

| Register | Offset |
|---|---|
| MAC_VLAN_Hash_Table | 58h |

### Function

If MAC_VLAN_Tag_Ctrl[VTHM] = 1, the 16-bit VLAN hash table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on MAC_VLAN_Tag_Ctrl[ETV]) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC value are used to index the contents of the VLAN hash table. For example, hash value of 1000b selects bit 8 of the VLAN hash table.

Perform these steps to calculate the hash value of the destination address:

1. Calculate the 32-bit CRC for DA (see section 3.2.8 of IEEE 802.3 for steps to calculate CRC32).
2. Perform bit-wise reversal for the value obtained in step 1.
3. Take the upper 4 bits from the value obtained in step 2.

If this register is configured to be double-synchronized with the (G)MII clock domain, the synchronization is triggered only when bits [15:8] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the register are written to.

If double-synchronization is enabled, consecutive writes to this register must be performed after at least four clock cycles in the destination clock domain.

### Diagram

## 72.17.26 MAC Q0 Tx Flow Control (MAC_Q0_Tx_Flow_Ctrl)

### Offset

| Register | Offset |
|---|---|
| MAC_Q0_Tx_Flow_Ctrl | 70h |

### Function

Controls the generation and reception of the control (pause command) packets by MAC's flow control module. A write to the register with the Busy field = 1 triggers the flow control block to generate a pause packet. The 802.3x specification indicates the way the fields of the control packet are selected, and the pause time value from this register is used in the PT field of the control packet. The Busy field remains 1 until the control packet is transferred onto the cable. You must make sure that the Busy field is 0 before writing to this register.

If the value of the PFCE field in the MAC_Rx_Flow_Ctrl register is 1, this register controls the generation of priority flow control (PFC) frames with priorities mapped according to MAC_RxQ_Ctrl2[PSRQ0].

### Diagram

### Fields

| Field | Function |
|---|---|
| 31-16<br>PT | Pause Time<br>Holds the value to be used in this field in the transmit control packet. If the bits of this field are configured to be double-synchronized with the (G)MII clock domain, consecutive writes to this register must be performed only after at least four clock cycles in the destination clock domain. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| 15-8<br>— | Reserved |
| 7<br>DZPQ | Disable Zero-Quanta Pause<br>Enables or disables zero-quanta pause packet generation.<br>• If this field is 1, it disables the automatic generation of the zero-quanta pause packets that the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i) deasserts.<br>• If this field is 0, normal operations with automatic zero-quanta pause packet generation are enabled.<br>0b - Enabled<br>1b - Disabled |
| 6-4<br>PLT | Pause Low Threshold<br>Configures the threshold of the pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the pause packet.<br>The threshold values must always be less than the pause time configured in bits [31:16]. For example, if the PT field = 100H (256 slot times), and the PLT field = 001, a second pause packet automatically transmits if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first pause packet transmits.<br>This list provides the threshold values for different values:<br>• The slot time is defined as the time taken to transmit 512 bits (64 bytes) on GMII or MII.<br>• This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + two pause packet sizes + IPG in slot times.<br>000b - Pause time minus 4 slot times (PT is 4 slot times)<br>001b - Pause time minus 28 slot times (PT is 28 slot times)<br>010b - Pause time minus 36 slot times (PT is 36 slot times)<br>011b - Pause time minus 144 slot times (PT is 144 slot times)<br>100b - Pause time minus 256 slot times (PT is 256 slot times)<br>101b - Pause time minus 512 slot times (PT is 512 slot times)<br>110b - Reserved |
| 3-2<br>— | Reserved |
| 1<br>TFE | Transmit Flow Control Enable<br>Indicates whether transmit flow control is enabled or disabled.<br>• Full-Duplex mode: If this field is 1, MAC enables the flow control operation to the transmit pause packets. When the field becomes 0, MAC's flow control operation disables and MAC does not transmit any pause packets. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | • Half-Duplex mode: If this field is 1, MAC enables the backpressure operation. When the field becomes 0, the backpressure operation disables.<br>0b - Disabled<br>1b - Enabled |
| 0<br>FCB_BPA | Flow Control Busy Or Backpressure Activate<br>Initiates if a pause packet is in Full-Duplex mode and activates the backpressure function in Half-Duplex mode if the TFE field is 1.<br>• Full-Duplex mode: In this mode, FCB_BPA must be read as 1'b0 before writing to this register. To initiate a pause packet, the application must set this field to 1'b1. During control packet transfer, the field's value continues to be 1 to indicate that a packet transmission is in progress. When pause packet transmission is complete, MAC resets this field to 1'b0. You must not write to this register until this field becomes 0.<br>• Half-Duplex mode: If FCB_BPA = 1 and TFE = 1 too, MAC asserts backpressure in this mode. During the backpressure function, when MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register field is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When you configure MAC using Full-Duplex mode, this field automatically becomes 0.<br>Access restrictions apply to this field: writing 1 sets it, writing 0 has no effect, and the field is self-clearing.<br>0b - Flow control busy or backpressure activate is disabled<br>1b - Flow control busy or backpressure activate is enabled |

### 72.17.27 MAC Receive Flow Control (MAC_Rx_Flow_Ctrl)

**Offset**

| Register | Offset |
|---|---|
| MAC_Rx_Flow_Ctrl | 90h |

**Function**
Controls the pausing of MAC transmit based on the received pause packet.

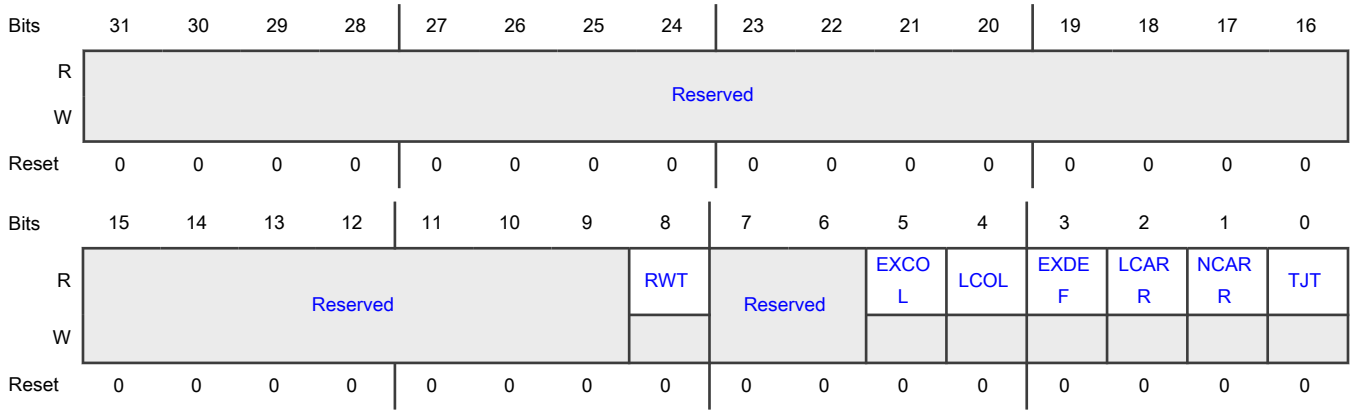
## 72.17.34 MAC Rx Transmit Status (MAC_Rx_Tx_Status)

**Offset**

| Register | Offset |
|---|---|
| MAC_Rx_Tx_Status | B8h |

**Function**
Contains the receive and transmit error status.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-9<br>— | Reserved |
| 8<br>RWT | Receive Watchdog Timeout<br>Indicates the status of receive watchdog.<br>This field becomes 1 when a packet with a length greater than 2,048 bytes is received (10,240 bytes when Jumbo Packet mode is enabled) and MAC_Configuration[WD] = 0. RWT becomes 1 when a packet with length greater than 16,383 bytes is received and MAC_Configuration[WD] = 1.<br>Access restrictions apply to RWT. It becomes 0 on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. RWT automatically becomes 1 on an internal event occurrence.<br>0b - No receive watchdog timed out<br>1b - Receive watchdog timed out |
| 7-6<br>— | Reserved |
| 5<br>EXCOL | Excessive Collisions<br>Indicates the status of excessive collision.<br>If MTL_Operation_Mode[DTXSTS] = 1, this field, EXCOL, indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet.<br>If MAC_Configuration[DR] = 1, EXCOL becomes 1 after the first collision and the packet transmission is aborted.<br>Access restrictions apply to EXCOL. It becomes 0 on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. EXCOL automatically becomes 1 on an internal event occurrence.<br>0b - No collision<br>1b - Excessive collision is sensed |
| 4 | Late Collision |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| LCOL | Indicates the status of late collision.<br>If MTL_Operation_Mode[DTXSTS] = 1, this field, LCOL, indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including preamble in MII mode; 512 bytes including preamble and carrier extension in GMII mode).<br>This field is invalid if an underflow error occurs.<br>Access restrictions apply to LCOL. It becomes 0 on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. LCOL automatically becomes 1 on an internal event occurrence.<br>0b - No collision<br>1b - Late collision is sensed |
| 3<br>EXDEF | Excessive Deferral<br>Indicates whether the transmission ended because of excessive deferral.<br>If MTL_Operation_Mode[DTXSTS] = 1 and MAC_Configuration[DC] = 1 too, this field, EXDEF, indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbit/s mode or when the jumbo packet is enabled).<br>Access restrictions apply to EXDEF. It becomes 0 on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. EXDEF automatically becomes 1 on an internal event occurrence.<br>0b - No excessive deferral<br>1b - Excessive deferral |
| 2<br>LCARR | Loss of Carrier<br>Indicates the status of carrier signal.<br>If MTL_Operation_Mode[DTXSTS] = 1, this field, LCARR, indicates that the loss of carrier occurred during packet transmission, which means, the PHY_CRS_I signal was inactive for one or more transmission clock periods during packet transmission. The field is valid only for packets transmitted without collision.<br>Access restrictions apply to LCARR. It becomes 0 on read or write of 1 when MAC_CSR_SW_Ctrl[RCWE] = 1. LCARR automatically becomes 1 on an internal event occurrence.<br>0b - Carrier is present<br>1b - Loss of carrier |
| 1<br>NCARR | No Carrier<br>Indicates whether the carrier signal is present from the PHY at the end of preamble transmission.<br>If MTL_Operation_Mode[DTXSTS] = 1, NCARR indicates that the carrier signal from the PHY is absent at the end of preamble transmission.<br>Access restrictions apply to NCARR. It becomes 0 after either of these actions:<br>• You read NCARR.<br>• You write 1 to NCARR when MAC_CSR_SW_Ctrl[RCWE] = 1.<br>NCARR automatically becomes 1 after an internal event occurs. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 0b - Present<br>1b - Absent |
| 0<br>TJT | Transmit Jabber Timeout<br>Indicates whether a transmit-jabber timer timeout occurred. The timeout occurs after any of these events:<br>• MAC_Configuration[JD] = 0 and the normal packet size exceeds 2,048 bytes.<br>• MAC_Configuration[JD] = 0 and the jumbo packet size exceeds 10240 bytes.<br>• MAC_Configuration[JD] = 1 and the normal packet size exceeds 16383 bytes.<br>Access restrictions apply to TJT. It becomes 0 after either of these actions:<br>• You read TJT.<br>• You write 1 to TJT when MAC_CSR_SW_Ctrl[RCWE] = 1.<br>TJT automatically becomes 1 after an internal event occurs.<br>0b - No transmit jabber timeout occurred<br>1b - Transmit jabber timeout occurred |

## 72.17.35 MAC Version (MAC_Version)

### Offset

| Register | Offset |
|---|---|
| MAC_Version | 110h |

### Function

Identifies the version of the module.

### Fields

| Field | Function |
|---|---|
| 31-28<br>— | Reserved |
| 27<br>PSE | Preamble Suppression Enable<br>Indicates the status of preamble suppression.<br>• If this field is 1, SMA suppresses the 32-bit preamble and transmits MDIO frames with only 1 preamble bit.<br>• If this field is 0, the MDIO frame always includes 32 bits of preamble as defined in the IEEE specification. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 0b - Disabled<br>1b - Enabled |
| 26<br>BTB | Back-To-Back Transactions<br>Indicates the status of back-to-back transactions.<br>When BTB = 1 and NTC > 0, MAC indicates the completion of a read or write command at the end of a frame transfer (before the trailing clocks are transmitted). Therefore, you can initiate the next command, and that command executes immediately irrespective of the number of trailing clocks generated for the previous frame.<br>When BTB = 0, the read or write command completes (GB = 0) only after the trailing clocks generate. In this mode, you must ensure that:<br>• NTC is always generated after each frame.<br>• BTB must not be equal to 1 when NTC = 0.<br>0b - Disabled<br>1b - Enabled |
| 25-21<br>PA | Physical Layer Address<br>Indicates whether MAC accesses clause 22 PHY devices (out of 32) or clause 45 capable PHYs (out of 32). |
| 20-16<br>RDA | Register Or Device Address<br>Indicates whether MAC accesses clause 22 PHY devices (out of 32) or clause 45 capable PHYs (out of 32). |
| 15<br>— | Reserved |
| 14-12<br>NTC | Number Of Trailing Clocks<br>Controls the number of trailing clock cycles generated on the GMII_MDC_O (MDC) signal after the end of MDIO frame transmission. The valid values can range from 0 to 7.<br>Writing 3h to this field indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer. |
| 11-8<br>CR | CSR Clock Range<br>Determines the frequency of the MDC clock according to the CSR clock frequencies used in your design:<br>• 0000: CSR clock = 60-100 MHz; MDC clock = CSR clock/42<br>• 0001: CSR clock = 100-150 MHz; MDC clock = CSR clock/62<br>• 0010: CSR clock = 20-35 MHz; MDC clock = CSR clock/16<br>• 0011: CSR clock = 35-60 MHz; MDC clock = CSR clock/26<br>• 0100: CSR clock = 150-250 MHz; MDC clock = CSR clock/102<br>• 0101: CSR clock = 250-300 MHz; MDC clock = CSR clock/124 |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | • 0110: CSR clock = 300-500 MHz; MDC clock = CSR clock/204<br>• 0111: CSR clock = 500-800 MHz; MDC clock = CSR clock/324<br>When bit 3 of this field is 0, the suggested CSR clock-frequency range applicable to each value ensures that the MDC clock frequency is approximately between 1.0 MHz and 2.5 MHz.<br>When bit 3 of this field is 1, you can achieve a higher MDC clock frequency than the IEEE 802.3 frequency limit of 2.5 MHz, and program a clock divider of a lower value. For example, if the CSR clock frequency is 100 MHz and you write 1010 to this field, the resultant MDC clock frequency equals 12.5 MHz, which is above the range specified in IEEE 802.3. Program these values only if the interfacing chips support faster MDC clocks:<br>• 1000: CSR clock/4<br>• 1001: CSR clock/6<br>• 1010: CSR clock/8<br>• 1011: CSR clock/10<br>• 1100: CSR clock/12<br>• 1101: CSR clock/14<br>• 1110: CSR clock/16<br>• 1111: CSR clock/18<br>These bits are not used for accessing RevMII. They are read-only if the RevMII interface is selected as a single PHY interface. |
| 7-5<br>— | Reserved |
| 4<br>SKAP | Skip Address Packet<br>Indicates the status of the skip address packet.<br>If this field is 1, SMA does not send the address packets before read, write, or post-read increment address packets. This field is valid only when C45E = 1.<br>0b - Disabled<br>1b - Enabled |
| 3<br>GOC_1 | GMII Operation Command 1<br>Indicates the status of GMII operation command 1.<br>GMII operation command 1 represents the higher bit of the operation command to PHY or RevMII. The fields GOC_1 and GOC_O indicate these values:<br>• 00: Reserved<br>• 01: Write<br>• 10: Post-read increment address for clause 45 PHY<br>• 11: Read |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | When clause 22 PHY or RevMII is enabled, only write and read commands are valid.<br>0b - Disabled<br>1b - Enabled |
| 2<br>GOC_0 | GMII Operation Command 0<br>Indicates the status of GMII operation command 0.<br>GMII operation command 0 represents the lower bit of the operation command to PHY or RevMII. When in SMA mode (MDIO master), this field, along with the GOC_1 field, determines the operation to be performed to PHY.<br>This field is read-only and tied to 1 when only RevMII is selected in configuration.<br>0b - Disabled<br>1b - Enabled |
| 1<br>C45E | Clause 45 PHY Enable<br>Indicates the status of clause 45 PHY.<br>• If this field is 1, clause 45 capable PHY is connected to MDIO.<br>• If this field is 0, clause 22 capable PHY is connected to MDIO.<br>0b - Disabled<br>1b - Enabled |
| 0<br>GB | GMII Busy<br>Indicates the status of GMII busy.<br>Writing 1 to this field instructs SMA to initiate a read or write access to the MDIO slave. MAC writes 0 to the field after the MDIO frame transfer is complete. Therefore, you must not write or change any of the fields in the MAC_MDIO_Address and MAC_MDIO_Data registers as long as the value of this field is 1.<br>For write transfers, before writing 1 to this field, you must write a 16-bit data to MAC_MDIO_Data[GD] and MAC_MDIO_Data[RA] if C45E = 1.<br>If C45E = 1, you must also write to MAC_MDIO_Data[RA] before initiating a read transfer.<br>After a read transfer completes (GB = 0), a data read from the PHY register is valid in MAC_MDIO_Data[GD].<br>**NOTE**<br>Even if the addressed PHY is not present, there is no change in the functionality of this field.<br>Access restrictions apply to this field. It clears automatically and writing 0 to it has no effect.<br>0b - Disabled<br>1b - Enabled |

## 72.17.46 MAC MDIO Data (MAC_MDIO_Data)

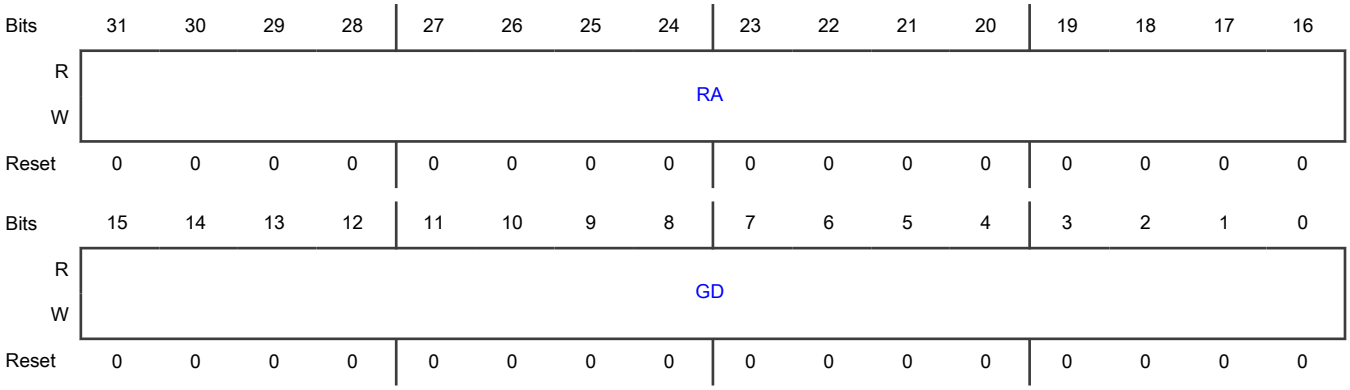
### Offset

| Register | Offset |
|---|---|
| MAC_MDIO_Data | 204h |

### Function

Is used to store the write data to be written to the PHY register located at the address specified in MAC MDIO Address (MAC_MDIO_Address). This register also stores the read data from the PHY register located at the address that MAC MDIO Address (MAC_MDIO_Address) specifies.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-16<br>RA | Register Address<br>Contains the PHY register address intended for the MDIO frame.<br>This field is valid only when MAC_MDIO_Address[C45E] = 1. |
| 15-0<br>GD | GMII Data<br>Contains the 16-bit data value read from PHY or RevMII after a management read operation or the 16-bit data value to be written to PHY or RevMII before a management write operation. |

## 72.17.47 MAC CSR Software Control (MAC_CSR_SW_Ctrl)

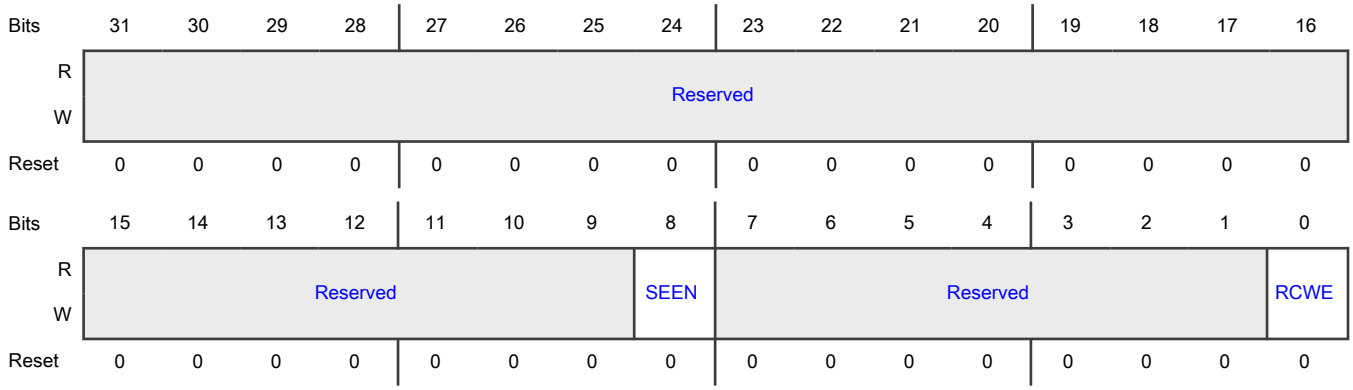
### Offset

| Register | Offset |
|---|---|
| MAC_CSR_SW_Ctrl | 230h |

### Function

Contains software programmable controls for changing the CSR access response and clearing the status bits on read.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-9<br>— | Reserved |
| 8<br>SEEN | Slave Error Response Enable<br>Indicates the status of the slave error response.<br>• If this field is 1, MAC responds with a slave error for accesses to reserved registers in the CSR space.<br>• If this field is 0, MAC sends an "okay" response to registers accessed from the CSR space.<br>0b - Disabled<br>1b - Enabled |
| 7-1<br>— | Reserved |
| 0<br>RCWE | Enable Register Write 1 To Clear (W1C)<br>Enables and disables the W1C feature for some registers.<br>When this field is 1, the access mode of some of the other fields changes from R2C to W1C.<br>When this field is 0, the access mode of those fields remains R2C.<br>0b - Disabled<br>1b - Enabled |

## 72.17.48 MAC FPE Control STS (MAC_FPE_CTRL_STS)

### Offset

| Register | Offset |
|---|---|
| MAC_FPE_CTRL_STS | 234h |

### Function

Controls the operation of frame preemption.

### Diagram

## 72.17.49 MAC Presentation Time (MAC_Presn_Time_ns)

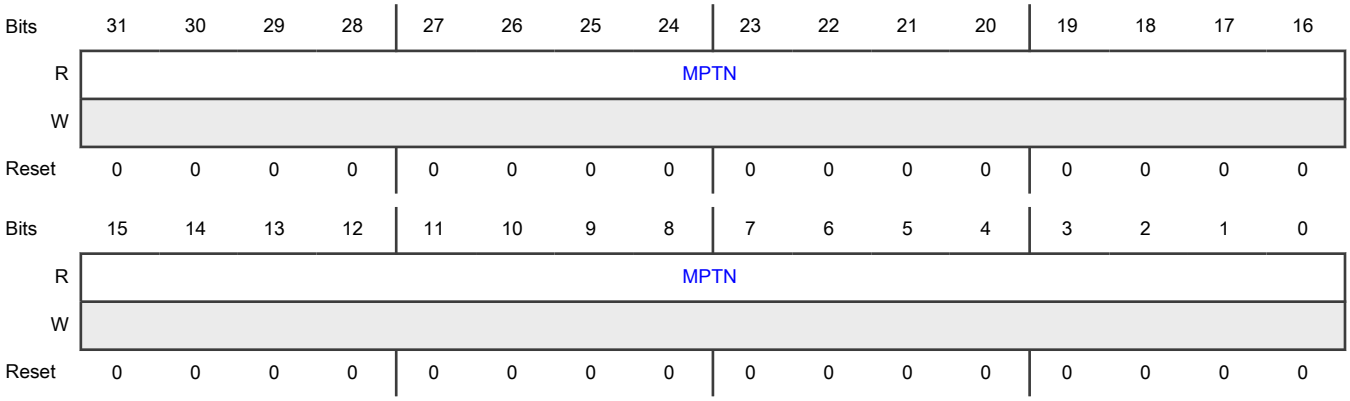
### Offset

| Register | Offset |
|---|---|
| MAC_Presn_Time_ns | 240h |

### Function

Contains the 32-bit binary rollover equivalent time of the PTP system time (in nanoseconds) and exists when DWC_EQOS_FLEXI_PPS_OUT_EN is configured.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>MPTN | MAC 1722 Presentation Time (In Nanoseconds)<br>Indicates the value of the 32-bit binary rollover equivalent time of the PTP System Time (in ns). |

## 72.17.50 MAC Presentation Time Update (MAC_Presn_Time_Updt)

### Offset

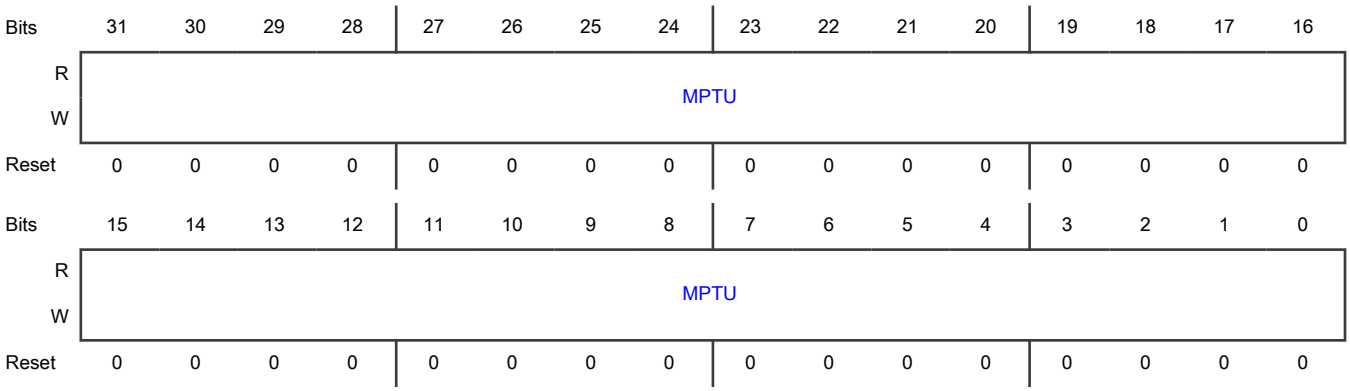
| Register | Offset |
|---|---|
| MAC_Presn_Time_Updt | 244h |

### Function

Holds the 32-bit value of MAC 1722 presentation time (in ns), which must be added to the current presentation time counter value. Initialization happens when MAC_Timestamp_Control[TSINIT] = 1, and an update happens when MAC_Timestamp_Control[TSUPDT] = 1.

Exists when DWC_EQOS_FLEXI_PPS_OUT_EN is configured.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>MPTU | MAC 1722 Presentation Time Update<br>Holds the initial value or the update value for the presentation time. When used for an update, this field holds the 32-bit value (in ns), which must be added to the current presentation time counter value. Initialization happens when MAC_Timestamp_Control[TSINIT] = 1, and an update happens when MAC_Timestamp_Control[TSUPDT] = 1.<br>When MAC_System_Time_Nanoseconds_Update[ADDSUB] = 1, this value is directly used for subtraction. |

## 72.17.51 MAC Address 0 High (MAC_Address0_High)

### Offset

| Register | Offset |
|---|---|
| MAC_Address0_High | 300h |

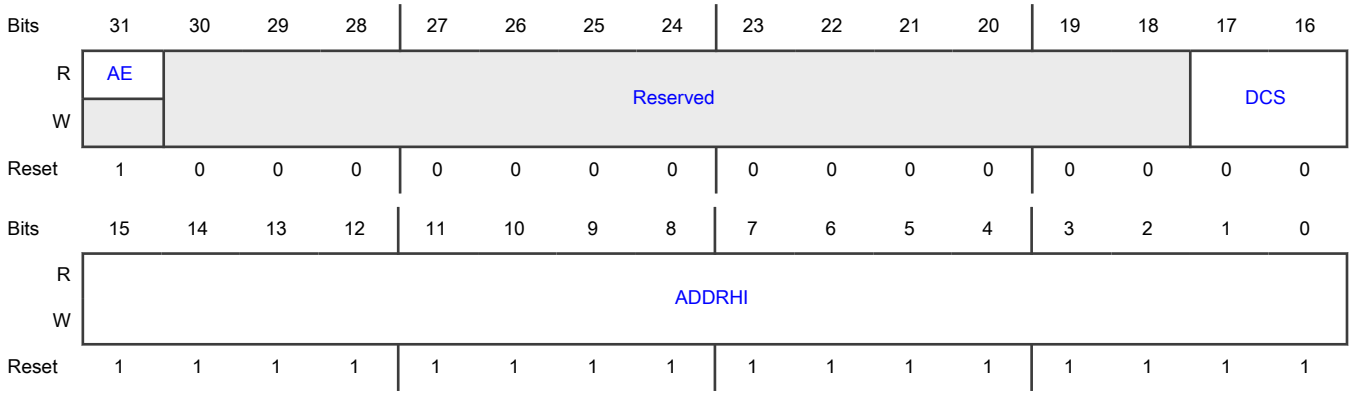
### Function

Holds the upper 16 bits of the first 6-byte MAC address of the station.

The first DA byte that is received on the (G)MII interface corresponds to the LS byte (bits [7:0]) of MAC Address 0 Low (MAC_Address0_Low). For example, if 112233445566h is received (11h in lane 0 of the first column) on (G)MII as the destination address, MAC Address 0 Low (MAC_Address0_Low)[47:0] is compared to 665544332211h.

If MAC address registers are configured to be double-synchronized with the (G)MII clock domains, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of MAC Address 0 Low (MAC_Address0_Low) are written to. For proper synchronization updates, the consecutive writes to MAC Address 0 Low (MAC_Address0_Low) must be performed after at least four clock cycles in the destination clock domain.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>AE | Address Enable<br>Enables MAC address<br>0b - Disabled and invalid (the field's value must always be 1)<br>1b - Enabled |

| 17-16<br>DCS | DMA Channel Select<br>If MAC_Ext_Configuration[PDC] = 0, this field contains the binary representation of the DMA channel number to which a receive packet whose DA matches MAC Address 0 Low (MAC_Address0_Low) content is routed.<br>If MAC_Ext_Configuration[PDC] = 1, this field contains the one-hot representation of one or more DMA channel numbers to which a receive packet whose DA matches MAC Address 0 Low (MAC_Address0_Low) content is routed. |
| 15-0<br>ADDRHI | MAC Address 0 [47:32]<br>Contains the upper 16 bits [47:32] of the first 6-byte MAC address.<br>MAC uses this field for filtering the received packets and inserting the MAC address in the transmit flow control (pause) packets. |

## 72.17.52 MAC Address 0 Low (MAC_Address0_Low)

### Offset

| Register | Offset |
|---|---|
| MAC_Address0_Low | 304h |

### Function

Holds the lower 32 bits of the 6-byte first MAC address of the station.

### Diagram

### Fields

| Field | Function |
|---|---|
| 31-0<br>ADDRLO | MAC Address 0 [31:0]<br>Contains the lower 32 bits of the first 6-byte MAC address. MAC uses this field to filter the received packets and insert the MAC address in the transmit flow control (pause) packets. |

## 72.17.53 MAC Address 1 High (MAC_Address1_High)

### Offset

| Register | Offset |
|---|---|
| MAC_Address1_High | 308h |

### Function

Holds the upper 16 bits of the second 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized with the (G)MII clock domains, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of MAC Address 1 Low (MAC_Address1_Low) are written to. For proper synchronization updates, the consecutive writes to MAC Address 1 Low (MAC_Address1_Low) must be performed after at least four clock cycles in the destination clock domain.

| 3<br>CNTFREEZ | MMC Counter Freeze<br>Indicates the status of MMC counter freeze.<br>If this field is 1, the field freezes all the MMC counters to their current values.<br>Until this field becomes 0, no MMC counter is updated because of any transmitted or received packets. If an MMC counter is read when RSTONRD = 1, that counter is also cleared in this mode.<br>0b - Disabled<br>1b - Enabled |
| 2<br>RSTONRD | Reset On Read<br>Indicates whether the reset on read for MMC counters is enabled or disabled.<br>If this field is 1, MMC counters are reset to 0 after read (they clear automatically after reset). The counters are cleared when the least significant byte lane (bits [7:0]) is read.<br>0b - Disabled<br>1b - Enabled |
| 1<br>CNTSTOPRO | Counter Stop Rollover<br>Indicates the status of counter stop rollover.<br>If this field is 1, the counter does not roll over to 0 after reaching the maximum value.<br>0b - Disabled<br>1b - Enabled |
| 0<br>CNTRST | Counters Reset<br>Indicates whether MMC counters are reset.<br>If this field is 1, all the counters are reset. This field clears automatically after 1 clock cycle.<br>Access restrictions apply to this field that clears automatically.<br>0b - Counters are not reset<br>1b - All counters are reset |

## 72.17.58 MMC Receive Interrupt (MMC_Rx_Interrupt)

### Offset

| Register | Offset |
|---|---|
| MMC_Rx_Interrupt | 704h |

### Function

Maintains the interrupts generated from all receive statistics counters when the following conditions occur:

- Receive statistic counters reach half of their maximum values (8000_0000h for a 32-bit counter and 8000h for a 16-bit counter).
- Receive statistic counters cross their maximum values (FFFF_FFFFh for a 32-bit counter and FFFFh for a 16-bit counter).

If MMC_Control[CNTSTOPRO] = 1, interrupts are set but the counter remains at all-ones. This is a 32-bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits [7:0]) of the respective counter must be read to clear the interrupt bit.

**NOTE**

R_SS_RC means that this register bit is set internally, and is cleared when the counter register is read.

## 72.17.59 MMC Transmit Interrupt (MMC_Tx_Interrupt)

**Offset**

| Register | Offset |
|---|---|
| MMC_Tx_Interrupt | 708h |

### Function

Maintains the interrupts generated from all the transmit statistics counters.

This register maintains those interrupts that are generated when transmit statistic counters:

- Reach half of their maximum values (8000_0000h for a 32-bit counter and 0x8000 for a 16-bit counter)
- Cross their maximum values (FFFF_FFFFh for a 32-bit counter and FFFFh for a 16-bit counter)

If MMC_Control[CNTSTOPRO] = 1, the interrupts are set but the counter remains at all-ones.

This is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.

The least significant byte lane (bits [7:0]) of the respective counter must be read to clear the interrupt bit.

## 72.17.60 MMC Receive Interrupt Mask (MMC_Rx_Interrupt_Mask)

**Offset**

| Register | Offset |
|---|---|
| MMC_Rx_Interrupt_Mask | 70Ch |

### Function

Maintains the masks for interrupts generated from all the receive statistic counters. These interrupts are generated when the receive statistic counters reach half of their maximum values or the maximum values.

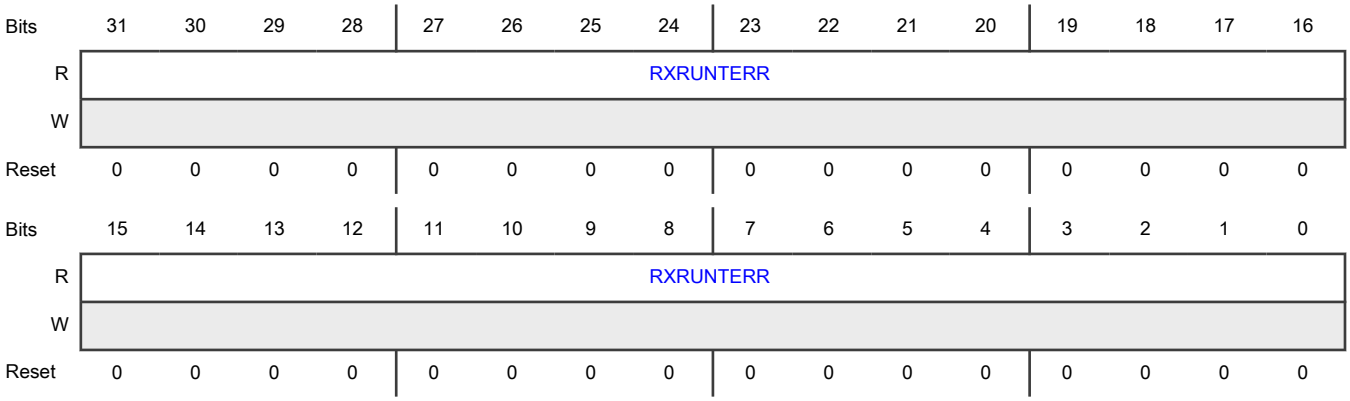
| Rx_Runt_Error_Packets | 79Ch |

### Function
Provides the number of runt packets, which have a length less than 64 bytes and a CRC error, that the module received.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>RXRUNTERR | Receive Runt Error Packets<br>Indicates the number of runt packets received. |

## 72.17.96 Receive Jabber Error Packets (Rx_Jabber_Error_Packets)

### Offset

| Register | Offset |
|---|---|
| Rx_Jabber_Error_Packets | 7A0h |

### Function

Provides the number of giant packets that the module received, having a length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN-tagged packets), and with a CRC error. If Jumbo Packet mode is enabled, packets of length greater than 9,018 bytes (9,022 bytes for VLAN-tagged packets) are considered as giant packets.

### Diagram

| 31-0<br>RXCTRLG | Receive Control Packets Good<br>Indicates the number of good control packets received. |

## 72.17.114 MMC Transmit FPE Fragment Counter Interrupt Status (MMC_FPE_Tx_Interrupt)

### Offset

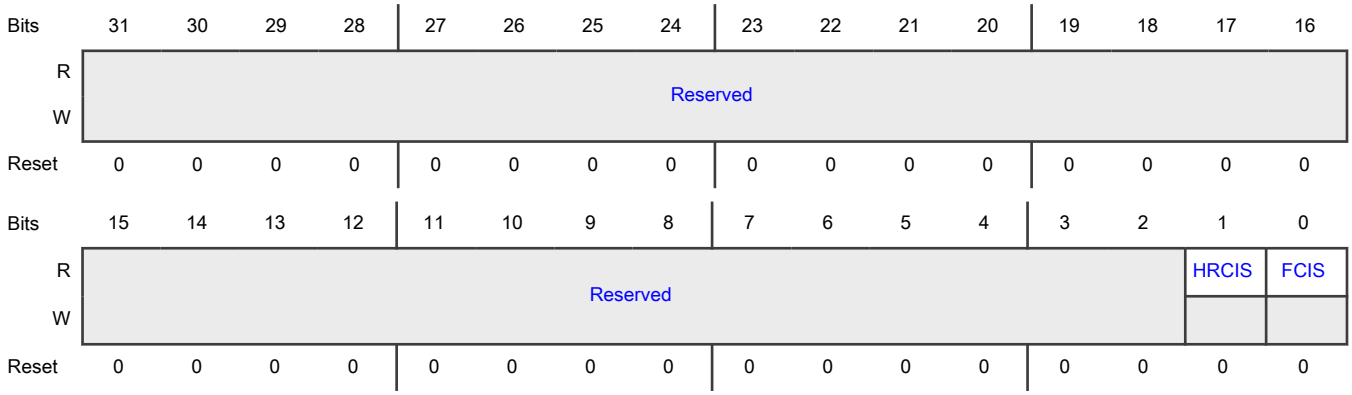
| Register | Offset |
|---|---|
| MMC_FPE_Tx_Interrupt | 8A0h |

### Function

Maintains the interrupts generated from all the FPE-related transmit statistic counters when they reach half of their maximum values (8000_0000h for a 32-bit counter and 8000h for a 16-bit counter), and when they cross their maximum values (FFFF_FFFFh for a 32-bit counter and FFFFh for a 16-bit counter). When MMC_Control[CNTSTOPRO] = 1, the interrupts are set but the counter remains at all-ones.

An interrupt bit of this register becomes 0 when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits [7:0]) of the respective counter must be read to clear the interrupt bit.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-2<br>— | Reserved |
| 1<br>HRCIS | MMC Transmit Hold Request Counter Interrupt Status<br>Indicates whether the MMC Transmit hold request counter interrupt status is detected.<br>This field:<br>• Becomes 1 when the Tx_Hold_Req_Cntr counter reaches half of the maximum value or the maximum value.<br>• Exists when any one of the receive or transmit MMC counters is enabled during FPE with AV_EST-enabled configuration.<br>Access restrictions apply to this field that clears on read and automatically becomes 1 on an internal event occurrence.<br>0b - Not detected<br>1b - Detected |
| 0<br>FCIS | MMC Transmit FPE Fragment Counter Interrupt Status<br>Indicates whether the MMC Transmit FPE fragment counter interrupt status is detected.<br>This field:<br>• Becomes 1 when the Tx_FPE_Fragment_Cntr counter reaches half of the maximum value or the maximum value.<br>• Exists when any one of the receive or transmit MMC counters is enabled during FPE-enabled configuration.<br>Access restrictions apply to this field that clears on read and automatically becomes 1 on an internal event occurrence.<br>0b - Not detected<br>1b - Detected |

## 72.17.115 MMC FPE Transmit Interrupt Mask (MMC_FPE_Tx_Interrupt_Mask)

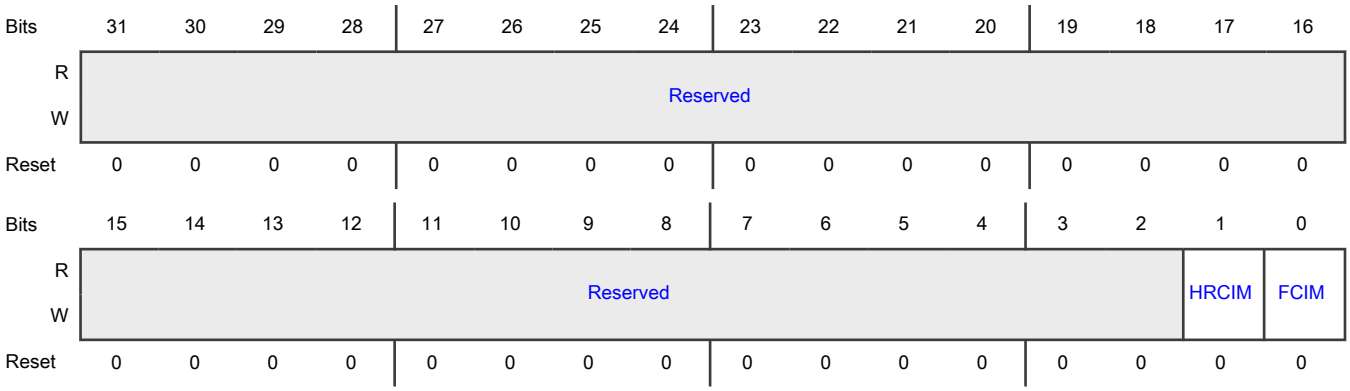
### Offset

| Register | Offset |
|---|---|
| MMC_FPE_Tx_Interrupt_Mask | 8A4h |

### Function

Maintains the masks for interrupts generated from all FPE-related transmit statistics counters. MMC Receive Interrupt Mask (MMC_Rx_Interrupt_Mask) maintains the masks for the interrupts generated when FPE-related receive statistic counters reach half of their maximum value or the maximum value.

### Diagram



### Fields

### Fields

| Field | Function |
|---|---|
| 31-0<br>TXFFC | Transmit FPE Fragment Counter<br>Indicates the number of additional mPackets transmitted because of preemption.<br>Exists when any one of the receive, transmit, or MMC counters is enabled during FPE-enabled configuration. |

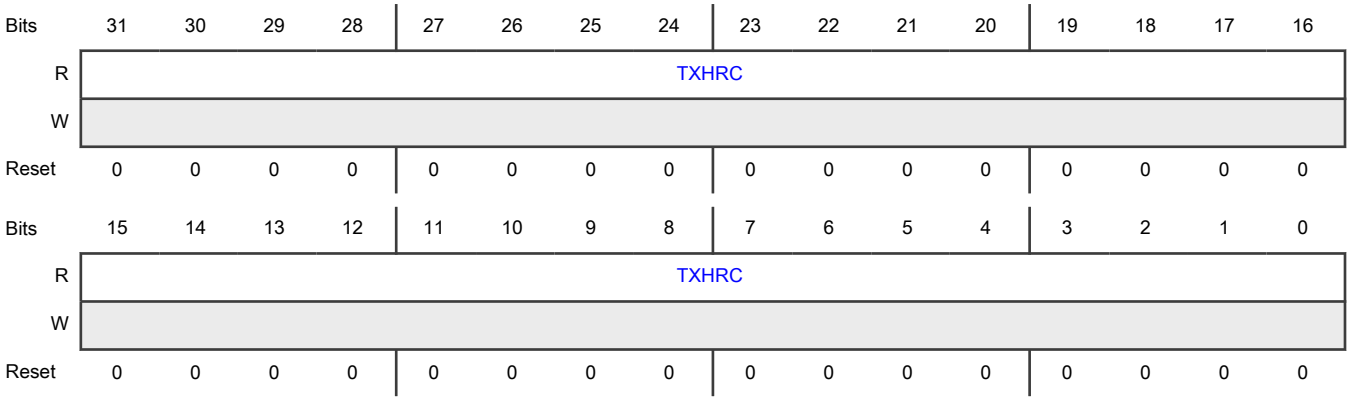
## 72.17.117 Transmit Hold Request Counter (MMC_Tx_Hold_Req_Cntr)

### Offset

| Register | Offset |
|---|---|
| MMC_Tx_Hold_Req_Cntr | 8ACh |

### Function
Provides the count of times that a hold request is given to MAC.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>TXHRC | Transmit Hold Request Counter<br>Indicates the count of times that a hold request is given to MAC.<br>Exists when any one of the receive, transmit, or MMC counters is enabled during FPE with AV_EST-enabled configuration. |

## 72.17.118 MMC Receive Packet Assembly Error Counter Interrupt Status (MMC_FPE_Rx_Interrupt)

### Offset

| Register | Offset |
|---|---|
| MMC_FPE_Rx_Interrupt | 8C0h |

### Function
Maintains the interrupts generated from all the FPE-related receive statistic counters, when these transmit statistic counters reach half of their maximum values (8000_0000h for a 32-bit counter and 8000h for a 16-bit counter), and when they cross their maximum values (FFFF_FFFFh for a 32-bit counter and FFFFh for 16-bit counter). When MMC_Control[CNTSTOPRO] = 1, the interrupts are set but the counter remains at all-ones. An interrupt bit of this register becomes 0 when the respective

MMC counter that caused the interrupt is read. The least significant byte lane (bits [7:0]) of the respective counter must be read to clear the interrupt bit.

### Diagram

## 72.17.125 MAC Layer 4 Address 0 (MAC_Layer4_Address0)

### Offset

| Register | Offset |
|---|---|
| MAC_Layer4_Address0 | 904h |

### Function

Provides the layer 4 source and destination port numbers.

MAC Layer 4 Address 1 (MAC_Layer4_Address1), MAC L3 L4 Control 1 (MAC_L3_L4_Control1), MAC Layer 3 Address 0 Reg 1 (MAC_Layer3_Addr0_Reg1), MAC Layer 3 Address 1 Reg 1 (MAC_Layer3_Addr1_Reg1), MAC Layer 3 Address 2 Reg 1 (MAC_Layer3_Addr2_Reg1), and MAC Layer 3 Address 3 Reg 1 (MAC_Layer3_Addr3_Reg1) are reserved registers (RO with a default value) if MAC_Packet_Filter[IPFE] is 0 when configuring the core.

You can configure the layer 3 and layer 4 address registers to be double-synchronized by selecting the synchronize layer 3 and layer 4 address registers to the receive clock domain option while configuring the core. When you select this option, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the layer 3 and layer 4 address registers are written to. For proper synchronization updates, you must perform consecutive writes to the same layer 3 and layer 4 address registers after a delay of at least four destination clock cycles.

## 72.17.131 MAC Layer 4 Address 1 (MAC_Layer4_Address1)

### Offset

| Register | Offset |
|---|---|
| MAC_Layer4_Address1 | 934h |

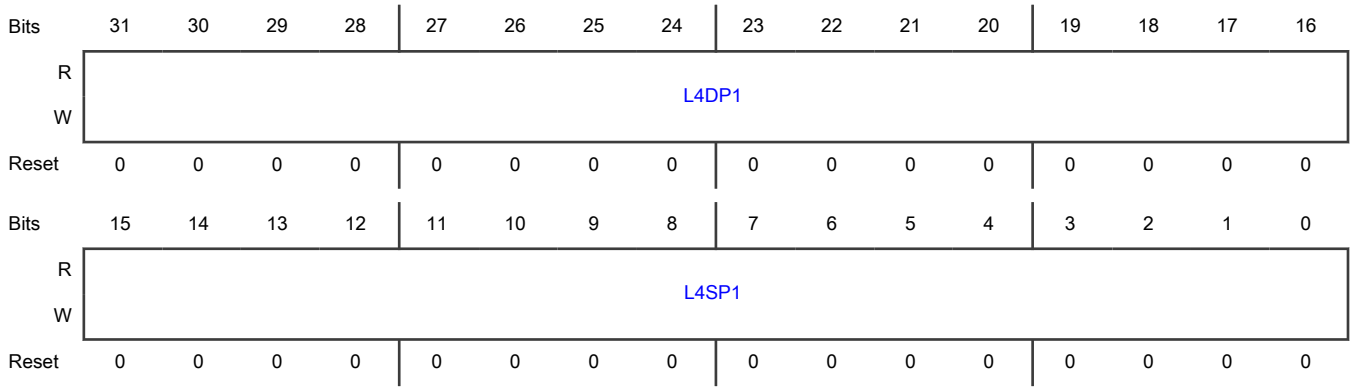
### Function

Provides the layer 4 source and destination port numbers.

MAC Layer 4 Address 1 (MAC_Layer4_Address1), MAC L3 L4 Control 1 (MAC_L3_L4_Control1), MAC Layer 3 Address 0 Reg 1 (MAC_Layer3_Addr0_Reg1), MAC Layer 3 Address 1 Reg 1 (MAC_Layer3_Addr1_Reg1), MAC Layer 3 Address 2 Reg 1 (MAC_Layer3_Addr2_Reg1), and MAC Layer 3 Address 3 Reg 1 (MAC_Layer3_Addr3_Reg1) are reserved registers (RO with a default value) if the enable layer 3 and layer 4 packet filter option is not selected when configuring the core.

You can configure the layer 3 and layer 4 address registers to be double-synchronized by selecting the synchronize layer 3 and layer 4 address registers to the receive clock domain option while configuring the core. When you select this option, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the layer 3 and layer 4 address registers are written to. For proper synchronization updates, you must perform consecutive writes to the same layer 3 and layer 4 address registers after a delay of at least four destination clock cycles.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-16<br>L4DP1 | Layer 4 Destination Port Number 1<br>Indicates layer 4 destination port number.<br>If MAC_L3_L4_Control0[L4PEN0] = 0 and MAC_L3_L4_Control0[L4DPM0] = 1, this field contains the value to be matched with the TCP destination port number field in the IPv4 or IPv6 packets.<br>If MAC_L3_L4_Control0[L4PEN0] and MAC_L3_L4_Control0[L4DPM0] are 1, this field contains the value to be matched with the UDP destination port number field in the IPv4 or IPv6 packets. |
| 15-0<br>L4SP1 | Layer 4 Source Port Number 1<br>Indicates layer 4 source port number.<br>If MAC_L3_L4_Control0[L4PEN0] = 0 and MAC_L3_L4_Control0[L4SPM0] = 1, this field contains the value to be matched with the TCP source port number field in the IPv4 or IPv6 packets.<br>If MAC_L3_L4_Control0[L4PEN0] and MAC_L3_L4_Control0[L4SPM0] are 1, this field contains the value to be matched with the UDP source port number field in the IPv4 or IPv6 packets. |

## 72.17.137 MAC Layer 4 Address 2 (MAC_Layer4_Address2)

### Offset

| Register | Offset |
|---|---|
| MAC_Layer4_Address2 | 964h |

### Function

Provides the layer 4 source and destination port numbers.

MAC Layer 4 Address 1 (MAC_Layer4_Address1), MAC L3 L4 Control 1 (MAC_L3_L4_Control1), MAC Layer 3 Address 0 Reg 1 (MAC_Layer3_Addr0_Reg1), MAC Layer 3 Address 1 Reg 1 (MAC_Layer3_Addr1_Reg1), MAC Layer 3 Address 2 Reg 1 (MAC_Layer3_Addr2_Reg1), and MAC Layer 3 Address 3 Reg 1 (MAC_Layer3_Addr3_Reg1) are reserved registers (RO with a default value) if the enable layer 3 and layer 4 packet filter option is not selected when configuring the core.

You can configure the layer 3 and layer 4 address registers to be double-synchronized by selecting the synchronize layer 3 and layer 4 address registers to the receive clock domain option while configuring the core. When you select this option, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the layer 3 and layer 4 address registers are written to. For proper synchronization updates, you must perform consecutive writes to the same layer 3 and layer 4 address registers after a delay of at least four destination clock cycles.

## 72.17.143 MAC Layer 4 Address 3 (MAC_Layer4_Address3)

### Offset

| Register | Offset |
|---|---|
| MAC_Layer4_Address3 | 994h |

### Function

Provides the layer 4 source and destination port numbers.

MAC Layer 4 Address 1 (MAC_Layer4_Address1), MAC L3 L4 Control 1 (MAC_L3_L4_Control1), MAC Layer 3 Address 0 Reg 1 (MAC_Layer3_Addr0_Reg1), MAC Layer 3 Address 1 Reg 1 (MAC_Layer3_Addr1_Reg1), MAC Layer 3 Address 2 Reg 1 (MAC_Layer3_Addr2_Reg1), and MAC Layer 3 Address 3 Reg 1 (MAC_Layer3_Addr3_Reg1) are reserved registers (RO with a default value) if the enable layer 3 and layer 4 packet filter option is not selected when configuring the core.

You can configure the layer 3 and layer 4 address registers to be double-synchronized by selecting the synchronize layer 3 and layer 4 address registers to the receive clock domain option while configuring the core. When you select this option, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the layer 3 and layer 4 address registers are written to. For proper synchronization updates, you must perform consecutive writes to the same layer 3 and layer 4 address registers after a delay of at least four destination clock cycles.

### Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved |
| 23-16<br>SSINC | Sub-Second Increment Value |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | Contains the sub-second increment value, which accumulates every clock cycle (of clk_ptp_i) with the contents of the Subsecond register. For example, if the PTP clock is 50 MHz (period is 20 ns), you must program 20 (14h) when MAC System Time In Nanoseconds (MAC_System_Time_Nanoseconds) has an accuracy of 1 ns (MAC_Timestamp_Control[TSCTRLSSR] = 1). When TSCTRLSSR = 0, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you must program a value of 43 (2Bh), which is derived by 20 ns/0.465. |
| 15-8<br>SNSINC | Sub-Nanosecond Increment Value<br>Contains the sub-nanosecond increment value, represented in nanoseconds multiplied by 2^8. This value is accumulated in the sub-nanoseconds field of the Subsecond register. For example, if MAC_Timestamp_Control[TSCTRLSSR] = 1, and if the required increment is 5.3 ns, then this field must be 4Ch and the SSINC field must be 05h. |
| 7-0<br>— | Reserved |

## 72.17.150 MAC System Time In Seconds (MAC_System_Time_Seconds)

### Offset

| Register | Offset |
|---|---|
| MAC_System_Time_Seconds | B08h |

### Function

Indicates, along with MAC System Time In Nanoseconds (MAC_System_Time_Nanoseconds), the current value of the system time that MAC maintains. Although it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from CLK_PTP_REF_I to the CSR clock).

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### Fields

| Field | Function |
|---|---|
| 31-0<br>TSS | Timestamp Second<br>Indicates the current value, in seconds, of the system time that MAC maintains. |

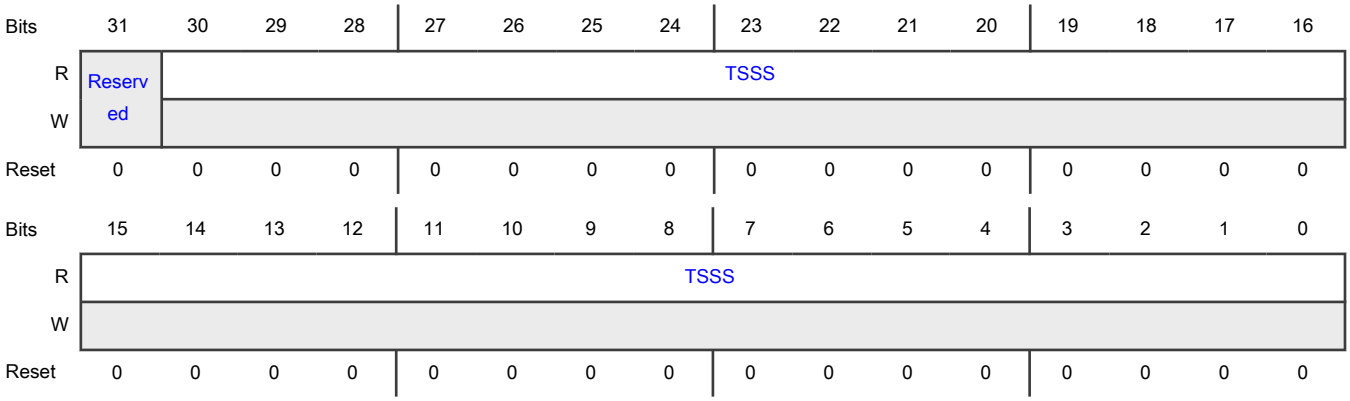
## 72.17.151 MAC System Time In Nanoseconds (MAC_System_Time_Nanoseconds)

### Offset

| Register | Offset |
|---|---|
| MAC_System_Time_Nanoseconds | B0Ch |

### Function
Indicates, along with MAC System Time In Seconds (MAC_System_Time_Seconds), the current value of the system time that MAC maintains.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>— | Reserved |
| 30-0<br>TSSS | Timestamp Sub Seconds<br>Indicates the sub-second representation of time, with an accuracy of 0.46 ns. When MAC_Timestamp_Control[TSCTRLSSR] = 1, each bit represents 1 ns. The maximum value is 3B9A_C9FFh after which it rolls over to 0. |

## 72.17.152 MAC System Time Seconds Update (MAC_System_Time_Seconds_Update)

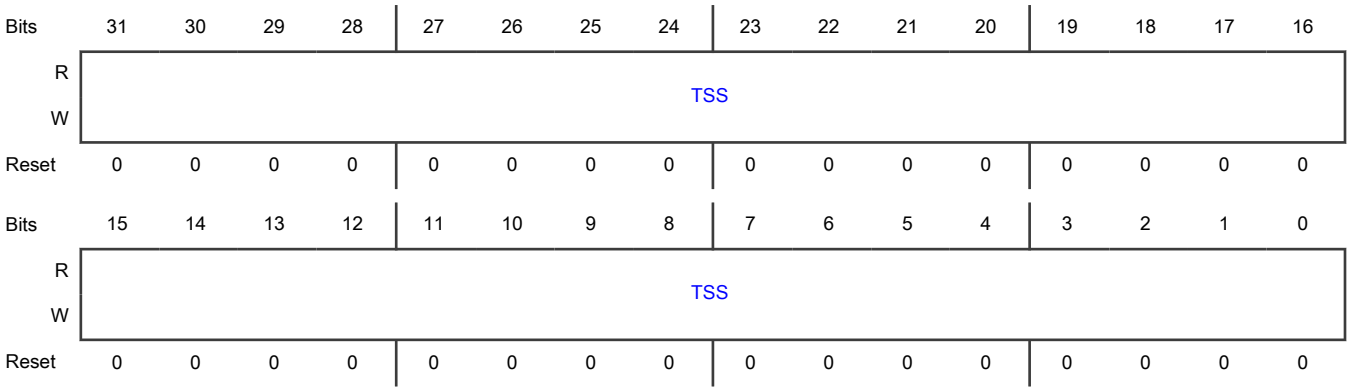
### Offset

| Register | Offset |
|---|---|
| MAC_System_Time_Seconds_Update | B10h |

### Function

Initializes or updates, along with MAC System Time Nanoseconds Update (MAC_System_Time_Nanoseconds_Update), the system time that MAC maintains. You must write both to this register and the MAC System Time Nanoseconds Update register before writing 1 to MAC_Timestamp_Control[TSINIT] and MAC_Timestamp_Control[TSUPDT].

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>TSS | Timestamp Seconds<br>Indicates the timestamp seconds value.<br>The value in this field is the seconds part of the update.<br>• If MAC_System_Time_Nanoseconds_Update[ADDSUB] = 0, this field must be programmed with the seconds part of the update value.<br>• If MAC_System_Time_Nanoseconds_Update[ADDSUB] = 1, this field must be programmed with the complement of the seconds part of the update value.<br>For example, if 2.000000001 seconds need to be subtracted from the system time, MAC_System_Time_Seconds[TSS] must be FFFF_FFFEh (that is, 2^32 - 2). |

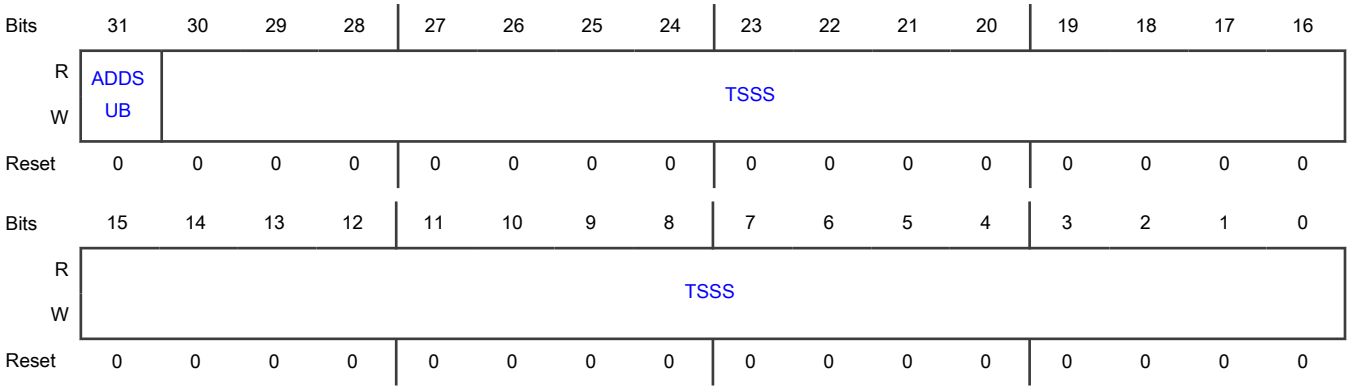
## 72.17.153 MAC System Time Nanoseconds Update (MAC_System_Time_Nanoseconds_Update)

### Offset

| Register | Offset |
|---|---|
| MAC_System_Time_Nanoseconds_Update | B14h |

### Function
Indicates system time nanoseconds update.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>ADDSUB | Add Or Subtract Time<br>Indicates whether the time value is added or subtracted from the contents of the update register.<br>• If this field is 1, the time value is subtracted from the contents of the update register.<br>• If this field is 0, the time value is added to the contents of the update register.<br>0b - Add time<br>1b - Subtract time |
| 30-0<br>TSSS | Timestamp Subseconds<br>Indicates the sub-second part of the update.<br>• If ADDSUB = 0, this field must be programmed with the sub-second part of the update value, with an accuracy based on MAC_Timestamp_Control[TSCTRLSSR].<br>• If ADDSUB = 0, this field must be programmed with the complement of the sub-second part of the update value as described below.<br>• If MAC_Timestamp_Control[TSCTRLSSR] = 1, the programmed value must be 10^9 - <sub-second value>, and if MAC_Timestamp_Control[TSCTRLSSR] = 0, the programmed value must be 2^31 - <sub-second_value>. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | • If MAC_Timestamp_Control[TSCTRLSSR] = 0, each bit of it represents an accuracy of 0.46 ns, and if MAC_Timestamp_Control[TSCTRLSSR] = 1, each bit represents 1 ns and the programmed value must not exceed 3B9A_C9FFh.<br>For example, if 2.000000001 seconds need to be subtracted from the system time, this field must be 7FFF_FFFFh (that is, 2^31 - 1) if MAC_Timestamp_Control[TSCTRLSSR] = 0. This field must be 3B9A_C9FFh (that is, 10^9 - 1) if MAC_Timestamp_Control[TSCTRLSSR] = 1. |

## 72.17.154 MAC Timestamp Addend (MAC_Timestamp_Addend)

### Offset

| Register | Offset |
|---|---|
| MAC_Timestamp_Addend | B18h |

### Function

Is used only when the system time is configured for Fine Update mode (MAC_Timestamp_Control[TSINIT] = 1). The contents of this register are added to a 32-bit accumulator in every clock cycle (of CLK_PTP_REF_I), and the system time is updated whenever the accumulator overflows.

## 72.17.157 MAC Transmit Timestamp Status In Nanoseconds (MAC_Tx_Timestamp_Status_Nanoseconds)

### Offset

| Register | Offset |
|---|---|
| MAC_Tx_Timestamp_Status_Nanoseconds | B30h |

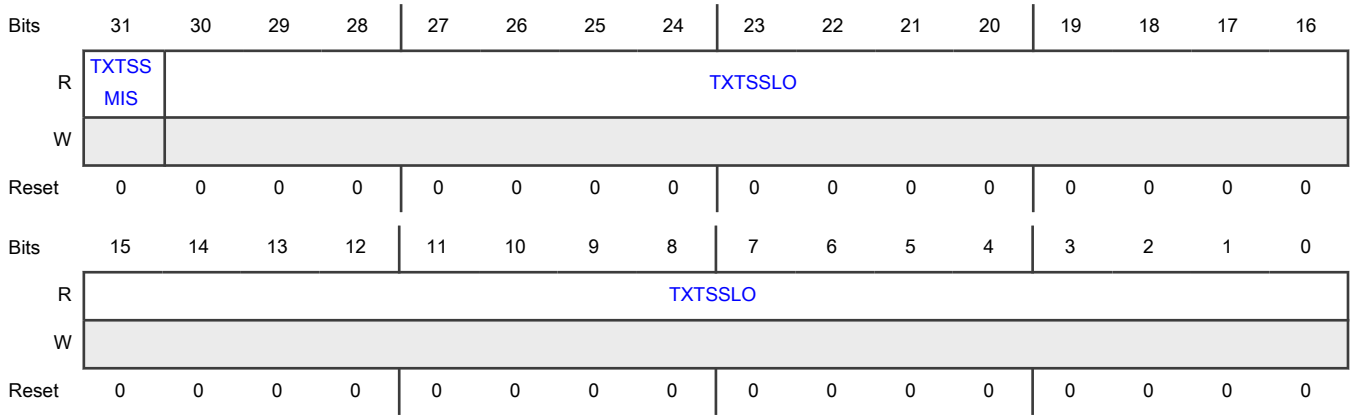
### Function

Contains the nanosecond part of the timestamp captured for tansmit packets when the transmit status is disabled.

This register, along with MAC Transmit Timestamp Status In Seconds (MAC_Tx_Timestamp_Status_Seconds), gives the 64-bit timestamp captured for the PTP packet that MAC successfully transmits. The application considers reading this value after the last byte of this register is read. In Little-Endian mode, this means when bits [31:24] are read, and in Big-Endian mode, this means when bits [7:0] are read.

If the application does not read these registers and the timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the settings specified in MAC_Timestamp_Control[TXTSSTSM]. The status bit TXTSC bit [15] in the MAC_Timestamp_Status register is set whenever the MAC transmitter captures the timestamp.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>TXTSSMIS | Transmit Timestamp Status Missed<br>Indicates whether the transmit timestamp missed status is detected.<br>If this field is 1, it indicates one of these conditions:<br>• The timestamp of the current packet is ignored if MAC_Timestamp_Control[TXTSSTSM] = 0.<br>• The timestamp of the previous packet is overwritten with the timestamp of the current packet if MAC_Timestamp_Control[TXTSSTSM] = 1.<br>Access restrictions apply to this field that cleas on read and automatically becomes 1 on an internal event occurrence.<br>0b - Not detected<br>1b - Detected |
| 30-0<br>TXTSSLO | Transmit Timestamp Status Low<br>Contains 31 bits of the Nanoseconds field of the transmit packet's captured timestamp. |

## 72.17.158 MAC Transmit Timestamp Status In Seconds (MAC_Tx_Timestamp_Status_Seconds)

### Offset

| Register | Offset |
|---|---|
| MAC_Tx_Timestamp_Status_Seconds | B34h |

### Function

Contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Field | Function |
|---|---|
| | If MCGREN1 = 1, the bits included in PPSCMD1 [11:8] are considered as presentation time control bits for media clock generation and recovery for comparator instance 1. The functioning of PPSCMD1 is similar to that of the PPSCMD0 presentation time control bits. If MCGREN1 is not 1, only three bits [10:8] are used as PPSCMD1 and the fourth bit becomes 0.<br>Access restrictions apply to this field that clears automatically. Writing 0 to it has no effect. |
| 7<br>MCGREN0 | MCGR Mode Enable For PPS0 Output<br>Indicates whether the 0th PPS instance is enabled to operate in PPS or MCGR mode. If this field is 1, it operates in MCGR mode, and if the value is 0, it operates in PPS mode.<br>0b - PPS mode<br>1b - MCGR mode |
| 6-5<br>TRGTMODSEL0 | Target Time Register Mode For PPS0 Output<br>Indicates MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) and MAC PPS0 Target Time In Nanoseconds (MAC_PPS0_Target_Time_Nanoseconds) mode for the PPS0 output signal.<br>00b - Target Time registers are programmed only for generating the interrupt event. The flexible PPS function must not be 1 in this mode, otherwise spurious transitions may be observed on the corresponding PTP_PPS_O output port.<br>01b - Reserved<br>10b - Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS0 output signal generation.<br>11b - Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No interrupt is asserted. |
| 4<br>PPSEN0 | Flexible PPS Output Mode Enable 0<br>Indicates the status of Flexible PPS Output mode.<br>• If this field is 1, the PPSCTRL_PPSCMD field functions as PPSCMD.<br>• If this field is 0, the PPSCTRL_PPSCMD field functions as PPSCTRL (fixed PPS mode).<br>0b - Disabled<br>1b - Enabled |
| 3-0<br>PPSCTRL_PPSCMD | PPS Output Frequency Control<br>Controls the frequency of the PPS0 output (PTP_PPS_O[0] signal). The default value of this field is 0, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For the other values of PPSCTRL, the PPS output becomes a generated clock having these frequencies:<br>• 0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz.<br>• 0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz.<br>• 0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz.<br>• 0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | • ..<br>• 1111: The binary rollover is 32.768 kHz and the digital rollover is 16.384 kHz.<br>**NOTE**<br>In Binary Rollover mode, the PPS output (PTP_PPS_O) has a duty cycle of 50 percent with these frequencies. In Digital Rollover mode, the PPS output frequency is an average number. The actual clock has a different frequency that is synchronized every second.<br>For example,<br>• If PPSCTRL = 0001, PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms.<br>• If PPSCTRL = 0010, PPS (2 Hz) is a sequence of one clock of 50 percent duty cycle and a 537 ms period. The second clock has a period of 463 ms (268 ms low and 195 ms high).<br>• If PPSCTRL = 0011, PPS (4 Hz) is a sequence of three clocks of 50 percent duty cycle and a 268 ms period, and the fourth clock of 195 ms period (134 ms low and 61 ms high).<br>This behavior is a result of the non-linear toggling of bits in Digital Rollover mode in MAC System Time In Nanoseconds (MAC_System_Time_Nanoseconds) or flexible PPS output (PTP_PPS_O[0]) control.<br>Programming these bits with a non-zero value instructs MAC to initiate an event. When the command is transferred or synchronized with the PTP clock domain, these bits automatically become 0. You must ensure that these bits are programmed only when they are "all-zero." The following list describes the values of PPSCMD0.<br>• 0000: No command<br>• 0001: Start a single pulse. This command generates a single pulse rising at the start point defined in MAC PPS0 Target Time In Seconds (MAC_PPS0_Target_Time_Seconds) and MAC PPS0 Target Time In Nanoseconds (MAC_PPS0_Target_Time_Nanoseconds), for a duration defined in MAC PPS0 Width (MAC_PPS0_Width).<br>• 0010: Start pulse train. This command generates the train of pulses rising at the start point defined in the Target Time registers and for a duration defined in MAC PPS0 Width (MAC_PPS0_Width), repeated at an interval defined in the PPS Interval registers. By default, the PPS pulse train runs freely unless the "stop pulse train at time" or "stop pulse train immediately" command stops it.<br>• 0011: Cancel start. This command cancels the start single pulse and start pulse train commands if the system time has not crossed the programmed start time.<br>• 0100: Stop pulse train at time. This command stops the train of pulses that the start pulse train command (PPSCMD = 0010) initiates after the time programmed in the Target Time registers elapses.<br>• 0101: Stop pulse train immediately. This command immediately stops the train of pulses that the start pulse train command (PPSCMD = 0010) initiates.<br>• 110: Cancel stop pulse train. This command cancels the stop pulse train at the time command if the programmed stop time has not elapsed. The PPS pulse train runs freely if the command executes successfully.<br>• 0111-1111: Reserved or presentation time control. If MAC_PPS_Control[MCGREN0] = 0, then these are treated as presentation time control bits.<br>This list describes the values of PPSCMD0: |

### Fields

| Field | Function |
|---|---|
| 31-0<br>PPSINT2 | PPS Output Signal Interval 2<br>Stores the interval between the rising edges of the PPS0 signal output. The interval is stored in terms of the number of units of the sub-second increment value.<br>You must program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and the desired interval between the rising edges of the PPS0 signal output is 100 ns (that is, five units of the sub-second increment value), you must program value 4 (5-1) in this register. |

## 72.17.179 MAC PPS2 Width (MAC_PPS2_Width)

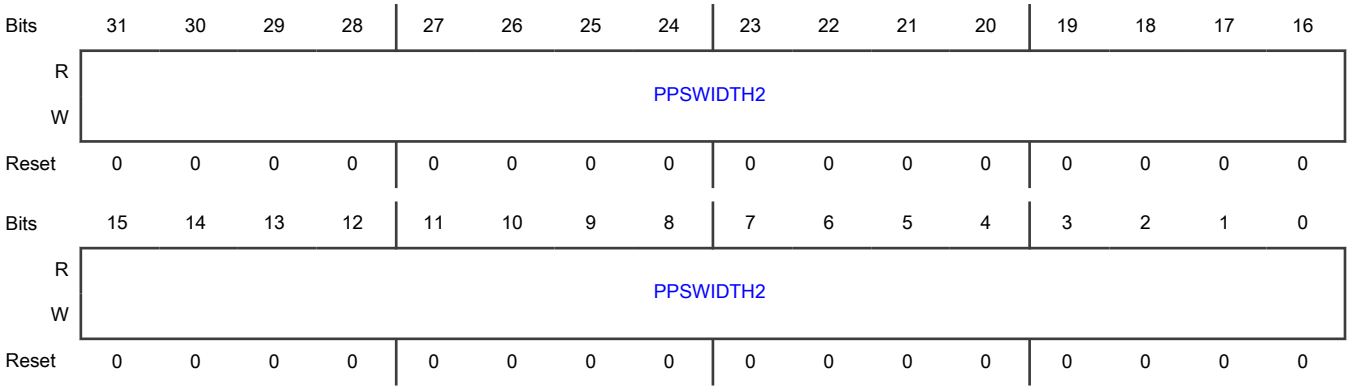
### Offset

| Register | Offset |
|---|---|
| MAC_PPS2_Width | BACh |

### Function

Contains the number of units of the sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output (PTP_PPS_O[0]).

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>PPSWIDTH2 | PPS Output Signal Width 2<br>Stores the width between the rising and corresponding falling edges of the PPS0 signal output. The width is stored in terms of the number of units of the sub-second increment value.<br>You must program one value less than the required interval. For example, if the PTP reference clock has a frequency of 50 MHz (period of 20 ns), and a width between the rising and corresponding falling edges of the PPS0 signal output is 80 ns (that is, four units of the sub-second increment value), you should program value 3 (4-1) in this register.<br>**NOTE**<br>The value programmed in this register must be lesser than the value programmed in MAC PPS0 Interval (MAC_PPS0_Interval). |

## 72.17.180 MAC PPS3 Target Time In Seconds (MAC_PPS3_Target_Time_Seconds)

### Offset

| Register | Offset |
|---|---|
| MAC_PPS3_Target_Time_Seconds | BB0h |

### Function

Is used to schedule an interrupt event (MAC_Timestamp_Status[TSTARGT0]), along with the PPS Target Time Nanoseconds register, when the system time exceeds the value programmed in these registers.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | TSTRH3 | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | TSTRH3 | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### Fields

| Field | Function |
|---|---|
| 31-0<br>TSTRH3 | PPS Target Time In Seconds 3<br>Stores the target time in seconds.<br>When the timestamp value matches or exceeds both the Target Timestamp registers, MAC starts or stops the PPS signal output and generates an interrupt, if enabled, based on Target Time mode selected for the corresponding PPS output in MAC PPS Control (MAC_PPS_Control).<br>If DWC_EQOS_FLEXI_PPS_OUT_EN is enabled in the configuration and MAC_Timestamp_Control[PTGE] = 1, with the presentation time control set in Recovery mode, these fields indicate that the application programs the TPT. In Generation mode, it indicates that CPT is generated at the sampled trigger. |

## 72.17.181 MAC PPS3 Target Time In Nanoseconds (MAC_PPS3_Target_Time_Nanoseconds)

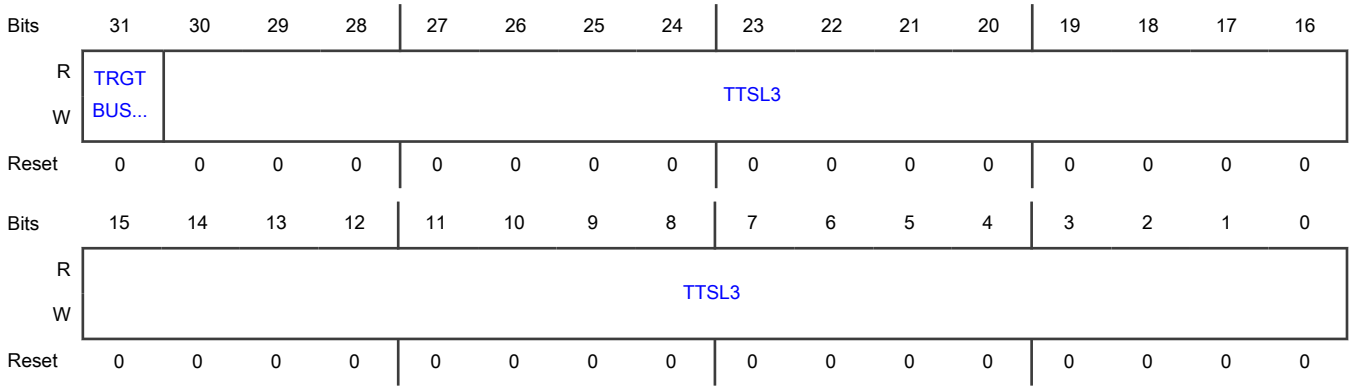
### Offset

| Register | Offset |
|---|---|
| MAC_PPS3_Target_Time_Nanoseconds | BB4h |

### Function

Indicates the target time in nanoseconds for PPS3.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>TRGTBUSY3 | PPS Target Time Register Busy 3<br>Indicates whether the PPS target time register busy status is detected.<br>MAC writes 1 to this field when MAC_PPS_Control[PPSCTRL_PPSCMD] is programmed to 010 or 011. This instructs MAC to synchronize the Target Time registers with the PTP clock domain.<br>MAC writes 0 to this field after synchronizing the Target Time registers with the PTP clock domain. The application must not update the Target Time registers when this field is read as 1. Otherwise, the synchronization of the previously programmed time is corrupted.<br>0b - Not detected<br>1b - Detected |
| 30-0<br>TTSL3 | Target Time Low For PPS3<br>Stores the time in (signed) nanoseconds.<br>If the value of the timestamp matches the value in both the Target Timestamp registers, MAC starts or stops the PPS signal output and generates an interrupt, if enabled, based on MAC_PPS_Control[TRGTMODSEL0].<br>• If MAC_Timestamp_Control[TSCTRLSSR] = 0, this value must be defined as (time in ns / 0.465). The actual start or stop time of the PPS signal output might have an error margin up to one unit of the sub-second increment value.<br>• If MAC_Timestamp_Control[TSCTRLSSR] = 1, this value must not exceed 3B9A_C9FFh. The actual start or stop time of the PPS signal output might have an error margin up to one unit of the sub-second increment value.<br>Access restriction apply to this field that clears automatically. Writing 0 to it has no effect. |

## 72.17.182 MAC PPS3 Interval (MAC_PPS3_Interval)

### Offset

| Register | Offset |
|---|---|
| MAC_PPS3_Interval | BB8h |

### Function

Contains the number of units of the sub-second increment value between the rising edges of the PPS0 signal output (PTP_PPS_O[0]).

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### Fields

| Field | Function |
|---|---|
| 31-0<br>PPSINT3 | PPS Output Signal Interval<br>Stores the interval between the rising edges of the PPS0 signal output. The interval is stored in terms of the number of units of the sub-second increment value.<br>You must program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and the desired interval between the rising edges of the PPS0 signal output is 100 ns (that is, five units of the sub-second increment value), you must program value 4 (5-1) in this register. |

## 72.17.183 MAC PPS3 Width (MAC_PPS3_Width)

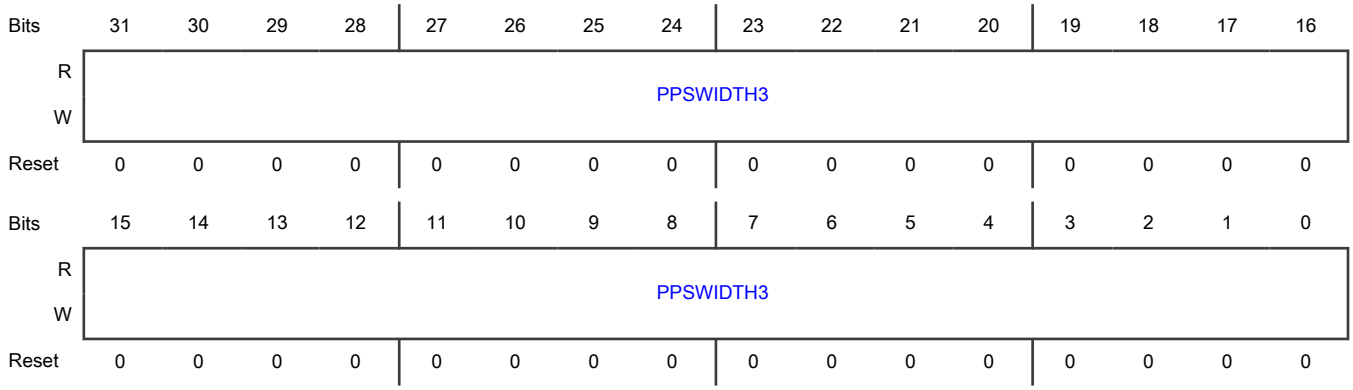
### Offset

| Register | Offset |
|---|---|
| MAC_PPS3_Width | BBCh |

### Function

Contains the number of units of the sub-second increment value between the rising and corresponding falling edges of the PPS0 signal output (PTP_PPS_O[0]).

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>PPSWIDTH3 | PPS Output Signal Width 3<br>Stores the width between the rising and corresponding falling edges of the PPS0 signal output. The width is stored in terms of the number of units of the sub-second increment value.<br>You must program one value less than the required interval. For example, if the PTP reference clock has a frequency of 50 MHz (period of 20 ns), and a width between the rising and corresponding falling edges of the PPS0 signal output is 80 ns (that is, four units of the sub-second increment value), you should program value 3 (4-1) in this register.<br>**NOTE**<br>The value programmed in this register must be lesser than the value programmed in MAC PPS0 Interval (MAC_PPS0_Interval). |

## 72.17.184 MTL Operation Mode (MTL_Operation_Mode)

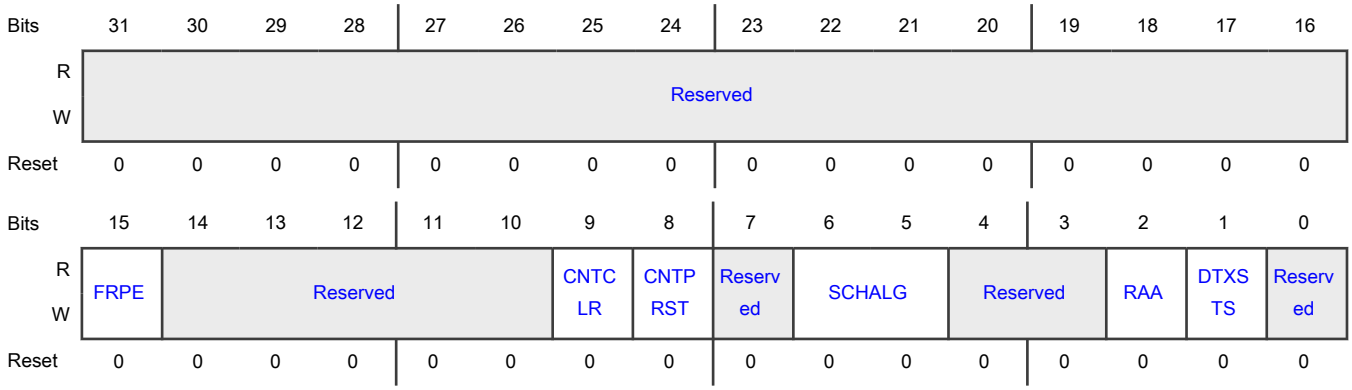
### Offset

| Register | Offset |
|---|---|
| MTL_Operation_Mode | C00h |

### Function

Establishes the transmit and receive operating modes and commands.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15<br>FRPE | Flexible Receive Parser Enable<br>Indicates the status of the flexible receive parser.<br>• If this field is 1, the programmable receive parser functionality is enabled.<br>• If the receive parser is disabled and is in the middle of parsing, the receive parser functionality is disabled only after completing the current packet parsing.<br>When the receive parser is enabled from the disabled state, the receive parser is activated for the next immediate packet.<br>0b - Disabled<br>1b - Enabled |
| 14-10<br>— | Reserved |
| 9<br>CNTCLR | Counters Reset<br>Indicates whether the counters are reset.<br>• If this field is 1, all the counters are reset. The field clears automatically after one clock cycle.<br>• If you write 1 to this field along with the CNTPRST field, the CNT_PRESET field takes precedence.<br>Access restrictions apply to this field that clears automatically. Writing 0 to it has no effect.<br>0b - Not reset<br>1b - Reset |
| 8<br>CNTPRST | Counters Preset<br>Indicates the status of preset counters.<br>If this field is 1, |

### Fields

| Field | Function |
|---|---|
| 31-0<br>FDBGDATA | FIFO Debug Data<br>Contains the data to be written to the transmit FIFO, receive FIFO, or TSO FIFO during a debug or slave access write operations. The field contains the data read from the transmit FIFO, receive FIFO, TSO FIFO, or transmit status FIFO during debug or slave access read operations. |

## 72.17.188 MTL Interrupt Status (MTL_Interrupt_Status)

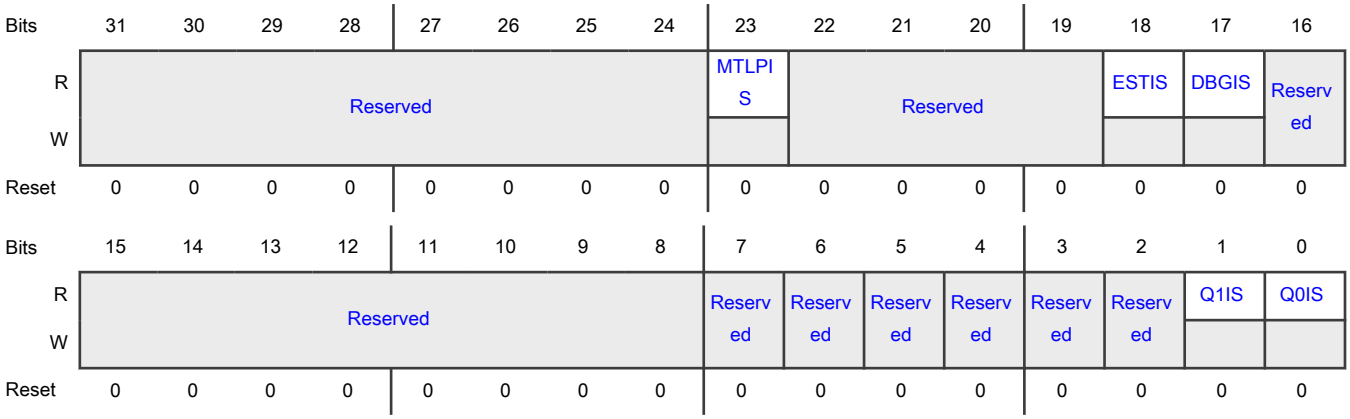
### Offset

| Register | Offset |
|---|---|
| MTL_Interrupt_Status | C20h |

### Function

Determines the interrupt status of MAC and MTL queues. The software driver (application) reads this register during an interrupt service routine or polling to perform this function.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved |
| 23<br>MTLPIS | MTL Receive Parser Interrupt Status<br>Indicates whether the MTL receive parser interrupt status is detected.<br>This field indicates an interrupt from the receive parser block. To reset this field, the application must read MTL Rx Parser Interrupt Control Status (MTL_RXP_Interrupt_Control_Status) to get the exact cause of the interrupt and clear its source.<br>0b - Not detected<br>1b - Detected |
| 22-19<br>— | Reserved |

### Fields

| Field | Function |
|---|---|
| 31-8<br>LEOS | Launch Expiry Offset<br>Computes the launch expiry time.<br>To compute the launch expiry time the value in units of 256 nanoseconds is added to the launch time. The field value is valid only if MTL_TBS_CTRL[LEOV] is 1.<br>Max value: 999,999,999 nanosecond should be smaller than CTR-1 value when ESTM mode = 1, because this value is a modulo CTR value. |
| 7<br>— | Reserved. |
| 6-4 | Launch Expiry GSN Offset |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| LEGOS | Computes the Launch expiry time.<br>To compute the launch expiry time the number of GSN slots is to be added to the launch GSN. The field value is valid only if MTL_TBS_CTRL[LEOV] is 1. |
| 3-2<br>— | Reserved. |
| 1<br>LEOV | Launch Expiry Offset Valid<br>Indicates if MTL_TBS_CTRL[LEOS] is valid or invalid.<br>When this field is 1, it indicates that MTL_TBS_CTRL[LEOS] is valid.<br>When not 1, it indicates that the launch expiry Offset is not valid and the MTL must not check for launch expiry time.<br>0b - Invalid<br>1b - Valid |
| 0<br>ESTM | EST offset Mode<br>Enables or disables EST Offset mode.<br>If this field is 1, the launch time value used in Time Based Scheduling is interpreted as an EST offset value and is added to the BTR of the current list.<br>When this field becomes 0, the launch time value is used as an absolute value that must be compared with the system time [39:8].<br>0b - Disabled<br>1b - Enabled |

## 72.17.191 MTL EST Control (MTL_EST_Control)

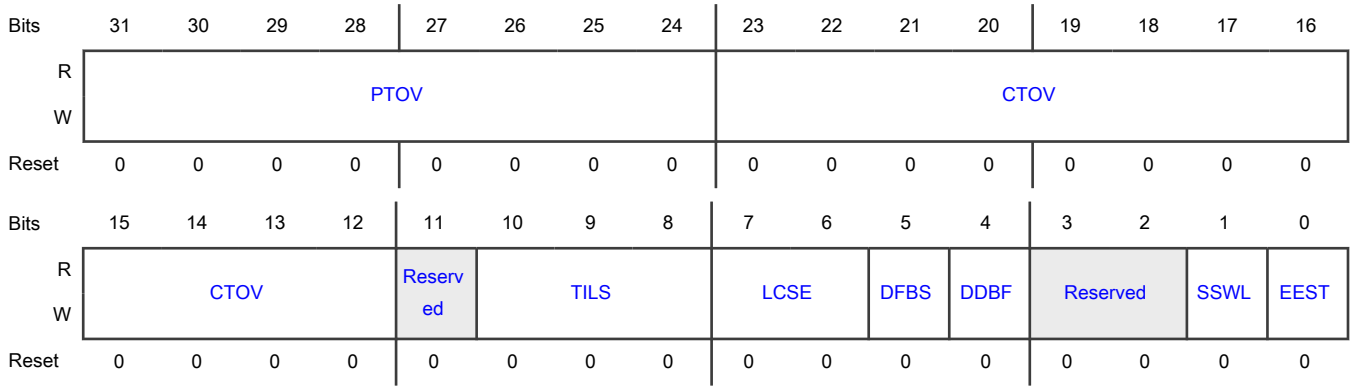
### Offset

| Register | Offset |
|---|---|
| MTL_EST_Control | C50h |

### Function

Controls the operation of enhancements to scheduled transmission (IEEE802.1Qbv).

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-24<br>PTOV | PTP Time Offset Value<br>Indicates the PTP time offset value.<br>You must multiply 6 to the value of PTP clock period in nanoseconds. At the beginning of the installation of a new GCL this value avoid transmission overruns. |
| 23-12<br>CTOV | Current Time Offset Value<br>Provides a 12 bit time offset value in nano second which is added to the current time to compensate for all the implementation pipeline delays such as the CDC sync delay, buffering delays, data path delays and so on. This offset ensures that the impact of gate controls is visible on the line exactly at the pre-determined schedule (or as close to the schedule as possible). |
| 11<br>— | Reserved. |
| 10-8<br>TILS | Time Interval Left Shift Amount<br>Provides the left shift amount for the programmed time interval values used in the gate control lists.<br>000b - No left shift needed (equal to x1ns)<br>001b - Left shift TI by 1 bit (equal to x2ns)<br>010b - Left shift TI by 2 bits (equal to x4ns)<br>-<br>-<br>100b - Left shift TI by 7 bits (equal to x128ns)<br>On the basis of configuration you must consider one or more bits of this field as reserved or read-only. |
| 7-6<br>LCSE | Loop Count to Report Scheduling Error<br>Provides programmable number of GCL list iterations before reporting an HLBS error which is defined in MTL_EST_Status. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 00b - 4 iterations<br>01b - 8 iterations<br>10b - 16 iterations<br>11b - 32 iterations |
| 5<br>DFBS | Drop Frames Causing Scheduling Error<br>Provides the status of the frames causing scheduling error.<br>If this field is 1 then the frames report to cause an HOL blocking because the MTL_EST_Status[HLBS] is not scheduled after 4,8,16,and 32 (on the basis of MTL_EST_Control[LCSE]) GCL iterations are dropped.<br>0b - Do not drop frames<br>1b - Drop frames |
| 4<br>DDBF | Do not Drop Frames during Frame Size Error<br>Provides status of frames during Frame Size Error.<br>If this field is 1, it indicates that the frames are not dropped during head-of-line blocking because of the frame size error (MTL_EST_Status[HLBF]).<br>0b - Drop frames during frame size error<br>1b - Do not Drop frames during frame size error |
| 3-2<br>— | Reserved. |
| 1<br>SSWL | Switch to Software Owned List<br>If this field is 1, it indicates that the software has programmed that list that it currently owns (SWOL) and the hardware should switch to the new list based on the new BTR. Hardware clears this bit when the switch to the SWOL happens to indicate the completion of the switch or when an BTR error (BTRE in Status register) is set. When BTRE is set this bit is cleared but SWOL is not updated as the switch was not successful.<br>Access restriction apply to this field that clears on read and automatically becomes 1 on an internal event occurrence.<br>Enables or disables the switch to the software owned list.<br>0b - Disabled<br>1b - Enabled |
| 0<br>EEST | Enable EST<br>Enables or disables EST.<br>If the field becomes 0, it indicate that the gate control list processing is halted and all gates are assumed to be in open state. The field must be 1 for the hardware to start processing the gate control lists. During the toggle from 0 to 1, when the MTL_EST_Control[SSWL] is 1, the gate control list processing starts.<br>During the configuration when DWC_EQOS_ASP_ECC is selected, the hardware resets this field and disables the EST function if any uncorrectable error is detected in the EST memory . |

## 72.17.192 MTL EST Status (MTL_EST_Status)

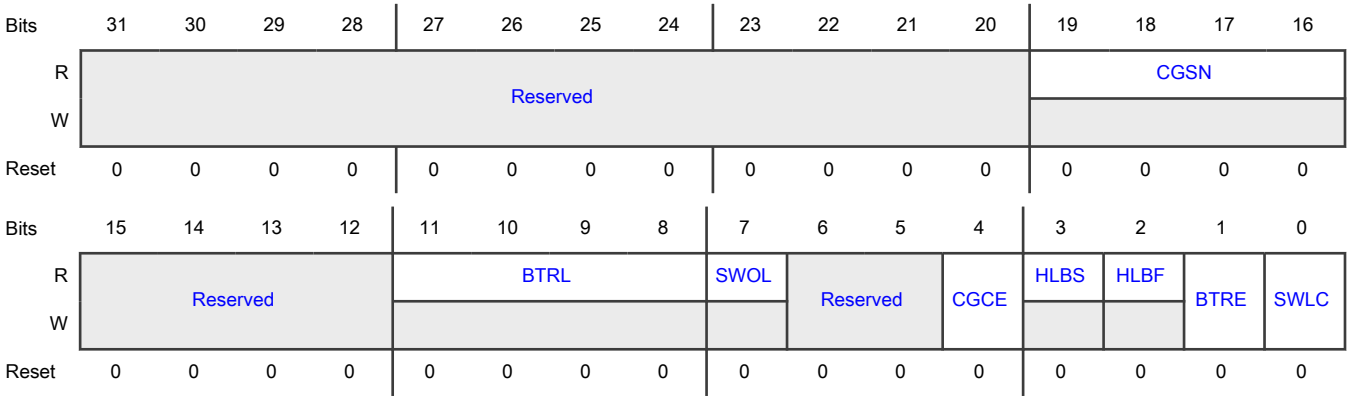
### Offset

| Register | Offset |
|---|---|
| MTL_EST_Status | C58h |

### Function

Provides status of enhancements to scheduled transmission (IEEE802.1Qbv).

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-20<br>— | Reserved. |
| 19-16<br>CGSN | Current GCL Slot Number<br>Indicates the slot number of the GCL list. Slot number is a modulo 16 count of the GCL List loops executed so far.<br>Even if a new GCL list is installed, the count is incremental. |
| 15-12<br>— | Reserved. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| 11-8<br>BTRL | BTR Error Loop Count<br>Provides the minimum count (N) for which the equation Current Time =< New BTR + (N * New Cycle Time) becomes true. N = "1111" indicates the iterations exceeded the value of 8 and the hardware was not able to update New BTR to be equal to or greater than Current Time. Software intervention is needed to update the New BTR. Value cleared when BTRE field of this register is cleared. |
| 7<br>SWOL | S/W owned list<br>When '0' indicates Gate control list number "0" is owned by software and when "1" indicates the Gate Control list "1" is owned by the software. Any reads/writes by the software (using indirect access via GCL_Control) is directed to the list indicated by this value by default. The inverse of this value is treated as HWOL.<br>R/W operations performed by hardware are directed to the list pointed by HWOL by default.<br>0b - Gate control list number "0" is owned by software<br>1b - Gate control list number "1" is owned by software |
| 6-5<br>— | Reserved. |
| 4<br>CGCE | Constant Gate Control Error<br>This error occurs when the list length (LLR) is 1 and the Cycle Time (CTR) is less than or equal to the programmed Time Interval (TI) value after the optional Left Shifting. The above programming implies Gates are either always Closed or always Open based on the Gate Control values; the same effect can be achieved by other simpler (non TSN) programming mechanisms. Since the implementation does not support such a programming an error is reported.<br>Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.<br>0b - Constant Gate Control Error not detected<br>1b - Constant Gate Control Error detected |
| 3<br>HLBS | Head-Of-Line Blocking due to Scheduling<br>Set when the frame is not able to win arbitration and get scheduled even after 4 iterations of the GCL. Indicates to software a potential programming error. The one hot encoded values of the Queue Numbers that are not able to make progress are indicated in the MTL_EST_Sch_Error register. Bit cleared when MTL_EST_Sch_Error register is all zeros.<br>0b - Head-Of-Line Blocking due to Scheduling not detected<br>1b - Head-Of-Line Blocking due to Scheduling detected |
| 2<br>HLBF | Head-Of-Line Blocking due to Frame Size<br>Set when HOL Blocking is noticed on one or more Queues as a result of none of the Time Intervals of gate open in the GCL being greater than or equal to the duration needed for frame size (or frame fragment size when preemption is enabled) transmission. The one hot encoded Queue numbers that are experiencing HLBF are indicated in the MTL_EST_Frm_Size_Error register. Additionally, the first Queue number that experienced HLBF along with the frame size is captured in MTL_EST_Frm_Size_Capture register. Bit cleared when MTL_EST_Frame_Size_ Error register is all zeros. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 0b - Head-Of-Line Blocking due to Frame Size not detected<br>1b - Head-Of-Line Blocking due to Frame Size detected |
| 1<br>BTRE | BTR Error<br>Indicates whether the BTR error is detected.<br>When this field is 1, it indicates a programming error in the BTR of SWOL where the programmed value is less than the current time. If the BTRL = "1111", SWOL is not updated and software must reprogram the BTR to a value greater than current time and then set SSWL to reinitiate the switch to SWOL. Else if the value of BTRL < "1111", SWOL is updated and this field indicates the number of iterations (of + CycleTime) taken by hardware to update the BTR to a value greater than Current Time.<br>Access restrictions apply to this field. It sets automatically to 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect.<br>0b - BTR Error not detected<br>1b - BTR Error detected |
| 0<br>SWLC | Switch to Software Owned List Complete<br>Indicates whether the switch to software owned list complete is detected.<br>When the field is 1, it indicates that the hardware has successfully switched to the SWOL, and updated the MTL_EST_Status[SWOL] to that effect.<br>This field is 0 when MTL_EST_Control[SSWL] transitions from 0 to 1, or on a software write.<br>Access restrictions apply to this field. It clears automatically and writing 0 to it has no effect.<br>0b - Not detected<br>1b - Detected |

## 72.17.193 MTL EST Scheduling Error (MTL_EST_Sch_Error)

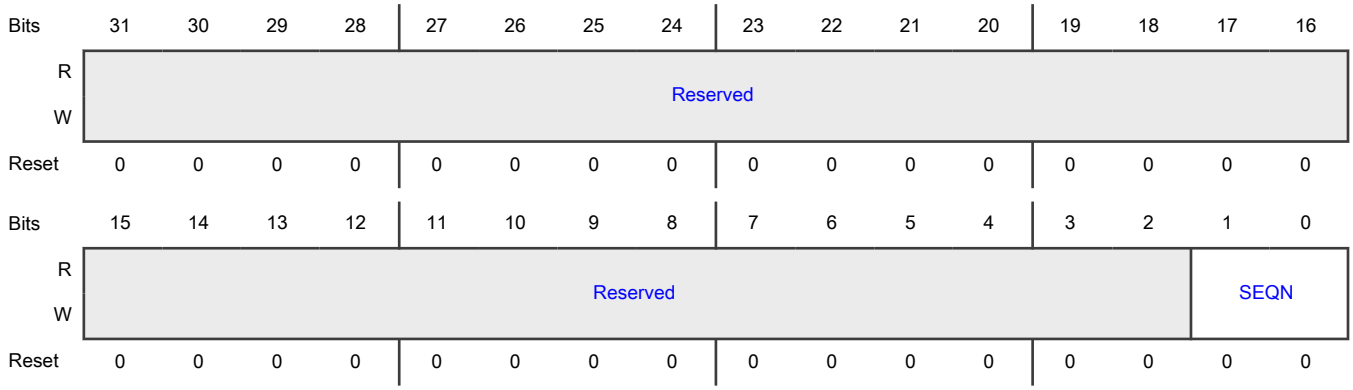
### Offset

| Register | Offset |
|---|---|
| MTL_EST_Sch_Error | C60h |

### Function

Provides the one hot encoded queue numbers that have the scheduling related error (timeout).

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-2<br>— | Reserved. |
| 1-0<br>SEQN | Schedule Error Queue Number<br>Provides the one hot encoded queue numbers that have experienced error or timeout described in MTL_EST_Status[HLBS].<br>Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect. |

## 72.17.194 MTL EST Frame Size Error (MTL_EST_Frm_Size_Error)

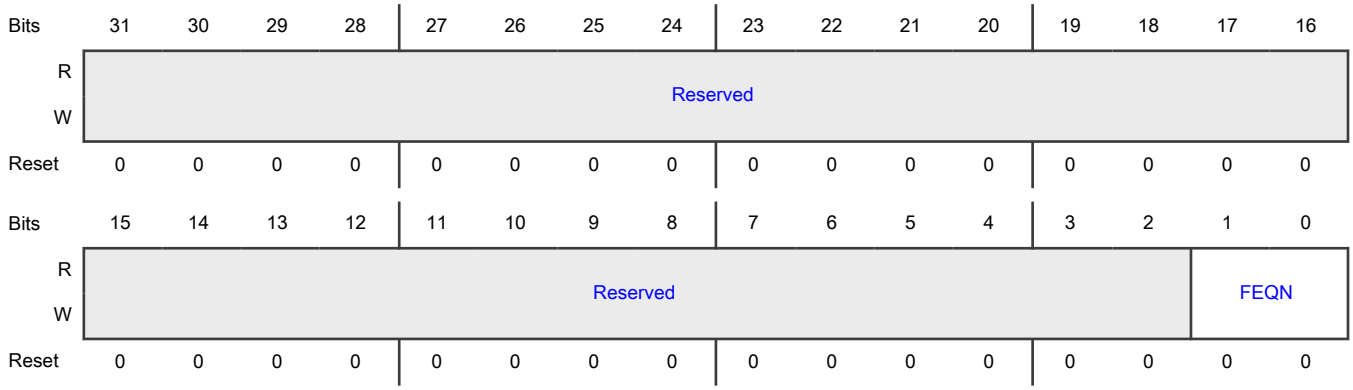
### Offset

| Register | Offset |
|---|---|
| MTL_EST_Frm_Size_Error | C64h |

### Function

Provides the one hot encoded queue numbers that have the frame Size related error.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-2<br>— | Reserved. |
| 1-0<br>FEQN | Frame Size Error Queue Number<br>Provides the one hot encoded queue Nnumbers that have experienced error described in MTL_EST_Status[HLBF].<br>Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect. |

## 72.17.195 MTL EST Frame Size Capture (MTL_EST_Frm_Size_Capture)

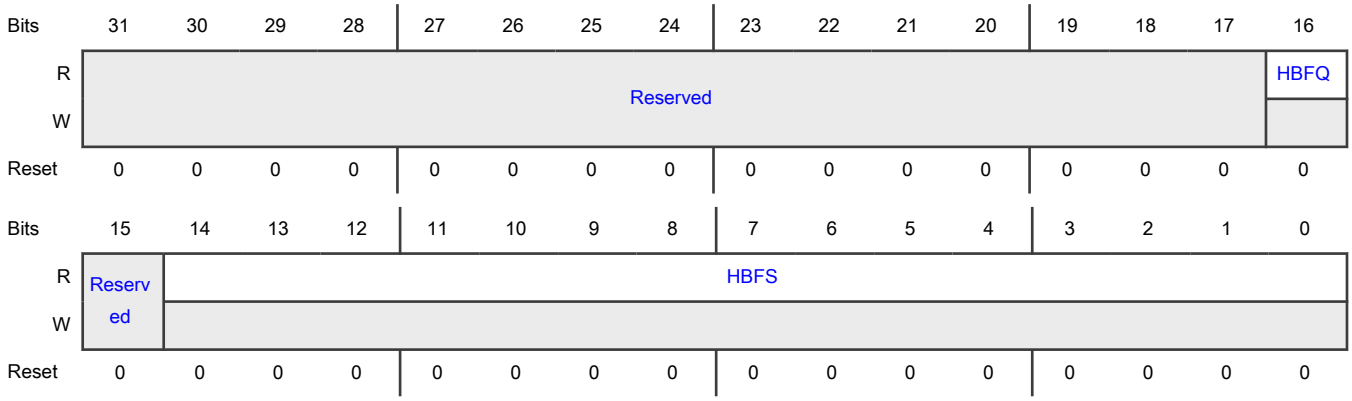
### Offset

| Register | Offset |
|---|---|
| MTL_EST_Frm_Size_Capture | C68h |

### Function

Captures the frame Size and queue number of the first occurrence of the frame Size related error. When you write 0, it captures the data of immediate next occurrence of a similar error.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-17<br>— | Reserved. |
| 16<br>HBFQ | Queue Number of HLBF<br>Captures the binary value of the first queue (number) which experiences the HLBF error (see MTL_EST_Status[HLBF]). Any subsequent queue errors similar to HLBF errors does not alter the value after it is written. After this field is 0, it captures the queue number of the next occurring HLBF error.<br>Field's width is based on the number of transit queues configured; remaining fields are read-only. This field clears when MTL_EST_Frm_Size_Error is all zeros. |
| 15<br>— | Reserved. |
| 14-0<br>HBFS | Frame Size of HLBF<br>Captures the frame Size of the dropped frame related to queue number indicated in MTL_EST_Frm_Size_Capture[HBFQ].<br>If this field is zero, then this register must be considered invalid.<br>This field clears when MTL_EST_Frm_Size_Error is all zeros. |

## 72.17.196 MTL EST Interrupt Enable (MTL_EST_Intr_Enable)

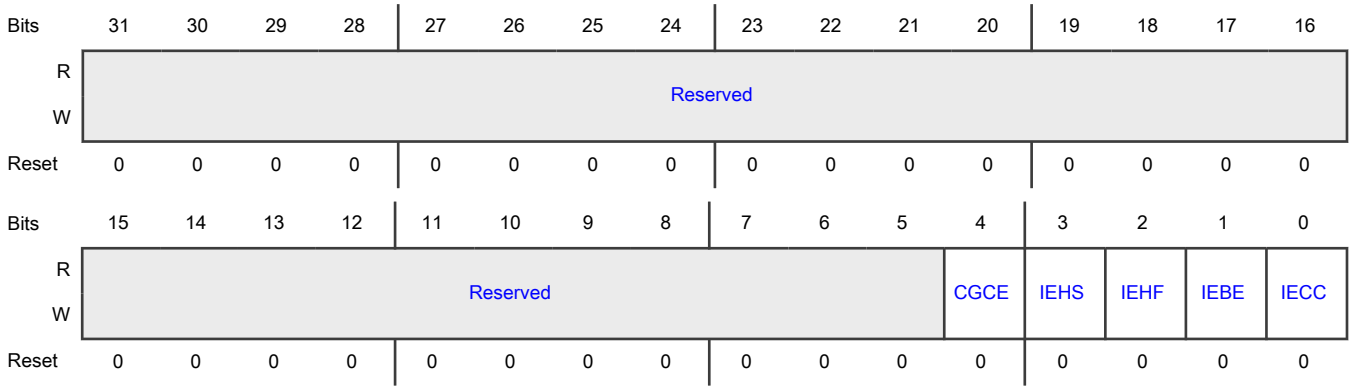
### Offset

| Register | Offset |
|---|---|
| MTL_EST_Intr_Enable | C70h |

### Function

Implements the interrupt enable fields for the various events that generate an interrupt. Bit positions have a 1 to 1 correlation with the status bit positions in MTL_ETS_Status register.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-5<br>— | Reserved. |
| 4<br>CGCE | Interrupt Enable for CGCE<br>Indicates whether an interrupt for MTL_EST_Intr_Enable[CGCE] is enabled.<br>When this field is 1, it generates an interrupt when the constant gate control error occurs and is indicated in the status. When this field becomes 0, this event does not generate an interrupt<br>0b - Disabled<br>1b - Enabled |
| 3<br>IEHS | Interrupt Enable for HLBS<br>Indicates whether an interrupt for MTL_EST_Status[HLBS] is enabled.<br>When this field is 1, it generates an interrupt when the head-of-line blocking due to scheduling issue occurs and is indicated in the status. When this field becomes 0, this event does not generate an interrupt.<br>0b - Disabled<br>1b - Enabled |
| 2<br>IEHF | Interrupt Enable for HLBF<br>Indicates whether an interrupt for MTL_EST_Status[HLBF] is enabled.<br>When this field is 1, it generates an interrupt when the head-of-line blocking due to frame size error occurs and is indicated in the status. When this field becomes 0, this event does not generate an interrupt.<br>0b - Disabled<br>1b - Enabled |
| 1<br>IEBE | Interrupt Enable for BTR Error<br>Indicates whether an interrupt for BTR error is enabled. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | When this field is 1, it generates an interrupt when the BTR error occurs and is indicated in the status. When this field becomes 0, this event does not generate an interrupt.<br>0b - Disabled<br>1b - Enabled |
| 0<br>IECC | Interrupt Enable for Switch List<br>Indicates whether the interrupt for switch list is enabled.<br>When this field is 1, it generates an interrupt when the configuration change is successful and the hardware switches to the new list. When this field becomes 0, this event does not generate an interrupt.<br>0b - Disabled<br>1b - Enabled |

## 72.17.197 MTL EST GCL Control (MTL_EST_GCL_Control)

### Offset

| Register | Offset |
|---|---|
| MTL_EST_GCL_Control | C80h |

### Function

Provides the control information for reading and writing to the gate control lists.

### Diagram

**Fields**

| Field | Function |
|---|---|
| 31-29<br>— | Reserved. |
| 28<br>HRS | Hold/Release Status<br>Indicates whether a set-and-release-MAC operation which was last executed and the pMAC is in release state or in hold state.<br>0b - Release state<br>1b - Hold state |
| 27-16<br>— | Reserved. |
| 15-10<br>— | Reserved. |
| 9-8<br>PEC | Preemption Classification<br>When this field is 1, it indicates that you must classify the corresponding queue as preemptable.<br>When this field is 0, it indicates that you must classify the queue as express.<br>When set indicates the corresponding Queue must be classified as preemptable, when '0' Queue is classified as express. When both EST (Qbv) and Preemption are enabled, Queue-0 is always assumed to be preemptable. When you enables EST (Qbv), the preemptable queues are always assumed to be in open state in gate control list. |
| 7-2<br>— | Reserved. |
| 1-0<br>AFSZ | Additional Fragment Size<br>Indicates that, in units of 64 bytes, the minimum number of bytes over 64 bytes required in non-final fragments of preempted frames. The minimum non-final fragment size is (AFSZ +1) * 64 bytes. |

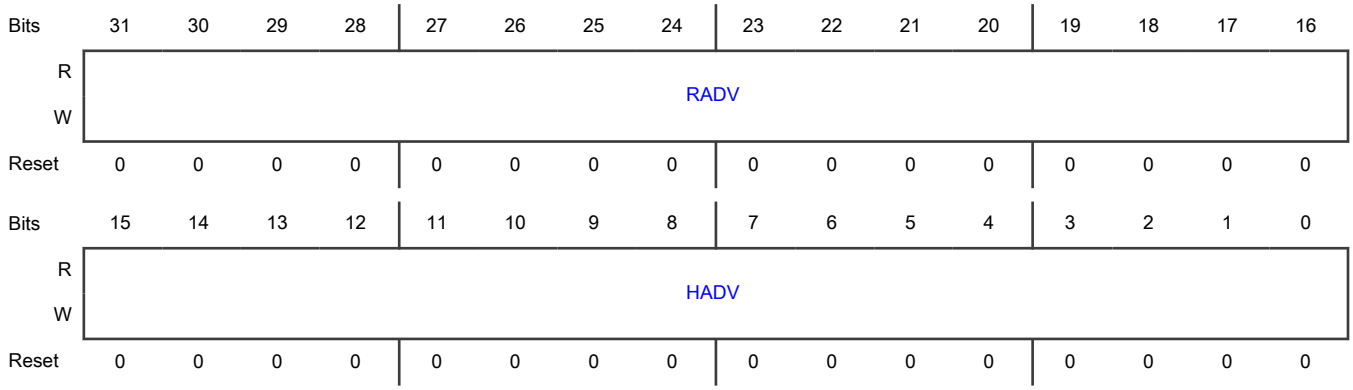
## 72.17.200 MTL FPE Advance (MTL_FPE_Advance)

**Offset**

| Register | Offset |
|---|---|
| MTL_FPE_Advance | C94h |

**Function**
Holds the hold and release advance time.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-16<br>RADV | Release Advance<br>Provides the maximum time in nanoseconds that can elapse between issuing a release to the MAC and the MAC being ready to resume transmission of preemptable frames, in the absence of there being any express frames available for transmission. |
| 15-0<br>HADV | Hold Advance<br>Provides the maximum time in nanoseconds that can elapse between issuing a hold to the MAC and the MAC ceasing to transmit any preemptable frame that is in the process of transmission or any preemptable frames that are queued for transmission. |

## 72.17.201 MTL Rx Parser Control Status (MTL_RXP_Control_Status)

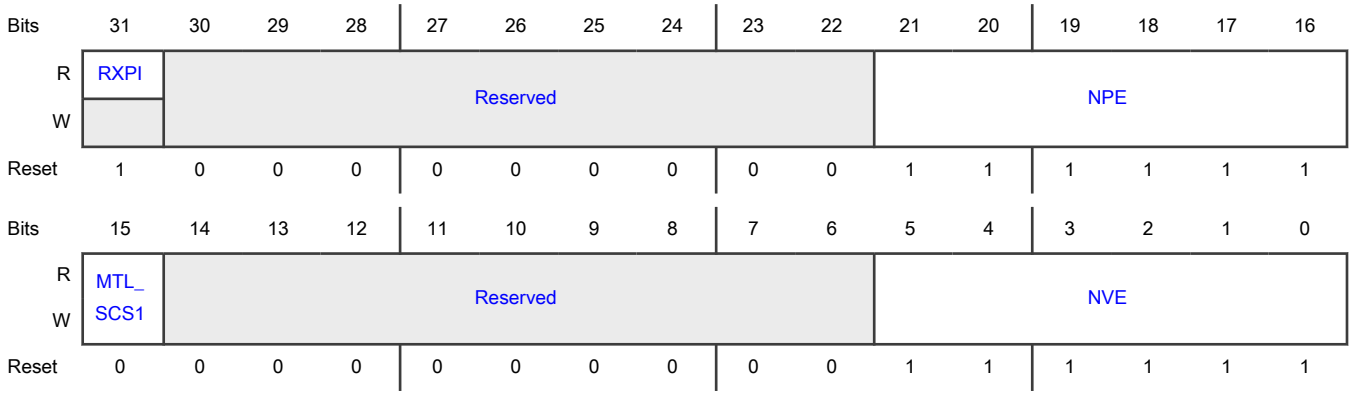
### Offset

| Register | Offset |
|---|---|
| MTL_RXP_Control_Status | CA0h |

### Function

Establishes the operating mode of receive parser and provides some status.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>RXPI | RX Parser in Idle State<br>Indicates whether the receive parser is in idle state.<br>When this field is 1, it indicates that the receive parser is in idle state and waiting for the processing of a new packet. When parser disables, you can use this field as a handshake with software and also the software can update the receive parser instruction table when you write 1 to this field.<br>0b - Not in Idle state<br>1b - Idle state |
| 30-22<br>— | Reserved. |
| 21-16<br>NPE | Number of parsable entries in the Instruction table<br>Indicates the number of parsable entries in the instruction memory. This is used in receive parser logic to detect programming error.<br>MTL_RXP_Interrupt_Control_Status[NPEOVIS] = 1, if the number of parsed entries for a packet is more than this entry. |
| 15<br>MTL_SCS1 | MTL_SCS1<br>Is reserved for NXP internal use.<br>The value of this field must always be 0 unless NXP instructs you otherwise. Writing 1 to any of the bits of this field might cause unexpected behavior in th IP. |
| 14-6<br>— | Reserved. |
| 5-0<br>NVE | Number Of Valid Entry Address Or Index In The Instruction Table<br>Indicates the number of valid entry address or index in the instruction memory. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | The maximum valid entry address is = NVE + 1 and the addresses or indices range from 0 to 32. Therefore, if the value of this field is 32, the number of valid entry address is 33. This value is used in receive parser logic to detect if any programming errors exist. When parsing, the module writes 1 to NVEOVIS if the number of the memory address is found to be more than the defined maximum valid entry address number.<br>**NOTE**<br>The minimum value of this field must be two. |

## 72.17.202 MTL Rx Parser Interrupt Control Status (MTL_RXP_Interrupt_Control_Status)

### Offset

| Register | Offset |
|---|---|
| MTL_RXP_Interrupt_Control_Status | CA4h |

### Function

Provides enable control for the interrupts and also provides interrupt status.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### Fields

| Field | Function |
|---|---|
| 31-20<br>— | Reserved. |
| 19<br>PDRFIE | Packet Drop due to RF Interrupt Enable<br>Indicates whether the packet drop due to RF interrupt is enabled.<br>If this field is 1, it enables the PDRFIS interrupt. When this field becomes 0, it disables the PDRFIS interrupt. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 0b - Disabled<br>1b - Enabled |
| 18<br>FOOVIE | Frame Offset Overflow Interrupt Enable<br>Indicates whether the frame offset overflow interrupt is enabled.<br>If this field is 1, it enables the FOOVIS interrupt.<br>When this field becomes 0, it disables the FOOVIS interrupt.<br>0b - Disabled<br>1b - Enabled |
| 17<br>NPEOVIE | Number of Parsable Entries Overflow Interrupt Enable<br>Enables or disables the number of parsable entries overflow interrupt.<br>If this field is 1, it enables the NPEOVIS interrupt.<br>When this field becomes 0, it disables the NPEOVIS interrupt.<br>0b - Disable<br>1b - Enable |
| 16<br>NVEOVIE | Number of Valid Entries Overflow Interrupt Enable<br>Enables or disables the number of valid entries overflow interrupt.<br>If this field is 1, it enables the NVEOVIS interrupt.<br>When this field becomes 0, it disables the NVEOVIS interrupt.<br>0b - Disable<br>1b - Enable |
| 15-4<br>— | Reserved. |
| 3<br>PDRFIS | Packet Dropped due to RF Interrupt Status<br>Indicates whether the packet dropped due to RF interrupt status is detected.<br>If the Rx Parser result says to drop the packet by setting RF=1 in the instruction memory, then this bit is set to 1.<br>This field clears when the application writes 1 to this field.<br>Access apply to this field. It automatically sets to 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect.<br>0b - Not detected<br>1b - Detected |
| 2 | Frame Offset Overflow Interrupt Status |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| FOOVIS | Indicates whether the frame offset overflow interrupt status is detected.<br>If this field is 1, it indicates that when parsing, the instruction table entry's frame offset is more than the EOF offset.<br>This field clears when the application writes 1 to this field.<br>Access apply to this field. It automatically sets to 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect.<br>0b - Not detected<br>1b - Detected |
| 1<br>NPEOVIS | Number of Parsable Entries Overflow Interrupt Status<br>Indicates whether the number of parsable entries overflow interrupt status is detected.<br>If this field is 1, it indicates that when parsing a packet the number of parsed entries are more than NPE[] (MTL_RXP_Control_Status[NPE]).<br>This field clears when the application writes 1 to this field.<br>Access apply to this field. It automatically sets to 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect.<br>0b - Not detected<br>1b - Detected |
| 0<br>NVEOVIS | Number of Valid Entry Address/Index Overflow Interrupt Status<br>Indicates whether the number of valid entry address or index overflow interrupt status is detected.<br>If this field is 1, it indicates that when parsing, the instruction address is more than MTL_RXP_Control_Status[NVE].<br>For example, when MTL_RXP_Control_Status[NVE] = 31, the maximum valid entry address/index is NVE+1 that is 32 (addresses/indices = 0 to 32, or 33 entries). MTL_RXP_Interrupt_Control_Status[NVEOVIS] = 1 when currently processed entry indicates that the next address is 33 or more, that is 34th or later entries.<br>This field clears when the application writes 1 to this field.<br>Access apply to this field. It automatically sets to 1 on an internal event occurrence. Writing 1 clears this field and writing 0 to it has no effect.<br>0b - Not detected<br>1b - Detected |

## 72.17.203 MTL Rx Parser Drop Count (MTL_RXP_Drop_Cnt)

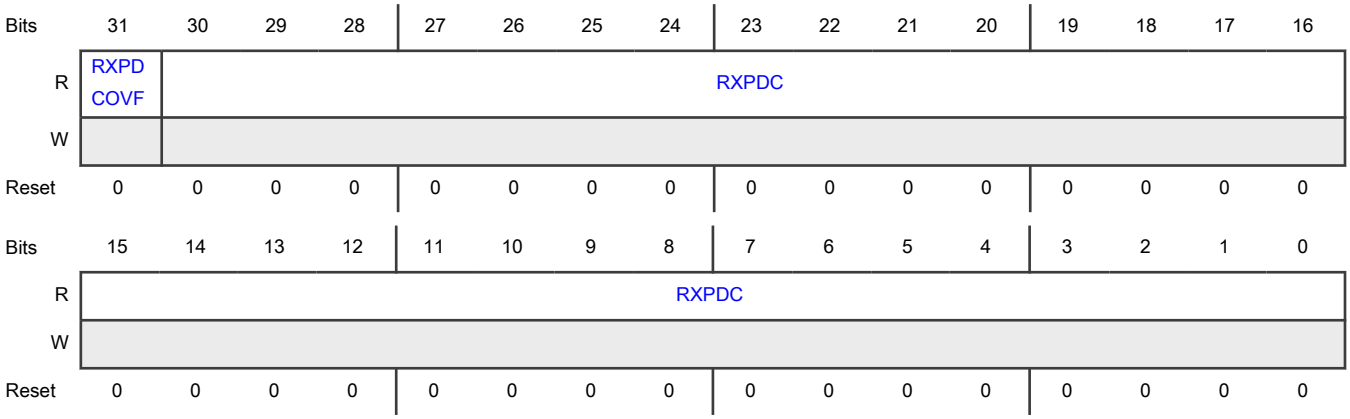
### Offset

| Register | Offset |
|---|---|
| MTL_RXP_Drop_Cnt | CA8h |

### Function

Provides the drop count of receive parser initiated drops.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>RXPDCOVF | Rx Parser Drop Counter Overflow Bit<br>Indicates whether the receive parser drop count overflow has occurred.<br>When this field is 1, it indicates that the MTL_RXP_Drop_Cnt[RXPDC] counter field has crossed the maximum limit.<br>Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence.<br>0b - Not occurred<br>1b - Occurred |
| 30-0<br>RXPDC | Rx Parser Drop Count<br>Provides the receive parser drop count.<br>This 31-bit counter is implemented whenever a receive parser drops a packet due to RF = 1. The counter clears when you read the register. |

## 72.17.204 MTL Rx Parser Error Count (MTL_RXP_Error_Cnt)

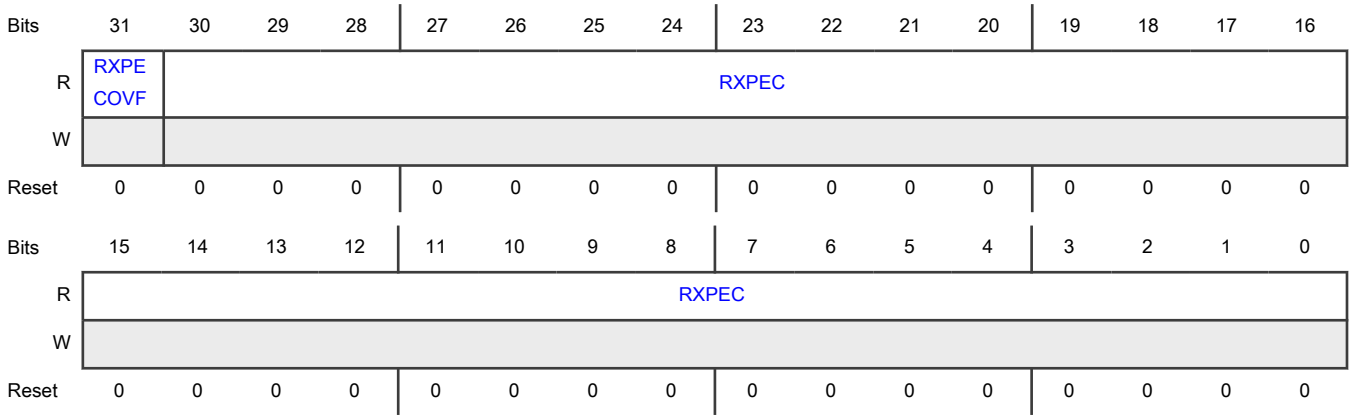
### Offset

| Register | Offset |
|---|---|
| MTL_RXP_Error_Cnt | CACh |

### Function

Provides the receive parser related error occurrence count.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>RXPECOVF | Rx Parser Error Counter Overflow Bit<br>Indicates whether the receive parser error counter overflow has occurred.<br>When this field is 1, it indicates that MTL_RXP_Error_Cnt[RXPEC] counter field has crossed the maximum limit.<br>Access restrictions apply to this field, which clears on read and automatically becomes 1 on an internal event occurrence.<br>0b - Not occurred<br>1b - Occurred |
| 30-0<br>RXPEC | Rx Parser Error Count<br>Provides the receive parser error count.<br>This 31-bit counter is implemented whenever a receive parser encounters following error scenarios:<br>Entry address >= NVE[]<br>Number parsed entries >= NPE[]<br>Entry address > EOF data entry address<br>The counter clears when you read the register. |

## 72.17.205 MTL Rx Parser Indirect Access Control Status (MTL_RXP_Indirect_Acc_Control_Status)

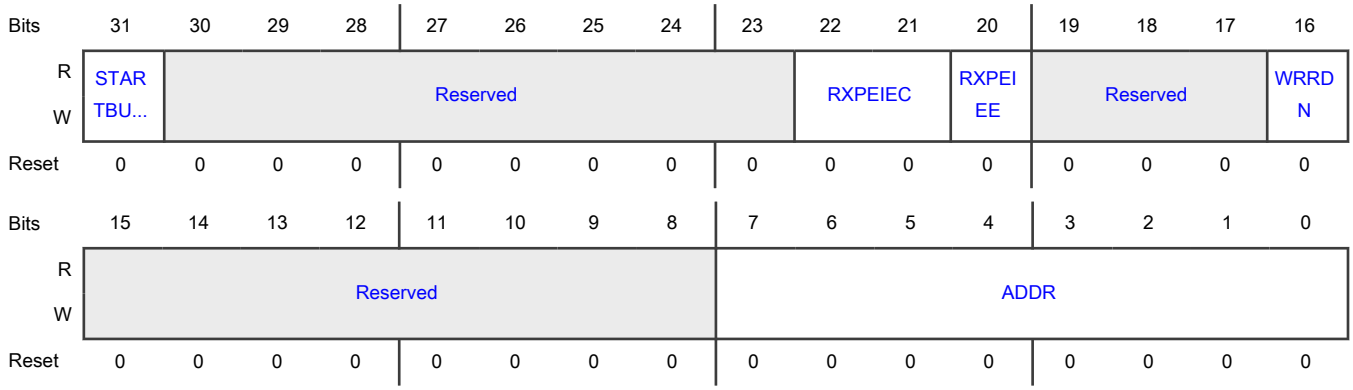
### Offset

| Register | Offset |
|---|---|
| MTL_RXP_Indirect_Acc_Control_Status | CB0h |

### Function

Provides the indirect access control and status for receive parser memory.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>STARTBUSY | FRP Instruction Table Access Busy<br>When this bit is set to 1 by the software then it indicates to start the Read/Write operation from/to the Rx Parser Memory.<br>Software should read this bit as 0 before issuing read or write request to access the Parser Memory Instructions.<br>This bit when set to 1 indicates that hardware is busy until its gets cleared by hardware and software should not issue any read or write operation.<br>0b - hardware not busy<br>1b - hardware is busy (Read/Write operation from/to the Rx Parser Memory) |
| 30-23<br>— | Reserved. |
| 22-21<br>RXPEIEC | ECC Inject Error Control for Rx Parser Memory<br>Controls the ECC inject error for receive parser memory.<br>When MTL_RXP_Indirect_Acc_Control_Status[RXPEIEE] = 1, it indicates that on the basis of the value encoded in this field following errors are inserted:<br>00b - Insert 1 bit error<br>01b - Insert 2 bit errors<br>10b - Insert 3 bit errors<br>11b - Insert 1 bit error in address field |
| 20<br>RXPEIEE | ECC Inject Error Enable for Rx Parser Memory<br>Indicates whether the ECC inject error for receive parser memory is enabled.<br>If this field is 1, it enables the ECC error injection feature.<br>When this field becomes 0, it disables the ECC error injection feature. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |

When this field is 0, it disables the parity protection for EQOS datapath.<br>0b - Disable<br>1b - Enable |

## 72.17.215 MTL Tx Queue 0 Operation Mode (MTL_TxQ0_Operation_Mode)

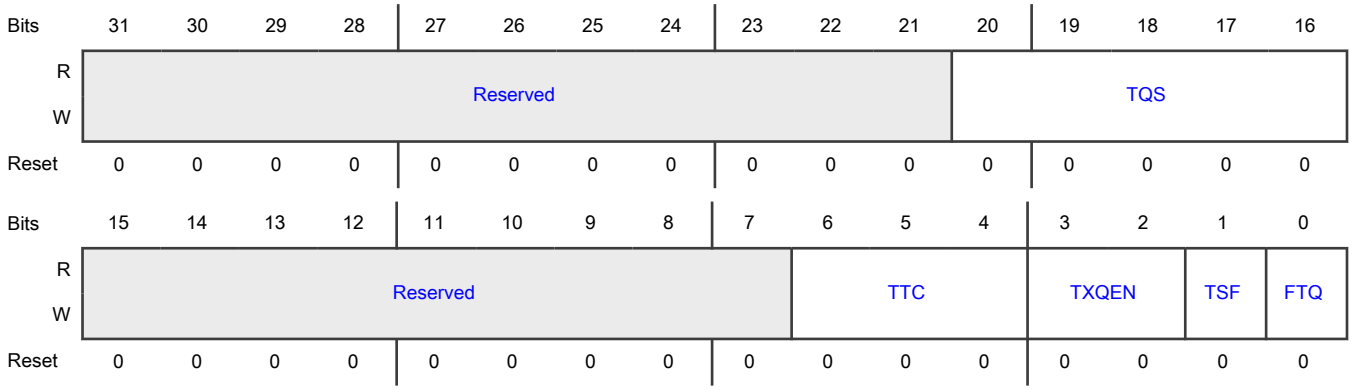
### Offset

| Register | Offset |
|---|---|
| MTL_TxQ0_Operation_Mode | D00h |

### Function

Establishes the transmit queue operating modes and commands.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-21<br>— | Reserved. |
| 20-16<br>TQS | Transmit Queue Size<br>Indicates the size of the allocated transmit queues in blocks of 256 bytes. This field is read-write only if the number of transit queues are more than one, the reset value is 0x0 and indicates 256 bytes size. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. You must program TQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes . In general, the size of the Queue = (TQS+1)*256 bytes.<br>When the number of transit queue is one, the field is read-only and the reset value reflects the configured TX FIFO size in blocks of 256 bytes.<br>The field's width depends on the transit memory size selected in your configuration. For example, if the memory size is 2048, the field's width is 3 bits:<br>LOG2(2048/256) = LOG2(8) = 3 bits |
| 15-7<br>— | Reserved. |
| 6-4<br>TTC | Transmit Threshold Control<br>Controls the threshold level of the MTL transit queue. The transmission starts when the packet size within the MTL transit queue is larger than the threshold, also transmits full packets with length less than the threshold. These fields are used only when MTL_TxQ0_Operation_Mode[TSF] resets.<br>000b - 32<br>001b - 64<br>010b - 96<br>011b - 128<br>100b - 192<br>101b - 256 |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 110b - 384<br>111b - 512 |
| 3-2<br>TXQEN | Transmit Queue Enable<br>Enables or disables the transmit queue 0.<br>2'b00 - Not enabled<br>2'b01 - Reserved<br>2'b10 - Enabled<br>2'b11 - Reserved<br>This field is read only in single queue configurations and read write in multiple queue configurations.<br>**NOTE**<br>In multiple transit queue configuration, all the queues disables by default and programming this field enables the transit queue.<br>00b - Not enabled<br>01b - Enable in AV mode (Reserved in non-AV)<br>10b - Enabled<br>11b - Reserved |
| 1<br>TSF | Transmit Store and Forward<br>Indicates whether the transmit store and forward is enabled.<br>When this field is 1, it indicates that the transmission starts when a full packet resides in the MTL transit queue and the TTC values specified in Bits[6:4] of this register are ignored. This field must be changed only when you stop the transmission.<br>0b - Disabled<br>1b - Enabled |
| 0<br>FTQ | Flush Transmit Queue<br>Indicates whether the flush transmit queue is enabled.<br>When this field is 1, it indicates that the transit queue controller logic resets to its default values. Therefore, all the data in the transit queue is lost or flushed. After the flushing operation completes this field resets internally. You must not write to the MTL_TxQ1_Operation_Mode until this field resets. The data to which the MAC transmitter has already accepted is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission.<br>**NOTE**<br>The flush operation completes only when the transit queue is empty and the application accepts the pending transit status of all the transmitted packets. To complete the flush operation, the PHY Tx clock (CLK_TX_I) must be active. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | Access restriction apply to this field. It clears automatically. Writing 1 sets this field and writing 0 has no effect.<br>0b - Disabled<br>1b - Enabled |

## 72.17.216 MTL Tx Queue 0 Underflow (MTL_TxQ0_Underflow)

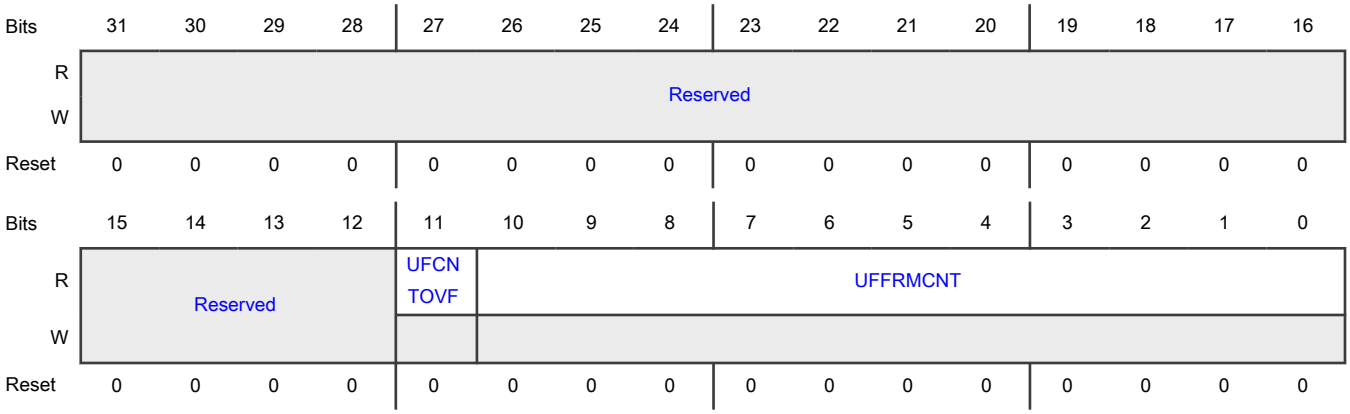
### Offset

| Register | Offset |
|---|---|
| MTL_TxQ0_Underflow | D04h |

### Function

Contains the counter for packets aborted because of transmit queue underflow and packets missed because of receive queue packet flush.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-12<br>— | Reserved. |
| 11<br>UFCNTOVF | Overflow Bit for Underflow Packet Counter<br>Indicates whether the overflow is detected for underflow packet counter. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | This field is 1, when the transit queue underflow packet counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter resets to all-zeros and this field indicates that the rollover occurred.<br>Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.<br>0b - Not detected<br>1b - Detected |
| 10-0<br>UFFRMCNT | Underflow Packet Counter<br>Indicates the number of packets aborted by the controller because of transit queue underflow. This counter increments each time the MAC aborts outgoing packet because of underflow. The counter clears when this register is read with mci_be_i[0] at 1'b1.<br>Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. |

## 72.17.217 MTL Tx Queue 0 Debug (MTL_TxQ0_Debug)

### Offset

| Register | Offset |
|---|---|
| MTL_TxQ0_Debug | D08h |

### Function

Provides the debug status of various blocks related to the transmit queue.

### Diagram

## 72.17.221 MTL Rx Queue 0 Operation Mode (MTL_RxQ0_Operation_Mode)

### Offset

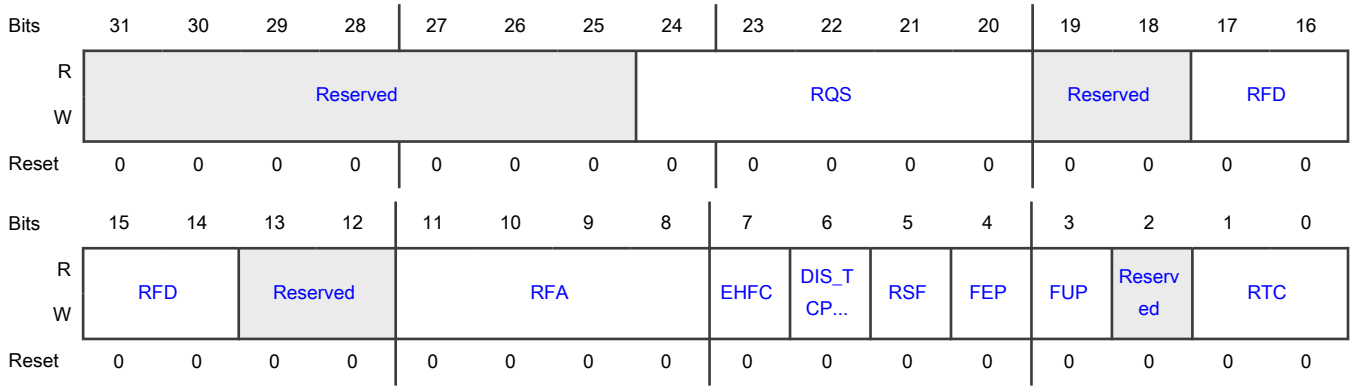
| Register | Offset |
|---|---|
| MTL_RxQ0_Operation_Mode | D30h |

### Function

Establishes the receive queue operating modes and command.

The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-25<br>— | Reserved. |
| 24-20<br>RQS | Receive Queue Size<br>Indicates the size of the allocated receive queues in blocks of 256 bytes. The MTL_RxQ0_Operation_Mode[RQS] is read-write only if the number of receive queues are more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. You must program RQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (RQS+1)*256 bytes.<br>When the number of receive queues is one, the field is read-only and the configured receive FIFO size in blocks of 256 bytes is reflected in the reset value.<br>The field width depends on the receive memory size selected in your configuration. For example, if the memory size is 2048, the field width is 3 bits:<br>LOG2(2048/256) = LOG2(8) = 3 bits |
| 19-18<br>— | Reserved. |
| 17-14<br>RFD | Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes)<br>Controls the threshold (fill-level of Rx queue) at which the flow control is de-asserts after activation.<br>0 - Full minus 1 KB, that is, FULL 1 KB<br>1 - Full minus 1.5 KB, that is, FULL 1.5 KB<br>2 - Full minus 2 KB, that is, FULL 2 KB<br>3 - Full minus 2.5 KB, that is, FULL 2.5 KB<br>...<br>14 - Full minus 8 KB, that is, FULL 8 KB<br>15 - Full minus 8.5 KB, that is, FULL 8.5 KB |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | De-assertion is effective only after flow control is asserted.<br>**NOTE**<br>You must program the value in such a way that the threshold is a positive number.<br>When MTL_RxQ0_Operation_Mode[EHFC] = 1, these values are applicable only when the receive queue size which the MTL_RxQ0_Operation_Mode[RQS] determines is equal to or greater than 4 KB.<br>For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size which the MTL_RxQ0_Operation_Mode[RQS] determines.<br>The field width depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only. |
| 13-12<br>— | Reserved. |
| 11-8<br>RFA | Threshold for Activating Flow Control (in half-duplex and full-duplex)<br>Controls the threshold (fill-level of receive queue) at which the flow control is activated.<br>See MTL_RxQ0_Operation_Mode[RFD] for more information on encoding for this field. |
| 7<br>EHFC | Enable Hardware Flow Control<br>Enables or disables hardware flow control.<br>If this field is 1, it enables the flow control signal operation, on the basis of the fill-level of receive queue.<br>When this field becomes 0, it disables the flow control operation.<br>0b - Disable<br>1b - Enable |
| 6<br>DIS_TCP_EF | Disable Dropping of TCP/IP Checksum Error Packets<br>Enables or disable dropping of TCP or IP checksum error packets.<br>When this field is 1, it indicates that the MAC does not drop the packets which only have the errors which the receive checksum offload engine detects. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC.<br>When this field becomes 0, it indicates that all error packets are dropped if MTL_RxQ0_Operation_Mode[FEP] resets.<br>0b - Enable<br>1b - Disable |
| 5<br>RSF | Receive Queue Store and Forward<br>Indicates whether the receive queue store and forward is enabled.<br>When this field is 1, it indicates that the module reads a packet from the receive queue only after the complete packet has been written to it, ignores the MTL_RxQ0_Operation_Mode[RTC]. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | When this field becomes 0, it indicates that the receive queue operates in the Threshold (cut-through) mode, subject to the threshold which the MTL_RxQ0_Operation_Mode[RTC] specifies.<br>0b - Disabled<br>1b - Enabled |
| 4<br>FEP | Forward Error Packets<br>Indicates whether the forward error packets are enabled.<br>When this field becomes 0, it indicates that the receive queue drop packets with an error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, the packet does not drop if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode).<br>When this field is 1, it indicates that all packets except the runt error packets are forwarded to the application or DMA. The packet is dropped irrespective of the setting of this field, if MTL_RxQ0_Operation_Mode[RSF] is 1 and the receive queue overflows when a partial packet is written. However, if MTL_RxQ0_Operation_Mode[RSF] becomes 0 and the receive queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA.<br>0b - Disabled<br>1b - Enabled |
| 3<br>FUP | Forward Undersized Good Packets<br>Indicates whether the forward undersized good packets are enabled.<br>When this field is 1, it indicates that the receive queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC.<br>When this field becomes 0, it indicates that the receive queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of receive threshold, for example, MTL_RxQ0_Operation_Mode[RTC] = 01.<br>0b - Disabled<br>1b - Enabled |
| 2<br>— | Reserved. |
| 1-0<br>RTC | Receive Queue Threshold Control<br>Controls the threshold level of the MTL receive queue (in bytes).<br>The received packet is transferred to the application or DMA when the packet size within the MTL receive queue is larger than the threshold. In addition, automatically transfer full packets with length less than the threshold.<br>This field is valid only when MTL_RxQ0_Operation_Mode[RSF] = 0.<br>This field is ignored when MTL_RxQ0_Operation_Mode[RSF] = 1.<br>00b - 64 |

### Fields

| Field | Function |
|---|---|
| 31-4<br>— | Reserved. |
| 3<br>RXQ_FRM_ARBIT | Receive Queue Packet Arbitration<br>Indicates whether the receive queue packet arbitration is enabled. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | When this field is 1, it indicates that the module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue transmits before switching to other queue.<br>When this field becomes 0, it indicates that the module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue transmits before switching to other queue:<br>• PBL amount of data (indicated by ari_qN_pbl_i[]), or<br>• Complete data of a packet<br>The status and the timestamp are not a part of the PBL data. Therefore, the module drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode).<br>0b - Disabled<br>1b - Enabled |
| 2-0<br>RXQ_WEGT | Receive Queue Weight<br>Indicates the weight assigned to receive queue 0.<br>You must write a value to this field that is 1 less than the required queue weight. Therefore, if this field is 0, it indicates that the queue weight is 1, if this field is 1, it indicates that the queue weight is 2, and so on. You must use this weight to calculate the number of continuous PBL or packet requests, depending on the value of RXQ_FRM_ARBIT, allocated to the queue in an arbitration cycle.<br>The field's value changes when the current service round completes or when there is a change from RAA=SP to RAA=WSP algorithm. This approach is required for a smooth transition. You must configure MTL Rx Queue 0 Control 0 (MTL_RxQ0_Control) before MTL Operation Mode (MTL_Operation_Mode) if you want to change the field's value before either of these two processes completes. |

## 72.17.225 MTL Tx Queue 1 Operation Mode (MTL_TxQ1_Operation_Mode)

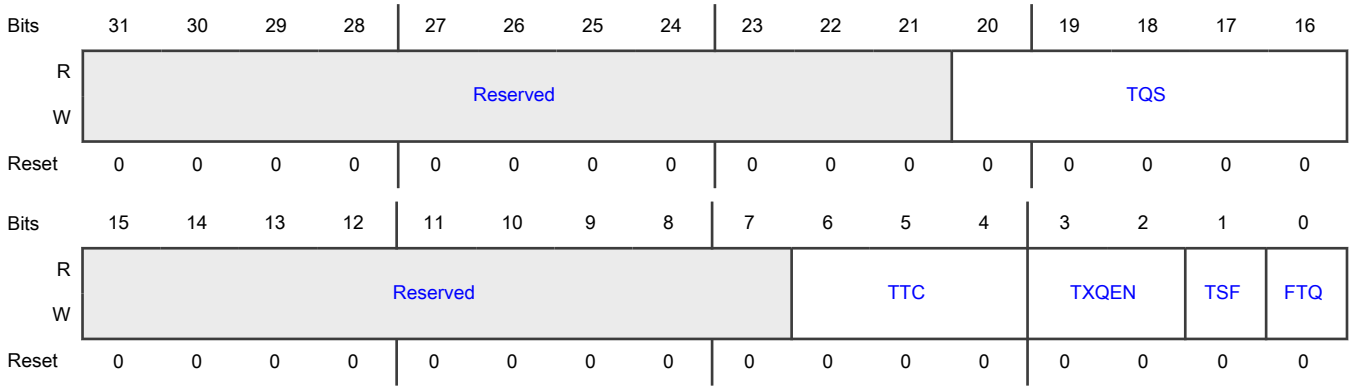
### Offset

| Register | Offset |
|---|---|
| MTL_TxQ1_Operation_Mode | D40h |

### Function

Establishes the transmit queue operating modes and commands.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-21<br>— | Reserved. |
| 20-16<br>TQS | Transmit Queue Size<br>Indicates the size of the allocated transmit queues in blocks of 256 bytes. This field is read-write only if the number of transit queues is more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. You must program TQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the queue = (TQS+1)*256 bytes.<br>When the number of transit queues is one, the field is read-only and the reset value reflects the configured TX FIFO size in blocks of 256 bytes.<br>The field width depends on the transit memory size selected in your configuration. For example, if the memory size is 2048, the field width is 3 bits:<br>LOG2(2048/256) = LOG2(8) = 3 bits |
| 15-7<br>— | Reserved. |
| 6-4<br>TTC | Transmit Threshold Control<br>Controls the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, it also transmit full packets with length less than the threshold. These fields are used only when the MTL_TxQ1_Operation_Mode[TSF] resets.<br>000b - 32<br>001b - 64<br>010b - 96<br>011b - 128<br>100b - 192<br>101b - 256 |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 110b - 384<br>111b - 512 |
| 3-2<br>TXQEN | Transmit Queue Enable<br>Enables or disables the transmit queue 0.<br>2'b00 - Not enabled<br>2'b01 - Enable in AV mode<br>2'b10 - Enabled<br>2'b11 - Reserved<br>**NOTE**<br>All the queues disables by default, in multiple transit queues configuration. You must program this field to enable the transit queue.<br>00b - Not enabled<br>01b - Enable in AV mode (Reserved in non-AV)<br>10b - Enabled<br>11b - Reserved |
| 1<br>TSF | Transmit Store and Forward<br>Indicates whether the transmit store and forward is enabled.<br>When this field is 1, it indicates that the transmission starts when full packet resides in the MTL transit queue and the TTC values specified in MTL_TxQ1_Operation_Mode[TTC] are ignored. This field must change only when the transmission stops.<br>0b - Transmit Store and Forward is disabled<br>1b - Transmit Store and Forward is enabled |
| 0<br>FTQ | Flush Transmit Queue<br>Indicates whether the flush transmit queue is enabled.<br>When this field is 1, it indicates that the transmit queue controller logic resets to its default values. Therefore, all the data in the transit queue is lost or flushed. This field resets internally when the flushing operation completes. Until this field becomes 0, you must not write to MTL_TxQ1_Operation_Mode. The data which the MAC transmitter has already accepted is not flushed. It is scheduled for transmission and results in an underflow and runt packet transmission.<br>**NOTE**<br>The flush operation completes only when the transit queue is empty and the application has accepted the pending transit status of all transmitted packets. To complete this flush operation, the PHY Tx clock (CLK_TX_I) must be active.<br>Access restriction apply to this field. Writing 1 sets this field and it clears automatically. Writing 0 has no effect. |

|---|---|
| 31-21<br>— | Reserved. |
| 20-0<br>ISCQW | idleSlopeCredit, Quantum or Weights<br>idleSlopeCredit<br>Contains the idleSlopeCredit value required for the credit-based shaper algorithm for queue 1, when you enables the AV feature. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbit/s; 8 ns for 1000 Mbit/s; 3.2 ns for 2500 Mbit/s) when the credit is increasing. You must program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbit/s mode and 0x1000 in 100 Mbit/s mode. Bits[20:14] must be written to zero.<br>Quantum<br>Contains the quantum value in bytes to be added to credit during every queue scanning cycle, when you enables the DCB operation with DWRR algorithm for queue 1 traffic. The maximum value is 0x1312D0 bytes.<br>Weights<br>Contains the weight for this queue, when you enables the DCB operation with WFQ algorithm for queue 1 traffic. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero.<br>Contains the weight for this queue, when you enables the DCB operation or generic queuing operation with WRR algorithm for queue 1 traffic. The maximum value is 0x64.<br>Bits [20:7] must be written to zero. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | **NOTE**<br>In multiple Queue configuration you must program this field in respective per queue register to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. You must not program this field when only Q0 is enabled. In general, you must program a non-zero value on both receive and transmit when WRR algorithm is selected. In receive, the register is MTL_Operation_Mode register.<br>**NOTE**<br>For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that transmit queue. The finish time is not a function of particular packet alone but it is according to the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size))<br>**NOTE**<br>The programmed weights do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time. |

## 72.17.231 MTL Tx Queue 1 Sendslope Credit (MTL_TxQ1_SendSlopeCredit)

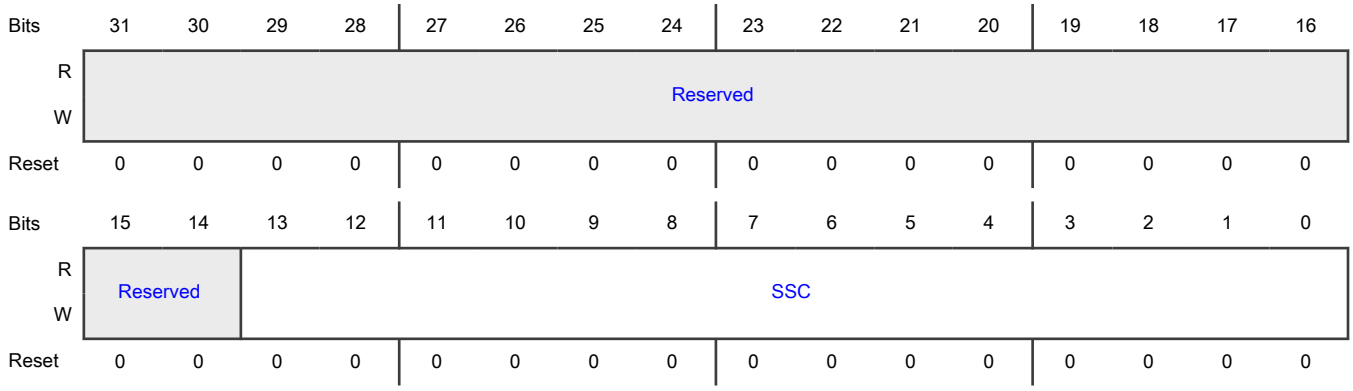
### Offset

| Register | Offset |
|---|---|
| MTL_TxQ1_SendSlopeCredit | D5Ch |

### Function

Contains the sendSlope credit value required for the credit-based shaper algorithm for the queue.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-14<br>— | Reserved. |
| 13-0<br>SSC | sendSlopeCredit Value<br>Contains the sendSlopeCredit value required for credit-based shaper algorithm for Queue 1, when you enables the AV operation. This is the rate of change of credit in bits per cycle (40 ns, 8 ns and 3.2 ns for 100 Mbit/s, 1000 Mbit/s and 2500 Mbit/s respectively) when the credit is decreasing. You must program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbit/s mode and 0x1000 in 100 Mbit/s mode. You must program this field with absolute sendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when channel 1 is selected for transmission. |

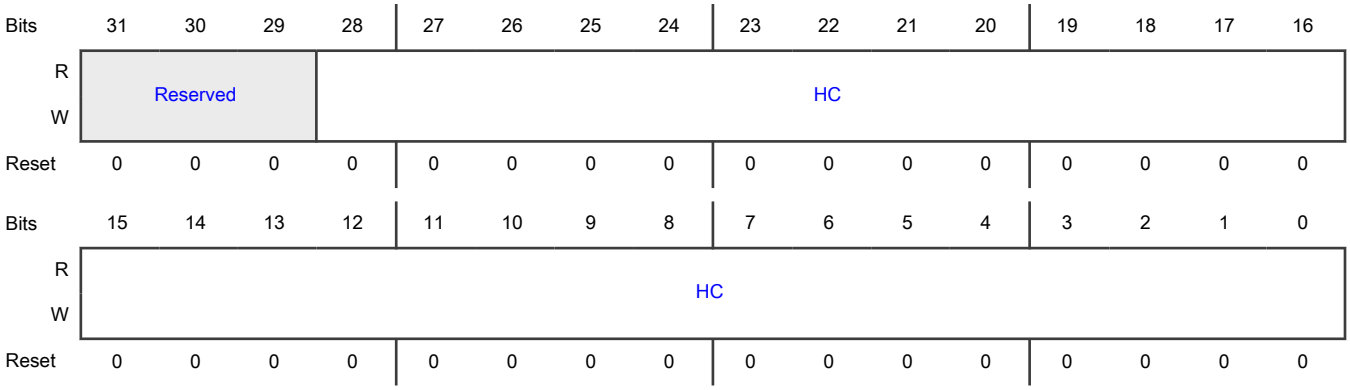
## 72.17.232 MTL Tx Queue 1 HiCredit (MTL_TxQ1_HiCredit)

### Offset

| Register | Offset |
|---|---|
| MTL_TxQ1_HiCredit | D60h |

### Function
Contains the hiCredit value required for the credit-based shaper algorithm for the queue.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-29<br>— | Reserved. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| 28-0<br>HC | hiCredit Value<br>Contains the hiCredit value required for the credit-based shaper algorithm, when you enables the AV feature. This is the maximum value that you can accumulate in the credit parameter. This is specified in bits scaled by 1,024.<br>The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16,384 bytes or 131,072 bits). The specified value is 131,072 * 1,024 = 134,217,728 or 0x0800_0000. |

## 72.17.233 MTL Tx Queue 1 LoCredit (MTL_TxQ1_LoCredit)

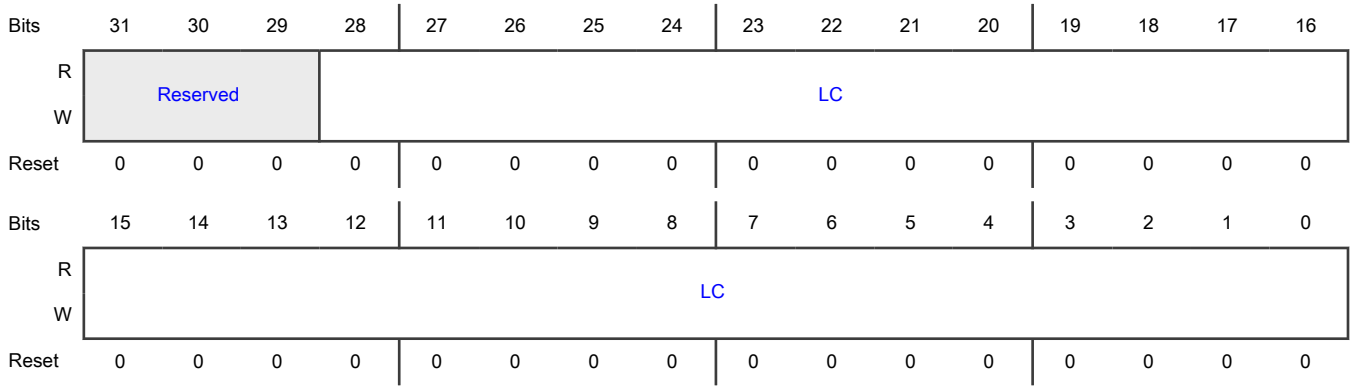
### Offset

| Register | Offset |
|---|---|
| MTL_TxQ1_LoCredit | D64h |

### Function

Contains the loCredit value required for the credit-based shaper algorithm for the queue.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-29<br>— | Reserved. |
| 28-0<br>LC | loCredit Value<br>Contains the loCredit value required for the credit-based shaper algorithm, when you enables the AV operation. This is the minimum value that you can accumulate in the credit parameter. This is specified in bits scaled by 1,024. The maximum value you can program corresponds to twice the maxFrameSize this queue transmits. If the maxFrameSize is 8192 bytes, then (8192*2) * 8 * 1024 = 134,217,728 or 0x0800_0000. The programmed value is 2's complement of the value, that is, 0x1800_0000 because it is a negative value. |

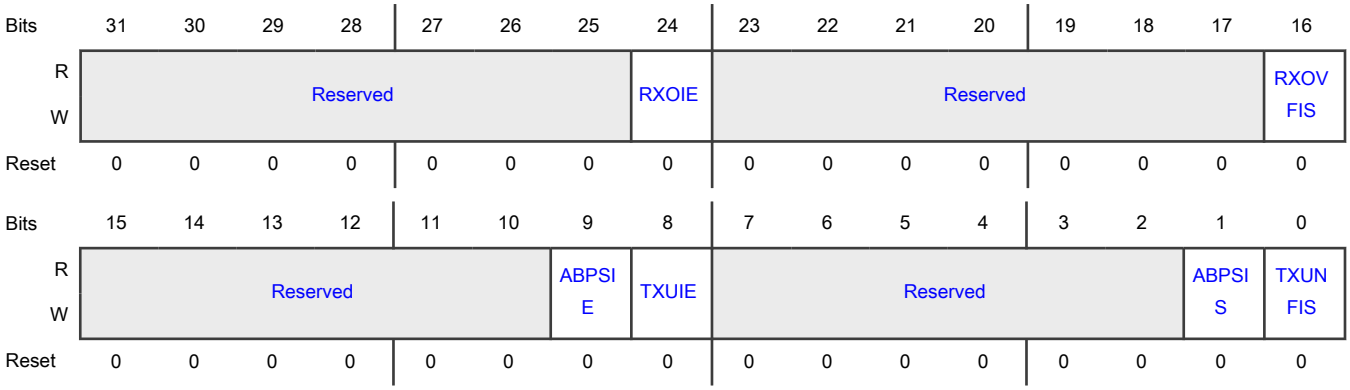
## 72.17.234 MTL Queue 1 Interrupt Control Status (MTL_Q1_Interrupt_Control_Status)

### Offset

| Register | Offset |
|---|---|
| MTL_Q1_Interrupt_Control_Status | D6Ch |

### Function
Contains the interrupt enable and status bits for the queue 1 interrupts.

### Diagram



### Fields

## 72.17.235 MTL Rx Queue 1 Operation Mode (MTL_RxQ1_Operation_Mode)

### Offset

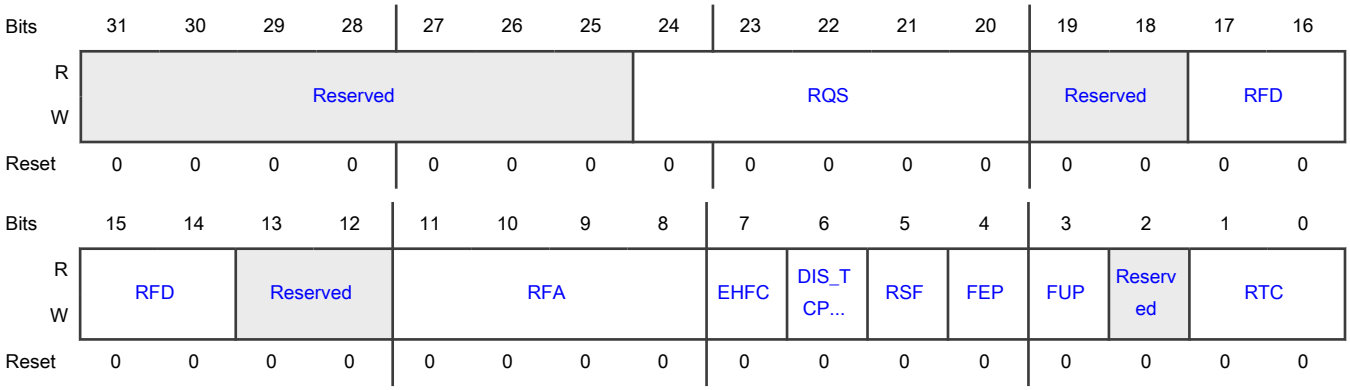
| Register | Offset |
|---|---|
| MTL_RxQ1_Operation_Mode | D70h |

### Function

Establishes the receive queue operating modes and command.

The MTL_RxQ1_Operation_Mode[RFA] and MTL_RxQ1_Operation_Mode[RFD] are not backward compatible with the RFA and RFD fields of 4.00a release.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-25<br>— | Reserved. |
| 24-20<br>RQS | Receive Queue Size<br>Indicates the size of the allocated receive queues in blocks of 256 bytes.<br>MTL_RxQ1_Operation_Mode[RQS] is read-write only if the number of receive queues is more than one, the |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | reset value is 0x0 and indicates 256 bytes size. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. You must program RQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (RQS+1)*256 bytes.<br>When the number of receive queues is one, the field is read-only and the reset value reflects the configured RX FIFO size in blocks of 256 bytes.<br>The field width depends on the receive memory size selected in your configuration. For example, if the memory size is 2048, the field width is 3 bits:<br>LOG2(2048/256) = LOG2(8) = 3 bits |
| 19-18<br>— | Reserved. |
| 17-14<br>RFD | Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes)<br>Controls the threshold (fill-level of Rx queue) at which the flow control de-asserts after activation<br>0 - Full minus 1 KB, that is, FULL 1 KB<br>1 - Full minus 1.5 KB, that is, FULL 1.5 KB<br>2 - Full minus 2 KB, that is, FULL 2 KB<br>3 -Full minus 2.5 KB, that is, FULL 2.5 KB<br>...<br>14 - Full minus 8 KB, that is, FULL 8 KB<br>15 - Full minus 8.5 KB, that is, FULL 8.5 KB<br>The de-assertion is effective only when flow control asserts.<br>**NOTE**<br>Program the value in such a way that the threshold is a positive number.<br>When MTL_RxQ1_Operation_Mode[EHFC] = 1, these values are applicable only when the receive queue size which MTL_RxQ1_Operation_Mode[RQS] determines, is equal to or greater than 4 KB.<br>For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 KB) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size which MTL_RxQ1_Operation_Mode[RQS] determines.<br>The field width depends on RX FIFO size selected during the configuration. Remaining bits are reserved and read only. |
| 13-12<br>— | Reserved. |
| 11-8<br>RFA | Threshold for Activating Flow Control (in half-duplex and full-duplex<br>Controls the threshold (fill-level of Rx queue) at which the flow control activates.<br>See MTL_RxQ1_Operation_Mode[RFD], for more information on encoding for this field. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| 7<br>EHFC | Enable Hardware Flow Control<br>Enables or disables hardware flow control.<br>If this field is 1, it enables the flow control signal operation, based on the receive queue's fill-level.<br>When this field becomes 0, it disables the flow control operation.<br>0b - Disable<br>1b - Enable |
| 6<br>DIS_TCP_EF | Disable Dropping of TCP or IP Checksum Error Packets<br>Indicates whether the dropping of TCP or IP checksum error packets is enabled.<br>When this field is 1, it indicates that the MAC does not drop the packets which only have the errors that the receive checksum offload engine detects. Such packets have errors only in the encapsulated payload. MAC receives an Ethernet packet in which there are no errors (including FCS error).<br>When this field becomes 0, it indicates that all the error packets drop if MTL_RxQ1_Operation_Mode[FEP] resets.<br>0b - Enabled<br>1b - Disabled |
| 5<br>RSF | Receive Queue Store and Forward<br>Indicates whether the receive queue store and forward is enabled.<br>When this field is 1, it indicates that the module reads a packet from the receive queue only after the complete packet is written to it and ignores MTL_RxQ1_Operation_Mode[RTC].<br>When this field becomes 0, it indicates that the receive queue operates in the Threshold (cut-through) mode, subject to the threshold which MTL_RxQ1_Operation_Mode[RTC] specifies.<br>0b - Disabled<br>1b - Enabled |
| 4<br>FEP | Forward Error Packets<br>Indicates whether the forward error packets are enabled.<br>If this field becomes 0, it indicates that the receive queue drops the packets with an error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, the packet does not drops, if the start byte (write) pointer of a packet is already transferred to the read controller side in Threshold mode.<br>When this field is 1, it indicates that all the packets except the runt error packets forward to the application or DMA. If MTL_RxQ1_Operation_Mode[RSF] is 1 and the receive queue overflows when a partial packet is written, the packet drops irrespective of the setting of this field. However, if MTL_RxQ1_Operation_Mode[RSF] resets and the receive queue overflows when a partial packet is written, you may forward a partial packet to the application or DMA.<br>0b - Disabled<br>1b - Enabled |
| 3 | Forward Undersized Good Packets |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| FUP | Indicates whether the forward undersized good packets are enabled.<br>When this field is 1, it indicates that the receive queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC.<br>When this field becomes 0, it indicates that the receive queue drops all the packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01.<br>0b - Disabled<br>1b - Enabled |
| 2<br>— | Reserved. |
| 1-0<br>RTC | Receive Queue Threshold Control<br>Controls the threshold level of the MTL Rx queue (in bytes):<br>The received packet is transferred to the application or DMA when the packet size within the MTL receive queue is larger than the threshold. Also, the full packets with length less than the threshold are automatically transferred.<br>This field is valid only when MTL_RxQ1_Operation_Mode[RSF] = 0.<br>This field is ignored when MTL_RxQ1_Operation_Mode[RSF] = 1.<br>00b - 64<br>01b - 32<br>10b - 96<br>11b - 128 |

## 72.17.236 MTL Rx Queue 1 Missed Packet Overflow Counter (MTL_RxQ1_Missed_Packet_Overflow_Cnt)

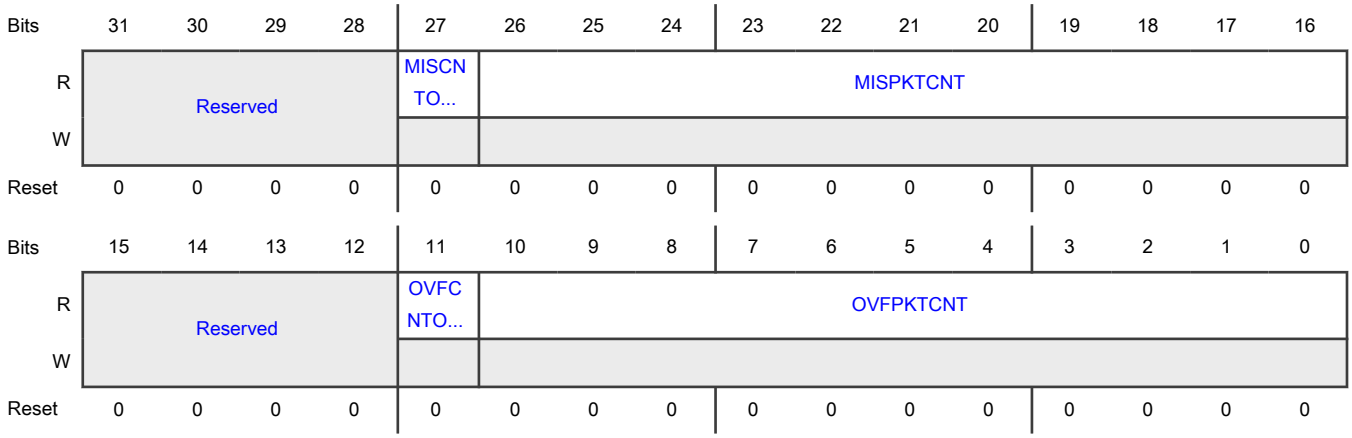
### Offset

| Register | Offset |
|---|---|
| MTL_RxQ1_Missed_Packet_Overflow_Cnt | D74h |

### Function

Contains the counter for packets missed because of receive queue packet flush and packets discarded because of receive queue overflow.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-28<br>— | Reserved. |
| 27<br>MISCNTOVF | Missed Packet Counter Overflow Bit<br>Indicates whether the missed packet counter overflow is detected.<br>When this field is 1, it indicates that the receive queue missed packet counter has crossed the maximum limit.<br>Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.<br>0b - Not detected<br>1b - Detected |
| 26-16<br>MISPKTCNT | Missed Packet Counter<br>Indicates the number of packets the module has missed because the application asserted ari_pkt_flush_i[] for this queue. This counter resets when this register is read with mci_be_i[0] at 1b1.<br>This counter increases by 1 when the DMA discards the packet because of buffer unavailability.<br>Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. |
| 15-12<br>— | Reserved. |
| 11<br>OVFCNTOVF | Overflow Counter Overflow Bit<br>Indicates whether the counter overflow status is detected.<br>When this field is 1, it indicates that the receive queue overflow packet counter field has crossed the maximum limit. |

*Table continues on the next page...*

| 0<br>RWCSTS | MTL Rx Queue Write Controller Active Status<br>Indicates whether the MTL receive queue write controller active status is detected.<br>When this field is 1, it indicates that the MTL receive queue write controller is active, and it is transferring a received packet to the receive queue.<br>0b - Not detected<br>1b - Detected |

## 72.17.238 MTL Rx Queue 1 Control (MTL_RxQ1_Control)

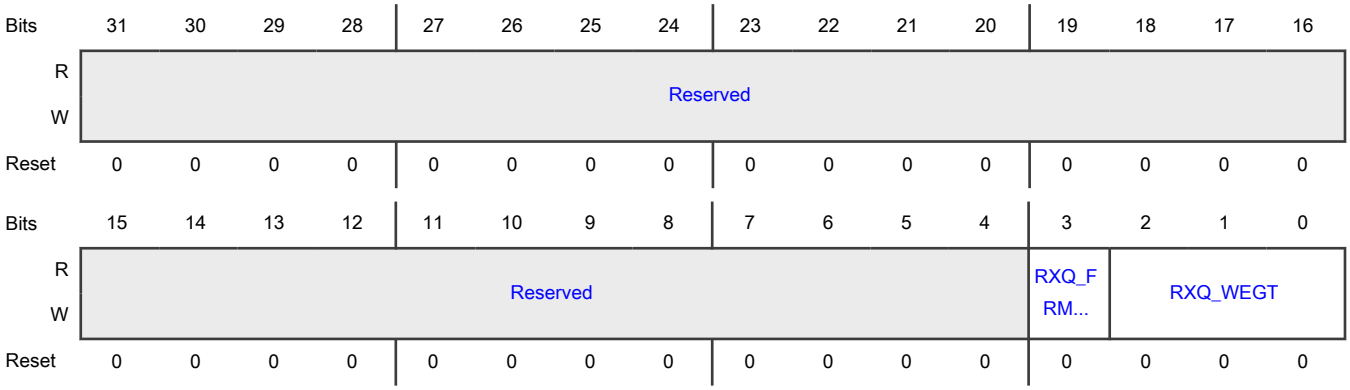
**Offset**

| Register | Offset |
|---|---|
| MTL_RxQ1_Control | D7Ch |

### Function

Controls the receive arbitration and passing of received packets to the application.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-4<br>— | Reserved. |
| 3<br>RXQ_FRM_ARBIT | Receive Queue Packet Arbitration<br>Indicates whether the receive queue packet arbitration is enabled.<br>When this field is 1, it indicates that the module drives the packet data to the ARI interface such that the entire packet data of currently-selected queue transmits before switching to other queue.<br>When this field becomes 0, it indicates that the module drives the packet data to the ARI interface such that the following amount of data of currently-selected queue transmits before switching to other queue:<br>• PBL amount of data (indicated by ari_qN_pbl_i[]), or<br>• Complete data of a packet<br>The status and the timestamp are not a part of the PBL data. Therefore, the module drives the complete status (including timestamp status) during the packet's first PBL request (in store-and-forward mode) or the last PBL request (in Threshold mode).<br>0b - Disabled<br>1b - Enabled |
| 2-0<br>RXQ_WEGT | Receive Queue Weight<br>Indicates the weight assigned to the receive queue 0. Program this field with one value less than the required weight, that is reset value of 0 indicates weight of 1, value of 1 indicates weight of 2, and so on. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle.<br>Note: The change in value of RXQ_WEGT takes effect only after the completion of current service round or when there is change from RAA=SP to RAA=WSP algorithm. This approach is taken so that there is smooth transition. For the RXQ_WEGT value to take effect at the start, the MTL_RxQ(#i)_Control registers must be programmed before the MTL_Operation_Mode register. |

## 72.17.239 DMA Mode (DMA_Mode)

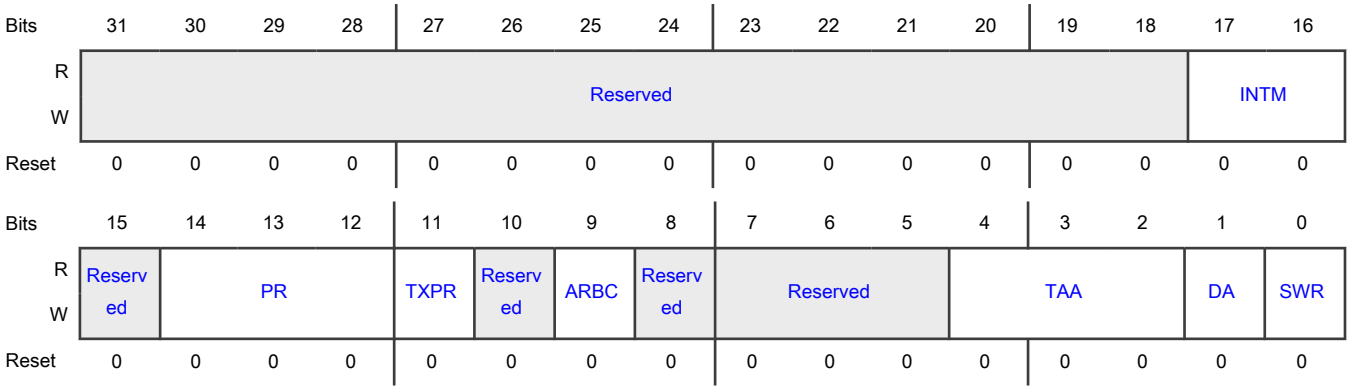
### Offset

| Register | Offset |
|---|---|
| DMA_Mode | 1000h |

### Function

Establishes the bus operating modes for the DMA.

### Diagram



### Fields

| Field | Function |
|---|---|

## 72.17.241 DMA Interrupt Status (DMA_Interrupt_Status)

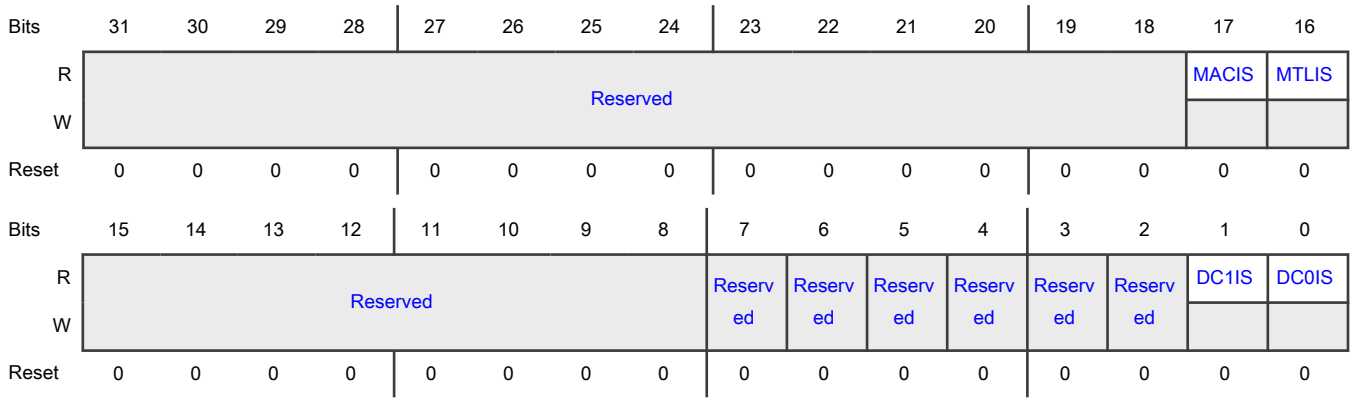
**Offset**

| Register | Offset |
|---|---|
| DMA_Interrupt_Status | 1008h |

### Function

The application reads this Interrupt Status register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-18<br>— | Reserved. |
| 17<br>MACIS | MAC Interrupt Status<br>Indicates whether the MAC interrupt status is detected.<br>You must read the corresponding register in the MAC to get the exact cause of the interrupt and clear its source, to reset this field to 1'b0.<br>0b - Not detected<br>1b - Detected |
| 16<br>MTLIS | MTL Interrupt Status<br>Indicates whether the MTL interrupt status is detected.<br>You must read the corresponding register in the MTL to get the exact cause of the interrupt and clear its source, to reset this field to 1'b0.<br>0b - Not detected<br>1b - Detected |

| 28<br>EDSE | Enhanced Descriptor Enable<br>Indicates whether an enhanced descriptor is enabled.<br>When this field is 1, it indicates that the corresponding channel uses 32 bytes enhanced descriptors for both normal and context descriptors.<br>When this field becomes 0, it indicates that the corresponding channel uses the 16 bytes descriptors.<br>0b - Disabled<br>1b - Enabled |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| 27-24<br>— | Reserved. |
| 23<br>— | Reserved. |
| 22<br>ETIC | Early Transmit Interrupt Control<br>Indicates whether an early transmit interrupt is enabled.<br>When this field is 1, it indicates that an early transmit interrupt (ETI) status = 1 after the data transfer from buffers of a transmit descriptor completes in which IOC bit (TDES2[31]) = 1.<br>When this field becomes 1, it indicates that ETI = 1 only after a complete packet transfers to the MTL TX FIFO memory.<br>0b - Disabled<br>1b - Enabled |
| 21-16<br>TxPBL | Transmit Programmable Burst Length<br>Indicates the maximum number of beats to transfer in one DMA block data transfer. DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of these values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior.<br>Perform these steps to transfer more than 32 beats:<br>1. Set DMA_CH0_Control[PBLx8].<br>2. Set the TxPBL.<br>**NOTE**<br>The maximum value of TxPBL must be less than or equal to half the transit queue size (TQS field of MTL_TxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the transit queue has space to store at least another TxPBL worth of data while the MTL Tx queue controller transfers data to MAC. For example, in 64-bit data width configurations the total locations in transit queue of size 512 bytes is 64. You must program TxPBL and 8xPBL to less than or equal to 32. |
| 15<br>— | Reserved. |
| 14-13<br>— | Reserved. |
| 12<br>— | Reserved. |
| 11-5<br>— | Reserved. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| 4<br>OSF | Operate on Second Packet<br>Indicates whether the operation on second packet is enabled.<br>When this field is 1, it instructs DMA to process the second packet of the transmit data even before you receive the status for the first packet.<br>0b - Disabled<br>1b - Enabled |
| 3-1<br>TCW | Transmit Channel Weight<br>Indicates the weight assigned to the corresponding transmit channel. When reset completes, this field is 0 for all the channels by default, which results in equal weights to all channels. |
| 0<br>ST | Start or Stop Transmission Command<br>Indicates whether to start or stop the transmission command.<br>When this field is 1, it indicates that the transmission is in the running state. DMA checks the transmit list at the current position for a packet to be transmitted.<br>DMA tries to acquire descriptor from either of these positions:<br>• The current position in the list. This is the base address of the transmit list to which DMA_CH0_TxDesc_List_Address sets.<br>• The position at which the transmission was previously stopped.<br>The transmission enters the suspended state and DMA_CH0_Status[TBU] = 1, if DMA does not own the current descriptor. The start transmission command is effective only when the transmission stops. If the command is issued before setting DMA_CH0_TxDesc_List_Address, you cannot predict the DMA behavior.<br>When this field becomes 0, it indicates that the transmission process is placed in the stopped state when the transmission of the current packet completes . The next descriptor position in the transmit list is saved, and it becomes the current position when you restart the transmission. To change the list address, you must program DMA_CH0_TxDesc_List_Address with a new value when this field becomes 0.You can consider the new value when this field is 1 again. The stop transmission command is effective only when the transmission of the current packet completes or the transmission is in the suspended state.<br>0b - Stop<br>1b - Start |

## 72.17.247 DMA Channel Rx Control (DMA_CH0_Rx_Control)

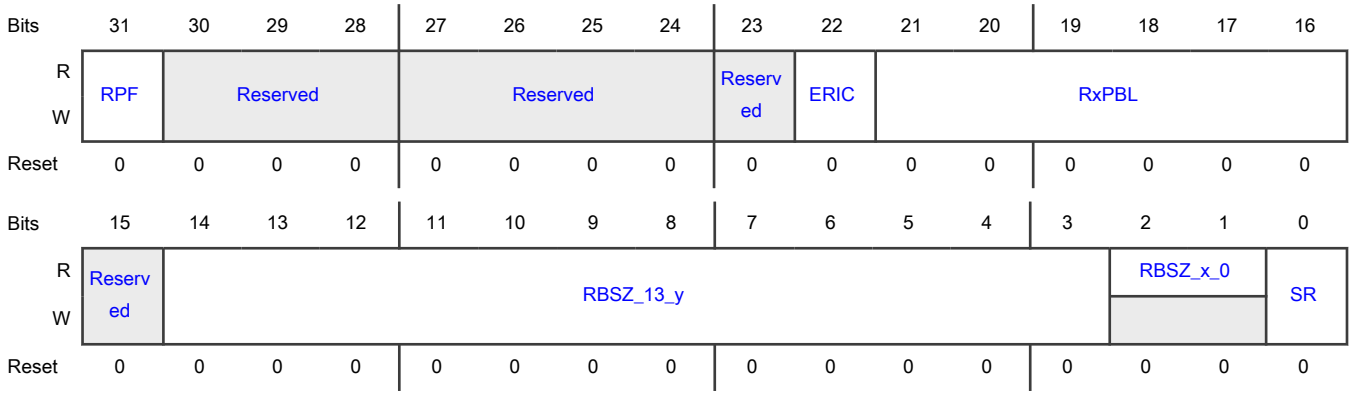
### Offset

| Register | Offset |
|---|---|
| DMA_CH0_Rx_Control | 1108h |

### Function

Controls the receive features such as PBL, buffer size, and extended status.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>RPF | Rx Packet Flush<br>Indicates whether the receive packet flush is enabled.<br>When this field is 1, it indicates that the module automatically flushes the packet from the receive queues destined to this DMA receive channel, when it stops. When this field remains 1 and the software driver re-starts DMA, the packets residing in the receive queues that were received when this RxDMA stops and flushes out. The packets that MAC receives after the RxDMA re-starts, route to the RxDMA. The flushing takes place on the read side of the receive queue.<br>When this field is 0, it indicates that the module do not flush the packet in the receive queue destined to this RxDMA channel when it is in STOP state. This may cause head-of-line blocking in the corresponding receive queue.<br>**NOTE**<br>The packet flow from a receive DMA channel to the application by writing 1 to this field stops, only when there is one-to-one mapping of receive queue to receive DMA channels. In Dynamic mapping mode, writing 1 to this field in any DMA_CH(#i)_Rx_Control register might flush packets from an unintended receive queues which are destined to the stopped receive DMA channel.<br>0b - Disabled<br>1b - Enabled |
| 30-28<br>— | Reserved. |
| 27-24<br>— | Reserved. |
| 23<br>— | Reserved. |
| 22 | Early Receive Interrupt Control |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| ERIC | Indicates whether an early receive interrupt is enabled.<br>When this field is 1, it indicates that the early receive interrupt (ERI) status sets after every burst transfer of data from the Rx DMA to the buffer completes.<br>When this field becomes 0, it indicates that ERI sets only after a complete buffer is filled by the RxDMA.<br>0b - Disabled<br>1b - Enabled |
| 21-16<br>RxPBL | Receive Programmable Burst Length<br>Indicates the maximum number of beats to be transferred in one DMA block data transfer. DMA always attempts max burst as specified in PBL every time it starts a burst transfer on the application bus. You can program PBL with any of these values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior.<br>To transfer more than 32 beats, perform the following steps:<br>1. Set DMA_CH0_Control[PBLx8].<br>2. Set the RxPBL.<br>**NOTE**<br>The maximum value of RxPBL must be less than or equal to half the receive queue size (RQS field of MTL_RxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the receive queue has space to store at least another Rx PBL worth of data while the receive DMA transfers a block of data. For example, in 64-bit data width configurations the total locations in receive queue of size 512 bytes is 64. You must program RxPBL and 8xPBL to less than or equal to 32. |
| 15<br>— | Reserved. |
| 14-3<br>RBSZ_13_y | Receive Buffer size High<br>RBSZ[13:0] splits into two fields, higher field is RBSZ_13_y and lower field is RBSZ_x_0. RBSZ[13:0] field indicates the receive buffers size specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled.<br>**NOTE**<br>The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the buffer address pointer value is not aligned with data bus width. Hence the lower RBSZ_x_0 fields are read-only and the value is considered as all-zero. Thus RBSZ_13_y field indicates the buffer size in terms of locations (with the width same as bus-width). |
| 2-1<br>RBSZ_x_0 | Receive Buffer size Low<br>RBSZ[13:0] splits into two fields RBSZ_13_y and RBSZ_x_0. The RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration.<br>The field width is of 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO). |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| 0<br>SR | Start or Stop Receive<br>Indicates whether to start or stop receive.<br>When this field is 1, it indicates that the DMA tries to acquire the descriptor from the receive list and processes the incoming packets.<br>DMA tries to acquire descriptor from either of these positions:<br>• The current position in the list. This is the address which DMA_CH0_RxDesc_List_Address sets.<br>• The position at which the receive process was previously stopped.<br>If DMA does not own the current descriptor, the reception is suspended and DMA_CH0_Status[RBU] = 1. The start receive command is effective only when the reception stops. If the command is issued before setting DMA_CH0_RxDesc_List_Address, the DMA behavior is unpredictable.<br>When this field becomes 0, it indicates that the receive DMA operation stops after the transfer of the current packet. The next descriptor position in the receive list is saved, and it becomes the current position after the receive process restarts. The stop receive command is effective only when the receive process is in the running (waiting for receive packet) or suspended state.<br>0b - Stop<br>1b - Start |

## 72.17.248 DMA Channel 0 Tx Descriptor List Address (DMA_CH0_TxDesc_List_Address)

### Offset

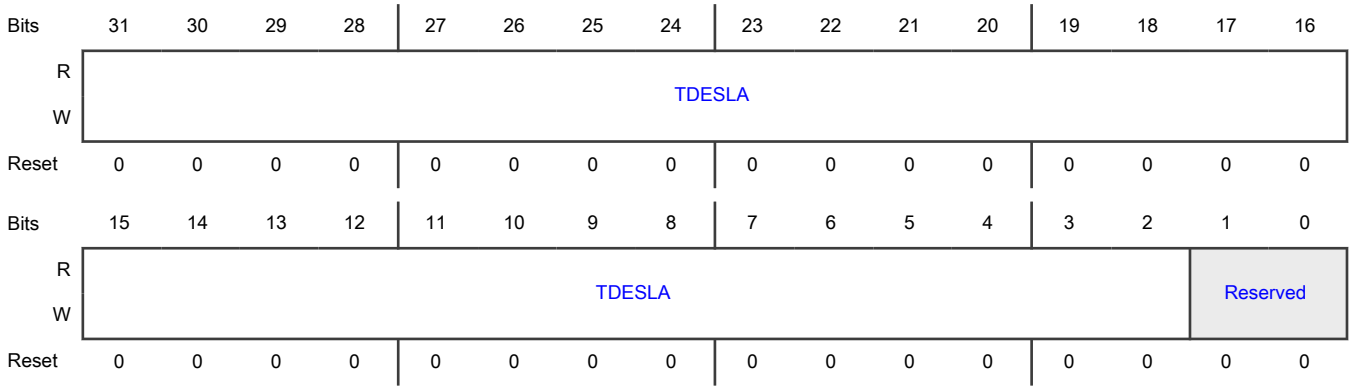
| Register | Offset |
|---|---|
| DMA_CH0_TxDesc_List_Address | 1114h |

### Function

Specifies DMA to the start of transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). DMA internally converts it to bus width aligned address by making the corresponding LSB low.

You can write to this register only when the transit DMA stops, that is, DMA_CH0_Tx_Control[ST] = 0. When stopped, write this register with a new descriptor list address. When DMA_CH0_Tx_Control[ST] = 1, DMA uses the newly-programmed descriptor base address. If this register does not change when DMA_CH0_Tx_Control[ST] = 0, DMA uses the descriptor address where it was stopped earlier.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-2<br>TDESLA | Start of Transmit List<br>Contains the base address of the first descriptor in the transmit descriptor list. DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).<br>The field width depends on the configuration:<br>31:2 for 32-bit configuration<br>31:3 for 64-bit configuration<br>31:4 for 128-bit configuration |
| 1-0<br>— | Reserved. |

## 72.17.249 DMA Channel 0 Rx Descriptor List Address (DMA_CH0_RxDesc_List_Address)

### Offset

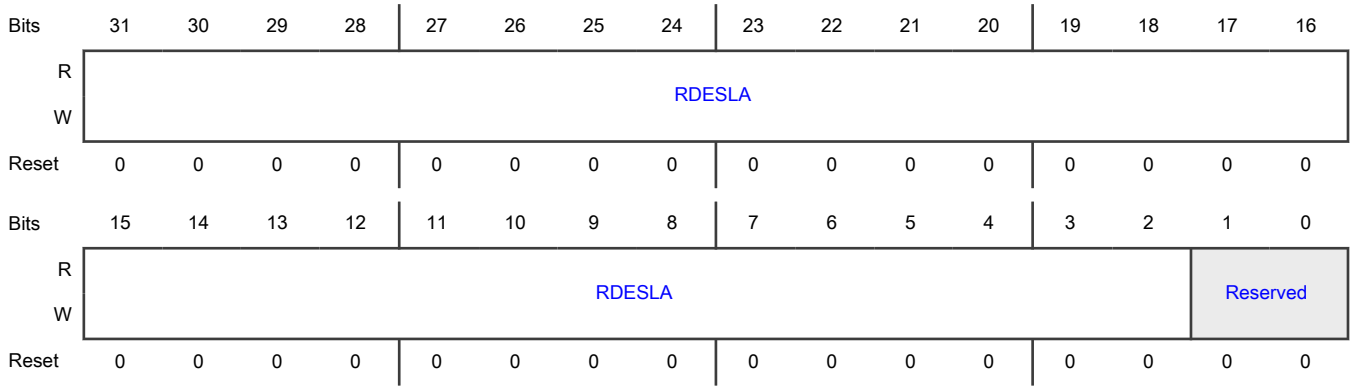
| Register | Offset |
|---|---|
| DMA_CH0_RxDesc_List_Address | 111Ch |

### Function

Specifies DMA to the start of receive descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). DMA internally converts it to bus width aligned address by making the corresponding LS bits low. You can write to this register only when reception stops. When stopped, write this register before the receive start command is given. You can write to this register only when Rx DMA stops, that is, DMA_CH0_Rx_Control[SR] = 0. When stopped, write this register with a new descriptor list address.

When DMA_CH0_Rx_Control[SR] = 1, it indicates that DMA takes the newly programmed descriptor base address.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-2<br>RDESLA | Start of Receive List<br>Contains the base address of the first descriptor in the receive descriptor list. DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).<br>The field width depends on the configuration:<br>31:2 for 32-bit configuration<br>31:3 for 64-bit configuration<br>31:4 for 128-bit configuration |

| 31-10<br>— | Reserved. |
| 9-0<br>RDRL | Receive Descriptor Ring Length<br>Sets the maximum number of receive descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. For example, you can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. Program this field to a value of 0x9, if you want to have 10 descriptors. |

## 72.17.254 DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable)

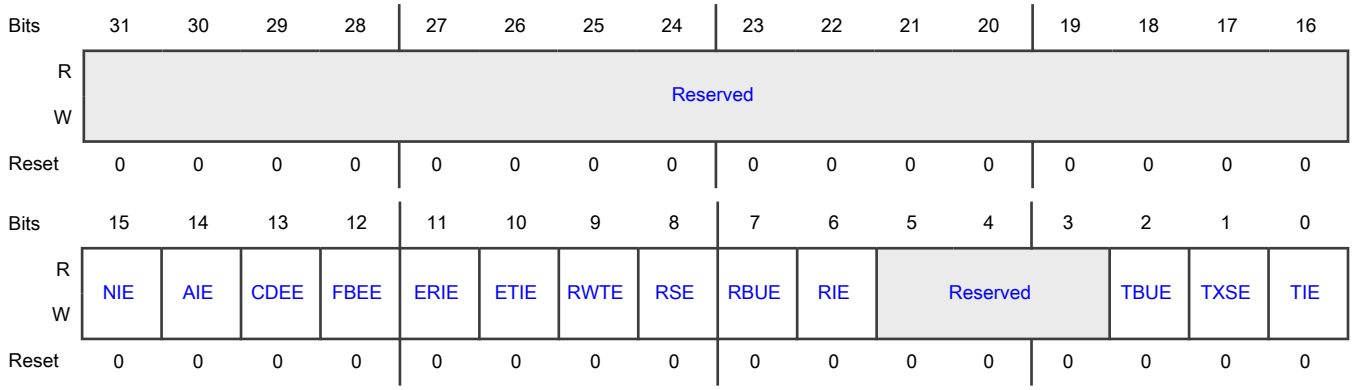
### Offset

| Register | Offset |
|---|---|
| DMA_CH0_Interrupt_Enable | 1134h |

### Function

Enables the interrupts which the status register report.

### Diagram



### Fields

## 72.17.255 DMA Channel 0 Rx Interrupt Watchdog Timer (DMA_CH0_Rx_Interrupt_Watchdog_Timer)

### Offset

| Register | Offset |
|---|---|
| DMA_CH0_Rx_Interrupt_Watchdog_Timer | 1138h |

### Function

Indicates the watchdog timeout for receive interrupt (RI) from DMA. When you write this register with a non-zero value, it enables the watchdog timer for the RI bit of the DMA_CHi_Status register.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Field | Function |
|---|---|
| 31-18<br>— | Reserved. |
| 17-16<br>RWTU | Receive Interrupt Watchdog Timer Count Units<br>Indicates the system clock cycles number corresponding to one unit in DMA_CH0_Rx_Interrupt_Watchdog_Timer[RWT]. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 2'b00 - 256<br>2'b01 - 512<br>2'b10 - 1024<br>2'b11 - 2048<br>For example, when DMA_CH0_Rx_Interrupt_Watchdog_Timer[RWT] = 2 and DMA_CH0_Rx_Interrupt_Watchdog_Timer[RWTU] = 1, the watchdog timer sets for 2*512=1024 system clock cycles. |
| 15-8<br>— | Reserved. |
| 7-0<br>RWT | Receive Interrupt Watchdog Timer Count<br>Indicates the number of system clock cycles, multiplied by factor which DMA_CH0_Rx_Interrupt_Watchdog_Timer[RWTU] indicates, for which you set the watchdog timer.<br>The watchdog timer triggers with the programmed value after the receive DMA completes the packet transfer for which the RI bit is not set in the DMA_CH(#i)_Status register, because of the setting of interrupt enable bit in the corresponding descriptor RDES3[30].<br>When the watchdog timer runs out, it indicates that the RI bit is 1 and the timer stops. The watchdog timer resets when the RI bit is 1 because of automatic setting of RI per the interrupt enable bit RDES3[30] of any received packet. |

## 72.17.256 DMA Channel 0 Slot Function Control Status (DMA_CH0_Slot_Function_Control_Status)

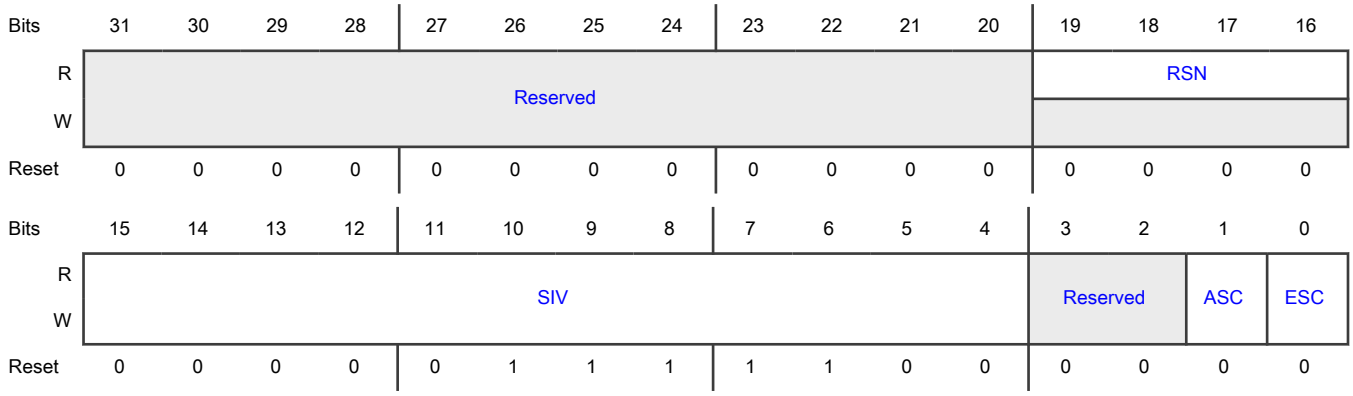
### Offset

| Register | Offset |
|---|---|
| DMA_CH0_Slot_Function_Control_Status | 113Ch |

### Function

Contains the control bits for slot function and the status for transmit path.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-20<br>— | Reserved. |
| 19-16<br>RSN | Reference Slot Number<br>Provides the current value of the reference slot number in DMA. It is used for slot comparison. |
| 15-4<br>SIV | Slot Interval Value<br>Controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096 us. The default or reset value is 0x07C which corresponds to slot interval of 125 us |
| 3-2<br>— | Reserved. |
| 1<br>ASC | Advance Slot Check<br>Indicates whether the advance slot check is enabled.<br>When this field is 1, it enables DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the transit descriptor is either:<br>Equal to the reference slot number given in DMA_CH0_Slot_Function_Control_Status[RSN], or<br>Ahead of the reference slot number by up to two slots.<br>This field is applicable only when DMA_CH0_Slot_Function_Control_Status[ESC] = 1.<br>0b - Disabled<br>1b - Enabled |
| 0<br>ESC | Enable Slot Comparison<br>Indicates whether the slot comparison is enabled. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | When this field is 1, it enables the checking of the slot numbers programmed in the transit descriptor with the current reference given in DMA_CH0_Slot_Function_Control_Status[RSN]. DMA fetches the data from the corresponding buffer only when the slot number is either:<br>• Equal to the reference slot number, or<br>• Ahead of the reference slot number by one slot.<br>When this field becomes 0, it disables the checking of the slot numbers. DMA fetches the data immediately after you process the descriptor.<br>**NOTE**<br>You must not enable the UFO (UDP Fragmentation over IPv4)/TSO/USO along with TBS/AVB slot number check. The UFO/TSO/USO involves multiple packets/segments/ fragments transmission for single packet received from application and the slot number check are applicable for fetching only first segment/fragment. As a result it might be difficult for you to specify slot number for subsequent packets.<br>0b - Disabled<br>1b - Enabled |

## 72.17.257 DMA Channel 0 Current Application Transmit Descriptor (DMA_CH0_Current_App_TxDesc)

### Offset

| Register | Offset |
|---|---|
| DMA_CH0_Current_App_TxDesc | 1144h |

### Function
Specifies the current transmit descriptor which DMA reads.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### Fields

| Field | Function |
|---|---|
| 31-0<br>CURTDESAPTR | Application Transmit Descriptor Address Pointer<br>Indicates that DMA updates this pointer during the transit operation. This pointer clears when reset. |

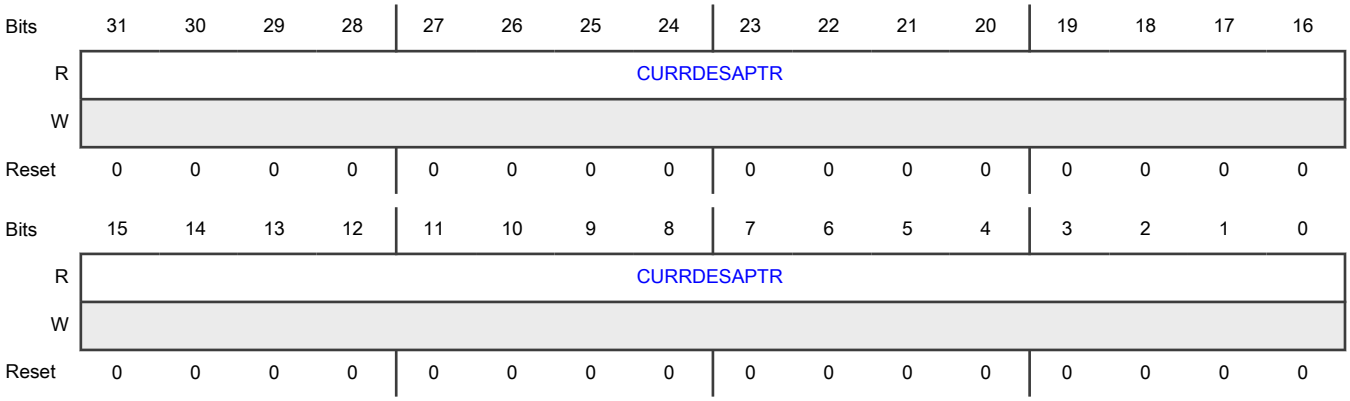
## 72.17.258 DMA Channel 0 Current Application Receive Descriptor (DMA_CH0_Current_App_RxDesc)

### Offset

| Register | Offset |
|---|---|
| DMA_CH0_Current_App_RxDesc | 114Ch |

### Function
Specifies the current receive descriptor which DMA read.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>CURRDESAPTR | Application Receive Descriptor Address Pointer<br>Indicates that the DMA updates this pointer during the receive operation. This pointer clears when reset. |

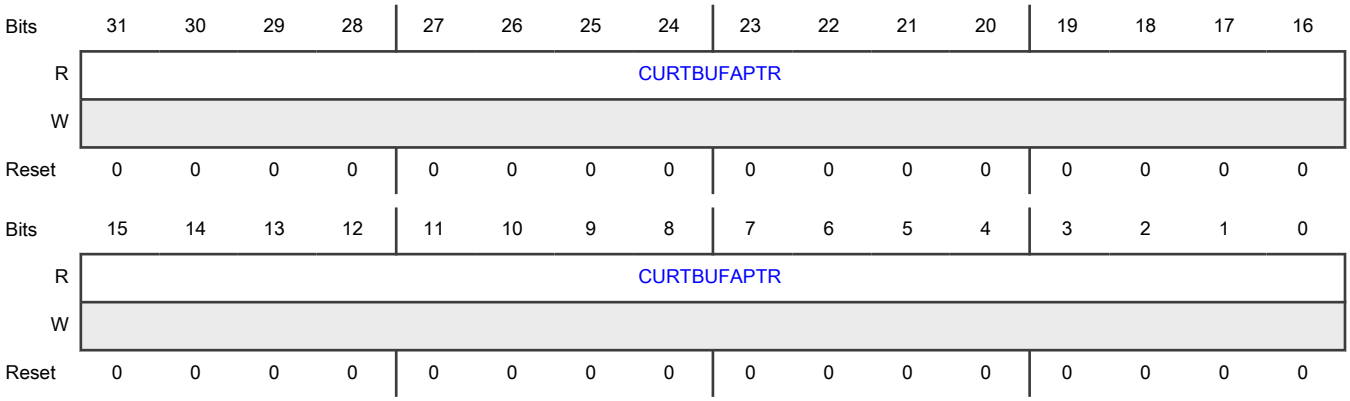
## 72.17.259 DMA Channel 0 Current Application Transmit Descriptor (DMA_CH0_Current_App_TxBuffer)

### Offset

| Register | Offset |
|---|---|
| DMA_CH0_Current_App_TxBuffer | 1154h |

### Function
Specifies the current transit buffer address which DMA reads.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>CURTBUFAPTR | Application Transmit Buffer Address Pointer<br>Indicates that DMA updates this pointer during the transit operation. This pointer clears when reset. |

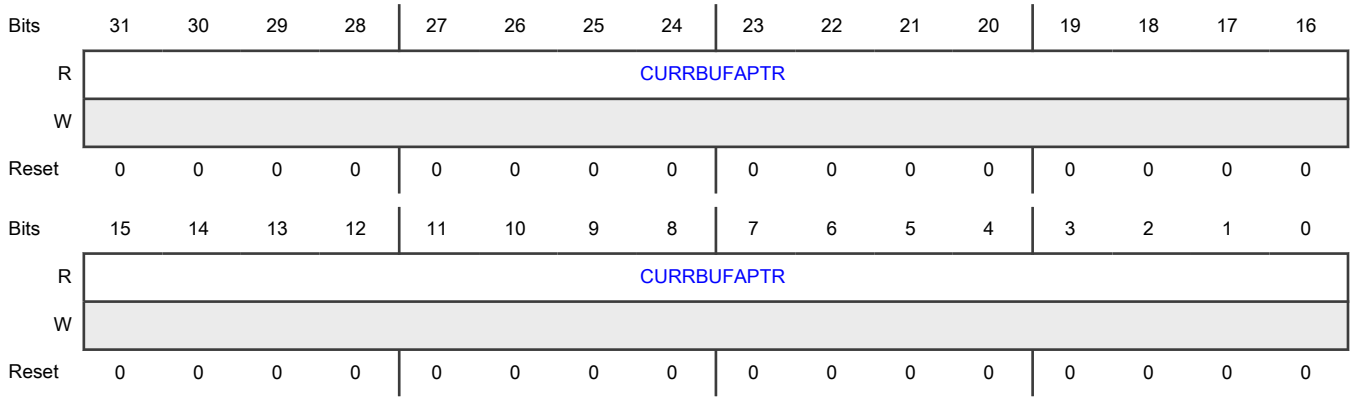
## 72.17.260 DMA Channel 0 Current Application Receive Buffer (DMA_CH0_Current_App_RxBuffer)

### Offset

| Register | Offset |
|---|---|
| DMA_CH0_Current_App_RxBuffer | 115Ch |

### Function
Specifies the current receive buffer address which DMA read.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>CURRBUFAPTR | Application Receive Buffer Address Pointer<br>Indicates that DMA updates this pointer during the receive operation. This pointer clears when reset. |

## 72.17.261 DMA Channel 0 Status (DMA_CH0_Status)

### Offset

| Register | Offset |
|---|---|
| DMA_CH0_Status | 1160h |

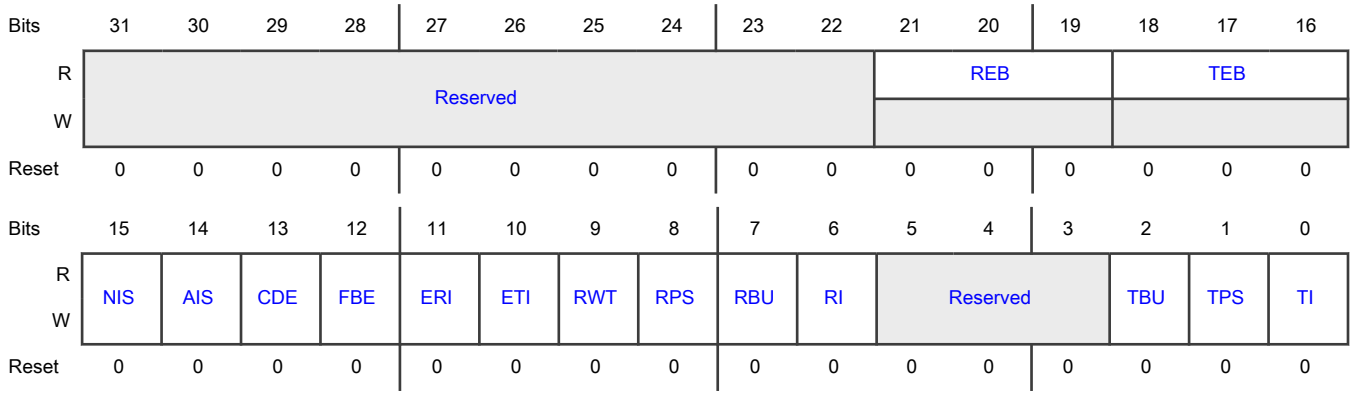
### Function

Indicates that the software driver (application) reads the status register during an interrupt service routine or polling to determine the DMA status.

**NOTE**

The number of DMA_CH(#i)_Status register in the configuration is the higher of number of receive DMA channels and transit DMA channels.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-22<br>— | Reserved. |
| 21-19<br>REB | Rx DMA Error Bits<br>Indicates the type of error that causes a bus error. For example, error response on the AHB or AXI interface.<br>Bit 21<br>1'b1 - Error during data transfer by Rx DMA<br>1'b0 - No Error during data transfer by Rx DMA<br>Bit 20<br>1'b1 - Error during descriptor access<br>1'b0 - Error during data buffer access<br>Bit 19<br>1'b1 - Error during read transfer<br>1'b0 - Error during write transfer<br>This field is valid only when DMA_CH0_Status[FBE] = 1. This field does not generate an interrupt. |
| 18-16<br>TEB | Tx DMA Error Bits<br>Indicates the type of error that causes a bus error. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 0b - Not detected<br>1b - Detected |
| 13<br>CDE | Context Descriptor Error<br>Indicates whether the context descriptor error status is detected.<br>This field indicates that the DMA Tx/Rx engine receives a descriptor error, which indicates an invalid context in the middle of packet flow ( intermediate descriptor) or all one's descriptor in transit case and on receive side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid.<br>Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect.<br>0b - Not detected<br>1b - Detected |
| 12<br>FBE | Fatal Bus Error<br>Indicates whether the fatal bus error status is detected.<br>This field indicates that a bus error occurred (as described in the EB field). When this field is 1, it indicates that the corresponding DMA channel engine disables all bus accesses.<br>Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect.<br>0b - Not detected<br>1b - Detected |
| 11<br>ERI | Early Receive Interrupt<br>Indicates whether an early receive interrupt status is detected.<br>When this field is 1, it indicates that the RxDMA completes the packet data transfer to the memory.<br>In configs supporting ERIC, this field is 1 only after the receive DMA fills a complete receive buffer with packet data, when DMA_CH0_Rx_Control[ERIC] = 0. This field is 1 after every burst transfer of data from the receive DMA to the buffer, when DMA_CH0_Rx_Control[ERIC] = 1.<br>Writing 1 to RI field automatically clears this field.<br>Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect.<br>0b - Not detected<br>1b - Detected |
| 10<br>ETI | Early Transmit Interrupt<br>Indicates whether an early transmit interrupt status is detected.<br>When this field is 1, it indicates that the TxDMA completes the packet data transfer to the MTL TXFIFO memory. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | In configs supporting ERIC: this field is 1 only after the transit DMA transfers a complete packet to MTL, when DMA_CH0_Tx_Control[ETIC] = 0. This field is 1 after packet data transfers from buffer completes (partial) in the transmit descriptor in which IOC = 1, when DMA_CH0_Tx_Control[ETIC] = 1.<br>Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect.<br>0b - Not detected<br>1b - Detected |
| 9<br>RWT | Receive Watchdog Timeout<br>Indicates whether the receive watchdog timeout status is detected.<br>Asserts when you receives a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled).<br>0b - Not detected<br>1b - Detected |
| 8<br>RPS | Receive Process Stopped<br>Indicates whether the receive process stopped status is detected.<br>Asserts when the receive process enters the stopped state.<br>Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect.<br>0b - Not detected<br>1b - Detected |
| 7<br>RBU | Receive Buffer Unavailable<br>Indicates whether the receive buffer unavailable status is detected.<br>This field indicates that the application owns the next descriptor in the receive list, and DMA cannot acquire it. The receive process is suspended. To resume processing receive descriptors, the application must change the ownership of the descriptor and issue a receive poll demand command. If this command is not issued, the receive process resumes when you receive the next recognized incoming packet. In ring mode, the application must advance the receive descriptor tail pointer register of a channel. This field is 1 only when DMA owns the previous receive descriptor.<br>Access restriction apply to this field. It automatically becomes 1 on an internal event occurrence. Writing 1 clears this field and writing 0 has no effect.<br>0b - Not detected<br>1b - Detected |
| 6<br>RI | Receive Interrupt<br>Indicates that the receive interrupt status is detected. |

## 72.17.262 DMA Channel 0 Miss Frame Counter (DMA_CH0_Miss_Frame_Cnt)

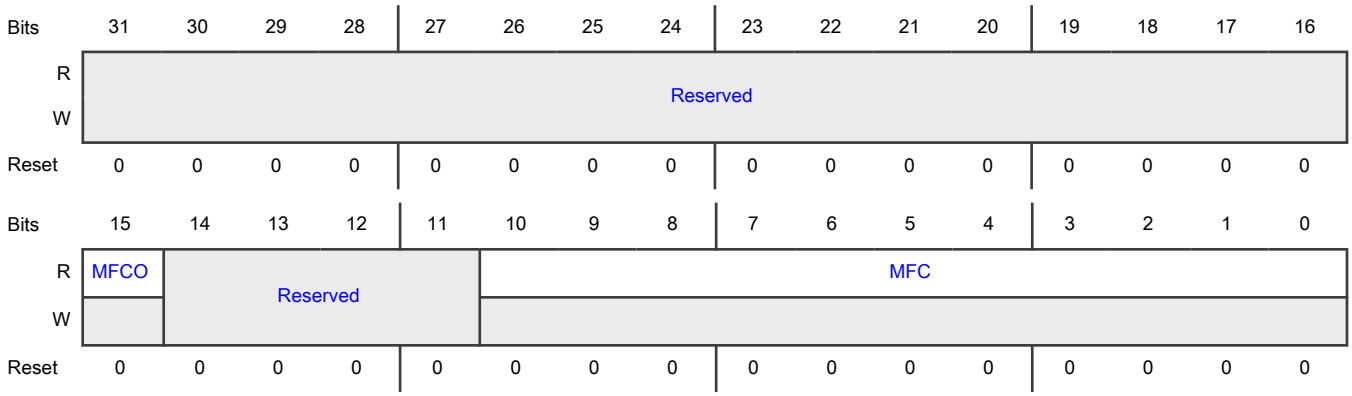
### Offset

| Register | Offset |
|---|---|
| DMA_CH0_Miss_Frame_Cnt | 1164h |

### Function

Indicates the number of packet counter that DMA drops either due to bus error or due to programming RPF field in DMA_CH${i}_Rx_Control register.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved. |
| 15<br>MFCO | Overflow status of the MFC Counter<br>Indicates whether the miss frame counter overflow has occurred.<br>When this field is 1, it indicates that the MFC counter does not increment further. This field is 0 when this register is read. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.<br>0b - Not occurred<br>1b - Occurred |
| 14-11<br>— | Reserved. |
| 10-0<br>MFC | Dropped Packet Counters<br>Indicates the number of packet counters that DMA drops either because of bus error or because of programing RPF field in DMA_CH${i}_Rx_Control register. This field is 0 when this register is read.<br>Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence. |

## 72.17.263 DMA Channel 0 Rx Parser Accept Count (DMA_CH0_RXP_Accept_Cnt)

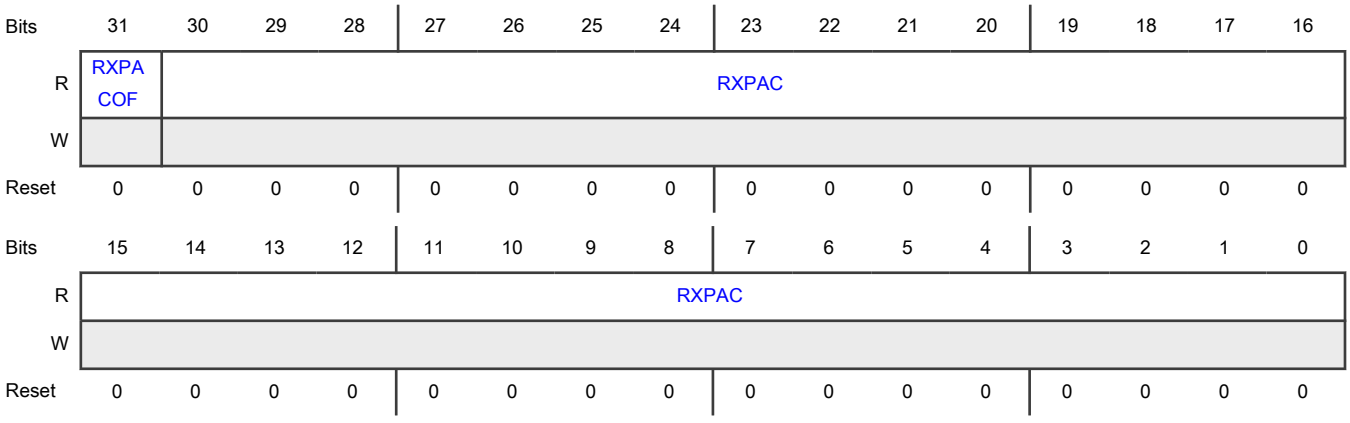
### Offset

| Register | Offset |
|---|---|
| DMA_CH0_RXP_Accept_Cnt | 1168h |

### Function

Provides the count of the number of frames which the receive parser accept.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>RXPACOF | Rx Parser Accept Counter Overflow Bit<br>Indicates whether the receive parser accept counter overflow has occurred.<br>When this field is 1, it indicates that the RXPAC counter field has crossed the maximum limit.<br>Access restriction apply to this field. It clears on read and automatically becomes 1 on an internal event occurrence.<br>0b - Not occurred<br>1b - Occurred |
| 30-0<br>RXPAC | Rx Parser Accept Counter<br>Implements whenever a receive parser accept a packet because AF = 1. The counter clears when the register is read. |

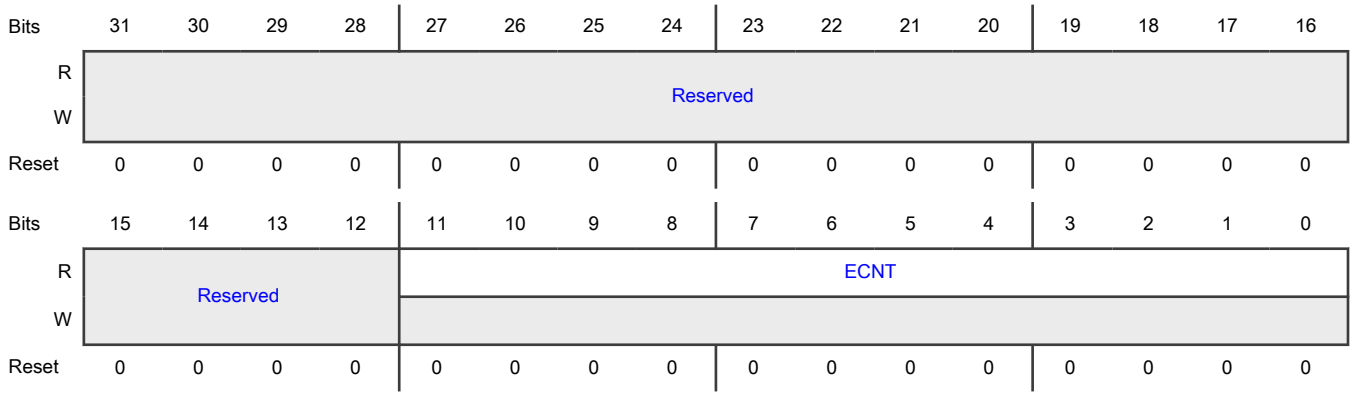
## 72.17.264 DMA Channel 0 Rx ERI Count (DMA_CH0_RX_ERI_Cnt)

### Offset

| Register | Offset |
|---|---|
| DMA_CH0_RX_ERI_Cnt | 116Ch |

### Function
Provides the count of the number of times ERI is asserted.

### Diagram



### Fields

## 72.17.266 DMA Channel 1 Tx Control (DMA_CH1_Tx_Control)

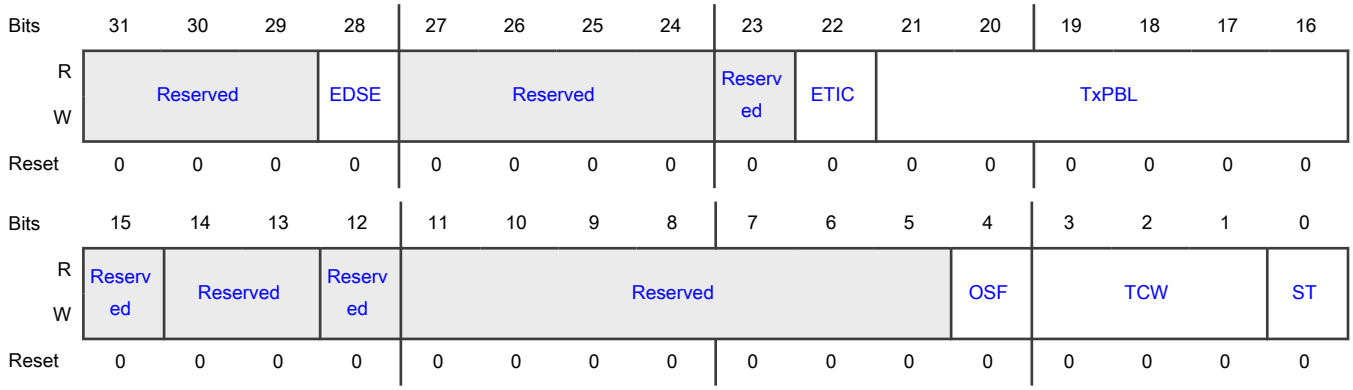
### Offset

| Register | Offset |
|---|---|
| DMA_CH1_Tx_Control | 1184h |

### Function

Controls the transmit features such as PBL, TCP segmentation, and transmit channel weights.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-29<br>— | Reserved. |
| 28<br>EDSE | Enhanced Descriptor Enable<br>Indicates whether an enhanced descriptor is enabled.<br>When this field is 1, it indicates that the corresponding channel uses enhanced descriptors that are 32 Bytes for both normal and context descriptors.<br>When this field becomes 0, it indicates that the corresponding channel uses the descriptors that are 16 Bytes.<br>0b - Disabled<br>1b - Enabled |
| 27-24<br>— | Reserved. |
| 23<br>— | Reserved. |
| 22<br>ETIC | Early Transmit Interrupt Control<br>Indicates whether an early transmit interrupt is enabled.<br>When this field is 1, it indicates that an early transmit interrupt (ETI) status sets after the data transfer completes from buffers of a transmit descriptor in which IOC bit (TDES2[31]) sets.<br>When this field becomes 0, it indicates that the ETI sets only after a complete packet transfers to the MTL TX FIFO memory.<br>0b - Disabled<br>1b - Enabled |
| 21-16 | Transmit Programmable Burst Length |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| TxPBL | Indicates the maximum number of beats to transfer in one DMA block data. DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of these values: 1, 2, 4, 8, 16, or 32. Any other value results in an undefined behavior.<br>To transfer more than 32 beats, perform the following steps:<br>1. Write 1 to DMA_CH0_Control[PBLx8].<br>2. Write 1 to this field.<br>**NOTE**<br>The maximum value of this field must be less than or equal to half the transit queue size (TQS field of MTL_TxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the transit queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue controller transfers data to MAC. For example, in 64-bit data width configurations the total locations in transit queue of size 512 bytes is 64. You must program TxPBL and 8xPBL to less than or equal to 32. |
| 15<br>— | Reserved. |
| 14-13<br>— | Reserved. |
| 12<br>— | Reserved. |
| 11-5<br>— | Reserved. |
| 4<br>OSF | Operate on Second Packet<br>Indicates whether an operation on second packet is enabled.<br>When this field is 1, it instructs DMA to process the second packet of the transmit data even before the first packet status is obtained.<br>0b - Disabled<br>1b - Enabled |
| 3-1<br>TCW | Transmit Channel Weight<br>Indicates the weight assigned to the corresponding transmit channel. When reset completes, this field becomes 0 for all channels by default, resulting in equal weights to all channels. |
| 0<br>ST | Start or Stop Transmission Command<br>Indicates whether to start or stop transmission command.<br>When this field is 1, it indicates that the transmission is placed in the running state. DMA checks the transmit list at the current position to transmit a packet. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | DMA tries to acquire descriptor from either of the following positions:<br>• The current position in the list. This is the base address of the transmit list which DMA_CH0_TxDesc_List_Address sets.<br>• The position at which the transmission was previously stopped<br>If DMA does not own the current descriptor, the transmission enters the suspended state and DMA_CH0_Status[TBU] = 1. The start transmission command is effective only when the transmission stops. If you issue the command before writing 1 to DMA_CH0_TxDesc_List_Address, then DMA behavior is unpredictable.<br>When this field becomes 0, it indicates that the transmission process is placed in the stopped state after the transmission of the current packet completes. The next descriptor position in the transmit list is saved, and it becomes the current position when the transmission restarts. To change the list address, you must program DMA_CH0_TxDesc_List_Address with a new value when this field becomes 0. The new value is considered when this field is 1 again. The stop transmission command is effective only when the transmission of the current packet completes or the transmission is in the suspended state.<br>0b - Stop<br>1b - Start |

## 72.17.267 DMA Channel 1 Rx Control (DMA_CH1_Rx_Control)

### Offset

| Register | Offset |
|---|---|
| DMA_CH1_Rx_Control | 1188h |

### Function

Controls the receive features such as PBL, buffer size, and extended status.

### Diagram

### Fields

| Field | Function |
|---|---|
| 31<br>RPF | Rx Packet Flush<br>Indicates whether the receive packet flush is enabled.<br>When this field is 1, it indicates that the module automatically flushes the packet from the receive queues destined to this DMA receive channel, when it stops. When this field remains 1 and the software driver re-starts DMA, the packets residing in the receive queues that were received when this RxDMA was stopped, flushes out. Route the packets to the RxDMA that the MAC receives after the RxDMA re-starts. The flushing takes place on the read side of the receive queue.<br>When this field is 0, it indicates that the module do not flush the packet in the receive queue destined to this RxDMA channel when it is in stop state. This might in turn cause head-of-line blocking in the corresponding RxQueue.<br>**NOTE**<br>The stopping of packet flow from a Rx DMA Channel to the application by writing 1 to this field works only when there is one-to-one mapping of receive queue to the receive DMA channels. In Dynamic mapping mode, writing 1 to this field in any DMA_CH(#i)_Rx_Control register might flush packets from unintended receive queues which are destined to the stopped Rx DMA Channel.<br>0b - Disabled<br>1b - Enabled |
| 30-28<br>— | Reserved. |
| 27-24<br>— | Reserved. |
| 23<br>— | Reserved. |
| 22<br>ERIC | Early Receive Interrupt Control<br>Indicates whether an early receive interrupt control status is enabled.<br>When this field is 1, it indicates that an early receive interrupt (ERI) status sets after every burst transfer of data from the receive DMA to the buffer completes.<br>When this field becomes 0, it indicates that ERI sets only after the RxDMA fills the complete buffer is filled.<br>0b - Disabled<br>1b - Enabled |
| 21-16<br>RxPBL | Receive Programmable Burst Length<br>Indicates the maximum number of beats to transfer in one DMA block data. DMA always attempts max burst as specified in PBL, each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in an undefined behavior.<br>To transfer more than 32 beats, perform the following steps: |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 1. Write 1 to DMA_CH0_Control[PBLx8].<br>2. Write 1 to RxPBL.<br>**NOTE**<br>The maximum value of RxPBL must be less than or equal to half the receive queue size (RQS field of MTL_RxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the receive queue has space to store at least another Rx PBL worth of data when the receive DMA transfers a block of data. For example, in 64-bit data width configurations the total locations in receive queue of size 512 bytes is 64, so you must program RxPBL and 8xPBL to less than or equal to 32. |
| 15<br>— | Reserved. |
| 14-3<br>RBSZ_13_y | Receive Buffer size High<br>Indicates that RBSZ[13:0] splits into two fields higher RBSZ_13_y and lower RBSZ_x_0. RBSZ[13:0] field indicates the size of the receive buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when you enable split headers.<br>**NOTE**<br>The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_x_0 bits are read-only and the value is considered as all-zero. Thus RBSZ_13_y indicates the buffer size in terms of locations (with the width same as bus-width). |
| 2-1<br>RBSZ_x_0 | Receive Buffer size Low<br>Indicates that RBSZ[13:0] splits into two fields RBSZ_13_y and RBSZ_x_0. RBSZ_x_0 is the lower field whose width is based on data bus width of the configuration.<br>This field width is of 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO). |
| 0<br>SR | Start or Stop Receive<br>Indicates whether to start or stop receive.<br>When this field is 1, it indicates that DMA tries to acquire the descriptor from the receive list and processes the incoming packets.<br>DMA tries to acquire descriptor from either of the following positions:<br>• The current position in the list. This is the address that DMA_CH0_RxDesc_List_Address sets.<br>• The position at which the receive process was previously stopped<br>If DMA does not own the current descriptor, the reception suspends and DMA_CH0_Status[RBU] = 1. The start receive command is effective only when the reception stops. If the command is issued before writing 1 to DMA_CH0_RxDesc_List_Address, DMA behavior is unpredictable. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | When this field becomes 0, it indicates that the receive DMA operation stops after the transfer of the current packet. The next descriptor position in the receive list is saved, and it becomes the current position after the receive process restarts. The stop receive command is effective only when the receive process is in the running (waiting for Rx packet) or suspended state.<br>0b - Stop<br>1b - Start |

## 72.17.268 DMA Channel 1 Tx Descriptor List Address (DMA_CH1_TxDesc_List_Address)

### Offset

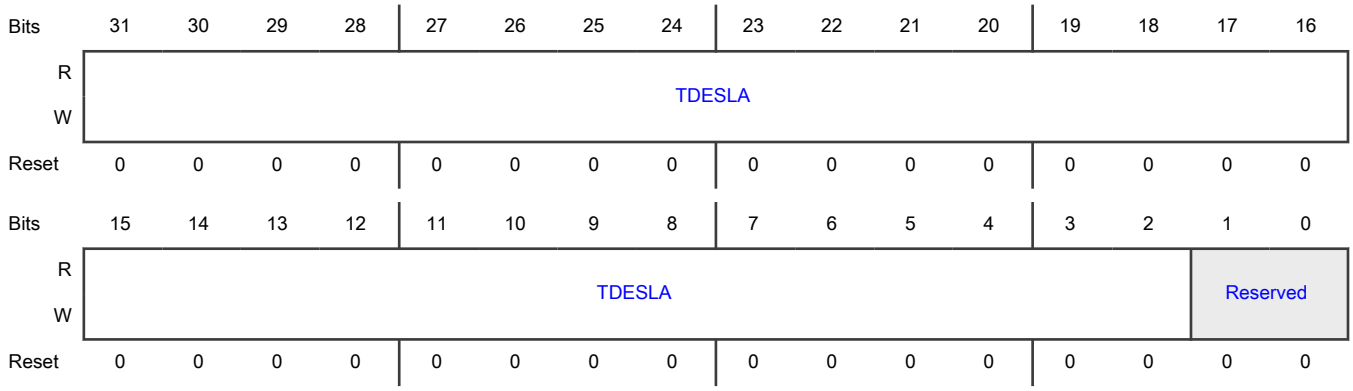
| Register | Offset |
|---|---|
| DMA_CH1_TxDesc_List_Address | 1194h |

### Function

Specifies DMA to the start of transmit descriptor list. The descriptor lists reside in the application's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA converts the corresponding LSB bits to low to internally convert the descriptor lists to bus width aligned address.

You can write to this register only when the transmit DMA stops, that is, DMA_CH0_Tx_Control[ST] = 0. When stopped, you can write this register with a new descriptor list address. When DMA_CH0_Tx_Control[ST] = 1, the DMA takes the newly-programmed descriptor base address. If this register do not change when DMA_CH0_Tx_Control[ST] = 0, DMA takes the descriptor address where it was stopped earlier.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-2 | Start of Transmit List |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| TDESLA | Contains the first descriptor base address in the transmit descriptor list. DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally assumes these bits as all-zero. Therefore, these LSB bits are read-only (RO).<br>The field width depends on the configuration:<br>31:2 for 32-bit configuration<br>31:3 for 64-bit configuration<br>31:4 for 128-bit configuration |
| 1-0<br>— | Reserved. |

## 72.17.269 DMA Channel 1 Rx Descriptor List Address (DMA_CH1_RxDesc_List_Address)

### Offset

| Register | Offset |
|---|---|
| DMA_CH1_RxDesc_List_Address | 119Ch |

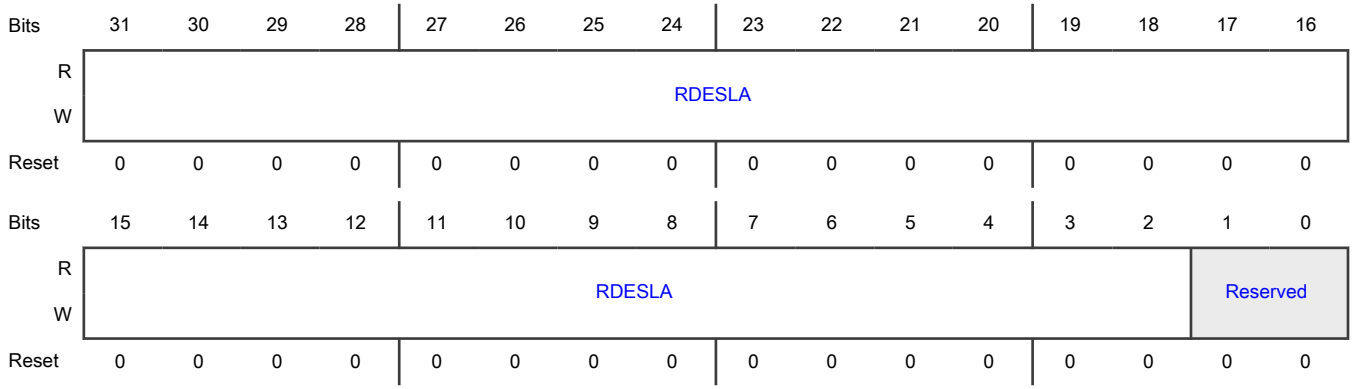
### Function

Specifies DMA to the start of receive descriptor list. The descriptor lists resides in the application's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). DMA converts the corresponding LS bits low to internally convert the descriptor lists to bus width aligned address. You can write to this register only when reception stops. When stopped, you must write this register before the receive start command is given.

You can write to this register when receive DMA has stopped, that is, DMA_CH0_Rx_Control[SR] = 0. When stopped, you can this register with a new descriptor list address.

When DMA_CH0_Rx_Control[SR] = 1, DMA takes the newly programmed descriptor base address.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-2<br>RDESLA | Start of Receive List<br>Contains the first descriptor base address in the receive descriptor list. DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally assume these bits as all-zero. Therefore, these LSB bits are read-only (RO).<br>The field width depends on the configuration:<br>31:2 for 32-bit configuration<br>31:3 for 64-bit configuration<br>31:4 for 128-bit configuration |

| 17-16<br>RWTU | Receive Interrupt Watchdog Timer Count Units<br>Indicates the number of system clock cycles corresponding to one unit in DMA_CH1_Rx_Interrupt_Watchdog_Timer[RWT].<br>2'b00 - 256<br>2'b01 - 512<br>2'b10 - 1024<br>2'b11 - 2048<br>For example, the watchdog timer sets for 2*512=1024 system clock cycles, when DMA_CH1_Rx_Interrupt_Watchdog_Timer[RWT] = 2 and DMA_CH1_Rx_Interrupt_Watchdog_Timer[RWTU] = 1. |
| 15-8<br>— | Reserved. |
| 7-0<br>RWT | Receive Interrupt Watchdog Timer Count<br>Indicates the number of system clock cycles, multiplied by factor indicated in DMA_CH1_Rx_Interrupt_Watchdog_Timer[RWTU], for which the watchdog timer sets.<br>The watchdog timer triggers with the programmed value after the receive DMA completes the packet transfer for which the RI bit is not 1 in DMA_CH(#i)_Status register, because of the setting of interrupt enable bit in the corresponding descriptor RDES3[30].<br>RI bit is 1 and the timer stops when the watchdog timer runs out. The watchdog timer becomes 0 when RI bit is 1 because RI sets automatically per the interrupt enable bit RDES3[30] of any received packet. |

## 72.17.276 DMA Channel 1 Slot Function Control Status (DMA_CH1_Slot_Function_Control_Status)

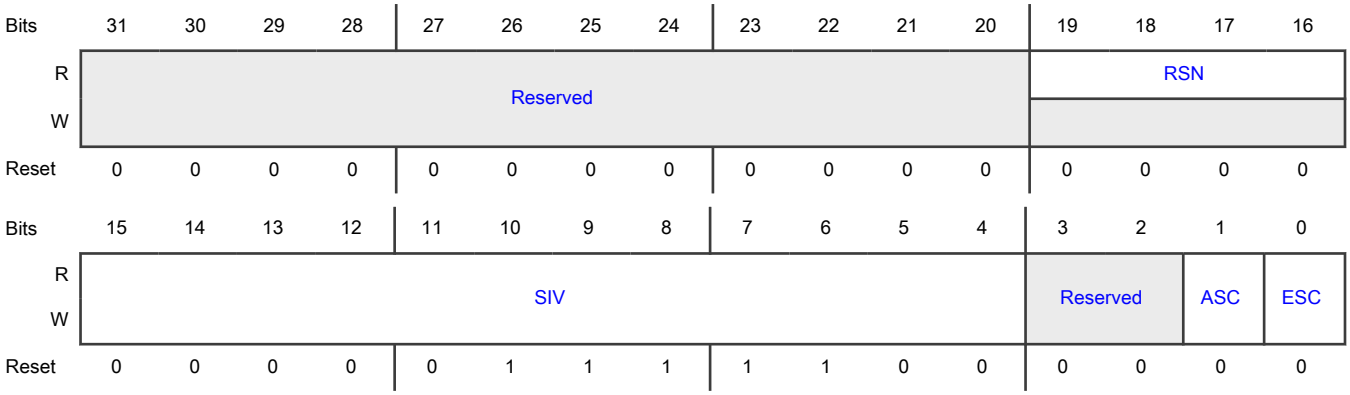
### Offset

| Register | Offset |
|---|---|
| DMA_CH1_Slot_Function_Control_Status | 11BCh |

### Function

Contains the control field for slot function and the status for transmit path.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-20<br>— | Reserved. |
| 19-16<br>RSN | Reference Slot Number<br>Provides the current value of the reference slot number in DMA. It is used for slot comparison. |
| 15-4<br>SIV | Slot Interval Value<br>Controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096 us. The default or reset value is 0x07C which corresponds to slot interval of 125 us. |
| 3-2<br>— | Reserved. |
| 1<br>ASC | Advance Slot Check<br>Indicates whether an advance slot check is enabled.<br>When this field is 1, it enables DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the transmit descriptor is: |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | • Equal to the reference slot number given in DMA_CH1_Slot_Function_Control_Status[RSN], or<br>• Ahead of the reference slot number by up to two slots.<br>This field is applicable only when DMA_CH1_Slot_Function_Control_Status[ESC] = 1.<br>0b - Disabled<br>1b - Enabled |
| 0<br>ESC | Enable Slot Comparison<br>Enables slot comparison.<br>When this field is 1, it enables the checking of the slot numbers programmed in the transmit descriptor with the current reference given in DMA_CH1_Slot_Function_Control_Status[RSN]. DMA fetches the data from the corresponding buffer only when the slot number is:<br>• Equal to the reference slot number, or<br>• Ahead of the reference slot number by one slot.<br>When this field becomes 0, it disables the checking of the slot numbers. DMA fetches the data immediately after you process the descriptor.<br>**NOTE**<br>You must not enable the UFO (UDP Fragmentation over IPv4)/TSO/USO along with TBS/AVB slot number check. The UFO/TSO/USO involves multiple packets or segments or fragments transmission for single packet received from application and the slot number check are applicable for fetching only first segment/fragment. As a result it might be difficult for you to specify slot number for subsequent packets.<br>0b - Disable<br>1b - Enable |

## 72.17.277 DMA Channel 1 Current Application Transmit Descriptor (DMA_CH1_Current_App_TxDesc)

**Offset**

| Register | Offset |
|---|---|
| DMA_CH1_Current_App_TxDesc | 11C4h |

**Function**
Specifies the current transmit descriptor which DMA reads.

### Diagram

### Fields

| Field | Function |
|---|---|
| 31-0<br>CURRDESAPTR | Application Receive Descriptor Address Pointer<br>Indicates that DMA updates this pointer during the receive operation. This pointer is 0 on reset. |

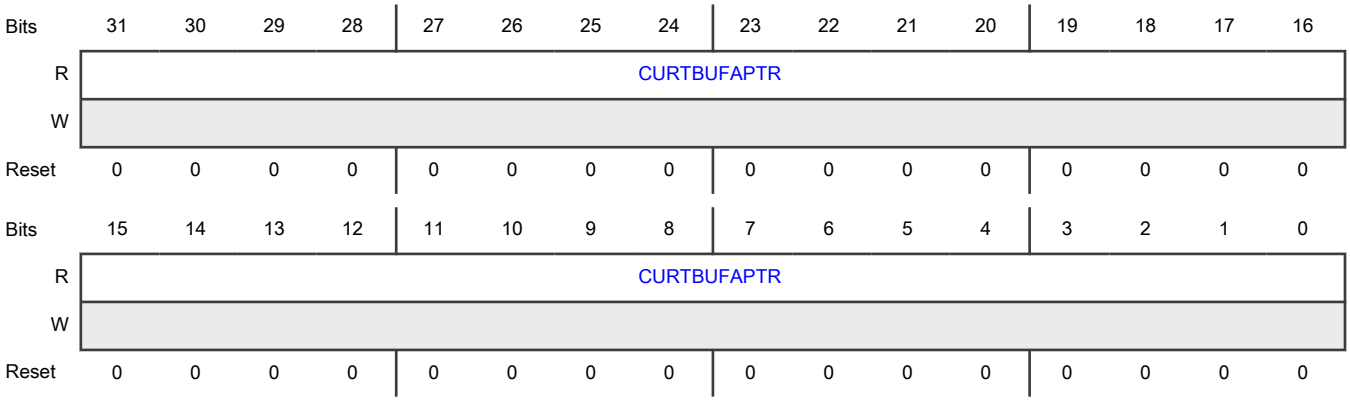
## 72.17.279 DMA Channel 1 Current Application Transmit Buffer (DMA_CH1_Current_App_TxBuffer)

### Offset

| Register | Offset |
|---|---|
| DMA_CH1_Current_App_TxBuffer | 11D4h |

### Function
Specifies the current transmit buffer address which DMA reads.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>CURTBUFAPTR | Application Transmit Buffer Address Pointer<br>Indicates that DMA updates this pointer during the transmit operation. This pointer is 0 on reset. |

## 72.17.280 DMA Channel 1 Current Application Receive Buffer (DMA_CH1_Current_App_RxBuffer)

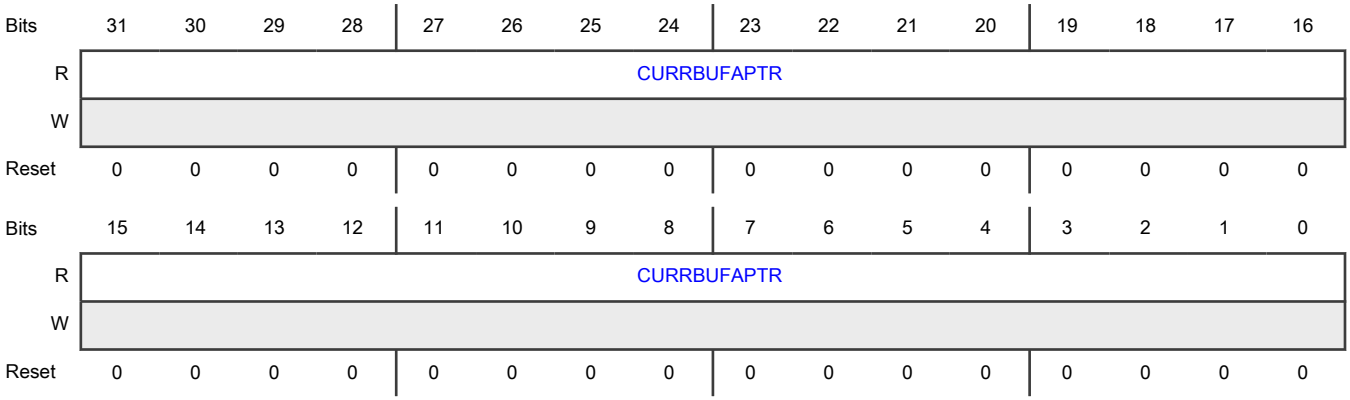
### Offset

| Register | Offset |
|---|---|
| DMA_CH1_Current_App_RxBuffer | 11DCh |

### Function

Indicates that DMA_CH0_Current_App_RxBuffer points to the current receive buffer address which the DMA reads.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>CURRBUFAPTR | Application Receive Buffer Address Pointer<br>Indicates that DMA update this pointer during the receive operation. This pointer is 0 on reset. |

## 72.17.281 DMA Channel 1 Status (DMA_CH1_Status)

### Offset

| Register | Offset |
|---|---|
| DMA_CH1_Status | 11E0h |

### Function

Indicates that to determine the status of DMA, the application reads the status register during an interrupt service routine or polling.

**NOTE**

The number of DMA_CH(#i)_Status register in the configuration is the higher of number of receive DMA Channels and transmit DMA Channels.

Table 543. LPUART Configuration

| Feature | Configuration |
|---|---|
| | MCXE317 |
| TX FIFO size | 4 Words |
| RX FIFO size | 4 Words |
| Functionality supported | Standard LPUART functionality with MODEM/IrDA |
| | LIN master and slave operation |

**NOTE**

LPUART instances are not available during Standby.

LPUART[0:2]_trg_input is coming from TRGMUX and you should take care of the pulse width of trigger. It should follow the requirement mentioned in section "Peripheral Triggers". These triggers are not present in MCXE31B.

## 73.2 Overview

LPUART provides asynchronous, serial communication capabilities with external devices. It supports the non-return-to-zero (NRZ) encoding format and infrared data association (IrDA)-compatible, low-speed serial infrared (SIR) protocol. LPUART can continue operating when the processor is in Low-Power mode, if an appropriate peripheral clock is available.

### 73.2.1 Block diagram

Figure 423 shows the transmitter portion of LPUART.

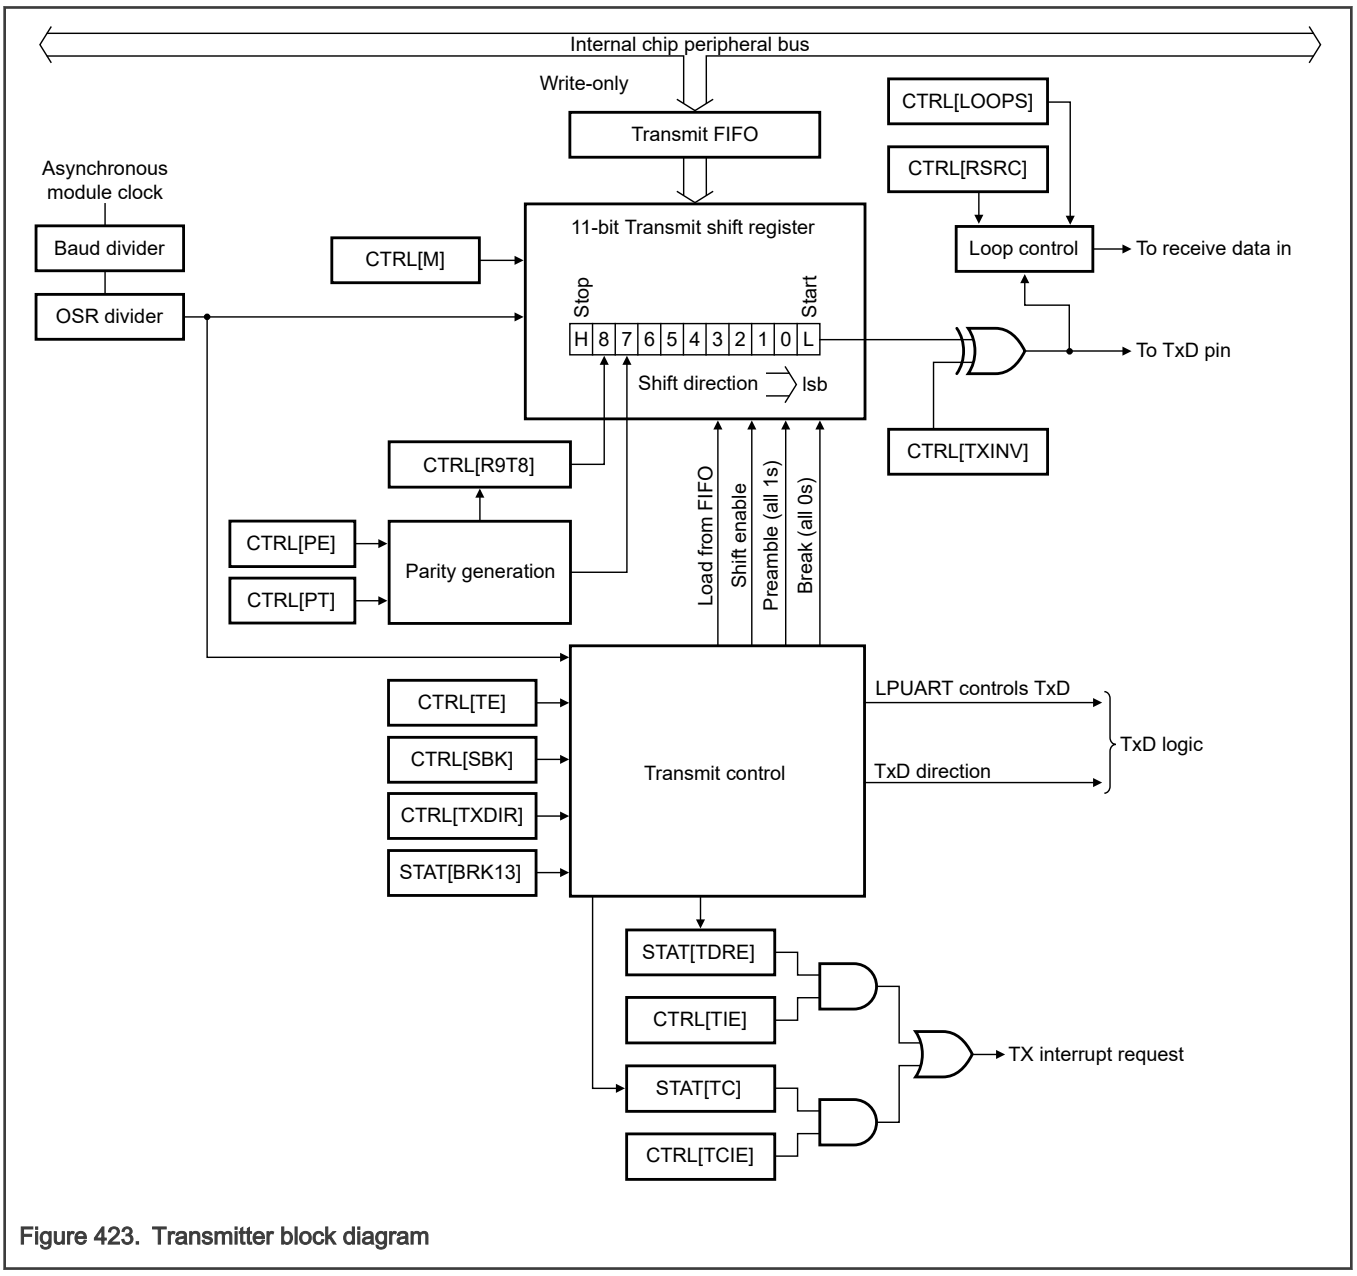

**Figure 423. Transmitter block diagram**

Figure 424 shows the receiver portion of LPUART.

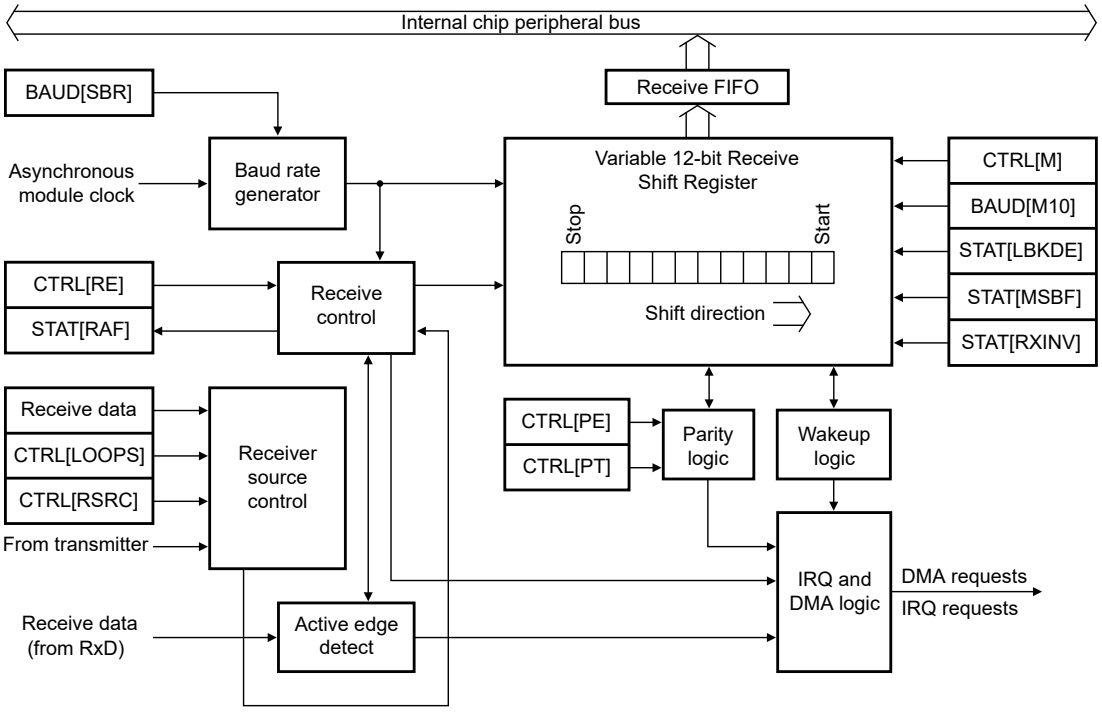

**Figure 424. Receiver block diagram**

## 73.2.2 Features

- Full-duplex, standard NRZ format
- Programmable baud rates (13-bit modulo divider) with a configurable oversampling ratio (OSR) from 4× to 32×
- Asynchronous operation of transmit and receive baud rates with respect to the bus clock:
  - Baud rate can be configured independently of the bus clock frequency.
  - Operation in Low-Power modes is supported.
- Interrupt, DMA, or polled operations:
  - Transmit data empty and transmission complete
  - Receive data full
  - Receive overrun, parity error, framing error, and noise error
  - Idle receiver detect
  - Active edge on receive pin
  - Break detect supporting LIN
  - Receive data match
- Hardware parity generation and checking
- Programmable 7-bit, 8-bit, 9-bit, or 10-bit character length
- Programmable 1-bit or 2-bit stop bits
- Support for three receiver wake-up methods:

  - Idle line wake-up
  - Address mark wake-up
  - Receive data match
- Automatic address matching to reduce ISR overhead:
  - Address mark matching
  - Idle line address matching
  - Address match start, address match end
- Optional 13-bit and 11-bit break character generation
- Configurable idle length detection supporting 1, 2, 4, 8, 16, 32, 64, or 128 idle characters
- Selectable transmitter output and receiver input polarity
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with a programmable pulse width
- Independent FIFO structure for transmit and receive functions:
  - Separate configurable watermarks for receive and transmit requests
  - Option for receiver to assert request after a configurable number of idle characters, if receive FIFO is not empty

## 73.3 Functional description

LPUART supports full-duplex, asynchronous, NRZ serial communication and comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. The following sections describe all LPUART blocks.

### 73.3.1 Baud rate generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and transmitter. The value, ranging from 1 to 8191, written to BAUD[SBR] determines the baud clock divisor for the asynchronous LPUART baud clock. The baud rate clock drives the receiver, while a bit clock, generated from the baud rate clock divided by the OSR, drives the transmitter. Depending on the OSR, the receiver has an acquisition rate of 4 to 32 samples per bit time. LPUART requires BAUD[SBR] and BAUD[OSR] to accurately match the baud rate requirement. There is a relationship between the required baud rate and the input clock frequency, SBR, and OSR. See the below figure for details.

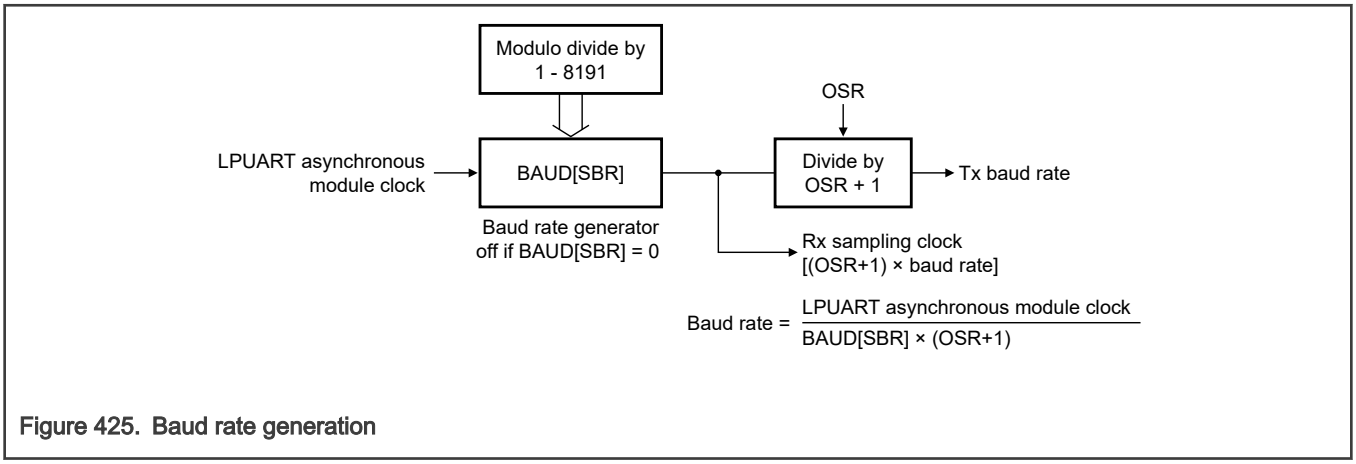

**Figure 425. Baud rate generation**

Baud rate generation is subject to these sources of error:

- Integer division of the asynchronous LPUART baud clock may not give the exact target frequency.
- Synchronization with the asynchronous LPUART baud clock can lead to a phase shift.

Baud rate generation is a free-running counter that continues whenever the transmitter or receiver is enabled. The transmitter bit clock continues whenever the transmitter is enabled; each transmitted character aligns to the next edge of the transmit bit clock.

In general, configuring OSR for a higher ratio and/or sampling on both edges of the clock slightly improves LPUART's tolerance to baud rate mismatch between the received data and LPUART configured baud rate. However, the three data samples in each bit (see Data sampling technique) are also closer together, which may impact noise sensitivity.

### 73.3.2 Baud rate tolerance

A transmitting device may operate at a baud rate below or above that of the receiver.

Accumulated bit time misalignment can cause one of the three stop bit data samples to fall outside the actual stop bit. A noise error will occur if the three samples are not all the same logical values. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the three stop bit samples are a logic zero.

As the receiver samples an incoming frame, it may resynchronize the oversampling clock on any valid falling edge within the frame. Resynchronization within frames will correct a misalignment between transmitter bit times and receiver bit times.

In general, increasing the number of samples per bit will increase the baud rate tolerance and decreasing the number of samples per bit will reduce the baud rate tolerance. Note that since LPUART implements triple voting on consecutive receive data samples, increasing the number of samples per bit will move those samples closer together which would reduce the width of noise that can be filtered by the triple voting logic.

### 73.3.3 Calculating baud rate tolerance

Using the following definitions:

- SAM is the number of sample points per bit (valid range from 8 to 32; equal to (OSR + 1) × (BOTHEDGE + 1)).
- BIT is the number of bits in a character including start, data and stop bits (valid range from 9 to 13).

The ideal baud rate tolerance can be calculated as follows:

- Slow data rate tolerance = ( (SAM ÷ 2) - 1) ÷ ((SAM × BIT) - (SAM ÷ 2) + 2)
- Fast data rate tolerance = ( (SAM ÷ 2) - 2) ÷ (SAM × BIT)

As an example, if configured for 8-bit data, 1 stop bit (BIT = 10) and with OSR=0x7 and BOTHEDGE = 1 (SAM = 16):

- Slow data rate tolerance = (8 - 1) ÷ (160 - 8 + 2) = 7 ÷ 154 = 4.54%
- Fast data rate tolerance = (8 - 2) ÷ 160 = 6 ÷ 160 = 3.75%

If configured for 9-bit data with 1 stop bit (BIT = 11) with same oversampling configuration, then:

- Slow data rate tolerance = (8 - 1) ÷ (176 - 8 + 2) = 7 ÷ 170 = 4.12%
- Fast data rate tolerance = (8 - 2) ÷ 176 = 6 ÷ 176 = 3.41%

**NOTE**

Additional factors can contribute to a lower baud rate tolerance than the ideal. These include clock uncertainty or jitter on the LPUART functional clock source, differences in rise and fall times on the transmitter output and synchronization of the external receive pin to the local LPUART functional clock.

### 73.3.4 Transmitter functional description

This section describes the functioning of the LPUART transmitter, as shown in the transmitter portion of Block diagram, as well as specialized functions for sending break and idle characters.

The transmitter output (TXD) idle state defaults to logic high; the transmitter output is inverted when you write 1 to CTRL[TXINV], which becomes 0 following reset. You can enable the transmitter by writing 1 to CTRL[TE]. This queues a preamble character that is one full character frame of the Idle state. The transmitter then remains idle until data is available in the transmit FIFO and programs store data in the transmit FIFO by writing to Data (DATA).

The central element of the LPUART transmitter is the transmit shift register that is 9-bit to 13-bit long depending on the settings of CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS]. Going forward in this discussion, assume that CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS] are 0, selecting the normal 8-bit Data mode, in which the shift register holds a start bit, eight data bits, and a stop bit. When the transmit shift register is available for a new character, the value waiting in transmit FIFO is transferred to the transmit shift register, synchronized with the baud rate clock, and STAT[TDRE] becomes 1 to indicate that another character may be written to the transmit FIFO at Data (DATA).

If no new character is waiting in the transmit FIFO after a stop bit is shifted out of the TXD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TXD high, waiting for more characters to transmit.

Writing 0 to CTRL[TE] does not immediately disable the transmitter. The current transmit activity in progress must first be completed (that could include a data character, idle character, or break character), although the transmitter does not start transmitting another character.

#### 73.3.4.1 Break character length

CTRL[SBK] sends break characters, originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 9-bit to 12-bit times, including the start and stop bits. You can enable a longer break of 13-bit times by writing 1 to STAT[BRK13]. Normally, a program waits for STAT[TDRE] to become 1 to indicate that the last character of a message has moved to the transmit shifter. Next, the program writes 1 and then writes 0 to CTRL[SBK]. This action queues a break character to be sent as soon as the shifter is available. If CTRL[SBK] remains 1 when the queued break moves into the shifter, synchronized with the baud rate clock, an additional break character is queued. When LPUART is the receiving module, it receives a break character as 0s in all data bits and a framing error (STAT[FE] = 1) is detected.

You can also transmit a break character by writing to Data (DATA) with DATA[FRETSC] = 1 and the data bits clear. This supports transmitting the break character as part of the normal data stream and also allows DMA to transmit a break character.

When idle line wake-up is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program waits for STAT[TDRE] to become 1 to indicate that the last character of a message has moved to the transmit shifter. Next, write 0 and then write 1 to CTRL[TE]. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while CTRL[TE] becomes 0, the LPUART transmitter does not release control of the TXD pin.

You can also write to Data (DATA) to transmit an idle character, with DATA[FRETSC] and DATA[R9T9] = 1 and the values of all the other fields = 0. This supports transmitting the idle character as part of the normal data stream and also allows DMA to transmit an idle character.

As shown in the following table, STAT[BRK13], CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS] affect the length of the break character.

**Table 544. Break character length**

| STAT[BRK13] | CTRL[M] | BAUD[M10] | CTRL[M7] | BAUD[SBNS] | Break character length (in bit times) |
|---|---|---|---|---|---|
| 0 | 0 | 0 | 0 | 0 | 10 |
| 0 | 0 | 0 | 0 | 1 | 11 |
| 0 | 0 | 0 | 1 | 0 | 9 |
| 0 | 0 | 0 | 1 | 1 | 10 |
| 0 | 1 | 0 | — | 0 | 11 |
| 0 | 1 | 0 | — | 1 | 12 |
| 0 | — | 1 | — | 0 | 12 |
| 0 | — | 1 | — | 1 | 13 |
| 1 | 0 | 0 | 0 | 0 | 13 |

*Table continues on the next page...*

Table 544. Break character length (continued)

| STAT[BRK13] | CTRL[M] | BAUD[M10] | CTRL[M7] | BAUD[SBNS] | Break character length (in bit times) |
|---|---|---|---|---|---|
| 1 | 0 | 0 | 0 | 1 | 13 |
| 1 | 0 | 0 | 1 | 0 | 12 |
| 1 | 0 | 0 | 1 | 1 | 12 |
| 1 | 1 | 0 | — | 0 | 14 |
| 1 | 1 | 0 | — | 1 | 14 |
| 1 | — | 1 | — | 0 | 15 |
| 1 | — | 1 | — | 1 | 15 |

#### 73.3.4.2 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS_B. If the CTS operation is enabled, the character is transmitted when CTS_B is asserted. If CTS_B is deasserted in the middle of a transmission with characters remaining in the transmitter FIFO, the character in the transmit shift register is complete. Any characters in the FIFO wait for CTS_B to assert again, and TXD remains in the mark state (idle state) until CTS_B is reasserted. The CTS_B pin must assert for longer than one bit period to guarantee that a new transmission is started when the transmitter is idle with CTS.

If the CTS operation is disabled, the transmitter ignores the state of CTS_B.

The transmitter's CTS_B signal can be enabled even if the same LPUART receiver's RTS_B signal is disabled.

#### 73.3.4.3 Transceiver driver enable

The transmitter can use RTS_B as an enable signal for the driver of an external transceiver. See Transceiver driver enable using RTS_B for details. If the RTS operation is enabled, when a character is placed into an empty transmit shift register, RTS_B asserts 1-bit time before the start bit is transmitted. RTS_B remains asserted for the whole time that the transmit shift register has any characters. RTS_B deasserts 1-bit time after all characters in the transmit FIFO and shift register are completely sent, including the last stop bit. In other words, when RTS_B is used as a transceiver enable, RTS_B asserts 1-bit time before the transmitter starts transmitting and negates 1-bit time after the transmitter goes idle.

Transmitting a break character also asserts RTS_B, with the same assertion and deassertion timing as having a character in the transmit shift register.

The transmitter's RTS_B signal asserts only when the transmitter is enabled. However, the transmitter's RTS_B signal is unaffected by its CTS_B signal. RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled mid-way through a data transfer.

#### 73.3.4.4 Transceiver driver enable using RTS_B

RS-485 is a multiple drop communication protocol in which the LPUART transceiver's driver is three-stated unless LPUART is driving. The transmitter can use the RTS_B signal to enable the driver of a transceiver. The polarity of RTS_B can be matched to the polarity of the transceiver's driver enable signal.

The following figure shows the receiver enable signal asserted. This connection can also connect RTS_B to both DE and RE_B. The transceiver's receiver is disabled when driving. A pullup can pull RXD to a nonfloating value during this time. You can refine this option further by operating LPUART in Single-Wire mode, freeing the RXD pin for other uses.

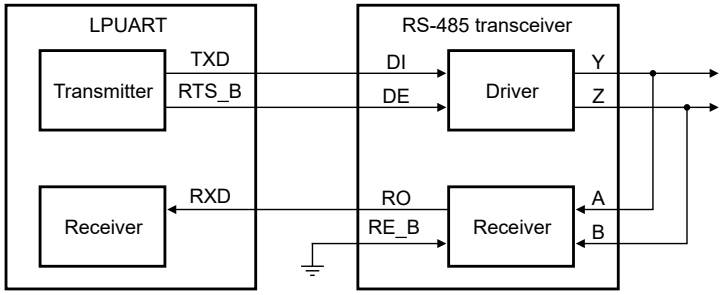

Figure 426. Transceiver driver enable using RTS_B

## 73.3.5 Receiver functional description

This section discusses the functioning of the LPUART receiver, as shown in the receiver portion of Block diagram. The section also discusses:

- The data sampling technique used to reconstruct receiver data.
- Different variations of the receiver wake-up function.

You can invert the receiver input by writing 1 to STAT[RXINV] and enable the receiver by writing 1 to CTRL[RE]. Character frames consist of a start bit of logic 0, along with N (7, 8, 9, 10) bits (MSB or LSB first), and one or two stop bits of logic 1. For information about 7-bit, 9-bit, or 10-bit Data mode, see Data modes. Going forward in this discussion, assume that LPUART is configured for a normal 8-bit Data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full (STAT[RDRF] = 0), the data character is transferred to the receive FIFO, resulting in STAT[RDRF] becoming 1. However, if STAT[RDRF] is already 1, indicating that the receive data buffer is already full, STAT[OR] becomes 1 and the new data is lost.

Because the LPUART receiver is separate from the receive FIFO, the receive shift register can receive the next word when the receive FIFO is full, and it is only at the end of the character that the next data is written into the receive FIFO, potentially triggering the overrun flag if the FIFO is full.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the FIFO by reading Data (DATA). See Interrupts for details about flag clearing.

### 73.3.5.1 Data sampling technique

The LPUART receiver supports a configurable oversampling rate of between 4× and 32× of the baud rate clock for sampling. The receiver starts by considering logic level samples at the oversampling rate times the baud rate to search for a falling edge on the RXD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The oversampling baud rate clock divides the bit time into 4 to 32 segments from 1 to OSR (where OSR is the configured oversampling ratio). When a falling edge is located, three more samples are taken at (OSR ÷ 2), (OSR ÷ 2) + 1, and (OSR ÷ 2) + 2 to ensure that this is a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes they are synchronized to a received character. If another falling edge is detected before the receiver is considered synchronized, the receiver restarts sampling from the first segment.

The receiver then samples each bit time, including the start and stop bits, at (OSR ÷ 2), (OSR ÷ 2) + 1, and (OSR ÷ 2) + 2, to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. If any sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, noise flag (STAT[NF]) becomes 1 when the received character is transferred to the receive FIFO.

When the LPUART receiver is configured to sample on both edges of the baud rate clock (that is, when BAUD[BOTHEDGE] = 1), the number of segments in each received bit is effectively doubled (from 1 to OSR× 2). The start and data bits are then sampled at OSR, OSR + 1, and OSR + 2. You must enable sampling on both edges of the clock for oversampling rates of 4× to 7×. This sampling is optional for higher oversampling rates.

The synchronization feature of LPUART synchronizes the internal oversampling counter with a detected falling edge on the receive signal, and to adjust the data sampling window. The falling edge detection needs three consecutive 1s prior to the "1->0" (one to zero) transition. After the initial falling edge detection for the start bit, the circuit continuously monitors the next falling edge, and resets the counter after another falling edge is detected. This synchronization to the start bit is termed as resynchronization.

When BAUD[RESYNCDIS] is 0, you perform this falling edge detection and resynchronization not only for the start bit but also for the rest of the character reception after the start bit.

When BAUD[RESYNCDIS] is 1, you perform the falling edge detection and resynchronization only for the start bit. The use case for disabling the resynchronization is protocols that require this (for example, LIN 2.1 prohibits resynchronization within a byte).

The following table and figure explain LPUART resynchronization.

**Table 545. LPUART resynchronization settings**

| Resynchronization | BAUD[RESYNCDIS] = 0 | BAUD[RESYNCDIS] = 1 |
|---|---|---|
| For the starting bit falling edge | Yes | Yes |
| For all falling edges after the start bit | Yes | No |

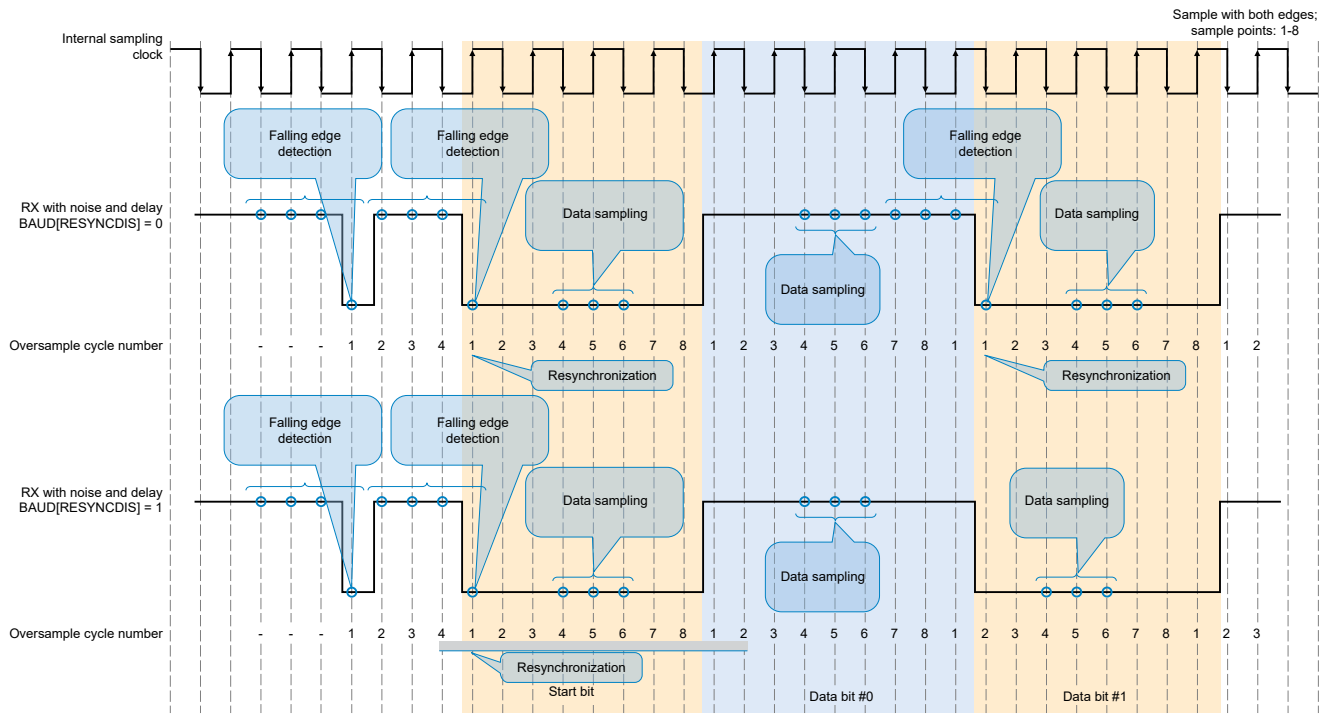

**Figure 427. LPUART resynchronization diagram**

### 73.3.5.2 Receiver wake-up operation

Receiver wake-up and receiver address matching are hardware mechanisms that allow an LPUART receiver to ignore the characters in a message intended for a different receiver.

During receiver wake-up, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write 1 to CTRL[RWU].

When CTRL[RWU] and STAT[RWUID] are 1, the status fields associated with the receiver, with the exception of STAT[IDLE], are inhibited from becoming 1, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, all receivers automatically force CTRL[RWU] to become 0. This results in all receivers waking up in time to look at the first character(s) of the next message.

During receiver address matching, the address matching is performed in hardware and the LPUART receiver ignores all characters that do not meet the address match requirements.

Table 546. Receiver wake-up options

| CTRL[RWU] | BAUD[MAEN1] \| BAUD[MAEN2] | BAUD[MATCFG] | CTRL[WAKE]: STAT[RWUID] | Receiver wake-up |
|---|---|---|---|---|
| 0 | 0 | X | X | Normal operation |
| 1 | 0 | 00 | 00 | Receiver wake-up on idle line; STAT[IDLE] = 0 |
| 1 | 0 | 00 | 01 | Receiver wake-up on idle line; STAT[IDLE] = 1 |
| 1 | 0 | 00 | 10 | Receiver wake-up on address mark |
| 1 | 1 | 11 | 10 | Receiver wake-up on data match |
| 0 | 1 | 00 | X0 | Address mark address match; STAT[IDLE] = 0 for discarded characters |
| 0 | 1 | 00 | X1 | Address mark address match; STAT[IDLE] = 1 for discarded characters |
| 0 | 1 | 01 | X0 | Idle line address match |
| 0 | 1 | 10 | X0 | Match on and match off; STAT[IDLE] = 0 for discarded characters |
| 0 | 1 | 10 | X1 | Match on and match off; STAT[IDLE] = 1 for discarded characters |

#### 73.3.5.2.1 Idle line wake-up

When CTRL[WAKE] is 0, you can configure the receiver for an idle line wake-up. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a full character time of the idle-line level.

CTRL[M], CTRL[M7], and BAUD[M10] select 7-bit to 10-bit Data mode and BAUD[SBNS] selects a 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 9 to 13 bit times because of the start and stop bits.

When CTRL[RWU] is 1 and STAT[RWUID] is 0, the idle condition that wakes up the receiver does not lead to STAT[IDLE] becoming 1. The receiver wakes up and waits for the first data character of the next message that leads to STAT[RDRF] becoming 1 and generates an interrupt if enabled. When STAT[RWUID] is 1, any idle condition leads to STAT[IDLE] becoming 1 and generates an interrupt if enabled, regardless of whether CTRL[RWU] is 0 or 1.

These are the ways to detect an idle line:

- When CTRL[ILT] is 0, the idle bit counter starts after the start bit so that the stop bit and any logic 1s at the end of a character count to calculate the full character time of idle.
- When CTRL[ILT] is 1, the idle bit counter does not start until after the stop bit time so that the data in the last character of the previous message does not impact the idle detection.

#### 73.3.5.2.2 Address mark wake-up

When CTRL[WAKE] is 1, you can configure the receiver for an address mark wake-up. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a logic 1 in the most significant bit of the received character. When parity is enabled, the second most significant bit is used for address mark wake-up.

Address mark wake-up allows messages to contain idle characters, but requires one bit to be reserved for use in address frames. The logic 1 in the most significant bit (or second most significant bit when parity is enabled) of an address frame writes 0 to CTRL[RWU] and writes 1 to STAT[RDRF]. In this case, the character with the address mark bit is received even if the receiver is sleeping during most of this character time.

#### 73.3.5.2.3 Data match wake-up

When CTRL[RWU] and CTRL[WAKE] are 1, and BAUD[MATCFG] equals 11, the receiver is configured for a data match wake-up. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a character that matches MATCH[MA1] when BAUD[MAEN1] is 1, or that matches MATCH[MA2] when BAUD[MAEN2] is 1.

#### 73.3.5.2.4 Address match operation

You can enable the address match operation when either BAUD[MAEN1] or BAUD[MAEN2] is 1 and BAUD[MATCFG] is 0. In this function, a character that the RXD pin receives with a logic 1 in the most significant bit (or the second most significant bit when parity is enabled) is considered an address and is compared to the associated MATCH[MA1] or MATCH[MA2]. The character is only transferred to the receive buffer, and STAT[RDRF] becomes 1 if the comparison matches. All subsequent characters received with a logic 0 in the most significant bit (or the second most significant bit when parity is enabled) are considered to be data associated with the address and are transferred to the receive FIFO. If no marked address match occurs, no transfer is made to the receive FIFO, and all the characters that follow, with logic 0 in the most significant bit (or second most significant bit when parity is enabled), are also discarded. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

The address match operation functions in the same way for both MATCH[MA1] and MATCH[MA2]:

- If either BAUD[MAEN1] or BAUD[MAEN2] is 1, a marked address is compared only to the associated Match Address (MATCH) and data is transferred to the receive FIFO only on a match.
- If both BAUD[MAEN1] and BAUD[MAEN2] are 1, a marked address is compared to both MATCH[MA1] and MATCH[MA2] and data is transferred only on a match with either of these fields.

#### 73.3.5.2.5 Idle match operation

You can enable the idle match operation when either BAUD[MAEN1] or BAUD[MAEN2] is 1 and BAUD[MATCFG] is 1. In this function, the first character that the RXD pin receives after an idle line condition is considered an address and is compared to the associated MATCH[MA1] or MATCH[MA2]. The character is transferred only to the receive buffer, and STAT[RDRF] becomes 1, if the comparison matches. All subsequent characters are considered to be data associated with the address and are transferred to the receive FIFO until the next idle line condition is detected. If no address match occurs, no transfer is made to the receive FIFO, and all the frames that follow, until the next idle condition, are also discarded. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

An idle match operation functions in the same way for both MATCH[MA1] and MATCH[MA2]:

- If either BAUD[MAEN1] or BAUD[MAEN2] is 1, the first character after an idle line is compared only to the associated Data (DATA) and data is transferred to the receive FIFO only on a match.

- If both BAUD[MAEN1] and BAUD[MAEN2] are 1, the first character after an idle line is compared to both MATCH[MA1] and MATCH[MA2] and data is transferred only on a match with either of these fields.

#### 73.3.5.2.6 Match on, match off operation

The match on, match off operation is enabled when both BAUD[MAEN1] and BAUD[MAEN2] are 1 and BAUD[MATCFG] = 10. In this function, a character that the RXD pin receives matches MATCH[MA1] and is transferred to the receive buffer, and STAT[RDRF] becomes 1. All subsequent characters are considered to be data and are also transferred to the receive FIFO, until a character that matches MATCH[MA2] is received. The character that matches MATCH[MA2], along with all subsequent characters, is discarded; and this continues until another character that matches MATCH[MA1] is received. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

**NOTE**

The match on, match off operation requires both BAUD[MAEN1] and BAUD[MAEN2] to be 1.

### 73.3.5.3 Hardware flow control

To support hardware flow control, you can program the receiver to automatically assert and deassert RTS_B:

- RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See Transceiver driver enable using RTS_B for more information.
- If the receiver RTS functionality is enabled, the receiver automatically deasserts RTS_B if STAT[RDRF] is 1 or a start bit is detected that causes STAT[RDRF] to become 1.
- The receiver asserts RTS_B when STAT[RDRF] is 0 and has not detected a start bit that causes STAT[RDRF] to become 1. There is no impact if STAT[RDRF] is 1 already.
- Even if RTS_B is deasserted, the receiver continues to receive characters until the receive FIFO is overrun.
- If the receiver RTS functionality is disabled, the receiver's RTS_B remains deasserted.
- When RTS is driven by receiver, it will be negated when the receiver is disabled irrespective of the FIFO level.

## 73.3.6 Additional LPUART functions

### 73.3.6.1 Data modes

You can configure the LPUART transmitter and receiver to operate in 7-bit Data mode by writing 1 to CTRL[M7], 9-bit Data mode by writing 1 to CTRL[M], or 10-bit Data mode by writing 1 to BAUD[M10]. In 9-bit Data mode, there exists a ninth data bit and in 10-bit mode, there exists a tenth data bit.

When performing 8-bit writes to the transmit FIFO, the ninth and tenth bits are pushed into the FIFO from CTRL[T8] and CTRL[T9]. For coherent 8-bit writes, you must write to CTRL[T8] and CTRL[T9] before writing to Data (DATA)[7:0]. However, if the values in CTRL[T8] or CTRL[T9] do not need to change, it is not necessary to update CTRL[T8] and CTRL[T9] before every 8-bit write to Data (DATA).

When performing 16-bit or 32-bit writes to the transmit FIFO, all 10 bits are pushed into the transmit FIFO from the write data.

When performing 8-bit reads of the receive FIFO, the ninth and tenth bits are held in CTRL[R8] and CTRL[R9] but you must read them before reading Data (DATA). A 16-bit or 32-bit read of the receive FIFO returns all 10 bits in Data (DATA).

The 9-bit Data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with the address mark wake-up so that the ninth data bit can serve as the wake-up bit. The 10-bit Data mode is typically used with parity and address mark wake-up so that the ninth data bit can serve as the wake-up bit and the tenth bit can serve as the parity bit. In custom protocols, the ninth and/or tenth bits can also serve as software-controlled markers.

#### 73.3.6.2 Idle length

An idle character is one where the start bit, all data bits, and stop bits are in the mark position (idle state, generally logic 1). You can configure CTRL[ILT] to start detecting an idle character from the previous start bit (any data bits and stop bits count for idle character detection) or from the previous stop bit.

You can also use CTRL[IDLECFG] to configure the number of idle characters that must be received before an idle line condition is detected. This field configures the number of idle characters that must be received before STAT[IDLE] becomes 1, STAT[RAF] becomes 0, and DATA[IDLINE] becomes 1 with the next received character.

CTRL[IDLECFG] also affects the idle line wake-up and idle match operations. When either the address match or match on/off operation is enabled, writing 1 to STAT[RWUID] causes any discarded characters to be treated as idle characters.

#### 73.3.6.3 Loop mode

Enable Loop mode by setting CTRL[LOOPS] = 1 and CTRL[RSRC] = 0. You, sometimes, use Loop mode to check software, independent of connections in the external system, to help isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and LPUART does not use the RXD pin.

#### 73.3.6.4 Single-Wire mode

Enable Single-Wire mode by setting CTRL[LOOPS] = 1 and CTRL[RSRC] = 1. Single-Wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and TXD pin (the RXD pin is not used).

In Single-Wire mode, CTRL[TXDIR] controls the direction of serial data on the TXD pin. When CTRL[TXDIR] becomes 0, the TXD pin is an input to the receiver and the transmitter is temporarily disconnected from the TXD pin so that an external device can send serial data to the receiver. When CTRL[TXDIR] = 1, the TXD pin is an output that the transmitter drives. The internal loop back connection is disabled, and as a result, the receiver is unable to receive characters that the transmitter sends out.

### 73.3.7 Peripheral triggers

The connection of the LPUART peripheral triggers with other peripherals is chip-specific.

#### 73.3.7.1 Output triggers

LPUART generates the following output triggers that can be connected to other peripherals on the chip:

- The transmit word trigger asserts at the end of each transmitted word and negates after 1-bit period.
- The transmit data trigger is identical to the TXD pin output, but without support for input trigger modulation.
- The receive word trigger asserts at the end of each received word that is written to the receive FIFO, for one oversampling clock period.
- The receive idle trigger asserts when STAT[IDLE] becomes 1, for one oversampling clock period.

#### 73.3.7.2 Input trigger

LPUART supports a peripheral input trigger that you can configure in one of the following ways:

- By enabling the CTS function: You can connect the input trigger instead of the CTS_B pin input. The input trigger must assert for longer than 1-bit clock period when the transmitter is idle, with data to send, to guarantee a new transmission.
- By making the input trigger modulate the transmit data output (trigger is logically ANDed with the TXD output): The input trigger is expected to be a free-running clock (carrier signal) that generates from a timer or PWM source with a frequency that is greater than the bit-clock frequency. The carrier signal must not toggle faster than the maximum supported bit time.
- By connecting the input trigger instead of the RXD pin input: The input trigger is expected to be generated from a receive data source, such as an analog comparator or external pin.

### 73.3.8 Infrared (IR) interface

LPUART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses, transforming them to serial bits, which are then sent to LPUART. The IrDA physical layer specification defines a half-duplex IR communication link for exchanging data. The full standard includes data rates up to 16 Mbit/s. The LPUART IrDA support is limited to SIR mode that supports data rates only between 2.4 kbit/s and 115.2 kbit/s.

LPUART has an infrared transmit encoder and a receive decoder. The infrared decoder converts the received character from the IrDA format to the NRZ format, which the receiver uses. It also has an OSR oversampling baud rate clock counter that filters noise and indicates when a 1 is received. LPUART transmits serial bits of data, which the infrared submodule encodes, to transmit a narrow pulse for every zero bit. No pulse is transmitted for every single bit. When receiving data, an IR photo diode (external to LPUART) detects the IR pulses. The IR receive decoder transforms them to CMOS levels. The infrared receive decoder then stretches the narrow pulses to get back to a serial bit stream that LPUART receives. You can invert the polarity of transmitted pulses and expected receive pulses so that a direct connection can be made to external IrDA transceiver modules that use active-high pulses.

The IR submodule receives its clock sources from LPUART. The submodule selects one of these clocks to generate either 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR narrow pulses during transmission.

#### 73.3.8.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from the transmit shift register to the TXD signal. A narrow pulse is transmitted for a 0 bit and no pulse is transmitted for a 1 bit. The narrow pulse is sent at the start of the bit with a duration of 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR of a bit time. A narrow low pulse is transmitted for a 0 bit when CTRL[TXINV] is 0, while a narrow high pulse is transmitted for a 0 bit when CTRL[TXINV] is 1.

#### 73.3.8.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each 0 received and no pulse is expected for each 1 received. A narrow low pulse is expected for a 0 bit when STAT[RXINV] is 0, while a narrow high pulse is expected for a 0 bit when STAT[RXINV] is 1. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

#### 73.3.8.3 Start-bit detection

When STAT[RXINV] is 0, the first falling edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently of each other.

#### 73.3.8.4 Noise filtering

The decoder ignores any rising edges detected during the first half of the infrared decoder counter, and can leave any pulses less than one oversampling baud clock as undetected. This is regardless of whether the pulse is seen in the first or second half of the count.

#### 73.3.8.5 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as 0, which is sent to the receiver. The decoder counter is also reset.

#### 73.3.8.6 High-bit detection

At OSR oversampling baud rate clocks after the previous rising edge, if a rising edge is not seen, the decoder sends a 1 to the receiver.

If the next bit is 0, which arrives late, a low bit is detected according to Low-bit detection. The value sent to the receiver is changed from 1 to 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, the delay of a 0 is not recorded as noise.

## 73.3.9 Modes of operation

### 73.3.9.1 Low-Power modes

LPUART remains functional during low-power modes, provided CTRL[DOZEEN] is 0 and the LPUART functional clock is enabled. LPUART can generate an interrupt or DMA request to cause a wake-up from low-power modes.

You can configure LPUART to be disabled in low-power modes, when CTRL[DOZEEN] is 1. In this case, the transmitter and receiver finish transmitting and receiving the current word.

If LPUART is disabled in low-power modes, it can generate a wake-up via STAT[RXEDGIF] if the receiver detects an active edge.

**NOTE**

See the chip-specific information for specific low-power modes available on your chip.

### 73.3.9.2 Debug mode

LPUART remains functional in Debug mode.

## 73.3.10 Clocking

**Table 547. Types of clocks**

| Clock | Description |
|---|---|
| Functional | Is asynchronous to the bus clock and can remain enabled in Low-Power modes to support transmit and/or receive functions, including low-power wake-up. |
| Bus | Is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPUART transmit and receive registers, including the FIFOs. |

## 73.3.11 Reset

**Table 548. Types of resets**

| Reset | Description |
|---|---|
| Chip | Enables the logic and registers for the LPUART transmitter and receiver to reset to their default states. |
| Software | Resets the LPUART logic and registers to their default states, except for Global (GLOBAL).<br>GLOBAL[RST] controls the LPUART software reset. |
| FIFO | Implements write-only control fields that reset the transmit FIFO (FIFO[TXFLUSH]) and receive FIFO (FIFO[RXFLUSH]). After a FIFO is reset, that FIFO becomes empty. |

## 73.3.12 Interrupts

The LPUART transmitter has two status fields that can optionally generate hardware interrupt requests. If STAT[TDRE] is 1, it indicates that there is room in the transmit FIFO to write another transmit character to Data (DATA). If CTRL[TIE] is 1, a hardware interrupt is requested when STAT[TDRE] is 1.

STAT[TC] indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TXD at the inactive level. This field is often used in systems with modems to determine when it is safe to turn off the modem. If CTRL[TCIE] is 1, a hardware interrupt is requested when STAT[TC] is 1. Instead of hardware interrupts, software polling may be used to monitor STAT[TDRE] and STAT[TC] if the corresponding CTRL[TIE] or CTRL[TCIE] field is 0.

When a program detects that STAT[RDRF] is 1, it gets the data from this field by reading Data (DATA). The field becomes 0 by reading Data (DATA).

STAT[IDLE] includes logic that prevents it from becoming 1 repeatedly when the RXD line remains idle for an extended period of time. STAT[IDLE] becomes 0 when you write 1 to it, and cannot become 1 again until the receiver has received at least one new character and has 1 as the value of STAT[RDRF].

If the associated error is detected in the received character that caused STAT[RDRF] to become 1, STAT[NF], STAT[FE], and STAT[PF] become 1 at the same time STAT[RDRF] becomes 1. These flags do not become 1 in overrun cases.

If STAT[RDRF] is already 1 when a new character is ready to be transferred from the receive shifter to the receive FIFO, STAT[OR] becomes 1, instead of the data along with any associated STAT[NF], STAT[FE], or STAT[PF] condition getting lost.

If the received character matches the contents of MATCH[MA1] and/or MATCH[MA2], then STAT[MA1F] and/or STAT[MA2F] become 1 at the same time that STAT[RDRF] becomes 1.

At any time, an active edge on the RXD serial data input pin causes STAT[RXEDGIF] to become 1. STAT[RXEDGIF] becomes 0 when you write 1 to it. This function depends on the receiver being enabled (the value of CTRL[RE] being 1).

## 73.4 External signals

**Table 549. External signals**

| Signal | Description | I/O |
|---|---|---|
| TXD | Transmit data: This pin is normally an output, but is an input (tristated) in Single-Wire mode whenever the transmitter is disabled or the transmit direction is configured for receive data. | I/O |
| RXD | Receive data | I |
| CTS_B | Clear-to-send | I |
| RTS_B | Request-to-send | O |

## 73.5 Initialization

This module does not require initialization.

## 73.6 LPUART register descriptions

LPUART includes registers to control baud rate, select options, report status, and store transmit and receive data. Access to an address outside the valid memory map generates a bus error.

**NOTE**

Writing to a read-only (RO) register or reading a write-only (WO) register can cause bus errors. LPUART does not verify whether programmed values in the registers are correct; you must write valid values to them.

### 73.6.1 LPUART memory map

LPUART_0 base address: 4032_8000h

LPUART_1 base address: 4032_C000h

LPUART_2 base address: 4033_0000h

LPUART_3 base address: 4033_4000h

LPUART_4 base address: 4033_8000h

LPUART_5 base address: 4033_C000h

LPUART_6 base address: 4034_0000h

LPUART_7 base address: 4034_4000h

LPUART_8 base address: 4048_C000h

LPUART_9 base address: 4049_0000h

LPUART_10 base address: 4049_4000h

LPUART_11 base address: 4049_8000h

LPUART_12 base address: 4049_C000h

LPUART_13 base address: 404A_0000h

LPUART_14 base address: 404A_4000h

LPUART_15 base address: 404A_8000h

You must change the value of this field only when the receiver is disabled.<br>If this field is 0, during the Receive Standby state (CTRL[RWU] = 1), STAT[IDLE] does not become 1 upon detection of an idle character. During address match wake-up, STAT[IDLE] does not become 1 when an address does not match.<br>If this field is 1, during the Receive Standby state (CTRL[RWU] = 1), STAT[IDLE] becomes 1 upon detection of an idle character. During address match wake-up, STAT[IDLE] becomes 1 when an address does not match.<br>0b - STAT[IDLE] does not become 1<br>1b - STAT[IDLE] becomes 1 |
| 26<br>BRK13 | Break Character Generation Length<br>Selects the longer transmitted break character length. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | The state of this field does not affect the detection of a framing error. You must change the value of this field only when the transmitter is disabled. You can send a break character by writing 1 to CTRL[SBK], or by writing the transmit FIFO when DATA[FRETSC] is 1 and DATA[R9T9] is 0.<br>0b - 9 to 13 bit times<br>1b - 12 to 15 bit times |
| 25<br>LBKDE | LIN Break Detection Enable<br>Enables LIN break detection.<br>If this field is 0, LIN break detect is disabled, and only a normal break character can be detected.<br>If this field is 1, LIN break detect is enabled and the LIN break character is detected at a length of 11 bit times (if CTRL[M] is 0), 12 bit times (if CTRL[M] is 1), or 13 bit times (if BAUD[M10] is 1).<br>This field selects a longer break character detection length. When the field is 1, receive data is not stored in the receive FIFO.<br>**NOTE**<br>This field enables the LIN break detect circuit and disables writing receive data to FIFO. Therefore, it ignores all characters except a LIN break.<br>0b - Disable<br>1b - Enable |
| 24<br>RAF | Receiver Active Flag<br>Indicates whether the LPUART receiver is idle or active.<br>This field becomes 1 when the receiver detects the beginning of a valid start bit, and the field becomes 0 automatically when the receiver detects an idle line.<br>0b - Idle, waiting for a start bit<br>1b - Receiver active (RXD pin input not idle) |
| 23<br>TDRE | Transmit Data Register Empty Flag<br>Indicates whether the transmit FIFO level is greater than, equal to, or less than the watermark.<br>After the transmit FIFO is enabled, this field becomes 1 when the number of datawords in the transmit FIFO is equal to, or less than the number that WATER[TXWATER] indicates. To make the value of this field 0, write to it until the number of words in the transmit FIFO is greater than the number that WATER[TXWATER] indicates. After the transmit FIFO is disabled, this field becomes 1 to indicate that the FIFO level is less than the watermark. To make the value of this field 0 again, write to Data (DATA).<br>This register is not affected by a character that is in the process of being transmitted; it is updated at the start of each transmitted character.<br>0b - Greater than watermark<br>1b - Equal to or less than watermark |
| 22 | Transmission Complete Flag<br>Indicates whether the transmitter is active. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| TC | This field becomes 0 when a transmission is in progress or a preamble or break character is loaded; in other words, when the transmitter is active (sending data, a preamble, or a break). The field becomes 1 when the transmit buffer is empty and no data, preamble, or break character is being transmitted; in other words, when the transmission activity is complete. When this happens, the transmit data output signal becomes idle (logic 1). This field becomes 0 after you write to Data (DATA) to transmit new data, queuing a preamble by first writing 0 and then writing 1 to CTRL[TE], queuing a break character by writing 1 to CTRL[SBK].<br>0b - Transmitter active<br>1b - Transmitter idle |
| 21<br>RDRF | Receive Data Register Full Flag<br>Indicates whether the receive FIFO level is less than, equal to, or greater than the watermark.<br>This field becomes 1 when the number of datawords in the receive buffer is greater than the number that WATER[RXWATER] indicates and the receive FIFO is enabled. To write 0 to this field, read Data (DATA) until the number of datawords in the receive FIFO is equal to, or less than the number that WATER[RXWATER] indicates. When the receive FIFO is disabled, this field (RDRF) becomes 1 if the receive buffer (Data (DATA)) is full. To make this field 0, read Data (DATA).<br>A character that is in the process of being received does not cause a change in this field until the entire character is received. Even if this field is 1, the character continues to be received until an overrun condition occurs after the entire character is received.<br>0b - Equal to or less than watermark<br>1b - Greater than watermark |
| 20<br>IDLE | Idle Line Flag<br>Indicates whether an idle line is detected.<br>This field becomes 1 when the LPUART receive line becomes idle for a full character time after a period of activity. When CTRL[ILT] is 0, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bit time count towards the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. After CTRL[ILT] becomes 1, the receiver does not start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count towards the full character time of logic high needed for the receiver to detect an idle line.<br>For this field to become 0, write 1 to it. After the field becomes 0, you cannot write 1 to it again until after a new character is stored in the receive buffer or a LIN break character writes 1 to STAT[LBKDIF]. This field becomes 1 only once, even if the receive line remains idle for an extended period.<br>**NOTE**<br>This field behaves differently for register reads and writes.<br>When reading<br>0b - Idle line detected<br>1b - Idle line not detected<br>When writing |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 0b - No effect<br>1b - Clear the flag |
| 19<br>OR | Receiver Overrun Flag<br>Indicates whether there is receive overrun.<br>This field becomes 1 when you cannot prevent STAT[RDRF] from overflowing with data. The field becomes 1 immediately after the stop bit is completely received for the dataword that overflows the buffer and all the other error fields (STAT[FE], STAT[NF], and STAT[PF]) are prevented from becoming 1. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If STAT[LBKDE] is enabled and a LIN break is detected, this field becomes 1 if STAT[LBKDIF] is not 0 before the next data character is received.<br>When this field is 1, no additional data is stored in the receive FIFO even if sufficient room exists.<br>**NOTE**<br>This field behaves differently for register reads and writes.<br>When reading<br>0b - No overrun<br>1b - Receive overrun (new LPUART data is lost)<br>When writing<br>0b - No effect<br>1b - Clear the flag |
| 18<br>NF | Noise Flag<br>Indicates whether noise is detected in the received character of Data (DATA).<br>The advanced sampling technique used in the receiver takes three samples in each of the received bits. If some of these samples disagree with the rest of the samples within any bit time in the frame, then noise is detected for that character. This field becomes 1 whenever the next character to be read from Data (DATA) is received with noise detected within the character.<br>**NOTE**<br>This field behaves differently for register reads and writes.<br>When reading<br>0b - No noise detected<br>1b - Noise detected<br>When writing<br>0b - No effect<br>1b - Clear the flag |
| 17<br>FE | Framing Error Flag<br>Indicates whether a framing error is detected. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | This field becomes 1 whenever the next character to be read from Data (DATA) is received with logic 0 detected where a stop bit was expected.<br>**NOTE**<br>This field behaves differently for register reads and writes.<br>When reading<br>0b - No framing error detected (this does not guarantee that the framing is correct)<br>1b - Framing error detected<br>When writing<br>0b - No effect<br>1b - Clear the flag |
| 16<br>PF | Parity Error Flag<br>Indicates whether a parity error is detected.<br>This field becomes 1 whenever the next character to be read from Data (DATA) is received when parity is enabled (CTRL[PE] is 1) and the parity bit in the received character does not agree with the expected parity value.<br>**NOTE**<br>This field behaves differently for register reads and writes.<br>When reading<br>0b - No parity error detected<br>1b - Parity error detected<br>When writing<br>0b - No effect<br>1b - Clear the flag |
| 15<br>MA1F | Match 1 Flag<br>Indicates whether the received data is equal to MATCH[MA1].<br>This field becomes 1 whenever the next character to be read from Data (DATA) matches the value of MATCH[MA1].<br>**NOTE**<br>This field behaves differently for register reads and writes.<br>When reading<br>0b - Not equal to MA1<br>1b - Equal to MA1<br>When writing |

### Fields

| Field | Function |
|---|---|
| 31<br>R8T9 | Receive Bit 8 Transmit Bit 9<br>Contains R8 and T9 that correspond to different functions. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | R8 is the ninth data bit received after you configure LPUART for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading Data (DATA).<br>T9 is the tenth data bit transmitted after you configure LPUART for 10-bit data formats. When writing 10-bit data, write T9 before writing to Data (DATA). If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, then you need not write to it each time you write to Data (DATA).<br>**NOTE**<br>R8 is a read-only bit and T9 is a write-only bit; the value read is different from the value written. |
| 30<br>R9T8 | Receive Bit 9 Transmit Bit 8<br>Contains R9 and T8 that correspond to different functions.<br>R9 is the tenth data bit received after you configure LPUART for 10-bit data formats. When reading 10-bit data, read R9 before reading Data (DATA).<br>T8 is the ninth data bit transmitted after you configure LPUART for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing to Data (DATA). If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, then you need not write to it each time you write to Data (DATA).<br>**NOTE**<br>R9 is a read-only field and T8 is a write-only field; the value read is different from the value written. |
| 29<br>TXDIR | TXD Pin Direction in Single-Wire Mode<br>Determines the direction of data at the TXD pin, in Single-Wire mode, when LPUART is configured for a single-wire half-duplex operation (CTRL[LOOPS] and CTRL[RSRC] are 1). When writing 0 to this field, the transmitter finishes transmitting the current character (if any) before the receiver starts receiving data from the TXD pin.<br>0b - Input<br>1b - Output |
| 28<br>TXINV | Transmit Data Inversion<br>Specifies whether transmit data is inverted.<br>Writing 1 to this field reverses the polarity of the transmitted data output. This action inverts the TXD output for all cases: data bits, start and stop bits, break, and idle.<br>0b - Not inverted<br>1b - Inverted |
| 27<br>ORIE | Overrun Interrupt Enable<br>Enables STAT[OR] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when OR interrupts are disabled. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 0b - Disable<br>1b - Enable |
| 26<br>NEIE | Noise Error Interrupt Enable<br>Enables STAT[NF] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when NF interrupts are disabled.<br>0b - Disable<br>1b - Enable |
| 25<br>FEIE | Framing Error Interrupt Enable<br>Enables STAT[FE] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when FE interrupts are disabled.<br>0b - Disable<br>1b - Enable |
| 24<br>PEIE | Parity Error Interrupt Enable<br>Enables STAT[PF] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when PF interrupts are disabled.<br>0b - Disable<br>1b - Enable |
| 23<br>TIE | Transmit Interrupt Enable<br>Enables STAT[TDRE] to generate interrupt requests if STAT[TDRE] is 1.<br>0b - Disable<br>1b - Enable |
| 22<br>TCIE | Transmission Complete Interrupt Enable<br>Enables STAT[TC] to generate interrupt requests if STAT[TC] is 1.<br>0b - Disable<br>1b - Enable |
| 21<br>RIE | Receiver Interrupt Enable<br>Enables STAT[RDRF] to generate hardware interrupt requests if STAT[RDRF] is 1.<br>0b - Disable<br>1b - Enable |
| 20<br>ILIE | Idle Line Interrupt Enable<br>Enables hardware interrupts.<br>This field enables STAT[IDLE] to generate interrupt requests. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | If this field is 0, hardware interrupts from STAT[IDLE] are disabled and polling is used, and if this field is 1, hardware interrupts are enabled when STAT[IDLE] is 1.<br>0b - Disable<br>1b - Enable |
| 19<br>TE | Transmitter Enable<br>Enables the LPUART transmitter.<br>Using this field, you can also queue an idle preamble by first writing 0 and then writing 1 to this field. After this field becomes 0, the field reads 1 until the transmitter has completed the current character and the TXD pin is tristated.<br>You can also queue a single idle character by writing to the transmit FIFO with DATA[FRETSC] and DATA[R9T9] = 1.<br>0b - Disable<br>1b - Enable |
| 18<br>RE | Receiver Enable<br>Enables the LPUART receiver.<br>After you write 0 to this field, this field remains 1 until the receiver finishes receiving the current character (if any).<br>0b - Disable<br>1b - Enable |
| 17<br>RWU | Receiver Wake-Up Control<br>Specifies whether the LPUART receiver in standby is waiting for a wake-up condition.<br>You can write 1 to this field to place the LPUART receiver in a Standby state. The field becomes 0 automatically when an RWU event occurs, that is, in case of an idle event when CTRL[WAKE] is 0 or an address match when CTRL[WAKE] is 1 and STAT[RWUID] is 0.<br>**NOTE**<br>You must write 1 to this field only when CTRL[WAKE] is 0 (wake-up on idle), if the channel is currently not idle. You can determine this by the value of STAT[RAF]. If the field is 1 to wake up an idle event and the channel is already idle, LPUART, possibly, discards the data. This is because the data must be received or a LIN break is detected after an Idle condition is detected before the IDLE flag is allowed to be reasserted.<br>0b - Normal receiver operation<br>1b - LPUART receiver in standby, waiting for a wake-up condition |
| 16<br>SBK | Send Break<br>Specifies whether queue break character(s) are to be sent.<br>Writing 1 and then 0 to this field queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if STAT[BRK13] is 1, and bit times of logic 0 are queued as long |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | as this field is 1. Depending on the timing when this field is 1 and 0, relative to the character currently being transmitted, a second break character may be queued before you write 0 to this field. If the time taken to write 0 to this field is too long, for example, if the field does not become 0 by the end of the first break character, a second break character is sent. This is compared to queuing a break character through the transmit FIFO that guarantees only one break character is sent.<br>You can also queue a single break character by writing to the transmit FIFO when DATA[FRETSC] is 1 and DATA[R9T9] is 0.<br>0b - Normal transmitter operation<br>1b - Queue break character(s) to be sent |
| 15<br>MA1IE | Match 1 (MA1F) Interrupt Enable<br>Enables the MA1F interrupt.<br>0b - Disable<br>1b - Enable |
| 14<br>MA2IE | Match 2 (MA2F) Interrupt Enable<br>Enables the MA2F interrupt.<br>0b - Disable<br>1b - Enable |
| 13<br>— | Reserved |
| 12<br>— | Reserved |
| 11<br>M7 | 7-Bit Mode Select<br>Specifies the data characters that the receiver and transmitter use.<br>You must change the value of this field only after both the transmitter and receiver are disabled.<br>0b - 8-bit to 10-bit<br>1b - 7-bit |
| 10-8<br>IDLECFG | Idle Configuration<br>Configures the number of idle characters that must be received before you write 1 to STAT[IDLE].<br>000b - 1<br>001b - 2<br>010b - 4<br>011b - 8<br>100b - 16 |

| Field | Function |
|---|---|
| | 101b - 32<br>110b - 64<br>111b - 128 |
| 7<br>LOOPS | Loop Mode Select<br>Selects Loop mode.<br>After this field becomes 1, the RXD pin is disconnected from LPUART and the transmitter output is internally connected to the receiver input. The transmitter and receiver must be enabled to use the loop function. In Loop mode or Single-Wire mode, the transmitter outputs are internally connected to the receiver input (see CTRL[RSRC]).<br>0b - Normal operation: RXD and TXD use separate pins<br>1b - Loop mode or Single-Wire mode |
| 6<br>DOZEEN | Doze Mode<br>Enables LPUART in Doze mode.<br>If this field is 1, LPUART remains active when not in Doze mode.<br>0b - Enable<br>1b - Disable |
| 5<br>RSRC | Receiver Source Select<br>Determines the source of the receiver shift register input if CTRL[LOOPS] is 1.<br>This field has no effect unless CTRL[LOOPS] is 1.<br>If this field is 0, internal Loopback mode is selected. LPUART does not use the RXD pin.<br>If this field is 1, single-wire LPUART mode is selected where the TXD pin is connected to the transmitter output and receiver input.<br>0b - Internal Loopback mode<br>1b - Single-wire mode |
| 4<br>M | 9-Bit Or 8-Bit Mode Select<br>Specifies the data characters that the receiver and transmitter use.<br>0b - 8-bit<br>1b - 9-bit |
| 3<br>WAKE | Receiver Wake-Up Method Select<br>Determines which condition wakes up LPUART when CTRL[RWU] = 1 and BAUD[MATCFG] = 0 (this field must be 1 when BAUD[MATCFG] = 11):<br>• Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | • An idle condition on the receive pin input signal<br>If this field is 0, CTRL[RWU] is configured for idle line wake-up, and if this field is 1, CTRL[RWU] is configured with address mark wake-up.<br>0b - Idle<br>1b - Mark |
| 2<br>ILT | Idle Line Type Select<br>Determines when the receiver starts counting logic 1s as idle character bits.<br>The count begins either after a valid start bit or the stop bit. If the count begins after the start bit, a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions.<br>**NOTE**<br>In case you write 1 to this field, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count.<br>0b - After the start bit<br>1b - After the stop bit |
| 1<br>PE | Parity Enable<br>Enables hardware parity generation and checking.<br>If parity is enabled, the bit immediately before the stop bit is treated as the parity bit.<br>0b - Disable<br>1b - Enable |
| 0<br>PT | Parity Type<br>Selects the type of parity, even or odd, if parity is enabled (CTRL[PE] = 1):<br>• Odd parity means that the total number of logic 1 bits in the data character, including the parity bit, is odd.<br>• Even parity means that the total number of 1s in the data character, including the parity bit, is even.<br>0b - Even parity<br>1b - Odd parity |

## 73.6.9 Data (DATA)

**Offset**

| Register | Offset |
|---|---|
| DATA | 1Ch |

### Function

Supports 8-bit, 16-bit, or 32-bit writes, each type of write performing a separate function. An 8-bit write to DATA[7:0] pushes {CTRL[R8T9], CTRL[R9T8], DATA[7:0]} the transmit FIFO with TSC clear. A 16-bit or 32-bit write pushes the data written into the FIFO and does not update the value of CTRL[R8T9] or CTRL[R9T8].

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status fields.

**NOTE**

Reads return the contents of the read-only receive FIFO and writes go to the write-only transmit FIFO, making this register work as a set of two separate registers.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15<br>NOISY | Noisy Data Received<br>Indicates whether the current received dataword contained in DATA[R9:R0] is received with noise.<br>0b - Received without noise<br>1b - Received with noise |
| 14<br>PARITYE | Parity Error<br>Indicates whether the current received dataword contained in DATA[R9:R0] is received with a parity error.<br>0b - Received without a parity error<br>1b - Received with a parity error |
| 13<br>FRETSC | Frame Error Transmit Special Character<br>Specifies the way the dataword is received. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | For reads, this field indicates that the current received dataword contained in DATA[R9:R0] is received with a frame error. For writes, the field indicates that a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 indicates a break character when it is 0 and indicates an idle character when it is 1. The contents of DATA[T8:T0] must be 0.<br>0b - Received without a frame error on reads or transmits a normal character on writes<br>1b - Received with a frame error on reads or transmits an idle or break character on writes |
| 12<br>RXEMPT | Receive Buffer Empty<br>Indicates whether the receive buffer contains valid data.<br>This field becomes 1 when there is no data in the receive buffer. The field does not consider data in the receive shift register.<br>0b - Valid data<br>1b - Invalid data and empty |
| 11<br>IDLINE | Idle Line<br>Indicates whether the receiver line was idle before receiving the character in DATA[9:0]. It can be read as “1” on the first character when the receiver is first enabled. The difference between this field and STAT[IDLE] is that, STAT[IDLE] flag does not set on an idle line after the receiver is first enabled, it needs to receive a character before it can become set, whereas this field does not have this limitation and can be set on the first character received if an idle line is detected beforehand.<br>0b - Not idle<br>1b - Idle |
| 10<br>LINBRK | LIN Break<br>Indicates whether the receiver line detected a LIN break before receiving the character in DATA[9:0]. This field requires the value of STAT[LBKDIF] to be 1. If this field is 0, the LIN break detect circuitry is disabled.<br>0b - Not detected<br>1b - Detected |
| 9<br>R9T9 | Read receive FIFO bit 9 or write transmit FIFO bit 9 |
| 8<br>R8T8 | Read receive FIFO bit 8 or write transmit FIFO bit 8 |
| 7<br>R7T7 | Read receive FIFO bit 7 or write transmit FIFO bit 7 |
| 6<br>R6T6 | Read receive FIFO bit 6 or write transmit FIFO bit 6 |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| 5<br>R5T5 | Read receive FIFO bit 5 or write transmit FIFO bit 5 |
| 4<br>R4T4 | Read receive FIFO bit 4 or write transmit FIFO bit 4 |
| 3<br>R3T3 | Read receive FIFO bit 3 or write transmit FIFO bit 3 |
| 2<br>R2T2 | Read receive FIFO bit 2 or write transmit FIFO bit 2 |
| 1<br>R1T1 | Read receive FIFO bit 1 or write transmit FIFO bit 1 |
| 0<br>R0T0 | Read receive FIFO bit 0 or write transmit FIFO bit 0 |

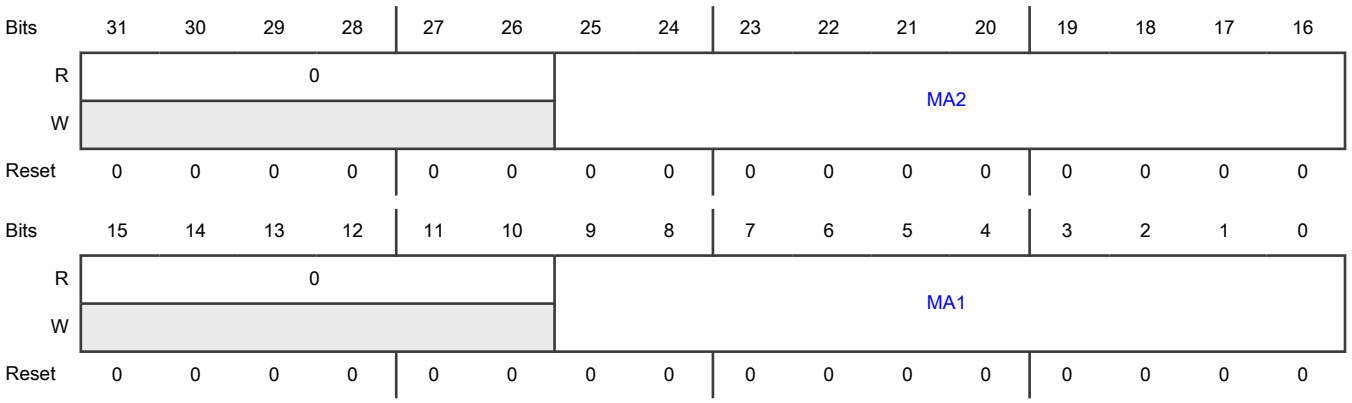
## 73.6.10 Match Address (MATCH)

### Offset

| Register | Offset |
|---|---|
| MATCH | 20h |

### Function
Provides addresses for address matching during the receiver operation.

### Diagram



### Fields

| 31-19<br>— | Reserved |
| 18<br>IREN | IR Enable<br>Enables IR modulation and demodulation.<br>You must change the value of this field only when both the transmitter and receiver are disabled.<br>0b - Disable<br>1b - Enable |
| 17-16<br>TNP | Transmitter Narrow Pulse<br>Specifies whether LPUART transmits a 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR narrow pulse when the IR pulse is enabled.<br>You must change the value of this field only when both the transmitter and receiver are disabled.<br>The IR pulse width must be configured to less than half of the OSR. Common pulse widths are 3 ÷ 16, 1 ÷ 16, 1 ÷ 32, or 1 ÷ 4 of the bit length. You can configure these by selecting the appropriate OSR and pulse width.<br>00b - 1 ÷ OSR<br>01b - 2 ÷ OSR<br>10b - 3 ÷ OSR<br>11b - 4 ÷ OSR |
| 15-10<br>— | Reserved |
| 9-8<br>RTSWATER | Receive RTS Configuration<br>Configures the assertion and negation of the receiver's RTS_B output.<br>The receiver's RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to the value of this field. If this field is 0, the RTS_B pin negates when the receive FIFO is full. For the purpose of receive RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both receive RTS_B and address or data matching is enabled, RTS_B could assert at the end of a character if there exists no match.<br>You must change the value of this field only when the receiver is disabled. |
| 7-6<br>— | Reserved |
| 5<br>TXCTSSRC | Transmit CTS Source<br>Configures the source of the CTS input.<br>0b - The CTS_B pin<br>1b - An internal connection to the receiver address match result |

*Table continues on the next page...*

## 73.6.12 FIFO (FIFO)

### Offset

| Register | Offset |
|---|---|
| FIFO | 28h |

### Function

Provides you the ability to turn on and turn off the FIFO functionality.

This register also provides you the size of the FIFO that has been implemented. You can read this register at any time and must write to it only when CTRL[RE] and CTRL[TE] are 0 and the FIFO is empty.

| 15-0<br>DATA | Receive Data<br>Indicates the first entry from the receive FIFO.<br>This register has the same functionality as that of Data (DATA). |

## 73.7 Glossary

**Baud rate** Number of bits per second that LPUART transmits or receives

| | |
|---|---|
| **Break character** | Break character is generated when the transmitter is holding the data line at the space level for at least one character time |
| **Oversampling** | Number of times the receive circuitry samples the receive input per baud period (that is, per data bit) |

# Chapter 74
# Quad Serial Peripheral Interface (QuadSPI)

## 74.1 Chip-specific QuadSPI information

### 74.1.1 QuadSPI configuration

**Table 550. QuadSPI instances**

| Instance | MCXE31B | MCXE315/ MCXE316/MCXE317 |
|---|---|---|
| QuadSPI | Yes | No |

**Table 551. QuadSPI configuration details**

| Configuration | MCXE317/ MCXE31B |
|---|---|
| QuadSPI Tx FIFO size | 32 words |
| QuadSPI Rx FIFO size | 32 words |
| Look Up Table Size | 4 words |
| AHB Buffer Size | 256 Bytes |

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to single serial flash devices, with up to four bidirectional data lines. The QuadSPI supports 4-pin Quad A interface only in SDR mode.

**NOTE**

Boot from QuadSPI is not supported but execution from external memory is supported.

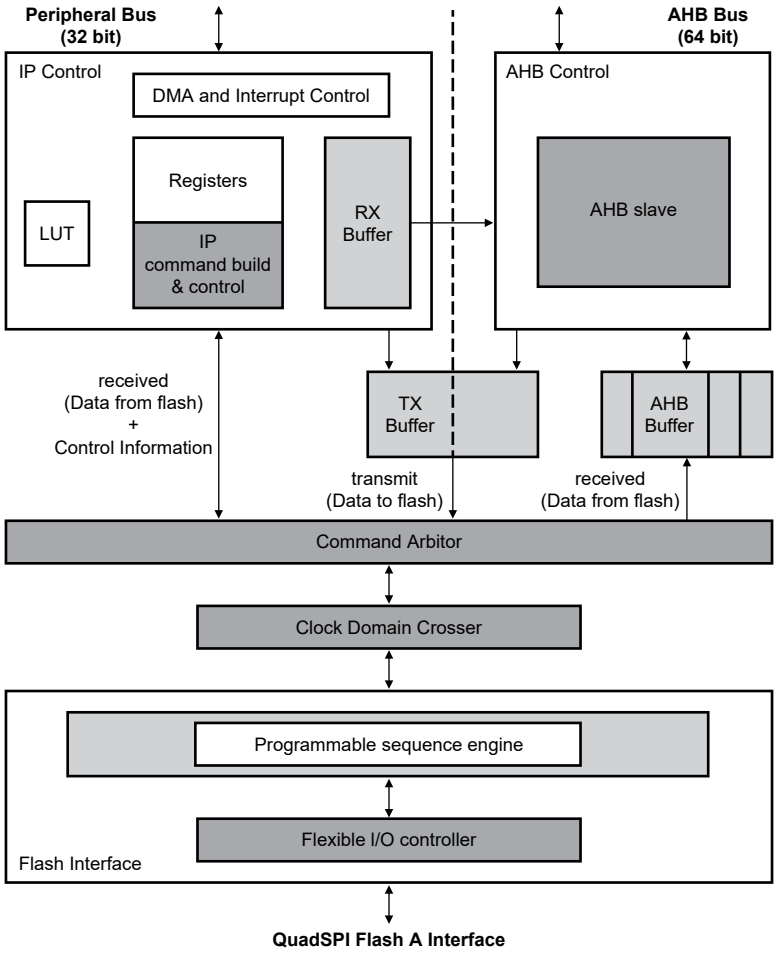

Figure 428. Block diagram

## 74.1.2 Supported read modes

The table below provides an overview of the QuadSPI read modes.

Table 552. QuadSPI read modes

| Read modes | | SDR support (QuadSPI_MCR [DDR_EN]=0) | QuadSPI_MCR [DQS_EN] | QuadSPI_MCR [DQS_FA_SEL] | DLL/Data learning support |
|---|---|---|---|---|---|
| DQS sampling method | Pad loopback | Yes | 1 | 01 | No |

## 74.1.3 QuadSPI initialization sequence

Following initialization sequence should be followed for proper QuadSPI operation:

- Enable QuadSPI module by MC_ME peripheral clock enable (register PRTNx_COFBy_CLKEN present within MC_ME). Refer MC_ME chapter for peripheral mapping.
- Configure the SIUL2 registers MSCR[OBE] as 1 and MSCR[SSS] as 0 for QuadSPI_SCKFA pin.
- Initialize QuadSPI SCKFA by writing a sequence of 1010 to the SIUL2 register GPDO[PDO_a] for QuadSPI_SCKFA pin.
- Configure the SIUL2 register MSCR[OBE] back as 0 for the pins.

- Initiate a dummy flash read to reset all DQS flops by itself and any crossing from DQS domain to IPS/AHB is taken care by CDC logic.
- Initiate a peripheral software reset to QuadSPI controller by writing to QuadSPI controller's MCR.
- Post this initialization sequence, the QuadSPI will work in intended deterministic manner.

**NOTE**

QuadSPI initialization is to be done before using QuadSPI after each functional reset.

### 74.1.4 Pad clock loopback

This chip supports pad clock loopback. The QuadSPI can be configured to use clock loopback to sample input data. SCK is delayed by the SCK pin output delay, plus the SCK pin input delay using pad loopback, and is configured by setting QuadSPI config registers SOCCR[SOCCFG] and MCR[DQS_FA_SEL]. Enabling the loopback version of SCK can inprove the setup time of the input data from the Flash.

For details of these register, see QuadSPI register descriptions.

### 74.1.5 QuadSPI SOC Configuration register SOCCR[SOCCFG] implementation

The QuadSPI SOC Configuration register QuadSPI_SOCCR[SOCCFG] register is used to control dummy loopback pads and obe_pull_timing_relax_b. Below is the description of it's bits:

**Table 553. SOCCR[SOCCFG] implementation**

| Bit | Description |
|---|---|
| Bit[0] | obe_pull_timing_relax_b : enables the timing relaxation by pulling obe for pad 1 for half cycle, if 0 then enabled else disabled. |
| Bit[1] | ibe of QSPIA_SCK_DUMMY pad. 0: Disable input reciever 1: Enable input reciever. |
| Bit[2] | obe of QSPIA_SCK_DUMMY pad. 0: Disable output driver 1: Enable output driver. |
| Bit[3] | dse of QSPIA_SCK_DUMMY pad. 0: Disable drive strength 1: Enable drive strength. |
| Bit[4] | pue of QSPIA_SCK_DUMMY pad. 0: Disable internal pullup or pulldown resistor 1: Enable internal pullup or pulldown resistor. |
| Bit[5] | pus of QSPIA_SCK_DUMMYpad. 0: Enable internal pulldown resistor if pue is set 1: Enable internal pullup resistor if pue is set. |
| Bit[6] | sre of QSPIA_SCK_DUMMY pad. 0: Disable slew rate control 1: Enable slew rate control. |
| Bit[31:7] | Reserved |

To Enable the Quadspi dummy PAD loopback use following settings

For Flash-A: MCR[DQS_FB_SEL] = 0x2

SOCCR[SOCCFG] = 0x0000000E (ibe=1, obe=1, dse=1 and sre=0)

### 74.1.6 QuadSPI AHB Buffer write access control

In MCXE31B and MCXE317 devices, the QuadSPI AHB buffer does not support writes. A write to QuadSPI AHB buffer results in error response from QuadSPI.

QuadSPI might behave unexpectedly in case if its AHB buffer is written with QuadSPI MCR[MDIS] =1. In cases wherein QuadSPI is disabled with above MDIS control bit, XRDC must also be appropriately configured to block the accesses to QSPI AHB buffer and indicate an error response.

## 74.2 Introduction

The QuadSPI module acts as an interface to a single serial flash memory device, with up to four bidirectional data lines.

### 74.2.1 Features

QuadSPI supports the following features:

- Flexible sequence engine to support various flash memory vendor devices. As there is no specific standard, the module supports various kinds of flash memories from different vendors. See Serial flash memory devices for example sequences.
- Single, dual, and quad modes of operation supported for Quad flash memories
- AHB master to read RX buffer data through AMBA AHB (64-bit width interface) or IPS registers space (32-bit access) and fill TX buffer via IPS registers space (32-bit access) or using AHB (64-bit width interface)
  - AHB master can be a DMA with a configurable inner loop size
- Multi-master accesses are allowed
  - Flexible and configurable buffer for each master—total available buffer size is 256 bytes.
- All AHB accesses to flash/RAM memory devices are directly memory mapped to the chip system memory
- Programmable sequence engine to cater to future command/protocol changes and ability to support all existing vendor commands and operations. The software needs to select the corresponding sequence according to the connected flash memory device.
  - Support for 3-byte and 4-byte addressing

### 74.2.2 RX buffer push event

To add the valid entries into the RX buffer

By default, each buffer push event adds two entries to the RX buffer because the interface to the serial clock domain is 64 bits in width. Depending on the number of bytes read from the serial flash memory device, it is possible for the very last buffer push event that only one entry is added.

RBSR[RDBFL] is incremented by the number of entries added to the RX buffer.

### 74.2.3 RX buffer POP event

To remove valid entries from the RX buffer

Each buffer POP event removes (RBCT[WMRK] + 1) valid entries from the buffer. BSR[RDBFL] is decremented by the same number and RBSR[RDCTR] is incremented accordingly.

### 74.2.4 Block diagram

The following figure shows a block diagram of the QuadSPI module.

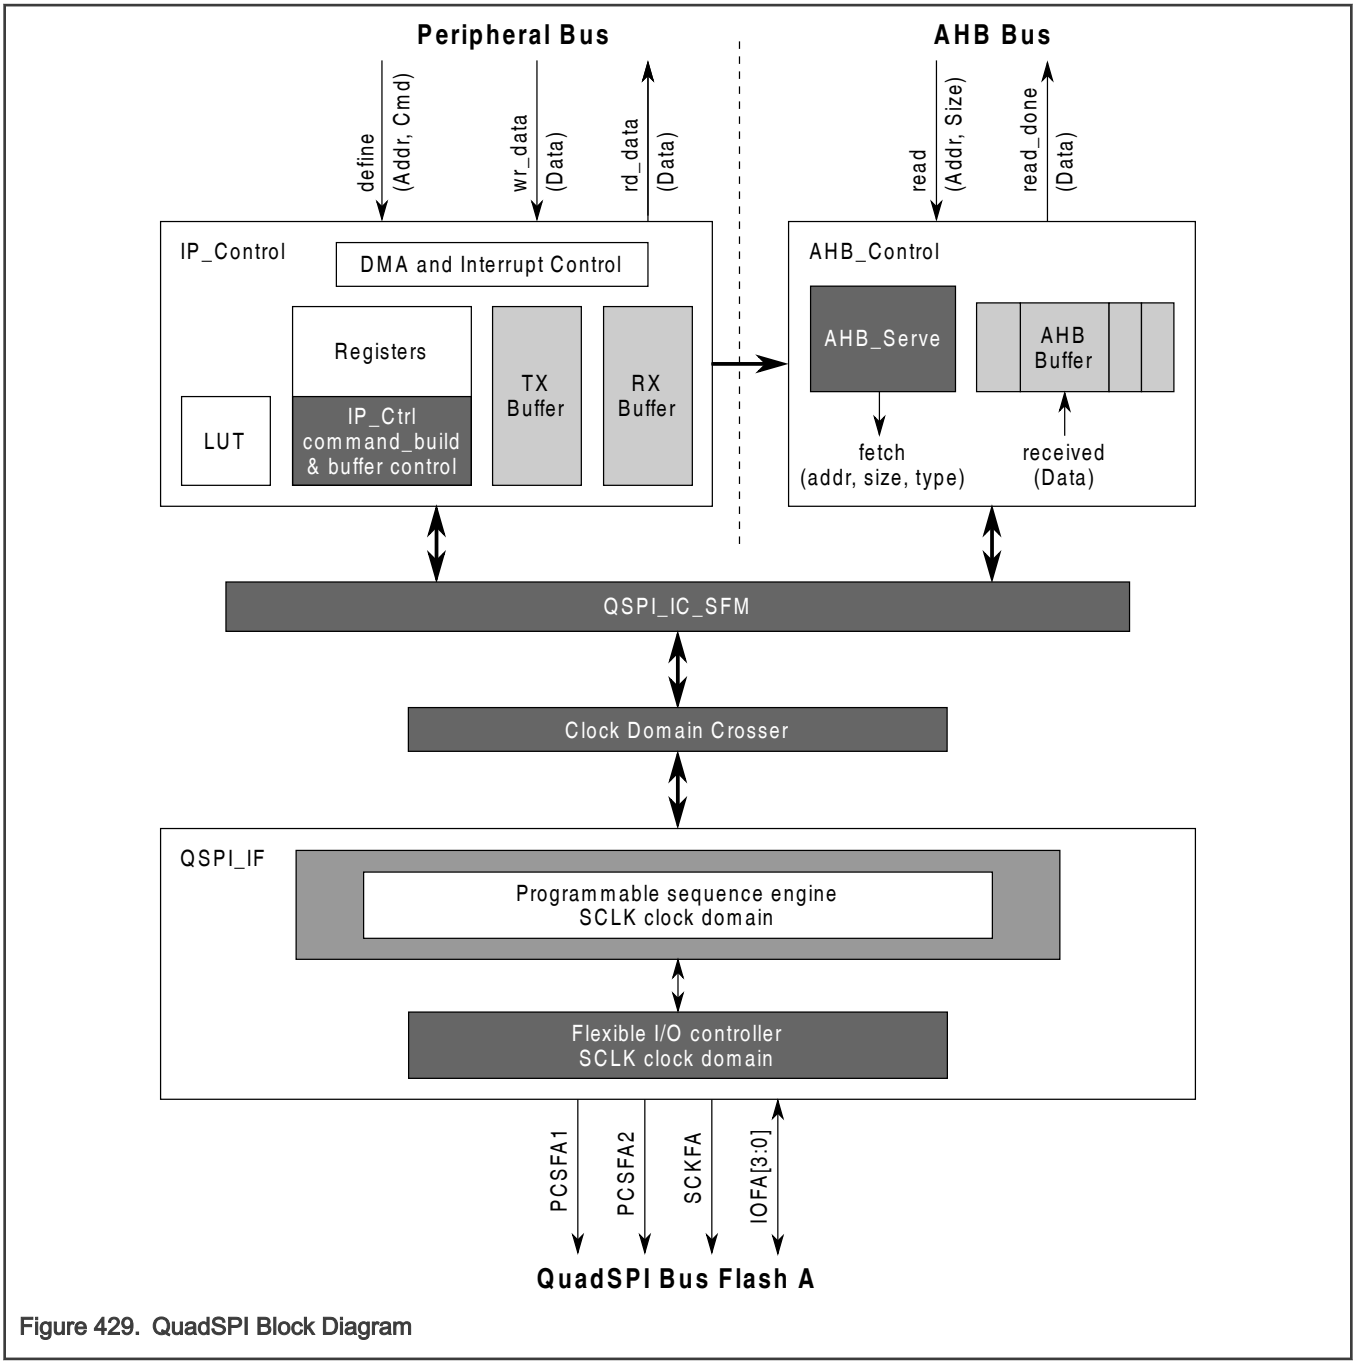

Figure 429. QuadSPI Block Diagram

## 74.2.5 QuadSPI modes of operation

QuadSPI supports the following modes of operation:

- Normal mode: You can use this mode for write or read accesses to an external serial flash memory device. See Normal mode for details.
  - Serial flash memory write: You can program data into the flash memory through the IP interface only. See Flash memory programming for details.
  - Serial flash memory read: Read the contents of the serial flash memory device. Two separate read channels are available through the RX buffer and AHB buffer. See Flash memory read for details.

- Module Disable mode: You can use this mode for disabling serial flash memory clock and AHB command. The clock to the non-memory mapped logic in QuadSPI can be stopped in the Module Disable mode. The module enters the mode by setting MCR[MDIS].

## 74.3 External signal description

This section provides the external signal information for the QuadSPI module.

The following table lists the external signals belonging to the module in conjunction with the different modes of operation.

**Table 554. Signal properties**

| Signal name | Function | Direction | Description |
|---|---|---|---|
| PCSFA1 | Peripheral Chip Select Flash Memory A1 | O | This signal is the chip select for the serial flash memory device A1 that represents the first of the two flash memory devices that share IOFA. |
| PCSFA2 | Peripheral Chip Select Flash Memory A2 | O | This signal is the chip select for the serial flash memory device A2 that represents the second of the two flash memory devices that share IOFA. |
| SCKFA | Serial Clock Flash Memory A | O | This signal is the serial clock output to the serial flash memory device A. |
| IOFA[3:0] | Serial I/O Flash memory A | I/O | These signals are the data I/O lines to/from the serial flash memory device A. See Driving external signals for details about the signal drive and timing behavior. Note that the signal pins of the serial flash memory device may change their function according to the SFM Command executed, leaving them as control inputs when single and dual instructions are executed. The module supports driving these inputs to dedicated values. In single I/O mode, QuadSPI drives data on IOFA[0] and expects data on IOFA[1]. |

**NOTE**

Please refer to chip specific information to check the configuration of QuadSPI block.

### 74.3.1 Driving external signals

Single/dual/quad instructions

Depending on the serial flash memory device connected to the QuadSPI module, there are instructions using a different number of data lines:

- Single pad: Single line I/O with one data out and one data in line to/from the serial flash memory device
- Dual pad: Dual line I/O with two bidirectional I/O lines, driven alternatively by the serial flash memory device or the QuadSPI module
- Quad pad: Quad line I/O with four bidirectional I/O lines, driven alternatively by the serial flash memory device or the QuadSPImodule

The different phases of the serial flash memory access scheme are shown in the following figure.

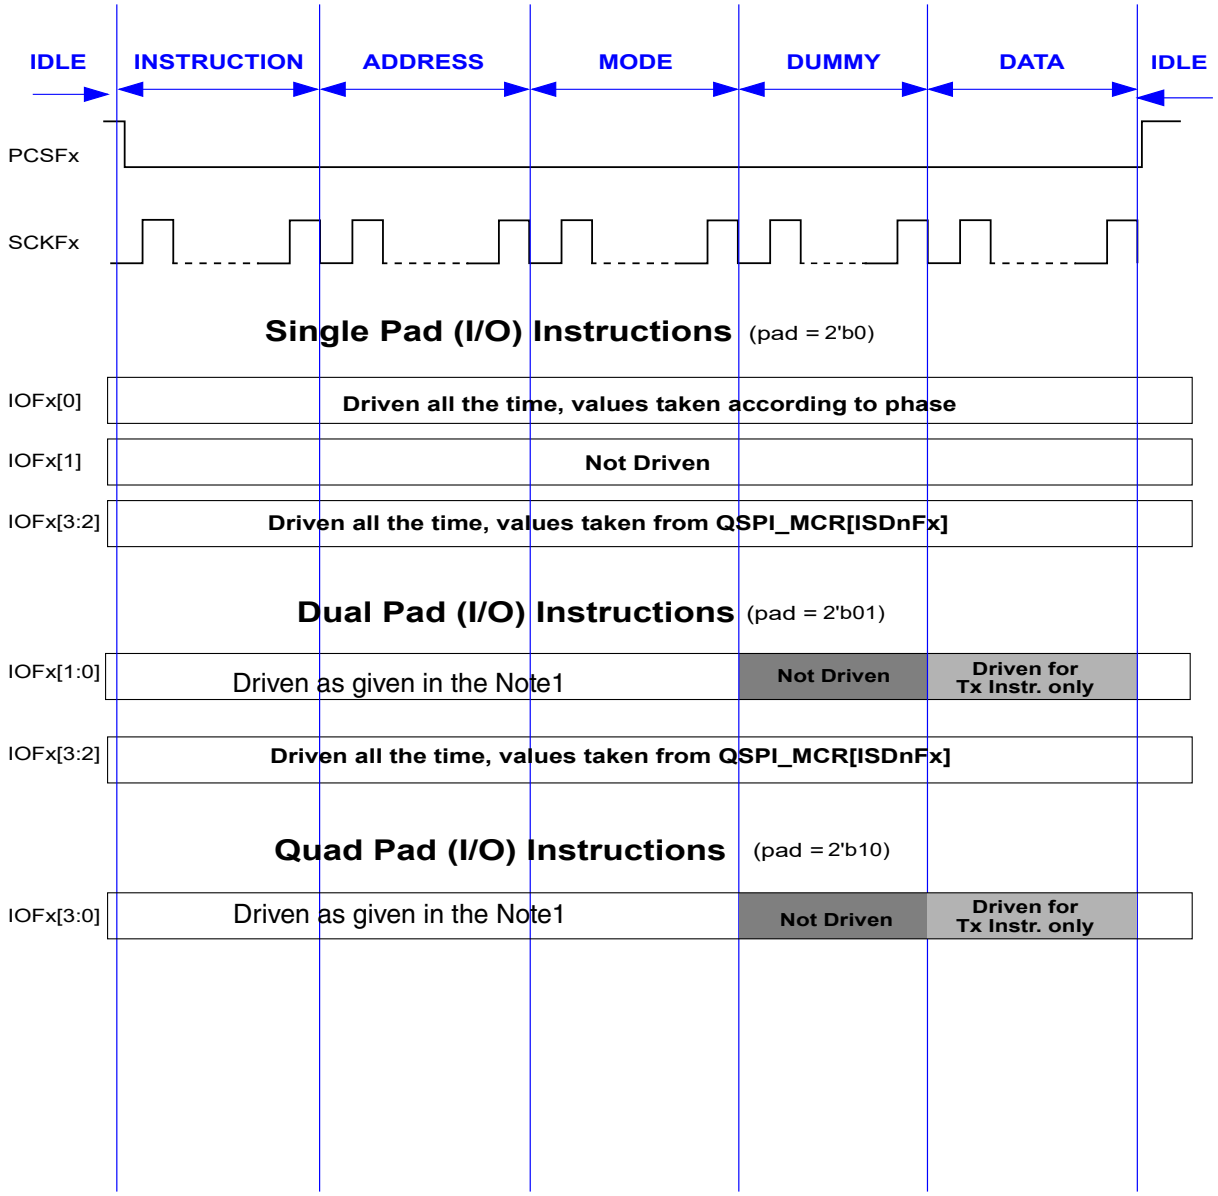

Figure 430. Serial flash memory access scheme

Note1:The IOs are driven from QuadSPI as per the number of pads configured for ongoing phase.

Note:The lines status will change based on command mode in case of instruction, address and mode phases. It can be either 1,2 or 4 lines

Following are the different phases and the I/O driving characteristics of the QuadSPI module:

- Idle: Serial flash memory device not selected – no interaction with the serial flash memory device and the IOFx signals are driven.
- Instruction: Serial flash memory device selected – the instruction is sent to the serial device and all the IOFx signals are driven.
- Address: Serial flash memory address is sent to the device – all the IOFx signals are driven and this phase is not applicable for all SFM commands.
- Mode: Mode bytes are sent to the serial flash memory device – all the IOFx signals are driven and this phase is not applicable for all SFM commands.

- Dummy: Dummy clocks are provided to the serial flash memory device. See Figure 430 for the IOFx signals driven. The actual data lines required for the SFM command executed are not driven for data read commands.

**NOTE**

— This phase is not applicable for all the SFM commands.

— All read commands in Dual pad, Quad pad modes must use a Dummy phase immediately before the Data phase. The Dummy phase pad configuration in the LUT must use the same number of pads as the subsequent Data phase. Note that this restriction is not applicable to Single-pad mode.

- Data: Serial flash memory data are sent to or received from the serial flash memory device. See the preceding figure for the IOFx signals driven. The actual data lines required for the SFM command executed are not driven for data read commands.

**NOTE**

This phase is not applicable for all the SFM commands.

The PCSFx and SCKFx signals are driven permanently throughout all the phases. In the individual flash memory mode, this applies to the selected flash memory device.

Access to a single, individual serial flash memory device

See Serial flash memory access schemes for details.

Read access to two serial flash memory devices attached to the QuadSPI module in parallel. See Serial flash memory access schemes for details.

## 74.4 Functional description

This section provides a functional description of the QuadSPI module.

### 74.4.1 Serial flash memory access schemes

In the individual flash memory mode, all supported commands are available.

### 74.4.2 Normal mode

This mode allows communication with an external serial flash memory device. Compared to the standard SPI protocol, this communication method uses up to four bidirectional data lines operating at high-data rates. The communication to the external serial flash memory device consists of an instruction code and optional address, mode, dummy, and data transfers. The flexible programmable core engine described below is immune to a wide variety of command or protocol differences in the serial flash memory devices provided by various flash memory vendors.

#### 74.4.2.1 Programmable sequence engine

The core of the QuadSPI module is a programmable sequence engine that works on "instruction-operand" pairs. The core controller executes each programmed instruction sequentially. The complete list of instructions and the corresponding operands are provided in the following table.

**Table 555. Instruction set**

| Instruction | Instruction encoding | Pins | Operand | Action on serial flash memories |
|---|---|---|---|---|
| CMD | 1d | N={0,1,2}d<br>0d - One pad<br>1d - Two pads<br>2d - Four pads | 8-bit command value | Provides the serial flash memory with the SFM command operand (Encoded) on the number of pads specified in STR mode. |

*Table continues on the next page...*

Table 555. Instruction set (continued)

| Instruction | Instruction encoding | Pins | Operand | Action on serial flash memories |
|---|---|---|---|---|
| ADDR | 2d | | Number of address bits to be sent (for example, 24d => 24 address bits required) | Provide the serial flash memory with address cycles according to the operand on the number of pads specified<br>The actual address to be provided is derived from the incoming address in case of AHB-initiated transactions and the value of SFAR in case of IPS-initiated transactions. |
| DUMMY | 3d | | Number of dummy clock cycles (should be <= 64 and > 2 cycles) | Provide the serial flash memory with dummy cycles according the operand<br>The PAD information defines the number of pads in input mode. For example, one pad implies that pad 1 is not driven, rest all are driven. |
| MODE | 4d | | 8-bit mode value | Provide the serial flash memory with 8-bit operand on the number of pads specified |
| MODE2 | 5d | N={0,1}d | 2-bit mode value | Provide the serial flash memory with 2-bit operand on the number of pads[1] specified |
| MODE4 | 6d | N={0,1,2}d | 4-bit mode value | Provide the serial flash memory with 4-bit operand on the number of pads[2] specified |
| READ | 7d | N={0,1,2}d<br>0d - One pad<br>1d - Two pads<br>2d - Four pads | Read data size in bytes (for AHB transactions, your application should ensure that data size is a multiple of 8 bytes) | Read data from flash memory on the number of pads specified<br>The data size can be overwritten by writing to the ADATSZ field of the BUFxCR registers for AHB-initiated transactions and to the IDATSZ field of the IP Configuration Register (IPCR) for IPS-initiated transactions. |
| WRITE | 8 | | Write data size in bytes | Write data on the number of pads specified<br>The data size can be overwritten by writing to the IDATSZ field of IP Configuration Register (IPCR). |
| JMP_ON_CS[3] | 9d | NA | Instruction number | Every time the CS is deasserted, jump to the instruction pointed to by the operand. This instruction allows the programmer to specify the behavior of the controller when a new read transaction is initiated following a CS deassertion. |
| STOP[3] | 0d | NA | NA | Stop execution; deassert CS |

1. For a one-pad instruction, MODE2 takes two serial flash memory clock cycles on the flash memory interface.
2. For a one-pad instruction, MODE4 takes four serial flash memory clock cycles on the flash memory interface. For a four-pad instruction, MODE4 takes one serial flash memory clock cycle on the flash memory interface.
3. Sequence ending with this instruction must have all remaining bits as 0s after it.

The programmable sequence engine allows you to configure the QuadSPI module according to the serial flash memory connected on board. This flexible structure is compatible with new command or protocol changes from different vendors.

#### 74.4.2.2 Flexible read xAHB buffers

To reduce the latency of the reads for AHB masters, the data read from serial flash memory is buffered in flexible AHB buffers. There are four such flexible buffers. The size of each of these buffers is configurable with the minimum size being 0 bytes and maximum size being the size of the complete buffer instantiated (256 bytes). The size of buffer 0 ranges from 0 to BUF0IND. The size of buffer 1 ranges from BUF0IND to BUF1IND, buffer2 from BUF1IND to BUF2IND and, buffer 3 ranges from BUF2IND to the size of the complete buffer (256 bytes).

Each flexible AHB buffer is associated with the following:

- An AHB master: Optionally, buffer3 may be configured as an "all master" buffer by writing 1 to BUF3CR[ALLMST]. When buffer3 is configured in such a way, any access from a master not associated with any other buffer is routed to buffer3.
- A datasize field representing the amount of data to be fetched from the flash memory on every missed access.

The master ID of every incoming request is checked and the data is returned or fetched into the corresponding associated buffer. See the chip-specific QuadSPI information for details about master IDs and their corresponding components. Every missed access to the buffer causes the controller to clear the buffer and fetch the BUFxCR[ADATSZ] amount of data from the serial flash memory. As such, you need not configure the buffer size to be greater than ADATSZ because the locations greater than ADATSZ are never used. For any AHB access, the sequence pointed to by BFGENCR[SEQID] is used for the initiated flash memory transaction. The data is returned to the master as soon as the requested amount is read from the serial flash memory. The controller; however, continues to prefetch the rest of the data in anticipation of a next consecutive request. See Figure 431 that shows flexible AHB buffers.

BFGENCR[SEQID] points to an index of the LUT. See LUT for details.

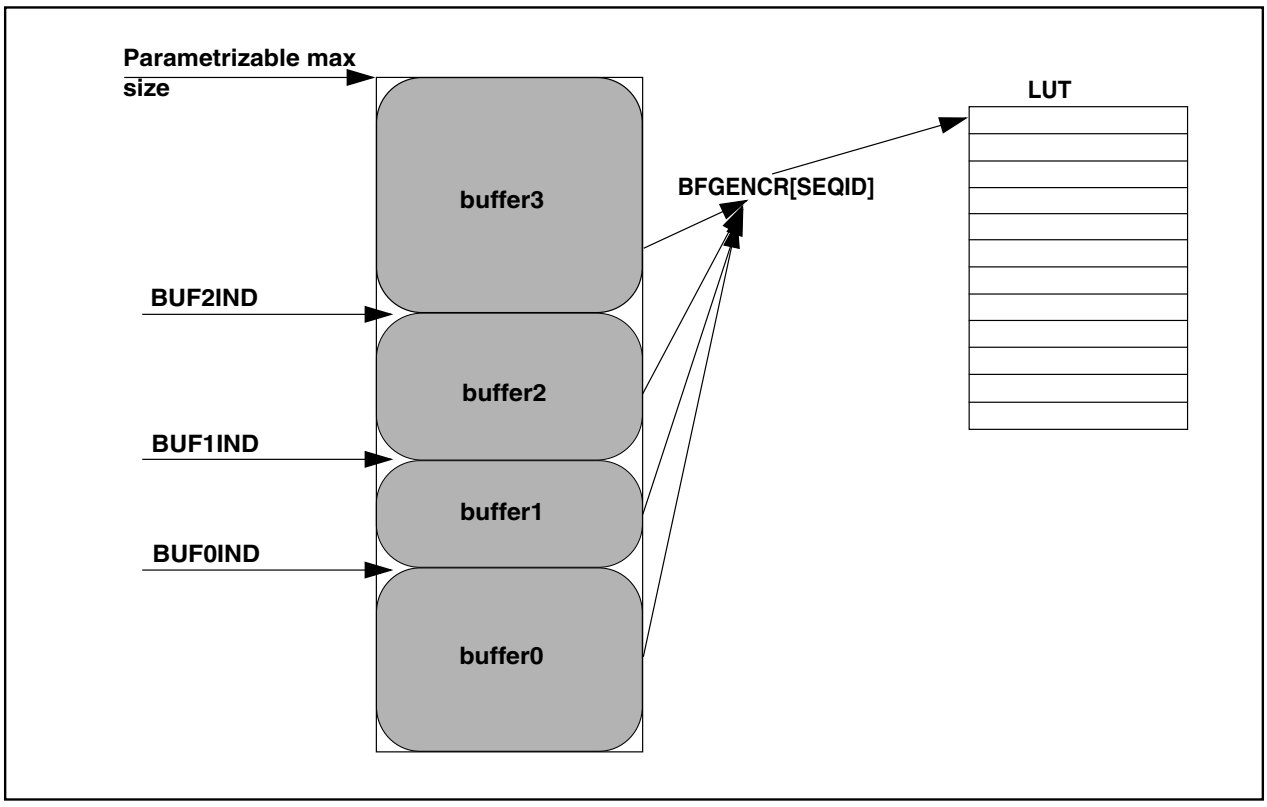

Figure 431. Flexible read AHB buffers

#### 74.4.2.3 Extended prefetch or Streaming mode

There is an option in QuadSPI to fetch more data than the maximum size of AHB prefetch buffer, which is 1024 bytes. This mode can be used in streaming use cases where the data is constantly read in incremental order.

To use this mode, configure buffer3 as an "all master" buffer by writing 1 to BUF3CR[ALLMST], and program BUF3CR[ADATSZ] greater than 1024 bytes. Also ensure that complete buffer is assigned to Buffer 3 Configuration Register (BUF3CR) and remaining buffer sizes should be programmed to 0 by writing 0 to Buffer 0 Top Index Register (BUF0IND), Buffer 1 Top Index Register (BUF1IND), and Buffer 2 Top Index Register (BUF2IND) registers. The maximum size that can be programmed for prefetch is 4096 bytes. In this mode, the complete 1K buffer size is used in rollover fashion, such that when the complete buffer is written, it starts writing the prefetch data again from starting location 0. So, if the AHB read is done continuously at sufficient speed, complete 4K data can be read without the buffer going full. In this mode, QuadSPI considers last AHB read address as the read pointer in AHB buffer, and when the prefeched data is being written in one location before the read pointer, it generates AHB full flag and prefetch is aborted. So, to efficiently utilize the streaming mode, ensure that AHB read is done in incremental/serial addresses with sufficient throughput. Also when the software is switching from streaming mode to normal modes, or vice-versa, it should clear the AHB buffers using software abort.

#### 74.4.2.4 Abort mechanism during AHB read

Any ongoing read transaction is aborted if a request from the same master arrives for a location other than the location at which the transaction is going on. The abort can happen at any point of time.

#### 74.4.2.5 HBURST support with AHB read

QuadSPI controller supports HBURST and HSIZE on the AHB read interface. HBURST indicates if the transfer forms part of a burst. Four, eight, and sixteen beat bursts are supported and the bursts might either be incrementing or wrapping. HSIZE indicates the size of the transfer, and supports 8-, 16-, 32-, and 64-bit data sizes. In case of WRAP accesses, QuadSPI generates aligned accesses to serial flash memory if there is no buffer hit for any incoming, non-sequential AHB read access. In case there is a buffer hit, the incoming address in the haddr line is latched as it is. If the total burst size is more than the data prefetch size, an error response is generated and the value of FR[AIBSEF] is configured as 1. The data prefetch size can be defined by BUFxCR[ADATSZ] or data size mentioned in the sequence pointed to by the SEQID field when ADATSZ is programmed as 0. In case of wrap burst, data prefetch size must be greater than or equal to the wrap burst size + 32 bytes. A few examples are shown in the figure below:

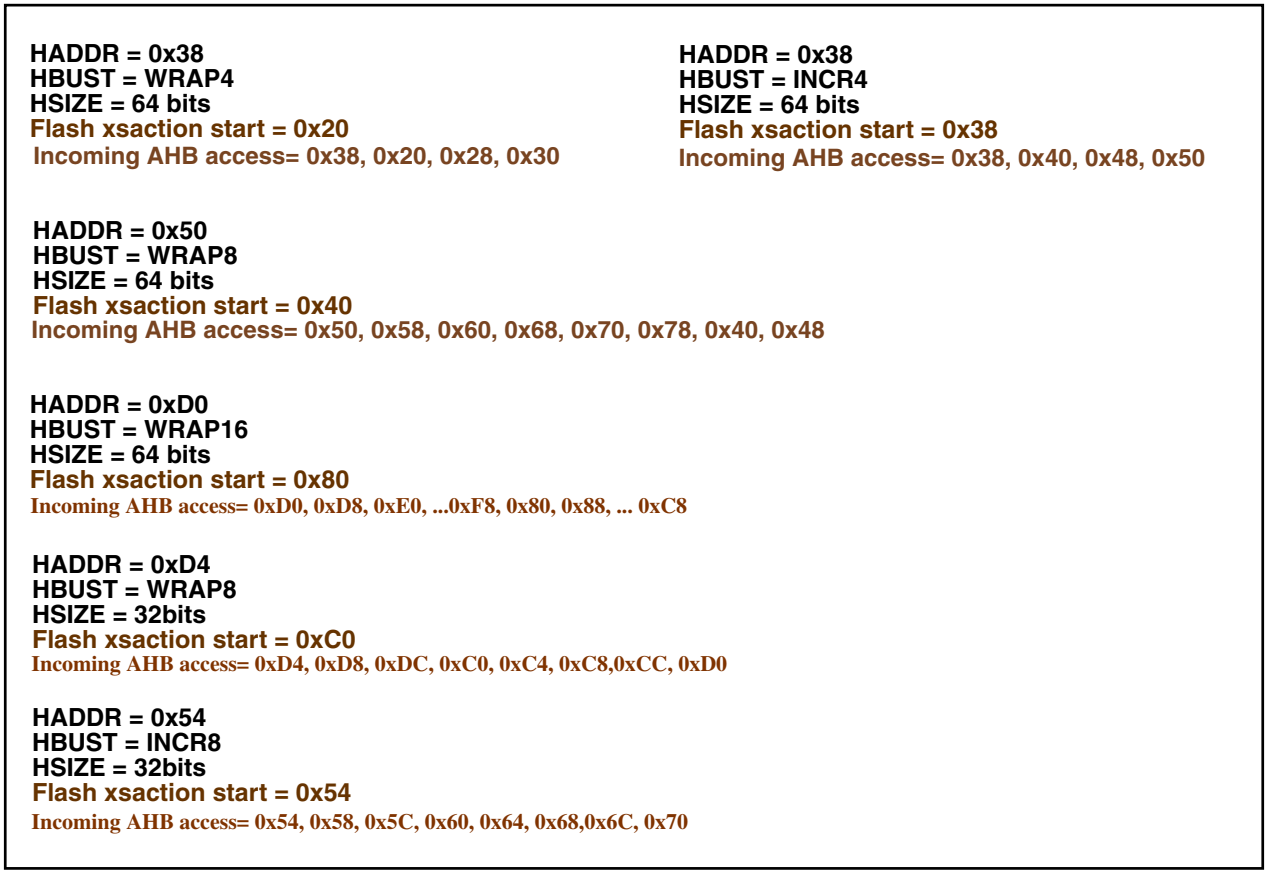

Figure 432. QuadSPI HBURST support

**NOTE**

The software must take care that the prefetch size should never be set less than the minimum data needed by any external interface to start processing.

**NOTE**

Whenever a core accesses QuadSPI memory with cache enabled, the prefetch size must be configured as equal or more than the cache line size; otherwise, FR[AIBSEF] error appears.

#### 74.4.2.6 LUT

The LUT consists of a number of pre-programmed sequences. Each sequence is basically a sequence of instruction-operand pairs, which when executed sequentially, generate a valid serial flash memory transaction. Each sequence can have a maximum of 10 instruction-operand pairs. The LUT can hold a maximum of sequences. The figure below shows the basic structure of the sequence in the LUT.

At reset, the index 0 of the LUT[0..4] is programmed with a basic read sequence as described in Read sequence. After reset, the complete LUT may be reprogrammed according to the chip connected on board. To protect its contents, during a code runover, the LUT might be locked, after which a write to the LUT will not be successful until it has been unlocked again. The key for locking or unlocking the LUT is 5AF05AF0h, and the associated processes are as follows:

**Locking the LUT**

1. Write the key 5AF05AF0h into the LUT Key Register (LUTKEY).
2. Write 0b01 to the LUT Lock Configuration Register (LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued). A successful write to this register locks the LUT.

**Unlocking the LUT**

1. Write the key 5AF05AF0h into the LUT Key Register (LUTKEY).
2. Write 0b10 to the LUT Lock Configuration Register (LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write to this register unlocks the LUT.

The lock status of the LUT can be read from the LCKCR[UNLOCK] and LCKCR[LOCK] fields.

Some example sequences are defined in Example sequences. After reset the instruction sequence 0 is populated with the default read sequence shown in the table below.

**Table 556. Read sequence**

| Instruction | Pad | Operand | Comment |
|---|---|---|---|
| CMD | 0h | 3h | Read data byte command on one pad |
| ADDR | 0h | 18h | 24 address bits to be sent on one pad |
| READ | 0h | 8h | Read 64 bits |
| JMP_ON_CS | 0h | 0h | Jump to instruction 0 (CMD) |

**NOTE**

If DLL is disabled then JMP_ON_CS or STOP instruction can be used else only STOP instruction can be used.

#### 74.4.2.7 Issuing SFM commands

Each access to the external device follows this sequence:

1. You must pre-populate the LUT with the serial flash memory command sequences that are required for the flash memory device being used.
2. The module executes the instructions in this sequence one by one. The transaction starts and the module configures the value of SR[BUSY].
3. Communication with the external serial flash memory device starts and the transaction executes.
4. After the transaction is complete (all transmit and receive operations with the external serial flash memory device are complete), the module resets SR[BUSY]. In case of an IP command, FR[TFF] is asserted.

For details, see Flash memory programming and Flash memory read.

You can trigger the processing of SFM commands in the QuadSPI module in one of the following ways:

**Using IP commands**

For IP commands, the required components need to be written into the following registers and in this sequence:

1. Write the serial flash memory address to be used as provided in the Serial Flash Address Register (SFAR). For IP commands not related to specific addresses, the base address of the related flash memory needs to be programmed. For example, for an instruction which does not require an address (that is, write enable instruction), the SFAR should be programmed with the base address of the memory the command is to be sent to.
2. Write the sequence ID and data size details in the IP Configuration Register (IPCR).
3. Note that writing a value to IPCR[SEQID] must be the last step of the sequence. It is possible to combine all the fields of the IPCR into one single write. See IP Configuration Register (IPCR) for details.

**Using AHB commands**

Any AHB memory-mapped access is routed to one of the buffers depending on the master ID of the request. If the access is a "miss," a new serial flash memory transaction is initiated. The transaction is based on the sequence pointed to by BFGENCR[SEQID] as described in Flexible read xAHB buffers.

An AHB access is considered memory mapped when the access is to the memory-mapped serial flash memories, as described in Memory Mapped Serial Flash Data - Individual Flash mode on Flash memory A.

#### 74.4.2.8 Flash memory programming

In all NOR Flash devices memory sector to be written needs to be erased first. The programming sequence is then initiated in the following way:

1. Check that SR[BUSY] is de-asserted or the value of the BUSY field is 0, also, check that the TX buffer is empty. If you need to discard the data present in the TX buffer (SR[TXNE]) then the TX buffer must be cleared by writing 1 to MCR[CLR_TXF].
2. Program the address related to the command in SFAR.
3. Provide initial data for the program command into the circular buffer through the TBDR. At least one words of data must be written into the TX buffer up to a maximum of 32 entries.
4. Program the IPCR to trigger the command. IPCR[SEQID] should point to an index of the LUT that has the flash memory program sequence pre-programmed. Write an appropriate value to IPCR[IDATSZ] to denote the size of the write in bytes.
5. Repeat step 3, depending on the amount of data required, until all of the required data is written to the TBDR. SR[TXFULL] can be used to check if the buffer is ready to receive more data. At any time, TBSR[TRCTR] can be read to check how many words have been written into the TX buffer.

After writing to IPCR[SEQID] (see step 4), the module starts executing the programmed sequence . The software ensures that the correct sequence is programmed into the LUT in accordance with the flash memory connected to the module. The data is fetched from the TX buffer. It consists of 32 entries of 32-bit sizes and is organized as a circular FIFO, the read pointer for which is incremented after each fetch. When all the data is transmitted, the QuadSPI module returns from the busy state to the idle state. However, this is not true for the external device because the internal programming is still ongoing. You may monitor the relevant status information available from the serial flash memory device and ensure that the programming is done appropriately.

#### 74.4.2.9 Flash memory read

Host access to the data stored in the external serial flash memory device is performed in two steps. First, the data must be read into the internal buffers and in the second step, these internal buffers can be read by the host.

**Reading serial flash memory data into the QuadSPImodule internal buffers**

A read access to the external serial flash memory device can be triggered in two different ways:

- IP command read: For reading flash memory data into the RX buffer, you must provide the correct sequence ID in IPCR[SEQID]. The sequence ID points to a sequence in the LUT. The software needs to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash memory device connected on board. You must program the SFAR , and IPCRs. All available read commands supported by the external serial flash memory are possible.

  Optionally, it is possible to clear the RX buffer pointer prior to triggering the IP command by writing a 1 to MCR[CLR_RXF]. This will invalidate the data currently present in the RX buffer and any new read data will overwrite the old one.

  Using these inputs, the complete transaction is built when IPCR[SEQID] is written to The transaction related to the read access starts and the requested number of bytes is fetched from the external serial flash memory device into the RX buffer. As the read access is triggered by an IP command, the value of both SR[IP_ACC] and SR[BUSY] is set to 1.. A count of the number of entries currently in the Rx buffer can be obtained from RBSR[RDBFL].

  Communication with the external serial flash memory stops if the specified number of bytes are read (on successful completion of the transaction).

- AHB command read: For reading flash memory data into the AHB buffer, you must:
  - Set up a read access by a master to the address range in the system memory map, which the external serial flash memory devices are mapped to.

—

— Program the buffer registers corresponding to the AHB master initiating the request.

— Provide the correct sequence ID in the BFGENCR. The software ensures that a correct read sequence is programmed in the LUT in accordance with the serial flash memory device connected on board. Flash memory device selection and access mode are determined by the address accessed in the AHB address space associated with the QuadSPI module (see Memory-mapped serial flash memory data—individual flash memory mode on flash memory A

On each AHB read access to the memory mapped area, the valid data in the AHB buffer is checked against the address requested in the actual read. When the AHB read request cannot be served from the content of the AHB buffer, the buffer is flushed and the controller executes the sequence pointed to by the sequence ID. The requested number of buffer entries defined in BUFxCR[ADATSZ] is then fetched from the external serial flash memory device into the internal AHB buffer. As the read access is triggered through the AHB bus, the value of SR[AHB_ACC] is set, driving SR[BUSY] in turn, until the transaction is complete. Communication with the external serial flash memory stops when the specified number of entries is filled.

### Data transfer from the QuadSPI module internal buffers

The data read out from the external serial flash memory device by the QuadSPI module is stored in the internal buffers. The means of accessing the data from the buffer differs depending on which buffer the data is loaded to. See Block diagram for details on the two available buffers, the RX buffer and the AHB buffer, in this module. The buffer appears transparent to you and is non-memory mapped. See the "Flexible AHB Buffer" section for details.

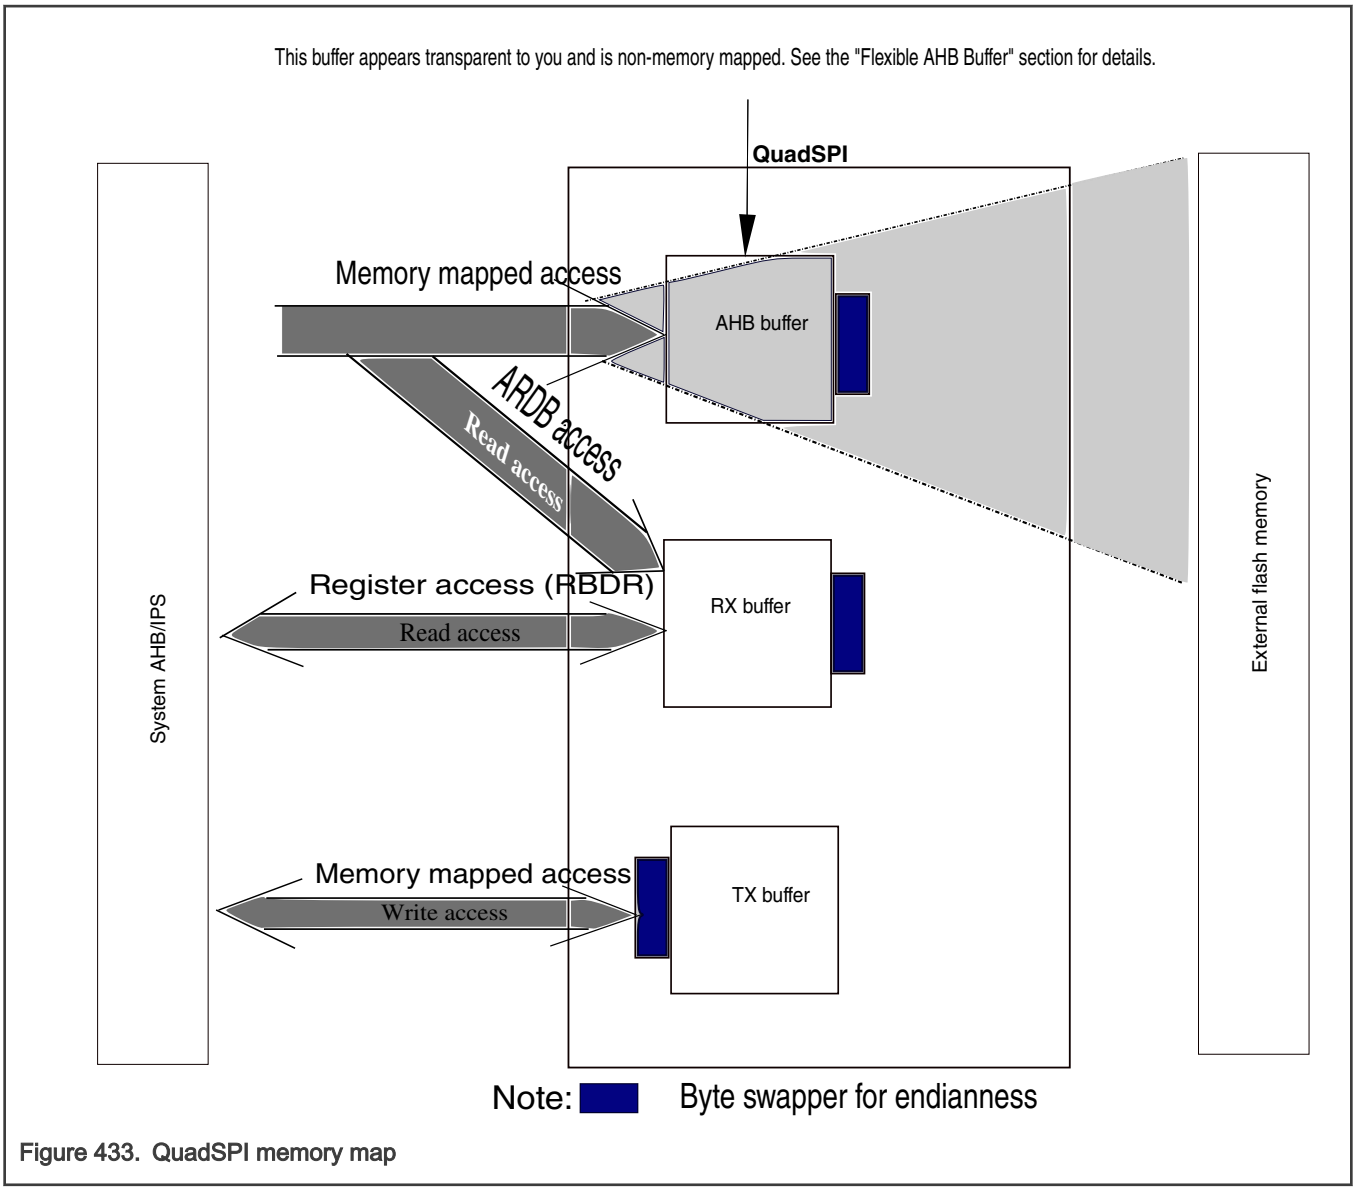

Figure 433. QuadSPI memory map

The RX buffer is implemented as FIFO of depth 32 entries of 4 bytes. Its content is accessible in two different address areas, both referring to identical data and the same physical memory:

- In the IPS address space in the area associated with RX Buffer Data Register (RBDR0 - RBDR31).
- In the AHB address space in the area associated with AHB RX Data Buffer Register (ARDB0 - ARDB127).Two successive entries are accessed with one single 64-bit AHB read operation.

The RX buffer operation can be summarized as follows:

- RBCT[WMRK] determines at which fill level SR[RXWE] is asserted and how many entries are removed from the RX buffer on each buffer POP operation.
- SR[RXWE] indicates that the configured number of data entries is available in the RX buffer and RBSR[RDBFL] indicates how many valid entries are available in total.
- The first entry (RBDR0 or ARDB0) always corresponds to the first valid entry in the RX buffer.

For details, see RX Buffer Data Register (RBDR0 - RBDR31) and AHB RX Data Buffer Register (ARDB0 - ARDB127).

- Flag-based data read of the RX buffer is performed by polling SR[RXWE]. When it is asserted, the valid entries can be read either via the IPS address space (RBDRn) or the AHB address space (ARDBn). A buffer POP operation must be

triggered by the application by writing a 1 to FR[RBDF]. This automatically updates the FIFO to point to the next entry as defined by RBCT[WMRK]. For example, if WMRK is set to 3, then the buffer discards 16 bytes of data.

- DMA-controlled data read of the RX buffer is performed by using the DMA module. The application must ensure that the DMA controller of the related chip is programmed appropriately, as described in DMA usage.
- DMA-controlled read out is triggered fully automatically by the assertion of SR[RXWE]. The related buffer POP operation is also handled completely inside the QuadSPI module. As in the case explained here, accessing the RX buffer content either on RBDRn or ARDBn related addresses is equivalent.
- AHB buffer data read via memory-mapped access: This kind of access is performed by reading one of the addresses assigned to the external serial flash memory device(s) within the range specified in Table 578. If this is not the case, a memory-mapped AHB command read is triggered as described above. If the requested data is already available in the AHB buffer, it is provided directly to the host.

When an AHB access is made to the flash memory mapped address, the data is fetched and returned to the AHB interface. The AHB interface is stalled until the data is fetched. As soon as the data from the requested address is read by the QuadSPI module, the AHB read access is served. Therefore, it is possible to run sequential reads from the AHB buffer at arbitrary speed without the need to monitor any information about the availability of the data. Nevertheless, this access scheme stalls the AHB bus for the time required to read the data from the serial flash memory device. If you know that the access is sequential, a better way is to have a prefetch enabled by programming the value of BUFxCR[ADATSZ] so that the data is fetched into the buffer before the next sequential AHB access.

As long as the host restricts its accesses to the data present in the buffer and to the data currently fetched from the serial flash memory, it is possible to run the host read from the AHB buffer simultaneously with the serial flash memory read into the AHB buffer.

#### 74.4.2.10 Byte ordering of serial flash memory read data

The basic scheme is that the first byte read out of the serial flash memory device, which is addressed by SFAR[SFADR], corresponds to RBDR0[31:24] for IP command read. Similarly, to send a single byte it should be positioned in TBDR[0:7]. In contrast to that for AHB command read, the bytes are always positioned according to the byte ordering of the AHB bus.

- Byte ordering in individual flash memory mode

  The following table provides the byte ordering scheme of how the byte oriented data space of the serial flash memory device is mapped into one single 32-bit entry of the RX buffer or the AHB buffer. The table is valid within the following context:

  — Flash memory A in individual flash memory mode

  — All AHB data read commands with 32-bit access size

**Table 557. Byte ordering in individual flash memory mode**

| Serial flash memory byte numbering | 3 | 2 | 1 | 0 |
|---|---|---|---|---|
| **Buffer entry bit position [31:0] (32-bit data width)** | [31:24] | [23:16] | [15:8] | [7:0] |

**NOTE**

For IP commands, the read size can be specified as number of bytes. If this number is not a multiple of four, then the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

  For AHB commands and reads, starting from an address not aligned to 32-bit boundaries, the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

- Buffer entry ordering for 64-bit read access

  For read access via the AHB interface, a 64-bit access is possible. Each 64-bit access reads two 32-bit entries, simultaneously. The ordering of these 32-bit entries within the 64-bit word is provided in the following table.

Table 558. 64-bit read access buffer entry ordering

| AHB read data bit position [63:0] | [63:32] | [31:0] |
|---|---|---|
| Buffer entry # | Odd (1, 3, 5, ...) | Even (0, 2, 4, ...) |

#### 74.4.2.11 Normal mode interrupt and DMA requests

The QuadSPI module has different flags that can only generate interrupt requests and one flag that can generate an interrupt as well as DMA requests. The following table lists the eight conditions. Note that the flags mentioned in the table are associated with the Flag Register (FR).

Table 559. Interrupt and DMA request conditions

| Condition | Flag (FR) | DMA |
|---|---|---|
| TX buffer fill | TBFF | - |
| TX buffer underrun | TBUF | - |
| Illegal instruction error | ILLINE | - |
| RX buffer drain | RBDF | X |
| RX buffer overflow | RBOF | - |
| AHB buffer overflow | ABOF | - |
| AHB sequence error | ABSEF | - |
| AHB illegal transaction error | AITEF | - |
| AHB illegal burst size error | AIBSEF | - |
| IP command trigger during AHB access error | IPAEF | - |
| IP command trigger could not be executed error | IPIEF | - |
| IP command related transaction finished | TFF | - |

Each condition has a corresponding field in Flag Register (FR) and a request enable field in DMA Request Select and Enable Register (RSER). FR[RBDF] has separate enable fields for generating IRQ and DMA requests. Note that not all the fields have an individual IRQ line. See the chip's Interrupt Vector table for details.

- Transmit buffer fill interrupt request

  This indicates that the TX buffer can accept new data. The buffer is asserted if FR[TBFF] is asserted and if the value of the corresponding enable field, RSER[TBFIE], is 1. See TX buffer Operation for details on the assertion of FR[TBFF].

  Apart from IRQ, it is possible to handle the TX buffer fill by using the DMA. If the value of RSER[TBFDE] is 1, a DMA request is triggered when the number of available space in the TX buffer is more than the TBCT[WMRK] valid entries and value of SR[TXWA] is set. The application must configure the environment appropriately (for example, the DMA controller) for the DMA transfer.

- Receive buffer drain interrupt or DMA request

  This is derived from FR[RBDF], indicating that the RX buffer of the QuadSPI module has data available from the serial flash memory device to be read by the host. It remains set as long as RBSR[RXWE] is configured. Also, RSER[RBDIE] enables the related IRQ.

Apart from the IRQ, it is possible to handle the RX buffer drain by using the DMA. If the value of RSER[RBDDE] is 1, a DMA request is triggered when the RX buffer contains more than RBCT[WMRK] valid entries. The application must set the environment appropriately (for example, the DMA controller) for the DMA transfers.

- Buffer overflow/underrun interrupt request

  This is a combination of the following fields (all located in the Flag Register (FR) with the related enable bits in the DMA Request Select and Enable Register (RSER)):

  — TBUF - TX buffer underrun, enabled by TBUIE

  — RBOF - RX buffer overflow, enabled by RBOIE

  — ABOF - AHB buffer overflow, enabled by ABOIE

  — The transmit buffer underrun indicates that an underrun condition in the TX buffer has occurred. It is generated when a write instruction is triggered whilst the TX buffer is empty and the value of RSER[TBUIE] is 1.

  — The receive buffer overflow indicates that an overflow condition in the RX buffer has occurred. It is generated when the RX buffer is full, an additional read transfer attempts to write into the RX buffer, and the value of RSER[RBOIE] is 1.

  — The AHB buffer overflow indicates that an overflow condition in the AHB buffer has occurred. It is generated when the AHB buffer is full, an additional read transfer attempts to write into the AHB buffer and the value of RSER[ABOIE] is 1.

  — The data from the transfers that generated the individual overflow conditions is ignored.

- Serial flash memory command error interrupt request

  If the IPAEF, IPIEF fields in the FR are set, and the related interrupt enable bits in the RSER are also set, then an interrupt is requested.

- Transaction finished interrupt request

  The IP command transaction finished IRQ indicates the completion of the current IP command. It is triggered by FR[TFF] and is masked by RSER[TFIE].

#### 74.4.2.12 TX buffer operation

The TX buffer provides the data used for page programming. For proper operation, it is required to provide at least one entry in the TX buffer prior to starting the execution of the page programming command. The application must ensure that the required number of data bytes is written into the TX buffer fast enough as long as the command is executed without a TX buffer overflow or underrun.

The QuadSPI module sets the FR[TBFF] field as long as the TX buffer is not full and can accept more data. At the end of write through TX buffer, you must clear FR[TBFF] to avoid unnecessary last TX buffer fill interrupt. However, there would always be a pending request asserted from QuadSPI controller at the end of any DMA transfer. When external DMA finishes transfer iteration, this request from QuadSPI is kept asserted for the next iteration loop.

**NOTE**

Even if the generation of DMA requests for filling the TX buffer is disabled by using RSER[TBFDE], the TX buffer still accepts a DMA transfer because of the last asserted pending request.

Disabling of DMA transfer should be controlled by an external DMA master.

When the QuadSPI module tries to pull data out of an empty TX buffer, FR[TBUB] signals the TX buffer underrun. The TX buffer underrun flag is also asserted when the TX buffer contains less than 32-bits of data and the QuadSPI module tries to pull out data from it. The current IP command leading to the underrun condition is continued until the specified number of bytes is sent to the serial flash memory device. Also, the data that is transferred is in the Fs[10] format. This means, after the underrun flag is set under this condition, it returns Fs until the required number of bytes are not sent. This has been done to ensure that the software does not erase the whole sector after underrun and just reprogramming from failure point serves the purpose. When this sequence command is complete, FR[TBFF] is asserted, indicating that the TX buffer is ready to be written again.

The TX buffer overflow is not signaled explicitly, but TBSR[TRBFL] can monitor the TX buffer fill level.

[10] Fs represents a value of FFFF_FFFF.

For more information, see TX Buffer Status Register (TBSR) and Flag Register (FR).

#### 74.4.2.13 Address scheme

Earlier, serial flash memories supported only a 24-bit address space, restricting the maximum memory size of the serial flash memory to 16 MB. The new memory specification supports two types of 32-bit addressing mode in addition to the legacy 24-bit address mode.

**Extended address mode**

In this mode, the legacy 24-bit commands are converted to accept 32-bit address commands. The flash memory needs to be configured for the 32-bit address mode. Also, while programming the LUT sequence in QuadSPI for 32-bit mode, the ADDR commands should be programmed with 32d as the operand value . By default, QuadSPI is in 24-bit legacy address mode. Each of the memory vendors have a different way of enabling this mode (see the memory specification from memory vendors). For example, the command B7h sent to the Macronix flash memory enables it for the 32-bit address mode.

**Extended address register**

In this mode, the upper 8 bits of the 32-bit register are provided by the Extended address register in the memory, which provides a specific register that is updated according to the address to be accessed. This effectively converts the legacy 24-bit address command into 32-bit address commands. The memories greater in size than 16 MB consist of banks of 16 MB each. The 8 bits occupied in the extended address register effectively enable a bank. For example, in Spansion memory, when the extended address register is updated with a value of 1h, with the help of the 17h command, it opens Bank1 of the memory. The consequent 24-bit address commands lead to Bank1. The extended address register needs to be updated with the respective value for access to other banks. This effectively converts the legacy 24-bit address command into 32-bit address commands.

### 74.4.3 Module Disable mode

Module Disable mode is a block-specific mode that the QuadSPI can enter to disable serial flash memory clock and AHB command. This mode can be entered by:

- The host software: by writing a '1' to MCR[MDIS]

Below are the condition that must be fulfilled to enter the Module Disable mode:

- SR[BUSY] = 0
- SR[AHBTRN] = 0
- RBSR[RDBFL] = 0
- SR[RXDMA] = 0
- SR[TXDMA] = 0
- None of the flags in FR are enabled as interrupts is set

The conditions mentioned above ensures the following:

- There is no SFM command currently being executed.
- All the data read into the RX buffer from the serial flash memory have been fetched by the application.
- There is no current AHB access.
- There is no active DMA request.
- There is no enabled interrupt that is pending.

Certain read or write operations have a different effect when the QuadSPI is in the Module Disable mode. In the Module Disable mode, not all of the status and flag bits of the QuadSPI module are updated, and writing to them has no effect. Interrupt and DMA request signals cannot be cleared while in the Module Disable mode.

**NOTE**

It is illegal to issue a new SFM command starting two clock cycles prior to raising the request of entering the Module Disable mode until the QuadSPI stays in this mode.

### 74.4.4 Leaving Module Disable mode

In the Module Disable mode, the serial flash memory clock and AHB command to the QuadSPI module are switched off.

After the QuadSPI has left this mode and has returned to Normal mode, the execution of the first SFM command is deferred until the clock to drive that part of the module related to the serial flash memory device is available. Depending upon the point in time when the first SFM command is triggered, the actual execution of the command starts with a delay, respective with the re-enabling of the flash memory clock signal.

## 74.5 Initialization/application information

This section provides the initialization and application information of the QuadSPI module.

### 74.5.1 Power up and reset

The serial flash memory devices connected to the QuadSPI module might require special voltage characteristics of their inputs during power up or reset. The application must ensure this.

**CAUTION**

Erase or program commands should be completed before issuing a reset or power cycle to avoid corrupted flash pages. The application shall ensure there is a backup of critical data stored at a different location to enable recovery from corrupted flash pages.

**Example: Flash reset sequence**

Use the following sequence to reset flash A:

1. Make sure that the flash supports a reset for the condition CS#=high and IOF[3]=low.
2. Set MCR[SWRSTSD] and MCR[SWRSTHD] fields and then clear them.
3. Set MCR[MDIS] field.
4. Reset MCR[ISD3FA] field for flash A.
5. Clear MCR[MDIS] field.
6. Set MCR[MDIS] field.
7. Set MCR[ISD3FA] field for flash A.
8. Clear MCR[MDIS] field.

### 74.5.2 Available status/flag information

This section provides an overview of the different flags and statuses available, and their interdependencies for different use cases. The SR and FR are the related registers.

#### 74.5.2.1 IP commands

See IP Configuration Register (IPCR) for additional details not explicitly covered in this paragraph.

- IP commands—normal operation

  Writing to IPCR[SEQID] triggers the execution of a new IP command. Given that this is a legal command, SR[IPACC] and SR[BUSY] are asserted simultaneously, immediately after the execution starts.

  After the instruction on the serial flash memory device is complete, these field deassert and FR[TFF] is configured.

- IP commands—error situations

See Overview_of_Error_Flags for details.

#### 74.5.2.2 AHB commands

See the "Reading serial flash memory data into the QuadSPI module internal buffers" topic in theFlash Memory Read section for details.

- AHB commands—normal operation

  Memory-mapped read access to a serial flash memory address not contained in the AHB buffer triggers the execution of an AHB command. Given that this is a legal command, SR[AHB_ACC] and SR[BUSY] are asserted simultaneously, immediately after the execution starts. After the instruction on the serial flash memory device is complete, these fields are deasserted.

- IP commands—error situations

  See Overview of FR error flags for details.

#### 74.5.2.3 SFM commands

An SFM command consists of an instruction code and all other parameters (for example, size or mode bytes) needed for that specific instruction code. Triggering a command either initiates a transaction on the external serial flash memory or results in an error. See Table 560 for details on errors.

#### 74.5.2.4 Overview of error flags

The following table provides an overview of the different error flags in the FR and additional error-related details.

**Table 560. Overview of FR error flags**

| Error category | Error flag in FR | Command execution on serial flash memory device<br>TFF behavior (in case of IP commands only) | Description |
|---|---|---|---|
| AHB error flag | ABOF | Flash memory transaction continues until it finishes | Set when the module tries to push data into the AHB buffer that exceeds the size of the AHB buffer. Occurs only because of the wrong programming of BUFxCR[ADATSZ]. |
| AHB error flag | AIBSEF | Flash memory transaction is aborted | Total burst size of the AHB transaction is greater than prefetch data size. |
| AHB error flag | AITEF | Flash memory transaction is aborted | No response is generated from QuadSPI to AHB bus in case of illegal transaction. Also, the watchdog timer expires. |
| Miscellaneous error flag | ILLINE | Flash memory transaction aborted | Illegal instruction error flag - set when an illegal instruction is encountered by the controller in any of the sequences. |
| Command arbitration error | IPIEF | TFF not asserted in conjunction with that command | IP command error - caused when IP access is currently in progress (IP_ACC is set) and during: |

*Table continues on the next page...*

Table 560. Overview of FR error flags (continued)

| Error category | Error flag in FR | Command execution on serial flash memory device<br>TFF behavior (in case of IP commands only) | Description |
|---|---|---|---|
| | | | • Write attempt to IPCR register<br>• Write attempt to SFAR register<br>• Write attempt to RBCT register |
| Command arbitration error | IPAEF | TFF not asserted in conjunction with that command | • AHB command already running, another IP command could not be executed<br>• AHB command already running, write attempt to IPCR[SEQID] |
| Buffer-related error | RBOF | TFF is asserted on completion | • RX buffer overrun |
| Buffer-related error | TBUF | TFF is asserted on completion | • TX buffer underrun |

Note that only the buffer-related errors are associated with a transaction on the external serial flash memory. All the other errors do not trigger an actual transaction.

#### 74.5.2.5 IP bus and AHB access command collisions

There are following flags related to this topic: FR[IPAEF] and FR[IPIEF]. See the "Reading serial flash memory data into the QuadSPI module internal buffers" topic of the Flash Memory read section for a description of the flags.

### 74.5.3 Flash memory device selection

Regardless of the SFM command (IP or AHB), the access mode is selected by specifying the 32-bit address value for the following SFM command.

For IP commands, the access mode is selected with the address programmed into the SFAR register. See Serial Flash Address Register (SFAR) for details.

For AHB commands, the access mode is determined by the memory-mapped address. See AMBA Bus Register Memory Map for details.

### 74.5.4 DMA usage

For a complete description of the DMA module, see the related DMA Controller chapter. This section only provides QuadSPI-specific DMA usage details.

#### 74.5.4.1 DMA usage in normal mode

##### 74.5.4.1.1 Bandwidth considerations

Careful consideration of the throughput rate of the entire chain (serial flash memory -> AHB bus / IP bus -> DMA controller) involved in the read/write data process is essential for a proper operation. Such analysis must take into account not only the data rate provided by the serial flash memory but also the data rate of the AHB bus and the performance of the DMA controller in reading/writing data from/to the RX/TX buffer.

Two figures must match for a proper operation, which means that the data rate provided by the serial flash memory device must not exceed the average RX buffer readout data rate. Otherwise, the longer this state persists, it results into an RX buffer overflow. Similarly, the data consumed by the serial flash memory device must not exceed the average TX buffer fill rate. If this persists, it leads to an underrun.

#### AHB bus side (data read)

The total number of bus cycles for each DMA minor loop completion is added from the following components:

The following table provides certain examples for typical use cases:

Case 1: DMA needs to read 4 bytes from SRAM and provide to QuadSPI. It costs total four bus clock cycles. Then, DMA handshake adds additional six bus clock cycles, resulting in a total of [6 + 4 * (32/4) = 38] bus clock cycles.

**Table 561. Access duration examples for bus clock side**

| TBCT[WMRK] | Number of bytes per DMA loop | Number of bus clock cycles for DMA minor loop | Time duration of DMA minor loop for 60 MHz bus clock frequency |
|---|---|---|---|
| 3 | 16 | 6+(16/4)*4 = 22 | ~366ns |
| 7 | 32 | 6+(32/4)*4 = 38 | ~633ns |
| 11 | 48 | 6+(48/4)*4 = 54 | ~900ns |
| 15 | 64 | 6+(64/4)*4 = 70 | ~1166ns |

Case 2: DMA needs to read 32 bytes from SRAM and provide to QuadSPI. DMA handshake takes an additional six bus cycles, with 32 bytes DMA read from SRAM costs (8 + 3) core clock cycles. DMA writes 32 bytes to QuadSPI, takes 2 * (32/4) = 16 bus cycles with one additional CPU access to QuadSPI, costing two bus clock cycles. This results in a total 6 + (8+3)/2 + 2 * (32/4) +2 = 30 bus clock cycles.

**Table 562. Access duration examples for bus clock side**

| TBCT[WMRK] | Number of bytes per DMA loop > | Number of bus clock cycles for DMA minor loop | Time duration of DMA minor loop for 80 MHz bus clock frequency |
|---|---|---|---|
| 3 | 16 | 6 + (4+3) /2 + (16/4)*2 + 2 = 20 | ~333ns |
| 7 | 32 | 6 + (8+3) /2 + (32/4)*2 + 2 = 30 | ~500ns |
| 11 | 48 | 6 + (4+3)/2*3 + (48/4)*2 + 2 = 44 | ~733ns |
| 15 | 64 | 6 + (8+3) + (64/4)*2 + 2 = 51 | ~810ns |

**NOTE**

This table figure represents an ideal scenario; actual performance depends on how the chip integrates DMA and QuadSPI modules.

#### Serial flash memory device side (data read)

The number of serial flash memory cycles can be determined in the following way:

- Number of serial flash memory clock cycles is required to read 4 bytes, corresponding to one RX buffer entry (setup of command and address not considered): , eight cycles for quad mode (SDR) instructions in individual flash memory mode, and so on.
- Overhead because of clock domain crossing: one cycle

The following table lists the number of clock cycles required to read the data from the serial flash memory corresponding to the different settings of RBCT[WMRK]:

**Table 563. Access duration examples for serial flash memory side**

| RBCT[WMRK] setting | Num bytes per DMA loop [1] | Num SCKFx for 80 MHz SCKFx | | Time duration of flash memory data readout for 80 MHz SCKFx (~12.5ns period) | |
|---|---|---|---|---|---|
| | | IFM [2] quad | IFM quad DDR | IFM quad | IFM quad DDR |
| 0 | 4 | 8 | 4 | ~100ns | ~50ns |
| 1 | 8 | 16 | 8 | ~200ns | ~100ns |
| 3 | 16 | 32 | 16 | ~400ns | ~200ns |
| 7 | 32 | 64 | 32 | ~800ns | ~400ns |
| 11 | 48 | 96 | 48 | ~1200ns | ~600ns |

1. DMA loop refers to one minor loop completion that is equivalent to one major loop iteration.
2. Individual flash memory mode

**NOTE**

The table figure represents an ideal scenario; actual performance depends on how the chip integrates with DMA and QuadSPI modules.

A complementary example is when the watermark is set to be too high. In such a case, the time taken by the DMA to read out the RX buffer entries should be lesser than the time taken by the controller to push in the remaining entries in the buffer.

**IPS bus side (data write)**

The total number of bus cycles for each DMA minor loop completion are added from the following components:

- Overhead for each minor loop, given by DMA controller: assume 10 cycles
- Overhead because to clock domain crossing: assume two cycles
- Number of bus clock cycles required for 16 bytes (128-bit write size): assume four cycles (read/write sequence of DMA controller)

Note that the size of the minor loop is determined by the size of TBCT[WMRK]; therefore, the overhead specified above distributes among (TBCT[WMRK]+1) write accesses of 32-bit each.

The following table provides some examples for typical use cases:

**Table 564. Access duration examples for bus clock side**

| TBCT[WMRK] | Number of bytes per DMA loop [1] | Number of bus clock cycles for DMA minor loop | Time duration of DMA minor loop for 80 MHz bus clock frequency |
|---|---|---|---|
| 3 | 16 | 12+4 = 16 | ~200ns |
| 7 | 32 | 12+8 = 20 | ~250ns |
| 11 | 48 | 12+12 = 24 | ~300ns |
| 15 | 64 | 12+16 = 28 | ~350ns |
| 19 | 80 | 12+20 = 32 | ~400ns |

1. DMA loop refers to one minor loop completion that is equivalent to one.

**NOTE**

The table figure represents an ideal scenario; actual performance depends on how the chip integrates with DMA and QuadSPI modules.

**Serial flash memory device side (data write)**

The number of serial flash memory cycles can be determined in the following way:

- Number of serial flash memory clock cycles required to write 16 bytes, corresponding to four TX buffer entry (setup of command and address not considered): 32 cycles for quad SDR writes in individual flash memory mode.
- Overhead due to clock domain crossing: one cycle

The following table lists the number of clock cycles required to read the data from the serial flash memory corresponding to the different settings of TBCT[WMRK]:

**Table 565. Access duration examples for serial flash memory side**

| TBCT[WMRK] setting | Num bytes per DMA loop [1] | Num SCKFx | | Time duration for consuming data at flash memory interface 100 MHz SCKFx (10 ns period)[2] | | Time for FIFO to get empty[3] | |
|---|---|---|---|---|---|---|---|
| | | IFM [4] quad | [5] single IO SDR mode | IFM quad | PFM single IO SDR | IFM quad | PFM single IO SDR |
| 3 | 16 | 32 | 64 | 320ns | 640ns | 2240ns | 4480ns |
| 7 | 32 | 64 | 128 | 640ns | 1280ns | 1920ns | 3840ns |
| 15 | 64 | 128 | 256 | 1280ns | 2560ns | 1280ns | 2560ns |
| 23 | 96 | 192 | 384 | 1920ns | 3840ns | 640ns | 1280ns |

1. DMA loop refers to one minor loop completion that is equivalent to one major loop iteration.
2. Not all flash memory devices support writes at 100 MHz. See the flash memory data sheet for the actual page program frequency supported.
3. The assumption for these timings is that the TX Fifo is full when the transaction is initiated
4. Individual flash memory mode
5. Parallel flash memory mode

**NOTE**

The tables mentioned above are only examples which must be correlated with the DMA in the system.

Considering the examples provided in the two tables above for TX FIFO, it is evident that depending on the relationship between the bus clock and serial flash memory clock frequencies, there are settings possible where the serial flash memory consumes data faster than the IPS bus can write data in TX buffer. In these cases, a TX buffer underrun situation occurs. To avoid TX buffer underrun, the data transaction size should be large enough.

### 74.5.5 Flash memory devices address mapping

QuadSPI is configured in Single mode for the supported flash memory port A

The sizes of the flash memory devices are mapped with the system memory space based on the configurations of the following registers:

- SFA1AD
- SFA2AD
- SFB1AD
- SFB2AD

The total memory region for the flash memory devices is mapped between QuadSPI_AMBA_BASE and TOP_ADDR_MEMB2 such that the corresponding CS is asserted based on SFA1AD, SFA2AD and SFB1AD register configurations.

#### 74.5.5.1 Single mode

For single mode configuration, you must write the same value to SFB1AD and SFB2AD registers that you write to the SFA2AD register.

For dual-die flash memories, the values you write to SFB1AD and SFB2AD registers corresponds to the mapped top addresses of each die.

For single-die flash memories, you must write the same value to SFA2AD register that you write to the SFA1AD register.

Following is a programming example for single mode single-die flash memory:

- QuadSPI_AMBA_BASE - 1000_0000h
- SFA1AD[TPADA1] - 2000_0000h
- SFA2AD[TPADA2] - 2000_0000h
- SFB1AD[TPADB1] - 2000_0000h
- SFB2AD[TPADB2] - 2000_0000h

The following figure illustrates the memory mapping for single mode QuadSPI configuration.

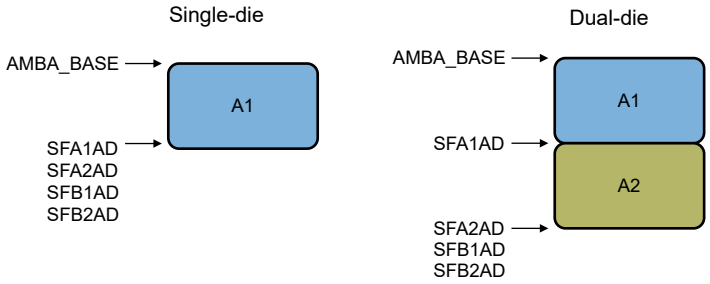

**Figure 434. Memory map for Single mode**

## 74.6 Byte ordering – endianness

The following topics show the byte ordering in 64-bit LE configuration for AHB buffer and 32-bit LE for TX/RX buffer.

### 74.6.1 Programming flash memory data

CPU writes instructions to the TBDR register, such as:

- Write TBDR: 4_03_02_01h
- Write TBDR: 8_07_06_05h

The following table shows the content against each TX buffer entry.

**Table 566. Example of QuadSPI TX buffer**

| TX buffer entry | Content |
|---|---|
| 0 | 4_03_02_01h |
| 1 | 8_07_06_05h |

Programming the TX buffer into the external serial flash memory device results in the following byte order to be sent to the serial flash memory:

- 01...02...03...04...05...06...07...08

### 74.6.2 Reading flash memory data into the RX buffer

Reading the content from the same address provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

The following table shows the content against each TX buffer entry.

**Table 567. Resulting RX buffer content**

| RX buffer entry | Content |
|---|---|
| 0 | 4_03_02_01h |
| 1 | 8_07_06_05h |

#### 74.6.2.1 Readout of the RX buffer through RBDRn

The RX buffer content appears at CPU read access through the peripheral bus interface in the following order:

- Read RBDR0: 4_03_02_01h
- Read RBDR1: 8_07_06_05h

#### 74.6.2.2 Readout of the RX buffer through ARDBn

The RX buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- 32-bit access: Read ARDB0: 4_03_02_01h
- 32-bit access: Read ARDB1: 8_07_06_05h
- 64-bit access: Read ARDB0: 8_07_06_05_04_03_02_01h

### 74.6.3 Reading flash memory data into the AHB buffer

Reading the content from the same address as it was written to provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

The following table shows the content against each TX buffer entry.

**Table 568. Resulting AHB buffer content**

| AHB buffer entry | Content |
|---|---|
| 0 | 8_07_06_05_04_03_02_01h |

#### 74.6.3.1 Readout of the AHB buffer through memory-mapped read

The AHB buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- 32-bit read access: 4_03_02_01h
- 32-bit read access: 8_07_06_05h
- 64-bit read access: 8_07_06_05_04_03_02_01h

## 74.7 Driving flash memory control signals in single and dual modes

In single and dual modes, the serial flash memory devices that can connect to the QuadSPI module expect additional control signals on the inputs, which are connected to IOFA[3], IOFA[2] in the quad mode. For easy interfacing, the outputs IOFA[3:2] for flash memory A are driven to the logic state given by the configuration fields MCR[ISD3FA], MCR[ISD2FA].

These outputs are driven all the time to the logic level programmed in the MCR except the time when quad commands of the serial flash memory are executed. See the specifications of the related serial flash memory device for details about the inactive level.

## 74.8 Serial flash memory devices

Several different vendors make flash memory devices with a QuadSPI interface. At present, there is no set standard for the QuadSPI instruction set. The most common commands currently have the same instruction code for all vendors; however, some commands are unique to specific vendors. Some of the example sequences are provided in the following sections.

### 74.8.1 Example sequences

This section provides the example sequences of the QuadSPI module.

**Table 569. Exit 4 x I/O read enhance performance mode (XIP) (Macronix) and read status**

| Instruction | Pad | Operand | Description |
|---|---|---|---|
| CMD | 0h | EBh | 4xIO read command |
| ADDR | 2h | 18h | 24-bit address to be sent on four pads |
| MODE | 2h | 0h | 2 mode cycles (exit XIP) |
| DUMMY | 2h | 4h | 4 dummy cycles |
| READ | 2h | 8h | Read 64 bits |
| CMD | 0h | 5h | Read Status register |
| READ | 0h | 1h | Status register data |
| STOP | 0h | 0h | Stop, instruction over |

#### 74.8.1.1 Fast read sequence (Macronix/Numonyx/Spansion/Winbond)

The following table shows the fast read sequence for Macronix/Numonyx/Spansion/Winbond flash memories.

**Table 570. Fast read sequence**

| Instruction | Pad | Operand | Description |
|---|---|---|---|
| CMD | 0h | Bh | Fast read command = 0Bh |
| ADDR | 0h | 18h | 24 address bits to be sent on one pad |
| DUMMY | 0h | 8h | Eight dummy cycles |
| READ | 0h | 4h | Read 32 bits on one pad |
| JMP_ON_CS | 0h | 0h | Jump to instruction 0 (CMD) |

**NOTE**

If DLL is disabled then JMP_ON_CS or STOP instruction can be used else only STOP instruction can be used.

#### 74.8.1.2 Fast read quad output (Winbond)

The following table shows the fast read quad output sequence for Winbond memories

**Table 571. Fast read quad output sequence**

| Instruction | Pad | Operand | Description |
|---|---|---|---|
| CMD | 0h | 6Bh | Fast read quad output command = 6Bh |
| ADDR | 0h | 18h | 24 address bits to be sent on one pad |
| DUMMY | 2h | 8h | Eight dummy cycles |
| READ | 2h | 4h | Read 32 bits on four pads |
| JMP_ON_CS | 0h | 0h | Jump to instruction 0 (CMD) |

**NOTE**

If DLL is disabled then JMP_ON_CS or STOP instruction can be used else only STOP instruction can be used.

#### 74.8.1.3 4 x I/O read enhance performance mode (XIP) (Macronix)

The following table shows the 4 x I/O read enhance performance mode for Macronix flash memories. The enhanced performance mode is also known as XIP mode.

**Table 572. Fast read quad output sequence**

| Instruction | Pad | Operand | Description |
|---|---|---|---|
| CMD | 0h | EBh | 4xI/O read command = EBh |
| ADDR | 2h | 18h | 24 address bits to be sent on four pads |
| MODE | 2h | A5h | Two mode cycles |
| DUMMY | 2h | 4h | Four dummy cycles |
| READ | 2h | 4h | Read 32 bits on four pads |
| JMP_ON_CS | 0h | 1h | Jump to instruction 1 (ADDR) |

When in XIP mode, the software must ensure that all the flash memories connected to the controller are in this mode. As a part of initializing the controller, all the flash memories might be enabled with XIP by carrying out dummy reads.

#### 74.8.1.4 Dual command page program (Numonyx)

The following table shows the dual command page program sequence for Numonyx flash memories.

**Table 573. Dual command page program sequence**

| Instruction | Pad | Operand | Description |
|---|---|---|---|
| CMD | 1h | 2h | Dual command page program = 02h on 2 pads |

*Table continues on the next page...*

Table 573. Dual command page program sequence (continued)

| Instruction | Pad | Operand | Description |
|---|---|---|---|
| ADDR | 1h | 18h | 24 address bits to be sent on two pads |
| WRITE | 1h | 20h | Write 32 bytes on two pads |
| STOP | 0h | 0h | Stop, instruction over |

#### 74.8.1.5 Sector erase (Macronix/Numonyx/Spansion)

The following table shows the Sector erase sequence for the Macronix/Numonyx/Spansion flash memories.

Table 574. Sector erase sequence

| Instruction | Pad | Operand | Description |
|---|---|---|---|
| CMD | 0h | 20h | Sector erase command = 20h |
| ADDR | 0h | 18h | 24 address bits to be sent on one pad |
| STOP | 0h | 0h | Stop, instruction over |

#### 74.8.1.6 Read status register (Macronix/Numonyx/Spansion/Winbond)

The following table shows the read status register sequence for Macronix/Numonyx/Spansion/Winbond flash memories.

Table 575. Read status register sequence

| Instruction | Pad | Operand | Description |
|---|---|---|---|
| CMD | 0h | 0h5 | Read status register command = 05h |
| READ | 0h | 0h1 | Read status register data |
| STOP | 0h | 0h | Stop, instruction over |

## 74.9 Sampling of serial flash memory input data

### 74.9.1 Basic description

QuadSPI is used to read data from the serial flash memory device. Depending on the actual implementation, there is a delay between the internal clocking in the QuadSPI module and the external serial flash memory device. See the following figure for an overview of this scheme.

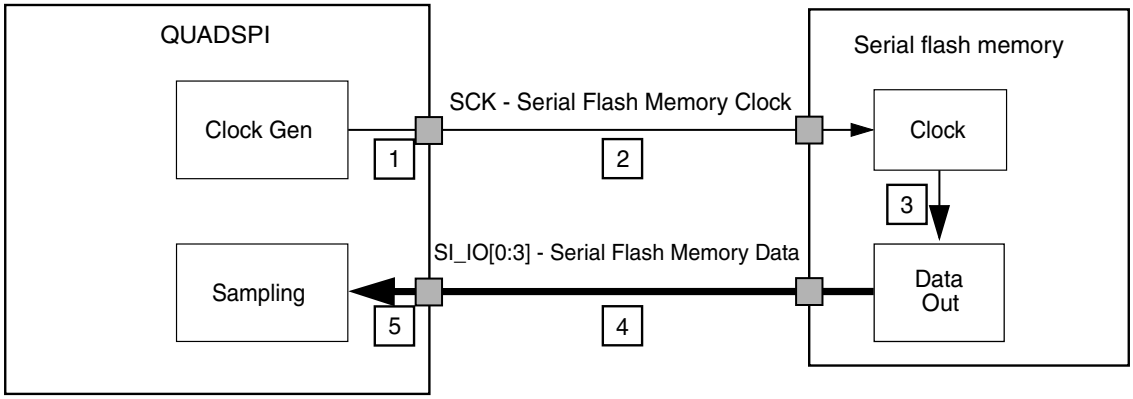

**Figure 435. Serial flash memory sampling clock overview**

The rising edge of the internal reference clock is taken as timing reference for the data output of the serial flash memory. After a time of $t_{total_delay}$ the data arrives at the internal sampling stage of the QuadSPI module. Considering the figure provided here, the following parts of the delay chain contribute to $t_{total_delay}$:

- Output delay of the serial flash memory clock output of the device containing the QuadSPI module
- Wire delay of application/PCB from the device containing the QuadSPI module to the external serial flash memory device
- Clock to data out delay of the external serial flash memory device, including input and output delays
- Wire delay of application/PCB from the external serial flash memory device to the device containing the QuadSPI module
- Device delay corresponding to the input data

**NOTE**

The $t_{total_delay}$ is specific to the characteristics of the actual implementation. Also, the serial flash memory device clock (SCK) is inverted with respect to the QuadSPI internal reference clock.

## 74.9.2 DQS sampling method

### 74.9.2.1 Basic description

In the DQS mode, the data strobe signal (DQS/RWDS) is used to sample the read data. Here, both DQS and the data sent by the flash memory move in the same direction; therefore, it is relatively easier to achieve at higher frequencies.

When using DQS for SDR reads, QuadSPI internally samples the incoming data on the rising edge of the strobe signal.

The next figure shows the sampling read data in the SDR mode using the DQS.

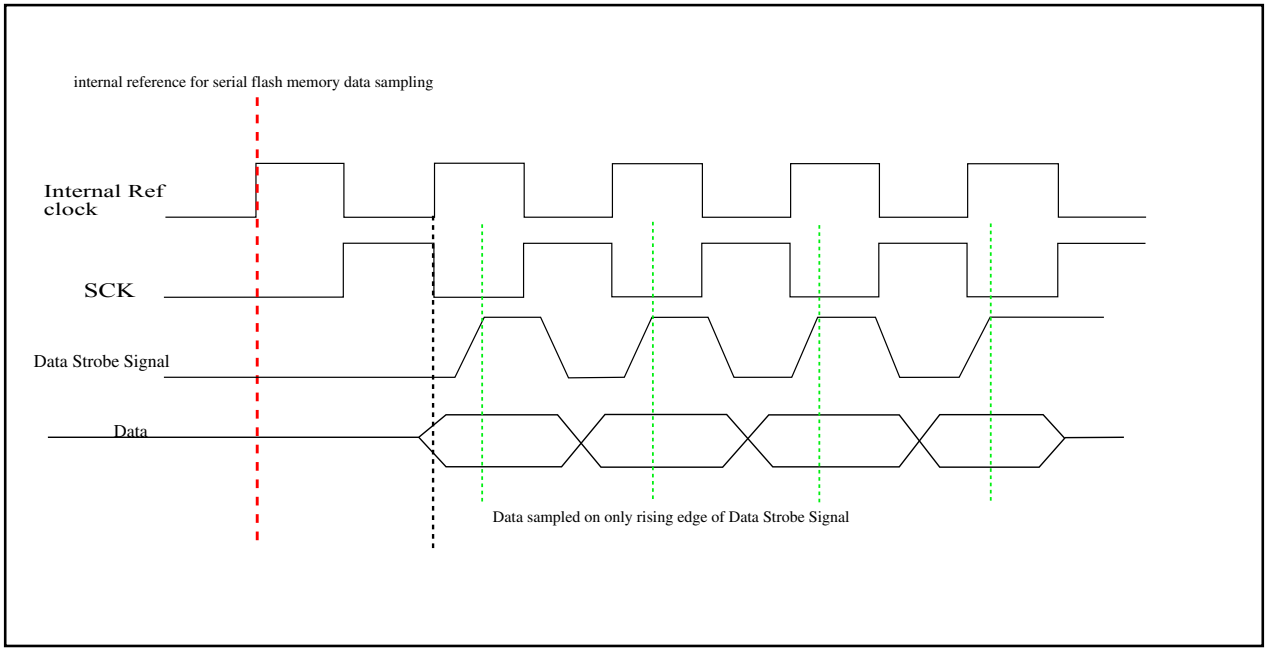

**Figure 436. Data strobe functionality in SDR mode for read operation.**

**NOTE**

Consider "Data Strobe Signal" as "Data Strobe Signal driven by memory" and "Data" as "Data from memory".

**NOTE**

Refer to the Datasheet for specific timing waveforms of QuadSPI

**NOTE**

For Specific details - Refer to the Data Sheet specification of QuadSPI module.

### 74.9.2.2 Dummy Pad loopback

The internal clock is loop-backed from the dummy internal pad to compensate data pad delays. This can be enabled by configuring the value of MCR[DQS_FA_SEL] as "01" for flash memory A. This mode can be used with the following configuration:

- High/low frequency delay chain manual programming in bypass mode using DLLCRA[SLV_DLY_COARSE] and DLLCR[FREQEN].

**NOTE**

Refer to Auto-DataLearning (4x Sampling method) section with DLL for further details

**NOTE**

This mode may not be available on the chip. See the "Supported read modes" section in the chip-specific QuadSPI information for the read modes that this chip supports.

## 74.10 Delay chain usage

**Slave delay chain programming sequence—**

Following is the programming sequence for DLL bypass mode.

1. Program DLLCRA[SLV_EN]=1, DLLCRA[SLV_DLL_BYPASS]=1, and DLLCRA[SLAVE_AUTO_UPDT]=0.

2. Program the following fields to provide the desired DQS delay for sampling: DLLCRA[SLV_FINE_OFFSET], DLLCRA[SLV_DLY_COARSE], and DLLCR[FREQEN]. See the chip-specific QuadSPI information for the supported programming settings.
3. Program DLLCRA[SLV_UPD]=1 to load these values in the slave delay chain.
4. Check the slave delay chain update status by polling DLLSR[SLVA_LOCK]=1 and clear DLLCRA[SLV_UPD] after confirming the update state.

## 74.11 Memory map and register definition

This section provides the memory map and register definitions for the QuadSPI module.

### 74.11.1 Register write access

Following are the write access restriction terms that apply to all the registers:

- Register write access restriction

  For each register field, the write access conditions are specified in the detailed register description.

  The following table provides a description of the write access conditions. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed.

  The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled.

**Table 576. Register write access restrictions**

| Condition | Description |
|---|---|
| Anytime | No write access restriction |
| Disabled mode | Write access only if MCR[MDIS] = 1 |
| Normal mode | Write access only if the module is in the normal mode |

- Register write access requirements

  You can access all registers using 8-bit, 16-bit, and 32-bit wide operations. For some of the registers, at least a 16-bit or 32-bit wide write access is required to ensure correct operation. This write access requirement is stated in the detailed register description for each affected register.

### 74.11.2 QUADSPI register descriptions

This section provides the memory map and register definitions for the QuadSPI module.

Access to the following addresses does not result in a transfer error:

- 50h
- 64h
- 104h
- 120h
- 138h
- 168h
- 188h
- 18Ch

### 74.11.2.1 QuadSPI memory map

QuadSPI base address: 404C_C000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Module Configuration Register (MCR) | 32 | RW | 000F_404Ch |
| 8h | IP Configuration Register (IPCR) | 32 | RW | 0000_0000h |

### 74.11.2.2 Module Configuration Register (MCR)

#### Offset

| Register | Offset |
|---|---|
| MCR | 0h |

#### Function

This register holds configuration data associated with the QuadSPI operation.

Special write-access is permitted in different modes:

- DQS_FA_SEL: Disabled mode
- ISD3FA, ISD2FA: Disabled mode
- All other fields: Anytime

#### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| | **NOTE**<br>The software resets need the clock to be running to propagate to the design. The value of MCR[MDIS] should therefore be 0 when the software reset bits are asserted. Also, before they can be deasserted again (by specifying 0 as the value for MCR[SWRSTSD]), it is recommended to specify 1 as the value for MCR[MDIS]. After the software resets are deasserted, the normal operation can be started by specifying 0 as the value for MCR[MDIS].<br>**NOTE**<br>Software must wait for at least three system cycles and three flash cycles after changing the value of this field. |

### 74.11.2.3 IP Configuration Register (IPCR)

#### Offset

| Register | Offset |
|---|---|
| IPCR | 8h |

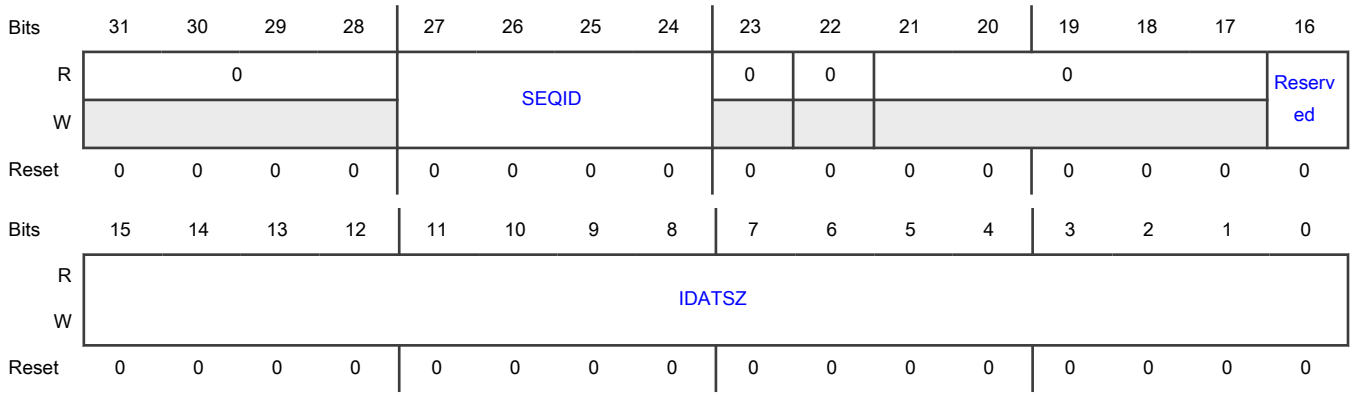
#### Function

This register provides all the configuration required for an IP-initiated command, which can be triggered by writing in the SEQID field of this register. If the SEQID field is written successfully, a new command to the external serial flash memory is initiated per the sequence pointed to by this field. See Normal mode for details on command triggering and command execution.

Special write-access is permitted if:

- SR[IP_ACC]=0

#### Diagram



**Fields**

| Field | Function |

| 15-0<br>IDATSZ | IP data transfer size<br>This field defines the data transfer size, in bytes, of the IP command. |

### 74.11.2.4 Flash Memory Configuration Register (FLSHCR)

**Offset**

| Register | Offset |
|---|---|
| FLSHCR | Ch |

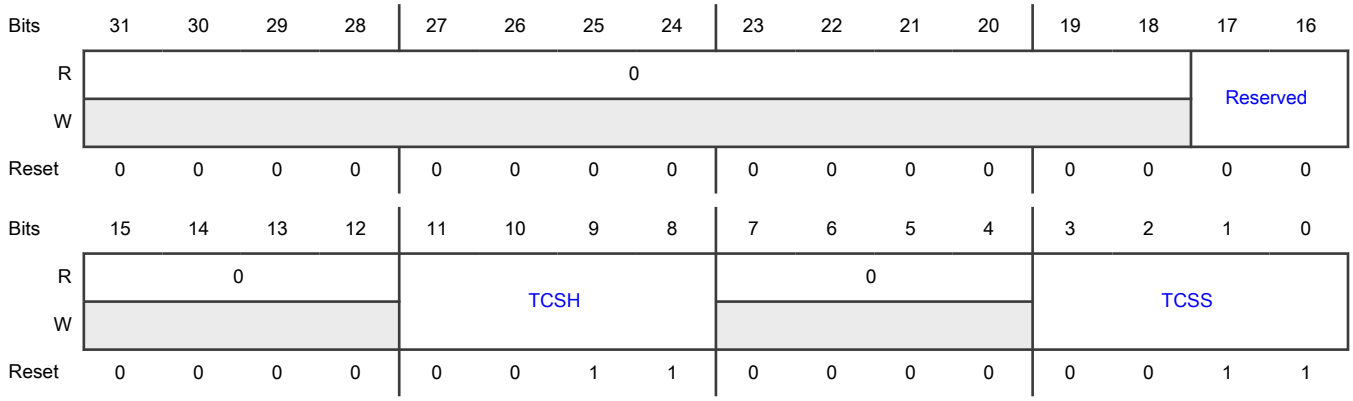
**Function**

This register contains the timings that are specific to the flash memory device. The QuadSPI controller must meet these timings for the device to function correctly.

Special write-access is permitted if:

- SR[AHB_ACC] = 0
- SR[IP_ACC] = 0

### Diagram



### Fields

| Field | Function |

| 7-4<br>— | Reserved |
| 3-0<br>TCSS | Serial flash memory CS setup time<br>This setup time is in terms of serial flash memory clock cycles, and it must be greater than or equal to two flash memory clock cycles. Refer the chip Datasheet for the exact value. |

## 74.11.2.5 Buffer 0 Configuration Register (BUF0CR)

### Offset

| Register | Offset |
|---|---|
| BUF0CR | 10h |

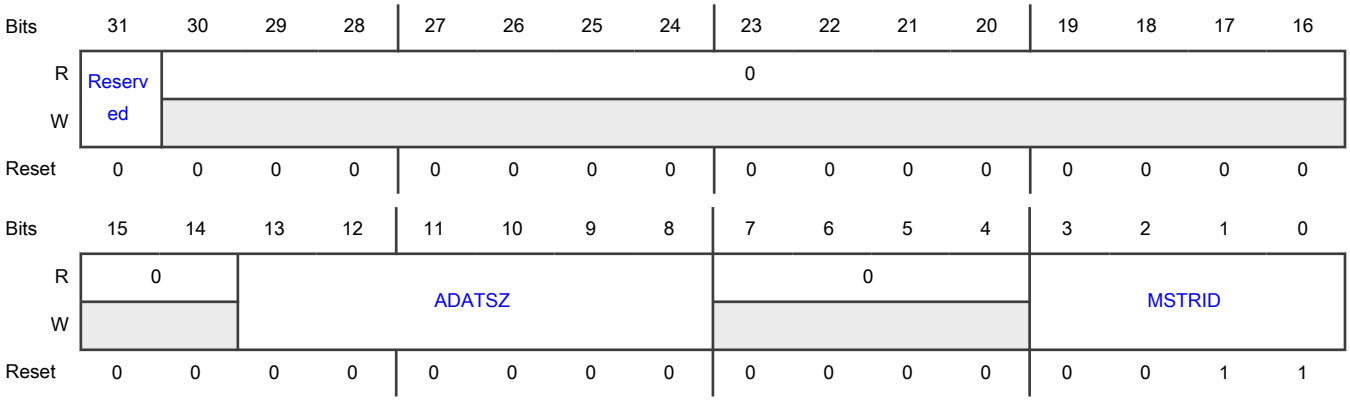
### Function

This register provides the configuration for any read access routed to buffer0, which happens when the master ID of the incoming AHB request matches BUF0CR[MSTRID]. Any buffer "miss" leads to a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

Special write-access is permitted if:

- SR[AHB_ACC] = 0

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>— | Reserved |
| 30-14<br>— | Reserved |
| 13-8<br>ADATSZ | AHB data transfer size<br>Defines the read data transfer size in 8 bytes of an AHB triggered read access to serial flash memory. For example, a value of 0x2 sets transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned in the sequence pointed to by the SEQID field overrides this value. The software should ensure that this transfer size is not greater than the size of the buffer. |
| 7-4<br>— | Reserved |
| 3-0<br>MSTRID | Master ID<br>ID of the AHB master associated with BUFFER 0<br>Any AHB read access with this master ID is routed to this buffer. You must ensure that the master IDs associated with all buffers are different.<br>**NOTE**<br>See the chip-specific QuadSPI information for details about master IDs and their corresponding components. |

### 74.11.2.6 Buffer 1 Configuration Register (BUF1CR)

#### Offset

| Register | Offset |
|---|---|
| BUF1CR | 14h |

#### Function

This register provides the configuration for any access routed to buffer 1, which happens when the master ID of the incoming AHB request matches the MSTRID field of this register. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

Special write-access is permitted if:

- SR[AHB_ACC] = 0

#### Diagram

| | Any AHB read access with this master ID is routed to this buffer. You must ensure that the master IDs associated with all buffers are different.<br>**NOTE**<br>See the chip-specific QuadSPI information for details about master IDs and their corresponding components. |

### 74.11.2.7 Buffer 2 Configuration Register (BUF2CR)

#### Offset

| Register | Offset |
|---|---|
| BUF2CR | 18h |

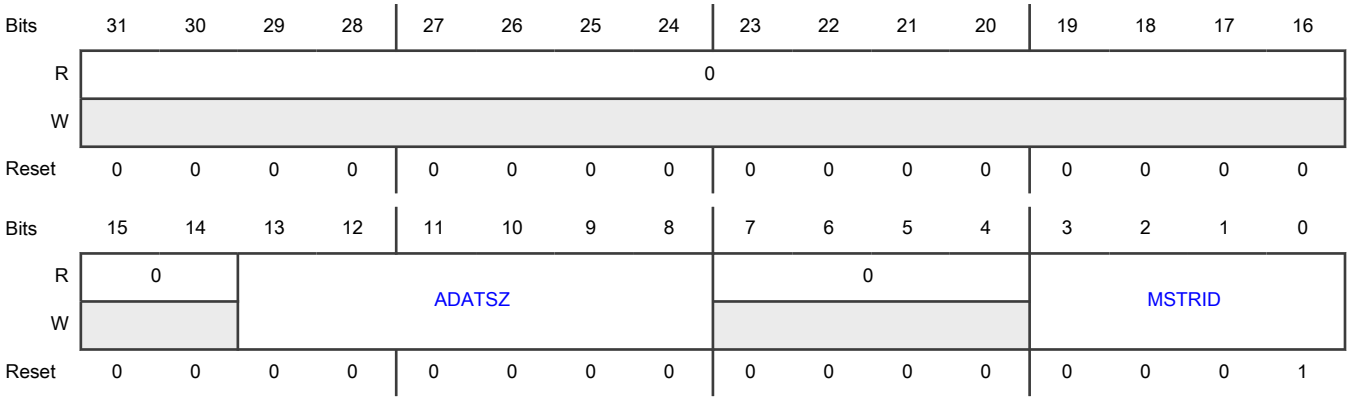
#### Function

This register provides the configuration for any access routed to buffer 2, which happens when the master ID of the incoming AHB request matches the MSTRID field of this register. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

Special write-access is permitted if:

- SR[AHB_ACC] = 0

#### Diagram



#### Fields

| Field | Function |
|---|---|
| 31-14<br>— | Reserved |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| 13-8<br>ADATSZ | AHB data transfer size<br>This field defines the read data transfer size in 8 bytes of an AHB triggered read access to the serial flash memory. For example, a value of 0x2 sets transfer size to 16 bytes. When ADATSZ = 0, the data size mentioned in the sequence pointed to by the SEQID field overrides this value. The software should ensure that this transfer size is not greater than the size of this buffer. |
| 7-4<br>— | Reserved |
| 3-0<br>MSTRID | Master ID<br>The ID of the AHB master associated with BUFFER2. Any AHB read access with this master ID is routed to this buffer.<br>It must be ensured that the master IDs associated with all buffers are different.<br>**NOTE**<br>See the chip-specific QuadSPI information for details about master IDs and their corresponding components. |

### 74.11.2.8 Buffer 3 Configuration Register (BUF3CR)

#### Offset

| Register | Offset |
|---|---|
| BUF3CR | 1Ch |

#### Function

This register provides the configuration for any access to buffer 3.

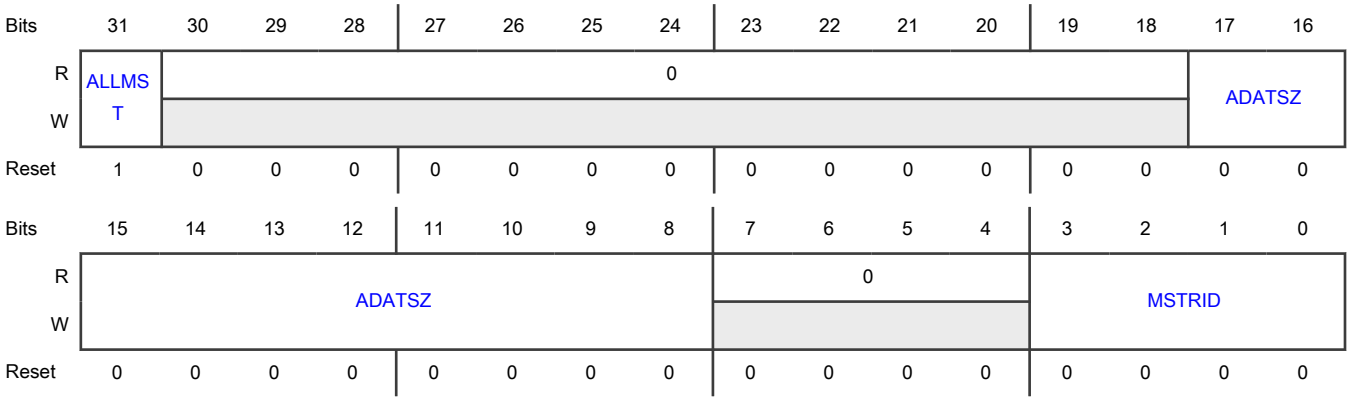
An access is routed to buffer 3 when the master ID of the incoming AHB request matches the MSTRID field of BUF3CR. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by BFGENCR[SEQID].

In case the value of the ALLMST field is not 1, any such transaction (where master ID does not match any of the MSTRID fields) is returned with an ERROR response.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>ALLMST | All master enable<br>When set, buffer3 acts as an all-master buffer. Any AHB access with a master ID not matching with the master ID of buffer0, buffer1, or buffer2 is routed to buffer3. When set, the MSTRID field of this register is ignored. |
| 30-18<br>— | Reserved |
| 17-8<br>ADATSZ | AHB data transfer size<br>Defines the read data transfer size in 8 bytes of an AHB triggered read access to serial flash memory. When ADATSZ = 0, the data size mentioned in the sequence pointed to by the SEQID field overrides this value. The software should ensure that this transfer size is not greater than the size of this buffer. If extended prefetch till 4K bytes has to be done then it can be programmed greater than the buffer size but should be always less than 512 just make sure that in this case ALLMST bit is also 1 and complete buffer is mapped to BUF3. |
| 7-4<br>— | Reserved |
| 3-0<br>MSTRID | Master ID<br>ID of the AHB master associated with BUFFER 3. Any AHB read access with this master ID is routed to this buffer. You must ensure that the master IDs associated with all buffers are different.<br>**NOTE**<br>See the chip-specific QuadSPI information for details about master IDs and their corresponding components. |

### 74.11.2.9 Buffer Generic Configuration Register (BFGENCR)

#### Offset

| Register | Offset |
|---|---|
| BFGENCR | 20h |

#### Function

This register provides generic configuration to any of the buffer accesses. Any buffer "miss" leads to the buffer being flushed and a serial flash memory transaction being triggered per the sequence pointed to by the SEQID field.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

#### Diagram

| 31-0<br>SOCCFG | SOC configuration<br>This field configuration is specific to chip. For details, see chip-specific QuadSPI information. |

### 74.11.2.11 Buffer 0 Top Index Register (BUF0IND)

#### Offset

| Register | Offset |
|---|---|
| BUF0IND | 30h |

#### Function

This register specifies the top index for buffer 0, which defines its size. Note that the three LSBs of this register are set to 0. This ensures that the buffer is 64-bit aligned because each buffer entry is 64-bits long.

The register value should be set to the desired number of bytes. For example, setting BUF0IND[31:3] to 0 gives 0 bytes, setting the value to 1 gives 8 bytes, and so on.

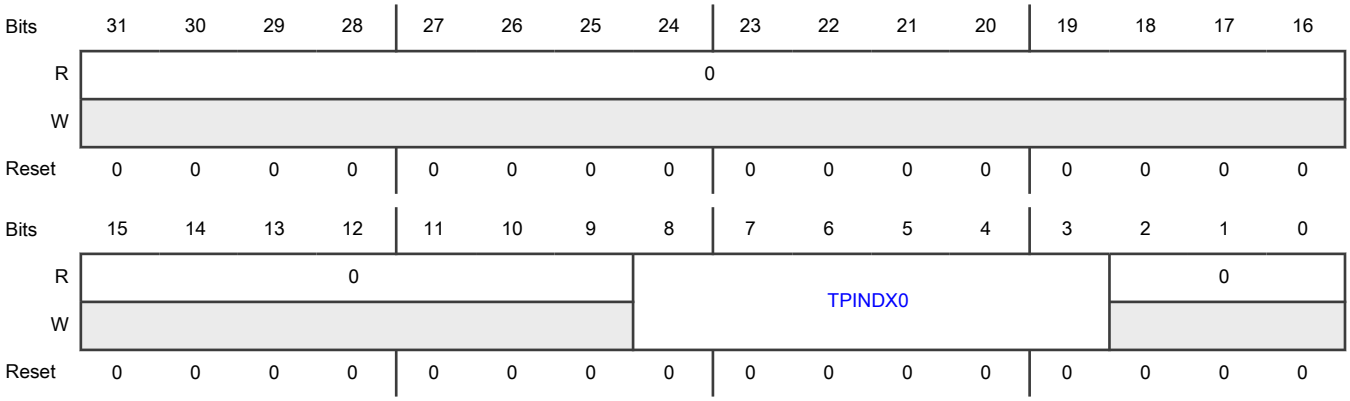
The size of buffer 0 is the difference between BUF0IND and 0.

The software must ensure that the value of TPINDX0 is not greater than the size of buffer 0.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

#### Diagram



#### Fields

| Field | Function |
|---|---|
| 31-9<br>— | Reserved |
| 8-3<br>TPINDX0 | Top index of buffer 0 |

### 74.11.2.12 Buffer 1 Top Index Register (BUF1IND)

#### Offset

| Register | Offset |
|---|---|
| BUF1IND | 34h |

#### Function

This register specifies the top index of buffer 1, which defines its size. Note that the three LSBs of this register are set to 0. This ensures that the buffer is 64-bit aligned because each buffer entry is 64-bits long.

The size of buffer 1 is the difference between BUF1IND and BUF0IND. The register value should be entered in bytes. For example, if BUF0IND = 0x100, then setting BUF1IND = 0x130 sets the size of buffer 1 to 0x30 bytes.

The software must ensure that the value of TPINDX1 is not greater than the size of buffer 1.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

#### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | | | | | | | | | | | | | | | |

### 74.11.2.13 Buffer 2 Top Index Register (BUF2IND)

#### Offset

| Register | Offset |
|---|---|
| BUF2IND | 38h |

#### Function

This register specifies the top index of buffer 2, which defines its size. Note that the three LSBs of this register are set to 0. This ensures that the buffer is 64-bit aligned because each buffer entry is 64-bits long.

The size of buffer 2 is the difference between BUF2IND and BUF1IND. The register value should be entered in bytes. For example, if BUF1IND = 0x130 then setting BUF2IND = 0x180 sets the size of buffer 2 to 0x50 bytes.

The software must ensure that the value of TPINDX2 is not greater than the size of buffer 2.

Special write-access is permitted if:

- SR[AHB_ACC] = 0

### 74.11.2.14 DLL Flash Memory A Configuration Register (DLLCRA)

#### Offset

| Register | Offset |
|---|---|
| DLLCRA | 60h |

#### Function

This register configures slave delay chain for flash memory A.

See Delay chain usage for the programming sequence.

**NOTE**

See the chip data sheet for information on programming register fields.

**NOTE**

Please see the chip specific section of QuadSPI DLLCRA register for delay elements data

#### Diagram

### 74.11.2.15 Serial Flash Memory Address Register (SFAR)

#### Offset

| Register | Offset |
|---|---|
| SFAR | 100h |

#### Function

The module automatically translates this address on the memory map to the address on the flash memory. When operating in a 24-bit mode, only bits 23-0 are sent to the flash memory. In the 32-bit mode, bits 27-0 are used with bits 31-28 driven to 0 . See Table 577 for the mapping between the access mode and the SFAR content and Normal mode for details on command triggering and command execution. The software must ensure that the serial flash memory address provided in the SFAR register lies in the valid flash memory address range, as defined in Table 577.

Special write-access is permitted if:

- SR[IP_ACC] = 0

#### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 74.11.2.16 Sampling Register (SMPR)

#### Offset

| Register | Offset |
|---|---|
| SMPR | 108h |

#### Function

This register allows configuration of how the incoming data from the external serial flash memory devices is sampled in the QuadSPI module.

**NOTE**

See the chip data sheet for programming the register fields.

Special write-access is permitted in the disabled mode.

#### Diagram

### 74.11.2.17 RX Buffer Status Register (RBSR)

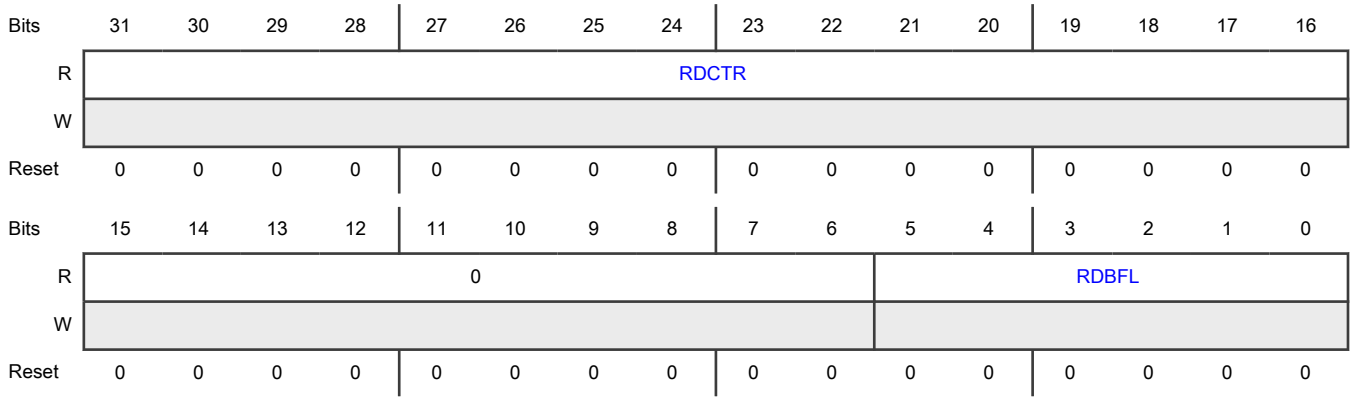
#### Offset

| Register | Offset |
|---|---|
| RBSR | 10Ch |

#### Function

This register contains information related to the receive data buffer.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-16<br>RDCTR | Read counter<br>Indicates the number of 4-byte entries removed from the RX buffer. For example, a value of 0x2 indicates that 8 bytes have been removed.<br>It is incremented by the number (RBCT[WMRK] + 1) on RX buffer POP event. The RX buffer can be popped using DMA or FR[RBDF]. The RSER[RBDDE] defines which pop should be pursued. For details, see AHB RX Data Buffer Register (ARDB0 - ARDB127) and Data Transfer from the QuadSPI Module Internal Buffers. |
| 15-6<br>— | Reserved |
| 5-0<br>RDBFL | RX buffer fill level<br>Indicates the number of 4-byte entries available in the RX buffer. For example, a value of 0x2 indicates 8 bytes are available. |

## 74.11.2.18 RX Buffer Control Register (RBCT)

### Offset

| Register | Offset |
|---|---|
| RBCT | 110h |

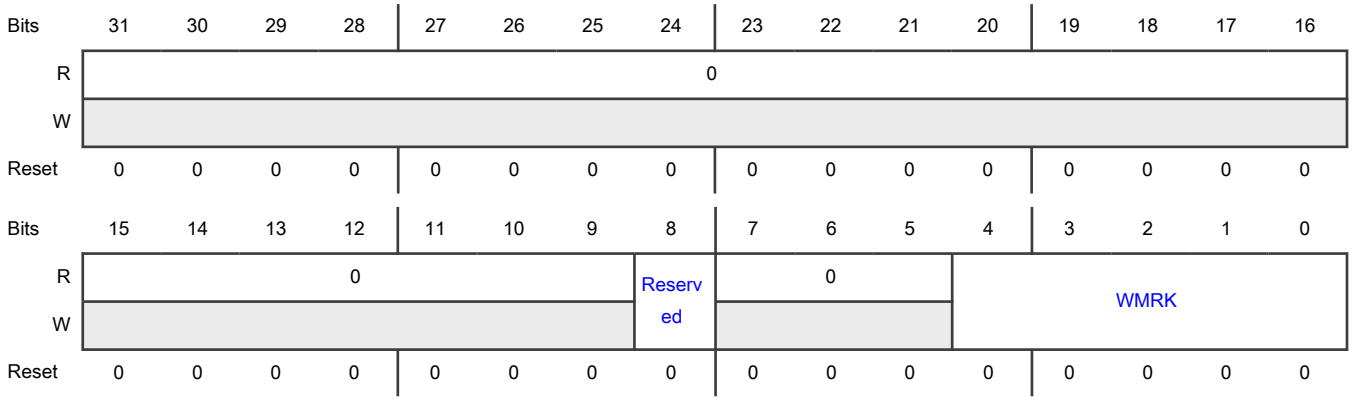
### Function

This register contains control data related to the receive data buffer.

Special write-access is permitted if:

- SR[IP_ACC] = 0

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-9<br>— | Reserved |
| 8<br>— | Reserved |
| 7-5<br>— | Reserved |
| 4-0<br>WMRK | RX buffer watermark<br>This field determines when the readout action of the RX buffer is triggered. When the number of valid entries in the RX buffer is equal to or greater than the number provided by (WMRK+1), the SR[RXWE] flag is asserted. The value should be entered as the number of 4-byte entries minus 1. For example, a value of 0x0 sets the watermark to 4 bytes, 1 to 8bytes, 2 to 12 bytes, and so on.<br>For details, see DMA usage.<br>**NOTE**<br>This field should never be programmed above 31 because there are only 32 memory mapped RBDR registers. If watermark is programmed above 31, data above 32 words will be lost. |

## 74.11.2.19 Data Learning Status Flash Memory A Register (DLSR_FA)

### Offset

| Register | Offset |
|---|---|
| DLSR_FA | 134h |

### Function

This register shows sampling point selected by data learning algorithm when the value of DLSR_FA[DLPFFA] is 0. Otherwise, it shows the pattern matching outline.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 7-0<br>NEG_EDGE | DLP negative edge match signature for flash memory A |

## 74.11.2.20 TX Buffer Status Register (TBSR)

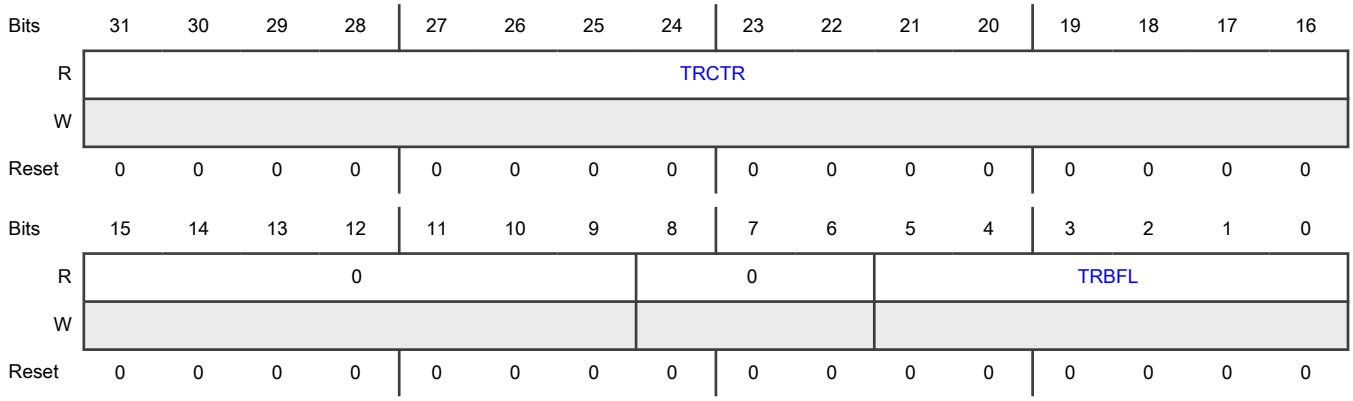
### Offset

| Register | Offset |
|---|---|
| TBSR | 150h |

### Function

This register contains information related to the transmit data buffer.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-16<br>TRCTR | Transmit counter<br>This field indicates how many entries of 4 bytes have been written into the TX buffer by host accesses. It is reset to 0 when a 1 is written to MCR[CLR_TXF]. It is incremented on each write access to the TBDR register when another word has been pushed onto the TX buffer. When it is not cleared, the TRCTR field wraps around to 0. See TX Buffer Data Register (TBDR) for details. |
| 15-9<br>— | Reserved |
| 8-6<br>— | Reserved |
| 5-0<br>TRBFL | TX buffer fill level<br>This field contains the number of entries of 4 bytes each available in the TX buffer for the QuadSPI module to transmit to the serial flash memory device. The value of this field can reach maximum up to the total TX buffer size. |

## 74.11.2.21 TX Buffer Data Register (TBDR)

### Offset

| Register | Offset |
|---|---|
| TBDR | 154h |

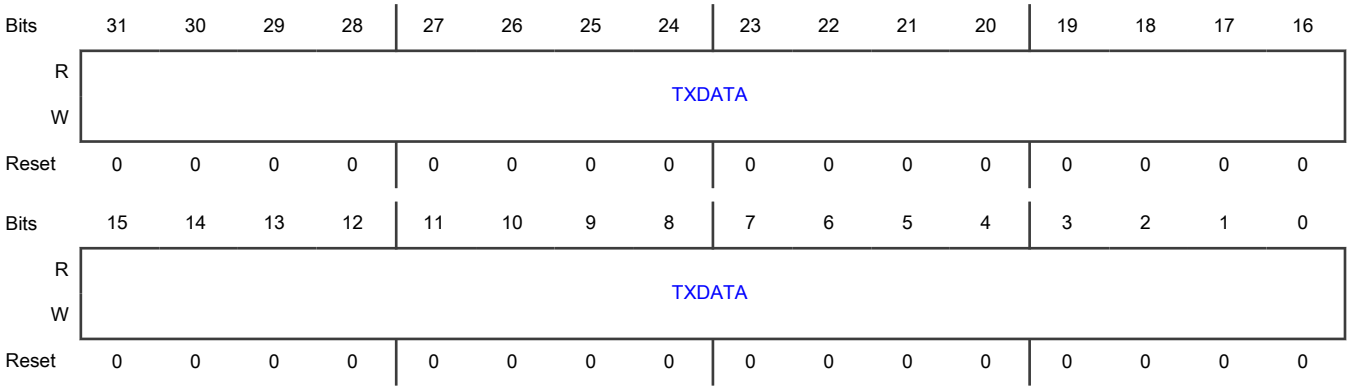
### Function

This register provides access to the circular TX buffer of depth 32 , so the total size is 32 * 4 bytes. This buffer provides the data written into it as write data for the page programming commands to the serial flash memory device. See Table 557 for the byte ordering scheme. A write transaction on the flash memory with data size of less than 32 bits leads to the removal of one data entry from the TX buffer. The valid bits are used and the rest of the bits are discarded.

Special write-access is permitted if:

- SR[TXFULL] = 0

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>TXDATA | TX data<br>On write access, the data is written to the next available entry of the TX buffer and TBSR[TRBFL] is updated accordingly.<br>On a read access, the last data written to the register is returned. |

## 74.11.2.22 TX Buffer Control Register (TBCT)

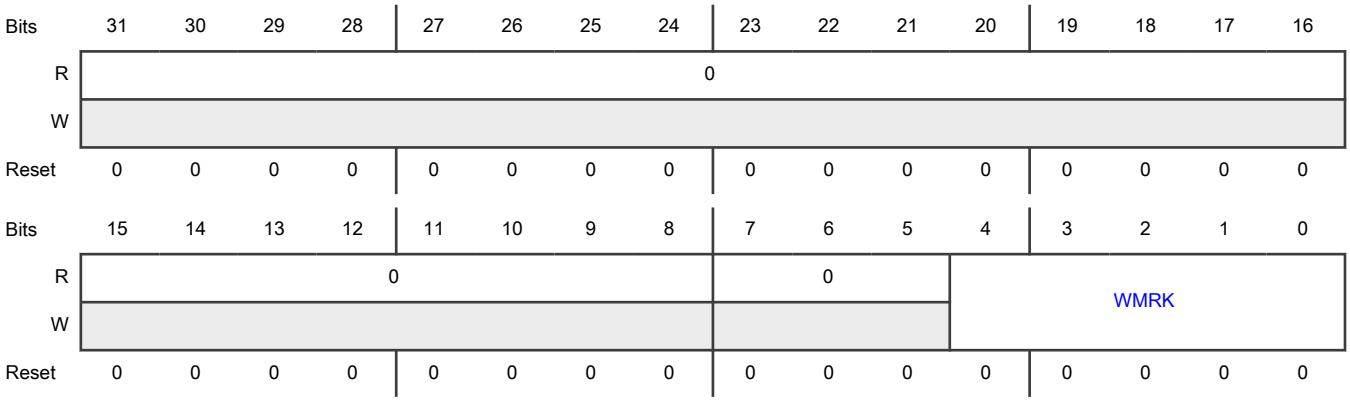
### Offset

| Register | Offset |
|---|---|
| TBCT | 158h |

### Function

This register contains control information for transmit data buffer.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-8<br>— | Reserved |
| 7-5<br>— | Reserved |
| 4-0<br>WMRK | Watermark for TX buffer<br>Determines the watermark for the TX buffer<br>When the number of available space in the TX buffer is greater than or equal to the number provided by WMRK (number of 4-byte entries), SR[TXWA] is asserted. For example, a value of 0x1 sets the watermark to 4 bytes, 0x2 sets it to 8 bytes, 0x3 sets it to 12 bytes, and so on. For details, see DMA usage.<br>WMRK = 0 is invalid. |

## 74.11.2.23 Status Register (SR)

### Offset

| Register | Offset |
|---|---|
| SR | 15Ch |

### Function

This register provides all the available status information about SFM command execution and arbitration, the RX buffer, TX buffer, and the AHB buffer.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 74.11.2.24 Flag Register (FR)

#### Offset

| Register | Offset |
|---|---|
| FR | 160h |

#### Function

This register provides all available flags about SFM command execution and arbitration, which may serve as the source for the generation of interrupt service requests. Note that the error flags in this register do not relate directly to the execution of the transaction in the serial flash memory device itself but only to the behavior and conditions visible in the QuadSPI module.

Special write-access is permitted in the enabled mode.

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | Before writing to the TX buffer, this field should be cleared. Then, it should be read back. If it is set, the TX buffer can include more data. If the field remains cleared, the TX buffer can be considered as full. See TX buffer operation for details. |
| 26<br>TBUF | TX buffer underrun flag<br>This field is set if the module tries to pull data when the TX buffer is empty.. The IP command leading to the TX buffer underrun is continued (data sent to the serial flash memory device is undefined ). Here, a valid underrun means that it should have occurred during the transaction so that few bytes (that is, less than 4 bytes) are left in FIFO and the remaining are filled with "FFFFh". This field does not set if transfer is less than 128 bits. The application must clear the TX buffer in response to this event by writing a 1 to MCR[CLR_TXF]. The application must clear the TX buffer in response to this event by writing a 1 to MCR[CLR_TXF]. |
| 25<br>— | Reserved |
| 24<br>— | Reserved |
| 23<br>ILLINE | Illegal instruction error flag<br>This field is set when an illegal instruction is encountered by the controller in any of the sequences. As soon as the field is set, you must assert MCR[SWRSTSD] and MCR[SWRSTHD]. That is, reset the flash memory and AHB domain after reconfiguring the correct sequence instruction. See Table 555 for a list of legal instructions. |
| 22-21<br>— | Reserved |
| 20<br>— | Reserved |
| 19-18<br>— | Reserved |
| 17<br>RBOF | RX buffer overflow flag<br>This field is set when no more data can be pushed into the RX buffer from the serial flash memory device.<br>The IP command leading to this condition is continued until the number of bytes in IPCR[IDATSZ] are read from the serial flash memory device.<br>The content of the RX buffer remains unchanged. |
| 16<br>RBDF | RX buffer drain flag<br>This field is set if SR[RXWE] is asserted.<br>Writing 1 to this field triggers one of the following actions: |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | • If the RX buffer has up to RBCT[WMRK] valid entries, then the flag is cleared.<br>• If the RX buffer has more than RBCT[WMRK] valid entries and the RSER[RBDDE] field is not set (flag driven mode), an RX buffer POP event is triggered.<br>The flag remains set if the RX buffer contains more than RBCT[WMRK] valid entries after the RX buffer POP event is complete.<br>The flag is cleared if the RX buffer contains less than or equal to RBCT[WMRK] valid entries after the RX buffer POP event is complete.<br>See the "Receive Buffer Drain Interrupt or DMA Request" section in Normal mode interrupt and DMA requests for details. |
| 15<br>AAEF | AHB abort error flag<br>This field is set in case software abort is asserted in an ongoing AHB transaction. The field should be cleared before starting any new AHB transaction. |
| 14<br>AITEF | AHB illegal transaction error flag<br>This is set whenever there is no response generated from QuadSPI to AHB bus in case of an illegal transaction and the watchdog timer expires. The timer value is considered as a parameter. |
| 13<br>AIBSEF | AHB illegal burst size error flag<br>This is set whenever the total burst size (size x beat) of an AHB transaction is greater than the prefetch data size, which is defined by BUFxCR[ADATSZ] or data size mentioned in the sequence pointed to by the SEQID field in case ADATSZ = 0. See HBURST support with AHB read details on HBURST feature. |
| 12<br>ABOF | AHB buffer overflow flag<br>ABOF has different behavior depending on which AHB buffer caused this flag. This is set when the size of the AHB access exceeds the size of the AHB buffer (0-2). This condition can occur if BUFxCR[ADATSZ] is programmed incorrectly. The AHB command leading to this condition is continued until the number of entries according to BUFxCR[ADATSZ] have been read from the serial flash memory device.The content of the AHB buffer is not changed. AHB buffer 3 has support for extended prefetch/streaming mode. It's not mandatory that ABOF bit is set for this buffer.If write location of prefetched data from flash in the AHB buffer equals the location of last AHB data read from the AHB buffer, AHB transaction is aborted. |
| 11<br>— | Reserved |
| 10<br>CRCAEF | Sets when there is CRC or ECC error for flash memory A<br>0b - CRCEF interrupt is not generated.<br>1b - CRCEF interrupt is generated. |

### 74.11.2.25 Interrupt and DMA Request Select and Enable Register (RSER)

#### Offset

| Register | Offset |
|---|---|
| RSER | 164h |

#### Function

This register provides enables and selectors for the interrupts in the QuadSPI module.

**NOTE**

Each field of the FR enabled as source for an interrupt prevents the QuadSPI module from entering the Stop mode or Module Disable mode when this flag is set.

Special write-access is permitted in the "Anytime" mode.

#### 74.11.2.26 Sequence Pointer Clear Register (SPTRCLR)

**Offset**

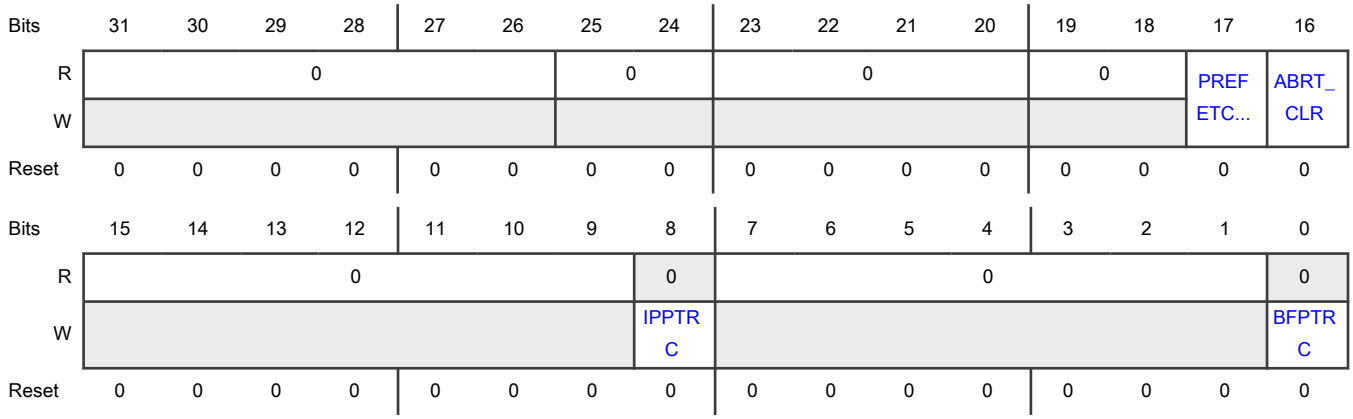
| Register | Offset |
|---|---|
| SPTRCLR | 16Ch |

**Function**

This register provides fields to reset the IP and buffer sequence pointers. The sequence pointer contains the index of instructions within the LUT entry that is to be executed next. For example, if the LUT entry ends on a JMP_ON_CS value of 2, the index is stored as 2.

The software should reset the sequence pointers defined by JMP_ON_CS operand whenever the sequence ID is required to be changed by updating the SEQID field in the IPCR or BFGENCR.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-26<br>— | Reserved |
| 25-24<br>— | Reserved |
| 23-20<br>— | Reserved |
| 19-18<br>— | Reserved |
| 17<br>PREFETCH_DIS | Prefetch disable<br>This field should be configured to disable the prefetch mechanism of receiver. It is not based on dynamic programming. Therefore, it should be programmed initially at once. When this field is set, then during an ongoing flash memory read, any subsequent AHB read is checked for buffer hit. However, after the end of flash memory read, as soon as chip select is deasserted, any subsequent AHB read results in flushing of the current AHB buffer data and issues fresh flash memory transaction if the AHB buffer data is not updated with the flash memory. |
| 16<br>ABRT_CLR | Flash memory Abort/AHB buffer clear<br>This is a dynamic field. Writing a 1 to it, irrespective of the prefetch disable, clears the AHB buffer pointers and also aborts any ongoing flash memory transaction (if any) and rejects any ongoing AHB read with an error response (if any).<br>QuadSPI sets this field to 0 after clearing the AHB buffer pointers. |

### 74.11.2.27 Serial Flash Memory A1 Top Address Register (SFA1AD)

#### Offset

| Register | Offset |
|---|---|
| SFA1AD | 180h |

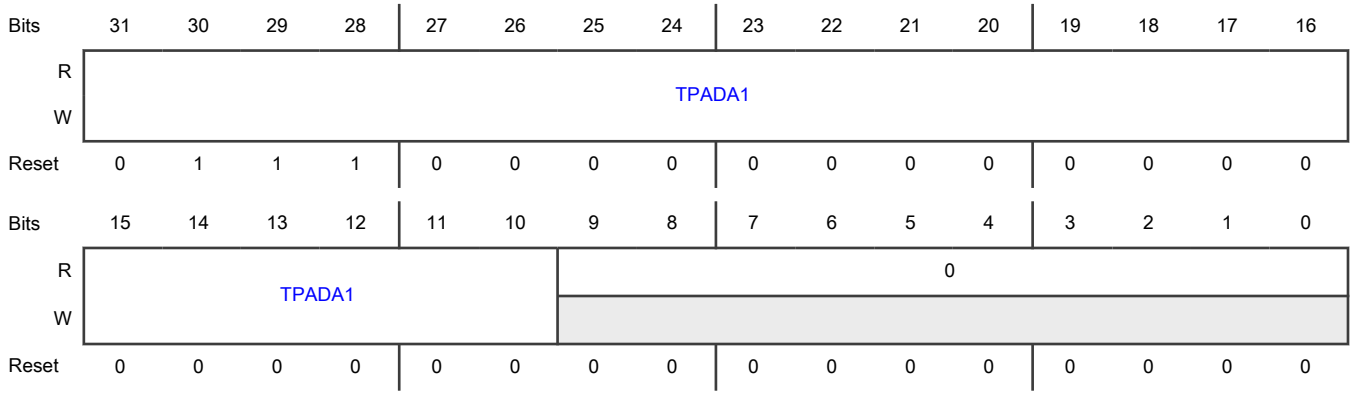
#### Function

This register provides the address mapping for serial flash memory A1. The difference between SFA1AD[TPADA1] and AMBA_BASE defines the size of the memory map for serial flash memory A1.

Special write-access is permitted if:

- SR[IP_ACC] = 0
- SR[AHB_ACC] = 0

#### Diagram



### Fields

| Field | Function |
|---|---|

### 74.11.2.31 RX Buffer Data Register (RBDR0 - RBDR31)

#### Offset

For a = 0 to 31:

| Register | Offset |
|---|---|
| RBDRa | 200h + (a × 4h) |

### Function

These registers provide access to individual entries in the RX buffer. See Table 557 for the byte ordering scheme.

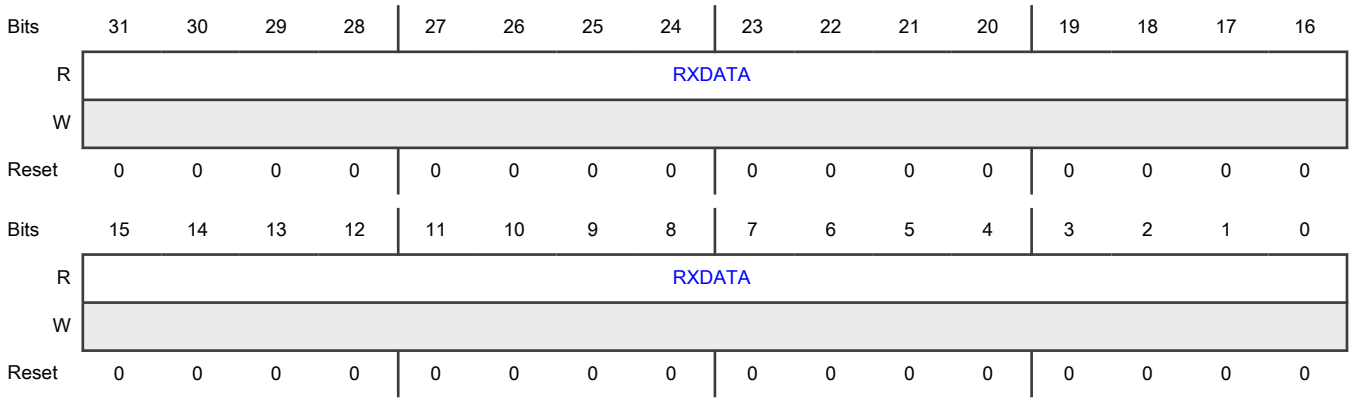
RBDR0 corresponds to the actual position of the read pointer within the RX buffer. The number of valid entries available depends on the number of RX buffer entries implemented and on the number of valid buffer entries available in the RX buffer.

Example 1 - RX buffer filled completely with 32 words: In this case, the address range for valid read access extends from RBDR0 to RBDR31 RBDR63.

Example 2 - RX buffer filled with five valid words: RX buffer fill level of RBSR[RDBFL] is 5. In this case, access to RBDR4 provides the last valid entry.

Any access beyond the range of valid RX buffer entries provides undefined results.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>RXDATA | RX data<br>This field contains the data associated with the related RX buffer entry. For data format and byte ordering, see Byte ordering of serial flash memory read data. |

## 74.11.2.32 LUT Key Register (LUTKEY)

### Offset

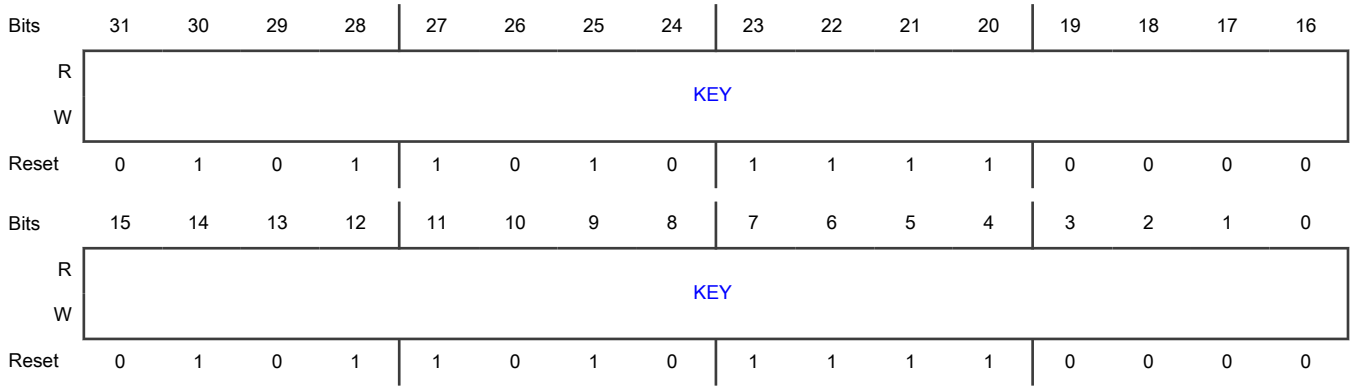
| Register | Offset |
|---|---|
| LUTKEY | 300h |

### Function

This register contains the key to lock and unlock the LUT. See LUT for details.

Special write-access is permitted in the "Anytime" mode. Write access is not permitted if MGC[11]=1b.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>KEY | Key to lock or unlock the LUT<br>The key is 0x5AF05AF0 and the read value is always 0x5AF05AF0. Write access is not permitted if MGC[11]=1b. |

## 74.11.2.33 LUT Lock Configuration Register (LCKCR)

### Offset

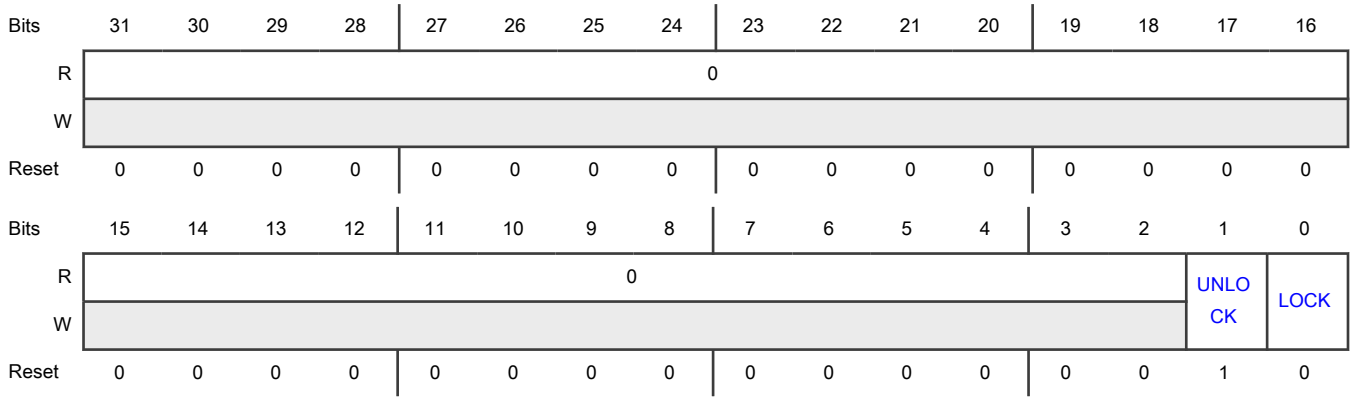
| Register | Offset |
|---|---|
| LCKCR | 304h |

### Function

This register is used along with the LUTKEY register to lock or unlock the LUT. This register should be written immediately after the LUTKEY register for the lock or unlock operation to be successful. See LUT for details. Setting both the LOCK and UNLOCK bits as "00" or "11" is not allowed.

Special write access is permitted after writing the LUT key register. Write access is not permitted if MGC[11]=1b.

### Diagram



#### Fields

| Field | Function |
|---|---|
| 31-2<br>— | Reserved |
| 1<br>UNLOCK | Unlock LUT<br>Unlocks the LUT when the following two conditions are met:<br>• This register is written just after the LUT Key Register (LUTKEY).<br>• The LUT key register was written with the 0x5AF05AF0 key. |
| 0<br>LOCK | Lock LUT<br>Locks the LUT when the following conditions are met:<br>• This register is written just after the LUT Key Register (LUTKEY).<br>• The LUT key register is written with the 0x5AF05AF0 key. |

### 74.11.2.34 LUT Register (LUT0)

#### Offset

| Register | Offset |
|---|---|
| LUT0 | 310h |

#### Function

A sequence of instruction-operand pairs may be pre-populated in the LUT according to the device connected on board. Each instruction-operand pair is of 16 bits (2 bytes) each. Every sequence preprogrammed by Program Sequence Engine in the LUT is referred to by its index. The LUT registers act as lookup tables for sequences of instructions. The programmable sequence engine executes the instructions in these sequences to generate a valid serial flash memory transaction. There are a total of 20 LUT registers. These 20 registers are divided into groups of 5 registers that make a valid sequence. Therefore, LUT[0], LUT[5], LUT[10] ..... LUT[15] are the starting registers of a valid sequence. Each of these sets of 5 registers can have a maximum of 10 instructions. Reset value of the register shown below is only applicable to LUT2 to LUT19. A maximum of 4 sequences can be defined at one time. See LUT that describes the LUT registers in detail.

Special write-access is permitted if the LUT is unlocked.

## 74.11.3 Serial flash memory address assignment

The serial flash memory address assignment can be modified by writing into Serial Flash Memory A1 Top Address Register (SFA1AD) and Serial Flash Memory A2 Top Address Register (SFA2AD) for device A

**Table 577. Serial flash memory address assignment**

| Parameter | Function | Access mode |
|---|---|---|
| QuadSPI_AMBA_BASE ((31:10) - 22 bits) | QuadSPI AHB base address<br>First address of the serial flash memory device as presented to the QuadSPI controller. This might be the base of the serial flash memory in the system address map or it may be a remapping, for instance to 0h, performed by the system. (See the system address map file attached to this document) | |
| QuadSPI_ARDB_BASE | First address of the QuadSPI Rx buffer on system memory map | |
| TOP_ADDR_MEMA1(TPADA1) | Top address for the external flash memory A1 (the first of the two independent flash memories sharing the IOFA) | Any access to the address space between TOP_ADDR_MEMA1 and QuadSPI_AMBA_BASE is routed to serial flash memory A1. |
| TOP_ADDR_MEMA2(TPADA2) | Top address for the external flash memory A2 (the second of the two independent flash memories sharing the IOFA) | Any access to the address space between TOP_ADDR_MEMA2 and TOP_ADDR_MEMA1 is routed to serial flash memory A2. |

## 74.12 Flash memory mapped AMBA bus

QuadSPI_AMBA_BASE defines the address to be used as the start address of the serial flash memory device, as defined by the system memory map. Note that this may be a remapping of the physical address of the serial flash memory in the system. See the system address map for details.

**Table 578. QuadSPI AMBA bus memory map**

| Address | Register name |
|---|---|
| QuadSPI_AMBA_BASE to (TOP_ADDR_MEMA2 - 1h) | • See Memory-mapped serial flash memory data—individual flash memory mode on flash memory A.<br>• For information about byte ordering, see Table 557 and Table 558. |
| QuadSPI_ARDB_BASE to... (32 * 4 Byte) QuadSPI_ARDB_BASE + 1FFh | • See AHB RX Data Buffer Register (ARDB0 - ARDB127).<br>• For information about the byte ordering, see Table 557. |

**NOTE**

Any read access to non-implemented addresses provides undefined results.

In individual flash memory modes, the 3/4 address bytes (as programmed in the instruction/operand in the sequence) available for the flash memory address are determined by SFADR[23:0] or SFADR[31:0] as provided in the table shown above.

### 74.12.1 AHB bus access read considerations

Note that all logic in the QuadSPI module implementing the AHB bus access is designed to read the content of an external serial flash memory device. Therefore, the following restrictions apply to the QuadSPI module with respect to accesses to the AHB bus:

- Any AHB command resulting in the assertion of the FR[ABSEF] flag is answered with the ERROR condition according to the AMBA_AHB specification. The resulting AHB command is ignored.
- AHB bus read access types—NONSEQ and BUSY—are fully supported.
- AHB read access type—SEQ—is treated in the same way as NONSEQ. See Flash memory mapped AMBA bus for details.
- Early burst termination is not supported for AHB transactions.
- An AHB error response occurs when FR[AITEF] bit is set
- An AHB bus stall along with error response occurs when FR[AAEF] bit is set

### 74.12.2 Memory-mapped serial flash memory data—individual flash memory mode on flash memory A

Starting with address QuadSPI_AMBA_BASE, the content of the first external serial flash memory device is mapped into the address space of the device containing the QuadSPI module. Serial flash memory byte address 0h corresponds to bus address, QuadSPI_AMBA_BASE, in an increasing order. . See the following table for the address mapping. The byte ordering for 32-bit access is provided in Table 557 and for 64-bit read access, the byte ordering is provided in Table 558.

**Table 579. Memory-mapped individual flash memory mode—flash memory A address scheme**

| Memory-mapped address 32-bit access | Memory-mapped address 64-bit access | Serial flash memory byte address | Flash memory device |
|---|---|---|---|
| QuadSPI_AMBA_BASE + 0h | QuadSPI_AMBA_BASE + 0h | 0h to 3h | A1 |
| QuadSPI_AMBA_BASE + 4h | | 4h to 7h | |
| ... | ... | ... | |
| TOP_ADDR_MEMA1 - 8h | TOP_ADDR_MEMA1 - 8h | (TOP_ADDR_MEMA1- 8h) to (TOP_ADDR_MEMA1 - 0h4 -0h1) | |
| TOP_ADDR_MEMA1 - 4h | | (TOP_ADDR_MEMA1 - 4h) to (TOP_ADDR_MEMA1 - 0h1) | |
| TOP_ADDR_MEMA1 + 4h | TOP_ADDR_MEMA1 + 0h | 0h to 3h | A2 |
| TOP_ADDR_MEMA1 + 0h4 | | 4h to 7h | |
| ... | ... | ... | |
| TOP_ADDR_MEMA2 - 8h | TOP_ADDR_MEMA2 - 8h | (TOP_ADDR_MEMA2 - 8h) to (TOP_ADDR_MEMA2 - 4h - 1h) | |
| TOP_ADDR_MEMA2 - 4h | | (TOP_ADDR_MEMA2 - 4h) to (TOP_ADDR_MEMA2 - 1h) | |

The available address range depends on the size of the external serial flash memory device. Any access beyond the size of the external serial flash memory provides undefined results.

For details concerning the read process, see Flash memory read.

## 74.12.3 ARDB register descriptions

**NOTE**

See the system memory map in this document for the base address of the QuadSPI AHB RX data buffer.

### 74.12.3.1 ARDB memory map

QuadSPI_ARDB base address: 6800_0000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h - 1FCh | AHB RX Data Buffer Register (ARDB0 - ARDB127) | 32 | R | 0000_0000h |

### 74.12.3.2 AHB RX Data Buffer Register (ARDB0 - ARDB127)

#### Offset

For a = 0 to 127:

| Register | Offset |
|---|---|
| ARDBa | 0h + (a × 4h) |

#### Function

This register is used to read the buffer content of the RX buffer from successive addresses. ARDB0 corresponds to the RX buffer register entry corresponding to the current value of the read pointer in an increasing order.

The increment of the read pointer depends on the access scheme (DMA or flag-driven). See Flash memory read, RX buffer, data read through register interface, and AHB read for the description of successive accesses to the RX buffer content. See Byte Ordering of Serial Flash Memory Read Data for the byte ordering scheme.

Valid address range accessible in the ARDB*n* range depends on the number of RX buffer entries implemented and on the number of valid buffer entries available in the RX buffer.

- Example 1 - RX buffer filled completely with 128 words: In this case, the address range for valid read access extends from ARDB0 to ARDB127.
- Example 2 - RX buffer filled with five valid words; RX buffer fill level RBSR[RDBFL] is 5. In this case, an access to ARDB4 provides the last valid entry.

#### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

**Fields**

| Field | Function |
|---|---|
| 31-0<br>ARXD | ARDB provided RX buffer data<br>Byte order (endianness) is identical to the RX buffer data registers. |

## 74.13 Glossary

| | |
|---|---|
| **AHB** | Advanced high-performance bus, a version of AMBA |
| **AMBA** | Advanced microcontroller bus architecture |
| **APB** | Advanced peripheral bus |
| **BE** | Big endian byte ordering |
| **CRS** | Center aligned read strobe |
| **CS** | Chip select |
| **FRAD** | Flash region access descriptor |
| **I/O** | Input output, I/O lines are also referred to as pads in this chapter |
| **IFM** | Individual flash memory mode |
| **LE** | Little endian |
| **MDAD** | Master domain access descriptors |
| **MGID** | Master-Group identifier |
| **PCS** | Peripheral chip select |
| **SCK** | Serial communications clock |
| **SFM** | Serial flash memory |

# Chapter 75
# Debug Subsystem

## 75.1 Introduction

This chapter discusses the debug and trace architecture of the chip that is based on the specifications provided in the *Arm® CoreSight™ SoC-400 Technical Reference Manual*. See References for a link to this document and to other related documentation available on the Arm website.

The chip architecture includes debug and trace modules. See Features for details on the debug and trace features that Cortex-M7 core clusters support.

The debug components that the Cortex-M7 core supports are accessible via the Arm DAP controller-based architecture. The DAP controller works in parallel with the system JTAGC. Both these controllers share the JTAG port and JTAG instruction set.

The system components are similar for different chips in the same family and include the primary core debug interfaces, the chip-level debug interfaces, and chip-level trace interfaces. The accelerator components include debug and trace circuits. These circuits are necessary for any application-specific accelerators required for the different application spaces that a chip supports. They vary from one chip to another and could include only trace components.

## 75.2 Interfaces supported in MCX E31 family

**Table 580. Interfaces supported in MCXE31 family**

| MCXE315/MCXE316/MCXE317 | MCXE31B |
|---|---|
| Cortex-M7_0 (CTI, DWT, BPU, ITM) | Cortex-M7_0 (CTI, DWT, BPU, ETM, ITM) |
| - | - |
| - | - |
| Cortex-M0+ | Cortex-M0+ |
| - | HTM (CTI+DMA/EMAC TRACE) |
| SWO | SWO |
| - | TPIU |
| - | ETF (4) |
| - | FUNNELs (3) |
| CTI (2) | CTI (3) |
| CTM (1) | CTM (1) |
| Timestamp | Timestamp |
| MDM_AP | MDM_AP |
| SDA_AP | SDA_AP |

## 75.3 Block diagram

This figure illustrates the DAP architecture of the MCX E31 family.

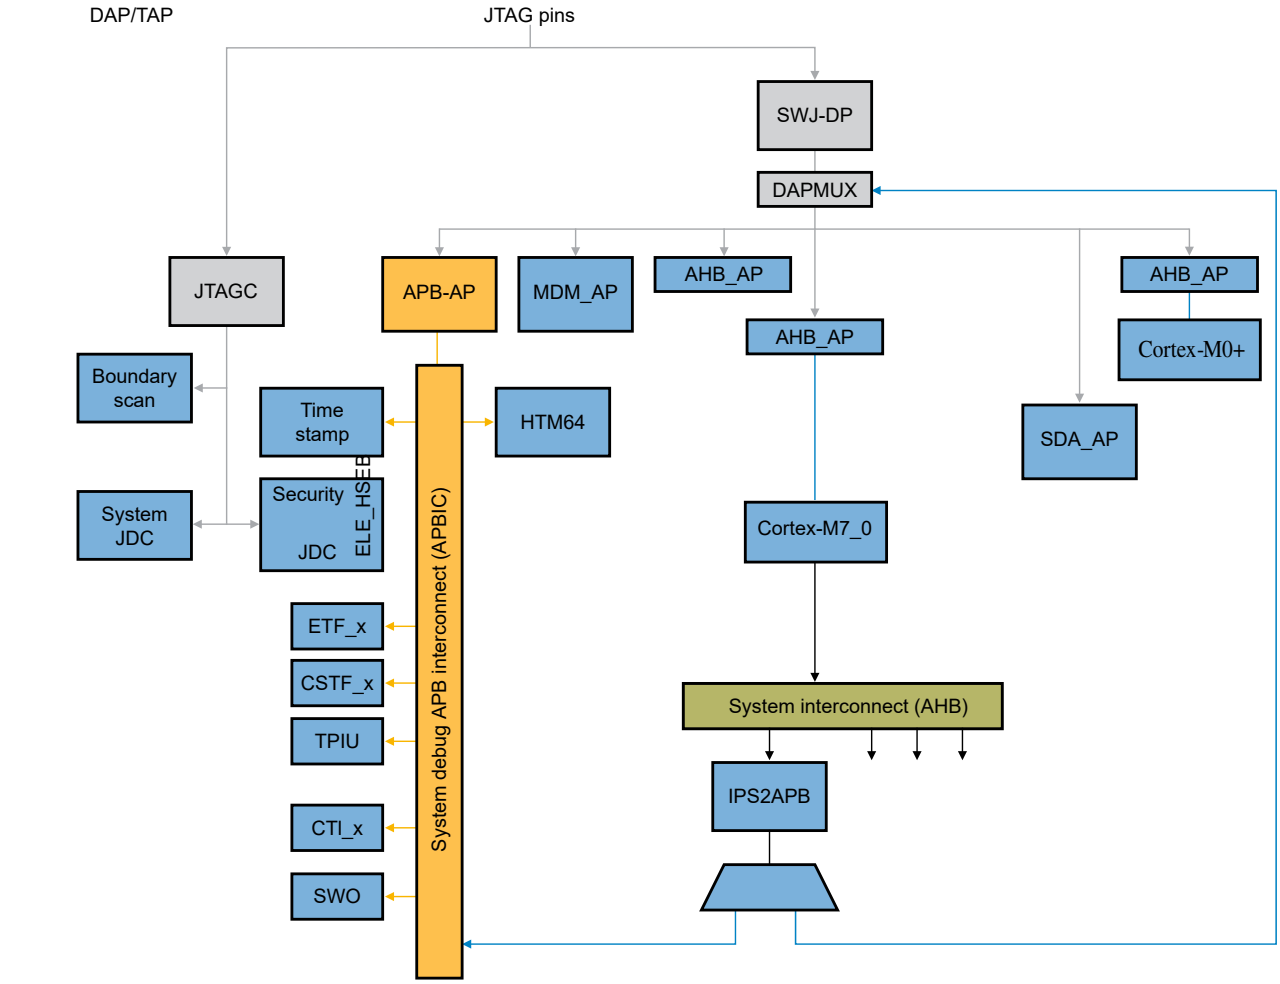

Figure 437. DAP architecture

**NOTE**

Debug components other than the Cortex-M0+ core are accessible through software path (CORE > AXBS > AIPS > DAPMUX > APs), that is, by directly specifying the memory mapped addresses without doing challenge response.

## 75.4 Features

This chip includes these features that support the functions listed under each feature type:

- Debug control
  - Is implemented via IEEE 1149.1-compliant JTAG
- Test control
  - Is implemented via IEEE 1149.1-compliant JTAG
  - Uses IEEE 1149.6 extension to IEEE 1149.1
- Trace interface
  - Includes four high-speed data pads and one clock pad @120 MHz (120 MB/s throughput per pad)
  - Includes 16 low-speed data pads and one clock pad @25 MHz (100 MB/s throughput per pad)
- Debug security

  - Includes a DAP/TAP interface that controls all debug features and is gated by Cortex M0+ JDC module
  - Includes security modes as described in the "Security" chapter
- Debugging and run control
  - Is implemeted through stopping points, starting points, breakpoints, and watchpoints
  - Cortex-M7 core supports eight instruction comparators and a watchpoint unit having four watchpoints
- Trace source
  - Includes Cortex-M7:
    - ETM that provides instruction and data trace
    - ITM that provides DWT, time-stamping, and diagnostic information
- Cross-triggering support
  - Controls run-control options of cores based on other cores
  - Provides a matrix having connections to:
    - HTM via system CTI
    - Cortex-M7 CPUs
- Ability to view and modify all memory-mapped areas that are not otherwise blocked—includes a system bus debug access port
- Performance monitoring of cores—implements a performance monitoring unit (PMU) on each Cortex core
- Safety
  - Supports monitoring of debug signals to avoid common mode faults
  - Allows checking of erroneous activation of debugging, especially if intrusive (for example, a CPU entering Debug state)
- Timestamps
  - Generates a timestamp bus for distribution to the trace sources
  - Includes a 48-bit binary timestamp bus
  - Clocks timestamp generator by a frequency of 160 MHz

## 75.5 Debug

### 75.5.1 TAP connectivity

This figure shows a detailed view of TAP connectivity. JTAG select, SWJ-DP, and JTAG-DP are parts of DAP.

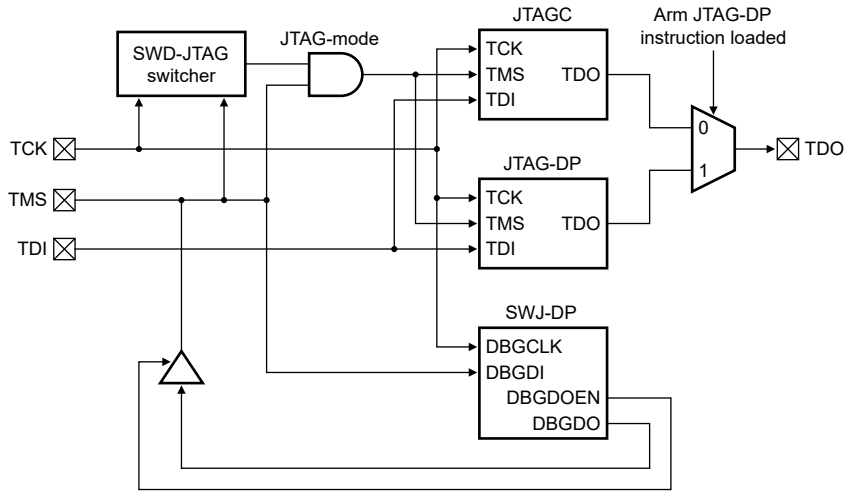

Figure 438. TAP connectivity

The debug port comes out of reset in a standard JTAG mode. It switches to another mode by using the change sequences. After the mode changes, unused debug pins can be reassigned to any of their alternative muxed functions.

JTAG-DP and JTAGC are connected in an overlay scheme and both have an Instruction Register (IR) length of 8 bits.

### 75.5.2 DAP TAP

DAP is an Arm component that provides multiple-master driving ports. A single external interface port accesses and controls these ports to provide system-wide debug.

The DAP Instruction Register (DAP IR) overlays with the system JTAG Instruction Register (JTAGC IR). Table 581 presents DAP instructions. In addition to the four codes listed in the table, DAP uses BYPASS, which is identical to JTAGC BYPASS and is therefore not shown in the table.

Table 581. DAP IR codes

| Code | DAP IR |
|---|---|
| 1111_1000b | ABORT |
| 1111_1010b | DPACC |
| 1111_1011b | APACC |
| 1111_1110b | IDCODE |

DAP offers an AHB master interface to access system buses. It also exports the internal DAP bus to extend the access ports. For more information on DAP TAP, see the *Arm Debug Interface Architecture Specification* document available in References.

In this chip:

- The AHB slave ports of all Cortex-M*x* cores provide debugger access to all memory units and registers in the system.
- The new pass-through approach allows the debugger to see a cache coherent view of the memory map for that core.
- The debugger must access the corresponding AHB_AP port to access the AHB-S port of that subsystem.
- XRDC controls system access.
- A core can access the debug components of another core through a DAPMUX to the bus interconnect.
- The exported DAP bus hosts AHB_AP and MDM_AP.

— MDM_AP hosts system-level JTAG status and control registers (see MDM_AP register descriptions). These registers can be used for cross triggering, synchronized debug, and other miscellaneous control and status functions.

— APB_AP uses an APSEL value of 1h to access any APB-mapped debug modules.

Table 585 describes the access addresses of APB-mapped debug modules. The value of the DAP select signal in the APSEL field of SWJ-DP's Select register selects the access ports in the DAP. Table 582 shows APSEL decoding.

Table 582. DAP master address mapping

| DAP master # | DAP component | DAPBUS base address (access from debugger) [1] | System memory map address (access from cores) | | Selected port or master | Applicability |
|---|---|---|---|---|---|---|
| | | | Page number | Base address | | |
| 0h | Reserved | 0000_0000h | 0 | 4025_0000h | Reserved | - |
| 1h | APB_AP to all APB-mapped debug modules (for example, ETFs, HTM, and trace funnels) | 0100_0000h | 0 | 4025_0100h | APB_AP to all APB-mapped debug modules (for example, ETFs, HTM, CSTF, and so on) | MCXE31B (for ETF, HTM, and CSTF see Table 580) |
| 2h | Reserved | 0200_0000h | 0 | 4025_0200h | Reserved | - |
| 4h | AHB_AP to Cortex-M7_0 debug modules and chip system memory map | 0400_0000h | 0 | 4025_0400h | AHB_AP to Cortex-M7_0 debug modules and chip system memory map | All |
| 5h | AHB_AP to Cortex-M7_1 debug modules and chip system memory map | 0500_0000h | 0 | 4025_0500h | AHB_AP to Cortex-M7_1 debug modules and chip system memory map | MCXE317 |
| 6h | MDM_AP | 0600_0000h | 0 | 4025_0600h | MDM_AP | All |
| 7h | SDA_AP | 0700_0000h | 0 | 4025_4700h | SDA_AP used for challenge-response (CR) in SWJ-DP mode | All |
| 8h—FFh | Reserved (default AP response) | — | — | — | — | - |

1. For example, 4000_XXYYh address is provided when accessing access ports (APs) via the debugger. Here, XX shows the AP select number and YY shows the address to be accessed. If you access SDA_AP via the debugger on 80h, you must provide the address 4000_0780h.

**NOTE**

Accessing SDA_AP simultaneously from the core and the debugger is prohibited. If you try to do so, you may receive unpredictable responses to core-initiated transactions (for example, incorrect data read, a failed attempt to write to the register, or a transfer error). Debugger-initiated transactions proceed correctly.

### 75.5.3 System JTAGC

JTAGC connects in parallel with the TAP controller (JTAG-DP of DAP), which has an IR length of 8 bits. The JTAGC IR codes overlay the ones of the DAP controller. DAP uses four instructions and JTAGC uses the remaining ones. The TAP outputs (TPOs) are multiplexed based on the selected IR code. This chip is fully JTAG-compliant and appears as a single TAP to the JTAG chain.

This table shows the JTAGC IR codes. The instructions that are used by Arm DAP TAP are shown in Table 581.

**Table 583. JTAG instructions for JTAGC**

| Code | JTAGC IR |
|---|---|
| 0000_0000b | IDCODE |
| 0000_0001b | Reserved |
| 0000_0010b | SAMPLE/PRELOAD |
| 0000_0011b | SAMPLE |

#### 75.5.3.1 Chip JTAG/Target ID

Each chip in the MCXE31 family includes a unique JTAG ID, which must be changed when instantiated with a different die in an SiP. The next table shows the JTAGC ID for this chip.

Table 584. JTAG/Target ID

| Chip | PRN | DC | PIN | MIC | IDCODE ID | JTAG ID | Target ID |
|---|---|---|---|---|---|---|---|
| MCXE31B | 0 | 26h (38d) | 160h (352d) | Eh (14d) | 1 | 0996_001Dh | 0996_001Dh |
| MCXE315/ MCXE316 | 0 | 26h (38d) | 16Ch (364d) | Eh (14d) | 1 | 0996_C01Dh | 0996_C01Dh |
| MCXE317 | 0 | 26h (38d) | 168h (360d) | Eh (14d) | 1 | 0996_801Dh | 0996_801Dh |

#### 75.5.3.2 JDC

JDC allows you to access two 32-bit data registers by using the JTAG interface and by software running on one of the CPUs in the chip. These registers exchange data between an internal CPU and an external debug tool.

### 75.5.4 Peripheral IPG debug implementation

MCXE31 is a multi-core chip. Any core can control a peripheral instance individually. You define the core's control over a peripheral during application development.

For peripheral halt, all individual cores have the same capability and are gated by a dedicated MDM_AP core halt register field. For more information, see the configurations defined in MDM_AP register descriptions.

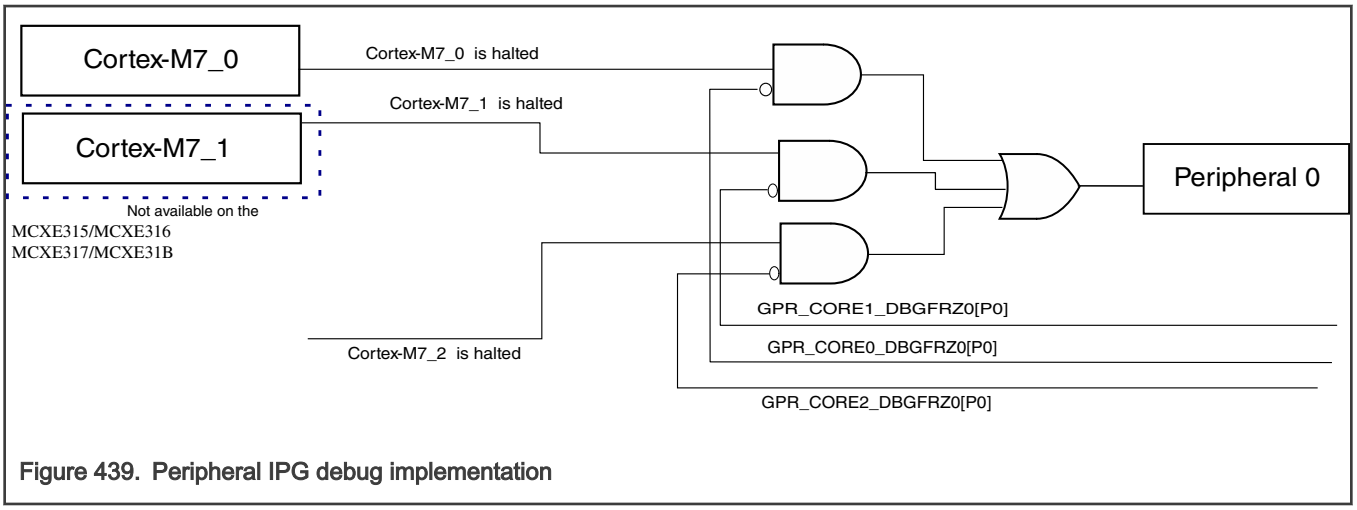

Figure 439. Peripheral IPG debug implementation

### 75.5.5 Application debugging

This section covers the following two cases:

- Case 1: Debugger connected—application debugging from the first instruction
- Case 2: Debugger not connected

#### 75.5.5.1 Application debugging from first instruction

This chip supports debugging from the first instruction on system power-up, destructive reset, functional reset, and standby exit. However, by default, debugging from the first instruction is disabled.

The next figure shows the timing diagram of application debug implementation from first instruction on system power-up or destructive reset.

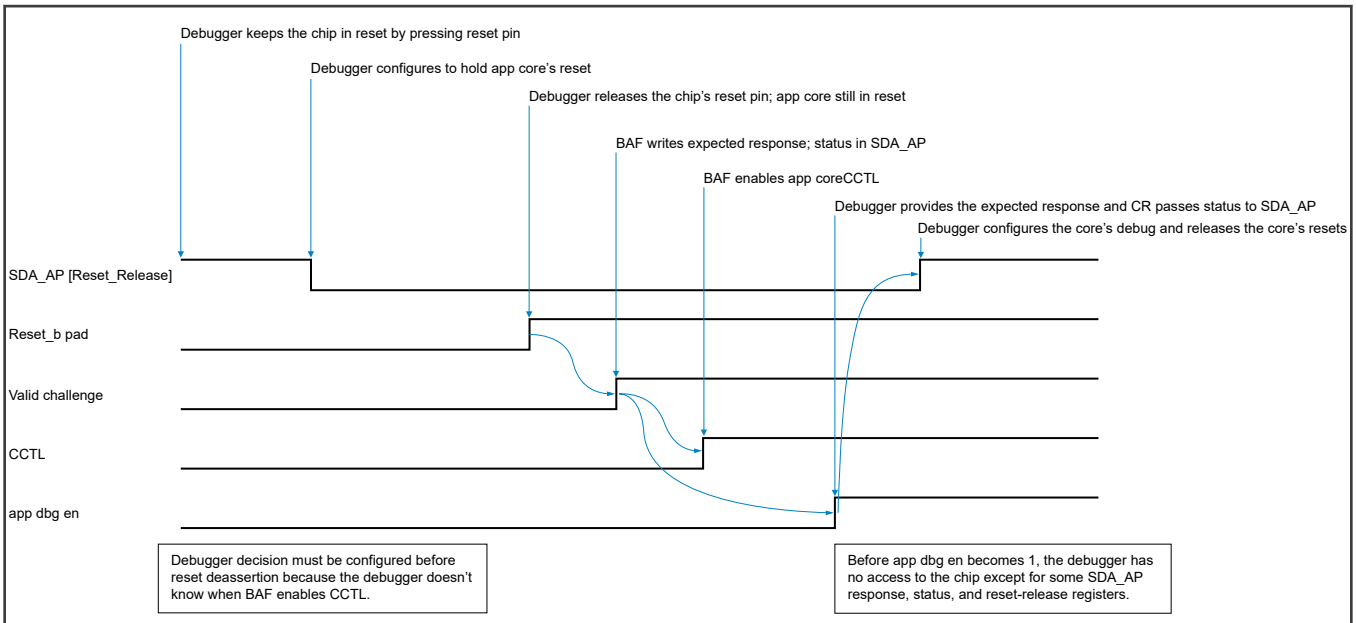

**Figure 440. Application debug implementation from first instruction**

These are the steps involved in enabling application debug from the first instruction on system power-up or destructive reset:

1. After the reset is applied, the debugger provides an option to debug from the first instruction. To do this:
   a. Write 1 to SDAAPRSTCTRL[RSTRELTLCM70] and SDAAPRSTCTRL[RSTRELTLCM7].
   b. Set the reset value of Reset Control (SDAAPRSTCTRL).
2. Cortex M0+ starts after the reset pin is released.
3. Debugger challenge-response (CR) starts.
4. Cortex-M7_0 and Cortex-M7_1 remain in reset until MC_ME's PRTN0_CORE0_PCONF[CCE] field becomes 1 for Cortex-M7_0 and PRTN0_CORE1_PCONF[CCE] field becomes 1 for Cortex-M7_1.
5. When BAF or FW writes 1 to MC_ME's PRTN0_CORE0_PCONF[CCE] field for Cortex-M7_0 and to PRTN0_CORE1_PCONF[CCE] field for Cortex-M7_1, and the debugger CR has passed:
   - If the value of SDAAPRSTCTRL[RSTRELTLCM71] and SDAAPRSTCTRL[RSTRELTLCM70] is 0 for their respective cores, the debugger configures the core debug registers and then enables these fields that start the code execution.
   - If the value of SDAAPRSTCTRL[RSTRELTLCM71] and SDAAPRSTCTRL[RSTRELTLCM70] is 1 for their respective cores, the debugger configures the core debug registers and then enables these fields that start the code execution.

To debug from the first instruction during the low-power debug protocol, the debugger:

1. Writes 0 to SDAAPRSTCTRL[RSTRELTLCM71] and SDAAPRSTCTRL[RSTRELTLCM70] for their respective cores.
2. Writes 1 to MDMAPWIRREL[WTRSTRGM].

### 75.5.5.2 Debugger not connected

If the debugger is not connected, the value of the DBGPWRUP_ACK signal is 0 as there is no DBGPWRUP_REQ. This results in the following scenario:

1. The booting core writes 1 to MC_ME's PRTN0_CORE0_PCONF[CCE] field for Cortex-M7_0 and to PRTN0_CORE1_PCONF[CCE] field for Cortex-M7_1.

2. The application core starts running. In case of Lock-step mode, the checker core executes the same code after a delay of two cycles.

### 75.5.6 Debugger considerations while flash program/erase

The flash programming can be done by application cores as well as debugger. The debugger can program/erase flash using either of the following two options:

1. Loading the program/erase code to SRAM from the debugger and then executing the program/erase sequence by application code from SRAM.
   - Debugger is connected and authenticated.
   - The debugger loads the code in the form of application binary image into the on-chip SRAM.
   - The debugger then initiates the application core to execute the binary from SRAM.
2. Debugger executing the program/erase sequence.
   - Debugger is connected and authenticated.
   - The debugger then initiates the flash programming by reading/writing the registers involved and following the program/erase sequence.

First option is the recommended because of less execution time. In second option, the debugger is the master and since the debug interface is serial, the execution takes more time.

In some cases, you might experience flash program/erase failure due to flash watchdog timeout when debugger executes the flash program/erase sequence due to the serial interface. Therefore, it is recommended to use the first option. In case second option is required, it should be performed in reduced clocking options (Option E and E2 only. For details, refer to the **Clocking details** section in the **Clocking** chapter).

### 75.5.7 SWJ-DP sequence for debug authentication

To perform the SWJ-DP sequence for debug authentication, the debugger:

1. Polls the AUTHSTTS[CHALRDY] field until it indicates the challenge status.
2. Reads Key Challenge (KEYCHAL0 - KEYCHAL7) if the challenge is valid and creates an authenticated 256-bit response key.
3. Writes a 256-bit response key to Key Response (KEYRESP0 - KEYRESP7).
4. Indicates that the response is ready by configuring AUTHCTL[HSEAUTHREQ].
5. Checks the status of Authentication Status (AUTHSTTS) to evaluate if the operation is successful.

   If the authentication process is successful and the debugger has write access to Debug Enable Control (DBGENCTRL), the challenge or response is considered successful too.

**NOTE**

SDA_AP supports challenge and response based on both JTAG and SWJ-DP modes. See SDAAPGENCTRL0[JTAG_CR_EN] for details.

## 75.6 APB memory map

You can access the debug registers via the APB_AP bus. The next table shows all the addresses for the CoreSight APB components and the addressing used for accessing the DAP components via the memory interface. You can also access all APB registers from the processing cores.

Table 585. APB components mapping

| Debug APB component | APBIC base address (access from debugger) | System memory map address (access from cores) | | Memory allocation (KB) | APB-AP0 slot number | Applicability |
|---|---|---|---|---|---|---|
| | | Page number | Base address | | | |
| APB_AP ROM table | F8h | 0 | 4024_00F8h | 4 | APBIC base | All |
| Funnel 0 | 1000h | 0 | 4024_1000h | 4 | 0 | ETM/ITM: MCXE31B<br>ITM: MCXE315/ MCXE316 and MCXE317 |
| Funnel 1 | 2000h | 0 | 4024_2000h | 4 | 1 | MCXE31B |
| Funnel 2 | 3000h | 0 | 4024_3000h | 4 | 2 | MCXE31B |
| CM7_cluster_ETF_ETMI | 4000h | 1 | 4024_4000h | 4 | 3 | MCXE31B |
| CM7_cluster_ETF_ETMD | 5000h | 1 | 4024_5000h | 4 | 4 | MCXE31B |
| HTM ETF | 6000h | 1 | 4024_6000h | 4 | 5 | MCXE31B |
| Shared_system_ETF | 7000h | 1 | 4024_7000h | 4 | 6 | MCXE31B |

| System SWO | B000h | 2 | 4024_B000h | 4 | 10 | All |
| Timestamp CTL | C000h | 3 | 4024_C000h | 4 | 11 | All |

## 75.7 Trace

### 75.7.1 Trace modules and connectivity

The Trace subsystem:

- Combines trace data from all internal clients that generate trace information
- Includes a 32-bit TPIU
- Includes these components:
  - ATB
  - ATBR
  - CSTF
  - Debug APB
  - ETF
  - TPIU

Multiple options for trace output allow parallel tracing. Trace information can be read from the trace interface or the DAP interface, and traces can be alternatively read out from ETF at a slow speed via APB_AP. Table 586 shows EFT sizes.

**Table 586. ETF sizes**

| FIFO | Memory interface data width (in bits) | Size (KB) |
|---|---|---|
| Cortex-M7 ETM/ITM cluster ETF | 64 | 1 |
| Cortex-M7 ETMD cluster ETF | 128 | 2 |
| HTM ETF | 64 | 1 |
| Shared system ETF | 64 | 2 |

**NOTE**

- The DMA-HTM trace supports four words at 80 MHz. For HTM trace, both DBGENCTRL[GSPNIDEN] and DBGENCTRL[GSPIDEN] must be 1.
- Enabling any one of data trace causes overflow inside ETM and trace packets get dropped. Enabling instruction trace of both the core simultaneously does not cause any overflow.

Control (MDMAPCTL) provides fields to override the speed control (see Table 587 for details) from some of the trace sinks (and TPIU). The complete trace pipeline bandwidth is limited by the slowest sink component. The default settings of these fields allow maximum bandwidth for the TPIU to trace. When tracing to memory (if supported), the fields may need to be changed.

**Table 587. Trace output overrides**

| Trace destination | SWO_override | TPIU_override |
|---|---|---|
| TPIU | 1 | 0 |

The trace sources of the chip are the cores and their related modules. Trace funnels exist for all possible trace clients. For more information on the various components in the trace bus connectivity, see the *CoreSight Components Technical Reference Manual* (available in References). See Table 588 for details on funnel assignments.

The ATBR is integrated to send a shared funnel output across TPIU. This figure illustrates the chip's detailed trace architecture.

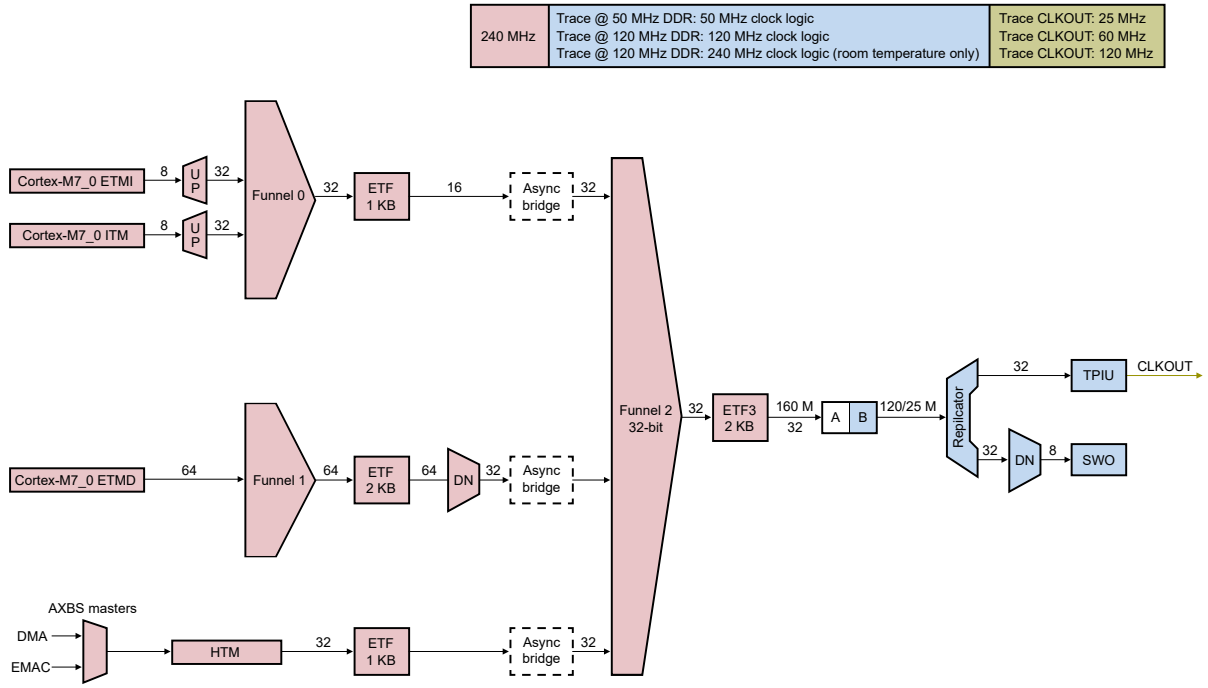

Figure 441. MCXE31B detailed trace architecture

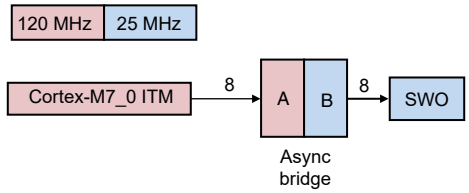

Figure 442. MCXE315/MCXE316 and MCXE317 detailed trace architecture

Table 588. Funnel assignments

| Funnel | Port | Input | MCXE314 Frquency (MHz) | Applicability |
|---|---|---|---|---|
| 0 | 0 | Cortex-M7_0 ETMI | 160 | MCXE31B |
| 0 | 3 | Cortex-M7_1 ITM | 160 | All |
| 0 | 4 | Cortex-M7_2 ETMI | - | MCXE314 |
| 0 | 6-7 | Reserved | - | - |
| 1 | 0 | Cortex-M7_0 ETMD | 160 | MCXE314, MCXE31B |
| 1 | 3-7 | Reserved | - | - |
| 2 | 0 | Cortex-M7 instruction ETF through an asynchronous bridge | 160 | MCXE314, MCXE31B |
| 2 | 1 | Cortex-M7 data ETF through an asynchronous bridge | 160 | MCXE314, MCXE31B |

*Table continues on the next page...*

Table 588. Funnel assignments (continued)

| Funnel | Port | Input | MCXE314 Frquency (MHz) | Applicability |
|---|---|---|---|---|
| 2 | 2 | HTM ETF through an asynchronous bridge | 160 | MCXE314, MCXE31B |
| 2 | 3-7 | Reserved | - | - |

#### 75.7.1.1 Chip's bus trace client

Chips in the MCXE31 family include a bus trace client.

HTM provides the address and data trace information about AXBS buses. The information from an HTM can be used with the debugger to enable easy, accurate debugging on AXBS-based embedded systems. The chip implements an HTM64 configuration to trace 64-bit AXBS masters in the system. To simplify the implementation, instead of tracing the individual ports of various AXBS masters and slaves, which may be running at different frequencies, HTM64 snoops the AXBS crossbar master ports that are all synchronous with a 160 MHz system clock. This table provides details related to the HTM input connectivity.

Table 589. HTM connections

| HTM64 port | AHB crossbar port |
|---|---|
| HTMBUSSELECT0 | M0 AXBS_Lite XBIC (DMA) |
| HTMBUSSELECT1 | M3 AXBS (Ethernet) |

#### 75.7.1.2 TPIU interface

A standard 16-bit parallel TPIU is integrated into the debug subsystem. Chips in the MCXE31 family generate the trace via the trace port.

To prevent instruction trace from being dropped in a multi-core environment, a TPIU throughput of 55.2 MB/s or higher must be maintained. You could use these pin and frequency combinations:

- Four high-speed data + one clock pads @120 MHz (240 Mbit/s throughput per pad) totaling 120 MB/s
- 16 low-speed data + one clock pads @25 MHz (50 Mbit/s throughput per pad) totaling 100 MB/s

High-end chips from the MCXE31 family support at least 56 MB/s of trace throughput on the TPIU interface.

Table 590. Throughput

| Core | Throughput value | Applicability |
|---|---|---|
| Cortex-M7_0 | 27.6 MB/s | All |
| Cortex-M7_1 | 27.6 MB/s | MCXE31B |
| Total | 82.8 MB/s | |

#### 75.7.1.3 TPIU flush

To allow the chip to enter Standby mode, software executes an WFI instruction indicating Standby entry. When the chip enters this mode, MC_RGM asserts a trace flush request to the TPIU and waits for a trace flush done signal from the TPIU before requesting MC_PCU to proceed. The TPIU and debug infrastructure clocks can be gated after this. Because the TPIU is sourced from system clock, the clock must not be gated until this point.

### 75.7.2 Trace assignments

ETF combines trace information from multiple clients into a single stream of trace data. This table shows the CoreSight funnel input assignments.

**Table 591. CoreSight funnel assignments**

| Instance name | Port assignment | Applicability |
|---|---|---|
| Funnel 0 (CSTF0) | Cortex-M7_0 ETMI | MCXE31B |
| | Cortex-M7_0 ITM | All |
| | Cortex-M7_1 ETMI | MCXE31B |
| | Cortex-M7_1 ITM | MCXE317 |
| Funnel 1 (CSTF1) | Cortex-M7_0 ETMD | MCXE31B |
| Funnel 2 (CSTF2) | Funnel 0 | MCXE31B |
| | Funnel 1 | MCXE31B |
| | HTM | MCXE31B |

## 75.8 Embedded cross trigger (ECT)

ECT allows multi-core run control and trace cross-triggering, such as synchronous stop-start for all cores or trigger trace on a trigger event from another core or module. See the *CoreSight Components Technical Reference Manual* (available in References) for detailed information on ECT.

ECT architecture involves CTMs and CTIs. The CTIs provide a cross-triggering interface between the cores and other debug and trace modules. The channels of these CTIs are interconnected using CTMs, as shown in this figure.

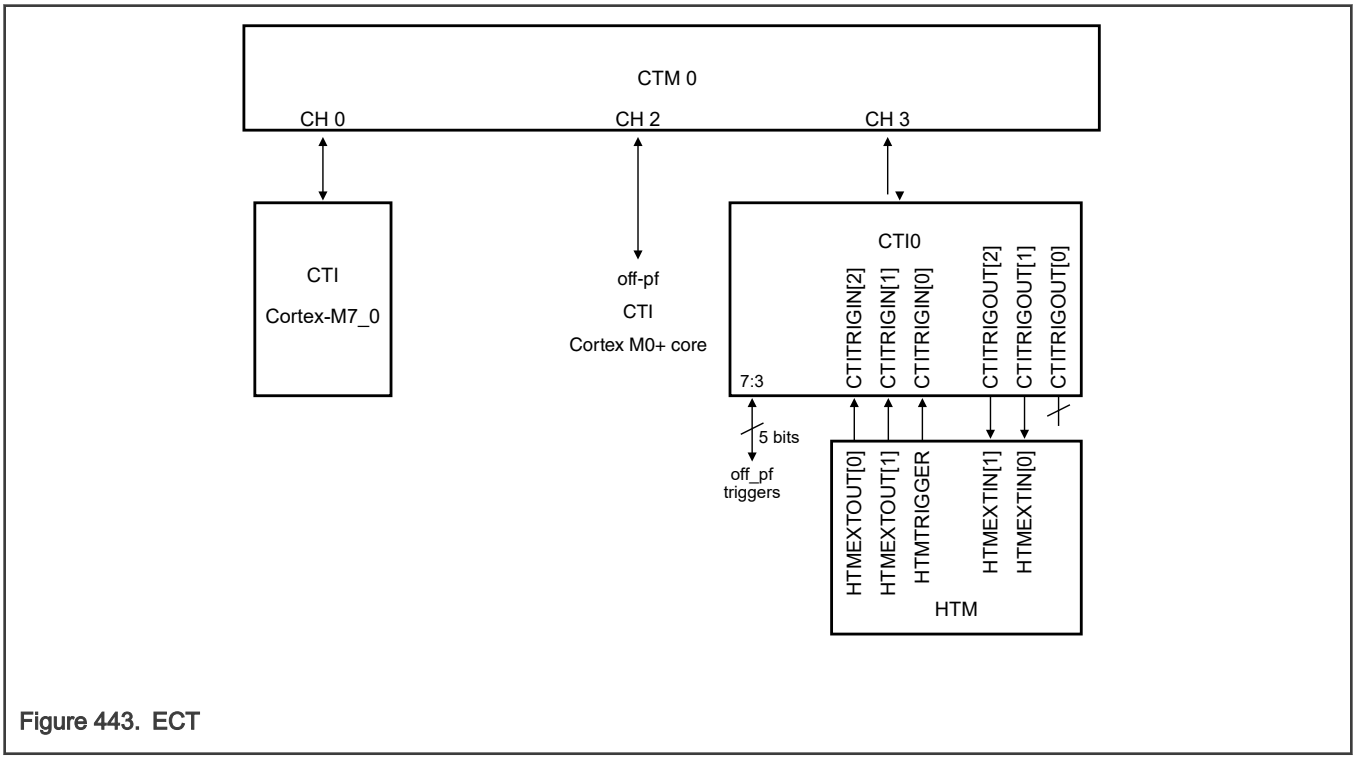

**Figure 443. ECT**

### 75.8.1 CTI assignments

**Table 592. CTI assignments**

| CTI instance | Trigger number | Trigger in | Trigger out |
|---|---|---|---|
| CTI_Cortex-M7_0 | 7 | ETM event output 3 | Processor restart |
| | 6 | ETM event output 2 | ETM event input 3 |
| | 5 | ETM event output 1 | ETM event input 2 |
| | 4 | ETM event output 0 | ETM event input 1 |
| | 3 | DWT comparator output 2 | ETM event input 0 |
| | 2 | DWT comparator output 1 | Interrupt request 1 |
| | 1 | DWT comparator output 0 | Interrupt request 0 |
| | 0 | Processor halted | Processor debug request |

| | 5 | ETF_2 full | ETF_2 trigger input |
| | 4 | ETF_1 full | ETF_1 trigger input |
| | 3 | ETF_0 full | ETF_0 trigger input |
| | 2 | HTM trigger out 2 | HTM trigger in 2 |

*Table continues on the next page...*

Table 592. CTI assignments (continued)

| CTI instance | Trigger number | Trigger in | Trigger out |
|---|---|---|---|
| | 1 | HTM trigger out 1 | HTM trigger in 1 |
| | 0 | Reserved | HTM trigger in 0 |

## 75.9 Low-power debug handshake protocol

The debugger must perform this sequence to enter or exit Standby mode, if the debugger handshake is enabled:

1. Power on DAP.

   The debugger connection is established.

2. Configure the Debug subsystem for the relevant operations.
3. Write 1 to MDMAPWIREN[LWPWREN] to gate entry into Standby mode with the debugger handshake.
4. Disable POR_WDG for monitoring the entry to or exit from Standby mode by writing 1 to DCM's DCMRWP1[8] field. This is required for low-power debug handshake because debugger configurations can be more time consuming than the POR_WDG threshold levels and can raise a false POR_WDG event.
5. Write 1 to DCMRWF1[STANDBY_IO_CONFIG] in the Device Configuration Module (DCM). This causes padkeeping to be disabled on standby entry itself without any software dependency. This is needed in case of low-power debug since otherwise the padkeeping on TDO would result in no debugger communication. In other cases, DCMRWF1[STANDBY_IO_CONFIG] should be configured as 0 before standby entry.
6. Initiate entry into Standby mode. See the "Power Management" chapter for the Standby mode entry sequence and configurations.
7. Identify whether the low-power debug is enabled on the low-power entry by reading MC_RGM's LPDEBUG[LP_DBG_EN] field.
   - If low-power debug is enabled and TPIU is enabled too, trace flush starts, and the debugger acknowledges the following:
     - Low-power debug traces
     - DAP-related configuration reception and context saving

       After this, the chip enters Standby mode.
   - If TPIU is disabled:
     - The debugger acknowledges DAP-related configuration reception and context saving by writing 1 to MDMAPWIRREL[PRVNTRSTRGM].

       After this, the chip enters Standby mode.
   - If low-power debug is disabled, the chip enters Standby mode without waiting for debugger acknowledgment.

   On any wakeup event, the chip starts the Standby mode exit sequence described in the "Power Management" chapter. After the chip exits Standby mode, the debugger connection is restored. By this time, the debugger is already aware that it has enabled the low-power debug handshake. In this case, the debugger must poll MDMAPSTTS[DESTRST] to check whether:
   - The debug infrastructure is out of reset.
   - The DAP connection can be established.

   After DAP is powered on (the debugger connection is established), the debugger:
   a. Reconfigures the debug and trace attributes using the fields in DBGENCTRL
   b. Writes 1 to MDMAPWIRREL[WTRSTRGM] after the debugger trace context is restored

      The chip exits Standby mode.

If low-power debug is not configured, the chip exits Standby mode without waiting for the debugger to write to MDMAPWIRREL[WTRSTRGM].

8. Reconfigure the debug and trace configuration in SDA_AP register descriptions after the chip exits Standby mode.

**NOTE**

If the chip wakes up from Standby mode through pad reset, the debugger must perform a CR again.

## 75.10 Debug resets

The debug subsystem follows this sequence on the source of reset:

1. POR resets the complete debug logic.
2. The destructive reset resets all types of debug logic except JTAGC.

Conversely, the debug subsystem can generate a system reset using these mechanisms:

- System destructive reset defined in Control (MDMAPCTL) that allows the debugger to provide the destructive reset to the system. The debugger loses connection to the system with this reset.
- System functional reset defined in Control (MDMAPCTL) that allows the debugger to hold the system in functional reset.

To program various debug registers, the functional clocks must be enabled. All debug and trace components must be on destructive reset.

## 75.11 Debug across device LifeCycles

The debug access to the system is available in early lifecycles and subsequently based on NVM configuration settings.

After the debug is set to 'Trusted', the system access is allowed after a successful authorization step between the debugger and the system.

The authorization provides provisions to allow debug for Cortex M0+ core and Cortex M7 cores.

Following table shows the debug access based on various configuration bits.

**Table 593. Debug access based on LifeCycle and bit configurations**

| LifeCycle | Configuration bits | | | | | | | | | Debug access | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | HSE_DIS_CR_MCU_PROD | HSE_DIS_CUS | DBG_EN_OEM | APP_DIS_OEM | HSE_DIS_OEM | DBG_EN_FLD | APP_DIS_FLD | HSE_DIS_FLD | HSE_DIS_PRE_FA | HSE Debug | Appl Core Debug |
| MCU_PROD | 0 | - | - | - | - | - | - | - | - | Trusted | Open |
| | 1 | - | - | - | - | - | - | - | - | Open | Open |
| CUST_DEL | - | 0 | - | - | - | - | - | - | - | Trusted | Open |
| | - | 1 | - | - | - | - | - | - | - | Disabled | Open |

*Table continues on the next page...*

Table 593. Debug access based on LifeCycle and bit configurations (continued)

| LifeCycle | Configuration bits | | | | | | | | | Debug access | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | HSE_DIS_CR_MCU_PROD | HSE_DIS_CUS | DBG_EN_OEM | APP_DIS_OEM | HSE_DIS_OEM | DBG_EN_FLD | APP_DIS_FLD | HSE_DIS_FLD | HSE_DIS_PRE_FA | HSE Debug | Appl Core Debug |
| OEM_PROD | - | - | 0 | - | - | - | - | - | - | Closed | Closed |
| | - | - | 1 | 0 | 0 | - | - | - | - | Trusted | Trusted |
| | - | - | 1 | 0 | 1 | - | - | - | - | Disabled | Trusted |
| | - | - | 1 | 1 | - | - | - | - | - | Disabled | Disabled |
| IN_FIELD | - | - | - | - | - | 0 | - | - | - | Closed | Closed |
| | - | - | - | - | - | 1 | 0 | 0 | - | Trusted | Trusted |
| | - | - | - | - | - | 1 | 0 | 1 | - | Disabled | Trusted |
| | - | - | - | - | - | 1 | 1 | - | - | Disabled | Disabled |
| PRE_FA | - | - | - | - | - | - | - | - | 0 | Trusted | Trusted |
| | - | - | - | - | - | - | - | - | 1 | Disabled | Trusted |
| FA | - | - | - | - | - | - | - | - | - | Open | Open |

**NOTE**

1. **Closed:** Debug is not possible in this state (not even if keys are known - no authentication is possible)
2. **Open:** Debug is always possible
3. **Trusted:** Debug is possible after successful authentication (Challenge/Response handshake with correct credentials)
4. **Disabled:** Debug has been explicitly disabled via burning of a fuse in that LC, otherwise behaves as Closed
5. HSE_DIS_CR_MCU_PROD bit disables the challenge-response based mechanism, making the debug open when asserted.
6. During functional reset, the debug-enable will retain its last status, while DCM scans NVM for lifecycle and DCF values. Debug status will be re-evaluated once dcm_done gets 1.
7. During temporary advancement of lifecycle, debug-en will immediately reflect the status based on updated lifecycle/DCF bits.

## 75.12 Pin interface

This table presents a summary of functional and power pins that are used for debugging purposes.

Table 594. Pin interface

| Pin type | Pins | Number of pins (balls)[1] | Nominal voltage |
|---|---|---|---|
| Functional JTAG | JCOMP, TCK, TMS, TDI, TDO | Five (only TDI and TDO can be multiplexed with GPIO or other functions) | 3.3 V, 5 V |
| Functional trace pins (parallel trace) | TRACE_CLK | One | 3.3 V, 5 V |
| | TRACE_D[15:0] | 16 | 3.3 V, 5 V |
| Ground | VSS | See the IOMUX file attached to this document for information on the number of VSS pins in various packages. | 0 V |

1. The terms pins and balls are used interchangeably. Some chip packages include pins and others include balls.

**NOTE**

Fast Trace pad TRACE_D[15:0] is available only in MCXE314.

### 75.12.1 Debug port and pin descriptions

The pads to which the debug signals are mapped operate using the JTAG functionality out of reset but can later be reassigned to their alternate functionalities. TDI and TDO can operate as alternate GPIO functions. See this table for pin assignments in different modes.

Table 595. Debug port pins

| Pin name | JTAG debug port | | Internal pullup or pulldown logic |
|---|---|---|---|
| | Type | Description | |
| TMS | I/O | JTAG test mode selection (TMS) | Pullup |
| TCK/SWCLK | I | JTAG test clock (TCK) | Pulldown |
| TDI | I | JTAG test data input (TDI) | Pullup |
| TDO/TRACESWO | O | JTAG test data output (TDO) | Not connected |

### 75.12.2 Trace port pin descriptions

This chip generates trace via TPIU that transmits the trace data out of the chip over a parallel trace port. The trace port consists of an ETM trace clock and 16 parallel trace data outputs. The Arm optional trace port control (TRACECTRL), debug request (DBGRQ), and debug acknowledge (DBGACK) signals are not implemented.

Table 596. Trace output port pins

| Pin name | Description |
|---|---|
| TRACE_DATA00 | ETM parallel trace data output 01 |
| TRACE_DATA01 | ETM parallel trace data output 01 |
| TRACE_DATA02 | ETM parallel trace data output 02 |
| TRACE_DATA03 | ETM parallel trace data output 03 |

*Table continues on the next page...*

Table 596. Trace output port pins (continued)

| Pin name | Description |
|---|---|
| TRACE_DATA04 | ETM parallel trace data output 04 |
| TRACE_DATA05 | ETM parallel trace data output 05 |
| TRACE_DATA06 | ETM parallel trace data output 06 |
| TRACE_DATA07 | ETM parallel trace data output 07 |
| TRACE_DATA08 | ETM parallel trace data output 08 |
| TRACE_DATA09 | ETM parallel trace data output 09 |
| TRACE_DATA10 | ETM parallel trace data output 10 |
| TRACE_DATA11 | ETM parallel trace data output 11 |
| TRACE_DATA12 | ETM parallel trace data output 12 |
| TRACE_DATA13 | ETM parallel trace data output 13 |
| TRACE_DATA14 | ETM parallel trace data output 14 |
| TRACE_DATA15 | ETM parallel trace data output 15 |
| TRACE_CLK | ETM parallel trace clock output |

**NOTE**

ETM is supported in MCXE314 only

**NOTE**

By default, Rx pins float and are not pulled inside. An internal active pulldown logic exists only when you enable Rx via software (IBE).

## 75.13 Timestamp distribution network

The timestamp distribution network uses CoreSight timestamp components to generate a 48-bit timestamp value for the trace sources, as shown in the next figure. The CoreSight timestamp generator generates a 64-bit counter value, but only the least significant 48 bits are distributed to the trace sources. A 7-bit narrow timestamp is derived from the 48-bit timestamp and distributed to the trace client, where a decoder regenerates the 48-bit timestamp. The generator must be programmed, and you could find the related programming information in the *CoreSight Components Technical Reference Manual* (available in References).

This chip supports 48-bit timestamping. The generator operates at a frequency of 160 MHz and gives a 64-bit timestamp value. The Cortex-M7_0 and Cortex-M7_1 cores operate at a frequency of 160 MHz.

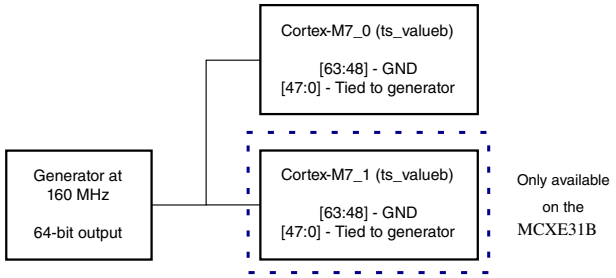

Figure 444. Timestamp distribution network

## 75.14 Peripheral debug freeze register descriptions

Implement the logic provided in this section for each peripheral instance supporting the debug operation.

**NOTE**

Debug freeze is enabled for all the peripherals so that as soon as the core halts, peripherals can be frozen to support debugging from the first instruction.

For register details, refer to the following registers in the Device Configuration Module (DCM):

- Read Write GPR On Destructive Reset Register (DCMRWD6)
- Read Write GPR On Destructive Reset Register (DCMRWD7)
- Read Write GPR On Destructive Reset Register (DCMRWD8)
- Read Write GPR On Destructive Reset Register (DCMRWD9)

## 75.15 MDM_AP register descriptions

The debugger has access to the status and control elements implemented as registers in MDM_AP, which is selected by APSEL (6h) on the DAP bus. These registers provide additional control and status information for typical debug, cross-triggering, and run-control scenarios. Also, the register fields provide a way for the debugger to get the updated status of the core without initiating a bus transaction across the crossbar switch, thus remaining less intrusive during a debug session.

MDM_AP is accessible as DAP (see DAP TAP for details).

### 75.15.1 MDM_AP memory map

MDM_AP base address: 4025_0600h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Status (MDMAPSTTS) | 32 | R | 5000_0000h |

### 75.15.3 Control (MDMAPCTL)

#### Offset

| Register | Offset |
|---|---|
| MDMAPCTL | 4h |

#### Function

Allows the debugger:

- To give the destructive reset to the system. A system destructive reset enables this. The debugger also loses connection to the system with this reset.
- To hold the system in functional reset. A system functional reset enables this.

**NOTE**

The trace functionality on trace pins is selected with this register and is retained across the functional reset.

## 75.16 SDA_AP register descriptions

The debugger and system have access to secure authentication control and status, implemented as registers in SDA_AP on the DAP bus. These registers provide authentication control, authentication status, key exchange information, and debug enable controls.

### 75.16.1 SDA_AP memory map

SDA_AP base address: 4025_4700h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Authentication Status (AUTHSTTS) | 32 | R | 6000_0004h |
| 4h | Authentication Control (AUTHCTL) | 32 | RW | 0000_0000h |
| 10h - 2Ch | Key Challenge (KEYCHAL0 - KEYCHAL7) | 32 | R | 0000_0000h |

# Chapter 76
# JTAG Controller (JTAGC)

## 76.1 Chip-specific JTAGC information

The following figure shows the detailed TAP connectivity. SWD/JTAG SELECT, SWDP and JTAG-DP are part of ARM DAP

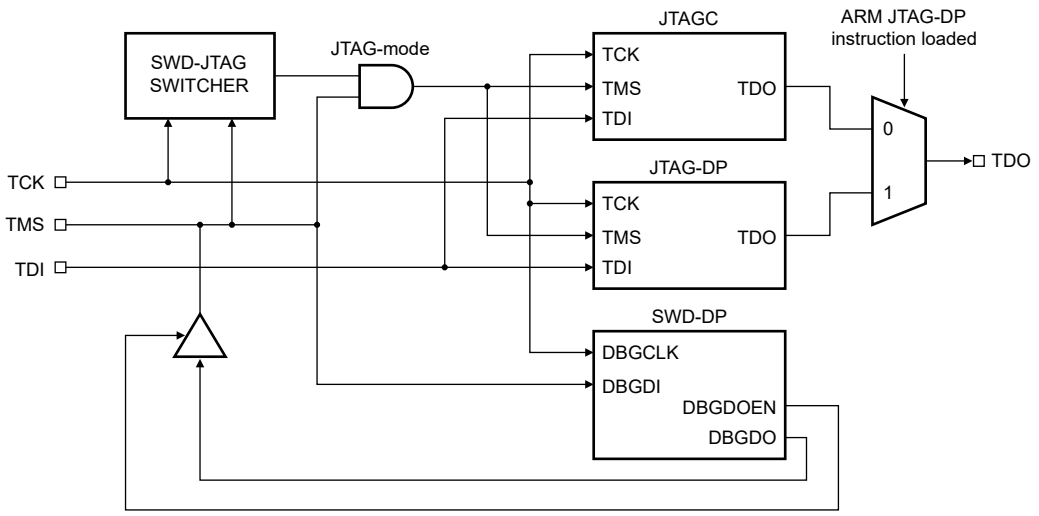

**Figure 445. Test and Debug Access Port (TAP) connectivity**

The debug port comes out of reset in a standard JTAG mode. It is switched to SWD mode by the change sequences described in JTAG to SWD change sequence . Once the mode has been changed, unused debug pins can be reassigned to any of their alternative muxed functions

JTAG-to-SWD change sequence:

1. Send more than 50 TCK cycles with TMS (SWDIO) =1
2. Send the 16-bit sequence on TMS (SWDIO) = 0111_1001_1110_0111 (MSB transmitted first)
3. Send more than 50 TCK cycles with TMS (SWDIO) =1

**NOTE**

In case of any reset event, JTAGC is moved to Test Logic Reset (TLR) state first and then JTAGC should be used.

**NOTE**

If JTAG pins are used for alternative functionality and reset event arrives, then these pins need to be reconfigured to required functionality before using it, in order to avoid unintentional entry in JTAG mode.

## 76.2 Overview

JTAGC allows you to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from JTAGC is communicated in serial format.

### 76.2.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. See the chip-specific configuration information within this chapter as well as Register description for more information about the JTAGC registers.

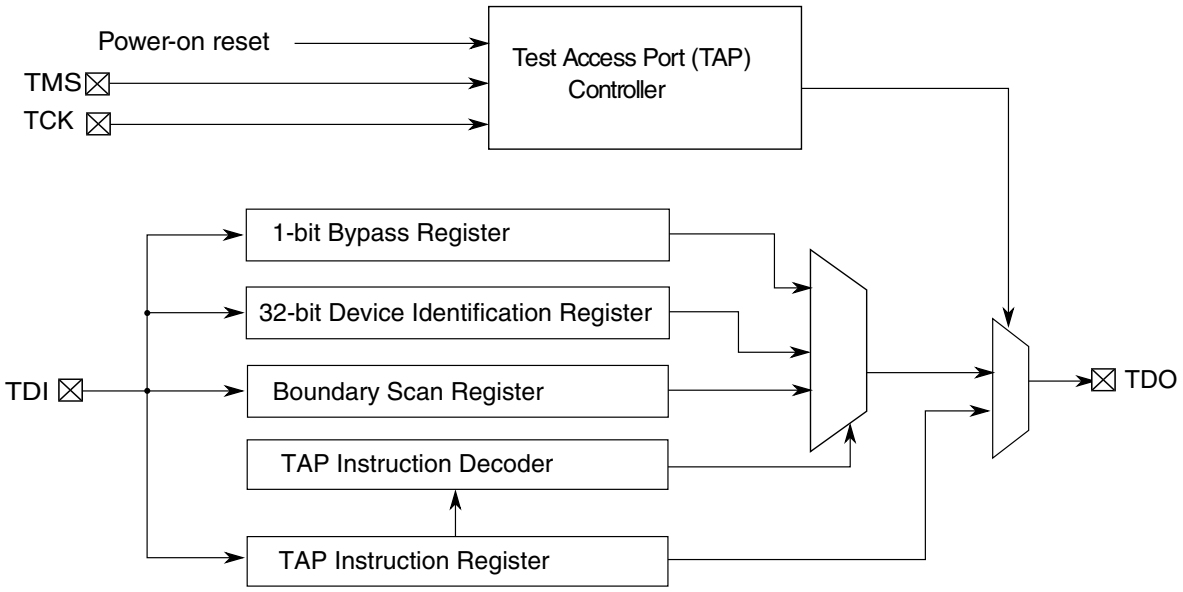

Figure 446. JTAG (IEEE 1149.1) block diagram

### 76.2.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 TAP interface
  - Four pins (TDI, TMS, TCK, and TDO)
- Instruction register that supports several IEEE 1149.1–2001 defined instructions as well as several public and private device-specific instructions (see JTAGC block instructions for a list of supported instructions).
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- Bypass register, boundary scan register, and device identification register
- TAP controller state machine that controls the operation of the data registers, instruction register, and associated circuitry

## 76.3 Functional description

### 76.3.1 Modes of operation

The JTAGC block uses a power-on reset indication as its primary reset signals. Several IEEE 1149.1–2001 defined test modes are supported, as well as a bypass mode.

#### 76.3.1.1 IEEE 1149.1–2001 defined test modes

The JTAGC block supports several IEEE 1149.1–2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register when the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, PRELOAD.

Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic when the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the following instructions are active:

- BYPASS

- HIGHZ
- CLAMP

The functionality of each test mode is explained in more detail in JTAGC block instructions.

#### 76.3.1.2 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. When in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

### 76.3.2 IEEE 1149.1-2001 (JTAG) TAP

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions, see ACCESS_AUX_x instructions .

Data is shifted between TDI and TDO through the selected register (instruction, test data, or the bypass register) starting with the least significant bit, as illustrated in the following figure.

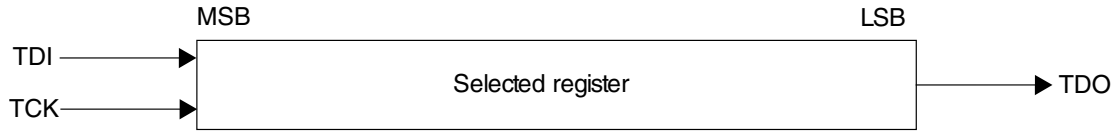

**Figure 447. Shifting data through a register**

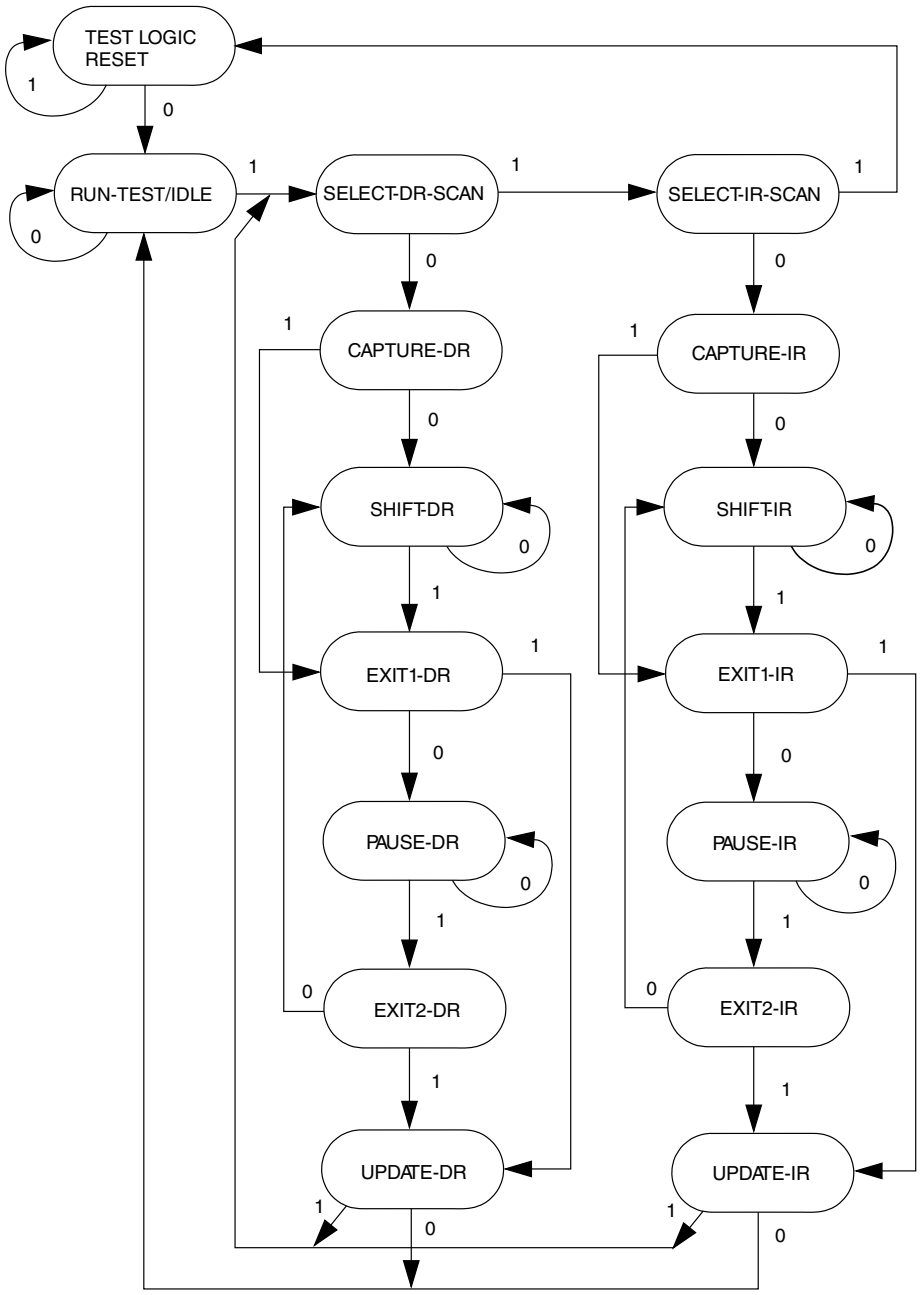
### 76.3.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin.

The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the figure shows, holding TMS at logic 1 when clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.



The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

**Figure 448. IEEE 1149.1-2001 TAP controller finite state machine**

### 76.3.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting the JTAGC enable to a logic 1 value.

### 76.3.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions when the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated after the required number of bits have been acquired.

### 76.3.4 JTAGC block instructions

The JTAGC implements instructions defined in IEEE 1149.1-2001. See the chip-specific JTAGC information for the JTAGC instructions implemented on this chip. See the IEEE 1149.1-2001 standard for additional information. All undefined opcodes are reserved.

#### 76.3.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

#### 76.3.4.2 PRELOAD instruction

The PRELOAD instruction has two functions:

- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

#### 76.3.4.3 EXTEST external test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the data is loaded into the boundary scan register using the PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state when performing external boundary scan operations.

#### 76.3.4.4 TEST_LEAKAGE instruction

The TEST_LEAKAGE instruction forces the jtag_leakage output signal to high. It is intended to tristate all output pad buffers and disable all of the part's pad input buffers except JCOMP and TEST. The jtag_leakage signal is asserted at the falling edge of TCK following the TAP controller state machine transition from the Update-IR state to the Run-Test-Idle state. When asserted, the part disables TCK, TMS, and TDI inputs and forces them to a logic 1. The TAP controller state machine remains in the Run-Test-Idle state until the JCOMP input is set to a value other than the JTAGC enable encoding. TEST_LEAKAGE also asserts the internal system reset for the MCU to force a predictable internal state.

#### 76.3.4.5 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. When HIGHZ is active all output drivers are placed in an inactive drive state (for example, high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

#### 76.3.4.6 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register when the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) when conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

#### 76.3.4.7 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers.

When this instruction is loaded, control of the JTAG pins is transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins.

The JTAGC gets back control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE when they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

#### 76.3.4.8 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. When the BYPASS instruction is active the MCU operates normally.

### 76.3.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

### 76.3.6 Clocking

There is one clock for this module. For more information See External signals.

### 76.3.7 Interrupts

This module has no interrupts.

### 76.3.8 Reset

The JTAGC block is placed in reset when:

- Power-on reset is asserted
- TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state

Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset results in asynchronous entry into the reset state.

When in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the MCU.
- The instruction register is loaded with the IDCODE instruction.

## 76.4 External signals

JTAGC includes a set of signals that connect to off-chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 597. JTAG signal properties

| Name | I/O | Function | Reset state |
|---|---|---|---|
| TCK | Input | Test clock | Weak pulldown |
| TDI | Input | Test data in | Weak pullup |
| TDO | Output | Test data out | High Z[1] |
| TMS | Input | Test mode select | Weak pullup |

1. TDO output buffer is disabled when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

### 76.4.1 Test clock input (TCK)

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

### 76.4.2 Test data input (TDI)

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

### 76.4.3 Test data output (TDO)

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is tristateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

### 76.4.4 Test mode select (TMS)

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

## 76.5 Initialization

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Place the JTAGC in reset through TAP controller state machine transitions controlled by TMS.
2. Load the appropriate instruction for the test or action to be performed.

## 76.6 Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

## 76.7 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

### 76.7.1 Instruction register

The JTAGC block uses a 8-bit instruction register as shown in the following figure.

The instruction register allows instructions to be loaded into the block to select the test to be performed, or the test data register to be accessed, or both. Instructions are shifted in through TDI when the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states.

Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 0b1, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

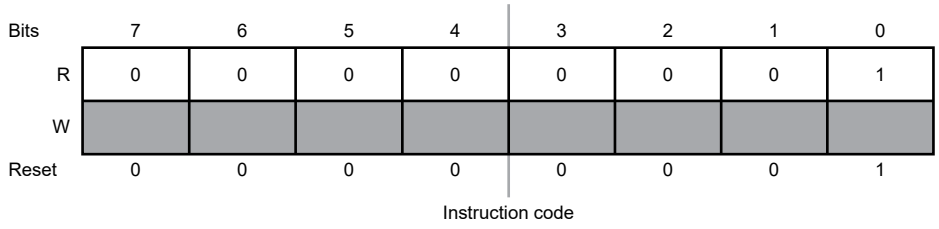


**Figure 449. Instruction register**

## 76.7.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

## 76.7.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP.

The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state when the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

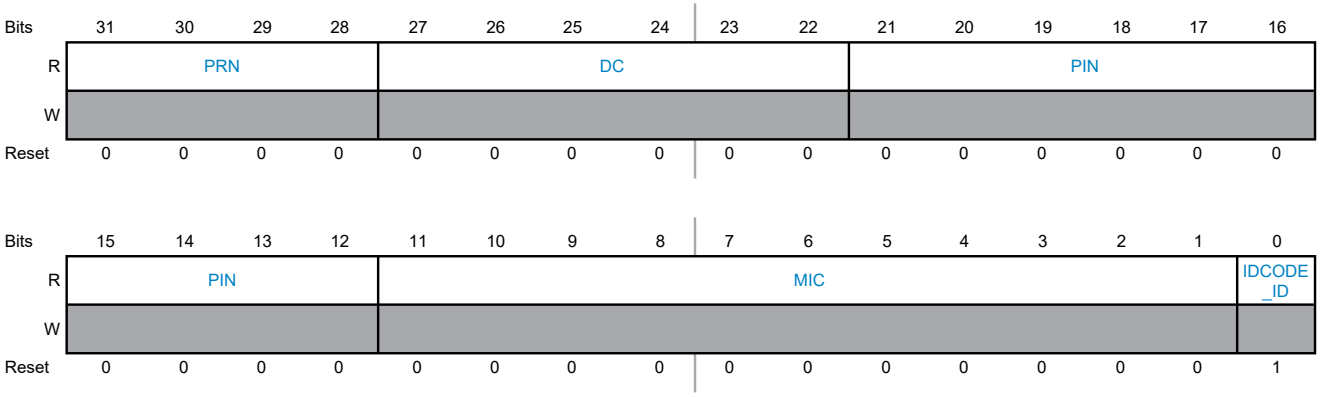

**Figure 450. Device identification register**

The following table describes the device identification register functions. The device identification register values are described in the chip-specific JTAGC information.

**Table 598. Device identification register field descriptions**

| Field | Function |
|---|---|
| PRN | Part revision number<br>Contains the revision number of the part. |
| DC | Design center<br>Indicates the design center. |
| PIN | Part identification number<br>Contains the part number of the device. |
| MIC | Manufacturer identity code<br>Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID . |
| IDCODE ID | IDCODE register ID<br>Identifies this register as the device identification register and not the bypass register. Always set to 1. |

### 76.7.4 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, PRELOAD instructions are active. It is used to:

- Capture input pin data
- Force fixed values on output pins
- Select a logic value and direction for bidirectional pins

Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

# Chapter 77
# JTAG Data Communication (JDC)

## 77.1 Overview

JDC module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory-mapped register space and an external tool that accesses the JTAG port.

The JDC module consists of:

- IPS-accessible registers
- JTAG-accessible registers
- Associated logic to coordinate movement of data from one register domain to another

The JDC implements the following IPS data registers, occupying separate memory space:

- 1 32-bit memory mapped register that can be read or written via IPS (JTAG Output Data Register (JOUT_IPS)), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 1 32-bit memory mapped register that can only be read via IPS (JTAG Input Data Register (JIN_IPS)), and whose contents are loaded from a JTAG register (JIN).

JDC indicates when:

- New data has been shifted in via the JTAG port and is ready to be read from the JTAG Input Data Register (JIN_IPS) register
- New data has been written to the JTAG Output Data Register (JOUT_IPS) register and is ready to be read via the JTAG port

A Module Status Register (MSR) captures the state of these flags and also provides the flags to a JTAG register (JOUT) for tool visibility.

### 77.1.1 Block diagram

There is a single bus interface to port register data out to the JTAGC, and a single bus interface to port data in from the JTAGC. The following figure is the JDC module block diagram.

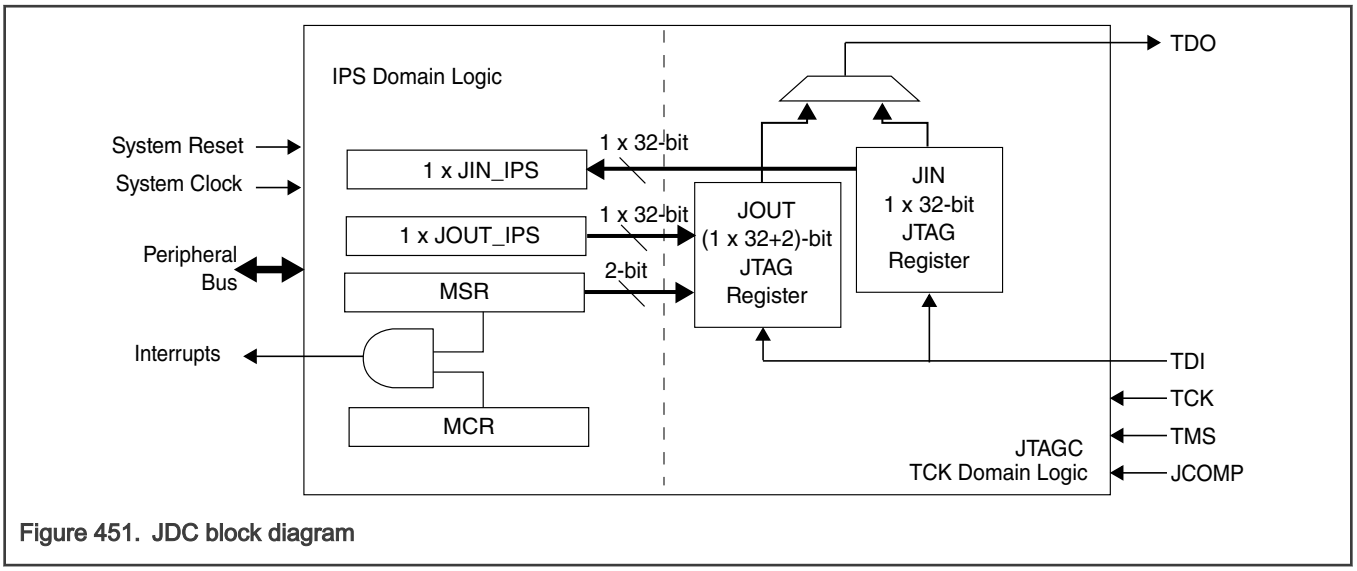

**Figure 451. JDC block diagram**

## 77.2 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data in memory-mapped register that can be accessed via IPS. It also provides the ability to capture data written to memory-mapped register into a JTAG shift register for output via the JTAG port.

### 77.2.1 JDC functionality

An overview of the module functionality is described here:

- Software write to the JOUT_IPS register:
  1. The JDC sets the JOUT_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port.
  2. The MSR reflects the state of the JOUT_RDY bit.
  3. The JDC also captures the state of the JOUT_RDY bit in the JOUT register.
  4. A JTAG read of the JOUT register via execution of the JOUT_READ instruction with a JOUT_RDY bit whose value is logic 1 indicates that the register contains new data.
  5. The JDC clears the JOUT_RDY flag bit upon exit of the Capture-DR JTAG state during execution of the JOUT_READ instruction.
  6. Clearing the JOUT_RDY bit indicates to software that a new data value can be written to the JOUT_IPS register.
- JTAG write to the JIN register via execution of the JIN_WRITE JTAG instruction:
  1. The JDC updates the contents of the JIN_IPS register upon exit of the Update-DR state.
  2. An update of the JIN_IPS register sets the JIN_RDY flag bit, indicating new data is available to be read via IPS.
  3. The MSR register reflects the state of the JIN_RDY bit.
  4. The JDC also captures the state of the JIN_RDY bit in the JOUT register.
  5. The JDC clears the JIN_RDY flag bit upon software read of the JIN_IPS register.
  6. A JTAG read of the JOUT register with a JIN_RDY value of logic 0 indicates that new data can be written to the JIN register.

### 77.2.2 JTAG register access

See the JTAGC documentation for information on how to access the JTAG registers.

#### 77.2.2.1 JDC block instructions

The JDC block implements the instructions listed in Table 599. This section gives an overview of each instruction. All undefined opcodes are reserved.

**Table 599. JTAG instructions**

| Instruction | Code[4:0] | Instruction summary |
|---|---|---|
| Reserved | 00001 | Factory debug reserved. |
| JOUT_READ | 00010 | Selects JOUT data register. The JDC captures data from JOUT_IPS into JOUT data register upon entry to Capture-DR state when JOUT_READ is active. |
| JIN_WRITE | 01110 | Selects JIN data register. The JDC captures data from JIN into JIN_IPS upon exit of Update-DR state when JIN_WRITE is active. |

*Table continues on the next page...*

Table 599. JTAG instructions (continued)

| Instruction | Code[4:0] | Instruction summary |
|---|---|---|
| BYPASS[1] | 11111 | Selects bypass register for data operations. |
| Reserved | All other opcodes | Decoded to select bypass register. |

1. This is an IEEE 1149.1-2001 defined instruction. See the IEEE 1149.1-2001 standard for more details.

### 77.2.3 Clocking

JDC module uses TCK and inverted TCK as clock source.

### 77.2.4 Interrupts

This module has no interrupts.

## 77.3 External signals

JDC signals are listed in the following table.

Table 600. Signal properties

| Name | Function | I/O | Reset |
|---|---|---|---|
| TCK | Test clock input | I | — |
| TMS | Test mode select | I | 0 |
| TDI | Test data in | I | 0 |
| JCOMP | JTAG compliance pin | I | 0 |
| TDO | Test data out | O | HiZ |

## 77.4 Initialization

This module does not require initialization.

## 77.5 Secure challenge/response connection procedure

A summary of how the JDC can be used to interact with a security module to perform challenge/response password authorization is as follows:

1. After exit of reset, all registers are at their reset values. JIN_RDY bit value of 0 indicates that the tool may write data to the JIN register. JOUT_RDY bit value of 0 indicates that software may write data to the JOUT_IPS register.
2. The MCR register is programmed to enable JOUT and JIN interrupts, or not.
3. Once the tool is ready to start the authorization process, it writes a value to the JIN register via execution of the JTAGC JIN_WRITE instruction.
4. Software monitors the state of the JIN_RDY bit or enables the JIN interrupt and uses the interrupt assertion as a trigger to start the authorization process.
5. Once the authorization process is started, software writes the first JOUT value to the JOUT_IPS register. This sets the JOUT_RDY bit value to 1.

6. Following the initial tool write to the JIN register, the tool polls the JOUT register to determine when software has provided a challenge word. Upon reading the JOUT register with JOUT_RDY bit set, the tool records the data value to be used to generate the appropriate response. The read of the JOUT register clears the JOUT_RDY bit. The clearing of the JOUT_RDY bit also sets the JOUT_INT bit and asserts the JOUT interrupt if the MCR[JOUT_IEN] is set.
7. With the JOUT_RDY bit cleared, software may now provide the next challenge word.
8. Once the tool has generated a response word, it uses the value of the JIN_RDY bit from the JOUT register read to determine when it can perform a write to the JIN register to provide the response.
9. The security module can provide additional challenge words and read back the corresponding response words as needed, repeating the process.

Simply providing a password without using the challenge/response protocol can be done in a similar way. The tool provides 32-bits of the password at a time with each write to the JIN register, and monitors the JIN_RDY bit value of the JOUT register to determine when the next JIN register value can be written. There is no need for software to write the JOUT_IPS register in this case.

For details related to the lifecycle stage at which this process is performed, see the "Hardware Security Engine" chapter.

## 77.6 JDC register descriptions

The following sections describe the implemented 32-bit registers. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.

### 77.6.1 JDC memory map

JDC base address: 4039_4000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Module Configuration Register (MCR) | 32 | RW | 0000_0000h |
| 4h | Module Status Register (MSR) | 32 | RW | 0000_0000h |
| 8h | JTAG Output Data Register (JOUT_IPS) | 32 | RW | 0000_0000h |
| Ch | JTAG Input Data Register (JIN_IPS) | 32 | R | 0000_0000h |

### 77.6.2 Module Configuration Register (MCR)

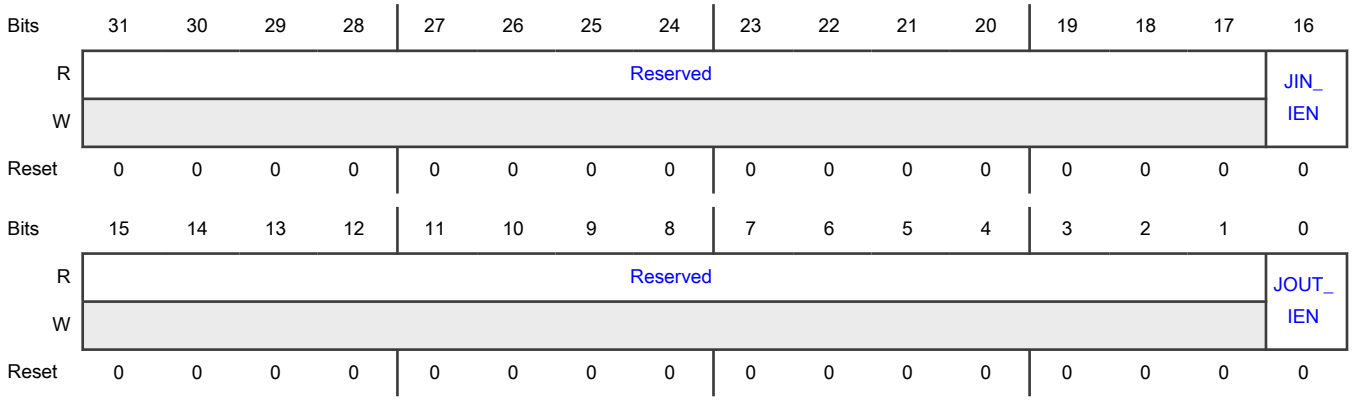
#### Offset

| Register | Offset |
|---|---|
| MCR | 0h |

#### Function

The MCR enables the interrupt outputs of the JDC. This register is reset by system destructive reset.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-17<br>— | Reserved |
| 16<br>JIN_IEN | JIN Interrupt Enable<br>0b - Setting MSR[JIN_INT] bit does not assert the JIN interrupt<br>1b - Setting MSR[JIN_INT] bit asserts the JIN interrupt |
| 15-1<br>— | Reserved |
| 0<br>JOUT_IEN | JOUT Interrupt Enable<br>0b - Setting MSR[JOUT_INT] bit does not assert the JOUT interrupt<br>1b - Setting MSR[JOUT_INT] bit asserts the JOUT interrupt |

## 77.6.3 Module Status Register (MSR)

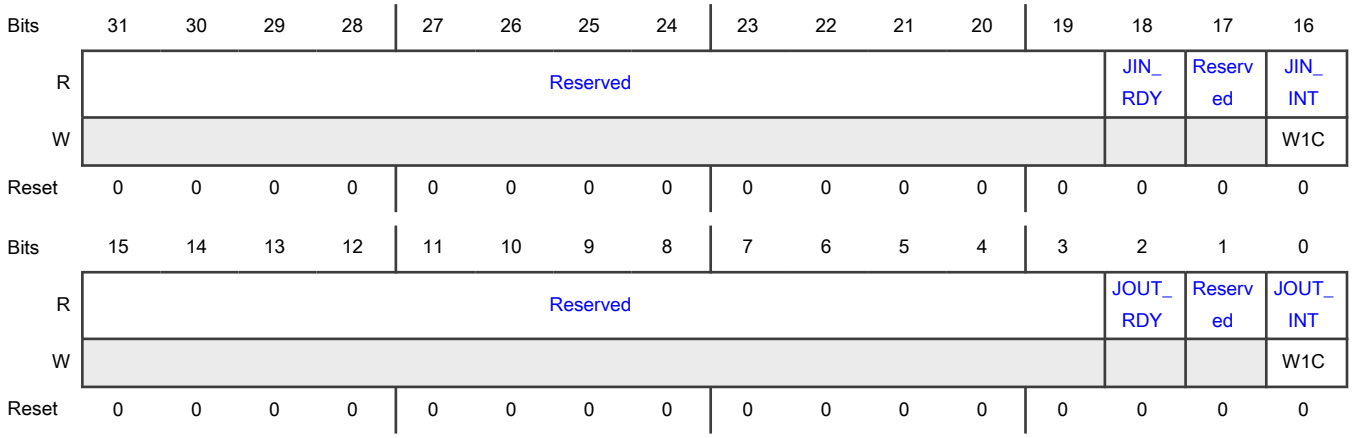
### Offset

| Register | Offset |
|---|---|
| MSR | 4h |

### Function

The MSR holds the JTAG register status and interrupt bits. This register is reset by system destructive reset.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-19<br>— | Reserved |
| 18<br>JIN_RDY | JIN Ready (read only)<br>0b - Cleared upon software read of JIN_IPS contents via IPS<br>1b - Set when new data is written to the JIN_IPS register |

## 77.6.4 JTAG Output Data Register (JOUT_IPS)

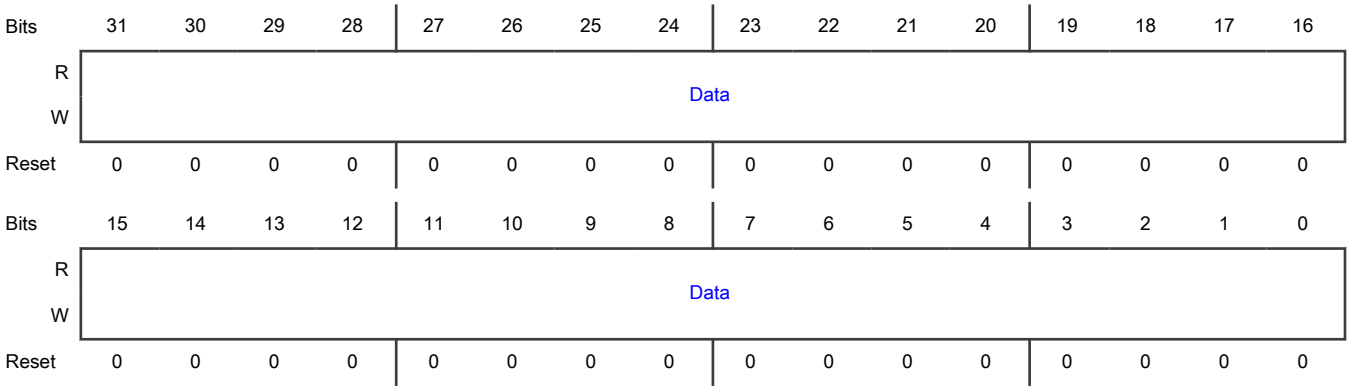
### Offset

| Register | Offset |
|---|---|
| JOUT_IPS | 8h |

### Function

The JOUT_IPS register holds data written via IPS. The JDC captures the JOUT_IPS contents into the JOUT register to be read via the JTAG port. This register is reset by system destructive reset.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>Data | JOUT_IPS Data |

## 77.6.5 JTAG Input Data Register (JIN_IPS)

### Offset

| Register | Offset |
|---|---|
| JIN_IPS | Ch |

### Function

The JIN_IPS register holds data written to the JTAG input data register (JIN) via the JTAG port, where the data can be read via IPS. Any IPS write to the JIN_IPS register returns a transfer error. This register is reset by system destructive reset.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### Fields

| Field | Function |
|---|---|
| 31-0<br>Data | JIN_IPS data |

## 77.7 Non-memory-mapped register definition

The JDC also implements two JTAG accessible registers that are not memory-mapped. One JTAG register shifts in data to be placed in the JIN_IPS register. The other JTAG register captures data from the JOUT_IPS register plus ready status from the MSR, to be shifted out via the JTAG port.

### 77.7.1 JTAG output data register (JOUT)

The JOUT register captures data from the JOUT_IPS register upon execution of the JOUT_READ JTAG instruction. It also holds the JIN_RDY and JOUT_RDY status bits. This register is reset by system destructive reset and JTAG reset. The reset value of the JOUT register is 0. The following figure shows the format of the JOUT register.

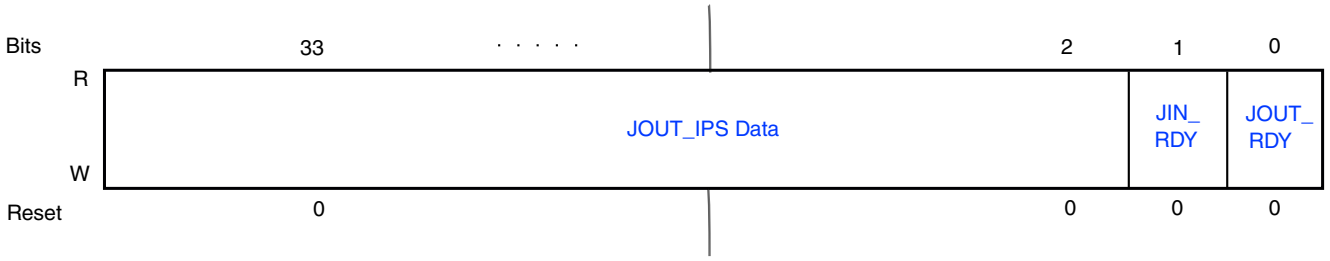

Figure 452. JOUT

The JOUT register is described in the following table.

Table 601. JOUT JTAG register field descriptions

| Field | Function |
|---|---|
| JOUT_IPS Data | JOUT_IPS Data<br>Data value from JOUT_IPS register |

| JIN_RDY | JIN_RDY<br>State of JIN_RDY bit from MSR |
| JOUT_RDY | JOUT_RDY<br>State of JOUT_RDY bit from MSR |

### 77.7.2 JTAG input data register (JIN)

The external tool writes data to the JIN register via JTAG during execution of the JIN_WRITE JTAG instruction. The JDC later captures JIN data in the JIN_IPS register to be read via IPS. This register is reset by system destructive reset and JTAG reset. The reset value of the JIN register is 0. The following figure shows the format of the JIN register.

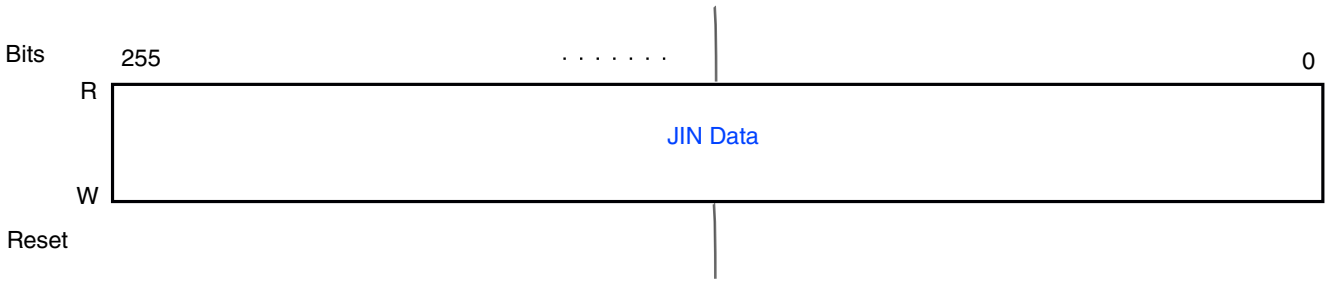

Figure 453. JIN

The JIN register is described in the following table.

Table 602. JIN JTAG register field descriptions

| Field | Description |
|---|---|
| JIN Data | Contains data to be captured in JIN_IPS register upon exit of Update-DR state when executing WRITE_JIN JTAG instruction. |

| **XBAR** | Crossbar bus interface |

# Chapter 78
# Temperature Sensor (TEMPSENSE)

## 78.1 Overview

TEMPSENSE is used to measure the temperature on the chip through an ADC and to flag if an overtemperature condition occurs.

The TEMPSENSE module contains control registers for use with the Engineering temperature sensor (ETS) hard block and the flag generation hard block. These registers use a peripheral bus interface to communicate with the chip.

### 78.1.1 Block diagram

The functional structure of the TEMPSENSE can be seen in the block diagram in Figure 454.

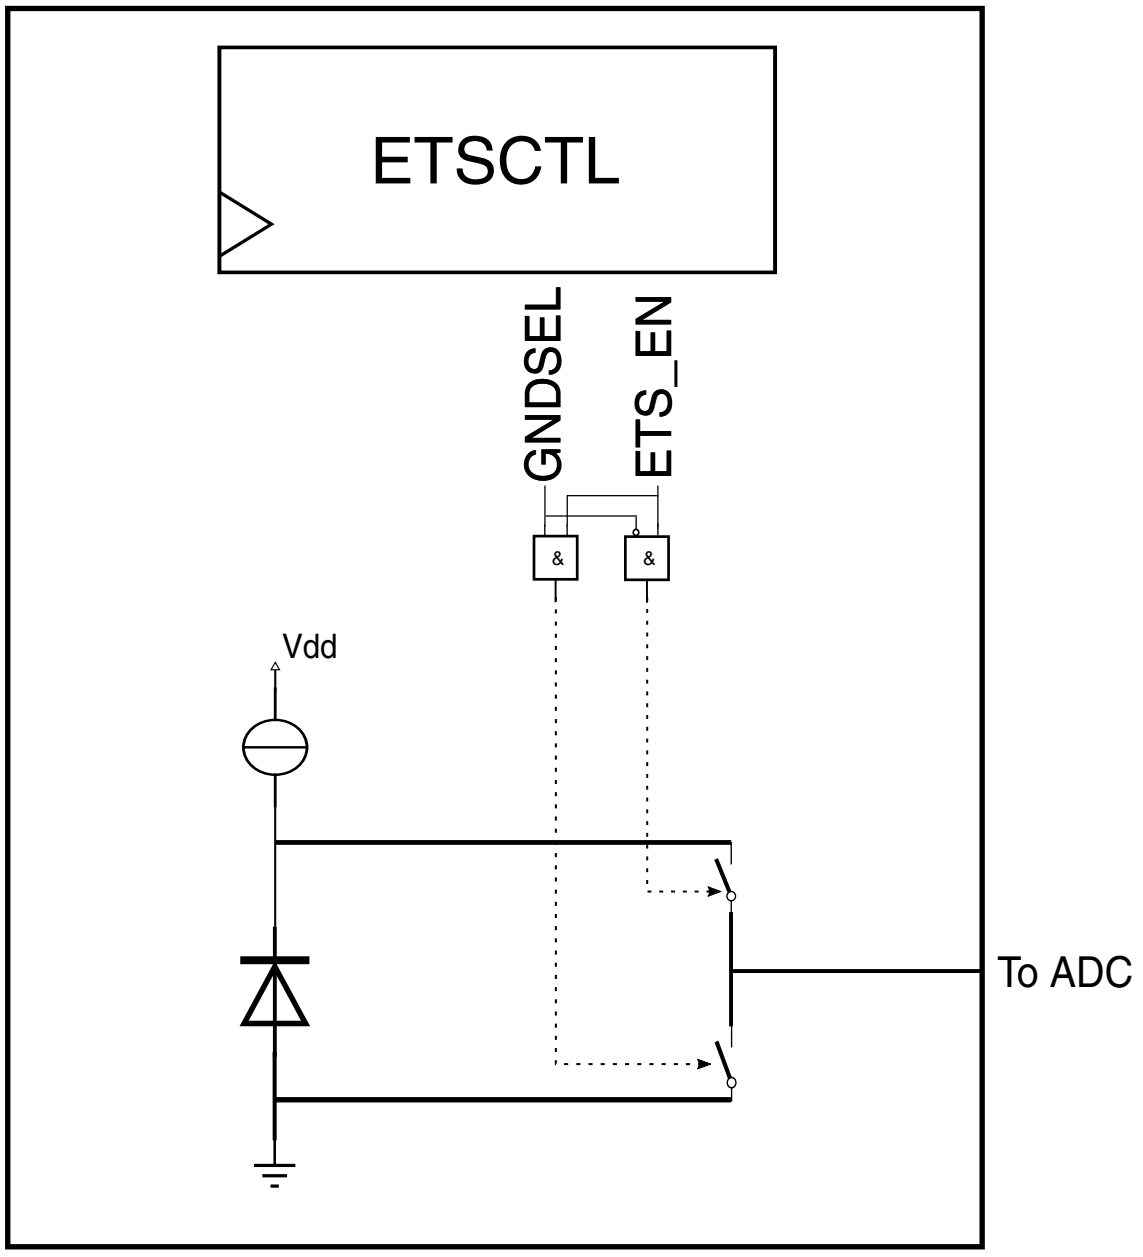

Figure 454. TEMPSENSE block diagram

### 78.1.2 Features

The TEMPSENSE includes the following features:

- Provide a voltage proportional to the temperature which will be read out by ADC
- Ground selection for improved precision in the ETS. The ETS ground could be different from the ADC ground. By exposing it to the ADC, the temperature calculation could be improved as the voltage value will be more precise.

## 78.2 Functional description

### 78.2.1 Clocking

This module has no clocking considerations.

### 78.2.2 Interrupts

This module has no interrupts.

### 78.2.3 General

The TEMPSENSE module is designed to measure the temperature on the chip.

The TEMPSENSE output can be read by an ADC on demand so that the software can determine the current die temperature. The software should enable the TEMPSENSE by setting ETSCTL[ETS_EN].

The TEMPSENSE output can be read by an ADC on demand so that the software can determine the current die temperature..

Coefficients are used to allow a simple and accurate calculation of linearized temperature directly from the ADC. The increase of the sampling time of the ADC from the minimum sampling value is increasing the temperature accuracy.

### 78.2.4 Initialization

#### 78.2.4.1 Conversion from voltage to temperature

Solve the equation for the conversion from voltage to temperature, where $V_{ETS}$ is the difference of $V_{be}$ and $V_{GND}$. $V_{GND}$ is expose on the ADC output when ETSCTL[GNDSEL] is set.

$$T_{ETS} = TCA_0 + TCA_1 \cdot V_{ETS} + TCA_2 \cdot V_{ETS}^2$$

The coefficients TCA0, TCA1 and TCA2 are read from the corresponding registers. They are stored in a signed fixed-point format as the following TCAx(11,4) (1 bit for the sign, 11 bits for the integer part and 4 bits for the decimal part).

The calculation of the temperature should be done with the actual coefficient values provided in the TCAx fields. See the example below for an ambient temperature of 25C, and an ADC reference voltage ($V_{REFH}$) of 5V. See the ADC section of the device data sheet for more details on $V_{REFH}$ and N-bit level resolution.

$$TCA0 = (000110100100.1110)_2 = (000110100100)_2 + (1110)_2 \times \frac{1}{2^4} = +((420)_{10} + (14)_{10} \times \frac{1}{2^4}) = +420.8750\ C$$

$$TCA1 = (100010101111.1110)_2 = (100010101111)_2 + (1110)_2 \times \frac{1}{2^4} = -((175)_{10} + (14)_{10} \times \frac{1}{2^4}) = -175.8750\ C/V$$

$$TCA2 = (100000011101.1110)_2 = (100000011101)_2 + (1110)_2 \times \frac{1}{2^4} = -((29)_{10} + (14)_{10} \times \frac{1}{2^4}) = -29.8750\ C\ /V^2$$

$$V_{ETS} = (010110001011)_2 = (1419)_{10} \times \frac{V_{REFH}}{2^N}$$

By using the formula, the junction temperature calculated is 26.5838 C.

The maximal calculation error is 0.0313 C.

## 78.3 External signals

There are no external signals for this module.

## 78.4 Memory map and register definition

### 78.4.1 Transfer error description

The following actions will cause a transfer error and will not change the register content:

- Any access to an unused register address
- Write access to a read-only register (TCAx)

### 78.4.2 TEMPSENSE register descriptions

#### 78.4.2.1 TEMPSENSE memory map

TEMPSENSE base address: 4037_C000h

| Offset | Register | Width (In bits) | Access | Reset value |

## A.8 Virtualization Wrapper (VIRT_WRAPPER)

### A.8.1 Chip-specific VIRT WRAPPER information changes

| |
|---|
| No substantial content changes. |

### A.8.2 VIRT_WRAPPER changes

| |
|---|
| • Updated the note from "Access to reserved spaces outside the register bank generates the transfer error. However, access to the reserved spaces within the register bank does not have any effect" to "Access to reserved spaces outside the register bank and holes (unimplemented registers) within register bank generates the transfer error.".<br>• Added the note "Any master can access holes (unimplemented registers) of SIUL2 through PDAC0." for REG_A and REG_B.<br>• Corrected the syntax to show the reserve RW Implemented hole bits within the registers REG_A and REG_B using MSCR_MAPPED parameter for REG_A and REG_B. |
| • Changed from PDAC to PDAC slot as applicable throughout the document.<br>• Added a note, "PDAC and PDAC slot are interchangeable terms." in Overview. |
| • Added section Initialization, Clocking, Application Information, and External signals. |
| • Made editorial updates. |
| • In Virtualization of interrupt control registers, added "The PDAC that...16 KB space" and "Access to mirrored...region".<br>• In Modes of operation, added see "Chip specific... for more details". |
| • Replaced "master" with "initiator" throughout the document.<br>• Removed, "This process is called ANY_MASTER" from PDAC-based protection scheme. |
| • Replaced "that is programmed by PDAC4 ... accessing PDAC0" with "that is programmed by specific PDAC ... accessing PDAC0" from Overview.<br>• Added a table in Register group mapping for SIUL2. |

## A.9 System Integration Unit Lite2 (SIUL2)

### A.9.1 Chip-specific SIUL2 information changes

| |
|---|
| No substantial content changes. |

### A.9.2 SIUL2 module changes

| |
|---|
| • In the note "For the array of 16-bit registers PGPDO*n* and PGPDI*n*": rephrased the second bullet-item. |

*Table continues on the next page...*

| |
|---|
| • Added field values 'Low' and 'High' for PGPDOn and PGPDIn registers. |
| • In External interrupt initialization added a new step 1 and added a note "When you chose external interrupt inputs for ...". |
| • Changed access type of reserved field from ROZ to RO in IFCPR and IFMCR*n* registers. |
| • Updated Figure 16.<br>• In the final note in register descriptions of MSCR*n* and IMCR*n*, added list items:<br>— "These registers are a part of SIUL memory map but physical implementation of these register is a part of IOMUX RTL.<br>— SIUL2 interprets accesses to MSCRn at module level." |
| • Throughout register descriptions, changed every instance of the character Á to × |
| • Added External signal description<br>• Moved block diagram related information to a new section: Block diagram<br>• Changed section title form "External interrupts/DMA requests (REQ Pins)" to External interrupts<br>• Added Clocking and has the following content: "This module has no clocking considerations".<br>• Added Initialization and has the following content: "This module does not require initialization".<br>• Updated DMA requests<br>• Throughout the register section, removed 'Register' from the register full names. |
| • In , replaced the existing content with: "See the IOMUX file attached to this document for more information". |
| • In Block diagram, mentioned that REQ pins mean interrupt request pins.<br>• In External interrupts, mentioned that IRC means Internal RC Oscillator. |
| • Updated the Block diagram. |
| • IFCPR register is removed. |

## A.10 Touch Sensing Pin Coupling (TSPC)

### A.10.1 Chip-specific TSPC information changes

| |
|---|
| No substantial content changes. |

### A.10.2 TSPC module changes

| |
|---|
| • Made editorial updates:<br>— Rephrased Overview.<br>— Added the following in Functional description "*... if any OBE within a group transitions from high to low, it enables that group of OBEs for simultaneous transition from high to low ...*". |
| • Made editorial changes. |

*Table continues on the next page...*

| |
|---|
| • Moved TSPC register descriptions to the end of TSPC chapter, just before Glossary. |
| • In Logic block description, replaced "gated output buffer enables" with "gated OBEs". |
| • Added topic Submodules.<br>• Added topic Operation.<br>• Added topic Clocking.<br>• Added topic External signals.<br>• Added topic Application information. |
| • Added sentence "See the chip-specific TSPC configuration for group of pads information" in Features. |

## A.11 Crossbar Switch (AXBS)

### A.11.1 Chip-specific AXBS information changes

| |
|---|
| No substantial content changes. |

### A.11.2 AXBS module changes

| |
|---|
| • Replaced "Master with Initiator" and "Slave with Target". |

## A.12 Peripheral Bridge (AIPS_Lite)

### A.12.1 Chip-specific AIPS_Lite information changes

| |
|---|
| No substantial content changes. |

### A.12.2 AIPS_Lite module changes

| |
|---|
| No substantial content changes. |

## A.13 Direct Memory Access Multiplexer (DMAMUX)

### A.13.1 Chip-specific DMAMUX information changes

| |
|---|
| No substantial content changes. |

### A.13.2 DMAMUX module changes

| |
|---|
| • Split the memory map within the DMAMUX register descriptions section into 2 sets of registers: one for channels having triggering capability (having TRIG bit) and the other for channels that don't have triggering capability (and hence no TRIG bit). |

*Table continues on the next page...*

| |
|---|
| • Split the memory map within the DMAMUX register descriptions section into 2 sets of registers: one for channels having triggering capability (having TRIG bit) and the other for channels that don't have triggering capability (and hence no TRIG bit).<br>• Added the footnote within the memory map as follows: "In this array, the index and offset values of the registers do not increment in direct alignment. For details, see the register description." |
| • Added the section Glossary and cross-referenced the first-time usage of the terms. |
| • Updated Glossary. |
| • Updated the section Functional description. |
| • Updated Block diagram.<br>• Updated the image "DMAMUX triggered channels" (Figure 24).<br>• Added a short introduction in Modes of operation. |

## A.14 Enhanced Direct Memory Access (eDMA)

### A.14.1 Chip-specific eDMA information changes

| |
|---|
| No substantial content changes. |

### A.14.2 eDMA3 module changes

| |
|---|
| No substantial content changes. |

## A.15 INTM module changes

| |
|---|
| • Added Register links all over the document.<br>• Updated Figure 34.<br>• Updated Registers, Initialization, Functional description topics.<br>• Topic Glossary removed. |
| • Updated Figure 34. |
| • Updated Functional description with a note to mention only level type interrupts are supported. |
| • Added description of the term FCCU in bullet no.5 of the topic Initialization. |
| • Updated Figure 34, added INTM_IRQSEL. |
| • Updated note in Functional description section. |
| • Removed ITRC occurence from Functional description.<br>• For INTM_TIMER0-INTM_TIMER3 registers, updated access of TIMER bit field to read only |
| • For INTM_TIMER0-INTM_TIMER3 registers, updated access of TIMER bit field to Read Write |

## A.16 Semaphores2 (SEMA42)

### A.16.1 Chip-specific SEMA42 information changes

| |
|---|
| No substantial content changes. |

### A.16.2 SEMA42 module changes

| |
|---|
| • Moved the block diagram to a new section Block diagram.<br>• Added following sections:<br>— Clocking<br>— Interrupts<br>— External signals<br>— Initialization<br>• Marked RSTGT_R[ROZ] as a reserved field in the field description table.<br>• Updated Functional description and Features.<br>• Updated Glossary.<br>• Updated GATEn state machine. |
| • Moved the Multi-core programming: software gates section to Functional description.<br>• Clarified the Function and field descriptions of Reset Gate Read (RSTGT_R) and Reset Gate Write (RSTGT_W) register. |
| • Updated Clocking section. |
| • Moved the "Initialization" and "External signals" section above "Memory map/register defination" section. |
| • Added NOTE in Overview section. |

## A.17 Crossbar Integrity Checker (XBIC)

### A.17.1 Chip-specific XBIC information changes

| |
|---|
| No substantial content changes. |

### A.17.2 XBIC module changes

| |
|---|
| • ESR.VLD: Updated the access to W1C |
| • Changed "Unsupported access type—an attempted write to a read-only register, for example" to "Writes to read-only registers generate a transfer error" in "XBIC register description" section<br>• Added text "This module has no interrupts." in the Interrupts section<br>• Added text "XBIC has no external interface signals." in the External signals section<br>• Added text "This module does not require initialization." in the Initialization section |

*Table continues on the next page...*

| |
|---|
| • Added Glossary section. Glossary<br>• Removed section "Signal description" and moved the text "XBIC has no external interface signals." to External signals section |
| • Removed "Writes to read-only registers generate a transfer error" from "XBIC register descriptions" section.<br>• Added note "Writes to read-only registers generate a transfer error" in the description of register XBIC Error Address (EAR)EAR. |
| • Changed the access type of bitfield "VLD" in register ESR from "RO" to "RW".<br>• Updated note in register XBIC Error Address (EAR) to "An attempted write to this read-only register results in a transfer error". |
| • Updated "Overview" section. |
| • Changed the access type of bitfield "VLD" of register ESR from "RW" to "RO". |
| • Updated the "Features". |
| • Replaced "Master with Initiator" and "Slave with Target". |

## A.18 Extended Resource Domain Controller (XRDC)

### A.18.1 Chip-specific XRDC information changes

| |
|---|
| No substantial content changes. |

### A.18.2 XRDC module changes

| |
|---|
| • Updated description of MRGD_W3_x[VLD] |
| • Overview:<br>— Added 'If the value of MDACFG*m*[NMDAR] is 1 ... rights granted for this DID.' |
| • Updated Process Identifier register.<br>• Added a bullet point "Register settings for DFMT1 direct domain assignment transactions" in Overview.<br>• UpdatedPID-based domain assignment and Transaction request sources.<br>• Added a bullet point "DFMT1 direct domain assignment example-single MDA" in XRDC transaction examples.<br>• Added DFMT1 direct domain assignment example-single MDA and its sub-sections. |
| • In MDA_W*r_m*_DFMT1[PA] field description Note, changed "secure" to "privileged" |
| • Added the text "This module has no clocking considerations" in Clocking<br>• Added Interrupts<br>• Added a note in MDA register structure |
| • Updated description of (MDA_Wn_m_DFMT0[VLD]) and (MDA_Wn_m_DFMT1[VLD]) |

*Table continues on the next page...*

| |
|---|
| • Added Exceptions and violations. |
| • Removed "Zipwire" and "FlexRay" from Transaction protection. |
| • Updated Handling domain access violation errors.<br>• Updated the register descriptions for DERR_W0_i, DERR_W1_i, and DERR_W3_i. |
| • Updated the register descriptions for DERR_W0_i and DERR_W1_i. |
| • Replaced "master" to "initiator" throughout the document. |
| • Added a note for deprecated terms in Overview. |
| • Updated Block descriptions, Peripheral ACP evaluation example, and Memory ACP evaluation example. |

## A.19 Memories and Memory Interfaces changes

| |
|---|
| No substantial content changes. |

## A.20 Embedded Flash Memory (c40asf)

### A.20.1 Chip-specific C40asf information changes

| |
|---|
| No substantial content changes. |

### A.20.2 Embedded Flash Memory (c40asf)

| |
|---|
| No substantial content changes. |

## A.21 Flash Memory Controller (PFLASH)

### A.21.1 Chip-specific PFLASH information changes

| |
|---|
| No substantial content changes. |

### A.21.2 PFLASH controller module changes

| |
|---|
| • Added PFAPR[M3AP] bit. |

## A.22 RAM Controller (PRAMC)

### A.22.1 Chip-specific PRAMC information changes

| |
|---|
| No substantial content changes. |

### A.22.2 PRAMC module changes

- Divided the Overview section to three sections: Overview, Block diagram, and Features.
- Added section for clocking, Clocking, and reset, Reset .
- Added Reset.
- Added information that the module has no external signals in the section External signals.
- Added information that the module has no interrupts in the section Interrupts.

- Block diagram - Removed internal content from the section.

## A.23 Clocking module changes

No substantial content changes.

## A.24 Clock Generation Module (MC_CGM)

### A.24.1 Chip-specific MC_CGM information changes

No substantial content changes.

### A.24.2 MC_CGM module changes

- Added following note in the MUX_n_DC_m register: Software-controlled clock multiplexer dividers are not expected to return to the default state on the hardware transitions and handshakes occurring as part of the functional reset entry sequence (only hardware-controlled clock multiplexer dividers return to the default state).

- Added following note in the MUX_n_DIV_UPD_STAT[DIV_STAT] field: This field clears once divider configuration is updated or on destructive reset. If functional reset comes when this field is 1 then it can remain fixed to 1 until divider input clock is restored.

## A.25 FIRC module changes

- Added text "This module has no external signals." in External signals section
- Added text "This module does not require initialization." to Initialization section

## A.26 SIRC module changes

- Added text "This module has no external signals" in the External signals section
- Added text "This module does not require initialization." in the Initialization section

## A.27 Fast Crystal Oscillator Digital Controller (FXOSC)

### A.27.1 Chip-specific FXOSC information changes

No substantial content changes.

### A.27.2 FXOSC module changes

| |
|---|
| • Added the CTRL[ALC_D] field. |
| • Updated Overview section as follows:<br>— Changed the title from "Introduction" to "Overview" in overview.dita file.<br>— Added "The Fast Crystal Oscillator (FXOSC) generates a clock which can be used at the SoC level. The FXOSC has a digital interface to control and configure the oscillator to generate multiple frequencies. When FXOSC is powered down at any time, it is designed not to generate any glitch at the output clock. A counter inside FXOSC handles different stabilization times." in the overview section.<br>— Commented out "This module provides the fast crystal oscillator to the chip." in overview section.<br>• Removed the note "For bypass mode applications, the EXTAL pin should be driven low when FXOSC is in off/disabled state" from "Functional Description" section.<br>• Removed the following notes from "Initialization section"<br>— "When the FXOSC is used in Bypass mode, the external clock source can only be enabled after the FXOSC is enabled."<br>— "When the FXOSC is used in Bypass mode, the external clock source must already be inactive before disabling the FXOSC."<br>• Added the new section Block diagram, , Clocking, External signals and Interrupts. |
| • Made changes in block diagram<br>• Replaced the content of Clocking section with "This module has no clocking considerations."<br>• Removed “to generate multiple frequencies” from the Overview section<br>• Added "CG cell is clock gating cell, it gates the clock till stabilization time." in Overview section<br>• Added note "When the FXOSC is used in Bypass mode, the clock from the external source can only be used after the FXOSC is enabled" in Initialization section. |
| • Updated Block diagram section |
| • Added long description to CTRL[ALC_D].<br>• In Initialization- Added a note "See Hardware design guide for further details and the recommended circuit for each mode." |
| • Updated the section Clock generation in Single-Input Bypass mode. |

## A.28 SXOSC module changes

| |
|---|
| • Updated the reset value of CTRL register. |
| • Updated the bit field value of CURR_PRG_COMP, CURR_PRG_SF and GM_SEL. |
| • As per TKT0613245, parameterized the Bypass mode(to hide it for S32K3xx) and other points are already updated as per TKT0611802. |
| • Fixed the shared review comments received on S32K5 RM. |

## A.29 PLL Digital Interface (PLLDIG)

### A.29.1 Chip-specific PLLDIG information changes

| |
|---|
| No substantial content changes. |

### A.29.2 PLLDIG module changes

| |
|---|
| • Note "The value of this field is 0b when the module is under reset." added in PLLSR[CGE_OUT2 and CGE_OUT1] register. |
| • Maximum possible modulation depth formula added in "Frequency modulation programming" topic. |
| • Maximum possible modulation depth formula added for "When PLL[RDIV] is 0" in "Frequency modulation programming" topic.<br>• LOL abbreviation added in LOL topic. |

## A.30 Reset module changes

| |
|---|
| No substantial content changes. |

## A.31 Boot Overview changes

| |
|---|
| No substantial content changes. |

## A.32 Reset Generation Module (MC_RGM)

### A.32.1 Chip-specific MC_RGM information changes

| |
|---|
| No substantial content changes. |

### A.32.2 MC_RGM module changes

| |
|---|
| • Added following note in section Reset state machine: See chip-specific MC_RGM information for chip-specific reset sequence details. |
| • Added following note in DES[F_POR] field: All reset status in the FES and DES registers must be ignored at power up if this field is set. |
| • Removed the following content from Functional reset entry timer: See the chip-specific section for the default value of timeout value and the details on the chip behavior in case of functional reset entry timer timeout.<br>• Added section: Alternate event generation. |
| • Removed the following statement from RESET_B pin assertion and pin safe state control: See STCU2 chapter for more details on its usage.<br>• Added following note in Functional reset escalation: Functional counter increments for each reset source for which escalation is enabled. For details, see "Reset sources" table in the Reset chapter. |

*Table continues on the next page...*

| |
|---|
| • Added following note in Destructive reset escalation: Destructive counter increments for each reset source for which escalation is enabled. For details, see "Reset sources" table in the Reset chapter. |
| • Editorial changes.<br>• Updated Figure 133.<br>• In Features, removed the first three features and added the following:<br>— Destructive and functional reset management<br>— Capturing the reset sources for each reset sequence (reset status flags)<br>— Assertion the Reset_B pin to propagate the reset sequence out of chip<br>• Changed the "Reset value" from 0 to 1 in Table 182.<br>• Updated the description in Table 182.<br>• Updated the last statement in RESET_B pin assertion and pin safe state control |
| • In Functional reset entry sequence, updated the second last paragraph for clarity.<br>• In Functional reset exit sequence, updated the second bullet.<br>• Moved content from External reset to RESET_B assertion control.<br>• Renamed the "External reset assertion control" section to RESET_B assertion control.<br>• Updated the second paragraph of the Destructive reset escalation for clarity.<br>• Updated the description of FREC, FRET[FRET] and DRET[DRET]. |
| • In Reset sources, removed "and the MC_RGM itself" from the last statement of the third paragraph.<br>• In Reset sources, removed "(for example, debug modules, flash modules)" from the last statement of the last paragraph. |
| • Updated the Figure 134. |
| • Updated the note in Functional /External Reset Status Register (FES).<br>• In External signal description, updated the reset value of "RESET_B" signal. |
| • Updated the note in Functional /External Reset Status Register (FES).<br>• Updated Figure 133 and Figure 134.<br>• Removed "(except for a small portion, for example FIRC, JTAG interface)" from Reset sources.<br>• Updated references to reset chapter to make them generic. |
| • Updated the note in DES[F_POR].<br>• Updated the note in Functional /External Reset Status Register (FES). |
| • Updated the note in Functional /External Reset Status Register (FES). |
| • Updated the description of the Functional /External Reset Status Register (FES). |
| • Removed the fields: MODE_CONF[POR_RST], MODE_CONF[FULL_WKUP], MODE_CONF[Standby]. |
| • Updated Figure 134. |

*Table continues on the next page...*

| |
|---|
| • Removed Standby mode related information from the chapter. |
| • Removed "LPRR_CONF" register. |

## A.33 POR_WDG module changes

| |
|---|
| No substantial content changes. |

## A.34 Security overview changes

| |
|---|
| No substantial content changes. |

## A.35 HSE_B module changes

| |
|---|
| No substantial content changes. |

## A.36 DCF module changes

| |
|---|
| No substantial content changes. |

## A.37 Chip-specific DCM information changes

| |
|---|
| No substantial content changes. |

## A.38 DCM module changes

| |
|---|
| • Removed the content related to CUST_DEL, NXP_PWD and MCU_PROD from the chapter. Removed the DCMLCC[DCMFLC] and DCMLCC[DCMLCFN] bits. |
| • Changed the access of Reserved bits 3,8 and 9 from ROz to RW in DCMLCC register. |
| • Changed the access of Reserved bits 0 to 11 from ROz to W1C in DCMLCS register. |
| • Revised Overview, Figure 139, and Features.<br>• Revised DCF mechanism, removed the content duplicate with DCF chapter of RM.<br>• Revised DCF client error mechanism, changed CERS to DCMCERS in figure title.<br>• Revised LC to update information of valid and invalid field types, and Table 196 to change PFA to Pre_FA.<br>• Revised Glossary, added OTP and DCF.<br>• Deleted DCMSTAT[9] DCMOTAS.<br>• Revised the description of DCM Status (DCMSTAT), LC and LC Control (DCMLCC), LC Scan Status (DCMLCS), LC Scan Status 2 (DCMLCS_2), DCMSTAT[DCMLCST], , DCMMISC[DCMDBGE], DCMMISC[DCMDBGT], DCF Error Count (DCMEC), DCMEC[DCMECT], DCMSRRn, DCMSRR1[DCMESF1], and DCMSRR1[DCMDCFF1]. |
| • Revised DCM error detection mechanism and Figure 141. Also, changed DCF to DCM in topic and figure title. |

- Revised DCF client error mechanism, Figure 140 and changed its title to "DCF error handling".
- Revised Features, updated debug related information.
- In LC, revised Table 196.
- In Glossary, added PFC.
- Revised description of LC and LC Control (DCMLCC).
- Revised DCMLCS[DCMLCE5], DCMDEB[DCM_APPDBG_STAT], DCMSRR1[DCMDCFF1] .

## A.39 Messaging Unit (MU)

### A.39.1 Chip-specific MU information changes

No substantial content changes.

### A.39.2 MU module changes

- Updated the reset value of the SR[MURS] register bit field as undefined.

- Revised Figure 143 - changed "Processor A side" and "Processor B side" to "MUA" and "MUB" respectively.
- Added new topics Submodules and Initialization.
- Updated Glossary.
- Added Clocking - "This module has no clocking considerations.".

- In Glossary and Features, corrected MUA and MUB from Message Unit A and Message Unit B to Messaging Unit A and Messaging Unit B respectively.

- Changed "external memory", and "memory array" to "shared memory" in Functional description.
- Added new clock "Bus clock" in "Clocking".
- Removed topic "Wake up core in low power mode".
- Revised Interrupts topic.
- Revised Table 201.
- Revised , TR0-TR3[TR_DATA], RR0-RR3[RR_DATA].
- Revised Table 206.

- Revised access type and reset value of CCR0[2].
- Revised access type and reset value of CCR0[4].

- Added note in MUA side and MUB side.

- Updated Asynchronous system reset.

- Deleted topic "Sending messages with interrupt" and revised Initialization to add information "MU does not require initialization.".

- Updated topics MUA side and MUB side, revised notes.

*Table continues on the next page...*

| |
|---|
| • Updated the description of SR[TEP] and RSR[RFn]. |
| • Updated receive and transmit interrupts related points in Interrupts. |

## A.40 Power management changes

| |
|---|
| No substantial content changes. |

## A.41 PMC changes

| |
|---|
| No substantial content changes. |

## A.42 PMC changes

| |
|---|
| No substantial content changes. |

## A.43 Mode Entry Module (MC_ME)

### A.43.1 Chip-specific MC_ME information changes

| |
|---|
| No substantial content changes. |

### A.43.2 MC_ME module changes

| |
|---|
| • Added following note in Partition 0 Process Configuration Register (PRTN0_PCONF), Partition 0 Process Update Register (PRTN0_PUPD), Partition 0 Status Register (PRTN0_STAT): See chip-specific MC_ME information to check if this register is implemented on chip. |
| • Added Main Core ID Register (MAIN_COREID). |

## A.44 MC_PCU changes

| |
|---|
| • Updated Table 217. |
| • Updated Power sequence FSM. |
| • Updated first statement in the second paragraph of Introduction. |

## A.45 Wakeup Unit (WKPU)

### A.45.1 Chip-specific WKPU information changes

| |
|---|
| No substantial content changes. |

### A.45.2 WKPU module changes

| |
|---|
| No substantial content changes. |

## A.46 Safety overview changes

| |
|---|
| No substantial content changes. |

## A.47 Error Injection Module (EIM)

### A.47.1 Chip-specific EIM information changes

| |
|---|
| No substantial content changes. |

### A.47.2 EIM module changes

| |
|---|
| • In Functional description, added information about enabling/disabling error injection. |
| • Added Initialization section stating that this module does not require initialization. |
| • Updated the definition of SEC-DED. |
| • Updated the first paragraph of Overview. |
| • Updated revision history title to "EIM module changes". |
| • Added NOTE in Overview section. |

## A.48 Error Reporting Module (ERM)

### A.48.1 Chip-specific ERM information changes

| |
|---|
| No substantial content changes. |

### A.48.2 ERM module changes

| |
|---|
| • Updated the description of the SR registers. |
| • Added following note in the "ERM register descriptions" section: To access the channel registers, corresponding channel clocks must be enabled. |
| • Added following note in the Non-correctable error events: Parity errors can be mapped to non-correctable errors where error attributes like SYNDROME, ADDRESS are not provided.<br>• Updated the last statement of the Overview as follows: ERM does not capture syndrome or error address for cache memories or memory with parity instead of ECC.<br>• Added following note in the "ERM Memory a Correctable Error Count Register": Non-correctable errors are considered a serious fault, so the ERM does not provide any mechanism to count non-correctable errors. Only correctable errors are counted. |
| • Removed the following statement from the CR*n*[ENCIE*m*] and CR*n*[ESCIE*m*] fields: This field is initialized by hardware reset. |

*Table continues on the next page...*

| |
|---|
| • Added following note in the "ERM Memory a Error Address Register": This register provides the offset of error location and not the absolute address. For example, if memory is SRAM0 (which starts from 0x20400000) if error occurs at 0x20400010 the EAR register gives value 0x10 and not 0x20400010. |
| • Removed following note from the "ERM Memory a Error Address Register": This register provides the offset of error location and not the absolute address. For example, if memory is SRAM0 (which starts from 0x20400000) if error occurs at 0x20400010 the EAR register gives value 0x10 and not 0x20400010. |
| • In introductory text of "ERM register descriptions", added information related to the XFR error behavior at the IPS interface.<br>• Added Figure 178. |

## A.49 Fault Collection and Control Unit (FCCU)

### A.49.1 Chip-specific FCCU information changes

| |
|---|
| No substantial content changes. |

### A.49.2 FCCU module changes

| |
|---|
| • Note "Software reset of FCCU by MC_RGM_PRST5[FCCU_RST] bit is optional since FCCU registers are not initialized during functional reset. MC_RGM_PRST5[FCCU_RST] has the same effect on FCCU as power on reset. If the bit is activated, it can change the state of the error pin, if the current state of the pin is different from default." removed from topic "Use cases and limitations". |
| • Reset interface topic moved into chip specific section. |
| • The equation changed from "Tmin = 250 µs + DELTA_T to "Tmin = (250us + DELTA_T) * (SAFE_CLK_FREQ/CLKSAFE freq). |
| • Added a topic External signals. |
| • Added EIN input signal in block diagram. |
| • Note "The FCCU is not reset by short functional resets" deleted from BG. |
| • Updated the description of "Not Fault-Toggle" value of Timer state in FAULT state of Fault-Output Timer (TMR_ETMR) register. |
| • Updated the External signals. |
| • For EINOUT, updated the bit field description for EINOUT[EIN1] and EINOUT[EIN0]. |

## A.50 SELFTEST_GPR module changes

| |
|---|
| No substantial content changes. |

## A.51 Self-Test Control Unit (STCU2)

### A.51.1 Chip-specific STCU2 information changes

| |
|---|
| No substantial content changes. |

### A.51.2 STCU2 module changes

| |
|---|
| • In Example: Multi-phase BIST sequence, changed the BIST number from 38 to 30 for phase 0. |
| • Removed MTR from the function of "MBIST interface" in Table 240. |
| • Updated the description of the STCU2 Online LBIST Unrecoverable FM (LBUFM0). |
| • Removed instances of "INT_FLG" from Peripheral bus interface. |
| • Added title to Figure 189. |
| • Updated the description of STCU2 SK Code (SKC). |
| • Removed topic "Use cases and limitations".<br>• Revised FSM description, changed state machine to FSM.<br>• Revised Peripheral bus interface and Glossary.<br>• Revised description for CFG[PTR], CFG[CLK_CFG] , CFG[LB_DELAY] , LB_CTRL0[PTR], and MB_CTRLn[PTR].<br>• Revised description for MBSSWn and MBESWn. |

## A.52 Register Protection (REG_PROT)

### A.52.1 Chip-specific REGPROT information changes

| |
|---|
| No substantial content changes. |

### A.52.2 REG_PROT module changes

| |
|---|
| No substantial content changes. |

## A.53 Clock Monitoring Unit – Frequency Check (CMU_FC)

### A.53.1 Chip-specific CMU_FC information changes

| |
|---|
| No substantial content changes. |

### A.53.2 CMU_FC module changes

| |
|---|
| • Updated Features, to remove clocking information.<br>• Added separate section for clocking, Clocking. |

*Table continues on the next page...*

| |
|---|
| • Added Reset.<br>• Added information that the module has no external signals in the section External signals. |
| • In Features<br>— Changed "Timeout functionality generates an FLL event if a monitored clock stops functioning" to "Timeout functionality generates an FLL event (if enable) when monitored clock is very slow or stop functioning." |
| • Updated the Features. |
| • Updated the Operating modes. |

## A.54 Clock Monitoring Unit – Frequency Meter (CMU_FM)

### A.54.1 Chip-specific CMU_FM information changes

| |
|---|
| No substantial content changes. |

### A.54.2 CMU_FM module changes

| |
|---|
| • Updated Features, to remove clocking information.<br>• Added separate section for clocking, Clocking.<br>• Added Reset.<br>• Added information that the module has no external signals in the section External signals. |
| • Fixed the Minimum RCCR[REF_CNT] formula calculation in Programming RCCR[REF_CNT]. |

## A.55 Cyclic Redundancy Check (CRC)

### A.55.1 Chip-specific CRC information changes

| |
|---|
| No substantial content changes. |

### A.55.2 CRC module changes

| |
|---|
| • Renamed the section "Introduction" to Overview<br>• Added the section External signals.<br>• Moved the section Modes of operation within the Functional description section.<br>• Moved the section Initialization after the Functional description section. |
| • Updated the following sections: Features, Calculating a 16-bit CRC, Memory map and register descriptions, Expected read data fields, and CTRL programming |
| • Updated the following section: Memory map and register descriptions. |
| • Updated Calculating a 32-bit CRC. |

*Table continues on the next page...*

| |
|---|
| • Added Clocking and Interrupts.<br>• Renamed section title "CRC initialization and reinitialization" to "Initialization".<br>• Updated the long description of CTRL[WAS]. |
| • Updated Clocking. |
| • In section Calculating a 16-bit CRC cross reference in step 2 “Program the transpose and complement options in Data (DATA) as required for the CRC calculation” )" changed to "Control (CTRL)".<br>• In section Calculating a 32-bit CRC cross reference in step 7 “CRC is computed on every data value write and the intermediate CRC result is stored back into DATA[LU] and DATA[LL]” changed to "DATA".<br>• In register DATA[HL] long description updated to "Generates CRC checksum in both 16-bit and 32-bit CRC modes if CTRL[WAS] = 0." |
| • Updated the description of Data (DATA) register.<br>• Updated the description of DATA[LL]. |
| • Updated Low-power modes and Clocking |

## A.56 PCMC changes

| |
|---|
| No substantial content changes. |

## A.57 Analog-to-Digital Converter (ADC)

### A.57.1 Chip-specific ADC information changes

| |
|---|
| No substantial content changes. |

### A.57.2 ADC module changes

| |
|---|
| • In AMSIO register: reserved bit AMSIO[16] was made visible to customer as AMSIO[CMPCTRL0], deleted text from function "you must write 3d to HSEN" and updated the description of field 18-17.<br>• In Clock section, the table "Clock configuration for highest conversion speeds" was updated with the new recommendation, that is for freq > 80MZ the setting AMSIO[HSEN]=01b and AMSIO[CMPCTRL0]=1b shall be used.<br>• In Clock section, deleted text "For some conversion clock frequencies, you must write 3d to AMSIO[HSEN]".<br>• In Conversion time section, change the text from "The evaluation time of a single bit is 4 AD_clk cycles if AMSIO[HS] = 0h, and 5 AD_clk cycles if AMSIO[HS] = 1h." to "The evaluation time of a single bit is 4 AD_clk cycles if AMSIO[HSEN] = 0h and AMSIO[CMPCTRL0] = 0b. The evaluation time of a single bit is 6 AD_clk cycles if AMSIO[HSEN] = 1h and AMSIO[CMPCTRL0] = 1b." |
| • Deleted statement about analog watchdog programming from topic Analog watchdog configuration (up to 16 watchdogs) "The threshold values to be selected for a channel must be programmed only once in CWSELRaIn." |
| • CDATA bit field description updated to "Contains conversion data from standard input n, determined by the SAR algorithm. The conversion data bit count is dependent on the conversion resolution selected (CALBISTREG[RESN]). Depending on the value of MCR[WLSIDE], the conversion data MSB bits start from 14 (MCR[WLSIDE] = 0) or 15 (MCR[WLSIDE] = 1). |

## A.58 Low Power Comparator (LPCMP)

### A.58.1 Chip-specific LPCMP information changes

| |
|---|
| No substantial content changes. |

### A.58.2 LPCMP module changes

| |
|---|
| • Removed references to "hard block" from CCR2[HYSTCTR] in register file for clarity.<br>• In Functional description, edited the title. |
| • Edited register file. |
| • Added Glossary of terms. |
| • Changed the name of the "Clocks" section to Clocking.<br>• Changed the name of the "Trigger Mode" sectionto Round-robin trigger mode and clarified the full name of the Round Robin Trigger mode.<br>• Clarified Latency issues.<br>• Added register links to Initialization. |
| • Updated External signal descriptions with RR_ACTIVE related description.<br>• Updated Block diagram with RR_ACTIVE and Round_robin FSM.<br>• Updated Round-robin trigger mode with RR_ACTIVE wave form. |
| • Updated Block diagram, including input channels and register references using REG[FIELD].<br>• Updated Initialization.<br>• Updated Application information. |
| • Reserved CCR3 register in LPCMP register descriptions. |
| • Updated LPCMP register descriptions by adding a note to Comparator Status (CSR). |
| • Updated Round-robin clock (RCLK) frequency requirement by changing "ms" to "µs". |
| • In LPCMP register descriptions, updated "ACMP" with "LPCMP" in the Note of CSR register. |
| • Added Version ID (VERID) register. |

## A.59 Logic Control Unit (LCU)

### A.59.1 Chip-specific LCU information changes

| |
|---|
| No substantial content changes. |

### A.59.2 LCU module

| |
|---|
| • Updated block diagram to show outputs that go to IO pads |
| • LC Diagram Revised the LC Diagram to update the LC0_FCTRL[FORCE_MODE0] mux values from 0 1 2 3 to 0 2 1 3.<br>• LC n Sync Control Revised the conditions for bit 8 and 9 to show bit 9 as Reserved whenever the input sync value is 1 or 2.<br>• Mux Select Added note "Access to Address space 200h + (a x 4h) does not generate a transfer error". |
| • Updated description of CFG[WP].<br>• Updated the bit information in title for Mapping of 12-bit input, output, and state fields to reflect the correct bit value. |
| • Changed bit 9 of LC n Sync Control (LC0_SCTRL - LC2_SCTRL) to RW from ROZ. |
| • Added note in LC output filters.<br>• Added new topic DMA.<br>• Revised Interrupts. |
| • Revised the long description for LC0_FFILT[FORCE_POL]. |
| • Removed "Glossary" section. |
| • Revised Features, LC diagram.<br>• Revised Figure 251, and Figure 252 to remove sync 2 and 3 inputs.<br>• Revised the long description of DBGEN[DBGEN]. |
| • Changed 1h to Eh in Table 299 for LUTCTRL0.<br>• Revised long description for LC0_SCTRL[SW_MODE].<br>• Revised Features to update register information.<br>• Revised Figure 251 |
| • Revised Block diagram to remove the note "3 LCs are shown in this block diagram.".<br>• Revised Figure 252. |

## A.60 Enhanced Modular IO Subsystem (eMIOS)

### A.60.1 Chip-specific eMIOS information changes

| |
|---|
| No substantial content changes. |

### A.60.2 eMIOS module changes

| |
|---|
| • Changed bit position from 0 to 31 for AS2 in Effect of C*n*[EDPOL] on edge capturing and SAIC submodes and MODE field values<br>• Added bitfield A*n*[RISE_FALL]. |

*Table continues on the next page...*

| |
|---|
| • Editorial updates. |
| • Deleted counter bus E from figures in UC block diagram and UC control and datapath. |

## A.61 Body Cross-triggering Unit (BCTU)

### A.61.1 Chip-specific BCTU information changes

| |
|---|
| No substantial content changes. |

### A.61.2 BCTU module changes

| |
|---|
| • Topic External Signals removed. |
| • Minor correction in figures of Trigger timing and Simultaneous trigger priority management.<br>• Updated Implementation. |
| • Updated no of triggers and ADC to (n) in Block diagram. |

## A.62 Trigger MUX (TRGMUX)

### A.62.1 Chip-specific TRGMUX information changes

| |
|---|
| No substantial content changes. |

### A.62.2 TRGMUX module changes

| |
|---|
| • Renamed the "Introduction" section to Overview.<br>• Nested Features within the "Overview" section. |
| • In #unique_3756/unique_3756_Connect_42_bitFieldTable, updated values for the SELx field from binary to hex format.<br>• In #unique_3757, updated description for SELn fields.<br>• Added Block diagram<br>• Updated Features to remove block diagram.<br>• Added Functional description |
| • Removed "Memory map and register definition" section. |
| • Removed "Memory map and register definition" section:<br>— Moved following content from the "Memory map and register definition" section to "TRGMUX memory map" sections:<br>"You can only write to TRGMUX registers in Supervisor mode."<br>— Removed redundant content "The TRGMUX registers contain fields for selecting trigger sources for peripheral modules." |

*Table continues on the next page...*

| |
|---|
| • Editorial updates:<br>— Renamed all the registers from "TRGMUX *Reg_Name* Register (*Reg_Name*)" to "TRGMUX *Reg_Name* (*Reg_Name*)", here *Reg_Name* refers to the register name.<br>— Updated the description of all the fields in all the registers. |
| • In Block diagram, updated reference to chip-specific TRGMUX information.<br>• In #unique_3757, removed reference to chip-specific TRGMUX information. |

## A.63 Software Watchdog Timer (SWT)

### A.63.1 Chip-specific SWT information changes

| |
|---|
| No substantial content changes. |

### A.63.2 SWT module changes

| |
|---|
| • In CR[FRZ], replaced "chip" with "core." |
| • In Behavior in different chip and core modes, replaced "chip" with "core." |
| • Edited throughout.<br>• Added Block diagram section.<br>• Added Clocking section.<br>• Added Reset section.<br>• Added Interrupts section. |
| • Updated Block diagram section.<br>• Updated Reset section. |
| • Updated Initialize the SWT section to remove the bullet "Select the clock source (if there are more than one possible sources)".<br>• Removed 'Select the clock source' section.<br>• Updated Clocking section to add the following details "See the chip-specific SWT information to find the clock source that drives the countdown timer." |
| • Updated terminology in this chapter as follows:<br>— Updated "Master" to "Initiator" |
| • In Clocking, added reference to the chip-specific SWT information for the clock source of the counter and reset logic. |

## A.64 System Timer Module (STM)

### A.64.1 Chip-specific STM information changes

| |
|---|
| No substantial content changes. |

### A.64.2 STM module changes

| |
|---|
| • Renamed "Introduction" to Overview.<br>• Restructured to conform to BGAC outline.<br>• Added the Clocking topic.<br>• Added the Interrupts topic.<br>• Restored the External signals topic.<br>• Added the Initialization topic. |

## A.65 Periodic Interrupt Timer (PIT)

### A.65.1 Chip-specific PIT information changes

| |
|---|
| No substantial content changes. |

### A.65.2 PIT module changes

| |
|---|
| • Updated description of MCR[MDIS]. Changed the sentence “You must write 1 to this field before setting up anything” to “You must ensure that the clock is disabled (MDIS = 1) before configuring PIT. After configuration, user must enable clock (MDIS=0).”<br>• Updated Modes of operation to include Debug mode. |
| • Added STOP mode section. |
| • Rearranged feature list for clarity and added an item for the number of timers.<br>• Rewrote all register and field descriptions for clarity and usability except LTMR64L. |
| • Removed STOP mode section. |
| • Removed unnecessary "Preface" section.<br>• Rewrote the following sections for clarity and usability.<br>  — LTMR64H and LTMR64L register and field descriptions<br>  — Interrupts<br>• Renamed "Introduction" to Overview and rewrote for clarity.<br>• In Modes of operation, replaced bulleted list with a table.<br>• Added new Clocking topic.<br>• Added new External signals topic. |
| • Corrected the link present in note of register RTI_LDVAL_STAT. |
| • Moved Modes of operation under Functional description.<br>• Updated in the sub-sections of Functional description.<br>• Updated in Application information and its sub-sections. |

*Table continues on the next page...*

- Updated the access row in "PIT memory map".
- Updated register function description in PIT Module Control (MCR).
- Updated description in RTI_LDVAL_STAT[RT_STAT].
- Updated description in RTI_TFLG[TIF].
- Added text "See LTMR64H and LTMR64L." in TCTRL0[CHN]."
- Updated description in TFLG0[TIF].

- In Example configuration using chained timers:
  - Updated the example configuration to (60 s/10 ns).
  - Updated the step 6 and 7 in the configuring PIT.
  - Updated the example code for Disable PIT to "PIT_MCR = 0x02"
- Updated the example code for Disable PIT to "PIT_MCR = 0x02" in Example configuration using the lifetimer.
- Updated the example code for Disable PIT to "PIT_MCR = 0x02" in Example configuration for general timers.

- Updated the section headings of Restart counter period, Change current timer period and Dynamically setting a new timer period.
- Replaced "...when it expires (CVALn - 0)" to "...when it expires (CVALn = 0)" in Chained timers.

- In PIT register descriptions, changed PIT_RTI to PIT.
- Moved the statements about chip-specific PIT information from PIT register descriptions to Functional description and rewrote it.

- In Example configuration using chained timers, corrected "(60 s/10 ns)" to "(60 s/100 ns)".

- In Clocking, added reference of the Clocking chapter.

## A.66 Real Time Clock (RTC)

### A.66.1 Chip-specific RTC information changes

No substantial content changes.

### A.66.2 RTC module changes

- Updated last para of RTC to :In case, RTC wakeup's are used as a wakeup source, bus clock (system clock or register interface clock of RTC) should be disabled (to save power in standby mode) after enabling the required wakeup and ensuring sufficient time gap (3-6 bus clock or RTC clock (rtc_clock) cycles, whichever is slower) between bus clock disabling and wakeup event. To ensure writing the register to enable the wakeup, the bus clock must be active, hence it should not be disabled before enabling wakeup. Correct operation is not guaranteed if the specification is not followed.

- Changed "ACMP" into "CMP" in TRIG_EN.

- Modified note in CLKSEL.

- Added a note "See the chip-specific RTC information and clocking chapter for mapping of clock sources" in Features .

## A.67 Low Power Serial Peripheral Interface (LPSPI)

### A.67.1 Chip-specific LPSPI information changes

| |
|---|
| No substantial content changes. |

### A.67.2 LPSPI module changes

| |
|---|
| • In Controller mode, Transmit and command FIFO commands, and Transmit Command (TCR), clarified that LPSPI must be enabled to update command word.<br>• Updated Features. |
| • Updated Timing parameters.<br>• Added a warning on writing data to Clock Configuration (CCR). |
| • Moved "SPI bus transfers" content from Transmit and command FIFO commands to subtopic<br>• Moved "Circular FIFO" content from Transmit and command FIFO commands to subtopic |
| • Updated CR[MEN]. |
| • Updated Timing parameters.<br>• Updated CCR[SCKDIV]. |
| • Updated Features. |
| • Updated CFGR1[SAMPLE]. |
| • In LPSPI memory map, the access display changed to "See description" for some registers that have mixed access types.<br>• Updated LPSPI register descriptions description. |
| • Updated CFGR1[PARTIAL]. |
| • Updated CFGR1[MATCFG] description and notes in Data Match 0 (DMR0) and Data Match 1 (DMR1). |
| • Removed Low-power mode.<br>• Updated Interrupts and DMA requests.<br>• Removed paragraph from introduction to register descriptions, content is in Overview.<br>• Updated IER[REIE] and IER[TEIE].<br>• Updated CFGR1[PCSPOL].<br>• Updated CFGR1[SAMPLE] description.<br>• Updated RSR[SOF]. |
| • Updated Transmit Command Burst (TCBR), Transmit Data Burst (TDBR0 - TDBR127), and Receive Data Burst (RDBR0 - RDBR127).<br>• Added DMA support registers. |

*Table continues on the next page...*

| |
|---|
| • Replaced "master" and "slave" with "controller" and "peripheral" throughout chapter. |
| • Updated note on CFGR1[PINCFG]. |
| • Clarified note on CFGR1[PINCFG]. |
| • Clarified description in Timing parameters, to say that you can only change CCR when LPSPI is disabled (CR[MEN] = 0), previously it said you cannot change CCR when LPSPI is busy. |

## A.68 Low Power Inter-Integrated Circuit (LPI2C)

### A.68.1 Chip-specific LPI2C information changes

| |
|---|
| No substantial content changes. |

### A.68.2 LPI2C module changes

| |
|---|
| • Changed MCFGR0[1] to reserved. |
| • Added MCFGR0[HRPOL]. |
| • Updated Low-power modes, Interrupts and DMA requests, Controller mode, and Target mode.<br>• Added cross references to LPI2C register descriptions. |
| • Updated MCFGR1[IGNACK]. |
| • Changed title of External signals |
| • Updated Low-power modes. |
| • Changed MCFGR0[3] reserved field to RW from ROZ. |
| • Updated Low-power modes. |
| • Updated Controller Configuration 1 (MCFGR1) register. |
| • Updated access type on MCRGR0[3] in Controller Configuration 0 (MCFGR0) register. |
| • In External signals, updated I2C Four-wire serial bus figure. |
| • Updated Timing parameters. |
| • Updated MCR[RST] description. |
| • Moved Interrupts and DMA requests and Peripheral triggers. |
| • Updated Overview. |
| • Added Initialization and Application information.<br>• Updated Timing parameters. |

*Table continues on the next page...*

| |
|---|
| • Text moved from Memory map and registers to LPI2C register descriptions.<br>• In memory map table, the access changed for some registers that have mixed access types.<br>• In Version ID (VERID), removed "Read-only field." from field descriptions.<br>• In Controller Status (MSR), updated the descriptions of fields: DMF, PLTF, FEF, ALF, NDF, SDF, and EPF.<br>• Updated MCFGR1[TIMECFG].<br>• Updated Controller Configuration 2 (MCFGR2), MCFGR2[FILTSDA], and MCFGR2[FILTSCL].<br>• Updated Controller Configuration 3 (MCFGR3) description and MCFGR3[PINLOW] description.<br>• Updated MDMR[MATCH1] and MDMR[MATCH0].<br>• Updated Controller Clock Configuration 0 (MCCR0), Controller Clock Configuration 1 (MCCR1), and Controller FIFO Control (MFCR).<br>• Updated Controller FIFO Control (MFCR) description, MFCR[RXWATER], and MFCR[TXWATER].<br>• Updated MTDR[CMD] and MTDR[DATA].<br>• Updated SCR[RRF] and SCR[RTF].<br>• In Target Status (SSR), updated description in fields: FEF, BEF, SDF, RSF, and AVF.<br>• Updated Target Configuration 1 (SCFGR1) description, SCFGR1[RXCFG], and SCFGR1[TXCFG] descriptions.<br>• Updated descriptions in Target Configuration 2 (SCFGR2), Target Address Match (SAMR), and Target Address Status (SASR). |
| • Updated Error conditions. |
| • Updated Features.<br>• Updated Address matching.<br>• Updated Timing parameters.<br>• Updated Controller operations.<br>• Updated Pin configuration. |
| • Updated MCFGR0[HRPOL] description. |
| • Updated Pin configuration. |
| • Updated Controller FIFO Control (MFCR) description.<br>• Updated Controller Control (MCR) fields, RRF and RTF. |
| • Updated Target Configuration 1 (SCFGR1) references to SSR register.<br>• Updated Target DMA Enable (SDER) references to SSR register. |

## A.69 Flexible I/O (FlexIO)

### A.69.1 Chip-specific FlexIO information changes

| |
|---|
| No substantial content changes. |

### A.69.2 FLEXIO module changes

| |
|---|
| No substantial content changes. |

## A.70 CAN (FlexCAN)

### A.70.1 Chip-specific FlexCAN information changes

| |
|---|
| No substantial content changes. |

### A.70.2 FlexCAN module changes

| |
|---|
| • In Overview, removed the text "See the chip-specific FlexCAN information for the actual number of message buffers configured in the chip". |
| • In Features, Overview and , updated the ISO 11898-1 to ISO 11898-1:2015.<br>• In Protocol timing, added text "It is the smallest time unit for all configuration values". |
| • Updated the ISO 11898-1 to ISO 11898-1:2015 throughout the chapter. |
| • In Bus interface added the following registers:<br>— EPRS<br>— ENCBT<br>— EDCBT<br>— ETDC<br>• In Enhanced RX FIFO Point 5, changed EFRCR[NFE] to ERFCR[NFE]. |
| • In FlexCAN initialization sequence, added text "FlexCAN memory must be initialized before switching to functional mode". |
| • Changed the topic title for External signal descriptions from "FlexCAN signal descriptions" to "External signal descriptions". |
| • In Enhanced RX FIFO, corrected register EFRCR to ERFCR. |
| • Revised Reset to add information about hard and soft reset. |
| • Interchangeable terms "message buffer" and "mailbox" consolidated to "message buffer" throughout chapter.<br>• In Clocks, clock signal names changed from "ipg_clk*" to "MODULE_CLK*". |
| • Added note in register section.<br>• Revised topic Reset. |
| • Added "NOTE" in MCR[SOFTRST]. |
| • Updated Features.<br>• Updated Freeze mode. |

*Table continues on the next page...*

| |
|---|
| • Removed the column "Affected by hard reset" from the table #unique_2735/unique_2735_Connect_42_id-25951b. |
| • Updated "NOTE" in MCR[LPMACK] and MCR[FRZACK]. |
| • Updated long description of ERFSR[ERFCLR]. |
| • Updated the section legacy RX FIFO structure (corrected the extended ID range in RXIDB_0 of format B from "296-" to "29-16"). |
| • Updated the section Reset. |
| • Combined notes into one in Overview. |

## A.71 Synchronous Audio Interface (SAI)

### A.71.1 Chip-specific SAI information changes

| |
|---|
| No substantial content changes. |

### A.71.2 SAI module changes

| |
|---|
| • Updated TCR2[BCI] and RCR2[BCI] with note about enabling buffers. |
| • Updated field descriptions: TCSR[FR], TCSR[SR], TCSR[FWDE], TCR1[TFW], TCR5[WNW], TCR5[W0W], TCR5[FBT]. RCSR[FR], RCSR[SR], RCSR[FWDE], RCR1[RFW], RCR3[WDFL], RCR4[FRSZ], RCR4[SYWD], RCR5[WNW], RCR5[W0W], and RCR5[FBT].<br>• In Receive Configuration 5 (RCR5), updated description. |
| • Updated access type on RCR4[5]. |
| • Updated reserved fields TCSR[30] and RCSR[30].<br>• Updated reserved field RCR4[5]. |
| • Added Initialization.<br>• Moved Interrupts and DMA requests. |
| • Updated Synchronous modes. |
| • Corrected bit field descriptions for TCR2[BCP] and RCR2[BCP]. |
| • Updated TCR1[TRW]. |
| • In Block diagram, changed input clock name to MCLK.<br>• Throughout, changed audio controller clock to audio clock or audio clock (MCLK). |

## A.72 Ethernet Media Access Controller (EMAC)

### A.72.1 Chip-specific EMAC information changes

| |
|---|
| No substantial content changes. |

### A.72.2 ENET_Controller module changes

| |
|---|
| • MAC_VLAN_HASH_TABLE register: Updated description as 'The upper four bits of the calculated CRC value are used to index the contents of the VLAN hash table'<br>• MAC_VLAN_Tag.DOVLTC: Added 'The VLAN filter is bypassed when VLAN type ... VLAN type in the VLAN filter' |
| • Renamed "Signal descriptions" to External signals.<br>• Renamed "Introduction" to Overview.<br>• Renamed "Functional block diagram" to Block diagram. |
| • Corrected spelling errors |
| • Removed SGMII from figure: System-level block diagram<br>• TDES3 context descriptor: Added note 'This error is categorized as an abnormal event ...' |
| • Features: Added note: "Only byte-aligned ..." |
| • Updated registers MAC_Hash_Table_Reg0 and MAC_Hash_Table_Reg1 to add the note "In this chip, upper 6 bits should be used for 64-bit Hash Table".<br>• Deleted DMA_Safety_Interrupt_Status[DECIS] and DMA_Safety_Interrupt_Status[DEUIS] and added DMA_Safety_Interrupt_Status[1:0] as reserved. |

## A.73 Low Power Universal Asynchronous Receiver/Transmitter (LPUART)

### A.73.1 Chip-specific LPUART information changes

| |
|---|
| No substantial content changes. |

### A.73.2 LPUART module changes

| |
|---|
| • Updated the following sections: Receiver wake-up operation, and Peripheral triggers. |
| • Updated the description of Watermark (WATER).<br>• Updated the bit field descriptions of PF and TXDIR. |
| • In BAUD[OSR], added a note to read "BAUD[OSR] in this bit field results an OSR of BAUD[OSR]+1, for example, BAUD[OSR] = 0_0101b results in final divide by 6". |
| • In Receiver functional description, updated "the data character is transferred to receive FIFO, resulting the bit STAT[RDRF] to 1".<br>• In Transmitter functional description, updated "the value waiting transmit FIFO is transferred to the transmit shift register...". Replaced "STAT[TDRE]" with "transmit FIFO". |
| • Updated 0b and 1b value for STAT[RDRF].<br>• In WATER[TXWATER] and WATER[RXWATER], added "generates an interrupt". This now reads as: "Generates an interrupt, or a DMA request when the number of datawords in the transmit FIFO or buffer is equal to or less than the value of this field". |

*Table continues on the next page...*

| |
|---|
| • Updated SBR 0 in BAUD[SBR]. |
| • Updated Clocking.<br>• Added Reset.<br>• Added Initialization.<br>• Added functions in the following registers: Global (GLOBAL), Pin Configuration (PINCFG), Baud Rate (BAUD), Status (STAT).<br>• Updated BAUD[SBR]. |
| • Replaced the instance of "IrDA" with "infrared data association (IrDA)" in Overview section.<br>• Updated the following sections: Receiver functional description, Data sampling technique, Receiver wake-up operation.<br>• Replaced section title "Interrupts and status fields" with "Interrupts". |
| • Replaced reserved field access type "RW" with "ROZ" in bit 12 of Control (CTRL) register. |
| • Updated Baud rate generation section. |
| • Added Baud rate tolerance and Calculating baud rate tolerance. |
| • Replaced "receive data" with "Receive data (from RxD)" in Figure 424.<br>• Replaced 'sever to 10 bits' with 'along with N (7, 8, 9, 10) bits' in Receiver functional description.<br>• Replaced "When CTRL[LOOPS] is 1,..... (CTRL[RSRC] = 1)." with "Enable Loop mode.....CTRL[RSRC] = 0" in Loop mode.<br>• Replaced "When CTRL[LOOPS] is 1.....(CTRL[RSRC] = 1)" with "Enable single.....CTRL[RSRC] = 1" in Single-Wire mode. |
| • Replaced the word ‘DTS’ with ‘CTS’ in Hardware flow control.<br>• Changed the line ‘This is called resynchronization’ with ‘This Synchronization.....as Resynchronization’ in Data sampling technique.<br>• Updated Figure 427.<br>• Updated the long description of DATA[IDLINE]. |
| • Replaced the term ‘Internal Slave peripheral bus‘ with ‘Internal chip peripheral bus’ in Figure 423 and Figure 424 . |
| • Updated Hardware flow control. |
| • In Baud rate generation, added statement "There is a relationship between the required baud rate and the input clock frequency, SBR, and OSR. See the below figure for details". |

## A.74 Quad Serial Peripheral Interface (QuadSPI)

### A.74.1 Chip-specific QuadSPI information changes

| |
|---|
| No substantial content changes. |

### A.74.2 QuadSPI module changes

| |
|---|
| • Updated field size ofBUF3CR[ADATSZ]. |
| • Added a new sectionExtended prefetch or Streaming mode.<br>• Updated field description ofFR[ABOF].<br>• Added footnote on JMP_ON_CSand STOP instructions inTable 555.<br>• Updated field description ofBUF3CR[ADATSZ]. |
| • UpdatedExtended prefetch or Streaming mode. |
| • Removed note saying "The hardware does not provide any protection against illegal programming" from register descriptions ofBuffer 0 Top Index Register (BUF0IND),Buffer 1 Top Index Register (BUF1IND), andBuffer 2 Top Index Register (BUF2IND). |
| • Removed the RSER[TBFIE] field.<br>• Added following information in the FRAD0_WORD2[MD0ACP]: If EAL is being written in same cycle (10 or 11), or if FRAD_WORD3 [LOCK] bits are written as 11. if LOCK bits are written as 10 then this field can be programmed only if master ID matches the ID check of respective MDAD queue. If MDAD descriptor is not valid then respective MDxACP also becomes read-only.<br>• Updated the description of the FRAD0_WORD3[VLD], FRAD0_WORD3[LOCK], FRAD0_WORD5[CMP_ERR] fields.<br>• Updated the descriptions of the TG0SFARS[VLD] and TG0SFARS[CLR] fields.<br>• Updated the descriptions of the TG0IPCRS[VLD] and TG0IPCRS[CLR], and FLSEQREQ[FRAD] fields.<br>• Updated the description of the value 11 of the FRAD0_WORD3[EAL] field.<br>• Updated the description of the value 00 of the TG0MDAD[SA] field.<br>• Added caution in the sectionPower up and reset.<br>• Changes access of the following reserved fields to RW: DLCR[25], FR[30], FR[31], FR[13], FR[14], FR[4], RSER[25]<br>• Changes access of the following reserved fields to RO: FR[29], SR[25], SR[26], SR[5], SR[3] |
| • Changed the access of the following reserved fields to RW: RSER[27].<br>• Changed the access of the following reserved fields to ROZ: FR[4].<br>• Changed the access of the following reserved field to ROZ: FR[30]. |
| • Added following note inRSER[WMRK]field: This field should never be programmed above 63 because there are only 64 memory mapped RBDR registers. If watermark is programmed above 63, data above 64 words will be lost.<br>• Changed the access of the following reserved field to ROZ: BFGENCR[17]. |
| • Changed the access of the following reserved field to ROZ: BFGENCR[28]. |
| • Added "Example: Flash reset sequence" inPower up and reset.<br>• Added following fields:MCR[ISD3FA]andMCR[ISD2FA]. |
| • Replaced all instances of "master/domain" ID with domain ID. |

*Table continues on the next page...*

| |
|---|
| • Added following information in theExtended prefetch or Streaming modesection: Also ensure that complete buffer is assigned toBuffer 3 Configuration Register (BUF3CR)and remaining buffer sizes should be programmed to 0 by writing 0 toBuffer 0 Top Index Register (BUF0IND),Buffer 1 Top Index Register (BUF1IND), andBuffer 2 Top Index Register (BUF2IND)registers.<br>• InFlash memory programming, updated the second statement of the fourth step as follows: Write an appropriate value to IPCR[IDATSZ] to denote the size of the write in bytes. |
| • Added RSER[TBFIE] field. |
| • Updated Basic description section<br>• In Table 554, removed row INTB<br>• In section Dummy Pad loopback, added following notes:<br>— "Refer to Auto-DataLearning... details"<br>• "Spansion hyperflash" changed to "hyperflash"<br>• Note added, "If DLL is disabled....can be used for JMP_ON_CS instruction " for sections<br>— Fast read quad output (Winbond)<br>— Fast read sequence (Macronix/Numonyx/Spansion/Winbond)<br>—<br>— LUT<br>• Figure 430 updated |
| • Replaced 'master port number' with 'master ID'<br>• In BUF0CR[MSTRID], added a Note, "See the chip-specific... components.<br>• Updated description of IPCR[SEQID] field.<br>• Access changed to reserved for RBCT[RXBRD] bitfield 8.<br>• In BFGENCR[SEQID] Function section, removed "This field....LUT index". |
| • In Flash memory read, removed "and this depends on the configuration of RBCT[RXBRD]" |
| • Figure title changed to "Data strobe functionality in SDR mode for read operation" in Figure 436.<br>• In Figure 430, added a note, "The IOs are driven ...ongoing phase"<br>• In Figure 430, removed 2nd and 3rd note<br>• Updated Figure 430 with Note1.<br>• In section Dummy Pad loopback, added content "DLLCR[FREQEN]" and "or DLLCRB[SLV_DLY_COARSE]" for high and low frequency delay chain manual programming |
| • In Basic description, changed the variable name "tDel,total" to "ttotal_delay" |
| • In section Features, added phrase "or using AHB (64-bit width interface)"<br>• In SR[RXFULL], updated description<br>• In MCR[SWRSTSD], updated description of 0b bit<br>• In MCR[SWRSTHD], updated description of 0b bit |

*Table continues on the next page...*

| |
|---|
| • In SR[TXWA], updated Function section |
| • In RSER[CRCAIE], updated description<br>• In FR[CRCAEF], updated description |
| • In Section Dummy Pad loopback, Title updated |
| • In Programmable sequence engine, updated the Instruction set entry for CMD instruction<br>• In LUT, updated the LUT section statement for Reset Sequence Table<br>• In Flash memory programming, description updated for Flash Programming memory section<br>• In Flash memory read, for Flash memory read section, description added "A read access to... the different ways"<br>• In Byte ordering of serial flash memory read data, description added in section "Byte ordering of serial flash memory read data" |
| • In DLLCRA[FREQEN], Note removed |
| • In Sequence Pointer Clear Register (SPTRCLR), Function section updated |
| • In SR[TXWA], updated Function section |
| • Removed RSER[ABSEIE], Reserved bitfield |
| • In Address scheme, removed sections:<br>— Separation of address into rows and columns<br>— Word addressable mode for flash memory<br>• FR[CRCBEF] access updated to Reserved<br>• RSER[CRCBIE] access updated to Reserved |
| • In Flexible read xAHB buffers, content updated |
| • Removed SPTRCLR[STREAM_EN] |
| • Updated note on MSTRID to "See the chip-specific... corresponding components" |
| • Updated Note on Master IDs |
| • In RBCT[WMRK], Note added. |
| • In SOC Configuration Register (SOCCR), updated Function section |
| • Removed from feature list, "Support for HyperFlash memory" |
| • In Module Disable mode, removed text "Software needs to ensure.... is requested." |
| • Section AHB bus access read considerations updated<br>• In Flash memory programming removed text, "If required,....addressable" |
| • Removed '4h' from section QUADSPI register descriptions |

*Table continues on the next page...*

| |
|---|
| • Driving external signals<br>— Note revised, "All read commands in Dual pad, Quad pad.... applicable to Single-pad mode" |
| • TGnSFARS[ERR]<br>— Bitfield description updated |
| • Revised Pad values of "DUMMY" instruction in the following tables:<br>— Table 571<br>— Table 569<br>— Table 572 |
| • FR[ABOF]<br>— Bitfield description updated |
| • Updated bitfield description of FR[TBUF]<br>• Updated bitfield description ofFR[ABOF] |
| • Function section updated in the following registers:<br>— In LUT*n* register, added text, "Write access.... if MGC[11]=1b"<br>— In register LUT Key Register (LUTKEY), added text, "Write access.... if MGC[11]=1b"<br>— In register LUT Lock Configuration Register (LCKCR), added text, "Write access.... if MGC[11]=1b"<br>— Buffer Generic Configuration Register (BFGENCR), added text, "Write access.... if MGC[11]=1b" |
| • Revised note in Dummy Pad loopback. |
| • Revised TX buffer operation: a footnote is added to Fs |
| • Updated title of Table 556 to "Read sequence" |

## A.75 Debug changes

| |
|---|
| No substantial content changes. |

## A.76 JTAG Controller (JTAGC)

### A.76.1 Chip-specific JTAGC information changes

| |
|---|
| No substantial content changes. |

### A.76.2 JTAGC module changes

| |
|---|
| • Marked SAMPLE instruction as internal.<br>• Marked SAMPLE keyword as internal in EXTEST external test instruction, IEEE 1149.1–2001 defined test modes, Boundary scan register, and Boundary scan.<br>• Marked SAMPLE keyword as internal in PRELOAD instruction |

*Table continues on the next page...*

| |
|---|
| • Renamed "Initialization/application information" to Initialization.<br>• Reordered and reorganized various subsections in Functional description.<br>• Added Clocking, Interrupts, and Application information. |
| • Moved "IDCODE instruction", "SAMPLE/PRELOAD instruction", "EXTEST external test instruction", "HIGHZ instruction", "ENABLE_SOC_DATA1 instruction" , "CLAMP instruction", "ACCESS_AUX_x instructions" and "BYPASS instruction" into JTAGC block instructions. |
| • Moved "TEST_LEAKAGE instruction" into JTAGC block instructions section. |

## A.77 JDC module changes

| |
|---|
| • Added Clocking section.<br>• Added Interrupts section containing text "This module has no interrupts".<br>• Added JDC functionality section.<br>• Renamed "Signal description" to External signals.<br>• Renamed "Introduction" to Overview. |
| • Added Initialization section. |
| • Updated Clocking section. |

## A.78 TEMPSENSE module changes

| |
|---|
| • Renamed Introduction to Overview.<br>• Added sections Clocking, External signals, and interrupt, to convey that there are no clock sources, external signals, and interrupts for this module.<br>• Added the section head "Initialization" to Conversion from voltage to temperature. |
| • Updated Overview and Conversion from voltage to temperature |
| • Added ipg_scan_mode signal in .<br>• Improved LVIX signal description in and changed the coefficient unit from C2/V2 to C/V2 in Conversion from voltage to temperature. |

# Legal information

## Definitions

**Draft** — A draft status on a document indicates that the content is still under internal review and subject to formal approval, which may result in modifications or additions. NXP Semiconductors does not give any representations or warranties as to the accuracy or completeness of information included in a draft version of a document and shall have no liability for the consequences of use of such information.

## Disclaimers

**Limited warranty and liability** — Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information. NXP Semiconductors takes no responsibility for the content in this document if provided by an information source outside of NXP Semiconductors.

In no event shall NXP Semiconductors be liable for any indirect, incidental, punitive, special or consequential damages (including - without limitation - lost profits, lost savings, business interruption, costs related to the removal or replacement of any products or rework charges) whether or not such damages are based on tort (including negligence), warranty, breach of contract or any other legal theory.

Notwithstanding any damages that customer might incur for any reason whatsoever, NXP Semiconductors' aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the Terms and conditions of commercial sale of NXP Semiconductors.

**Right to make changes** — NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

**Suitability for use** — NXP Semiconductors products are not designed, authorized or warranted to be suitable for use in life support, life-critical or safety-critical systems or equipment, nor in applications where failure or malfunction of an NXP Semiconductors product can reasonably be expected to result in personal injury, death or severe property or environmental damage. NXP Semiconductors and its suppliers accept no liability for inclusion and/or use of NXP Semiconductors products in such equipment or applications and therefore such inclusion and/or use is at the customer's own risk.

**Applications** — Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Customers are responsible for the design and operation of their applications and products using NXP Semiconductors products, and NXP Semiconductors accepts no liability for any assistance with applications or customer product design. It is customer's sole responsibility to determine whether the NXP Semiconductors product is suitable and fit for the customer's applications and products planned, as well as for the planned application and use of customer's third party customer(s). Customers should provide appropriate design and operating safeguards to minimize the risks associated with their applications and products.

NXP Semiconductors does not accept any liability related to any default, damage, costs or problem which is based on any weakness or default in the customer's applications or products, or the application or use by customer's third party customer(s). Customer is responsible for doing all necessary testing for the customer's applications and products using NXP Semiconductors products in order to avoid a default of the applications and the products or of the application or use by customer's third party customer(s). NXP does not accept any liability in this respect.

**Terms and conditions of commercial sale** — NXP Semiconductors products are sold subject to the general terms and conditions of commercial sale, as published at https://www.nxp.com/profile/terms, unless otherwise agreed in a valid written individual agreement. In case an individual agreement is concluded only the terms and conditions of the respective agreement shall apply. NXP Semiconductors hereby expressly objects to applying the customer's general terms and conditions with regard to the purchase of NXP Semiconductors products by customer.

**Export control** — This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from competent authorities.

**Suitability for use in non-automotive qualified products** — Unless this document expressly states that this specific NXP Semiconductors product is automotive qualified, the product is not suitable for automotive use. It is neither qualified nor tested in accordance with automotive testing or application requirements. NXP Semiconductors accepts no liability for inclusion and/or use of non-automotive qualified products in automotive equipment or applications.

In the event that customer uses the product for design-in and use in automotive applications to automotive specifications and standards, customer (a) shall use the product without NXP Semiconductors' warranty of the product for such automotive applications, use and specifications, and (b) whenever customer uses the product for automotive applications beyond NXP Semiconductors' specifications such use shall be solely at customer's own risk, and (c) customer fully indemnifies NXP Semiconductors for any liability, damages or failed product claims resulting from customer design and use of the product for automotive applications beyond NXP Semiconductors' standard warranty and NXP Semiconductors' product specifications.

**HTML publications** — An HTML version, if available, of this document is provided as a courtesy. Definitive information is contained in the applicable document in PDF format. If there is a discrepancy between the HTML document and the PDF document, the PDF document has priority.

**Translations** — A non-English (translated) version of a document, including the legal information in that document, is for reference only. The English version shall prevail in case of any discrepancy between the translated and English versions.

**Security** — Customer understands that all NXP products may be subject to unidentified vulnerabilities or may support established security standards or specifications with known limitations. Customer is responsible for the design and operation of its applications and products throughout their lifecycles to reduce the effect of these vulnerabilities on customer's applications and products. Customer's responsibility also extends to other open and/or proprietary technologies supported by NXP products for use in customer's applications. NXP accepts no liability for any vulnerability. Customer should regularly check security updates from NXP and follow up appropriately.

Customer shall select products with security features that best meet rules, regulations, and standards of the intended application and make the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP.

NXP has a Product Security Incident Response Team (PSIRT) (reachable at PSIRT@nxp.com) that manages the investigation, reporting, and solution release to security vulnerabilities of NXP products.

**NXP B.V.** — NXP B.V. is not an operating company and it does not distribute or sell products.

## Trademarks

Notice: All referenced brands, product names, service names, and trademarks are the property of their respective owners.

**NXP** — wordmark and logo are trademarks of NXP B.V.

**AMBA, Arm, Arm7, Arm7TDMI, Arm9, Arm11, Artisan, big.LITTLE, Cordio, CoreLink, CoreSight, Cortex, DesignStart, DynamIQ, Jazelle, Keil, Mali, Mbed, Mbed Enabled, NEON, POP, RealView, SecurCore, Socrates, Thumb, TrustZone, ULINK, ULINK2, ULINK-ME, ULINK-PLUS, ULINKpro, µVision, Versatile** — are trademarks and/or registered trademarks of Arm Limited (or its subsidiaries or affiliates) in the US and/or elsewhere. The related technology may be protected by any or all of patents, copyrights, designs and trade secrets. All rights reserved.

**Bluetooth** — the Bluetooth wordmark and logos are registered trademarks owned by Bluetooth SIG, Inc. and any use of such marks by NXP Semiconductors is under license.

**eIQ** — is a trademark of NXP B.V.

**I2C-bus** — logo is a trademark of NXP B.V.
