## 43.7.14 Partition 0 Core 0 Status Register (PRTN0_CORE0_STAT)

### Offset

| Register | Offset |
|---|---|
| PRTN0_CORE0_STAT | 148h |

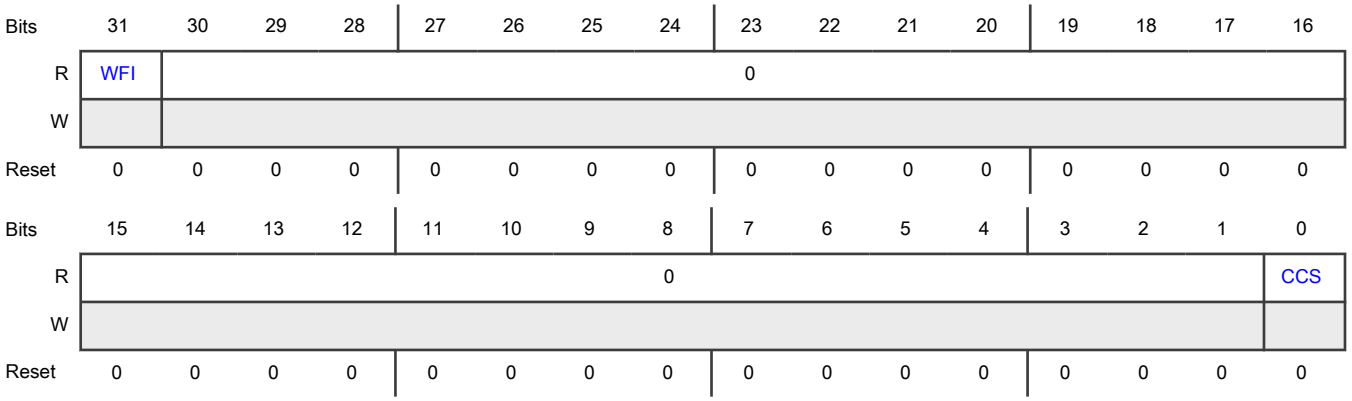
### Function

This register provides the status corresponding to Core 0 in partition 0. The status signal corresponds to clock states and the WFI signal included from Core 0.

**NOTE**

The value held in WFI field of this STATUS register is "current" value of the WFISTANDBY signal from the core. Hence out-of-reset, the reset value of this field will depend on the status of the core (core is running or in low power mode). So, simple reset read sweep will always return current value (different than other register reads such as on control registers).

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>WFI | Wait for interrupt status<br>This bit provides the WFI status approaching from Core 0 in partition 0.<br>0b - No WFI executed<br>1b - WFI executed |
| 30-1<br>— | Reserved<br>This field is reserved and read returns zeros. |
| 0<br>CCS | Core 0 clock process status<br>This bit provides the status of the clock corresponding to core clock enablement/disablement.<br>0b - Clock is inactive.<br>1b - Clock is active. |

## 43.7.15 Partition 0 Core 0 Address Register (PRTN0_CORE0_ADDR)

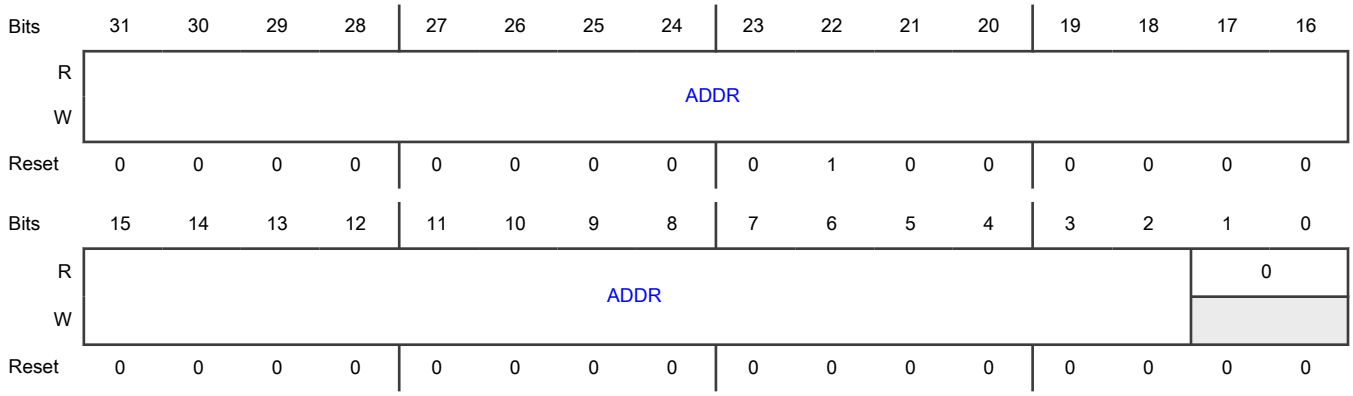
### Offset

| Register | Offset |
|---|---|
| PRTN0_CORE0_ADDR | 14Ch |

### Function

This register contains the boot address for Core 0 in partition 0.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-2<br>ADDR | Address<br>Core 0 boot address |
| 1-0<br>— | Reserved<br>This field is reserved and read returns zeros. |

## 43.7.16 Partition 0 Core 2 Status Register (PRTN0_CORE2_STAT)

### Offset

| Register | Offset |
|---|---|
| PRTN0_CORE2_STAT | 188h |

### Function

This register provides the status corresponding to Core 2 in partition 0. The status signal corresponds to clock states and the WFI signal included from Core 2.

**NOTE**

The value held in WFI field of this STATUS register is "current" value of the WFISTANDBY signal from the core. Hence out-of-reset, the reset value of this field will depend on the status of the core (core is running or in low power mode). So, simple reset read sweep will always return current value (different than other register reads such as on control registers).

## 43.7.18 Partition 1 Process Configuration Register (PRTN1_PCONF)

### Offset

| Register | Offset |
|---|---|
| PRTN1_PCONF | 300h |

### Function

This register provides a configuration for the hardware processes corresponding to partition 1. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN1_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN1_PCONF and PRTN1_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

**NOTE**

The partition clock enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

**NOTE**

See chip-specific MC_ME information to check if this register is implemented on chip.

### 43.7.19 Partition 1 Process Update Register (PRTN1_PUPD)

#### Offset

| Register | Offset |
|---|---|
| PRTN1_PUPD | 304h |

#### Function

This register provides trigger signaling for the hardware processes corresponding to partition 1. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN1_PCONF register. When the hardware process is finished the corresponding bit in this register is auto-cleared to logic-0.

**NOTE**

See chip-specific MC_ME information to check if this register is implemented on chip.

## 43.7.20 Partition 1 Status Register (PRTN1_STAT)

### Offset

| Register | Offset |
|---|---|
| PRTN1_STAT | 308h |

### Function

This register provides the current status of the control signals from the partition 1.

**NOTE**

See chip-specific MC_ME information to check if this register is implemented on chip.

## 43.7.21 Partition 1 COFB Set 0 Clock Status Register (PRTN1_COFB0_STAT)

### Offset

| Register | Offset |
|---|---|
| PRTN1_COFB0_STAT | 310h |

### Function

This register provides the status of set 0 of COFBs inside partition 1.

**NOTE**

The reset value of this register can vary depending on the availability of active clock pulses inside partition 1.

## 43.7.24 Partition 1 COFB Set 3 Clock Status Register (PRTN1_COFB3_STAT)

### Offset

| Register | Offset |
|---|---|
| PRTN1_COFB3_STAT | 31Ch |

### Function

This register provides the status of set 3 of COFBs inside partition 1.

**NOTE**

The reset value of this register can vary depending on the availability of active clock pulses inside partition 1.

### Diagram

### 43.7.25 Partition 1 COFB Set 0 Clock Enable Register (PRTN1_COFB0_CLKEN)

**Offset**

| Register | Offset |
|---|---|
| PRTN1_COFB0_CLKEN | 330h |

### Function

This register provides clock control signaling to the individual COFBs in set 0 inside partition 1. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

**NOTE**

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

## 43.7.28 Partition 1 COFB Set 3 Clock Enable Register (PRTN1_COFB3_CLKEN)

### Offset

| Register | Offset |
|---|---|
| PRTN1_COFB3_CLKEN | 33Ch |

### Function

This register provides clock control signaling to the individual COFBs in set 3 inside partition 1. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

**NOTE**

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

## 43.7.29 Partition 2 Process Configuration Register (PRTN2_PCONF)

### Offset

| Register | Offset |
|---|---|
| PRTN2_PCONF | 500h |

### Function

This register provides a configuration for the hardware processes corresponding to partition 2. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN2_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN2_PCONF and PRTN2_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

**NOTE**

The partition clock enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

**NOTE**

See chip-specific MC_ME information to check if this register is implemented on chip.

## 43.7.30 Partition 2 Process Update Register (PRTN2_PUPD)

**Offset**

| Register | Offset |
|---|---|
| PRTN2_PUPD | 504h |

**Function**

This register provides trigger signaling for the hardware processes corresponding to partition 2. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN2_PCONF register. When the hardware process is finished the corresponding bit in this register is auto-cleared to logic-0.

**NOTE**

See chip-specific MC_ME information to check if this register is implemented on chip.

## 43.7.31 Partition 2 Status Register (PRTN2_STAT)

### Offset

| Register | Offset |
|---|---|
| PRTN2_STAT | 508h |

### Function

This register provides the current status of the control signals from the partition 2.

**NOTE**

See chip-specific MC_ME information to check if this register is implemented on chip.

## 43.7.34 Partition 2 COFB Set 0 Clock Enable Register (PRTN2_COFB0_CLKEN)

### Offset

| Register | Offset |
|---|---|
| PRTN2_COFB0_CLKEN | 530h |

### Function

This register provides clock control signaling to the individual COFBs in set 0 inside partition 2. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

**NOTE**

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

## 43.8 Glossary

**WFI** Wait for interrupt

**COFB** Collection of functional blocks also referred as number of peripherals

# Chapter 44
# Power Control Unit (MC_PCU)

## 44.1 Introduction

The power control unit (MC_PCU) is used for initiating a Standby mode entry that reduces the overall chip power consumption. Power can be saved by disconnecting parts of the chip from the power supply. The blocks inside the chip are grouped into multiple parts having this capability, which are called "power domains".

When a power domain is disconnected from the supply, the power consumption is reduced to zero and the configuration of the every core and module that belongs to such power domain is completely lost. When you reconnect a power domain to the supply voltage, the domain draws an increased current until the power domain reaches its operational voltage. Maximum power saving is achieved by entering the Standby mode.

After the MC_ME asserts a standby entry request, MC_PCU initiates the power sequence, which is non-retractable and includes the handshake with the chip power management controller. The power-up/down sequences are handled by FSMs to ensure a smooth and safe transition into and out of the Standby mode. Exiting the Standby mode can only be done through a system wakeup event, power-on reset, destructive reset, or a functional reset.

## 44.2 Power sequence FSM

MC_PCU implements an FSM to initiate the power sequencing of the Standby mode entry/exit sequence for the chip.

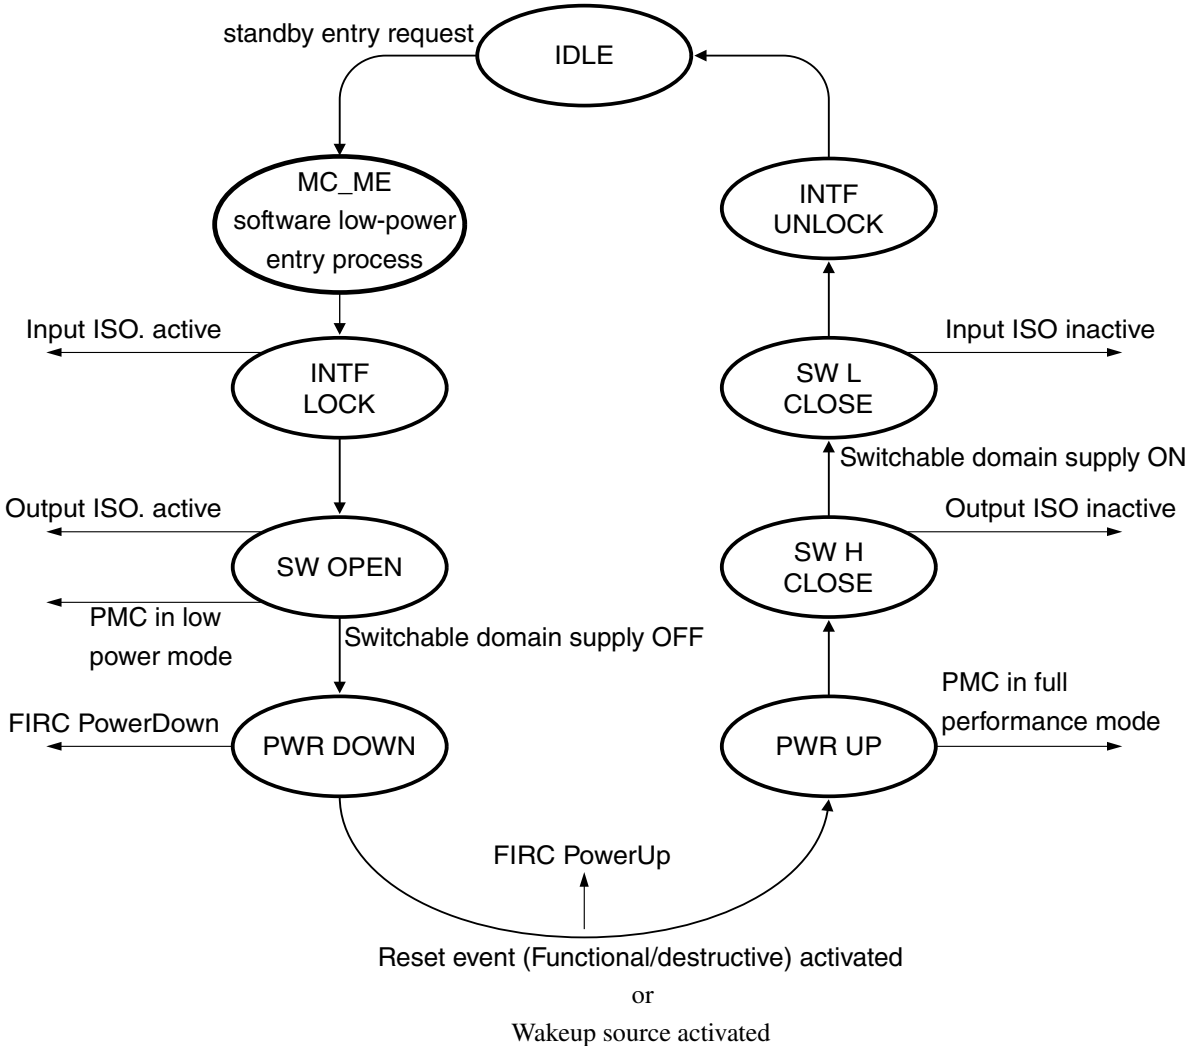

Figure 168. MC_PCU FSM

**NOTE**

When destructive reset is asserted from MC_RGM, MC_PCU FSM moves to the IDLE state immediately. Indication of this is not shown in the above figure.

Table 217. MC_PCU FSM transition description

| State | Name | Exit condition | Signal controlled | Signal monitored |
|---|---|---|---|---|
| IDLE | Idle state | Standby request received from MC_ME | - | - |
| MC_ME software low power entry process | MC_ME software low power entry process | Software entry sequence completed (SW4 process completed) | - | - |
| INTF LOCK | Interface lock state | Input isolation active | Input isolation activation | Input isolation active |

*Table continues on the next page...*

Table 217. MC_PCU FSM transition description (continued)

| State | Name | Exit condition | Signal controlled | Signal monitored |

## 44.3 Glossary

**FSM** Finite state machine

# Chapter 45
# Wakeup Unit (WKPU)

## 45.1 Chip-specific WKPU information

### 45.1.1 WKPU configuration on the chip

WKPU provides the following features:

- A configurable, low-power wake-up capability to the chip from multiple configurable asynchronous wake-up events.
- Support for four internal and 60 external sources that can generate interrupts or wake-up events.
- Support for an NMI input.

**Table 218. WKPU configuration on the chip**

| Number of sources, interrupts, and vectors | Value | Description |
|---|---|---|
| NMI sources | 1 | Single NMI pin routed to all application cores |
| Internal wake-up sources | 4 | • SWT_0 wake-up, RTC-API wake-up<br>• RTC timeout<br>• Analog comparator round robin wake-up (from LPCMP_0, 1, and 2 round robin wake-up)[1]<br>• RTI wake-up |
| External wake-up sources | 60 | 60 GPIO pins (WKPU[0]-WKPU[59]) support the wake-up functionality. See the IOMUX file attached to this document for details. |
| Glitch filters for external interrupts | 60 | Glitch filter on each external wake-up source |
| External interrupt vectors | 8 | — |

1. Both wake-up sources 0 (RTC-API) and 2 (CMP_*x* trigger mode wake-up) use RTC-API wake-up, with Trigger mode having a higher priority. This means, if you configure LPCMP_*x*.RRCR0[ERR_EN] for either of the comparators, the RTC_API wake-up is used only for the CMP_*x* trigger mode operation. The RTC-API wake-up does not cause wake-up from Standby mode in this scenario.

All of the aforementioned wake-up sources can be enabled or disabled. Also, you can configure these wake-up sources, by using WKPU configuration registers, to provide wake-up on rising or falling events. See the WKPU register memory map for details.

**NOTE**

You must use SIUL2 to perform WKPU pin configurations (PUE, PUS, and IBE). For this, you must first configure SIUL2.MSCR[IBE] for the corresponding pin. This chip does not support WKPU-provided pin configurations; it supports only bypass control.

### 45.1.2 WKPU NMI configuration

WKPU supports one external source that can cause non-maskable interrupts to on-chip cores and wake-up events to the system.

The following figure shows one application cores, Cortex-M7. In case of a wake-up event (internal or external), WKPU initiates the recovery of the chip and feeds an interrupt to the core depending on the configuration. The sections that follow provide details related to the associated configurations.

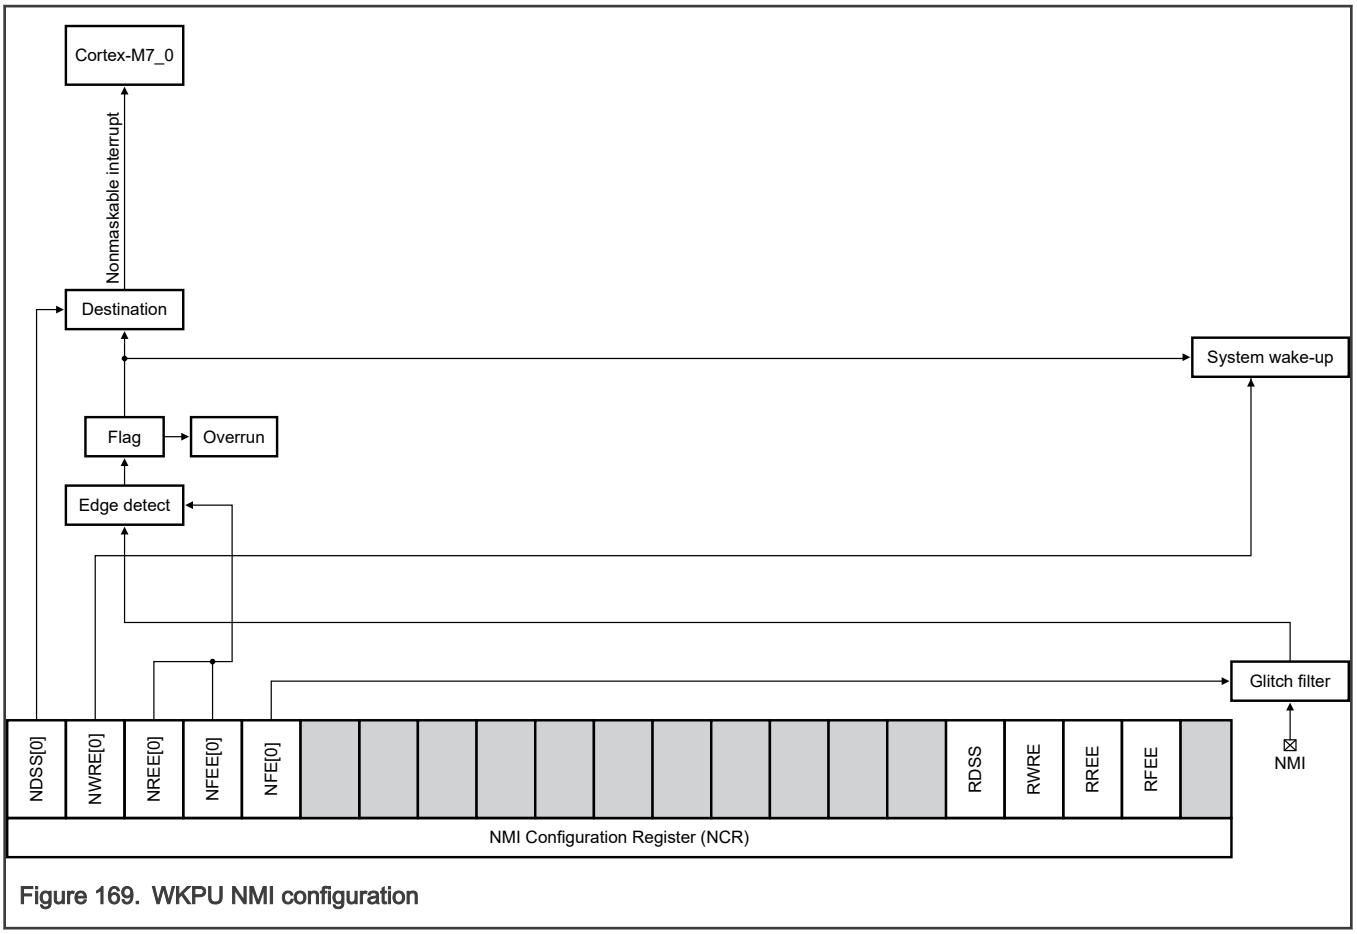

Figure 169. WKPU NMI configuration

### 45.1.3 WKPU wake-up source connectivity

WKPU allows the external NMI pin to assert the core NMIs on the chip. NMI supports NSR's status and overrun flags. This is what you could do using NCR:

- Control the NMI destination interrupt by configuring NCR[NDSS].
- Control the rising edge, falling edge, or either of the edge reactions to the NMI pin by using bits 2:0 of NCR[NFEE] and NCR[NREE]. The enabling of these edge reactions to the NMI pin is independent of each core.

WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.

The following figure shows routing of external wake-up events or interrupts with WKPU and the system interrupt controller.

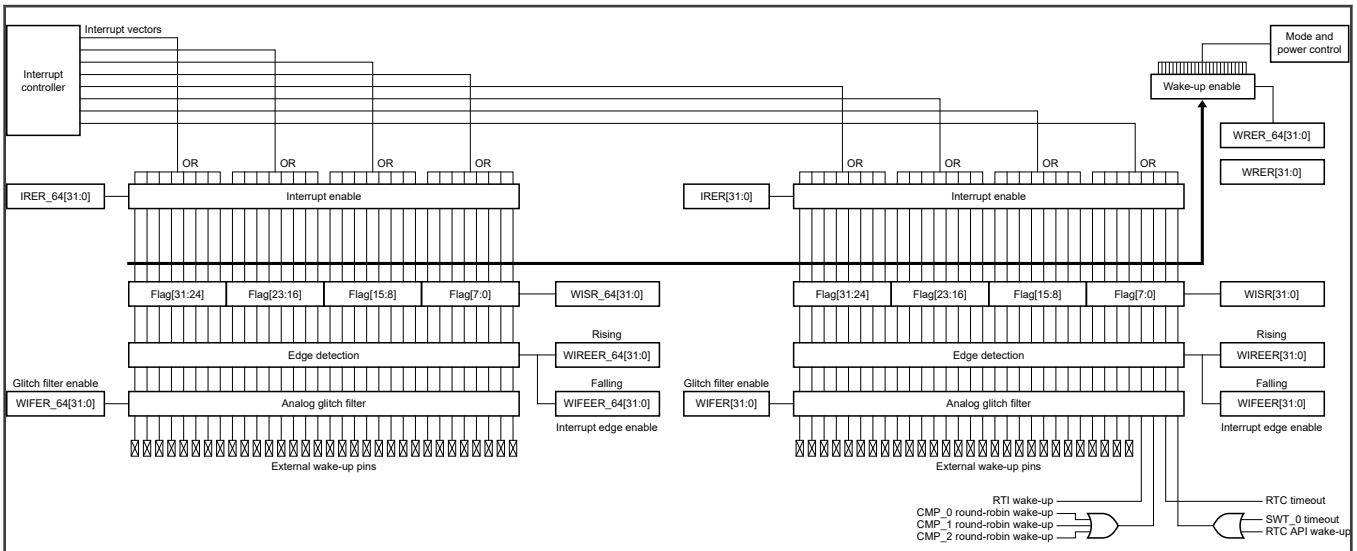

**Figure 170. WKPU wake-up source connectivity**

This is the wake-up source mapping to WKPU:

- Wake-up source 0 : SWT_0 timeout, RTC-API API wake-up
- Wake-up source 1 : RTC-API RTC timeout
- Wake-up source 2 : Round robin wake-up interrupt (Trigger mode interrupt) from LPCMP_0, LPCMP_1, or LPCMP_2
- Wake-up source 3 : RTI wake-up
- Wake-up source 4 : Wake-up source 63—external pin wake-up sources, WKPU[0] - WKPU[59]

If you configure any or all of the LPCMP_*x*.RRCR0[RR_EN] fields to be active, the corresponding CMP_*x* pins must be dedicated for the CMP_*x* operation. In case you are not using any of the CMPs, you can use SIUL2.MSCR*x*[SSS] to configure the pins for digital functionalities.

**NOTE**

You must enable WKPU (by using MC_ME.PRTN*x*_COFB*y*_CLKEN) before entering any of the chip's low-power modes.

## 45.2 Overview

WKPU supports 64 external sources that can generate interrupts or wake-up events, and 0 external sources that can cause nonmaskable interrupt requests or wake-up events. Additionally, it combines its wake-up events with those generated by other wake-up sources to supply a single wake-up to the system.

### 45.2.1 Block diagram

The following figure shows WKPU and its interfaces with the other system components.

**NOTE**

The signal widths in the following diagram do not depict a particular configuration of this chip. See the chip-specific WKPU information for details.

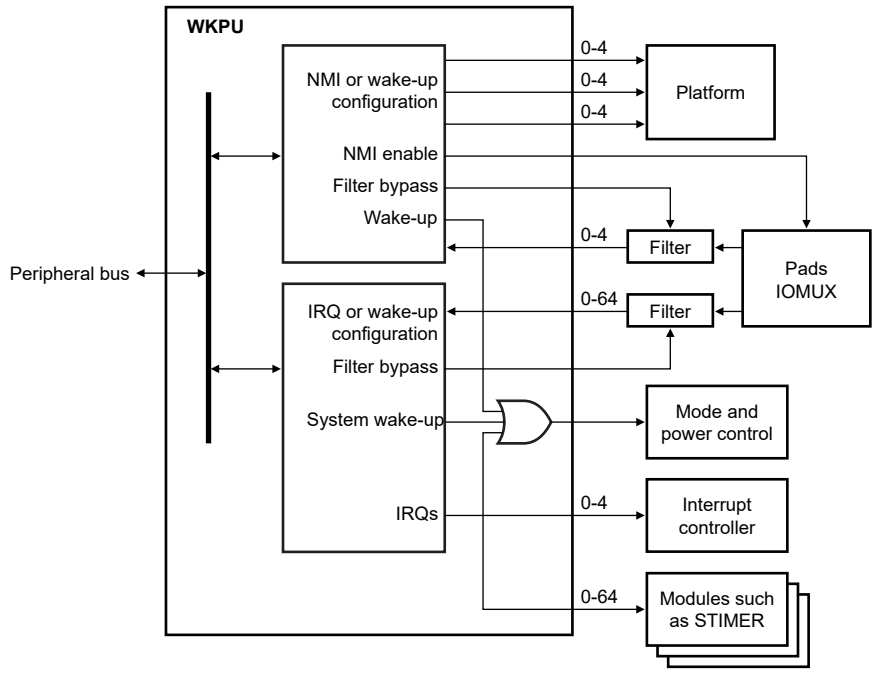

Figure 171. Block diagram

### 45.2.2 Features

- Supports nonmaskable interrupts including:
  - 2 NMI sources
  - 2 analog glitch filters
  - Independent interrupt destination for each core:
    - Nonmaskable interrupt
    - Critical interrupt
  - Active edge selection control (rise and fall) for events
  - Configurable system wake-up triggering from NMI sources
- Supports external wake-up and interrupts that include the following:
  - One System interrupt vector for interrupt sources
  - 64 analog glitch filters
  - Independent interrupt mask
  - Edge detection
  - Configurable system wake-up triggering from all interrupt sources

## 45.3 Functional description

### 45.3.1 Nonmaskable interrupts

WKPU supports the capturing of the second event according to the NMI input before the interrupt becomes 0. This reduces the chance of losing an NMI event, although it creates an overrun condition.

Each NMI passes through a bypassable analog glitch filter.

**NOTE**

When NMI is disabled, glitch filter control and pad configuration perform. This prevents erroneous triggering by glitches caused by the configuration process itself.

**NOTE**

The following figure represents a generic configuration and does not represent the configuration of this specific chip. See the chip-specific information for details on this chip's WKPU.

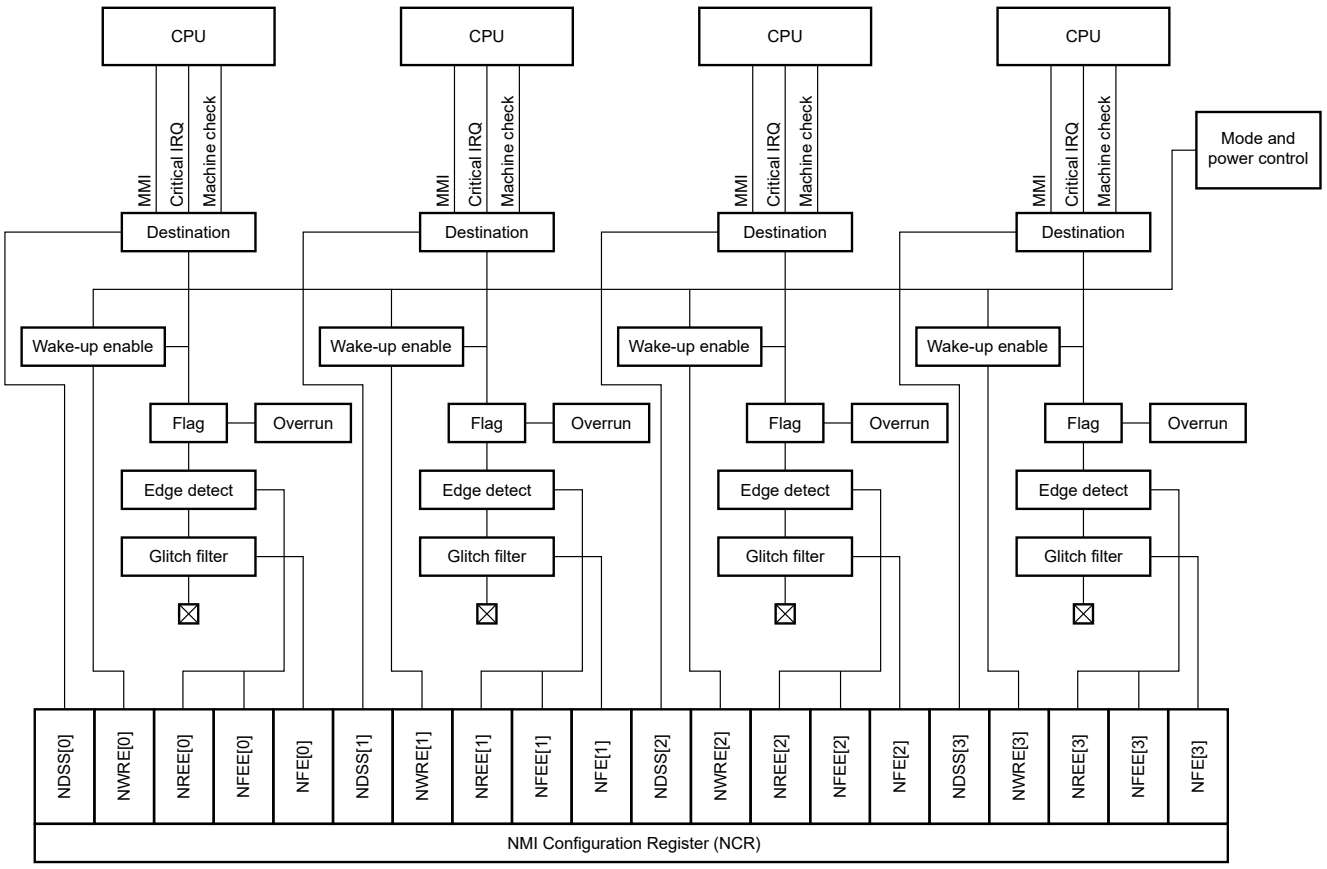

Figure 172. NMI pad diagram

### 45.3.1.1 NMI management

You can enable or disable each NMI independently. You can perform this by using the registers, NCR which are laid out to contain all configuration bits for a given NMI in a single byte (see NMI Configuration (NCR)). You can configure a pad defined as an NMI to recognize interrupts with an active rising edge, falling edge, or both edges being active. If both the edge events are disabled, it results in no interrupt being detected and does not get configured.

You can also control an active NMI edge through the configuration of the fields, NCR[NREE*n*] and NCR[NFEE*n*].

**NOTE**

After a reset, NREE and NFEE are set to 0, which disables the NMI functionality and software enables it explicitly.

After a pad's NMI functionality is enabled, the pad cannot be reconfigured to override or disable the NMI. See the chip-specific WKPU information for details of NMI implementation.

Additionally, you can control the NMI destination interrupt through the configuration of the field, NCR[NDSS*n*]. See NMI Configuration (NCR) for details.

Each NMI supports a status flag and an overrun flag, both of which are located in NMI Status Flag (NSR). This register prevents an inadvertent overwriting of the other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected when the status flag is still set (that is, the status flag has not yet been cleared).

**NOTE**

The overrun flag is cleared by writing 1 to the appropriate overrun field in NMI Status Flag (NSR). If the status field is 0 but the overrun field is still, the pending interrupt is not cleared.

During an NMI ISR, on wake-up of the chip from an NMI, any writes to the ECC-protected memory must have the correct ECC.

### 45.3.2 Clocking

This module has no clocking considerations.

WKPU has ipg_clk and ipg_clk_s as input clocks having the same clock frequency for register configuration and internal logic.

### 45.3.3 Interrupts

WKPU supports 4 interrupt vectors to the interrupt controller of the chip. Each interrupt vector supports multiple external interrupt sources from the device pads, with the total across all vectors being equal to the number of external interrupt sources. Each external interrupt source is assigned to exactly one interrupt vector. The interrupt vector assignment follows a sequence: one interrupt vector is for external interrupt sources 0 to N-1, the next is for N to N+M-1, and so on.

See the following figure for an overview of the external interrupt implementation, showing an example of four interrupt vectors with eight external interrupt sources each.

**NOTE**

The following figure represents a generic WKPU configuration. For details on this chip's configuration, see the chip-specific WKPU information.

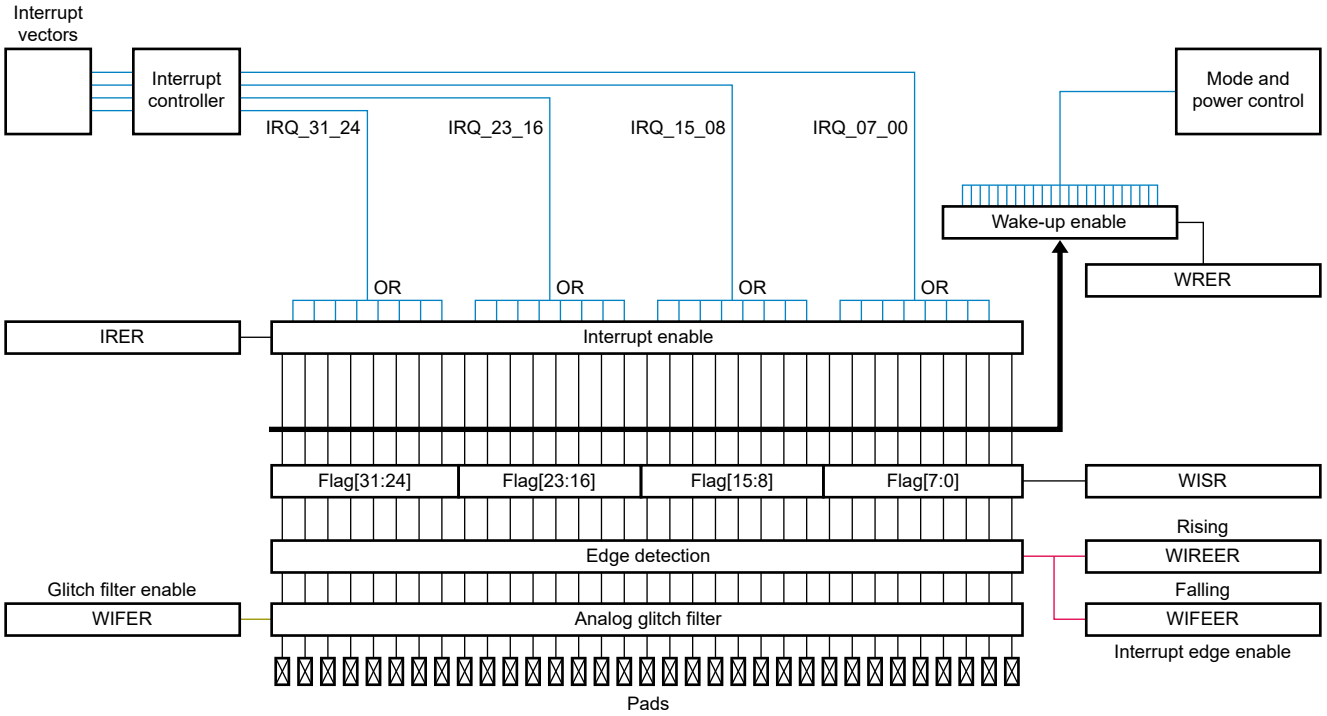

**Figure 173. External interrupt pad diagram**

All the external interrupt pads within a single group have equal priority. You must search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is set based on the platform and the priority levels of the interrupt controller. However, the chip can allow an independent configuration of pad allocation to each group of interrupts.

The external interrupt lines have a digital glitch filter applied to them.

#### 45.3.3.1 External interrupt management

You can enable or disable each external interrupt independently using a single rolled-up register (Interrupt Request Enable (IRER)). You can configure a pad defined as an external interrupt to recognize interrupts with an active rising edge, an active falling edge, or both edges being active.

**NOTE**

Writing 0 to both IREE[*n*] and IFEE[*n*] disables the external interrupt functionality for that pad completely (means no system wake-up or interrupt is generated from any activity on that pad).

You can control an active IRQ edge through the configuration of the registers, WIREER and WIFEER.

Each external interrupt supports an individual flag, which is held in the flag register, WISR. This W1C register prevents inadvertent overwriting of other flags in the same register.

### 45.3.4 External signals

This module has no external signals.

## 45.4 Initialization

To initialize this module, you must perform the following configuration:

- Glitch filter and pad configuration

- Nonmaskable interrupts
- Wake-up event

### 45.4.1 Glitch filter and pad configuration

You can perform glitch filter control and pad configuration when the NMI is disabled to avoid erroneous triggering by glitches caused by the configuration process.

When enabling the glitch filter, do not enable the rising and falling-edge events bits (that is, the NCR[NREE], NCR[NFEE], NCR[NREE], and NCR[NFEE]) in the same register write.

### 45.4.2 Nonmaskable interrupts

If IBE of NMI is tied off to 1, no false interrupt is expected.

### 45.4.3 Wake-up event

See the chip-specific WKPU information for wake-up event initialization.

## 45.5 WKPU memory map and registers

### 45.5.1 WKPU register descriptions

This section provides a detailed description of all the registers accessible in the WKPU module.

**NOTE**

Reserved registers read as zero and writes have no effect. A transfer error is generated when trying to access a completely reserved register space. The field length of external pad control registers depends on the number of WKPU channels implemented in a chip.

#### 45.5.1.1 WKPU memory map

WKPU base address: 402B_4000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | NMI Status Flag (NSR) | 32 | RW | 0000_0000h |
| 8h | NMI Configuration (NCR) | 32 | RW | 6060_0000h |
| 14h | Wake-Up and Interrupt Status Flag (WISR) | 32 | RW | 0000_0000h |
| 18h | Interrupt Request Enable (IRER) | 32 | RW | 0000_0000h |
| 1Ch | Wake-Up Request Enable (WRER) | 32 | RW | 0000_0000h |
| 28h | Wake-Up and Interrupt Rising-Edge Event Enable (WIREER) | 32 | RW | 0000_0000h |
| 2Ch | Wake-Up and Interrupt Falling-Edge Event Enable (WIFEER) | 32 | RW | 0000_0000h |
| 30h | Wake-Up and Interrupt Filter Enable (WIFER) | 32 | RW | 0000_0000h |
| 54h | Wake-Up and Interrupt Status Flag (WISR_64) | 32 | RW | 0000_0000h |
| 58h | Interrupt Request Enable (IRER_64) | 32 | RW | 0000_0000h |

| 70h | Wake-Up and Interrupt Filter Enable (WIFER_64) | 32 | RW | 0000_0000h |

### 45.5.1.2 NMI Status Flag (NSR)

#### Offset

| Register | Offset |
|---|---|
| NSR | 0h |

#### Function

Holds the nonmaskable interrupt status flags.

**NOTE**

This register is accessible by 8-, 16-, and 32-bit read/write operations.

#### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 45.5.1.3 NMI Configuration (NCR)

**Offset**

| Register | Offset |
|---|---|
| NCR | 8h |

### Function

Holds the configuration fields for the nonmaskable interrupt settings.

**NOTE**

- This register is accessible by 8-, 16-, and 32-bit read/write operations.
- Writing 0 to both NREE[*n*] and NFEE[*n*] disables the NMI functionality completely (means no nonmaskable interrupt is generated on any pad activity).

### Diagram

#### 45.5.1.4 Wake-Up and Interrupt Status Flag (WISR)

**Offset**

| Register | Offset |
|---|---|
| WISR | 14h |

### Function

Holds the wake-up and interrupt flags.

**NOTE**

- This register is accessible only by 32-bit read/write operations.
- The status fields associated with on-chip wake-up sources are located to the left of the external wake-up and interrupt status fields and are read-only. The wake-up for these sources must be configured and cleared at the on-chip wake-up source. Also, the configuration registers for the external interrupts/wake-ups do not have corresponding bits.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### Fields

| Field | Function |
|---|---|
| 31-0<br>EIF | External Wake-Up and Interrupt Status Flag<br>Specifies whether an event, as defined by WIREER and WIFEER, has occurred on the pad. If enabled (IRER[*n*]), EIF[*n*] causes an interrupt request.<br>0b - No event occurred<br>1b - An event occurred |

## 45.5.1.5 Interrupt Request Enable (IRER)

### Offset

| Register | Offset |
|---|---|
| IRER | 18h |

### Function

Enables the interrupt messaging from the wake-up and interrupt pads to the interrupt controller.

**NOTE**

This register is accessible only by 32-bit read/write operations.

If a pin is disabled through this register, you must write 0 to the corresponding fields in WIFEER and WIREER to ensure that the pin does not respond to any change.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 45.5.1.11 Interrupt Request Enable (IRER_64)

### Offset

| Register | Offset |
|---|---|
| IRER_64 | 58h |

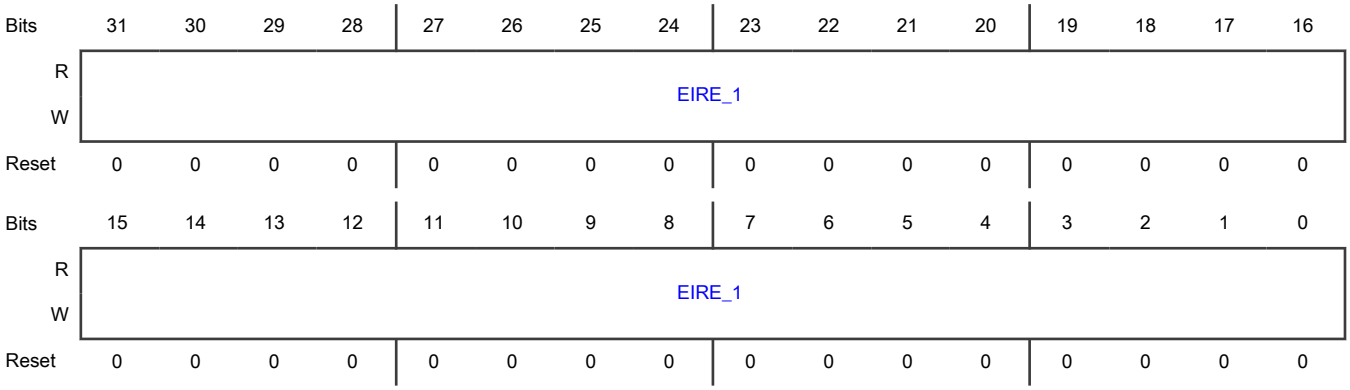
### Function

Enables interrupt messaging from the wake-up and interrupt pads to the interrupt controller.

**NOTE**

This register is accessible only by 32-bit read/write operations.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>EIRE_1 | External Interrupt Request Enable<br>Enables interrupt requests from the corresponding field, EIF[*n*].<br>0b - Disable<br>1b - Enable (with EIF[*n*] set) |

## 45.5.1.12 Wake-Up Request Enable (WRER_64)

### Offset

| Register | Offset |
|---|---|
| WRER_64 | 5Ch |

### Function

Enables system wake-up messaging from the wake-up and interrupt pads to the mode entry and power control modules.

**NOTE**

This register is accessible only by 32-bit read/write operations.

If a pin is disabled through this register, you must write 0 to the corresponding fields in WIFEER and WIREER to ensure that the pin does not respond to any change.

## 45.6 Glossary

**NMI** Nonmaskable interrupts

# Chapter 46
# Safety Overview

## 46.1 Introduction

This chip family is developed following the IEC 61508 standards, with derivatives targeting the chips that are operable in a system that fulfills the requirements of the SIL 2 safety integrity levels.

**Table 219. SIL levels**

| Chip | SIL level |
|---|---|
| MCXE315/MCXE316 | 2 |
| MCXE317 | |
| MCXE31B | |

The SIL level targets the safety processing, which means the software functions are executed as intended:

1. Read instructions from memory.
2. Execute instructions.
3. Read data from memory.
4. Process data.
5. Write back the result data into memory.

Some elements of the safety concept are based on the assumption that the chip is connected to an external SBC or PMIC. The SBC or PMIC performs observations and control functionalities that are essential to fulfill some related functional safety requirements. If you do not use an SBC or PMIC, you must ensure that your MCXE31 family chip provides an equivalent functionality that properly manages the corresponding interface(s).

The following figure illustrates the safety interface between the chip and the SBC or PMIC.

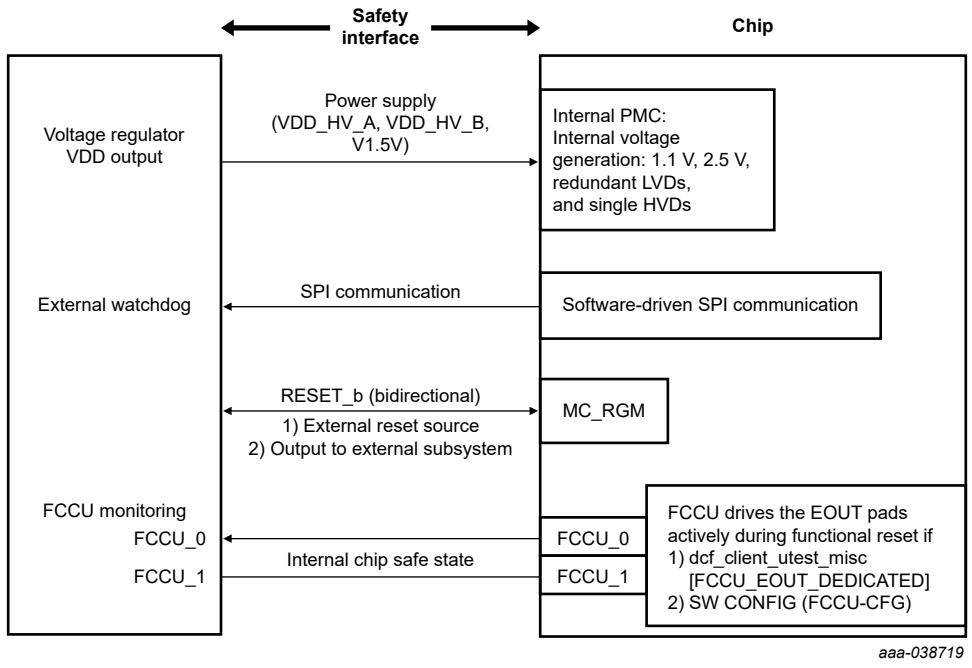

**Figure 174. Safety interface between the chip and the SBC or PMIC**

In the safety context, the chip interfaces can be classified into the groups shown in the table.

**Table 220. Chip interface groups**

| Interface | Description |
|---|---|
| Power supply | This interface is between the SBC and the chip. It ensures that the supply to the chip is in the correct range. In case of any low-voltage event, the chip has POR, LVR, and LVD circuits in place and in case of any HVD event, the chip raises an interrupt. The SBC must ensure that the voltage regulator outputs never exceed the allowed range (more specifically for HVD range). |
| Communication | Responsible for communication between the SBC and the chip. Though the chip supports multiple communication protocols (UART, LIN, SPI, I2C, FlexCAN, and so on), SPI is the preferred communication with SBC. This is relevant to initialize an external watchdog when the chip is inoperative for a considerably long time (this is indicated by the pin states of the communication interface). |
| Reset | The chip consists of a reset bidirectional pin interfaced with SBC. The SBC can initiate a chip reset via this pin as a safety reaction in case of:<br>• Extreme critical faults<br>• An inoperative chip<br>• Stuck cases based on the criticality and the application requirements<br>The SBC also samples the reset pin state to identify the chip condition (whether in running state or in reset). |
| FCCU | The chip indicates the chip faults to the SBC via FCCU EOUT pins through this interface. |

The interfaces in Table 220 ensure the chip's operational safety and integrity.

## 46.2 Safety architecture elements

The chip safety architecture consists of following elements that operate in an interconnected way to meet the SIL requirements:

- Cortex-M7 core complex
- eDMA controller
- Structural core self-test
- Internal windowed watchdogs with independent clock sources
- Power supply monitoring with redundant low-voltage detectors, single high-voltage detectors, and internal ADC connection to check the internal voltages during application
- Robust clock monitoring, including PLL loss of lock detection
- Embedded flash memory with ECC (single-bit data correction, double-bit data detection) and address encoding (parallel address path check)
- System RAM with ECC
  - Single-bit data correction

  - Double-bit data detection
  - Address detection
- Cortex-M7 cache memories with ECC (single-bit data correction, double-bit data detection)
- Peripherals memories (EMAC, FlexCAN) with ECC (single-bit data correction, double-bit data detection)
- End-to-End EDC (E2E EDC), with address encoding and monitoring of the control signals done by a dedicated module (XBIC). This ensures the safety of storage and of the data path to the internal storage (RAM, flash memory, core cache) and peripherals across the crossbar switch. See the XBIC chapter for details.
- Hardware CRC module that supports end-to-end data check integrity for any data transfer in the system (SRAM to peripherals via DMA transfer, external interfaces to SRAM/peripherals, and so on)
- Cortex-M7 MPUs
- XRDC for memory and peripheral protection
- AIPS_Lite peripheral protection with trusted master-slave connection
- Register protection mechanism for safety-critical registers
- On-chip temperature sensor for temperature monitoring
- Self-test:
  - LBIST to detect hidden dangerous faults in functional logic as well as in safety integrity mechanisms

**NOTE**

LBIST is not supported in MCXE315/MCXE316 and MCXE317.

  - MBIST to ensure integrity of the memories in the chip (SRAM, ITCM, DTCM, peripheral memories, and so on)
  - Check-the-checker software library
  - ADC self-test
- FCCU for error collection and reaction, including reporting error status to system; FCCU supports these programmable reaction types:
  - Interrupt
  - Functional reset
- Error pads indicate the chip's internal state to the external chip interface or SBC.
- EIM to inject errors into the memories and interface gaskets to verify the error-detection features of the memory controllers and the interface gaskets
- ERM to collect diagnostic information from memory controllers in case of an error event

## 46.3 I/O peripherals

The arrangement of I/O peripherals across peripheral bridges allows redundant use of peripherals while limiting possible causes of CCF. Redundant use includes using equivalent peripherals in a replicated way as well as using functionally different peripherals in, for example, feedback measurement loops. Comparison of redundant operation is the responsibility of the application software, not the safety hardware mechanism.

The peripherals are distributed evenly across the peripheral bridges (AIPS*n*), except for singular modules like EMAC, QuadSPI, and so on.

**NOTE**

EMAC and QuadSPI are not present in MCXE315/MCXE316 and MCXE317.

## 46.4 Self-test

The chip supports a self-test operation. Your safety software must initiate self-test by configuring STCU2; the chip does not initiate it. STCU2 then controls the self-test operation. Self-test supports both MBIST and LBIST. After the self-test operation completes, the chip enters a reset sequence. Self-test results are stored in STCU2 and your safety software can read the results after the reset sequence.

Figure 175 depicts the processing steps related to the self-test operation, and its linkage to the chip reset and an application start. You decide whether to run a self-test or to skip it before starting an application. You must also specify the self-test configuration before relinquishing control to STCU2 for performing the self-test operation. This processing finishes by reentering the chip reset sequence, depending on whether the chip encountered an unrecoverable fault during the self-test operation. When an unrecoverable fault is encountered during the self-test operation, the chip enters a reset sequence by performing a destructive reset. When no such fault is encountered, the self-test operation completes by entering the chip sequence with a functional reset sequence. You can prevent reset cycling by limiting the amount of resets permitted; the chip shuts down when this limit has been reached. See the "Functional reset escalation" and "Destructive reset escalation" sections in the MC_RGM chapter.

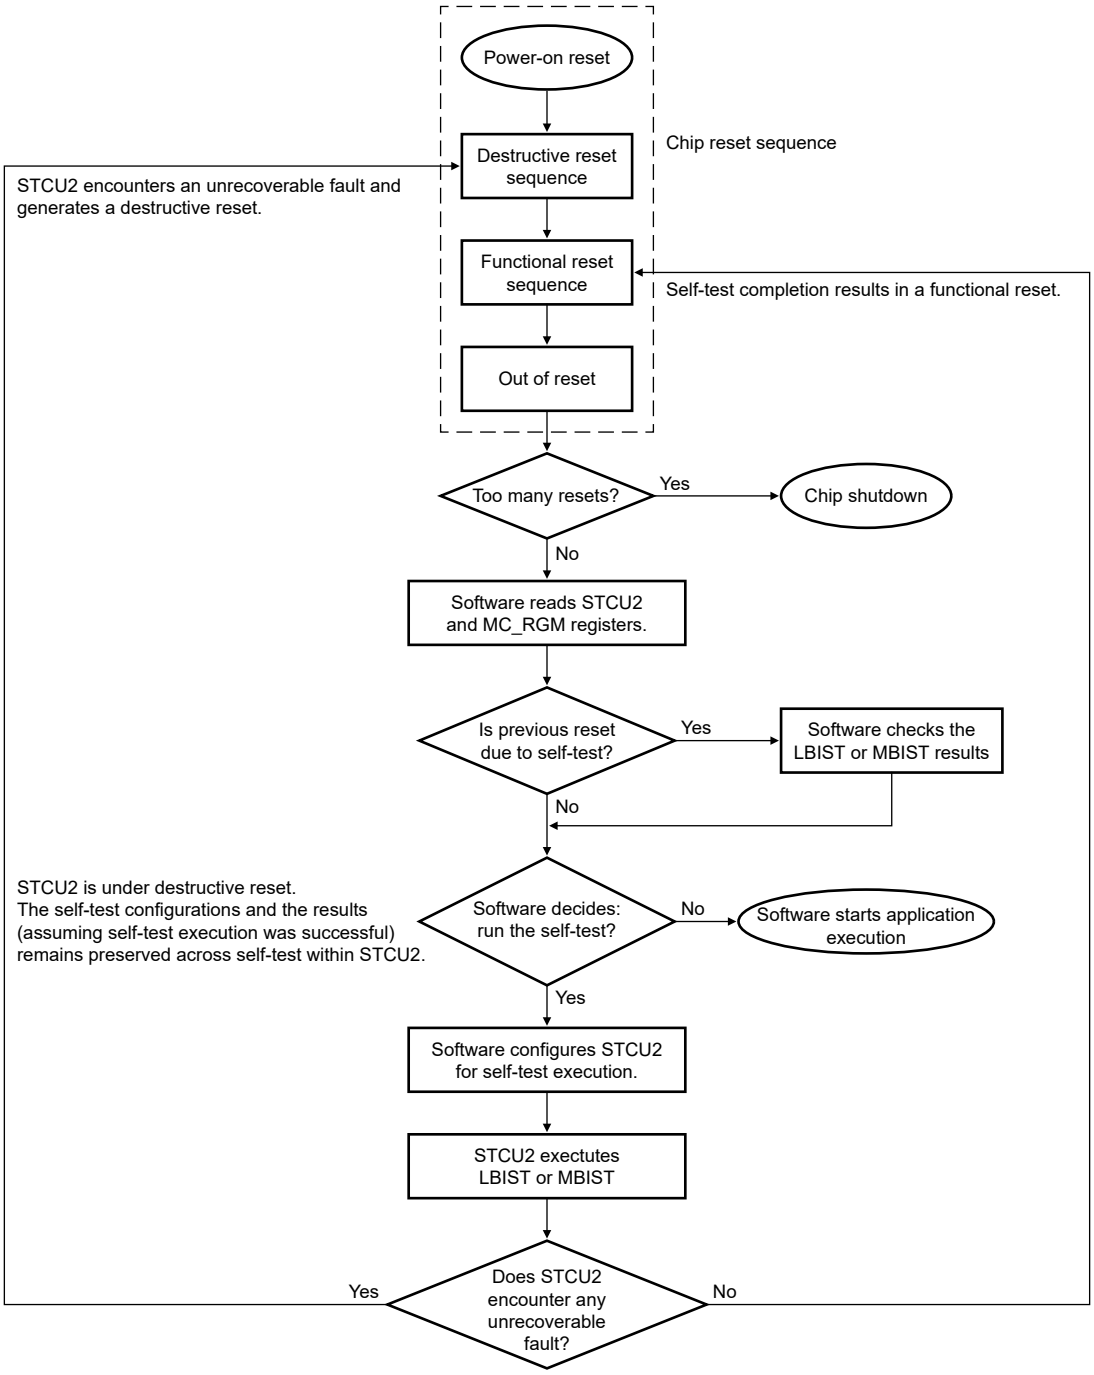

**Figure 175. LBIST/MBIST execution**

Figure 176 visualizes the top-level partitioning of the chip. The chip consists of two partitions, Run and Standby.

- Run: This partition consists of logic which is present in switchable domain and is shut off (has no supply) while the chip operates in low-power (Standby) mode.
- Standby: This partition consists of always-on logic which is functional even while the chip operates In low-power (Standby) mode.

The Run partition also contains the control logic that is essential for the chip self-test operation, as well as blocks that undergo self-test. The chip consists of a single LBIST partition, which is a subpartition within the Run partition. The LBIST subpartition

contains the logic over which self-test is executed. The logic outside the LBIST subpartition and within the Run partition consists of the LBIST control logic as well as logic which does not undergo LBIST.

The components within these different partitions are listed below the figure (they are not indicated in the figure for clarity).

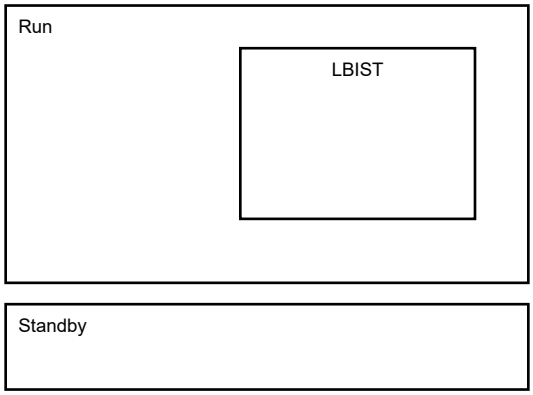

**Figure 176. MCXE31B chip top-level partition view**

The following list specifies the content of the LBIST partition and both power domains related to their participation in the self-test operation:

- Modules participating in the LBIST operation:

  **NOTE**

  LBIST is not supported in MCXE315/MCXE316 and MCXE317. The modules participating in the LBIST operation are out of LBIST in MCXE315/MCXE316 and MCXE317.

  — eDMA
  — EIM
  — ERM
  — XRDC
    - MDAC0 (Cortex-M7_0)
    - MDAC1 (eDMA)
    - MDAC2 (reserved)
    - MDAC3 (ELE_HSEB)
    - MDAC4 (Cortex-M7_1)
    - MDAC5 (EMAC)
    - MRC0 (flash memory)
    - MRC1 (PRAM)
    - MRC2 (QuadSPI)

      **NOTE**

      Cortex-M7, EMAC, and QuadSPI are not present in MCXE315/MCXE316 and MCXE317.

    - PDAC1
    - PDAC2
  — CRC
  — FCCU

- FOSU
- PFLASH_CTL
- PRAM_C0
- PRAM_C1
- SWT_1
- CMU
  - CMU_FC_0
  - CMU_FM_1
  - CMU_FM_2
  - CMU_FC_3
  - CMU_FC_4
  - CMU_FC_5
- IAHB gaskets

**NOTE**

An IAHB gasket is a frequency translation gasket in the system. These gaskets are used to add register walls and synchronize the timing domain across different operating frequencies. See the configurable gaskets in the 'Block diagram' in 'Introduction' chapter for the locations of the IAHB_GASKETs in the chip.

  - DMA_GSKT
  - HSE_GSKT
  - AIPS1_GSKT
  - AIPS2_GSKT
  - QSPI_GSKT

**NOTE**

AIPS2_GSKT and QSPI_GSKT are not present in MCXE315/MCXE316 and MCXE317.

  - TCM_GSKT
  - EMAC_GSKT
  - EDC master checker gaskets (See block diagram in Introduction chapter for details)
  - EDC slave checker gasket (See block diagram in Introduction chapter for details)
- Crossbar switches and bridges
  - AXBS_0 (main)
  - AXBS_1 (peripheral)
  - AXBS_2 (eDMA)
  - AXBS_3 (Cortex-M7 TCM)
  - AXBS_4 (HSE)
  - AIPS_Lite_1
  - AIPS_Lite_2

**NOTE**

AIPS2_Lite_ is not present in MCXE315/MCXE316 and MCXE317.

- Modules within the Standby domain (not participating in the LBIST operation):
  - 32 KB standby SRAM
  - LPCMP_0–LPCMP_2
  - Reset generation
    - MC_RGM
    - POR_WDG
  - Power management
    - PMC
    - MC_PCU
    - WKPU
    - Chip standby pins
  - Clock sources
    - FIRC
    - SIRC
    - FXOSC
    - SXOSC

**NOTE**

SXOSC is not present in MCXE315/MCXE316.

  - Timers
    - PIT_0
    - RTC
    - SWT_0
- Modules not participating in the LBIST operation (in the Run domain):
  - HSE subsystem
    - Engine
    - Memories
  - Cortex-M7_0
    - Core
    - I-cache
    - D-cache
    - ITCM
    - DTCM
  - Cortex-M7_1

**NOTE**

Cortex-M7_1 is not present in MCXE315/MCXE316 and MCXE317.

    - Core
    - I-cache

- D-cache
- ITCM
- DTCM

— CMUs
- CMU0
- CMU3

— Analog blocks
- ADC_0–ADC_2
- TempSense

**NOTE**

ADC_2 is not present in MCXE315/MCXE316 and MCXE317.

— Communication modules
- LPSPI_0–LPSPI_5
- LPI2C_0
- LPI2C_1
- LPUART_0–LPUART_15
- FlexCAN_0–FlexCAN_5
- SAI_0
- SAI_1

**NOTE**

SAI_0 and SAI_1 are not present in MCXE315/MCXE316 and MCXE317.

— Timers
- PIT_1
- PIT_2
- eMIOS
- BCTU
- STM_0
- STM_1

**NOTE**

PIT_2 and STM_1 are not present in MCXE315/MCXE316 and MCXE317.

— TRGMUX

— PLLDIG

— SIUL2

— LCU_0

— LCU_1

— STCU2

— DMAMUX

— MCM

— MCSM

— INTM

— SEMA42

— MU

**NOTE**

SEMA42 and chip MU are not present in MCXE315/MCXE316 and MCXE317.

— TSPC

**NOTE**

REG_PROT of an IP undergoes (or does not undergo) LBIST in conjunction with the protected module that undergoes (or does not undergo) LBIST.

The modules that are vital to the self-test operation are excluded from LBIST regions to allow LBIST to execute successfully.

You must run self-test with PLLDIG configured as the system clock. The LBIST clock controller controls the clock during serial shift, but returns clock control to the functional nodes during the self-test.

# Chapter 47
# Error Injection Module (EIM)

## 47.1 Chip-specific EIM information

### 47.1.1 EIM channel mapping

EIM integrates with the memory controller and memory array to enable error injection in a controlled way. Each memory controller has its own EIM channel.

EMAC, AIPS2 gasket, Cortex-M7, and QuadSPI gasket are not available in the MCXE317 and MCXE315/MCXE316 product variants of the MCXE31 family.

**Table 221. EIM channel mapping**

| Channel # | Target | Data bits [1] | Check bits[1] | # of data bits | # of check bits |

1. You must write to EICHDi_WORDj registers to inject errors in the desired data and check bits. For details, see tables "Error injection channel descriptor: DATA_MASK details" and "DATA_MASK bit: Channel-word mapping" in this chapter.
2. SRAM1 is not available for the MCXE317, and MCXE315/MCXE316 variants.

The two enables, GEIEN and EICHEN*n*, enable the error injection functionality. The former enables it globally and the latter does it for a particular channel. This double-layer enable provides protection against accidental enabling and reconfiguration of the error injection function for each channel.

EIM provides support for inducing single-bit and multi-bit inversions on read data when accessing peripheral RAMs through its data mask registers.

**NOTE**

For enabling error injection on EDC gaskets (corresponding to channel 28, channel 29, and channel 30), you must also enable the fields corresponding to the required EDC gasket in the MSCM_ENEDC register before enabling the EIM channel.

EIM_EICHD1_CH01, EIM_EICHD1_CH08, EIM_EICHD1_CH09, EIM_EICHD1_CH10, EIM_EICHD1_CH11, EIM_EICHD1_CH12, EIM_EICHD1_CH16, EIM_EICHD1_CH17, EIM_EICHD1_CH18, EIM_EICHD1_CH19, EIM_EICHD1_CH21, EIM_EICHD1_CH22, EIM_EICHD1_CH24, EIM_EICHD1_CH26, EIM_EICHD1_CH27 are not present in MCXE317, hence the registers corresponding to these channels are also not present in MCXE317.

### 47.1.2 Behavior of EIM error injection on gaskets

The error injection on gaskets don't impact the actual data flow. The gasket read data, write data and the monitor error don't get changed when EIM error injection is done. The gasket compares the actual data with the modified data (with error injection) and flags the gasket alarm. In case of single-bit error also, the alarm is flagged.

The channels which depict such behavior are the gasket channels listed below:

- Channel 19: EMAC gasket
- Channel 20: Cortex-M7 TCM gasket
- Channel 21: DMA AXBS S0 gasket
- Channel 22: DMA AXBS S1 gasket
- Channel 23: HSE gasket
- Channel 24: QuadSPI gasket
- Channel 25: AIPS1 gasket
- Channel 26: AIPS2 gasket

## 47.2 Overview

The Error Injection Module (EIM) is mainly used for diagnostic purposes. It provides a method to test the diagnostics (memory ECC, interconnect parity) by error injection in the field. See the chip-specific EIM information to determine which functional safety features are supported by this method.

EIM enables you to inject artificial errors on error-checking mechanisms of a system, such as ECC for RAM read data and parity bits. For each such mechanism that EIM supports on the chip, EIM can inject single-bit and multi-bit inversions on data in the applicable target bus. Injecting faults on memory accesses can be used to exercise the SEC-DED ECC function of the related system.

**NOTE**

Terminology in this chapter has been updated as follows:

**Table 222. Updated terms**

| Updated term | Deprecated term |
|---|---|
| Controller | Master |

### 47.2.1 Features

The EIM includes these features:

- Supports 31 error injection channels. See the chip-specific EIM information for channel assignment details.
- Protection against accidental enable and reconfiguration error injection function via two-stage enable mechanism

### 47.2.2 Block diagram

The following diagram shows an example of EIM implementation with a 64-bit read data bus and an 8-bit checkbit bus.

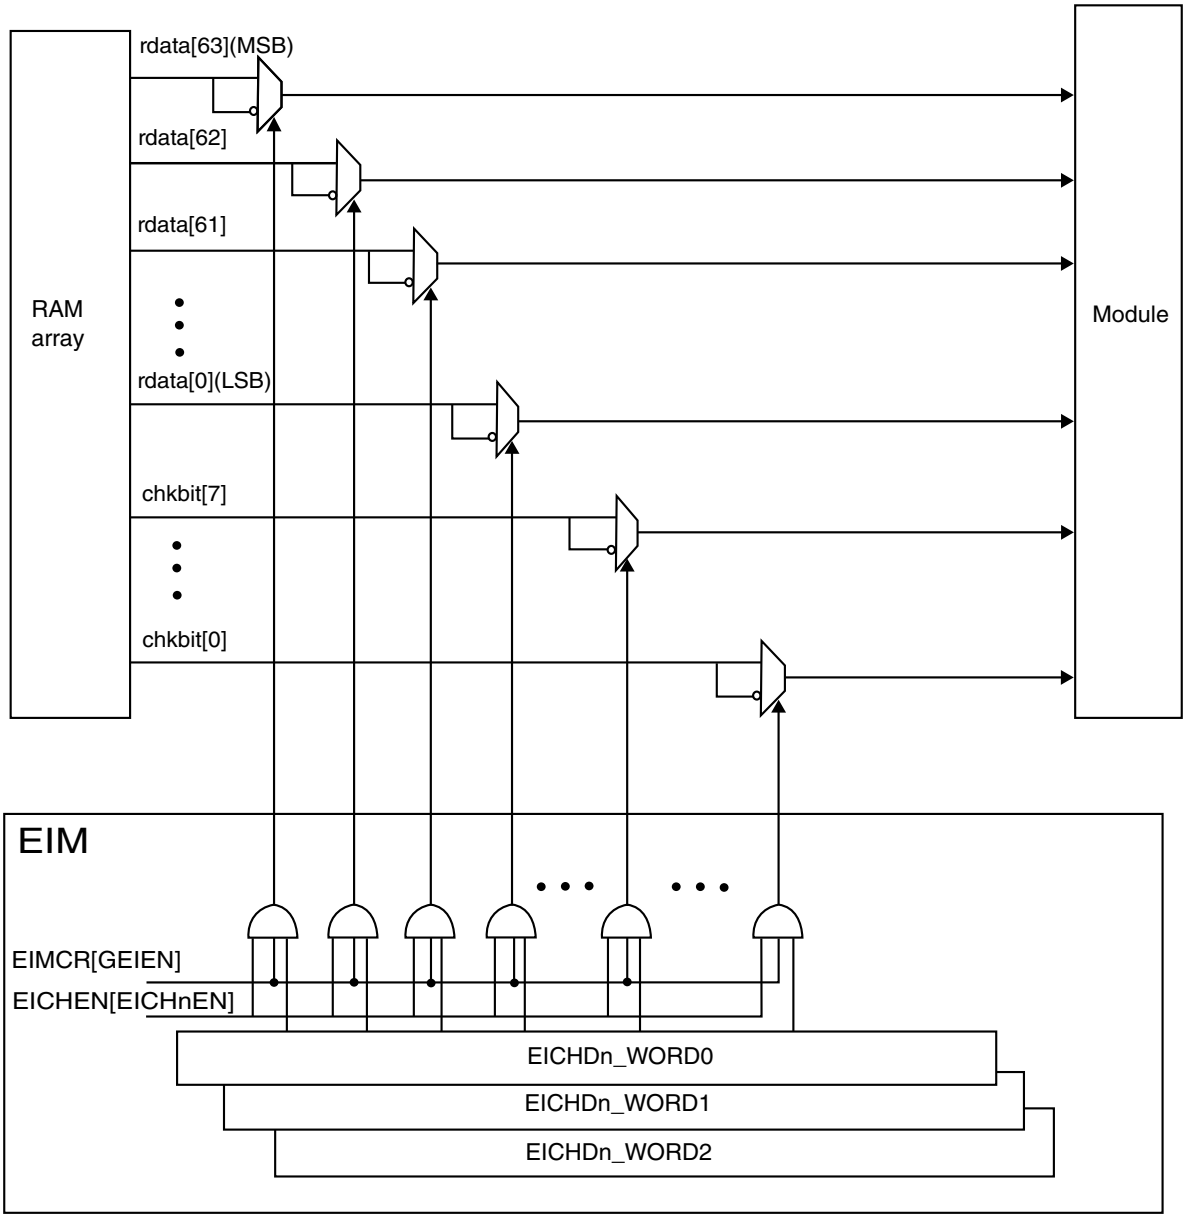

**Figure 177. EIM functional block diagram (64-bit read data bus and 8-bit check bit bus)**

Several memory elements are implemented within a device, which may not only be the large memory blocks (Flash and SRAM) but also smaller memories like caches, the TCD blocks, and the embedded peripheral memories. Some larger memories may actually be built from multiple memory elements, dependent on their size or function. Each of these memory elements implements its own control logic, the memory controller, that performs the accesses to the actual memory, the memory array. An EIM channel is associated with a memory controller and provides the capability to alter one or multiple signals in the read access path from the corresponding memory array(s). Only memory controllers controlling a safety related memory may be associated with an EIM channel.

## 47.3 Functional description

The EIM provides protection against accidental enabling and reconfiguration of the error injection function by enforcing a two-stage enablement mechanism. To properly enable the error injection mechanism for a channel:

- Write 1 to the EICHEN[EICH*n*EN] field, where *n* denotes the channel number.
- Write 1 to EIMCR[GEIEN].

**NOTE**

When the use case for a channel requires writing any EICHD*n*_WORD register, write the EICHD*n*_WORD register before executing the two-stage enablement mechanism. A successful write to any EICHD*n*_WORD register clears the corresponding EICHEN[EICH*n*EN] field.

The EIM supports 31 error injection channels. See the chip-specific EIM information for channel assignment details. Each channel:

- Can be assigned to a single memory array interface by intercepting the assigned memory read data bus and checkbit bus, and injects errors by inverting the value transmitted for selected bits on each bus line.
- Can be assigned to a redundant comparison unit by intercepting the signals being compared, and injecting errors by inverting the value transmitted for selected bits on each bus line.

On a memory read access, the applicable EICHD*n*_WORD registers define which bits of the read data and/or checkbit bus to invert.

Figure 177 depicts the interception and override of a 64-bit read data bus and an 8-bit checkbit data bus for an example memory array.

### Error injection scenarios

The EIM supports these cases of error injection:

- To generate a single-bit error, invert only 1 bit of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.
- To generate a multi-bit error, invert only 2 bits of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.

**NOTE**

An attempt to invert more than 2 bits in one operation might result in undefined behavior.

To enable error injection:

1. Set the EICHD*n*_WORD*m*[CHKBIT_MASK] and EICHD*n*_WORD*m*[B*a*_*b*DATA_MASK] fields for each channel that will be driving an injection.
2. Program the EICHEN register to enable the channels that will be injecting errors.
3. Set the EIMCR[GEIEN] field to globally allow all enabled channels to actively inject errors.

To disable error injection, either disable the EIMCR[GEIEN] field or disable the individual channel enable fields of the EICHEN register.

## 47.4 Initialization

This module does not require initialization.

## 47.6 EIM register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

### Programming model access

All system bus controllers can access the programming model:

- Only in supervisor mode

- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

**Error injection channel descriptor: function and structure**

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

**Error injection channel descriptor: DATA_MASK details**

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

**Table 223. Error injection channel descriptor: DATA_MASK details**

| Channel | DATA_MASK total width (bits) | Specific bits of DATA_MASK in | | |
|---|---|---|---|---|
| | | WORD1 | WORD2 | WORD3 |

### 47.6.2 Error Injection Module Configuration Register (EIMCR)

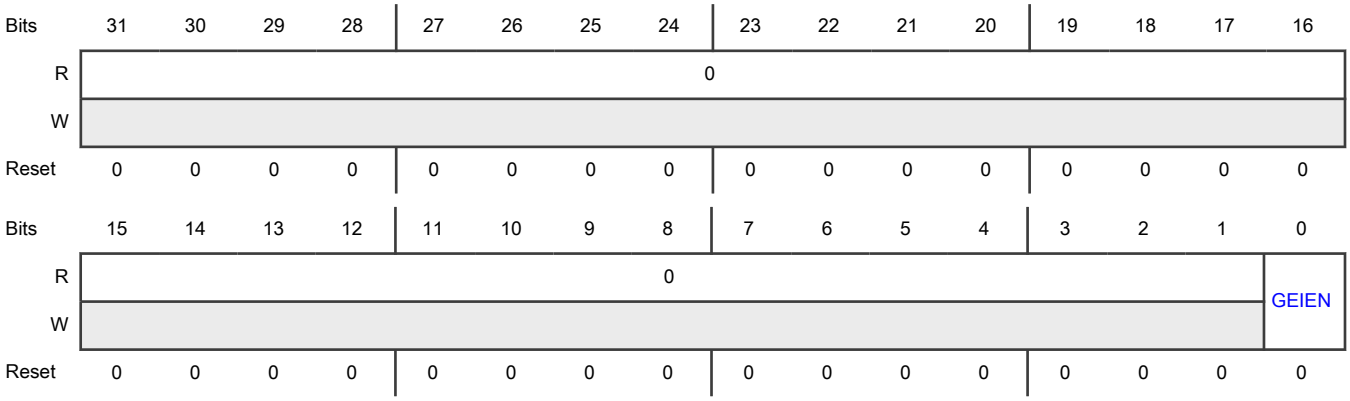
**Offset**

| Register | Offset |
|---|---|
| EIMCR | 0h |

**Function**

The EIM Configuration Register is used to globally enable/disable the error injection function.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved |
| 0<br>GEIEN | Global Error Injection Enable<br>This bit globally enables or disables the error injection function of the EIM. This field is initialized by hardware reset.<br>0b - Disabled<br>1b - Enabled |

## 47.6.3 Error Injection Channel Enable register (EICHEN)

### Offset

| Register | Offset |
|---|---|
| EICHEN | 4h |

### Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

**NOTE**

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

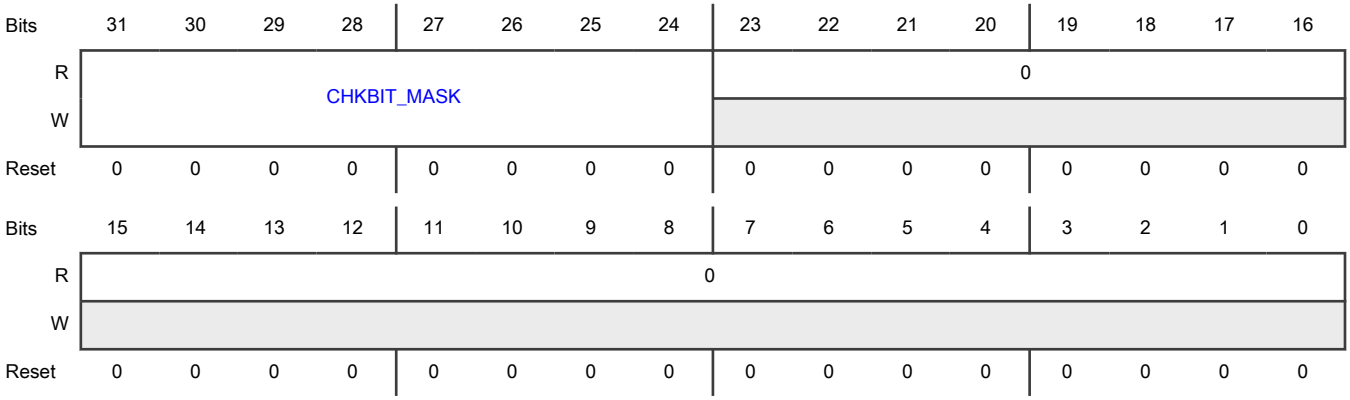
### Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-24<br>CHKBIT_MASK | Checkbit Mask<br>This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored.<br>For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information.<br>**NOTE**<br>Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[7:0] (8 bits wide), CHKBIT_MASK[7] is in the position of the most significant bit.<br>0b - The corresponding bit of the checkbit bus remains unmodified.<br>1b - The corresponding bit of the checkbit bus is inverted. |
| 23-0<br>— | Reserved |

Writes to unimplemented bits are ignored.<br>**NOTE**<br>For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details.<br>0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified.<br>1b - The corresponding bit of bytes 0-3 on the read data bus is inverted. |

## 47.6.20 Error Injection Channel Descriptor n, Word0 (EICHD10_WORD0 - EICHD12_WORD0)

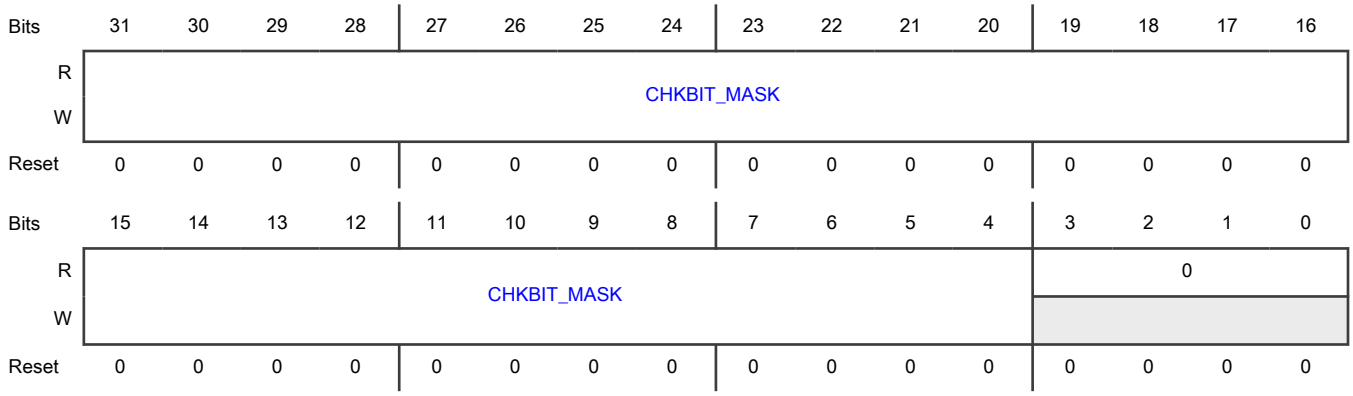
### Offset

| Register | Offset |
|---|---|
| EICHD10_WORD0 | 380h |
| EICHD11_WORD0 | 3C0h |
| EICHD12_WORD0 | 400h |

### Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-4<br>CHKBIT_MASK | Checkbit Mask<br>This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored.<br>For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information.<br>**NOTE**<br>Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[27:0] (28 bits wide), CHKBIT_MASK[27] is in the position of the most significant bit.<br>0b - The corresponding bit of the checkbit bus remains unmodified.<br>1b - The corresponding bit of the checkbit bus is inverted. |
| 3-0<br>— | Reserved |

## 47.6.21 Error Injection Channel Descriptor 10, Word1 (EICHD10_WORD1)

### Offset

| Register | Offset |
|---|---|
| EICHD10_WORD1 | 384h |

### Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

| **ECC** | Error correction code |

# Chapter 48
# Error Reporting Module (ERM)

## 48.1 Chip-specific ERM information

### 48.1.1 ERM channel mapping

ERM provides information on memory events associated with ECC and parity. It also provides you an option to enable interrupt notification for these events.

**Table 225. ERM channel mapping**

| Channel # | Module | Captured status |
|---|---|---|
| 00 | SRAM0 | Single-bit error, multi-bit error, syndrome, absolute error address aligned to double-word (64-bit) boundary |
| 01 | SRAM1 [1] | Single-bit error, multi-bit error, syndrome, absolute error address+18000h aligned to double-word (64-bit) boundary[2] |
| 02 | Cortex-M7_0 I-cache tag RAM | Single-bit error, multi-bit error[3] |
| 03 | Cortex-M7_0 I-cache data RAM | Single-bit error, multi-bit error[3] |
| 04 | Cortex-M7_0 D-cache tag RAM | Single-bit error, multi-bit error[3] |
| 05 | Cortex-M7_0 D-cache data RAM | Single-bit error, multi-bit error[3] |
| 10 | Cortex-M7_0 ITCM | Single-bit error, multi-bit error, syndrome, offset error address |
| 11 | Cortex-M7_0 D0TCM | Single-bit error, multi-bit error, syndrome, offset error address |
| 12 | Cortex-M7_0 D1TCM | Single-bit error, multi-bit error, syndrome, offset error address[4] |
| 13 | Cortex-M7_1 ITCM | Single-bit error, multi-bit error, syndrome, offset error address |
| 14 | Cortex-M7_1 D0TCM | Single-bit error, multi-bit error, syndrome, offset error address |
| 15 | Cortex-M7_1 D1TCM | Single-bit error, multi-bit error, syndrome, offset error address[4] |
| 16 | DMA TCD | Single-bit error, multi-bit error, syndrome, offset error address[5] |
| 17 | Flash memory port p0 | Single-bit error, multi-bit error, absolute error address |
| 18 | Flash memory port p1 | Single-bit error, multi-bit error, absolute error address |
| 19 | Flash memory port p2 [6] | Single-bit error, multi-bit error, absolute error address |

1. SRAM1 is not available for the MCXE315/MCXE316/MCXE317 product variants.
2. The size of SRAM0 is 160 KB, and therefore, to align addresses to the next power of 2, an address space of 256 KB is reserved for error reporting. However, SRAM0 and SRAM1 are in contiguous locations in the memory map. So, you must subtract 18000h (256 KB-160 KB = 96 KB that corresponds to 18000h) from the reported address to get an absolute address. See the "Memory and Memory Interfaces" chapter for SRAM details on different MCXE31 variants.
3. The cache controller does not report error addresses and syndrome.
4. For address reporting, bit 2 of the address is masked because this bit decides whether the access (read or write) is for D0TCM or D1TCM. For example, if the offset address is 0h or 8h, it is routed to D0TCM, but if the offset address is 4h or Ch, it is routed to D1TCM. The errors that are latched for these offset addresses are as follows:
   - Offset 0h : Address 0h is latched into the ERM channel corresponding to D0TCM.
   - Offset 4h : Address 0h is latched into the ERM channel corresponding to D1TCM.
   - Offset 8h : Address 8h is latched into the ERM channel corresponding to D0TCM.
   - Offset Ch : Address 8h is latched into the ERM channel corresponding to D1TCM.

5. Bits [31:10] and [2:0] are always 0 because they are not connected.

   Bits [9:5] indicate the corresponding TCD out of all the 32 implemented TCDs.

   Bits [4:3] indicate an offset of TCDs with respect to a 64-bit aligned boundary.

   - If [4:3] is 00, it indicates that an error is on offset address 20h.
   - If [4:3] is 01, it indicates that an error is on offset address 28h.
   - If [4:3] is 10, it indicates that an error is on offset address 30h.
   - If [4:3] is 11, it indicates that an error is on offset address 38h.
6. Flash memory port p2 is not applicable for the MCXE315/MCXE316/MCXE317 product variants.

## 48.2 Overview

The Error Reporting Module (ERM) provides information and optional interrupt notification on memory error events associated with ECC and parity. The ERM collects error events on memory accesses for memory arrays, such as flash memory, system RAM, or peripheral RAMs. ERM supports various channels for memory sources where each ERM channel is associated with a different memory module. See the chip-specific ERM information for details about supported memory sources and specific memory channel assignments. If memory supports ECC then ERM syndrome and error address information is captured along with error event. ERM does not receive this information in case of cache or memory with parity along with error event.

### 48.2.1 Features

The ERM includes these features:

- Optional interrupt notification on captured error events
- Capturing of address and syndrome information on single-bit correction and non-correctable ECC events
- Support for error event capturing for memory sources, with individual reporting fields and interrupt configuration per memory channel
- Recording the count value of the number of corrected error events

### 48.2.2 Block diagram

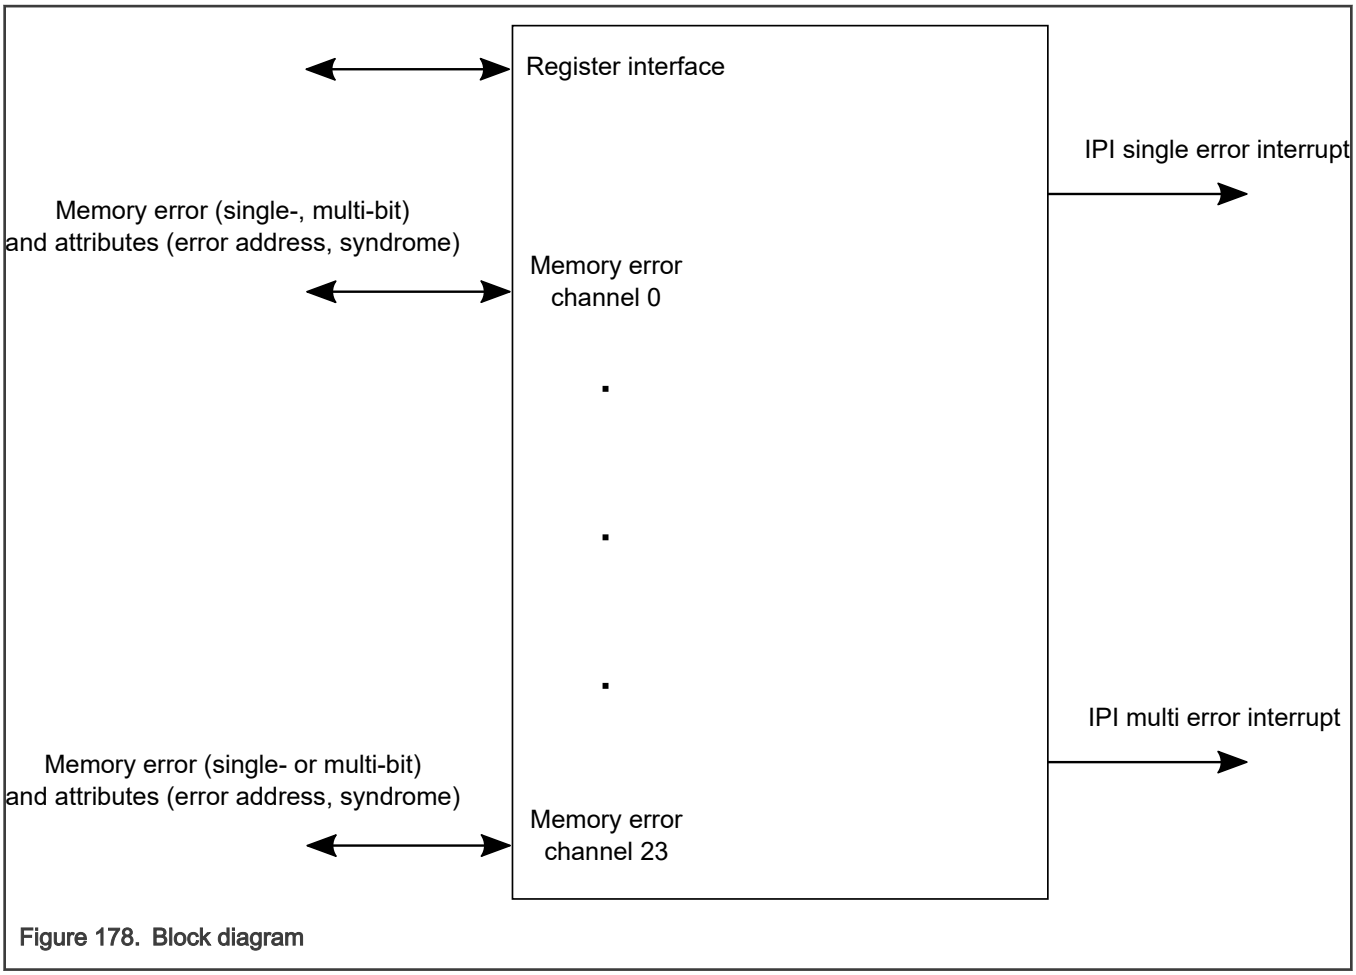

Figure 178. Block diagram

## 48.3 Functional description

### 48.3.1 Single-bit correction events

When a single-bit correction event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit SR*x*[SBC*n*] to 1.
- Increments the correctable error count value (until the counter reaches its maximum value): CORR_ERR_CNT*n*[COUNT].
- Records the corresponding access address that initiated the event in the Memory *n* Error Address Register: EAR*n* (if this register is present for the channel).
- Stores the corresponding ECC syndrome in the Memory *n* Error Syndrome Register: SYN*n* (if this register is present for the channel). This register identifies the bit position of the corrected data on single-bit data inversion.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[SBC*n*] to change its value to 0.

To reset the correctable error count value, write all zeros to CORR_ERR_CNT*n*[COUNT].

#### Optional interrupt notification for single-bit correction events

The ERM provides an option to generate an interrupt notification upon the report of a single-bit correction event. To enable single-bit correction interrupts for a channel:

1. To enable interrupt notification for single-bit correction events on Memory *n*, set CR*x*[ESCIE*n*] to 1.
2. Subsequently, a single-bit correction event on Memory *n* is detected, the ERM:
   - Records the event and address, and stores the ECC syndrome as usual.
   - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[SBC*n*] to change its value to 0.

### 48.3.2 Non-correctable error events

When a non-correctable ECC error event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit: SR*x*[NCE*n*] to 1.
- Records the corresponding access address that initiated the event in the Memory *n* Error Address Register: EAR*n* (if this register is present for the channel).
- Stores the corresponding ECC syndrome in the Memory *n* Error Syndrome Register: SYN*n* (if this register is present for the channel).
  - In the event of a non-correctable address bit inversion, SYN*n* identifies the pertinent address bit position.
  - In the event of a non-correctable, multi-bit data inversion, the syndrome value does not provide any additional diagnostic information.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[NCE*n*] to change its value to 0.

#### Optional interrupt notification for non-correctable error events

The ERM provides an option to generate an interrupt notification upon the report of a non-correctable ECC event. To enable non-correctable error interrupts for a channel:

1. To enable interrupt notifications for non-correctable error events on Memory *n*, set CR*x*[ENCIE*n*] to 1.
2. Subsequently, when a non-correctable error event on Memory *n* is detected, the ERM:
   - Records the event and address and stores the ECC syndrome as usual.
   - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[NCE*n*] to change its value to 0.

**NOTE**

Parity errors can be mapped to non-correctable errors where error attributes like SYNDROME, ADDRESS are not provided.

## 48.4 Initialization

For each ERM channel supporting memory with ECC, prepare the corresponding memory array before enabling ERM interrupts about errors for that memory.

1. Initialize the memory to a known value so that the correct corresponding ECC codeword is stored.
2. During the memory's initialization, if the ERM captures information about any ECC error event, clear the corresponding SR*x*[SBC*n*] or SR*x*[NCE*n*] field that stores the record of the event.
3. Program the applicable CR*x*[ESCIE*n*] and CR*x*[ENCIE*n*] fields to enable ERM interrupts as desired.

## 48.5 ERM register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Based on the design implementation, the following XFR error behavior is evident at the IPS interface.

- Within the ERM memory map, an XFR error is evident at reserved addresses from location 20h to FFh.
- No XFR error is evident at reserved addresses in memory spaces allocated to each channel. For example: For channel 0, for read/write accesses to reserved address 10Ch, the XFR error is 0.
- For accesses to locations beyond the addresses allocated for the final channel, the XFR error is 1.

**NOTE**

- See the chip-specific ERM information at the beginning of this chapter for details on Memory channel mapping.
- To access the channel registers, corresponding memory channel clock must be enabled.

### 48.5.1 ERM memory map

ERM base address: 4025_C000h

| Offset | Register | Width (In bits) | Access | Reset value |

### 48.5.8 ERM Memory a Error Address Register (EAR0 - EAR19)

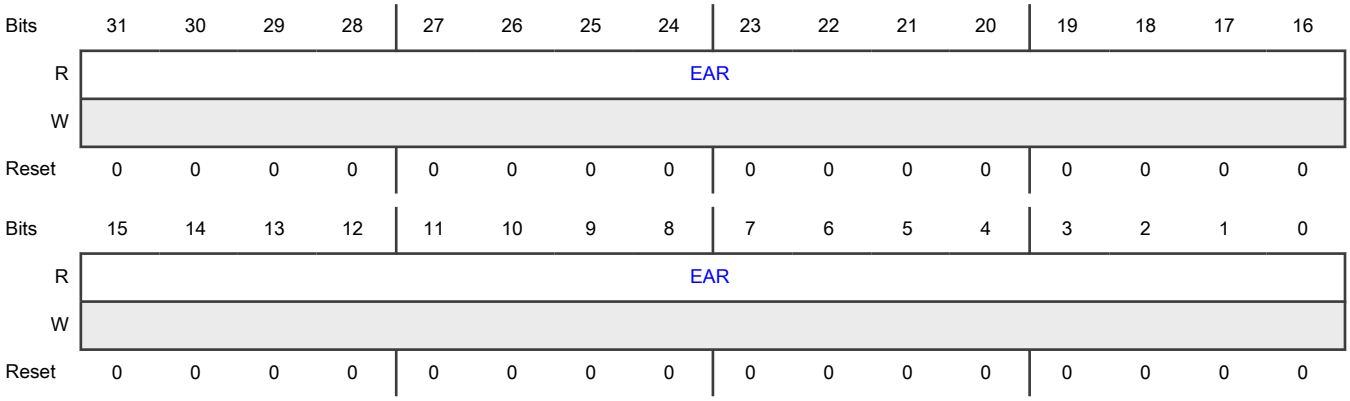
#### Offset

| Register | Offset |
|---|---|
| EAR0 | 100h |
| EAR1 | 110h |
| EAR10 | 1A0h |
| EAR11 | 1B0h |
| EAR12 | 1C0h |
| EAR13 | 1D0h |
| EAR14 | 1E0h |
| EAR15 | 1F0h |
| EAR16 | 200h |
| EAR17 | 210h |
| EAR18 | 220h |
| EAR19 | 230h |

#### Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory*n*, where*n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>EAR | EAR<br>Memory*n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory*n*. |

## 48.5.9 ERM Memory a Syndrome Register (SYN0 - SYN16)

### Offset

| Register | Offset |
|---|---|
| SYN0 | 104h |
| SYN1 | 114h |
| SYN10 | 1A4h |
| SYN11 | 1B4h |
| SYN12 | 1C4h |
| SYN13 | 1D4h |
| SYN14 | 1E4h |
| SYN15 | 1F4h |
| SYN16 | 204h |

### Function

The ERM Memory *n* Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory*n*, where*n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| CORR_ERR_CNT1 | 118h |
| CORR_ERR_CNT2 | 128h |
| CORR_ERR_CNT3 | 138h |
| CORR_ERR_CNT4 | 148h |
| CORR_ERR_CNT5 | 158h |
| CORR_ERR_CNT6 | 168h |
| CORR_ERR_CNT7 | 178h |
| CORR_ERR_CNT8 | 188h |
| CORR_ERR_CNT9 | 198h |
| CORR_ERR_CNT10 | 1A8h |
| CORR_ERR_CNT11 | 1B8h |

*Table continues on the next page...*

*Table continued from the previous page...*

| Register | Offset |
|---|---|
| CORR_ERR_CNT12 | 1C8h |
| CORR_ERR_CNT13 | 1D8h |
| CORR_ERR_CNT14 | 1E8h |
| CORR_ERR_CNT15 | 1F8h |
| CORR_ERR_CNT16 | 208h |
| CORR_ERR_CNT17 | 218h |
| CORR_ERR_CNT18 | 228h |
| CORR_ERR_CNT19 | 238h |

### Function

Each 32-bit ERM Memory *n* Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory*n*, where*n* denotes the memory channel.

**NOTE**

Non-correctable errors are considered a serious fault, so the ERM does not provide any mechanism to count non-correctable errors. Only correctable errors are counted.

### Diagram

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT value will stop when it reaches maximum value FFh and will not wrap even if additional errors occur.<br>Read this field to determine the correctable error count value so far.<br>Write all zeros to this field to reset the counter. Writing a non-zero value has no effect. |

## 48.6 Glossary

**ECC** Error correction code

# Chapter 49
# Fault Collection and Control Unit (FCCU)

## 49.1 Chip-specific FCCU information

### 49.1.1 FCCU NCF slots

**Table 226. FCCU NCF slots**

| Slot number | Source module (error type) |
|---|---|
| NCF[0] | • Cortex-M7 LS and core lockup<br>• ELE_HSEB lockup |
| NCF[1] | Interconnect:<br>• All EDC bus gaskets<br>• XBIC monitors and platform gaskets |
| NCF[2] | ECC errors:<br>• PRAMC<br>• TCMs<br>• Caches<br>• eDMA<br>• EDC after ECC<br>• ELE_HSEB RAM errors |
| NCF[3] | All flash memory errors:<br>• FMU<br>• PFLASH<br>• DCM flash memory |
| NCF[4] | Voltage-related errors:<br>• PMC 1.1 V and 2.5 V GNG<br>• Pad overvoltage |
| NCF[5] | Debug and test monitoring |
| NCF[6] | INTM |
| NCF[7] | Software notification |

### 49.1.2 Chip-boundary FCCU signals

**Table 227. Chip-boundary FCCU signals**

| FCCU signal | Chip signal |
|---|---|
| EOUT0 | FCCU_ERR0 |
| EOUT1 | FCCU_ERR1 |

### 49.1.3 FCCU clocking

Table 228. FCCU clocking

| FCCU clock signal | Chip clock signal |
|---|---|
| CLKSAFE | FIRC_CLK |
| CLKPRIM | AIPS_PLAT_CLK |

### 49.1.4 FOSU timer interval

The FOSU_COUNT value determines the FOSU timer interval. On this chip, FOSU_COUNT is 69780h.

### 49.1.5 Supported internal chip reactions

The short functional reset discussed in this chapter is equivalent to the chip functional reset. See the interrupt map file attached to this document for interrupts from FCCU to NVIC.

**NOTE**

After STCU2 completes the self-testing procedure, the chip reboots and FCCU resets.

### 49.1.6 Supported FCCU EOUT fault output modes (protocols)

This chip supports only the Bistable protocol of FCCU EOUT, and does not support the other protocols discussed in this chapter, Dual-Rail and Time-Switching.

### 49.1.7 Recommended reaction programming for faults

You can upgrade or downgrade the reaction of the faults according to the recommended reaction discussed in the fault map file attached to this document.

In case you upgrade a reaction, no issues are expected in the behavior. If you downgrade the reaction, the functionality is not guaranteed.

This is the recommendation for faults caused by lockstep errors:

1. The recommended reaction for the lockstep error fault is a functional reset.
2. Program the core to perform the following steps after rebooting:
    a. Initialize TCM (because TCMs can become corrupted)
    b. Invalidate the cache (because caches can become corrupted)
3. Write 1 to the corresponding bit in FCCU.NCF_S0 register to clear the non-critical fault status.
4. If the FCCU fault gets cleared, you have nothing else to do for fault handling (this means, the FCCU lockstep error is recovered).
5. If the error persists, it indicates that the internal registers of the two cores have different values. To bring them to the same value, you could perform any of these steps:
    a. Initialize destructive reset through software by using MC_ME.MODE_CONF[DEST_RST] to recover from lockstep. This initializes the FCCU with no pending faults.
    b. Reconfigure the Cortex-M7 debug configurations (which would have been lost in previous step due to destructive reset in the system).

### 49.1.8 FCCU NCF handling architecture

This chip supports eight NCFs. Therefore, multiple faults of similar nature are ORed together and then connected as a single NCF to FCCU. To control individual fault, there are enable/disable controls provided within DCM in registers DCMRWD3, DCMRWD4 and DCMRWD5.

Similarly, the FCCU.NCF_S0 captures the status of fault within FCCU. This fault might have resulted due to any fault mapped on the corresponding FCCU NCF channel. The DCM status registers, DCMROD3, DCMROD4 and DCMROD5 capture the status of individual faults which are mapped onto FCCU NCFs. Figure 179 shows this arrangement.

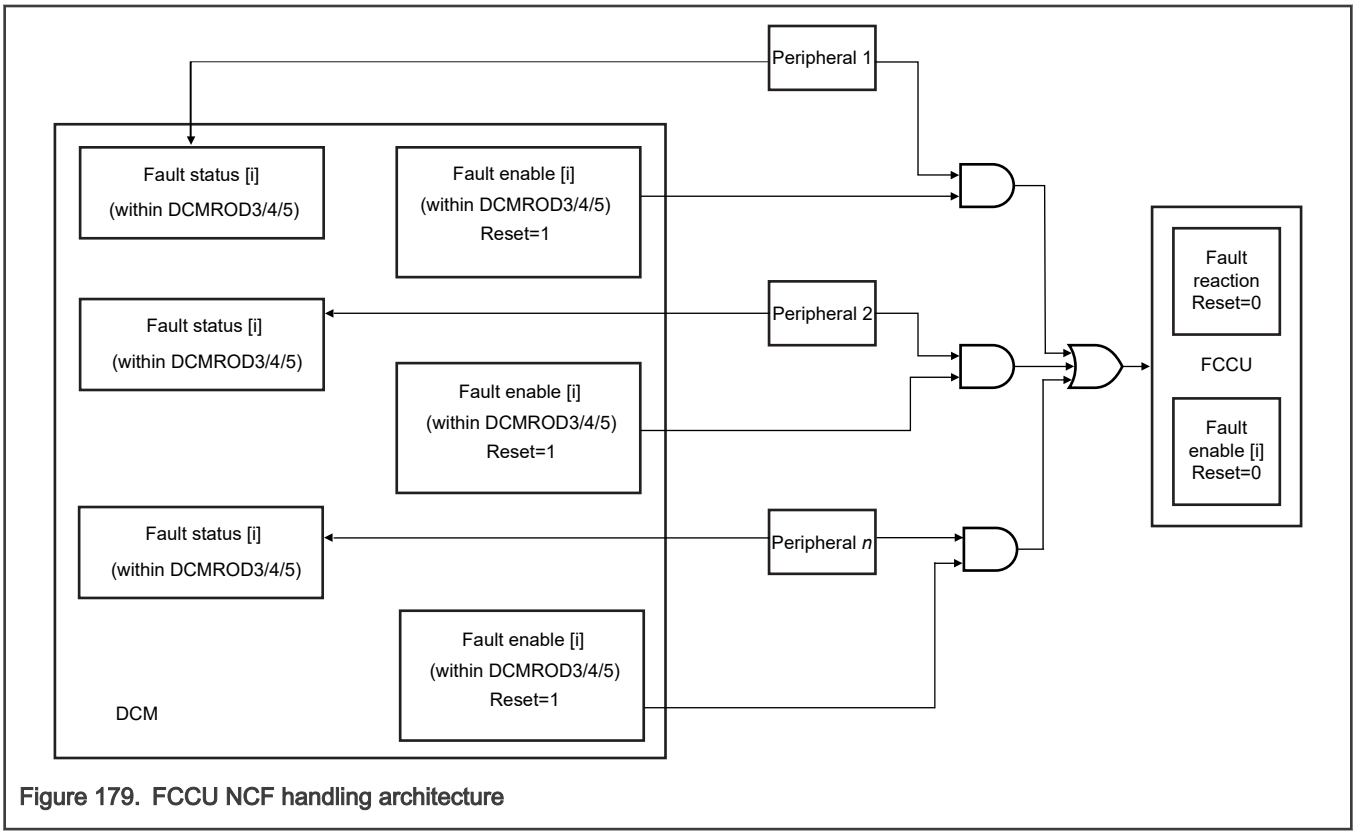

**Figure 179. FCCU NCF handling architecture**

## 49.2 Overview

The FCCU provides a hardware interface to collect faults and to place the device into a safe state when a failure is detected in the device. No CPU intervention is requested for collection and control operations. FCCU offers a systematic approach to fault collection and control.

### 49.2.1 Block diagram

The following figure represents a top-level diagram of the FCCU module.

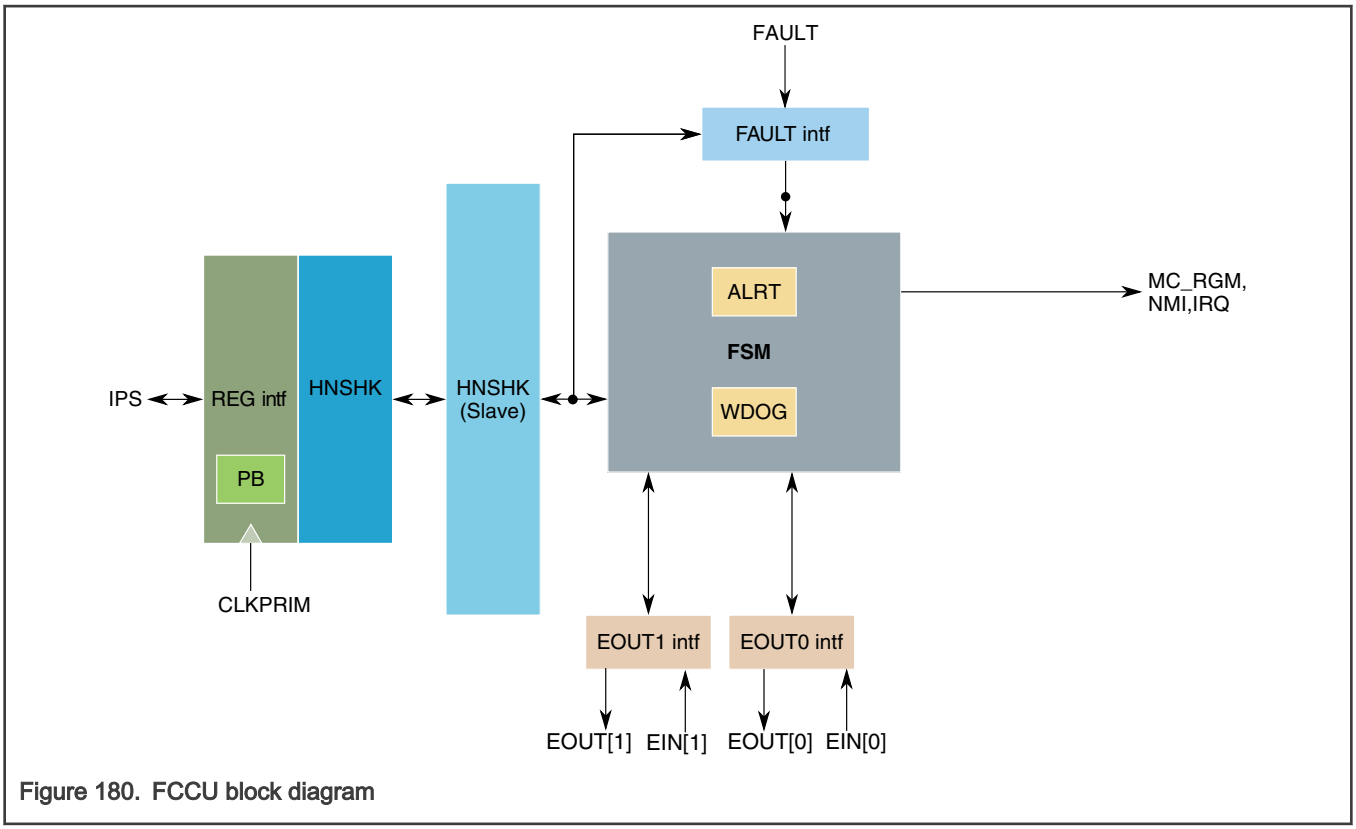

Figure 180. FCCU block diagram

This table describes the FCCU submodules.

Table 229. FCCU submodules

| Submodule | Description |
|---|---|
| REG intf | Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers |
| HNSHK blocks (master and slave blocks) | Includes the FSM ability to support the handshake between the REG interface and the FSM unit because of the usage of two asynchronous clocks [CLKPRIM(module clock) and CLKSAFE(RC oscillator clock)] |
| FSM unit | Implements the main functions of FCCU. The FSM also includes the:<br>• Watchdog timer (WDG)<br>• Alarm timer (ALRT) |
| FAULT intf | Implements the interface for fault conditioning and management |
| EOUTx units | Implement the output stage to manage the EOUT interfaces |

## 49.2.2 Features

The key features of the FCCU module are these:

- Management of non-critical faults
- HW or SW fault recovery management
- Fault collection from safety relevant modules on the device

- Fault injection (fake faults)
- Collection of test results
- Lockable configuration
  - Changes are only possible after entering the CONFIG state
  - Supports a transient and a permanent lock
  - Configuration changes observed by a watchdog timer
- Configurable fault control
- External reaction (FAULT state): EOUT signaling. Error indication via the pin(s) is controlled by FCCU.
- Internal chip reactions (ALARM state): interrupt request
- Configurable internal chip reactions for each NCF (FAULT state):
  - Short functional reset request pulse
  - NMI
  - No reaction
  - IRQ
- In Bi-Stable operational mode, one of the EOUT signals is high to indicate an OK operational state of FCCU.
- After power on, the EOUT signals have high impedance.[6] They indicate an operational state only after the software configures them.
- In case of a failure event or on software request for error pin indication, the pin(s) are set to faulty state for a minimum time $T_{min}$ (see DELTA_T[DELTA_T]), even if the software tries to release it before (for the case of error pin configured in Bi-Stable mode only).

The self-checking procedure checks the FCCU circuitry at the start up. The FCCU is operational with the default configuration immediately after the completion of the self-checking procedure. Internal (short functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable. The default configuration can be modified only in the Configuration (CONFIG) state. FCCU is designed to function when CLKPRIM is faster than the CLKSAFE clocks.

## 49.3 Functional description

### 49.3.1 Definitions

In general, the following definitions are applicable for fault management:

- HW recoverable fault: The fault indication is a level-sensitive signal that remains asserted until the fault cause is deasserted. That is, if logical 0 on the fault signal indicates fault, then the status flags are valid as long as the fault line stays at 0. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched external to the FCCU in the module where the fault occurred. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: The fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error sources by FCCU management SW, in case it is known that the fault is recoverable by itself when the fault condition is corrected.

For details related to reset interface, see the reset interface section in the chip reference manual.

### 49.3.2 FSM description

The functionality of FCCU is depicted by the FSM state diagram (see Figure 181).

[6] Actual value depends on device-specific setting at pad level.

FCCU has four states that are identified with the following meaning:

- CONFIG: Used only to modify the configuration of FCCU from its default. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, non-critical fault masking) can be accessed in write mode only in the CONFIG state.

  The CONFIG state is accessible only in the NORMAL state and if the configuration is not locked. A permanent configuration lock can be disabled by a reset that also resets the FCCU. The transient lock register is unlocked by writing BCh into it. FCCU gets transiently locked again if an invalid key is written into TRANS_LOCK[TRANSKEY] (that is, other than BCh). To lock FCCU for configuration, write FFh to PERMNT_LOCK[PERMNTKEY].

  After the release of reset, the state of the transient lock is locked, and the state of the permanent lock is unlocked.

  The locking feature only restricts the FSM movement into CONFIG state. After the user enters the CONFIG state and then tries to lock the configuration, the locking of configuration is effective only after FCCU moves to the NORMAL state; it will not be effective in the current CONFIG state.

  The CONFIG to NORMAL state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request for state change to NORMAL appears at the same time, watchdog timeout has the priority and hence the configuration registers (those that are writable only in the CONFIG state) are reset to their default values. The movement to the NORMAL state is made.

  The incoming faults, occurring during the configuration phase (CONFIG state) are latched in order to process them when FCCU is moved to the NORMAL state, according to the new configuration.

  All pending faults that occur during the CONFIG state result in both of the following:

  — Highest-priority state transition

  — Interrupt generation (NMI or alarm IRQ)

  If the state transition occurs, it gives the reset reaction corresponding to the worst case based on all the faults (pending or non-pending faults) that occurred during the CONFIG state.

- NORMAL: This is FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following state transitions occur on one of the following events:

  — Unmasked non-critical faults with the timeout disabled: FCCU moves to the FAULT state.

  — Unmasked non-critical faults with the timeout enabled: FCCU moves to the ALARM state.

  — Masked non-critical faults: FCCU stays in the NORMAL state.

- ALARM: FCCU moves into the ALARM state when an unmasked non-critical fault occurs and the timeout is enabled. Transition to the ALARM state goes along with an interrupt alarm, if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to the FAULT state. The timeout is reinitialized if FCCU enters the NORMAL state. The timeout restarts following the recovery from the FAULT state.
- FAULT: FCCU moves into the FAULT state when one of the following condition occurs:

  — Timeout related to a non-critical fault when FCCU is in the ALARM state

  — Unmasked non-critical faults with the timeout disabled

The transition from the NORMAL or ALARM to the FAULT state goes along with the generation of:

- Internal chip reaction—NMI interrupt (optional)
- External reaction—EOUT signaling (optional)
- Internal chip reaction—SW option: Soft reaction (Short functional reset request pulse if configured)
- Non Maskable Interrupt (NMI) is routed to all cores.

After moving to the FAULT state, if there is either a previous pending fault or a new fault for which NMI is enabled, NMI generation takes place.

Multiple faults can occur at the same time.

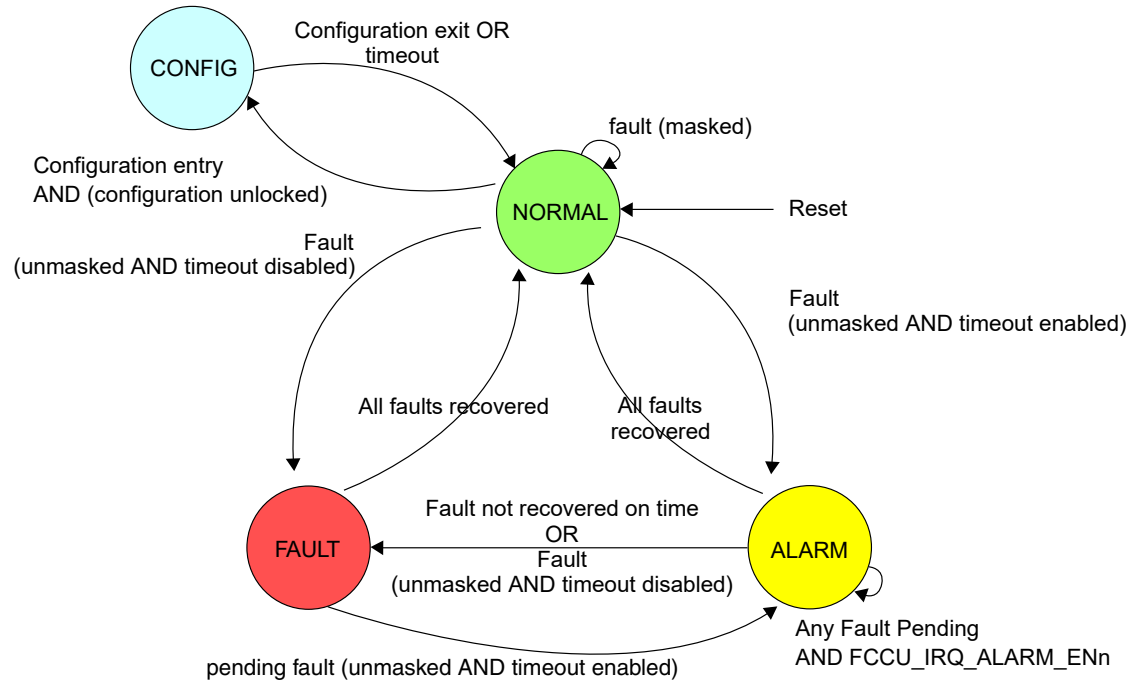

Figure 181. FCCU state diagram

### 49.3.3 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (non-critical) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a non-critical fault (unmasked and with timeout disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU remains in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU moves to the ALARM state (if any non-critical fault is still pending and the timeout is not elapsed).

In general, no fault nesting is supported except for the non-critical faults that cause an ALARM to FAULT state transition. In this case, the NCF timer is stopped until the FAULT state is recovered. If FCCU is in the ALARM state and another fault occurs, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

### 49.3.4 Fault recovery

The following timing diagrams describe the main use cases of FCCU in terms of fault events and related recovery.

A typical sequence related to non-critical fault management (ALARM state), see Figure 182 and Figure 183, is as follows:

1. Non-critical fault assertion
2. FCCU state transition (automatic): NORMAL to ALARM
   - Alarm interrupt request (if enabled)
   - Timeout running
3. System state: RUN
4. Alarm interrupt management: fault recovery

- FCCU state transition: ALARM to NORMAL

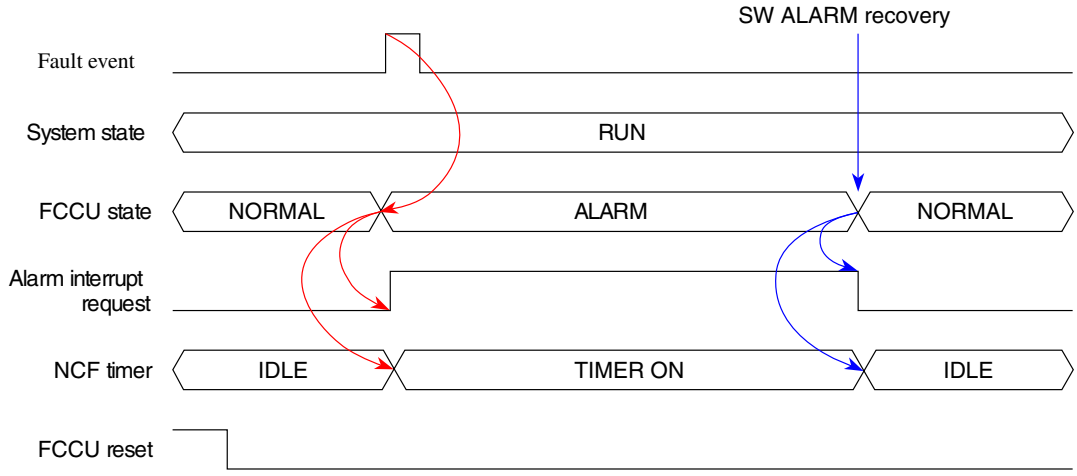

**Figure 182. Non-critical fault (ALARM state) SW recovery**

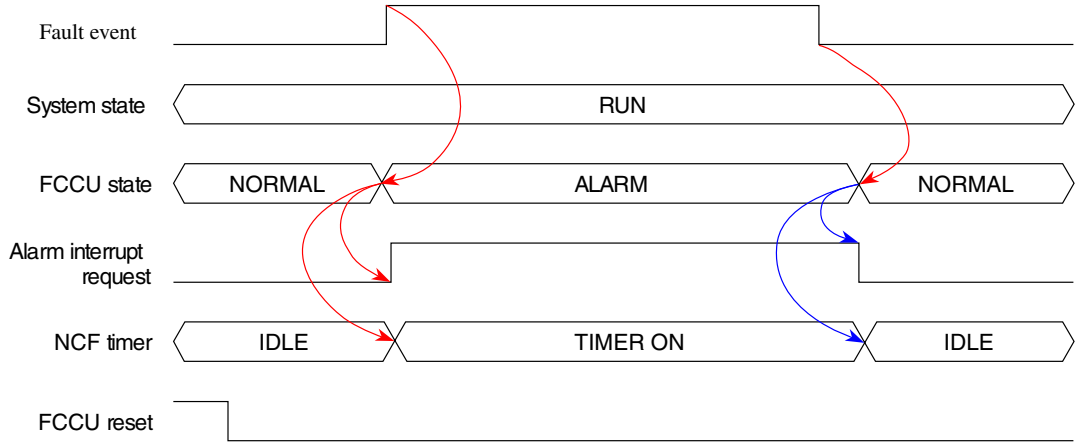

**Figure 183. Non-critical fault (ALARM state) HW recovery**

A typical sequence related to non-critical fault management (ALARM to FAULT state), see Figure 184, is as follows:

1. Non-critical fault assertion
2. FCCU state transition (automatic): NORMAL to ALARM
   - Alarm interrupt request (if enabled)
   - Timeout running
3. FCCU state transition (following the timeout trigger): ALARM to FAULT
   - NMI assertion (if enabled)
4. NMI interrupt management (if enabled)
   - Fault recovery (by software): FCCU state transition: FAULT to NORMAL

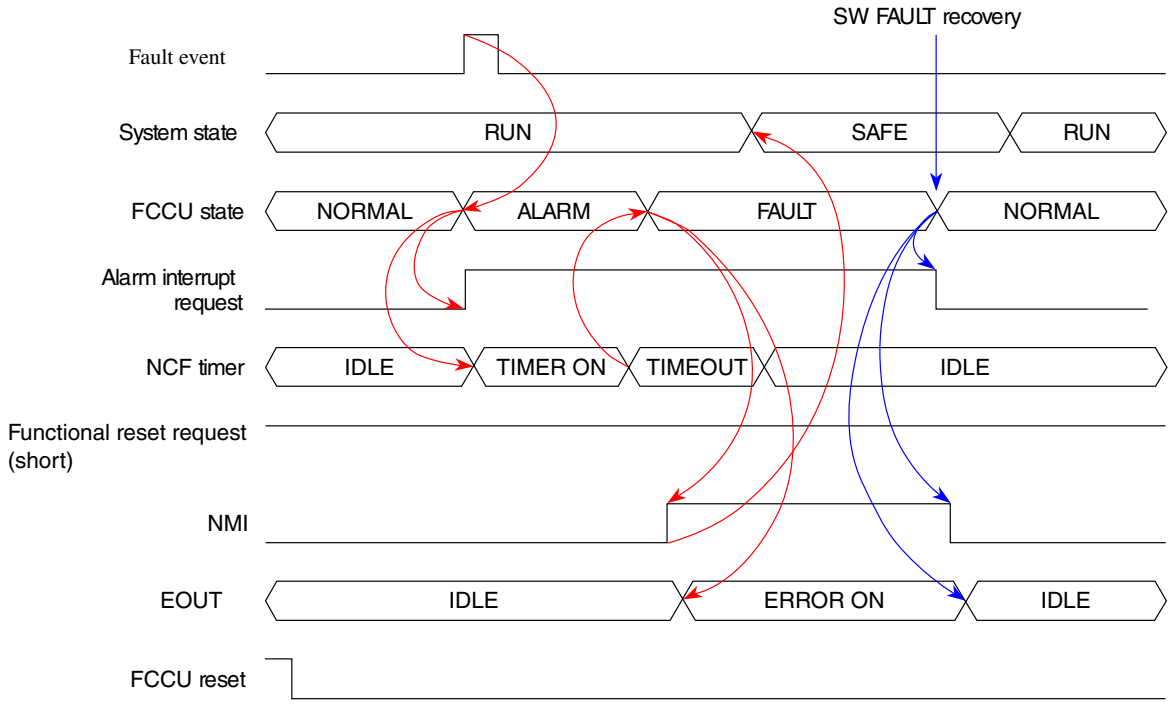

**Figure 184. Non-critical fault (ALARM to FAULT state) recovery**

## 49.3.5 EOUT interface

### Introduction

You use the EOUT[1:0] signals to indicate FCCU's condition to off-chip logic.

**NOTE**

For information on the availability and names of these FCCU signals on the boundary of this chip, see the chip-specific FCCU information.

### The FCCU conditions

There are three FCCU conditions:

| Condition | Description |
|---|---|
| Faulty | All of the following are true:<br>• The fault-output (EOUT) timer is running (see How the fault-output (EOUT) timer works in Bi-Stable fault-output mode).<br>• FCCU is in FAULT state. |
| Non-faulty | All of the following are true:<br>• The fault-output (EOUT) timer is not running.<br>• FCCU is in ALARM or NORMAL state. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Condition | Description |
|---|---|
| Configuration | All of the following are true:<br>• The fault-output (EOUT) timer is not running.<br>• FCCU is in CONFIG state. |

### How the fault-output (EOUT) timer works in Bi-Stable fault-output mode

In Bi-Stable fault-output mode (FOM), FCCU starts the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bi-Stable FOM, and the EOUT signals are not programmed to be always low (CFG[FCCU_SET_CLEAR]).
- The EOUT timer is not already running.
- FCCU enters the FAULT state as the result of a fault.

When the fault-output (EOUT) timer is already running and a new fault occurs:

- If FCCU is in the CONFIG state: FCCU does not restart the EOUT timer.
- If FCCU is in the NORMAL or ALARM state:
  - And ALARM state is enabled for the fault (non-critical): FCCU enters (or remains in) the ALARM state but does not restart the EOUT timer.
  - And ALARM state is disabled for the fault (non-critical): FCCU enters the FAULT state and restarts the EOUT timer.
- If FCCU is in the FAULT state: FCCU restarts the fault-output (EOUT) timer.

FCCU stops and reinitializes the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bi-Stable fault-output mode (CFG[FOM]), and $T_{min}$ (see DELTA_T[DELTA_T]) has expired.
- All faults that caused FCCU to enter or remain in the FAULT state since FCCU started the fault-output (EOUT) timer have been cleared, causing FCCU to return to the NORMAL state.

### Prepare the EOUT signals to indicate FCCU's condition

- If the EOUT signals are in Bi-Stable fault-output mode (CFG[FOM]), ensure that the EOUT signals are controlled by FCCU's FSM (CFG[FCCU_SET_CLEAR]).
- Ensure that the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]).

**NOTE**

If the EOUT signals are in Bi-Stable fault-output mode, you must deactivate and then reactivate the EOUT signals (CFG[FCCU_SET_AFTER_RESET]) to correctly initialize them so they have opposite states.

### More about the EOUT interface

Different fault-output modes (protocols) for the fault-output (EOUT) interface are supported (CFG[FOM]):

- Bi-Stable

**NOTE**

See the chip-specific FCCU information for the fault-output modes supported by this chip.

You can further configure the fault-output modes using the following attributes:

| Attribute | Field | Setting used in the example diagrams and tables that follow |
|---|---|---|
| Configuration mode | CFG[CM] | Different |
| Polarity selection | CFG[PS] | For the faulty indication, EOUT1 is high, and EOUT0 is low. |

**EOUT frequency:** This frequency is generated by dividing the CLKSAFE frequency by a fixed factor of $2^{18}$.

$$EOUT_{freq} = \frac{CLKSAFE_{freq}}{2^{18}}$$

For example, with a CLKSAFE frequency of 16 MHz, this drives a signal of 61 Hz on EOUT.

In case of a failure event or on software request for EOUT indication, the signal(s) are set to the faulty state for a minimum time ($T_{min}$), even if software tries to release it before. If software configures the error pins to OK(1), and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and the error signals indicate NOK, such as an incoming fault is not masked even when software has set the error signal to high. Also, if the error signals are forced to low by software by writing to CFG[FCCU_SET_CLEAR], then the signals shall remain low (or high) for the entire duration of $T_{min}$. During the $T_{min}$ by a non-software fault, the FCCU FSM moves independently of this signal state (low), and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in, and it is not possible to set the signals to OK by software moving FCCU to the CONFIG state, as long as this timer is running. No software intervention is needed to bring the signal from the low state.

Software can bring the pin back to OK state by clearing the faults and waiting for the $T_{min}$ interval to expire, after which the FCCU automatically enters the NORMAL state and the error signal indicates OK.

In case another failure event happens within $T_{min}$ after a first one, the $T_{min}$ counter is restarted.

#### 49.3.5.1 Bi-Stable protocol

The encoding scheme is provided in Table 230 and the related timing diagram is shown in Figure 185.

**Table 230. Bi-Stable encoding**

| Condition | EOUT[1:0] (CFG[PS] is 0) | EOUT[1:0] (CFG[PS] is 1) |
|---|---|---|
| Non-faulty | Static 01 | Static 10 |
| Faulty | Static 10 | Static 01 |
| Reset | High-impedance (no toggling)[1] | High-impedance (no toggling) |
| Configuration (CFG[CM] is 1 and CFG[FCCU_SET_AFTER_RESET] is 0) | High-impedance (no toggling)[2] | High-impedance (no toggling) |
| Configuration (When CFG[CM] is 1 and CFG[FCCU_SET_AFTER_RESET] is 1) | Static 01 | Static 10 |

1. Final value depends on device specific settings at pad level.
2. Ensure that the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]); otherwise, the EOUT signals stay in a high-impedance state after reset lifts.

**NOTE**

Figure 185 is formatted to display the behavior in all four conditions (reset, non-faulty, faulty, and configuration), not to imply transitions between one condition and another. In particular, a transition from the faulty condition to the configuration condition is not possible.

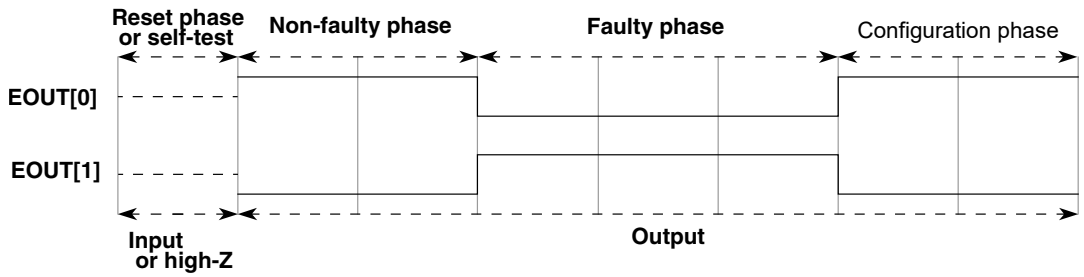

Figure 185. Bi-Stable protocol

## 49.3.6 Modes of operation

### 49.3.6.1 Put FCCU in the NORMAL state

#### 49.3.6.1.1 Introduction

You put FCCU in the NORMAL state to save changes to the configuration, and to allow FCCU to enter the ALARM or FAULT state when a fault occurs on an enabled fault channel.

#### 49.3.6.1.2 About putting FCCU in NORMAL state

When putting FCCU in the NORMAL state:

- If you attempt to lock the configuration while FCCU is in CONFIG state, FCCU does not actually lock the configuration until FCCU leaves CONFIG state—that is, either you put FCCU in the NORMAL state, or FCCU puts itself in the NORMAL state because the Configuration-state timeout interval (CFG_TO[TO]) expires.
- After you permanently lock the configuration, you must reset FCCU before you can put FCCU in the CONFIG state.

#### 49.3.6.1.3 Put FCCU in the NORMAL state

1. Check the FCCU status (STAT[STATUS]).
   - If the FCCU status is NORMAL, go to step 6.
   - If the FCCU status is CONFIG, go to step 2.
   - If the FCCU status is ALARM or FAULT, go to step 4.
2. Run the OP2 operation (see Run an operation).
3. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, FCCU is in the NORMAL state. Go to step 6.
   - If the operation status is Aborted, go to step 2.
4. Recover all faults (see Fault recovery).
5. Go to step 1.
6. Lock the configuration if you want to prevent any changes to it:
   - To require a key to unlock the configuration, from Supervisor mode, temporarily lock the configuration (TRANS_LOCK[TRANSKEY]).

- To require a reset of FCCU to unlock the configuration, from Supervisor mode, permanently lock the configuration (PERMNT_LOCK[PERMNTKEY]).

  The configuration is permanently locked until FCCU is reset.

#### 49.3.6.2 Manage faults

##### 49.3.6.2.1 Introduction

After saving changes to the configuration, you are ready to use FCCU to manage faults.

##### 49.3.6.2.2 Determine if there are any unrecovered non-critical faults

Check the unrecovered-fault indicators for the non-critical faults (NCF_Sa[NCFSn]).

##### 49.3.6.2.3 Recover a software-recoverable non-critical fault

1. Resolve the source of the software-recoverable non-critical fault.
2. Unlock the NCF_Sa registers (NCFK[NCFK]) using a 32-bit write.
3. Initiate clearing of the unrecovered-fault indicator for the software-recoverable non-critical fault (NCF_Sa[NCFSn]) using a 32-bit write.

   FCCU initiates the OP12 operation.

   **NOTE**

   If you want to clear multiple unrecovered-fault indicators and those indicators reside in different NCF_Sa registers, you must perform steps 2 and 3 for each individual register.

4. Check the operation status (CTRL[OPS]).
   - If the operation status is In Progress, go to step 4.
   - If the operation status is Successful, go to step 5.
   - If the operation status is Aborted, go to step 2.
5. Check the unrecovered-fault indicator for the software-recoverable non-critical fault (NCF_Sa[NCFSn]).
   - If the indicator indicates no unrecovered fault, the fault has been recovered. Stop.
   - If the indicator still indicates an unrecovered fault, go to step 2.

##### 49.3.6.2.4 Clear the freeze-status indicators

1. Run the OP13 operation (see Run an operation).
2. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, stop .
   - If the operation status is Aborted, go to step 1.

#### 49.3.6.3 Run operations

##### 49.3.6.3.1 Introduction

You run operations to perform actions such as putting FCCU in the CONFIG state or setting the operation status to Idle. For a complete list of operations you can run, see CTRL[OPR].

#### 49.3.6.3.2 About running operations

When running operations:

- FCCU ignores any operations initiated while the operation status is In Progress.
- Certain operations must be unlocked before you can initiate them. After you initiate them, they are locked again.

#### 49.3.6.3.3 Run an operation

1. Check the operation status (CTRL[OPS]).
2. Go to step 1 if the operation status is In Progress.
3. Unlock the operation (CTRLK[CTRLK]) using a 32-bit write, if the operation must be unlocked before you can initiate it.

   **NOTE**

   The Control Key (CTRLK) register used in this step and the Control (CTRL) register used in the next step must be written with consecutive instructions. Do not use read-modify-write instructions, such as bit-field instructions, to modify these registers.

4. Initiate the operation (CTRL[OPR]) using a 32-bit write.
5. Check the operation status (CTRL[OPS]).
6. Go to step 5 if the operation status is In Progress.

The operation status is now Idle (OP15 only), Aborted, or Successful.

### 49.3.7 FOSU

The FOSU provides a supervision of the primary fault notification path by analyzing FCCU's behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after a fault is signaled.

The intention of the FOSU is to provide a secondary fault reaction path in most cases when the FCCU fails but not to needlessly propagate a fault which is already handled by the FCCU in a full chip reset. Only a failed primary fault reaction (that is, FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from FCCU which indicates that the FCCU is programmed for no reaction for ALL FAULTS. It is a "static" input in the sense that it does not change after FCCU configuration. The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted (that is, a disabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during the CONFIG state.

The FOSU contains a timer with a duration of FOSU_COUNT, driven by CLKSAFE. The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FOSU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: short functional reset
- IRQ (triggered by ALARM state)
- NMI
- Error out triggered (by FCCU or by SW)

When the timer is stopped, the fault capture logic is cleared to ensure that the timer is not restarted because of faults still 'stuck' in the capture logic. The timer is then restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static "fccu program to do nothing" signal is deasserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.

The FOSU's failure indicator output is connected to one of the MC_RGM's 'destructive' reset inputs, so its assertion will cause a reset sequence to be initiated starting at DEST0. The FOSU module is reset with the same reset as is used by the FCCU. When

this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

**NOTE**

FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times out without reaction.

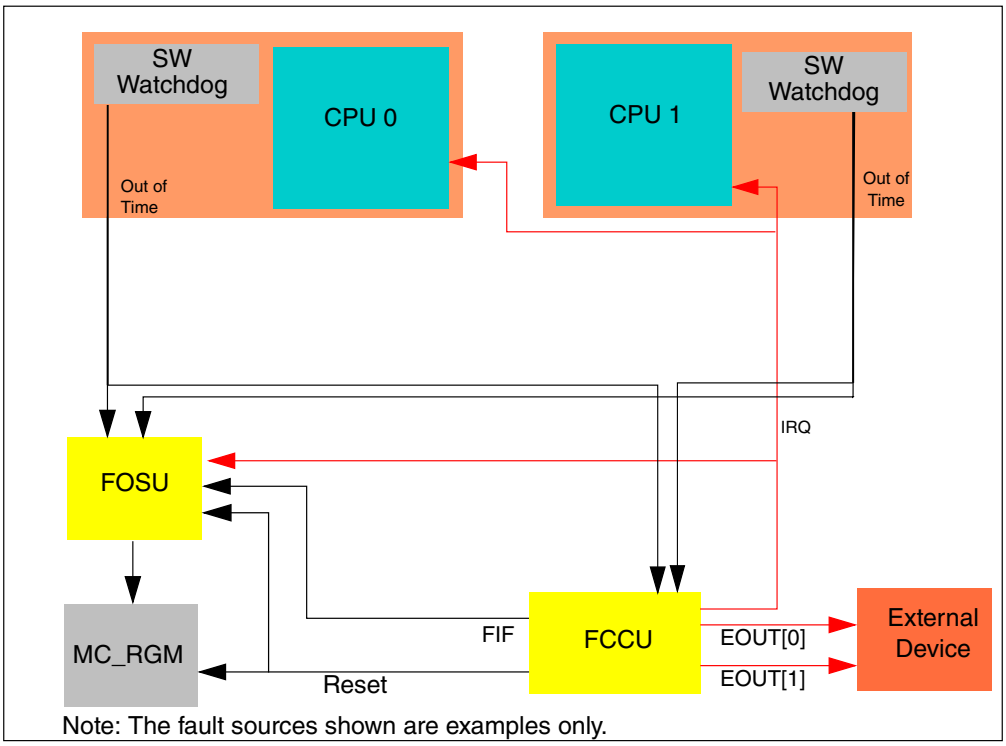

**Figure 186. FOSU connections to the FCCU and MC_RGM**

### 49.3.8 Clocking

This module has no clocking considerations.

### 49.3.9 Interrupts

This module has no interrupts.

## 49.4 External signals

FCCU interfaces with the EOUT pin. Signaling on the EOUT pin depends on whether the module is processing an error or is idle.

## 49.5 Initialization

### 49.5.1 Prepare FCCU for configuration

#### 49.5.1.1 Introduction

You prepare FCCU for configuration by first configuring the CONFIG state and then putting FCCU in that state.

#### 49.5.1.2 About preparing FCCU for configuration

When preparing FCCU for configuration, keep the following in mind:

- To put FCCU in CONFIG state, FCCU must be in NORMAL state.
- After FCCU is reset, the configuration is temporarily locked. You must temporarily unlock the configuration before you can put FCCU in the CONFIG state.
- When FCCU is in the CONFIG state, FCCU does not actually save the changes you make to the configuration. To save changes to the configuration, you must manually put FCCU in the NORMAL state. If FCCU automatically leaves the CONFIG state and enters the NORMAL state because the Configuration-state timeout interval (CFG_TO[TO]) expires (called a Configuration-state timeout), FCCU changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. FCCU also changes the value of the Configuration-State Timeout Interval (CFG_TO) register to its reset value. For information on the Configuration-state timeout value, see CFG register bit value at different events. For a list of configuration registers, see Configuration registers.

#### 49.5.1.3 Configure the CONFIG state

1. Set the Configuration-state timeout interval (CFG_TO[TO]).
2. Enable the Configuration-state-timeout interrupt signal (IRQ_EN[CFG_TO_IEN]), if you want FCCU to request an interrupt when a Configuration-state timeout occurs.

#### 49.5.1.4 Put FCCU in the CONFIG state

1. Unlock the configuration temporarily (TRANS_LOCK[TRANSKEY]) in Supervisor mode.
2. Check the FCCU status (STAT[STATUS]).
   - If the FCCU status is CONFIG, FCCU is in the CONFIG state. Stop.
   - If the FCCU status is NORMAL, go to step 3.
   - If the FCCU status is ALARM or FAULT, go to step 5.
3. Run the OP1 operation (see Run an operation).
4. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, FCCU is in the CONFIG state. Stop.
   - If the operation status is Aborted, the configuration is probably permanently locked. Go to step 7.
5. Recover all faults (see Fault recovery).
6. Go to step 2.
7. Reset FCCU.

### 49.5.2 Configure FCCU

#### 49.5.2.1 Introduction

You configure FCCU so it functions according to the needs of your particular application.

#### 49.5.2.2 About configuring FCCU

When configuring FCCU:

- If you enable a non-critical fault channel but disable all reactions for that channel, FCCU changes state when necessary but does not perform any reaction because reactions are disabled. If you enable reactions for a non-critical fault channel but disable that channel, and FCCU is in the NORMAL state when a fault occurs on the channel, FCCU does not enter the ALARM or FAULT state and therefore does not perform any reaction.

#### 49.5.2.3 Configure the non-critical fault channels

For each non-critical fault channel that you want FCCU to monitor:

1. Set the recovery type (NCF_CFGa[NCFCn]).
2. Enable at least one type of Fault-state reaction:
   - Chip functional reset (NCFS_CFGa[NCFSCn])
   - Non-maskable interrupt (NMI_ENa[NMIENn])
   - EOUT signaling (EOUT_SIG_ENa[EOUTENn])

   **NOTE**

   If you enable the chip functional reset as the type of Fault-state reaction for a channel, enable at least one other type of Fault-state reaction for the channel or enable the ALARM state (step 4) for the channel.
3. Set the Alarm-state timeout interval (NCF_TO[TO]), if you plan to enable the ALARM state for any non-critical fault channel.

   **NOTE**

   Ensure that the Alarm-state timeout interval is less than the FOSU module's timeout interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timeout interval (FOSU_COUNT) is a chip-specific value. See the chip-specific FCCU information.
4. Enable the ALARM state (NCF_TOEa[NCFTOEn]) for any non-critical fault channel for which you want FCCU to enter the ALARM state before entering the FAULT state.
5. Enable the Alarm-state reaction (IRQ_ALARM_ENa[IRQENn]) for each non-critical fault channel for which you enabled the ALARM state.
6. Enable the corresponding NCF_Ea[NCFEn] field for each non-critical fault channel that you want FCCU to monitor.

## 49.6 Application information

### 49.6.1 Use cases and limitations

#### Configuration guidelines

Follow these guidelines to configure FCCU:

- If you want FCCU to react to a fault on a non-critical fault channel:
  - Enable the channel (Non-critical Fault Enable (NCF_E0)).
  - Enable at least one type of Fault-state reaction for the channel: chip reset (Non-critical Fault-State Configuration (NCFS_CFG0)), fault-output (EOUT) signaling (Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0)), or non-maskable interrupt (Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0)).
  - If you enable chip reset as the type of Fault-state reaction for the channel (Non-critical Fault-State Configuration (NCFS_CFG0)), enable either ALARM state (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)) or at least one other type of Fault-state reaction for the channel: fault-output (EOUT) signaling (Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0)) or non-maskable interrupt (Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0)).
  - If you enable ALARM state for the channel (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)), enable the Alarm-state reaction (Non-critical Alarm-State Interrupt-Request Enable (IRQ_ALARM_EN0)).
  - If you enable ALARM state for the channel (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)), make sure the Alarm-state timer interval (Non-critical-Fault Alarm-State Timeout Interval (NCF_TO)) is less than the FOSU module's timer interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timer interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information.

**Recommendations to configure FCCU**

1. After a power on, or 'destructive' reset (when initiated by the assertion of the chip reset pin, RESET_B), where both system and FCCU are reset, the following steps could be followed to configure FCCU:
    a. Check and clear any pending fault status
    b. Verify FCCU is in NORMAL state, else repeat step(a) above
    c. Configure FCCU
2. After any 'functional' reset of the system, arising out of a reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
    a. If active, wait for the Error out $T_{min}$ to expire
    b. Check and clear fault status
    c. Error pin moves to "non faulty" state, once fault status is cleared and $T_{min}$ expires
    d. Verify FCCU is in NORMAL state, else repeat step(a) above
    e. Read and verify value in NCF_En
    f. Reconfigure FCCU, if necessary

## 49.7 Register descriptions

### 49.7.1 FCCU register descriptions

The FCCU registers are listed in the table below. Any address offset not explicitly mentioned in this table is reserved.

The FCCU supports word (32-bit), half-word (16-bit), and byte (8-bit) read and write accesses.

Follow these register-access guidelines:

- Do not read from or write to any addresses that are not shown in the following table. Doing so may or may not result in a transfer error.
- Do not write to any of the configuration registers unless FCCU is in the CONFIG state. Doing so results in a transfer error.
- Do not write to the Transient Configuration Lock (TRANS_LOCK) or Permanent Configuration Lock (PERMNT_LOCK) registers unless your code runs in the Supervisor mode. Doing so results in a transfer error.

For each possible NCF failure source, a different reaction—including no reaction—is configurable through the use of NMI, IRQ, and short reset selection registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

#### 49.7.1.1 FCCU memory map

FCCU base address: 4038_4000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Control (CTRL) | 32 | RW | 0000_00C0h |
| 4h | Control Key (CTRLK) | 32 | W | 0000_0000h |
| 8h | Configuration (CFG) | 32 | RW | 0000_0000h |
| 1Ch | Non-critical Fault Configuration (NCF_CFG0) | 32 | RW | 0000_00FFh |

*Table continues on the next page...*

*Table continued from the previous page...*

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|

**Fields**

| Field | Function |
|---|---|
| 31-0<br>CTRLK | Locked-Operation Control Key<br>Writable only with a 32-bit write. Unlocks locked operations (CTRL[OPR]) so you can initiate them. For information on how to unlock locked operations before you initiate them, see Run an operation.<br>**NOTE**<br>• You must initiate an operation in the FCCU register access that immediately follows the one that unlocks it; otherwise, the operation is again locked.<br>• Reading from this register always returns the value 0000_0000h.<br>Operations not listed here are not locked and do not need to be unlocked.<br>9137_56AFh: Unlock OP1.<br>825A_132Bh: Unlock OP2.<br>Any other value: Do nothing. |

### 49.7.1.4 Configuration (CFG)

**Offset**

| Register | Offset |
|---|---|
| CFG | 8h |

**Function**

Writable only when FCCU is in the CONFIG state. Changed by FCCU to another value when the chip resets FCCU, a Configuration-state timeout occurs, or you run an OP31 operation. See CFG register bit value at different events for more information. Specifies the global configuration for FCCU.

**NOTE**

If you specify a new value for any of the fields in this register that affect the EOUT signals while the fault-output (EOUT) timer is running (FCCU is indicating a fault on the EOUT signals), FCCU does not use the new settings you specified until after the fault-output (EOUT) timer expires (FCCU stops indicating a fault on the EOUT signals).

|---|---|
| 31-0<br>TO | Non-critical-Fault Alarm-State Timeout Interval<br>Writable only when FCCU is in the CONFIG state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Controls the maximum amount of time that FCCU can be in the ALARM state ($T_{Max\ Alarm}$) according to this equation:<br>$T_{Max\ Alarm} = TO \times T_{CLKSAFE}$<br>where $T_{CLKSAFE}$ is the safe-clock period.<br>If FCCU enters the ALARM state (because a fault occurs on an enabled non-critical fault channel for which the ALARM state is enabled) and this timeout interval expires (called an Alarm-state timeout), then FCCU leaves the ALARM state and enters the FAULT state.<br>**NOTE**<br>Make sure the Alarm-state timeout interval is less than the FOSU module's timeout interval; otherwise, a fault that occurs while FCCU is in the ALARM state can cause FOSU to generate a chip reset. The FOSU timeout interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information. |

## 49.7.1.12 Configuration-State Timeout Interval (CFG_TO)

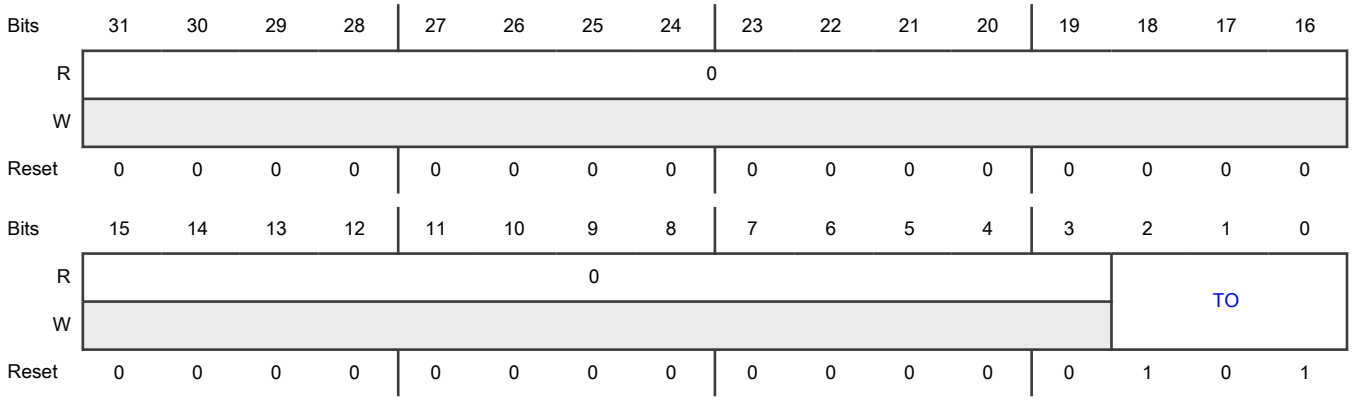
### Offset

| Register | Offset |
|---|---|
| CFG_TO | B8h |

### Function

See CFG_TO[TO]

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-3<br>— | Reserved |
| 2-0<br>TO | Configuration-State Timeout Interval<br>Writable only when FCCU is in the NORMAL, ALARM, or FAULT state (not in the CONFIG state). Changed by FCCU to its reset value when a Configuration-state timeout occurs. Not accessible while a Configuration-state timeout (OP14 operation) is in progress. Controls the maximum amount of time that FCCU can be in the CONFIG state ($T_{\text{Max configuration}}$) according to this equation:<br>$T_{\text{Max configuration}} = T_{\text{CLKSAFE}} \times 2^{(\text{TO} + 13)}$<br>where $T_{\text{CLKSAFE}}$ is the safe-clock period.<br>If you put FCCU in the CONFIG state and this timeout interval expires (called a Configuration-state timeout), then FCCU:<br>• Automatically leaves the CONFIG state and enters the NORMAL state<br>• Changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration (CFG) register's Configuration-state-timeout value, see CFG register bit value at different events. For a list of configuration registers, see Configuration registers. |

## 49.7.1.13 IO Control (EINOUT)

### Offset

| Register | Offset |
|---|---|
| EINOUT | BCh |

### Function

The EINOUT register allows the following operations typically in the NORMAL state:

- To control the EOUT[1] output level when the FCCU is configured in "Test1" or "Test0" fault output mode (CFG[FOM])

- To control the EOUT[0] output level when the FCCU is configured in "Test1" or "Test2" fault output mode (CFG[FOM])
- to observe the state of signals at EIN[1:0] pins

The following table shows Bi-Stable encoding.

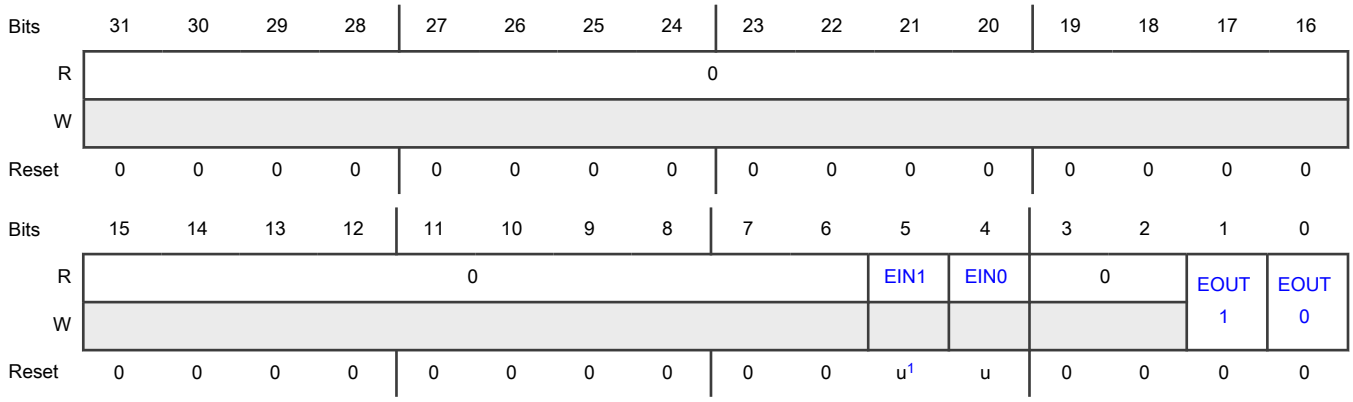
**Table 231. Bi-Stable encoding**

| Mode = CFG[FOM] | EOUT[0] | EOUT[1] |
|---|---|---|
| Test1 | output | output |
| Test2 | output | input |
| Test0 | input | output |

**NOTE**

Because of the resynchronization stage of the EOUT interface, there is a latency of a few CLKSAFE cycles following a write/read operation of the EINOUT register.

### Diagram



1. Reset value varies as per the corresponding EIN signal.

## 49.7.1.19 Non-critical Fault Fake (NCFF)

### Offset

| Register | Offset |
|---|---|
| NCFF | DCh |

### Function

This register contains a unique code to set a non-critical fault in mutually exclusive mode by the external FAULT interface (signal setting). It allows the SW emulation of the non-critical faults, by injecting the fault directly in the FAULT root, to verify the entire path and reaction. The reaction following a fake non-critical fault cannot be masked.

This is a write-only register with a set of codes corresponding to each non-critical fault injection.

### Diagram

## 49.7.1.20 IRQ Status (IRQ_STAT)

### Offset

| Register | Offset |
|---|---|
| IRQ_STAT | E0h |

### Function

This register provides the FCCU interrupt status related to the following events:

- Configuration-state timeout error
- Alarm interrupt
- NMI interrupt

The configuration-state timeout interrupt is asserted if both IRQ_STAT[CFG_TO_STAT] and IRQ_EN[CFG_TO_IEN] bits are asserted. It is cleared when a 1 is written to the IRQ_STAT[CFG_TO_STAT] bit.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the IRQ_STAT trace the status of the related interrupt lines.

### Diagram

## 49.7.1.30 Fault-Output Timer (TMR_ETMR)

### Offset

| Register | Offset |
|---|---|
| TMR_ETMR | 138h |

### Function

See TMR_ETMR[COUNT].

This table shows how the fault-output timer's state and value vary by FCCU state:

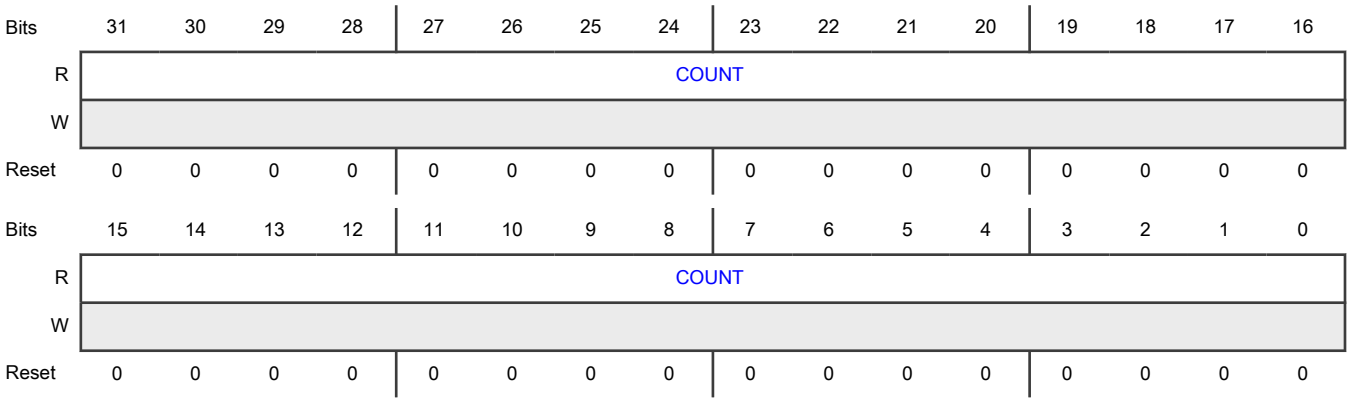
| FCCU state | Timer state (value) |
|---|---|
| CONFIG | Idle (0000_0000h) |

*Table continues on the next page...*

*Table continued from the previous page...*

| FCCU state | Timer state (value) |
|---|---|
| NORMAL | Idle (0000_0000h) |
| ALARM | Idle (0000_0000h) |
| FAULT | Running (value when read. It is an up-counter which rollbacks to zero after reaching maximum value and then it begins counting again.) |

**Diagram**



**Fields**

| Field | Function |
|---|---|
| 31-0<br>COUNT | Fault-Output Timer Count<br>Specifies the value of the fault-output timer in CLKSAFE periods. |

## 49.7.2 Configuration registers

### 49.7.2.1 Definition

*Configuration registers* are registers that:

- Let you configure FCCU's Alarm-state timer interval, fault channels, and fault-output (EOUT) signals.
- You can write to only when the configuration is not locked and FCCU is in CONFIG state (see Put FCCU in the CONFIG state).
- Save the values you write to them while FCCU is in CONFIG state only after you manually put FCCU in NORMAL state. If FCCU automatically leaves CONFIG state and enters NORMAL state because the configuration-timer interval (CFG_TO[TO]) expires (called a Configuration-state timeout), FCCU changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value; FCCU also changes the value of the Configuration-State Timeout Interval (CFG_TO) register to its reset value. For information on the Configuration-state timeout value, see CFG register bit value at different events.

### 49.7.2.2 Configuration registers

Following is the list of configuration registers in this module. They are listed in an offset order from lowest to highest.

- Configuration (CFG)
- Non-critical Fault Configuration (NCF_CFGa)
- Non-critical Fault-State Configuration (NCFS_CFG0)
- Non-critical Fault Enable (NCF_E0)
- Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)
- Non-critical-Fault Alarm-State Timeout Interval (NCF_TO)
- Delta T (DELTA_T)
- Non-critical Alarm-State Interrupt-Request Enable (IRQ_ALARM_EN0)
- Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0)
- Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0)

### 49.7.3 CFG register bit value at different events

In this chip, there are no events that affect the bits in the configuration register.

## 49.8 Glossary

| | |
|---|---|
| **CF** | Critical fault |
| **EOUT** | Error out |
| **FOSU** | FCCU output supervision unit |
| **FSM** | Finite state machine |
| **intf** | Interface |
| **IRQ** | Interrupt request |
| **NCF** | Non-critical fault |
| **NMI** | Non-maskable interrupt |

# Chapter 50
# Self-test General-Purpose Registers (SELFTEST_GPR)

## 50.1 Introduction

SELFTEST_GPR configures the STCU2 LBIST shift cycles. Programming self-test GPRs is a part of the self-test programming sequence. See the "Self-test programming sequence" section in the STCU2 chapter.

NXP supports only STCU2 Built-In Self-Test (BIST) sequences that have been validated by NXP for in-field testing usage.

The detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative).

The values for SELFTEST_GPR registers must be aligned with the NXP supported configurations only.

**NOTE**

SELFTEST_GPR is not present in MCXE315/MCXE316 and MCXE317.

**NOTE**

While accessing SELFTEST_GPR space, software must ensure that the STCU2 block has its clock enabled, i.e., MC_ME.PRTN1_COFB3_CLKEN[REQ104] configured as 1'b1. Not ensuring this might result in unpredictable device behaviour.

## 50.2 Peripheral shift clock switching (PCS)

The PCS feature is used to avoid current surges at the start and/or end of LBIST. Since LBIST can cause sudden current surges which might lead to chip malfunction.

With PCS enabled, there are additional (SELFTEST_GPR.CONFIG_GPR[PCS_STEP_SIZE] + 1)*16 patterns beyond the configured count. If enabled at the start of LBIST (using SELFTEST_GPR.CONFIG_GPR[PCS_ENABLE_START]), it would cause the shift clock to scale up in this duration from divide by 16 to the original frequency (by changing divider in each step).

Similarly, if configured at the end of LBIST (using SELFTEST_GPR.CONFIG_GPR[PCS_ENABLE_END]), the shift clock frequency will be scaled down from original frequency to divide by 16.

## 50.3 SELFTEST_GPR register descriptions

### 50.3.1 SELFTEST_GPR memory map

SELFTEST.SELFTEST base address: 403B_0000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Configuration register (CONFIG_REG) | 32 | RW | 0000_ADD5h |
| 14h | LBIST Program (LBIST_PROG_REG) | 32 | RW | 0003_0050h |

## 50.3.2 Configuration register (CONFIG_REG)

### Offset

| Register | Offset |

### 50.3.3 LBIST Program (LBIST_PROG_REG)

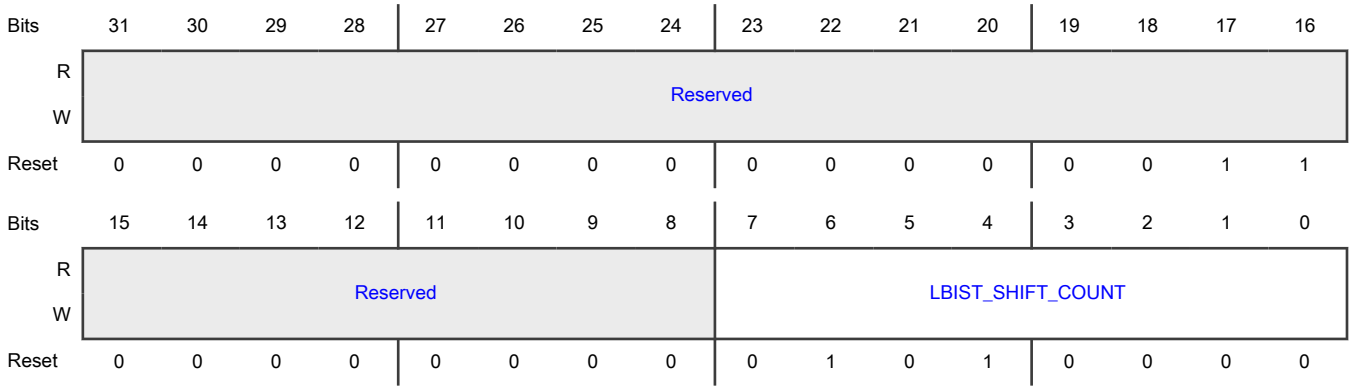
#### Offset

| Register | Offset |
|---|---|
| LBIST_PROG_REG | 14h |

#### Function

Configures the LBIST shift count.

#### Diagram



#### Fields

| Field | Function |
|---|---|
| 31-8<br>— | Reserved |
| 7-0<br>LBIST_SHIFT_COUNT | LBIST Shift Count<br>Specifies the number of shift cycles in a scan chain in one pattern count for the LBIST partition. |

## 50.4 Glossary

| | |
|---|---|
| **BIST clock** | The BIST clock refers to the BIST operational clock which is the clock source used while LBIST is operational by the LBIST controller, which is the MC_CGM clock node LBIST_CLK for the chip. See the system block diagram for details. |
| **LBIST** | Logic built-in self-test |
| **Pattern count** | The pattern count refers to an empirically determined value of shift patterns run in LBIST on a scan chain to result in predetermined fault coverage, based on device safety integrity level. Since the LBIST scheme is Pseudo Random Testing, a sufficiently good value of pattern count is used which provides the required fault coverage. |
| **Scan chain** | A sequential chain of flops in scan mode over which one scan pattern (generated by PRPG, that is, Pseudo Random Pattern Generator) in LBIST will be shifted and the output MISR (Multi Input Signature Register) will be matched with earlier known value to determine pass or fail criterion of that particular chain. |

# Chapter 51
# Self-Test Control Unit (STCU2)

## 51.1 Chip-specific STCU2 information

### 51.1.1 Supported BIST sequences

This chip supports only STCU2 BIST sequences that NXP has validated for in-field testing usage. The detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative for this information).

### 51.1.2 Self-test overview

STCU2 provides the overall control of both LBIST and MBIST, in serial or parallel, depending on the power, timing, or coverage constraints.

**NOTE**

LBIST is not available for MCXE317 and MCXE315/MCXE316

The application software initiates the self-test sequence or procedure (please use whichever term is correct), and has provisions to bypass the self-test configuration to directly move to normal Run mode.

There is a programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence. In case the selected LBISTs or MBISTs are not complete during the assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into ERR_STAT[WDTOSW] and MBESWx or LBESW.

The STCU2 execution includes three phases:

- Software configuration. Load or program the test configuration parameters to be executed, depending on SIL target and performance requirements. The self-test configuration parameters allow the self-test sequence to run with different times depending on pattern numbers and types, achieving different levels of coverage.
- Start of BIST execution. This involves software register configuration in STCU2. The BIST completion is followed by a functional reset.
- End of BIST execution. After BIST execution and functional reset are complete, the BIST results are made available and you decide how to continue (trigger a new reset or start a safety application). The BIST execution completion is signalized in an internal STCU2 register (LBESWn) bit which is not affected by the functional reset. The BIST test results are also not affected by the functional reset.

The following figure shows a pictorial representation of two LBIST partitions having two and one MBIST groups, respectively. STCU2 interacts with LBIST_CTRL for the respective partitions to configure and control the LBIST sequence and compare results. It also interacts with MTR controller (MCT) for MBIST. Each LBIST partition has its corresponding controller whereas a single MCT can cater to multiple MBIST groups.

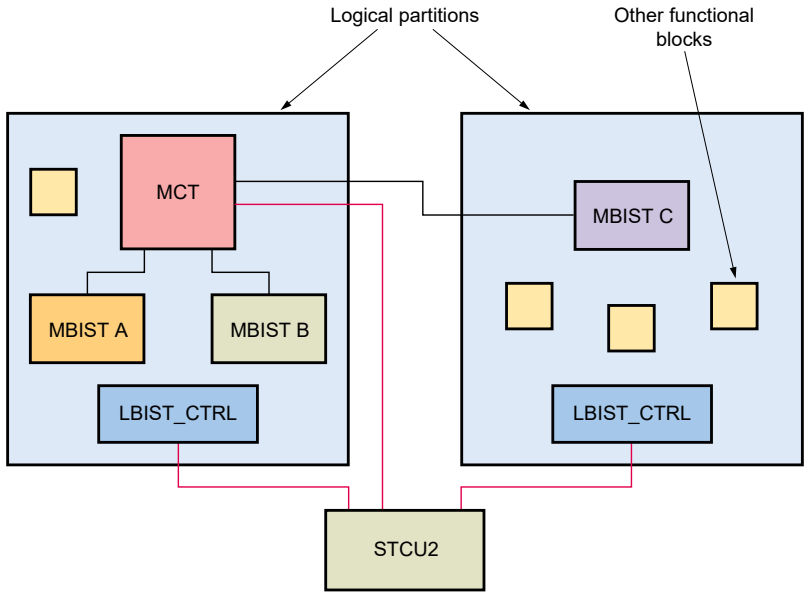


Figure 187. Self-test overview

**NOTE**

LBIST_CTRL is not available for MCXE317 and MCXE315/MCXE316.

Each LBIST partition also includes a block called Self-test GPR involving a set of registers that provide miscellaneous configuration and parameter details for an LBIST operation.

When you trigger a self-test sequence, the chip becomes unavailable for software application during the self-test run.

### 51.1.3 STCU2 LBIST/MBIST mapping

This topic covers STCU2 LBIST/MBIST mapping.

#### LBIST mapping

The below table lists the LBIST mapping of the chip. The NLBIST value is 1.

Table 233. LBIST mapping

| BIST ID (NLBIST) | BIST instance name | Modules |
|---|---|---|
| 0 | LBIST | DMA:<br>• DMA controller |
| | | EIM |

### 51.1.4 Clock connectivity

STCU2 works on the system clock domain. The scan operations while LBIST are done on TCK clock.

Table 236. Clock connectivity

| STCU2 clock | Clock connected to the chip | Remarks |
|---|---|---|
| CORE_CLK | AIPS_SLOW_CLK | System clock divider output clock node for STCU2 operations and register interface accesses |
| REG_INTF_CLK | | |
| SHIFT_CLK | JTAG_TCK | JTAG_TCK used for shift operations when self-test is in progress |

### 51.1.5 Memory map for self-test GPRs

See the memory map file attached to this document and 'SELFTEST_GPR' chapter for details.

### 51.1.6 Handling unrecoverable faults

Only recoverable and non-critical faults from STCU2 are mapped to FCCU. The unrecoverable and critical faults are mapped to MC_RGM. Therefore, ignore any references to mapping of unrecoverable and critical faults with FCCU in this chapter.

### 51.1.7 Indicating fault state during the main reset domain Self-Test

FCCU EOUT indicates the fault state during the Self-Test as soon as the UTEST_MISC[FCCU_EOUT_ DEDICATED] is enabled and DCMRWD2[EOUT_STAT_DUR_STEST] is enabled at the time of Self-Test setup steps.

The fault state remains asserted until the bit DCMRWD2[EOUT_STAT_DUR_STEST] is cleared post Self-Test reset sequence.

In case it is not required to indicate the fault state during the Self-Test, then the bit DCMRWD2[EOUT_STAT_DUR_STEST] should not be programmed.

### 51.1.8 Error events management in main reset domain Self-Test

Error events should be mapped to unrecoverable faults in STCU2_ERR_FM register for main reset domain Self-Test.

### 51.1.9 AUTOLOCK_VALUE for register write access via STCU2_SKC

Register write-access watchdog timer explains that access to STCU2 registers via the STCU2_SKC security-key mechanism times out after a number of STCU2 clock cycles equal to AUTOLOCK_VALUE. On this chip, AUTOLOCK_VALUE is 32'hFFFF_FFFF.

### 51.1.10 PLL loss of lock during Self-Test

Detection of PLL loss of lock during LBIST or MBIST causes a destructive reset in the system.

CMU0 programming is required before the Self-Test programming begins.

All the registers present in LBIST domains do not retain their content after Self-Test reset.

### 51.1.11 STCU2 BIST start (BSTART) register description

Attempted accesses with the undefined reserved values in the BSTART register can result in undefined behavior. The following table defines the BSTART field on this chip.

Table 237. BSTART description

| Field value | Description |
|---|---|
| 000b | NOP (reset value) |
| 001b | RUN_ONLY: Run BISTs.<br>MTR controller (MCT) runs the selected BISTs without programming them first. |
| 010b | Reserved |
| 011b | Reserved |
| 100b | PROG_ONLY: Program BISTs only.<br>MCT only programs BISTs and does not start them. This enables different BISTs to be programmed with different algorithms before all the selected BISTs are started using the RUN_ONLY command. |
| 101b | PROG_RUN: Program BISTs and start them. |
| 110b | Reserved |
| 111b | Reserved |

### 51.1.12 STCU2 algorithm select (ALGOSEL) register description

This register selects any one of the predefined algorithms. The value used in this register is mapped to a predefined algorithm register in BIST. After MCT has programmed information on this register and starts some BIST operation, this value is transferred to the predefined algorithm register in every BIST that is selected.

If multiple predefined algorithms are selected, the order of execution is from LSB to MSB.

Any field that does not have a predefined algorithm associated with it is a reserved bit. No data is written to reserved bits and when you read these bits, they always return 0. These predefined algorithms include:

- Backgrounds
- Address modes and other register programming that may be necessary
- The number of BIST runs needed to perform the exact coverage requested.

MCT decodes this information through a series of look-up tables. The following table describes the high-level BIST algorithms that can be invoked through the MCT. The columns in that table have the following meaning:

- Index: The position in this MCT register enables this algorithm.
- Name: The symbolic name for this algorithm.
- Description: The intent and use model for this algorithm.
- BIST runs: The sequence of BIST invocations comprising this algorithm.
- Sequences: The ordered list of march elements to run. Each march element consists of a direction indicator (for increasing addresses and for decreasing addresses) and a set of march phases. A march phase consists of reading (R) or writing (W), the non-inverted (0) or inverted (1) background pattern.
- Used by default: Whether this algorithm is selected in the post-reset state of this register.

Table 238. ALGOSEL description

| Index | Name | Description | BIST runs | Sequences | Used by default |
|---|---|---|---|---|---|
| 3 | March C+ single | March C+ with column fast and solid background | MarchC+ column fast 1x (#4) | W0, R0W1, R1W0R0W1, R1W0, R0W1R1W0, R0 | Yes |
| 13 | BasicChk | Basic selfcontained checkerboard, using column fast | BasicChk (#18) | R0W1R1 | - |

### 51.1.13 Self-Test programming sequence

This section describes a high level programming sequence for executing Self-Test. The detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative).

- Program clock sources and MC_CGMs as per the clock configuration.

  **NOTE**

  While running MBIST on EMAC timestamp memory, MC_CGM.MUX_9_DC_0[DIV] should be appropriately configured to ensure EMAC_CLK_TS should be atleast 1.5 times the AIPS_SLOW_CLK frequency.

- Program SELFTEST_GPR[CONFIG_REG] and SELFTEST_GPR[LBIST_PROG_REG] as per the LBIST configurations.

  **NOTE**

  This is not applicable for MCXE317 and MCXE315/MCXE316 wherein LBIST is not supported.

- Program STCU2 as per NXP recommended.
- Program dcf_client_utest_misc[FCCU_EOUT_DEDICATED] and DCMRWD2[EOUT_STAT_DUR_STEST] to configure EOUT pins as dedicated and to indicate FCCU error states on EOUT pins during Self-Test respectively.
- Configure ERCTRL[ERASSERT] register bit in MC_RGM to achieve desired behaviour of Reset Pin as documented in Reset Section and Pad States Section.
- Disable functional reset sources to avoid false Self-Test abort scenarios. For example, software watchdog timers cannot be serviced while Self-Test because the software is not accessible and can cause invalid timeout reset. See Reset events and configurations while Self-Test.
- Program the PCS_ENABLE[8:7] fields of the CONFIG_REG register (SELFTEST_GPR) to 0 to disable PCS.
- Trigger Self-Test execution by programming RUNSW register in STCU2.
- At the end of the Self-Test run, a functional reset is generated. Out of reset, the software can check the status registers inside STCU2 and take actions accordingly.

### 51.1.14 Modules operation during/post Self-Test

The clock, reset, power generation modules, such as RGM, PMC, CGM, FIRC, PLL, and SIRC will be available during and post Self-Test. However, because the chip undergoes the reset sequence, PLL and CGM will be reset.

CMU0 and CMU3 will be available during Self-Test if enabled prior to Self-Test, but will be Reset post Self-Test.

STCU2 will also be available during Self-Test and the results can be read post Self-Test.

### 51.1.15 Reset events and configurations while Self-Test

As Self-Test is a software initiated Self-Test, it is expected by software to ensure all the peripherals are disabled as documented in Software considerations before Self-Test.

The functional reset sources should be appropriately configured to avoid any functional reset while Self-Test is running (disable SWT_RST and HSE_SWT_RST. JTAGC should not be in EXTEST, HIGHZ or CLAMP instructions). This ensures no selftest abort while running selftest due to functional reset source. The below table specifies the state of functional reset sources for Self-Test.

**Table 239. Reset events and configurations while self-test**

| Reset source | Reset description | Configurations/remarks for selftest |
|---|---|---|
| FCCU_RST | FCCU reset reaction | The FCCU is a part of logic which is under Self-Test and thus it would be disabled during the Self-Test |
| ST_DONE | Self-Test done reset | The selftest done indication resets the device post selftest. While Self-Test is running, the Self-Test done indication will be in disabled state |
| SWT_RST | SWT reset request | SWT should be disabled in Self-Test configuration sequence. |
| JTAG_RST | JTAG Reset | JTAG communication should be inactive while Self-Test and JTAGC state machine should not be in EXTEST, HIGHZ or CLAMP instructions |
| HSE_SWT_RST | HSE SWT timeout | HSE_SWT should be disabled in Self-Test configuration sequence. |
| SW_FUNC | software 'functional' reset | The software is inactive during Self-Test and hence software functional reset will not arrive while the chip is under Self-Test. |
| DEBUG_FUNC | debug 'functional' reset | MDM DAP should not be configured for debug functional reset generation while Self-Test is running. |

The destructive reset sources are available while in Self-Test. In case of any destructive reset event, the device undergoes a destructive reset sequence, thereby resetting the STCU2 and Self-Test logic itself.

After completion of Self-Test (LBIST or MBIST), a functional reset sequence is executed by MC_RGM.

### 51.1.16 Software considerations before Self-Test

1. As all the communication peripherals are not in LBIST partitions; hence, it is required by SW to stop all communications and disable all the PCTLs of the communication peripherals before initiating Self-Test as the device will be unusable in Self-Test. This is needed so that there is graceful safe stating of inputs of non-lbisted peripheral modules.
2. Configure RGM functional reset sources as interrupts before Self-Test as per the considerations mentioned in Reset events and configurations while Self-Test, i.e., the SWTs should be disabled, the JTAGC should not be in states which can cause a JTAG reset event (EXTEST, HIGHZ, CLAMP instructions) and the software should not trigger a functional reset event via MC_ME or MDM_AP while the selftest is ongoing. This is to avoid any abort scenario due to any functional reset source as Self-Test is initiated by SW.

There is no issue with Reset pin as Reset pin is a source of destructive reset and will reset STCU2 and Self-Test related logic etc.

### 51.1.17 End of Self-Test

The Self-Test completion is a source of functional reset to the device, by which the device executes a functional reset sequence. The logic which is LBISTed additionally undergoes a complete POR sequence to ensure that the random content shifted during BIST sequence get cleared.

**At the end of MBIST**, the software should execute below steps:

1. Software reads the MBIST end flag to identify that the MBIST sequence had ended properly without any interruption or abort, by reading STCU2.MBESWn.
2. Software reads the MBIST status to identify whether the MBIST was successful or not, by reading STCU2.MBSSWn.

**NOTE**

The MBIST status should always be read in accordance with MBIST end flag. The STCU2.MBSSWn status is irrelevant if STCU2.MBESWn indicates that MBIST execution is incomplete.

**At the end of LBIST**, the software should execute below steps:

1. Software reads the LBIST end flag to identify that the LBIST sequence had ended properly without any interruption or abort, by reading STCU2.LBESWn.
2. Software reads the LBIST status to identify whether the LBIST was successful or not, by reading STCU2.LBSSWn.

**NOTE**

The LBIST status should always be read in accordance with LBIST end flag. The STCU2.LBSSWn status is irrelevant if STCU2.LBESWn indicates that LBIST execution is incomplete.

## 51.2 Introduction

STCU2 is a comprehensive programmable hardware module that:

- Manages the execution of BISTs
- Indicates whether each BIST passed
- Manages the chip's LBIST and the MBIST blocks

## 51.3 Main features

STCU2 includes:

- System interface for reading from and writing to the STCU2 registers (online) via the CPU
- Programmable scheduler for BIST execution
- Control over LBIST concurrent or sequential execution
- Control over MBIST concurrent or sequential execution
- Programmable LBIST delayed concurrent start
- Programmable internal clock prescaler to reduce internal and BIST clocks
- PLL lock signal monitoring during BIST sequences
- Programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence
- Fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them
- Fields that indicate the pass/fail indication of each BIST, see Types of BIST sequences and Types of BIST partitions
- Fields that indicate the status of each type of online STCU2 internal error condition
- Programmable fault mapping of each BIST for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the BIST fails to execute
- Programmable fault mapping of each STCU2 internal error condition for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the condition occurs
- Signals to report recoverable and unrecoverable faults to the FCCU module
- Redundant recoverable and unrecoverable fault-generation logic to improve reliability
- FCCU recoverable and unrecoverable fault-injection mechanism
- Global register write-protection mechanism that requires two security key codes
- Global automatic power saving after a BIST sequence is completed when watchdog timer time-out is detected

- Watchdog automatic clock wake-up mechanism when software unlocks the STCU2 registers for write access
- Watchdog automatic power saving when the fixed register-write-access watchdog timer times out

## 51.4 Block diagram

This diagram shows the parts of STCU2:

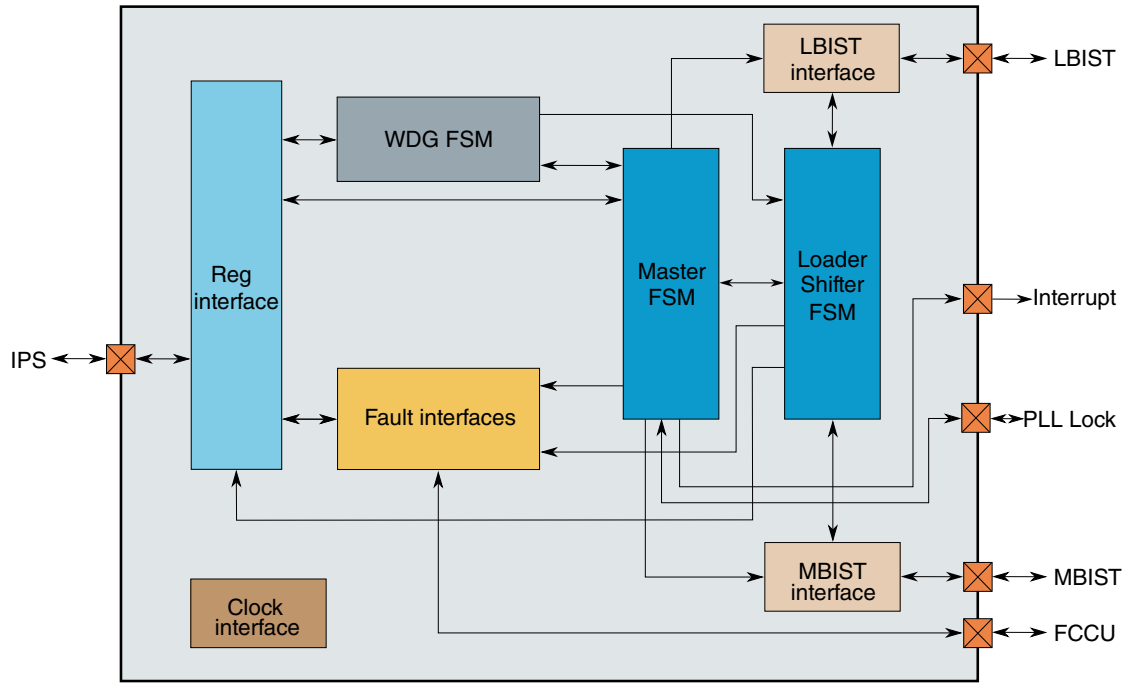

**Figure 188. STCU2 block diagram**

This table describes the parts of STCU2:

**Table 240. STCU2 parts**

| Part | Function |
|---|---|
| Reg interface | Provides access to:<br>• Registers<br>• The security key logic<br>• The IPS interface |
| Fault interfaces | Performs the following tasks:<br>• Collects the fault conditions caused by STCU2 internal error conditions and each BIST executed in a sequence<br>• Sets the global recoverable or unrecoverable status flag, depending on the fault mapping for a given BIST<br>• Manages the recoverable and unrecoverable fault lines to and from the FCCU module |

*Table continues on the next page...*

Table 240. STCU2 parts (continued)

| Part | Function |
|---|---|
| | • Manages the set/clear injection mechanism provided by the FCCU module<br>To improve the intrinsic reliability of this critical logic, the generation logic is duplicated. |
| Clock interface | Manages the internal and the BIST clock prescaler, the internal clock-gating power saving, and the wake-up clock feature |
| WDG FSM | Provides the following:<br>• A programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence<br>• A fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them |
| Master FSM | Coordinates and schedules all of the operations performed during a BIST sequence |
| Loader Shifter FSM | Programs the BIST registers and reads back the data to be checked at the end of each test operation |
| LBIST interface | Provides the interface between the chip's LBIST engines and the STCU2 controllers |
| MBIST interface | Provides the interface between the MBIST controller and the STCU2 controller |

## 51.5 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration purposes via CPU. The module supports the following bus read operations:

- Word (32 bits) data read operations to any registers
- Any other operation is not supported.

Word, low and high half-words, byte operations are supported in write mode only:

- Write access is allowed by software only when CFG[WRP] is cleared. The default value of CFG[WRP] is cleared, exceptions are the following read/write fields: CFG[WRP], ERR_STAT[UFSF] and ERR_STAT[RFSF].
- STCU2 Configuration (CFG) should only be accessed in 32 bit (partial access not allowed).

The STCU2 module generates a transfer error in the following cases:

- Any read access to the registers after writing Key1 and before writing Key2 (in online ) and before register write-access watchdog timer expires.
- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register
- Any write operation on Double Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Double Security keys have not been applied

- Any write operation performed on registers when CFG[WRP] is set and the access is performed through software (internal peripheral interface). The exceptions are SKC register (for valid keys value and sequence) in which STCU2 does not assert transfer error.
- Any write operation performed on Read Only registers

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor, or test.

In case there are write operations on bits marked as reserved, the transfer error is not generated.

**NOTE**

See the chip-specific STCU2 information for the wait time necessary to write to the online registers.

## 51.6 BISTs and BIST partitions

### 51.6.1 Definition: BIST

A BIST is a test that the chip can execute to verify the functional integrity of a part of itself. The chip uses STCU2 and other on-chip hardware to execute a BIST.

### 51.6.2 Definition: BIST partition

A BIST partition is a part of a chip for which a BIST has been defined. The hardware that is included in a given BIST partition is chip-specific. For a list of the hardware included in each of the BIST partitions on this chip, see the chip-specific STCU2 information.

### 51.6.3 Example: BIST partitions on a chip

This is an example of a chip with six BIST partitions:

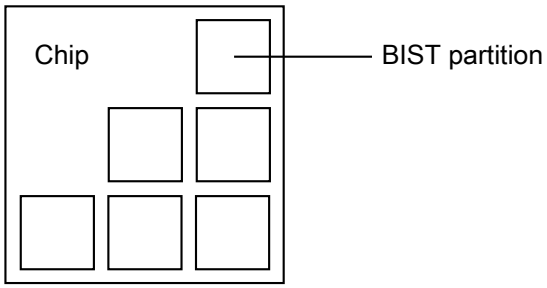

**Figure 189. BIST partitions on a chip**

### 51.6.4 Types of BIST partitions

The STCU2 module on this chip supports the following types of BIST partitions:

**Table 241. Types of BIST partitions**

| BIST partition type | Description |
|---|---|
| MBIST partition | An SRAM or ROM block |
| LBIST partition | One or more digital modules |

## 51.7 BIST sequences

### 51.7.1 Definition: BIST sequence

A BIST sequence is a programmable series of one or more phases, each of which executes one or more individual BISTs.

### 51.7.2 STCU2 executes MBISTs before LBISTs

If a BIST sequence includes both MBISTs and LBISTs; STCU2 executes the MBISTs first.

### 51.7.3 Example: Single-phase BIST sequence

This is an example of a single-phase BIST sequence in which STCU2 executes only one BIST:

**Table 242. Example: Single-phase BIST sequence**

| Phase | BIST executed |
|---|---|
| 0 | MBIST 16 |

### 51.7.4 Example: Multi-phase BIST sequence

This is an example of a multiphase BIST sequence in which STCU2 executes more than one BIST in parallel in some phases:

**Table 243. Example: Multi-phase BIST sequence**

| Phase | BISTs executed |
|---|---|
| 0 | MBISTs 7, 30 |
| 1 | MBIST 23 |
| 2 | MBISTs 6, 16, 29, 23 |
| 3 | LBIST 12 |
| 4 | LBISTs 13, 8, 11 |
| 5 | LBISTs 19, 6 |

### 51.7.5 Types of BIST sequences

The STCU2 module on this chip supports these types of BIST sequences:

**Table 244. Example: Types of BIST sequences**

| BIST sequence type | Description |
|---|---|
| Online BIST sequence | A BIST sequence that STCU2 executes during runtime at the request of software. Application software configures and initiates execution of the BIST sequence by loading values into STCU2 registers. |

### 51.7.6 Supported BIST sequences

NXP supports only a specific set of BIST sequences for this chip. For the list of supported BIST sequences, see the chip-specific STCU2 information.

## 51.8 Functional description

### 51.8.1 FSM description

The module has three FSM that work together: Master FSM, Loader/Shifter FSM, and the Watchdog FSM. Basically the Master FSM is the core unit of the STCU2 module. It coordinates all the self-test operations and the other FSM. The Loader/Shifter FSM is used to program the MBIST and the LBIST parameters and to retrieve the related results depending on the parameters stored into the STCU2 registers and under the control of the Master FSM. The Watchdog FSM evaluates all the schedule time for MBIST and LBIST and the time-out in case of wrong STCU2 programming.

### 51.8.2 BIST scheduling

STCU2 is designed to program the parallel/serial execution of the MBIST or LBIST depending on the power, timing, and coverage constraints.

The mechanism used to provide this flexibility is a linked list of BIST descriptors where the starting pointer is defined in CFG[PTR]. The first LBIST is mapped on 0, the second on 1, and so on. A BIST descriptor identifies a LBIST or MBIST via an index that is associated with its control register (STCU2 LBIST Control (LB_CTRL0) or STCU2 MBIST Control (MB_CTRL0 - MB_CTRL11)). The first MBIST is mapped on (00000080h + 0), the second on (00000080h + 1), and so on. The additional pointers of the linked list are in LB_CTRL*n*[PTR] for LBIST *n* (where *n* is the selected LBIST) and MB_CTRL*m*[PTR] for MBIST *m* (where *m* is the selected MBIST) and must be populated depending on the selected run sequence. The additional fields LB_CTRL[CSM] and MB_CTRL[CSM] provide the flexibility to run concurrently or sequentially the chosen set of the LBIST or MBIST or to close the linked list by setting the NIL pointer.

### 51.8.3 FCCU interface

The FCCU interface is the hardware flag mechanism towards the system, to indicate the occurrence of an Unrecoverable fault and/or a Recoverable fault failure during the Self Test sequence. Two independent signals have been used to mitigate the common cause faults.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. In this case, the FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set/clear mechanism works.

### 51.8.4 Watchdogs

The STCU2 implements different watchdogs to ensure that operations are finished in time.

#### 51.8.4.1 BIST watchdog timer

The LBIST and MBIST execution time has to be configured as described in STCU2 Watchdog Granularity (WDG), to account for the overall execution time of the self test sequence. In case the selected LBISTs or MBISTs are not yet completed during assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into ERR_STAT[WDTOSW] and MBESWx or LBESW.

In case of multiple sequential run in the same online session and the time-out happens in the middle of a sequential run, the next sequential run will be skipped and the execution ends with the current updated status of the registers reported above.

#### 51.8.4.2 Register write-access watchdog timer

As explained in the STCU2 SK Code (SKC):

- A key mechanism protects STCU2 registers during the self-test configuration phase by preventing any unwanted access.
- A hardware watchdog timer locks register-write access after a number of STCU2 clock cycles. To refresh the hardware watchdog timer before it times out, write Key1 and Key2 sequences.

AUTOLOCK_VALUE is the number of STCU2 clock cycles after which the hardware watchdog timer locks register-write access. See the chip-specific STCU2 information for the value of AUTOLOCK_VALUE.

The hardware watchdog timer is particularly useful in case CFG[WRP] is 0 during the software self-test configuration. In this case, the software application might enable write access to the STCU2 registers.

## 51.9 STCU2 register descriptions

The STCU2 registers are listed in this section.

**NOTE**

Always write the reset value for the Reserved fields.

During online self-test, after the STCU2 registers are configured, they must not be overridden via internal peripheral system until the self-test is complete.

### 51.9.1 STCU2 memory map

STCU base address: 403A_0000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 4h | STCU2 Run Software (RUNSW) | 32 | RW | 0000_0000h |
| 8h | STCU2 SK Code (SKC) | 32 | W | 0000_0000h |
| Ch | STCU2 Configuration (CFG) | 32 | RW | 0000_0000h |
| 14h | STCU2 Watchdog Granularity (WDG) | 32 | RW | 0000_FFFFh |
| 24h | STCU2 Error (ERR_STAT) | 32 | RW | 0000_0000h |
| 28h | STCU2 Error FM (ERR_FM) | 32 | RW | 0000_0000h |
| 4Ch | STCU2 Online LBIST Status (LBSSW0) | 32 | R | 0000_0000h |
| 5Ch | STCU2 Online LBIST End Flag (LBESW0) | 32 | R | 0000_0000h |
| 7Ch | STCU2 Online LBIST Unrecoverable FM (LBUFM0) | 32 | RW | 0000_0000h |
| 10Ch | STCU2 Online MBIST Status (MBSSW0) | 32 | R | 0000_0000h |
| 14Ch | STCU2 Online MBIST End Flag (MBESW0) | 32 | R | 0000_0000h |
| 18Ch | STCU2 MBIST Unrecoverable FM (MBUFM0) | 32 | RW | 0000_0000h |
| 200h | STCU2 LBIST Control (LB_CTRL0) | 32 | RW | 0000_0000h |
| 204h | STCU2 LBIST PC Stop (LB_PCS0) | 32 | RW | 0000_0000h |
| 220h | STCU2 Online LBIST MISR Expected Low (LB_MISRELSW0) | 32 | RW | FFFF_FFFFh |
| 224h | STCU2 Online LBIST MISR Expected High (LB_MISREHSW0) | 32 | RW | FFFF_FFFFh |
| 228h | STCU2 Online LBIST MISR Read Low (LB_MISRRLSW0) | 32 | R | 0000_0000h |
| 22Ch | STCU2 Online LBIST MISR Read High (LB_MISRRHSW0) | 32 | R | 0000_0000h |
| 2200h | STCU2 Algorithm Select (ALGOSEL) | 32 | RW | 0000_0000h |
| 220Ch | STCU2 MBIST Stagger (STGGR) | 32 | RW | 0000_0000h |
| 2210h | STCU2 BIST Start (BSTART) | 32 | RW | 0000_0000h |
| 2214h - 2240h | STCU2 MBIST Control (MB_CTRL0 - MB_CTRL11) | 32 | RW | 0000_0000h |

## 51.9.2 STCU2 Run Software (RUNSW)

### Offset

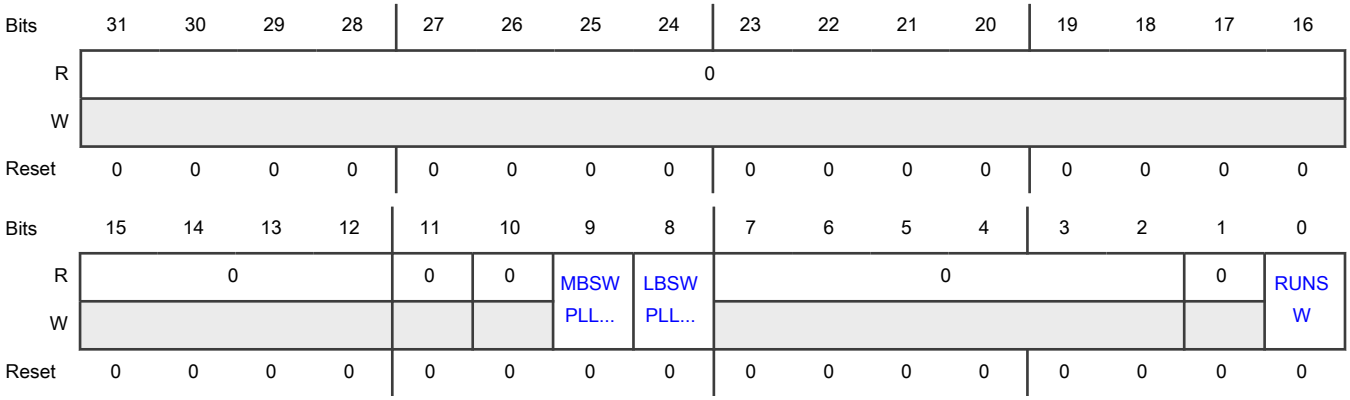
| Register | Offset |
|---|---|
| RUNSW | 4h |

### Function

The RUNSW register defines the RUNSW bit to start the online self-testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when CFG[WRP] = 0.

### Diagram



### Fields

### 51.9.3 STCU2 SK Code (SKC)

#### Offset

| Register | Offset |
|---|---|
| SKC | 8h |

#### Function

The SKC register implements the security key code mechanism needed to access in write mode to the other STCU2 registers.

To unlock STCU2 access after the STCU2 asynchronous reset and at the end of the STCU2 run, the software (IPS bus) need to apply the following sequence:

- write the key1 into the SKC register
- write the key2 into the SKC register

Depending on the online test step, the two keys are different. Byte write operation is not allowed because the full key has to be recognized as one unit.

A hard-coded WDG counter (Register write-access watchdog timer) starts decrementing its value right after POR is deasserted. Therefore, user must ensure to complete unlocking and programming sequence before its expiry. In case the STCU2 register access lasts more cycles than the one defined in the hard-coded WDG timeout, the STCU2 write access is locked and the WDG and register interface clocks are switched off. Also, in this case, to enable the write access to the STCU2 again and the WDG and register interface clocks, it is required to apply the sequence again. In case of invalid access or sequence (Key1/2 have to be applied consecutively), a transfer error on the IPS is asserted. The STCU2 write access is locked and to unlock the access, the sequence has to be applied again. This can also happen if watchdog expires between key1 and key2. In this case, user needs to apply the key1-key2 sequence again. In case it is required to extend the STCU2 register access cycles before the hard-coded WDG timeout expires, Key1 and Key2 sequences need to be applied. The effect of this write operation is to re-initialize the WDG timeout counter. The STCU2 write access is locked and to unlock the access, the sequence has to be applied again.

The SKC register is not readable. The value 00000000h is always returned in case of read operation.

## 51.9.4 STCU2 Configuration (CFG)

### Offset

| Register | Offset |
|---|---|
| CFG | Ch |

### Function

The CFG register includes the global configuration of the STCU2 and can be updated in the online test steps.

The access to this register is described in the following figure. It further depends on the state of the WRP bit as follows:

- When WRP = 0: The register can be written during the online self-test case without restrictions.
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - In case there are software operations that write all the register's bits, a transfer error is raised only if the value of the selected byte written differs from the current status of the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

### 51.9.5 STCU2 Watchdog Granularity (WDG)

#### Offset

| Register | Offset |
|---|---|
| WDG | 14h |

#### Function

The WDG register defines the time budget of LBIST and MBIST execution providing a protection mechanism in case of dead-lock or endless conditions during the self-test procedure.

In case online self-test sequence is run, it defines the timeout of the execution run.

The R/W fields in this register are readable at any time. You can write to these fields when online self-test phase is active and CFG[WRP] = 0.

### Diagram

## 51.9.6 STCU2 Error (ERR_STAT)

### Offset

| Register | Offset |
|---|---|
| ERR_STAT | 24h |

### Function

The ERR_STAT register includes the status flags related to the STCU2 internal error conditions occurred during the configuration or the online self-testing execution.

The UFSF and RFSF can be set/cleared using the FCCU dedicated channels.

The access to this register is described in the following figure and as follows:

- If you select the byte write capability to write only UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set/clean capability.

## 51.9.7 STCU2 Error FM (ERR_FM)

### Offset

| Register | Offset |
|---|---|
| ERR_FM | 28h |

### Function

The ERR_FM register defines the fault mapping of the STCU2 faults described in the register ERR_STAT in terms of UF or RF. All sources of internal faults can be routed to UF and RF.

The R/W fields in this register are readable at any time. You can write to these fields when online self-test phase is active and CFG[WRP] = 0.

# Chapter 52
# Register Protection (REG_PROT)

## 52.1 Chip-specific REG_PROT information

### 52.1.1 REG_PROT configuration

The MCU safety relevant configuration registers are protected against unauthorized HW/S changes during read/write/clear access by implementing them with register protection module. See the REG_PROT details file attached to this document.

#### 52.1.1.1 CMU_BRIDGE register protection

The CMUs in the device reside on a common peripheral slot as CMU_BRIDGE in the system memory map. Figure 190 indicates the locations of the CMUs alongwith the memory map.

Based on the CMU location in system peripheral memory map, the below locations in the CMU 16KB space are reserved and any access on these locations results in a bus transfer error.

402B_C018 – 402B_C01F

402B_C030 – 402B_C03F

402B_C050 – 402B_C05F

402B_C078 – 402B_C07F

402B_C098 – 402B_C09F

402B_C0B8 – 402B_CFFF

Since the register protection is available in the device for CMU_BRIDGE, the 4KB offset locations (refers as the Area 2 in register protection) are also reserved and accesses over these regions also result in bus transfer error.

402B_D018 – 402B_D01F

402B_D030 – 402B_D03F

402B_D050 – 402B_D05F

402B_D078 – 402B_D07F

402B_D098 – 402B_D09F

402B_D0B8 – 402B_DFFF

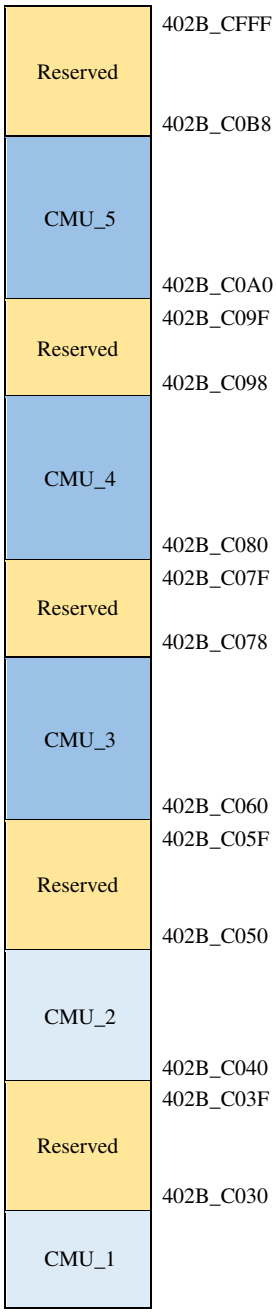

Figure 190. Location of CMUs

## 52.2 Introduction

REG_PROT offers a mechanism to protect defined memory-mapped address locations, in a module under protection, from being written.

REG_PROT is a protection module that is located between the module under protection and the peripheral interface. The address locations to be protected exist in the module under protection and the address locations that can be protected are module specific. Writes to these protected address locations are locked using a Soft Lock Bit Register (SLBR*n*). Any access to address locations in the module under protection is restricted if their corresponding Soft lock fields in a Soft Lock Bit Register (SLBR*n*) are 1.

The configured soft-lock fields can also be write-restricted by using GCR[HLB]. When GCR[HLB]=1, you cannot write to the soft-lock fields. The address locations in the module under protection can be restricted to Supervisor mode access using GCR[UAA]. This is shown in the following figure.

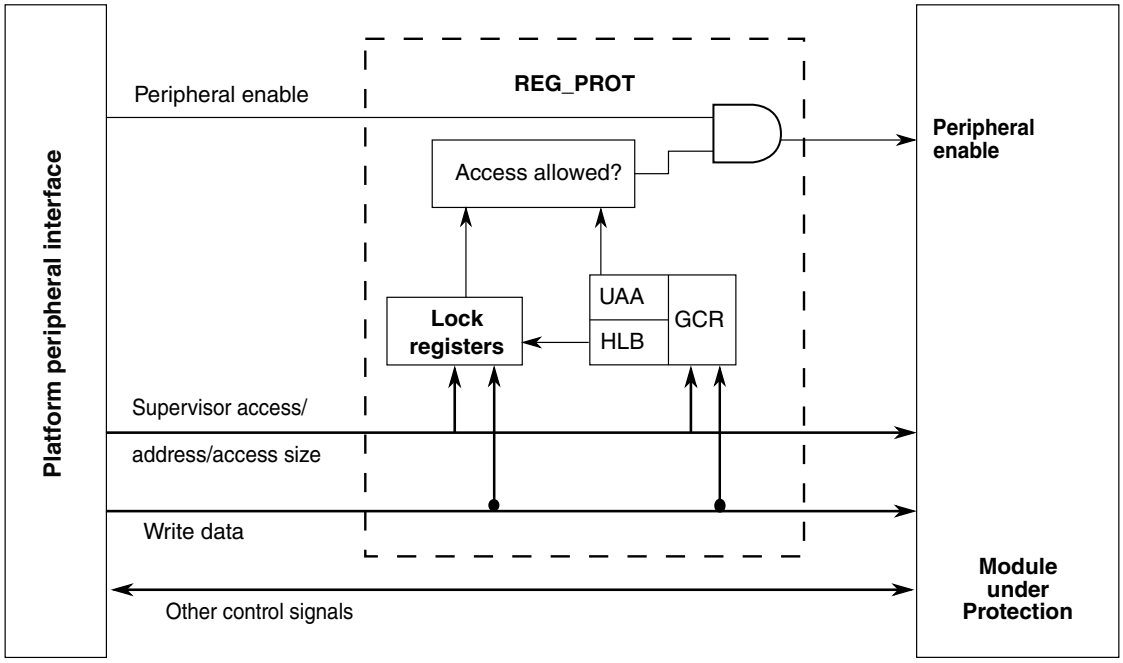

Figure 191. Block diagram

## 52.3 Features

REG_PROT includes these distinctive features:

- Write accesses for the module under protection can be restricted to the supervisor mode only.
- Registers of modules with their register slot size occupying 1 KB to 32 KB of memory-mapped address space, depending on the PROT_MEM parameter, can be dynamically locked. See Memory map and register definition.
- Multiple ways are present to set the lock bits.
- After the lock bits are configured, they can be protected from changes.

## 52.4 Modes of operation

The REG_PROT module is operable when the module under protection is operable.

## 52.5 External signal description

There are no external signals.

## 52.6 Functional description

The following sections describe the functional characteristics of the REG_PROT module.

### 52.6.1 General

This module provides a generic register (address) write-protection mechanism. The register protection size can be:

- 32 bits (address == multiples of 4)

- 16 bits (address == multiples of 2)
- 8 bits (address == multiples of 1)

The addresses that are protected and the register protection size depends on the chip and/or module.

For all addresses that are protected, there are SLBR*n*[SLB*m*] bits that specify whether the address is locked. When an address is locked, it can only be read but not written in any mode (supervisor/normal). If an address is unprotected, the corresponding SLBR*n*[SLB*m*] bit is always 0, regardless of what the software writes to that field.

**NOTE**

For more information on register protection specification, see the REG_PROT details file attached to this document.

## 52.6.2 Change lock settings

To change the setting whether an address is locked or unlocked, the corresponding SLBR*n*[SLB*m*] bit needs to be changed. This can be done using the following methods:

- Set the SLBR*n*[SLB*m*] bit(s) by writing to area #2
- Modify the SLBR*n*[SLB*m*] directly by writing to area #3

Both methods are explained in the following sections.

### 52.6.2.1 Change lock settings via area #2

You can lock a register after writing to it. Note that reading area #2 does not affect soft lock bits. To do so, you can use area # 2.

The following shows an example with PROT_MEM = 8 KB where SLBs are modified using area #2.

When writing 16-bit to address 0008h, MR9 and MR8 in the protected module are updated. The corresponding lock fields remain unchanged (see the left part of Figure 192).

When writing 16-bit to address 2008h, MR9 and MR8 in the protected module are updated. The corresponding lock fields SLBR2[SLB0:1] become 1, and the lock fields SLBR2[SLB2:3] remain unchanged (see the right part of Figure 192).

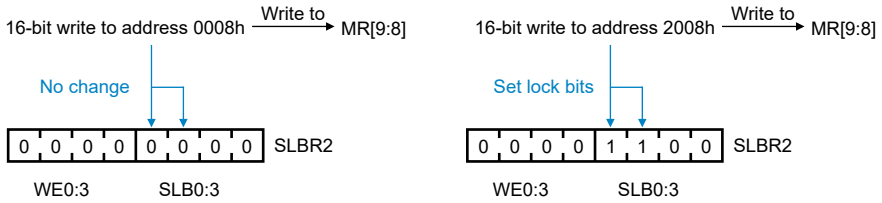

**Figure 192. Enable locking via area #2**

The following figure shows an example where some addresses are protected and some are not.

In Figure 193, addresses 000Ch and 000Dh are unprotected. Therefore, their corresponding lock fields SLBR3[SLB0:1] are always 0 (shown in bold). During a 32-bit write access to address 200Ch, the lock fields in SLBR3 change as follows:

- SLBR3[SLB2:3] become 1.
- SLBR3[SLB0:1] remain 0.

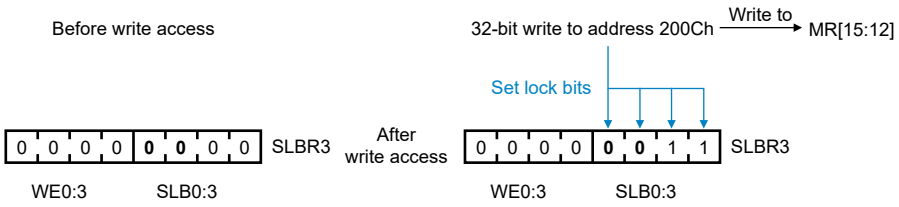

**Figure 193. Enable locking for protected and unprotected addresses**

### 52.6.2.2 Change lock settings via area #3

The lock bits are located in area #3 (see Table 245). You can modify them by writing to them. Each SLB*m* field in Soft Lock Bit Register (SLBR*n*) has a mask field, WE*m*, that protects SLB*m* from modification. This masking makes read-modify-write operations unnecessary.

Figure 194 shows two modification examples for registers with 8-bit protection. In part A, a write access to SLBR*n* specifies a mask value that allows modification of all SLBR*n*[SLB0:3] fields. Part B specifies a mask that allows modification only to SLBR*n*[SLB1:3].

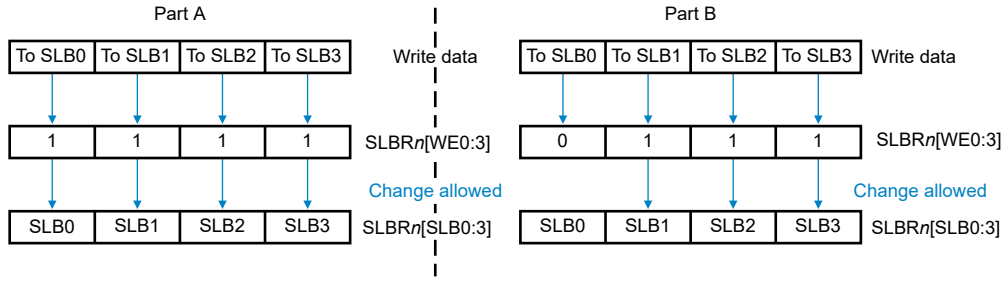

**Figure 194. Change lock settings directly via area #3**

Figure 195 shows examples for registers with 16-bit protection.

Part A of Figure 195 shows that for SLBR*n*:

- The data written to SLBR*n*[SLB0] is automatically written to SLBR*n*[SLB1].
- The data written to SLBR*n*[SLB2] is automatically written to SLBR*n*[SLB3].

This is because the address reflected by SLBR*n*[SLB0] and SLBR*n*[SLB2] are protected 16-bit wise. Note that in this case, the write enable SLBR*n*[WE0] and SLBR*n*[WE2] must be set while SLBR*n*[WE1] and SLBR*n*[WE3] don't matter.

Part B of Figure 195 shows that the data written to SLBR*n*[SLB0] is automatically written to SLBR*n*[SLB1]. This is done because the address reflected by SLBR*n*[SLB0] has 16-bit protection. In this case, SLBR*n*[WE0] must be 1 and SLBR*n*[WE1] does not matter. SLBR*n*[SLB2] and SLBR*n*[SLB3] remain unchanged because SLBR*n*[WE2] and SLBR*n*[WE3] are 0.

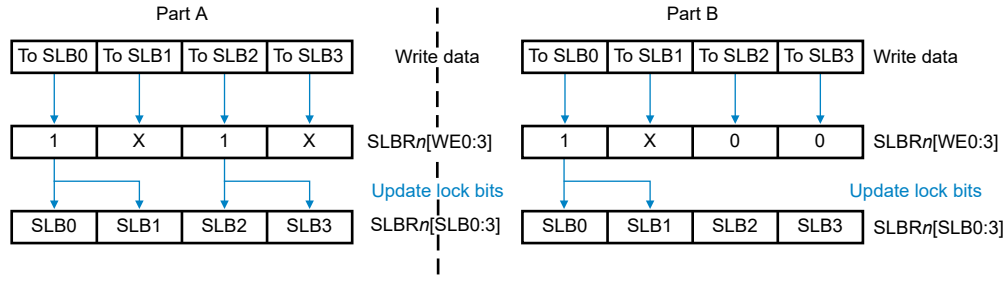

**Figure 195. Change lock settings for addresses with 16-bit protection**

Figure 196 shows a register with 32-bit protection. In SLBR*n*:

- When SLBR*n*[WE0]=1, the data written to SLBR*n*[SLB0] is automatically written to SLBR*n*[SLB1:3] as well.
- When SLBR*n*[WE0]=0, then SLBR*n*[SLB0:3] remain unchanged. Note that in this case, the write enable SLBR*n*[WE0] must be set while SLBR*n*[WE1:3] does not matter.

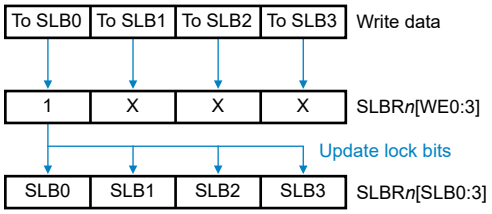

**Figure 196. Change lock settings for addresses with 32-bit protection**

The following figure shows a mixed protection size configuration.

In SLBR*n*:

- The data written to SLBR*n*[SLB0] is mirrored to SLBR*n*[SLB1] because the corresponding register has 16-bit protection.
- The data written to SLBR*n*[SLB2] is blocked because the corresponding register is unprotected.
- The data written to SLBR*n*[SLB3] is successfully written to SLBR*n*[SLB3] because the corresponding register has 8-bit protection.

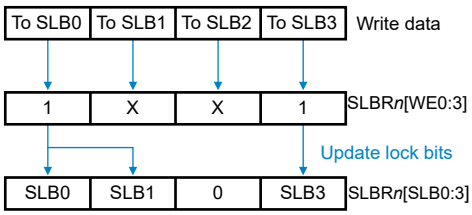

**Figure 197. Change lock settings for mixed protection**

### 52.6.2.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in Change lock settings via area #3 and Change lock settings via area #2 is only possible as long as the field GCR.HLB is cleared. After you write 1 to this field, the locking bits cannot be modified until there is a system reset.

## 52.6.3 Access errors

REG_PROT generates transfer errors under several circumstances, as described below. For the area definition, see Memory map and register definition.

- If accessing area #1 or area #2, REG_PROT sends any access error from the underlying module under protection.
- If User mode is not allowed, the attempted User mode writes to all areas cause a transfer error, and the writes are blocked.
- If accessing the reserved area, a transfer error is asserted.
- If accessing unimplemented 32-bit registers in areas #3 and #4, a transfer error is asserted.
- If writing to a register in areas #1 and #2, and an SLB field is 1 for any of the affected bytes, then:
  - A transfer error is asserted.
  - The write is blocked.
  - The complete write operation to non-protected bytes in this word is ignored.

- If writing to an SLBR in area #3 with GCR[HLB]=1, a transfer error is asserted.
- Any write operation in any access mode to area #2, when GCR[HLB]=1, is not allowed.

### 52.6.4 Sequence

You must configure the REG_PROT first. And then, you need to write 1 to the HLB field in REG_PROT. This ensures that registers under protection are not updated in the user access mode. You need to follow these steps:

1. Enable XRDC protection for the module to enable writes in the supervisor mode only. This step is mandatory, if protected registers of the module are expected to be configured multiple times.
2. Configure REG_PROT to enable write on registers of module under protection.
3. Configure the registers of module under protection.
4. Configure the REG_PROT for the required SLB fields.
5. Set the HLB field in REG_PROT. This step is mandatory, if protected registers of module are expected to be configured only once.

## 52.7 Memory map and register definition

This section provides a detailed description of the memory map of a module using REG_PROT.

The PROT_MEM size varies per chips. It can be:

- 1 KB
- 2 KB
- 4 KB
- 8 KB
- 16 KB
- 32 KB

The resulting memory space is divided into four areas. Memory locations within area #1 and area #2 are a part of the module under protection. Area #3 and area #4 are a part of REG_PROT.

The proper register slot size for each module is mentioned in the Memory Map file attached to this document.

Following is the memory map for a module that is protected by the REG_PROT module. Reserved registers in area #1 are handled as specified in the protected module's documentation. There is a single register in configuration space that corresponds to area #4 while the size mentioned in Area size column is to turn the whole area multiple of 4 KB. See the Offset column to know the exact location of the GCR register.

**Table 245. Area offset based on protection size**

| PROT_MEM | Area | Area size | Use | Offset |
|---|---|---|---|---|
| 1 KB | Area 1 | 1 KB | Module Register(MR0—MR1023) | 0000h—03FFh |
| | Area 2 | 1 KB | Module Register and Set Soft Lock Bit (LMR0—LMR1023) | 0400h—07FFh |
| | Area 3 | 256 B | Soft Lock Bit Register (SLBR0—255) | 0800h—08FFh |
| | Area 4 | 256 B | Global Configuration Register (GCR) | 0900h—09FFh |
| | | 1.5 KB | Reserved | 0A00h— 0FFFh |
| 2 KB | Area 1 | 2 KB | Module Register (MR0—MR2047) | 0000h—07FFh |
| | Area 2 | 2KB | Module Register and Set Soft Lock Bit (LMR0—LMR2047) | 0800h—0FFFh |

*Table continues on the next page...*

| | Area 2 | 4 KB | Module Register and Set Soft Lock Bit (LMR0—LMR4095) | 1000h—1FFFh |
| | Area 3 | 1 KB | Soft Lock Bit Register (SLBR0—1023) | 2000h—23FFh |
| | Area 4 | 256 B | Global Configuration Register (GCR) | 2400h—24FFh |
| | | 6.75 KB | Reserved | 2500h—3FFFh |
| 8 KB | Area 1 | 8 KB | Module Register (MR0—MR8191) | 0000h—1FFFh |
| | Area 2 | 8 KB | Module Register and Set Soft Lock Bit (LMR0—LMR8191) | 2000h—3FFFh |
| | Area 3 | 2 KB | Soft Lock Bit Register (SLBR0—2047) | 4000h—47FFh |
| | Area 4 | 256 B | Global Configuration Register (GCR) | 4800h—48FFh |
| | | 1.75 KB | Reserved | 4900h—4FFFh |
| 16 KB | Area 1 | 16 KB | Module Register (MR0—MR16383) | 0000h—3FFFh |
| | Area 2 | 16 KB | Module Register and Set Soft Lock Bit (LMR0—LMR16383) | 4000h—7FFFh |
| | Area 3 | 4 KB | Soft Lock Bit Register (SLBR0—4095) | 8000h—8FFFh |
| | Area 4 | 4 KB | Global Configuration Register (GCR) | 9000h—9FFFh |
| 32 KB | Area 1 | 32 KB | Module Register (MR0—MR32767) | 0000h—7FFFh |
| | Area 2 | 32 KB | Module Register and Set Soft Lock Bit (LMR0—LMR32767) | 8000h—FFFFh |
| | Area 3 | 8 KB | Soft Lock Bit Register (SLBR0—8191) | 10000h—11FFFh |
| | Area 4 | 4 KB | Global Configuration Register (GCR) | 12000h—12FFFh |

- Area #1 can take the memory space of 1 KB/2 KB/4 KB/8 KB/16 KB/32 KB, which holds the normal functional module registers and is transparent for all read/write operations.
- Area #2 can take the memory space of 1 KB/2 KB/4 KB/8 KB/16 KB/32 KB and is a mirror of area #1. For an example, if area #1 takes 8 KB of memory space, then read/write access to an offset 2000+X reads/writes the register at offset X. However, a write access to offset 2000+X additionally sets the optional soft lock bits for this offset X in the same cycle as the register at offset X is written. This provides for an automatic write and lock operation. Not all registers in area #1 need to have protection defined by the associated soft lock bits. For unprotected registers at offset Y, accesses to offset 2000+Y are identical to accesses at offset Y.
- Area #3 can take the memory space of 256 B/512 B/1 KB/2 KB/4 KB/8 KB and hold soft lock bits, one bit per byte in area #1. The four soft lock bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area #4 can take the memory space of 1.75 KB/3.5 KB/7 KB/2 KB/4 KB/4 KB and holds the configuration bits of the protection mode. There is one configuration Hard lock bit per module that prevents all further modifications to the soft lock bits and can only be cleared by a system reset after it is set. When user access allowed bit is set, it allows user access to the protected module.

If you access a locked byte with a write transaction, a bus error is issued to the system and the write transaction is not executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32—bit registers in area #3 results in a bus transfer error. In area #4, there will not be any transfer error for the address range mentioned in the table above because these address spaces of area #4 are mapped to the GCR register. Accesses in area #4, beyond the address range mentioned in the Module memory map table, are prohibited and might or might not result into a bus abort.

### 52.7.1 Module register (MR)

Each functional module has its own unique set of registers. This chapter refers to these registers generically as module registers (MR), which exist in the lower module memory space (memory area 1), and receive protection from the REG_PROT module.

### 52.7.2 Module Register and Set Soft Lock Bit (LMR)

This is memory area #2 that provides mirrored access to module registers with the side-effect of setting soft lock bits in case of a write access to a register that is defined as protectable by the locking mechanism. Each MR byte is protectable by one associated bit in SLBR*n* [SLB*m*], according to the mapping described in Soft Lock Bit Register (SLBR*n*).

## 52.8 REG_PROT register descriptions

This register information documents memory area #3 and area #4.

### 52.8.1 REG_PROT memory map

REG_PROT base address: base address of protected module instance

**Table 246. REG_PROT memory map**

| PROT_MEM | Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|---|
| 1kB | 0x800 – 0x8FF | Soft Lock Bit Register (SLBR0-255) | 8 | RW | 00h |
| | 0x900 – 0x9FF | Global Configuration Register (GCR) | 32 | RW | 0000_0000h |
| 2kB | 0x1000 – 0x11FF | Soft Lock Bit Register (SLBR0-511) | 8 | RW | 00h |
| | 0x1200 – 0x12FF | Global Configuration Register (GCR) | 32 | RW | 0000_0000h |
| 4kB | 0x2000 – 0x23FF | Soft Lock Bit Register (SLBR0-1023) | 8 | RW | 00h |
| | 0x2400 – 0x24FF | Global Configuration Register (GCR) | 32 | RW | 0000_0000h |
| 8kB | 0x4000 – 0x47FF | Soft Lock Bit Register (SLBR0-2047) | 8 | RW | 00h |
| | 0x4800 – 0x48FF | Global Configuration Register (GCR) | 32 | RW | 0000_0000h |
| 16kB | 0x8000 – 0x8FFF | Soft Lock Bit Register (SLBR0-4095) | 8 | RW | 00h |
| | 0x9000-0x9FFF | Global Configuration Register (GCR) | 32 | RW | 0000_0000h |
| 32kB | 0x10000-0x11FFF | Soft Lock Bit Register (SLBR0-8191) | 8 | RW | 00h |
| | 0x12000 – 0x12FFF | Global Configuration Register (GCR) | 32 | RW | 0000_0000h |

### 52.8.2 Soft Lock Bit Register (SLBR*n*)

#### Offset

See REG_PROT memory map for SLBR*n* offset ranges. For SLBR*n* addresses, see the REG_PROT details file attached to this document.

### Function

These registers hold the Soft Lock Bits (SLBs) for the protected registers in memory area #1, which is the normal register address space of the protected module. Multiple Soft Lock Bit Registers (SLBR*n*) can be implemented, depending on the number of protected module register bytes. Each SLBR*n* has four soft lock fields (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each soft lock field also has a corresponding write enable field in the same register that controls whether the soft lock field can be written. The following table shows the mapping between the soft lock fields to the bytes in memory area #1.

**Table 247. SLBs vs. protected address**

| SLB | Protected address |
|---|---|
| SLBR0[SLB0] | MR0 |
| SLBR0[SLB1] | MR1 |
| SLBR0[SLB2] | MR2 |
| SLBR0[SLB3] | MR3 |
| SLBR1[SLB0] | MR4 |
| SLBR1[SLB1] | MR5 |
| SLBR1[SLB2] | MR6 |
| SLBR1[SLB3] | MR7 |
| SLBR2[SLB0] | MR8 |
| ... | ... |

### Diagram

## 52.9 Glossary

**PROT_MEM** Integration parameter that specifies the size of the module register slot protected. The PROT_MEM size depends on the chip or module.

**Hard lock** A lock that restricts access to any register bit. You can unlock or clear this lock through the hardware reset.

**Soft lock** A lock that restricts access to any register bit. You can unlock or clear this lock through the software.

# Chapter 53
# Clock Monitoring Unit – Frequency Check (CMU_FC)

## 53.1 Chip-specific CMU_FC information

### 53.1.1 CMU_FC configuration

The device consists of a robust clock monitoring architecture targeted to monitor various clock nodes to ensure device clock robustness. There are 6 clock monitoring units present in the device out of which 4 are of type CMU_FC. See 'Clock monitoring' section in Clocking chapter for details on device clock monitoring architecture.

**NOTE**

CMU_5 is accessible by Cortex-M0+ core only.

**CMU_FC combined spec variation:**The combined spec variation for CMU (used for configuring CMU_FCx.HTCR[HFREF] and CMU_FCx.HTCR[LFREF]) is the absolute sum of frequency variations of the clock sources. Refer device datasheet for frequency variations for the corresponding clock sources.

## 53.2 Overview

CMU_FC ensures the clock integrity of selected clocks and allows continuous clock integrity verification.

CMU_FC checks if the frequency of a monitored clock (*monitored_clock*) is within a programmable frequency range specified by the user. If the frequency is outside the specified limits, it could lead to performance, protocol, and timing failures. CMU_FC requires a clock used as a base reference for the frequency check operation. This reference clock (*reference_clock*) must be within documented limits for correct CMU_FC operation.

### 53.2.1 Block diagram

CMU_FC counts clock cycles of the monitored clock during a user programmable time duration of *n* clock cycles of the reference clock. There is a comparison between the final count of the monitored clock and the user programmable upper and lower threshold count limits. The control logic determines whether the cycle count is within the programmed limits. If not it sets the Frequency Higher than High frequency reference threshold event status (FHH) field or the Frequency Lower than Low frequency reference threshold event status (FLL) field in the Status Register (SR). If you enable interrupts, an interrupt asserts when the status flag sets.

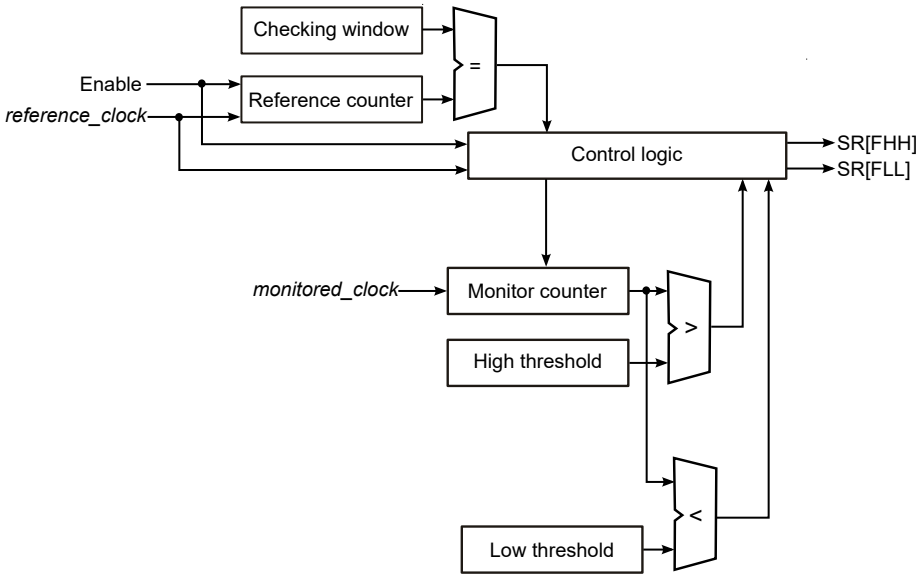

Figure 198. CMU_FC block diagram

CMU_FC cannot detect the following:

- Monitored clock duty cycle variations
- Instantaneous monitored clock frequency variations that do not cross upper or lower threshold limits

### 53.2.2 Features

The CMU_FC features are:

- Programmable duration of reference clock cycles
- Initiates an event if a monitored clock frequency is higher than high frequency reference (FHH)
- Initiates an event if a monitored clock frequency is lower than low frequency reference (FLL)
- FLL event (if enabled) is generated when monitored clock is very slow or stops functioning
- Masking of FHH event interrupt
- Masking of FLL event interrupt

## 53.3 Functional description

### 53.3.1 Operating modes

CMU_FC supports the following operating modes:

- Frequency checking

See the succeeding sections for detailed descriptions of the functions.

### 53.3.2 Frequency checking

Frequency checking starts when software writes GCR[FCE] = 1. The Run Status field SR[RS] shows 1 after frequency check operation starts.

CMU_FC performs continuous periodic clock checking of the monitored clock. Each checking window involves the following operations:

- Stage 1 – Reference clock counter runs for RCCR[REF_CNT] reference clock cycles. Monitored clock counter runs in parallel for the same time duration as reference clock counter.
- Stage 2 – After stage 1, the module compares the final monitored clock count against the programmed thresholds.

If the monitored clock count is greater than the high threshold value in HTCR[HFREF], an FHH event occurs.

If the monitored clock count is lower than the low threshold value in LTCR[LFREF], an FLL event occurs.

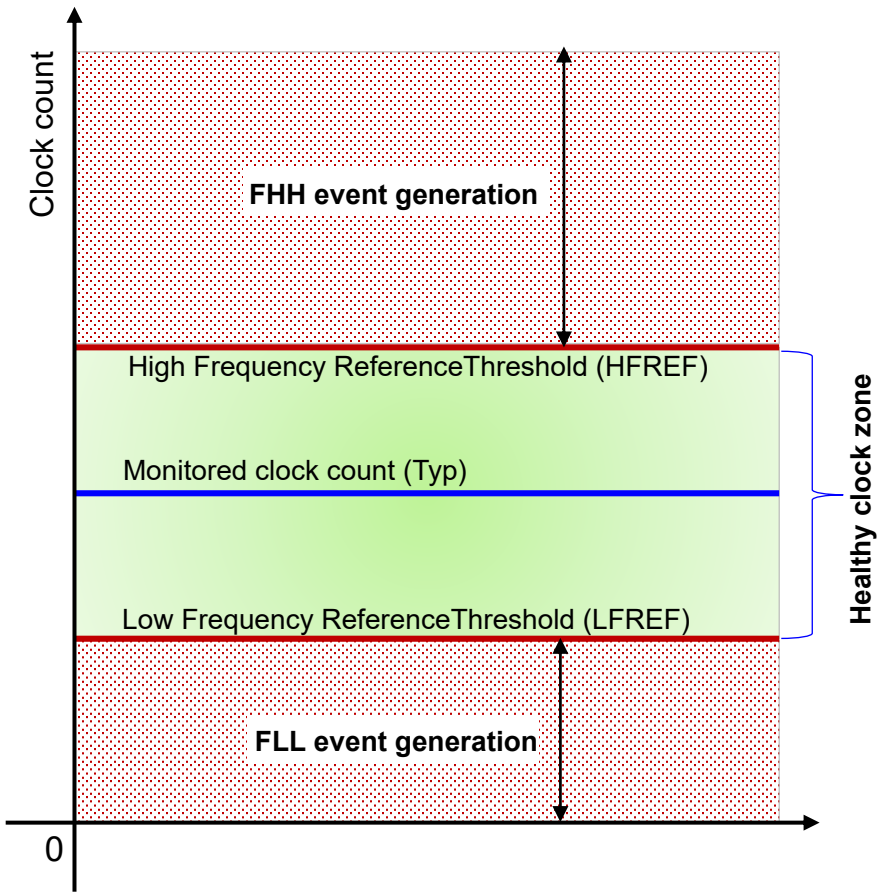

Figure 199. Frequency checking HFREF and LFREF thresholds

### 53.3.2.1 Monitored clock lost

If a monitored clock ceases operation before evaluation of that clock (Stage 2, see Frequency checking), CMU_FC waits for RCCR[REF_CNT] reference clock periods by extending Stage 2 before triggering an FLL event.

- If *monitored_clock* is not running when enabling CMU_FC:

| Worst case FLL response time = (2 × RCCR[REF_CNT] + 12) *reference_clock* cycles + 15 *bus_clock* cycles |
|---|

- If *monitored_clock* stops when the CMU_FC is running:

| Worst case FLL response time = (2 × RCCR[REF_CNT] + 2) *reference_clock* cycles + 3 *bus_clock* cycles |
|---|

### 53.3.3 Clocking

This module has the following clock sources.

**Table 248. Clock description**

| Clock | I/O | Description |
|---|---|---|
| *reference_clock* | I | Clock signal that the module uses as a reference to evaluate *monitored_clock* |
| *monitored_clock* | I | Clock signal on which frequency check is performed |
| *bus_clock* | I | Clock signal on which register read/write operation is performed |

**NOTE**

See the Clocking chapter for details of monitored and reference clocks used on this chip.

### 53.3.4 Reset

This module has the following reset sources.

- Global hard reset input
- Reset port synchronized to reference clock domain input
- Reset port synchronized to monitored clock domain input

## 53.4 External signals

This module has no external signals.

## 53.5 Programming guidelines

### 53.5.1 Programming RCCR[REF_CNT]

RCCR[REF_CNT] defines the duration of the checking operation in number of *reference_clock* cycles. The minimum RCCR[REF_CNT] value can be calculated using the following formula:

**Minimum RCCR [REF_CNT]** = CEILING value of MAX $\left(3 \text{ X } \left(\frac{f_{reference_clock}}{f_{bus_clock}}\right), 8 + 5 \text{ X } \left(\frac{f_{reference_clock}}{f_{monitored_clock}}\right)\right)$

...where:

- $f_{reference_clock}$ is the frequency of the reference clock
- $f_{bus_clock}$ is the frequency of the bus clock
- $f_{monitored_clock}$ is the frequency of the monitored clock

**Example to determine RCCR[REF_CNT]:**

- $f_{bus_clock}$ = 16 MHz
- $f_{reference_clock}$ = 8 MHz
- $f_{monitored_clock}$ = 48 MHz

| | |
|---|---|
| Formula #1: | $3 \times \left( \frac{f_{reference_clock}}{f_{bus_clock}} \right)$ |
| Inserting the values: | 3 × (8 / 16) = 1.5 |
| Formula #2: | $8 + 5 \times \left( \frac{f_{reference_clock}}{f_{monitored_clock}} \right)$ |
| Inserting the values: | 8 + 5 × (8 / 48) ≈ 8.83 |
| MAX (1.5, 8.83): | 8.83 |
| CEILING value of MAX: | 9 |
| Therefore, minimum RCCR[REF_CNT]: | 9 |

Programmed RCCR[REF_CNT] value must be greater than or equal to the calculated minimum value and should be decided after considering application requirements of frequency check completion response time and overall accuracy required from CMU_FC.

- Higher values of RCCR[REF_CNT] results in longer measurement window, leading to better accuracy in monitored clock check.
- Lower values of RCCR[REF_CNT] results in shorter measurement window, leading to faster FHH and FLL event response, but higher inaccuracy in reported result.

For measurement window calculation, see step 8 in Programming HFREF and LFREF

### 53.5.2 Programming HFREF and LFREF

You must consider the following when programming HFREF/LFREF:

- Tolerable monitored clock frequency variation
- Maximum reference clock frequency variation
- Inherent module inaccuracy

CMU_FC has an expected maximum deviation of ± 3 *monitored_clock* cycles ($CMU_FC_{VAR+}$ = 3, $CMU_FC_{VAR-}$ = –3).

The following procedure shows how to calculate optimum values for HTCR[HFREF] and LTCR[LFREF] (numbers shown are from example in table):

1. Determine the ideal *monitored_clock* frequency ($f_{monitored_clock}$ (ideal), 48 MHz).
2. Determine the specified variation of the *monitored_clock* (1.1%).
3. Calculate *monitored_clock* frequency variation: .

   $$f_{monitored_clock}\,(ideal) \times (1 \pm variation\,(\text{step 2}))$$

   - $f_{monitored_clock}$ (max) = 48 MHz × (1 + (1.1 ÷ 100)) = 48.53 MHz
   - $f_{monitored_clock}$ (min)= 48 MHz × (1 – (1.1 ÷ 100)) = 47.47 MHz
4. Determine the ideal *reference_clock* frequency ($f_{reference_clock}$ (ideal), 8 MHz).
5. Determine the specified variation of the *reference_clock* (3.3%).

6. Calculate ideal *reference_clock* frequency variation:

$$f_{reference_clock}\ (ideal) \times (1 \pm variation\ (\text{step 5}))$$

   - $f_{reference_clock}$ (max) = 8 MHz × (1 + (3.3 ÷ 100)) = 8.26 MHz
   - $f_{reference_clock}$ (min) = 8 MHz × (1 – (3.3 ÷ 100)) = 7.74 MHz
7. Select the value of RCCR[REF_CNT] needed (80). See Programming RCCR[REF_CNT].
8. Calculate ideal measurement window:

$$\frac{RCCR\,[REF_CNT]}{f_{reference_clock}\ (ideal)}$$

   - 80 ÷ 8 MHz = 10000 ns
9. Calculate ideal *monitored_clock* count:

$$\frac{RCCR[REF_CNT]}{f_{reference_clock}(ideal)} \times f_{monitored_clock}\ (ideal)$$

   - 80 ÷ 8 MHz × 48 MHz = 480.00 (round off this value, 480 in this case)
10. Calculate high threshold value (HTCR[HFREF]):

$$\text{Ceiling value of } \left(\frac{f_{monitored_clock}\ (max)}{f_{reference_clock}\ (min)} \times RCCR[REF_CNT]\right) + CMU_FC_{VAR+}$$

    - HTCR[HFREF] = Ceiling(48.53 MHz ÷ 7.74 MHz × 80 + 3) = 505
11. Calculate low threshold value (LTCR[LFREF]):

$$\text{Floor value of } \left(\frac{f_{monitored_clock}\ (min)}{f_{reference_clock}\ (max)} \times RCCR[REF_CNT]\right) - CMU_FC_{VAR-}$$

    - LTCR[LFREF] = Floor(47.47 MHz ÷ 8.26 MHz × 80 – 3) = 456

**Table 249. HTCR[HFREF] and LTCR[LFREF] calculation example**

| Property | Value | Unit |
|---|---|---|
| Bus clock frequency ($f_{bus_clock}$) | 16 | MHz |
| Monitored clock frequency ($f_{monitored_clock}$ (ideal)) | 48 | MHz |
| Specified variation of monitored clock | 1.1 | % |
| Monitored clock frequency (maximum after specified variation, $f_{monitored_clock}$ (max)) | 48.53 | MHz |

*Table continues on the next page...*

Table 249. HTCR[HFREF] and LTCR[LFREF] calculation example (continued)

| Property | Value | Unit |
|---|---|---|
| Monitored clock frequency (minimum after specified variation, $f_{monitored_clock}$ (min)) | 47.47 | MHz |
| | | |
| Reference clock frequency ($f_{reference_clock}$ (ideal)) | 8 | MHz |
| Specified variation of reference clock | 3.3 | % |
| Reference clock frequency (maximum after specified variation, $f_{reference_clock}$ (max)) | 8.26 | MHz |
| Reference clock frequency (minimum after specified variation, $f_{reference_clock}$ (min)) | 7.74 | MHz |
| | | |
| Minimum reference count (RCCR[REF_CNT]) | 9 | — |
| Programmed reference count (RCCR[REF_CNT])<br>(must be ≥ minimum RCCR[REF_CNT]) | 80 | — |
| Measurement window | 10000.00 | ns |
| | | |
| Calculated monitored clock count | 480.00 | — |
| Calculated monitored clock Count (rounded) | 480 | — |
| | | |
| Module positive variation ($CMU_FC_{VAR+}$) | 3 | — |
| Module negative variation ($CMU_FC_{VAR-}$) | -3 | — |
| | | |
| Programmed higher threshold (HTCR[HFREF]) | 505 | — |
| Programmed lower threshold (LTCR[LFREF]) | 456 | — |

## 53.5.3 Module programming sequence

### 53.5.3.1 Module programming sequence

The recommended programming sequence for CMU_FC frequency checking is:

1. In any order, complete the following:
   - Program RCCR[REF_CNT] to define the frequency measuring window duration in *reference_clock* cycles.
   - Program LTCR[LFREF] and HTCR[HFREF] to set the permissible frequency range of the *monitored_clock*.
   - Program IER to enable interrupt.
2. Write GCR[FCE] = 1 to start the frequency check operation.

   **NOTE**

   When GCR[FCE] = 1, you must not write to RCCR, HTCR, LTCR, or IER. Attempting to do so generates a bus transfer error.

3. To reconfigure RCCR, LTCR, HTCR , and IER or to stop frequency check operation, wait for SR[RS] = 1, then write GCR[FCE] = 0.

# 53.6 CMU_FC register descriptions

### 53.6.1 CMU_FC memory map

This section describes the address order of all the CMU_FC registers. Each description includes a standard register diagram and associated field descriptions.

CMU_0 base address: 402B_C000h

CMU_3 base address: 402B_C060h

CMU_4 base address: 402B_C080h

CMU_5 base address: 402B_C0A0h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Global Configuration Register (GCR) | 32 | RW | 0000_0000h |
| 4h | Reference Count Configuration Register (RCCR) | 32 | RW | 0000_0000h |
| 8h | High Threshold Configuration Register (HTCR) | 32 | RW | 00FF_FFFFh |
| Ch | Low Threshold Configuration Register (LTCR) | 32 | RW | 0000_0000h |
| 10h | Status Register (SR) | 32 | RW | 0000_0000h |
| 14h | Interrupt Enable Register (IER) | 32 | RW | 0000_0000h |

### 53.6.2 Global Configuration Register (GCR)

#### Offset

| Register | Offset |
|---|---|
| GCR | 0h |

#### Function

Controls module level configurations such as enabling frequency check.

## 53.6.3 Reference Count Configuration Register (RCCR)

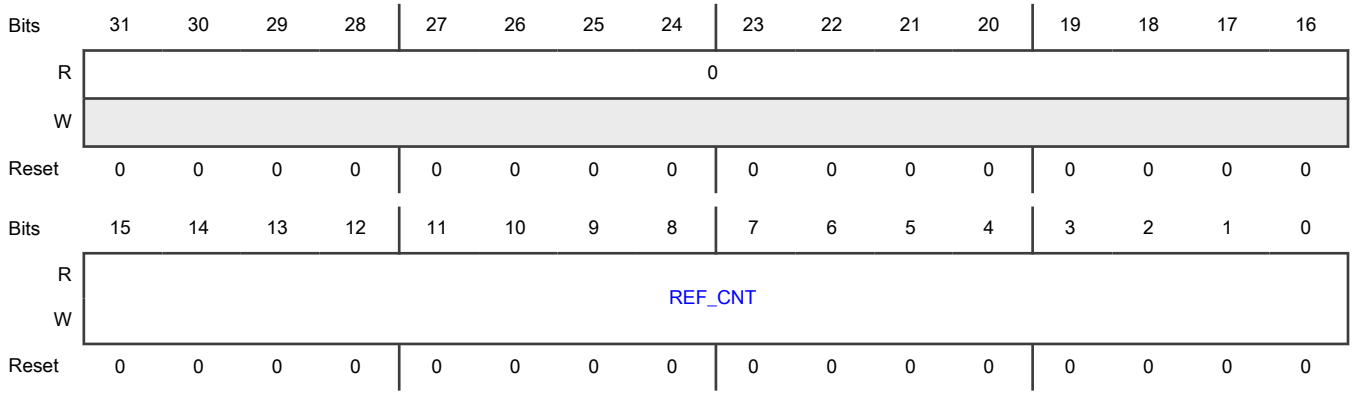
**Offset**

| Register | Offset |
|---|---|
| RCCR | 4h |

**Function**
Programs reference count duration of the frequency check window.

**NOTE**
Write to RCCR only when GCR[FCE] = 0. A bus transfer error results if software writes RCCR when GCR[FCE] = 1.

**Diagram**



**Fields**

### 53.6.4 High Threshold Configuration Register (HTCR)

#### Offset

| Register | Offset |
|---|---|
| HTCR | 8h |

#### Function
Determines the high threshold limit of the monitored clock counter.

**NOTE**
Write HTCR only when GCR[FCE] = 0. A bus transfer error results if software writes HTCR when GCR[FCE] = 1.

#### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 0<br>FLL | Frequency lower than low frequency reference threshold event status<br>Hardware writes 1 to FLL when the monitored clock frequency becomes lower than the low threshold value in LTCR[LFREF]. FLL clears when software writes 1.<br>0b - No FLL event<br>1b - FLL event occurred |

### 53.6.7 Interrupt Enable Register (IER)

#### Offset

| Register | Offset |
|---|---|
| IER | 14h |

#### Function

Enables CMU_FC interrupts.

**NOTE**

Write IER only when GCR[FCE] = 0. A bus transfer error results if software writes IER when GCR[FCE] = 1.

Enable only either asynchronous FHH event interrupt or synchronous FHH event interrupt at a time.

For example:

- If IER[FHHIE] is set to 1 then set IER[FHHAIE] to 0.
- If IER[FHHAIE] is set to 1 then set IER[FHHIE] to 0.

Enable only either asynchronous FLL event interrupt or synchronous FLL event interrupt at a time.

For example:

- If IER[FLLIE] is set to 1 then set IER[FLLAIE] to 0.
- If IER[FLLAIE] is set to 1 then set IER[FLLIE] to 0.

See Clocking chapter for interrupt usage information based on CMU_FC instances.

## 53.7 Glossary

**FHH** The state that the monitored clock frequency is higher than the high frequency reference. FHH is also the name of the register field that indicates this state.

**FHH event** The event that the module triggers when it detects FHH.

**FLL** The state that the monitored clock frequency is lower than the lower frequency reference. FLL is also the name of the register field that indicates this state.

**FLL event** The event that the module triggers when it detects FLL.

# Chapter 54
# Clock Monitoring Unit – Frequency Meter (CMU_FM)

## 54.1 Chip-specific CMU_FM information

### 54.1.1 CMU_FM configuration

The device consists of a robust clock monitoring architecture targeted to monitor various clock nodes to ensure device clock robustness. There are 6 clock monitoring units present in the device out of which 2 are of type CMU_FM. See 'Clock monitoring' section in Clocking chapter for details on device clock monitoring architecture.

**NOTE**

CMU metering interrupt is not generated if the clock which is being metered is lost. A timeout status flag, CMU.SR[FMTO] is updated in this case.

**NOTE**

Software must ensure that CMU1 interrupt is serviced within POR_WDG timeout. In absence of CMU1 interrupt servicing, the POR_WDG detects this as an FIRC failure and initiates a POR recovery.

## 54.2 Overview

CMU_FM measures the frequency of the metered clock (*metered_clock*) using another clock as reference. This reference clock (*reference_clock*) must be within documented limits for correct CMU_FM operation. CMU_FM operation is only guaranteed if a reference clock is within normal operating parameters.

### 54.2.1 Block diagram

The CMU_FM counts the clock cycles of a metered clock in the user programmable time duration *n* number of clock cycles of the reference clock. After completion of a metered clock operation, a register field sets, indicating the operation has completed. The count of the metered clock also updates in the Status Register (SR) after completion of a metered clock operation.

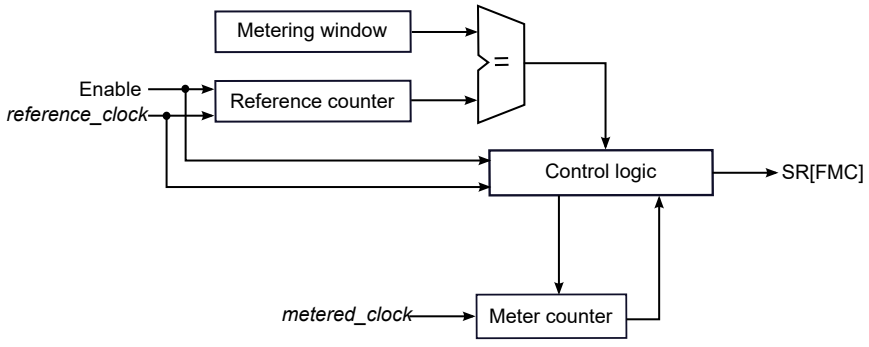

**Figure 200. Block diagram**

### 54.2.2 Features

Features of the CMU_FM are:

- Programmable duration of *reference_clock* cycles
- Maskable interrupt generation when frequency metering completes
- Timeout feature indicates loss of *metered_clock*

## 54.3 Functional description

The frequency meter operation initiates when software writes GCR[FME] = 1. When the operation starts, hardware writes SR[RS] = 1. Safety critical applications must poll SR[RS] to determine when metering operation starts.

Frequency metering window involves these operations:

1. Stage 1 — The reference clock counter runs for RCCR[REF_CNT] cycles of *reference_clock*. The metered clock counter runs in parallel for the same time duration as the *reference_clock* counter.
2. Stage 2 — At the end of stage 1, SR[FMC] = 1, SR[MET_CNT] updates with the *metered_clock* count, and CMU_FM writes GCR[FME] = 0.

### 54.3.1 Clocking

The following table lists the clock sources for this module.

**Table 250. Clock description**

| Clock | I/O | Description |
|---|---|---|
| *reference_clock* | I | Clock signal that the module uses as a reference to evaluate *metered_clock* |
| *metered_clock* | I | Clock signal on which frequency metering is performed |
| *bus_clock* | I | Clock signal on which register read/write operation is performed |

**NOTE**

See the Clocking chapter for details of metered and reference clocks used on this chip.

### 54.3.2 Reset

This module has the following reset sources.

- Global hard reset input
- Reset port synchronized to reference clock domain input
- Reset port synchronized to monitored clock domain input

## 54.4 Programming guidelines

### 54.4.1 Programming RCCR[REF_CNT]

RCCR[REF_CNT] defines the duration of the metering operation in number of *reference_clock* cycles. The minimum RCCR[REF_CNT] value can be calculated using the following formula:

$$\textbf{Minimum RCCR [REF_CNT]} = \text{CEILING value of MAX}\left(3 \text{ X } \left(\frac{f_{reference_clock}}{f_{bus_clock}}\right), 8 + 5 \text{ X } \left(\frac{f_{reference_clock}}{f_{monitored_clock}}\right)\right)$$

...where:

- $f_{reference_clock}$ is the frequency of the reference clock
- $f_{bus_clock}$ is the frequency of the bus clock
- $f_{metering_clock}$ is the frequency of the metered clock

**Example to determine RCCR[REF_CNT]:**

- $f_{bus_clock}$ = 16 MHz
- $f_{reference_clock}$ = 8 MHz
- $f_{metered_clock}$ = 48 MHz

Formula #1:

$$3 \text{ X } \left( \frac{f_{reference_clock}}{f_{bus_clock}} \right)$$

Inserting the values: 3 × (8 / 16) = 1.5

Formula #2:

$$8 + 5 \text{ X } \left( \frac{f_{reference_clock}}{f_{monitored_clock}} \right)$$

Inserting the values: 8 + 5 × (8 / 48) ≈ 8.83

MAX (1.5, 8.83): 8.83

CEILING value of MAX: 9

Therefore, minimum RCCR[REF_CNT]: 9

Programmed RCCR[REF_CNT] value must be greater than or equal to the calculated minimum value and should be decided after considering application requirements of frequency metering completion response time and overall accuracy required from CMU_FM.

- Higher values of RCCR[REF_CNT] results in longer metering window, leading to better accuracy in metered clock measurement.
- Lower values of RCCR[REF_CNT] results in shorter metering window, leading to faster FMC response, but higher inaccuracy in reported result.

### 54.4.2 Module programming sequence

The recommended programming sequence of CMU_FM is:

1. In any order, complete the following:
   - Program RCCR[REF_CNT] to define the frequency metering window duration in *reference_clock* cycles.
   - Program IER[FMCIE] to enable interrupt.
2. Write GCR[FME] = 1 to start frequency metering operation. Writes to RCCR and IER are disabled after GCR[FME] = 1. Attempting a write to any of them after GCR[FME] = 1 generates a bus transfer error.
3. To reconfigure RCCR and IER or to stop frequency metering operation, wait for SR[RS] = 1, then write GCR[FME] = 0.

Upon completion of metering operations:

- Hardware writes SR[FMC] = 1
- SR[MET_CNT] updates with metered count value
- Hardware writes GCR[FME] = 0

## 54.5 External signals

This module has no external signals.

## 54.6 CMU_FM register descriptions

### 54.6.1 CMU_FM memory map

This section describes the address order of all the CMU_FM registers. Each description includes a standard register diagram and associated field descriptions.

CMU_1 base address: 402B_C020h

CMU_2 base address: 402B_C040h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Global Configuration Register (GCR) | 32 | RW | 0000_0000h |
| 4h | Reference Count Configuration Register (RCCR) | 32 | RW | 0000_0000h |
| 8h | Status Register (SR) | 32 | RW | 0000_0000h |
| Ch | Interrupt Enable Register (IER) | 32 | RW | 0000_0000h |

### 54.6.2 Global Configuration Register (GCR)

#### Offset

| Register | Offset |
|---|---|
| GCR | 0h |

#### Function

Controls module level configurations such as enabling frequency metering.

#### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

# Chapter 55
# Cyclic Redundancy Check (CRC)

## 55.1 Chip-specific CRC information

This chip supports one instance of CRC module.

## 55.2 Overview

CRC generates 16-bit or 32-bit CRC codes output for error detection. You can calculate these codes for up to 32 bits input data at a time.

CRC provides a programmable polynomial and other parameters to meet 16-bit or 32-bit CRC standards.

### 55.2.1 Block diagram

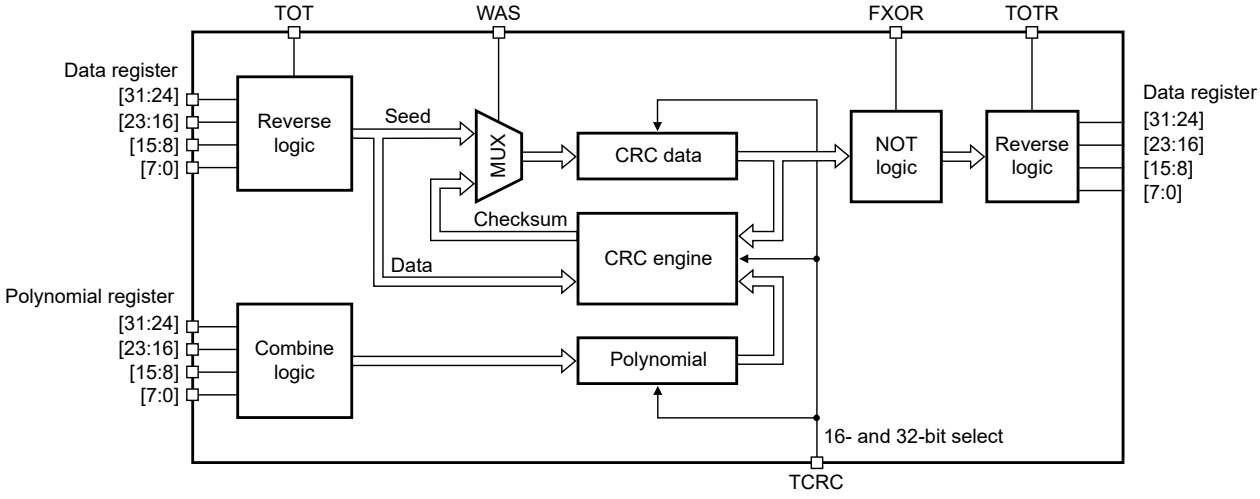

Figure 201. Block diagram

### 55.2.2 Features

CRC has the following features:

- Hardware CRC generator circuit using 16-bit or 32-bit programmable shift registers
- Programmable initial seed value and polynomial
- Transpose of input or output data (CRC result) in bitwise or bytewise (this option is required for certain CRC standards. You cannot perform a bytewise transpose operation when accessing DATA via 8-bit access.)
- Invert final CRC result
- 32-bit CPU register programming interface

## 55.3 Functional description

### 55.3.1 Modes of operation

The following sections describe various modes of operation that affect the functionality of CRC: Run mode and Low power mode.

#### 55.3.1.1 Run mode

Run mode is the basic mode of operation.

#### 55.3.1.2 Low-power modes

When the chip enters the low-power mode, the CRC module clock (ipg_clk and ipg_clk_s) is disabled and the in-progress CRC calculation stops. The calculation resumes after the CRC module clock is enabled or the chip exits low power mode via system reset.

**NOTE**

See the chip-specific power management chapter to know the specific low-power modes supported on your device.

### 55.3.2 CRC calculations

In 16-bit and 32-bit CRC modes, you can program data values as 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes lead to an incorrect CRC calculation.

#### 55.3.2.1 Calculating a 16-bit CRC

Perform these steps to calculate a 16-bit CRC:

1. Write 0 to CTRL[TCRC] to enable 16-bit CRC mode.
2. Program the transpose and complement options in Control (CTRL) as required for the CRC calculation.
3. Write a 16-bit polynomial to GPOLY[LOW].

   GPOLY[HIGH] is not usable in 16-bit CRC mode.
4. Write 1 to CTRL[WAS] to program the seed value.
5. Write a 16-bit seed to DATA[LU] and DATA[LL].

   DATA[HU] and DATA[HL] are not used.
6. Write 0 to CTRL[WAS] to start writing data values.
7. Write data values into DATA[LU], and DATA[LL]

   CRC is calculated on every data value write and the intermediate CRC result is stored back into DATA[LU] and DATA[LL]
8. After writing all the data values, read the final CRC result from DATA[LU] and DATA[LL].

CRC is calculated bytewise and two clocks are required to complete one CRC calculation.

The transpose and complement operations are performed on-the-fly when reading or writing values. See Transpose feature and Result complement for details.

#### 55.3.2.2 Calculating a 32-bit CRC

Perform these steps to calculate a 32-bit CRC:

1. Write 1 to CTRL[TCRC] to enable 32-bit CRC mode.
2. Program the transpose and complement options in Control (CTRL) as required for CRC calculation. See Transpose feature and Result complement for details.
3. Write a 32-bit polynomial to GPOLY[HIGH] and GPOLY[LOW] .
4. Write 1 to CTRL[WAS] to program the seed value.
5. Write a 32-bit seed to DATA[HU], DATA[HL], DATA[LU], and DATA[LL].
6. Write 0 to CTRL[WAS] to start writing data values.
7. Write data values into DATA[HU], DATA[HL], DATA[LU], and DATA[LL]

CRC is computed on every data value write and the intermediate CRC result is stored back into DATA .

8. After writing all the values, read the final CRC result from DATA[HU], DATA[HL], DATA[LU], and DATA[LL].

   CRC is calculated bytewise and two clocks are required to complete one CRC calculation.

The transpose and complement operations are performed on-the-fly when reading or writing values. See Transpose feature and Result complement for details.

### 55.3.3 Transpose feature

Transpose is not enabled by default. However, CRC requires input data and/or final checksum to be transposed. You have an option to configure each transpose operation separately to meet CRC standards. The data is transposed on-the-fly while being read or written.

Some protocols use the little-endian format for data stream to calculateCRC. In this case, transpose flips bits.

#### 55.3.3.1 Types of transpose

CRC provides several types of transpose to flip bits and/or bytes for both writing input data and reading result separately using the CTRL[TOT] and CTRL[TOTR] according to the CRC calculation being used.

The following types of transpose are available for writing to and reading from DATA.

1. CTRL[TOT] or CTRL[TOTR] is 0.

   No transposition occurs.

2. CTRL[TOT] or CTRL[TOTR] is 1.

   Bits in a byte are transposed when bytes are not transposed.

   reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}.

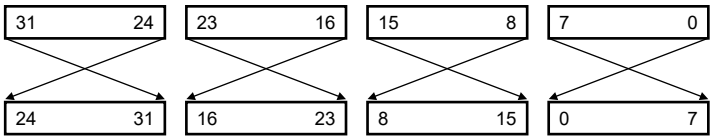

**Figure 202. Transpose type 1b**

3. CTRL[TOT] or CTRL[TOTR] is 10b.

   Both bits in bytes and bytes are transposed.

   reg[31:0] becomes {reg[0:7], reg[8:15], reg[16:23], reg[24:31]}.

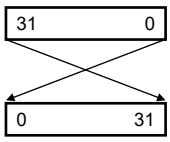

**Figure 203. Transpose type 10b**

4. CTRL[TOT] or CTRL[TOTR] is 11b.

   Bytes are transposed but bits are not transposed.

   reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}.

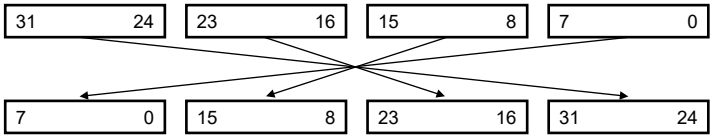

Figure 204. Transpose type 11b

**NOTE**

For 8-bit and 16-bit write accesses to Data (DATA), the data is transposed with 0s on the unused byte or bytes (taking 32 bits as a whole), but CRC is calculated on the valid byte(s) only. When reading the Data (DATA) for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in DATA[HU] and DATA[HL]. You must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

### 55.3.4 Result complement

When CTRL[FXOR] = 1, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in Data (DATA) every time Data (DATA) is read. When CTRL[FXOR] = 0,, reading Data (DATA) accesses the raw checksum value.

### 55.3.5 Clocking

Table 251. CRC clocks

| Type of clock | Description |
|---|---|
| Bus clock (ipg_clk/ipg_clk_s) | ipg_clk_s controls the access to the CRC registers. ipg_clk and ipg_clk_s function the CRC module. |

**NOTE**

See the chip-specific clocking chapter, to know the specific CRC clocks supported on your device.

### 55.3.6 Interrupts

This module has no interrupts.

## 55.4 External signals

There is no CRC signal that connects off chip.

## 55.5 Initialization

To enable CRC calculation, you must program:

- CTRL[WAS] .
- Polynomial (GPOLY).
- Parameters for transposition and CRC result inversion in the applicable registers.

Writing 1 to CTRL[WAS] enables you to program the seed value into CRC Data registers.

After writing all the data, you must wait for at least two clock cycles to read the data from CRC Data (DATA) register.

After a CRC calculation completes, you can reinitialize the module for a new CRC computation by again writing 1 to CTRL[WAS] and programming a new, or previously used, seed value. You must set all other parameters before programming the seed value and subsequent data values.

## 55.6 Use cases

The following tables use the little-endian format.

### 55.6.1 CTRL programming

The following table shows Control (CTRL) programming for 16-bit CRC.

**Table 252. CTRL programming for 16-bit CRC**

| Algorithm | Polynomial | Seed | Ref in | Ref out | XOR out | CTRL[TOT] | CTRL[TOTR] | CTRL[FXOR] |
|---|---|---|---|---|---|---|---|---|
| CRC-16_CCITT_FALSE | 1021h | FFFFh | 0 | 0 | 0000h | 0h | 0h | 0h |
| CRC-16_ARC | 8005h | 0000h | 1 | 1 | 0000h | 1h | 2h | 0h |
| CRC-16_AUG_CCITT | 1021h | 1D0Fh | 0 | 0 | 0000h | 0h | 0h | 0h |
| CRC-16_BUYPASS | 8005h | 0000h | 0 | 0 | 0000h | 0h | 0h | 0h |
| CRC-16_CCITT_ZERO | 1021h | 0000h | 0 | 0 | 0000h | 0h | 0h | 0h |
| CRC-16_CDMA2000 | C867h | FFFFh | 0 | 0 | 0000h | 0h | 0h | 0h |
| CRC-16_DDS_110 | 8005h | 800Dh | 0 | 0 | 0000h | 0h | 0h | 0h |
| CRC-16_DECT_X | 589h | 0000h | 0 | 0 | 0000h | 0h | 0h | 0h |
| CRC-16_DNP | 3D65h | 0000h | 1 | 1 | FFFFh | 1h | 2h | 1h |

## 55.7 Memory map and register descriptions

**NOTE**

You must reconfigure CRC engine in case an IPS transfer error occurs (ips_xfr_err).

The CRC module generates a transfer error in the following cases:

- Write accesses to the register addresses that are not mapped to the peripherals but included in the address spaces of the peripherals.

### 55.7.1 CRC register descriptions

#### 55.7.1.1 CRC memory map

CRC base address: 4038_0000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Data (DATA) | 32 | RW | FFFF_FFFFh |
| 4h | Polynomial (GPOLY) | 32 | RW | 0000_1021h |
| 8h | Control (CTRL) | 32 | RW | 0000_0000h |

### 55.7.1.2 Data (DATA)

#### Offset

| Register | Offset |
|---|---|
| DATA | 0h |

#### Function

Configures the value of seed, data, and checksum. When CTRL[WAS] = 1, any write to this register is regarded as the seed value. When CTRL[WAS] becomes 0, any write to this register is regarded as data for general CRC calculation.

In 16-bit CRC mode, DATA[HU] and DATA[HL] are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, you can program to write 8 bits, 16 bits, or 32 bits in big endian order, provided all bytes are contiguous, with the MSB of data value written first.

After writing all data values, you can read the CRC result from DATA register. In 16-bit CRC mode, the CRC result is available in DATA[LU] and DATA[LL]. In 32-bit CRC mode, all fields contain the result. After writing all data, you must wait for at least two clock cycles to read the data from CRC data (DATA) register.

#### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

# Chapter 56
# Power Conversion and Motor Control (PCMC)

## 56.1 Introduction

The PCMC subsystem is a group of modules that can be interconnected to perform a variety of real-time tasks, such as:

- Motor control
- Power conversion
- Advanced PWM generation
- Lighting control

The modules that make up PCMC are:

- ADC
- BCTU
- eMIOS
- LCU
- LPCMP
- TRGMUX

See Feature comparison for the number of instances of each module in your chip.

## 56.2 Block diagram

The figure and table below show a typical configuration.

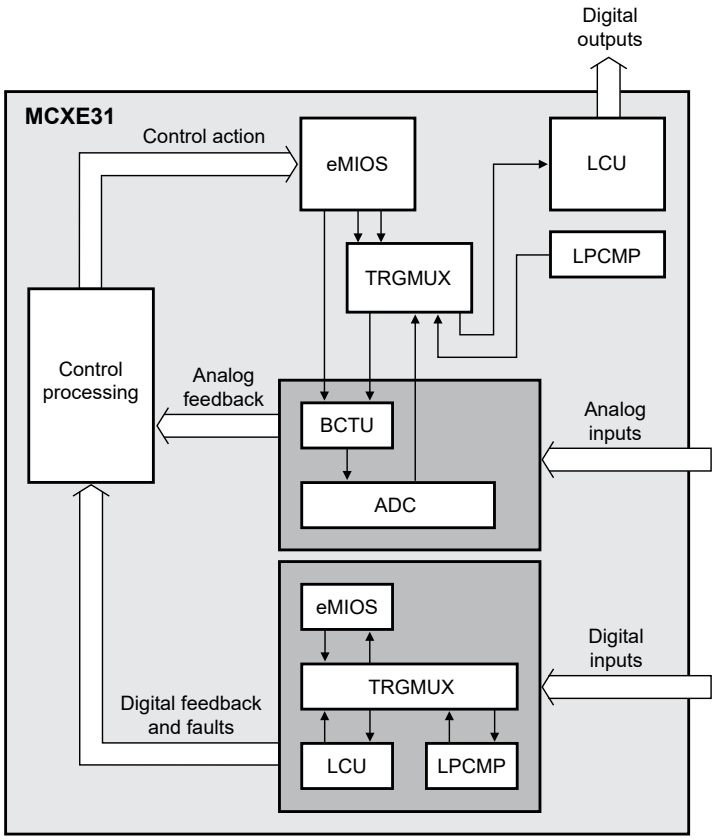

Figure 205. Block diagram

Table 256. Block diagram components

| Component | Description |
|---|---|
| ADC | Measures external analog signals |
| BCTU | Performs advanced ADC triggering |
| Control processing | Arm Cortex-M7 core:<br>• Processes digital and analog inputs to generate control outputs<br>• Writes control outputs to peripherals |
| eMIOS | • Generates high-resolution PWM outputs<br>• Measures time-based digital inputs |
| LCU | Performs programmable logic functions and fault control |
| LPCMP | Compares analog values to detect faults |
| TRGMUX | • Routes signals between internal peripherals<br>• Routes external signals to internal peripherals |

## 56.3 Functional overview

### 56.3.1 Analog signal measurement

ADC measures the voltage of external analog signals and converts that voltage to a digital value. Each ADC instance operates independently of other instances. Software or hardware can trigger conversions. Together with BCTU and eMIOS, ADC can preempt normal measurements by injecting high-priority measurements when needed.

See Analog-to-Digital Converter.

### 56.3.2 Advanced ADC triggering

BCTU works with ADC to initiate conversions triggered by outputs from other modules in the PCMC subsystem, such as PWM signals from eMIOS or LCU sequential logic outputs.

With BCTU, you can group measurements into configuration lists containing up to 32 items. Each item contains information such as:

- ADC instance to use for the conversion
- The ADC channel
- The trigger event for initiating the next conversion
- The conversion list address

BCTU can store conversion results by routing them through DMA or putting them in FIFO queues. The FIFO queues enable conversions to occur seamlessly by storing conversion results without software intervention.

BCTU has 72 trigger inputs, 69 of which come from the eMIOS channel outputs. The three remaining trigger inputs come from other on-chip modules via TRGMUX. You can also trigger conversions by software through the BCTU register interface.

BCTU can issue a single conversion or a list of conversions based on a single trigger occurrence. BCTU signals the eMIOS timers when ADC receives a single command or a list of commands. ADC sends conversion data back to BCTU, which loads it in the ADC*n* Result Data (ADC*n*DR) register for the CPU to read.

BCTU-to-ADC interface illustrates the connections between BCTU and an ADC.

See also:

- Body cross-triggering unit (BCTU)
- PCDR*n*, ICDR*n*, and ECDR*n* register descriptions in ADC register descriptions

### 56.3.3 BCTU-to-ADC interface

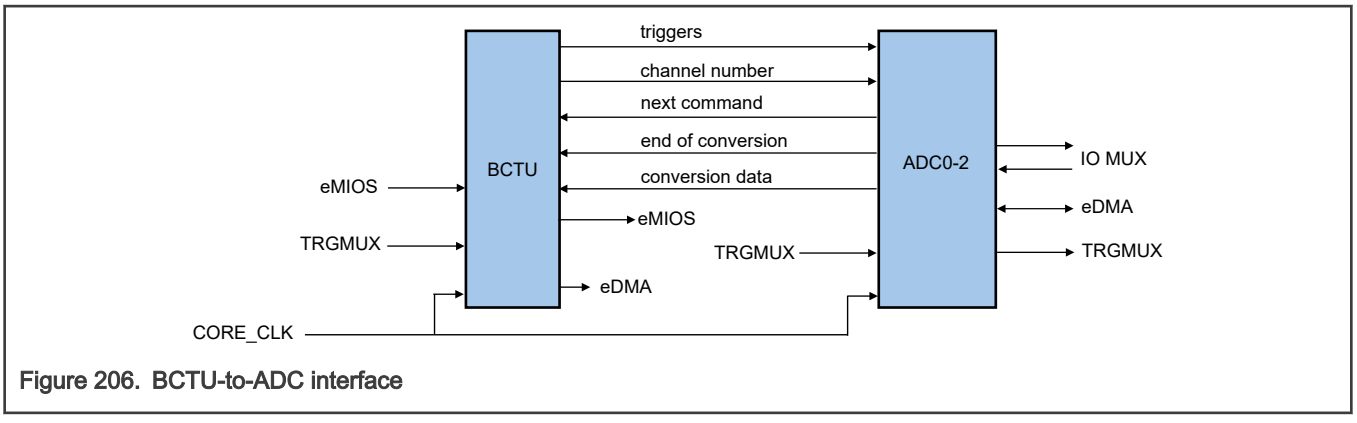

Figure 206. BCTU-to-ADC interface

### 56.3.4 Generate PWM outputs and measure digital inputs

eMIOS generates high-resolution PWM outputs. Each eMIOS instance has 23 dedicated channel outputs. You can configure each channel to operate in a different mode. Depending on the mode, eMIOS channels can:

- Measure the period of an input signal
- Measure the width of an input pulse
- Function as general-purpose I/O
- Count pulses or edges
- Capture input values
- Compare outputs

For example, eMIOS can generate periodic ADC triggers. Using TRGMUX, you can route eMIOS triggers to other on-chip peripherals such as LCU, another eMIOS instance, external chip I/O, and so on.

eMIOS connections illustrates the input and output connections for eMIOS.

See also:

- Enhanced Modular IO Subsystem (eMIOS)
- Body cross-triggering unit (BCTU)
- Trigger Mux (TRGMUX)

### 56.3.5 eMIOS connections

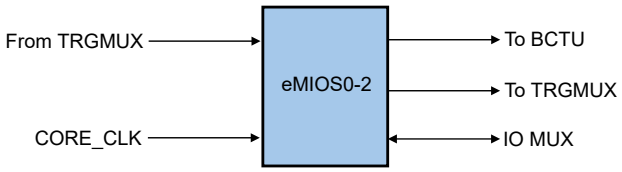

Figure 207. eMIOS connections

### 56.3.6 Create combinatorial and sequential logic functions

LCU enables you to implement hardware-based combinatorial and sequential logic on the chip. This capability reduces cost and decreases application size.

Each LCU instance has 12 dedicated inputs and 12 outputs. You can use LCU to implement a variety of combinatorial and sequential logic functions with no CPU intervention, including a simple OR gate, flip flops, and motor control logic. As detailed in Fault detection, LCU also plays a significant role in fault management.

LCU connections shows the input and output connections for LCU.

See also:

- Logic Control Unit (LCU)
- LCU use case examples
- Trigger MUX (TRGMUX)
- TRGMUX connectivity file attached to this document

### 56.3.7 LCU connections

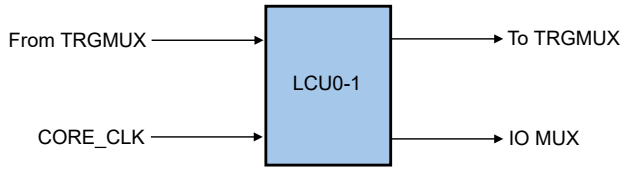

Figure 208. LCU connections

### 56.3.8 Fault detection

The PCMC subsystem uses LPCMP and LCU to implement fault detection.

LPCMP can detect fault conditions (such as short circuits, over-voltages, and excessive temperature) by comparing an external input voltage to a programmable reference voltage. It produces a digital output that indicates whether the input voltage is higher or lower than the reference voltage.

The chip can detect faults via external digital or analog signals. TRGMUX routes digital signals from SIUL to a peripheral to trigger the appropriate behavior.

LCU has four force inputs that you can use to manage fault assertion via its own internal logic mechanism.

The typical reaction to the presence of fault is to put the system in a safe state by:

- Deasserting output signals such as PWM outputs controlling a power stage.
- Disconnecting an entire circuit by switching off a relay.

See also Low Power Comparator (LPCMP).

### 56.3.9 Programmable module interconnections

TRGMUX enables you to interconnect on-chip peripherals to create application-specific configurations. TRGMUX has 128 inputs and 111 outputs, which you can interconnect in hundreds of combinations through software during runtime.

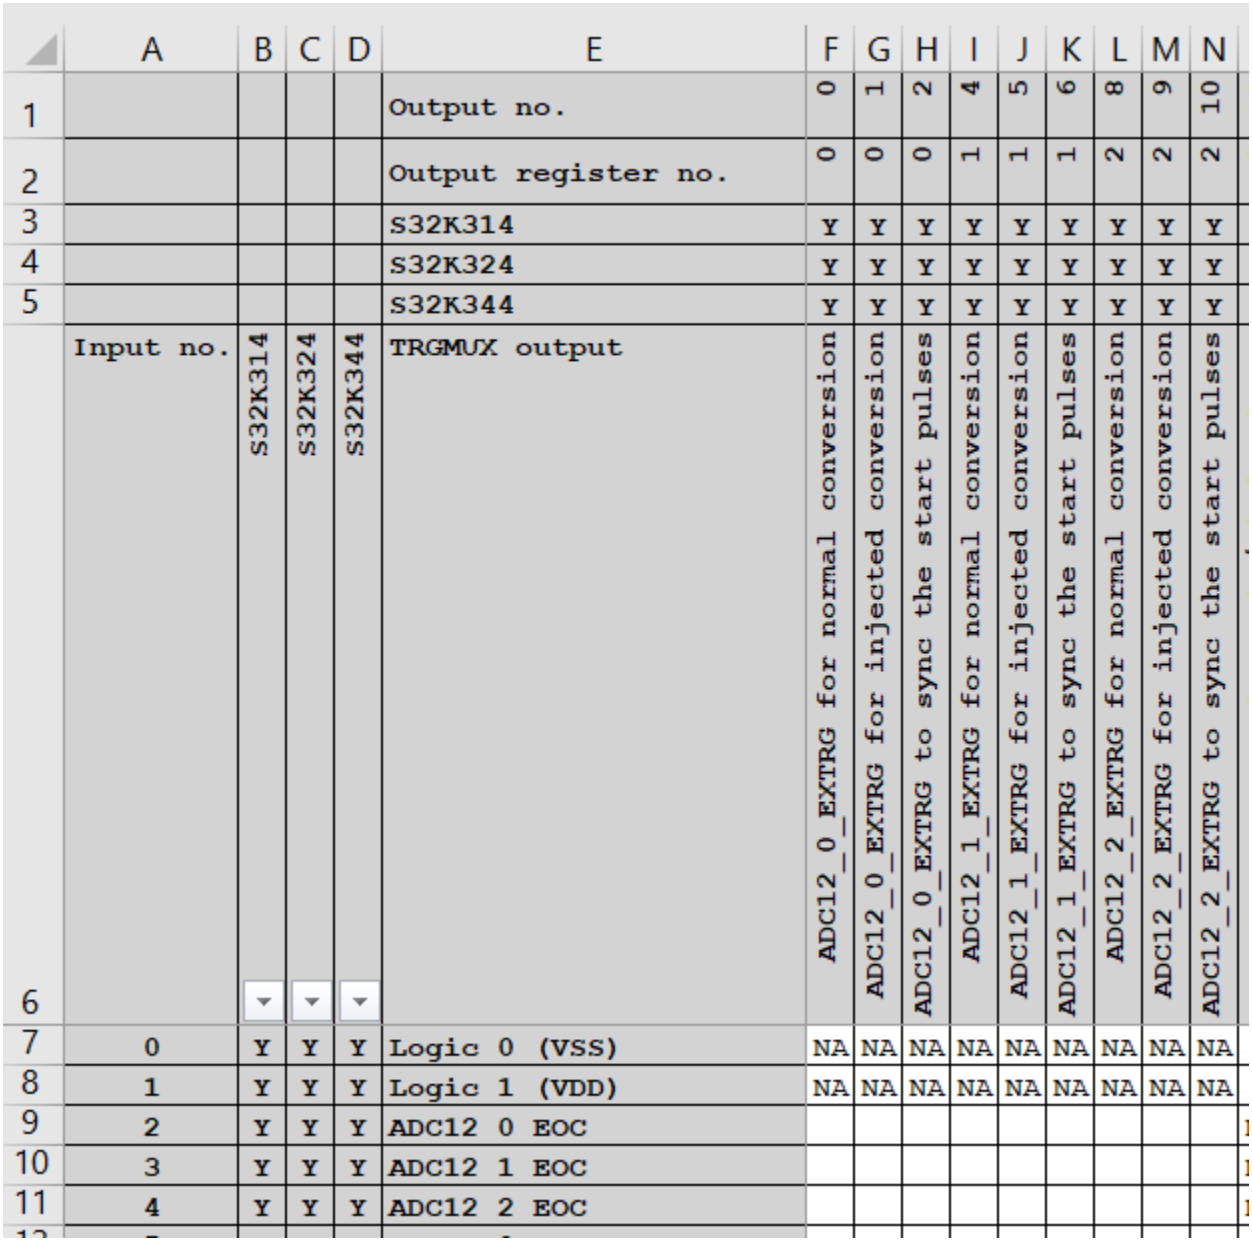
You can also route on-chip peripheral outputs to chip I/O pins to enable signal debugging. Similarly, you can route external signals to on-chip peripheral inputs.

**NOTE**

There is a two-cycle AIPS_SLOW_CLK delay through TRGMUX.

For details of PCMC interconnections, see PCMC connections diagram.

The attached TRGMUX connectivity file, a portion of which appears below, shows the interconnections possible between module instances. Column B in the spreadsheet lists TRGMUX inputs. Row 3 lists TRGMUX outputs. A connection between an input and an output is possible if the intersecting cell of the input row and the output column is blank. "NA" indicates that a connection is not possible.



| | A | B | C | D | E | F | G | H | I | J | K | L | M | N |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | | | | | Output no. | 0 | 1 | 2 | 4 | 5 | 6 | 8 | 9 | 10 |
| 2 | | | | | Output register no. | 0 | 0 | 0 | 1 | 1 | 1 | 2 | 2 | 2 |
| 3 | | | | | S32K314 | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| 4 | | | | | S32K324 | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| 5 | | | | | S32K344 | Y | Y | Y | Y | Y | Y | Y | Y | Y |
| 6 | Input no. | S32K314 | S32K324 | S32K344 | TRGMUX output | ADC12_0_EXTRG for normal conversion | ADC12_0_EXTRG for injected conversion | ADC12_0_EXTRG to sync the start pulses | ADC12_1_EXTRG for normal conversion | ADC12_1_EXTRG for injected conversion | ADC12_1_EXTRG to sync the start pulses | ADC12_2_EXTRG for normal conversion | ADC12_2_EXTRG for injected conversion | ADC12_2_EXTRG to sync the start pulses |
| 7 | 0 | Y | Y | Y | Logic 0 (VSS) | NA | NA | NA | NA | NA | NA | NA | NA | NA |
| 8 | 1 | Y | Y | Y | Logic 1 (VDD) | NA | NA | NA | NA | NA | NA | NA | NA | NA |
| 9 | 2 | Y | Y | Y | ADC12 0 EOC | | | | | | | | | |

## 56.4 Reset, clocking, and other considerations

### 56.4.1 Reset

ADC, BCTU, eMIOS, LCU, and TRGMUX fully reset during a POR, destructive reset, or functional reset.

See also:

- Module reset status
- Software reset

### 56.4.2 Clocking

Detailed clocking information is given in the links below. In summary:

- CORE_CLK clocks ADC, BCTU, eMIOS, and LCU.
- AIPS_SLOW_CLK clocks TRGMUX.
- In general, you must set AIPS_SLOW_CLK to one-fourth or one-half the frequency of CORE_CLK.

See also:

- ADC and motor control modules
- Clocking use case examples
- System clock frequency limitations
- Clock frequency

### 56.4.3 Power modes

All ADC, BCTU, eMIOS, LCU, and TRGMUX instances operate only in Run mode. None of the instances operate in Standby mode.

See also:

- Module reset status
- ADC modes of operation
- LCU modes of operation

## 56.5 Use case examples

### 56.5.1 Motor control use case

The following sections show:

- A PMSM control system
- A BLDC control system

Both PMSM and BLDC use a rotating magnetic stator field to turn the stator consisting of permanent magnets. The stator is driven by 3-phase AC voltage. The difference between PMSM and BLDC is in how stator position is calculated.

- PMSM calculates stator position by measuring back EMF from the motor.
- BLDC calculates stator position based on feedback from motor sensors.

#### 56.5.1.1 PMSM motor control use case

##### 56.5.1.1.1 Generic PMSM motor control

The following figure and table illustrate a generic PMSM motor control system. The feedback loops in the system create a motor control loop.

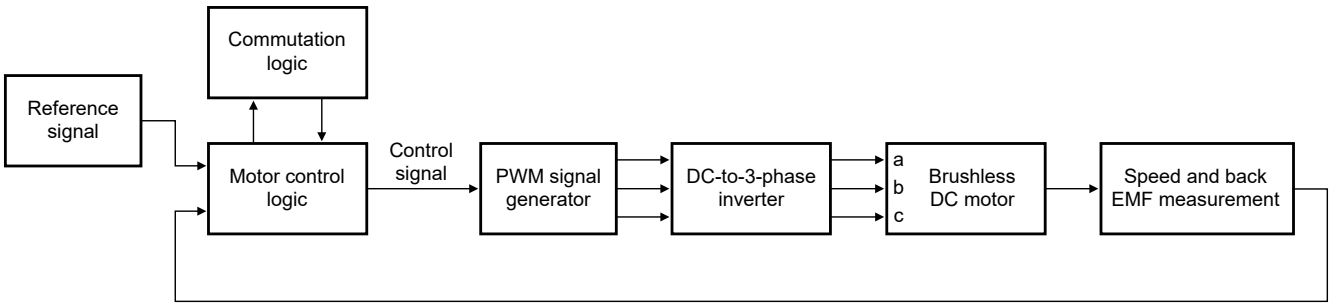

Figure 211. Generic PMSM motor control

Table 257. Block diagram components

| Block | Description |
|---|---|
| Angular position sensor | Generates data that enables commutation logic to calculate rotor position. |
| Brushless DC motor | Electronically commutated electric motor. |
| Commutation logic | Compares values from the rotor angular position sensors to entries in a lookup table, and applies voltage to stator winding corresponding to same set of values in lookup table. |

*Table continues on the next page...*

Table 257. Block diagram components (continued)

| Block | Description |
|---|---|
| DC-to-3-phase inverter | Switching network that transmits power to the motor stator windings according to a control signal. |
| Motor control logic | • Compares speed measurement to required speed and adjusts the PWM signal generator.<br>• Generates the assertions for the PWM signal generator according to commutation logic input. |
| PWM signal generator | Generates PWM signal voltage source. |
| Reference signal | Signal that indicates required motor speed. |
| Speed and back EMF measurement | An ADC is linked to a shunt resistor to perform measurements and detect over-current conditions. If one is found, then hardware generates a fault interrupt. |

#### 56.5.1.1.2 PMSM motor control

The PCMC subsystem consists of a group of modules that enable you to implement PMSM motor control loops in a variety of ways. The following figure and table illustrate one possible implementation.

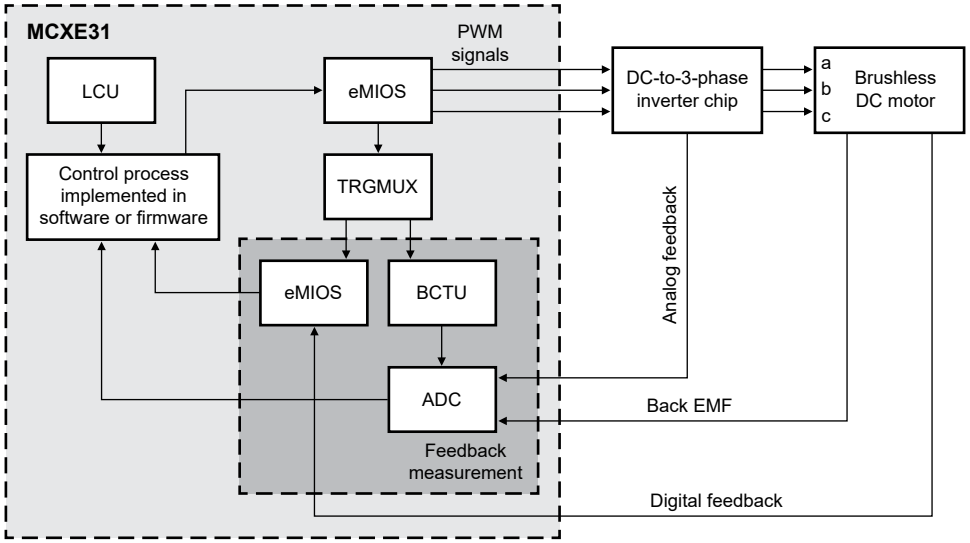

Figure 212. PMSM motor control

Table 258. Block diagram components

| Block | Description |
|---|---|
| ADC | Measures analog inputs (currents and/or voltages) and converts to digital values. Typically, it measures currents and can be configured to generate a fault interrupt when a measured input is outside a pre-defined acceptable range. |
| BCTU | Triggers conversions by ADC. |
| Control process | Provides top-level system control functions for FOC or another feasible control algorithm: |

*Table continues on the next page...*

Table 258. Block diagram components (continued)

| Block | Description |
|---|---|
| | • Compares speed measurement to required speed and adjusts the PWM signal generator.<br>• Generates the assertions for the PWM signal generator according to commutation logic input. |
| DC-to-3-phase inverter | Switching network that transmits power to the motor stator windings according to a control signal. |
| eMIOS | • Generates PWM input for DC to 3-phase inverter.<br>• Measures digital feedback inputs—BLDC position sensors, for example. |
| LCU | Implements commutation lookup table. Control Process compares values from the angular position sensors to entries in the lookup table. It then applies voltage to stator winding corresponding to same set of values in lookup table. |
| TRGMUX | • Enables interconnect to the required set of on-chip peripherals.<br>• Indirectly triggers ADC sampling via BCTU.<br>• Triggers eMIOS to measure digital feedback signals. |

### 56.5.1.2 Sensored BLDC motor control use case

#### 56.5.1.2.1 Generic sensored BLDC motor control

The following figure and table illustrate a generic sensored BLDC motor control system. The feedback loops in the system create a motor control loop.

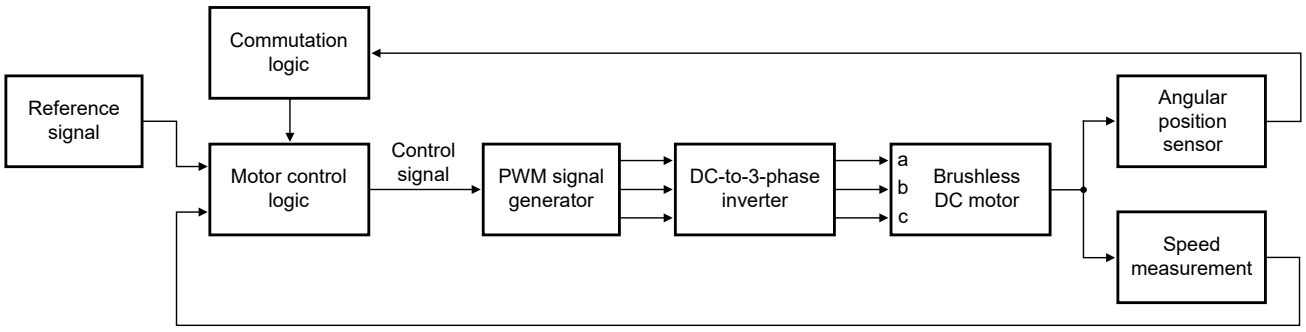

Figure 213. Generic sensored BLDC motor control

Table 259. Block diagram components

| Block | Description |
|---|---|
| Angular position sensor | Hall effect sensors or optical decoders detect rotor position |
| Commutation logic | Compares values from the angular position sensors to entries in a lookup table and applies voltage to stator winding corresponding to same set of values in lookup table |
| Reference signal | Signal that indicates required motor speed |

*Table continues on the next page...*

Table 259. Block diagram components (continued)

| Block | Description |
|---|---|
| DC-to-3-phase inverter | Switching network that transmits power to the stator windings according to a control signal |
| Motor control logic | • Compares speed measurement to required speed and adjusts the PWM signal generator<br>• Generates the assertions for the PWM signal generator according to commutation logic input |
| Speed measurement | Uses an ADC linked to a shunt resistor to perform measurements and detect over-current conditions, in which case hardware generates an interrupt. |

#### 56.5.1.2.2 PCMC sensored field-oriented control (FOC) of 3-phase BLDC motor

FOC is a VFD control method in which the stator currents of a 3-phase AC electric motor (such as BLDC, PMCM, reluctance motor, or other spinning electrical machine) is identified as a vector.

The PCMC subsystem consists of a group of modules that enable you to implement sensored FOC BLDC motor control loops in a variety of ways. The following figure and table show one possible implementation.

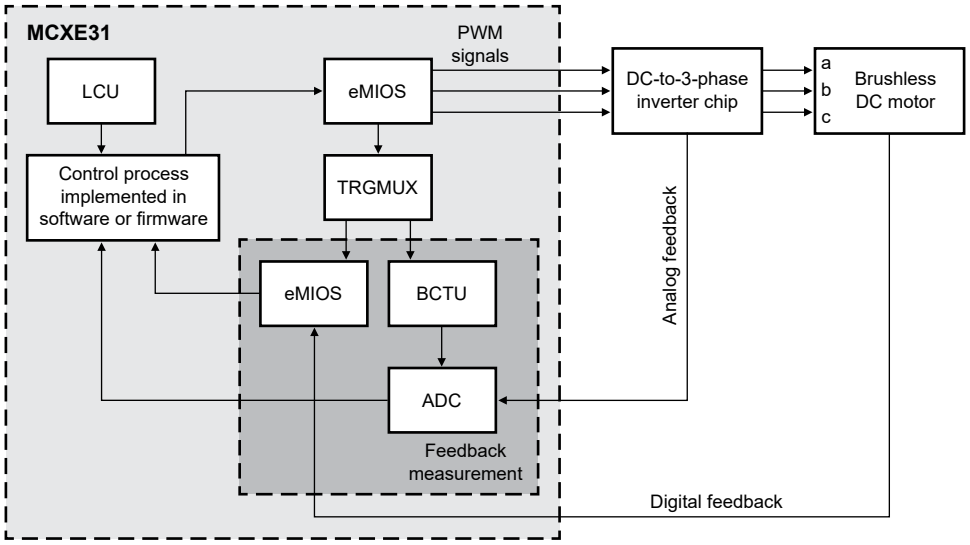

Figure 214. PCMC sensored BLDC motor control

Table 260. Block diagram components

| Block | Description |
|---|---|
| ADC | Measures analog inputs (currents and/or voltages) and converts to digital values. Typically, it measures currents, and can be configured to generate a fault interrupt when a measured input is outside a pre-defined acceptable range. |
| BCTU | Triggers conversions by ADC. |
| Control process | Provides top-level system control functions for FOC control: |

*Table continues on the next page...*

| Block | Description |
|---|---|
| | • Compares speed measurement to required speed and adjusts the PWM signal generator.<br>• Generates the assertions for the PWM signal generator according to commutation logic input. |
| DC-to-3-phase inverter | Switching network that transmits power to the motor stator windings according to a control signal. |
| eMIOS | • Generates PWM input for DC to 3-phase inverter.<br>• Measures digital feedback inputs—BLDC position sensors, for example. |
| LCU | Implements commutation lookup table. Control process compares values from the angular position sensors to entries in the lookup table. It then applies voltage to stator winding corresponding to same set of values in lookup table. |
| TRGMUX | • Enables interconnect of the required set on on-chip peripherals.<br>• Indirectly triggers ADC sampling via BCTU.<br>• Triggers eMIOS to measure digital feedback signals. |

## 56.6 Design considerations

### 56.6.1 ADC design considerations

The following topics discuss factors that affect ADC function in applications.

#### 56.6.1.1 ADC measurement accuracy

The FOC motor control algorithm requires a high degree of confidence in the reliability of conversion data. Here are some best practices that contribute to ADC precision.

- Use precision channels (see ADC precision channels).
- Minimize input noise (see ADC input noise).
- Use BCTU triggering (see ADC triggering).

##### 56.6.1.1.1 ADC precision channels

See the chip-specific ADC configuration information for the number of precision channels for each ADC instance.

See the channel mapping table for the channel numbers for the precision channels.

##### 56.6.1.1.2 ADC input noise

Regardless of the application, ADCs are inherently sensitive to input noise. The following best practices help minimize input noise.

- Avoid simultaneous conversions.
- Consider using a low-pass filter on input pins.

All variants of this chip include multiple, independent ADC instances, so it is easily possible to have simultaneous sampling by different ADC instances. This should be avoided, though, because ADC sampling can cause noise on adjacent device ADC inputs. Avoidance of simultaneous sampling should be ensured by software design. This is important for implementations of the FOC algorithm.

Additionally, an RC low-pass filter on ADC input pins can help reduce noise and enhance accuracy.

#### 56.6.1.1.3 ADC triggering

Some applications, including FOC motor control, must use BCTU for precise triggering of ADC measurement. This is because the FOC algorithm requires sampling at specific times to implement the “observer/predictor”. BCTU makes it possible to perform precisely-timed ADC measurement.

For less exigent algorithms or non-closed-loop controlled motors, BCTU triggering and precision ADC channels are not necessarily required.

### 56.6.1.2 Example ADC configurations

Following are some ADC configurations that might be used for FOC motor control.

**Table 261. Example ADC configurations**

| Description | Settings |
|---|---|
| Single-shot mode | • Enable Overwrite (OWREN=1)<br>• Disable Write Left-Aligned (WLSIDE=0)<br>• Select single shot (MODE=0)<br>• Disable External Trigger (TRGEN=0)<br>• Disable Injection Trigger (JTRGEN=0)<br>• Disable BCTU triggering (BCTUEN=0)<br>• Disable averaging (AVGEN=0)<br>• Select conversion clock = 1/2 module clock (ADCCLKSEL=01) |
| Normal conversion scan mode | • Enable Overwrite (OWREN=1)<br>• Disable Write Left-Aligned (WLSIDE=0)<br>• Select looped conversions (MODE=1)<br>• Disable External Trigger (TRGEN=0)<br>• Disable Injection Trigger (JTRGEN=0)<br>• Disable BCTU triggering (BCTUEN=0)<br>• Disable averaging (AVGEN=0)<br>• Select conversion clock = 1/2 module clock (ADCCLKSEL=01) |
| BCTU control mode | • Enable Overwrite (OWREN=1)<br>• Disable Write Left-Aligned (WLSIDE=0)<br>• Select single shot (MODE=0)<br>• Disable External Trigger (TRGEN=0)<br>• Disable Injection Trigger (JTRGEN=0)<br>• Enable BCTU triggering (BCTUEN=1)<br>• Disable averaging (AVGEN=0)<br>• Select conversion clock = 1/2 module clock (ADCCLKSEL=01) |

*Table continues on the next page...*

Table 261. Example ADC configurations (continued)

| Description | Settings |
|---|---|
| BCTU trigger mode | • Enable Overwrite (OWREN=1)<br>• Disable Write Left-Aligned (WLSIDE=0)<br>• Select single shot (MODE=0)<br>• Disable External Trigger (TRGEN=0)<br>• Disable Injection Trigger (JTRGEN=0)<br>• Enable BCTU triggering (BCTUEN=1)<br>• Enable all trigger sources (BCTU_MODE=1)<br>• Disable averaging (AVGEN=0)<br>• Select conversion clock = 1/2 module clock (ADCCLKSEL=01) |

## 56.6.2 BCTU design considerations

For reasons discussed in ADC triggering, some applications require precise ADC triggering and BCTU provides that capability. The following topics discuss some design considerations when using BCTU.

### 56.6.2.1 BCTU or ADC data retrieval

Although the primary function of BCTU is to provide precisely timed triggers for ADC conversions, there is some overlap in BCTU and ADC function in that conversion data can be retrieved from either module. For applications in which frequent conversions are performed, such as real-time motor control, BCTU offers a distinct advantage over ADC, because BCTU trigger sources can be configured to route conversion results to a BCTU internal FIFO. Doing so prevents subsequent conversion data from overwriting previous data, making it available for either direct access or DMA transfer to system RAM.

### 56.6.2.2 Disabling BCTU triggers

There are fault scenarios in which an application must disable BCTU triggers as part of putting the system into a safe state. Examples include:

- Over-voltage condition
- Under-voltage condition
- Calibration parameter mismatch between the embedded motor control system and the motor

Application fault reaction design must include the disabling of BCTU triggers in scenarios in which either system conditions indicate an impending failure, or ADC conversion data is outside control boundaries.

## 56.6.3 eMIOS design considerations

In a BLDC motor control application, eMIOS plays a central role, providing the driving PWM signal as well as performing feedback signal measurements. The following topics discuss eMIOS considerations in the application design.

### 56.6.3.1 PWM considerations

In a BLDC motor control application, PWM/power signal requirements are affected by a number of parameters, including:

- Displacement Power Factor
- DF
- THD
- DVA

- CF
- FF

Ensure that the above parameters are included when choosing the timebase and prescaler combination for eMIOS channels producing PWM signals.

#### 56.6.3.2 Input measurement

In a BLDC motor control application, eMIOS measures feedback signals for the motor and provides critical information to the control system. Selecting a timebase and prescaler for eMIOS channels performing input measurement tasks is usually a tradeoff between application requirements for precision and the computational cost in relation to the selected clock speed.

For example, some applications like electric steering demand an extremely precise control for position and torque. This is different from a compressor e-motor, where speed and torque do not demand rigid precision requirements.

Other considerations are related to control of:

- THD
- FF
- GM
- pf correction

The above considerations are significant from the perspective of the PWM reaction speed for the output signal for BLDC applications. These parameters must be considered in the design.

#### 56.6.3.3 eMIOS channel modes useful in motor control

**Table 262. eMIOS channel modes useful in motor control**

| Mode | Description | Use in motor control |
|---|---|---|
| MCB | Modulus Counter Buffered (Up/Down) | Time base<br>• PWM frequency<br>• Reload |
| IPWM | Input Pulse Width Measurement | Capture modes:<br>• Speed measurement<br>• Position measurement<br>• Voltage (duty cycle) |
| IPM | Input Period Measurement | Speed measurement |
| PEC | Pulse Edge Counting | Position measurement |
| OPWMCB | Center aligned Output PWM Buffered with dead time | PWM duty cycle |
| OPWMB | Output Pulse Width Modulation Buffered | Trigger placement within the period |
| OPWMT | Output Pulse Width Modulation Trigger | Trigger placement within the period |

##### 56.6.3.3.1 MCB PWM and trigger generation

The following figure shows one option for PWM and trigger generation.

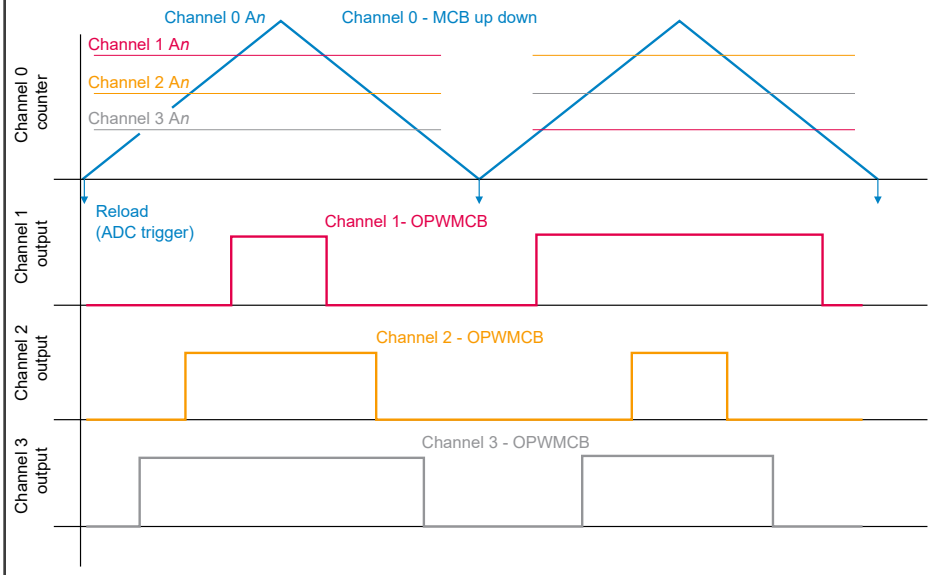

Figure 215. MCB PWM trigger generation

### 56.6.3.3.2 OPWMCB PWM and trigger generation

The following figure shows another option for PWM and trigger generation.

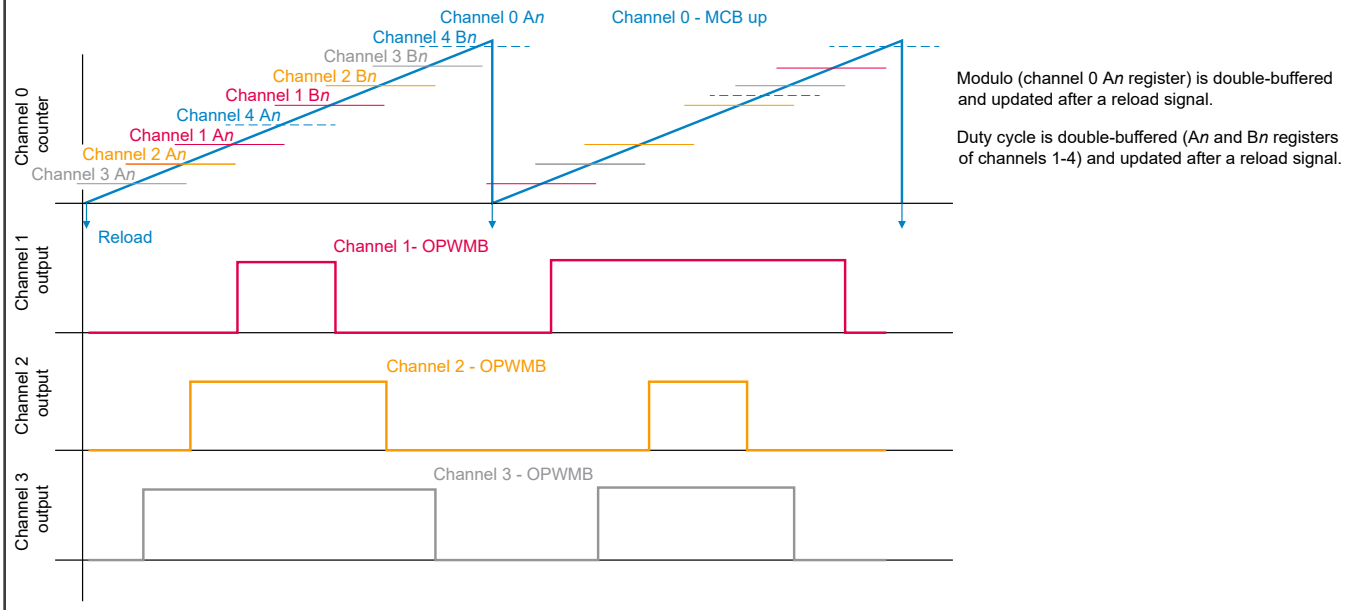

Figure 216. OPWMCB PWM trigger generation

## 56.7 Glossary

| | |
|---|---|
| **BLDC** | Brushless DC. An electronically commutated DC motor. |
| **CF** | Crest Factor. A waveform parameter that is the ratio of peak values to its RMS value. |
| **DF** | Distortion Factor. |

| | |
|---|---|
| **Displacement Power Factor** | In power electronics, the phase relationship between voltage and current: $\cos(\theta_v - \theta_i)$, where $\theta_v$ is the phase of the voltage and $\theta_i$ is the phase of the current. |
| **DVA** | Distortion Volt-Amps. |
| **FF** | Form Factor. |
| **FOC** | Field-Oriented Control. |
| **GM** | Gain Margin. |
| **pf** | Power factor. In power electronics, it is the ratio of average power to RMS power. |
| **PMSM** | Permanent Magnet Synchronous Motor. |
| **THD** | Total Harmonic Distortion. |
| **VFD** | Variable-Frequency Drive. |

## 57.1 Chip-specific ADC information

### 57.1.1 ADC Configuration

This chip has up to 3 instances of ADC. ADC channels are divided into 3 groups - Precision, Standard and External (each with independent configuration settings and different accuracy/performance level). The following table shows the ADC configuration:

**Table 263. ADC instances**

| Instance | MCXE31B | MCXE315/MCXE316 and MCXE317 |
|---|---|---|
| ADC_0 | Yes | Yes |
| ADC_1 | Yes | Yes |
| ADC_2 | Yes | No |

**Table 264. ADC configuration**

| Feature | ADC_0 | ADC_1 | ADC_2 |
|---|---|---|---|
| No. of precision channels | 8 | 8 | 8 |
| No. of standard channels | 16 | 16 | 16 |
| No. of special internal channels | 1[1] | 0 | 0 |
| No. of external channels | 32 | 32 | 0 |
| BCTU trigger support | Yes | Yes | Yes |
| DMA support | Yes | Yes | Yes |
| Hardware interleaving | Yes | Yes | Yes |
| No. of watchdogs | 4 | 4 | 4 |
| No. of Hardware trigger | 3 | 3 | 3 |

1. CHAN_INT0 - channel 50(S)

**Table 265. ADC maximum clock frequency**

| Feature | MCXE31B | MCXE317 | MCXE315/ MCXE316 |
|---|---|---|---|
| ADC module clock frequency (f_mc) | 160 / 120 MHz | 120 MHz | 120 MHz |

**NOTE**

For register configurations need for different frequencies, see 'Functional description' section in this chapter.

**ADC Channel mapping Table**

Table 266. ADC channel mapping

| Channel Number | ADC_0 | ADC_1 | ADC_2 |

1. Channels marked with “-“ means they are reserved and access to any reserved channel may result in inappropriate data.

**NOTE**

The decoding signals for the selection of external ADC channels (ADC_X) are gray-encoded.

**NOTE**

Value of ANAMUX_OUT is selected by DCMRWF1[SUPPLY_MON_SEL] field.

**NOTE**

The module clock mentioned in this chapter is CORE_CLK for this chip.

### 57.1.2 ANAMUX for internal supply monitoring

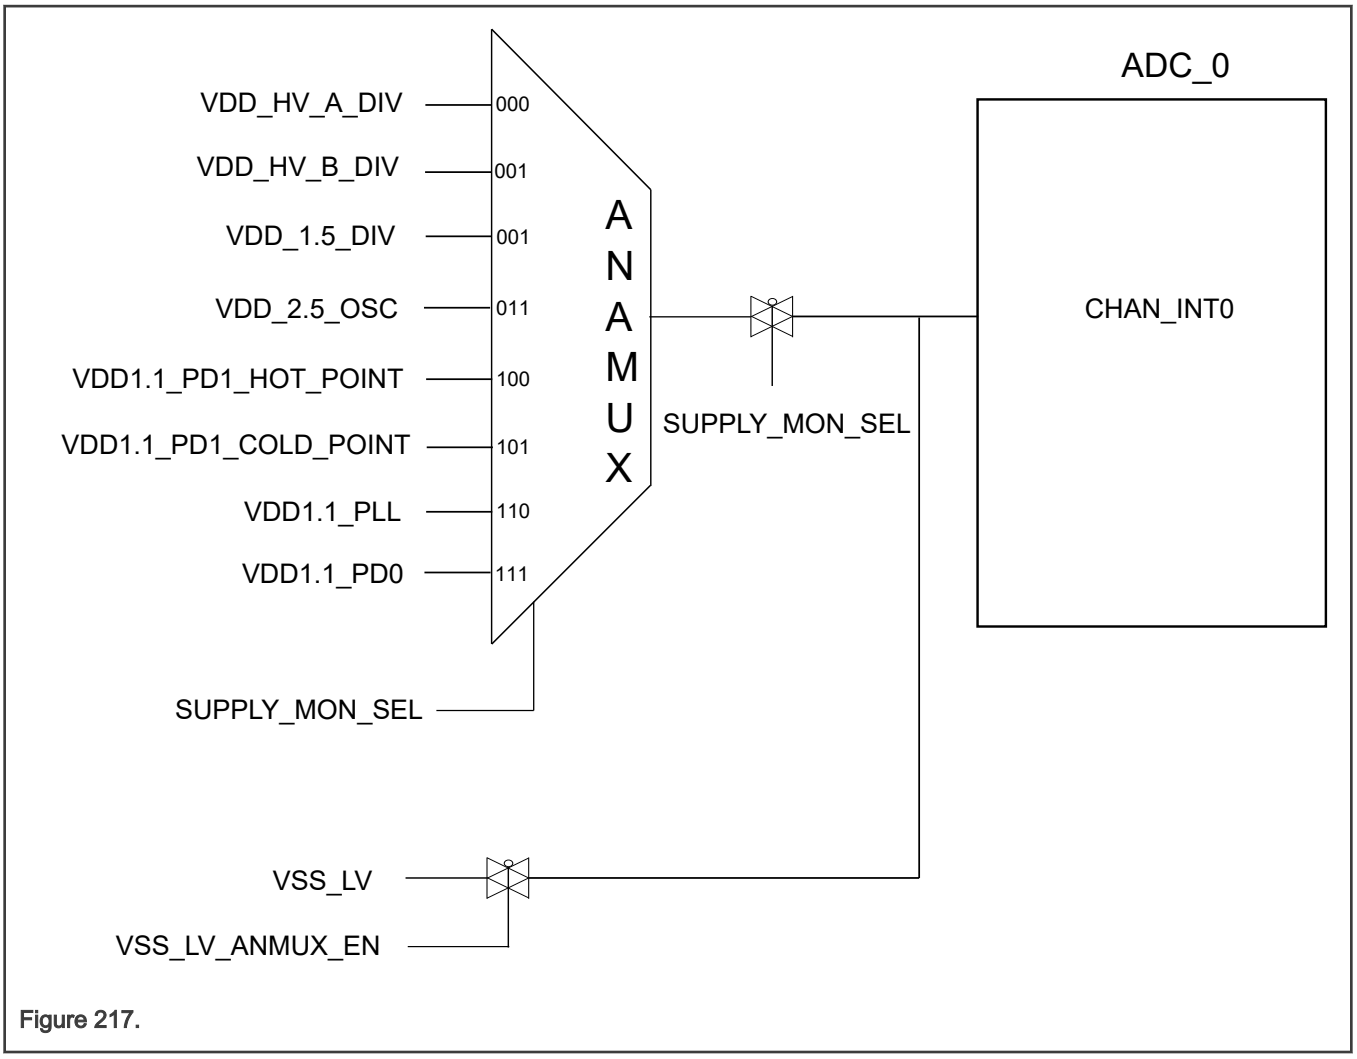

Figure 217.

**NOTE**

VDD_HV_B_DIV, VDD_1.5_DIV are not available in MCXE317 and MCXE315/MCXE316.

### 57.1.3 BCTU Interface

All 3 instances of ADC are triggered from the BCTU. The BCTU provides channel conversion commands to the ADC (includes channel number information). In addition, the ADC provides the conversion result back to the BCTU.

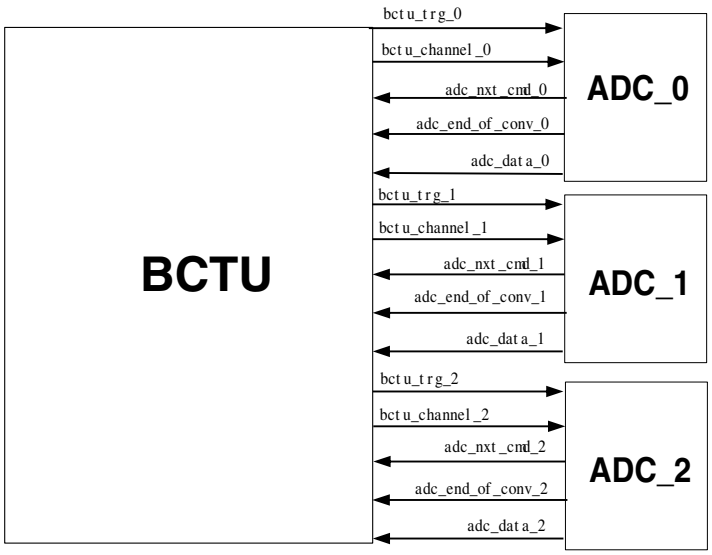

Figure 218. ADC Cross-triggering Unit

BCTU gives trigger pulse to all the 72 channels of ADC to initiate a conversion based on BCTU channel number.

#### BCTU-ADC result register

ADC result registers (ADCx_PCDRn[CDATA], ADCx_ICDRn[CDATA] and ADCx_ECDRn[CDATA]) store 15 bit conversion data. The BCTU ADC registers store 15-bit conversion data (BCTU_ADC0DR[ADC0_DATA], BCTU_ADC1DR[ADC1_DATA] and BCTU_ADC2DR[ADC2_DATA]).

### 57.1.4 DMA interface

Each ADC supports a single DMA request that can be requested after the conversion of every channel. The conversion result is stored into a register DMAR and is transferred via DMA or host access.

**NOTE**

The last ongoing conversion will be aborted as soon as ADC gets STOP request from the software and it will move to STOP mode.

### 57.1.5 Hardware triggers

In this chip, hardware trigger signals can be provided from TRGMUX outputs. This feature enables synchronous conversion of two independent ADC instances in parallel. If ADC is in Idle state (that is, no conversion phase ongoing and the MCR[PWDN] and MCR[ACKO] fields are 0) and the MCR[XSTRTEN] is set, an event on the external start signal causes ADC to start either normal or injected conversion operation. The MCR[NSTART]/MCR[JSTART] field is automatically set respectively. The normal conversion sync pulse is used with normal conversion trigger to synchronize the start timing of normal conversion between multiple ADC instances.

Table 267. Hardware triggers

| TRGMUX output number | Hardware trigger functions |
|---|---|
| 0 | ADC_0 Normal Conversion |
| 1 | ADC_0 Injected Conversion |
| 2 | ADC_0 Normal Conversion Sync Pulse |

*Table continues on the next page...*

Table 267. Hardware triggers (continued)

| TRGMUX output number | Hardware trigger functions |
|---|---|
| 4 | ADC_1 Normal Conversion |
| 5 | ADC_1 Injected Conversion |
| 6 | ADC_1 Normal Conversion Sync Pulse |
| 8 | ADC_2 Normal Conversion |
| 9 | ADC_2 Injected Conversion |
| 10 | ADC_2 Normal Conversion Sync Pulse |

### 57.1.6 ADC Self-Test

It is important to check at regular intervals if the ADC is operating correctly. For this purpose a self test feature is provided. When self-test is enabled, the ADC automatically checks its components and flags errors.

### 57.1.7 ADC mux-mode channels

There are some channels in ADC which are driven by multiple pads. For this, GPR bits from DCM are used to define which pad is connected to a particular ADC channel.

For example as below, where ADC0 S8 is driven by GPIO_PAD0 (default) and GPIO_PAD45 (mux_mode). ADC2 S8 is driven by GPIO_PAD133 (default) and GPIO_PAD45 (mux_mode). ADC1 S8 has a dedicated pad GPIO45, so its TGATE doesn't need GPR bit gating. Similar implementation is for ADC0_S9 and ADC2_S9. Following DCM GPR bits have been used:

Table 268. ADC mux_mode GPR

| ADC channel | GPR_bit | Connected pad |
|---|---|---|
| ADC0 Standard channel 8 (ADC0 S8) | DCM.DCMRWF4[1] | 0: GPIO PAD0 (default)<br>1: GPIO PAD45 |
| ADC0 Standard channel 9 (ADC0 S9) | DCM.DCMRWF4[2] | 0: GPIO PAD1 (default)<br>1: GPIO PAD46 |
| ADC 1 standard channel 14 (ADC1 S14) | DCM.DCMRWF4[3] | 0: GPIO PAD69 (default)<br>1: GPIO PAD32 |
| ADC 1 standard channel 15 (ADC1 S15) | DCM.DCMRWF4[4] | 0: GPIO PAD4 (default)<br>1: GPIO PAD33 |
| ADC1 Standard channel 22 (ADC1 S22) | DCM.DCMRWF4[5] | 0: GPIO PAD124 (default)<br>1: GPIO PAD145 |
| ADC1 Standard channel 23 (ADC1 S23) | DCM.DCMRWF4[6] | 0: GPIO PAD125 (default)<br>1: GPIO PAD146 |
| ADC2 Standard channel 8 (ADC2 S8) | DCM.DCMRWF4[9] | 0: GPIO PAD133 (default)<br>1: GPIO PAD45 |
| ADC2 Standard channel 9 (ADC2 S9) | DCM.DCMRWF4[10] | 0: GPIO PAD132 (default)<br>1: GPIO PAD46 |

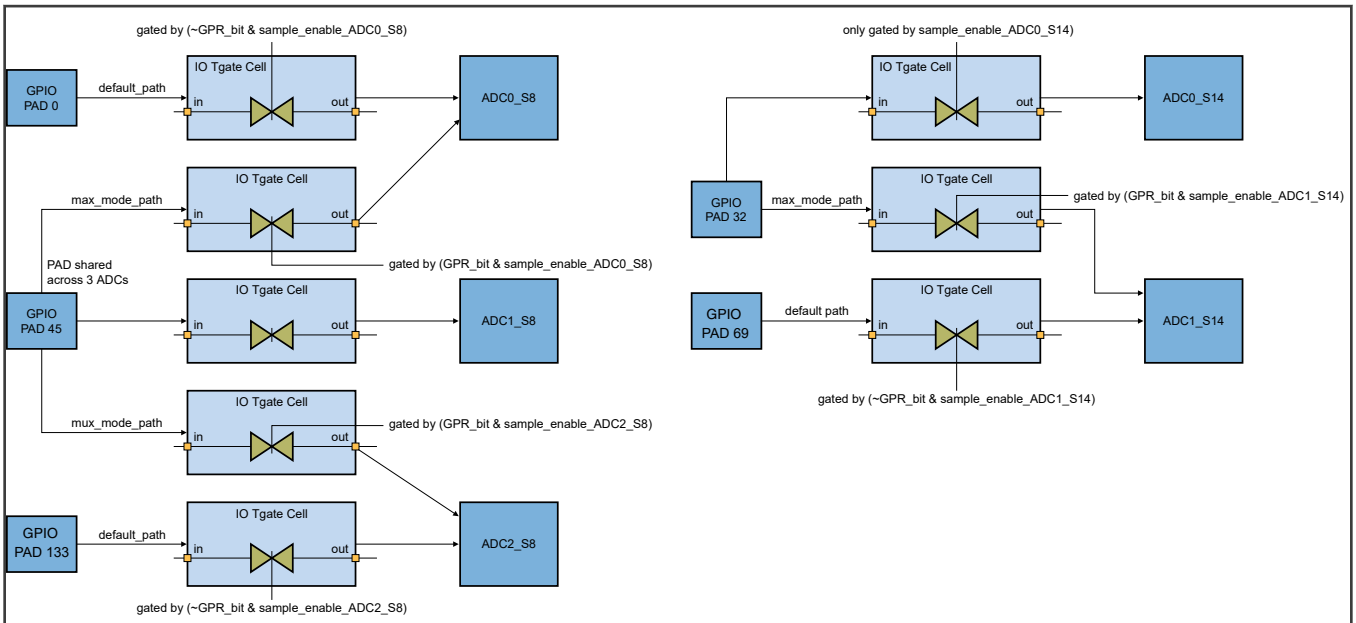

Figure 219. ADC channel interleaving

## 57.2 Overview

ADC produces a digital value from an input analog voltage using the SAR algorithm. It features various methods to trigger a conversion and offers flexibility in the selection of input channels. ADC is useful for a wide range of applications.

A configurable self-test capability supports use cases with increased requirements for functional safety.

## 57.2.1 Block diagram

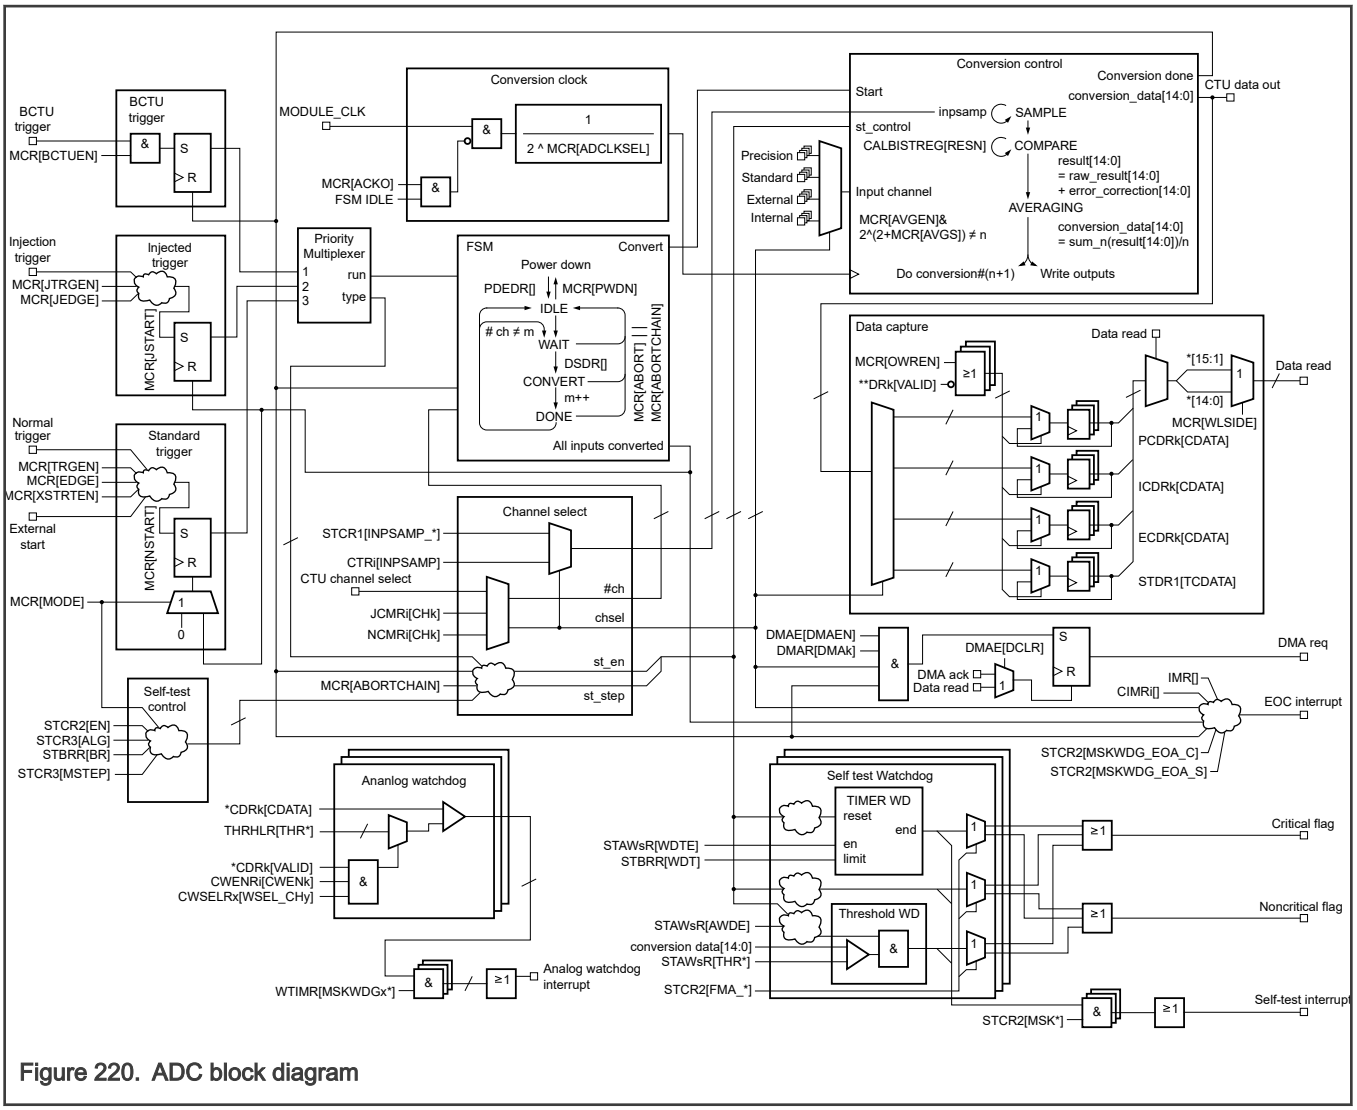

Figure 220. ADC block diagram

Guide to the diagram:

- The signal flow through the diagram is from left to right: inputs to blocks are on the left side, outputs are on the right.
- Block names have the first letters in uppercase and the other letters in lowercase—"Conversion Control," for example).
- Register names are in uppercase followed by a field name in brackets ("MCR[NSTART]," for example). Letters in lowercase are indexes. Asterisks are placeholders for letters (wildcards). Register names in the block diagram map to the names in ADC register descriptions.
- Signal names are in lowercase ("conversion done," for example).
- All digital signals shown are synchronous signals. Asynchronous inputs to the ADC are internally synchronized (synchronizers not shown).

The block diagram shows the signal flow through ADC from the left to the right and from the top to the bottom:

1. When ADC receives one of the three different types of triggers (BCTU, injected, or normal), the priority multiplexer initiates the conversion.
2. The input to be converted is selected in the Channel Select subblock, based on the type of trigger and on the self-test configuration.

3. The state machine (FSM) transitions from Idle state to Convert state. In case the channel to convert changed since the last conversion and this new channel is an external channel, the conversion starts after a delay configured by DSDR[DSD].
4. After a conversion begins, the Conversion Control block holds the internal capacitance network CDAC in the sample phase for a time defined by CTRi[INPSAMP].
5. During the compare phase, CALBISTREG[RESN] defines the number of steps used to execute the successive approximation algorithm. The error_correction values, determined during calibration, are added to the raw result. If averaging is enabled (MCR[AVGEN] = 1), up to 32 (specified via MCR[AVGS]) conversion results are averaged to obtain the result.
6. When the conversion completes and all averaging steps have completed:
    a. The conversion done signal indicates completion.
    b. Conversion_data[14:0] is written to the result registers in the Data Capture subblock.
    c. The FSM transitions into Done state.
7. The next input in the Channel Select block is selected and the next conversion is started by the transition of the FSM to Convert state. This continues until all selected inputs have been converted.
8. If an analog watchdog is enabled, the conversion result is compared to the configured threshold. If the limits are exceeded, an interrupt can be triggered.
9. Self-test can check the integrity of ADC, either interleaved with normal conversions or as a standalone check.
10. If an ongoing conversion is aborted (by writing 1 to MCR[ABORT]) or an ongoing conversion of a set of input channels is aborted (by writing 1 to MCR[ABORTCHAIN]), the FSM transitions into Idle state. The Conversion Control block stops the current conversion if MCR[ABORT] was written with 1, or finishes the current conversion if MCR[ABORTCHAIN] was written with 1. In both cases, the conversion done output signal of the Conversion Control block is set to 1.

Some details are not shown in the block diagram:

- Calibration must be performed to determine the error_correction values (see Calibration) before ADC can do meaningful conversions.
- An input can presample the internal low or high reference voltages to avoid a memory effect that may be present in the comparison due to a previous conversion (see Presampling).
- Monitor ADC status via status flags.
    - See Main Status (MSR) for the FSM state.
    - See Interrupt Status (ISR) to monitor interrupts.
    - See Channel End Of Conversion Flag For Precision Inputs (CEOCFR0) for conversion phase per input.
    - See the following registers to monitor analog watchdogs:
        - Analog Watchdog Out Of Range For Precision Inputs (AWORR0)
        - Analog Watchdog Out Of Range For Standard Inputs (AWORR1)
        - Analog Watchdog Out Of Range For External Inputs (AWORR2)

      See Analog Watchdog Threshold Interrupt Status (WTISR) to monitor analog watchdog interrupts.
    - See Self-Test Status 1 (STSR1) – Self-Test Status 4 (STSR4) to monitor self-test.

### 57.2.2 Features

- Selectable resolution (8-, 10-, 12-, 14-bit). Note that the conversion result is always 15 bits wide, even though the selected resolution is smaller (see CALBISTREG[RESN])
- Conversion data captured in a separate register for each input channel.
- Option to improve accuracy via averaging, which calculates conversion data by averaging the data of up to 32 conversions.

- Conversion triggers:
  - Normal conversion trigger converts a number of input channels, either once per trigger or continuously.
  - Injected conversion trigger interrupts an ongoing normal conversion and converts another set of input channels.
  - BCTU conversion trigger interrupts an ongoing conversion and converts an input channel, in which the input is selected and the conversion is started via the BCTU.
- An analog watchdog optionally monitors conversion data for each input channel and issues an interrupt if the converted data is below or above configurable limits.
- DMA functionality transfers conversion data to other modules.
- Programmable interrupts optionally issue an interrupt when conversion of one or of a set of input channels is finished.
- Self-test functions validate ADC structural integrity during functional operation and generate events with different severities on any finding.
- Conversion clock (AD_clk) control enables the use of ADC in systems with a higher clock frequency by using internal clock dividers.
- Auto turn-off of the conversion clock when ADC is idle.

## 57.3 Functional description

### 57.3.1 Clock

ADC is controlled by one clock signal, the module clock. Internally, the conversion circuit is controlled by the conversion clock, which is derived from the module clock.

The frequency of the conversion clock has to be within the limits defined in the data sheet. If the module clock frequency is higher than the maximum frequency of the conversion clock allowed during the functional conversion or during the calibration (see the chip data sheet), then you must configure the ADC conversion clock divider (MCR[ADCLKSEL]) so that the frequency of the conversion clock is within allowed limits. See Table 269.

**Table 269. Clock configuration for highest conversion speeds**

| Module Clock Frequency f_mc[1] | Configuration during calibration | Configuration during functional conversion |
|---|---|---|
| 40 MHz < f_mc ≤ 80 MHz | MCR[ADCLKSEL] = 1h<br>AMSIO[HSEN] = 0h<br>AMSIO[CMPCTRL0] = 0b | MCR[ADCLKSEL] = 0h<br>AMSIO[HSEN] = 0h<br>AMSIO[CMPCTRL0] = 0b |
| 80 MHz < f_mc ≤ 120 MHz | MCR[ADCLKSEL] = 1h<br>AMSIO[HSEN] = 1h<br>AMSIO[CMPCTRL0] = 1b | MCR[ADCLKSEL] = 0h<br>AMSIO[HSEN] = 1h<br>AMSIO[CMPCTRL0] = 1b |
| 120 MHz < f_mc ≤ 160 MHz | MCR[ADCLKSEL] = 2h<br>AMSIO[HSEN] = 0h<br>AMSIO[CMPCTRL0] = 0b | MCR[ADCLKSEL] = 1h<br>AMSIO[HSEN] = 0h<br>AMSIO[CMPCTRL0] = 0b |
| 160 MHz < f_mc ≤ 240 MHz | MCR[ADCLKSEL] = 2h<br>AMSIO[HSEN] = 1h<br>AMSIO[CMPCTRL0] = 1b | MCR[ADCLKSEL] = 1h<br>AMSIO[HSEN] = 1h<br>AMSIO[CMPCTRL0] = 1b |

*Table continues on the next page...*

Table 269. Clock configuration for highest conversion speeds (continued)

| Module Clock Frequency f_mc[1] | Configuration during calibration | Configuration during functional conversion |
|---|---|---|
| 240 MHz < f_mc ≤ 320 MHz | MCR[ADCLKSEL] = 3h<br>AMSIO[HSEN] = 0h<br>AMSIO[CMPCTRL0] = 0b | MCR[ADCLKSEL] = 2h<br>AMSIO[HSEN] = 0h<br>AMSIO[CMPCTRL0] = 0b |
| 320 MHz < f_mc ≤ 480 MHz | MCR[ADCLKSEL] = 3h<br>AMSIO[HSEN] = 1h<br>AMSIO[CMPCTRL0] = 1b | MCR[ADCLKSEL] = 2h<br>AMSIO[HSEN] = 1h<br>AMSIO[CMPCTRL0] = 1b |

1. Lower resulting frequencies are allowed—see the chip data sheet.

When ADC is not converting (state machine is in Idle state), the conversion clock can be turned off (MCR[ACKO]).

### 57.3.2 Modes of operation

ADC is always in Functional mode. No other mode selection exists.

- Put ADC into Power Down state by writing 1 to MCR[PWDN] to reduce power consumption.
- Gate the clock signal by writing 1 to MCR[ACKO] when ADC is in Idle state.

### 57.3.3 Conversion

ADC measures the voltage of a signal—it converts an analog input value into a digital representation. When you read the conversion result, you must divide this conversion result by the number of codes (defined by selected conversion resolution in CALBISTREG[RESN]), and multiply it with the reference voltage value. This calculation provides the voltage value of the converted signal.

To convert an analog input voltage into its digital representation, ADC:

1. Receives a signal, referred to as a trigger, indicating it is to perform a conversion.
2. Captures the voltage of a signal via internal capacitances in a process referred to as sampling.
3. Compares the voltage to the reference voltage, using the SAR algorithm.

Before a conversion can be performed, you must select:

- The trigger source(s) to use (on the chip level)
- The input channel(s) to convert (NCMR0–2, JCMR0–2)

Additionally, you can tailor the conversion to meet your needs by changing the default configuration. For example, you can:

- Configure ADC to convert the selected input channel(s) only once or continuously in a loop (MCR[MODE]).
- Specify the duration that ADC samples the input signal (CTR0/1/2).
- Specify the resolution of the conversion result by selecting the number of bits (CALBISTREG[RESN]).
- Enable an analog watchdog to generate an interrupt when a conversion result falls outside a specified range (see Analog watchdog functions).
- Enable the DMA interface to send requests and receive acknowledgments (see DMA functionality).
- Check the operational integrity of ADC by running a self-test (see Self-test).

After power-up or a functional reset, ADC remains in Power Down state until enabled by writing 0 to MCR[PWDN]. After the system is powered on, you must run the calibration (see Calibration), before you can do a meaningful conversion with ADC.

Some configuration fields (listed below) are writeable only in Power Down state. If you intend to write to them, you must do so before exiting Power Down state.

- Select the conversion clock frequency to be within the allowed limits for a conversion.

### 57.3.4 Normal trigger

Select the input channels to convert by configuring the fields in NCMR0, NCMR1, and NCMR2.

These registers must be programmed before the start of conversion. You cannot reconfigure them until the conversion of all selected channels is complete. The sequence is always to convert the selected input channels in this order:

1. Start from the lowest input channel of the precision input channels.
2. Proceed through the standard input channels in ascending order.
3. End with the highest input channel of the external input channels.

#### 57.3.4.1 Starting conversions in normal conversion mode

After programming the required fields of the following registers, you can start a conversion by writing 1 to MCR[NSTART]:

- Normal Conversion Enable For Precision Inputs (NCMR0)
- Normal Conversion Enable For Standard Inputs (NCMR1)
- Normal Conversion Enable For External Inputs (NCMR2)
- Main Configuration (MCR)

A hardware trigger can also start a normal conversion.

- If the external trigger is enabled (MCR[TRGEN] = 1), an external trigger enable is detected to start the conversion. The enable is checked only during start of conversion.
- Detection of an active edge defined by MCR[EDGE] (rising = 1, falling = 0) on an external trigger transitions MCR[NSTART] to 1 and starts the normal conversion.
- When MCR[TRGEN] = 1 (for example, when external trigger is enabled), conversion can be started by software.
- Any external trigger or software initiated conversion in normal conversion mode is ignored during any ongoing conversion chain.

**NOTE**

To have reliable operation there must be a gap of 3 clock cycles between configuration of NCMRx and the start of a conversion (by writing 1 to MCR[NSTART], or arrival of an external or internal hardware start trigger). ADC calculates the number of channels to be converted during this period.

#### 57.3.4.2 Operation modes in normal conversions

Two operational modes are available during normal conversion:

- One-Shot mode
- Scan mode

For normal conversion, select the mode via MCR[MODE]. The first phase of the conversion process involves sampling the analog channel. The next phase is the conversion phase, curing which the sampled analog value is converted to digital as shown in the following figure.

Figure 221. Normal conversion flow

In One-Shot mode (MCR[MODE] = 0), a sequential conversion specified in the NCMR*n* mask registers is performed only once. At the end of each conversion, the digital result of the conversion is stored in the corresponding data register (CDR*n*).

For example: Channels A→B→C→D→E→F→G→H are present in a device where channels B→D→E are to be converted in One-Shot mode. Conversion begins with channel B, followed by conversion of channels D and E. At the end of conversion of channel E, the scanning of channels stops.

MSR[NSTART] automatically transitions to 1 when a normal conversion starts. At the same time, MCR[NSTART] is reset to zero by hardware, enabling software to program a new start of conversion in advance. In this case, the new requested conversion starts after completion of the running/current conversion. However, for correct functioning of the device, you should program MCR[NSTART] for the new conversion only after completion of the current conversion. The application can wait for an ECH interrupt prior to writing 1 to MCR[NSTART] again.

If an external trigger starts the conversion chain, ADC does not observe the trigger input until the conversion chain is finished. After the chain is finished, the next chain can be triggered by another hardware trigger edge.

In Scan mode operation (MCR[MODE]=1), a sequential conversion of N channels specified in the NCMR*n* registers is continuously performed. At the end of each conversion, the result is stored in the corresponding data register, as in One-Shot mode.

MSR[NSTART] automatically transitions to 1 when a normal conversion starts. Unlike One-Shot mode, MCR[NSTART] is not reset to 0 in Scan mode. It can be reset by software when you must exit Scan mode. In that case, ADC completes the current chain and after the last conversion, it resets MCR[NSTART] to 0.

For example: Channels A→B→C→D→E→F→G→H are present in the device where channels B→D→E are to be converted in Scan mode. MCR[MODE] = 1 selects Scan mode operation. Conversion starts from channel B followed by conversion of channels D→E. After conversion of channel E, the scanning of channel B starts followed by conversion of the channels D→E. This sequence repeats itself until MCR[NSTART] is reset to 0 by software.

If an external trigger starts a conversion, then MCR[NSTART] does not transition to 1. This scan chain can be stopped by writing 0 to MCR[NSTART]. The conversion stops when the ongoing chain is finished. Consequently, after it starts, the only way to stop Scan mode conversion is to write 0 to MCR[MODE].

**End of conversion**

In both modes, at the end of each conversion, an End of Conversion (EOC) interrupt is issued if enabled by the corresponding mask fields in CIMR*n* and IMR).

After conversion of all selected channels in NCMR*n* is complete, the conversion operation is considered finished. Then ISR[ECH] transitions to 1 and the End of Chain (ECH) interrupt is issued (if enabled in IMR[MSKECH]).

The corresponding channel field in the CEOCFR*n* register(s) is updated to indicate that data is available on data register CDR*n* of the respective channel.

If there is no channel selected in NCMR*n* and there is a start-of-conversion trigger, then ISR[ECH] is set to 1 and the End of Chain (ECH) interrupt is immediately issued (if enabled).

### 57.3.5 Injected trigger

An injected trigger enables you to convert a set of input channels although the standard trigger has already started conversion of another set of input channels. Each channel can be individually enabled by writing 1 to the corresponding field in JCMR0, JCMR1, or JCMR2.

The set of input channels of the injected trigger is converted only once. A continuous conversion of a set of input channels in a loop is only possible when started by a standard trigger. When an injected trigger is received, an ongoing conversion started by a standard trigger is interrupted. After the set of input channels of the injected trigger is converted once, the interrupted conversion of the set of input channels of the standard trigger resumes from the input channel that was interrupted, as shown in the following figure.

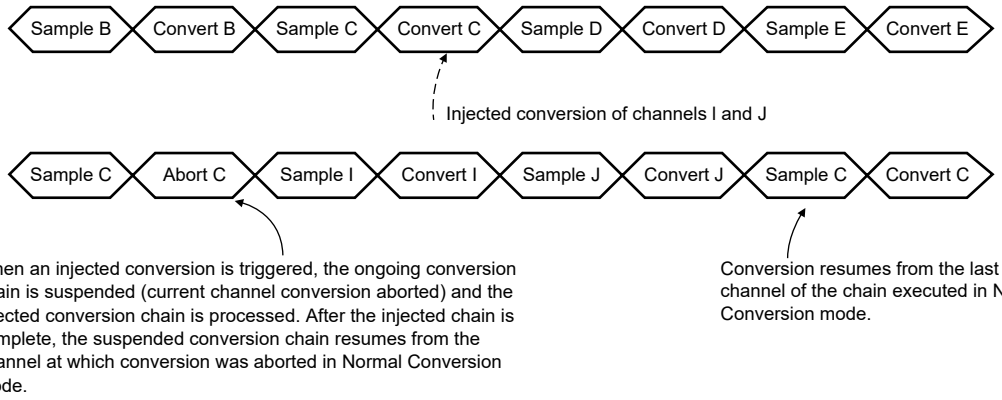

**Figure 222. Injected trigger conversion sequence**

#### 57.3.5.1 Starting conversions in injected conversion mode

An injected conversion chain can be started:

- By software: When external triggering is disabled (MCR[JTRGEN] = 0), you can write 1 to MCR[JSTART], which causes the current conversion chain processed in Normal Conversion mode to be suspended and the injected chain to be processed.
- By external trigger: When external triggering is enabled (MCR[JTRGEN] = 1), a programmed event (rising/falling edge depending on the value of MCR[JEDGE]) on the injection external input starts the injected conversion.

MCR[JSTART] automatically transitions to 1 when the injected conversion chain starts. At the same time MCR[JSTART] is reset to 0, enabling software to program a new start of conversion in advance. In that case the new requested conversion starts after the running conversion completes.

At the end of each conversion, an End Of Injected Conversion (JEOC) interrupt is issued, if enabled by the corresponding mask field in Interrupt Mask (IMR). At the end of a chain, an End Of Injected Chain (JECH) interrupt is issued, if enabled by the corresponding mask field. Additionally, ADC writes 1 to ISR[JECH].

**NOTE**

If the content of all the Injected Conversion mask registers (JCMR*n*) is zero, that is, no channel is selected, the JECH interrupt is immediately issued after the start of conversion.

To have reliable ADC operation, there must be a gap of 3 cycles between configuration of JCMRx and starting of conversion (writing 1 to MCR[JSTART] or arrival of either an external or internal hardware start trigger). ADC calculates the total channel numbers to be converted during this period.

The corresponding channel bit in the CEOCFR*n* register is updated to indicate data is available in the channel's conversion data register, CDR*n*.

After starting, an injected chain conversion cannot be interrupted.

### 57.3.6 BCTU interface

The BCTU interface enhances ADC's injected conversion capability. It contains control inputs to select the channels to be converted from the appropriate event configuration register. Figure 223 shows the interface.

The BCTU generates a trigger (bctu_trigger) and a channel number (bctu_numchannel) to be converted. A single channel is converted for each request. After performing the conversion, ADC returns the result on the bctu_dataout bus together with two output signals named bctu_nextcmd and bctu_push. The assertion of signal bctu_nextcmd means ADC is ready to accept the next trigger from BCTU. The bctu_push signal is asserted at the end of conversion, meaning that conversion is finished and the conversion result available at output bctu_dataout is valid.

The conversion result is also saved in the corresponding channel's data register and is compared with analog watchdog thresholds if requested.

The signals bctu_trigger, bctu_nextcmd and bctu_push are all of type single-cycle active-high-pulse in the ADC clock domain. The channel number provided from BCTU must be valid when bctu trigger is active-high. The result data from ADC is valid with bctu_push high.

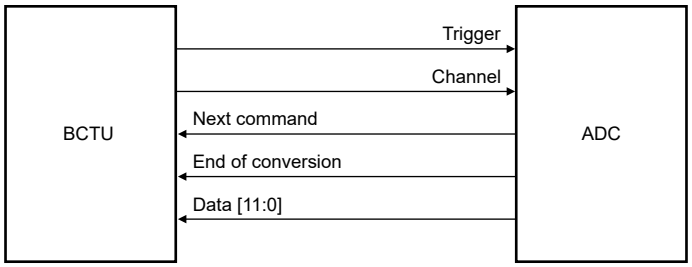

**Figure 223. BCTU interface**

The BCTU interface has two modes of operation:

- Trigger
- Control

To enable the BCTU interface, write 1 to MCR[BCTUEN]. The operating mode (Trigger or Control) can be fixed or programmable.

### 57.3.6.1 BCTU Trigger mode

In Trigger mode, normal and injected conversions can also be performed. All types of conversions can be initiated in this mode. The priorities among the three types of conversions are discussed below.

When a trigger is received, the channel number is taken as an injected channel value and the triggered injected conversion starts. MSR[BCTUSTART] transitions to 1 automatically at this point and it is also automatically reset to 0 when the triggered injected conversion is completed.

BCTU conversions must be requested only after successful ADC calibration. The application must prevent any BCTU trigger during calibration.

If a BCTU trigger is received during an ongoing injected conversion, the injected chain is aborted immediately and only the BCTU-triggered injected conversion proceeds. Additionally, MSR[JSTART] is reset to zero. The abort of an injected conversion is indicated by MSR[JABORT].

If a BCTU trigger is received during an ongoing normal conversion, the ongoing normal channel conversion is suspended and the BCTU-triggered injected conversion is processed. Normal conversion resumes from the suspended channel after completion of the BCTU-triggered conversion.

If a normal conversion is requested during BCTU conversion (MSR[BCTUSTART] = 1), the normal conversion starts after the BCTU conversion completes (MSR[BCTUSTART] is reset to zero).

Any injected conversion is discarded if requested during BCTU conversion and MCR[JSTART] is immediately reset to zero.

### 57.3.6.2 BCTU Control mode

In BCTU control mode (MCR[BCTU_MODE] = 0), only the BCTU can start a conversion. All other trigger sources are ignored.

Along with BCTU trigger, the information provided with signal bctu_numchannel is taken as the channel number for injected channel and BCTU triggered conversion starts. MSR[BCTUSTART] transitions to 1 automatically at the start of the conversion and it remains 1 unless BCTU is disabled by writing 0 to MCR[BCTUEN].

The conversion must be requested (generating bctu_trigger) when calibration has finished successfully. If a BCTU trigger is received during calibration execution, calibration is stopped immediately in order to satisfy the BCTU request. Calibration fails in this case.

### 57.3.7 Aborting a conversion

Two abort functions are provided:

- Abort of a single channel
- Abort of a chain

To abort an ongoing conversion, write 1 to MCR[ABORT]. The current conversion aborts and conversion of the next channel of the chain begins immediately.

Depending on the current state of a conversion, an Abort action may take 1 to 4 cycles of the bus clock. At the start of any conversion, and at the end of a particular conversion when internal state counters are changing, an abort action is delayed by a maximum of 3 cycles to put all states in a stable condition.

To ensure that the abort action completes, do not change MCR[ABORT] for the next 3 cycles.

Avoid writing 1 to MCR[ABORT] along with, and within 3 cycles of, writing 1 to MCR[NSTART] or MCR[JSTART].

During an abort:

- MCR[NSTART] and MCR[JSTART] remain 1, if not in the last channel of the chain.
- MCR[ABORT] is reset to 0 when the channel is aborted.
- The EOC interrupt corresponding to the aborted channel is not generated. This behavior applies to normal and injected conversions. If the last channel of a chain is aborted, the end of chain is reported by generating an ECH interrupt.

It is possible to abort the current chain of conversions by writing 1 to MCR[ABORTCHAIN]. In this case, the behavior of ADC depends on the value of MCR[MODE] (One-Shot/Scan operation modes). If Scan operation mode is disabled, MCR[NSTART] is automatically reset to 0 along with MCR[ABORTCHAIN]. Otherwise, in Scan Operation mode, a new chain is started. The EOC interrupt of the current aborted conversion is not generated but an ECH interrupt is generated to signal the end of the chain.

**NOTE**

For a single channel chain, an ECH interrupt is not generated for an abort or abort chain.

When an abort chain is requested while an injected chain is running over a suspended normal chain, both the injected and normal chains are aborted, and both MCR[NSTART] and MCR[JSTART] are reset to 0.

### 57.3.8 Configuring ADC clock divider and sample time settings

You can scale the AD_clk frequency via MCR[ADCLKSEL]. ADCLKSEL can only be written in Power Down state (MCR[PWDN] = 1). Depending on the frequency of the module clock, there might be different settings necessary for functional conversion and for calibration. See the chip data sheet for ADC electrical characteristics.

Three conversion timing registers are used (CTR*n*) to support different sampling times for the different types of channels. An exception exists for the temperature sensor channel, which always uses the Conversion Timing For Standard Inputs (CTR1) value. See the register description for details.

### 57.3.9 Presampling

The presampling feature enables pre-charge or discharge of the ADC internal sample capacitor node to a defined level before sampling of the selected analog input channel starts. This is useful for resetting information (history effect/offset) from the most recent conversion. During presampling, ADC samples the internally generated voltage. During the sampling phase, ADC samples analog input coming from pads.

Enable presampling on a per-channel basis by setting the corresponding fields in the PSR*n* registers to one.

After enabling presampling for a channel, the normal sequence of operation for the channel is:

1. Presampling
2. Sampling
3. Evaluation

You can bypass sampling of all channels by writing 1 to PSCR[PRECONV]. When sampling of a channel is bypassed, the sampled and stored internal voltage applied during the presampling phase is converted (Figure 224). See Conversion time for the timing equation for conversion.

Presampling does not apply for self-test channels.

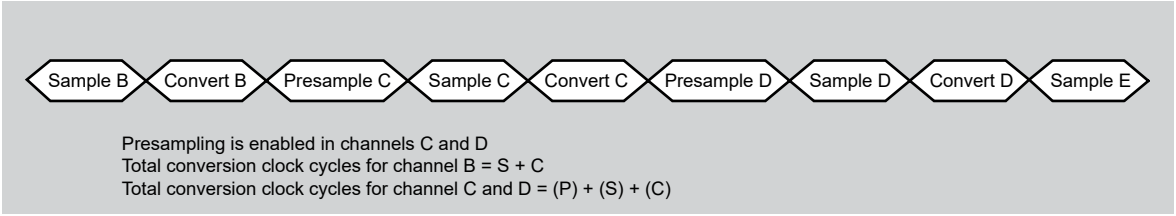

**Figure 224. Presampling sequence**

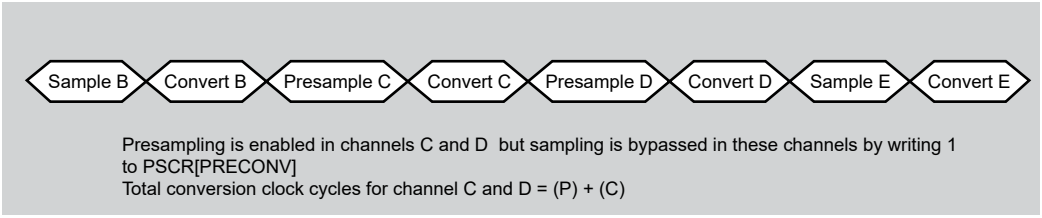

**Figure 225. Presampling sequence with PRECONV=1**

### 57.3.9.1 Enabling presampling per channel

Enable presampling for specific channels by programming Presampling Control (PSCR). You can select between two internally generated voltages by configuring the PREVAL*n* fields in Presampling Control (PSCR) to the appropriate values, as given in the following table.

**Table 270. Presampling voltage selection via PREVAL*n***

| PREVAL*n* | Presampling voltage |
|---|---|
| 0 | Presample voltage – 0: VREFL |
| 1 | Presample voltage – 1: VREFH |

The presampling configuration field(s) (PSCR[PREVAL0], PSCR[PREVAL1], PSCR[PREVAL2]) are located in Presampling Control (PSCR). These fields enable selection of the presampling channel.

The temperature sensor channel has an exception. This channel is mapped with a fixed channel depending on device configuration, but it uses the presampling configuration defined for channel group 2. So, when the temperature sensor channel is selected, the presampling voltage defined by PSCR[PREVAL1] is selected. This voltage might be different from the one selected for channel group 1 via PSCR[PREVAL0].

## 57.3.10 Analog watchdog functions

When enabled, an analog watchdog monitors conversion results for an associated channel and reports an issue if it determines a result is outside customer-defined limits (as shown in Analog watchdog configuration (up to 16 watchdogs) ). These limits are specified by an upper and a lower threshold value named THRH and THRL respectively.

After the conversion of the selected channel a comparison is performed between the converted value and the threshold values. If the converted value is outside that threshold value, then ADC generates a corresponding threshold violation interrupt.

The comparison result is stored as HAWIFx and LAWIFx fields in Analog Watchdog Threshold Interrupt Status (WTISR), as explained in the following table. Depending on the values of WTIMR[LAWIFENx] and WTIMR[HDWIFENx] mask fields, an interrupt is generated on a threshold violation.

**Table 271. Values of HAWIFx and LAWIFx**

| HAWIFx | LAWIFx | Conversion result |
|---|---|---|
| 1 | 0 | Conversion result > THRH |
| 0 | 1 | Conversion result < THRL |
| 0 | 0 | THRH ≥ conversion result ≥ THRL |

Depending on the chip's factory settings, up to 16 analog watchdogs are available. See the chip-specific configuration information for availability.

There are two types of mutually exclusive settings for analog watchdogs. Both types are described in the following sections. The availability depends on device configuration. See the chip-specific configuration information for availability.

Different capabilities are available with the two settings, as described below.

### 57.3.10.1 Channel analog watchdog select registers

ADC configuration includes selecting the analog watchdog threshold register (THRHLR*n*) that provides limits to monitor inputs of a given type. You select the THRHLR*n* using CWSELR*a*l*n* registers.

**Table 272. CWSELR*a*l*n* register naming**

| Index | Description |
|---|---|
| *a* | ADC input type associated with a CWSELR*a*l*n* register.<br>• P = Precision inputs<br>• S = Standard inputs<br>• E = External inputs |
| *n* | 0-indexed register number. |

### 57.3.10.2 Analog watchdog configuration (up to 16 watchdogs)

ADC can have up to 16 watchdogs in the factory configuration. (See the chip-specific configuration information for availability.) For each watchdog there is one threshold value register, THRHLR*n*, that contains the high and low thresholds.

You can independently enable the analog watchdog for each channel by programming the appropriate CWENR*n* register.

The threshold values for each channel can be selected independently from a maximum of 16 threshold registers (THRHLR*n*) using the corresponding WSEL_CH*n* field in the appropriate CWSELR*a*l*n*, where *a* indicates the input type:

- P = precision
- S = standard
- E = external

Each CWSELR*a*l*n* register is associated with 8 consecutive channels. CWSELR*a*l0 holds 8 WSEL_CH fields for channels 0 to 7. CWSELR*a*l1 is for channels 8 to 15 and so on. The availability of fields and registers depends on device configuration. See the chip-specific configuration information for availability.

If the conversion result of a selected channel is outside the range specified by threshold values, then the corresponding field in the Analog Watchdog Out of Range register (AWORR*n*) transitions to 1. For example, if channel 7 is to be monitored with the threshold values in THRHLR3, then CWSELR*a*l0[WSEL_CH7] must be programmed with 3. Enabling the watchdog is done by writing 1 to the corresponding field for channel 7 in CWENR0.

In this configuration, a set of threshold values (THRHLR*n*) can be linked to several ADC channels.

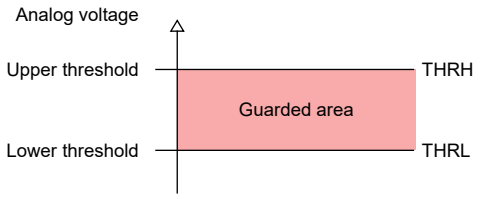

**Figure 226. Guarded area**

**NOTE**

If the higher threshold of the analog watchdog is programmed below the lower threshold and the conversion result is below the lower threshold, then the WDG*n*L interrupt for the low threshold violation transitions to 1. If the conversion result is greater than the lower threshold (and therefore also greater than the higher threshold), then the interrupt WDG*n*H for high threshold violation is generated. Thus you should take care to avoid that situation, as it could lead to misinterpretation of the watchdog interrupts.

### 57.3.11 DMA functionality

Conversion result data from any channel can be transferred from a register to system memory via Direct Memory Access (DMA). DMA transfers are enabled by writing 1 to DMAE[DMAEN]. After being enabled, the on-chip DMA controller can receive a DMA request after the conversion of each channel by writing 1 to the respective masking field in:

- DMA Request Enable For Precision Inputs (DMAR0)
- DMA Request Enable For Standard Inputs (DMAR1)
- DMA Request Enable For External Inputs (DMAR2)

DMA masking registers must be programmed before starting any conversion.

A DMA request to the DMA controller can be cleared at different times in two modes:

- Mode-1: Clearing of DMA request on acknowledgment from DMA controller (DMAE[DCLR] = 0)
- Mode-2: Clearing of DMA request on read to data registers (DMAE[DCLR] = 1)

The figures below show the operation of DMA in two modes (cycle counts are typical values).

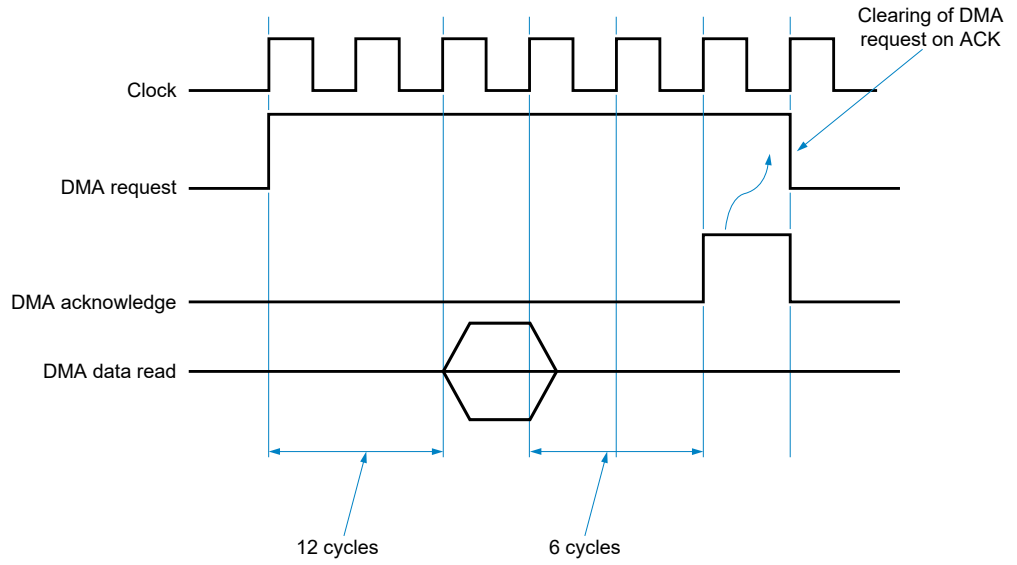

Figure 227. DMA operation Mode-1 (DMAE[DCLR] = 0)

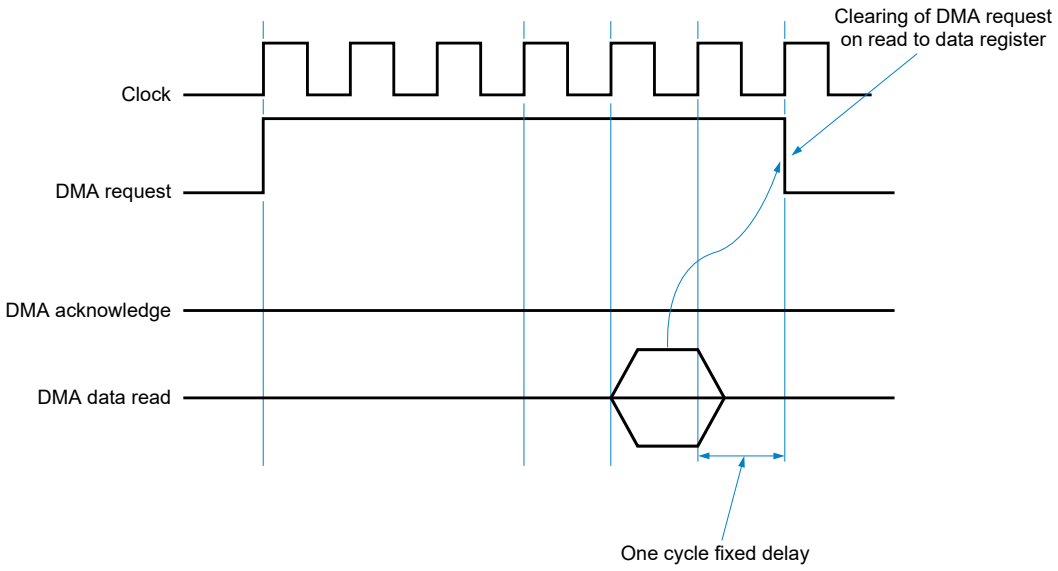

Figure 228. DMA operation Mode-2 (DMAE[DCLR] = 1)

### 57.3.12 Interrupts

ADC generates the following maskable interrupts:

- EOC (End of Conversion)
- ECH (End of Chain)
- JEOC (End of Injected Conversion)
- JECH (End of Injected Chain)
- EOBCTU (End of BCTU-triggered Conversion)
- LAWIFx and HDWIFx (Watchdog threshold)

- Self-testing interrupts

Interrupts are generated during the conversion process to signal events such as End Of Conversion (EOC), and so on, as described in Interrupt Status (ISR). ISR and another register, Interrupt Mask (IMR), are provided to check and enable the interrupt request to an external interrupt controller.

Interrupts can be individually enabled on a per-channel basis by programming EOC Interrupt Enable For Precision Inputs (CIMR0).

CEOCFR*n* are used for pending End of Conversion interrupts, with one field per channel to indicate completed conversions on a per-channel basis.

Interrupts generated due to the analog watchdogs are managed by two 32-bit registers, Analog Watchdog Threshold Interrupt Status (WTISR) and Analog Watchdog Threshold Interrupt Enable (WTIMR), to check and enable the interrupt request. A watchdog interrupt causes two corresponding fields to transition to 1 for each channel monitored. One field is in WTISR[WDG*n*H] and another in WTISR[WDG*n*L].

Generated events are logged into status registers and used to generate interrupts if enabled in corresponding Mask registers.

There are three different interrupt outputs. The interrupt structure is shown in Figure 229.

Each interrupt is generated by combining a group of events.

The following interrupts are combined (logic OR) into one interrupt output.

- EOC
- ECH
- EOBCTU
- JEOC
- JECH
- End of self-test algorithm (WDG_EOA_S and WDG_EOA_C)

Interrupts of all HDWIFx and LAWIFx are combined on the second interrupt output.

Interrupts of all self-test errors (watchdog threshold, sequence, and timer violations) in Self-Test Status 1 (STSR1) are combined on the third interrupt output. The errors are:

- WDSERR
- WDTERR
- ERR_S0
- ERR_S1
- ERR_S2
- ERR_C

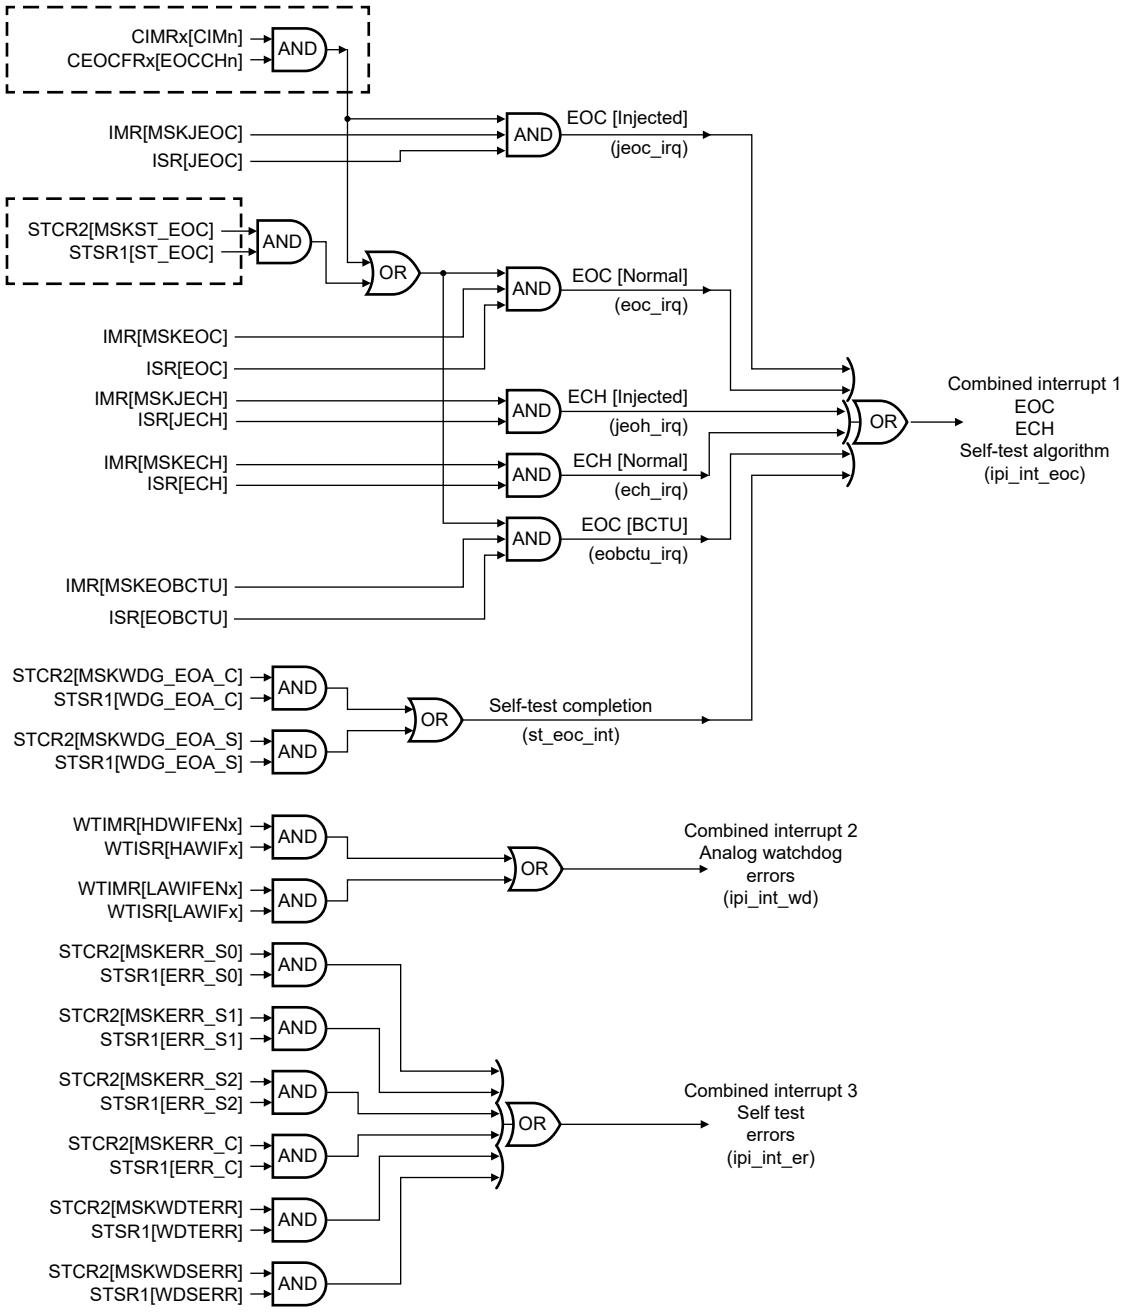

**Figure 229. Interrupt structure of ADC**

Interrupt Status (ISR) Indicates the interrupt pending request status. Write 1 to the corresponding status field to clear the pending interrupt flag (at this write operation all the other fields in Interrupt Status (ISR) must be maintained at 0).

ISR checks for three types of interrupts.

The first type, Interrupt 1, relates to the following:

- End of normal or injected conversion (EOC or JEOC)
- End of normal or injected conversion chain (ECH or JECH)
- End of algorithm C or algorithm S self-test (WD_EOA_C or WD_EOA_S)

Perform the following actions for this type of interrupt:

1. Read Interrupt Status (ISR) to determine whether the event is an EOC, JEOC, ECH, JECH, or EOBCTU event.
2. Read Self-Test Status 1 (STSR1) to identify the end of self-test algorithm events (WDG_EOA_S or WDG_EOA_C), if present.
3. If the interrupt is an EOC or JEOC event:
   - Clear the respective channel pending field in the appropriate CEOCFR*n* register for an EOC by writing a 1 to it.
   - Clear ISR[EOC] or ISRJEOC] by writing a 1 to it.
4. If the interrupt is an ECH or JECH, clear ISR[ECH] or ISR[JECH] by writing 1 to it.
5. If the interrupt is EOBCTU, clear ISR[EOBCTU] by writing 1 to it.
6. If the interrupt is for self-test end of algorithm, clear STSR1[WDG_EOA_S] or STSR1[WDG_EOA_C] by writing 1 to it.

The second type, Interrupt 2, relates to analog watchdog errors. Perform the following actions for this type of interrupt:

1. Read Analog Watchdog Threshold Interrupt Status (WTISR) to determine which watchdog triggered the interrupt.
2. Read the AWORRx register(s) to determine which channel's data caused the interrupt (if present).
3. Clear the respective field of the WTISR[WDG*n*H/WDG*n*L] register, where *n* = watchdog number, by writing 1 to it.
4. Clear the respective field of the AWORR*n*[AWOR_CH*n*] register, where x = register, n = channel, by writing 1 to it.

The third type, Interrupt 3, relates to self-test errors. Perform the following actions for this type of interrupt:

1. Read Self-Test Status 1 (STSR1) to determine the type of error encountered in self-test (WDSERR, WDTERR, ERR_S0, ERR_S1, ERR_S2, ERR_C, and so on) if present.
2. Clear the respective field in Self-Test Status 1 (STSR1) by writing 1 to it.

The connectivity of interrupt lines at the chip level (external to ADC) determines whether software must read all the registers for all three interrupts or any one or combination of any two.

### 57.3.13 External decode signals delay

The ADC provides three external decode signals which it uses to select one channel out of eight in the external analog multiplexers. There can be a maximum of four such multiplexers used to connect the 32 external channels. The ADC automatically sets the decode signals to control these external analog multiplexers, based on the current channel selected for conversion. Delay Start Of Data Conversion (DSDR) is provided to take the switching time of the external analog multiplexer into account. It enables you to program the delay between the decoding signal selection and the actual start of conversion.

If presampling is enabled, the DSD delay starts after the presample phase (presampling time is the same duration as sample time).

### 57.3.14 Power Down state

The analog part, along with the ADC controller, can be put in Power Down state by writing 1 to MCR[PWDN]. This shuts down ADC and stops the clock to the ADC controller. After release of reset, MCR[PWDN] remains 1, so the ADC analog module is kept in Power Down state by default. You must exit this state before starting any operation, by writing 0 to MCR[PWDN]. In Power Down state, no conversion can be started. If a BCTU trigger pulse is received during this state, it is discarded. You must ensure that a BCTU trigger is not initiated to ADC before writing 0 to MCR[PWDN], as it may cause the BCTU module to be stuck in a wait state.

You can set MCR[PWDN] by writing 1 to it at any time. If a conversion is ongoing, ADC does not move into Power Down state immediately. ADC enters Power Down state only after completion of the ongoing conversion. During scan operation, the ongoing operation should be aborted manually by writing 0 to MCR[NSTART] before or after writing 1 to MCR[PWDN].

ADC Power Down state status is indicated by MSR[ADCSTATUS] when ADC enters into Power Down state.

If the BCTU is enabled and MSR[BCTUSTART] = 1, then you cannot write 1 to PWDN. When BCTU Trigger mode is enabled, the application must wait for the end of conversion (MSR[BCTUSTART] is automatically reset to 0). When BCTU Control mode is enabled, before entering Power Down state the application must write 0 to BCTUEN also.

If Power Down state is entered by writing 1 to MCR[PWDN], the process running before entry into Power Down state must be restarted manually (by writing 1 to the appropriate START field in Main Configuration (MCR)) after exiting Power Down state.

**NOTE**

Writing 0 to MCR[PWDN] and writing 1 to MCR[NSTART] or MCR[JSTART] during the same cycle is not supported.

### 57.3.15 Low Power mode support

For low-power operation, ADC must be in Idle state and then put into Power Down state to ensure proper signal condition at the analog boundary.

From any of the states listed below, follow the sequence of steps shown to put ADC into Power Down state.

1. Idle condition
    a. Verify that ADC is in Idle state (MSR[ADCSTATUS] = 000b).
    b. Write 1 to MCR[PWDN], to shut off the clock to the hard macro with the proper state of signals required for Low Power mode.
    c. Verify that ADC is in Power Down state (MSR[ADCSTATUS] = 001b).
2. During calibration

    **NOTE**

    Writing 1 to MCR[PWDN] during calibration is prohibited. After calibration is started it should be allowed to finish normally. Alternatively, it can be terminated by starting a normal conversion before writing 1 to MCR[PWDN].

    a. Check the current ADC state either via MSR[ADCSTATUS] (000b = Idle, 011b = Calibration), or via CALBISTREG[C_T_BUSY] (1 = calibration is in progress).
    b. When ADC is in Idle state, write 1 to MCR[PWDN] to shut off the clock to the hard macro with the proper state of signals required for Low Power mode.
    c. Verify that ADC is in Power Down state (MSR[ADCSTATUS] = 001b).
3. During conversion (normal [one-shot]/Injected/BCTU):
    a. Write 1 to MCR[PWDN].
    b. ADC enters Power Down mode after completing the current conversion chain (for normal and injected conversions) or the conversion for conversion triggered by BCTU.
    c. Check the ADC state via MSR[ADCSTATUS] (000b = Idle state, 001b = Power Down state).
4. During Scan mode operation of normal conversion

    **NOTE**

    Writing 1 to MCR[PWDN] during scan mode operation has no effect other than to prevent software from starting a new normal or injected conversion. It does not stop a conversion in progress and cannot put ADC into Power Down state.

    a. Software must write 0 to MCR[NSTART] to stop the ongoing scan conversion before (or after) writing 1 to MCR[PWDN]. This stops conversion at the current chain boundary.
    b. ADC enters Power Down mode after coming to an Idle state after MCR[PWDN] is written with 1. This shuts the clock off to the hard macro and puts analog inputs in the proper state required for Low Power mode.
    c. Verify that ADC is in Power Down state (MSR[ADCSTATUS] = 001b).

### 57.3.16 Auto Clock Off mode

To reduce power consumption during Idle state (without going into Power Down state), an auto-clock-off feature can be enabled by writing 1 to MCR[ACKO]. When enabled, the internal ADC operating clock (AD_Clk) is automatically switched off during an idle period (for example, no conversion is programmed).

### 57.3.17 Calibration and self-test

#### 57.3.17.1 Calibration

ADC must be calibrated before it can do meaningful conversions. The application must prevent any start of conversion before the ongoing calibration has finished successfully. No conversion trigger may be received during calibration.

During calibration, a known reference voltage is sampled and converted under controlled conditions to determine the correction values (calibration values) for offset, gain, and capacitor mismatch.

These calibration values (except gain calibration) are used in a post-processing step after conversion, reducing or eliminating the various error contribution effects. The gain calibration is used during sample phase to define the additional charge to be loaded to compensate for gain failure.

You must run calibration after every power-up reset (check device-specific reset connectivity for appropriate reset applied). You must also run calibration if it is indicated by the self-test (see Self-test).

Configuration and start of calibration is done by programming the Control And Calibration Status (CALBISTREG). During calibration, internal hardware averaging function should be enabled. Maximum averaging is recommended, and 16 should be the minimum.

Calibration status is captured by a status flag (CALBISTREG[TEST_FAIL]) to indicate any fault detected during calibration execution or if calibration was prematurely aborted. Calibration is aborted if any normal conversion is initiated during the calibration execution, which is called premature termination. (Flag TEST_FAIL = 1 indicates a calibration fail, for example when a calibration value is out of internally defined limits.)

To execute the calibration algorithm, perform the following steps:

1. Select the conversion clock frequency to be within the allowed limits for the calibration.
2. Bring ADC from Power Down state to active conversion (program MCR[PWDN] = 0b).
3. Configure the Control And Calibration Status (CALBISTREG). The default values are set for maximum accuracy (recommended).
4. Disable the error correction for the smaller capacitances in the CDAC of the ADC (write 0h to CAL2[ENX]).
5. Start calibration (program CALBISTREG[TEST_EN] = 1b), and calibration starts immediately.
6. Poll the status of CALBISTREG[C_T_BUSY] for 0 (wait until it transitions to 0).
7. Check CALBISTREG[TEST_FAIL] to determine the final status. If 1, then calibration failed.
8. Check the status of MSR[CALIBRTD]. If calibration was successful this field is 1.

#### 57.3.17.2 Self-test

For safety applications, it is important to verify correct operation at regular intervals. ADC has a self-test feature for this purpose. When self-test is enabled, ADC automatically checks its components and flags errors, if any are found.

Tests can be enabled to check the reference (VrefH) and calibrated values.

The following test algorithms have been implemented:

- Supply self-test (algorithm S): It includes the conversion of the band gap and VREF voltages. It includes a sequence of num_supply_steps test conversions (steps). The supply test conversions must be an atomic operation (that is, all supply algorithm conversions must be performed one after another with no functional conversions in between).

- Capacitive self-test (algorithm C): It includes a sequence of test steps per definition of algorithm C (see Table 273) which executes the capacitive matrix of the CDAC used for sampling and conversion.

Individual steps can take up to 1 µs at 80 MHz ADC clock frequency.

**Table 273. Self-test steps**

| STCR3[ALG] | STCR3 [step](per algorithm definition) | Description | Outcome | Comment |
|---|---|---|---|---|
| 00 (algorithm S) | 0 | Supply self-test (band gap voltage) | Measures the internal band gap voltage | |
| | 1 | Supply self-test (reference voltage high) | Measures ADC high reference voltage | |
| | 2 | Supply self-test (reference voltage high) | Measures ADC high reference voltage | |
| 01 (Reserved) | Reserved | | | |
| 10 (algorithm C) | 0 – 11 | Capacitive self-test. One of the calibration steps is being run. | The difference/error of the individual offset value from the previously calibrated value is being returned as an ADC result that is compared with the programmed value in the self-test analog watchdog register(s) to detect any fault. | The ideal result value is expected to be 0. If the returned value is higher, it indicates a runtime fault or accuracy shift. The error is indicated in the status register and can be used to generate an interrupt also. It that indicates ADC should be recalibrated to check whether the reported error can be managed by calibration or that permanent damage occurred to ADC. |
| 11 (algorithm S + C) | 0 – 2 (S), 0 – 11 (C) | Supply for One-Shot mode and (supply + capacitive) for Scan mode only. | Same as above. | |

ADC:

- Schedules self-testing algorithms using configuration registers.
- Monitors the converted data using analog watchdog registers.
- Flags any errors to a fault control unit (FCCU), if one exists.

Self-test steps can be activated from software (CPU) or BCTU.

| ADC mode | TEST algorithm (CPU) | TEST algorithm/step (BCTU) |
|---|---|---|
| CPU mode (MCR[BCTUEN] = 0) | Yes | No |

*Table continues on the next page...*

*Table continued from the previous page...*

| ADC mode | TEST algorithm (CPU) | TEST algorithm/step (BCTU) |
|---|---|---|
| | • One-Shot operation mode<br>• Scan operation mode | |
| BCTU mode | No | Yes |

#### 57.3.17.2.1 CPU mode

In this mode, self-test conversion is similar to normal conversion. You enable self-test by writing 1 to STCR2[EN].

Self-test conversions execute along with the functional conversions. The sequencing of steps of the selected algorithm depends on the operating mode of normal conversions (selected by MCR[MODE]).

In One-Shot operation mode, if self-test is enabled, only one step of the selected self-testing algorithm is executed at the end of the chain. The step number and algorithm to be executed are programmed in Self-Test Status 3 (STSR3). In One-Shot operation mode the sequence is:

1. Program NCMR*n* to select channels to be converted for normal conversion.
2. Write 0 to MCR[MODE] to select one-shot operation.
3. Configure the self-test algorithm threshold values (see Table 274).
4. Program sampling duration values in STCR1[INPSAMP*m*] (*m* = S, C).
5. Select the self-testing algorithm (in STCR3[ALG]), and step (in STCR3[MSTEP]). The default is algorithm S, step 0.
6. Enable self-testing by writing 1 to STCR2[EN].
7. Start the normal conversion by writing 1 to MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of all normal conversions in the chain, the step number (programmed in STCR3[MSTEP]) of the self-testing algorithm (selected by STCR3[ALG]), is executed similar to a normal functional channel.
10. At the end of the conversion for the self-test channel:
    - The result is written to STDR1[TCDATA].
    - STDR1[VALID] transitions to 1.
    - ISR[EOC], ISR[ECH], and STSR1[ST_EOC] transition to 1.
11. ADC returns to Idle state.

For example: Channels A→B→C→D→E→F→G→H are present in the device where channels B→D→E are to be converted in One-Shot operation mode. At the end of conversion for channels B→D→E, self-test conversion is performed and ISR[ECH] and ISR[EOC] transition to 1. The sequence is B→D→E→self-test step.

MSR[NSTART] transitions to 1 when the normal conversion starts and transitions to 0 at the end of conversion for the test channel.

In Scan operation mode, consecutive steps of the selected self-test algorithm are converted continuously at the end of each chain of normal conversions. The number of channels converted at the end of each chain is 1 (except for algorithm S, in which all the steps are performed sequentially without any functional conversion interleaved). So, in Scan operation mode the sequence is:

1. Program NCMR*n* to select the channels to be converted for normal conversion.
2. Write 1 to MCR[MODE] to select Scan operation mode.
3. Configure the self-test algorithm threshold values (see Table 274).
4. Program sampling duration values in STCR1[INPSAMP*m*] field (*m* = S, C).

5. Select the self-testing algorithm in STCR3[ALG]. By default, all algorithms (supply and capacitive) are selected, that is, all algorithms are executed step-by-step, one after the other.
6. Enable self-testing by writing 1 to STCR2[EN].
7. Start the normal conversion by writing 1 to MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of the chain of normal conversions (assuming the default value of STCR3[ALG]), all steps of algorithm S are performed (as algorithm S is always atomic). MSR[SELF_TEST_S] transitions to 1.
10. At the end of the conversion of the self-test channel for the last step of algorithm S, the result is written to STDR1[TCDATA] and STDR1[VALID] transitions to 1. At the same time, MSR[SELF_TEST_S] transitions to 0. The following registers also transition to 1:
    - ISR[EOC]
    - ISR[ECH]
    - STSR1[ST_EOC]
11. The next chain of normal conversions then starts.
12. At end of the chain of normal conversions, ADC executes step 0 of algorithm C.
13. At the end of the conversion of the test channel for step 0 of algorithm C, the result is stored in STDR1[TCDATA] and STDR1[VALID] transitions to 1 (if STSR1[OVERWR] is 1). Also, ISR[EOC] and ISR[ECH] transition to 1. STSR1[ST_EOC] also transitions to 1.
14. The next chain of normal conversion then starts.
15. At the end of the normal conversion chain, ADC executes step1 of algorithm C.

This process continues for all steps of all three algorithms. The state machine returns to Idle state when MCR[NSTART] transitions to 0.

For example: channels A→B→C→D→E→F→G→H are present in the device where channels B→D→E are to be converted in Scan operation mode. At the end of every conversion chain for channels B→D→E, one step of the self-test conversion is performed and ISR[ECH] and ISR[EOC] transition to 1.

The sequence is:

B→D→E→ST-S0→ST-S1→ST-S2→B→D→E→ST-C0→B→D→E→ST-C1→B→D→E→ST-C2→ . . . B→D→E→ST-C11→B→D→E→ST-S0 . . .

ST-Sx - Self-test supply step x (x = 0, 1, 2)

ST-Cx - Self-test capacitive step x (x = 0 to 11)

MSR[NSTART] transitions to 1 when normal conversion starts.

**NOTE**

- If instead of starting normal conversion by software (by writing 1 to MCR[NSTART]), it is started by an external trigger, the self-test behavior remains the same.
- Self-test channel conversion is not performed for injected conversions. It is performed only during normal conversions.
- If, during a test channel conversion, an injected conversion arrives, the test conversion is aborted (just as a normal functional channel) and the injected conversion is performed. After the injected conversion is complete, the test conversion resumes from the step at which it was aborted. In this case, MSR[SELF_TEST_S] remains 1 during the injected conversion.
- For self-test, MCR[MODE] should be programmed (at least one cycle) before writing 1 MCR[NSTART] and should not be changed until the conversion is finished or terminated.

Table 274. Recommended self-test threshold values

| Register field | Hex value | Decimal value | Comment |
|---|---|---|---|

#### 57.3.17.2.2 BCTU mode

BCTU mode is enabled by writing 1 to MCR[BCTUEN].

Self-test conversion behaves in the same way for all BCTU operating modes (Trigger mode and Control mode). In both cases, if MCR[BCTUEN] = 1, the self-test conversion can be started only by BCTU—software cannot start it. MCR[BCTUEN] must not be changed during normal conversion. The interface between BCTU and ADC (for self-test) is shown in the following figure.

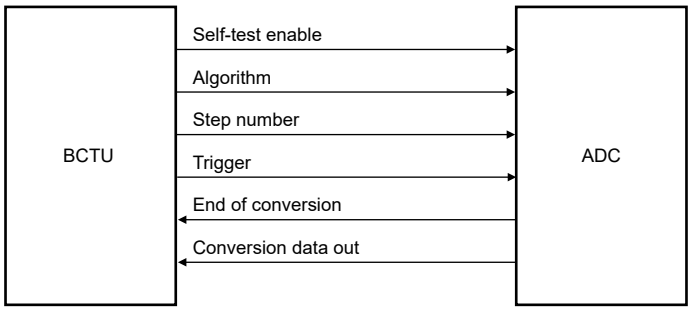

Figure 230. Self-test interface between ADC and BCTU

For self-test conversions in BCTU mode, BCTU asserts self-test enable along with the Trigger command. The algorithm and the step number to be executed is put on algorithm and step number, respectively. The other commands (Trigger, End Of Conversion, and Conversion Data Out) have the same meaning, like normal BCTU functional conversion.

As already mentioned for algorithm S, the three steps must be atomic. In BCTU mode, this is managed by BCTU, that is, BCTU sends three triggers (one for each step) asserting self-test enable and updating test_step for each step.

#### 57.3.17.2.3 Abort and abort chain for self-testing channel

Writing 1 to MCR[ABORT] during self-test channel conversion has no effect.

In One-Shot operation mode, if you write 1 to MCR[ABORTCHAIN] during the self-test channel conversion, the self-test channel is aborted and ISR[ECH] transitions to 1. In this case, ISR[EOC] for the self-test channel is not generated.

In Scan operation mode, if MCR[ABORTCHAIN] = 1 when self-test channel step *n* is ongoing, self-test channel step *n* is aborted and the next chain conversion begins. At the end of the chain, the step *n* conversion is performed again. (For algorithm S, the full algorithm is executed again).

#### 57.3.17.2.4 Self-test analog watchdog

ADC provides monitoring options for conversion data generated by self-test algorithms. Analog watchdogs determine whether the conversion results for self-test algorithms are in the range of a particular guard area. ADC provides separate self-test analog watchdog registers for each algorithm.

After the conversion of each step of a self-test algorithm, ADC compares the converted value and the threshold values if the analog watchdog feature has been enabled by writing 1 to STAW*n*R[AWDE] (for example, STAW0R[AWDE]). If the converted value is not between the upper and lower threshold values specified by the Self-Test Analog Watchdog Register for the particular algorithm, the corresponding error flag, STSR1[ERR_x], transitions to 1 and the step number in which error occurred is captured in STSR1[STEP_x] (for algorithm C). Erroneous data is written to STSR4[DATA*n*]. The STSR1[ERR_x] flags generate an interrupt if enabled by the corresponding mask bit in Self-Test Configuration 2 (STCR2). The fault indication is also forwarded to the fault control unit, if present, so that necessary action can be taken at the chip level. The fault type (critical or noncritical) is specified by the configuration in Self-Test Configuration 2 (STCR2).

The analog watchdog feature works differently for algorithm S. Algorithm S is always an atomic operation. Self-Test Status 1 (STSR1) has a separate error field for each step of algorithm S to avoid overwrite in case an error occurs in more than one step. Therefore, there are separate mask bits for each step in STCR1. For the same reason, the status registers (Self-Test Status 2 (STSR2) and Self-Test Status 3 (STSR3)) have separate fields for each step to store erroneous data.

In step 0 of the supply algorithm, ADC measures the band gap voltage (1.2 V), which is assumed to be stable. The conversion result of step 0 is compared against high (THRH) and low (THRL) thresholds as defined in Self-Test Analog Watchdog S0 (STAW0R), if enabled (STAW0R[AWDE] = 1). The STSR1[ERR_S0] flag transitions to 1 if any of the thresholds are violated. STSR1[ERR_S0] is cleared by writing 1 to it. The conversion result of ADC can be calculated with the following formula:

- ADC data (decimal) = ( Vin × $2^{15}$ ÷ (Vrh - Vrl))

Where:

- Vin: input voltage (band gap voltage in this case)
- Vrh: ADC reference high voltage
- Vrl: ADC reference low voltage

The upper and lower threshold value can be calculated with the above formula using maximum and minimum values of Vin, Vrh, Vrl (Vin is the band gap supply voltage in this case):

- Upper threshold (THRH, decimal) = (Vin[max] × $2^{15}$) ÷ (Vrh[min] - Vrl[max])
- Lower threshold (THRL, decimal) = (Vin[min] × $2^{15}$) ÷ (Vrh[max] - Vrl[min])

The minimum and maximum voltages can be obtained from the chip data sheet. The band gap voltage tolerance, as well as the actual reference voltage used and its tolerances, must be considered when calculating high and low thresholds.

For algorithm S steps 1 and 2, (VREF/VREF) is measured in order to check the integrity of the sampling signal. For these particular conversions, no higher threshold value is required as the ideal value is FFFh. Only the lower threshold value is programmed in Self-Test Analog Watchdog S1 (STAW1R) and Self-Test Analog Watchdog S2 (STAW2R).

For algorithm C, a separate register is provided for step 0. In step 0 an offset for other steps is measured. The converted data is compared with the threshold values in Self-Test Analog Watchdog C (STAW5R) if STAW4R[AWDE] = 1. For other steps, this offset is subtracted from converted data before performing watchdog checks.

#### 57.3.17.2.5 Watchdog timer

The watchdog timer is an additional check that monitors the sequence of the self-testing algorithm that has been implemented, and also checks whether the algorithm is completed within a safe time period. The watchdog timers are enabled for CPU as well as BCTU conversions. Each algorithm has an independent watchdog timer. The watchdog timer for a particular algorithm is enabled by writing 1 to STAWxR[WDTE]. The safe time value is programmed in STBRR[WDT] (the default value is 10 ms, assuming an 80 MHz clock).

The safe time is measured starting from step 0 of the algorithm (including all normal chain conversions in between) to the point where step 0 of the same algorithm starts again.

The programming sequence is:

1. Program NCMR*n* to select the channels for normal conversion in Scan operation mode (MCR[MODE] = 1).
2. Select the self-test algorithm in STCR3[ALG]. By default, all algorithms (supply and capacitive) are selected (all algorithms are executed step-by-step, one after the other).
3. Enable the self-test channel by writing 1 to STCR2[EN].
4. Program the safe period value in STBRR[WDT].
5. Enable the watchdog timer by writing 1 to STAWxR[WDTE]. Assume writing 1 to STAWxR[WDTE] occurs at time *t*0. It is important to do all configuration programming before writing 1 to STAWxR[WDTE], because the safe time check is also performed between writing 1 to STAWxR[WDTE] and the start of step 0. This is to verify that the algorithm has started within the safe time.
6. Start the normal conversion by writing 1 to MCR[NSTART].
7. At the end of the first conversion chain, three steps (steps 0, 1, and 2) of algorithm S are executed in sequence. Assume the start of Step 0 occurs at time *t*1.
8. After completion of algorithm S, ADC performs conversion of the next chain.
9. At the end of the conversion chain, the first step (step 0) of algorithm C is performed.
10. In this way, one step of algorithm C is performed after completion of one conversion chain until all steps are finished. Steps are executed in sequence (steps 0–11)
11. After the last step of algorithm C, another chain conversion is executed. At the end of this chain conversion, step 0 of algorithm S is started again, repeating the whole sequence. Assume this time (starting of step 0 of the supply algorithm) to be at time *t*2.
12. For algorithm S, if (*t*1 - *t*0) > safe period or (*t*2 - *t*1) > safe period, the watchdog timer flags an error and STSR1[WDTERR] transitions to 1. ADC asserts a fault signal per the criticality configuration (critical or noncritical) and an interrupt is generated, if enabled (STCR2[MSKWDTERR] = 1). Otherwise, the watchdog timer counter is reset and starts again to monitor the next sequence.
13. A similar sequence is followed for watchdog timers for algorithm C.

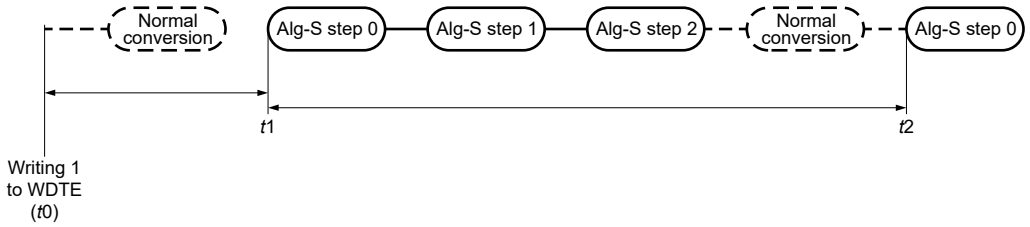

**Figure 231. Watchdog timer monitor for algorithm S**

**NOTE**

1. Because BCTU may not incorporate any safe period checking mechanism, the watchdog timers can also be enabled for BCTU conversions.
2. You must disable watchdog timers for self-test algorithms that are not executed.

#### 57.3.17.2.5.1 Watchdog sequence checking

The self-test watchdog timer incorporates sequence checking features to verify that the steps of each algorithm are executed in the correct order. If the steps are not in the correct order, STSR1[WDSERR] transitions to 1 to indicate the error. A fault is indicated by an interrupt flag if STCR2[MSKWDSERR] = 1. A fault is also asserted as per criticality configuration (critical or noncritical) and an interrupt generated if STCR2[MSKWDSERR] = 1.

A watchdog sequence error is flagged in the following cases:

- The steps of any algorithm are not executed in proper order.
- The step numbers provided by BCTU for a BCTU conversion are not in order. Watchdog sequence checking is significant only for BCTU burst mode.
- When an abort chain occurs during a self-test channel conversion, that step must be repeated at the end of the next chain. This generates a sequence error as soon as the self-test channel conversion resumes. There is an exception, however. If an abort chain occurs during the last step of algorithm S, the sequence error is not flagged because the whole algorithm must be repeated.

If an injected conversion occurs during self-test channel conversion, a watchdog sequence error is not flagged, although the ongoing step number is aborted and is repeated.

**NOTE**

The watchdog timer feature is applicable for Scan operation mode but not for One-Shot operation mode.

#### 57.3.17.2.6 Baud rate control for test channel

The baud rate control feature controls the scheduling of self-test channel conversions between normal conversion chains. The scheduling rate is specified by STBRR[BR].

By default, if the self-test channel is enabled, one step of the selected algorithm is executed after each normal conversion chain. The bandwidth consumed by the self-test channel depends on the number of channels in the normal chain. For example, if you have 50 normal conversions in a chain, then the self-test channel consumes only 2% of the total bandwidth, which is very small. If the number decreases to just 3 channels, the bandwidth consumed by the self-test channel is 25%, which is significant (and may not be desirable because it slows down the normal conversion rate).

STBRR[BR] provides flexibility by scheduling the self-test channel conversion to be performed not at the end of every chain, but at the end of BR + 1 chains. For example, if STBRR[BR] = 5, a single step of the selected algorithm for the test channel is performed after 6 chain conversions. The next step is performed at the end of the next six chain conversions, and so on. By default, STBRR[BR] = 0.

**NOTE**

This feature is applicable only for Scan operation mode and not for One-Shot operation mode. STBRR[BR] should be written with 0 for One-Shot operation mode.

To use the baud rate control feature in Scan operation mode, NCMR*n* should have a nonzero value.

##### 57.3.17.2.6.1 Abort chain when baud rate is nonzero

As already described, for a nonzero value of STBRR[BR], the self-test channel conversion is performed at the end of BR + 1 chains. If an abort chain occurs during the chain in which a self-test channel conversion is scheduled to be performed, the self-test channel conversion is performed after the next BR + 1 chains.

For example, if STBRR[BR] = 2, the sequence is two normal chains (without any self-test channel conversion), followed by a chain with the self-test channel converted at the end. If an abort chain occurs during the first two chains, it is treated as a normal chain abort and the self-test channel is converted at the end of the third chain only (as in the case without any abort chain). However, if an abort chain occurs during the third chain in which the self-test channel is scheduled to be converted, the self-test channel is converted after the next three chains (for example, at the end of the sixth chain, counting from the beginning).

### 57.3.18 Conversion time

Total conversion time depends on the conversion clock frequency, which is configured by programming MCR[ADCLKSEL].

The components of conversion time and affecting configurations are:

- PST
- ST
- CT

- DP
- TPT

Presample phase time is equal to the sample time with a one AD_clk cycle delay for phase transition from presample phase to sample phase. CTR*n*[INPSAMP] controls sample time for different types of channels and is specified in terms of AD_clk cycles, so the presampling time is sample time plus one cycle of AD_clk. The minimum value of sample time is 8. If the value programmed is less than 8, it has no effect on sample time and the sample time is 8 AD_clk cycles.

Compare phase time is controlled by:

- The evaluation time of a single bit
- The number of bits converted

For *n*-bit conversions, the value of CT is *n* multiplied by the evaluation time of a single bit in terms of AD_clk cycles.

The evaluation time of a single bit is 4 AD_clk cycles if AMSIO[HSEN] = 0h and AMSIO[CMPCTRL0] = 0b. The evaluation time of a single bit is 6 AD_clk cycles if AMSIO[HSEN] = 1h and AMSIO[CMPCTRL0] = 1b.

The data processing time is 2 cycles of AD_clk. During these cycles raw converted data is corrected for offset, gain, capacitor mismatch, and so on.

Trigger processing time consists of:

- One module_clock cycle, which is required to prepare the channel and calculate the initial gain value used by ADC for the first conversion.
- BCTU triggering time:
  - Triggers from the synchronous BCTU interface require 1 cycle of the module clock for processing. One more cycle is required to register the BCTU trigger in synchronous mode.

The total conversion time, in terms of the module clock cycles, is calculated using the following equation for normal and injected conversions:

Total_conversion_time = ( [(PST + ST + CT + DP) × chain_length] + TPT) × TAD_clk

Example:

The ADC controller clock is equal to the module clock (80 MHz, clock cycle = 12.5 ns)

- ADC resolution 12 bit + 1 bit for a special capacitor (CS)
- Three channels are programmed in NCMR*n*, so a chain of three is to be converted
- Default sample time (22 cycles) is specified
- No presampling
- Conversion time (4 cycles per bit)

The total time for the three conversions = [(0 + 22 + (4×13) + 2) × 3] + 1 = 229 cycles ~= 2.862 µs

Conversion timing in Calibration for full test:

- Single conversion time = [sample time (CALBISTREG[TSAMP]) + compare time (11 × 4) + data proc(2)]
- Inter-conversion gap = 1 cycle
- Total number of tests = 12
- Averaging = 32

One test duration = (single conversion time + inter-conversion gap) × averaging samples

Total test duration = ( ( one test duration ) × total number of tests).

Example: sample time = 22

Total test time = ( ( ( (22 + (11×4) +2)+1) × 32) × 12) = 26496 cycles × 12.5 ns (80 MHz) = 331200 ns

Conversion time in self-test:

Self-test conversion time equals one test period multiplied by the number of consecutive (atomic) steps. For supply self-test, the atomic step is 3 and for other tests it is 1.

One test period for self-test is as below.

- For supply tests: ( [ sample_time + (13 × 4) + 2] )
- For other algorithms: ( [ sample_time + (11 × 4) + 2] )

**NOTE**

Algorithm S steps (conversions) always run in atomic operation, required for an algorithmic procedure. In Scan operation mode, when all algorithms are selected, three steps of algorithm S run together after the end of the conversion chain. algorithm C steps are not required to be run together, so after each conversion chain one step is executed serially. Conversion time with self-test must also be calculated accordingly.

Example.

- Channels in chain A→B→C.
- Scan operation mode.
- All self-test algorithms are selected.

So, the resulting conversion order is:

[A→B→C→AS_step0→AS_step1→AS_step2→A→B→C→AC_step0→A→B→C→AC_step1→A→B→C→AC_step2→.....→A→B→C→AC_step11]→[same sequence repeats]

**NOTE**

- AS = Algorithm S (supply self-test)
- AC = Algorithm C (capacitive self-test)

### 57.3.19 Conversion data processing

Raw converted data contains many types of errors, such as offset, gain, and so on. ADC processes raw conversion data before writing the result to a data register, to reduce or eliminate error contributions. The process of error correction happens in parallel with bit-by-bit evaluation, using the correction values generated during the offset determination and calibration process.

The error correction value is subtracted from the raw conversion result whenever the comparator output for one of the calibrated capacitors evaluates high during the conversion period.

To reduce data processing time, error correction is done in parallel during each bit evaluation of a conversion. Lower-weighted capacitors (smaller than C9) are not calibrated, so no error correction is performed for these capacitors. However, they are self-tested to guarantee that the error contribution is below specified accuracy limits.

The final result is checked for any overflow or underflow. When the processed data is above the maximum value that can be represented by ADC resolution, the output data is forced to all 1s (FFFh for 12-bit resolution). Similarly, if the processed data is negative then output data is forced to all 0s (000h for 12-bit resolution).

### 57.3.20 User-defined offset and gain values

In addition to the ADC-calculated offset value and gain value, ADC enables you to specify another set of offset and gain values in Offset And Gain User (OFSGNUSR). These values must be stored in two's complement format, where the leftmost bit (the most significant bit) is the sign bit.

ADC subtracts these values from the final processed conversion result. The values are used to removed fixed DC bias or any other known errors—for instance those caused by board design, sensors, and so on.

## 57.4 External signals

This module has no external signals.

## 57.5 Clock frequency

ADC's internal blocks are designed for an input clock frequency up to the Fin (Input Signal Bandwidth) maximum (see the ADC electrical specification section in the chip data sheet). The specified speed can be achieved with this clock frequency. If the input clock frequency exceeds the specified maximum frequency, ADC accuracy degrades and, in the worst case scenario, ADC malfunctions. ADC accuracy also degrades if the input clock frequency is below the specified minimum frequency. Sampling time has an absolute maximum value to guarantee the specified parameters and accuracy. For slower clocks, the sampling clock count must be programmed accordingly.

## 57.6 Memory map and register definition

ADC has a wide range of configurations to tailor its operation to application requirements. This comes with the drawback of possible corner cases. To avoid unintended behavior, configure ADC before starting a conversion and change any configuration only when ADC is idle, in other words when MSR[ADCSTATUS] = 0.

### 57.6.1 Transfer error description

The following register accesses cause a transfer error and do not change register content:

- Any access to an unused address.
- Any write access to a read-only register.

### 57.6.2 ADC register descriptions

### 57.6.2.2 Main Configuration (MCR)

#### Offset

| Register | Offset |
|---|---|
| MCR | 0h |

#### Function

Configures most ADC features. You must change field values only when ADC is in Idle state, except for the ABORTCHAIN and ABORT fields.

#### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

#### Fields

| Field | Function |
|---|---|
| 31<br>OWREN | Overwrite Enable<br>Specifies whether a conversion data register accepts new data before the current conversion data has been read. When enabled, the new conversion result overwrites the older data, regardless of the validity of the older conversion data. When PCDR*n*[VALID] = 1, the conversion data has not been read.<br>0b - Disable<br>1b - Enable |
| 30<br>WLSIDE | Write Left-Aligned |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | Specifies whether conversion data is right-aligned or left-aligned when written to one of the conversion data registers:<br>• PCDR*n*<br>• ICDR0*n*<br>• ECDR*n*<br>Right-aligned data occupies *CDR[14:0]. Left-aligned data occupies *CDR[15:1],<br>0b - Right aligned<br>1b - Left-aligned |
| 29<br>MODE | Normal Conversion Mode<br>Specifies whether the set of input channels selected for a normal conversion are converted only once per start event or continuously after a start event.<br>If a conversion is done only once, ADC enters an idle state after conversion is complete.<br>For continuous conversion, all input channels selected for the normal conversion are converted continuously in a loop. Stop the loop by writing 0 to NSTART.<br>0b - Single conversion<br>1b - Continuous conversion |
| 28<br>— | Reserved |
| 27<br>TRGEN | External Trigger Enable<br>Specifies whether the normal trigger input starts a conversion.<br>0b - Normal trigger input does not start a conversion<br>1b - Normal trigger input starts a conversion |
| 26<br>EDGE | External Trigger Edge Selection<br>Selects which edge of the normal trigger input starts a conversion.<br>0b - Falling edge<br>1b - Rising edge |
| 25<br>XSTRTEN | Auxiliary External Start Enable<br>Enables the auxiliary normal trigger source to start a conversion. You can use this field to synchronize the start of a conversion of two ADC instances.<br>0b - Disable<br>1b - Enable |
| 24<br>NSTART | Start Normal Conversion |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | Starts a normal conversion. If the continuous mode is selected (MODE = 1), the value of this field remains 1. Write 0 to this field to stop the in-progress conversion loop after conversion of the last input channel of the selected set of input channels is complete.<br>If continuous mode is not selected (MODE = 0), this field automatically resets to 0 after writing 1.<br>0b - No effect<br>1b - Starts conversion |
| 23<br>— | Reserved |
| 22<br>JTRGEN | Injection Trigger Enable<br>Enables the injected trigger input as a source to start a conversion.<br>0b - Disable<br>1b - Enable |
| 21<br>JEDGE | Injected Trigger Edge Selection<br>Selects which edge of the injected trigger input starts an injected conversion.<br>0b - Falling edge<br>1b - Rising edge |
| 20<br>JSTART | Injected Start<br>Interrupts any ongoing normal conversion and starts an injected conversion. This field automatically resets to 0. If an injected conversion is already ongoing, the field value remains 1 until the next injected conversion starts. This field can only be written with 1.<br>0b - Injected conversion can be started<br>1b - Starts an injected conversion |
| 19-18<br>— | Reserved |
| 17<br>BCTUEN | Body Cross Trigger Unit Enable<br>Enables BCTU as a trigger source.<br>0b - Disable<br>1b - Enable |
| 16<br>BCTU_MODE | Body Cross Trigger Unit Mode Select<br>Specifies whether sources other than BCTU can start a conversion when the BCTU is enabled as a trigger source (BCTUEN = 1). This field is writeable only when ADC is in Power Down state (PWDN = 1).<br>0b - Only BCTU can trigger conversion<br>1b - All trigger sources can trigger conversion |

*Table continues on the next page...*

### 57.6.2.10 EOC Interrupt Enable For Standard Inputs (CIMR1)

#### Offset

| Register | Offset |
|---|---|
| CIMR1 | 28h |

#### Function
Specifies whether a completed conversion of a standard input flags an EOC interrupt.

#### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 57.6.2.11 EOC Interrupt Enable For External Inputs (CIMR2)

#### Offset

| Register | Offset |
|---|---|
| CIMR2 | 2Ch |

#### Function
Specifies whether a completed conversion of an external input flags an EOC interrupt.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| ADC_0 | CIMR2 | — |
| ADC_1 | CIMR2 | — |
| ADC_2 | — | CIMR2 |

## 57.6.2.12 Analog Watchdog Threshold Interrupt Status (WTISR)

### Offset

| Register | Offset |
|---|---|
| WTISR | 30h |

### Function

Contains flags that indicate the result of a comparison between the conversion result and the threshold value defined in the analog watchdog.

### Diagram

## 57.6.2.23 Conversion Timing For Precision Inputs (CTR0)

### Offset

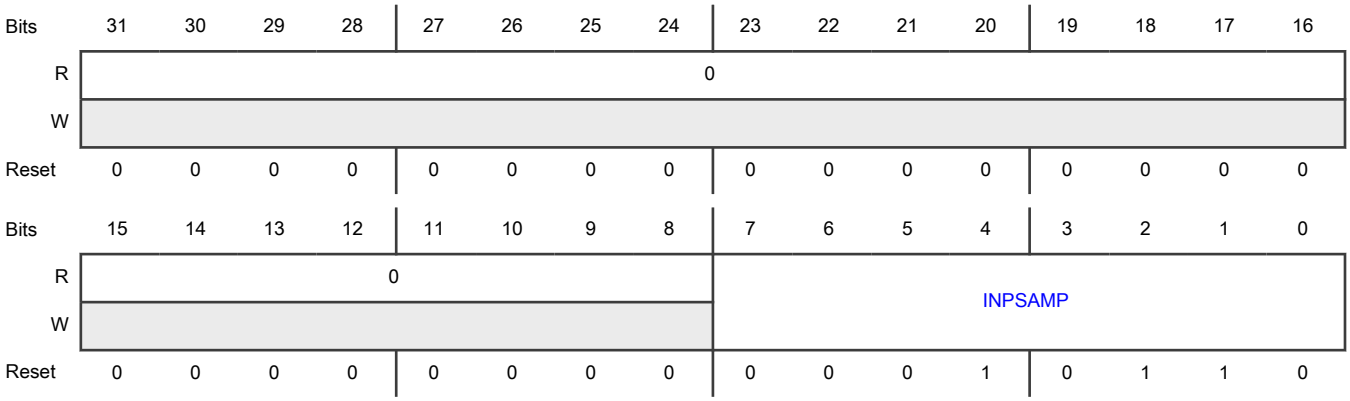
| Register | Offset |
|---|---|
| CTR0 | 94h |

### Function

Specifies duration, in terms of the number of conversion clock cycles, of the sampling of precision inputs.

The conversion clock frequency depends on the configuration of MCR[ADCLKSEL].

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-8<br>— | Reserved |
| 7-0<br>INPSAMP | Input Sample Cycles<br>Specifies the sample duration in terms of conversion clock cycles. The minimum value is 8. Specifying a lower value automatically forces a value of 8. |

### 57.6.2.24 Conversion Timing For Standard Inputs (CTR1)

#### Offset

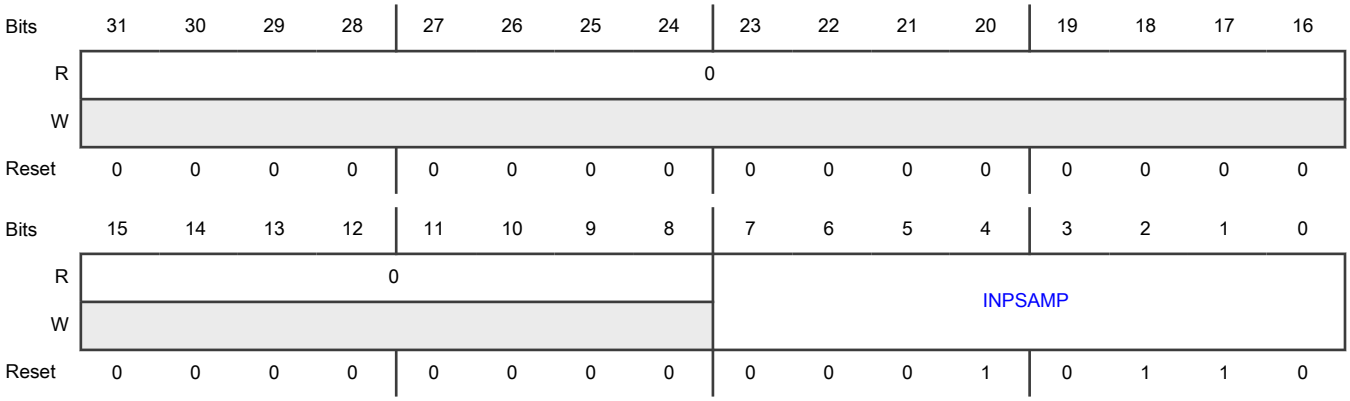
| Register | Offset |
|---|---|
| CTR1 | 98h |

#### Function

Specifies the duration, in terms of the number of conversion clock cycles, of the sampling of standard inputs or the temperature sensor.

The conversion clock frequency depends on the configuration of MCR[ADCLKSEL].

#### Diagram



#### Fields

| Field | Function |
|---|---|
| 31-8<br>— | Reserved |
| 7-0<br>INPSAMP | Input Sample Cycles<br>Specifies the sample duration in terms of conversion clock cycles. The minimum value is 8. Specifying a lower value automatically forces a value of 8. |

### 57.6.2.25 Conversion Timing For External Inputs (CTR2)

#### Offset

| Register | Offset |
|---|---|
| CTR2 | 9Ch |

#### Function

Specifies the number of conversion clock cycles when the external inputs are sampled.

The conversion clock frequency depends on the configuration of MCR[ADCLKSEL].

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| ADC_0 | CTR2 | — |

## 57.6.2.32 Delay Start Of Data Conversion (DSDR)

### Offset

| Register | Offset |
|---|---|
| DSDR | C4h |

### Function

Delays the start of the conversion when another input channel is selected. The necessary delay depends on the device characteristics of, for example, the input channel multiplexer.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| ADC_0 | DSDR | — |
| ADC_1 | DSDR | — |
| ADC_2 | — | DSDR |

### Diagram

| 15-0<br>DSD | Delay<br>Specifies the delay in terms of the number of module clock cycles. |

## 57.6.2.33 Power Down Exit Delay (PDEDR)

### Offset

| Register | Offset |
|---|---|
| PDEDR | C8h |

### Function

Delays the transition out of Power Down into Idle state to wait for necessary settling times. See the device data sheet for the minimal time between the power-down exit request and when ADC can start a conversion.

### 57.6.2.34 Precision Input n Conversion Data (PCDR0 - PCDR7)

#### Offset

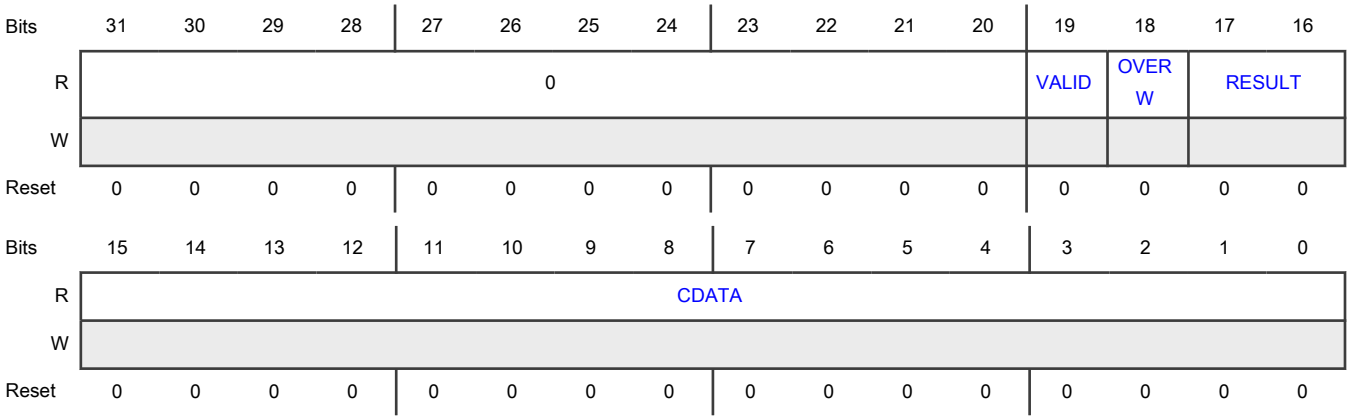
For n = 0 to 7:

| Register | Offset |
|---|---|
| PCDRn | 100h + (n × 4h) |

#### Function

Contains conversion data from precision input *n*.

#### Diagram



#### Fields

| Field | Function |
|---|---|
| 31-20<br>— | Reserved |
| 19<br>VALID | Conversion Data Available<br>Indicates whether new conversion data is available. This field is automatically reset to 0 when the data is read.<br>0b - No unread conversion data<br>1b - Unread conversion data is available |
| 18<br>OVERW | Overwrite Status Flag<br>Indicates whether the previous conversion data was overwritten without having been read, in which case the overwritten data is lost.<br>The ability to overwrite conversion data is controlled by MCR[OWREN].<br>0b - No unread data is overwritten<br>1b - Unread data is overwritten |

*Table continued from the previous page...*

| Field | Function |
|---|---|
| 17-16<br>RESULT | Conversion Data Type<br>Indicates the type of trigger that started the conversion for this conversion data.<br>00b - Normal trigger<br>01b - Injected trigger<br>10b - BCTU trigger |
| 15-0<br>CDATA | Conversion Data<br>Contains conversion data from precision input *n*, determined by the successive approximation algorithm. The conversion data is always 15 bits wide, regardless of the conversion resolution selected (CALBISTREG[RESN]).<br>Depending on the value of MCR[WLSIDE], the conversion data can be in bits [14:0] (MCR[WLSIDE] = 0), or in bits [15:1] (MCR[WLSIDE] = 1). |

### 57.6.2.35 Standard Input n Conversion Data (ICDR0 - ICDR23)

#### Offset

For a = 0 to 23:

| Register | Offset |
|---|---|
| ICDRa | 180h + (a × 4h) |

#### Function

Contains conversion data from standard input *n*.

#### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 57.6.2.67 Control And Calibration Status (CALBISTREG)

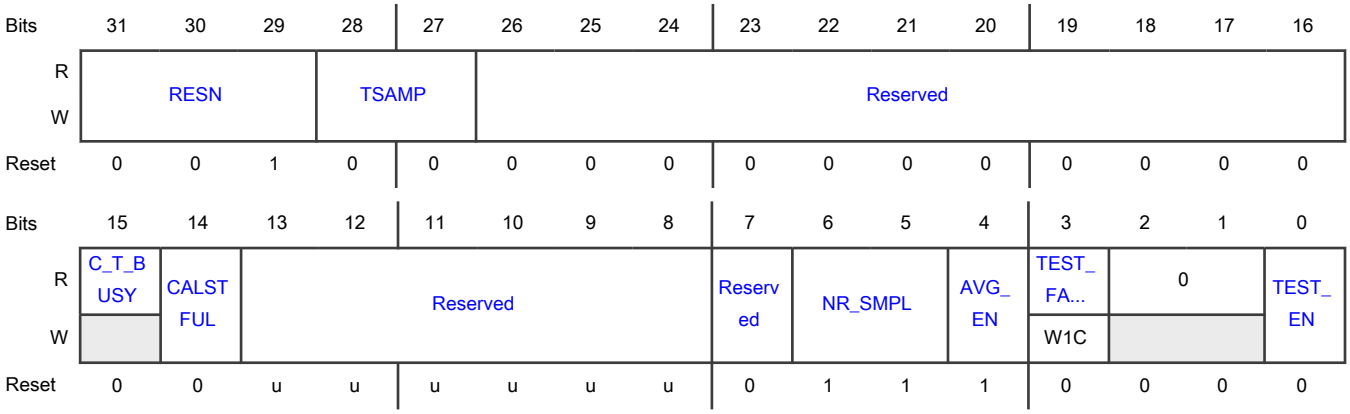
#### Offset

| Register | Offset |
|---|---|
| CALBISTREG | 3A0h |

#### Function

Controls several ADC functions for data conversion, calibration, and calibration status.

#### Diagram



### Fields

| Field | Function |
|---|---|
| 31-29<br>RESN | Conversion Resolution<br>Specifies the number of significant bits per conversion data (functional conversion only, not for calibration or self-test). Reducing this number speeds up the conversion because the SAR algorithm executes fewer steps. This field must be modified only when ADC is idle.<br>000b - 14-bit resolution<br>001b - 12-bit resolution<br>010b - 10-bit resolution<br>011b - 8-bit resolution |
| 28-27<br>TSAMP | Sample Period In Calibration<br>Specifies the number of conversion clock cycles during which the reference voltage is sampled.<br>00b - 22 conversion clock cycles<br>01b - 8 conversion clock cycles<br>10b - 16 conversion clock cycles<br>11b - 32 conversion clock cycles |
| 26-16<br>— | Reserved<br>The value of this field must not be modified. |
| 15<br>C_T_BUSY | Calibration Busy<br>Indicates whether calibration is running.<br>0b - Calibration can be started<br>1b - Calibration is in progress |
| 14<br>CALSTFUL | Calibration And Self-Test Full Range Comparison<br>Specifies the range of conversion data bits compared when ADC is calibrated or running self-test. Because the results from calibration and self-test are so low that the significant bits are in the lower 11 bits only, the comparison cycles for the upper 4 bits can be skipped to reduce the execution duration of the calibration and of the self-test.<br>0b - Lowest 11 bits are compared.<br>1b - All 15 bits are compared. |
| 13-8<br>— | Reserved<br>**CAUTION**<br>This field contains a value that ADC uses internally. Writing to this field can cause ADC to operate unreliably. |
| 7<br>— | Reserved<br>This field is reserved and always has the value 0. Only the reset value can be written to this field. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |

## 57.7 Glossary

| | |
|---|---|
| **CDAC** | Capacitive digital to analog converter |
| **CT** | Compare phase time |
| **DMA** | Direct memory access |
| **DP** | Data processing time |

| | |
|---|---|
| **PST** | Presample phase time |
| **ST** | Sample phase time |
| **SAR** | Successive approximation |
| **TPT** | Trigger processing time |
| **VrefH** | Reference voltage high |
| **VrefL** | Reference voltage low |

# Chapter 58
# Low Power Comparator (LPCMP)

## 58.1 Chip-specific LPCMP information

### 58.1.1 Instantiation information

Table 275. LPCMP instances

| Chip | Instance | No. of external inputs |
|---|---|---|
| MCXE31B | LPCMP_0 | 8 |
| | LPCMP_1 | 4 |
| | LPCMP_2 | 4 |
| MCXE317 | LPCMP_0 | 8 |
| | LPCMP_1 | 4 |
| MCXE315/MCXE316 | LPCMP_0 | 8 |

### 58.1.2 LPCMP input output connections

See the IOMUX file attached to this document for pin/pad assignments corresponding to CMP pins.

The LPCMP channels can be used as a wakeup source in trigger mode to wakeup the device from standby mode.

### 58.1.3 LPCMP-DAC "vrefh0" and "vrefh1" references

The 8-bit DAC sub-block supports selection of "vrefh0" and "vrefh1" by CMPx_DCR[VRSEL]. For this device, the references are connected as follows:

- vrefh0 (External Reference): VDD_HV_A
- vrefh1 (Internal Reference): 1.2 V PMC bandgap reference

**NOTE**

1.2 V internal reference voltage is not available in Standby mode.

### 58.1.4 LPCMP window control

The window mode operation of all the comparator instances in the chip can be enabled/disabled by the TRGMUX. See the TRGMUX connectivity file attached to this document for details.

**NOTE**

Window signal must be of minimum 4 cycle pulse for window mode to function.

### 58.1.5 Comparator Trigger Mode

The comparator modules in the device support trigger mode operation as described in 'Trigger Mode' section. Device can operate in trigger mode in both standby and run mode to continuously scan the input channels. The main features of the device trigger mode operation are:

- Round robin clock: RTC_CLK
- Round robin trigger source: RTC_API

**NOTE**

It must be ensured that the RTC_CLK period is greater than the comparison time corresponding to the value of C0[PMODE]. It is also required to **not** select the internal reserved channels, if available on the package, for trigger mode operation by INPSEL and INNSEL. See the IOMUX file attached to this document for the pins available in various packages supported for the device.

**NOTE**

Only SIRC and SXOSC are supported as RTC_CLK for trigger mode operation. The LPCMP initialization delay is not supported by RRCR0[RR_INITMOD] with FXOSC or FIRC as RTC_CLK.

**NOTE**

In run mode, the generated trigger is delayed by 3 RTC_CLK cycles before being given to comparator trigger input.

### 58.1.6 Interaction with RTC API to cause wakeup

LPCMP can be used for waking up the chip from standby. For this, RTC-API and LPCMP must be configured before entering into standby mode as per below shown figure.

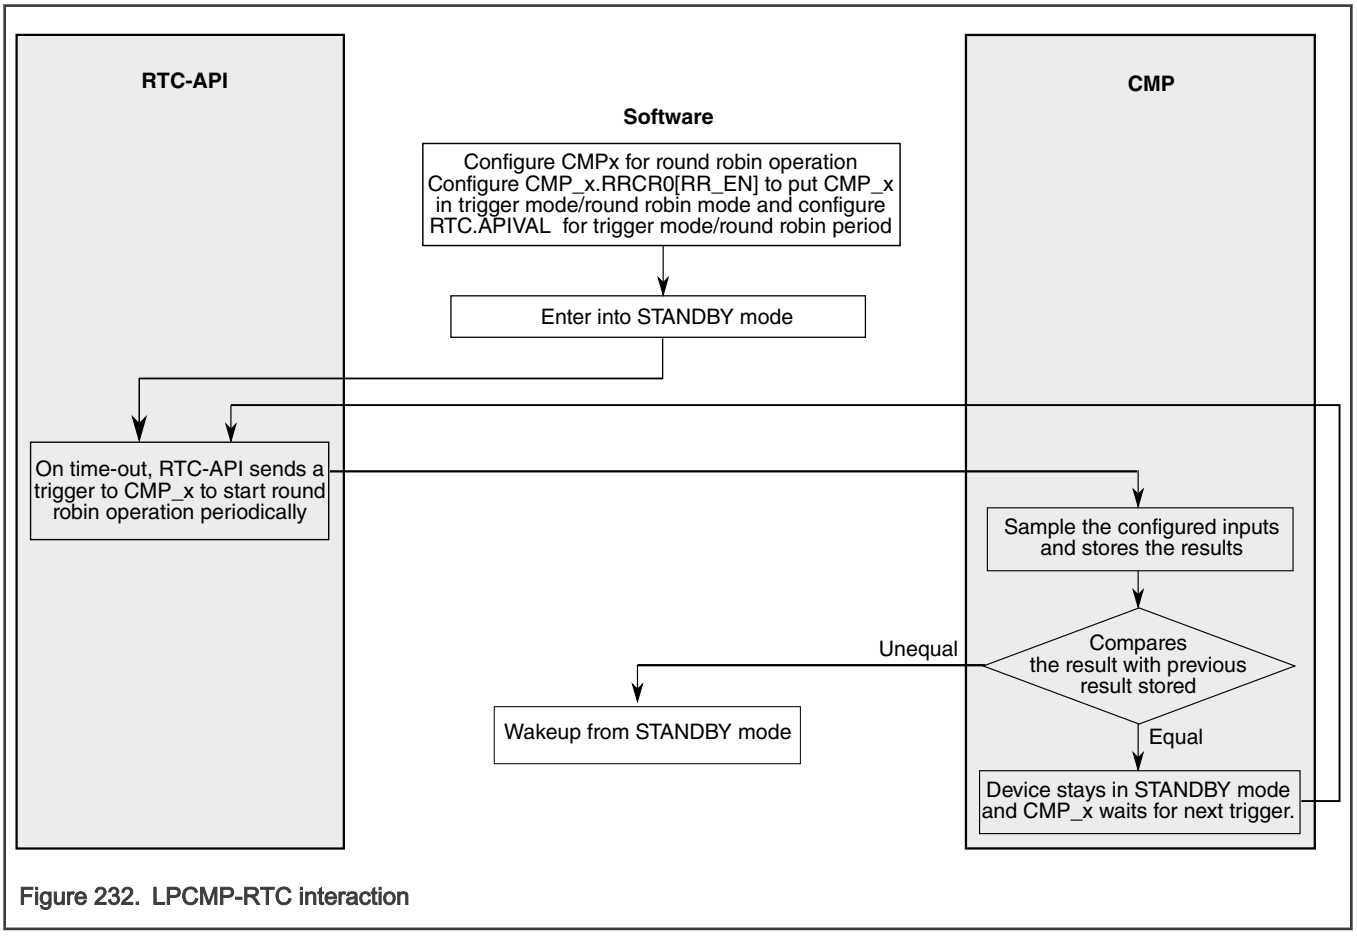

Figure 232. LPCMP-RTC interaction

In the trigger mode operation, only the continuous mode is supported. None of the window/filter/sample functions should be used. Refer to the "Functional Modes" section for details on comparator modes of operation.

**Register configurations before entering Standby mode for LPCMP trigger mode operation:**

1. Configure RTC.APIVAL to set the period of the round robin operation.
2. Execute standby mode entry.

## 58.2 Overview

The LPCMP module provides a circuit to compare two analog input voltages. It includes the following:

- A low power comparator (CMP)
- A DAC
- An analog mux (ANMUX)

See Block diagram for more information.

LPCMP can operate across the full range of the supply voltage, known as rail-to-rail operation.

DAC is a 256-tap resistor ladder network that provides a selectable voltage reference for applications requiring a voltage reference. DAC divides the supply reference $V_{in}$ into 256 voltage levels. An 8-bit digital signal input selects the output voltage level, which varies from $V_{in}$ to $V_{in}/256$.

You can select $V_{in}$ from the following voltage sources:

- VREFH0
- VREFH1

See the Chip-specific LPCMP information for more information on source of VREFH0 and VREFH1.

**NOTE**

The LPCMP's internal DAC output is available as an on-chip internal signal only and is not available for an external chip pin.

ANMUX allows you to select an analog input signal from among eight channel options. One channel option is the DAC output. Other chip resources are connected to the other channels. See the Chip-specific LPCMP information section for more information. ANMUX can operate across the full range of the supply voltage.

### 58.2.1 Block diagram

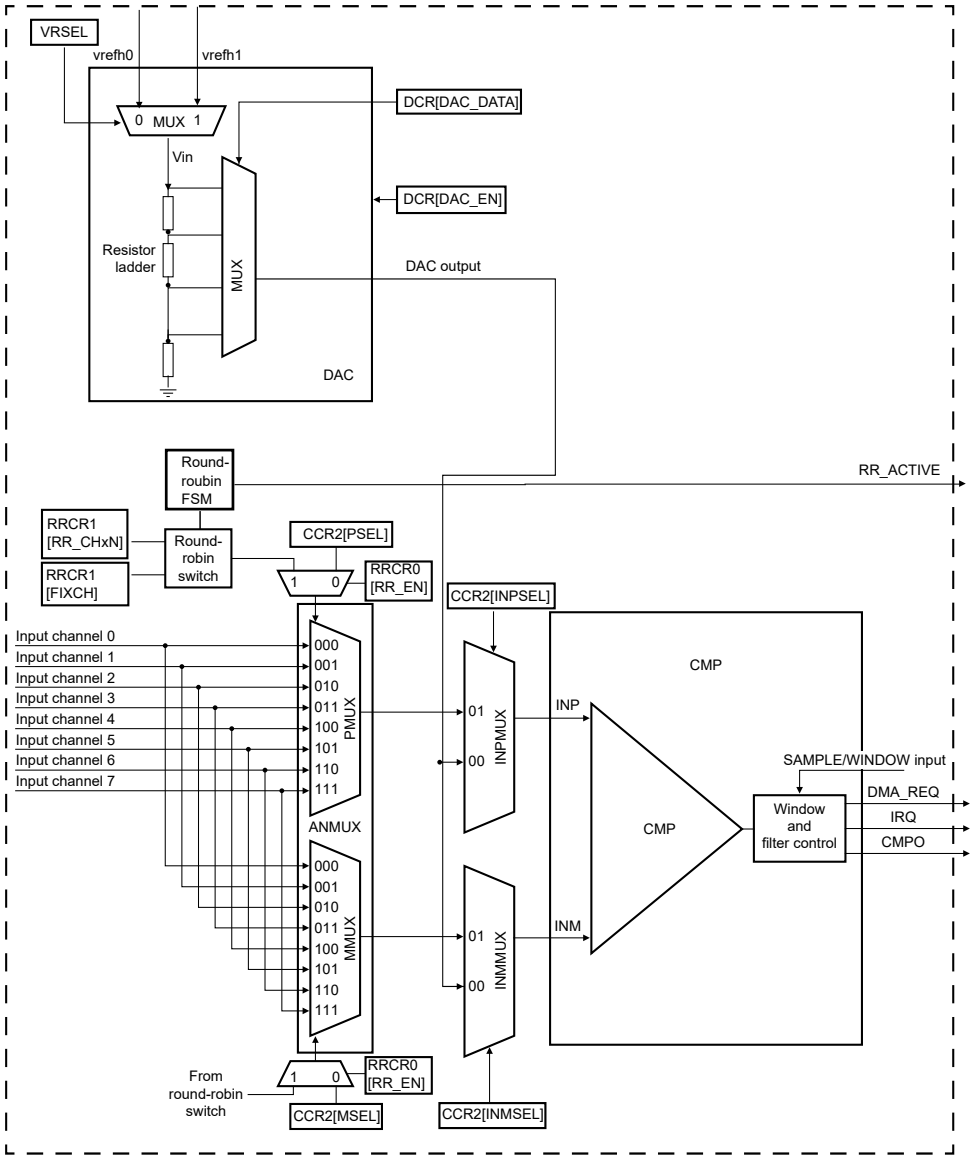

Figure 233. Block diagram

### 58.2.2 Features

The features of the LPCMP module include：

- Includes two 8-to-1 channel MUXes to select input signal from eight channels
- Supports multiple operation modes to produce a wide range of outputs such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally filtered
- Provides the following advance features for window and sample:

- Window and sample signals can be inverted.
- CMPO rising, falling or both edges closes the window.
- CMPO level can be defined when window is closed.

- Provides selectable performance levels:
  - Low-Power (speed) mode
  - High-Power (speed) mode
- Supports programmable hysteresis control
- Provides a selectable inversion on comparator output
- Uses an external hysteresis at the same time the output filter is used for internal functions
- Provides interrupt and DMA support
- Supports Round Robin Trigger mode
- Includes an 8-bit resolution DAC
- Provides a selectable supply reference source for DAC

## 58.3 Functional description

### 58.3.1 Functional block diagram

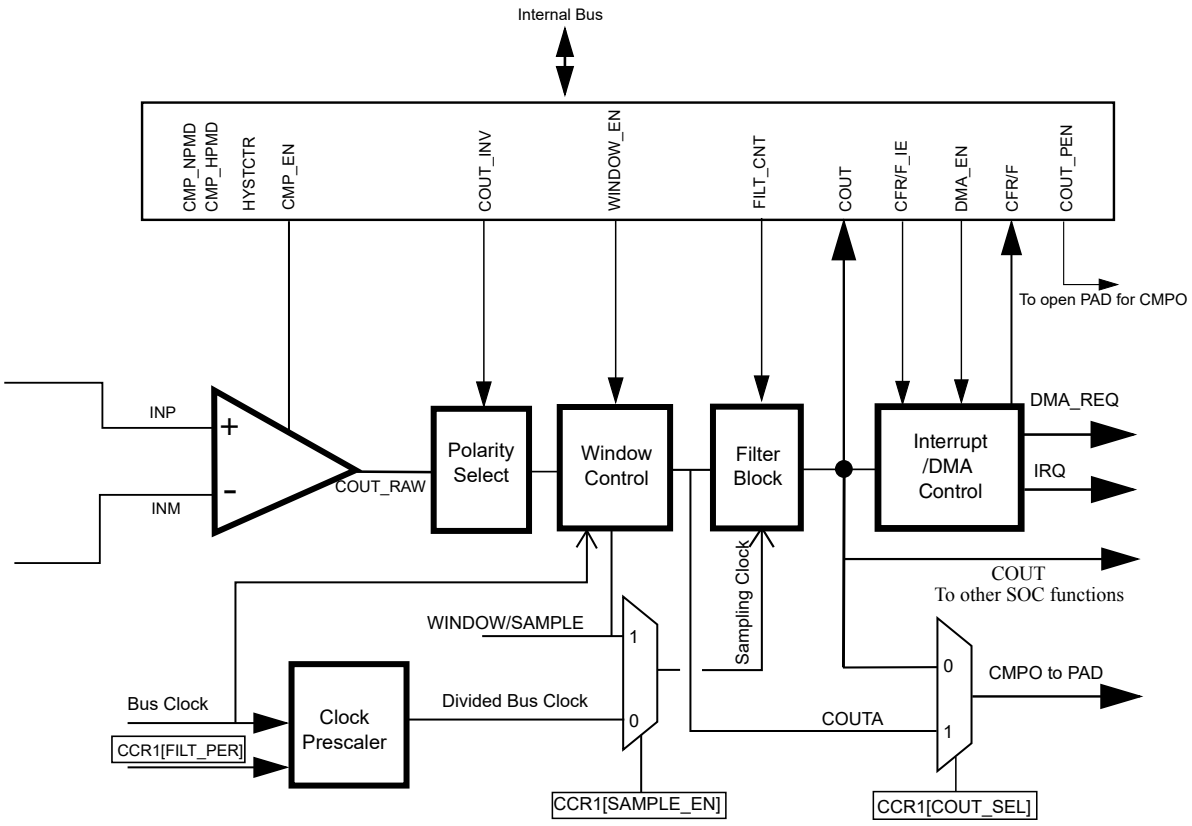

Figure 234. Functional block diagram

As shown in the block diagram, the functions are:

- Compared two analog input voltages applied to INP and INM, COUT_RAW is high when the INP input voltage is greater than the INM input voltage, and COUT_RAW is low when the INP input voltage is less than the INM input voltage.
- The COUT_RAW signal can be inverted by enabling CCR1[COUT_INV].
- The optionally inverted comparator output COUT_RAW is sampled on every bus clock when you enable the CCR1[WINDOW_EN] to generate COUTA. In this case, the comparator output is ignored during time periods when the input voltages are not valid. This is useful when you implement zero-crossing-detection for certain PWM applications.
- The window control block is bypassed when CCR1[WINDOW_EN] is disabled.
- The filter block acts as a simple sampler when CCR1[FILT_CNT] is set to 01h.
- The filter block acts as a filter based on multiple samples when CCR1[FILT_CNT] is set to be greater than 01h.
  - If CCR1[SAMPLE_EN] is set to 1, use the external SAMPLE input as the sampling clock.
  - If CCR1[SAMPLE_EN] is set to 0, use the divided bus clock as the sampling clock.
- Bypasses the filter block when it is not in use.

```
Bypass_Filter_Block = (FILT_CNT == 0x00) |  (~SAMPLE_EN & (FILT_PER == 0x00))
```

- Both COUTA and COUT can be configured as module output CMPO by configuring CCR1[COUT_SEL], and are used for different purposes within the system.
- The optionally filtered COUT can be read directly in CSR[COUT].
- The SAMPLE/WINDOW signal can be inverted by setting CCR1[WINDOW_INV].
- The SAMPLE/WINDOW signal can be closed by CMPO's falling edge and/or rising edge by setting CCR1[WINDOW_CLS] in Window mode.
- In Window mode, when window is closed, define the COUTA value as CCR1[COUTA_OW] by setting CCR1[COUTA_OWEN]. If CCR1[COUTA_OWEN] is not set, COUTA holds the last sampled value.

**NOTE**

See the chip configuration section for the source of SAMPLE/WINDOW input.

### 58.3.2 Round-robin trigger mode

You can enable Round-Robin Trigger mode by setting RRCR0[RR_EN] and CCR0[CMP_EN] to 1. A trigger event initiates a comparison sequence. The next trigger event should not occur before the current sequence completes.

RRCR1[FIXP] and RRCR1[FIXCH] select the reference channel for the plus side mux or the minus side mux. RRCR1[RR_CHnEN] selects active channels.

When a trigger comes, the analog comparator enables. After the comparison sequence completes, the analog comparator disables again. RRCR0[RR_INITMOD] controls the analog stabilization time.

**NOTE**

RR_INITMOD*round robin clock period must be longer than the initialization delay specified in the Comparator and 8-bit DAC electrical specifications section of LPCMP datasheet.

After the stabilization process completes, the round robin manner comparison sequence begins. Sample the comparison result for the selected active channel after RRCR0[RR_NSAM] defines the configurable number of operation clocks.

After all the active channels are sampled/compared, if the comparison result changes from its pre-programmed state, the corresponding flag in RRSR[RR_CHnF] is set. Write to RRCSR[RR_CHnOUT] to configure the pre-programmed state for each channel. Update RRCSR[RR_CHnOUT] to store the last comparison result for each channel. If any flag in RRSR[RR_CHnF] sets, CSR[RRF] also sets. If IER[RRF_IE] sets, an asynchronous interrupt asserts. Note that these flags do not support generating a DMA transfer event.

The following diagram shows the basic flow of this mode. In the diagram, RRCR1[RR_CH1EN], RRCR1[RR_CH3EN], and RRCR1[RR_CH4EN] are 1, so channels #1, #3, and #4 are selected for round-robin depending on their priority setting. RRCR0[RR_NSAM] sets to 2'b01, so you can sample one clock later the comparison result of the selected channel. After you compare the channel #4, the result is sampled, and round-robin ends. If any of the comparison results from channel #1, #3, or #4 changed from their programmed value (written to RRCSR[RR_CH1OUT], RRCSR[RR_CH3OUT], and RRCSR[RR_CH4OUT]), generates an interrupt. Software can then poll RRSR[RR_CHnF] to see which channel input(s) changed value.

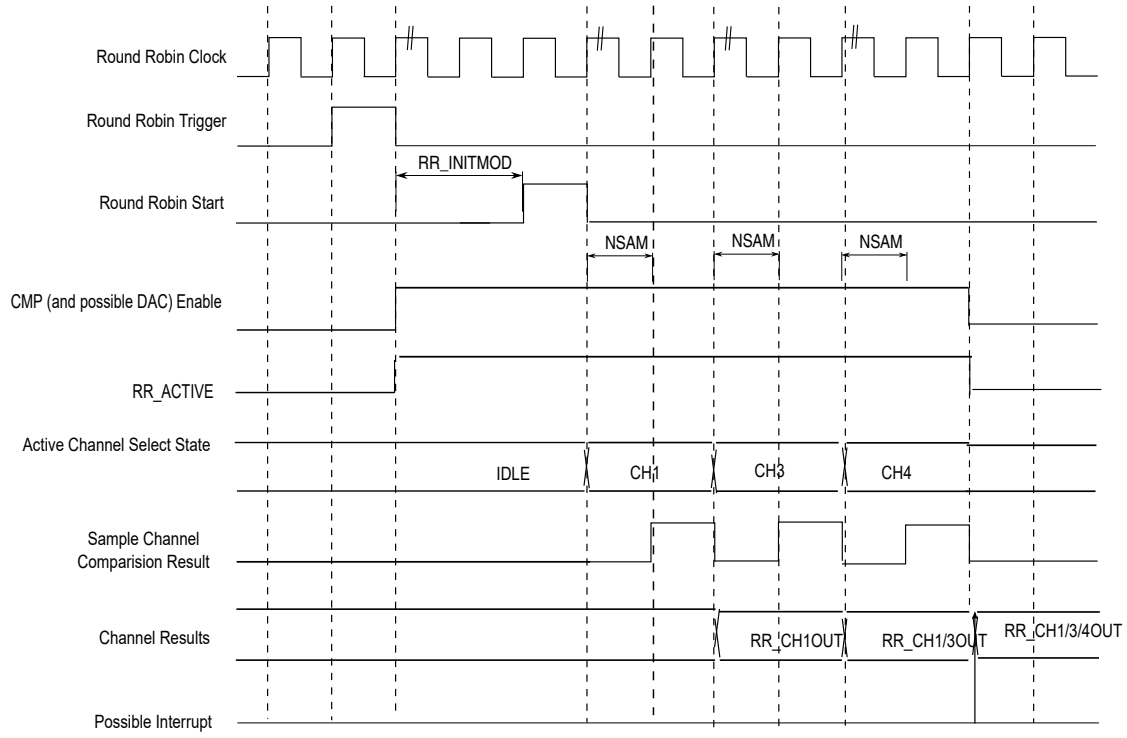

**Figure 235. Trigger mode**

The table below shows the channel decode in both Functional mode and Trigger mode. Other cases not in the table are illegal.

**Table 276. CMP channel decode in functional mode and round-robin trigger mode**

| Mode | RR_EN | PSEL[2:0] | MSEL[2:0] | INPSEL[1:0] | INMSEL[1:0] | FIXP | FIXCH[2:0] | RR_CHxN | INP | INM | CMP Behavior |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Functional mode | 0 | x[1] | 0 to 7 | 0 | 1 | x | x | x | DAC | Channel decoded from MSEL[2:0] | Channel 0 to 7 can be compared with DAC |

*Table continues on the next page...*

Table 276. CMP channel decode in functional mode and round-robin trigger mode (continued)

| Mode | RR_EN | PSEL[2:0] | MSEL[2:0] | INPSEL[1:0] | INMSEL[1:0] | FIXP | FIXCH[2:0] | RR_CHxN | INP | INM | CMP Behavior |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | 0 to 7 | x | 1 | 0 | x | x | x | Channel decoded from PSEL[2:0] | DAC | Channel 0 to 7 can be compared with DAC |
| | | 0 to 7 | 0 to 7 | 1 | 1 | x | x | x | Channel decoded from PSEL[2:0] | Channel decoded from MSEL[2:0] | Channel 0 to 7 can be compared with channel 0 to 7[2] |
| Trigger mode | 1 | x | x | 0 | 1 | 0 | x | 0 to 7 | DAC | Channel sweep (RR_CHxN) | Channel 0 to 7 can be swept with DAC |
| | | x | x | 1 | 0 | 1 | x | 0 to 7 | Channel sweep (RR_CHxN) | DAC | Channel 0 to 7 can be swept with DAC |
| | | x | x | 1 | 1 | 0 | 0 to 7 | 0 to 7 | Channel fixed by FIXCH[2:0] | Channel sweep (RR_CHxN) | Channel 0 to 7 can be swept with a fixed channel(0 to 7)[3] |
| | | x | x | 1 | 1 | 1 | 0 to 7 | 0 to 7 | Channel sweep (RR_CHxN) | Channel fixed by FIXCH[2:0] | Channel 0 to 7 can be swept with a fixed channel(0 to 7)[3] |

1. "x" means "don't care"
2. PSEL should not be same as MSEL.
3. Channel in the sweep side should not be same as the fixed side.

### 58.3.3 Low-pass filter mode

The low-pass filter mode operates on an unfiltered, optionally inverted comparator output COUTA, and generates the filtered and synchronized output COUT. You can configure both COUTA and COUT as module outputs and use for different purposes within the system.

Synchronization and edge detection determine the bit values of status register. They also apply to COUT for all sampling and windowed modes. You can perform filtering using an internal timebase defined by CCR1[FILT_PER], or use an external sample input to determine sample time.

The need for digital filtering and the amount of filtering depends on your requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, generate a high-frequency oscillations at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

#### 58.3.3.1 Enabling low-pass filter mode

You can enable low-pass filter mode by setting the following:

- CCR1[FILT_CNT] > 01h
- CCR1[FILT_PER] to a nonzero value or writing 1 to CCR1[SAMPLE_EN].

If you use the divided bus clock to drive the low-pass filter, it samples COUTA every CCR1[FILT_PER] bus clock cycle.

If CCR1[SAMPLE_EN] is set to 1, the low-pass filter samples COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive CCR1[FILT_CNT] samples agree that the output value has changed.

#### 58.3.3.2 Latency issues

Program the value of CCR1[FILT_PER] or sample period such that the sampling period is longer than the period of the expected noise, ensuring that a given noise spike corrupts only one sample. You must choose the value of CCR1[FILT_CNT] to reduce the probability of noisy samples causing an incorrect transition to recognize. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CCR1[FILT_CNT].

You must trade off the values of CCR1[FILT_PER] or sample period and CCR1[FILT_CNT] against the need for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CCR1[FILT_CNT].

Table 278 summarizes maximum latency values for the various modes of operation in the absence of noise. Filtering latency restarts each time the noise masks an actual output transition.

### 58.3.4 Low power mode operation

Below table introduces the mode of operation of lower power.

**Table 277. Low power mode operation**

| Mode of operation | Description |
|---|---|
| STANDBY | LPCMP can operate only in Continuous mode or Round-robin trigger mode. |

### 58.3.5 Functional modes

You can combine the comparator window and filter features as shown in the following table.

**Table 278. Functional modes**

| Mode # | CMP_EN | WINDOW_EN | SAMPLE_EN | FILT_CNT | FILT_PER | Operation | Maximum latency[1] |
|---|---|---|---|---|---|---|---|
| 1 | 0 | X | X | X | X | See the Disabled mode (#1). | N/A |
| 2A | 1 | 0 | X | 0x00 | X | See the Continuous mode (#2A and #2B). | $T_{PD}$ |
| 2B | 1 | 0 | 0 | X | 0x00 | | |
| 3A | 1 | 0 | 1 | 0x01 | X | See the Sampled, non-filtered mode (#3A and #3B). | $T_{PD} + T_{SAMPLE} + 3T_{per}$ |
| 3B | 1 | 0 | 0 | 0x01 | > 0x00 | | $T_{PD} + (FILT_PER * T_{per}) + 3T_{per}$ |

*Table continues on the next page...*

Table 278. Functional modes (continued)

| Mode # | CMP_EN | WINDOW_EN | SAMPLE_EN | FILT_CNT | FILT_PER | Operation | Maximum latency[1] |
|---|---|---|---|---|---|---|---|
| 4A | 1 | 0 | 1 | > 0x01 | X | See the Sampled, filtered mode (#4A and #4B). | $T_{PD}$ + (FILT_CNT * $T_{SAMPLE}$) + $3T_{per}$ |
| 4B | 1 | 0 | 0 | > 0x01 | > 0x00 | | $T_{PD}$ + (FILT_CNT * FILT_PER x $T_{per}$) + $3T_{per}$ |
| 5A | 1 | 1 | 0 | 0x00 | X | See the Windowed mode (#5A and #5B). | $T_{PD}$ + $2T_{per}$ |
| 5B | 1 | 1 | 0 | X | 0x00 | | |
| 6 | 1 | 1 | 0 | 0x01 | > 0x00 | See the Windowed/ Resampled mode (#6). | $T_{PD}$ + (FILT_PER * $T_{per}$) + $3T_{per}$ |
| 7 | 1 | 1 | 0 | > 0x01 | > 0x00 | See the Windowed/ Filtered mode (#7). | $T_{PD}$ + (FILT_CNT * FILT_PER x $T_{per}$) + $3T_{per}$ |
| All other combinations of CMP_EN, WINDOW_EN, SAMPLE_EN, FILT_CNT, and FILT_PER are illegal. | | | | | | | |

1. $T_{PD}$ represents the intrinsic delay of the analog component plus the polarity select logic. $T_{SAMPLE}$ is the clock period of the external sample clock. $T_{per}$ is the period of the bus clock.

#### 58.3.5.1 Disabled mode (#1)

In this mode:

- The analog comparator is non-functional and consumes no power.
- CSR[COUT] and CMPO are the same as CCR1[COUT_INV].

### 58.3.5.2 Continuous mode (#2A and #2B)

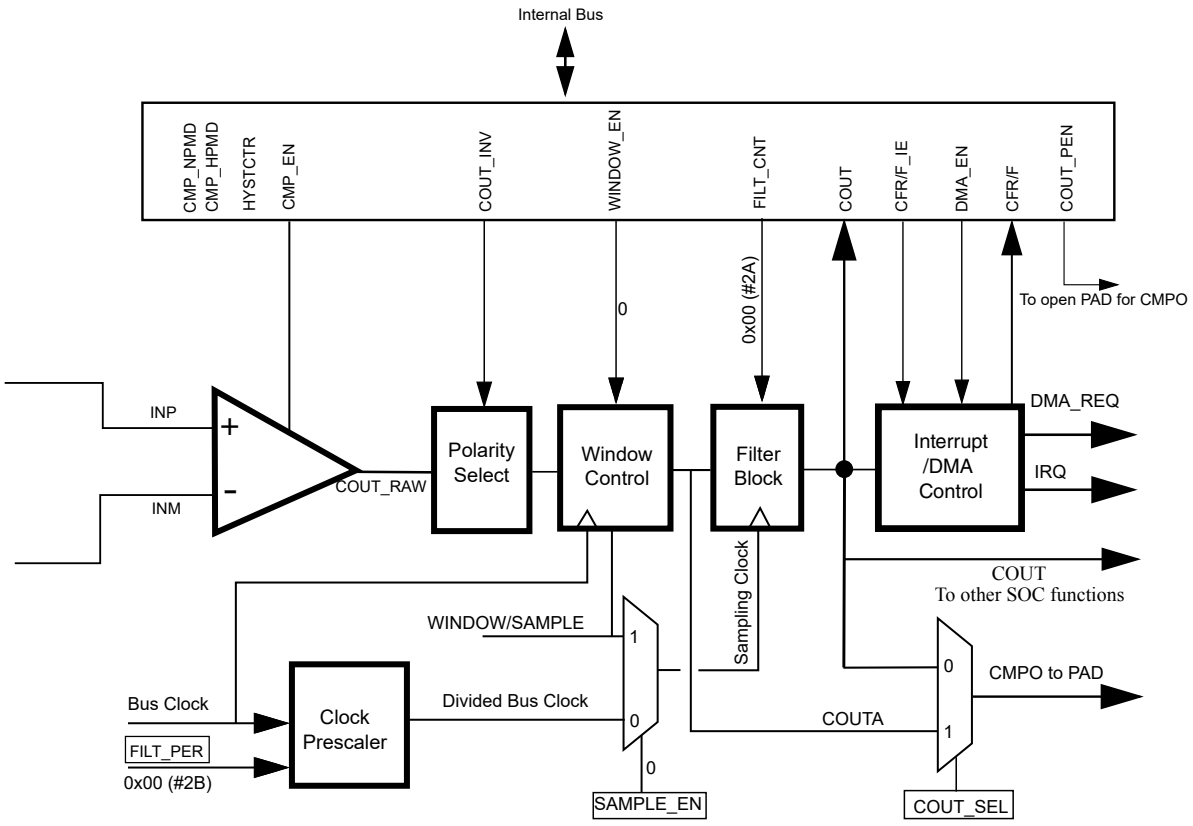

Figure 236. Comparator operation in continuous mode

COUT_RAW is optionally inverted in this mode but is not subject to external sampling or filtering. Both window control and filter blocks bypass completely, and CSR[COUT] updates continuously. The path from comparator input pins to output pins operates in a combinational (unclocked) mode. COUT and COUTA are identical in this mode.

For cases where a comparator drives a fault input, you must configure it to operate in Continuous mode so that an external fault can immediately pass to the target fault circuitry through the comparator.

### 58.3.5.3 Sampled, non-filtered mode (#3A and #3B)

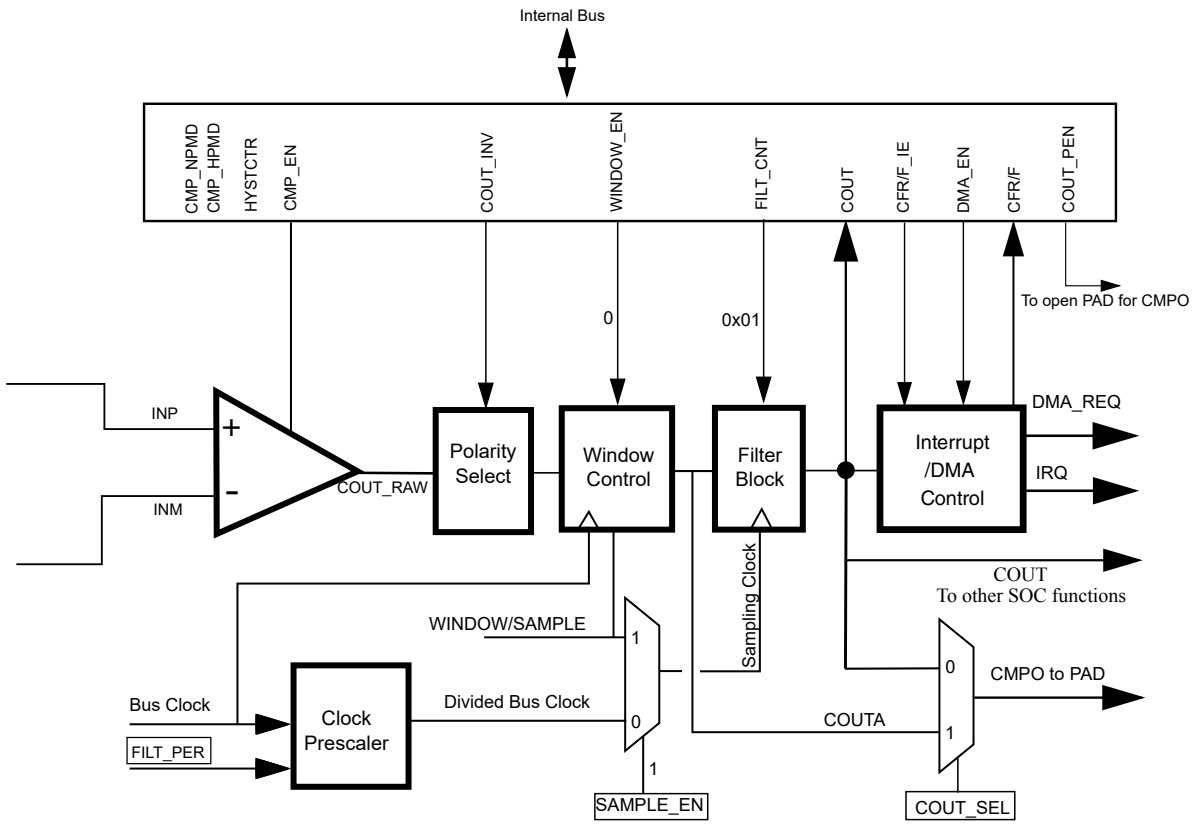

Figure 237. Sampled, non-filtered (#3A): sampling point externally driven

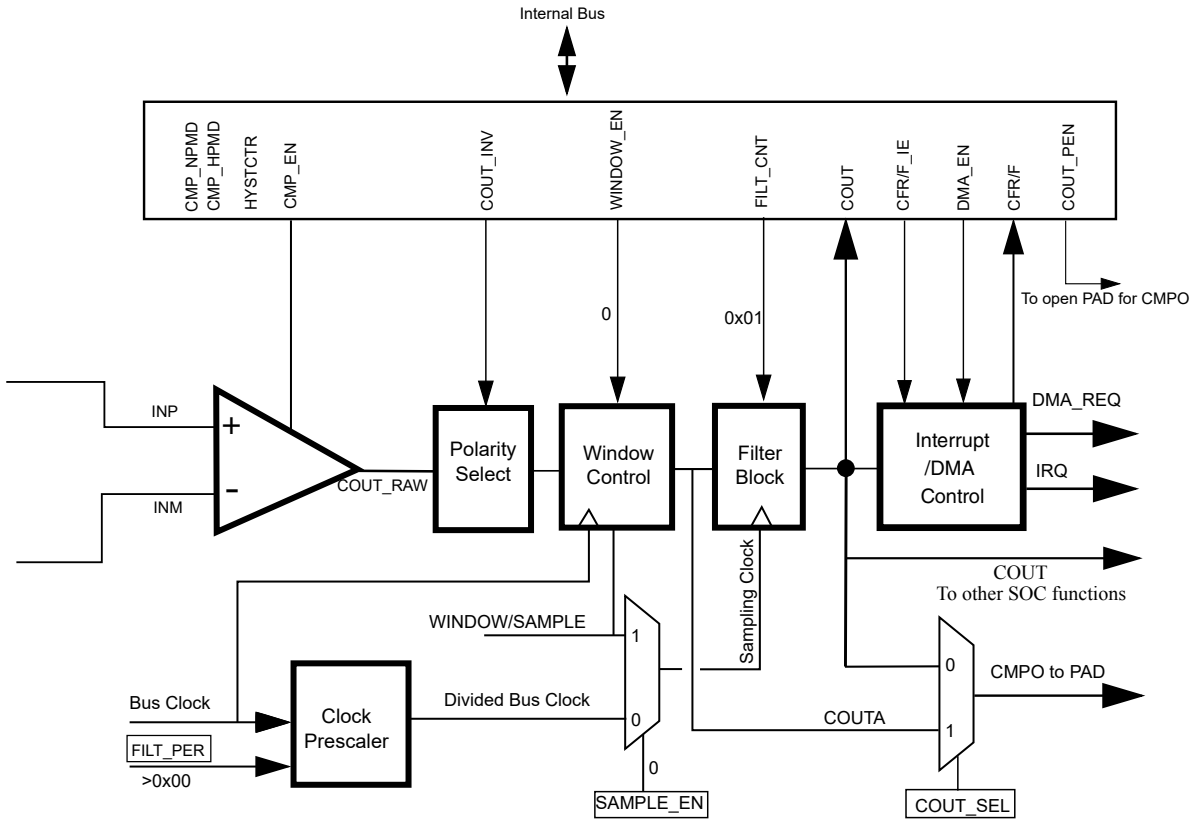

Figure 238. Sampled, Non-Filtered (#3B): sampling interval internally derived

In this mode, the path from analog inputs to COUTA is combinational (unclocked). Windowing control bypasses completely. You can sample COUTA whenever you detect a rising edge on the sampling clock.

The difference in two operation modes (#3A and #3B) of sampled, non-filtered mode is that how you drive the clock to the filter block. In #3A, the clock to filter block drives externally, and in #3B, the clock to filter block drives internally.

The filter block has no other function than sample or hold of the comparator output in this mode.

The following figure shows the comparator operation in this mode, assuming that the polarity select sets to a non-inverting state.

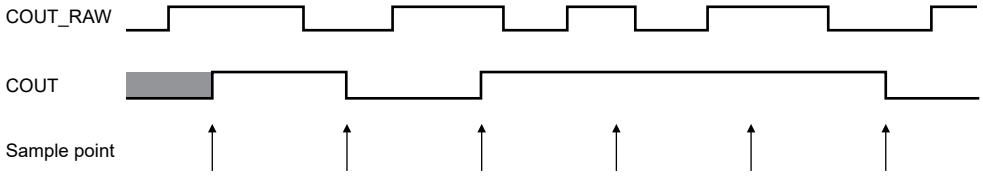

Figure 239. Sampled, Non-Filtered mode timing diagram

### 58.3.5.4 Sampled, filtered mode (#4A and #4B)

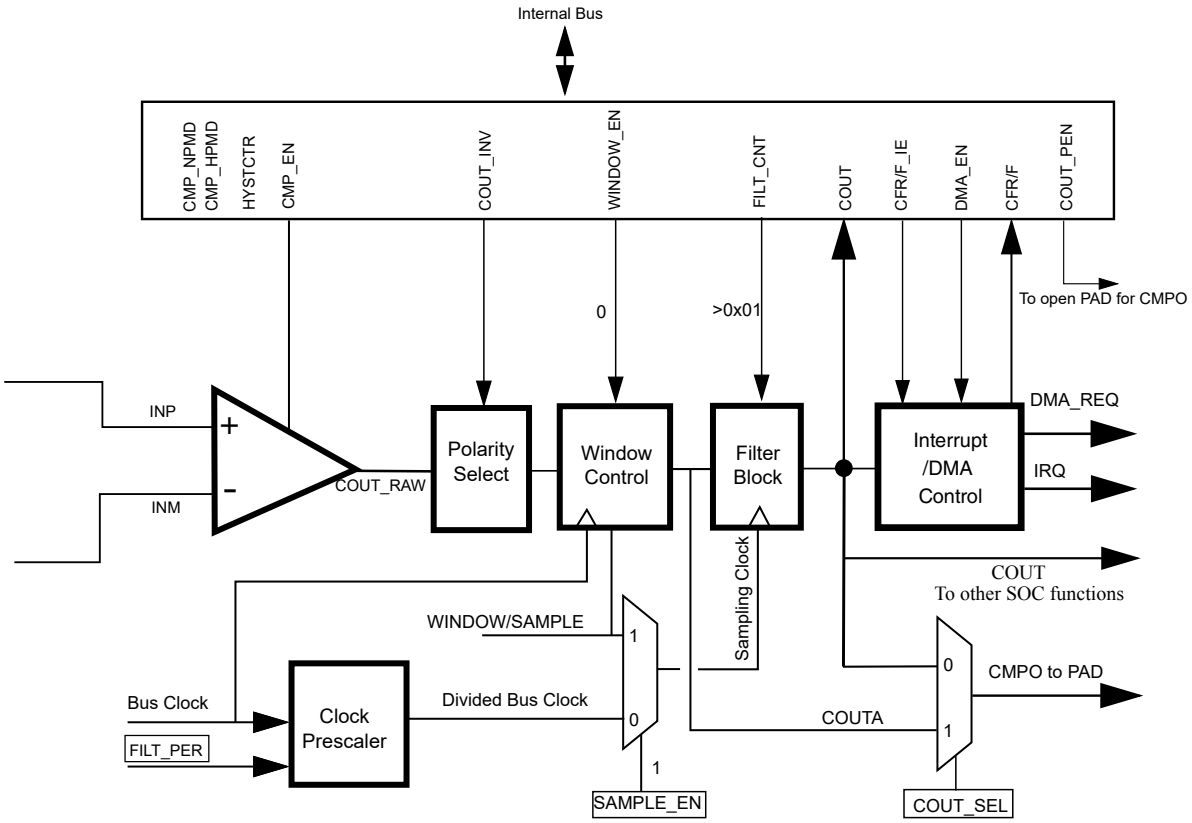

Figure 240. Sampled, filtered (#4A): sampling point externally driven

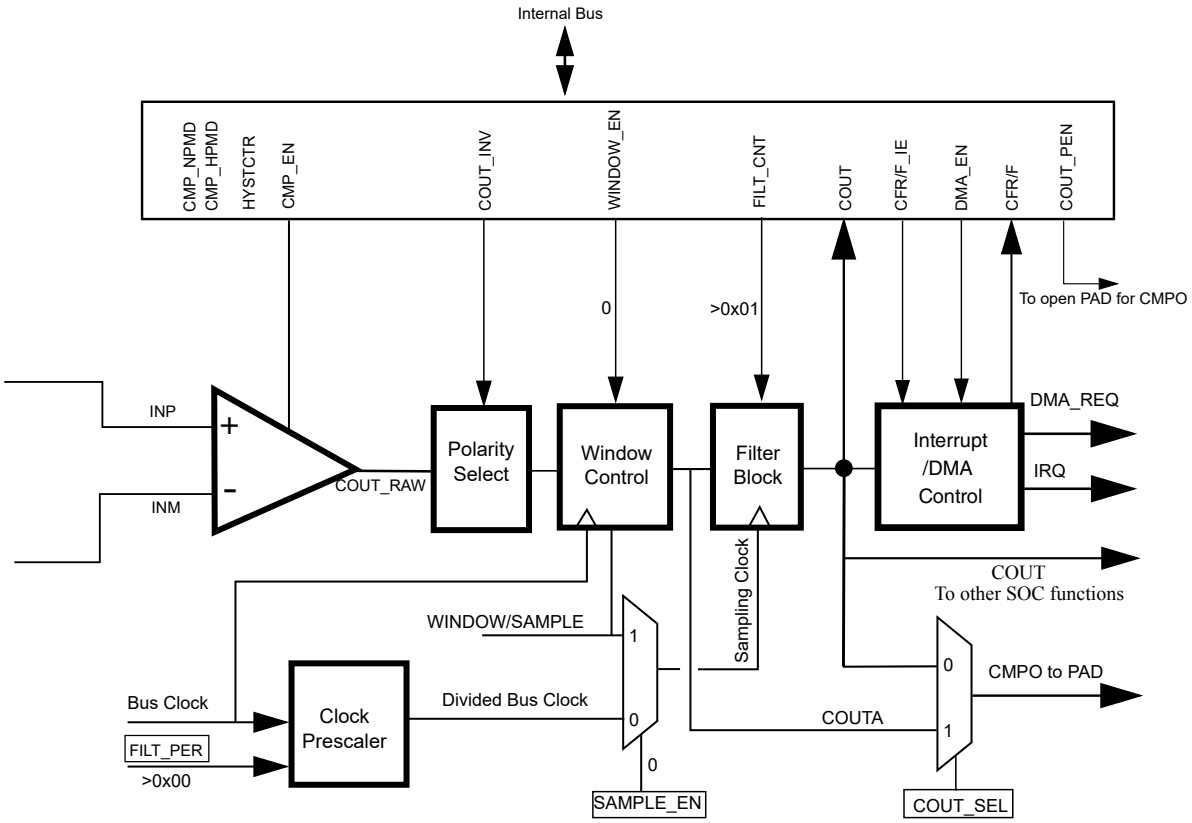

**Figure 241. Sampled, filtered (#4B): sampling point internally derived**

In this mode, the path from the analog inputs to COUTA is combinational(unclocked). Windowing control bypasses completely. You can sample COUTA whenever you detect a rising edge on the sampling clock.

The only difference in operation between sampled, non-filtered (#3A) mode and sampled, filtered (#4A) mode is that CCR1[FILT_CNT] is larger than 1, which activates filter operation.

The only difference in operation between sampled, non-filtered (#3B) mode and sampled, filtered (#4B) mode is that CCR1[FILT_CNT] is larger than 1, which activates filter operation.

### 58.3.5.5 Windowed mode (#5A and #5B)

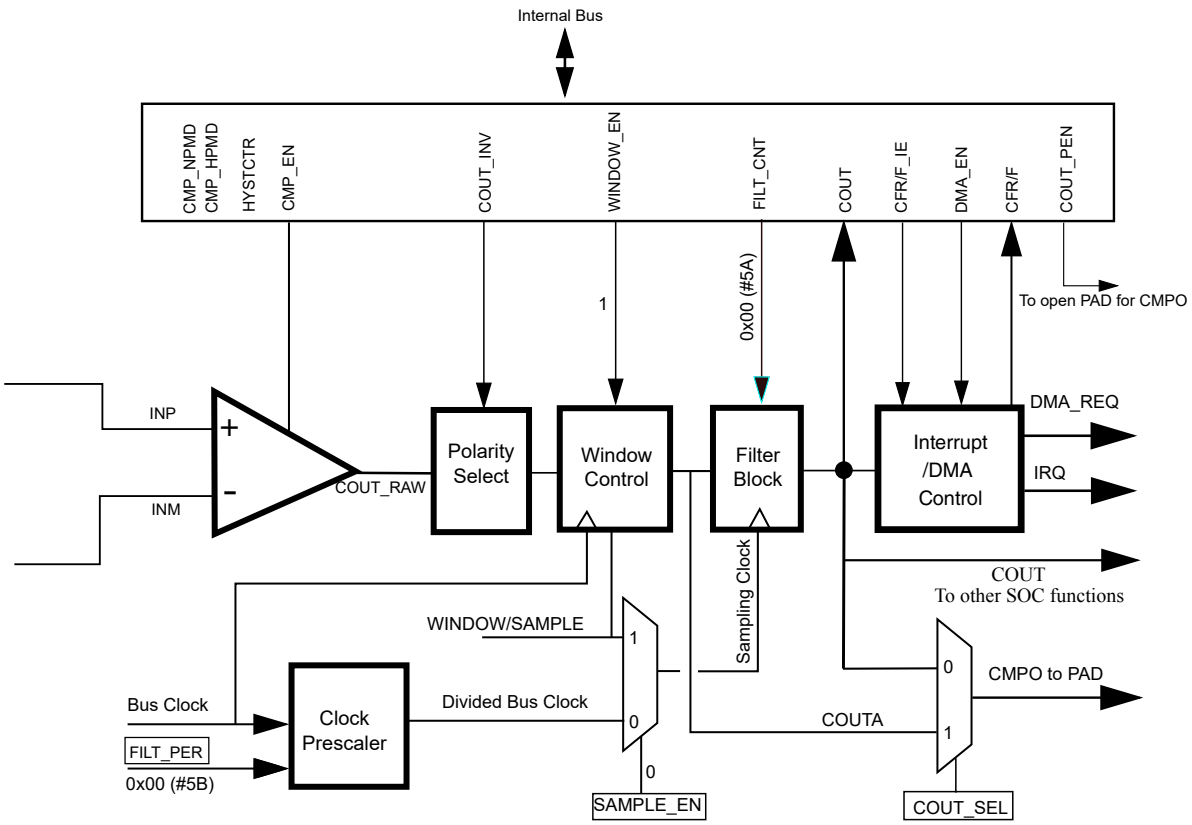

Figure 242. Windowed mode

The bus clock clocks COUTA whenever you enable the window in this mode. The last latched value holds after you disable the window and the filter block is bypassed.

The following figure shows the comparator operation in this mode, ignoring the latency of the analog comparator, polarity select, and window control block. The polarity select sets to a non-inverting state.

COUTA may lag the analog inputs by up to two functional clock cycles plus the combinational path delay through the comparator and polarity select logic in the actual operation.

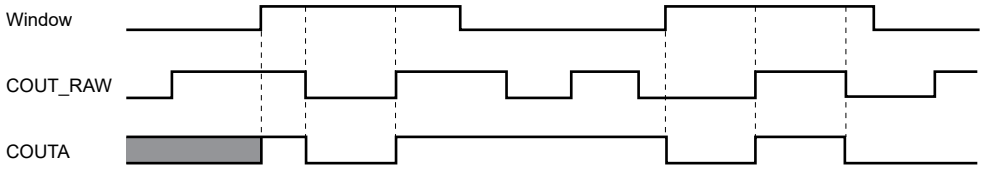

Figure 243. Windowed mode timing diagram

The following figure shows that if CCR1[COUTA_OWEN] becomes 1, you can define COUTA level as CCR1[COUTA_OW], after you closes the window.

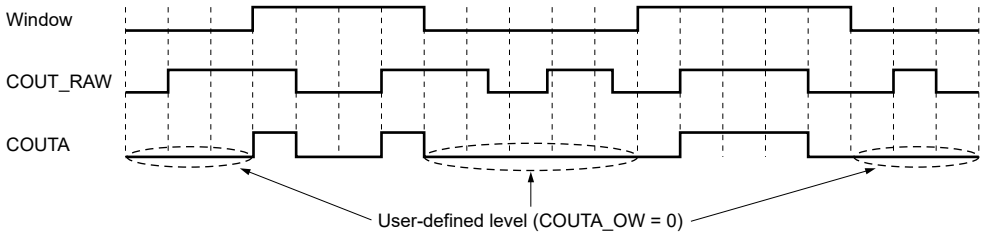

**Figure 244. Windowed mode timing diagram with user defined value 0 outside window**

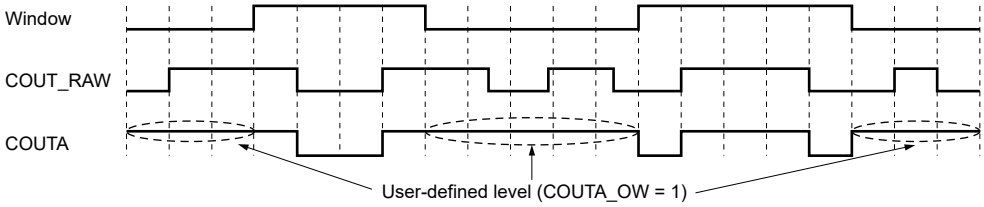

**Figure 245. Windowed mode timing diagram with user defined value 1 outside window**

**NOTE**

When the window is open, COUT_A will switch from COUTA_OW to COUT_RAW. When the window is closed, COUT_A will switch from COUT_RAW to COUTA_OW. This may generate unnecessary transition flags, for instance, CFR or CFF. User needs to choose COUTA_OW carefully according to the actual application, and select the appropriate flag CFR or CFF to generate interrupt.

If CCR1[WINDOW_CLS] becomes 1, you can define the CMPO event (rising edge, falling edge or both edges that CCR1[EVT_SEL] selects) to close the window. The external window signal has to go to zero and back to one to enable the internal window again. The following figure shows an example that CMPO rising edge closes the internal window.

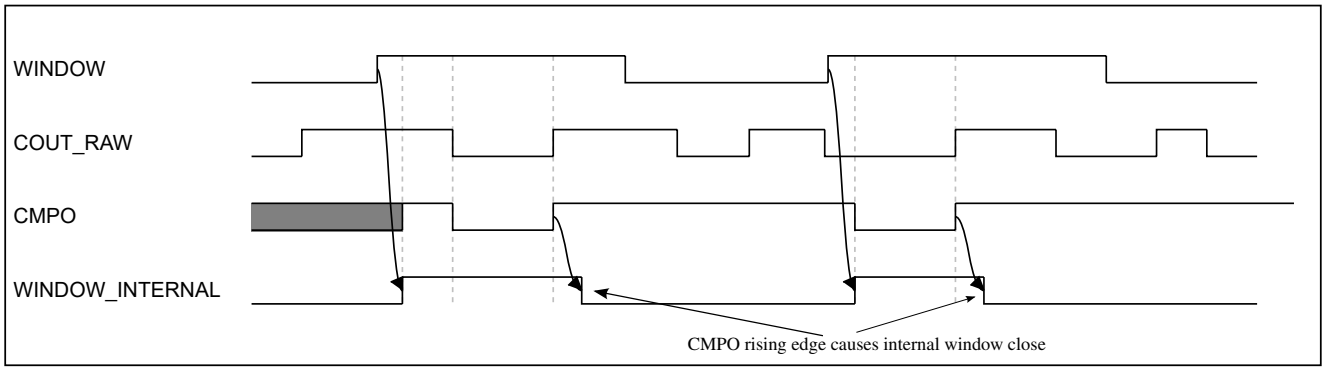

**Figure 246. Windowed mode timing diagram with CMPO rising edge close window**

The following figure shows that if CCR1[WINDOW_INV] becomes 1, you can invert the window signal before you use it.

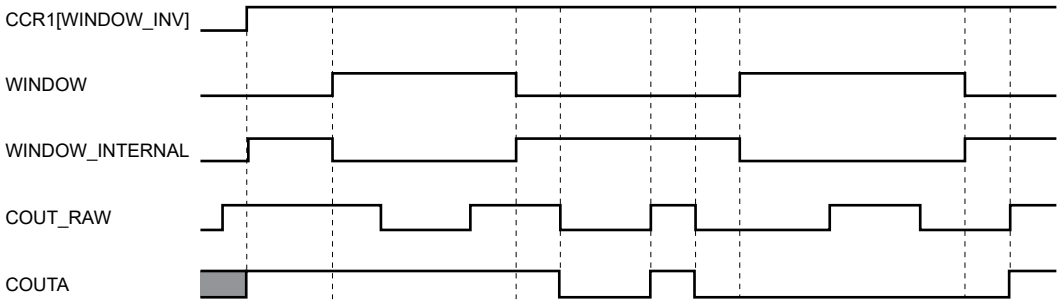

Figure 247. Windowed mode timing diagram with window signal inverted

### 58.3.5.6 Windowed/Resampled mode (#6)

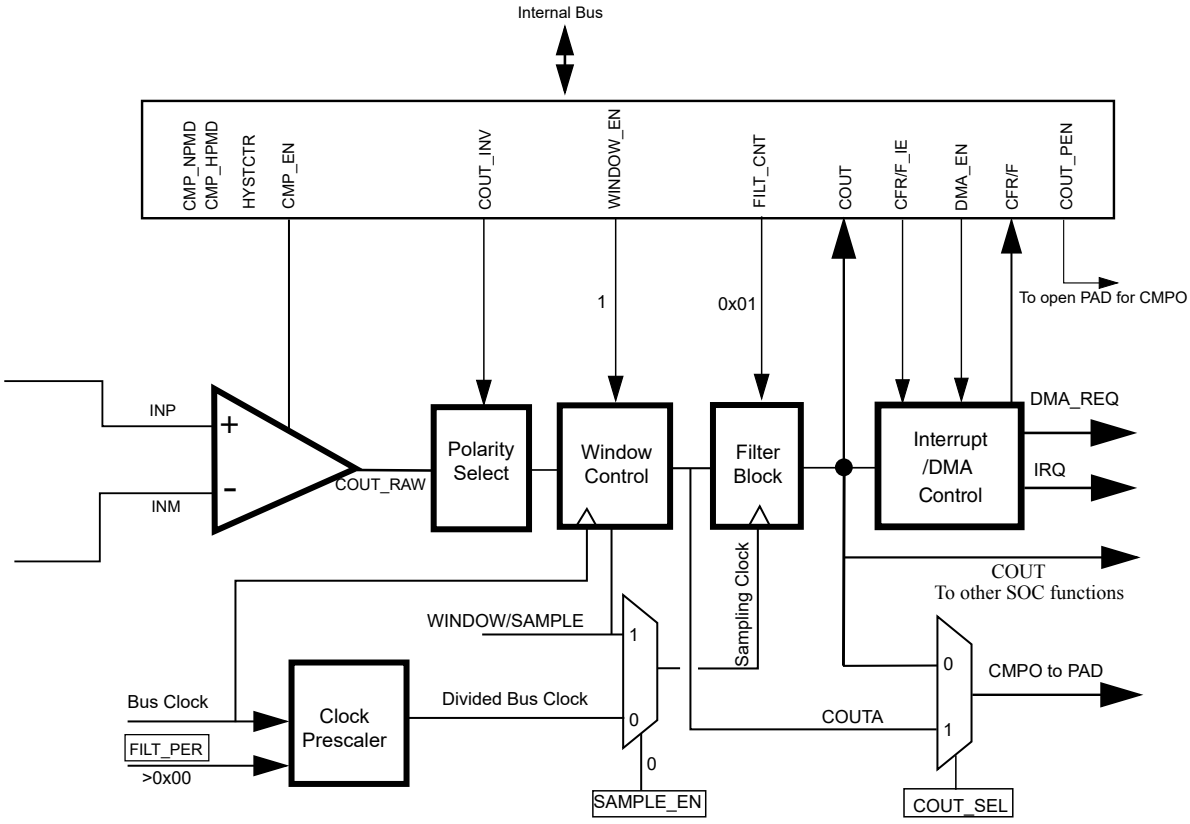

Figure 248. Windowed/Resampled mode

This mode of operation results in an unfiltered string of comparator samples where CCR1[FILT_PER] and the bus clock rate determines the interval between the samples. The following section shows that the configuration for this mode is virtually identical to that for the Windowed/Filtered mode. The only difference is that the value of CCR1[FILT_CNT] must be 1 in this mode.

The following figure uses the same input stimulus shown in Figure 243, and adds resampling of COUTA to generate COUT. The arrows in the figure indicate the time points at which the samples are taken. You can ignore prop delays and latency for clarity.

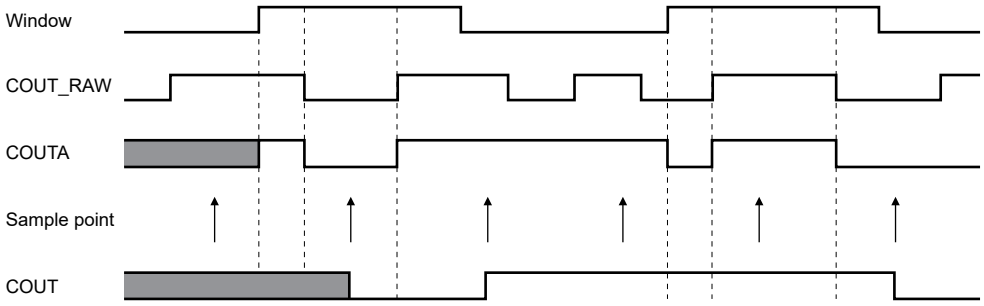

Figure 249. Windowed/Resampled mode operation

This example demonstrates the operation of the comparator in Windowed/Resampled mode, and does not reflect any specific application. Based on the sampling rate and window placement, COUT may not see zero-crossing events that the analog comparator detects. You must carefully consider the sampling period and/or window placement for a given application.

### 58.3.5.7 Windowed/Filtered mode (#7)

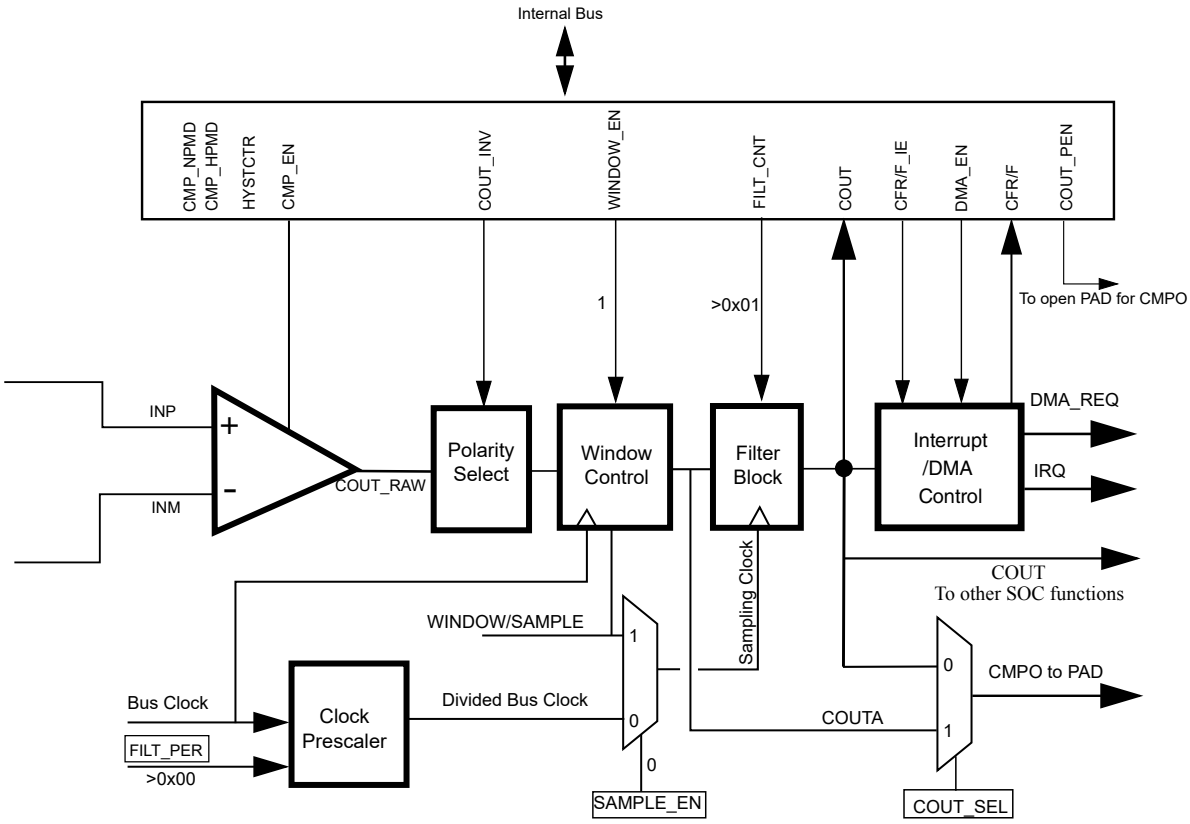

Figure 250. Windowed/Filtered mode

The only difference in operation between Windowed/Resampled mode (#6) and Windowed/Filtered mode (#7) is that CCR1[FILT_CNT] is >1, which activates filter operation.

This mode is the most complex mode of operation for the comparator block, as it utilizes both windowing and filtering features. It also has the highest latency of any of the modes. This is approximately: up to 2 peripheral clock synchronization in the window function + ((CCR1[FILT_CNT] x CCR1[FILT_PER]) + 1) x peripheral clock for the filter function.

### 58.3.6 DMA

After DMA is enabled by writing 1 to CCR1[DMA_EN] and interrupt is enabled by writing 1 to IER[CFR_IE], IER[CFF_IE], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt. After the DMA completes the transfer, it sends a transfer completing indicator signal that deasserts the DMA transfer request and clears the flags (both CSR[CFR] and CSR[CFF]) to allow a subsequent change on comparator output to occur and forces another DMA request.

### 58.3.7 Clocking

LPCMP requires the following clocks to operate:

**Table 279. LPCMP clocks**

| Type of clock | Description |
|---|---|
| Bus | Controls the access to LPCMP registers and window/ filter function. |
| Round-robin clock (RCLK) | Controls Round-robin trigger mode. |

### 58.3.8 Resets

The global chip reset signal resets LPCMP.

### 58.3.9 Interrupts

After the corresponding IER becomes 1, CSR[CFR], CSR[CFF], and CSR[RRF] can generate an interrupt, assuming that CCR1[DMA_EN] is not 1. You can clear either the flag or IER to deassert the interrupt.

## 58.4 External signal descriptions

Below table introduces external signals.

**Table 280. External signal descriptions**

| Signal | Description | I/O |
|---|---|---|
| CMPO | Filtered or unfiltered comparator output | O |
| Input_Analog_Channels | Analog input channels (see the chip-specific information for more on the connections). | I |
| VREFH_EXT | External reference voltage for the CMP-DAC (see the chip-specific information for more on the connections). | I |
| RR_ACTIVE | Round-robin trigger mode enabled. | O |

## 58.5 Initialization

You can enable LPCMP by writing 1 to CCR0[CMP_EN], and then configuring the control registers (CCR1, CCR2, DCR, and so on).

To disable LPCMP, write 0 to CCR0[CMP_EN]. Switching operation modes or changing control register fields on-the-fly (when CCR0[CMP_EN] is set to 1) may cause noise on the COUT or COUTA signals. To avoid unwanted signal noise, you must ensure to disable the module before switching modes or changing control fields.

The time required to stabilize COUT is the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function, and filter (see the Comparator and 8-bit DAC electrical specifications section of LPCMP datasheet for more information on propagation delay and power-up delay). Table 278 specifies the delay that the windowing and filter function causes.

During operation, you must always consider the propagation delay of the selected data paths. It can take many bus clock cycles for COUT and CSR[CFR]/CSR[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.

## 58.6 Application information

### 58.6.1 Round-robin trigger mode programing recommendation

Configure the Round-robin trigger mode as follows:

1. Configure the comparison cycles by RRCR0[RR_NSAM]. Note: It is a mandatory request that the round robin cycling period must set longer than the time that all the active channels complete the specified comparison cycles set by RRCR0[RR_NSAM].
2. Configure CMP initialization delay by RRCR0[RR_INITMOD]. Note: In programming RRCR0[RR_INITMOD], the RR_INITMOD x round robin clock period must be longer than the initialization delay, see the LPCMP datasheet for more information.
3. Configure RRCR1[FIXP] to select the fixed port of CMP and
    a. If you use one input channel to compare with other channels, configure RRCR1[FIXCH] to select the fixed channel.
    b. If you use DAC output to compare with input channels, configure CCR2[INPSEL] or CCR2[INMSEL] (according to RRCR1[FIXP] ) to select the DAC output.
4. Configure channels for comparison by RRCR1[RR_CHnEN].
5. Write RRCSR[RR_CHnOUT] to define the pre-set state of channel n.
6. Clear channel flags RRSR[RR_CHnF].
7. Enable round robin interrupt by IER[RRF_IE] (disable IER[CFR_IE] and IER[CFF_IE]).
8. Enable round-robin trigger mode by setting RRCR0[RR_EN] to 1.
9. Enable comparator by setting CCR0[CMP_EN] to 1.

### 58.6.2 Round-robin clock (RCLK) frequency requirement

(1) RCLK high frequency limit

RCLK high frequency limit depends on two facts:

1. The analog CMP and DAC initialization time (see the chip data sheet for more information on the initialization time.)
    - RRCR0[RR_INITMOD] provides a maximum 63 RCLK cycles for the analog CMP and DAC initialization.
    - RCLK must be slow to assure: 63 * ($1/f_{RCLK}$) > $T_{initialization}$, where $f_{RCLK}$ is in MHz, and $T_{initialization}$ is in microsecond.
    - so $f_{RCLK} < 63 / T_{initialization}$
    - Example: $T_{initialization}$ = 40 µs, then $f_{RCLK}$ should be smaller than 1.575 MHz.
2. The analog CMP propagation delay (see the Comparator and 8-bit DAC electrical specifications section of LPCMP datasheet for more information on the CMP propagation delay.)
    - RRCR0[RR_NSAM] provides a maximum 4 RCLK cycles for the analog CMP propagation delay.
    - RCLK must be slow to assure: 4 * ($1/f_{RCLK}$) > $T_{propagation}$, where $f_{RCLK}$ is in MHz, and $T_{propagation}$ is in microsecond.
    - $f_{RCLK} < 4 / T_{propagation}$
    - Example: $T_{propagation}$ = 0.1 µs, then $f_{RCLK}$ must be smaller than 40 MHz.

(2) RCLK low frequency limit

In theory, RCLK frequency has no low limit. But the lower the RCLK frequency, the longer the scan time. Therefore, the lower limit of the RCLK frequency depends on the system application.

## 58.7 LPCMP register descriptions

The memory map comprises of 32-bit aligned registers, which you can access via 8-, 16- or 32-bit reads and 32-bit write. Attempted accesses using unsupported write data sizes, writes to read-only resources, or to reserved spaces terminate with an error. Read access to reserved address generates a transfer error and the read data bus shows all 0s.

### 58.7.1 LPCMP memory map

LPCMP_0 base address: 4037_0000h

LPCMP_1 base address: 4037_4000h

LPCMP_2 base address: 404E_8000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Version ID (VERID) | 32 | R | 0100_0001h |
| 4h | Parameter (PARAM) | 32 | R | 0000_0002h |
| 8h | Comparator Control Register 0 (CCR0) | 32 | RW | 0000_0002h |
| Ch | Comparator Control Register 1 (CCR1) | 32 | RW | 0000_0000h |
| 10h | Comparator Control Register 2 (CCR2) | 32 | RW | 0000_0000h |

### 58.7.2 Version ID (VERID)

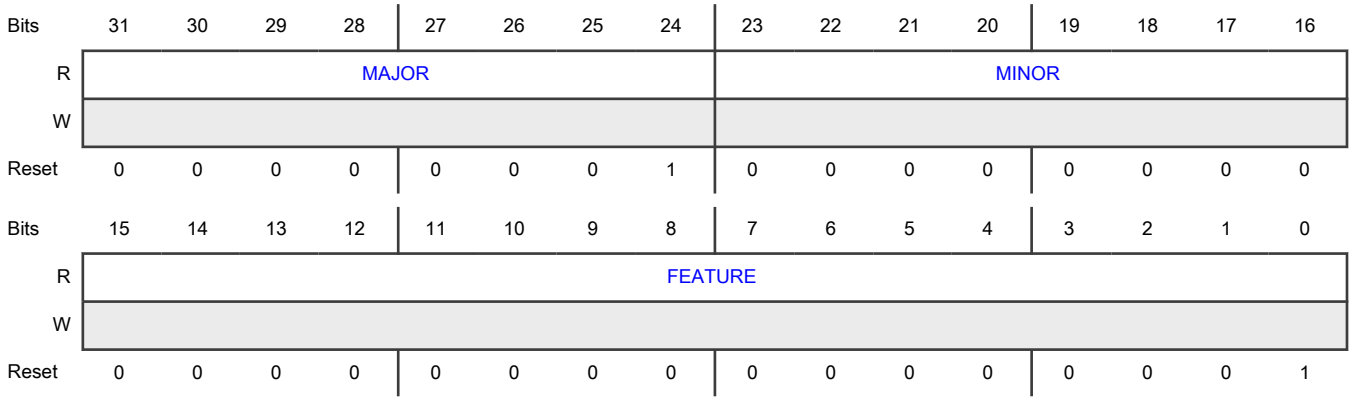
**Offset**

| Register | Offset |
|---|---|
| VERID | 0h |

**Function**

Contains version numbers for the module design and feature set.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-24<br>MAJOR | Major Version Number<br>Returns the major version number for the module design. |
| 23-16<br>MINOR | Minor Version Number<br>Returns the minor version number for the module design. |
| 15-0<br>FEATURE | Feature Specification Number<br>Returns the feature set number.<br>0000_0000_0000_0001b - Round robin feature |

## 58.7.3 Parameter (PARAM)

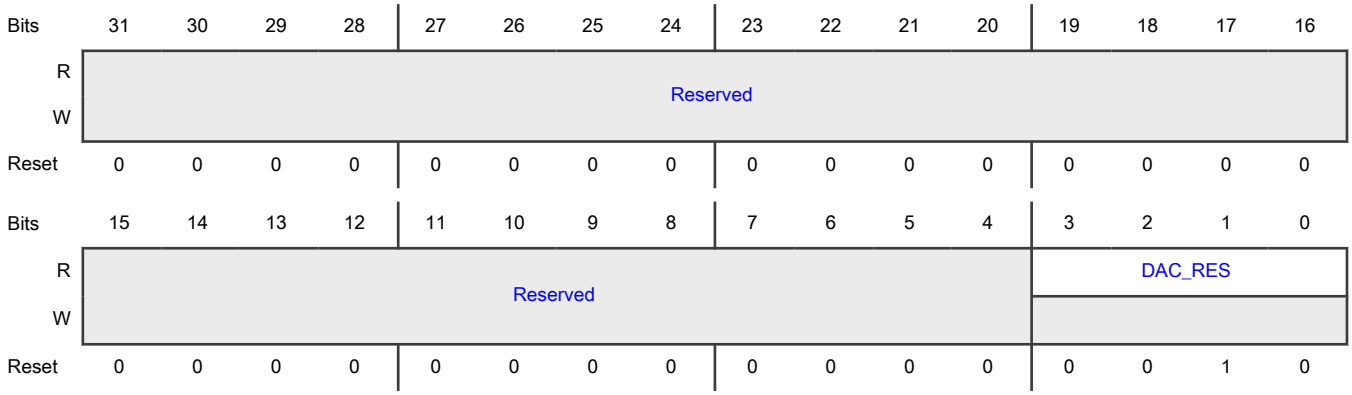
### Offset

| Register | Offset |
|---|---|
| PARAM | 4h |

### Function

Contains parameter values that are implemented in the module.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-4<br>— | Reserved |
| 3-0<br>DAC_RES | DAC Resolution<br>Indicates supported DAC resolutions.<br>**NOTE**<br>All other bit field values are reserved.<br>0000b - 4-bit DAC<br>0001b - 6-bit DAC<br>0010b - 8-bit DAC<br>0011b - 10-bit DAC<br>0100b - 12-bit DAC<br>0101b - 14-bit DAC<br>0110b - 16-bit DAC |

## 58.7.4 Comparator Control Register 0 (CCR0)

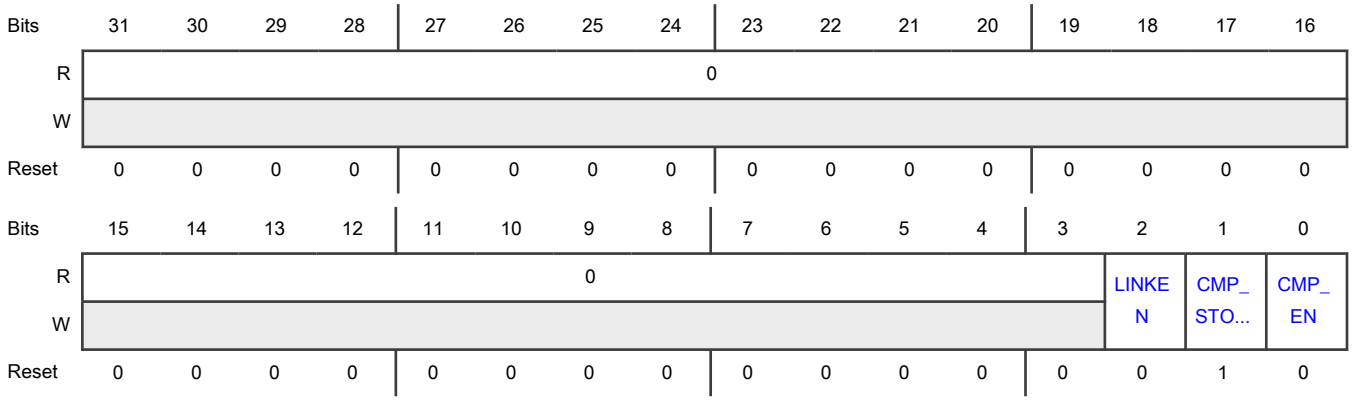
### Offset

| Register | Offset |
|---|---|
| CCR0 | 8h |

### Function

Contains configuration options for enabling the analog comparator and the DAC.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-3<br>— | Reserved |
| 2<br>LINKEN | CMP-to-DAC Link Enable<br>Enables the CMP-to-DAC link.<br>0b - Disable: enabling or disabling the DAC is independent from enabling or disabling the CMP.<br>1b - Enable: enabling/disabling DAC is controlled by the CMP_EN bit instead of DCR[DAC_EN]. Also, when the CMP is auto-disabled because software selects the same signal for both the plus and minus comparator inputs, the DAC is disabled too. |
| 1<br>CMP_STOP_EN | Comparator STANDBY Mode Enable<br>Enables the analog comparator or the DAC when the module is in STANDBY mode.<br>**NOTE**<br>This field has no effect in Round-robin Trigger mode.<br>0b - Disables the analog comparator regardless of CMP_EN.<br>1b - Allows CMP_EN to enable the analog comparator. |
| 0<br>CMP_EN | Comparator Enable<br>Enables the analog comparator.<br>**NOTE**<br>When CCR0[LINKEN]=1, CMP_EN also controls the enabling/disabling of the DAC instead of DCR[DAC_EN].<br>0b - Disable (The analog logic remains off and consumes no power.)<br>1b - Enable |

## 58.7.5 Comparator Control Register 1 (CCR1)

### Offset

| Register | Offset |
|---|---|
| CCR1 | Ch |

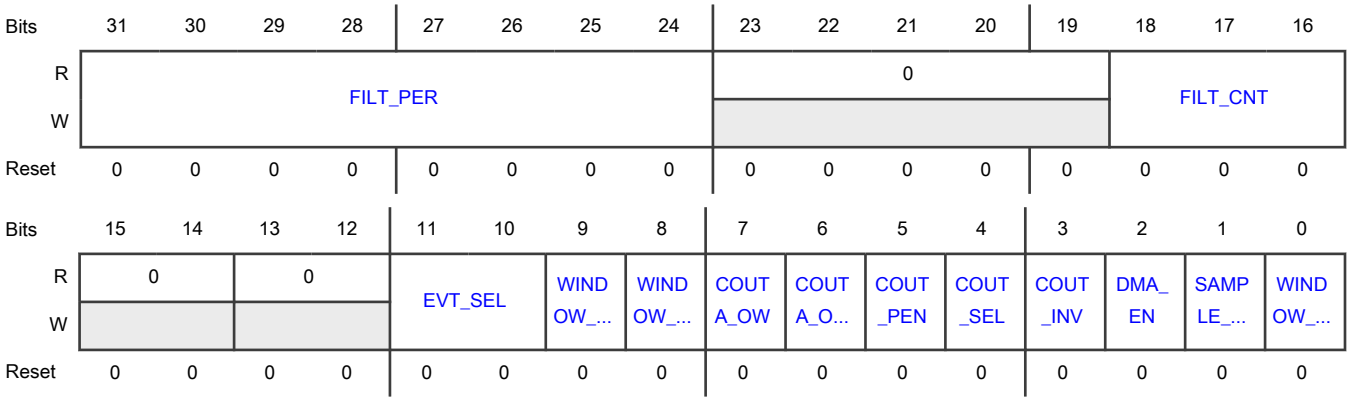
### Function

Contains configuration options for the comparator operation, such as enabling Sampling or Windowing mode.

**NOTE**

You cannot enable Sampling and Windowing modes both at the same time. Sampling mode takes precedence over Windowing mode. If you write 1 to both SAMPLE_EN and WINDOW_EN, only SAMPLE_EN becomes 1.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-24<br>FILT_PER | Filter Sample Period<br>Specifies the sampling period (in bus clock cycles) of the comparator output filter. Programming this field to 00h bypasses the filter. See Functional description for more information on filter programming and latency.<br>**NOTE**<br>FILT_PER has no effect in Sampling mode (CCR1[SAMPLE_EN] = 1). |
| 23-19<br>— | Reserved |
| 18-16<br>FILT_CNT | Filter Sample Count<br>Specifies the number of consecutive samples that must agree before the comparator output filter accepts the sample as a new valid output state. See Functional description for more information on filter programming and latency. |

## 58.7.9 Comparator Status (CSR)

### Offset

| Register | Offset |
|---|---|
| CSR | 20h |

### Function

Indicates comparator status, including COUT, CFF, CFR, and RRF.

**NOTE**

LPCMP may output a glitch and affect the value of CSR[CFF] and CSR[CFR] at the moment of enabling CMP. In order to ensure correctness, it is recommended to write one to clear (W1C) CSR[CFF] and CSR[CFR] before further configuring CMP.

# Chapter 59
# Logic Control Unit (LCU)

## 59.1 Chip-specific LCU information

### 59.1.1 LCU instances

This chip has two identical LCU instances, LCU_0 and LCU_1.

## 59.2 Overview

LCU selects multiple inputs from timers, Pulse Width Modulation (PWM) signals, and Input/Output (I/O) pads, and combines them using a programmable logic function to create output waveforms.

### 59.2.1 Block diagram

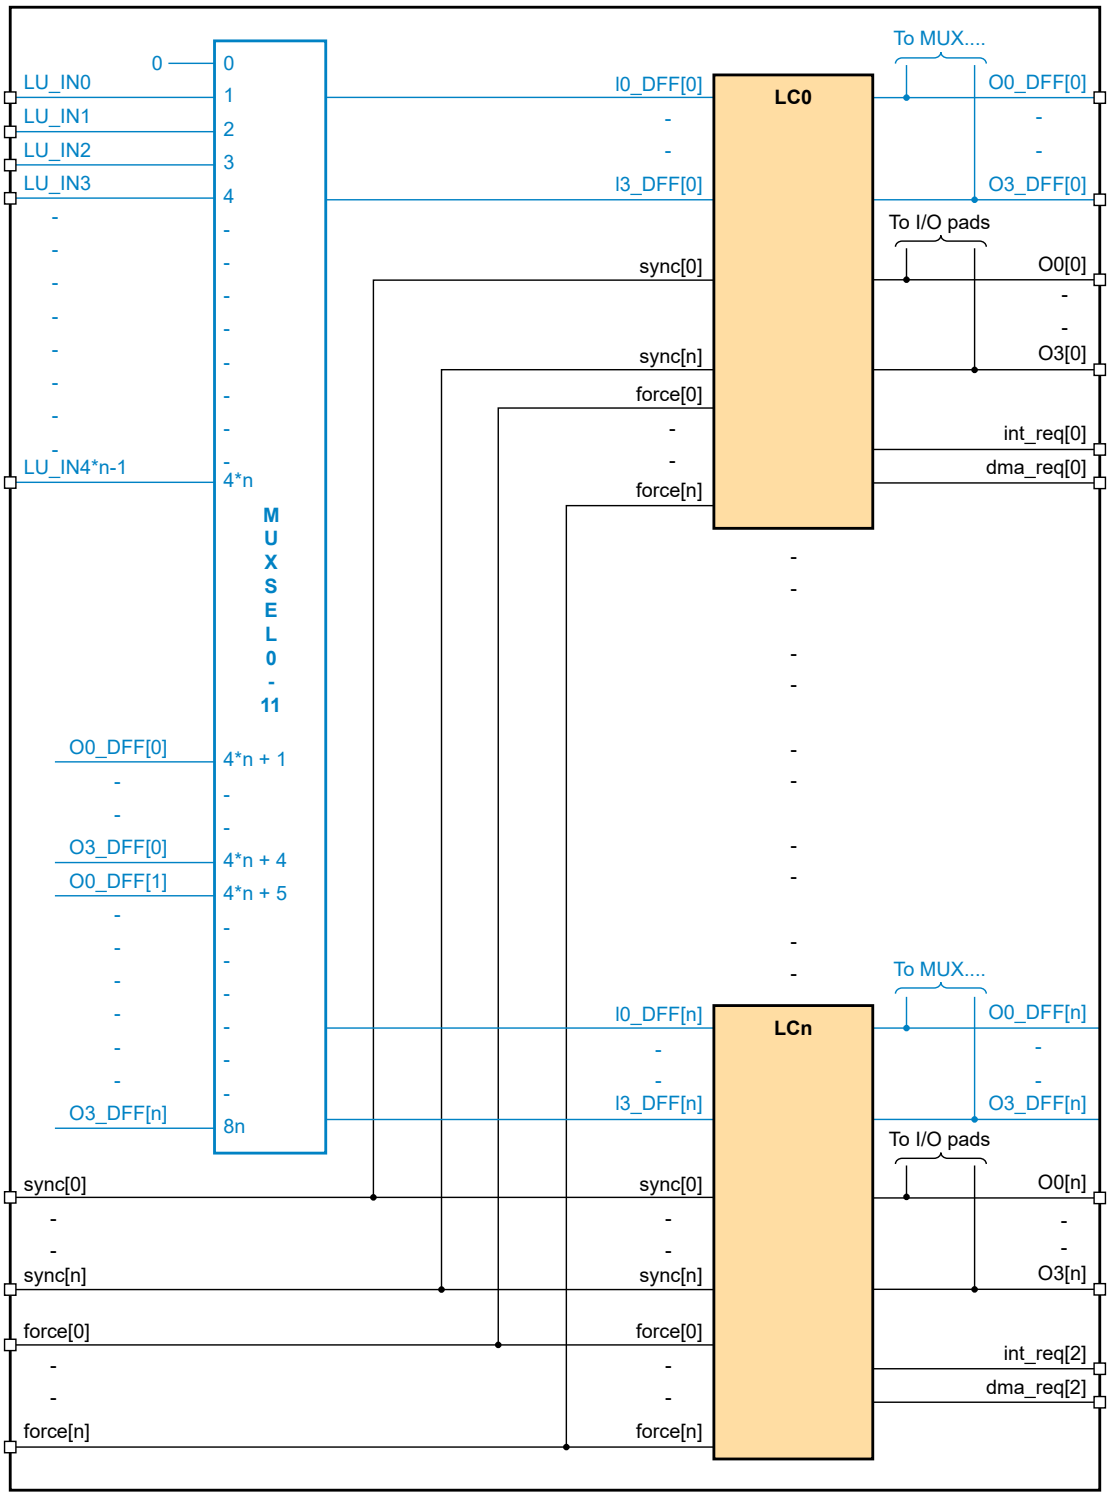

Figure 251. Block diagram

### 59.2.2 Features

- 3 LCs with programmable logic function for generating output results

- 12 inputs to and 12 outputs from LCs
- Muxing to map any input to any LC
- Independent filters for the rising and falling output states of each LC
- Software override logic for inputs using multiple modes
- 3 force inputs with programmable edge filtering to force output states using multiple modes
- 2 sync inputs to control transition timing
- Lock bit to block writes to CFG[WP]
- Interrupt request generation based on output change or force event
- DMA transfer request generation based on output change or force event

## 59.3 Functional description

### 59.3.1 LC operation

#### 59.3.1.1 Overview

An LC performs logic operations based on the lookup table principle, as described in Logic operations.

Each LC supports the following features:

- Independent filter thresholds for the rising and falling output states support different transition delays.
- Bypass of the output state filter by setting the filter threshold to zero. Bypassing the filter causes the asynchronous signal to propagate to the output of the LC.
- Force logic that instantly switches an LC output to the inactive state upon external fault signal assertion. The return from the inactive state to the output state is either:
  - Instantaneous: when LCU deasserts the force signal.
  - Instantaneous synchronized: when LCU deasserts the force signal and then the sync input asserts.
  - Manual: when you write 1 to the force status bit and then the LCU deasserts the force input.
  - Manual synchronized: when you write 1 to the force status bit and LCU deasserts the force input, and then the sync input asserts.
- Input software override logic to override external inputs by writing to the following registers:
  - LC*n* Sync Control (LC*n*_SCTRL[SW_MODE])
  - Software Override Value (SWVALUE[SWVALUE])
  - Software Override Enable (SWEN[SWEN])
- Generation of interrupt requests or DMA transfer requests.

#### 59.3.1.2 LC diagram

This figure illustrates an example LC implementation with:

- One LC
- Four force inputs
- Two sync inputs

For the number of each resource in this chip, see Features.

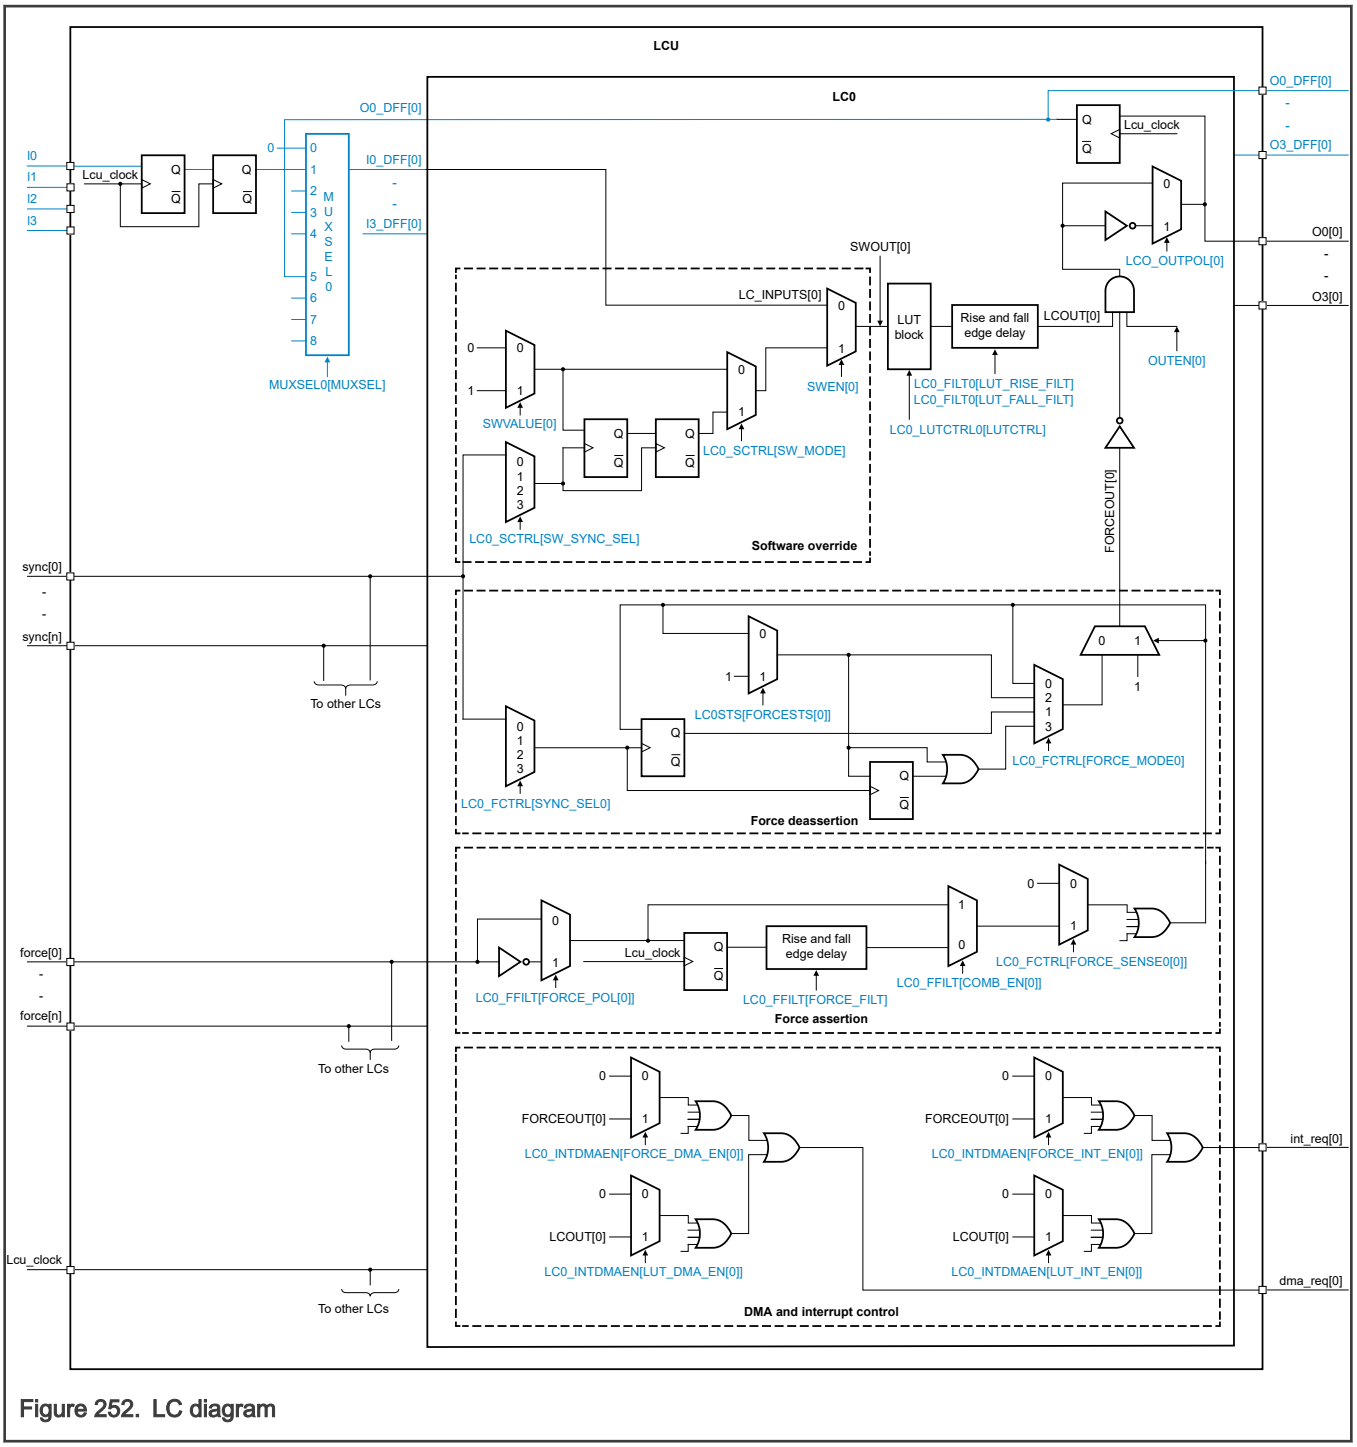

Figure 252. LC diagram

### 59.3.1.3 Logic operations

An LC reads its set of inputs (inputs 3, 2, 1, and 0) as a four-bit binary value, with Input 3 as the most-significant bit and Input 0 as the least-significant bit. For example, if:

Input 0 = 0

Input 1 = 1

Input 2 = 0

Input 3 = 1

then the combined input value is 1010b (10 decimal).

Each possible four-bit input value corresponds to a bit position in the LUT Control (LCn_LUTCTRLm[LUTCTRL]), as illustrated in LC LUT. For a given LC output, if the combined LC input value corresponds to a bit position in that output's LUTCTRL value that equals 1, then the LC asserts that output.

For example, if you write 35h to LUTCTRL (shown in the Example column of the LC LUT), then the combined input values 0 (0000b), 2 (0010b), 4 (0100b), and 5 (0101b) cause assertion of the output. All other input values cause deassertion of the output.

LCU processes each look-up table asynchronously.

#### 59.3.1.4 LC LUT

The LUT maps the combined LC input value to a bit position in LC*n*_LUTCTRL*m*.

**Table 281. LC LUT**

| Input 3 | Input 2 | Input 1 | Input 0 | LUTCTRL bit position | Example LUTCTRL value: 35h |
|---|---|---|---|---|---|
| 0 | 0 | 0 | 0 | 0 | 1 |
| 0 | 0 | 0 | 1 | 1 | 0 |
| 0 | 0 | 1 | 0 | 2 | 1 |
| 0 | 0 | 1 | 1 | 3 | 0 |
| 0 | 1 | 0 | 0 | 4 | 1 |
| 0 | 1 | 0 | 1 | 5 | 1 |
| 0 | 1 | 1 | 0 | 6 | 0 |
| 0 | 1 | 1 | 1 | 7 | 0 |
| 1 | 0 | 0 | 0 | 8 | 0 |
| 1 | 0 | 0 | 1 | 9 | 0 |
| 1 | 0 | 1 | 0 | 10 | 0 |
| 1 | 0 | 1 | 1 | 11 | 0 |
| 1 | 1 | 0 | 0 | 12 | 0 |
| 1 | 1 | 0 | 1 | 13 | 0 |
| 1 | 1 | 1 | 0 | 14 | 0 |
| 1 | 1 | 1 | 1 | 15 | 0 |

#### 59.3.1.5 LC output filters

Each LC supports two optional digital filters, a Rise Filter (LC*n*_FLIT*m*[LUT_RISE_FILT]) and a Fall Filter (LC*n*_FLIT*m*[LUT_FALL_FILT]), to post-process the LUT output and delay the output signal change.

Each filter starts accumulating clock cycles on the occurrence of the associated LUT event. The Rise Filter counts from an output assertion, and the Fall Filter counts from an output deassertion. When the number of clock cycles reaches the filter threshold (matches the specified filter value), the output flips to the new state. For example, if you specify a Rise Filter value of 100h, and the LUT event triggers an output assertion, the output signal does not assert until the 256th clock cycle after the event.

A filter value of 0 bypasses the filter.

**NOTE**

LCU usecase (intercell/feedback loop path along with TRGMUX Path) does not work with default RISE/FALL filter time. You must configure RISE/FALL Filter delay at least for 1 cycle to avoid such glitches/failures.

### 59.3.2 Behavior in different chip modes of operation

Table 282. Modes of operation

| Operation mode | Status of outputs |
|---|---|
| Normal | • Controlled by LC*n*_LUTCTRL*m* and MUXSEL*n*<br>• Toggled based on the states of the selected inputs |
| Debug | Inactive or normal operation controlled by Debug Mode Enable (DBGEN) |

### 59.3.3 Clocking

This module has no clocking considerations.

### 59.3.4 Interrupts

Each LC has a single interrupt request output int_req[n]. Interrupt request enables bits for all the 4 outputs in each LC defined in LC*n*_INTDMAEN with LC*n*_INTDMAEN[FORCE_INT_EN] for interrupt request generation when a force event occurs and LC*n*_INTDMAEN[LUT_INT_EN] for interrupt request generation when a LUT event occurs.

When user enables interrupt for a force event on an output and the force event occurs on that output, LCU generates an interrupt request if LC*n*_STS[FORCESTS] and LC*n*_INTDMAEN[FORCE_INT_EN] for that output is 1. Similarly when user enables interrupt for a LUT event on an output and a LUT event occurs on that output, LCU generates an interrupt request if LC*n*_STS[LUT_STS] and LC*n*_INTDMAEN[LUT_INT_EN] for that output is 1.

### 59.3.5 DMA

Each LC has a single DMA request output dma_req[n]. DMA request enables bits for all the 4 outputs in each LC defined in LC*n*_INTDMAEN with LC*n*_INTDMAEN[FORCE_DMA_EN] for DMA request generation when a force event occurs and LC*n*_INTDMAEN[LUT_DMA_EN] for DMA request generation when a LUT event occurs.

When user enables DMA for a force event on an output and the force event occurs on that output, LCU generates a DMA request if LC*n*_STS[FORCESTS] and LC*n*_INTDMAEN[FORCE_DMA_EN] for that output is 1. Similarly when user enables DMA for a LUT event on an output and a LUT event occurs on that output, LCU generates a DMA request if LC*n*_STS[LUT_STS] and LC*n*_INTDMAEN[LUT_DMA_EN] for that output is 1.

## 59.4 External signals

This module has no external signals.

## 59.5 Initialization

This module does not require initialization.

## 59.6 Application information

### 59.6.1 Use-case examples

#### 59.6.1.1 Two-channel multiplexer

#### 59.6.1.1.1 Overview

A multiplexer (or mux) takes multiple inputs and, based on some control mechanism, passes only one of those inputs to the output. You can implement a two-channel multiplexer controlled by an external signal or a software override using three inputs and one output of a single LC, as illustrated in Logic diagram and Implementation.

This example implementation controls the multiplexer with the SEL input signal and a software override. The software override controls the multiplexer output regardless of the SEL signal state. To use software override, you must enable it for the corresponding output (SWEN[SWEN]). You assert software override by writing 1 to the corresponding bit of the Software Override Value (SWVALUE[SWVALUE]).

#### 59.6.1.1.7 Waveforms

In this figure, the SWEN and SWVALUE signals represent the states of the software override control registers. Writes to SWEN and SWVALUE have immediate impact on LC outputs, whereas LC inputs require input synchronization to prevent metastability.

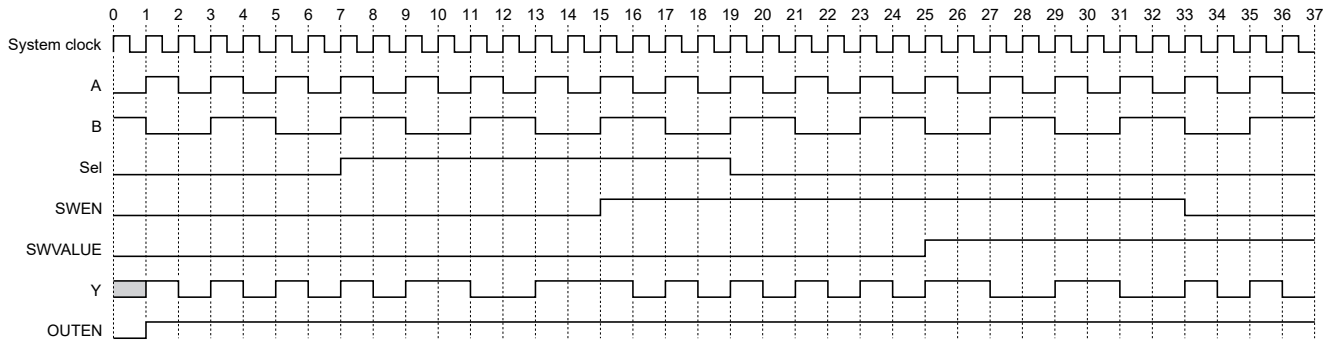

Figure 255. Waveforms

### 59.6.1.2 Binary to Gray code converter

#### 59.6.1.2.1 Overview

Gray code, also known as reflected binary code (RBC), is a non-weighted, minimum change code. In this code, any two adjacent code numbers differ by only one bit. This code solves the problem of physical switch transitions by changing only one switch at a time, so there is never any ambiguity of position.

You can implement binary to Gray code conversion using a single LC, as illustrated in Logic diagram and Implementation.

In this example, the LC also generates a DMA request on each rising edge of output 3, which is bit 0 of the Gray code (G0).

#### 59.6.1.2.2 Conversion table

Table 286. Conversion table

| Decimal | Binary | Gray |
|---|---|---|
| 0 | 0000 | 0000 |
| 1 | 0001 | 0001 |
| 2 | 0010 | 0011 |
| 3 | 0011 | 0010 |
| 4 | 0100 | 0110 |

#### 59.6.1.2.8 Waveforms

The LC outputs are delayed by two clock cycles because of the two-stage input synchronizers.

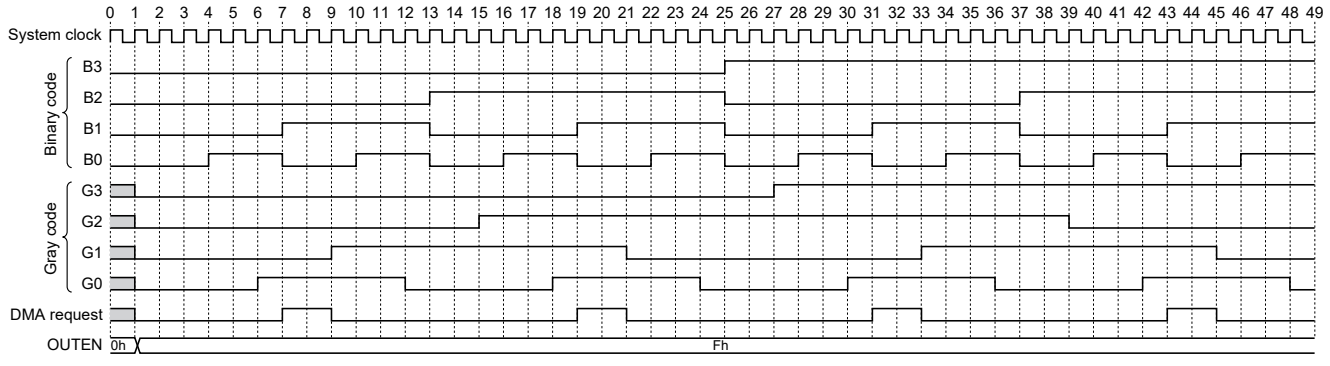

Figure 258. Waveforms

### 59.6.1.3 Manchester encoder and decoder

#### 59.6.1.3.1 Overview

Manchester encoding (also known as phase encoding) is a data-modulation technique for binary data transfer based one of these signals:

- Analog
- RF
- Optical
- High-speed-digital
- Long-distance-digital

The fundamental idea behind Manchester encoding is to use voltage transitions, instead of voltage levels, to represent 1s and 0s. It performs an exclusive OR of data and clock signals to encode and decode data. A high-to-low transition on the falling clock edge indicates 0. A low-to-high transition on the rising clock edge indicates 1.

#### 59.6.1.3.2 Logic diagram

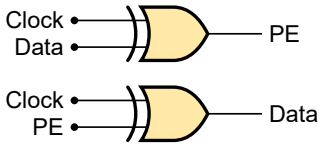

Figure 259. Logic diagram

#### 59.6.1.3.8 Waveforms for encoder

This figure includes the Manchester-encoded waveform (labeled PE) of the input waveform (labeled "Data in"). The PE waveform is delayed by two clock cycles because of two-stage input synchronization.

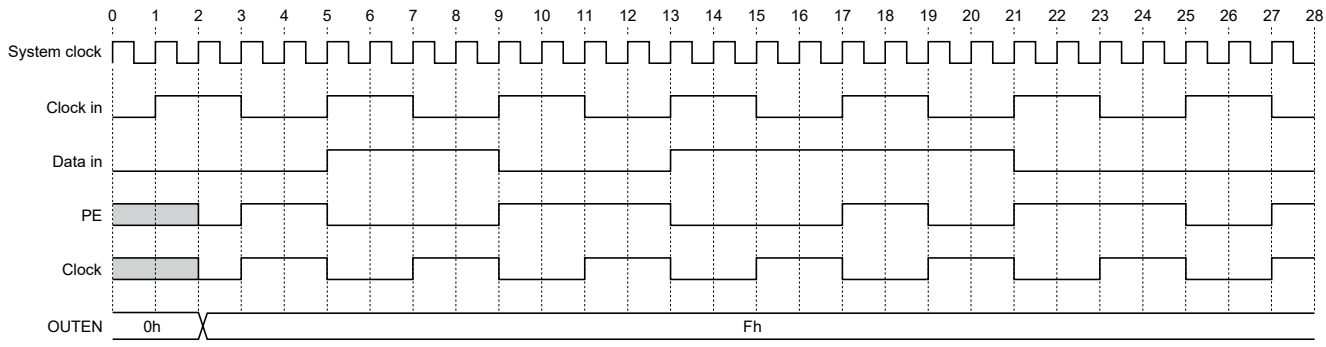

Figure 261. Waveforms for encoder

#### 59.6.1.3.9 Waveforms for decoder

The output waveform (labeled "Data out") is delayed by four clock cycles from the input waveform (labeled "Data in") because of two-stage input synchronization. In this example, the Manchester encoder also propagates the Clock waveform that the decoder uses to reconstruct the "Data in" waveform from the Manchester-decoded waveform (labeled PE).

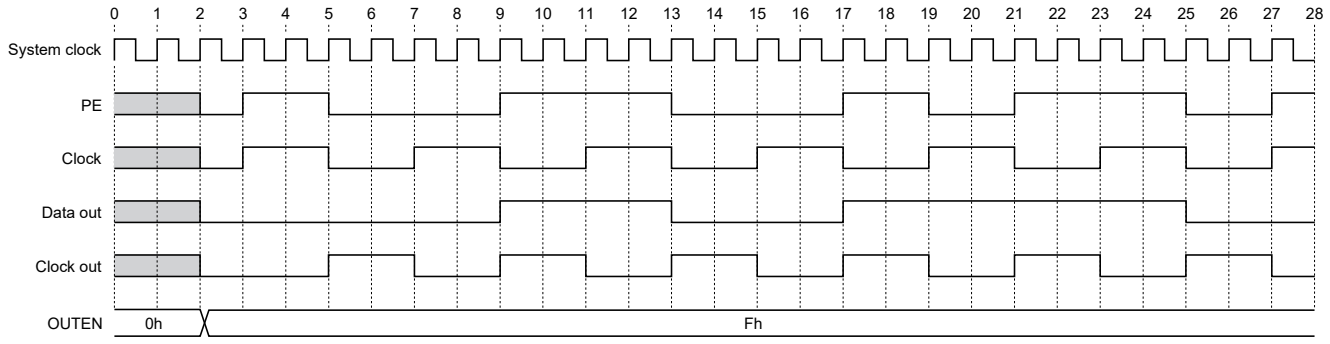

Figure 262. Waveforms for decoder

### 59.6.1.4 Adjustable PWM/FM generator

#### 59.6.1.4.1 Overview

In many cases, it is useful to route an LC output back to one of its inputs, as illustrated in Implementation. In addition, you can delay outputs with a digital filter with different time constants for delaying rising and falling edges. Combining these capabilities, you can use an LC to generate output waveforms with adjustable pulse width and frequency.

In addition to waveform generation, the software-override feature forces the generator output low or high by software. You control the override via Software Override Enable (SWEN) and Software Override Value (SWVALUE).

#### 59.6.1.4.2 Implementation

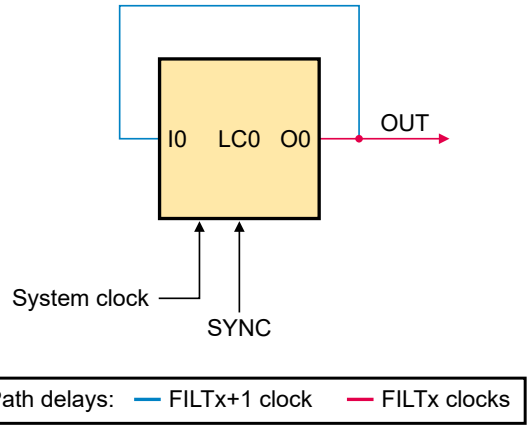

Figure 263. Implementation

#### 59.6.1.4.3 Connections and controls

Table 294. Connections and controls

| Name | Description |
|---|---|
| I0 | Delayed output routed back to LC input |
| O0 and OUT | Delayed output |
| System clock | Clock frequency supplied to LC |
| SYNC | Software override synchronization signal |

#### 59.6.1.4.4 Truth table

This example generates an adjustable PWM/FM waveform according to the following table. In the table:

- OUT is the LC output signal that is also routed to the LC input using an internal multiplexer.
- TdH is the digital filter value to delay the rising edge of the output signal.
- TdL is the digital filter value to delay the falling edge of the output signal.

**Table 295. Truth table**

| I0 | OUT |
|---|---|
| 0 | 1 delayed by TdH (see Output edge delays) |
| 1 | 0 delayed by TdL (see Output edge delays) |

#### 59.6.1.4.5 Output edge delays

#### 59.6.1.4.7 Waveforms for immediate software override

In this figure, the SWEN and SWVALUE signals represent the states of the software override control registers. Writes to Software Override Enable (SWEN) and Software Override Value (SWVALUE) have immediate impact on LC outputs, whereas LC inputs require input synchronization to prevent metastability.

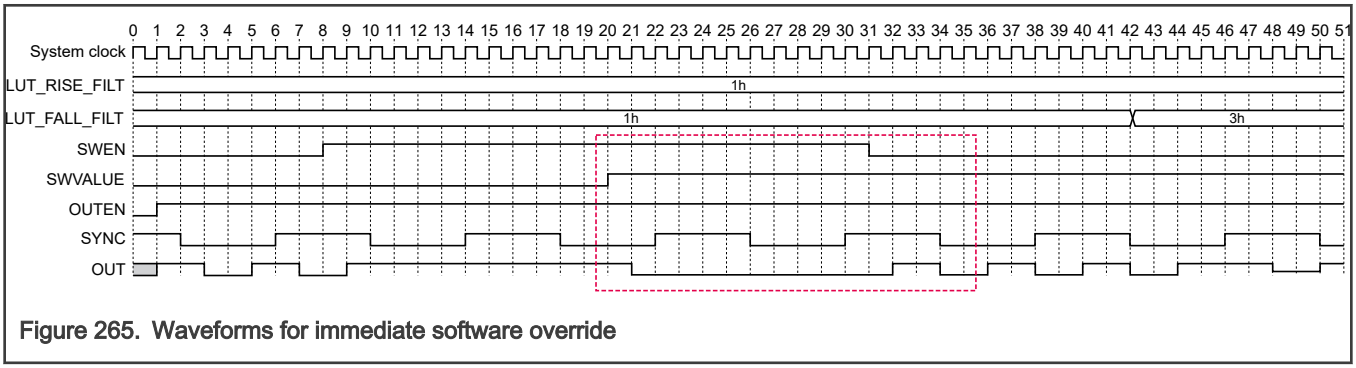

Figure 265. Waveforms for immediate software override

#### 59.6.1.4.8 Waveforms for synced software override

In this example, software override control is synced with the rising edges of the SYNC waveform.

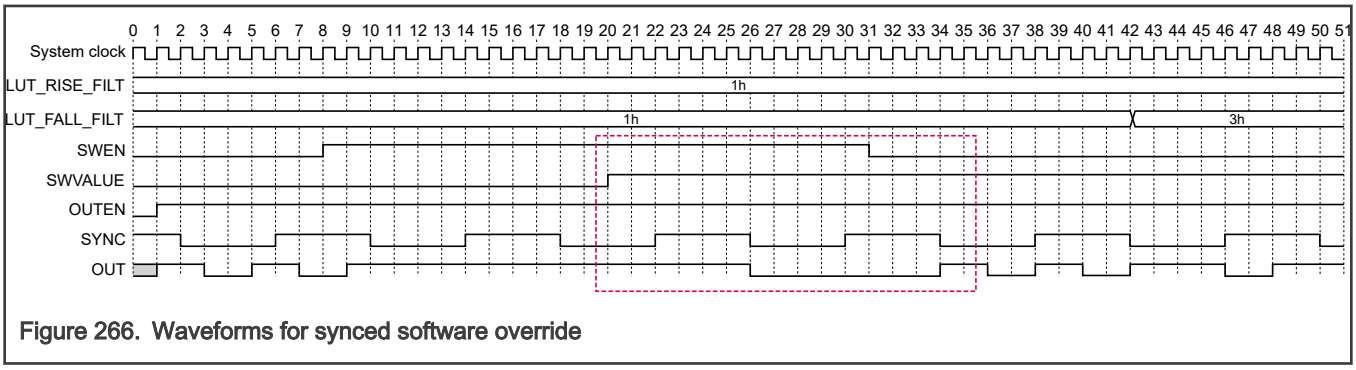

Figure 266. Waveforms for synced software override

### 59.6.1.5 SR latch

#### 59.6.1.5.1 Overview

An SR latch is the simplest bistable device and a fundamental component of data storage.

This example implementation uses one LC that includes an internal feedback path configured by the internal multiplexer, as illustrated in Implementation. Output Q responds to inputs S (set) and R (reset). It changes with a delay of two clock cycles—the time required for the S and R signal inputs to pass through the internal two-stage synchronizers. This example implementation bypasses the Q digital filter; therefore, the loop of Q back to the input experiences a delay of one clock cycle." See Waveforms.

#### 59.6.1.5.2 Implementation

### 59.6.1.6 D flip-flop

#### 59.6.1.6.1 Overview

A D flip-flop stores and outputs whatever logic level is applied to its data terminal at the time its clock input goes high.

You can implement a D flip-flop element using an LC as illustrated in Implementation. On a clock rising edge, the LC either asserts or deasserts the Q output based on the D input.

The Q output and CLKO digital filters are bypassed. Therefore, the states of these variables are fed to inputs with a delay of one clock cycle. See Waveforms.

#### 59.6.1.6.2 Implementation

### 59.6.1.7 JK flip-flop

#### 59.6.1.7.1 Overview

A JK flip-flop is a gated SR latch (see SR latch) with an added clock input circuit that prevents the illegal or invalid output condition that can occur when both SR-latch inputs (S and R) are asserted.

Truth table for JK flip-flop presents the four possible input combinations for a JK flip-flop. All output changes occur at the clock rising edge.

You can create a JK flip-flop using two LCs, as illustrated in Implementation. The first LC detects rising edges of the CLK clock input (see Truth table for LC0). The second LC processes J and K inputs at every rising clock edge (see Truth table for LC1).

Output Q and CLKO digital filters are bypassed. Therefore, the states of these variables are fed to inputs with a delay of one clock cycle (see Waveforms).

#### 59.6.1.7.8 Waveforms

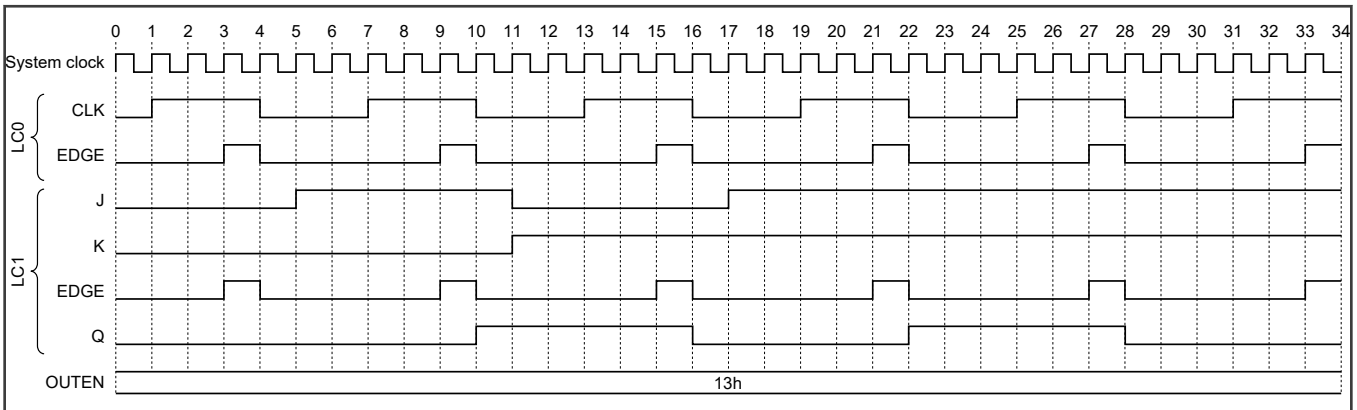

Figure 272. Waveforms

#### 59.6.1.8 Incremental encoder

##### 59.6.1.8.1 Overview

An incremental encoder provides A and B pulse outputs in the form of 90-degree shifted waveforms (see Outputs). The decoding circuit processes these waveforms to detect the rotor position and the direction of rotation.

This example implementation requires two LCs (see Implementation):

- LC0 provides pulse streams on clockwise (CW) or counterclockwise (CCW) output at every A and B signal edge. If the encoder rotation is CW (A signal leading), then pulses appear at the CW output. If the encoder rotation is CCW (B signal leading), then pulses appear at the CCW output. Two pulse counters accumulate these pulse streams to provide the actual absolute encoder position in the respective direction of rotation.
- LC1 then uses the LC0 outputs to detect the direction of the rotation.

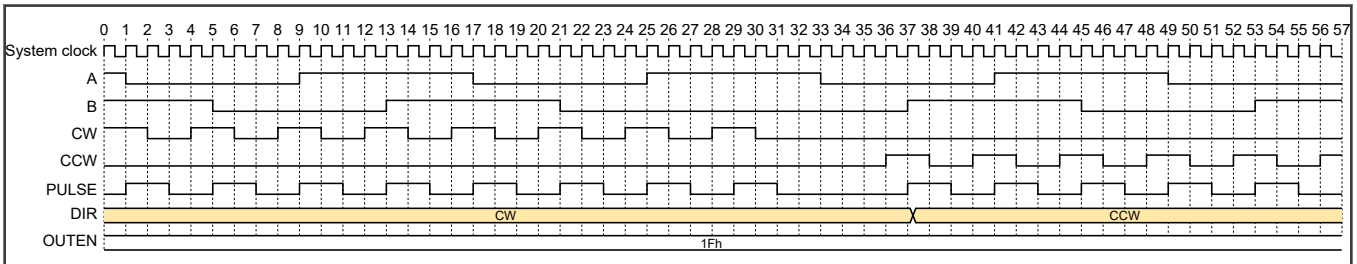

Figure 275. Waveforms

### 59.6.1.9 AC motor PWM controller

#### 59.6.1.9.1 Overview

Driving a three-phase AC motor requires dedicated PWMs to perform:

- Complementary signal generation
- Dead time insertion
- Fault-state assertion
- Manual or automatic fault recovery

LCU enhances basic timer functionality with the necessary complementary features available only on dedicated motor control PWMs.

Implementation for AC motor controller shows all input and output signals of LCU in a typical three-phase motor control application.

TdH is the time delay preceding each rising edge of the complementary PWM output signals. See Truth table for details.

Fault signals are routed from analog comparators or external protection circuits to protect power switches against damage caused by overcurrent. Any active fault must immediately change all PWM outputs to the inactive state. Force logic causes PWM outputs to transition to the inactive state upon an external fault event. See Truth table for details.

The dead time is one clock cycle. On a fault event, both PWM outputs transition to the inactive state (logic 0). When the fault event deasserts, both PWM signals start operating according to FORCE_MODE = 00 (cleared on force deassertion). See Waveforms for force cleared on force deassertion for details.

#### 59.6.1.9.7 Waveforms for force cleared on force deassertion

This example shows two behaviors, depending on the Force Clearing mode (LC0_FCTRL[FORCE_MODE0]).

00b - Both PWM signals start normal operation when the fault event deasserts. See Waveforms for force cleared on force deassertion for details.

01b - Both PWM signals start normal operation on rising sync after the fault event deasserts. See Waveforms for force cleared on rising sync after force deassertion for details.

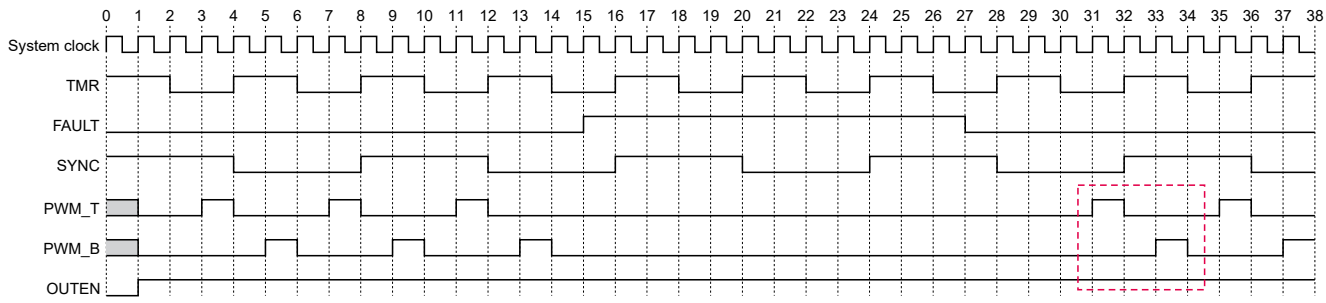

Figure 278. Waveforms for force cleared on force deassertion

#### 59.6.1.9.8 Waveforms for force cleared on rising sync after force deassertion

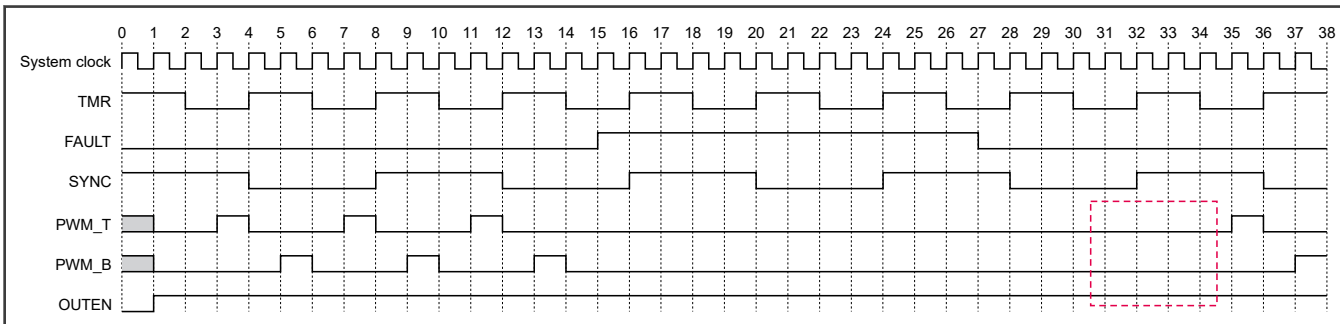

Figure 279. Waveforms for force cleared on rising sync after force deassertion

### 59.6.1.10 AC motor double-switching controller

#### 59.6.1.10.1 Overview

The simplest method of obtaining motor winding currents is to measure the current in each phase by placing a shunt resistor in two or three inverter legs (phases).

This example implementation of an AC motor drive for low-cost and high-volume applications uses a single shunt on the DC bus return path, as illustrated in AC motor power stage schematic. LCU supports double-switching by XORing two timer channel outputs. The implementation uses two LCs arranged to perform double switching, dead time generation, and the processing of three external fault signals.

#### 59.6.1.10.2 Double-switching

The double-switching technique requires:

- Six synchronized timer pulses
- Three fault signals
- Six PWM outputs for controlling top and bottom power switches
- A sync signal for automatic fault recovery

Waveforms for double-switching technique example applies the PWM switching cycle to an AC motor to reconstruct currents in three phases using a single DC bus shunt resistor (RSH). It applies the non-zero switching vectors 100, 110, and 101 to the power switches, which sample currents IA[0], -IC[0], -IC[1], and IA[1]. Because the durations (T1) of active vectors 110 and 101 are the same, it also applies the zero switching vector (000) with durations T2 and T3 in the middle of the switching cycle to allow phase current reconstruction. This technique can only be used by PWM modules targeted at motor control and power conversion applications.

#### 59.6.1.10.3 Fault inputs and deadtime insertion

Fault signals are routed from analog comparators or external protection circuits to protect power switches against damage caused by overcurrent. You must program the Combinational Force Path (LCn_FFILT[COMB_EN]) to enable an active fault input to immediately force all PWM outputs to the inactive state.

#### 59.6.1.10.4 Deadtime insertion

In Waveforms for generation of PWM complementary signals using an LC, the PWMA_T output is generated by XORing timer outputs TMR0 and TMR1. The PWMA_B output is complementary to PWMA_T. Digital filters insert a dead time of one system clock cycle to delay the rising edges of both PWM signals.

#### 59.6.1.10.5 Fault events

Waveforms for force cleared on force deassertion shows the reaction to the fault event. On a fault event, both the PWM outputs transition to the inactive state (logic 0). When fault event deasserts, both the PWM signals start operating according to FORCE_MODE = 00 (cleared on force deassertion).

Alternatively, after the fault event deasserts, fault clearing can be performed according to FORCE_MODE = 01 (cleared on rising sync force deassertion). See Waveforms for force cleared on rising sync after force deassertion for details.

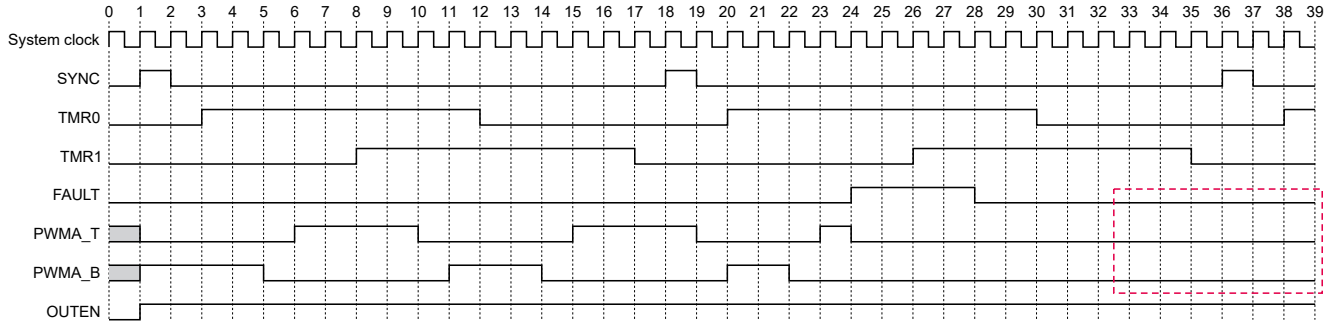

Figure 286. Waveforms for force cleared on rising sync after force deassertion

### 59.6.1.11 Brushless DC (BLDC) motor PWM controller

#### 59.6.1.11.1 Overview

You can use LCU to replace the mechanical commutator in the BLDC motor control application with Hall-sensor position measurement.

In this example implementation, LC0 receives the direction (DIR) and Hall A, Hall B, and Hall C sensor output states, and from those inputs generates the switching states S1, S2, and S3. LC1 and LC2 convert the switching states to PWM or on-off signals for controlling power switches, as illustrated in Waveforms for BLDC motor control technique.

BLDC motor power stage schematic and BLDC motor electrical arrangement illustrate a three-phase BLDC motor power stage with switching pulses and phase currents controlling motor rotation in the CCW direction. The state of the Hall sensors is 010. As the rotor shaft rotates, Hall sensors track the motor position. You accelerate or decelerate the motor by controlling the width of the PWM signal. You can include one or more faults (force inputs) to force power switches instantaneously into the inactive state if there is an overcurrent.

#### 59.6.1.11.2 Implementation

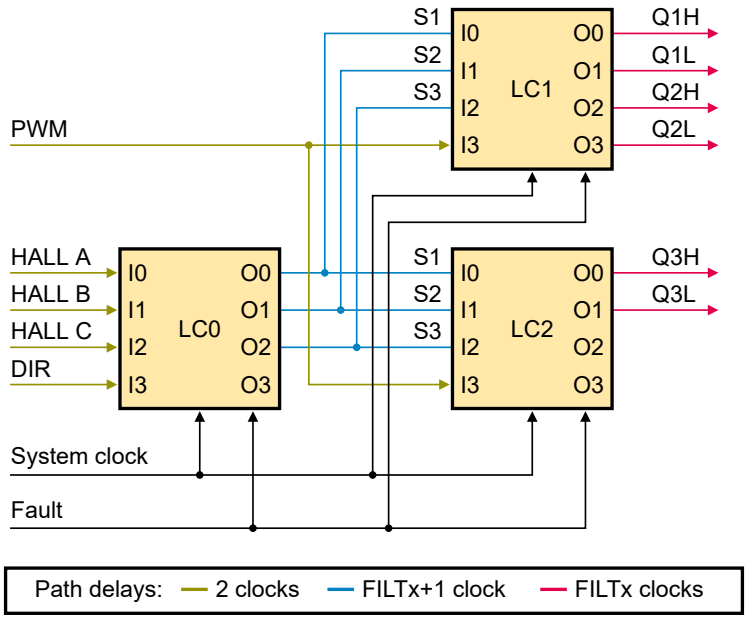

Figure 287. Implementation

### 59.6.1.11.3 BLDC motor power stage schematic

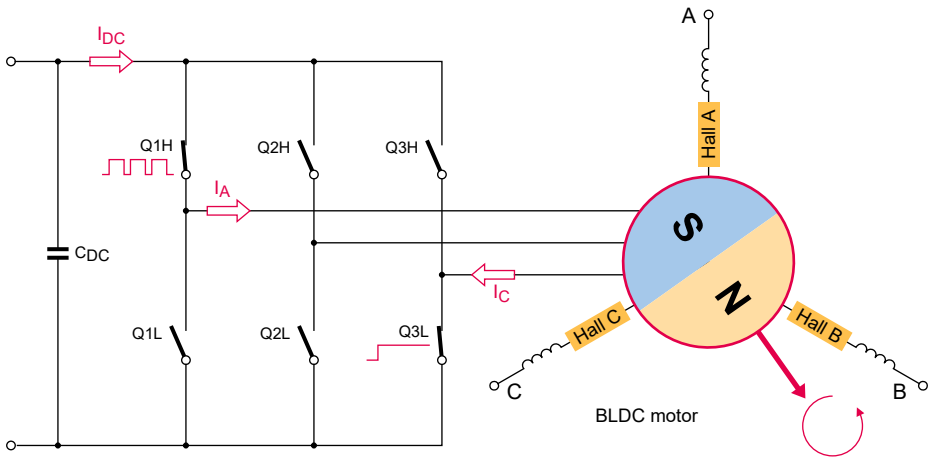

Figure 288. BLDC motor power stage schematic

### 59.6.1.11.4 BLDC motor electrical arrangement

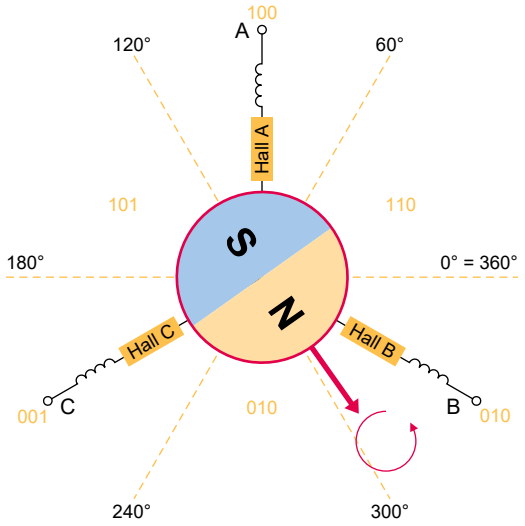

Figure 289. BLDC motor electrical arrangement

### 59.6.1.11.5 Waveforms for BLDC motor control technique

This figure illustrates the basic waveforms for controlling a BLDC motor with stator windings and Hall sensors arranged according to BLDC motor electrical arrangement. Configure the external hardware (motor or sensor) so that it can produce these waveforms; then you can configure LCU.

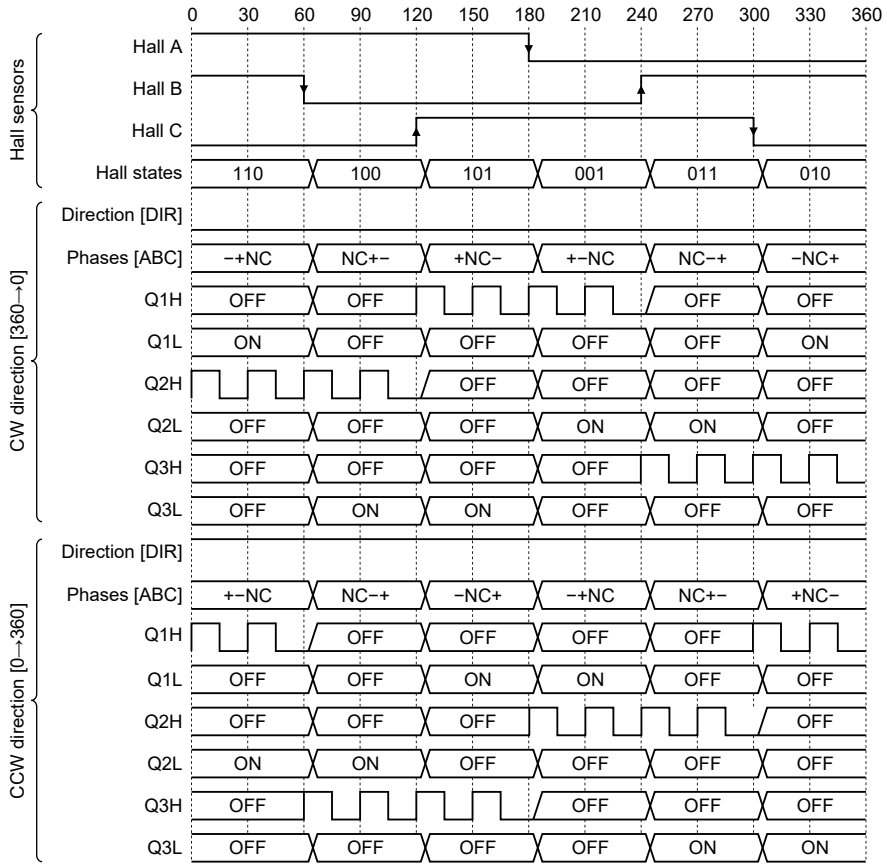

Figure 290. Waveforms for BLDC motor control technique

### 59.6.1.11.6 Connections and controls

Table 318. Connections and controls

| Input-output group | Name | Description |
|---|---|---|
| LC0 inputs | HALL A | Hall sensor A output state |
| | HALL B | Hall sensor B output state |
| | HALL C | Hall sensor C output state |
| | DIR | Direction of shaft rotation, as illustrated in Waveforms for reversing BLDC motor. |
| LC1 and LC2 inputs | S1 | Switching state 1 (output 0 from LC0) |
| | S2 | Switching state 2 (output 1 from LC0) |
| | S2 | Switching state 3 (output 2 from LC0) |
| | PWM | Output from PWM |
| LC0, LC1, and LC2 inputs | Clock | LCU clock input |
| | Fault | Optional fault input |

*Table continues on the next page...*

Table 318. Connections and controls (continued)

| Input-output group | Name | Description |
|---|---|---|
| LC1 outputs | Q1H | Motor control switch outputs, as illustrated in BLDC motor electrical arrangement |
| | Q1L | |
| | Q2H | |
| | Q2L | |
| LC2 outputs | Q3H | |
| | Q3L | |

### 59.6.1.11.7 Truth table for generating switching states

This table includes all Hall sensor states, even those that never occur because of sensor displacement by 120°.

Table 319. Truth table for generating switching states

| Inputs | | | | Outputs | | | Comments |
|---|---|---|---|---|---|---|---|
| DIR | Hall C | Hall B | Hall A | S1 | S2 | S3 | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | Not used |
| 0 | 0 | 0 | 1 | 1 | 0 | 0 | Hall states |

### 59.6.1.11.13 Waveforms for reversing BLDC motor

This figure illustrates the waveforms for controlling a reversing BLDC motor. The DIR input indicates the direction of rotation:

- Logic 0 for CW rotation
- Logic 1 for CCW rotation

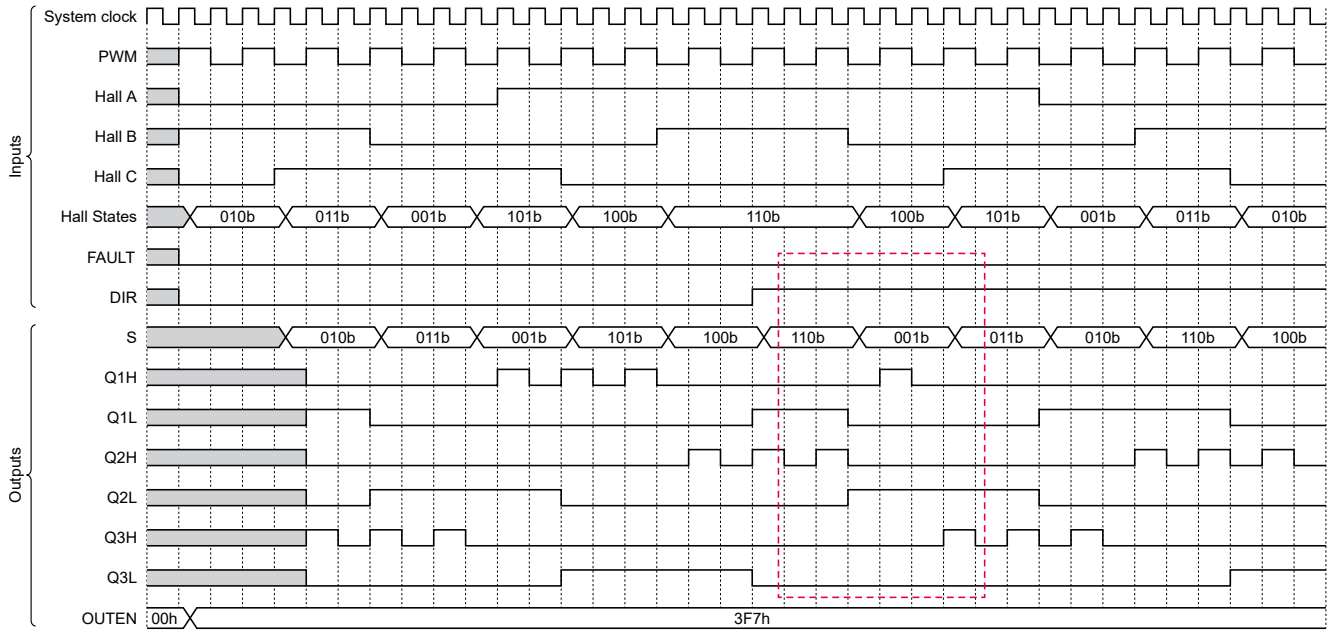

Figure 291. Waveforms for reversing BLDC motor

#### 59.6.1.11.14 Waveforms for reversing BLDC motor with fault assertion

This figure illustrates the waveforms for the reaction to an external fault in addition to reversing the BLDC motor. On the occurrence of an external fault event, the power switches transition to the inactive state (logic 0). Two clock cycles after external fault deassertion, the power switches start operating normally.

Switching state outputs S1, S2, and S3, generated by LC0, receive an additional delay of one clock cycle on their way to the inputs of other LCs (digital filters bypassed).

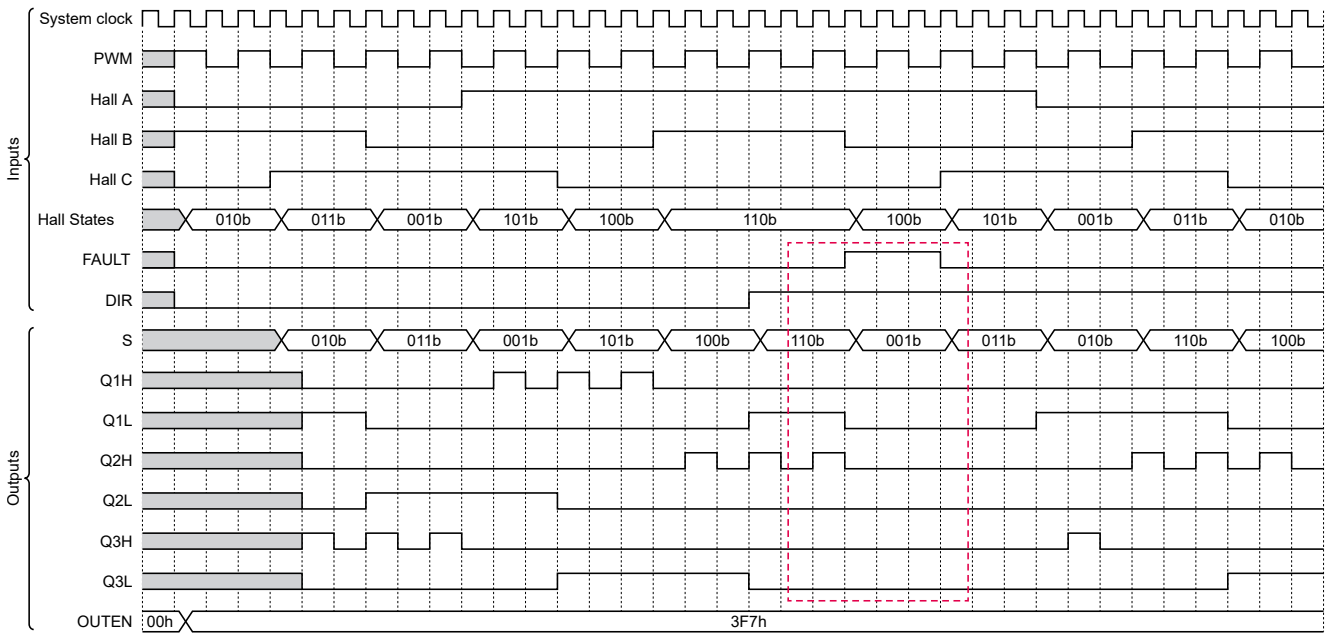

Figure 292. Waveforms for reversing BLDC motor with fault assertion

## 59.7 Mapping of 12-bit input, output, and state fields

This table maps inputs, outputs, or states to the bit positions in the following 12-bit fields:

- SWEN[SWEN]
- SWVALUE[SWVALUE]
- OUTEN[OUTEN]
- LCIN[LC_INPUTS]
- SWOUT[SWOUT]
- LCOUT[LCOUT]
- FORCEOUT[FORCEOUT]
- FORCESTS[FORCESTS]
- DBGEN[DBGEN]

| LC | Input, output, or state | Bit |
|---|---|---|
| 0 | 0 | 0 |
| | 1 | 1 |

*Table continues on the next page...*

## 59.8.2 LC n Output m LUT Control (LC0_LUTCTRL0 - LC2_LUTCTRL3)

### Offset

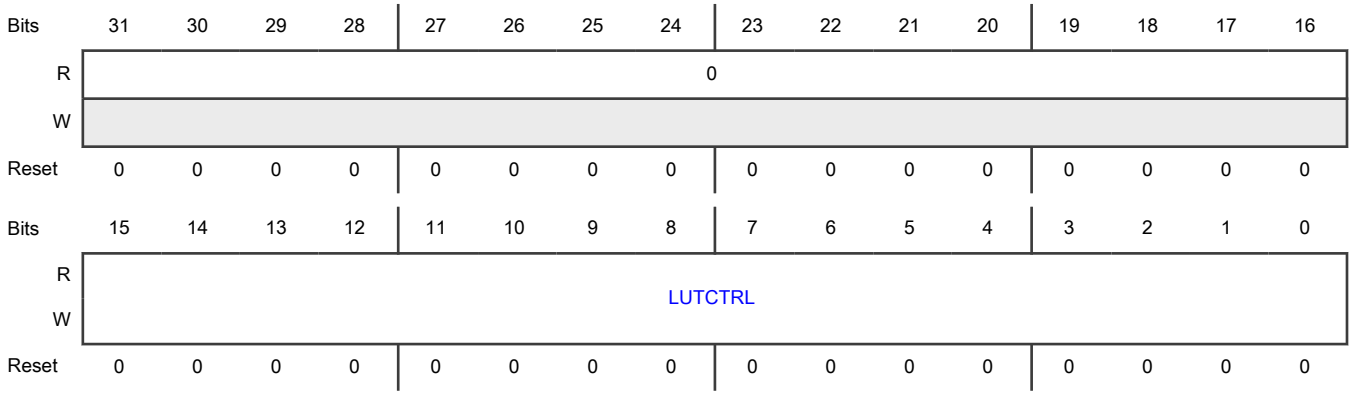
For n = 0 to 2; m = 0 to 3:

| Register | Offset |
|---|---|
| LCn_LUTCTRLm | 0h + (n × 40h) + (m × 4h) |

### Function

See LUTCTRL.

### Diagram



**Fields**

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15-0<br>LUTCTRL | LUT Control<br>Specifies the LUT positions, based on the combined LC input value, that result in assertion of this output. For more information, see Logic operations. |

## 59.8.3 LC n Output m Filter (LC0_FILT0 - LC2_FILT3)

**Offset**

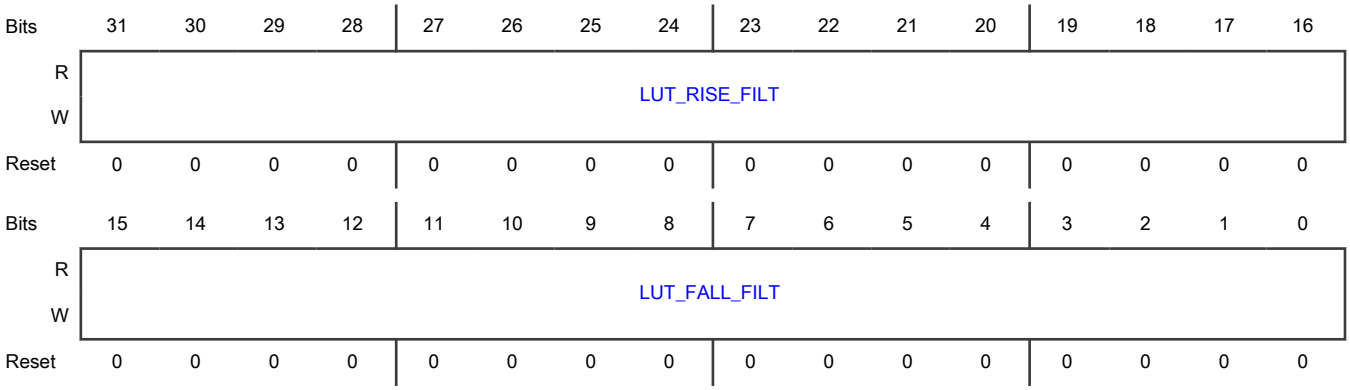
For n = 0 to 2; m = 0 to 3:

| Register | Offset |
|---|---|
| LCn_FILTm | 10h + (n × 40h) + (m × 4h) |

**Function**

Specifies the rising- and falling-edge thresholds for the LC output filters.

**Diagram**



**Fields**

### Fields

| Field | Function |
|---|---|
| 31-12<br>— | Reserved |
| 11-8<br>FORCESTS | Force Event<br>Indicates that a force event has occurred on the associated output.<br>For each bit:<br>0b - No event<br>1b - Event occurred<br>Mapping of bits: |

| Output | Register bit |
|---|---|
| 0 | 8 |
| 1 | 9 |
| 2 | 10 |
| 3 | 11 |

When you enable DMA for a force output (LC*n*_INTDMAEN[FORCE_DMA_EN]) and a force event occurs on that output, LCU generates a DMA request. The resulting DMA done signal causes LCU to change the bit to 0, or you can write 1 to the bit.

You can also change these bits to 0 by writing to the corresponding Force Status bits (FORCESTS[FORCESTS]).

The timing of status clearing depends on the selected Force Mode (LC*n*_FCTRL[FORCE_MODEm]).

## 59.8.7 LC n Force Filter (LC0_FFILT - LC2_FFILT)

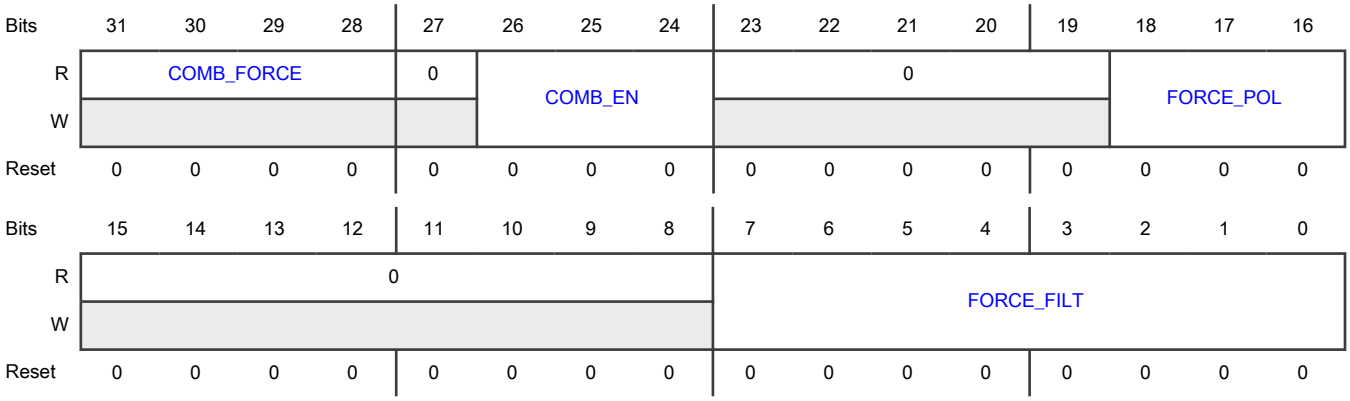
### Offset

| Register | Offset |
|---|---|
| LC0_FFILT | 2Ch |
| LC1_FFILT | 6Ch |
| LC2_FFILT | ACh |

### Function

Controls the force filter for this LC.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-28<br>COMB_FORCE | Combined Sensed Force Input<br>Indicates the combined value of force inputs to each output.<br>For each bit:<br>0b - Logic low<br>1b - Logic high<br>Mapping of bits: |

| Output | Bit |
|---|---|
| 0 | 28 |
| 1 | 29 |
| 2 | 30 |
| 3 | 31 |

| Field | Function |
|---|---|
| 27<br>— | Reserved |
| 26-24<br>COMB_EN | Combinational Force Path (CFP) Enable<br>Enables an active force input to combinationally affect the LC outputs. When CFP is not enabled, force inputs must be synchronized and then optionally filtered. When you enable CFP (write 1 to one of these bits), the corresponding force input bypasses synchronization and filtering and immediately affects the LC output.<br>The Force Filter (FORCE_FILT) is still in effect. Force inputs that do not meet the pulse width requirements for synchronization and filtering are not registered in Force Status (FORCESTS) and you do not need to write 1 to change the bit to 0. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | CFP provides a safety factor when the LC outputs drive a motor and immediate response is required. In some topologies, an oscillation can result if the assertion of the force input causes the LC output to turn off. This situation in turn leads to deassertion of the force input and the output turning back on. In general, you must disable CFP unless the LCU outputs drive a motor or similar safety-critical application, which requires an immediate response without synchronization delays. |
| 23-19<br>— | Reserved |
| 18-16<br>FORCE_POL | Force Input Polarity<br>Specifies the polarity of the force inputs to this LC.<br>For each bit:<br>0b - Not inverted<br>1b - Inverted<br>Mapping of bits: |

## 59.8.16 Overridden Inputs (SWOUT)

### Offset

| Register | Offset |
|---|---|
| SWOUT | 294h |

### Function

Indicates states of LC inputs or states of software-overridden inputs, depending upon the state of the corresponding SWEN bit.

If you write to this register, LCU generates a bus transfer error.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

# Chapter 60
# Enhanced Modular IO Subsystem (eMIOS)

## 60.1 Chip-specific eMIOS information

### 60.1.1 eMIOS configuration

This chip has up to 3 instances of eMIOS that are each configured as shown in the following tables.

**Table 325. eMIOS instances**

| Instance | MCXE31B | MCXE315/MCXE316/ MCXE317 |
|---|---|---|
| eMIOS_0 | Yes | Yes |
| eMIOS_1 | Yes | Yes |
| eMIOS_2 | Yes | No |

**Table 326. eMIOS configuration**

| Parameter | eMIOS_0 | eMIOS_1 | eMIOS_2 |
|---|---|---|---|
| Timer width | 16 bits | 16 bits | 16 bits |
| Number of channels | 24 | 24 | 24 |
| Channels configuration | See EMIOS channel configuration figure below | | |
| Local Channel prescaler width | 4 | 4 | 4 |
| Number of global counter buses | 2 | 2 | 2 |
| Number of global prescaler | 1 | 1 | 1 |
| Global channel prescaler width | 8 | 8 | 8 |

**NOTE**

eMIOS is clocked by CORE_CLK.

### 60.1.2 Channel types

The eMIOS contain 4 different types of channel, which are listed below.

**Table 327. eMIOS channel types**

| Mode Description | Name | Ch TypeX | Ch TypeY | Ch TypeG | Ch TypeH |
|---|---|---|---|---|---|
| General Purpose Input / Output | GPIO | X | X | X | X |
| Single Action Input Capture | SAIC | X | X | X | X |
| Single Action Output Compare | SAOC | X | X | X | X |

*Table continues on the next page...*

Table 327. eMIOS channel types (continued)

| Mode Description | Name | Ch TypeX | Ch TypeY | Ch TypeG | Ch TypeH |
|---|---|---|---|---|---|
| Modulus Counter | MC | X | | | |
| Modulus Counter Buffered (Up / Down) | MCB | X | | X | |
| Input Pulse Width Measurement | IPWM | | | X | X |
| Input Period Measurement | IPM | | | X | X |
| Double Action Output Compare | DAOC | | | X | X |
| Output Pulse Width and Frequency Modulation Buffered | OPWFMB | X | | X | |
| Center aligned Output PWM Buffered with dead time | OPWMCB | | | X | |
| Output Pulse Width Modulation Buffered | OPWMB | X | X | X | X |
| Output Pulse Width Modulation Trigger | OPWMT | X | X | X | X |
| Pulse Edge Counting | PEC | | | X | |

**NOTE**

ChType X and G has internal counters.

Table 328. eMIOS channel configuration

| Channel number | eMIOS0 | eMIOS1 | eMIOS2 |
|---|---|---|---|
| CH0 | X | X | X |
| CH8 | X | X | X |
| CH16 | X | X | X |
| CH22 | X | X | X |

### 60.1.3 Channel configuration

The eMIOS channel configuration with respect to Type and Counter_bus is shown below.

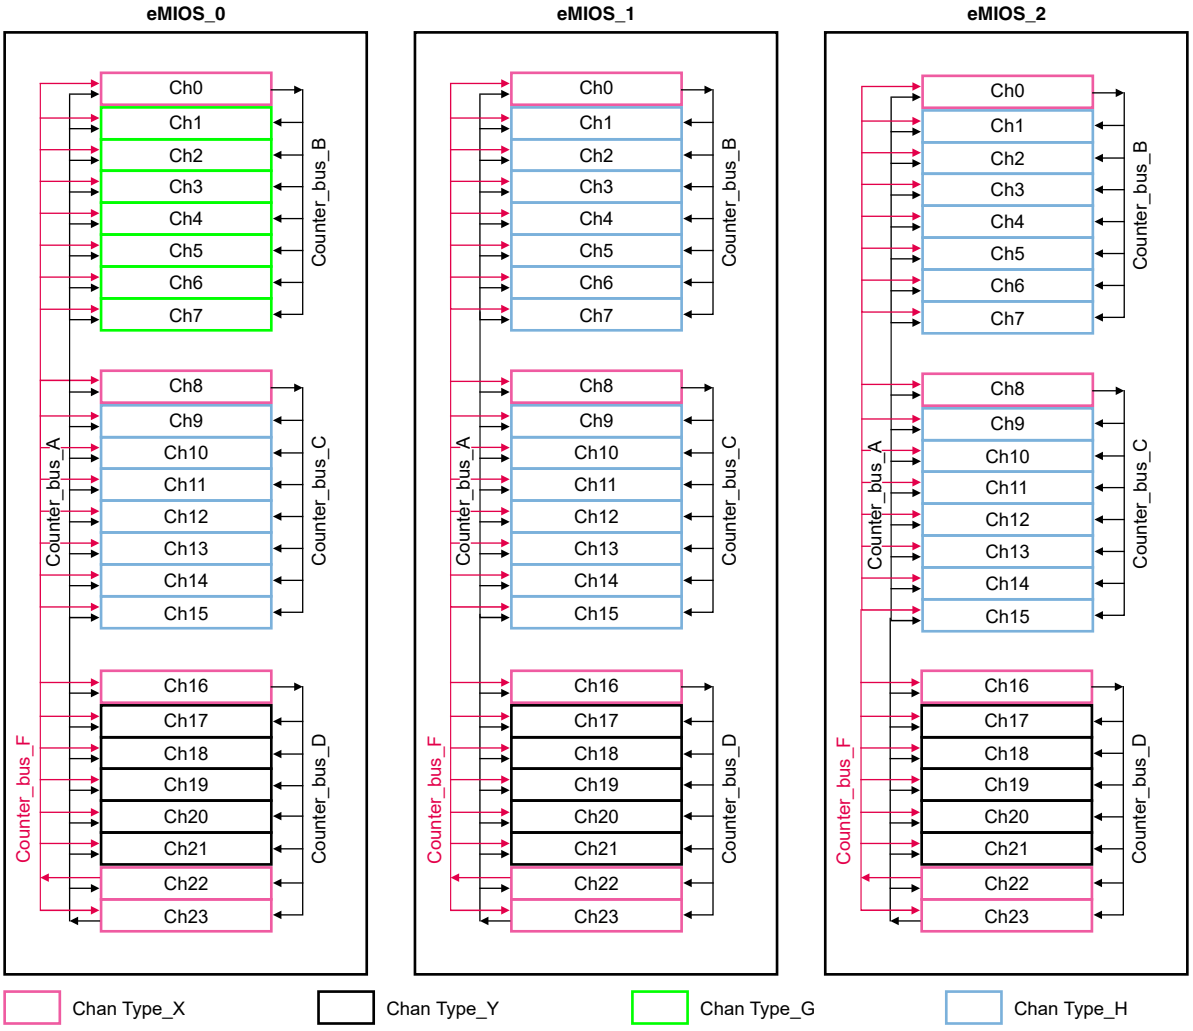

Figure 293. EMIOS channel types

## 60.1.4 eMIOS disabling

eMIOS can disable it's output using it's disable inputs. Disable inputs[3:0] are driven from the flag out bits[11:8].

| Disable inputs | |
|---|---|
| eMIOS0 Output disable input[3:0] | trgmux_output[31:28] |
| eMIOS1 Output disable input[3:0] | trgmux_output[31:28] |
| eMIOS2 Output disable input[3:0] | trgmux_output[31:28] |

For details, see the TRGMUX connectivity file attached to this document.

## 60.1.5 BCTU Interface

Each eMIOS channel, with the exception of the main counterbus channel (ch[23]) is capable of triggering the BCTU. See BCTU chapter for mapping. BCTU allows triggering from as many eMIOS modes as possible.

## 60.2 Introduction

eMIOS provides independent channels, UCs, that you configure to generate or measure time events for different functions in different chip applications.

eMIOS distributes these channels across a number of global and local counter buses. Each local bus is dedicated to a group of eight contiguous channels. Each channel can generate its own timebase, and each counter bus has its timebase provided by a dedicated channel. For a list of counter buses with their assigned channels and timebase sources, see Counter buses, channels, and timebase sources.

## 60.3 Block diagram

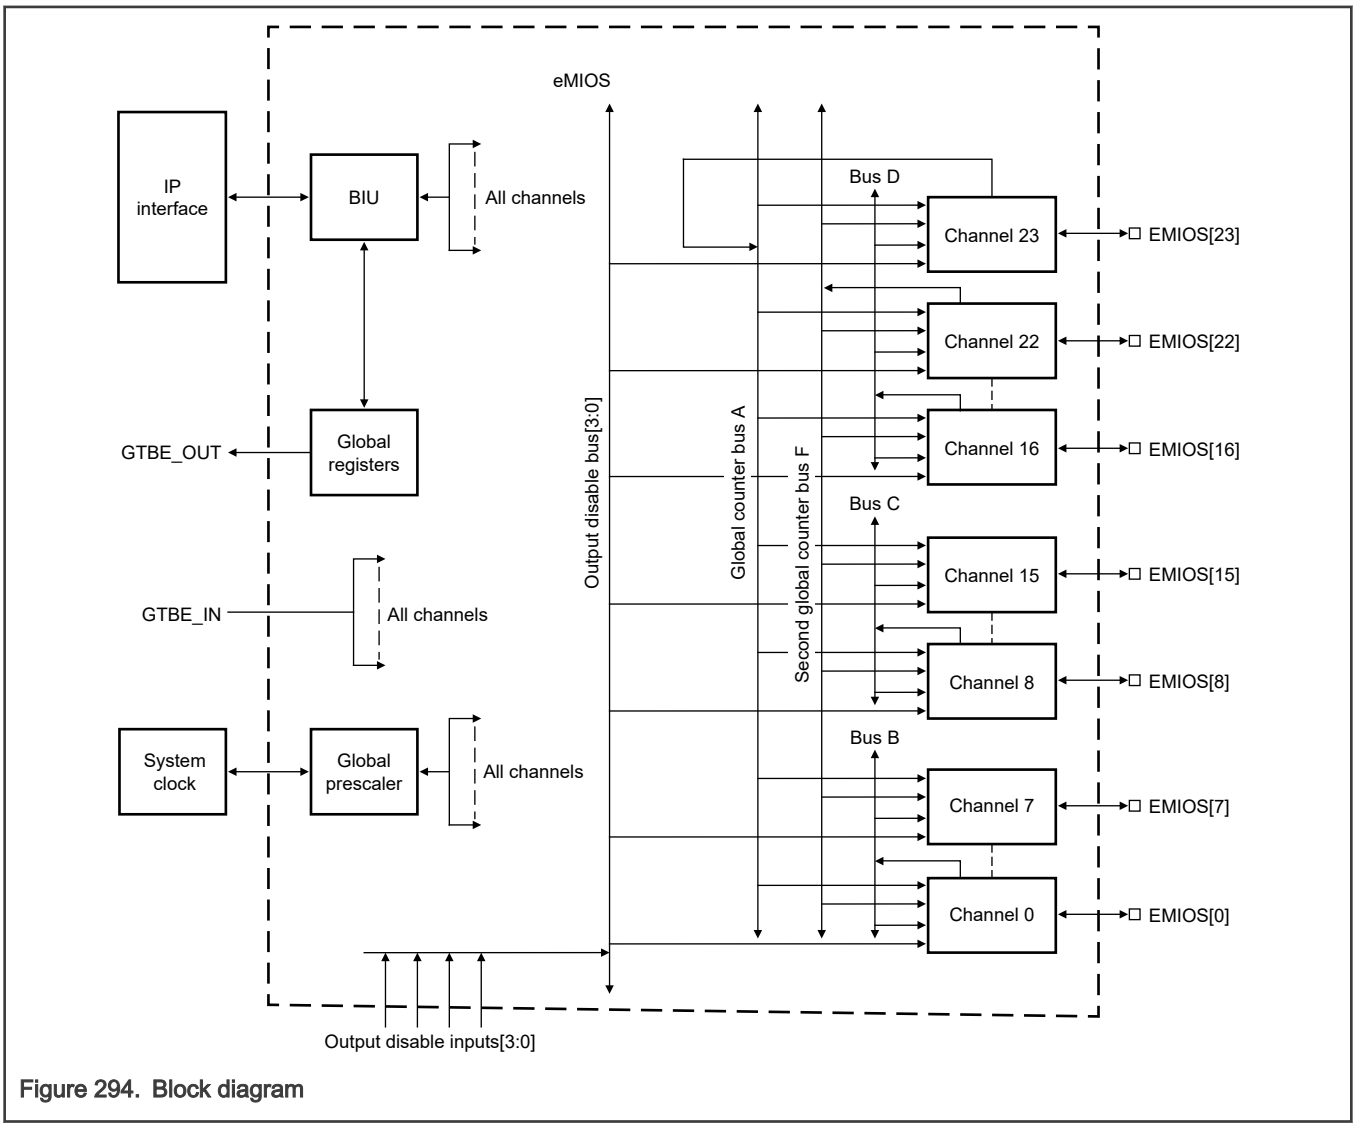

Figure 294. Block diagram

## 60.4 Features

- 24 UCs distributed across local counter buses as shown in Counter buses, channels, and timebase sources
- Global counter bus A driven by UC23
- Global counter bus F driven by UC22
- Synchronized timebases shared through the counter buses

- Dedicated timebase for each channel, distinct from the counter buses
- Global clock prescaler (GCP)
- One CP per channel
- Dedicated set of control and status registers for each UC
- 16-bit–wide data registers
- Shadow flag register (GFLAG) to access all channel flags with one read access
- Ability to freeze the UC state for debug purposes
- Motor control capability

## 60.5 Functional description

### 60.5.1 Reset

eMIOS resets asynchronously. Reset affects all registers.

On reset, UCs enter GPIO input mode.

### 60.5.2 Counter buses, channels, and timebase sources

**Table 329. Counter buses, channels, and timebase sources**

| Counter bus | Channels | Timebase channel |
|---|---|---|
| Global bus A | All UCs | 23 |
| Local bus B | • UC0<br>• UC1<br>• UC2<br>• UC3<br>• UC4<br>• UC5<br>• UC6<br>• UC7 | 0 |

| | • UC17<br>• UC18<br>• UC19<br>• UC10<br>• UC21<br>• UC22<br>• UC23 | |
| Global bus F | All UCs | 22 |

## 60.5.3 Unified channels (UC)

### 60.5.3.1 Overview

Each UC contains the following:

- Two double-buffered data registers, A*n* and B*n*, that allow up to two events—input capture, output compare, or both—to occur before software intervention is needed
- Two comparators, A and B, that indicate when the selected counter bus is equal to the value in A*n* and B*n*
- An internal counter (CNT*n*[C]) that runs in all modes except GPIO.

  You can use this counter as a local timebase or to count input events. You can use it as a timebase if CNT*n*[C] is not used in the current mode.
- An output flip-flop that holds the logic level to be applied to the output pin
- A status register, UC Status n (S0 - S23), that flags input capture and match events, indicates flag overruns and overflows, and shows the input and output pin states
- A control register, UC Control n (C0 - C23), that controls UC operation

You control the following operational characteristics for each UC:

- The logic (C*n*[MODE]) that specifies the behavior of the UC (see UC modes)
- The counter bus (C*n*[BSL]) that provides the timebase for all timing functions
- The CP (C*n*[UCPRE] and C2_*n*[UCEXTPRE])
- The minimum input pulse width (C*n*[IF]) for the input filter that determines valid pin transitions
- Which input edges to detect (C*n*[EDSEL])
- Which of four output disable input signals (C*n*[ODISSL]) to use for disabling outputs
- For all output modes except GPIO, whether to disable the output flip-flop (C*n*[ODIS])

UC block diagram illustrates the basic UC architecture.

For a list of counter buses and their assigned channels and timebase sources, see Counter buses, channels, and timebase sources.

### 60.5.3.2 UC block diagram

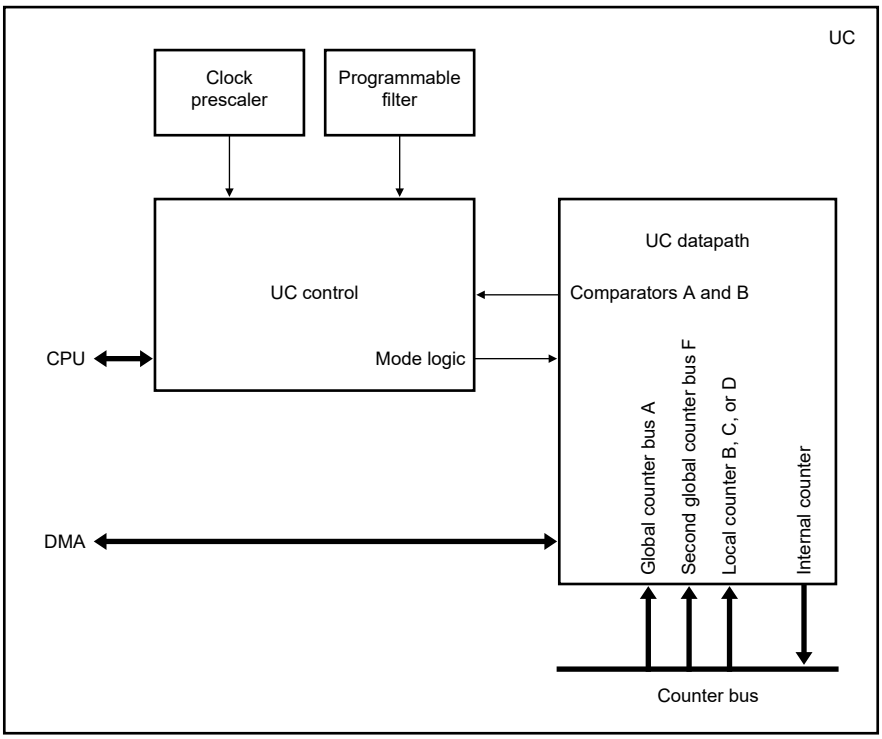

Figure 295. UC block diagram

### 60.5.3.3 Buffered modes

To provide smooth waveform generation even when A*n*[A] and B*n*[B] are changing, the following modes double buffer the A*n* and B*n* registers:

- Modulus Counter Buffered (MCB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Output PWM Buffered (OPWMB) mode

These modes appear in separate sections because there are several basic differences in UC operation between them and their corresponding nonbuffered modes.

### 60.5.3.4 UC control and datapath

As illustrated in UC control and datapath diagram, the UC contains control and datapath sub-blocks.

The control sub-block generates signals to control the multiplexers in the datapath sub-block. eMIOS implements each UC mode in dedicated logic independent from the other modes. The UC modes share a set of registers allowing the storing of sequential events.

The datapath block contains the channel A and B registers, the internal timebase, and the comparators. Multiplexers receive inputs from the control sub-block to configure the datapath for the specific channel modes. This configuration consists of selecting the input of comparators and data for the register inputs. The outputs of the A and B comparators connect to the control block.

### 60.5.3.5 UC control and datapath diagram

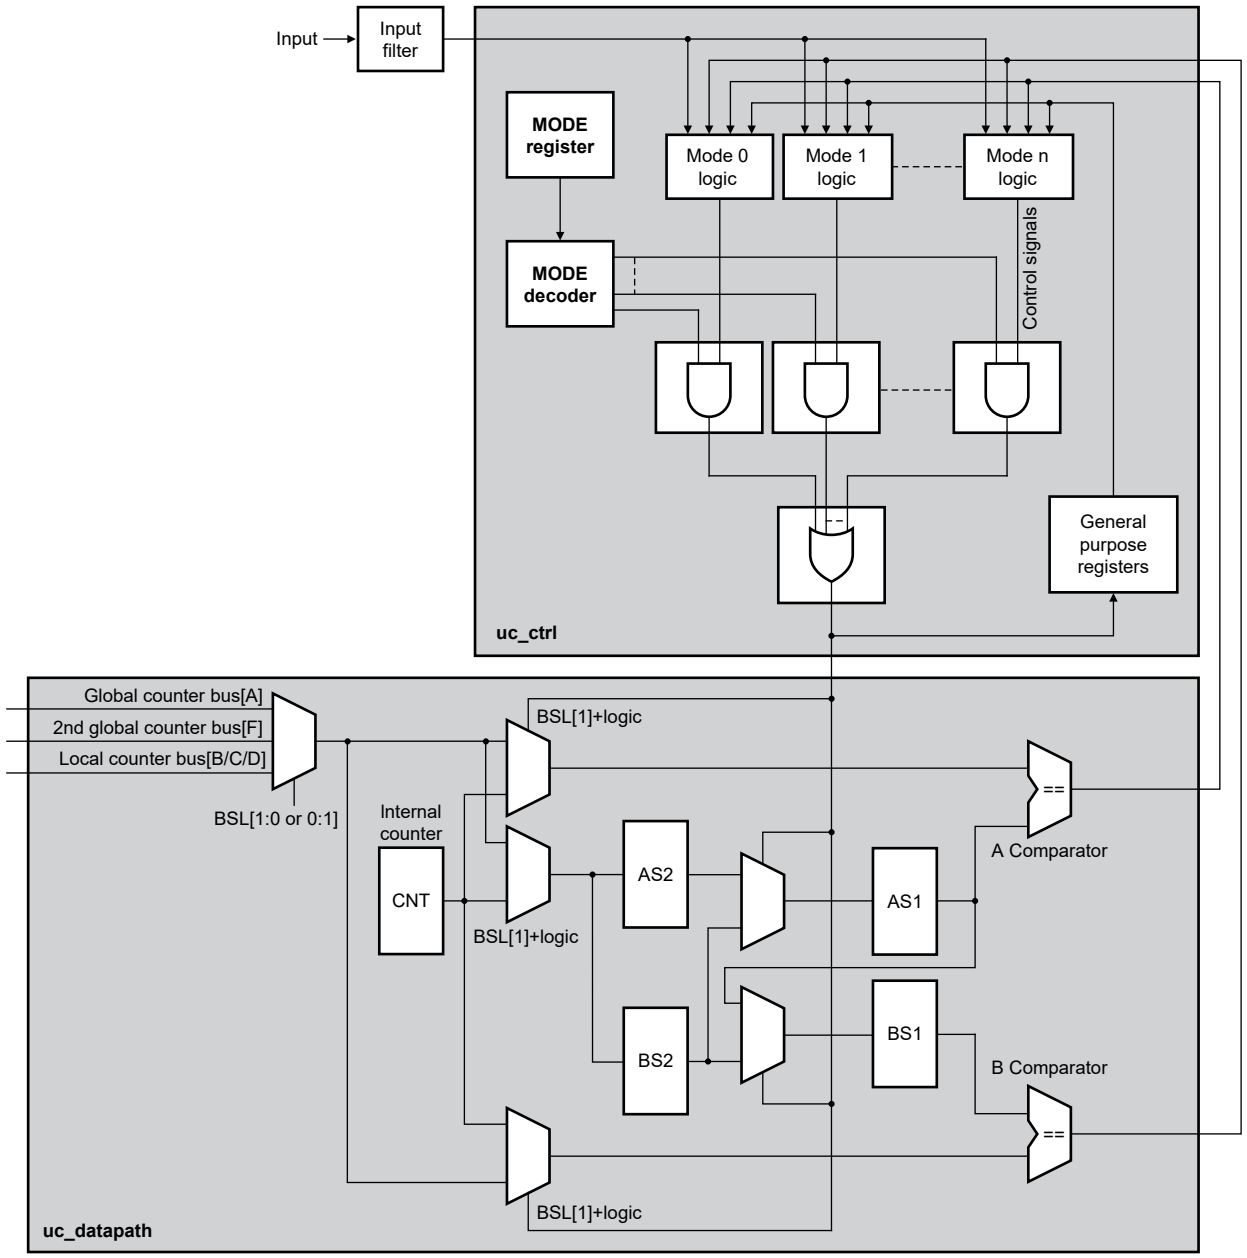

Figure 296. UC control and datapath diagram

### 60.5.3.6 UC modes

You can configure UCs to operate in the following modes:

- General-Purpose Input and Output (GPIO) mode
- Single Action Input Capture (SAIC) mode
- Single Action Output Capture (SAOC) mode
- Input Pulse Width Measurement (IPWM) mode
- Input Period Measurement (IPM) Mode

- Double Action Output Compare (DAOC) mode
- Pulse Edge Counting (PEC) mode
- Modulus Counter (MC) mode
- Modulus Counter Buffered (MCB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode
- Output PWM Buffered (OPWMB) mode
- Output PWM with Trigger (OPWMT) mode

Each channel supports a specific subset of these modes. See the chip-configuration information to see which modes each channel supports.

### 60.5.3.7 General-Purpose Input and Output (GPIO) mode

#### 60.5.3.7.1 Overview

This mode disables all UC input-capture and output-compare functions, and resets and disables the internal counter (C*n*[C]). All control fields remain accessible.

To change the UC from one operation mode to another, you must first change to GPIO mode and then change to the desired final mode. To prepare the UC for a new operation mode, you must configure AS1, BS1, AS2, and BS2 before exiting GPIO mode and entering the desired final mode (see AS1, AS2, BS1, and BS2 shadow registers). Specifically:

- Writing to A*n*[A] stores the same value in AS1 and AS2.
- Writing to B*n*[B] stores the same value in BS1 and BS2.
- Writing to ALTA*n*[ALTA] stores a value only in AS2.

As its name implies, GPIO mode supports both input and output submodes. See Differences for input and output submodes.

#### 60.5.3.7.2 Differences for input and output submodes

**Table 330. Differences for input and output submodes**

| Submode | To enter submode, write this value to C*n*[MODE] | Characteristics |
|---|---|---|
| Input | 0 | • You control the generation of input-capture flags with C*n*[EDPOL] and C*n*[EDSEL].<br>• You can determine the input pin status by reading S*n*[UCIN]. |
| Output | 1 | • The UC performs as a single output port pin.<br>• The value of C*n*[EDPOL] permanently drives the output flip-flop. |

### 60.5.3.8 Single Action Input Capture (SAIC) mode

#### 60.5.3.8.1 Overview

In this mode, when a triggering event occurs on the input pin, eMIOS:

- Captures the selected timebase into AS2
- Changes S*n*[FLAG] to 1 to indicate that an input capture has occurred

A*n*[A] returns the value of AS2. As soon as the UC enters SAIC mode after exiting GPIO mode, the channel is ready to capture events.

eMIOS captures the events as soon as they occur. Therefore, reading A*n*[A] always returns the value of the latest captured event. Subsequent capture events occur regardless of whether you read the previous event from A*n*[A]. Each new capture event sets the input capture flag (writes 1 to S*n*[FLAG]).

The input capture is triggered by an edge transition on the input pin as configured by C*n*[EDPOL] and C*n*[EDSEL].

SAIC with rising edge triggering and SAIC with both edges triggering show how to use the UC for input capture.

#### 60.5.3.8.2 SAIC submodes and MODE field values

**Table 331. SAIC submodes and MODE field values**

| Capture behavior | C*n*[MODE] (binary) |
|---|---|
| The UC only captures the timestamp. | 000_0010 |
| • The UC captures a timestamp.<br>• AS2 bit 31 indicates the input signal level. | 100_0010 |

#### 60.5.3.8.3 Effect of C*n*[EDPOL] on edge capturing

**Table 332. Effect of C*n*[EDPOL] on edge capturing**

| C*n*[EDPOL] | Input signal transition | Resulting value of AS2 bit 31 |
|---|---|---|
| 0 | 0→1 | 0 |
| | 1→0 | 1 |
| 1 | 0→1 | 1 |
| | 1→0 | 0 |

#### 60.5.3.8.4 SAIC with rising edge triggering

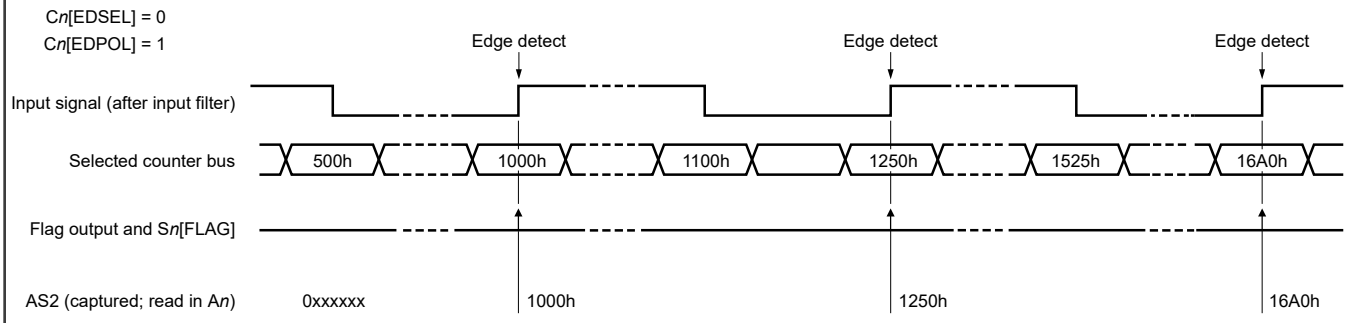

**Figure 297. SAIC with rising edge triggering**

#### 60.5.3.8.5 SAIC with both edges triggering

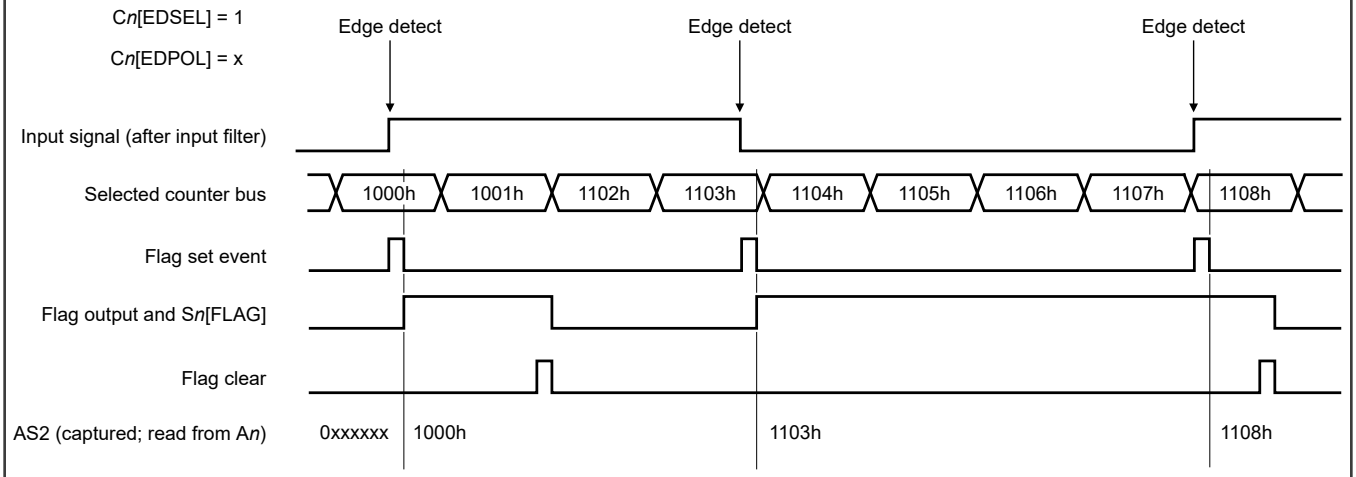

**Figure 298. SAIC with both edges triggering**

### 60.5.3.9 Single Action Output Capture (SAOC) mode

#### 60.5.3.9.1 Overview

In this mode, eMIOS loads a match value into AS2 and then immediately transfers it to AS1 for comparison with the selected timebase. When an output-compare match occurs, eMIOS:

- Either toggles the output flip-flop or transfers C*n*[EDPOL] to the output flip-flop, as determined by C*n*[EDSEL].
- Sets the input capture flag (changes S*n*[FLAG] to 1).

Along with the match, S*n*[FLAG] becomes 1 to indicate that the output-compare match has occurred. Writing to A*n*[A] stores the value in AS2, and reading A*n*[A] returns the AS1 value.

The channel internal counter in SAOC mode is free-running. It starts counting as soon as the UC enters SAOC mode.

You can force an output-compare match by writing 1 to C*n*[FORCMA]. A forced output-compare match does not set the input capture flag (S*n*[FLAG]).

When the UC enters SAOC mode after exiting GPIO mode, the output flip-flop value becomes the complement of C*n*[EDPOL].

You select the internal or external counter bus with C*n*[BSL].

SAOC with C*n*[EDPOL] transferred to the output flip-flop shows how to perform a single output compare and transfer C*n*[EDPOL] to the output flip-flop.

SAOC toggling the output flip-flop shows how to perform a single output compare and toggle the output flip-flop at each match.

#### 60.5.3.9.2 Preload the desired match value

eMIOS enables matches immediately after the UC enters SAOC mode. Therefore, you must write the desired match value to AS1 before the UC enters SAOC mode. You can update AS1 at any time. This modifies the match value reflected in the channel-generated output signal. Subsequent capture events occur regardless of whether you write to A*n*[A] again. Each new capture event sets the input capture flag (S*n*[FLAG]). See SAOC with flag behavior.

### 60.5.3.9.3 SAOC with C*n*[EDPOL] transferred to the output flip-flop

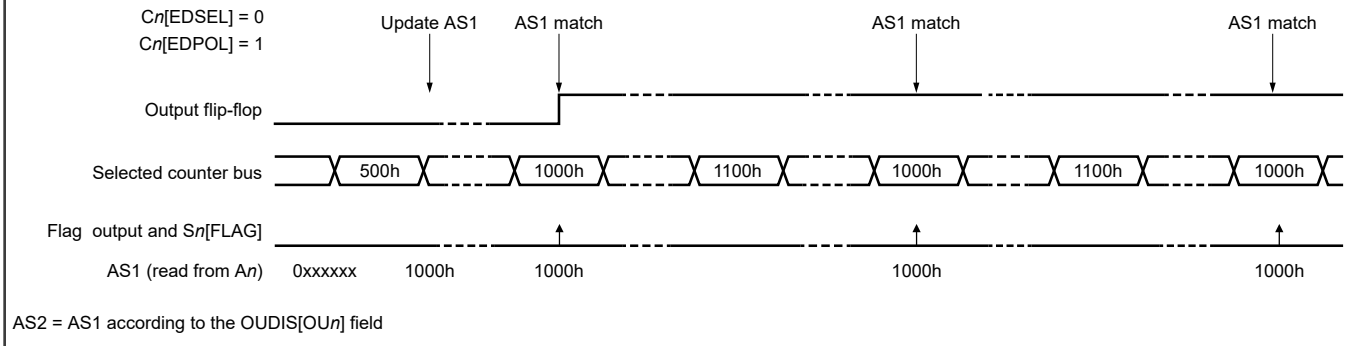

**Figure 299. SAOC with C*n*[EDPOL] transferred to the output flip-flop**

### 60.5.3.9.4 SAOC toggling the output flip-flop

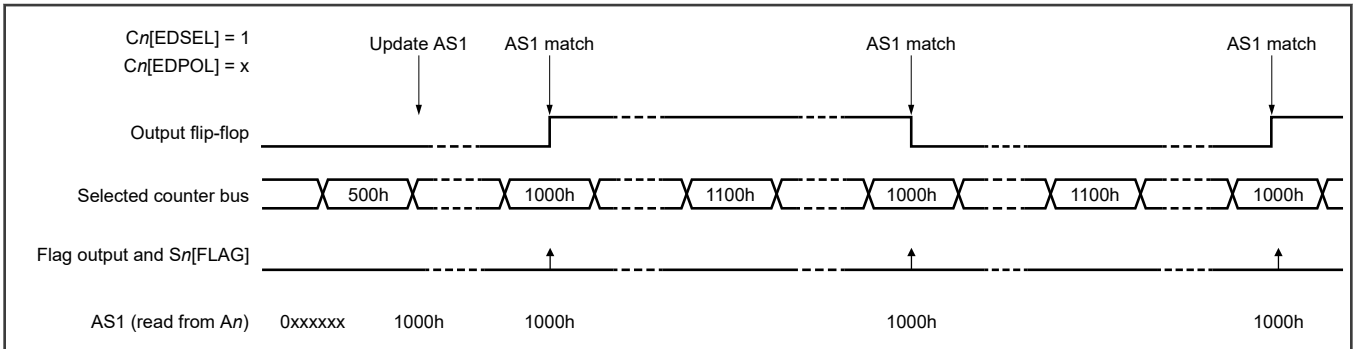

**Figure 300. SAOC toggling the output flip-flop**

### 60.5.3.9.5 SAOC with flag behavior

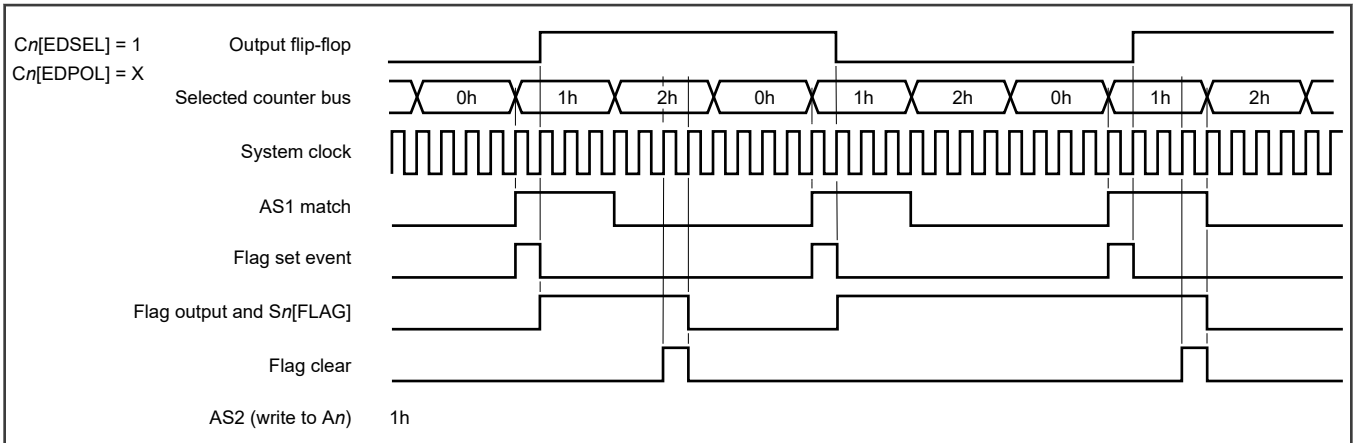

**Figure 301. SAOC with flag behavior**

### 60.5.3.10 Input Pulse Width Measurement (IPWM) mode

#### 60.5.3.10.1 Overview

This mode allows you to measure the width of a positive or negative pulse. Select whether to measure from the rising or falling edge with Edge Polarity (Cn[EDPOL]).

The first leading edge:

- Triggers the first input capture, which latches the count value of the selected timebase into BS2 (see AS1, AS2, BS1, and BS2 shadow registers)
- Does not set the input-capture flag (Sn[FLAG])
- Enables AS2 capture

The next trailing edge:

- Latches the selected timebase into AS2
- Sets the input-capture flag (Sn[FLAG])
- Transfers BS2 to BS1 and AS1

eMIOS captures successive values on consecutive edges of opposite polarity. If you initiate subsequent input capture events while the input-capture flag (Sn[FLAG]) is set, eMIOS updates AS2, BS1, and AS1 with the latest captured values and keeps the flag set.

#### 60.5.3.10.2 Coherency

Reading A*n*[A] updates BS1 with AS1. It also disables transfers from BS2 and BS1 until the next read of B*n*[B].

Reading Bn updates BS1 with AS1. It also re-enables transfers from BS2 to BS1, which takes effect at the next trailing edge capture.

Because transfers from BS2 to AS1 are never blocked, to guarantee data coherency you must read An, then read Bn.

If you do not require coherent data, you should read Bn before you read An, although doing so requires a second read of Bn to unblock BS1 updates.

#### 60.5.3.10.3 Timing example: measure pulse width

This figure shows how to measure the input pulse width by subtracting BS1 from AS2.

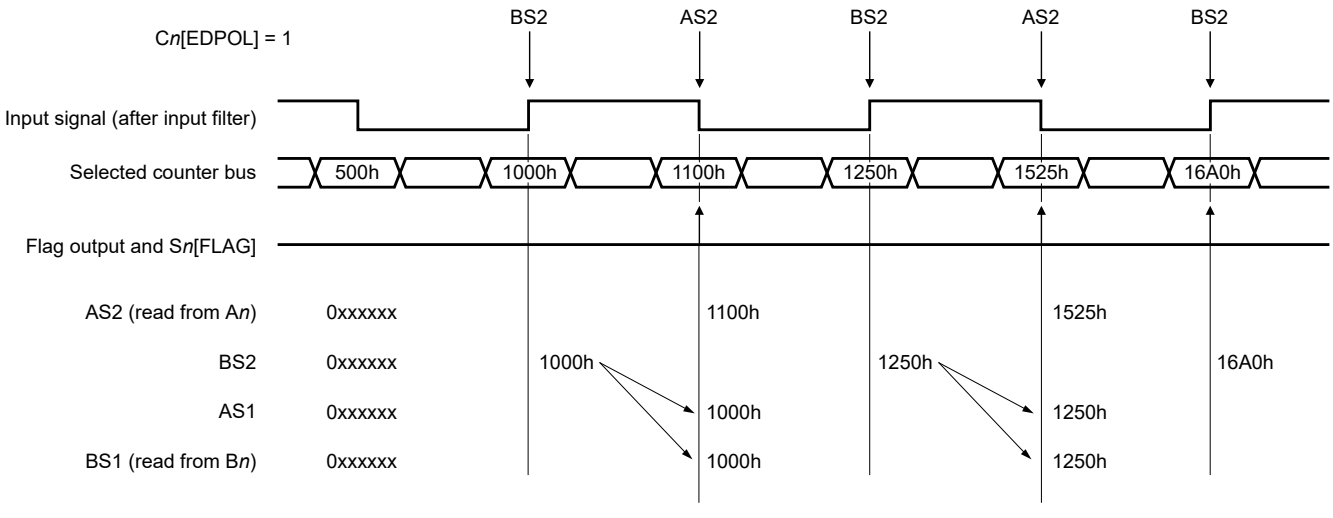

**Figure 302. Timing example: measure pulse width**

#### 60.5.3.10.4 Timing example: AS1 and BS1 updates on channel reads

This example illustrates AS1 and BS1 updates when you read A*n*[A] and B*n*[B]. AS1 always has coherent data related to AS2 (see Coherency).

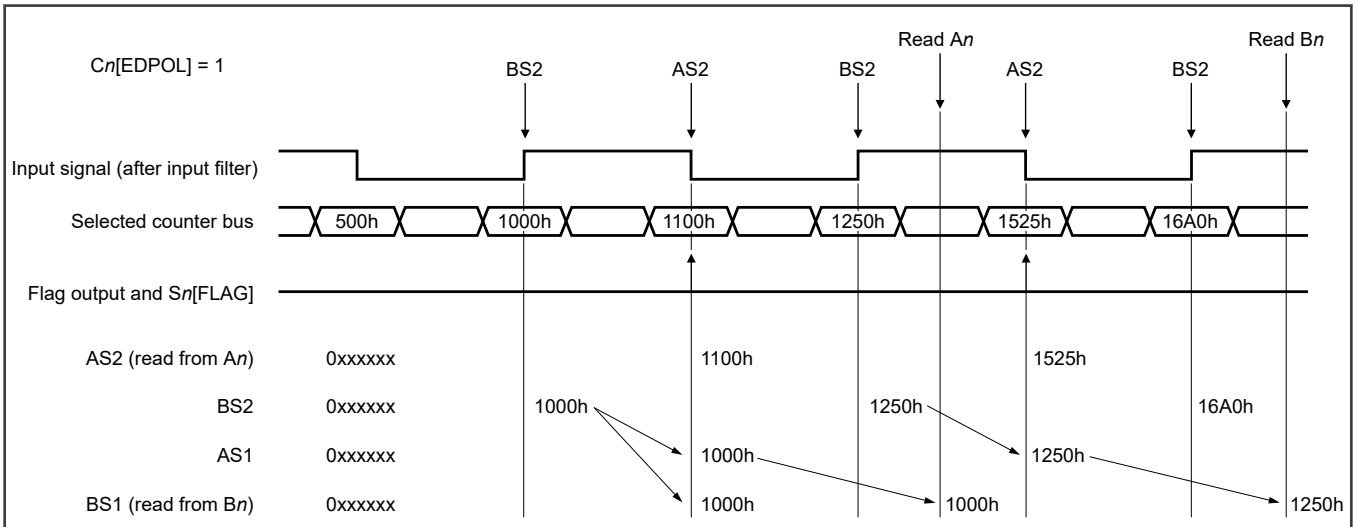

**Figure 303. Timing example: BS1 and AS1 updates on channel reads**

### 60.5.3.11 Input Period Measurement (IPM) Mode

#### 60.5.3.11.1 Overview

This mode allows you to measure the period of an input signal. Select whether to measure from the rising or falling edges with Edge Polarity (C*n*[EDPOL]).

The first edge of selected polarity:

- Latches the selected timebase into AS2 and BS2 (see AS1, AS2, BS1, and BS2 shadow registers)
- Transfers BS2 to BS1
- Does not set the input-capture flag (S*n*[FLAG])

The second edge of the same polarity:

- Latches the counter bus value into AS2 and BS2
- Transfers BS2 to BS1 and AS1
- Sets the input-capture flag (S*n*[FLAG])

eMIOS repeats this process for each subsequent capture.

eMIOS captures successive values on two consecutive edges of the same polarity. The measured input signal must have a period of at least four system clock cycles to be properly captured by the synchronization logic at the channel input, even if the input filter is in bypass mode.

#### 60.5.3.11.2 Coherency

Reading A*n*[A] updates BS1 with AS1, which provides coherent data in AS2 and BS1 (see Timing example: AS1 and BS1 updates on channel reads). It also disables transfers from BS2 and BS1 until the next read of B*n*[B].

Reading B*n*[B] updates BS1 with AS1. It also re-enables transfers from BS2 to BS1, which takes effect at the next edge capture.

#### 60.5.3.11.3 Timing example: measure input period

This example illustrates how to measure the input period by subtracting BS1 from AS2.

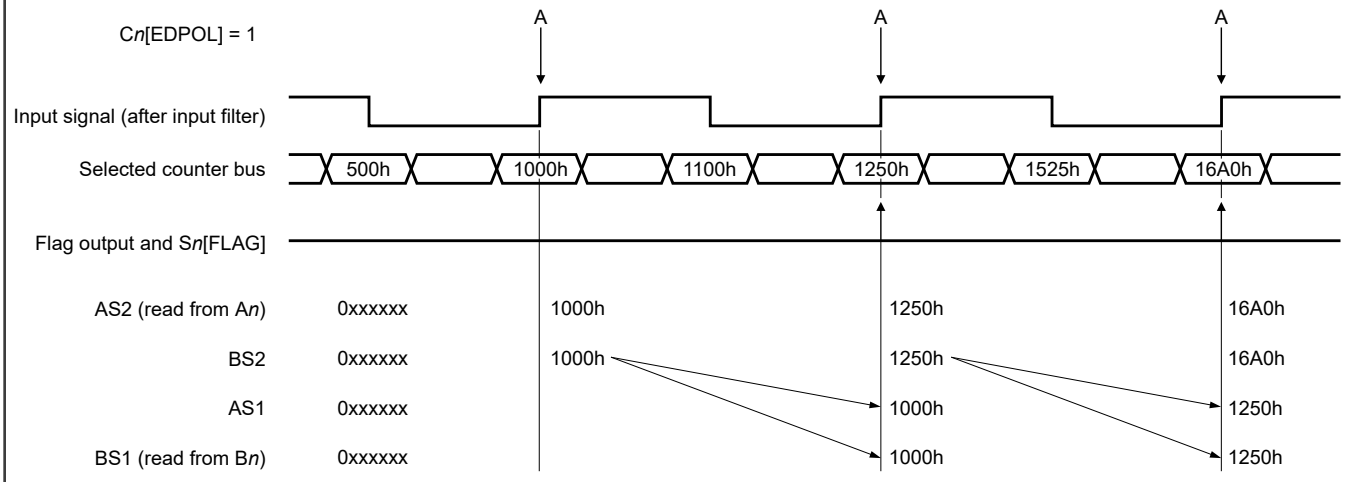

**Figure 304. Timing example: measure input period**

#### 60.5.3.11.4 Timing example: AS1 and BS1 updates on channel reads

This diagram illustrates AS1 and BS1 updates when you read A*n*[A] and B*n*[B].

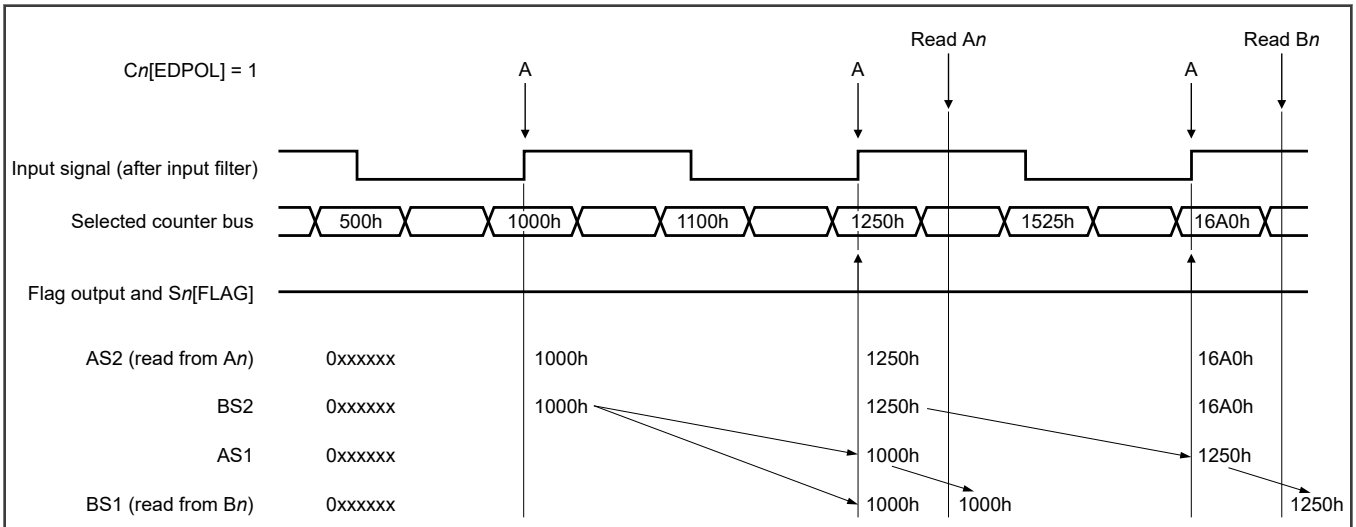

**Figure 305. Timing example: AS1 and BS1 updates on channel reads**

### 60.5.3.12 Double Action Output Compare (DAOC) mode

#### 60.5.3.12.1 Overview

In this mode, matches on comparators A and B cause the UC to generate the leading and trailing edges of the variable pulse width output. See DAOC submodes and MODE field values. There is no restriction on the order in which A and B matches occur.

When the UC enters DAOC mode from GPIO mode, eMIOS disables both comparators and drives the complement of Edge Polarity (C*n*[EDPOL]) onto the output flip-flop.

#### 60.5.3.12.2 DAOC submodes and MODE field values

Table 333. DAOC submodes and MODE field values

| When set flag event occurs | C*n*[MODE] (binary) |
|---|---|
| Only on B matches | 000_0110 |
| On A or B matches | 000_0111 |

#### 60.5.3.12.3 Data transfer and compare

If you enable output (write 0 to OUDIS[OU*n*]), on the next clock cycle the UC transfers AS2 and BS2 to AS1 and BS1 respectively (see Timing example: leading dead time insertion). If you disable output (write 1 to OUDIS[OU*n*]), no transfer occurs.

eMIOS enables and disables the A and B comparators independently. It enables comparator A only after the transfer to AS1 completes, and disables comparator A on the next A match. Similarly, eMIOS enables comparator B only after the transfer to BS1 completes, and disables comparator B on the next B match.

When a match occurs on comparator A, the output flip-flop acquires the value of Edge Polarity (C*n*[EDPOL]). When a match occurs on comparator B, the output flip-flop acquires the complement of Edge Polarity (C*n*[EDPOL]).

#### 60.5.3.12.4 Differences between flag on A match and flag on A and B matches

In the flag on B match submode (see DAOC submodes and MODE field values), the UC sets the input-capture flag (S*n*[FLAG]) only for matches on the B comparator. In the flag on both A and B matches submode, it sets the flag for matches on either comparator.

If subsequent enabled output compares occur on AS1 or BS1, the UC continues generating pulses regardless of the flag state.

If you load both AS1 and BS1 with the same value, the B match takes precedence and the UC drives the complement of Edge Polarity (C*n*[EDPOL]) onto the output flip-flop.

#### 60.5.3.12.5 Forced operation by Cn[FORCMA] and Cn[FORCMB]

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to the comparator, Edge Polarity (C*n*[EDPOL]) for an A match, or the complement of Edge Polarity for a B match. The force-match operations do not set the input-capture flag (S*n*[FLAG]).

#### 60.5.3.12.6 Timing example: flag on both matches

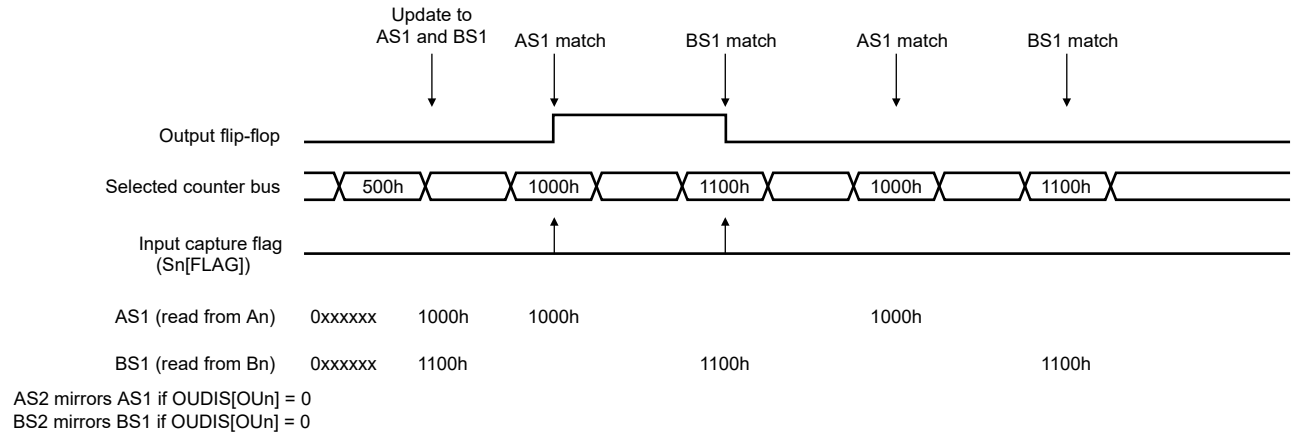

Figure 306. Timing example: flag on both matches

### 60.5.3.12.7 Timing example: flag on second match

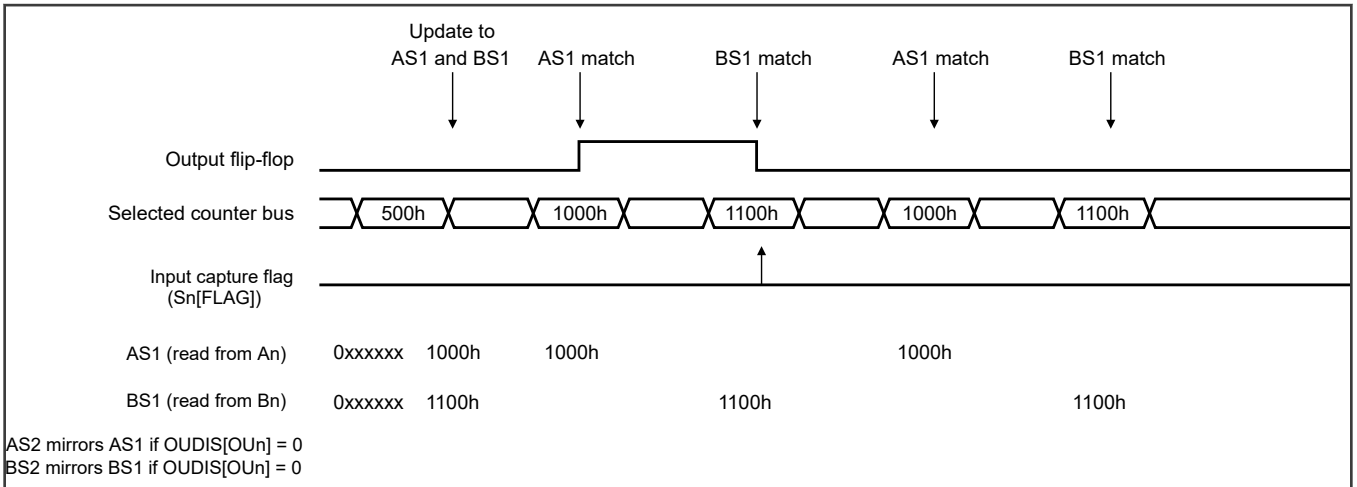

Figure 307. Timing example: flag on second match

### 60.5.3.12.8 Timing example: transfer disabling

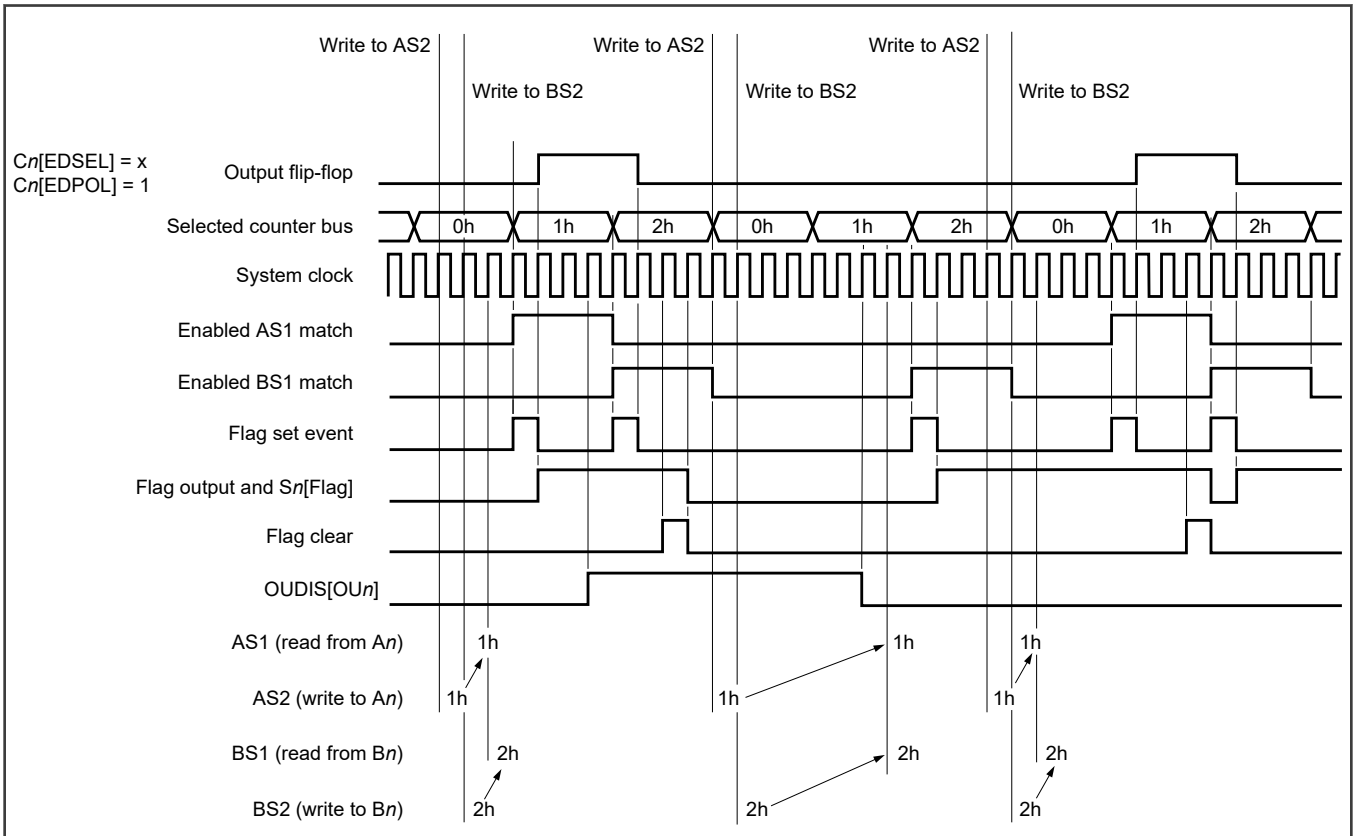

Figure 308. Timing example: transfer disabling

### 60.5.3.13 Pulse Edge Counting (PEC) mode

#### 60.5.3.13.1 Overview

This mode counts the number of pulses or edges detected on the input for a desired time window. C*n*[EDSEL] and C*n*[EDPOL] determine which edges the UC counts.

Specify the window start time in AS1 and the end time in BS1. After you write to AS1, when the selected timebase matches comparator A, eMIOS resets the internal counter and starts counting input events. When the timebase matches comparator B, eMIOS:

- Disables the internal counter.
- Transfers the counter's content to AS2.
- Sets the input-capture flag (changes S*n*[FLAG] to 1).

You obtain the number of detected pulses by reading C*n*[C] or AS2.

Timing example continuous and Timing example single-shot show how to use the UC in continuous or single-shot operation.

#### 60.5.3.13.2 PEC submodes and MODE field values

**Table 334. PEC submodes and MODE field values**

| Operation | C*n*[MODE] (binary) |
|---|---|
| Continuous; the next match between comparator A and the selected timebase resets the internal counter and enables counting again. To guarantee coherent measurements when you read C*n*[C] after S*n*[FLAG] becomes 1, you must check if the timebase value is out of the time interval defined by AS1 and BS1. Alternately, AS2 (available in ALTA*n*[ALTA]) always holds the latest available measurement, providing coherent data at any time after the first set-flag event. | 000_1010 |
| Single-shot; The next match between comparator A and the selected timebase has no effect until you write to A*n*[A]. eMIOS also transfers the C*n*[C] value to AS2 when a match in the B comparator occurs. | 000_1011 |

#### 60.5.3.13.3 Timing example continuous

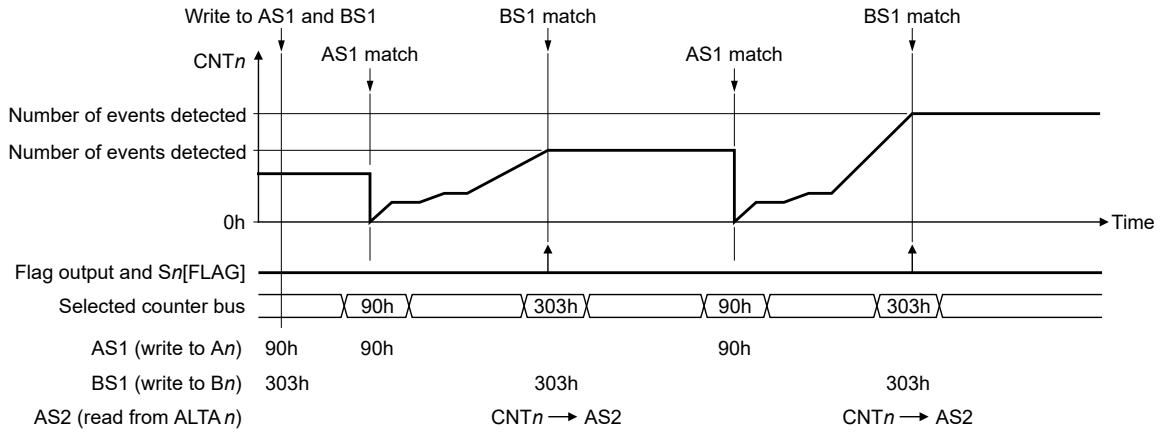

**Figure 309. Timing example continuous**

#### 60.5.3.13.4 Timing example single-shot

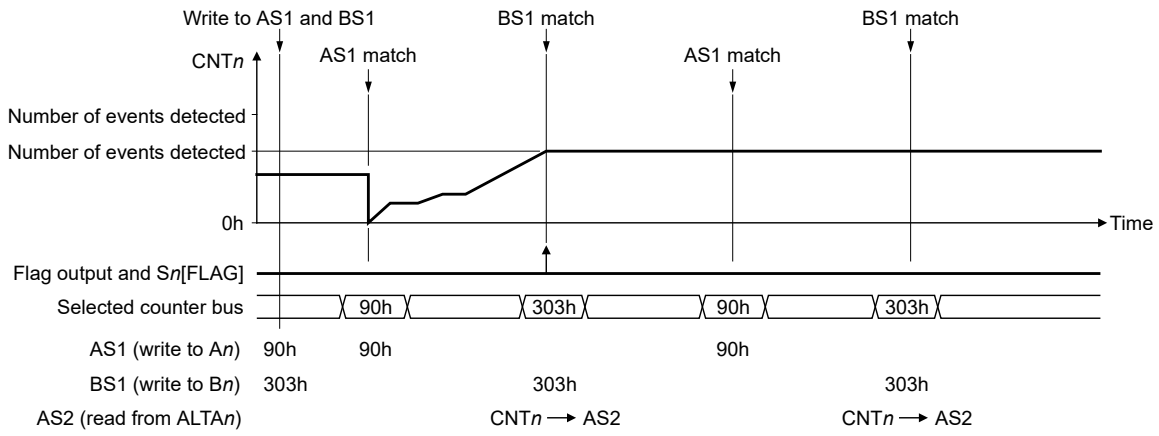

**Figure 310. Timing example single-shot**

### 60.5.3.14 Modulus Counter (MC) mode

#### 60.5.3.14.1 Overview

In this mode, the UC produces a timebase for a counter bus or as a general purpose timer. The internal counter (C*n*[C]) counts up from the current value until it matches AS1.

Selecting external clock source (see MC submodes and MODE field values) causes the UC to uses the input signal pin as the source. You select the triggering polarity edge using Edge Polarity (C*n*[EDPOL]) and Edge Select (C*n*[EDSEL]).

You must write only non-zero values to A*n*[A]. Writing to A*n*[A] or the internal counter may cause a match to be missed and the counter to roll over and resume operation in the next cycle. The channel writes 0 to BS1, which is not accessible by the MCU. You can read and write BS2, but it is not used in this mode.

#### 60.5.3.14.2 MC submodes and MODE field values

**Table 335. MC submodes and MODE field values**

| Submode or function | C*n*[MODE] (binary) |
|---|---|
| Internal clock source | 001_0pp0[1] |
| External clock source | 001_0pp1[1] |
| Internal counter reset on match start | 001_0p0p[1] |
| Internal counter reset on match end | 001_0p1p[1] |
| Up Count | 001_00pp[1] |
| Up Count-Down Count | 001_01pp[1] |

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

### 60.5.3.14.3 Up Count submode

**Table 336. Up Count submode operation**

| Counter reset timing[1] | C*n*[MODE] | | |
|---|---|---|---|
| | Bit 1 | External clock (Bit 0 = 1) | Internal clock (Bit 0 = 0) |
| Reset on match start | 0 | When the AS1 match occurs, the UC:<br>• Writes 0 to the internal counter.<br>• Sets the input-capture flag (S*n*[FLAG]).<br>• Increments the internal counter at the next input event, resulting in a short zero count. | When the AS1 match occurs, the UC:<br>• Writes 0 to the internal counter.<br>• Sets the input-capture flag (S*n*[FLAG]).<br>• Maintains the internal counter at 0 on the next prescaler tick after the match.<br>• Resumes counting on the next prescaler tick. |
| | | See Timebase with the fastest prescaler ratio and Timebase generation with clear on match start and internal clock. | |
| Clear on match end | 1 | When the next input event after the AS1 match occurs, the UC:<br>• Writes 0 to the internal counter.<br>• Sets the input-capture flag (S*n*[FLAG]). | When the next internal counter tick after the AS1 match occurs, the UC:<br>• Writes 0 to the internal counter.<br>• Sets the input-capture flag (S*n*[FLAG]). |
| | | See Timebase with the fastest prescaler ratio and Timebase generation with clear on match end. | |

1. If you select internal clock source and a prescaler value of 1 for the internal counter, the behavior is the same for both submodes.

See Timing example: Up Count submode.

### 60.5.3.14.4 Timing example: Up Count submode

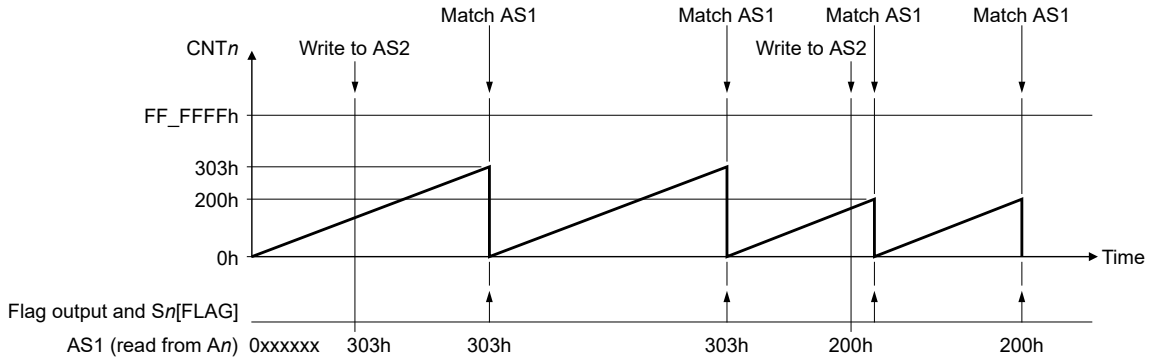

**Figure 311. Timing example: Up Count submode**

### 60.5.3.14.5 Up Count-Down Count submode operation

In Up Count-Down Count submode:

- When the internal counter matches AS1, the counter begins decrementing and the UC sets the input-capture flag (S*n*[FLAG]).
- When the internal counter matches BS1, the counter begins incrementing and, if in clear on match end operation (C*n*[1] = 1), the UC sets the input-capture flag (S*n*[FLAG]).

See Timing example: Up Count-Down Count submode.

### 60.5.3.14.6 Timing example: Up Count-Down Count submode

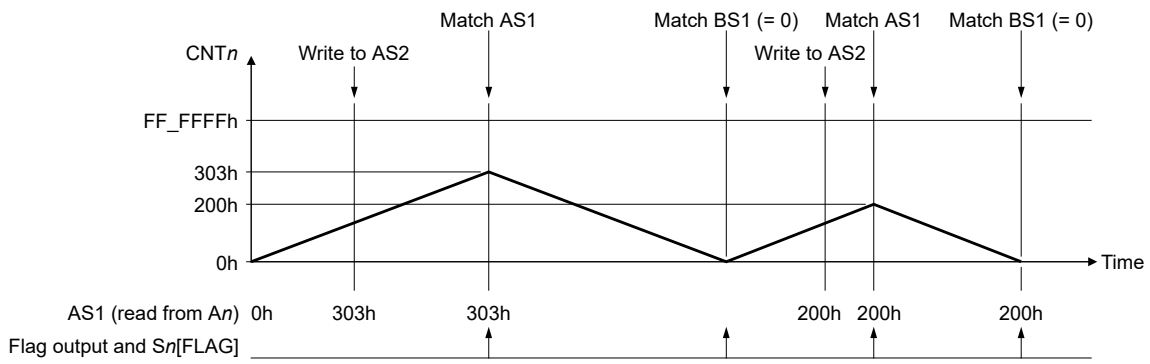

**Figure 312. Timing example: Up Count-Down Count submode**

### 60.5.3.14.7 Up Count with delayed reload operation

When the internal counter matches AS1 in the Up Count submode or BS1 in the Up Count-Down Count submode, the UC asserts the counter bus reload signal. You can read the counter bus reload signal in the following modes:

- Output PWM Buffered (OPWMB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode

You can use the Reload Signal Output Delay Interval (C2*n*[UCRELDEL_INT]) to cause the UC to assert the reload signal only after a specified number of match events (from 2 to 32).

See Timing example: Up Count mode with delayed reload.

#### 60.5.3.14.8 Timing example: Up Count mode with delayed reload

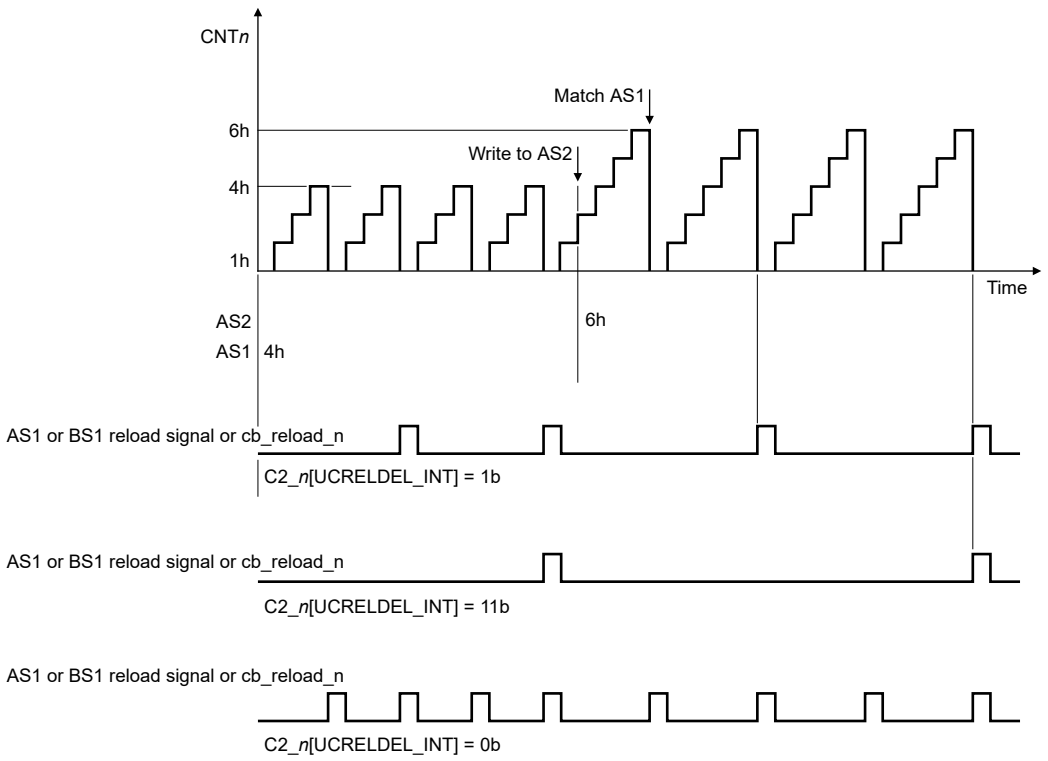

**Figure 313. Timing example: Up Count mode with delayed reload**

### 60.5.3.15 Modulus Counter Buffered (MCB) mode

#### 60.5.3.15.1 Overview

In this mode, the UC generates a timebase that can be shared with other channels through the internal counter buses. AS1 is double-buffered, so you can change AS2 at any time with smooth transitions. The UC updates AS1 at the counter period boundary, which is when the internal counter (CNT*n*[C]) transitions to 1h.

Selecting external clock (see MCB submodes and MODE field values) causes the UC to use the input signal as the source. You select the triggering edge with Edge Polarity (C*n*[EDPOL]) and Edge Select (C*n*[EDSEL]).

You must ensure the internal counter is in the range from 1h to the AS1 value; otherwise, the A*n*[A] match does not occur and this causes the internal counter to wrap at the maximum counter value (FFFFh for a 16-bit counter). After a counter wrap occurs, the UC resets the counter to 1h and resumes normal operation.

**NOTE**

Do not write 1h to the internal counter when the UC is in Freeze state. Doing so can cause the match to be missed and the counter to overflow.

#### 60.5.3.15.2 Changing to MCB mode

To avoid causing an unexpected interrupt or DMA request, you must use the following procedure to change to MCB mode:

1. Put the UC in GPIO mode (write 0b or 1b to C*n*[MODE]).
2. Disable the UC input capture flag (write 0 to C*n*[FEN]).
3. Write the correct values for MCB mode to A*n* and B*n*.

4. Put the UC in MCB mode (write the appropriate value to C*n*[MODE], as described in MCB submodes and MODE field values).
5. Clear the UC input capture flag (write 1 to S*n*[FLAG]).
6. Enable the UC input capture flag (write 1 to C*n*[FEN]).

### 60.5.3.15.3 MCB submodes and MODE field values

**Table 337. MCB submodes and MODE field values**

| Submode or function | C*n*[MODE] (binary) |
|---|---|
| Internal clock source | 101_0pp0b[1] |
| External clock source | 101_0pp1b[1] |
| Up Count | 101_000p[1] |
| Reserved | 101_001p[1] |
| Up Count-Down Count | 101_01pp[1] |
| Flag set only on match start | 101_010p[1] |
| Flags also set at counter period boundary | 101_011p[1] |

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

### 60.5.3.15.4 Up Count submode

In the Up Count submode:

- The internal counter (CNT*n*[C]) starts counting up (incrementing) from its current value.
- When the internal counter matches AS1 and a clock tick occurs (either prescaled clock or input pin event), the UC resets the internal counter to 1h.
- The UC sets the input-capture flag (S*n*[FLAG]) one system clock cycle after the match occurs.

You must write only values greater than 1h to AS1.

The boundary between counter period *n* and period *n*+1 occurs when the UC changes the internal counter from the AS1 value in period *n* to 1h in period *n*+1. AS1 defines the counter period.

The UC asserts the AS1 load signal (which has a duration of one system clock cycle) at the last system clock cycle of a counter period. This causes the UC to update AS1 with AS2 at the period boundary, at the same time that it resets the counter to 1h. Therefore, any value you write to AS2 during period *n* updates AS1 at the next period boundary and the UC uses it in period *n*+1. See Timing example: Up Count submode.

You can use Output Update Disable (OUDIS) to delay the update of AS1 for synchronization.

The UC sets the input-capture flag (S*n*[FLAG]) at the period boundary. See Timing example: Up Count submode flag assertion.

### 60.5.3.15.5 Timing example: Up Count submode

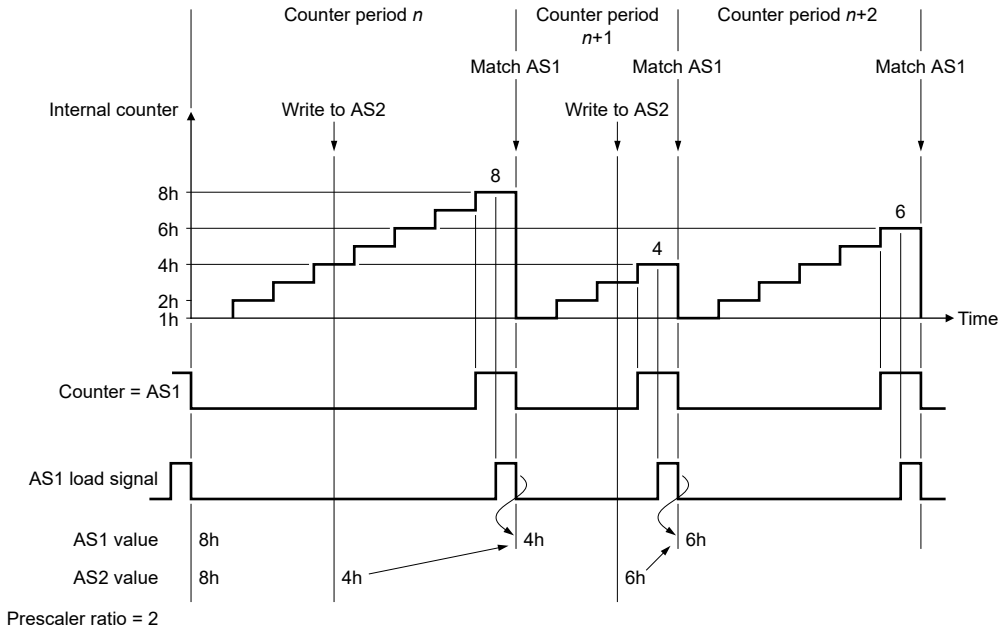

Figure 314. Timing example: Up Count submode

### 60.5.3.15.6 Timing example: Up Count submode flag assertion

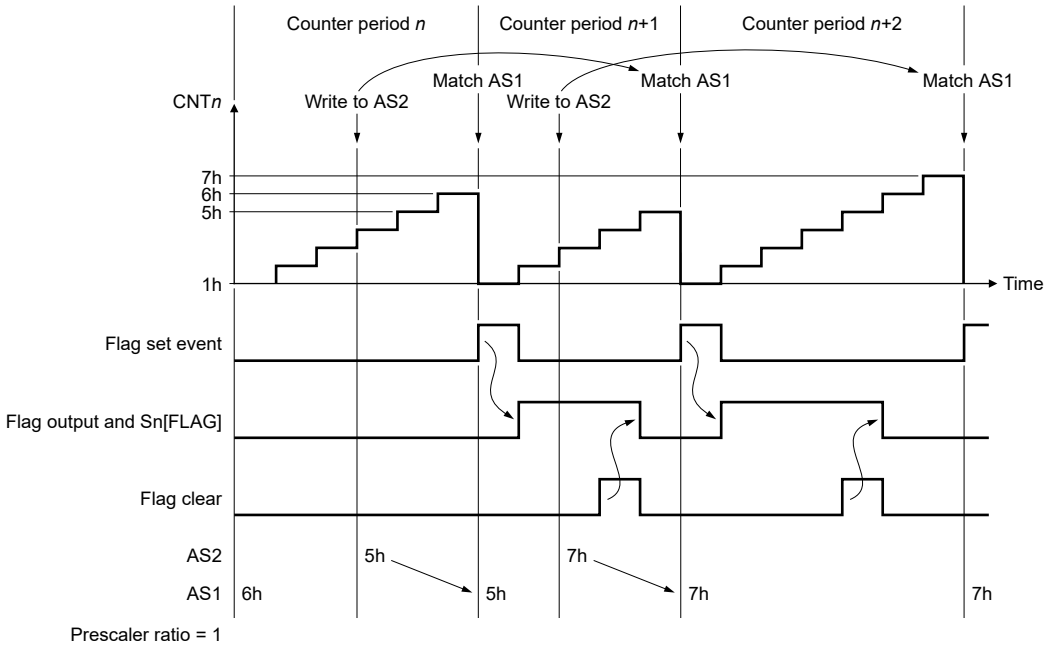

Figure 315. Timing example: Up Count submode flag assertion

### 60.5.3.15.7 Up Count-Down Count submode

In Up Count-Down Count submode:

- The counter period is: (2 x AS1) – 2. The counter changes direction at AS1 match and counts down (decrements) until it reaches 1h, then counts up (increments) again.
- BS1 generates a match to start the internal counter incrementing, and BS1 cannot be changed in this submode.

The UC updates AS1 at the counter period boundary. If you write AS2 (write A*n*[A]) during period *n*, the UC uses this new value in period *n*+1 for AS1 match. You can disable updates of AS1 (OUDIS[OU*n*]). See Timing example: Up Count-Down Count submode.

The UC sets the input-capture flag (S*n*[FLAG]) at AS1 match start, and may also do so at the period boundary. See Overview and Timing example: Up Count-Down Count submode flag assertion.

### 60.5.3.15.8 Timing example: Up Count-Down Count submode

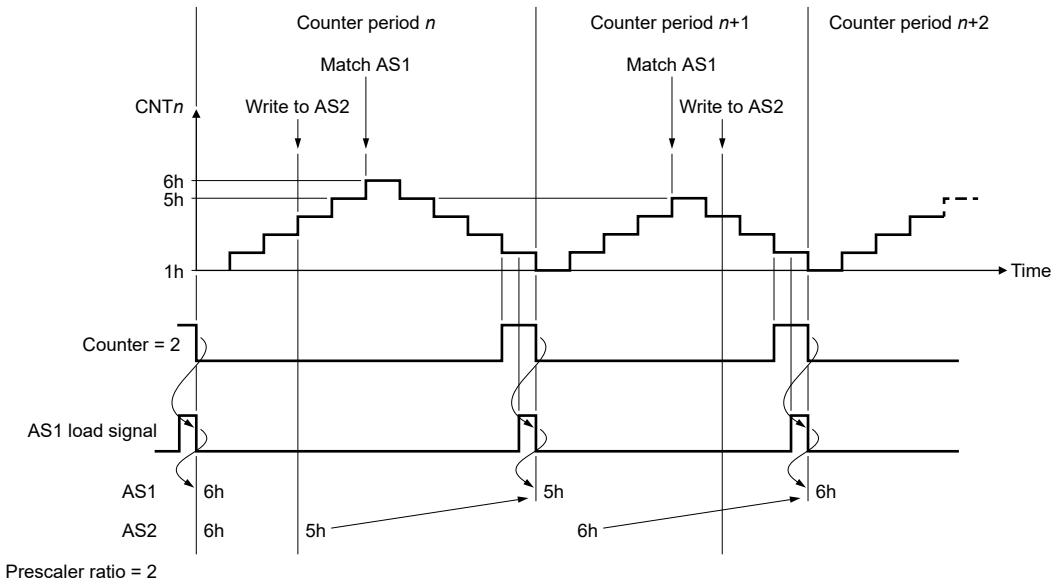

Figure 316. Timing example: Up Count-Down Count submode

### 60.5.3.15.9 Timing example: Up Count-Down Count submode flag assertion

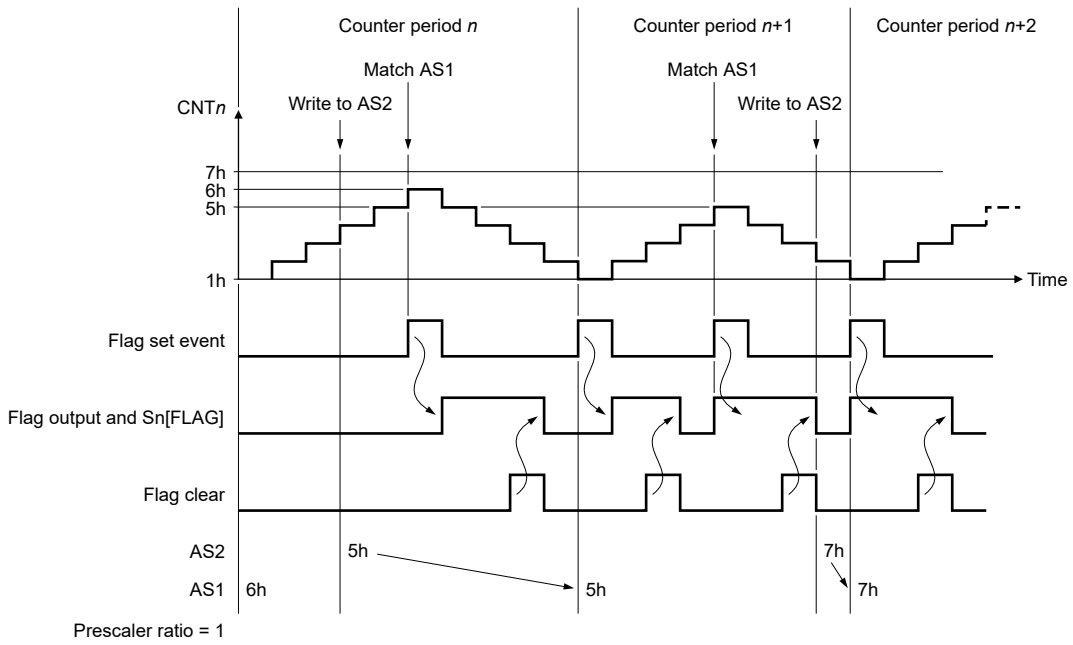

**Figure 317. Timing example: Up Count-Down Count submode flag assertion**

### 60.5.3.15.10 Up Count mode with delayed reload operation

When the internal counter matches AS1 in the Up Count submode or 1h in the Up Count-Down Count submode (see MCB submodes and MODE field values), the UC asserts the counter bus reload signal. You can read the counter bus reload signal in the following modes:

- Output PWM Buffered (OPWMB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode

You can use the Reload Signal Output Delay Interval (C2[UCRELDEL_INT]) to cause the UC to assert the reload signal only after a specified number of match events (from 2 to 32).

See Timing example: Up Count mode with delayed reload.

#### 60.5.3.15.11 Timing example: Up Count mode with delayed reload

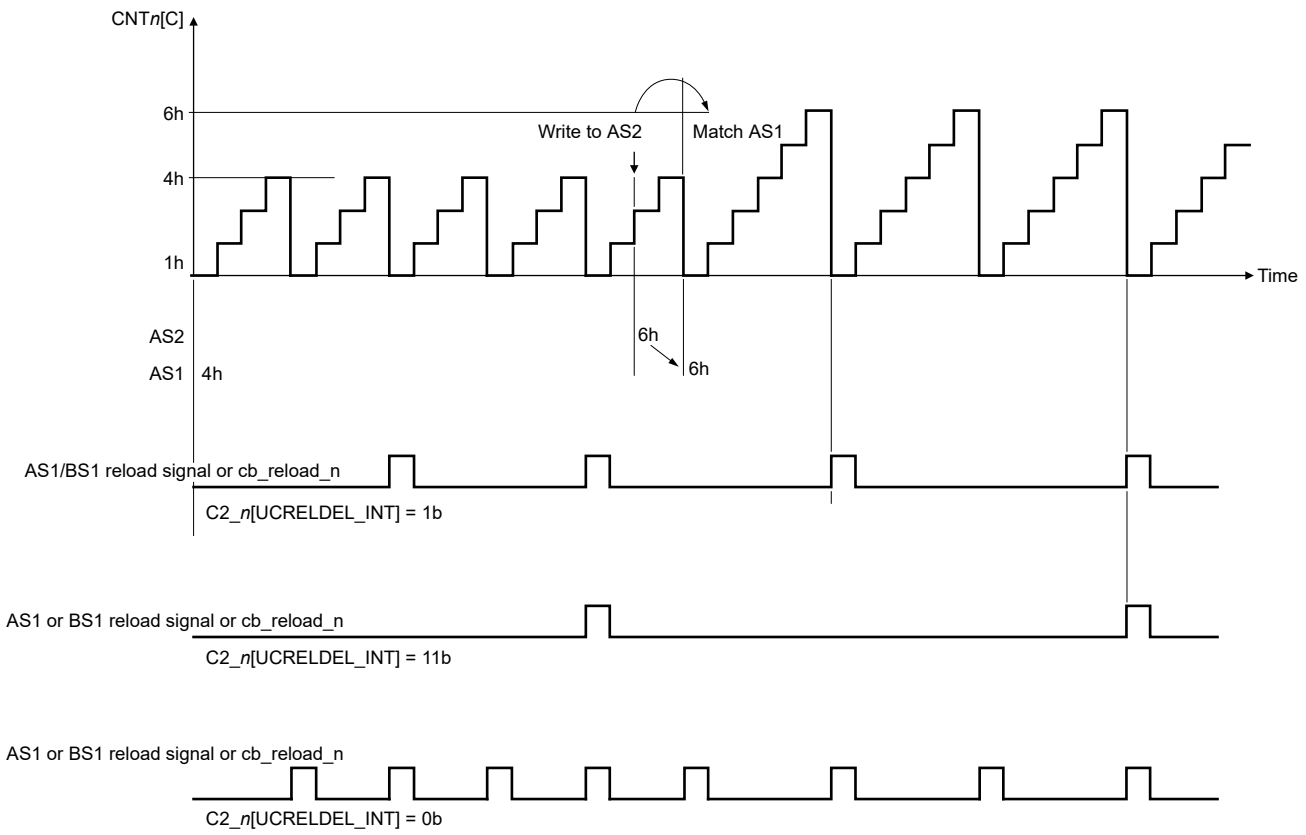

**Figure 318. Timing example: Up Count mode with delayed reload**

### 60.5.3.16 Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode

#### 60.5.3.16.1 Overview

In this mode, the UC produces an output signal that has:

- A duty cycle determined by AS1.
- A period of BS1.

The double-buffered AS1 and BS1 registers produce smooth duty-cycle and period transitions when you change AS1 and BS1 during runtime.

See Table 344 for the values that you must write to C*n*[MODE] to enter this mode.

To provide smooth and consistent channel operation:

- AS1 and BS1 are both double-buffered to allow smooth signal generation when changing the register values.
- There is a delay from the AS1 match to the output pin transition (see AS1 and BS1 match timing).
- The internal counter ranges from 1h to BS1. When you write to BS1, you must write only values greater than 1h. Writing 0h or 1h leads to unpredictable results.

When a match on comparator A occurs, the UC drives C*n*[EDPOL] onto the output flip-flop. When a match on comparator B occurs, the UC drives the complement of C*n*[EDPOL] onto the output flip-flop. A BS1 match also causes the internal counter to transition to 1h, thus restarting the counter cycle.

The UC automatically selects the internal channel counter as the timebase when you select this mode. The mode supports duty cycles ranging from 0% to 100%.

#### 60.5.3.16.2 OPWFMB submodes and MODE field values

**Table 338. OPWFMB submodes and MODE field values**

| Match behavior | C*n*[MODE] (binary) |
|---|---|
| When BS1 matches the selected counter | 101_1000 |
| When AS1 or BS1 match the selected counter | 101_1010 |

#### 60.5.3.16.3 Avoid counter wrapping

When the UC enters OPWFMB mode, the output flip-flop acquires the value of C*n*[EDPOL]. If the UC transitions from GPIO to OPWFMB mode when the internal counter value is not within the range 1h–BS1, then the B match never occurs. Because the match never occurs, the internal counter wraps at the maximum counter value—FFFFh for a 16-bit counter. When the counter wrap occurs, the counter returns to 1h and normal OPWFMB operation resumes. Therefore, to avoid this counter wrapping, ensure that the counter value is within the range 1h–BS1 before the UC enters OPWFMB mode.

#### 60.5.3.16.4 AS1 and BS1 match timing

As illustrated in Timing example: AS1 and BS1 match, the output pin transition occurs when the AS1 or BS1 match signal deasserts, as indicated by the AS1 match negative-edge detection signal. If you write 4h to AS1, the output pin transitions 4 counter increments plus one system clock cycle after the counter period starts.

#### 60.5.3.16.5 Timing example: AS1 and BS1 match

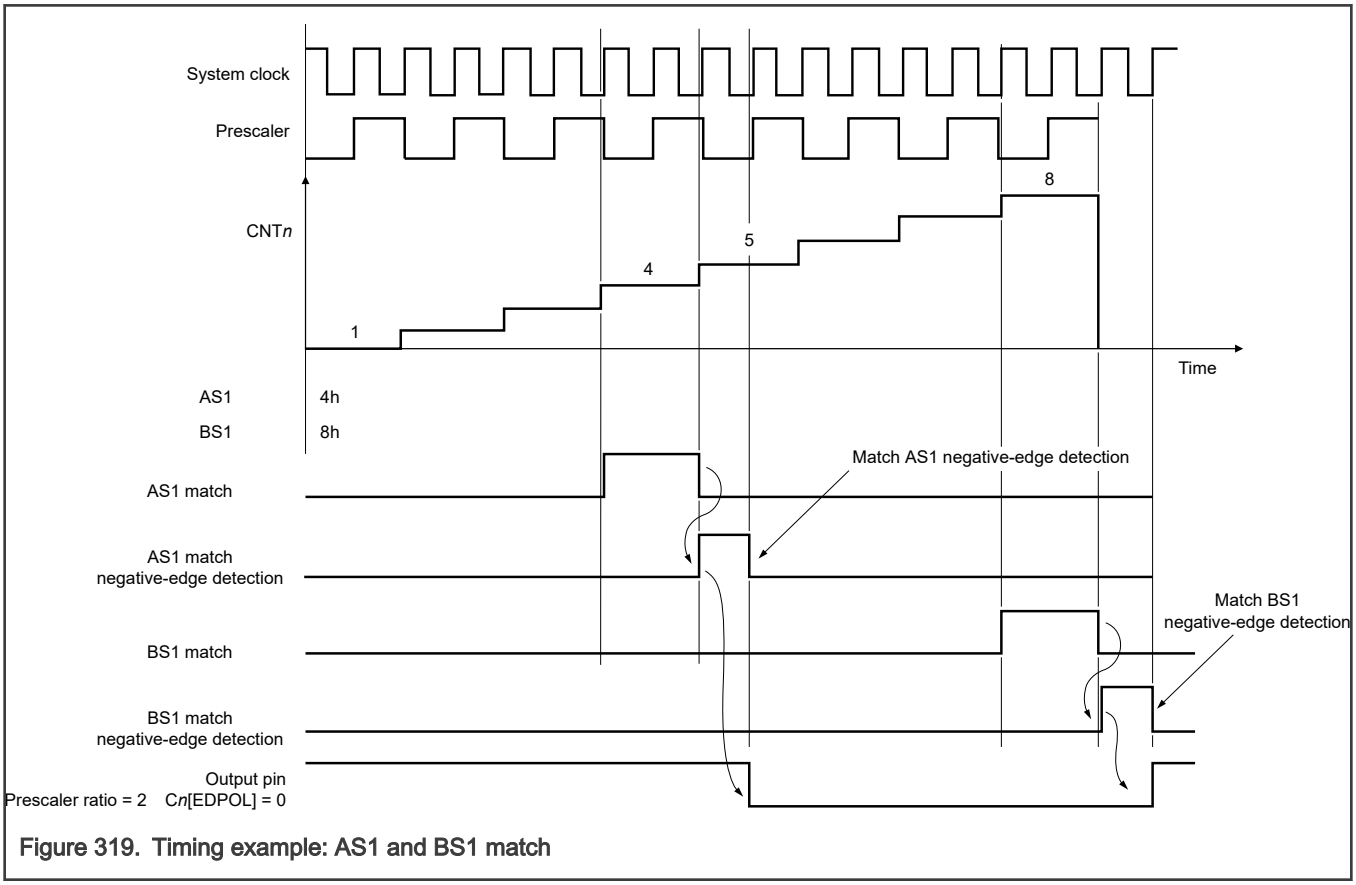

**Figure 319. Timing example: AS1 and BS1 match**

### 60.5.3.16.6 0% duty cycle

Timing example: AS1 = 0 illustrates the generated output signal when AS1 = 0, which results in a 0% duty cycle.

Because the internal counter never reaches zero in this situation, the UC infers a match as if AS1 = 1h. However, it is the positive edge of the match signal that triggers the output pin transition instead of the negative edge, which is what happens when AS1 = 1h. The AS1 positive-edge match signal from period *n*+1 occurs at the same time as the BS1 negative-edge match signal from period *n*. This timing allows the AS1 positive-edge match to mask the BS1 negative-edge match when they occur at the same time. As a result, no transition occurs on the output flip-flop and the UC generates a 0% duty cycle.

### 60.5.3.16.7 Timing example: AS1 = 0

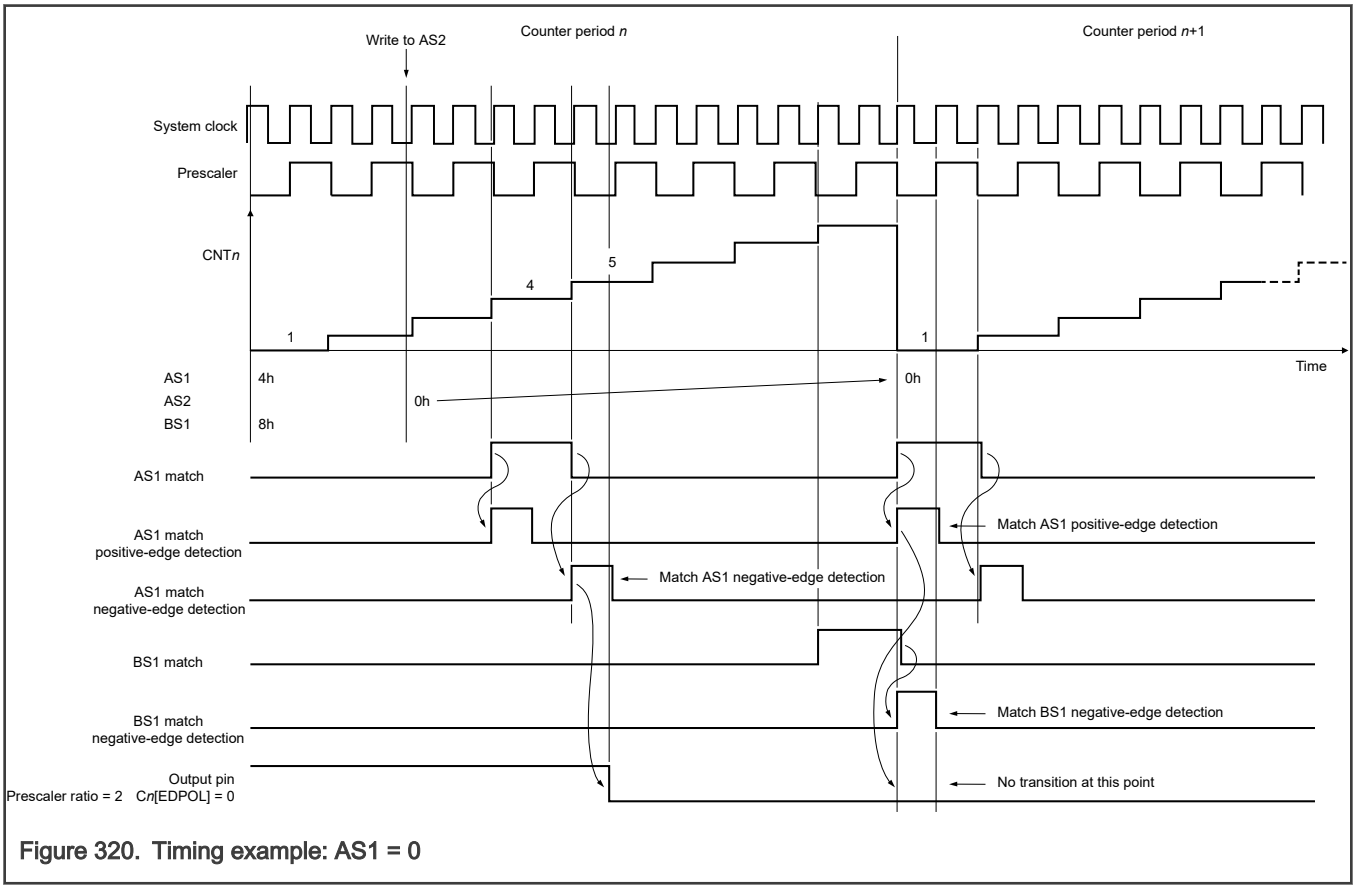

Figure 320. Timing example: AS1 = 0

### 60.5.3.16.8 Loading AS1 and BS1

As illustrated in Timing example: AS1 and BS1 update and FLAGs, AS1 and BS1 both use the same signal, generated at the last system clock cycle of a counter period. Therefore, eMIOS updates AS1 and BS1 with AS2 and BS2 values, respectively, at the same time that it changes the internal counter (CNT*n*[C]) to 1h. This event is the counter period boundary. The load signal pulse lasts for one system clock cycle. If you write AS2 and BS2 within counter period *n*, their values are available in AS1 and BS1, respectively, at the first clock cycle of counter period *n*+1. The UC then uses these new values for matches at counter period *n*+1. You can use Output Update Disable (OUDIS) to delay updating AS1 and BS1 for synchronization purposes.

### 60.5.3.16.9 Timing example: AS1 and BS1 update and FLAGs

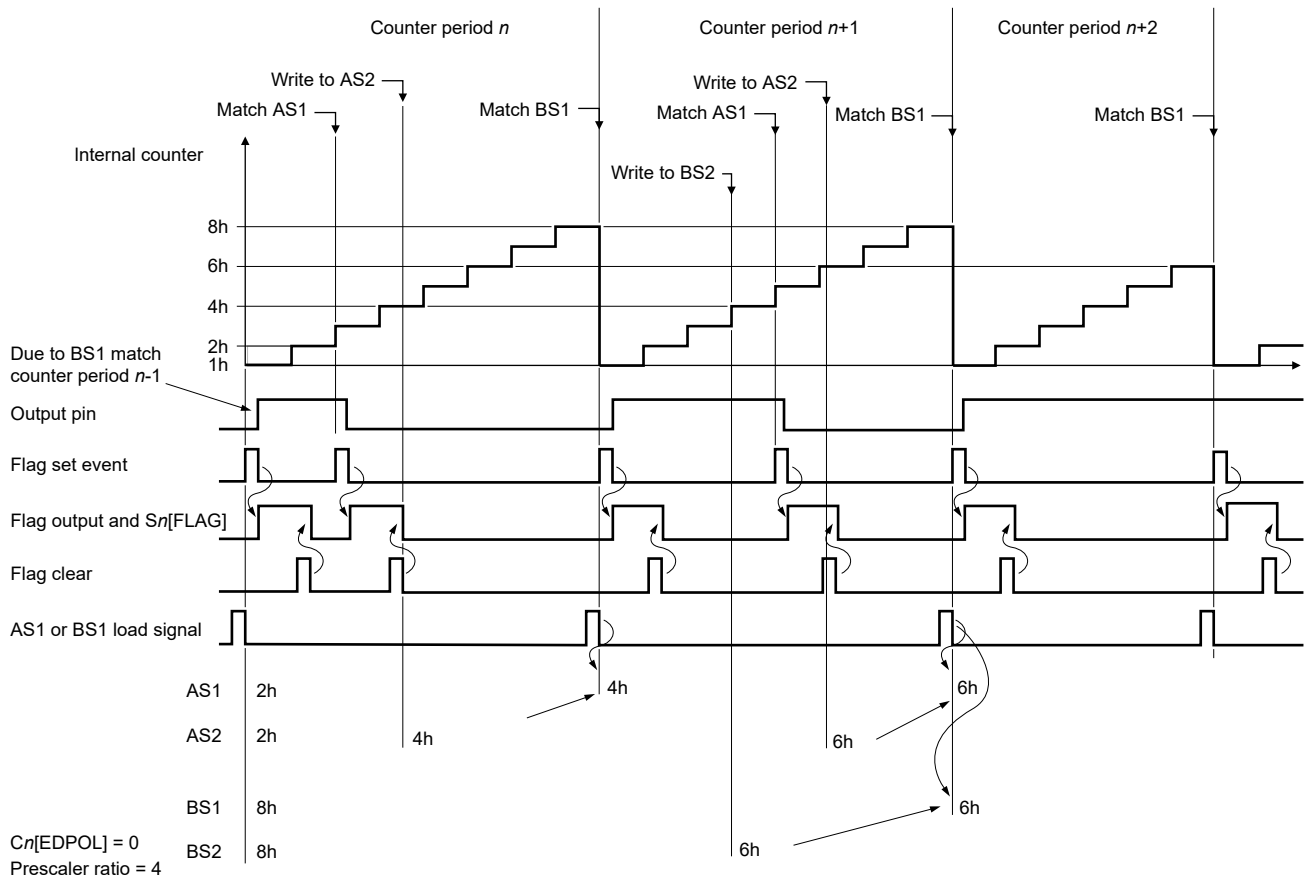

Figure 321. Timing example: AS1 and BS1 update and FLAGs

### 60.5.3.16.10 Flag generation

Timing example: AS1 and BS1 update and FLAGs assumes that both the channel and global prescalers are 1h (divide ratio of 2), causing the internal counter to transition every four system clock cycles. You can configure flags to be generated only on BS1 matches when bit 1 of C*n*[MODE] is 0, or on both AS1 and BS1 matches when that bit is 1. Because the BS1 flag occurs at the period boundary, you can use this flag to indicate that the AS2 or BS2 data written in period *n* has been loaded to AS1 or BS1, respectively, thereby generating matches in period *n*+1. Flag operation is synchronous, which means the flag sets one system clock cycle after the set-flag event.

### 60.5.3.16.11 Output disable

As illustrated in Timing example: active output disabled, the output-disable feature in OPWFMB mode forces the channel output flip-flop to the value of C*n*[EDPOL]. This functionality supports applications that use active-high signals and a high-to-low transition at an AS1 match. In this case, you must write 0 to C*n*[EDPOL]. You also must configure the internal counter to transition on every system clock cycle (write 0 to both GCP and CP).

The output-disable feature operates synchronously, meaning that the assertion of the Output Disable input signal causes the channel output flip-flop to transition to C*n*[EDPOL] at the next system clock cycle. If the Output Disable input pin deasserts, the output-signal transition occurs at the next AS1 or BS1 match.

Timing example: active output disabled assumes that the Output Disable input is enabled (using C*n*[ODIS]) and selected (using C*n*[ODISSL]). See UC Control n (C0 - C23) for a detailed description of the ODIS and ODISSL fields that enable and select the Output Disable inputs, respectively.

### 60.5.3.16.12 Timing example: active output disabled

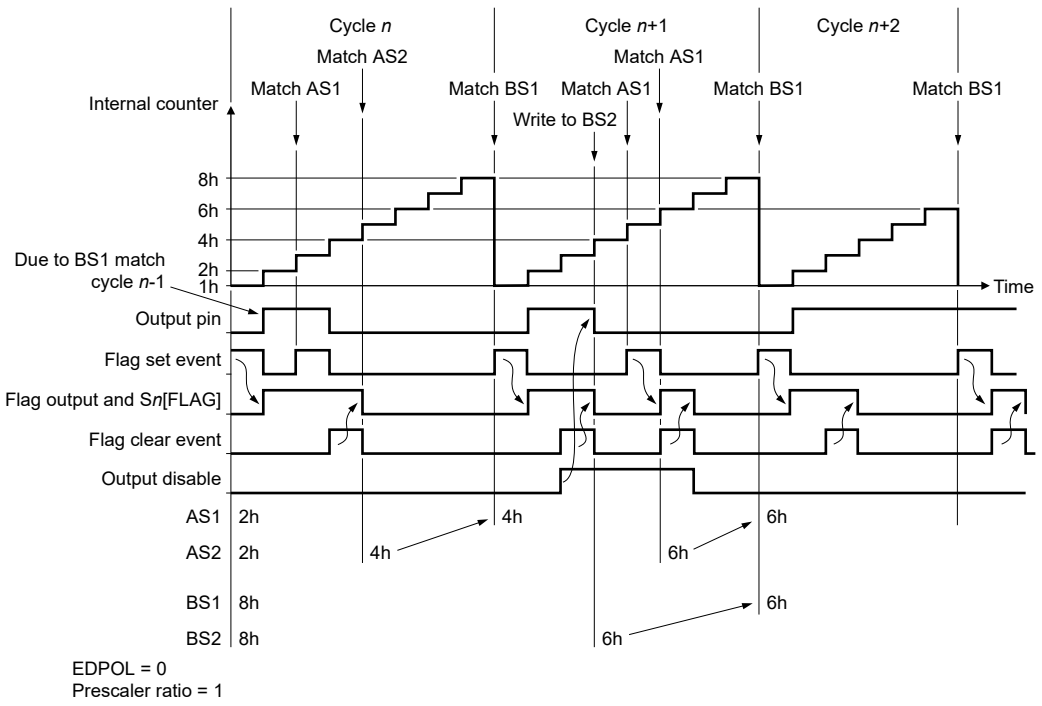

**Figure 322. Timing example: active output disabled**

### 60.5.3.16.13 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. Similarly to a BS1 match, Force Match B changes the internal counter to 1h. The force-match operations do not set the input-capture flag (S*n*[FLAG]).

### 60.5.3.16.14 100% and 0% duty cycles

Timing example: from 100% to 0% duty cycle illustrates the generation of 100% and 0% duty-cycle signals. Initially, AS1 = 8h and BS1 = 8h. In this case, a BS1 match has precedence over an AS1 match—therefore, the output flip-flop acquires the complement of C*n*[EDPOL]. This configuration corresponds to a 100% duty-cycle signal. The same output signal can be generated for any AS1 value greater than or equal to BS1.

If AS1 is 0, the UC generates a 0% duty-cycle signal. In this case, the BS1 = 8h match from period 8 occurs at the same time as the AS1 = 0h match from period 9. See Timing example: AS1 = 0 for AS1 and BS1 match generation. In this case, an AS1 match has precedence over a BS1 match, and the output signal transitions to C*n*[EDPOL].

#### 60.5.3.16.15 Timing example: from 100% to 0% duty cycle

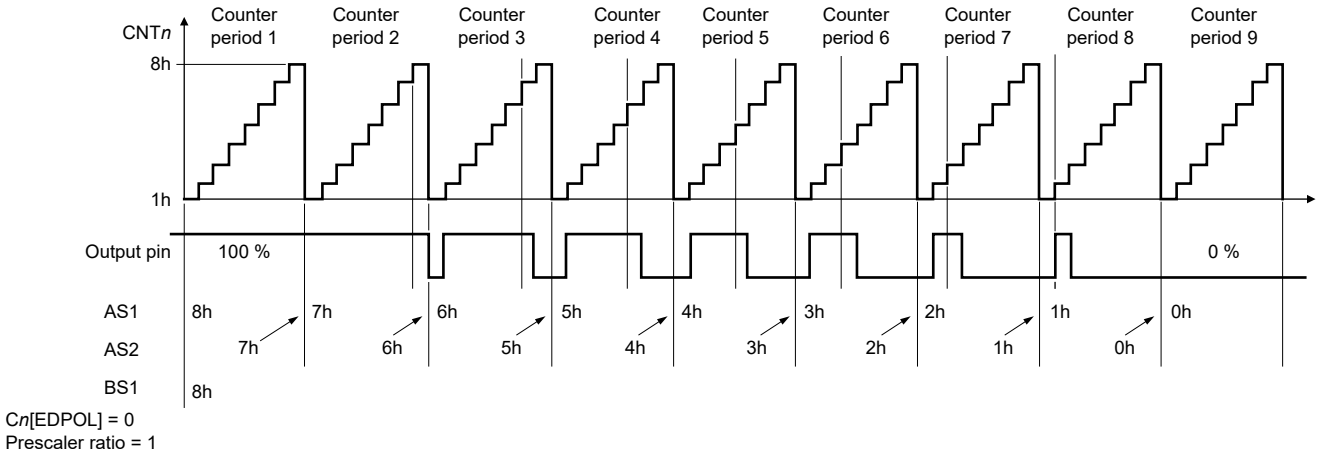

**Figure 323. Timing example: from 100% to 0% duty cycle**

### 60.5.3.17 Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode

#### 60.5.3.17.1 Overview

In this mode, the UC generates a center-aligned PWM pulse with dead time insertion in the leading or trailing edge. See OPWMCB functions and MODE field values. AS1 and BS1 are double-buffered to allow smooth output signal generation when you change the AS2 or BS2 values.

When the UC enters OPWMCB mode from GPIO mode:

- The UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Select the timebase using Bus Select (C*n*[BSL]). The timebase you select must be running in Up Count-Down Count mode. See Timing example: Up Count submode flag assertion. You must start the MCB timebase after the UC enters OPWMCB mode to avoid missing a match on the first duty cycle.
- Store the ideal duty cycle for the PWM signal in AS1 (write to A*n*[A]), which the UC compares with the selected timebase.
- Store the dead time value in BS1 (write to B*n*[B]), which the UC compares with the internal counter (CNT*n*[C]).

The internal counter may use the internal prescaler ratio, while the selected timebase may use a different prescaler ratio. The UC always resets the internal counter to 1h when an AS1 match occurs.

As in OPWMB and OPWFMB modes, the UC generates the match signal which compares the selected timebase with AS1 or BS1. When the UC deasserts the channel's combinational comparator output signal, it uses the match signal to assert or negate the channel's output flip-flop. See Timing example: AS1 and BS1 match for an illustration of the delay from match to output flip-flop transition in OPWFMB mode. The operation of OPWMCB mode is similar to OPWFMB mode with respect to match behavior and output pin transition.

See Entering OPWMCB mode.

#### 60.5.3.17.2 OPWMCB functions and MODE field values

**Table 339. OPWMCB functions and mode field values**

| Function | C*n*[MODE] (binary) |
|---|---|
| Insert trailing edge dead time with duty cycle determined by BS1 + AS1 | 101_11p0[1] |

*Table continues on the next page...*

Table 339. OPWMCB functions and mode field values (continued)

| Function | C*n*[MODE] (binary) |
|---|---|
| Insert leading edge dead time with duty cycle determined by BS1 – AS1 | 101_11p1[1] |
| Assert the input capture flag (Sn[FLAG]) on the trailing edge of the output PWM signal | 101_110p[1] |
| Assert the input capture flag (Sn[FLAG]) on both edges of the output PWM signal | 101_111p[1] |

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

#### 60.5.3.17.3 Entering OPWMCB mode

To enter OPWMCB mode (this procedure assumes the channel is initially in GPIO mode):

1. Disable the GCP (write 0 to MCR[GPREN]).
2. For the timebase (MCB) channel:
   a. Disable the CP (write 0 to C*n*[UCPREN]).
   b. Initialize the internal counter (write 1h to CNT*n*[C]).
   c. Initialize the A data (write appropriate value to A*n*[A]).
   d. Configure the UC for MCB Up Count-Down Count mode (write 101_01*xy*b to C*n*[MODE], where *x* = 0 for flag set on match start or *x* = 1 for flag set at period boundary, and *y* = 0 for internal clock source or *y* = 1 for external clock source).
   e. Select the CP ratio (C*n*[UCPRE]).
   f. Enable the CP (write 1 to C*n*[UCPREN]).
3. For the OPWMCB channel:
   a. Disable the CP (write 0 to C*n*[UCPREN]).
   b. Initialize the A data (write appropriate value to A*n*[A]).
   c. Initialize the B data (write appropriate value to B*n*[B]).
   d. Select the timebase input (C*n*[BSL]).
   e. Configure the UC for MCB Up Count-Down Count mode (write 101_01*xy*b to C*n*[MODE], where *x* = 0 for flag set on match start or *x* = 1 for flag set at period boundary, and *y* = 0 for internal clock source or *y* = 1 for external clock source).
   f. Select the CP ratio (C*n*[UCPRE]).
   g. Enable the CP (write 1 to C*n*[UCPREN]).
4. Enable the GPC (write 1 to MCR[GPREN]).

#### 60.5.3.17.4 Timing example: AS1 and BS1 load

When the selected counter bus transitions from 2h to 1h:

- The UC loads AS1 and BS1 as shown in the following figure.
- This event defines the counter period boundary.

The UC loads the values you write to AS2 or BS2 within period *n* into AS1 or BS1, respectively, and uses them to generate matches in period *n*+1.

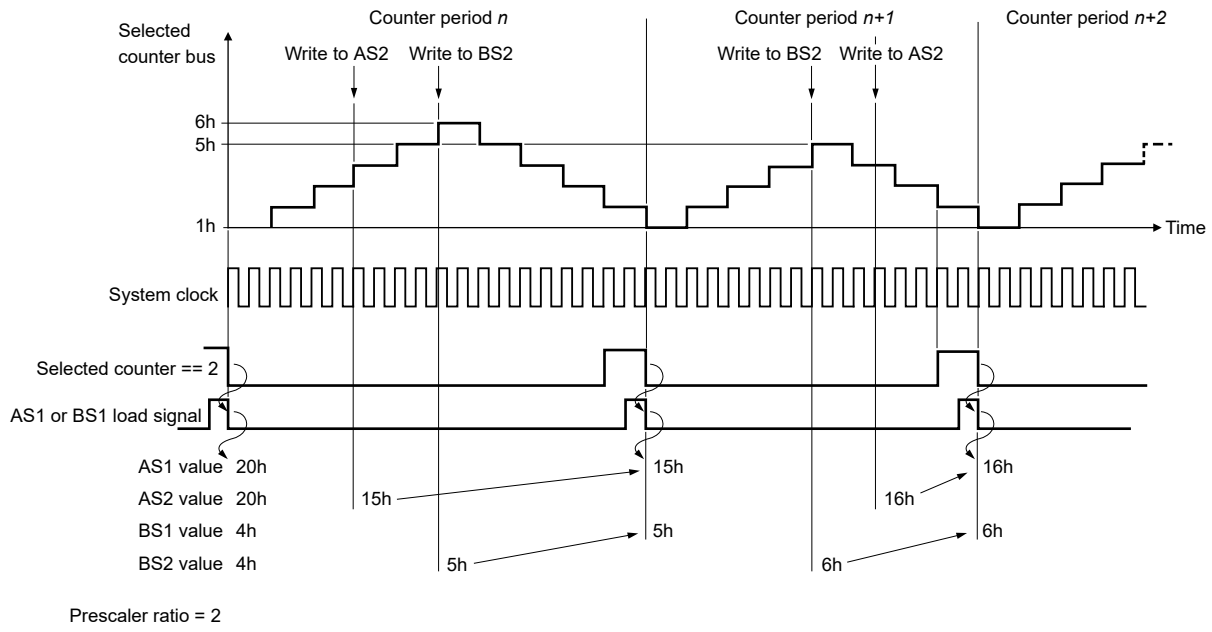

**Figure 324. Timing example: AS1 and BS1 load**

### 60.5.3.17.5 Operation sequence with leading edge dead time insertion

When operating with leading edge dead time insertion:

1. When the first AS1 match occurs, the UC writes 1h to the internal counter.
2. When a match between BS1 and the internal timebase occurs, the UC drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
3. When the next match between AS1 and the selected timebase occurs, the UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

The UC repeats the above sequence continuously.

You must not allow the internal counter to reach 0h as the result of a rollover. To avoid this, you must not write a value greater than

2 x ((external Count Up limit) – A*n*[A])

into B*n*[B].

See Timing example: leading dead time insertion.

### 60.5.3.17.6 Timing example: leading dead time insertion

This example illustrates two cycles of a center-aligned PWM signal. AS1 and BS1 values change within the same period, which allows you to change the duty cycle and dead time values at the same time.

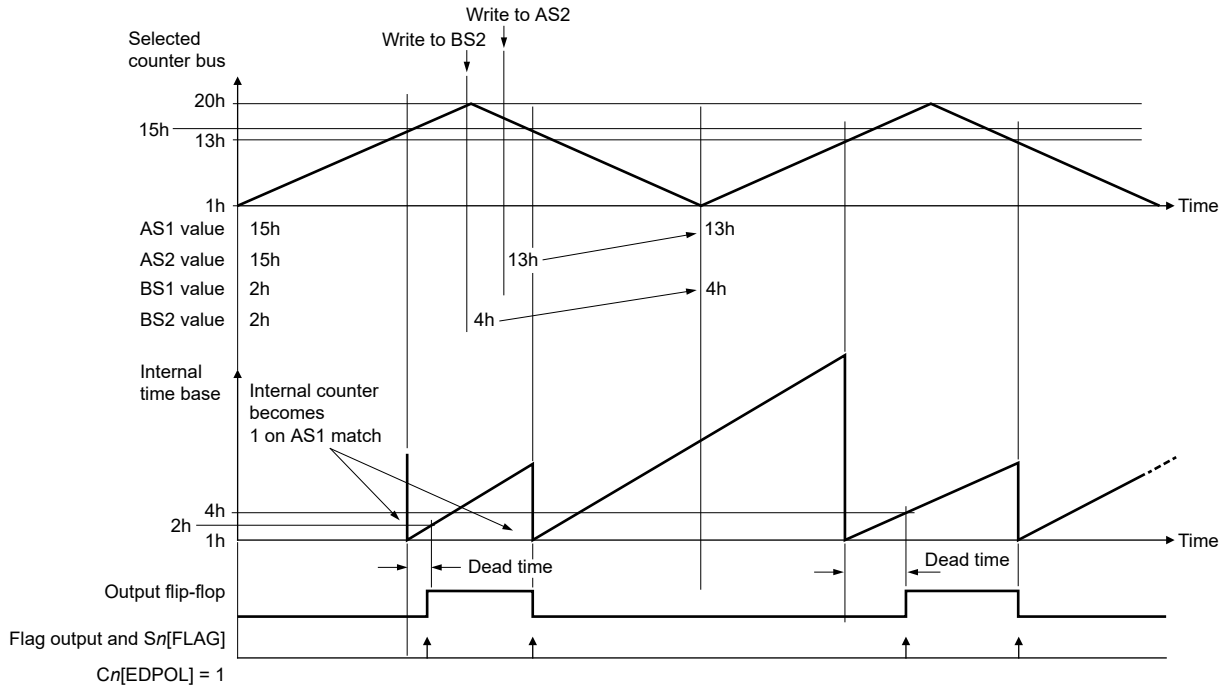

**Figure 325. Timing example: leading dead time insertion**

### 60.5.3.17.7 Operation sequence with trailing edge dead time insertion

When operating with trailing edge dead time insertion:

1. When the first match between AS1 and the selected timebase occurs, the UC:
   a. Drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
   b. Writes the internal counter (CNT*n*[C]) to 1h.
2. When the second match between AS1 and the selected timebase occurs, the UC:
   a. Writes the internal counter to 1h.
   b. Enables BS1 matches.
3. When a match between BS1 and the selected timebase occurs, the UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

The UC repeats this sequence continuously.

### 60.5.3.17.8 Timing example: trailing dead time insertion

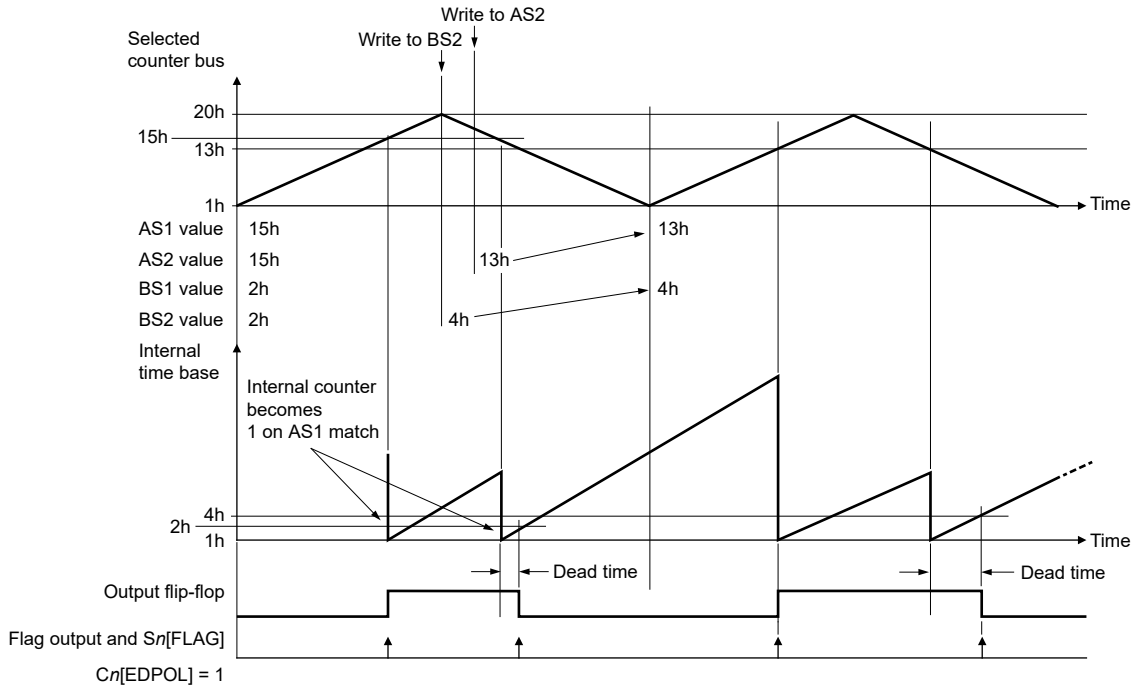

**Figure 326. Timing example: trailing dead time insertion**

### 60.5.3.17.9 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. If subsequent matches occur on comparators A and B, the UC continues to generate PWM pulses regardless of the input capture flag (S*n*[FLAG]). The force-match operations do not set the input-capture flag (S*n*[FLAG]).

When you select leading edge dead time insertion:

- Force Match A drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Force Match B drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

When you select trailing edge dead time insertion:

- Force Match A drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Force Match B drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

Force Match operation does not write 1h to the internal timebase.

Force Match operation does not set the input-capture flag.

When you assert Force Match A and Force Match B at the same time, the UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop. This is the equivalent of saying that Force Match A has precedence over Force Match B when you select leading edge dead time insertion, and Force Match B has precedence over Force Match A when you select trailing edge dead time insertion.

Force Match A and Force Match B have the same output transition behavior in both Freeze state and unfrozen state.

### 60.5.3.17.10 Duty cycle

You generate a duty cycle from 0% to 100% by writing appropriate values to AS1 and BS1 relative to the period of the external timebase.

To generate a 100% duty cycle waveform:

- Select trailing edge dead time insertion (see OPWMCB functions and MODE field values).
- Write 1h to Edge Polarity (C*n*[EDPOL]).
- The BS1 match must occur on or after the counter period boundary (external counter = 1).

You can also generate a 100% duty cycle waveform by writing 1h to AS1. However, if you do this before the UC enters OPWMCB mode, a 100% duty cycle may not occur in the first PWM period depending upon the pin state at mode entry.

To generate a 0% duty cycle waveform:

- AS1 must be greater than the maximum value of the selected counter period.
- The pin must start the current period with the complement value of Edge Polarity (C*n*[EDPOL]). If starting at 100% duty cycle, you can change Edge Polarity (C*n*[EDPOL]) to its complement by forcing the pin (see Force match).

You must write only non-zero values to AS1. If you write the maximum value of the external counter given by

(external counter period)/2

to AS1, the UC constantly drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

UC logic prevents matches from one period propagating to the next period. In trailing edge dead time insertion, the UC masks out BS1 matches that occur late in period *n*, so matches in period *n*+1 are unaffected and the output flip-flop does not transition.

### 60.5.3.17.11 Timing example: duty cycle

To generate a 100% duty cycle output waveform, write 4h to AS1 and 3h to BS1, as illustrated in this diagram. In this case, the trailing edge is at the boundary of counter period *n*+1, which actually belongs to period *n*+2 and therefore does not cause the output flip-flip to transition.

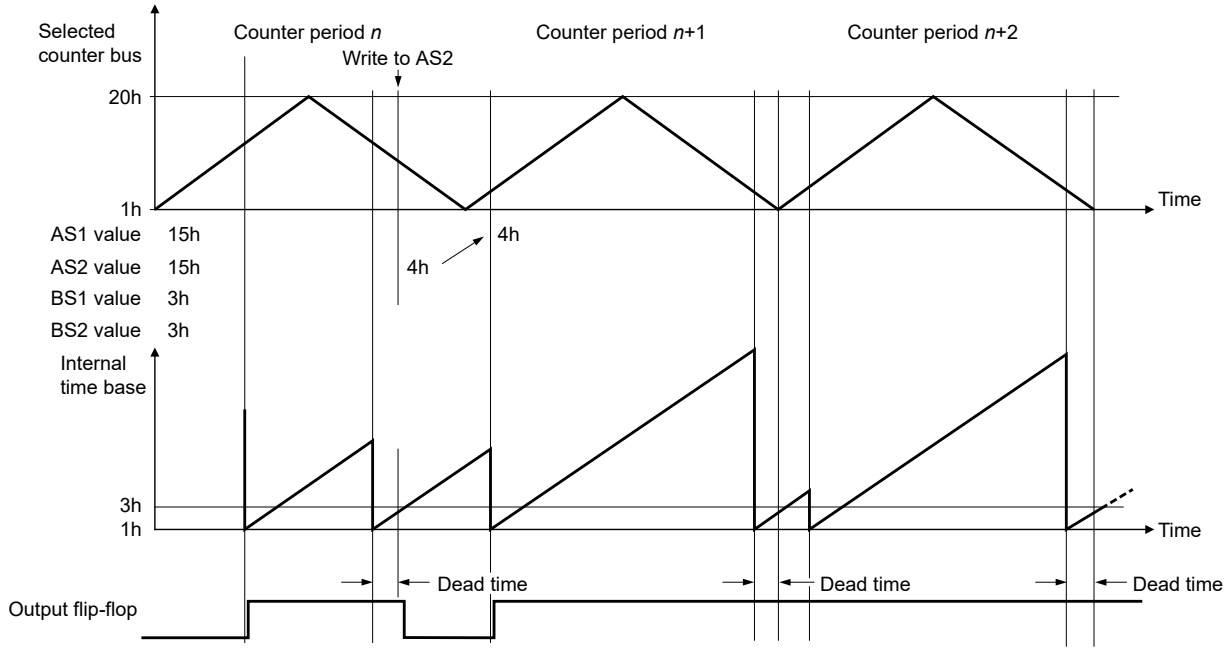

Figure 327. Timing example: duty cycle

### 60.5.3.17.12 Output disable

You can use Output Update Disable (write 0 to OUDIS[OU*n*]) to disable AS1 and BS1 updates. This allows you to update AS1 and BS1 in the same counter period and synchronize the loading of these registers with the loading of AS1 or BS1 in other channels.

Asserting Output Update Disable drives the complement of Edge Polarity (C*n*[EDPOL]) on output flip-flop. The internal channel matches continue to occur, and therefore the UC continues to set flags.

When you deassert Output Update Disable, the output flip-flop is again controlled by AS1 and BS1 matches. The UC transitions the output flip-flop only on system clock edges.

### 60.5.3.18 Output PWM Buffered (OPWMB) mode

#### 60.5.3.18.1 Overview

In this mode, the UC produces PWM pulses with programmable leading and trailing edge placement. You must select an external counter driven in MCB Up mode from one of the counter buses. AS1 and BS1 define the first and second edges, respectively. C*n*[EDPOL] defines the output signal polarity. If C*n*[EDPOL] = 0, a negative edge occurs when AS1 matches the selected counter bus and a positive edge occurs when BS1 matches the selected counter bus.

See OPWMB submodes and MODE field values for the values that you must write to C*n*[MODE] to enter this mode.

AS1 and BS1 are double-buffered and updated from AS2 and BS2, respectively, at the cycle boundary. The load operation is similar to the one that occurs in OPWFMB mode. See Timing example: AS1 and BS1 update and FLAGs for more information about AS1 and BS1 updates.

When the UC enters OPWMB mode, the UC drives C*n*[EDPOL] on the output flip-flop.

These rules apply to OPWMB mode:

- If the AS1 and BS1 matches occur at the same time within the same counter period, the BS1 match has precedence over the AS1 match.
- An AS1 = 0 match in period *n* has precedence over a BS1 match in period *n*-1.
- The UC masks out AS1 matches if they occur after a BS1 match within the same period.
- The UC loads any value that you write to AS2 or BS2 in period *n* into AS1 and BS1 at the following period boundary (assuming that the corresponding OU*n* field of Output Update Disable (OUDIS) is 0). Therefore, the UC uses the new values for AS1 and BS1 matches in period *n*+1.

Timing example: 100% to 0% duty cycle illustrates a waveform changing from 100% to 0% duty cycle. In this example, BS1 is programmed to the same value as the period of the external selected timebase. If you write a value smaller than 8h to BS1, you cannot achieve a 0% duty cycle by only changing AS1. Because BS1 matches have precedence over AS1 matches, the flag output transitions to the complement of C*n*[EDPOL] at a BS1 match. For another example, if you write 9h to BS1, a BS1 match does not occur, and the UC generates a 0% duty-cycle signal.

#### 60.5.3.18.2 OPWMB submodes and MODE field values

**Table 340. OPWMB submodes and MODE field values**

| When FLAG generation occurs | C*n*[MODE] (binary) |
|---|---|
| At a BS1 match | 110_0000 |
| At an AS1 or BS1 match | 110_0010 |

#### 60.5.3.18.3 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. If subsequent matches occur on comparators A and B, the UC continues to generate PWM pulses regardless of the input capture flag (S*n*[FLAG]). The force-match operations do not set the input-capture flag (S*n*[FLAG]).

### 60.5.3.18.4 Matches and flag operation

Timing example: matches and flags illustrates the operation of OPWMB mode with an emphasis on AS1 and BS1 matches and the transition of the channel output pin. The output pin transitions are based on the negative edges of the AS1 and BS1 match signals. AS1 becomes zero in period *n*+1. In this case, the UC uses the match positive edge instead of the negative edge to transition the output flip-flop.

### 60.5.3.18.5 Timing example: matches and flags

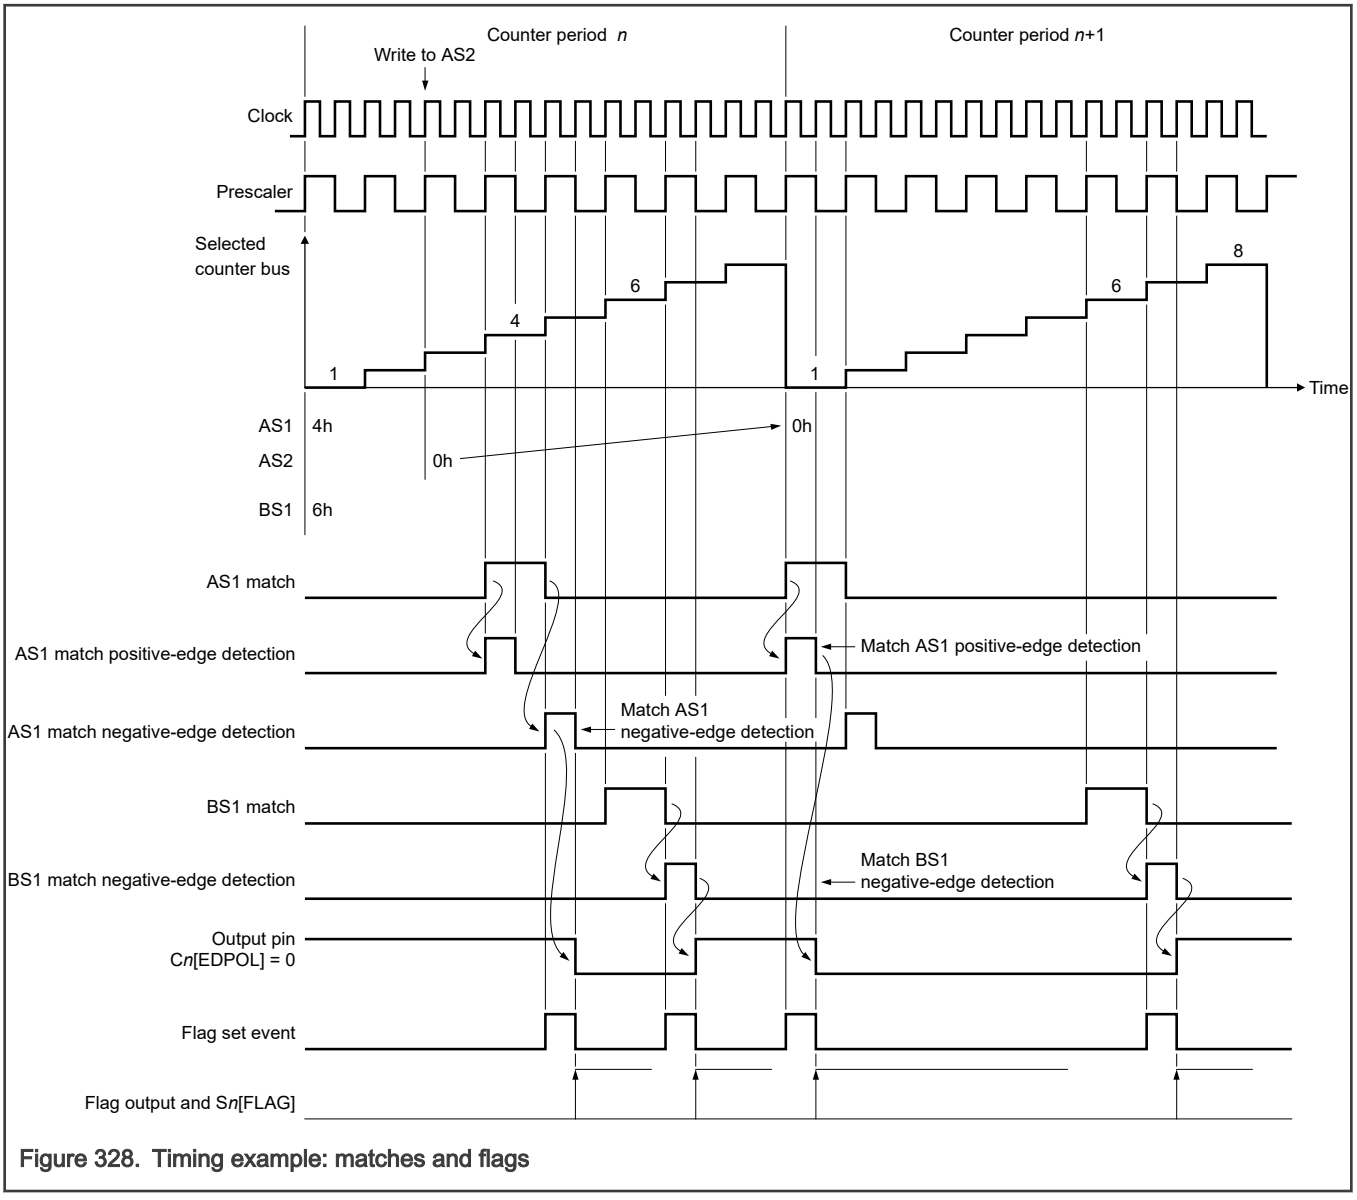

**Figure 328. Timing example: matches and flags**

### 60.5.3.18.6 0% duty cycle

Timing example: 0% duty cycle illustrates the channel operation for a 0% duty cycle. The AS1 match positive-edge signal occurs at the same time as the BS1 = 8h negative-edge signal. In this case, the AS1 match has precedence over the BS1 match, causing the output pin to remain at the value of C*n*[EDPOL] and generating a 0% duty-cycle signal.

### 60.5.3.18.7 Timing example: 0% duty cycle

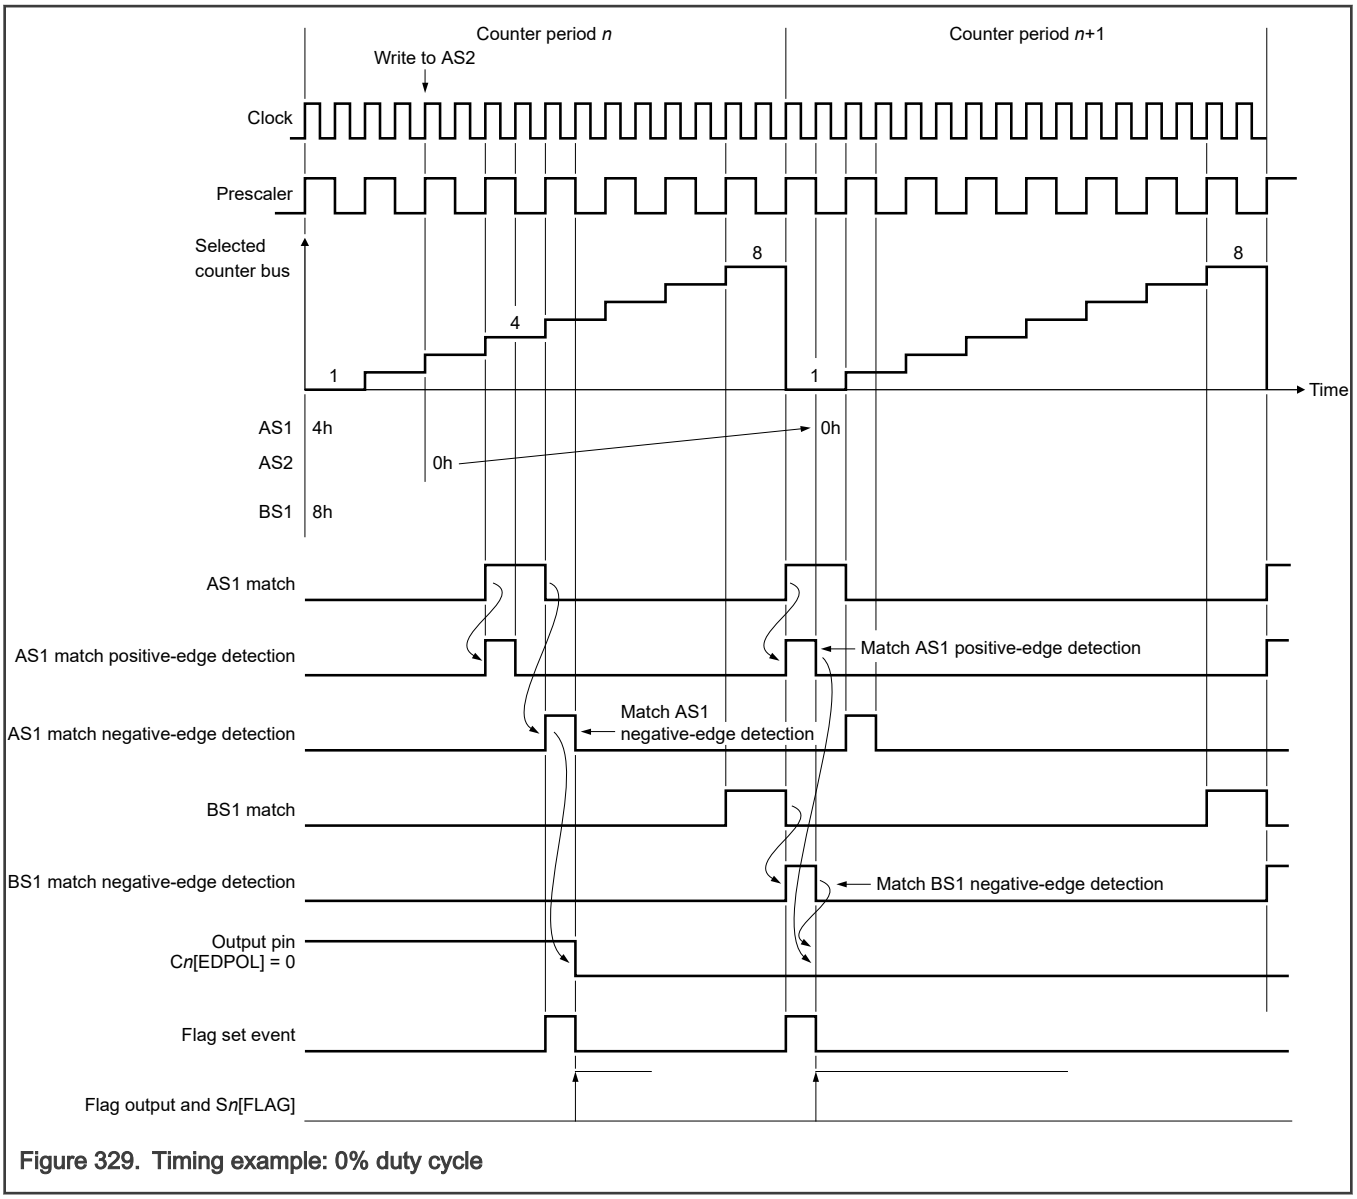

**Figure 329. Timing example: 0% duty cycle**

### 60.5.3.18.8 Active output disabled

Timing example: active output disabled illustrates the operation of the OPWMB mode with an emphasis on the assertion of the output-disable signal. The output disable forces a transition in the output pin to the value of C*n*[EDPOL]. The deassertion of the output-disable signal allows the output pin to transition at the following AS1 or BS1 match. The output disable does not modify the behavior of S*n*[FLAG]. A delay of one system clock cycle exists between the assertion of the output-disable signal and the transition of the output pin to C*n*[EDPOL].

### 60.5.3.18.9 Timing example: active output disabled

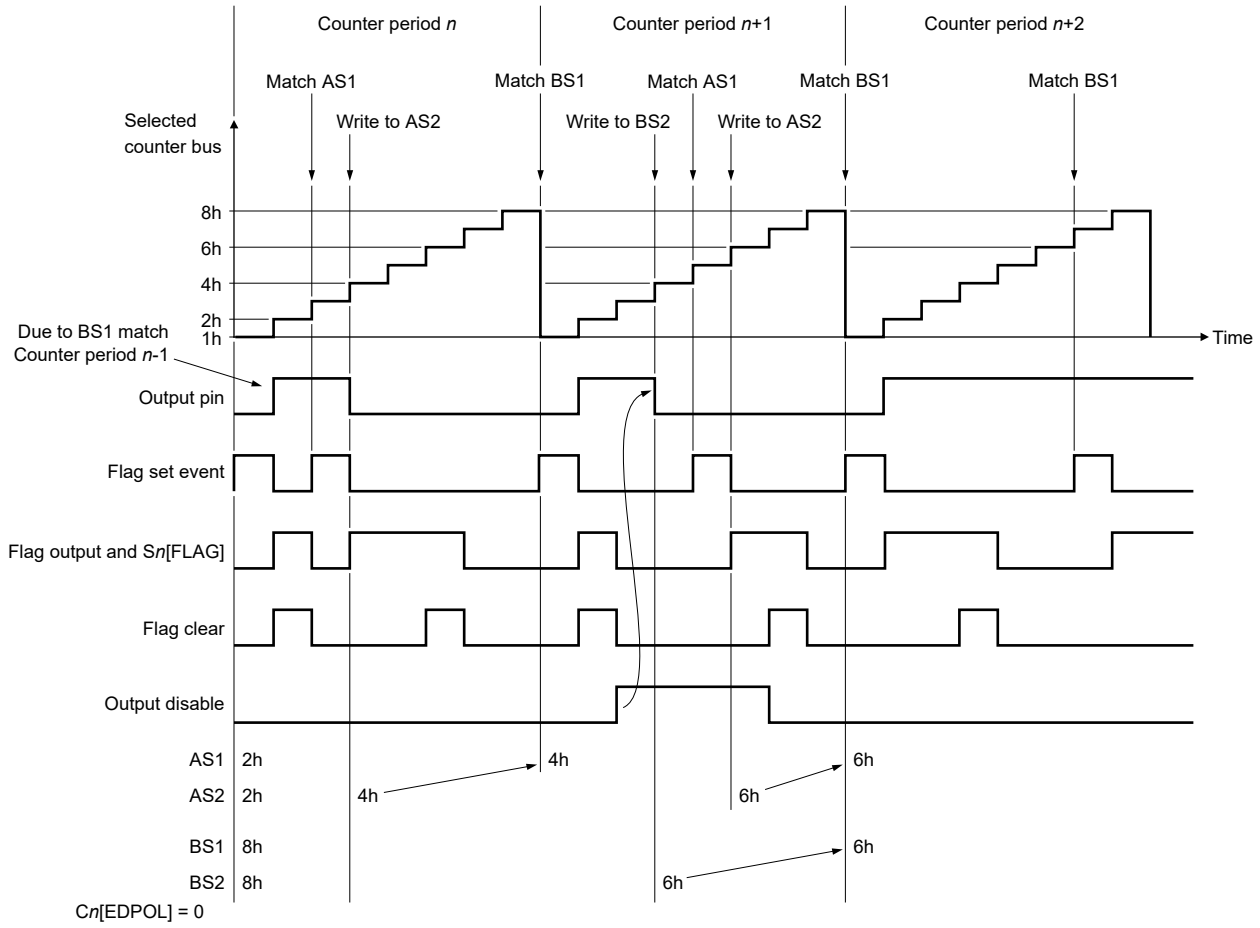

Figure 330. Timing example: active output disabled

### 60.5.3.18.10 Changing from 100% to 0% duty cycle

Timing example: 100% to 0% duty cycle illustrates a waveform changing from 100% to 0% duty cycle. In this example, BS1 has the same value as the period of the external selected timebase. If you write a value smaller than 8h to BS1, you cannot achieve a 0% duty cycle by only changing AS1. Because BS1 matches have precedence over AS1 matches, the output pin transitions to the complement of C*n*[EDPOL] at a BS1 match. For another example, if you write 9h to BS1, a BS1 match does not occur, and the UC generates a 0% duty-cycle signal.

#### 60.5.3.18.11 Timing example: 100% to 0% duty cycle

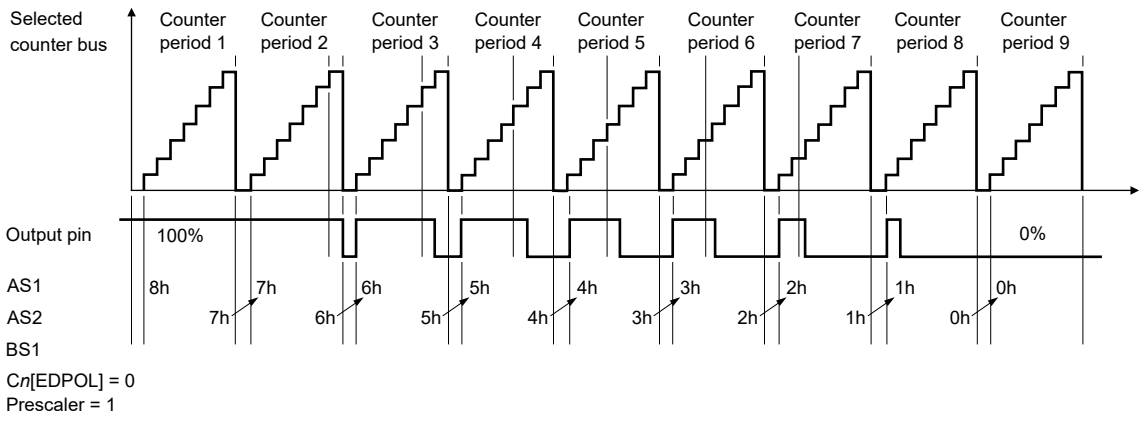

**Figure 331. Timing example: 100% to 0% duty cycle**

### 60.5.3.19 Output PWM with Trigger (OPWMT) mode

#### 60.5.3.19.1 Overview

In this mode, the UC generates PWM pulses where the period does not change while the UC outputs the signal, but the duty cycle changes. When the duty cycle changes, it must not create glitches. The mode supports multiple UCs executing in the same mode and sharing a common timebase. Each UC can have a fixed PWM leading-edge position with respect to the other UCs. It can also generate a trigger signal at any point in the period. eMIOS can output this trigger signal to initiate activity in other parts of the chip—for example, to start ADC conversions.

You must select an external counter, driven in either MC Up or MCB Up mode (see Modulus Counter Buffered (MCB) mode), from one of the counter buses.

AS1 in OPWMT mode, AS2 in OPWMT mode, and BS1 and BS2 in OPWMT mode describe the configuration and behavior of the individual shadow registers in this mode.

To account for the shift in the AS1-defined leading edge of the waveform, the BS1-defined trailing edge may roll over into the next period. This means that a match against BS1 does not have to be qualified by a match in AS1. This also means that if you incorrectly write a value less than AS1 to BS1, the output persists over a period boundary until the UC encounters the BS1 value.

This mode provides a buffered update of the trailing edge by updating BS1 with BS2 contents only at a match of AS1.

The positive edges of the AS1, BS1, and AS2 match signals drive the output pin and flag transitions. See Timing example: matches and flags for details on positive-edge matches.

The UC sets the input capture flag (S*n*[FLAG]) only at an AS2 match. An AS1, BS1, or BS2 match has no effect on the flag.

When the UC enters OPWMT mode, it drives the complement of C*n*[EDPOL] on the output flip-flop.

Timing example: OPWMT illustrates the UC running in OPWMT mode with trigger-event generation and duty-cycle update after the next-period update.

### 60.5.3.19.2 Timing example: OPWMT

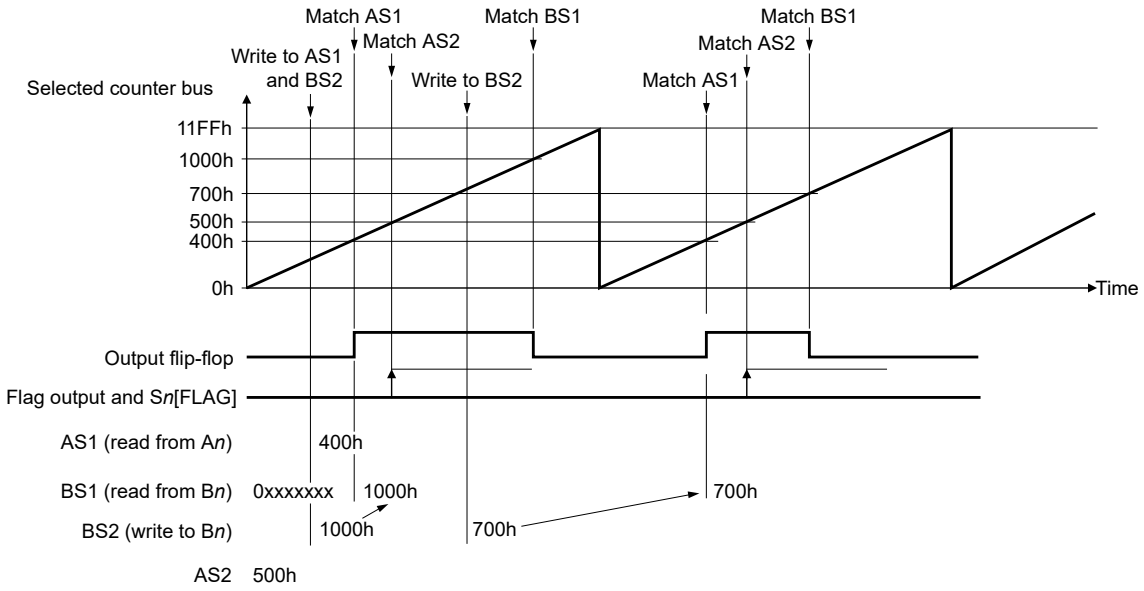

**Figure 332. Timing example: OPWMT**

### 60.5.3.19.3 AS1 in OPWMT mode

AS1 defines the leading edge of the PWM pulse output, and therefore the beginning of the PWM period. Using this fact, you can ensure that, when using a shared timebase, the leading edges of multiple UCs in OPWMT mode occur at specific times with respect to the other UCs. You can also introduce a fixed offset for each UC, which is particularly useful in the generation of lighting control signals. For this application, to reduce or eliminate noise generation, you can shift the PWM pulse of each UC with respect to the selected timebase by adjusting the AS1 value for each channel. The value you write to AS1 must be within the range of the selected timebase. Shadow registers (AS1, AS2, BS1, and BS2) loaded with 0h do not produce matches if the channel driving the timebase is in MCB mode.

AS1 is not buffered, because the shift of a PWM channel must not change while the UC generates the PWM signal. If you modify AS1, it updates immediately and one PWM pulse could be lost.

The UC compares AS1 to the selected timebase. When a match on AS1 occurs, the UC drives C*n*[EDPOL] on the output flip-flop. When a match occurs on comparator B, the UC drives the complement of C*n*[EDPOL] on the output flip-flop.

### 60.5.3.19.4 AS2 in OPWMT mode

AS2 defines the generation of a trigger event within the PWM period. The value you write to AS2 must be within the range of the selected timebase—otherwise the UC does not generate a trigger. A match on the comparator asserts the input-capture flag, but the match has no effect on the PWM output signal generation. The typical setup to obtain a trigger with a flag is to enable DMA and drive the DMA acknowledgement or DMA completion input high.

AS2 is not buffered, and therefore the UC updates it immediately. If the UC is running when you make a change, this could cause either of the following:

- The loss of one trigger event
- The generation of two trigger events within the same period

You access AS2 by reading or writing ALTA*n*[ALTA].

### 60.5.3.19.5 BS1 and BS2 in OPWMT mode

You access BS1 and BS2 using B*n*[B]:

- When you read B*n*[B], you read BS1.
- When you write to B*n*[B], you write to BS2.

BS1 defines the trailing edge of the PWM pulse output, and therefore the duty cycle of the PWM signal. To synchronize the BS1 update with the PWM signal and to ensure a correct output pulse generation, the BS2→BS1 transfer occurs at every AS1 match. This behavior is the same as in OPWM mode with next-period update.

Output Update Disable (OUDIS) affects transfers between BS2 and BS1 only.

#### 60.5.3.19.6 Force match

At any time, Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on AS1 or BS1, respectively. Similarly to a BS1 match, Force Match B changes the internal counter to 1h. The force-match operations do not set the input-capture flag (S*n*[FLAG]). Any match resulting from writing 1 to FORCMA or FORCMB has priority over any simultaneous match regarding output pin transitions. BS2→BS1 transfer at an A match is not inhibited by writing 1 simultaneously to both FORCMA or FORCMB. If you write 1 to both FORCMA and FORCMB simultaneously, the output pin acquires the complement of C*n*[EDPOL], as if AS1 and BS1 had the same value. FORCMA assertion causes the UC to process the BS2→BS1 transfer as a regular A match comparison and not due to FORCMA assertion, regardless of FORCMB assertion. If subsequent matches occur on comparators AS1 and B, the UC continues to generate PWM pulses, regardless of the state of S*n*[FLAG].

#### 60.5.3.19.7 Duty cycle

To achieve 0% duty cycle, you must write the same value to AS1 and BS2. When a simultaneous match on comparators A and B occurs, the UC drives the complement of C*n*[EDPOL] on the output flip-flop at every period.

To achieve 100% duty cycle, you must write a value to BS1 that is greater than the maximum value of the selected timebase. The maximum counter value for the timebase is FF_FFFEh for a 24-bit counter and FFFEh for a 16-bit counter. When a match on comparator AS1 occurs, the UC drives C*n*[EDPOL] on the output flip-flop at every period. The match at comparator A still triggers the BS2→BS1 transfer.

Timing example: 0% duty cycle illustrates the UC running in OPWMT mode with trigger-event generation and a 0% duty cycle.

Timing example: 100% duty cycle illustrates the UC running in OPWMT mode with trigger-event generation and a 100% duty cycle.

### 60.5.3.19.8 Timing example: 0% duty cycle

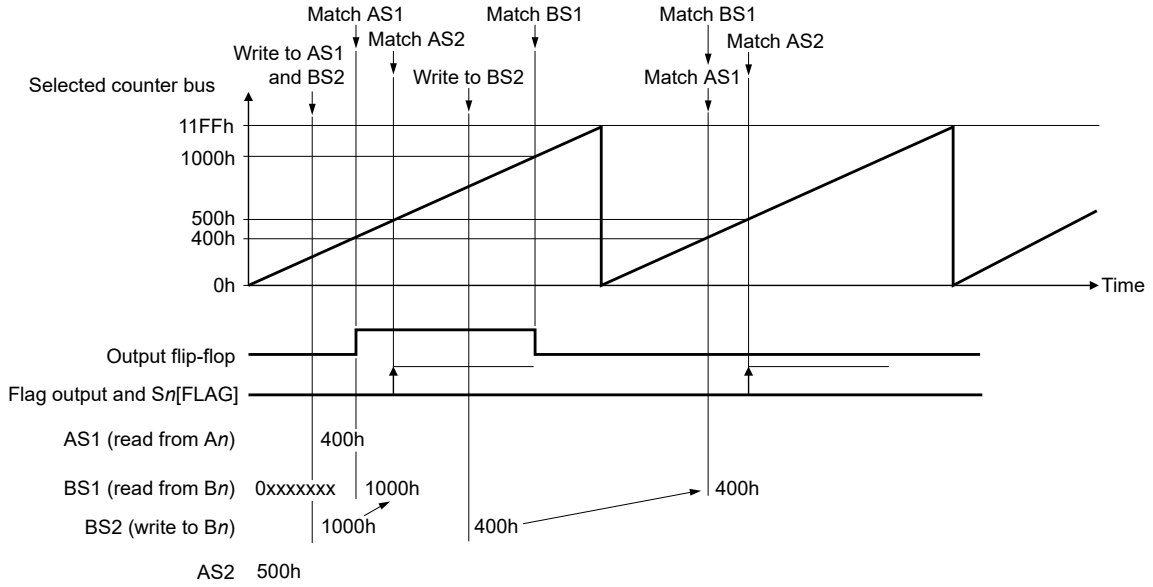

**Figure 333. Timing example: 0% duty cycle**

### 60.5.3.19.9 Timing example: 100% duty cycle

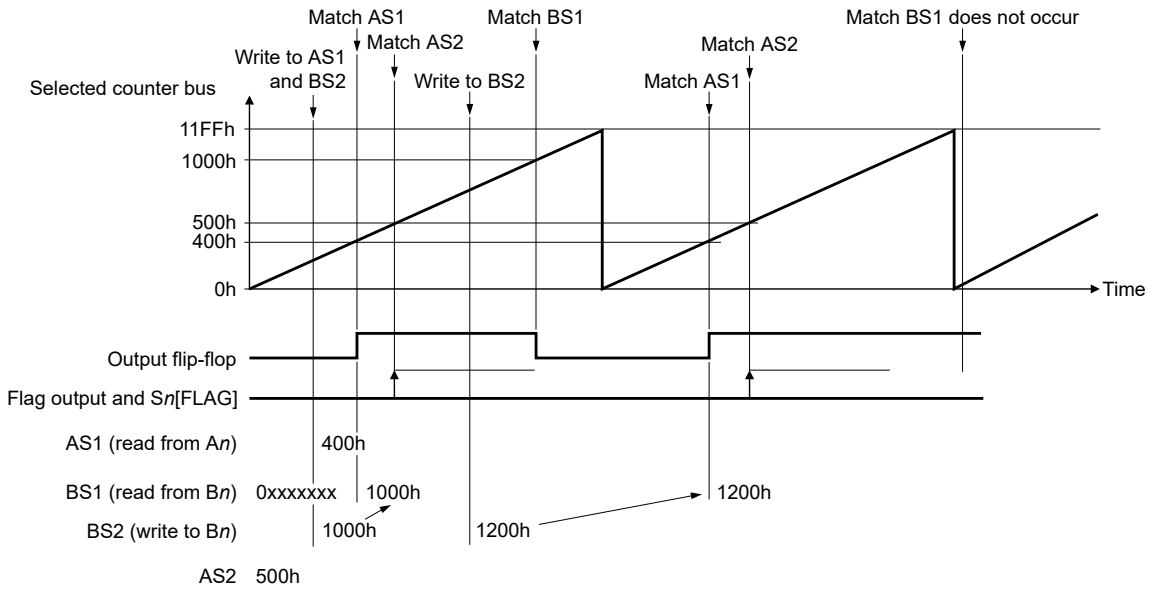

**Figure 334. Timing example: 100% duty cycle**

### 60.5.3.19.10 Output disable

As with other UC modes, OPWMT mode implements the output-disable function. When C*n*[ODIS] = 1, assertion of the output-disable input causes the UC to drive C*n*[EDPOL] on the output. Other than the fixed output, the UC continues to operate normally. When the output-disable signal deasserts, the UC returns to full normal operation.

### 60.5.3.20 Programmable input filter (PIF)

#### 60.5.3.20.1 Overview

The PIF specifies the minimum input pulse width, in clock cycles, that can pass through the filter. It supports bypass operation (C*n*[IF]), with the input signal synchronized before arriving at the digital filter, or from 2 to 16 clock cycles in powers of 2.

#### 60.5.3.20.2 Counter

The PIF is a 5-bit programmable up counter. The selected clock source increments the up counter after the number of clock cycles specified by the input filter (C*n*[IF]0.

The system clock synchronizes the input signal. When this signal changes state, the counter begins incrementing. As long as the new signal state is stable, the counter continues incrementing. If the counter overflows, eMIOS validates the new signal value. In this case, it transmits the value as a pulse edge to the edge detector. If the opposite edge appears on the signal before validation (overflow), eMIOS resets the counter. At the next transition, the counter starts incrementing again. A glitch does not occur on the edge detector for any pulse shorter than the full range of the masked counter.

Neither Freeze state nor deasserted GTBE disables the filter.

#### 60.5.3.20.3 UC PIF logic

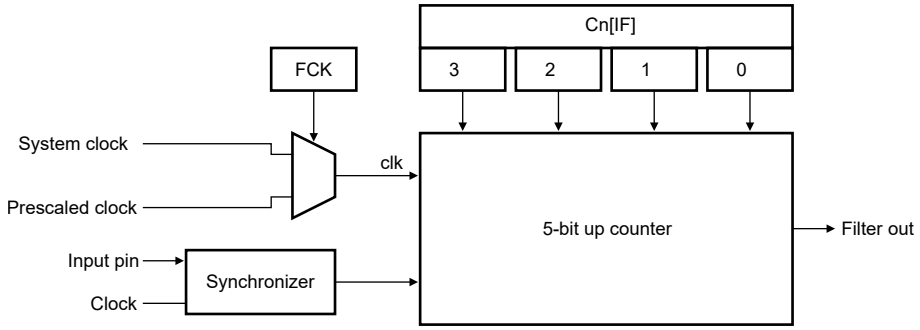

Figure 335. UC PIF logic

#### 60.5.3.20.4 Timing example: UC PIF at 4 cycles

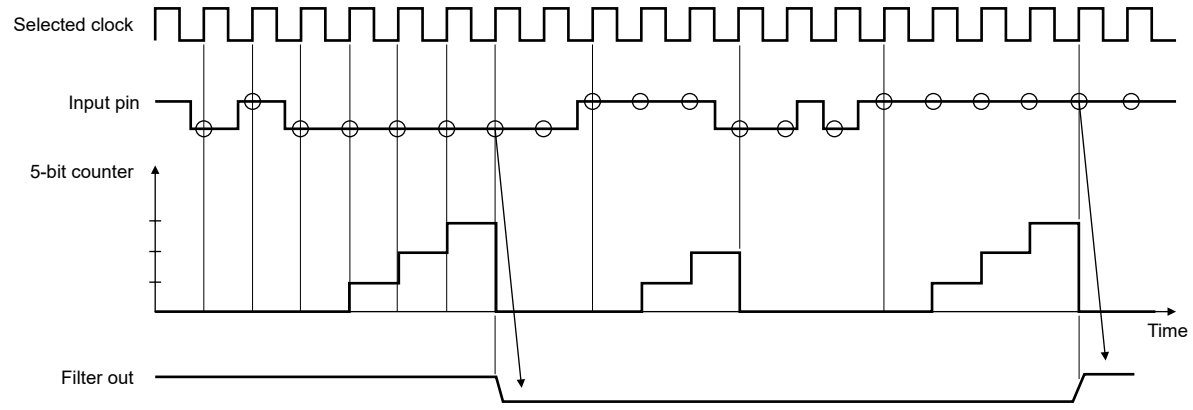

Figure 336. Timing example: UC PIF at 4 cycles

#### 60.5.3.21 UC clock prescaler (CP)

eMIOS divides the GCP output signal by the UC CP (C*n*[UCPRE] + 1) to generate a clock enable for the UC internal counter. See Global clock prescaler (GCP). You enable the UC CP by writing 1 to C*n*[UCPREN]. If you disable the CP (write 0 to the same field), eMIOS stops the UC internal counter.

To ensure safe operation and avoid glitches, you must perform the following steps to change the UC CP:

1. Disable the GCP (write 0 to MCR[GPREN]).
2. Disable the UC CP (write 0 to C*n*[UCPREN]).
3. Specify the new prescaler value (write CP – 1 to C*n*[GPRE].
4. Enable the UC CP (write 1 to C*n*[UCPREN]).
5. Enable the GCP (write 1 to MCR[GPREN]).

### 60.5.4 Peripheral bus interface unit (BIU)

The BIU provides the interface between the IIB and the peripheral bus, which allows communication among all submodules and the IP interface. The BIU supports 8-, 16-, and 32-bit accesses performed over a 32-bit data bus in a single clock cycle.

### 60.5.5 Global clock prescaler (GCP)

eMIOS divides the system clock by the GCP (MCR[GPRE] + 1) and routes the resulting prescaled clock output to the channel CPs. You enable the GCP by writing 1 to MCR[GPREN]. If you disable the GCP (write 0 to the same field), eMIOS clears the prescaler counter and stops the prescaler clock.

To ensure safe operation and avoid glitches, you must perform the following steps to change the GCP:

1. Disable the GCP (write 0 to MCR[GPREN]).
2. Specify the new prescaler value (write GCP – 1 to MCR[GPRE].
3. Enable the GCP (write 1 to MCR[GPREN]).

### 60.5.6 Freeze and chip Debug mode

#### 60.5.6.1 Enter and exit Freeze state

When the chip is in Debug mode (the chip Debug signal is asserted), you can freeze individual UCs. For the effects of Freeze state on eMIOS functions, see Freeze effects.

To put a channel in Freeze state, you must meet all of the following conditions:

- The chip must assert Debug.
- Prepare eMIOS for the Freeze state (write 1 to MCR[FRZ]).
- Enable Freeze for each channel you want to freeze:
  - Write 1 to C*n*[FREN].

A channel exits Freeze state when any of the following conditions occur:

- The chip deasserts Debug.
- You take eMIOS out of the Freeze state (write 0 to MCR[FRZ]).
- You disable Freeze for the channel:
  - write 0 to C*n*[FREN].

#### 60.5.6.2 Freeze effects

| Function | Effects of freeze |
|---|---|
| GCP | No effect |
| UC | • Halts counter, capture, and compare operation.<br>• Freezes UC in its current state.<br>• Makes all registers accessible.<br>• In output modes, force match remains operational, allowing software to force the output to the desired level.<br>• In input modes, the UC ignores input events.<br>• When eMIOS exits Freeze state then UC operations resume, but they may be inconsistent until the UC reenters GPIO mode. |
| STAC | No effect |
| BIU | No effect |

## 60.6 Initialization information

When initializing eMIOS, take the following considerations into account.

For eMIOS behavior on reset, see Reset.

Before changing the UC operating mode, you must:

1. Put the UC in GPIO mode (write 0b or 1b to C*n*[MODE]).
2. Write the correct values for the next operating mode to A*n* and B*n*.
3. Put the UC in the new operating mode (write the appropriate value to C*n*[MODE]).

If you change a UC from one mode to another without performing this procedure, the first operation cycle of the selected timebase can be random; that is, matches can occur in random time because you did not update A*n* and B*n* with correct values before the timebase matches the previous contents of either register.

**NOTE**

To to avoid causing an unexpected interrupt or DMA request when changing from GPIO to MCB mode, you must use the procedure described in Changing to MCB mode.

When you enable interrupts, any interrupt service routine must clear the flag before exiting.

## 60.7 Application information

### 60.7.1 Overview

All output operation modes can generate correlated output signals. You can disable updates of the output signals for each UC (OUDIS).

To guarantee that incrementing of the internal counters of correlated channels occurs in the same clock cycle, you must configure the internal CPs before enabling the GCP. If you configure the internal CPs after enabling the GCP, the internal counters may increment in the same ratio, but at different clock cycles.

You should drive the Output Disable Input signals with the flag signals of some UCs running in SAIC mode. When an output disable condition happens, the interrupt service routine must process the output channels before processing the channels running SAIC. This sequence avoids glitches in the output pins.

### 60.7.2 Timebase generation

In the MC and OPWFM modes with internal clock sources, you can modify the internal counter rate by configuring the CP ratio. Timebase with the fastest prescaler ratio illustrates a timebase with a prescaler ratio of one.

**NOTE**

The buffered modes, MCB and OPWFMB, behave differently.

If the prescaler ratio is greater than one or you select an external clock, the internal counter behaves in one of four different ways depending on the channel mode:

- In MC mode with Clear on Match Start and External Clock: Timebase generation with clear on match start and external clock.
- In MC mode with Clear on Match Start and Internal Clock source: Timebase generation with clear on match start and internal clock.
- In MC mode with Clear on Match End: Timebase generation with clear on match end.
- In OPWFM mode: Timebase generation with clear on match start and internal clock. The internal counter clears at the start of the match signal, skips the next prescaled clock edge, and then increments in the subsequent prescaled clock edge.

### 60.7.3 Timebase with the fastest prescaler ratio

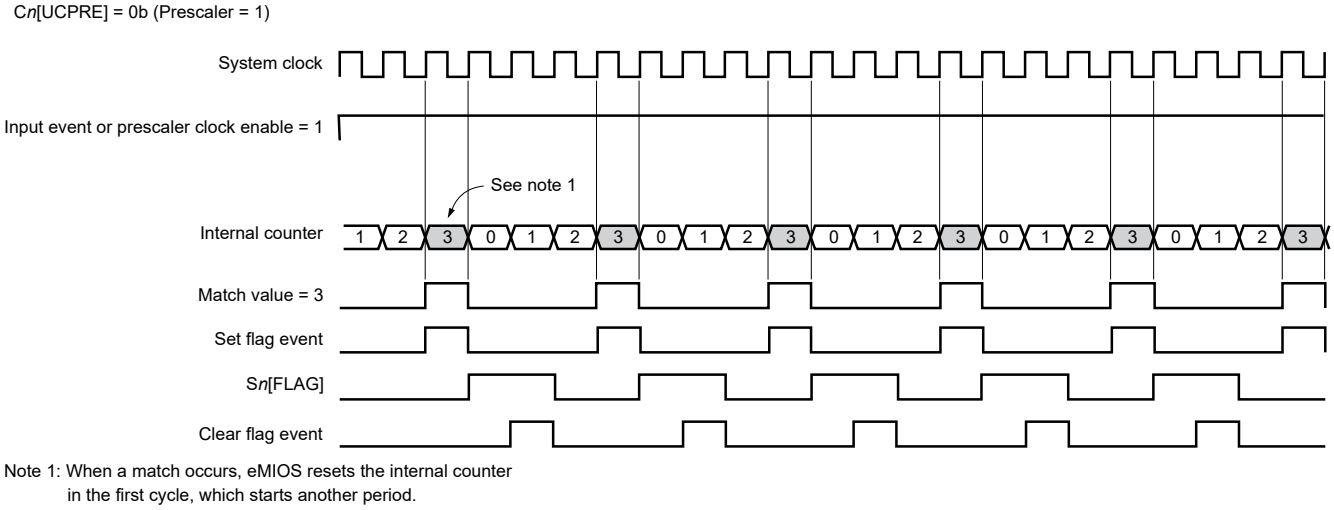

**Figure 337. Timebase with fastest prescaler ratio**

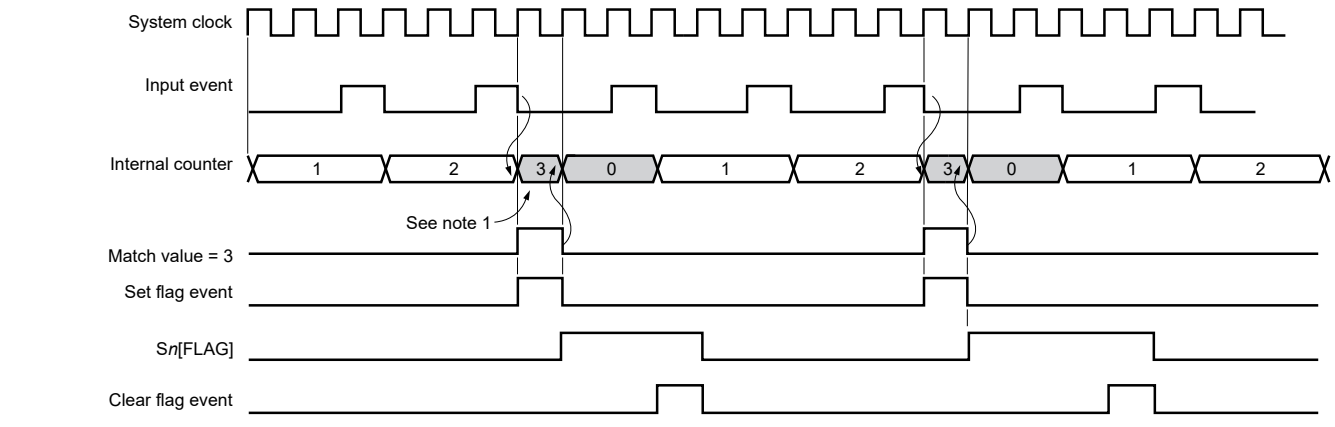
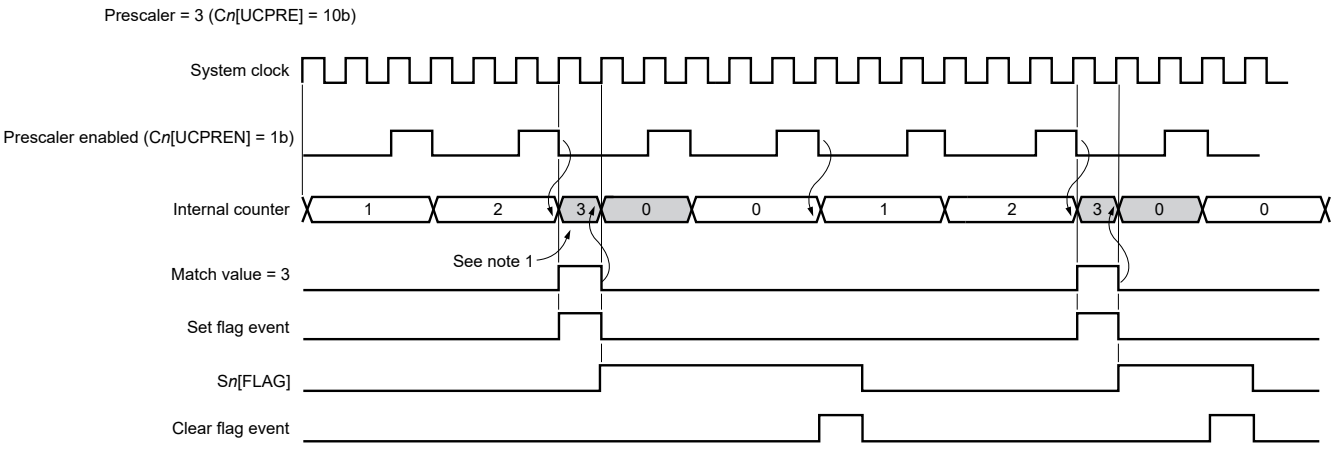
## 60.7.4 Timebase generation with clear on match start and external clock



Note 1: When a match occurs, eMIOS resets the internal counter in the first clock cycle.
The counter starts counting at the next edge of the prescaler clock enable.

**Figure 338. Timebase generation with clear on match start and external clock**

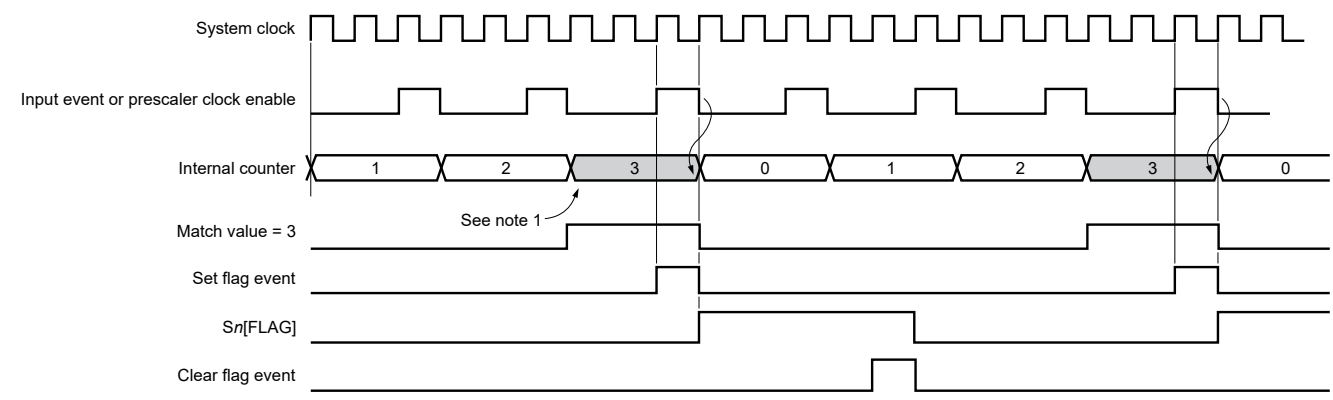
## 60.7.5 Timebase generation with clear on match start and internal clock



Note 1: When a match occurs, eMIOS clears the internal counter in the first clock cycle.
The counter starts counting again only after the second edge of the prescaled clock.

**Figure 339. Timebase generation with clear on match start and internal clock**

### 60.7.6 Timebase generation with clear on match end



Note 1: The match occurs only when the input event or prescaler clock enable is active.
When the match occurs, eMIOS resets the internal counter immediately.

**Figure 340. Timebase generation with clear on match end**

### 60.7.7 Coherent accesses

Reading A*n*[A] again in the same period as the last read of B*n*[B] results in incoherent results if the last read of B*n*[B] occurred after a disabled BS2→BS1 transfer.

### 60.7.8 Initializing channels and modes

Perform the following basic steps for output mode startup. This procedure assumes the channels are initially in GPIO mode:

1. Disable the GPC (write 0 to MCR[GPREN]).
2. For each timebase UC:
    a. Disable the CP (write 0 to C*n*[UCPREN]).
    b. Write an initial value to the internal counter (CNT*n*[C]).
    c. Write initial values to A*n*[A] and B*n*[B].
    d. Configure the UC for MC or MCB Up mode (write the appropriate value to C*n*[MODE]).
    e. Select the CP ratio (C*n*[UCPRE]).
    f. Enable the CP (write 1 to C*n*[UCPREN]).
3. For each output UC:
    a. Disable the CP (write 0 to C*n*[UCPREN]).
    b. Write initial values to A*n*[A] and B*n*[B].
    c. Select the timebase input (C*n*[BSL]).
    d. Specify the output mode (write the appropriate value to C*n*[MODE]).
    e. Select the same CP ratio as the timebase UC (C*n*[UCPRE]).
    f. Enable the CP (write 1 to C*n*[UCPREN]).
4. Enable the GPC (write 1 to MCR[GPREN]).
5. Enable GBTE (write 1 to MCR[GBTE]).

The timebase channel and the output channel may be the same for some applications such as in OPWFM or OPWFMB mode, or whenever the output channel drives the timebase itself.

You may configure flags at any time.

## 60.8 Memory maps and registers

### 60.8.1 Overall address map organization

All address locations not explicitly mentioned in this table are reserved. When you access an absent register, absent channel, or reserved address space, the transfer terminates with an error.

**Table 341. Overall address map organization**

| Base address (hex) | Description |
|---|---|
| 0 | Module Configuration (MCR) |
| 4 | Global Flag (GFLAG) |
| 8 | Output Update Disable (OUDIS) |
| C | Disable Channel (UCDIS) |
| 20 | Channels 0–7 |
| 120 | Channels 8–15 |
| 220 | Channels 16–23 |

### 60.8.2 UC memory overview

**Table 342. UC memory overview**

| Offset from UC *n* base address (hex) | Description |
|---|---|
| 0 | UC A n (A0 - A23) |
| 4 | UC B n (B0 - B23) |
| 8 | UC Counter n (CNT0 - CNT23) |
| C | UC Control n (C0 - C23) |
| 10 | UC Status n (S0 - S23) |
| 14 | Alternate Address n (ALTA0 - ALTA23) |
| 18 | UC Control 2 n (C2_0 - C2_23) |
| 1C–1F | Reserved |

### 60.8.3 AS1, AS2, BS1, and BS2 shadow registers

When you use eMIOS UC modes, you rely heavily on four shadow registers:

- AS1
- AS2
- BS1
- BS2

You use A*n*[A], B*n*[B], and ALTA*n*[ALTA] to access these shadow registers:

- Each instance of A*n*[A] has a separate associated instance of AS1 and AS2. In some UC modes, you also use ALTA*n*[ALTA] to access AS2.
- Each instance of B*n*[B] has a separate associated instance of BS1 and BS2.

See Relationship between A*n*, B*n*, ALTA*n*, and shadow registers.

Each UC mode uses the AS1-AS2 and BS1-BS2 shadow register pairs for various match and capture functions, as described in Unified channels (UC).

A reset clears all shadow registers.

Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA] describes how you write to and read from the shadow registers for all operation modes. Values not listed are reserved. For more information, see Unified channels (UC).

## 60.8.4 Relationship between A*n*, B*n*, ALTA*n*, and shadow registers

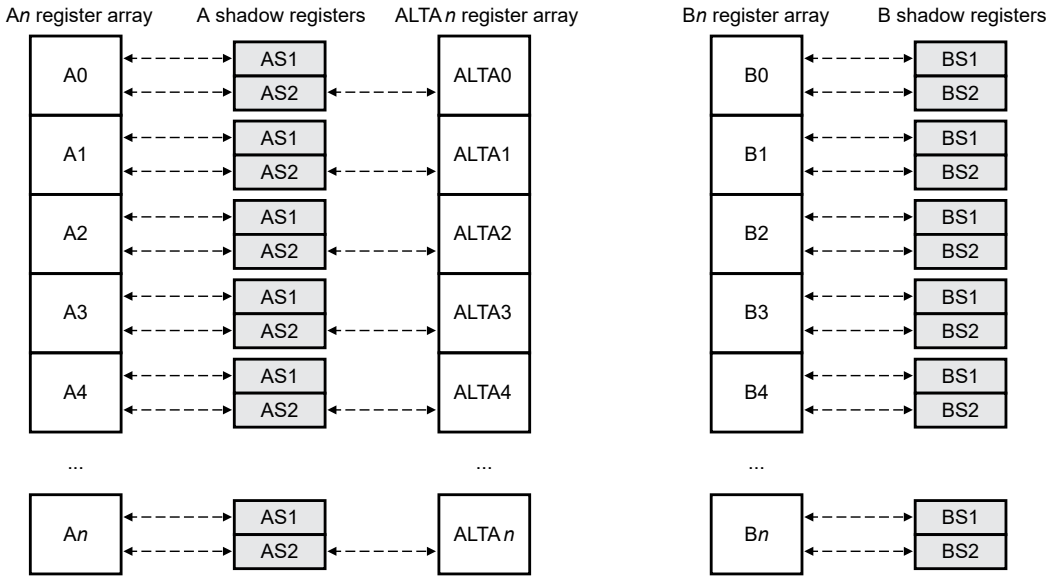


**Figure 341. Relationship between A*n*, B*n*, ALTA*n*, and shadow registers**

## 60.8.5 Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA]

This table describes how you write to and read from the following registers for all operation modes:

- UC A n (A0 - A23)
- UC B n (B0 - B23)
- Alternate Address n (ALTA0 - ALTA23)

Values not listed are reserved. For more information, see Unified channels (UC).

**Table 343. Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA]**

| Operation mode | Register access | | | | | |
|---|---|---|---|---|---|---|
| | A*n* | | B*n* | | ALTA*n* | |
| | Write | Read | Write | Read | Write | Read |
| GPIO | AS1 and AS2[1] | AS1 | BS1 and BS2[2] | BS1 | AS2 | AS2 |

*Table continues on the next page...*

Table 343. Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA] (continued)

| Operation mode | Register access | | | | | |
|---|---|---|---|---|---|---|
| | A*n* | | B*n* | | ALTA*n* | |
| | Write | Read | Write | Read | Write | Read |
| SAIC[3] | — | AS2 | BS2 | BS2 | — | — |
| SAOC[3] | AS2 | AS1 | BS2 | BS2 | — | — |
| IPWM | — | AS2 | — | BS1 | — | — |
| IPM | — | AS2 | — | BS1 | — | — |
| DAOC | AS2 | AS1 | BS2 | BS1 | — | — |
| PEA | AS1 | AS2 | — | BS1 | — | — |
| PEC[3] | AS1 | AS1 | BS1 | BS1 | — | AS2 |
| WPTA | AS1 | AS1 | BS1 | BS1 | — | AS2 |
| MC[3] | AS2 | AS1 | BS2 | BS2 | — | — |
| OPWFM | AS2 | AS1 | BS2 | BS1 | — | — |
| OPWMC | AS2 | AS1 | BS2 | BS1 | — | — |
| OPWM | AS2 | AS1 | BS2 | BS1 | — | — |
| OPWMT | AS1 | AS1 | BS2 | BS1 | AS2 | AS2 |
| MCB[3] | AS2 | AS1 | BS2 | BS1 | — | — |
| OPWFMB | AS2 | AS1 | BS2 | BS1 | — | — |
| OPWMCB | AS2 | AS1 | BS2 | BS1 | — | — |
| OPWMB | AS2 | AS1 | BS2 | BS1 | — | — |

1. This operation writes the same value to AS1 and AS2.
2. This operation writes the same value to BS1 and BS2.
3. These modes do not require UC B n (B0 - B23), but you can still use it to access BS2.

## 60.8.6 eMIOS register descriptions

All control registers are 32 bits wide. Data fields are 16 bits wide. There are 24 UCs, as mapped in Counter buses, channels, and timebase sources.

### 60.8.6.1 eMIOS memory map

eMIOS_0 base address: 4008_8000h

eMIOS_1 base address: 4008_C000h

eMIOS_2 base address: 4009_0000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Module Configuration (MCR) | 32 | RW | 0000_0000h |

*Table continues on the next page...*

### 60.8.6.2 Module Configuration (MCR)

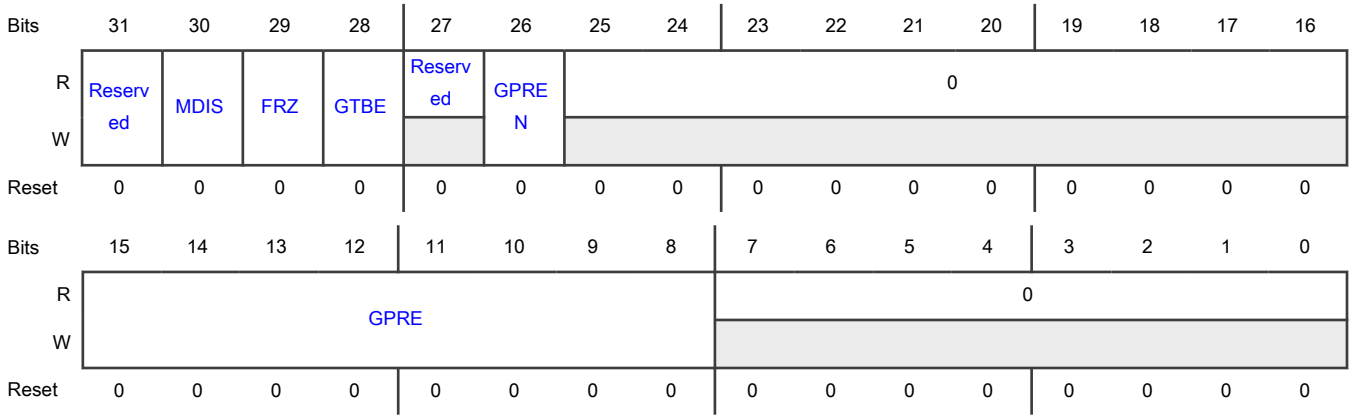
#### Offset

| Register | Offset |
|---|---|
| MCR | 0h |

#### Function

Configures eMIOS operation.

#### Diagram



#### Fields

| Field | Function |
|---|---|
| 31<br>— | Reserved<br>Write only the reset value to this field. |
| 30<br>MDIS | Module Disable<br>Disables eMIOS by stopping the clock. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | When you disable eMIOS, its clock stops, it consumes less power, and you can access only the following registers:<br>• Module Configuration (MCR)<br>• Output Update Disable (OUDIS)<br>• Disable Channel (UCDIS)<br>0b - Enable<br>1b - Disable |
| 29<br>FRZ | Freeze<br>Prepares eMIOS to enter Freeze state (see Freeze and chip Debug mode). eMIOS does not enter Freeze state until both of the following conditions occur:<br>• The chip asserts Debug mode.<br>• You enable Freeze for each UC (write 1 to C*n*[FREN]).<br>A channel remains frozen until one or more of the following occur:<br>• You force eMIOS to exit the Freeze state (write 0 to FRZ).<br>• The chip deasserts Debug mode.<br>• You disable Freeze for that UC (write 0 to C*n*[FREN]).<br>0b - Exit Freeze state<br>1b - Enter Freeze state |
| 28<br>GTBE | Global Timebase Enable<br>Asserts the GTBE_OUT signal. If GTBE_OUT is connected to the GTBE_IN input of one or more eMIOS instances, asserting the signal turns on the internal counters of those eMIOS instances simultaneously.<br>**NOTE**<br>The GTBE_IN input enables (asserted) or disables (deasserted) the internal counters.<br>0b - Deassert GTBE_OUT<br>1b - Assert GTBE_OUT |
| 27<br>— | Reserved |
| 26<br>GPREN | Global Prescaler Enable<br>Enables the global prescaler counter. Disabling the global prescaler clears the prescaler counter and stops the prescaler clock.<br>0b - Disable<br>1b - Enable |
| 25-16 | Reserved |

| 15-8<br>GPRE | Global Prescaler<br>Specifies the global clock prescaler. Write the desired clock divide ratio minus 1. For example, for a divide ratio of 8, write 111b. The prescaler can range from 1 (0b) to 256 (11111111b). |
| 7-0<br>— | Reserved |

### 60.8.6.3 Global Flag (GFLAG)

#### Offset

| Register | Offset |
|---|---|
| GFLAG | 4h |

#### Function

Groups the flag fields from all channels into one register to improve interrupt handling.

For UCs, each field mirrors the corresponding channel flag (S*n*[FLAG]).

#### Diagram

### 60.8.6.4 Output Update Disable (OUDIS)

#### Offset

| Register | Offset |
|---|---|
| OUDIS | 8h |

#### Function

Disables transfers from AS2 to AS1 and BS2 to BS1 on a per-channel basis. This applies to any channel operating in MC, MCB, or any output mode that writes to AS2 and BS2.

When a field is 0, transfers on that channel occur immediately or in the next period, depending on the operation mode. Unless that mode's description states otherwise, the transfer occurs immediately.

### 60.8.6.6 UC A n (A0 - A23)

#### Offset

For n = 0 to 23:

| Register | Offset |
|---|---|
| An | 20h + (n × 20h) |

#### Function

Accesses the AS1 and AS2 shadow registers for each UC, depending on the selected UC mode. See AS1, AS2, BS1, and BS2 shadow registers.

For information about how you write to and read from A*n*, B*n*, and ALTA*n* for all UC modes, see Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA].

### 60.8.6.8 UC Counter n (CNT0 - CNT23)

#### Offset

| Register | Offset |
|---|---|
| CNT0 | 28h |
| CNT1 | 48h |
| CNT2 | 68h |
| CNT3 | 88h |
| CNT4 | A8h |
| CNT5 | C8h |
| CNT6 | E8h |
| CNT7 | 108h |
| CNT8 | 128h |
| CNT16 | 228h |
| CNT22 | 2E8h |
| CNT23 | 308h |

#### Function

Indicates the value of the UC internal counter.

When eMIOS is in GPIO mode or the UC is frozen, this register is read-write. For all other modes, this register is read-only. When entering some UC modes, eMIOS automatically clears this register. See Unified channels (UC) for details.

The following modes use the UC counter:

- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode
- Pulse Edge Counting (PEC) mode
- Modulus Counter (MC) mode
- Modulus Counter Buffered (MCB) mode

All other modes not in this list do not use the internal counter.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| eMIOS_0 | CNT0–CNT8<br>CNT16<br>CNT22–CNT23 | — |
| eMIOS_1 | CNT0<br>CNT8<br>CNT16<br>CNT22–CNT23 | CNT1–CNT7 |

### 60.8.6.9 UC Control n (C0 - C23)

#### Offset

For n = 0 to 23:

| Register | Offset |
|---|---|
| Cn | 2Ch + (n × 20h) |

#### Function

Controls UC operation.

**Table 344. MODE field values**

| UC mode | MODE (binary) |
|---|---|
| GPIO (input) | 000_0000 |
| GPIO (output) | 000_0001 |
| SAIC | 000_0010 |

| OPWMT | 010_0110 |
| Reserved | 010_0111–100_1111 |

*Table continues on the next page...*

Table 344. MODE field values (continued)

| UC mode | MODE (binary) |
|---|---|
| MCB (up counter) | 101_000p[1] |
| Reserved | 101_001p |
| MCB (up or down counter) | 101_01pp[1] |
| OPWFMB | 101_10p0[1] |
| Reserved | 101_10p1 |
| OPWMCB (with trailing edge dead time) | 101_11p0[1] |
| OPWMCB (with leading edge dead time) | 101_11p1[1] |
| OPWMB | 110_00p0[1] |
| Reserved | 110_0001–111_1111 |

1. p = Adjust parameters for the mode of operation. See Unified channels (UC) for details.

Table 345. Edge Polarity (EDPOL) settings

| For these modes: | EDPOL does this: | and EDPOL values mean: |
|---|---|---|
| Input | Selects which edge triggers the internal counter, an input capture, or the input capture flag. If EDPOL does not appear in the UC mode description, it has no effect on UC operation. | 0b - Trigger on a falling edge<br>1b - Trigger on a rising edge |
| Output | Selects the logic level on the output pin. | 0b - A match on comparator A deasserts the output flip-flop, while a match on comparator B sets it<br>1b - A match on comparator A asserts the output flip-flop, while a match on comparator B clears it |

Table 346. Edge Select (EDSEL) settings

| For these modes: | EDSEL does this: | and EDSEL values mean: |
|---|---|---|
| Input | Selects whether the internal counter is triggered by both edges of a pulse or by a single edge as defined by EDPOL. If EDSEL does not appear in the UC mode description, it has no effect on UC operation. | 0b - Single-edge triggering on edge specified in EDPOL<br>1b - Both-edges triggering |
| GPIO in | Selects whether an edge asserts the input capture flag (S*n*[FLAG]). | 0b - Sets S*n*[FLAG] on the edge specified in EDPOL<br>1b - Does not set S*n*[FLAG] |
| SAOC | Selects the behavior of the output flip-flop at each match. | 0b - Drive the EDPOL value on the output flip-flop<br>1b - Toggle output flip-flop |

### 60.8.6.11 Alternate Address n (ALTA0 - ALTA23)

#### Offset

For n = 0 to 23:

| Register | Offset |
|---|---|
| ALTAn | 34h + (n × 20h) |

#### Function

Provides an alternate address to access AS2 shadow registers in these restricted modes:

- General-Purpose Input and Output (GPIO) mode
- Pulse Edge Counting (PEC) mode
- Output PWM with Trigger (OPWMT) mode

In these modes, you can use A*n*[A] together with ALTA*n*[ALTA] to access both AS1 and AS2. Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA] summarizes the ALTA*n* writing and reading accesses for all ALTA*n* operation modes.

In modes that do not require this register, any write access is ignored and any read access returns unspecified data.

**NOTE**

You must clear triggers to BCTU after TRGMUX programming using TRGCFG_n[TRG_FLAG] bit.

## 61.2 Overview

BCTU accepts ADC conversion-request trigger inputs and routes those requests to one or more ADCs.

BCTU accepts the following trigger sources:

- Hardware triggers (outputs from on-chip timer modules)
- Software triggers through the SFTRGRn register

BCTU maps each trigger input to a Trigger Configuration (TRGCFG_0 - TRGCFG_71) register, which specifies the target ADC channel and other control data for the requested conversion.

You can configure a list of ADC channels, the CL, that processes a sequence of conversions in response to a single trigger input. See the Conversion list (CL) section.

BCTU stores each ADC conversion result for CPU access or routing to memory through DMA.

If the same ADC is targeted by multiple triggers, priority logic selects the next trigger to process from all active trigger inputs. See Priority of simultaneous triggers.

BCTU input trigger signals are level-sensitive; thus, if a logical level 1 is detected, an event is captured by the BCTU.

### 61.2.1 Block diagram

The following figure shows the top-level block diagram of BCTU.

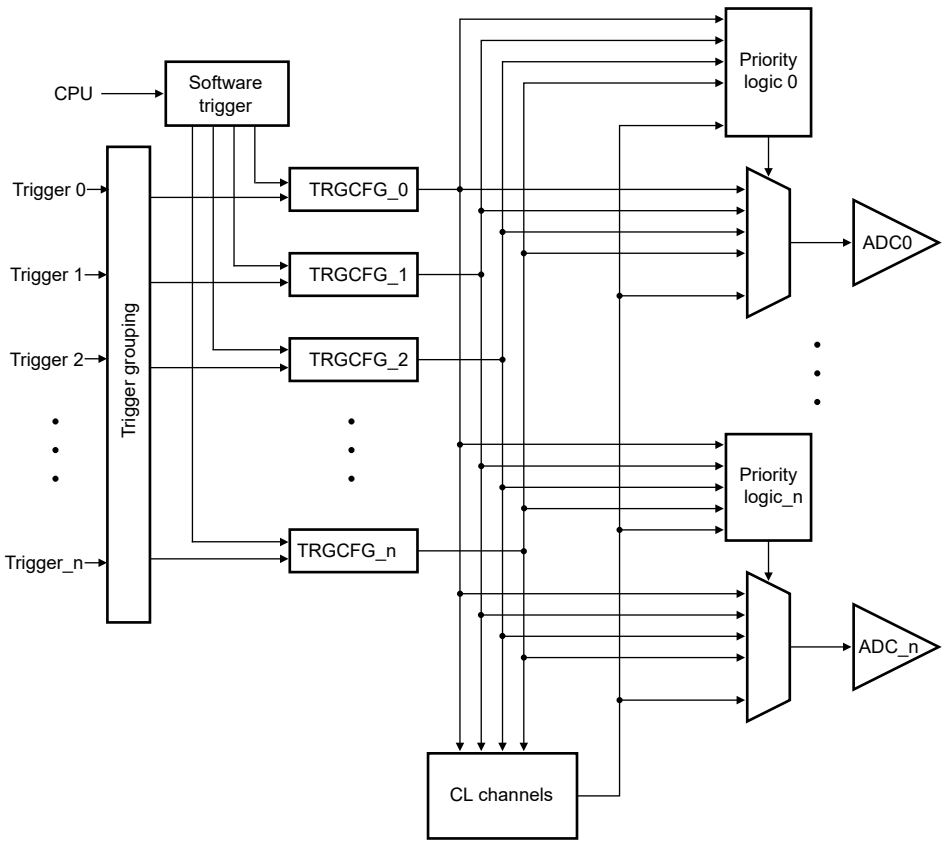

Figure 342. BCTU block diagram

### 61.2.2 Features

BCTU supports:

- 72 Trigger inputs, configured with the Trigger Configuration (TRGCFG_0 - TRGCFG_71) registers
- Trigger outputs to 3 ADCs
- BCTU to ADC0 and ADC1
- One priority selection logic block per ADC
- Selection multiplexers to select one trigger at a time for each ADC

- A CL of 32 ADC channels
- A trigger grouping block to latch the hardware triggers. BCTU clears these triggers when the ADC sends an acknowledgement for conversion completion.

### 61.2.3 Interaction with other peripherals

BCTU works together with timer and ADC modules on the chip. Use the trigger configuration registers (TRGCFG_*n*) to map BCTU triggers to ADC inputs. When a timer output asserts a BCTU trigger, BCTU passes the trigger to an ADC input and stores the trigger assertion until the corresponding ADC begins the requested conversion. When the ADC completes the conversion, BCTU asserts a trigger clear signal to clear both the internally stored trigger and the external trigger source if they are still asserted. Implementation illustrates the modules that interact with BCTU.

**NOTE**

A timer trigger can remain active until the corresponding ADC initiates conversion. Therefore, another match may occur in the timer before the ADC conversion begins. BCTU does not detect this trigger overrun. Your application must look for and respond to such conditions.

### 61.2.4 Implementation

The following figure shows the implementation structure of the BCTU.

**NOTE**

For more details of the actual trigger sources implemented in this device, see the chip-specific information section.

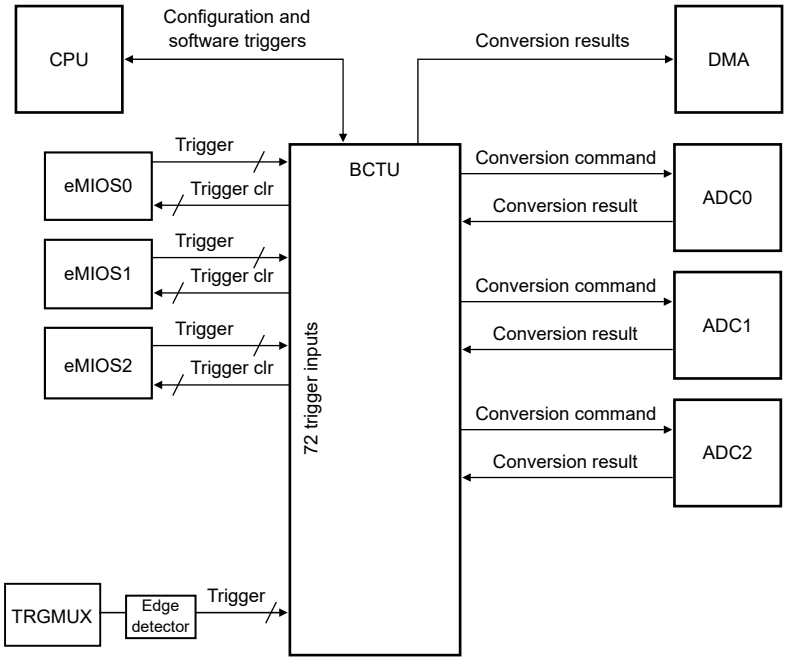

Figure 343. Implementation

## 61.3 Functional description

### 61.3.1 Triggers

#### 61.3.1.1 Overview

BCTU prioritizes ADC trigger inputs based on the input number: the lower the number, the higher the priority associated with it. Therefore, trigger 0 is the highest priority trigger and trigger 71 is the lowest priority. The trigger input priority scheme determines which trigger takes precedence when more than one trigger occurs at the same time, or when the triggered ADC is busy with a conversion. Therefore, there are two possible scenarios for the trigger priority selection:

- When there are no ongoing conversions
- When a triggered ADC is executing a conversion

BCTU supports two types of trigger sources:

- Hardware triggers from timer modules
- Software triggers (SFTRGR*n*)

#### 61.3.1.2 Hardware triggers

To request an ADC conversion through the BCTU, a timer module such as eMIOS asserts its output signal, which is connected to a BCTU trigger input. When BCTU detects the asserted trigger, it routes that request to the ADCs selected in the corresponding Trigger Configuration (TRGCFG_*n*[ADC_SEL*m*]). The trigger remains asserted until the requested conversion begins, at which time BCTU clears the trigger. If the timer asserts the trigger input when the trigger is already set, BCTU ignores the new trigger. If BCTU receives a new trigger input at the same time it is clearing the trigger, then the trigger remains asserted and BCTU initiates a new conversion.

If you configure the trigger for CL, trigger assertion begins a sequence of conversions controlled by the CL Channel Address (LISTCHR_0 - LISTCHR_15) registers. In this event, BCTU clears the trigger when the last conversion in the CL begins.

**NOTE**

Any new trigger input participates in the trigger priority selection scheme and therefore may not trigger the next conversion.

#### 61.3.1.3 Software triggers

You assert a software trigger by writing 1 to the corresponding field of the appropriate software trigger (SFTRGR*n*) register. Similar to the hardware triggers, BCTU changes the software trigger field to 0 when the requested conversion begins. If you write 1 to the software trigger field while the conversion is still in progress, BCTU ignores the request. If you write 1 to the field at the same time BCTU is attempting to clear the trigger (change the field to 0), the trigger remains asserted and BCTU triggers a new conversion following the trigger priority criteria.

#### 61.3.1.4 Configure all triggers

Global trigger enable (MCR[GTRGEN]) allows you to configure the BCTU trigger inputs and then activate them all at one time.

To configure and then activate all BCTU triggers:

1. Clear any currently active and asserted trigger inputs (write 0 to TRGFG_*n*[TRG_FLAG]), which also causes BCTU to assert trigger clear to the trigger sources.
2. Disable global triggers (MCR[GTRGEN]). This action deactivates all trigger inputs and prevents BCTU from generating any ADC conversion requests.
3. Configure the individual trigger inputs (see Configure individual triggers).
4. Enable global triggers (MCR[GTRGEN]). This action activates all individually enabled triggers at the same time.

#### 61.3.1.5 Configure individual triggers

Using Trigger Configuration (TRGCFG_0 - TRGCFG_71), for each trigger:

- Enable the trigger (TRIGEN).

- Specify the target ADC (ADC_SEL*n*).
- Specify the ADC channel (CHANNEL_VALUE_OR_LADDR).
- Specify whether the trigger initiates a single conversion or a CL (TRS).
- For a CL trigger, specify a pointer to the CL element (TRGCFG_x[CHANNEL_VALUE_OR_LADDR]).

#### 61.3.1.6 Reconfigure triggers on-the-fly

**NOTE**

Reconfigure BCTU triggers only when the individual trigger is not active (TRG_FLAG). If TRG_FLAG is 1, the requested conversion is still in progress and it is not safe to modify the trigger configuration.

To reconfigure a trigger on-the-fly (while BCTU is in full operation):

1. Disable the trigger (TRIGEN) to prevent it from requesting a new conversion.
2. Check the current state of the trigger (TRG_FLAG) to be sure no conversion or CL is in progress.
3. When any in-progress conversion or CL completes (TRG_FLAG == 0), clear the trigger source by writing 1 to TRG_FLAG. This action ensures that only trigger inputs that assert after you reconfigure and re-enable the trigger are able to request a new conversion or CL.
4. Reconfigure the trigger (see Configure individual triggers).
5. Enable the trigger (TRIGEN).

#### 61.3.1.7 Enable software triggers

To allow software triggers (SFTRGRn) to request conversions, you must enable global trigger enable (MCR[GTRGEN]). If you disable global trigger enable, software triggers do not initiate a conversion but asserted triggers remain asserted. However, when you enable global trigger enable, any asserted software triggers initiate conversions following the priority scheme of lowest to highest trigger number.

Software triggers operate regardless of individual trigger enable (TRGCFG_x[TRIGEN]). That is, writing 1 to any Software Trigger (SFTRGRn) initiates a conversion (following the priority scheme) regardless of the value of trigger enable. This software trigger independence supports the elimination of conflict between software and hardware triggers.

#### 61.3.1.8 Trigger timing

There are four clock cycles from assertion of a BCTU trigger input to assertion of the trigger output to the ADC. For single conversions, BCTU asserts trigger clear back to the trigger source simultaneous to asserting the trigger to the ADC.

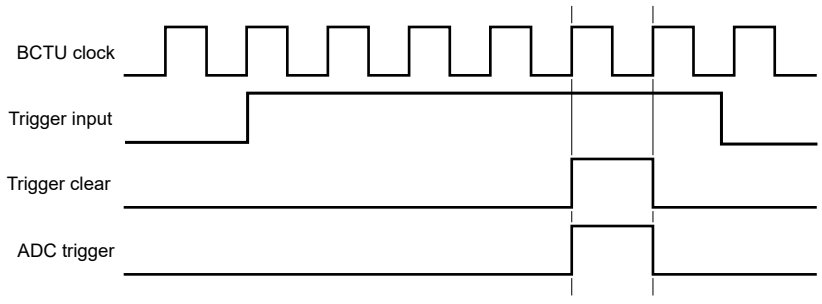

Figure 344. Trigger timing

#### 61.3.1.9 Priority of simultaneous triggers

When more than one trigger input asserts a conversion request to the same ADC at the same time—that is, in the same BCTU clock cycle—BCTU employs a priority scheme to determine which asserted trigger to process next. BCTU prioritizes trigger inputs based on the trigger number. The lowest number, trigger 0, has the highest priority, and the highest number, trigger 71, has the lowest priority.

If two triggers assert in the same clock cycle, BCTU gives priority to the lower numbered trigger. For example, if trigger 0 and trigger 1 both assert in the same cycle, BCTU selects trigger 0 for trigger generation. Trigger 1 remains active (pending) until the conversion requested by trigger 0 completes. See Simultaneous trigger priority management.

If trigger 0 asserts again before the next trigger selection opportunity at the end of the current conversion, then BCTU selects it again and trigger 1 remains asserted (pending) during the next ADC conversion time frame.

As illustrated in Trigger timing, BCTU requires four clock cycles to transmit a conversion request to an ADC if that ADC is not already executing a conversion. However, if the ADC is busy at the time of trigger assertion, BCTU requires only three clock cycles to generate the conversion request for a subsequent conversion.

Triggers that assert in the same clock cycle but target different ADCs are not in conflict, and BCTU processes both triggers at the same time.

#### 61.3.1.10 Simultaneous trigger priority management

The following figure shows the simultaneous triggers for priority management.

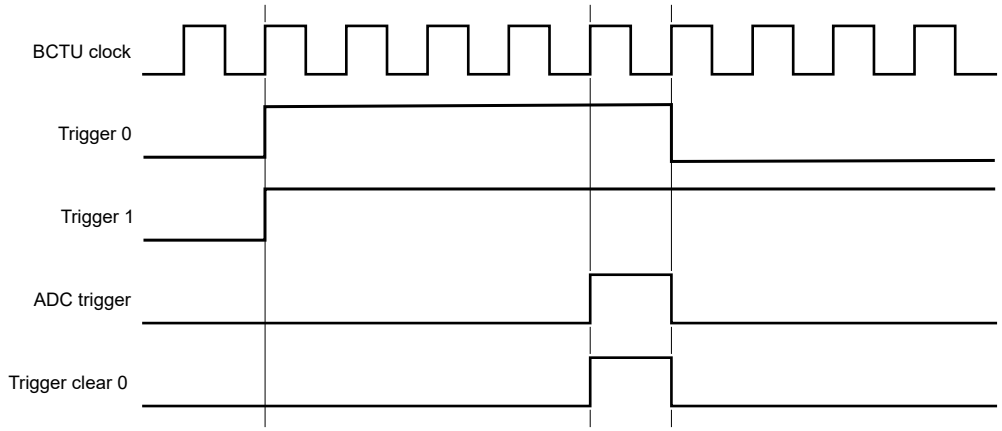

**Figure 345. Simultaneous trigger priority management**

#### 61.3.1.11 Trigger management when ADC is busy

When a trigger input asserts a conversion request to an ADC that is already processing a conversion requested by a different trigger, the new trigger remains active (pending) until the conversion in progress completes. This behavior is the same as if the two triggers had been simultaneous (occurred in the same clock cycle). When the in-progress conversion completes, the pending trigger then competes for priority with any other active trigger for that ADC.

#### 61.3.1.12 Trigger clearing mechanism

There are two sources of ADC conversion triggers: hardware trigger, from the trigger inputs and software triggers, from SFTRGRn register.

A logical level 1 is detected in the input and captured into an input trigger register. This register remains set until the related conversion starts. At this time, the input trigger register is cleared. If another logical level 1 is detected while the trigger register is already set, the new level is not considered by the BCTU hardware. If a new logical level 1 occurs at the same time the trigger register is being cleared, then the register remains set and a new conversion is triggered by this input.

**NOTE**

The new triggered conversion will participate in the trigger priority selection thus may not trigger the next conversion.

The software trigger behaves similarly to the hardware trigger. The difference is that the trigger register is set by a CPU write operation. The trigger register is cleared by the BCTU hardware when the related conversion starts. If the CPU tries to set the trigger register by writing to the SFTRGR register corresponding bit, while the register is already set, the new attempt to set the register is not considered by the BCTU hardware. If a set occurs at the same time the hardware is attempting to clear the same trigger register, then the set has precedence and the register remains set. A new conversion will be triggered following the trigger priority criteria implemented in the hardware.

In case a LIST of conversions is triggered, instead of a single conversion, the trigger register is cleared at the start of the last conversion in the LIST.

## 61.3.2 Conversion list (CL)

### 61.3.2.1 CL overview

A CL executes a sequence of conversions on one or more target ADCs. See CL architecture and operation. It also stores information from the last conversion executed in a sequence except for the target ADC, which is stored in ADC select n (TRGCFG_*m*[ADC_SEL*n*]).

If the channel or CL address (TRGCFG_x[CHANNEL_VALUE_OR_LADDR]) points to a CL element containing one or more entries:

1. The trigger initiates a sequence of conversions starting with the target CL element.
2. The sequence executes until the LAST channel (LISTCHR_*n*[LAST_y] is 1), and stops after that channel is converted.

When you configure the CL element for next channel wait for trigger (write 1 to LISTCHR_*n*[NEXT_CH_WAIT_ON_TRIG_y]):

1. BCTU clears the trigger source.
2. CL execution pauses after the current conversion is completed.
3. CL execution resumes when the same trigger asserts again.

BCTU determines trigger priority before executing any CL. See Priority of simultaneous triggers.

### 61.3.2.2 CL architecture and operation

The following figure shows the CL architecture and operation.

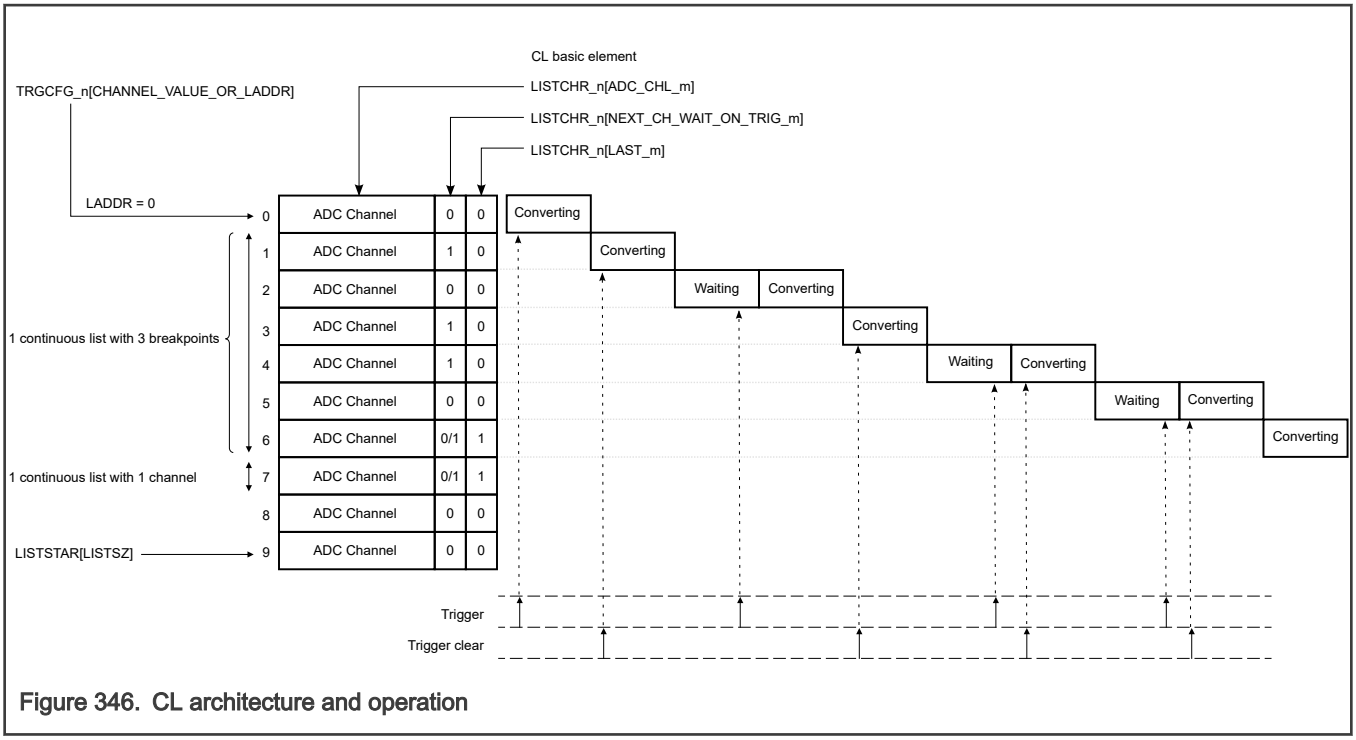

Figure 346. CL architecture and operation

### 61.3.2.3 CL channel rules

CL conversion obeys the following rules:

- The sequence of conversions executes until the Last Channel (LISTCHR_*n*[LAST_y] is 1).
- A CL conversion sequence precludes other conversions on the same ADC. If the CL is waiting (LISTCHR_*n*[NEXT_CH_WAIT_ON_TRIG_y] is 1), BCTU cannot route a non-CL conversion to that ADC (although that ADC remains available for normal and injected conversions).
- Two or more triggers for different ADCs may point to the same CL. This CL can drive parallel execution on the selected ADCs.
- If the Channel or CL Address (TRGCFG_x[CHANNEL_VALUE_OR_LADDR]) does not point to a valid list address, BCTU uses address 0 by default.
- When the CL pointer reaches the last available list address (LISTSTAR[LISTSZ] minus 1), the pointer wraps to list address 0.
- You can select more than one ADC per trigger using the ADC Select n (TRGCFG_x[ADC_SELn]) fields, but selecting more than one ADC is valid only for multiple parallel CL operation. If you select more than one ADC for a single-conversion trigger, BCTU ignores the trigger.

## 61.3.3 ADC conversion results access

### 61.3.3.1 Overview

The value of DATA_DEST determines access to ADC results.

- DATA_DEST = 000: ADC results are available in the ADC data registers.
- DATA_DEST = 001: ADC results are available in FIFO 1 Result Data (FIFO Result Data (FIFO1DR - FIFO2DR)). See Route conversion data to FIFO.
- DATA_DEST = 010: ADC results are available in FIFO 2 Result Data (FIFO Result Data (FIFO1DR - FIFO2DR)). See Route conversion data to FIFO.

You can access ADC results using flags and interrupt requests (see Access on interrupt request) or DMA (see Access on DMA request). Interrupt requests are based on Module Status (MSR) flags. ADC*n*DR provides the following information, with one register used for each ADC:

- The conversion results
- The channel that was used for the conversion
- The trigger input that initiated the conversion
- Whether a CL element generated the conversion
- Whether the data was the last conversion of a CL

#### 61.3.3.2 Access on interrupt request

If interrupts are enabled for ADC*n* Result Data (MCR[IEN*n*] is 1) and DMAs are disabled for ADC*n* Result Data (MCR[DMA*n*] is 0), BCTU generates an interrupt request for each available conversion data in ADC*n*DR. Because BCTU executes conversions on different ADCs in parallel, conversion results may be available on multiple ADCs at the same time. New Data (MSR[NDATAn] is 1) indicates that new conversion data is available in the corresponding ADC Data Result (ADC*n*DR). To clear the New Data flag, write 1 to MSR[NDATAn_CLR].

#### 61.3.3.3 Access on DMA request

If you enable DMA requests (MCR[DMA*n*]):

- You must select one channel for DMA per ADC.
- New conversion result data (ADC*n*DR) generates a DMA request.
- The DMA controller deasserts the DMA request and writes 1 to MSR[NDATAn_CLR] to clear the flag.

When an ADC generates new data (MSR[NDATAn]), BCTU processes the DMA request. See Clear a DMA request.

#### 61.3.3.4 Clear an interrupt request

BCTU clears an interrupt request when:

- The number of valid entries is less than or equal to the FIFOn watermark level (FIFOWM[WM_FIFO*n*]).
- You write 1 to FIFO watermark interrupt status (FIFOERR[WM_INT_FIFO*n*]).

#### 61.3.3.5 Clear a DMA request

BCTU clears a DMA request when:

- The number of valid entries is less than or equal to the FIFOn watermark level (FIFOWM[WM_FIFO*n*]).
- The DMA controller sends acknowledgment to BCTU.

#### 61.3.3.6 Clear an error-generated interrupt request

Clear an interrupt generated because of an error condition by writing 1 to the appropriate error flag:

- FIFOERR[OVR_ERR_FIFO1]
- FIFOERR[UNDR_ERR_FIFO1]
- FIFOERR[OVR_ERR_FIFO2]
- FIFOERR[UNDR_ERR_FIFO2]

#### 61.3.3.7 Conversion data overrun

If new ADC conversion data becomes available before you read the previous data (ADC*n*DR), then BCTU indicates a data overrun (MSR[DATAOVRn] is 1).

If you enable interrupts for the ADC (MCR[IEN*n*]), a data overrun also generates an interrupt request, regardless of the DMA request configuration.

To clear a data overrun (MSR[DATAOVRn]), write 1 to data overrun clear (MSR[DATAOVRn_CLR]). See Clear an error-generated interrupt request.

#### 61.3.3.8 Route conversion data to FIFO

BCTU allows you to route multiple ADC conversion results to one of 2 internal data FIFOs. Any trigger source can route results to an available FIFO based on the trigger index. Each FIFO has a dedicated counter (FIFOCNTR[CNTR_FIFO*n*]) to indicate the number of entries in the FIFO.

Each FIFO also has its own result data register (FIFO*n*DR) that contains the following information about the last conversion result routed to the FIFO.

- ADC result data
- Trigger source index
- ADC number
- ADC channel number

#### 61.3.3.9 Read ADC result from FIFO

Each FIFO has DMA and interrupt interfaces. The DMA interface reads data. The interrupt interface indicates watermark and error conditions:

- An overrun error (FIFOERR[OVR_ERR_FIFO*n*]) occurs when you attempt to write data to an already full FIFO.
- An underrun error (FIFOERR[UNDR_ERR_FIFO*n*]) occurs when you attempt to read data from an empty FIFO.
- BCTU asserts a watermark interrupt request if the number of valid FIFO entries exceeds the watermark level (FIFOWM[WM_FIFO*n*]).

You can read a FIFO:

- by enabling DMA requests (FIFOCR[DMA_EN_FIFO*n*])
- by polling the FIFO full status (FIFOSR[FULL_FIFO*n*])

See Configuration of DMA and interrupt behavior.

#### 61.3.3.10 Configuration of DMA and interrupt behavior

**Table 350. Configuration of DMA and interrupt behavior**

| FIFOCR[DMA_EN_FIFO*n*] | FIFOCR[IEN_FIFO*n*] | Condition |
|---|---|---|
| 0 | 0 | No DMA request; no interrupt request |
| 0 | 1 | Interrupt request when FIFO exceeds watermark level; interrupt request on error |
| 1 | 0 | DMA request when FIFO exceeds watermark level |
| 1 | 1 | DMA request when FIFO exceeds watermark level; interrupt request on error |

## 61.3.4 Multiple parallel conversions (MPC)

### 61.3.4.1 Overview

The MPC mechanism allows you to execute a series of simultaneous ADC conversions by selecting more than one ADC for any CL-configured trigger.

### 61.3.4.2 Configure MPC

To configure a CL to perform MPC:

1. Select CL for the trigger resolution (write 1 to TRGCFG_*m*[TRS]).
2. Select more than one ADC for the trigger (TRGCFG_*m*[ADC_SEL*n*]).
3. Specify the CL address for the first CL element (TRGCFG_*m*[CHANNEL_VALUE_OR_LADDR]).

### 61.3.4.3 CL address selection for MPC

When the trigger input for the CL asserts, BCTU uses the channel or list address (CHANNEL_VALUE_OR_LADDR) as an index into the CL for the lowest numbered ADC selected (ADC_SEL*n*), and each subsequent element of the CL for each remaining selected ADC. The set of selected ADC channels perform their conversions in parallel. When that set of conversions is complete, the next set of CL elements determine the next set of ADC channels to perform parallel conversions, as illustrated in:

- Example: MPC with two ADCs
- Example: MPC with three ADCs

### 61.3.4.4 Example: MPC with two ADCs

The following figure shows the example of MPC with two ADCs.

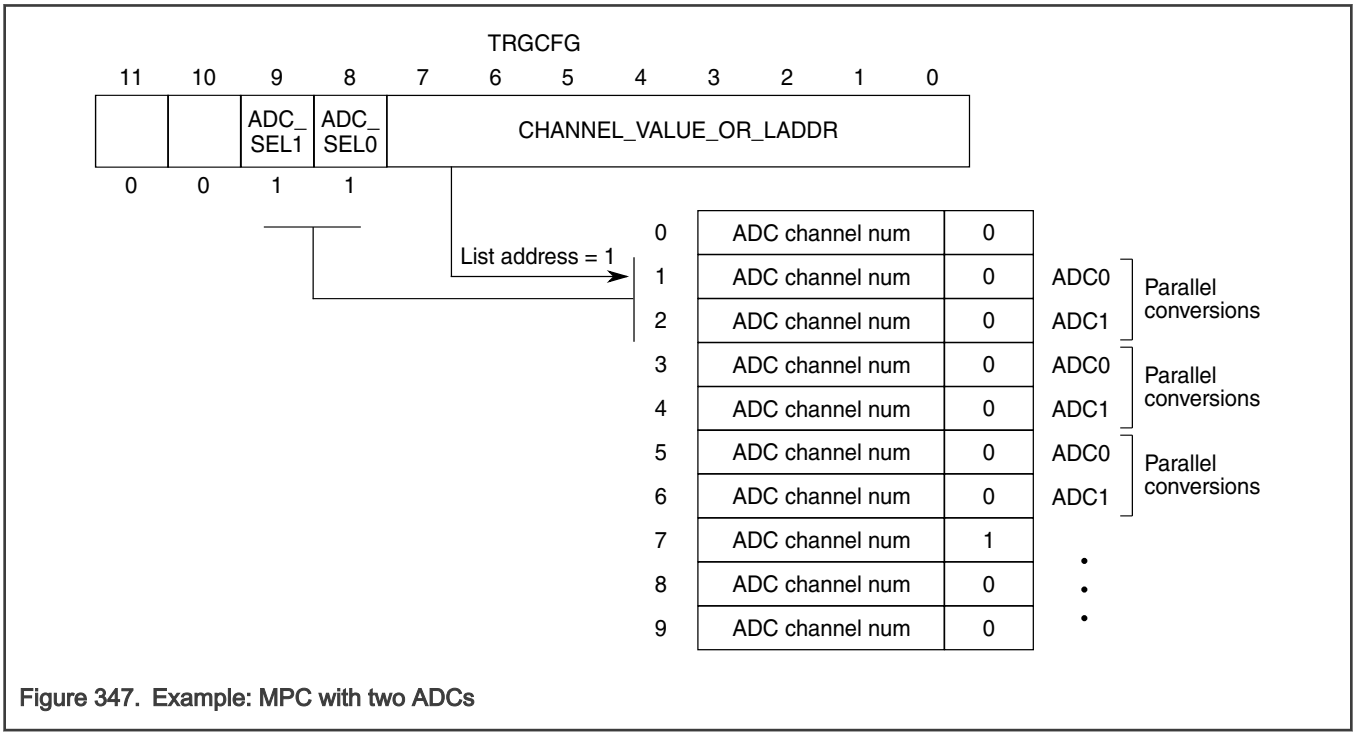

**Figure 347. Example: MPC with two ADCs**

### 61.3.4.5 Example: MPC with three ADCs

The following figure shows the example of MPC with three ADCs.

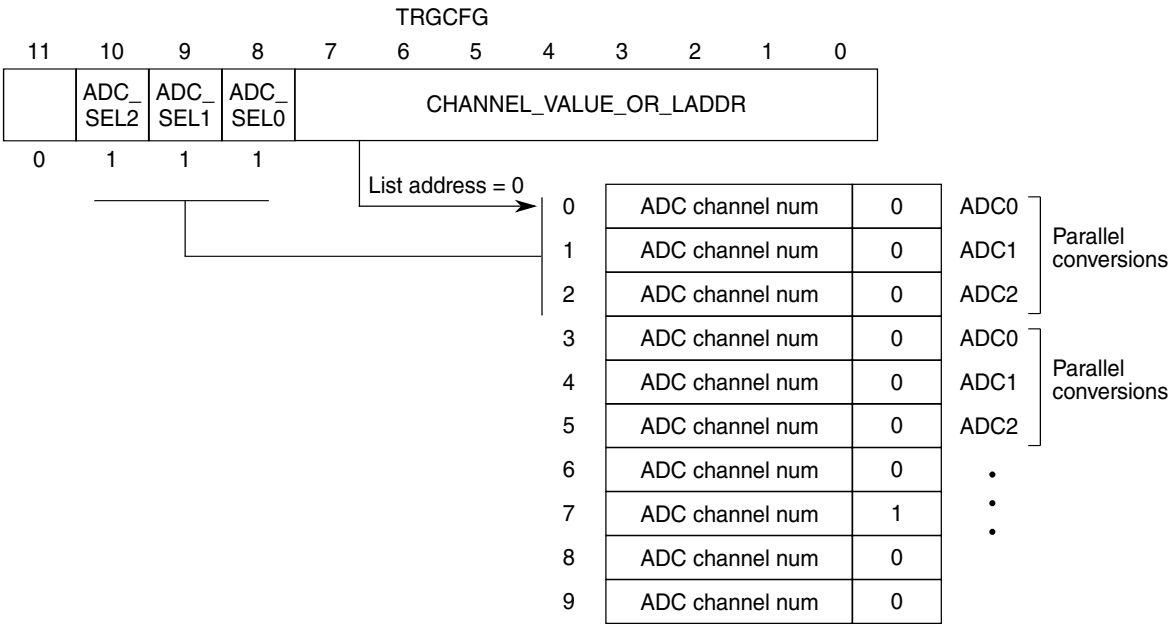

Figure 348. Example: MPC with three ADCs

#### 61.3.4.6 MPC priority rules

MPC follows the same priority rules as for single conversions, which is based on the trigger input number: the lower the trigger, the higher the priority. However, MPC cannot start until all ADCs selected for the CL are available; that is, they are not currently engaged in conversion. For example, if a trigger input asserts for a CL using ADC0 and ADC1, BCTU does not initiate the CL until ADC0 and ADC1 are both available.

Also, if ADC0 is available but there is a higher priority trigger for ADC1, the MPC does not start. If trigger inputs assert for two MPCs that have at least one ADC in common, the lower trigger number has higher priority. A priority conflict occurs only when separate requested CLs have at least one ADC in common. If the MPCs use different ADCs, there is no conflict and the MPCs execute at the same time.

### 61.3.5 Modes

#### 61.3.5.1 Module Disable (Low Power state)

Module disable (MCR[MDIS]) stops the BCTU clock, resulting in reduced power consumption.

When you disable BCTU (write 1 to MDIS), it:

- Waits for the completion of any in-progress conversions before stopping the clock.
- Ignores all trigger inputs.
- Does not trigger any ADC conversion requests.
- Maintains any asserted trigger inputs, which you can clear if necessary.

When you re-enable BCTU (write 0 to MDIS) and global triggers are enabled (MCR[GTRGEN]), BCTU processes all active asserted trigger inputs and sends conversion requests to ADCs according to the priority scheme.

### 61.3.6 Clocking

This module has two clock ports.

1. ipg_clk_bctu - is the main clock of complete BCTU IP.

2. ipg_clk_s - is the gated IPG clock to be used in BCTU registers only.

### 61.3.7 Software reset

You can reinitialize all BCTU registers to their reset values with software reset (MCR[Software_Reset]).

Software reset does not clear any active trigger inputs, but it does put the ADC interface into the Reset state. Therefore, to avoid data incoherency, you must terminate any BCTU-triggered conversions or wait until they are complete before asserting software reset.

### 61.3.8 Interrupts and DMA requests

**Table 351. Interrupts and DMA requests**

| Event | Enable interrupt | Enable DMA request | Description |
|---|---|---|---|
| Trigger Flag | MCR[TRGEN] | — | Interrupt request on assertion of trigger flag (MSR[TRGF]) |
| ADC Data Ready | MCR[IEN*n*] | MCR[DMA*n*] | Interrupt or DMA request when ADC result data is available (ADC*n*DR) |
| CL Last | MCR[LIST_IEN] | — | Interrupt request when the last conversion of any CL executes |
| FIFO Watermark | FIFOCR[IEN_FIFO*n*] | FIFOCR[DMA_EN_FIFO*n*] | Interrupt or DMA request when the number of valid FIFO entries exceeds the FIFO |

## 61.4 BCTU register descriptions

All BCTU registers are 32 bits wide. 8-bit write operations are allowed. The BCTU module does not include any coherence mechanism, so application software must ensure coherency.

**NOTE**

- You must always write 0 to reserved writable registers and fields. Read accesses of reserved registers and fields do not return meaningful data.
- For registers with write protection, if protection is active and you attempt to write to those registers, register content is unaffected and BCTU issues a transfer error.

### 61.4.1 BCTU memory map

BCTU base address: 4008_4000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Module Configuration (MCR) | 32 | RW | 0000_0000h |
| 8h | Module Status (MSR) | 32 | RW | 0000_0000h |
| 18h - 134h | Trigger Configuration (TRGCFG_0 - TRGCFG_71) | 32 | RW | 0000_0000h |
| 228h | Write Protection (WRPROT) | 32 | RW | 0000_0000h |
| 22Ch | Software Trigger 1 (SFTRGR1) | 32 | RW | 0000_0000h |
| 230h | Software Trigger 2 (SFTRGR2) | 32 | RW | 0000_0000h |

*Table continues on the next page...*

*Table continued from the previous page...*

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 234h | Software Trigger 3 (SFTRGR3) | 32 | RW | 0000_0000h |
| 23Ch - 244h | ADCn Result Data (ADC0DR - ADC2DR) | 32 | R | 0000_0000h |
| 24Ch | CL Size Status (LISTSTAR) | 32 | R | 0000_0020h |
| 250h - 28Ch | CL Channel Address (LISTCHR_0 - LISTCHR_15) | 32 | RW | 0000_0000h |
| 450h - 454h | FIFO Result Data (FIFO1DR - FIFO2DR) | 32 | R | 0000_0000h |
| 460h | FIFO Control (FIFOCR) | 32 | RW | 0000_0000h |
| 464h | FIFO Watermark Configuration (FIFOWM) | 32 | RW | 0000_0000h |
| 468h | FIFO Error/Status (FIFOERR) | 32 | RW | 0000_0000h |
| 46Ch | FIFO Status (FIFOSR) | 32 | R | 0000_0000h |
| 470h | FIFO Counter (FIFOCNTR) | 32 | R | 0000_0000h |

### 61.4.2 Module Configuration (MCR)

#### Offset

| Register | Offset |
|---|---|
| MCR | 0h |

#### Function

Configures the following aspects of BCTU behavior:

- Low power
- Debug
- Trigger control
- DMA control
- Interrupt control

Access: User read/write

### Diagram

Also enables an interrupt request on an overrun in ADC*n*DR, which indicates the previous data has been overwritten by a new conversion result. See also MSR[NDATA*n*] and MSR[DATAOVR*n*]].<br>Enabling ADC*n*DR DMA (DMA*n* field) disables the interrupt for new data in ADC*n*DR, but the interrupt for ADC*n*DR data overrun remains enabled.<br>0b - Disable<br>1b - Enable |

## 61.4.3 Module Status (MSR)

### Offset

| Register | Offset |
|---|---|
| MSR | 8h |

### Function

Indicates the status of various BCTU functions, including:

- Whether conversion data is available for each ADC
- CL operation, such as the last conversion command executed in a CL
- Whether BCTU triggered any of the ADCs

All flag fields become 0 upon assertion of a low-power (software) or clock-stop (hardware) request. You can turn off individual flags by writing 1 to the field.

Access: User read/write

### 61.4.4 Trigger Configuration (TRGCFG_0 - TRGCFG_71)

#### Offset

For a = 0 to 71:

| Register | Offset |
|---|---|
| TRGCFG_a | 18h + (a × 4h) |

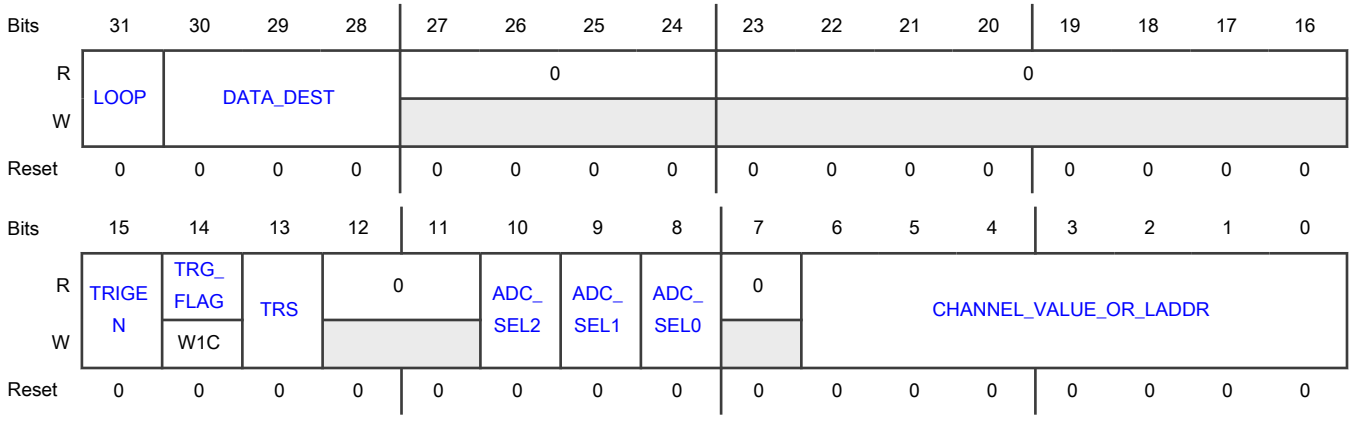
#### Function

Configures the corresponding trigger:

- Specifies the target ADC and ADC channel to use for conversion.
- Specifies whether to use a CL or a single ADC conversion command.

Access: User read/write

#### Diagram



**Fields**

| Field | Function |
|---|---|
| 31<br>LOOP | Loop<br>Specifies that the current trigger executes in a loop; that is, the triggered conversion repeats until you disable Loop. Each loop-triggered conversion wins the priority evaluation among all pending triggers, and executes only if it is the highest-priority triggered conversion at the moment the conversion starts.<br>0b - Disable<br>1b - Enable |
| 30-28<br>DATA_DEST | Data Destination<br>Specifies the destination for storing the conversion results. You can route each ADC's conversion result to either of the following:<br>• ADC-specific data registers<br>• One of the available FIFOs<br>BCTU routes conversion results to different destinations based on the trigger index that requested the conversion. ## 61.4.5 Write Protection (WRPROT)

### Offset

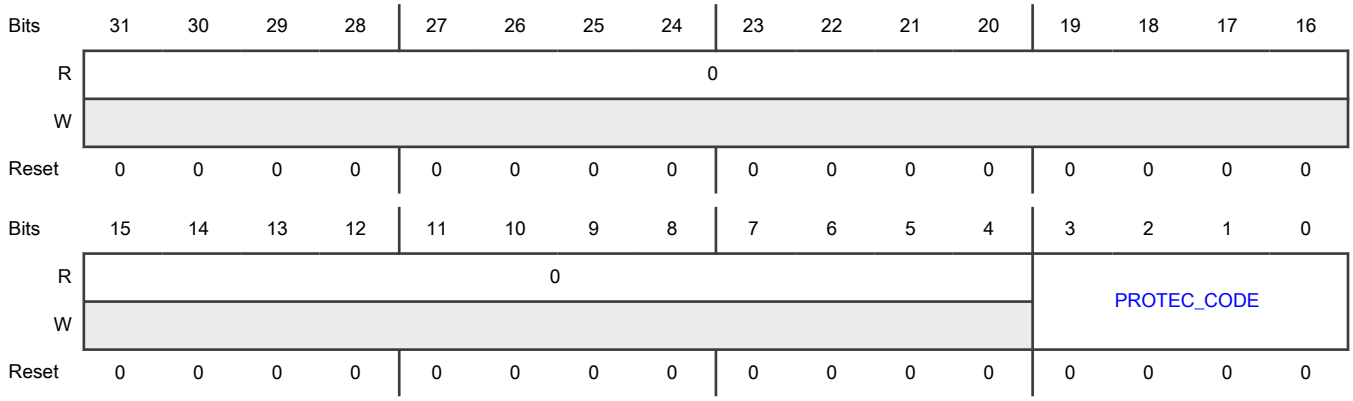
| Register | Offset |
|---|---|
| WRPROT | 228h |

### Function

Enables write protection at reset exit. To allow writes to protected registers, you must write a special code into PROTEC_CODE. There are two codes to remove protection: one that permanently disables the protection; one that disables protection during one write cycle to a protected register, after which the protection code returns to the initial (protected) value of 0000b.

Access: User read/write

### Diagram



### Fields

| Field | Function |

## 61.4.6 Software Trigger 1 (SFTRGR1)

### Offset

| Register | Offset |
|---|---|
| SFTRGR1 | 22Ch |

### Function

Allows you to trigger conversions on the associated triggers.

To use a software trigger, you must first disable the corresponding hardware trigger (TRGCFG_x[TRIGEN]).

BCTU writes 0 to a software trigger field on completion of the triggered conversion.

Access: User read/write; this register is write protected by Write Protection (WRPROT). If protection is enabled, writes to this register generate a transfer error and do not modify its content.

### Diagram

## 61.4.10 CL Size Status (LISTSTAR)

### Offset

| Register | Offset |
|---|---|
| LISTSTAR | 24Ch |

### Function

Indicates the size of the CL. Each element of the CL contains the channel number used in one conversion.

Access: User read

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 61.4.15 FIFO Error/Status (FIFOERR)

### Offset

| Register | Offset |
|---|---|
| FIFOERR | 468h |

### Function

Allows you to clear FIFO error and status flags. Each FIFO has its own error and status flags that can be configured to generate an interrupt. FIFO Status (FIFOSR) maintains the status of these flags. BCTU writes a 1 to these flags, and you must then clear them using FIFOERR.

Access: User read/write

### Diagram

## 61.5 Glossary

**CL** Conversion list. The set of ADC channels, configured through the CL Channel Address (LISTCHR_0 - LISTCHR_15) registers, used for performing multiple sequential conversions initiated by a single trigger.

**MPC** Multiple parallel conversions

**PSI** Parallel side interface

**RWB** Read/write bus

**WDATA** Write Data bus

# Chapter 62
# Trigger MUX (TRGMUX)

## 62.1 Chip-specific TRGMUX information

### 62.1.1 TRGMUX input output configuration and instances

This chip has 1 instance of TRGMUX module.

The device supports the triggering scheme between peripherals. For the supported trigger sources and destination, see the TRGMUX connectivity file attached to this document.

This device has 16 pads (SIUL2) mapped from TRGMUX inputs and TRGMUX outputs are mapped to the eMIOS channels, hence two timers channels can use a single pin of the device to do input capture.

**While using TRGMUX, below points need to be taken care:**

- User must ensure the minimum pulse of 100 ns on SIUL2 pads when using them as trigger source on TRGMUX.
- Pulses which are visible on pads depends on the pad type. Different pad supports different frequencies. For more details on pad types and their respective bandwidth, see section "IO signal table" in "Signal Multiplexing" chapter.
- End of conversion (EOC) signals of ADC modules are mapped on TRGMUX inputs as trigger sources. The EOC signal is asserted after ADC conversion regardless whether conversion is signaled by polling flags, interrupt or DMA transfer. The signal shall not be used to start injected conversion on same ADC channel as it will overwrite current result register.
- The minimum pulse length requirement is 1.5X of destination clock, so that it gets properly sampled at the destination IP connected to TRGMUX outputs, otherwise there are chances of missing the triggers generated from source. For example, the trigger generated from PAD for ADC conversion should be kept high/low for at least 1.5X of ADC clock so that it gets sampled in ADC clock domain. To ensure this, pulse strechers have been placed before some of the hardware modules mapped on TRGMUX outputs.
- Some PADS are being shared by both ADC and TRGMUX. It is recommended that trigger initiated from such PADS should not be used to trigger a conversion on the ADC channel mapped on same PAD. Failing to do this will cause congestion on same PAD.
- Out of all the pads mapped on TRGMUX, first four pads have glitch filters. For details, see the TRGMUX connectivity file attached to this document. The trigger pulse width should honour the pulse width requirement as per Glitch Filter specifications. The same signal can be observed at output pin if the pulse width of the input data signal is more than 400ns and no output signal should be observed if the pulse width of the input data signal is less than 20ns. A signal with a pulse width that is between 20ns and 400 ns should not be applied as the behavior is not guaranteed.
- Trigger outputs are grouped peripheral-wise and have a common lock bit based on TRGMUX REGx. For instance, normal_trigger, injected_trigger and external_sync of ADC_0 are grouped onto TRGMUX_REG0 and have a common lock bit.

### 62.1.2 Pulse strechers in TRGMUX

TRGMUX has some hardware modules on its input side running at faster clock than some of the IPs present on output side. For instance, eMIOS reload outputs running at 160 MHz can trigger LPI2C trigger input clocked at 40 MHz, in that case there is a high chance that trigger from eMIOS will be missed. Following Pulse strechers are added for the IPs on output side of TRGMUX.

Table 352. Pulse strechers in TRGMUX

| Evaluation Parameter | ADC_0/1/2 external trigger to sync the start pulse | BCTU trigger 23/47/71 | FlexIO trigger input_0/1/2/3[1] | LPI2C_0 Trigger input | LPSPI_0/1/2 Trigger input | CM7_0/1_RXEV |
|---|---|---|---|---|---|---|
| **IP expects** | Synchronized single cycle pulse | Synchronized pulse | IP requirement is to have 2 cycle pulse of flexio_clk | IP requirement is to have 2 cycle pulse of lpi2c_clk | IP requirement is to have 2 cycle pulse of lpspi_clk | Single cycle pulse |
| **Frequency** | CORE_CLK | CORE_CLK | CORE_CLK | AIPS_SLOW_CLK | LPSPI_0 - PLAT_AIPS_CLK<br>LPSPI_1/2/3 - AIPS_SLOW_CLK | CORE_CLK |
| **Inside IP** | Used as combo signal | Flopped inside IP and clear after ADC conversion completed | Synchronized inside IP | Synchronized inside IP | Synchronized inside IP | - |
| **At SoC** | Since it an ASYNC signal and IP required synchronized single cycle pulse, so a pulse stretcher is added to convert pulse from any frequency domain into a signle cycle pulse of CORE_CLK | Since slow IP such as LPCMP or from PAD can also trigger BCTU and BCTU wants that trigger should clear after the ADC conversion. So a pulse stretcher is added which convert any size of pulse to a single cycle pulse of BCTU clock (CORE_CLK) | Pulse stretcher is added to convert any pulse into a two cyle pulse of FLEXIO_CLK | Pulse stretcher is added to convert any pulse into a two cyle pulse of LPI2C_CLK | Pulse stretcher is added to convert any pulse into a two cyle pulse of LPSPI_CLK | Pulse stretcher is added to convert any pulse into a single cyle pulse of CORE_CLK |
| **Output slot at which pulse stretcher is added** | 2, 6, 10 | 24, 25, 26 | 64, 65, 66, 67 | 84 | 88, 92, 96 | 156, 157 |

1. These pulse stretchers are available in MCXE31B variants only.

**NOTE**

The trigger outputs which have pulse stretcher before them, there should be atleast a gap of 5 cycle of destination clock for back to back trigger.

## 62.2 Overview

TRGMUX allows you to configure the trigger inputs for various peripherals.

### 62.2.1 Block diagram

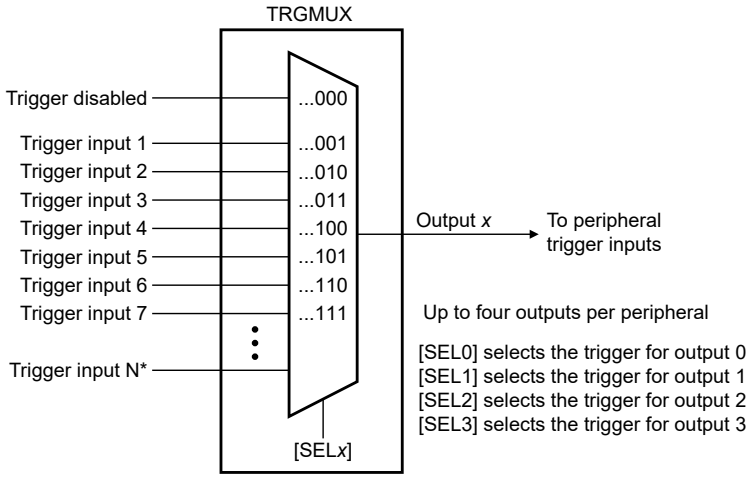

Figure 349. Block diagram

**NOTE**

Up to 255 trigger inputs may be available for SEL0, SEL1, and SEL2. For SEL3, up to 127 trigger inputs may be available. When the number of trigger inputs is 255, SEL3 is not available and becomes reserved. See the chip-specific TRGMUX information for details about trigger input and output configuration on this chip.

### 62.2.2 Features

- Configurable trigger sources for peripherals
- Dedicated TRGMUX register for each peripheral

## 62.3 Functional description

### 62.3.1 Clocking

This module has no clocking considerations.

### 62.3.2 Interrupts

This module has no interrupts.

## 62.4 External signals

This module has no external signals.

## 62.5 Initialization

This module does not require initialization.

## 62.6 TRGMUX register descriptions

### 62.6.1 TRGMUX memory map

You can only write to TRGMUX registers in Supervisor mode.

**Table 353. Select bit fields**

# Chapter 63
# Software Watchdog Timer (SWT)

## 63.1 Chip-specific SWT information

### 63.1.1 SWT instances and configuration

This chip supports up to three instances of SWT, one for each Cortex-M7 core.

**Table 354. SWT configuration**

| Instance | Core | Reset type | Clock Source | SWT_MIN_TO (100µs) | SWT_TO_RST (25ms) |
|---|---|---|---|---|---|
| SWT_0[1] | Cortex-M7_0 | Functional Reset - RAM retention | SIRC (32K) | 3 | 320h |

1. SWT_0 supports operation in STANDBY mode.

**NOTE**

When using SWT as a wakeup source from standby, software should ensure proper value of timeout such that SWT timeout doesn't get expired again (after wakeup till standby exit is completed). The timeout should be programmed to a value greater than the time till standby exit is complete (sum of standby exit time and the time till software disables padkeeping).

**NOTE**

The "Reset only the SWT" feature using SWT_RRR[RRF] is supported only when SWT reset reaction is demoted to interrupt within MC_RGM.

#### Protect SWT from service by non-core masters

You must program protection for the SWT registers so that only core masters can service SWT.

When an SWT timeout takes place, the logic generating a reset to the system runs off the slow internal RC oscillator (32KHz). It could therefore take the SWT almost 31.25µs to reset the system, after timeout, leaving more time for runaway code to execute. The register interface clock of SWT is running from AIPS_SLOW_CLK, see Clocking chapter for more details. The register interface clock is responsible for generating the abort for invalid access while the counter clock is responsible for generating the SWT reset request. Since there is a synchronization happening between the register interface clock and counter clock domains before generating the SWT reset request, thus the generation of the reset request can take a number of register interface clock cycles after an invalid access is done.

#### Clock source

SWT is clocked by SIRC only.

## 63.2 Overview

The Software Watchdog Timer (SWT) is a 32-bit window watchdog timer that enables the system to recover from situations such as:

- Software trapped in a loop
- A bus transaction failing to terminate

In regular operation, SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified timeout period. If this servicing action does not occur before the timer expires, SWT generates an interrupt or a hardware reset request.

You can configure SWT to generate a reset request or an interrupt on the initial timeout. SWT always generates a reset request on a second consecutive timeout.

**NOTE**

Terminology in this chapter has been updated as follows:

**Table 355. Updated terms**

| Updated terms | Deprecated term |
|---|---|
| Initiator | Master |

### 63.2.1 Block diagram

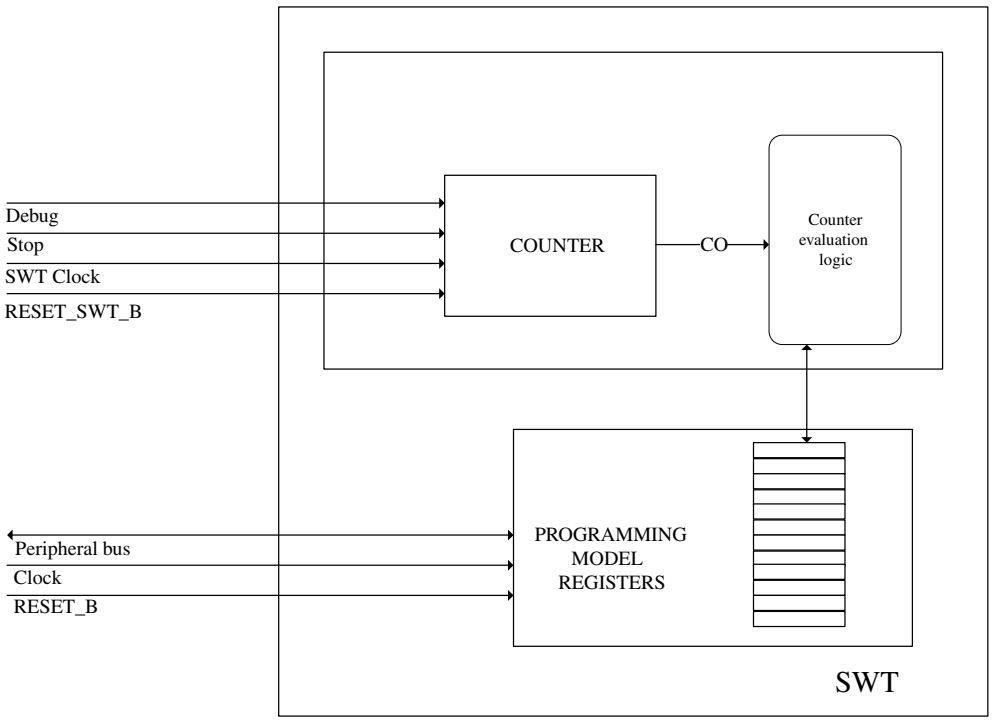

**Figure 350. SWT block diagram**

### 63.2.2 Features

SWT has the following features:

- 32-bit countdown timer
- Selection of regular or window servicing
- Selection of reset request or interrupt on an initial timeout
- Selection of fixed or keyed service sequence
- Initiator access protection
- Hard and soft configuration lock bits

## 63.3 Functional description

### 63.3.1 Behavior in different chip and core modes

SWT supports the core modes of operation as follows:

| Core mode | SWT behavior |
|---|---|
| Normal | When SWT is enabled (CR[WEN] = 1), the SWT timer counts down continuously. |
| Debug | If CR[FRZ] = 1, SWT stops the timer; otherwise, the timer continues to run. |
| Stop or Standby | If CR[STP] = 1, SWT stops the timer; otherwise, the timer continues to run. |

### 63.3.2 Register access latency

Accesses to SWT registers occur with no peripheral bus wait states. The peripheral bus bridge may add 1 or more system wait states. However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system clock cycles plus seven counter clock cycles.

### 63.3.3 Service key generation

SWT generates service keys with the pseudorandom key generator defined by the following equation.

$$SK_{n+1} = (17 \times SK_n + 3) \bmod 2^{16}$$

**Figure 351. Pseudorandom key generator**

This algorithm generates a sequence of $2^{16}$ different key values before repeating. In keyed service sequence mode, each time you write a valid key to SR[WSC], SWT updates SK[SK] with the next key.

For example, if the previous service key (SK[SK]) is 100h, then the next service sequence keys are 1103h followed by 2136h.

### 63.3.4 Clocking

The SWT has two clock domains, one for the IPS interface and the other for the counter and reset request logic. The two clocks can be asynchronous to each other and have independent resets.

See the chip-specific SWT information for the clock source of the counter and reset logic.

See the chip-specific SWT information to find the clock source that drives the countdown timer.

### 63.3.5 Reset

The following table describes the SWT resets:

**Table 356. SWT resets**

| Reset | Description |
|---|---|
| RESET_B | It is used to reset the programming model registers. |
| RESET_SWT_B | It is used to reset the functional domain of the SWT. |

### 63.3.6 Interrupts

The SWT generates one interrupt:

- Timeout interrupt: it is asserted when the watchdog timer count exceeds the timeout period in the TO register.

### 63.3.7 Reset only the SWT

When a timeout triggers a reset request and the application does not require a system reset, you can make the SWT instance reset itself rather than the whole system.

To make a timeout reset request trigger only an SWT reset (rather than the whole system), write 1 to the Reset Request Flag (RRR[RRF]).

This action causes SWT to:

- Clear the reset request.
- If an interrupt request also occurred, clear the interrupt request (IR[TIF]).
- Reset and restart the SWT.

For systems with multiple SWT instances, this feature allows you to reset an individual SWT instance, avoiding the widespread impact of a system reset.

### 63.3.8 Test SWT operation

When you disable SWT, it loads the current countdown timer into CO[CNT]. When you enable SWT, it clears this register. You can use CO[CNT] to perform a software self-test of SWT.

To test SWT operation:

1. Enable the SWT (CR[WEN] = 1).
2. Do not service SWT for a fixed period of time that is less than the timeout value.
3. Disable the SWT (CR[WEN] = 0).
4. Read the value in CO[CNT] to determine whether the internal countdown timer is working properly.

**NOTE**

The value shown in CO[CNT] can lag behind the actual internal timer up to six system clock cycles plus eight counter clock cycles.

## 63.4 External signals

This module has no external signals.

## 63.5 Initialization

### 63.5.1 Initialize the SWT

To initialize the SWT, you must do the following:

- Set the timeout period.
- Control timeout behavior. There are two options:
  - Select reset request on timeout, or
  - Select interrupt on initial timeout.

You must initialize all registers before enabling SWT (CR[WEN]). You can initialize the registers in any sequence.

#### 63.5.1.1 Set the timeout period

When you enable SWT, it loads the greater of the specified watchdog timeout period or the minimum timeout period into an internal 32-bit countdown timer every time you perform a valid service operation.

To set the watchdog timeout period:

- Write the desired timeout period to TO[WTO].

The minimum timeout period is 3 clock cycles.

#### 63.5.1.2 Control timeout behavior

SWT can respond to a timeout in one of two ways:

- Generate an immediate reset request on any timeout.
- Generate an interrupt and load the countdown timer on an initial timeout, then generate a reset request on a subsequent timeout.

##### 63.5.1.2.1 Select reset request on timeout

To configure SWT to generate an immediate reset request on any timeout:

- Write 0 to CR[ITR].

##### 63.5.1.2.2 Select interrupt on initial timeout

To configure SWT to generate an interrupt on an initial timeout:

- Write 1 to CR[ITR].

In this configuration, on the initial timeout:

- SWT loads the countdown timer with the timeout period (TO[WTO]).
- SWT indicates the interrupt with the timeout interrupt flag (IR[TIF]).
- If a second consecutive timeout occurs before writing the service sequence for the first timeout, SWT generates a reset request.

You clear the interrupt flag by writing 1 to IR[TIF].

#### 63.5.1.3 Configure locking and unlocking

You can lock the SWT configuration with either a hard lock or a soft lock. When either lock is in effect, CR, TO, WN, and SK are read-only.

##### 63.5.1.3.1 Enable the hard lock

To enable the hard lock:

- Write 1 to CR[HLK].

Hard lock is disabled only by a reset.

##### 63.5.1.3.2 Enable the soft lock

To enable the soft lock:

- Write 1 to CR[SLK].

##### 63.5.1.3.3 Unlock the soft lock

To unlock the soft lock:

1. Write C520h to SR[WSC].
2. Write D928h to SR[WSC].

This unlock sequence:

- Ignores service sequence writes.
- Recognizes the unlock sequence regardless of previous writes.

- Recognizes the unlock sequence regardless of the time between writes.
- Does not require CR[WEN] to be 1.

You can write this unlock sequence at any time.

**NOTE**

It is possible for a keyed service sequence to unlock soft lock. See Avoid soft unlock for the procedure to handle this situation.

#### 63.5.1.3.4 Avoid soft unlock

When SWT operates in keyed sequence service, the sequence of service keys generated by the pseudorandom generator includes the unlock keys for soft lock. If one or more service routines use both unlock keys in the proper order, 0xC520 followed at any future time by 0xD928, SWT unlocks soft lock (CR[SLK] = 0). The unlock sequence logic ignores any service keys other than the unlock keys, so the unlock keys don't have to be inserted consecutively. If the second unlock key is also the second key of a service operation, unlock occurs before the service operation completes.

To avoid unlock:

If the service routine writes a key value of C520h to SR[WSC] as a key of the service operation, then do the following:

1. Complete the service operation.
2. Complete the unlock sequence by writing the second unlock key, D928h, to SR[WSC].
3. Reinitiate the soft lock (CR[SLK] = 1).

### 63.5.1.4 Select behavior on an invalid access

SWT can respond to an invalid access one of two ways:

- Generate a bus error.
- Generate a bus error and, if SWT is enabled, a reset request.

To select how SWT responds to an invalid access:

- Write the appropriate value to CR[RIA].

## 63.5.2 Initiate service operations

When enabled, SWT requires periodic execution of a servicing operation.

SWT can operate in one of the following service sequence modes:

- Fixed service sequence
- Keyed service sequence

### 63.5.2.1 Initiate a fixed service sequence

To initiate the fixed service sequence:

1. Select the fixed servicing mode (write 00b to CR[SMD]).
2. Write A602h to SR[WSC].
3. Write B480h to SR[WSC].

There is no timing requirement between the two writes. The service sequence logic ignores unlock-sequence writes.

### 63.5.2.2 Initiate a keyed service sequence

To initiate the keyed service sequence:

1. Select the keyed servicing mode (write 01b to CR[SMD]).
2. Read the initial service key from SK[SK].
3. Calculate the next service key using the provided equation.
4. Write that service key to SR[WSC].
5. Repeat steps 2 through 4 one time.

See Service key generation for information about service keys.

#### 63.5.2.3 Select window service mode

In window service mode, you must write the service sequence only when the watchdog timer is less than the window start value (WN[WST]). If you write the service sequence outside of this window, the access is invalid and generates a bus error or reset request depending on the Reset on Invalid Access setting (CR[RIA]).

For example, if the timeout period is 5000 and the window start value is 1000, you must write the service sequence during the last 20% of the timeout period.

Synchronization logic in SWT causes a slight delay in the opening of the window. This delay can be up to three system clock cycles plus four counter clock cycles.

To select window service mode:

- Write 1 to (CR[WND]).

## 63.6 SWT register descriptions

The SWT programming model allows only 32-bit (word) accesses.

Any of the following attempted accesses are invalid:

- Non-32-bit accesses
- Writes to read-only registers
- Writes of incorrect values to SR when SWT is enabled
- Accesses to reserved addresses
- Accesses by initiators without permission

You control how SWT responds to an invalid access with CR[RIA].

### 63.6.1 SWT memory map

SWT_0 base address: 4027_0000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|

# Chapter 64
# System Timer Module (STM)

## 64.1 Chip-specific STM information

### 64.1.1 STM instances and configuration

This chip has up to three instances of STM, one for each Cortex-M7 core. The STM counter increments at the STM module clock frequency divided by a pre-scaled value.

Table 357. STM instances

| Instance | MCXE31B | MCXE315/MCXE316/MCXE317 |
|---|---|---|
| STM_0 | Yes | Yes |
| STM_1 | Yes | No |

## 64.2 Overview

STM supports commonly required system and application software timing functions. STM includes a 32-bit count-up timer and four 32-bit compare channels with a separate interrupt source for each channel. The timer is driven by the STM module clock divided by an 8-bit prescale value (1 to 256).

### 64.2.1 Block diagram

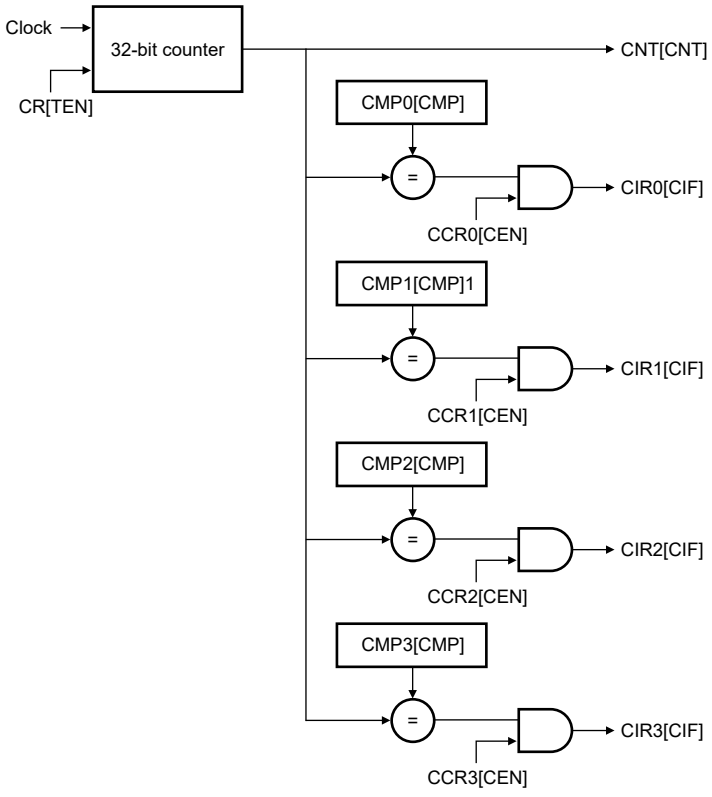

Figure 352. Block diagram

### 64.2.2 Features

STM has the following features:

- One 32-bit count-up timer with an 8-bit prescaler
- Four 32-bit compare channels
- An independent interrupt source for each channel
- Ability to stop the timer in Debug mode

## 64.3 Functional description

### 64.3.1 Count-up timer

STM has one 32-bit count-up timer that serves as the time base for four compare channels. When enabled, the counter increments at the module clock frequency divided by a prescaler value in the range from 1 to 256. When enabled in Normal mode, the timer increments continuously. The counter rolls over at FFFF_FFFFh to 0000_0000h with no restrictions at this boundary.

### 64.3.2 Compare channels

STM has four identical compare channels. Each channel includes a channel control register (CCR*n*), a channel interrupt register (CCR*n*), and a channel compare register (CMP*n*). When the channel is enabled and its channel compare value matches the timer count, STM sets the channel interrupt flag and generates an IRQ on that channel.

### 64.3.3 Behavior in different chip modes

STM supports the chip modes of operation as follows:

| Chip mode | STM behavior |
|---|---|
| Normal | When the timer is enabled (CR[TEN] = 1), the timer counts up continuously. |
| Debug | If CR[FRZ] = 1, STM stops the timer. Otherwise, when the timer is enabled (CR[TEN] = 1), the timer counts up continuously. |

### 64.3.4 Clocking

This module has no clocking considerations.

### 64.3.5 Interrupts

STM can generate a channel interrupt. For information, see:

- Compare channels
- Respond to compare channel events
- Channel Interrupt (CIR0 - CIR3)

## 64.4 External signals

This module has no external signals.

## 64.5 Initialization

This module does not require initialization.

## 64.6 Application information

### 64.6.1 Configure the timer

1. Set the initial timer count (CNT[CNT]).
2. Specify STM behavior in chip Debug mode (CNT[FRZ]).
3. Set the counter prescaler (CR[CPS]).
4. Start the timer (CR[TEN]).

### 64.6.2 Configure the compare channels

For each compare channel:

1. Set the channel compare value (CMP*n*[CMP]).
2. Enable the compare channel (CCR*n*[CEN]).

### 64.6.3 Respond to compare channel events

For each compare channel:

1. Check the channel interrupt flag (CIR*n*[CIF]).
2. If the channel interrupt flag is set, respond to the interrupt request.
3. When the channel interrupt has been handled, clear the channel interrupt flag (CIR*n*[CIF]).

## 64.7 STM register descriptions

The STM programming model allows only 32-bit (word) accesses. An attempted reference using a different size or to a reserved address generates a bus error termination.

### 64.7.1 STM memory map

STM_0 base address: 4027_4000h

STM_1 base address: 4047_4000h

| Offset | Register | Width (In bits) | Access | Reset value |

## 64.8 Glossary

| | |
|---|---|
| **IRQ** | Interrupt request |

# Chapter 65
# Periodic Interrupt Timer (PIT)

## 65.1 Chip-specific PIT information

### 65.1.1 PIT instances and configuration

This chip has up to 3 instances of the PIT each with 4 PIT timers/channels, each channel being 32 bits in length.

**Table 358. PIT instances**

| Instance | MCXE31B | MCXE317 | MCXE315/MCXE316 |
|---|---|---|---|
| PIT_0 | Yes | Yes | Yes |
| PIT_1 | Yes | Yes | Yes |
| PIT_2 | Yes | No | No |

**Table 359. PIT instances and features**

| Feature | PIT_0 | PIT_1 | PIT_2 |
|---|---|---|---|
| Real time interrupt (RTI) | Yes (32-bit)[1] | No | No |
| Lifetime Timer | Yes | No | No |
| Timer chaining to create a 64-bit timer | Yes | No | No |
| Number of 32-bit timer channels | 4 | 4 | 4 |
| Timer value unchanged by a non-destructive reset | No | No | No |

1. The RTI on PIT_0 supports operation in STANDBY mode

The RTI shall be possible to set the timer resolution to 1us independently to other timers. The interrupt can be generated by programming LDVAL0, LDVAL1, LDVAL2 and LDVAL3 to 48 in case of 48 MHz FIRC as system clock and 40 in case of 40 MHz system clock to generate an interrupt after 1us.

### 65.1.2 Input Output

All the PIT instances are capable of generating periodic triggers. PIT triggers are routed to motor control IPs such as eMIOS, LCU, BCTU, ADC etc. via TRGMUX. See the TRGMUX connectivity file attached to this document for details.

## 65.2 Overview

PIT includes:

- An array of timers that can be used to raise interrupts and triggers.
- A dedicated RTI timer that runs on a separate oscillator clock and can be used for system wakeup

### 65.2.1 Block diagram

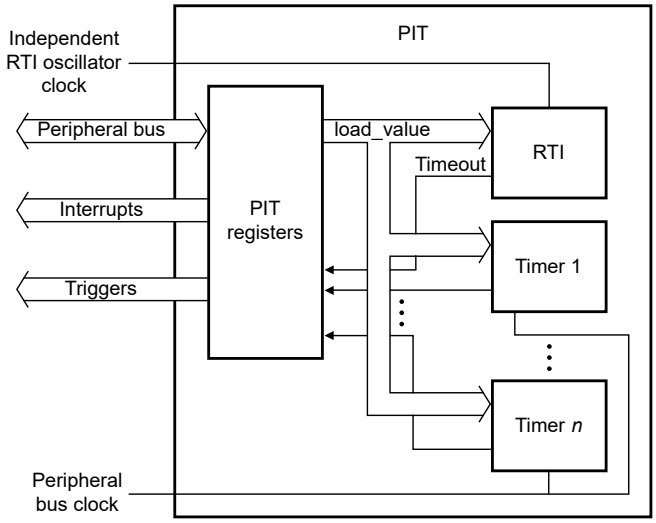

Figure 353. Block diagram

### 65.2.2 Features

The key features of the module are:

- 4 32-bit countdown timers
- Independent timeout periods for each timer
- Ability to chain two timers into a 64-bit lifetimer
- Ability of timers to generate interrupts
- Ability of timers to generate trigger pulses
- Maskable interrupts
- One RTI countdown timer to wake up the CPU
- Option to generate the RTI even when the bus clock is off
- Power saving with a separate input clock for the RTI timer. All other timers share a common core clock.

## 65.3 Functional description

See the chip-specific PIT information for the number of PIT modules and their channel configuration on this chip.

### 65.3.1 Modes of operation

| Mode | Description |
|---|---|
| Run | All functional parts of the PIT operate normally. |
| Debug | Timers run or stop depending on the Freeze setting (MCR[FRZ]). See Debug mode. |

### 65.3.2 Timer operation

When you enable a timer (write 1 to TCTRL*n*[TEN] or RTI_TCTRL[TEN]), the timer counts down (one count per clock cycle) from its initial start value (LDVAL*n*[TSV] or RTI_LDVAL[TSV]). When the timer period expires (CVAL*n*[TVL] or RTI_CVAL[TVL] reaches 0), PIT sets the Timer Interrupt Flag (writes 1 to TFLG*n*[TIE] or RTI_TFLG[TIE]). It then reloads the timer start value and starts the timer counting down again.

If the timer interrupt is enabled (TCTRL*n*[TIE] or RTI_TCTRL[TIE] = 1), it generates an interrupt when it sets the Timer Interrupt Flag. The timer cannot generate a new interrupt until you clear the flag from the previous interrupt. Because clearing the RTI crosses clock domains, you should use a minimum RTI timer load value of 32.

You can read the current counter value of any timer (CVAL*n*[TVL] or RTI_CVAL[TVL]). Because the RTI timer is synchronized to the RTI clock domain, the value of the RTI counter may be several cycles old when read.

See these related topics:

- Stop and start a timer
- Change timer period
- Change timer period dynamically

**NOTE**

- If Freeze is enabled (MCR[FRZ] = 1) when the timer nears 0, the Debug mode command may not reach PIT before the timer expires and generates a trigger.
- If a timer is at zero when Debug mode is asserted, the interrupt trigger remains asserted until the device exits Debug mode. Clear the Timer Interrupt Flag (write 1 to TFLG*n*[TIF] or RTI_TFLG[TIF]) upon Debug exit.
- If Freeze is enabled (MCR[FRZ] = 1), sufficient time must be ensured for the IP to react.

#### 65.3.2.1 Stop and start a timer

To restart a running timer:

1. Disable the timer (write 0 to TCTRL*n*[TEN] or RTI_TCTRL[TEN]).
2. Enable the timer (write 1 to TCTRL*n*[TEN] or RTI_TCTRL[TEN]).

   Enabling the timer reloads the start value and starts the timer counting down again. See Restart counter period.

#### 65.3.2.2 Restart counter period

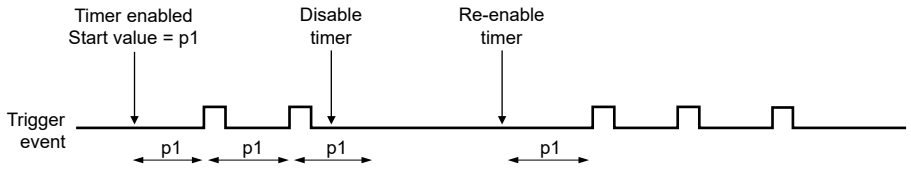

Figure 354. Restart counter period

#### 65.3.2.3 Change timer period

To change the counter period of a running timer:

1. Disable the timer (write 0 to TCTRL*n*[TEN] or RTI_TCTRL[TEN]).
2. Specify a new start value (LDVAL*n*[TSV] or RTI_LDVAL[TSV]).
3. Enable the timer (write 1 to TCTRL*n*[TEN] or RTI_TCTRL[TEN]).

   Enabling the timer loads the new start value and starts the timer counting down again. See Change current timer period.

#### 65.3.2.4 Change current timer period

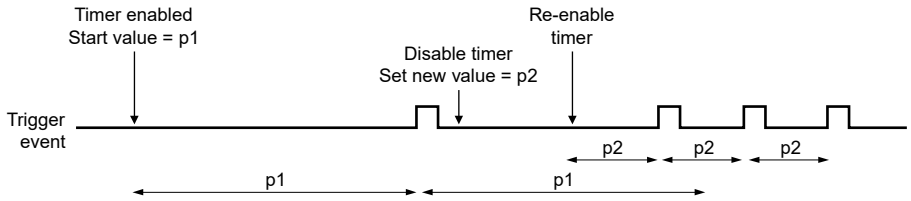

**Figure 355. Change timer period dynamically timing**

#### 65.3.2.5 Change timer period dynamically

To change the counter period of a running timer:

- Specify a new start value (LDVAL*n*[TSV] or RTI_LDVAL[TSV])

  The next time the timer expires, it loads the new start value. See Dynamically setting a new timer period.

#### 65.3.2.6 Dynamically setting a new timer period

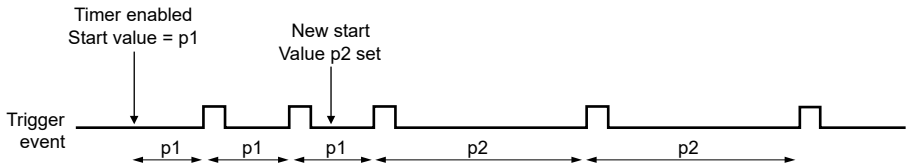

**Figure 356. Dynamically setting a new timer period**

### 65.3.3 Chained timers

PIT supports chaining two timers together to support timer periods greater than FFFFFFFFh. When a timer *n* has chain mode enabled, it decrements each time timer *n* - 1 expires. The chained timer sets its Timer Interrupt Flag when it expires (CVAL*n* = 0).

For example, assume you need to configure a timer period of 6,000,000,000 cycles. You could specify a start value of 10 for timer *n* and 599,999,999 for timer *n* - 1. With these values, the chained timer expires after timer *n* - 1 has expired ten times.

You cannot chain timer 0 or the RTI timer to another timer.

For an example configuration of a chained timer, see Example configuration using chained timers.

### 65.3.4 Lifetimer

PIT supports a 64-bit lifetimer. You configure the lifetimer by chaining timer 1 to timer 0 and populating the start values for both timers with the maximum value of FFFFFFFFh. You read the lifetimer in the LTMR64H and LTMR64L registers. LTMR64H returns the upper 32 bits of the lifetimer value and LMTR64L returns the lower 32 bits. When a timer 1 has chain mode enabled, it decrements each time timer 0 expires. The lifetimer expires when CVAL1 expires.

When you chain timer 1 to timer 0, timer 1 decrements every time timer 0 expires. To obtain the correct lifetimer value, read LTMR64H first and then read LTMR64L. When you read LTMR64H, it returns the value in CVAL1 (the chained timer value), and immediately latches the value from CVAL0 into LTMR64L. This latching eliminates the carryover effects of the running counter.

For an example configuration of the lifetimer, see Example configuration using the lifetimer.

### 65.3.5 Debug mode

If Freeze is enabled (MCR[FRZ] = 1), the timers stop if the device enters Debug mode. This freeze allows the software developer to halt the processor, investigate the current state of the system, including the PIT timer values, and then continue operation.

### 65.3.6 Clocking

The PIT general-purpose timers are driven by the peripheral bus clock. See the Clocking chapter for more information.

The RTI timer is driven by an independent oscillator clock. This clock input continues running when the device is in Stop mode. Driving the RTI timer with an independent clock allows the RTI to trigger periodic wake-up from Stop mode.

### 65.3.7 Interrupts

All of the timers support interrupt generation.

You enable interrupt generation for each individual timer (TCTRL*n*[TIE]). Each interrupt is available on a separate interrupt output.

When a timer expires (CVAL*n*[TVL] = 0), it sets the Timer Interrupt Flag (TFLG*n*[TIF]) regardless of whether the interrupt is enabled. To enable generation of an interrupt when the Timer Interrupt Flag is set, write 1 to TCTRL*n*[TIE]. To clear the Timer Interrupt Flag, write 1 to it.

When the RTI timer expires (RTI_CVAL*n*[TVL] = 0), PIT sets the RTI Timer Interrupt Flag (RTI_TFLG*n*[TIF]) regardless of whether the RTI is enabled. To enable generation of an RTI when the RTI Timer Interrupt Flag is set, write 1 to TCTRL*n*[TIE]. To clear the RTI Timer Interrupt Flag, write 1 to it.

The RTI is typically used for periodic wake-up from Standby mode, but it can also be used to generate a general-purpose interrupt.

## 65.4 External signals

PIT has no external inputs.

## 65.5 Initialization

To initialize PIT:

1. For each timer *n* you plan to use:
    a. Specify the timer period (LDVAL*n*[TSV]).

       To calculate the load value for a timer:

       Start value = (timer period / clock period) - 1

    b. If you want the timer to generate an interrupt each time it expires, enable the timer interrupt (write 1 to TCTRL*n*[TIE]).
    c. If you want to use this timer as the divisor of a pair of chained timers, chain this timer to the next lower-numbered timer (write 1 to TCTRL*n*[CHN]). You cannot chain timer 0. If you want to use the lifetimer, chain timer 1 to timer 0.
    d. Enable the timer (write 1 to TCTRL*n*[TEN]).
2. If you want to use the RTI feature:
    a. Specify the RTI timer period (RTI_LDVAL*n*[TSV]).
    b. Enable the RTI timer interrupt (write 1 to RTI_TCTRL*n*[TIE]).
    c. Enable the RTI timer (write 1 to RTI_TCTRL*n*[TEN]).
3. Activate, or enable, PIT (write 0 to MCR[MDIS]).

   All enabled timers load their start values and begin counting down.

For example configurations, see Application information.

## 65.6 Application information

### 65.6.1 Example configuration for general timers

In this example configuration:

- The PIT clock frequency is 50 MHz, which equates to a clock cycle of 20 ns.
- The RTI clock frequency is 10 MHz, which equates to a clock cycle of 100 ns.
- The RTI timer needs to generate a wake-up interrupt every 500 ms.
- Timer 1 needs to generate an interrupt every 5.12 ms.
- Timer 3 needs to generate a trigger event every 30 ms.

To configure PIT for this example:

1. Disable PIT (write 1 to MCR[MDIS]).
2. Use the formula in Initialization to calculate the load value for the RTI timer:

   (500 ms/100 ns) - 1 = 4,999,999 cycles, or 004C4B3Fh.
3. Specify the RTI timer load value (write 004C4B3Fh to RTI_LDVAL[TSV]).
4. Enable the RTI (write 1 to RTI_TCTRL[TIE])
5. Enable the RTI timer (write 1 to RTI_TCTRL*n*[TEN]).
6. Use the formula in Initialization to calculate the load value for timer 1:

   (5.12 ms/20 ns) - 1 = 255,999 cycles, or 0003E7FFh.
7. Disable timer 1 (write 0 to TCTRL1[TEN]).
8. Specify the timer 1 value (write 0003E7FFh to LDVAL1[TSV]).
9. Enable the timer 1 interrupt (write 1 to TCTRL1[TIE])
10. Enable timer 1 (write 1 to TCTRL1[TEN]).
11. Calculate the load value for timer 3:

    (30 ms/20 ns) - 1 = 1,499,999 cycles, or 0016E35Fh.
12. Disable timer 3 (write 0 to TCTRL3[TEN]).
13. Specify the timer 3 value (write 0016E35Fh to LDVAL3[TSV]).
14. Enable timer 3 (write 1 to TCTRL3[TEN]).
15. Activate, or enable, PIT (write 0 to MCR[MDIS]).

**NOTE**

You can configure timers without first disabling PIT or the timer itself. However, if PIT is running, be aware that when a timer begins using a new start value depends on whether the timer is running or disabled when you specify the new start value. For more information, see Timer operation.

The following example code provides the described configuration:

```
// Disable PIT (see note above)
PIT_MCR = 0x02;
```

```
// RTI
PIT_RTI_LDVAL = 0x004C4B3F; // Configure RTI for 5000000 cycles
```

```
PIT_RTI_TCTRL = PIT_TIE;    // Enable RTI
PIT_RTI_TCTRL |= PIT_TEN;   // Start RTI timer
```

```
// Timer 1
PIT_LDVAL1 = 0x0003E7FF;    // Configure timer 1 for 256000 cycles
PIT_TCTRL1 = TIE;           // Enable Timer 1 interrupts
PIT_TCTRL1 |= TEN;          // Start Timer 1
```

```
// Timer 3
PIT_LDVAL3 = 0x0016E35F;    // Configure timer 3 for 1500000 cycles
PIT_TCTRL3 = TEN;           // Enable Timer 3
```

```
 // Enable PIT
 PIT_MCR = 0x00;
```

### 65.6.2 Example configuration using chained timers

In this example configuration:

- The PIT clock frequency is 100 MHz, which equates to a clock cycle of 10 ns.
- Timers 1 and 2 are available.
- An interrupt is needed every minute. Using the formula in Initialization, a 1 minute timer period requires:

  (60 s/100 ns) - 1 = 5,999,999,999 cycles, or 165A0BBFFh

  This value requires more than 32 bits.

To configure PIT for this example:

1. Disable PIT (write 1 to MCR[MDIS]).
2. Disable timer 1 (write 0 to TCTRL1[TEN]).
3. Disable timer 2 (write 0 to TCTRL2[TEN]).
4. Chain timer 2 to timer 1 (write 1 to TCTRL2[CHN]).
5. For the timer 2 start value, select a value that divides evenly into the desired period. For this example, we are using 10. For the timer 1 value, divide the full timer period by the selected divisor: 6,000,000,000/10 = 600,000,000.
6. Specify the timer 2 value as the selected divisor (write 00000009h to LDVAL2[TSV]).
7. Specify the timer 1 value as the quotient minus 1, or 599,999,999 (write 0x23C345FFh to LDVAL1[TSV]).
8. Enable the timer 2 interrupt (write 1 to TCTRL2[TIE])
9. Enable timer 2 (write 1 to TCTRL2[TEN]).
10. Enable timer 1 (write 1 to TCTRL1[TEN]).
11. Activate, or enable, PIT (write 0 to MCR[MDIS]).

The following example code matches the described configuration:

```
// Disable PIT
PIT_MCR = 0x02;
```

```
// Timer 2
PIT_LDVAL2 = 0x00000009; // Configure Timer 2 to the divisor (10)
PIT_TCTRL2 = TIE;        // Enable Timer 2 interrupt
PIT_TCTRL2 |= CHN;       // Chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN;       // Enable Timer 2
```

```
// Timer 1
PIT_LDVAL1 = 0x23C345FF; // Configure Timer 1 to 600,000,000 cycles
PIT_TCTRL1 = TEN;        // Enable Timer 1
```

```
 // Enable PIT
 PIT_MCR = 0x00;
```

### 65.6.3 Example configuration using the lifetimer

To configure the lifetimer:

1. Disable PIT (write 1 to MCR[MDIS]).
2. Disable timer 0 (write 0 to TCTRL0[TEN]).
3. Disable timer 1 (write 0 to TCTRL1[TEN]).
4. Chain timer 1 to timer 0 (write 1 to TCTRL1[CHN]).
5. Specify the maximum start value for timer 1 (write FFFFFFFFh to LDVAL1[TSV]).
6. Specify the maximum start value for timer 0 (write FFFFFFFFh to LDVAL0[TSV]).
7. Enable timer 1 (write 1 to TCTRL1[TEN]).
8. Enable timer 0 (write 1 to TCTRL0[TEN]).
9. Activate, or enable, PIT (write 0 to MCR[MDIS]).

To access the lifetimer, first read LTMR64H and then LTMR64L. For more information, see Lifetimer.

The following example code matches the described setup:

```
// Disable PIT
PIT_MCR = 0x02;
```

```
// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1
```

```
// Timer 0
```

```
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

```
// Read lifetimer
current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;
```

```
 // Enable PIT
 PIT_MCR = 0x00;
```

## 65.7 PIT register descriptions

This section provides a detailed description of all PIT registers.

Program RTI registers only when the RTI clock is running.

### 65.7.1 PIT memory map

PIT_0 base address: 400B_0000h

PIT_1 base address: 400B_4000h

PIT_2 base address: 402F_C000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | PIT Module Control (MCR) | 32 | RW | See section |
| E0h | PIT Upper Lifetimer (LTMR64H) | 32 | R | 0000_0000h |
| E4h | PIT Lower Lifetimer (LTMR64L) | 32 | R | 0000_0000h |
| ECh | RTI Timer Load Value Sync Status (RTI_LDVAL_STAT) | 32 | RW | 0000_0000h |
| F0h | RTI Timer Load Value (RTI_LDVAL) | 32 | RW | 0000_0000h |
| F4h | Current RTI Timer Value (RTI_CVAL) | 32 | R | 0000_0000h |
| F8h | RTI Timer Control (RTI_TCTRL) | 32 | RW | 0000_0000h |
| FCh | RTI Timer Interrupt Flag (RTI_TFLG) | 32 | RW | 0000_0000h |
| 100h | Timer Load Value (LDVAL0) | 32 | RW | 0000_0000h |
| 104h | Current Timer Value (CVAL0) | 32 | R | 0000_0000h |
| 108h | Timer Control (TCTRL0) | 32 | RW | 0000_0000h |
| 10Ch | Timer Flag (TFLG0) | 32 | RW | 0000_0000h |
| 110h | Timer Load Value (LDVAL1) | 32 | RW | 0000_0000h |
| 114h | Current Timer Value (CVAL1) | 32 | R | 0000_0000h |
| 118h | Timer Control (TCTRL1) | 32 | RW | 0000_0000h |
| 11Ch | Timer Flag (TFLG1) | 32 | RW | 0000_0000h |

*Table continues on the next page...*

*Table continued from the previous page...*

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 120h | Timer Load Value (LDVAL2) | 32 | RW | 0000_0000h |
| 124h | Current Timer Value (CVAL2) | 32 | R | 0000_0000h |
| 128h | Timer Control (TCTRL2) | 32 | RW | 0000_0000h |
| 12Ch | Timer Flag (TFLG2) | 32 | RW | 0000_0000h |
| 130h | Timer Load Value (LDVAL3) | 32 | RW | 0000_0000h |
| 134h | Current Timer Value (CVAL3) | 32 | R | 0000_0000h |
| 138h | Timer Control (TCTRL3) | 32 | RW | 0000_0000h |
| 13Ch | Timer Flag (TFLG3) | 32 | RW | 0000_0000h |

## 65.7.2 PIT Module Control (MCR)

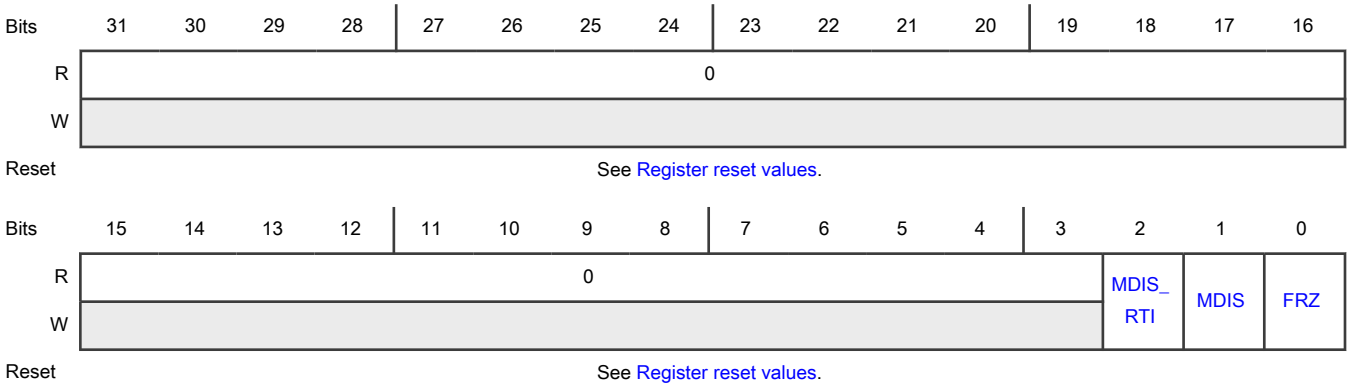
### Offset

| Register | Offset |
|---|---|
| MCR | 0h |

### Function

Enables the PIT timer clocks and specifies the behavior of the timers when PIT enters Debug mode.

### Diagram



### Register reset values

| Register | Reset value |
|---|---|
| MCR | PIT_0: 0000_0006h<br>PIT_1,PIT_2: 0000_0002h |

**Fields**

| Field | Function |
|---|---|
| 31-3<br>— | Reserved |
| 2<br>MDIS_RTI | Module Disable for RTI<br>Disables the RTI timer. You must write 1 to this field before setting up an RTI.<br>**NOTE**<br>This field is not supported in every instance. The following table includes only supported registers.<br>0b - Enables<br>1b - Disables |
| 1<br>MDIS | Module Disable for PIT<br>Disables the standard timers. This field does not affect the RTI timer. You must disable the clock (write 1 to MDIS) before configuring PIT. After configuration, you must enable the clock (write 0 to MDIS).<br>0b - Enables<br>1b - Disables |
| 0<br>FRZ | Freeze<br>Stops the timers when the device enters Debug mode.<br>0b - Timers run in Debug mode<br>1b - Timers stop in Debug mode |

| PIT_1 | — | MCR |
| PIT_2 | — | MCR |

## 65.7.3 PIT Upper Lifetimer (LTMR64H)

**Offset**

| Register | Offset |
|---|---|
| LTMR64H | E0h |

**Function**

Combined with LTMR64L, provides a 64-bit lifetimer constructed from the values in two chained PIT timers.

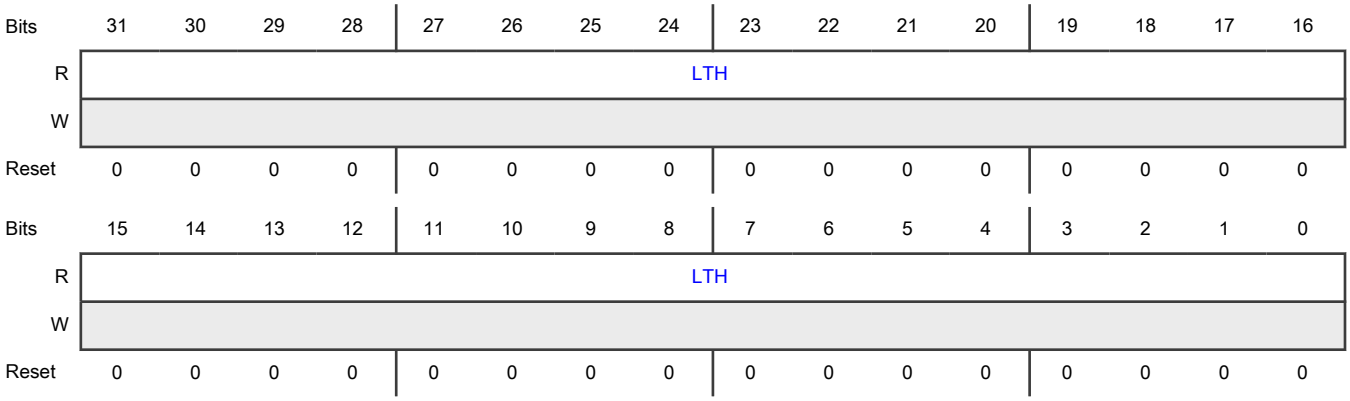
For more information, see Lifetimer.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| PIT_0 | LTMR64H | — |
| PIT_1 | — | LTMR64H |
| PIT_2 | — | LTMR64H |

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>LTH | Lifetimer Value<br>Indicates the timer value of timer 1. This value is the upper 32 bits of the 64-bit lifetimer value. When you read this register at t1, the value of timer 0 at t1 is latched into LTMR64L. |

## 65.7.4 PIT Lower Lifetimer (LTMR64L)

### Offset

| Register | Offset |
|---|---|
| LTMR64L | E4h |

### Function

Combined with LTMR64H, provides a 64-bit lifetimer.

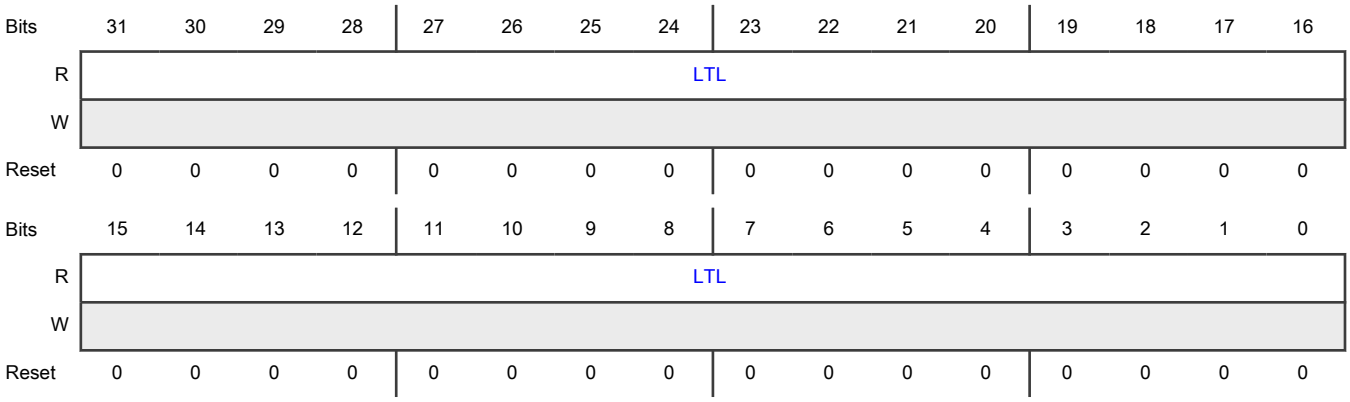
For more information, see Lifetimer.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| PIT_0 | LTMR64L | — |
| PIT_1 | — | LTMR64L |
| PIT_2 | — | LTMR64L |

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>LTL | Lifetimer Value<br>Indicates the timer value of timer 0 at the moment LTMR64H was last read. This value is the lower 32 bits of the 64-bit lifetimer value. This field updates only when LTMR64H is read. |

## 65.7.5 RTI Timer Load Value Sync Status (RTI_LDVAL_STAT)

### Offset

| Register | Offset |
|---|---|
| RTI_LDVAL_STAT | ECh |

### Function

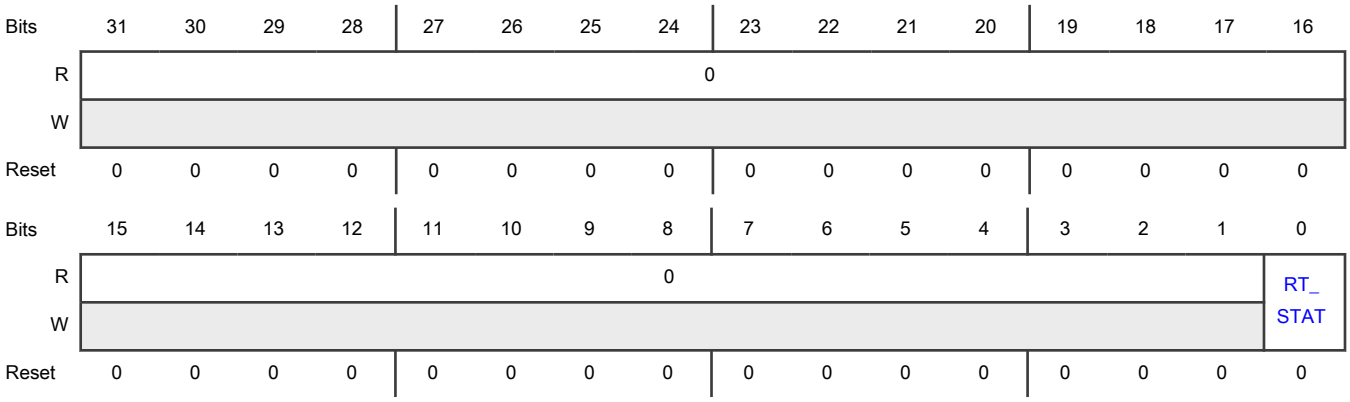
Indicates whether the RTI timer start value has been loaded (RTI_LDVAL). This status is necessary because it takes several cycles for the RTI start value to synchronize into the RTI clock domain.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| PIT_0 | RTI_LDVAL_STAT | — |
| PIT_1 | — | RTI_LDVAL_STAT |
| PIT_2 | — | RTI_LDVAL_STAT |

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved |
| 0<br>RT_STAT | Sync Status<br>Indicates whether the RTI start value is loaded.<br>**NOTE**<br>This field behaves differently for register reads and writes.<br>When reading<br>0b - Not loaded<br>1b - Loaded<br>When writing<br>0b - Clears status<br>1b - Clears status |

## 65.7.6 RTI Timer Load Value (RTI_LDVAL)

### Offset

| Register | Offset |
|---|---|
| RTI_LDVAL | F0h |

### Function

Specifies the length of the RTI timeout period in clock cycles.

It takes several cycles for this value to synchronize into the RTI clock domain.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| PIT_0 | RTI_LDVAL | — |
| PIT_1 | — | RTI_LDVAL |
| PIT_2 | — | RTI_LDVAL |

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | TSV | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | TSV | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### Fields

| Field | Function |
|---|---|
| 31-0<br>TSV | Timer Start Value<br>Specifies the starting RTI timer value. The timer counts down until it reaches 0, then sets the interrupt flag and reloads this value. When you write a new value to this register, the timer does not restart with the new value until the current timing period expires. To terminate the current period and start a new period with the new value, you must disable the timer (write 0 to RTI_TCTRL*n*[TEN]) and then enable it again (write 1 to RTI_TCTRL*n*[TEN]). |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | **NOTE**<br>Because it may take several cycles to clear the RTI interrupt, setting the value to something less than 32 cycles may result in a lost interrupt. |

## 65.7.7 Current RTI Timer Value (RTI_CVAL)

### Offset

| Register | Offset |
|---|---|
| RTI_CVAL | F4h |

### Function

Indicates the current RTI timer value. Because this timer might be driven from a different clock domain from the other timers, the value may be several cycles old.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| PIT_0 | RTI_CVAL | — |
| PIT_1 | — | RTI_CVAL |
| PIT_2 | — | RTI_CVAL |

### Diagram

**Fields**

| Field | Function |
|---|---|
| 31-0<br>TVL | Current Timer Value<br>Indicates the current RTI timer value.<br>**NOTE**<br>• If the timer is disabled (RTI_TCTRL*n*[TEN] = 0), this value has no meaning.<br>• If PIT is frozen in Debug mode (MCR[FRZ] = 1), timer values are frozen when the device is in Debug mode. |

## 65.7.8 RTI Timer Control (RTI_TCTRL)

**Offset**

| Register | Offset |
|---|---|
| RTI_TCTRL | F8h |

**Function**

Controls RTI timer behavior.

The RTI may take several RTI clock cycles to enable or update. Therefore, you must wait for at least three RTI clock cycles after RTI configuration before relying on the RTI timer.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| PIT_0 | RTI_TCTRL | — |
| PIT_1 | — | RTI_TCTRL |
| PIT_2 | — | RTI_TCTRL |

### Diagram

## 65.8 Glossary

**RTI** Real-time interrupt

# Chapter 66
# Real Time Clock (RTC)

## 66.1 Chip-specific RTC information

### 66.1.1 RTC instances and configuration

The chip contains one instance of RTC (Real Time Clock) timer and API (Autonomous Periodic Interrupt) timer, where both can perform 32-bit comparisons.

The RTC is present in always ON domain, hence available in RUN mode as well as in STANDBY mode. Both RTC and API timers can generate interrupts as well as wakeup from low power modes.

RTC supports a resolution of 1µs with high speed internal oscillator clock (1/48MHz (FIRC) * 48 (RTC counter) = 1µs)

This chip supports seamless RTC operation across functional reset with the clock sources SIRC and SXOSC.

**NOTE**

SXOSC is not present in MCXE315/MCXE316, thus RTC will run from SIRC clock.

API has the capability to change the Timer compare value (APIVAL) independently without stopping the timer.

API can also be used in conjunction with the Comparator module. In STANDBY mode configuration, the API is configured to generate a START / NEXT type signal to inform the Comparator module that a 'compare' must be carried out.

**Table 360. RTC instances**

| Module | MCXE315/MCXE316/MCXE317/MCXE31B |
|---|---|
| RTC | Yes |

## 66.2 Overview

The Real-Time Clock (RTC) is a free-running counter used for time keeping applications. The RTC can be configured to generate an interrupt at a pre-defined interval independent of the mode of operation (run mode or low power mode). If in a low power mode, the RTC interval is reached, the RTC first generates a wakeup and then asserts the interrupt request. The RTC also supports an API function used to generate a periodic wakeup request to exit a low-power mode or an interrupt request.

### 66.2.1 Block diagram

The following figure shows clock gating for RTC clocks.

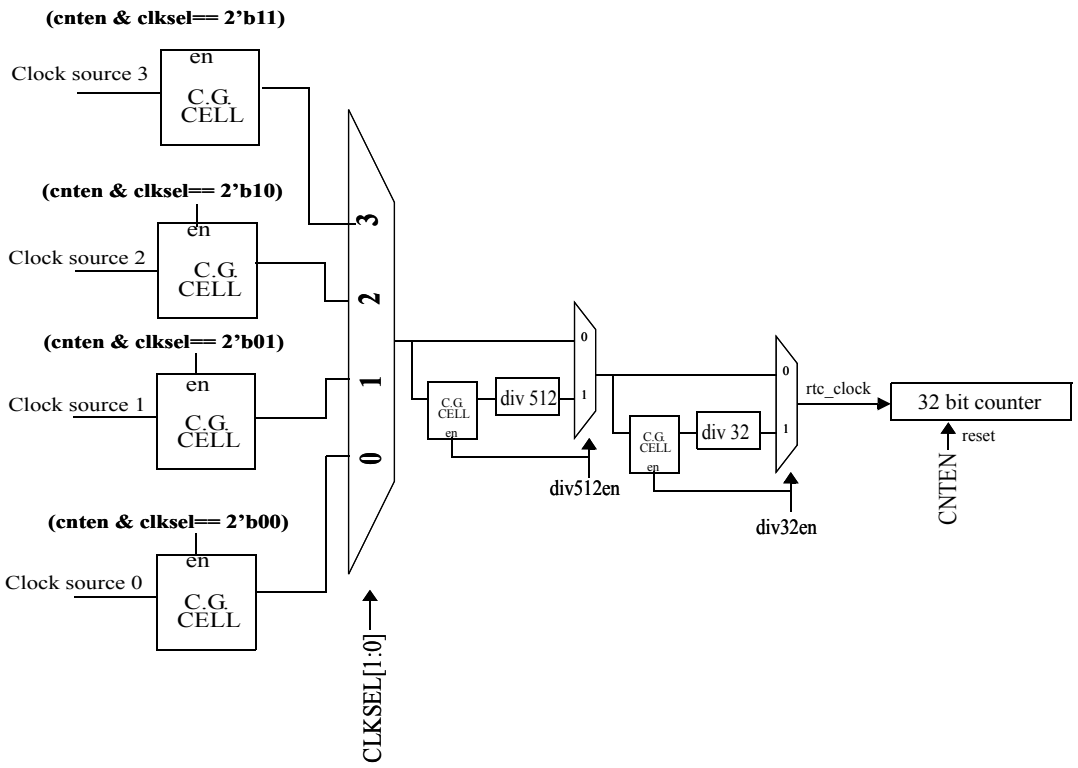

Figure 357. Clock gating for RTC clocks

The following figure shows the block diagram of RTC.

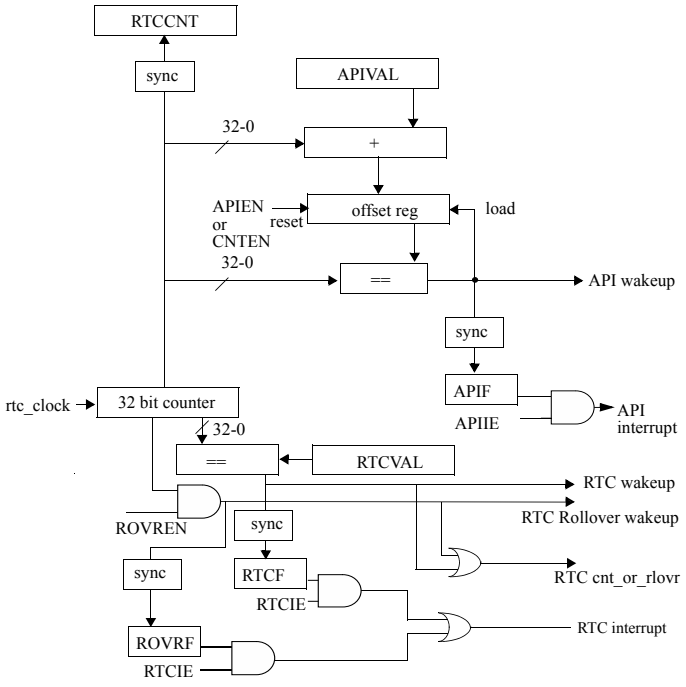

Figure 358. Block diagram

### 66.2.2 Features

RTC features include:

- 32-bit counter
- Selectable counter clock sources (IRCs and OSCs)
  - Clock source 0
  - Clock source 1
  - Clock source 2
  - Clock source 3

**NOTE**

See the chip-specific RTC information and clocking chapter for mapping of clock sources.

- Optional 512 prescaler and optional 32 prescaler to run the 32 bit counter.
- RTC interrupt with interrupt enable.
- Counter runs in all modes of operation.
- RTC counter is reset when the counter is disabled by software and by reset to RTC block.
- Autonomous periodic interrupt support includes:
  - 32-bit compare value to support range of wakeup intervals/interrupts
  - API logic has a separate enable to support changing compare value while RTC is running
  - API interrupt with interrupt enable
  - Operates in all modes
  - API compare value can be modified while RTC is running
- Optional interrupt for RTC match, API match, and RTC rollover.

## 66.3 Functional description

### 66.3.1 RTC

The RTC consists of a 32-bit free running counter enabled with the CNTEN bit (CNTEN, when negated, asynchronously resets the counter and synchronously enables the counter when enabled). After disabling CNTEN, RTCVAL, APIVAL, needs to be written again for desired functionality. The value of the counter may be read via the RTC Count (RTCCNT) register. Note that because of clock synchronization, the RTC Count (RTCCNT) value may represent a previous counter value. The difference between the counter and the read value depends on the ratio of counter clock and bus clock. Maximum possible difference between the two is 6 count values.

The clock source to the counter is selected with the CLKSEL field, which gives four options for clocking the RTC/API. The four clock sources are assumed to be on these:Clock source 0, Clock source 1, Clock source 2, and Clock source 3. The output of the clock mux can be optionally divided by a combination of 512 and 32 to give various count periods for different clock sources. Note that the CNTEN bit should be disabled when the RTC/API clock source is switched.

When the RTC Count (RTCCNT) counter value for counter bits 31-0 match the 32-bit value in the RTCVAL field, then the RTCF interrupt flag bit is set (after proper clock synchronization). If the RTCIE interrupt enable bit is set, then the RTC interrupt request is generated. RTC Compare value register (RTCVAL) register can be written only when INV_RTC bit is clear. Initially INV_RTC=0, and hence RTC Compare value register (RTCVAL) can be written once and hence INV_RTC gets set. This bit can now be cleared only by enabling the RTC counter. After the counter is enabled, RTC Compare value register (RTCVAL) can be written anytime, until RTC is disabled again. RTC Compare value register (RTCVAL) is first synchronized to the RTC clock domain, therefore, if RTC Compare value register (RTCVAL) is updated at the point where a counter match is due to happen in the next 2-3 RTC clocks because of previous RTC Compare value register (RTCVAL), the RTCF flag is set. However, if the RTC Compare value register

(RTCVAL) is updated at the point where no counter match is due as per the previous RTC Compare value register (RTCVAL), the RTCF flag is set when the counter matches the new RTC Compare value register (RTCVAL). If there is a match when in the low-power mode, then the RTC first generates a wakeup request to force a wakeup to run mode,and then the RTCF flag is set.

If RTC Compare value register (RTCVAL) is updated just after counter match, new RTC Compare value register (RTCVAL) value should not be within next 6 RTC counter values.

A rollover wakeup and/or interrupt can be generated when the RTC transitions from a count of 0xFFFF_FFFF to 0x0000_0000. The rollover flag is enabled by setting the ROVREN bit. If RTCIE is enabled, an interrupt request is generated for an RTC counter rollover. If system is in low power mode, RTC counter rollover with this bit causes a wakeup from the low-power mode.

Both rollover wakeup and RTC wakeup gets asynchronously de-asserted with disabling of CNTEN.

All the flags and counter values are synchronized with the Bus clock. It is assumed that the Bus clock and RTC clock selected through CLKSEL follows the below relation:

Bus clock >= (1.5 * RTC clock )/(div_factor)

- if both DIV32EN and DIV512EN bits are disabled, div_factor = 1
- if DIV32EN=1 and DIV512EN=0, div_factor = 32
- if DIV32EN=0 and DIV512EN=1, div_factor = 512
- if both DIV32EN and DIV512EN bits are enabled, div_factor = 512*32 = 16384

In case, RTC wakeup's are used as a wakeup source, bus clock (system clock or register interface clock of RTC) should be disabled (to save power in standby mode) after enabling the required wakeup and ensuring sufficient time gap (3-6 bus clock or RTC clock (rtc_clock) cycles, whichever is slower) between bus clock disabling and wakeup event. To ensure writing the register to enable the wakeup, the bus clock must be active, hence it should not be disabled before enabling wakeup. Correct operation is not guaranteed if the specification is not followed.

### 66.3.2 API functional description

Setting APIEN bit enables the autonomous interrupt function. The 32-bit APIVAL field selects the time interval for triggering an interrupt and/or wakeup event. Because the RTC is a free-running counter, the APIVAL is added to the current count to calculate an offset. When the counter reaches the offset count, an interrupt and/or wakeup request is generated. Then the offset value is recalculated and again re-triggers a new request when the new value is reached. API function is enabled only when CNTEN and APIEN bits are asserted and APIVAL is non-zero. Also APIVAL can be updated anytime. After APIVAL is updated, the first API interrupt is generated according to the previous value. From the second interrupt onwards, the API interrupt is generated with the new APIVAL. When a compare is reached, the APIF interrupt flag bit is set (after proper clock synchronization). If the APIIE interrupt enable bit is set, then the API interrupt request is generated. If there is a match while being in the low-power mode, then the API first generates a wakeup request to force a wakeup into normal operation, and then the APIF flag is set.

When the CNTEN is de-asserted, the API function is reset , though wakeup API is not asynchronously de-asserted with CNTEN. If APIEN is disabled when counter matches the offset APIF can be missed.

### 66.3.3 Modes of operation

#### 66.3.3.1 Functional mode

There are two functional modes of operation for RTC, normal operation and low-power mode. In normal operation, all RTC registers can be read or written . The RTC/API and associated interrupts are optionally enabled. In low-power mode, the bus interface is disabled. The RTC/API is enabled (if enabled prior to entry into low-power mode).

#### 66.3.3.2 Debug mode

On entering into the debug mode, the RTC counter freezes on the last valid count if the FRZEN is set. On exit from debug mode, counter continues from the frozen value.

## 66.4 Initialization

Recommended programming flow as follow

1. Program RTCVAL register with the value greater than 4 if RTCF related functionality is required.
2. Program APIVAL register with the value greater than 4 if API functionality is required.
3. Program all fields (as required) of RTC Control (RTCC) register with CNTEN=1. After setting CNTEN field, counter starts running and RTC/API functionality will be active as per the configurations.
4. If RTCVAL or APIVAL needs to be updated during run, check corresponding INV_RTC or INV_API bit is cleared before writing and do meet all the restrictions of the corresponding register.
5. If CLKSEL or DIV32EN or DIV512EN needs to be updated, first update RTC Control (RTCC) register with CNTEN=0 (when all INV_RTC or INV_API are 0) keeping other field values same. Wait for minimum 3 RTC clock cycles so that CNTEN will be synchronized to RTC clock domain. Then write the RTC Control (RTCC) register with new configuration required with CNTEN=1.

## 66.5 RTC register descriptions

The RTC registers are listed in this section.

**NOTE**

Address offset - 0x18h should not be accessed by application as corresponding feature/s are not available. Therefore, transfer error will not be generated at this offset.

**NOTE**

XFR error will be generated when RTCSUPV is accessed in user mode, any other register is accessed in user mode when SUPV bit is set, write attempt is made for RTCCNT register and any register accessed out of address range.

### 66.5.1 RTC memory map

RTC base address: 4028_8000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | RTC Supervisor control register (RTCSUPV) | 32 | RW | 8000_0000h |
| 4h | RTC Control (RTCC) | 32 | RW | 0000_0000h |
| 8h | RTC Status register (RTCS) | 32 | RW | 0000_0000h |
| Ch | RTC Count (RTCCNT) | 32 | R | 0000_0000h |
| 10h | API Compare value register (APIVAL) | 32 | RW | 0000_0000h |
| 14h | RTC Compare value register (RTCVAL) | 32 | RW | 0000_0000h |

### 66.5.2 RTC Supervisor control register (RTCSUPV)

**Offset**

| Register | Offset |
|---|---|
| RTCSUPV | 0h |

### Function

The RTCSUPV register contains the SUPV bit that determines whether other registers are accessible in supervisor mode or user mode.

**NOTE**

You can access this register only in Supervisor mode, and you must write a value only to the SUPV field of the register.

# Low Power Serial Peripheral Interface (LPSPI)

## 67.1 Chip-specific LPSPI information

### 67.1.1 LPSPI instances and configuration

Table 361. LPSPI instances

| Instance | MCXE31B | MCXE315/MCXE316/MCXE317 |
|---|---|---|
| LPSPI0 | Yes | Yes |
| LPSPI1 | Yes | Yes |
| LPSPI2 | Yes | Yes |
| LPSPI3 | Yes | Yes |
| LPSPI4 | Yes | No |
| LPSPI5 | Yes | No |

Table 362. LPSPI instances configuration

| Instances | TX FIFO Size | RX FIFO Size | Chip Selects |
|---|---|---|---|
| LPSPI0 | 4x32 bit | 4x32 bit | 8 |
| LPSPI1 | 4x32 bit | 4x32 bit | 6 |
| LPSPI2 | 4x32 bit | 4x32 bit | 4 |
| LPSPI3 | 4x32 bit | 4x32 bit | 4 |
| LPSPI4 | 4x32 bit | 4x32 bit | 4 |
| LPSPI5 | 4x32 bit | 4x32 bit | 4 |

- MCXE31B supports data rate up to 20 Mbps, MCXE315/MCXE316/MCXE317 supports data rate up to 15 Mbps. Only one LPSPI instance support 20 MHz in loopback mode that is LPSPI0
- All LPSPIs supports a minimum a 10 MHz data rate on standard plus pads and 7.5 MHz on standard pads.
- Low leakage and Wait modes are not supported in this device.

The number of chip selects that each LPSPI instance supports varies. Because of that, in the Configuration Register 1 (CFGR1), the Peripheral Chip Select (PCS) field and the Peripheral Chip Select Polarity (PCSPOL) field also vary. See the next 2 tables.

Table 363. LPSPI instances mapped against Peripheral Chip Select (PCS) field support

| PCS supported in | PCS not supported in |
|---|---|
| LPSPI0_TCR[26-24] | — |
| LPSPI1_TCR[26-24] | — |
| LPSPI2_TCR[25–24] | LPSPI2_TCR[26] |
| LPSPI3_TCR[25–24] | LPSPI3_TCR[26] |
| LPSPI4_TCR[25–24] | LPSPI4_TCR[26] |

*Table continues on the next page...*

Table 363. LPSPI instances mapped against Peripheral Chip Select (PCS) field support (continued)

| PCS supported in | PCS not supported in |
|---|---|
| LPSPI5_TCR[25–24] | LPSPI5_TCR[26] |

Table 364. LPSPI instances mapped against Peripheral Chip Select Polarity (PCSPOL) field support

| PCSPOL supported in | PCSPOL not supported in |
|---|---|
| LPSPI0_CFGR1[15-8] | — |
| LPSPI1_CFGR1[13–8] | LPSPI1_CFGR1[15–14] |
| LPSPI2_CFGR1[11–8] | LPSPI2_CFGR1[15–12] |
| LPSPI3_CFGR1[11–8] | LPSPI3_CFGR1[15–12] |
| LPSPI4_CFGR1[11–8] | LPSPI4_CFGR1[15–12] |
| LPSPI5_CFGR1[11–8] | LPSPI5_CFGR1[15–12] |

### 67.1.2 LPSPI HREQ considerations for MCXE31B

It is recommended that the HREQ pin (when PCS[1] is used as HREQ) should get de-asserted before the completion of frame transfer. In case if the HREQ state is still asserted and LPSPI returns to idle state after frame transfer completion, the HREQ state is internally latched and the next data is written to the transmit FIFO without waiting for the next HREQ assertion.

This limitation is present only while using PCS[1] as HREQ and HREQ remains asserted throughout frame transfer. In case of using trigger input as HREQ, there is no issue.

## 67.2 Overview

LPSPI provides an efficient interface (either as a controller or peripheral) to an SPI bus, which is a synchronous serial communication interface used in embedded systems. It is typically used to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing with secure digital cards and LCD displays.

**NOTE**

The terminology in this chapter has been updated to align with NXP's inclusive language standards, as shown in the table below.

Table 365. Updated terms

| Updated term | Deprecated term |
|---|---|
| Controller | Master |
| Peripheral | Slave |

### 67.2.1 Block diagram

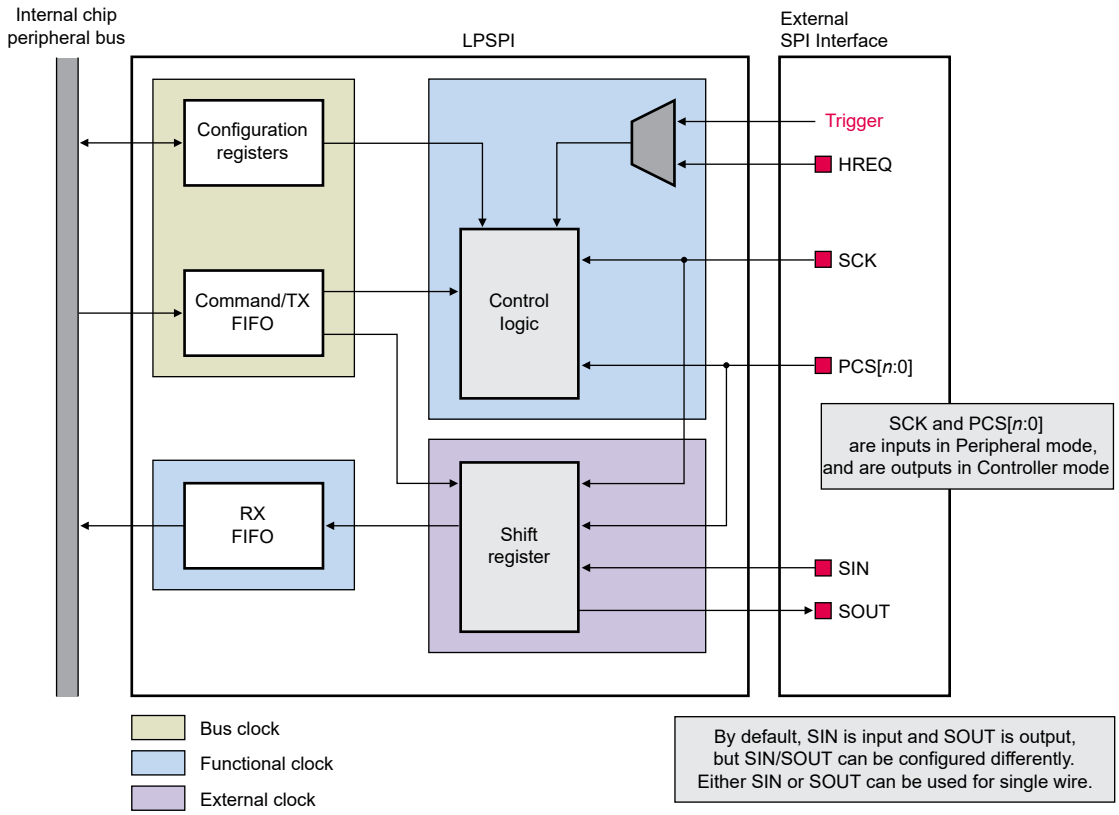

Figure 359. Block diagram

### 67.2.2 Features

- Minimal CPU overhead, with DMA transmit and receive requests supporting FIFO register accesses
- Support available for 32-bit word size
- Configurable clock polarity and phase
- Support available for 8 peripheral chip selects in Controller mode
- Support available for Peripheral mode
- 4-word transmit and command FIFO
- 4-word receive FIFO
- Flexible timing parameters in Controller mode, including SCK frequency and duty cycle, and delays between PCS and SCK edges
- Continuous transfer option to keep PCS asserted across multiple frames
- Full-duplex transfers that support 1-bit transmit and receive on each clock edge
- Half-duplex transfers that support:
  - 1-bit transmit or receive on each clock edge
  - 2-bit transmit or receive on each clock edge
  - 4-bit transmit or receive on each clock edge
  - 8-bit transmit or receive on each clock edge

- Option to use host request to control the start of an SPI bus transfer

## 67.3 Functional description

### 67.3.1 Controller mode

#### 67.3.1.1 Transmit and command FIFO commands

The transmit and command FIFO is a combined FIFO that includes both transmit data words and command words. You store:

- Transmit data words in the transmit and command FIFO, by writing to Transmit Data (TDR).
- Command words in the transmit and command FIFO, by writing to Transmit Command (TCR).

When a command word is at the top of the transmit and command FIFO, the actions that can occur depend on whether LPSPI is busy or between frames (see TCR[CONT] and TCR[CONTC]). See Table 366 for conditions and possible corresponding actions when a command word is at the top of the transmit and command FIFO.

**Table 366. Possible actions when a command word is at the top of the transmit and command FIFO**

| Condition | Action |
|---|---|
| LPSPI is enabled and idle. | The command word is pulled from the FIFO, and this command word controls all subsequent transfers. |
| LPSPI is busy and TCR[CONTC] is 0. | The SPI frame completes at the end of the existing word, ignoring TCR[FRAMESZ]. The command word is then pulled from the FIFO and that command word controls all subsequent transfers (or until the next update to the command word). Note that a command word with TCR[CONTC] = 0 always terminates the existing transfer regardless of the previous TCR[CONT] value. |
| LPSPI is busy; the existing TCR[CONT] value is 1 and the new TCR[CONTC] value is 1. | The command word must be updated at the frame boundary. The command word is pulled from the FIFO during the last SCK pulse of the existing frame (based on the value of FRAMESZ), and the frame continues using the new command value for the rest of the frame (or until the next update to the command word). When TCR[CONTC] = 1, only the lower 24 bits of the command word are updated. If the command word is updated at a word boundary, then the transfer halts (stops) after that word. TCR[CONTC] is ignored when not at a frame boundary, so the frame ends prematurely. |

TCR[CONT] = 1 keeps PCS asserted at end of frame, allowing the transfer to continue.

TCR[CONTC] = 1 specifies that this command word must not terminate the existing frame, and the transfer can continue using the new command word.

TCR[CONTC] = 1 is restricted in the sense that the new command must load on a frame boundary, and the only way for a transfer to continue from a frame boundary is when the previous command has TCR[CONT] = 1.

You can read the current state of the existing command word from Transmit Command (TCR). It requires at least three LPSPI functional clock cycles for Transmit Command (TCR) to update after you write to it (assuming an empty FIFO), and LPSPI must be enabled (CR[MEN] = 1).

Writing to Transmit Command (TCR) does not initiate an SPI bus transfer, unless TCR[TXMSK] = 1. When TCR[TXMSK] = 1, a new command word is not loaded until the end of the existing frame (based on the value of TCR[FRAMESZ]); at the end of the transfer, TCR[TXMSK] transitions to 0.

In Controller mode, the LPSPI command word in Transmit Command (TCR) controls SPI attributes based on the selections in register fields. See Table 367 for TCR fields and associated functionality related to data transfer.

Table 367. Command word in Controller mode

| Transmit Command (TCR) | | Description | Can this field be modified during a data transfer? |
|---|---|---|---|
| Field | Name | | |
| CPOL | Clock polarity | Specifies the polarity of the SCK pin. Any change of CPOL value causes a transition on the SCK pin. | N |
| CPHA | Clock phase | Specifies the clock phase of the transfer. | N |
| PRESCALE | Prescaler value | Specifies a prescaler used to divide the LPSPI functional clock, to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS enables LPSPI to connect to different peripheral devices at different frequencies. | N |
| PCS | Peripheral chip select | Specifies which PCS pin asserts for the transfer; the polarity of PCS is static and specified by CFGR1[PCSPOL].<br>If CFGR1[PCSCFG] = 1, do not select PCS[3:2]. | N |
| LSBF | LSB first | Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first. | Y |
| BYSW | Byte swap | Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing with devices that organize data as big-endian. | Y |
| CONT | Continuous transfer | Configures LPSPI for a continuous transfer that keeps PCS asserted between frames (as specified by FRAMESZ). You must write a new command word to cause PCS to negate. Also, this field supports changing the command word at frame size boundaries. | Y |
| CONTC | Continuing command | Indicates that this is a new command word for the existing continuous transfer. When CONTC = 1, the command word must only be written to the transmit and command FIFO on a frame boundary. | Y |
| RXMSK | Receive data mask | Masks the receive data and does not store the masked receive data in the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching. | Y |
| TXMSK | Transmit data mask | Masks the transmit data; masked transmit data is not pulled from the transmit FIFO, and the output data pin is 3-stated (unless otherwise configured by CFGR1[OUTCFG]). This option is useful for half-duplex transfers. | Y |
| WIDTH | Transfer width | Specifies the number of bits shifted on each SCK pulse:<br>• 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats.<br>• 2-bit and 4-bit half-duplex transfers are useful for interfacing with QuadSPI memory devices, and either TXMSK or RXMSK must also be 1.<br>• 8-bit half-duplex transfers are useful for interfacing with OctelSPI memory devices, and either TXMSK or RXMSK must also be 1. | Y |

*Table continues on the next page...*

Table 367. Command word in Controller mode (continued)

| Transmit Command (TCR) | | Description | Can this field be modified during a data transfer? |
|---|---|---|---|
| Field | Name | | |
| FRAMESZ | Frame size | Configures the frame size in number of bits equal to (FRAMESZ + 1):<br>• The minimum frame size is 8 bits, or 16 bits for an 8-bit transfer.<br>• If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.<br>• If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remaining bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits. | Y |

#### 67.3.1.1.1 SPI bus transfers

LPSPI initiates an SPI bus transfer when all these conditions are true:

- Data is written to the transmit FIFO.
- The HREQ pin is asserted (or the HREQ function is disabled).
- LPSPI is enabled.

To perform the SPI bus transfer, LPSPI uses the attributes configured in Transmit Command (TCR) and the timing parameters defined in Clock Configuration (CCR).

The SPI bus transfer ends after the number of bits indicated by the value of FRAMESZ have been transferred (provided CONT = 0), or at the end of a word when a new transmit command word is at the top of the transmit and command FIFO. When LPSPI is disabled, the SPI bus transfers end after the transmit FIFO is empty and LPSPI is idle.

The HREQ input is only checked when PCS is negated.

#### 67.3.1.1.2 Circular FIFO

The transmit and command FIFO supports a circular FIFO feature. This feature enables the LPSPI controller to (periodically) repeat a short data transfer that fits within the transmit and command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled (CFGR0[CIRFIFO] = 1), the current state of the FIFO read pointer is saved and the status flags are not updated. After the FIFO is empty and LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit and command FIFO are not permanently pulled from the FIFO when Circular FIFO mode is enabled.

### 67.3.1.2 Receive FIFO and data match

The receive FIFO stores received data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of being stored in the receive FIFO:

- Received data is written to the receive FIFO when the last bit of the word is sampled.
- If the transmit FIFO is empty during a multiple-word or continuous transfer, then the receive data is written to the receive FIFO before the transfer stalls (assuming CFGR1[NOSTALL] = 0) while waiting for new transmit data or for a command word to be written.

LPSPI provides a receive data match function that can match received data against one of the two words in DMR0 and DMR1, or against a masked data word. You can also configure the received data match function to compare only the first one or two received data words since the start of the frame:

- Received data that is already discarded because of TCR[RXMSK] cannot cause the data match flag to set, and delays the receive data match on the first received data word, until all discarded data is received.
- You can configure the receive data match function to discard all received data until a data match is detected, using CFGR0[RDMO].
- After a receive data match, to allow all subsequent data to be received, write 0 to CFGR0[RDMO], and then write 0 to SR[DMF].

#### 67.3.1.3 Timing parameters

The timing parameters that are used for all SPI bus transfers are relative to the LPSPI functional clock divided by the selection specified in TCR[PRESCALE]. Although you can only change Clock Configuration (CCR) when LPSPI is disabled (CR[MEN] = 0), to support interfacing with different peripheral devices at different frequencies, you can change the TCR[PRESCALE] selection between SPI bus transfers by using Transmit Command (TCR).

**NOTE**

The minimum value shown in Table 368 is the minimum counter value, but the values of Clock Configuration (CCR) must also satisfy the data sheet specs based on the LPSPI functional clock frequency and prescaler value.

**Table 368. Timing parameters**

| Clock Configuration (CCR)<br>Clock Configuration 1 (CCR1) | | Description | Minimum value | Maximum value |
|---|---|---|---|---|
| Field | Name | | | |
| SCKSET | SCK setup phase | Configures the SCK setup phase to (SCKSET + 1) cycles. The setup phase is the SCK high period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK low period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD. | 0 (1 cycle) | 255 (256 cycles) |
| SCKHLD | SCK hold phase | Configures the SCK hold phase to (SCKHLD + 1) cycles. The hold phase is the SCK low period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK high period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD. | 0 (1 cycle) | 255 (256 cycles) |
| PCSPCS | PCS-to-PCS delay | Configures the minimum delay between PCS negation and the next PCS assertion to (PCSPCS + PCSPCS + 2) cycles. When the command word is updated between transfers, there is a minimum of (PCSPCS + 1) cycles between the command word update and any change on PCS pins. | 0 (2 cycles) | 255 (512 cycles) |
| SCKSCK | SCK-to-SCK delay | Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (SCKSCK + 1) cycles. This is useful when the external peripheral | 0 (1 cycle) | 255 (256 cycles) |

*Table continues on the next page...*

Table 368. Timing parameters (continued)

| Clock Configuration (CCR) Clock Configuration 1 (CCR1) | | Description | Minimum value | Maximum value |
|---|---|---|---|---|
| Field | Name | | | |
| | | requires a large delay between different words of an SPI bus transfer. | | |
| PCSSCK | PCS-to-SCK delay | Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles. | 0 (1 cycle) | 255 (256 cycles) |
| SCKPCS | SCK-to-PCS delay | Configures the minimum delay between the last SCK edge and the PCS negation to (SCKPCS + 1) cycles. | 0 (1 cycle) | 255 (256 cycles) |

Figure 360 shows the timing settings controlled by:

- TCR[CPHA]
- TCR[CPOL]
- CCR[SCKPCS]
- CCR[PCSSCK]
- CCR1[SCKSET]
- CCR1[SCKHLD]

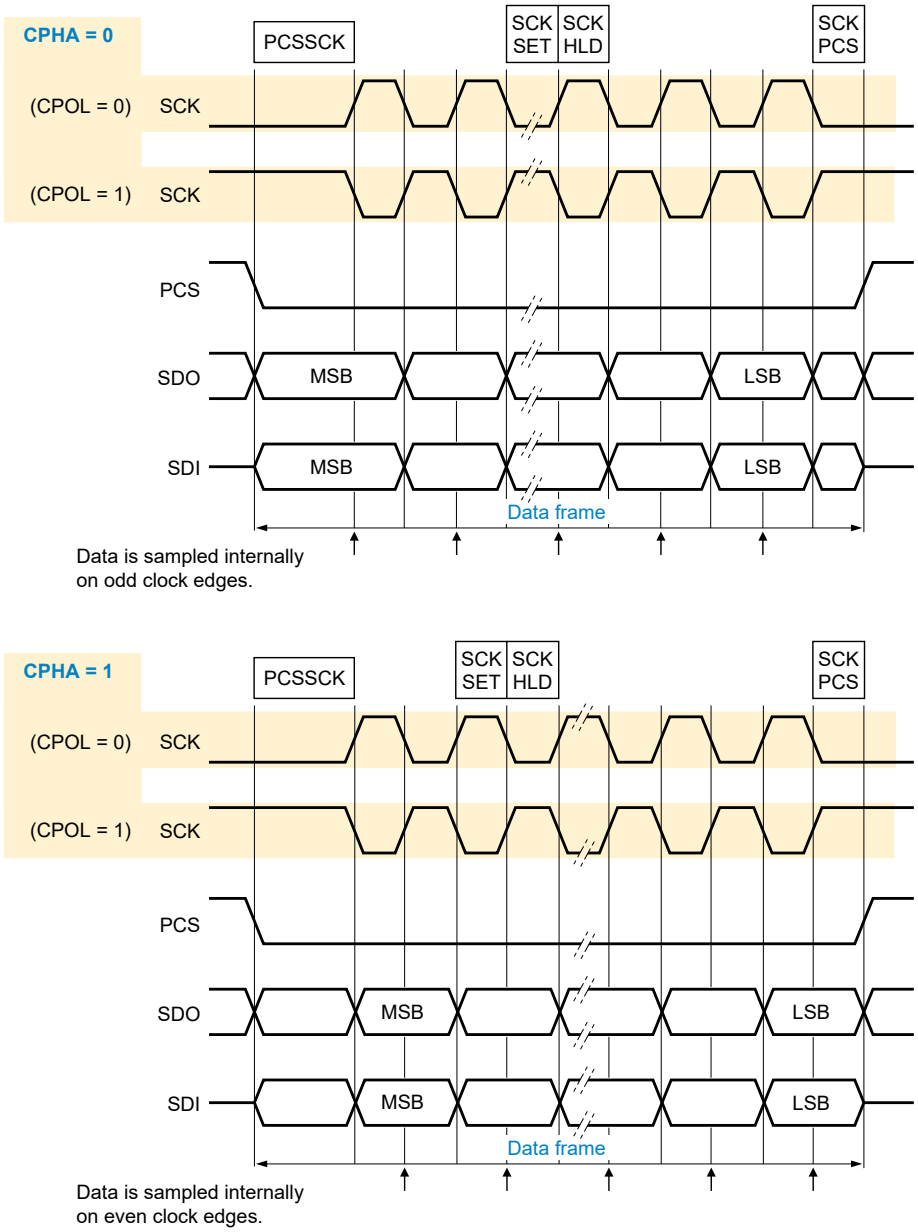

**Figure 360. Clock phase (TCR[CPHA]) timing diagram example**

To configure for a baud rate of 10 MHz with 50/50 duty cycle and with a functional clock frequency of 100 MHz, use the following settings:

- CCR1[SCKSET] = 0x4 (5 cycles)
- CCR1[SCKHLD] = 0x4 (5 cycles)
- CCR1[PCSPCS] = 0x8 (10 cycles)
- CCR1[SCKSCK] = 0x4 (5 cycles)
- CRR[PCSSCK] = 0x4 (5 cycles)
- CRR[SCKPCS] = 0x4 (5 cycles)
- TCR[PRESCALE] = 0x0 (divide by 1)

#### 67.3.1.4 Pin configuration

Following are the pin configuration settings for half-duplex transfers:

- To swap directions or to support half-duplex transfers on the same pin, you can configure the SIN and SOUT pins using CFGR1[PINCFG].
- To specify whether an output data pin (SOUT, for example) 3-states when PCS is negated, or if the output data pin retains the last value, use CFGR1[OUTCFG].
- When configuring half-duplex transfers, you must configure the output data pins to 3-state when PCS is negated (CFGR1[OUTCFG] = 1).
- When performing half-duplex 2-bit transfers, you can write any value to CFGR1[PCSCFG].
- When performing half-duplex 4-bit transfers, you must write 1h to CFGR1[PCSCFG].

#### 67.3.1.5 Clock loopback

Configure the LPSPI controller to use one of the following clocks to sample the input data:

- The SCK output clock
- A delayed version of the SCK output clock

The delayed version of the SCK is chosen by the SCK pin output delay, plus the SCK pin input delay, and is selected by writing 1 to CFGR1[SAMPLE]. Enabling the loopback version of the SCK pin can improve the setup time of the input data from the peripheral.

See the chip data sheet for the specific input setup time in Controller Loopback mode.

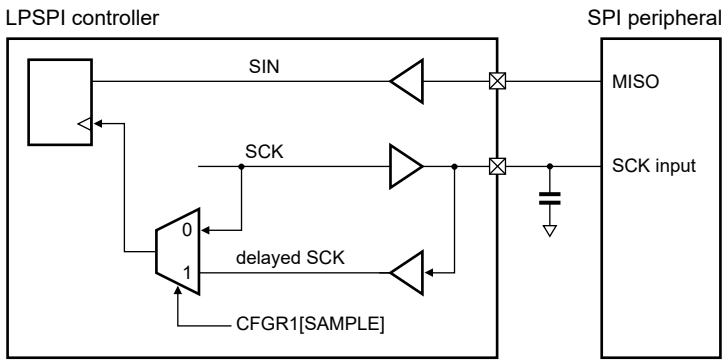

**Figure 361. Clock loopback**

### 67.3.2 Peripheral mode

LPSPI Peripheral mode:

- Uses the same shift register and logic that Controller mode uses.
- Does not use Clock Configuration (CCR).
- Requires Transmit Command (TCR) to remain static (unchanged) during SPI bus transfers.

#### 67.3.2.1 Transmit and command FIFO commands

You must initialize Transmit Command (TCR) before enabling LPSPI in Peripheral mode, although this register is not updated until after LPSPI is enabled. After LPSPI is enabled, you must make changes to this register only when LPSPI is idle. In Peripheral mode, the LPSPI command word in this register controls SPI attributes. Before the PCS input asserts, the transmit FIFO must be filled with transmit data, or the transmit error flag sets.

Table 369. Command word in Peripheral mode

| Transmit Command (TCR) | | Description |
|---|---|---|
| Field | Name | |
| CPOL | Clock polarity | Specifies the polarity of the external SCK input. |
| CPHA | Clock phase | Specifies the clock phase of transfer. |
| PRESCALE | Prescaler value | Specifies the LPSPI functional clock prescaler. |
| PCS | Peripheral chip select | Specifies which PCS is used. The polarity of PCS is static and configured by CFGR1[PCSPOL].<br>If CFGR1[PCSCFG] is not equal to zero, then do not select the PCS[3:2] pins. |
| LSBF | LSB first | Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first. |
| BYSW | Byte swap | Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing with devices that organize data as big-endian. |
| CONT | Continuous transfer | When continuous transfer is selected in Peripheral mode, after the number of bits indicated by FRAMESZ are transferred, LPSPI passes through and transmits the received data until the next PCS negation. Whatever is shifted in on the receive data is shifted out as transmit data considering that there is a 32-bit shift register. |
| CONTC | Continuing command | When the continuing command is enabled in Peripheral mode, after the number of bits indicated by FRAMESZ are transferred, RXMSK is considered equal to 1 and TXMSK is considered equal to 0 until the next PCS negation. CONTC can be used to change the direction of a transfer after the number of bits indicated by FRAMESZ. |
| RXMSK | Receive data mask | Masks the receive data; LPSPI does not store masked receive data in the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching. |
| TXMSK | Transmit data mask | Masks the transmit data so that the masked transmit data is not pulled from transmit FIFO, and the output data pin is 3-stated (unless otherwise specified in CFGR1[OUTCFG]). This option is useful for half-duplex transfers. |
| WIDTH | Transfer width | Specifies the number of bits shifted on each SCK pulse:<br>• 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats.<br>• 2-bit and 4-bit half-duplex transfers are useful for interfacing with QuadSPI memory devices, and at least either TCR[TXMSK] or TCR[RXMSK] must be 1.<br>• 8-bit half-duplex transfers are useful for interfacing with OctelSPI memory devices, and at least either TCR[TXMSK] or TCR[RXMSK] must also be 1. |
| FRAMESZ | Frame size | Specifies the frame size in number of bits equal to (FRAMESZ + 1):<br>• The minimum frame size is 8 bits, or 16 bits for an 8-bit parallel transfer.<br>• If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.<br>• If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contain the remainder bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits. |

#### 67.3.2.2 Receive FIFO and data match

The receive FIFO stores receive data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of storing the received data in the receive FIFO.

Receive data supports a receive data match function that can match received data against one of the two words in DMR0 and DMR1 or against a masked data word. You can also configure the data match function to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded because TCR[RXMSK] = 1 cannot cause the data match to set, and delays the match on the first received data word, until all discarded data is received.
- By using CFGR0[RDMO], you can also configure the receiver match function to discard all received data until a data match is detected.
- After a receive data match, to allow all subsequent data to be received, first write 0 to CFGR0[RDMO], then clear SR[DMF].

#### 67.3.2.3 Partial received word

When the PCS pin deasserts and the receive shift register shifts in a partial word, you can configure the receive shift register to either discard the partial word or to store it in the receive FIFO. You must specify this using CFGR1[PARTIAL].

A partial word is defined as less than TCR[FRAMESZ] bits (when TCR[FRAMESZ] is equal or less than 32 bits, or it is the last word in a multi-word frame) or less than 32 bits (when TCR[FRAMESZ] is greater than 32 bits and not the last word in a multi-word frame).

A single-bit frame is not supported. A partial received word of 1 bit is supported, but a partial received frame of 1 bit is not supported.

#### 67.3.2.4 Clocked interface

LPSPI supports interfacing with external controllers that provide only clock and data pins (PCS is not required). This interface requires:

- Writing 1 to TCR[CPHA] (data is changed on the leading edge of SCK and captured on the following edge).
- Configuring the PCS input to be always asserted (CFGR1[PCSPOL*n*] = 1). For example, to configure PCS[0] to be always asserted, write 1 to PCSPOL[0], and do not configure PCS[0] in the pin muxing. The chip-level drives PCS to a certain value (ideally 1); you could use CFGR1[PCSPOL*n*] to invert that value.
- Writing 1 to CFGR1[AUTOPCS] to enable automatic PCS generation. When CFGR1[AUTOPCS] = 1, a minimum of four LPSPI functional clock cycles (divided by the selection specified in TCR[PRESCALE]) is required between the last SCK edge of one word and the first SCK edge of the next word.

### 67.3.3 Debug mode

**Table 370. Debug mode**

| Chip mode | LPSPI operation |
|---|---|
| Debug (the core is in Debug or Halted mode) | Can continue operating in Debug mode, if CR[DBGEN] = 1 |

### 67.3.4 Clocking

**Table 371. LPSPI clocks**

| Type of clock | Description |
|---|---|
| Functional | • Asynchronous to the bus clock.<br>• If the LPSPI functional clock remains enabled in low-power modes, then LPSPI can perform SPI bus transfers and low-power wakeups in both Controller and Peripheral modes.<br>• LPSPI divides the functional clock by a prescaler; the resulting frequency must be at least two times faster than the SPI external clock frequency (SCK). |
| External | • The LPSPI shift register is clocked directly by the SCK clock.<br>• How the SCK clock is generated or supplied depends on the mode (Controller or Peripheral):<br>— In Controller mode, the SCK clock is generated internally.<br>— In Peripheral mode, the SCK clock is supplied externally. |
| Bus | The bus clock is only used for bus accesses to the LPSPI control and configuration registers. The bus clock frequency must be high enough to support the data bandwidth requirements of the LPSPI registers, including the FIFOs. |

See the chip-specific LPSPI information for more.

### 67.3.5 Reset

**Table 372. LPSPI resets**

| Type of reset | Description |
|---|---|
| Chip | Resets the LPSPI logic and registers to their default states. |
| Software | • Resets the LPSPI logic and registers to their default states, except for the Control register.<br>• The LPSPI software reset is controlled using CR[RST]. |
| FIFO | • Resets the transmit and command FIFO and the receive FIFO.<br>• CR[RTF] and CR[RRF] are write-only.<br>• After being reset, FIFO is empty. |

### 67.3.6 Interrupts and DMA requests

The following table lists sources (status flags) that can generate LPSPI interrupts and LPSPI transmit and receive DMA requests.

**Table 373. Interrupts and DMA requests**

| Status (SR) | | Description | Can generate | | |
|---|---|---|---|---|---|
| Status flag | Name | | Interrupt? | DMA request? | Low-power wake-up? |
| TDF | Transmit data flag | Indicates that data can be written to transmit FIFO, as configured by the transmit FIFO watermark, FCR[TXWATER]. | Y | TX | Y |

*Table continues on the next page...*

Table 373. Interrupts and DMA requests (continued)

| Status (SR) | | Description | Can generate | | |
|---|---|---|---|---|---|
| Status flag | Name | | Interrupt? | DMA request? | Low-power wake-up? |
| RDF | Receive data flag | Indicates that data can be read from the receive FIFO, as configured by the receive FIFO watermark, FCR[RXWATER]. | Y | RX | Y |
| WCF | Word complete flag | Indicates that the word is complete and the last bit of the word has been sampled. | Y | N | Y |
| FCF | Frame complete flag | Indicates that the frame is complete and PCS is deasserted. | Y | N | Y |
| TCF | Transfer complete flag | Indicates that transfer is complete, PCS is deasserted, and the transmit and command FIFO is empty. | Y | N | Y |
| TEF | Transmit error flag | Indicates a transmit and command FIFO underrun. In Controller mode, when CFGR1[NOSTALL] = 0 (transfers stall when transmit FIFO is empty), TEF cannot be set. | Y | N | Y |
| REF | Receive error flag | Indicates a receive FIFO overflow. In Controller mode, when CFGR1[NOSTALL] = 0 (transfers stall when receive FIFO is full), REF cannot be set. | Y | N | Y |
| DMF | Data match flag | Indicates that the received data matches the configured data match value. | Y | N | Y |
| MBF | Module busy flag | Indicates that LPSPI is busy performing an SPI bus transfer. | N | N | N |

#### 67.3.6.1 DMA support registers

To support efficient DMA transfers to the transmit and control FIFO, an alias register supports 32-bit write access to the Transmit Command (TCR) and an alias region supports incrementing 32-bit write accesses to the Transmit Data (TDR).

- Transmit Command Burst (TCBR) is a 32-bit alias register for writing to TCR.
- Transmit Data Burst (TDBR0 - TDBR127) is a 512-byte alias region that supports writing to the TDR.

The burst alias locations are contiguous. A DMA transfer can start by writing to the TCBR register to initialize the transfer and then increment into the TDBR region without changing the DMA transfer size. The alias registers can also be used by the DMA to perform burst transfers when accessing the transmit FIFO.

The transmit FIFO prevents writes that overflow the FIFO, but this prevention does not signal an error. Do not perform writes to the TDBR unless there is sufficient room in the transmit FIFO.

Receive Data Burst (RDBR0 - RDBR127) is a 512-byte alias region that supports reading the Receive Data. This can be used by the DMA to perform burst transfers when accessing the receive FIFO.

### 67.3.7 Peripheral triggers

The connection of the LPSPI peripheral triggers with other peripherals depends on the device that is used.

Table 374. Peripheral triggers

| Type of trigger | Description | Additional information |
|---|---|---|
| Frame output | The frame output trigger:<br>• Asserts at the end of each frame (when PCS deasserts).<br>• Remains asserted for one cycle of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE]. | LPSPI generates two output triggers that can be connected to other peripherals on the chip. |
| Word output | The word output trigger:<br>• Asserts at the end of each received word.<br>• Remains asserted for one cycle of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE]. | |
| Input | To control the start of an LPSPI bus transfer, the LPSPI input trigger can be selected instead of the HREQ input:<br>• The LPSPI input trigger is synchronized, and must assert for at least two cycles of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE] so that the input trigger can be detected.<br>• When LPSPI is busy, the HREQ input (and therefore the LPSPI input trigger) is ignored.<br>• When LPSPI is busy, both the HREQ and LPSPI input triggers are ignored. They are used to start a new transfer when LPSPI is idle. | |

## 67.4 External signals

Table 375. External signals

| Signal | Name | Description | I/O |
|---|---|---|---|
| SCK | Serial clock | • Input in Peripheral mode<br>• Output in Controller mode | I/O |
| PCS[0] | Peripheral chip select | • Input in Peripheral mode<br>• Output in Controller mode | I/O |
| PCS[1]/HREQ | Peripheral chip select<br>or<br>host request | Host request pin is selected when CFGR0[HREN] = 1 and CFGR0[HRSEL] = 0:<br>• Input in either Peripheral mode or when used as controller host request<br>• Output in either Controller mode or when used as peripheral host request | I/O |
| PCS[2]/DATA[2] | Peripheral chip select or data pin 2 during parallel data transfers | When CFGR1[PCSCFG] = 0:<br>• Input in Peripheral mode<br>• Output in Controller mode<br>When CFGR1[PCSCFG] = 1: | I/O |

*Table continues on the next page...*

Table 375. External signals (continued)

| Signal | Name | Description | I/O |
|---|---|---|---|
| | | • Input in half-duplex parallel data receive transfers<br>• Output in half-duplex parallel data transmit transfers | |
| PCS[3]/DATA[3] | Peripheral chip select or data pin 3 during parallel data transfers | When CFGR1[PCSCFG] = 0:<br>• Input in Peripheral mode<br>• Output in Controller mode<br>When CFGR1[PCSCFG] = 1:<br>• Input in half-duplex parallel data receive transfers<br>• Output in half-duplex parallel data transmit transfers | I/O |
| PCS[4]/DATA[4] | Peripheral chip select or data pin 4 during parallel data transfers | When CFGR1[PCSCFG] = 0:<br>• Input in Peripheral mode<br>• Output in Controller mode<br>When CFGR1[PCSCFG] = 11b:<br>• Input in half-duplex parallel data receive transfers<br>• Output in half-duplex parallel data transmit transfers | I/O |
| PCS[5]/DATA[5] | Peripheral chip select or data pin 5 during parallel data transfers | When CFGR1[PCSCFG] = 0:<br>• Input in Peripheral mode<br>• Output in Controller mode<br>When CFGR1[PCSCFG] = 11b:<br>• Input in half-duplex parallel data receive transfers<br>• Output in half-duplex parallel data transmit transfers | I/O |
| PCS[6]/DATA[6] | Peripheral chip select or data pin 6 during parallel data transfers | When CFGR1[PCSCFG] = 0:<br>• Input in Peripheral mode<br>• Output in Controller mode<br>When CFGR1[PCSCFG] = 11b:<br>• Input in half-duplex parallel data receive transfers<br>• Output in half-duplex parallel data transmit transfers | I/O |

*Table continues on the next page...*

Table 375. External signals (continued)

| Signal | Name | Description | I/O |
|---|---|---|---|
| PCS[7]/DATA[7] | Peripheral chip select or data pin 7 during parallel data transfers | When CFGR1[PCSCFG] = 0:<br>• Input in Peripheral mode<br>• Output in Controller mode<br>When CFGR1[PCSCFG] = 11b:<br>• Input in half-duplex parallel data receive transfers<br>• Output in half-duplex parallel data transmit transfers | I/O |
| SOUT/DATA[0] | Serial data output | Can be configured as serial data input signal (used as data pin 0 in half-duplex parallel data transfers) | I/O |
| SIN/DATA[1] | Serial data input | Can be configured as serial data output signal (used as data pin 1 in half-duplex parallel data transfers) | I/O |

## 67.5 Initialization

This module does not require initialization.

## 67.6 Memory map and registers

**NOTE**

- Writing to a read-only register or reading a write-only register can cause bus errors.
- LPSPI does not check values programmed in registers for validity, so you must take care to write valid values only.

### 67.6.1 LPSPI register descriptions

#### 67.6.1.1 LPSPI memory map

LPSPI_0 base address: 4035_8000h

LPSPI_1 base address: 4035_C000h

LPSPI_2 base address: 4036_0000h

LPSPI_3 base address: 4036_4000h

LPSPI_4 base address: 404B_C000h

LPSPI_5 base address: 404C_0000h

| Offset | Register | Width (In bits) | Access | Reset value |

### 67.6.1.2 Version ID (VERID)

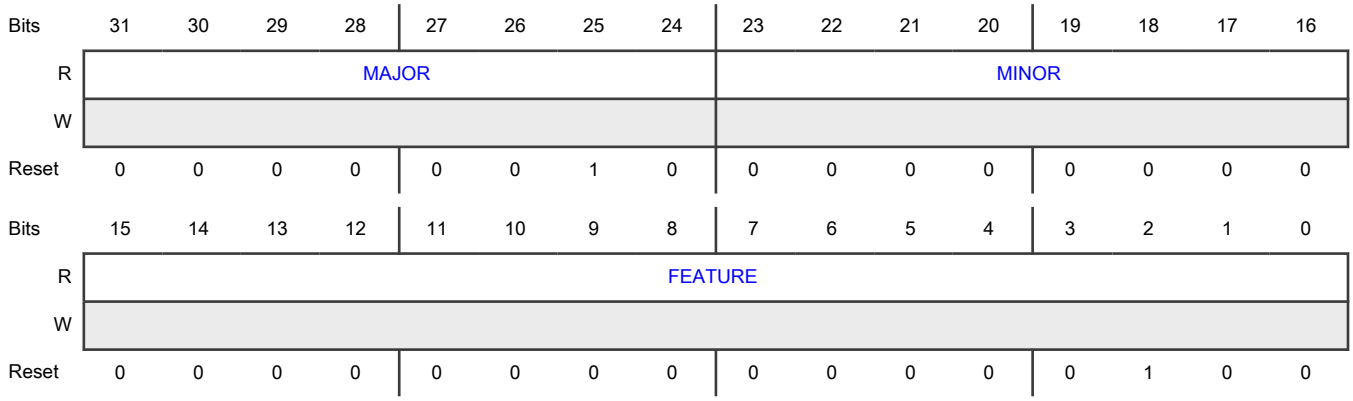
**Offset**

| Register | Offset |
|---|---|
| VERID | 0h |

**Function**

Contains version numbers for the module design and feature set.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-24<br>MAJOR | Major Version Number<br>Indicates the major version number of the module specification. |
| 23-16<br>MINOR | Minor Version Number<br>Indicates the minor version number of the module specification. |
| 15-0<br>FEATURE | Module Identification Number<br>Indicates the feature set number<br>0000_0000_0000_0100b - Standard feature set supporting a 32-bit shift register.<br>All other values are reserved. |

## 67.6.1.3 Parameter (PARAM)

### Offset

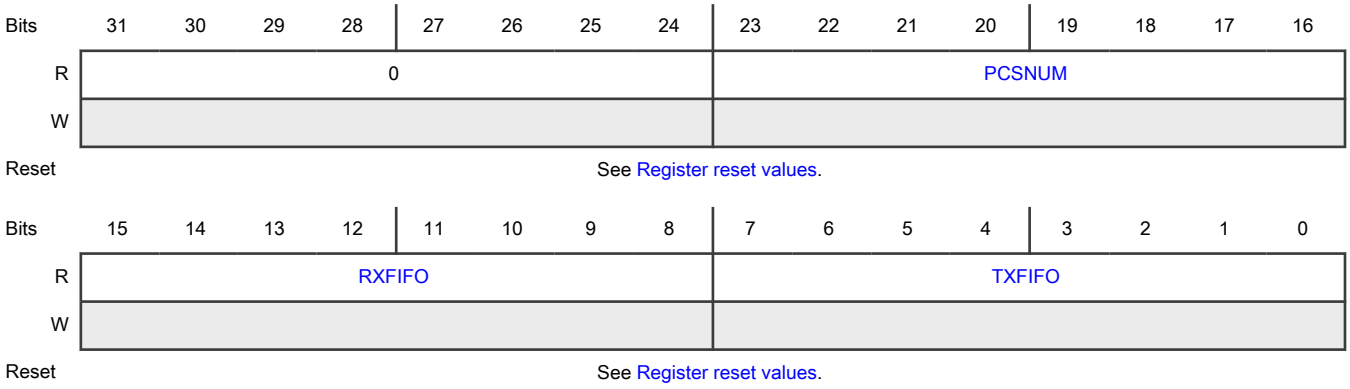
| Register | Offset |
|---|---|
| PARAM | 4h |

### Function

Contains:

- Number of PCS pins.
- Receive FIFO size.
- Transmit FIFO size.

### Diagram



### Register reset values

| Register | Reset value |
|---|---|
| PARAM | LPSPI_0: 0008_0202h<br>LPSPI_1: 0006_0202h<br>LPSPI_2–LPSPI_5: 0004_0202h |

### Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved |
| 23-16<br>PCSNUM | PCS Number<br>Indicates the number of PCS pins supported. |
| 15-8<br>RXFIFO | Receive FIFO Size<br>Indicates the maximum number of words in the receive FIFO. The maximum number of words is $2^{RXFIFO}$. |
| 7-0<br>TXFIFO | Transmit FIFO Size<br>Indicates the maximum number of words in the transmit FIFO. The maximum number of words is $2^{TXFIFO}$. |

## 67.6.1.4 Control (CR)

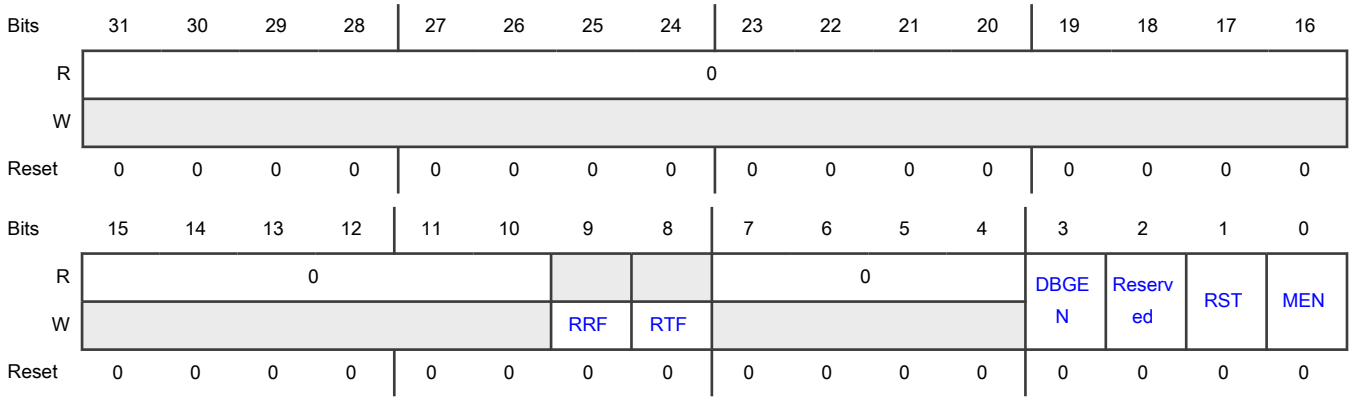
### Offset

| Register | Offset |
|---|---|
| CR | 10h |

### Function

Contains fields that control the module operation.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-10<br>— | Reserved |
| 9<br>RRF | Reset Receive FIFO<br>Deletes all entries in the receive FIFO. This field always reads 0.<br>0b - No effect<br>1b - Reset |
| 8<br>RTF | Reset Transmit FIFO<br>Deletes all entries in the transmit FIFO. This field always reads 0.<br>0b - No effect<br>1b - Reset |
| 7-4<br>— | Reserved |
| 3<br>DBGEN | Debug Enable<br>Enables LPSPI when the CPU is in Debug mode.<br>If this field is 0, LPSPI is disabled when the CPU is halted; the PCS pin is deasserted after the transmit FIFO is empty regardless of the state of Transmit Command (TCR).<br>You must update this field only when LPSPI is disabled (MEN = 0).<br>0b - Disable<br>1b - Enable |
| 2<br>— | Reserved |
| 1 | Software Reset |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| RST | Resets all internal logic and registers, except Control (CR). The reset takes effect immediately and remains asserted until you write 0 to it. There is no minimum delay required before clearing the software reset by writing 0.<br>0b - Not reset<br>1b - Reset |
| 0<br>MEN | Module Enable<br>Enables the module. After writing 0, MEN remains set until LPSPI has completed the current transfer and is idle.<br>0b - Disable<br>1b - Enable |

### 67.6.1.5 Status (SR)

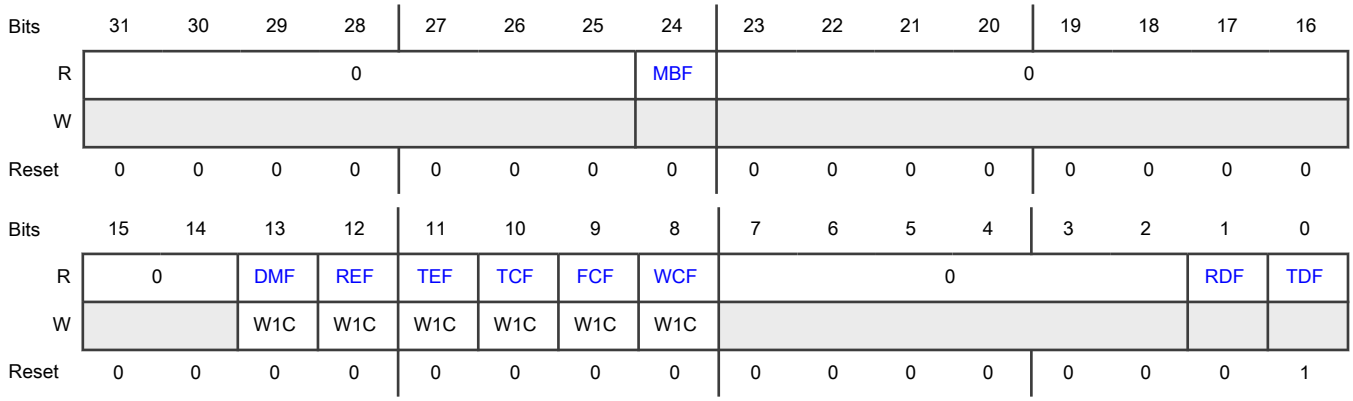
#### Offset

| Register | Offset |
|---|---|
| SR | 14h |

#### Function

Contains data flow status.

#### Diagram



#### Fields

| Field | Function |

### 67.6.1.7 DMA Enable (DER)

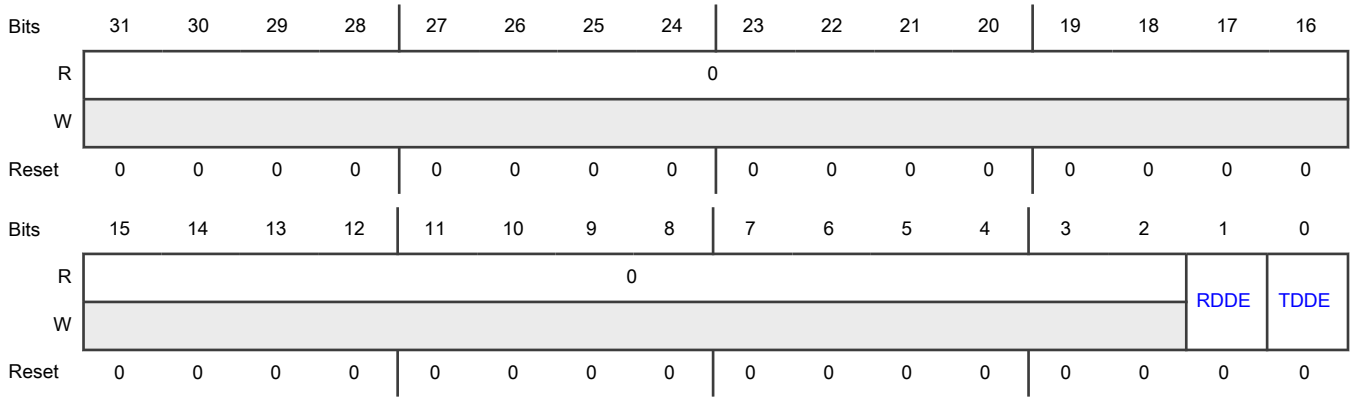
#### Offset

| Register | Offset |
|---|---|
| DER | 1Ch |

#### Function

Enables the DMA data flow.

#### Diagram



### Fields

| Field | Function |
|---|---|
| 31-2<br>— | Reserved |
| 1<br>RDDE | Receive Data DMA Enable<br>Enables the receive data DMA.<br>0b - Disable<br>1b - Enable |
| 0<br>TDDE | Transmit Data DMA Enable<br>Enables the transmit data DMA.<br>0b - Disable<br>1b - Enable |

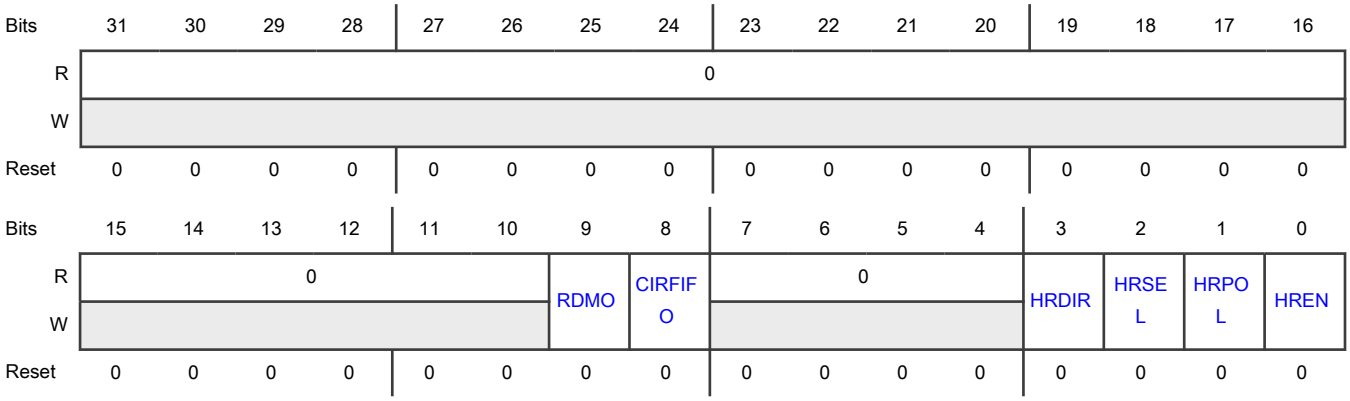
## 67.6.1.8 Configuration 0 (CFGR0)

### Offset

| Register | Offset |
|---|---|
| CFGR0 | 20h |

### Function
Includes fields to configure LPSPI.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-10<br>— | Reserved |
| 9<br>RDMO | Receive Data Match Only<br>Enables receive data match.<br>When enabled, all received data that does not cause SR[DMF] to assert is discarded:<br>• Write 1 to this field when LPSPI is idle and SR[DMF] = 0.<br>• After SR[DMF] = 1, this field is ignored.<br>• To ensure that no receive data is lost when disabling RDMO, write 0 to this field before clearing SR[DMF].<br>See CFGR1[MATCFG] for the received data matching options. When disabled, all received data is stored in the receive FIFO.<br>0b - Disable<br>1b - Enable |
| 8<br>CIRFIFO | Circular FIFO Enable<br>Enables circular FIFO.<br>When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO is emptied as in normal operation, but when LPSPI is idle and the transmit FIFO is empty, the read pointer value is restored from the temporary register.<br>This restoring of the read pointer causes the contents of the transmit FIFO to be cycled through repeatedly.<br>**NOTE**<br>The read pointer is restored for as long as this field is 1. Writing additional words to the FIFO when this field is 1 adds them to the end of the FIFO, up to the size of the transmit FIFO.<br>0b - Disable<br>1b - Enable |
| 7-4<br>— | Reserved |
| 3<br>HRDIR | Host Request Direction<br>Specifies the direction of the HREQ pin. You must configure the HREQ pin only as an output when LPSPI is in Peripheral mode. The HREQ pin direction must be an input for Controller mode.<br>0b - Input<br>1b - Output |
| 2<br>HRSEL | Host Request Select<br>Specifies the source of the host request input. When the host request function is enabled with the HREQ pin, the PCS[1] function is disabled. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 0b - HREQ pin<br>1b - Input trigger |
| 1<br>HRPOL | Host Request Polarity<br>Specifies the polarity of the HREQ pin or input trigger.<br>0b - Active high<br>1b - Active low |
| 0<br>HREN | Host Request Enable<br>Enables LPSPI, in Controller mode, to start a new SPI bus transfer only if the host request input is asserted. When LPSPI is busy, the host request input is ignored.<br>In Peripheral mode, causes the HREQ output pin to assert when data is available to be transmitted.<br>0b - Disable<br>1b - Enable |

### 67.6.1.9 Configuration 1 (CFGR1)

#### Offset

| Register | Offset |
|---|---|
| CFGR1 | 24h |

#### Function

Includes fields to configure LPSPI. You must write to this register only when LPSPI is disabled.

In addition to pin and output configurations, this register contains match configuration details; the following table shows match conditions specified in MATCFG.

**Table 376. Match conditions for CFGR1[MATCFG]**

| Condition | Description |
|---|---|
| Match first data word with compare word | Match if first data word equals MATCH0 logically ORed with MATCH1<br>first_data_word == (MATCH0 \|\| MATCH1) |
| Match any data word with compare word | Match if any data word equals MATCH0 logically ORed with MATCH1<br>any_data_word == (MATCH0 \|\| MATCH1) |
| Sequential match, first data word | Match if first data word equals MATCH0, and second data word equals MATCH1<br>(first_data_word == MATCH0) && (second_data_word == MATCH1) |
| Sequential match, any data word | Match if any data word equals MATCH0, and the next data word equals MATCH1 |

*Table continues on the next page...*

Table 376. Match conditions for CFGR1[MATCFG] (continued)

| Condition | Description |
|---|---|
| | (any_data_word == MATCH0) && (next_data_word == MATCH1) |
| Match first data word (masked) with compare word (masked) | Match if first data word logically ANDed with MATCH1 equals MATCH0 logically ANDed with MATCH1<br>(first_data_word && MATCH1) == (MATCH0 && MATCH1) |
| Match any data word (masked) with compare word (masked) | Match if any data word logically ANDed with MATCH1 equals MATCH0 logically ANDed with MATCH1<br>(any_data_word && MATCH1) == (MATCH0 && MATCH1) |

## 67.6.1.12 Clock Configuration (CCR)

### Offset

| Register | Offset |
|---|---|
| CCR | 40h |

### Function

Contains clock configuration fields that are used only in Controller mode; you can only change them when LPSPI is disabled (CR[MEN] = 0).

**Warning**

Writing a 32-bit value to this register overwrites Clock Configuration 1 (CCR1); DBT and SCKDIV always read 0.

To avoid overwriting CCR1, do one of the following:

- Write to all four fields in Clock Configuration (CCR) simultaneously and only once in a 32-bit data.
- Modify the values of CCR[SCKPCS] and/or CCR[PCSSCK]; write only these two upper bytes in a 16-bit data or one of them in an 8-bit data.
- Modify CCR1[PCSPCS] and CCR1[SCKSCK] only or CCR1[SCKSET] and CCR1[SCKHLD] only, write respectively to CCR[DBT] or CCR[SCKDIV] in 8-bit data.

### 67.6.1.16 Transmit Command (TCR)

#### Offset

| Register | Offset |
|---|---|
| TCR | 60h |

#### Function

Pushes the data into the transmit FIFO, in the same order as written.

When you write to either this register or to Transmit Data (TDR), each write pushes data into the transmit FIFO. You must write to this register only using 32-bit writes, which are tagged and cause the command register to update; after that the entry reaches the top of the FIFO and LPSPI is enabled. This allows changes to the command word and the transmit data itself to be interleaved. That is, writes to the two registers can be interleaved (write command word, then data word, then command word, and so on). Changing the command word causes all subsequent SPI bus transfers to be performed using the new command word:

- In Controller mode, writing a new command word does not initiate a new transfer, unless TXMSK is 1. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK = 1). Hardware writes 0 to TXMSK when PCS deasserts.
- In Controller mode, if the command word is changed before an existing frame has completed, then the existing frame terminates and the command word updates. The command word can be changed during a continuous transfer, if CONTC of the new command word is 1 and the command word is written on a frame size boundary.
- In Peripheral mode, the command word must be changed only when LPSPI is idle and there is no SPI bus transfer.

Avoid resetting the transmit FIFO after writing to this register; wait for the command register to update from the FIFO first.

Avoid register reading problems: Reading this register returns the current state of the register. Reading this register at the same time that it is loaded from the transmit FIFO can return an incorrect register value. It is recommended to:

- Read this register when the transmit FIFO is empty.
- Read this register more than once and then compare the returned values.

| 11-0<br>FRAMESZ | Frame Size<br>Configures the frame size in number of bits equal to (FRAMESZ + 1):<br>• The minimum frame size is 8 bits, or 16 bits for an 8-bit transfer.<br>• If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.<br>• If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remainder bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits. |

### 67.6.1.17 Transmit Data (TDR)

#### Offset

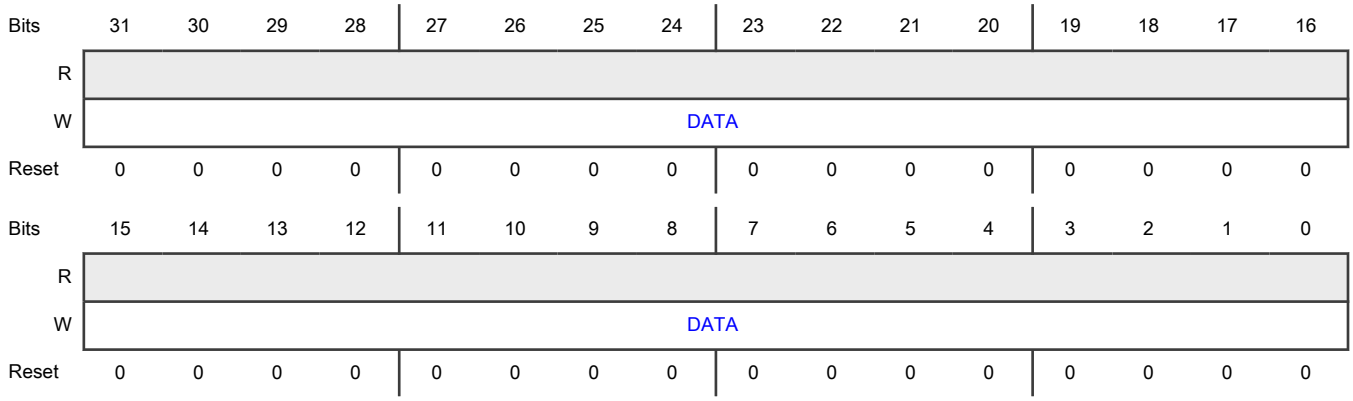
| Register | Offset |
|---|---|
| TDR | 64h |

#### Function

Pushes the data into the transmit FIFO, in the same order that the data is written. You can write to this register using 32-, 16-, or 8-bit writes.

When you write to this register or to Transmit Command (TCR), each write pushes data into the FIFO with zero pushed in unwritten bytes.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>DATA | Transmit Data<br>Indicates transmit data. Both 8-bit and 16-bit writes of transmit data zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8-bit and 16-bit writes (to 32 bits) means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes. |

## 67.6.1.18 Receive Status (RSR)

### Offset

| Register | Offset |
|---|---|
| RSR | 70h |

### Function

Contains data flow status fields for receive FIFO.

# Chapter 68
# Low Power Inter-Integrated Circuit (LPI2C)

## 68.1 Chip-specific LPI2C information

### 68.1.1 LPI2C instances and configuration

This chip has two instances of LPI2C.

**Table 377. LPI2C instances**

| Instance | MCXE315/MCXE316/MCXE317/MCXE31B |
|---|---|
| LPI2C_0 | Yes |
| LPI2C_1 | Yes |

**Table 378. LPI2C configuration**

| Instances | TX FIFO Size | RX FIFO Size | SMBus[1] | Slave Mode Enable |
|---|---|---|---|---|
| LPI2C_0 | 4x11 bit | 4x8 bit | Yes | Yes |
| LPI2C_1 | 4x11 bit | 4x8 bit | Yes | Yes |

1. System Management Bus

- LPI2C slave mode operation supports up to high speed mode = 3.4MHz (3.4 Mbps data rate; effective data rate reduces according to I2C protocol).
- LPI2C master mode operation supports up to fast Mode = 400KHz (400 kbps data rate; effective data rate reduces according to I2C protocol).
- The LPI2C module includes SMBus (System Management Bus) support and DMA support.
- LPI2C RX FIFO is 8-bit and TX FIFO is 11-bit (8bit data + 3bit command)
- LPI2C supports fast data communication as per I2C standard v3.0.

## 68.2 Overview

LPI2C supports an efficient interface to an I2C bus as a controller and target:

- Implements logic support for Standard, Fast, Fast+, HS-mode (target only) and Ultra-Fast modes of operation
- Uses little CPU overhead, with DMA offloading of FIFO register accesses

LPI2C also complies with the System Management Bus (SMBus) Specification, version 3. The SMBus is a single-ended simple two-wire bus, which is typically used for low-bandwidth communications.

The Inter-Integrated Circuit ($I^2C$) serial bus is multi-controller, multi-target, packet-switched, and single-ended, and is often used to attach microcontroller ICs to lower-speed peripheral ICs.

**NOTE**

Terminology in this chapter has been updated to align with I²C-bus specification, Rev. 7.0, as shown in Table 379.

**Table 379. Updated terms**

| Updated term | Deprecated term |
|---|---|
| Controller | Master |
| Target | Slave |

## 68.2.1 Block diagram

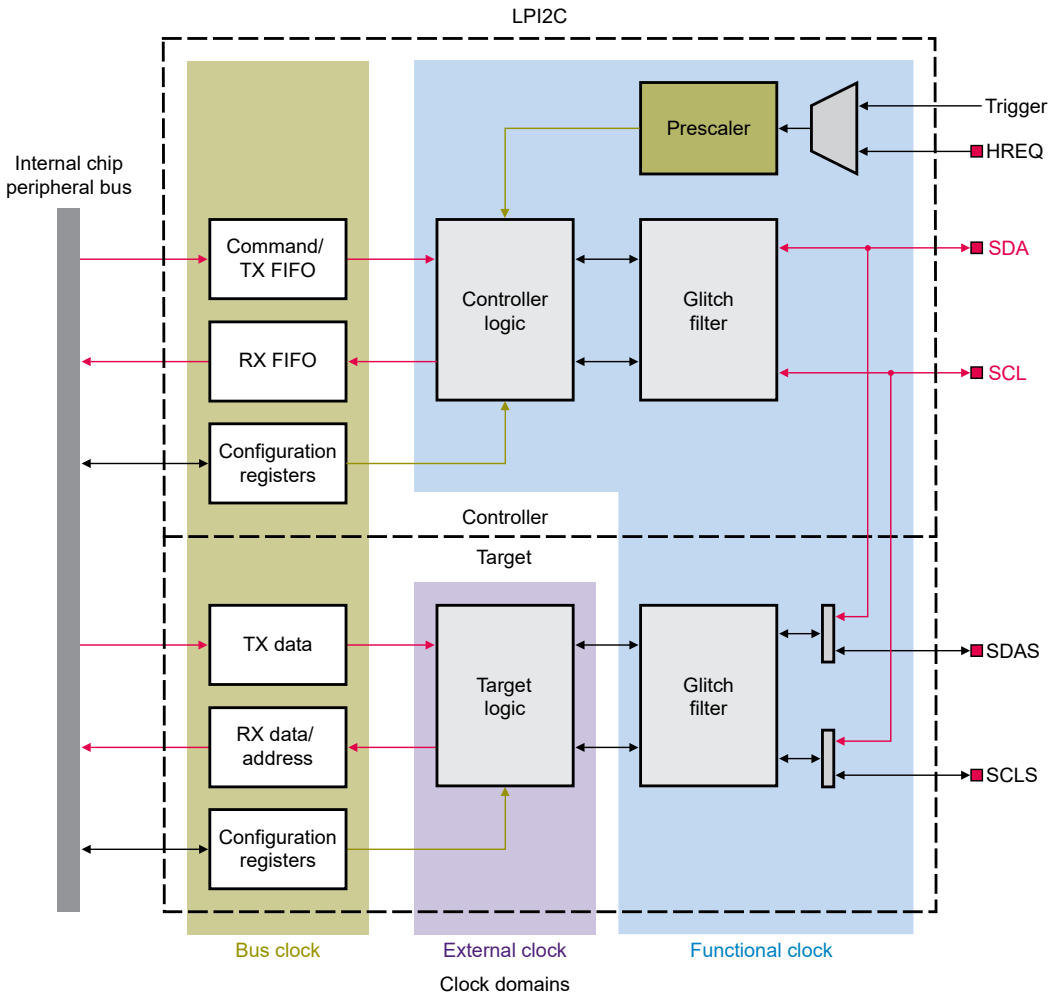

**Figure 362. Block diagram**

## 68.2.2 Features

LPI2C supports:

- Standard, Fast, Fast+ and Ultra Fast modes
- HS mode in target mode
- Multicontroller, including synchronization and arbitration, means that any number of controller nodes can be present. Also, controller and target roles can be changed between messages (after a Stop signal is sent).

- Clock stretching. Used on the SCL line, as an I2C flow control mechanism.
- Arbitration for when the system has more than one controller. When used on the SDA line, ensures that there is only one I2C transmitter at a time.
- General call, seven-bit addressing, and ten-bit addressing
- Software reset, Start byte, and device ID (also require software support)

The LPI2C controller supports:

- Command and transmit FIFO of 4 words (8-bit transmit data + 3-bit command)
- Receive FIFO of 4 words (8-bit receive data).
- Command FIFO waiting for an I2C idle bus before initiating a transfer
- Initiation of repeated Start and Stop conditions and one or more controller-receiver transfers by command FIFO
- Stop condition generation from command FIFO, or automatic generation of Stop condition when the transmit FIFO is empty
- Host request input to control the start time of an I2C bus transfer
- Interrupt generation on data match and unwanted data rejection, via flexible receive data match
- Flags and optional interrupt signals at repeated Start condition, Stop condition, loss of arbitration, unexpected NACK, and command word errors
- Configurable bus idle timeout and pin-stuck-low timeout

The LPI2C target supports:

- Separate I2C target registers to minimize software overhead because of controller or target switching
- 7-bit or 10-bit addressing, address range, SMBus alert, and general call address.
- Transmit data register that supports interrupt or DMA requests
- Receive data register that supports interrupt or DMA requests
- Software-controllable ACK or NACK, with optional clock stretching on ACK or NACK field
- Configurable clock stretching, to avoid transmit-FIFO-underrun and receive-FIFO-overrun errors
- Flags and optional interrupt at end of packet, Stop condition, or bit error detection

## 68.3 Functional description

### 68.3.1 Controller mode

The LPI2C controller logic operates independently from the target logic to perform all controller-mode transfers on the I2C bus.

#### 68.3.1.1 Transmit and Command FIFO commands

The transmit FIFO stores command data to initiate various I2C operations. The following operations can be initiated through commands in the transmit FIFO:

- Start or repeated Start condition with address byte, expecting ACK or NACK.
- Transmit data. This operation is the default for zero-extended-byte writes to the transmit FIFO.
- Receive 1-256 bytes of data. You can configure this operation to discard received data and not to store it in the receive FIFO.
- Stop condition. You can configure this operation to send a Stop condition when the transmit FIFO is empty.

Multiple transmit and receive commands can be inserted between the Start and Stop conditions. To comply with the I2C specification, transmit and receive commands must not be interleaved. The receive data command and the receive data and

discard commands can be interleaved. This interleaving ensures that only the desired received data is stored in the receive FIFO (or compared with the data match logic).

The LPI2C controller automatically transmits a NACK on the last byte of a receive data command. It transmits the NACK unless the next command in the FIFO is also a receive data command. If the transmit FIFO is empty when a receive data command completes, a NACK is also automatically transmitted.

The LPI2C controller supports 10-bit addressing via a (repeated) Start condition, followed by a transmit data byte containing the second address byte, followed by any number of data bytes with the controller transmit data.

A Start or repeated Start condition expecting a NACK (for example, HS mode controller code) must be followed by a Stop or (repeated) Start condition.

#### 68.3.1.2 Controller operations

When LPI2C is enabled, it monitors the I2C bus to detect when the I2C is idle (MSR[BBF]). If either SCL or SDA are low, the I2C bus is no longer considered idle. The bus becomes idle if a Stop condition is detected or if a bus idle timeout is detected (as configured by MCFGR2[BUSIDLE]). After the bus is idle, if the transmit FIFO is not empty and the host request is asserted or disabled, the LPI2C controller initiates a transfer on the bus. This transfer involves the following steps:

1. Wait the bus idle time equal to (MCCR0[CLKLO] + 1) multiplied by the prescaler (MCFGR1[PRESCALE]).
2. Transmit a Start condition and address byte using the timing configuration in Controller Clock Configuration 0 (MCCR0). If an HS mode transfer is configured, the timing configuration from Controller Clock Configuration 1 (MCCR1) is used instead.
3. Perform controller transmit or controller receive transfers, as configured by the transmit FIFO.
4. Transmit NACK on the last byte of a controller receive transfer. This action is performed unless the next command in the transmit FIFO is also a receive data command and the transmit FIFO is not empty.
5. Transmit a repeated Start or Stop condition as configured by the transmit FIFO or MCFGR1[AUTOSTOP]. A repeated Start can change which timing configuration register is used.

When the LPI2C controller is disabled, LPI2C continues emptying the transmit FIFO until a Stop condition is transmitted. (The controller could be disabled due to MCR[MEN] being 0, or automatically due to mode entry.) However, LPI2C no longer stalls the I2C bus by waiting for the transmit or receive FIFO. After the transmit FIFO is empty, LPI2C generates a Stop condition automatically.

The LPI2C controller can stall the I2C bus under certain conditions. This stalling results in SCL pulled low continuously on the first bit of a byte, until these conditions change:

- The LPI2C controller is enabled and busy, the transmit FIFO is empty, and MCFGR1[AUTOSTOP] is 0. The LPI2C controller continues to stall the bus until the transmit FIFO is loaded with more data.
- The LPI2C controller is enabled and receiving data, receive data is not being discarded (due to command or receive data match), and the receive FIFO is full. The LPI2C controller continues to stall the I2C bus until the receive FIFO is emptied.

#### 68.3.1.3 Receive FIFO and data matching

The receive FIFO stores receive data during controller-receiver transfers. You can configure the LPI2C controller to discard received data instead of storing it in the receive FIFO. This option is configured via the command word in the transmit FIFO.

Received data supports a receive data match function that can match received data against one of two bytes, or against a masked data byte. You can configure the data match function to compare only the first one or two data words received since the last (repeated) Start condition. Received data that is already discarded due to the command word cannot cause a data match. It delays the match on the first data word received until after the discarded data is received.

You can configure the receiver match function to discard all received data until a data match is detected, using MCFGR0[RDMO]. Following a data match, write 0 to MCFGR0[RDMO] before writing 0 to MSR[DMF] to allow all subsequent data to be received.

#### 68.3.1.4 Timing parameters

The LPI2C controller can configure the following timing parameters. Parameters are configured separately for HS mode (Controller Clock Configuration 1 (MCCR1)) and other modes (Controller Clock Configuration 0 (MCCR0)). This separation allows the HS mode controller code to be sent using regular timing parameters. Then it allows a switch to HS mode timing (following a repeated Start) until the next STOP condition.

Configure the LPI2C controller timing parameters, measured in LPI2C functional clock cycles, as shown in Table 380. You must configure these parameters to meet the I2C timing specification for the required mode.

**Table 380. Timing parameters**

| I2C specification timing parameter | I2C specification timing symbol | LPI2C timing parameter (in LPI2C functional clock cycles) |
|---|---|---|
| SCL clock period | tSCL | (CLKHI + CLKLO + 2 + SCL_LATENCY) × (2 ^ PRESCALE) |
| Hold time (repeated) Start condition | tHD:STA | (SETHOLD +1) × (2 ^ PRESCALE) |
| Low period of the SCL clock | tLOW | (CLKLO + 1) × (2 ^ PRESCALE) |
| High period of the SCL clock | tHIGH | (CLKHI + 1 + SCL_LATENCY) × (2 ^ PRESCALE) |
| Setup time for a repeated Start condition or Stop condition | tSU:STA, tSU:STO | (SETHOLD + 1 + SCL_LATENCY) × (2 ^ PRESCALE) |
| Data hold time | tHD:DAT | (DATAVD + 1) × (2 ^ PRESCALE) |
| Data setup time | tSU:DAT | (SDA_LATENCY + 1) × (2 ^ PRESCALE) |
| Bus free time between a Stop and Start condition | tBUF | (CLKLO + 1 + SDA_LATENCY) × (2 ^ PRESCALE) |
| Data valid time, data valid acknowledge time | tVD:DAT, tVD:ACK | (DATAVD + 1) × (2 ^ PRESCALE) |

Table 381 defines the latency parameters. These parameters assume that the risetime is less than one LPI2C functional clock cycle. The risetime depends on a number of factors, including the I/O propagation delay, the I2C bus loading, and the external pullup resistor sizing. A larger risetime increases the number of cycles that the signal takes to propagate through the synchronizer (and glitch filter), which increases the latency.

**Table 381. Synchronization latency**

| Timing parameter | Timing definition |
|---|---|
| SCL_LATENCY | ROUNDDOWN ((2 + FILTSCL + SCL_RISETIME) ÷ (2 ^ PRESCALE)) |
| SDA_LATENCY | ROUNDDOWN ((2 + FILTSDA + SDA_RISETIME) ÷ (2 ^ PRESCALE)) |

The following timing restrictions must be enforced to avoid unexpected Start or Stop conditions on the I2C bus. These restrictions also avoid unexpected Start or Stop conditions detected by the LPI2C controller. The timing restrictions can be summarized as "SDA cannot change when SCL is high outside a transmitted (repeated) Start or Stop condition."

**Table 382. LPI2C timing parameter restrictions**

| Timing parameter | Minimum | Maximum | Comment |
|---|---|---|---|
| CLKLO | 03h | — | CLKLO x (2 ^ PRESCALE) > SCL_LATENCY |

*Table continues on the next page...*

Table 382. LPI2C timing parameter restrictions (continued)

| Timing parameter | Minimum | Maximum | Comment |
|---|---|---|---|
| CLKHI | 01h | — | Configure CLKHI to meet the duty cycle requirements in the I2C specification |
| SETHOLD | 02h | — | SETHOLD × (2 ^ PRESCALE) > SDA_LATENCY |
| DATAVD | 01h | CLKLO – SDA_LATENCY – 1 | Configure DATAVD to meet the data hold requirement in the I2C specification |
| FILTSCL | 00h | [CLKLO × (2 ^ PRESCALE)] – 3 | FILTSCL and FILTSDA are the only parameters not multiplied by (2 ^ PRESCALE) |
| FILTSDA | FILTSCL | [CLKLO × (2 ^ PRESCALE)] – 3 | Configuring FILTSDA greater than FILTSCL can delay the SDA input to compensate for board level skew |
| BUSIDLE | (CLKLO + SETHOLD + 2) × 2 | — | Must also be greater than (CLKHI + 1) |

See the UM10204, *I2C-bus specification and user manual*.

See Application information for example LPI2C timing configurations.

#### 68.3.1.5 Error conditions

The LPI2C controller monitors errors while it is active. The following conditions generate an error flag and block a new Start condition from being sent, until the flag is cleared by software:

- A Start or Stop condition is detected and is not generated by the LPI2C controller (MSR[ALF] becomes 1).
- Transmitting data on SDA and different values are received (MSR[ALF] becomes 1).
- NACK is detected when transmitting data, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- NACK is detected and is expecting ACK for the address byte, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- ACK is detected and is expecting NACK for the address byte, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- Transmit FIFO is requesting to transmit or receive data without a Start condition (MSR[FEF] becomes 1).
- SCL (or SDA if MCFGR1[TIMECFG] is 1) is low for (MCFGR2[TIMELOW] × 256) prescaler cycles without a pin transition (MSR[PLTF] becomes 1).

You must respond to MSR[PLTF] to terminate the existing command. You can terminate the command cleanly by writing 0 to MCR[MEN], or you can terminate it abruptly by writing 1 to MCR[RST].

You can use MCFGR2[BUSIDLE] to force the I2C bus to be considered idle when SCL and SDA remain high for (BUSIDLE + 1) prescaler cycles. The bus is considered idle when the LPI2C controller is first enabled. When BUSIDLE is configured greater than zero, then SCL or SDA must be high for (BUSIDLE + 1) prescaler cycles before the I2C bus is considered idle.

#### 68.3.1.6 Pin configuration

| Configuration | Description |
|---|---|
| Open-drain support | The LPI2C controller defaults to open-drain configuration of the SDA and SCL pins. Support for true open drain depends on the specific device, and requires the pins where LPI2C pins are muxed to support true open drain. |
| HS mode support | Support for HS mode depends on the specific device. This mode requires the SCL pin to support the current source pullup required in the I2C specification. |
| Ultra-Fast mode support | The LPI2C controller supports the output-only push-pull function required for I2C Ultra-Fast mode using the SDA and SCL pins. Support for Ultra-Fast mode also requires MCFGR1[IGNACK] to be 1. |
| Push-pull two-wire support | A push-pull two-wire configuration is available to the LPI2C controller. If LPI2C is the only controller and all I2C pins on the bus are at the same voltage, this configuration may support a partial HS mode. A partial HS mode, not a full HS mode, because this configuration actively drives high rather than enabling a current service pull-up. This configuration sets the SCL pin as push-pull for every clock except the first clock pulse, to allow HS-mode-compatible targets to perform clock stretching. In this mode, the SDA pin is tristated for controller-receive data bits and controller-transmit ACK/NACK bits, and is configured as push-pull at other times. To avoid the risk of contention when SDA is push-pull, configure the pin for open-drain operation, as part of the device-specific configuration. |
| Push-pull four-wire support | The push-pull four-wire configuration separates the SCL input data and output data into separate pins. It also separates the SDA input data and output data into separate pins. The SCL/SDA pins are used for input data; the SCLS/SDAS pins are used for output data, with configurable polarity. This configuration simplifies external connections when connecting the LPI2C to the I2C bus through external level shifters or discrete components. When using this four-wire configuration, the LPI2C controller logic and LPI2C target logic cannot connect to separate I2C buses. |

### 68.3.2 Target mode

To perform all target mode transfers on the I2C bus, the LPI2C target logic operates independently from the LPI2C controller logic.

#### 68.3.2.1 Address matching

You can configure the LPI2C target:

- To match one of two addresses, using either 7-bit or 10-bit addressing modes for each address.
- To match a range of addresses in either 7-bit or 10-bit addressing modes.
- To match the general call address and generate appropriate flags.
- To match the SMBus alert address and generate appropriate flags.
- To detect the HS mode controller code address, and to disable the digital filters and output valid delay time until the next Stop condition is detected.

After a valid address is matched, the LPI2C target automatically performs target-transmit or target-receive transfers until:

- A NACK is detected (unless SCFGR1[IGNACK] becomes 1).
- A bit error is detected (the LPI2C target is driving SDA, but a different value is sampled).
- A (repeated) Start or Stop condition is detected.

#### 68.3.2.2 Transmit and receive data

Target Transmit Data (STDR) and Target Receive Data (SRDR) are double-buffered and only update during a target-transmit and target-receive transfer, respectively.

You can configure the target address that was received to be read from SRDR (for example, when using DMA to transfer data) or from Target Address Status (SASR).

You can configure STDR to request data only after a target-transmit transfer is detected. You can also configure it to request new data whenever STDR is empty.

Write to STDR only when SSR[TDF] is set.

Read SRDR only when SSR[RDF] is set, or when SSR[AVF] is set and SCFGR1[RXCFG] = 1.

Read SASR only when SSR[AVF] is set.

#### 68.3.2.3 Clock stretching

The LPI2C target supports many configurable options for clock stretching. You can configure these conditions to perform clock stretching:

- SSR[AVF] is set during the ninth clock pulse of the address byte.
- SSR[TDF] is set during the ninth clock pulse of a target-transmit transfer.
- SSR[RDF] is set during the ninth clock pulse of a target-receive transfer.
- SSR[TAF] is set during the eighth clock pulse of an address byte or a target-receive transfer. In HS mode, this option is disabled.
- Clock stretching can be extended for a number of cycles equal to the value of SCFGR2[CLKHOLD] cycles. This stretching allows additional setup time to sample the SDA pin externally. In HS mode, this option is disabled.

When clock stretching is enabled, clock stretching extends for one peripheral bus clock cycle after SDA updates, unless extended by the SCFGR2[CLKHOLD] configuration.

#### 68.3.2.4 Timing parameters

The LPI2C target can configure the following timing parameters:

- SDA data valid time from SCL negation to SDA update
- SCL hold time when clock stretching is enabled to increase setup time when sampling SDA externally
- SCL glitch filter time
- SDA glitch filter time

These parameters are disabled when SCR[FILTEN] is 0, when SCR[FILTDZ] is 1 in Doze mode, and when LPI2C target detects HS mode. When disabled, the LPI2C target is clocked directly from the I2C bus. In this case, the target may not satisfy all timing requirements of the I2C specification (such as SDA minimum hold time in Standard/Fast mode).

The LPI2C target places the following restrictions on the timing parameters:

- You must configure SCFGR2[FILTSDA] to be greater than or equal to SCFGR2[FILTSCL] (unless compensating for board level skew between SDA and SCL).
- You must configure SCFGR2[DATAVD] to be less than the minimum SCL low period.

#### 68.3.2.5 Error conditions

The LPI2C target can flag the following error conditions:

- SSR[BEF] is set when the LPI2C target is driving SDA but it samples a different value than what is expected.
- SSR[FEF] is set due to a transmit data underrun or a receive data overrun. To eliminate the possibility of underrun and overrun, enable clock stretching.
- SSR[FEF] is also set due to an address overrun, but only when SCFGR1[RXCFG] is 1. To eliminate the possibility of overrun, enable clock stretching.

The LPI2C target does not implement a timeout due to SCL or SDA being stuck low. If this detection is required, use the LPI2C controller logic so you can reset the LPI2C target when this condition is detected.

### 68.3.3 Low-power modes

LPI2C remains functional during low-power modes, if MCR[DOZEN] = 0 and LPI2C uses an external or internal clock source that remains enabled. LPI2C can generate an interrupt or DMA request to cause a wake-up from low-power modes.

You can configure LPI2C to be disabled in low-power modes when MCR[DOZEN] = 1. In this case, LPI2C waits for the current transfer to complete any pending operation.

**NOTE**

See the chip-specific information for low-power modes available on your chip.

### 68.3.4 Debug mode

**Table 383. Debug mode**

| Mode | LPI2C operation |
|---|---|
| Debug | If MCR[DBGEN] = 1, can continue operating in Debug mode. |

### 68.3.5 Peripheral triggers

The connection of the LPI2C peripheral triggers to other peripherals depends upon the specific device being used.

**Table 384. LPI2C triggers**

| Trigger | Description |
|---|---|
| Controller output trigger | Generates an output trigger that can be connected to other peripherals on the device. The controller output trigger asserts on either a repeated Start or a Stop condition. The trigger remains asserted for one cycle of the LPI2C functional clock divided by MCFGR1[PRESCALE]. |
| Target output trigger | Generates an output trigger that can be connected to other peripherals on the device. The target output trigger asserts on either a repeated Start or a Stop condition that occurs after a target address match. The target output trigger remains asserted until the next target SCL pin negation. |
| Input trigger | To control the start of a LPI2C bus transfer, the LPI2C input trigger can be selected instead of the HREQ input. The input trigger is synchronized. To be detected, the input trigger must assert for at least two cycles of the LPI2C functional clock divided by the value of MCFGR1[PRESCALE]. When LPI2C is busy, the HREQ input (and therefore the input trigger) is ignored. |

### 68.3.6 Clocking

**Table 385. LPI2C clocks**

| Clock | Description |
|---|---|
| LPI2C functional clock | The LPI2C functional clock is asynchronous to the bus clock. It can remain enabled in low-power modes to support I2C bus transfers by the LPI2C controller. The functional clock is also used by the LPI2C target to support digital filter and data hold time configurations. The LPI2C controller divides the functional clock by a prescaler (MCFGR1[PRESCALE]) and the resulting frequency must be at least eight times faster than the I2C bus bandwidth. |

*Table continues on the next page...*

Table 385. LPI2C clocks (continued)

| Clock | Description |
|---|---|
| External clock | The LPI2C target logic is clocked directly from the external pins. These pins are SCL and SDA, or SCLS and SDAS if the controller and target are implemented on separate pins). This clocking allows the LPI2C target to remain operational, even when the LPI2C functional clock is disabled.<br>**NOTE**<br>If the LPI2C functional clock is disabled, the LPI2C target digital filter must be disabled. This condition can affect compliance with some timing parameters of the I2C specification, such as data hold time. |
| Bus clock | The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPI2C controller and target registers. |

For chip-specific clocking information, see the Clocking chapter.

### 68.3.7 Reset

Table 386. LPI2C resets

| Reset | Description |
|---|---|
| Chip reset | The logic and registers for the LPI2C controller and target are reset to their default states after a chip reset. |
| Software reset | The LPI2C controller implements a software reset field in its control register. MCR[RST] resets all controller logic and registers to their default states, except for Controller Control (MCR) itself.<br>The LPI2C target implements a software reset field in its control register. SCR[RST] resets all target logic and registers to their default states, except for Target Control (SCR) itself. |
| FIFO reset | The LPI2C controller implements write-only control fields that reset the transmit FIFO (MCR[RTF]) and receive FIFO (MCR[RRF]). After a FIFO is reset, that FIFO is empty.<br>The LPI2C target implements write-only control fields that reset the transmit data register (SCR[RTF]) and receive data register (SCR[RRF]). After a data register is reset, that data register is empty. |

### 68.3.8 Interrupts and DMA requests

Depending on the configuration, interrupts and DMA requests can be combined:

- LPI2C controller and target interrupts
- LPI2C controller and target transmit DMA requests
- LPI2C controller and target receive DMA requests

#### 68.3.8.1 Controller mode

Table 387 lists the Controller mode sources that can generate LPI2C controller interrupts and LPI2C controller transmit and receive DMA requests.

Table 387. Controller interrupts and DMA requests

| Status flag | Description | Can generate | | |
|---|---|---|---|---|
| | | Interrupt? | DMA request? | Low-power wake-up? |
| Transmit Data Flag (MSR[TDF]) | Data can be written to transmit FIFO, as configured by MFCR[TXWATER]. | Y | TX | Y |
| Receive Data Flag (MSR[RDF]) | Data can be read from the receive FIFO, as configured by MFCR[RXWATER]. | Y | RX | Y |
| End Packet Flag (MSR[EPF]) | Controller has transmitted a repeated Start or Stop condition. | Y | N | Y |
| Stop Detect Flag (MSR[SDF]) | Controller has transmitted a Stop condition . | Y | N | Y |
| NACK Detect Flag (MSR[NDF]) | During an address byte, the controller expects an ACK but detects a NACK.<br>During an address byte, the controller expects a NACK but detects an ACK.<br>During a controller-transmitter data byte, the controller detects a NACK. | Y | N | Y |
| Arbitration Lost Flag (MSR[ALF]) | The controller lost arbitration due to a Start or Stop condition detected at the wrong time, or the controller was transmitting data but received data different from the data that was transmitted. | Y | N | Y |
| FIFO Error Flag (MSR[FEF]) | The controller expects a Start condition in the command FIFO, but the next entry in the command FIFO is not a Start condition. | Y | N | Y |
| Pin Low Timeout Flag (MSR[PLTF]) | Pin low timeout is enabled and SCL (or SDA, if configured) is low for longer than the configured timeout. | Y | N | Y |
| Data Match Flag (MSR[DMF]) | The received data matches the configured data match, but the received data is not discarded due to a command FIFO entry. | Y | N | Y |
| Controller Busy Flag (MSR[MBF]) | LPI2C controller is busy transmitting or receiving data. | N | N | N |
| Bus Busy Flag (MSR[BBF]) | LPI2C controller is enabled and activity is detected on the I2C bus, but no Stop condition is detected and no bus idle timeout (if enabled) occurred. | N | N | N |

#### 68.3.8.2 Target mode

Table 388 lists the target mode sources that can generate LPI2C target interrupts and LPI2C target transmit and receive DMA requests.

Table 388. Target interrupts and DMA requests

| Status flag | Description | Can generate | | |
|---|---|---|---|---|
| | | Interrupt? | DMA request? | Low-power wake-up? |
| Transmit Data Flag (SSR[TDF]) | Data can be written to Target Transmit Data (STDR). | Y | TX | Y |
| Receive Data Flag (SSR[RDF]) | Data can be read from Target Receive Data (SRDR). | Y | RX | Y |
| Address Valid Flag (SSR[AVF]) | Address can be read from Target Address Status (SASR). | Y | RX | Y |
| Transmit ACK Flag (SSR[TAF]) | ACK or NACK can be written to Target Transmit ACK (STAR). | Y | N | Y |
| Repeated Start Flag (SSR[RSF]) | Target has detected an address match followed by a repeated Start condition. | Y | N | Y |
| Stop Detect Flag (SSR[SDF]) | Target has detected an address match followed by a Stop condition. | Y | N | Y |
| Bit Error Flag (SSR[BEF]) | Target was transmitting data, but received data is different from what was transmitted. | Y | N | Y |
| FIFO Error Flag (SSR[FEF]) | This flag is set by:<br>• Transmit data underrun<br>• Receive data overrun<br>• Address status overrun when SCFGR1[RXCFG] = 1<br>This flag can only be set when clock stretching is disabled. | Y | N | Y |
| Address Match 0 Flag (SSR[AM0F]) | Target detected an address match SAMR[ADDR0]. | Y | N | N |
| Address Match 1 Flag (SSR[AM1F]) | Target detected an address match with SAMR[ADDR1] or using an address range. | Y | N | N |
| General Call Flag (SSR[GCF]) | Target detected an address match with the general call address. | Y | N | N |
| SMBus Alert Response Flag (SSR[SARF]) | Target detected an address match with the SMBus alert address. | Y | N | N |
| Target Busy Flag (SSR[SBF]) | LPI2C target is busy receiving an address byte or is transmitting or receiving data. | N | N | N |
| Bus Busy Flag (SSR[BBF]) | LPI2C target is enabled and a Start condition is detected on I2C bus, but no Stop condition detected. | N | N | N |

## 68.4 External signals

**Table 389. External signals**

| Signal | Name | Two-wire scheme | Four-wire scheme | Direction |
|---|---|---|---|---|
| SCL | LPI2C clock line | SCL | In Four-Wire mode, this pin is the SCL input pin. | Input or output |
| SDA | LPI2C data line | SDA | In Four-Wire mode, this pin is the SDA input pin. | Input or output |
| SCLS | Secondary I2C clock line | Not used | In Four-Wire mode, this pin is the SCLS output pin. If LPI2C controller/target are configured to use separate pins, then this pin is the LPI2C target SCL pin. | Input or output |
| SDAS | Secondary I2C data line | Not used | In Four-Wire mode, this pin is the SDAS output pin. If LPI2C controller/target are configured to use separate pins, then this pin is the LPI2C target SDA pin. | Input or output |
| HREQ | Host request | If host request is asserted and the I2C bus is idle, then it initiates an LPI2C controller transfer.<br>HREQ is an additional pin separate from the two-wire or four-wire scheme. | | Input |

Figure 363 shows the two-signal connection.

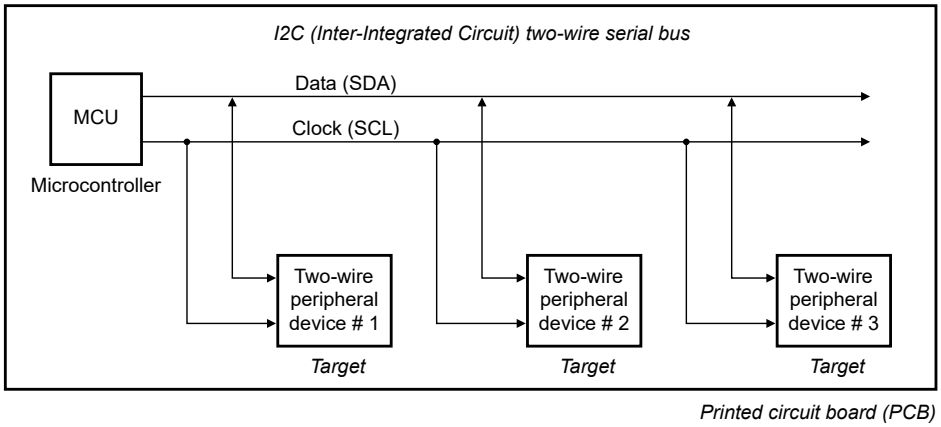

**Figure 363. I²C two-wire serial bus**

Figure 364 shows a possible four-signal connection.

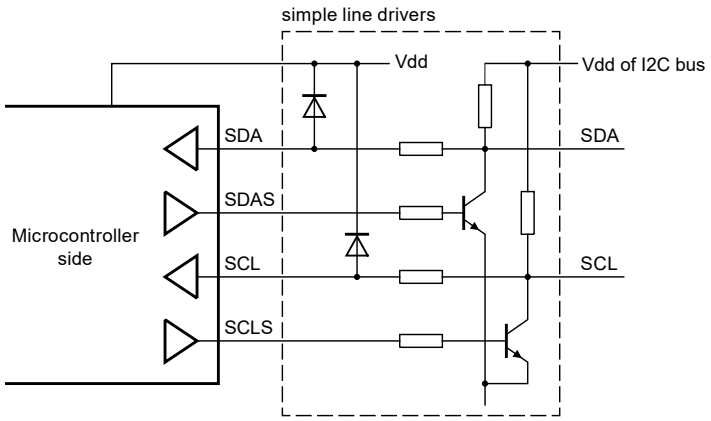

Figure 364. I2C four-wire serial bus

## 68.5 Initialization

To initialize the LPI2C controller:

1. Configure Controller Configuration 0 (MCFGR0)–Controller Configuration 3 (MCFGR3) as required by the application.
2. Configure Controller Clock Configuration 0 (MCCR0) and Controller Clock Configuration 1 (MCCR1) to satisfy the timing requirements of the I2C mode supported by the application.
3. Enable controller interrupts and DMA requests as required by the application.
4. Enable the LPI2C controller by writing 1 to MCR[MEN].

To initialize the LPI2C target:

1. Configure Target Address Match (SAMR) with the I2C address of the target location on the I2C bus.
2. Configure Target Configuration 1 (SCFGR1) as required by the application.
3. Configure Target Configuration 2 (SCFGR2) to satisfy the timing requirements of the I2C mode supported by the application.
4. Enable target interrupts and DMA requests as required by the application.
5. Enable the LPI2C target by writing 1 to SCR[SEN].

## 68.6 Application information

Configure the I2C timing parameters to meet the requirements of the I2C specification. This configuration depends on the supported mode and LPI2C functional clock frequency. When switching between two modes using different clock configuration registers (for example, Fast mode and HS mode), MCFGR1[PRESCALE] must remain constant between the modes.

Table 390. Example timing configurations

| I2C mode | Clock frequency | Baud rate | PRESCALE | FILTSCL / FILTSDA | SETHOLD | CLKLO | CLKHI | DATAVD |
|---|---|---|---|---|---|---|---|---|
| Standard | 8 MHz | 100 kbit/s | 0h | 0h/0h | 24h | 28h | 24h | 02h |
| Standard | 48 MHz | 100 kbit/s | 2h | 1h/1h | 37h | 3Fh | 37h | 03h |
| Standard | 60 MHz | 100 kbit/s | 2h | 1h/1h | 45h | 50h | 44h | 04h |
| Fast | 8 MHz | 400 kbit/s | 0h | 0h/0h | 04h | 0Bh | 05h | 02h |

*Table continues on the next page...*

Table 390. Example timing configurations (continued)

| I2C mode | Clock frequency | Baud rate | PRESCALE | FILTSCL / FILTSDA | SETHOLD | CLKLO | CLKHI | DATAVD |
|---|---|---|---|---|---|---|---|---|
| Fast+ | 8 MHz | 1 Mbit/s | 0h | 0h/0h | 02h | 03h | 01h | 01h |
| Fast | 48 MHz | 400 kbit/s | 0h | 1h/1h | 1Dh | 3Eh | 35h | 0Fh |
| Fast | 48 MHz | 400 kbit/s | 2h | 1h/1h | 07h | 11h | 0Bh | 03h |
| Fast+ | 48 MHz | 1 Mbit/s | 2h | 1h/1h | 03h | 06h | 04h | 04h |
| HS | 48 MHz | 3.2 Mbit/s | 0h | 0h/0h | 07h | 08h | 03h | 01h |
| Fast | 60 MHz | 400 kbit/s | 1h | 2h/2h | 11h | 28h | 1Fh | 08h |
| Fast+ | 60 MHz | 1 Mbit/s | 1h | 2h/2h | 07h | 0Fh | 0Bh | 01h |
| HS | 60 MHz | 3.33 Mbit/s | 1h | 0h/0h | 04h | 04h | 02h | 01h |

## 68.7 Memory map and registers

### 68.7.1 LPI2C register descriptions

Writing to a read-only register or reading from a write-only register can cause bus errors. This module does not check whether programmed values in the registers are correct; you must ensure that valid programmed values are written to the registers.

#### 68.7.1.1 LPI2C memory map

LPI2C_0 base address: 4035_0000h

LPI2C_1 base address: 4035_4000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Version ID (VERID) | 32 | R | 0102_0003h |
| 4h | Parameter (PARAM) | 32 | R | 0000_0202h |
| 10h | Controller Control (MCR) | 32 | RW | 0000_0000h |
| 14h | Controller Status (MSR) | 32 | RW | 0000_0001h |

### 68.7.1.10 Controller Configuration 2 (MCFGR2)

#### Offset

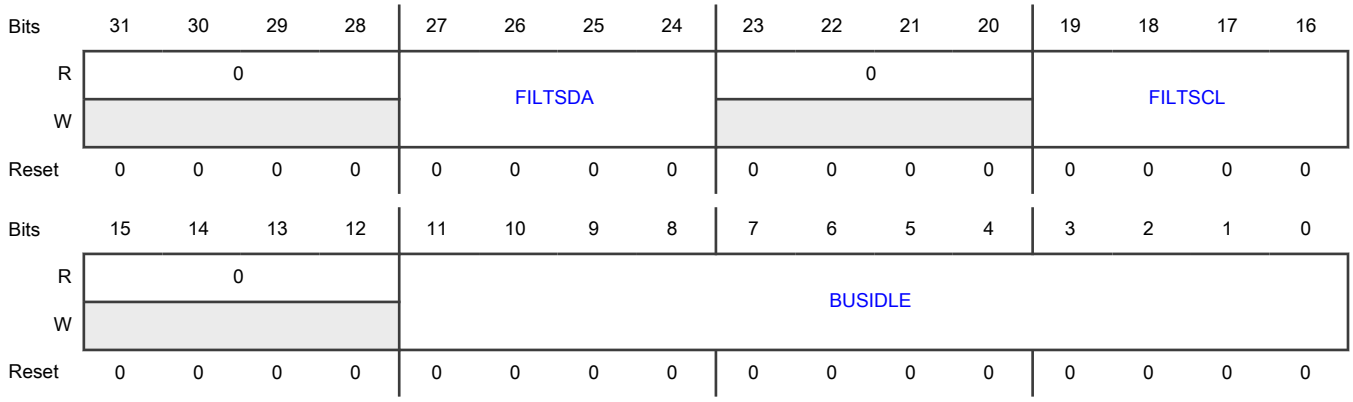
| Register | Offset |
|---|---|
| MCFGR2 | 28h |

#### Function

Contains the configuration for the bus idle timeout and glitch filters for SDA and SCL.

Write to this register only when the I2C controller is disabled.

#### Diagram



**Fields**

| Field | Function |
|---|---|
| 31-28<br>— | Reserved |
| 27-24<br>FILTSDA | Glitch Filter SDA<br>Configures the I2C controller digital glitch filters for the SDA input.<br>The latency through the glitch filter is equal to the number of cycles defined by this field. The value of this field must be less than the minimum SCL low or high period.<br>Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. Writing 0 to this field disables the glitch filter.<br>MCFGR1[PRESCALE] does not affect the glitch filter cycle count. It is automatically bypassed in HS mode. |
| 23-20<br>— | Reserved |
| 19-16<br>FILTSCL | Glitch Filter SCL<br>Configures the I2C controller digital glitch filters for SCL input.<br>The latency through the glitch filter is equal to the number of cycles defined by this field. The value of this field must be less than the minimum SCL low or high period.<br>Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. These cycles are based on the functional clock. Writing 0 to this field disables the glitch filter.<br>MCFGR1[PRESCALE] does not affect the glitch filter cycle count. It is automatically bypassed in HS mode. |
| 15-12<br>— | Reserved |
| 11-0<br>BUSIDLE | Bus Idle Timeout<br>Configures the bus idle timeout period, in clock cycles.<br>If both SCL and SDA are high for longer than the number of cycles defined by this field, the I2C bus is assumed to be idle and the controller can generate a Start condition.<br>Writing 0 to this field disables the bus idle timeout. |

### 68.7.1.11 Controller Configuration 3 (MCFGR3)

**Offset**

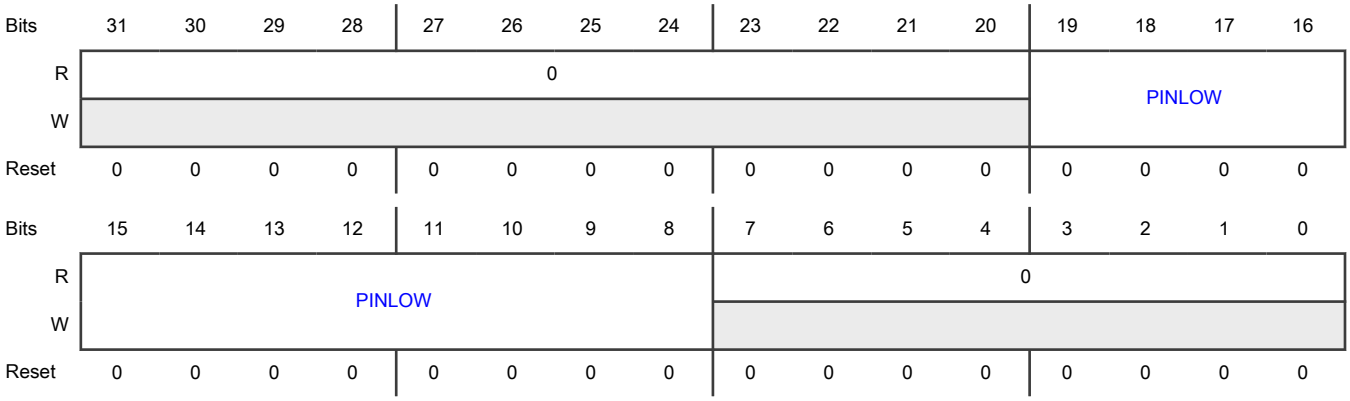
| Register | Offset |
|---|---|
| MCFGR3 | 2Ch |

**Function**

Configures the threshold value for the pin low timeout flag.

Write to this register only when the I2C controller is disabled.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-20<br>— | Reserved |
| 19-8<br>PINLOW | Pin Low Timeout<br>Configures the threshold value, in clock cycles, that sets MSR[PLTF].<br>If SCL or SDA (selected by MCFGR1[TIMECFG]) is low for longer than (PINLOW × 256) cycles, MSR[PLTF] is set.<br>When this field is 0, the pin low timeout feature is disabled. |
| 7-0<br>— | Reserved |

## 68.7.1.12 Controller Data Match (MDMR)

### Offset

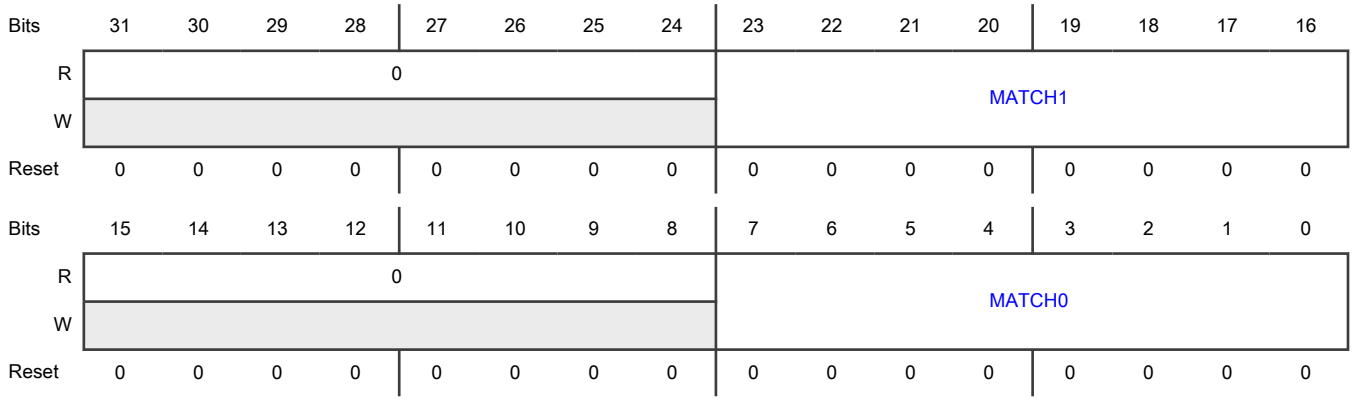
| Register | Offset |
|---|---|
| MDMR | 40h |

### Function

Contains data match values.

Write to this register only when the I2C controller is disabled or idle.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved |
| 23-16<br>MATCH1 | Match 1 Value<br>Specifies match 1 value that is compared to the received data when receive data match is enabled. |
| 15-8<br>— | Reserved |
| 7-0<br>MATCH0 | Match 0 Value<br>Specifies match 0 value that is compared to the received data when receive data match is enabled. |

## 68.7.1.13 Controller Clock Configuration 0 (MCCR0)

### Offset

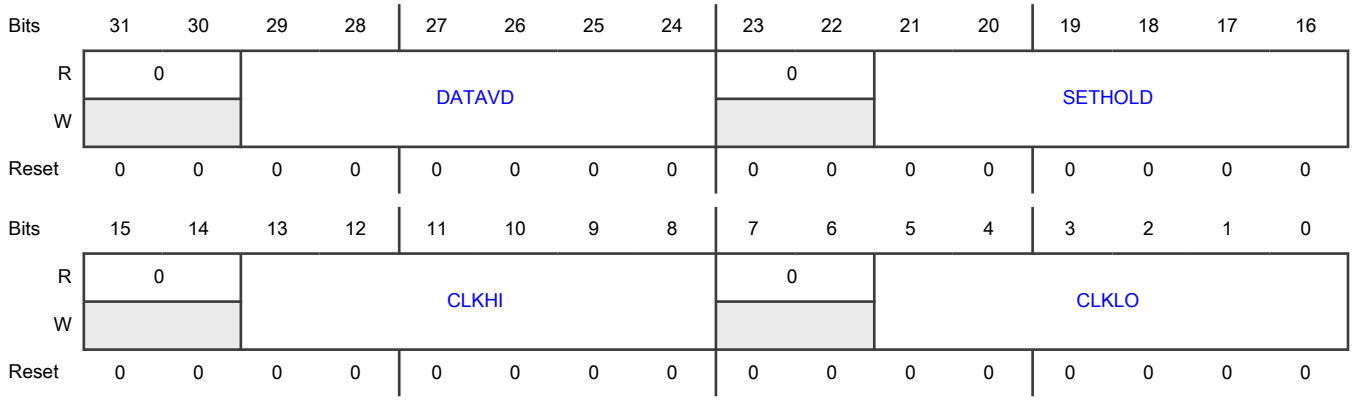
| Register | Offset |
|---|---|
| MCCR0 | 48h |

### Function

Configures various clock controls.

You cannot make changes to this register when the I2C controller is enabled and is used for standard, fast, fast-mode plus, and ultra-fast transfers.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-30<br>— | Reserved |
| 29-24<br>DATAVD | Data Valid Delay<br>Specifies the minimum number of cycles (minus one) used as the data hold time for SDA. This value must be less than the minimum SCL low period. |

| Field | Function |
|---|---|
| 5-0<br>CLKLO | Clock Low Period<br>Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock low. This value is also used for the minimum bus free time between a Stop and a Start condition. This period is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles. |

### 68.7.1.14 Controller Clock Configuration 1 (MCCR1)

#### Offset

| Register | Offset |
|---|---|
| MCCR1 | 50h |

#### Function

Configures various clock controls.

You cannot makes changes to this register when the I2C controller is enabled and is used for HS mode transfers. The separate clock configuration for HS mode allows arbitration to take place in Fast mode (with timing configured by Controller Clock Configuration 0 (MCCR0)), before switching to HS mode (with timing configured by MCCR1).

## 68.7.1.17 Controller Transmit Data (MTDR)

### Offset

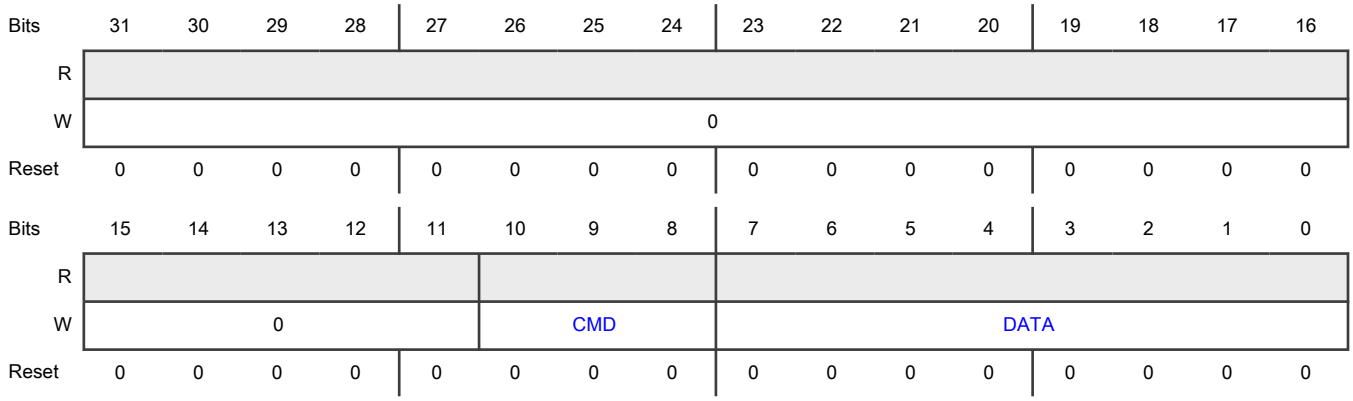
| Register | Offset |
|---|---|
| MTDR | 60h |

### Function

Configures transmit data:

- An 8-bit write to MTDR[CMD] is ignored and does not increment the FIFO write pointer.
- An 8-bit write to MTDR[DATA] zero-extends the value of MTDR[CMD] and increments the FIFO write pointer.
- A 16-bit or 32-bit write operation writes to both MTDR[CMD] and MTDR[DATA] and increments the FIFO write pointer.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-11<br>— | Reserved |
| 10-8<br>CMD | Command Data<br>Selects command transmitted by controller.<br>000b - Transmit the value in DATA[7:0]<br>001b - Receive (DATA[7:0] + 1) bytes. DATA[7:0] is used as a byte counter. Receive that many bytes and check each for a data match (if configured) before storing the received data in the receive FIFO.<br>010b - Generate Stop condition on I2C bus<br>011b - Receive and discard (DATA[7:0] + 1) bytes. DATA[7:0] is used as a byte counter. Receive that many bytes but do not check for a data match or store those bytes in the receive FIFO.<br>100b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0]<br>101b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] (this transfer expects a NACK to be returned)<br>110b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] using HS mode<br>111b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] using HS mode (this transfer expects a NACK to be returned) |
| 7-0<br>DATA | Transmit Data<br>Contains data used by the commands listed in MTDR[CMD]. Performing an 8-bit write to this field zero-extends the value of MTDR[CMD]. |

### 68.7.1.18 Controller Receive Data (MRDR)

#### Offset

| Register | Offset |
|---|---|
| MRDR | 70h |

#### Function

Contains the status of the receive FIFO and the data received by the I2C controller that has not been discarded.

#### Diagram

| 0<br>— | Reserved |

### 68.7.1.26 Target Address Status (SASR)

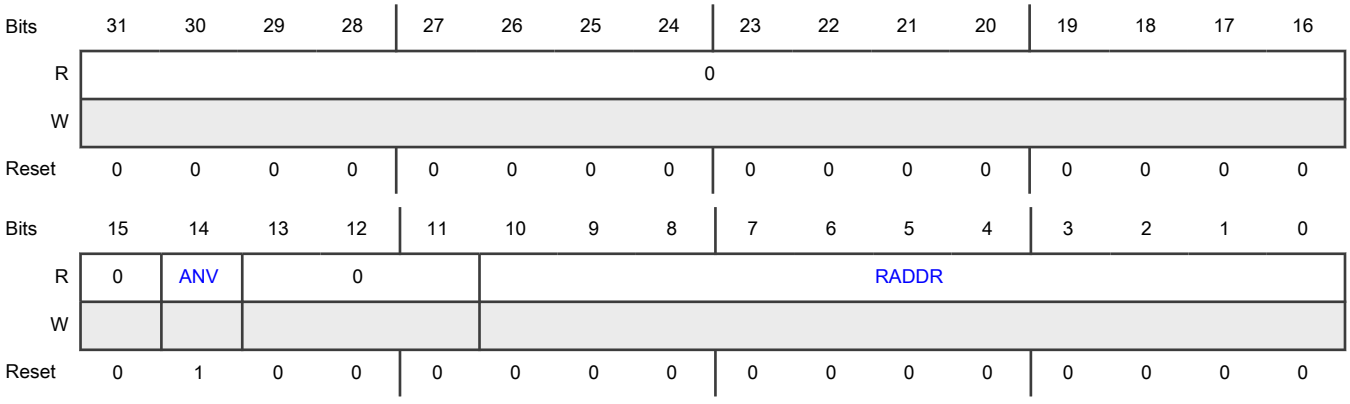
#### Offset

| Register | Offset |
|---|---|
| SASR | 150h |

#### Function

Contains the received address and its validity.

#### Diagram



#### Fields

| Field | Function |
|---|---|
| 31-15 | Reserved |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| — | |
| 14<br>ANV | Address Not Valid<br>Indicates whether SASR[RADDR] is valid.<br>0b - Valid<br>1b - Not valid |
| 13-11<br>— | Reserved |
| 10-0<br>RADDR | Received Address<br>Contains the received address. Updates whenever SSR[AM0F] or SSR[AM1F] is set. Reading Target Address Status (SASR) clears SSR[AM0F] and SSR[AM1F].<br>In 7-bit mode, the address byte is stored in RADDR[7:0].<br>In 10-bit mode, the first address byte is {11110, RADDR[10:9], RADDR[0]} and the second address byte is RADDR[8:1]. The Read-or-Write bit is therefore always stored in RADDR[0].<br>When SCFGR1[ACKSTALL] = 1, if the first address byte matches in 10-bit mode, the first address byte is stored in RADDR[7:0] so you can read this field before writing the Transmit ACK. If the second address byte matches, this field is then updated with the full 10-bit address. |

### 68.7.1.27 Target Transmit ACK (STAR)

#### Offset

| Register | Offset |
|---|---|
| STAR | 154h |

#### Function

Configures choice of ACK or NACK on each received word.

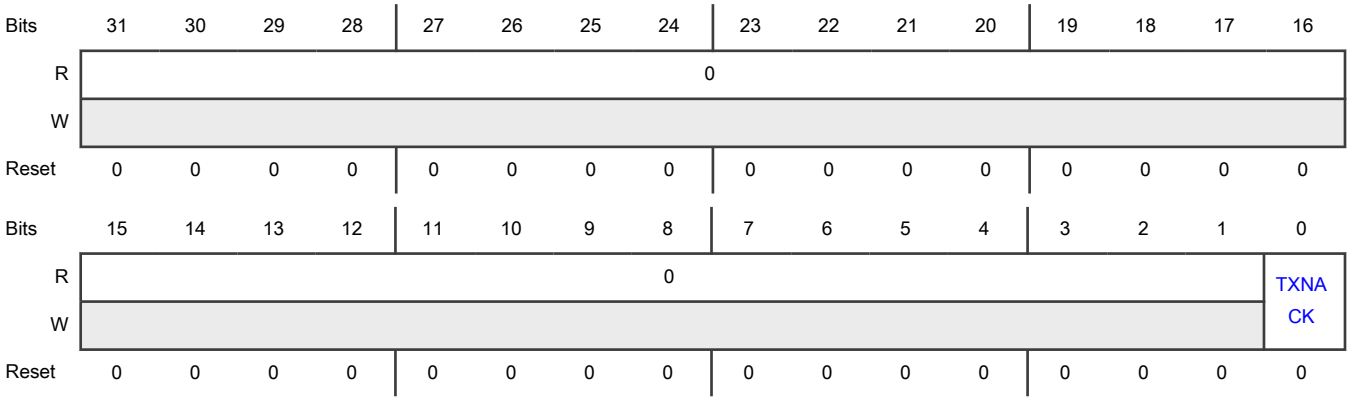
You can write to this register only when SCFGR1[ACKSTALL] = 1.

SCFGR1[ACKSTALL] enables clock stretching during the ACK-or-NACK bit slot. During this time, you can write to this register.

The logic ensures that the clock stretching continues for at least one bus clock cycle after this register is updated.

This clock stretching time can be extended via SCFGR2[CLKHOLD].

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved |
| 0<br>TXNACK | Transmit NACK<br>Selects whether transmit ACK (logic 0) or NACK (logic 1) is returned on the bus by the I2C target after receiving each word.<br>• When SCFGR1[ACKSTALL] = 1, a transmit NACK signal must be written once for each matching address byte and each received word. SCFGR1[ACKSTALL] must be 1, because that setting stalls the data transfer until software reads the received word (and determines whether to respond with an ACK or NACK).<br>• To configure the default (ACK or NACK), you can write to this field when LPI2C target is disabled or idle.<br>0b - Transmit ACK<br>1b - Transmit NACK |

## 68.7.1.28 Target Transmit Data (STDR)

### Offset

| Register | Offset |
|---|---|
| STDR | 160h |

### Function

Contains the I2C target data to transmit.

Clock stretching (enabled or disabled) affects when the transmit data is transferred. SCFGR1[TXDSTALL] enables clock stretching during the first data bit of a target-transmit transfer.

If clock stretching is enabled (SCFGR1[TXDSTALL] = 1), the transmit data transfer is stalled until this register is updated. Clock stretching is extended by at least 1 bus clock cycle after this register is updated. Clock stretching can be delayed further by using SCFGR2[CLKHOLD].

If clock stretching is disabled (SCFGR1[TXDSTALL] = 0), the transmit data must be written before the start of the target-transmit transfer, otherwise SSR[FEF] is set.

### Diagram

# Chapter 69
# Flexible I/O (FlexIO)

## 69.1 Chip-specific FlexIO information

### 69.1.1 FlexIO instances and configuration

The device contains one instance of FlexIO.

FlexIO is a highly configurable module providing a wide range of functionality including:

- Emulation of a variety of serial communication protocols like UART, I2C, SPI, SAI. It can work either as master or slave.
- Flexible 16-bit timers with support for a variety of trigger, reset, enable and disable conditions.

**Table 391. FlexIO instances**

| Chip | Instance | No. of pins | No. of timers | No. of shift registers | No. of bits in counter |
|---|---|---|---|---|---|
| MCXE317/ MCXE31B | FlexIO | 32 | 8 | 8 | 16 |
| MCXE315/ MCXE316 | FlexIO | 16 | 8 | 8 | 16 |

**Table 392. Data rate limitation**

| FlexIO operation | Data rate limitation |
|---|---|
| Master Tx | FlexIO_clk/4 |
| Slave Tx | FlexIO_clk/10 |
| Master Rx | FlexIO_clk/8 |
| Slave Rx | FlexIO_clk/6 |

**NOTE**

FlexIO supports 32 bit accesses only.

**NOTE**

When I2S is emulated on FlexIO, you could observe a skew between bit-clock (BCLK) and frame sync pulse amounting to 1/2 of BCLK.

**Table 393. FlexIO configuration**

| No. of pins | No. of timers | No. of shift registers | No. of bits in counter |
|---|---|---|---|
| 32 | 8 | 8 | 16 |

## 69.2 Overview

FLEXIO is a highly configurable module that provides:

- Emulation of various serial or parallel communication protocols.
- Flexible 16-bit timers with support for various trigger, reset, enable, and disable conditions.

- Programmable logic blocks that allow the implementation of digital logic functions on-chip and configurable interaction of internal and external modules.
- Programmable state machine for offloading basic system control functions from the CPU.

### 69.2.1 Block diagram

The following diagram provides a high-level overview of the FLEXIO timer and shifter configuration.

FLEXIO uses shifters, timers, and external triggers to shift data into or out of FLEXIO. As shown in the block diagram, timers control the timing of this data shift. You can configure the timers to use generic timer functions, external triggers, or various other conditions to determine the control.

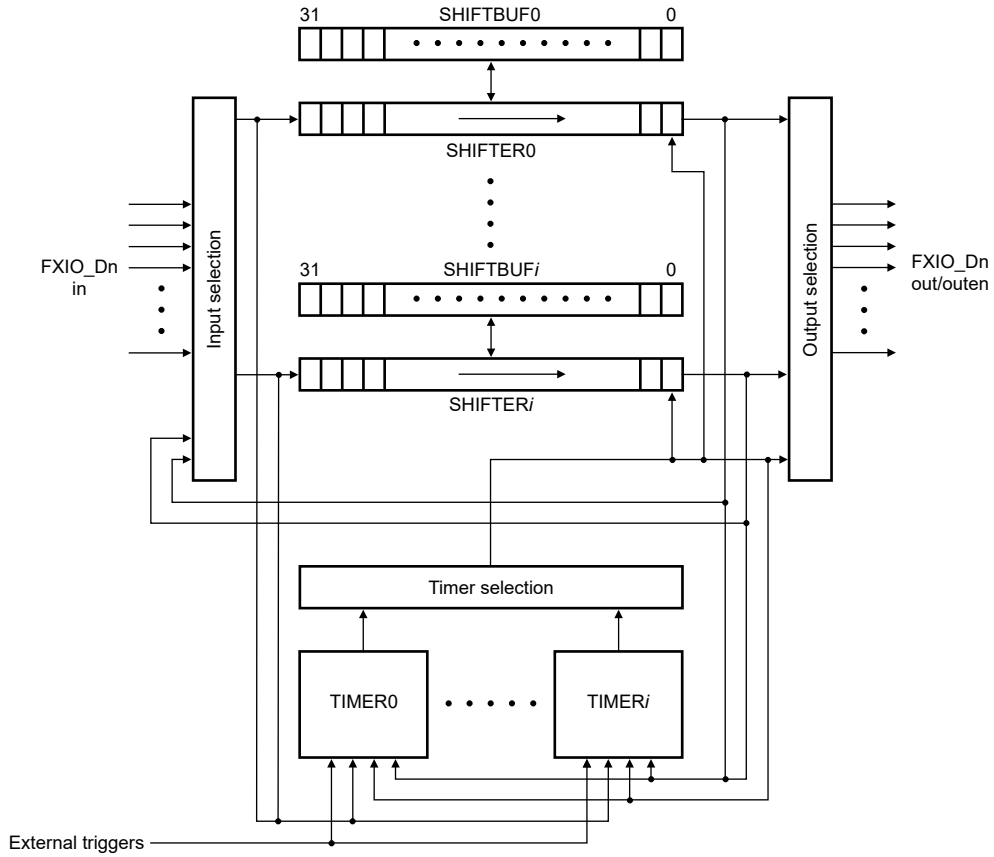

Figure 365. Block diagram

### 69.2.2 Features

- Array of 32-bit shift registers with transmit, receive, data match, logic, and state modes:
  - Double-buffered shifter operation for continuous data transfer
  - Shifter concatenation to support large transfer sizes
  - Automatic start and stop bit generation
  - 1, 2, 4, 8, 16, or 32 multi-bit shift widths for parallel interface support
  - Interrupt, DMA, or polled transmit and receive operation
- Highly flexible 16-bit timers with support for various internal or external triggers, reset, enable, and disable conditions:
  - Programmable baud rates independent of bus clock frequency

— Programmable logic mode for integrating external digital logic functions on-chip, or combining pin, shifter, or timer functions to generate complex outputs

— Programmable state machine for offloading basic system control functions from CPU, with support for up to eight states, eight outputs, and three selectable inputs per state

- Integrated general-purpose I/O registers and pin rising or falling edge interrupts to simplify software support
- Support for a wide range of protocols, including but not limited to:
  — UART
  — I2C
  — SPI
  — I2S
  — Camera IF
  — Motorola 68K or Intel 8080 bus
  — PWM or waveform generation
  — Input-capture (pulse-edge interval measurement), such as SENT

## 69.3 Functional description

### 69.3.1 Shifter operation

Shifters are responsible for buffering and shifting data into or out of FLEXIO. The timer assigned to the shifter controls the timing of shift, load, and store events via SHIFTCTL*n*[TIMSEL]. Shifters are designed to support either DMA, interrupt, or polled operations. The following figure provides a detailed view of the shifter microarchitecture.

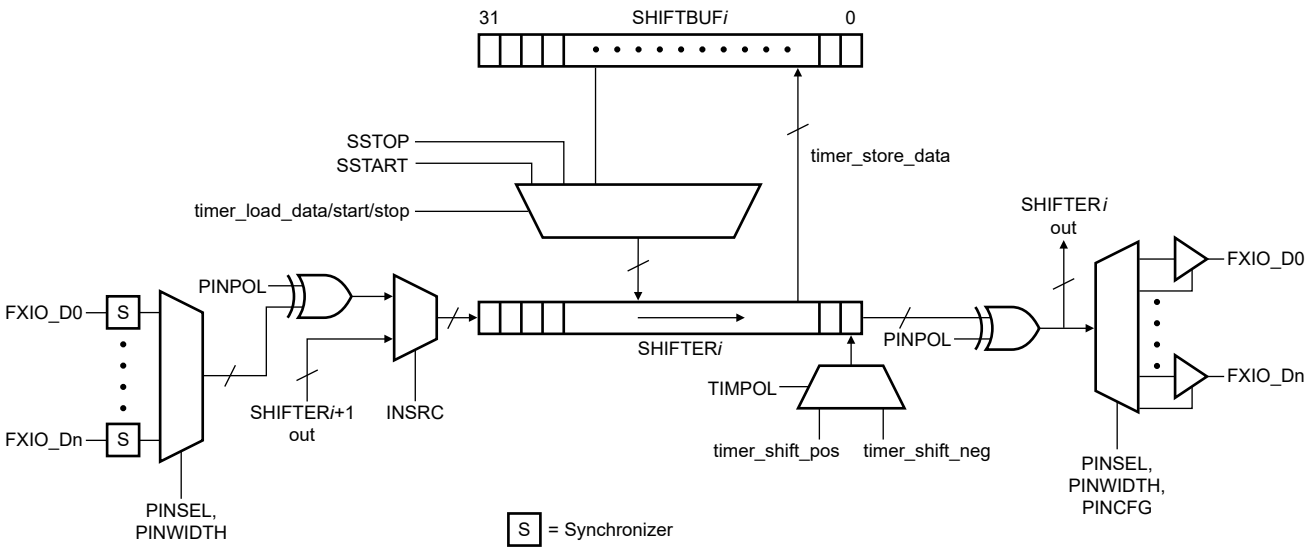

**Figure 366. Shifter microarchitecture**

#### 69.3.1.1 Transmit mode

In Transmit mode (SHIFTCTL*n*[SMOD] = 010b), the shifter loads data from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) and shifts data out when the assigned timer signals a load event. An optional start and stop bit can be automatically loaded before or after SHIFTBUF register data by configuring either SHIFTCFG[SSTART] and TIMCFG[TSTART], or SHIFTCFG[SSTOP] and TIMCFG[TSTOP] in the shifter and timer.

**NOTE**

If a stop bit is enabled, the shifter immediately loads a stop bit when it is initially configured for Transmit mode.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has either been loaded from the SHIFTBUF register into the shifter or when the shifter is initially configured for Transmit mode. To clear the flag, write 1 or write new data to SHIFTBUF. In Transmit mode, write any value to the SHIFTBUF register to clear the corresponding shifter status flag, which is cleared regardless of what is writing to the register (DMA or interrupt), or the state of the DMA or interrupt enables. See the functional description of SHIFTSTAT[SSF] for information on how the flag is set and cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). Clear the flag by writing 1.

#### 69.3.1.2 Receive mode

When the assigned timer signals a store event in Receive mode (SHIFTCTL*n*[SMOD] = 001b), the shifter shifts and stores data in Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). You can check for a start and stop bit before or after the shifter data is sampled by configuring either SHIFTCFG[SSTART] and TIMCFG[TSTART], or SHIFTCFG[SSTOP] and TIMCFG[TSTOP] in the shifter and timer.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data is stored in the SHIFTBUF register from the shifter. To clear the flag, write 1 to or read the data from SHIFTBUF. Any read of the SHIFTBUF register clears the corresponding shifter status flag when the shifter is in Receive mode. The flag is cleared regardless of what is reading the register (DMA or interrupt) or the state of the DMA or interrupt enables. See the functional description of SHIFTSTAT[SSF] for information on how the flag is set or cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set either when an attempt to store data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start or stop bit check. Write 1 to clear the flag.

#### 69.3.1.3 Match Store mode

In Match Store mode (SHIFTCTL*n*[SMOD] = 100b), the shifter shifts data in, checks for a match result, and stores matched data in Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) when the assigned timer signals a store event. By configuring either SHIFTCFG[SSTART], TIMCFG[TSTART], and SHIFTCFG[SSTOP], or TIMCFG[TSTOP] in the shifter and timer, you can check for a start and stop bit before or after the shifter data is sampled. You can compare up to 16 bits of data using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs and the matched data is stored in the SHIFTBUF register from the shifter. To clear the flag, read the matched data from the SHIFTBUF register or write 1 to the flag. Any read of the SHIFTBUF register clears the corresponding shifter status flag when the shifter is configured in Match Store mode. The flag is cleared regardless of what is reading the register (DMA or interrupt) or the state of the DMA or interrupt enables. See the functional description for SHIFTSTAT[SSF] to know how the flag is set or cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun), or when a mismatch occurs on a start or stop bit check. Write 1 to clear the flag.

#### 69.3.1.4 Match Continuous mode

In Match Continuous mode (SHIFTCTL*n*[SMOD] = 101b), the shifter shifts data in and continuously checks for a match result whenever a shift event is signaled by the assigned timer. You can compare up to 16 bits of data using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs. The flag clears automatically as soon as no match exists between the shifter data and Shifter Buffer (SHIFTBUF0 - SHIFTBUF7).

You cannot clear the flag by reading the SHIFTBUF register.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when a match occurs. To clear the flag, write 1 or perform a read from the SHIFTBUF register.

### 69.3.1.5 State mode

State mode enables you to implement any state machine with up to eight states, eight outputs, and three selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU.

In State mode (SHIFTCTL*n*[SMOD] = 110b), when the shifter is selected by the current state pointer (SHIFTSTATE[STATE]), use the SHIFTBUF register to drive the output and compute the next state values. The following figure provides a detailed view of the shifter microarchitecture when configured for State mode.

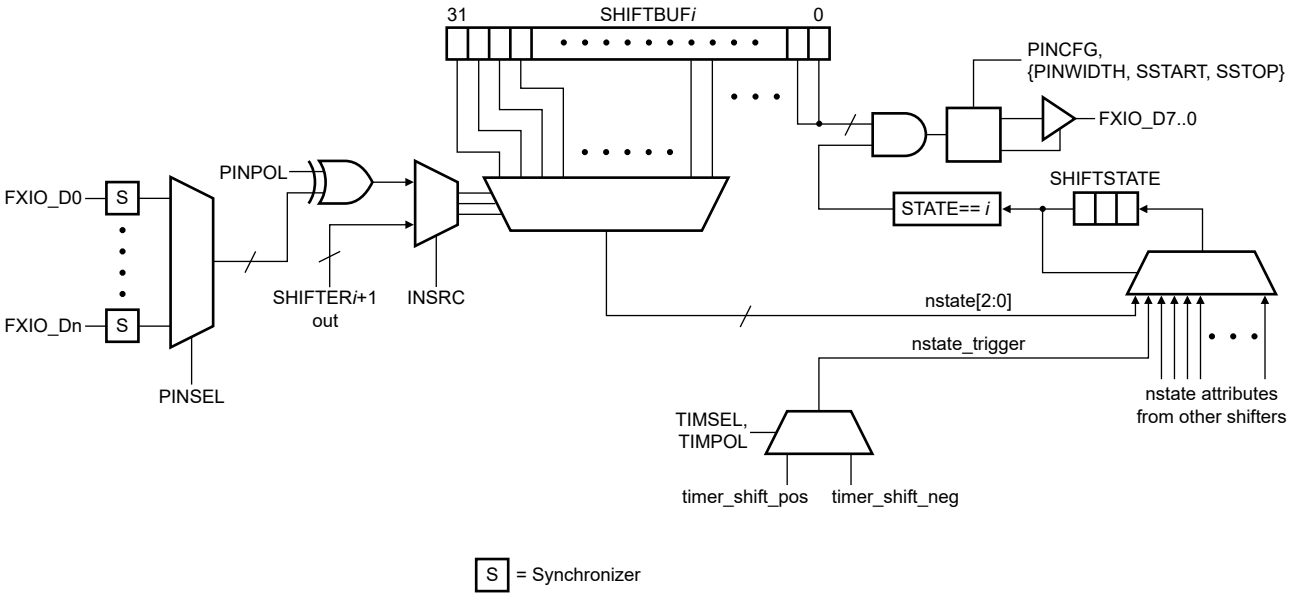

Figure 367. State microarchitecture

When the current state pointer selects a specific shifter (shifter *n*), output pins FXIO_D[7:0] are driven by SHIFTBUF*n*[31:24]; the configuration is defined by SHIFTCTL*n*[PINCFG]. Write 1 to Shifter Configuration (SHIFTCFG0 - SHIFTCFG7) {PWIDTH[3:0],SSTOP[1:0],SSTART[1:0]} to disable the output drive on pins FXIO_D[7:0] for state machine applications that require less than eight output pins.

Use the three input pins selected by SHIFTCTL*n*[PINSEL] and SHIFTBUF*n*[23:0] to compute the next state value.

**NOTE**

Each state can use a different set of three input pins.

The following table shows how the next state value is computed when the current state pointer is pointing to shifter *n*.

Table 394. Next state computation for SHIFTSTATE[STATE] = *n*

| FXIO_D[PINSEL + 2] | FXIO_D[PINSEL + 1] | FXIO_D[PINSEL] | Next state value |
|---|---|---|---|
| 0 | 0 | 0 | SHIFTBUF*n*[2:0] |
| 0 | 0 | 1 | SHIFTBUF*n*[5:3] |
| 0 | 1 | 0 | SHIFTBUF*n*[8:6] |
| 0 | 1 | 1 | SHIFTBUF*n*[11:9] |
| ... | ... | ... | ... |
| 1 | 1 | 1 | SHIFTBUF*n*[23:21] |

**NOTE**

You can configure other shifters and timers to drive the input pins of a given state, allowing you to create complex combinations of shifters and timers as needed. For example, the output of a shifter configured for Logic mode can be used to drive a state machine input.

The next state transition is triggered using the timer output selected by SHIFTCTL*n*[TIMSEL], with polarity controlled by SHIFTCTL*n*[TIMPOL].

**NOTE**

Each state can use a different timer to trigger each next state transition, allowing various internal or external trigger sources and clocking configurations to be used. See Timer section for more information.

The current state pointer defaults to shifter 0 at reset; however, you can write to select a different shifter for the initial state. If the current state pointer selects a shifter that is not configured for State mode, then outputs are not driven and the next state transition is never triggered.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when the shifter is selected by the current state pointer. The flag is cleared when the current state pointer is updated to a different shifter.

### 69.3.1.6 Logic mode

Logic mode enables you to implement a small amount of programmable digital logic within a FLEXIO shifter.

In Logic mode (SHIFTCTL*n*[SMOD] = 111b), use Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) to implement a 5-input, 32-bit programmable logic lookup table. The following figure provides a detailed view of shifter microarchitecture when configured for Logic mode.

Use the SHIFTBUF register to configure the lookup table for the four pin inputs. You can also use SHIFTER*n* to configure a feedback or delayed pin source as the fifth input to the lookup table.

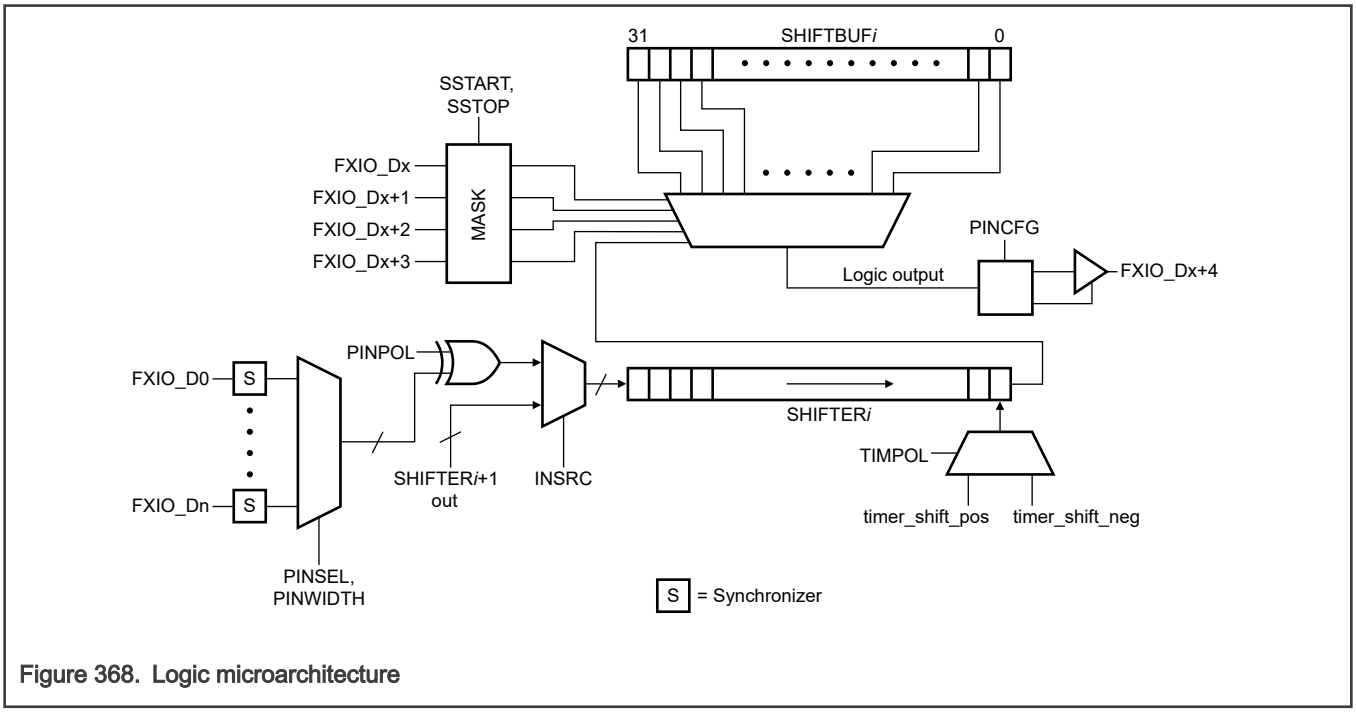

**Figure 368. Logic microarchitecture**

The lookup table is driven using four pin inputs (maskable using SHIFTCFG[SSTOP] and SHIFTCFG[SSTART]), plus one input from the internal shifter. It can be configured to drive an output pin using SHIFTCTL[PINCFG]. Pin inputs and outputs are fixed for each logic lookup table and are not selectable. The following table lists the logic output value selected by the lookup table for shifter *n*.

Table 395. Logic lookup table for shifter *n*

| SHIFTER*n*[0] | FXIO_D[*x* + 3][1] | FXIO_D[*x* + 2] | FXIO_D[*x* + 1] | FXIO_D[*x*] | Logic output to FXIO_D[*x* + 4] |
|---|---|---|---|---|---|
| 0 | 0 | 0 | 0 | 0 | SHIFTBUF*n*[0] |
| 0 | 0 | 0 | 0 | 1 | SHIFTBUF*n*[1] |
| 0 | 0 | 0 | 1 | 0 | SHIFTBUF*n*[2] |
| 0 | 0 | 0 | 1 | 1 | SHIFTBUF*n*[3] |
| ... | ... | ... | ... | ... | ... |
| 1 | 1 | 1 | 1 | 1 | SHIFTBUF*n*[31] |

1. for shifters *n* = 0...3, *x* = *n*

   for shifter *n* = 4...7, *x* = *n* + 4

To minimize output glitches, use SHIFTCFG*n*[SSTOP] and SHIFTCFG*n*[SSTART] to mask unused input pins. When these fields are 1, {SSTOP[1:0] and SSTART[1:0]} mask FXIO_D[*x* + 3]...FXIO_D[*x*] inputs respectively so that any transitions on these pins do not cause the logic output to glitch.

**NOTE**

You can configure other shifters and timers to drive the input pins of a given lookup table, allowing you to concatenate lookup tables or create complex combinations of shifters and timers as needed.

SHIFTCFG[PWIDTH] controls the number of delay stages introduced by the internal shifter input (SHIFTER*n*[0]). For example, when configured for a 1-bit shift (SHIFTCFG[PWIDTH] = 0), the internal shifter introduces a 32-shift clock delay before passing its input (selected by SHIFTCTL[PINSEL]) to the lookup table. When configured for a 32-bit shift (SHIFTCFG[PWIDTH] = 16...31), the internal shifter introduces a 1-shift clock delay to its input.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set whenever the output pin allocated to the logic lookup table has a value of 1 after being synchronized with the FLEXIO clock. The flag clears when the output pin has a value of 0. This also allows SHIFTSTAT[SSF] to be used as a trigger to a timer if needed.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when the output pin allocated to the logic lookup table is asserted. Clear the flag by writing 1 to it.

The Logic mode input pins, including pins driven by other shifters and timers, are synchronized with the FLEXIO functional clock before they are input to the programmable logic lookup table.

### 69.3.2 Timer operation

The FLEXIO 16-bit timers control the loading, shifting, and storing of the shift registers. The counters load the contents of the compare register and decrement down to zero on the FLEXIO clock. The counters can perform generic timer functions such as generating a clock, select output, or a PWM waveform. You can configure these timers to perform any of the following functions:

- Enable in response to a trigger, pin, or shifter condition.
- Decrement always or only on a trigger or pin edge.
- Reset in response to a trigger or pin condition.
- Disable on a trigger or pin condition or on a timer compare.

Timers can optionally include a start condition and a stop condition.

Although each timer operates independently, you can configure a timer to enable or disable at the same time as the previous timer (for example, timer 1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently as a timer output, shifter status flag, pin input, or an external trigger

input. The trigger configuration is separate from pin configuration; you can perform it to configure input, output data, or output enable. See the chip-specific FLEXIO information for information on external trigger connections.

You must configure Timer Configuration (TIMCFG0 - TIMCFG7) before writing 1 to TIMCTL*n*[TIMOD].

#### 69.3.2.1 Timer 8-bit Baud Counter mode

In 8-bit Baud Counter mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the baud rate of the shift clock and the upper 8 bits are used to configure the number of shift clock edges in the transfer. When the lower 8 bits decrement to zero, the timer output is toggled and the lower 8 bits reload from the compare register. The upper 8 bits decrement when the lower 8 bits become zero and decrement.

**NOTE**

A timer reset event in 8-bit Baud Counter mode only resets the lower 8-bit counter. The upper 8-bit counter is not affected and can decrement if the timer reset is configured to update the state of the timer output, which toggles as a result of the timer reset event.

A timer compare event occurs when the upper 8 bits equal zero and decrement. The timer status flag is set on a timer compare event.

#### 69.3.2.2 Timer 8-bit High PWM mode

In 8-bit High PWM mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the timer output high period and the upper 8 bits are used to configure the timer output low period. The lower 8 bits decrement when the output is high. When the lower 8 bits become zero and decrement, the timer output is cleared and the lower 8 bits are reloaded from the compare register. The upper 8 bits decrement when the output is low. When the upper 8 bits become zero and decrement, the timer output is set and the upper 8 bits are reloaded from the compare register.

A timer compare event occurs when the upper 8 bits become zero and decrement. The timer status flag is set on a timer compare event.

#### 69.3.2.3 Timer 16-bit Counter mode

In 16-bit Counter mode, you can use the 16-bit counter to configure either the baud rate of the shift clock (for example, TIMDEC[1:0] ≠ 10 or 11) or the number of shift clock edges in the transfer (for example, TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.

#### 69.3.2.4 Timer 16-bit Counter Disable mode

In 16-bit Counter Disable mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (for example, TIMDEC[1:0] ≠ 10 or 11) or the number of shift clock edges in the transfer (for example, TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer disable event.

#### 69.3.2.5 Timer 8-bit Word Counter mode

In 8-bit Word Counter mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the number of shift clock edges in each word and the upper 8 bits are used to configure the number of words in the transfer. When the lower 8 bits decrement to zero, the timer output is toggled and the lower 8 bits reload from the compare register. The upper 8 bits only decrement when the lower 8 bits become zero and decrement.

A timer compare event occurs when the lower 8 bits become zero and decrement. The timer status flag is set when the upper 8 bits become zero and decrement.

#### 69.3.2.6 Timer 8-bit Low PWM mode

In 8-bit Low PWM mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the timer output low period and the upper 8 bits are used to configure the timer output high period. The lower 8 bits decrement when the output is low. When the lower 8 bits become zero and decrement, the timer output is set and the lower 8 bits are reloaded from the compare register. The upper 8 bits decrement when the output is high. When the upper 8 bits become zero and decrement, the timer output is cleared and the upper 8 bits are reloaded from the compare register.

A timer compare event occurs when the upper 8 bits become zero and decrement. The timer status flag is set on a timer compare event.

#### 69.3.2.7 Timer enable and start functions

The following events occur when you configure TIMCTL*n*[TIMOD] for the desired mode and the condition configured by the timer enable (TIMCFG*n*[TIMENA]) is detected. When TIMCTL*n*[ONETIM] is 1, the timer status flag must be clear to generate a timer enable event; otherwise, the timer enable event is blocked. You can use this to enforce software intervention after each timer iteration:

- The timer counter loads the current value of the compare register and starts decrementing, as configured by TIMCFG*n*[TIMDEC].
- The timer output may update to its initial state depending on the configuration of TIMCFG*n*[TIMOUT]. Shifters that are controlled by this timer do not see this as a rising edge on the timer shift clock.
- Transmit shifters controlled by this timer either output their start bit value or load the shift register from the shift buffer and output the first bit, as configured by SHIFTCFG*n*[SSTART].

If the timer start bit is enabled, the timer counter reloads with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMCFG*n*[TIMOUT] = 1), a shifter that is configured to shift on the falling edge and load on the first shift does not load correctly.

#### 69.3.2.8 Timer decrement and reset functions

The timer generates the timer output and timer shift clock depending on the fields, TIMCTL*n*[TIMOD] and TIMCFG*n*[TIMDEC]. The shifter clock is either equal to the timer output (when TIMCFG*n*[TIMDEC] ≠ 10 or 11) or equal to the decrement clock (when TIMCFG*n*[TIMDEC] = 10 or 11). If you configure TIMCFG*n*[TIMDEC] to decrement from a pin or trigger, the timer decrements on both rising and falling edges.

If a timer is configured to decrement on the FLEXIO functional clock divided by 16 or 256 (when TIMCFG*n*[TIMDEC] = 100 or 101), then a common prescaler that is shared by all timers is used to generate the two divide ratios. This prescaler is reset when all timers are either idle or configured not to use the prescaler (TIMCFG*n*[TIMDEC] ≠ 100 or 101).

If you configure the timer to reset as determined by TIMCFG*n*[TIMRST], then the timer counter loads the current value of the compare register again. You can configure the timer output and timer shift clock to update on timer reset, as configured by TIMCFG*n*[TIMOUT]. If the time output toggles as a result of the timer reset, this can result in a timer shift clock edge. In 8-bit Baud Counter mode, this also decrements the upper 8 bits of the counter.

In general, when the timer counter decrements to zero, a timer compare event is triggered. The timer compare event causes:

- The timer counter to load the contents of the timer compare register.
- The timer output to toggle.
- Any configured transmit shift registers to load.
- Any configured receive shift registers to store.

Depending on the timer mode, the timer status flag may also be set.

#### 69.3.2.9 Timer disable and stop functions

When the timer is configured to add a stop bit on each compare, the following additional events occur:

- Transmit shifters controlled by this timer output their stop bit value (if configured by SHIFTCFG*n*[SSTOP]).

- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SHIFTCFG*n*[SSTOP].
- The timer counter reloads the current value of the compare register on the first rising edge of the shifter clock after the compare.

If you configure the timer to insert a stop bit on each compare, you must configure the transmit shifters to load on the first shift.

When the condition configured by timer disable (TIMCFG*n*[TIMDIS]) is detected, the following events occur:

- Timer counter reloads the current value of the compare register and starts decrementing as configured by TIMCFG*n*[TIMDEC].
- Timer output clears. Shifters that are controlled by this timer do not see this as a falling edge on the timer shift clock, but can generate a shift event if the timer shift clock otherwise generates one.
- Transmit shifters controlled by this timer output their stop bit value (if configured by SHIFTCFG*n*[SSTOP]).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SHIFTCFG*n*[SSTOP].

If the timer stop bit is enabled, the timer counter continues decrementing until the next rising edge of the shift clock is detected, at which point it finishes decrementing. Although the timer output is forced low during the stop bit, the timer shift clock can toggle during the stop bit. The timer output does not generate shift events during the stop bit.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). When TIMCTL*n*[ONETIM] is 1, the timer status flag must be clear before the next timer enable condition is detected. When the timer is in the stop state condition, receive shift registers with stop bit enabled store the contents of the shift register into the shift buffer and verify the state of the input data on the configured shift edge. If there is no configured edge between the timer disable and the next rising edge of the shift clock, then the final store and verify do not occur.

### 69.3.3 Pin operation

The pin configuration for each timer and shifter can be set to use any FLEXIO pin with either polarity. You can configure each timer and shifter as an input, output data, output enable, or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity because the output enable assertion causes logic zero to be output on the pin) or to control the enable on the bidirectional output. You can configure any timer or shifter to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

When more than one shifter or timer is configured to use the same pin for output data, then the output data to the pin is combined using an OR function. This also applies if more than one timer or shifter is configured to use the same pin for output enable.

#### 69.3.3.1 Parallel interface

You can configure shifters to use multiple FLEXIO pins simultaneously by using SHIFTCFG*n*[PWIDTH], which is used to configure the following settings of a shifter:

1. Number of bits shifted per shift clock.
2. Number of pins driven by the shifter per shift clock (only on shifters supporting parallel transmit—that is, SHIFTER0 and SHIFTER4.)
3. Number of pins sampled by the shifter per shift clock (only on shifters supporting parallel receive—that is, SHIFTER3 and SHIFTER7.)

When configured for parallel shift, either 4, 8, 16, or 32 bits can be shifted on every shift clock. If an adjacent shifter is selected as the input source (SHIFTCFG*n*[INSRC] = 1), the least significant 4, 8, 16, or 32 bits from the adjacent shifter are sampled on each shift clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), you can configure the shifter to sample multiple pins (INSRC = 0), with PWIDTH and PINSEL selecting the pins as FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].

**NOTE**

If PWIDTH is less than the number of bits being shifted on each shift clock, then the most significant bits are masked with 0. For example, if PINSEL = 7 and PWIDTH = 6, then SHIFTER[31:24] samples {0,0,FXIO_D[12:7]} on each shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), you can configure the shifter to drive multiple pins using SHIFTCTL*n*[PINCFG], with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].

**NOTE**

If PWIDTH is less than the number of bits being shifted on each shift clock, then the most significant pins are not driven. For example, if PINSEL = 7 and PWIDTH = 6, then SHIFTER[5:0] drives only FXIO_D[12:7] on each shift clock.

#### 69.3.3.2 Pin synchronization

When you configure a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized with the FLEXIO clock before a timer or shifter could use the signal. This introduces a small latency of 0.5–1.5 FLEXIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FLEXIO clock cycles.

If an input is used by more than one timer or shifter, then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

**NOTE**

FLEXIO pins are also connected internally. Configuring a FLEXIO shifter or timer to output data on an unused pin makes an internal connection that allows other shifters and timers to use this pin as an input. This allows a shifter output to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized with the FLEXIO clock and therefore incurs a one-cycle latency.

When using a pin input as a timer trigger, timer clock, or shifter data input, the following synchronization delays occur:

- 0.5–1.5 FLEXIO clock cycles for an external pin
- One FLEXIO clock cycle for an internally driven pin

See Application information for timing considerations such as output valid time and input setup time for specific applications (SPI controller, SPI target, I2C controller, I2S controller, and I2S target).

#### 69.3.3.3 Pin override

You can change the state of any FLEXIO pin at any time. Pin Output Enable (PINOUTE) configures any pin as an output and drives that pin with the value in Pin Output Data (PINOUTD).

Alias registers for PINOUTE and data registers also exist. Writing a logic 1 to an alias register updates the corresponding register fields in both PINOUTE and PINOUTD as follows:

- Pin Output Disable (PINOUTDIS) clears Pin Output Enable (PINOUTE) and Pin Output Data (PINOUTD).
- Pin Output Clear (PINOUTCLR) sets Pin Output Enable (PINOUTE) and clears Pin Output Data (PINOUTD).
- Pin Output Set (PINOUTSET) sets Pin Output Enable (PINOUTE) and Pin Output Data (PINOUTD).
- Pin Output Toggle (PINOUTTOG) sets Pin Output Enable (PINOUTE) and toggles Pin Output Data (PINOUTD).

#### 69.3.3.4 Pin interrupt

You can read the state of any FLEXIO pin at any time and also configure any pin to set a status flag when either a rising or falling edge is detected on that pin. Additionally, you can configure the pin status flag to generate an interrupt.

### 69.3.4 Low-power modes

FLEXIO remains functional during low-power modes, if the FLEXIO functional clock remains enabled.

### 69.3.5 Debug mode

FLEXIO remains functional in Debug mode, provided the value of CTRL[DBGE] is 1.

### 69.3.6 Clocking

**Table 396. FLEXIO clocks**

| Clock | Description |
|---|---|
| Functional clock | Is asynchronous to the bus clock and can remain enabled in low-power modes. You must enable the FLEXIO functional clock before accessing any of the FLEXIO registers. Provided the FLEXIO functional clock is at least equal to the bus clock, you can configure CTRL[FASTACC] to support fast register accesses. |
| Bus clock | Is used only for bus accesses to the control and configuration registers. |

### 69.3.7 Reset

**Table 397. FLEXIO reset types**

| Reset | Description |
|---|---|
| Chip reset | Resets the FLEXIO logic and registers to their default states on chip reset. |
| Software reset | Resets, using CTRL[SWRST], all logic and registers to their default states, except for the Control register. |

### 69.3.8 Interrupts and DMA requests

The following table shows the status flags that generate the FLEXIO interrupt and DMA requests.

**Table 398. FLEXIO interrupts and DMA requests**

| Flag | Description | Interrupt | DMA request | Low-power wake-up |
|---|---|---|---|---|
| SHIFTSTAT[SSF] | Shifter status flag | Y | Y | Y |
| SHIFTERR[SEF] | Shifter error flag | Y | N | Y |
| TIMSTAT[TSF] | Timer status flag | Y | Y | Y |
| PINSTAT[PSF] | Pin status flag | Y | N | Y |
| TRGSTAT[ETSF] | External trigger status flag | Y | N | Y |

### 69.3.9 Peripheral triggers

The connection between FLEXIO peripheral triggers and other peripherals is device-specific.

#### 69.3.9.1 Output triggers

Each FLEXIO timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.

#### 69.3.9.2 Input trigger

FLEXIO supports multiple external trigger inputs that can be used to trigger one or more FLEXIO timers. If a rising edge is detected on an external trigger when FLEXIO is enabled, then the external trigger status flag is set. The external triggers are synchronized to the FLEXIO functional clock and must assert for at least two cycles of the FLEXIO functional clock to be sampled correctly.

## 69.4 External signals

**Table 399. External signals**

| Signal | Description | Direction |
|---|---|---|
| FXIO_D*n* (*n* = 0...31) | Bidirectional FLEXIO shifter and timer pin | Input or output |

## 69.5 Initialization

Perform the following procedure to initialize FLEXIO registers:

1. Enable FLEXIO by writing 1 to CTRL[FLEXEN].
2. Configure shift registers for the given application. It is recommended to write to Shifter Configuration (SHIFTCFG0 - SHIFTCFG7) before writing to the corresponding register, Shifter Control (SHIFTCTL0 - SHIFTCTL7).
3. Configure timer registers for the given application. It is recommended to write to Timer Compare (TIMCMP0 - TIMCMP7) and Timer Configuration (TIMCFG0 - TIMCFG7) before writing to the corresponding register, Timer Control (TIMCTL0 - TIMCTL7).
4. Enable interrupts and/or DMA requests, as appropriate, for the given application.
5. Write transmit data to initiate a transfer (depending on the given application).

## 69.6 Application information

This section provides examples for a variety of FLEXIO module applications. See FLEXIO register descriptions for more information.

### 69.6.1 UART transmit

UART transmit can be supported using one timer, one shifter, and one pin (two pins, if supporting CTS). The start and stop bit insertion is handled automatically, and multiple transfers are supported using the DMA controller. The timer status flag is used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention. Before transmitting a break or idle character, you must modify SHIFTCFG*n*[SSTART] and SHIFTCFG*n*[SSTOP] to transmit the required state, and the data to transmit must equal FFh or 00h. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). When performing byte writes to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) (or Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) for transmitting MSB first), the rest of the register remains unaltered. This allows an address mark bit or additional stop bit to remain undisturbed.

**NOTE**

FLEXIO does not support automatic insertion of parity bits.

**Table 400. UART transmit configuration**

| Register | Value | Configuration |
|---|---|---|
| SHIFTCFG*n* | 0000_0032h | Configure start bit of 0 and stop bit of 1. |

*Table continues on the next page...*

Table 400. UART transmit configuration (continued)

| Register | Value | Configuration |
|---|---|---|
| SHIFTCTL*n* | 0003_0002h | Configure transmit using timer 0 on the positive edge of clock with output data on pin 0. You can configure the PINPOL field to invert output data, or support open-drain by writing 1h to the PINPOL and PINCFG fields. |
| TIMCMP*n* | 0000_0F01h | Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1. |
| TIMCFG*n* | 0000_2222h | Configure start bit, stop bit, enable on trigger asserted and disable on compare. You can support CTS by configuring the TIMENA field as 3h. |
| TIMCTL*n* | 01C0_0001h | Configure the dual 8-bit counter using the shifter 0 status flag as an inverted internal trigger source. To support CTS, configure the PINSEL (for pin 1) and PINPOL fields as 1h. |
| SHIFTBUF*n* | Data to transmit | Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the shifter status flag to indicate when data can be written using an interrupt or a DMA request. Write to SHIFTBUFBBS[7:0] instead to support MSB first transfer. |

The following table shows an alternative configuration that supports slower baud rates. This configuration requires two timers.

Table 401. UART transmit configuration for slow baud rate

| Register | Value | Configuration |
|---|---|---|
| SHIFTCFG*n* | 0000_0032h | Configure start bit of 0 and stop bit of 1. |
| SHIFTCTL*n* | 0003_0002h | Configure transmit using timer 0 on the positive edge of clock with output data on pin 0. Invert output data by writing 1 to the PINPOL field. Support open-drain by configuring the PINPOL and PINCFG fields as 1h. |
| TIMCMP*n* | 0000_000Fh | Configure for 8-bit transfer, and configure TIMCMP[15:0] as (number of bits × 2) - 1. |
| TIMCFG*n* | 0030_2622h | Configure start bit, stop bit, enable on trigger rising edge, decrement on trigger and disable on compare. |

*Table continues on the next page...*

Table 401. UART transmit configuration for slow baud rate (continued)

| Register | Value | Configuration |
|---|---|---|
| TIMCTL*n* | 0740_0003h | Configure the 16-bit counter using the timer 1 output as an internal trigger source. |
| TIMCMP(*n* + 1) | 0000_0001h | Configure baud rate of divide by 4 of the FLEXIO clock, and configure TIMCMP[15:0] as (baud rate divider ÷ 2) - 1. |
| TIMCFG(*n* + 1) | 0000_1200h | Configure enable on trigger asserted and disable on timer 0 disable. You can configure the TIMEN field as 3h to support CTS. |
| TIMCTL(*n* + 1) | 01C0_0003h | Configure the 16-bit counter using the shifter 0 status flag as an inverted internal trigger source. You can support CTS by configuring the PINSEL (for pin 1) and PINPOL fields as 1h. |
| SHIFTBUF*n* | Data to transmit | Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the shifter status flag to indicate when data can be written using an interrupt or a DMA request. Write to SHIFTBUFBBS[7:0] instead to support MSB first transfer. |

### 69.6.2 UART receive

UART receive can be supported using one timer, one shifter, and one pin (two timers and two pins, if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers are supported using the DMA controller. The timer status flag is used to indicate when the stop bit of each word is received.

FLEXIO does not support triple voting of the received data, which is sampled only once in the middle of each bit. You can use a timer to implement a glitch filter on the incoming data and a different timer to detect an idle line of programmable length. Break characters cause the error flag to set, and the shifter buffer register returns 00h.

**NOTE**

FLEXIO does not support automatic verification of parity bits.

Table 402. UART receiver configuration

| Register | Value | Configuration |
|---|---|---|
| SHIFTCFG*n* | 0000_0032h | Configure start bit of 0 and stop bit of 1. |
| SHIFTCTL*n* | 0080_0001h | Configure receive using timer 0 on the negative edge of clock with input data on pin 0. You can invert input data by writing 1 to the PINPOL field. |
| TIMCMP*n* | 0000_0F01h | Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set |

*Table continues on the next page...*

Table 402. UART receiver configuration (continued)

| Register | Value | Configuration |
|---|---|---|
| | | TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1. |
| TIMCFG*n* | 0204_2422h | Configure start bit, stop bit, enable on pin positive edge and disable on compare. Enable resynchronization to received data with TIMOUT = 2h and TIMRST = 4h. |
| TIMCTL*n* | 0000_0081h | Configure the dual 8-bit counter using the inverted pin 0 input. |
| SHIFTBUF*n* | Data to receive | You can read received data from SHIFTBUFBYS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from SHIFTBUFBIS[7:0] instead to support MSB first transfer. |

The UART receiver with RTS configuration uses a second timer to generate the RTS output. RTS asserts when the start bit is detected and negates when the data is read from the shifter buffer register. If no start bit is detected when the RTS is asserted, the received data is ignored.

Table 403. UART receiver with RTS configuration

| Register | Value | Configuration |
|---|---|---|
| SHIFTCFG*n* | 0000_0032h | Configure start bit of 0 and stop bit of 1. |
| SHIFTCTL*n* | 0080_0001h | Configure receive using timer 0 on the negative edge of clock with input data on pin 0. Invert input data by writing 1 to the PINPOL field. |
| TIMCMP*n* | 0000_0F01h | Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1. |
| TIMCFG*n* | 0204_2522h | Configure start bit, stop bit, enable on pin positive edge with trigger asserted and disable on compare. Enable resynchronization to received data with TIMOUT = 2h and TIMRST = 4h. |
| TIMCTL*n* | 02C0_0081h | Configure dual 8-bit counter using the inverted pin 0 input. Trigger is internal using the inverted pin 1 input. |
| TIMCMP(*n* + 1) | 0000_FFFFh | Never compare. |

*Table continues on the next page...*

Table 403. UART receiver with RTS configuration (continued)

| Register | Value | Configuration |
|---|---|---|
| TIMCFG(*n* + 1) | 0030_6100h | Enable on timer *n* enable and disable on the trigger falling edge. Decrement on trigger to ensure no compare. |
| TIMCTL(*n* + 1) | 0143_0003h | Configure 16-bit counter and output on pin 1. Trigger is internal using the shifter 0 flag. |
| SHIFTBUF*n* | Data to receive | You can read received data using SHIFTBUFBYS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from SHIFTBUFBIS[7:0] instead to support MSB first transfer. |

### 69.6.3 SPI controller

SPI Controller mode can be supported using two timers, two shifters, and four pins. Using the DMA controller, either CPHA = 0 or CPHA = 1 and transfers can be supported. For CPHA = 1, the chip select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of one clock cycle between the target chip select negating and before the next transfer. To initiate each transfer, either the core or DMA writes to the transmit buffer.

**NOTE**

Because of synchronization delays, the setup time for the serial input data is 1.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 4 of the FLEXIO clock frequency.

Table 404. SPI controller (CPHA = 0) configuration

| Register | Value | Configuration |
|---|---|---|
| SHIFTCFG*n* | 0000_0000h | Start and stop bit disabled. |
| SHIFTCTL*n* | 0083_0002h | Configure transmit using timer 0 on the negative edge of clock with output data on pin 0. |
| SHIFTCFG(*n* + 1) | 0000_0000h | Start and stop bit disabled. |
| SHIFTCTL(*n* + 1) | 0000_0101h | Configure receive using timer 0 on the positive edge of clock with input data on pin 1. |
| TIMCMP*n* | 0000_3F01h | Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1. |
| TIMCFG*n* | 0100_2222h | Configure start bit, stop bit, enable on trigger high and disable on compare; initial clock state is logic 0. |

*Table continues on the next page...*

Table 404. SPI controller (CPHA = 0) configuration (continued)

| Register | Value | Configuration |
|---|---|---|
| TIMCTL*n* | 01C3_0201h | Configure dual 8-bit counter using the pin 2 output (shift clock), with shifter 0 flag as the inverted trigger. Write 1 to the PINPOL field to invert the output shift clock. |
| TIMCMP(*n* + 1) | 0000_FFFFh | Never compare. |
| TIMCFG(*n* + 1) | 0000_1100h | Enable when timer 0 is enabled and disable when timer 0 is disabled. |
| TIMCTL(*n* + 1) | 0003_0383h | Configure 16-bit counter (never compare) using the inverted pin 3 output as target select. |
| SHIFTBUF*n* | Data to transmit | You can write transmit data to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer. |
| SHIFTBUF(*n* + 1) | Data to receive | Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer. |

Table 405. SPI controller (CPHA = 1) configuration

| Register | Value | Configuration |
|---|---|---|
| SHIFTCFG*n* | 0000_0021h | Start bit loads data on first shift. |
| SHIFTCTL*n* | 0003_0002h | Configure transmit using timer 0 on the positive edge of clock with output data on pin 0. |
| SHIFTCFG(*n* + 1) | 0000_0000h | Start and stop bit disabled. |
| SHIFTCTL(*n* + 1) | 0080_0101h | Configure receive using timer 0 on the negative edge of clock with input data on pin 1. |
| TIMCMP*n* | 0000_3F01h | Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits x 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1. |

*Table continues on the next page...*

Table 405. SPI controller (CPHA = 1) configuration (continued)

| Register | Value | Configuration |
|---|---|---|
| TIMCFG*n* | 0100_2222h | Configure start bit, stop bit, enable on trigger high and disable on compare; initial clock state is logic 0. |
| TIMCTL*n* | 01C3_0201h | Configure dual 8-bit counter using pin 2 output (shift clock), with the shifter 0 flag as the inverted trigger. Write 1 to the PINPOL field to invert the output shift clock, and set the TIMDIS field as 3 to keep target select asserted for as long as there is data in the transmit buffer. |
| TIMCMP(*n* + 1) | 0000_FFFFh | Never compare. |
| TIMCFG(*n* + 1) | 0000_1100h | Enable when timer 0 is enabled and disable when timer 0 is disabled. |
| TIMCTL(*n* + 1) | 0003_0383h | Configure 16-bit counter (never compare) using inverted pin 3 output (as target select). |
| SHIFTBUF*n* | Data to transmit | Transmit data can be written to SHIFTBUF. Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer. |
| SHIFTBUF(*n* + 1) | Data to receive | Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer. |

### 69.6.4 SPI target

SPI Target mode can be supported using one timer, two shifters, and four pins. Either CPHA = 0 or CPHA = 1 can be supported and transfers can be supported using the DMA controller. For CPHA = 1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

You must write the transmit data to the transmit buffer register before the external target select asserts; otherwise, the shifter error flag is set.

**NOTE**

Because of synchronization delays, the output valid time for the serial output data is 2.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

**Table 406. SPI target (CPHA = 0) configuration**

| Register | Value | Configuration |
|---|---|---|
| SHIFTCFG*n* | 0000_0000h | Start and stop bit disabled. |
| SHIFTCTL*n* | 0083_0002h | Configure transmit using timer 0 on the falling edge of shift clock with output data on pin 0. |
| SHIFTCFG(*n* + 1) | 0000_0000h | Start and stop bit disabled. |
| SHIFTCTL(*n* + 1) | 0000_0101h | Configure receive using timer 0 on the rising edge of shift clock with input data on pin 1. |
| TIMCMP*n* | 0000_003Fh | Configure 32-bit transfer. Set TIMCMP[15:0] as (number of bits × 2) - 1. |
| TIMCFG*n* | 0120_0600h | Configure enable on trigger rising edge. Initial clock state is logic 0 and decrements on pin input. |
| TIMCTL*n* | 06C0_0203h | Configure 16-bit counter using pin 2 input (shift clock), with pin 3 input (target select) as the inverted trigger. |
| SHIFTBUF*n* | Data to transmit | Transmit data can be written to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer. |
| SHIFTBUF(*n* + 1) | Data to receive | Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer. |

| TIMCFG*n* | 0120_6602h | Configure start bit, enable on trigger rising edge, disable on trigger falling edge. Initial clock state is logic 0 and decrements on pin input. |
| TIMCTL*n* | 06C0_0203h | Configure 16-bit counter using pin 2 input (shift clock), with pin 3 input (target select) as the inverted trigger. |
| SHIFTBUF*n* | Data to transmit | Transmit data can be written to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer. |
| SHIFTBUF(*n* + 1) | Data to receive | Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer. |

### 69.6.5 I2C controller

I2C Controller mode can be supported using two timers, two shifters, and two pins. One timer is used to generate the SCL output and another one is used to control the shifters. The two shifters that are used to transmit and receive for every word, when receiving the transmitter, must transmit FFh to 3-state the output. FLEXIO inserts a stop bit after every word to generate and verify the ACK or NACK. FLEXIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (start to repeated start or stop condition), so you must program the compare register with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin is equal to output. However, this increases both the clock high and clock low periods by at least one FLEXIO clock cycle each. The second timer uses the SCL input pin to control the transmit and receive shift registers. This enforces an SDA data hold time by an extra two FLEXIO clock cycles.

Both the transmit and receive shifters must be serviced for each word in the transfer. The transmit shifter must transmit FFh when receiving, and the receive shifter returns the data present on the SDA pin. The transmit shifter loads one additional word on the last falling edge of the SCL pin. When generating a stop condition or a repeated start condition, this word must be 00h and FFh, respectively. During the last word of a controller-receiver transfer, you must set the transmit SHIFTCFG*n*[SSTOP] field to generate a NACK.

The receive shift register asserts an error interrupt if a NACK is detected, but you are responsible for generating the stop or repeated start condition. If a NACK is detected during controller-transmit, the interrupt routine must immediately write 00h (when generating a stop condition) or FFh (when generating a repeated start condition) to the transmit shifter register. You must wait for the next rising edge on SCL before disabling both timers. The transmit shifter must be disabled after the setup delay for a repeated start or stop condition.

**NOTE**

Because of synchronization delays, the data valid time for the transmit output is two FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

To guarantee SDA hold time, the I2C controller data valid is delayed by two cycles because the clock output is passed through a synchronizer before clocking the transmit or receive shifter. Because the SCL output is synchronous with FLEXIO clock, the synchronization delay is one cycle, and then an additional cycle is involved to generate the output.

**Table 408. I2C controller configuration**

| Register | Value | Configuration |
|---|---|---|
| SHIFTCFG*n* | 0000_0032h | Start bit enabled (logic 0) and stop bit enabled (logic 1). |
| SHIFTCTL*n* | 0101_0082h | Configure transmit using timer 1 on the rising edge of clock with inverted output enable (open-drain output) on pin 0. |
| SHIFTCFG(*n* + 1) | 0000_0020h | Start bit disabled and stop bit enabled (logic 0) for ACK or NACK detection. |
| SHIFTCTL(*n* + 1) | 0180_0001h | Configure receive using timer 1 on the falling edge of clock with input data on pin 0. |
| TIMCMP*n* | 0000_2501h | Configure 2 word transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of words × 18) + 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1. |
| TIMCFG*n* | 0102_2222h | Configure start bit, stop bit, enable on trigger high, disable on compare, reset if output equals pin. Initial clock state is logic 0 and is not affected by reset. |
| TIMCTL*n* | 01C1_0101h | Configure dual 8-bit counter using pin 1 output enable (SCL open-drain), with the shifter 0 flag as the inverted trigger. |
| TIMCMP(*n* + 1) | 0000_000Fh | Configure 8-bit transfer. Set TIMCMP[15:0] as (number of bits x 2) - 1. |
| TIMCFG(*n* + 1) | 0020_1112h | Enable when timer 0 is enabled; disable when timer 0 is disabled. Enable start bit and stop bit at the end of each word and decrement on pin input. |
| TIMCTL(*n* + 1) | 01C0_0183h | Configure 16-bit counter using inverted pin 1 input (SCL). |

*Table continues on the next page...*

Table 408. I2C controller configuration (continued)

| Register | Value | Configuration |
|---|---|---|
| SHIFTBUF*n* | Data to transmit | Transmit data can be written to SHIFTBUFBBS[7:0]. Use the shifter status flag to indicate when data can be written using interrupt or DMA request. |
| SHIFTBUF(*n* + 1) | Data to receive | Received data can be read from SHIFTBUFBIS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request. |

### 69.6.6 I2S controller

I2S Controller mode can be supported using two timers, two shifters, and four pins. One timer is used to generate the bit clock and control the shifters and another timer is used to generate the frame sync. FLEXIO waits for the first write to the transmit data buffer before enabling bit clock and frame sync generation. Data transfers are supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FLEXIO clock frequency. The initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure that the frame sync is generated one clock cycle before the first output data.

**NOTE**

Because of synchronization delays, the setup time for the receiver input is 1.5 FLEXIO clock cycles. This means that the maximum baud rate is divide by 4 of the FLEXIO clock frequency.

Table 409. I2S controller configuration

| Register | Value | Configuration |
|---|---|---|
| SHIFTCFG*n* | 0000_0001h | Load transmit data on first shift and stop bit disabled. |
| SHIFTCTL*n* | 0003_0002h | Configure transmit using timer 0 on the rising edge of clock with output data on pin 0. |
| SHIFTCFG(*n* + 1) | 0000_0000h | Start and stop bit disabled. |
| SHIFTCTL(*n* + 1) | 0080_0101h | Configure receive using timer 0 on the falling edge of clock with input data on pin 1. |
| TIMCMP*n* | 0000_3F01h | Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1. |
| TIMCFG*n* | 0000_0202h | Configure start bit, enable on trigger high and never disable. Initial clock state is logic 1. |
| TIMCTL*n* | 01C3_0281h | Configure dual 8-bit counter using inverted pin 2 output (bit clock), with |

*Table continues on the next page...*

Table 409. I2S controller configuration (continued)

| Register | Value | Configuration |
|---|---|---|
| | | shifter 0 flag as the inverted trigger. Write 0 to the PINPOL field to invert the polarity of the output shift clock. |
| TIMCMP(*n* + 1) | 0000_007Fh | Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:0] as (number of bits × baud rate divider) ÷ 1. |
| TIMCFG(*n* + 1) | 0000_0100h | Enable when timer 0 is enabled and never disable. |
| TIMCTL(*n* + 1) | 0003_0383h | Configure 16-bit counter using inverted pin 3 output (as frame sync). Write 0 to the PINPOL field to invert the polarity of the output frame sync. |
| SHIFTBUF*n* | Data to transmit | Transmit data can be written to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) instead to support LSB first transfer. |
| SHIFTBUF(*n* + 1) | Data to receive | Received data can be read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) instead to support LSB first transfer. |

### 69.6.7 I2S target

I2S Target mode can be supported using three timers, two shifters, and four pins. For single transmit and single receive, other combinations of transmit and receive are possible.

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag is set.

**NOTE**

Because of synchronization delays, the output valid time for the serial output data is 2.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

The output valid time of I2S target is maximum 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization, plus one cycle to output the data.

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until the rising edge of bit clock (when the frame sync is normally sampled). Timer 0 detects the rising edge of bit clock with timer 2 output asserted and asserts output for length of frame. Timer 1 detects the falling edge of bit clock with timer 0 output asserted and controls shift registers for 32-bit transfers.

Table 410. I2S target configuration

| Register | Value | Configuration |
|---|---|---|
| SHIFTCFG*n* | 0000_0000h | Start and stop bit disabled. |
| SHIFTCTL*n* | 0103_0002h | Configure transmit using timer 1 on the rising edge of shift clock with output data on pin 0. |
| SHIFTCFG(*n* + 1) | 0000_0000h | Start and stop bit disabled. |
| SHIFTCTL(*n* + 1) | 0180_0101h | Configure receive using timer 1 on the falling edge of shift clock with input data on pin 1. |
| TIMCMP*n* | 0000_007Fh | Configure two 32-bit transfers per frame. Set TIMCMP[15:0] as (number of bits × 4) - 1. |
| TIMCFG*n* | 0020_2500h | Configure enable on pin rising edge (inverted bit clock) with trigger high (timer 2) and disable on compare. Initial clock state is logic 1 and decrements on pin input (bit clock). |
| TIMCTL*n* | 0B40_0203h | Configure 16-bit counter using pin 2 input (bit clock), with timer 2 output as the trigger. |
| TIMCMP(*n* + 1) | 0000_003Fh | Configure 32-bit transfers. Set TIMCMP[15:0] as (number of bits × 2) - 1. |
| TIMCFG(*n* + 1) | 0020_2500h | Configure enable on pin (bit clock) rising edge with trigger (timer 0) high and disable on compare. Initial clock state is logic 1 and decrement on pin input (bit clock). |
| TIMCTL(*n* + 1) | 0340_0283h | Configure 16-bit counter using inverted pin 2 input (bit clock), with timer 0 output as the trigger. |
| TIMCMP(*n* + 2) | 0000_0000h | Compare on zero (first edge). |
| TIMCFG(*n* + 2) | 0020_6400h | Configure enable on inverted pin (frame sync) rising edge and disable on trigger falling edge (bit clock). Initial clock state is logic 1 and decrement on inverted pin input (frame sync). |
| TIMCTL(*n* + 2) | 04C0_0383h | Configure 16-bit counter using inverted pin 3 input (frame sync), with pin 2 inverted input (bit clock) as the trigger. |
| SHIFTBUF*n* | Data to transmit | Transmit data can be written to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be written |

|---|---|---|
| | | using interrupt or DMA request. Write to the SHIFTBUF register instead to support LSB first transfer. |
| SHIFTBUF(*n* + 1) | Data to receive | Received data can be read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from the SHIFTBUF register instead to support LSB first transfer. |

### 69.6.8 SENT receiver

The SENT receiver can be supported by using one timer and one pin. The timer is configured as Input-Capture mode, and captures the counter value at the falling edge of the pin input. After the counter value is captured, the counter is automatically restarted from counter value 0. Therefore, the captured value always indicates the period between the previous falling edge and current falling edge. You can configure the CPU interrupt or DMA trigger at each capture of the counter. The CPU software performs the entire SENT frame decoding with the latest tick width adjustment.

Table 411. SENT receiver configuration

| Register | Value | Configuration |
|---|---|---|
| TIMCMP*n* | — | Stores counter value at the falling edge of the pin. |
| TIMCFG*n* | 0000_6000h | Timer is always enabled. It is disabled on trigger falling edge, decrement counter on FLEXIO clock. |
| TIMCTL*n* | 0040_0007h | Single 16-bit input capture mode. The PINSEL field selects the timer pin input and output. Timer pin output disabled, internal trigger selected, select pin 0 as trigger. |

### 69.6.9 Camera interface

Camera interface can be supported using one timer, one or more shifters, and multiple pins. Multiple transfers can be supported using the DMA controller.

The example configuration shown in the following table describes the FLEXIO configuration for interfacing with an 8-bit CMOS sensor with PCLK, VSYNC, HREF, and D[7:0] outputs. The example uses a 128-bit buffer to capture 16 pixels of image data before an interrupt or DMA transfer. You can use a bigger or smaller buffer depending on system DMA performance and FLEXIO resource usage by other applications.

**NOTE**

You can use additional timers to track the number of pixels per row and number of rows per frame, or HREF or VSYNC can be assigned as GPIO interrupts for software tracking.

Table 412. Camera interface configuration for 8-bit CMOS sensor

| Register | Value | Configuration |
|---|---|---|
| SHIFTCFG*n*...*n*+2[1] | 0007_0100h | Configure 8-bit parallel shift in from adjacent shifter. |
| SHIFTCFG*n*+3 | 0007_0000h | Configure 8-bit parallel shift in from pins FXIO_D[7:0] (D[7:0]). |
| SHIFTCTL*n*...*n*+3 | 0080_0001h | Configure receive using timer 0 on the negative edge of clock. |
| TIMCMP*n* | 0000_001Fh | Configure 16 pixel (8 bits/pixel × 16 pixels = 128 bits) transfer. Set TIMCMP[15:0] as (number of pixels × 2) - 1. |
| TIMCFG*n* | 0120_6600h | Configure enable on trigger (HREF) rising edge and disable on trigger falling edge. Initial shift clock state is logic 0 and decrement on PCLK input. |
| TIMCTL*n* | 12C0_0803h | Configure 16-bit counter using FXIO_D[8] input (PCLK), with FXIO_D[9] input (HREF) as the inverted trigger. |
| SHIFTBUF*n*...*n*+3 | Data to receive | Received data can be read from SHIFTBUF*n*...*n*+3. Use the shifter status flag to indicate when data can be read using interrupt or DMA request. |

1. *n* = 0 or 4

## 69.6.10 Motorola 68K and Intel 8080 bus interface

Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by smart and asynchronous LCD controllers. With GPIO, FLEXIO can drive these interfaces using one timer and one shifter. Additional shifters can be used to support large transfers via the DMA controller.

Example configurations are provided for 1-beat and 16-beat transfers. Other lengths are also supported.

The following table provides an example of how to drive a 16-bit 68K or 8080 bus. For an 8080 bus, two GPIOs are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

Table 413. Motorola 68K and Intel 8080 write configuration

| Register | Value | Configuration |
|---|---|---|
| SHIFTCFG0...7 | 000F_0100h | Configure 16-bit parallel shift in from adjacent shifter. |
| SHIFTCTL0 | 0003_0002h | Configure transmit using timer 0 on the positive edge of clock with data output to FXIO_D[15:0]. |
| SHIFTCTL1...7 | 0000_0002h | Configure transmit using timer 0 on the positive edge of clock. |

*Table continues on the next page...*

Table 413. Motorola 68K and Intel 8080 write configuration (continued)

| Register | Value | Configuration |
|---|---|---|
| TIMCMP0 | 0000_0101h (1 beat)<br>0000_1F01h (16 beats) | Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of beats × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1. |
| TIMCFG0 | 0000_2200h | Configure enable on trigger high and disable on compare. Timer output high on enable. |
| TIMCTL0 | 01C3_1001h (Motorola 68K, 1 beat)<br>1DC3_1001h (Motorola 68K, 16 beats)<br>01C3_1081h (Intel 8080, 1 beat)<br>1DC3_1081h (Intel 8080, 16 beats) | Configure dual 8-bit counter using FXIO_D[16] output (EN pin for 68K, nWR pin for 8080), with shifter 0 (1-beat) or shifter 7 (16 beats) flag as the inverted trigger. |
| SHIFTBUF0...7 | Data to transmit | Transmit data can be written to SHIFTBUF0 (1 beat) or SHIFTBUF0...7 (16-beats) to initiate a transfer; use the shifter status flag to indicate when data can be written using interrupt or DMA request. |

Table 414. Motorola 68K and Intel 8080 read configuration

| Register | Value | Configuration |
|---|---|---|
| SHIFTCFG0...6 | 000F_0100h | Configure 16-bit parallel shift in from the adjacent shifter. |
| SHIFTCFG7 | 000F_0000h | Configure 16-bit parallel shift in from pin. |
| SHIFTCTL0...7 | 0080_0001h | Configure receive using timer 0 on the negative edge of clock with data input from FXIO_D[15:0]. |
| TIMCMP0 | 0000_0101h (1 beat)<br>0000_1F01h (16 beats) | Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] = (number of beats × 2) - 1, and set TIMCMP[7:0] = (baud rate divider ÷ 2) - 1. |
| TIMCFG0 | 0000_2220h | Configure stop_bit. Enable on trigger high and disable on compare. Timer output high on enable. |
| TIMCTL0 | 1DC3_1001h (Motorola 68K, 1 beat)<br>01C3_1001h (Motorola 68K, 16 beats)<br>1DC3_1181h (Intel 8080, 1 beat)<br>01C3_1181h (Intel 8080, 16 beats) | Configure dual 8-bit counter using either FXIO_D[16] output (EN pin for 68K) or FXIO_D[17] output (nRD pin for 8080), with shifter 7 flag (1-beat) or shifter 0 flag (16 beats) as the inverted trigger. |

*Table continues on the next page...*

Table 414. Motorola 68K and Intel 8080 read configuration (continued)

| Register | Value | Configuration |
|---|---|---|
| SHIFTBUF0...7 | Data received | Received data can be read from SHIFTBUF0 (1 beat) or SHIFTBUF0...7 (16 beats). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. |

In general, any operation to a 68K or 8080 bus target begins with a register write cycle followed by one or more data read or write cycles. To accomplish this, perform the following procedure:

1. Configure FLEXIO with 1-beat write configuration.
2. Configure GPIO to assert the nCS and RS pins (and deassert the RDWR pin for 68K).
3. Write register index data to SHIFTBUF0[15:0].
4. Configure GPIO to deassert the RS pin (and assert the RDWR pin for 68K data read).
5. Configure FLEXIO with the desired read or write configuration (1 or 16 beats).
6. Use the shifter status flag to trigger interrupt or DMA driven data transfers to and from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7).
7. Configure GPIO to deassert the nCS pin.

### 69.6.11 Low-power state machine

Table 415 shows an example of a hypothetical state machine to illustrate the flexibility allowed in Shifter State mode.

In this example, FLEXIO waits for the FXIO_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO_CLK/131072 on the FXIO_D[1:0] pins while the comparator output is asserted. This assumes that the comparator is connected to external trigger 15. See the chip-specific FLEXIO information for actual FLEXIO trigger mappings. Figure 369 shows the states and transitions implemented by this example.

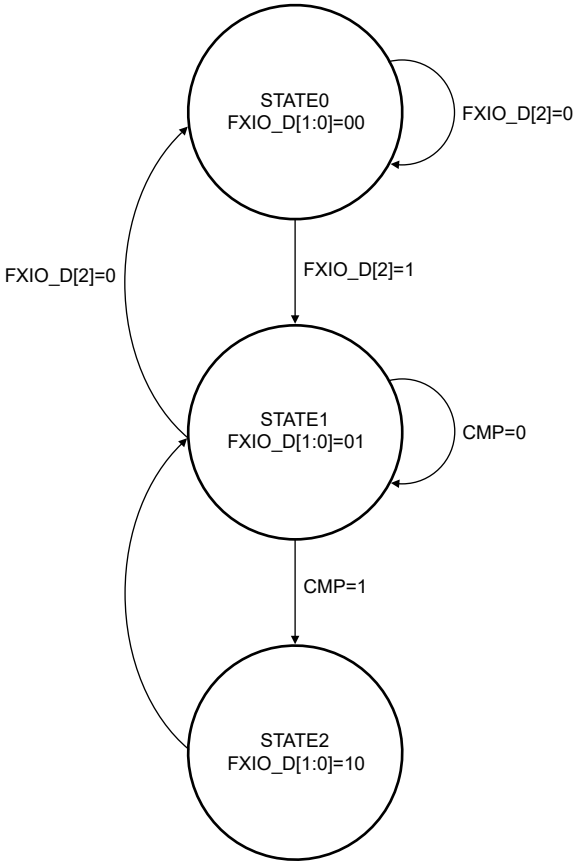

Figure 369. State diagram

Table 415. State machine configuration

| Register | Value | Configuration |
|---|---|---|
| SHIFTCFG0...2 | 0000_0003h | Enable FXIO_D[1:0] as outputs. |
| SHIFTCTL0 | 0080_0206h | Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output low to trigger next state. |
| SHIFTBUF0 | 0020_8208h | State0: Drive FXIO_D[1:0] = 00; transition to state0 if FXIO_D[2] = 0, state1 if FXIO_D[2] = 1. |
| SHIFTCTL1 | 0000_0206h | Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output high to trigger next state. |
| SHIFTBUF1 | 0140_8408h | State1: Drive FXIO_D[1:0]=01; transition to state0 if FXIO_D[2]=0, state1 if CMP = 0, state2 if CMP = 1 (FXIO_D[3]=1). |

*Table continues on the next page...*

Table 415. State machine configuration (continued)

| Register | Value | Configuration |
|---|---|---|
| SHIFTCTL2 | 0080_0206h | Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output low to trigger next state. |
| SHIFTBUF2 | 0224_9249h | State2: Drive FXIO_D[1:0] = 10, transition to state1 with timer 0 output low. |
| TIMCMP0 | 0000_FFFFh | Configure baud rate of divide by 131072 of the FLEXIO clock. Set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1. |
| TIMCFG0 | 0000_0000h | Configure timer always enabled. |
| TIMCTL0 | 0000_0003h | Configure single 16-bit counter. |
| TIMCFG1 | 0010_7600h | Configure timer enabled on trigger rising edge, disabled on trigger falling edge, decrement on trigger edge. |
| TIMCTL1 | 0F03_0303h | Configure timer output enabled on FXIO_D[3], external trigger 15 (comparator output) selected. |

### 69.6.12 Keypad interface

The keypad interface can support a 3 × 4 keypad matrix using three timers and three shifters, although a larger matrix can be supported using additional shifters. The configuration is designed for four columns configured as active low open-drain pins and three rows configured as input pins with pull-up resistors enabled.

One shifter is configured in Logic mode to assert its output when any of the row inputs are low, indicating a key is pressed. Use a timer to filter the shifter output to ensure that the key is pressed for a minimum amount of time before performing the column scan.

A different shifter is configured for parallel transmit. Use this shifter to scan each column when a keypress is detected. When not scanning, the shifter output is configured to assert all active low open-drain column outputs to detect any keypress. Use a dedicated timer to control the transmit shifter.

The last shifter is configured for parallel receive. Use this shifter to capture the result of the column scanning so that you can decode which key (or keys) was pressed. This configuration captures the state of both row and column pins for each scan, although the row state can also be deduced by the shift order. Use a dedicated timer to control the receive shifter, which shifts at half the frequency of the transmit shifter.

When the result of the key scan is available in the receive shifter register, FLEXIO continues to monitor the row inputs and can trigger multiple scans from a single keypress. To support debouncing, you can decide how many consecutive scans must be considered as a single keypress.

**NOTE**

Because the pins used in Logic mode are fixed per shifter and the shifters that support parallel shifts are limited, this configuration is restricted to what pins and shifters it can use. Increasing the matrix beyond four-row inputs requires multiple shifters in Logic mode. Increasing beyond four-column outputs requires concatenating transmit shifters to create a larger shift register.

Table 416. Keypad interface configuration

| Register | Value | Configuration |
|---|---|---|
| SHIFTCFG0 | 0003_0032h | Start bit enabled (logic 0) and stop bit enabled (logic 1), configured for 4-bit shift. |
| SHIFTCTL0 | 0101_0402h | Configure transmit using timer 1 on the rising edge of clock generating open-drain output on pins[7:4] (column outputs). |
| SHIFTBUF0 | 0804_0201h | Static data containing the column scan pattern; each column is scanned one-hot with dead time in between. |
| SHIFTCFG1 | 0000_0020h | In Logic mode, mask input 3. |
| SHIFTCTL1 | 0000_0007h | Configure Logic mode. |
| SHIFTBUF1 | 07FF_07FFh | Static data configuring Logic mode LUT. Output asserts if pins [3:1] are logic 0. |
| SHIFTCFG3 | 0007_0000h | Configured for 8-bit shift. |
| SHIFTCTL3 | 0280_0001h | Configure receive using timer 2 on falling edge of clock with input data on pins [7:0] (both rows and columns; pin 0 is don't care). |
| TIMCMP0 | 0000_00ffh | Configure prescanning glitch filter to 256 FLEXIO clock cycles. For different filter cycles, configure TIMCMP[15:0] as (filter cycles) - 1. |
| TIMCFG0 | 0103_6600h | Configure enable on trigger rising edge and disable on trigger falling edge. Initial clock state is logic 0 and is not affected by reset. |
| TIMCTL0 | 0540_0003h | Configure 16-bit counter using the shifter 1 flag (logic state) as trigger. |
| TIMCMP1 | 0000_0F3Fh | Configure eight shifts (twice for each column) at column scan rate of divide by 128. For a different scan frequency, define TIMCMP[7:0] as (scan divider ÷ 2) - 1. |
| TIMCFG1 | 0020_2622h | Enable on trigger rising edge, disable on compare. Start and stop bits are enabled. |
| TIMCTL1 | 0340_0001h | Configure dual 8-bit counter using timer 0 output as the trigger. |
| TIMCMP2 | 0000_0801h | Configure four shifts at half the frequency of the timer 1 trigger. |

*Table continues on the next page...*

Table 416. Keypad interface configuration (continued)

| Register | Value | Configuration |
|---|---|---|
| TIMCFG2 | 0110_2100h | Enable on timer 1 enable, disable on compare, decrement on trigger input with output initially negated, and not affected by reset. |
| TIMCTL2 | 0740_0001h | Configure dual 8-bit counter using timer 1 output as the trigger. |
| SHIFTBUF3 | Keypad scan result | Keypad scan result can be read from SHIFTBUF3. Each byte is the result of one scan with both row and column pin state from the scan (pin 0 is not used). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. |

## 69.7 Memory map and registers

### 69.7.1 FLEXIO register descriptions

**NOTE**

Invalid register accesses, which include reading a write-only register, writing to a read-only register, or accessing an invalid address, result in a bus error.

#### 69.7.1.1 FLEXIO memory map

FlexIO base address: 4032_4000h

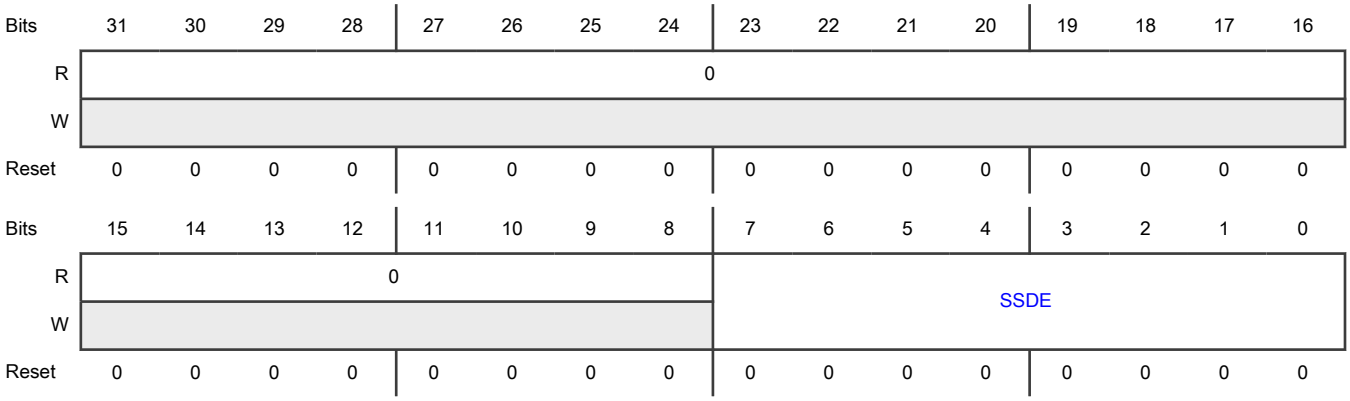
### 69.7.1.12 Shifter Status DMA Enable (SHIFTSDEN)

#### Offset

| Register | Offset |
|---|---|
| SHIFTSDEN | 30h |

#### Function
Enables shifter DMA requests.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-8<br>— | Reserved |
| 7-0<br>SSDE | Shifter Status DMA Enable<br>Enables DMA request generation when the corresponding SHIFTSTAT[SSF] flag is set. If you write 0 to this field, SHIFTSTAT[SSF] is disabled; and if you write 1 to this field, SHIFTSTAT[SSF] is enabled.<br>0b - Disable<br>1b - Enable |

## 69.7.1.13 Timer Status DMA Enable (TIMERSDEN)

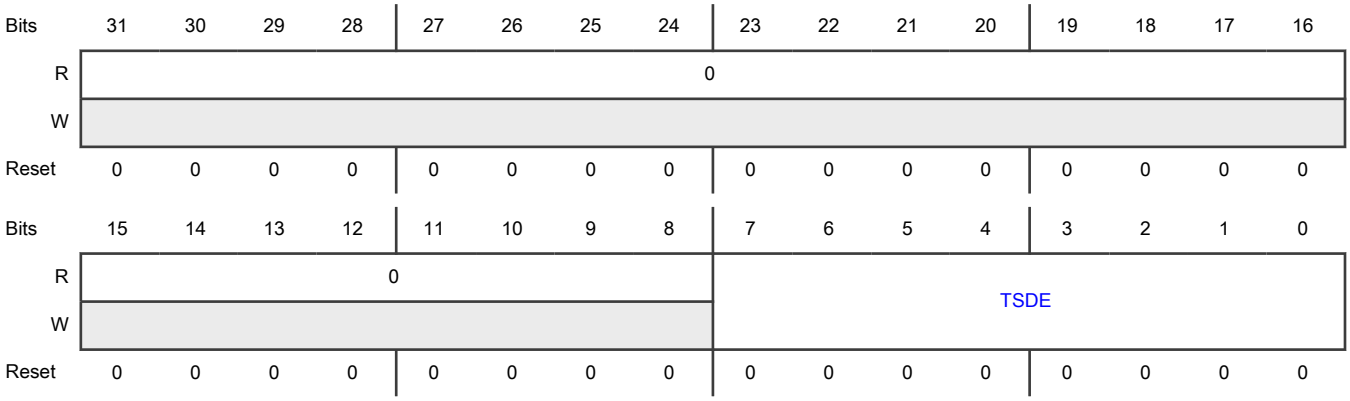
### Offset

| Register | Offset |
|---|---|
| TIMERSDEN | 38h |

### Function

Enables DMA requests when the timer status flag is set.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-8<br>— | Reserved |
| 7-0<br>TSDE | Timer Status DMA Enable<br>Enables DMA request generation when the corresponding TIMSTAT[TSF] flag is set.<br>When the timer status DMA request is enabled, reading or writing to a timer compare register clears the corresponding timer status register. The DMA must therefore read or write to the timer compare register as part of the DMA transfer; otherwise, the DMA request remains asserted.<br>0b - Disable<br>1b - Enable |

## 69.7.1.14 Shifter State (SHIFTSTATE)

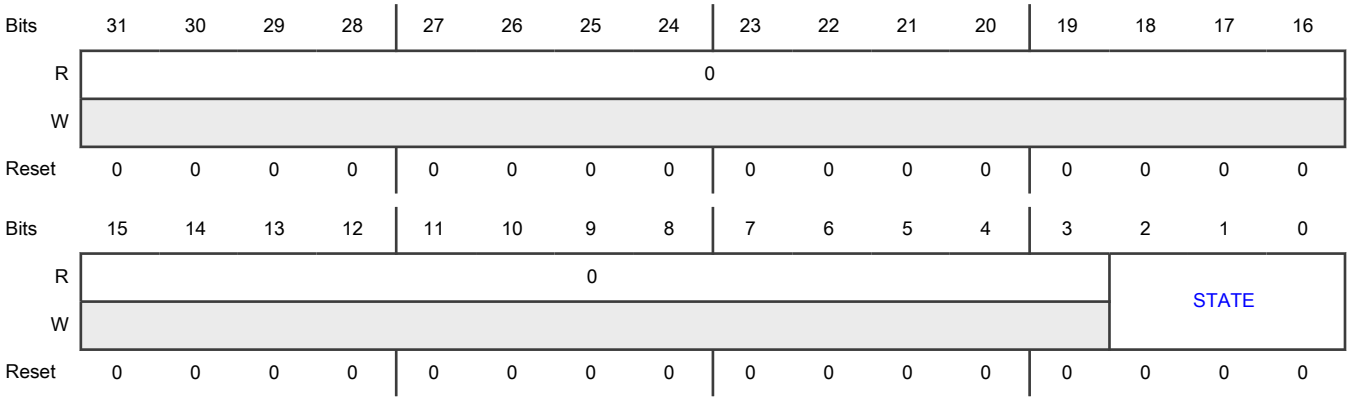
### Offset

| Register | Offset |
|---|---|
| SHIFTSTATE | 40h |

### Function

Contains a pointer to track the current shifter.

### Diagram



### Fields

| Field | Function |

| 1-0<br>SSTART | Shifter Start<br>Allows automatic start bit insertion, if the selected timer has also enabled a start bit, when SHIFTCTL*n*[SMOD] is 10b (Transmit mode).<br>If SHIFTCTL*n*[SMOD] = 1b (Receive mode) or 100b (Match Store mode), this field allows automatic start bit checking if the selected timer has also enabled a start bit.<br>If SHIFTCTL*n*[SMOD] is 110b (State mode), this field disables state outputs (see State mode).<br>If SHIFTCTL*n*[SMOD] = 111b (Logic mode), this field masks logic pin inputs (see Logic mode).<br>00b - Start bit disabled for Transmitter, Receiver, and Match Store modes; Transmitter mode loads data on enable<br>01b - Start bit disabled for Transmitter, Receiver, and Match Store modes; Transmitter mode loads data on first shift<br>10b - Transmitter mode outputs start bit value 0 before loading data on first shift; if start bit is not 0, Receiver and Match Store modes set error flag<br>11b - Transmitter mode outputs start bit value 1 before loading data on first shift; if start bit is not 1, Receiver and Match Store modes set error flag |

### 69.7.1.29 Shifter Buffer (SHIFTBUF0 - SHIFTBUF7)

#### Offset

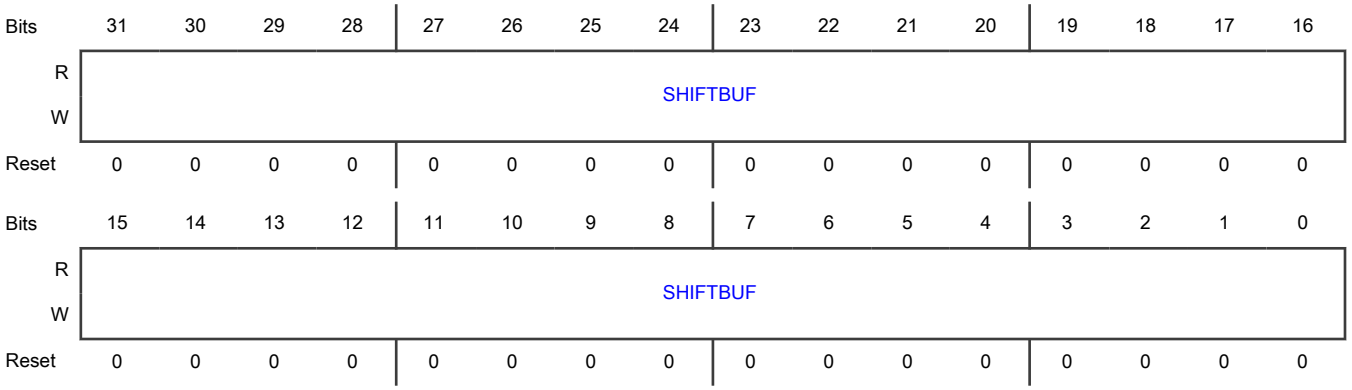
For n = 0 to 7:

| Register | Offset |
|---|---|
| SHIFTBUFn | 200h + (n × 4h) |

#### Function

Contains shift buffer data.

#### Diagram



**Fields**

| Field | Function |
|---|---|
| 31-0<br>SHIFTBUF | Shift Buffer<br>Contains the data to be matched with the shifter contents and is used for various other functions, depending on the setting of SHIFTCTL*n*[SMOD]:<br>• If SHIFTCTL0[SMOD] is 1b (Receive mode), shifter data is transferred into SHIFTBUF at the expiration of the timer. You must read this register only when the corresponding SHIFTSTAT[SSF] flag is set, indicating that new shifter data is available.<br>• If SHIFTCTL0[SMOD] is 10b (Transmit mode), SHIFTBUF data is transferred into the shifter before the timer begins.<br>• If SHIFTCTL0[SMOD] is 100b (Match Store mode), SHIFTBUF[31:16] contains the data to be matched with the shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1 = mask, 0 = no mask). The match is checked when the timer expires. Shifter data [31:16] is written to SHIFTBUF[31:16] whenever a match event occurs. You must read this register only when the corresponding shifter status flag is set, indicating that new shifter data is available.<br>• If SHIFTCTL0[SMOD] is 101b (Match Continuous mode), SHIFTBUF[31:16] contains the data to be matched with the shifter contents, and SHIFTBUF[15:0] can be used to mask the match result (1 = mask, 0 = no mask).<br>• If SHIFTCTL0[SMOD] is 111b (Logic mode), SHIFTBUF[31:0] implements a 5-input, 32-bit programmable logic lookup table (see Logic mode).<br>• If SHIFTCTL0[SMOD] is 110b (State mode), use SHIFTBUF[31:24] to drive the output value when this shifter is selected by the current state pointer and use SHIFTBUF[23:0] to configure the value of the next state transition (see State mode). |

### 69.7.1.30 Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7)

**Offset**

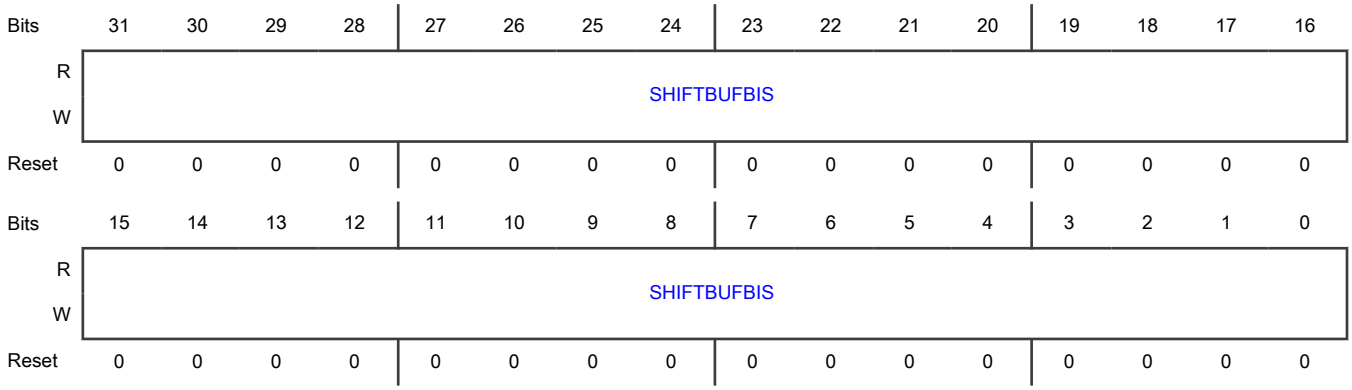
For n = 0 to 7:

| Register | Offset |
|---|---|
| SHIFTBUFBISn | 280h + (n × 4h) |

**Function**

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is bit-swapped.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>SHIFTBUFBIS | Shift Buffer<br>Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register are bit-swapped. Reads return SHIFTBUF[0:31]. |

## 69.7.1.31 Shifter Buffer Byte Swapped (SHIFTBUFBYS0 - SHIFTBUFBYS7)

### Offset

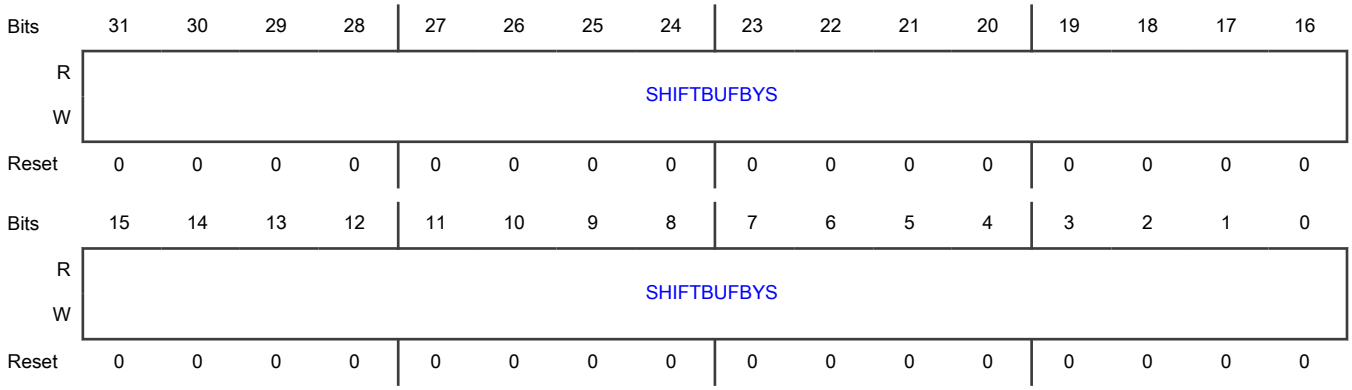
For n = 0 to 7:

| Register | Offset |
|---|---|
| SHIFTBUFBYSn | 300h + (n × 4h) |

### Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is byte-swapped.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>SHIFTBUFBYS | Shift Buffer<br>Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register are byte-swapped. Reads return {SHIFTBUF[7:0], SHIFTBUF[15:8], SHIFTBUF[23:16], SHIFTBUF[31:24]}. |

## 69.7.1.32 Shifter Buffer Bit Byte Swapped (SHIFTBUFBBS0 - SHIFTBUFBBS7)

### Offset

For n = 0 to 7:

| Register | Offset |
|---|---|
| SHIFTBUFBBSn | 380h + (n × 4h) |

### Function

Contains the register data for Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but it is bit-swapped within each byte.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 7<br>PINPOL | Timer Pin Polarity<br>Specifies the timer pin polarity. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register.<br>0b - Active high<br>1b - Active low |
| 6<br>PININS | Timer Pin Input Select<br>Specifies what selects the timer pin input. If this field is 1, the timer input pin is different from the timer output pin. PINSEL must select an even-numbered pin when this field is 1, which means that the output pin is even-numbered and input pin is odd-numbered.<br>0b - PINSEL selects timer pin input and output<br>1b - PINSEL + 1 selects the timer pin input; timer pin output remains selected by PINSEL |
| 5<br>ONETIM | Timer One Time Operation<br>Configures the timer to perform a single enable or disable iteration. Clear the timer status flag for the timer to be enabled again.<br>0b - Generate the timer enable event as normal<br>1b - Block the timer enable event unless the timer status flag is clear |
| 4-3<br>— | Reserved |
| 2-0<br>TIMOD | Timer Mode<br>Specifies the timer mode:<br>• In 8-bit baud counter mode, the lower 8 bits of the counter and compare register are used to configure the baud rate of the timer shift clock. The upper 8 bits are used to configure the shifter bit count.<br>• In 8-bit PWM high mode, the lower 8 bits of the counter and compare register are used to configure the high period of the timer shift clock. The upper 8 bits are used to configure the low period of the timer shift clock. The shifter bit count is configured using another timer or external signal.<br>• In 16-bit counter mode, the full 16 bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count.<br>• In 16-bit counter disable mode, the full 16 bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | • In 8-bit word counter mode, the lower 8 bits of the counter and compare register are used to configure the shifter bit count. The upper 8 bits are used to configure the shifter word count.<br>• In 8-bit PWM low mode, the lower 8 bits of the counter and compare register are used to configure the low period of the timer shift clock. The upper 8 bits are used to configure the high period of the timer shift clock. Use another timer or external signal to configure the shifter bit count.<br>• In 16-bit input capture mode, the inverted value of the 16-bit counter is latched into the compare register when a timer counter disable condition is detected (as configured by TIMCFG*n*[TIMDIS]). This also sets the timer status flag. The timer counter is immediately restarted from FFFFh.<br>000b - Timer disabled<br>001b - Dual 8-bit counters baud mode<br>010b - Dual 8-bit counters PWM high mode<br>011b - Single 16-bit counter mode<br>100b - Single 16-bit counter disable mode<br>101b - Dual 8-bit counters word mode<br>110b - Dual 8-bit counters PWM low mode<br>111b - Single 16-bit input capture mode |

### 69.7.1.34 Timer Configuration (TIMCFG0 - TIMCFG7)

#### Offset

For n = 0 to 7:

| Register | Offset |
|---|---|
| TIMCFGn | 480h + (n × 4h) |

#### Function

Controls various aspects of timer configuration.

The options to enable or disable the timer using the timer *n* - 1 enable or disable are reserved when *n* is evenly divisible by 4 (timer 0, for example).

**NOTE**

The pin and trigger level and edges specified in this register refer to the signal state after being modified by the settings of TIMCTL*n*[PINPOL] and TIMCTL*n*[TRGPOL]. For example, "trigger low" means that a trigger is actually at logic level 1 if TIMCTL*n*[TRGPOL] is 1 (active low).

| Field | Function |
|---|---|
| 31-0<br>SHIFTBUFEOS | Shift Buffer<br>Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register have the even and odd bits partitioned separately. Only 32-bit accesses are supported for this register. Reads return {SHIFTBUF[30], SHIFTBUF[28], SHIFTBUF[26], SHIFTBUF[24], SHIFTBUF[22], SHIFTBUF[20], SHIFTBUF[18], SHIFTBUF[16], SHIFTBUF[14], SHIFTBUF[12], SHIFTBUF[10], SHIFTBUF[8], SHIFTBUF[6], SHIFTBUF[4], SHIFTBUF[2], SHIFTBUF[0], SHIFTBUF[31], SHIFTBUF[29], SHIFTBUF[27],SHIFTBUF[25],SHIFTBUF[23],SHIFTBUF[21],SHIFTBUF[19],SHIFTBUF[17],SHIFTBUF[15],SHIFTBUF[13],SHIFTBUF[11],SHIFTBUF[9], SHIFTBUF[7], SHIFTBUF[5], SHIFTBUF[3], SHIFTBUF[1]}. |

### 69.7.1.41 Shifter Buffer Halfword Byte Swapped (SHIFTBUFHBS0 - SHIFTBUFHBS7)

#### Offset

For n = 0 to 7:

| Register | Offset |
|---|---|
| SHIFTBUFHBSn | 900h + (n × 4h) |

### Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is halfword byte-swapped.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | SHIFTBUFHBS | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### Fields

| Field | Function |
|---|---|
| 31-0<br>SHIFTBUFHBS | Shift Buffer<br>Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register are halfword byte-swapped. Reads return {SHIFTBUF[23:16], SHIFTBUF[31:24], SHIFTBUF[7:0], SHIFTBUF[15:8]}. |

## 69.8 Glossary

| | |
|---|---|
| **Baud rate** | Number of bits that LPUART transmits or receives per second |
| **Break character** | Break character is generated when the transmitter is holding the data line at the space level for at least 1 character time |
| **Idle character** | Idle character is generated when the transmitter is holding the data line at logic 1 for at least 1 character time |
| **PWM** | Pulse width modulation |

# Chapter 70
# CAN (FlexCAN)

## 70.1 Chip-specific FlexCAN information

### 70.1.1 FlexCAN instances and configuration

This chip contains up to 8 instances of FlexCAN:

- FlexCAN_0
- FlexCAN_1
- FlexCAN_2
- FlexCAN_3
- FlexCAN_4
- FlexCAN_5

**Table 417. FlexCAN configuration and instances**

| Chip | Instances | Flexible Data Rate (CAN FD) protocol specification and CAN protocol. | Number of message buffers (assuming 8B payload) | Rx FIFO ID Filtering | ECC | External tick time | DMA | Enhanced RX FIFO feature (size) |
|---|---|---|---|---|---|---|---|---|
| MCXE31B | FlexCAN_0 | Yes | 96 | Yes | Yes | Yes (PIT_RTI_2) | Yes | Yes (20) |
| | FlexCAN_1 | Yes | 64 | Yes | Yes | Yes (PIT_RTI_2) | Yes | No |
| | FlexCAN_2 | Yes | 64 | Yes | Yes | Yes (PIT_RTI_2) | Yes | No |
| | FlexCAN_3 | Yes | 32 | Yes | Yes | Yes (PIT_RTI_2) | Yes | No |
| | FlexCAN_4 | Yes | 32 | Yes | Yes | Yes (PIT_RTI_2) | Yes | No |
| | FlexCAN_5 | Yes | 32 | Yes | Yes | Yes (PIT_RTI_2) | Yes | No |
| MCXE317 | FlexCAN_0 | Yes | 64 | Yes | Yes | Yes (PIT_RTI_1) | Yes | Yes (20) |
| | FlexCAN_1 | Yes | 64 | Yes | Yes | Yes (PIT_RTI_1) | Yes | No |
| | FlexCAN_2 | Yes | 64 | Yes | Yes | Yes (PIT_RTI_1) | Yes | No |
| | FlexCAN_3 | Yes | 32 | Yes | Yes | Yes (PIT_RTI_1) | Yes | No |

*Table continues on the next page...*

Table 417. FlexCAN configuration and instances (continued)

| Chip | Instances | Flexible Data Rate (CAN FD) protocol specification and CAN protocol. | Number of message buffers (assuming 8B payload) | Rx FIFO ID Filtering | ECC | External tick time | DMA | Enhanced RX FIFO feature (size) |
|---|---|---|---|---|---|---|---|---|
| | FlexCAN_4 | Yes | 32 | Yes | Yes | Yes (PIT_RTI_1) | Yes | No |
| | FlexCAN_5 | Yes | 32 | Yes | Yes | Yes (PIT_RTI_1) | Yes | No |

**NOTE**

See attached interrupt map file for the vector numbers for the CAN instances and their corresponding interrupt sources.

## 70.1.2 FlexCAN error injection

### Error injection address mapping

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM (where pairs of values are provided, the first is the address for MCR[FDEN] negated, the second is for MCR[FDEN] asserted):

| RAM contents | Memory map | Injection address | | | | |
|---|---|---|---|---|---|---|
| — | — | FlexCAN0 | FlexCAN0 | FlexCAN1/2 | FlexCAN3 | FlexCAN4/5 |
| | | MCXE31B | MCXE317 | MCXE31 | MCXE31B | MCXE31B |
| | | | | | MCXE315/ MCXE316 | MCXE317 |
| | | | | | MCXE317 | |
| FlexCAN Registers | — | Not mapped | Not mapped | Not mapped | Not mapped | Not mapped |
| MBs | 0080h | 0000h | 0000h | 0000h | 0000h | 0000h |
| RXIMRs | 0880h | 600h | 400h | 400h | 200h | 200h |

| RXIFR_1 | 0A84h | 784h | 504h | 504h | 284h | 284h |
| RXIFR_2 | 0A88h | 788h | 508h | 508h | 288h | 288h |

*Table continues on the next page...*

*Table continued from the previous page...*

| RAM contents | Memory map | Injection address | | | | |
|---|---|---|---|---|---|---|
| RXIFR_3 | 0A8Ch | 78Ch | 50Ch | 50Ch | 28Ch | 28Ch |
| RXIFR_4 | 0A90h | 790h | 510h | 510h | 290h | 290h |
| RXIFR_5 | 0A94h | 794h | 514h | 514h | 294h | 294h |
| Reserved | 0A98h | — | — | — | — | — |
| RXMGMASK | 0AA0h | 7A0h | 520h | 520h | 2A0h | 2A0h |
| RXFGMASK | 0AA4h | 7A4h | 524h | 524h | 2A4h | 2A4h |
| RX14MASK | 0AA8h | 7A8h | 528h | 528h | 2A8h | 2A8h |
| RX15MASK | 0AACh | 7ACh | 52Ch | 52Ch | 2ACh | 2Ach |
| Tx_SMB | 0AB0h/0F28h | 7B0h | 530h | 530h | 2B0h | 2B0h |
| Rx_SMB0 | 0AC0h/0F70h | 7C0h/7F8h | 540h/578h | 540h/578h | 2C0h/2F8h | 2C0h/2F8h |
| Rx_SMB1 | 0AD0h/0FB8h | 7D0h/840h | 550h/5C0h | 550h/5C0h | 2D0h/340h | 2D0h/340h |
| Rx_SMB0_TIME_STAMP | 0C20h | 888h | 608h | 608h | 388h | 388h |
| Rx_SMB1_TIME_STAMP | 0C24h | 88Ch | 60Ch | 60Ch | 38Ch | 38Ch |
| HR_TIME_STAMP | 0C30h | 890h | 610h | 610h | 390h | 390h |
| Enhanced RX FIFO | 2000h | A10h | 710h | — | — | — |
| ERFFEL | 3000h | 1050h | D50h | — | — | — |

### FlexCAN memory initialization

All FlexCAN memory must be initialized before starting its operation in order to have the parity bits in memory properly updated. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization.

These locations are as listed in this table from 080h–ADFh and from C20h–31FFh.:

| Chip | Instance | Offset address ranges to be initialized |
|---|---|---|
| MCXE31B | FlexCAN0 | 080h–ADFh; C20h–31FFh |
| | FlexCAN1–FlexCAN5 | 080h–ADFh; C20h–FFFh |
| MCXE317 | FlexCAN0 | 080h–DFh; C20h–31FFh |
| | FlexCAN1–FlexCAN5 | 080h–ADFh; C20h–FFFh |
| MCXE315/MCXE316 | FlexCAN0 | 080h–ADFh; C20h–31FFh |
| | FlexCAN1–FlexCAN2 | 080h–ADFh; C20h–FFFh |

**NOTE**

The reset value of CAN0_CTRL2 register for MCXE317 is 0080_0000h.

### 70.1.3 Reset value of MDIS bit

The CAN_MCR[MDIS] bit is set to 1 when the module is reset. Therefore, FlexCAN module is disabled following a reset. For details of CAN_MCR[MDIS] register refer to "CAN register description" section.

### 70.1.4 CAN Timestamp Implementation

FlexCAN uses Ethernet Media Access Controller (EMAC) and System Timer Module (STM_0) counters as time source. For details see 'FlexCAN timestamp implementation' section in Clocking chapter.

### 70.1.5 CAN clock setup

For clock setup, see Clocking chapter.

## 70.2 Overview

FlexCAN is a communication controller implementing the CAN protocol according to the ISO 11898-1:2015 standard and CAN 2.0 Part B protocol specifications.

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific real-time processing and reliable operation requirements in the electromagnetic interference (EMI) environment of a vehicle. FlexCAN is a full implementation of the CAN protocol specification, the CAN with flexible data rate (CAN FD) protocol, and the CAN version 2.0 Part B protocol. It supports both standard and extended message frames and long payloads.

**NOTE**

Legacy Receive (RX) FIFO cannot be used in CAN Flexible Data (FD) mode. In CAN FD mode, use the Enhanced Receive FIFO feature instead of the Legacy Receive FIFO.

### 70.2.1 Block diagram

Figure 370 shows the main submodules implemented in FlexCAN.

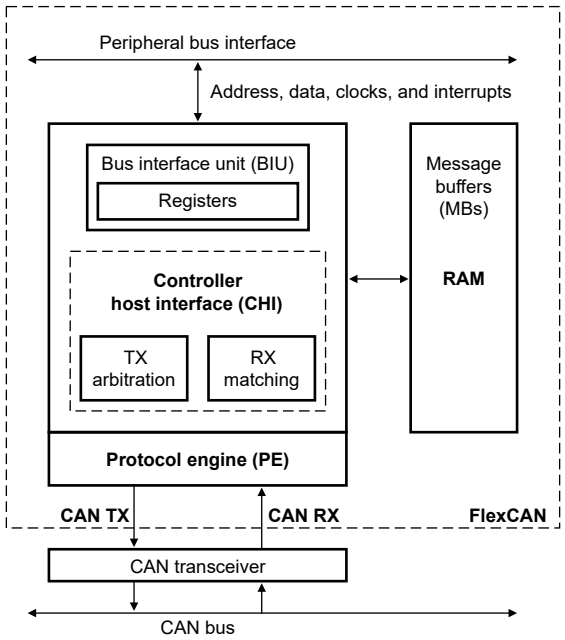

Figure 370. Block diagram

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- RAM access for receiving and transmitting message frames

- Receive message validation
- Error handling
- CAN FD message detection

Controller Host Interface (CHI) manages:

- Message buffer (MB) selection for reception and transmission
- Arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats

Bus Interface Unit (BIU) controls access to and from the internal interface bus to establish connection to the CPU and to other blocks. The BIU manages access to:

- Clocks
- Address and data buses
- Interrupt outputs
- DMA
- Test signals

### 70.2.2 Features

- Full implementation of *CAN with Flexible data rate (CAN FD) protocol specification* and *CAN Specification Version 2.0, Part B*:
  - Standard data frames
  - Extended data frames
  - Data length of 0–64 bytes
  - Programmable bit rate (see chip-specific FlexCAN information for specific maximum rate configuration)
  - Content-related addressing
- Compliance with ISO 11898-1:2015 standard
- Flexible message buffers that can be configured to store a payload of 0, 8, 16, 32, or 64 bytes
  - Increasing the payload size decreases the number of supported message buffers (see FlexCAN memory partition for CAN FD).
  - Message buffers are configurable as receive or transmit, supporting standard and extended messages.
- Individual Receive Mask registers for each message buffer
- Full-featured Legacy RX FIFO with storage capacity for six frames and automatic internal pointer handling with DMA support
- Full-featured Enhanced RX FIFO with storage capacity of 20 CAN FD frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Optional general purpose RAM space, using RAM not used by reception or transmission structures
- Listen-Only mode
- Programmable loopback mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Timestamp based on 32-bit free-running timer, with optional external time tick
- Global network time, synchronized by specific message
- Maskable interrupts

- Independence from transmission medium (external transceiver is assumed)
- Short latency time due to arbitration scheme for high-priority messages
- Low-power mode
- Transceiver delay compensation when transmitting CAN FD messages at faster data rates
- Management of remote request frames, automatically or by software
- Restriction only to write CAN bit time settings and configuration bits in Freeze mode
- Transmit message buffer status (lowest-priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- ESR1[SYNCH] to indicate module is synchronous with CAN bus
- CRC status for transmitted message
- Legacy RX FIFO Global Mask register
- Selectable priority between message buffers and receive FIFO during matching process
- Powerful legacy RX FIFO ID filtering, capable of matching incoming IDs against either 128 extended IDs, 256 standard IDs, or 512 partial (8-bit) IDs, with 32 individual masking capability
- Powerful enhanced RX FIFO ID filtering, capable of matching incoming IDs against either 64 extended or 128 standard ID filter elements with three filtering schemes: mask plus filter, range, and two filters without mask
- Complete backward compatibility with previous FlexCAN version
- Detection and correction of errors in memory read accesses:
  - Each byte of FlexCAN memory is associated to five parity bits.
  - The error correction mechanism ensures that errors in one bit of this 13-bit word can be corrected (correctable errors).
  - Errors in two bits can be detected but not corrected (noncorrectable errors).

## 70.3 Functional description

FlexCAN is a CAN protocol engine with a flexible message buffer system for transmitting and receiving CAN frames. The system is a set of message buffers (MBs) that stores configuration and control data, timestamp, message ID, and data (see Message buffer structure). The memory corresponding to the first 38 message buffers can be configured to support a Legacy FIFO reception scheme with a powerful ID filtering mechanism. This scheme can check incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with an individual mask register for up to 32 ID filter table elements.

For classical CAN frames, FlexCAN supports simultaneous reception through Legacy FIFO and message buffer. For CAN FD frames, FlexCAN supports reception through message buffer and enhanced receive FIFO.

For message buffer reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed in the ID field. A masking scheme makes it possible to match the ID programmed on the message buffer with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of message buffers to be transmitted based on the message ID (optionally augmented by three local priority bits) or the message buffer ordering.

A message buffer is active at a given time if it can participate in both the matching and arbitration processes. A receive message buffer with a 0b code is inactive (see Table 453). A transmit message buffer with a 1000b or 1001b code is also inactive (see Table 454).

FlexCAN can receive and transmit messages in CAN FD format. The message buffers are sized to store the quantity of data bytes selected by FDCTRL[MBDSRn]. The quantity of FD message buffers available for a given quantity of data bytes is described in the CAN FD Control (FDCTRL) register. See also FlexCAN memory partition for CAN FD.

### 70.3.1 Modes of operation

FlexCAN has these functional modes:

**Table 418. Functional modes**

| Mode | Description |
|---|---|
| Normal (User or Supervisor) | In Normal mode, FlexCAN receives and transmits message frames, manages errors normally, and enables all CAN Protocol functions. User and Supervisor modes differ in the access to some restricted control registers. |
| Freeze | Freeze mode is enabled when MCR[FRZ] = 1. If enabled, FlexCAN enters Freeze mode when MCR[HALT] is 1 or when is requested at chip level and FlexCAN writes 1 to MCR[FRZACK]. In this mode, no transmission or reception of frames is done, and synchronicity to the CAN bus is lost. See Freeze mode. |
| Loopback | FlexCAN enters this mode when CTRL1[LPB] becomes 1. In this mode, FlexCAN performs an internal loopback that can be used for self-test. The bit stream output of the transmitter is internally fed back to the receiver input. The receiving CAN input pin is ignored and the transmitting CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. To ensure proper reception of its own message, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. Both transmit and receive interrupts are generated. |
| Listen-Only | FlexCAN enters this mode when CTRL1[LOM] becomes 1. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error (without changing the REC), as if it was trying to acknowledge the message. |
| CAN FD Active | In this mode, FlexCAN can transmit and receive all messages formatted according to the CAN FD Standard (2.0) and 2.0B Protocol in an interleaved fashion. The CPU can put FlexCAN into CAN FD Active mode by configuring MCR[FDEN] in Freeze mode. |

Some features available in classical CAN are unavailable in CAN FD mode.

**Table 419. Differences between classical CAN and CAN FD**

| Feature | Classical CAN | CAN FD |
|---|---|---|
| Legacy RX FIFO DMA | Yes | No |
| Legacy RX FIFO | Yes | No |
| Enhanced RX FIFO DMA | Yes | Yes |
| Enhanced RX FIFO | Yes | Yes |

FlexCAN can operate in these low-power modes:

**Table 420. Low-power modes**

| Mode | Description |
|---|---|
| Module Disable | FlexCAN enters this mode when the CPU writes 1 to MCR[MDIS] and FlexCAN writes 1 to MCR[LPMACK]. After FlexCAN is disabled, it issues a request to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Writing 0 to MCR[MDIS] exits this mode. See Module Disable mode. |

#### 70.3.1.1 Modes of operation details

FlexCAN has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following subsections contain functional details about Freeze mode and low-power modes.

**CAUTION**

FlexCAN does not support "Permanent Dominant" failure on the CAN bus line. If a Low-Power request or Freeze mode request occurs during a "Permanent Dominant" condition, the corresponding acknowledgment field can never be 1.

##### 70.3.1.1.1 Freeze mode

This mode is requested either by the CPU writing 1 to MCR[HALT] or when the chip is put into Debug mode. MCR[FRZ] must be 1 and the module must not be in a low-power mode.

When MECR[NCEFAFRZ] becomes 1 and a noncorrectable error is detected in a memory read access performed by FlexCAN internal processes (see Error response), FlexCAN also requests Freeze mode. This request occurs via both MCR[HALT] and MCR[FRZ] automatically becoming 1.

To obtain acknowledgment, FlexCAN writes 1 to MCR[FRZACK]. The CPU must only consider FlexCAN to be in Freeze mode when both request and acknowledgment conditions are satisfied.

When Freeze mode is requested, FlexCAN:

1. Waits to be in either Intermission, Error Passive, Bus Off, or Idle state.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent entering Freeze mode.
3. Ignores the receive input pin and drives the transmit pin as recessive.
4. Stops the prescaler, halting all CAN protocol activities.
5. Grants write access to the Error Counters register, which is read-only in other modes.
6. Writes 1 to MCR[NOTRDY] and MCR[FRZACK].

After requesting Freeze mode, you must wait for MCR[FRZACK] to become 1 before executing any other action, otherwise FlexCAN may operate unpredictably. In Freeze mode, all memory-mapped registers are accessible.

Freeze mode is exited in one of these conditions:

- CPU writes 0 to MCR[FRZ].
- The chip is removed from Debug mode or the MCR[HALT] becomes 0.

MCR[FRZACK] becomes 0 after the protocol engine recognizes the negation of the freeze request. After leaving Freeze mode, FlexCAN tries to resynchronize to the CAN bus by waiting for 11 consecutive recessive bits.

##### 70.3.1.1.2 Module Disable mode

This low-power mode is normally used to disable a complete FlexCAN block temporarily, with no power consumption. The CPU requests this mode by writing 1 to MCR[MDIS], and FlexCAN acknowledges the request by writing 1 to MCR[LPMACK]. The CPU must only consider FlexCAN to be in Disable mode when both the request and acknowledgment conditions are satisfied.

If FlexCAN is disabled during Freeze mode, the module requests to disable the clocks to the PE and CHI submodules, writes 1 to MCR[LPMACK] and writes 0 to MCR[FRZACK].

If the module is disabled during transmission or reception, FlexCAN:

1. Waits to be in either Idle or Bus Off state, or waits for the third bit of Intermission and then checks that it is recessive.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. FlexCAN does not take a pending move-in into account.
3. Ignores its receive input pin and drives its transmit pin as recessive.

4. Shuts down the clocks to the PE and CHI submodules.
5. Writes 1 to MCR[NOTRDY] and MCR[LPMACK].

In this mode, the Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except for:

- The Receive Message Buffers Global Mask registers
- The Receive Buffer 14 Mask register
- The Receive Buffer 15 Mask register
- The Legacy Receive FIFO Global Mask register

When in Disable mode, these items may not be accessed:

- The Legacy Receive FIFO Information register
- The message buffers
- The Receive Individual Mask registers
- The reserved words within RAM

To exit this mode, the CPU writes 0 to MCR[MDIS], causing FlexCAN to request to resume the clocks and write 0 to MCR[LPMACK]. This write occurs after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

### 70.3.2 Transmission process

**NOTE**

Instances of MB_CS in this topic refer to items in message buffers. See Message buffer structure for details.

To transmit a CAN frame, the CPU must prepare a message buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt flag is set, and clear it if necessary.
2. If the message buffer is active (transmission pending), request an abort of the transmission. Write the ABORT code (1001b) to the CODE field of the Control and Status word.
3. Poll the IFLAG register until the corresponding IFLAG flag is set, or wait for the interrupt request (if enabled by the respective IMASK field).
4. Read the CODE field to identify whether the transmission was aborted or transmitted (see Transmission abort mechanism).
5. Clear the corresponding interrupt flag.
6. Write the ID register (containing the local priority if enabled via MCR[LPRIOEN]).
7. Write payload data bytes.
8. Configure the Control and Status word as needed.
    a. Set ID type via MB_CS[IDE].
    b. Set Remote Transmission Request (if needed) via MB_CS[RTR].
    c. If MCR[FDEN] = 1, configure MB_CS[EDL] and MB_CS[BRS]. For details about the relationship between the written value and transmitted value of MB_CS[ESI], see Table 431.[7]
    d. Configure Data Length Code in bytes via MB_CS[DLC]. See Table 457 for detailed information.
    e. To transmit the CAN frame, activate the message buffer by writing Ch to MB_CS[CODE].

[7] There is no need to write the ESI field; it is automatically transmitted as dominant by error active nodes and as recessive by error passive nodes. If FlexCAN is operating as a network gateway, however, the CPU writes MB_CS[ESI] according to the error status of the node that sent the message.

**NOTE**

To maximize software performance, configure all the fields in the MB_CS word in a single 32-bit write operation. If the fields are configured in separate writes, MB_CS[CODE] must be the last write in the Control and Status word.

When the MB is activated, it participates in the arbitration process and its contents are eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission exceeds the MB payload size, FlexCAN completes the expected DLC by adding a constant CCh pattern.

After a successful transmission:

1. The value of the free-running timer is written into the timestamp field.
2. The CODE field in the Control and Status word is updated.
3. Both Cyclic Redundancy Check (CRCR) and CAN FD CRC (FDCRC) are updated.
4. A status flag is set in the Interrupt Flag register.
5. If allowed by the corresponding Interrupt Mask Register field, an interrupt is generated.

After transmission, the new CODE field depends on the code used to activate the message buffer (see Table 453 and Table 454 in Message buffer structure).

When the Abort feature is enabled (MCR[AEN] is 1), after the Interrupt flag is set for an MB configured as transmit buffer, the message buffer is blocked. The CPU cannot update the message buffer until the Interrupt Flag is cleared by the CPU. The CPU must clear the corresponding IFLAG flag before preparing this MB for a new transmission or reception.

**NOTE**

For backward compatibility (MCR[AEN] is 0), write the INACTIVE code (1000b) to the CODE field to deactivate the MB. In this case, the pending frame may be transmitted without notification (see Message buffer inactivation).

### 70.3.3 Arbitration process

The arbitration process scans the message buffers, searching for the transmission MB that holds the message to be sent at the next opportunity. This MB is called the arbitration winner. The scan starts from the lowest number MB and continues to the higher ones.

The arbitration process is triggered when at least one of the following occur:

- CRC field of the CAN frame arrives. The starting point depends on the value of CTRL2[TASD].
- Error Delimiter field of a CAN frame is in progress.
- Overload Delimiter field of a CAN frame is in progress.
- The winner of the arbitration is deactivated, and the CAN bus has not reached the first bit of the Intermission field.
- CPU writes to the Control and Status word of a winner MB, and the CAN bus has not reached the first bit of the Intermission field.
- CHI is in the Idle state and the CPU writes to the Control and Status word of any message buffer.
- FlexCAN exits Bus Off state.
- FlexCAN leaves Freeze mode or a low-power mode.

If the arbitration process does not evaluate all message buffers before the CAN bus reaches the first bit of the Intermission field, the temporary arbitration winner is invalidated. FlexCAN will not compete for the CAN bus at the next opportunity.

The arbitration process selects the winner among the active transmission message buffers at the end of the scan according to the values of CTRL1[LBUF] and MCR[LPRIOEN].

See Arbitration process (continued) for more information about this process.

#### 70.3.3.1 Lowest-number message buffer first

If CTRL1[LBUF] is 1, the first (lowest number) active transmission message buffer found is the arbitration winner. MCR[LPRIOEN] has no effect when CTRL1[LBUF] is 1.

#### 70.3.3.2 Highest-priority message buffer first

If CTRL1[LBUF] is 0, the arbitration process searches for the active transmission message buffer with the highest priority. The frame of this message buffer has a higher probability of winning the arbitration on the CAN bus when multiple external nodes compete for the bus simultaneously.

The sequence of bits considered for this arbitration is called the arbitration value of the message buffer. The transmission message buffer with the lowest arbitration value among all transmission message buffers has the highest priority.

If two or more message buffers have equivalent arbitration values, the message buffer with the lowest number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIOEN].

##### 70.3.3.2.1 Local priority disabled

If MCR[LPRIOEN] = 0, the arbitration value is built using the exact sequence of bits that would be transmitted in a CAN frame where local priority is disabled.

**Table 421. Composition of the arbitration value when local priority is disabled**

| Format | Message buffer arbitration value (32 bits) | | | | |
|---|---|---|---|---|---|
| Standard (IDE = 0) | Standard ID (11 bits) | RTR (1 bit) | IDE (1 bit) | — (18 bits) | — (1 bit) |
| Extended (IDE = 1) | Extended ID[28:18] (11 bits) | SRR (1 bit) | IDE (1 bit) | Extended ID[17:0] (18 bits) | RTR (1 bit) |

##### 70.3.3.2.2 Local priority enabled

To enable local priority, MCR[LPRIOEN] must be 1. In this case, the message buffer PRIO field (see Message buffer structure) is included at the very left of the arbitration value.

**Table 422. Composition of the arbitration value when local priority is enabled**

| Format | Message buffer arbitration value (35 bits) | | | | | |
|---|---|---|---|---|---|---|
| Standard (IDE = 0) | PRIO (3 bits) | Standard ID (11 bits) | RTR (1 bit) | IDE (1 bit) | — (18 bits) | — (1 bit) |
| Extended (IDE = 1) | PRIO (3 bits) | Extended ID[28:18] (11 bits) | SRR (1 bit) | IDE (1 bit) | Extended ID[17:0] (18 bits) | RTR (1 bit) |

Because the PRIO field is the most significant part of the arbitration value, message buffers with low PRIO values have higher priority than message buffers with high PRIO values. This priority is maintained regardless of the rest of their arbitration values.

The PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

#### 70.3.3.3 Arbitration process (continued)

After the arbitration winner is found (see Arbitration process), its content is copied to a hidden auxiliary message buffer called a transmit serial message buffer (TX SMB). The TX SMB has the same structure as a normal message buffer, but is not user-accessible. This copy operation is called move-out. After it is done, write access to the Control and Status word of the corresponding MB is blocked (if MCR[AEN] = 1). Write access is restored in one of the following events:

- The CPU clears the corresponding IFLAG flag after the message buffer is transmitted.
- FlexCAN enters Freeze mode or Bus Off state.
- FlexCAN loses the bus arbitration, or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the TX SMB is transmitted according to the CAN protocol rules.

The arbitration process can be triggered under the following conditions:

- During RX and TX frames from CAN CRC field to end of frame. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.
- During CAN Bus Off state from TX_ERR_CNT = 124 to 128. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.
- During Control and Status write by CPU in Bus Idle. The first Control and Status write starts the arbitration process, and a second Control and Status write during this same arbitration restarts the process. If other Control and Status writes are performed, the transmission arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and Bus Idle state starts, then an arbitration process is triggered. In this case, the first and second Control and Status writes in Bus Idle do not restart the arbitration process. If there is not enough time to finish arbitration in the Wait for Bus Idle state and the next state is Idle, the scan is not interrupted. That scan is completed during Bus Idle state. During this arbitration, a Control and Status write does not cause an arbitration restart.
- Deactivation of an arbitration winner during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the Wait for Bus Idle state). If a resynchronization occurs during the Wait for Bus Idle state, the arbitration process is restarted.

The arbitration process stops when:

- All message buffers are scanned.
- A transmission message buffer is found (if lowest buffer feature is enabled).
- An arbitration winner deactivates or aborts during any arbitration process.
- There is not enough time to finish the transmission arbitration process (for instance, when a deactivation is performed near the end of frame). In this case, the arbitration process is pending.
- An error or overload flag occurs in the bus.
- A low-power or Freeze mode request occurs in Idle state.

Arbitration is considered pending when:

- It is not possible to finish arbitration process in time.
- A Control and Status write occurs during arbitration, when that write is performed in an MB whose number is lower than the transmission arbitration pointer.
- Any Control and Status write occurs when there is no transmission arbitration process in progress.
- RX Match has updated an RX code to TX code.
- FlexCAN enters the Bus Off state.

If a Control and Status write is performed in the arbitration winner, a new process is restarted immediately.

If a Control and Status write is performed in an MB whose number is higher than the transmission arbitration pointer, the ongoing arbitration process scans this MB as normal.

### 70.3.4 Receive process

To be able to receive CAN frames into a message buffer, the CPU must prepare it for reception by executing the following steps:

1. If the message buffer is active (either TX or RX), deactivate it (see Message buffer inactivation), preferably with a safe deactivation (see Transmission abort mechanism).

2. Write the ID word into the message buffer.
3. To activate the message buffer, write the EMPTY code (0100b) to the CODE field of the Control and Status word. No setup is required for EDL, BRS, and ESI fields. The respective fields in the received message overwrite these fields.

After the MB is activated, it can receive frames that match the programmed filter. At the end of a successful reception, the move-in process updates the message buffer (see Move-in) as follows:

1. The received data field (up to eight bytes for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.
3. The value of the free-running timer when the second bit of the Identifier field of the frame is written into the Timestamp field of the MB.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 453 and Table 454 in Section Message buffer structure).
6. If allowed by the corresponding Interrupt Mask field, a status flag is set in the Interrupt Flag register and an interrupt is generated.

The recommended way for the CPU to service (read) the frame received in a message buffer is:

1. Read the Control and Status word of that message buffer.
2. Verify that the BUSY bit is 0, indicating that the message buffer is locked. If it is not 0, repeat step 1 until it becomes 0. See Message buffer lock mechanism.
3. Read the contents of the message buffer. After the message buffer is locked, FlexCAN move-in processes do not modify its contents. See Move-in.
4. Acknowledge the proper flag in the IFLAG registers.
5. Unlock the message buffer by reading the free-running timer.

To verify frame reception, the CPU should poll the status flag bit for that specific message buffer in one of the IFLAG registers, not the CODE field of that message buffer. Polling the CODE field does not work in this case. After a frame is received and the CPU services the message buffer (by reading the Control and Status word and unlocking the message buffer), the CODE field does not return to EMPTY. It remains FULL, as explained in Table 453. If the CPU tries to work around this behavior by writing to the Control and Status word to force an EMPTY code after reading the message buffer without a prior safe deactivation, a newly received frame matching the filter of that message buffer may be lost.

**CAUTION**

In summary: never poll by reading the Control and Status word of the message buffers directly. Instead, read the IFLAG registers.

The Identifier field of the received frame is always stored in the matching message buffer. If the match was due to masking, the contents of the ID field in a message buffer may change. When MCR[SRXDIS] becomes 1, FlexCAN does not store frames transmitted by itself in any MB, even if it contains a matching receive MB. Also, no interrupt flag or interrupt signal is generated. Otherwise, when MCR[SRXDIS] becomes 0, if a matching receive MB exists, FlexCAN can receive frames transmitted by itself.

To be able to receive CAN frames through the Legacy RX FIFO, the CPU must enable and configure the Legacy RX FIFO during Freeze mode (see Legacy RX FIFO). Upon receiving the Frames Available in the Legacy RX FIFO interrupt (see MCR[BUF5I]), the CPU must service the received frame using the following procedure:

1. If a mask was used for IDE and RTR bits, read the Control and Status word.
2. If a mask was used, read the ID field.
3. Read the data field.
4. If the Identifier Acceptance Filter Hit Indicator (IDHIT) is required in the application, read Legacy RX FIFO Information (RXFIR).

5. Clear the Frames Available in Legacy RX FIFO interrupt by writing one to IFLAG1[BUF5I]. This step is mandatory; it releases the MB and allows the CPU to read the next RX FIFO entry.

When MCR[DMA]) becomes 1, upon receiving a frame in the Legacy FIFO, IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see Legacy RX FIFO in DMA operation). The IMASK1 fields in the Legacy RX FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 80h address, optional).
2. Read the ID field (read 84h address, optional).
3. Read all data bytes (start read at 88h address, optional).
4. Read the last data bytes (read 8Ch address, mandatory).

### 70.3.5 Matching process

The matching process scans the message buffer memory for RX MBs programmed with the same ID as the one received from the CAN bus. If the Legacy RX or Enhanced RX FIFO is enabled, the priority of scanning can be selected between MBs and FIFO filters. The matching starts from the lowest number message buffer and continues toward the higher-numbered ones. If no match is found within the first structure, the other is scanned afterward. If the FIFO is full, the matching algorithm always looks for a matching MB outside the FIFO region.

For enhanced RX FIFO, see Enhanced RX FIFO.

For legacy RX FIFO, see Legacy RX FIFO.

As the frame is received, it is stored in a hidden auxiliary MB called Receive Serial Message Buffer (RX SMB).

The starting point of the matching process depends on the following conditions:

- If the received frame is a remote frame, the starting point is the CRC field of the frame.
- If the received frame is a data frame with DLC field equal to zero, the starting point is the CRC field of the frame.
- If the received frame is a data frame and the DLC field has a nonzero value, the starting point is the DATA field of the frame.

If a matching ID is found in the FIFO table or in one of the message buffers, the move-in process transfers the contents of the RX SMB to the FIFO or to the matched MB. If any CAN protocol error is detected, no match results are transferred to the FIFO or to the matched MB at the end of reception.

The matching process scans all matching elements of the RX FIFO (if enabled) and active receive MBs (CODE is EMPTY, FULL, OVERRUN, or RANSWER). The process searches for a successful comparison to the matching elements of the RX SMB that is receiving the frame on the CAN bus. The RX SMB has the same structure as a message buffer. The reception structures (RX FIFO or message buffers) associated with the matching elements that had a successful comparison are the matched structures. The matching winner is selected at the end of the scan among those matched structures. The matching winner depends on conditions described in Table 423.

**Table 423. Matching architecture**

| Structure | SMB[RTR] | CTRL2[RRS] | CTRL2[EACEN] | MB[IDE] | MB[RTR] | MB[ID[1]] | MB[CODE] |
|---|---|---|---|---|---|---|---|
| Message buffer | 0 | — | 0 | cmp[2] | no_cmp[3] | cmp_msk[4] | EMPTY, FULL, or OVERRUN |
| Message buffer | 0 | — | 1 | cmp_msk | cmp_msk | cmp_msk | EMPTY, FULL, or OVERRUN |

*Table continues on the next page...*

Table 423. Matching architecture (continued)

| Structure | SMB[RTR] | CTRL2[RRS] | CTRL2[EACEN] | MB[IDE] | MB[RTR] | MB[ID[1]] | MB[CODE] |
|---|---|---|---|---|---|---|---|
| Message buffer | 1 | 0 | — | cmp | no_cmp | cmp | RANSWER |
| Message buffer | 1 | 1 | 0 | cmp | no_cmp | cmp_msk | EMPTY, FULL, or OVERRUN |
| Message buffer | 1 | 1 | 1 | cmp_msk | cmp_msk | cmp_msk | EMPTY, FULL, or OVERRUN |
| Legacy RX FIFO[5] | — | — | — | cmp_msk | cmp_msk | cmp_msk | — |

1. For message buffer structure, if SMB[IDE] is 1, the ID is 29 bits (ID Standard plus ID Extended). If SMB[IDE] is 0, the ID is 11 bits (ID Standard). For Legacy RX FIFO structure, the ID depends on IDAM.
2. cmp: Compares the RX SMB contents to the MB contents regardless of masks.
3. no_cmp: The RX SMB contents are not compared to the MB contents.
4. cmp_msk: Compares the RX SMB contents to MB contents, accounting for masks.
5. SMB[IDE] and SMB[RTR] are not considered when IDAM is type C.

**NOTE**

For Enhanced RX FIFO, see Enhanced RX FIFO matching process.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the message buffer is EMPTY.
- The CODE field of the message buffer is either FULL or OVERRUN, and it has already been serviced (the CPU has read the Control and Status word and unlocked it as described in Message buffer lock mechanism).
- The CODE field of the message buffer is either FULL or OVERRUN and an inactivation (see Message buffer inactivation) is performed.
- The Legacy RX FIFO or Enhanced RX FIFO is not full.

The scan order for message buffers and Legacy Receive FIFO is from the matching element with the lowest number to the higher ones.

### 70.3.5.1 Matching priority

MCR[IRMQ] affects the matching winner search for MBs. If the field is 0, the matching winner is the first matched MB whether it is free-to-receive or not. If it is 1, the matching winner is selected according to this priority:

1. The first free-to-receive matched message buffer
2. The last non-free-to-receive matched message buffer

It is possible to select the priority of scan between MBs and Legacy RX FIFO or Enhanced RX FIFO with CTRL2[MRP].

If the selected priority is RX FIFO first:

- If the RX FIFO is a matched structure and is free-to-receive, the RX FIFO is the matching winner regardless of the scan for MBs.
- Otherwise, the matching winner is searched for among MBs as described above.

If the selected priority is MBs first:

- If a free-to-receive matched MB is found, it is the matching winner regardless of the scan for RX FIFO.

- If no matched MB is found, then the matching winner is searched for in the scan for the RX FIFO.
- If both conditions above are not satisfied and a non-free-to-receive matched MB is found, then the matching winner depends on the value of MCR[IRMQ]:
  - If MCR[IRMQ] = 0, the matching winner is the first matched MB.
  - If MCR[IRMQ] = 1, the matching winner is the RX FIFO if it is a free-to-receive matched structure. Otherwise, the matching winner is the last non-free-to-receive matched MB.

**Table 424. Matching possibilities and resulting reception structures**

| RFEN or ERFEN | IRMQ | MRP | Matched in MB | Matched in FIFO | Reception structure | Description |
|---|---|---|---|---|---|---|
| **No FIFO, only MB, match is always MB first** | | | | | | |
| 0 | 0 | X[1] | None[2] | —[3] | None | Frame lost by no match |
| 0 | 0 | X | Free[4] | — | First MB | — |
| 0 | 1 | X | None | — | None | Frame lost by no match |
| 0 | 1 | X | Free | — | First MB | — |
| 0 | 1 | X | Not free | — | Last MB | Overrun |
| **FIFO enabled, no match in FIFO; is as if FIFO does not exist** | | | | | | |
| 1 | 0 | X | None | None[5] | None | Frame lost by no match |
| 1 | 0 | X | Free | None | First MB | — |
| 1 | 1 | X | None | None | None | Frame lost by no match |
| 1 | 1 | X | Free | None | First message buffer | — |
| 1 | 1 | X | Not free | None | Last message buffer | Overrun |
| **FIFO enabled; queue disabled** | | | | | | |
| 1 | 0 | 0 | X | Not full[6] | FIFO | — |
| 1 | 0 | 0 | None | Full[7] | None | Frame lost by FIFO full (FIFO overflow) |
| 1 | 0 | 0 | Free | Full | First MB | — |
| 1 | 0 | 0 | Not free | Full | First MB | |
| 1 | 0 | 1 | None | Not full | FIFO | |
| 1 | 0 | 1 | None | Full | None | Frame lost by FIFO full (FIFO overflow) |
| 1 | 0 | 1 | Free | X | First message buffer | — |

*Table continues on the next page...*

Table 424. Matching possibilities and resulting reception structures (continued)

| RFEN or ERFEN | IRMQ | MRP | Matched in MB | Matched in FIFO | Reception structure | Description |
|---|---|---|---|---|---|---|
| 1 | 0 | 1 | Not free | X | First message buffer | Overrun |
| **FIFO enabled; queue enabled** | | | | | | |
| 1 | 1 | 0 | X | Not full | FIFO | — |
| 1 | 1 | 0 | None | Full | None | Frame lost by FIFO full (FIFO overflow) |
| 1 | 1 | 0 | Free | Full | First message buffer | — |
| 1 | 1 | 0 | Not free | Full | Last message buffer | Overrun |
| 1 | 1 | 1 | None | Not full | FIFO | — |
| 1 | 1 | 1 | Free | X | First message buffer | — |
| 1 | 1 | 1 | Not free | Not full | FIFO | — |
| 1 | 1 | 1 | Not free | Full | Last message buffer | Overrun |

1. Indicates a don't care condition.
2. Matched in message buffer "None" means that the frame has not matched any message buffer (free-to-receive or non-free-to-receive).
3. This condition is forbidden.
4. Matched in message buffer "Free" means that the frame matched at least one message buffer free-to-receive regardless of whether it has matched MBs that are non-free-to-receive.
5. Matched in FIFO, "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO did not exist (CTRL2[RFFN] = 0 and ERFCR[ERFEN] = 0).
6. Matched in FIFO, "Not full" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO, "Full" means that the frame matched a FIFO filter but could not store it, because it has no empty slots to receive it.

### 70.3.5.2 Special cases

If a non-safe MB inactivation (see Message buffer inactivation) occurs during the matching process and the inactivated MB is the temporary matching winner, the temporary matching winner is invalidated. The matching elements scan is not stopped and not restarted; it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist. In this case, a message may be lost.

Consider an example where:

- The FIFO is disabled.
- MCR[IRMQ] is 1.
- There are two message buffers with the same ID: the second and fifth MBs in the array.
- FlexCAN starts receiving messages with that ID.

When the first message arrives, the matching algorithm finds the first match in message buffer number 2. The code of this message buffer is EMPTY, so the message is stored in that MB. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive." It continues looking, finds MB number 5, and stores the message in that MB.

If yet another message with the same ID arrives, the matching algorithm finds no matching free-to-receive MBs, so it overwrites the last matched message buffer (MB number 5). In doing so, it updates the CODE field of the message buffer to OVERRUN.

The ability to match the same ID in more than one MB can be used to implement a reception queue (in addition to the full-featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the message buffers. The CPU can examine the Timestamp field of the message buffers to determine the order in which the messages arrived.

Matching a range of IDs is possible via ID acceptance masks. FlexCAN supports individual masking per message buffer (see Receive Individual Mask (RXIMR0 - RXIMR95)). During the matching algorithm, if a mask field is 1, the corresponding ID bit is compared. If the mask field is 0, the corresponding ID bit is a "don't care". Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed when the module is in Freeze mode; otherwise, the module blocks them.

FlexCAN also supports an alternate masking scheme with only Legacy RX FIFO Global Mask (RXFGMASK), RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), and Receive 15 Mask (RX15MASK) for backward compatibility with legacy applications. This alternate masking scheme is enabled when the MCR[IRMQ] = 0.

## 70.3.6 Move process

There are two types of move process: move-in and move-out.

### 70.3.6.1 Move-in

The move-in process is the copying of a message received by an RX SMB to an RX message buffer or FIFO that has matched it. If the move destination is the Legacy RX FIFO, attributes of the message are also copied to the CAN_RXFIR FIFO. Each RX SMB has its own move-in process, but only one is performed at a given time. The move-in starts only when the message held by the RX SMB has a corresponding match (see Matching process) and all of the following conditions are true:

- The CAN bus has reached or already gone past:
  - The second bit of Intermission field next to the frame that carried the message that is in the RX SMB.
  - The first bit of an overload frame next to the frame that carried the message in the RX SMB.
- There is no ongoing matching process.
- The CPU is not locking the destination message buffer.
- No move-in process from another RX SMB is ongoing. If more than one move-in process is to be started at the same time, both are performed and the newest process substitutes for the oldest.

The term "pending move-in" is used throughout the documentation and stands for a move-to-be that does not satisfy all of the above conditions.

If any of the following conditions is satisfied, the move-in is canceled and the RX SMB is able to receive another message:

- The destination message buffer is inactivated after the CAN bus has reached the first bit of the Intermission field next to the frame that carried the message. Also, its matching process has finished.
- There is a previous pending move-in to the same destination message buffer.
- The RX SMB is receiving a frame transmitted by FlexCAN itself and self-reception is disabled (MCR[SRXDIS] = 1).
- Any CAN protocol error is detected.

If the module enters Freeze or Low-Power mode, the pending move-in is not canceled. It remains on hold, waiting for Freeze and Low-Power mode to be exited and for the module to be unlocked. If a message buffer is unlocked during Freeze mode, the move-in occurs immediately.

The move-in process is FlexCAN executing the following steps:

1. Push IDHIT into the RXFIR FIFO if the message is destined for the Legacy RX FIFO.
2. Read all data words from the RX SMB in accordance with the selected payload size for the RX storage element.

3. Write all data words to the RX message buffer according to the selected payload size for the RX storage element. If the data size of the storage element is smaller than the original payload size described in the DLC field of the message, the payload is truncated. The high-order bytes that do not fit the destination size are lost.
4. Read the Control and Status and ID words from the RX SMB.
5. Write the Control and Status and ID words to the RX message buffer, and update the CODE field.

The move-in process is not atomic; the inactivation of the destination message buffer immediately cancels it (see Message buffer inactivation). In this case, the message buffer may remain partially updated, and therefore incoherent. When the move-in destination is a Legacy or Enhanced RX FIFO message buffer, however, the process cannot be canceled.

To alert the CPU that the message buffer content is temporarily incoherent, the BUSY Bit (least significant bit of the CODE field) of the destination message buffer becomes 1 during move-in.

#### 70.3.6.2 Move-out

The move-out process is the copying of content from a TX message buffer to the TX SMB when a message for transmission is available (see Arbitration process). The move-out occurs in the following conditions:

- In the first bit of the Intermission field
- During the Bus Off state, when the TX error counter is in the 124 to 128 range
- During the Bus Idle state
- During the Wait for Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently outside the Bus Idle state. In Bus Idle, the move-out has the lowest priority of the concurrent memory accesses.

### 70.3.7 Data coherence

In order to maintain data coherency and proper FlexCAN operation, the CPU must obey the rules described in Transmission process and Receive process.

#### 70.3.7.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU whether the transmission was aborted or the frame could not be aborted and was transmitted instead.

These primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] must be 1.
- The first CPU action must be the writing of abort code (1001b) into the CODE field of the Control and Status word.

Active message buffers configured for transmission must be aborted before they can be updated. The write operation is blocked and the transmission is not disturbed when the abort code is written to:

- A message buffer currently being transmitted.
- A message buffer that was already loaded into the TX SMB for transmission.

In this case, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration.
- There is an error during the transmission.
- The module is put into Freeze mode.
- The module enters the Bus Off state.
- There is an overload frame.

If none of the conditions above are reached:

1. The message buffer is transmitted correctly.
2. The interrupt flag is set in the proper IFLAG register.
3. If enabled, an interrupt to the CPU is generated.

The abort request is automatically cleared when the interrupt flag is set. If only one of the above conditions is reached, the frame is not transmitted. In this case:

1. The abort code is written into the CODE field.
2. The interrupt flag is set in the proper IFLAG register.
3. Optionally, an interrupt is generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, the write operation is not blocked. The MB is updated and the interrupt flag is set. In this way, the CPU only needs to read the abort code to verify that the active MB was safely inactivated. In this case, although MCR[AEN] = 1 and the CPU wrote the abort code, the MB is inactivated and not aborted, because the transmission did not start yet. A message buffer is aborted only when the abort request is captured and kept pending until one of the previous conditions is satisfied.

#### 70.3.7.2 Message buffer inactivation

Inactivation protects the message buffer against updates by FlexCAN internal processes. It allows the CPU to rely on message buffer data coherence after having updated it, even in Normal mode.

Inactivation of transmission message buffers must be performed only when MCR[AEN] = 0.

If a message buffer is inactivated, it does not participate in the arbitration process or the matching process until it is reactivated. See Transmission process and Receive process for detailed instructions on how to inactivate and reactivate a message buffer.

To inactivate a message buffer, the CPU must update its CODE field to INACTIVE (either 0b or 1000b).

Because you cannot synchronize the CODE field update with FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of an inactivated RX message buffer may be lost without notice. This loss can occur even if there are other message buffers with the same filter.
- A frame containing the message within an inactivated TX message buffer may be transmitted without setting the respective IFLAG flag.

To perform a safe inactivation and avoid the above consequences for TX message buffers, the CPU must use the transmission abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the message buffer (see Message buffer lock mechanism).

**NOTE**

Message buffers that are part of the Legacy RX FIFO or Enhanced RX FIFO cannot be inactivated. There is no write protection on the Legacy FIFO region by FlexCAN. The CPU must maintain data coherency in the Legacy FIFO region when MCR[RFEN] = 1.

#### 70.3.7.3 Message buffer lock mechanism

In addition to message buffer inactivation, FlexCAN uses a message buffer lock mechanism to maintain data coherence for the receive process. When the CPU reads the Control and Status word of an RX message buffer with codes FULL or OVERRUN, FlexCAN is configured to allow the CPU to read the whole message buffer in an atomic operation. FlexCAN sets an internal lock flag for that message buffer.

The lock is released in any of the following events:

- The CPU reads the free-running timer (global unlock operation).
- The CPU reads the Control and Status word of another message buffer, regardless of its code.

- The CPU writes into the Control and Status word. This procedure is not recommended for normal unlocking, because it cancels a pending move and may lose a received message.

The message buffer lock prevents a new frame from being written into the message buffer when the CPU is reading it.

**NOTE**

The locking mechanism applies only to RX message buffers that are not part of the Legacy RX FIFO and have a code other than INACTIVE (0b) or EMPTY[1] (0100b). TX message buffers cannot be locked.

Consider an example where:

- The Legacy RX FIFO is disabled.
- The second and the fifth message buffers of the array are programmed with the same ID.
- FlexCAN has already received and stored messages into these two message buffers.
- The CPU reads message buffer number 5 while another message with the same ID is arriving.

When the CPU reads the Control and Status word of message buffer number 5, this message buffer is locked. The new message arrives and the matching algorithm finds no free-to-receive message buffers, so it overrides message buffer number 5. This message buffer is locked, so the new message cannot be written to it. The message remains in the RX SMB until the message buffer is unlocked, and only then is it written to the message buffer.

If the message buffer remains locked and another new message with the same ID arrives, the new message overwrites the one in the RX SMB. There is no indication of lost messages in the CODE field of the message buffer or in Error and Status 1 (ESR1).

When the message is moved from the RX SMB to the message buffer, the BUSY bit on the CODE field becomes 1. If the CPU reads the Control and Status word and identifies that the BUSY bit is 1, it must wait until the BUSY bit becomes 0 to access the MB.

**NOTE**

If the BUSY bit is 1 or the message buffer is empty, reading the Control and Status word does not lock the message buffer.

Inactivation takes precedence over locking. If the CPU inactivates a locked receive message buffer, then its lock status is negated and the message buffer is marked as invalid for the current matching round. Any pending message on the RX SMB is not transferred to the message buffer. A message buffer is unlocked when the CPU reads Free-Running Timer (TIMER) or the Control and Status word of another message buffer.

The lock and unlock mechanisms have the same functionality in Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. If unlocking occurs during a low-power mode, however, the move-in is postponed (see Modes of operation). Move-in takes place only when the module returns to Normal or Freeze mode.

### 70.3.8 Enhanced RX FIFO

FlexCAN supports an enhanced RX FIFO engine which can store up to 20 CAN FD messages. The region 2000h–204Fh contains the output of the FIFO, which the CPU should read. To enable the enhanced RX FIFO, write 1 to ERFCR[ERFEN]. FlexCAN has two FIFO options, Legacy RX FIFO and Enhanced RX FIFO, but both options cannot be enabled at the same time. See Legacy RX FIFO for additional information.

To configure the enhanced RX FIFO watermark, write a value to ERFCR[ERFWM]. If ERFCR[ERFWM] is configured, the CPU is notified only if a minimum number of messages is stored in the FIFO. When the number of stored messages is greater than the value in ERFCR[ERFWM], the module sets ERFSR[ERFWMI]. Optionally, if MCR[DMA] or ERFIER[ERFWMIIE] are enabled, a DMA transfer or an interrupt can be triggered, respectively.

For the enhanced RX FIFO to receive, the CPU must execute the configuration procedure below. If the CPU must change any configurations of the Enhanced RX FIFO, the same procedure must be followed.

[1] In previous FlexCAN versions, reading the Control and Status word locked the message buffer even when CODE indicates it is EMPTY. This behavior is maintained when the IRMQ bit is 0.

**Prerequisites**

MCR[RFEN] must be 0.

**Procedure**

| Step | Purpose | Programming | Notes |
|---|---|---|---|
| 1 | Enter Freeze mode. | See Freeze mode. | — |
| 2 | If enhanced RX FIFO is not already enabled, enable it. | Write 1 to ERFCR[ERFEN]. | — |
| 3 | Reset enhanced RX FIFO engine. | Write 1 to ERFSR[ERFCLR]. | — |
| 4 | If the enhanced RX FIFO error flags are set, clear them. | Write 1 to these flags:<br>• ERFSR[ERFUFW]<br>• ERFSR[ERFOVF]<br>• ERFSR[ERFWMI]<br>• ERFSR[ERFDA] | — |
| 5 | Specify the total number of enhanced RX FIFO filter elements to be used in Enhanced RX FIFO reception. | Write the number to ERFCR[NFE]. | — |
| 6 | Specify the number of extended ID and standard ID filter elements to be used in Enhanced RX FIFO reception. | Write the number to ERFCR[NEXIF]. | ERFCR[NEXIF] ≤ ERFCR[NFE] + 1. |
| 7 | If you are using DMA, enable DMA. | Write 1 to MCR[DMA]. | — |
| 8 | If you are using DMA, specify the number of words to transfer for each Enhanced RX FIFO data element. | Write the number to ERFCR[DMALW]. | — |
| 9 | Specify the Enhanced RX FIFO watermark. | Write the number to ERFCR[ERFWM]. | If MCR[DMA] = 1, ERFCR[ERFWM] should be 0h. |
| 10 | If you are using interrupts, enable the interrupts. | Write 1 to the interrupt enables in Enhanced RX FIFO Interrupt Enable (ERFIER). | — |
| 11 | Configure the filter elements. | Write to the ERFFEL*n* registers. | ERFFEL*n* registers are implemented in RAM; you must explicitly initialize them before prior any reception. |
| 12 | Exit Freeze mode. | See Freeze mode. | — |

There are two types of enhanced RX FIFO filter elements that can be stored in ERFFEL*n* registers: extended-ID filter elements and standard-ID filter elements. Each extended-ID filter element is stored in two ERFFEL*n* registers, and each standard-ID filter element is stored in one ERFFEL*n* register. ERFCR[NFE] defines the total number of Enhanced RX FIFO filter elements.

In addition, the filter memory space can be split into two regions: one for extended-ID filter elements and another for standard-ID filter elements, according to ERFCR[NEXIF]. Figure 371 shows how the enhanced RX filter elements are defined. See Enhanced RX FIFO matching process for information about the Enhanced RX FIFO matching process and filter element formats.

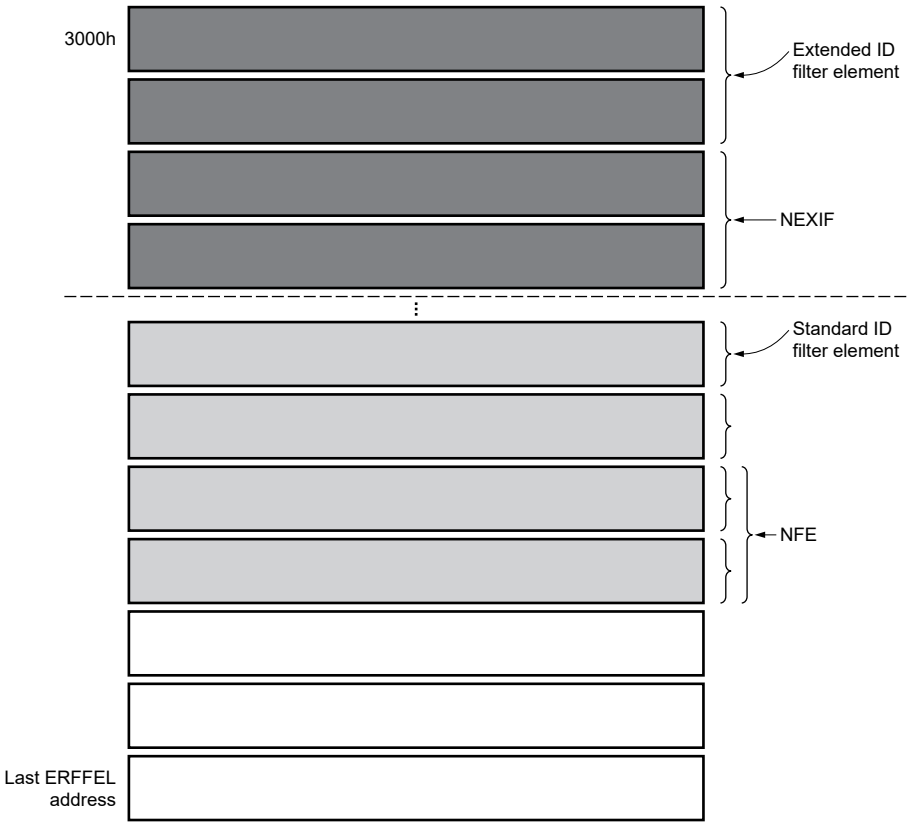

Figure 371. Number of enhanced RX FIFO filter elements

### 70.3.8.1 Enhanced RX FIFO matching process

When ERFCR[ERFEN] = 1, FlexCAN scans the ERFFEL*n* memory region. If at least one filter element satisfies the matching criteria, the CAN message content is transferred to the enhanced RX FIFO memory. If multiple filters match the incoming message ID, the first matching filter found by the matching process must be indicated in IDHIT.

Each ERFFEL*n* register can store one standard filter element. ERFFEL*n*[FEL][31:30], also called FSCH, determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base-frame format (IDE = 0).
  2. (ID[*n*] = STD ID filter [*n*]) or (STD ID Mask[*n*] = 0) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

In this explanation, RTR and ID are the Remote Transmit Request field and the ID from a CAN message, respectively.

If FSCH = b00, the filters and masks are defined as shown in Table 425.

Table 425. Standard ID filter element with filter and mask scheme (FSCH = b00)

| 31 | 30 | 29 | 28 | 27 | 26 | 16 | 15 | 12 | 11 | 10 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|
| FSCH = b00 | | Reserved | | RTR Filter | STD ID Filter | | Reserved | | RTR MASK | STD ID MASK | |

- If FSCH = b01, the filter scheme is based on range. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. ID ≥ STD ID Filter1.
  3. ID ≤ STD ID Filter2.
  4. (RTR = RTR filter) or (RTR MASK = 0).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b01, the filters and mask are defined as shown in Table 426.

**Table 426. Standard ID filter element with range scheme (FSCH = b01)**

| 31 | 30 | 29 | 28 | 27 | 26 | 16 | 15 | 12 | 11 | 10 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|
| FSCH = b01 | | Reserved | | RTR Filter | STD ID Filter2 | | Reserved | | RTR MASK | STD ID Filter1 | |

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. (ID[*n*] = STD ID Filter1[*n*]) or (ID[*n*] = STD ID Filter2[*n*]) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b10, the filters are defined as shown in Table 427.

**Table 427. Standard ID filter element with two-filter scheme (FSCH = b10)**

| 31 | 30 | 29 | 28 | 27 | 26 | 16 | 15 | 12 | 11 | 10 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|
| FSCH = b10 | | Reserved | | RTR Filter 2 | STD ID Filter2 | | Reserved | | RTR Filter 1 | STD ID Filter1 | |

Each pair of ERFFEL*n* registers can store one extended filter element. ERFFEL*n*[FSCH] determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID filter [*n*]) or (EXT ID Mask[*n*] = 0) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b00, the filters and masks are defined as shown in Table 428.

**Table 428. Extended ID filter element with filter + mask scheme (FSCH = b00)**

| 31 | 30 | 29 | 28 | 0 |
|---|---|---|---|---|
| FSCH | | RTR Filter | EXT ID Filter | |
| Reserved | | RTR MASK | EXT ID MASK | |

- If FSCH = b01, the filter scheme is based on range. A CAN message matches an extended ID filter element only if the following criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. ID ≥ EXT ID Filter1.
  3. ID ≤ EXT ID Filter2.
  4. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b01, the filters and masks are defined as shown in Table 429.

**Table 429. Extended ID filter element with range scheme (FSCH = b01)**

| 31 | 30 | 29 | 28 | 0 |
|---|---|---|---|---|
| FSCH | | RTR Filter | EXT ID Filter2 | |
| Reserved | | RTR MASK | EXT ID Filter 1 | |

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID Filter1[*n*]) or (ID[*n*] = EXT ID Filter2[*n*]) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

If FSCH = b10, the filters are defined as shown in Table 430.

**Table 430. Extended ID filter element with two-filter scheme (FSCH = b10)**

| 31 | 30 | 29 | 28 | 0 |
|---|---|---|---|---|
| FSCH | | RTR Filter2 | EXT ID Filter2 | |
| Reserved | | RTR Filter1 | EXT ID Filter 1 | |

### 70.3.8.2 Enhanced RX FIFO under DMA operation

You can enable the DMA feature by writing 1 to both ERFCR[ERFEN] and MCR[DMA]. The DMA controller can read the received message by reading a message buffer structure at the enhanced FIFO output port at the address range defined in Enhanced RX FIFO structure.

**NOTE**

FlexCAN supports 32-bit access only for DMA transfers.

For proper FIFO engine operation, the CPU should not access the Enhanced FIFO output port address range during DMA operation. Before writing 1 to MCR[DMA], the CPU must service Enhanced RX FIFO status bits. Otherwise, these bits may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must first clear the ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFWMI], and ERFSR[ERFDA] flags. It must then clear the enhanced RX FIFO engine by writing one to ERFSR[ERFCLR].

When there is one frame available to be read from the Enhanced RX FIFO, FlexCAN sets ERFSR[ERFDA]. Upon receiving the request, the DMA controller can read the message in the Enhanced RX FIFO output. Each message reading process must end by the address defined in ERFCR[DMALW].

Follow these rules for Enhanced RX FIFO DMA operation:

- Because a DMA transfer cannot be changed dynamically, program ERFCR[DMALW] so the enhanced RX FIFO element can store the largest CAN message present on the CAN bus.
- Data bytes are valid according to the DLC field. See Table 457.

Each time the DMA controller reads one message from the FIFO, FlexCAN clears ERFSR[ERFDA]. If there is at least one message stored in the FIFO, FlexCAN sets it again.

Consider an example where the maximum number of bytes in the data field of a CAN frame for a certain application is eight, and high-resolution timestamp is enabled. In that case, the last enhanced RX FIFO address offset can be found in Table 467 and Table 468. Using this address offset, ERFCR[DMALW] can be determined in this way:

- Maximum number of data bytes = 8
- HR_TIME_STAMP enabled
- Last address offset = TS_OFF = 2014h
- DMALW = 5

#### 70.3.8.3 Enhanced RX FIFO clear operation

When ERFCR[ERFEN] is 1, the CPU can clear the Enhanced RX FIFO by writing 1 to ERFSR[ERFCLR]. The clear operation resets the internal FIFO pointers, but the FIFO content stored in RAM is not changed. This operation can only be performed in Freeze mode; the module blocks the operation in other modes. This operation does not clear ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFDA], or ERFSR[ERFWMI]. The CPU must service all these fields before executing the clear FIFO operation.

### 70.3.9 Legacy RX FIFO

The Legacy RX FIFO is receive-only. To enable it, write 1 to MCR[RFEN]. To maintain software backward compatibility with previous versions of FlexCAN that did not have the Legacy FIFO feature, the reset value of this field is zero.

**CAUTION**

Do not enable Legacy RX FIFO when the CAN FD feature is enabled.

The Legacy FIFO is six messages deep. The memory region the Legacy FIFO structure occupies (both message buffers and Legacy FIFO engine) is described in legacy RX FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the Legacy FIFO.

IFLAG1[BUF5I] (Frames Available in Legacy RX FIFO) is set when at least one frame is available to be read from the Legacy FIFO. If the corresponding mask bit enables it, an interrupt is generated. Upon receiving the interrupt, the CPU can read the message (accessing the output of the Legacy FIFO as a message buffer) and Legacy RX FIFO Information (RXFIR), then clear the interrupt. If there are more messages in the Legacy FIFO, clearing the interrupt:

1. Updates the output of the Legacy FIFO with the next message.
2. Updates RXFIR with the attributes of that message.
3. Reissues the interrupt to the CPU.

Otherwise, the flag remains cleared. The output of the Legacy FIFO is valid only when IFLAG1[BUF5I] is set.

IFLAG1[BUF6I] (Legacy RX FIFO Warning) is set when the Legacy RX FIFO receives a new message that increases the number of unread messages from four to five. This change means that the Legacy RX FIFO is almost full. The flag remains set until the CPU clears it.

IFLAG1[BUF7I] (Legacy RX FIFO Overflow) is set when an incoming message is lost because the Legacy RX FIFO is full. The flag is not set when the Legacy RX FIFO is full and a message buffer captures the message. The flag remains set until the CPU clears it.

Clearing one of the three flags above does not affect the state of the other two.

If an IFLAG flag is set and the corresponding mask bit is 1, an interrupt is generated.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria are specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN]. This table can be configured to one of the following formats (see also legacy RX FIFO structure):

- Format A: 128 Identifier Acceptance Filters (IDAFs) — extended or standard IDs including IDE and RTR
- Format B: 256 IDAFs — standard IDs or extended 14-bit ID slices including IDE and RTR
- Format C: 512 IDAFs — standard or extended 8-bit ID slices

**NOTE**

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the Legacy RX FIFO has a corresponding Identifier Acceptance Filter Hit Indicator (IDHIT). The IDHIT can be read in the IDHIT field in the Control and Status word, as shown in the Legacy RX FIFO Structure description. The CPU can also obtain this information by accessing Legacy RX FIFO Information (RXFIR). RXFIR[IDHIT] refers to the message at the output of the Legacy FIFO, and is valid when IFLAG1[BUF5I] is set. RXFIR must be read only before clearing the flag, guaranteeing that the information refers to the correct frame within the Legacy FIFO.

The Individual Mask Registers (RXIMR*n*) individually affect up to 32 elements of the filter table, according to the value of CTRL2[RFFN]. This configuration allows very powerful filtering criteria to be defined. If MCR[IRMQ] is 0, the Legacy RX FIFO filter table is affected by Legacy RX FIFO Global Mask (RXFGMASK).

**NOTE**

See Table 419 for information about the difference between FD and non-FD regarding this feature.

#### 70.3.9.1 Legacy RX FIFO in DMA operation

The receive-only Legacy FIFO can support DMA. To enable this feature, write 1 to both MCR[RFEN] and MCR[DMA]. To maintain backward compatibility with previous versions of the module that did not have the DMA feature, the reset value of MCR[DMA] is zero.

The DMA controller can read the received message by reading a message buffer structure at the Legacy FIFO output port in the 80h–8Ch address range.

**NOTE**

FlexCAN supports 32-bit access only for DMA transfers.

When MCR[DMA] = 1, the CPU must not access the Legacy FIFO output port address range. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. Otherwise, these flags may indicate that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must perform a clear Legacy FIFO operation.

When at least one frame available to be read from the FIFO, IFLAG1[BUF5I] (Frames available in Legacy RX FIFO) is set. A DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the Legacy FIFO as a message buffer). The DMA reading process must end by reading address 8Ch. This read operation:

- Clears IFLAG1[BUF5I].
- Updates the FIFO output with the next message (if the FIFO is not empty).
- Updates Legacy RX FIFO Information (RXFIR) with the attributes of the new message.

If there are more messages stored in the FIFO, IFLAG1[BUF5I] is reasserted and another DMA request is issued. Otherwise, the flag remains cleared.

**NOTE**

RXFIR contents cannot be read after DMA completes the Legacy FIFO read. The IDHIT information is also available in the Control and Status word at address 080h (see legacy RX FIFO structure).

IFLAG1[BUF6I] and IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Legacy RX FIFO interruption and must not clear the related IFLAG flags. The related IMASK bits are not used to mask the generation of DMA requests.

**NOTE**

See Table 419 for information about the difference between FD and non-FD regarding this feature.

#### 70.3.9.2 Clear legacy FIFO

When MCR[RFEN] = 1, you can use the clear Legacy FIFO operation to empty Legacy FIFO contents. When the CPU writes 1 to IFLAG1[BUF0I], the clear FIFO operation occurs. This operation can only be performed in Freeze mode; FlexCAN blocks it in other modes. This operation does not clear the FIFO IFLAG flags; the CPU must service all FIFO IFLAG flags before executing the clear FIFO operation.

When Legacy RX FIFO is working with DMA, the clear FIFO operation clears IFLAG1[BUF5I], and the DMA request is canceled.

**CAUTION**

The clear Legacy FIFO operation does not clear IFLAG flags, except when MCR[DMA] = 1; in this case, only IFLAG1[BUF5I] is cleared.

### 70.3.10 CAN protocol-related features

#### 70.3.10.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure-detection capability that was in the original CAN FD protocol. This original protocol is also called non-ISO CAN FD, by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-ISO CAN FD protocol. FlexCAN still supports non-ISO CAN FD, so it can be used during an intermediate phase, for evaluation and development purposes.

It is recommended that you configure FlexCAN with the ISO CAN FD protocol by writing 1 to CTRL2[ISOCANFDEN].

#### 70.3.10.2 CAN FD frames

ISO 11898-1:2015 specifies the Classical Frame format compliant to ISO 11898-1:2003 (2003) and introduces the CAN Flexible Data Rate Frame format (CAN FD). The Classical Frame format allows bit rates up to one Mbit/s and payloads up to eight bytes per frame. The Flexible Data Rate Frame format allows bit rates faster than one Mbit/s and payloads longer than eight bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

There are additional control bits in the CAN FD frame:

- The Extended Data Length (EDL) bit enables a longer data payload with different data length coding.
- The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame.
- The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes.

There are no Remote Frames (see Remote frames) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in Classical CAN format. When an FD frame is received and matches a message buffer, the RTR bit in the receiving message buffer becomes 0. The RTR bit must be considered in classical frames only.

##### 70.3.10.2.1 CAN FD messages

CAN FD messages may be formatted as long frames where the data field exceeds eight bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching. In this case, the control field, data field, and CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and end of the frame. Messages in the classical CAN format are limited to transport a maximum payload of eight bytes at nominal rate. Figure 372 illustrates the message formats for classical and FD frames with either standard or extended ID.

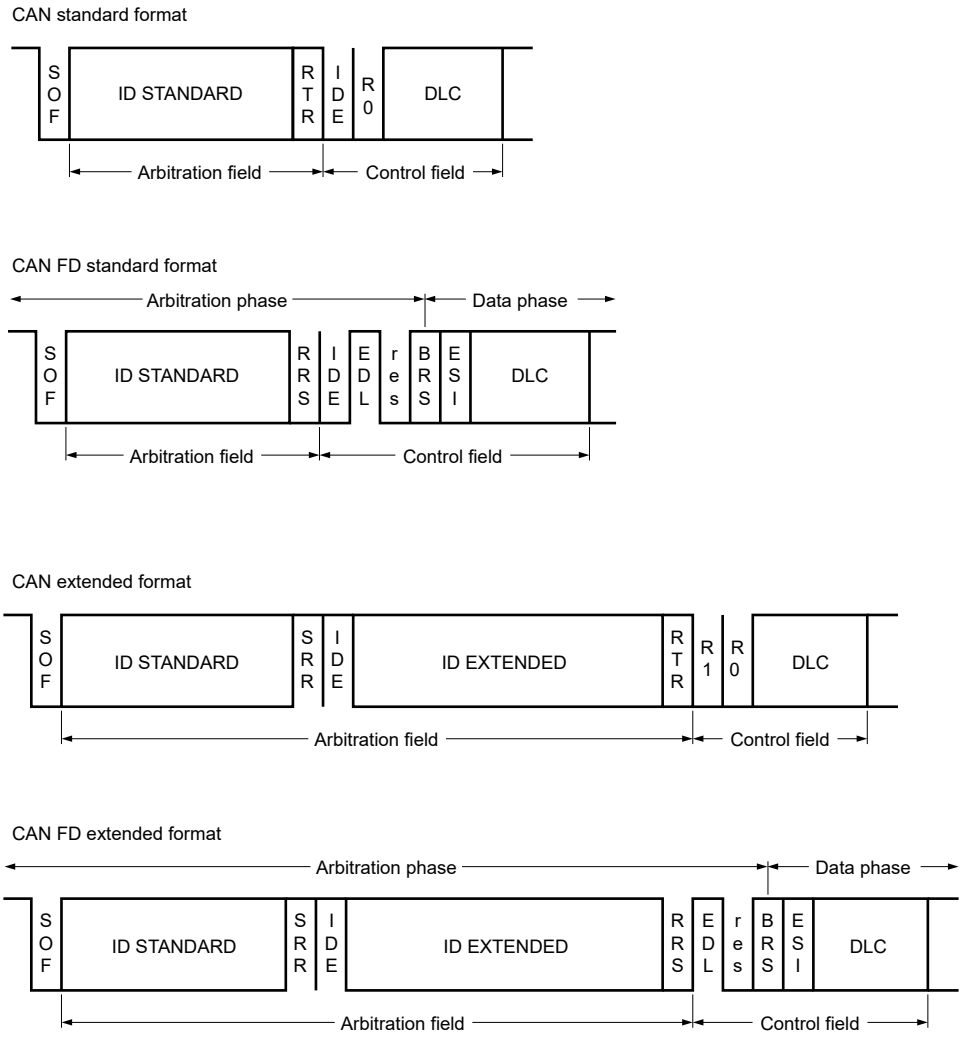

**Figure 372. CAN message formats**

MCR[FDEN] enables the ability to receive and transmit CAN FD messages. A recessive R0 bit in CAN frames with 11-bit identifiers, or a recessive R1 bit in CAN frames with 29-bit identifiers, is decoded as an EDL bit (not a reserved one). A recessive EDL bit identifies a CAN FD frame, and a dominant EDL bit identifies a Classical CAN frame. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded according to the DLC field value (see DLC definition in Message buffer structure).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start of Frame (SOF) bit until the Bit Rate Switch (BRS) bit is called the arbitration phase. This part is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, is called the data phase. When this second part is transmitted, a second set of CAN data bit timing configuration values determines the data bit rate. Finally, from the CRC delimiter until the Intermission bits, the transmission returns to nominal bit rate.

### 70.3.10.2.2 BRS in CAN FD

In CAN FD frames with bit rate switching, the bit timing changes inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by CAN Bit Timing (CBT). (Control 1 (CTRL1) also defines this timing for backward compatibility.) Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by CAN FD Bit Timing (FDCBT).

**NOTE**

If the time quantum length in nominal bit timing and in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase, and it lasts until the next synchronization event. The length of the time quantum should be the same in nominal and data bit timing. This configuration minimizes the chance of error frames on the CAN bus, and optimizes the clock tolerance in networks that use FD frames.

If BRS = 1 in the selected TX MB, FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching. If FDCTRL[FDRATE] = 0, the transmission is performed at nominal rate regardless of the BRS bit value. FDCTRL[FDRATE] can be written at any time but takes effect only for the next message transmitted or received.

Nominal bit timing is resumed at the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. Figure 373 describes the mechanism for entering and leaving the data phase when the BRS bit is recessive.

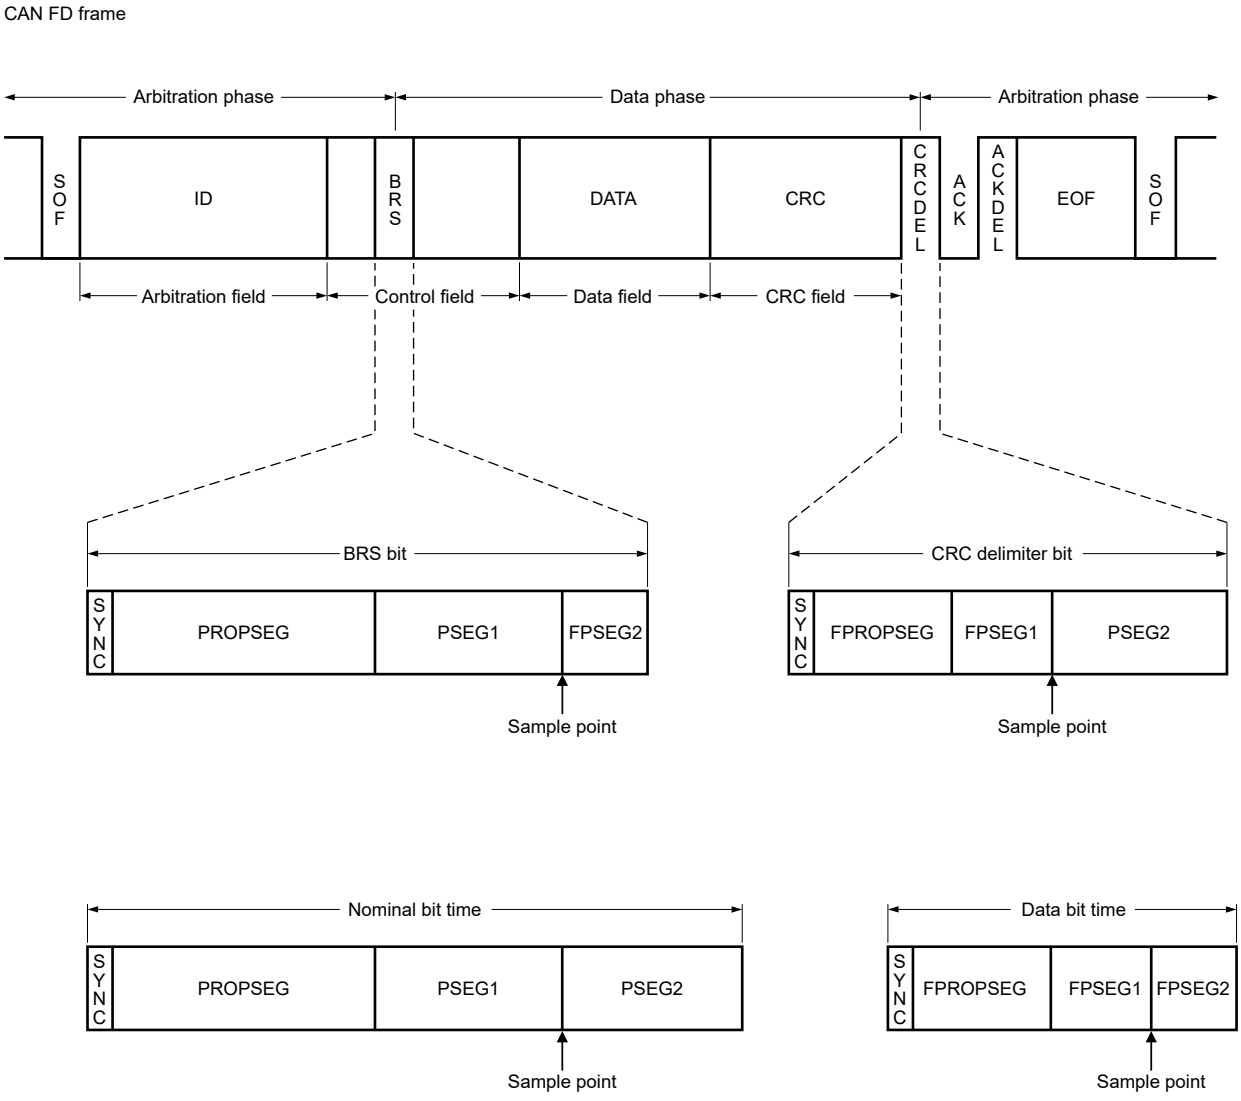

**Figure 373. Bit rate switching mechanism for CAN FD messages**

**NOTE**

In Classical CAN frames, the CRC delimiter is one recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter. It accepts two recessive bits before the recessive-to-dominant edge that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of the CAN_PE subblock. For example, for a CAN_PE clock frequency of 40 MHz and the shortest configurable bit time of 5 time quanta, the bit rate in the data phase is 8 Mbit/s.

**NOTE**

The frequency used in this example may not be supported on this chip. It is shown only to demonstrate how the maximum configurable bit rate is calculated.

#### 70.3.10.2.3 ESI in CAN FD

The value of the ESI field is determined by either of the following:

- The error state of the transmitter at the start of the transmission, if the frame is originated in the FlexCAN node
- The original transmitting node when FlexCAN is acting as a gateway for the message

If the transmitter is error-passive, ESI is transmitted recessive; otherwise, it is transmitted dominant. The permutations of the relationship between the written value and the transmitted value of the ESI are shown in Table 431.

**Table 431. Written versus transmitted values of the ESI field**

| FlexCAN fault confinement status at start of frame | ESI field of TX MB | Transmitted ESI |
|---|---|---|
| Error active | 0 | 0 (Error Active) |
| Error passive | 0 | 1 (Error Passive) |
| Error active | 1 | 1 (Error Passive) |
| Error passive | 1 | 1 (Error Passive) |

#### 70.3.10.2.4 CRC calculations in CAN FD

Different CAN frame formats have different CRC polynomials. The first polynomial, CRC_15, is used for all frames in Classical CAN format. The second, CRC_17, is used for frames in CAN FD format with a data field up to 16 bytes long. The third, CRC_21, is used for frames in CAN FD format with a data field longer than 16 bytes. Each polynomial results in a Hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The values of the EDL bit and the DLC field select the CRC sequence to be transmitted. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, CAN FD CRC (FDCRC) stores the calculated CRC for the transmitted message. This storage is performed with adequate length for the type of message, for CAN FD and non-FD messages. Cyclic Redundancy Check (CRCR) reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method changes for the CRC sequence, so the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence. This insertion occurs even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN receives a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

#### 70.3.10.2.5 CAN FD errors

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters ECR[RXERRCNT] and ECR[TXERRCNT] accumulate the counts of RX and TX errors, respectively, for both FD and non-FD frames indiscriminately. Two extra error counters, ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST], accumulate RX and TX errors occurring in the data phase of CAN FD frames with BRS = 1 only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see Error Counter (ECR)).

These error flags report errors in both CAN FD and non-FD frames:

- ESR1[BIT1ERR]
- ESR1[BIT0ERR]
- ESR1[ACKERR]
- ESR1[CRCERR]
- ESR1[FRMERR]
- ESR1[STFERR]

If CTRL1[ERRMSK] = 1, they also generate the ERRINT interrupt.

These additional error flags indicate the occurrence of errors in the data phase of CAN FD frames with BRS = 1:

- ESR1[BIT1ERR_FAST]
- ESR1[BIT0ERR_FAST]
- ESR1[CRCERR_FAST]
- ESR1[FRMERR_FAST]
- ESR1[STFERR_FAST]

No ACKERR is detected in the data phase of a CAN FD frame. Fault confinement status reported in ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on ECR[RXERRCNT] and ECR[TXERRCNT] only. Information in ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST] may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN detects an error while transmitting or receiving a CAN FD message in the data phase, it immediately switches:

- Back to the arbitration phase, and
- Back to the nominal rate to start an error flag.

#### 70.3.10.2.6 CAN FD synchronization

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in Classical CAN ones. A hard synchronization is also performed at the recessive-to-dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize when transmitting in the CAN FD data phase.

### 70.3.10.3 Transceiver delay compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase, when BRS = 1 in the message. This feature enables the use of rates up to 8 Mbit/s.

During the data phase of a CAN FD frame, if the transmitter cannot receive its own latest transmitted bit at the sample point of that bit, it detects a bit error. When bit rate switching is enabled (BRS = 1), the CAN bit time in the data phase can become shorter than the loop delay of the transceiver. This condition impedes the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

The transceiver delay compensation (TDC) process defines a secondary sample point where the transmitted bit is correctly compared to the received bit to check for bit errors.

You can enable the TDC mechanism via FDCTRL[TDCEN] or ETDC[ETDCEN]. The TDC mechanism is effective only during the data phase of FD frames with BRS = 1. It has no effect on either non-FD frames or FD frames transmitted at the normal bit rate. When the transmitted message has BRS = 1, TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit. When TDC is active, the real received bit is compared to the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

**NOTE**

The transmitters using TDC disregard the value of the CRC delimiter bit. A global error at the end of the CRC field causes the receivers to send error frames that the transmitter detects during Acknowledge or End of Frame.

For every transmitted FD frame with BRS = 1, the transition from the recessive EDL bit to the dominant R0 bit triggers the delay measurement (as shown in Figure 374). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see Protocol timing), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The measured loop delay time added to an offset value specified in FDCTRL[TDCOFF] or ETDC[ETDCOFF] determines the position of the secondary sample point. FDCTRL[TDCVAL] or ETDC[ETDCVAL] stores the result of this calculation. The TDCVAL and ETDCVAL value saturates at its maximum value of 63 CANCLK and 255 CANCLK when the delay measurement is too long.

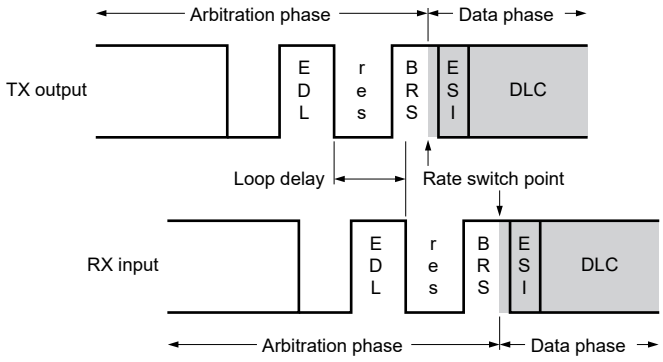

Figure 374. Transceiver loop delay measurement

The measured loop delay is not enough to define the secondary sample point, because it relates to the CAN bit edges. The transceiver delay compensation offset FDCTRL[TDCOFF] or ETDC[ETDCOFF] is used to shift the secondary sample point to an intermediate point inside the bit time, far away from its edges. The value of FDCTRL[TDCOFF] or ETDC[ETDCOFF] cannot be larger than the CAN bit duration in the data phase.

If the secondary sample point is set very near the CAN bit edge (SYNC field), problems may occur during the bit sampling in the data phase. For the TDC to work reliably, the offset must use optimal settings. To ensure that bit sampling is performed in the best region, configure the TDC offset as shown in this equation:

$$Offset = (FPSEG1 + FPROPSEG + 2) \times (FPRESDIV + 1)$$
*or*
$$Offset = (DTSEG1 + 2) \times (EDPRESDIV + 1), \textit{ if ETDCEN}$$

Equation 12. TDC offset calculation

Figure 375 shows the SSP position when these settings are used.

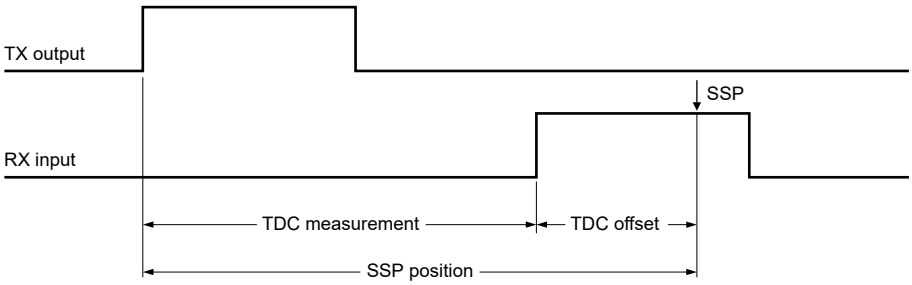

**Figure 375. SSP position with optimal values**

Alternatively, if CTRL2[BTE] and ETDC[ETDCEN] are 1, you can write 1 to ETDC[TDMDIS] to disable the transceiver delay measurement. In this case, only ETDC[ETDCOFF] defines the SSP position. Figure 376 shows the secondary sample point position when the transceiver delay measurement is disabled.

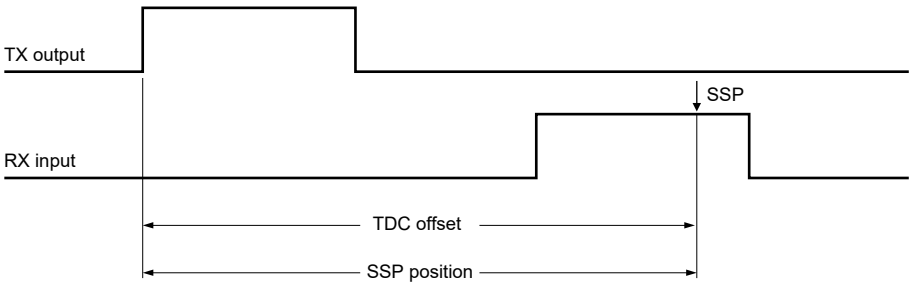

**Figure 376. SSP position with TDC measurement disabled by ETDCEN and TDMDIS**

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every TX CAN bit:

- The transmitted TX bit value is temporarily stored in a buffer.
- A time countdown based on FDCTRL[TDCVAL] or ETDC[ETDCVAL] is started. This countdown ends with the comparison of the received RX bit (delayed by the external loop delay plus the specified offset) to the stored TX bit.

If a bit error is detected at the secondary sample point, FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase, delay compensation is always disabled. During the data phase, the TDC mechanism of FlexCAN can compensate a maximum delay of 3 CAN bit times − 2 Tq. Beyond this limit, the FDCTRL[TDCFAIL] or ETDC[ETDCFAIL] flag is set. The flag indicates when the TDC mechanism is out of range and is unable to compensate the transceiver loop delay.

### 70.3.10.4 Remote frames

A remote frame is a special type of frame. You can program a message buffer to be a remote request frame by configuring the message buffer as Transmit with the RTR = 1. After the remote request frame is transmitted successfully, the message buffer becomes a receive message buffer, with the same ID as before.

When FlexCAN receives a remote request frame, the frame can be treated in different ways, depending on remote request storing (CTRL2[RRS]) and RX FIFO Enable (MCR[RFEN]):

- If RRS = 0, the ID of the frame is compared to the IDs of the transmit message buffers with the CODE field 1010b. If a matching ID exists, this message buffer frame is transmitted. If the matching message buffer has the RTR = 1, FlexCAN transmits a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response.

  The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. If a remote request frame is received and matches a message buffer, this message buffer immediately enters the internal arbitration process. However, it is considered a normal TX message buffer, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.

- If CTRL2[RRS] = 1, the ID of the frame is compared to the IDs of the receive message buffers with the CODE field 0100b, 0010b, or 0110b. If a matching ID exists, this message buffer stores the remote frame in the same fashion as a data frame. No automatic remote response frame is generated. The mask registers are used in the matching process.
- If MCR[RFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Legacy FIFO filtering criteria. If the remote frame matches one of the target IDs, it is stored in the Legacy FIFO and presented to the CPU.

  For filtering formats A and B (see legacy RX FIFO structure), it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted if they match the ID. Remote request frames are considered as normal frames. They generate a Legacy FIFO overflow when a successful reception occurs and the Legacy FIFO is already full.
- If ERFCR[ERFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Enhanced RX FIFO filtering criteria. Remote Request Frames are considered normal frames. They generate an Enhanced RX FIFO overflow when a successful reception occurs and the enhanced RX FIFO is already full.

**NOTE**

There is no remote frame in the CAN FD format. A fixed dominant RRS bit replaces the RTR bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

#### 70.3.10.5 Overload frames

When a dominant bit is detected on the CAN bus in these locations, FlexCAN transmits overload frames:

- The first or second bit of Intermission.
- The seventh bit (last) of End of Frame field (RX frames).
- The eighth bit (last) of Error Frame Delimiter or Overload Frame Delimiter.

#### 70.3.10.6 Message buffer timestamp

The value of the free-running timer is sampled at the beginning of the Identifier field on the CAN bus. This value is stored at the end of move-in in the TIME_STAMP field of a message buffer, providing network behavior regarding time.

When CTRL2[TIMER_SRC] = 1, an external time tick continuously clocks the free-running timer.

When CTRL2[TIMER_SRC] = 0, the FlexCAN bit clock clocks the free-running timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The free-running timer is not incremented during Disable and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See CTRL1[TSYN].

Alternatively, by configuring CTRL2[MBTSBASE], the timestamp of the message buffer can capture the lower or higher 16 bits of the high-resolution dedicated counter. See the chip-specific FlexCAN timestamp implementation.

#### 70.3.10.7 High-resolution timestamp

The high-resolution timestamp (HR_TIME_STAMP) uses a dedicated timer with a 32-bit counter operating in free-running mode. CTRL2[TSTAMPCAP] enables the high-resolution timestamp. When this field is not zero, the dedicated 32-bit counter value is captured during a valid CAN frame and stored in an HR_TIME_STAMP*n* register.

Each HR_TIME_STAMP*n* corresponds to a specific message buffer. For example, HR_TIME_STAMP0 stores the 32-bit timestamp associated with message buffer 0. HR_TIME_STAMP1 stores the 32-bit timestamp associated with message buffer 1, and so on.

The counter value is captured according to CTRL2[TSTAMPCAP]. For classical CAN frames, the capture points can be the start of frame bit or the point in time a CAN frame is considered valid. This valid point is the seventh bit of end of frame for transmission and the sixth bit of end of frame for reception.

For CAN FD frames, the capture points can be:

- The start of frame

- The point in time a CAN FD frame is considered valid
- The res bit of a CAN FD frame

The 16-bit timestamp of the message buffer can be configured to capture the lower or higher 16 bits of the high-resolution timer. This configuration is made by CTRL2[MBTSBASE]. See the chip-specific FlexCAN timestamp implementation.

#### 70.3.10.8 Protocol timing

Figure 377 shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule.

**NOTE**

To identify the proper clock source, see the clock distribution chapter (module clocks table).

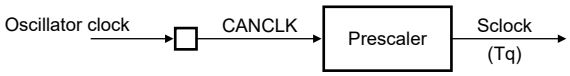

**Figure 377. CAN engine clocking scheme**

##### 70.3.10.8.1 Bit timing configuration

FlexCAN supports various means to configure bit timing parameters required by the CAN protocol. Control 1 (CTRL1) has various fields to control bit timing parameters:

- CTRL1[PRESDIV]
- CTRL1[PROPSEG]
- CTRL1[PSEG1]
- CTRL1[PSEG2]
- CTRL1[RJW]

CAN Bit Timing (CBT) extends the range of the CAN bit timing variables in CTRL1. Enhanced Data Phase CAN Bit Timing (EDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) = 1.

Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in CBT. Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in FDCBT. When using ENCBT and EDCBT, you must program the nominal bit timing and data phase serial clock (Sclock) dividers in Enhanced CAN Bit Timing Prescalers (EPRS).

**NOTE**

When the CAN FD feature is enabled, always write 1 to CBT[BTF] or CTRL2[BTE] and specify the CAN bit timing variables in CBT or ENCBT. See CAN Bit Timing (CBT) or Enhanced Nominal CAN Bit Timing (ENCBT).

CTRL1[PRESDIV], and its extended range CBT[EPRESDIV] (or EPRS[ENPRESDIV]) and FDCBT[FPRESDIV] (or EPRS[EDPRESDIV]) for the data phase bits of CAN FD messages, defines the prescaler value that generates the serial clock (Sclock). (See Equation 13.) The period of Sclock defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time managed by the CAN engine. It is the smallest time unit for all configuration values.

$$Tq = \frac{(PRESDIV + 1)}{f_{CANCLK}}$$

**Equation 13. Time quantum**

The bit rate, which defines the rate the CAN message is received or transmitted, is calculated with the formula:

$$CAN\ bit\ time = (Number\ of\ time\ quanta\ in\ 1\ bit\ time) \times Tq$$

$$Bit\ rate = \frac{1}{CAN\ bit\ time}$$

**Equation 14. CAN bit time and baud rate**

### 70.3.10.8.2 Bit time segments

A bit time is subdivided into three segments as shown in Figure 378. See also Figure 379 , Figure 380, and Table 432.

**NOTE**

For further explanation of the underlying concepts, see ISO 11898-1:2015. See also *CAN Specification Version 2.0, Part A and Part B* for bit timing.

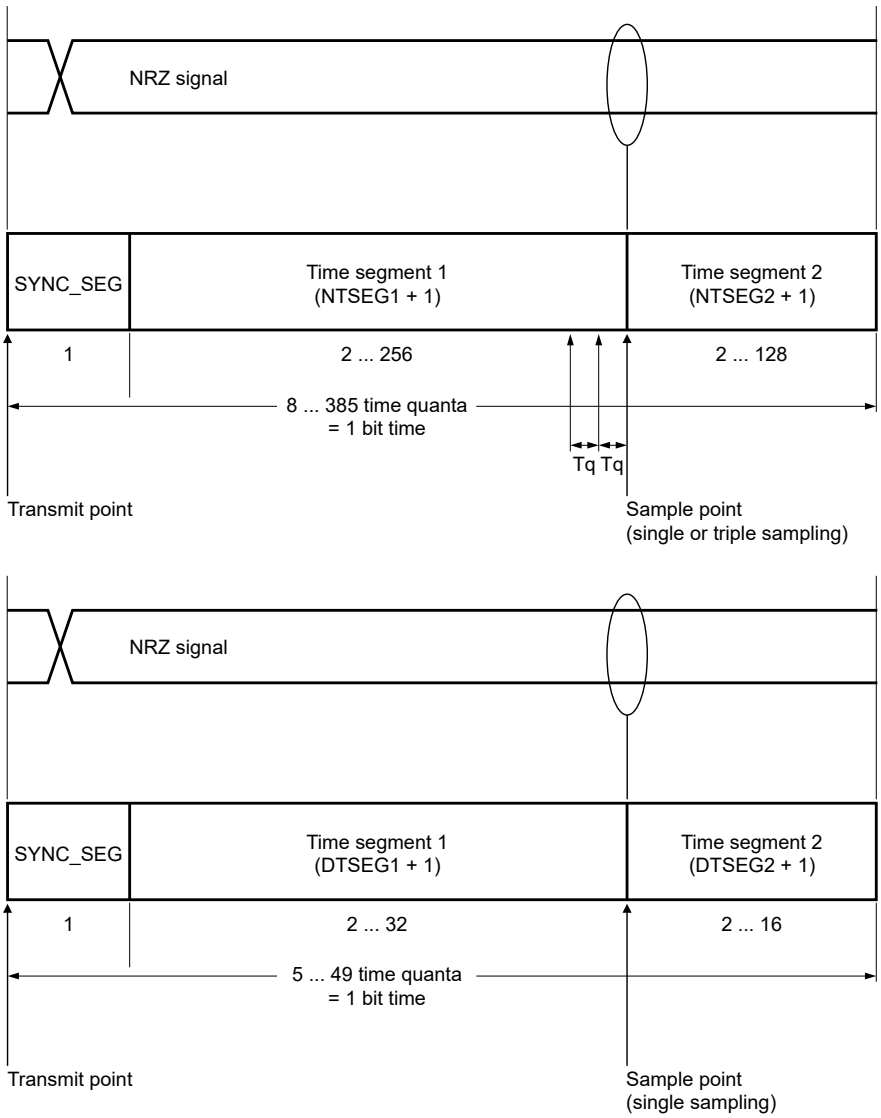

**Figure 378. Segments within the bit timing (example using ENCBT and EDCBT bit timing variables)**

The three bit time segments are:

- SYNC_SEG—this segment has a fixed length of one time quantum. Signal edges are expected to occur within this section.
- Time Segment 1—this segment includes the propagation segment and the phase segment 1 of the CAN standard.

  It can be programmed by configuring CTRL1[PROPSEG] and CTRL1[PSEG1] so that the sum (plus 2) is 2–16 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPROPSEG] and CBT[EPSEG1] so that the sum (plus 2) is 2–96 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses FDCBT[FPROPSEG] and FDCBT[FPSEG1] so that the sum (plus 1) is 2–39 time quanta.

  If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG1] to configure time segment 1 to 2–256 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG1] must be used for configuring time segment 1 to 2–32 time quanta.
- Time Segment 2—this segment represents the phase segment 2 of the CAN standard.

  It can be programmed by configuring CTRL1[PSEG2] (plus 1) to be 2–8 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPSEG2] so that its value (plus 1) is 2–32 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses FDCBT[FPSEG2] instead, so that its value (plus 1) is 2–8 time quanta. Time segment 2 cannot be smaller than the Information Processing Time (IPT), which is 2 time quanta in FlexCAN.

  If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG2] to configure time segment 2 to 2–128 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG2] must configure time segment 2 to 2–16 time quanta.

**NOTE**

The bit time defined by the above time segments must not be smaller than five time quanta. For bit time calculations, use an Information Processing Time (IPT) of two, which is the value implemented in the FlexCAN module.

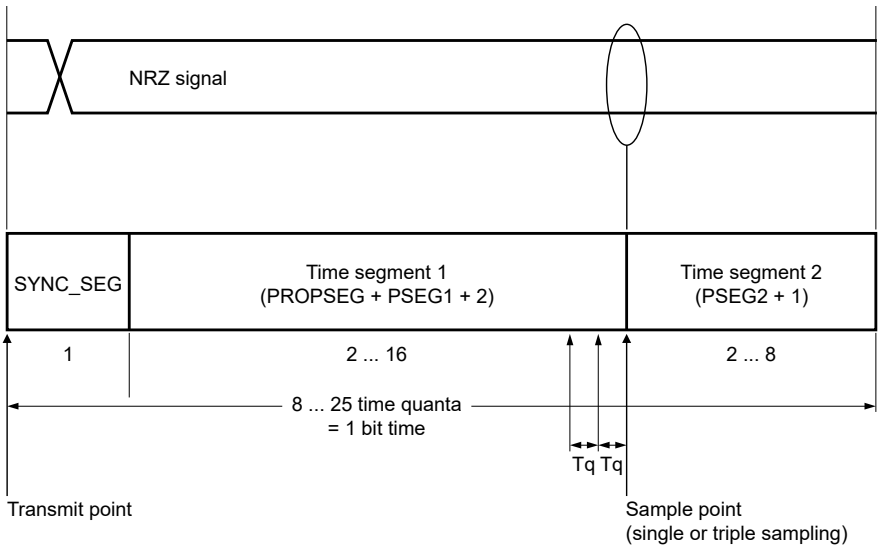

**Figure 379. Segments within the bit time (example using CTRL1 bit timing variables for Classical CAN format)**

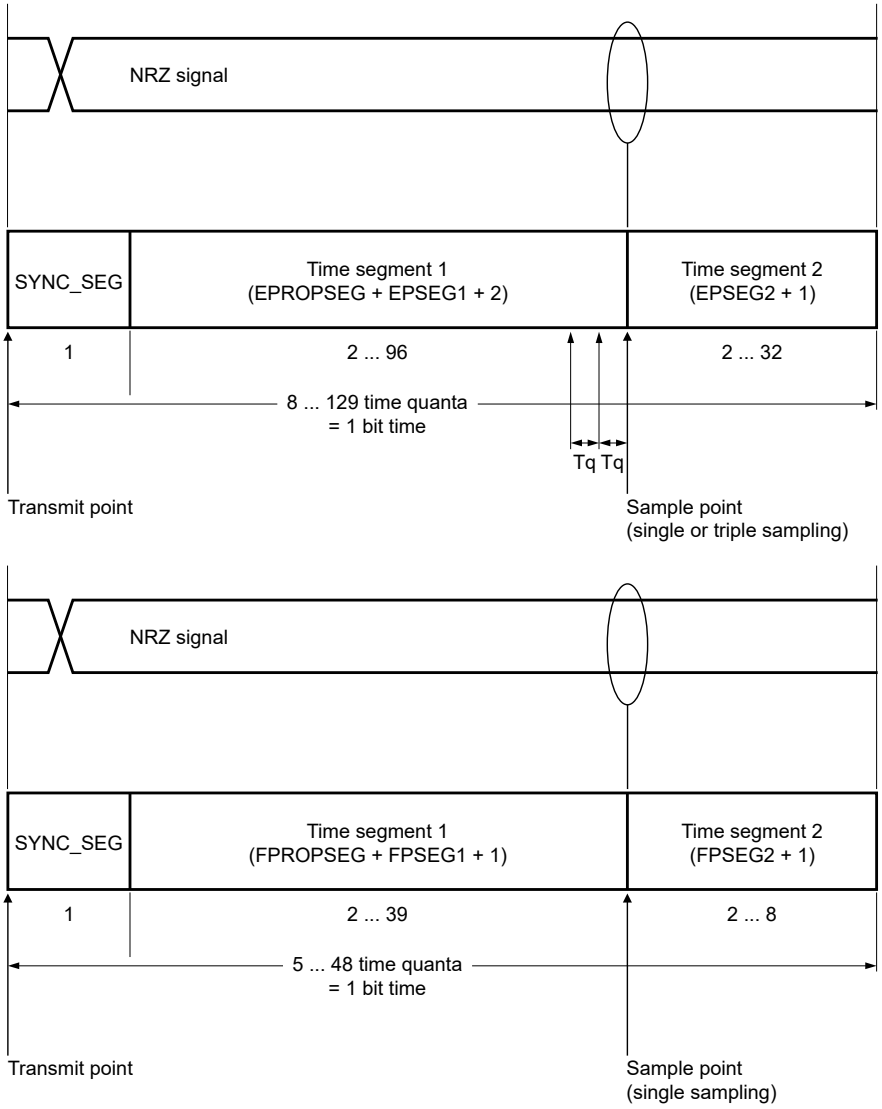

**Figure 380. Segments within the bit time (example using CBT and FDCBT bit timing variables for CAN FD format)**

**Table 432. Time segment syntax**

| Syntax | Description |
|---|---|
| SYNC_SEG | Period during which the system expects transitions to occur on the bus |
| TSEG1 | Period corresponding to the sum of PROPSEG and PSEG1 |
| TSEG2 | Period corresponding to the PSEG2 value |
| Transmit point | Point at which a node in Transmit mode transfers a new value to the CAN bus |
| Sample point | Point at which a node samples the bus. If the option of three samples per bit is selected, this point marks the position of the third sample. |

Table 433 gives some examples of the CAN-compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 433. Bosch CAN 2.0B standard compliant bit time segment settings

| Time segment 1 | Time segment 2 | Resynchronization jump width |
|---|---|---|
| 5 to 10 | 2 | 1 to 2 |
| 4 to 11 | 3 | 1 to 3 |
| 5 to 12 | 4 | 1 to 4 |
| 6 to 13 | 5 | 1 to 4 |
| 7 to 14 | 6 | 1 to 4 |
| 8 to 15 | 7 | 1 to 4 |
| 9 to 16 | 8 | 1 to 4 |

**NOTE**

You must ensure the bit time settings comply with the CAN Protocol standard (ISO 11898-1:2015).

### 70.3.10.8.3 Calculating peripheral clocks

A CAN bit can be used as a measure of duration (for example, estimating the occurrence of a CAN bit event in a message). When a CAN bit is used in this way, the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

Equation 15. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 0

Or, if CTRL2[BTE] = 1:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (ENPRESDIV + 1) \times (NTSEG1 + NTSEG2 + 3)$$

Equation 16. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 1

Where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- $f_{CANCLK}$ is the Protocol Engine (PE) Clock (see Figure 377), in Hz.
- $f_{SYS}$ is the frequency of operation of the system (CHI) clock, in Hz.
- PSEG1 is the value of CTRL1[PSEG1].
- PSEG2 is the value of CTRL1[PSEG2].
- PROPSEG is the value of CTRL1[PROPSEG].
- PRESDIV is the value in CTRL1[PRESDIV].
- ENPRESDIV is the value of EPRS[ENPRESDIV].
- NTSEG1 is the value of ENCBT[NTSEG1].
- NTSEG2 is the value of ENCBT[NTSEG2].

The formula above is also applicable to the alternative CAN bit timing variables described in:

- CAN Bit Timing (CBT)

- Enhanced Nominal CAN Bit Timing (ENCBT)
- CAN FD Bit Timing (FDCBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

For example, 180 CAN bits = (180 × NumClkBit) peripheral clock periods.

### 70.3.10.9 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in, and move-out processes are executed during certain time windows inside the CAN frame. These windows are shown in the following figures.

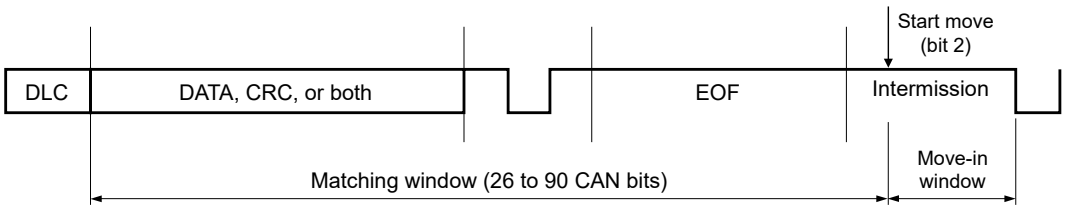

Figure 381. Matching and move-in time windows

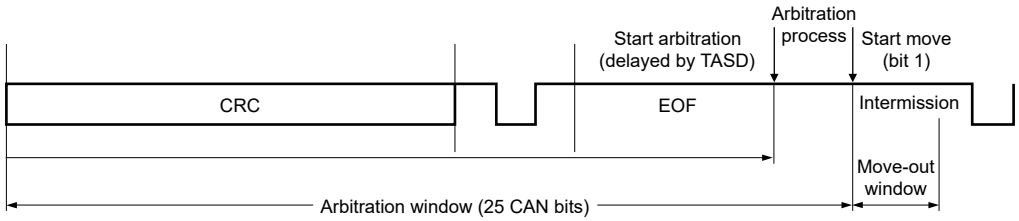

Figure 382. Arbitration and move-out time windows

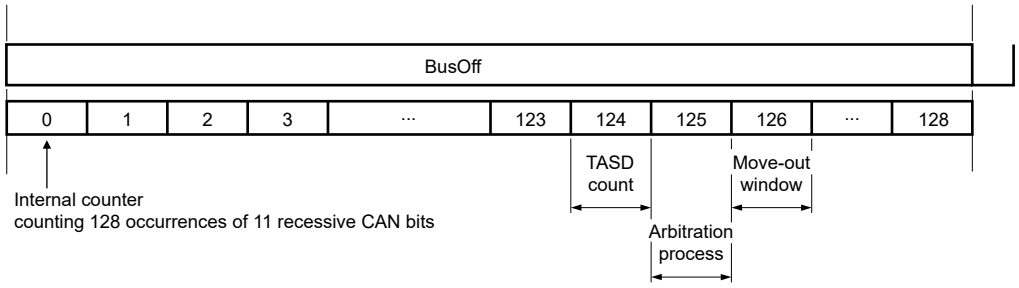

Figure 383. Arbitration at the end of bus off and move-out time windows

**NOTE**

In these figures, the matching and arbitration timing do not consider delays caused by concurrent memory access due to the CPU or other internal FlexCAN subblocks.

### 70.3.10.10 TX arbitration start delay

TX Arbitration Start Delay (CTRL2[TASD]) indicates the number of CAN bits that FlexCAN uses to delay the TX arbitration process starting point from the first bit of the CRC field of the current frame. This variable can be written only in Freeze mode; FlexCAN blocks it in other modes.

The ability of the CPU to reconfigure message buffers for transmission after the end of the internal arbitration process impacts transmission performance. In the arbitration process, FlexCAN finds the winner MB for transmission (see Arbitration process). If

the arbitration ends too early (before the first bit of the Intermission field) the CPU may reconfigure some TX message buffers. It is possible that the winning message buffer is no longer the best candidate to be transmitted.

TASD can optimize the transmission performance by defining the arbitration start point, as shown in Figure 384, based on factors such as:

- Peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- Number of message buffers in use by the matching and arbitration processes

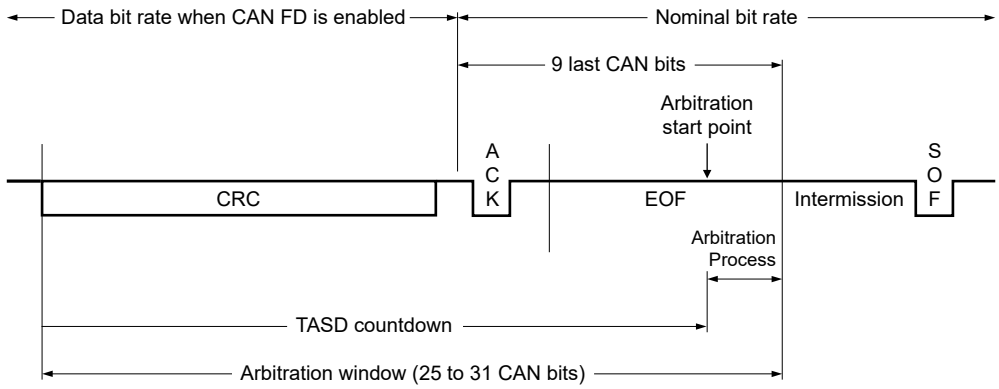

**Figure 384. Optimal TX arbitration start point**

The duration of an arbitration process, in terms of CAN bits, is:

- Directly proportional to the number of available message buffers
- Directly proportional to the CAN bit rate
- Inversely proportional to the peripheral clock frequency

The optimal arbitration timing occurs when the last message buffer is scanned immediately before the first bit of the Intermission field of a CAN frame. For instance, if the following are true:

- There are few message buffers.
- The peripheral-to-oscillator clock ratio is high.
- The CAN baud rate is low.

Then the arbitration can be placed closer to the end of the frame, adding more delay to its starting point, and vice versa.

If CTRL2[TASD] = 0, the arbitration start is not delayed, and more time is reserved for arbitration. Alternatively, if CTRL2[TASD] is close to 24, the CPU can configure a TX message buffer later, and less time is reserved for arbitration. If too little time is reserved for arbitration, FlexCAN may not be able to find a winner MB in time. The transmitted arbitration winner may not have the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

For CAN FD frames and (MAXMB + 1) ≤ $NMB_{END}$

$$TASD = 31 - \frac{2 * (MAXMB + 1) + 4}{CPCB_N}$$

For CAN FD frames and (MAXMB + 1) > $NMB_{END}$

$$TASD = 22 - \frac{2 * (MAXMB + 1) - NMB_{END}}{CPCB_F}$$

For non-FD frames

$$TASD = 25 - \frac{2 * (MAXMB + 1) + 4}{CPCB}$$

**Equation 17. Optimal value for TASD**

Where:

$$NMB_{END} = \frac{(9 \times CPCB_N) - 4}{2}$$

$$BITRATE_N = \left( \frac{f_{CANCLK}}{[1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] \times (EPRESDIV + 1)} \right)$$

$$BITRATE_F = \left( \frac{f_{CANCLK}}{[1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] \times (FPRESDIV + 1)} \right)$$

$$CPCB_N = \frac{f_{SYS}}{BITRATE_N}$$

$$CPCB_F = \frac{f_{SYS}}{BITRATE_F}$$

$$CPCB = CPCB_N$$

**Equation 18. Variables used in TASD calculation**

- MAXMB is the value in MCR[MAXMB].
- $NMB_{END}$ is the number of message buffers that the arbitration process can scan during the last nine CAN bits at the end of a frame. (See Equation 18.)
- $BITRATE_N$ is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- $BITRATE_F$ is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- $CPCB_N$ is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- $CPCB_F$ is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- $f_{CANCLK}$ is the oscillator clock, in Hz.
- $f_{SYS}$ is the peripheral clock, in Hz.
- EPSEG1 is the value in CBT[EPSEG1] (CTRL1[PSEG1] can also be used).
- EPSEG2 is the value in CBT[EPSEG2] (CTRL1[PSEG2] can also be used).
- EPROPSEG is the value in CBT[EPROPSEG] (CTRL1[PROPSEG] can also be used).
- EPRESDIV is the value in CBT[EPRESDIV] (CTRL1[PRESDIV] can also be used).
- FPSEG1 is the value in FDCBT[FPSEG1].

- FPSEG2 is the value in FDCBT[FPSEG2].
- FPROPSEG is the value in FDCBT[FPROPSEG].
- FPRESDIV is the value in FDCBT[FPRESDIV].
- NTSEG1 is the value in ENCBT[NTSEG1].
- NTSEG2 is the value in ENCBT[NTSEG2].
- ENPRESDIV is the value in EPRS[ENPRESDIV].
- DTSEG1 is the value in EDCBT[DTSEG1].
- DTSEG2 is the value in EDCBT[DTSEG2].
- EDPRESDIV is the value in EPRS[EDPRESDIV].

If CTRL2[BTE] = 1, then:

$$BITRATE_N = \frac{f_{CANCLK}}{[1 + (NTSEG1 + 1) + (NTSEG2 + 1)] \times (ENPRESDIV + 1)}$$

**Equation 19. Nominal baud rate when CTRL2[BTE] = 1**

$$BITRATE_F = \frac{f_{CANCLK}}{[1 + (DTSEG1 + 1) + (DTSEG2 + 1)] \times (EDPRESDIV + 1)}$$

**Equation 20. Fast baud rate when CTRL2[BTE] = 1**

See also Protocol timing for more details.

#### 70.3.10.10.1 TASD configuration examples

The following tables show the TASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (for example, peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

**Table 434. TASD values in Case 1**

| Number of message buffers | TASD value | Maximum bit rate in data phase (MBd) |
|---|---|---|
| 16 | 24 | Invalid |
| 32 | 24 | 8.0 |
| 64 | 23 | 8.0 |
| 96 | 22 | 8.0 |

Case 2:

- Clock ratio = 1:1 (for example, peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

**Table 435. TASD values in Case 2**

| Number of message buffers | TASD value | Maximum bit rate in data phase (MBd) |
|---|---|---|
| 16 | 24 | Invalid |

*Table continues on the next page...*

Table 435. TASD values in Case 2 (continued)

| Number of message buffers | TASD value | Maximum bit rate in data phase (MBd) |
|---|---|---|
| 32 | 23 | 6.67 |
| 54 | 22 | 5.0 |
| 64 | 21 | 3.33 |
| 96 | 20 | 1.6 |

Case 3:

- Clock ratio = 2:1 (for example, peripheral clock 40 MHz and oscillator clock 20 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 436. TASD values in Case 3

| Number of message buffers | TASD value | Maximum bit rate in data phase (MBd) |
|---|---|---|
| 16 | 24 | Invalid |
| 32 | 23 | 4.0 |
| 54 | 22 | 4.0 |
| 64 | 21 | 3.33 |
| 96 | 20 | 1.54 |

## 70.3.11 Clocks

The following table describes the clock sources for FlexCAN. See the chip clocking chapter for clock setting, configuration, and gating information.

Table 437. FlexCAN clocks

| Clock name | Description |
|---|---|
| MODULE_CLK (system_clk) | Peripheral clock |
| MODULE_CLK_CHI (host_clock) | Control Host Interface (CHI) clock |
| MODULE_CLK_PE (protocol_engine_clock) | Protocol Engine (PE) clock |
| MODULE_CLK_PE_NOGATE (protocol_engine_clock_nogate) | Protocol Engine clock (no gating) |
| MODULE_CLK_S (system_clock_nogate) | Peripheral access clock |

### 70.3.11.1 Clock domains and restrictions

FlexCAN has two clock domains asynchronous to each other:

- The bus domain feeds the Control Host Interface (CHI) submodule.
- The oscillator domain feeds the CAN Protocol Engine (PE) submodule.

When the two domains are connected to clocks with different frequencies or phases, the frequency relationship between the two clock domains is restricted. In asynchronous operation, the bus domain clock frequency must always be greater than the oscillator domain clock frequency.

**NOTE**

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When performing matching and arbitration, FlexCAN must scan the whole message buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. To provide sufficient time for the scan, observe the following requirements:

- The peripheral clock frequency cannot be less than the oscillator clock frequency.
- There must be a minimum number of peripheral clocks per CAN bit, as specified in Table 438.

**Table 438. Minimum number of peripheral clocks per CAN bit for Classical CAN format**

| Number of message buffers | Value of MCR[RFEN] | Value of ERFCR[ERFEN] | Minimum number of peripheral clocks per CAN bit |
|---|---|---|---|
| 16 | 0 | 0 | 16 |
| 32 | 0 | 0 | 16 |
| 64 | 0 | 0 | 25 |
| 96 | 0 | 0 | 37 |
| 16 | 1 | 0 | 16 |
| 32 | 1 | 0 | 17 |
| 64 | 1 | 0 | 30 |
| 96 | 1 | 0 | 42 |
| 16 | 0 | 1 | 16 |
| 32 | 0 | 1 | 19 |
| 64 | 0 | 1 | 31 |
| 96 | 0 | 1 | 42 |

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in Table 438 determines the minimum peripheral clock frequency for a given number of message buffers and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit. This number can be defined by adjusting one or more of the bit timing values contained in:

- Control 1 (CTRL1)
- CAN Bit Timing (CBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be eight, so the oscillator clock frequency should be at least eight times the CAN bit rate.

#### 70.3.11.1.1 Clock restrictions for CAN FD

For CAN FD frame format, some constraints must be satisfied. The equation below calculates the number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit).

$$NumClkNomBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

$$= \frac{f_{SYS}}{NomBitRate}$$

**Equation 21. Number of peripheral clocks per nominal CAN bit**

Where PRESDIV, PSEG1, and PSEG2 are CAN bit time values in Control 1 (CTRL1). Alternatively, EPRESDIV, EPSEG1, and EPSEG2 values in CAN Bit Timing (CBT) or the values of EPRS[ENPRESDIV], ENCBT[NTSEG1], and ENCBT[NTSEG2] can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate), as shown in the equation above.

The number of CAN bits in the data phase of an FD frame with BRS = 1 (fast CAN bits) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in Table 439. Having fewer data bytes means having fewer fast CAN bits. It also means that less time is available for FlexCAN to scan the whole message buffer memory during the internal matching and arbitration processes.

**Table 439. Number of fast CAN bits in a CAN FD frame**

| Minimum number of data bytes | DLC field | NumOfFastBits |
|---|---|---|
| 0 | 0h | 21 |
| 1 | 1h | 29 |
| 2 | 2h | 37 |
| 3 | 3h | 45 |
| 4 | 4h | 53 |
| 5 | 5h | 61 |
| 6 | 6h | 69 |
| 7 | 7h | 77 |
| 8 | 8h | 85 |
| 12 | 9h | 117 |
| 16 | Ah | 149 |
| 20 | Bh | 186 |
| 24 | Ch | 218 |
| 32 | Dh | 282 |
| 48 | Eh | 410 |
| 64 | Fh | 538 |

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the message buffer memory during reception and transmission. The equation below calculates this constraint.

$$MinNumClkFastBit_A = \frac{(8.5 \times MaxNumOfMb) + [ERFEN \times (2 \times NFE + 4)] + 64 - (9 \times NumClkNomBit)}{NumOfFastBits}$$

**Equation 22. Minimum number of peripheral clocks per fast CAN bit for FlexCAN scan process**

Where MaxNumOfMb is the maximum number of available message buffers defined in MCR[MAXMB]. NFE and ERFEN are the fields defined in Enhanced RX FIFO Control (ERFCR).

The clock-domain-crossing circuit between the CHI and PE subblocks also imposes a minimum number of peripheral clocks per fast CAN bit. This minimum is required for the handshake mechanism to work properly without losing status information through the interface, as shown in the equation below.

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{f_{SYS}}{f_{CANCLK}}\right)$$

**Equation 23. Minimum number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface**

Therefore, the larger of the two values calculated above determines the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit).

$$MinNumClkFastBit = Maximum\ (MinNumClkFastBitA, MinNumClkFastBitB)$$

**Equation 24. Minimum number of peripheral clocks per fast CAN bit**

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) can be calculated as below.

$$DataBitrate_{MAX} = \frac{f_{CANCLK}}{ROUNDUP\left(\frac{MinNumClkFastBit \times f_{CANCLK}}{f_{SYS}}\right)}$$

**Equation 25. Maximum achievable baud rate for data phase**

These factors affect the maximum data bit rate attainable by FlexCAN in CAN FD mode:

- The peripheral and oscillator clock frequencies
- The maximum number of message buffers
- The expected nominal bit rate

Also, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the configuration of FlexCAN variables affects the CAN FD bit rate, consider this application example:

- The peripheral clock frequency is set to 50 MHz
- The oscillator clock frequency is set to 40 MHz

1. Considering the nominal bit rate as 1 Mbit/s, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

   $$NumClkNomBit = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

   **Equation 26. Calculation example for number of peripheral clocks per nominal CAN bit**

2. The number of fast CAN bits (NumOfFastBits) is determined in Table 439. For example, if the minimum payload in FD frames is 8 bytes, there are 85 CAN bits in the data phase.
3. Assuming the maximum number of message buffers is 96, and Enhanced RX FIFO is disabled, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated.

   $$MinNumClkFastBit_A = \frac{(8.5 \times 96) + 64 - (9 \times 50)}{85} = 5.06$$

   **Equation 27. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN scan process**

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{50}{40}\right) = 6.75$$

**Equation 28. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface**

$$MinNumClkFastBit = Maximum\ (\ 5.06, 6.75\ ) = 6.75$$

**Equation 29. Calculation example for number of peripheral clocks per fast CAN bit**

4. The maximum CAN bit rate in the data phase can finally be found.

$$DataBitRate_{MAX} = \frac{40 \times 10^6}{ROUNDUP\left(\frac{6.75 \times 40 \times 10^6}{50 \times 10^6}\right)} = 6.667\ Mbps$$

**Equation 30. Calculation example for maximum achievable baud rate**

Even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbit/s in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbit/s. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

Table 440 shows the maximum data rate for CAN FD with Enhanced RX FIFO disabled according to clock frequencies, payload size, and number of available message buffers. For some cases, if the number of available message buffers is reduced, FlexCAN can then achieve a data rate up to 8 Mbit/s.

**Table 440. Maximum CAN bit rate in data phase on CAN FD frames with Enhanced RX FIFO disabled**

| Peripheral clock frequency (MHz) | Payload size | Number of available message buffers | Maximum data rate (Mbit/s) |
|---|---|---|---|
| 40 | 8 | 94 | 6.667 |
| 40 | 8 | 114 | >5.0 |
| 40 | 12 | >117 | 6.667 |
| 40 | 12 | 128 | 5.714 |
| 50 | 12–64 | 128 | 6.667 |
| 60 | 8 | 126 | 8.0 |
| 60 | 12 | 128 | 8.0 |
| 67 | 6 | 128 | 8.0 |
| 80 | 3 | 128 | 8.0 |
| 100 | 0 | 128 | 8.0 |

## 70.3.12 Reset

You can reset FlexCAN in the following ways:

- Soft reset:
  - MCR[SOFTRST], which resets some of the memory-mapped registers synchronously. To see which registers soft reset affects, see Table 443.
  - Chip-level soft reset, which has the same effect as MCR[SOFTRST].

Soft reset is synchronous and must follow an internal request-and-acknowledge procedure across clock domains. Therefore, it may take some time to propagate its effects fully. MCR[SOFTRST] remains 1 when soft reset is pending, so software can poll this field to identify when the reset has completed. Soft reset cannot be applied when clocks are shut down in a low-power mode. The low-power mode should be exited and the clocks resumed before applying soft reset.

When the module is enabled (MCR[MDIS] becomes 0), FlexCAN automatically enters Freeze mode. In Freeze mode:

1. FlexCAN is unsynchronized to the CAN bus.
2. MCR[HALT] and MCR[FRZ] become 1.
3. The internal state machines are disabled.
4. MCR[FRZACK] and MCR[NOTRDY] become 1.

The TX pin is in the recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Reset does not affect the message buffers and the RX Individual Mask registers, so they are not automatically initialized.

### 70.3.13 Interrupts

FlexCAN has many interrupt sources:

- Interrupts due to message buffers
- Interrupts due to interrupts combined via an OR operator from:
  - Message buffers
  - Bus Off
  - Bus Off Done
  - Error
  - Error Fast (errors detected in the data phase of CAN FD format messages with BRS = 1)
  - TX Warning
  - RX Warning

If its corresponding IMASK bit is 1, each message buffer can be an interrupt source. There is no distinction between TX and RX interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each buffer has an assigned flag bit in the IFLAG registers. When the corresponding buffer completes a successful transfer, the flag is set. When the CPU writes 1 to it, the flag is cleared (unless another interrupt is generated at the same time).

**NOTE**

The CPU must clear only the bit causing the current interrupt. For this reason, do not use bit manipulation instructions (BSET) to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt handler.

If the Legacy RX FIFO is enabled (MCR[RFEN] = 1) and DMA is disabled (MCR[DMA] = 0), the interrupts corresponding to message buffers 0–7 have different meanings.

- Bit 7 of Interrupt Flags 1 (IFLAG1) becomes the Legacy FIFO Overflow flag
- Bit 6 becomes the Legacy FIFO Warning flag
- Bit 5 becomes the Frames Available in Legacy FIFO flag
- Bits 4–0 are unused.

See Interrupt Flags 1 (IFLAG1) for more information.

If both Legacy RX FIFO and DMA are enabled (MCR[RFEN] = 1 and MCR[DMA] = 1), FlexCAN does not generate any Legacy FIFO interrupt. Bit 5 of IFLAG1 still indicates Frames Available in Legacy FIFO and generates a DMA request. Bits 7, 6, and 4–0 are unused.

**CAUTION**

Legacy FIFO cannot be enabled when CAN FD is enabled.

When multiple message buffer interrupt sources are combined via an OR operator into a single interrupt, the interrupt is generated when any associated message buffer (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which message buffer or FIFO source caused the interrupt.

These interrupt sources generate interrupts like the message buffer interrupt sources, and can be read from Error and Status 1 (ESR1):

- Bus Off
- Bus Off Done
- Error
- Error Fast
- TX Warning
- RX Warning

The Bus Off, Error, TX Warning, and RX Warning interrupt masks are located in Control 1 (CTRL1).

### 70.3.14 Bus interface

CPU access to FlexCAN registers is subject to the following rules:

- Unrestricted read and write access to supervisor registers results in an access error. In Table 443, supervisor registers are registers identified with an S, and registers that are identified with S/U that are in Supervisor Mode
- Read and write access to implemented reserved address space results in an access error.
- Write access to positions whose bits are all currently read-only results in an access error. If at least one of the bits is not read-only, no access error is issued. Write permission to specific positions or some of their bits can change depending on the mode of operation or transitory state. See register and field descriptions for details.
- Read and write access to unimplemented address space results in an access error.
- Read and write access to RAM-located positions during Low-Power mode results in an access error.
- The RXIMR memory region can be considered as general-purpose memory and available for access via these methods:
  - If you write 0 to MCR[IRMQ], the individual masks (RXIMR) are disabled. In this case, the RXIMR memory region is considered general-purpose memory.
  - If MCR[MAXMB] is programmed with a value smaller than the available number of message buffers, the unused memory space can be used as general-purpose RAM space. Reserved words within RAM cannot be used.
    For example, suppose the RAM in FlexCAN can support up to 16 message buffers, CTRL2[RFFN] = 0h, and MCR[MAXMB] = 0.
    - In this case, the maximum number of message buffers becomes one.
    - The RAM starts at 0080h, and the space 0080h–008Fh is used by the one message buffer.
    - The memory space 0090h–017Fh is available.
    - The space 0180h–087Fh is reserved.
    - The space 0880h–0883h is used by the one individual mask and the available memory in the mask register space is 0884h–08BFh.
    - In the space from 08C0h–09DFh, there are reserved words for internal use which cannot be used as general-purpose RAM.

    As a rule, free memory space for general purpose depends only on MCR[MAXMB].
  - If MCR[FDEN] = 1, general-purpose memory can be used only outside Freeze mode.

Table 441. Access permissions

1. Access in low power is only possible if RAM_clk and MODULE_CLK are enabled.
2. If MCR[RFEN] = 1, see Legacy FIFO access rules in the rows below.
3. Write operation has no effect.
4. If MCR[RFEN] = 1, do not access Enhanced RX FIFO.

### 70.3.15 Detection and correction of memory errors

To update the parity bits in memory properly, all FlexCAN memory must be initialized before starting its operation. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization, from 080h–ADFh and from C20h–31FFh. You must also initialize these registers:

- RX Message Buffers Global Mask (RXMGMASK)
- Receive 14 Mask (RX14MASK)
- Receive 15 Mask (RX15MASK)
- Legacy RX FIFO Global Mask (RXFGMASK)

MCR[RFEN] and ERFCR[ERFEN] must not be 1 during memory initialization.

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated with five parity bits that ensure a Hamming distance of 4. The error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors). Errors in two bits can be detected but not corrected (uncorrectable errors). Errors in more than two bits may not be detected. For uncorrectable errors, the error correction logic does not change the corrupted data. When a read access is performed, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

When an all-zeroes or an all-ones read occurs, FlexCAN detects an uncorrectable error. See Error Report Syndrome (RERRSYNR).

Memory errors are indicated to the host via status register (Error Status (ERRSR)) and bus transfer errors. Memory errors are reported via these report registers:

- Error Report Address (RERRAR)
- Error Report Data (RERRDR)

- Error Report Syndrome (RERRSYNR)

MECR[ECCDIS] determines whether the error detection and correction mechanism can be activated. When disabled, updates on indications and reporting registers are stopped. To ensure that memory has consistent parity bits associated with the data, the parity bits are still calculated and written with data in memory write operations.

To avoid accidentally changing the critical error correction configuration, follow this protocol to enable the update of Memory Error Control (MECR):

1. Write 1 to CTRL2[ECRWRE]. (By default, CTRL2[ECRWRE] is 0 and MECR[ECRWRDIS] is 1.)
2. Write 0 to MECR[ECRWRDIS].
3. All writes to Memory Error Control (MECR) must keep MECR[ECRWRDIS] = 0.
4. After configuration is done, lock MECR by writing 1 to MECR[ECRWRDIS] or writing 0 to CTRL2[ECRWRE].

#### 70.3.15.1 Sources of memory access

These major sources (or requestors) can access FlexCAN memory:

- Host (CPU). The largest word accessed is 32-bit.
- FlexCAN internal processes:
  - RX matching
  - TX arbitration
  - Move-in on reception
  - Move-out on transmission

  The largest word accessed is 64-bit.

The source of access determines the way that uncorrectable errors are indicated and reported.

#### 70.3.15.2 Error indication

These flags indicate memory errors:

- ERRSR[HANCEIF]
- ERRSR[FANCEIF]
- ERRSR[CEIF]

Uncorrectable errors detected in memory reads requested by the host are indicated separately from the errors detected in requests by FlexCAN internal processes. When correctable errors are detected, FlexCAN makes no distinction of the source of the access. There are three independent flags for these three cases, and each flag raises an interrupt unless a mask in Memory Error Control (MECR) masks it. If both uncorrectable and correctable errors are found in different bytes in the same read operation, both flags are set.

An uncorrectable error detected in host access is also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If ERRSR[HANCEIF] is not masked, the same uncorrectable error raises a bus transfer error and an interrupt request.

Each indication flag has one overrun flag in Error Status (ERRSR). The overrun flags do not request interrupts. Overrun flags for uncorrectable errors indicate that other errors of the same nature were detected after the current error being treated. Overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated.

The recommended handling sequence for error indication is:

1. Get error report information from report registers.
2. Use this information to take proper measures in the application.
3. Clear the ERRSR[HANCEIF], ERRSR[FANCEIF], and ERRSR[CEIF] flags.

4. If the overrun flag is active:
    a. Alert the application that at least one error could not be managed.
    b. Clear the overrun flag.

FlexCAN internal processes can access memory in transactions larger than 32 bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in two or more 32-bit words, the interrupt and overrun flags are set simultaneously.

### 70.3.15.3 Error reporting

The error report registers provide detailed information about the address read, raw data, and syndrome read with error. The flags described in Error indication indicate these report registers:

- Error Report Address (RERRAR)
- Error Report Data (RERRDR)
- Error Report Syndrome (RERRSYNR)

The address, data, and syndrome registers are updated simultaneously with the error flags, according to these rules:

1. If either of the uncorrectable error flags is set, the report registers are not updated. The previous uncorrectable error reporting is preserved.
2. Otherwise, either no error flag is set or only the correctable error flag is set. The report registers are updated according to the new error, or according to the most severe new error, if uncorrectable and correctable errors are simultaneously detected.

Reporting of errors detected in accesses larger than 32 bits follows the rules described in Error indication and in the description of Error Report Address (RERRAR).

The addresses reported in RERRAR and defined in ERRIAR are not the same as the addresses listed in the module memory map. The relation between the reported addresses and the respective ones in the module memory map is shown in the description of Error Injection Address (ERRIAR).

Addresses reported when reading memory portions organized as FIFOs refer to the address of the specific entry accessed in the FIFO, not to the FIFO base address. Such memory portions include:

- Legacy RX FIFO Structure
- Enhanced RX FIFO Structure
- Legacy RX FIFO Information (RXFIR)

To ensure coherence of error report registers, disable the report update by writing 1 to MECR[RERRDIS] before reading the report registers.

### 70.3.15.4 Error response

Correctable errors have no consequence to FlexCAN operation because the host or FlexCAN internal processes corrects affected data before its use.

For host-initiated reads, an uncorrectable error may affect the host, but does not affect FlexCAN operation.

Uncorrectable errors detected on memory read operations requested by FlexCAN internal processes may result in incorrect operation depending on the state of MECR[NCEFAFRZ], as follows:

- During reception (either matching or move-in process), when an uncorrectable error occurs:
    — An incorrect destination may be selected to store the incoming frame.
    — A corrupted frame may be stored in the correct destination.
    — Both of these events may occur.

If MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode to prevent corrupted data from being treated as valid by FlexCAN internal processes. If MECR[NCEFAFRZ] = 0, FlexCAN continues working, and a corrupted frame is received.

- During arbitration, when an uncorrectable error occurs:
  - A non-highest-priority TX message buffer may be mistakenly selected for transmission.
  - Its data may be corrupted.

  If MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode before starting the move-out. If MECR[NCEFAFRZ] = 0, FlexCAN proceeds to move-out with a corrupted frame that will be transmitted on the CAN bus.
- During move-out, when an uncorrectable error occurs, a corrupted frame is copied from the selected TX MB that won the arbitration to the TX SMB for transmission. If MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode before starting the transmission. When MECR[NCEFAFRZ] = 0, the corrupted frame is transferred from the TX SMB to the Protocol Engine (PE) subblock and is transmitted on the CAN bus.
- An uncorrectable error can also be detected beyond move-out, when TX data is read from TX SMB (buffer located in RAM) to be transferred to the PE subblock for transmission. In this case, a frame with corrupted ID or data is transmitted on the CAN bus.

  To prevent the external nodes from successfully receiving the frame, FlexCAN inverts all bits in the CRC field (CRC sequence plus CRC delimiter). Also, it transmits an error flag just after CRC delimiter due to self-detecting a Bit1 error and a form error due to the CRC field inversion. When MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode just after the error frame. When MECR[NCEFAFRZ] = 0, FlexCAN may attempt to retransmit the same frame, as long as no other higher-priority TX MB is configured for transmission after.

  If the uncorrectable error persists, FlexCAN eventually reaches the Bus Off state due to consecutive error detections. ECR[TXERRCNT] is updated every time FlexCAN inverts the CRC field, causing errors as described above.

When MECR[NCEFAFRZ] = 1 and FlexCAN enters Freeze mode, only the CPU can cause FlexCAN to exit Freeze mode and resume Normal mode. MECR[NCEFAFRZ] becoming 1 is the only way to prevent corrupted frames from being transmitted on the CAN bus to the move-out internal process.

The error report registers can provide information to the application for customized management of these situations.

#### 70.3.15.5 Error injection

These error injection registers are used to inject errors in memory reads to force errors and update the indication and reporting registers:

- Error Injection Address (ERRIAR)
- Error Injection Data Pattern (ERRIDPR)
- Error Injection Parity Pattern (ERRIPPR)

The relation between the error injection addresses and the corresponding addresses in the module memory map is shown in Error Injection Address (ERRIAR).

The injection is done by flipping the data and parity bits corresponding to the bits set to 1 in ERRIDPR and ERRIPPR. You can select injection specifically for memory accesses requested by the host or by FlexCAN internal processes.

For accesses larger than 32 bits, MECR[EXTERRIE] extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

**NOTE**

It is possible, but very unlikely, for error injection to correct a bit with error. This correction does not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, you must clear MECR[HAERRIE] and MECR[FAERRIE] when configuring the memory injection registers.

## 70.4 External signal descriptions

FlexCAN has two I/O signals connected to the external chip pins. These signals are summarized in Table 442 and described in the following subsections.

**Table 442. FlexCAN signal descriptions**

| Signal | Description | I/O |
|---|---|---|
| CAN RX | CAN receive pin | Input |
| CAN TX | CAN transmit pin | Output |

### 70.4.1 CAN RX

This pin is the receive pin from the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

### 70.4.2 CAN TX

This pin is the transmit pin to the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

## 70.5 Initialization and application information

### 70.5.1 FlexCAN initialization sequence

For any configuration change or initialization, you must put FlexCAN into Freeze mode (see Freeze mode). The module must be initialized after every reset. FlexCAN memory must be initialized before switching to functional mode.

The following is a generic initialization sequence applicable to FlexCAN:

1. Initialize Module Configuration (MCR).
    a. Enable the individual filtering per message buffer and reception queue features by writing 1 to MCR[IRMQ].
    b. Enable the warning interrupts by writing 1 to MCR[WRNEN].
    c. If required, disable frame self-reception by writing 1 to MCR[SRXDIS].
    d. Enable the Legacy RX FIFO by writing 1 to MCR[RFEN] or enable the Enhanced RX FIFO by writing 1 to ERFCR[ERFEN].
    e. If Legacy RX FIFO or Enhanced RX FIFO is enabled and DMA is required, write 1 to MCR[DMA].
    f. Enable the abort mechanism by writing 1 to MCR[AEN].
    g. Enable the local priority feature by writing 1 to MCR[LPRIOEN].
2. Initialize Control 1 (CTRL1) and CAN FD Bit Timing (FDCBT). Optionally initialize CAN Bit Timing (CBT).
    a. Determine the bit timing parameters: CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW].
    b. Optionally determine the bit timing parameters: CBT[EPROPSEG], CBT[EPSEG1], CBT[EPSEG2], and CBT[ERJW].
    c. Determine the CAN FD bit timing parameters: FDCBT[FPROPSEG], FDCBT[FPSEG1], FDCBT[FPSEG2], and FDCBT[FRJW].
    d. Determine the bit rate by programming CTRL1[PRESDIV] and optionally programming CBT[EPRESDIV].
    e. Determine the CAN FD bit rate by programming FDCBT[FPRESDIV].
    f. Determine the internal arbitration mode by programming CTRL1[LBUF].

3. If Error Code Correction (ECC) is enabled, you must initialize all FlexCAN memory. See Detection and correction of memory errors.
4. Initialize the message buffers. (See Message buffer structure for message buffer details.)
    a. The control and status word of all message buffers must be initialized.
    b. If RX FIFO is enabled, the ID filter table must be initialized.
    c. Other entries in each message buffer should be initialized as required.
5. Initialize Receive Individual Mask (RXIMR0 - RXIMR95).
6. Write 1 to required interrupt mask bits in:
    - IMASK registers (for all message buffer interrupts)
    - Control 1 (CTRL1) and Control 2 (CTRL2) (for Bus Off and Error interrupts)
7. Write 0 to MCR[HALT].

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

## 70.6 Memory map and register definition

This section describes the registers and data structures in FlexCAN. The base address of the module depends on the particular memory map of the chip.

### 70.6.1 FlexCAN memory mapping

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0080h.

Each individual register is identified by its complete name and corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most registers can be configured to have either Supervisor or Unrestricted access by programming MCR[SUPV]. These registers are identified as S/U in the Access column of Table 443.

**NOTE**

An invalid register access results in a bus error. Invalid accesses include reading a write-only register, writing a read-only register, and accessing an invalid address.

**NOTE**

To update the parity bits in memory properly, all FlexCAN memory must be initialized before reading registers which are implemented in memory. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization, from 080h–ADFh and from C20h–31FFh. You must also initialize RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK) and Legacy RX FIFO Global Mask (RXFGMASK). MCR[RFEN] and ERFCR[ERFEN] must not be 1 during memory initialization.

**Table 443. Register access and reset information**

| Register | Access type | Affected by hard reset | Affected by soft reset |
|---|---|---|---|
| Module Configuration (MCR) | S | Yes | Yes |
| Control 1 (CTRL1) | S/U | Yes | No |
| Free-Running Timer (TIMER) | S/U | Yes | Yes |
| RX Message buffers Global Mask (RXMGMASK) | S/U | No | No |

*Table continues on the next page...*

Table 443. Register access and reset information (continued)

| Register | Access type | Affected by hard reset | Affected by soft reset |
|---|---|---|---|
| RX Buffer 14 Mask (RX14MASK) | S/U | No | No |
| RX Buffer 15 Mask (RX15MASK) | S/U | No | No |
| Error Counter (ECR) | S/U | Yes | Yes |
| Error and Status 1 (ESR1) | S/U | Yes | Yes |
| Interrupt Masks 2 (IMASK2) | S/U | Yes | Yes |
| Interrupt Masks 1 (IMASK1) | S/U | Yes | Yes |
| Interrupt Flags 2 (IFLAG2) | S/U | Yes | Yes |
| Interrupt Flags 1 (IFLAG1) | S/U | Yes | Yes |
| Control 2 (CTRL2) | S/U | Yes | No |
| Error and Status 2 (ESR2) | S/U | Yes | Yes |
| Cyclic Redundancy Check (CRCR) | S/U | Yes | Yes |
| RX FIFO Global Mask (RXFGMASK) | S/U | No | No |
| RX FIFO Information (RXFIR) | S/U | No | No |
| CAN Bit Timing (CBT) | S/U | Yes | No |
| Interrupt Masks 3 (IMASK3) | S/U | Yes | Yes |
| Interrupt Flags 3 (IFLAG3) | S/U | Yes | Yes |
| Message buffers | S/U | No | No |
| RX Individual Masks | S/U | No | No |
| Memory Error Control (MECR) | S/U | Yes | Yes |
| Error Injection Address (ERRIAR) | S/U | Yes | Yes |
| Error Injection Data Pattern (ERRIDPR) | S/U | Yes | Yes |
| Error Injection Parity Pattern (ERRIPPR) | S/U | Yes | Yes |
| Error Report Address (RERRAR) | S/U | Yes | Yes |
| Error Report Data (RERRDR) | S/U | Yes | Yes |
| Error Report Syndrome (RERRSYNR) | S/U | Yes | Yes |

*Table continues on the next page...*

Table 443. Register access and reset information (continued)

| Register | Access type | Affected by hard reset | Affected by soft reset |
|---|---|---|---|
| Error Status (ERRSR) | S/U | Yes | Yes |
| Enhanced CAN Bit Timing Prescalers (EPRS) | S/U | Yes | No |
| Enhanced Nominal CAN Bit Timing (ENCBT) | S/U | Yes | No |
| Enhanced Data Phase CAN bit Timing (EDCBT) | S/U | Yes | No |
| Enhanced Transceiver Delay Compensation (ETDC) | S/U | Yes | No |
| CAN FD Control (FDCTRL) | S/U | Yes | No |
| CAN FD Bit Timing (FDCBT) | S/U | Yes | No |
| CAN FD CRC (FDCRC) | S/U | Yes | Yes |
| Enhanced RX FIFO Control (ERFCR) | S/U | Yes | Yes |
| Enhanced RX FIFO Interrupt Enable (ERFIER) | S/U | Yes | Yes |
| Enhanced RX FIFO Status (ERFSR) | S/U | Yes | Yes |
| High-Resolution Timestamp (HR_TIME_STAMP) | S/U | No | No |
| Enhanced RX FIFO | S/U | No | No |
| Enhanced RX FIFO Filter Element (ERFFEL) | S/U | No | No |

FlexCAN can store CAN messages for transmission and reception using message buffers and RX FIFO structures.

## 70.6.2 FlexCAN register descriptions

The table below shows the FlexCAN memory map.

The address range from offset 80h–67Fh allocates the ninety-six 128-bit message buffers. The memory maps for the message buffers are in FlexCAN message buffer memory map.

The address range from offset 2000h–204Ch allocates the Enhanced RX FIFO output, and the address range from offset 2050h–263Ch allocates the rest of Enhanced RX FIFO 19 elements. The memory map for the Enhanced RX FIFO is in Enhanced RX FIFO structure.

### 70.6.2.1 FlexCAN memory map

FLEXCAN_0 base address: 4030_4000h

FLEXCAN_1 base address: 4030_8000h

FLEXCAN_2 base address: 4030_C000h

FLEXCAN_3 base address: 4031_0000h

FLEXCAN_4 base address: 4031_4000h

FLEXCAN_5 base address: 4031_8000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Module Configuration (MCR) | 32 | RW | D890_000Fh |
| 4h | Control 1 (CTRL1) | 32 | RW | 0000_0000h |

### Fields

| Field | Function |
|---|---|
| 31<br>MDIS | Module Disable<br>Disables FlexCAN. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Soft reset does not affect this field.<br>0b - Enable<br>1b - Disable |
| 30<br>FRZ | Freeze Enable<br>Specifies FlexCAN behavior when MCR[HALT] = 1 or when Debug mode is requested at chip level. When this field becomes 1, FlexCAN can enter Freeze mode. Writing 0 to this field causes FlexCAN to exit from Freeze mode. The chip writes 1 to this field when a noncorrectable error is detected (MECR[NCEFAFRZ] becomes 1).<br>0b - Disable<br>1b - Enable |
| 29<br>RFEN | Legacy RX FIFO Enable<br>Enables the Legacy RX FIFO feature. When this field is 1, message buffers 0–5 cannot be used for normal reception and transmission. The corresponding memory region (80h–DCh) is used by the FIFO engine and additional message buffers (up to 32, depending on CTRL2[RFFN]). These message buffers are used as Legacy RX FIFO ID filter table elements. This field also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 438. This field can be written in Freeze mode only; the module blocks it in other modes.<br>**NOTE**<br>When CAN FD operation is enabled (see MCR[FDEN]), you cannot write 1 to this field.<br>**NOTE**<br>This field must not be 1 if ERFCR[ERFEN] = 1.<br>0b - Disable<br>1b - Enable |
| 28<br>HALT | Halt FlexCAN<br>Puts FlexCAN into Freeze mode. The CPU should write 0 to this field after initializing the message buffers and Control 1 (CTRL1) and Control 2 (CTRL2). FlexCAN performs no reception or transmission before this field becomes 0. Freeze mode cannot be entered when FlexCAN is in a low-power mode. The module writes 1 to this field when a noncorrectable error is detected and MECR[NCEFAFRZ] = 1.<br>0b - No request<br>1b - Enter Freeze mode, if MCR[FRZ] = 1. |
| 27<br>NOTRDY | FlexCAN Not Ready<br>Indicates whether FlexCAN is in Disable mode or Freeze mode. When FlexCAN has exited these modes, this field becomes 0. Soft reset does not affect this field. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 0b - FlexCAN is in Normal mode, Listen-Only mode, or Loopback mode.<br>1b - FlexCAN is in Disable mode or Freeze mode. |
| 26<br>— | Reserved<br>When writing to this field, always write the reset value. |
| 25<br>SOFTRST | Soft Reset<br>Resets internal state machines of FlexCAN and some memory-mapped registers.<br>The CPU can write 1 to this field directly. Because soft reset is synchronous and must follow a request-and-acknowledge procedure across clock domains, it may take some time to propagate its effect fully. When reset is pending, this field remains 1; it automatically becomes 0 when reset completes. You can poll this field to know when the soft reset has completed.<br>Soft reset cannot be applied when clocks are shut down in a low-power mode. Transfer the module out of the low-power mode before applying soft reset. Soft reset does not affect this field.<br>**NOTE**<br>This field becomes 0 within 2 CAN bits after assertion of this bit.<br>0b - No reset<br>1b - Soft reset affects reset registers |
| 24<br>FRZACK | Freeze Mode Acknowledge<br>Indicates whether FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore, you can poll this field to know when FlexCAN has entered Freeze mode. If the Freeze mode request is negated, this field becomes 0 after the FlexCAN prescaler is running again. If Freeze mode is requested when FlexCAN is in a low-power mode, this field becomes 1 only when the low-power mode is exited. See Freeze mode. Soft reset does not affect this field.<br>**NOTE**<br>This field becomes 1 within 180 CAN bits if current transmission or reception is ongoing for classical frames and 730 CAN bits if current transmission or reception is ongoing for FD frames after the low-power mode requested by CPU. This field becomes 0 within 2 CAN bits after the Freeze mode request removal (see Protocol timing).<br>0b - Not in Freeze mode, prescaler running.<br>1b - In Freeze mode, prescaler stopped. |
| 23<br>SUPV | Supervisor Mode<br>Configures FlexCAN to be either in Supervisor or User mode. The registers that this field affects are marked as S/U in the Access type column of Table 443. The affected registers start with Supervisor access allowance only. In User mode, affected registers allow both Supervisor and Unrestricted accesses.<br>In Supervisor mode, affected registers allow only Supervisor access. Unrestricted access behaves as though the access is performed on an unimplemented register location.<br>This field can be written only in Freeze mode; the module blocks it in other modes. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 0b - User mode<br>1b - Supervisor mode |
| 22<br>— | Reserved<br>When writing to this field, always write the reset value. |
| 21<br>WRNEN | Warning Interrupt Enable<br>Enables the generation of the flags ESR1[TWRNINT] and ESR1[RWRNINT]. When this field is 1, TWRNINT and RWRNINT flags are set when the respective error counter transitions from less than 96 to greater than or equal to 96. When this field is 0, the TWRNINT and RWRNINT flags are always zero, independent of the values of the error counters. No warning interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes.<br>0b - Disable<br>1b - Enable |
| 20<br>LPMACK | Low-Power Mode Acknowledge<br>Indicates whether FlexCAN is in a low-power mode (Disable mode). A low-power mode cannot be entered until all current transmission and reception processes have finished. The CPU can poll this field to know when FlexCAN has entered low-power mode. Soft reset does not affect this field.<br>**NOTE**<br>This field becomes 1 within 180 CAN bits if current transmission or reception is ongoing for classical frames and 730 CAN bits if current transmission or reception is ongoing for FD frames after the low-power mode requested by CPU. This field becomes 0 within 2 CAN bits after the low-power mode request removal (see Protocol timing).<br>0b - Not in a low-power mode<br>1b - In a low-power mode |
| 19<br>— | Reserved<br>When writing to this field, always write the reset value. |
| 18<br>— | Reserved<br>When writing to this field, always write the reset value. |
| 17<br>SRXDIS | Self-Reception Disable<br>Determines whether FlexCAN can receive frames transmitted by itself. If 1, frames transmitted by the module are not stored in any MB, regardless of whether the MB is programmed with an ID that matches the transmitted frame. No interrupt flag or interrupt signal is generated due to the frame reception. This field can be written only in Freeze mode; the module blocks it in other modes.<br>0b - Enable<br>1b - Disable |
| 16 | Individual RX Masking and Queue Enable |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| IRMQ | Indicates whether RX matching process is based on individual masking and queue, or based on a masking scheme with RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK), and Legacy RX FIFO Global Mask (RXFGMASK).<br>When this field is disabled, for backward compatibility with legacy applications, reading the Control and Status word locks the MB even if it is empty.<br>This field can be written in Freeze mode only. The module blocks it in other modes.<br>0b - Disable<br>1b - Enable |
| 15<br>DMA | DMA Enable<br>Enables DMA. The DMA feature can only be used in Legacy RX FIFO or Enhanced RX FIFO, so MCR[RFEN] or ERFCR[ERFEN] must be 1. When DMA and RFEN are 1, IFLAG1[BUF5I] generates the DMA request, and no RX FIFO interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes.<br>0b - Disable<br>1b - Enable |
| 14<br>— | Reserved |
| 13<br>LPRIOEN | Local Priority Enable<br>Enables the local priority feature. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word. However, the actual transmitted ID is 11 bits for standard frames and 29 bits for extended frames.<br>This field can be written only in Freeze mode; the module blocks it in other modes.<br>This bit is provided for backward compatibility with legacy applications.<br>0b - Disable<br>1b - Enable |
| 12<br>AEN | Abort Enable<br>Enables the TX abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This field can be written only in Freeze mode; the module blocks it in other modes.<br>**NOTE**<br>When this field is 1, only use the abort mechanism (see Transmission abort mechanism) to update message buffers configured for transmission.<br>**CAUTION**<br>Writing the abort code into RX message buffers can cause unpredictable results when this field is 1. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 0b - Disabled<br>1b - Enabled |
| 11<br>FDEN | CAN FD Operation Enable<br>Enables the CAN with flexible data rate (CAN FD) operation. This field can be written in Freeze mode only. FlexCAN can receive and transmit messages in CAN 2.0 format. If this field is enabled, FlexCAN can also receive and transmit messages in CAN FD format.<br>FlexCAN can transmit FD frame format according to ISO 11898-1:2015.<br>**NOTE**<br>If the value of this field is 1, the Legacy RX FIFO Enable (MCR[RFEN]) field cannot be 1.<br>0b - Disable<br>1b - Enable |
| 10<br>— | Reserved |
| 9-8<br>IDAM | ID Acceptance Mode<br>Identifies the format of the Legacy RX FIFO ID filter table elements. This field configures all elements of the table at the same time; they are all the same format. See legacy RX FIFO structure. This field can be written only in Freeze mode; the module blocks it in other modes.<br>00b - Format A: One full ID (standard and extended) per ID filter table element.<br>01b - Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element.<br>10b - Format C: Four partial 8-bit standard IDs per ID filter table element.<br>11b - Format D: All frames rejected. |
| 7<br>— | Reserved |
| 6-0<br>MAXMB | Number of the Last Message Buffer<br>Defines the number of the last message buffer that takes part in the matching and arbitration processes. The reset value (0Fh) is equivalent to a 16-MB configuration. This field can be written only in Freeze mode; the module blocks it in other modes.<br>**NOTE**<br>You must write a value smaller than or equal to the number of available message buffers to this field, as described in FlexCAN memory partition for CAN FD.<br>Additionally, the MAXMB value must consider the region of message buffers occupied by Legacy RX FIFO and its ID filters table space defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit, as described in Table 438. |

### 70.6.2.3 Control 1 (CTRL1)

#### Offset

| Register | Offset |
|---|---|
| CTRL1 | 4h |

#### Function

Contains specific FlexCAN control features related to the CAN bus. These features include bit rate, programmable sampling point within an RX bit, Loopback mode, Listen-Only mode, Bus Off recovery behavior, and interrupt enabling (Bus-Off, Error, Warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW]) can also be configured in CAN Bit Timing (CBT), which extends the range of all these variables. If CBT[BTF] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] become read-only.

If CTRL2[BTE] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] are not used by the module. Instead, these fields are read as zero, and a write operation to them has no effect.

**NOTE**

When the CAN FD feature is enabled, do not use CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] for CAN bit timing. Instead use CBT[EPRESDIV], CBT[ERJW], CBT[EPSEG1], CBT[EPSEG2], and CBT[EPROPSEG].

The CAN bit variables in CTRL1 and in CBT are stored in the same internal register.

Soft reset does not affect the contents of this register.

#### Diagram

#### Fields

| Field | Function |
|---|---|
| 31-24<br>PRESDIV | Prescaler Division Factor<br>Determines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The maximum value of this field is FFh, which gives a minimum Sclock frequency |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | equal to the PE clock frequency divided by 256. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes.<br>Sclock frequency = PE clock frequency ÷ (PRESDIV + 1). |
| 23-22<br>RJW | Resync Jump Width<br>Defines the maximum number of time quanta that one resynchronization can change a bit time. One time quantum is equal to one Sclock period. The valid programmable values are 0–3. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes.<br>Resync Jump Width = RJW + 1. |
| 21-19<br>PSEG1 | Phase Segment 1<br>Defines the length of phase segment 1 in the bit time. The valid programmable values are 0–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes.<br>Phase Buffer Segment 1 = (PSEG1 + 1) × Time Quanta. |
| 18-16<br>PSEG2 | Phase Segment 2<br>Defines the length of phase segment 2 in the bit time. The valid programmable values are 1–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes.<br>Phase Buffer Segment 2 = (PSEG2 + 1) × Time Quanta. |
| 15<br>BOFFMSK | Bus Off Interrupt Mask<br>Provides a mask for the Bus Off interrupt ESR1[BOFFINT].<br>0b - Interrupt disabled<br>1b - Interrupt enabled |
| 14<br>ERRMSK | Error Interrupt Mask<br>Provides a mask for the Error interrupt ESR1[ERRINT].<br>0b - Interrupt disabled<br>1b - Interrupt enabled |
| 13<br>— | Reserved<br>**NOTE**<br>Writeable only if the module is disabled. Otherwise the access type is read-only. |
| 12<br>LPB | Loopback Mode<br>Configures FlexCAN to operate in Loopback mode. In this mode, FlexCAN performs an internal loopback that can be used for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The RX CAN input pin is ignored and the TX CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. It generates an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This field can be written only in Freeze mode; the module blocks it in other modes.<br>**NOTE**<br>In this mode, MCR[SRXDIS] cannot become 1, because it would impede the self-reception of a transmitted message.<br>**NOTE**<br>FDCTRL[TDCEN] and MCR[ETDCEN] must be 0 when this field is 1.<br>0b - Disabled<br>1b - Enabled |
| 11<br>TWRNMSK | TX Warning Interrupt Mask<br>Provides a mask for the TX Warning interrupt associated with the ESR1[TWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1.<br>0b - Disabled<br>1b - Enabled |
| 10<br>RWRNMSK | RX Warning Interrupt Mask<br>Provides a mask for the RX Warning interrupt associated with the ESR1[RWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1.<br>0b - Disabled<br>1b - Enabled |
| 9<br>— | Reserved |
| 8<br>— | Reserved |
| 7<br>SMP | CAN Bit Sampling<br>Determines the sampling mode of CAN bits at the RX input. This field can be written in Freeze mode only; the module blocks it in other modes.<br>**NOTE**<br>For proper operation, to write 1 to this field, you must guarantee a minimum value of two time quanta in CTRL1[PSEG1] (or CBT[EPSEG1]).This bit cannot become 1 when CAN FD is enabled (MCR[FDEN] = 1).<br>0b - One sample is used to determine the bit value. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 1b - Three samples are used to determine the value of the received bit: the regular one (sample point) and two preceding samples. A majority rule is used. |
| 6<br>BOFFREC | Bus Off Recovery<br>Determines how FlexCAN recovers from Bus Off state. If 0, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If 1, automatic recovering from Bus Off is disabled. The module remains in Bus Off state until you write 1 to this field.<br>If this field becomes 0 before 128 sequences of 11 recessive bits are detected on the CAN bus, Bus Off recovery happens as if this field had never become 1. If this field becomes 0 after 128 sequences of 11 recessive bits occurred, FlexCAN resynchronizes to the bus. It waits for 11 recessive bits before joining the bus.<br>After this field becomes 0, it can become 1 again during Bus Off, but it will only be effective the next time the module enters Bus Off. If this field becomes 0 when the module is in Bus Off, writing 1 to this field is not effective for the current Bus Off recovery.<br>**NOTE**<br>See Bus Off in the CAN Protocol standard (ISO 11898-1:2015) for details.<br>0b - Enabled<br>1b - Disabled |
| 5<br>TSYN | Timer Sync<br>Enables a mechanism that resets the free-running timer each time a message is received in message buffer 0. This feature provides the means to synchronize multiple FlexCAN stations with a special "SYNC" message (that is, global network time). If MCR[RFEN] = 1 (Legacy RX FIFO enabled), the first available message buffer, according to CTRL2[RFFN], is used for timer synchronization instead of MB0. This field can be written in Freeze mode only; the module blocks it in other modes.<br>0b - Disable<br>1b - Enable |
| 4<br>LBUF | Lowest Buffer Transmitted First<br>Determines the ordering mechanism for message buffer transmission. When 1, MCR[LPRIOEN] does not affect the priority arbitration. This field can be written in Freeze mode only; the module blocks it in other modes.<br>0b - Buffer with highest priority is transmitted first.<br>1b - Lowest number buffer is transmitted first. |
| 3<br>LOM | Listen-Only Mode<br>Configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in Error Counter (ECR) are frozen, and the module operates in CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error without changing the receive error counter (ECR[RXERRCNT]), as if it is trying to acknowledge the message. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | FlexCAN acknowledges Listen-Only mode when ESR1[FLTCONF] = 1, indicating the Error Passive state. There can be some delay between the Listen-Only mode request and its acknowledgment.<br>This field can be written in Freeze mode only; the module blocks it in other modes.<br>0b - Listen-Only mode is deactivated.<br>1b - FlexCAN module operates in Listen-Only mode. |
| 2-0<br>PROPSEG | Propagation Segment<br>Defines the length of the propagation segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode; the module blocks it in other modes.<br>Propagation segment time = (PROPSEG + 1) × Time Quanta.<br>One Time Quantum = one Sclock period. |

### 70.6.2.4 Free-Running Timer (TIMER)

#### Offset

| Register | Offset |
|---|---|
| TIMER | 8h |

#### Function

Represents a 16-bit free-running counter that the CPU can read and write. The timer starts from 0h after reset, counts linearly to FFFFh, and wraps around.

When CTRL2[TIMER_SRC] = 1, an external time tick continuously increments the timer. The time tick must be synchronous to the peripheral clock, with a minimum pulse width of one clock cycle.

When CTRL2[TIMER_SRC] = 0, the CAN bit clock increments the timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable and Freeze modes.

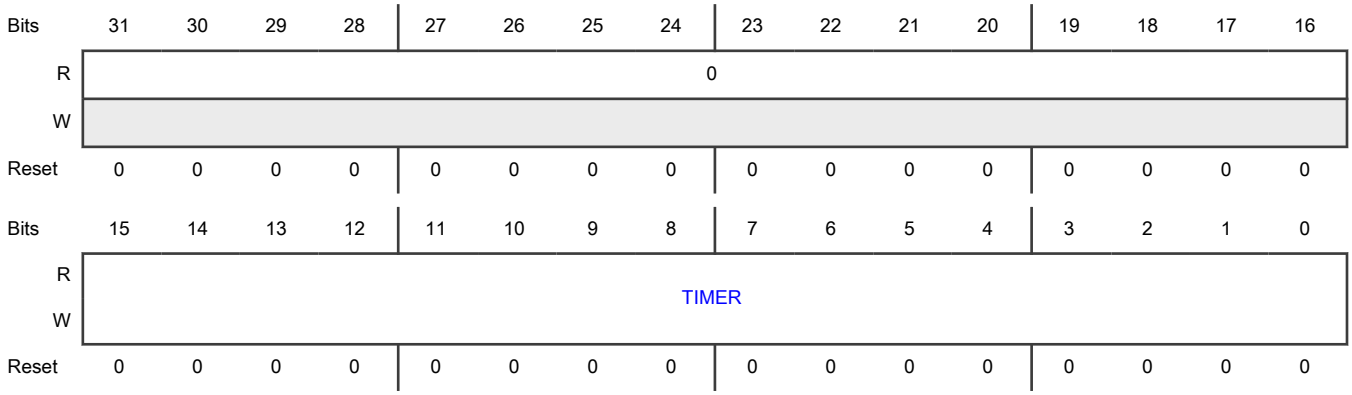
The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the timestamp entry in a message buffer after a successful reception or transmission of a message.

If CTRL1[TSYN] = 1, the timer is reset whenever a message is received in the first available message buffer, according to CTRL2[RFFN].

The CPU can write to this register anytime. However, if the write occurs simultaneously with the timer being reset by a reception in the first message buffer, the write value is discarded.

Reading this register affects the message buffer unlocking procedure (see Message buffer lock mechanism).

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved |
| 15-0<br>TIMER | Timer Value<br>Contains the free-running counter value. |

## 70.6.2.5 RX Message Buffers Global Mask (RXMGMASK)

### Offset

| Register | Offset |
|---|---|
| RXMGMASK | 10h |

### Function

Masks the filter bits of all RX message buffers, excluding MB14 and MB15, which have individual mask registers.

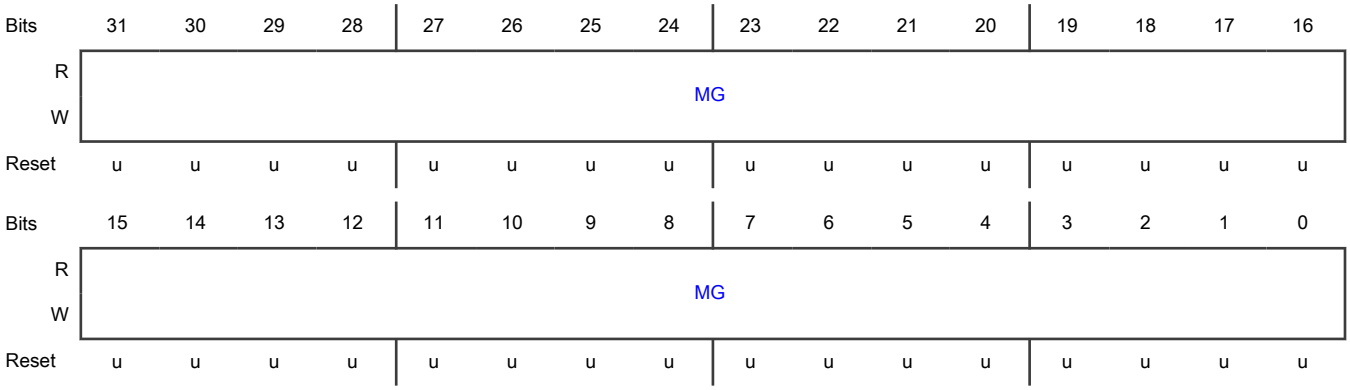
This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When MCR[IRMQ] is 0, RXMGMASK is always in effect. The bits in RXMGMASK[MG] mask the MB filter bits.
- When MCR[IRMQ] is 1, RXMGMASK has no effect. The bits in RXMGMASK[MG] do not mask the MB filter bits.

This register can only be written in Freeze mode; the module blocks it in other modes.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>MG | Global Mask for RX Message Buffers<br>Masks the message buffer filter bits. The alignment with the ID word of the message buffer is imperfect. The two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status word of the MB. The following table shows which MG bits mask each MB filter field. |

| SMB[RTR] [1] | CTRL2[RRS] | CTRL2[EACEN] | Message buffer filter fields | | | |
|---|---|---|---|---|---|---|
| | | | MB[RTR] | MB[IDE] | MB[ID] | Reserved |
| 0 | - | 0 | Note [2] | Note [3] | MG[28:0] | MG[31:29] |
| 0 | - | 1 | MG[31] | MG[30] | MG[28:0] | MG[29] |
| 1 | 0 | - | - | - | - | MG[31:0] |
| 1 | 1 | 0 | - | - | MG[28:0] | MG[31:29] |
| 1 | 1 | 1 | MG[31] | MG[30] | MG[28:0] | MG[29] |

1. RTR bit of the incoming frame. It is saved into an auxiliary MB called RX serial message buffer (RX SMB).
2. If CTRL2[EACEN] is 0, the RTR bit of MB is never compared with the RTR bit of the incoming frame.
3. If CTRL2[EACEN] is 0, the IDE bit of MB is always compared with the IDE bit of the incoming frame.

0b - The corresponding bit in the filter is "don't care."

1b - The corresponding bit in the filter is checked.

## 70.6.2.6 Receive 14 Mask (RX14MASK)

### Offset

| Register | Offset |
|---|---|
| RX14MASK | 14h |

### Function

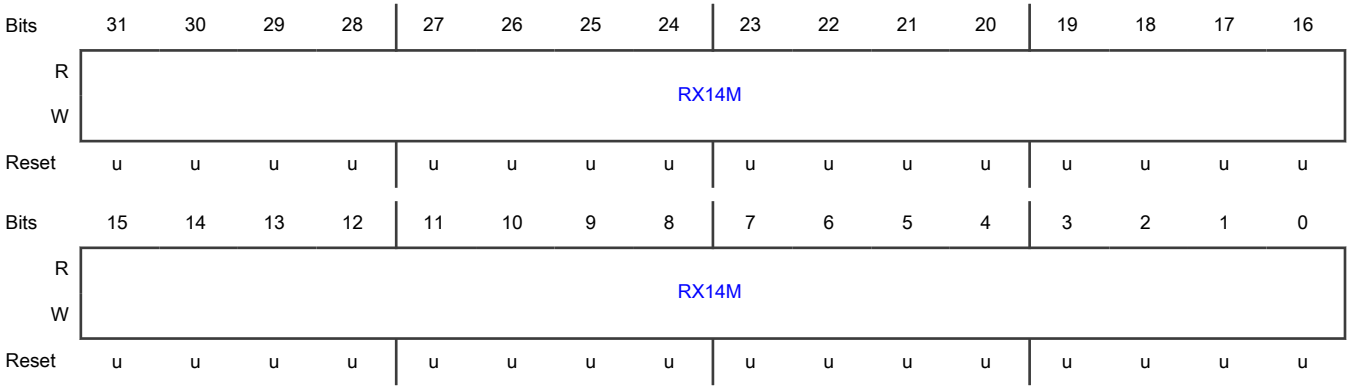
Masks the filter fields of MB14.

This register is located in RAM.

RX14MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX14MASK has no effect.

This register can only be programmed when the module is in Freeze mode; the module blocks it in other modes.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>RX14M | RX Buffer 14 Mask Bits<br>Masks the corresponding MB14 filter field in the same way that RX Message Buffers Global Mask (RXMGMASK) masks the filters of the other message buffers.<br>0b - The corresponding bit in the filter is "don't care."<br>1b - The corresponding bit in the filter is checked. |

## 70.6.2.7 Receive 15 Mask (RX15MASK)

### Offset

| Register | Offset |
|---|---|
| RX15MASK | 18h |

### Function

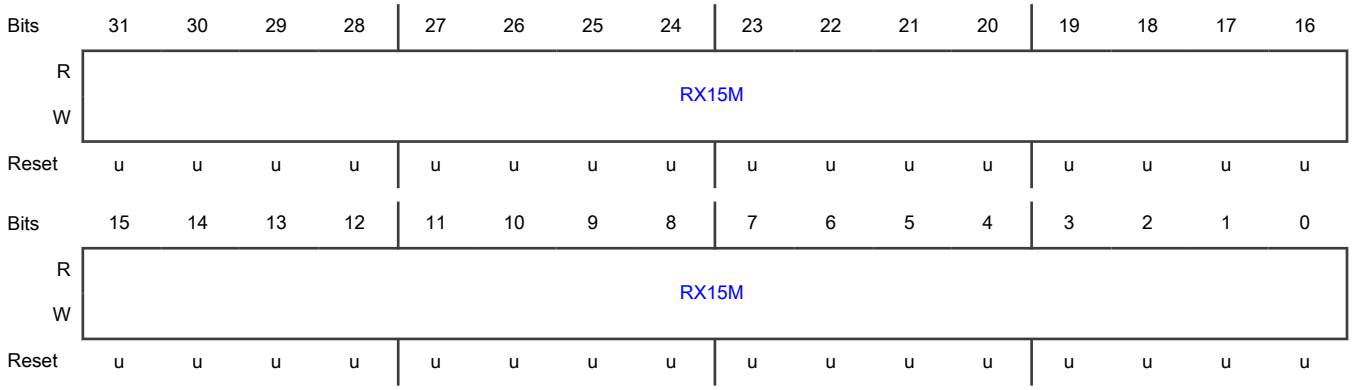
Masks the filter fields of MB15.

This register is located in RAM.

RX15MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX15MASK has no effect.

This register can be programmed only when the module is in Freeze mode; the module blocks it in other modes.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>RX15M | RX Buffer 15 Mask Bits<br>Masks the corresponding MB15 filter field in the same way that RX Message Buffers Global Mask (RXMGMASK) masks the filters of other message buffers.<br>0b - The corresponding bit in the filter is "don't care."<br>1b - The corresponding bit in the filter is checked. |

## 70.6.2.8 Error Counter (ECR)

### Offset

| Register | Offset |
|---|---|
| ECR | 1Ch |

### Function

Contains error counters for received and transmitted messages.

TXERRCNT and RXERRCNT consider all errors in both CAN FD and non-FD message formats. TXERRCNT_FAST and RXERRCNT_FAST count only the errors that occur in the data phase of CAN FD frames that have BRS = 1.

The Fault Confinement state (ESR1[FLTCONF]) is updated based on TXERRCNT and RXERRCNT counters only. The rules for increasing and decreasing these counters are described in the CAN protocol and are entirely implemented in FlexCAN.

The basic rules for FlexCAN bus state transitions are:

- If the value of TXERRCNT or RXERRCNT becomes greater than or equal to 128, ESR1[FLTCONF] is updated to reflect Error Passive state.
- If the state of FlexCAN is Error Passive, and TXERRCNT or RXERRCNT decrements to a value less than 128 when the other already satisfies this condition, ESR1[FLTCONF] is updated to reflect Error Active state.
- If the value of TXERRCNT becomes greater than 255, ESR1[FLTCONF] is updated to reflect Bus Off state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in Bus Off, TXERRCNT is cascaded with another internal counter to count the occurrences of 11 consecutive recessive bits on the bus. TXERRCNT is reset to zero. It counts in a manner where the internal counter

counts 11 such bits and then wraps around when incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, ESR1[FLTCONF] is updated to Error Active, and both error counters are reset to zero. Upon any instance of a dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT_FAST counter is frozen during Bus Off.

- If only one node is operating during system startup, its TXERRCNT increases upon each attempted message transmission, as a result of acknowledge errors (indicated by ESR1[ACKERR]). After the transition to Error Passive state, TXERRCNT no longer increments upon acknowledge errors. The chip never goes into the Bus Off state.
- If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected when being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to return to the Error Active state.
- TXERRCNT_FAST and RXERRCNT_FAST error counter values increment and decrement based on errors detected only in the data phase of CAN FD frames that have BRS = 1. These counters follow the same increment and decrement rules as TXERRCNT and RXERRCNT. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen when FlexCAN is in the Bus Off state. They are reset when FlexCAN leaves the Bus Off state and resume counting after FlexCAN returns to the Error Active state.

**NOTE**

See Fault confinement in the CAN Protocol standard (ISO 11898-1:2015) for details.

### 70.6.2.9 Error and Status 1 (ESR1)

#### Offset

| Register | Offset |
|---|---|
| ESR1 | 20h |

#### Function

Reports various error conditions detected in the reception and transmission of a CAN frame. This register provides status information about the chip, and is the source of some interrupts to the CPU. The reported error conditions are:

**NOTE**

Reading host can clear these fields.

- Errors detected in CAN frames of any format:
  - BIT1ERR
  - BIT0ERR
  - ACKERR
  - CRCERR
  - FRMERR
  - STFERR
- Errors detected in the data phase of CAN FD frames with the BRS bit set only:
  - BIT1ERR_FAST
  - BIT0ERR_FAST
  - CRCERR_FAST
  - FRMERR_FAST
  - STFERR_FAST

One or more error flags may report an error detected in a single CAN frame. To account for more error events occurring in subsequent frames when the CPU does not attempt to read this register, error reporting is cumulative.

Status flags:

- TXWRN
- RXWRN
- IDLE
- TX

- FLTCONF
- RX
- SYNCH

Interrupt flags:

- BOFFINT
- BOFFDONEINT
- ERRINT
- ERRINT_FAST
- TWRNINT
- RWRNINT

The CPU should follow this procedure when servicing interrupt requests generated by these flags:

1. Read this register to capture all error condition and status flags. This action clears the respective flags that were set since the last read access.
2. Write 1 to clear the interrupt flag that triggered the interrupt request.
3. Write 1 to clear the ERROVR flag, if it is set.

Starting from all error flags cleared, a first error event sets either ERRINT or ERRINT_FAST (provided the corresponding mask bit is 1). If other error events in subsequent frames occur before the CPU serves the interrupt request, the ERROVR flag is set to indicate that errors from different frames have accumulated.

**Table 444. CAN bus status**

| SYNCH | IDLE | TX | RX | FlexCAN state |
|---|---|---|---|---|
| 0 | 0 | 0 | 0 | Not synchronized to CAN bus |
| 1 | 1 | X | X | Idle |
| 1 | 0 | 1 | 0 | Transmitting |
| 1 | 0 | 0 | 1 | Receiving |

**NOTE**

See Fault confinement in the CAN Protocol standard (ISO 11898-1:2015) for details.

### 70.6.2.10 Interrupt Masks 2 (IMASK2)

#### Offset

| Register | Offset |
|---|---|
| IMASK2 | 24h |

#### Function

Masks interrupt flags. This register allows any of the 32 message buffer interrupts to be enabled or disabled for MB63–MB32. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding Interrupt Flags 2 (IFLAG2) flag is set.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| FLEXCAN_0 | IMASK2 | — |
| FLEXCAN_1 | IMASK2 | — |
| FLEXCAN_2 | IMASK2 | — |
| FLEXCAN_3 | — | IMASK2 |

### 70.6.2.11 Interrupt Masks 1 (IMASK1)

#### Offset

| Register | Offset |
|---|---|
| IMASK1 | 28h |

#### Function

Masks interrupt flags. This register allows any of the 32 message buffer interrupts to be enabled or disabled for MB31–MB0. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding Interrupt Flags 1 (IFLAG1) flag is set.

#### Diagram

### 70.6.2.12 Interrupt Flags 2 (IFLAG2)

#### Offset

| Register | Offset |
|---|---|
| IFLAG2 | 2Ch |

#### Function

Contains the flags for the 32 message buffer interrupts for MB63–MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective flag in this register. If the corresponding Interrupt Masks 2 (IMASK2) bit is set, an interrupt is generated.

Before updating MCR[MAXMB], the CPU must service the IFLAG2 flags whose MB value is greater than the MAXMB to be updated. Otherwise, those flags remain set and are inconsistent with the number of message buffers available.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| FLEXCAN_0 | IFLAG2 | — |
| FLEXCAN_1 | IFLAG2 | — |
| FLEXCAN_2 | IFLAG2 | — |
| FLEXCAN_3 | — | IFLAG2 |
| FLEXCAN_4 | — | IFLAG2 |

## 70.6.2.13 Interrupt Flags 1 (IFLAG1)

### Offset

| Register | Offset |
|---|---|
| IFLAG1 | 30h |

### Function

Contains the flags for the 32 message buffer interrupts for MB31–MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding Interrupt Masks 1 (IMASK1) bit is set, an interrupt is generated. There is an exception when DMA for Legacy RX FIFO is enabled, as described below.

The BUF7I–BUF5I flags also represent Legacy FIFO interrupts when the Legacy RX FIFO is enabled. When MCR[RFEN] is 1 and MCR[DMA] is 0, the function of the eight least significant interrupt flags changes:

- BUF7I, BUF6I, and BUF5I indicate operating conditions of the Legacy FIFO.
- BUF4I–BUF1I fields are reserved.
- BUF0I empties the Legacy FIFO.

Before writing 1 to MCR[RFEN], the CPU must service the IFLAG flags set in the Legacy RX FIFO region; see Legacy RX FIFO. Otherwise, these IFLAG flags mistakenly show the related message buffers now belonging to Legacy FIFO as having contents to be serviced. When MCR[RFEN] is 0, the Legacy FIFO flags must be cleared. The same care must be taken when a CTRL2[RFFN] value is selected, extending Legacy RX FIFO filters beyond MB7. For example, when RFFN is 8h, Legacy RX FIFO filters occupy the MB23–MB0 range, and related IFLAG flags must be cleared.

When MCR[RFEN] and MCR[DMA] are 1 (DMA feature for Legacy RX FIFO enabled), the function of the eight least significant interrupt flags (BUF7I–BUF0I) changes to support DMA operation. BUF7I, BUF6I, and BUF4I–BUF1I are not used.

BUF5I indicates the operating condition of the Legacy FIFO, and BUF0I empties the Legacy FIFO. Moreover, BUF5I does not generate a CPU interrupt, but it does generate a DMA request. IMASK1 bits in the Legacy RX FIFO region are not considered when bit MCR[DMA] = 1. In addition, the CPU must not clear the BUF5I flag when DMA is enabled. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. When MCR[DMA] is 0, the Legacy FIFO must be empty. Legacy FIFO must be disabled when MCR[FDEN] = 1.

Before updating MCR[MAXMB], the CPU must service the IFLAG1 flags whose MB value is greater than the MCR[MAXMB] to be updated. Otherwise, those flags remain set and are inconsistent with the number of message buffers available.

### 70.6.2.14 Control 2 (CTRL2)

#### Offset

| Register | Offset |
|---|---|
| CTRL2 | 34h |

#### Function

Complements Control 1 (CTRL1), providing control bits for memory write-access in Freeze mode. This register extends Legacy FIFO filter quantity, and adjusts the operation of internal FlexCAN processes such as matching and arbitration.

Soft reset does not affect the contents of this register.

Table 445 shows how the value of CTRL2[RFFN] determines the Legacy RX FIFO filter structure.

**Table 445. Possible Legacy RX FIFO filter structures**

| RFFN[3:0] | Number of Legacy RX FIFO filter elements | Message buffers occupied by Legacy RX FIFO and ID filter table | Remaining available message buffers | Legacy RX FIFO ID filter table elements affected by RX individual masks | Legacy RX FIFO ID filter table elements affected by Legacy RX FIFO global mask |

### 70.6.2.15 Error and Status 2 (ESR2)

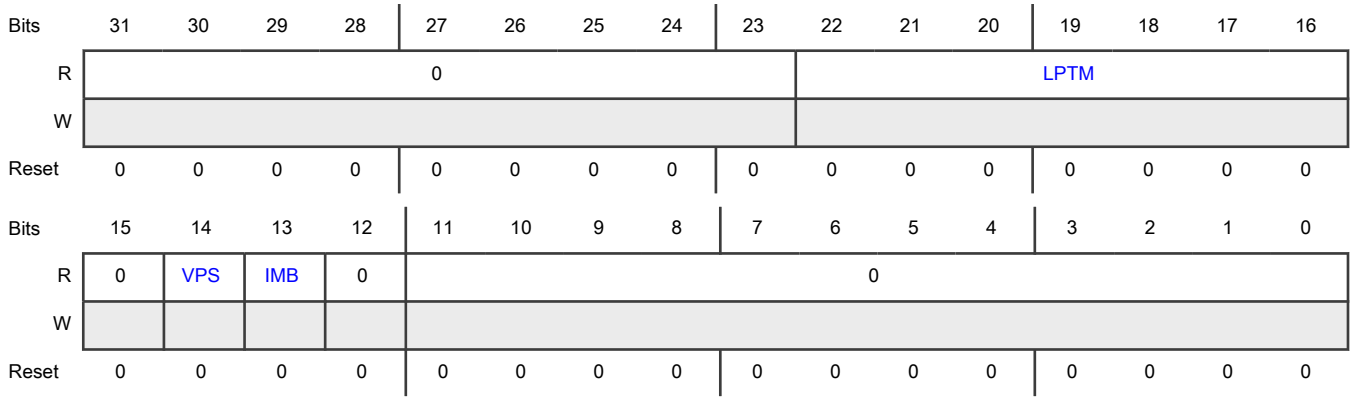
#### Offset

| Register | Offset |
|---|---|
| ESR2 | 38h |

#### Function

Reports general status information.

#### Diagram



### Fields

| Field | Function |
|---|---|
| 31-23<br>— | Reserved |
| 22-16<br>LPTM | Lowest Priority TX Message Buffer<br>Indicates the lowest number inactive message buffer when ESR2[VPS] = 1 (see ESR2[IMB]). If no message buffer is inactive, the message buffer indicated depends on the value of CTRL1[LBUF]. If CTRL1[LBUF] = 0, the message buffer indicated is the one with the greatest arbitration value (see Highest-priority message buffer first). If CTRL1[LBUF] = 1, the message buffer indicated is the active TX message buffer with the highest number.<br>If a TX message buffer is being transmitted, it is not considered in the LPTM calculation. If ESR2[IMB] is not 0 and a frame is transmitted successfully, the value of LPTM is updated with its message buffer number. |
| 15<br>— | Reserved |
| 14<br>VPS | Valid Priority Status<br>Indicates whether the contents of ESR2[IMB] and ESR2[LPTM] are valid. It becomes 1 upon every complete TX arbitration process, unless the CPU writes to the Control and Status word of a message buffer already scanned. In other words, it is behind the TX Arbitration Pointer, during the TX arbitration process. If there is no inactive message buffer and only one TX message buffer that is being transmitted, this field remains 0. This field becomes 0 upon the start of every TX arbitration process or upon a write to the Control and Status word of any message buffer.<br>**NOTE**<br>No CPU write to the Control and Status of a message buffer that the abort mechanism blocks affects this field. When MCR[AEN] = 1, the abort code write to the Control and Status of an MB being transmitted (pending abort) is blocked. Any write attempt to a TX MB with its IFLAG flag set is also blocked.<br>0b - Invalid<br>1b - Valid |
| 13<br>IMB | Inactive Message Buffer<br>Indicates whether any message buffer is inactive (CODE field is either 1000b or 0b) when ESR2[VPS] = 1. This field becomes 1 when:<br>• A lowest-priority TX message buffer (ESR2[LPTM]) is found and it is inactive during arbitration.<br>• This field is not 1, and a frame is transmitted successfully.<br>This field always becomes 0 at the start of arbitration (see Arbitration process).<br>If a message buffer is successfully transmitted and this field is 0 (no inactive message buffer), ESR2[VPS] and this field both become 1. The index related to the MB transmitted is loaded into ESR2[LPTM]. In this case, the value of ESR2[LPTM] is the number of the first inactive message buffer.<br>0b - Message buffer indicated by ESR2[LPTM] is not inactive.<br>1b - At least one message buffer is inactive. |

### 70.6.2.16 Cyclic Redundancy Check (CRCR)

#### Offset

| Register | Offset |
|---|---|
| CRCR | 44h |

#### Function

Provides information about the CRC of transmitted messages for non-FD messages. This register only reports the 15 low-order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, you must use the CAN FD CRC (FDCRC). This register is updated at the same time that the TX interrupt flag is set.

**NOTE**

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1:2015) for details.

#### Diagram

### 70.6.2.17 Legacy RX FIFO Global Mask (RXFGMASK)

#### Offset

| Register | Offset |
|---|---|
| RXFGMASK | 48h |

#### Function

Masks the Legacy RX FIFO ID filter table elements that do not have a corresponding RXIMR according to CTRL2[RFFN], when Legacy RX FIFO is enabled.

This register is located in RAM.

You can only write to this register in Freeze mode; the module blocks it in other modes.

The following table shows how the FGM bits correspond to each IDAF field.

**Table 446. Correspondence of Legacy RX FIFO global mask bits to IDF fields**

| Legacy RX FIFO ID filter table elements format (MCR[IDAM]) | Identifier acceptance filter fields | | | | | |
|---|---|---|---|---|---|---|
| | RTR | IDE | RXIDA | RXIDB [1] | RXIDC [2] | Reserved |
| A | FGM[31] | FGM[30] | FGM[29:1] | — | — | FGM[0] |
| B | FGM[31],<br>FGM[15] | FGM[30],<br>FGM[14] | — | FGM[29:16],<br>FGM[13:0] | | — |
| C | — | — | | — | FGM[31:24],<br>FGM[23:16],<br>FGM[15:8],<br>FGM[7:0] | |

1. If MCR[IDAM] is equivalent to format B, only the 14 most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.
2. If MCR[IDAM] is equivalent to format C, only the eight most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.

### Diagram

|---|---|
| 31-0<br>FGM | Legacy RX FIFO Global Mask Bits<br>Masks the ID filter table elements bits in a perfect alignment.<br>0b - The corresponding bit in the filter is "don't care."<br>1b - The corresponding bit in the filter is checked. |

## 70.6.2.18 Legacy RX FIFO Information (RXFIR)

### Offset

| Register | Offset |
|---|---|
| RXFIR | 4Ch |

### Function

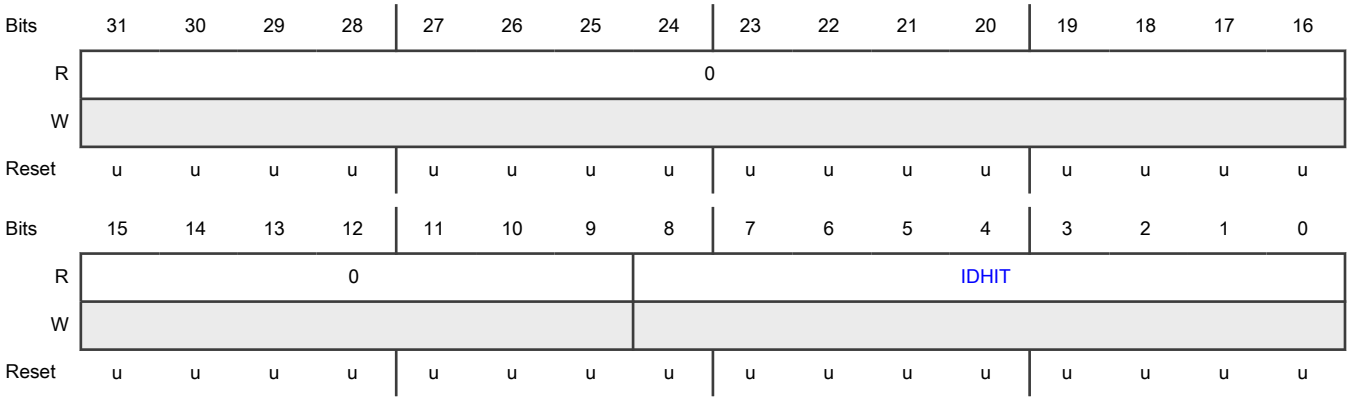
Provides information about Legacy RX FIFO.

This register is the port through which the CPU accesses the output of the Legacy RXFIR FIFO located in RAM. FlexCAN writes to the Legacy RXFIR FIFO when a new message is moved into the Legacy RX FIFO. Also, its output is updated whenever the output of the Legacy RX FIFO is updated with the next message. See Legacy RX FIFO for instructions on reading this register.

**NOTE**

RXFIR can be written only during memory initialization, due to the error code correction (ECC) feature. In every other case, this register is read-only.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-9<br>— | Reserved |
| 8-0<br>IDHIT | Identifier Acceptance Filter Hit Indicator<br>Indicates which Identifier Acceptance filter that the received message hit in the output of the Legacy RX FIFO. If multiple filters match the incoming message ID, the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only when IFLAG1[BUF5I] is set. |

## 70.6.2.19 CAN Bit Timing (CBT)

### Offset

| Register | Offset |
|---|---|
| CBT | 50h |

### Function

Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1). EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW are extended versions of CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] respectively.

**NOTE**

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

CBT[BTF] selects the use of the timing variables defined in this register.

When the CAN FD feature is enabled (MCR[FDEN] = 1), always write 1 to CBT[BTF].

Soft reset does not affect the contents of this register.

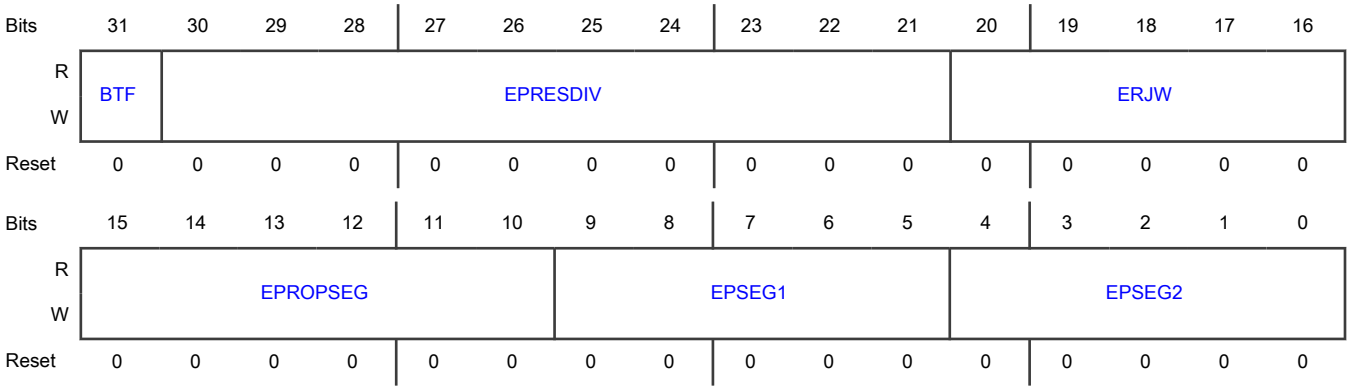
**NOTE**

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

**NOTE**

If CTRL2[BTE] = 1, EPRESDIV, ERJW, EPROPSEG, EPSEG1, and EPSEG2 are read as zero. A write operation to them has no effect.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>BTF | Bit Timing Format Enable<br>Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW. These fields replace the CAN bit timing variables defined in Control 1 (CTRL1). This field can be written in Freeze mode only.<br>0b - Disable<br>1b - Enable |
| 30-21<br>EPRESDIV | Extended Prescaler Division Factor<br>Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PRESDIV] value range.<br>The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode; the module blocks it in other modes.<br>Sclock frequency = PE clock frequency ÷ (EPRESDIV + 1) |
| 20-16<br>ERJW | Extended Resync Jump Width<br>Defines the maximum number of time quanta that one resynchronization can change a bit time when CBT[BTF] = 1. Otherwise, it has no effect. It extends the CTRL1[RJW] value range.<br>This field can be written only in Freeze mode; the module blocks it in other modes.<br>Resync Jump Width = ERJW + 1.<br>One Time Quantum = one Sclock period. |

| 4-0<br>EPSEG2 | Extended Phase Segment 2<br>Defines the length of phase segment 2 in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PSEG2] value range. This field can be written only in Freeze mode; the module blocks it in other modes.<br>Phase Buffer Segment 1 = (EPSEG2 + 1) × Time Quanta.<br>One Time Quantum = one Sclock period. |

### 70.6.2.20 Interrupt Masks 3 (IMASK3)

#### Offset

| Register | Offset |
|---|---|
| IMASK3 | 6Ch |

#### Function

Enables or disables any number of the 32 message buffer interrupts for MB95–MB64. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding IFLAG3 flag is set.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| FLEXCAN_0 | IMASK3 | — |
| FLEXCAN_1 | — | IMASK3 |

*Table continues on the next page...*

*Table continued from the previous page...*

|---|---|
| 31-0<br>BUF95TO64M | Buffer MBi Mask<br>Enables or disables the corresponding FlexCAN message buffer interrupt for MB95–MB64. When CAN FD is enabled, the MB range is defined in accordance with FDCTRL[MBDSRn].<br>**NOTE**<br>If the corresponding IFLAG3 flag is set, writing 1 or 0 to a field in IMASK3 can set or clear an interrupt request.<br>0b - The corresponding buffer interrupt is disabled.<br>1b - The corresponding buffer interrupt is enabled. |

## 70.6.2.21 Interrupt Flags 3 (IFLAG3)

### Offset

| Register | Offset |
|---|---|
| IFLAG3 | 74h |

### Function

Defines the flags for the 32 message buffer interrupts for MB95–MB64. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG3 flag. If the corresponding IMASK3 bit is 1, an interrupt is generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB], the CPU must service the IFLAG3 flags whose MB value is greater than the MAXMB to be updated. Otherwise, they remain set and are inconsistent with the number of message buffers available.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| FLEXCAN_0 | IFLAG3 | — |
| FLEXCAN_1 | — | IFLAG3 |
| FLEXCAN_2 | — | IFLAG3 |
| FLEXCAN_3 | — | IFLAG3 |

### 70.6.2.22 Receive Individual Mask (RXIMR0 - RXIMR95)

#### Offset

For n = 0 to 95:

| Register | Offset |
|---|---|
| RXIMRn | 880h + (n × 4h) |

#### Function

Stores the acceptance masks for ID filtering in RX message buffers and the Legacy RX FIFO.

When the Legacy RX FIFO is disabled (MCR[RFEN] = 0), an individual mask is provided for each available RX message buffer on a one-to-one correspondence. When the Legacy RX FIFO is enabled (MCR[RFEN] = 1), an individual mask is provided for each Legacy RX FIFO ID filter table element on a one-to-one correspondence. This correspondence depends on the setting of CTRL2[RFFN] (see Legacy RX FIFO).

RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0. RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

The CPU can only access the RXIMR registers when the module is in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general-purpose memory. See Bus interface for more information.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| FLEXCAN_0 | RXIMR0–RXIMR95 | — |
| FLEXCAN_1 | RXIMR0–RXIMR63 | RXIMR64–RXIMR95 |
| FLEXCAN_2 | RXIMR0–RXIMR63 | RXIMR64–RXIMR95 |
| FLEXCAN_3 | RXIMR0–RXIMR31 | RXIMR32–RXIMR95 |
| FLEXCAN_4 | RXIMR0–RXIMR31 | RXIMR32–RXIMR95 |

### 70.6.2.27 Error Report Address (RERRAR)

#### Offset

| Register | Offset |
|---|---|
| RERRAR | AF0h |

#### Function

Reports the address used for an access operation in which an error (correctable or noncorrectable) was detected. Also reports the identification of the source of that access.

This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] nonzero) are reported with the address aligned, and data is reported in Error Report Data (RERRDR) shifted accordingly. When errors are detected in accesses larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word where the error was detected is reported. For errors detected in more than one 32-bit word, only the least significant address is reported.

**Table 447. Source of memory access**

| SAID[2:0] | Error during... |
|---|---|
| 0 | Move-out FlexCAN access |
| 1 | Move-in |
| 2 | TX arbitration |

### 70.6.2.28 Error Report Data (RERRDR)

#### Offset

| Register | Offset |
|---|---|
| RERRDR | AF4h |

#### Function

Reports the raw data (unmodified by the correction performed by ECC logic) read from memory with error. The value reported does not represent the transient values of the BUSY bit (see Table 453) when reading a message buffer.

#### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 70.6.2.29 Error Report Syndrome (RERRSYNR)

#### Offset

| Register | Offset |
|---|---|
| RERRSYNR | AF8h |

### Function

Contains the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYND*n* field indicates the type of error and which bit in byte (*n*) the error affects. SYND3 corresponds to the most significant byte in the data word read from memory; SYND0 corresponds to the least significant.

**Table 448. Syndrome definition**

| SYND*n* (hex) | Type | Bit affected |
|---|---|---|
| 00 | — | None (no error) |
| 01 | Code | 0 |
| 02 | Code | 1 |
| 04 | Code | 2 |
| 07 | Data | 5 |
| 08 | Code | 3 |
| 0E | Data | 7 |
| 10 | Code | 4 |
| 13 | Data | 2 |
| 15 | Data | 6 |
| 16 | Data | 1 |
| 19 | Data | 3 |
| 1A | Data | 4 |
| 1C | Data | 0 |
| 06 | — | All-zeroes noncorrectable error |
| 1F | — | All-ones noncorrectable error |
| All others | — | Noncorrectable error |

Each BE*n* field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, including the non-read ones. Errors detected in non-read bytes are indicated (see Error indication) and reported (see Error reporting).

### Diagram

### 70.6.2.31 Enhanced CAN Bit Timing Prescalers (EPRS)

#### Offset

| Register | Offset |
|---|---|
| EPRS | BF0h |

#### Function

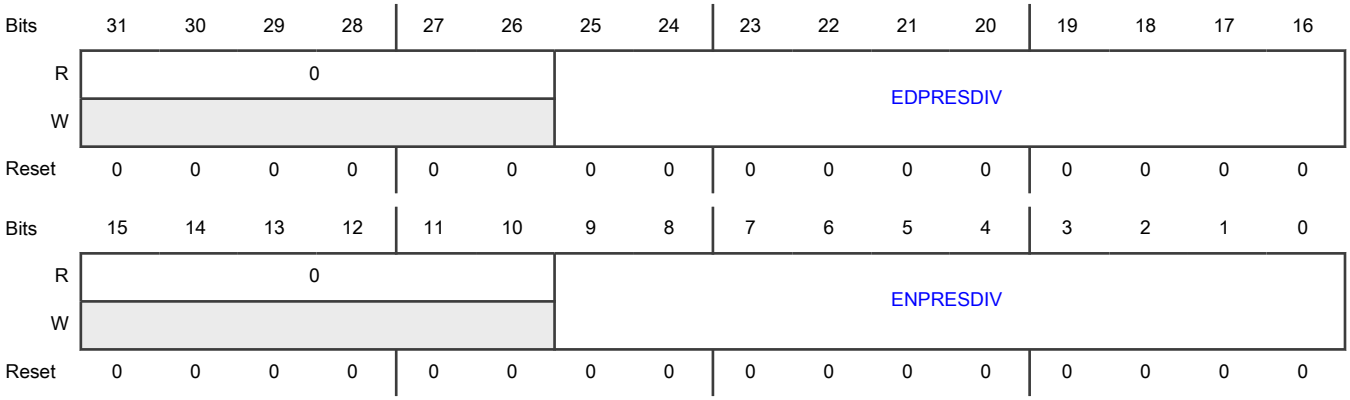
Defines the CAN bit timing prescalers for the nominal phase and data phase when CTRL2[BTE] = 1.

Used by the module only if CTRL2[BTE] = 1; otherwise, a write operation has no effect and all fields are read as zero.

This register can be written only in Freeze mode; the module blocks it in other modes.

Soft reset does not affect the contents of this register.

### Diagram



### Fields

| Field | Function |

| 15-10<br>— | Reserved |
| 9-0<br>ENPRESDIV | Extended Nominal Prescaler Division Factor<br>Defines the ratio between the PE clock frequency and the Sclock frequency when CTRL2[BTE] = 1. Otherwise, it reads as 0 and a write operation has no effect.<br>The Sclock period defines the time quantum of the CAN protocol in the nominal phase. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing).<br>Sclock frequency = PE clock frequency ÷ (ENPRESDIV + 1) |

### 70.6.2.32 Enhanced Nominal CAN Bit Timing (ENCBT)

#### Offset

| Register | Offset |
|---|---|
| ENCBT | BF4h |

#### Function

Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1) and CAN Bit Timing (CBT), to get higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

### 70.6.2.33 Enhanced Data Phase CAN Bit Timing (EDCBT)

#### Offset

| Register | Offset |
|---|---|
| EDCBT | BF8h |

#### Function

Provides an alternative way to store the data phase CAN bit timing variables described in CAN FD Bit Timing (FDCBT) to achieve higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1; otherwise, a write operation has no effect and all fields are read as zero.

Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

**NOTE**

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

**NOTE**

DTSEG1 must be at least two time quanta.

### Diagram

### 70.6.2.34 Enhanced Transceiver Delay Compensation (ETDC)

#### Offset

| Register | Offset |
|---|---|
| ETDC | BFCh |

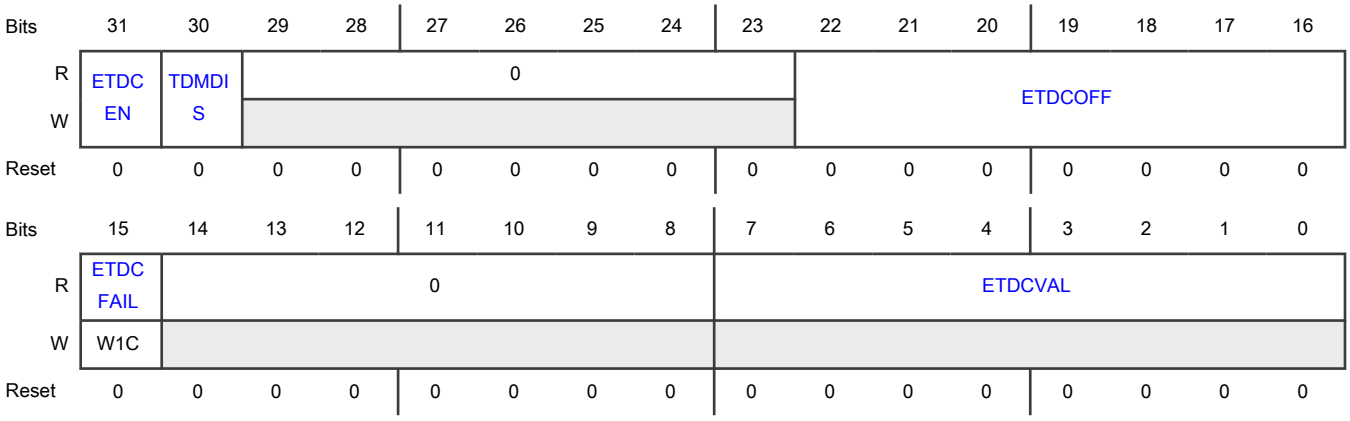
#### Function

Contains extended versions of FDCTRL[TDCOFF] and FDCTRL[TDCVAL]. This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

**NOTE**

See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details.

#### Diagram



#### Fields

| Field | Function |
|---|---|
| 31<br>ETDCEN | Transceiver Delay Compensation Enable<br>Enables the TDC feature. It can be written in Freeze mode only.<br>**NOTE**<br>See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details.<br>**NOTE**<br>TDC must be disabled when the Loop Back Mode is enabled. | 30<br>TDMDIS | Transceiver Delay Measurement Disable |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | Disables the transceiver delay measurement. When the TDC measurement is disabled, only ETDC[ETDCOFF] determines the secondary sample point position. If TCD measurement is enabled, the sum of the transceiver delay measurement plus the enhanced TDC offset determines the secondary sample point position.<br>Soft reset does not affect this field.<br>**NOTE**<br>This bit can be enabled only if CTRL2[BTE] = 1.<br>0b - Enable<br>1b - Disable |
| 29-23<br>— | Reserved |
| 22-16<br>ETDCOFF | Enhanced Transceiver Delay Compensation Offset<br>Contains the offset value to be added to the loop delay of the measured transceiver. This value defines the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for details on how the loop delay measurement is performed.<br>This field can be written in Freeze mode only. Its value can be defined in protocol engine (PE) clock periods (CANCLK, see Protocol timing for more details). It must be smaller than the CAN bit duration in the data bit rate for proper operation.<br>Do not write 0 to this field.<br>**NOTE**<br>If CTRL2[BTE] becomes 1 after a chip-level hard reset, this field is read as 1h. |
| 15<br>ETDCFAIL | Transceiver Delay Compensation Fail<br>Indicates whether the transceiver delay compensation (TDC) mechanism is out of range. In this case, it is unable to compensate the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones. (See Transceiver delay compensation.) This field becomes 0 the first time FlexCAN detects the out of range condition.<br>0b - In range<br>1b - Out of range |
| 14-8<br>— | Reserved |
| 7-0<br>ETDCVAL | Enhanced Transceiver Delay Compensation Value<br>Contains ETDC[ETDCOFF] added to the measured value of the transceiver loop delay in the latest transmitted CAN FD frame, with BRS = 1.<br>The module only updates this field when ETDC[ETDCEN] = 1.<br>Soft reset affects this field. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | **NOTE**<br>If ETDC[TDMDIS] = 1, this field stores ETDC[ETDCOFF] only. |

### 70.6.2.35 CAN FD Control (FDCTRL)

#### Offset

| Register | Offset |
|---|---|
| FDCTRL | C00h |

#### Function

Contains control bits for CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in Table 449.

When an 8-byte payload is selected:

- Block R0 allocates MB0–MB31.
- Block R1 allocates MB32–MB63.
- Block R2 allocates MB64–MB95.

When a payload larger than eight bytes is selected, the maximum number of message buffers in a block is limited as described below.

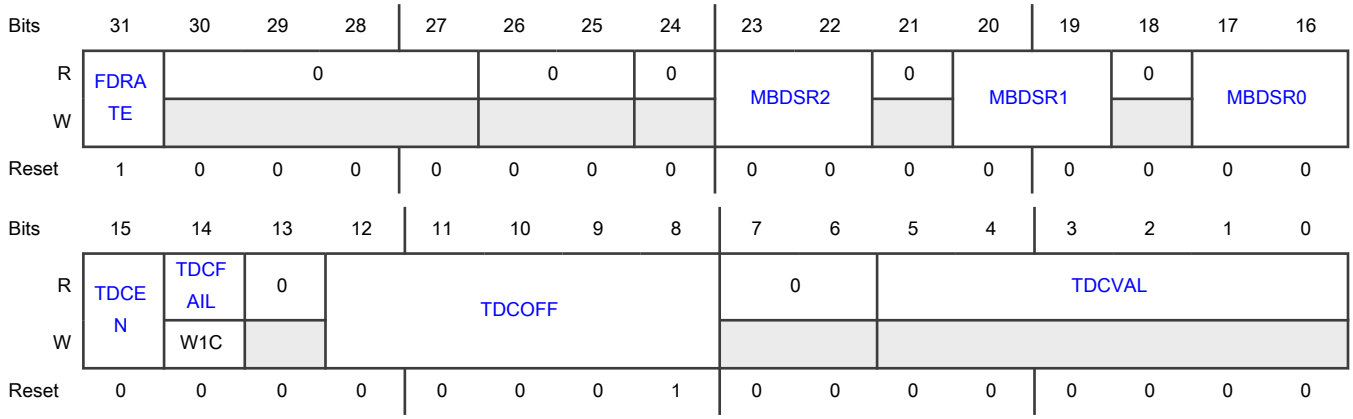
**Table 449. Number of message buffers**

| Payload size | Maximum number of message buffers per RAM block |
|---|---|
| 8 bytes | 32 |
| 16 bytes | 21 |
| 32 bytes | 12 |
| 64 bytes | 7 |

One memory block fits exactly 32 message buffers with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last message buffer in a block and the beginning of the next block. This empty memory corresponds to less than one message buffer, and must not be used.

Soft reset does not affect the contents of this register.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>FDRATE | Bit Rate Switch Enable<br>Enables the effect of the Bit Rate Switch (BRS bit) during the data phase of TX messages. When 1, if BRS = 1 in the TX message buffer, frames are transmitted with bit rate switching. When 0, frames are transmitted at a nominal rate, and the BRS bit in the TX MB has no effect.<br>The CPU can write to this field at any time. However, its effect becomes active only under one of these conditions:<br>• The CAN bus is in the Wait for Bus Idle state.<br>• The CAN bus is in the Bus Idle state.<br>• The CAN bus is in the Bus Off state.<br>• The current frame under reception or transmission reaches the interframe space.<br>By writing 0 to FDCTRL[FDRATE], the CPU can force all bits in CAN FD messages to be transmitted at nominal bit rate. This transmission occurs regardless of the value in the BRS bit of the TX message buffers.<br>0b - Disable<br>1b - Enable |

### 70.6.2.36 CAN FD Bit Timing (FDCBT)

#### Offset

| Register | Offset |
|---|---|
| FDCBT | C04h |

#### Function

Stores the CAN bit timing variables used in the data phase of CAN FD messages when the FDCTRL[FDRATE] = 1, compatible with the CAN FD specification. Fields in this register define:

- The time quantum duration
- The number of time quanta per CAN bit
- The sample point position for the data bit rate portion of a CAN FD message with BRS = 1

Soft reset does not affect the contents of this register.

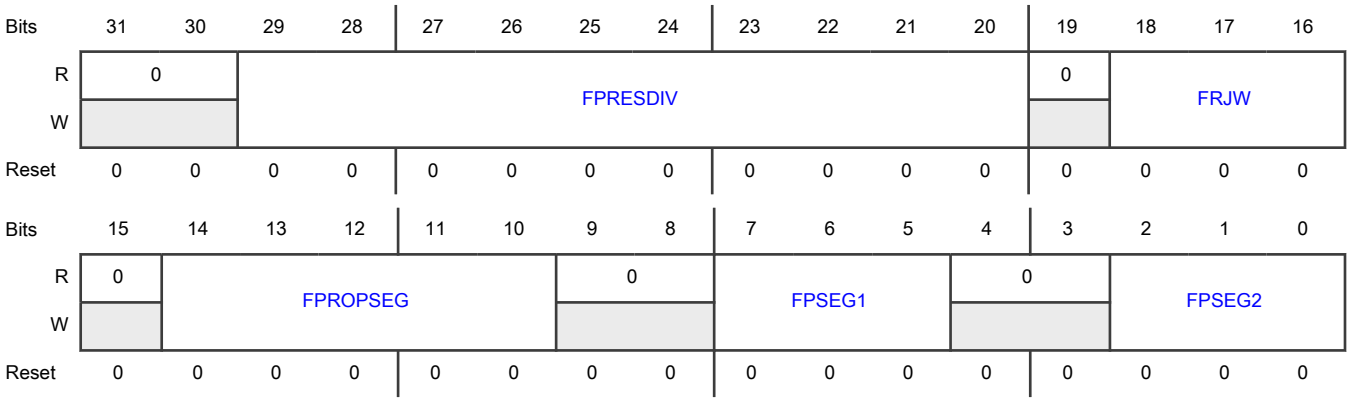
The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

Ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

**NOTE**

If CTRL2[BTE] = 1, this register is read as zero and a write operation has no effect.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-30<br>— | Reserved |
| 29-20<br>FPRESDIV | Fast Prescaler Division Factor<br>Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency in the data bit rate portion of a CAN FD message with BRS = 1.<br>The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. This field can be written only in Freeze mode; the module blocks it in other modes.<br>Sclock frequency = PE clock frequency ÷ (FPRESDIV + 1).<br>**NOTE**<br>To minimize errors when processing FD frames, use the same value for this field and for CTRL1[PRESDIV] or CBT[EPRESDIV]. See the first note in CAN FD frames for details. |
| 19<br>— | Reserved |
| 18-16<br>FRJW | Fast Resync Jump Width<br>Defines the maximum number of time quanta that one resynchronization can change a bit time in the data bit rate portion of a CAN FD message with BRS = 1.<br>This field can be written only in Freeze mode; the module blocks it in other modes.<br>Resync Jump Width = FSJW + 1. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | One Time Quantum = one Sclock period. |
| 15<br>— | Reserved |
| 14-10<br>FPROPSEG | Fast Propagation Segment<br>Defines the length of the propagation segment in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes.<br>Propagation Segment Time = FPROPSEG × Time Quanta.<br>One Time Quantum = one Sclock period. |
| 9-8<br>— | Reserved |
| 7-5<br>FPSEG1 | Fast Phase Segment 1<br>Defines the length of phase segment 1 in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes.<br>Phase Segment 1 = (FPSEG1 + 1) × Time Quanta.<br>One Time Quantum = one Sclock period. |
| 4-3<br>— | Reserved |
| 2-0<br>FPSEG2 | Fast Phase Segment 2<br>Defines the length of phase segment 2 in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes.<br>Phase Segment 2 = (FPSEG2 + 1) × Time Quanta.<br>One Time Quantum = one Sclock period. |

### 70.6.2.37 CAN FD CRC (FDCRC)

#### Offset

| Register | Offset |
|---|---|
| FDCRC | C08h |

#### Function

Provides information about the cyclic redundancy check (CRC) of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats.

- The CRC_15 polynomial is used for all frames in CAN format.
- The CRC_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to 16 bytes.

- The CRC_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than 16 bytes.

Each polynomial shown below results in a Hamming distance of 6. This register is updated at the same time that the TX Interrupt flag is set.

$$CRC_15 = C599h:\ (x^{15} + x^{14} + x^{10} + x^{8} + x^{7} + x^{4} + x^{3} + 1)$$

$$CRC_17 = 3685Bh:\ (x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^{6} + x^{4} + x^{3} + x^{1} + 1)$$

$$CRC_21 = 302899h:\ (x^{21} + x^{20} + x^{13} + x^{11} + x^{7} + x^{4} + x^{3} + 1)$$

**Equation 31. CRC polynomial used on CAN frame**

**NOTE**

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1:2015) for details.

### Fields

| Field | Function |
|---|---|
| 31<br>— | Reserved |
| 30-24<br>FD_MBCRC | CRC Message Buffer Number for FD_TXCRC<br>Indicates the number of the message buffer corresponding to the value in FDCRC[FD_TXCRC], for both FD and non-FD frames.<br>It reports the same information as in CRCR[MBCRC]. |
| 23-21<br>— | Reserved |
| 20-0<br>FD_TXCRC | Extended Transmitted CRC value<br>Contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | For CRC_15 and CRC_17, the six most significant bits and the four most significant bits are reported as zeroes, respectively.<br>For CRC_15, this field has the same content as Cyclic Redundancy Check (CRCR). |

### 70.6.2.38 Enhanced RX FIFO Control (ERFCR)

#### Offset

| Register | Offset |
|---|---|
| ERFCR | C0Ch |

#### Function

Defines the Enhanced RX FIFO configuration.

This register can be written only in Freeze mode.

Soft reset does not affect any of the contents of this register.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| FLEXCAN_0 | ERFCR | — |
| FLEXCAN_1 | — | ERFCR |
| FLEXCAN_2 | — | ERFCR |
| FLEXCAN_3 | — | ERFCR |
| FLEXCAN_4 | — | ERFCR |
| FLEXCAN_5 | — | ERFCR |

| 15<br>— | Reserved |
| 14-6<br>— | Reserved |
| 5-0<br>ERFEL | Enhanced RX FIFO Elements<br>Indicates the number of CAN messages stored in the Enhanced RX FIFO. |

### 70.6.2.41 High-Resolution Timestamp (HR_TIME_STAMP0 - HR_TIME_STAMP95)

**Offset**

For n = 0 to 95:

| Register | Offset |
|---|---|
| HR_TIME_STAMPn | C30h + (n × 4h) |

### Function

Stores a copy of a 32-bit timer at the start or end of a CAN frame.

HR_TIME_STAMP0 stores the 32-bit timestamp associated with MB0, HR_TIME_STAMP1 stores the 32-bit timestamp associated with MB1, and so on.

Reset does not affect these registers.

**NOTE**

Do not write to these registers outside Freeze mode.

**Table 450. High-Resolution Timestamp register operation**

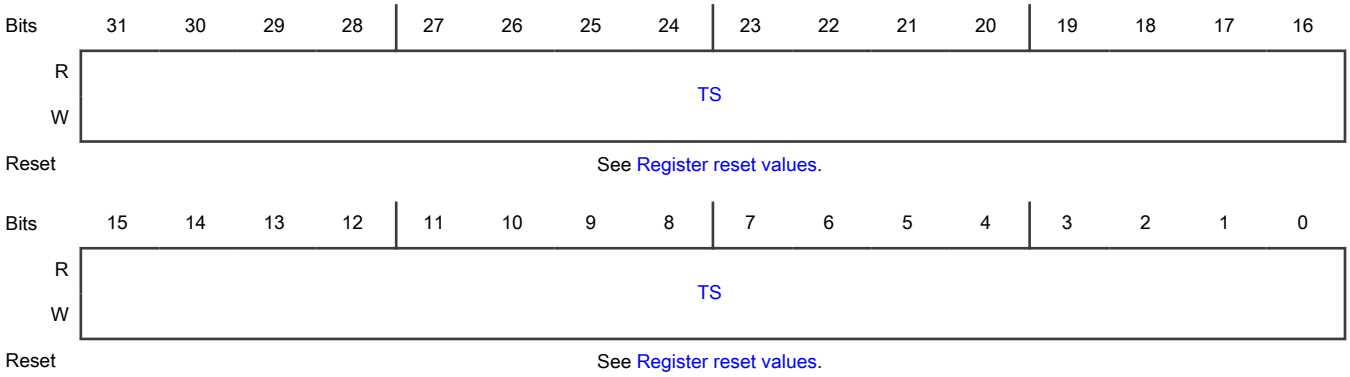
| TSTAMPCAP | Captured timebase | Capture point |
|---|---|---|
| b00 | None | None |
| b01 | 32 bits of high-resolution on-chip timer | Seventh bit of the end-of-frame field for transmission and sixth bit of the end-of-frame field for reception. |
| b10 | 32 bits of high-resolution on-chip timer | Start of frame |
| b11 | 32 bits of high-resolution on-chip timer | Start of frame for classical CAN frame format and res bit for CAN FD frame format |

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| FLEXCAN_0 | HR_TIME_STAMP0–HR_TIME_STAMP95 | — |
| FLEXCAN_1 | HR_TIME_STAMP0–HR_TIME_STAMP63 | HR_TIME_STAMP64–HR_TIME_STAMP95 |
| FLEXCAN_2 | HR_TIME_STAMP0–HR_TIME_STAMP63 | HR_TIME_STAMP64–HR_TIME_STAMP95 |
| FLEXCAN_3 | HR_TIME_STAMP0–HR_TIME_STAMP31 | HR_TIME_STAMP32–HR_TIME_STAMP95 |
| FLEXCAN_4 | HR_TIME_STAMP0–HR_TIME_STAMP31 | HR_TIME_STAMP32–HR_TIME_STAMP95 |
| FLEXCAN_5 | HR_TIME_STAMP0–HR_TIME_STAMP31 | HR_TIME_STAMP32–HR_TIME_STAMP95 |

### Diagram



### Register reset values

| Register | Reset value |
|---|---|
| HR_TIME_STAMP0–HR_TIME_STAMP31 | FLEXCAN_0–FLEXCAN_5: undefined |
| HR_TIME_STAMP32–HR_TIME_STAMP63 | FLEXCAN_0–FLEXCAN_2: undefined<br>FLEXCAN_3–FLEXCAN_5: Register not supported |
| HR_TIME_STAMP64–HR_TIME_STAMP95 | FLEXCAN_0: undefined<br>FLEXCAN_1–FLEXCAN_5: Register not supported |

### Fields

| Field | Function |
|---|---|
| 31-0<br>TS | High-Resolution Timestamp<br>Captures the copy of the timestamp of corresponding message buffer. This field always captures a 32-bit timer value. |

## 70.6.2.42 Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL127)

### Offset

For n = 0 to 127:

| Register | Offset |
|---|---|
| ERFFELn | 3000h + (n × 4h) |

### Function

Stores the filter elements of the Enhanced RX FIFO.

For standard ID filtering, each ERFFEL register stores one filter element. For extended ID filtering, each pair of ERFFEL registers stores one filter element.

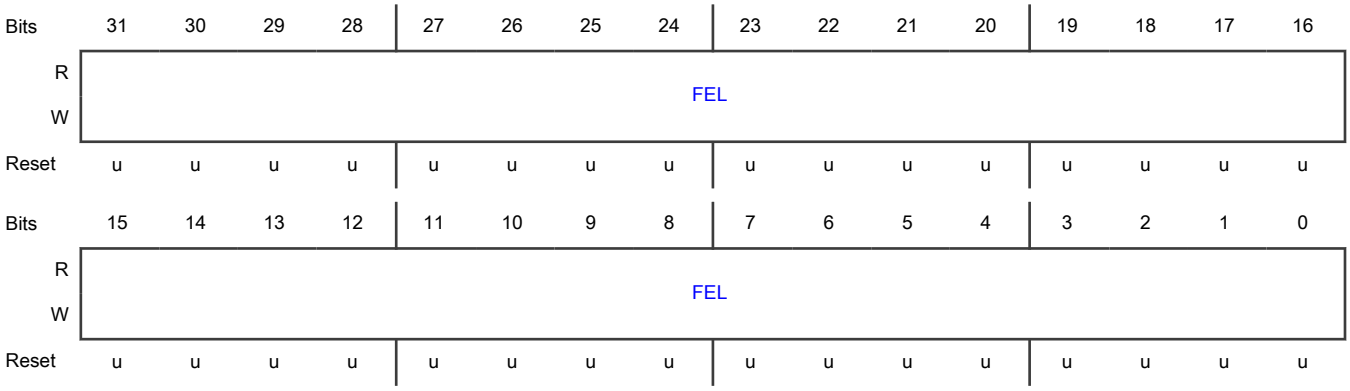
ERFFEL registers can be written only in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

**NOTE**

Each module instance supports a different number of registers.

| Instance | Register supported | Register not supported |
|---|---|---|
| FLEXCAN_0 | ERFFEL0–ERFFEL127 | — |
| FLEXCAN_1 | — | ERFFEL0–ERFFEL127 |
| FLEXCAN_2 | — | ERFFEL0–ERFFEL127 |
| FLEXCAN_3 | — | ERFFEL0–ERFFEL127 |
| FLEXCAN_4 | — | ERFFEL0–ERFFEL127 |
| FLEXCAN_5 | — | ERFFEL0–ERFFEL127 |

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>FEL | Filter Element Bits<br>Stores filter elements. Each filter element is used during the match process. If the matching criteria are met, a message is stored in the Enhanced RX FIFO. |

## 70.6.3 Message buffer structure

The message buffer structure used by FlexCAN is represented in the following figure. Both extended (29-bit identifier) and standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual message buffer is 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area 80h–67Fh is used by the message buffers. When CAN FD is enabled, the exact address for each message buffer depends on the size of its payload. See FlexCAN memory partition for CAN FD.

**Table 451. Message buffer structure example with 64-byte payload**

| | 31 | 30 | 29 | 28 | 27 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 8 | 7 | 0 |

= Unimplemented or reserved

**Table 452. Field descriptions**

| Mnemonic | Field | Description |
|---|---|---|
| EDL | Extended Data Length | Distinguishes between CAN format and CAN FD format frames. EDL must not be 1 for message buffers configured to RANSWER with code field 1010b (see Table 453). |
| BRS | Bit Rate Switch | Defines whether the bit rate is switched inside a CAN FD format frame. |
| ESI | Error State Indicator | Indicates whether the transmitting node is error-active or error-passive. |
| CODE | Message Buffer Code | Can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 453 and Table 454. See Functional description. |

Table 453. Message buffer code for RX buffers

| CODE description | RX code BEFORE RX new frame | SRV[1] | RX code AFTER successful reception[2] | RRS[3] | Comment |
|---|---|---|---|---|---|
| 0000b: INACTIVE. Message buffer is not active. | INACTIVE | — | — | — | Message buffer does not participate in the matching process. |
| 0100b: EMPTY. Message buffer is active and empty. | EMPTY | — | FULL | — | When a frame is received successfully (after Move-in), CODE is automatically updated to FULL. |
| 0010b: FULL. Message buffer is full. | FULL | Yes | FULL | — | The act of reading the Control and Status word followed by unlocking the message buffer (SRV) does not make CODE return to EMPTY. It remains FULL. If a new frame is moved to the message buffer after the message buffer is serviced, the code remains FULL. See Matching process for matching details related to FULL code. |
| | | No | OVERRUN | — | If the message buffer is FULL and a new frame is moved to this message buffer before the CPU services it, CODE is automatically updated to OVERRUN. See Matching process for details about overrun behavior. |
| 0110b: OVERRUN. Message buffer is being overwritten into a full buffer. | OVERRUN | Yes | FULL | — | If CODE indicates OVERRUN and the CPU has serviced the message buffer, when a new frame is moved to the message buffer, CODE returns to FULL. |
| | | No | OVERRUN | — | If CODE already indicates OVERRUN, and another new frame must be moved, the message buffer is overwritten |

*Table continues on the next page...*

Table 453. Message buffer code for RX buffers (continued)

| CODE description | RX code BEFORE RX new frame | SRV[1] | RX code AFTER successful reception[2] | RRS[3] | Comment |
|---|---|---|---|---|---|
| | | | | | again, and CODE remains OVERRUN. See Matching process for details about overrun behavior. |
| 1010b: RANSWER[4]. A frame was configured to recognize a Remote Request frame and transmit a Response frame in return.[5] | RANSWER | — | TANSWER (1110b) | 0 | A Remote Answer was configured to recognize a Remote Request frame received. After that, a message buffer is set to transmit a response frame. CODE is automatically changed to TANSWER (1110b). See Matching process for details. If CTRL2[RRS] = 0, transmit a response frame when a remote request frame with the same ID is received. |
| | | — | — | 1 | This code is ignored during matching and arbitration process. See Matching process for details. |
| CODE[0] = 1: BUSY. FlexCAN is updating the contents of the message buffer. The CPU must not access the message buffer. | BUSY[6] | — | FULL | — | Indicates that the message buffer is being updated. It automatically becomes 0 and does not interfere with the next CODE. |
| | | — | OVERRUN | — | |

1. SRV: Serviced message buffer. Message buffer was read and unlocked by reading TIMER or another message buffer.
2. A frame is considered a successful reception after the frame is moved to a message buffer (move-in process). See Move-in.
3. Remote Request Stored field. See Control 2 (CTRL2).
4. Code 1010b is not considered TX and a message buffer with this code should not be aborted.
5. Code 1010b must be used in message buffers configured in CAN FD format, with EDL = 1.
6. For TX message buffers, the BUSY bit should be ignored upon read, except when MCR[AEN] = 1. If this field is 1, the corresponding message buffer does not participate in the matching process.

Table 454. Message buffer code for TX buffers

| CODE Description | TX Code BEFORE TX frame | MB RTR | TX Code AFTER successful transmission | Comment |
|---|---|---|---|---|
| 1000b: INACTIVE. Message buffer is not active. | INACTIVE | — | — | Message buffer does not participate in arbitration process. |
| 1001b: ABORT. Message buffer is aborted. | ABORT | — | — | Message buffer does not participate in arbitration process. |
| 1100b: DATA. Message buffer is a TX data frame (MB RTR must be 0). | DATA | 0 | INACTIVE | Transmit data frame unconditionally once. After transmission, the message buffer automatically returns to the INACTIVE state. |
| 1100b: REMOTE. Message buffer is a Transmit Remote Request frame (MB RTR must be 1). | REMOTE | 1 | EMPTY | Transmit remote request frame unconditionally once. After transmission, the message buffer automatically becomes an RX Empty message buffer with the same ID. |
| 1110b: TANSWER. Message buffer is a Transmit Response frame from an incoming Remote Request frame. | TANSWER | — | RANSWER | This intermediate code is automatically written to the message buffer by the CHI as a result of a match to a Remote Request frame. The Remote Response frame is transmitted unconditionally once, then the code automatically returns to RANSWER (1010b). The CPU can also write this code with the same effect. The Remote Response frame can be a data frame or another remote request frame, depending on the value of RTR. See Matching process and Arbitration process for details. |

Table 455. RX and TX message buffer field descriptions

| Mnemonic | Field | Description |
|---|---|---|
| SRR | Substitute Remote Request | Fixed recessive bit, used only in extended format. Write 1 to SRR for transmission (TX Buffers). SRR is stored with the value received on the CAN |

*Table continues on the next page...*

Table 455. RX and TX message buffer field descriptions (continued)

| Mnemonic | Field | Description |
|---|---|---|
| | | bus for RX receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss.<br>1: Recessive value is compulsory for transmission in extended format frames.<br>0: Dominant is not a valid value for transmission in extended format frames. |
| IDE | ID Extended Bit | Identifies whether the frame format is standard or extended.<br>1: Frame format is extended<br>0: Frame format is standard |
| RTR | Remote Transmission Request | Affects the behavior of remote frames and is part of the reception filter. See Table 453, Table 454, and CTRL2[RRS].<br>If FlexCAN transmits this field as 1 (recessive) and receives it as 0 (dominant), it is interpreted as an arbitration loss. If this field is transmitted as 0 (dominant) and it is received as 1 (recessive), FlexCAN treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.<br>1: If message buffer is TX, indicates that the current message buffer may have a Remote Request frame to be transmitted. If the message buffer is RX, incoming remote request frames may be stored.<br>0: Indicates that the current message buffer has a Data frame to be transmitted. In an RX message buffer, it may be considered in matching processes.<br>**NOTE**<br>When configuring CAN FD frames, this field must be 0. |
| DLC | Data Length Code | Indicates the length (in bytes) of the RX or TX data, which is located in offset 8h–Fh of the message buffer space (see Table 451).<br>In reception, this field is written by FlexCAN, copied from the DLC field of the received frame.<br>In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted.<br>When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 457). |
| TIMESTAMP | Free-Running Counter Timestamp | Provides a copy of the Free-Running Timer, captured for TX and RX frames when the beginning of the Identifier field appears on the CAN bus.<br>See Table 456 for Timestamp operation. |
| PRIO | Local priority | Used only when MCR[LPRIOEN] = 1, and only makes sense for transmit message buffers. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process. |
| ID | Frame Identifier | In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least |

*Table continues on the next page...*

Table 455. RX and TX message buffer field descriptions (continued)

| Mnemonic | Field | Description |
|---|---|---|
| | | significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases. |
| DATA BYTE 0–63 | Data Field | Up to 64 bytes can be used for a data frame, depending on the size of payload selected for the message buffers.<br>For RX frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC, as shown in Table 457. |

Table 456. Timestamp operation

| TSTAMPCAP | MBTSBASE | TIMER_SOURCE | Captured timebase | Capture point |
|---|---|---|---|---|
| b00 | bxx | 0 | CAN_TIMER incremented by CAN bit clock | Second bit of identifier field |
| b00 | bxx | 1 | CAN_TIMER incremented by on-chip timer clock | Second bit of identifier field |
| bxx | b00 | 0 | CAN_TIMER incremented by CAN bit clock | Second bit of identifier field |
| bxx | b00 | 1 | CAN_TIMER incremented by on-chip timer clock | Second bit of identifier field |
| b01 | b01 | x | Lower 16 bits of high-resolution on-chip timer | Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception |
| b01 | b10 | x | Upper 16 bits of high-resolution on-chip timer | Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception |
| b10 | b01 | x | Lower 16 bits of high-resolution on-chip timer | Start of frame |
| b10 | b10 | x | Upper 16 bits of high-resolution on-chip timer | Start of frame |
| b11 | b01 | x | Lower 16 bits of high-resolution on-chip timer | Start of frame for classical CAN frame format and res bit for CAN FD frame format |
| b11 | b10 | x | Upper 16 bits of high-resolution on-chip timer | Start of frame for classical CAN frame format and res bit for CAN FD frame format |

| 15 | DATA BYTE 0–63 |

### 70.6.4 FlexCAN memory partition for CAN FD

When CAN FD is enabled, FlexCAN RAM can be partitioned into blocks of 512 bytes each. Each block can accommodate a number of message buffers depending on the configuration provided by FDCTRL[MBDSR*n*] as shown in Table 458.

Table 458. RAM partition

| RAM block | Number of MBs with 8 bytes (default range) | Size control field in FDCTRL | Number of MBs of different sizes, per block |
|---|---|---|---|
| 0 | 0 to 31 | MBDSR0 | MBDSR0 = 00, 32 MBs with 8-byte payload<br>MBDSR0 = 01, 21 MBs with 16-byte payload<br>MBDSR0 = 10, 12 MBs with 32-byte payload<br>MBDSR0 = 11, 7 MBs with 64-byte payload |
| 1 | 32 to 63 | MBDSR1 | MBDSR1 = 00, 32 MBs with 8-byte payload<br>MBDSR1 = 01, 21 MBs with 16-byte payload<br>MBDSR1 = 10, 12 MBs with 32-byte payload<br>MBDSR1 = 11, 7 MBs with 64-byte payload |
| 2 | 64 to 95 | MBDSR2 | MBDSR2 = 00, 32 MBs with 8-byte payload<br>MBDSR2 = 01, 21 MBs with 16-byte payload<br>MBDSR2 = 10, 12 MBs with 32-byte payload<br>MBDSR2 = 11, 7 MBs with 64-byte payload |

Payload sizes of 16, 32, or 64 bytes may be configured in some or all of RAM blocks. In those cases, the total number of MBs and their respective number order may differ from the default configuration of 8 bytes. Consider an example where:

- Block0 is configured to an 8-byte payload
- Block1 is configured to a 16-byte payload
- Block2 is configured to 32-byte payload

In this case, Table 459 indicates how the message buffers are arranged in RAM.

**Table 459. RAM partition example**

| RAM block | Payload size | Number of MBs in the RAM block | Message buffer range |
|---|---|---|---|
| 0 | FDCTRL[MBDSR0] = 00, 8-byte payload | 32 | 0 to 31 |
| 1 | FDCTRL[MBDSR1] = 01, 16-byte payload | 21 | 32 to 52 |
| 2 | FDCTRL[MBDSR2] = 10, 32-byte payload | 12 | 53 to 64 |

### 70.6.5 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

### 70.6.6 legacy RX FIFO structure

When MCR[RFEN] = 1, the memory area 80h–DCh (which is normally occupied by MBs 0–5) is used by the reception Legacy FIFO engine.

The region 80h–8Ch contains the output of the Legacy RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read. The region 90h–DCh is reserved for internal use of the Legacy RX FIFO engine.

An additional memory area, which starts at E0h and may extend up to 2DCh (normally occupied by MBs 6–37) depending on the value of CTRL2[RFFN], contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the Legacy RX FIFO.

Out of reset, the ID filter table flexible memory area defaults to E0h and extends only to FCh, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Legacy RX FIFO data structure.

**Table 464. Legacy RX FIFO structure**

| | 31 28 | 24 23 | 22 | 21 | 20 | 19 18 17 16 | 15 8 | 7 0 |
|---|---|---|---|---|---|---|---|---|
| 80h | IDHIT | | SRR | IDE | RTR | DLC | TIMESTAMP | |
| 84h | | ID standard | | | | ID extended | | |
| 88h | Data byte 0 | | Data byte 1 | | | | Data byte 2 | Data byte 3 |
| 8Ch | Data byte 4 | | Data byte 5 | | | | Data byte 6 | Data byte 7 |
| 90h–DCh | Reserved | | | | | | | |
| E0h | ID filter table element 0 | | | | | | | |
| E4h | ID filter table element 1 | | | | | | | |
| E8h–2D4h | ID filter table elements 2 to 125 | | | | | | | |
| 2D8h | ID filter table element 126 | | | | | | | |
| 2DCh | ID filter table element 127 | | | | | | | |
| | | | | | | | | |
| | = Unimplemented or reserved | | | | | | | |

Each ID filter table element occupies an entire 32-bit word. One, two, or four Identifier Acceptance Filters (IDAF) can compound each element, depending on MCR[IDAM]. The following tables show the IDAF indexing.

Table 465 shows the three different formats of the ID table elements. All elements of the table must have the same format. See Legacy RX FIFO for more information.

**Table 465. ID table structure**

| Format | 31 | 30 | 29 24 | 23 16 | 15 | 14 | 13 8 | 7 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|
| A | RTR | IDE | RXIDA (standard = 29–19, extended = 29–1) | | | | | | |
| | | | | | | | | | |
| B | RTR | IDE | RXIDB_0 (standard = 29–19, extended = 29–16) | | RTR | IDE | RXIDB_1 (standard = 13–3, extended = 13–0) | | |
| | | | | | | | | | |
| C | RXIDC_0 (std and ext = 31–24) | | RXIDC_1 (std and ext = 23–16) | | RXIDC_2 (std and ext = 15–8) | | RXIDC_3 (std and ext = 7–0) | | |
| | | | | | | | | | |
| | = Unimplemented or Reserved | | | | | | | | |

Table 466. Field descriptions

| Mnemonic | Field | Description |
|---|---|---|
| RTR | Remote Frame | Specifies whether remote frames are accepted into the Legacy FIFO if they match the target ID.<br>1: Remote frames can be accepted and data frames are rejected.<br>0: Remote frames are rejected and data frames can be accepted. |
| IDE | Extended Frame | Specifies whether extended or standard frames are accepted into the Legacy FIFO if they match the target ID.<br>1: Extended frames can be accepted and standard frames are rejected.<br>0: Extended frames are rejected and standard frames can be accepted. |
| RXIDA | RX Frame Identifier (Format A) | Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used. |
| RXIDB_0, RXIDB_1 | RX Frame Identifier (Format B) | Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID. |
| RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3 | RX Frame Identifier (Format C) | Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID. |
| IDHIT | Identifier Acceptance Filter Hit Indicator | Indicates which identifier acceptance filter the received message in the output of the Legacy RX FIFO hit. See Legacy RX FIFO for more information. |

## 70.6.7 Enhanced RX FIFO structure

When ERFCR[ERFEN] = 1, the Enhanced RX FIFO is enabled. The region 2000h–204Ch contains the output of the Enhanced RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read.

Table 467. Enhanced RX FIFO structure

| | 31 | 30 | 29 | 28 ... 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 ... 8 | 7 | 6 ... 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 2000h | EDL | BRS | ESI | Reserved | | SRR | IDE | RTR | DLC | | | | TIMESTAMP LEGACY | | |
| 2004h | Reserved | | | ID (standard/extended) | | | | | | | | | ID (extended) | | |
| 2008h | Data byte 0 | | | | | Data byte 1 | | | | | | | Data byte 2 | | Data byte 3 |
| 200Ch | Data byte 4 | | | | | Data byte 5 | | | | | | | Data byte 6 | | Data byte 7 |
