# MCXE31x Reference Manual

Supports MCXE315, MCXE316, MCXE317, and MCXE31B

# Contents

Chapter 1 About This Manual..... 7

Chapter 2 Introduction..... 14

Chapter 3 Memory Map..... 23

Chapter 4 Signal Multiplexing..... 27

Chapter 5 Cortex-M7 Overview..... 39

Chapter 6 Miscellaneous Control Module (MCM)..... 43

Chapter 7 Miscellaneous System Control Module (MSCM).....62

Chapter 8 Virtualization Wrapper (VIRT_WRAPPER)..... 94

Chapter 9 System Integration Unit Lite2 (SIUL2).....113

Chapter 10 Touch Sensing Pin Coupling (TSPC).....232

Chapter 11 Crossbar Switch (AXBS)..... 240

Chapter 12 Peripheral Bridge (AIPS_Lite)..... 252

Chapter 13 Direct Memory Access Multiplexer (DMAMUX)..... 254

Chapter 14 Enhanced Direct Memory Access (eDMA).....264

Chapter 15 Interrupt Monitor (INTM).....365

Chapter 16 Semaphores2 (SEMA42)..... 374

Chapter 17 Crossbar Integrity Checker (XBIC).....383

Chapter 18 Extended Resource Domain Controller (XRDC)..... 397

Chapter 19 Memory and Memory Interfaces..... 472

Chapter 20 Embedded Flash Memory (c40asf)..... 477

Chapter 21 Flash Memory Controller (PFLASH)..... 538

Chapter 22 RAM Controller (PRAMC)..... 562

Chapter 23 Clocking..... 569

Chapter 24 Clock Generation Module (MC_CGM)..... 637

Chapter 25 Fast Internal RC Oscillator (FIRC)..... 731

Chapter 26 Slow Internal RC Oscillator (SIRC)..... 734

Chapter 27 Fast Crystal Oscillator Digital Controller (FXOSC)..... 737

Chapter 28 Slow Crystal Oscillator Digital Controller (SXOSC)..... 744

Chapter 29 PLL Digital Interface (PLLDIG)..... 750

Chapter 30 Reset Overview..... 766

Chapter 31 Boot Overview..... 788

Chapter 32 Reset Generation Module (MC_RGM)..... 814

Chapter 33 Power-on Reset Watchdog (POR_WDG)..... 842

Chapter 34 Security Overview..... 845

Chapter 35 EdgeLock Secure Enclave (HSE_B)..... 847

Chapter 36 Device Configuration Format (DCF) records..... 867

Chapter 37 Device Configuration Module General-Purpose Registers (DCM_GPR)..... 872

Chapter 38 Device Configuration Module (DCM)..... 953

Chapter 39 Messaging Unit (MU)..... 995

Chapter 40 Power Management..... 1124

Chapter 41 Power Management Controller (PMC for MCXE31B)..... 1144

Chapter 42 Power Management Controller (PMC for MCXE315, MCXE316, and MCXE317)..... 1156

Chapter 43 Mode Entry Module (MC_ME)..... 1169

Chapter 44 Power Control Unit (MC_PCU)..... 1275

Chapter 45 Wakeup Unit (WKPU)..... 1278

Chapter 46 Safety Overview..... 1304

Chapter 47 Error Injection Module (EIM)..... 1314

Chapter 48 Error Reporting Module (ERM)..... 1370

Chapter 49 Fault Collection and Control Unit (FCCU)..... 1401

Chapter 50 Self-test General-Purpose Registers (SELFTEST_GPR)..... 1457

Chapter 51 Self-Test Control Unit (STCU2)..... 1461

Chapter 52 Register Protection (REG_PROT)..... 1506

Chapter 53 Clock Monitoring Unit – Frequency Check (CMU_FC)..... 1518

Chapter 54 Clock Monitoring Unit – Frequency Meter (CMU_FM)..... 1534

Chapter 55 Cyclic Redundancy Check (CRC)..... 1542

Chapter 56 Power Conversion and Motor Control (PCMC)..... 1553

Chapter 57 Analog-to-Digital Converter (ADC)....1570

Chapter 58 Low Power Comparator (LPCMP)....1733

Chapter 59 Logic Control Unit (LCU)....1774

Chapter 60 Enhanced Modular IO Subsystem (eMIOS)....1850

Chapter 61 Body Cross-triggering Unit (BCTU)....1937

Chapter 62 Trigger MUX (TRGMUX)....1976

Chapter 63 Software Watchdog Timer (SWT)....2038

Chapter 64 System Timer Module (STM)....2055

Chapter 65 Periodic Interrupt Timer (PIT)....2064

Chapter 66 Real Time Clock (RTC)....2088

Chapter 67 Low Power Serial Peripheral Interface (LPSPI)....2101

Chapter 68 Low Power Inter-Integrated Circuit (LPI2C)....2155

Chapter 69 Flexible I/O (FlexIO)....2218

Chapter 70 CAN (FlexCAN)....2297

Chapter 71 Synchronous Audio Interface (SAI)....2469

Chapter 72 Ethernet Media Access Controller (EMAC)....2519

Chapter 73 Low Power Universal Asynchronous Receiver/Transmitter (LPUART)....3109

Chapter 75 Debug Subsystem....3251

Chapter 76 JTAG Controller (JTAGC)..... 3294

Chapter 77 JTAG Data Communication (JDC)..... 3303

Chapter 78 Temperature Sensor (TEMPSENSE).....3312

Appendix A Release notes.....3319

Legal information..... 3357

# Chapter 1
# About This Manual

## 1.1 Audience

This reference manual (RM) is intended for system software, hardware developers, and applications programmers who need to develop products using this chip. It assumes that its users understand operating systems, microprocessor system design, and basic principles of software and hardware.

## 1.2 Organization

This manual has two main sets of chapters.

- Chapters in the first set contain information that applies to all components on the chip.
- Chapters in the second set are organized into functional groupings that detail particular areas of functionality.
  - Examples of these groupings are clocking, timers, and communication interfaces.
  - Each grouping includes chapters that provide a technical description of individual modules.

### 1.2.1 Attachments

This manual includes key information in the files attached to it. For example, memory map and I/O details. Use the content in these attachments in conjunction with this manual's content.

**NOTE**

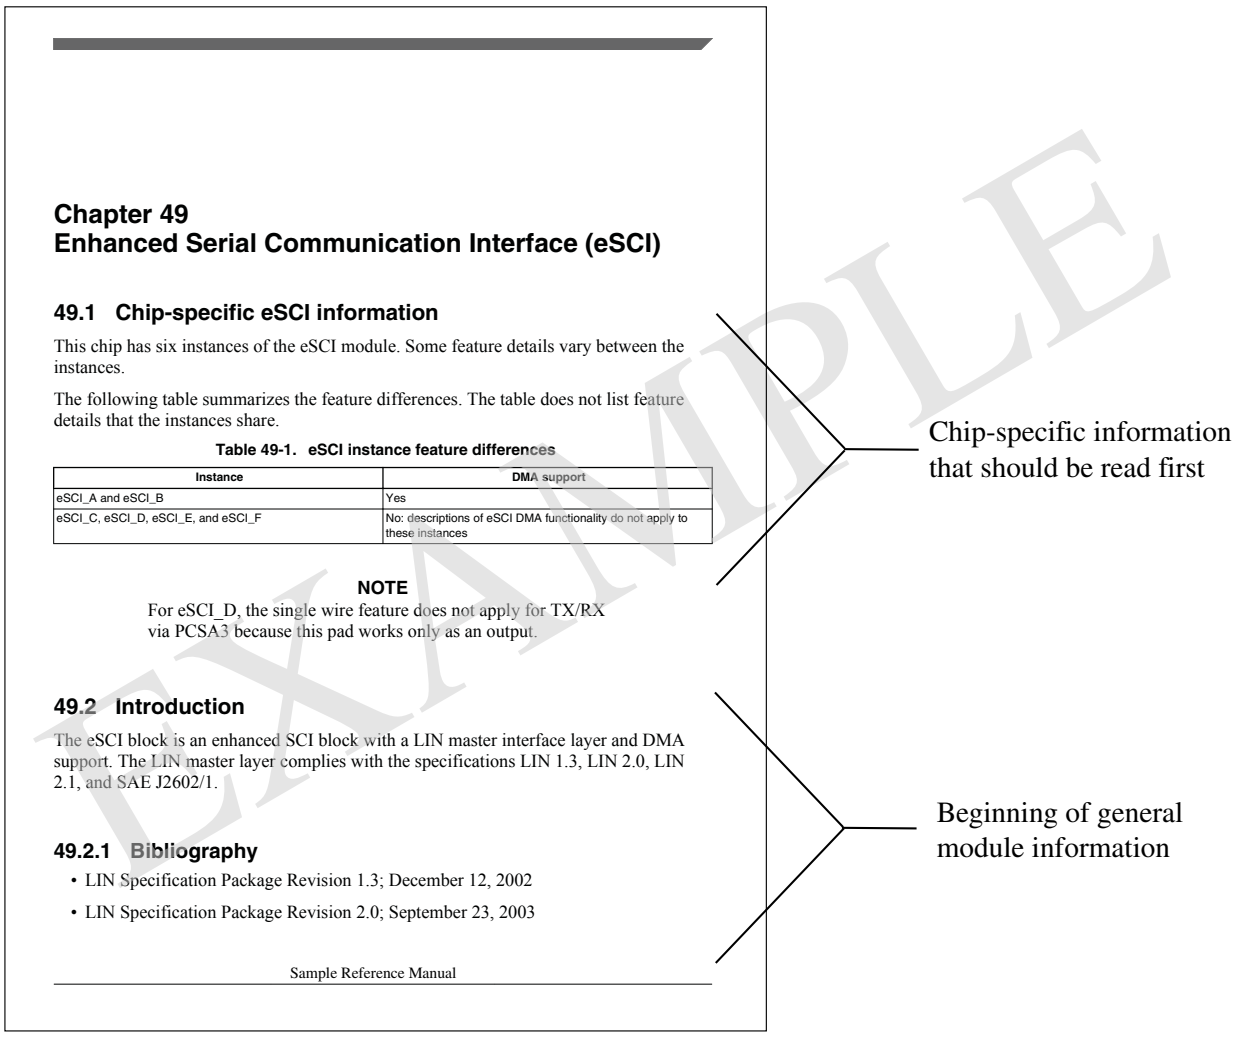
Select the paperclip icon on the left side of the PDF window to see the list of attachments.

## 1.3 Module descriptions

Each module chapter has two main parts:

- The first section, *chip-specific [module name]* information, provides details such as the number of module instances on the chip and connections between that module and the other ones. Read this section *first* because its content is crucial for understanding the information in the other sections of the chapter.
- The subsequent sections provide general information about the module, including its signals, registers, and functional description.

The following figure shows you an example of this demarcation.



Chapter 49
Enhanced Serial Communication Interface (eSCI)

49.1 Chip-specific eSCI information

This chip has six instances of the eSCI module. Some feature details vary between the instances.

The following table summarizes the feature differences. The table does not list feature details that the instances share.

Table 49-1. eSCI instance feature differences

| Instance | DMA support |
|---|---|
| eSCI_A and eSCI_B | Yes |
| eSCI_C, eSCI_D, eSCI_E, and eSCI_F | No: descriptions of eSCI DMA functionality do not apply to these instances |

NOTE
For eSCI_D, the single wire feature does not apply for TX/RX via PCSA3 because this pad works only as an output.

49.2 Introduction

The eSCI block is an enhanced SCI block with a LIN master interface layer and DMA support. The LIN master layer complies with the specifications LIN 1.3, LIN 2.0, LIN 2.1, and SAE J2602/1.

49.2.1 Bibliography

- LIN Specification Package Revision 1.3; December 12, 2002
- LIN Specification Package Revision 2.0; September 23, 2003

Sample Reference Manual

EXAMPLE

Figure 1. Example of chapter chip-specific information and general module information

### 1.3.1 Chip-specific information that clarifies content in the same chapter

The following figure shows an example of chip-specific information that clarifies general module information presented later in the chapter. In this case, the chip-specific register reset values supercede the reset values that appear in the register diagram.

**Chapter 9**
**System Integration Unit Lite2 (SIUL2)**

### 9.1 Chip-specific SIUL2 information

#### 9.1.1 Feature configurations

In this device, the SIUL2_0 module instance does not support the following features described in the generic description:

- Interrupts
- DMA channels

#### 9.1.2 Notes for IMCR

Out of reset, PA_00, PA_04, and PA_05 pads have JTAG input functionality selected by default. It should be disabled in the corresponding IMCR registers (IMCR61, IMCR60, and IMCR50 respectively) in order to use other functionality such as GPIO.

### 9.2 Introduction

#### 9.2.1 Overview

The System Integration Unit Lite2 provides control over all the electrical pin controls and ports with 16 bits of bidirectional, general-purpose input and output signals. One of the most important functions of the SIUL2 is to enable the user to select the functions and electrical characteristics that appear on external device pins. It also controls the multiplexing of internal signals from one module to another and controls chip I/O. It supports as many as 32 external interrupts with trigger event configuration. The following figure is the block diagram of SIUL2 and its interfaces to other system components.

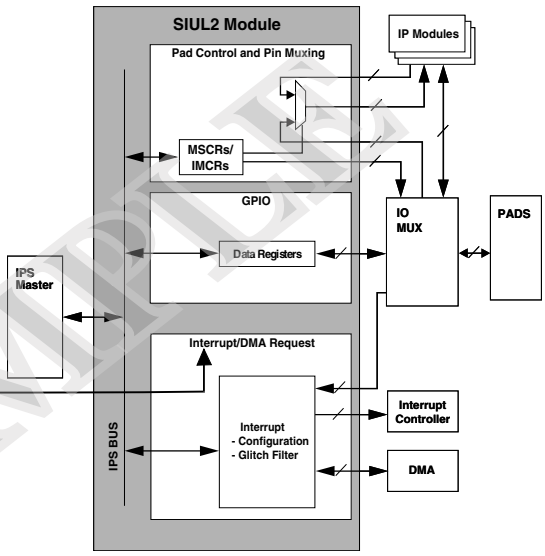


**Figure 23. System Integration Unit Lite2 block diagram**

This module provides dedicated pad control to general-purpose pads that can be configured as either inputs or outputs. The SIUL2 module provides registers that enable user software to read values from GPIO pads configured as inputs, and write values to GPIO pads configured as outputs:

- When configured as output, you can write to an internal register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from an internal register.
- When configured as input and output, the pad value can be read back, which can be used as a method of checking if the written value appeared on the pad.

To assist software development, GPIO data registers can be accessed using various mechanisms. These differing mechanisms allow support for port access or for bit manipulation without the need to use read-modify-write operations:

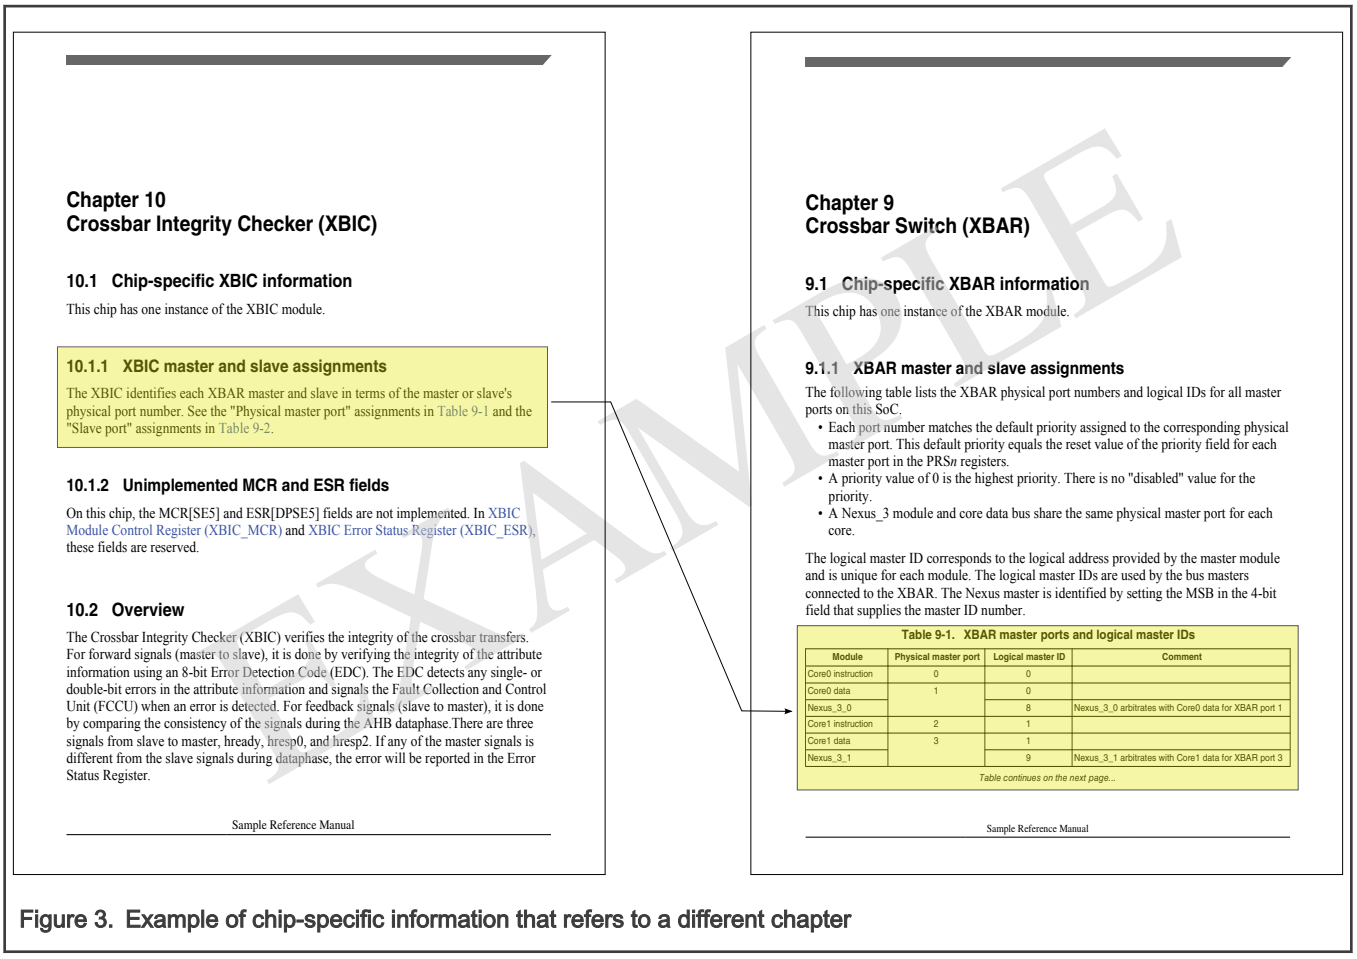
- Access to two 16-bit ports in one access
- Read/write access to a single bit
- A 16-bit port write with a bit mask, using single 32-bit access.

EXAMPLE

Figure 2. Example of chip-specific information that clarifies content in the same chapter

## 1.3.2 Chip-specific information that refers to a different chapter

Related chip-specific information may be provided in different chapters of the manual. The following figure shows an example of two such connected pieces of information. In this case, read both before you proceed.



Chapter 10
Crossbar Integrity Checker (XBIC)

10.1 Chip-specific XBIC information

This chip has one instance of the XBIC module.

10.1.1 XBIC master and slave assignments

The XBIC identifies each XBAR master and slave in terms of the master or slave's physical port number. See the "Physical master port" assignments in Table 9-1 and the "Slave port" assignments in Table 9-2.

10.1.2 Unimplemented MCR and ESR fields

On this chip, the MCR[SE5] and ESR[DPSE5] fields are not implemented. In XBIC Module Control Register (XBIC_MCR) and XBIC Error Status Register (XBIC_ESR), these fields are reserved.

10.2 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers. For forward signals (master to slave), it is done by verifying the integrity of the attribute information using an 8-bit Error Detection Code (EDC). The EDC detects any single- or double-bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. For feedback signals (slave to master), it is done by comparing the consistency of the signals during the AHB dataphase.There are three signals from slave to master, hready, hresp0, and hresp2. If any of the master signals is different from the slave signals during dataphase, the error will be reported in the Error Status Register.

Sample Reference Manual

Chapter 9
Crossbar Switch (XBAR)

9.1 Chip-specific XBAR information

This chip has one instance of the XBAR module.

9.1.1 XBAR master and slave assignments

The following table lists the XBAR physical port numbers and logical IDs for all master ports on this SoC.

- Each port number matches the default priority assigned to the corresponding physical master port. This default priority equals the reset value of the priority field for each master port in the PRS*n* registers.
- A priority value of 0 is the highest priority. There is no "disabled" value for the priority.
- A Nexus_3 module and core data bus share the same physical master port for each core.

The logical master ID corresponds to the logical address provided by the master module and is unique for each module. The logical master IDs are used by the bus masters connected to the XBAR. The Nexus master is identified by setting the MSB in the 4-bit field that supplies the master ID number.

Table 9-1. XBAR master ports and logical master IDs

| Module | Physical master port | Logical master ID | Comment |
|---|---|---|---|
| Core0 instruction | 0 | 0 | |
| Core0 data | 1 | 0 | |
| Nexus_3_0 | | 8 | Nexus_3_0 arbitrates with Core0 data for XBAR port 1 |
| Core1 instruction | 2 | 1 | |
| Core1 data | 3 | 1 | |
| Nexus_3_1 | | 9 | Nexus_3_1 arbitrates with Core1 data for XBAR port 3 |

*Table continues on the next page...*

Sample Reference Manual

Figure 3. Example of chip-specific information that refers to a different chapter

## 1.4 Register descriptions

Module chapters present register information in the following:

- Memory maps, which contain:
  - An offset from the module's base address
  - The mnemonic and name of each register
  - The width of each register (in bits)
  - The reset value of each register
- Register figures
- Field-description tables
- Associated text

The following figure shows register figure conventions used throughout the manual.

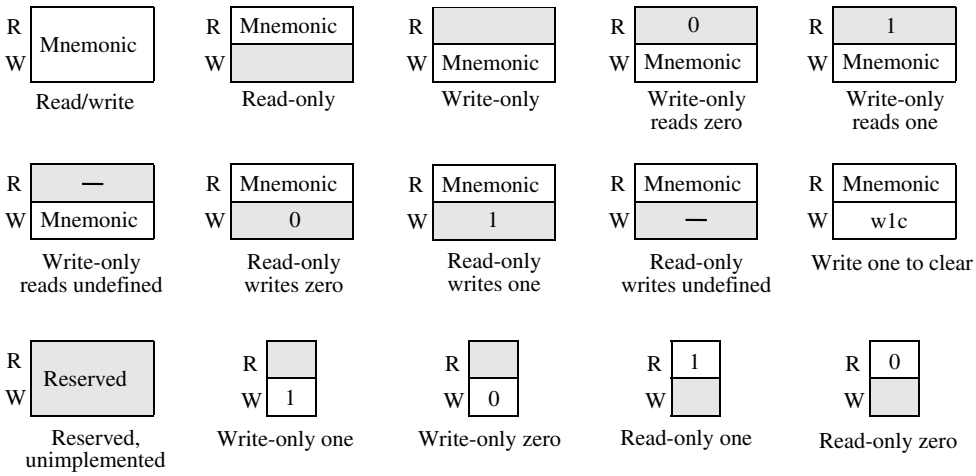


**Figure 4. Register figure conventions**

**NOTE**

Reset values of reserved locations documented in this manual are subject to change and must not be used for diagnostic purposes.

## 1.5 Conventions

### 1.5.1 Notes and cautions

Specific information is provided as part of notes and cautions throughout this manual.

**NOTE**

Emphasizes information that deserves extra attention.

**CAUTION**

Informs you of situations that could lead to highly undesirable outcomes—such as damage to the chip or irreversible malfunction.

### 1.5.2 Numbering systems

The following suffixes identify different numbering systems:

**Table 1. Numbering systems**

| This suffix | Identifies a |
|---|---|
| b | Binary number. For example, the binary equivalent of the number 5 is mentioned as 101b. In some cases, *0b* is prefixed to binary numbers. |
| d | Decimal number. Decimal numbers are followed by this suffix only when there is a possibility of confusion. In general, decimal numbers are used without a suffix. |
| h | Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is mentioned as 3Ch. In some cases, *0x* is prefixed to hexadecimal numbers. |

### 1.5.3 Typographic notation

The following typographic notations are used throughout this document:

Table 2. Typographic notation

| Example | Description |
|---|---|
| *x* and other italicized text | The italized, lowercase *x* is used as a placeholder for replaceable numbers. In general, italicized text is used for titles of publications and for emphasis. Additionally, italics could be used for metasymbols in syntax descriptions. Plain lowercase letters are used as placeholders for single letters and numbers. |
| `code font` | Fixed-width font (such as Courier) used for code. It is used for a letter, word, or phrase that you want the user to type. For example, "Type `Read` and press Enter."<br>This type of font is also used for instruction mnemonics, directives, symbols, subcommands, parameters, operators, computer-language elements, code listings, commands that appear in running text, and for sample code. Instruction mnemonics and directives in text and tables are mentioned in all caps; for example, BSR. |
| SR[SCM] | A mnemonic in square brackets represents the name of a register field. This example refers to the Scaling Mode (SCM) field in the Status Register (SR). |
| REVNO[6:4], XAD[7:0] | Numbers in brackets that are separated by a colon represent either:<br>• A subset of a register's named field<br>For example, REVNO[6:4] refers to bits 6-4 that are part of the COREREV field occupying bits 6-0 of the REVNO register.<br>• A continuous range of individual signals of a bus<br>For example, XAD[7:0] refers to signals 7-0 of the XAD bus. |
| MOD.REG | A period separates the elements of a hierarchy: subsystem.module.register. For example:<br>• SWT.TO means that the TO register is located in the SWT module.<br>• SMU.XRDC.CR means that the CR register is located in the XRDC module within the SMU subsystem. |

### 1.5.4 Special terms

The following terms have special meanings.

Table 3. Special terms

| Term | Meaning |
|---|---|
| Asserted | Refers to the state of a signal as follows:<br>• An active-high signal is asserted when high (1).<br>• An active-low signal is asserted when low (0). |
| Deasserted | Refers to the state of a signal as follows:<br>• An active-high signal is deasserted when low (0).<br>• An active-low signal is deasserted when high (1).<br>In some cases, deasserted signals are described as *negated*. |
| Reserved | Refers to a memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior. You must: |

*Table continues on the next page...*

Table 3. Special terms (continued)

| Term | Meaning |
|---|---|
| | • Not modify the default value of a reserved programming setting, such as the reset value of a reserved register field.<br>• Consider undefined locations in memory to be reserved.<br>• Not use the reset values of reserved locations documented in this manual for diagnostic purposes. They subject to change. |
| Write 1 to clear (w1c) | Refers to the access type of a register field that is used to clear the field by writing the value 1 to it. |
| Undefined (u) | Refers to undefined reset values |

## 1.6 Editorial changes

Each new release of this document includes editorial improvements such as:

- Spelling
- Grammar
- Punctuation
- Voice
- Tense
- Capitalization
- Formatting
- Punctuation
- Presentation
- Navigation

## 1.7 Glossary

The "Glossary" section provides a list of selected terms and definitions used in a chapter. The glossary, if present, is placed at the end of the chapter.

A glossary contains:

- NXP-specific terms, symbols, and notations, with definitions.
- Terms, symbols, and notations that can have different meanings in different contexts. The glossary defines the way they are used in the chapter—especially if the meaning is different from the meaning in standard references.

A glossary does not contain:

- Field mnemonics
- Register mnemonics
- Module mnemonics
- Signal names
- Industry-standard terms

# Chapter 2
# Introduction

## 2.1 Overview

The MCXE 31 product series further extends the highly-scalable portfolio of MCX E family in the commercial and industrial industries with the Arm Cortex-M7 core at higher frequency, more memory, SIL-2 rating and advanced security module. With a focus on industrial environment robustness, the MCXE31 product series devices are well suited to a wide range of applications in electrical harsh environments, and are optimized for cost-sensitive applications offering new, space saving package options. The MCX E31 series offers a broad range of memory, peripherals and performance options. Devices in this series share common peripherals and pin-out, allowing developers to migrate easily within a chip series or among other chip series to take advantage of more memory or feature integration.

**CAUTION**

MCXE315/MCXE316/MCXE317 and MCXE31B specific information is preliminary until these devices are qualified and may change without notice.

## 2.2 MCXE31 Series Introduction

**NOTE**

MCXE31 series has only a single ARM core and does not support lockstep mode. Any content in this manual related to multi-core or lockstep mode or dual-core interconnection must be ignored.

The MCXE31 series comes to market together with easy-to-use enablement software, application specific software, and various development tools, supported by broad third parties in different development phases.

The portfolio scalability, future proof feature like advanced security, as well as software/tool/third-party development support allows developers to standardize on the MCXE31 series for their end product platforms, maximizing hardware and software reuse, and reducing time-to-market.

Following are the general features of the MCXE31 series chips:

- 32-bit Arm Cortex-M7 core with IEEE-754 compliant SPFPU, executing up to 160 MHz
- Scalable memory footprints up to 4 MB flash memory and up to 512 KB SRAM
- Precision mixed-signal capability with low power comparators (LPCMP) and multiple 12-bit ADCs
- Powerful timers for a broad range of applications including motor control, lighting control and body applications
- Serial communication interfaces such as Serial communication interfaces including LPUART, LPSPI, LPI2C, FlexCAN with ISOCAN-FD support, Ethernet and QuadSPI. FXIO configuration allows other communication options including SENT.
- SESIP level 2 compliant EdgeLock Secure Enclave (HSE_B)
- Power supply (3.0 – 5.5 V) with fully functional flash memory program/erase/read operations
- Functional safety compliance with IEC 61508 SIL 2 hardware integrity and SIL 3 systematic capability (features depend on device specification)
  - Multiple internal watchdogs
  - Voltage monitors
  - Clock monitors
  - Memory protection
  - Data transport checks
  - ECC on memories

— Cyclic redundancy checking

- Ambient operation temperature range: –40°C to 135°C
- Junction temperature range: –40°C to 135°C

## 2.3 Feature summary

The MCX E31 product family includes the Arm Cortex-M7 core features described in the following table.

**Table 4. MCXE 31 chip's feature summary**

| Feature | Inclusions |
|---|---|
| Core and architecture | • Singel Arm Cortex-M7 core running up to 160 MHz<br>• Arm core based on the Armv7 architecture and ThumbR-2 ISA with 2.14 DMIPS/MHz<br>• 8 KB data and 8 KB instruction cache for optimizing wait state execution from memories<br>• 96 KB Tightly Coupled Memory associated with each core<br>• On-core MPU for dynamic task protection (16 regions)<br>• SPFPU, IEEE 754 compliant<br>• Harvard bus architecture implementing dedicated instruction and data path<br>• 5-stage pipeline with branch speculation<br>• XRDC integrated with a crossbar switch to provide memory and peripheral protection<br>• DSP<br>• I/O protection (VIRT_WRAPPER)<br>• ETM supporting instruction trace<br>• Arm third-party ecosystem support: software and tools to help minimize development time and cost |
| DMA | • Up to 2x64-channel DMAMUX<br>• eDMA with up to 32 channels<br>• Complex data transfers performed with minimal intervention from a host processor<br>• Programmable support for scatter-gather DMA processing |
| System and power management | • Support for simplified power modes (Run and Standby)<br>• Support for clock gating of unused modules; specific peripherals continue to work in low-power modes<br>• Support for external ballast transistor to generate core supply<br>• Fully independent CPU and peripheral clocking scheme<br>• Rapid start-up from a 48 MHz FIRC |

*Table continues on the next page...*

Table 4. MCXE 31 chip's feature summary (continued)

| Feature | Inclusions |
|---|---|
| | • Various low-power oscillators such as the 32 kHz SIRC and an external 32 kHz crystal support SXOSC<br>• PMC with LVD and selectable trip points<br>• Support for multiple power modes<br>• NMI |
| Memory and memory interfaces | • Up to 4 MB program flash memory, up to 128 KB data flash memory, and up to 512 KB SRAM, all with an ECC<br>• 4-bit/8-bit QuadSPI |
| Clocks | • External 8 MHz–40 MHz crystal oscillator or resonator<br>• External 32 kHz crystal oscillator<br>• Internal clock references<br>— 48 MHz FIRC ±5%<br>— 32 kHz SIRC ±10%<br>• Up to 960 MHz PLL for divided system clock operation |
| Security and integrity | • EdgeLock Secure Enclave (HSE_B)<br>— Upgradable Firmware delivered by NXP, to be programmed by the user<br>• Security ciphers:<br>— Symmetric: AES-128/192/256<br>— Cipher modes: ECB, CBC, CMAC, GMAC, CTR, OFB, CCM, and GCM<br>— Asymmetric: RSA (up to 4096 bits) and ECC (up to 521 bits)<br>— Hash: Miyaguchi-Preneel, SHA-2/SHA-3 (up to 512 bits)<br>— Number of keys is configurable and controlled by HSE FW<br>— Random number generator<br>• Security use case supported:<br>— Secure boot<br>— Secure communication<br>— Component protection<br>— Secure storage<br>— Key exchange |
| Safety IEC61508 | • Classification up to SIL-2<br>• ERM and EIM support<br>• WDOG with an independent clock source |

*Table continues on the next page...*

Table 4. MCXE 31 chip's feature summary (continued)

| Feature | Inclusions |
|---|---|
| | • Voltage monitors<br>• Bandgap voltage available as ADC input<br>• External clock source monitoring using an independent reference<br>• PLL lock and loss-of-lock protection<br>• XRDC<br>• ECC on code flash memory, data flash memory, and system RAM<br>• ADC self-test feature<br>• Internal analog monitoring of all supplies available<br>• CRC generation module<br>• FCCU failure output |
| Analog | • 12-bit ADC<br>— Up to 72 external analog inputs<br>— 1 µs conversion time<br>— Internal bandgap voltage reference channel, supporting automatic compare and an optional hardware trigger<br>— Up to five internal reference inputs<br>— Automatic compare with interrupt<br>— Self-test and self-calibration scheme<br>• ACMP with an internal 8-bit DAC as a reference<br>— ACMP with both positive and negative inputs, separately selectable interrupts on rising and falling comparator output<br>— Ability to cross trigger the timers from both the ADC and ACMP outputs<br>• Temperature Sensor (TempSense) with output measurable by ADC. |
| Timers | • 16-bit eMIOS timers, offering up to 72 standard channels<br>— Input capture, output compare, and PWM modes<br>— Fault input support with global fault control<br>— Multiple features such as deadtime insertion, configurable polarity, quadrature decoding, and so on<br>• 32-bit PITs, with four channels, for raising interrupts and triggering DMA channels<br>• 32-bit RTC<br>• Motor control and power conversion using combination of eMIOS, LCU , BCTU, and ADC<br>• Up to one STMs, with four channels each |

*Table continues on the next page...*

Table 4. MCXE 31 chip's feature summary (continued)

| Feature | Inclusions |
|---|---|
| Communications | • LPSPI supporting DMA with full-duplex or single-wire bidirectional communication in Master or Slave mode<br>• FlexIO, with an option to configure it as different communication peripherals, offering support for SENT<br>• LPI2C modules with DMA support, low-power availability, master or slave support, and system management bus<br>• LPUART with DMA support, having an optional 13-bit break, full-duplex non-return- to-zero (NRZ), low-power availability and supports LIN protocol versions 1.3, 2.0, 2.1, 2.2A, and SAE J2602 with using SW LIN driver<br>• FlexCAN modules with ISOCAN-FD and DMA support<br>• SAI capable of supporting stereo audio channels<br>• EMAC complex (10/100 Ethernet) that supports 1588 timers, MII/RMII interface, AVB, and TSN support |
| Debug | • DWT, with four configurable comparators as hardware watchpoints<br>• SWO-synchronous trace data support<br>• ITM with software and hardware trace, plus time stamping<br>• FPB with an ability to patch code and data from code space to system space<br>• Trace of all execution units and bus masters made available through an Arm TPIU over GPIO pins; a very low bandwidth trace option also available via the SWO<br>• Embedded trace FIFO (ETF)—a dedicated trace buffer available for each of the core masters, allowing data to be captured internally before being optionally routed to external trace pins<br>• SWV—trace capability providing displays of reads, writes, exceptions, PC samples, and print |
| I/O and package | • Up to 145 GPIO pins<br>• Up to 142 GPIO pins with interrupt functionality<br>• Up to 59 GPIO pins with wakeup capability<br>• Pseudo open drain support on LPUART, FlexIO, LPI2C<br>• Package options of 172 MAX QFP, 100 MAX QFP, 48 LQFP, and 100 LQFP |

## 2.4 Block diagram

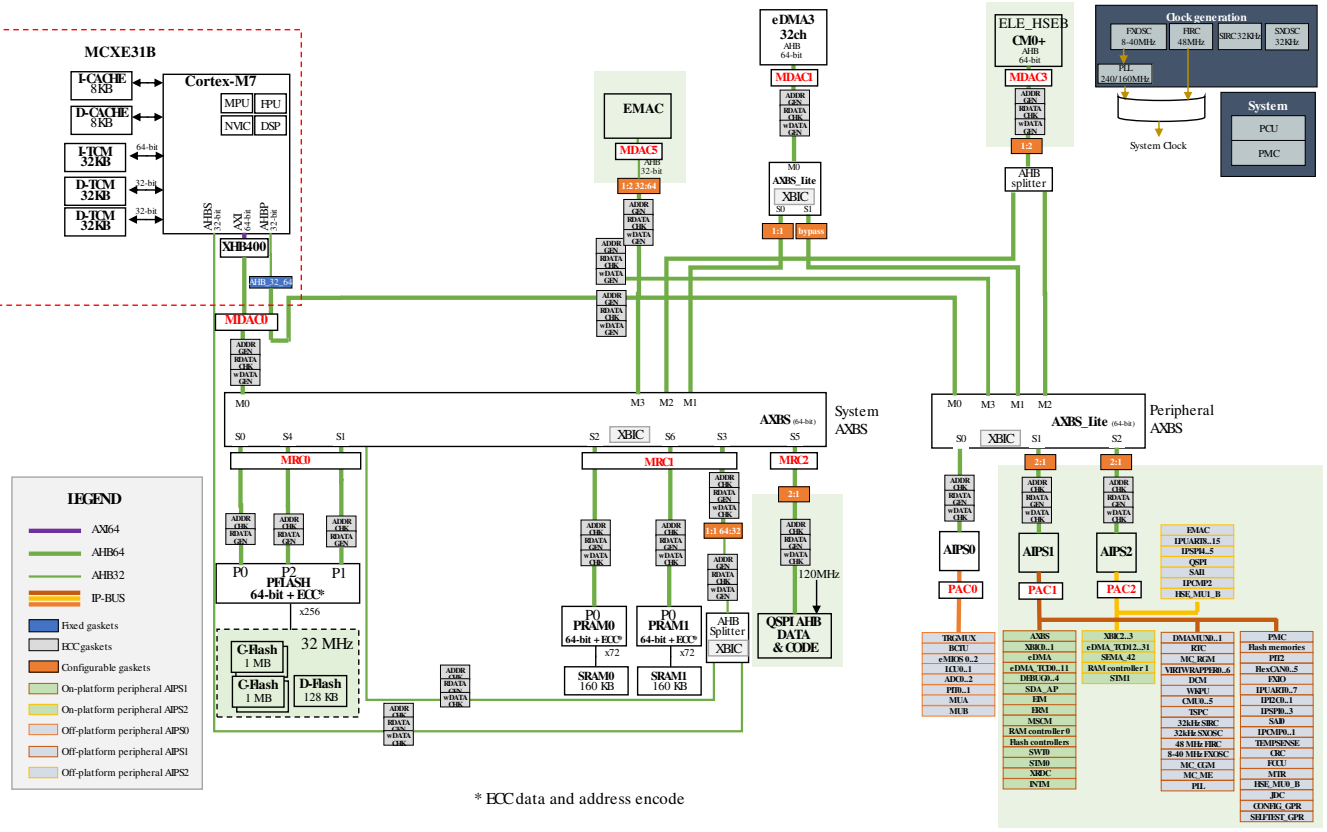

Figure 5. Block diagram - MCXE31B

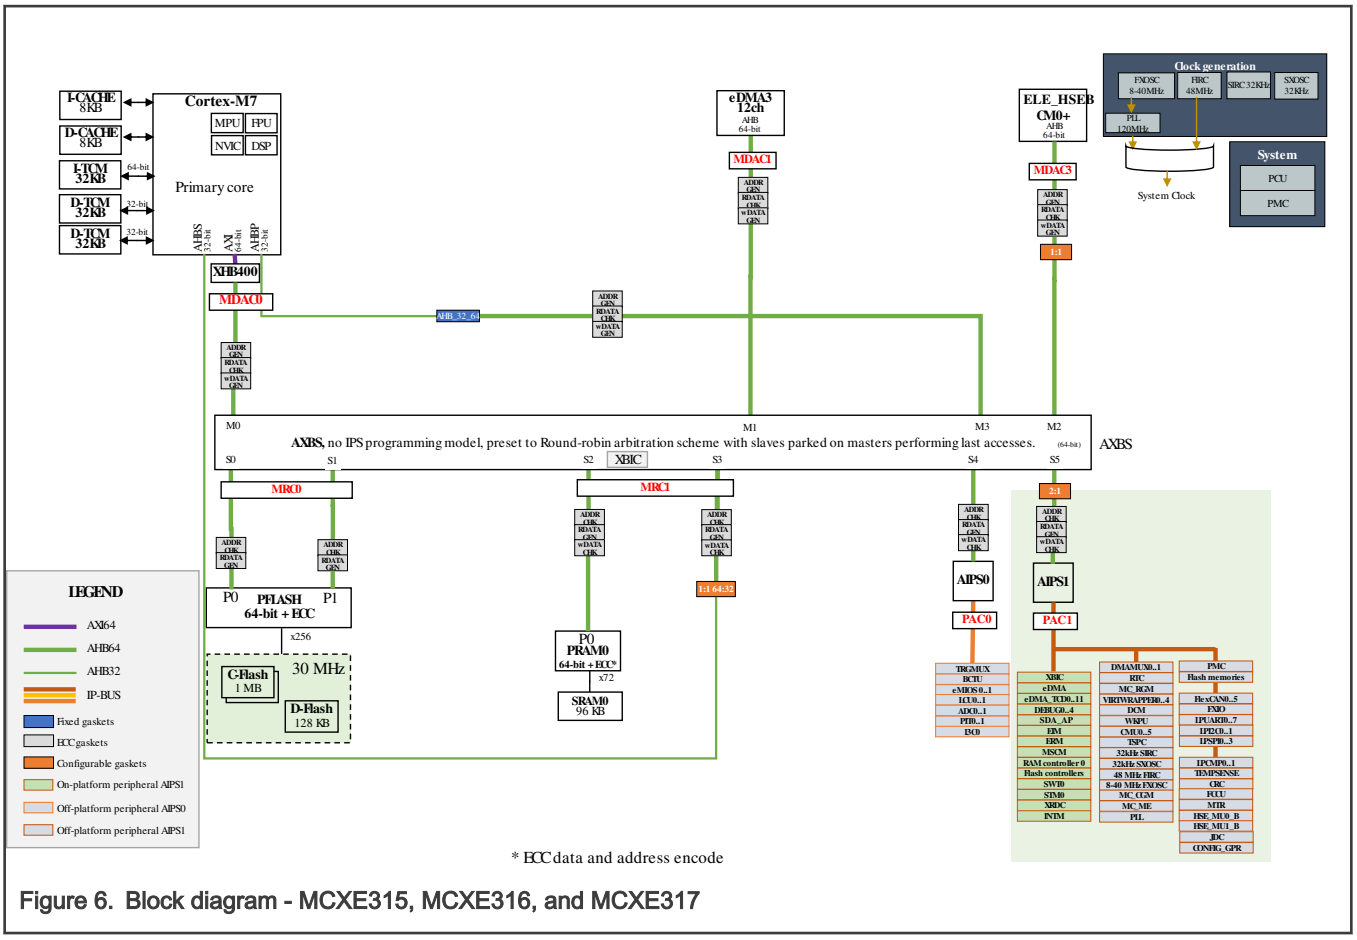

Figure 6. Block diagram - MCXE315, MCXE316, and MCXE317

## 2.5 Feature comparison

The following table compares some of the prominent features related to memory and package options of these chips from the MCXE31 family/product series:

- MCXE315
- MCXE316
- MCXE317
- MCXE31B

Table 5. MCXE31 chip's feature comparison

| Feature | Chip | | | |
|---|---|---|---|---|
| | MCXE315 | MCXE316 | MCXE317 | MCXE31B |
| Core | 1 x M7 | | | |
| Safety/SIL | 2 | | | |
| Program flash memory | 512 KB | 1 MB | 2 MB | 4 MB |
| Data flash memory (KB) | 64 | | 128 | |
| Total RAM (KB) | 112KB (incl. 96KB TCM) | 128KB (incl. 96KB TCM) | 192KB (incl. 96KB TCM) | 512KB (including 96KB TCM) |

*Table continues on the next page...*

Table 5. MCXE31 chip's feature comparison (continued)

| Feature | Chip | | | |
|---|---|---|---|---|
| | MCXE315 | MCXE316 | MCXE317 | MCXE31B |
| Standby RAM | 16 KB | 32 KB | | |
| Security | EdgeLock Secure Enclave (HSE_B) | | | |
| Frequency (MHz) | 120 | | | 160 |
| DMA channels | 12 | | | 32 |

| PLL | Phase locked loop oscillator |
| PWM | Pulse width modulation |
| SDK | Software development kit |
| SENT | Single edge nibble transmission |
| SWV | Serial wire viewer |
| SPFPU | Single precision floating point unit |
| SWO | Serial wire output |
| TPIU | Trace port interface unit |
| TSN | Time sensitive networking |
| WDOG | Windowed watchdog |

# Chapter 3
# Memory Map

## 3.1 Introduction

This chip contains various memories and memory-mapped peripherals that are placed in a 32-bit contiguous memory space, and this chapter describes the memory and peripheral locations within that memory space.

For high-level chip memory map details, see the memory map file attached to this document.

## 3.2 SRAM memory map

A total of 512 KB RAM is available on MCXE31B product series, and it is partitioned as follows:

- ITCMs (64 KB)
- D0TCMs (64 KB)
- D1TCMs (64 KB)
- PRAMC_0 (160 KB)
- PRAMC_1 (160 KB)

PRAMC_0 controls the first 160 KB of RAM that is implemented as follows:

- 32 KB of memory supports content retention in Standby mode
- 128 KB of memory is available only in Run mode

PRAMC_1 controls the second 160 KB of RAM that is implemented as follows: :

- 32 KB of memory is available only in Run mode
- 128 KB of memory is available only in Run mode

The memory map file attached to this document provides a complete architectural address space definition for various sections that the RAM is partitioned into and across the MCXE31 product series. Based on the physical sizes of the memories and peripherals, the actual address regions used may be smaller.

In addition to ITCM, DTCM, and SRAM, a particular section of the RAM is associated with the Arm Cortex-M7 (CM7) internal cache. This chip includes 8 KB of I-cache RAM and 8 KB of D-cache RAM for each Cortex-M7 core.

The cache attributes in the MCXE31 cache scheme are defined for a given address range and core, and not according to the physical RAM or flash memory block.

## 3.3 Access-related details of the memory types used in this chip

The Cortex-M7 core can access these memories sequentially:

- ITCM
- DTCM
- I-cache
- D-cache

ITCM and DTCM can be accessed via 32-bit AHBS interface by any master, e.g., different Cortex-M7 cores, eDMA, etc to bootload instructions in ITCM. EMAC is another master that can access DTCM. See 'Block diagram' in the 'Introduction' chapter for details on the transaction path.

Access to SRAM beyond the RAM available on the chip terminates the bus cycle with an error followed by an appropriate response in the requesting bus master.

## 3.4 Considerations related to TCM's implementation

You must first initialize TCM (ITCM and DTCM) and system RAMs by 64-bit writes before performing read accesses. The system RAM can be initialized using eDMA and core. The ITCM initialization can be performed only by core using either direct or back-door accesses. The DTCM can be initialized also by 32-bit writes performed either using core's direct and back-door accesses as or eDMA. These writes are required to set up the initial ECC code words after chip power-on reset.

Each Cortex-M7 core is equipped with a 32 KB ITCM and 64 KB DTCM with a zero wait-state access.

See table 'Memory ECC initialization summary' in chapter 'Memory and Memory Interfaces' for details on memory ECC initialization.

## 3.5 Flash memory map

For details, see the memory map file attached to this document.

## 3.6 AIPS-Lite memory map

You can access the peripheral memory map via a crossbar slave port. The next table shows the three regions associated with peripheral space.

**Table 6. Regions associated with peripheral space**

| Address of region | Region description |
|---|---|
| 4000_0000h–401F_FFFFh | This 2048 KB region (AIPS_Lite_0) is partitioned into 128 spaces, each 16 KB in size, having 32 on-platform and 96 off-platform spaces. AIPS_Lite generates unique module enables for all the 32 on-platform spaces. |
| 4020_0000h–403F_FFFFh | This 2048 KB region (AIPS_Lite_1) is partitioned into 128 spaces, each 16 KB in size, having 32 on-platform and 96 off-platform spaces. AIPS_Lite generates unique module enables for all the 32 on-platform spaces. |
| 4040_0000h–405F_FFFFh | This 2048 KB region (AIPS_Lite_2) is partitioned into 128 spaces, each 16 KB in size, having 32 on-platform and 96 off-platform spaces. AIPS_Lite generates unique module enables for all the 32 on-platform spaces. |

Modules that are disabled via their clock gate control fields in the MC_CGM registers disable the associated AIPS_Lite slots. Access to any address within an unimplemented or disabled peripheral bridge slot results in a transfer error termination.

Multiple instances of same peripherals are connected to different bridges on the interconnect. For details, see the memory map file attached to this document.

## 3.7 Serialization of memory operations

In particular cases, you must complete the process of writing to a peripheral before the subsequent action occurs. Examples of such situations include:

- Exiting an interrupt service routine
- Changing a mode
- Configuring a function

In these situations, you must perform a read-after-write sequence to achieve the required serialization of memory operations. The following table provides this sequence.

Table 7. Read-after-write sequence for serialization of memory operations

| Step | Action |
|---|---|
| 1 | Write to the associated peripheral register. |
| 2 | Read the register to verify the write process. |
| 3 | Continue with the subsequent operations. |

## 3.8 PPB memory map

PPB is a part of the defined Arm bus architecture and provides access to specific processor-local modules. You can access these modules only through the core, and not through other system masters.

Table 8. PPB memory map

| Starting hex address | Ending hex address | Size (KB) | Module |
|---|---|---|---|
| E000_0000 | E000_0FFF | 4 | ITM |
| E000_1000 | E000_1FFF | | DWT |
| E000_2000 | E000_2FFF | | FPB |
| E000_3000 | E000_DFFF | 44 | — |

| **TPIU** | Trace port interface unit |

# Chapter 4
# Signal Multiplexing

## 4.1 Introduction

The signal multiplexing enables the sharing of single pad for multiple functions.

The signal multiplexing unit comprises control signals from SIUL2 and pad interface logic. The signal multiplexing unit consists of several individual sub-units, each handling the signal multiplexing of one pad.

The "SIUL2 Multiplexed Signal Configuration Register (MSCR)" controls the module specific pad settings (pull-up etc) and the signal present on the external pin. See SIUL2_MSCR for the description of control signals. The pad attributes may vary depending on the pad type.

For the pad attributes of each pad type and their reset values per port, see the IOMUX file attached to this document. The pads specific to the packages and their multiplexing is also documented in the IOMUX file attached to this document.

**NOTE**

The input functions for the protocols which are not to be used should be appropriated configured as 'disabled low'/'disabled high' with appropriate SIUL2.IMCR configurations corresponding for that function.

## 4.2 Pad description

Following figure shows the basic representation of a GPIO pad.

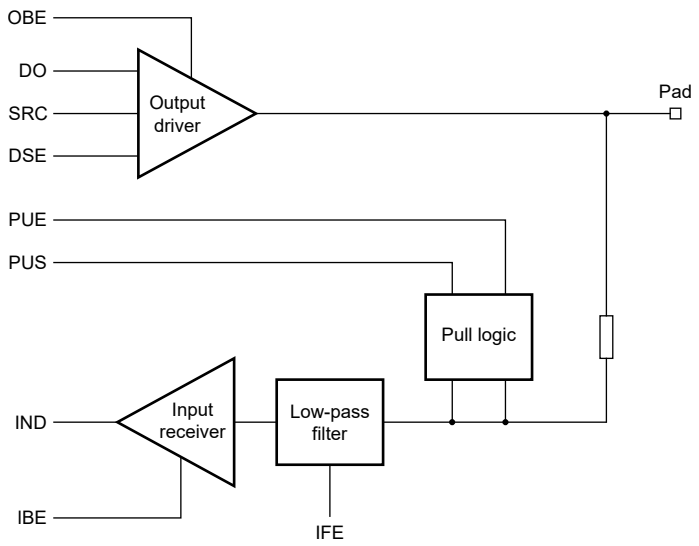

**Figure 7. GPIO pad representation**

**Table 9. Pad Signal description**

| Signal name | Direction | Descriprtion |
|---|---|---|
| Pad | I/O | I/O to external world |
| DO | I | Data coming from the core into the pad |
| OBE | I | Enable output driver |

*Table continues on the next page...*

Table 9. Pad Signal description (continued)

| Signal name | Direction | Descriprtion |
|---|---|---|
| PUE | I | 0: Disable internal pullup or pulldown resistor 1: Enable internal pullup or pulldown resistor |
| PUS | I | 0: Enable internal pulldown resistor if pue is set 1: Enable internal pullup resistor if pue is set |
| IBE | I | Enable input receiver |
| IND | O | Data coming out of the pad into the core |
| SRC | I | Slew Rate Control |
| PKE | I | Pad keeping enable |
| IFE | I | Input filter enable |
| DSE | I | Drive Strength enable |

Table 10. Input buffer enable

| IBE | Pad | IND | Description |
|---|---|---|---|
| 0 | X | 0 | Input buffer disabled, ind gets low |
| 1 | 0/1 | 0/1 | Input buffer enabled, ind = pad |

Table 11. Output buffer enable

| OBE | DO | Pad | Description |
|---|---|---|---|
| 0 | X | Z | Output buffer disabled, pad hi-Z (If not configured as input) |
| 1 | 0/1 | 0/1 | Output buffer enable, pad = do |

Table 12. Input filter enable

| IFE | Description |
|---|---|
| 1 | Input filter enabled |
| 0 | Input filter disabled |

Table 13. Pull up/Pull down

| PUE | PUS | Pad | Description |
|---|---|---|---|
| 0 | X | - | Weak pull disabled. Pad retains previous state |
| 1 | 0 | 0 | Weak pull down enabled |
| 1 | 1 | 1 | Weak pull up enabled |

Table 14. Slew rate control

| SRC | Description |
|---|---|
| 0 | Slew rate enabled |
| 1 | Slew rate disabled |

Table 15. Drive strength enable

| DSE | Description |
|---|---|
| 1 | Drive strength supported |
| 0 | Drive strength not supported |

Table 16. Pad keeping enable

| PKE | Description |
|---|---|
| 0 | Pad keeping disabled |
| 1 | Pad keeping enabled |

**NOTE**

The default state of GPIO pins on a reset event is high-Z. The high-Z state might settle to active high or active low at chip depending on the supply, temperature and other factors. Hence, it is recommended to use external pulls to ensure safe inactive state in event of a reset.

## 4.3 Functional description

The signal multiplexing architectural implementation is as shown in the following figure.

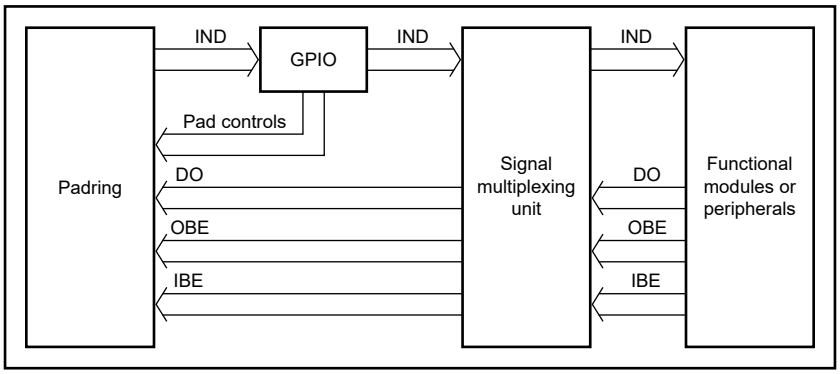

Figure 8. Signal Multiplexing

## 4.4 Signal Multiplexing sheet

IO Signal Description Input Multiplexing sheet(s) attached to the Reference Manual contains information on pins/balls of this device.

The 'IO Signal Table' and 'Input Muxing' tabs in the sheet correspond to the signal multiplexing information. The 'IO Signal Table' consists of all the pin muxing details and the 'Input Muxing' specifies the priority for the input muxing where an input path is driven by more than one pad.

### 4.4.1 IO Signal Table

Following is an example snippet of IO Signal Table. For selecting any functionality, the pad MSCR register (refer to SIUL2_MSCRn) needs to be configured accordingly.

| Port | CR | SSS | Function | Module | Description | I/O Direction | Pad Type | MCXE314_172mqf | I/O Power Domain | Pad State During Destructive Reset | Pad State After Destructive Reset | Pad State During Functional Reset | Pad State After Functional Reset | Pad State After Selftest | Pad State After FCCU Error | I/O Power Segment | MSCR | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | | | | | | | | | | | OBE[31] | IBE[19] | INV[17] | SMC[16] | DSE[14] | PUE[13] | PUS[11] | IDS[8] | IF[3:0] | SMC[5] | SSS[2:0] |
| PTA0 | SIUL_MSCR0 | 0000_0000 | GPIO[0] | SIUL | GPIO[0] | I/O | GPIO-STANDARD | 137 | VDD_HV_A | Hi-Z | Hi-Z | Hi-Z | Hi-Z | Hi-Z | Hi-Z | | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | - | - | 000 |

**Figure 9. IO signal table snippet**

The columns of the above figure are described below:

- Port: This field in IO Signal Table specifies the PAD names of the device.
- CR(Control Register): This field specifies the name of MSCR corresponding to the Port field. 'On this device, there are eight port groups (PTA, PTB, PTC, PTD, PTE, PTF and PTG) that are controlled by SIUL2_MSCRn registers. The below table shows the mapping of ports with respect to SIUL2_MSCRn registers.

**Table 17. Port/MSCR mapping**

| Port | SIUL2_MSCRn index |
|---|---|
| PortA[0-31] | MSCR0 - MSCR31 |
| PortB[0-31] | MSCR32 - MSCR63 |
| PortC[0-31] | MSCR64 - MSCR95 |
| PortD[0-31] | MSCR96 - MSCR127 |
| PortE[0-31] | MSCR128 - MSCR159 |
| PortF[0-31] | MSCR160 - MSCR191 |
| PortG[0-27] | MSCR192 - MSCR219 |

See SIUL2_MSCR/IMCR (See following Input Muxing section section for details on IMCR) for description of MSCR/IMCR fields.

- SSS: This field specifies the ALT mode of operation as per MSCR[Mux_mode]. Not all pins support all pin muxing slots. Unimplemented pin muxing slots are reserved. The corresponding pin is configured in the following pin muxing slot as follows:
  - 000: Alternative 0 (GPIO)
  - 001: Alternative 1 (chip-specific)
  - 010: Alternative 2 (chip-specific)
  - 011: Alternative 3 (chip-specific)
  - 100: Alternative 4 (chip-specific)
  - 101: Alternative 5 (chip-specific)
  - 110: Alternative 6 (chip-specific)
  - 111: Alternative 7 (chip-specific)

**NOTE**

The analog functionalities are specified with '-' in this field.

- Function: This field specifies the functionality of the pad as per the corresponding ALT mode specified by SSS field.
- Module: The Module field contains the module which is governing the pad for the ALT mode.

- Description: This field mentions a short description of pad functionality.
- Direction: This field specifies the direction (Input, Output or Input/Output) of the pad for the concerned functionality.
- Pad Type: This field mentions the pad type of the corresponding pad.
  - GPIO-Standard:
    - Switching up to 10MHz
    - High drive-strengh not supported.
    - Slew-rate control not supported.
  - GPIO-Standard plus:
    - Switching up to 25MHz
    - Supports high drive-strengh.
    - Slew-rate control not supported.
  - GPIO-Medium:
    - Switching up to 50MHz
    - Supports high drive-strengh.
    - Supports slew-rate control.
  - GPIO-Fast:
    - Switching up to 120MHz
    - Supports high drive-strengh.
    - Supports slew-rate control.
- The next columns specify the pin number in the supported packages for the device.
- I/O Power Domain: This field refers to the power domain of associated pad (VDD_HV_A / VDD_HV_B).
- Pad State during/after Reset: These fields represent the pad states during and post different device resets.
- MSCR: This field specifies the default MSCR value for corresponding pad. Refer SIUL2_MSCRn for description of MSCR fields.
- The next two columns specify the reset value and the configurable bit fields of MSCR corresponding to pad.

### 4.4.2 Input muxing table

As the same function can be multiplexed to several pads by configuring their respective IMCRs, there is priority input muxing. In case of same input being driven from multiple pads, the one with highest priority (1 being the highest) will drive the input. Following is a snippet of Input Muxing Table.

| Destination Instance | Destination Function | CR Instance | Input CR# | Input SSS | Source Instance | Source Signal | MCXE31x_172mqfp_DC |
|---|---|---|---|---|---|---|---|
| CAN0 | CAN0_RX | SIUL | SIUL_IMCR512 | 0000_0000 | - | disable low | |
| | | | | 0000_0001 | IO_PAD | PTC2 | 50 |
| | | | | 0000_0010 | IO_PAD | PTA6 | 102 |
| | | | | 0000_0011 | IO_PAD | PTB0 | 95 |
| | | | | 0000_0100 | IO_PAD | PTA28 | 30 |
| | | | | 0000_0101 | IO_PAD | PTF21 | - |

Figure 10. Input muxing table snippet

The columns of the figure are briefly described below:

- Destination Instance: This field contains the instance name of the input path to where the signal will propagate from padring.
- Destination Function: This field mentions the function name of the input path.

- Input SSS: This field specifies the IMCR[Mux_mode] value corresponding to the pad specified in source signal column.
- Source Instance: This field specifies the source pad type. A blank is mentioned for the default source when no pad is driving the input path.
- Source Signal: This field mentions the pad name. A ‘disable low’/’disable high’ specifies the signal behavior when none of the pads are driving the input path.
- The next columns specify the pin number in the supported packages for the device.

### 4.4.3 MSCR/IMCR description/explanation

#### MSCR assignments

The Implemented SIUL2 Multiplexed Single Configuration Register details is provided in the I/O Signal Description Table attached as excel.

Example:

If user wants to configure PTB0 as CAN0RX and PTB1 as CAN0TX, then the following configuration can be used in SIUL2 registers:

```
//.CAN0.RX.(PTB0):
SIUL2.IMCR0.B.SSS.=.0b011;.//.Select.CAN0-RX
SIUL2.MSCR32.B.IBE.=.1;....//.Enable.the.input.buffer

//.CAN0.TX.(PTB1):
SIUL2.MSCR33.B.SSS.=.0b101;.//.Select.CAN0-TX
SIUL2.MSCR33.B.OBE.=.1;.//.Enable.the.output.buffer
```

MSCR bit fields correspond to pin/pad basis, these are independent of muxing implemented on that specific pin/pad. As an example, pad PTA31 has SSS, SMC, DSE, PUS, PKE, INV, IBE and OBE are implemented with the reset value 0 and SRC is implemented with reset value 1.

In the 'IO Signal Table' tab of the IOMUX file attached, the MSCR register bits shows ‘0’, ‘1’, and ‘-’ for state of all bits associated with different ports. ‘0’ or ’1’ represents the reset state and ‘-’ represents the bit is not supported on the respective port.

**NOTE**

The GPIOs 38 and 39 are used for direct connections and FXOSC.

### 4.4.4 Pinout diagrams

See IO Signal Description Input Multiplexing sheet(s) attached to the Reference Manual for pinout diagrams corresponding to available packages.

## 4.5 Pin States

The tables in the upcoming sections mention the state of pins of the device under various conditions/event like Functional Reset, Destructive Reset, Power Up condition, during Selftest Phase etc. The details of the Reset events can be found in the Reset overview Chapter. The Details of Selftest can be found in the STCU chapter.

### 4.5.1 Pin numbers

The pin numbers which have been referenced to the tables are explicitly mentioned here

- RESET_B: PTA5 = GPIO5. The pad state tables below assume RESET_B configured as Reset pin (See UTEST DCF record 'dcf_client_reset_pad_dedicated' in the DCF clients file attached to this document for Reset pin control as dedicated/muxed GPIO'.
- JTAG_TMS : PTA4 = GPIO4
- JTAG_TCK : PTC4 = GPIO68
- JTAG_TDI : PTC5 = GPIO69
- JTAG_TDO : PTA10 = GPIO10
- TRACE_ETM_CLKOUT : PTG6 = GPIO[198] (Slow pad trace), PTC2=GPIO[66] (Fast pad trace)
- TRACE_ETM_D0 : PTG7 = GPIO[199] (Slow pad trace), PTD7=GPIO[103] (Fast pad trace)
- TRACE_ETM_D1 : PTG15 = GPIO[207] (Slow pad trace), PTD12=GPIO[108] (Fast pad trace)
- TRACE_ETM_D2 : PTG16 = GPIO[208] (Slow pad trace), PTD11=GPIO[107] (Fast pad trace)
- TRACE_ETM_D3 : PTF31 = GPIO[191] (Slow pad trace), PTD10=GPIO[106] (Fast pad trace)
- TRACE_ETM_D4 : PTG17 = GPIO[209] (Slow pad trace)
- TRACE_ETM_D5 : PTF28 = GPIO[188] (Slow pad trace)
- TRACE_ETM_D[6:15] : PTG18:PTG27 = GPIO[210]:GPIO[219] (Slow pad trace)
- CLKOUT_STANDBY : PTA12 = GPIO12
- FCCU_ERR[0:1] : PTA2:PTA3 = GPIO[2]:GPIO[3]

### 4.5.2 Power up

This table mentions the pin behavior on power up condition of the device.

**Table 18. Power up**

| Pin function | POWER UP until SW comes up[1] |
|---|---|
| RESET_B | LOW |
| JTAG_TMS,JTAG_TCK,JTAG_TDI,JTAG_TDO as JTAG | PULLED Values:<br>(TMS = HIGH, TCK = LOW, TDI =HIGH)<br>TDO: HIGH Z |
| ETM_TRACE | HIGH Z |
| FCCU_ERR | HIGH Z |
| CLKOUT_STANDBY | HIGH Z |
| GPIOs | HIGH Z |
| EXTAL | HIGH Z till extal is connected |
| XTAL | HIGH Z till xtal is connected |

1. The IO pad states are undefined until Supply rises sufficiently to enable the POR circuits.

### 4.5.3 Destructive Reset

This table mentions the Pin behavior when any Destructive Reset event is triggered.

Table 19. Destructive Reset

| Pins | ON Destructive Reset until SW comes up |
|---|---|
| RESET_B | LOW |
| TMS,TCK,TDI,TDO as JTAG | PULLED Values:<br>(TMS = HIGH TCK = LOW, TDI =HIGH)<br>TDO: HIGH Z |
| ETM_TRACE (Only on 17trace Pins) | HIGH Z |
| FCCU_ERR | HIGH Z |
| CLKOUT_STANDBY | Clkout expose if CLKOUT_STANDBY is configured to be Enabled<br>Else HIGH Z |
| GPIOs | HIGH Z |

### 4.5.4 Functional Reset including Functional entry sequence

This table mentions the Pin behavior when any functional Reset event is triggered. Also, when the FCCU reaction is configured as Functional Reset , then also the same behavior is achieved.

Table 20. Functional Reset including Functional entry sequence

| Pins | Functional Reset Entry | Reset until SW comes up |
|---|---|---|
| RESET_B | LOW | LOW |
| TMS,TCK,TDI,TDO as JTAG | TMS,TCK,TDI: PULLED Values if configured as JTAG<br>(TMS = HIGH TCK = LOW, TDI =HIGH)<br>HIGH Z if configured as GPIO<br>TDO: HIGH Z | PULLED Values<br>(TMS = HIGH TCK = LOW, TDI =HIGH)<br>TDO: HIGH Z |
| ETM_TRACE | Trace if MDMAPCTL[DBGRSTSLOWPAD] or MDMAPCTL[DBGRSTFASTPAD] is configured to be Enabled<br>Else HIGH Z | Trace if MDMAPCTL[DBGRSTSLOWPAD] or MDMAPCTL[DBGRSTFASTPAD] is configured to be Enabled<br>Else HIGH Z |
| FCCU_ERR | ERR from FCCU if UTEST_MISC[FCCU_EOUT_DEDICATED] is configured to be Enabled<br>Else HIGH Z | ERR from FCCU if UTEST_MISC[FCCU_EOUT_DEDICATED] is configured to be Enabled.<br>Else HIGH Z |
| CLKOUT_STANDBY | Clkout expose if DCMRWP1[CLKOUT_STANDBY] is configured to be Enabled<br>Else HIGH Z | Clkout expose if DCMRWP1[CLKOUT_STANDBY] is configured to be Enabled<br>Else HIGH Z |

*Table continues on the next page...*

Table 20. Functional Reset including Functional entry sequence (continued)

| Pins | Functional Reset Entry | Reset until SW comes up |
|---|---|---|
| GPIOs | HIGH Z | HIGH Z |

### 4.5.5 SELFTEST(MC_RGM.ERCTRL[ERASSERT] configured as 1)

Table 21. SELFTEST(MC_RGM.ERCTRL[ERASSERT] configured as 1)

| Pins | Selftest | Reset until SW comes up |
|---|---|---|
| RESET_B | LOW if configured as Reset Pin<br>High Z if configured as GPIO | LOW if configured as Reset Pin<br>High Z if configured as GPIO |
| TMS,TCK,TDI,TDO as JTAG | PULLED Values if configured as JTAG<br>(TMS = HIGH, TCK = LOW, TDI = HIGH)<br>TDO: HIGH Z | PULLED Values<br>(TMS = HIGH, TCK = LOW, TDI = HIGH)<br>TDO: HIGH Z |
| ETM_TRACE | Trace if MDMAPCTL[DBGRSTSLOWPAD] or MDMAPCTL[DBGRSTFASTPAD] is configured to be Enabled.<br>Else HIGH Z | Trace if MDMAPCTL[DBGRSTSLOWPAD] or MDMAPCTL[DBGRSTFASTPAD] is configured to be Enabled.<br>Else HIGH Z |
| FCCU_ERR | FCCU Error State if UTEST_MISC[FCCU_EOUT_DEDICATED] is Enabled and DCMRWD2[EOUT_STAT_DUR_STEST] is Enabled<br>Else HIGH Z | FCCU Error State if UTEST_MISC[FCCU_EOUT_DEDICATED] is Enabled and DCMRWD2[EOUT_STAT_DUR_STEST] is Enabled<br>Else HIGH Z |
| CLKOUT_STANDBY | Clkout expose if DCMRWP1[CLKOUT_STANDBY] is configured to be Enabled<br>Else HIGH Z | Clkout expose if DCMRWP1[CLKOUT_STANDBY] is configured to be Enabled<br>Else HIGH Z |
| GPIOs | HIGH Z | HIGH Z |

### 4.5.6 SELFTEST (RGM_ERCTRL[ERASSERT]=0 and RGM_FRBE[ST_DONE] =0)

Table 22. SELFTEST (RGM_ERCTRL[ERASSERT]=0 and RGM_FRBE[ST_DONE] =0)

| Pins | Selftest | Reset after Selftest until SW comes up |
|---|---|---|
| RESET_B | Same state as before selftest | Same state as before selftest |
| TMS,TCK,TDI,TDO as JTAG | Same state as before selftest | PULLED Values<br>(TMS = HIGH, TCK = LOW, TDI = HIGH)<br>TDO: No change |
| ETM_TRACE | Same state as before selftest | Same state as before selftest |

*Table continues on the next page...*

Table 22. SELFTEST (RGM_ERCTRL[ERASSERT]=0 and RGM_FRBE[ST_DONE] =0) (continued)

| Pins | Selftest | Reset after Selftest until SW comes up |
|---|---|---|
| FCCU_ERR | FCCU Error State if UTEST_MISC[FCCU_EOUT_DEDICATED] is Enabled and DCMRWD2[EOUT_STAT_DUR_STEST] is Enabled<br>Else No change | FCCU Error State if UTEST_MISC[FCCU_EOUT_DEDICATED] is Enabled and DCMRWD2[EOUT_STAT_DUR_STEST] is Enabled<br>Else No change |
| CLKOUT_STANDBY | Same state as before selftest | Same state as before selftest |
| GPIOs | Same state as before selftest | Same state as before selftest |

### 4.5.7 FCCU fault in RUN mode when the fault reaction is not Reset

**NOTE**

For any GPIO PAD If SMC=1 then the pad would retain it's state during the fault mode else if SMC=0 then the pad would become high Z during the fault mode.

Table 23. FCCU fault in RUN mode, fault reaction not Reset

| Pins | ON FCCU Fault |
|---|---|
| RESET_B | If RESET_B is assigned as a dedicated PAD then no change in the state of the PAD else if RESET_B is configured as GPIO then it would behave as per the SMC configuration.<br>• Case 1: If dcf_client_reset_pad_dedicated[reset pad dedicated] is configured as 1'b1, the pad functions as per the reset state machine.<br>• Case 2: If dcf_client_reset_pad_dedicated[reset pad dedicated] is configured as 1'b0 and SIUL2.MSCR5[SMC] is configured as 1'b1, the pad functions as per the configured protocol status, the protocol being configured via SIUL2.MSCR5[SSS].<br>• Case 3: If dcf_client_reset_pad_dedicated[reset pad dedicated] is configured as 1'b0 and SIUL2.MSCR5[SMC] is configured as 1'b0, the pin gets tristated (high-Z). |
| TMS, TCK, TDI, TDO as JTAG | If the PAD is configured as a JTAG PAD then no change and the pad would continue performing the operation else if it is a GPIO PAD then it would behave as per the SMC configuration.<br>• Case 1: If the pad is configured for JTAG mode and SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b1, the pad functions as per the JTAGC state machine or protocol.<br>• Case 2: If the pad is configured for non-JTAG mode and SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b0, the pins get tristated (high-Z). |
| ETM_TRACE | If the PAD is configured as a dedicated PAD then no change and the pad would continue performing the operation else if it is a GPIO PAD then it would behave as per the SMC configuration.<br>• Case 1: If the pad is configured for ETM_TRACE functionality and SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b1, the pad functions as per the ETM trace control logic.<br>• Case 2: If the pad is configured for non-ETM_TRACE mode and SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b0, the pins get tristated (high-Z). |

*Table continues on the next page...*

Table 23. FCCU fault in RUN mode, fault reaction not Reset (continued)

| Pins | ON FCCU Fault |
|---|---|
| FCCU_ERR | If the PAD is configured as a dedicated PAD by programming the UTEST_MISC[FCCU_EOUT_DEDICATED] as well as Eout indication is enabled then it would be indicating error state else if it is a GPIO PAD then it would behave as per the SMC configuration.<br>• Case 1: If dcf_client_utest_misc[FCCU_EOUT_DEDICATED] is configured as 1'b1, the FCCU_ERR pins indicate the error state.<br>• Case 2: If dcf_client_utest_misc[FCCU_EOUT_DEDICATED] is configured as 1'b0 and SMC bit of the SIUL2's corresponding MSCR register is configured as 1'b1, the pin retains its state.<br>• Case 3: If dcf_client_utest_misc[FCCU_EOUT_DEDICATED] is configured as 1'b0 and SIUL2.MSCR5[SMC] is configured as 1'b0, the pin gets tristated (high-Z). |
| CLKOUT_STANDBY | If the PAD is configured as a dedicated PAD then no change and the pad would continue performing the operation else if it is a GPIO PAD then it would behave as per the SMC configuration.<br>• Case 1: If the pad is configured for CLKOUT_STANDBY functionality and SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b1, the pin continues functioning as the CLKOUT_STANDBY pin.<br>• Case 2: If the SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b0, the pin gets tristated (high-Z). |
| GPIOs | If the PAD is configured as a dedicated PAD then no change and the pad would continue performing the operation else if it is a GPIO PAD then it would behave as per the SMC configuration.<br>• Case 1: If the SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b1, the pin continues its operation.<br>• Case 2: If the SMC bit of SIUL2's MSCR register of the corresponding pin is configured as 1'b0, the pins get tristated (high-Z). |

### 4.5.8 STANDBY ( DCMRWF1[STANDBY_IO_CONFIG] must be configured as 1)

- Please refer to Padkeeping Section for steps to configure the various pad states during standby

Table 24. STANDBY

| Pins | Standby until SW comes up |
|---|---|
| RESET_B | Alive / HighZ /LOW/HIGH (Depends on Software configuration before entering STANDBY) |
| TMS,TCK,TDI,TDO as JTAG | HighZ /LOW/HIGH (Depends on Software configuration before entering STANDBY) |
| ETM_TRACE | HighZ /LOW/HIGH (Depends on Software configuration before entering STANDBY) |
| FCUU_ERR | HighZ /LOW/HIGH (Depends on Software configuration before entering STANDBY) |
| CLKOUT_STANDBY | Alive / HighZ /LOW/HIGH (Depends on Software configuration before entering STANDBY) |
| GPIOs | HighZ /LOW/HIGH (Depends on Software configuration before entering STANDBY) |

## 4.6 Glossary

| | |
|---|---|
| **DSE** | Drive strength enable |
| **EXTAL** | External crystal input |
| **GPIO** | General purpose input/output |
| **IBE** | Input buffer enable |
| **INV** | Invert enable |
| **JTAG_TMS** | JTAG test mode select |
| **JTAG_TCK** | JTAG test clock input |
| **JTAG_TDI** | JTAG test data input |
| **JTAG_TDO** | JTAG test data output |

# Chapter 5
# Cortex-M7 Overview

## 5.1 Introduction

Cortex-M7 is a high-performance embedded processor intended for deeply embedded applications that require fast interrupt response features. The configuration of the processor is based on little-endian format, and you must compile the execution testbench tests in this format too.

### 5.1.1 Features

Cortex-M7 provides:

- Low interrupt latency
- Low-cost debug
- Backwards compatibility with existing Cortex-M profile processors
- In-order superscalar pipeline
- Dual-issue support for load/load and load/store instruction pairs to multiple memory interfaces
- An MPU that you could configure to protect regions of memory
- A NVIC
- A debug and trace unit (CoreSight components)
- Floating-point arithmetic functionality, with support for single-precision arithmetic
- The ability to perform speculative load from any Normal type memory space through its AXIM bus, if D-cache is enabled
- Several memory interfaces that include:
  - Harvard architecture-based instruction and data caches, and an AXIM interface
  - A dedicated low-latency AHBP interface
  - A 64-bit AXI AMBA4 memory interface with a 8 KB instruction cache and an 8 KB data cache for efficient access to external resources. The instruction and data caches are ECC protected.
  - A 32-bit AHBS for interfacing with slaves such as DMA
  - 64-bit and 32-bit memory interfaces for the connection to local Tightly Coupled Memories called ITCM and DTCM.

### 5.1.2 Related information

For detailed information on:

- Cortex-M7 processor, see Arm Cortex-M7 Processor Technical Reference Manual.
- Cortex-M7 peripherals and control, see Arm Cortex-M7 Devices Generic User Guide.
- System memory map, see the memory map file attached to this document.

### 5.1.3 Buses, interconnects, and interfaces

This table discusses Cortex-M7 buses and their associated interconnects and interfaces.

Table 25. Buses and associated information

| Bus name | Description |
|---|---|
| AXIM | Using the XHB400 module, this bus is first translated to the AHB-Lite bus that interfaces with the AXBS crossbar switch providing high-bandwidth access to on-chip memories and peripherals. |
| AHBP | This bus connects to the AXBS crossbar switch providing high-bandwidth access to on-chip peripherals. |
| PPB | This bus provides access to these modules:<br>• Arm modules such as NVIC, ETM, ITM, DWT, and ROM tables<br>• Miscellaneous Control Module (MCM) |

**NOTE**

MCXE31 AHBP bus is enabled after reset. Therefore, accesses of all cores to on-chip peripherals are performed exclusively through this bus.

### 5.1.4 Core configuration

This table describes Cortex-M7 parameter settings.

Table 26. Core configuration

| Parameter | Configuration[1] |
|---|---|
| FPU | Single precision |
| DSP extension instructions | • Single cycle 16/32-bit MAC<br>• Single cycle dual 16-bit MAC<br>• 8/16-bit SIMD arithmetic<br>• Hardware divide (2-12 cycles) |
| Armv8-M security extensions | Not implemented |
| I-cache | Implemented |
| D-cache | Implemented |
| Caches ECC | Implemented |
| On core MPU region | 16 |
| Number of IRQs | 240 |
| IRQ priority width configuration | 4 (16 interrupt priority levels) |
| Debug (breakpoint/watchpoint) | Full comparator set: 4 DWT and 8 FPB comparators |
| Internal trace support | ITM and DWT trace functionality implemented |
| ETM support | Instruction and data ETM interface implemented |
| CTI | Implemented |
| WIC support | Not implemented |
| Dual-redundant core (lock-step) CPU functionality | Not implemented |

*Table continues on the next page...*

Table 26. Core configuration (continued)

| Parameter | Configuration[1] |
|---|---|
| RAR | All asynchronously reset |
| I-cache size | 8 KB |
| D-cache size | 8 KB |
| ITCM | 32 KB for CM7_0 |
| DTCM0 | 32 KB for CM7_0 |
| DTCM1 | 32 KB for CM7_0 |

1. Armv7-M (Harvard architecture), six-stage superscalar plus branch prediction

## 5.2 Speculative accesses

The Arm Cortex M7 processor can issue speculative read accesses that may access any location within the complete memory address range. This behavior can be controlled, but not disabled. Corresponding effects must be considered for a proper operation of your system.

Speculative accesses do not cause any processor faults. The processor is aware whether an access is speculative, and ignores any error response signaled by the system due to the speculative access. However, the system that is integrating the processor cannot distinguish speculative accesses from non-speculative accesses.

Addresses used by speculative accesses are not validated against the memory map of the device, and may attempt to also access non-existing memory regions or hardware elements having side effects. For details about corresponding behavior of the Arm Cortex M7 processor see Related information. Important processing aspects are listed in section “Memory Model” within the Generic User Guide.

Speculative accesses can result in improved performance when the related memory regions are properly characterized. It is imperative to properly setup the attributes within the Memory Protection Unit (MPU) to avoid any unwanted impact of a speculative access. Examples for possible, corresponding issues are usually the result of side effects unknown to the processor:

- Speculative access to an uninitialized RAM memory location that causes a double bit error {the related fault processing by the FCCU is performed independently from the processor}.
- Speculative access to a peripheral that causes an unwanted operation; for example, a FIFO read {the corresponding data may be removed from the FIFO without being processed}.
- Speculative access to a peripheral that is not clocked, powered down, or cannot respond {the access may not be terminated, resulting an access that is stalled, system blockage}.
- Speculative access to an address range that causes an unexpected error being reported; for example, a read-while-write error of the embedded flash (indicated by setting MCRS[RWE]) during a flash erase or program operation {which may hide real errors}.

Speculative accesses can be controlled by a proper assignment of memory regions within the MPU:

- Speculative instruction fetches are never made to memory addresses in an Execute Never region.
- Speculative data reads are never made to memory addresses marked as non-accessible in the MPU.
- Speculative cache line-fills are never made to non-cacheable memory addresses.
- Speculative data reads and speculative cache line-fills are never made to memory addresses in a region having a Device or Strongly-ordered attribute.
- Speculative reads are never made on the AHBP interface.
- Speculative writes are never made.

Memory regions mapped to a TCM are always treated as Normal Memory (equivalent to the MPU attribute) and are therefore always subject to speculation. Related issues can be avoided by properly initializing any TCM memory before a corresponding access may occur.

When no speculative accesses should be initiated to a memory region, it is recommended to set all of the following attributes within the MPU for this region: Device or Strongly-ordered, and Execute Never. These attributes are often also used for address ranges associated with peripherals.

Unwanted processing of side effects caused by a speculative access can also be inhibited by disabling the related events while a speculative access may occur. As an example, the FCCU can be enabled after the ECC of the RAM memories has been initialized. As a second example, read accesses to a Flash block can be inhibited by configuring an MPU region while it is being erased.

## 5.3 Debug facilities

This chip has extensive debug capabilities such as run control and tracing. It includes the standard Arm debug port that supports the JTAG and SWD interfaces.

## 5.4 Vector fetch behavior on Cortex-M7

In Cortex-M7, the vector fetches are looked up into the I-Cache. if the vector table is located in a region of memory that is cacheable, any load or store to the vector must be treated as self-modifying code and cache maintenance instructions should be used to synchronize the updates to the data and instruction caches. The Cortex-M7 Device Generic User Guide chapter 'Cache maintenance design hints and tips' specifies a recommendation for synchronization of the D-Cache and I-Cache.

If cache maintenance is to be avoided each time when the vector table gets updated, then the vector table must be allocated in the ITCM or DTCM, as those are non-cacheable regions. Alternatively, the I-Cache must be enabled after the vector table has been initialized.

## 5.5 TCM retry

TCM retry is disabled and software should disable the TCM retry bit at startup by programming the relevant core's CM7_ITCMCR[RETEN] and CM7_DTCMR[RETEN] fields to disable state.

## 5.6 Glossary

| | |
|---|---|
| **AHBP** | AHB-lite peripheral |
| **AHBS** | AHB-slave port |
| **AXIM** | Advanced extensible interface master |
| **DWT** | Data watchpoint and trace unit |
| **ETM** | Embedded trace macrocell |
| **FPU** | Floating point unit |
| **FPB** | Flash patch and breakpoint |
| **ITM** | Instrumentation trace macrocell |
| **MAC** | Multiplier accumulator (refers to a multiplier accumulator unit as well as multiplier accumulator operation) |
| **NVIC** | Nested vectored interrupt controller |
| **RCCU** | Redundancy control checking unit |
| **RAR** | Reset-all-registers |
| **SIMD** | Single instruction multiple data |

# Chapter 6
# Miscellaneous Control Module (MCM)

## 6.1 Chip-specific MCM information

### 6.1.1 MCM instances and configuration

This chip has one MCM instance.

Table 27. Memories

| Memory / Variant | MCXE315/MCXE316/MCXE317/MCXE31B (single core) |
|---|---|
| DTCM | 64 KB |
| ITCM | 32 KB |
| Icache | 8 KB |
| Dcache | 8 KB |

## 6.2 Overview

MCM provides miscellaneous control functions and contains local memory descriptors for the Cortex-M7 core. For more information about core-related registers, see the Cortex-M7 core overview chapter.

**NOTE**

The terminology in this chapter has been updated to align with Arm's AMBA AHB Protocol Specification, as shown in the table below.

Table 28. Updated terms

| Updated term | Deprecated term |
|---|---|
| Manager | Master |
| Subordinate | Slave |

### 6.2.1 Features

The MCM includes the following features:

- Program-visible information on the platform configuration and revision
- Floating Point Exception monitor and interrupt control
- Local memory descriptors:
  - ITCM
  - D0TCM
  - D1TCM
  - I-cache
  - D-cache

## 6.3 Functional description

### 6.3.1 Interrupts

MCM generates an interrupt if any of the following are true:

- FPU input denormal interrupt is enabled (FIDCE) and an input is denormalized (FIDC).
- FPU inexact interrupt is enabled (FIXCE) and a number is inexact (FIXC).
- FPU underflow interrupt is enabled (FUFCE) and an underflow occurs (FUFC).
- FPU overflow interrupt is enabled (FOFCE) and an overflow occurs (FOFC).
- FPU divide-by-zero interrupt is enabled (FDZCE) and a divide-by-zero occurs (FDZC).
- FPU invalid operation interrupt is enabled (FIOCE) and an invalid operation occurs (FIOC).
- Write abort interrupt is enabled (WABE) and a write abort occurs (CORTEX-M7 WABORTS INDICATOR).

#### Determining interrupt source

To determine the exact source of the interrupt for Cortex-M7 core, qualify the interrupt status flags with the corresponding interrupt enable fields.

- MCM_ISCR[31:16] && MCM_ISCR[15:0]
- Search the result for asserted flags, which indicate the exact interrupt sources.

## 6.4 Memory map and register descriptions

The memory map and register descriptions below describe the registers using byte addresses.

**NOTE**

The following actions result in bus errors:

- Writing to read-only registers at 0x0.
- Reading from or writing to an address from offset 480h and above.
- Accessing any MCM register while in User mode. These registers are only accessible while in Supervisor mode.

### 6.4.1 MCM register descriptions

#### 6.4.1.1 MCM memory map

MCM_0 base address: E008_0000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | SoC-defined Platform Revision (PLREV) | 16 | R | 0000h |
| 2h | Processor Core Type (PCT) | 16 | R | AC70h |
| Ch | Core Platform Control (CPCR) | 32 | RW | 0000_0200h |
| 10h | Interrupt Status and Control (ISCR) | 32 | RW | 0000_0000h |

| 40Ch | Local Memory Descriptor 3 (LMEM_DESC_3) | 32 | R | 8426_4000h |
| 410h | Local Memory Descriptor 4 (LMEM_DESC_4) | 32 | R | 8444_6000h |

### 6.4.1.2 SoC-defined Platform Revision (PLREV)

#### Offset

| Register | Offset |
|---|---|
| PLREV | 0h |

#### Function

Specifies a chip-defined platform revision number. A platform input signal defines the state of this register; it can only be read from the IPS programming model. Any attempted write is ignored.

#### Diagram

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | PLREV | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### Fields

| Field | Function |
|---|---|
| 15-0<br>PLREV | Defines the software-visible revision number, specified by a platform input signal. |

### 6.4.1.3 Processor Core Type (PCT)

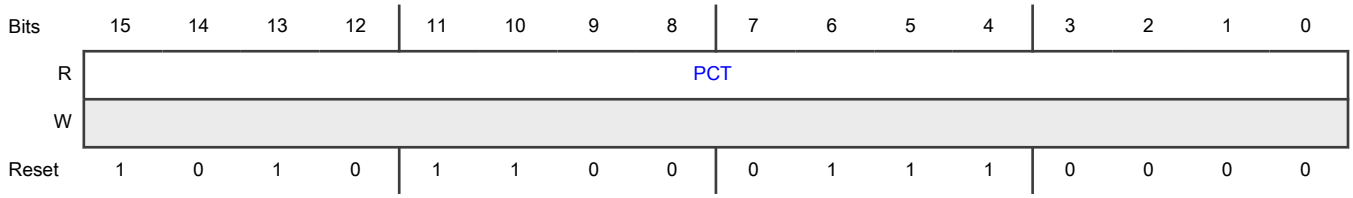
#### Offset

| Register | Offset |
|---|---|
| PCT | 2h |

### Function

Specifies the architecture of the processor core within the platform on the chip. A module input signal defines the state of this register, which can only be read from the IPS programming model. Any attempted write is ignored.

### Diagram



### Fields

| Field | Function |
|---|---|
| 15-0<br>PCT | Core Complex Identifier<br>Identifies the core complex. This MCM design supports the Arm Cortex M7 core.<br>1010_1100_0111_0000b - Arm Cortex-M7 |

## 6.4.1.4 Core Platform Control (CPCR)

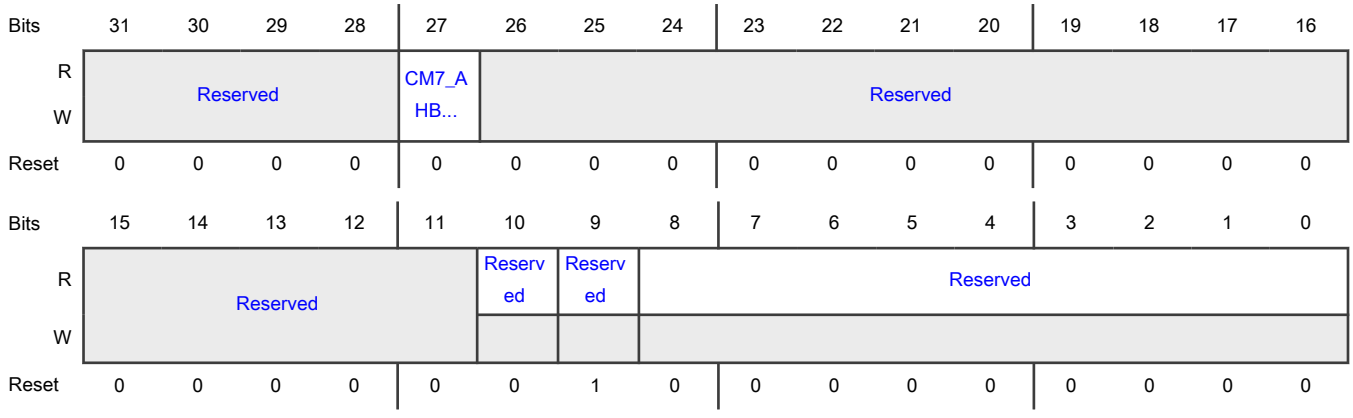
### Offset

| Register | Offset |
|---|---|
| CPCR | Ch |

### Function

Defines the arbitration and protection schemes for the two system RAM arrays.

### Diagram



**Fields**

| Field | Function |
|---|---|
| 31-28<br>— | Reserved |
| 27<br>CM7_AHBSPRI | AHB Subordinate Priority<br>Indicates the access priority on the AHBS port of the Cortex-M7.<br>**NOTE**<br>This setting has no effect unless enabled by AHBSCR[CTL][1] of the Cortex-M7 core.<br>0b - Uses a round-robin arbitration scheme<br>1b - AHB-subordinate access has priority over a core access |

| 10<br>— | Reserved |
| 9<br>— | Reserved |
| 8-0<br>— | Reserved |

1. For more information see Cortex-M7 documentation: Arm Cortex-M7 Processor Technical Reference Manual at www.arm.com.

### 6.4.1.5 Interrupt Status and Control (ISCR)

**Offset**

| Register | Offset |
|---|---|
| ISCR | 10h |

**Function**

Defines the configuration and reports the status for a number of core-related interrupt exception conditions. It includes:

- Enable and status fields associated with the core's floating-point exceptions
- Bus errors associated with the core's cache write buffer

The individual event indicators are first qualified with their exception enables, and then logically summed to form an interrupt request sent to the core's NVIC.

Bits 15-8 are read-only indicator flags based on the processor's FPSCR register. Attempted writes to these fields are ignored. When these flags are 1, they retain this value until software clears the corresponding FPSCR field. For more information see Cortex-M7 documentation: Arm Cortex-M7 Processor Technical Reference Manual at www.arm.com.

| **D-cache** | Data Cache Memory |

# Chapter 7
# Miscellaneous System Control Module (MSCM)

## 7.1 Chip-specific MSCM information

### 7.1.1 MSCM instance

This chip has one MSCM instance.

**NOTE**

The XN_CTRL register is used to restrict execution from SRAM, including TCMs and their backdoors, which will be permanent until next device reset, while still allowing data R/W.

XN_CTRL register is reserved for MCXE31B.

## 7.2 Introduction

MSCM contains registers for:

- CPU configuration
- On-chip memory control
- Interrupt router control
- Message-based interrupt configuration
- Virtual management

### 7.2.1 Features

- Software-accessible processor core configuration information
- Support for interrupt router control
- Support for message-based interrupt configuration

## 7.3 Functional description

MSCM provides information of the system cores and can identify the core that is running currently.

### 7.3.1 MSI routing

MSIs are interrupts that are indirectly broadcast to a target core by writing configuration bits in MSCM. These MSIs can be initiated by one core targeting another core in the system (known as core-to-core interrupts). These MSIs are initiated via writes to Interrupt Router CPn Interrupt Generation (IRCP0IGR0 - IRCP1IGR3) and managed through Interrupt Router CPn Interrupt Status (IRCP0ISR0 - IRCP1ISR3), where *n* indicates the logical core number (0-1) and *m* represents the interrupt number (0-3). CM7_0 core can support up to four outstanding core-to-core interrupts.

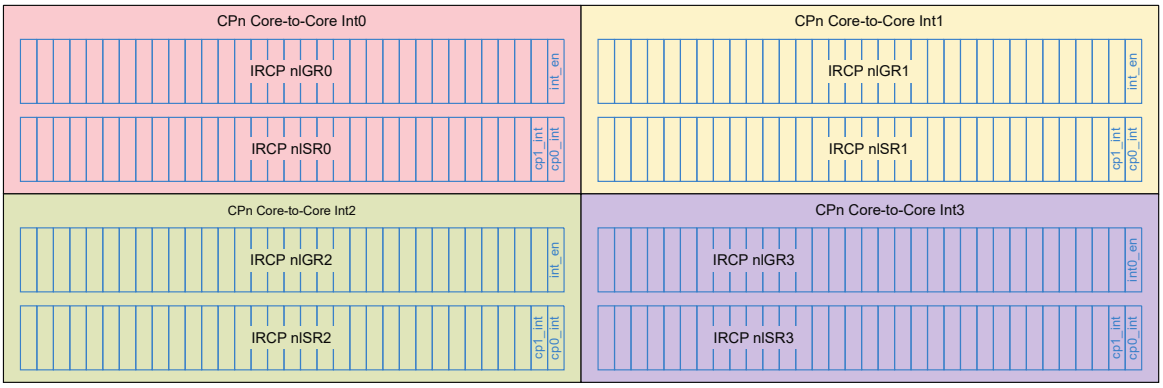

Figure 11. IRCP*n*IGR*m*/IRCP*n*ISR*m* pairs for one core

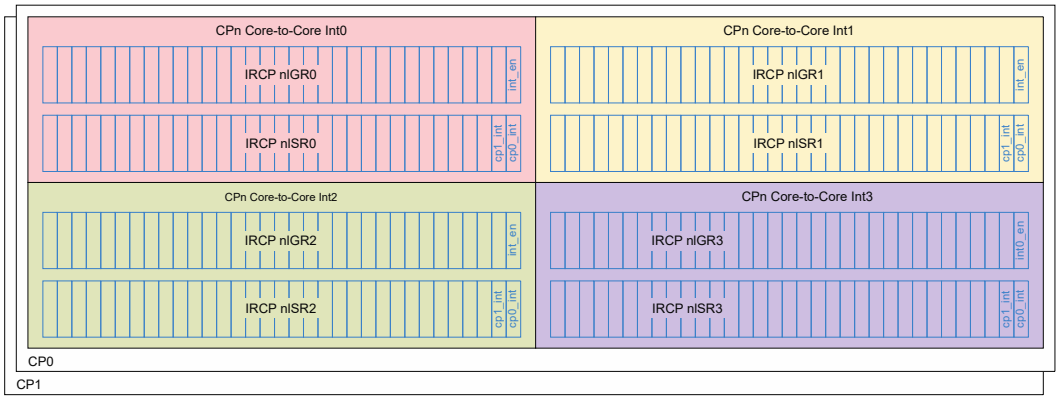

Figure 12. IRCP*n*IGR*m*/IRCP*n*ISR*m* pairs per core

### 7.3.1.1 Core-to-core MSIs

The next figure depicts the sequence for initiating a core-to-core MSI, in which *m* represents the initiating core, *n* represents the target core, and *x* indicates the MSI number. CP*m* writes to IRCP*n*IGR*x* to initiate an MSI. The outstanding MSI that CP*m* initiates, targeting CP*n*, is reflected in the corresponding bit-mapped field in IRCP*n*ISR*x*.

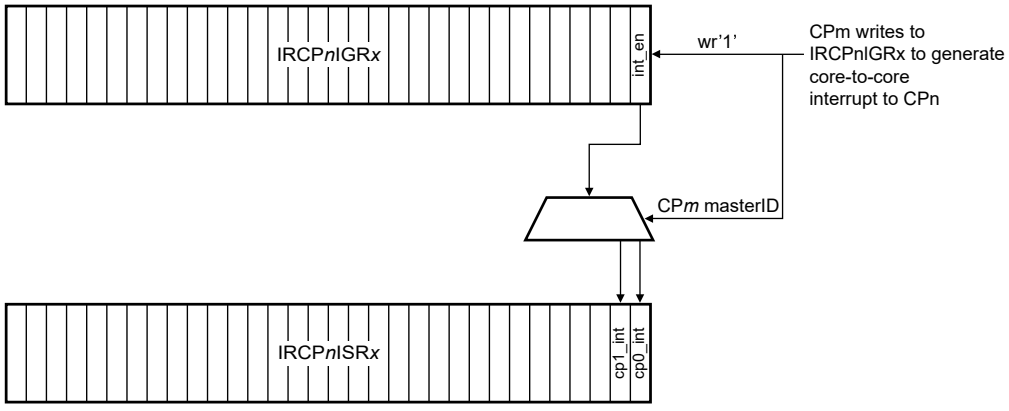

Figure 13. Initiating a core-to-core MSI via IRCP*n*IGR*x*/IRCP*n*ISR*x*

## 7.3.2 Interrupt steering and semaphores

#### 7.3.2.1 Interrupt handling overview

The interrupt handling mechanisms of the CM7 cores are very similar. These cores have a NVIC tightly coupled to the processor core. The real-time performance of the cores means the NVIC directly provides an appropriate interrupt vector, in the form of the starting instruction address for the interrupt service routine, to the core. These core architectural features directly translate into a faster ISR entry and exit capabilities, coupled with an improved runtime performance. See the Arm modules and Arm core technical reference manuals for details.

In this architecture, a total of 240 IRQs are supported, where this parameter is defined by the realistic limits of the NVIC implementation, both in terms of silicon size and supported frequency of operation. These 240 IRQs are split into a total of four directed requests and 236 shared peripheral requests. Unless noted otherwise, let the directed requests be defined as IRQ[3:0] and the shared peripheral requests as IRQ[239:4]. See the interrupt map file attached to this document for details.

#### 7.3.2.2 MSCM interrupt router functional description

As described in MSCM register descriptions, the interrupt routing registers enable the steering of requests to the processor cores.

## 7.4 Memory map and register definition

**NOTE**

The CP1 registers shown in the MSCM memory map section (from offset value 220h to 23Ch) are unavailable for the MCXE315, MCXE316, and MCXE317 variants.

### 7.4.1 Core configuration registers

These read-only registers contain data that defines the core setup for this chip. You can access the registers using 32-bit read references; other access sizes terminate with an error. Attempted write accesses to the read-only core configuration registers also terminate with an error.

The core configuration portion of the MSCM programming model map is organized based on the logical core number, and not on any type of physical port number. The following table shows how the configuration is partitioned.

**Table 29. MSCM core configuration partitioning**

| Offset address range | Purpose |
|---|---|
| 0h–018h | Defines the generic core x configuration information. Only the CM7 cores on the chip can access this region in either User or Privileged mode; reads by non-core bus masters (including the debugger) are treated as read as zero (RAZ) accesses. Write attempts are not permitted and terminate with a system bus error. |
| 020h–038h | Defines the configuration information for core 0 (CP0). Any bus master can access this region in either User or Privileged mode. Write attempts are not permitted and terminate with a system bus error. |

**NOTE**

Attempted accesses to reserved locations are not permitted and terminate with a system bus error.

### 7.4.2 Shared peripheral interrupt (SPI) routing

The SPI router portion of MSCM provides a set of memory-mapped registers defining the interrupt routing for all the SPIs on this chip.

### 7.4.3 MSCM register descriptions

#### 7.4.3.1 MSCM memory map

### 7.4.3.2 Processor X Type (CPXTYPE)

#### Offset

| Register | Offset |
|---|---|
| CPXTYPE | 0h |

#### Function

Provides a CPU-specific response indicating the personality of the core making the access. The 32-bit response includes four ASCII characters defining the CPU type (Cortex-M7 cores) along with a byte defining the logical revision number and a byte defining the instance number of the core.

A read from Cortex-M7 returns the appropriate processor information. Reads from any other bus master return all 0s and attempted write accesses terminate with an error.

Access: User or privileged read-only

#### 7.4.3.16 Interrupt Router CPn Interrupt Status (IRCP0ISR0 - IRCP1ISR3)

**Offset**

For n = 0 to 1; m = 0 to 3:

| Register | Offset |
|---|---|
| IRCPnISRm | 200h + (n × 20h) + (m × 8h) |

### Function

Provides an interrupt bit map, where each bit defines the state of a unique MSI based on the initiating core. An MSI interrupt clears in an interrupt service routine by writing 1 to the appropriate field in IRCP*n*ISR*m*.

In this discussion, CP*m* represents the initiating core and CP*n* represents the target core for a core-to-core interrupt. For more information on interrupt source mapping, see the interrupt map file attached to this document.

For read access:

- Reads to IRCP*n*ISR*m* are only accessible in Privileged mode using 32-bit (word) accesses.
- Privileged 32-bit read accesses from non-core (and non-debugger) bus masters are treated as RAZ.
- Attempted accesses in User mode or the ones using a size other than 32 bits are not permitted. They terminate with an error.
- When CP*n* requests to read IRCP*n*ISR*m*, MSCM returns the entire content of IRCP*n*ISR*m*.
- When a trusted core, as indicated by Interrupt Router Configuration (IRCPCFG), requests to read IRCP*n*ISR*m*, MSCM returns the entire content of IRCP*n*ISR*m*.
- When the debugger requests to read IRCP*n*ISR*m*, MSCM returns the entire content of IRCP*n*ISR*m*.
- When CP*m* requests to read IRCP*n*ISR*m*, MSCM returns the value of the corresponding status, CP*m*_INT, while not exposing all the other pending interrupts that the cores initiated.
- When CP*m* requests to read IRCP*n*ISR*m*, MSCM returns the value of the corresponding status, CP*m*_INT, in bit position 0, reflecting how CP*m* set the MSI when it wrote to IRCP*n*IGR*m*. All the other fields on the returned read value are zero-filled.

For write access:

- Writes to IRCP*n*ISR*m* are only accessible in Privileged mode using 32-bit (word) accesses.
- Attempted accesses in User mode or the ones using a size other than 32 bits are not permitted. They terminate with an error.
- Writes to IRCP*n*ISR*m* follow the Write 1 to Clear (W1C) protocol, whereby writing 1 causes the corresponding field to become 0, and writing 0 is ignored.
- The target core, CP*n*, has full access to write to all the fields of IRCP*n*ISR*m*.
- A trusted core, as indicated by Interrupt Router Configuration (IRCPCFG), has full access to write to all the fields of IRCP*n*ISR*m*.
- When CP*m* is different from CP*n*, the W1C action by CP*m* only clears IRCP*n*ISR*m*[CP*m*_INT].
- The CP*m* field must present W1C in bit position 0 to clear its corresponding interrupt. Write data bits 1-31 that CP*m* presents are ignored.
- Privileged write accesses from the non-core (and non-debugger) bus masters are treated as Writes Ignored (WI).
- Privileged write accesses from the debugger are treated as WI.

Access: Privileged mode only

### Fields

| Field | Function |
|---|---|
| 31-2<br>— | Reserved |
| 1<br>— | Reserved |
| 0<br>CP0_INT | CP0-to-CPn Interrupt<br>Generates a directed interrupt initiated by core 0 targeting core *n*, if the appropriate interrupt routing bit is enabled. The interrupt is negated when the target core, a trusted core, or core 0 writes 1 to clear the field.<br>0b - No interrupt asserted to CPn<br>1b - Interrupt to CPn asserted |

## 7.4.3.17 Interrupt Router CPn Interrupt Generation (IRCP0IGR0 - IRCP1IGR3)

### Offset

For n = 0 to 1; m = 0 to 3:

| Register | Offset |
|---|---|
| IRCPnIGRm | 204h + (n × 20h) + (m × 8h) |

### Function

Provides a mechanism for cores to initiate an MSI to another core in the system.

Privileged, 32-bit accesses from the:

- Cortex-M7 cores are treated as RAZ/W.
- Debugger are treated as RAZ/WI.
- Non-core (and non-debugger) bus masters are treated as RAZ/WI.

Access: Privileged mode only. Attempted accesses in User mode or the ones using a size other than 32 bits are not permitted and terminate with an error.

## 7.4.3.18 Interrupt Router Configuration (IRCPCFG)

### Offset

| Register | Offset |
|---|---|
| IRCPCFG | 400h |

### Function

Provides a mechanism to designate specific cores in the system as trusted. These trusted cores are allowed to access and manage outstanding MSIs.

Privileged, 32-bit accesses from the:

- Cortex-M7 cores are treated as R/W.
- Debugger are treated as R/WI.
- Non-core (and non-debugger) bus masters are treated as RAZ/WI.

Attempted accesses in User mode or the ones using a size other than 32 bits are not permitted. They terminate with an error.

Access: Privileged mode only

### 7.4.3.21 Interrupt Router Shared Peripheral Routing Control (IRSPRC0 - IRSPRC239)

#### Offset

For n = 0 to 239:

| Register | Offset |
|---|---|
| IRSPRCn | 880h + (n × 2h) |

#### Function

Provides an array of 16-bit registers, where each register defines the routing control for the corresponding interrupt request. Starting from IRQ = 0 (first on-platform interrupt vector). See the interrupt map file attached to this document for details.

For this chip, each interrupt request can be either routed to a subset or to all the cores using the bit-mapped fields in IRSPRC*n*. If all the CP*x*E*n* fields are cleared, the interrupt request is disabled. Each routing control halfword can be locked by writing 1 to the LOCK field.

Privileged accesses from non-core (and non-debug) bus masters are treated as RAZ/WI, and any attempted User mode reference terminates with an error. Attempted accesses using a size other than a 16-bit halfword also terminate with an error.

If you write 1 to all the CP*x*En bits, all the cores service the interrupt. It is up to software to ensure that no conflicts arise from this setup either via the interrupt handler or through programming core level interrupt routing (the NVIC/GIC).

Reads and writes to this register beyond IRSPRC207 lead to unpredictable results.

Access: Privileged mode only

# Chapter 8
# Virtualization Wrapper (VIRT_WRAPPER)

## 8.1 Chip-specific VIRT_WRAPPER information

### 8.1.1 System overview of PDAC scheme

This figure shows the interaction of XRDC (containing PDACs), related to different cores (domain IDs), with VIRT_WRAPPER.

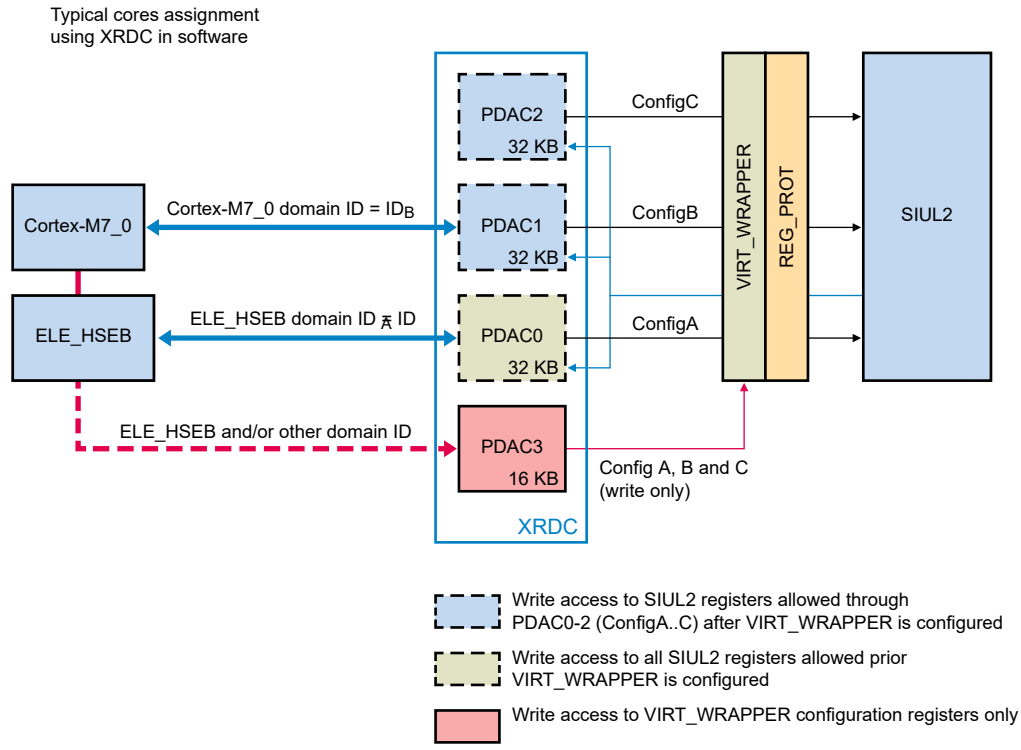

Figure 14. System overview of PDAC scheme

### 8.1.2 Initial VIRT_WRAPPER operation

Initially, VIRT_WRAPPER:

- Protects the "ConfigB-C" paths to SIUL2. You must configure VIRT_WRAPPER to define the SIUL2 R/W control registers that you can access through the "ConfigB-C" VIRT_WRAPPER access paths.
- Does not protect the direct path to SIUL2. It allows write accesses to all the SIUL2 R/W control registers. If PDAC0 is set to allow write access only to master core, for example ELE_HSEB core (variant supported by the chip), then other masters cannot program the SIUL2 register. However, if these non-ELE_HSEB masters program SIUL2 registers using other PDAC slots, a transfer error occurs. Any core can act as master core.

### 8.1.3 Additional VIRT_WRAPPER details

See the "SIUL2 memory map overview and protection" table, later in this chapter, for an overview of the SIUL2 registers and their protection attributes.

By default, any core can access SIUL2 registers through PDAC0. This process is called ANY_MASTER. However, after XRDC configuration, ELE_HSEB:

- Assigns PDACs to the respective cores or domain IDs

- Locks the XRDC configuration
- Programs VIRT_WRAPPER registers for pad assignments

ELE_HSEB accesses PDAC0 solely for the pads having 11b as the value in their corresponding registers. Also, ELE_HSEB retains the same value for the pads that it stores. In case ELE_HSEB needs to take control of some pins, it can still configure PDAC*n* to be accessible not only from a specific core master, but also from ELE_HSEB, before it allows other cores to execute.

PDAC3 protects the IPS register portal of VIRT_WRAPPER configuration registers that any master can access but only via the memory slot assigned to PDAC3. The configuration via IPS register portal can be locked to prevent any further changes until the next functional reset. PDAC3 implements this locking.

The protection information of the parallel port output registers is inherited from the protection information of the included pads, according to these rules:

- When all the pads assigned to a GPIO port share the same protection information, the corresponding parallel port output register for this port inherits the same protection information.
- When at least one of the pads assigned to a GPIO port has different protection information than the other pads assigned to this GPIO port, access to the corresponding parallel port output register for this port is disabled for all the masters. Because of the aforementioned protection group mapping, the data bits of a register encode the protection control information related to one full GPIO port, or a chunk of 16 pads.
- You can assign the following SIUL2 registers to individual PDAC control:
  - DISR0
  - DIRER0
  - DIRSR0
  - IREER0
  - IFEER0
  - IFER0
  - IFMCR0–31
  - IFCPR

  Then, you can access all these registers only through the assigned PDAC because the VIRT_WRAPPER_REG_C1039_1024 register controls the SIUL2 interrupt registers.
- You cannot access the SIUL2 R/W control registers configured through PDAC3 to be accessible through the ConfigA VIRT_WRAPPER access path, using the ConfigB VIRT_WRAPPER access path.
- You cannot access any of the SIUL2 R/W control registers through ConfigB-C VIRT_WRAPPER access paths prior to VIRT_WRAPPER configuration. By default, any core can access SIUL2 registers through PDAC0 after reset.
- The same PDAC that accesses the main SIUL2 registers is used to access the SIUL2-mirrored registers and soft-lock-bit registers. This is because these registers are a part of the same 16 KB space.
- Access to mirrored SIUL2 registers sets the bit in Soft lock bit as an inherent property of register protection. See the "Register Protection" chapter for details on the soft lock bit behavior, when accessing the mirrored region.

## 8.2 Introduction

Virtualization refers to the various techniques, methods, or approaches of creating a virtual (rather than actual) version of something, such as a virtual hardware platform, operating system (OS), storage device, or network resources. The term "hardware virtualization" refers to the creation of a virtual machine that acts like a real computer with an operating system. The underlying hardware resources separate the software executed on these virtual machines (named "guest program"). In many cases, the specifically modified guest programs are required to run in such a virtual environment.

There are different types of hardware virtualization. One of them is para-virtualization. The para-virtualization is a non-simulated hardware environment. However, a guest program is executed in its own isolated domain, as if it is running on a separate

system. Such a behavior is especially beneficial for the software targeted toward functional safety, because it allows freedom of interference for certain aspects of this software.

The hardware-assisted virtualization is a way of improving the efficiency of hardware virtualization. It involves employing specially designed CPUs and hardware components that help improve the performance of a guest environment. VIRT_WRAPPER, described in this chapter, is such a hardware component.

### 8.2.1 Overview

VIRT_WRAPPER is an extension of the Register Protection (REG_PROT) wrapper methodology. It works in parallel with an existing REG_PROT wrapper by virtualizing registers within the virtualized module. In this chip, SIUL2 is the virtualized module. Virtualized module is the module instance associated with VIRT_WRAPPER. Virtualization is implemented by protecting (for example, granting or inhibiting) the access to a register within the virtualized module, dependent on the specific criteria. It also virtualizes registers within REG_PROT when associated with registers within the virtualized module.

Registers within virtualized module or the REG_PROT wrapper are virtualized by granting, or inhibiting the access to different PDAC (Peripheral domain access control (note that PDAC and PDAC slot are interchangeable terms.))s as encoded within virtualization pad assignments in VIRT_WRAPPER configuration registers. For this purpose, the virtualization information is programmed into VIRT_WRAPPER configuration registers that specify the grouping of registers within virtualized module. Upon an access to virtualized module through the peripheral interface, the grouping information is exercised to identify whether the corresponding transaction should be granted, or inhibited. A corresponding signal is forwarded to the REG_PROT wrapper that then grants, or inhibits the transaction. The following figure depicts the usage of VIRT_WRAPPER in combination with the REG_PROT wrapper and virtualized module.

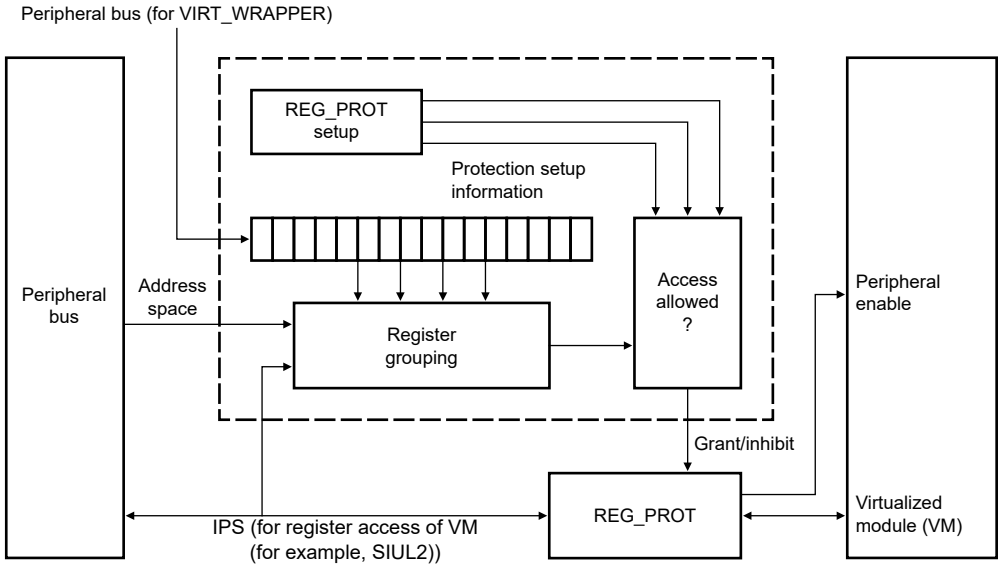

Figure 15. VIRT_WRAPPER block diagram

On a high level, VIRT_WRAPPER is an extension of the REG_PROT wrapper along those lines:

- There is a set of GPRs that receive data over peripheral bus of the VIRT_WRAPPER module. The output of these clients is a quasi-static bus providing the "Protection Control Information" to the remaining logic; this information is kept stable, that is programmed by specific PDAC after boot-up. That should be accessed only by that initiator(s) that is accessing PDAC0. This is taken care by XRDC programming at the SoC.
- The remaining functionality added by VIRT_WRAPPER module consists of two sub-blocks:
  - A first sub-block (the "Grouping PLA") defines the grouping of the registers within the virtualized module. This sub-block is module specific and generated, since this information is specific for the virtualized module, It receives the address information from the peripheral bus and selects the corresponding data from the "Protection Control Information".

— A second sub-block (the "Protection" sub-block) encodes the previously selected "Protection Control Information" and combines it with the information about the received access request. The current protection methodology allows to inhibit only write accesses for a specific initiator or set of initiators. For this purpose, this sub-block evaluates the received access information; especially the byte enables and the PDAC of the accessing initiator. The output of this sub-block is an internal signal "access granted" that is used to flag an access inhibited by the virtualization information.

### 8.2.2 Features

VIRT_WRAPPER includes these features:

- A programmable chip-specific virtualization setup, capable to select a subset of the available initiators in combination with up to four available address spaces
- Virtualizing accesses to the registers within a VM (Virtualized module, such as SIUL2) by inhibiting accesses to a subset of these registers under control of the specified virtualization information. Only write accesses can be inhibited for a specific initiator or set of initiators.
- Inhibiting accesses to registers within REG_PROT associated with VM; in cases, these registers are associated with a register in the VM to which the access is also inhibited. Additionally, accesses to the global control register (GCR) within REG_PROT can be protected separately.

### 8.2.3 Modes of operation

VIRT_WRAPPER is operable when the VM is operable. For details about the availability of the VM, see the chapter of the corresponding module. When there is no virtualization information specified for the VIRT_WRAPPER module, if XRDC is not configured, PDAC slot 0 is open as the default value of configuration register is 11b that is assigned with PDAC slot 0 and any initiator can access through it.

For more details, see "Chip specific VIRT_WRAPPER information".

## 8.3 Functional description

This section describes the following topics:

- PDAC-based protection scheme
- Register group mapping considering SIUL2
- Access errors

### 8.3.1 PDAC-based protection scheme

VIRT_WRAPPER uses a protection scheme of the PDACs sub-blocks of XRDC. Each PDAC slot is assigned to one or more cores (by domain ID assignment in XRDC) as shown in Chip-specific VIRT_WRAPPER information section. Only the write accesses are protected by the virtualization feature. Read accesses are not impacted.

For any protection group defined within the register, two bits specify the protection control information according to the following table.

**Table 30. Protection control information for a single group**

| Value | Mnemonic | Protection | Description |
|---|---|---|---|
| 00 | PDAC1 | Restricted access of registers, MSCR, IMCR, and INTINT, and GCR to PDAC slot 1 | Protection setup information for PDAC slot 1 is used. |
| 11 | PDAC0 | By default, any core can access SIUL2 registers through PDAC slot 0. | Protection setup information for PDAC slot 0 is used. |

### 8.3.2 Clocking

This module has no major clocking considerations.

### 8.3.3 Register group mapping for SIUL2

For the SIUL2 instance, the corresponding virtualization information within the VIRT_WRAPPER module is defined on a per-pad basis. Additionally, the virtualization information protects the control registers (controlling the input multiplexing scheme).

**Table 31. Register group mapping details**

| Register name | Description |
|---|---|
| Reg A | Virtualization of pad output registers |
| Reg B | Virtualization of input multiplexing control registers |
| Reg C | Virtualization of interrupt control registers |
| Reg D | Virtualization of interrupt control registers |

#### 8.3.3.1 Virtualization of pad output registers

Any functional pad (controlled by the SIUL2 instance) is assigned to a separate protection group. This scheme excludes the pads that an MSCR register does not control within an SIUL2 instance (for example, power supply pads). As a result, the protection granularity defined by the virtualization information is a single pad. The control information associated with this protection group affects all the registers related to this pad.

The protection control information for pad *i* is specified within the protection group *i*; thus, it enables a very simple assignment scheme for the related protection control data that is hard-coded. The protection control information for pad *i* affects all the registers related to this pad, in the MSCR*i* and the GPDO*i* registers (in case such registers exist).

SIUL2 can control up to 512 pads that the MSCR, GPDO, and GPDI registers can access individually. The actual number of pads associated with a SIUL2 instance is specific to implementation. GPIO pads are also organized in GPIO ports consisting of a maximum of 16 pads that the parallel port registers (PGPDO, PGPDI, MPGPDO) can access.

Only the pad control and pad output registers are protected. Accesses to the read-only registers GPDI and PGPDI are not affected by virtualization.

As the protection granularity is a single pad, any virtualization information associated with this pad affects the corresponding MCSR and GPDO registers directly. Additionally, any consequence that an illegal access has on the registers implemented within the REG_PROT wrapper is inhibited. For this purpose, any access to the mirrored address space and the corresponding Soft Lock Bit Register (SLBR) is also observed.

The parallel port output registers (PGPDO, MPGPDO) inherit the protection information from the protection information of the included pads according to the following rules:

- When all pads assigned to a GPIO port share the same protection information, the corresponding parallel port output register for this port inherits the same protection information.
- When at least one of the pads assigned to a GPIO port has a different protection information than the other pads assigned to this GPIO port, the write access to the corresponding parallel port output register (PGPDO and MPGPDO) for this port is disabled for all the initiators through all the PDAC slots and a transfer error is generated.

Due to the aforementioned protection group mapping, the data bits of a register encode the protection control information related to one full GPIO port, or a chunk of 16 pads.

#### 8.3.3.2 Virtualization of input multiplexing control registers

Additionally, the SIUL2 instance supports the control of an input multiplexer (INMUX) scheme. This scheme provides the capability to select one of a set of the input pads to be the source of an input function for some of the peripheral modules. Any INMUX

controlled by the SIUL2 instance is assigned to a separate protection group. It therefore provides an equivalent protection granularity within the virtualization information.

The protection group 512+*i* specifies the protection control information for the input multiplexer INMUX *i*. This enables a very simple assignment scheme for the related protection control data that is hard-coded. The protection control information for INMUX *i* affects the input multiplexing control register related to this input—namely, IMCR*i*.

SIUL2 can control up to 512 MSCRs and 512 IMCRs input multiplexers that the IMCRs can access individually. GPIO inputs are not affected by the input multiplexer scheme. Therefore, the associated virtualization information does not affect the corresponding pad input registers.

As the protection granularity is a single INMUX, any virtualization information associated with this INMUX affects the corresponding IMCR directly. Additionally, any consequence that an illegal access has on the registers implemented within the REG_PROT wrapper is inhibited. For this purpose, any access to the mirrored address space and the corresponding SLBR is also observed.

#### 8.3.3.3 Virtualization of interrupt control registers

Additionally, the complete set of interrupt control registers within SIUL2 (address offset range 0010h–00C3h) can be protected as a separate group (protection group #1024).

Another additional protection group (protection group #1055) is defined for the global control register (GCR) of the related REG_PROT wrapper.

The PDAC that accesses the main SIUL2 registers is used to access the SIUL2-mirrored registers and soft-lock-bit registers. This is because these registers are a part of the same 16 KB space.

Access to mirrored SIUL2 registers sets the bit in Soft lock bit as an inherent property of register protection. See the "Register Protection" chapter for details on the soft lock bit behavior, when accessing the mirrored region.

The following table shows an overview of the SIUL2 registers and their protection attributes.

**Table 32. SIUL2 memory map overview and protection**

| Offset range | Register | Size (bits) | Protected | Description |
|---|---|---|---|---|
| 0000–000Fh | MIDR1, MIDR2 | 32 | N | Read-only registers, not protected |
| 0010–00C3h | Interrupt registers | 32 | Y | Protected as a single group—no individual protection of related registers |
| 0240–A3Fh [1] | MSCR | 32 | Y | Amount of registers defines maximum number of PADs to be controlled and protected |
| 0A40–0123Fh | IMCR | 32 | Y | Amount of registers defines maximum number of INMUXes to be controlled and protected |
| 1300–14FFh | GPDO GPDO[0] (8-bit) register controls single PAD[0] pad means that if PAD[0] is assigned to PDAC slot 1 then PDAC slot 1 can write to GPDO[0] (8-bit). | 8 | Y | There are fewer GPDO registers than MSCR registers, as some PADs are not made available as GPIO PADs, but their electrical characteristics can still be programmed |
| 1500–16FFh | GPDI | 8 | N | PAD input register, not protected |
| 1700–173Fh | PGPDO PGPDO[0] (16-bit) register | 16 | Y | Writable with 8-, 16-, and as a pair with 32-bit accesses |

*Table continues on the next page...*

Table 32. SIUL2 memory map overview and protection (continued)

| Offset range | Register | Size (bits) | Protected | Description |
|---|---|---|---|---|
| | controls PAD[0-15] pads meaning if only all the PADs[0-15] are assigned to PDAC slot 1, then PDAC slot 1 can write to PGPDO[0] (16-bit). | | | |
| 1740–177Fh | PGPDI | 16 | N | PAD input register, not protected |
| 1780–17FFh | MPGPDO MPGPDO[0] (32-bit) register controls PAD[0-15] pads meaning if only all the PADs[0-15] are assigned to PDAC slot 1, then PDAC slot 1 can write to MPGPDO[0] (32-bit). | 32 | Y | Only writable with 32-bit accesses |
| 2010–20C3h | Interrupt registers (mirror) The DISR0 DIRER0 DIRSR0 IREER0 IFEER0 IFER0 IFMCR0-31 IFCPR0 can be assigned to individual PDAC control, then all these registers are only accessible through assigned PDAC.[2] | 32 | Y | Mirrored access to interrupt registers in SIUL2 instance |
| 2240–2A3Fh | MSCR (mirror)[3] | 32 | Y | Mirrored access to MSCRs in SIUL2 instance |
| 2A40–323Fh | IMCR (mirror)[3] | 32 | Y | Mirrored access to IMCRs in SIUL2 instance |
| 3300–34FFh | GPDO (mirror)[4] | 8 | Y | Mirrored access to GPDOs in SIUL2 instance |
| 4000–47FFh | SLBR[5] | 8 | Y | Soft lock bit registers within REG_PROT wrapper for this SIUL2 instance |
| 4800–48FFh | GCR | 32 | Y | Global configuration register within REG_PROT wrapper for this SIUL2 instance. There is a single register in configuration space that is area 4 of REG_PROT. The size mentioned is to make the whole area a multiple of 4 kB. See the table "Address accesses |

*Table continues on the next page...*

Table 32. SIUL2 memory map overview and protection (continued)

| Offset range | Register | Size (bits) | Protected | Description |
|---|---|---|---|---|
| | | | | as a function of PROT_MEM" in the REG_PROT chapter to know the exact area for GCRs. |

1. The SIUL2 block guide specifies the support of a maximum of 512 MSCRs.
2. Access to mirrored register address range results in a change of the related SLBR within the REG_PROT wrapper if REG_PROT protects the register. For registers unprotected by REG_PROT, a write to a register mirror has the same impact as a write to the register.
3. Access to mirrored register address range results in a change of the related SLBR within the REG_PROT wrapper if REG_PROT protects the register. For registers unprotected by REG_PROT, write to register mirror has the same impact as write to register.
4. Access to mirrored register address range results in a change of the related SLBR within the REG_PROT wrapper if REG_PROT protects the register. For registers unprotected by REG_PROT, a write to a register mirror has the same impact as a write to the register.
5. Only SLBRs protecting accesses to the interrupt registers, IMCRs, and the MSCR registers are protected. See the register protection sheet attached to the reference manual for a complete list of SIUL2 registers that REG_PROT protects.

## 8.4 External signals

This module has no external signals.

## 8.5 Initialization

This module does not require initialization.

## 8.6 Application Information

This module supports virtualization of accesses to the registers within a SIUL2 by inhibiting or granting accesses to a subset of these registers under control of the specified initiator(core) information.

## 8.7 VIRT_WRAPPER memory map register descriptions

**NOTE**

Access to reserved spaces outside the register bank and holes (unimplemented registers) within register bank generates the transfer error.

### 8.7.1 VIRT_WRAPPER memory map

VIRT_WRAPPER base address: 402A_8000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Parameter_n Register (REG_A15_0) | 32 | RW | FFFF_FFFFh |
| 4h | Parameter_n Register (REG_A31_16) | 32 | RW | FFFF_FFFFh |

### Function

This register set is for PAD0-511. They control MSCR, GPDO, PGPDO, and MPGPDO. Two bits assigned per PDAC have attributes of one of the implemented PDACs:

- 00-SIUL2_VIRTWRAPPER_PDAC1
- 11-SIUL2_VIRTWRAPPER_PDAC0

**NOTE**

- Any initiator can access holes (unimplemented registers) of SIUL2 through PDAC0.
- After reset, when XRDC is not configured, any initiator can access SIUL2 registers through PDAC0 without getting transfer error. However, if SIUL2 registers are accessed through other PDAC slots, a transfer error will be generated.

### Function

Controls access to pads 0 to 255 specific for IMCR registers. Two bits assigned per IMCR register have attributes of one of the implemented PDACs:

- 00-SIUL2_VIRTWRAPPER_PDAC1
- 11-SIUL2_VIRTWRAPPER_PDAC0

**NOTE**

- Any initiator can access holes (unimplemented registers) of SIUL2 through PDAC0.
- After reset, when XRDC is not configured, any initiator can access SIUL2 registers through PDAC0 without getting transfer error. However, if SIUL2 registers are accessed through other PDAC slots, a transfer error will be generated.

### 8.7.4 Parameter_n Register (REG_C1039_1024)

#### Offset

| Register | Offset |
|---|---|
| REG_C1039_1024 | 100h |

#### Function

Controls access to DISR0, DIRER0, DIRSR0, IREER0, IFEER0, IFER0, IFMCR, and IFCPR0 interrupt registers. Two bits assigned per PDAC have attributes of one of the implemented PDACs:

- 00-SIUL2_VIRTWRAPPER_PDAC1
- 11-SIUL2_VIRTWRAPPER_PDAC0

**NOTE**

After reset, when XRDC is not configured, any initiator can access SIUL2 registers through PDAC0 without getting transfer error. However, if SIUL2 registers are accessed through other PDAC slots, a transfer error will be generated.

### Diagram

## 8.8 Glossary

**VM** Virtualized module, such as SIUL2.

**PDAC** Peripheral domain access control. PDAC and PDAC slot are interchangeable terms.

# Chapter 9
# System Integration Unit Lite2 (SIUL2)

## 9.1 Chip-specific SIUL2 information

### 9.1.1 Feature availability

This chip:

- Supports input filter enable (MSCR5[IFE]) only for the reset pad (PTA5). For details, see the "Pad signal description" table in the "Signal Multiplexing" chapter.
- Does not implement the open-drain feature. LPI2C directly configures only the pads related to the I2C and LPUART functions in pseudo open-drain when these functions are muxed to the pads. See the LPI2C and LPUART chapters for more information.
- Reserves GPDO[25:24] and PGPDO1[7:6] because PTA24 and PTA25 are input-only pins.

**NOTE**

EIRQ[0-15] can be used either for interrupt or DMA request. EIRQ[16-31] can only be used for interrupt request.

### 9.1.2 Mapping of MSCR and IMCR instances

- CR numbers 0-511 correspond to the MSCR instances.
- CR numbers 512-1023 correspond to the IMCR instances. IMCRs defined in the attached IOMUX file have an offset of 512 with respect to the IMCR number defined in SIUL2 memory map section.

**NOTE**

IMCR register only supports 32 bit access, any other access might result in unexpected data. See IOMUX file attached to this document for the exact number of IMCR and MSCR register instances.

### 9.1.3 SIUL2 register configuration

There are additional registers as compared to what is mentioned in section 'SIUL2 memory map'. See following table for details.

**Table 33. Registers and applicability**

| Register | Offset | MCXE315/MCXE316 | MCXE317 | MCXE31B |
|---|---|---|---|---|
| MUX0_EMIOS_EN1 | 100h | Yes | No | No |
| MUX0_MISC_EN | 104h | Yes | No | No |
| MUX1_EMIOS_EN | 108h | Yes | No | No |
| MUX1_MISC_EN | 10Ch | Yes | No | No |
| UDR1 | 100h | No | Yes | No |
| UDR0 | 104h | No | Yes | No |
| UDR3 | 108h | No | Yes | No |
| UDR2 | 10Ch | No | Yes | No |

## 9.2 Overview

SIUL2 provides control over all electrical pin controls and ports with 16 bits of bidirectional, general-purpose input and output (I/O) signals. It also performs the following functions:

- Enables you to select the functions and electrical characteristics that appear on external chip pins
- Controls the multiplexing of internal signals from one module to another and controls the chip I/O
- Supports a maximum of 32 external interrupts with trigger event configuration

### 9.2.1 Block diagram

SIUL2 provides a dedicated pad control to general-purpose pads that you can configure as either inputs or outputs. It provides registers for you to read values from GPIO pads configured as inputs and to write values to GPIO pads configured as outputs. Based on the configuration of GPIO, you can:

- Write to an internal register to control the state driven on the associated output pad (when configured as output).
- Detect the state of the associated pad by reading the value from an internal register (when configured as input).
- Read back the pad value to check whether the written value appears on the pad (when configured as input and output).

Access the GPIO data registers in the following ways to allow port access and bit manipulation without read-modify-write operations:

- Access to two 16-bit ports in one access
- Read/write access to a single bit
- 16-bit port write with a bit mask using a single 32-bit access

You can configure:

- External interrupt sources at the chip level to be used with any chip pad.
- Interrupt sources to have a digital filter to reject short glitches on the inputs.

The external interrupt or DMA requests map to the interrupt request pins (REQ) in the chip packages.

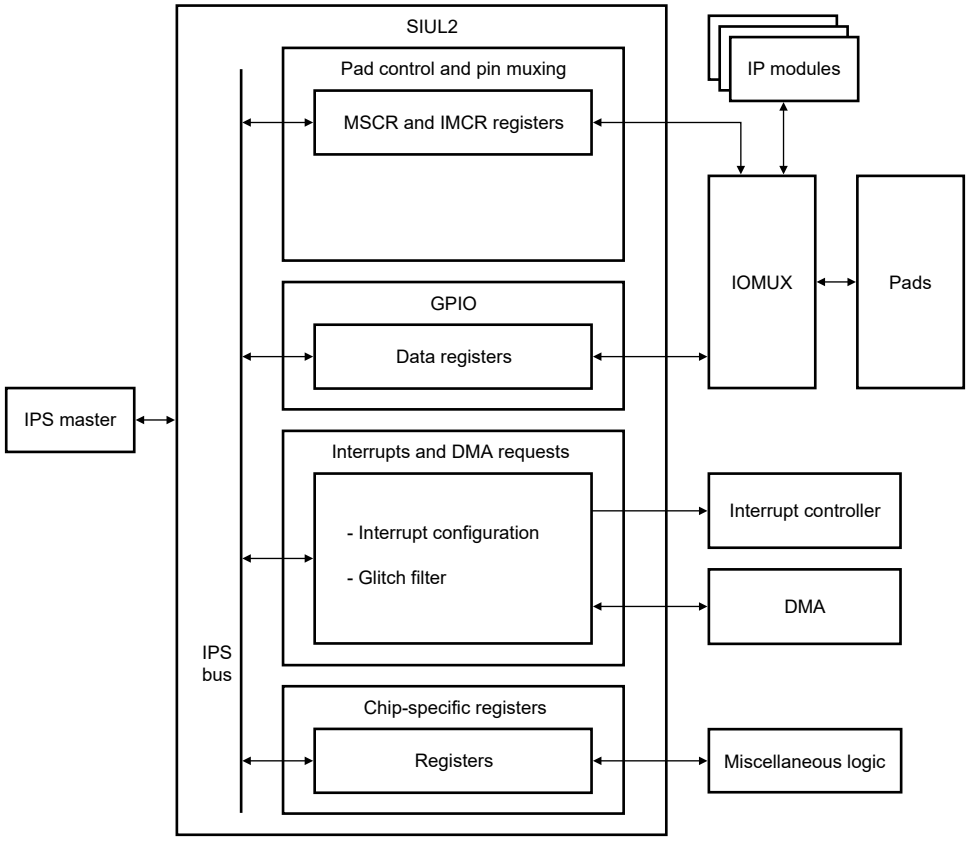

Figure 16. Block diagram

## 9.2.2 Features

SIUL2 supports the following:

- 1 to 32 GPIO ports with data control:
  - Drives data to as many as 16 independent I/O channels
  - Samples data from as many as 16 independent I/O channels
- Read or write of two 16-bit registers with one access for a 32-bit port
- External interrupt and DMA requests:
  - 1 to 32 programmable digital glitch filters, one for each interrupt REQ pin
  - Edge detection
- Multiplexed Signal Configuration Registers (MSCR) to configure the electrical parameters and settings for as many as 512 functional pads.

See the interrupt map file and the DMAMUX map file attached to this document for mapping of interrupt and DMA sources to interrupt vectors and DMA channels.

## 9.3 Functional description

### 9.3.1 Pad control

SIUL2 controls the electrical characteristics of around 512 pads. It provides a consistent interface for all pads, both on a by-port and a by-bit basis.

The setting of each pad out of reset is fixed per chip but you can configure it individually. This way you can select special pull settings or peripheral pad ownership.

You can configure each pad independently of all other pads on the chip or other pads grouped within a single port, therefore allowing grouping of different pad types together in ports and operating the pads individually. Grouping the various functions for each pad into a single register allows configuration of each pad with a single write to a register, which further allows you to duplicate software for similar pads with index changes.

### 9.3.2 General-purpose input and output pads (GPIO)

SIUL2 allows each pad to be configured as either of the following:

- General-purpose input or output pad (GPIO)
- A pad for one or more alternate functions (input or output) determined by the peripheral that uses the pad

You can also implement the GPIO pads without any alternate function.

SIUL2 manages as many as 512 GPIO pads organized as ports that can be accessed for data reads and writes as 8-bit, 16-bit, or 32-bit.

All port accesses are identical, with each read or write performed only at a different location to access a different port width.

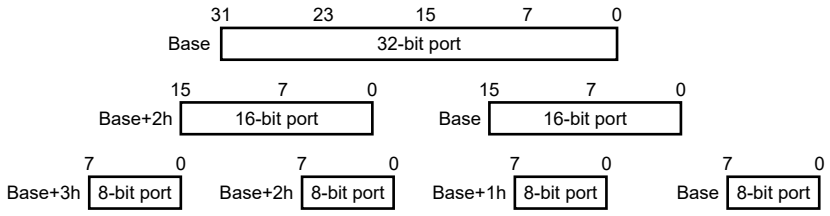

**Figure 17. Data port example arrangement showing configuration for different port width accesses**

SIUL2 has separate data input and data output registers for all pads. You can therefore directly read back an input or output value of a pad to validate what is present on the pad instead of confirming the value that was written to the data input registers. The data output registers support both read and write operations whereas the data input registers support only the read access.

When you configure a pad for using one of its alternate functions, the data input values reflect the respective value of the pad. If you perform a write operation to the data output register for a pad configured as an alternate function (non-GPIO), this write is not reflected by the pad value until reconfigured to GPIO. All general-purpose pads are implemented as bidirectional.

If a bidirectional operation impacts the performance or is not needed for a pad function, you can limit the functionality of the pad to input-only.

### 9.3.3 Clocking

This module has no clocking considerations.

### 9.3.4 External interrupts

SIUL2 supports 1–32 external interrupts allocated to pads by the chip.

See the interrupt map file and the DMAMUX map file attached to this document (device reference manual) for mapping of interrupt and DMA sources to interrupt vectors and DMA channels.

SIUL2 supports 1–4 interrupt vectors to the interrupt controller of the chip. Each interrupt vector can support as many as eight external interrupt sources from the chip pads.

All the external interrupt pads within a single group have equal priority. It is your responsibility to search for the application through a group of sources in an appropriate way.

**NOTE**

Glitch filters applied to external interrupts require a running internal oscillator clock. If such a clock is not available, enabling the glitch filter on an external interrupt disables the interrupt.

The external interrupt signals from a pad have internal synchronizers. Therefore, the width of the interrupt signals should be at least 2.5 or 3 times the internal RC oscillator (IRC) clock cycles to correctly capture the interrupts.

#### 9.3.4.1 External interrupt initialization

Perform the following procedure to enable external interrupts (if you do not perform these steps, you may get a false interrupt flag during interrupt initialization):

1. Write 1 to the appropriate IFER[IFE*n*] fields to enable the glitch filter.
2. Write 0 to DIRER0[EIRE*n*] to mask interrupts.
3. Write 1 to the appropriate IREE*n* fields in Interrupt Rising-Edge Event Enable 0 (IREER0) and IFEE*n* fields in Interrupt Falling-Edge Event Enable 0 (IFEER0) as needed to select the pin polarity.
4. Configure the appropriate fields in MSCR for the external interrupt pins:
    a. Write 0 to the OBE and ODE to disable the output.
    b. Write 1 to IBE field to enable the input buffer of the pin.
    c. If you are using the internal pull-up or pull-down resistors, configure the appropriate PUE and PUS fields.

    **NOTE**

    If you select external interrupt inputs for external interrupt pins, do not configure them as outputs (that is, MSCR[OBE] must not be 0) because it can cause false interrupt detection (such as from a GPIO configuration).
5. Write to the appropriate DIRSR0[DIRS*n*] fields to select a request between DMA or interrupt.
6. Select the desired glitch filter setup for the pins:
    a. Write an appropriate value to IFMCR0[MAXCNT] for the respective external interrupt to the filter counter.
    b.
    c. Write to the appropriate IFER0[IFE*n*] fields to enable the glitch filter for the external interrupt pins.
7. Set the appropriate DISR0[EIF*n*] to clear any flags.
8. Write to the appropriate DIRER0[EIRE*n*] fields to enable the interrupt pins.

**NOTE**

If you do not follow these steps you may get a false interrupt flag during interrupt initialization.

#### 9.3.4.2 External interrupt management

You can enable or disable each interrupt independently using a single rolled up register, DIRER0.

You can configure a pad defined as an external interrupt to recognize interrupts with an active rising edge, an active falling edge, or both, using Interrupt Rising-Edge Event Enable 0 (IREER0) and Interrupt Falling-Edge Event Enable 0 (IFEER0).

**NOTE**

You cannot disable both edge events of a given interrupt.

Each external interrupt has an individual flag, held in DMA or Interrupt Status Flag 0 (DISR0). DISR0 is a clear-by-write-1 register, which prevents inadvertent overwriting of other flags in the same register.

Figure 18 provides an overview of the external interrupt implementation.

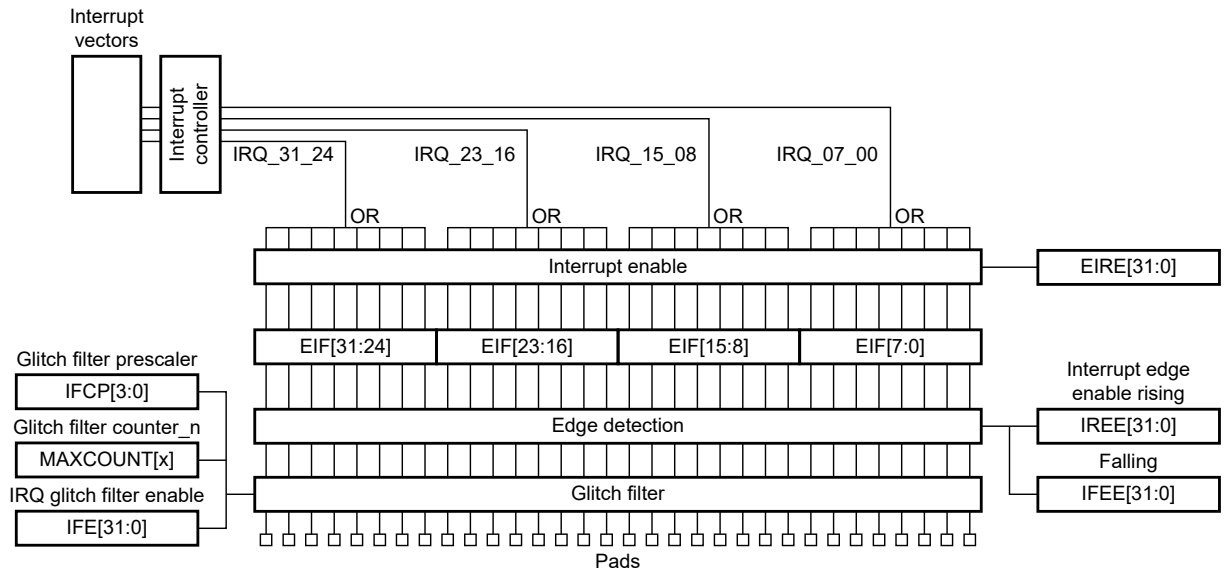

**Figure 18. External interrupt pad diagram**

### 9.3.4.3 External interrupt request

The REQ input pins on the chip are the sources for interrupt or DMA requests. The chip provides one possible interrupt vector for SIUL2. The 32 interrupt request sources map to vectors and channels as shown in Table 34.

**Table 34. Interrupt source mapping to SIUL2 interrupt request output for 32 interrupt sources**

| Vector or channel # | Interrupt vector source |
|---|---|
| 0 | REQ[07] \| REQ[06] \| REQ[05] \| REQ[04] \| REQ[03] \| REQ[02] \| REQ[01] \| REQ[00] |
| 1 | REQ[15] \| REQ[14] \| REQ[13] \| REQ[12] \| REQ[11] \| REQ[10] \| REQ[09] \| REQ[08] |
| 2 | REQ[23] \| REQ[22] \| REQ[21] \| REQ[20] \| REQ[19] \| REQ[18] \| REQ[17] \| REQ[16] |
| 3 | REQ[31] \| REQ[30] \| REQ[29] \| REQ[28] \| REQ[27] \| REQ[26] \| REQ[25] \| REQ[24] |

## 9.3.5 DMA requests

The REQ pins on the chip map to the independent DMA request channels in the DMA controller. See the DMAMUX map file attached to this document for the mapping of DMA sources to DMA channels.

DISR0 and DIRSR0 manage DMA requests in the following way:

- Service a DMA request to clear the DISR0 register flags.
- Write to the appropriate DIRSR0[DIRS*n*] to select a request between DMA or interrupt.
- If you select DMA in DIRSR0 and set the corresponding DISR0 flag for it, SIUL2 sends a DMA request signal as an output.

## 9.4 External signal description

See the IOMUX file attached to this document for more information.

## 9.5 Initialization

This module does not require initialization.

## 9.6 SIUL2 register descriptions

This section describes the SIUL2 registers.

- Undocumented register spaces in the SIUL2 memory map, including addresses shown as blanks, are reserved:
  - Reserved registers or spaces are read as 0.
  - Writes to reserved registers or spaces generate a transfer error.
- Writes to read-only registers generate a transfer error.

**NOTE**

- For the array of 8-bit registers, GPDO*n* and GPDI*n*:
  - An 8-bit access to an unimplemented address (a "hole") within the array region generates a transfer error.
  - However, when you perform a 16-bit or 32-bit access and if any register instance is implemented within the accessed range, a transfer error is not generated even if the range includes a hole.
- For the array of 16-bit registers, PGPDO*n* and PGPDI*n*:
  - A 16-bit access to an unimplemented address (a "hole") within the array region generates a transfer error.
  - However, a 32-bit access does not generate a transfer error for a hole irrespective of whether the other 16-bit range includes a register instance.

### 9.6.1 SIUL2 memory map

SIUL2 base address: 4029_0000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 4h | SIUL2 MCU ID Register #1 (MIDR1) | 32 | R | See section |
| 8h | SIUL2 MCU ID Register #2 (MIDR2) | 32 | R | See section |

1. In this array, the index and offset values of the registers do not increment in direct alignment. For details, see the register description.

## 9.6.2 SIUL2 MCU ID Register #1 (MIDR1)

### Offset

| Register | Offset |
|---|---|
| MIDR1 | 4h |

### Function

This register holds identification information about the device.

**NOTE**

This register supports only 32-bit accesses. Byte and half-word accesses are not supported.

### Diagram

### 9.6.4 DMA or Interrupt Status Flag 0 (DISR0)

#### Offset

| Register | Offset |
|---|---|
| DISR0 | 10h |

#### Function

Contains flags that record an event on the external IRQ pins. This register supports 8-, 16-, and 32-bit accesses.

When an event (as defined in and IFEER0) occurs, the corresponding flag is set. The IRQ flag is set regardless of the state of the corresponding DIRER0[EIRE*n*]. The IRQ flag remains set until you clear it or is cleared by servicing of a DMA request. The IRQ flags are cleared when you write 1 to them. A write of 0 has no effect.

### 9.6.5 DMA or Interrupt Request Enable 0 (DIRER0)

#### Offset

| Register | Offset |
|---|---|
| DIRER0 | 18h |

#### Function

Enables the assertion of a DMA or interrupt request to the interrupt controller if the corresponding DISR0[EIF*n*] flag is 1. The type of request is determined by the corresponding DIRSR0[DIRSR*n*] field.

This register supports 8-, 16-, and 32-bit accesses.

**NOTE**

You cannot enable or disable DIRSR0 after it selects a DMA request.

## 9.6.7 Interrupt Rising-Edge Event Enable 0 (IREER0)

### Offset

| Register | Offset |
|---|---|
| IREER0 | 28h |

### Function

Enables the rising-edge triggered events on the corresponding interrupt pads. This register supports 8-, 16-, and 32-bit accesses.

**NOTE**

If you write 0 to both the IREE and IFEE fields for the same interrupt source, the interrupt status flag for the corresponding external interrupt never sets.

### 9.6.10 Interrupt Filter Maximum Counter (IFMCR0 - IFMCR31)

#### Offset

For a = 0 to 31:

| Register | Offset |
|---|---|
| IFMCRa | 40h + (a × 4h) |

#### Function

Configures the filter counter associated with each of the digital glitch filter and supports only 32-bit accesses. It does not support byte and halfword accesses.

## 9.6.13 Multiplexed Signal Configuration (MSCR0 - MSCR323)

### Offset

For a = 0 to 323:

| Register | Offset |
|---|---|
| MSCRa | 240h + (a × 4h) |

### Function

Selects the source signal connected to the register's associated destination, which is a chip output pin or a chip pin that can be configured as an output. It also specifies the electrical properties of the associated pin.

This register supports only 32-bit accesses. Byte and half-word write accesses are not supported.

For chip-pin MSCR assignments and pin types, see the IOMUX file attached to this document.

**NOTE**

- Configure these registers only during application initialization; you must not modify them during application runtime.
- Accessing a reserved MSCR*n* register generates a transfer error.
- These registers are a part of the SIUL memory map but the physical implementation of these registers is a part of the IOMUX RTL.
- SIUL2 interprets accesses to MSCR*n* at the module level.

## 9.6.14 Input Multiplexed Signal Configuration (IMCR0 - IMCR473)

### Offset

For a = 0 to 473:

| Register | Offset |
|---|---|
| IMCRa | A40h + (a × 4h) |

### Function

Selects the source signal connected to the register's associated destination, which is an internal module port that is an input port or can be configured as an input.

This register supports only 32-bit accesses. Byte and half-word write accesses are not supported.

For IMCR assignments and field values, see the IOMUX file attached to this document.

**NOTE**

- Configure these registers only during application initialization; you must not modify them during application runtime.
- Accessing a reserved IMCR*n* register generates a transfer error.
- These registers are a part of the SIUL memory map but the physical implementation of these registers is a part of the IOMUX RTL.
- SIUL2 interprets accesses to MSCR*n* at the module level.

## 9.6.15 GPIO Pad Data Output (GPDO0 - GPDO219)

### Offset

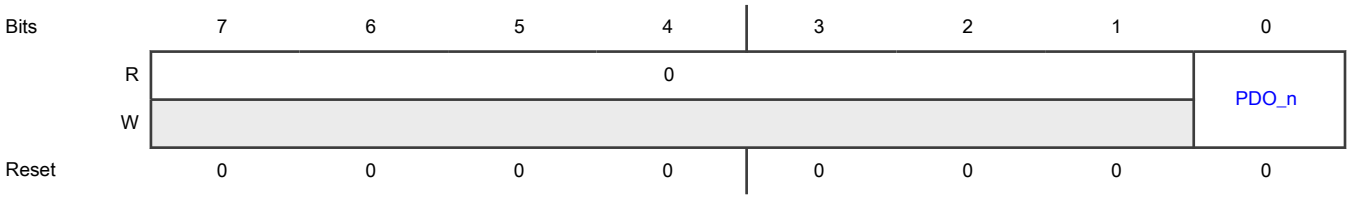
For n = 0 to 37; n = 40 to 219:

| Register | Offset |
|---|---|
| GPDOn | 1300h + (n + 3 - 2 × (n mod 4)) |

### Function

Writes 0 or 1 to a single GPIO pad with a byte access and supports 8-, 16-, and 32-bit accesses.

### Diagram



### Fields

| Field | Function |
|---|---|
| 7-1<br>— | Reserved |
| 0<br>PDO_n | Pad Data Out<br>Stores the data to be driven out on an external GPIO pad (controlled by this register) when you configure the pad as an output.<br>It also represents PDO[*n*], where *n* is the instance of the register.<br>0b - Logic low value<br>1b - Logic high value |

## 9.6.16 GPIO Pad Data Input (GPDI0 - GPDI219)

### Offset

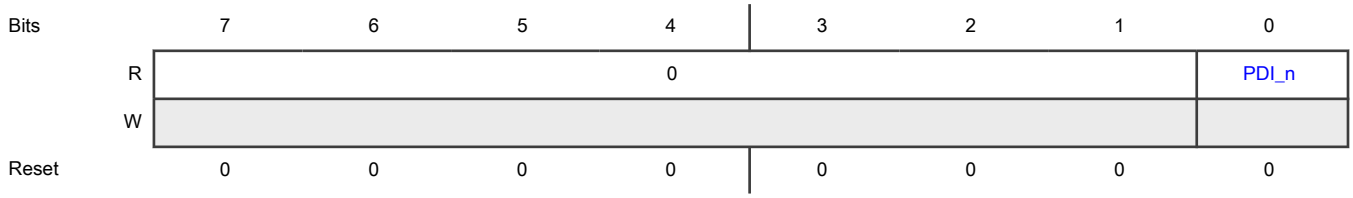
For n = 0 to 37; n = 40 to 219:

| Register | Offset |
|---|---|
| GPDIn | 1500h + (n + 3 - 2 × (n mod 4)) |

### Function

Reads the GPIO pad data with a byte access and supports 8-, 16-, and 32-bit accesses.

### Diagram



### Fields

| Field | Function |
|---|---|
| 7-1<br>— | Reserved |
| 0<br>PDI_n | Pad Data In<br>Stores the value of the external GPIO pad associated with this register.<br>It represents PDI[*n*], where *n* is the instance of the register.<br>0b - Logic low<br>1b - Logic high |

## 9.6.17 Parallel GPIO Pad Data Output (PGPDO0 - PGPDO3)

### Offset

| Register | Offset |
|---|---|
| PGPDO1 | 1700h |
| PGPDO0 | 1702h |
| PGPDO3 | 1704h |

### Function

Sets or clears the respective pads of the chip and supports 8-, 16-, and 32-bit accesses. This register also accesses the same physical resource as the PDO and MPGPDO address locations.

This register sets the values of all the output pins assigned to a chip port with a single 16-bit register write, while the GPDO*n* register sets the value on a specific pin with byte writes.

The access to this register's location is coherent with access to the bitwise GPDO*n*.

For a given PGPDO*x*[PPDO*y*], where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDO*n*[PDO_*n*] field:

PGPDO*x*[PPDO*y*] = GPDO(*x* × 16) + (15 - *y*)[PDO_(*x* × 16) + (15 - *y*)]

Following are some of the examples of mapping:

- PGPDO0[PPDO15] = GPDO0[PDO_0]
- PGPDO2[PPDO15] = GPDO32[PDO_32]
- PGPDO31[PPDO0] = GPDO511[PDO_511]

### 9.6.18 Parallel GPIO Pad Data Output (PGPDO2)

#### Offset

| Register | Offset |
|---|---|
| PGPDO2 | 1706h |

#### Function

Sets or clears the respective pads of the chip and supports 8-, 16-, and 32-bit accesses. This register also accesses the same physical resource as the PDO and MPGPDO address locations.

This register sets the values of all the output pins assigned to a chip port with a single 16-bit register write, while the GPDO*n* register sets the value on a specific pin with byte writes.

The access to this register's location is coherent with access to the bitwise GPDO*n*.

For a given PGPDO*x*[PPDO*y*], where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDO*n*[PDO_*n*] field:

PGPDO*x*[PPDO*y*] = GPDO(*x* × 16) + (15 - *y*)[PDO_(*x* × 16) + (15 - *y*)]

Following are some of the examples of mapping:

- PGPDO0[PPDO15] = GPDO0[PDO_0]
- PGPDO2[PPDO15] = GPDO32[PDO_32]
- PGPDO31[PPDO0] = GPDO511[PDO_511]

## 9.6.19 Parallel GPIO Pad Data Output (PGPDO4 - PGPDO11)

### Offset

For n = 4 to 11:

| Register | Offset |
|---|---|
| PGPDOn | 1708h + 2 × (n + 1 – 2 × (n mod 2)) |

### Function

Sets or clears the respective pads of the chip and supports 8-, 16-, and 32-bit accesses. This register also accesses the same physical resource as the PDO and MPGPDO address locations.

This register sets the values of all the output pins assigned to a chip port with a single 16-bit register write, while the GPDO*n* register sets the value on a specific pin with byte writes.

The access to this register's location is coherent with access to the bitwise GPDO*n*.

For a given PGPDO*x*[PPDO*y*], where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDO*n*[PDO_*n*] field:

PGPDO*x*[PPDO*y*] = GPDO(*x* × 16) + (15 - *y*)[PDO_(*x* × 16) + (15 - *y*)]

Following are some of the examples of mapping:

- PGPDO0[PPDO15] = GPDO0[PDO_0]
- PGPDO2[PPDO15] = GPDO32[PDO_32]
- PGPDO31[PPDO0] = GPDO511[PDO_511]

## 9.6.20 Parallel GPIO Pad Data Output (PGPDO13)

### Offset

| Register | Offset |
|---|---|
| PGPDO13 | 1718h |

### Function

Sets or clears the respective pads of the chip and supports 8-, 16-, and 32-bit accesses. This register also accesses the same physical resource as the PDO and MPGPDO address locations.

This register sets the values of all the output pins assigned to a chip port with a single 16-bit register write, while the GPDO*n* register sets the value on a specific pin with byte writes.

The access to this register's location is coherent with access to the bitwise GPDO*n*.

For a given PGPDO*x*[PPDO*y*], where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDO*n*[PDO_*n*] field:

PGPDO*x*[PPDO*y*] = GPDO(*x* × 16) + (15 - *y*)[PDO_(*x* × 16) + (15 - *y*)]

Following are some of the examples of mapping:

- PGPDO0[PPDO15] = GPDO0[PDO_0]
- PGPDO2[PPDO15] = GPDO32[PDO_32]
- PGPDO31[PPDO0] = GPDO511[PDO_511]

## 9.6.22 Parallel GPIO Pad Data Input (PGPDI0 - PGPDI3)

### Offset

| Register | Offset |
|---|---|
| PGPDI1 | 1740h |
| PGPDI0 | 1742h |
| PGPDI3 | 1744h |

### Function

Holds the synchronized input value from the pads and supports 8-, 16-, and 32-bit accesses.

This register reads the values of all input pins assigned to a chip port with a single 16-bit register read, while GPDI*n* registers read the value on a specific pin with a byte read.

The access to this register's location is coherent with the access to the bitwise GPDI*n*.

For a given PGPDI*x*[PPDI*y*], where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDI*n*[PDI_*n*] field:

PGPDI*x*[PPDI*y*] = GPDI(*x* × 16) + (15 - *y*)[PDI_(*x* × 16) + (15 - *y*)]

Following are some of the examples of mapping:

- PGPDI0[PPDI15] = GPDI0[PDI_0]
- PGPDI2[PPDI15] = GPDI32[PDI_32]
- PGPDI31[PPDI0] = GPDI511[PDI_511]

## 9.6.24 Parallel GPIO Pad Data Input (PGPDI4 - PGPDI11)

### Offset

For n = 4 to 11:

| Register | Offset |
|---|---|
| PGPDIn | 1748h + 2 × (n + 1 – 2 × (n mod 2)) |

### Function

Holds the synchronized input value from the pads and supports 8-, 16-, and 32-bit accesses.

This register reads the values of all input pins assigned to a chip port with a single 16-bit register read, while GPDI*n* registers read the value on a specific pin with a byte read.

The access to this register's location is coherent with the access to the bitwise GPDI*n*.

For a given PGPDI*x*[PPDI*y*], where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDI*n*[PDI_*n*] field:

PGPDI*x*[PPDI*y*] = GPDI(*x* × 16) + (15 - *y*)[PDI_(*x* × 16) + (15 - *y*)]

Following are some of the examples of mapping:

- PGPDI0[PPDI15] = GPDI0[PDI_0]
- PGPDI2[PPDI15] = GPDI32[PDI_32]
- PGPDI31[PPDI0] = GPDI511[PDI_511]

## 9.6.25 Parallel GPIO Pad Data Input (PGPDI13)

### Offset

| Register | Offset |
|---|---|
| PGPDI13 | 1758h |

### Function

Holds the synchronized input value from the pads and supports 8-, 16-, and 32-bit accesses.

This register reads the values of all input pins assigned to a chip port with a single 16-bit register read, while GPDI*n* registers read the value on a specific pin with a byte read.

The access to this register's location is coherent with the access to the bitwise GPDI*n*.

For a given PGPDI*x*[PPDI*y*], where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDI*n*[PDI_*n*] field:

PGPDI*x*[PPDI*y*] = GPDI(*x* × 16) + (15 - *y*)[PDI_(*x* × 16) + (15 - *y*)]

Following are some of the examples of mapping:

- PGPDI0[PPDI15] = GPDI0[PDI_0]
- PGPDI2[PPDI15] = GPDI32[PDI_32]
- PGPDI31[PPDI0] = GPDI511[PDI_511]

## 9.6.26 Parallel GPIO Pad Data Input (PGPDI12)

### Offset

| Register | Offset |
|---|---|
| PGPDI12 | 175Ah |

### Function

Holds the synchronized input value from the pads and supports 8-, 16-, and 32-bit accesses.

This register reads the values of all input pins assigned to a chip port with a single 16-bit register read, while GPDI*n* registers read the value on a specific pin with a byte read.

The access to this register's location is coherent with the access to the bitwise GPDI*n*.

For a given PGPDI*x*[PPDI*y*], where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDI*n*[PDI_*n*] field:

PGPDI*x*[PPDI*y*] = GPDI(*x* × 16) + (15 - *y*)[PDI_(*x* × 16) + (15 - *y*)]

Following are some of the examples of mapping:

- PGPDI0[PPDI15] = GPDI0[PDI_0]
- PGPDI2[PPDI15] = GPDI32[PDI_32]
- PGPDI31[PPDI0] = GPDI511[PDI_511]

## 9.6.27 Masked Parallel GPIO Pad Data Output (MPGPDO0 - MPGPDO1)

**Offset**

| Register | Offset |
|---|---|
| MPGPDO0 | 1780h |
| MPGPDO1 | 1784h |

### Function

Modifies the pad values associated with PGPDO*n* selectively and supports only 32-bit accesses. It does not support byte and half-word accesses.

**NOTE**

Access this register only with 32-bit writes. 8-bit or 16-bit writes do not modify any bits in the register resulting in a transfer error. Read access returns 0.

The accesses to each of this register location is coherent with access to the bitwise GPDO*n*.

For a given MPGPDO*x*[MPPDO*y*], where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDO*n*[PDO_*n*]:

MPGPDO*x*[MPPDO*y*] = GPDO(*x* × 16) + (15 - *y*)[PDO_(*x* × 16) + (15 - *y*)]

Following are some of the examples of mapping:

- MPGPDO0[MPPDO15] = GPDO0[PDO_0]
- MPGPDO2[MPPDO15] = GPDO32[PDO_32]
- MPGPDO31[MPPDO0] = GPDO511[PDO_511]

## 9.6.29 Masked Parallel GPIO Pad Data Output (MPGPDO3 - MPGPDO12)

### Offset

For a = 3 to 12:

| Register | Offset |
|---|---|
| MPGPDOa | 1780h + (a × 4h) |

### Function

Modifies the pad values associated with PGPDO*n* selectively and supports only 32-bit accesses. It does not support byte and half-word accesses.

**NOTE**

Access this register only with 32-bit writes. 8-bit or 16-bit writes do not modify any bits in the register resulting in a transfer error. Read access returns 0.

The accesses to each of this register location is coherent with access to the bitwise GPDO*n*.

For a given MPGPDO*x*[MPPDO*y*], where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDO*n*[PDO_*n*]:

MPGPDO*x*[MPPDO*y*] = GPDO(*x* × 16) + (15 - *y*)[PDO_(*x* × 16) + (15 - *y*)]

Following are some of the examples of mapping:

- MPGPDO0[MPPDO15] = GPDO0[PDO_0]
- MPGPDO2[MPPDO15] = GPDO32[PDO_32]
- MPGPDO31[MPPDO0] = GPDO511[PDO_511]

### 9.6.30 Masked Parallel GPIO Pad Data Output (MPGPDO13)

#### Offset

| Register | Offset |
|---|---|
| MPGPDO13 | 17B4h |

#### Function

Modifies the pad values associated with PGPDO*n* selectively and supports only 32-bit accesses. It does not support byte and half-word accesses.

**NOTE**

Access this register only with 32-bit writes. 8-bit or 16-bit writes do not modify any bits in the register resulting in a transfer error. Read access returns 0.

The accesses to each of this register location is coherent with access to the bitwise GPDO*n*.

For a given MPGPDO*x*[MPPDO*y*], where *x* is the register instance index and *y* is the field index, the following equation shows the equivalent GPDO*n*[PDO_*n*]:

MPGPDO*x*[MPPDO*y*] = GPDO(*x* × 16) + (15 - *y*)[PDO_(*x* × 16) + (15 - *y*)]

Following are some of the examples of mapping:

- MPGPDO0[MPPDO15] = GPDO0[PDO_0]
- MPGPDO2[MPPDO15] = GPDO32[PDO_32]
- MPGPDO31[MPPDO0] = GPDO511[PDO_511]

# Chapter 10
# Touch Sensing Pin Coupling (TSPC)

## 10.1 Chip-specific TSPC information

### 10.1.1 TSPC instances and configuration

This chip has one instance of TSPC module. The GPIO pads being used for TSPC should be configured with Source Signal Select (SSS) = 0. TSPC module works in conjunction with SIUL2.

For the GPIOs and ADC pads supporting TSPC, see the IOMUX file attached to this document. There are two groups of pads which can be configured via TSPC:

1. Group 1 consists of 32 ADC channels and 14 GPIOs
2. Group 2 consists of 32 ADC channels and 6 GPIOs

**NOTE**

Use preferably the same type of I/O pins for driving each electrode. Such I/O pins matching will improve resolution of the capacitance sensing. For more information about types of I/O pins, see the IOMUX file attached to this document.

## 10.2 Overview

TSPC provides simultaneous transitioning of a group of pads into high impedance to support a more robust recognition of touch sense.

### 10.2.1 Block diagram

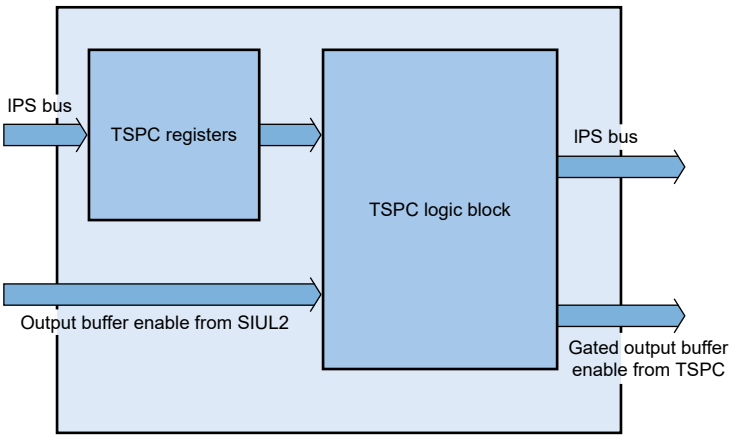

Figure 21. TSPC block diagram

### 10.2.2 Features

TSPC provides a set of control registers for pairing up GPIO pads for the touch sensing pairing operation. These control registers select the set of GPIO pads to pair with the set of ADC channels of an ADC instance. See the chip-specific TSPC configuration for group of pads information.

TSPC supports the following features:

- Up to 512 GPIO pads allow grouping

- OBE of all the grouped pads transitions from high to low simultaneously if SIUL2 transitions a pad's OBE from high to low
- Programming of group registers defines grouping

## 10.3 Functional description

TSPC contains these types of registers:

- Group enable: Each field of this register enables the respective group's OBE register—that is, if any OBE within a group transitions from high to low, it enables that group of OBEs for simultaneous transition from high to low. For example, GRP1_EN is the enable field for group 1 OBE registers. The number of fields in this register is equal to the number of groups.
- Group *n* OBE register *n*: The number of registers for a particular group *n* depends on the number of grouped OBEs in the respective group. For example, if the number of OBEs in group 1 is 36, then two registers of 32 fields each exist. Each field of this register represents an OBE pad. If you write 1 to the field, it indicates the OBE's participation in the grouping. If one of the pad's OBEs transitions from high to low, all the participating OBEs transition from high to low. The remaining OBEs that are not participating in the grouping are not affected.

### 10.3.1 Submodules

#### 10.3.1.1 Logic block description

This block takes the information from register fields to produce gated OBEs.

The simultaneous transition of grouped OBEs occurs when the GRP*n*_EN field in Group Enable (GRP_EN) for the respective group becomes 1.

The logic diagram below shows that if the GRP_EN is high for a particular group, and one of the output buffer enable (ipp_obe_in_b) from SIUL2 belonging to that group transitions from high to low, then all the other output buffer enables belonging to that group also transitions from high to low. If the GRP_EN is set low, the transitions in OBE do not affect the other OBE's belonging to that group.

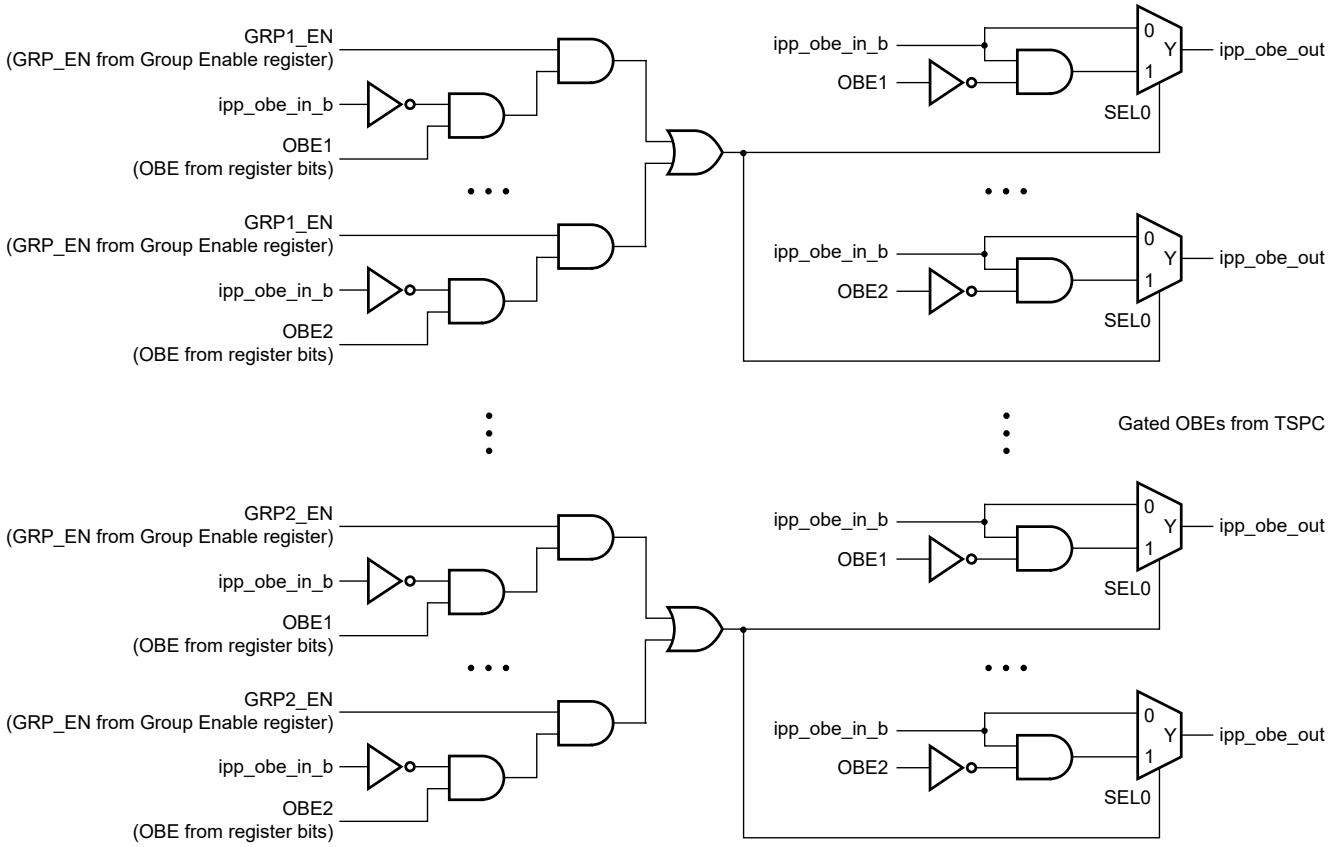

Figure 22. Logic block diagram

## 10.3.2 Operation

This section describes the TSPC_SPEC module's operations.

1. Reset all the registers.
2. Write 1 to the GRP*n*_OBE*x*[OBE*n*] of the OBEs that participate in grouping.
3. Program the corresponding group enable field participating in grouping in Group Enable (GRP_EN).

You must write 0 to the corresponding GRP_EN field when you configure the group *n* OBE fields. You must write 1 to the OBE*n* field in Group OBE (GRP1_OBE1 - GRP2_OBE1) and then write 1 to the corresponding GRP_EN field in Group Enable (GRP_EN).

## 10.3.3 Clocking

The TSPC module has two clocks.

| Clock |
|---|
| ipg_clk |
| ipg_clk_s |

## 10.3.4 Interrupts

This module has no interrupts.

## 10.4 External signals

The TSPC module has two external signals.

| Signal | IO | Description |
|---|---|---|
| ipp_obe_out | Output | Gated output buffer enable from TSPC |
| ipp_obe_in_b | Input | Output buffer enable from SIUL and input for TSPC |

## 10.5 Initialization

This module does not require initialization.

## 10.6 Application information

TSPC IP block provides the functionality of simultaneously transitioning two pads into high impedance, in order to experience a more robust recognition of touch sense.

## 10.7 TSPC register descriptions

### 10.7.1 TSPC memory map

TSPC base address: 402C_4000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Group Enable (GRP_EN) | 32 | RW | 0000_0000h |
| 50h | Group OBE (GRP1_OBE1) | 32 | RW | 0000_0000h |
| 54h | Group OBE (GRP1_OBE2) | 32 | RW | 0000_0000h |
| A0h | Group OBE (GRP2_OBE1) | 32 | RW | 0000_0000h |
| A4h | Group OBE (GRP2_OBE2) | 32 | RW | 0000_0000h |

### 10.7.2 Group Enable (GRP_EN)

**Offset**

| Register | Offset |
|---|---|
| GRP_EN | 0h |

**Function**
Allows enabling of the group, the pads of which participate in simultaneous transition.

## 11.2 Overview

This section provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus initiators and bus targets using a crossbar switch structure. This structure allows all bus initiators to access different bus targets simultaneously, while providing arbitration among the bus initiators when they access the same target. A variety of bus arbitration methods and attributes may be programmed on a target-by-target basis.

### 11.2.1 Features

- Symmetric crossbar bus switch implementation
  - Allows concurrent access from different Initiators to different Targets
  - Target arbitration attributes configured on a Target-by-Target basis
- Single-clock 64-bit transfer
- Support for burst transfers of 64 bits of data
- Support for low-power park mode
- Initiator high-priority elevation
- 64-bit AHB crossbar bus switch compatible with ARM's AMBA Specification v2.0

## 11.3 Functional description

Information about general operation and arbitration are provided in this section.

### 11.3.1 General operation

When a Initiator accesses the crossbar switch, the access is immediately taken. If the targeted target port of the access is available, then the access is immediately presented on the target port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted target port of the access is busy or parked on a different Initiator port, the requesting Initiator sees wait states inserted until the targeted target port can service the Initiator's request. The latency in servicing the request depends on each Initiator's priority level and the responding target's access time.

Because the crossbar switch appears to be just another target to the Initiator device, the Initiator device does not know whether it owns the target port it is targeting. The Initiator waits while it does not have control of the target port it is targeting.

After the Initiator acquires control of the target port, it controls the port until it relinquishes the port by running an IDLE cycle or by targeting a different target port for its next access.

The Initiator can also lose control of the target port if another higher-priority Initiator makes a request to the target port. However, if the Initiator is running a fixed-length burst transfer, it retains control of the target port until that transfer completes.

The crossbar terminates all Initiator IDLE transfers, as opposed to allowing the termination to come from one of the target buses. Additionally, when no Initiator is requesting access to a target port, the crossbar drives IDLE transfers onto the target bus, even though a default Initiator may be granted access to the target port.

When a target bus is being idled by the crossbar, it can park the target port on the Initiator port indicated by CRS*n*[PARK]. This is done to save the initial clock of arbitration delay that otherwise would be seen if the same Initiator had to arbitrate to gain control of the target port. The target port can also be put into low-power park mode to save power, by using CRS*n*[PCTL].

### 11.3.2 Register coherency

The operation of the crossbar is affected as soon as a register is written. The values of the registers do not track with target-port-related Initiator accesses, but instead track only with target accesses.

### 11.3.3 Arbitration

The crossbar switch supports the following arbitration algorithms:

- Fixed priority
- Round-robin

The arbitration scheme is independently programmable for each target port.

#### 11.3.3.1 Fixed-priority operation

When operating in fixed-priority mode, each initiator is assigned a unique priority level in the priority registers (PRS*n*). If two initiators request access to the same target port, the initiator with the highest priority in the selected priority register gains control over the target port.

**NOTE**

In this arbitration mode, a higher-priority initiator can monopolize a target port, preventing access from any lower-priority initiator to the port.

When a initiator makes a request to a target port, the target port checks whether the new requesting initiator's priority level is higher than that of the initiator that currently has control over the target port, unless the target port is in a parked state. The target port performs an arbitration check at every clock edge to ensure that the initiator, if any, has control of the target port.

The following table describes possible scenarios based on the requesting initiator port.

Table 38. Methods of how the crossbar switch grants control of a target port to a initiator

| When | Then the crossbar switch grants control to the requesting initiator |
|---|---|
| Both of the following are true:<br>• The current initiator is not running a transfer.<br>• The new requesting initiator's priority level is higher than that of the current initiator. | At the next clock edge |
| Both of the following are true:<br>• The current initiator is running a fixed-length burst transfer or a locked transfer.<br>• The requesting initiator's priority level is higher than that of the current initiator. | At the end of the burst transfer or locked transfer |
| The requesting initiator's priority level is lower than the current initiator. | At the conclusion of one of the following cycles:<br>• An IDLE cycle<br>• A non-IDLE cycle to a location other than the current target port |

#### 11.3.3.2 Round-robin priority operation

When operating in round-robin mode, each initiator is assigned a relative priority based on the initiator port number. This relative priority is compared to the initiator port number (ID) of the last initiator to perform a transfer on the target bus. The highest priority requests the initiator owns the target bus at the next transfer boundary, accounting for locked and fixed-length burst transfers. Priority is based on how far ahead the ID of the requesting initiator is of the ID of the last initiator.

After a initiator is granted access to a target port, a initiator may perform as many transfers as desired to that port until another initiator requests the same target port. The next initiator in line is granted access to the target port at the next transfer boundary, or possibly on the next clock cycle, if the current initiator has no pending access request.

As an example of arbitration in round-robin mode, assume that the crossbar is implemented with initiator ports 0, 1, 4, and 5. If the last initiator of the target port was initiator 1, and initiators 0, 4, and 5 make simultaneous requests, they are serviced in this order: 4,5, and then 0.

Parking may continue to be used in a round-robin mode, but does not affect the round-robin pointer unless the parked initiator performs a transfer. Handoff occurs to the next initiator in line after one cycle of arbitration. If the target port is put into low-power park mode, the round-robin pointer is reset to point at initiator port 0, giving it the highest priority.

#### 11.3.3.3 Clocking

This module has no clocking considerations.

#### 11.3.3.4 Interrupts

This module has no interrupts.

#### 11.3.3.5 Priority assignment

Each initiator port must be assigned a unique 3-bit priority level. If an attempt is made to program multiple initiator ports with the same priority level within the priority registers (PRS*n*), the crossbar switch responds with a bus error and the registers are not updated.

## 11.4 External signals

This module has no external signals.

## 11.5 Initialization/application information

No initialization is required for the crossbar switch.

Hardware reset ensures that all the register bits used by the crossbar switch are properly initialized to a valid state. However, the following settings and priorities may be programmed to achieve the maximum system performance:

- During the configuration of the crossbar switch, all other initiators must be IDLE.
- To prevent reconfiguration of the crossbar switch, write 1 to CRS*n*[RO].

## 11.6 Memory map and register definition

Each target port of the crossbar switch contains configuration registers. Read- and write transfers require two bus clock cycles. The registers can be read from and written to only in supervisor mode. Additionally, these registers can be read from or written to only by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The CRS*n* and PRS*n* registers can be programmed as read-only to prevent changes to their configuration. After being read-only protected, future writes to them terminate with a data storage error.

**NOTE**

This section shows the registers for all eight initiator and target ports. If a initiator or target is not used on this particular chip, then unexpected results occur when writing to its registers. See the chip configuration details for the exact initiator and target assignments for your chip.

All references to the crossbar switch registers are based on the physical port connections.

### 11.6.1 AXBS register descriptions

#### 11.6.1.1 AXBS memory map

### 11.6.1.2 Priority Target Registers (PRS0 - PRS6)

#### Offset

| Register | Offset |
|---|---|
| PRS0 | 0h |
| PRS1 | 100h |
| PRS2 | 200h |
| PRS3 | 300h |
| PRS4 | 400h |
| PRS5 | 500h |
| PRS6 | 600h |

#### Function

The priority target registers(PRS*n*) set the priority of each initiator port on a per target port basis and reside in each target port. The priority register can be accessed only with 32-bit access. After the CRS*n*[RO] bit is set, the PRS*n* register can only be read; attempts to write to it have no effect on PRS*n* and result in a bus-error response to the initiator initiating the write.

Two available initiators must not be programmed with the same priority level. Attempts to program two or more initiators with the same priority level result in a bus-error response and the PRS*n* is not updated.

**NOTE**

Valid values for the M*n* priority fields depend on which initiators are available on the chip. This information can be found in the chip-specific information for the crossbar.

- If the chip contains fewer than three initiators, only one bit is valid.
- If the chip contains fewer than five initiators, only two bits are valid.
- If five or more initiators are present, all three bits of the priority field are used.

### 11.6.1.3 Control Register (CRS0 - CRS6)

#### Offset

| Register | Offset |
|---|---|
| CRS0 | 10h |
| CRS1 | 110h |
| CRS2 | 210h |
| CRS3 | 310h |
| CRS4 | 410h |
| CRS5 | 510h |
| CRS6 | 610h |

#### Function

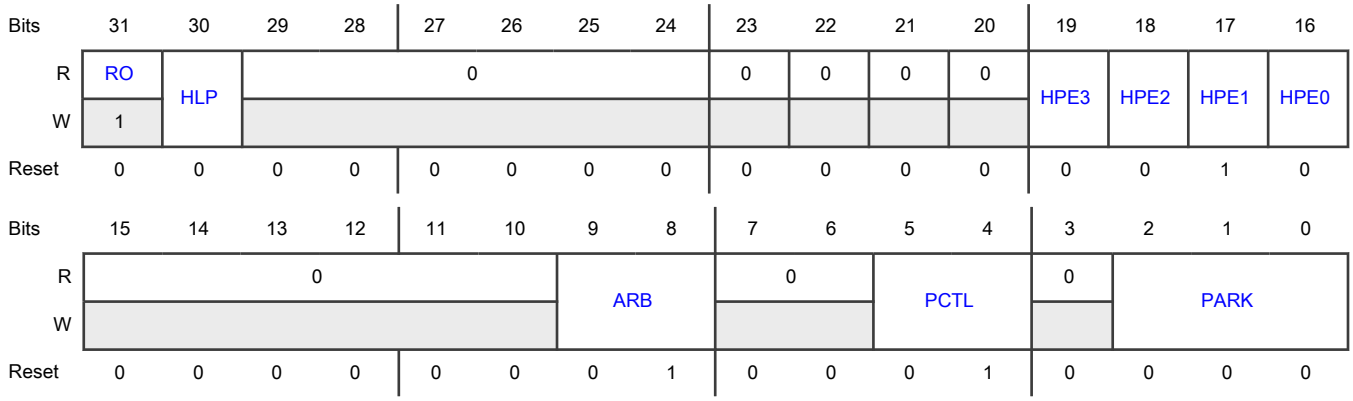
These registers control several features of each target port and must be accessed using 32-bit accesses. After CRS*n*[RO] is set, the PRS*n* can only be read; attempts to write to it have no effect and results in an error response.

**NOTE**

See the chip-specific crossbar information for the reset value of this register.

Not all HPE *n* fields may be active. See the chip-specific crossbar information for which initiators support initiator high-priority elevation. Setting a field corresponding to a initiator that does not support initiator, high-priority elevation has no effect.

### Diagram



### Fields

## 11.7 Glossary

**AMBA** Advanced Microcontroller Bus Architecture

**IDLE** A type of transfer that a initiator uses when it does not want to perform a data transfer

**ID** Initiator port number

# Chapter 12
# Peripheral Bridge (AIPS_Lite)

## 12.1 Chip-specific AIPS_Lite information

### 12.1.1 AIPS_Lite instances

The following table summarizes AIPS_Lite instances on MCXE31 product series to support simultaneous data transfers to different peripherals. See the memory map file attached to this document to find information related to these peripherals that are associated with AIPS_Lite instances.

**Table 39. AIPS_Lite instances**

| Instance | MCXE31B | MCXE317 | MCXE315/MCXE316 |
|---|---|---|---|
| AIPS_0 | Yes | Yes | Yes |
| AIPS_1 | Yes | Yes | Yes |
| AIPS_2 | Yes | No | No |

## 12.2 Overview

AIPS_Lite converts the crossbar switch interface to an interface that can access most of the slave peripherals on this chip.

This peripheral bridge occupies 64 MB of the address space, which is divided into peripheral slots of 16 KB each. All the peripherals may not be used. See the memory map chapter for details on slot assignments. The bridge includes separate clock enable inputs for each of the slots to accommodate slower peripherals.

### 12.2.1 Features

Following are the key features of the peripheral bridge:

- Supports peripheral slots with 8-, 16-, and 32-bit datapath width
- Supports a pair of 32-bit transactions for selected 64-bit memory accesses

### 12.2.2 General operation

The slave devices connected to the peripheral bridge are modules that contain a programming model of control and status registers. The system masters read and write these registers through the peripheral bridge.

The register maps of the peripherals are located on 16 KB boundaries. Each peripheral is allocated one or more 16-KB block(s) of the memory map.

## 12.3 Functional description

The peripheral bridge functions as a bus protocol translator between the crossbar switch and the slave peripheral bus. Support is provided for generating a pair of 32-bit slave accesses when performing certain 64-bit peripheral accesses.

The peripheral bridge manages all transactions for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

### 12.3.1 Access support

All combinations of access size and peripheral data port width are supported. An access that is larger than the target peripheral's data width is decomposed to multiple, smaller accesses. Bus decomposition is terminated by a transfer error caused by an access to an empty register area.

### 12.3.2 Clocking

This module has no clocking considerations.

### 12.3.3 Interrupts

This module has no interrupts.

## 12.4 External signals

This module has no external signals.

## 12.5 Memory map and register definition

The AIPS module(s) on this chip do(es) not contain any user-programmable registers.

# Chapter 13
# Direct Memory Access Multiplexer (DMAMUX)

## 13.1 Chip-specific DMAMUX information

### 13.1.1 DMAMUX instances

This chip has two instances of DMAMUX: DMAMUX_0 and DMAMUX_1. See the DMAMUX map file attached to this document to find information related to the slot number for each DMA trigger source.

For MCXE31B, DMAMUX_0 channels 0-15 and DMAMUX_1 channels 0-15 are mapped to eDMA Transfer Control Descriptor (TCD) 0-15 and eDMA Transfer Control Descriptor (TCD) 16-31, respectively. For the remaining chips, DMAMUX_0 channels 0-5 and DMAMUX_1 channels 0-5 are mapped to eDMA Transfer Control Descriptor (TCD) 0-5 and eDMA Transfer Control Descriptor(TCD) 6-11, respectively. Therefore, it is not recommended to program DMAMUX_0 channels 6-15 and DMAMUX_1 channels 6-15. When programmed, any access terminates with either an error response for channels 8-15 or without an error response for channels 6-7.

### 13.1.2 Periodic DMA triggering

PIT generates periodic trigger events to DMAMUX as shown in this table.

**Table 40. PIT channel assignment for periodic DMA triggering through DMAMUX**

| DMAMUX0/1 ports | PIT channel |
|---|---|
| pit_dma_trigger[0] | PIT0 channel 0 |
| pit_dma_trigger[1] | PIT0 channel 1 |
| pit_dma_trigger[2] | PIT0 channel 2 |
| pit_dma_trigger[3] | PIT0 channel 3 |

## 13.2 Introduction

### 13.2.1 Overview

DMAMUX routes a DMA source, called slot, to any of the 16 DMA channels. See the chip-specific information for details.

### 13.2.2 Block diagram

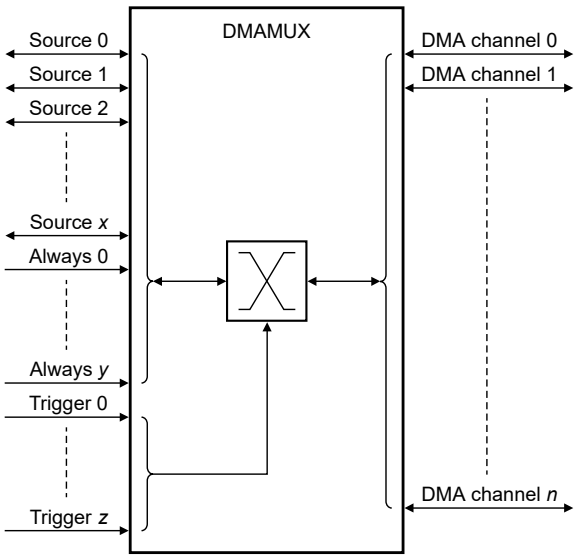

Figure 23. Block diagram

### 13.2.3 Features

- Ability to route up to 61 peripheral slots and up to 2 always-on slots to 16 channels
- Supports 16 independently selectable DMA channel routers (the first 4 channels provide an additional trigger functionality)
- Allows assignment of each channel router to one of the possible peripheral DMA slots or always-on slots

### 13.2.4 Modes of operation

The following table describes the functional operating modes of DMAMUX.

Table 41. Modes of operation

| Mode | Description |
|---|---|
| Disabled | In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. You can also use this mode to temporarily suspend a DMA channel while system reconfiguration takes place, for example, by changing the period of a DMA trigger. |
| Normal | In this mode, a DMA source is routed directly to the specified DMA channel. The operation of DMAMUX in this mode is completely transparent to the system. |
| Periodic trigger | In this mode, a DMA source can only request a DMA transfer, such as, when a transmit buffer becomes empty or a receive buffer becomes full, periodically.<br>You configure the period using an external periodic interrupt timer (PIT). This mode is available only for channels 0–3. See the chip-specific section for more details. |

## 13.3 Functional description

The primary purpose of DMAMUX is to provide flexibility in the system's use of the available DMA channels. Configuration of DMAMUX is intended to be a static procedure performed during the execution of the system boot code. However, if you follow the procedure outlined in Enabling and configuring sources, you can change the configuration of DMAMUX during the normal operation of the system. All DMA channels must be inactive before and during a configuration change.

Functionally, DMAMUX channels can be divided into two classes:

- Channels that implement the normal routing functionality plus the periodic triggering capability
- Channels that implement only the normal routing functionality

### 13.3.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first four channels of DMAMUX provide a special periodic triggering capability that you can use to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention (see Figure 24).

An external periodic interrupt timer (PIT) generates the trigger; for example, by configuring the external periodic timer, you configure the periodic triggering interval.

**NOTE**

Because of the dynamic nature of the system (owing to DMA channel priorities, bus arbitration, interrupt service routine lengths, and so on), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

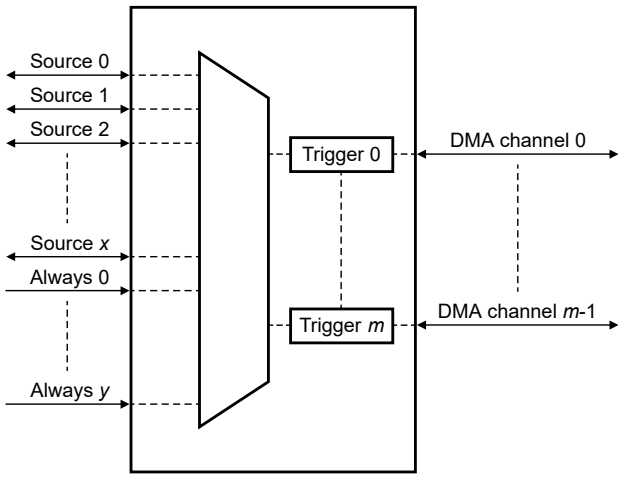

**Figure 24. DMAMUX triggered channels**

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to DMA until a trigger event is observed (see Figure 25).

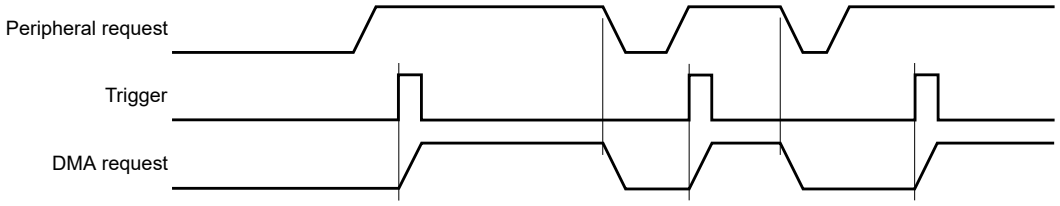

**Figure 25. DMAMUX channel triggering: normal operation**

After the DMA request is serviced, the peripheral negates its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger is ignored (see Figure 26).

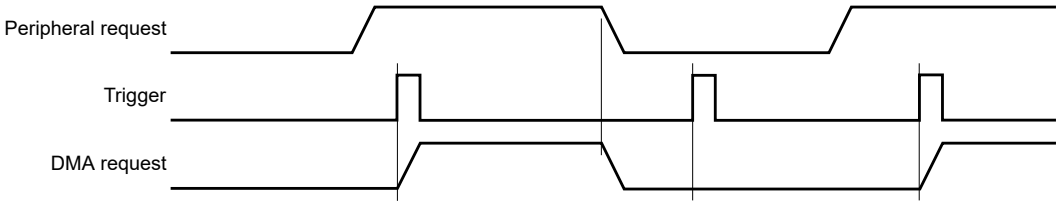

**Figure 26. DMAMUX channel triggering: ignored trigger**

You can use this triggering capability with any peripheral that supports DMA transfers, and is most useful in the following situations:

- Periodic polling of external devices on a particular bus: as an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described in the aforementioned text. After periodic polling is set up, SPI requests DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 µs (as an example). On the receive side of SPI, you can configure SPI and DMA to transfer the received data into memory, effectively implementing a method to periodically read data from external devices and transferring the results into memory without processor intervention.
- Using the GPIO ports to drive or sample waveforms: by configuring DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in a tabular form in on-chip memory.

### 13.3.2 DMA channels with no triggering capability

The other channels of DMAMUX provide the normal routing functionality as described in Modes of operation.

### 13.3.3 Always-enabled DMA sources

In addition to the peripherals that you can use as DMA sources, 2 additional DMA sources are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always enabled provide no such "throttling" of data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to and from GPIO: moving data to and from one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability)
- Performing DMA transfers from memory to memory: moving data from memory to memory, typically as fast as possible, sometimes with software activation
- Performing DMA transfers from memory to the external bus, or vice-versa: similar to memory-to-memory transfers, this is typically done as quickly as possible
- Any DMA transfer that software must explicitly start or activate

In cases where software must initiate the start of a DMA transfer, an always-enabled DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation or a transfer request from the DMA channel MUX. The options for doing this are as follows.

- Transfer all data in a single minor loop: by configuring DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage of this option is reduced granularity in determining the load that the DMA transfer imposes on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.
- Use explicit software reactivation: using this option, DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers after every minor loop. For this option, the DMA channel must be disabled in the DMA channel MUX.
- Use an always-enabled DMA source: using this option, DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, you must enable the DMA channel and point it to an "always-enabled" source. Channel reactivation can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of data packets from one source to another, without processor intervention.

## 13.4 Initialization and application information

This section provides instructions for initializing the DMA channel MUX.

### 13.4.1 Reset

The reset state of each field is shown in Memory map and register definition. In summary, after reset, all channels are disabled and you must enable them explicitly before use.

### 13.4.2 Enabling and configuring sources

#### 13.4.2.1 Enable a source with periodic triggering

Perform the following procedure to enable a source with periodic triggering:

1. Determine the DMA channel with which the source is associated. Only the first 4 DMA channels have periodic triggering capability.
2. Write 0 to CHCFG*n*[ENBL] and CHCFG*n*[TRIG] of the DMA channel.
3. Ensure that the DMA channel is properly configured in DMA. You can enable the DMA channel at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG*n*[ENBL] and CHCFG*n*[TRIG] are 1.

The following is an example. See the chip-specific information for the number of DMA channels on this chip that have triggering capability.

Example: To configure source 5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0h to CHCFG1.
2. Configure channel 1 in DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write C5h to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);

In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;                              /* Clear all the fields of CHCFG1 register */
*CHCFG1 = 0xC5;                              /* ENBL = 1  DMA Channel is enabled */
                                             /* TRIG = 1  Triggering is enabled */
                                             /* SOURCE = 5  DMA Source 5 is selected */
```

**Code Listing 1. Configuring source 5 with DMA channel 1 (with periodic triggering)**

#### 13.4.2.2 Enable a source without periodic triggering

Perform the following procedure to enable a source without periodic triggering:

1. Determine the DMA channel with which the source is associated. Only the first 4 DMA channels have periodic triggering capability.
2. Write 0 to CHCFG*n*[ENBL] and CHCFG*n*[TRIG] of the DMA channel.
3. Ensure that the DMA channel is properly configured in DMA. You can enable the DMA channel at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG*n*[ENBL] is 1 while CHCFG*n*[TRIG] is 0.

The following is an example. See the chip configuration details for the number of DMA channels on this chip that have triggering capability.

Example: To configure source 5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0h to CHCFG1.
2. Configure channel 1 in DMA, including enabling the channel.
3. Write 85h to CHCFG1.

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);

In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;                              /* Clear all the fields of CHCFG1 register */
*CHCFG1 = 0x85;                              /* ENBL = 1  DMA Channel is enabled */
                                             /* TRIG = 0  Triggering is disabled */
                                             /* SOURCE = 5  DMA Source 5 is selected */
```

**Code Listing 2. Configuring source 5 with DMA channel 1 (without periodic triggering)**

#### 13.4.2.3 Disable a source

You can disable a particular DMA source by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configurations may be necessary. See the "Enhanced Direct Memory Access (eDMA)" chapter for details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Write 0 to CHCFG*n*[ENBL] and CHCFG*n*[TRIG] of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG*n*[ENBL] and CHCFG*n*[TRIG] are 1.

Example: To switch DMA channel 8 from source 5 transmit to source 7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 does not have the triggering capability.
2. Write 0h to CHCFG8.
3. Write 87h to CHCFG8. (In this example, writing 1 to CHCFG[TRIG] has no effect because of the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);

In File main.c:
#include "registers.h"
:
:
*CHCFG8 = 0x00;                              /* Clear all the fields of CHCFG1 register */
*CHCFG8 = 0x87;                              /* ENBL = 1  DMA Channel is enabled */
                                             /* TRIG = 0  Triggering is disabled */
                                             /* SOURCE = 7  DMA Source 7 is selected */
```

**Code Listing 3. Switching DMA channel 8 from source 5 transmit to source 7 transmit**

## 13.5 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in DMAMUX.

### 13.5.1 DMAMUX register descriptions

#### 13.5.1.1 DMAMUX memory map

DMAMUX_0 base address: 4028_0000h

DMAMUX_1 base address: 4028_4000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Channel Configuration (CHCFG3) | 8 | RW | 00h |

*Table continues on the next page...*

*Table continued from the previous page...*

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 1h | Channel Configuration (CHCFG2) | 8 | RW | 00h |
| 2h | Channel Configuration (CHCFG1) | 8 | RW | 00h |
| 3h | Channel Configuration (CHCFG0) | 8 | RW | 00h |
| 4h | Channel Configuration (CHCFG7) | 8 | RW | 00h |
| 5h | Channel Configuration (CHCFG6) | 8 | RW | 00h |
| 6h | Channel Configuration (CHCFG5) | 8 | RW | 00h |
| 7h | Channel Configuration (CHCFG4) | 8 | RW | 00h |
| 8h | Channel Configuration (CHCFG11) | 8 | RW | 00h |
| 9h | Channel Configuration (CHCFG10) | 8 | RW | 00h |
| Ah | Channel Configuration (CHCFG9) | 8 | RW | 00h |
| Bh | Channel Configuration (CHCFG8) | 8 | RW | 00h |
| Ch | Channel Configuration (CHCFG15) | 8 | RW | 00h |
| Dh | Channel Configuration (CHCFG14) | 8 | RW | 00h |
| Eh | Channel Configuration (CHCFG13) | 8 | RW | 00h |
| Fh | Channel Configuration (CHCFG12) | 8 | RW | 00h |

### 13.5.1.2 Channel Configuration (CHCFG0 - CHCFG15)

#### Offset

For n = 0 to 15:

| Register | Offset |
|---|---|
| CHCFGn | 0h + (n + 3 - 2 × (n mod 4)) |

#### Function

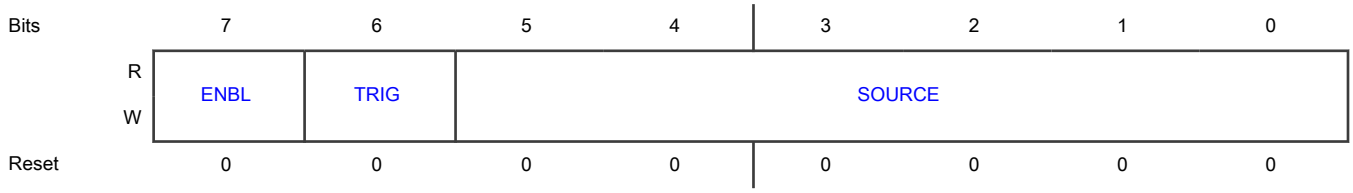
Provides you with the configuration to enable or disable, and to associate each of the DMA channels with one of the DMA slots (peripheral slots or always-on slots) in the system.

**NOTE**

Writing to multiple CHCFG registers with the same source value results in unpredictable behavior. This is true, even if a channel is disabled (CHCFG*n*[ENBL] == 0).

Before changing the trigger or source settings, you must disable a DMA channel using CHCFG*n*[ENBL].

### Diagram



### Fields

| Field | Function |
|---|---|
| 7<br>ENBL | DMA Channel Enable<br>Enables the DMA channel.<br>The condition when the DMA channel is disabled (ENBL = 0) is called Disabled mode. This mode is primarily used during the configuration of DMAMUX. DMA has separate channel enables or disables, which you must use to disable or reconfigure a DMA channel.<br>0b - Disable<br>1b - Enable |
| 6<br>TRIG | DMA Channel Trigger Enable<br>Enables the periodic triggering capability for the triggered DMA channel.<br>If triggering is disabled and ENBL = 1, the DMA channel routes the specified source to the DMA channel (Normal mode).<br>If triggering is enabled and ENBL = 1, then DMAMUX is in Periodic Trigger mode.<br>0b - Disable<br>1b - Enable |
| 5-0<br>SOURCE | DMA Channel Source (Slot)<br>Specifies which DMA source, if any, is routed to a particular DMA channel. See the chip-specific DMAMUX information for details about peripherals and their slot numbers. |

## 13.6 Glossary

| | |
|---|---|
| **Slot** | DMA source that either reflects a peripheral source or an always-enabled source |
| **Periodic trigger** | Trigger that an external source generates at periodic intervals for DMA transfer |

# Chapter 14
# Enhanced Direct Memory Access (eDMA)

## 14.1 Chip-specific eDMA information

### 14.1.1 DMA channels

See the following table for number of DMA channels across MCXE31 product series.

**Table 42. DMA channels**

| Chip | No. of DMA channels |
|---|---|
| MCXE31B | 32 |
| MCXE315/MCXE316/MCXE317 | 12 |

**NOTE**

TCD_CH[12-31] are not available in MCXE317, so the registers corresponding to these channels are not available in MCXE317 variant. See the memory map file attached to this document for details.

## 14.2 Introduction

The enhanced direct memory access (eDMA) controller is capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 32 channels

### 14.2.1 eDMA system block diagram

Figure 27 illustrates the components of the eDMA system, including the eDMA module (engine).

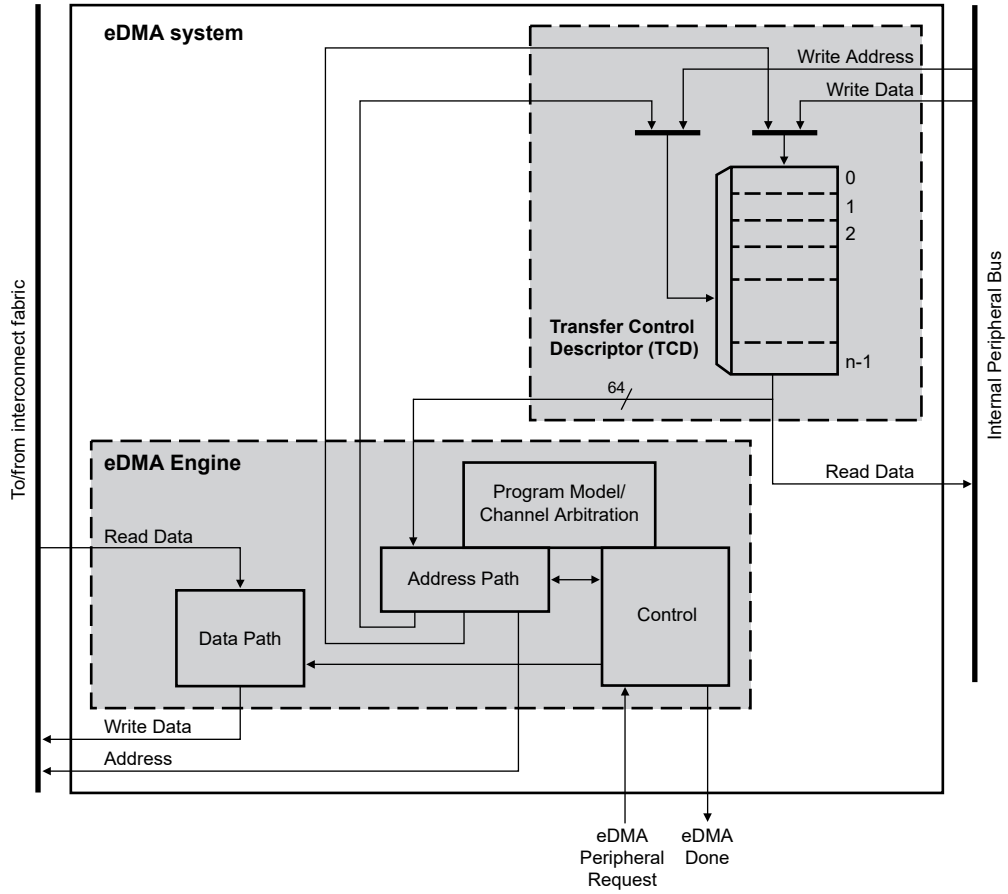


Figure 27. eDMA system block diagram

## 14.2.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 43. eDMA engine submodules

| Submodule | Function |
|---|---|
| Address path | This block:<br>• Implements a primary channel and secondary (preempt) channel<br>• Manages all master bus-address calculations<br>All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the primary channel is active.<br>After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by CH*n*_PRI[ECP]) where a large data transfer can be preempted to minimize the time another channel is blocked from execution. |

*Table continues on the next page...*

Table 43. eDMA engine submodules (continued)

| Submodule | Function |
|---|---|
| | When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of a new TCD*n* from memory as part of a scatter/gather operation. See Dynamic scatter/gather for more details. |
| Data path | This block implements the bus master read/write data path. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output.<br>The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), and the data path module implements the second stage of the pipeline (data phase). |
| Program model/channel arbitration | This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic). |
| Control | This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has been moved from the source to the destination.<br>For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, the eDMA performs two reads, then one 32-bit write. |

The transfer control descriptor local memory is further partitioned into:

Table 44. Transfer control descriptor memory

| Submodule | Description |
|---|---|
| Memory controller | This logic implements the required dual-ported controller, and manages accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled. |
| Memory array | TCD storage for each channel's transfer profile. |

### 14.2.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for complex address calculations
- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage for all transfers

  - Connections to the crossbar switch for bus mastering the data movement
- TCD organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel that are logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module, *n* is used to reference the channel number.

## 14.3 Modes of operation

The eDMA operates in the following modes:

**Table 45. Modes of operation**

| Mode | Description |
|---|---|
| Normal | In Normal mode, eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with eDMA.<br>A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the TCD. The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data. |
| Debug | eDMA operation is configurable in Debug mode via the control register:<br>• If CSR[EDBG] is cleared to 0, eDMA continues to operate.<br>• If CSR[EDBG] is set to 1, eDMA stops transferring data. If Debug mode is entered when a channel is active, eDMA continues operation until the channel retires. |

## 14.4 Functional description

The operation of eDMA is described in the following subsections.

### 14.4.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

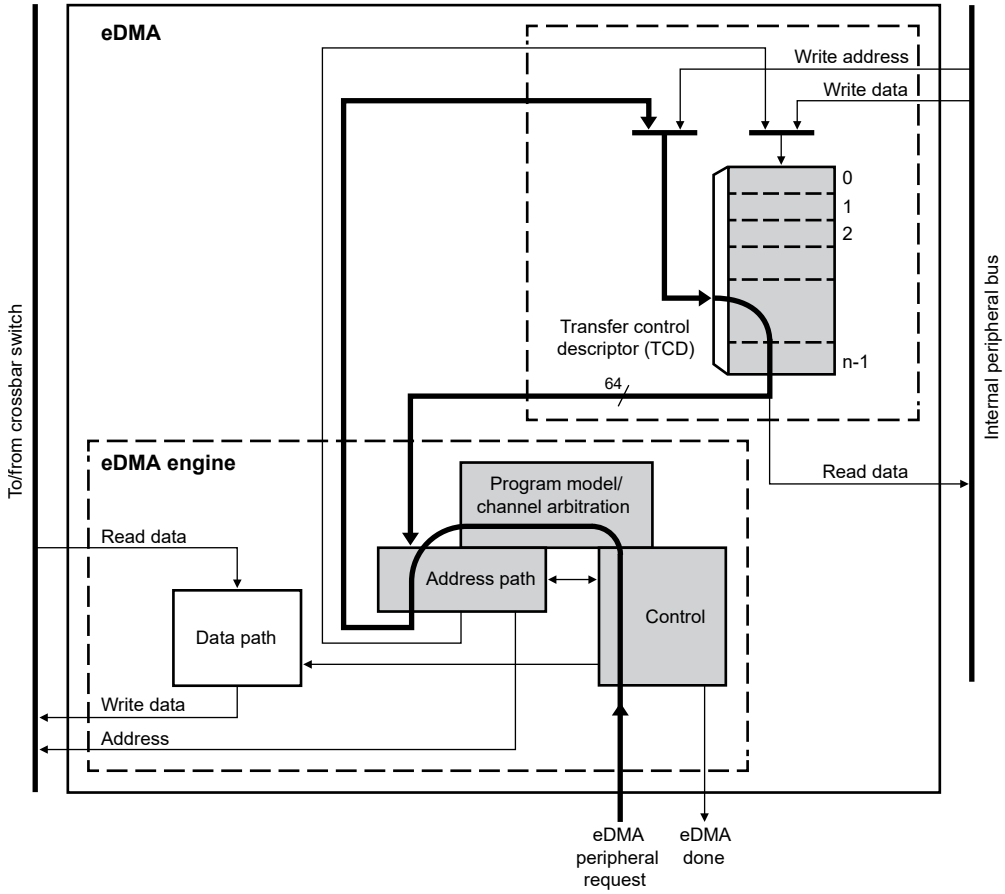

Figure 28. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] field follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration.

In the next cycle, the channel arbitration begins using fixed-priority plus the optional round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor is read from the local memory and then loaded into the eDMA engine address path's primary or secondary channel execution registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path registers.

The following diagram illustrates the second part of the basic data flow:

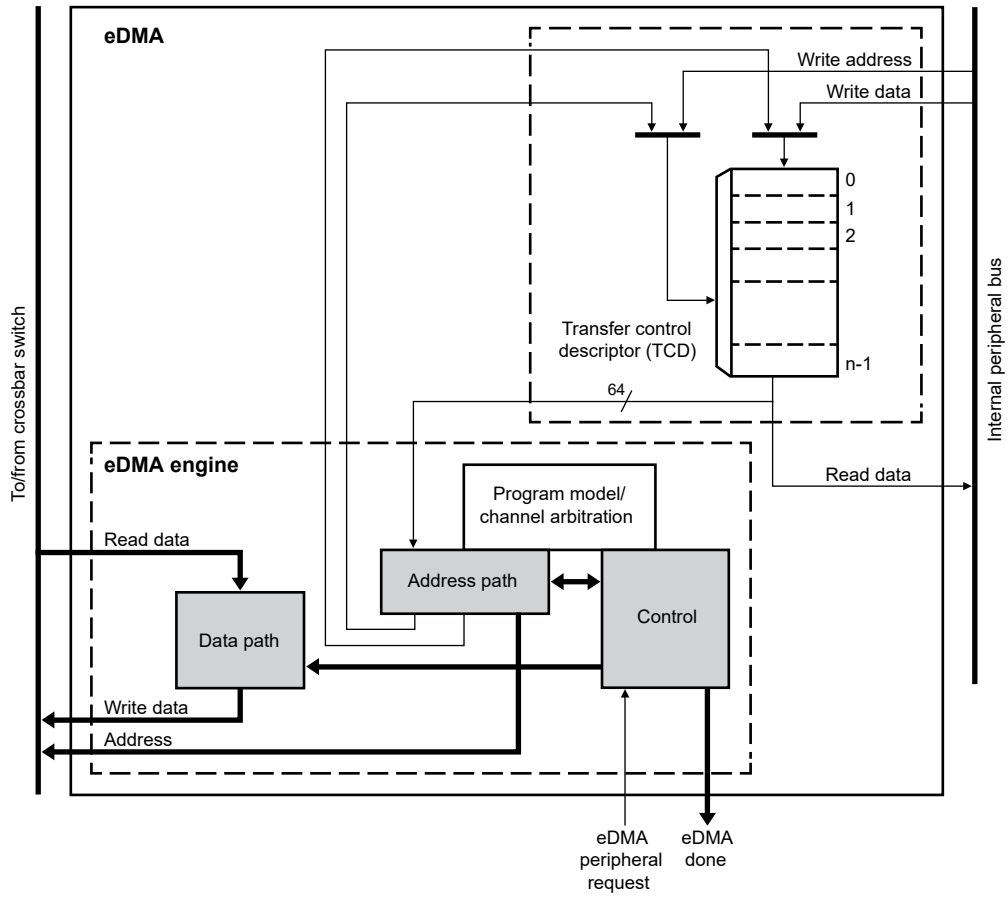

Figure 29. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) go through the required sequence of source reads and destination writes to perform the actual data movement. The source reads are initiated, and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the byte count, NBYTES, has been transferred.

After NBYTES of data has been moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD (for example, SADDR, DADDR, CITER). If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER field. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

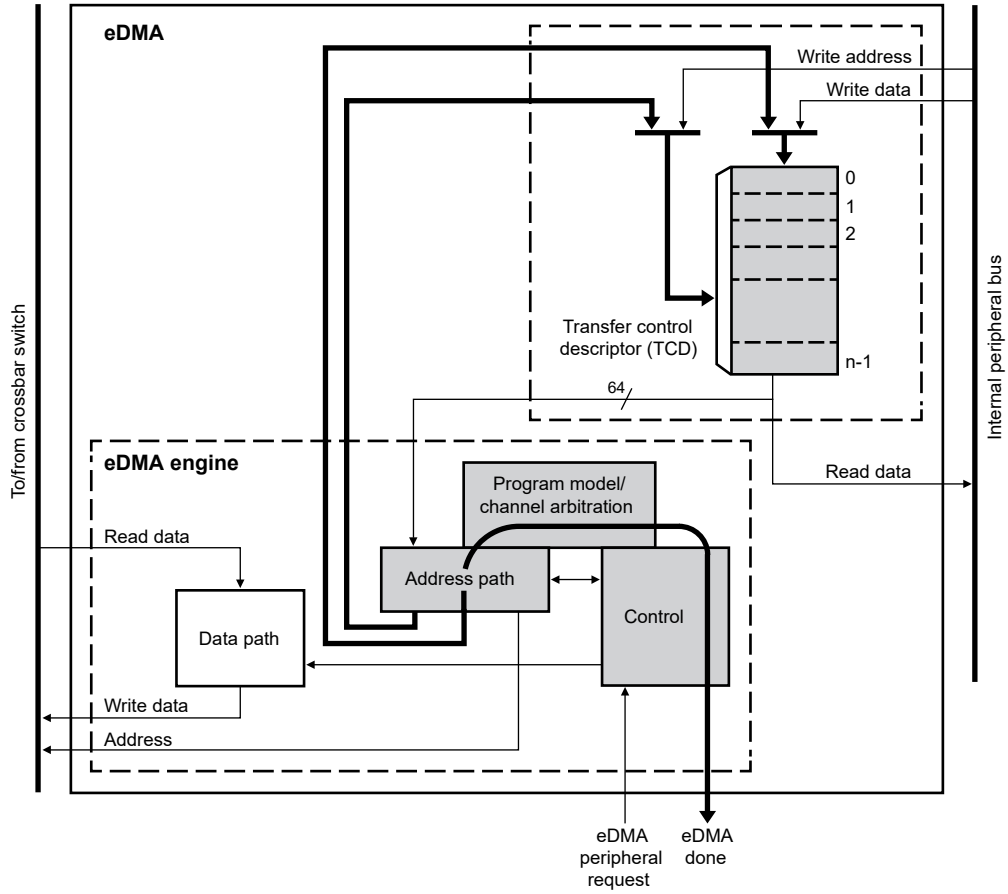

Figure 30. eDMA operation, part 3

## 14.4.2 Fault reporting and handling

Channel errors are reported in the Error Status register (CHn_CSR and TCDn_CSR) and can be caused by any of the following:

- A configuration error, which is an illegal setting in the transfer control descriptor
- An active channel canceled via a "cancel transfer with error" hardware or software request
- A TCD memory error
- An error termination to a bus master read or write cycle

A configuration error is reported when an inconsistent state is represented by one of these factors:

- Starting source or destination address
- Source or destination offsets
- Minor loop byte count
- Transfer size

Each of these possible causes is detailed below:

- The addresses and offsets must be aligned on zero-modulo-transfer-sized boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size.

**NOTE**

To aid in debugging, set the Halt After Error field in the DMA's Control Status register, CSR[HAE]. Upon any error condition, the DMA is halted after the error is recorded. The DMA remains halted and does not process any channel service requests. After the error is fixed, the DMA may be enabled again by clearing the Halt field, CSR[HALT].

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[ELINK] field does not equal the TCDn_BITER[ELINK] field.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, are reported as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion if properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel field in the eDMA error register is set to 1. At the same time, the details of the error condition are loaded into the Error Status register (CHn_CSR and TCDn_CSR). The major loop complete indicators, setting the transfer control descriptor DONE flag, and the possible assertion of an interrupt request are not affected when an error is detected.

After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

The error status fields are read-only. These error indicators are sticky and cannot be cleared. They show the last recorded error until the DMA is reset. The valid field (VLD) is used to determine if a new error condition exists. This field is the logical OR of each channel's error interrupt field (ERR).

After the software has resolved any errors and cleared all of the error interrupt fields, the valid field is cleared to 0 but the cause of the last error is still indicated.

### 14.4.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the CHn_PRI[ECP] field. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher-priority channel. After the preempting channel has completed all of its minor loop data transfers, the preempted channel is restored and resumes execution.

After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended, and the higher-priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted.

A channel's ability to preempt another channel can be disabled by setting CHn_PRI[DPA] to 1. When a channel's preempt ability is disabled, that channel cannot suspend a lower-priority channel's data transfer, regardless of the lower-priority channel's ECP setting. This allows for a pool of low-priority, large-data-moving channels to be defined.

You can configure these low-priority channels to not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true high-priority channel. When you enable round-robin channel arbitration mode (CSR[ERCA] is set to 1), any channel with a priority level equal to 0 (CHn_PRI[APL] = 0) has preemption disabled and cannot preempt another channel.

## 14.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

### 14.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the CSR if a configuration other than the default is wanted.
2. Write the channel priority levels to the CHn_PRI registers and group priority levels to the CHn_GRPRI registers if a configuration other than the default is wanted.
3. Enable error interrupts in the CHn_CSR[EEI] registers if they are wanted.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the CHn_CSR[ERQ] registers.
6. Request channel service via either:
   - Software: setting TCDn_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in Table 46, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, defined by TCDn_SADDR, to the destination, defined by TCD_DADDR, continue until the number of bytes specified by TCDn_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCDn_SADDR, TCDn_DADDR, and TCDn_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, then eDMA executes further post-processing, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

**Table 46. TCD control and status (TCDn_CSR) fields**

| TCDn_CSR field name | Description |
|---|---|
| START | Control field to start the channel explicitly when using a software-initiated DMA service (automatically cleared by hardware) |
| EEOP | Control field to enable end-of-packet processing |
| ESDA | Control field to enable storing of the destination address to system memory after the major loop completes |
| DREQ | Control field to disable hardware-initiated DMA service requests after major loop completion |
| BWC | Control field for throttling the bandwidth control of a channel |
| ESG | Control field to enable the scatter-gather feature |
| INTHALF | Control field to enable interrupt when major loop is half-complete |
| INTMAJOR | Control field to enable interrupt when major loop completes |

**Table 47. Channel control and status (CHn_CSR) fields**

| CHn_CSR field name | Description |
|---|---|
| ACTIVE | Status field indicating the channel is currently in execution |
| DONE | Status field indicating major loop completion (cleared by software when a channel begins execution) |
| EEI | Control field to enable error interrupts |

*Table continues on the next page...*

Table 47. Channel control and status (CHn_CSR) fields (continued)

| CHn_CSR field name | Description |
|---|---|
| EARQ | Control field to enable external, asynchronous wakeup event in conjunction with the ERQ field |
| ERQ | Control field to enable hardware service requests |

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

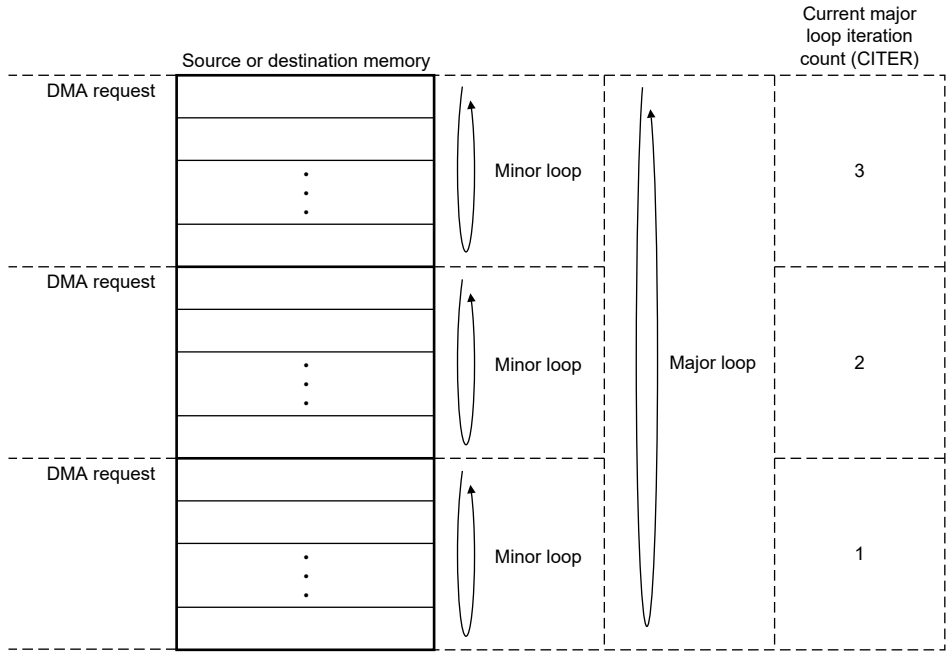

Figure 31. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings are related.

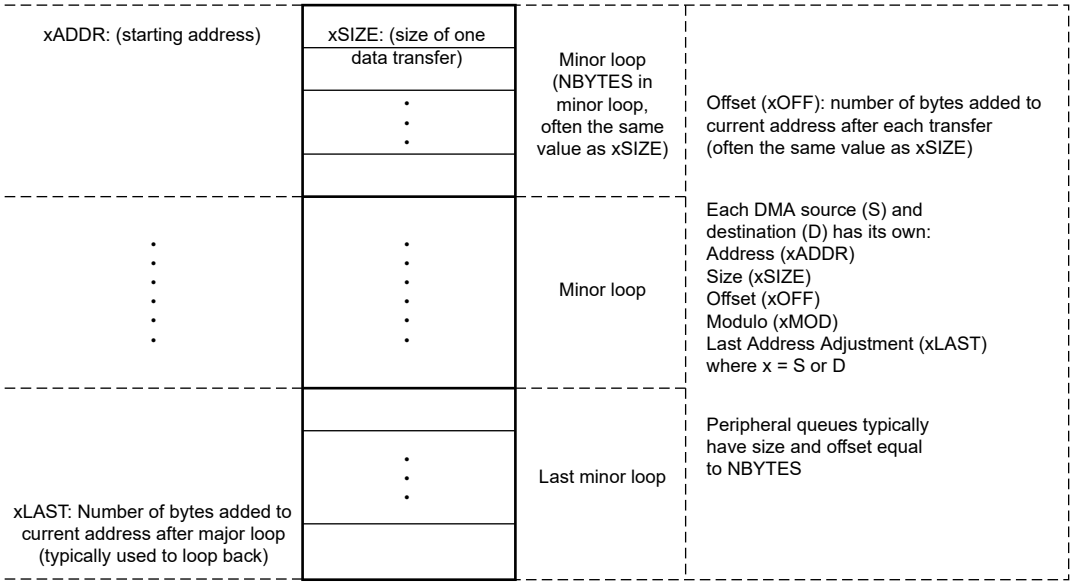

**Figure 32. Memory array terms**

## 14.5.2 eDMA arbitration

The eDMA uses a layered arbitration scheme composed of multiple priority levels. The eDMA uses a fixed-priority arbitration scheme with optional round-robin arbitration under specific conditions. The priorities are evaluated in the following order:

**Table 48. eDMA arbitration priorities**

| Priority | Scheme | Description |
|---|---|---|
| 1 (Highest) | Arbitration group priority | Each channel is assigned an arbitration group via the CHn_GRPRI registers. Priority is given to the highest value (31 being the highest possible value) down to the lowest value (zero, the default). |
| 2 | Channel priority | Each channel is assigned a channel priority level via the CHn_PRI registers. The channel priority is a relative priority level within an arbitration group. Priority is given to the highest value (seven being the highest possible value) down to the lowest value (zero, the default). Channel priorities within each arbitration group need not be unique. If multiple channels have the same channel priority level, the channel number will be used to determine priority as defined in row three. |
| 3 | Channel number | When two or more channels have the same arbitration group priority and channel priority, the channel number (CHn_NUM) is used to determine the highest priority. Priority is giver to the |

*Table continues on the next page...*

Table 48. eDMA arbitration priorities (continued)

| Priority | Scheme | Description |
|---|---|---|
| | | highest channel number. Lowest priority is channel 0. The channel numbers are static and cannot be changed in the programmer's model. |
| 4 (Lowest) | Round-robin | When round-robin is enabled, any channel configured for round-robin operation has lowest priority within an arbitration group. Round-robin is enabled by setting the CSR[ERCA] field to 1. After being enabled, channels with a channel priority of zero (CHn_PRI=0) will use round-robin arbitration. Round-robin arbitration will rotate the channel selection among the channels requesting service with CHn_PRI=0 within the arbitration group. Any non-zero channel within the arbitration group will continue to use fixed-priority arbitration, and if requesting service will be selected over any round-robin channels. |

For fixed arbitration, the overall priority can be considered a number composed of three concatenated priority levels: CHn_GRPRI:CHn_PRI:CH_NUM. The largest number has the highest priority and the lowest number has the lowest priority.

For round-robin arbitration, the priority number is CHn_GRPRI:0:X. The module rotates through the CHn_PRI=0 channels requesting service without regard to priority among these channels. Any channel within the arbitration group for which CHn_PRI is greater than 0 will be serviced before the round-robin channels.

### 14.5.3 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data.

The channel number causing the error is recorded in the Error Status register (CHn_CSR and TCDn_CSR). If the error source is not removed before the next activation of the problematic channel, the error is detected and recorded again. Setting the halt after error field, CSR[HAE], will halt the DMA and prevent reoccurrence of the error.

### 14.5.4 Arbitration mode considerations

This section discusses arbitration considerations for eDMA.

#### 14.5.4.1 Fixed group arbitration, fixed channel arbitration

In this mode, eDMA selects for execution the channel service request from the highest-priority channel in the highest-priority group. If eDMA is programmed so that the channels within a high-priority group have a high number of requests or large data transfers, that group may consume all the bandwidth of the eDMA controller. That is, no lower-priority groups are serviced if there is always at least one DMA request pending on a channel in the highest-priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly.

#### 14.5.4.2 Fixed group arbitration, round-robin channel arbitration

The highest-priority group with a request is serviced. Lower-priority groups are serviced if no pending requests exist in the higher-priority groups.

Within each group, channels are serviced starting with the highest non-zero channel priority. For all channels with a channel priority programmed to 0, selection begins with the highest channel number requesting service and then rotates through to the lowest channel number requesting service. The round-robin channel arbitration can provide a fairness mechanism to lower-priority channels.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, fixed channel arbitration, but all the channels in the highest-priority group will be serviced. Service latency is short on the highest-priority group, but could potentially be very much longer as the group priority decreases.

## 14.5.5 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

### 14.5.5.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the CH*n*_CSR[DONE] field is set to 1 and an interrupt is generated if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte-wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source, and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INTMAJ] = 1
TCDn_CSR[START] = 1 (should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] field requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes:
   - CH*n*_CSR[DONE] = 0
   - TCD*n*_CSR[START] = 0
   - CH*n*_CSR[ACTIVE] = 1
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.

e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.

f. Write 32 bits to location 0x2008 → third iteration of the minor loop.

g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.

h. Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.

6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

#### 14.5.5.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop, transferring 16 bytes per iteration. After the channel's hardware requests are enabled via the CHn_CSR[ERQ] register field, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32 bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0.
8. The channel retires, which concludes one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware (eDMA peripheral) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: Channel TCD data from local memory to internal register file.
13. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.

b. Write 32 bits to location 0x2010 → first iteration of the minor loop.

c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.

d. Write 32 bits to location 0x2014 → second iteration of the minor loop.

e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.

f. Write 32 bits to location 0x2018 → third iteration of the minor loop.

g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.

h. Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.

14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).
15. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
16. The channel retires, which concludes with the major loop complete. The eDMA goes idle or services the next channel.

#### 14.5.5.3 Using the modulo feature

The modulo feature of the eDMA allows implementation of a circular data queue in which the size of the queue is a power of 2. xMOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature. Modulo addressing applies to cases where the minor loop offset is enabled; that is, the upper address bits remain the same after the minor loop offset is added to the source or destination address.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value but the 28 upper address bits (0x1234567*x*) retain their original value. In this example, the source address is set to 0x12345670, the offset is set to four bytes, and the MOD field is set to four, which allows for a $2^4$ byte (16 byte) queue size.

Table 49. Modulo example

| Transfer number | Address |
|---|---|
| 1 | 0x12345670 |
| 2 | 0x12345674 |
| 3 | 0x12345678 |
| 4 | 0x1234567C |
| 5 | 0x12345670 |
| 6 | 0x12345674 |

### 14.5.6 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

#### 14.5.6.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software-initiated service requests.

1. The first method is to read the TCDn_CITER field and test for a change.
2. The second method, extracted from the sequence shown below, is to test the TCDn_CSR[START] field and the CHn_CSR[ACTIVE] field. The minor-loop-complete condition is indicated by both fields reading 0 after TCDn_CSR[START] is set to 1. Polling the CHn_CSR[ACTIVE] field only may be inconclusive because the active status may be missed if the channel execution is short in duration.

The CHn_CSR and TCDn_CSR status fields execute the following sequence for a software-activated channel:

| Stage | TCDn_CSR field | CHn_CSR fields | | State |
|---|---|---|---|---|
| | START | ACTIVE | DONE | |
| 1 | 1 | 0 | 0 | Initiate channel service request via software. |
| 2 | 0 | 1 | 0 | Channel is executing. |
| 3a | 0 | 0 | 0 | Channel has completed the minor loop and is idle. |
| 3b | 0 | 0 | 1 | Channel has completed the major loop and is idle. |

The best method to test for minor-loop completion when using hardware-initiated (that is, peripheral-initiated) service requests is to read the TCDn_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status fields execute the following sequence for a hardware-activated channel:

| Stage | TCDn_CSR field | CHn_CSR fields | | State |
|---|---|---|---|---|
| | START | ACTIVE | DONE | |
| 1 | 0 | 0 | 0 | Initiate channel service request via hardware (peripheral request asserted). |
| 2 | 0 | 1 | 0 | Channel is executing. |
| 3a | 0 | 0 | 0 | Channel has completed the minor loop and is idle. |
| 3b | 0 | 0 | 1 | Channel has completed the major loop and is idle. |

For both activation types, the major-loop-complete status is explicitly indicated via the CHn_CSR[DONE] field.

The TCDn_CSR[START] field is cleared to 0 automatically when the channel begins execution, regardless of how the channel activates.

#### 14.5.6.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCDn_SADDR, TCDn_DADDR, and TCDn_NBYTES values if they are read when a channel executes. The true values of SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file, and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES (which decrements to zero as the transfer progresses), can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

#### 14.5.6.3 Checking channel preemption status

A preemptive situation is one in which a preempt-enabled channel is executing and a higher-priority request becomes active. When round-robin channel arbitration mode is enabled, all channels with their channel priority set to 0 lose their preempt ability. Channel priorities of 0 are treated as equal, that is, they are constantly rotating, when round-robin arbitration mode is enabled.

The CHn_CSR[ACTIVE] field for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended when the preempting channel executes one major loop iteration. If two CHn_CSR[ACTIVE] fields are set simultaneously in the global TCD map, a higher-priority channel is actively preempting a lower-priority channel.

### 14.5.7 Channel linking

Channel linking (or chaining) is a mechanism in which one channel sets the TCDn_CSR[START] field of another channel (or itself), thus initiating a service request for that channel. When properly enabled, the eDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCDn_CITER[ELINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, using an initial field setting of:

```
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJORELINK] = 1
TCDn_CSR[MAJORLINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] field
2. Minor loop done → set TCD12_CSR[START] field
3. Minor loop done → set TCD12_CSR[START] field
4. Minor loop done, major loop done→ set TCD7_CSR[START] field

When minor loop linking is enabled (TCDn_CITER[ELINK] = 1), the TCDn_CITER[CITER] field uses a nine-bit vector to form the current iteration count. When minor loop linking is disabled (TCDn_CITER[ELINK] = 0), the TCDn_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCDn_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

**NOTE**

The TCDn_CITER[ELINK] field and the TCDn_BITER[ELINK] field must be equal — if they are not, a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop halfway done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, that is, use another channel's TCD, at the end of a loop.

**Table 50. Channel linking parameters**

| Wanted link behavior | TCD control field name | Description |
|---|---|---|
| Link at end of minor loop | TCDn_CITER[ELINK] | Enable channel-to-channel linking on minor loop completion (current iteration) |
| | TCDn_CITER[LINKCH] | Link channel number when linking at end of minor loop (current iteration) |
| Link at end of major loop | TCDn_CSR[MAJORELINK] | Enable channel-to-channel linking on major loop completion |
| | TCDn_CSR[MAJORLINKCH] | Link channel number when linking at end of major loop |

### 14.5.8 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

#### 14.5.8.1 Dynamically changing the channel priority

To change group or channel priority levels:

1. Halt the DMA by writing 1 to the CSR[HALT] field.
2. Change the group or channel priorities as wanted.
3. Enable normal DMA operations by writing 0 to the CSR[HALT] field.

#### 14.5.8.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCDn_CSR[MAJORELINK] field during channel execution (see the diagram in TCD structure). This field is read from the TCD local memory at the end of channel execution, thus allowing you to enable the feature during channel execution.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic channel link by enabling the TCDn_CSR[MAJORELINK] field at the same time the eDMA engine is retiring the channel. TCDn_CSR[MAJORELINK] would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

We recommend that you use the following coherency model when executing a dynamic channel link request.

1. Write 1 to the TCDn_CSR[MAJORELINK] field.
2. Read back the TCDn_CSR[MAJORELINK] field.
3. Test the TCDn_CSR[MAJORELINK] request status:
   - If TCDn_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
   - If TCDn_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCDn_CSR[MAJORELINK] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field is set to 1, indicating the major loop is complete.

**NOTE**

You must clear the CHn_CSR[DONE] field to 0 before writing to the TCDn_CSR[MAJORELINK] field. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution.

#### 14.5.8.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in the eDMA programmer's model, thus replacing the current descriptor.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic scatter/gather operation by enabling the TCDn_CSR[ESG] field at the same time the eDMA engine is retiring the channel. The TCDn_CSR[ESG] field would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods are recommended for executing a dynamic scatter/gather request. Whenever the TCDn_CSR is written, the TCD local memory controller forces the TCDn_CSR[ESG] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field has been set to 1, indicating the major loop is complete. If attempting to set the ESG, ensure the DONE field is cleared to 0.

**NOTE**

You must clear the CHn_CSR[DONE] field to 0 before writing the TCDn_CSR[MAJORELINK] or TCDn_CSR[ESG] fields. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution and is set to 1 upon major loop completion.

#### 14.5.8.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCDn_CSR[MAJORELINK] field is 0, the TCDn_CSR[MAJORLINKCH] field is not used by the eDMA. In this case, the TCDn_CSR[MAJORLINKCH] bits may be used for other purposes. This method uses the TCDn_CSR[MAJORLINKCH] field as a TCDn_CSR identification (ID).

When the descriptors are built, write a unique TCDn_CSR ID in the TCDn_CSR[MAJORLINKCH] field for each TCDn_CSR associated with a channel using dynamic scatter/gather.

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the TCDn_CSR[DREQ] field to 1 will prevent future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the 16-bit TCDn_CSR control/status field.
5. Test the TCDn_CSR[ESG] request status and TCDn_CSR[MAJORLINKCH] value:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0 and the MAJORLINKCH (ID) did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the MAJORLINKCH (ID) changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

#### 14.5.8.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCDn_DLAST_SGA field as a TCD identification (ID).

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the DREQ field to 1 will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the TCDn_CSR[ESG] field.
5. Test the TCDn_CSR[ESG] request status:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0, read the 32-bit TCDn_DLAST_SGA field.
   - If ESG = 0 and the TCDn_DLAST_SGA did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the TCDn_DLAST_SGA changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

### 14.5.9 Suspend/resume a DMA channel with active hardware service requests

The DMA allows you to move data from memory or peripheral registers to another location in memory or to peripheral registers without CPU interaction. After the DMA and peripherals are configured and active, it is rare but supported to suspend a peripheral's service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For

coherency, you must follow a specific procedure. This section provides guidance on how to coherently suspend and resume a Direct Memory Access (DMA) channel when the DMA is triggered by a slave module such as the Serial Peripheral Interface (DSPI), Sigma Delta Analog to Digital Convertor (SDADC), or other module.

#### 14.5.9.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check the DMA's Hardware Request Status (HRS) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ field to 0 on the appropriate DMA channel.

For example, assume the DSPI is set as a master for transmitting data via a DMA service request when the TXFIFO has an empty slot. The DMA will transfer the next command and data to the TXFIFO upon the request. If you need to suspend the DMA/DSPI transfer loop, perform the following steps:

1. Disable the DMA service request at the source by writing 0 to DSPI_RSER[TFFF_RE]. Confirm that DSPI_RSER[TFFF_RE] is 0.
2. Ensure there is no DMA service request from the DSPI by verifying that HRS[HRS] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ field to 0. If a service request is present, wait until the request has been processed and the HRS field reads 0.

#### 14.5.9.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting its ERQ field to 1.
2. Enable the DMA service request at the peripheral.

## 14.6 Memory map/register definition

The eDMA programming model is partitioned into three parts:

1. The first part defines a number of registers providing overall control functions and is known as the management page.
2. The second part corresponds to the channel (CH) control, status, and configuration.
3. The third part corresponds to the local TCD memory.

#### TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the data movement operation. Each TCDn definition is presented as 11 registers of 16 or 32 bits.

#### TCD initialization

The TCD memory is in an unknown state after reset. Only the TCD START bit is initialized to 0. Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

TCD structure

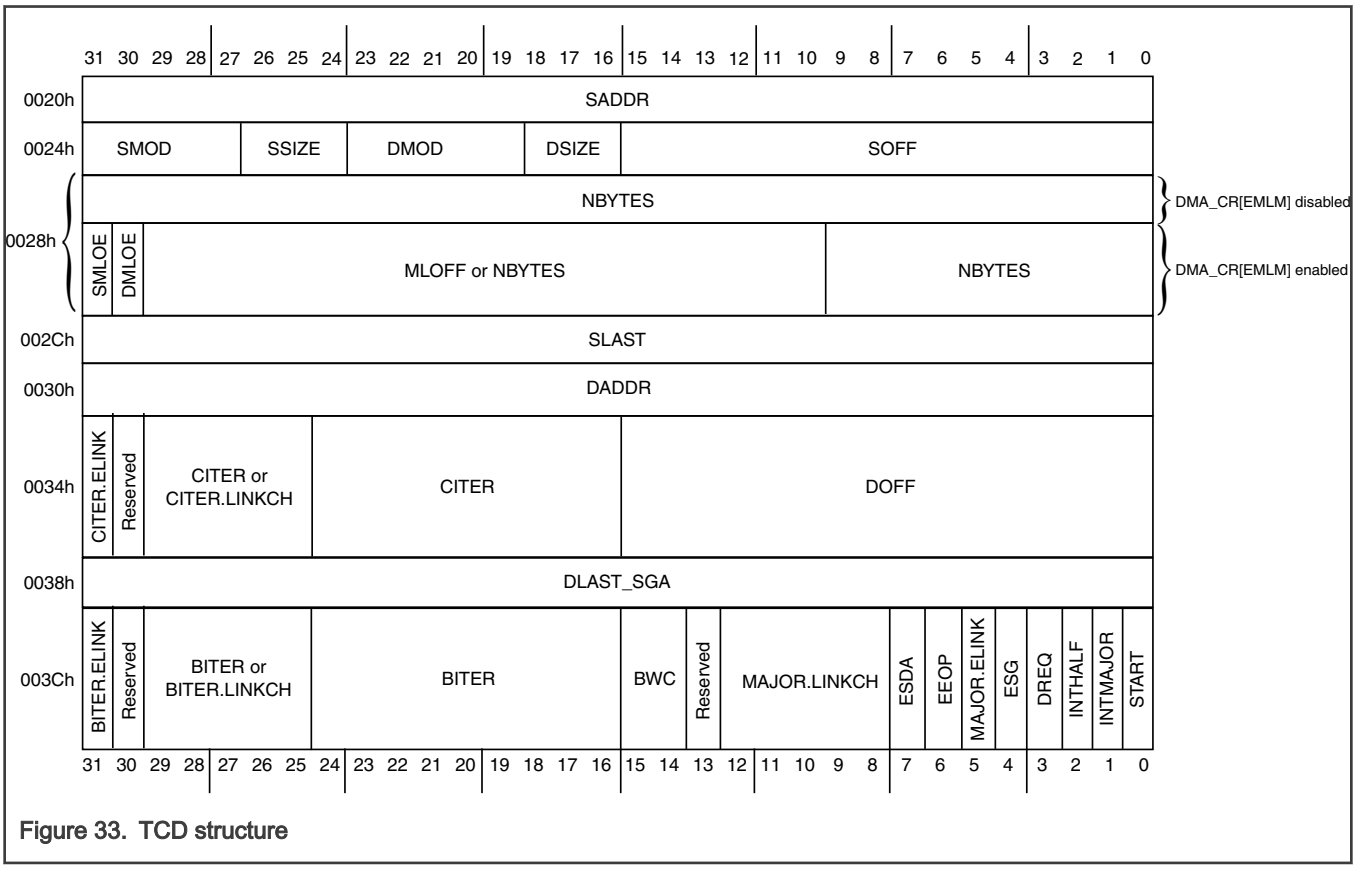

Figure 33. TCD structure

Accesses to reserved memory and fields

- Reading reserved fields in a register returns the value of zero.
- Writes to reserved fields in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

## 14.6.1 eDMA register descriptions

### 14.6.1.1 eDMA memory map

eDMA base address: 4020_C000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Management Page Control (CSR) | 32 | RW | 0030_0000h |
| 4h | Management Page Error Status (ES) | 32 | R | 0000_0000h |
| 8h | Management Page Interrupt Request Status (INT) | 32 | R | 0000_0000h |
| Ch | Management Page Hardware Request Status (HRS) | 32 | R | 0000_0000h |
| 100h - 17Ch | Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI) | 32 | RW | 0000_0000h |

### 14.6.1.2 Management Page Control (CSR)

#### Offset

| Register | Offset |
|---|---|
| CSR | 0h |

#### Function

The Management Page Control register defines the basic operating configuration of the DMA.

Arbitration uses a two-tier priority system; group and channel priority. The eDMA assigns each channel to a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed priority and may be configured to use a selective round-robin scheme for specified channels within each priority group. For fixed-priority arbitration, eDMA selects for execution the highest priority channel requesting service in the highest priority arbitration group.

The channel priority registers assign the relative priorities within each arbitration group; see CHn_PRI. All channels with a non-zero CHn_PRI value use fixed-priority arbitration.

When you enable round-robin arbitration, all channels with channel priority set to zero do not have a priority and, of those channels requesting service, are cycled through (from high to low channel number) without regard to priority relative to each other within the same priority group. Any channel with a non-zero CHn_PRI value automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI).

**NOTE**

For correct operation, changes to the CSR[ERCA, GCLC, GMRC] fields must be performed when the DMA channels are inactive; that is, when the CSR[ACTIVE] field is 0.

DMA resumes channel execution when the system exits debug mode or clears the EDBG field to 0.<br>0b - Debug mode disabled. When in debug mode, the DMA continues to operate<br>1b - Debug mode is enabled. When in debug mode, the DMA stalls the start of a new channel |
| 0<br>— | Reserved |

#### 14.6.1.3 Management Page Error Status (ES)

**Offset**

| Register | Offset |
|---|---|
| ES | 4h |

**Function**

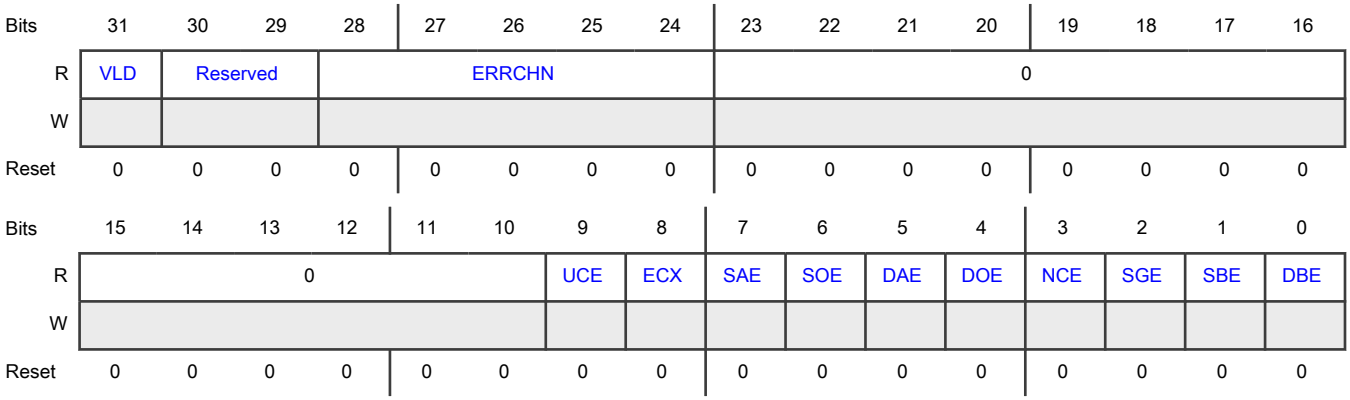
The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus master read or write cycle

- An uncorrectable error that occurred when the device was accessing the TCD SRAM
- A "cancel transfer with error" request was made via the corresponding cancel transfer field or input signal

Upon any error condition, the software must initialize the TCD of the channel that contains the error, as it is in an incomplete state after an error. See Fault reporting and handling for more details.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>VLD | Valid<br>Logical OR of all ERR status fields.<br>0b - No ERR fields are set to 1<br>1b - At least one ERR field is set to 1, indicating a valid error exists that software has not cleared |
| 30-29<br>— | Reserved |
| 28-24<br>ERRCHN | Error Channel Number or Canceled Channel Number<br>The channel number of the last recorded error or last recorded error-canceled transfer. |
| 23-10<br>— | Reserved |
| 9<br>UCE | Uncorrectable TCD Error During Channel Execution<br>UCE is set to 1 only when an uncorrectable ECC error occurs on an access generated by the DMA. If a CPU access to the TCD causes an uncorrectable ECC error, then that access receives a bus error response.<br>**NOTE**<br>When the eDMA sees a RAM error on an IPS access (when you are accessing a TCD), it reports the error as a bus abort. When the DMA engine receives a RAM error (the execution engine is accessing a TCD) it is recorded in the Error Status register, ES[UCE], along with the channel number. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 0b - No uncorrectable ECC error<br>1b - Last recorded error was an uncorrectable TCD RAM error |
| 8<br>ECX | Transfer Canceled<br>The ECX operation is a management page function. When employed, the targeted channel's CHn_ES register reports an unspecified error; that is, only the ERR field is set to 1. The management page has full view of the error condition.<br>0b - No canceled transfers<br>1b - Last recorded entry was a canceled transfer by the error cancel transfer input |
| 7<br>SAE | Source Address Error<br>When this field is 1, it indicates that TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].<br>0b - No source address configuration error<br>1b - Last recorded error was a configuration error detected in the TCDn_SADDR field |
| 6<br>SOE | Source Offset Error<br>When this field is 1, it indicates that TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE].<br>0b - No source offset configuration error<br>1b - Last recorded error was a configuration error detected in the TCDn_SOFF field |
| 5<br>DAE | Destination Address Error<br>When this field is 1, it indicates that TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE].<br>0b - No destination address configuration error<br>1b - Last recorded error was a configuration error detected in the TCDn_DADDR field |
| 4<br>DOE | Destination Offset Error<br>When this field is 1, it indicates that TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE].<br>0b - No destination offset configuration error<br>1b - Last recorded error was a configuration error detected in the TCDn_DOFF field |
| 3<br>NCE | NBYTES/CITER Configuration Error<br>This error indicates that one of the following has occurred:<br>• TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE]<br>• TCDn_CITER[CITER] is equal to zero<br>• TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK]<br>0b - No NBYTES/CITER configuration error<br>1b - The last recorded error was NBYTES equal to zero or a CITER not equal to BITER error. Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields |

*Table continues on the next page...*

| 2<br>SGE | Scatter/Gather Configuration Error<br>When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled.<br>0b - No scatter/gather configuration error<br>1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field |
| 1<br>SBE | Source Bus Error<br>0b - No source bus error<br>1b - Last recorded error was a bus error on a source read |
| 0<br>DBE | Destination Bus Error<br>0b - No destination bus error<br>1b - Last recorded error was a bus error on a destination write |

#### 14.6.1.4 Management Page Interrupt Request Status (INT)

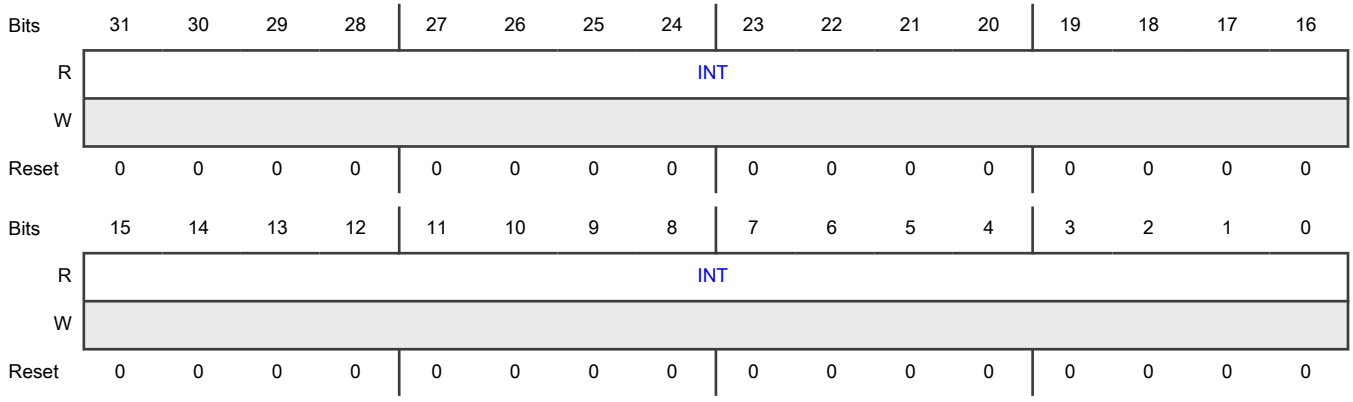
##### Offset

| Register | Offset |
|---|---|
| INT | 8h |

##### Function

This register shows the current state of the interrupt service requests for all eDMA channels.

##### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>INT | Interrupt Request Status<br>The INT register presents the interrupt request status for each eDMA channel. Depending on the appropriate field setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion or an error condition. The eDMA routes channel interrupt requests to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate field in the channel's interrupt request register, CHn_INT, thus negating the interrupt request.<br>0b - Interrupt request for corresponding channel not present<br>1b - Interrupt request for corresponding channel present |

## 14.6.1.5 Management Page Hardware Request Status (HRS)

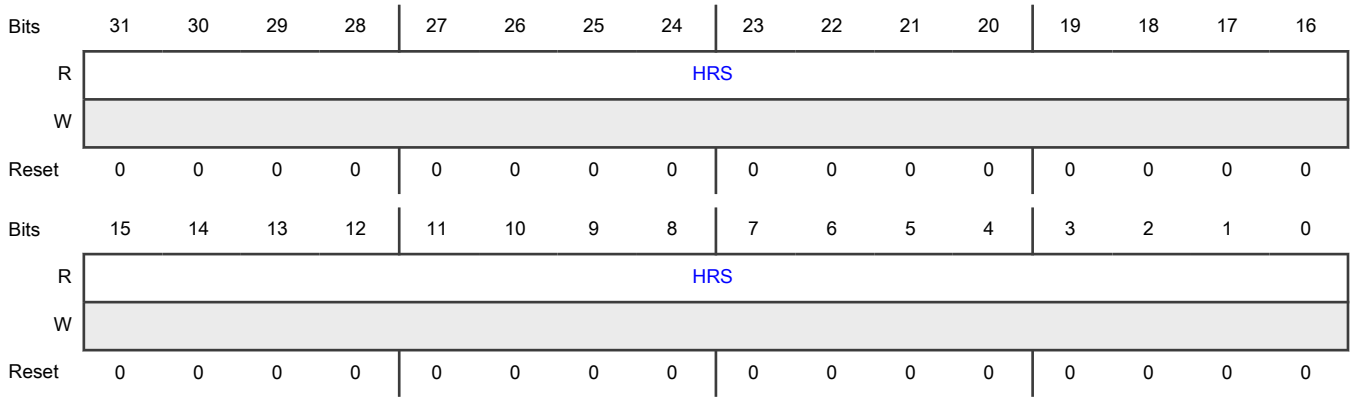
### Offset

| Register | Offset |
|---|---|
| HRS | Ch |

### Function

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by eDMA's arbitration logic.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>HRS | Hardware Request Status |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel. After the request is completed and the channel is free, the hardware automatically clears the corresponding HRS bit to 0.<br>0b - Hardware service request for corresponding channel is not present<br>1b - Hardware service request for corresponding channel is present |

### 14.6.1.6 Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI)

#### Offset

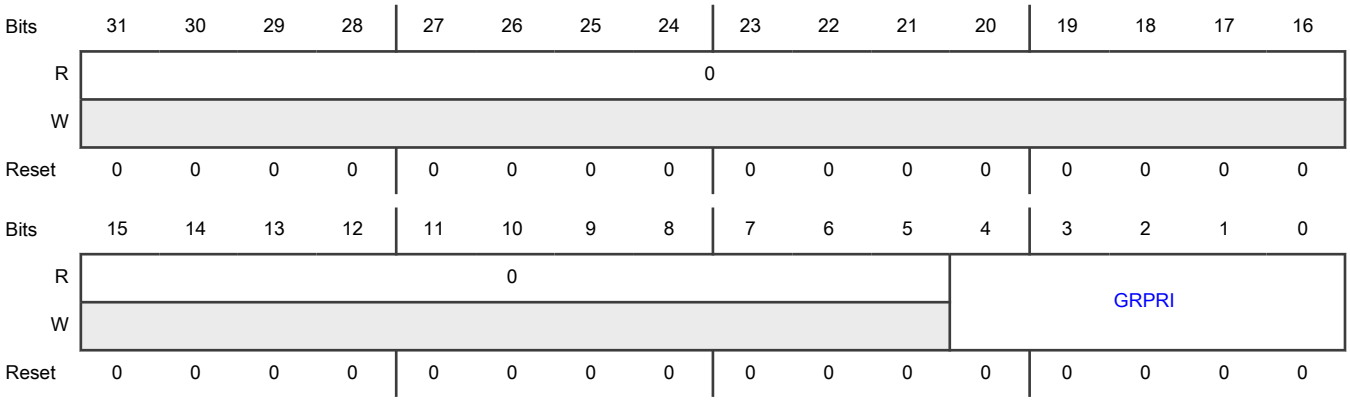
For n = 0 to 31:

| Register | Offset |
|---|---|
| CHn_GRPRI | 100h + (n × 4h) |

#### Function

The contents of this register define the arbitration group associated with each channel. Using a fixed-priority group arbitration scheme, eDMA evaluates the arbitration group priorities by numeric value from highest group number to lowest; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. The range of the group priority values is limited to the values of 0 through 31. Within each arbitration group, the channel priority assignment CH*n*_PRI determines the highest-priority channel.

#### Diagram



#### Fields

| Field | Function |
|---|---|
| 31-5<br>— | Reserved |
| 4-0<br>GRPRI | Arbitration Group For Channel n<br>Fixed-priority arbitration group number. |

## 14.6.2 TCD register descriptions

### 14.6.2.1 TCD memory map

TCD base address: 4021_0000h

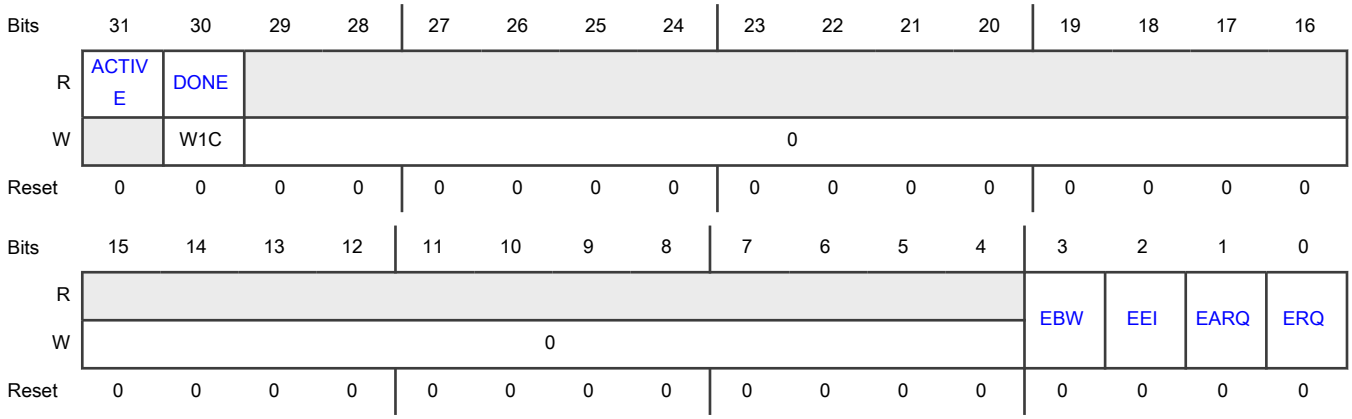
### Function

This register contains several fields related to hardware and interrupt requests, configuration, and status for the given channel.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>ACTIVE | Channel Active<br>The ACTIVE field indicates the channel was selected by arbitration and is executing the prescribed transfers. The eDMA sets it to 1 when channel service begins, and clears it to 0 as the minor loop completes or when any error condition is detected. Except for dynamic scatter/gather or dynamic channel linking, you must not modify the transfer control descriptor when a channel is active. |
| 30<br>DONE | Channel Done<br>The DONE field indicates the eDMA has completed the major loop. The eDMA engine sets this field as the CITER count reaches zero. If enabled, the eDMA generates an interrupt request corresponding to this completed channel. The software clears it, or the hardware clears it when the channel is activated.<br>**NOTE**<br>This field must be cleared to 0 before writing the MAJORELINK or ESG fields. |
| 29-4<br>— | Reserved |
| 3<br>EBW | Enable Buffered Writes<br>When buffered writes are enabled, all writes except for the last write sequence of the minor loop are signaled by the eDMA as bufferable.<br>0b - Buffered writes on system bus disabled. Buffered writes on system bus disabled<br>1b - Buffered writes on system bus enabled. Bufferable write signal asserted on all system bus writes except during last write sequence |
| 2<br>EEI | Enable Error Interrupt<br>The EEI field enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.<br>0b - Error signal for corresponding channel does not generate error interrupt |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 1b - Assertion of error signal for corresponding channel generates error interrupt request |
| 1<br>EARQ | Enable Asynchronous DMA Request In Stop Mode For Channel<br>The enable asynchronous DMA request field (EARQ) does not affect DMA operations. When set to 1, this field allows the hardware service request enable field (ERQ) to propagate out of the DMA to the power controller. When cleared to 0, this field masks the hardware service request enable field to the power controller.<br>0b - Disable asynchronous DMA request for the channel<br>1b - Enable asynchronous DMA request for the channel |
| 0<br>ERQ | Enable DMA Request<br>Disable a channel's hardware service request at the source before clearing the channel's ERQ field. The DMA hardware request input signal and the enable request field (ERQ) must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request field does not affect a channel service request made explicitly through software or channel linking. The state of the ERQ field does not affect the channel's START field.<br>0b - DMA hardware request signal for corresponding channel disabled<br>1b - DMA hardware request signal for corresponding channel enabled |

#### 14.6.2.3 Channel Error Status (CH0_ES - CH31_ES)

| CH31_ES | 24_C004h |

### Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus master read or write cycle

The ERR field signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the CHn_CSR[EEI] field, then logically summed across all channels to form an error interrupt request, which may be routed to the interrupt controller. In addition, this enabled error status is logically OR'd onto the channel done interrupt, CHn_INT[INT], thus forming a done or error interrupt on a per channel basis.

During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when eDMA detects an error. The contents of this ERR register field can also be polled because a non-zero value indicates the presence of a channel error, regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing a 1 to the ERR field clears the channel's error status, and writing a 0 has no effect.

An unspecified error, where only the ERR field is set to 1, indicates that either a transfer was cancelled with an error or else an uncorrectable TCD error occurred. The Management Page Error Status register has full view of the error condition.

See Fault reporting and handling for more details.

| CH31_INT | 24_C008h |

### Function

The INT field signals the presence of an interrupt request for the channel. Depending on the appropriate bit setting in the transfe control descriptors, the eDMA engine generates an interrupt on data transfer completion or an error condition.

The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. On writes to INT, a 1 clears the channel's interrupt request. A zero has no effect on the channel's current interrupt status.

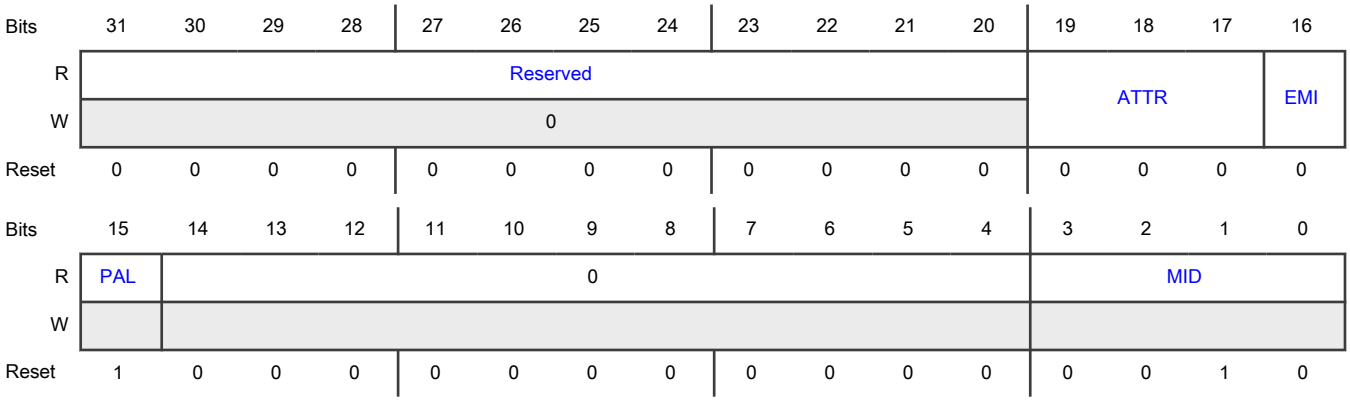
### Function

The Channel System Bus register places identification and attribute information on the system bus interface for the eDMA.

The ATTR register outputs the register values onto the system bus interface for further decoding by the security system.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-20<br>— | Reserved |
| 19-17<br>ATTR | Attribute Output<br>DMA's system bus attribute output value. |
| 16<br>EMI | Enable Master ID Replication<br>The eDMA master ID replication field allows the eDMA to use the same protection level and system bus ID of the master programming the eDMA's TCD. When enabled, the eDMA uses the master ID and protection level stored in the CHn_SBR registers, instead of the eDMA's default values. When a master (for example a core) programs a TCD, its master ID and protection level are captured when the TCD*n*_CSR control attributes are written. A scatter/gather operation does not affect the CHn_SBR registers. You can write the EMI only if CSR[GMRC] = 1, which means Global Master ID Replication Control is enabled; otherwise, the EMI is forced to zero.<br>**NOTE**<br>If master ID replication is disabled, the privileged protection level (Supervisor mode) for DMA transfers is used.<br>0b - Master ID replication is disabled<br>1b - Master ID replication is enabled |
| 15<br>PAL | Privileged Access Level<br>This field controls DMA's protection level on the system bus when the channel is active.<br>**NOTE**<br>When you enable master ID replication, the value captured in this register is the privilege level of the core or other master writing the channel's transfer control descriptor, which is the lower byte of TCD*n*_CSR.<br>0b - User protection level for DMA transfers<br>1b - Privileged protection level for DMA transfers |
| 14-4<br>— | Reserved |
| 3-0<br>MID | Master ID<br>This field controls the DMA's master ID on the system bus when the channel is active.<br>**NOTE**<br>The ID captured in this register reflects the master ID of the core or other master writing the channel's control attributes, which are in the lower byte of TCD*n*_CSR. |

#### 14.6.2.6 Channel Priority (CH0_PRI - CH31_PRI)

**Offset**

| Register | Offset |

*Table continues on the next page...*

*Table continued from the previous page...*

| Register | Offset |
|---|---|
| CH30_PRI | 24_8010h |
| CH31_PRI | 24_C010h |

### Function

The contents of these registers define unique priorities associated with each channel within the same channel group. Channel grouping is programmed via Channel Arbitration Group (CH0_GRPRI - CH31_GRPRI).

The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, channel numbers with the same, non-zero value, will be selected based on channel number with the higher channel number having higher priority.

If more than one channel in a group has an arbitration priority level value of zero, then the arbitration mode field CSR[ERCA] is used to determine the arbitration scheme for all channels with APL=0 within a group.

When you enable round-robin channel arbitration (CSR[ERCA] = 1), all channels with APL=0 within a group will use a round-robin arbitration scheme, which rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group.

When you enable fixed-priority channel arbitration (CSR[ERCA] = 0), eDMA selects channels with APL=0 based on channel number, with the higher channel number having higher priority.

### Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR), or destination address (TCDn_DADDR), upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. When minor loop offsets are enabled, the minor loop offset value (TCDn_NBYTES_MLOFFYES[MLOFF]) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both, prior to the addresses being written back to the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (SMLOE or DMLOE is 1), TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is redefined. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is used to specify multiple fields:

- A source enable bit (SMLOE) to specify the minor loop offset must be applied to the source address (TCDn_SADDR) upon minor loop completion
- A destination enable bit (DMLOE) to specify the minor loop offset must be applied to the destination address (TCDn_DADDR) upon minor loop completion
- The sign extended minor loop offset value (MLOFF)

The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is defined as follows:

- If SMLOE = 0 and DMLOE = 0, then see the TCDn_NBYTES_MLOFFNO register description.
- If either SMLOE or DMLOE is 1, then see the TCDn_NBYTES_MLOFFYES register description.

| TCD31_NBYTES_MLOFFYES | 24_C028h |

### Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offset is an address offset value added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion occurs when the channel has finished the service request and has transferred NBYTES. Minor loop offsets are enabled by setting either the source enable bit (SMLOE) or the destination enable bit (DMLOE).

The source enable bit (SMLOE) specifies the minor loop offset value (MLOFF) that is to be applied to the source address (TCDn_SADDR) upon minor loop completion. The destination enable bit (DMLOE) specifies the minor loop offset (MLOFF) that is to be applied to the destination address (TCDn_DADDR) upon minor loop completion.

If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When you enable the minor loop offset overlay (either SMLOE or DMLOE is 1), eDMA redefines TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES specifies the sign-extended minor loop offset value (MLOFF). The same offset value (MLOFF) applies to both source and destination minor loop offsets. When the minor loop offset is enabled, you must align it to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFNO) defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFYES is defined as follows:

- If either minor loop offset is enabled (SMLOE or DMLOE = 1), then see the TCDn_NBYTES_MLOFFYES register description.
- If SMLOE and DMLOE are both 0, then see the TCDn_NBYTES_MLOFFNO register description.

### Fields

| Field | Function |
|---|---|
| 31-0<br>SLAST_SDA | Last Source Address Adjustment / Store DADDR Address<br>Source last address adjustment or the system memory address for destination address (DADDR) storage.<br>If (TCDn_CSR[ESDA] = 0), then:<br>• Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure.<br>• This field uses two's complement notation for the final source address adjustment.<br>Otherwise:<br>• This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation.<br>The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero. |

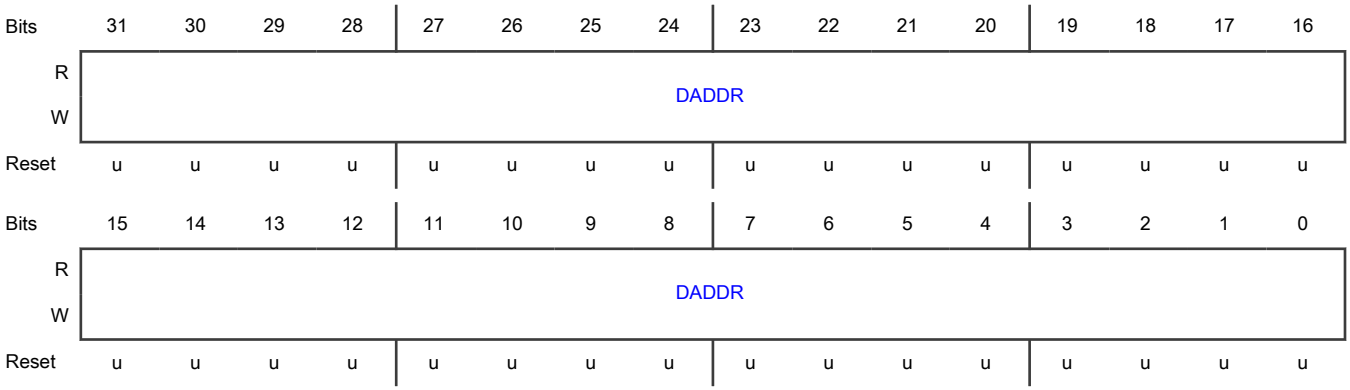
### Diagram



### Fields

| Field | Function |
|---|---|
| 15-14<br>BWC | Bandwidth Control<br>Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces eDMA to stall after the completion of each read/write access, to control the bus request bandwidth seen by the system bus interconnect.<br>**NOTE**<br>If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency.<br>00b - No eDMA engine stalls<br>01b - Enable eDMA master high-priority elevation (HPE) mode. No eDMA engine stalls.<br>10b - eDMA engine stalls for 4 cycles after each R/W<br>11b - eDMA engine stalls for 8 cycles after each R/W |
| 13<br>— | Reserved |
| 12-8<br>MAJORLINKCH | Major Loop Link Channel Number<br>If (MAJORELINK = 0) then:<br>• No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted.<br>Otherwise:<br>• After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field to 1. |
| 7<br>ESDA | Enable Store Destination Address<br>As the channel completes the major loop by either the current iteration counter (CITER) decrementing to 0, or by receiving an enabled end-of-packet signal, this field enables writing the destination address (DADDR) to the address stored in the SLAST_SDA field. The value written to system memory is the last DADDR value prior to the DLAST_SGA offset being applied, or overwritten by an enabled scatter/gather operation. When the SDA bit is 1, SLAST_SDA contains the write pointer instead of the final source address offset. Because this is a pointer and not a final offset, a last source address offset of zero is applied to SADDR instead of the SLAST_SGA value.<br>0b - Ability to store destination address to system memory disabled |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 1b - Ability to store destination address to system memory enabled |
| 6<br>EEOP | Enable End-Of-Packet Processing<br>When enabled by the EEOP field, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel, and to treat the shutdown as the major-loop-completed event. If the EEOP field is 1, the end-of-packet signal from supported peripherals is accepted. If the EEOP field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA-saved destination address), minus the software-saved initial address (DADDR), reflects the total amount of data transferred.<br>0b - End-of-packet operation disabled<br>1b - End-of-packet hardware input signal enabled |
| 5<br>MAJORELINK | Enable Link When Major Loop Complete<br>As the channel completes the major loop, this flag enables linking to another channel defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel.<br>**NOTE**<br>To support the dynamic linking coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1.<br>0b - Channel-to-channel linking disabled<br>1b - Channel-to-channel linking enabled |
| 4<br>ESG | Enable Scatter/Gather Processing<br>As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses TCDn_DLAST_SGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure, which is loaded as the transfer control descriptor into local memory.<br>**NOTE**<br>To support the dynamic scatter/gather coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1.<br>0b - Current channel's TCD is normal format<br>1b - Current channel's TCD specifies scatter/gather format. |
| 3<br>DREQ | Disable Request<br>If this flag is 1, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches 0.<br>0b - No operation. Channel's ERQ field not affected<br>1b - Clear the ERQ field to 0 upon major loop completion, thus disabling hardware service requests. Channel's ERQ field cleared to 0 when major loop complete |
| 2 | Enable Interrupt If Major Counter Half-complete |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|

Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress.<br>**NOTE**<br>If BITER = 1, do not use INTHALF; use INTMAJOR instead.<br>0b - Halfway point interrupt disabled<br>1b - Halfway point interrupt enabled |
| 1<br>INTMAJOR | Enable Interrupt If Major count complete<br>If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count (CITER) reaches 0.<br>0b - End-of-major loop interrupt disabled<br>1b - End-of-major loop interrupt enabled |
| 0<br>START | Channel Start<br>If this flag is 1, the channel is requesting service. The eDMA hardware automatically clears this flag to 0 after the channel begins execution.<br>0b - Channel not explicitly started<br>1b - Channel explicitly started via a software-initiated service request |

**TCD** Transfer control descriptor

# Chapter 15
# Interrupt Monitor (INTM)

## 15.1 Overview

INTM provides a mechanism to monitor the latency of the responses on interrupt requests to ensure that the processing of these critical interrupts executes within the expected time frame, increasing the reliability of the device.

### 15.1.1 Block diagram

The following block diagram shows the major registers involved in monitoring the interrupt sources.

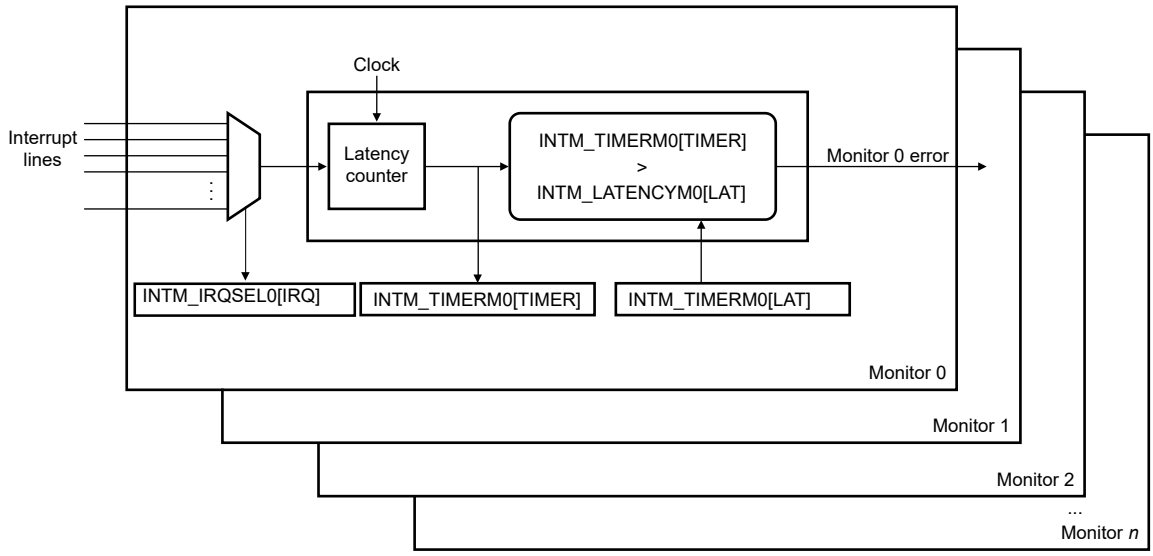

Figure 34. INTM block diagram

### 15.1.2 Features

INTM supports the following features:

- 4 programmable interrupt monitors
- Programmable interrupt source per monitor
- Programmable 24-bit maximum latency counter per monitor
- Timer expired status bit per monitor
- One interrupt acknowledge for all monitors

## 15.2 Functional description

Interrupt Request Select for Monitor a (INTM_IRQSEL0 - INTM_IRQSEL3) provides selection of the source, Monitor Mode (INTM_MM) enables the monitor, Interrupt Acknowledge (INTM_IACK) captures the event when the interrupt is acknowledged, Interrupt Latency for Monitor a (INTM_LATENCY0 - INTM_LATENCY3) can be programmed to trigger a monitor error when a threshold value is exceeded, Status for Monitor a (INTM_STATUS0 - INTM_STATUS3) is available to read the monitor error over peripheral bus.

**NOTE**

INTM supports only level-type interrupts. Hence, the pulse-type interrupts are converted into level-type interrupts for INTM.

### 15.2.1 Clocking

This module has no clocking considerations.

### 15.2.2 Interrupts

This module has no interrupts.

## 15.3 External signals

This module has no external signals.

## 15.4 Initialization

To monitor a subset of interrupt sources:

1. Program Interrupt Request Select for Monitor a (INTM_IRQSEL0 - INTM_IRQSEL3) with a value corresponding to the interrupt source number to be monitored.
   - You can monitor only defined interrupt sources.
2. Program Interrupt Latency for Monitor a (INTM_LATENCY0 - INTM_LATENCY3) to the maximum expected latency time for each monitored interrupt source.
3. Write 1 to INTM_MM[MM] to monitor the registers.
4. During the interrupt service routine, write the IRQ of the ISR to Interrupt Acknowledge (INTM_IACK).
5. If the maximum expected latency time exceeds the limit defined in Interrupt Latency for Monitor a (INTM_LATENCY0 - INTM_LATENCY3), then an error indication is sent to Fault Collection Control Unit(FCCU). You can also read Status for Monitor a (INTM_STATUS0 - INTM_STATUS3) to see this information.

To clear an error condition, write 0 to the corresponding INTM_TIMERa[TIMER] field for which the interrupt source exceeded the programmed latency value. In case the source is unknown, NXP recommends you to write 0 to all INTM_TIMERa[TIMER] fields.

## 15.5 INTM register descriptions

INTM allows you to set a maximum timer count for the interrupt latency from interrupt request to interrupt acknowledge. This mechanism monitors the latency of interrupt sources to ensure that these critical interrupts execute within the expected time frame, increasing the reliability of the chip. The hardware for this function is isolated in its own hierarchy to decrease the risk of fault interference.

An error indication is sent to FCCU if the interrupt processing latency exceeds the programmed threshold of the expected latency. The error indication can be read from INTM_STATUSa[STATUS].

### 15.5.1 INTM memory map

INTM base address: 4027_C000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Monitor Mode (INTM_MM) | 32 | RW | 0000_0000h |

*Table continues on the next page...*

*Table continued from the previous page...*

| 38h | Interrupt Request Select for Monitor 3 (INTM_IRQSEL3) | 32 | RW | 0000_0000h |
| 3Ch | Interrupt Latency for Monitor 3 (INTM_LATENCY3) | 32 | RW | 0000_0000h |
| 40h | Timer for Monitor 3 (INTM_TIMER3) | 32 | RW | 0000_0000h |
| 44h | Status for Monitor 3 (INTM_STATUS3) | 32 | R | 0000_0000h |

### 15.5.2 Monitor Mode (INTM_MM)

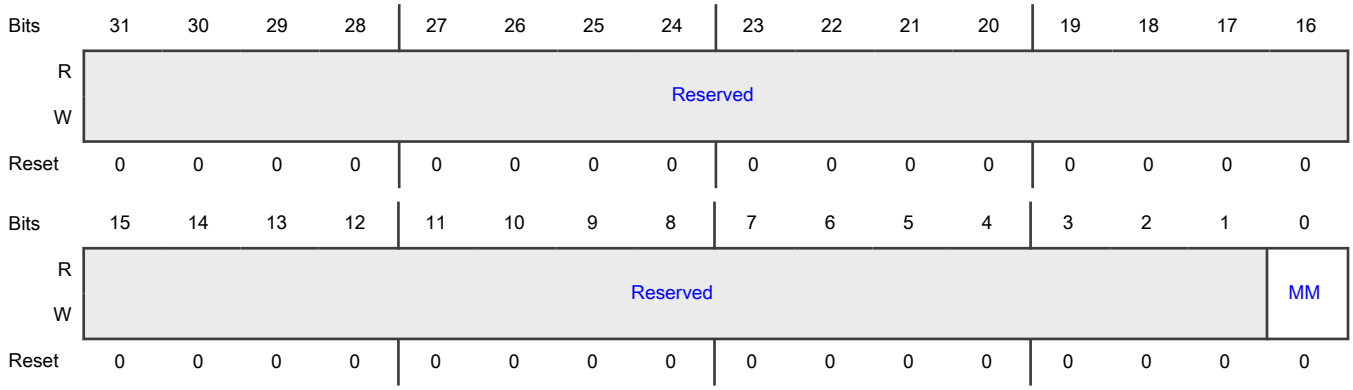
#### Offset

| Register | Offset |
|---|---|
| INTM_MM | 0h |

#### Function

Enables the cycle count timer on a monitored interrupt request for comparison to the latency register.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved |
| 0<br>MM | Monitor Mode<br>Controls whether the INTM monitors the latency of an interrupt response.<br>0b - Disable<br>1b - Enable |

## 15.5.3 Interrupt Acknowledge (INTM_IACK)

### Offset

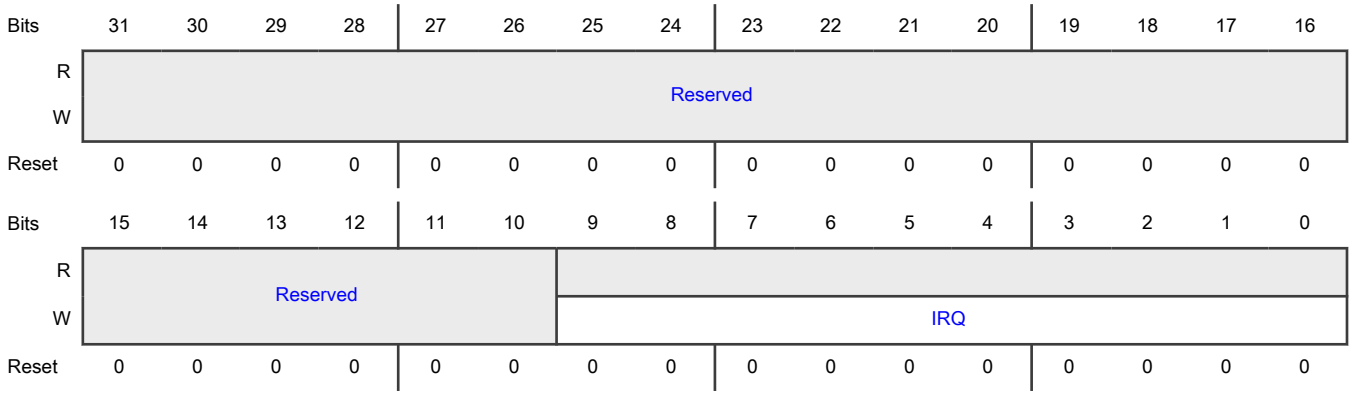
| Register | Offset |
|---|---|
| INTM_IACK | 4h |

### Function

Acknowledges the interrupt processing.

The Interrupt service routine writes to this register after the register acknowledges interrupt processing. This write operation must provide the number of the processed interrupt, which is compared with the interrupt request number in each Interrupt Request Select for Monitor a (INTM_IRQSEL0 - INTM_IRQSEL3) and stops the corresponding Timer for Monitor a (INTM_TIMER0 - INTM_TIMER3) when it found a match.

### Diagram



### Fields

### Offset

| Register | Offset |
|---|---|
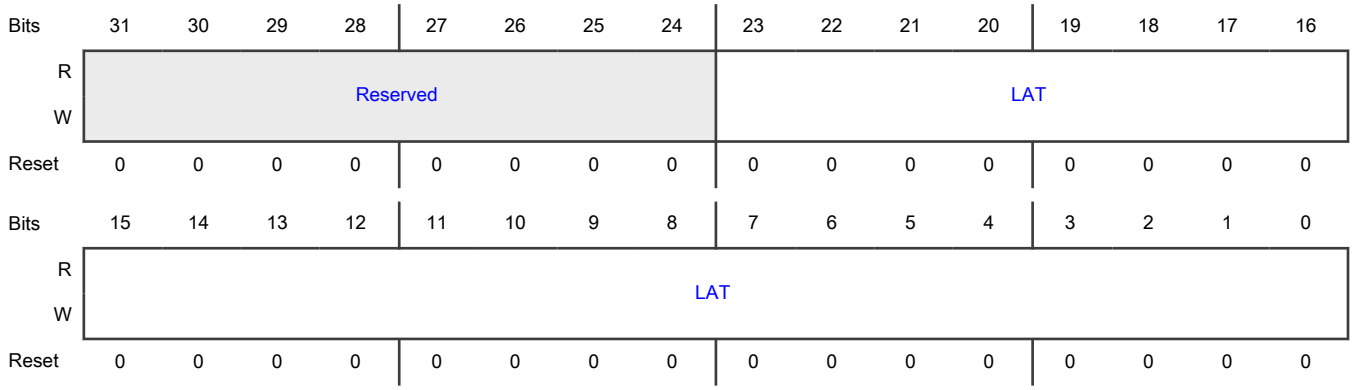
| INTM_LATENCY0 | Ch |
| INTM_LATENCY1 | 1Ch |
| INTM_LATENCY2 | 2Ch |
| INTM_LATENCY3 | 3Ch |

### Function

Indicates the maximum time before an error signal is asserted for a detected interrupt request to interrupt acknowledge.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved |
| 23-0<br>LAT | Latency<br>Specifies the maximum number of INTM clock cycles allowed for the monitored interrupt request.<br>Maximum programmed value must not exceed FF_FFFDh to allow for proper timer error capture. |

## 15.5.6 Timer for Monitor a (INTM_TIMER0 - INTM_TIMER3)

### Offset

| Register | Offset |
|---|---|
| INTM_TIMER0 | 10h |
| INTM_TIMER1 | 20h |
| INTM_TIMER2 | 30h |
| INTM_TIMER3 | 40h |

### Function

Counts the number of INTM clock cycles for a detected interrupt request to an acknowledged interrupt processing.

Initializes to 1 in following conditions:

- Interrupt Latency for Monitor a (INTM_LATENCY0 - INTM_LATENCY3) is nonzero
- Monitor error is not asserted
- Zero to one transition on the monitored interrupt request

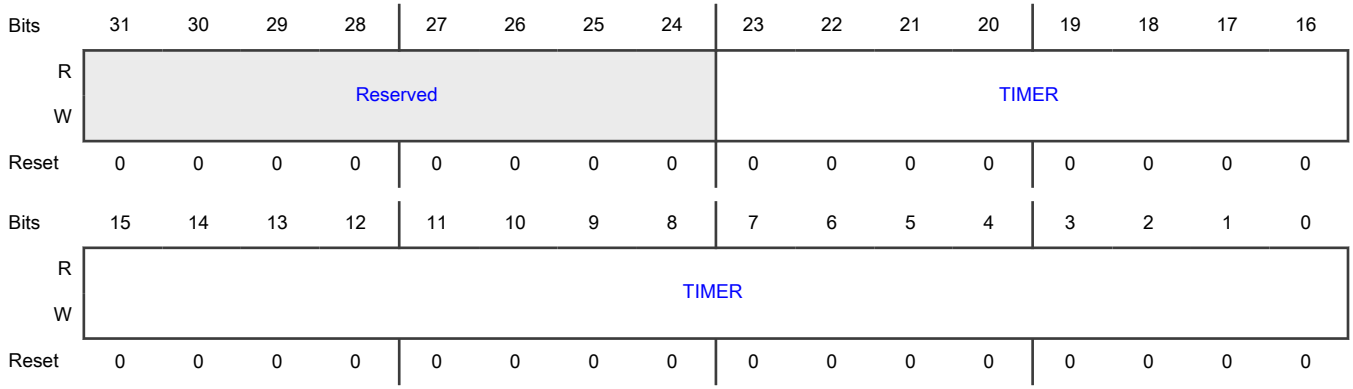
Following are the conditions to enable Timer for Monitor a (INTM_TIMER0 - INTM_TIMER3):

- INTM_MM = 1 and zero-to-one transition on the monitored interrupt source

Following are the conditions to disable Timer for Monitor a (INTM_TIMER0 - INTM_TIMER3):

- Reset
- INTM_MM = 1 and monitor error
- INTM_MM = 1 and monitored interrupt request is not asserted
- Interrupt acknowledge for corresponding interrupt request
- After the timer is enabled, writing 0 to INTM_MM[MM] has no effect.

### Diagram



### Fields

| Field | Function |
|---|---|

# Chapter 16
# Semaphores2 (SEMA42)

## 16.1 Chip-specific SEMA42 information

### 16.1.1 SEMA42 instance and configuration

This chip has up to one instance of SEMA42. See the following table for availability of SEMA42 instance across MCXE31 product series.

**Table 51. SEMA42 instance**

| Instance | MCXE31B |
|---|---|
| SEMA42 | Yes |

See "Chip-specific XRDC information" for the domain ID of each master on the MCXE31 product series. The following table shows the number of domains per chip:

## 16.2 Overview

SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single - write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

**NOTE**

Terminology in this chapter has been updated as follows:

**Table 52. Updated terms**

| Updated term | Deprecated term |
|---|---|
| Initiator | Master |
| Target | Slave |
| Stop | Abort |

### 16.2.1 Block diagram

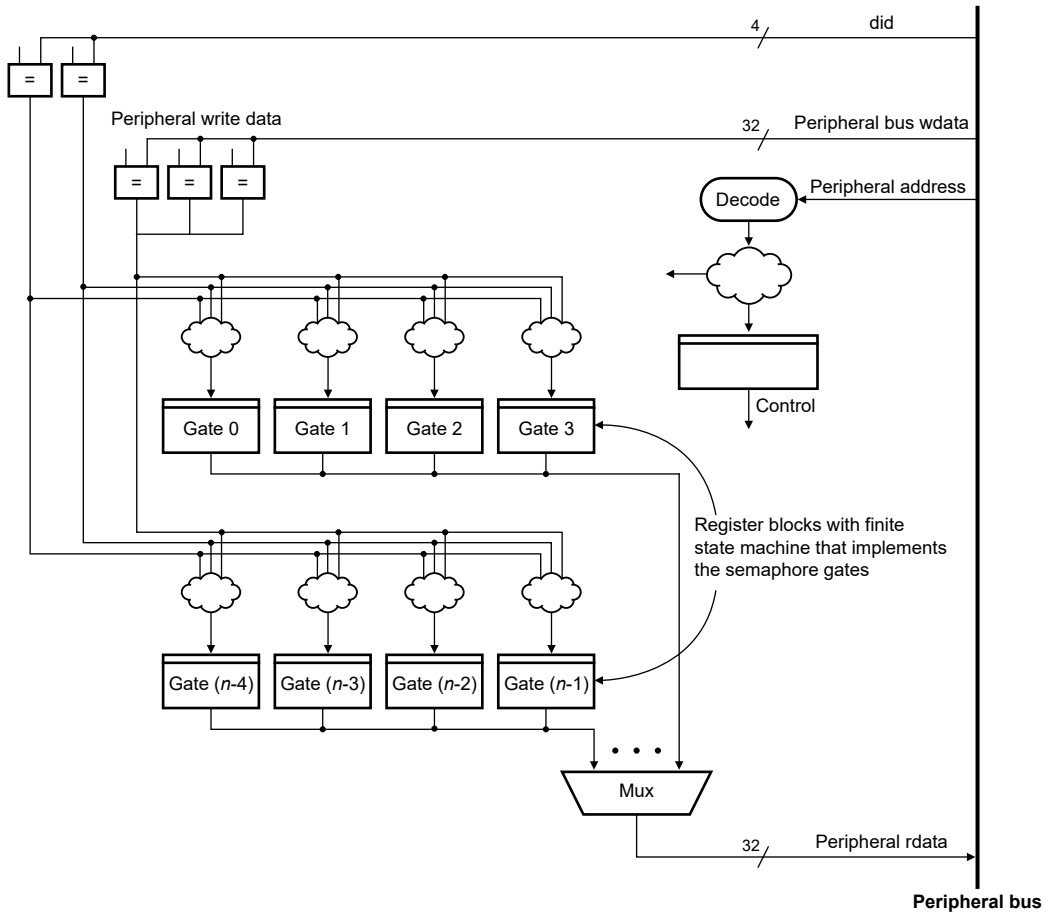

Figure 35. SEMA42 block diagram

### 16.2.2 Features

SEMA42 implements hardware-enforced semaphores as an IPS-mapped target peripheral device. The feature set includes:

- Support for 16 hardware-enforced gates in a multi-domain configuration that supports up to 15 domains.
- Each hardware gate appears as a 16-state, 4-bit state machine.
- Support for secure reset mechanisms to clear the contents of individual gates, as well as a clear-all capability.
- Memory-mapped target peripheral that offers programming-model accesses.

## 16.3 Functional description

The intent of the hardware gate implementation is to specify a protocol where the locking domain must unlock the gate. However, some systems may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset. To support this special gate reset requirement, SEMA42 implements a secure reset mechanism that allows you to initialize a hardware gate (or all the gates) by following a specific dual-write access pattern. The secure-gate reset:

- Uses a technique similar to that required for the servicing of a software watchdog timer
- Requires two consecutive writes with pre-defined data patterns from the same domain

You must do this to force the clearing of the specified gate(s). The required access pattern as follows:

1. A domain performs a 16-bit write to the RSTGT memory location. The most significant byte ( RSTGT_W[RSTGDP] ) must be E2h. The value of least significant byte is irrelevant for this reference and can be anything.
2. The same domain then performs a second 16-bit write to the RSTGT location. For this write, the upper byte ( RSTGT_W[RSTGDP] ) is the logical complement of the first data pattern (1Dh) and the lower byte (RSTGT_W[RSTGTN] ) specifies the gate(s) to be reset. This gate field can specify a single gate or all gates to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, SEMA42 stops the special gate reset sequence and does not assert an error signal.
3. Reads of the RSTGT location return information on the 2-bit reset state machine (RSTGT_R[RSTGSM] ) that implements these functions:
   - The domain performing the reset ( RSTGT_R[RSTGMS] )
   - The last-cleared gate number(s) (RSTGT_R[RSTGTN] )

   Reads of the RSTGT register do not affect the secure-reset finite state machine in any manner.

### 16.3.1 Multi-core programming: software gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism for system software to control access to shared data structures, shared hardware resources, and so on. The software uses the gating mechanisms to serialize (and synchronize) accesses to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and domains.

Consider the following description of a typical use-case: dm*X* enters a section of code, where shared data values are to be updated. The domain must first acquire a semaphore. Think of this as the locking (or closing) of a software gate. After the gate locks, a properly-architected software system does not allow other processes (or domains) to execute the same code segment or modify the shared data structure protected by the gate. In other words, the system locks out other processes/domains. Many software implementations include a spin-wait loop within the lock function until the gate locks. After domain X obtains the lock, domain X continues execution and updates the data values protected by the particular lock. After domain X completes the updates, it unlocks (or opens) the software gate, allowing other processes/domains access to the updated data values.

A correctly-implemented system solution must follow these important rules:

- A gate variable must protect all writes to shared data values or shared hardware resources.
- After a domain locks a gate, the system must block other processes/domains from accessing the shared data or resources. Software conventions enforce this.
- The domain that locks a particular gate is the only domain that can open (unlock) that gate.

Information in the hardware gate identifying the locking domain can be extremely useful for system-level debugging.

### 16.3.2 16 Hardware-enforced gates

Gates appear as a 16-entry byte-size array with read and write accesses.

Domains lock gates by writing "domainID_number+1" to the appropriate gate and must read back the gate value to verify that the lock operation succeeded.

After the gate locks, the locking domain unlocks the gate by writing zeroes.

- 16-state implementation

  If gate = 0h, then state = unlocked

  if gate = 1h, then state = locked by domain (initiator) 0

  if gate = 2h, then state = locked by domain (initiator) 1

  …

  if gate = Fh, then state = locked by domain (initiator) 14

SEMA42 uses the logical domain number and the specified data patterns as reference attributes to validate all write operation.

After a gate locks, the locking domain must unlock the gate by writing zeroes.

### 16.3.3 State machine of the GATE*n* registers

This section describes more about the SEMA42 functional operation and specific details of the state machines of the GATE*n* registers.

As described previously, each of the GATE*n* registers implements a 4-bit, 16-state machine. The following figure shows a simplified diagram of the state transitions for each gate.

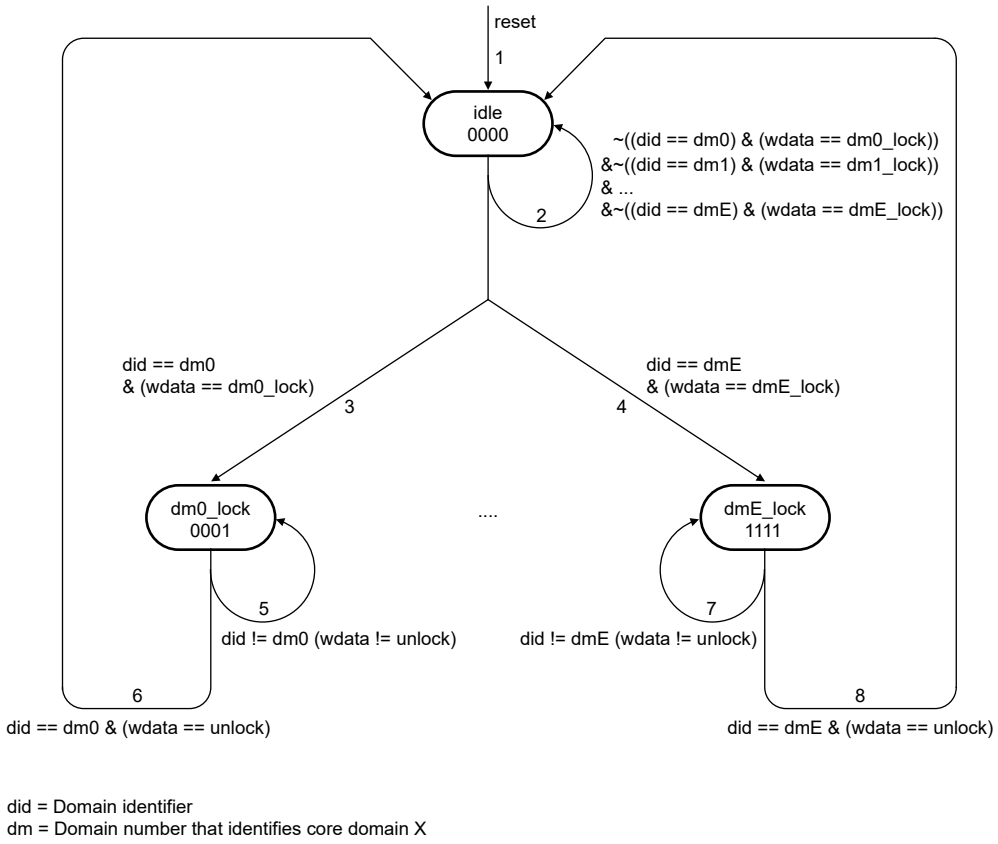

**Figure 36. GATE*n* state machine**

In the figure above, "dmE" represents domain 14 (E in hexadecimal). The platform passes the domain number to SEMA42.

The following table defines the GATE*n* state transitions.

**Table 53. GATE*n* state transitions**

| Current state | Next state | Transition | Description |
|---|---|---|---|
| – | idle | 1 | Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state. |
| idle | idle | 2 | Unless a write of the appropriate lock value from the corresponding domain occurs, the gate remains in the idle state. |
| idle | dm0_lock | 3 | When domain 0h initiates a write of the dm0_lock data value, the gate transitions into the dm0_lock state. |

*Table continues on the next page...*

Table 53. GATE*n* state transitions (continued)

| Current state | Next state | Transition | Description |
|---|---|---|---|
| idle | dmE_lock | 4 | When domain Eh initiates a write of the dmE_lock value, the gate transitions into the dmE_lock state. |
| dm0_lock | dm0_lock | 5 | When in this state, the gate remains here if any attempted write is not from domain 0h with the unlock data value. |
| dm0_lock | idle | 6 | The gate returns to the idle (unlocked) state after a write from domain 0h with the unlock data value occurs. |
| dmE_lock | dmE_lock | 7 | When in this state, the gate remains here if any attempted write is not from domain Eh with the unlock data value. |
| dmE_lock | idle | 8 | The gate returns to the idle (unlocked) state after a write from domain Eh with the unlock data value occurs. |

SEMA42 uses these gate data values:

- The lock data value is (domain number) + 1.
- The unlock data value is 00h.

### 16.3.4 Clocking

| Type of clock | Description |
|---|---|
| Module clock (clk) | Functions the module and controls the access to the registers. |

### 16.3.5 Interrupts

This module has no interrupts.

## 16.4 External signals

This module has no external signals.

## 16.5 Initialization

This module does not require initialization.

## 16.6 Memory map/register definition

You can access these registers only in Supervisor mode. User accesses terminate with an error.

### 16.6.1 SEMA42 register descriptions

#### 16.6.1.1 SEMA42 memory map

SEMA42 base address: 4046_0000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h - Fh | Gate (GATE0 - GATE15) [1] | 8 | RW | 00h |
| 42h | Reset Gate Read (RSTGT_R) | 16 | R | 0000h |
| 42h | Reset Gate Write (RSTGT_W) | 16 | W | See section |

1. In this array, the index and offset values of the registers do not increment in direct alignment. For details, see the register description.

### 16.6.1.2 Gate (GATE0 - GATE15)

#### Offset

For n = 0 to 15:

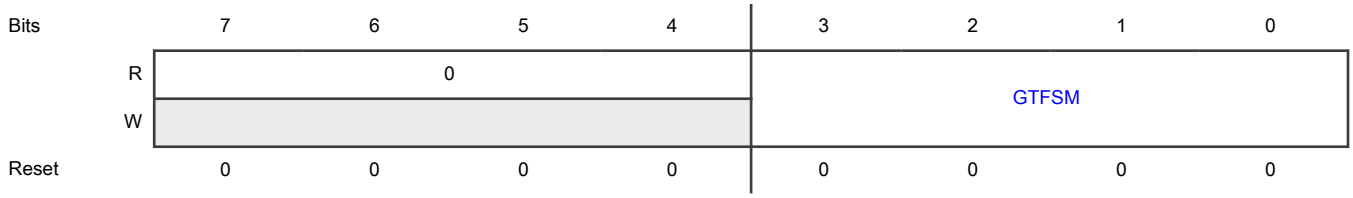
| Register | Offset |
|---|---|
| GATEn | 0h + (n + 3 - 2 × (n mod 4)) |

#### Function

Implements each semaphore gate in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical domain-identifier number in conjunction with the data patterns to validate all attempted write operations. Only domain initiators can modify the gate registers. After a gate locks, only the locking domain must open (unlock) the gate.

You can read multiple gate values in a single access. However, you can update only a single gate at a time, via a write operation. If you attempt to write a byte-wide value that is neither the unlock value (00h) nor the appropriate lock value (domainID_number + 1), SEMA42 considers this as "no operation" and does not change any gate state. Attempts to write multiple gates in a single-aligned access with a size larger than 8 bits (byte) generate an error termination and do not allow any gate state changes.

#### Diagram



#### Fields

| Field | Function |

| 3-0<br>GTFSM | Gate Finite State Machine<br>Indicates the state of the gate for the last domain that locked the gate. This can be useful during system debug. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | The hardware gate has a 16-state implementation, defined as:<br>0000b - The gate is unlocked (free).<br>0001b - Domain 0 locked the gate.<br>0010b - Domain 1 locked the gate.<br>0011b - Domain 2 locked the gate.<br>0100b - Domain 3 locked the gate.<br>0101b - Domain 4 locked the gate.<br>0110b - Domain 5 locked the gate.<br>0111b - Domain 6 locked the gate.<br>1000b - Domain 7 locked the gate.<br>1001b - Domain 8 locked the gate.<br>1010b - Domain 9 locked the gate.<br>1011b - Domain 10 locked the gate.<br>1100b - Domain 11 locked the gate.<br>1101b - Domain 12 locked the gate.<br>1110b - Domain 13 locked the gate.<br>1111b - Domain 14 locked the gate. |

#### 16.6.1.3 Reset Gate Read (RSTGT_R)

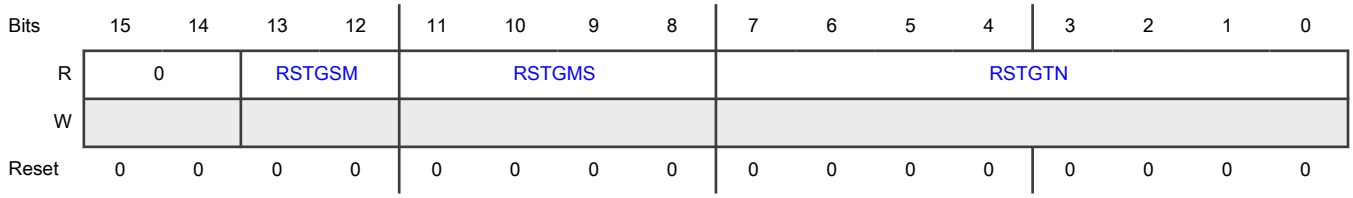
**Offset**

| Register | Offset |
|---|---|
| RSTGT_R | 42h |

**Function**

Describes the specific hardware gate to be reset and records the logic number of domain. Reset Gate Write (RSTGT_W) also describe the same register showing the fields when you write it.

### Diagram



### Fields

| Field | Function |
|---|---|
| 15-14<br>— | Reserved |
| 13-12<br>RSTGSM | Reset Gate Finite State Machine<br>Indicates the encoded state machine value when you read the register. RSTGSM = 10b is valid for only a single machine cycle, so a read can never return this value. SEMA42 maintains the reset state machine in a 2-bit, 3-state implementation, defined as follows:<br>00b - Idle, waiting for the first data pattern write.<br>01b - Waiting for the second data pattern write<br>10b - The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state.<br>11b - This state encoding is never used and therefore reserved. |
| 11-8<br>RSTGMS | Reset Gate Domain<br>Records the logical number of the domain performing the gate reset function. The logical number is the domain number. This domain number is determined by the XRDC's initiator Domain Assignment Controller (XRDC_MDAC). To succeed, this function requires that the same domain initiate the two consecutive writes to this register. SEMA42 updates the field each time a write to this register occurs. |
| 7-0<br>RSTGTN | Reset Gate Number<br>Specifies the specific hardware gate to be reset. The second write updates this field.<br>If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates. |

## 16.6.1.4 Reset Gate Write (RSTGT_W)

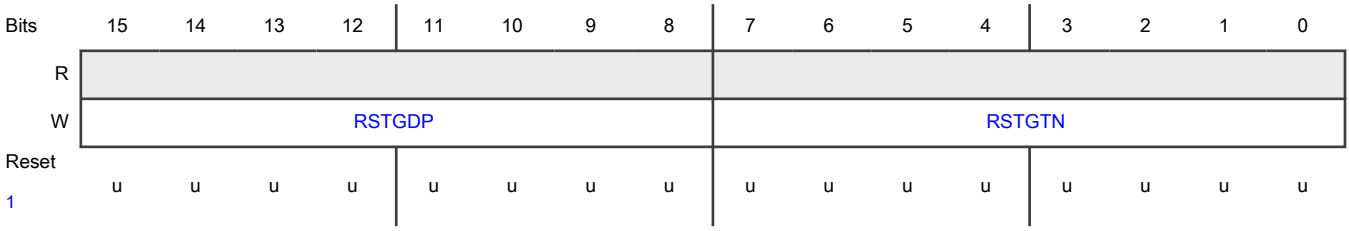
### Offset

| Register | Offset |
|---|---|
| RSTGT_W | 42h |

### Function

Specifies the hardware gate to reset when data patterns are specified.

### Diagram



1. Reset value is not applicable for writes.

### Fields

| Field | Function |
|---|---|
| 15-8<br>RSTGDP | Reset Gate Data Pattern<br>You access this field with the specified data patterns on the two consecutive writes to enable the gate-reset mechanism. For the first write, RSTGDP must be E2h. For the second write, RSTGDP must be 1Dh. |
| 7-0<br>RSTGTN | Reset Gate Number<br>Specifies the specific hardware gate to be reset. The second write updates this field.<br>If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates. |

The errors detected are connected to FCCU. See the memory map file attached to this document for details.

### 17.1.2 Target master IDs

See "Chip-specific XRDC information" for master IDs.

## 17.2 Overview

XBIC is a safety module that verifies the integrity of crossbar transfers.

### 17.2.1 Block diagram

The chip routes crossbar transfer attribute information for all mapped initiator and target ports to XBIC, which calculates and checks the EDC value of the attribute information, as shown in the following diagram.

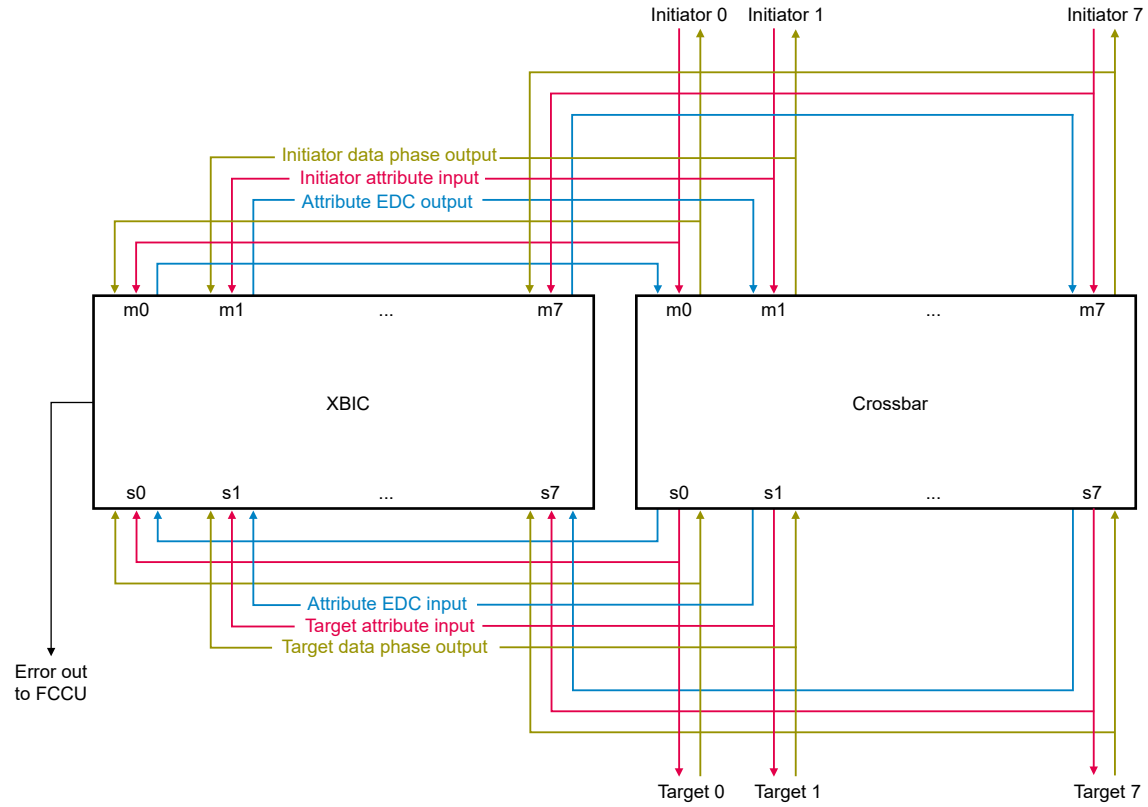

Figure 37. XBIC system block diagram

The above figure illustrates one of many possible XBIC and crossbar configurations. See the Chip-specific XBIC information section for actual port mappings.

### 17.2.2 Features

XBIC includes the following features:

- Verification of attribute information for crossbar transfers [1],[2]
  - EDC detects single-bit and double-bit errors
- Verification of feedback information for each data phase during crossbar transfers
- Error injection for testing
  - Programmable initiator and target port specifiers
  - Programmable 8-bit toggle vector to insert error in initiator EDC value
  - Address, EDC syndrome, initiator, and target port information are captured when error is detected
- Crossbar transfer attribute integrity check programmable on a per-target-port basis
- Feedback integrity check programmable on a per-initiator-port basis

## 17.3 Functional description

XBIC verifies the integrity of the crossbar interface on an individual port basis according to the configuration specified via the MCR register. When XBIC detects an error, it reports relevant information and sends an error signal to the FCCU module, but does

[1] See Table 57 for a list of crossbar attribute signals verified.
[2] The chip verifies read and write data separately, via the end-to-end ECC architecture.

not generate a bus error. XBIC integrity checking is independent of end-to-end ECC, which monitors the integrity of the transfer address and data.

During the address phase of a transfer, XBIC verifies the crossbar attribute information using an 8-bit EDC, which detects any single-bit or double-bit errors. When XBIC detects an error (an attribute integrity error), due to either hardware fault or error injection, it reports information related to the error in ESR and EAR.

During the data phase of a data transfer, XBIC verifies the integrity of response signals from target to intiator as they pass through the crossbar. When XBIC detects an error in the response signals (a feedback integrity error), it reports the XBIC target and intiator ports in ESR[DPSE0] - ESR[DPSE7] and ESR[DPME0] - ESR[DPME7], respectively.

During the data phase, XBIC sends an alarm to the FCCU module if a intiator port attempts back-to-back accesses in which:

1. The first access terminates normally.
2. The second attempts access to an address space not mapped to any target on the crossbar.

The resultant 'absent target error' causes the crossbar to generate a bus error response to the requesting intiator. XBIC detects the bus error response as a difference because the bus error did not originate from the target port.

You can program XBIC to inject EDC errors for testing purposes. Error injection targets a single target port and a single intiator port, as specified by the configuration settings in the EIR register. When XBIC inserts an error, it changes the EDC syndrome, causing the XBIC to assert an error indication to the FCCU module. Otherwise, transfers are unaffected by error injection. This enables verification of the check logic without compromising the integrity of the data transfer. After you enable error injection function by writing 1 to EIR[EIE], XBIC induces errors on all subsequent targeted transactions until you write a 0 to the field. After the FCCU error indication asserts, it remains asserted even after you write 0 to EIR[EIE]. The error indication deasserts after FCCU specifically clears the existing error. After FCCU clears the XBIC error, additional error injection testing can continue.

To trace a fault reported by the XBIC to the FCCU:

1. Note the error reported by the FCCU. For example, "NCF[46]".
2. Locate the source module and error description in the attached fault mapping spreadsheet. For example:
   - Channel number: NCF[46]
   - Source module: AXBS_1 integrity checker
   - Description: Instruction crossbar error indication to FCCU if syndrome calculated using EDC on the data is not zero
3. Refer to the Chip-specific XBIC information section for the source XBIC module to determine the specific XBIC module instanceâ€""XBIC_1", for example.
4. Determine the type of error (attribute integrity error or feedback integrity error) and the XBIC port(s) involved by reading the information reported in the ESR register of the reported XBIC instance.
5. For attribute integrity check errors, read the XBIC EAR register for the target address of the requested transfer.
6. Refer to the Chip-specific XBIC information section and possibly the Chip-specific AXBS information section for port mapping of XBIC ports to AXBS ports.

Decode a single-bit error syndrome value reported in ESR[SYN] by finding the value in the following table. Any syndrome value not included in the table indicates a multi-bit error.

**Table 57. Hexadecimal attribute single-bit error syndromes**

| Signal | SYN | Signal | SYN | Signal | SYN | Signal | SYN |

### 17.3.1 Interrupts

This module has no interrupts.

## 17.4 External signals

XBIC has no external interface signals.

## 17.5 Initialization

This module does not require initialization.

## 17.6 XBIC register descriptions

The XBIC programming model consists of four 32-bit registers. Software can access this model only in supervisor mode using 32-bit (word) accesses. Each of the following generates a transfer error back to the requesting intiator. Such errors could cause core exceptions apart from other problems.

- Access size other than 32-bit
- Access to an undefined (reserved) address
- Access in user mode

### 17.6.1 XBIC memory map

XBIC_AXBS base address: 4020_4000h

XBIC_AXBS_PERI base address: 4020_8000h

XBIC_AXBS_TCM base address: 4040_0000h

XBIC_AXBS_eDMA base address: 4040_4000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | XBIC Module Control (MCR) | 32 | RW | FFFF_0000h |
| 4h | XBIC Error Injection Attributes (EIR) | 32 | RW | 0000_0000h |
| 8h | XBIC Error Status Attributes (ESR) | 32 | RW | 0000_0000h |
| Ch | XBIC Error Address (EAR) | 32 | R | 0000_0000h |

### 17.6.2 XBIC Module Control (MCR)

**Offset**

| Register | Offset |
|---|---|
| MCR | 0h |

**Function**

Use this register to turn attribute integrity checking and feedback integrity checking on or off on a per-port basis.

- Turn on attribute integrity checking on one or more XBIC target ports by ensuring that the associated SE*n* field(s) have a value of 1. For example, setting field SE*0* enables attribute integrity checking for target port 0. The default (reset) behavior is for attribute integrity checking to be performed for all target ports. XBIC performs EDC-based checks on all transfer requests targeting the selected target port(s). The signals verified are transfer attribute signals going from initiator to target. When XBIC detects an attribute integrity error, it reports relevant information in the ESR and EAR registers.
- Turn on feedback integrity checking on one or more XBIC initiator ports by ensuring that the associated ME*n* field(s) have a value of 1. For example, setting field ME*0* to 1 enables feedback integrity checking for initiator port 0. The default (reset) behavior is for feedback integrity checking to be performed for all initiator ports. XBIC checks target-to-initiator feedback signals for transfer requests originating from the selected XBIC initiator port(s). If any feedback signal value is different at the initiator and target ports during the data phase, XBIC reports the relevant initiator and target ports in the ESR register.

Each field in this register references a specific initiator or target port using XBIC port numbering. Referring to Figure 37, "target port 0" refers to XBIC port "s0" in the figure, "target port 1" refers to port "s1", and so on. Similarly, "initiator port 0" refers to XBIC port "m0", "initiator port 1" refers to port "m1", and so on. See the "Chip-specific XBIC information" section in this document for the mapping of XBIC instances to AXBS instances and XBIC ports to AXBS ports. See the "Chip-specific AXBS information" section in this document for the device component(s) mapped to each port of an AXBS instance.

## 17.6.3 XBIC Error Injection Attributes (EIR)

### Offset

| Register | Offset |
|---|---|
| EIR | 4h |

### Function

Use this register to configure the XBIC error injection function and turn it on or off. When enabled, the XBIC error injection function inserts an attribute integrity error when the targeted initiator requests a transaction of the targeted target port. The inserted error changes the calculated EDC syndrome value, causing XBIC to:

- Capture transfer information in the ESR and EAR registers
- Assert an error signal to the FCCU module

Otherwise, XBIC error injection does not affect transfers.

| 7-0<br>SYN | Syndrome<br>XBIC performs an exclusive OR operation on the value in this field and the calculated syndrome, to generate an error with the specified syndrome. A value of zero does not generate an error. See Table 57 for a list of transfer attribute single-bit error syndromes, noting that the values given in the table are hexadecimal. |

### 17.6.4 XBIC Error Status Attributes (ESR)

#### Offset

| Register | Offset |
|---|---|
| ESR | 8h |

#### Function

In this register, XBIC reports information about the most recent transfer with an error detected. If XBIC detects an attribute integrity check error, it reports:

- The target port identifier (SLV)
- The initiator port identifier (MST) and the error syndrome (SYN)

If XBIC detects a mismatch among feedback signals during the data phase:

- The DPSE0 - DPSE7 field with a value of 1 indicates the XBIC target port. In the DPSE0-DPSE7 field descriptions, the target port number refers to the XBIC target port number. Referring to Figure 37, "target port 0" refers to XBIC port "s0" in the figure, "target port 1" refers to port "s1", and so on. See the "Chip-specific XBIC information" section in this document for the mapping of XBIC instances to AXBS instances and XBIC ports to AXBS ports. See the "Chip-specific AXBS information" section in this document for the device component(s) mapped to each port of an AXBS instance.
- The DPME0 - DPME7 field with a value of 1 indicates the XBIC initiator port. In the DPME0-DPME7 field descriptions, the initiator port number refers to the XBIC initiator port number. Referring to Figure 37, "initiator port 0" refers to XBIC port "m0" in the figure, "initiator port 1" refers to port "m1", and so on. See the "Chip-specific XBIC information" section in this document for the mapping of XBIC instances to AXBS instances and XBIC ports to AXBS ports. See the "Chip-specific AXBS information" section in this document for the device component(s) mapped to each port of an AXBS instance.

XBIC sets this register to all 0s only on reset.

## 17.6.5 XBIC Error Address (EAR)

### Offset

| Register | Offset |
|---|---|
| EAR | Ch |

### Function

In this register, XBIC reports the address of the most recent transfer with an attribute integrity check error detected—either because of a hardware fault or error injection. XBIC sets this register to all 0s only on reset.

**NOTE**

An attempted write to this read-only register results in a transfer error.

### 18.1.2 MRC configuration

Table 59. MRC configuration

| Submodule instance | Region format | Number of region descriptors | Slaves protected (port number) | Applicability |
|---|---|---|---|---|
| XRDC_MRC0 | Auto | 16[1] or 8 | PFLASH_0 (0)<br>PFLASH_1 (1)<br>PFLASH_2 (2)[1]<br>PFLASH_WR (3) | MCXE315/MCXE316/ MCXE317/MCXE31B |
| XRDC_MRC1 | Auto | 16[1] or 8 | PRAM0_0 (0)<br>PRAM1_0[1] (2) | MCXE315/MCXE316/ MCXE317/MCXE31B |

*Table continues on the next page...*

Table 59. MRC configuration (continued)

| Submodule instance | Region format | Number of region descriptors | Slaves protected (port number) | Applicability |
|---|---|---|---|---|
| | | | TCM backdoor (1) | |
| XRDC_MRC2 | Auto | 4 | QuadSPI (0) | MCXE31B |

1. Applicable to MCXE31B

### 18.1.3 PAC configuration

Table 60. PAC configuration

| Module name | Slaves protected | Applicability |
|---|---|---|
| XRDC_PAC0 | AIPS_0 | MCXE315/MCXE316/MCXE317/MCXE31B |
| XRDC_PAC1 | AIPS_1 | MCXE315/MCXE316/MCXE317/MCXE31B |
| XRDC_PAC2 | AIPS_2 | MCXE31B |

**NOTE**

For PDAC registers assignment to peripherals, see the memory map file attached to this document.

### 18.1.4 Domain Error Word registers (DERR_W*x*_0-18) mapping

The mapping of the domain error capture registers is as follows:

Table 61. Domain Error Word registers mapping

| Register | Corresponding MRC/PAC | Available in chips |
|---|---|---|
| DERR_W*x*_0 | MRC0 | MCXE315/MCXE316/MCXE317/MCXE31B |
| DERR_W*x*_1 | MRC1 | MCXE315/MCXE316/MCXE317/MCXE31B |
| DERR_W*x*_2 | MRC2 | MCXE31B |
| DERR_W*x*_16 | PAC0 | MCXE315/MCXE316/MCXE317/MCXE31B |
| DERR_W*x*_17 | PAC1 | MCXE315/MCXE316/MCXE317/MCXE31B |
| DERR_W*x*_18 | PAC2 | MCXE31B |

Where *x*: 0, 1, 2, 3.

If the above registers are accessed in chips wherein they are not present, a bus error gets reported.

### 18.1.5 Exceptions and violations

A write attempt by a noncore bus master outside the defined ranges leads to an exception in case the XRDC region is defined to prevent noncore master access. The chip generates a bus error if you violate XRDC policies.

### 18.1.6 Configuration using SBAF

SBAF must protect access to its own resources. Hence, XRDC is configured during initialization. SBAF provides the mechanism for you to configure XRDC during boot. You must program the configuration data in the application flash memory region.

#### 18.1.6.1 Default configuration of MDAC when ELE_HSEB firmware feature is disabled

Table 62. MDAC registers default value

| MDAC register | Value | Domain number assigned |
|---|---|---|
| ELE_HSEB CPU (MDAC3) | C000_0002h | 0 |

All the other MDAC domain numbers are 0 and SBAF does not lock them.

#### 18.1.6.2 Default configuration of MRC registers when ELE_HSEB firmware usage feature flag is disabled

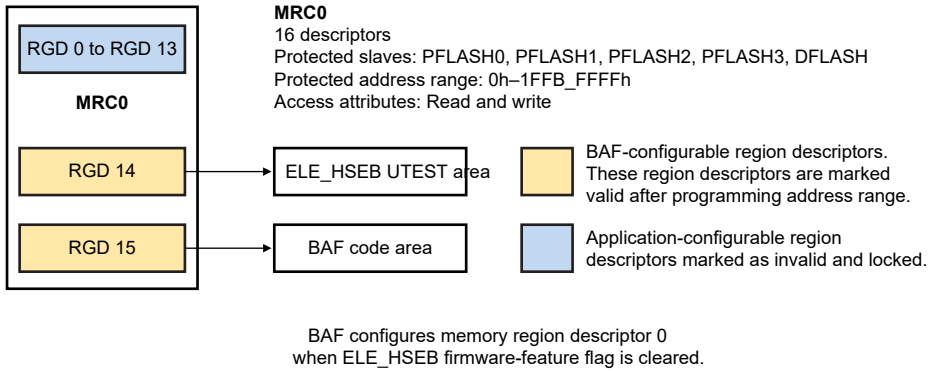

Figure 38. Default configuration of MRC registers when ELE_HSEB firmware usage feature flag is disabled

Table 63. Default configuration of MRC registers when ELE_HSEB firmware usage feature flag is disabled

| MRC number | Region descriptor number | Region address range (in hex) | Name | Remarks | SBAF's configuration |
|---|---|---|---|---|---|
| 0 | 14 | 1B00_0200 - 1B00_06FF | ELE_HSEB UTEST area | UTEST area that is accessible by ELE_HSEB core only. Start address is 1B00_0200h and 1B00_06FFh for others LC | W0 = start address = 1B00_0200h<br>W1 = end address = 1B00_06FFh<br>W2 = {SE = 0, SNUM = 0, D3ACP = 7h [all permission]} |
| 1 | 15 | 007F_4000 - 007F_FFFF | SBAF code area | Code area for SBAF and ELE_HSEB firmware | W0 = start address= 007F_4000h<br>W1 = end address= 007F_FFFFh<br>W2 = {SE = 0, SNUM = 0, D2ACP =7h [all permission], D1ACP = 0h [no permission], D0ACP = 0h [no permission]} |

#### 18.1.6.3 PDAC default configuration

SBAF configures and lock the following peripherals for its exclusive use. Read and write access to these peripheral are not provided to application domains.

Table 64. PDAC default configuration

| Peripheral | Peripheral PDAC number | Remarks |
|---|---|---|
| Flash memory controller alternate | 155 | ELE_HSEB uses the alternate interface exclusively. |
| Flash memory alternate | 188 | ELE_HSEB uses the alternate interface exclusively. |
| HSE_GPR | 231 | All cores have all permissions. |

### 18.1.7 Configuration when ELE_HSEB firmware-feature flag is cleared

When the ELE_HSEB firmware-feature flag is cleared, SBAF:

- Does not permit XRDC configuration.
- Locks the aforementioned configurations.

## 18.2 Overview

XRDC manages access control between initiators (cores and noncore initiators) and targets (memories and peripherals) by placing them in virtual groups called domains.

Conceptually, a domain is one or more initiators and memories and peripherals, that are isolated from others. It may help to look at a domain as a permissions group within a computing environment. All initiators in a domain have the same access to chip resources such as memory and peripherals. See Introduction to domains for more information on domains.

The protection provided by XRDC access control is in addition to the local memory protection unit contained within each core.

**NOTE**

Terminology in this chapter has been updated as follows:

Table 65. Updated terms

| Updated term | Deprecated term |
|---|---|
| Initiator | Master |
| Target | Slave |

### 18.2.1 Features

- Enables you to partition chip resources (initiator and target) into access-controlled domain.
  - Each domain has a unique DID .
  - The DID is an attribute of every system bus transaction.
- Provides a four-level hierarchical access control scheme for defining an ACP for each target in a domain. See Access control model for more information.
  - Memory region descriptors define access policies for address ranges within memories.
  - Peripheral access control registers define access policies for individual peripherals.
- Supports optional hardware semaphores to dynamically modify access rights for target resources.

### 18.2.2 Block diagram

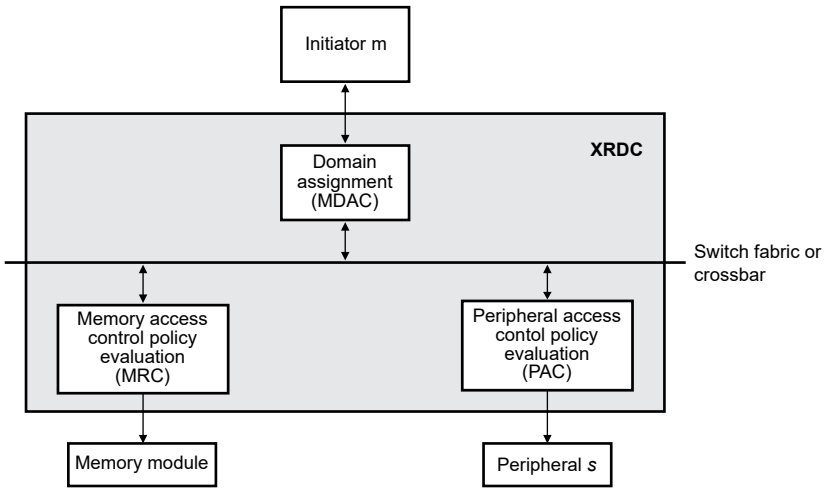

Figure 39. Block diagram

### 18.2.3 Block descriptions

| Block | Description |
|---|---|
| Domain assignment | A process that adds information to transactions, including:<br>• DID<br>• Privileged attribute<br>• Secure attribute<br>Domain assignment is performed by the MDAC submodule.<br>See:<br>• Domain assignment<br>• Master domain assignment controller (MDAC) |
| Initiator | A core or noncore (for example, DMA) module that can initiate transactions with memory or peripheral resources. |
| Memory | Non-volatile memory, RAM, or other memory. |
| Memory access control policy evaluation | A process that determines whether the domain associated with a transaction has access rights to a memory location. The process is performed by the MRC submodule.<br>See:<br>• Memory region ACP evaluation<br>• Memory region controller (MRC) |
| Peripheral | A nonmemory resource module within the chip—an ADC, timer module, or communications module, for example. |
| Peripheral access control policy evaluation | A process that determines whether the domain associated with a transaction has access rights to a peripheral. The process is performed by the PAC submodule. |

### 18.2.4 Indexes used in this chapter

**Table 66. Indexes used in this chapter**

| Index | Description |
|---|---|
| *c* | Memory controller number. For example, MRC*c*. |
| *d* | Domain number. For example, PDAC_W0_6[D*d*ACP]. |
| *m* | Initiator number. For example, PID*m*. |
| *r* | Memory region number. For example, RGD_W0_*r*. |
| *s* | PDAC slot number. For example, PDAC_W0_*s*[D0ACP]. |
| *w* | Word number. In a group of registers consisting of consecutive 32-bit registers, *w* is the 0-indexed register number. For example, MRGD_W*w*_0. |

### 18.2.5 Exceptions and violations

A write attempt by a noncore bus initiator outside the defined ranges leads to an exception in case the XRDC region is defined to prevent noncore initiator access. The chip generates a bus error if you violate XRDC policies.

## 18.3 Modes of operation

XRDC does not support any special modes of operation.

## 18.4 External signal description

XRDC does not have any external signals.

## 18.5 Functional description

### 18.5.1 Introduction to domains

A domain typically consists of one or more initiators, along with the memories and peripherals those initiators are allowed to access. Because it is access-controlled, a domain acts as an independent computing environment.

Domains enable applications to coexist on the same silicon with a firewall between them, enforcing absolute interference protection.

Generally, you create each domain to meet a specific need. Examples of XRDC domain usage include:

- Isolation of real-time from non-real-time applications to ensure resource availability
- Isolation of safety-critical code from non-safety-critical code
- Isolation of third-party untrusted applications from trusted software
- Isolation of memory regions to ensure data security or to prevent accidental overwrites
- Limiting write access for a specific area of system memory to a single DMA module instance

- Limiting read access for a specific area of system memory to a specific processor core

You can assign a core to multiple domains but only one of those domains can be active at a given time.

Within each XRDC instance, each domain has a unique identifier, known as its DID. If an XRDC instance has 16 DIDs, that means the instance has 16 available domains.

You control which initiators can access a peripheral by configuring the domain ACP for each peripheral. Similarly, you control which initiators can access a memory region by configuring the ACP for each memory region.

## 18.5.2 Submodules

XRDC implements its functionality through its hardware submodules:

- Master domain assignment controller (MDAC)
- Memory region controller (MRC)
- Peripheral access controller (PAC)

### 18.5.2.1 Master domain assignment controller (MDAC)

The MDAC submodule performs domain assignment logic. XRDC contains an MDAC submodule for each XRDC-protected initiator. Each MDAC assigns a DID to every transaction from its associated initiator. You configure the domain assignment activity for each MDAC through a set of registers, in one of two formats:

- DFMT0 core domain assignment registers
- DFMT1 noncore domain assignment registers

To understand the role of domains in XRDC protection, see Introduction to domains.

For a full explanation of the domain assignment process, see Domain assignment.

### 18.5.2.2 Memory region controller (MRC)

The MRC submodule performs memory region access control. Each XRDC instance contains the number of MRCs indicated in HWCFG0[NMRC]. Each MRC is associated with one or more memories (see the chip-specific XRDC information for details). The MRC controls memory access using memory region descriptors. MRCFG*d*[NMRGD] indicates the number of region descriptors available for MRC *c*.

Each memory region descriptor defines a memory address range and a configurable access control policy for each domain using a set of four or five 32-bit registers (see Memory ACP evaluation registers).

Memory region descriptors also support including an optional hardware semaphore in the ACP evaluation for memory regions shared by multiple domains (see Hardware semaphores and dynamic access rights).

For a full explanation of the memory region ACP evaluation process, see Memory region ACP evaluation.

### 18.5.2.3 Peripheral access controller (PAC)

The PAC submodule provides domain access control for all peripherals connected to a single peripheral bus. Each XRDC contains the number of PACs indicated in HWCFG0[NPAC]. Each PAC supports up to 128 peripheral slots (see Finding the PDAC slot number for a peripheral). You configure the ACP for each peripheral using a set of PDAC_W*w*_*s* registers (see Peripheral ACP evaluation registers).

Peripheral access control also enable a hardware semaphore to be included in the access control policy evaluation for peripherals shared by multiple domains. See Hardware semaphores and dynamic access rights for more details.

For a full explanation of the peripheral ACP evaluation process, see Peripheral ACP evaluation process.

### 18.5.3 Transaction protection

During application execution, high-level chip modules such as cores or DMA, Ethernet, known as initiators, initiate transaction requests to memory and peripheral resources. XRDC adds protection capabilities to ensure the requesting initiator accesses only the resources that it is authorized to access. These capabilities support security and safety requirements.

XRDC provides this protection by adding two steps to the unprotected transaction flow, as shown in XRDC transaction flow.

XRDC transaction processing differs depending on:

- The type of initiator making the request (see Transaction request sources).
- The type of target receiving the request (see Transaction targets).

**NOTE**

See chip-specific XRDC information for the domain ID of each initiator on chip.

### 18.5.4 XRDC transaction flow

**Table 67. XRDC transaction flow**

| Step | Operation | Performed by | Description |
|---|---|---|---|
| 1 | Transaction request | Initiator | An initiator requests a read or write transaction targeting memory or a peripheral. |
| 2 | Domain assignment | XRDC | XRDC MDAC submodule intercepts the request and performs domain assignment, which adds this metadata to the transaction:<br>• DID<br>• Privileged attribute<br>• Secure attribute |
| 3 | Interconnect | Chip | The chip transmits the domain-assigned transaction request across the interconnect (crossbar). |
| 4 | ACP evaluation | XRDC | XRDC MRC or PAC submodule intercepts the transaction request and evaluates it against the target's ACP to determine whether the requesting initiator has sufficient access rights to the target. If it does, the transaction continues. Otherwise, XRDC generates an access violation error and the transaction terminates. |
| 5 | Transaction response | Target resource | If the previous step does not generate an access violation error, the target resource processes the transaction request and transmits data (for read transactions) and transaction status information (for all transactions) back across the interconnect to the requesting initiator.<br>XRDC is not involved in the flow of information from the target resource back to the requesting initiator. |

### 18.5.5 Domain assignment

#### 18.5.5.1 Overview

Domain assignment associates a DID with each transaction request from an initiator. To determine the DID for a transaction, XRDC evaluates the domain-specific configuration data in the set of MDAC registers (MDA_W*n*_*m*_DFMT0 or MDA_W*n*_*m*_DFMT1) associated with the requesting initiator. The exact process depends on the source of the request (see Transaction request sources).

If the value of MDACFG*m*[NMDAR] is 1, which means a single W*w* register for a given initiator, the specified domain identifier is used directly. In case this value is more than 1, which means there are multiple W*w* registers for a given initiator, MDAC evaluates the conditional terms to determine a "hit". For all W*w* hits, their corresponding domain identifiers are logically summed together (boolean OR). Use cases are typically expected to hit in a single W*w*. Special care is needed if none of the conditional terms hit in any Wn evaluation; in this case, the generated DID = 0 and you must be aware of any potential access rights granted for this DID.

The number of MDAC registers can vary for each initiator. See the chip-specific information. MDACFG*m*[NMDAR] indicates the number of MDA registers, where *m* is the initiator number. You need *m* to locate the registers relevant for domain assignment. See the chip-specific XRDC information for more on initiator numbers. See:

- Register settings for DFMT0 direct domain assignment transactions
- Register settings for DFMT0 PID-based transactions
- Register settings for DFMT1 direct domain assignment transactions

Domain assignment also assigns the secure and privileged attributes to the transaction.

#### 18.5.5.2 PID-based domain assignment

To provide more flexibility in routing core tasks to chip resources in different access-controlled domains, XRDC supports the use of a PID. If the core initiator contains a built-in PID register, indicated by HWCFG2[PIDP*m*] = 1 , XRDC reflects the core PID value in PID*m*[PID], and bit 5 of that field indicates the secure attribute for the transaction request. Otherwise, an application can mimic PID-based domain assignment by writing a value to that field.

#### 18.5.5.3 Transaction request sources

The domain assignment process for an XRDC-protected transaction request depends on the source of the request.

**Table 68. Transaction request sources**

| Request source | Topic | Brief description |
|---|---|---|
| Core initiator | DFMT0 direct domain assignment example | Direct domain assignment using a DFMT0 master domain assignment register. |
| Core initiator | DFMT0 PID-based domain assignment example | PID-based domain assignment using a DFMT0 master domain assignment register. |
| Core initiator | DFMT1 direct domain assignment example-single MDA | Direct domain assignment using a DFMT1 master domain assignment register with single MDA. |

#### 18.5.5.4 DFMT0 core domain assignment registers

**Table 69. DFMT0 core domain assignment registers**

| Register | Index |
|---|---|
| MDACFG*m* | *m* = initiator number. See the chip-specific XRDC information for the available list of initiators with their IDs. |
| MDA_W*w*_*m*_DFMT0[1] | *m* = initiator number.<br>*w* = word (see MDA register structure). MDACFG*m*[NMDAR] indicates the number of MDA registers (words) per initiator. |
| PID*m* | *m* = initiator number. |

1. See MDA register structure.

#### 18.5.5.5 DFMT1 noncore domain assignment registers

**Table 70. DFMT1 noncore domain assignment registers**

| Register | Index |
|---|---|
| MDACFG*m* | *m* = initiator number. See the chip-specific XRDC information for the available list of initiators and their IDs. |
| MDA_W*w*_*m*_DFMT1[1] | *m* = initiator number.<br>*w* = word. MDACFG*m*[NMDAR] indicates the number of MDA registers (words) per initiator. |

1. See MDA register structure.

#### 18.5.5.6 MDA register structure

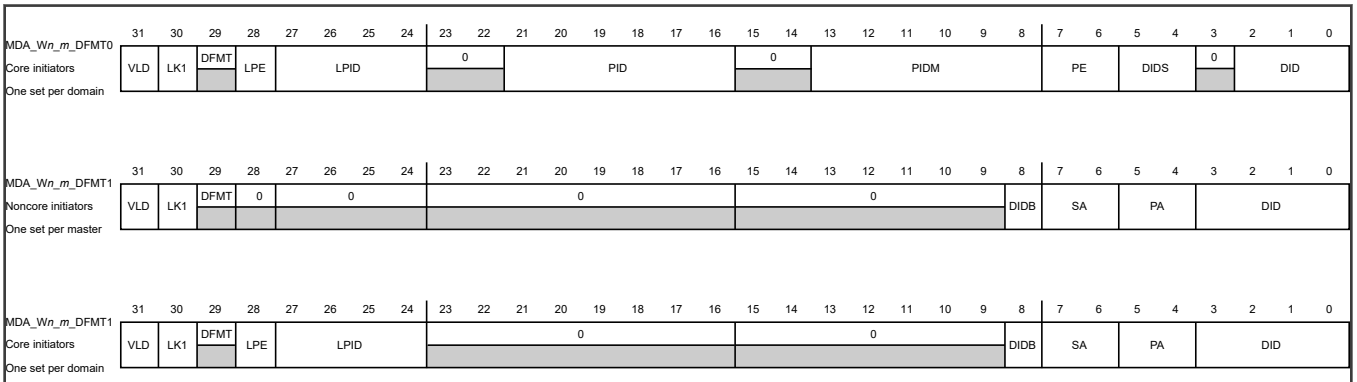

**Figure 40. MDA register structure**

**NOTE**

This XRDC configuration does not have LPE and LPID fields and should be considered as reserved fields.

### 18.5.6 ACP evaluation

#### 18.5.6.1 Overview

When XRDC is not enabled, all peripherals and memories allow unrestricted access. XRDC allows you to limit that access to requests from a particular domain or domains with an application-specified ACP. XRDC intercepts the transaction request and evaluates it against the target's ACP to determine whether the requesting initiator has sufficient access rights to the target, based on the:

- Domain ID assignment (DID)
- Privileged attribute
- Secured attribute

XRDC obtains the target resource's domain ACP from the associated Domain Access Control Policy (D*d*ACP) field (see Domain ACP specification) in the appropriate register set:

- Peripheral ACP evaluation registers
- Memory ACP evaluation registers

If ACP evaluation determines that the transaction request has sufficient access rights to the target resource, XRDC allows the transaction to continue. Otherwise, it terminates the request with an error and captures the address and attribute information in the appropriate error registers.

The exact process depends on the target of the request (see Transaction targets).

XRDC optionally supports the inclusion of a hardware semaphore to dynamically alter the ACP of a memory region or peripheral (see Hardware semaphores and dynamic access rights).

### 18.5.6.2 Transaction targets

The ACP evaluation for an XRDC-protected transaction request depends on the target of the request.

**Table 71. Transaction targets**

| Request target | Topic | Brief description |
|---|---|---|
| Peripheral | Peripheral ACP evaluation example | Process for a transaction request to a target peripheral that is within a protected domain, with ACP evaluation configured by PDAC_W*w*_*s*. |
| Memory | Memory ACP evaluation example | Process for a transaction request to a target memory region that is within a protected domain, with ACP evaluation configured by MRGD_W*w*_*r*. |

### 18.5.6.3 Peripheral ACP evaluation registers

**Table 72. Peripheral ACP evaluation registers**

| Register | Index | Brief description |
|---|---|---|
| PDAC_W0_*s*[1] | *s* = peripheral slot | Specifies the ACP for an XRDC-protected peripheral, and an optional hardware semaphore. |
| PDAC_W1_*s*[1] | *s* = peripheral slot | Enables the set of PDAC registers for the associated peripheral and locks the set. Typically, you configure the peripheral by writing to the PDAC registers and then limiting their respective domains from making updates to the D*d*ACP fields or by locking the set for all updates. |

1. See PDAC register structure.

### 18.5.6.4 PDAC register structure

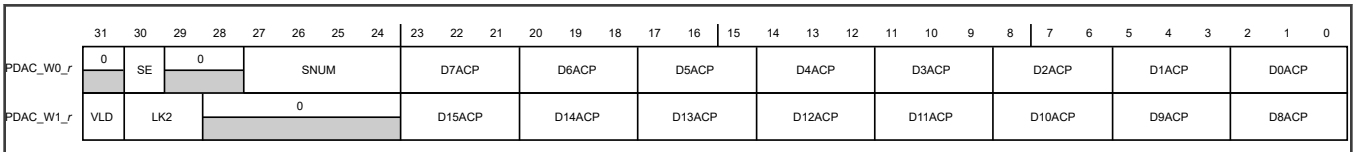

**Figure 41. PDAC register structure**

### 18.5.6.5 Memory ACP evaluation registers

When XRDC is enabled (CR[GVLD] = 1), you cannot access any XRDC-protected memory unless you configure at least one set of memory region descriptors (see MRGD_W*w*_*r*) that includes the targeted memory.

Table 73. Memory ACP evaluation registers

| Register | Index | Brief description |
|---|---|---|
| MRCFG*c* | *c* = memory controller instance | Indicates the number of memory regions per memory controller (NMRGD). Each memory region is configured by a set of memory region descriptor registers (MRGD_W*w*_*r*) described below. |
| MRGD_W0_*r*[1] | *r* = memory region | Specifies starting address for the memory region. |
| MRGD_W1_*r*[1] | *r* = memory region | Specifies ending address for the memory region. |
| MRGD_W2_*r*[1] | *r* = memory region | Specifies the ACP for each supported domain, and an optional hardware semaphore. |
| MRGD_W3_*r*[1] | *r* = memory region | Enables the set of MRGD registers for the associated region and locks the set. Typically, you define the memory region by writing to the MRGD registers and then limiting their respective domains from updating the D*d*ACP fields or by locking the set for all updates. |

1. See MRGD register structure.

### 18.5.6.6 MRGD register structure

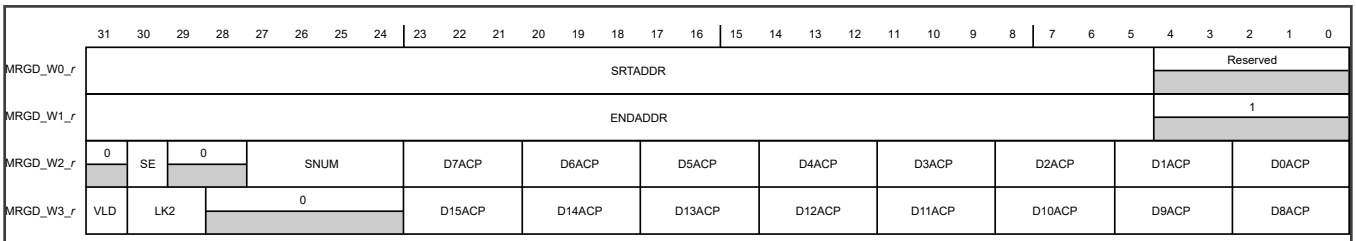

Figure 42. MRGD register structure

### 18.5.6.7 Access control model

XRDC supports a four-level hierarchical access control model. This model combines the traditional privileged (also known as supervisor) and user access levels with an additional signal for the secure attribute of each memory reference, as shown in Access control model levels.

Each level has different access control policies that specify the read and write accessibility for a target. XRDC combines the privileged and secure attributes with the DID assigned to each system bus transaction to form the hardware basis for the access control mechanism. You specify the ACP for target resources using the D*d*ACP fields (see Domain ACP specification) found in the configuration registers shown in Peripheral ACP evaluation registers and Memory ACP evaluation registers.

You can dynamically control access to shared memory regions and target peripherals with the optional inclusion of a hardware semaphore (see Hardware semaphores and dynamic access rights). If you enable this semaphore for a given address space or peripheral, XRDC allows writes to the target resource only if the requesting domain owns the semaphore.

For cores that support only the three-state access control model (Secure Privileged, Secure User, Nonsecure User), XRDC forces the nonsecure output signal from the MDAC submodule to 0 in privileged mode. This change enables precise state transitions between user and privileged modes. Specifically, the MDAC logic for initiator *m* generates the nonsecure attribute output signal as a function of the Three-State Model (PID*m*[TSM]) and PID Present (HWCFG2[PIDP*m*]) fields, as shown in Generation of secure attribute).

#### 18.5.6.7.1 Access control model levels

Table 74. Access control model levels

| Secure | Nonsecure | Privileged (supervisor) | Not privileged (user) | Level |
|---|---|---|---|---|
| Yes | Not applicable | Yes | Not applicable | Most restricted |
| Yes | Not applicable | Not applicable | Yes | More restricted |
| Not applicable | Yes | Yes | Not applicable | Less restricted |
| Not applicable | Yes | Not applicable | Yes | Least restricted |

#### 18.5.6.7.2 Generation of secure attribute

This table shows how XRDC generates the secure attribute for a transaction.

Table 75. Generation of secure attribute

| Access levels [1] | PID*m*[TSM] (b) | PID present [2] | Secure attribute determined by |
|---|---|---|---|
| 4 | 0 | No | Initiator secure attribute |
| 4 | 0 | Yes | Initiator secure attribute && ~initiator privileged attribute |
| 3 | 1 | No | PID*m*[5] && ~initiator privileged attribute |
| 3 | 1 | Yes | Local secure attribute && ~initiator privileged attribute |

1. XRDC assumes a core initiator supports the four-level access model. If a core supports only the three-state access control model, you must write 1 to PID*m*[TSM] before loading any nonsecure value into the PID.
2. Indicated in HWCFG2–3[PIDP*m*].

### 18.5.6.8 Domain ACP specification

Table 76. Domain ACP specification

| D*d*ACP | Allowable accesses | | | |
|---|---|---|---|---|
| | Secure Privileged | Secure User | Nonsecure Privileged | Nonsecure User |
| 111b | R, W | R, W | R, W | R, W |
| 110b | R, W | R, W | R, W | None |
| 101b | R, W | R, W | R | R |
| 100b | R, W | R, W | R | None |
| 011b | R, W | R, W | None | None |
| 010b | R, W | None | None | None |
| 001b | R | R | None | None |
| 000b | None | None | None | None |

#### 18.5.6.9 Memory region ACP evaluation

During ACP evaluation of a memory transaction request, if the target memory location falls within the address range specified by any XRDC memory region descriptor, then XRDC identifies the request as a memory region hit. For each memory region hit, XRDC compares the DID, privileged attribute, and secured attribute of the transaction to the associated domain ACP (MRGD_W{2,3}_*r*[D*d*ACP]) in the memory region descriptor. See ACP evaluation for additional details on this function.

The following conditions cause XRDC to report an access error:

- The target memory location does not fall within any defined memory regions; in other words, the transaction request is not a hit.
- The transaction request does not have the appropriate access permissions for the region, which triggers a domain violation.
- The transaction request hits multiple (overlapping) regions, and all of those regions signal access violations.

Unimplemented domain identifiers default to no access privileges, and therefore the access type of a D*d*ACP field for an unimplemented domain is read-as-zero/writes-ignored (RAZ/WI).

#### 18.5.6.10 Hardware semaphores and dynamic access rights

XRDC memory region descriptors and peripheral access control support an optional hardware semaphore in their access evaluations. This hardware semaphore allows hardware enforcement of dynamic access rights, based on the state of the semaphore for shared memory regions or shared peripherals.

If enabled, the state of the semaphore dynamically modifies the access control policies so that only the domain owning it has write access to the resource. The write permissions for all other domains are revoked based on the semaphore state. If no domain owns the semaphore, the PAC and MRC submodules evaluate DdACP normally.

If you enable a hardware semaphore (by writing 1 to MRGD_W2_*r*[SE] or PDAC_W0_*r*[SE]) then, before the normal DdACP evaluation, XRDC checks the state of the hardware semaphore specified in MRGD_W2_*r*[SNUM] or PDAC_W0_*r*[SNUM].

On a write transaction, if the semaphore is not idle (the semaphore state is non-zero) and the requesting domain does not own the semaphore, the memory or peripheral access terminates with an error. In other words, writes into a semaphore-enabled address space or peripheral are allowed only if the semaphore is idle or the requesting domain owns the semaphore.

### 18.5.7 XRDC transaction examples

To see the complete transaction process for an XRDC-protected transaction request from an initiator to target:

1. Follow one of these examples of domain assignment:
   - DFMT0 direct domain assignment example
   - DFMT0 PID-based domain assignment example
   - DFMT1 direct domain assignment example-single MDA
2. Then follow one of these examples of ACP evaluation:
   - Peripheral ACP evaluation example
   - Memory ACP evaluation example

#### 18.5.7.1 DFMT0 direct domain assignment example

This configuration assigns a specific domain to all incoming transactions.

- A core initiator has initiator number = 6.
- The core has one MDAC register (MDACFG6[NMDAR] = 1), configured as shown in Register settings for DFMT0 direct domain assignment transactions.

MDAC_W*w*_*m*_DFMT0 registers do not include fields for secure and privileged attributes. Those attributes are part of the transaction data from core initiators and are forwarded with the transaction after domain assignment.

#### 18.5.7.1.1 Register settings for DFMT0 direct domain assignment transactions

**Table 77. Register settings for DFMT0 direct domain assignment transactions**

| Field | MDA_W0_6_DFMT0 | Comments |
|---|---|---|
| VLD | 1 | Enables this register for use in domain assignment. |
| LK1 | 1 | Locks the settings in this register until the next module reset. |
| DFMT | 0 | Indicates that this is a DFMT0 register. |
| PID | 00_0000b | Not used because PE = 00b. |
| PIDM | 00_0000b | Not used because PE = 00b. |
| PE | 00b | Disables PID-based filtering. |
| DIDS | 00b | All incoming transactions are to be assigned to the domain specified by the DID field. |
| DID | 01b | Because PE = 00b and DIDS = 00b, all incoming transactions are to be assigned DID value 01b. |

#### 18.5.7.1.2 DFMT0 direct domain assignment process

The application configures XRDC as it boots. After application boot completes, a core issues a read request to a target peripheral.

1. XRDC intercepts the request and performs domain assignment using the configuration in MDA_W0_6_DFMT0. In this example, XRDC assigns DID = 01b to all incoming transactions.
2. The transaction proceeds with DID = 01b and the privileged and secure attributes provided by the core.

### 18.5.7.2 DFMT0 PID-based domain assignment example

This example configuration demonstrates PID-based domain assignment:

- A core initiator with initiator number = 4 processes both safety-critical tasks and routine tasks, using two domains:
  - Domain 0 is reserved for safety-critical tasks (PID = 0–15).
  - Domain 1 is reserved for routine tasks (PID > 15).
- The core has eight MDAC registers (MDACFG4[NMDAR] = 8), configured as follows (see Register settings for DFMT0 PID-based transactions):
  - MDA_W0_4_DFMT0 assigns safety-critical tasks (PID = 0–15) to domain 0.
  - MDA_W1_4_DFMT0 assigns routine tasks (PID = 16–31) to domain 1.
  - MDA_W2_4_DFMT0 assigns routine tasks (PID = 32–63) to domain 1.
  - MDA_W3_4_DFMT0 through MDA_W7_4_DFMT0 are not used.

MDAC_W*w*_*m*_DFMT0 registers do not include fields for secure and privileged attributes. Those attributes are part of the transaction data from core initiators and are forwarded with the transaction after domain assignment.

#### 18.5.7.2.1 Register settings for DFMT0 PID-based transactions

**Table 78. Register settings for PID-based transactions**

| Field | Registers | | | | |
|---|---|---|---|---|---|
| | MDA_W0_4_DFMT0 | MDA_W1_4_DFMT0 | MDA_W2_4_DFMT0 | MDA_W[3–7]_4_DFMT0 | Comments |
| VLD | 1 | 1 | 1 | 0 | Enables this register for use when assigning domains. |
| LK1 | 1 | 1 | 1 | 1 | Locks the settings in each register until the next device reset. |
| DFMT | 0 | 0 | 0 | 0 | Indicates that these registers apply to domain assignment for core initiators. |
| PID | 00_0000b | 01_0000b | 10_0000b | — | Constant match value to be used for PID-based filtering. |
| PIDM | 00_1111b | 10_1111b | 01_1111b | — | Each 0 bit causes the corresponding PID bit to be considered in domain assignment. |
| PE | 10b | 10b | 10b | — | Specifies the type of pattern matching used for PID evaluation. |
| DIDS | 00b | 00b | 00b | — | Assign all incoming transactions with PIDs that pass the filtering criteria to the domain specified by the DID field. |
| DID | 00b | 01b | 01b | — | This DID value is assigned to incoming transactions with PIDs that pass the filtering criteria. |

#### 18.5.7.2.2 DFMT0 PID-based domain assignment process

The application configures XRDC as it boots. After booting completes, a core issues a read request to a target peripheral. The task making the request has PID = 6, indicating that it is a safety-critical task.

1. XRDC intercepts the request and performs domain assignment using each enabled MDA_W*n*_4_DFMT0 register, regardless of whether it has already found a match. In this example, XRDC performs the domain assignments as shown in DFMT0 PID-based domain assignment evaluation.
2. After XRDC completes all domain assignment evaluations, it logically ORs the assigned DIDs to determine the final DID assigned to the transaction. In this example, only one evaluation results in a DID assignment, so there is no OR operation.
3. The transaction proceeds with DID 00b and the privilege and secure attributes provided by the core.

#### 18.5.7.2.3 DFMT0 PID-based domain assignment evaluation

**Table 79. DFMT0 PID-based domain assignment evaluation**

| Register | Evaluation steps | Boolean math | Result |
|---|---|---|---|
| MDA_W0_4_DFMT0 | 1. Bitwise AND of PID with inverted PIDM. | 00_0000b & 11_0000b | 00_0000b |
| | 2. Bitwise AND of transaction PID (PID4[PID]) with inverted PIDM. | 000110b & 11_0000b | 00_0000b |
| | 3. Compare the results of steps 1 and 2. | 00_0000b == 000000b | True: Assign DID 0 |

*Table continues on the next page...*

Table 79. DFMT0 PID-based domain assignment evaluation (continued)

| Register | Evaluation steps | Boolean math | Result |
|---|---|---|---|
| MDA_W1_4_DFMT0 | 1. Bitwise AND of PID with inverted PIDM. | 01_0000b & 01_0000b | 01_0000b |
| | 2. Bitwise AND of transaction PID (PID4[PID]) with inverted PIDM. | 00_0110b & 01_0000b | 00_0000b |
| | 3. Compare the results of steps 1 and 2. | 01_0000b == 00_0000b | False: No DID assignment |
| MDA_W2_4_DFMT0 | 1. Bitwise AND of PID with inverted PIDM. | 10_0000b & 10_0000b | 10_0000b |
| | 2. Bitwise AND of transaction PID (PID4[PID]) with inverted PIDM. | 00_0110b & 10_0000b | 00_0000b |
| | 3. Compare the results of steps 1 and 2. | 10_0000b == 00_0000b | False: No DID assignment |

#### 18.5.7.3 DFMT1 direct domain assignment example-single MDA

This configuration assigns a specific domain to all incoming transactions.

- An initiator has initiator number = 6.
- The initiator has one MDAC register (MDACFG6[NMDAR] = 1) as shown in Register settings for DFMT1 direct domain assignment transactions.

##### 18.5.7.3.1 Register settings for DFMT1 direct domain assignment transactions

Table 80. Register settings for DFMT1 direct domain assignment transactions

| Field | MDA_W0_6_DFMT1 | Comments |
|---|---|---|
| VLD | 1 | Enables this register for use in domain assignment. |
| LK1 | 1 | Locks the settings in this register until the next chip reset. |
| DFMT | 1 | Indicates that this is a DFMT1 register. |
| DIDB | 0b | All incoming transactions are to be assigned to the domain that the DID field specifies. |
| SA | 10b | All incoming transactions retain their Secure attribute value. |
| PA | 10b | All incoming transactions retain their Privileged attribute value. |
| DID | 01b | Because DIDB = 0b, all incoming transactions are to be assigned DID value 01b. |

##### 18.5.7.3.2 DFMT1 direct domain assignment process

The application configures XRDC as it boots. After application boot completes, an initiator issues a read request to a target peripheral.

1. XRDC intercepts the request and assigns a domain using the configuration in MDA_W0_6_DFMT1. In this example, XRDC assigns DID = 01b to all incoming transactions.
2. The transaction proceeds with DID = 01b and the privileged and secure attributes provided by the initiator.

#### 18.5.7.4 Peripheral ACP evaluation example

This example configuration demonstrates ACP evaluation for a target peripheral.

- The core initiator must have exclusive access to the ADC0 peripheral for safety-critical tasks in domain 0.
- The core initiator supports 8 domains (HWCFG0[NDID] = 111b).
- ADC occupies PDAC slot 40 in the chip, as defined in an example memory map file (see Finding the PDAC slot number for a peripheral).
- Given 8 domains and PDAC slot 40, the PDAC registers associated with ADC0 are PDAC_W0_40 and PDAC_W1_40.

The following sections describe the register configurations for this example.

#### 18.5.7.4.1 Finding the PDAC slot number for a peripheral

This topic shows how to find the PDAC slot number for a peripheral, but it is a generic example. Memory map file organization and appearance can vary.

To find the PDAC slot number for a peripheral:

1. Open the memory map file attached to this document and view the peripherals page.
2. Locate the peripheral in the "Instance" column.
3. The PDAC slot number for the peripheral is at the intersection of the "PDAC slot number" column and the peripheral row.

In this figure, for peripheral ADC_0, the PDAC slot number is 40. Therefore, the PDAC registers for ADC0 are PDAC_W*w*_40.

| | A | B | D | E | I | J |
|---|---|---|---|---|---|---|
| 1 | Instance | Description | Start address | End address | PDAC slot number | AIPS instance |
| 8 | LCU_0 | Logic Control Unit 0 | 0x40098000 | 0x4009BFFF | 38 | AIPS_0 |
| 9 | LCU_1 | Logic Control Unit 1 | 0x4009C000 | 0x4009FFFF | 39 | AIPS_0 |
| 10 | ADC_0 | Analog-to-digital converter 0 | 0x400A0000 | 0x400A3FFF | 40 | AIPS_0 |
| 11 | ADC_1 | Analog-to-digital converter 1 | 0x400A4000 | 0x400A7FFF | 41 | AIPS_0 |
| 12 | ADC_2 | Analog-to-digital converter 2 | 0x400A8000 | 0x400ABFFF | 42 | AIPS_0 |

**Figure 43. Finding the PDAC slot number for a peripheral**

#### 18.5.7.4.2 Register settings for peripheral ACP evaluation

This table shows the PDAC_W*w*_40 settings for a safety-critical task assigned to domain 0.

**Table 81. Register settings for peripheral ACP evaluation**

| Register | Field | Value (b) | Comments |
|---|---|---|---|
| PDAC_W0_40 | SE | 0 | The hardware semaphore (see the SEMA42 chapter) is disabled. |
| | SNUM | (don't care) | The hardware semaphore is not used in this example. |
| | D7ACP | 000 | Domain 7 has no access to the peripheral. |
| | D6ACP | 000 | Domain 6 has no access to the peripheral. |
| | D5ACP | 000 | Domain 5 has no access to the peripheral. |
| | D4ACP | 000 | Domain 4 has no access to the peripheral. |
| | D3ACP | 000 | Domain 3 has no access to the peripheral. |
| | D2ACP | 000 | Domain 2 has no access to the peripheral. |

*Table continues on the next page...*

Table 81. Register settings for peripheral ACP evaluation (continued)

| Register | Field | Value (b) | Comments |
|---|---|---|---|
| | D1ACP | 000 | Domain 1 has no access to the peripheral. |
| | D0ACP | 010 | Only privileged, secure transactions from domain 0 have access. |
| PDAC_W1_40 | VLD | 1 | Use this register set in domain ACP evaluations. |
| | LK2 | 11 | Lock the settings in this register until the next device reset. |

#### 18.5.7.4.3 Peripheral ACP evaluation process

XRDC performs the following process for ACP evaluation:

1. When the application is running, the core issues a read request to a target peripheral. The task making the request has PID = 0, indicating that it is a safety-critical task. The transaction request is privileged and secured.
2. Between the chip interconnect and ADC0, XRDC intercepts the request and compares its DID, privileged attribute, and secured attribute to the configuration in PDAC_W0_40 and PDAC_W1_40.
3. Because the ADC0 D0ACP field is 010b for privileged, secured access, XRDC grants access to the transaction.
4. The transaction proceeds normally without any further intervention from XRDC.

### 18.5.7.5 Memory ACP evaluation example

This example configuration demonstrates ACP evaluation for a target memory. Following are the desired features:

- The core initiator must have exclusive access to the memory region for safety-critical tasks in domain 0.
- The target memory is the address range 1B00_0000h–1B00_1FFFh, protected by memory controller 0 (MRC0), for example.
- Access to the entire memory range will be controlled by the memory region descriptor defined by MRGD_W*w*_0.
- The requested transaction is secure privileged.

With the configuration settings shown in Register settings for memory ACP evaluation, XRDC grants access and the transaction proceeds normally. There is no further XRDC intervention.

#### 18.5.7.5.1 Register settings for memory ACP evaluation

Table 82. Register settings for memory ACP evaluation

| Register | Field | Value | Comments |
|---|---|---|---|
| MRGD_W0_0 | SRTADDR | 1B00_0000h | Starting address of the memory region. |
| MRGD_W1_0 | ENDADDR | 1B00_1FFFh | Ending address of the memory region. |
| MRGD_W2_0 | SE | 0 | The hardware semaphore (see the SEMA42 chapter) is disabled. |
| | SNUM | (don't care) | The hardware semaphore is not used in this example. |
| | D7ACP | 000b | Domain 7 has no access to the peripheral. |
| | D6ACP | 000b | Domain 6 has no access to the peripheral. |
| | D5ACP | 000b | Domain 5 has no access to the peripheral. |
| | D4ACP | 000b | Domain 4 has no access to the peripheral. |
| | D3ACP | 000b | Domain 3 has no access to the peripheral. |

*Table continues on the next page...*

Table 82. Register settings for memory ACP evaluation (continued)

| Register | Field | Value | Comments |
|---|---|---|---|
| | D2ACP | 000b | Domain 2 has no access to the peripheral. |
| | D1ACP | 000b | Domain 1 has no access to the peripheral. |
| | D0ACP | 010b | Only privileged, secure transactions from domain 0 have access. |
| MRGD_W3_0 | VLD | 1 | Use this register set in domain ACP evaluations. |
| | LK2 | 11b | Lock the settings in this register until the next device reset. |

#### 18.5.7.5.2 Memory ACP evaluation process

In this example, XRDC performs the following process for ACP evaluation:

1. When the application is running, the core issues a read request to address 1B00_0100h. The transaction request is secure privileged.
2. Between the chip interconnect and the memory, XRDC intercepts the request and compares its DID, memory location of the address, privileged attribute, and secured attribute to the configuration in MRGD_W0_0, MRGD_W1_0, MRGD_W2_0 and MRGD_W3_0.
3. Because the address 1B00_0100h is in the memory range 1B00_0000h–1B00_1FFFh and its D0ACP field is 010b for privileged, secured access, XRDC grants access to the transaction.
4. The transaction proceeds normally without any no further intervention from XRDC.

### 18.5.8 Clocking

This module has no clocking considerations.

### 18.5.9 Interrupts

This module outputs an interrupt signal which can be connected to interrupt controller. Check chip-specific interrupt assignment for details. Interrupt is asserted on detection of access violation by any checker, and it remains asserted until DERRLOC registers are cleared.

## 18.6 Initialization information

Out of reset, XRDC is disabled (CR[GVLD] = 0), which allows secure privileged startup code to configure the entire programming model.

### 18.6.1 Initialization procedure

1. Read the hardware configuration registers to obtain the implemented XRDC hardware capabilities for the chip:
   - HWCFG0
   - HWCFG1
   - HWCFG2
   - MDACFG*m* (one for each supported bus initiator—number indicated in HWCFG0[NMSTR])
   - MRCFG*c* (one for each supported memory controller—number indicated in HWCFG0[NMRC])
2. Use the information retrieved in step 1 and the desired domain architecture to configure:
   - Domain assignments (MDA_W*w_m*_DFMT0 and MDA_W*w_m*_DFMT1)
   - Memory region descriptors (MRGD_W*w_n*)

- Peripheral access control (PDAC_W*w*_*s*)

Ensure that you enable the necessary registers and register sets using the appropriate VLD fields. Also, you can limit access to these registers or lock them after you configure them, by using the appropriate LK1 fields.

3. Enable XRDC (write 1 to CR[GVLD]).

XRDC is now fully operational.

### 18.6.2 Minimize access errors

When you configure and enable XRDC, it begins generating DIDs for transaction requests and evaluating access rights at the target memory and peripheral resources. Because of the distributed design hierarchy and the pipelined nature of the hardware system bus fabric, it can take multiple cycles for a generated DID to propagate. Until that happens, XRDC uses the initiator's default DID. Depending on the programmed ACPs, the default DID might generate an access error response.

If XRDC generates incorrect error responses, you can use the following approaches to minimize or eliminate these extraneous access errors:

- Minimize the amount of system bus traffic when XRDC is enabled (CR[GVLD] = 1).
- Ensure that all target memory addresses provide sufficient access rights for any default DIDs and for the newly programmed DIDs. After XRDC is fully operational, as confirmed by a read of HWCFG1, you can remove the permissions for the default DIDs.
- Try to have the bus initiator that programs and configures XRDC use the same DID, that is, its default DID, for both initialization and configuration, besides normal system operation. You do this when you define the DID assignments for the system.

## 18.7 Application information

### 18.7.1 Master domain assignments

The typical use case for master domain assignments is to include one or more core bus initiators in a single domain, possibly combined with other noncore bus initiator modules such as DMA. This configuration may be static or may be changed dynamically to select between a small number of domains. HWCFG0[NDID] indicates the maximum number of supported domains. XRDC also supports the optional use of PIDs to create multiple classes of cores, each in different domains.

For example, you can group critical tasks—safety-critical, performance-critical, and so on—into one domain and all other tasks into a second domain. Typically, you assign the DID at initialization, but you can also reconfigure domain assignment while the application is running.

A core bus initiator typically has multiple MDA_W*w*_*m*_DFMT0 registers associated with it.

A noncore bus initiator typically has a single MDA_W*w*_*m*_DFMT1 register associated with it.

The master domain assignment, memory region descriptor, and peripheral domain access control registers have lock fields that enable you to limit access to, or to lock, the registers. These actions protect the configuration.

### 18.7.2 Memory region descriptor management

There are two important concepts to consider for managing the memory region descriptors.

Each MRC*c* configuration is chip-specific. See the chip-specific XRDC information for the number of implemented memory region descriptors (MRGD_W*w*_*n*) in a given MRC*c* instance, and the specific port numbers associated with the target memories being monitored.

Second, as detailed in Memory region ACP evaluation, after you enable the XRDC, a memory reference must hit one or more of the configured regions. Otherwise, the transaction results in an access violation. Two other conditions also result in access errors:

- The access hits a single region descriptor and that region signals a domain violation.
- The access hits multiple (overlapping) regions and all regions signal violations.

The second condition reflects that XRDC gives priority to permission granting over access denying for overlapping regions. This approach provides more flexibility to system software in memory region descriptor assignments.

## 18.7.3 Domain error capture management

### 18.7.3.1 Domain error capture registers

When an MRC or PAC detects a domain access violation, XRDC captures information about the transaction in the following registers:

**Table 83. Domain error capture registers**

| Register[field] | Index | Information |
|---|---|---|
| DERRLOC*d*[MRCINST] | *d* = DID | Domain error location for MRC instances, with asserted bits indicating which MRC instance numbers are reporting an error |
| DERRLOC*d*[PACINST] | *d* = DID | Domain error location for PAC instances, with asserted bits indicating which PAC instance numbers are reporting an error |
| DERR_W0_*i* | *i* = instance number | Transaction target address |
| DERR_W1_*i* | *i* = instance number | Additional information about the transaction |
| DERR_W3_*i* | *i* = instance number | Reset and rearm domain error capture for the instance |

### 18.7.3.2 Handling domain access violation errors

When an MRC or PAC instance detects a domain access violation, it reports the error by asserting the associated bit in DERRLOCd[MRCINST] or [PACINST], and XRDC asserts the error interrupt output. To retrieve information about the error, the error handler must:

1. Read each DERRLOC*d* register until it finds a non-zero MRCINST or PACINST value.

   The index of the DERRLOC*d* register is the DID for the domain in which the error occurred.

2. Configure the domain assignment for the master executing the exception handler (MDA_Ww_m_DFMTf[DID]) to assign the DID that corresponds to the DERRLOC*d* register index, such that the DERR_Ww_i registers show the error for that domain.

3. Read HWCFG1[DID] to be sure the error handler is now operating in the correct domain. In other words, make sure HWCFG1[DID] equals the value written to MDA_Ww_m_DFMTf[DID].

4. Find the number of an MRC or PAC instance reporting an error by parsing DERRLOC*d*[MRCINST] and DERRLOC*d*[PACINST] for an asserted bit.

   There may be multiple access violations, across multiple MRC or PAC instances, pending for a given domain. To quickly find the lowest numbered instance reporting an access violation, execute a "find first one bit" instruction (alternatively known as "count leading zeroes") on the MRCINST and PACINST fields.

5. Retrieve the error address (DERR_W0_*i*[EADDR]).

6. Retrieve the error information (DERR_W1_*i*).

   More than one error may have occurred in the MRC or PAC instance, as indicated by the error status (DERR_W1_*i*[EST] = 11b). If more than one error has occurred in the instance, XRDC captures data only for the first error.

7. Use the error address and information to handle the error (whatever that may require).

8. Reset the DERR_W*w*_*i* registers and rearm error capture (write 1b to DERR_W3_*i*[RECR]).

   Rearming error capture deasserts the instance bit in DERRLOC*d*.

9. Repeat steps 1 and 8 for each asserted bit in PACINST and MRCINST until there are no more asserted bits.

Domain error retrieval illustrates an example error retrieval.

#### 18.7.3.3 Domain error retrieval

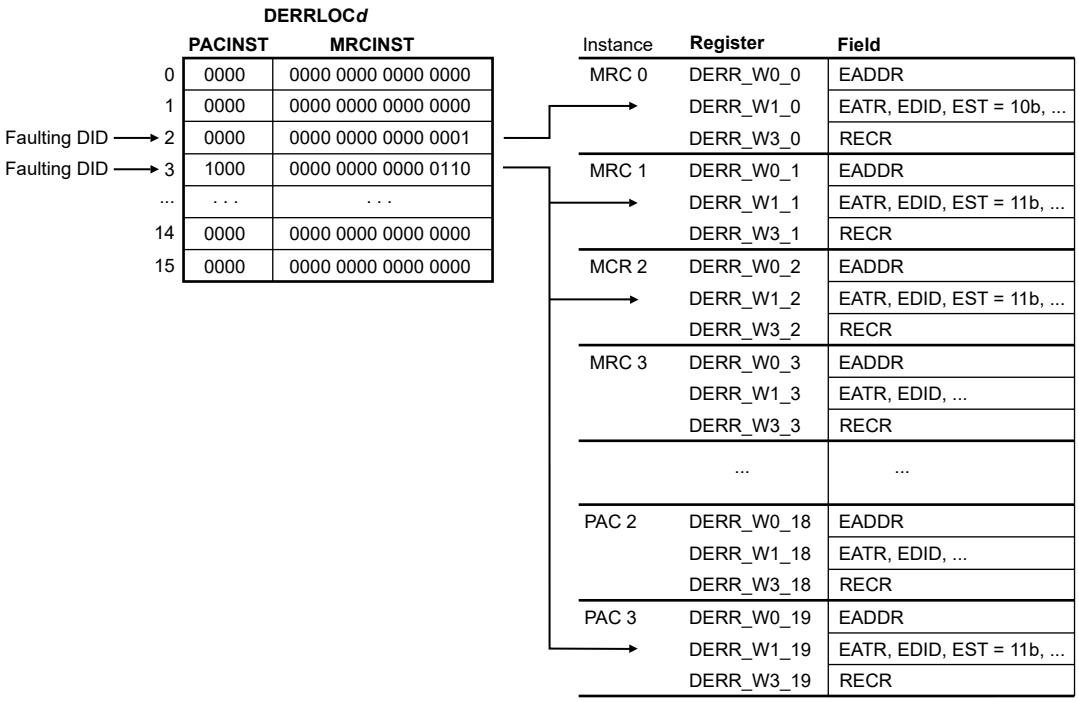

Figure 44. Domain error retrieval

## 18.8 Memory map and register definitions

### 18.8.1 Register organization

XRDC registers are partitioned into these groups:

- Basic hardware control and configuration
- Domain errors (including location and details)
- Master domain assignments
- Peripheral domain access controls
- Memory region descriptors

### 18.8.2 Register access guidelines

The following guidelines apply to XRDC register access:

- You can access the XRDC registers only in secure, privileged access mode.
- Unless stated otherwise, the registers support 8-, 16-, and 32-bit reads, and 32-bit writes.
- Unless stated otherwise, XRDC terminates the following access attempts with an error:
  - Accesses in a different access mode
  - Unsupported write data size
  - Writes to read-only resources

- Writes to reserved address spaces

- Accesses to these memory map holes return an error:
  - Any access to a register that does not exist
  - Holes in the 0–F0h and DERR to PID register space
  - For MDAC, gaps in the master domain assignment (MDA_W*w*_*m*_DFMT*n*) registers
  - For MRCs, any gap in the MRGD_W*w*_*r* registers (for example, if there are four memory region descriptors, attempted access to a fifth descriptor fails)
- Accesses to these memory map holes do not return a bus error:
  - MRCs: Memory region descriptors occupy only four words but have an additional four words of address available: words 4–7
  - PDAC: Registers associated with unimplemented PDAC slots
- Read accesses to these memory map holes do not return a bus error:
  - Offset F8h and FCh
  - Offset 100–13Fh
  - Offset 140–14Fh
  - Offset 200–23Ch

## 18.8.3 XRDC register descriptions

### 18.8.3.1 XRDC memory map

XRDC base address: 4027_8000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Control (CR) | 32 | RW | 0000_008Ah |
| F0h | Hardware Configuration 0 (HWCFG0) | 32 | R | 1202_0502h |
| F4h | Hardware Configuration 1 (HWCFG1) | 32 | R | See section |
| F8h | Hardware Configuration 2 (HWCFG2) | 32 | R | 0000_0000h |

| | 0b - No effect<br>1b - Locks |
| 29-9<br>— | Reserved |
| 8<br>VAW | Virtualization Aware<br>Indicates whether domain assignments support the optional inclusion of a logical partition identifier, which is also known as an operating system number or Arm virtual machine identifier (VMID).<br>0b - Not virtualization-aware<br>1b - Virtualization-aware |
| 7<br>MRF | Memory Region Format<br>Indicates the format of memory region descriptors.<br>0b - Reserved<br>1b - SMPU family format |
| 6-5<br>— | Reserved |
| 4-1<br>HRL | Hardware Revision Level<br>Indicates the XRDC hardware revision level, which is associated with a set of functional characteristics of the module. |
| 0<br>GVLD | Global Valid (XRDC Global Enable/Disable)<br>Enables XRDC. When XRDC is disabled, all bus initiators can access all targets.<br>0b - Disables<br>1b - Enables |

### 18.8.3.3 Hardware Configuration 0 (HWCFG0)

#### Offset

| Register | Offset |
|---|---|
| HWCFG0 | F0h |

#### Function

Indicates XRDC configuration details, including:

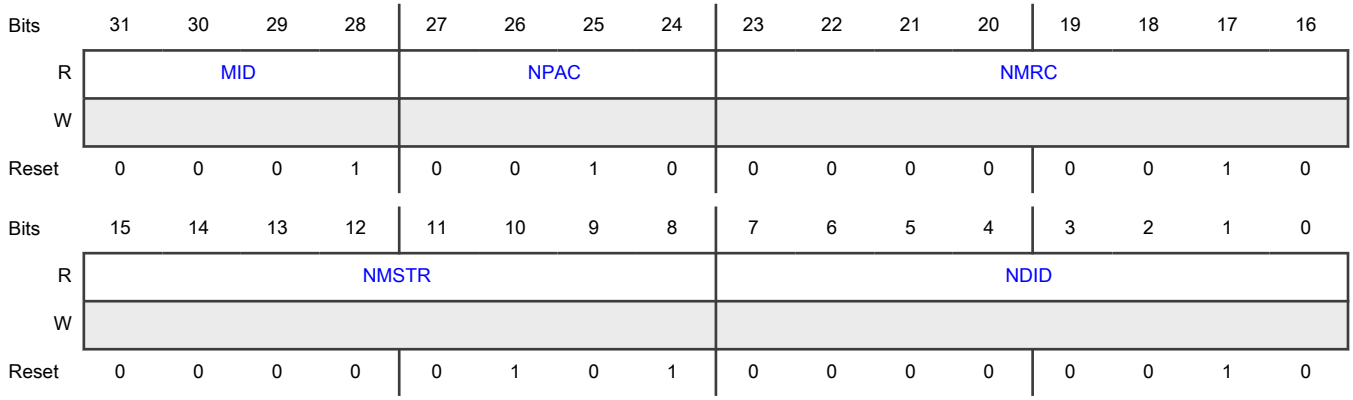
- XRDC module ID
- Number of implemented domains

- Number of bus initiators
- Number of MRCs
- Number of PACs

Attempting to write to this register causes an error.

Access: Secure privileged read

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-28<br>MID | Module ID |
| 27-24<br>NPAC | Number Of PACs<br>Indicates the number of PACs minus 1. In other words, the actual number of PACs is NPAC + 1. |
| 23-16<br>NMRC | Number of MRCs<br>Indicates the number of MRCs minus 1. In other words, the actual number of MRCs is NMRC + 1. |
| 15-8<br>NMSTR | Number Of Bus Initiators<br>Indicates the number of bus initiators minus 1. In other words, the actual number of bus initiators is NMSTR + 1. |
| 7-0<br>NDID | Number Of DIDs<br>Indicates the number of domains (DIDs) minus 1. In other words, the actual number of DIDs is NDID + 1. |

## 18.8.3.4 Hardware Configuration 1 (HWCFG1)

### Offset

| Register | Offset |
|---|---|
| HWCFG1 | F4h |

### Function

Indicates the DID of the bus initiator making the current transaction request. See Domain error capture management for information about typical usage.

Attempting to write to this register causes an error.

Access: Secure privileged read

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | 0 | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| R | 0 | | | | | | | | | | | | DID | | | |
| W | | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | u[1] | u | u | u |

1. The reset value is determined by the current configuration of the accessing initiator.

### Fields

| Field | Function |
|---|---|
| 31-4<br>— | Reserved |
| 3-0<br>DID | Domain Identifier<br>Indicates the DID of the requesting bus initiator. |

## 18.8.3.5 Hardware Configuration 2 (HWCFG2)

### Offset

| Register | Offset |
|---|---|
| HWCFG2 | F8h |

### Function

For initiators 0–31, indicates whether a given initiator has a built-in PID register as part of its programming model. If not, you must use the corresponding PIDm register to mimic the functionality of a built-in PID register.

Each bit corresponds to the same numbered initiator. For example, if PIDP18 is 1, bus initiator 18 has its own PID register. If PIDP18 is 0, then initiator 18 does not have its own PID register and you must use PID18.

Attempting to write to this register causes an error.

Access: Secure privileged read

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

### Fields

| Field | Function |
|---|---|
| 31-0<br>PIDPn | Process Identifier Present<br>0b - Does not have PID register<br>1b - Has PID register |

## 18.8.3.6 Master Domain Assignment Configuration (MDACFG0 - MDACFG5)

### Offset

| Register | Offset |
|---|---|
| MDACFG0 | 100h |
| MDACFG1 | 101h |
| MDACFG2 | 102h |
| MDACFG3 | 103h |
| MDACFG5 | 105h |

### Function

Indicates the number of implemented master domain assignment registers (MDA_W*w*_*m*_DFMT0 or MDA_W*w*_*m*_DFMT1) for initiator *m*, where *m* ranges from 0 to 63. You can read these registers using 8-, 16-, or 32-bit accesses.

If NMDAR is 0, the associated initiator does not exist.

Attempting to write to this register causes an error.

Access: Secure privileged read

### Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R | NCM | 0 | | | NMDAR | | | |
| W | | | | | | | | |
| Reset | See Register reset values. | | | | | | | |

### Register reset values

| Register | Reset value |
|---|---|
| MDACFG0 | 01h |
| MDACFG1–MDACFG2 | 81h |
| MDACFG3 | 01h |
| MDACFG4 | — |
| MDACFG5 | 81h |

### Fields

| Field | Function |
|---|---|
| 7<br>NCM | Noncore Master<br>If NMDAR is greater than zero, indicates whether initiator *m* uses MDA_W*w*_*m*_DFMT0 or MDA_W*w*_*m*_DFMT1 to configure domain assignment.<br>This field is 0 for a non-existent initiator.<br>0b - Core initiator or initiator does not exist<br>1b - Noncore initiator |
| 6-4<br>— | Reserved |
| 3-0<br>NMDAR | Number Of Master Domain Assignment Registers<br>Indicates the number of master domain assignment registers (MDA_W*w*_*m*_DFMT0 or MDA_W*w*_*m*_DFMT1) associated with initiator *m*.<br>0000b - Initiator does not exist<br>0001b-1000b - Number of registers<br>All other values are reserved. |

### 18.8.3.7 Memory Region Configuration (MRCFG0 - MRCFG2)

#### Offset

| Register | Offset |
|---|---|
| MRCFG0 | 140h |
| MRCFG1 | 141h |
| MRCFG2 | 142h |

#### Function

Indicates the number of memory region descriptors (*r*) for MRC*c*, from 4 to 16 in increments of four, with 0 indicating a non-existent MRC. These registers are organized as byte-sized data arrays and can be read using 8-, 16-, or 32-bit accesses.

Attempting to write to this register causes an error.

Access: Secure Privileged Read

#### Diagram

| Bits | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| R | 0 | | | | NMRGD | | | |
| W | | | | | | | | |
| Reset | See Register reset values. | | | | | | | |

#### Register reset values

| Register | Reset value |
|---|---|
| MRCFG0–MRCFG1 | 10h |
| MRCFG2 | 04h |

#### Fields

| Field | Function |
|---|---|
| 7-5<br>— | Reserved |
| 4-0<br>NMRGD | Number Of Memory Region Descriptors<br>Indicates the number of memory region descriptors associated with the MRC.<br>0_0000b - MRC does not exist<br>0_0100b - 4<br>0_1000b - 8 |

*Table continues on the next page...*

### 18.8.3.8 Domain Error Location (DERRLOC0 - DERRLOC2)

#### Offset

| Register | Offset |
|---|---|
| DERRLOC0 | 200h |
| DERRLOC1 | 204h |
| DERRLOC2 | 208h |

#### Function

Indicates the MRC or PAC instance in domain *d* where an access violation has occurred. Each bit corresponds to the like-numbered instance. For more information, see Domain error capture management.

Attempting to write to this register causes an error.

Access: Secure privileged read

#### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Field | Function |
|---|---|
| 19-16<br>PACINST | PAC Instance<br>Indicates the presence of a detected access violation for domain *d* in a PAC instance. Each bit corresponds to the instance index for the DERR_W*w*_*i* registers: bit 16 of the register corresponds to the DERR_W*w*_*16* registers, which show error information for PAC 0, and so on. Multiple bits can be 1 at any time, indicating access violations have been detected across multiple PACs.<br>For each bit in this field:<br>0b - No access violation error or the PAC instance is not physically present<br>1b - Access violation detected |
| 15-0<br>MRCINST | MRC Instance<br>Indicates the presence of a detected access violation for domain *d* in an MRC instance. Each bit corresponds to the like-numbered MRC instance: bit 0 (bit 0 of the register) corresponds to MRC instance 0, and so on. Multiple bits can be 1 at any time, indicating access violations have been detected across multiple MRCs.<br>For each bit in this field:<br>0b - No access violation error or the MRC instance is not physically present<br>1b - Access violation detected |

### 18.8.3.9 Domain Error Word 0 (DERR_W0_0 - DERR_W0_18)

#### Offset

| Register | Offset |
|---|---|
| DERR_W0_0 | 400h |
| DERR_W0_1 | 410h |
| DERR_W0_2 | 420h |
| DERR_W0_16 | 500h |
| DERR_W0_17 | 510h |
| DERR_W0_18 | 520h |

#### Function

Indicates the address of an access violation detected by an MRC or a PAC, indexed by the MRC or PAC instance (*i*) that detected the violation, as indicated in DERRLOC*d*. This register is part of a 16-byte set:

- DERR_W0_*i*: Word 0, the first 4 bytes
- DERR_W1_*i*: Word 1, the second 4 bytes
- Word 2, 4 reserved bytes
- DERR_W3_*i*: Word 3, the fourth 4 bytes

The first 16 sets (*i* from 0 to 15) are associated with MRCs and the rest (starting with *i* = 16) are associated with PACs. For more information, see Domain error capture management.

The error capture registers in the memory region controller and peripheral access controller submodules contain physical registers for each domain, but are organized in the DERR_Wn registers to provide the information for the requesting domain only. The registers return the error information for the domain id that is used to read the registers. When no error occurred for this domain id, it returns 0 data.

When the error capture logic is rearmed by writing the required data pattern to DERR_W3_n, this register is cleared.

When XRDC detects an access violation, it captures the error information and disables subsequent updates to the error capture registers until you write to DERR_W3_*i*.

**NOTE**

If initiators with the same DID cause simultaneous error accesses, the error capture registers record only the error of the lowest target index.

Attempting to write to this register causes an error. Attempting to read the error registers for a non-existent MRC or PAC instance causes an error.

Access: Secure privileged read

| 7-4<br>— | Reserved |
| 3-0<br>EDID | Error Domain Identifier<br>Indicates the DID of the access violation. |

### 18.8.3.11 Domain Error Word 3 (DERR_W3_0 - DERR_W3_18)

#### Offset

| Register | Offset |
|---|---|
| DERR_W3_0 | 40Ch |
| DERR_W3_1 | 41Ch |
| DERR_W3_2 | 42Ch |
| DERR_W3_16 | 50Ch |
| DERR_W3_17 | 51Ch |
| DERR_W3_18 | 52Ch |

#### Function

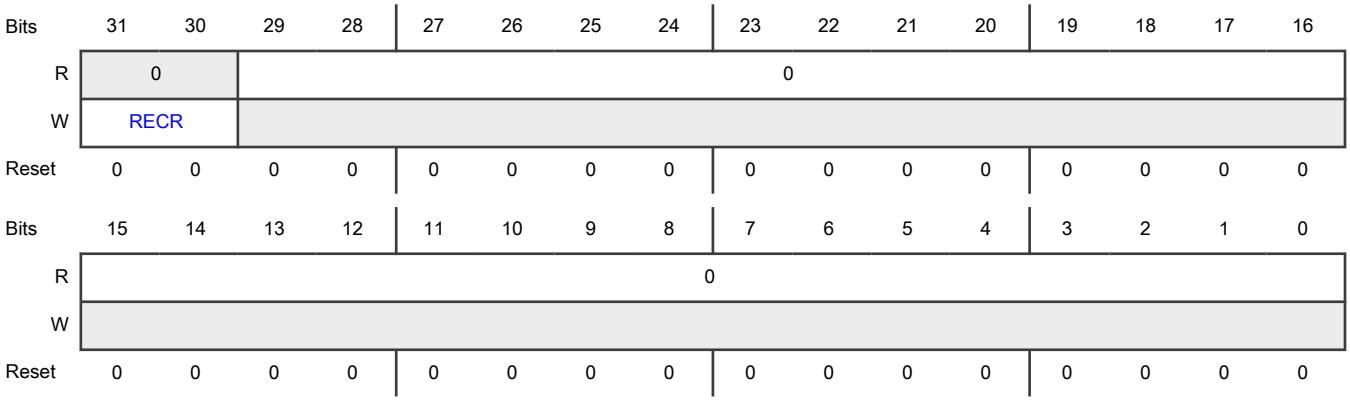
Rearms instance error capture, resets the error capture registers (DERR_W0_*d*, DERR_W1_*d*), and deasserts the instance bit in DERRLOC*d*. After reading the access violation error information, an error handler must write 1 to RECR.

Register write only rearms error capture registers for the domain id that is used to write this register.

This register returns 0000h when read. Attempted reads of an MRC or PAC instance that is not physically present cause an error.

For more information, see Domain error capture management.

#### Diagram



#### Fields

| Field | Function |
|---|---|
| 31-30 | Rearm Error Capture Registers |
| RECR | Resets and rearms the domain error capture registers for this instance, including deasserting the instance bit in DERRLOC*d*.<br>00b,10b,11b - No effect<br>01b - Rearms error capture, resets error capture registers, and deasserts instance bit in DERRLOCd |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| 29-0<br>— | Reserved |

### 18.8.3.12 Process Identifier (PID0 - PID3)

#### Offset

| Register | Offset |
|---|---|
| PID0 | 700h |
| PID3 | 70Ch |

#### Function

Specifies the PID for the associated core initiator *m*.

Some cores contain a built-in PID register. If the core has a built-in PID register, XRDC populates the PID field with the value from the core PID register. If the core does not have the built-in register, the XRDC PID register allows applications to mimic PID operation for that core by writing the desired PID to the associated register.

HWCFG2 provides a bitmap of the implemented PID*m* registers. Noncore initiators do not have an associated PID register.

For information about PID-based operation, see PID-based domain assignment.

### Function

In conjunction with PDAC_W1_*s*, specifies the ACP configuration for peripheral slot *s*. The ACP controls access to the peripheral by all initiators within the domain. For the available ACPs, see Domain ACP specification. For more information, see Peripheral access controller (PAC).

Access: Secure privileged read/write

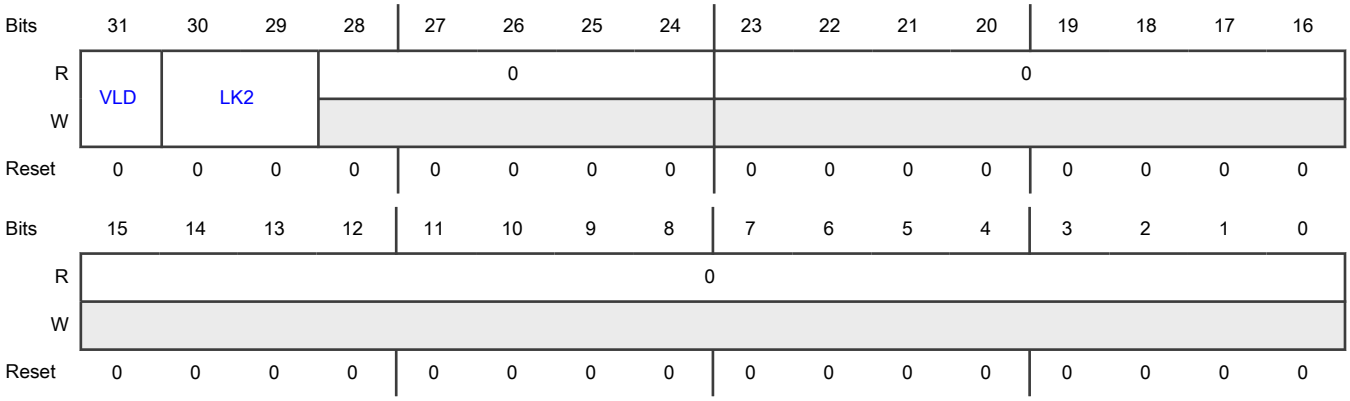
### Function

In conjunction with PDAC_W0_*s*, specifies the ACP configuration for peripheral slot *s*.

Access: Secure privileged read/write

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>VLD | Valid<br>Specifies whether this domain assignment is valid. In other words, if VLD and CR[GVLD] are both asserted, XRDC uses the configuration in this pair of registers. If either CR[GVLD] or this field is 0, all accesses to the peripheral are allowed. To support a coherent register state, any write to PDAC_W0_*s* forces this field to zero.<br>This field has no effect unless XRDC is enabled (CR[GVLD] = 1).<br>0b - Invalid<br>1b - Valid |
| 30-29<br>LK2 | Lock<br>Limits or prohibits writes to the set of PDAC words (PDAC_W0_*s* and PDAC_W1_*s*) for this peripheral slot.<br>When you assert a bit in this field, it remains asserted until the next module reset.<br>00b-01b - Both words can be written to<br>10b - Domain d can update only its associated DdACP field—all other fields are read-only<br>11b - Locks (both words are read-only) |
| 28-24<br>— | Reserved |
| 23-0<br>— | Reserved |

## 18.8.3.17 Memory Region Descriptor Word 0 (MRGD_W0_0 - MRGD_W0_35)

### Offset

Registers in this array exist only for the following combinations of index values.

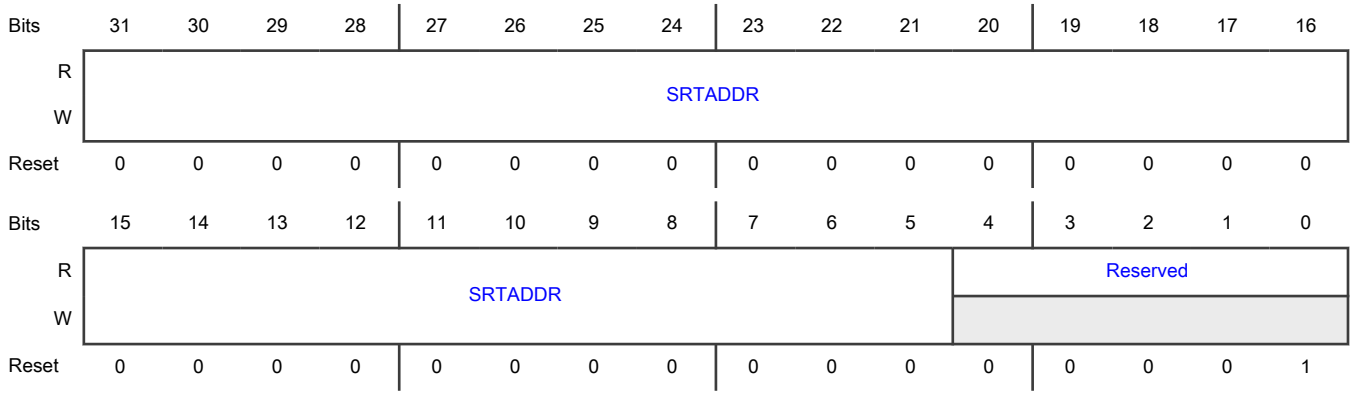
| Index *n* | Index *m* |
|---|---|
| 0–1 | 0–15 |
| 2 | 0–3 |

| Register | Offset |
|---|---|
| MRGD_W0_(n * 16 + m) | 2000h + (n × 200h) + (m × 20h) |

### Function

Specifies the starting address of memory region *r*.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-5<br>SRTADDR | Start Address<br>Specifies the most significant bits of the 0-modulo 32-byte start address of the memory region. The minimum region size is 32 bytes. |
| 4-0<br>— | Reserved |

## 18.8.3.18 Memory Region Descriptor Word 1 (MRGD_W1_0 - MRGD_W1_35)

### Offset

Registers in this array exist only for the following combinations of index values.

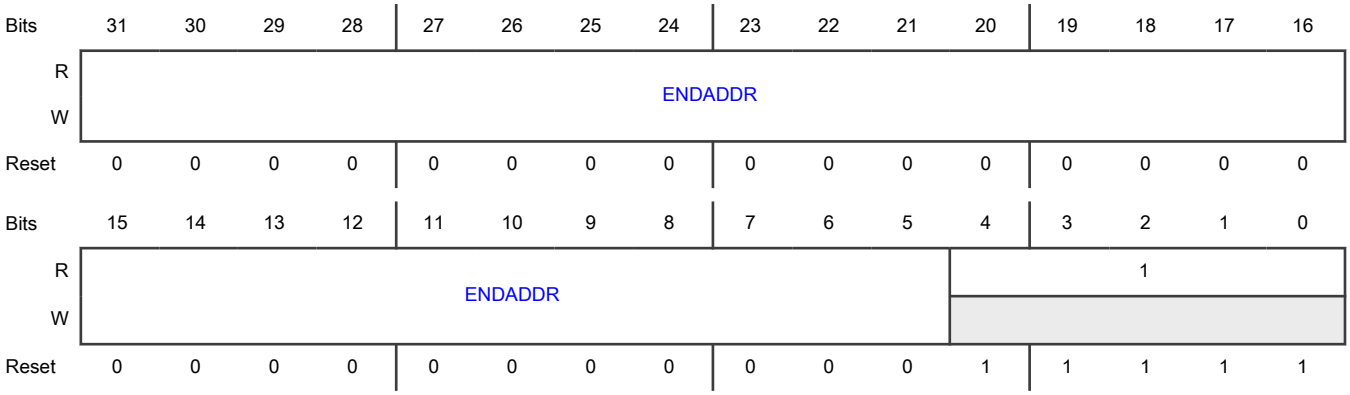
| Index *n* | Index *m* |
|---|---|
| 0–1 | 0–15 |
| 2 | 0–3 |

| Register | Offset |
|---|---|
| MRGD_W1_(n * 16 + m) | 2004h + (n × 200h) + (m × 20h) |

### Function

Specifies the ending address of memory region *r*.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-5<br>ENDADDR | End Address<br>Specifies the most significant bits of the 31-modulo 32-byte end address of memory region *r*. |
| 4-0<br>— | Reserved |

## 18.8.3.19 Memory Region Descriptor Word 2 (MRGD_W2_0 - MRGD_W2_35)

### Offset

Registers in this array exist only for the following combinations of index values.

| Index *n* | Index *m* |
|---|---|
| 0–1 | 0–15 |
| 2 | 0–3 |

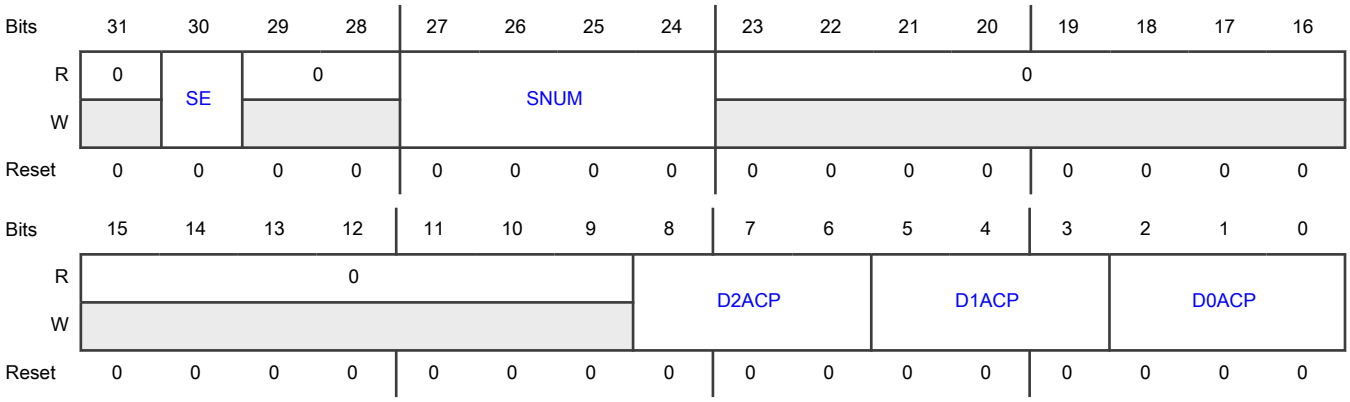
| Register | Offset |
|---|---|
| MRGD_W2_(n * 16 + m) | 2008h + (n × 200h) + (m × 20h) |

### Function

Specifies the ACP for the associated domain. The encodings specify read and write access capabilities based on the four operating states. This field applies only for a supported DID; if the DID is not implemented, the field is read-only zero (no access rights).

For field values, see Domain ACP specification.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>— | Reserved |
| 30<br>SE | Semaphore Enable<br>Enables the inclusion of the semaphore specified in SNUM in the D*d*ACP evaluation.<br>0b - Disables<br>1b - Enables |
| 29-28<br>— | Reserved |
| 27-24<br>SNUM | Semaphore Number<br>Specifies the hardware semaphore to include in the D*d*ACP access evaluation. This field applies only if you enable semaphore (write 1 to SE). |
| 23-9<br>— | Reserved |
| 8-6: D2ACP<br>5-3: D1ACP<br>2-0: D0ACP | Domain Access Control Policy<br>Specifies the ACP for the associated domain. This field applies only for a supported DID; if the DID is not implemented, the field is read-only zero (no access rights). For field values, see Domain ACP specification. |

### 18.8.3.20 Memory Region Descriptor Word 3 (MRGD_W3_0 - MRGD_W3_35)

#### Offset

Registers in this array exist only for the following combinations of index values.

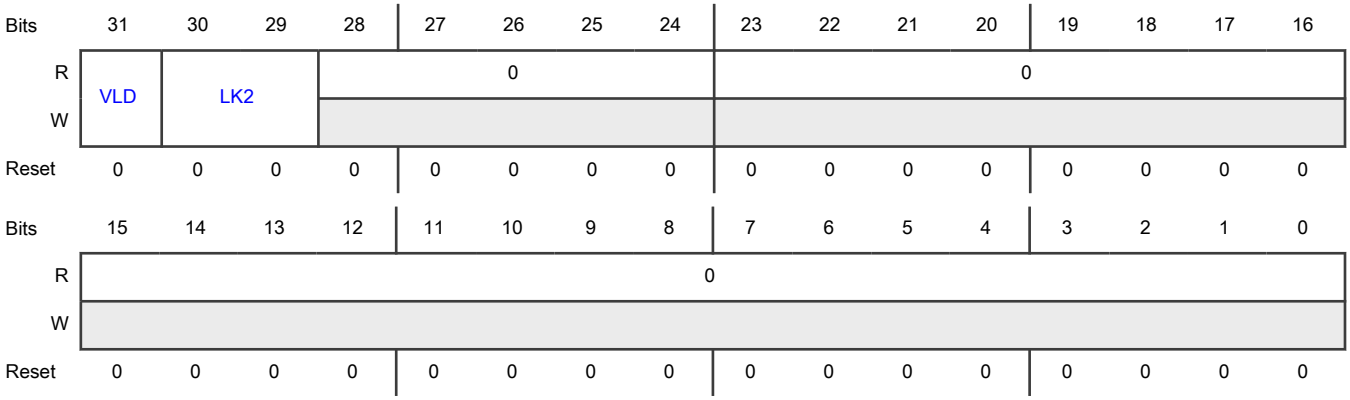
| Index *n* | Index *m* |
|---|---|
| 0–1 | 0–15 |
| 2 | 0–3 |

| Register | Offset |
|---|---|
| MRGD_W3_(n * 16 + m) | 200Ch + (n × 200h) + (m × 20h) |

#### Function

Specifies whether this memory region descriptor is enabled and limits or prohibits writes to it.

#### Diagram



#### Fields

| Field | Function |
|---|---|
| 31<br>VLD | Valid<br>Specifies whether this domain assignment is valid. In other words, if VLD and CR[GVLD] are both asserted, XRDC uses the configuration in this set of registers. If CR[GVLD] is 0, all accesses to the memory are allowed. If CR[GVLD] is 1 and VLD is 0, all accesses are blocked. To support a coherent register state, a write to any of the MRGD W0–W2 registers forces this field to zero.<br>This field has no effect unless XRDC is enabled (CR[GVLD] = 1).<br>0b - Invalid<br>1b - Valid |
| 30-29 | Lock<br>Limits or prohibits writes to the set of MRGD words (MRGD_W*w_n*) for this memory region. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| LK2 | When you assert a bit in this field, it remains asserted until the next module reset.<br>00b - All words in the set can be written to<br>01b - Reserved<br>10b - Domain d can update only its associated DdACP field; all other fields are read-only<br>11b - Locks (all words are read-only) |
| 28-24<br>— | Reserved |
| 23-0<br>— | Reserved |

## 18.9 Glossary

**ACP** access control policy. The access limitations specified for memory and peripheral resources.

**DID** domain identifier. A numeric value that identifies a specific domain.

**domain** An access-controlled virtual group of on-chip initiators (cores and noncore initiators) and targets (memories and peripherals) that comprise an isolated computing environment. All initiators in a domain have the same access to chip resources within that domain.

See Introduction to domains for more information.

**initiator** A processor core or non-processor module, such as DMA or a communications channel, that can initiate transactions with memory and peripheral resources. This term replaces "master".

**LPID** logical partition identifier. Also called an operating system ID or VMID, the LPID identifies a virtual initiator (either core or noncore) that runs on a hypervisor.

**MDAC** Master Domain Assignment Controller. Manages resource assignments and DIDs.

**MGR** Manager. Manages accesses through the XRDC programming model.

**MRC** Memory Region Controller. Controls access to memories based on memory region descriptors.

**PAC** Peripheral Access Controller (also sometimes called PDAC). Controls access to peripherals.

**PDAC** See PAC.

**PID** process identifier. A numeric value provided by some core processors to identify the currently active process.

**SDAC** Deprecated. See MRC.

**target** A peripheral or memory resource that one or more initiators can access. This term replaces "slave".

**transaction** A read or write request made by an initiator to a target peripheral or memory.

**VMID** virtual machine identifier. See LPID.

# Chapter 19
# Memory and Memory Interfaces

## 19.1 Introduction

This chapter discusses the configuration of memories and memory interfaces, such as flash memory, flash memory controller, and SRAM.

## 19.2 Flash memory controller and flash memory modules

For information on this, see the following chapters:

- Flash Memory Controller (PFLASH)
- Embedded Flash Memory

## 19.3 Related information

**Table 84. Related information**

| Topic | Related chapters | For additional information |
|---|---|---|
| System memory map | Memory Map | See the memory map file attached to this document. |
| Clocking | • Clocking Overview<br>• Clock Generation Module (MC_CGM) | — |

| EIM | Error Injection Module | — |
| ERM | Error Reporting Module | — |

## 19.4 SRAM access

In case a master accesses an SRAM with multi-bit ECC errors, the chip may respond as follows:

- Map all such faults to FCCU. The recommended reaction for the fault is to generate the functional reset.
- Map such faults to ERM. If the ERM interrupt is enabled, ERM generates an interrupt.

## 19.5 Memories

The following table provides information on the types of memories, with their associated configurations, available in MCXE31.

Table 85. Memory configuration

| Memory | Size | Configuration (words × bits) | ECC or parity | ECC or parity width | Diagnostic information or error report | Applicability |
|---|---|---|---|---|---|---|
| SRAM0 | 160 KB | 32 KB with STANDBY mode retention (4096 × (64 + 8)) | ECC (SECDED) | 8 | ERM | MCXE31B |

## 19.6 Recommendations for ARM memories

As per ARM M-7 Safety manual, following considerations must be ensured for proper operation of ARM memories:

- ITCM and DTCM must be properly initialized with correct ECC before any read operation to avoid any code runaway or software malfucntion or core lockup.

**NOTE**

ITCM must be initialized with 64-bit writes whereas DTCM can be initialized with 32-bit writes also.

- To safely disable TCM:
  1. Clear ITCMCR[EN] or DTCMCR[EN] as required. See ARM Cortex-M7 Devices Generic User Guide for details on ITCMCR and DTCMCR register.
  2. Execute DSB instruction
  3. Execute ISB instruction

**NOTE**

Care must be taken if disabling the ITCM while executing from it. In this case, software must ensure that the switch-off code is stored in the L2 code memory region from where execution continues when the ITCM is disabled.

- To safely disable the I-cache:
  1. Clear CCR[IC]. See ARM Cortex-M7 Devices Generic User Guide for details on CCR register.
  2. Execute DSB instruction
  3. Execute ISB instruction
- To safely disable the D-cache:
  1. Clean and invalidate non-WT locations in D-cache
  2. Clear CCR[DC]
  3. Execute DSB instruction

See Table 86 for details on memory ECC initialization.

## 19.7 Memory ECC initialization summary

The table below summarizes memory ECC initialization.

Table 86. Memory ECC initialization summary

| Memory | Write access size | Masters |
|---|---|---|

*Table continues on the next page...*

Table 86. Memory ECC initialization summary (continued)

| | | CM7_ n | CM7_ m | eDMA |
|---|---|---|---|---|
| SRAM | 64-bits only | System | System | System |
| CM7_n ITCM | 64-bits only | Direct or Backdoor | Backdoor | Not possible |
| CM7_n DTCM | 32-bits or 64-bits | Direct or Backdoor | Backdoor | Backdoor |
| CM7_m ITCM | 64-bits only | Backdoor | Direct or Backdoor | Not possible |
| CM7_m DTCM | 32-bits or 64-bits | Backdoor | Direct or Backdoor | Backdoor |

## 19.8 Glossary

| | |
|---|---|
| **DTCM** | Data tightly coupled memory |
| **ECC** | Error code correction |
| **ETF** | Embedded trace FIFO |
| **ETMD** | Embedded trace macrocell-data |
| **ETMI** | Embedded trace macrocell-instruction |
| **ITCM** | Instruction tightly coupled memory |
| **MTB** | Macrocell trace buffer |
| **PKC** | Public key cryptography |
| **RXPARSER** | Receive parser memory |
| **SECDED** | Single error correction double error detection |
| **SRAM** | Static random access memory |
| **TSN** | Time sensitive network |

# Chapter 20
# Embedded Flash Memory (c40asf)

## 20.1 Chip-specific c40asf flash memory information

### 20.1.1 Flash memory configuration and register settings

Table 87 shows flash memory blocks and their associated configuration.

**Table 87. Flash block configuration**

| Block or address number | Block name | Start address (hex) | End address (hex) | Size | Applicability |
|---|---|---|---|---|---|
| 0 | Code flash memory 0 | 0040_0000 | 004F_FFFF | 1 MB | MCXE31B and MCXE317 |
| | | | | 512 KB | MCXE315 and MCXE316 |
| 1 | Code flash memory 1 | 0050_0000 | 005F_FFFF | 1 MB | MCXE31B and MCXE317 |
| | | | | 512 KB | MCXE315 and MCXE316 |
| 2 | Code flash memory 2 | 0060_0000 | 006F_FFFF | 1 MB | MCXE31B |
| 3 | Code flash memory 3 | 0070_0000 | 007F_FFFF | 1 MB | MCXE31B |
| 4 | Data flash memory | 1000_0000 | 1001_FFFF | 128 KB | MCXE31B |
| 2 | | | | 128 KB | MCXE317 |
| | | 1000_0000 | 1000_FFFF | 64 KB | MCXE315/MCXE316 |
| 0 [1] | UTest NVM | 1B00_0000 | 1B00_1FFF | 8 KB | MCXE31B, MCXE317, MCXE315 and MCXE316 |

1. The address region number is the same as block number for all the blocks except this one. Address region is called UTest NVM address region in this case.

No application cores except ELE_HSEB can access the address regions shown in Table 88.

**Table 88. Secure flash memory configuration**

| Description | MCXE315/MCXE316 | | MCXE317 | | MCXE31B | | Size |
|---|---|---|---|---|---|---|---|
| | Start address | End address | Start address | End address | Start address | End address | |
| Secure BAF code (SBAF_CODE) | 004F_4000h | 004F_FFFFh | 005F_4000h | 005F_FFFFh | 007F_4000h | 007F_FFFFh | 48 KB |

**NOTE**

For HSE memory configuration, see *'Memory map when HSE firmware usage feature flag is enabled'* section in *'Boot Overview'* chapter.

The flash memory can perform multiple reads in parallel (between different blocks), using the single-, dual-, or quad-read feature. It also includes an internal UTest mode that can generate single- and double-bit ECC errors.

The code flash memory lets you access three data paths simultaneously.

You can configure the flash memory sectors as erase- or write-protected by using the flash memory's sector and super-sector locking features.

Data flash and/or Code flash memory blocks can be altered by a code executing from different flash block or SRAM.

Data flash memory is the same as code flash memory—supporting program, erase, and read operations.

After the completion of the program or erase operations, the MCR and MCRS registers notify you as soon as the code flash memory code can be executed. At the end of reset recovery, MCRS[DONE] transitions from 0 to 1.

**NOTE**

MCRS[RWE] might become 1 during the program or erase operation because of speculative accesses by Cortex-M7 core(s). If there are memory regions where no speculative accesses must be initiated, Arm recommends to configure the on-core MPU to set those regions with these attributes:

- Device or strongly-ordered
- Execute never

**NOTE**

- ADR[A3] and ADR[A4] field are reserved for MCXE317, as code flash memory size in 2 MB for MCXE317.
- For MCXE317, reset value of FLASH_SSPELOCK and FLASH_XSSPELOCK register is 0x0FFF_FFFF.

### 20.1.2 MCRE register reset value

The reset value of the MCRE register depends on the chip-specific flash memory configuration. This table provides the flash memory configuration of the chip and the associated register reset values.

**Table 89. MCRE register reset value**

| MCRE fields | Reset value |
|---|---|
| n1M (bit position 23:21) | 100b – Four 1 MB blocks |
| | 010b – Two 1 MB blocks |
| n512K (bit position 15:14) | 00b – Zero 512 KB blocks |
| n256K (bit position 7:6) | 01b – One 256 KB blocks |
| MCRE register reset value | MCXE31B - 0080_0040h |
| | MCXE317 - 0040_0040h |

### 20.1.3 Debugger considerations while Flash Program/Erase

While flash programming is done via debugger, special considerations should be taken care off. See "Debug Subsystem" chapter for details.

## 20.2 Introduction

The primary function of the embedded flash memory serves as an electrically programmable and erasable non-volatile memory (NVM) that may be used for instruction or data storage.

### 20.2.1 Overview

The embedded flash memory is designed for use in embedded MCU and SoC applications. It supports a total memory size up to 8.5 MB of NVM in main space and 8 KB of UTest NVM space per module. Multiple flash modules may be instantiated within an SoC to achieve higher density. The embedded flash memory is addressable by page (256 bits) for read operation and double-word(s) and page and quad page for program operations. Flash memory reads always return 256 bits, although read page buffering may

be performed by the PFC. The flash memory is able to do multiple reads in parallel (between different blocks), utilizing the quad read feature.

For details on the embedded flash memory architecture and features, see Functional description.

The following figure shows the top-level diagram and functional organization of the flash memory unit.

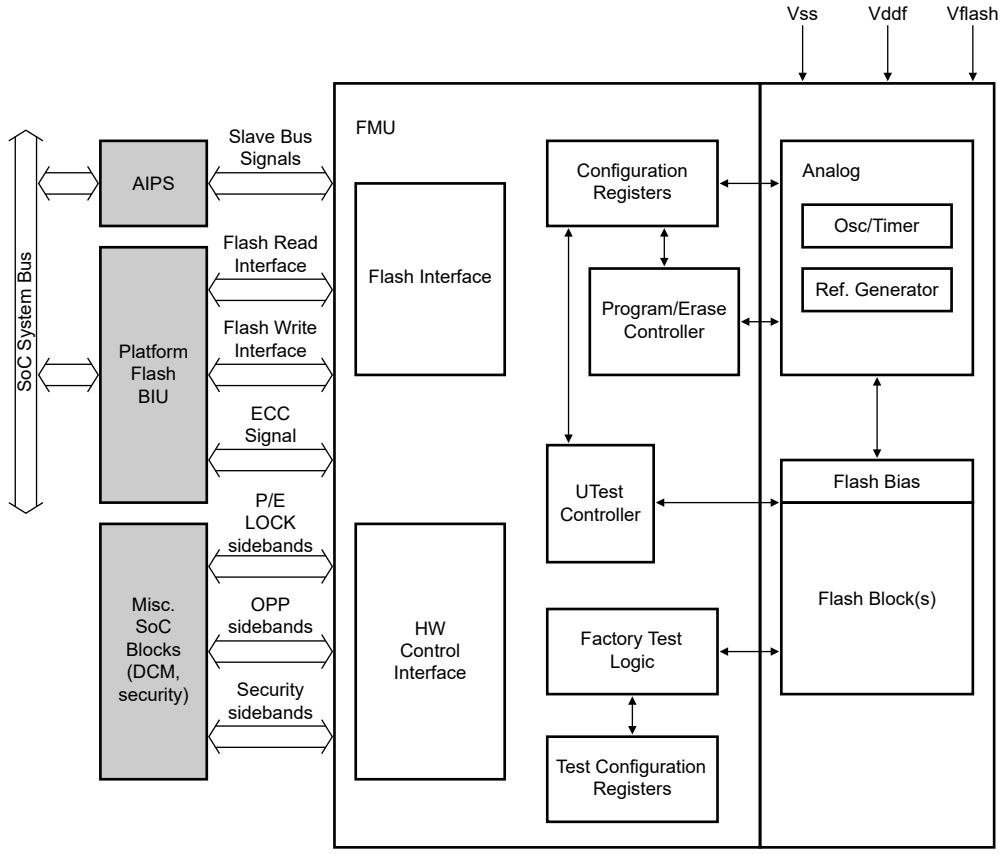

**Figure 45. Block diagram**

## 20.2.2 Features

The embedded flash memory includes these distinct features:

- Test information stored in a dedicated non-volatile sector (referred to as the UTest sector)
- OTP space made available in the UTest sector
- Read page size of 256 bits (8 words)
- ECC with single bit correction, double bit detection (all 1s valid) with 64-bit granularity
- Quad page programming (256-bit granularity)
- Hardware programmable sector and super sector program or erase restriction control
- Erasing of selected sector or block erase
- Independent programming of the UTest NVM sector
- Embedded hardware program and erase algorithms
- Support for reading while writing when the accesses are to different blocks
- UTest mode (user-accessible test modes) including array integrity and margin read

- Triple-voted flops for safety-critical flash memory functions (for example, internal trimming, redundancy, mode control, and others)

### 20.2.3 Modes of operation

Following is a brief description of the embedded flash memory operating modes.

- User mode is the default operating mode of the embedded flash memory. In this mode, it is possible to read and write registers (including register-based interlock writes), read the memory array, program the memory array, and erase the memory array. In this mode program and erase operations are initiated by doing register writes. Program and erase operations are controlled by an internal state machine.
- Low-Power mode turns off all DC current sources within the embedded flash memory and enables VFLASH and VDDF to be power gated. The embedded flash memory is not accessible for read, write, program, or erase when in Low-Power mode. This mode results in the lowest current draw that embedded flash memory can achieve.
- UTest mode is a tiered test mode strategy in which a portion of the factory test modes are made available. This mode is protected but accessible.

## 20.3 UTest NVM sector

The UTest NVM sector may be enabled by PEADR[PEASAD] during interlock writes. When the UTest NVM space is enabled, all program and erase operations are mapped to the UTest NVM sector. User-mode programming of the UTest NVM sector is enabled only when PEADR[PEASAD] is high.

The UTest NVM sector is an OTP sector (assuming Test mode disable seal is written) . Therefore, performing an erase operation is not permitted.

The UTest NVM sector supports RWW, and is grouped with the sectors in partition 0.

The UTest NVM sector may be locked against program by using hardware program and erase protection input to the flash module (MCRS[TSPELOCK]).

The UTest NVM sector contains specified data that is needed for embedded flash memory or SoC features.

Programming of the UTest NVM space has restrictions that are similar to those of the main space in terms of how ECC is calculated. Only one program operation is allowed per 64-bit ECC segment.

## 20.4 Test mode disable seal

The UTest NVM sector includes a mechanism to disable factory entry into Test mode selectable by block. Extreme care must be taken when using this feature, because blocks that are selected to be protected in this method will not have possible failures analyzed by factory failure analysts. Once sealed, the UTest sector becomes OTP (erase locked, and OPP enabled). The UTest sector is not accessible in Test Mode.

Protection of this sort prevents all high voltage operations to the flash memory executed by the internal state-machine, as well as reads through this state machine, and reads through the array integrity state machine when using Test mode interfaces.

UTest operations, margin read and array integrity, are also protected by preventing MISR updates on blocks selected for protection, although reads are still performed, and single bit corrections and double bit detections will be logged. Protection through other interfaces is provided by normal User mode protection mechanisms and is device-specific.

The method to disable factory entry into Test mode is to first program the Test mode disable seal location to be 5A4B_3C2Dh. After the next reset is asserted, Test mode is disabled.

It is possible to create a password to enable factory entry into Test mode. This can be programmed into the Test mode disable override passcode. The passcode may not be 0000_0000h, FFFF_FFFFh, or 5555_5555h. These are all invalid passcodes and will not be accepted to override. If it is desired, by the customer, that override never be possible, one of the three invalid passcodes must be put into the Test mode disable override passcode location. Passcode may be entered to authenticate entry, if enabled, by performing a 32-bit register write to register address 90h.

Even if the Test mode disable seal password is written, the UTest NVM sector is always protected and the UTest operations, margin read and array integrity, are always protected.

Only blocks selected in the Test mode disable block select field are controlled by the Test mode disable feature. Therefore, it is possible for customers to selectively pick blocks that have this type of protection and will not be eligible for factory failure analysis. Bits programmed to 0 in the Test mode disable block select field(s) designate blocks that are controlled by the Test mode disable feature.

In order to let two opportunities to select blocks for the Test mode disable, two regions are available, Test mode disable bock select - 1 and Test mode disable block select - 2. If either Test mode disable block select - 1 or Test mode disable block select - 2 has a 0 programmed, that block will be protected. The bits of these two regions are logically ANDed to define the blocks that are effectively selected for the Test mode disable feature. The bock select field is organized as shown in the next table:

**Table 90. Test mode disable block select**

| Block | Bits used to select blocks |
|---|---|
| Block 0 disable | Data[0] |
| Block 1 disable | Data[8] |
| Block 2 disable | Data[16] |
| Block 3 disable | Data[24] |
| Block 4 disable | Data[32] |
| Block 5 disable | Data[40] |

## 20.5 Functional description

The embedded flash memory module consists of blocks with the following options:

- 2 MB blocks (0, 1, 2, 3 or 4 blocks allowed per module)
- 1 MB blocks (0, 1, 2, 3 or 4 blocks allowed per module)
- 512 KB blocks (0, 1, 2 or 4 blocks allowed per module)
- 256 KB blocks (0, 1, 2 or 4 blocks allowed per module)
- A total of six blocks are allowed per module

Read while Write is allowed within a module, and is determined based on block boundaries. Read while Write partitions are used to determine locations for valid read-while-write (RWW) operations. While the embedded flash memory performs a write (program or erase) to a given partition, it can simultaneously perform a read from any other partition. For program and erase operations, only the address specified by an interlock write determines the partition being written (sector or super sector locking does not determine the RWW partitions being written).

The main address space is also divided into sectors and super sectors to implement independent erase and program protection. The UTest NVM space also exists as a sector and has independent program protection. The UTest NVM sector is included to support systems that require non-volatile memory (NVM) for security or to store system initialization information.

A number of MCR bits are protected against write when another field, or set of fields, is in a specific state. These write locks are covered on a bit-by-bit basis in Module Configuration Register. The write locks do not consider the effects of trying to write two or more bits simultaneously. This module does not allow fields to be written simultaneously that put the device into an illegal state. This is implemented through a priority mechanism among the fields, and the next table shows this mechanism.

Table 91. MCR field set and clear priority levels

| Priority level | MCR field(s) |
|---|---|
| 1 | ERS |
| 2 | PGM |
| 3 | EHV |

If two or more MCR fields are written simultaneously, only the field with the lowest priority number is accepted for modification. For example, writing 1 to ERS and PGM simultaneously results in 1 being written only to ERS.

Each read of the embedded flash memory retrieves a page, or eight consecutive words (256 bits), of information. The address for each word retrieved within a page differs from the other addresses in the page only by address bits [4:2]. The flash memory page read architecture easily supports both cache and burst mode at the PFC BIU level for high-speed read applications.

The embedded flash memory supports fault tolerance through error correction code (ECC) and error detection. ECC implemented within the embedded flash memory corrects single bit failures and detects double bit failures.

Program and erase of the embedded flash memory requires multiple system clock cycles to complete. Program and erase may be aborted.

The embedded flash memory may operate in various modes as described in the following sections.

## 20.5.1 User mode

In User mode, the embedded flash memory may be read and written (register writes and interlock writes), programmed or erased. The following sub-sections define all actions that may be performed in User mode.

### 20.5.1.1 Read and write

The default state of the embedded flash memory is read. The main and UTest NVM address spaces can be read only in the read state. The flash registers are always available for read, except when the embedded flash memory is in Low-Power mode. The module enters the read state on reset, and remains in the read state under two sets of conditions:

- The read state is active when the embedded flash memory is enabled (User mode read).
- The read state is active when MCR[PGM] or MCR[ERS] are 1 and a high voltage operation is ongoing (RWW).

**NOTE**

Reads done to the partition(s) being operated on (either erased or programmed) result in MCRS[RWE] becoming 1.

In embedded flash memory, flash core reads return 256 bits (1 page). Register reads return 32 bits of data.

**NOTE**

Flash core reads are performed through the PFC BIU. In many cases, the BIU does read page buffering to allow sequential reads to be done with higher performance. This could provide a data coherency issue that must be handled with software. Data coherency may be an issue after a program or erase operation, as well as UTest NVM sector operations.

In user mode, registers may be written (including interlock writes using registers).

Register reads to unmapped register address space return all 0s.

Register writes to unmapped register address space have no effect.

Interlock writes that are attempted during a high voltage operation (MCR[EHV] = 1 or MCRS[DONE] =0) result in the interlock write being ignored, and address and data will not be updated.

#### 20.5.1.2 Program

A flash memory program sequence operates on any page within the flash core. Within a page, up to eight words may be altered in a single program operation. Also, up to four pages can be altered in a single program operation. Whenever the array is programmed, the ECC bits also get programmed.

ECC is handled on a 64-bit boundary. Thus, if only one word in any given 64-bit ECC segment is programmed, the adjoining word in that segment should not be programmed, because ECC calculation is already complete for that 64-bit segment. Attempts to program the adjoining word may likely result in an operation failure. It is recommended that all programming operations ranger from 64 bits to 1024 bits, and be 64-bit aligned. The programming operation should completely fill selected ECC segments within the page. Only one program is allowed per 64-bit ECC segment between erases.

**Caution**

In rare cases, over-programming of a 64-bit ECC segment may be done (EEPROM emulation in data flash region). In this case, approved EEPROM emulation drivers must be used, and they must limit the number of over-program operations to three times (four total programs between erases).

Programming changes the value stored in an array bit from logic 1 to logic 0 only. Programming cannot change a stored logic 0 to a logic 1.

**NOTE**

If a logic 0 is attempted to be over-programmed by a logic 1, the resulting operation fails (MCRS[PEG] = 0), and the 0s that are interlocked are merged (ORed) with the 0s that are already present in the 64-bit ECC segment, unless the block is designated as an over-orogram protected block.

Addresses in locked sectors cannot be programmed. Values may be programmed in any or all of eight words, within a page, with a single program sequence. Up to four pages can be programmed at once on a quad-page boundary. The program operation consists of the following sequence of events:

1. Write the address to be programmed using logical address registers located in the PFC. The result of this write will also be reflected physically in the PEADR register.

   **NOTE**

   PEADR writes are initiated by writes that first occur in the PFC. Please see the platform flash memory controller chapter for more information. PEADR reads are allowed, and represent the flash memory physical address.

   **NOTE**

   Ensure the sector that contains the address to be programmed is unlocked. Sector and super sector lock status is latched at this step and does not change until the next program or erase sequence is started.

2. Data to be programmed must be written in the appropriate DATAX register (where X is 0 to 31). All unwritten data words default to FFFF_FFFFh.
3. Change the value in MCR[PGM] from a 0 to a 1.
4. Write a 1 to MCR[EHV] to start the internal program sequence or skip to step 8 to terminate.
5. Wait until MCRS[DONE] becomes 1.

   **NOTE**

   Since MCRS[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCRS[DONE] as 0 between step 4 and step 5, depending on the operation selected.

6. Confirm MCRS[PEG] = 1.
7. Write 0 to MCR[EHV].
8. Write 0 to MCR[PGM] to terminate the program sequence.

Program may be initiated with the writing of the PEADR register (enabled with a write done in the PFC block). The PEADR write to initiate the program sequence determines the quad-page address to be programmed. Data must also be written to the DATA register(s). This first write is referred to as an interlock write. Unwritten locations default to a data value of FFFF_FFFFh.

An interlock write must be performed before writing 1 to MCR[PGM], and MCR[PGM] must be set before writing 1 to MCR[EHV] during a program sequence. A program sequence may be terminated by writing 0 to MCR[PGM] prior to writing 1 to MCR[EHV].

While MCR[EHV] is 1 and MCRS[DONE] is 0, MCR[EHV] may be cleared, resulting in a program abort. A program abort forces the embedded flash memory to step 8 of the program sequence. An aborted program results in PEG becoming 0, indicating a failed operation. The data space being operated on before the abort contains indeterminate data.

**Caution**

Aborting a program operation leaves the FC addresses being programmed in an indeterminate data state. This may be recovered by executing an erase on the affected block.

#### 20.5.1.2.1 Program hardware locking

Hardware locking which affects the program and erase operations is available for UTest sector and all array blocks.

#### 20.5.1.2.2 Over-program protection enable

One-time programming can be enabled. If over-program protection is enabled, any double word that has already been programmed cannot be programmed again. The over-program protection enable does not affect the erase operation. Attempts to over-program result in MCRS[PEG] becoming 0. If any double word within a quad-page has an over-program protection violation, MCRS[PEG] becomes 0, and no double words are programmed.

One-time programming can be enabled for the UTest NVM sector.

### 20.5.1.3 Erase

An erase changes the value stored in all bits of the selected sector or block to logic 1, and operates on a sector or a block in the main address space. The erase sequence is fully automated within the flash memory. Locked sectors cannot be erased. The erase sequence consists of the following events:

1. Write to the sector or block address to be erased using logical address registers located in the PFC. The result of this write is reflected physically in the PEADR register. One, and only one, DATA register must also be written. This is referred to as an erase interlock write.

   **NOTE**

   PEADR writes are initiated by writes that first occur in the PFC. Please see the platform memory flash controller chapter for more information. PEADR reads are allowed, and represent the flash memory physical address.

   **NOTE**

   The selected block or sector must be unlocked prior to initiating an erase with the appropriate sector or super sector lock registers. Sector and super sector lock status is latched at this step and does not change until the next program or erase sequence starts. If a block is selected for erase, all the sectors and super sectors must be unlocked within that block.

2. Change the value in MCR[ERS] from a 0 to a 1, and at the same time select the size of erase using MCR[ESS].
3. Write a 1 to MCR[EHV] to start the internal erase sequence or skip to step 6 to terminate.
4. Wait until MCRS[DONE] becomes 1.

   **NOTE**

   Since MCRS[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCRS[DONE] as 0 between step 3 and step 4, depending on the operation selected.

5. Confirm MCRS[PEG] = 1.

6. Write 0 to MCR[EHV].
7. Write 0 to MCR[ERS] to terminate the erase, and if set MCR[ESS] should also be cleared (else the field auto clears).

Erase may be initiated with the writing of the PEADR register (enabled with a write done in the Platform Flash Controller block). The PEADR write to initiate the erase sequence determines the sector or block to be erased. One write must also occur to a DATA register. Data word written during an erase sequence interlock write is ignored. This write is referred to as an erase interlock write.

An erase interlock write must occur before writing 1 to MCR[ERS] (and optionally MCR[ESS]), and MCR[ERS] must be set before writing 1 to MCR[EHV] during an erase sequence. The erase sequence may be terminated by writing 0 to MCR[ERS] prior to writing 1 to MCR[EHV].

While MCR[EHV] is 1 and MCRS[DONE] is 0, MCR[EHV] may be cleared, resulting in an erase abort. An erase abort forces the embedded flash memory to step 7 of the erase sequence. An aborted erase results in PEG becoming 0, indicating a failed operation. The sector or block being operated on before the abort contain indeterminate data.

#### 20.5.1.3.1 Erase hardware locking

Hardware locking which affects the erase and program operations is available for UTest sector and all array blocks. For details, see Program hardware locking.

### 20.5.1.4 Express program

A mechanism is made available to provide an express method to program up to 1024 bits of flash memory. When activated, all ongoing program and erase operations through the register interface are automatically aborted (MCR[EHV] becomes 0 automatically) and the express interface is given priority. When using the express interface, sequence requirements are ignored, although a XPEADR write is required to start the express program sequence.

The flash express program mechanism provides a quicker way to get information programmed into a block of flash memory when an application needs an immediate diary access, or a crash log access.

Addresses in locked sectors cannot be express programmed.

The express program operation consists of the following sequence of events:

1. Write the address to be programmed using the logical address register located in the PFC. The result of this write will also be reflected physically in the XPEADR register.

**NOTE**

XPEADR writes are initiated by writes that first occur to the PFC. Please see the platform flash controller chapter for more information. XPEADR reads are allowed, and represent the flash memory physical address.

**NOTE**

Ensure the sector that contains the address to be programmed is unlocked. Sector and super sector lock status is latched at this step and does not change until the next program, erase or express program is started.

**NOTE**

If XMCR[XPGM] interrupts a program or erase setup after MCR[EHV] is written to 1, the MCR and MCRS registers indicate if the operation was automatically aborted (MCR[EHV] = 0, MCRS[PEG] = 0, MCR[PGM] =1 or MCR[ERS] = 1), or if the operation was successful (MCR[EHV] = 1, MCRS[PEG] = 1, MCR[PGM] =1 or MCR[ERS] = 1). If express program interrupts a program or erase setup prior to MCR[EHV] being written to a 1, the MCR and PEADR registers will be preserved to show the state of the setup upon interruption. If fields MCR[PGM] = 1 or MCR[ERS] = 1 at interruption, the user must terminate the event by writing 0 to these fields. However, if MCR[PGM] or MCR[ERS] were not 1 at interruption, PEADR is preserved and does not need to be rewritten, but the PDATA registers are required to be rewritten for the interrupted operation. After the PDATA write(s) are repeated to finish the interlock write, the remainder of the program and erase sequence can be done to restart the interrupted operation (including doing a terminate after PGM or ERS are written to 1, if desired).

**NOTE**

Before starting the express program, ensure that UTest operations (array integrity or user margin read) are not ongoing (or about to be started). UT0[UTE] must be low before requesting the express program, and remain low during express program operations. Hardware locks are in place to ensure this occurs.

2. Wait until XMCR[XDOK] goes high.
3. Write the DATA registers with the data desired to be programmed. Up to 1024b (128B) may be programmed with express program. Only DATA registers that are written will receive program pulses.
4. Change the value in XMCR[XPGM] from a 0 to a 1.
5. Write a 1 to XMCR[XEHV] to start the internal express program sequence.
6. Wait until XMCR[XDONE] becomes 1.
7. Confirm XMCR[XPEG] = 1.
8. Write 0 to XMCR[XEHV].
9. Write 0 to XMCR[XPGM] to terminate the express program sequence.

### 20.5.2 Low-Power mode

In Low-Power mode, the embedded flash memory is put into a state where VDDF power gating and VFLASH power gating is allowed. It is the lowest current mode for the flash memory. No reads from or writes to the embedded flash memory are possible when in this mode. Most power dissipation is due to leakage in this mode.

Prior to entering Low-Power mode, it is required that all program, erase, and UTest operations be stopped.

When in Low-Power mode, register access is prevented. Flash core accesses are also prevented until power mode is exited. Flash core reads and writes may occur after power mode is exited.

The embedded flash memory returns to a post-reset state in all cases.

### 20.5.3 Program and erase watchdog timer

The embedded flash memory contains an internal watchdog timer that is used to prevent denial of service issues and events.

The watchdog timer is active during two periods of a program and erase event: program/erase setup and program/erase cleanup. If it is desired that program and erase operations also be checked with a watchdog timer, a system resource may be used for this purpose.

Program/erase setup always starts at the time of the PEADR write. An express program setup starts with a write to XPEADR and XMCR[XDOK] = 1. In the event of an Express program interrupt of main or alternate interface setup, the timer starts at the time when the express program operation completes (write of XMCR[XPGM] = 0). The watchdog stops when either MCR[EHV] is set to start the operation, or when the operation is terminated. Termination can occur when MCR[PGM] or MCR[ERS] are written to 0 (prior to MCR[EHV] being written to 1), or MCRS[PES] written to 0. If the express program interrupts the program/erase setup, this also stops the timer on that interface, and express program maintains priority. The above statements also apply to the alternate interface.

**NOTE**

If PEADR writes occur while UT0[UTE] is 1, the watchdog feature does not activate for setup. Watchdog timer is not active during UTest operations.

Program/erase cleanup always starts at the time of MCRS[DONE] = 1 on completion or an abort. In the event of an express program auto-abort of main or alternate interface, the cleanup starts at the time of MCRS[DONE] becoming 1 and the express program operation completed (XMCR[XPGM] written to 0). The watchdog stops when MCR[PGM] or MCR[ERS] are written to 0 at the end of the operation. If express program interrupts the program/erase cleanup, the timer on that interface also stops. The above statements also apply to the alternate interface.

Watchdog timers exist for each interface (main, alternate and express).

If a watchdog timeout occurs, the watchdog interrupt will be reflected in MCRS[WDI], AMCRS[AWDI] or XMCR[XWDI]. Interrupts can be enabled on the main and alternate interfaces using MCR[WDIE] or AMCR[AWDIE]. When a watchdog timeout occurs and an interrupt register asserts, the PEID restrictions on that interface are released. At that point, any master can complete the operation, and PEID locking is no longer enforced. If the watchdog timeout occurs, the EHV bit on that interface (MCR[EHV], AMCR[AEHV], and XMCR[XEHV]) are locked for writing to a 1. In this instance, any master can take the interface to a program and erase terminate. This enables accepted MCRS[WDI], AMCRS[AWDI] or XMCR[XWDI] to become 0, and the operation may restart with a new interlock write.

**NOTE**

If the watchdog timeout occurs before PGM becomes 1 (on any interface), or ERS becomes 1 (on any interface), the sequence must be taken to the point that the PGM or ERS bit for that interface is written and then the field for that interface can be cleared to create the terminate event and to clear the watchdog interrupt.

By default, the watchdog is enabled. Through the alternate MCR, the watchdog may be disabled (AMCR[WDD]), and the watchdog timeouts maybe adjusted (AMCR[WDT]) for all timeouts and all interfaces.

### 20.5.4 UTest mode

UTest mode enables customers to do specific tests that check the integrity of the embedded flash memory.

**NOTE**

When entering UTest mode, a best practice is to ensure all error flags and address error reporting in ADR are cleared to their reset value to ensure robust software and procedure execution.

**NOTE**

UTest mode diagnostic features ECC Logic Check, EDC after ECC Logic Check, Address Encode Logic Check, and Read Reference and Voltage Check, require serialization of flash reads starting with mode setup and ending with mode exit. This may be accomplished by executing diagnostic code from system RAM (with single reads to flash tagged address) as well as ensuring any flash reads outside of this diagnostic code are idle (single core).

#### 20.5.4.1 Array integrity self check

Array integrity is checked using a predefined address sequence (based on UT0[AIS]), and this operation is executed on selected blocks.

The data to be read is customer-specific user code programmed into the flash memory and the correct MISR signature is calculated based on that code.

Any random or nonrandom code is valid. After the operation completes, the results of the reads can be checked by reading the MISR value, to determine if an incorrect read or ECC detection was noted. Array integrity MISR value is calculated after ECC detection and correction. Array integrity requires that the read wait states control registers in the CTL register be set to match the system frequency being used.

The array integrity self check consists of the following steps:

1. Enable UTest mode.
2. Select the block to receive the array integrity check by performing an interlock write to that block. Write logical address register in the PFC (which will be reflected in the PEADR register) and 1 DATA register (PDATA is ignored). The block selected for array integrity check does not need to be unlocked.

**NOTE**

Blocks protected with the Test mode disable seal are still read as part of the array integrity sequence. The resulting read on sealed blocks is not captured in the MISR, but single bit correction, double bit detection and breakpoints are still honored.

**NOTE**

It is not possible to perform array integrity operations on the UTest NVM sector.

3. If desired, write 1 to UT0[AIS] for sequential addressing only.

   **NOTE**

   For normal integrity checks of the flash memory, sequential addressing is recommended. If it is required to more thoroughly check the read path (in a diagnostic mode), AIS shall remain 0 to examine more read transitions. This sequence takes more time.

4. Seed the MISR registers (UM0 - UM9) with desired values.
5. If breakpoints are desired, write 1 to UT0[AIBPE], and ensure that MCRS[EER] and MCRS[SBC] are 0. If it is desired to break on a single bit correction, ensure that UT0[SBCE] = 1.
6. Write 1 to UT0[AIE].
   a. If desired, the array integrity operation may be aborted before UT0[AID] goes high. This may be done by writing 0 to UT0[AIE] and then continuing to the next step. Note that in the event of an aborted array integrity check, MISRs contain a signature for the portion of the operation that was completed prior to the abort and are not deterministic. Before performing another array integrity operation, the UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8, and UM9 registers may need to be initialized to the desired seed value by doing register writes.
   b. If desired, the array integrity operation may be suspended before UT0[AID] goes high. This may be done by writing 1 to UT0[AISUS] to request an array integrity suspend. After UT0[AISUS] becomes 1, the user should wait for UT0[AID] to become 1, which indicates that the flash memory has entered the suspend state, and normal reads to the flash memory may be done. After UT0[AID] becomes 1, UT0[AISUS] may be written to 0 to resume the array integrity sequence.

   **NOTE**

   User mode array reads requested during the array integrity test are ignored to ensure that the array integrity operation is not corrupted. The memory array does not respond to array read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

7. Wait until UT0[AID] becomes 1.
8. If breakpoints are enabled, check if UT0[NAIBP] = 1. If the value of this field is 1, MCRS[EER], MCRS[SBC], and ADDR may be checked to determine the cause of the break and the address of the break. Prior to resuming the operation, write 1 to clear MCRS[SBC] or MCRS[EER]. Then, the operation may be resumed by writing 0 to UT0[NAIBP]. Continue to wait until UT0[AID] becomes 1. If breakpoints are not enabled, or if UT0[NAIBP] = 0 when UT0[AID] becomes 1, the operation is complete. Continue to the next step.
9. Read values in MISRs (UM0 - UM9) to ensure correct signature.

   **NOTE**

   Array integrity reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISRs, MCRS[EER] and MCRS[SBC].

10. Write 0 to UT0[AIE].

#### 20.5.4.2 User margin read

User margin read may be done using the array integrity interface, and has all the associated features of the array integrity interface (MISR and breakpoints).

User margin reads are done at a read margin level, checking for erased bits or programmed bits encroaching on the nominal read level.

User margin read requires that the Read Wait States control registers in the CTL register be written to match the system frequency being used. Margin ECC corrections and detections are noted during the user margin read test. Margin read MISR value is calculated after ECC detection and correction.

The data to be read is customer-specific user code programmed into the flash memory.

Any random or non-random code is valid. After the operation completes, the margin read results can be checked by reading MCRS[EER] and the MCRS[SBC] to determine if zero, one, or two bits are being detected by the margin read, as well as checking the MISR signature.

The use model for margin read is in the event of a user-detected single bit correction (through user reads), a margin read may be done to check for a possible second bit falling within the selected margin levels.

The user margin read consists of the following steps:

1. Enable UTest mode.
2. Select the block to receive the array integrity check by performing an interlock write to that block. Write logical address register in the PFC (which will be reflected in the PEADR register) and 1 DATA register (PDATA is ignored). The block selected for user margin read check does not need to be unlocked.

   **NOTE**

   Blocks protected with the Test mode disable seal are still read as part of the margin read sequence. The resulting read on sealed blocks is not captured in the MISR, but single bit correction, double bit detection and breakpoints are still honored.

   **NOTE**

   It is not possible to perform margin read operations on the UTest NVM sector.

3. Write 1 to UT0[AIS] for sequential addressing only.

   **NOTE**

   For margin read checks of the flash memory, sequential addressing is recommended. Writing 0 to UT0[AIS] is possible for margin reads, but using the sequence takes more time, and is not recommended.

4. Seed the MISR registers (UM0 - UM9) with desired values.
5. Ensure that MCRS[EER] and MCRS[SBC] are 0.
6. To enable single bit correction reporting during margin read, write UT0[SBCE] = 1.
7. Write 1 to UT0[MRE].
8. Write UT0[MRV] to the desired value depending on if it is desired to do one's margin or zero's margin.
9. Write 1 to UT0[AIE].

   **NOTE**

   User mode array reads requested during the margin read test are ignored to ensure that the margin read operation is not corrupted. The memory array does not respond to array read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

   **NOTE**

   During margin read operations, with UT0[AID] = 0, it is not recommended to attempt write operations to MCRS[SBC] and MCRS[EER]. It is recommended that these fields only be written during suspend, breakpoints or at the completion of the margin read operation.

10. Wait until UT0[AID] becomes 1.
11. If breakpoints are enabled or a suspend was requested during margin read, the operation may be at a breakpoint or a suspend state. See Array integrity self check for more information.
12. Read values in the MISRs (UM0 - UM9) to ensure correct signature.

**NOTE**

Margin reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISRs, MCRS[EER] and MCRS[SBC].

13. Write 0 to UT0[AIE].

#### 20.5.4.3 ECC logic check

ECC logic can be checked by providing data to be read in UD0[EDATA], UD1[EDATA] and/or UD2[EDATAC]. Array reads can then be performed, ensuring expected results.

The ECC logic check consists of the following steps:

1. Enable UTest mode.
2. Write 1 to UT0[EIE].
3. Write to UD0[EDATA], UD1[EDATA] and/or UD2[EDATAC] to provide data and check bit values to be read. Single bit corrections or double bit detections can be simulated by properly selecting data and check bit combinations.
4. Write the page address to receive data provided in step 3 into ADR.
5. Write to UD2[ED3], UD2[ED2], UD2[ED1] and/or UD2[ED0] to select the double words on the page to receive the check.
6. Reads can now be done through the BIU using an array read request. In the event of a BIU read requested from an address that matches the address in ADR, expected data and corrections or detections are observed based on data written into UD0[EDATA], UD1[EDATA] and/or UD2[EDATAC]. MCRS[EER] and MCRS[SBC] can be checked to evaluate the status of reads done.

**NOTE**

In the event of an ECC error or single bit correction, during the ECC logic check (UT0[EIE] = 1), ADR is not loaded, and the address tagged to receive the ECC logic check values is preserved.

7. Once completed, write UT0[EIE] to 0.

#### 20.5.4.4 EDC after ECC logic check

EDC after ECC logic can be checked by providing data to be read in UD3[EDDATA], UD4[EDDATA] and/or UD5[EDDATAC]. Array reads can then be performed, ensuring expected results.

The EDC after ECC logic check consists of the following steps:

1. Enable UTest mode.
2. Write 1 to UT0[EDIE].
3. Write to UD3[EDDATA], UD4[EDDATA] and/or UD5[EDDATAC] to provide data and check bit values to be read.
4. Write the page address to receive data provided in step 3 into ADR.
5. Write to UD5[EDD3], UD5[EDD2], UD5[EDD1] and/or UD5[EDD0] to select the double words on the page to receive the check.
6. Reads can now be done through the BIU using an array read request. In the event of a BIU read requested from an address that matches the address in ADR, expected EDC after ECC errors are observed based on data written into UD3[EDDATA], UD4[EDDATA] and/or UD5[EDDATAC]. MCRS[EEE] can be checked to evaluate the status of reads done.
7. Once completed, write UT0[EDIE] to 0.

#### 20.5.4.5 Address encode logic check

Address encode logic can be checked by inverting the address encode information from the memory array in UA0[AEI] and UA1[AEI]. Array reads can then be performed, ensuring expected results.

The Address encode check consists of the following steps:

1. Enable UTest mode.
2. Write 1 to UT0[AEIE].
3. Write to UA0[AEI] and/or UA1[AEI] to provide address bit(s) to be inverted.
4. Write the page address to receive inverted addresses provided in step 3 into ADR.
5. Reads can now be done through the BIU using an array read request. In the event of a BIU read requested from an address that matches the address in ADR, expected address encode errors are observed based on address invert values written into UA0[AEI] and/or UA1[AEI]. MCRS[AEE] can be checked to evaluate the status of reads done.
6. Once completed, write UT0[AEIE] to 0.

#### 20.5.4.6 Read reference and voltage check

Read reference and voltage detection logic can be checked by writing 1 to UT0[RRIE]. Array reads can be then be performed, ensuring expected results.

The read reference and voltage check consists of the following steps:

1. Enable UTest mode.
2. Write 1 to UT0[RRIE].
3. Write the page address to receive a read reference error MCRS[RRE] and a read voltage error MCRS[RVE] into ADR.
4. Reads can now be done through the BIU using an array read request. In the event of a BIU read requested from an address that matches the address in ADR, expected read reference and read voltage errors are observed based on ADR registers. MCRS[RRE] and MCRS[RVE] can be checked to evaluate the status of reads done.
5. Once completed, write UT0[RRIE] to 0.

### 20.5.5 Data flash memory requirements for EEPROM emulation

The embedded flash memory may be used to emulate an EEPROM utilizing software drivers, strategic over-programming of double words in the flash memory and following the below requirement and best practices in EEPROM software drivers.

It is required that the EEPROM emulation driver must build in fault tolerance allowing for the ability to “skip” records. In the case of an unsuccessful program, the ability to retry programming in the next available record location is required (record retirement). In the case of an unsuccessful sector erase, the ability to retire a sector is required (sector retirement).

In addition, following are best practices for the EEPROM emulation software driver to be considered:

- Choose a record scheme which allows for grouping of EEPROM data contents that are updated at one time such that unchanged data is not needlessly copied while minimizing record qualifier and status overhead. A variable length record scheme may be used to allow for grouping of data that is written together and limiting total record overhead.
- Copy only the valid records during a sector change and re-constitution of EEPROM data set to avoid needless copying of data within flash memory. This avoids rebuilding the entire data set.
- Only redundantly storing critical data which cannot be recovered in two sectors if attempting to protect against record or sector failures.
- Load level total program/erase cycles applied to flash memory locations allocated for EEPROM emulation by using a round-robin sector scheme.

When combining round-robin with sector retirement requirement, three or more sectors must be allocated for EEPROM emulation inclusive of extra spare sector(s).

For details, see NXP application notes published on this topic.

## 20.6 Initialization information

A reset is the highest priority operation for the embedded flash memory and terminates all other operations.

The embedded flash memory uses reset to initialize register and status fields to their default reset values. If the embedded flash memory is executing a program or erase operation (MCR[PGM] = 1 or MCR[ERS] = 1) and a reset is issued, the operation aborts and the embedded flash memory disables the high voltage logic without causing any damage to the high voltage circuits. Reset aborts all operations and forces the embedded flash memory into User mode, ready to receive accesses.

After reset is requested, MCRS[DONE] becomes 0, and remains low during reset and reset recovery.

At the end of reset recovery, MCRS[DONE] transitions from 0 to 1.

After a reset completes, register reads may be performed.

**NOTE**

Registers that require updating from UTest NVM information, or other inputs, may not read updated values until MCRS[DONE] becomes 1.

During reset recovery, register writes are not allowed until MCRS[DONE] becomes 1 to indicate reset recovery is complete.

**Caution**

Resetting during a program or erase operation leaves the FC blocks being programmed or erased in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

## 20.7 Memory map and register description

### 20.7.1 c40asf flash memory register descriptions

The embedded flash memory map consists of a flash memory array (which includes main array space and UTest NVM space) and a region of registers associated with the programming model that enable flash memory array operation and modification.

The address space consists of up to 6 blocks (with restrictions), and blocks can be 2 MB, 1 MB, 512 KB or 256KB in size.

#### 20.7.1.1 c40asf_flash memory map

FLASH base address: 402E_C000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Module Configuration (MCR) | 32 | RW | 00FF_0000h |
| 4h | Module Configuration Status (MCRS) | 32 | RW | 0000_C100h |
| 8h | Extended Module Configuration (MCRE) | 32 | R | 0000_0000h |

### 20.7.1.2 Module Configuration (MCR)

#### Offset

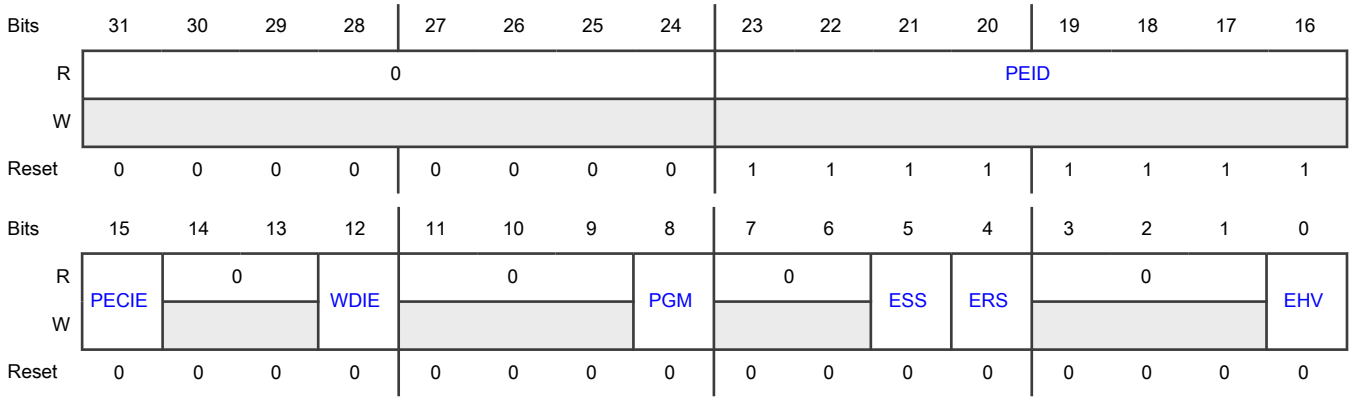
| Register | Offset |
|---|---|
| MCR | 0h |

#### Function

**NOTE**

- A number of Module Configuration Register (MCR) bits are locked against write by other bits. These locks are discussed in relationship to each bit in this section. Simultaneously writing bits which lock each other out is also discussed in Functional description.
- See Functional description for information about simultaneous MCR writes, and priority levels.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-24<br>— | Reserved |
| 23-16<br>PEID | Program and Erase Master/Domain ID<br>This field shows the ID of the master that has started the Program or Erase sequence (as well as Array Integrity and User Margin Reads). The ID is latched when the sequence has started (writing of the PEADR register). Upon completion of an operation (Program (MCR[PGM] written to 0 and MCRS[PES] equals 0), Erase (MCR[ERS] written to 0 and MCRS[PES] equals 0), Array Integrity (UT0[AIE] written to 0), User Margin Read(UT0[AIE] written to 0)), or Program and Erase Sequence clear (MCRS[PES] cleared to 0) the PEID field will return to an all ones state. See the chip-specific information for a list of Master IDs. |
| 15<br>PECIE | Program/Erase Complete Interrupt Enable<br>PECIE provides a mechanism to trigger an interrupt request upon the assertion of the DONE status due to a high voltage event (program or erase) finishing (normal, abort). If PECIE is written while not in a high voltage event, the interrupt will not immediately trigger, but will trigger after the next high voltage event is completed. Writing (and reading) of this bit will be restricted to the master that updated the PEADR register as captured in the PEID register at the start of the Program or Erase sequence.<br>**NOTE**<br>See the chip-specific information for interrupt details<br>0b - Interrupt request not generated when MCRS[DONE] is 1<br>1b - Interrupt request generated when MCRS[DONE] is 1 |
| 14-13<br>— | Reserved |
| 12<br>WDIE | Watch Dog Interrupt Enable<br>WDIE provides a mechanism to trigger an interrupt request upon the assertion of the WDI bit on the main interface. If WDIE is asserted, when WDI asserts, an interrupt from the flash will trigger to the system. The interrupt from the flash will mirror exactly the WDI bit. WDIE does not affect the register bit WDI. Writing (and |

|---|---|
| | reading) of this bit will be restricted to the master that updated the PEADR register as captured in the PEID register at the start of the Program or Erase sequence.<br>**NOTE**<br>See the chip-specific information for interrupt details<br>0b - Watchdog interrupt not enabled<br>1b - Watchdog interrupt enabled |
| 11-9<br>— | Reserved |
| 8<br>PGM | Program<br>PGM is used as part of the setup for a program operation. A 0 to 1 transition of PGM after program interlock write(s) is part of the program sequence. A 1 to 0 transition of PGM ends the program sequence. PGM can be set while in user mode read (ERS is low and UTE is low), and after the interlock write is completed. PES must also be low to enable PGM to be set.<br>PGM can be cleared only when EHV is low and DONE is high. PGM is cleared on reset. Writing (and reading) of this bit will be restricted to the master that updated the PEADR register as captured in the PEID register at the start of the Program or Erase sequence.<br>0b - Flash memory not executing a program sequence<br>1b - Flash memory executing a program sequence |
| 7-6<br>— | Reserved |
| 5<br>ESS | Erase Size Select<br>ESS is used to qualify the embedded flash memory erase operation for either sector erase or block erase. If ESS is selected for block erase, only the main array of that block will be erased.<br>**NOTE**<br>Block erase is for Factory use only, under controlled conditions. See Appendix A (Electrical Specifications) for more information on environmental condition requirements, and cycle limit.<br>**NOTE**<br>If interlock write occurs to UTest sector, ESS will be locked from setting to a 1. Block Erase of UTest sector is not supported, only sector erase is allowed. Erase of UTest space is not allowed if sealed, although ERS can be set and a PEG error will occur in response to the HV request.<br>ESS can only be written to a 1 at the same time that ERS is written to a 1. If ESS is set, ESS will auto clear with ERS clearing (independent of the value written to ESS). ESS can not be cleared by writing a zero. ESS is cleared on reset. Writing (and reading) of this bit will be restricted to the master that updated the PEADR register as captured in the PEID register at the start of the Program or Erase sequence. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 0b - Flash memory erase is on a sector<br>1b - Flash memory erase is on a block |
| 4<br>ERS | Erase<br>ERS is used as part of the setup for an erase operation. A 0 to 1 transition of ERS after an erase interlock write is part of the erase sequence. A 1 to 0 transition of ERS ends the erase sequence. ERS can only be set in user mode read (PGM is low and UTE is low), and after the interlock write is completed. PES must also be low to enable ERS to be set.<br>ERS can be cleared only when EHV is low and DONE is high. ERS is cleared on reset. Writing (and reading) of this bit will be restricted to the master that updated the PEADR register as captured in the PEID register at the start of the Program or Erase sequence.<br>0b - Flash memory not executing an erase sequence<br>1b - Flash memory executing an erase sequence |
| 3-1<br>— | Reserved |
| 0<br>EHV | Enable High Voltage<br>The EHV bit enables the embedded flash memory for a high voltage program/erase operation. EHV is cleared on reset. EHV must be set after the PGM or ERS bit is set in a program or erase sequence. Writing (and reading) of this bit will be restricted to the master that updated the PEADR register as captured in the PEID register at the start of the Program or Erase sequence. EHV may be set, initiating a program/erase under one of the following conditions:<br>• Erase (ERS = 1, PEP = 0, PES = 0, WDI = 0)<br>• Program (PGM = 1, PEP = 0, PES = 0, WDI = 0)<br>Clearing EHV while DONE is low will abort the current program/erase high voltage operation. An abort causes the value of PEG to be cleared, indicating a failed program/erase; address locations being operated on by the aborted operation contain indeterminate data after an abort. EHV may not be written to a 1 after an abort is requested (EHV being cleared) and before DONE transitions high. EHV may not be written to a 1 after it is cleared as part of a program or erase cleanup, until after the next PEADR write.<br>**NOTE**<br>Aborting a high voltage operation leaves addresses in an indeterminate data state. This may be recovered by executing an erase on the affected sectors.<br>0b - Flash memory is not enabled to perform a high voltage operation.<br>1b - Flash memory is enabled to perform a high voltage operation. |

### 20.7.1.3 Module Configuration Status (MCRS)

#### Fields

| Field | Function |
|---|---|
| 31<br>EER | ECC Event Error<br>This bit provides information on previous reads (either user initiated reads or internally initiated reset reads).If a double bit detection occurred, the EER bit is set to a '1'. This bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be set by software. In the event of a single bit detection and correction, this bit is not set. If EER is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of EER) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.<br>0b - Reads occurring normally<br>1b - ECC error occurred during a previous read |
| 30<br>SBC | Single Bit Correction<br>SBC provides information on previous reads, if the SBCE is set. If a single bit correction occurred, the SBC bit is set to a 1. This bit must then be cleared, or a reset must occur before this bit returns to a 0 state. If SBC is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of SBC) did not require a correction. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.<br>0b - Reads occurring without corrections<br>1b - Single bit correction occurred during a previous read |
| 29<br>AEE | Address Encode Error |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | AEE provides information on previous reads monitoring the address encode feature. On every read request to the flash, the incoming address is compared to an encoded address (row, column, and block) coming back from the memory array using the read data sense amplifier timing. If these two values do not match (zero selected, multiple selected, wrong selected), or the timing is incorrect, an address encode error will be recorded. If an address encode mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.<br>0b - Reads are occurring without address encode mismatches<br>1b - Previous read may be corrupted based on address encode mismatch |
| 28<br>EEE | EDC after ECC Error<br>EEE provides information on previous reads monitoring the EDC after ECC feature. On every read request to the flash, ECC is recalculated serially, and if there is a mismatch between the ECC calculations (taking into account corrections or detections) a late error will be reported. If an EDC after ECC mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.<br>0b - Reads are occurring without EDC after ECC mismatches<br>1b - Previous read may be corrupted based on ECC calculation errors |
| 27-26<br>— | Reserved |
| 25<br>RVE | Read Voltage Error<br>RVE provides information on previous reads monitoring the read voltage. If the read voltage is detected to be out of range, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.<br>0b - Reads are occurring without voltage issues<br>1b - A previous read may have been corrupted due to read voltage being out of range |
| 24<br>RRE | Read Reference Error<br>RRE provides information on previous reads monitoring the read reference. If the read reference is detected to be out of range, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.<br>0b - Reads occur without reference issues<br>1b - Previous read may be corrupted because of read reference being out of range |
| 23-21<br>— | Reserved |
| 20<br>RWE | Read-While-Write Event Error<br>This bit provides information on previous read-while-write (RWW) reads. If an RWW error occurs, this bit is set to 1. The bit must then be cleared, or a reset must occur before it returns to a 0 state. If RWE is not set, or |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | remains 0, this indicates that all previous RWW reads (from the last reset, or clearing of RWE) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.<br>0b - Reads occur normally<br>1b - RWW error occurred during a previous read |
| 19-18<br>— | Reserved |
| 17<br>PEP | Program and Erase Protection Error<br>PEP provides information about program and erase operations with respect to protection errors. A protection error occurs if a program is attempted to a locked sector or super sector, or if an erase is selected to a locked sector or super sector. This is evaluated prior to the operation beginning, and if an error is detected, high voltage operations (either a Program or Erase) will not be attempted for this request.<br>**NOTE**<br>If a location has both OTP and Lock protection, the response from the NVM will be PEP=1 only.<br>If PEP is asserted, it must be cleared prior to attempting another high voltage operation. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.<br>0b - Program and erase protection errors do not exist<br>1b - Previous program or erase protection error encountered |
| 16<br>PES | Program and Erase Sequence Error<br>PES provides information about program and erase operations with respect to sequence errors. A sequence error occurs when the program or erase sequence is not followed exactly. If an “out-of-order” event is detected, PES will assert, and the remainder of the sequence will not be accepted. PES monitoring begins when the PEADR register is written and ends when EHV is set to start the operation. PES monitoring only applies to Program and Erase (Sector and Block). It does not apply to Express Program, or UTest operations. Following is a complete list of sequence error conditions:<br>• Any specific DATA register written twice.<br>• More than one DATA register write for ERS operations.<br>• Attempts to write PGM or ERS register out of sequence.<br>• Attempts to write PGM after ERS, or ERS after PGM.<br>• Attempts to write DATA registers after PGM or ERS are written.<br>• Attempts to write EHV out of sequence.<br>Writes to the MCR that are protected by the MCR Priority Levels (i.e. simultaneous PGM, ERS and EHV writes) will not result in a PES condition.<br>Attempts to write MCR or DATA registers by a master that does not match the PEID, will not result in a PES condition. Those reads and writes will be blocked, and the master in control of the interface may continue with its' sequence. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | Clearing of PES (due to a sequence error) has the same effect as the clearing of PGM or ERS after a program or erase operation. PEADR and DATA registers are cleared, PEID is cleared, and the operation must be re-started from the beginning. If PGM or ERS are already set, they must be cleared before PES is cleared. PES can only be cleared once the PGM or ERS bit for the sequence in progress is cleared. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.<br>0b - Program and erase sequence errors do not exist<br>1b - Previous program or erase sequence encountered an error |
| 15<br>DONE | State Machine Status<br>DONE indicates whether the embedded flash memory is performing a high voltage operation. DONE is set to a 1 on termination of the embedded flash memory reset. DONE is read only. DONE is set to a 1 at the end of program and erase high voltage sequences.<br>**NOTE**<br>This field transitions from a 0 to 1 during reset and remains at 1 after reset.<br>0b - Performing a high voltage operation<br>1b - Not executing a high voltage operation |
| 14<br>PEG | Program/Erase Good<br>The value of PEG is updated automatically during the program and erase high voltage operations. Aborting a program/erase high voltage operation causes PEG to be cleared, indicating the sequence failed. PEG is set to a 1 when the embedded flash memory is reset. PEG is read only.<br>The value of PEG is valid only when PGM = 1 or ERS = 1 and after DONE transitions from 0 to 1 due to an abort or the completion of a program/erase operation. PEG is valid until PGM/ERS makes a 1 to 0 transition or EHV makes a 0 to 1 transition.<br>**NOTE**<br>1. If program or erase operations are attempted on sector(s) that are locked, the response from embedded flash memory is PEG = 1, indicating that the operation was successful, and the contents of the sector(s) are properly protected from the program or erase operation. PEG = 1 is also true if an abort occurs during an HV request to a locked sector.<br>2. If a program or erase operation is attempted to a location marked as OTP, the response from the embedded flash memory is PEG = 0, indicating that the operation was not allowed. The value interlocked is not programmed, since desired double word was already programmed with a previous program operation. Erase is prevented on OTP locations.<br>0b - Program or erase operation failed<br>1b - Program or erase operation successful |
| 13<br>— | Reserved |
| 12 | Watch Dog Interrupt |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| WDI | WDI is a status register to indicate that the Watchdog Timer for Program or Erase had expired. WDI is status only, and will be automatically cleared once the operation that caused the watchdog timeout is terminated or clean up from the operation is completed (clearing of PGM (with PES low), ERS (with PES low) or PES bit).<br>0b - Normal Operation, Watchdog Timer has not expired.<br>1b - Program Watchdog Timer has expired. |
| 11-10<br>— | Reserved |
| 9<br>EPEG | ECC Enabled Program/Erase Good<br>EPEG is a qualifier to PEG to indicate if a passing program or erase required ECC Enabled verifies to pass. In the event of a failed operation (PEG=0), EPEG will always remain 0. The value of EPEG is updated automatically during the program and erase high voltage operations. EPEG is set to a 0 when the embedded flash memory is reset. EPEG is read only.<br>The value of EPEG is valid only when PGM = 1 or ERS = 1 and after DONE transitions from 0 to 1 due to an abort or the completion of a program/erase operation. EPEG is valid until PGM/ERS makes a 1 to 0 transition or EHV makes a 0 to 1 transition.<br>0b - Program or erase operation did not require ECC Enabled verifies.<br>1b - Program or erase operation required ECC Enabled verifies to pass. |
| 8<br>TSPELOCK | UTest NVM Program and Erase Lock<br>TSPELOCK reflects the status of the hardware program and erase protection input to the flash module.<br>The TSPELOCK register is latched on the PEADR[PEASAD] write (UTest Sector Interlock), is not writable, and is status only. During high voltage events, the status is locked. When not interlocked this bit will read 1.<br>The default value of the TSPELOCK bits is program and erase protected.<br>0b - Corresponding sector not locked, and may be programmed or erased<br>1b - Corresponding sector protected from the program and erase sequences |
| 7-1<br>— | Reserved |
| 0<br>RE | Reset Error<br>This bit provides information on previous resets. Checks are done within the flash and if a coherency issue or ECC error is detected during the reset reads used for trimming on the flash, this status flag will assert. This bit is status only, and is not writable.<br>0b - Reset occurred without errors<br>1b - Reset error encountered |

### 20.7.1.6 Address (ADR)

#### Offset

| Register | Offset |
|---|---|
| ADR | 10h |

#### Function

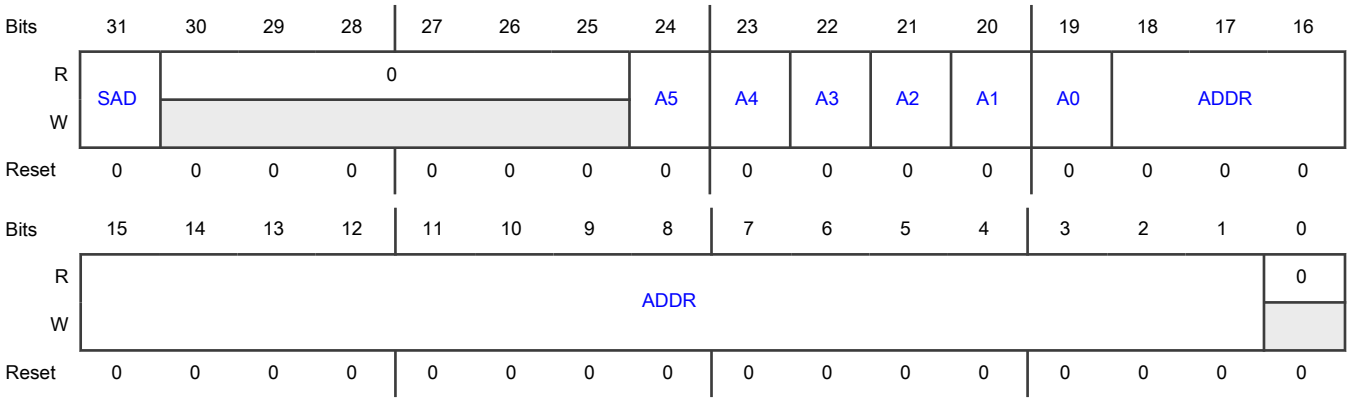
The Address register (ADR) provides the first failing address in the event of a failure (ECC or PGM/Erase state machine), as well as single bit correction information. The address register is also writable for UTest Mode operations. The address is identified using a combination of bits that identify the memory region and offset address.

**NOTE**

- The address given is an offset from the base address of the address space.
- The block numbering scheme that corresponds to the offset address is based on the flash memory's *internal* addressing scheme, which may be different than the chip's system addressing scheme.

Understanding the mapping between the flash address, which is specified relative to the flash module's internal addressing scheme, and the location within the chip's system memory map requires a clear understanding of the flash memory layout. See the chip-specific information for a detailed explanation of the chip's flash memory layout and how to map system addresses to the flash module's internal addressing.

#### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>SAD | UTest NVM Address<br>Qualifies the address captured during an ECC event error, single bit correction, or state machine operation.<br>See the description of the ADDR field for more information. | 20 | Address Region 1 |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| A1 | Qualifies the address field (ADDR) to the region<br>If the value of this field is 1, the ADDR field maps to region 1. See the description for the ADDR field for more information. If the region is not present, this field is locked to 0.<br>0b - Address captured or to be accessed is not from region 1<br>1b - Address captured or to be accessed is from region 1 |
| 19<br>A0 | Address Region 0<br>Qualifies the ADDR field to region 0. If A0 = 1, then the ADDR field maps to that region. If the region is not present, this field is locked to 0. For details, see the field description for ADDR.<br>0b - Address captured or to be accessed is not from region 0<br>1b - Address captured or to be accessed is from region 0 |
| 18-1<br>ADDR | Address<br>The ADR register provides the first failing address in the event of ECC event error (EER set), single bit correction (SBC set), as well as providing the address of a failure that may have occurred in a state machine operation (PEG cleared). ECC event errors take priority over single bit corrections, which take priority over state machine errors. This is especially valuable in the event of an RWW operation, where the read senses an ECC error or single bit correction, and the state machine fails simultaneously. The failing address for ECC event error is held until EER is cleared. The failing address for single bit correction is held until an ECC event error, or until SBC is cleared. State machine address is held until an ECC event error or single bit correction event occurs, or until the next state machine event (PEG cleared) occurs. This address is always a double word address that selects 64 bits.<br>The ADR register is writable, and can be used in the UTest ECC Logic Test, UTest EDC after ECC Logic Test, and UTest Address Encode Logic Test. If any of these tests are enabled (UT0[EIE] = 1, UT0[EDIE] = 1, or UT0[AEIE] = 1) then the ADR register will not update for ECC event error, single bit correction or state machine errors.<br>If MCRS[EER] or MCRS[SBC] are set, the ADR register is locked from writing. MCRS[PEG] does not affect the writeability of the ADR register.<br>ADDR[18:1] is an offset from a base address of 0h for each block region. The A0, A1, A2, A3, A4, and A5 bits qualify the block size region the ADDR field. |
| 0<br>— | Reserved<br>Reserved; reset to 0 |

### 20.7.1.7 Program and Erase Address (PEADR)

**Offset**

| Register | Offset |
|---|---|
| PEADR | 14h |

### Function

The Program and Erase Address register (PEADR) is used to provide the address to be programmed or the location of the sector or block to be erased. The program and erase address register is read only in user mode (user mode writes occur with writes done to the Platform Flash Controller). The address is identified using a combination of bits that identify the memory region and offset address.

**NOTE**

- The address provided is an offset from the base address of the address space.
- The block numbering scheme that corresponds to the offset address is based on the flash memory's *internal* addressing scheme, which may be different from the chip's system addressing scheme.

Understanding the mapping between the flash address, which is specified relative to the flash module's internal addressing scheme, and the location within the chip's system memory map requires a clear understanding of the flash memory layout. See the chip-specific information for a detailed explanation of the chip's flash memory layout and how to map system addresses to the flash module's internal addressing.

### 20.7.1.8 Sector Program and Erase Hardware Lock (SPELOCK)

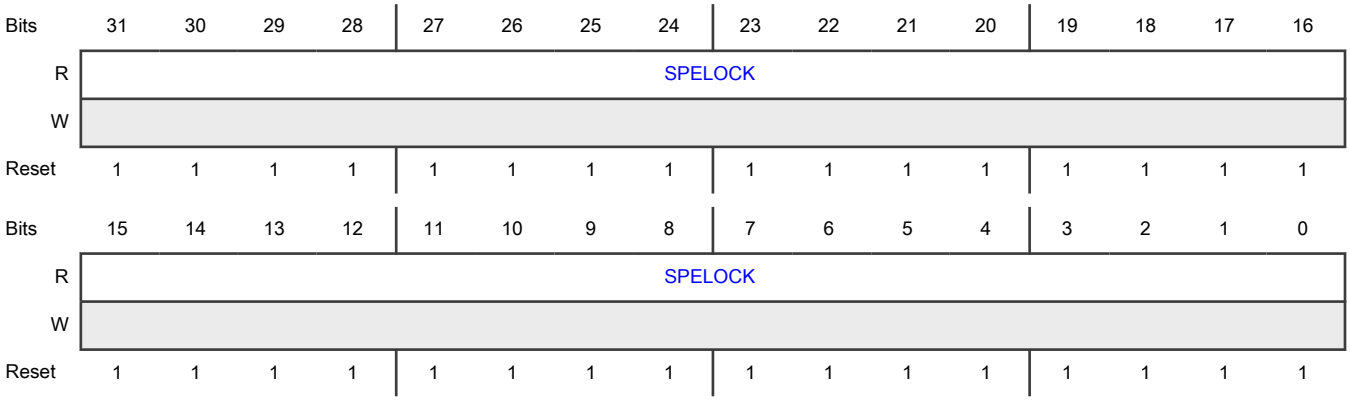
#### Offset

| Register | Offset |
|---|---|
| SPELOCK | 50h |

#### Function

The Sector Program and Erase Lock register provides a means to protect sectors from being programed and erased on the main interface. The last 256 KB of all blocks have sector lock protection capability. The rest of the block (if applicable) is protected with super sector protection capability. This register shows the status of the pelock hardware input for the block that is interlocked. For more information on hardware program and erase protection see Program hardware locking and Erase hardware locking .

### Diagram



### Fields

| 31-0<br>SPELOCK | Sector Program and Erase Lock [31:0]<br>SPELOCK reflects the status of the hardware program and erase protection input to the flash module for the block interlocked on the main interface.<br>The SPELOCK register is latched on the PEADR write, is not writable, and is status only. SPELOCK will return back to all ones at the same time that PEADR is cleared. When not interlocked this register will read all ones. During high voltage events, the status is locked.<br>The default value of the SPELOCK bits is program and erase protected. In the event that sectors are not present (due to configuration or total memory size), the SPELOCK bits default to locked, and will remain 1.<br>0 - The corresponding sector is not locked, and may be programed or erased.<br>1 - The corresponding sector is protected from program or erase. |

## 20.7.1.9 Super Sector Program and Erase Hardware Lock (SSPELOCK)

### Offset

| Register | Offset |
|---|---|
| SSPELOCK | 54h |

### Function

The Program and Erase Lock register provides a means to protect super sectors from being programed and erased on the main interface. Super Sector protection is available on block space greater than 256 KB. For 256 KB blocks, this register is not applicable. For 512 KB blocks, the first half of the block is protected with super sector granularity. For 1 MB blocks, the first 768 KB is protected with super sector granularity. For 2 MB blocks, the first 1792 KB is protected with super sector granularity. This register shows the status of the pelock hardware input for the block interlocked. For more information on hardware program and erase protection see Program hardware locking and Erase hardware locking .

## 20.7.1.10 Express Sector Program and Erase Hardware Lock (XSPELOCK)

### Offset

| Register | Offset |
|---|---|
| XSPELOCK | 70h |

### Function

The Express Program and Erase Lock register provides a means to protect sectors from being programed and erased on the express program interface. The last 256 KB of all blocks have sector lock protection capability. The rest of the block (if applicable) is protected with super sector protection capability. This register shows the status of the pelock hardware input for the block that is interlocked. For more information on hardware program and erase protection see Program hardware locking and Erase hardware locking .

## 20.7.1.12 Test Mode Disable Password Check (TMD)

### Offset

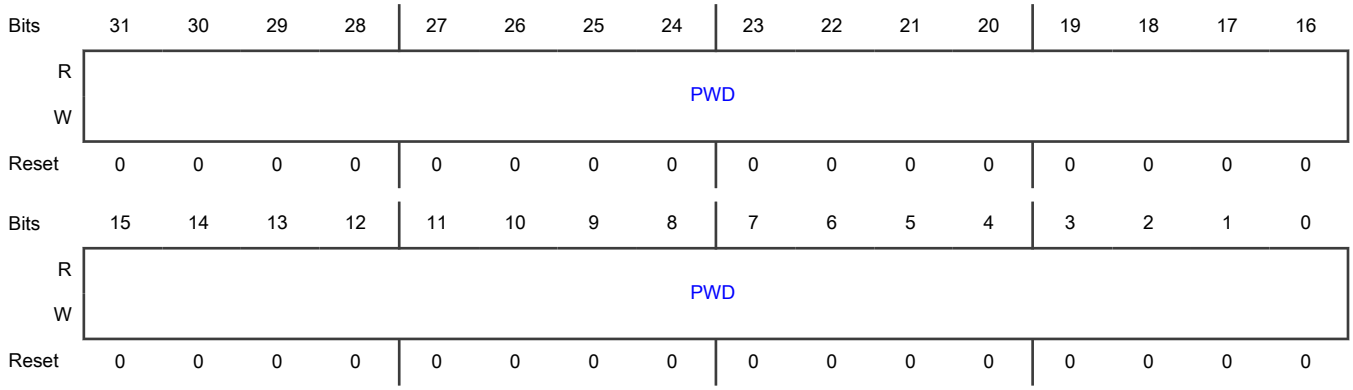
| Register | Offset |
|---|---|
| TMD | 90h |

### Function

Provides a means to supply a challenge password to disable the Test mode disable seal block select.

Writes to the register have no effect except for a password challenge. Reads to this register always return 0.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>PWD | Password Challenge |

## 20.7.1.13 UTest 0 (UT0)

### Offset

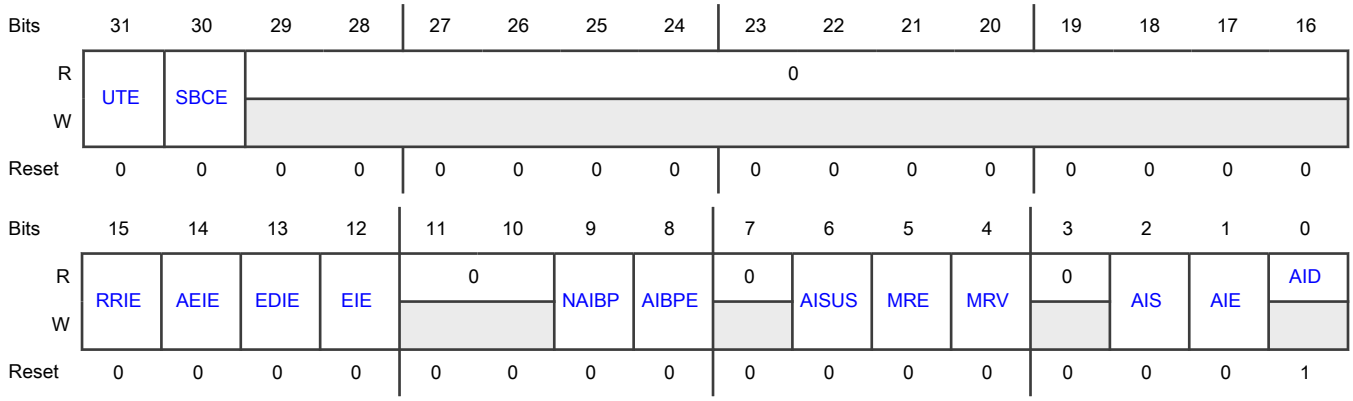
| Register | Offset |
|---|---|
| UT0 | 94h |

### Function

Provides a means to control UTest.

UTest mode provides the ability to perform test features on the flash memory. This register is only writeable when the flash memory is put into UTest mode by writing a passcode.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>UTE | UTest Enable<br>This status bit indicates when U-Test is enabled. All bits in UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8, UM9, UD0, UD1, UD2, UD3, UD4, UD5, UA0 and UA1 registers are locked when this bit is 0. This bit is not writeable to a 1, but may be cleared. The reset value is 0. The method to set this bit is to provide a password, and if the password matches, the UTE bit is set to reflect a status of enabled, and is enabled until it is cleared by a register write. The UTE password (set UTE=1) and UTE clearing to 0 will only be accepted if Program or Erase are not in progress (PEADR write through clearing of PGM/ERS/PES), Alternate Program or Erase are not in progress (APEADR write through clearing of APGM/AERS/APES), AI/MR Operation are not in progress (PEADR write through clearing of AIE), and an Express Program operation is not in progress (XPEADR write through the clearing of XPGM). UTE can only be cleared if AID = 1, MRE, AIE, EIE, EDIE, AEIE, and RRIE are all equal to 0. While successfully clearing UTE, writes to set AIE, MRE, EIE, EDIE, AEIE or RRIE will be ignored. For UTE, the password F9F9_9999h must be written to the UT0 register, and this must be a 32bit write.<br>0b - U-Test mode is not enabled.<br>1b - U-Test mode is enabled. |
| 30<br>SBCE | Single Bit Correction Enable<br>SBCE enables single bit correction results to be observed in SBC. ECC corrections that occur when SBCE is cleared will not be logged.<br>0b - Disabled<br>1b - Enabled |
| 29-16<br>— | Reserved<br>Reserved; reset to 0 |
| 15<br>RRIE | Read Reference Input Enable<br>RRIE enables the force of an error on the read reference detection circuit. This is useful in the Read Reference Error check. If this bit is set, the read reference error register MCRS[RRE] will set when an address match is achieved to the ADR register. RRIE is not simultaneously writable to a 1 as UTE is being successfully cleared to a 0.<br>0b - Read reference input disabled<br>1b - Read reference input enabled |
| 14<br>AEIE | Address Encode Invert Enable<br>AEIE enables the input register AEI to invert the address encode value received from the array, and force a mismatch in the address encode comparison. This is useful in the Address Encode logic check. If this bit is set, address encode information from the memory array will be inverted based on values in the AEI register when an address match is achieved to the ADR register. AEIE is not simultaneously writable to a 1 as UTE is being successfully cleared to a 0.<br>0b - Address encode invert is disabled<br>1b - Address encode values are inverted based on UA0[AEI] |
| 13 | EDC after ECC Data Input Enable |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| EDIE | EDIE enables the input registers EDDATA and EDDATAC to be the source of data to the EDC after ECC comparator or EDC after ECC encoder. This is useful in the EDC after ECC logic check. If this bit is set, data read via a BIU read request will be from the EDDATA and EDDATAC registers when an address match is achieved to the ADR register. EDIE is not simultaneously writable to a 1 as UTE is being successfully cleared to a 0.<br>0b - EDC after ECC data input is disabled<br>1b - Data read is from UD3[EDDATA] and UD5[EDDATAC] |
| 12<br>EIE | ECC Data Input Enable<br>EIE enables the input registers EDATA and EDATAC to be the source of data to the ECC logic (instead of from the memory array). This is useful in the ECC logic check. If this bit is set, data read via a BIU read request will be from the EDATA and EDATAC registers when an address match is achieved to the ADR register. EIE is not simultaneously writable to a 1 as UTE is being successfully cleared to a 0.<br>0b - ECC data input is disabled<br>1b - Data read is from UD0[EDATA] and UD2[EDATAC] |
| 11-10<br>— | Reserved |
| 9<br>NAIBP | Next Array Integrity Break Point<br>If AIBPE is set, NAIBP will be set once a single bit correction (if enabled) or double bit detection is noted during the Array Integrity test. NAIBP is not writable to 1, but may be cleared to 0. Clearing NAIBP to 0, will enable the Array Integrity operation to be re-started after a breakpoint is encountered. NAIPB may only be cleared to 0 if both EER = 0 and SBC = 0. If the Array Integrity operation completes without encountering another correction or detection, AID will be set with NAIBP remaining 0.<br>0b - Array integrity state machine is not currently at a breakpoint<br>1b - Array integrity state machine is at a breakpoint |
| 8<br>AIBPE | Array Integrity Break Point Enable<br>To enable breakpoints during an array integrity test, AIBPE may be set. See NAIBP description for more information about array integrity breakpoints.<br>0b - Array integrity breakpoints disabled<br>1b - Array integrity breakpoints enabled during array integrity checks |
| 7<br>— | Reserved<br>Reserved; reset to 0 |
| 6<br>AISUS | Array Integrity Suspend<br>AISUS enables a suspend of an Array Integrity Operation. Array Integrity may be suspend by setting AISUS, and resumed by clearing AISUS. AISUS is writeable to a 1 only when AID is low. AISUS is clearable to a 0 only when AID is high. Attempting to write AISUS and AIE on the same clock cycle will result in only AIE getting written. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 0b - Array integrity sequence not suspended.<br>1b - Array integrity sequence is suspended. |
| 5<br>MRE | Margin Read Enable<br>MRE combined with MRV enables user margin reads to be done. Normal user reads are not affected by MRE, although user reads while the margin read operation is ongoing are not supported. MRE is not writable if AID is low, or if AISUS is high, or if NAIBP is high. MRE is not simultaneously writable to a 1 as UTE is being successfully cleared to a 0.<br>0b - Margin reads are not enabled.<br>1b - Margin reads are enabled. |
| 4<br>MRV | Margin Read Value<br>MRV selects the margin level that is being checked. Margin can be checked to an erased level (MRV=1) or to a programmed level (MRV=0). In order for this value to be valid, MRE must also be set. MRV is not writable if AID is low, or if AISUS is high, or if NAIBP is high.<br>0b - Zero's margin reads are requested.<br>1b - One's margin reads are requested. |
| 3<br>— | Reserved |
| 2<br>AIS | Array Integrity Sequence<br>AIS determines the address sequence to be used during array integrity checks. The default sequence (AIS = 0) is meant to replicate sequences that normal user code follows, and thoroughly checks the read propagation paths. This sequence is proprietary. The alternative sequence (AIS = 1) is logically sequential.<br>It should be noted that the time to run a sequential sequence is shorter than the time to run the proprietary sequence. AIS is not writeable if AIE is high.<br>0b - Array integrity sequence is proprietary sequence<br>1b - Array integrity sequence is sequential |
| 1<br>AIE | Array Integrity Enable<br>AIE set to one starts the array integrity check done on all selected blocks. The address sequence is determined by AIS, and the MISR (UM0 through UM9) can be checked after the operation is complete, to determine if a correct signature has been obtained. Once an array integrity operation is requested (AIE=1), it may be terminated by clearing AIE if the operation has finished (AID = 1) or aborted by clearing AIE if the operation is ongoing (AID = 0). AIE is locked from writing unless an interlock write occurred (PEADR write and DATA write). AIE is not simultaneously writable to a 1 as UTE is being successfully cleared to a 0.<br>0b - Array integrity checks not enabled<br>1b - Array integrity checks enabled |
| 0 | Array Integrity Done |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| AID | AID is cleared upon an array integrity check being enabled (to signify the operation is ongoing). Once completed, AID is set to indicate that the array integrity check is complete. At this time the MISR (UMR registers) can be checked. AID may also assert if breakpoints are enabled (AIBPE is set), an abort is requested or a suspend is requested. AID cannot be written, and is status only.<br>0b - Array integrity check ongoing<br>1b - Array integrity check complete |

### 20.7.1.14 UMISRn (UM0 - UM8)

#### Offset

For a = 0 to 8:

| Register | Offset |
|---|---|
| UMa | 98h + (a × 4h) |

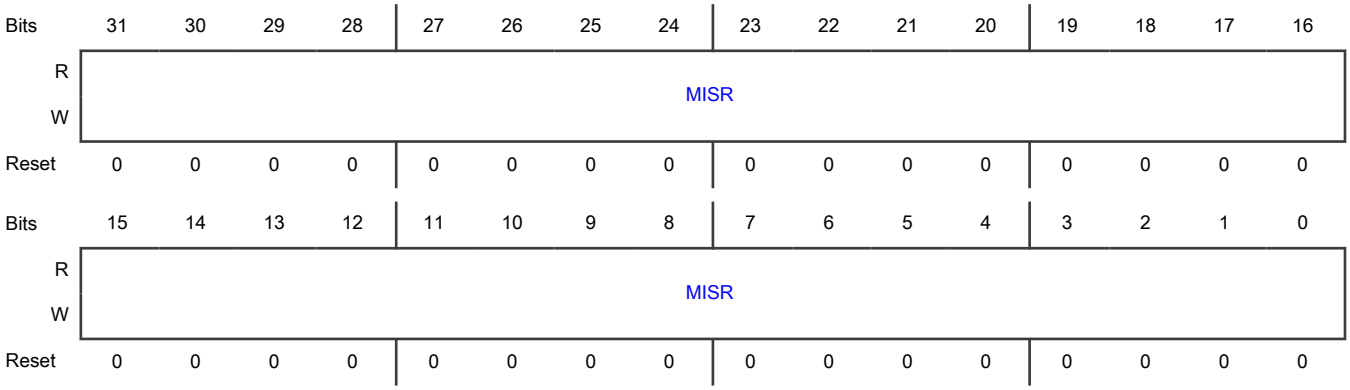
#### Function

Provides a means to evaluate array integrity. UM9 to UM0 are a set of multiple-input signature registers (MISRs) that hold the 289-bit MISR value as shown in the next table.

**Table 92. MISR mapping**

| UM register | MISR bits |
|---|---|
| UM0 | MISR[31:0] |
| UM1 | MISR[63:32] |
| UM2 | MISR[95:64] |
| UM3 | MISR[127:96] |
| UM4 | MISR[159:128] |
| UM5 | MISR[191:160] |
| UM6 | MISR[223:192] |
| UM7 | MISR[255:224] |
| UM8 | MISR[287:256] |
| UM9 | MISR[288] |

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>MISR | MISR[31:0]<br>The MISR registers accumulate a signature from an array integrity event. The MISR captures all data fields, as well as ECC fields, and the ECC error signal. Data (read and ECC) captured in the MISR is after the ECC logic, and represents corrected data (if required).<br>The MISR can be seeded to any value by writing the MISR registers.<br>**NOTE**<br>Writing the MISR register during an array integrity operation (including suspend or breakpoint) although possible, is not recommended. A write of the MISR registers at this point may alter the final signature in an unpredictable way. Writing the MISR registers prior to an Array Integrity operation (to seed the MISR) is allowed.<br>The MISR register provides a means to calculate a MISR during array integrity operations.<br>The MISR can be represented by the following polynomial:<br>$x^{289} + x^{7} + x^{6} + x^{5} + x^{4} + x^{2} + 1$<br>The MISR is calculated by taking the previous MISR value and then "exclusive ORing" the new data. In addition the most significant bit (in this case it is MISR[288]), is then "exclusive ORed" into input of MISR[7], MISR[6], MISR[5], MISR[4], MISR[2] and MISR[0]. The result of the "exclusive OR" is shifted left on each read.<br>The MISR register is used in array integrity operations.<br>If during address sequencing, reads extend into an invalid address location (in other words, greater than the maximum address for a given array size) then reads are still executed to the array, but the results from the array read are not deterministic. In this instance, the MISR registers are not recalculated, and the previous value is retained. Once the AIE register is cleared, the MISR register will return to an all 0's state. |

### 20.7.1.22 UTest Address 0 (UA0)

#### Offset

| Register | Offset |
|---|---|
| UA0 | E8h |

#### Function

Provides a means to enable address to be inverted during UTest procedures.

**NOTE**

- UTest Address 0 (UA0) and UTest Address 1 (UA1) combine to represent a 52-bit wide field, which matches the width of the address internally to the flash memory that is used for the address encode comparison.
- Writing 1 to any one of the fields in UA0 or UA1 leads to flagging an AEE error when causing the error injection.
- When the value of a field within the range of bits 18:3 is 1, the corresponding address signal to the flash memory controller or BIU is inverted.

#### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | AEI | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bits | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R<br>W | AEI | | | | | | | | | | | | | | | |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### Fields

| Field | Function |
|---|---|
| 31-0<br>AEI | Address Encode Invert [31:0]<br>Enables checks of address encode logic by allowing address bits to be inverted into the address encode compare logic, forcing a miscompare. Performing array reads on the page selected in ADR allows the address encode invert(s) to be active. |

*Table continues on the next page...*

| Field | Function |
|---|---|
| | Additionally, in the event of an address encode error during normal user mode operation, the page address provided to the PFC is inverted when an address encode error is encountered. AEI[18:3], which reflects the page address, can be used with the Address Encode Logic Check to control this inversion feature (aligning with ADR). Any bit in AEI[18:3] written to a 1 also enables the inversion of the corresponding signal of that address, allowing checks to be performed on the comparison logic that exists in the PFC.<br>**NOTE**<br>Multiple bits in AEI[18:3] may be written to a 1, which causes these bits to miscompare on the address encode comparison logic, as well as causing multiple bits to have their inversion enabled as part of the address provided to the BIU. |

### 20.7.1.23 UTest Address 1 (UA1)

#### Offset

| Register | Offset |
|---|---|
| UA1 | ECh |

#### Function

Provides a means to enable address to be inverted during UTest procedures.

**NOTE**

- UTest Address 0 (UA0) and UTest Address 1 (UA1) combine to represent a 52-bit wide field, which matches the width of the address internally to the flash that is used for the address encode comparison.
- Writing 1 to any one of the fields in UA0 or UA1 leads to flagging an AEE error when causing the error injection.

| Field | Function |
|---|---|
| | automatically after the program operations. See MCRS[EPEG] for more information, as the features of that bit apply to XEPEG as well.<br>0b - Program operation did not require ECC-enabled verifies<br>1b - Program operation required ECC-enabled verifies to pass |
| 8<br>XPGM | Express Program<br>XPGM is used as part of the setup for an express program operation.<br>A 0 to 1 transition of XPGM after program interlock write(s) is part of the setup for an express program sequence. A 1 to 0 transition of XPGM ends the express program sequence.<br>XPGM can be set at any time if UT0[UTE] is low, and after the interlock write is completed (XPEADR written, XDOK asserted, and DATAn register(s) written).<br>XPGM may be cleared when XEHV is low. Writing (and reading) of this bit will be restricted to the master that updated the XPEADR register as captured in the XPEID register at the start of the Program sequence.<br>0b - Flash memory not executing an express program sequence<br>1b - Flash memory executing an express program sequence |
| 7-1<br>— | Reserved |
| 0<br>XEHV | Express Enable High Voltage<br>The XEHV field enables the embedded flash memory for a high voltage program/erase operation. XEHV is cleared on reset. XEHV must be set after DATA writes to start an express program operation and XPGM is set. This field may be set when XPGM = 1, XDOK = 1, and XWDI = 0. XEHV may not be written to a 1 after it is cleared as part of an express program cleanup, until after the next XPEADR write.<br>Express Program operations may not be aborted. XEHV may only be cleared once XDONE is set to 1. Writing (and reading) of this bit will be restricted to the master that updated the XPEADR register as captured in the XPEID register at the start of the Program sequence.<br>0b - Flash memory is not enabled to perform an express high voltage operation.<br>1b - Flash memory is enabled to perform an express high voltage operation. |

### 20.7.1.25 Express Program Address (XPEADR)

#### Offset

| Register | Offset |
|---|---|
| XPEADR | F4h |

#### Function

The Express Program Address register (XPEADR) is used to provide the address to be programmed. The express program address register is read only in user mode (user mode writes occur with writes done to the Platform Flash Controller). The address is identified using a combination of bits that identify the memory region and offset address.

**NOTE**

- The address given is an offset from the base address of the address space.
- The block numbering scheme that corresponds to the offset address is based on the flash memory's *internal* addressing scheme, which may be different than the chip's system addressing scheme.

Understanding the mapping between the flash address, which is specified relative to the flash module's internal addressing scheme, and the location within the chip's system memory map requires a clear understanding of the flash memory layout. See the chip-specific information for a detailed explanation of the chip's flash memory layout and how to map system addresses to the flash module's internal addressing.

| 31-0 | Program Data |

*Table continues on the next page...*

| Field | Function |
|---|---|
| PDATA | PDATA registers will reset to all ones.<br>PDATA is not writable before PEADR is written or updated to start a program, express program, erase or UTest operation, and will read a value of all ones.<br>Once PEADR is written, all PDATA registers will be made available for writing. Writing (and reading) of the PDATA registers will be restricted to the master that updated the PEADR register as captured in the PEID register.<br>**NOTE**<br>PDATA restrictions related to PEID will be disabled if UT0[UTE] is set.<br>**NOTE**<br>For Express Program a similar behavior exists on the PDATA registers. Once XPEADR is written, and XDOK comes back as a 1, all PDATA registers will switch to all 1's (program safe state) and be made available for writing (and reading) to the master's ID that matches XPEID captured during the XPEADR update. In the event of an interrupted operation, XPEID permissions will override PEID permissions until the express program operation is completed (XPGM written to a 0).<br>Upon completion of an operation (Program (MCR[PGM] written to 0 and MCRS[PES] equals 0), Erase (MCR[ERS] written to 0 and MCRS[PES] equals 0), Express Program (XMCR[XPGM] written to 0), Array Integrity (UT0[AIE] written to 0), User Margin Read(UT0[AIE] written to 0)) or Program and Erase Sequence clear (MCRS[PES] written to 0) the PDATA registers will return to an all ones state.<br>When UT0[AIE] is set, PDATA bits will not be writeable.<br>When MCRS[PES] is set, PDATA bits will not be writeable except when an express program request occurs and XMCR[XDOK] is set.<br>Also, when MCR[PGM] or MCR[ERS] are set, PDATA bits will not be writeable except when an express program request occurs and XMCR[XDOK] is set. When an express program operation is in process, PDATA bits will not be writeable once XMCR[XEHV] is set until XMCR[XPGM] is cleared.<br>Only PDATA Bits that are written will receive program or express program pulses. |

## 20.8 Glossary

**Abort** Premature end of a mode, sequence, state or operation. An abort may leave the embedded flash memory in a state in which it contains indeterminate or corrupted data.

**BIU** Bus interface unit(Contains all system-level customization required to make the embedded flash memory part of an SoC)

**Block** Subdivision of the Flash Module containing NVM memory bits. Block sizes range from 256KB to 2MB. Each block is made up of 8KB sectors.

**Double word** Two words, or 64 bits.

**ECC** Error correction code(Internally used to correct single bit errors, or detect double errors within a 64-bit double word.)

**ECC segment** 64 bit double word, representing the size of data used to calculate ECC information.

**EDC** Error detection code

**FC** Flash memory core

| | |
|---|---|
| **FMU** | Flash Management Unit - Logic that enables program, erase, read, and other flash functions. |
| **Interlock Write** | A write to the PEADR register followed by a write to any DATA register performed while initiating a program, erase, array integrity, or user margin read sequence. Interlock in cleared once the operation is finished by clearing the appropriate control bit, causing PEADR register to clear. |
| **MCU** | Microcontroller unit |
| **Module** | Flash memory instance that contains flash block(s), FMU, and required analog support structures. |
| **NVM** | Nonvolatile memory |
| **OTP** | One time programmable |
| **PFC** | Platform flash memory controller(Contains all system-level customization required to make the embedded flash memory part of an SoC) |
| **Page** | 8 words of data (256 bits). When doing reads to the embedded flash memory, this is the width of data read. Up to 4 pages can be programmed at a time. |
| **Partition** | Subdivision of the Flash Module. Used for read-while-write operation, where addresses in the partition being written may not be read. Partitions is always equal to 1 block, and contains multiple sectors. |
| **RWW** | Read-while-write (operation) |
| **Sector** | Subdivision of the Flash Block that is independently erasable. Sector Size is always 8 KB. |
| **Super sector** | Subdivision of the flash block that includes a group of sectors. Super Sector Size is always 64 KB, and consists of 8 sectors. |
| **SoC** | System-on-chip |
| **UTest NVM sector** | 8 KB sector outside the main address space |
| **Word** | 32 bits |

# Chapter 21
# Flash Memory Controller (PFLASH)

## 21.1 Chip-specific PFLASH information

### 21.1.1 Flash memory architecture

The flash memory on the chip consists of a flash memory controller and a flash memory array module. The flash memory controller provides flash–memory configuration and control functions and manages the interface between the flash memory array and the chip's crossbar switch.

This chip implements three 64-bit AHB buses.

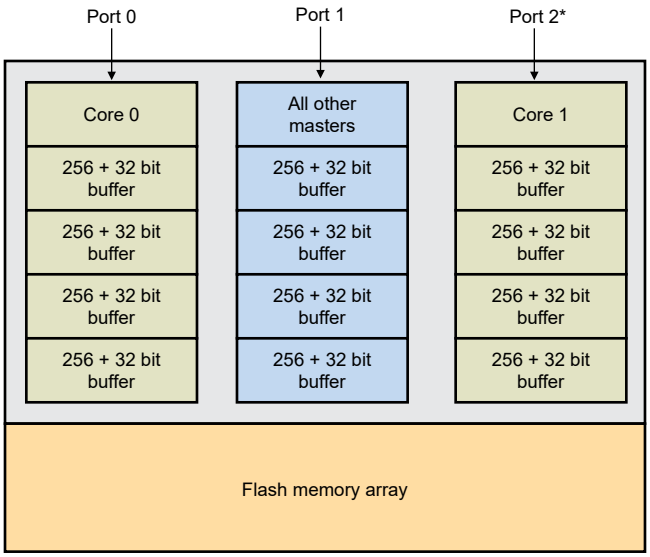

**Figure 46. Flash memory architecture**

### 21.1.2 Flash memory controller

The flash memory controller:

- Acts as an interface between the system bus and flash memory array.
- Is a triple-ported controller with a dedicated line buffering per port and per master ID. This enables you to use the line buffers more efficiently because various masters have dedicated buffers that are not compromised when other masters perform read operations.

Also, by having separate ports, you can have separate connections for each CPU instruction bus and a single port for all data accesses as shown in Figure 46.

In general, the flash memory controller registers affect the global flash memory behavior (for example, read buffering and access control).

**NOTE**

In MCXE317:

- PFLASH block 3 and block 4 are not present, so both the sector and super sector registers are not available.
- For PFLASH block 2, the super sector registers are not available.

### 21.1.3 Platform flash configuration registers (PFCR*n*)

The table below defines the PFCR*n* fields that the chip uses.

**Table 93. Platform flash configuration registers (PFCR*n*)**

| Master | Buffer enable field | Prefetch enable field |
|---|---|---|
| Cortex–M7_0 | P0_CBFEN, P0_DBFEN | P0_CPFEN, P0_DPFEN |
| eDMA + ELE_HSEB + EMAC[1] | P1_CBFEN, P1_DBFEN | P1_CPFEN, P1_DPFEN |

1. MCXE315/MCXE316 and MCXE317 do not support EMAC.

### 21.1.4 Platform flash access protection register (PFAPR)

This table defines the PFAPR[M*n*AP] fields that the chip uses. This chip does not use the other master access protection fields, but those fields are readable and writable.

**Table 94. Platform flash access protection register (PFAPR)**

| Master number | Master name | Access protection field |
|---|---|---|
| 0 | Cortex–M7_0 | M0AP |
| 2 | eDMA | M2AP |
| 3 | ELE_HSEB | M3AP |
| 4 | EMAC | M4AP |
| 5 | Reserved | |
| 6 | | |
| 7 | | |

## 21.2 Overview

PFLASH acts as an interface between the system bus (AHB-Lite 2.v6) and flash memory array.

PFLASH supports three 64-bit AHB buses and a 256-bit read data interface from each flash memory array. The slave port assignments and buffer organization are organized to offer maximum performance of code execution in a multicore architecture. The buffer mechanism serves to deliver flash memory read data with zero-wait state response on lines that reside in cache. AHB requests that miss the prefetch cache generate the needed flash memory array access and are forwarded to the AHB upon completion. Each cache entry is 256 bits, matching the flash memory array page size and providing 512 bytes of high-speed local storage.

### 21.2.1 Block diagrams

The following figure provides a block diagram showing PFLASH and the attached flash memory array.

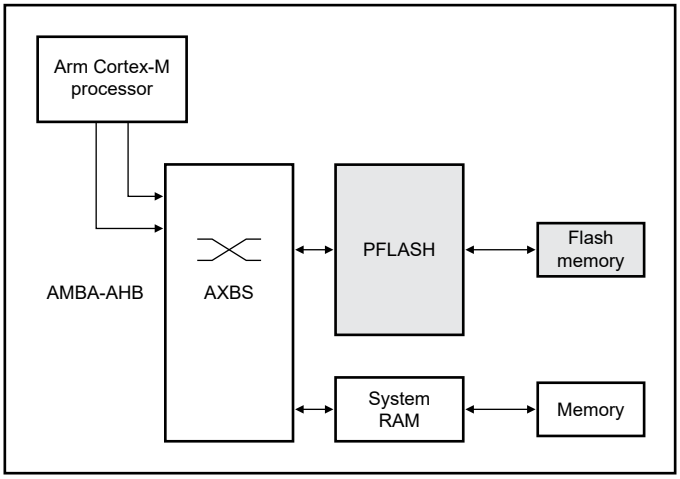

Figure 47. Platform-centric simple block diagram with PFLASH

### 21.2.2 Features

- Two 64-bit AHB interface ports (p0, p1) allowing simultaneous access to dedicated prefetch mini-cache per slave port
- 256-bit read data bus and 64-bit write data bus
- Configurable read buffering and line prefetching support via a mini-cache, plus a prefetch controller for each AHB port to provide single-cycle buffer hit read response
- Configurable access control based on read/write and AHB master ID attributes
- Support for reporting single-bit and multi-bit flash memory ECC events on a 64-bit doubleword boundary

## 21.3 Functional description

As shown in Figure 47, PFLASH interfaces between:

- The AHB system bus ports
- The flash memory array

For accesses targeting flash memory, the PFLASH generates as inputs to the flash memory array:

- Read and write enables
- Block selects
- Array address
- Write size
- Write data

PFLASH captures read data from the flash memory array and drives it onto the AHB system bus. Up to four pages of data (256-bit page size) may be buffered in each prefetch buffer for AHB Port0 and Port1 . Lines may be prefetched in advance of being requested, allowing single-cycle (zero AHB wait-states) read data responses on buffer hits.

Access protections may be applied on a per-master basis for both reads and writes to support security and privilege mechanisms.

### 21.3.1 Read transactions

On an incoming AHB read request, a mini-cache lookup and access privilege evaluation are performed during the AHB address phase. If a buffer hit occurs, the requested data is retrieved from the previously loaded prefetch buffer entry and returned on the system bus with a zero wait-state response. If a buffer miss occurs, a flash memory access is initiated.

Read accesses are terminated under control of the appropriate wait state settings. Access timing can be varied to account for the operating conditions of the chip (for example, frequency, voltage, temperature, and so on) by appropriately setting the read wait state field in flash memory.

### 21.3.2 Write transactions

An interlock write on a program or erase sequence is initiated by first writing to Platform Flash Memory Program Erase Address Logical (PFCPGM_PEADR_L), Platform Flash Memory Express Program Erase Address Logical (PFCPGM_XPEADR_L)(see the Flash Memory chapter for write sequence details).

### 21.3.3 Access protections

#### 21.3.3.1 PFAPR

PFLASH provides programmable, configurable access protections for read cycles on a per-master basis in PFAPR[M*n*AP]. This field restricts read access on a per-master basis. This functionality is described in Platform Flash Memory Access Protection (PFAPR). Detection of a protection violation based on PFAPR settings results in an error response from PFLASH on the AHB transfer.

### 21.3.4 Error termination

PFLASH can invoke a system bus error termination in the following scenarios:

- Access privilege violation (see Access protections for details)
- Attempted access by an AHB master to a reserved region in the flash memory map
- Multi-bit ECC error detection on AHB read, and PFCR4[DMEEE] = 0 (for data flash memory, it is further qualified by PFCR4[DERR_SUP] = 0)

### 21.3.5 Line read buffers and prefetch operation

The PFLASH AHB ports of the each contain a mini-cache. PFLASH uses the buffers for both prefetch and normal demand fetches. Also, the buffers are shared for code and data fetches, and can be controlled independently for code and data from control registers.

Prefetch triggering is controllable on a per-port basis. A PFLASH read access may trigger a prefetch to the next sequential line of array data on the cycle following the request. The access address is incremented by 32 bytes, and a subsequent flash memory access is initiated. A flash memory array prefetch is initiated if the data is not already resident in a line read buffer. Prefetched data is always loaded into the least-recently-used buffer.

For Port0 and Port1 there are four line buffer entries in their respective prefetch mini-caches that follow a fully associative, least-recently-used replacement policy.

For prefetching to occur, you must set the following configuration fields, where *n* corresponds to the port number and *m* corresponds to *C* (code) or *D* (data):

PFCRn[Pn_mBFEN] = 1 and PFCRn[Pn_mPFEN] = 1

### 21.3.6 Array integrity considerations

During an array integrity sequence, the flash memory array ignores any incoming read requests. When a flash memory array integrity check is in progress, PFLASH terminates all flash memory access requests with an error. More specifically, it aborts the incoming flash memory access requests and terminates the system bus transfer with an error.

### 21.3.7 Safety considerations

#### 21.3.7.1 Flash memory address generation check

Functional safety coverage of the address path and control within PFLASH rely on a feedback path between PFLASH and flash memory. Remember that on a requested access to flash memory, PFLASH must decode the system AHB bus signals to generate the corresponding flash memory interface signals to invoke a flash memory lookup. In addition to providing the requested read data, the flash memory also provides output sidebands reflecting the encoded address and block selects used to perform the actual row lookup.

PFLASH uses this sideband information to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within PFLASH or the transmission path between PFLASH and the flash memory array, then the event is forwarded to the chip fault collection module and the corresponding buffer is invalidated.

### 21.3.8 ECC error handling on data flash block

When PFCR4[DERR_SUP] is enabled, ECC errors on data flash blocks are handled specially.

If there is a noncorrectable error detection, a fixed, illegal opcode value is returned to the requesting master along with the associated ECC checkbits as determined by the requesting address.

For noncorrectable error detection, PFLASH returns a value of 1555_1555h to the requesting master.

This is mainly used for EEPROM emulation applications.

### 21.3.9 Read cycles—buffer miss

On an incoming AHB read request, a mini-cache lookup and access privilege evaluation are performed during the AHB address phase. If a buffer miss occurs, a flash memory access is initiated.

If the flash memory access was the direct result of an AHB transaction, the corresponding page buffer is loaded and marked as the most-recently-used. If the flash memory access was the result of a speculative prefetch to the next sequential line, it is loaded into the least-recently-used buffer. The status of this buffer is not changed to most-recently-used until a subsequent buffer hit occurs as a result of an AHB read request.

### 21.3.10 Read cycles—buffer hit

PFLASH allows single-cycle read responses to the AHB when the requested read access was previously loaded into one of the page buffers. In these cases of a buffer hit, read data is returned on the system bus with a zero wait-state response.

### 21.3.11 Flash memory error response operation

The flash memory array may signal an error response to terminate a requested access because of improper sequencing during program/erase operations and improper sequencing during array integrity testing. When an error response is received, PFLASH does not update or validate a page read buffer. An error response may be signaled on a read or interlock write operation. For more information on the specifics related to signaling of flash memory errors, including flash memory ECC events, array integrity testing, and read-while-write events, see the flash memory chapter.

### 21.3.12 Clocking

This module has no clocking considerations.

### 21.3.13 Interrupts

This module has no interrupts.

## 21.4 External signals

This module has no external signals.

## 21.5 PFLASH register descriptions

PFLASH provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model consists of flash memory access configuration.

You can reference the programming model only by using a 32-bit (word) access. References that are attempted using different access sizes, or to undefined (reserved) addresses, or in User mode generate an IPS error termination. PFLASH allows access to the programming model by all system bus masters.

Write to read only registers don't generate error termination.

You can only access the programming model in Supervisor mode, except *PEADR* registers which can be accessed in Supervisor or User mode.

Attempted updates to the programming model when PFLASH is in the middle of an operation results in non-deterministic behavior. You must architect software to avoid this scenario. The recommended flow for multicore devices is:

1. Start only one core.
2. Execute initialization code until it is complete.
3. Start the remaining cores.

If you need to reconfigure the flash memory, code execution must be temporarily moved to system RAM.

### 21.5.1 PFLASH memory map

PFLASH base address: 4026_8000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|

### 21.5.6 Platform Flash Memory Program Erase Address Logical (PFCPGM_PEADR_L)

#### Offset

| Register | Offset |
|---|---|
| PFCPGM_PEADR_L | 300h |

#### Function

Provides the flash memory address to be programmed, or the location of the sector or block to be erased through main flash memory (pgm/erase) queue. Write access to this register is domain-ID aware.

The respective bus master must have program/erase permission to the flash memory address written to this register. Otherwise a transfer error results. For further information on flash memory address restrictions see the XRDC chapter.

A write to this register is managed via three-cycle access. Before updating the register, you must ensure that no ongoing high-voltage operation is executing through the flash memory main queue.

Unauthorized flash memory address writes result in a transfer error.

Writes to this register during an ongoing high-voltage operation (initiated through the flash memory main queue) or during express program operation are ignored.

| PFCPGM_PEADR_P | 304h |

### Function

Reflects the flash memory block number and offset address corresponding to Platform Flash Memory Program Erase Address Logical (PFCPGM_PEADR_L). This register has the same format as the PEADR register in the Flash Memory chapter—see it for details.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 21.5.8 Platform Flash Memory Express Program Erase Address Logical (PFCPGM_XPEADR_L)

### Offset

| Register | Offset |
|---|---|
| PFCPGM_XPEADR_L | 308h |

### Function

Provides the flash memory address to be programmed using the flash memory express program feature. Write access to this register is domain-ID aware.

The respective bus master must have program/erase permission to the flash memory address written to this register. Otherwise a transfer error results. See the XRDC chapter for further information on flash memory address restrictions.

A write to this register is managed via three-cycle access. Before updating the register, you must ensure that no ongoing high-voltage operation is executing through the flash memory main queue.

Unauthorized flash memory address writes result in a transfer error.

Writes to this register during an ongoing express program operation are ignored.

### Diagram

## 21.5.10 Block n Sector Program Erase Lock (PFCBLK0_SPELOCK - PFCBLK4_SPELOCK)

### Offset

| Register | Offset |
|---|---|
| PFCBLK0_SPELOCK | 340h |
| PFCBLK1_SPELOCK | 344h |
| PFCBLK2_SPELOCK | 348h |
| PFCBLK3_SPELOCK | 34Ch |
| PFCBLK4_SPELOCK | 350h |

### Function

Provides a way to protect sectors from being modified. Sector protection is available on the last 256 KB of every block (for 256 KB blocks, all sectors are available for protection). Each lock bit can be associated with a particular domain ID by writing 1 to the appropriate bit in PFCBLKn_SETSLOCK[SETSLCK]. After the lock is acquired, only a master having the same domain ID can modify the corresponding lock bit. If the corresponding PFCBLKn_SETSLOCK[SETSLCK] bit is not equal to 1, any master can modify the appropriate SLCK bit. If a lock bit is already acquired by a particular domain ID, any effort to modify (1 to 0, or 0 to 1) the lock bit by a master with a different domain ID results in a transfer error.

### Diagram

| Field | Function |
|---|---|
| 31-0<br>SLCK | Sector Lock<br>Locks selected sector. If vector bit value = 0, the sector is available for program and erase operations. If vector bit value = 1, the sector is locked and not available for program and erase operations. |

## 21.5.11 Block UTEST Sector Program Erase Lock (PFCBLKU_SPELOCK)

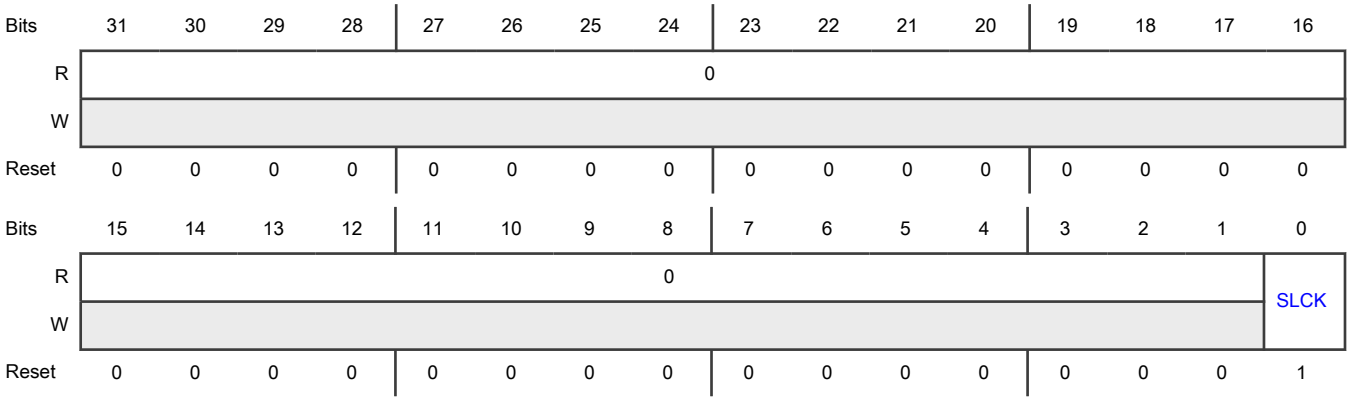
### Offset

| Register | Offset |
|---|---|
| PFCBLKU_SPELOCK | 358h |

### Function

Provides a way to protect sectors from being modified. Sector protection is available on the last 256 KB of every block (for 256 KB blocks, all sectors are available for protection). Each lock bit can be associated with a particular domain ID by writing 1 to PFCBLKU_SETSLOCK[SETSLCK]. After the lock is acquired, only a master having the same domain ID can modify the corresponding lock bit. If the corresponding PFCBLKU_SETSLOCK[SETSLCK] bit is not equal to 1, any master can modify the SLCK bit. If a lock bit is already acquired by a particular domain ID, any effort to modify (1 to 0, or 0 to 1) the lock bit by a master with a different domain ID results in a transfer error.

### Diagram



### Fields

|---|---|
| 31-1<br>— | Reserved |
| 0<br>SLCK | Sector Lock<br>Locks selected sector. If vector bit value = 0, the sector is available for program and erase operations. If vector bit value = 1, the sector is locked and not available for program and erase operations. |

## 21.5.12 Block n Super Sector Program Erase Lock (PFCBLK0_SSPELOCK - PFCBLK3_SSPELOCK)

### Offset

| Register | Offset |
|---|---|
| PFCBLK0_SSPELOCK | 35Ch |
| PFCBLK1_SSPELOCK | 360h |
| PFCBLK2_SSPELOCK | 364h |
| PFCBLK3_SSPELOCK | 368h |

### Function

Provides a way to protect super sectors from being modified. Super sector protection is available on block space larger than 256 KB. For 256 KB blocks, this register is not applicable. For 512 KB blocks, the first half of the block is protected with super sector granularity. For 1 MB blocks, the first 768 KB is protected with super sector granularity. Each lock bit can be associated with a particular domain ID by writing 1 to the appropriate bit in PFCBLKn_SSETSLOCK[SSETSLCK]. After the lock is acquired, only a master having the same domain ID can modify the corresponding lock bit. If the corresponding PFCBLKn_SSETSLOCK[SSETSLCK] bit is not equal to 1, any master can modify the SSLCK bit. If a lock bit is already acquired by a particular domain ID, any effort to modify (1 to 0, or 0 to 1) the lock bit by a master with a different domain ID results in a transfer error.

### Diagram

| PFCBLK2_SETSLOCK | 388h |
| PFCBLK3_SETSLOCK | 38Ch |
| PFCBLK4_SETSLOCK | 390h |

### Function

Provides a mechanism for the masters to gain the ownership of the corresponding PFCBLKn_SPELOCK lock bit based on domain id . After it is equal to 1, the bit is returned to 0 at next reset. If any SETSLOCK bit is not equal to 1, the corresponding LOCK bit can be modified by any master. If a bit is already acquired by a particular domain ID, any effort to modify the lock bit by a master with a different domain ID is ignored without transfer error.

### Diagram

# Chapter 22
# RAM Controller (PRAMC)

## 22.1 Chip-specific PRAMC information

### 22.1.1 PRAMC instances and configuration

Table 95. PRAMC instances and configuration

| Instance | SRAM array | Size (KB) | Applicability |
|---|---|---|---|
| PRAMC_0 | SRAM 0 | 32 | MCXE31B, MCXE31/MCXE315/MCXE316 |
| | SRAM 0 | 128 | MCXE31B (128KB support)<br>MCXE317 (64KB support) |
| PRAMC_1 | SRAM 1 | 32 | MCXE31B |
| | SRAM 1 | 128 | MCXE31B |

### 22.1.2 RAM initialization

After chip power-on reset, you must initialize RAM to a known value using a 64-bit master before 32-bit masters can read or write to RAM. If you do not initialize RAM this way, any attempt to execute a 32-bit read or write access terminates with an uncorrectable ECC error event on this chip.

### 22.1.3 SRAM0 behavior while XRDC is configured to block access to SRAM0

While XRDC is configured to restrict access to SRAM0, the below behaviors should be considered:

1. In case if XRDC is configured to restrict access to SRAM0 and a read transaction to SRAM0 is performed: To ensure faster SRAM0 accesses, the access is routed to SRAM0 and blocked by PRAMC if XRDC is configured to block access. In such a case, if an error is present on the SRAM0 data, (that is error on data or error injected by EIM), the same is latched by ERM as well. This data is not used by application core since PRAMC gives a bus error in this case.
2. In case if XRDC is configured to restrict access to SRAM0 and a 32-bit write access is performed: Since SRAM is 64-bit wide, so a 32-bit write transaction is performed as a read-modify-write. In the read cycle, again as described in previous scenario, the PRAMC will initiate an error response. In this case also, if there is any error on SRAM0 data bus (i.e., error or error injected via EIM), the same is captured in ERM as well.

## 22.2 Overview

The RAM controller is an interface between the system bus (AHB-Lite 2.v6) and the integrated system RAM. It converts the protocols between the system bus and the dedicated RAM array interface.

The RAM controller supports one 64-bit AHB interface and a 64-bit RAM array interface. The AHB port provides a connection to the platform crossbar for direct RAM access from the various crossbar masters.

### 22.2.1 Block diagram

Shown below in Figure 48 is a simplified block diagram depicting the position of the RAM controller within a typical platform architecture.

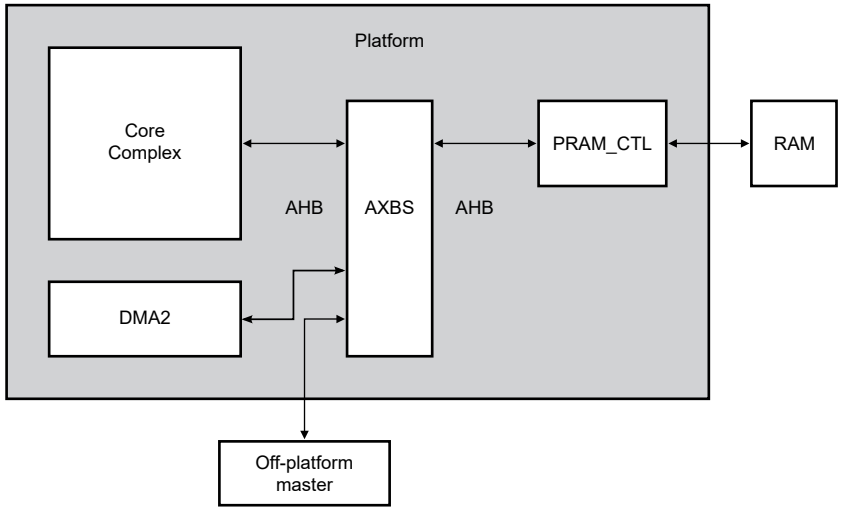

Figure 48. Simplified platform block diagram

### 22.2.2 Features

The following list summarizes the key features of the RAM controller:

- System bus supports 64-bit data
- Array interface supports a 64-bit data + 8-bit ECC interface
- Late-write support via 64-bit data + 8-bit ECC storage buffer supports single-cycle write accesses
- Configurable read access timing (zero or one wait state programmable) allowing use in large range of frequency targets
- Read-modify-write operation supports array write size smaller than a double-word
- Hardware EDC after ECC feature to check the ECC logic.

## 22.3 Functional description

This section describes the functions of the RAM controller.

### 22.3.1 Read and write operations

The RAM controller processes read and write requests to on-chip RAM and provides a register interface for access to performance tuning functions.

**NOTE**

The RAM controller register interface is accessible only in supervisor mode. Accesses in user mode return a transfer error.

#### 22.3.1.1 Reads

Read transfers, of any size, can be configured to complete with a zero or one additional wait state response on the system bus.

#### 22.3.1.2 Optional read wait state

The RAM controller can be optionally programmed to register RAM read data prior to returning it on the system bus. Setting the PRCRx[FT_DIS] field inserts a register in the read data path for use when operating the controller at high frequencies. The state of PRCRx[FT_DIS] field has no effect on writes.

A random, initial access takes two clock cycles (2T) to complete if PRCRx[FT_DIS]=0, and a WRAP4 burst will have an access time of 2-2-2-2. A random, initial access takes three clock cycles (3T) to complete if PRCRx[FT_DIS]=1, and a WRAP4 burst has an access time of 3-2-2-2.

**NOTE**

The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes two clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either one or two cycles depending on RAM speed relative to the PRAMC controller clock frequency.

## 22.3.2 Writes

This section discusses various write operations of the RAM controller.

### 22.3.2.1 64-bit writes

Aligned 64-bit writes execute in a single AHB data phase cycle, resulting in zero wait states on back-to-back writes of these sizes. If, during the data phase of a write, a read is requested on the AHB, the write is registered in the late-write buffer, enabling the read to take place without a wait state. The valid buffered or late-write data is stored on the next available array address phase.

Back-to-back 64-bit writes execute slightly differently. The first write bypasses the late-write buffer—the write data is stored directly to the array in the same cycle in which it is valid on the AHB.

### 22.3.2.2 Less than 64-bit writes

Writes of size less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme's 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The write data is merged into the appropriate byte lanes along with the potentially corrected read data. A new codeword is generated based on the newly formed double-word. This double-word and its associated check-bits are subsequently written to RAM. Figure 49 provides details on the read-modify-write data path.

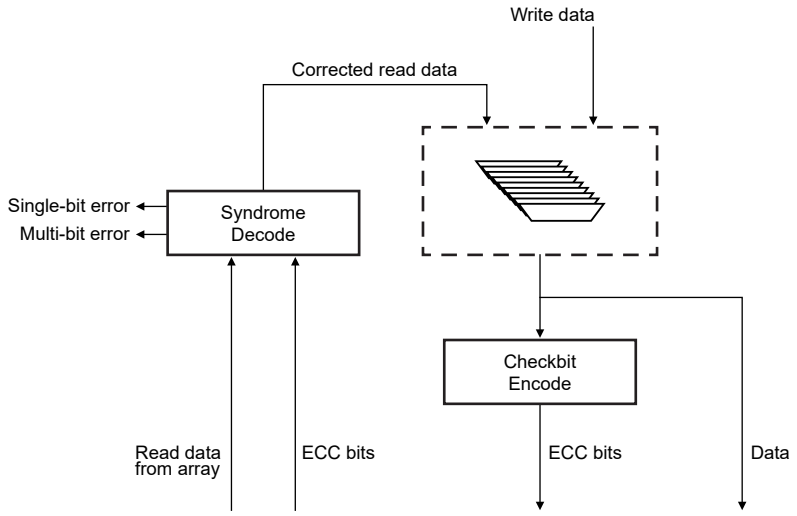

**Figure 49. Read-modify-write data path**

On a read-modify-write operation, the array read data is registered after it is decoded and before it is merged with the AHB write data. Therefore, writes of size less than 64 bits require the insertion of one wait state before the data phase can be completed.

#### 22.3.2.3 Unaligned writes

The RAM controller is compliant with the AMBA-AHB2.v6 Extensions specification with regard to byte strobes. The size of the transfer is sufficient to cover all bytes being written, and covers more bytes in the case of an unaligned transfer. The address of the transfer is rounded down to the nearest boundary of the size of the transaction.

**NOTE**

Unaligned writes always generate read-modify-write operations in the RAM controller in order to preserve the validity of the ECC codeword.

### 22.3.3 Clocking

The following table describes clocks used in this module.

**Table 96. Clock sources**

| Clock name | Description |
|---|---|
| System clock | This is the system clock used for accessing the PRAM controller over the system bus interconnect. |

### 22.3.4 Reset

**Table 97. Reset types**

| Reset | Description |
|---|---|
| System reset | This is the asynchronous system reset used for resetting the PRAM controller. |

### 22.3.5 Interrupts

This module has no interrupts.

## 22.4 External signals

There are no external signals for this module.

## 22.5 Initialization/application information

Each memory address must be written to a known value before it is read, to initialize the ECC. This includes reads generated from the read-modify-write operation that occurs when a write transfer of less than 64 bits or an unaligned write is requested. Without first writing an address to a known value, a read from the address will most likely generate an uncorrectable ECC event.

## 22.6 PRAMC register descriptions

The RAM controller module provides an IPS programming model mapped to a standard on-platform peripheral slot.

**NOTE**

1. The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses generate an IPS error termination.
2. Attempted updates to the PRAMC programming model while a PRAMC operation is in progress will result in non-deterministic behavior. Software architect must be such as to avoid this scenario by ensuring that PRAMC configuration changes are made only during system boot or when only one master is enabled. In multi-core devices, update the PRAMC configuration only when one core is active and no other masters, for example, DMA or communications modules, are enabled. Move any instruction execution or memory references outside the system RAM while updating the PRAMC configuration, for example, to the core local memory space.

## 22.6.1 PRAMC memory map

PRAMC_0 base address: 4026_4000h

PRAMC_1 base address: 4046_4000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Platform RAM Configuration register 1 (PRCR1) | 32 | RW | 0000_0100h |

## 22.6.2 Platform RAM Configuration register 1 (PRCR1)

### Offset

| Register | Offset |
|---|---|
| PRCR1 | 0h |

### Function

The Platform RAM Configuration register 1 (PRCR1) is used to specify operation of the RAM controller.

**NOTE**

This register is accessible only in supervisor mode. Accesses in user mode return a transfer error.

# Chapter 23
# Clocking

## 23.1 Introduction

This chapter describes the clocking architecture and includes the following information:

- System clock specifics
- Clock sources
- Clock architecture
- Clock control registers
- Clock monitoring
- Clock gating
- Module clocking

This chapter discusses the clocks generated on the chip. Peripheral-specific protocol clocks are described in the corresponding peripheral chapters.

## 23.2 Features

- Multiple clock sources supported for clock generation:
  - Fast internal RC oscillator (FIRC)
  - Slow internal RC oscillator (SIRC)
  - Fast external crystal oscillator (FXOSC)
  - Slow external crystal oscillator (SXOSC)

    **NOTE**

    SXOSC is not available in 100-MAX QFP, 48-pin LQFP, and 100-pin LQFP packages. For details, see 'MCXE31 chip's feature comparison' table in Introduction chapter.

  - Phase-locked loop (PLL)
- Frequency-modulated PLL output clock to reduce electromagnetic emissions
- Precise clocks for timers and communication functions
- Glitchless clock switching Clock Generation module (MC_CGM) clock selectors
- System clock progressive clock frequency switching (PCFS)
- Clock monitoring units (CMU_FC, CMU_FM) to check clock integrity
- Core and peripheral clock gating using the Mode Entry module's (MC_ME) partition process configuration registers

## 23.3 Clocking overview

The MCXE31 clocking architecture consists of multiple:

- Clock sources
- Monitors
- Multiplexers
- Dividers

The blocks in the above bullet list provide the required clocking domains for the different functional blocks.

The sections in the following list show the clocking configuration of the chip:

- Clock source generation: PLL, FXOSC, FIRC, SIRC, and SXOSC
- MC_CGM mux 0 clocks: MC_CGM mux 0 generated clocks (not including EMAC clock signals)
- Clockout overview: CLKOUT_STANDBY and CLKOUT_RUN
- Other clocks
- EMAC clocking: Ethernet utilized clocking

The figures shown in MCXE31B clock system diagram, MCXE317 clock system diagram, and MCXE315/MCXE316 clock system diagram show the overall clock tree for the different chip variants of the MCXE31 family, which are a combination of the sections mentioned in the bullet list above.

### 23.3.1 Clock source generation

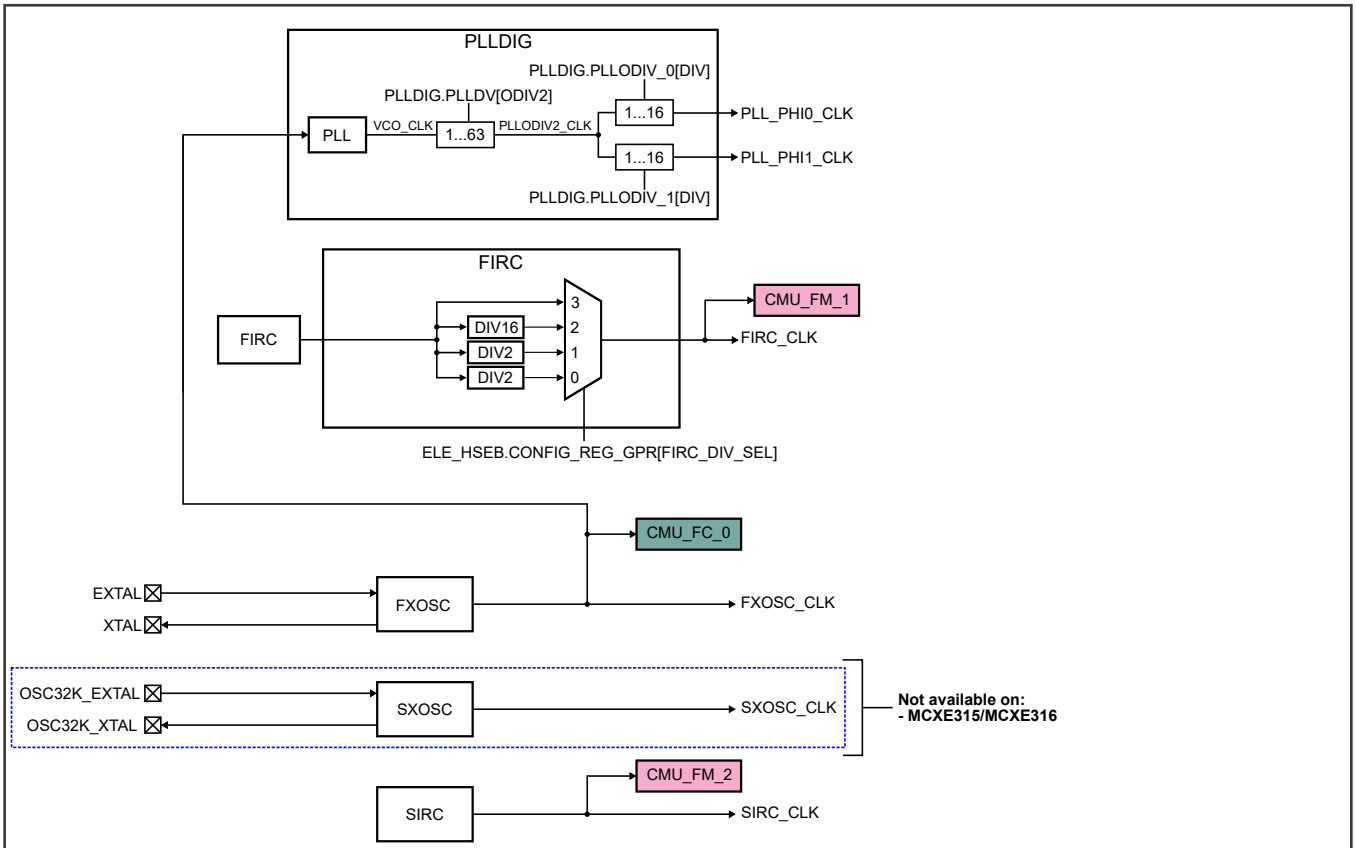

Figure 50. Clock source generation

### 23.3.2 MC_CGM mux 0 clocks

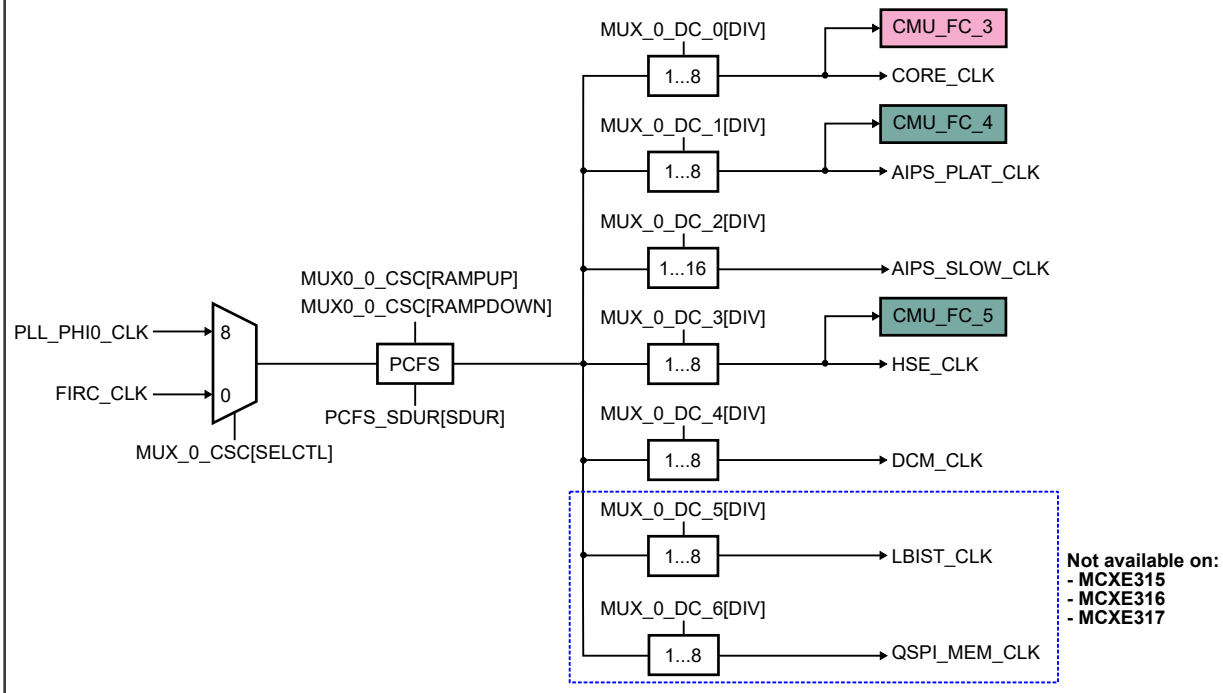

**Figure 51. MC_CGM mux 0 clocks**

**NOTE**

The clock frequency relationship between TCK and HSE_CLK clocks for ELE_HSEB must be a minimum ratio of 1:1.5. For example, if HSE_CLK equals 80 MHz, then TCK must be less than or equal to 53 MHz (80 MHz ÷ 1.5).

### 23.3.3 Clockout overview

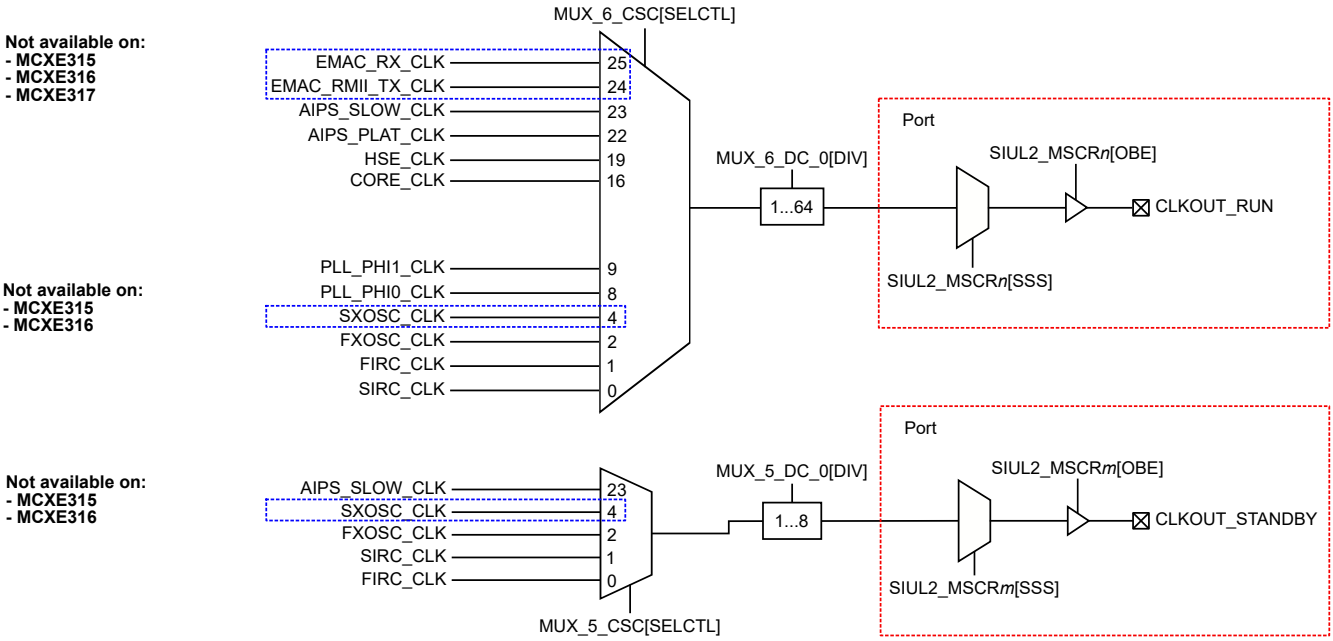

Figure 52. Clockout overview

**NOTE**

CLKOUT_RUN is not available during Standby mode.

#### 23.3.3.1 SIUL2 options for CLKOUT_RUN

Table 98. SIUL2 options for CLKOUT_RUN

| Source | Destination | Port | MSCR*n* | MSCR fields | | |

## 23.4 Clock sources

### 23.4.1 Introduction

The chip contains the following clock sourcing modules:

- FIRC
  - FIRC_CLK is the default system clock source.
- SIRC
- PLL
- FXOSC
- SXOSC (not available on the MCXE315/MCXE316)

The following list shows some of the clock system features:

- All clock sources support software configurability for enabling or disabling. [3]
- All clock sources, except SXOSC_CLK, are initialized to their default state on functional reset.
- The SXOSC_CLK supports RTC applications across functional reset and is reset on destructive reset.

Only SIRC_CLK and FIRC_CLK are enabled out of reset and are enabled on any functional reset. The other clock sources are disabled on reset.

#### 23.4.1.1 Chip clock sources

**Table 100. Chip clock sources**

| Clock source | Divider | Default state | Reset | Uses |
|---|---|---|---|---|
| FIRC_CLK (48 MHz) | 1, 2, 16 | On | POR (enabled on functional and destructive reset)<br>POR assertion - FIRC_CLK disabled asynchronously<br>POR deassertion - FIRC_CLK enabled | • Boot clock<br>• Default system clock source<br>• Safe clock for safety modules FCCU and FOSU<br>• SIUL2 filter clock<br>• MC_RGM clock source |
| PLL_PHI*n*_CLK (640-1280 MHz) | 1...16 | Off | Functional (disabled on functional reset) | • Optional system clock source<br>• Communication modules (FlexCAN, EMAC, QuadSPI, and so on) |
| FXOSC_CLK (8-40 MHz) | — | Off | Functional (disabled on functional reset) | • Reference clock source for PLL<br>• Communication modules (FlexCAN, EMAC, QuadSPI, and so on) |
| SXOSC_CLK (32.768 KHz) | — | Off | Destructive (disabled on destructive reset) | • RTC source for operation across functional reset (SXOSC_CLK is not available on the MCXE315/MCXE316) |

*Table continues on the next page...*

[3] FIRC_CLK and SIRC_CLK cannot be disabled during Run mode.

Table 100. Chip clock sources (continued)

| Clock source | Divider | Default state | Reset | Uses |
|---|---|---|---|---|
| SIRC_CLK (32 KHz) | — | On | POR (enabled on functional reset) | • Safe clock along with FIRC_CLK<br>• SWT clock source<br>• POR_WDG source clock |

## 23.4.2 Chip input clocks

Table 101. Chip input clocks

| Pin | Description |
|---|---|
| XTAL | FXOSC crystal pins |
| EXTAL | |
| OSC32K_XTAL | SXOSC crystal pins (not available on the MCXE315/MCXE316) |
| OSC32K_EXTAL | |
| EMAC_MII_RMII_TX_CLK | EMAC transmitter clock/EMAC RMII clock (not availalble on the MCXE315/MCXE316 or MCXE317) |
| EMAC_MII_RX_CLK | EMAC receiver clock (not availalble on the MCXE315/MCXE316 or MCXE317) |
| JTAG_TCLK/SWD_CLK | JTAG/SWD clock |
| SAI*n*_MCLK | SAI_*n* clock in slave mode (not availalble on the MCXE315/MCXE316 or MCXE317) |
| SAI*n*_BCLK | SAI_*n* bit clock in slave mode (not availalble on the MCXE315/MCXE316 or MCXE317) |
| LPSPI*n*_SCK | LPSPI*n* serial clock in slave mode |
| LPI2C*n*_SCL | LPI2C_*n* clock |
| LPI2C*n*_SCLS | LPI2C_*n* secondary clock |

## 23.4.3 Chip output clocks

Table 102. Chip output clocks

| Pin | Description |
|---|---|
| CLKOUT_RUN | Available during Run mode, unavailable during Standby mode |
| CLKOUT_STANDBY | Available during both Run and Standby modes |
| LPSPI*n*_SCK | LPSPI*n* serial clock in master mode |
| LPI2C*n*_SCL | LPI2C_*n* clock |
| LPI2C*n*_SCLS | LPI2C_*n* secondary clock |
| EMAC_MII_RMII_MDC | EMAC clock for control data transfer to PHY (not availalble on MCXE315/MCXE316 or MCXE317) |
| EMAC_MII_RMII_TX_CLK | EMAC transmit clock (not availalble on MCXE315/MCXE316 or MCXE317) |

*Table continues on the next page...*

Table 102. Chip output clocks (continued)

| Pin | Description |
|---|---|
| TRACE_ETM_CLKOUT | ETM trace clock (not availalble on MCXE315/MCXE316, MCXE317) |
| SAI*n*_BCLK | SAI_*n* bit clock in master mode (not availalble on MCXE315/MCXE316 or MCXE317) |
| QuadSPI_SCKFA | QuadSPI serial clock for serial flash device A (fast) (not availalble on MCXE315/MCXE316 or MCXE317) |

### 23.4.4 Fast internal RC oscillator (FIRC)

The chip has an FIRC with the following features:

- Acts as the system clock source on power-up and after any reset event.
  - Important to detect FIRC_CLK failure and recovery
- Acts as the chip's safe clock for safety-relevant applications.
- Is always enabled in Run mode and can be optionally enabled in Standby mode.
- Used as clock source for the following:
  - MC_RGM
  - FCCU and FOSU
  - SIUL2 filters

#### 23.4.4.1 FIRC failure detection

The FIRC_CLK is the safe clock source used as the FCCU and FOSU clock source. The chip supports FIRC_CLK failure detection and recovery by the mechanisms described in the following cases:

- Case 1 - FIRC_CLK not used as system clock and goes out of range:
  - CMU_FM_1 continuously measures the FIRC_CLK clock frequency using FXOSC_CLK as the reference. On each metering window completion, CMU_FM_1 asserts an interrupt (if configured, CMU_FM_1.IER[FMCIE] is 1). You store a configured reference clock count CMU_FM_1.RCCR[REF_CNT] (for example, number of FXOSC_CLK cycles in metering window). Your software checks the FIRC_CLK clock counts by reading CMU_FM_1.SR[MET_CNT].
  - In the event FIRC_CLK goes out of range, the software detects the frequency variation after the subsequent metering window by checking CMU_FM_1.SR[MET_CNT] and takes necessary action by either of the recommended options:
    - SBC-driven power cycle: The SBC receives indication from the chip (through GPIO toggle, QuadSPI communication, and so on). The SBC initiates a power cycle sequence.
    - Software-driven functional reset: The chip executes a functional reset as configured by your software.
- Case 2 - FIRC_CLK not used as system clock and fails (becomes stuck):
  - CMU_FM_1 continuously measures the FIRC_CLK frequency with FXOSC_CLK as the reference. Application software must check FIRC_CLK after a defined time limit by reading CMU_FM_1.SR[MET_CNT] and CMU_FM_1.SR[FMTO].
  - If there is an FIRC_CLK failure, the CMU_FM_1 writes a 1 to the timeout status flag CMU_FM_1.SR[FMTO].
  - When CMU_FM_1.SR[FMTO] is 1, application software takes necessary action by an SBC-driven power cycle wherein the chip provides an indication to the SBC (through GPIO toggle, QuadSPI communication, and so on). The SBC then initiates a power cycle sequence.
- Case 3 - FIRC_CLK used as system clock and goes out of range or fails (becomes stuck):
  - CMU_FC_3, CMU_FC_4, and CMU_FC_5 continuously monitor the system clock nodes with FXOSC_CLK as reference for FLL or FHH events.

- In the event of FIRC_CLK failure (when FIRC_CLK acts as the system clock source), these CMUs report the FLL event, acting as a destructive reset source.
- The system then undergoes the reset sequence, during which the FIRC_CLK is reinitialized.
- The MC_RGM.DES fields indicate the source of the reset event.
- In addition, CMU_FM_1 monitors FIRC_CLK. If the software is not able to service the CMU_FM_1 interrupt before POR_WDG timeout, POR_WDG treats this as a critical FIRC_CLK failure and initiates a POR_WDG recovery. Therefore, you must ensure that, if enabled, the CMU_FM_1 interrupt must be serviced within the POR_WDG timeout duration.

#### 23.4.4.2 FIRC_CLK behavior in Standby mode

FIRC_CLK can be optionally enabled in Standby mode by configuring FIRC.STDBY_ENABLE[STDBY_EN].

When the PMC acknowledges the Standby mode entry, the FIRC_CLK switches from the On state to the Standby mode configuration selected by the FIRC.STDBY_ENABLE[STDBY_EN] configuration. On wakeup from Standby mode, the FIRC_CLK configuration switches from the Standby mode configured state to the On state.

**NOTE**

When the trims are being applied, the FIRC will appear as momentarily disabled as shown in Reset timing diagram in the Reset overview chapter.

### 23.4.5 SIRC

The chip has a SIRC having the following features:

- Is always enabled in Run mode and can be optionally enabled in Standby mode. Having the SIRC always enabled improves system robustness by ensuring that a clock is always available for various SWTs when reducing the chip power consumption in Standby mode.
- Used as clock source for the following:
  - SWT
  - POR_WDG

#### 23.4.5.1 SIRC failure detection

Like the FIRC_CLK, the SIRC_CLK is a safe clock for the design. The SIRC_CLK is used as clock source for SWTs and POR_WDG and therefore it is important to detect SIRC failure and ensure its recovery. The chip supports SIRC_CLK failure detection and recovery by the mechanism described below.

- Case 1 - SIRC_CLK goes out of range:
  - CMU_FM_2 continuously measures the SIRC_CLK clock frequency with FXOSC_CLK as reference. On each metering window completion, the CMU_FM_2 raises an interrupt. The software checks the SIRC clock counts by CMU_FM_2.SR[MET_CNT] with respect to the reference clock counts CMU_FM_2.RCCR[REF_CNT].
  - In the event of clock going out of range, the software detects the frequency variation after the subsequent metering window by checking CMU_FM_2.SR[MET_CNT] and takes necessary action by either of the recommended options:
    1. SBC-driven power cycle. The chip gives an indication to the SBC (through GPIO toggle, QuadSPI communication, and so on.). The SBC then initiates a power cycle sequence.
    2. SW-driven functional reset. The chip executes a functional reset by software.
- Case 2 - SIRC_CLK fails (becomes stuck):
  - CMU_FM_2 continuously measures the SIRC clock frequency with FXOSC_CLK as reference. Software needs to check this reference after a predefined time by checking CMU_FM_2.SR[MET_CNT] and CMU_FM_2.SR[FMTO].

— In the event of SIRC_CLK clock failure, the CMU_FM_2 writes 1 to the timeout status flag field in its status register, namely, CMU_FM_2.SR[FMTO].

— When CMU_FM_2.SR[FMTO] is 1, the software takes necessary action by either of the recommended options:

1. SBC-driven power cycle: The chip gives an indication to the SBC (through GPIO toggle, QuadSPI communication, and so on). The SBC then initiates a power cycle sequence.
2. Software-driven functional reset: User software executes a functional reset.

#### 23.4.5.2 SIRC behavior in Standby mode

SIRC can optionally be enabled in Standby mode by configuring SIRC.MISCELLANEOUS_IN[STANDBY_ENABLE].

When PMC acknowledges the Standby mode entry, the SIRC switches from the On state to the standby configuration selected by SIRC.MISCELLANEOUS_IN[STANDBY_ENABLE] configuration. On wake-up from Standby mode, the SIRC configuration switches back from the standby-configured state to the On state.

**NOTE**

When the trims are being applied, the SIRC will appear as momentarily disabled similar to FIRC, as shown in section Reset timing diagram.

### 23.4.6 FXOSC

The chip supports an 8–40 MHz fast crystal oscillator which has following features:

- Acts as the reference for PLL.
- Supports crystal input mode and bypass mode if using an external oscillator.
- Acts as a clock source for communication modules:
  — FlexCAN
  — QuadSPI[4]
  — EMAC (EMAC_CLK_TS)[4]

### 23.4.7 SXOSC

The chip supports a slow crystal oscillator (SXOSC) which has the following features (not available on the MCXE315/MCXE316):

- Supports crystal input mode and bypass mode.
- Acts as a clock source for RTC. As SXOSC is not affected by functional reset, it supports RTC operation across functional reset. SXOSC is only reset on destructive reset.

### 23.4.8 PLL

The chip contains up to two PLL to provide precision clock source with the following features:

- Optional system clock source (in high performance applications)
- System clock source in safety applications
- Can be used as clock source for communication modules, when configured as system clock source:
  — FlexCAN (in SYNC mode operation)
  — EMAC (not available on MCXE315/MCXE316 or MCXE317)
  — QuadSPI (not available on MCXE315/MCXE316 or MCXE317)
  — LPSPI

[4] Not present in MCXE315/MCXE316 and MCXE317.

- LPI2C
- FlexIO
- LPUART

- Supports frequency modulation
- Contains lock status monitoring logic which supports loss-of-lock indication

**NOTE**

See PLL Digital Interface (PLLDIG) for PLL configuration details. See the *MCXE31 Data Sheet* for PLL limitations.

#### 23.4.8.1 PLL configurations

The PLL output predivider frequency depends on the PLLDIG.PLLDV[RDIV] and PLLDIG.PLLDV[MFI] configurations. The PLL VCO clock can be divided further by configuring PLLDIG.PLLODIV_0[DIV] for PLL_PHI0_CLK and PLLDIG_PLLODIV_1[DIV] for PLL_PHI1_CLK (see the PLL Digital Interface (PLLDIG) chapter for configuration details).

##### 23.4.8.1.1 PLL configuration sequence

Before enabling the PLL, you must enable FXOSC_CLK and wait until it is stable. FXOSC.STAT[OSC_STAT] must be monitored to determine the FXOSC_CLK status.

To disable the PLL, the software must disable PLL first and only then disable FXOSC (if required).

### 23.4.9 Chip clock outputs

The chip supports two CLKOUT_*x* pins for allowing viewing of some internal clocks as follows:

- CLKOUT_STANDBY
  - Used for showing clocks available in Run and Standby modes.
- CLKOUT_RUN
  - Used for showing only Run mode clocks.

See the Clockout overview section and the Clock Generation Module (MC_CGM) chapter for details on available clocks and configuration.

**NOTE**

The CLKOUT_STANDBY registers are latched when the chip enters Standby mode and are reset in Standby mode sequence. Therefore, the CLKOUT_STANDBY signal needs to be reconfigured on Standby mode exit.

**NOTE**

CLKOUT_STANDBY is available on two pads GPIO[12] and GPIO[138] but CLKOUT across functional reset and standby is supported only on GPIO[12] and OBE(output buffer enable) is controlled by DCM GPR bit. Please refer to DCMRWP1[3] bit for detail.

## 23.5 MC_CGM

The MC_CGM controls the clock functionality of the chip. See the Clock Generation Module (MC_CGM) chapter for details on MC_CGM clocking controls.

### 23.5.1 MC_CGM clock multiplexer types

In this chip, CLKOUT_RUN, CLKOUT_STANDBY, and TRACE_CLK multiplexers are software-controlled multiplexers. The rest are hardware-controlled multiplexers (see the Clock Generation Module (MC_CGM) chapter for details on software and hardware multiplexers).

### 23.5.2 MC_CGM clock multiplexers for MCXE315/MCXE316 and MCXE317

Table 103. MC_CGM clock multiplexers for MCXE315/MCXE316 and MCXE317

| Clock mux | Register description | Source inputs [1] | Register | Selector output | Divider output |
|---|---|---|---|---|---|
| Clock mux 0 | Select Control | FIRC_CLK<br>PLL_PHI0_CLK | MUX_0_CSC | | — |
| | Select Status | | MUX_0_CSS | | |

1. The default clock selected for all clock mux selectors is FIRC_CLK (out of reset).

### 23.5.4 MC_CGM clock sources mapping

Table 105. MC_CGM clock sources mapping

| Clock selector index [1] | MC_CGM clock source | Clock source |
|---|---|---|
| 0 | clk_src_0 | FIRC_CLK |
| 1 | clk_src_1 | SIRC_CLK |
| 2 | clk_src_2 | FXOSC_CLK |
| 3 | Reserved | Reserved |
| 4 | clk_src_4 | SXOSC_CLK [2] |
| 5–7 | Reserved | Reserved |
| 8 | clk_src_8 | PLL_PHI0_CLK |
| 9 | clk_src_9 | PLL_PHI1_CLK |
| 10–11 | Reserved | Reserved |
| 12 | clk_src_12 | PLL_AUX_PHI0_CLK |
| 13 | clk_src_13 | PLL_AUX_PHI1_CLK |
| 15 | Reserved | Reserved |
| 16 | clk_src_16 | CORE_CLK |
| 17–18 | Reserved | Reserved |
| 19 | clk_src_19 | HSE_CLK |
| 20–21 | Reserved | Reserved |
| 22 | clk_src_22 | AIPS_PLAT_CLK |
| 23 | clk_src_23 | AIPS_SLOW_CLK |

*Table continues on the next page...*

Table 105. MC_CGM clock sources mapping (continued)

| Clock selector index [1] | MC_CGM clock source | Clock source |
|---|---|---|
| 24 | clk_src_24 | EMAC_RMII_TX_CLK [3] |
| 25 | clk_src_25 | EMAC_RX_CLK [3] |
| 26–49 | Reserved | Reserved |
| 50 | clk_src_50 | CLKOUT_RUN |

1. All clock selector indexes not shown are reserved.
2. SXOSC_CLK is not available on the MCXE315/MCXE316.
3. EMAC_RMII_TX_CLK and EMAC_RX_CLK are not available on the MCXE315/MCXE316 or MCXE317.

## 23.6 Peripheral clocking

The module clocking diagrams for the peripherals are shown in the following subsections (see Peripheral clock gating for peripheral clock gating possibilities).

### 23.6.1 Module clocking

The following sections show how the chip modules use MODULE_CLK and REG_INTF_CLK to control their functionality.

#### 23.6.1.1 Communication modules

Figure 57 shows the REG_INTF_CLK and MODULE_CLK connections, and Table 106 shows the REG_INTF_CLK and MODULE_CLK signals used by these modules. Any module diagram that does not explicitly show a REG_INTF_CLK uses the same source for REG_INTF_CLK as used by MODULE_CLK.

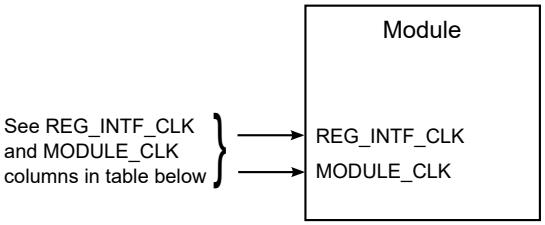

Figure 57. Communication module clocks

Table 106. Communication module clocking

| Module | MODULE_CLK | REG_INTF_CLK |
|---|---|---|
| LPSPI | See LPSPI*n* clocking. | |
| LPI$^2$C | See LPI2C_*n* clocking. | |
| FlexIO | See FlexIO clocking. | |
| FlexCAN | See FlexCAN_*n* clocking. | |
| SAI | See SAI_*n* clocking. | |

#### 23.6.1.1.1 FlexCAN_*n* clocking

The figure below shows the FlexCAN_*n* clocking.

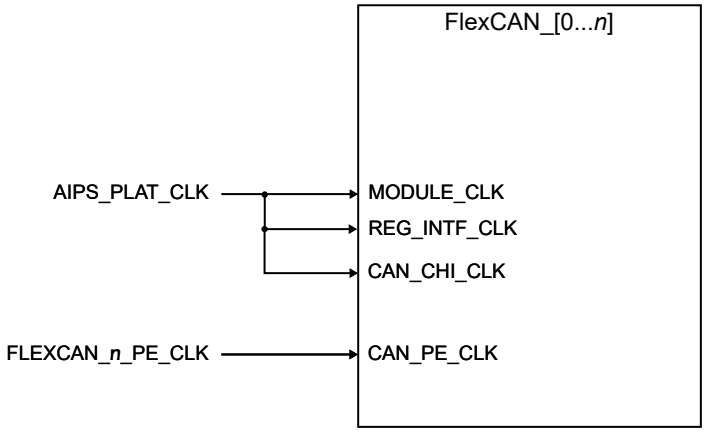

**Figure 58. FlexCAN_*n* clocking**

FlexCAN has the following unique clocks:

- CAN_CHI_CLK—FlexCAN controller host interface clock
- CAN_PE_CLK—FlexCAN protocol engine clock

FlexCAN supports up to an 8 Mbps data rate using a 40 MHz CAN_PE_CLK. With a 16 MHz crystal source, 3.2 Mbps is achievable for baud rate calculations (see the section Protocol timing in the "CAN (FlexCAN)" chapter for details).

For MCXE317, the maximum data rate supported in FlexCAN_0 instance is 5.7 Mbps.

**NOTE**

See Feature comparison for details on this module's availability on your chip variant.

##### 23.6.1.1.1.1 FlexCAN timestamp implementation

The following figure shows the FlexCAN timestamping implementation. The related table shows the timestamp sources and corresponding clock nodes.

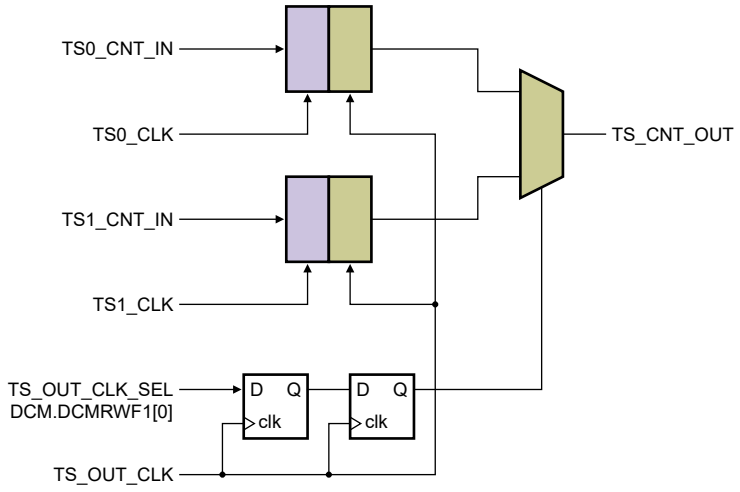

**Figure 59. FlexCAN timestamping**

Table 107. Timestamp sources and clock nodes

| Timestamp | Module | TS clock domain |
|---|---|---|
| TS0_CLK | EMAC | TS0_CLK—EMAC_TS_CLK |
| TS1_CLK | STM0 | TS1_CLK—AIPS_PLAT_CLK |
| TS_OUT_CLK | FlexCAN_*n* | TS_OUT_CLK—EMAC_TS_CLK |

**NOTE**

The timestamp clock (TS_OUT_CLK, EMAC_TS_CLK for MCXE31) must be greater than or equal to FLEXCAN_*n*_PE_CLK. When using STM0 as the timestamp source, the FlexCAN timestamp clock (TS_OUT_CLK, EMAC_TS_CLK for MCXE31) must be greater than or equal to STM0_CLK.

#### 23.6.1.1.2 LPI2C_*n* clocking

The following figure shows LPI2C_*n* clocking, and the related table shows the LPI2C SIUL2 configuration.

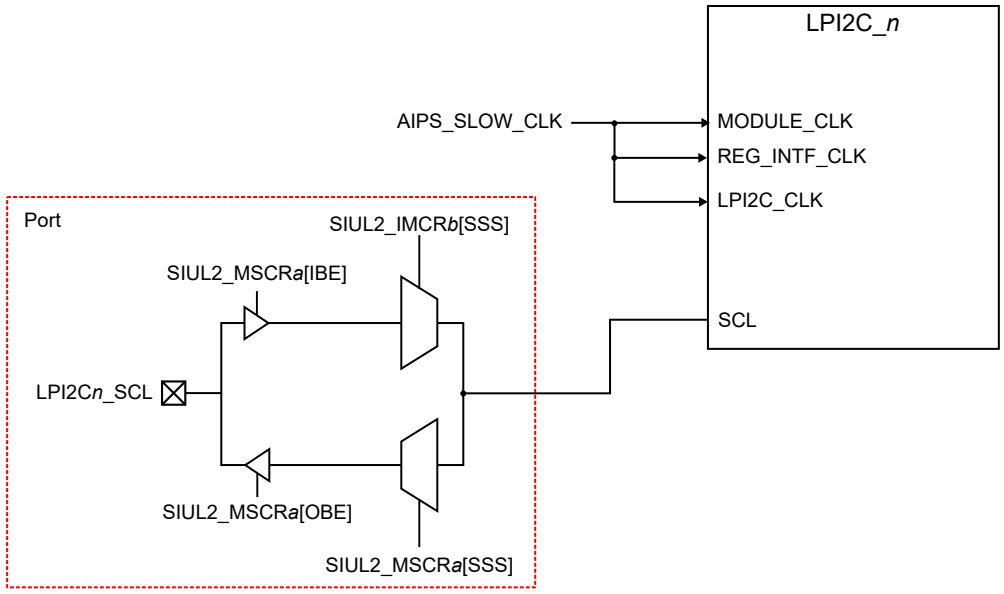

Figure 60. LPI2C clocking

**NOTE**

See Feature comparison for details on this module's availability on your chip variant.

Table 108. SIUL2 options for LPI2C*n*_SCL clock

| $I^2C$_*n* signal | $I^2C$ mode | I/O signal | Port | MSCR*a* | MSCR fields | | | IMCR*b* | IMCR[SSS] |
|---|---|---|---|---|---|---|---|---|---|
| | | | | | OBE | IBE | SSS | | |
| I2C_0_SCL | Slave | LPI2C0_SCL | PTC8 | 72 | 0 | 1 | X | 212 | 0001b |

| | Master | | | | 1 | 0 | 100b | | X |

1. PTF20 pad is not present in MCXE315/MCXE316 and MCXE317
2. PTF7 pad is not present in MCXE315/MCXE316 and MCXE317.

#### 23.6.1.1.3 EMAC clocking

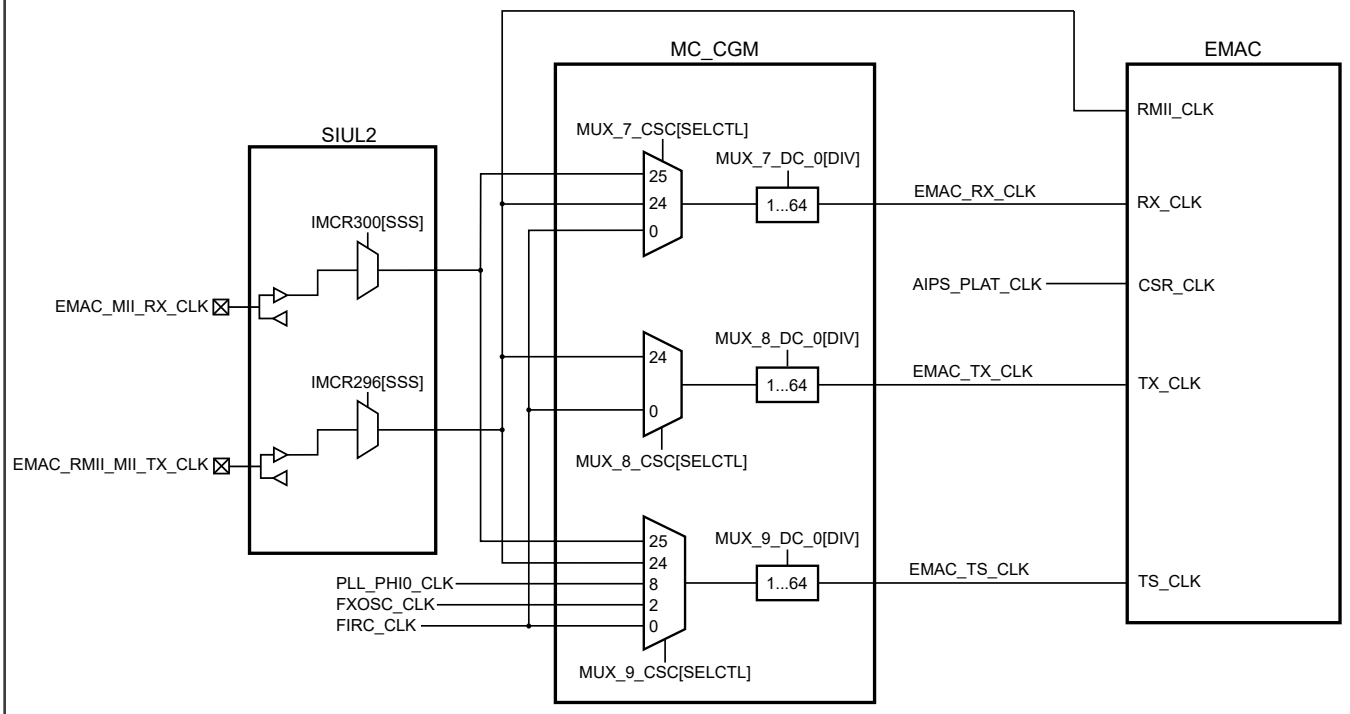

Figure 61. EMAC clocking

**NOTE**

EMAC operates only in Clock options A and B, since the module clock becomes lower than the protocol clock (RMII/MII clocks) in other modes.

**NOTE**

See Feature comparison for details on this module's availability on your chip variant.

#### 23.6.1.1.3.1 EMAC RMII clocking

The following table shows the EMAC RMII clocking, and the related table shows the SIUL2 clock signal configuration for RMII.

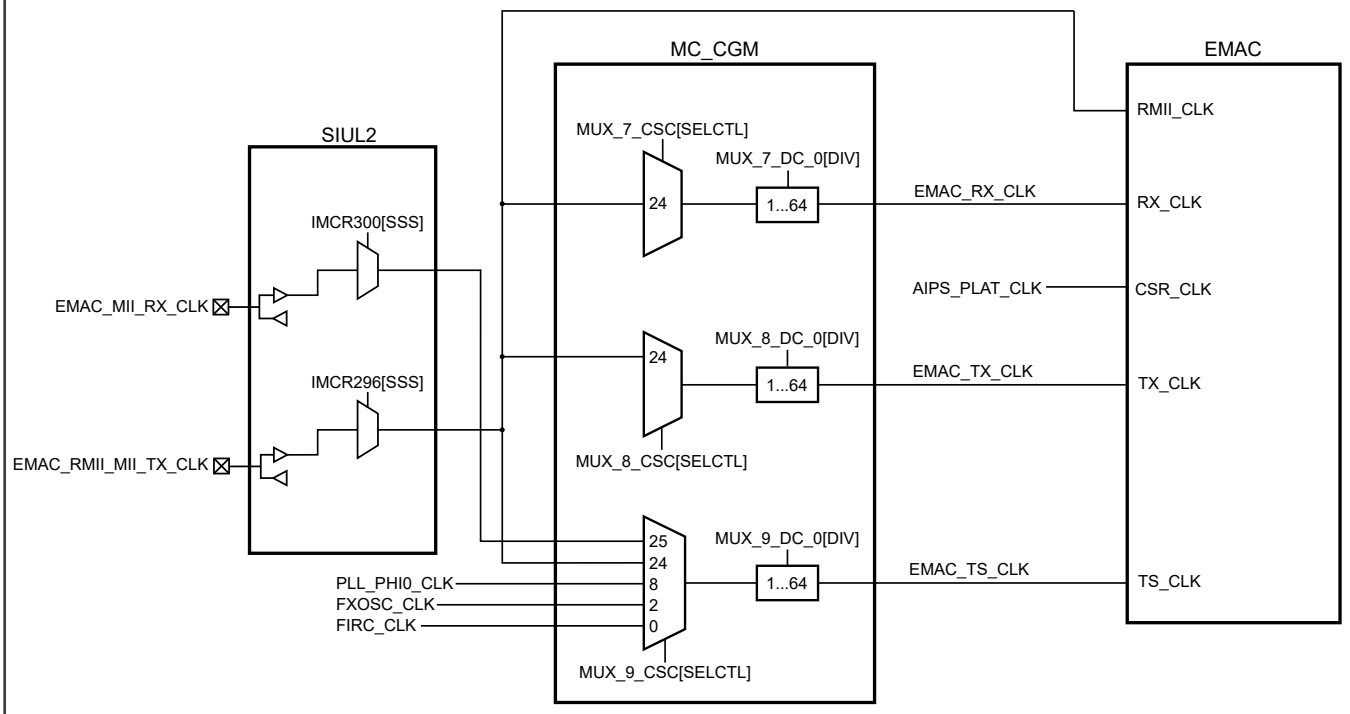

Figure 62. EMAC RMII clocking

Table 109. EMAC RMII clock configuration

| Source clock | Destination clock | Port | SIUL2 | | | | | |
|---|---|---|---|---|---|---|---|---|
| | | | MSCR*a* | MSCR fields | | | IMCR*b* | IMCR[SSS] |
| | | | | OBE | IBE | SSS | | |
| EMAC_RMII_MII_TX_CLK | EMAC_RX_CLK | PTC0 | 64 | 0 | 1 | X | 296 | 0100b |
| | EMAC_TX_CLK | | | | | | | |
| | EMAC_TX_CLK | PTD6 | 102 | 0 | 1 | X | | 0010b |
| | EMAC_RX_CLK | | | | | | | |
| | EMAC_TX_CLK | PTD11 | 107 | 0 | 1 | X | | 0001b |
| | EMAC_RX_CLK | | | | | | | |
| | EMAC_TX_CLK | PTD12 | 108 | 0 | 1 | X | | 0011b |
| | EMAC_RX_CLK | | | | | | | |
| | | | | | | | | |
| EMAC_RMII_MII_TX_CLK (MC_CGM.MUX_9_CSC[SELCTL] = 18h) | EMAC_TS_CLK | PTC0 | 64 | 0 | 1 | X | 296 | 0100b |
| | | PTD6 | 102 | 0 | 1 | X | | 0010b |
| | | PTD11 | 107 | 0 | 1 | X | | 0001b |
| | | PTD12 | 108 | 0 | 1 | X | | 0011b |

*Table continues on the next page...*

Table 109. EMAC RMII clock configuration (continued)

| Source clock | Destination clock | Port | SIUL2 | | | | | |
|---|---|---|---|---|---|---|---|---|
| | | | MSCR*a* | MSCR fields | | | IMCR*b* | IMCR[SSS] |
| | | | | OBE | IBE | SSS | | |
| EMAC_MII_RX_CLK (MC_CGM.MUX_9_CSC[SELCTL] = 19h) | EMAC_TS_CLK | PTC1 | 65 | 0 | 1 | X | 300 | 0011b |
| | | PTD5 | 101 | 0 | 1 | X | | 0010b |
| | | PTD10 | 106 | 0 | 1 | X | | 0001b |

**NOTE**

The EMAC time-stamp clock (EMAC_TS_CLK) can use either of the source clocks show in the table above, but can also select other clocks as selected in MC_CGM.MUX_9_CSC[SELCTL].

### 23.6.1.1.3.2 EMAC MII clocking

The following figure shows the EMAC MII clocking, and the related table shows the SIUL2 clock signal configuration for MII.

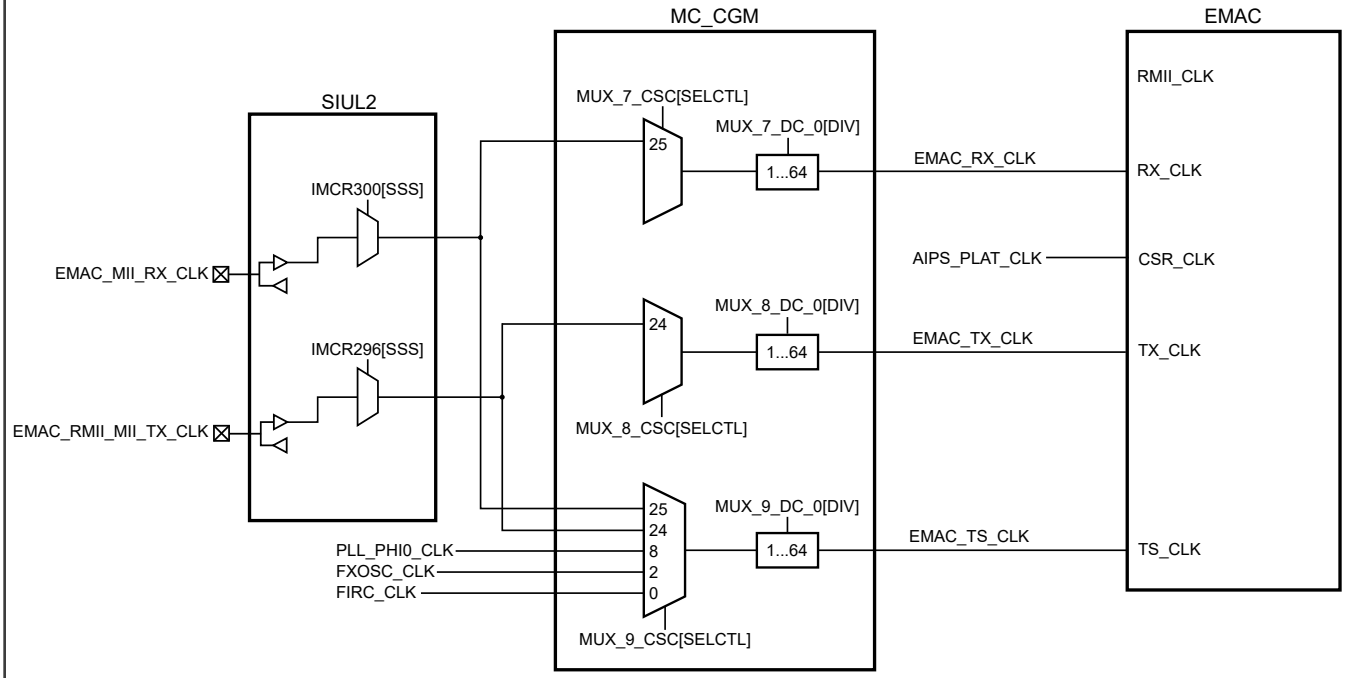

Figure 63. EMAC MII clocking

Table 110. SIUL2 EMAC MII clock configuration

| Source clock | Destination | Port | SIUL2 | | | | | |
|---|---|---|---|---|---|---|---|---|
| | | | MSCR*a* | MSCR fields | | | IMCR*b* | IMCR[SSS] |
| | | | | OBE | IBE | SSS | | |
| EMAC_RMII_MII_TX_CLK | EMAC_TX_CLK | PTC0 | 64 | 0 | 1 | X | 296 | 0100b |
| | | PTD6 | 102 | 0 | 1 | X | | 0010b |

*Table continues on the next page...*

Table 110. SIUL2 EMAC MII clock configuration (continued)

| Source clock | Destination | Port | SIUL2 | | | | | |
|---|---|---|---|---|---|---|---|---|
| | | | MSCR*a* | MSCR fields | | | IMCR*b* | IMCR[SSS] |
| | | | | OBE | IBE | SSS | | |
| | | PTD11 | 107 | 0 | 1 | X | | 0001b |
| | | PTD12 | 108 | 0 | 1 | X | | 0011b |
| | | | | | | | | |
| EMAC_MII_RX_CLK | EMAC_RX_CLK | PTC1 | 65 | 0 | 1 | X | | 0011b |
| | | PTD5 | 101 | 0 | 1 | X | 300 | 0010b |
| | | PTD10 | 106 | 0 | 1 | X | | 0001b |
| | | | | | | | | |
| EMAC_RMII_MII_TX_CLK (MC_CGM.MUX_9_CSC[SELCTL] = 18h) | EMAC_TS_CLK | PTC0 | 64 | 0 | 1 | X | | 0100b |
| | | PTD6 | 102 | 0 | 1 | X | | 0010b |
| | | PTD11 | 107 | 0 | 1 | X | 296 | 0001b |
| | | PTD12 | 108 | 0 | 1 | X | | 0011b |
| EMAC_MII_RX_CLK (MC_CGM.MUX_9_CSC[SELCTL] = 19h) | EMAC_TS_CLK | PTC1 | 65 | 0 | 1 | X | | 0011b |
| | | PTD5 | 101 | 0 | 1 | X | 300 | 0010b |
| | | PTD10 | 106 | 0 | 1 | X | | 0001b |

**NOTE**

The EMAC time-stamp clock (EMAC_TS_CLK) can use any of the signals shown in the figure above which includes either EMAC_RX_CLK or EMAC_RMII_MII_TX_CLK source clocks. MC_CGM.MUX_9_CSC[SELCTL] selects the specific source clock for EMAC_TS_CLK.

#### 23.6.1.1.4 LPSPI*n* clocking

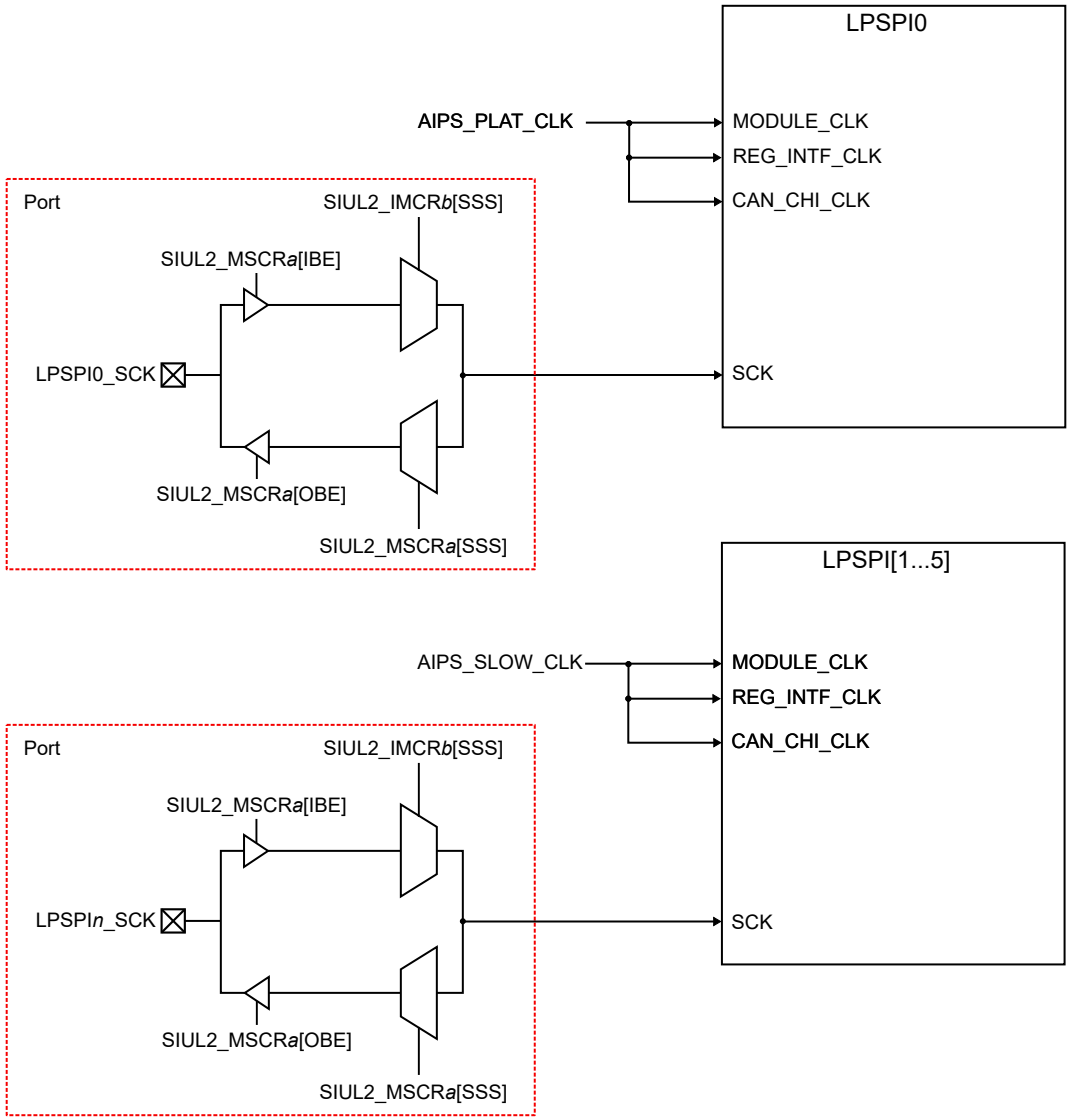

**Figure 64. LPSPI*n* clocking**

**NOTE**

See Feature comparison for details on this module's availability on your chip variant.

**Table 111. SIUL2 options for LPSPI*n* SCK**

#### 23.6.1.1.5 LPUART clocking

The following figure shows the LPUART clocking configuration, and the related table shows LPUART use case baud rates.

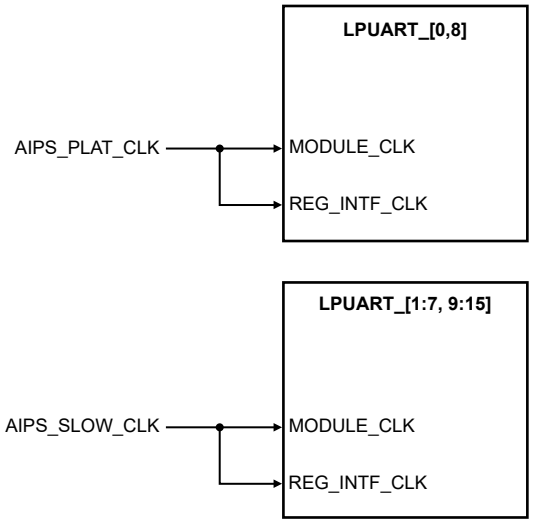

Figure 65. LPUART clocking

**NOTE**

See Feature comparison for details on this module's availability on your chip variant.

Table 112. LPUART baud rate calculation

| Required baud rate (bps) | LPUART_CLK (MHz) | OSR | SBR[12:0] | Calculated baud rate (bps) [1] |
|---|---|---|---|---|
| 8192 | 40 | 4 | 976 | 8196 |
| 8192 | 80 | 15 | 610 | 8196 |
| 8192 | 48 | 15 | 366 | 8196 |
| 115200 | 48 | 15 | 26 | 115384 |
| 115200 | 40 | 7 | 43 | 116279 |
| 19200 | 80 | 4 | 833 | 19207 |
| 19200 | 40 | 7 | 260 | 19230 |
| 38400 | 40 | 7 | 130 | 38461 |

1. MODULE_CLK ÷ (LPUART.BAUD[SBR] × (LPUART.BAUD[OSR] + 1))

#### 23.6.1.1.6 FlexIO clocking

The following figure shows the FlexIO clocking interface. The related two tables show the FlexIO baud rate use cases.

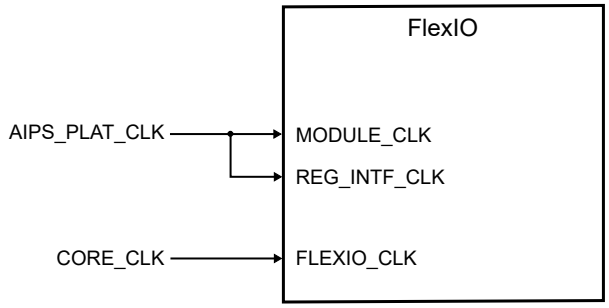

Figure 66. FlexIO clocking

**NOTE**

See Feature comparison for details on this module's availability on your chip variant.

Table 113. FlexIO baud rate calculation (FlexIO.TIMCFG*n*[TIMDEC] = 101b)

| FLEXIO_CLK (CORE_CLK) | Required baud rate | TIMCMP*n*[CMP] | | Theoretical baud rate [1] | Bit duration | Observed baud rate |
|---|---|---|---|---|---|---|
| | | Hex | Decimal | | | |
| 88 MHz | 9600 | 0010h | 16 | 10110.29 | 101.33 µs | 9868 |
| 88 MHz | 19200 | 0007h | 7 | 21484.37 | 47.44 µs | 21079 |
| 88 MHz | 57600 | 0001h | 1 | 85937.50 | 11.66 µs | 85763 |
| 88 MHz | 115200 | 0000h | 0 | 171875.00 | 5.88 µs | 170068 |

1. Theoretical baud rate = Frequency ÷ (256 × 2 × (TIMCMP*n*[CMP] + 1))

Table 114. FlexIO baud rate calculation (FlexIO.TIMCFG*n*[TIMDEC] = 100b)

| FLEXIO_CLK (CORE_CLK) | Required baud rate | TIMCMP*n*[CMP] | | Theoretical baud rate [1] | Bit duration | Observed baud rate |
|---|---|---|---|---|---|---|
| | | Hex | Decimal | | | |
| 88 MHz | 9600 | — | — | — | — | — |
| 88 MHz | 19200 | 8Eh | 142 | 19230.77 | 51.88 µs | 19275 |
| 88 MHz | 57600 | 2Eh | 46 | 58510.64 | 16.89 µs | 59206 |
| 88 MHz | 115200 | 16h | 22 | 119565.21 | 8.44 µs | 118483 |

### 23.6.1.1.7 QuadSPI clocking

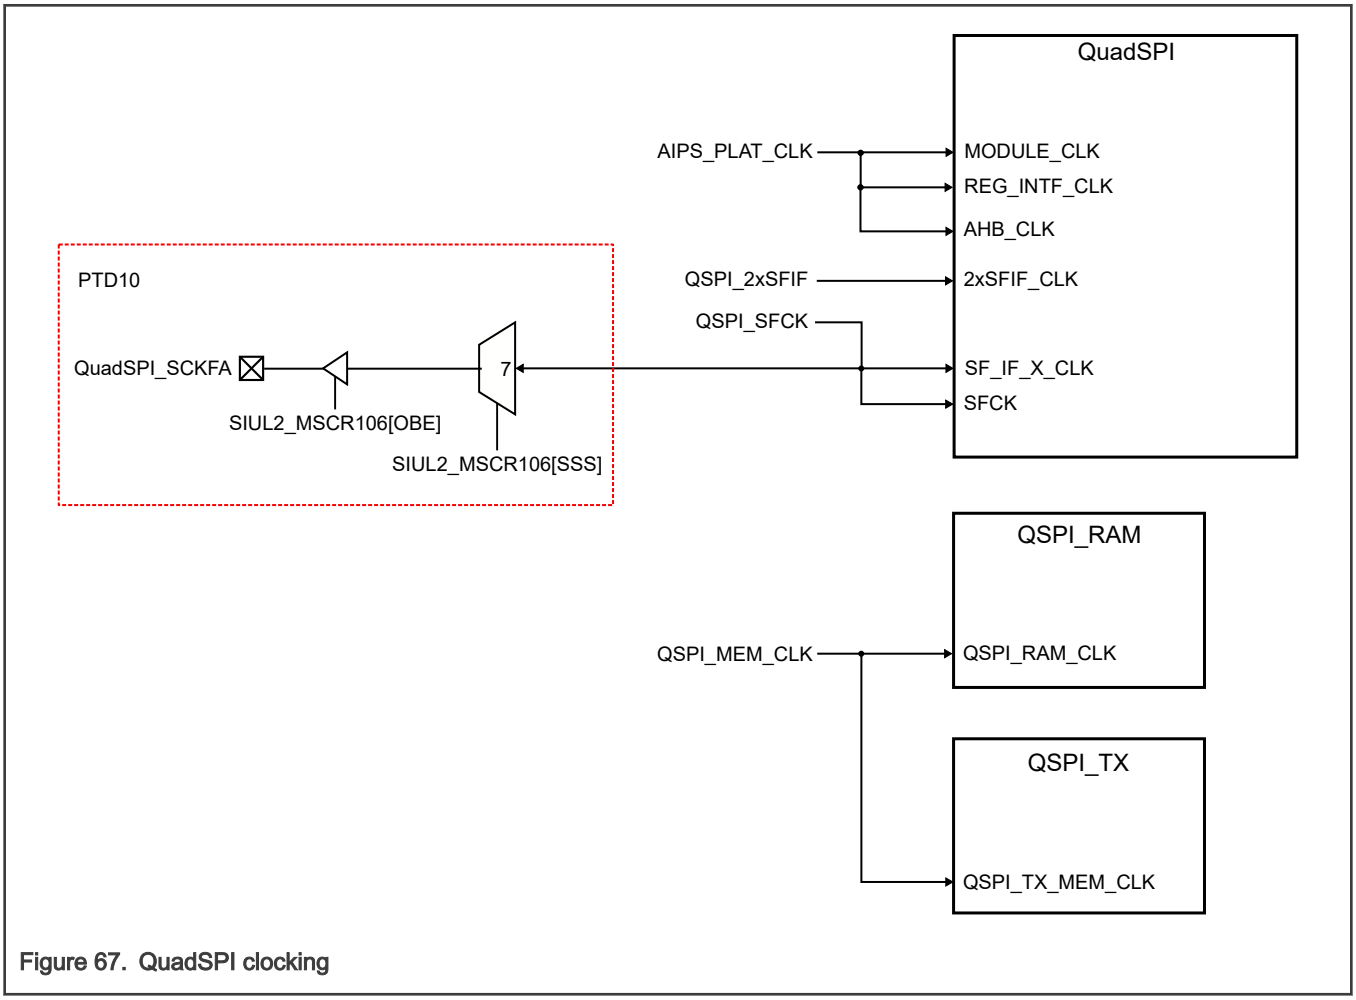

Figure 67. QuadSPI clocking

**NOTE**

See Feature comparison for details on this module's availability on your chip variant.

Table 115. QuadSPI clocking

| Clock option | AIPS_PLAT_CLK | QSPI_SFCK | QSPI_MEM_CLK |
|---|---|---|---|
| See Option A - High Performance mode (CORE_CLK @ 160 MHz) | 80 MHz | 120 MHz | 160 MHz |
| See Option B - Reduced Speed mode (CORE_CLK @ 120 MHz) | 60 MHz | 120 MHz or 80 MHz | 120 MHz |
| See Option F - Operation in 1:1 mode with CORE_CLK and AXBS_CLK at same speed | 80 MHz | 80 MHz | 160 MHz |

#### 23.6.1.1.8 SAI_*n* clocking

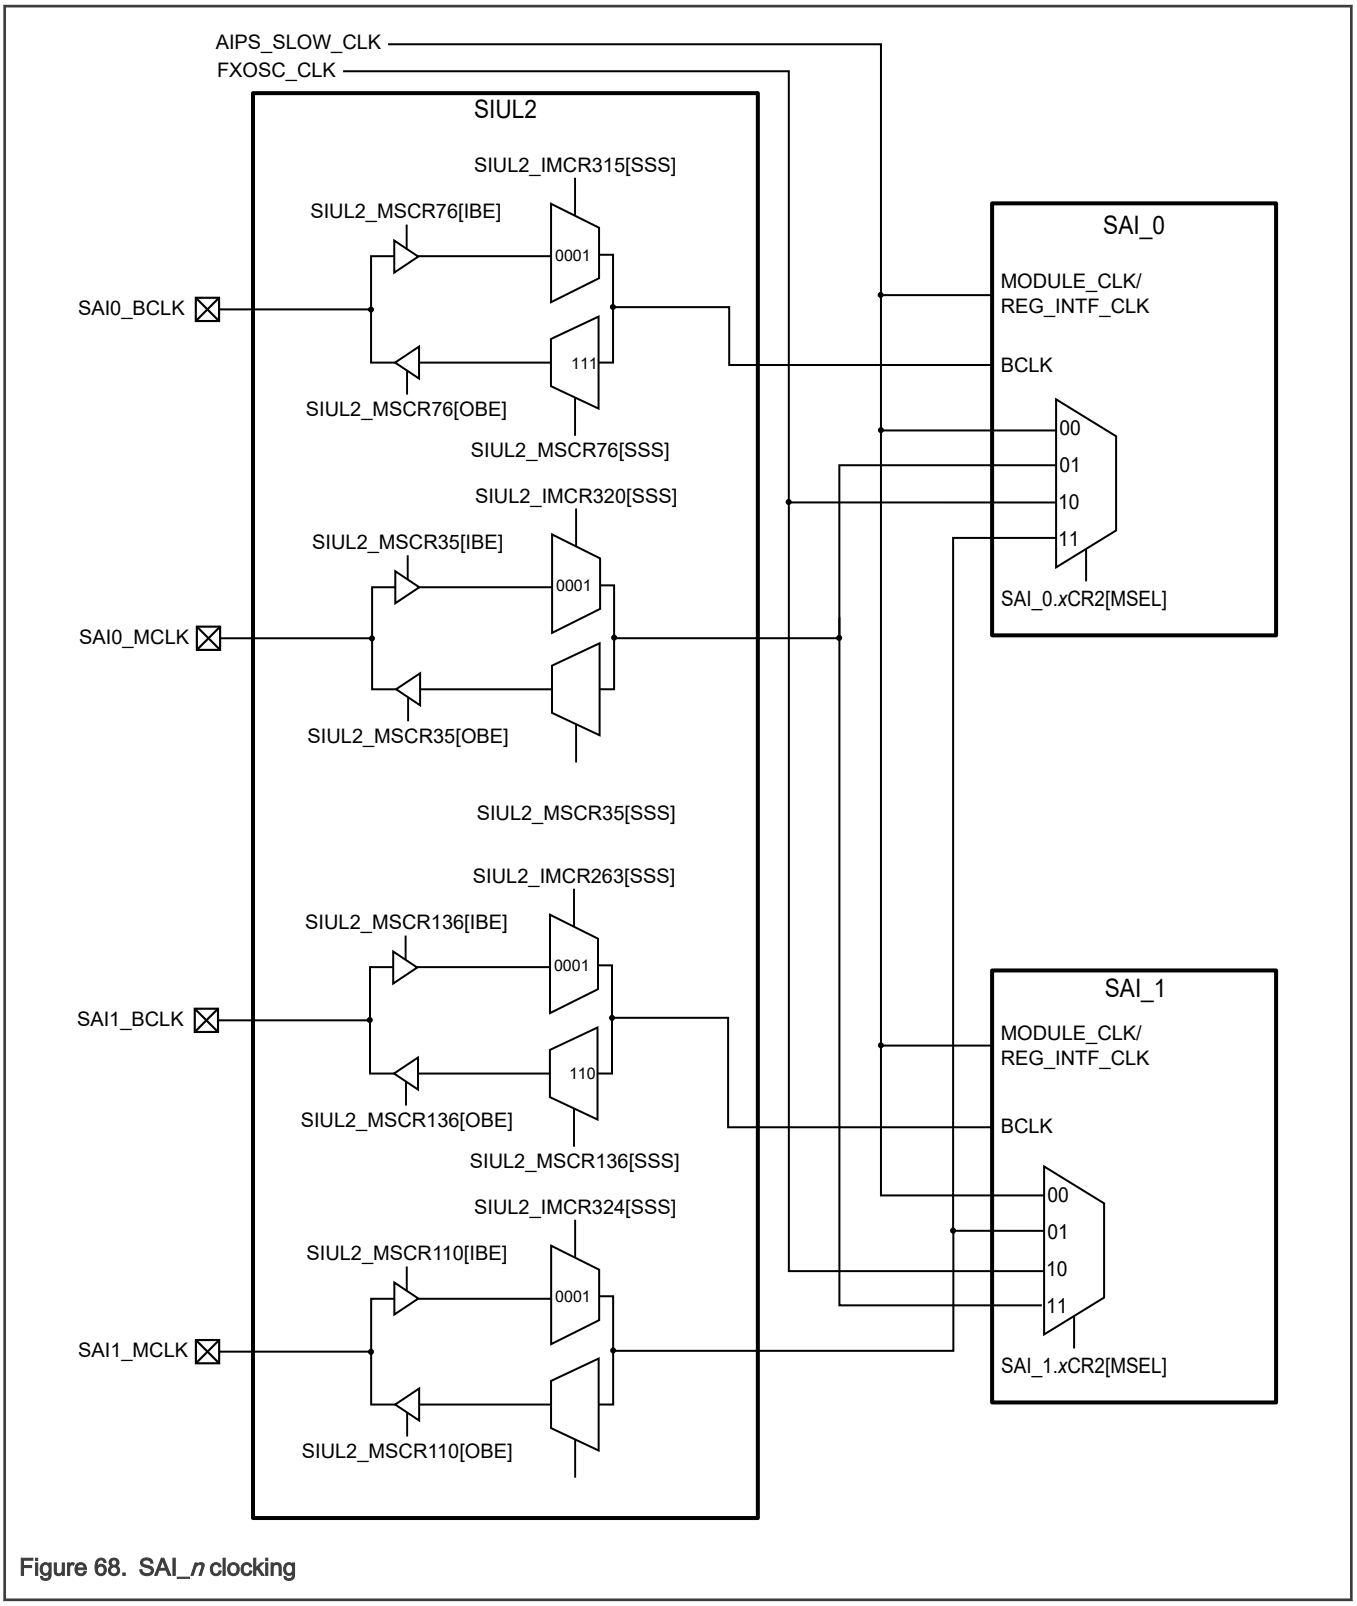

Figure 68. SAI_*n* clocking

**NOTE**

See Feature comparison for details on this module's availability on your chip variant.

Table 116. SIUL2 options for SAI_*n*

| Source | Destination | Port | MSCR *a* | MSCR fields | | | IMCR *b* | IMCR[SSS] |
|---|---|---|---|---|---|---|---|---|
| | | | | OBE | IBE | SSS | | |
| SAI0_MCLK | SAI_0.*x*CR2[MSEL] = 01b<br>SAI_1.*x*CR2[MSEL] = 11b | PTB3 | 35 | 0 | 1 | X | 320 | 0001b |
| | | | | — | — | Not available | | X |
| SAI1_MCLK | SAI_0.*x*CR2[MSEL] = 11b<br>SAI_1.*x*CR2[MSEL] = 01b | PTD14 | 110 | 0 | 1 | X | 324 | 0001b |
| | | | | 1 | 0 | Not available | | X |
| SAI0_BCLK | SAI0 BCLK | PTC12 | 76 | 0 | 1 | X | 315 | 0001b |
| SAI0 BCLK | SAI0_BCLK | | | 1 | 0 | 111b | | X |
| SAI1_BCLK | SAI1 BCLK | PTE8 | 136 | 0 | 1 | X | 322 | 0001b |
| SAI1 BCLK | SAI1_BCLK | | | 1 | 0 | 110b | | X |

Internally generated MCLK is not supported on the MCXE31 chip family.

### 23.6.1.2 System modules

Figure 69 shows the REG_INTF_CLK and MODULE_CLK connections, and Table 117 shows the REG_INTF_CLK and MODULE_CLK signals used by these modules. Any module diagram that does not explicitly show a REG_INTF_CLK uses the same source for REG_INTF_CLK as used by MODULE_CLK.

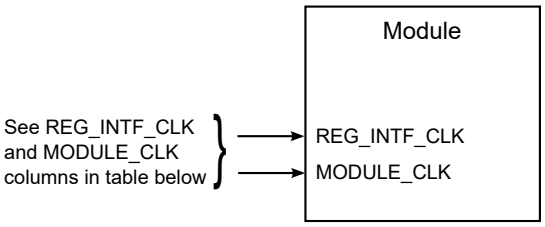

Figure 69. System module clocks

Table 117. System module clocking

| Module | MODULE_CLK | REG_INTF_CLK |
|---|---|---|
| MSCM | AIPS_PLAT_CLK | AIPS_PLAT_CLK |
| MCM | AIPS_SLOW_CLK | AIPS_SLOW_CLK |
| SIUL2 | See SIUL2 clocking. | |
| VIRT_WRAPPER | AIPS_SLOW_CLK | AIPS_SLOW_CLK |
| AXBS | CORE_CLK | AIPS_PLAT_CLK |

*Table continues on the next page...*

Table 117. System module clocking (continued)

| Module | MODULE_CLK | REG_INTF_CLK |

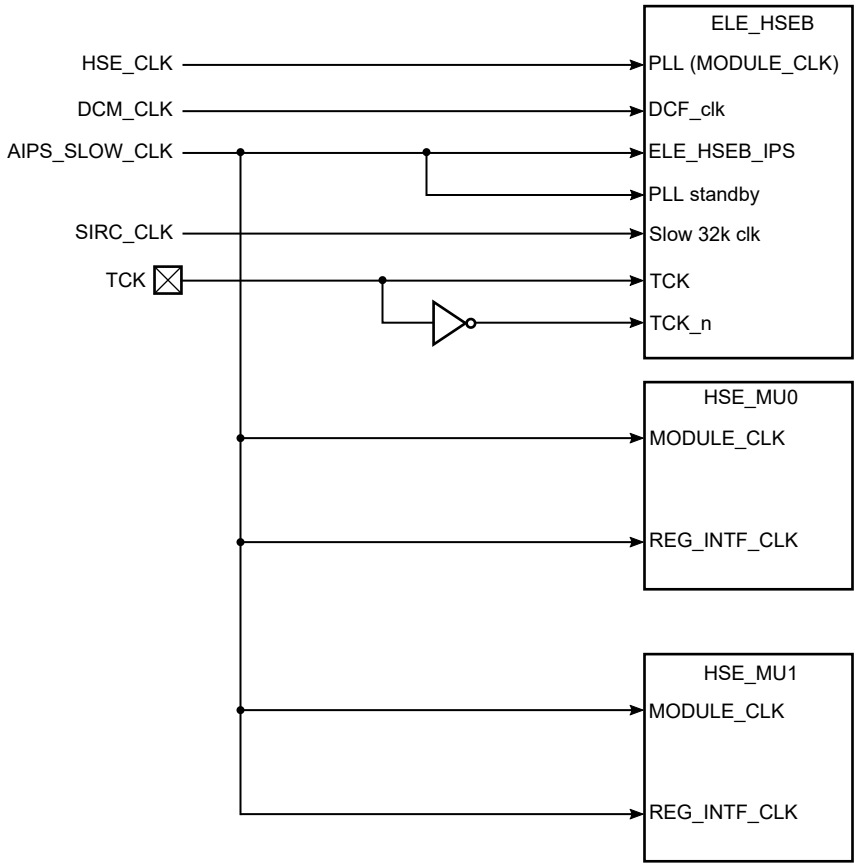

Figure 79. ELE_HSEB clocking

### 23.6.1.6 Power-management modules

Figure 80 shows the REG_INTF_CLK and MODULE_CLK connections, and Table 121 shows the REG_INTF_CLK and MODULE_CLK signals used by these modules. Any module diagram that does not explicitly show a REG_INTF_CLK uses the same source for REG_INTF_CLK as used by MODULE_CLK.

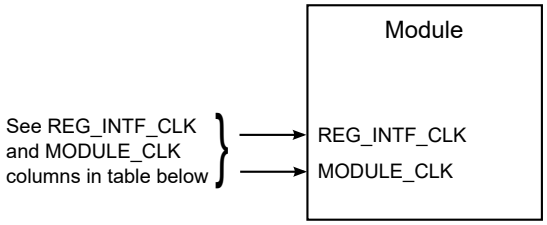

Figure 80. Power-management module clocks

Table 121. Power-management module clocking

| Module | MODULE_CLK | REG_INTF_CLK |
|---|---|---|
| PMC | AIPS_SLOW_CLK | AIPS_SLOW_CLK |
| MC_ME | AIPS_SLOW_CLK | AIPS_SLOW_CLK |
| MC_PCU | FIRC_CLK | FIRC_CLK |
| WKPU | AIPS_SLOW_CLK | AIPS_SLOW_CLK |

#### 23.6.1.7 Safety modules

Figure 81 shows the REG_INTF_CLK and MODULE_CLK connections, and Table 122 shows the REG_INTF_CLK and MODULE_CLK signals used by these modules. Any module diagram that does not explicitly show a REG_INTF_CLK uses the same source for REG_INTF_CLK as used by MODULE_CLK.

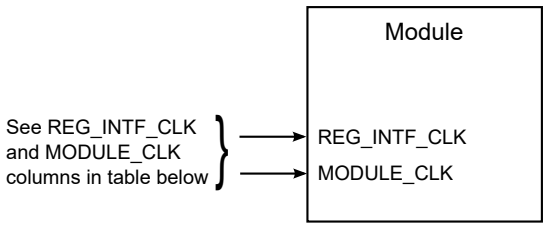

Figure 81. Safety module clocks

Table 122. Safety module clocking

| Module | MODULE_CLK | REG_INTF_CLK |
|---|---|---|
| EIM | AIPS_PLAT_CLK | AIPS_PLAT_CLK |
| ERM | See ERM clocking. | |
| FCCU | See FCCU clocking. | |
| STCU2 | See STCU2 clocking. | |
| REG_PROT | AIPS_SLOW_CLK | AIPS_SLOW_CLK |
| CMU_FC | AIPS_SLOW_CLK | AIPS_SLOW_CLK |
| CMU_FM | AIPS_SLOW_CLK | AIPS_SLOW_CLK |
| CRC | AIPS_PLAT_CLK | AIPS_PLAT_CLK |

#### 23.6.1.7.2 STCU2 clocking

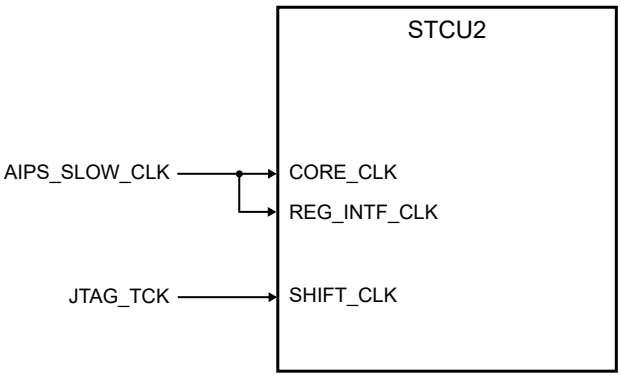

Figure 83. STCU2 clocking

#### 23.6.1.7.3 ERM clocking

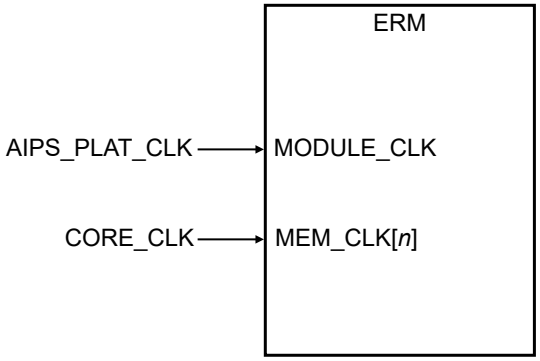

Figure 84. ERM clocking

**NOTE**

MEM_CLK[20:23] are not used. Source clock for MEM_CLK[0:19] is CORE_CLK.

#### 23.6.1.8 ADC and motor control modules

Figure 85 shows the REG_INTF_CLK and MODULE_CLK connections, and Table 123 shows the REG_INTF_CLK and MODULE_CLK signals used by these modules. Any module diagram that does not explicitly show a REG_INTF_CLK uses the same source for REG_INTF_CLK as used by MODULE_CLK.

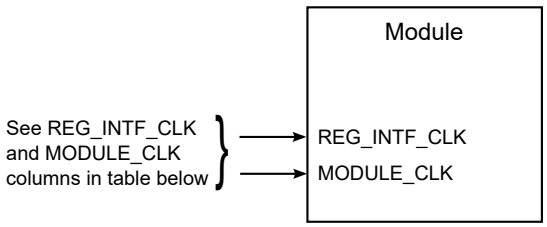

**Figure 85. Motor control module clocks**

**Table 123. Motor control module clocking**

| Module | MODULE_CLK | REG_INTF_CLK |
|---|---|---|
| ADC | See ADC_*n* clocking. | |
| LCU | CORE_CLK | |
| eMIOS | See eMIOS_*n* clocking. | |
| BCTU | See BCTU clocking. | |
| TRGMUX | AIPS_SLOW_CLK | |
| TSPC | AIPS_SLOW_CLK | |

##### 23.6.1.8.1 ADC_*n* clocking

The following figure shows ADC_*n* clocking configuration.

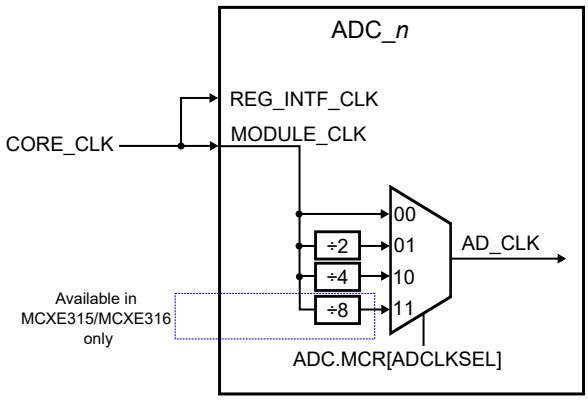

**Figure 86. ADC_*n* clocking**

**NOTE**

See Feature comparison for details on this module's availability on your chip variant.

The prescaler can be bypassed when using FIRC_CLK as the source (see MC_CGM mux 0 clocks for FIRC_CLK use details). The prescaler must be controlled such that the AD_CLK frequency is less than or equal to 120 MHz for MCXE317/MCXE315/MCXE316. For other MCXE31 products the frequency is 80 MHz.

The minimum operating speed of AD_CLK is 6 MHz using the following configuration:

1. Use FIRC_CLK (48 MHz) as clock source (MC_CGM.MUX_0_CSC[SELCTL] equal to 0000b).
2. Divide FIRC_CLK by 2 for CORE_CLK speed (MC_CGM.MUX_0_DC_0[DIV] equal to 1 (FIRC_CLK divide by 2 = 24 MHz)).
3. Write ADC.MCR[ADCCLKSEL] equal to 10b to divide the FIRC_CLK further by 4 (AD_CLK = 6 MHz).

However, at this lower speed, the ADC_*n* results will be degraded.

#### 23.6.1.8.2 eMIOS_*n* clocking

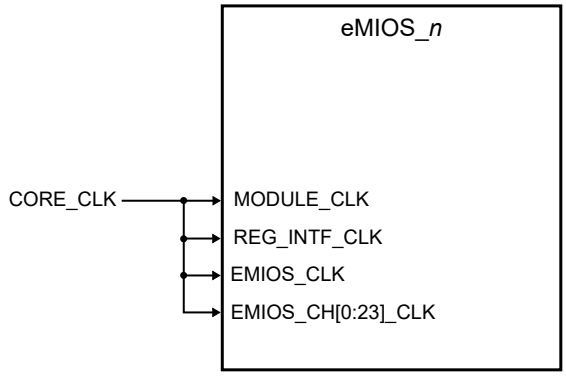

Figure 87. eMIOS_*n* clocking

**NOTE**

See Feature comparison for details on this module's availability on your chip variant.

#### 23.6.1.8.3 BCTU clocking

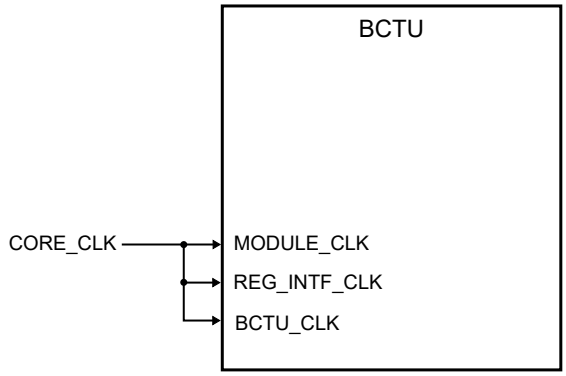

Figure 88. BCTU clocking

### 23.6.1.9 Timer modules

Figure 89 shows the REG_INTF_CLK and MODULE_CLK connections, and Table 124 shows the REG_INTF_CLK and MODULE_CLK signals used by these modules. Any module diagram that does not explicitly show a REG_INTF_CLK uses the same source for REG_INTF_CLK as used by MODULE_CLK.

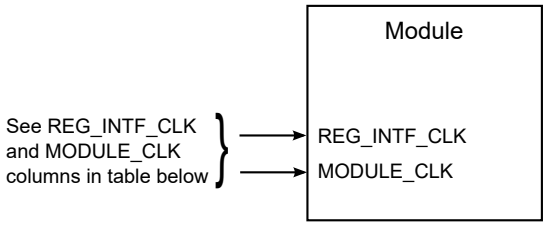

Figure 89. Timer module clocks

Table 124. Timer module clocking

| Module | MODULE_CLK | REG_INTF_CLK |
|---|---|---|
| PIT | See PIT_*n* clocking. | |
| SWT | See SWT_*n* clocking. | |
| STM_*n* | STM0_CLK | STM0_CLK |
| RTC | See RTC clocking. | |

#### 23.6.1.9.1 PIT_*n* clocking

The following figure shows the PIT_*n* clocking configuration. The related tables show the use case configuration.

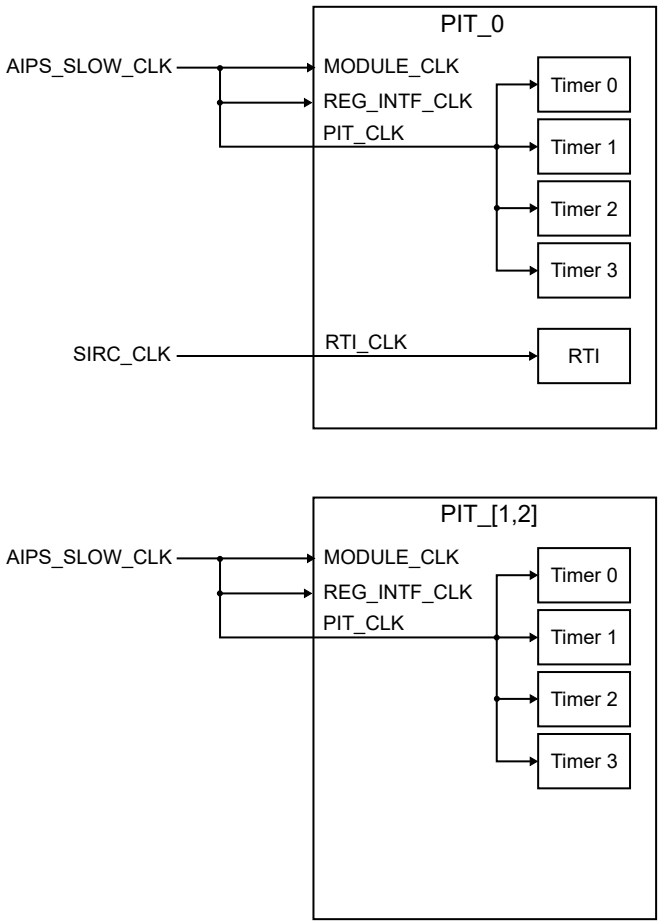

Figure 90. PIT_*n* clocking

**NOTE**

See Feature comparison for details on this module's availability on your chip variant.

Table 125. PIT_0 modes of operation

| MC_ME.PRTN0_COFB1_CLKEN[REQ44] | PIT_0.MCR[MDIS] | PIT_0.MCR[MDIS_RTI] | Mode | Application |
|---|---|---|---|---|
| 0 | X | X | PIT_0 clock gated (minimum power) | Module clock gated and unused / Standby mode, PIT and RTI unused |
| 1 | 0 | 0 | Both PIT and RTI enabled | Run mode |
| 1 | 0 | 1 | PIT running, RTI disabled | Run mode with only PIT active |
| 1 | 1 | 0 | PIT disabled, RTI enabled | Standby mode with RTI enabled |
| 1 | 1 | 1 | Both PIT and RTI disabled | Standby mode with RTI disabled |

Table 126. PIT_[1,2] modes of operation

| MC_ME.PRTN*n*_COFB1_CLKEN[REQ[45,63]] [1] | PIT_[1,2].MCR[MDIS] | Mode | Application |
|---|---|---|---|
| 0 | X | PIT_[1,2] clock gated (minimum power) | Module clock gated and unused, Standby mode |
| 1 | 0 | PIT_[1,2] enabled | Run mode |
| 1 | 0 | PIT_[1,2] running | Run mode with PIT active |
| 1 | 1 | PIT_[1,2] disabled | Standby mode |

1. PIT_1 and PIT_2 MC_ME partition registers used are:
   - PIT_1 - MC_ME.PRTN0_COFB1_CLKEN[REQ45]
   - PIT_2 - MC_ME.PRTN1_COFB1_CLKEN[REQ63]

### 23.6.1.9.2 SWT_*n* clocking

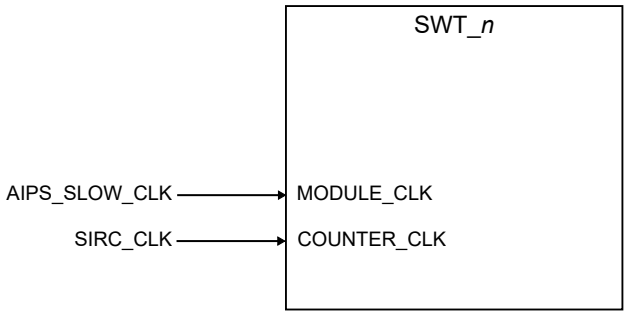

Figure 91. SWT_*n* clocking

**NOTE**

See Feature comparison for details on this module's availability on your chip variant.

#### 23.6.1.9.3 RTC clocking

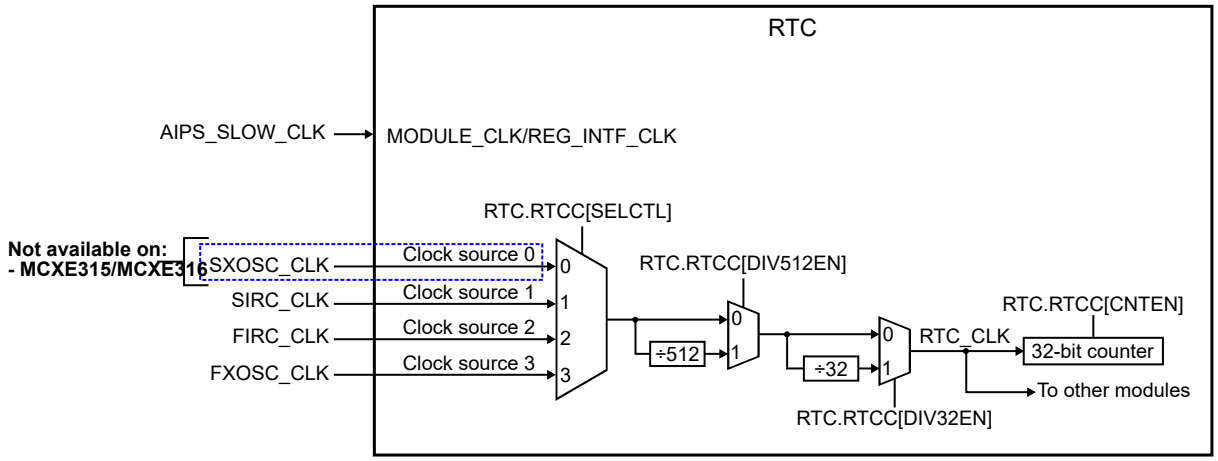

Figure 92. RTC clocking

**NOTE**

The RTC is available in Standby mode. Although bus clock is gated, the RTC can run on FIRC_CLK, SIRC_CLK, FXOSC_CLK, or SXOSC_CLK.

### 23.6.1.10 Debug modules

Figure 93 shows the REG_INTF_CLK and MODULE_CLK connections, and Table 127 shows the REG_INTF_CLK and MODULE_CLK signals used by these modules. Any module diagram that does not explicitly show a REG_INTF_CLK uses the same source for REG_INTF_CLK as used by MODULE_CLK.

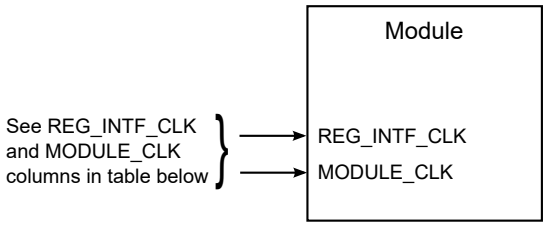

Figure 93. Debug module clocks

Table 127. Debug module clocking

| Module | MODULE_CLK | REG_INTF_CLK |
|---|---|---|
| JTAGC | See JTAGC clocking. | |
| JDC | See JDC clocking. | |

#### 23.6.1.10.1 JTAGC clocking

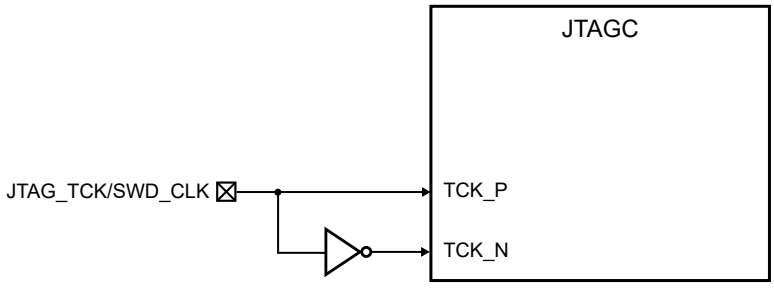

Figure 94. JTAGC clocking

#### 23.6.1.10.2 JDC clocking

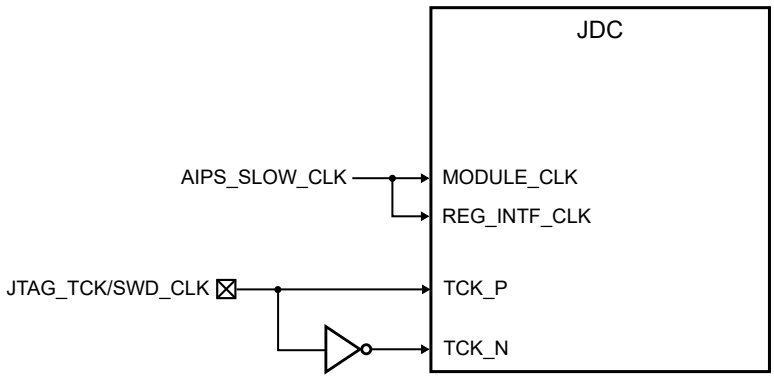

Figure 95. JDC clocking

### 23.6.1.11 Analog modules

Figure 96 shows the REG_INTF_CLK and MODULE_CLK connections, and Table 128 shows the REG_INTF_CLK and MODULE_CLK signals used by these modules. Any module diagram that does not explicitly show a REG_INTF_CLK uses the same source for REG_INTF_CLK as used by MODULE_CLK.

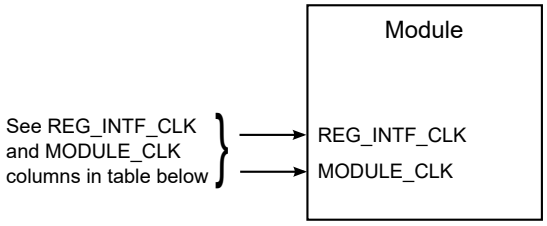

Figure 96. Analog module clocks

Table 128. Analog module clocking

| Module | MODULE_CLK | REG_INTF_CLK |
|---|---|---|
| LPCMP | See LPCMP_*n* clocking. | |
| Temperature Sensor | AIPS_SLOW_CLK | AIPS_SLOW_CLK |

#### 23.6.1.11.1 LPCMP_*n* clocking

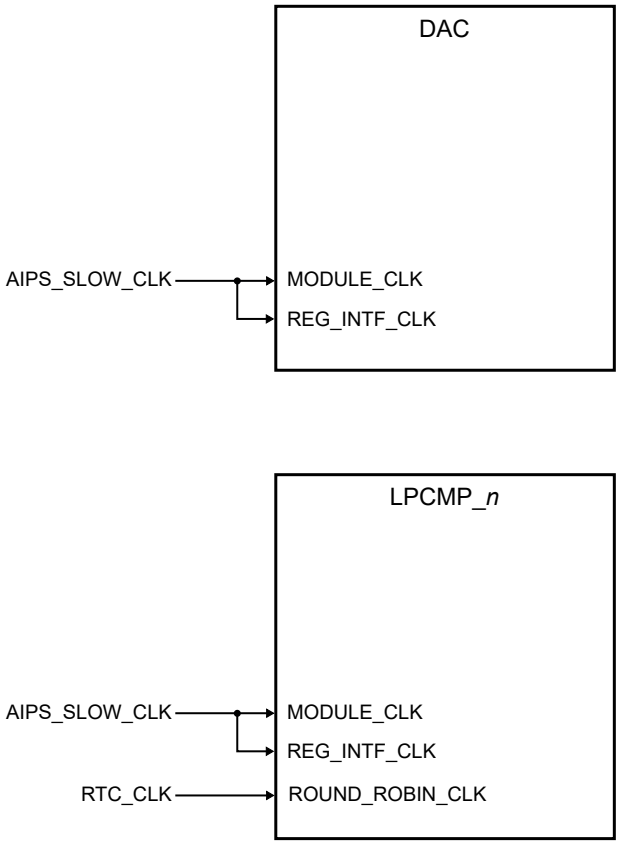

**Figure 97. LPCMP_*n* clocking**

**NOTE**

See Feature comparison for details on this module's availability on your chip variant.

### 23.6.1.12 Memory modules

Figure 98 shows the REG_INTF_CLK and MODULE_CLK connections, and Table 129 shows the REG_INTF_CLK and MODULE_CLK signals used by these modules. Any module diagram that does not explicitly show a REG_INTF_CLK uses the same source for REG_INTF_CLK as used by MODULE_CLK.

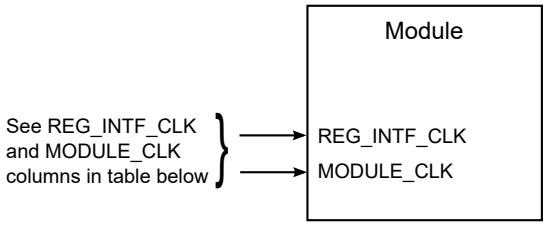

**Figure 98. Memory module clocks**

Table 129. Memory module clocking

| Module | MODULE_CLK | REG_INTF_CLK |
|---|---|---|
| PFLASH/ FLASH | CORE_CLK | AIPS_SLOW_CLK |
| PRAM/ SRAM | CORE_CLK | AIPS_SLOW_CLK |

### 23.6.2 Peripheral data rates

Table 130. Peripheral data rates

| Peripheral | Maximum data rate | |
|---|---|---|
| | MCXE31B | MCXE315/MCXE316 and MCXE317 |
| ADC | See the *MCXE31 Data Sheet* for details. | See the *MCXE31 Data Sheet* for details. |
| eMIOS[1] | Able to shift PWM edge by 1 ÷ (160 MHz) = 6.25 ns. | Able to shift PWM edge by 1 ÷ (120 MHz) = 8.33 ns. |
| BCTU[2] | BCTU to generate triggers at 160 MHz. | BCTU to generate triggers at 120 MHz. |
| LCU | Same domain as EMIOS and BCTU. | Same domain as EMIOS and BCTU. |
| QuadSPI | • Flash memory interface: SDR 120 MHz<br>• DDR and hyperflash not supported | • Flash memory interface: SDR 120 MHz<br>• DDR and hyperflash not supported |
| EMAC | See the section EMAC instance and configuration in the "Ethernet Media Access Controller (EMAC)" chapter for details. | See the section EMAC instance and configuration in the "Ethernet Media Access Controller (EMAC)" chapter for details. |
| FlexCAN[3] | 8 Mbps | 8 Mbps |

5. See the section Clocking in the "Low Power Serial Peripheral Interface (LPSPI)" chapter.
6. See the section Clocking in the "Synchronous Audio Interface (SAI)" chapter and SAI_*n* clocking for details.
7. See the section Application information and FlexIO instances and configuration in the "Flexible I/O (FlexIO)" chapter and FlexIO clocking for baud configuration details.

## 23.6.3 Core and peripheral clock control

The chip provides provisions for core and peripheral clock gating. The next sections describe the details on clock gating possibilities and controls (see Power Management Controller (PMC) and Mode Entry Module (MC_ME) for details).

### 23.6.3.1 Clock gating

Application core clocks are gated by individual MC_ME core clock enable bits. Additionally, application cores can be clock gated by executing WFI (see the "Mode Entry Module (MC_ME)" chapter for details).

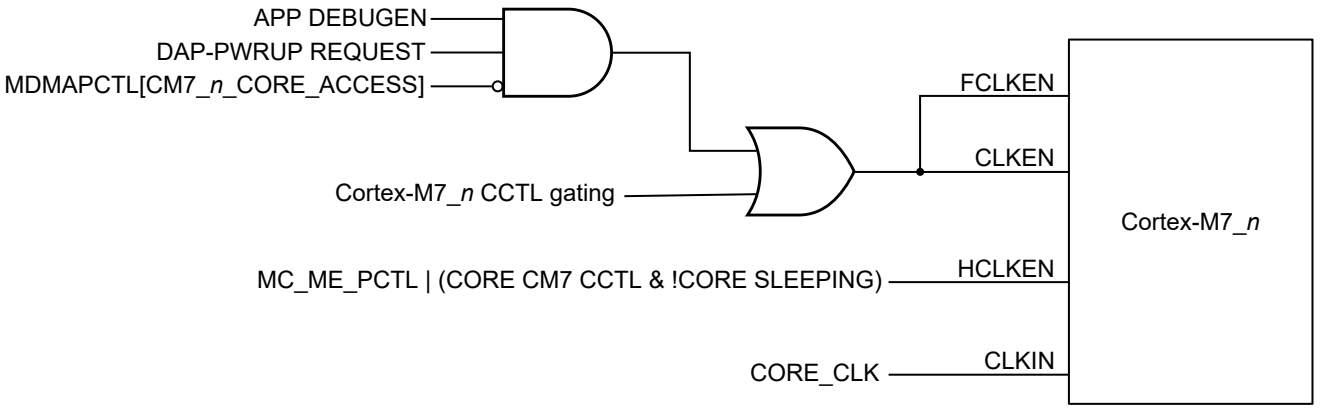

Figure 99. Cortex-M7 core clock gating

To support core debug across functional reset, challenge response done (application debug enable) gating is done so that the debugger can access core debug logic. When the debugger completes its programming with core debug logic, it must program the MDM_AP DAP control bit to shift the control of CLKIN and FCLK to CCTL.

There are two cases in which other masters can access the TCM of each core:

- When the TCM is used as system memory—HCLK will always remain on if TCM PCTL is 1.

- In applications where TCM is not used as system memory, TCM PCTL is written to 0. TCM will then function as the core's memory and HCLK will be gated on WFI.

See the section "MDM_AP register descriptions" in the Debug Subsystem chapter and the Memory Map chapter for details.

#### 23.6.3.2 Peripheral clock gating

See the tables in section "Peripheral clock gating" for the chip partitions, plus peripheral initialization and shutdown details.

## 23.7 Clocking details

### 23.7.1 System clock frequency limitations

**Table 131. System clock frequency limitations**

| System clock node | System clock divider | Maximum frequency allowed | Remarks |
|---|---|---|---|
| CORE_CLK | MC_CGM.MUX_0_DC_0[DIV] | • 160 MHz: MCXE31B<br>• 120 MHz: MCXE315/ MCXE316 and MCXE317 | CORE_CLK is always greater than or equal to AIPS_PLAT_CLK. |
| AIPS_PLAT_CLK | MC_CGM.MUX_0_DC_1[DIV] | 80 MHz | AIPS_PLAT_CLK is always less than or equal to CORE_CLK. |
| AIPS_SLOW_CLK | MC_CGM.MUX_0_DC_2[DIV] | 40 MHz | AIPS_SLOW_CLK is always less than or equal to AIPS_PLAT_CLK. |
| HSE_CLK | MC_CGM.MUX_0_DC_3[DIV] | 120 MHz | When CORE_CLK is equal to or less than 120 MHz, HSE_CLK can be equal to CORE_CLK. When CORE_CLK is higher than 120 MHz, HSE_CLK must be half of the CORE_CLK. |
| DCM_CLK | MC_CGM.MUX_0_DC_4[DIV] | 48 MHz | DCM_CLK |
| LBIST_CLK | MC_CGM.MUX_0_DC_5[DIV] | 48 MHz | LBIST clock |
| QSPI_MEM_CLK | MC_CGM.MUX_0_DC_6[DIV] | 160 MHz | QSPI_MEM_CLK is always equal to CORE_CLK except in 1:1 mode (see Option F - Operation in 1:1 mode with CORE_CLK and AXBS_CLK at same speed). |

**NOTE**

The chip supports 1:1 clocking mode, whereby the core(s) are clocked at the same frequency as the slave ports (flash memory, PRAM controller, AIPS controller). Option F - Operation in 1:1 mode with CORE_CLK and AXBS_CLK at same speed supports this requirement.

The frequencies in the table above are maximum frequencies for a specific clock. However, any clock frequency selected must adhere to the same clock divider ratios shown in Clocking use case examples.

### 23.7.2 Clocking use case examples

The chip supports the clocking modes shown in the subsequent sections, as follows:

- Option A - High Performance mode (CORE_CLK @ 160 MHz) (only available in Run mode)
- Option B - Reduced Speed mode (CORE_CLK @ 120 MHz) (only available in Run mode)

- Option C - Boot Standby mode (CORE_CLK @ 24 MHz)
- Option D - Low-Speed RUN mode (CORE_CLK @ 48 MHz)
- Option E - Low-Speed Run mode (CORE_CLK @ 3 MHz)
- Option E2 - Very-Low-Speed Run mode (CORE_CLK @ 750 kHz)
- Option F - Operation in 1:1 mode with CORE_CLK and AXBS_CLK at same speed (only available in Run mode)

The following list are requirements when configuring the clocking system.

- Configure PRAM/SRAM wait states and flash memory read/write wait cycles in clock configurations where CORE_CLK equals AIPS_PLAT_CLK. See "Option B" in Gasket configurations in various clocking modes for PRAM/SRAM wait states and gasket configurations for clocking options.
- Enable PLL_PHI*n*_CLK only if using it as the system clock source.
- Disable PLL_PHI*n*_CLK when using FIRC_CLK as the system clock, you must.
- Configure the PMC last mile regulator before enabling the PLL. Configure PMC.CONFIG[LMEN] and PMC.CONFIG[LMBCTLEN] (if using an external BJT) to enable the last mile regulator.
- Disable the PLL before disabling the last mile regulator (see PMC last-mile regulator auto-enable feature (for MCXE31B) for last mile regulator details).

### 23.7.2.1 Option A - High Performance mode (CORE_CLK @ 160 MHz)

**Table 132. Option A - High Performance mode (CORE_CLK @ 160 MHz)**

| Clocking options | Clock frequencies | |
|---|---|---|
| | MCXE31B[1] | |
| PLL VCO frequency | 960 MHz | |
| PLLODIV2_CLK<br>(PLLDIG.PLLDV[ODIV2]) | 480 MHz<br>(02h) | |
| FIRC_CLK<br>(ELE_HSEB.CONFIG_REG_GPR[FIRC_DIV_SEL]) | — | |
| **PLL_PHI1_CLK-related clocks** [2] | | |
| PLL_PHI1_CLK<br>(PLLDIG.PLLODIV_1[DIV]) | 240 MHz<br>(0001b) | 160 MHz<br>(0010b) |
| QSPI_SFCK<br>(MC_CGM.MUX_10_DC_0[DIV]) | 120 MHz<br>(0001b) | 80 MHz<br>(0001b) |
| TRACE_CLK<br>(MC_CGM.MUX_11_DC_0[DIV]) | **For fast pads** | |
| | 120 MHz<br>(0001b) | 80 MHz<br>(0001b) |
| | **For medium pads** | |
| | 48 MHz<br>(0100b) | 40 MHz<br>(011b) |
| **PLL_PHI0_CLK-related clocks** [3] | | |

*Table continues on the next page...*

Table 132. Option A - High Performance mode (CORE_CLK @ 160 MHz) (continued)

| Clocking options | Clock frequencies |
|---|---|
| | MCXE31B[1] |
| PLL_PHI0_CLK<br>(PLLDIG.PLLODIV_0[DIV]) | 160 MHz<br>(0010b) |
| CORE_CLK<br>• Application cores<br>• AXBS<br>• SRAM<br>• Flash memory controller port clock<br>• AIPS0 (high-speed peripheral clock)<br>(MC_CGM.MUX_0_DC_0[DIV]) | 160 MHz<br>(0000b) |
| QSPI_MEM_CLK<br>(MC_CGM.MUX_0_DC_6[DIV]) | 160 MHz<br>(0000b) |
| AIPS_PLAT_CLK (medium-speed peripheral clock)<br>(MC_CGM.MUX_0_DC_1[DIV]) | 80 MHz<br>(0001b) |
| AIPS_SLOW_CLK (slow-speed peripheral clock)<br>(MC_CGM.MUX_0_DC_2[DIV]) | 40 MHz<br>(0011b) |
| DCM_CLK<br>(MC_CGM.MUX_0_DC_4[DIV]) | 40 MHz<br>(0011b) |
| HSE_CLK<br>(MC_CGM.MUX_0_DC_3[DIV]) | 80 MHz<br>(0001b) |
| LBIST_CLK<br>(MC_CGM.MUX_0_DC_5[DIV]) | 40 MHz<br>(0011b) |

1. This table does not apply to MCXE315/MCXE316 or MCXE317.
2. MC_CGM.MUX_10_CSC[SELCTL] and MC_CGM.MUX_11_CSC[SELCTL] must equal 1001b.
3. MC_CGM.MUX_0_CSC[SELCTL] must equal 1000b.

#### 23.7.2.2 Option B - Reduced Speed mode (CORE_CLK @ 120 MHz)

Table 133. Option B - Reduced Speed mode (CORE_CLK @ 120 MHz)

| Clocking options | Clock frequencies | |
|---|---|---|
| | MCXE31B | MCXE315/MCXE316 and MCXE317 |
| PLL VCO frequency | 960 MHz | 960 MHz |
| PLLODIV2_CLK<br>(PLLDIG.PLLDV[ODIV2]) | 480 MHz<br>(02h) | 240 MHz<br>(04h) |

*Table continues on the next page...*

Table 133. Option B - Reduced Speed mode (CORE_CLK @ 120 MHz) (continued)

| Clocking options | Clock frequencies | | |
|---|---|---|---|
| | MCXE31B | | MCXE315/MCXE316 and MCXE317 |
| FIRC_CLK (ELE_HSEB.CONFIG_REG_GPR[FIRC_DIV_SEL]) | — | | |
| **PLL_PHI1_CLK-related clocks** [1], [2] | | | |
| PLL_PHI1_CLK (PLLDIG.PLLODIV_1[DIV]) | 240 MHz (0001b) | 160 MHz (0010b) | 48 MHz) (0100b) |
| QSPI_SFCK (MC_CGM.MUX_10_DC_0[DIV]) | 120 MHz (001b) | 80 MHz (001b) | — |
| TRACE_CLK (MC_CGM.MUX_11_DC_0[DIV]) | **For fast pads** | | — |
| | 120 MHz (001b) | 80 MHz (001b) | — |
| | **For medium pads** | | — |
| | 48 MHz (100b) | 40 MHz (011b) | — |
| **PLL_PHI0_CLK-related clocks** [3] | | | |
| PLL_PHI0_CLK (PLLDIG.PLLODIV_0[DIV]) | 120 MHz (011b) | | 120 MHz (001b) |
| CORE_CLK<br>• Application cores<br>• AXBS<br>• SRAM<br>• Flash memory controller port clock<br>• AIPS0 (high-speed peripheral clock)<br>(MC_CGM.MUX_0_DC_0[DIV]) | 120 MHz (000b) | | 120 MHz (000b) |
| QSPI_MEM_CLK (MC_CGM.MUX_0_DC_6[DIV]) | 120 MHz (000b) | | — |
| AIPS_PLAT_CLK (medium-speed peripheral clock) (MC_CGM.MUX_0_DC_1[DIV]) | 60 MHz (001b) | | 60 MHz (001b) |
| AIPS_SLOW_CLK (slow-speed peripheral clock) (MC_CGM.MUX_0_DC_2[DIV]) | 30 MHz (011b) | | 30 MHz (011b) |

*Table continues on the next page...*

Table 133. Option B - Reduced Speed mode (CORE_CLK @ 120 MHz) (continued)

| Clocking options | Clock frequencies | | | |
|---|---|---|---|---|
| | MCXE31B | | MCXE315/MCXE316 and MCXE317 | |
| DCM_CLK<br>(MC_CGM.MUX_0_DC_4[DIV]) | 30 MHz<br>(011b) | | 30 MHz<br>(011b) | |
| HSE_CLK<br>(MC_CGM.MUX_0_DC_3[DIV]) | 120 MHz<br>(000b) | 60 MHz<br>(001b) | 120 MHz<br>(000b) | 60 MHz<br>(001b) |
| LBIST_CLK<br>(MC_CGM.MUX_0_DC_5[DIV]) | 30 MHz<br>(011b) | | 30 MHz<br>(011b) | |

1. MC_CGM.MUX_10_CSC[SELCTL] and MC_CGM.MUX_11_CSC[SELCTL] must equal 1001b.
2. Do not use the combination of different frequencies mentioned below across the 2x2 matrix. The values shown in each cell are valid and must not be clubbed with the values mentioned in any other cells.
3. MC_CGM.MUX_0_CSC[SELCTL] must equal 1000b.

#### 23.7.2.3 Option C - Boot Standby mode (CORE_CLK @ 24 MHz)

Table 134. Option C - Boot Standby mode (CORE_CLK @ 24 MHz)

| Clocking options | Clock frequencies |
|---|---|
| | MCXE31 |
| PLL VCO frequency | — |
| PLLODIV2_CLK<br>(PLLDIG.PLLDV[ODIV2]) | — |

| AIPS_PLAT_CLK (medium-speed peripheral clock)<br>(MC_CGM.MUX_0_DC_1[DIV]) | 24 MHz<br>(0000b) |
| AIPS_SLOW_CLK (slow-speed peripheral clock)<br>(MC_CGM.MUX_0_DC_2[DIV]) | 12 MHz<br>(0001b) |
| DCM_CLK<br>(MC_CGM.MUX_0_DC_4[DIV]) | 24 MHz<br>(0000b) |
| HSE_CLK<br>(MC_CGM.MUX_0_DC_3[DIV]) | 24 MHz<br>(0000b) |

1. The FIRC_DIV_SEL is configured by the sBAF code. It is set to 11b after reset or normal standby exit and FIRC_CLK is 48 MHz. In case of fast standby exit, FIRC_DIV_SEL is 00b and FIRC_CLK is 24 MHz.
2. MC_CGM.MUX_10_CSC[SELCTL] and MC_CGM.MUX_11_CSC[SELCTL] values are don't care since QSPI_SFCK and TRACE_CLK are not used in this use case.
3. MC_CGM.MUX_0_CSC[SELCTL] must equal 0.

#### 23.7.2.4 Option D - Low-Speed RUN mode (CORE_CLK @ 48 MHz)

Table 135. Option D - Low-Speed RUN mode (CORE_CLK @ 48 MHz)

| Clocking options<br>(SYS_CLK = FIRC_CLK) | Clock frequencies |
|---|---|
| | MCXE31 |
| PLL VCO frequency | — |
| PLLODIV2_CLK<br>(PLLDIG.PLLDV[ODIV2]) | — |

| AIPS_PLAT_CLK (medium-speed peripheral clock) (MC_CGM.MUX_0_DC_1[DIV]) | 48 MHz (0000b) |
| AIPS_SLOW_CLK (slow-speed peripheral clock) (MC_CGM.MUX_0_DC_2[DIV]) | 24 MHz (0001b) |
| DCM_CLK (MC_CGM.MUX_0_DC_4[DIV]) | 48 MHz (0000b) |
| HSE_CLK (MC_CGM.MUX_0_DC_3[DIV]) | 48 MHz (0000b) |

1. MC_CGM.MUX_10_CSC[SELCTL] and MC_CGM.MUX_11_CSC[SELCTL] values are don't care since QSPI_SFCK and TRACE_CLK are not used in this use case.
2. MC_CGM.MUX_0_CSC[SELCTL] must equal 0.

### 23.7.2.5 Option E - Low-Speed Run mode (CORE_CLK @ 3 MHz)

Table 136. Option E - Low-Speed Run mode (CORE_CLK @ 3 MHz)

| Clocking options | Clock frequencies |
|---|---|
| | MCXE31 |
| PLL VCO frequency | — |
| PLLODIV2_CLK<br>(PLLDIG.PLLDV[ODIV2]) | — |
| FIRC_CLK<br>(ELE_HSEB.CONFIG_REG_GPR[FIRC_DIV_SEL]) | 3 MHz<br>(10b) |
| **PLL_PHI1_CLK-related clocks** [1] | |
| PLL_PHI1_CLK<br>(PLLDIG.PLLODIV_1[DIV]) | — |
| QSPI_SFCK<br>(MC_CGM.MUX_10_DC_0[DIV]) | — |
| TRACE_CLK<br>(MC_CGM.MUX_11_DC_0[DIV]) | — |
| **PLL_PHI0_CLK-related clocks** [2] | |
| PLL_PHI0_CLK<br>(PLLDIG.PLLODIV_0[DIV]) | — |
| LBIST_CLK<br>(MC_CGM.MUX_0_DC_5[DIV]) | — |
| QSPI_MEM_CLK<br>(MC_CGM.MUX_0_DC_6[DIV]) | — |
| CORE_CLK<br>• Application cores<br>• AXBS<br>• SRAM<br>• Flash memory controller port clock<br>• AIPS0 (high-speed peripheral clock)<br>(MC_CGM.MUX_0_DC_0[DIV]) | 3 MHz<br>(0000b) |
| AIPS_PLAT_CLK (medium-speed peripheral clock)<br>(MC_CGM.MUX_0_DC_1[DIV]) | 3 MHz<br>(0000b) |
| AIPS_SLOW_CLK (slow-speed peripheral clock)<br>(MC_CGM.MUX_0_DC_2[DIV]) | 1.5 MHz<br>(0001b) |

*Table continues on the next page...*

Table 136. Option E - Low-Speed Run mode (CORE_CLK @ 3 MHz) (continued)

| Clocking options | Clock frequencies |
|---|---|
| | MCXE31 |
| DCM_CLK<br>(MC_CGM.MUX_0_DC_4[DIV]) | 3 MHz<br>(0000b) |
| HSE_CLK<br>(MC_CGM.MUX_0_DC_3[DIV]) | 3 MHz<br>(0000b) |

1. MC_CGM.MUX_10_CSC[SELCTL] and MC_CGM.MUX_11_CSC[SELCTL] values are don't care since QSPI_SFCK and TRACE_CLK are not used in this use case.
2. MC_CGM.MUX_0_CSC[SELCTL] must equal 0.

**NOTE**

For FIRC_CLK frequency modes less than 24 MHz, safety modules like the CMU_F*x_n* must be disabled for safety applications, because safety applications are to run on the PLL clocks. The CMU_F*x_n* will cause erroneous FHH events if not disabled.

### 23.7.2.6 Option E2 - Very-Low-Speed Run mode (CORE_CLK @ 750 kHz)

Table 137. Option E2 - Very-Low-Speed Run mode (CORE_CLK @ 750 kHz)

| Clocking options<br>(SYS_CLK = (FIRC_CLK ÷ 8) ÷ 8) | Clock frequencies |
|---|---|
| | MCXE31 |
| PLL VCO frequency | — |
| PLLODIV2_CLK<br>(PLLDIG.PLLDV[ODIV2]) | — |
| FIRC_CLK<br>(ELE_HSEB.CONFIG_REG_GPR[FIRC_DIV_SEL]) | 3 MHz<br>(10b) |
| **PLL_PHI1_CLK-related clocks** [1] | |
| PLL_PHI1_CLK<br>(PLLDIG.PLLODIV_1[DIV]) | — |

| Gasket configurations | Option B[1] | Option C[2] | Option D[3] | Option E[4] | Option E2[5] | Option F[6] |
|---|---|---|---|---|---|---|
| AIPS1 | 2:1 | Bypass | | | | |
| PRAM/SRAM | WS disabled | | | | | |
| BDRAM 64:32 (TCM WS) | 1:1 | | | | | |

1. See Option B - Reduced Speed mode (CORE_CLK @ 120 MHz) for details.
2. See Option C - Boot Standby mode (CORE_CLK @ 24 MHz) for details.
3. See Option D - Low-Speed RUN mode (CORE_CLK @ 48 MHz) for details.
4. See Option E - Low-Speed Run mode (CORE_CLK @ 3 MHz) for details.
5. See Option E2 - Very-Low-Speed Run mode (CORE_CLK @ 750 kHz) for details.
6. See Option F - Operation in 1:1 mode with CORE_CLK and AXBS_CLK at same speed for details.

### 23.7.4 Default clock configuration

At reset recovery, the chip runs on the FIRC_CLK as the default configuration as shown in Option C - Boot Standby mode (CORE_CLK @ 24 MHz). Clocking configuration Option_C is the default configuration out of reset with the ELE_HSEB core as the boot core. The Cortex-M7_*n* application core clocks are gated by default. You need to enable the core clocks by the configuring the corresponding core clock enable bits shown in Core Clock Gating.

### 23.7.5 PCFS

The chip supports software-controllable PCFS for MC_CGM MUX_0 (see section "Progressive Clock Frequency Switching (PCFS)" in the "Clock Generation Module (MC_CGM)" chapter for details). PCFS increases and decreases the frequency in steps, avoiding any overshoots or undershoots. When a functional reset event occurs with PCFS enabled, the PCFS process runs and is then followed by the divider configuration updates.

### 23.7.6 Updating dividers: crossbar halt handshake

The clock divider update process consists of the crossbar halt handshake sequence (see section "Clock dividers update" in the "Clock Generation Module (MC_CGM)" chapter for the clock divider update process). A divider update asserts a request to the crossbar switch to halt any transaction that is in process. The dividers are updated when the crossbar switch acknowledges the request for halt. The halt request disables the crossbar switch gaskets in the following order:

1. Core gaskets (ELE_HSEB gaskets)
2. Crossbar switch (AXBS)
3. Flash AXBS bridge
4. PRAM/SRAM gasket

Dividers are updated after the gaskets acknowledge the halt request.

### 23.7.7 Changing system clock configurations

Software sequence for switching clock configurations from FIRC to PLL or PLL to PLL:

1. Before changing clock dividers/clock switching, the communication modules must be disabled by software. This ensures that erroneous communications do not occur during the clock transition.
2. All peripherals must be clock-gated using the MC_ME PCTL configurations.
3. All cores must be clock-gated, except the core being used to control the clock switching.
4. MC_CGM divider configurations can be done to change divider values as described above. The requisite system divider frequency relations must be ensured.

5. Configure MC_CGM_MUX_0_DIV_TRIG_CTRL (enable HHEN and TCTL).
6. Configure MC_CGM_MUX_0_DIV_TRIG.
7. System clock switching can be done by configuration of MC_CGM_MUX_0_CSC[SELCTL]

Software sequence for switching clock configurations from PLL to FIRC clock switching:

1. Before changing clock dividers/clock switching, communication modules must be disabled by software. This ensures that erroneous communications do not occur during the clock transition.
2. All the peripherals must be clock-gated using the MC_ME PCTL configurations.
3. All cores must be clock-gated, except the core being used to control the clock switching.
4. System clock switching can be done by configuration of MC_CGM_MUX_0_CSC[SELCTL].
5. MC_CGM divider configurations can be done to change divider values as described above. The requisite system divider frequency relations must be ensured.
6. Configure MC_CGM_MUX_0_DIV_TRIG_CTRL (enable HHEN and TCTL).
7. Configure MC_CGM_MUX_0_DIV_TRIG.

**NOTE**

When enabling PLL, the PMC last mile regulator should be enabled first by configuring PMC_CONFIG[LMEN] and PMC_CONFIG[LMBCTLEN] (if using an external BJT). The last mile regulator must be disabled after PLL is disabled.

## 23.8 Clock monitoring

The chip contains an independent clock monitoring mechanism which signals malfunctions in the clocking system. This chip consists of six Clock Monitoring Units (CMU_F*x*_[0:5]) for monitoring system clock and clocking module outputs. Figure 100 and Figure 101 show a lower-level view of the clocking monitoring system. Table 141 describes each CMU instance. Each CMU instance provides an independent interrupt or reset indication when the clock signal is out of range or lost. The CMU_FM_*n* provides a timeout indication in case there is a loss of metered clock. Your software must periodically check the CMU_FM_1 and CMU_FM_2 status within the chip FTTI (as specified in the Safety Manual).

**NOTE**

You must disable the CMU corresponding to the system clocks if the application changes the system clock source or changes the system clock divider configuration.

You must disable the CMU monitoring a clock source before disabling the clock source, then enable it after enabling the clock source.

The CMUs should be turned ON only after device has moved to PLL source (wherein LMR is ON).

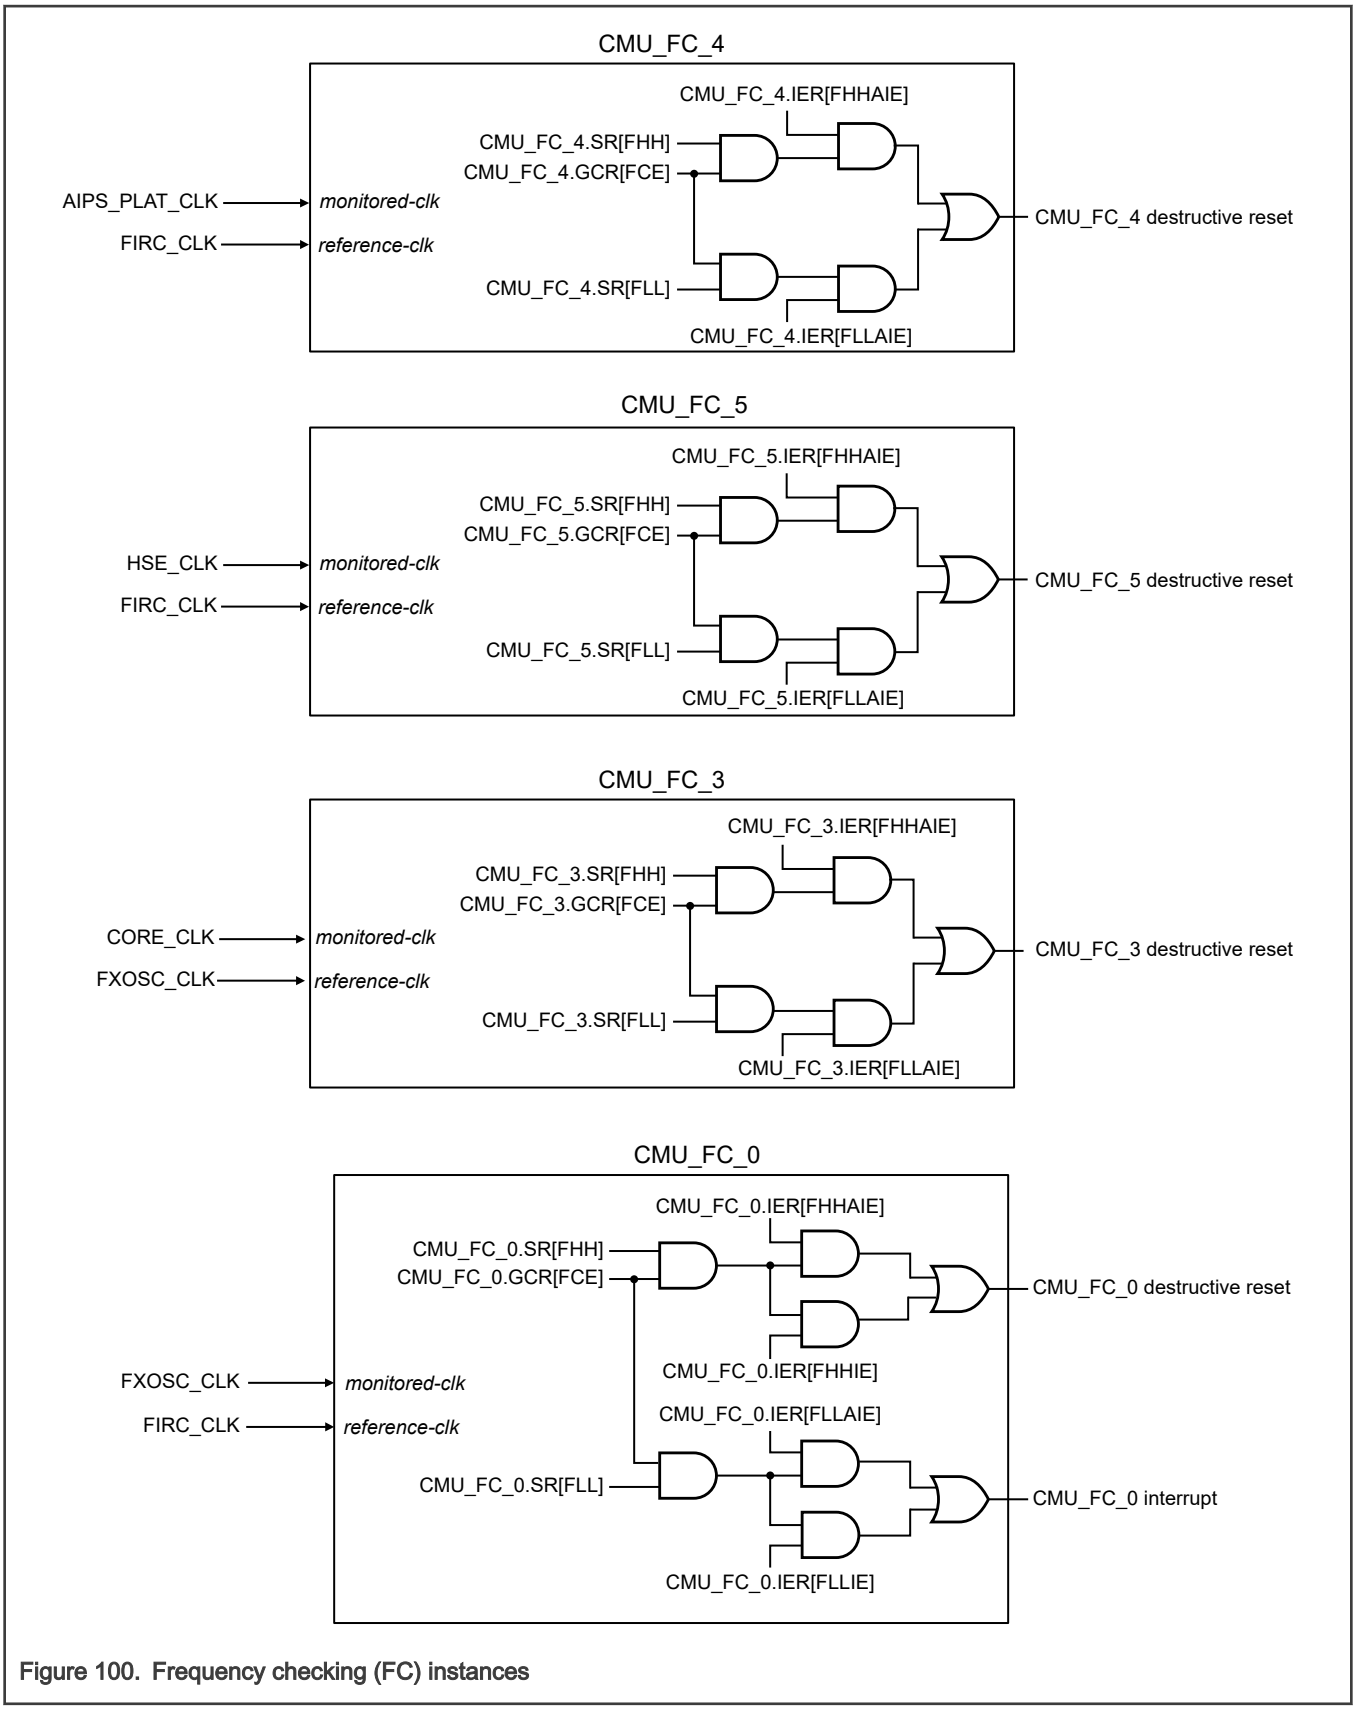

Figure 100. Frequency checking (FC) instances

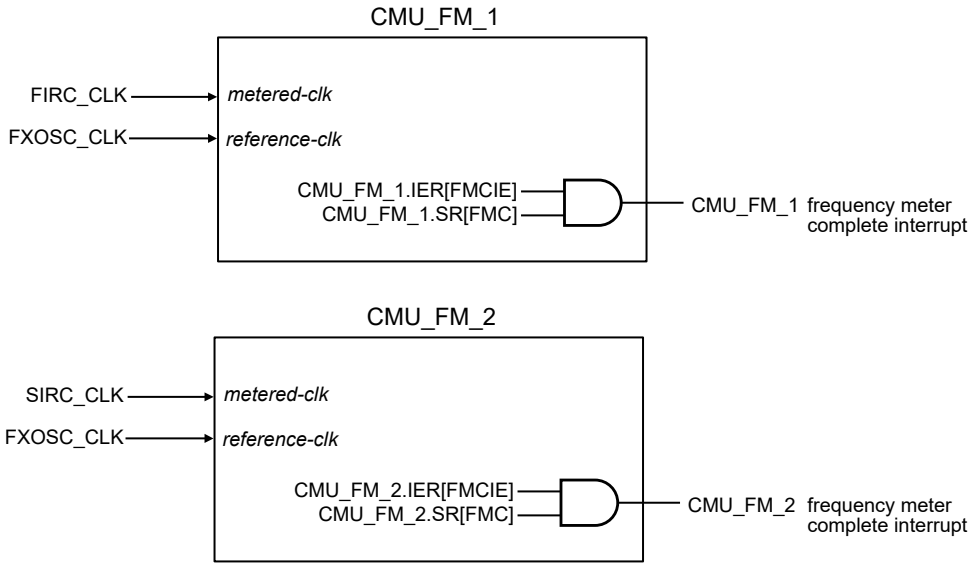

Figure 101. Frequency metering (FM) instances

Table 141. System clock monitors

| CMU | Reference clock | Monitored or metered clock | Failure reaction | Monitoring type description |
|---|---|---|---|---|
| CMU_FC_0 | FIRC_CLK | FXOSC_CLK | Destructive reset or interrupt | Precision over and under frequency |
| CMU_FM_1 | FXOSC_CLK | FIRC_CLK | Interrupt | Current frequency measurement periodically triggered by software |
| CMU_FM_2 | FXOSC_CLK | SIRC_CLK | Interrupt | Current frequency measurement periodically triggered by software |
| CMU_FC_3 | FXOSC_CLK | CORE_CLK | Destructive reset | Precision over and under frequency |
| CMU_FC_4 | FIRC_CLK | AIPS_PLAT_CLK | Destructive reset | Precision over and under frequency |
| CMU_FC_5 | FIRC_CLK | HSE_CLK | Destructive reset | Precision over and under frequency |

## 23.9 Glossary

| | |
|---|---|
| **MODULE_CLK** | Module operating clock |
| **REG_INTF_CLK** | Module register interface clock used for register read and write |
| **PCFS** | Progressive Clock Frequency Switching (see section PCFS for details) |

# Chapter 24
# Clock Generation Module (MC_CGM)

## 24.1 Chip-specific MC_CGM information

### 24.1.1 Associated content references

See the Clocking chapter for details pertaining to these:

- Chip clocking
- MC_CGM clock source mapping (see the "MC_CGM clock sources mapping" section for this)
- MC_CGM clock multiplexers (see the "MC_CGM clock multiplexers" section for this)

**CAUTION**

MC_CGM clock multiplexer configurations to non-supported and reserved clock sources are prohibited and can result in chip malfunctioning.

## 24.2 Introduction

The clock generation module (MC_CGM) is used to set up the configurable clock domains used by various chip blocks as per the application needs. It includes the clock multiplexers that allow software to select the desired clock sources for these domains. This is managed by the MC_CGM to ensure that the changing of the clock selection from one source to another occurs in a glitch-less fashion. In addition, the MC_CGM includes the clock dividers that can be configured by software.

See following figure for the MC_CGM block diagram:

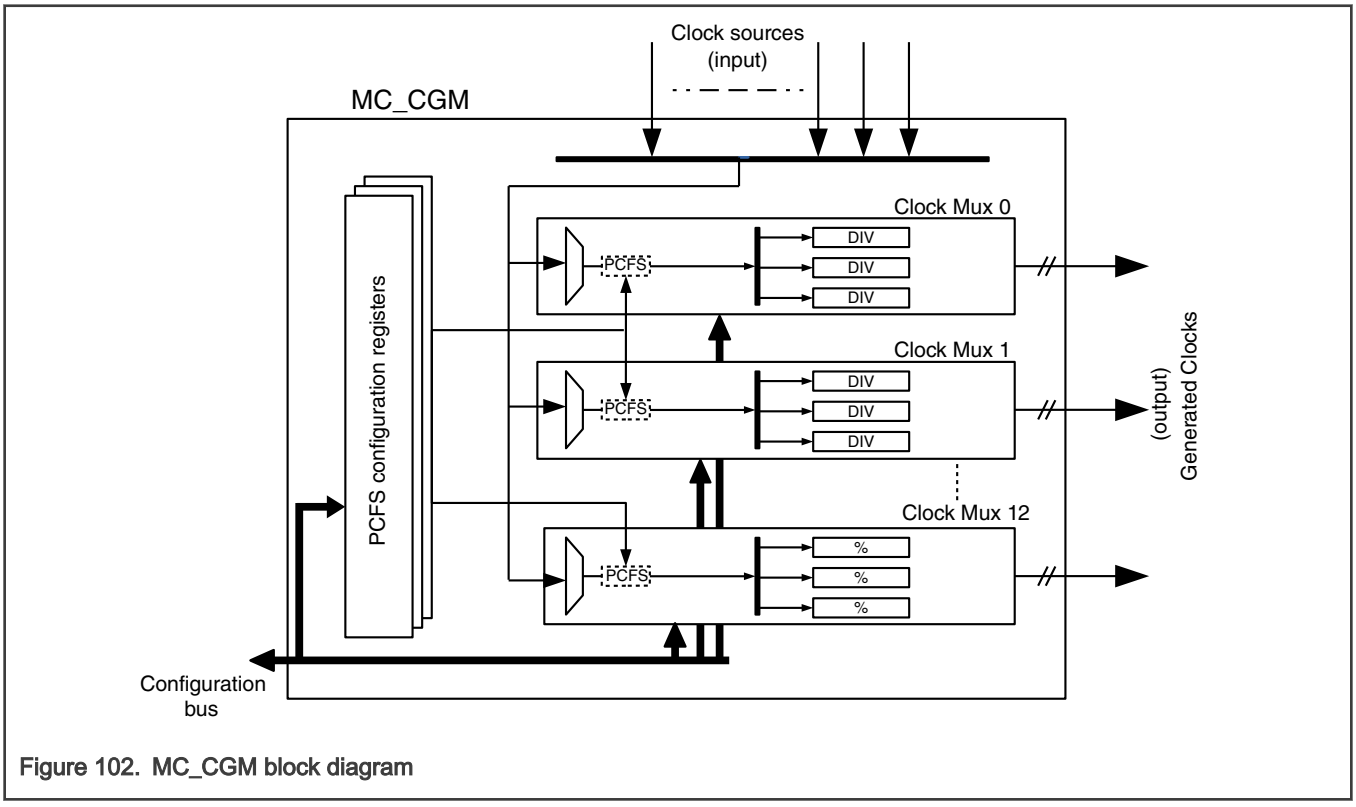

Figure 102. MC_CGM block diagram

**NOTE**

The block diagram is generic and does not necessarily reflect any specific MC_CGM implementation.

## 24.3 Features

MC_CGM includes the following features:

- Implements software configurable clock multiplexers for selecting from various clock sources
- Provides hardware-controlled multiplexers that guarantee glitchless transition, while the software-controlled multiplexers need a software sequence to ensure such a transition
- Provides software configurable automatic PCFS on certain clocks to minimize the impact of a sudden power consumption change through a gentle ramp-down and -up of the clock frequency when switching clock sources
- Implements software configurable clock dividers

## 24.4 Functional description

### 24.4.1 Clock selection multiplexer

Each of the clock multiplexers inside the MC_CGM either implements a fully hardware-controlled clock multiplexer or a software-controlled clock multiplexer. The following sections describe the two variants of the clock multiplexer.

#### 24.4.1.1 Hardware-controlled clock multiplexer

In hardware-based clock multiplexing, the underlying assumption is that under some conditions, error or reset states, software may not be active. Therefore, the clock switching is fully hardware based and is glitchless. To facilitate clock switching requests with software, the MUX_n_CSC and MUX_n_CSS registers implement request and status for the clock multiplexer, the rest is managed in hardware. Using these registers, the software can monitor the state of the hardware-based clock multiplexer and also make clock switching requests. It is recommended that a new clock switch request is given only when there are no pending/ongoing clock switching requests. However, a switch to the safe clock, that is, FIRC, can be performed at any instance of time. A switch to the safe clock is always completed. Software should ensure that while making a software-based switch to safe clock, the register configuration clock should be available, at least for completing the write to the MUX_n_CSC register. This means that the clock should be running for the register write to complete. Hardware clock multiplexer also supports hardware-based switch to safe clock, which is requested externally to MC_CGM (for example, by MC_RGM). For a hardware-based switch to safe clock, it is not required to have a register configuration clock for MC_CGM.

**NOTE**

- "Switch to safe clock" from software is requested by programming the MUX_n_CSC[SAFE_SW] bit field only and not by combining the MUX_n_CSC[CLK_SW] and MUX_n_CSC[SELCTL] bit fields of the MUX_n_CSC register. Writes to other fields are ignored when requesting switch for safe clock.
- After the switch to the safe clock requested by the MC_RGM has completed, the MC_RGM also requests the clock dividers to switch to their default values. This hardware-triggered divider update can be monitored in the same manner as for software-configured updates, and software should use it to ensure that the configuration update has completed before reconfiguring the clocks.
- Write accesses to the MUX_n_CSC register with clock select pointing to the "reserved" input clock source are aborted with bus transfer errors.

See Figure 103 that shows the flowchart representation for the sequence of steps to be followed when making a clock switch request to hardware-controlled clock multiplexer. Switch to safe clock can be requested at any instance of time, and for clarity reasons, it is not shown in Figure 103.

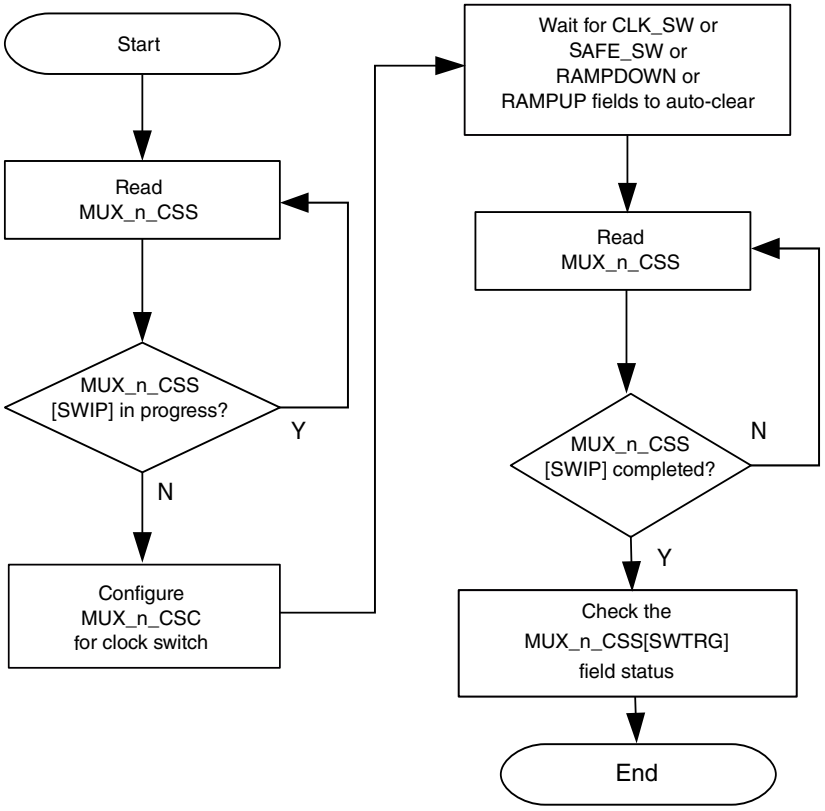

**Figure 103. Flow for clock switch request on hardware-controlled clock multiplexer**

**NOTE**

- A switch to the safe clock command always leads to a ramp-down from the currently selected clock and then a switch to "safe clock", except when there is an ongoing clock switch requested by the software without ramp-up and ramp-down. A safe clock switch request when there is an ongoing clock switch without ramp-up or ramp-down results in a switch to the safe clock without performing a ramp-down (either by MC_RGM or provided using the MUX_n_CSC register) does not perform a ramp-down before switching to "safe clock".
- The above flowchart steps can be preceded by points 1 and 3 below:
  1. Disable the divider.
  2. Switch clocks through hardware multiplexer.
  3. Enable and configure the dividers (atomic write instruction).

### 24.4.1.2 Software-controlled clock multiplexer

In software-based clock multiplexing, the underlying assumption is that the software is always available and there are no error or reset conditions in the chip. This implies that a glitchless switch between input clock sources of MC_CGM MUX can be achieved by following a sequence of steps in software. The software-based clock multiplexer implements a clock gate at the output of the clock mux. The software can gate the selected clock of MC_CGM MUX using a synchronous/graceful clock gate bit (that is, MUX_n_CSC[CG]) or a forced clock gate bit (that is, MUX_n_CSC[FCG]). The hardware does not guarantee that any glitches will escape when using forced clock gating. When a forced clock gate bit is written to 1, the internal clock gate forcefully gates the selected clock to logic-0, therefore, to avoid clock glitches, it should be ensured that the selected clock source is not running. See Figure 104 that shows the flowchart representation for the sequence of steps to be followed when making a clock switch request to software-controlled clock multiplexer. No switch to safe clock is supported in software-controlled clock multiplexer.

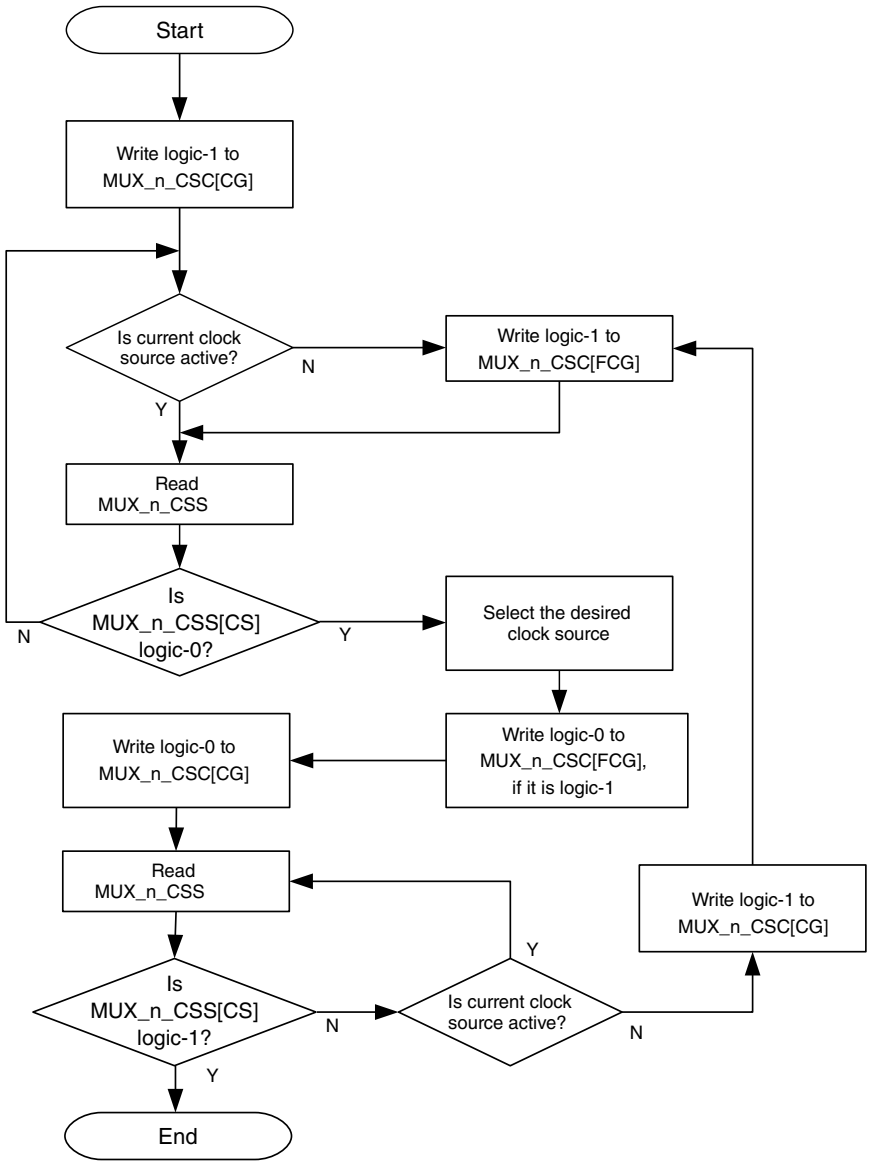

**Figure 104. Flow for clock switch request on software controlled clock multiplexer**

**NOTE**

- Ensure that before using the force gate bit, any IP or other logic using the clock of MC_CGM MUX is in the inactive state or a clock glitch resulting from usage of forced gating does not effect the IP (that is, it is clock gated after the MC_CGM).
- In Figure 104, the clock source to be selected should be active at the time of clock switch, else the MUX_n_CSS[CS] field will remain set to logic-0. In case the clock source to be selected becomes inactive (that is, loss of clock, and so on) during the switching operation, the switch to another clock source can be initiated by writing both the MUX_n_CSC[CG] and MUX_n_CSC[FCG] fields to logic-1.
- Writing a 'reserved' value for the MUX_n_CSC[SELCTL] field may result in an unpredictable clock at the output of the clock multiplexer.

**NOTE**

The above flowchart steps can be preceded by points 1 and 3 below:

1. Disable the divider.
2. Switch clocks through software multiplexer.
3. Enable and configure the dividers (atomic write instruction).

### 24.4.2 PCFS

MC_CGM implements PCFS when changing clock source at an MC_CGM clock mux. The PCFS is only implemented in a hardware-controlled clock multiplexer and not in a software-controlled clock multiplexer. It allows a gradual load change for a power/voltage supply unit by employing a gradual frequency changeover from one to another. The frequency changeover is achieved by clock division of input clock source with a sequence of division values, where frequency ramp down and ramp up is achieved when the sequence of division values are ascending and descending in nature, respectively. As the clock division (fractional) is implemented in digital logic, therefore, it is a coarse-level clock division rather than being an accurate-level division, implying that the duty cycle of the progressively divided clock can vary with time.

The PCFS feature is utilized when a drain current to frequency relationship is known, that is, for a given drain current what is the maximum allowed change in frequency ($f_{chg}$). The $f_{chg}$ is the first input parameter for PCFS and other parameters for PCFS are specified or calculated in relation to FIRC.

The PCFS hardware generates the clock division factors based on certain values that are programmed into the PCFS configuration register. The following pseudo codes represent the generation of clock division value sequence ($d_i$).

```
/* ramp down division values (d_n) with k steps*/
      delta_1 = RATE/1000;
      delta_2 = RATE/1000;
      d_0     = 1.0;
      for i=1 to k-1 do
        d_i = d_i-1 + delta_1;
        delta_1 = delta_1 + delta_2;
      endfor
```

```
/* ramp up division values (d_n) with k steps*/
      delta_1 = RATE*k/1000;
      delta_2 = RATE/1000;
      d_0     = 1.0 + RATE*k*(k+1)/2;
      for i=1 to k-1 do
        d_i = d_i-1 - delta_1;
        delta_1 = delta_1 - delta_2;
    endfor
```

As the generation of clock division values is not a closed-bounded function, calculating RATE for a given $f_{chg}$ is an iterative process. Find a value of RATE that produces a clock division sequence, which when used does not lead to a frequency change greater than $f_{chg}$. See Table 142 that tabulates some of the RATE values against $a_{max}$, where

$$a_{max}=f_{chg}/F_i$$

where, $F_i$ is the frequency of $i^{th}$ input clock source of the clock mux.

**Table 142. PCFS RATE values**

| $a_{max}$ | PCFS rate |
|---|---|
| 0.005 | 12 |
| 0.01 | 48 |

*Table continues on the next page...*

Table 142. PCFS RATE values (continued)

| $a_{max}$ | PCFS rate |
|---|---|
| 0.15 | 112 |
| 0.20 | 184 |

The last clock division factor in case of ramp-down or the first clock in case of ramp-up (following a ramp-down procedure), should be such that clock switch from any input clock source to another should be termed as safe, indicating that load changes have sustainable power effects. This frequency level is referred to as "safe frequency", equivalent to frequency of FIRC referred to as "safe clock" with frequency "safe clock frequency" ($f_{safe}$). The last clock division factor in the sequence of clock division factors happens after "k" steps. The factor k (=steps) is calculated by using the following formula:

```
k = ceil(0.5 + sqrt(0.25 - (2000 * (1 -(Fi/fsafe)) / RATE)))
```

Using the above formula, all the PCFS register configuration values can be calculated for a given frequency of a clock source:

```
PCFS_DIVEi.DIV = (Fi/fsafe)*1000-1;
        PCFS_DIVCi.INIT = RATE * k;
        PCFS_DIVCi.RATE = RATE;
        PCFS_DIVSi.DIV  = 999 + (RATE * k * (k+1)/2);
```

See Figure 105 that shows a graphical representation of the change in frequency, which happens during PCFS ramp-down and ramp-up.

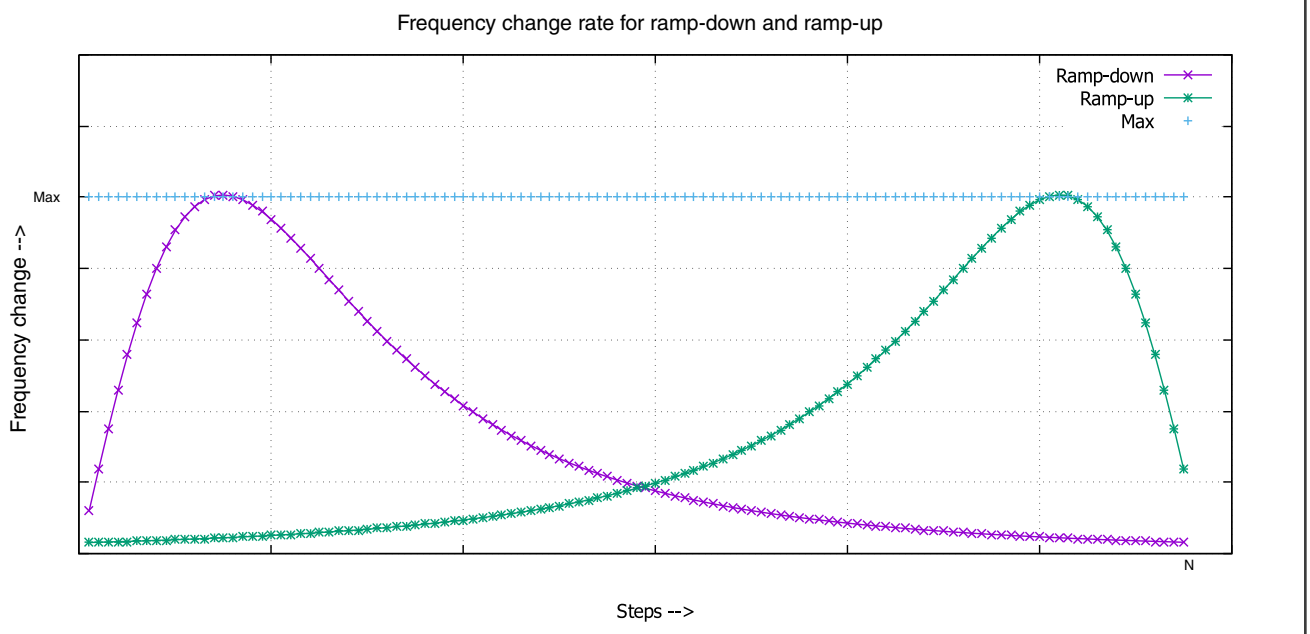

Figure 105. PCFS steps vs frequency changes

For any given clock source, if its frequency is less than that of FIRC, then its corresponding registers should be programmed to default values, where the default values are such that PCFS divider start and PCFS divider end values are same and equal to divide-by-1. The default values ensure that no progressive clock division is done when a clock switch request is given to switch from or to that source.

**NOTE**

Calculate the minimum frequency during the PCFS RAMPDOWN and RAMPUP operations by using the formula:

```
(FIRC/((PCFS_DIVE+1)/1000)) MHz
```

#### 24.4.2.1 PCFS control

The PCFS operation is configured by a set of configuration registers. One set pertains to the calculation of the clock division factors, which are PCFS_DIVC, PCFS_DIVE, PCFS_DIVS, and PCFS_SDUR, while the registers MUX_n_CSC and MUX_n_CSS implement trigger and status of the PCFS operation. The clock division factors are expected to be programmed before any other MC_CGM operation is initiated and remain unchanged. All the registers corresponding to the clock division factors should be programmed with FIRC as the configuration clock and before doing any clock switch or PCFS operation on any of the MC_CGM mux. It should be noted that the default values of the register corresponding to clock division factors are such that only the clock division factor is calculated by hardware that is divide-by-1. The PCFS operation is always triggered when the safe clock request is generated except when there is an on-going clock switch without ramp-up or ramp-down. Therefore, the software needs to ensure that the PCFS configuration is complete and correct.

While configuring MUX_n_CSC, only valid PCFS and clock switch requests should be provided. PCFS or clock switch requests should only be provided if the PCFS operation is in the idle state. If there is an ongoing PCFS operation, it is recommended not to provide any new PCFS triggers (except switch to safe clock) until the ongoing operation is completed. Switch to safe clock via hardware or by register configuration can be provided at any instance of time and is always completed. Valid combinations of PCFS and clock switches triggers are listed in Table 143. All the PCFS commands should be atomic in nature, which means a single register write should provide complete PCFS sequence to be executed that is ramp-down, clock switch, and ramp-up.

**Table 143. Valid PCFS and clock switch requests**

| PCFS operation state | Command |
|---|---|
| Idle | Ramp-down, clock switch, and ramp-up |
| Idle | Clock switch only (without ramp-up or ramp-down) |

When a switch to safe clock is provided by writing to MUX_n_CSC, then writes to other register fields are ignored.

#### 24.4.2.2 Clock source power-up and selection

This section provides guidelines for powering up a given clock source and selecting it at the MC_CGM clock multiplexer.

Following is the power-up procedure for a clock source:

1. Configure the parameter, if any.
2. Configure the power-up (or power-down) control field.
3. Wait for the power-up status indication.

After a power-up indication, the clock source can be selected to provide output clock at an MC_CGM clock multiplexer. A clock-monitoring setup can also be activated on the powered-up clock source.

See Figure 106 that shows a flow chart representation of this sequence.

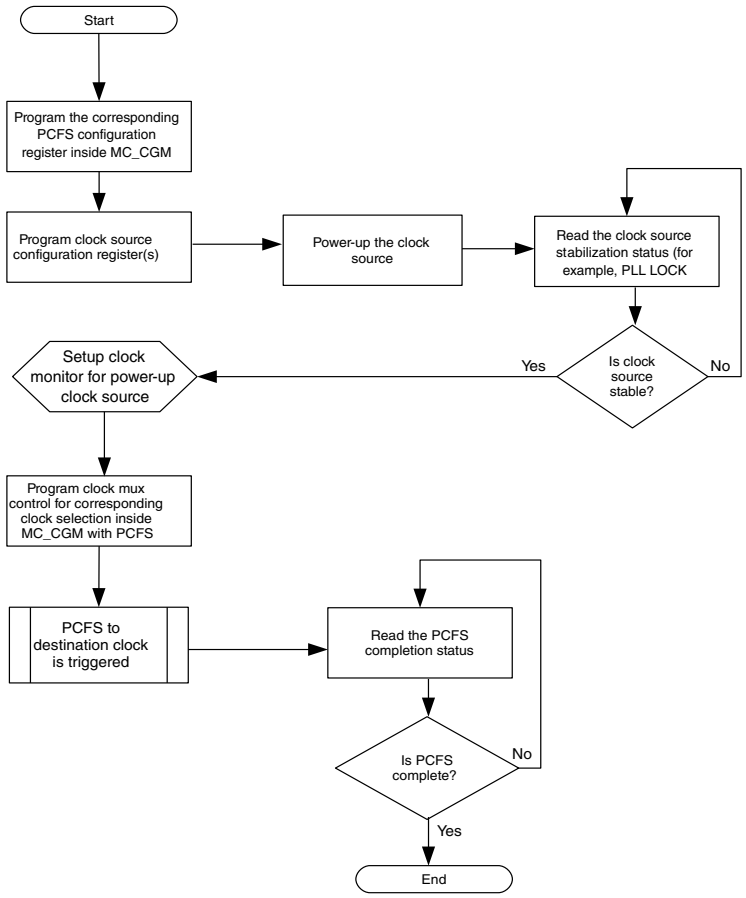

**Figure 106. Clock source power-up and selection procedure**

### 24.4.2.3 Clock source power-down and deselection

This section provides guidelines for powering down a given clock source and deselecting it at MC_CGM clock multiplexer.

Following is the power-down procedure for a clock source:

1. Deselect the clock source at all MC_CGM clock multiplexers.
2. Configure the power-up (or power-down) control field.
3. Wait for the power-down status indication.

See Figure 107 that shows a flow chart representation of this sequence.

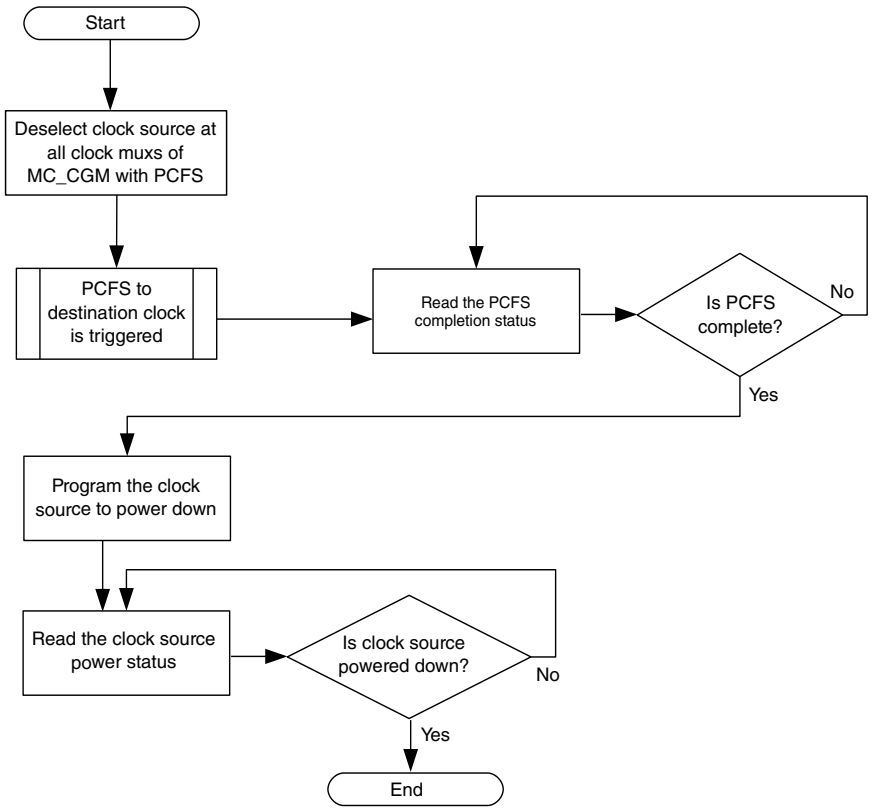

Figure 107. Clock source power-down and clock source deselection procedure

#### 24.4.2.4 Clock switch with load change

This section provides guidelines to switch between two high-frequency clock sources along with load changes in the system. Load change is referred to switching ON or OFF of logic/peripherals in the system, which has an effect of significant capacitance changes on the chip. This triggers the voltage regulation for the chip.

When a large number of peripherals or digital logic is enabled or disabled, it is recommended that this step should be performed at a low frequency. Independent of whether a clock switch is required, this criteria needs to be met. When a clock switch is required at two high frequencies, the recommended sequence is as follows:

1. Intermediately switch to FIRC.
2. Change load (that is, enable/disable peripherals).
3. Switch to the target clock.

See the following figure that shows a flow chart representation of this sequence.

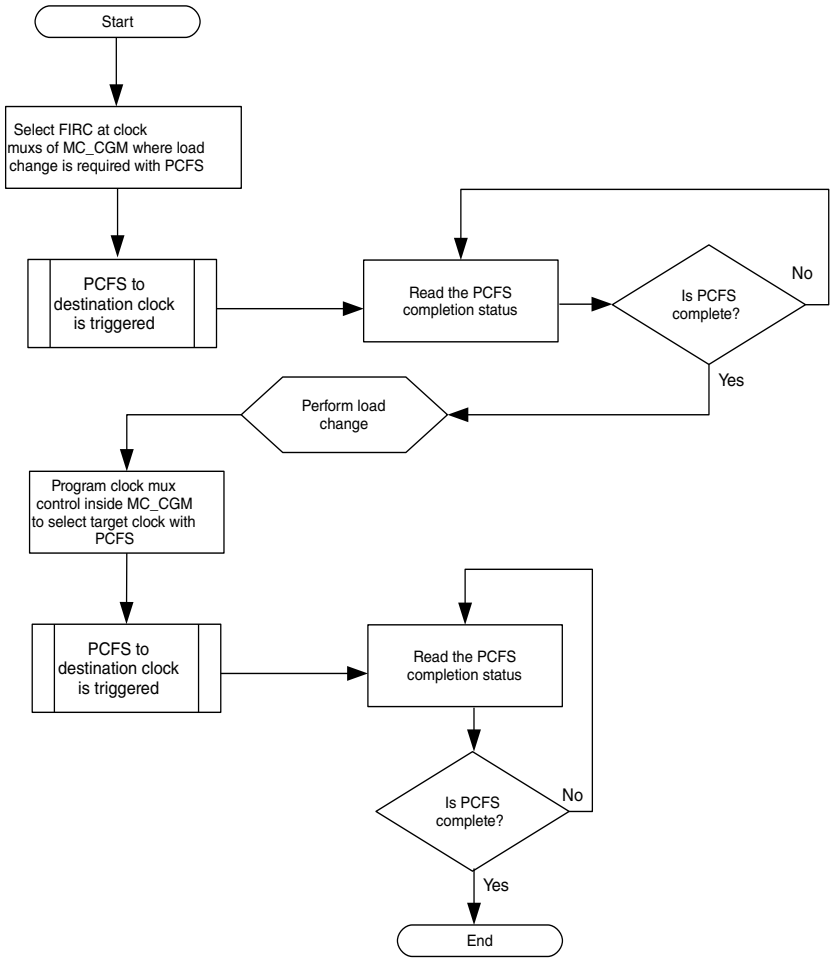

**Figure 108. Clock switch with load change procedure**

## 24.4.3 Clock dividers

Clock dividers are used for the generation of a divided clock that is used for running IPs or peripherals. The MC_CGM provides the following built-in dividers at each clock mux:

- 50% clock dividers

Each divider can be controlled by the Divider Enable (DE) bit and the Division Value (DIV) field. If a divider has its DE bit set to logic-0 in the respective configuration register, then that divider is disabled and the output divided clock is held to logic-0. If the DE bit is logic-1, the divider is enabled and provides a divided clock according to the value set in the DIV field.

### 24.4.3.1 50% clock divider

50% duty cycle dividers generate a real divided clock. The division factor is always an integer but is not restricted to even numbers. The rising edge of the divided clock is always synchronous to the rising edge of the divider source clock, but the falling edge is synchronous to the rising edge or the falling edge depending on whether the division factor is even or odd, respectively. If the input clock has a duty cycle of 50%, the divided output clock maintains the same 50% duty cycle. See Figure 109 that shows the 50% clock divider operation and its associated signals.

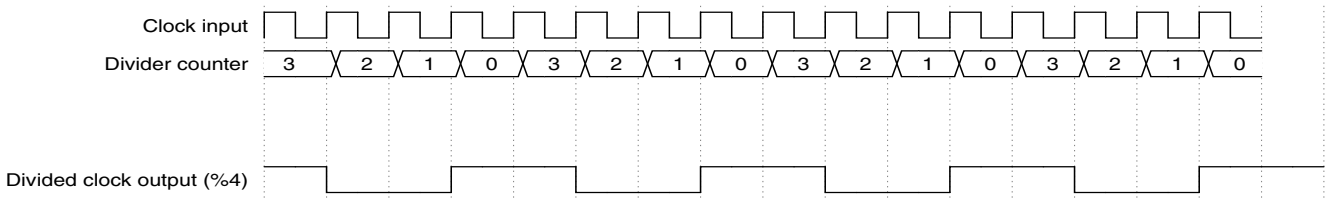

**Figure 109. 50% clock divider programmed for divide by 4 (DIV=3)**

A 50% divided clock can be considered asynchronous (not edge aligned) to other divided clocks from dividers at the same clock mux. 50% clock dividers are implemented without an active closed loop, and are expected not to get stuck if the input clock glitches for a single cycle.

### 24.4.3.2 Clock dividers update

To update the division value or the divider enable, the software should follow the procedure as shown in Figure 110. These updates happen only after the current division cycle has elapsed. However, if the phase of the clock divider is updated, the update happens independently from the state of the division cycle. Any update to the clock divider fields does not result in clock glitch either at the divided clock output or the phase-divided clock output.

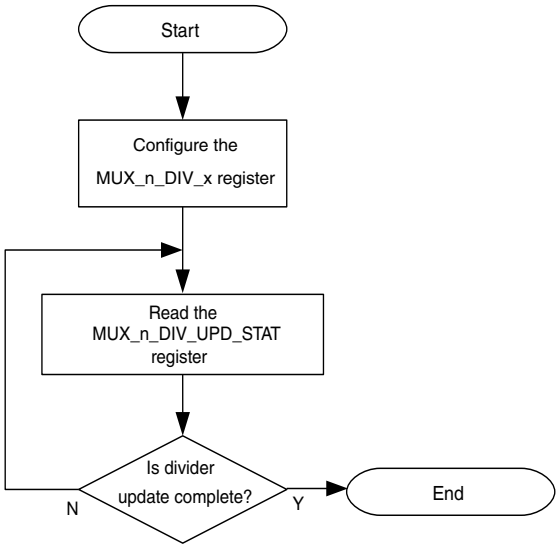

**Figure 110. Flow for clock divider programming update**

Following is the procedure for updating the dividers using the common trigger update:

1. Configure the MUX_n_DIV_TRIG_CTRL register.
2. Wait for the update to finish (until MUX_n_DIV_UPD_STAT is 0).
3. Update the clock dividers (only 50%) per the divider update procedure.
4. After the divider update is finished, perform a write operation on the MUX_n_DIV_TRIG register.
5. Wait for the update to finish, that is, until MUX_n_DIV_UPD_STAT is 0. During this period, the following process takes place:
   - Halt handshake is initiated if configured in step 1.
   - Clock dividers is updated only when AXBS is halted (that is, halt acknowledgment is received by MC_CGM). It is initiated, else the dividers are updated at alignment.
   - After the clock dividers are updated, MUX_n_DIV_UPD_STAT is asserted to 0.

- When the bit fields MUX_x_DIV_TRIG_CTRL[TCTL] and MUX_x_DIV_TRIG_CTRL[HHEN] are set to 1, then any write operation on trigger register will assert (MUX_n_DIV_UPD_STAT). Once the dividers are updated and aligned (MUX_n_DIV_UPD_STAT) will be deasserted.

**NOTE**

- The MUX_x_DIV_TRIG_CTRL[HHEN] bit should only be set when MUX_x_DIV_TRIG_CTRL[TCTL] is set, otherwise it may lead to misalignment of the dividers.
- In case of divider initialization by MC_RGM, a halt handshake protocol is initiated if the corresponding register bit is set and the clock dividers are initialized after the halt handshake protocol completion.

6. This completes the divider update.
7. When multiple writes to the dividers of same clock MUX is made without waiting for the previous update status signal to finish may lead to misalignment of the dividers.

For aligned dividers, the LCM of the division values programmed in the dividers of respective clock mux should be less than 100.

**NOTE**

Performing multiple writes to the divider without waiting for the earlier update to complete can lead to misalignment of the dividers.

Recommended software sequence for ensuring no undivided output at MC_CGM:

1. Reset is de-asserted
2. MC_RGM goes to IDLE
3. Enable the clock dividers of MC_CGM to provide FIRC clock so that reset of fixed dividers can be lifted.
4. Program the MC_CGM as per use case division values.
5. Switch the clock of MC_CGM Mux to desired one, and run the system.

## 24.5 MC_CGM register descriptions

MC_CGM implements a set of clock multiplexers that share PCFS configuration registers. MC_CGM registers have the following properties:

- All registers are 32-bit wide.
- Only 32-bit read and write accesses are supported.
- Read/write accesses of less than 32 bits terminate with an error.
- Writes to read-only register fields in writable registers are ignored and do not provide an error response.
- Writes to read-only registers are aborted with an error response.

### 24.5.1 MC_CGM memory map

MC_CGM base address: 402D_8000h

| Offset | Register | Width (In bits) | Access | Reset value |

## 24.5.2 PCFS Step Duration (PCFS_SDUR)

### Offset

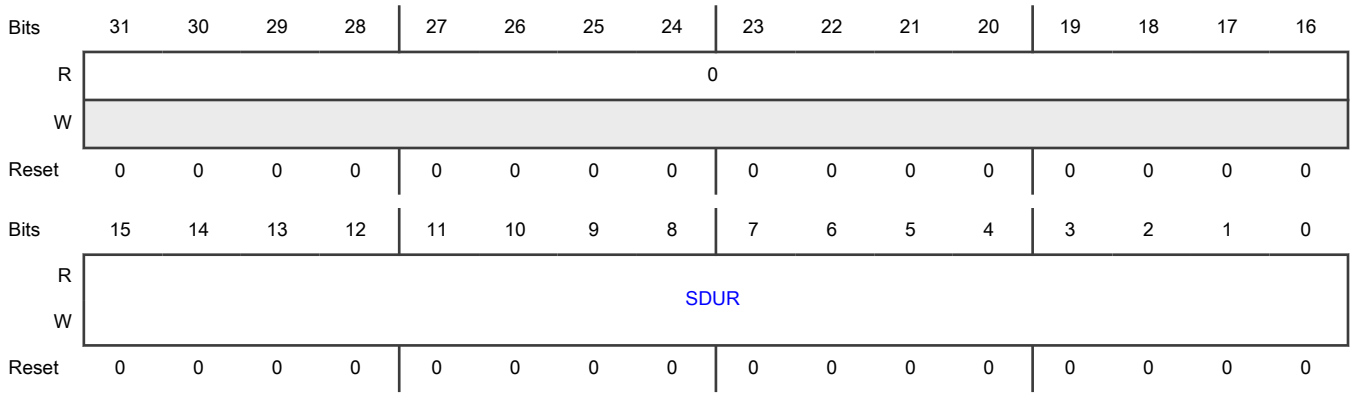
| Register | Offset |
|---|---|
| PCFS_SDUR | 0h |

### Function

This register specifies the step duration of each PCFS step. The value provided in this register specifies the PCFS step duration in terms of the number of cycles of FIRC.

This register is reset only by a destructive reset. For details, see PCFS.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-16<br>— | This field is reserved and reads return zeros. |
| 15-0<br>SDUR | Step duration<br>Count value of the step duration |

## 24.5.3 PCFS Divider Change 8 Register (PCFS_DIVC8)

### Offset

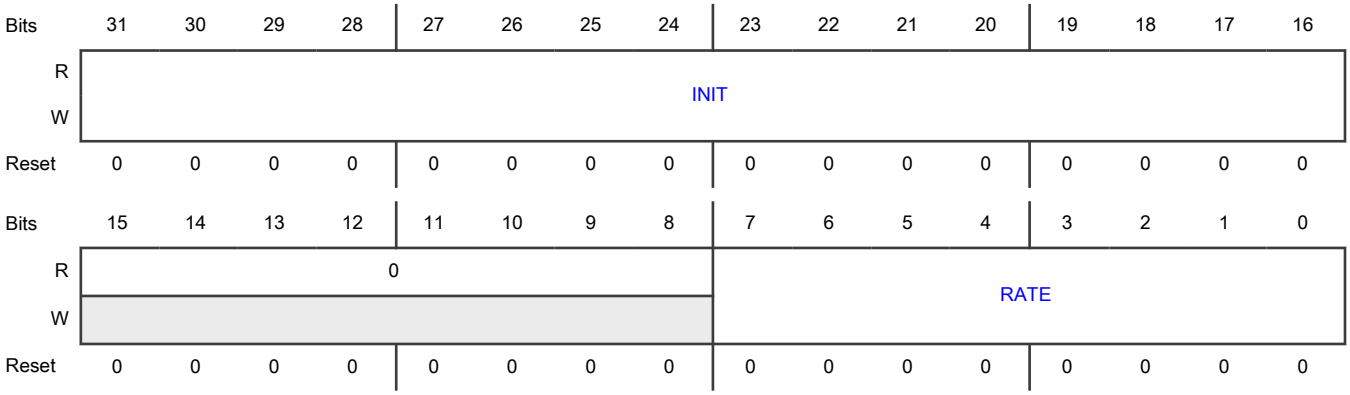
| Register | Offset |
|---|---|
| PCFS_DIVC8 | 58h |

### Function

This register defines the rate of frequency change and initial change value on frequency ramp-up for the Progressive Clock Frequency switching of PLL_PHI0_CLK.

This register is reset only on destructive reset.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-16<br>INIT | Divider change initial value<br>This field provides the initial change value of the clock divider for the clock ramp-up phase of PLL_PHI0_CLK. |
| 15-8<br>— | This field is reserved and reads return zeros. |
| 7-0<br>RATE | Divider change rate<br>This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase of PLL_PHI0_CLK. |

## 24.5.4 PCFS Divider End 8 Register (PCFS_DIVE8)

### Offset

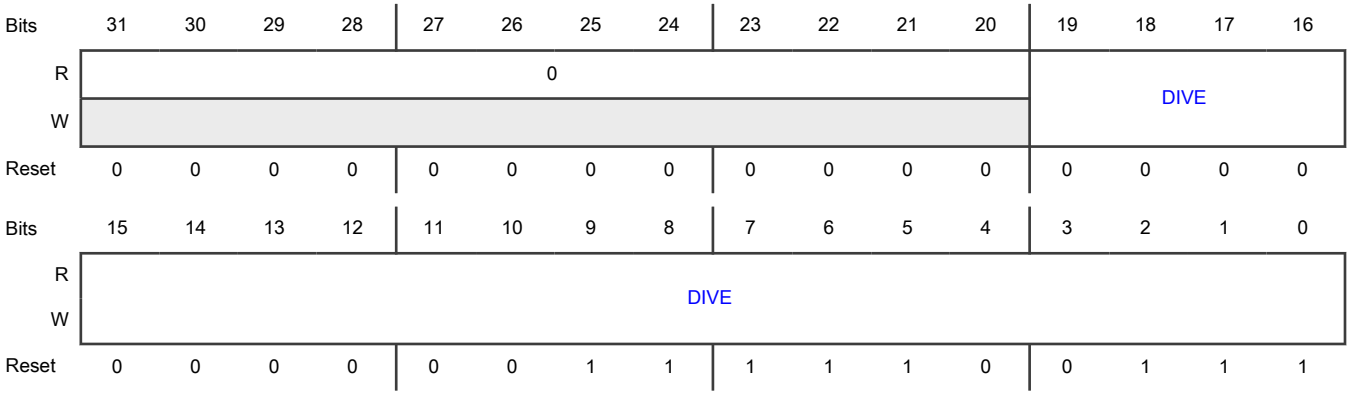
| Register | Offset |
|---|---|
| PCFS_DIVE8 | 5Ch |

### Function

This register defines the final division value on frequency ramp-down for the progressive system clock switching of PLL_PHI0_CLK.

This registers is reset only on destructive reset.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-20<br>— | This field is reserved and reads return zeros. |

## 24.5.5 PCFS Divider Start 8 Register (PCFS_DIVS8)

### Offset

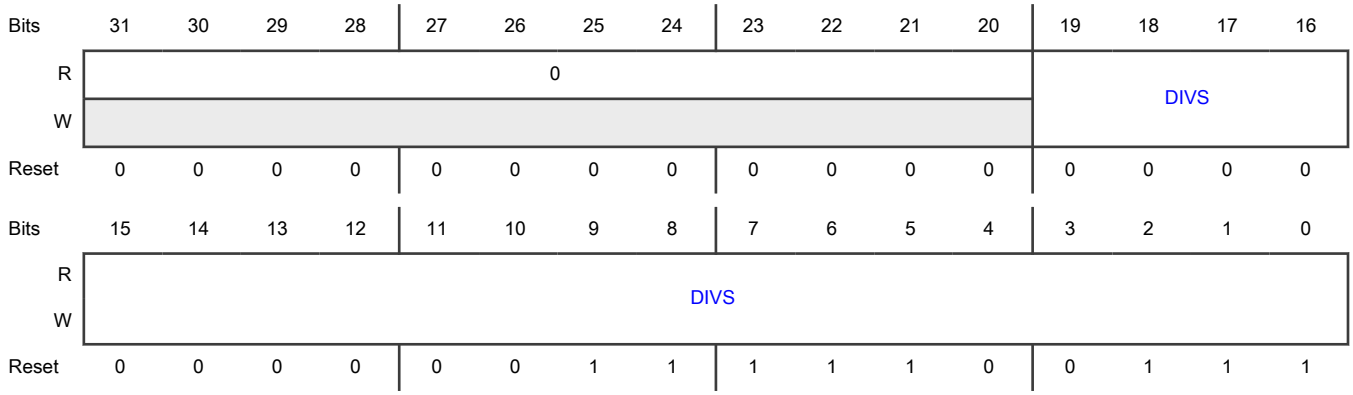
| Register | Offset |
|---|---|
| PCFS_DIVS8 | 60h |

### Function

This register defines the initial division value on frequency ramp-up for the progressive system clock switching of PLL_PHI0_CLK.

This register is reset only on destructive reset.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-20<br>— | This field is reserved and reads return zeros. |

## 24.5.6 Clock Mux 0 Select Control Register (MUX_0_CSC)

### Offset

| Register | Offset |
|---|---|
| MUX_0_CSC | 300h |

### Function

This register provides the clock source selection control for clock mux 0. Clock mux 0 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

An update to all the PCFS-related fields of this register must be an atomic write, which means a single write must update the CLK_SW, RAMPDOWN, and RAMPUP fields. It is necessary to set both RAMPUP and RAMPDOWN bits together even if you want to trigger either RAMPUP or RAMPDOWN process otherwise the desired PCFS sequence will not be executed.

### Diagram

| 1<br>RAMPDOWN | PCFS ramp-down<br>Writing 1 to this bit makes a PCFS ramp-down request to clock mux 0. After a PCFS ramp-down operation is requested, this bit is auto cleared and a corresponding bit in the status register is set. |
| 0<br>RAMPUP | PCFS ramp-up<br>Writing 1 to this bit makes a PCFS ramp-up request to clock mux 0. After a PCFS ramp-up operation is requested, this bit is auto cleared and a corresponding bit in the status register is set. |

## 24.5.7 Clock Mux 0 Select Status Register (MUX_0_CSS)

### Offset

| Register | Offset |
|---|---|
| MUX_0_CSS | 304h |

### Function

This register provides the current clock source selection status for clock mux 0.

This register is reset on destructive reset only.

## 24.5.8 Clock Mux 0 Divider 0 Control Register (MUX_0_DC_0)

### Offset

| Register | Offset |
|---|---|
| MUX_0_DC_0 | 308h |

### Function

This register controls the clock divider 0 for clock mux 0.

This divider is a 50% duty cycle divider.

**NOTE**

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 30-19<br>— | This field is reserved and reads return zeros. |
| 18-16<br>DIV | Division value<br>This field provides the division value for the clock divider. The clock period of the clock after division is 'DIV+1' times the time period of the current input clock to the divider. |
| 15-0<br>— | This field is reserved and reads return zeros. |

## 24.5.9 Clock Mux 0 Divider 1 Control Register (MUX_0_DC_1)

### Offset

| Register | Offset |
|---|---|
| MUX_0_DC_1 | 30Ch |

### Function

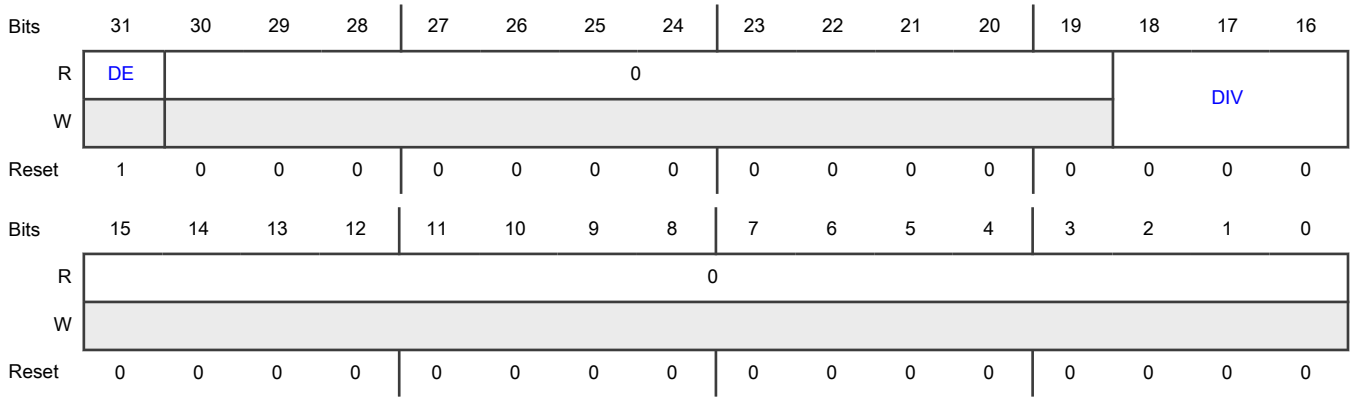
This register controls the clock divider 1 for clock mux 0.

This divider is a 50% duty cycle divider.

**NOTE**

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>DE | Divider enable<br>0b - Unused<br>1b - Divider is enabled. |
| 30-19<br>— | This field is reserved and reads return zeros. |
| 18-16<br>DIV | Division value<br>This field provides the division value for the clock divider. The clock period of the clock after division is 'DIV+1' times the time period of the current input clock to the divider. |
| 15-0<br>— | This field is reserved and reads return zeros. |

## 24.5.10 Clock Mux 0 Divider 2 Control Register (MUX_0_DC_2)

### Offset

| Register | Offset |
|---|---|
| MUX_0_DC_2 | 310h |

### Function

This register controls the clock divider 2 for clock mux 0.

This divider is a 50% duty cycle divider.

**NOTE**

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 15-0<br>— | This field is reserved and reads return zeros. |

## 24.5.11 Clock Mux 0 Divider 3 Control Register (MUX_0_DC_3)

### Offset

| Register | Offset |
|---|---|
| MUX_0_DC_3 | 314h |

### Function

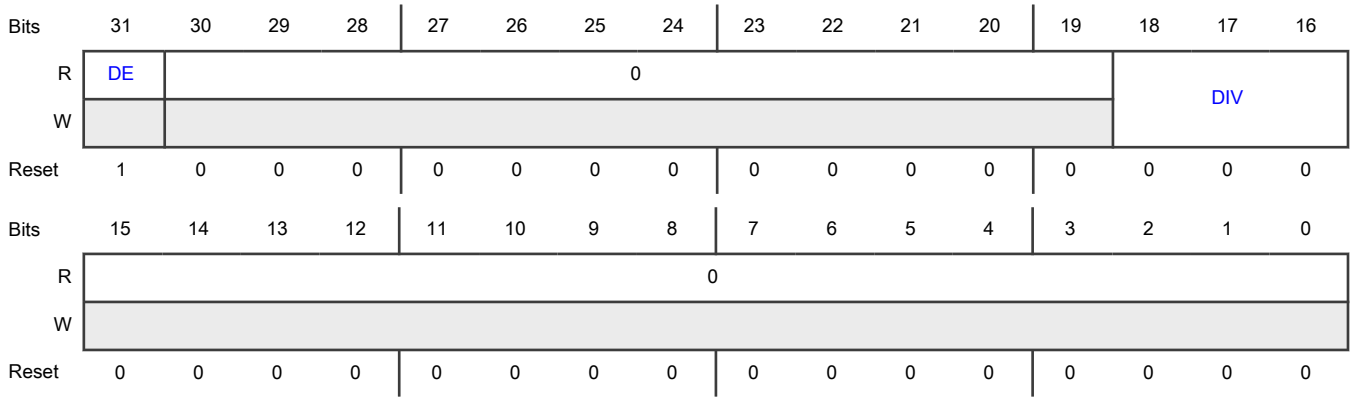
This register controls the clock divider 3 for clock mux 0.

This divider is a 50% duty cycle divider.

**NOTE**

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>DE | Divider enable<br>0b - Unused<br>1b - Divider is enabled. |
| 30-19<br>— | This field is reserved and reads return zeros. |
| 18-16<br>DIV | Division value<br>This field provides the division value for the clock divider. The clock period of the clock after division is 'DIV+1' times the time period of the current input clock to the divider. |
| 15-0<br>— | This field is reserved and reads return zeros. |

## 24.5.12 Clock Mux 0 Divider 4 Control Register (MUX_0_DC_4)

### Offset

| Register | Offset |
|---|---|
| MUX_0_DC_4 | 318h |

### Function

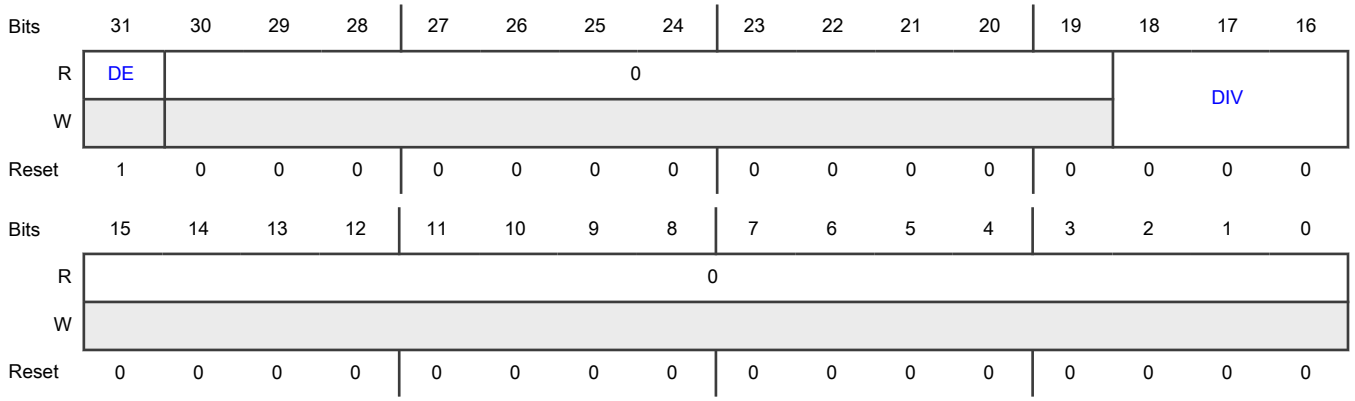
This register controls the clock divider 4 for clock mux 0.

This divider is a 50% duty cycle divider.

**NOTE**

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>DE | Divider enable<br>0b - Unused<br>1b - Divider is enabled. |
| 30-19<br>— | This field is reserved and reads return zeros. |

| 15-0<br>— | This field is reserved and reads return zeros. |

## 24.5.13 Clock Mux 0 Divider 5 Control Register (MUX_0_DC_5)

### Offset

| Register | Offset |
|---|---|
| MUX_0_DC_5 | 31Ch |

### Function

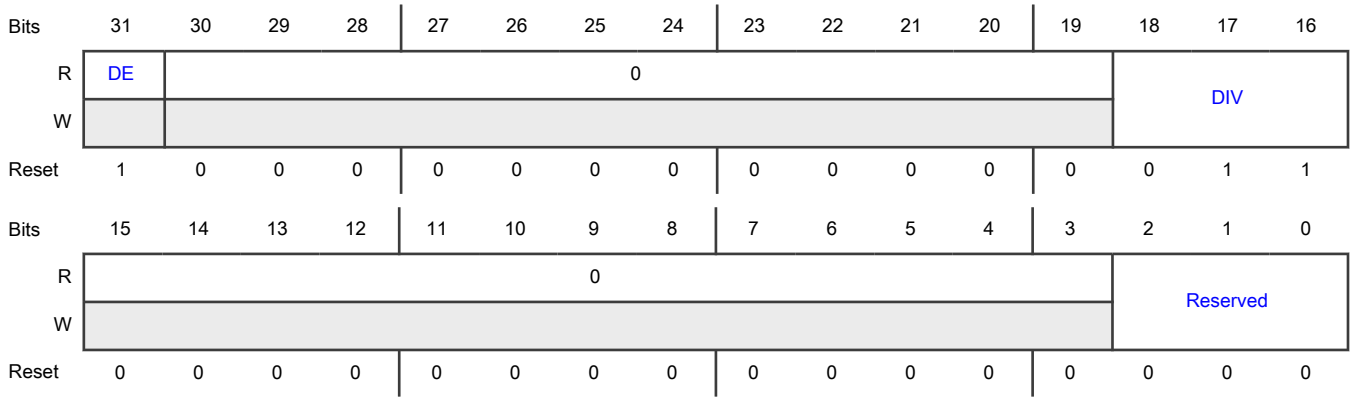
This register controls the clock divider 5 for clock mux 0.

This divider is a 50% duty cycle divider.

**NOTE**

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

### Diagram



**Fields**

| Field | Function |
|---|---|
| 31<br>DE | Divider enable<br>0b - Unused<br>1b - Divider is enabled. |
| 30-19<br>— | This field is reserved and reads return zeros. |
| 18-16<br>DIV | Division value<br>This field provides the division value for the clock divider. The clock period of the clock after division is 'DIV+1' times the time period of the current input clock to the divider. |
| 15-3<br>— | Reserved |

### 24.5.14 Clock Mux 0 Divider 6 Control Register (MUX_0_DC_6)

**Offset**

| Register | Offset |
|---|---|
| MUX_0_DC_6 | 320h |

**Function**

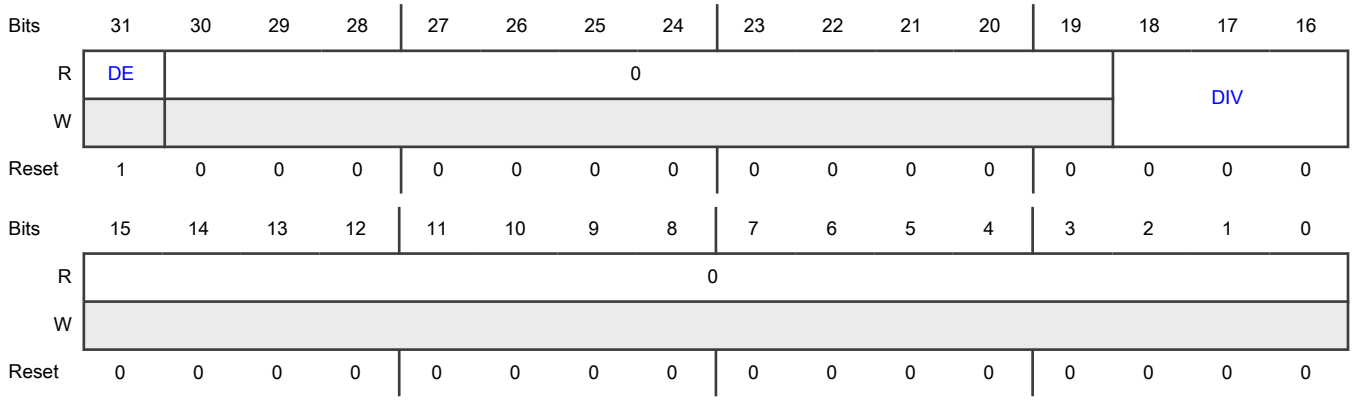
This register controls the clock divider 6 for clock mux 0.

This divider is a 50% duty cycle divider.

**NOTE**

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>DE | Divider enable<br>0b - Unused<br>1b - Divider is enabled. |
| 30-19<br>— | This field is reserved and reads return zeros. |
| 18-16<br>DIV | Division value<br>This field provides the division value for the clock divider. The clock period of the clock after division is 'DIV+1' times the time period of the current input clock to the divider. |
| 15-0<br>— | This field is reserved and reads return zeros. |

## 24.5.15 Clock Mux 0 Divider Trigger Control Register (MUX_0_DIV_TRIG_CTRL)

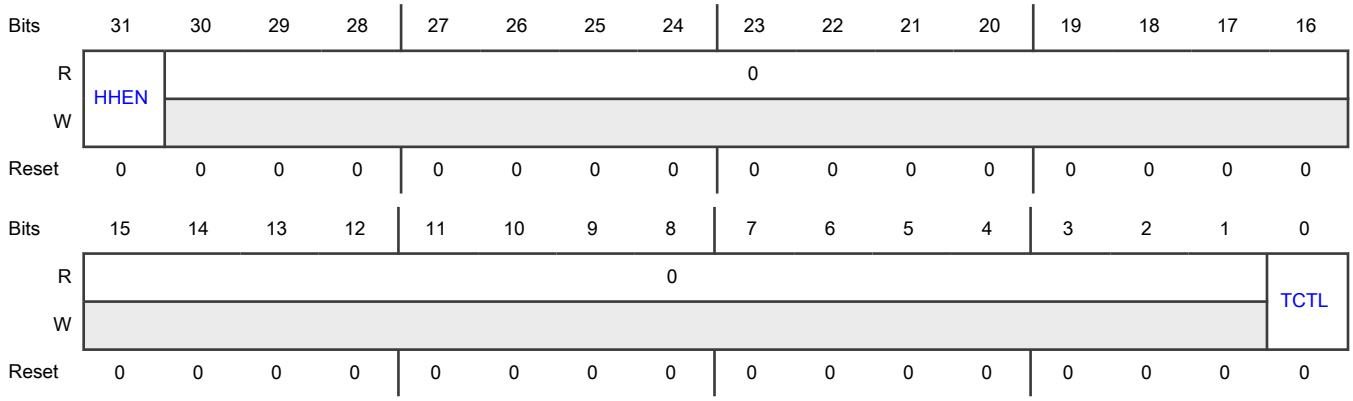
### Offset

| Register | Offset |
|---|---|
| MUX_0_DIV_TRIG_CTRL | 334h |

### Function

This register selects whether the dividers associated with clock mux 0 are updated immediately on writing to the corresponding divider configuration register (referred to as immediate divider update) or only on writing to the MC_CGM_MUX_0_DIV_TRIG register (referred to as common trigger update). When common trigger update is configured, this register also controls initiation of the halt handshake protocol with the on-chip AXBS. Software is required to configure HHEN field for handshaking with on-chip AXBS when the ratio of division value among the clock dividers need to be changed.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>HHEN | Halt handshake enable<br>This field controls the initiation of the halt handshake protocol with AXBS when a common trigger divider update is initiated.<br>0b - No halt handshake protocol is initiated.<br>1b - Halt handshake protocol is initiated. |
| 30-1<br>— | This field is reserved and reads return zeros. |
| 0<br>TCTL | Trigger control<br>This field controls the divider update configuration between immediate and common update.<br>0b - Immediate divider update<br>1b - Common trigger divider update |

## 24.5.16 Clock Mux 0 Divider Trigger Register (MUX_0_DIV_TRIG)

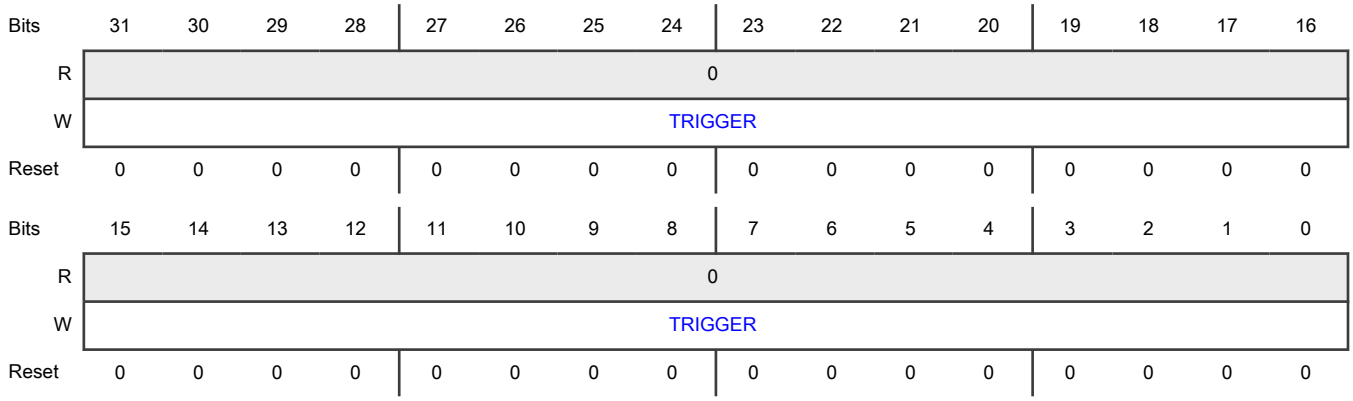
### Offset

| Register | Offset |
|---|---|
| MUX_0_DIV_TRIG | 338h |

### Function

This register provides a common trigger for the clock dividers (only 50% duty cycle dividers) of clock mux 0. Writing any value to this register provides a trigger to the dividers. This register should only be written after appropriately configuring the MC_CGM_MUX_0_DIV_TRIG_CTRL register.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>TRIGGER | Trigger for divider update |

## 24.5.17 Clock Mux 0 Divider Update Status Register (MUX_0_DIV_UPD_STAT)

### Offset

| Register | Offset |
|---|---|
| MUX_0_DIV_UPD_STAT | 33Ch |

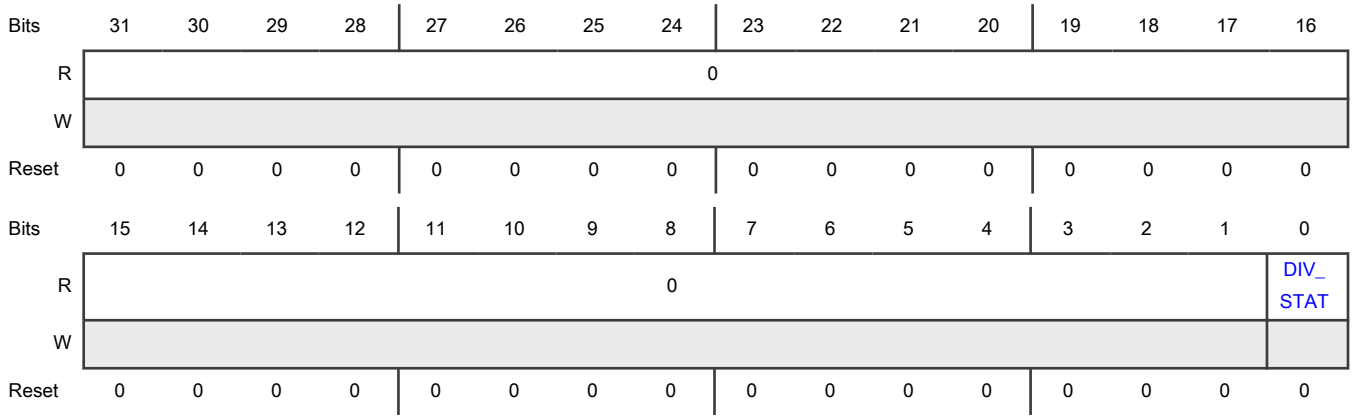
### Function

This register provides the update status of the clock dividers corresponding to clock mux 0. When a write operation on any divider control register is performed, the divider status bit in this register is set to logic-1. The bit is set to logic-0 when the divider has sampled the new divider configuration. Performing multiple writes without tracking the status bit on same or other clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

**NOTE**

Read accesses to MUX_n_DIV_UPD_STAT always complete without returning bus transfer error independent of whether any divider(s) are implemented inside MC_CGM clock mux.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-1<br>— | This field is reserved and reads return zeros. |
| 0<br>DIV_STAT | Divider status for clock mux 0<br>On reading MUX_n_DIV_UPD_STAT after updating a divider control register, if the value of this field is fixed to 1 because of an error in the selected clock source, perform the following steps to switch the mux to a new clock source:<br>1. Switch the mux to a working clock source without polling this field.<br>2. Update MUX_n_DC_m and poll this field.<br>**NOTE**<br>This field clears once divider configuration is updated or on destructive reset. If functional reset comes when this field is 1 then it can remain fixed to 1 until divider input clock is restored.<br>0b - No divider configuration update is pending.<br>1b - Divider configuration update on at least one divider associated with this multiplexer is pending. |

## 24.5.18 Clock Mux 1 Select Control Register (MUX_1_CSC)

### Offset

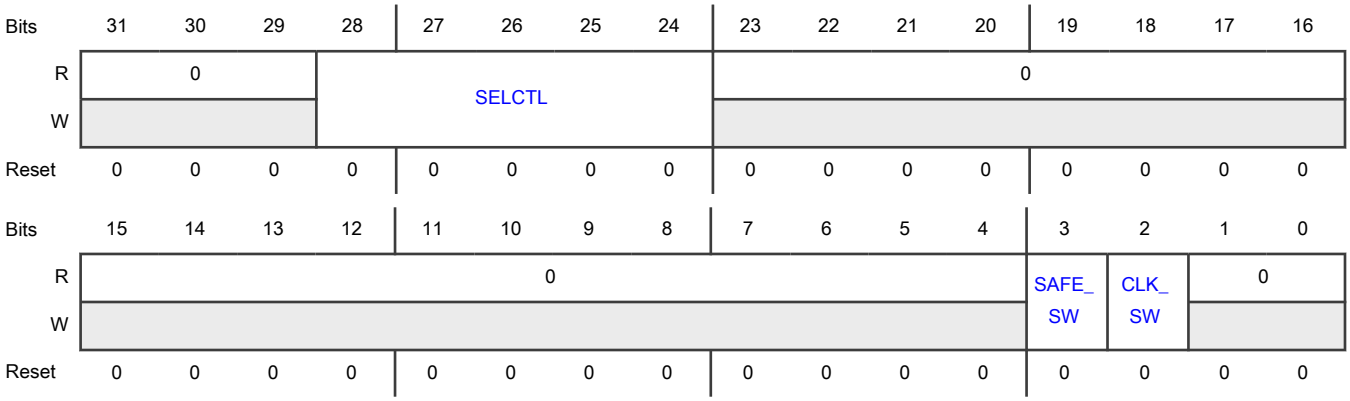
| Register | Offset |
|---|---|
| MUX_1_CSC | 340h |

### Function

This register provides the clock source selection control for clock mux 1. Clock mux 1 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-29<br>— | This field is reserved and reads return zeros. |

### 24.5.23 Clock Mux 2 Select Status Register (MUX_2_CSS)

#### Offset

| Register | Offset |
|---|---|
| MUX_2_CSS | 384h |

#### Function

This register provides the current clock source selection status for clock mux 2.

This register is reset on destructive reset only.

### Diagram

### 24.5.24 Clock Mux 2 Divider 0 Control Register (MUX_2_DC_0)

**Offset**

| Register | Offset |
|---|---|
| MUX_2_DC_0 | 388h |

**Function**

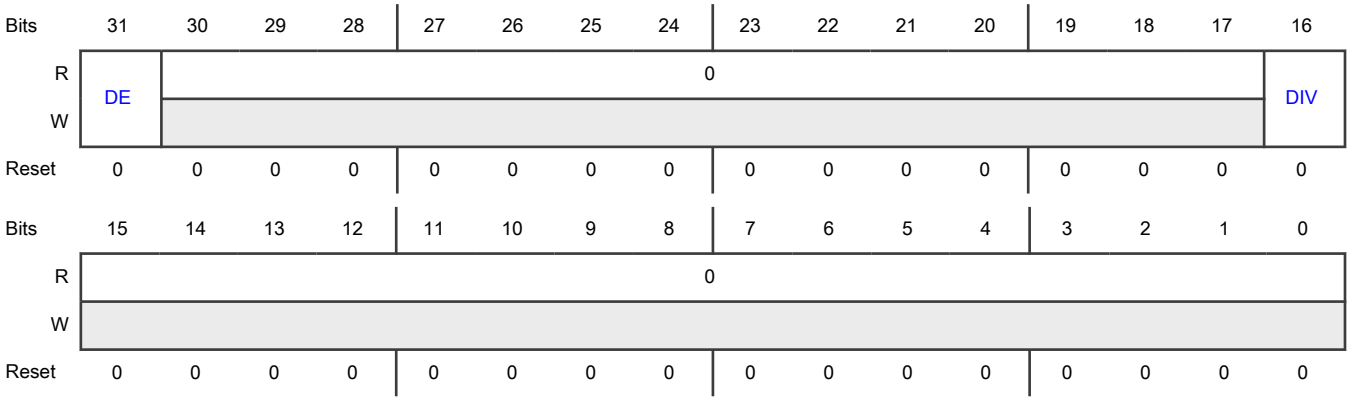
This register controls the clock divider 0 for clock mux 2.

This divider is a 50% duty cycle divider.

**NOTE**

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31<br>DE | Divider enable<br>0b - Divider is disabled.<br>1b - Divider is enabled. |
| 30-17<br>— | This field is reserved and reads return zeros. |
| 16<br>DIV | Division value<br>This field provides the division value for the clock divider. The clock period of the clock after division is 'DIV+1' times the time period of the current input clock to the divider. |
| 15-0<br>— | This field is reserved and reads return zeros. |

## 24.5.25 Clock Mux 2 Divider Update Status Register (MUX_2_DIV_UPD_STAT)

### Offset

| Register | Offset |
|---|---|
| MUX_2_DIV_UPD_STAT | 3BCh |

### Function

This register provides the update status of the clock dividers corresponding to clock mux 2. When a write operation on any divider control register is performed, the divider status bit in this register is set to logic-1. The bit is set to logic-0 when the divider has sampled the new divider configuration. Performing multiple writes without tracking the status bit on same or other

clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

**NOTE**

Read accesses to MUX_n_DIV_UPD_STAT always complete without returning bus transfer error independent of whether any divider(s) are implemented inside MC_CGM clock mux.

### Diagram

Switch the mux to a working clock source without polling this field.<br>2. Update MUX_n_DC_m and poll this field.<br>**NOTE**<br>This field clears once divider configuration is updated or on destructive reset. If functional reset comes when this field is 1 then it can remain fixed to 1 until divider input clock is restored.<br>0b - No divider configuration update is pending.<br>1b - Divider configuration update on at least one divider associated with this multiplexer is pending. |

## 24.5.26 Clock Mux 3 Select Control Register (MUX_3_CSC)

### Offset

| Register | Offset |
|---|---|
| MUX_3_CSC | 3C0h |

### Function

This register provides the clock source selection control for clock mux 3. Clock mux 3 implements hardware control clock switching ensuring that the clock switch happens in a graceful manner (without glitches). See the "Hardware-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

### Diagram

### Offset

| Register | Offset |
|---|---|
| MUX_5_DC_0 | 448h |

### Function

This register controls the clock divider 0 for clock mux 5.

This divider is a 50% duty cycle divider.

**NOTE**

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

**NOTE**

Software-controlled clock multiplexer dividers are not expected to return to the default state on the hardware transitions and handshakes occurring as part of the functional reset entry sequence (only hardware-controlled clock multiplexer dividers return to the default state).

| 15-0<br>— | This field is reserved and reads return zeros. |

### 24.5.37 Clock Mux 5 Divider Update Status Register (MUX_5_DIV_UPD_STAT)

**Offset**

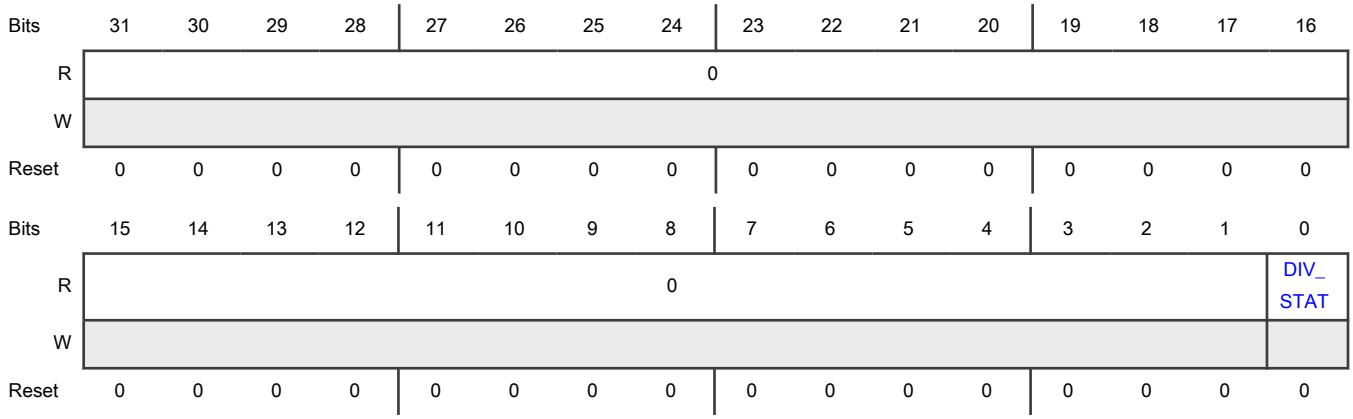
| Register | Offset |
|---|---|
| MUX_5_DIV_UPD_STAT | 47Ch |

**Function**
This register provides the update status of the clock dividers corresponding to clock mux 5. When a write operation on any divider control register is performed, the divider status bit in this register is set to logic-1. The bit is set to logic-0 when the divider has sampled the new divider configuration. Performing multiple writes without tracking the status bit on same or other clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

**NOTE**

Read accesses to MUX_n_DIV_UPD_STAT always complete without returning bus transfer error independent of whether any divider(s) are implemented inside MC_CGM clock mux.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-1<br>— | This field is reserved and reads return zeros. |
| 0<br>DIV_STAT | Divider status for clock mux 5<br>On reading MUX_n_DIV_UPD_STAT after updating a divider control register, if the value of this field is fixed to 1 because of an error in the selected clock source, perform the following steps to switch the mux to a new clock source:<br>1. Switch the mux to a working clock source without polling this field.<br>2. Update MUX_n_DC_m and poll this field.<br>**NOTE**<br>This field clears once divider configuration is updated or on destructive reset. If functional reset comes when this field is 1 then it can remain fixed to 1 until divider input clock is restored.<br>0b - No divider configuration update is pending.<br>1b - Divider configuration update on at least one divider associated with this multiplexer is pending. |

## 24.5.38 Clock Mux 6 Select Control Register (MUX_6_CSC)

### Offset

| Register | Offset |
|---|---|
| MUX_6_CSC | 480h |

### Function

This register provides the clock source selection control of clock mux 6. Clock mux 6 implements software control clock switching, and a graceful clock switch can be performed by executing a sequence of steps in software. See "Software-controlled clock multiplexer" section for details.

This register is reset on destructive reset only.

### Diagram

### 24.5.49 Clock Mux 8 Divider Update Status Register (MUX_8_DIV_UPD_STAT)

#### Offset

| Register | Offset |
|---|---|
| MUX_8_DIV_UPD_STAT | 53Ch |

#### Function

This register provides the update status of the clock dividers corresponding to clock mux 8. When a write operation on any divider control register is performed, the divider status bit in this register is set to logic-1. The bit is set to logic-0 when the divider has sampled the new divider configuration. Performing multiple writes without tracking the status bit on same or other clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

**NOTE**

Read accesses to MUX_n_DIV_UPD_STAT always complete without returning bus transfer error independent of whether any divider(s) are implemented inside MC_CGM clock mux.

## 24.5.53 Clock Mux 9 Divider Update Status Register (MUX_9_DIV_UPD_STAT)

### Offset

| Register | Offset |
|---|---|
| MUX_9_DIV_UPD_STAT | 57Ch |

### Function

This register provides the update status of the clock dividers corresponding to clock mux 9. When a write operation on any divider control register is performed, the divider status bit in this register is set to logic-1. The bit is set to logic-0 when the

divider has sampled the new divider configuration. Performing multiple writes without tracking the status bit on same or other clock dividers inside the same clock mux leads to inconsistent reporting, that is, the divider status maybe be set to logic-0 when the corresponding divider update is pending.

**NOTE**

Read accesses to MUX_n_DIV_UPD_STAT always complete without returning bus transfer error independent of whether any divider(s) are implemented inside MC_CGM clock mux.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 24.5.60 Clock Mux 11 Divider 0 Control Register (MUX_11_DC_0)

### Offset

| Register | Offset |
|---|---|
| MUX_11_DC_0 | 5C8h |

### Function

This register controls the clock divider 0 for clock mux 11.

This divider is a 50% duty cycle divider.

**NOTE**

The update to the fields of this register should be an atomic write, that is, one single write should update the complete register.

**NOTE**

Software-controlled clock multiplexer dividers are not expected to return to the default state on the hardware transitions and handshakes occurring as part of the functional reset entry sequence (only hardware-controlled clock multiplexer dividers return to the default state).

### Diagram

# Chapter 25
# Fast Internal RC Oscillator (FIRC)

## 25.1 Overview

The FIRC digital interface controls the internal 48 MHz RC oscillator system.

### 25.1.1 Features

FIRC can be disabled in Standby mode via software.

- Status register provides the current operating state:
  - On and stable
  - Off or on but not stable

## 25.2 External signals

This module has no external signals.

## 25.3 Initialization

This module does not require initialization.

## 25.4 FIRC register descriptions

### 25.4.1 FIRC memory map

FIRC base address: 402D_0000h

| Offset | Register | Width (In bits) | Access | Reset value |

# Chapter 26
# Slow Internal RC Oscillator (SIRC)

## 26.1 Overview

The SIRC digital interface controls the slow internal on-chip 32 KHz RC oscillator system.

### 26.1.1 Features

The SIRC module:

- Status register provides the current operating state:
  - On and stable
  - Off or on but not stable
- Operates at a frequency of 32 kHz in Functional mode

## 26.2 Operating mode

Only a POR reset will initialize the SIRC. Destructive or Functional resets do not impact the SIRC functionality.

SIRC stabilization occurs after 96 SIRC_CLK cycles.

The SIRC output clock remains invalid until the analog SIRC stabilizes. The output clock does not glitch or overshoot its frequency during enabling or disabling. Also, the clock does not get stuck or produce glitches on a very short hardware disable pulse.

## 26.3 External signals

This module has no external signals.

## 26.4 Initialization

This module does not require initialization.

## 26.5 SIRC register descriptions

### 26.5.1 SIRC memory map

Access to registers use 8-bit, 16-bit, or 32-bit addressing.

SIRC base address: 402C_8000h

# Chapter 27
# Fast Crystal Oscillator Digital Controller (FXOSC)

## 27.1 Chip-specific FXOSC information

### 27.1.1 Chip-specific FXOSC information

**For MCXE31B:** For bypass mode applications, the EXTAL pin should be driven low when FXOSC is in off/disabled state.

- While initializing FXOSC: When the FXOSC is used in Bypass mode, the external clock source can only be enabled after the FXOSC is enabled.
- While disabling FXOSC: When the FXOSC is used in Bypass mode, the external clock source must already be inactive before disabling the FXOSC.

## 27.2 Overview

The Fast Crystal Oscillator (FXOSC) generates a clock which can be used at the SoC level. The FXOSC has a digital interface to control and configure the oscillator. When FXOSC is powered down at any time, it is designed not to generate any glitch at the output clock. A counter inside FXOSC handles different stabilization times. CG cell is clock gating cell, it gates the clock till stabilization time.

### 27.2.1 Block diagram

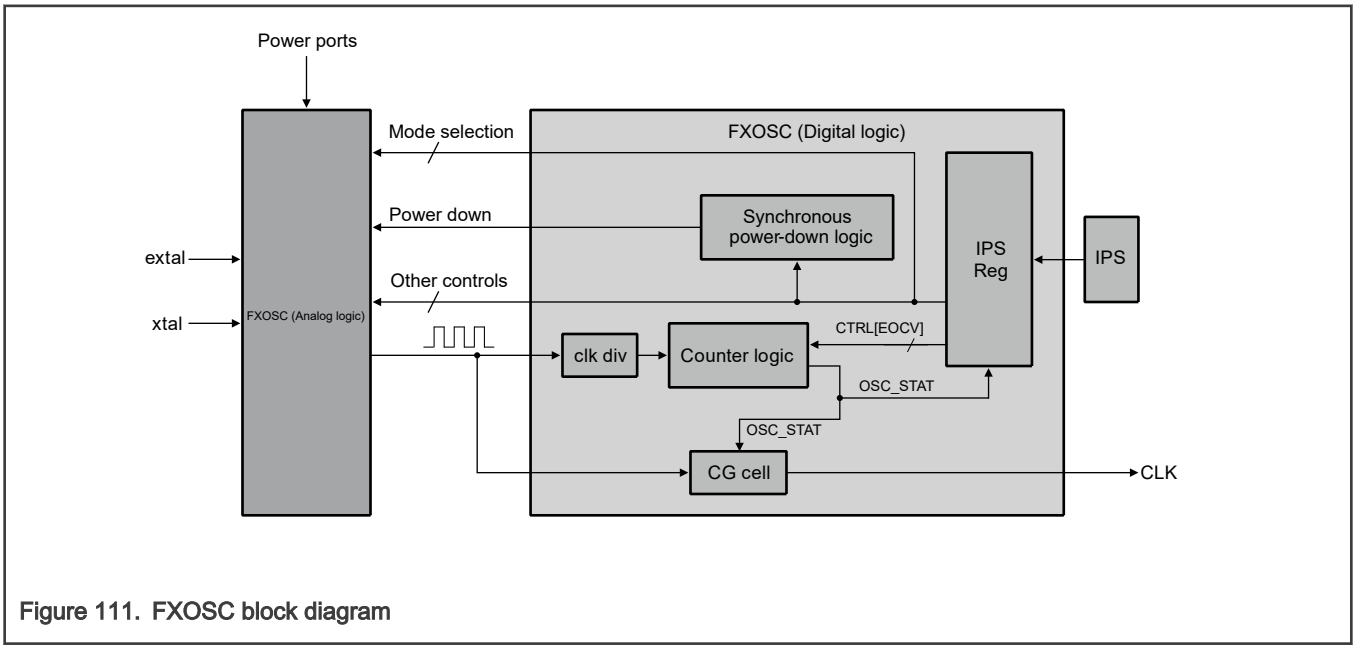

Figure 111. FXOSC block diagram

### 27.2.2 Features

FXOSC features are as follows:

- Status register shows current module state.
- Control register can:
  - Select a mode of operation:
    - Crystal mode
    - Single-Input Bypass mode using EXTAL clock input

— Disable the module (Power-Down mode)

## 27.3 Functional description

The table below shows configuration settings for the different FXOSC modes set by the CTRL register:

**Table 144. FXOSC operation mode settings**

| Mode | CTRL[OSCON] | CTRL[OSC_BYP] | CTRL[COMP_EN] | FXOSC_CLK |
|---|---|---|---|---|
| Power-Down mode | 0 | X | X | 0 |
| Crystal mode | 1 | 0 | 1 | Crystal clock |
| Single-Input Bypass mode | 1 | 1 | 0 | EXTAL |

Power-Down mode is the FXOSC default condition after any reset: POR, Destructive, or Functional.

### 27.3.1 Clock generation in Crystal mode

FXOSC_CLK start when counter value reaches FXOSC_CTRL[EOCV] × 128.

### 27.3.2 Clock generation in Single-Input Bypass mode

This mode bypasses the oscillator and uses a single-input external clock (EXTAL input) for FXOSC_CLK. When FXOSC enters Bypass mode:

- Enable the external clock after enabling FXOSC during FXOSC initialization.
- Disable the external clock beforehand when disabling FXOSC.

### 27.3.3 Clocking

This module has no clocking considerations.

### 27.3.4 Interrupts

This module has no interrupts.

## 27.4 External signals

This module has no external signals.

## 27.5 Initialization

#### Initializing FXOSC

Initialize FXOSC as follows:

1. Write the desired value to CTRL[OSC_BYP] and CTRL[COMP_EN] to select an operation mode as shown in Table 144.

   **NOTE**

   FXOSC must be disabled when the operation mode is modified.

2. Configure CTRL[GM_SEL].
   - In Crystal mode configure the transconductance based on the module specification in the chip data sheet.
   - In Single-Input Bypass mode write 0000b to this field.

**NOTE**

In Crystal mode FXOSC will not function with zero transconductance (GM_SEL = 0000b).

3. Set CTRL[EOCV] calculating the value as follows:
   - EOCV (in decimal) = (stabilization time in ns) ÷ (4×128×(period of clock in ns))
4. Write 1 to CRTL[OSCON] to enable FXOSC.

**NOTE**

When the FXOSC is used in Bypass mode, the clock from the external source can only be used after the FXOSC is enabled

5. Confirm the clock is stable (STAT[OSC_STAT] = 1) before using it.

**NOTE**

See Hardware design guide for further details and the recommended circuit for each mode.

#### Disabling FXOSC

Write 0 to CRTL[OSCON] to disable FXOSC when FXOSC_CLK is running and stable.

FXOSC enters Power-down mode after at least four crystal clocks. No glitches occur during the transition to Power-Down mode because synchronizers are used.

**NOTE**

After disabling FXOSC:

- Wait for at least 2µs before enabling FXOSC again.
- You must not change other values in FXOSC registers for at least 16 FXOSC_CLK cycles.

## 27.6 FXOSC register descriptions

This section provides the descriptions of all registers used for configuring the FXOSC.

### 27.6.1 FXOSC memory map

Use 8-bit, 16-bit, or 32-bit addressing to access registers.

FXOSC base address: 402D_4000h

| Offset | Register | Width (In bits) | Access | Reset value |

# Chapter 28
# Slow Crystal Oscillator Digital Controller (SXOSC)

## 28.1 Overview

The Slow crystal oscillator (SXOSC) generates a clock which can be used at the SoC level. The SXOSC has a digital interface to control and configure the oscillator. When SXOSC is powered down at any time, it is designed not to generate any glitch at the output clock. A counter inside SXOSC handles different stabilization times. CG cell is clock gating cell, it gates the clock till stabilization time.

### 28.1.1 Block diagram

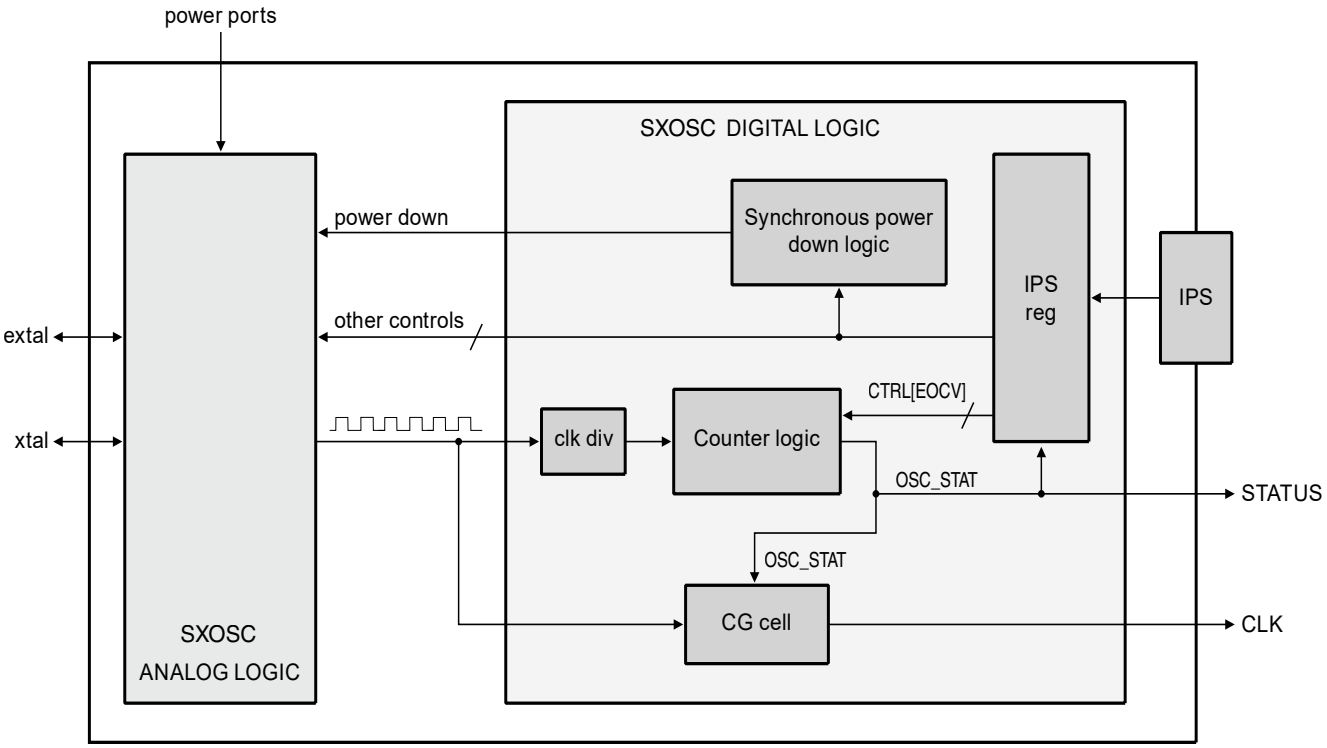

Figure 112. Block diagram

## 28.2 Features

- SXOSC generates a 32 KHz clock output in crystal mode
- SXOSC contains a status register, the value of which becomes 1 when the crystal stabilization time is complete
- SXOSC can be powered down through software bit.

## 28.3 Functional description

SXOSC generates control signals to configure the analog module to operate in specific modes.

The following table shows the mode of operation available for selection and its settings.

Table 145. Operation mode settings

| Mode | Value of SXOSC_CTRL[OSCON] | Output clock |
|---|---|---|
| Functional Oscillator | 0 (oscillator switched off) | 0 (indicates no output) |
| | 1 (oscillator switched on) | Crystal clock |

### 28.3.1 Clock generation in crystal mode

After hard reset, the crystal oscillator is switched off by default. For clock generation in crystal mode, see Table 145. The counter logic starts counting and the stable clock starts running one clock cycle after reaching the value of SXOSC_CTRL[EOCV] x 128 counter value. The module writes 1 to SXOSC_STAT[OSC_STAT] after two module clock cycles.

### 28.3.2 Clock stopping in crystal mode

To stop a stable, running clock, configure the power down mode as specified in Table 145. A glitch does not occur because synchronizers are used.

### 28.3.1 Modes of operation

The SXOSC has following modes of operation.

#### 28.3.1.1 Crystal mode

In this mode crystal is connected between extal and xtal ports, to select crystal mode see Table 145

#### 28.3.1.2 Bypass mode

The bypass mode is handled outside the DA Wrapper.

**NOTE**

In this mode crystal is removed from extal and xtal ports and extal is driven by external clock and xtal is unconnected.

### 28.3.2 Clocking

This module has no clocking considerations.

### 28.3.3 Interrupts

This module has no interrupts.

## 28.4 External signals

This module has no external signals.

## 28.5 Initialization information

To enter into any mode the following sequences must be followed. By default IP is disabled.

- Power-down Mode:
  - When SXOSC is running in any mode, de-assert SXOSC_CTRL[OSCON]
- Crystal Mode:
  1. Disable the IP by de-asserting SXOSC_CTRL[OSCON] bit
  2. Connect the crystal between extal and xtal ports

3. Write an appropriate value to SXOSC_CTRL[EOCV]
4. Program recommended value in SXOSC_CTRL[GM_SEL]
5. Enable the IP by asserting SXOSC_CTRL[OSCON] bit
6. SXOSC_STAT[OSC_STAT] bit will be set after counter runs as per programming of SXOSC_CTRL[EOCV] and clock will be released to SoC

## 28.6 SXOSC register descriptions

This section provides the description of all registers for configuring the SXOSC.

### 28.6.1 SXOSC memory map

Addresses are given as offsets from the module base address. All registers can be accessed using 8-bit, 16-bit or 32-bit addressing.

**NOTE**

Some of the register reset values are specifically configured for each unique device by external configuration signals or parameters.

SXOSC base address: 402C_C000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Oscillator Control Register (SXOSC_CTRL) | 32 | RW | 007D_0000h |
| 4h | Oscillator Status Register (SXOSC_STAT) | 32 | R | 0000_0000h |

### 28.6.2 Oscillator Control Register (SXOSC_CTRL)

# Chapter 29
# PLL Digital Interface (PLLDIG)

## 29.1 Chip-specific PLLDIG information

### 29.1.1 PLL-supported accesses and frequencies

The PLLODIV_0 and PLLODIV_1 registers support only word accesses. When you write to these registers, you must retain the default values of the reserved fields.

PLLDIG supports a down-spread modulation of up to 160 MHz PLL PHI clock output only.

### 29.1.2 Register implementation

In MCXE315/MCXE316 there are additional registers as compared to what is mentioned in section 'PLLDIG memory map'. See following table for details.

**Table 146. Register details**

| Register/Bitfield | Offset | Availability |
|---|---|---|
| PLLCLKMUX[REFCLKSEL][1] | 20h | Only available in MCXE315/MCXE316 |

1. See section 'PLLCLKMUX definition' for register definition

#### 29.1.2.1 PLLCLKMUX definition

Register PLLCLKMUX (PLL Clock Multiplexer) is available at offset 20h. This register selects the PLL clock source. Bitfield definition of this register is as shown below:

**Table 147. PLLCLKMUX Definition**

| Bitfield offset | Bitfield name | Bitfield description |
|---|---|---|
| 0 | REFCLKSEL | Reference Clock Select: Selects the PLL clock source.<br>• 0b-FXOSC_CLK<br>• 1b-FIRC_DIV2_CLK |
| 1-31 | Reserved | |

### 29.1.3 Initialization information for MCXE315/MCXE316

Perform the following steps to initialize PLL:

1. Confirm that PLLODIV_*n*[DE] is 0 for all dividers.
2. Confirm that PLLCR[PLLPD] is 1.
3. Program PLLCLKMUX to select the appropriate reference clock.
4. Program the following as needed:
   - PLLDV
   - PLLFD
   - PLLFM to the desired value
5. Program PLLDV[ODIV2] and PLLODIV_*n*[DIV] to the desired values.
6. Wait for the PLL reference clock to be stable.

7. Write 0 to PLLCR[PLLPD].
8. Wait for PLLSR[LOCK] to be 1.
9. Write 1 to PLLODIV_*n*[DE].

Perform the following steps to shut down PLL:

1. Write 0 to PLLODIV_n[DE] for all dividers.
2. Write 1 to PLLCR[PLLPD].

## 29.2 Overview

PLL can multiply or divide the frequency of a given clock input.

### 29.2.1 Block diagram

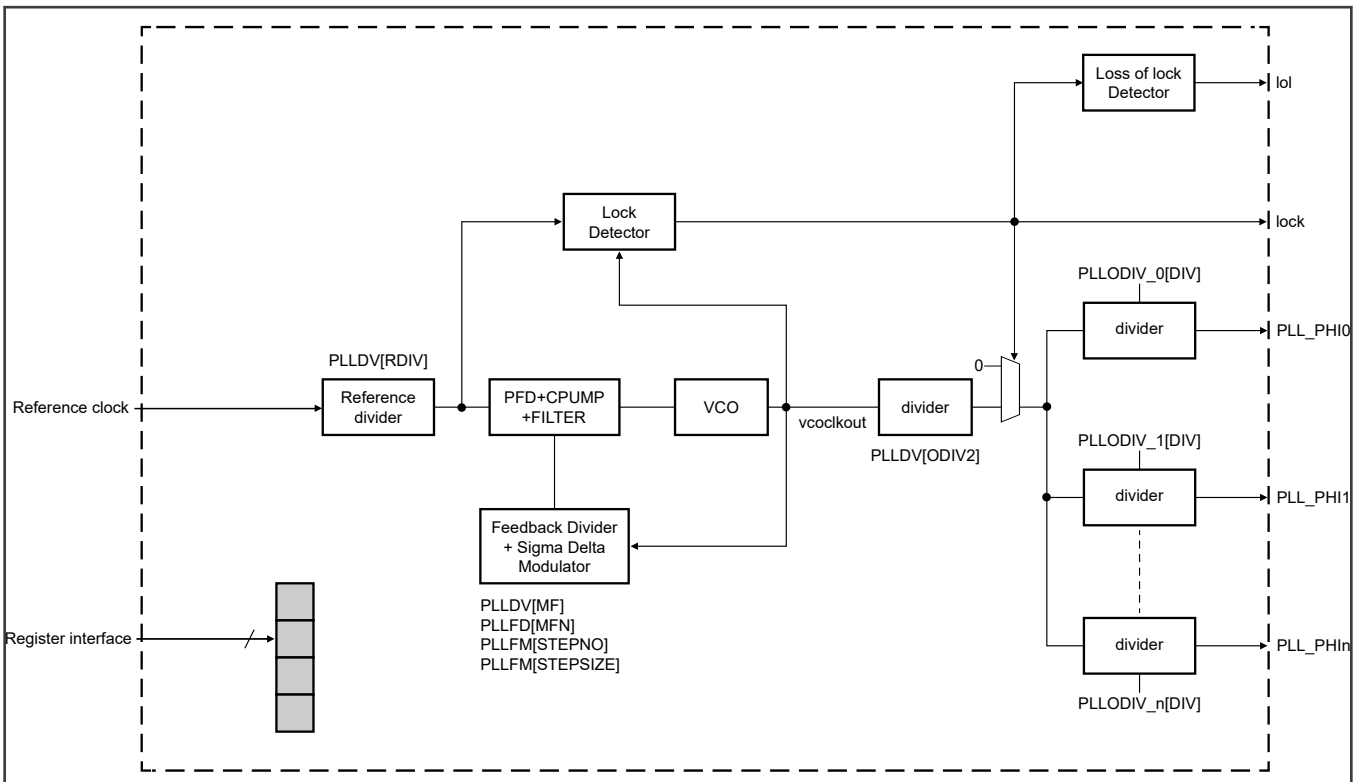

Figure 113. Block diagram

The number of output dividers can vary with the module instance. See the Clocking chapter to confirm the number of PLL output dividers.

### 29.2.2 Features

PLL includes the following features:

- Programmable frequency modulation
- Multiple integer dividers on PLL outputs
- Lock detection circuitry reports when PLL achieves frequency lock
- Continuous monitoring of lock status to report Loss of Lock (LOL) condition
- Powering down the module for low-power operation (Power-Down mode)

## 29.3 Functional description

This section explains PLL operation and configuration.

### 29.3.1 Modes of operation

**Table 148. Modes of operation**

| PLLCR[PLLPD] | PLLFD[SDMEN] | PLLFM[SSCGBYP] | Description |
|---|---|---|---|
| 1 | x | x | PLL is disabled. |
| 0 | 0 | 1 | Functional mode – PLL operates in integer-only mode. See Clock configuration. |
| 0 | 1 | 1 | Functional mode – PLL operates in Fractional mode (non-Frequency modulation). See Clock configuration. |
| 0 | 1 | 0 | Functional mode – PLL operates in Frequency Modulation mode. See Frequency modulation. |

### 29.3.2 Input clock frequency

PLL is designed to operate over a specified input clock frequency range. PLL source frequency limits are discussed in this chip's data sheet.

### 29.3.3 Clock configuration

See the equations below and the corresponding register configuration that determine the relationship between VCO frequency ($f_{VCO}$) and PLL reference frequency.

- Integer-only mode:
  - When PLLDV[RDIV] is 0:

$$f_{\text{pll_VCO}} = f\text{pll_ref} \times \text{PLLDV[MFI]}$$

**Equation 1. PLL VCO frequency in integer-only mode when PLLDV[RDIV] is 0**

  - When PLLDV[RDIV] is not 0:

$$f_{\text{pll_VCO}} = \frac{f_{\text{pll_ref}}}{\text{PLLDV[RDIV]}} \times \text{PLLDV[MFI]}$$

**Equation 2. PLL VCO frequency in integer-only mode when PLLDV[RDIV] is not 0**

- Fractional mode:
  - When PLLDV[RDIV] is 0:

$$f_{\text{pll_VCO}} = f_{\text{pll_ref}} \times \left(\text{PLLDV[MFI]} + \frac{\text{PLLFD[MFN]}}{18432}\right)$$

**Equation 3. PLL VCO frequency in Fractional mode when PLLDV[RDIV] is 0**

  - When PLLDV[RDIV] is not 0:

$$f_{\text{pll_VCO}} = \frac{f_{\text{pll_ref}}}{\text{PLLDV[RDIV]}} \times \left(\text{PLLDV[MFI]} + \frac{\text{PLLFD[MFN]}}{18432}\right)$$

**Equation 4. PLL VCO frequency in Fractional mode when PLLDV[RDIV] is not 0**

See the equation below and the corresponding register configuration that determine the relationship between reference and PLL_PHI*n* output frequencies.

$$f_{\text{pll_phi}} = \frac{f_{\text{pll_VCO}}}{\text{PLLDV[ODIV2]} \times \left(\text{PLLDIV_}n\text{[DIV]} + 1\right)}$$

**Equation 5. PLL PHI output frequency**

When configuring PLL, you must not violate the maximum system clock frequency or maximum and minimum VCO frequency specification of PLL (see this chip's data sheet for frequency limits).

You must disable PLL by writing 1 to PLLCR[PLLPD] before any PLL configuration or input clock are modified.

You must disable PLL by writing 1 to PLLCR[PLLPD] for at least 5 µs before writing 0 to PLLCR[PLLPD] to enable PLL.

The recommended procedure to program PLL and enter Normal mode is shown in Initialization information.

### 29.3.4 Loss of lock (LOL)

PLL provides LOL indication. The LOL indication can only be generated when PLL is in Functional mode (see Modes of operation). When PLL detects a LOL, it asserts its LOL event output.

PLL does not detect loss of reference clock. If the reference clock stops after PLL achieves lock, PLL continues to indicate lock. It is assumed that monitoring of PLL's reference clock that is done outside PLL is enabled while PLL is in operation.

PLL LOL is intended for detection of gross failures. Use CMUs for accurate frequency monitoring.

### 29.3.5 Frequency modulation

In Frequency Modulation mode, PLL generates a frequency-modulated clock. The modulation depth and modulation frequency are calculated using the equations shown in Frequency modulation programming.

Write 1 to PLLFM[SPREADCTL] to select down-spread modulation. See Figure 114 that shows an example of down-spread modulation.

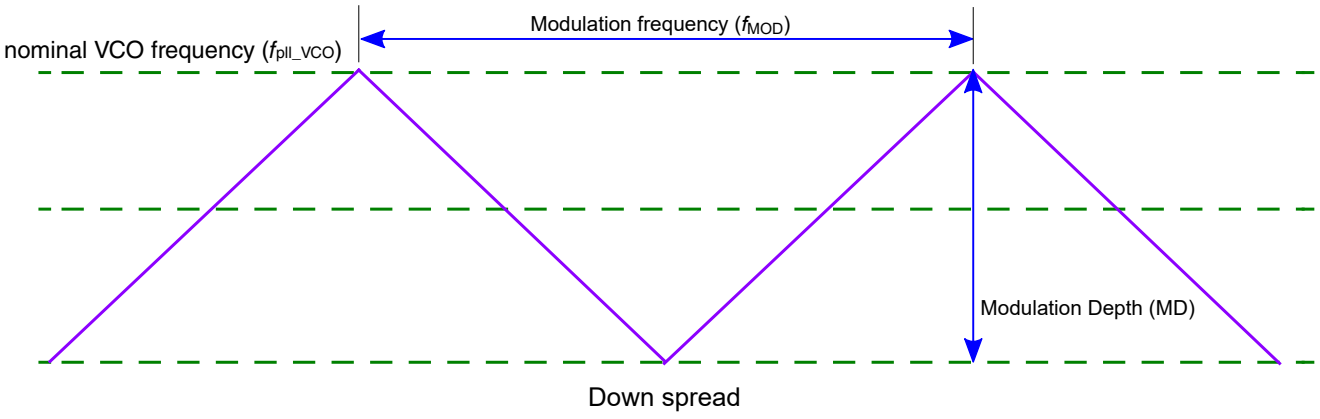

**Figure 114. Frequency modulation**

### 29.3.5.1 Frequency modulation programming

Modulation depth and modulation frequency programming uses step number (PLLFM[STEPNO]) and step size (PLLFM[STEPSIZE]). The table below shows variables used during calculations when programming PLL for frequency modulation.

**Table 149. Variables for configuring modulation depth and frequency**

| Variable | Description |
|---|---|
| $f_{REF}$ | Input clock frequency |
| $f_{MOD}$ | Expected modulation frequency |
| MD | Expected modulation depth in percentage |
| LDF | Loop division factor |
| $f_{pll_VCO}$ | Nominal VCO frequency |

Use the following equations to configure PLL for frequency modulation.

$$LDF = PLLDV[MFI] + \frac{PLLFD[MFN]}{18432}$$

**Equation 6. LDF**

$$PLLFM[STEPNO] = \frac{f_{REF}}{\left(2 \times f_{MOD} \times PLLDV[RDIV]\right)}$$

**Equation 7. Step number**

$$PLLFM[STEPSIZE] = \frac{MD \times LDF}{100 \times PLLFM[STEPNO]} \times 18432$$

**Equation 8. Step size**

Frequency modulation is only possible if the condition shown in Equation 9 is met.

$$(PLLFM[STEPSIZE] \times PLLFM[STEPNO]) < 18432$$

**Equation 9. Requirement to achieve FM**

You must write 0 to PLLFM[SSCGBYP] and write 1 to PLLFD[SDMEN] to enable frequency modulation.

$$Max\ (MD\ \%) = \frac{(f_{REF} \times 100)}{f_{pll_VCO}}$$

**Equation 10. Maximum possible modulation depth when PLL[RDIV] is 0**

$$Max\ (MD\ \%) = \frac{(f_{REF} \times 100)}{PLLDV[RDIV] \times f_{pll_VCO}}$$

**Equation 11. Maximum possible modulation depth when PLL[RDIV] is not 0**

**CAUTION**

The effective modulation depth may differ from the intended modulation depth because of rounding operations applied to PLLFM[STEPSIZE] and PLLFM[STEPNO].

### 29.3.6 Interrupt signals

This module has no interrupt signals.

## 29.4 External signals

This module has no external signals.

## 29.5 Initialization information

Perform the following steps to initialize PLL:

1. Confirm that PLLODIV_*n*[DE] is 0 for all dividers.
2. Confirm that PLLCR[PLLPD] is 1.
3. Program the following as needed:
   - PLLDV
   - PLLFD
   - PLLFM to the desired value
4. Program PLLDV[ODIV2] and PLLODIV_*n*[DIV] to the desired values.
5. Wait for the PLL reference clock to be stable.
6. Write 0 to PLLCR[PLLPD].
7. Wait for PLLSR[LOCK] to be 1.
8. Write 1 to PLLODIV_*n*[DE].

Perform the following steps to shut down PLL:

1. Write 0 to PLLODIV_n[DE] for all dividers.
2. Write 1 to PLLCR[PLLPD].

## 29.6 PLLDIG register descriptions

This section provides the memory map and detailed descriptions of registers used for configuring PLL. The table below shows the memory map. Addresses are given as offsets from the module base address. All registers are accessed using 8-bit, 16-bit, or 32-bit addressing.

### 29.6.1 PLLDIG memory map

PLL base address: 402E_0000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | PLL Control (PLLCR) | 32 | RW | 8000_0000h |
| 4h | PLL Status (PLLSR) | 32 | RW | 0000_0300h |

*Table continues on the next page...*

*Table continued from the previous page...*

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 8h | PLL Divider (PLLDV) | 32 | RW | 0C3F_1032h |
| Ch | PLL Frequency Modulation (PLLFM) | 32 | RW | 4000_0000h |
| 10h | PLL Fractional Divider (PLLFD) | 32 | RW | 0000_0000h |
| 18h | PLL Calibration Register 2 (PLLCAL2) | 32 | RW | 0006_0000h |
| 80h - 84h | PLL Output Divider (PLLODIV_0 - PLLODIV_1) | 32 | RW | 0000_0000h |

## 29.6.2 PLL Control (PLLCR)

### Offset

## 29.6.8 PLL Output Divider (PLLODIV_0 - PLLODIV_1)

### Offset

| Register | Offset |
|---|---|
| PLLODIV_0 | 80h |
| PLLODIV_1 | 84h |

### Function

Controls the PLL output clock divider settings.

This divider has a 50% duty cycle.

**NOTE**

These registers support only word accesses. Other write accesses lead to the following:

- Unpredictable behavior
- No transfer error generated

# Chapter 30
# Reset Overview

## 30.1 Introduction

This chip's reset logic consists of a reset sequence that leads the chip to a fixed deterministic state after predefined reset events occur. These events can pertain to chip failure events, the chip's special operating conditions, or certain software-governed events to initiate a chip reset sequence. This chapter discusses the chip reset scheme and related topics such as:

- Types of reset reactions
- Reset event sources
- Chip reset sequences
  - POR
  - Destructive reset
  - Functional reset
- RAM retention across functional reset
- Reset pin (RESET_b) behavior
- Debug system reset
- Signal-level reset flow

## 30.2 Chip reset types and reactions

### 30.2.1 Chip reset blocks

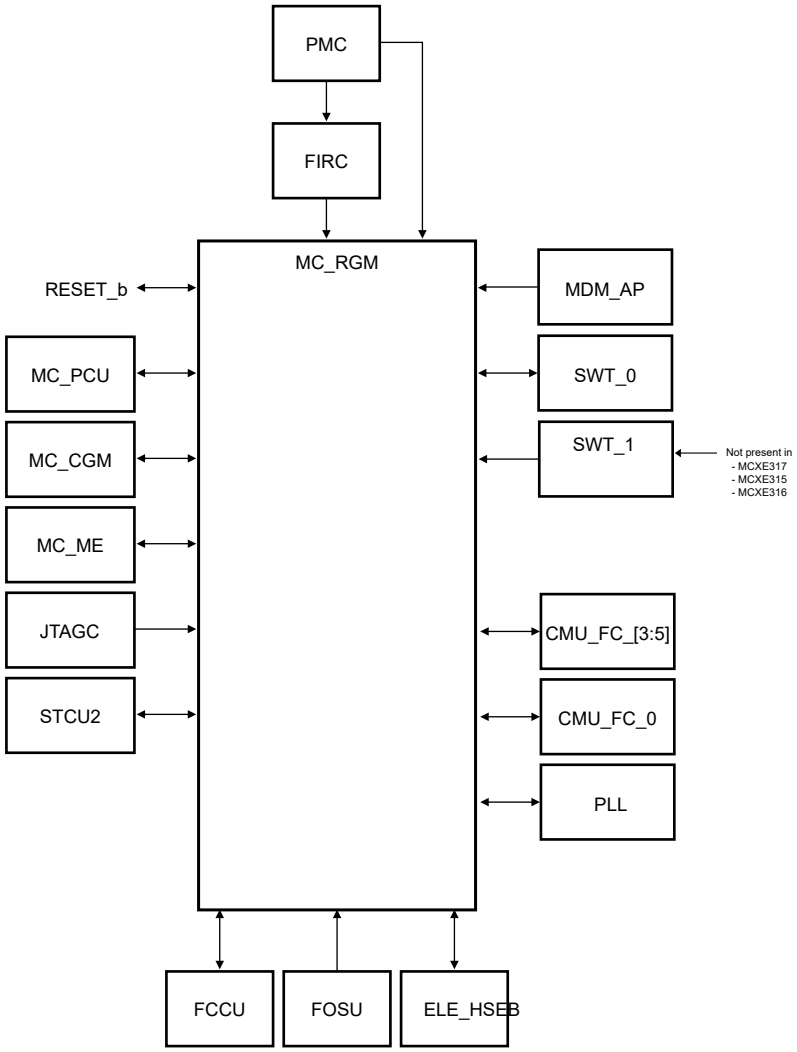

Figure 115. Chip reset blocks

### 30.2.2 Chip reset types

Table 150. Chip reset types

| Reset event type | Functional description |
|---|---|
| POR | Leads to a complete chip reset. |
| Destructive | Leads most parts of the chip, except a few modules, to reset. SRAM content is lost after this reset event. |
| Functional | Leads all the communication peripherals and cores to reset. The communication protocols' sanity is not guaranteed and they are assumed to be reinitialized after reset. The SRAM content, and the functionality of certain modules, is preserved across functional reset. |

### 30.2.3 High-level reset sequence overview

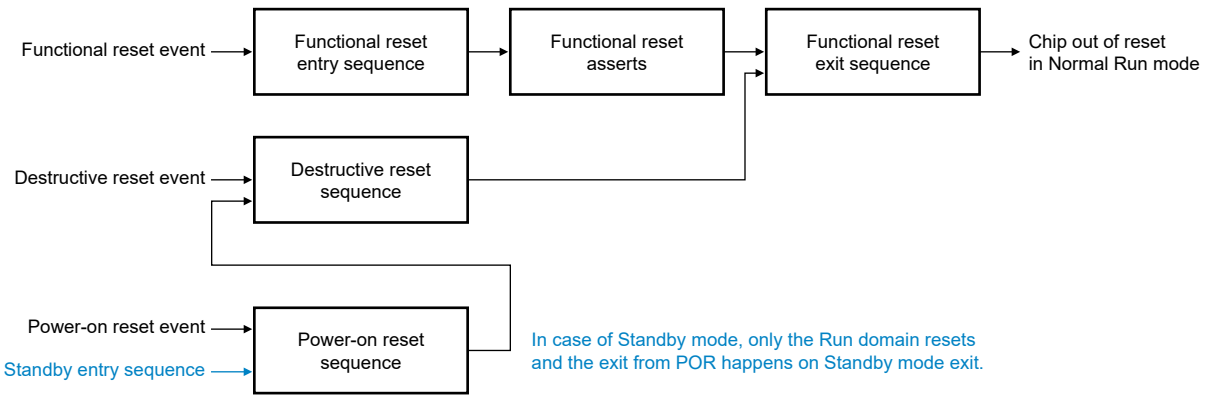

Figure 116. High-level reset sequence overview

#### 30.2.3.1 Reset event reactions

Table 151. Reset event reactions

| Reset event type | Triggered from | Reaction |
|---|---|---|
| POR | Anywhere | Moves to the beginning of the power-on sequence |
| Destructive reset | Power-on sequence | No reset sequence change |
| | Anywhere in the chip operation except in the power-on-sequence | Moves to the beginning of the destructive reset sequence |
| Functional reset | Out-of-reset | Moves to the beginning of the functional reset entry sequence |
| | | |
| | Anywhere within the functional reset sequence | No reset sequence change |

#### 30.2.3.2 Chip action after reset event

For each reset event, immediately after MC_RGM captures it, the chip performs these actions:

1. Writes 1 to the corresponding reset event status fields in MC_RGM.DES and MC_RGM.FES (see the MC_RGM chapter for more information).
2. Places its pins in their default states (see the IOMUX file attached to this document for more information).
3. Asserts the RESET_b pin.

**NOTE**

After self-test completes, you can configure RESET_b assertion using MC_RGM.FES[ST_DONE].

4. Enters the reset sequence as described in Reset event reactions, depending on the current state and reset event type.

## 30.3 Reset sources—POR, destructive, and functional

MC_RGM records reset events in MC_RGM.FES and MC_RGM.DES, indicating the source of functional reset events and destructive reset events, respectively. You must read these fields to identify the reset source on reset recovery.

### 30.3.1 POR sources

**Table 152. POR sources**

| Source module | Field in MC_RGM.DES | RESET_b assertion | Description |
|---|---|---|---|
| PMC | F_POR | Always | VDD_LV POR |
| | | | LVR on 1.1 V supply in Standby mode |
| | | | LVR on 1.1 V supply in Run mode |
| | | | LVR on 2.5 V supply in Standby mode |
| | | | LVR on 2.5 V supply in Run mode |
| | | | LVR on VDD_HV_A supply in Standby mode |
| | | | LVR on VDD_HV_A supply in Run mode |
| | | | LVR on VDD_HV_B supply in Standby mode [1] |
| | | | LVR on VDD_HV_B supply in Run mode [1] |
| POR_WDG | | | POR_WDG timeout (see the POR_WDG chapter for more information) |

1. LVR on VDD_HV_B run mode and LVR on VDD_HV_B standby mode are not present in MCXE315/MCXE316 and MCXE317.

**NOTE**

You cannot escalate or demote POR to an interrupt.

### 30.3.2 Stages of the POR sequence

**Table 153. Stages of the POR sequence**

| Stage | Process |
|---|---|
| PWRUP | 1. Starts after a POR event (for example, a POR source assert).<br>2. Waits for the power-up sequence to complete.<br>3. Exits when all the POR sources clear.<br>4. Transitions to the FIRC_STRT stage after the procedure completes. |
| FIRC_STRT | 1. Enters this stage after exiting the PWRUP stage.<br>**NOTE**<br>FIRC_CLK, if enabled, becomes available after it is stable. The duration depends on the clock startup time (see the chip datasheet for more information). The MC_RGM state machine proceeds further after FIRC_CLK is available.<br>2. Transitions to the destructive reset sequence after the procedure completes. |

### 30.3.3 Destructive reset sources

**Table 154. Destructive reset sources**

| Source module[1] | Field in MC_RGM.DES | Description |
|---|---|---|
| FOSU | FCCU_FTR | FCCU failure to react |
| STCU2 | STCU_URF | STCU2 unrecoverable fault |
| MC_RGM | MC_RGM_FRE | Functional reset escalation |
| CMU_FC_0 | FXOSC_FAIL | FXOSC failure |
| PLL | PLL_LOL | PLL loss of lock |
| CMU_FC_3 | CORE_CLK_FAIL | Core clock failure |
| CMU_FC_4 | AIPS_PLAT_CLK_FAIL | AIPS_PLAT_CLK failure |
| CMU_FC_5 | HSE_CLK_FAIL | HSE_CLK failure |
| MC_CGM | SYS_DIV_FAIL | System clock dividers alignment failure |
| ELE_HSEB | HSE_TMPR_R ST | ELE_HSEB tamper detect reset |
| ELE_HSEB | HSE_SNVS_RST | ELE_HSEB SNVS tamper detection |
| MC_ME | SW_DEST | Software destructive reset |
| MDM_AP | DEBUG_DEST | Debug destructive reset |
| RESET_b pin | EXT_RST | RESET_b pin assertion |

1. All destructive resets can be escalated, but only the PLL LOL destructive reset can be demoted to an interrupt (see Destructive reset event bypass for PLL LOL destructive reset bypass details).

**NOTE**

All reset sources in the table above assert the RESET_b pin.

### 30.3.4 Destructive sequence stage description

**Table 155. DEST0 description**

| Stage | Process |
|---|---|
| DEST0 | 1. Asserts reset to the entire chip, except logic running on POR.<br>2. Waits for all the destructive reset events to clear.<br>3. Waits for the minimum destructive reset assertion duration of eight FIRC_CLK cycles.<br>4. Deassets after stage completion. |

### 30.3.5 Functional reset sources

**Table 156. Functional reset sources**

| Source module | Field in MC_RGM.FES | RESET_b assertion | Demotable to IRQ[1] | Escalation[2] | Description |
|---|---|---|---|---|---|
| FCCU soft reaction[3] | FCCU_RST | Always | Yes[4] | Yes | FCCU reset reaction |

*Table continues on the next page...*

Table 156. Functional reset sources (continued)

| Source module | Field in MC_RGM.FES | RESET_b assertion | Demotable to IRQ[1] | Escalation[2] | Description |
|---|---|---|---|---|---|
| STCU2 | ST_DONE | Configurable | No | No | Self-test done |
| SWT_0 | SWT0_RST | Always | Yes[5] | Yes | SWT reset request |
| SWT_1[6] | SWT1_RST | Always | Yes[7] | Yes | SWT reset request |
| JTAGC | JTAG_RST | Always | Yes [8] | No | JTAG reset |
| ELE_HSEB | HSE_SWT_RST | Always | No | Yes | ELE_HSEB SWT timeout |
| ELE_HSEB | ELE_HSEBOOT_RST | Always | No | Yes | ELE_HSEB boot reset |
| MC_ME | SW_FUNC | Always | No | Yes | Software functional reset |
| MDM_AP | DEBUG_FUNC | Always | Yes [9] | Yes | Debug functional reset |

1. See Functional reset demotion to an interrupt for more information.
2. See Reset escalation for more information.
3. An FCCU soft functional reset is a chip functional reset (see the FCCU chapter for more information).
4. Controlled by MC_RGM.FERD[D_FCCU_RST].
5. Controlled by MC_RGM.FERD[D_SWT0_RST].
6. SWT_1 is not present in MCXE315/MCXE316 and MCXE317.
7. Controlled by MC_RGM.FERD[D_SWT1_RST].
8. Controlled by MC_RGM.FERD[D_JTAG_RST].
9. Controlled by MC_RGM.FERD[D_DEBUG_FUNC].

### 30.3.6 Functional reset sequence descriptions

Table 157. Functional reset sequence descriptions

| Stage | Series of events |
|---|---|
| **Functional reset entry sequences** | |
| FUNC0 | This stage starts after any functional reset event.<br>The FCCU fault monitoring and CMU_F*x_n* monitoring for FLL events is masked in this step to avoid any false fault or reset. |
| FUNC1 | In this stage, a halt sequence that includes daisy chaining of all the gaskets halts, disabling the crossbar.<br>The stage completes after the halt-handshake sequence completes. |
| FUNC2 | In this stage, MC_RGM triggers the MC_CGM hardware clock multiplexers to switch to FIRC_CLK.<br>• Software-based clock multiplexers do not support switching to FIRC_CLK on functional reset.<br>• If PCFS is enabled, the system clock switching can be done via PCFS.<br>This stage completes after MC_CGM switches the system clock to FIRC. |
| FUNC3 | In this stage, MC_RGM triggers all the MC_CGM hardware-based clock multiplexers with PCFS enabled or disabled to move their dividers to default values. |

*Table continues on the next page...*

**Table 157. Functional reset sequence descriptions (continued)**

| Stage | Series of events |
|---|---|
| | • Software-based clock multiplexers do not support this feature.<br>This stage completes after all the clock multiplexer dividers initialize to their corresponding default values. |
| FUNC4 | In this stage, PLLDIG turns off synchronously.<br>The stage completes after PLLDIG turns off. |
| FUNC5 | FXOSC_CLK switches off synchronously.<br>The FUNC4 and FUNC5 stages ensure that PLLDIG disables cleanly to ensure there are no glitches on the PLLDIG clock because of reset.<br>The stage completes after FXOSC switches off. |
| FUNC6 | In this stage, clocks of modules that are a part of LBIST and working on the destructive reset are enabled to meet their synchronous reset requirements, if any. For the self-test logic, in self-test, the destructive reset deasserts after this stage completes and after safe stating is removed.<br>**NOTE**<br>In the self-test sequence, the logic, which is a part of self-test (LBIST logic) resets when self-test completes. All the parts of logic in self-test (POR, destructive, and functional reset) reset after self-test completes whereas the rest of the chip undergoes a functional reset sequence because of self-test completion (MC_RGM.FES[ST_DONE] = 1). See the Safety Overview and STCU2 chapters for more information on the self-test operation. |
| FUNC7 | MC_RGM asserts the functional reset and triggers a counter running on FIRC_CLK (for up to 64 cycles) to enable clocks for the modules having synchronous reset requirements.<br>Flash memory comes out of reset after this stage completes.<br>**NOTE**<br>The flash memory resets after a functional reset event but comes out of reset, before the rest of the modules do, at the start of the functional reset exit sequence. The rest of the modules reset when the functional reset comes out of reset at the end of the functional reset exit sequence. Therefore, the reset to flash memory is an early functional reset that deasserts earlier than the functional reset, even if asserted at the same time. |
| **Functional reset exit sequences** | |
| FUNC8 | This stage consists of flash memory and MC_RGM handshaking.<br>Flash memory indicates the completion of its initialization to MC_RGM. |
| FUNC9 | DCM initiates the scanning of flash memory DCF records.<br>This state completes after the flash memory scanning completes. See the DCF clients file attached to this document for more information. |
| FUNC10 | After DCM scans the DCF records from the flash memory, DCM initiates the trim loading sequence for analog blocks.<br>The analog blocks are loaded with the configured trimmed values in this stage, which completes after a trim-loading sequence completes. |

*Table continues on the next page...*

Table 157. Functional reset sequence descriptions (continued)

| Stage | Series of events |
|---|---|
| FUNC11 | In this stage, MG_RGM stops driving RESET_b and checks that the signal does not assert externally.<br>If you enable low-power debug, MC_RGM waits for a debug acknowledge.<br>The completion of this stage indicates that MC_RGM completed the reset sequence, deasserting the functional reset to the system. |

## 30.4 Reset and boot sequence

The chip reset sequence consists of several reset stages based on the occurrence of a particular reset event. All reset events follow the same chip reset sequence; only the entry points vary depending on the type of reset event. MC_RGM triggers each stage after the previous stage completes. These stages execute in a specific order, which ensures a deterministic state of the chip when a reset event completes.

Figure 117 shows a high-level representation of the chip startup sequence.

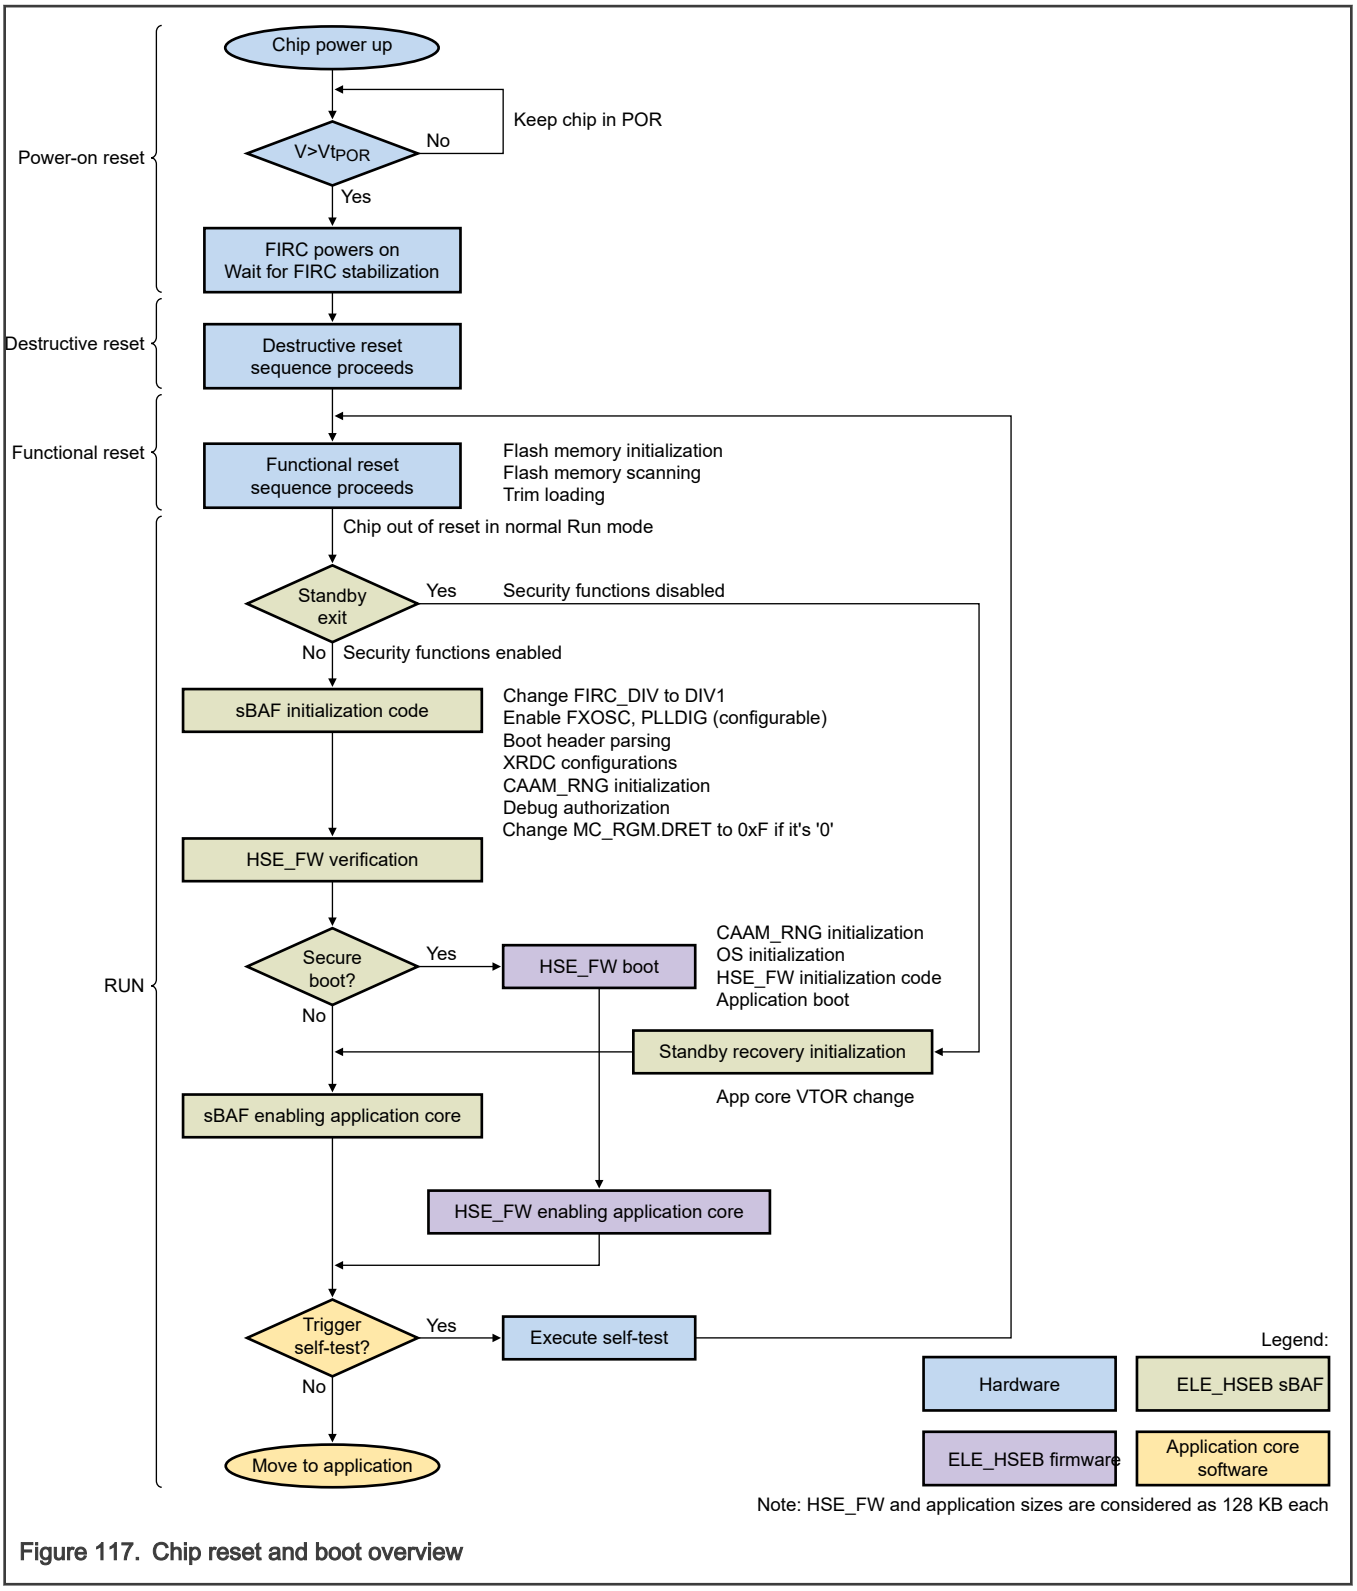

**Figure 117. Chip reset and boot overview**

## 30.4.1 POR

This stage starts when the POR event occurs, that is, when a POR source asserts. The logic within the Run power domain running on POR also resets in the chip Standby entry sequence.

**NOTE**

The logic in the Standby power domain does not reset in the chip Standby mode entry sequence.

The POR sequence consist of two stages:

1. Power-up (PWRUP)
2. FIRC oscillator start (FIRC_STRT)

See POR sequence for more information and Stages of the POR sequence for POR stages and their descriptions.

#### 30.4.1.1 POR sequence

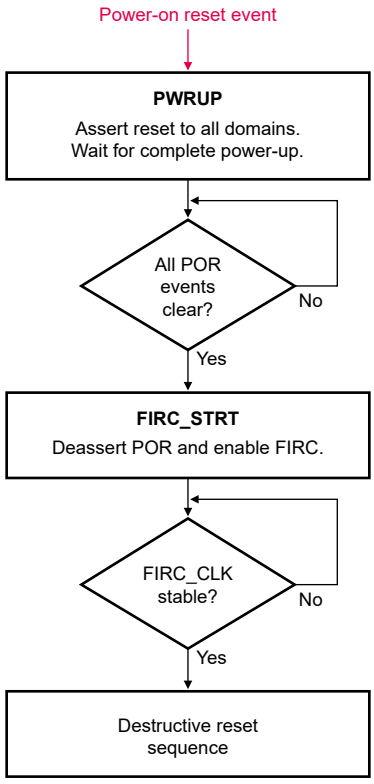

Figure 118. POR flow

### 30.4.2 Destructive reset

The chip enters a destructive reset sequence after the POR sequence or any destructive reset event completes. Destructive reset sequence illustrates the destructive reset sequence and Destructive sequence stage description discusses the stages of destructive sequence.

#### 30.4.2.1 Destructive reset sequence

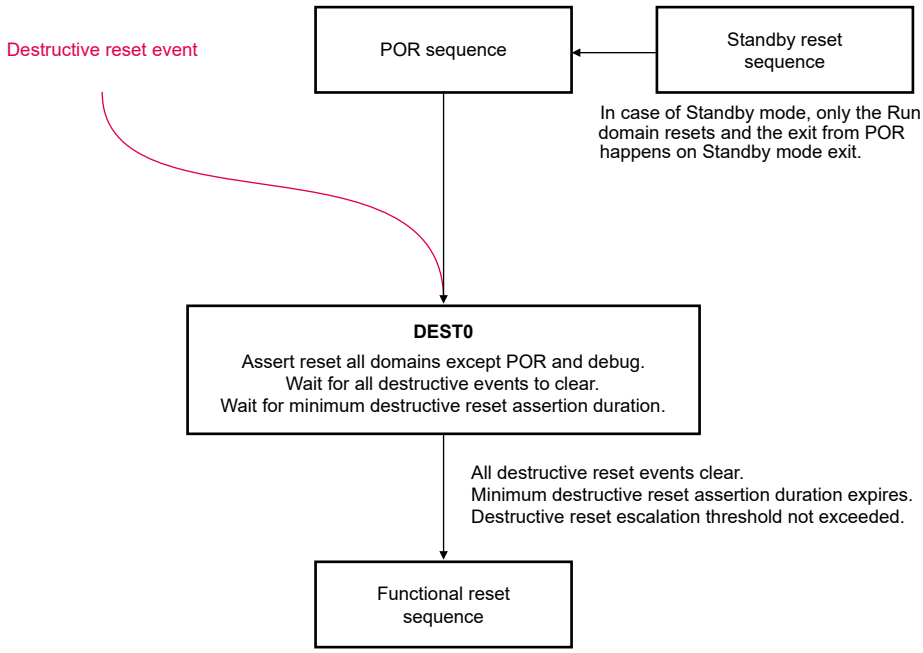

Figure 119. Destructive reset sequence

##### 30.4.2.1.1 Destructive sequence stage description

Table 158. DEST0 description

| Stage | Process |
|---|---|
| DEST0 | 1. Asserts reset to the entire chip, except logic running on POR.<br>2. Waits for all the destructive reset events to clear.<br>3. Waits for the minimum destructive reset assertion duration of eight FIRC_CLK cycles.<br>4. Deassets after stage completion. |

#### 30.4.2.2 Destructive reset event bypass

This chip supports a destructive reset event demotion mechanism that the application software configures. The destructive reset bypasses and an interrupt event occurs (demotion). Table 159 discusses details related to GPR configuration and corresponding interrupt identification.

A successful chip operation is not guranteed if a destructive reset event is bypassed.

Table 159. Destructive reset event bypass

| Destructive reset event | Destructive reset event description | DCM field to bypass reset event | NVIC interrupt ID |
|---|---|---|---|
| MC_RGM.DES[PLL_LOL] | PLL loss of lock | DCM.DCMRWP3[9] | 212 |

### 30.4.3 Functional reset

The chip enters the functional reset sequence when any of the following events occur:

- Functional reset
- POR or destructive reset (after the DEST0 stage completion)

On any functional reset event, the chip starts a functional reset entry sequence before the functional reset asserts and ensures the stability of logic running on a destructive reset and POR. On a destructive reset event or POR events the functional reset entry sequence does not execute.

The functional reset exit sequence consists of steps that ensure proper initialization of the chip after functional reset recovery.

#### 30.4.3.1 Functional reset sequence

Functional reset flow illustrates the functional reset flow and Functional reset sequence descriptions discusses the functional reset stages and their descriptions.

Stages FUNC0 to FUNC6 present the functional reset entry sequence. It occurs on any functional reset event before the functional reset. In other words, when a functional reset event occurs, MC_RGM holds the asserted reset and executes the functional reset entry sequence. After the sequence completes, MC_RGM resets the chip, which remains in Run mode during the functional reset entry sequence.

Stages FUNC7 to FUNC11 present the functional reset exit sequence, which occurs after a functional reset event before deasserting the chip reset. This includes handshaking with the flash memory and analog blocks, ensuring correct operation after reset exit.

#### 30.4.3.1.1 Functional reset flow

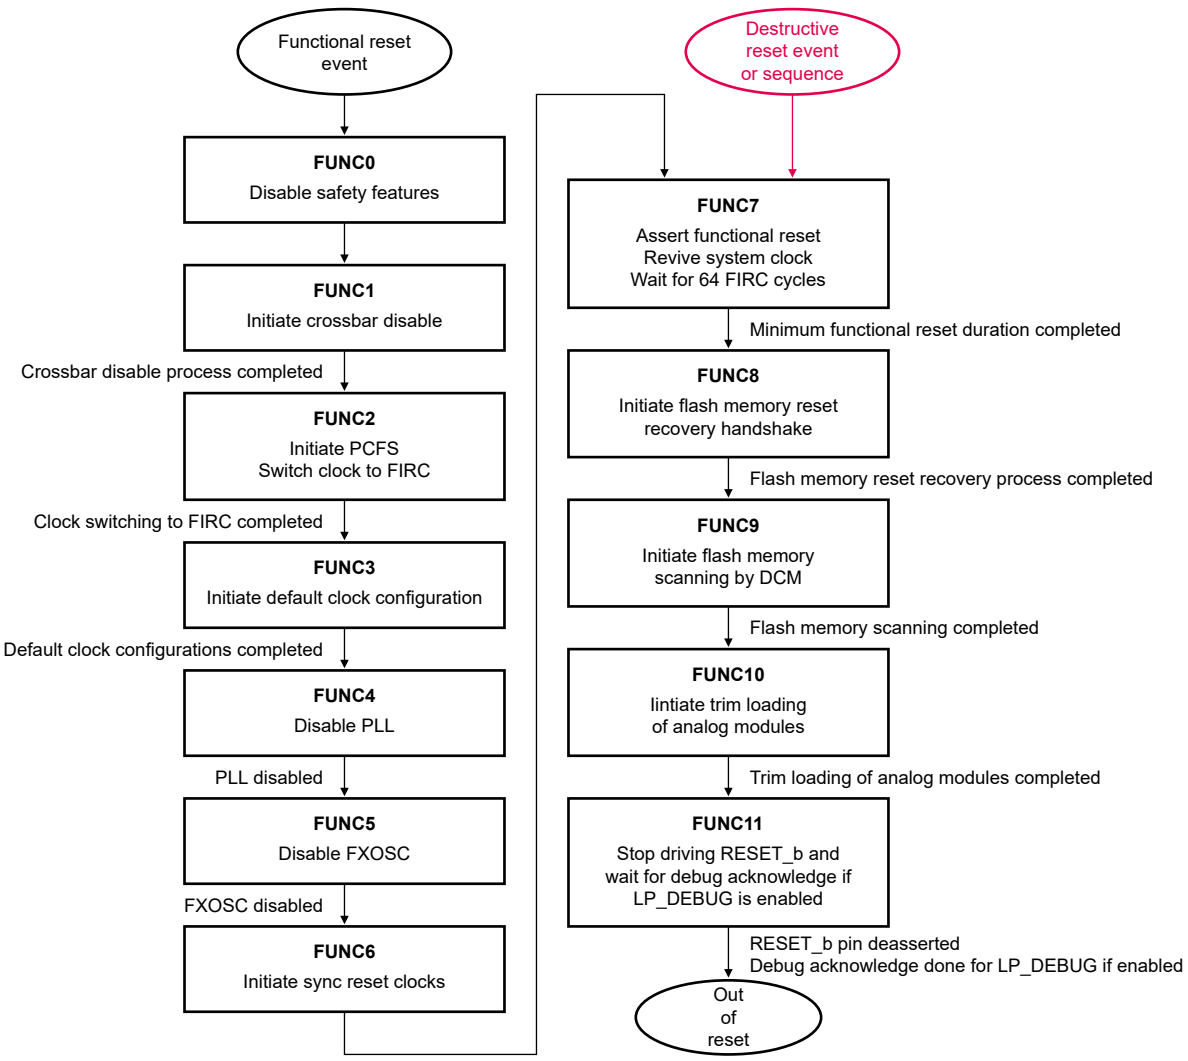

Figure 120. Functional reset flow

### 30.4.3.2 FUNC9 and FUNC10 stage bypass for faster Standby mode exit

The chip supports optional bypassing of the FUNC9 and FUNC10 (only FIRC and PMC phases) stages on Standby mode exit to considerably reduce the Standby mode exit duration. This feature is recommended only for Standby mode exit and must be configured on:

- Standby mode entry sequence
- SW3
- Disabled on Standby mode exit

See the "Faster Standby recovery" section in the "Power Management" chapter for more information.

### 30.4.3.3 Standby reset sequence

The logic within Run domain is reset additionally apart from the reset sequence in the chip standby entry sequence, wherein all the resets assert (POR, destructive, and functional) to the Run domain logic. The chip standby entry sequence does not have any impact on the logic in Standby power domain.

Wake-up from Standby mode removes the resets to the Run domain in the standby entry sequence.

See the "Peripheral reset status" section in the "Reset Overview" chapter for the logic present in Run domain.

#### 30.4.3.4 Reset function redirection

Resets may escalate or demote to an IRQ, depending on the chip configuration.

##### 30.4.3.4.1 Functional reset demotion to an interrupt

This chip supports the reset sequence demotion feature for functional resets. You can configure a functional reset to create an interrupt instead of a reset (see the MC_RGM chapter for details).

##### 30.4.3.4.2 Reset escalation

The chip supports the reset escalation feature. If multiple functional or destructive resets occur, the related reset can escalate to a higher priority reset sequence (see the "Functional reset escalation" and "Destructive reset escalation" sections in the MC_RGM chapter).

###### 30.4.3.4.2.1 Destructive reset escalation

You can enable destructive reset escalation by configuring a DCF client. You must also configure the destructive count threshold in MC_RGM.DRET (see "Destructive Reset Escalation Enable Register (DEST_RST_ESC):dcf_client_dest_rst_esc" in the DCF file attached to this document). The escalation event can individually be enabled or disabled for each reset source, and the fields in the dcf_client_dest_rst_esc register correspond with the fields in MC_RGM.DES register.

After being configured, MC_RGM immediately asserts a destructive reset escalation when the destructive event count reaches the threshold count in MC_RGM.DRET[DRET]. When the destructive and escalation reset assert, the reset sequence immediately enters the DEST0 state. The reset sequencing remains in DEST0 until a POR event occurs. If enabled, the destructive reset escalation counter increments with each destructive reset event. The application software clears the destructive reset escalation counter by writing any value to MC_RGM.DRET[DRET].

**NOTE**

You can configure GPR settings to allow demotion of destructive resets to interrupts instead of escalation (DCMRWP3[DEST_RST9_AS_IPI]). See Destructive reset event bypass for more information.

## 30.5 Reset timing diagram

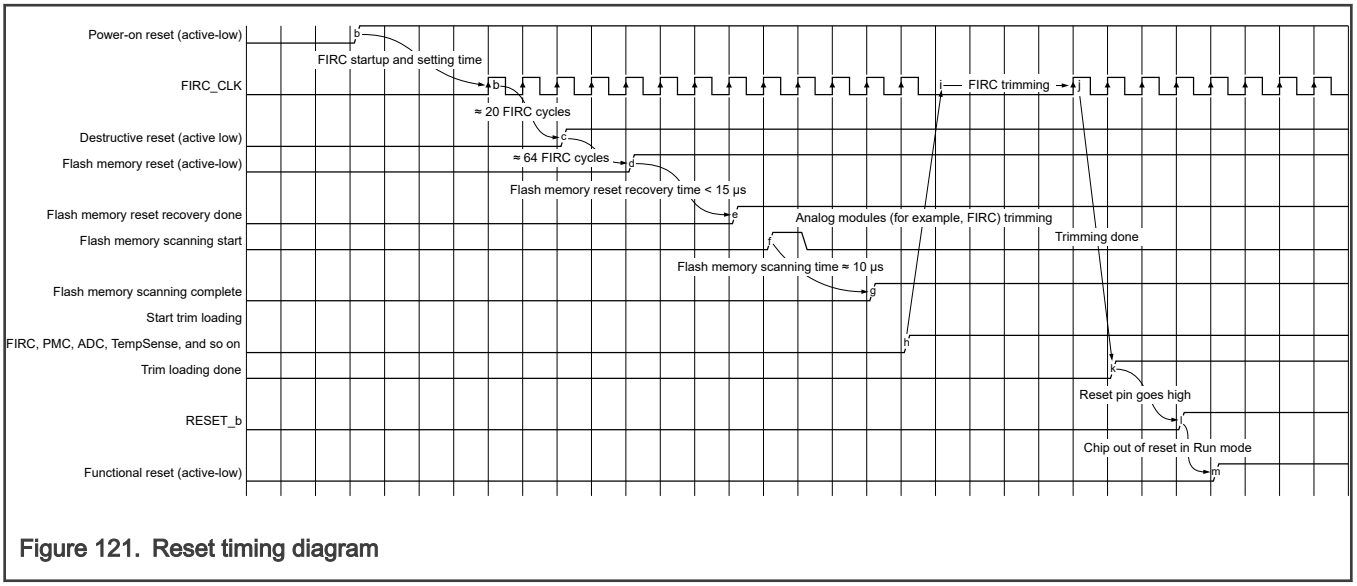

Figure 121. Reset timing diagram

## 30.6 Chip status after reset deassertion

**Table 160. Chip status after reset deassertion**

| Function or feature | After POR deassertion | After destructive reset deassertion | After functional reset deassertion |
|---|---|---|---|
| Clock sources | • FIRC_CLK and SIRC_CLK on<br>• Others off | • FIRC_CLK and SIRC_CLK on<br>• Others off | • FIRC_CLK and SIRC_CLK on<br>• SXOSC_CLK same as before functional reset<br>• FXOSC_CLK and PLL_PHIn_CLK off |
| Clock selection | FIRC_CLK | FIRC_CLK | FIRC_CLK |
| Clock dividers | Default configuration | Default configuration | Default configuration |
| Reset status flags | MC_RGM.DES[F_POR] equals 1, others equal 0 | MC_RGM.DES[F_DR_n] equals 1, others equal 0 | MC_RGM.FES[F_FR_n] equals 1, others equal 0 |
| MC_ME previous mode | Reset | Reset | Reset |
| FCCU fault information | Cleared | Cleared | Retained |
| ELE_HSEB RAM | Initialized | Initialized | Initialized |
| SRAM content | Invalid | Invalid | Retained |
| DCF configurations in DCM | Reset value | Existing loaded value (reset value after POR) | Reloaded from flash memory |
| Cores | All off | All off | ELE_HSEB core on, others off |
| Logic on POR[1] | Out of reset with default configuration | Out of reset with default configuration | Out of reset with default configuration |
| Logic on destructive reset [1] | Under reset with default configuration | Out of reset with default configuration | Out of reset with default configuration |
| Logic on functional reset [1] | Under reset with default configuration | Under reset with default configuration | Out of reset with default configuration |

1. For the list of peripherals affected by POR, destructive reset, and functional reset events, see Module reset status.

## 30.7 Module reset status

**Table 161. Module reset status**

| Cortex-M7_0 | Y | Y[13] | Run | No |
| Cortex-M7_0 AHB-AP | Y | N | Run | No |
| MC_PCU | Y | N | Standby | No |

| Legends: | |
|---|---|
| Y | The entire module resets on this particular reset. |
| Y | Only a portion of the module resets on this particular reset. |
| N | No portion of the module resets on this particular reset |

1. All the modules listed in this table are reset on a POR event. See the memory map file attached to this document for the availability of modules across various parts in the MCXE31 family.
2. The modules in the RUN domain get reset on standby exit. The modules in STANDBY domain are not impacted by standby exit and retain their contents. However in case of standby exit via functional reset or destructive reset event, the corresponding flops within the STANDBY domain modules will also get reset.
3. The modules in the LBIST logic get reset on selftest completion.
4. Flash memory scanning logic is available in the Run domain. GPRs and LC decode logic are available in Standby domain.

5. All memory-mapped registers are on functional reset. The trimming logic is on destructive reset. Rest of counter and other stuff is on POR.
6. During functional reset stages FUNC2 and FUNC3 (see the Functional reset sequence descriptions for functional reset stage descriptions), MC_CGM.MUX_*n*_CSC and MC_CGM.MUX_*n*_DIV_*m* are automatically set to their default values. The default value of the MC_CGM.MUX_*n*_CSC[SELCTL] selects FIRC_CLK as the source clock for all multiplexers. The default value of the MC_CGM.MUX_*n*_DIV_*m* is register instance specific (see the "MC_CGM register descriptions" section in the Clock Generation Module (MC_CGM) chapter).
7. Only PIT_0 supports the RTI feature, and exists in the Standby domain.
8. The system domain is reset on functional reset. A POR will reset it completely.
9. PMC registers are reset on a destructive reset except PMC.LVSC, which is reset only by own PMC.LVSC[PORF] flag. The LVR and POR logic is reset on an LVR or own PORF (see PMC.CONFIG and PMC.LVSC descriptions for details).
10. Reset on a functional reset; however, reset recovery occurs before the chip functional reset recovery, at the functional reset exit sequence start, for proper trim scanning and loading.
11. SXOSC is reset on a destructive reset so that the RTC operates properly across a functional reset.
12. RTC operates during a functional reset.
13. The functional reset maps to nSYSRESET to Arm Cortex-M7 and the destructive reset maps to nPORESET to Arm Cortex-M7. See the Cortex-M7 TRM for further description on part of logic on different domains within Cortex-M7.

## 30.8 System RAM retention across functional reset

System RAM retains content during functional reset through the crossbar halt handshake. The system crossbar halts during the functional reset entry sequence. Therefore, the accesses do not cause any content corruption (see Functional reset sequence for more information).

Follow this sequence for the crossbar halt handshake (see Halt handshake using the daisy-chaining method for gasket locations):

1. Send a halt request to the ELE_HSEB AXBS, DMA AXBS, and EMAC IAHB bridges in parallel.
2. Wait for a halt acknowledgement from HSE_AXBS and DMA AXBS.
3. Send a halt request to the DMA IAHB and ELE_HSEB IAHB gaskets.
4. Wait for a halt acknowledgement from all the gaskets listed in the aforementioned steps.
5. Send a halt request to the system AXBS.
6. Wait for a halt acknowledgement from the system AXBS.
7. Send a halt request to a peripheral AXBS.
8. Wait for a halt acknowledgement from a peripheral AXBS.
9. Send a halt request to the TCM IAHB and QSPI IAHB gaskets.
10. Wait for a halt acknowledgement from all the gaskets listed in the aforementioned steps.
11. Send a halt request to the AIPS0 IAHB and AIPS1 IAHB gaskets.
12. Wait for a acknowledgement from all of the gaskets listed in the aforementioned steps.
13. Send a halt request to TCM AXBS.
14. Wait for a halt acknowledgement from TCM AXBS.

After this halt sequence completes, the crossbar halt acknowledgement sequence also completes and the chip proceeds to the FUNC1 stage in the functional reset entry sequence.

**NOTE**

RAM retention is supported across the functional reset event for system RAMs only and not for ELE_HSEB or peripheral memories.

### 30.8.1 Halt handshake using the daisy-chaining method

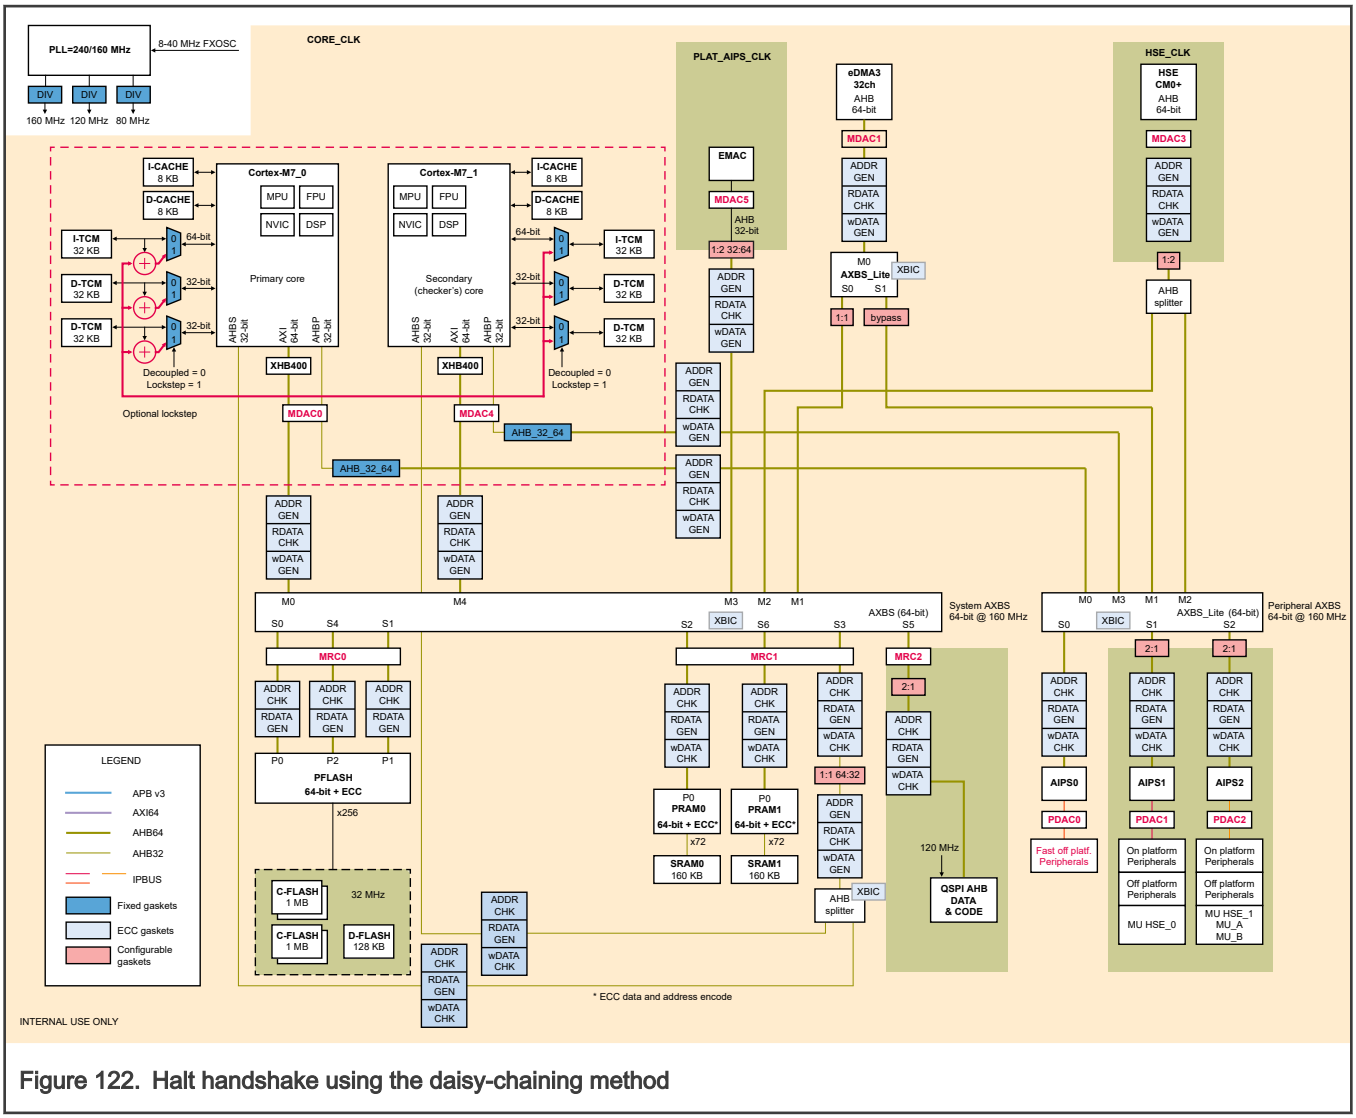

**Figure 122. Halt handshake using the daisy-chaining method**

## 30.9 Pad state during reset and after reset

SIUL2 controls the GPIO functionality. It sets to its default state on a functional reset, and ensures that every pad initializes to its default state (see the default configurations and reset states of the chip's GPIO in the IOMUX file attached to this document).

## 30.10 Reset pin

This chip contains a bidirectional reset pin (RESET_b) indicating the reset state. RESET_b multiplexes with the other functions on port PTA5 (see the IOMUX file attached to this document).

The DCF configuration controls the multiplexing capabilities of RESET_b. The default configuration of the RESET_b port is that of a dedicated reset signal (for example, not multiplexed. See the DCF clients file attached to this document for more information).

The RESET_b pin offers the following uses if you configure it for the reset functionality:

- Acts as an external destructive reset source
- Acts as an indicator for the chip reset sequence for both functional and destructive reset sequences

**NOTE**

MC_RGM.FES[F_EXR] captures an externally sourced RESET_b assertion for a destructive reset.

The RESET_b pin also indicates an internally asserted reset to external modules. It has a weak internal pullup. In normal Run mode, it keeps the chip out of reset.

### 30.10.1 Reset pin control during self-test

You can write 1 to MC_RGM.ERCTRL[ERASSERT] to assert RESET_b (writes only in Supervisor mode), before LBIST or MBIST executes. MC_RGM then asserts RESET_b and tristates the GPIO pins placing them in a safe state. Tristating GPIO ensures a safe state for the chip pins when LBIST or MBIST executes. Following BIST, the chip executes a reset sequence. The chip configures again for the application software, before executing the safety function. MC_RGM.ERCTRL[ERASSERT] clears on a functional reset. See Figure 8 for an illustration.

**NOTE**

Writing 1 to SIUL2.MSCR*n*[SMC] enables the GPIO pins and the chip continues its normal I/O functionality.

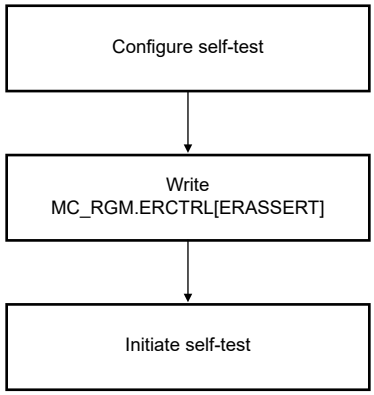

**Figure 123. Reset pin control before self-test**

Multiple chip configuration scenarios cause RESET_b to react differently after self-test completion:

- You can write 1 to MC_RGM.ERCTRL[ERASSERT] causing RESET_b to assert. This assertion does not impact the reset sequence, and the reset indicates that the chip is not available in Functional mode (although the chip is not in reset sequence).

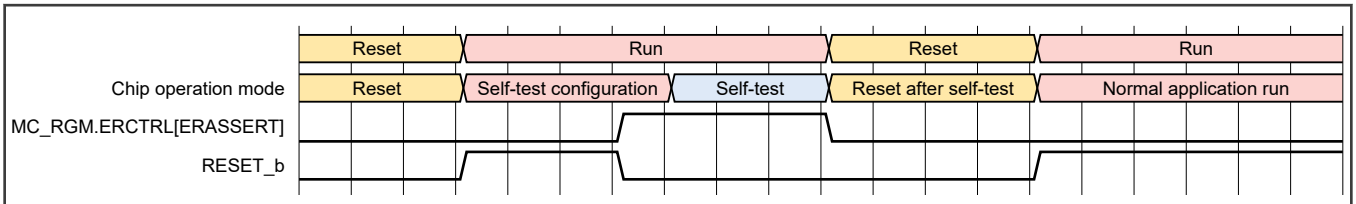

**Figure 124. Reaction when MC_RGM.ERCTRL[ERASSERT] = 1**

- If MC_RGM.ERCTRL[ERASSERT] = 0 (the default value), the RESET_b pin goes low after self-test completes. After self-test, the chip undergoes a functional reset in which the chip hardware writes 0 to MC_RGM.ERCTRL[ERASSERT]. The RESET_b pin goes high after the reset deasserts.

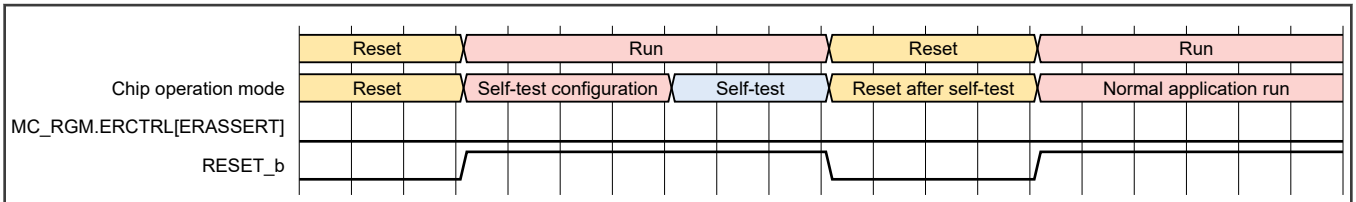

**Figure 125. Reaction when MC_RGM.ERCTRL[ERASSERT] = 0**

- If MC_RGM.ERCTRL[ERASSERT] = 0 (the default value), but you write 1 to MC_RGM.FBRE[ST_DONE], the RESET_b pin does not assert after self-test completes.

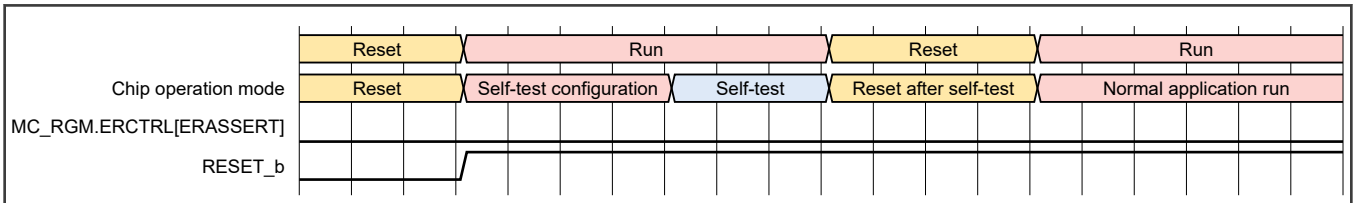

**Figure 126. Reaction when MC_RGM.ERCTRL[ERASSERT] = 0 and MC_RGM.FBRE[ST_DONE] = 1**

## 30.11 Application core debug from first instruction

The chip supports application core debug starting on the first instruction. This is supported on any functional reset and through a RESET_b pin destructive reset for debug from destructive reset.

### 30.11.1 Debug from first instruction on power-up or destructive reset onwards

1. When RESET_b is held low, the chip goes through a destructive reset sequence.
2. When you pull down the RESET_b pin, the chip goes through a destructive reset sequence, exits from the destructive reset, and remains in functional reset, until the reset pin is released.
3. When the RESET_b pin remains pulled down, the debugger configures SDA_AP.SDAAPRSTCTRL[RSTRELTLCM70] and SDA_AP.SDAAPRSTCTRL[RSTRELTLCM71] according to the requirements. To enable debug from first instruction, you write 0 to these fields. To disable, you write 1. By default, the debug disables from the first instruction.
4. On releasing the reset pin, the chip exits from the functional reset sequence and ELE_HSEB starts executing.
5. The PORESETn deassertion occurs for the application cores simultaneously (in case of lockstep, Cortex-M7_1 PORESETn deasserts after a two-cycle delay). The corresponding core clock enable gates the deassertion of SYSRESETn to cores. The SYSRESETn to the cores deasserts as follows.
6. On the basis of whether the debugger authentication is performed via challenge, response, or neither of them, you can consider these scenarios:
    a. Debugger not connected (DBG_PWRUP_REQ = 0):
        i. BAF or FW writes to the clock enable control field in MC_ME for application cores, that is, to MC_ME.PRTN0_CORE0_PCONF[CCE] for Cortex-M7_0, MC_ME.PRTN0_CORE1_PCONF[CCE] for Cortex-M7_1, or both the fields as required.
        ii. The clock enables in the subsequent clock cycle.
        iii. SYSRESETn deasserts after ten clock cycles (adding eight clock cycles of delay ensures that reset always deasserts when the clock is available; two cycle of reset deassertion delay). In case of lockstep, Cortex-M7_1 reset is delayed by two additional clock cycles.
    b. Debugger connected (DBG_PWRUP_REQ = 1):

i. BAF or FW writes to the clock enable control field in MC_ME for application cores, that is, to MC_ME.PRTN0_CORE0_PCONF[CCE] for Cortex-M7_0,MC_ME.PRTN0_CORE1_PCONF[CCE] for Cortex-M7_1 or to both the fields as required.

ii. The clock is enabled.

iii. The debugger waits for sometime (at least ten clock cycles) and then writes 1 to SDA_AP.SDAAPRSTCTRL[RSTRELTLCM70] for Cortex-M7_0 and to SDA_AP.SDAAPRSTCTRL[RSTRELTLCM71] for Cortex-M7_1 for releasing SYSRESETn of the corresponding core.

iv. SYSRESETn deasserts after ten clock cycles (adding eight clock cycles of delay ensures that the reset always deaserts when the clock is available; two cycle of RSL delay). In case of lockstep, the Cortex-M7_1 reset is delayed by two additional clock cycles.

**NOTE**

Cortex-M7_1 is not available in MCXE315/MCXE316/MCXE317/MCXE31B.

### 30.11.2 Debug from first instruction on functional reset onwards

If you enable debug, on functional reset, the debug connection is retained. That is because the complete debug infrastructure is on destructive reset domain.

### 30.11.3 Debug on standby exit by wake-up or functional reset

If you enable debug before standby entry, then the Standby domain stores the final status. The configuration for reset release is reset (SDA_AP.SDAAPRSTCTRL[RSTRELTLCM70] and SDA_AP.SDAAPRSTCTRL[RSTRELTLCM71] the reset value of both the fields is 1), which defaults to debug from the first instruction disabled.

You must configure the reset release on standby exit. It uses MC_RGM's low-power debug protocol before ungating the reset deassertion.

# Chapter 31
# Boot Overview

## 31.1 Overview

### 31.1.1 Introduction

This chapter describes the system boot sequence and provides details of boot options. The only CPU available when the hardware reset sequence completes is in the HSE subsystem hereafter referred to as HSE CPU.

The HSE CPU starts executing firmware code in HSE code flash from fixed location that contains the Secure BAF code . Secure BAF provides the boot sequence until control is passed as determined by the type of boot:

- Non-Secure boot - To customer software that executes on one or all the application cores.
- Secure boot - To the HSE FW running on HSE CPU.

## 31.2 Secure BAF features

The features of Secure BAF are as follows:

- Secure and Non-secure boot modes
- Application boot core selection
- Chip LC advancement
- Debug authorization
- XRDC configuration

## 31.3 Chip Configuration

This section describes the chip configuration details for MCXE31 variants when Secure BAF is programmed and HSE Firmware feature flag is disabled.

If HSE firmware feature flag is enabled see the HSE Firmware Reference manual.

### 31.3.1 Memory map

This section explains the memory sections used by the Secure BAF in various configurations.

#### 31.3.1.1 Memory map when HSE firmware usage feature flag is disabled

**Table 162. Memory map when HSE firmware usage feature flag is disabled**

| Memory Section | MCXE315/MCXE316 | MCXE317 | MCXE31B |
|---|---|---|---|
| Flash memory | 1 MB | 2 MB | 4 MB |
| IVT<br>Locations in Priority order | 0040_0000h,<br>0048_0000h,<br>1000_0000h | 0040_0000h,<br>0050_0000h,<br>1000_0000h | 0040_0000h,<br>0050_0000h,<br>0060_0000h,<br>0070_0000h<br>1000_0000h |

| Secure BAF UTEST flash | 1B00_0200h to 1B00_06FFh (1280 Bytes) | | |

#### 31.3.1.2 Memory map when HSE firmware usage feature flag is enabled

Following table explains the memory sections used by the Secure BAF in case HSE firmware feature flag is enabled in UTEST. Below tables are applicable for standard firmware in which HSE Firmware size is 128 KB. For custom firmware, the secure size depends on size of custom HSE Firmware. This table is provided for the information to the user that how much memory will be used by security firmware in case security feature is enabled.

Table 163. Memory map when full memory HSE firmware is installed

| Memory Section | MCXE315/MCXE316 | MCXE317 | MCXE31B |
|---|---|---|---|
| Flash memory | 1 MB | 2 MB | 4 MB |
| IVT Locations in Priority order | 0040_0000h, 0048_0000h, 1000_0000h | 0040_0000h, 0050_0000h, 1000_0000h | 0040_0000h, 0050_0000h, 0060_0000h, 0070_0000h 1000_0000h |

1. HSE firmware includes the Secure BAF in AB swap configuration

### 31.3.2 Hardware protection

Platform flash of MCXE31 has facilitated hardware protection exclusive to HSE core. BAF releases hardware protection of that area which is being used by Application as mentioned in previous section. If the hardware protection fails, for security purpose, Secure BAF issues a reset.

Below table explains default values of Hardware protection.

Table 165. Hardware protection by Secure BAF

| Register name | Register address | Secure memory | Configured value |
|---|---|---|---|
| CONFIG_RAMPR | 4039_C038h | SRAM memory | 4000_0000h |
| CONFIG_CFPRL | 4039_C03Ch | Code flash memory active block | 4000_0000h |
| CONFIG_CFPRH | 4039_C040h | Code flash memory passive block | 4000_C000h |
| CONFIG_DFPR | 4039_C044h | Data flash memory | 4002_0000h |

## 31.4 Device common configuration

### 31.4.1 Feature configuration in virgin device

Following table lists down the status of various features when device "LC = CUST_DEL". Many features are configurable directly or indirectly by application software.

| Feature | Configuration information | Status | Configurability |
|---|---|---|---|
| OTA functionality | Samples are always shipped in the OTA disabled configuration | Disabled | Yes<br>Can be enabled by application by requesting to HSE firmware or Secure BAF |
| HSE firmware usage feature flag | This flag indicates whether firmware installation allowed in the device or not. By default, this flag | Disabled | Yes |

*Table continues on the next page...*

*Table continued from the previous page...*

| Feature | Configuration information | Status | Configurability |
|---|---|---|---|
| | is unprogrammed and Secure BAF assumes that firmware installation is not allowed. | | Can be enabled by programming in the UTEST location. More details on “UTEST Flag description” section. |
| Secure BAF firmware | Samples are always shipped with Secure BAF programmed | Programmed | No |
| HSE Firmware | HSE firmware is always programmed by user/ Encrypted and signed firmware image is always<br>delivered to user. | Not programmed | Yes<br>Can be installed by the application software. |
| Image Vector Table | No IVT is programmed at any of the IVT locations. | Not programmed | Yes<br>Can be programmed by application software. |
| SWT0 | Application core watchdog SWT0 is disabled. | Disabled | Yes<br>It can be optionally enabled by BAF if SWT bit is configured in boot configuration word. |
| Boot Sequence | Boot sequence is non-secure boot<br>i.e. application are booted by Secure BAF without any authentication. | Non secure boot | Yes<br>It can be changed to secure boot by programming the BOOT_SEQ bit in IVT. |
| Life Cycle | Samples are always delivered in LC=CUST_DEL | Customer Delivery | Yes<br>It can be changed to OEM_PROD and IN_FIELD by application through Secure BAF and HSE firmware. |
| Application Core enablement status | All applications cores are in disable state. | Disabled. | Yes<br>Single or all application cores can be enabled at required address by programming the required fields in the IVT. |
| Clock Source | Fast Internal Reference clock | FIRC | Yes |

*Table continues on the next page...*

*Table continued from the previous page...*

| Feature | Configuration information | Status | Configurability |
|---|---|---|---|
| FIRC Frequency Value | 48 MHz | 48 MHz | Yes, application can configures after Secure BAF goes in WFI. |
| Application debug authorization mode | Debug Authorization mode of application cores is password based. It can be changed to challenge response mode by programming the configuration in UTEST. | Password based approach | When HSE Firmware Feature flag is disabled, debug authorization mode cannot be changed.<br>When HSE Firmware Feature flag is enabled, debug authorization mode can be changed to challenge response mode by requesting to HSE<br>firmware. |
| Application core debug status | Debug of application cores is enabled in customer delivery lifecycle. | Enabled | No |

### 31.4.2 Secure BAF memory map description

Following table explains the memory sections used by the Secure BAF.

**Table 166. Secure BAF memory**

| Memory Section | Remarks |
|---|---|
| IVT location | This is the base address of IVT. The size of IVT is always 256 byte starting from base address. IVT at one location must be programmed by the application. |
| Secure BAF boot location | Location where interrupt vector table of HSE core is present. Secure BAF on HSE CPU boots from this location. From this address 1024 bytes of interrupt vector table is present.<br>This location is protected by XRDC and it can be accessed only by HSE core. |
| Secure BAF code region | Secure BAF code area in flash. This area is protected by XRDC and it can be accessed only by HSE core. |
| UTEST flash location | 1280 Kbytes of UTEST area of flash. |

### 31.4.3 UTEST memory usage by Secure BAF

**Table 167. UTEST memory location usage by Secure BAF**

| Start address | End address | Size (bytes) | Description | Programmed by | Write protected |
|---|---|---|---|---|---|
| 1B00_0000h | 1B00_0007h | 8 | HSE Firmware Feature Usage | Application | No |

*Table continues on the next page...*

|---|---|---|---|---|---|
| | | | flag. For more detail, see UTEST flag description | | |
| 1B00_0040h | 1B00_0047h | 8 | Unique Chip Identifier (UID) 0 | NXP | No |
| 1B00_0050h | 1B00_0057h | 8 | FXOSC enablement flag<br>For more detail, UTEST flag description | Application | No |
| 1B00_0080h | 1B00_009Fh | 32 | Debug password(CUST_DB_PSWD_A).<br>When HSE FW feature Flag is disabled, this location is used by Secure BAF to run the debug authorization feature. Secure BAF copies this value in application expected response register and this value is used to derive the HSE expected response register. Size of this register is 16B and 1B00_0090h – 1B00_009h is reserved.<br>When HSE Firmware feature flag is enabled, password is programmed by HSE firmware at different location.<br>Password is scanned by DCM during Reset only. | Application | No |

*Table continues on the next page...*

Table 167. UTEST memory location usage by Secure BAF (continued)

| Start address | End address | Size (bytes) | Description | Programmed by | Write protected |
|---|---|---|---|---|---|
| | | | Password to be retained in standby. | | |
| 1B00_0220h | 1B00_022Fh | 16 | Lifecycle slot 1: CUST_DEL | NXP | Yes |
| 1B00_0230h | 1B00_023Fh | 16 | Lifecycle slot 2: OEM_PROD | Secure BAF | Yes |
| 1B00_0240h | 1B00_024Fh | 16 | Lifecycle slot 3: IN_FEILD | Secure BAF | Yes |
| 1B00_0250h | 1B00_025Fh | 16 | Lifecycle slot 4: Pre-FA | Secure BAF | Yes |
| 1B00_0260h | 1B00_026Fh | 16 | Lifecycle slot 5: FA | Secure BAF | Yes |

Detail description of each field is out of scope of this document. For details, see MCXE31_DCF_clients file attached with this document.

## 31.4.4 UTEST flag description

### 31.4.4.1 HSE firmware usage feature flag

This flag is an indication to Secure BAF that application intend to use HSE firmware on the device. By default, this flag is unprogrammed and Secure BAF assumes that HSE firmware installation is not allowed in the secure samples. But, if application decides to allow installation of HSE firmware, it can program the HSE Firmware Usage Feature flag in the UTEST at location 0x1B000000.

Description of the flag as follows:

Table 168. HSE firmware usage feature flag description

| Field type | Description | Remarks |
|---|---|---|
| Size | 64 bits | |
| Default value | 0xFFFFFFFFFFFFFFFF | |
| Default status | Disabled | Secure BAF does not allows installation of HSE firmware. |
| UTEST location | 0x1B000000 | |
| Programmed by | Application software | |
| LC in which programming is allowed | All LC | |
| Value to program to to enable HSE FW installation | Any value other than default value | Secure BAF allows installation of HSE firmware. |

Implication when this flag is not programmed by application

- Secure BAF never try to install the HSE firmware.
- Secure BAF does not protect the HSE firmware code flash area.
- The logic of debug authorization protocol is different. See Debug authorization for more details.
- Secure BAF does not protect the data flash area reserved for HSE firmware.
- Debug authorization always be password based for application cores.
- Secure BAF always boot the application without any authentication. BOOT_SEQ bit in the boot configuration word is ignored.
- Secure BAF does not authenticate the IVT and XRDC configuration table in all LC.
- Application password area in UTEST area is not read and write protected by XRDC in LC = CUST_DEL. In other LC, it is accessible only to HSE core.
- Number of region descriptors in MRC0 and MRC1 increased which can be configured by the application.
- Default configuration of XRDC and valid address range changed. For more details see XRDC configuration.

#### 31.4.4.2 Crystal oscillator configuration flag

Description of the flag as follows:

| Field type | Description |
|---|---|
| Size | 64 bits |
| Default Value | FFFF_FFFF_FFFF_FFFFh |
| Default Status | Boot via FIRC |
| UTEST Location | 1B00_0050h |
| Programmed by | Application |
| LC in which programming is allowed | All LC |

**Table 169. Crystal oscillator configuration flag in UTEST**

| | 63 | 62 | 61 | 60 | 59 | 58 | 57 | 56 | 55 | 54 | 53 | 52 | 51 | 50 | 49 | 48 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | FXOSC_ENABLE_MAGIC_NUMBER | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |
| | 47 | 46 | 45 | 44 | 43 | 42 | 41 | 40 | 39 | 38 | 37 | 36 | 35 | 34 | 33 | 32 |

| | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R | CRYSTAL_OSCILLATOR_FREQUENCY | | | | | | | | | | | | | | | |
| W | | | | | | | | | | | | | | | | |

**Table 170. Crystal oscillator configuration bit definition**

| Field | Description |
|---|---|
| 63-33 | FXOSC_ENABLE_MAGIC_NUMBER<br>AAAA_5555h – Enable<br>FFFF_FFFFh – Disable |
| 31 - 28 | GMSEL (Crystal overdrive protection):<br>For invalid values = 0x0 or 0xF, default value 0xC is used. |
| 27 - 20 | EOCV (End of count value):<br>For invalid value = 0x0, default value 9Dh is used. |
| 19 - 16 | Reserved |
| 15 - 0 | CRYSTAL_OSCILLATOR_FREQUENCY:<br>Crystal frequency in KHz. Valid Crystal frequency range is 8000 – 40000 KHz. BAF does not checks for invalid frequencies. This field is only necessary if HSE Firmware installation is required. |

## 31.5 Image Vector Table

The following section describes the various fields in Image Vector Table that is to be programmed by the application. IVT is scanned by Secure BAF after the device is out of reset. The structure is 256 bytes in size. This structure contains application start address, XRDC configuration etc. It must be programmed at least at one of the locations as mentioned in Chip Configuration

After reset, Secure BAF searches for the first valid IVT starting from the lowest address. If there are multiple valid IVT at IVT locations at the same time, the lowest address wins the priority.

**Table 171. Image Vector Table**

| Address offset | Size in bytes | Content | Comments |
|---|---|---|---|
| 00h | 4 | Image Vector Table Marker | It is a magic number which marks the starting of Image Vector Table location. Its value must be 5AA5_5AA5h |
| 04h | 4 | Boot Configuration Word | Configuration word that allows the user to select the various configuration in which device can be booted. Details are mentioned in the next section. |

*Table continues on the next page...*

Table 171. Image Vector Table (continued)

| Address offset | Size in bytes | Content | Comments |
|---|---|---|---|
| 08h | 4 | Reserved | |
| 0Ch | 4 | CM7_0<br>application<br>Start Address | Boot address of CM7_0 application in code flash area. It must honor core VTOR register alignment restrictions. This field is used by BAF when BOOT_SEQ bit is 0. |
| 10h | 4 | Reserved | |
| 14h | 4 | CM7_1<br>application<br>Start Address | Boot address of CM7_1 application in code flash area. It must honor core VTOR register alignment restrictions. This field is used by BAF only when BOOT_SEQ bit is 0.<br>This filed is ignored if Lockstep configuration is enabled.<br>Reserved for MCXE315/MCXE316/MCXE317/MCXE31B |
| 18h | 4 | Reserved | |
| 1Ch | 4 | CM7_2<br>application<br>Start Address | Boot address of CM7_2 application in code flash area. It must honor core VTOR register alignment restrictions. This field is used by BAF only when BOOT_SEQ bit is 0<br>Reserved for MCXE315/MCXE316/MCXE317/MCXE31B. |
| 20h | 4 | Reserved | |
| 24h | 4 | Address of<br>LC Configuration | Address of Configuration word that allows User to Advance LC. Details are mentioned below. |
| 28h | 216 | Reserved | |

### 31.5.1 Boot configuration word

This register informs Secure BAF to allow booting of selected applications.

Table 172. Boot configuration register

| | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| | | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| R | | | | | | | | | | | APP_SWT_INIT | RESERVED | BOOT_SEQ | CM7_2_ENABLE | CM7_1_ENABLE | CM7_0_ENABLE |
| W | | | | | | | | | | | | | | | | |

Table 173. Boot configuration register bit definition

| Field | Description |
|---|---|
| 31 – 6 | Reserved |
| 5 | APP_SWT_INIT: Control SWT0 enablement before control is passed to application core(s).<br>0 Disable<br>1 Enable<br>BAF initializes the SWT0 before enabling the application cores. BAF scans this bit only when BOOT_SEQ bit is 0. |
| 4 | RESERVED |
| 3 | BOOT_SEQ<br>Control the boot flow of the application.<br>0 Non-Secure Boot- Application image without any authentication is started by Secure BAF in parallel to HSE firmware.<br>1 Secure Boot- Application image is executed by HSE firmware after the authentication. Secure BAF only starts the HSE firmware after successful authentication.<br>(Only valid for HSE Firmware feature flag enabled) |
| 2 | CM7_2_ENABLE<br>0 Cortex-M7_2 application core clock gated after boot<br>1 Cortex-M7_2 application core clock un-gated after boot<br>Reserved for MCXE315/MCXE316/MCXE317/MCXE31B. |
| 1 | CM7_1_ENABLE<br>0 Cortex-M7_1 application core clock gated after boot<br>1 Cortex-M7_1 application core clock un-gated after boot<br>This field is ignored if Lockstep configuration is enabled. |
| 0 | CM7_0_ENABLE<br>0 Cortex-M7_0 application core clock gated after boot<br>1 Cortex-M7_0 application core clock un-gated after boot |

### 31.5.2 Address LC configuration word

This field allows User to Advance LC. To advance lifecycle User must program a valid 32 bits wide value at an address which must be given in IVT at address offset 24h. This address must be 4 bytes aligned and should not lie in Secure BAF/HSE FW protected areas.

Valid values for advancement in next lifecycles are mentioned in below table. For all other values at given address lifecycle advancement is not allowed.

**Table 174. Valid values for lifecycle advancement**

| Lifecyle | Valid values for lifecycle advancement |
|---|---|
| OEM_PROD | DADA_DADAh |
| IN_FIELD | BABA_BABAh |

Application password on the location depending on HSE FW Feature flag must be program before lifecycle advancement otherwise lifecycle advancement doesn't attempted by Secure BAF.

The SoC provides a LC mechanism for an irreversible progression of restrictions to accessing security related content on the device. The device LC cannot be reversed, so it is only possible to mature the device. Secure BAF takes on the responsibility of advancing the device through the LC:

- CUST_DEL --> OEM_PROD
- CUST_DEL and OEM_PROD --> IN_FIELD

Advancing the LC through Secure BAF involves configuring the LC configuration word in the IVT. Upon successful advancement, Secure BAF issues a Destructive reset. LC advancement is ignored if the device is found in same LC as indicated by the IVT.

### 31.5.3 Structure definition of Image Vector Table

Following structure can be used by application to configure the IVT configuration.

**NOTE**

The fields which are not valid for the specific configuration must be kept reserved. For Secure-Boot, see HSE Firmware Reference Manual.

```
typedef const struct image_vector_table
{
uint32_t Header; /*Header of IVT Structure */
uint32_t BootConfig; /*Boot Configuration Word */
const uint32_t Reserved1; /* Reserved */
const uint32_t * CM7_0_StartAddress; /*Start Address of Application on CM7_0 Core */
const uint32_t Reserved2; /* Reserved */
const uint32_t * CM7_1_StartAddress; /*Start Address of Application on CM7_1 Core */
const uint32_t Reserved3; /* Reserved */
const uint32_t * CM7_2_StartAddress; /*Start Address of Application on CM7_1 Core */
const uint32_t * Reserved4; /* Reserved */
const uint32_t * LCConfig; /*Address of LC configuration Word */
uint8_t Reserved5[216];
}ivt_t;
```

### 31.5.4 Invalid IVT scenarios

This section lists down the scenarios in which IVT is considered as invalid by Secure BAF.

1. IVT marker is not present.
2. ECC error is present in any of the 256 bytes of IVT memory.

## 31.6 Boot flow

Below diagram explains boot sequence flow of Secure BAF.

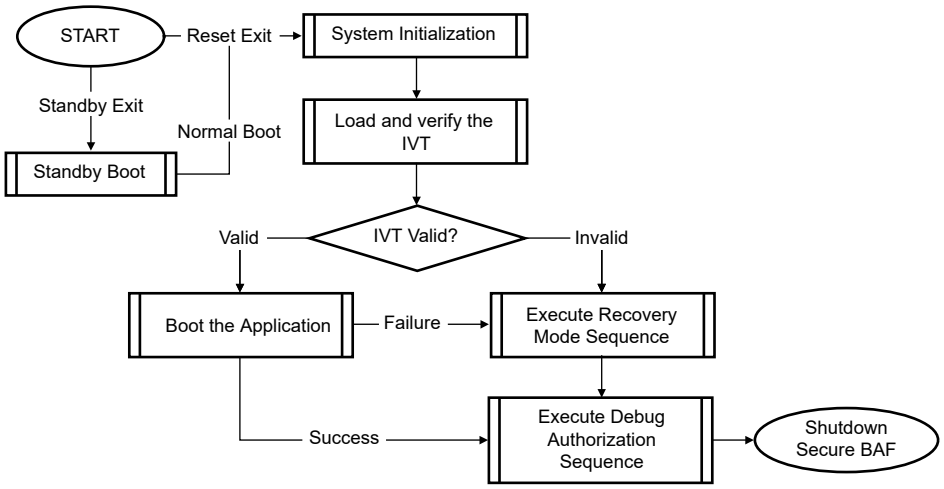

Figure 127. Boot flow

## 31.7 Standby boot

Secure BAF supports boot from Standby exit. SOC register DCMRWF5 (address 0x402AC610) provided to support boot on standby exit. This register gets clear on POR. For more details, see chapter Device Configuration Module (DCM) in MCXE31 Reference Manual.

Application is supposed to program this register before entering the standby mode.

There are two types of boot mode on exit from standby.

- Fast standby mode
- Normal boot on exit from standby

In Fast standby mode Secure BAF boots CM7_0 and halts the HSE core. The flow of standby boot is explained below:

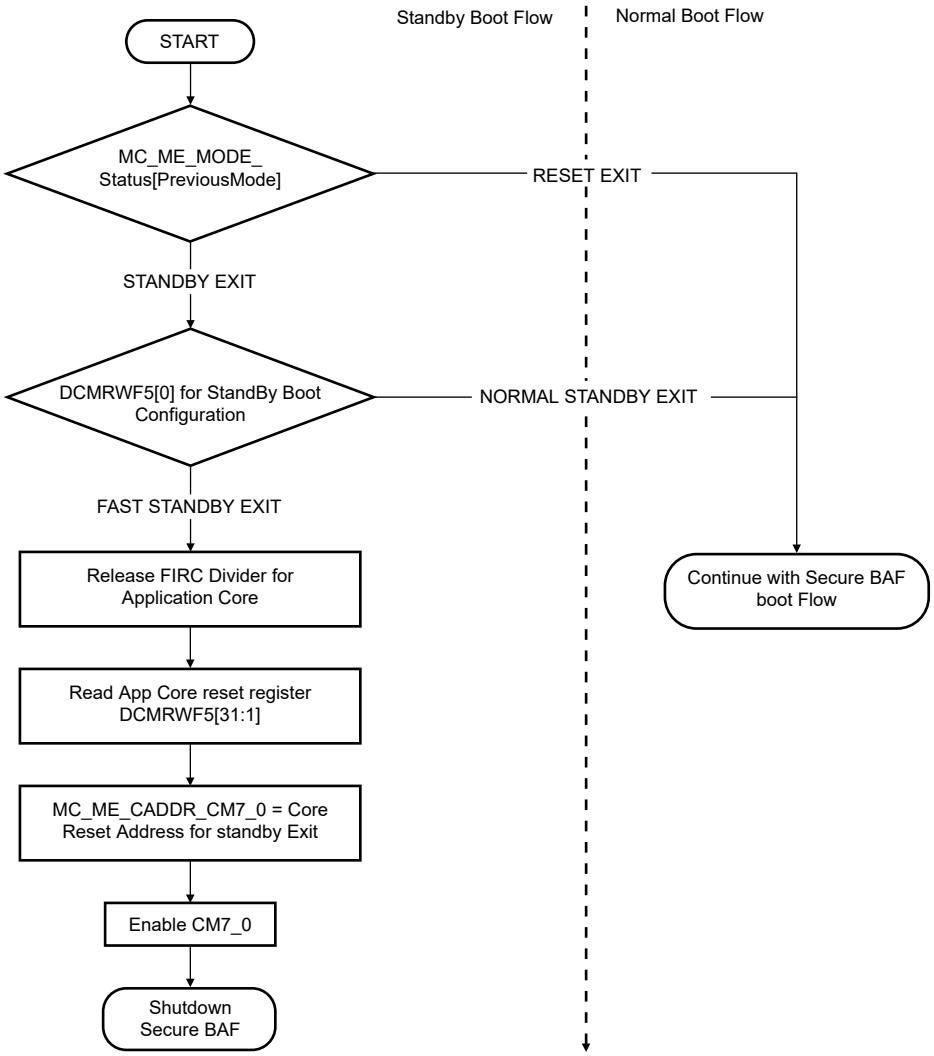

Figure 128. Standby boot flow

## 31.8 Reduced clock mode configuration

In case user wants to use clocking option B, application can enable this mode by setting “dcf_client_utest_misc” DCF record. For more details on DCF record, see the DCF sheet available with the MCXE31 Reference Manual.

After reset, Secure BAF checks for the HSE_CLK_MODE_OPTION field in DCMROF21 register in DCM. If this field is configured for clocking option B, Secure BAF configures the following dividers in MC CGM

- MUX_0_DC_1
- MUX_0_DC_2

Below figure explains steps for reduced clock mode configuration steps by Secure BAF.

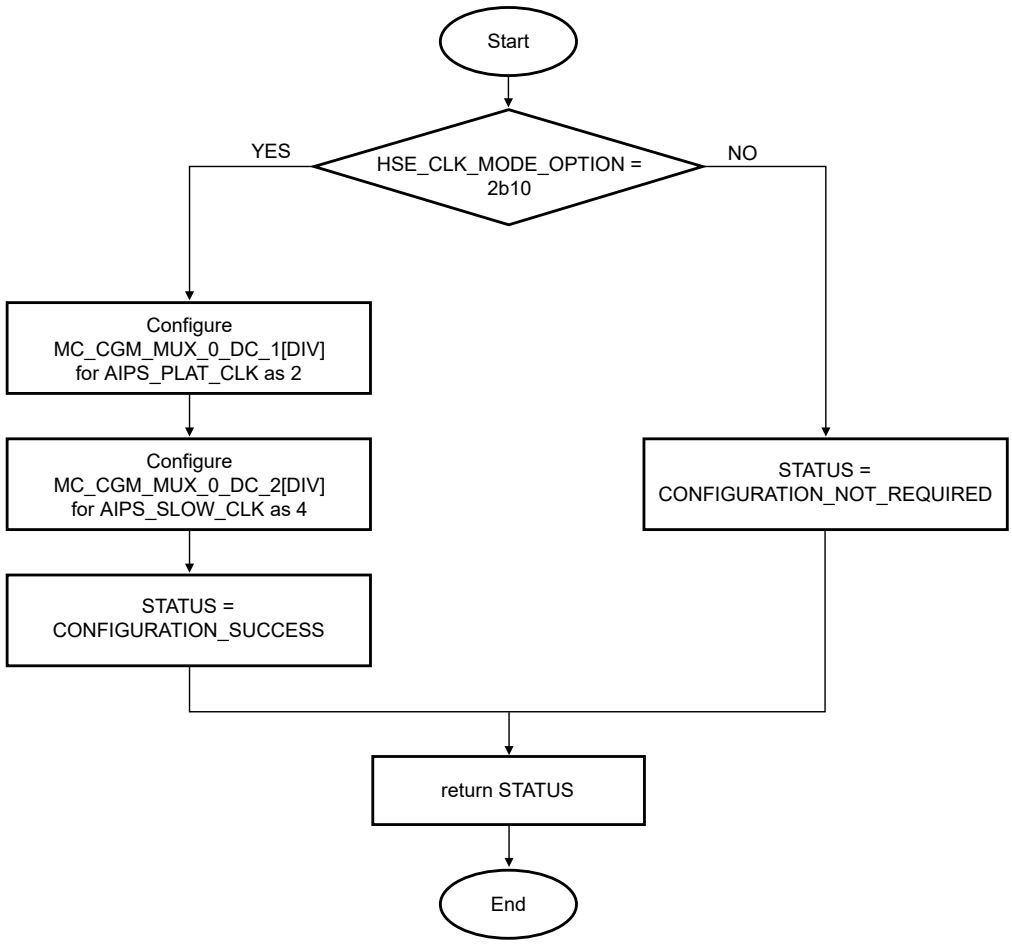

Figure 129. Reduced clock mode configuration

## 31.9 Debug authorization

If HSE firmware feature flag is disabled then application core debug is always password based. CUST_DB_PSWD_A must be programmed at location 1B00_0080h. See UTEST memory usage by Secure BAF more details.

## 31.10 FIRC divider register control

FIRC divider is controlled by Configuration HSE GPR Register (CONFIG_REG_GPR) address 0x4039C064. This HSE GPR register for FIRC divider is write protected by default and application can't modify it.

After Secure BAF executes WFI, it provides write access to FIRC divider field of this HSE GPR register and application can configure this register. Before access to this register, application should wait for Secure BAF to go in WFI by reading register PRTN0_CORE2_STAT.

## 31.11 Application boot

Secure-BAF is not responsible for booting application image in a secure way. The responsibility of booting application image in a secure way lies with HSE firmware. In case secure boot is not requested (by setting BOOT_SEQ bit in Boot configuration word in IVT structure to 0), the application image is always loaded by Secure-BAF without authentication in all LC of the device. By default, Secure-BAF releases the reset of every core which is configured to be enabled.

Following flow chart explains the steps of application boot performed by Secure-BAF when boot sequence field in boot configuration word is configured to 0.

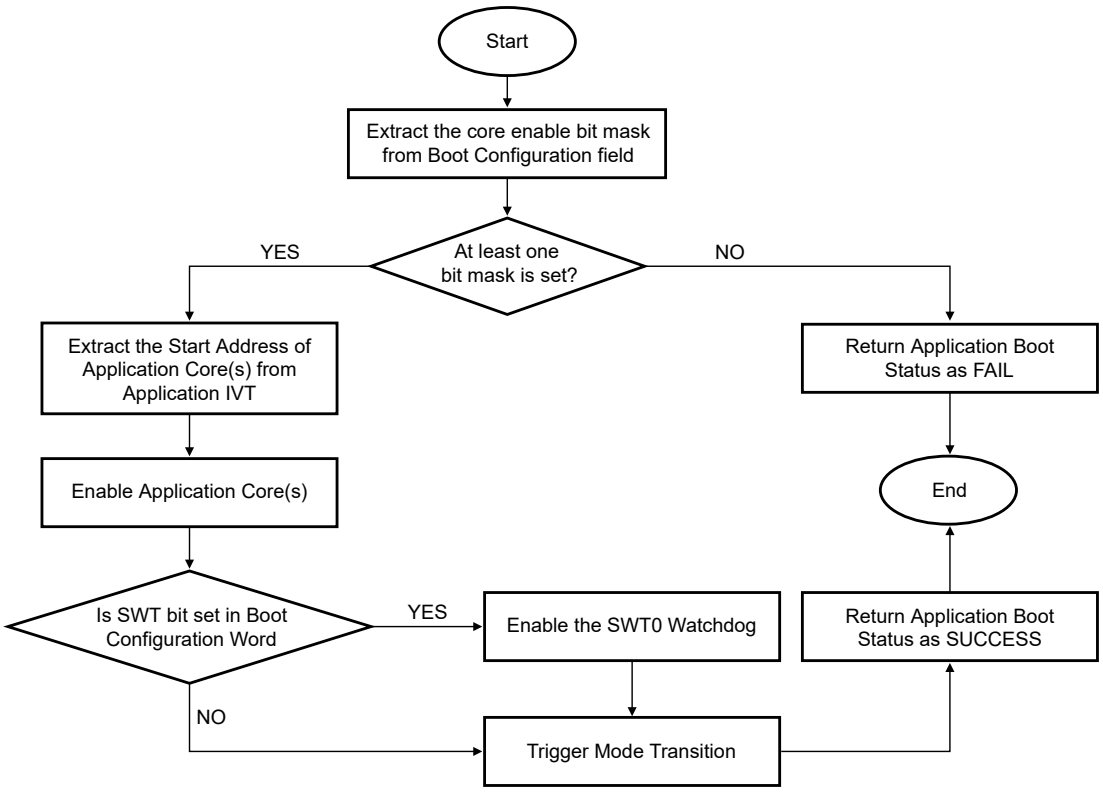

Figure 130. Application boot sequence

Before configuring HSE_CLK, application should wait for Secure BAF to go in WFI by reading register PRTN0_CORE2_STAT.

## 31.12 Recovery mode sequence

This feature is provided to allow the user to program the application image in LC = MCU_PROD and LC= CUST_DEL and debug the reason of corruption of IVT and re-program the IVT in other LC.

Below are the scenarios when Secure BAF executes recovery mode sequence.

- Valid IVT is not found.
- Application is not booted by Secure BAF.
- Application enablement bit is not programmed in Boot configuration word in IVT.
- Application issued more than eight functional reset and disable recovery mode on functional reset bit is not disabled in DCMRWP1 register.
- Application issued more than eight destructive reset and disable recovery mode on destructive reset bit is not disabled in DCMRWP1 register.

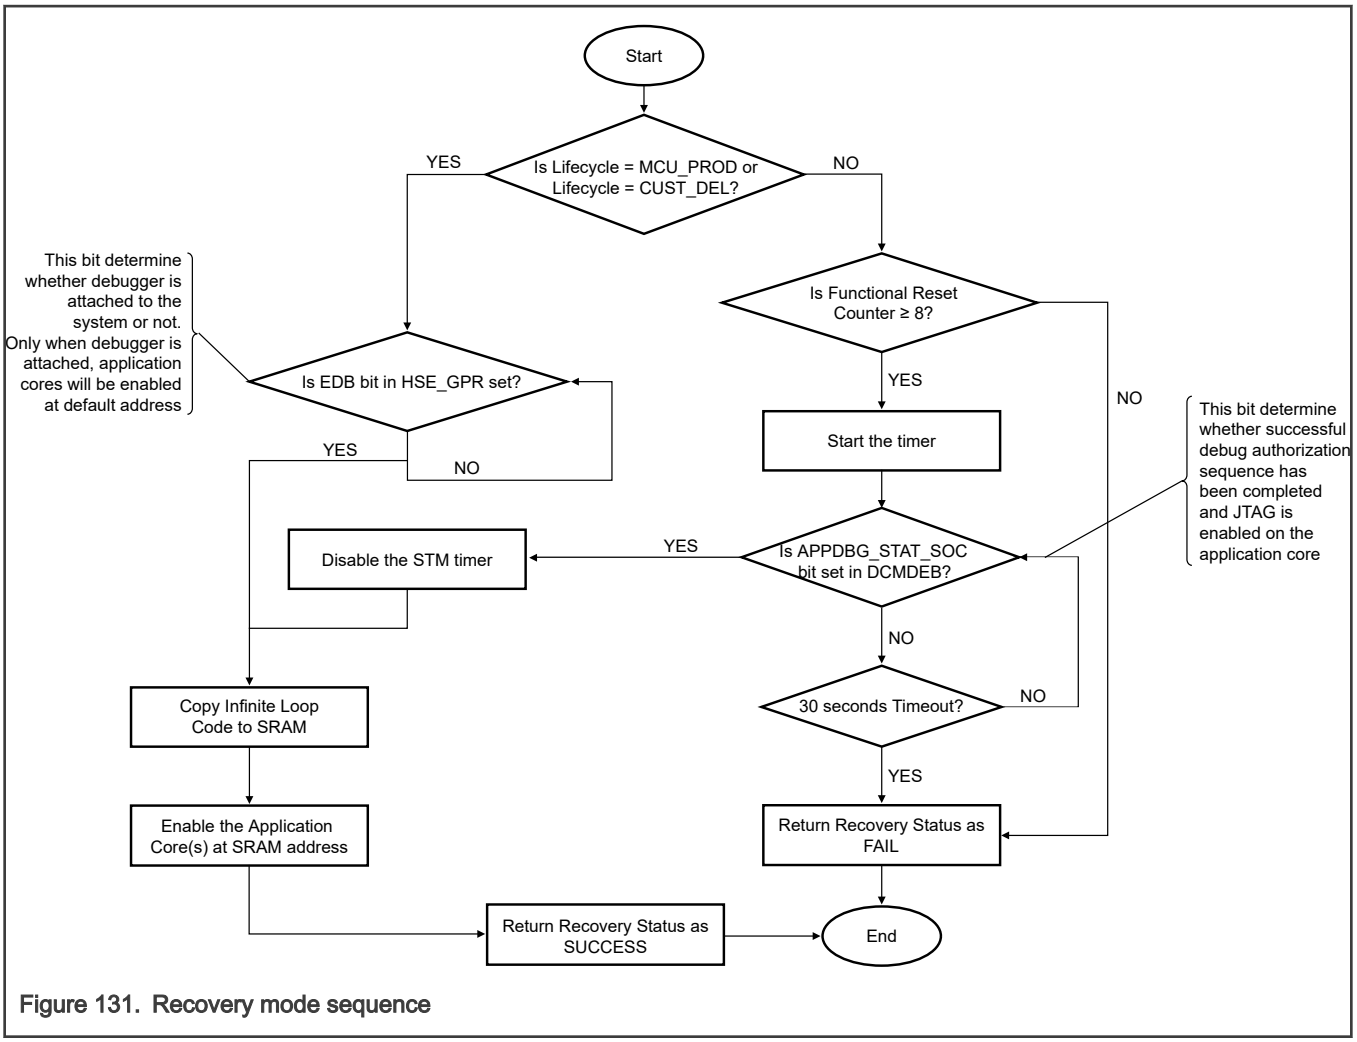

Figure 131. Recovery mode sequence

The infinite loop with WFI code is copied to SRAM1 i.e. 2040_0100h and size of code is 16B. To prevent prefetching errors in application cores, the Infinite loop instruction is placed at 2040_012Ch.

## 31.13 XRDC configuration

Secure BAF needs to ensure that is has access to its own resources and application don't have access to secure area. The following sections describe the XRDC default configuration values when HSE Firmware feature flag is disabled. In this scenario, application don't required to provide XRDC configuration via IVT and Secure BAF never enables the XRDC at any time.

When HSE Firmware Feature flag is enabled, Application can provide XRDC configuration via IVT. For this scenario, see ELE_HSEB Firmware reference manual for the details of XRDC configuration.

### 31.13.1 XRDC configuration of MDAC

Following table list down the default configuration of MDAC by Secure BAF.

Table 175. MDAC registers default value

| Device variant | MDAC Register HSE CPU | Value | Domain number assigned to HSE core |
|---|---|---|---|
| MCXE315/MCXE316/ MCXE317/MCXE31B | MDAC3 | C000_0001h | 1 |

All the other MDAC domain numbers are 0 and not locked by Secure-BAF.

### 31.13.2 XRDC configuration of MRC

Following table list down the default configuration of MRC by Secure BAF.

**Table 176. Default Configuration of MRC**

| MRC Number | Region Descriptor Number | Name | Remarks | Configuration done by Secure BAF |
|---|---|---|---|---|
| 0 | 14 | HSE UTEST area | UTEST area that is accessible by HSE core only.<br>See chip configuration chapter for Start address and End address. | W0- Start address W1= End Address W2={ SE=0,SNUM=0,<br>HSE domain =0x7[All permission] |
| 0 | 15 | Secure BAF Code area | Code area for Secure BAF. See chip configuration chapter for Start address and End address. | W0- Start address<br>W1= End Address<br>W2={ SE=0, SNUM=0,<br>HSE domain =0x7[All permission]<br>Other domains = 0x00 [No permission]<br>}<br>W3={VLD=1, LK2=0x3} |

## 31.14 BAF flash programming controls

Platform flash controller generates an exception of Read-while-Write if Read and Write are performed on the same block simultaneously. HSE core can also perform the Program and Erase for application, and the status is indicated at Configuration PE Lock Register (CONFIG_PE_LOCK) in the HSE space.

BAF locks the high addressing code flash block during its execution and it's cleared when HSE core enters into WFI. Address of high addressing code flash area should be referred to chip configuration chapter.

Before Programming/Erasing/Executing from this address space, application core is requested to poll for WFI bit of PRTN0_CORE2_STAT register to ensure HSE core is in WFI state.

For Boot Sequence 1 or flash synchronization with HSE Firmware, see HSE Firmware reference manual.

Below table explains PE lock bits setting in CONFIG_PE_LOCK register of HSE GPR during Secure BAF execution.

**Table 177. PE lock bits setting in CONFIG_PE_LOCK register of HSE GPR**

| Chip variants | UTEST Block | Data Flash Block | Code Flash Block 3 | Code Flash Block 2 | Code Flash Block 1 | Code Flash Block 0 |
|---|---|---|---|---|---|---|
| MCXE315/ MCXE316 | 1 | 0 | 0 | 0 | 0 | 1 |
| MCXE317 | 1 | 0 | 0 | 0 | 1 | 0 |
| MCXE31B | 1 | 0 | 1 | 0 | 0 | 0 |

## 31.15 Status registers for application usage

This section explain various status register configuration to provide status information to application.

### 31.15.1 Secure BAF version information

Secure BAF version is a 64-bit field. Secure BAF version can be read by application from HSE GPR register 4039_C020h. The version information is explained below.

**Table 178. Secure BAF version information**

| Bit number | Field Name | Description |
|---|---|---|
| 0 – 7 | RESERVED | Reserved, must be 0 |
| 8 - 15 | SOC_TYPE_ID | This field Identifies the SoC family<br>0 – not used<br>5 – ELE_HSEB MCXE31B<br>12 - ELE_HSEB MCXE315/MCXE316<br>13 - ELE_HSEB MCXE317 |
| 16 - 31 | FW_TYPE | This field identify the FW type:<br>0 – Standard generic FW targeting all customers<br>1-7 – Reserved<br>8 >= Custom1, Custom2 (For example: Custom1 = customer X’s project A, Custom2 = customer Y’s project B) |
| 32 - 39 | MAJOR_REV | Major version number<br>0 - EAR/BETA<br>1 - at first RTM and incremented by 1 for subsequent RTM |
| 40 - 47 | MINOR_REV | 4 – Pre-EAR<br>8 - EAR<br>9 - BETA<br>This field is reset for every new MAJOR_REV change. |
| 48 - 63 | PATCH_REV | bug fix releases (After BETA) or new feature for EAR/PRE-EAR releases. (least significant 8 bits are reserved for hotfix / frozen branch info) |

### 31.15.2 DCM Register DCMRWP1

Application can disable recovery mode entry by Secure BAF after programming bits 23 and 22 of DCM register DCMRWP1. This register gets clears on power on reset.

**Table 179. DCM register DCMRWP1 availalble at address 402A_C400h**

| Bits | Number of bits | R/W access by application | Description |
|---|---|---|---|
| 24-31 | 8 | | Reserved |

*Table continues on the next page...*

Table 179. DCM register DCMRWP1 availalble at address 402A_C400h (continued)

| Bits | Number of bits | R/W access by application | Description |
|---|---|---|---|
| 23 | 1 | R/W | Disable recovery mode on destructive reset.<br>This bit is reset by default and Secure BAF allows recovery mode sequence if Application issues >8 destructive reset. Application can set this bit to disable recovery mode when Application issues > 8<br>destructive reset. [1] |
| 22 | 1 | R/W | Disable recovery mode on functional reset.<br>This bit is reset by default and Secure BAF allows recovery mode sequence if Application issues >8 functional reset. Application can set this bit to disable recovery mode when Application issues > 8<br>functional reset. [1] |
| 21 | 1 | R | Reserved |
| 16-20 | 5 | R | Recovery mode Reset counter. For OEM_PROD and INFIELD lifecycle, to enable recovery mode functionality, Secure BAF increments this counter when Functional or destructive reset is issued. |
| 15 | 1 | R | Reserved |
| 11-14 | 4 | R | Destructive reset counter. Secure BAF increments this counter when Destructive reset is issued. |
| 0-10 | 11 | R | Reserved |

[1] Application core should not modify other bits of this register while updating these bits.

### 31.15.3 Status bits on HSE GPR register

HSE GPR register 4039_C028h is configured by Secure BAF to show various status information as explained in below table.

Table 180. Status bits on HSE GPR register available at 4039_C028h

| Bit | Description |
|---|---|
| 0 | HSE FW is present and booted by Secure BAF. |
| 1-4 | Reserved |
| 5 | Application cores booted in Recovery mode by SBAF. |
| 6 | Debug Authentication performed by SBAF. |
| 7-31 | Reserved. |

## 31.16 Interrupt and exception handling

### 31.16.1 Interrupt handling

No special interrupt handling routines are required during the boot process. Interrupts are disabled during Secure BAF execution.

### 31.16.2 Exception handling

Secure BAF enters the recovery mode after Enabling Debug Authorization.

After eight consecutive functional resets or destructive resets either from Application Firmware, the Device Enters the Recovery Mode.

### 31.16.3 Boot target watchdog

Secure BAF conditionally configures SWT0 watchdog with default timeout i.e. 25 ms, before enabling the application core(s). It is expected that the application services this watchdog before expiration.

## 31.17 Hardware modules used by Secure BAF

### 31.17.1 MC_ME

Secure BAF uses MC_ME to enable the Application cores, mode switch, and other operations during its execution. MC_ME operations supported by Secure BAF are discussed in below section.

### 31.17.2 FXOSC

Secure BAF configures FXOSC if FXOSC enablement flag is programmed in UTEST.

### 31.17.3 Clock Generation Module (MC_CGM)

Secure BAF configures MC_CGM in Reduced Clock Mode as well. See following section for the same.

### 31.17.4 DCM

Secure BAF uses the DCM to identify the Life-Cycle, Standby Boot Configuration, Lockstep, Reduced Clock Mode Configuration.

### 31.17.5 HSE_GPR

Secure BAF configures Hardware Protection, Program Erase Lock, FIRC Divider Control, Secure BAF Version number, HSE FW Handshaking via HSE-GPR.

### 31.17.6 XRDC

Secure BAF configures the XRDC Configuration. See XRDC Configuration for the same.

### 31.17.7 Flash module

Secure BAF always perform the write and erase operation on alternate interface.

See Chip Configuration for details of Flash memory usage by Secure BAF.

## 31.18 Hardware IP registers details modified by Secure BAF

Below table explains the registers details which are modified by Secure BAF when HSE Firmware Feature Flag is disabled.

Table 181. Hardware IP registers modified by Secure BAF

| IP | Register Name | Default value (hex) | Modified value (hex) |
|---|---|---|---|
| | Master Domain Assignment (MDA_W0_3_DFMT0) | 0000_0000h | C000_0002h<br>C000_0001h |
| | Memory Region Descriptor (MRGD_W0_14) | 0000_0001h | HSE Utest Start [1] |
| | Memory Region Descriptor (MRGD_W1_14) | 0000_001Fh | HSE Utest End [1] |
| | Memory Region Descriptor (MRGD_W2_14) | 0000_0000h | 0000_01C0h |
| | Memory Region Descriptor (MRGD_W3_14) | 0000_0000h | E000_0000h |
| | Memory Region Descriptor (MRGD_W0_15) | 0000_0001h | HSE Code Flash Start [1] |
| | Memory Region Descriptor (MRGD_W1_15) | 0000_001Fh | HSE code Flash End [1] |
| | Memory Region Descriptor (MRGD_W2_15) | 0000_0000h | 0000_01C0h |
| | Memory Region Descriptor (MRGD_W3_15) | 0000_0000h | E000_0000h |
| | Peripheral Domain Access Control (PDAC_W0_155) | 0000_0000h | 0000_01C0h |
| | Peripheral Domain Access Control (PDAC_W1_155) | 0000_0000h | E000_0000h |
| | Peripheral Domain Access Control (PDAC_W0_188) | 0000_0000h | 0000_01C0h |
| | Peripheral Domain Access Control (PDAC_W1_188) | 0000_0000h | E000_0000h |
| | Peripheral Domain Access Control (PDAC_W0_231) | 0000_0000h | 0000_01FFh |
| | Peripheral Domain Access Control (PDAC_W1_231) | 0000_0000h | E000_0000h |
| General purpose registers with write access by HSE core | Configuration Program and Erase Lock (CONFIG_PE_LOCK) | 0000_0000h | Protect only HSE Area [1] |
| | Configuration RAM Protected Region (CONFIG_RAMPR) | See chapter EdgeLock Secure Enclave (HSE_B) | Release Full memory [1] |
| | Configuration RAM Protected Region Alternate (CONFIG_RAMPR_ALT) | See chapter EdgeLock Secure Enclave (HSE_B) | Release Full memory [1] |
| | Configuration Code Flash Memory Active Block (CONFIG_CFPRL) | See chapter EdgeLock Secure Enclave (HSE_B) | Protect only HSE Code Flash Area [1] |
| | Configuration Code Flash Memory Active Block Alternate (CONFIG_CFPRL_ALT) | See chapter EdgeLock Secure Enclave (HSE_B) | Protect only HSE Code Flash Area [1] |

*Table continues on the next page...*

Table 181. Hardware IP registers modified by Secure BAF (continued)

| IP | Register Name | Default value (hex) | Modified value (hex) |
|---|---|---|---|
| | Configuration Code Flash Memory Passive Block (CONFIG_CFPRH) | See chapter EdgeLock Secure Enclave (HSE_B) | Protect only HSE Code Flash Area [1] |
| | Configuration Code Flash Memory Passive Block Alternate (CONFIG_CFPRH_ALT) | See chapter EdgeLock Secure Enclave (HSE_B) | Protect only HSE Code Flash Area [1] |

| | Interrupt (IR) | 0000_0000h | 0000_0001h |
| | Service (SR) | 0000_0000h | C520h and then D928h |

1. See Chip Configuration for details of HSE area addressing.

## 31.19 Appendix

Secure BAF takes into account for following scenarios to prevent bricking of device :

After Maximum Functional Resets are observed in the device, BAF enters into Recovery Mode, to recover application core's failing status.

BAF does not allows the LC to be advanced to OEM_PROD or IN_FIELD, if CUST_DBG_PSWD/ADKP is not programmed by the Application.

BAF boots the Application from System-RAM during recovery to avoid unpredictable behavior.

## 31.20 Glossary

**AES** Advanced Encryption Standard; a cipher primitive

**BAF** Boot Assist Flash

**CUST_DEL** Device Life Cycle customer delivery

# Chapter 32
# Reset Generation Module (MC_RGM)

## 32.1 Chip-specific MC_RGM information

### 32.1.1 MC_RGM configuration

The "Reset sources—POR, Destructive, and Functional" section of the "Reset Overview" chapter provides information about MC_RGM's reset sources. The chapter also provides details about the chip's reset architecture.

**NOTE**

The ERCTRL register configuration takes several cycles to be effective. Any further access to MC_RGM must happen after at least nine AIPS_SLOW_CLK cycles of writing to ERCTRL.

### 32.1.2 Functional reset entry timer implementation

The default timeout value of the functional reset entry timer is 2048 clocks of MC_RGM clock (FIRC). If the RGM entry sequence hangs, then POR_WDG would trigger and the status of this functional reset entry sequence timeout is indicated at chip-level status register. The status of timeout in such case, is indicated at DCM.DCMROPP1[28]. There is no impact to the device behavior if the functional reset entry sequence gets completed within the POR_WDG timeout window.

### 32.1.3 MCXE31 reset state machine

The reset sequence of the MCXE31 products is depicted in the figure below:

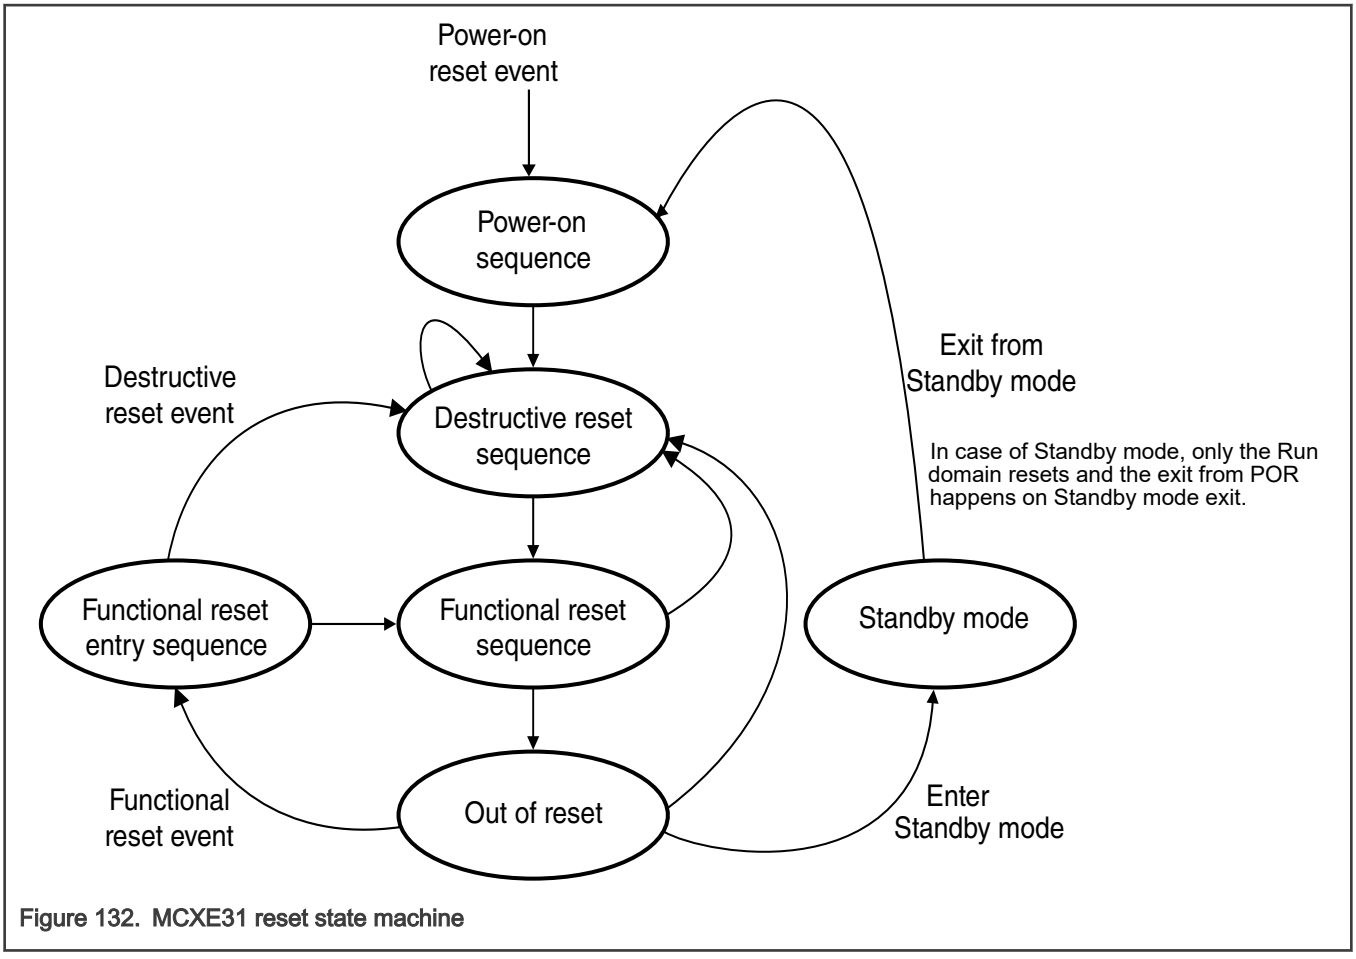

**Figure 132. MCXE31 reset state machine**

## 32.2 Introduction

The Reset Generation Module (MC_RGM) centralizes the different reset sources and manages the reset sequence of the chip. It provides a register interface and the reset sequencer. There are various registers available in this module to monitor and control the chip reset sequence.

The following figure shows the block diagram of MC_RGM.

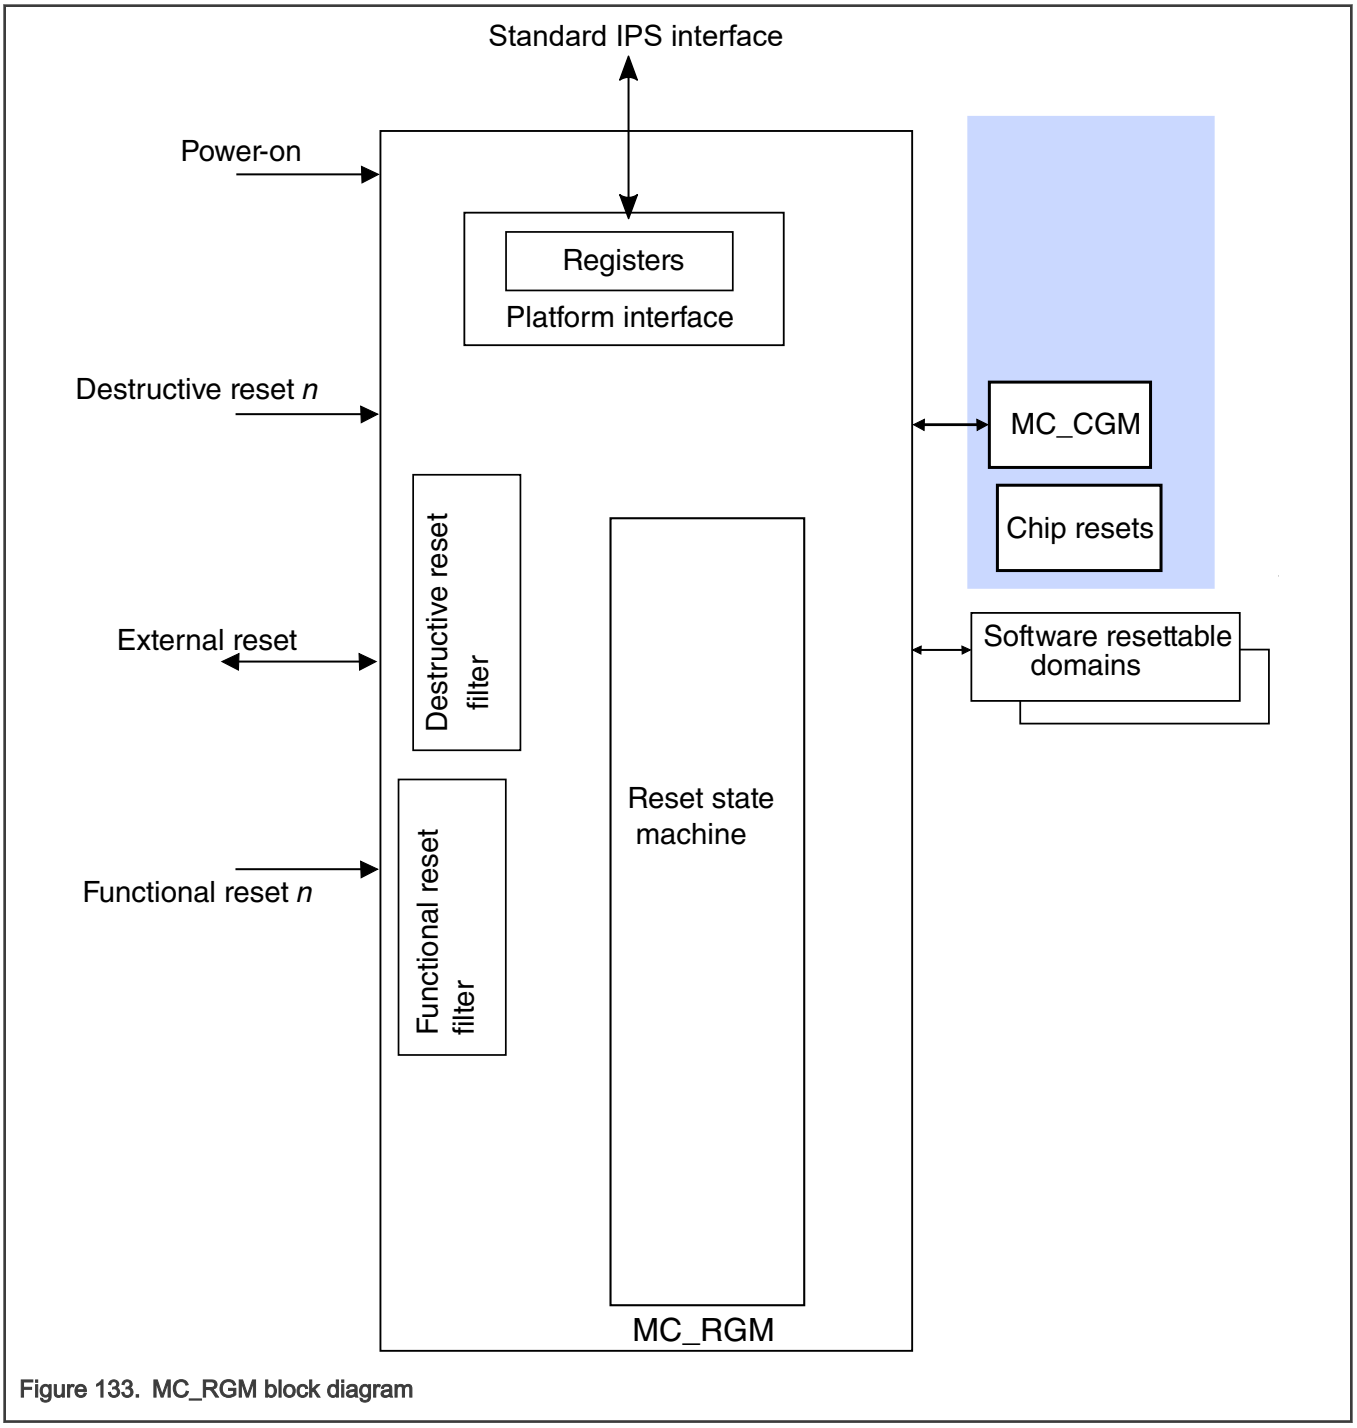

Figure 133. MC_RGM block diagram

## 32.3 Features

Here are the key features of MC_RGM:

- Destructive and functional reset management
- Capturing the reset sources for each reset sequence (reset status flags)
- Assertion the RESET_B pin to propagate the reset sequence out of chip
- Configurable escalation of recurring 'functional' resets to 'destructive' reset
- Configurable escalation of recurring 'destructive' resets to keep the chip in the reset state until the next power-on reset
- Software controllable reset assertion
- Pad safe state control generation

## 32.4 Reset sources

The reset sources are organized in three categories: power-on, destructive, and functional.

A power-on reset source is associated with an event typically related to power-up or low-voltage scenarios. When a power-on reset occurs, the full reset sequence is applied to the chip. This resets the full chip, including the MC_RGM, and the memory content must be considered to be invalid.

A destructive reset source is associated with an event related to a critical, usually hardware, error or dysfunction. When a destructive reset event occurs, the full reset sequence is applied to the chip. This resets the full chip ensuring a safe start-up state for both digital and analog modules, and the memory content must be considered to be invalid.

A functional reset source is associated with an event related to a less-critical, usually non-hardware, error or dysfunction. When a functional reset event occurs, a partial reset sequence is applied to the chip. In this case, most digital modules are reset normally, while the state of analog modules or specific digital modules as well as the system memory content is preserved.

## 32.5 External signal description

The MC_RGM interfaces with the RESET_B pin.

The following table describes the signals that are connected to the I/O pad ring.

**Table 182. MC_RGM external signals**

| Signal name | Reset value | Description |
|---|---|---|
| RESET_B | 0 | Active low external reset.<br>A bidirectional reset pin indicating the reset state. |

## 32.6 RESET_B pin assertion and pin safe state control

The MC_RGM asserts the RESET_B pin when the device is in a reset sequence, and it remains asserted until the end of the reset sequence. During this reset sequence, most of the chip's pins are safe/pad stated according to the values shown in the IOMUX table/spreadsheet. Note that the safe state values may vary according to the reset sequence type.

In addition, the MC_RGM has a feature to assert the RESET_B pin through software, without initiating a reset sequence. This is achieved by writing 1b to the ERCTRL[ERASSERT]. When this occurs, most of the chip's pins are safe-stated according to the values shown in the IOMUX table/spread sheet. The RESET_B assertion and pin safe-stating remain active until the end of the next reset sequence.

This features has to be used only with selftest of the main reset domain.

## 32.7 Functional description

### 32.7.1 Reset state machine

The main role of MC_RGM is the generation of the reset sequence that ensures that the correct parts of the chip are reset based on the reset source event.

For each reset event, immediately after it is captured by the MC_RGM, the following takes place:

1. The corresponding reset event status bit is set in the MC_RGM_DES and MC_RGM_FES registers.
2. The pins are put into their default states
3. The RESET_B pin is asserted.

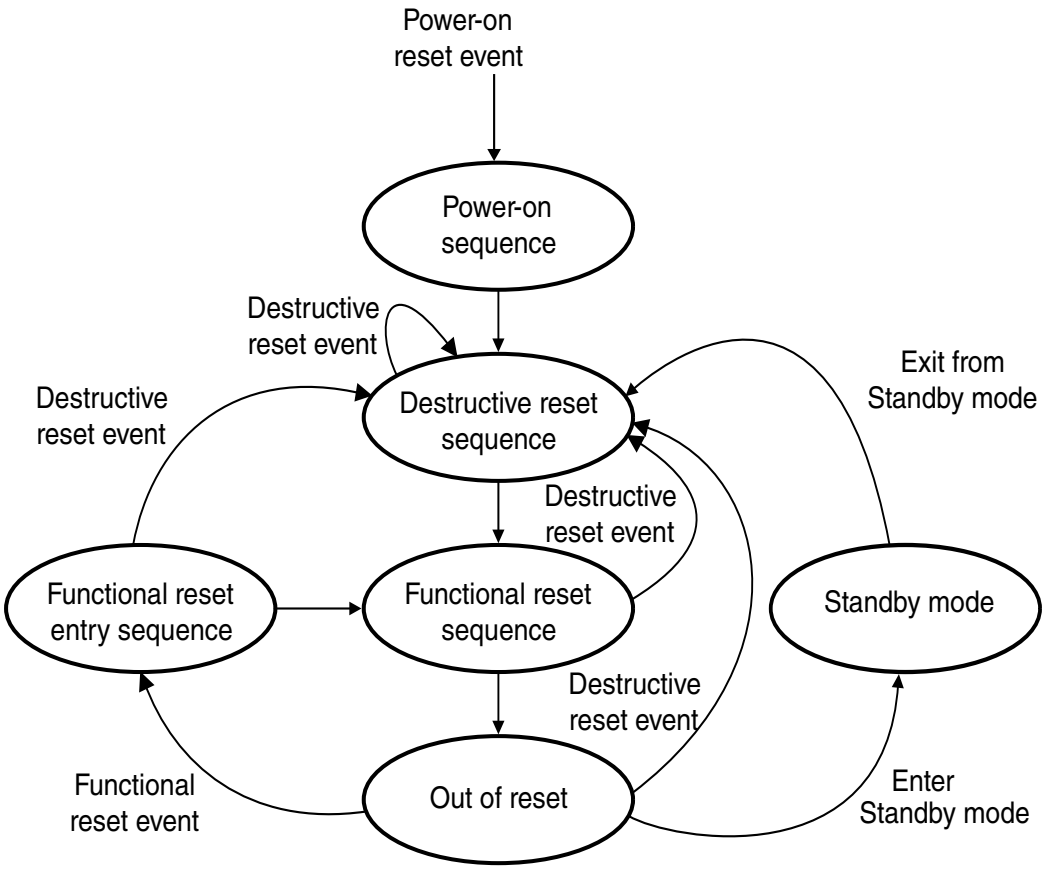

Figure 134. Reset sequence

**NOTE**

See chip-specific MC_RGM information for chip-specific reset sequence details.

#### 32.7.1.1 Power-on reset sequence

A reset is always generated when the power-on reset source is asserted, and it has priority over all other reset sources. Such a power-on reset forces the reset state machine to enter the power-on sequence resulting in the assertion of all reset signals. The reset state machine starts progressing when the following two conditions are verified:

1. All the power-on reset events are cleared
2. The MC_RGM's clock source (the FIRC) has started up and stabilized

If a power-on reset event has occurred, the DES[F_POR] bit is set.

The power-on reset cannot be demoted by the software.

#### 32.7.1.2 Destructive reset sequence

The 'Destructive reset sequence' is comprised of a number of phases, where DEST0 is the first phase and is followed by DEST1 and so forth.

This phase is entered immediately from any phase on a power-on, standby reset sequence, or enabled destructive reset event . A destructive reset counter starts immediately on entry in the DEST0 phase. The DEST0 state is exited to the DEST1 state on the rising edge of FIRC_CLK immediately after all of the following conditions have been established:

- The DEST0 duration time has expired
- All destructive reset inputs are cleared

The DEST0 state is immediately exited to the power-on state if a power-on reset event occurs.

The reset state machine exits the destructive reset sequence and enters the functional reset sequence when:

- All the destructive reset events are cleared.
- All the processes that take place during the destructive reset sequence have completed. For details, see Reset chapter.
- The 'destructive' reset escalator counter has not reached the value in DRET[DRET].

#### 32.7.1.3 Functional reset sequence

There are two functional reset sequence, the functional reset entry sequence and the functional reset exit sequence.

##### 32.7.1.3.1 Functional reset entry sequence

The functional reset entry sequence is only entered when a functional reset event occurs during the idle phase.

If a functional reset event occurs during an ongoing reset sequence, the corresponding event status flag is set, and the RESET_B pin is asserted per the reset event's configuration. However, the reset sequence is not influenced, and it continues to progress without interruption.

Functional reset is not asserted during functional reset entry sequence.

The functional reset entry sequence is exited to the DEST0 on the next rising edge of FIRC if a destructive reset event has occurred. The sequence immediately enters the power up sequence if a POR event occurs

In all other cases, the sequence exits to the first stage of functional reset exit sequence.

##### 32.7.1.3.2 Functional reset exit sequence

The functional reset exit sequence is entered either on exit from the destructive reset sequence or on completion of the functional reset entry sequence. The reset state machine exits this sequence and enters the idle phase on verification of the following:

- All the functional reset events are cleared.
- All the processes that take place during the functional reset sequence have completed. For details, see Reset chapter.

If a functional reset event occurs during an ongoing reset sequence, the corresponding event status flag is set, and the RESET_B pin is asserted per the reset event's configuration. However, the reset sequence is not influenced, and it continues to progress without interruption.

#### 32.7.1.4 Idle phase

This is the final phase and is entered on exit from the functional reset exit sequence . When this phase is reached, MC_RGM releases control of the system to the platform and waits for the new reset events that can trigger a reset sequence.

### 32.7.2 Destructive resets

A destructive reset indicates that an event has occurred after which critical register or memory content can no longer be guaranteed.

The status flag associated with a given destructive reset event (Destructive Event Status Register (DES)) is set when the destructive reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously and the software determines which reset source is the most critical for the application.

The low-voltage detector threshold ensures that when the reset corresponding to the core supply low-voltage detect is enabled, the supply is sufficient to have the destructive event correctly propagated through the digital logic. Therefore, if a given destructive reset is enabled, MC_RGM ensures that the associated reset event is correctly triggered to the full system.

An enabled destructive reset triggers a reset sequence starting from the beginning of DEST0.

### 32.7.3 External reset

MC_RGM manages the external reset coming from RESET_B. The detection of a falling edge on RESET_B starts the reset sequence from the beginning of the destructive reset entry sequence.

The status flag associated with the external reset falling edge event (the FES[F_EXR]) is set when the external reset is asserted and the power-on reset is not asserted.

### 32.7.4 Functional resets

A functional reset indicates that an event has occurred after which it can be guaranteed that critical register and memory content is still intact.

The status flag associated with a given functional reset event (Functional /External Reset Status Register (FES)) is set when the functional reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously and the software determines which reset source is the most critical for the application.

An enabled functional reset triggers a reset sequence starting from the beginning of the functional reset entry sequence.

### 32.7.5 Functional reset entry timer

The purpose of Functional Reset Entry Timer feature is to indicate any scenario wherein functional reset entry sequence does not get completed in prerequisite time .

When FRENTC[FRET_EN] is enabled, the functional reset entry timer starts from functional reset event point and gets terminated if the functional reset entry sequence is successfully completed or when it reached to the timeout value . It gets cleared on any destructive or POR reset events.

The timeout value is controlled by FRENTC[FRET_TIMEOUT]. The FRENTC[FRET_TIMEOUT] value should be greater than zero. If configured as zero, the default timeout value 200 gets used.

### 32.7.6 Alternate event generation

MC_RGM provides alternative events to be generated on reset source assertion. When a reset source is asserted, MC_RGM normally enters the reset sequence. Alternatively, it is possible for some reset source events to be converted from a reset to an interrupt request issued to the core. Alternate event selection for a given reset source is made through the RGM_FERD register as shown in the following table.

**Table 183. Functional Reset Disable Register (RGM_FERD) field descriptions**

| RGM bit FERD value | Generated event |
|---|---|
| 0 | Reset |
| 1 | Interrupt request |

The alternate event is cleared by deasserting the source of the request (that is, at the reset source that caused the alternate request) and also clearing the appropriate RGM_FES status bit.

### 32.7.7 RESET_B assertion control

The software indicates to the MC_RGM that the RESET_B is to be asserted by writing to the **ERASSERT** bit in the RGM_ERCTRL register. When this bit is set by the software, RESET_B gets asserted. Setting of this field does not impact the reset sequence in any way.

An example where the ERCTRL[ERASSERT] field could be set by the software is when entering the self test sequence, during which RESET_B is to be asserted. This indicates the chip is not available in the functional mode although a reset sequence is not in progress. The deassertion of RESET_B is not controlled by the software. Instead, the RESET_B pin remains asserted until the next time the chip exits a reset sequence.

**ERASSERT** bit is also cleared during the reset sequence.

MC_RGM asserts the external reset if the reset sequence is triggered by one of the following:

- A power-on reset
- A destructive reset event
- A functional reset event

In this case, external reset is asserted until all conditions for the exiting reset sequence have been met, with the exception of the RESET_B assertion check

### 32.7.8 Functional reset escalation

Functional reset escalation can be used to generate a destructive reset if a number of functional resets is occurred between software writes to the RGM_FRET register. This function is enabled by writing a non-zero value to the FRET field of this register.

After the functional reset escalation is enabled, MC_RGM increases a counter on each functional reset that causes a reset sequence to be initiated (which means, entrance into FUNC0 from the IDLE phase). This counter is cleared on a write of any value to the RGM_FRET register and on any power-on or destructive reset. If the counter reaches the value in the FRET field of the RGM_FRET register, MC_RGM asserts a destructive reset.

The following figure shows the functional reset escalation counter.

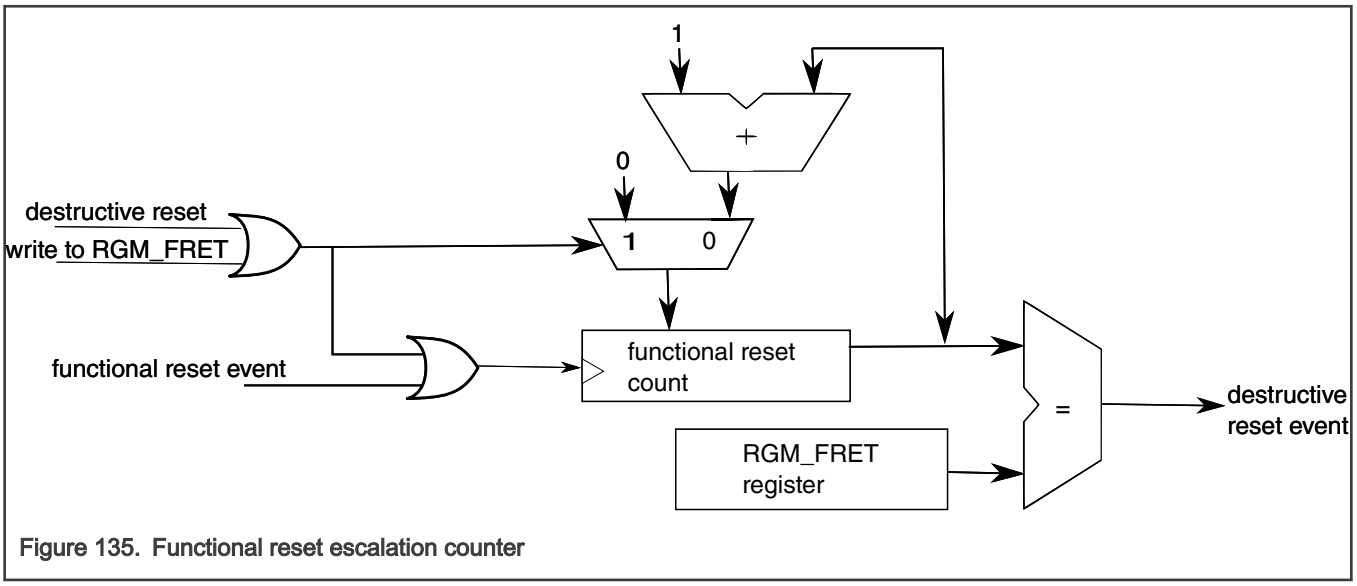

Figure 135. Functional reset escalation counter

**NOTE**

Functional counter increments for each reset source for which escalation is enabled. For details, see "Reset sources" table in the Reset chapter.

### 32.7.9 Destructive reset escalation

Destructive reset escalation can be used to keep the chip in the reset state until the power-on triggers a reset sequence if a number of destructive resets are occurred between software writes to the RGM_DRET register. This function is enabled by writing a non-zero value to the DRET field of this register.

After destructive reset escalation is enabled, MC_RGM increases a counter on each destructive reset that is enabled. . This causes a reset sequence to be initiated (that is, entrance into DEST0 from the idle phase or any other reset phase) or an ongoing reset sequence to restart (that is, entrance into DEST0 from any other reset phase). This counter is cleared on a write of any value to the RGM_DRET register and on any power-on reset. If the counter reaches the value in the DRET field of the RGM_DRET register, MC_RGM enters reset DEST0 and stays there until the next power-on reset occurs .

The following figure shows the destructive reset escalation counter.

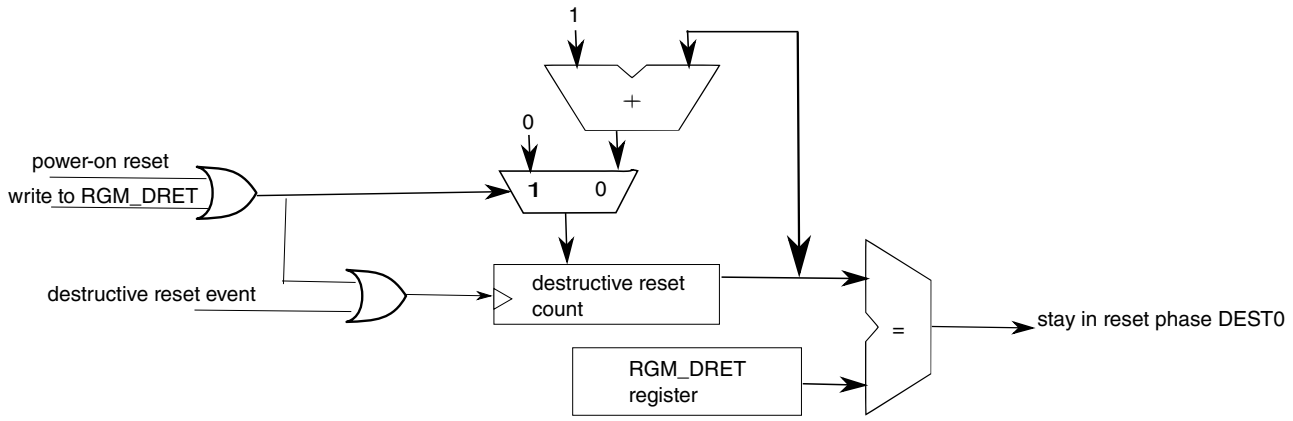

**Figure 136. Destructive reset escalation counter**

**NOTE**

Destructive counter increments for each reset source for which escalation is enabled. For details, see "Reset sources" table in the Reset chapter.

## 32.8 MC_RGM register descriptions

Access to the following locations do not generate transfer error:

- 2Ch

All registers can be accessed as read/write in supervisor mode.

### 32.8.1 MC RGM Register Map memory map

MC_RGM base address: 4028_C000h

| Offset | Register | Width (In bits) | Access | Reset value |

## 32.8.2 Destructive Event Status Register (DES)

### Offset

| Register | Offset |
|---|---|
| DES | 0h |

### Function

This register contains the status of the 'destructive' reset sources. This register can be accessed as read/write in supervisor mode and read-only in user mode. Register bits are cleared on write '1'. This register is reset only on power-on reset.

### Diagram

## 32.8.3 Functional /External Reset Status Register (FES)

### Offset

| Register | Offset |
|---|---|
| FES | 8h |

### Function

This register contains the status of the 'functional' and external reset sources. This register can be accessed as read/write in supervisor mode and read-only in user mode. Register fields are cleared on write '1' if the triggering event has already been cleared at the source. This register is reset only on power-on reset.

**NOTE**

- The startup self-test functional reset event to MC_RGM initiates a functional reset sequence after which the FES[ST_DONE] is set. This field is sticky in nature and gets cleared if software clears this field.
- If functional reset escalation to destructive reset is disabled, then the status of this register must be ignored if the fields of Destructive Event Status Register (DES) other than DES[F_POR] are set.
- If functional reset escalation to destructive reset is enabled and if the fields of Destructive Event Status Register (DES), other than DES[F_POR], are set, then based on these fields user should check if the cause of the destructive reset was due to functional reset escalation or if it was triggered directly by a destructive reset source, in which case FES needs to be ignored.
- See chip-specific MC_RGM information for applicability of the FES[ST_DONE] field.

### 32.8.4 Functional Event Reset Disable Register (FERD)

#### Offset

| Register | Offset |
|---|---|
| FERD | Ch |

#### Function

This register provides dedicated fields to disable functional reset sources. When any of these reset sources are disabled, the associated functional event is demoted to trigger an interrupt request. This register can be accessed as read/write in supervisor mode and read-only in user mode. Each byte can be written to only once after a destructive or power-on reset and this register is reset only on power-on and any destructive reset.

**NOTE**

It is important to clear the Functional /External Reset Status Register (FES) before writing 1 to any of the fields in this register. Otherwise a interrupt request may occur.

### Diagram

### 32.8.6 Functional Reset Escalation Counter Register (FREC)

**Offset**

| Register | Offset |
|---|---|
| FREC | 14h |

### Function

This register provides the current value of functional reset escalation counter. It can be accessed in read/write, in supervisor mode. It can be accessed in read in the user mode. This register is reset by power-on reset, destructive reset, when you reconfigure the FREC field to Fh and when you write any value to the Functional Reset Escalation Threshold Register (FRET) register.

### Diagram

| Bits | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 32.8.7 Functional Reset Escalation Threshold Register (FRET)

### Offset

| Register | Offset |
|---|---|
| FRET | 18h |

### Function

This register sets the threshold for 'functional' reset escalation to a 'destructive' reset. It can be accessed in read/write, either in supervisor mode. It can be accessed in read-only in the user mode. Writing a non-zero value to the FRET field enables the 'functional' reset escalation function. Writing any value to this register resets the 'functional' reset escalation counter. See Functional reset escalation for details on the 'functional' reset escalation function. This register is reset on power-on and any 'destructive' reset.

| 3-0<br>FRET | 'Functional' Reset Escalation Threshold<br>If the value of this field is 0, the 'functional' reset escalation function is disabled. Any other value is the number of 'functional' resets that causes a 'destructive' reset. |

## 32.8.8 Destructive Reset Escalation Threshold Register (DRET)

### Offset

| Register | Offset |
|---|---|
| DRET | 1Ch |

### Function

This register sets the threshold for 'destructive' reset escalation to keeping the chip in the reset state until the next power-on reset triggers a new reset sequence. It can be accessed in read/write, either in supervisor mode. It can be accessed in read-only in the user mode. Writing a non-zero value to the DRET field enables the 'destructive' reset escalation function. Writing any value to this register resets the 'destructive' reset counter. See Destructive reset escalation for details on the 'destructive' reset escalation function. This register is reset only on power-on reset.

| Field | Function |
|---|---|
| 31-4<br>— | Reserved |
| 3-0<br>DRET | 'Destructive' Reset Escalation Threshold<br>If the value of this field is 0, the 'destructive' reset escalation function is disabled. Any other value is the number of 'destructive' resets which keeps the chip in the reset state until the next power-on reset triggers a new reset sequence. |

## 32.8.9 External Reset Control Register (ERCTRL)

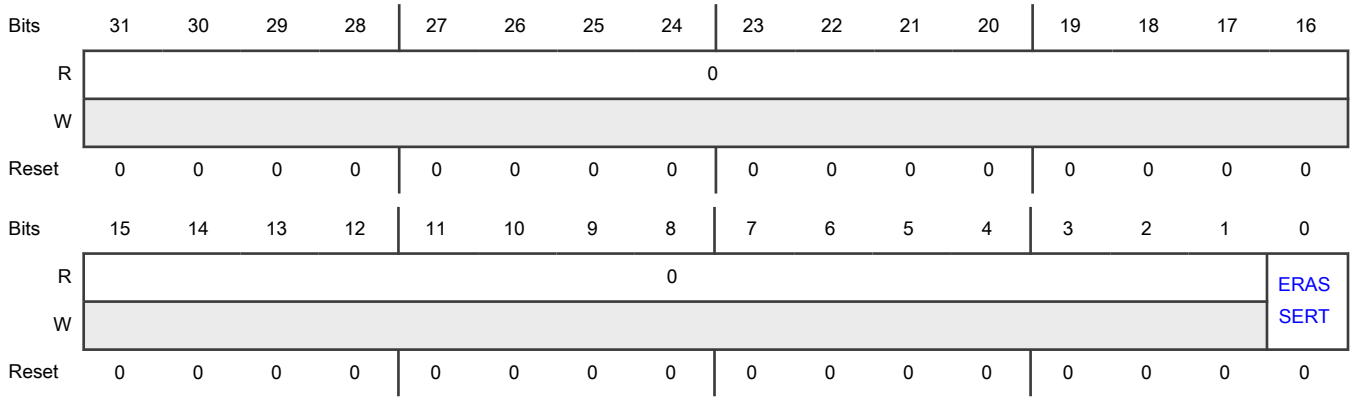
### Offset

| Register | Offset |
|---|---|
| ERCTRL | 20h |

### Function

This register allows software to control the assertion of External reset pin. It can be accessed in read/write, in supervisor mode. It can be accessed in read-only in the user mode. This register is reset on all resets.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved |
| 0<br>ERASSERT | ERASSERT<br>**NOTE**<br>Setting ERASSERT to 1b also safe/pad states most of the chip's pins. See the IOMUX table/spreadsheet for each pin's safe/pad state value. Software must use the ERASSERT field for this purpose only as part of the main reset domain self-test entry procedure. Using it at any other time may result in unpredictable system behavior.<br>0b - No change<br>1b - External reset is asserted |

## 32.8.10 Reset During Standby Status Register (RDSS)

### Offset

| Register | Offset |
|---|---|
| RDSS | 24h |

### Function

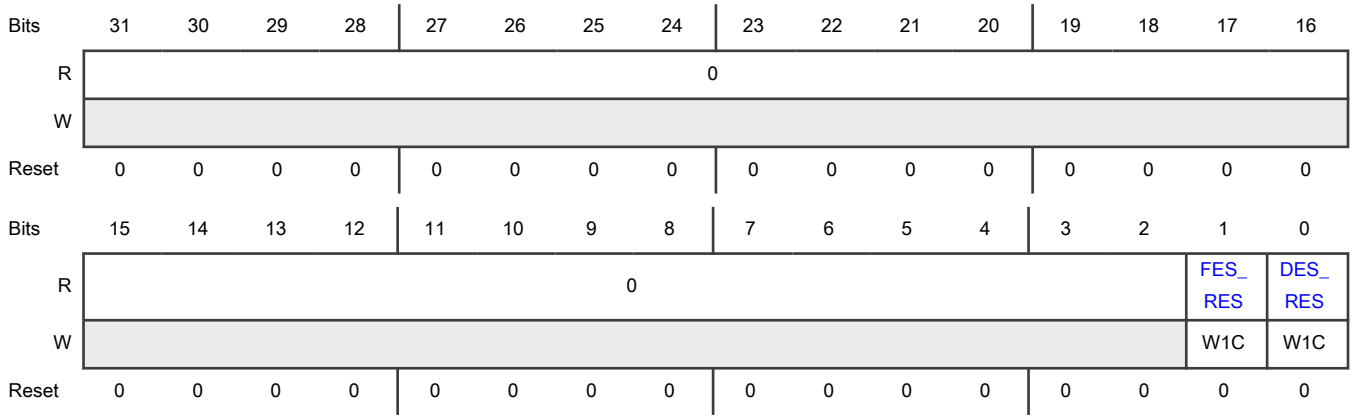
This register provides status of whether a reset event occurred during standby mode. Register bits are cleared on write '1'. This register is reset only on power-on reset.

**NOTE**

On exiting a reset sequence after standby exit, the software must perform a read operation on MC_ME[PREV_MODE] and RDSS register. If any field of the RDSS register is set, the software must ignore the status reported by MC_ME[PREV_MODE] register otherwise the status of MC_ME[PREV_MODE] register reports the device status.

If MC_ME indicates last mode as RESET, then perform a reset exit in software else a standby exit.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-2<br>— | Reserved |
| 1<br>FES_RES | FES_RES<br>0b - No functional reset event occurred during standby mode.<br>1b - Functional reset event occurred during standby mode. |
| 0<br>DES_RES | DES_RES<br>0b - No destructive reset event occurred during standby mode.<br>1b - Destructive reset event occurred during standby mode. |

## 32.8.11 Functional Reset Entry Timeout Control Register (FRENTC)

### Offset

| Register | Offset |
|---|---|
| FRENTC | 28h |

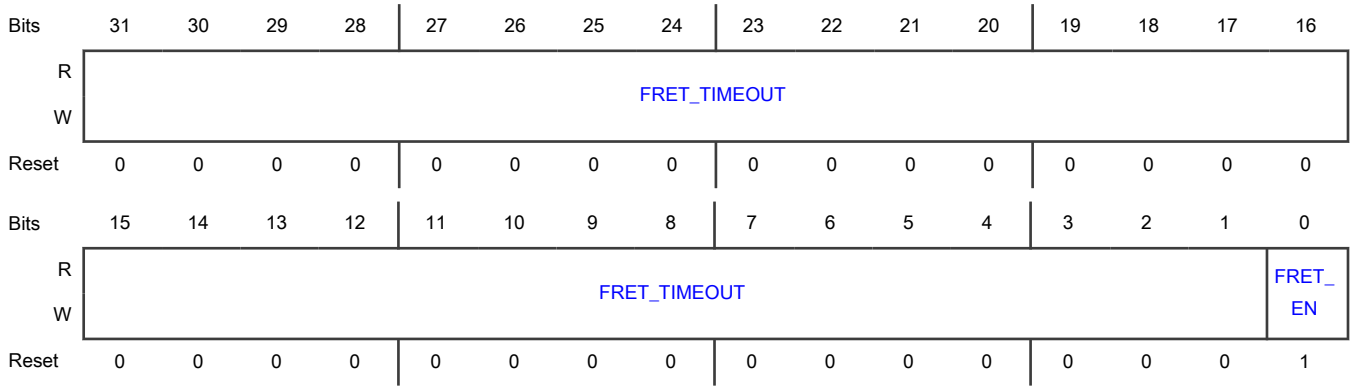
### Function

This register provides control for functional reset entry timeout counter. This register is reset on power-on and destructive reset events. This is a word accessible register. Byte accesses are not allowed on this register.

**NOTE**

This field should be set a value greater than one.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-1<br>FRET_TIMEOUT | Functional Reset Entry Timer Value<br>This field allows to override the timeout duration of the functional reset entry timer. The counter value is in terms of the Fast IRC clock cycles (typical clock frequency of 48 MHz). A non zero value of this field would indicate the timer value to be used during the functional reset entry sequence. |
| 0<br>FRET_EN | Functional Reset Entry Timer Enable/Disable<br>0b - Functional reset entry timer is disabled.<br>1b - Functional reset entry timer is enabled |

# Chapter 33
# Power-on Reset Watchdog (POR_WDG)

## 33.1 Introduction

POR_WDG monitors the chip for stuck or hang scenarios when in reset and standby sequences. It generates a chip power-on-reset event to recover the chip in case it remains stuck in reset or standby entry/exit duration for a pre-configured period of time.

POR_WDG consists of a watchdog counter with a configurable threshold. After the threshold is reached POR_WDG generates a chip power-on-reset event.

SIRC clocks POR_WDG.

## 33.2 Features

- Counter with four possible configurable threshold limits
- Associate register interfaces to capture the status of input signals
- Monitors reset, standby entry, and standby exit

## 33.3 Configurations

POR_WDG is enabled by default out of reset to actively monitor the chip reset sequence with the default timeout threshold duration. The POR_WDG configuration controls support provisions for enabling or disabling POR_WDG and the counter threshold, as described in the following sections.

### 33.3.1 Enable/disable configurations

By default POR_WDG is enabled for reset sequence monitoring, as well as standby entry/exit sequence monitoring for stuck scenarios. The following table describes the controls to enable or disable POR_WDG operation.

**Table 184. POR_WDG enable/disable control**

| POR_WDG monitoring | Default configuration | Enable/disable |
|---|---|---|
| Reset monitoring | Enabled | dcf_client_utest_misc[16]<br>Enables or disables POR_WDG for reset monitoring.<br>0: Disable<br>1: Enable<br>See the DCF clients file attached to this document for details. |
| Standby entry/exit monitoring | Disabled | DCM's DCMRWP1[8]<br>Enables or disables POR_WDG for standby entry/exit monitoring.<br>0: Enable<br>1: Disable<br>See the DCM chapter for details. |

### 33.3.2 Timeout configurations

POR_WDG supports four configurable counter threshold levels for its counter, as listed in the table below. The default POR_WDG timeout is 25 ms.

Table 185. POR_WDG timeout configuration

| DCM's DCMRWP1[10] | DCM's DCMRWP1[9] | POR_WDG timeout |
|---|---|---|
| 0 | 0 | 6.25 ms |
| 0 | 1 | 12.50 ms |
| 1 | 0 | 25.00 ms |
| 1 | 1 | 50.00 ms |

### 33.3.3 Event and status registers

POR_WDG provides indication of a POR_WDG event along with the status of the chip at the point when the POR_WDG counter overflows.

*POR_WDG event status register*: A POR_WDG event is captured in DCM status register DCMROPP4[0].

*POR_WDG status registers*: The status of the chip at the POR_WDG event is captured in DCM status registers DCMROPP1–DCMROPP3. See the DCM chapter for details.

DCM's DCMROPP*n* are reset on a POR caused by PMC and are unaffected by a POR_WDG reset.

## 33.4 Reset sequence monitoring

### 33.4.1 Introduction

At power-up POR_WDG is enabled for reset monitoring (DCF record in UTEST Misc can bypass POR_WDG, as described in Table 184).

On every reset event, POR_WDG starts monitoring the reset sequence (including the functional reset entry sequence, in case of functional reset event).

If the chip does not exit the reset sequence within the POR_WDG timeout threshold, then POR_WDG initiates a POR sequence to recover the chip from a stuck or hung scenario. You can view the POR_WDG status in DCM's DCMROPPn registers to obtain:

- Diagnostic status
- Chip details in the event of a POR_WDG reset

### 33.4.2 Inactive windows or bypass operation

POR_WDG monitoring of the reset sequence is inactive in the following conditions:

- POR_WDG is disabled for reset monitoring by chip configuration in UTEST via dcf_client_utest_misc[16]. See the DCF clients file attached to this document for details.
- MC_RGM destructive reset escalation (ensures that the chip stays in reset).
- Extend pin reset by keeping it pressed externally.
- During selftest, when MC_RGM.RGM_ERCTRL[ERASSERT] is configured as 1.

### 33.4.3 Windows of operation

POR_WDG monitors the reset sequence in the following scenarios:

- Reset pin is active (when chip is in reset, including the functional reset entry sequence).
- Standby domain functional reset is asserted (when reset pad is pulled up but functional reset is asserted).
- RUN domain destructive reset is asserted but flash memory is not in Low-Power mode (when RUN domain destructive reset fires unexpectedly in Run mode).

- RUN domain functional reset is asserted but flash memory is not in Low-Power mode (when RUN domain functional reset fires unexpectedly in RUN mode).

## 33.5 Standby entry/exit sequence monitoring

### 33.5.1 Introduction

On every low-power entry or exit event, POR_WDG starts monitoring the low-power sequence (standby entry and standby exit sequence).

If the chip does not exit the standby entry or exit sequence within the POR_WDG timeout threshold, POR_WDG initiates a POR sequence to recover the chip from the stuck or hung scenario. You can then check the POR_WDG status registers in DCM to check the chip status when POR_WDG raised the POR to the chip.

### 33.5.2 Inactive windows/bypass operation

You can configure DCM's DCMRWP1[8] to disable POR_WDG for standby entry and exit sequence monitoring.

### 33.5.3 Windows of operation

POR_WDG monitors the standby sequence (standby entry and standby exit) in these scenarios:

- Standby entry sequence monitoring: Monitoring from main core WFI execution until PMC acknowledges Low-Power mode entry.
- Standby exit sequence monitoring: Monitoring from wakeup event until the RUN domain reset recovery.

# Chapter 34
# Security Overview

## 34.1 Introduction

This chip has a comprehensive set of customer-configurable security features designed to protect code and data from unauthorized access. The content of this section is for non-secure operation only. Contact your NXP representative for details if you need secure operation.

## 34.2 Security features

MCXE31:

- Exceeds the EVITA- full [5] functionality and offers high performance for edge nodes applications.
- Bases its chip censorship on the life cycle model. Access to chip code and data becomes progressively more restricted as the chip matures through a defined set of life cycle steps.
- Offers these memory security features:
  - NVM censorship support
  - Debug password protection
  - OTP flash memory areas
- Supports a unique ID—The chip has a unique ID stored in an OTP flash memory area. Any core on the chip can read this unique ID.
- Includes ELE_HSEB, which is a dedicated security system providing:
  - A processor core
  - Dedicated SRAM
  - Symmetric Hardware Accelerator
  - Asymmetric Hardware Accelerator
  - True Random Number Generator (TRNG)
  - Pseudo Random Number Generator (PRNG)
  - Exclusive access to secure areas of the chip's flash memory
  - OTA : In Field Secure Code/Data updates

  **NOTE**

  Refer Security Reference Manual and Firmware Reference Manual for the details on OTA.

  Also, ELE_HSEB runs NXP firmware independently from the main chip processor cores and can implement advanced security and monitoring functions.
- Supports a secure debugger interface.
- Provides boot modes:

[5] EVITA was a European research project existing from 2008 to 2011. There is no standard or a specification to test compliancy. However, ELE_HSEB meets the common expectations often described in the industry as EVITA Full and exceeds them in these cases:
- ELE_HSEB supports up to AES-256 instead of AES-128
- ELE_HSEB supports up to ECC-521 instead of ECC-256
- ELE_HSEB supports SHA-2/Miyaguchi-Preneel instead of Whirlpool

  - Trusted and secure boot support
  - Handshake that supports BAF
- Monitors operating conditions to maximize tampering resistance.
- Includes basic debugger restrictions (on and off via censorship mode).

When ELE_HSEB detects a security failure, it moves the chip to a secure state. The chip secure states comply with the chip safe states. You enter a safe state as reset when there are security errors leading to reset. Moreover, if the chip stays in Run mode and the lifecycle moves to the IN_FIELD phase in reaction to errors, the safety application can continue running without glitches.

## 34.3 Security information

Chip security feature details are published in the HSE firmware reference manual and HSE service interface manual. Contact your NXP sales representative for more information.

## 34.4 Glossary

# Chapter 35
# EdgeLock Secure Enclave (HSE_B)

## 35.1 HSE subsystem

HSE is a security subsystem. It runs security functions for applications having stringent confidentiality and authenticity requirements. HSE has the following objectives:

- Isolating security-sensitive information (for example, secret keys) from the application (the host)
- Transferring the cryptographic operations from application cores and processing them
- Accelerating cryptographic operations with dedicated coprocessors
- Enforcing security measures on the application, during runtime and system startup

The HSE subsystem is the only master that is unconditionally released from reset after POR. It then releases the CPU subsystems in the host from reset, with the opportunity to apply certain checks beforehand (secure system startup). Based on certain conditions, HSE can also trigger interrupts and reset signals to the host during runtime.

### 35.1.1 CPU subsystem

The HSE CPU subsystems process the security functions and control system resources to provide security services to the application domain (the host).

### 35.1.2 Cryptographic accelerators

The HSE subsystem supports the following cryptographic accelerators:

- An AES engine supporting all standard key sizes (128, 192, 256 bits) and various complex ciphering modes (ECB, CBC, CTR, OFB, CFB, CCM, CMAC)
- A hash engine that supports standard several primitives: MD5, SHA-1, SHA-224, SHA-256
- PKC which accelerates RSA and ECC operations (key generation, signature generation, signature verification, ciphering)
  - RSA (1024, 2048, 3072, 4096-bit)
  - ECC over prime numbers
    - BN P256, P638
    - ANSI X9P192 to X9P512
    - Brainpool P160 to P512
    - Sec P128 to P521
    - TU Darmstadt prime Curve 1 to 35
    - Ed25519

The HSE subsystem supports several other cryptographic primitives through the software. See HSE firmware for more information.

### 35.1.3 Random number generator (RNG)

The RNG in this chip consists of a TRNG and a DRBG. Both are designed to be compliant to the highest strength in security as specified in

- BSI AIS20/31
- NIST SP800-90a,b,c

The TRNG function provides a seed for the DRBG, while the DRBG is available to the host via dedicated random number generation services.

### 35.1.4 Timers

The HSE subsystem features:

- An independent dedicated system timer
- HSE_STM (apart from chip timer resources), that allows recurring autonomous functions such as runtime memory verification checks
- A watchdog timer to reset the HSE subsystem in case of unexpected runtime failure

### 35.1.5 Memory resources

See Configuration_GPR memory map for more information on configuration controls related to HSE functions.

#### 35.1.5.1 Secure RAM

Secure RAM refers to RAM area that the HSE subsystem access exclusively. The HSE firmware use it to operate as well as to store a copy of the cryptographic keys in service.

#### 35.1.5.2 Secure NVM

Secure NVM refers to nonvolatile memory that the HSE subsystem accesses exclusively. It stores the HSE firmware and the security assets (for example, keys and private data).

The size of the secure NVM is configurable by the HSE firmware.

## 35.2 HSE interface

### 35.2.1 Messaging unit (MU)

The HSE subsystem has two messaging units:

- HSE_MU0
- HSE_MU1

See the "Messaging Unit (MU)" chapter for more information.

#### 35.2.1.1 Overview

MU is the communication interface between the host and the HSE subsystem. The host uses MU to trigger service requests and to receive service responses. The HSE firmware uses MU to receive service requests, return service responses, and provide a general status of the HSE subsystem.

Each of the two MU instances available in the HSE subsystem has:

- Two sides:
  - MUA: Only the HSE subsystem accesses it.
  - MUB: The host accesses it.

    The registers on one side have corresponding registers on the other side.
- A set of 32-bit readable and writable transmit registers (MUB_TRn), which the host uses to transfer the address of the service descriptor to the HSE firmware. The HSE firmware retrieves the address of the service descriptor in the corresponding registers MUA_RRn.
- A set of 32-bit read-only receive registers (MUB_RRn), which the host uses to retrieve the response to the service requests. The HSE firmware provides the response to service requests in the corresponding registers MUA_TRn.

- Control and status registers to manage MU and the access to transmit and receive registers.

The advantages of using the MU to manage the HSE service requests and responses are:

- Hardware mechanisms are in place on the transmit registers to avoid service request overrun.
- Interrupt signals are available to allow asynchronous management of the requests (avoiding active waiting loops).
- Freedom from interference between different application cores. You can configure each MU instance with specific access restrictions that can be used, for example, to isolate the requests that different masters make (in different MU instances). You configure such access controls using XRDC.

### 35.2.2 HSE interface RAM

The HSE interface RAM (also known as host interface RAM) is a secure RAM area. The host accesses it with the restrictions that HSE set via XRDC. This RAM area is a part of chip RAM and the size is configurable by secure core using CONFIG_RAMPR[SECURE_SIZE].

## 35.3 Debug

### 35.3.1 HSE subsystem debug

The debugging of the HSE subsystem and associated firmware is restricted to NXP engineering teams.

### 35.3.2 Host debug

The host debug is either open or protected, depending on the device Lifecycle state. See the ‘Life cycle’ section in ‘Device Configuration Module’ chapter for details on device lifecycle advancement and decoding. The details of the device security features is published in a separate document, the Security Reference Manual. Please contact your NXP sales representative for details. See the Debug chapter for details on host/application core debug.

The debug protection consists of locking the debugger access through the JTAG interface until the HSE firmware authenticates the debugger. This authentication is based on ADK/P, a 16-byte region within UTEST used for application core debug. See UTEST memory map in the DCF clients file attached to this document.

The authentication method can be:

- Static: In this case, ADK/P is a password which the debugger provides in plain form.
- Dynamic: In this case, ADK/P is a cryptographic key which the debugger uses to calculate a cryptographic response to a random challenge.

## 35.4 HSE firmware

Factory supplied firmware that runs in the HSE subsystem controls HSE functionality. It essentially serves the host with a set of security services as described in Table 186.

**Table 186. Summary of firmware security services**

| Service | Summary |
|---|---|
| Administration | Install, configure, update, and test the HSE firmware |
| Key management | Available for the application to manage different sets of keys that the HSE firmware manages, for example, cryptographic services |
| Cryptographic | Provide the application with cryptographic primitives that high level security stacks use in the application |
| Random number | Generate random streams that can be used in various security protocols |

*Table continues on the next page...*

**Table 186. Summary of firmware security services (continued)**

| Service | Summary |
|---|---|
| Memory verification | Allow the application to verify different memory areas at startup (after reset) and during runtime |
| Monotonic counter | Provide the application with a set of monotonic counters that can be read and only incremented |
| Secure time | Allow the configuration of a secure tick to be signaled to the application |

Table 187 provides an overview of services and features that the HSE firmware supports.

**Table 187. HSE firmware features**

| Service | Category | Feature |
|---|---|---|
| Cryptography | Ciphers | AES: ECB, CBC, CFB, OFB, CTR, XTS[1]<br>RSAES: PKCS1-v1_5, OAEP |
| | Message Authentication Code (MAC) | AES: CMAC, XCBC-MAC[1], HMAC[1], and GMAC[1] |

## 35.5 General purpose registers with write access by HSE core

This is a general purpose register bank that only the HSE core can write. Secure master ID gating allows only the secure core to write in these registers, whereas any application core can read.

## 35.6 Configuration_GPR register descriptions

### 35.6.1 Configuration_GPR memory map

This section describes the chip configurations that only the HSE core manages. These constitute control of peripherals, secure size configurations for SRAM and flash memory, flash memory program or erase control, and so on.

**NOTE**

Write accesses to configuration registers apart from 32-bit accesses might result in unpredictable chip behavior, therefore must not be done.

Configuration base address: 4039_C000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 1Ch | General Purpose Configuration 0 (CONFIG_REG0) | 32 | R | 0000_0000h |
| 34h | General Purpose Configuration 6 (CONFIG_REG6) | 32 | R | 0000_0035h |

| **XCBC-MAC** | Extended ciphertext block chaining MAC |
| **XTS** | XEX (XOR encrypt XOR) based tweaked-codebook mode with ciphertext stealing |

# Chapter 36
# Device Configuration Format (DCF) records

## 36.1 Introduction

DCF configures certain registers of this chip during system boot while the reset signal asserts. An individual DCF record points to an internal register in the chip and the data to be written to that register.

UTEST DCF—The UTEST DCF clients are present within the UTEST region of the flash and programmed during production testing. You may write the other records and program them at the same time the application code is programmed in the flash memory. See the DCF client file attached to this document for the description on the UTEST DCF records.

System boot is a complex process that requires you to initialize the chip properly before releasing reset. Before using the chip, you must write the user application code and the DCF records into their respective flash memory.

After power is supplied to an appropriately configured chip, PMC controls the chip, and after the system power supplies reach predefined levels, PMC signals MC_RCM to start the boot sequence. During this sequence, MC_RGM enables DCM to read the chip configuration records and then write the configuration information to the specified registers.

## 36.2 DCF clients

These are 32-bit wide hardware registers inside a module that receive and store data from a DCF record. This stored data is used to initialize registers and configure features.

DCF clients:

- Are assigned a default value before any DCF records are written.
- May have special writing constraints, such as:
  - Write once.
  - Change from 1 to 0 only.
  - Change from 0 to 1 only.
- May not implement all 32 bits.

### 36.2.1 Safety features of DCF clients

Depending on the DCF client's role in the chip, the client may be equipped with a safety feature or a combination of these features.

#### 36.2.1.1 Parity

If a DCF client implements parity checking, the client receives a parity bit in addition to its data in the DCF record. During chip operation, the client continuously monitors whether the data it stores matches the parity. It also reports errors to DCM in case of discrepancies.

#### 36.2.1.2 Triple voting

DCF clients that use triple voting have three copies of the register. DCM writes to all the three registers in a single write cycle. During chip operation, the DCF client continuously monitors whether all these three copies match. In case of discrepancies, the client reports errors to DCM. The chip uses the majority result, so single errors do not affect the chip's operation.

#### 36.2.1.3 Spreaded triple voting

DCF clients that use spreaded triple voting have three copies of the register that are individually addressed and where the data is stored in three different formats. DCM fetches these records independently. During chip operation, the DCF client continuously monitors whether all the three copies can be resolved from the stored format to the value. In case of discrepancies, the client reports errors to DCM. The chip uses the majority result, so single errors do not affect the chip's operation.

#### 36.2.1.4 Second write check

This feature is used by DCF clients that receive their records twice—for example, once before and once after BIST for clients that retain their value during self-test. The DCF client monitors whether the second write matches the first and reports deviations to DCM.

### 36.2.2 DCF client modification rules

Depending on its role in the chip, a DCF client may implement one or a combination of modification rules. If a modification rule is in effect, the order in which DCF records are placed in the record list may be important.

#### 36.2.2.1 Write once

A DCF client using the write once rule can only be written with a single DCF record. The records that are appended later in the list are ignored and do not change the value of the client.

#### 36.2.2.2 Write 0 only

A field in a DCF client can only be changed from 1 to 0. Therefore, if the value of a field in the previous DCF record is 0, an attempt by a later record to write 1 to it is ignored.

#### 36.2.2.3 Write 1 only

A field in a DCF client can only be changed from 0 to 1. Therefore, if the value of a field in the previous DCF record is 1, an attempt by a later record to write 0 to the field is ignored.

## 36.3 DCF record structure

A DCF record is a double-word (64-bit) entry that consists of the following:

- Control word—This provides information to locate the corresponding DCF client internal to the chip (pointer to the location of a register internal to the chip).
- Data word—This contains the data to be written to the DCF client.

DCF records select the target DCF client using a 30-bit field in the DCF record that consists of a 15-bit chip select field and a 15-bit address field. All modules that include DCF clients are assigned a chip select during chip definition. The address field is only relevant for address decoding within that module and may not necessarily relate to the address of a register that is visible to you.

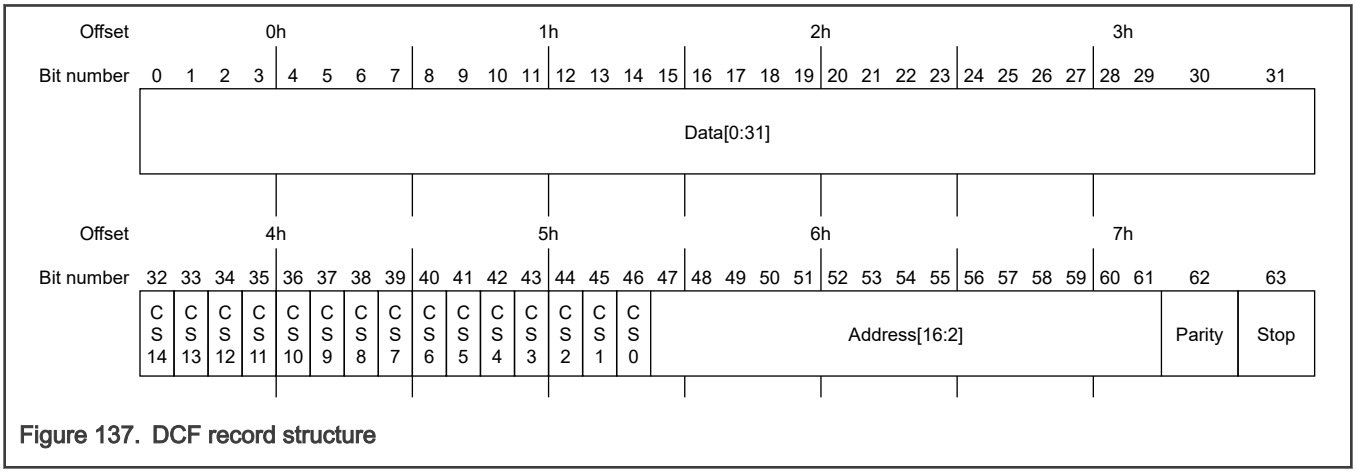

Figure 137. DCF record structure

Table 189. DCF record field descriptions

| Field | Name | Description |
|---|---|---|
| 0-31 | Data[0:31] | Provides the data that is to be written to the DCF client. |
| 32-46 | CS*n* | Indicates chip select *n*.<br>The value 1 is written to a chip select per DCF record to select the target module for the DCF client. The value 0 must be written to all other chip selects. |
| 47-61 | Address[16:2] | Contains the address of the DCF client within the selected module.<br>Address decoding for DCF clients may not match the standard software address map decoding. For details, see the DCF client addresses provided with each module. |
| 62 | Parity | Indicates parity for the DCF record. |
| 63 | Stop | Indicates the end of the list for DCF records.<br>0 – Not the end<br>1 – End<br>The erased state of flash memory is FFFF_FFFF_FFFF_FFFFh. Therefore, the list ends with the first unprogrammed double word.<br>This location can be programmed with a new record to extend the list. |

## 36.4 DCF records sequence

An individual DCF record contains information to locate the corresponding DCF client internal to the chip (control word) and the data to be written to that client (data word).

DCF records appear as contiguous series of entries programmed at a specific address within flash memory, and must present the following pattern:

- The first DCF record must be a start record. This record must be placed at the beginning of a DCF area in flash memory to indicate to the chip that the specified records must be processed.
- DCF records containing configuration data must immediately follow the start record with no blank records in between. An unprogrammed record is interpreted as a stop record and no DCF records following that are processed. This allows you to program the records in several sessions, appending new records at the end of the list each time.
- The presence of a stop record indicates the end of configuration records. It is not recommended to set valid UTEST DCF record programmed during production because that prevents appending additional UTEST records. The flash memory location following the last UTEST DCF record programmed at the factory is an unprogrammed location, which has FFFF_FFFFh as its content. Thus, the stop bit location in this unprogrammed flash memory location is logic 1, signifying that this is the last DCF record and it is not to be acted upon.

Table 190 shows the record that DCM recognizes as a start record.

Table 190. DCF start record

| 0h (0:31) | 4h (32:63) |
|---|---|
| 05AA_55AFh | 0000_0000h |

The factory sets the start bit at the beginning of the UTEST flash memory area.

Table 191 shows the record that DCM recognizes as a stop record.

**Table 191. DCF stop record**

| 0:31 | 32:62 | 63 |
|---|---|---|
| Ignored | Ignored | 1 |

The DCF records that you supply may be added in a contiguous manner immediately following the factory-written DCF records. You must never have an unprogrammed record in the series of DCF records because that is interpreted as a stop record.

Table 192 shows the series of DCF records when *n* data records are stored in the UTEST flash memory.

**Table 192. Series of DCF records in UTEST flash memory**

| Record type | Address offset | Data | | | |
|---|---|---|---|---|---|
| Start | 0h | 05AA_55AFh | | | |
| | 4h | 0000_0000h | | | STOP = 0 |
| Data | 8h | WDATA[31:0] | | | |
| | Ch | CS[14:0] | ADDR[16:2] | Parity | STOP = 0 |
| | 10h | WDATA[31:0] | | | |
| | 14h | CS[14:0] | ADDR[16:2] | Parity | STOP = 0 |
| | ... | ... | | | |
| Stop | 8(*n*-1) + 0h | Reserved | | | |
| | 8(*n*-1) + 4h | Reserved | | | 1 |
| | 8*n* + 0h | | | | |
| | 8*n* + 4h | | | | |

More than one DCF records can write to the same DCF client. In this case, the later record usually overrides a DCF client value defined by a previous record. However, not all DCF clients allow overwrites; this depends on individual implementation of DCF clients.

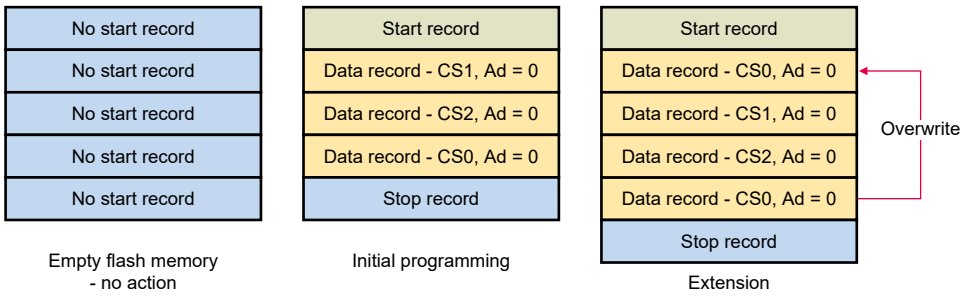

**Figure 138. Appending DCF records**

## 36.5 Chip configuration records

The DCF clients table contains information on DCF clients available in the chip. See the DCF clients file attached to this document.

The next table shows an example of how the information in this chapter is integrated with the attached DCF file.

**Table 193. Integration of DCF information**

| Type | Data(n) assuming Quad page program | Data | Comment |
|---|---|---|---|
| UTEST DCF start record | Data0 | 05AA_55AFh | — |
| | Data1 | 0000_0000h | — |
| Reset pad dedicated control DCF client | Data0 | 0000_0001h | Data to enable pad as dedicated reset pad |
| | Data1 | 00_10_0008h | Chip Select is 3 and address is 8, 0010_0000h+ 8h |

## 36.6 Glossary

**BIST** Built-in self-test

**OTP** One time programmable

**UTEST** User test. Refers to UTEST region of the flash.

# Chapter 37
# Device Configuration Module General-Purpose Registers (DCM_GPR)

## 37.1 DCM controlled features and availability in product family

Based on the chip features described in ‘Feature comparison’ section in ‘Introduction’ chapter, there are some features which are present only in specific parts in the MCXE31xx product family. The following table summarizes the corresponding DCM register fields along with the parts wherein the corresponding register fields are available. In rest of the parts within the product family, the corresponding fields are reserved.

**Table 194. DCM controlled features and availability in product family**

| Register field | Register field abbreviation | Register field description | Parts wherein this field is available |
|---|---|---|---|
| DCMROD3[5] | TCM_GSKT_ALARM | See Register section for details | MCXE31B, MCXE317, MCXE315/MCXE316 |
| DCMROD3[6] | DMA_SYS_GSKT_ALARM | See Register section for details | MCXE31B |
| DCMROD3[7] | DMA_PERIPH_GSKT_ALARM | See Register section for details | MCXE31B |
| DCMROD3[9] | DMA_AXBS_ALARM | See Register section for details | MCXE31B |

Table 194. DCM controlled features and availability in product family (continued)

| Register field | Register field abbreviation | Register field description | Parts wherein this field is available |
|---|---|---|---|
| DCMRWF1[7] | MAC_CONF_SEL | See Register section for details | MCXE31B |
| DCMRWF1[15] | VDD_HV_B_IO_CTRL_LATCH | See Register section for details | MCXE31B |
| DCMRWF1[26] | VDD_HV_B_VLT_DVDR_EN | See Register section for details | MCXE31B |
| DCMRWF1[27] | VDD_1_5_VLT_DVDR_EN | See Register section for details | MCXE31B |
| DCMRWF4[0] | MUX_MODE_EN_ADC1_S18 | Controls the selection of GPIOs to drive ADC1 standard channel 18th. | MCXE315/MCXE316 |
| DCMRWF4[5] | MUX_MODE_EN_ADC1_S22 | See Register section for details | MCXE31B, MCXE317 |
| DCMRWF4[6] | MUX_MODE_EN_ADC1_S23 | See Register section for details | MCXE31B, MCXE317 |
| DCMRWF4[7] | MUX_MODE_EN_ADC0_S12 | Controls the selection of GPIOs to drive ADC_0 standard channel 12. | MCXE315/MCXE316 |
| DCMRWF4[8] | MUX_MODE_EN_ADC0_S13 | Controls the selection of GPIOs to drive ADC_0 standard channel 13. | MCXE315/MCXE316 |
| DCMRWF4[9] | MUX_MODE_EN_ADC2_S8 | See Register section for details | MCXE31B |
| DCMRWF4[10] | MUX_MODE_EN_ADC2_S9 | See Register section for details | MCXE31B |
| DCMRWF4[11] | MUX_MODE_EN_ADC0_S14 | Controls the selection of GPIOs to drive ADC_0 standard channel 14. | MCXE315/MCXE316 |
| DCMRWF4[12] | MUX_MODE_EN_ADC0_S17 | Controls the selection of GPIOs to drive ADC_0 standard channel 17. | MCXE315/MCXE316 |
| DCMRWF4[28] | MUX_MODE_EN_ADC0_P2 | Controls the selection of GPIOs to drive ADC0 precision channel 2nd. | MCXE315/MCXE316 |

## 37.2 DCM_GPR register descriptions

**NOTE**

Do not write to the reserved locations, registers, or reserved bits in the registers. Chip behavior is not guaranteed in case of such writes.

**NOTE**

The MC_RGM_ERCTRL register configuration takes several cycles to be effective. Any further access to DCM should be made after at least 9 AIPS_SLOW_CLK cycles after writing to MC_RGM_ERCTRL

**NOTE**

The DCM Read Write registers, DCMRW*X* are synchronized. Hence changes to these configurations might take upto 4 CORE_CLK cycles to be effective.

**NOTE**

The DCM read only registers are present in standby domain and retain values across standby mode. Hence reading the status registers after standby exit might indicate a previously latched value. To read back these status registers after any reset event or standby exit, first clear these and then read. This would clear the previous status or transient information due to reset event and indicate the correct status.

### 37.2.1 DCM_GPR memory map

DCM_GPR base address: 402A_C000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 200h | Read Only GPR On Destructive Reset Register (DCMROD1) | 32 | RW | 0000_0000h |
| 208h | Read Only GPR On Destructive Reset Register (DCMROD3) | 32 | RW | 0000_0000h |

# Chapter 38
# Device Configuration Module (DCM)

## 38.1 Overview

DCM controls:

- LC
- DCF client registers
- Debug authorization (Export Control mode)

The module also establishes a RoT for the chip by parsing the master root key and other security records.

### 38.1.1 Block diagram

This figure is a block representation of DCM.

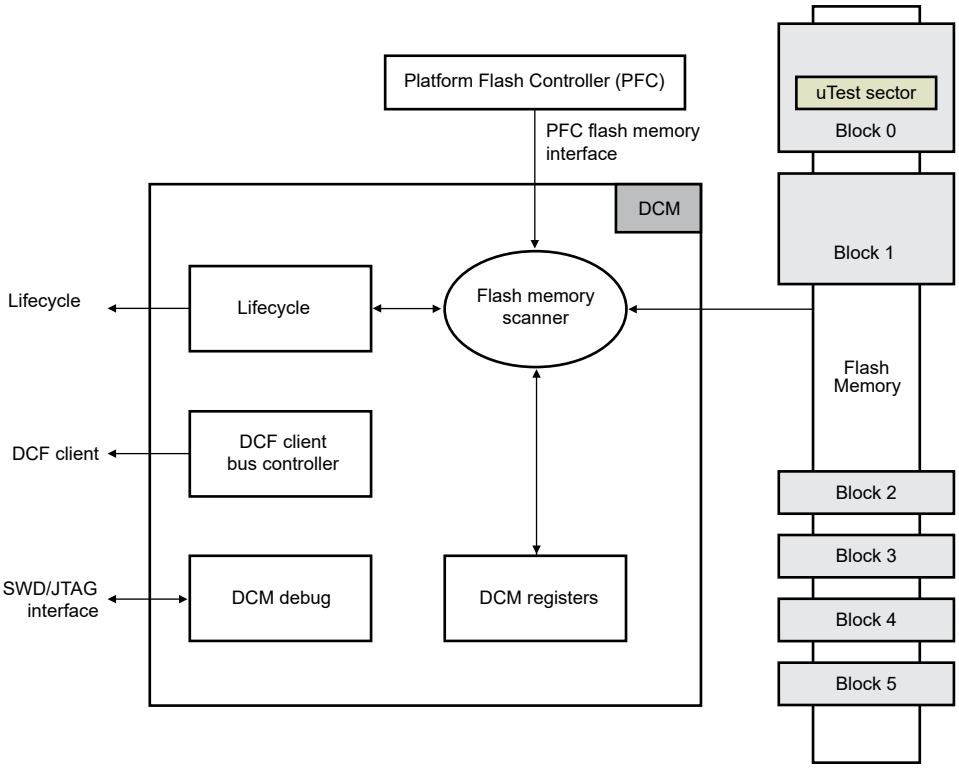

Figure 139. DCM block diagram

### 38.1.2 Features

- Scans flash memory and configures the system for following information:
  - LC detection
  - DCF records configuration using flash memory
- Allows debug features for flash memory content and the chip
- Provides debug enable control for HSE and application

- Provides a valid boot address detection
- Enables the DCF client to be writable via the IPS bus
- Parametrizes control to mask a set of DCF client chip select
- Supports temporary advancement of the LC by programming DCMLCC[DCMFLC]
- Manages debug features for flash memory content and the chip like debug enable control and debug authorization.

## 38.2 Functional description

DCM provides information about the current state and configuration of the system that you could use to:

- Configure the application software.
- Debug the system.

### 38.2.1 Modes of operation

DCM operates identically in all system modes of operation.

### 38.2.2 DCF mechanism

The DCF mechanism handles chip parameter settings via the OTP flash memory.

You can store a series of DCF records in UTEST flash memory, and each record is 64 bits in length. The chip processes these records during the system reset sequence before the CPU leaves reset.

### 38.2.3 DCF error recording

DCF errors are recorded in DCM for both types of clients—spread spectrum safe and normal. See DCF client error mechanism for details on spread spectrum safe clients.

### 38.2.4 DCF client error mechanism

The DCM consists of DCMMISC[DCMCERS] for detecting faulty DCF records. The DCMSRRn registers capture the details up to 16 faulty records. The DCMCERS bit can be cleared by writing 1 to it.

While scanning the flash, in case if a faulty record is encountered, the DCMMISC[DCMCERS] gets set indicating that there is atleast one faulty record. In such a case, the user can identify the details about the faulty record in the DCMSRRn registers and should update the flash memory with a new record, provided the record is not write-once.

For example, in the image below, if the faulty DCF record is DCF2, then the correct DCF record must also be DCF2. Even in case if the faulty record is updated, the DCM stores the faulty record via the DCMMISC[DCMCERS] and DCMSRRn registers.

This figure shows that a faulty DCF record is loaded between the original and final DCF record sets.

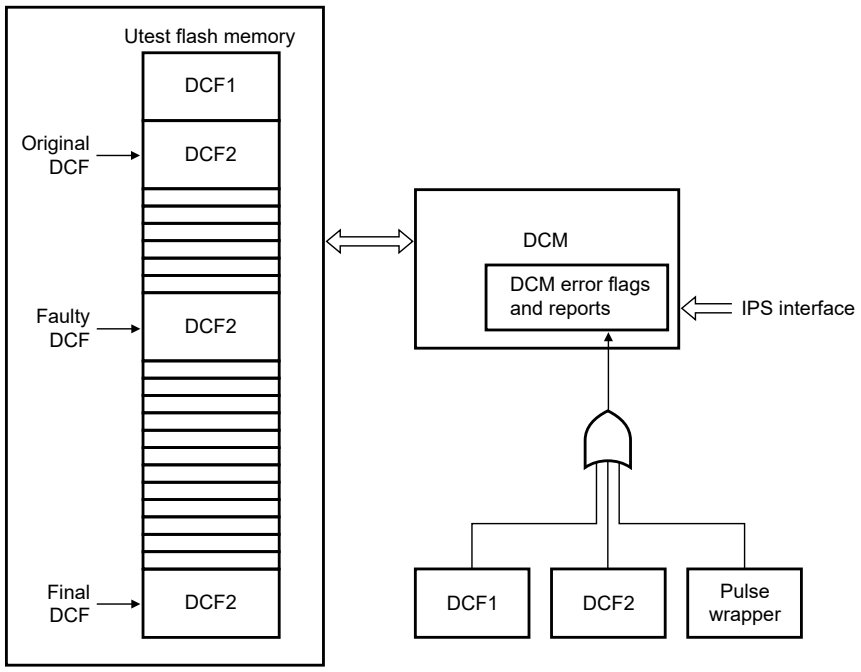

Figure 140. DCF error handling

### 38.2.5 DCM error detection mechanism

This figure shows the flow diagram of errors logged into DCM from DCF clients and Flash memory scanner. It also shows that DCM provides software control for lifecycle and export control mode.

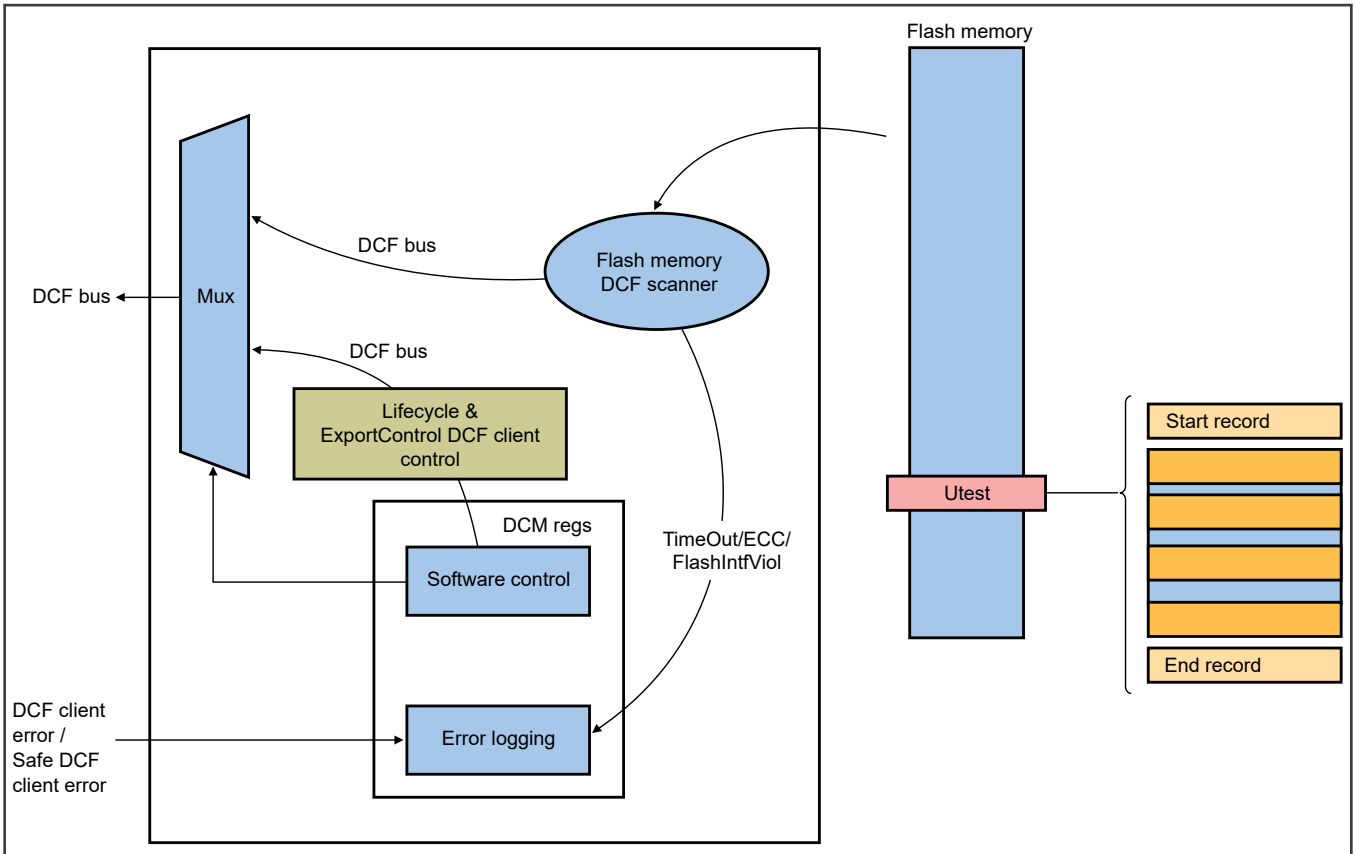

Figure 141. DCM error detection mechanism

## 38.2.6 LC

DCM determines the LC of the chip by reading the LC slots from the Utest flash memory. This read operation is performed during the reset phase, with normal timings. The operating monitors and an ECC check protect the operation. Additionally, a set of sanity checks executed over the LC read data guarantee the integrity of the final LC value.

At the end of the reset phase, the LC contains one of the following values:

- OEM production (OEM_PROD)
- In field (IN_FIELD)
- Pre-FA
- FA

The DCM LC progresses in the direction shown in this figure:

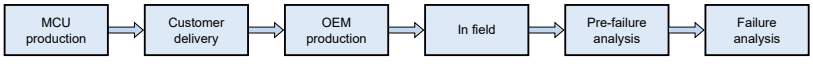

Figure 142. LC sequence

The LC is written into six slots, 128 bits each, and at fixed locations in the Utest flash memory block. Each LC slot is read in a single atomic operation and is organized in two types of fields:

- Valid (lower 64b of LC slot)
- Invalid (higher 64b of LC slot)

Depending on the possible combinations of data programmed into these fields, each LC slot indicates one of the four possible statuses as shown in Table 195. To know more about LC slots, see Table 196.

**Table 195. LC slot status**

| LC slots | | LC slot value |
|---|---|---|
| Valid field (64 bits) | Invalid field (64 bits) | |
| Erased | Erased | Erased |
| Marked | Erased | Active |
| Marked | Marked | Inactive |
| Other values | | Illegal |

In this case, "Marked" refers to a value that is configured based on the bit pattern 55AA_50AF_55AA_50AFh, and "Erased" is detected using the bit pattern FFFF_FFFF_FFFF_FFFFh.

**Table 196. LC slots**

| LC slot 2<br>OEM_PROD | LC slot 3<br>IN_FIELD | LC slot 4<br>Pre-FA | LC slot 5<br>FA | Resulting LC |
|---|---|---|---|---|
| Active | Erased | Erased | Erased | OEM_PROD |
| Inactive | Active | Erased | Erased | IN_FIELD |
| Inactive | Inactive | Active | Erased | Pre-FA |
| Inactive | Inactive | Inactive | Active | FA |

**NOTE**

When triggering DCM for rescanning, the software must ensure that the flash memory program and erase fields are not set. Otherwise, DCM does not configure the chip and ignores all data returned from the UTEST flash memory. This results in LC becoming IN_FIELD. All DCF clients indicate their default values in this case.

## 38.3 DCM register descriptions

### 38.3.1 DCM memory map

DCM base address: 402A_C000h

## 38.3.4 LC Scan Status (DCMLCS)

### Offset

| Register | Offset |
|---|---|
| DCMLCS | 8h |

### Function

Stores the status of LC scanning. By default, the status of each LC is "not yet scanned."

This register:

- Resets on destructive reset.
- Always returns 0 in a valid IN_FIELD LC (in LC without an error).

This register captures the errors related to LC scanning on each of these resets: POR, destructive, and functional. If an error is captured, its status in this register is cleared by writing 1 to the corresponding field or to any of the destructive or POR events.

All LC slot errors are captured and cleared independently.

### Diagram

## 38.3.24 LC Scan Status 2 (DCMLCS_2)

### Offset

| Register | Offset |
|---|---|
| DCMLCS_2 | 80h |

### Function

Stores the status of LC scanning. By default, the status of each LC is "not yet scanned."

This register:

- Resets on destructive reset.
- Always returns 0 in a valid IN_FIELD LC (in LC without an error).

This register captures the errors related to LC scanning on each of these resets: POR, destructive, and functional. If an error is captured, its status in this register is cleared by writing 1 to the corresponding field or to any of the destructive or POR events.

All LC slot errors are captured and cleared independently.

# Chapter 39
# Messaging Unit (MU)

## 39.1 Chip-specific MU information

### 39.1.1 MU instances and configuration

This chip includes MUs for communication across the different cores. Each MU includes two interfaces, MUA and MUB. Two different processors control them for communication.

**NOTE**

The ELE_HSEB core controls the MUA interface of MU_0 and MU_1. Therefore, the application core cannot control the interface.

The base address of MU_1's MUB interface is different across the MCXE31 product series because AIPS_2 is unavailable in MCXE317 and MCXE315/MCXE316. Table 197 summarizes this difference.

**Table 197. Base-address difference in MU_1's MUB interface across MCXE 31 product series**

| | MCXE31B | MCXE317 | MCXE315/MCXE316 |
|---|---|---|---|
| Base address | 404E_C000h | 4039_0000h | |

## 39.2 Overview

MU enables two processors on a chip to communicate and coordinate by passing messages (for example, data, status, and control) through the MU interface. MU also allows one processor to signal the other processor using interrupts.

MU must synchronize the accesses from one side to the other because MU can manage messaging between processors using different clocks. MU accomplishes synchronization using two sets of matching registers: processor A-facing and processor B-facing.

### 39.2.1 Block diagram

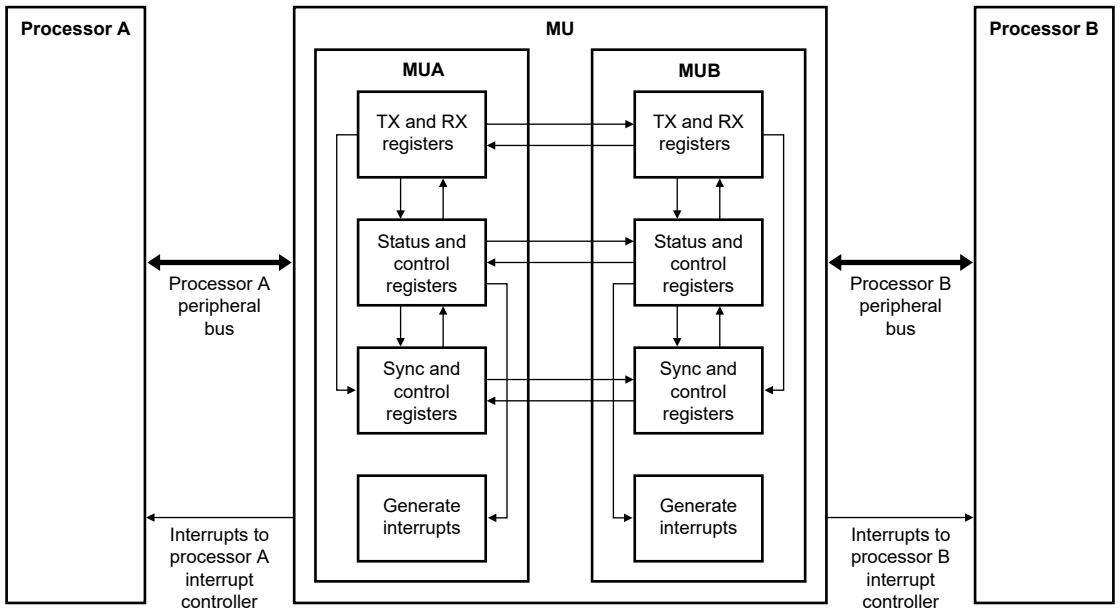

Figure 143. Block diagram

### 39.2.2 Features

- Memory-mapped registers (MU is connected as a peripheral under the peripheral bus on the processor A-side and processor B-side)
- Synchronized message transfers between cores
  - To send data or messages from one side to the other, MUA provides 4 transmit registers and 4 receive registers. MUB provides 4 transmit registers and 4 receive registers.
  - Transmit empty flags (TSR[TEn]) and receive full flags (RSR[RFn]) facilitate the transfer of data or messages between cores on both sides of MU.
  - A synchronization mechanism updates the transmit and the receive flags. There is an inherent latency between updating the flag on one side and reflecting its status on the other side. See Event update timing.
  - MU has a 3-bit flag data register, which you can use to send flag data between the two MU sides.
- Interprocessor interrupts
  - MU has 9 interrupt sources on each side (processor A-side, processor B-side) for signaling the other processor. You can use the interrupts for notification of receive and transmit events and for general-purpose signaling between processors. There are 1 general-purpose interrupt requests available and 8 receive and transmit interrupt sources.
- Reset (Each processor can issue a reset to MU via CR[MUR], which is a self-clearing field).

## 39.3 Functional description

MU enables two cores (processor A and processor B) to communicate with each other:

- By sharing messages and data.
- By enabling one core to wake the other core by using interrupts.

The messaging, control, and status registers of the two cores are mapped to processor A memory and processor B memory as a regular peripheral. The peripheral data bus is 32 bits wide inside MU.

Messaging logic is used with shared memory. Various messaging methods can implement a messaging protocol. For example, a message could mean one of the following:

- A message of *n* words has been written starting at offset *x* in the memory.
- The previous data block that was sent has been read.

The ability to keep messaging logic independent of the shared memory is not restricted to a predefined hardware protocol. The software required to manage the messaging is short and straightforward.

Most of the messaging mechanisms are symmetric. They are duplicated and are available on both the processor A side and processor B side. The messaging mechanisms are:

- 4 32-bit transmit registers, which are each reflected in 4 read-only receive registers on the side of the other processor. These registers can transfer 32-bit word messages or the frame information of the messages written to the shared memory. For example, they can transfer the number of words, initial address, and message type code.
- Writing to a transmitter-side transmit register (TR*n*) clears the Transmitter Empty flag in the transmitter-side Status register (TS*n*[TE*n*]), and sets the Receiver Full flag in the receiver-side Status register (RS*n*[RF*n*]). Setting the flag on the receiver side can trigger an interrupt on the receiver side (a maskable receive interrupt).
- Reading a receiver-side receive register (RR*n*) clears the Receiver Full flag in the receiver-side Status register (RS*n*[RF*n*]), and sets the Transmitter Empty flag in the transmitter-side Status register (TS*n*[TE*n*]). Setting the Transmitter Empty flag can trigger an interrupt on the transmitter side (a maskable transmit interrupt).
- 1 general-purpose interrupt request flags are reflected in General-purpose Status (GSR) on the receiver side.
- 3-bit flag data is transmitted from Flag Control (FCR) to Flag Status (FSR) on the side receiving the flag data. SR[FUP] sets when the flag data is transmitted and clears when the receiving side acknowledges the flag data (the flag is updated).

Writing to a transmit register signals to the receiver side that data is ready for retrieval.

Do not write to the transmit register again without verifying that the data is retrieved. The transmitter side cannot determine the exact time that the receiver attempts to retrieve the data. Before attempting to write to the transmit register again, the transmitter side must wait for the Transmitter Empty interrupt or it must poll TSR[TE*n*].

Reading a receive register signals to the transmitter side that data can be written to that register.

Do not read the receive register again without verifying that the data is written. The receiver side cannot determine the exact time that the transmitter attempts to write the data. Before attempting to read the receive register again, the receiver side must wait for the Receiver Full interrupt or it must poll RSR[RF*n*].

## 39.3.1 Submodules

### 39.3.1.1 MUA side

MUA receives its register configuration via the processor A peripheral bus. It sends or receives messages to or from MUB. Processor A can receive messages by reading MUA registers, and MUA can send interrupts to processor A when interrupts are enabled.

**NOTE**

Processor B should not access MUA registers. Processor C, if exist, should also not access MUA registers. TRDC might be needed to prevent such illegal access of Processor B or C to MUA registers.

### 39.3.1.2 MUB side

MUB receives its register configuration via the processor B peripheral bus. It sends or receives messages to or from MUA. Processor B can receive messages by reading MUB registers, and MUB can send interrupts to processor B when interrupts are enabled.

**NOTE**

Processor A should not access MUB registers. Processor C, if exist, should also not access MUB registers. TRDC might be needed to prevent such illegal access of Processor A or C to MUB registers.

### 39.3.2 Event update timing

The messaging side of each processor has a hardware mechanism to send event update requests to the other processor. An event occurs when the status register of the receiving processor must reflect any information change. The event update latency is the delay between the event being ready at one processor and the resulting update at the status register of the other processor:

- The minimum event latency is (1 clock cycle of the sending side) + (2.5 clock cycles of the receiving side). This minimum case happens when no event is pending when the new event occurs.
- The maximum event latency is (6 clock cycles of the sending side) + (6.5 clock cycles of the receiving side). The maximum case happens when the event occurs just after a previous event is sent to the other side.

The event update latency varies depending on the time at which the subsequent event is triggered.

### 39.3.3 Clocking

**Table 198. MU clocks**

| Clock name | Description |
|---|---|
| Bus clock MUA | Used only for bus accesses to MUA control and configuration registers |
| Bus clock MUB | Used only for bus accesses to MUB control and configuration registers |

### 39.3.4 Resets

The following sections list the reset sources included in MU. Each reset performs a different function for the MU module compared to the function it performs for the system.

#### 39.3.4.1 Asynchronous system reset

When the asynchronous system reset on either side of MU is asserted, SR[MURS] becomes 1 until the asynchronous system reset sequence on both the MUA and MUB sides ends. Verify that SR[MURS] becomes 0 before accessing MU.

The asynchronous system reset on one side of MU resets the other side of MU. The reset forces all control and status registers to return to their default values and clears all internal states. The following table shows the exceptions to this behavior.

**Table 199. Exceptions to asynchronous system reset**

| MUA-side exceptions | MUB-side exceptions |
|---|---|
| MUB_CR[MURIE] | MUA_CR[MURIE] |
| MUB_SR[MURIP] | MUA_SR[MURIP] |
| MUB_SR[MURS] | MUA_SR[MURS] |

#### 39.3.4.2 MU software reset

Writing 1 to CR[MUR] causes most control and status registers to return to their default values and clears all internal states.

The instruction immediately following the assertion of CR[MUR] must not write to the MU registers. The reset sequence may overwrite such a write, with the register retaining the reset value. To know the end of the reset sequence for both processors, monitor the value of SR[MURS]. After the reset sequence on both processors has ended, a write to the MU registers can be attempted.

**NOTE**

The process of CR[MUR] becoming 1 is delicate because it asynchronously affects the registers on the other side. CR[MUR] becoming 1 may cause unpredictable behavior if, for example, the other processor is concurrently testing an MU register field (TSR[TE*n*] in the other processor). Before writing 1 to CR[MUR], verify that the other processor is not engaged in an MU signaling activity.

### 39.3.5 Interrupts

MU controls interrupt requests that one processor makes to the other processor. This section describes all the interrupts that the module generates.

MU can generate these interrupt sources individually to send to the processors:

- 4 receive interrupts (asserted when the Receive Full flags are set in Receive Status (RSR) and enabled in Receive Control (RCR)) for each receive register. These interrupts are Ored into a single interrupt for each MUA or MUB, please consult the interrupt map file attached to this document.
- 4 transmit interrupts (asserted when the Transmit Empty flags are set in Transmit Status (TSR) and enabled in Transmit Control (TCR)) for each transmit register. These interrupts are Ored into a single interrupt for each MUA or MUB, please consult the interrupt map file attached to this document.
- 1 general-purpose interrupt (asserted when the GIP flag is set in General-Purpose Interrupt Enable (GIER) and enabled in General-Purpose Interrupt Enable (GIER))
- Core Reset Assertion interrupts (asserted when the processor enters the Reset state and enabled by RAIE)

All interrupts are maskable in the processor control registers: TCR, RCR, GIER, and CR. MU does not assume any internal priority of these interrupts. Multiple interrupts (for example, receive 0 and receive 1, or any transmit or general-purpose interrupt) can be asserted simultaneously. The interrupt controller must resolve the priority of these interrupts at the chip level.

Triggering any enabled interrupt wakes the processor from below mode before servicing the interrupt

- Wait mode
- Stop mode
- Power-down mode

The software (as part of the interrupt handler) must clear the general-purpose interrupt pending flag (GSR[GIP0]) to deassert the request to the interrupt controller.

When a processor writes to the general-purpose interrupt flag (GCR[GIR0]), MU synchronizes the write event to the other processor to set the general-interrupt request pending flag (GSR[GIP0]). When GSR[GIP0] is set, if the general-purpose interrupt is enabled on the receiving processor side (GIER[GIE0] is 1), the transmitting-side general-purpose interrupt is issued to the receiving processor, which clears this interrupt by writing 1 to GSR[GIP0]. The interrupt is deasserted as soon as the write to GSR[GIP0] occurs. MU synchronizes the write event of GSR[GIP0] to the other processor. The synchronized signal clears the GIR0 flag.

Before writing 1 to GCR[GIR0], verify that this field is 0, which means that a general interrupt is not pending. Generally, MU ignores writing 1 to this field while the field is already 1, but in some cases it may issue a second interrupt.

## 39.4 External signals

This module has no external signals.

## 39.5 Initialization

MU does not require initialization.

## 39.6 Application information

MU facilitates messages between processors. For example, MU passes:

- Short messages. Transmit registers can pass short messages from 1 to 4 words in length for processor A and from 1 to 4 words for processor B. For example, for a four-word message, only one register must have its corresponding interrupt enabled on the receiving side. The first three words of the message are written to the registers with masked interrupts. The fourth word is written to the last register, triggering an interrupt on the receiving side.
- Frame information. Transmit registers can pass frame information for long messages written to the shared system memory. Such frame information normally includes a start address and a number of words. It can include a message type code.
- Event notices and requests. MU can signal events and requests that do not include data words between processors using general-purpose interrupts. For example, one such event is acknowledging that a long message is read from the shared system memory.
- Fixed-length data. Formatted data with a fixed length can be written to predetermined locations in the shared memory. A processor can use general-purpose interrupts to signal to the other processor that the data is ready.
- Announcements. A processor can use the 3 flags to announce its current program state or other billboard messages to the other processor.

### 39.6.1 Messaging protocols using interrupts

The example below describes a four-word messaging sequence sent between the processor A and processor B.

The transmitting processor writes to the transmit registers sequentially. When *n* = 0, 1, and 2, the interrupts are disabled, so no interrupt goes to the processor (although interrupt conditions occur). For *n* = 3, the interrupt is enabled, and MU generates the last receive interrupt request.

1. Write sequence:
    a. The transmitting processor writes the message information sequentially to its Transmit registers 0, 1, 2.
    b. When the write to Transmit register 3 occurs, RSR[RF3] is set after synchronization. It immediately triggers the receive full 3 interrupt on the receiving processor.
2. Read sequence:
    a. The receiving processor receives the receive full 3 interrupt and starts reading the message transferred from the receive registers.
    b. After the receiving processor reads Receive register 3, MU clears RSR[RF3].

Table 200 and Figure 144 describe the messaging model, using transmit and receive registers and the interrupt messaging protocol.

**Table 200. Interrupt messaging protocol (generalized)**

| Step | Action | Description |
|---|---|---|
| 1 | Processor A writes data. | RR*n* on processor B's side reflects a data write to TR*n* by processor A. |
| 2 | Clear the transmitter empty flag and set the receiver full flag. | The data write to TR*n*:<br>• Clears TSR[TE*n*] on the processor A side.<br>• Sets RSR[RF*n*] on the processor B side. |
| 3 | Generate the receive interrupt request. | Setting RSR[RF*n*] generates a receive interrupt request to processor B. |
| 4 | Processor B reads the data. | After receiving the receive interrupt request, processor B performs a data read of RR*n*. |

*Table continues on the next page...*

Table 200. Interrupt messaging protocol (generalized) (continued)

| Step | Action | Description |
|---|---|---|
| 5 | Clear the receiver full flag and set the transmitter empty flag. | Reading the data from the RR*n* register:<br>• Clears RSR[RF*n*] on the processor B side.<br>• Sets TSR[TE*n*] on the processor A side. |
| 6 | Generate the transmit interrupt request. | Setting TSR[TE*n*] generates a transmit interrupt request to processor A. |

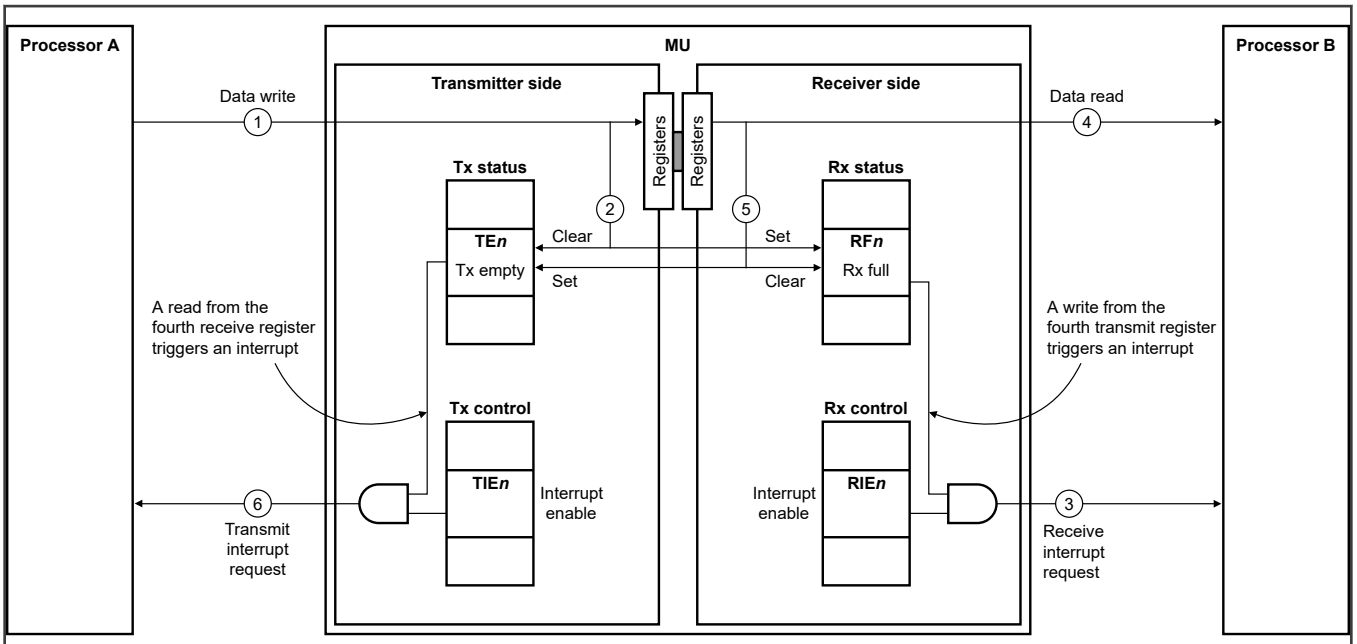

Figure 144. Messaging model using transmit and receive registers

You can use the messaging hardware to implement messaging protocols for an array of message types. MU provides full support for interrupt and polling management schemes.

## 39.6.2 Messaging protocols using event interrupts

MU can signal events and requests that do not include data words between processors using general-purpose interrupts.

Formatted data with a fixed length can be written to predetermined locations in the shared memory. A processor can use a general-purpose interrupt to signal to the other processor that the data is ready.

A processor can use the 3 flags to announce its current program state (or similar messages) to the other processor.

Table 201 and Figure 145 describe the event steps when the processor triggers a general-purpose interrupt.

Table 201. General-purpose interrupt messaging protocol (generalized)

| Step | Action | Description |
|---|---|---|
| 1 | Processor A sets its associated general-purpose interrupt request flag. | Processor A sets GCR[GIR0]. |

*Table continues on the next page...*

Table 201. General-purpose interrupt messaging protocol (generalized) (continued)

| Step | Action | Description |
|---|---|---|
| 2 | The general-purpose interrupt request pending status flag is set. | GSR[GIP0] is set. |
| 3 | MU generates the general-purpose interrupt request to processor B. | Setting GSR[GIP0] generates the general-purpose interrupt request to processor B. GIER[GIE0] must be set for processor B. |
| 4 | Processor B reads the status register. | Processor B reads GSR[GIP0]. |
| 5 | Processor B services the interrupt. | — |
| 6 | Processor B sets GSR[GIP0] to clear the interrupt. | Processor B writes 1 to the corresponding GSR[GIP0] flag to clear the interrupt. |
| 7 | GCR[GIR0] is cleared. | Setting GSR[GIP0] clears GCR[GIR0] on the processor A side. |

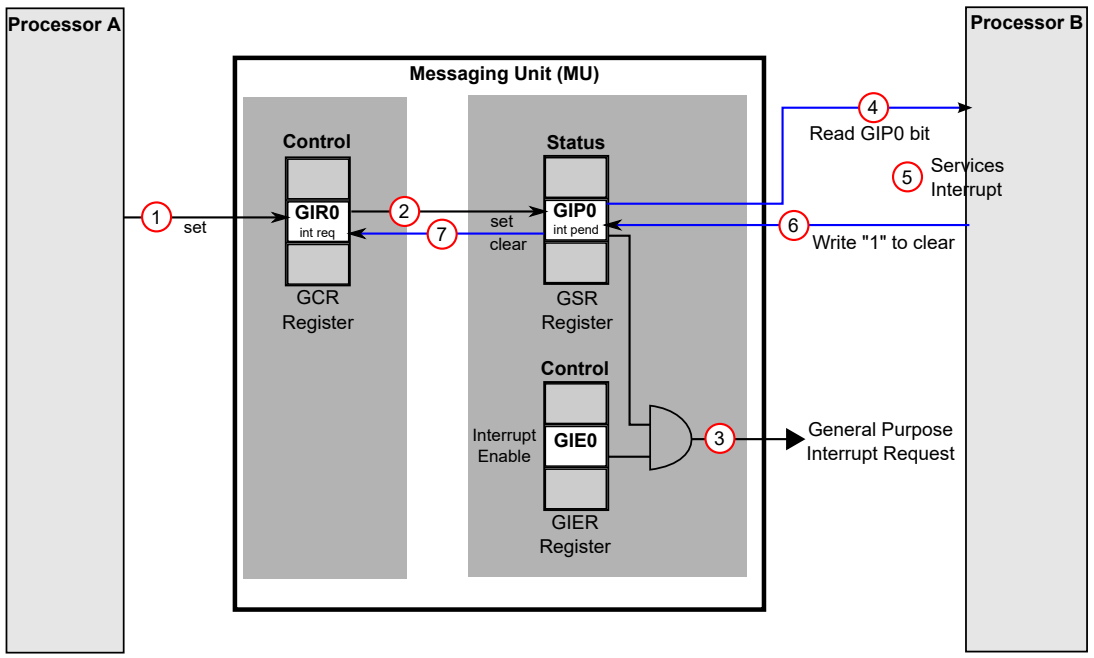

Figure 145. Messaging model using a general-purpose interrupt

## 39.6.3 Exclusive access to shared memory

MU can signal one processor about its current access to shared memory. This signaling prevents the other processor from overwriting data during the exclusive memory access period.

The following tables describe the signaling protocol that processor A uses to inform processor B about its current access (write) to shared memory:

- Table 202 shows processor A performing an exclusive access to shared memory.
- Table 203 shows processor B scanning for transaction information.

- Table 204 shows processor B accepting exclusive access from processor A.
- Table 205 shows processor B rejecting exclusive access from processor A.

According to the examples shown in the following tables, GCR[GIR0], RR*n*, and TR*n* are reserved to support exclusive access to the shared memory protocol.

**Table 202. Processor A performs an exclusive access to shared memory**

| Step | Action | Description |
|---|---|---|
| 1 | Processor A sends the GIR0 request to processor B using the processor A control register. | Before processor A performs an exclusive access to the shared memory, it sends a GIR0 request to processor B. |
| 2 | Processor A sends an exclusive-access request using a transmit data register (TR*n*). | Processor A sends an exclusive-access request (command, location, and length of target access) to processor B using a selected transmit data register (TR0). |
| 3 | Processor A waits for a dedicated interrupt from processor B. | Processor A waits for a dedicated interrupt (as an acknowledgment) triggered by processor B before proceeding. |
| 4 | Processor A accesses the shared memory. | After receiving a dedicated interrupt from processor B, processor A proceeds. |

**Table 203. Processor B scans for transaction information**

| Step | Action | Description |
|---|---|---|
| 1 | Processor B receives an interrupt from a receive data register (RR*n*). | — |
| 2 | Processor B reads the receive data register (RR*n*). | — |
| 3 | Processor B scans the receive data register contents. | Processor B scans for transaction information (whether processor A has requested exclusive access). |

**Table 204. Processor B accepts exclusive access from processor A**

| Step | Action | Description |
|---|---|---|
| 1 | Processor B triggers a dedicated interrupt. | Processor B acknowledges the request from processor A by triggering a dedicated interrupt (ack) to processor A. |
| 2 | Processor B sends a code message to processor A. | With the acknowledge interrupt, processor B sends a code message to processor A through the selected transmit register (TR*n*). The message informs processor A that it can exclusively access the shared memory. |

**Table 205. Processor B rejects exclusive access from processor A**

| Step | Action | Description |
|---|---|---|
| 1 | Processor B ignores the request from processor A for exclusive access. | If processor B does not provide permission to processor A, processor B ignores the exclusive-access request. |

### 39.6.4 Packet data transfers

The following table describes an example packet transfer sequence between processor B and processor A subsystems.

**Table 206. Packet data transfer sequence**

| Step | Action | Description |
|---|---|---|
| 1 | Processor B requests DMA. | Processor B sends a DMA request to initiate the packet data transfer. |
| 2 | DMA data transfer | DMA acknowledges. |
| 3 | | DMA starts transferring data from the specified processor B memory location to the specified shared memory. |
| 4 | | DMA interrupts processor B to signal that the packet transfer has finished. |
| 5 | Processor B informs processor A that data is in shared memory. | Using a B-side transmit register, processor B sends a packet information message to processor A about the arrival of new packet data stored in shared memory. The message contains the command, location, and length of packet data. |
| 6 | Processor A receives an interrupt. | Processor A receives an interrupt (assuming its corresponding processor A MU-side receive interrupt is enabled). The pending processing task becomes active and processes packet data from memory. |
| 7 | Processor A reads data, then writes data. | Processor A reads or processes packet data from shared memory. |
| 8 | | Processor A writes the result from packet processing to a separate buffer. |
| 9 | Processor A informs processor B that the transfer is finished. | After the processing of the packet data finishes, processor A informs processor B (using MU processor A-side transmit register, MUA_TR*n*). |
| 10 | Processor A sends an interrupt to processor B (a request for more data). | Processor B receives the next interrupt from processor A, in which processor A requests more packet data. |

### 39.6.5 Freeing a processor from deadlock

During normal operation, one processor may determine that the other processor is not working or is deadlocked. Using Status (SR), the processor can use the methods in the following table to identify and correct the problem.

**Table 207. Freeing a processor from deadlock**

| Processor mode | Technique | Description |
|---|---|---|
| — | Processor issues an interrupt. | The other processor can interrupt the processor by issuing one of the 9 (general purpose, receive, or transmit) interrupts. |
| — | Processor issues a hardware reset. | If the above methods are not helpful, the processor can issue a hardware reset strobe to the other processor. |

## 39.7 Register definition

MU provides transmit and receive data registers (*x*TR0–*n*, *x*RR0–*n*) for communication between processor A and processor B. It also provides control registers (*x*CR) for operations such as interrupts and resets, and status registers (*x*SR) for checking the status of the other MU-side. Figure 146 shows the schematic for MU registers.

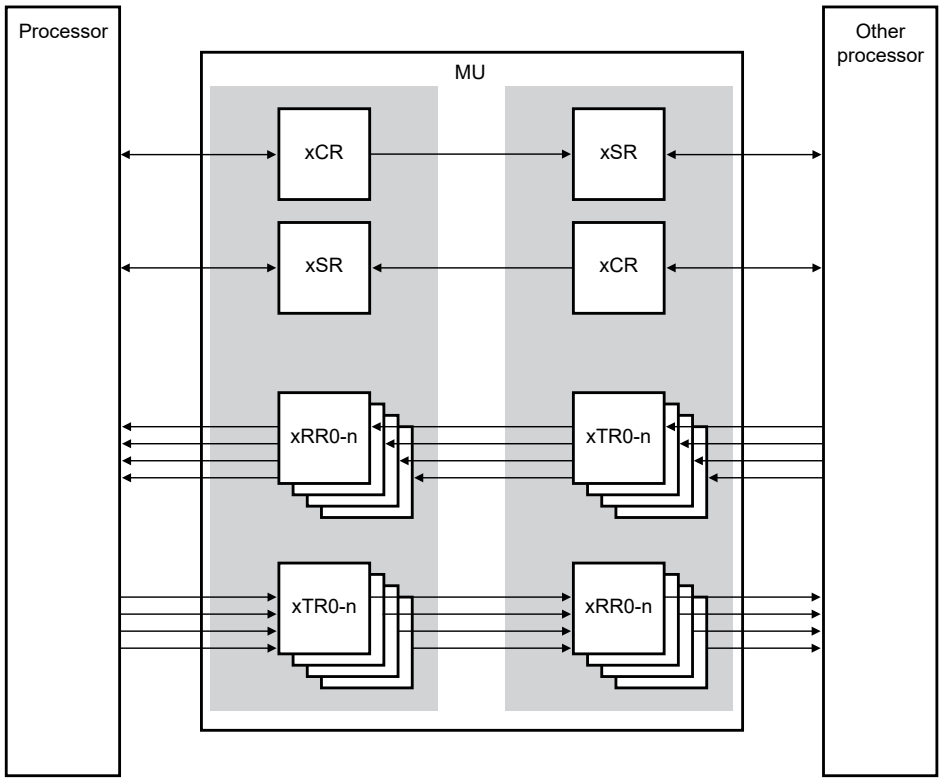

Figure 146. MU registers

### 39.7.1 MU register descriptions

This section contains the detailed register descriptions for MUA registers.

**NOTE**

A module transfer error to processor A or processor B is generated when:

- A read or write access is made to an invalid location.
- A write operation is performed on a read-only register on the processor A side or processor B side of MU.

#### 39.7.1.1 MU memory map

MU_1.MUA base address: 404E_C000h

### Fields

| Field | Function |
|---|---|
| 31-24<br>FLAG_WIDTH | Flag Width<br>Specifies the number of flag bits (3) in the Flag Control (FCR) and Flag Status (FSR) registers. |
| 23-16<br>GIR_NUM | General-Purpose Interrupt Request Number<br>Specifies the number of general-purpose interrupt requests available (1). |
| 15-8<br>RR_NUM | Receive Register Number<br>Specifies the number of receive registers (4). |
| 7-0<br>TR_NUM | Transmit Register Number<br>Specifies the number of transmit registers (4). |

## 39.7.1.4 Control (CR)

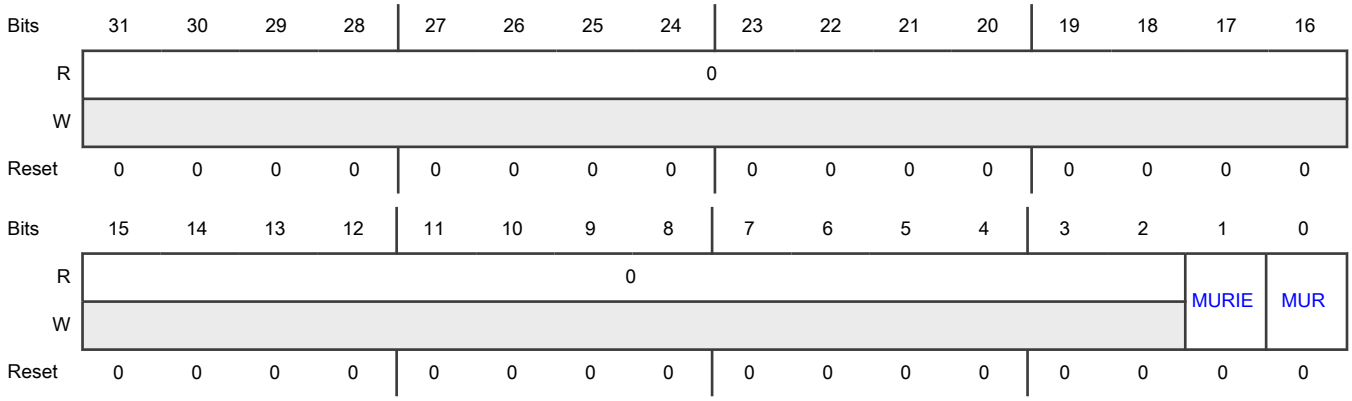
### Offset

| Register | Offset |
|---|---|
| CR | 8h |

### Function

Controls MU reset and reset interrupt enable.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-2<br>— | Reserved |
| 1<br>MURIE | MUA Reset Interrupt Enable<br>Enables the processor A-side MU reset interrupt request due to MU reset issued by MUB.<br>If the value of this field is 1, an MU reset interrupt request is issued to processor A when MUA_SR[MURIP] = 1.<br>If the value of this field is 0, MU ignores the value of MURIP and issues no MU reset interrupt request.<br>Only a system reset can reset this field. CR[MUR] cannot reset this field.<br>0b - Disable<br>1b - Enable |
| 0<br>MUR | MU Reset<br>Resets MU. Writing 1 to this field resets the MUA and MUB sides. All internal states are cleared. It forces all control and status registers to return to their default values (except in MUA/B_CCR0 registers; MURIE in MUA/B_CR registers; MURIP and MURS in MUA/B_SR registers).<br>Before writing 1 to this field, interrupt processor B because writing 1 to this field may affect the ongoing processor B program.<br>After writing 1 to this field, monitor the value of MUA_SR[MURS] to know when the reset sequence on the processor B-side has ended.<br>This field always reads 0, and it becomes 0 during the MU reset sequence.<br>0b - Idle<br>1b - Reset |

### 39.7.1.5 Status (SR)

#### Offset

| Register | Offset |
|---|---|
| SR | Ch |

#### Function

Shows the status of MU resets and the status of pending events and requests.

#### Diagram

#### Fields

| Field | Function |
|---|---|
| 31-8<br>— | Reserved |
| 7<br>— | Reserved |
| 6<br>RFP | MUA Receive Full Pending<br>Indicates whether a receive full message is pending.<br>This field becomes 1 when MUB writes to a TR*n* register to send data to MUA. After this field becomes 1, MU checks RSR[RF*n*] to determine whether the data in the Receive register is ready for MUA to read it.<br>This field becomes 0 when all MUA RR*n* registers are read, or when MU is reset.<br>0b - Not pending; MUB is not writing to a Transmit register<br>1b - Pending; MUB is writing to a Transmit register |
| 5<br>TEP | MUA Transmit Empty Pending<br>Indicates whether a transmit empty message is pending. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | This field becomes 1 when any TCR[TIE*n*] field is 1 and TSR[TE*n*] flag is set. After this field becomes 1, MU checks TSR[TE*n*] to determine whether the data in the Transmit (TR*n*) register is ready for MUA to write to it.<br>This field becomes 0 when write operations to all MUA Transmit (TR*n*) registers where TCR[TIE*n*] = 1 (transfer interrupt enabled) are completed, or when MU is reset.<br>0b - No MUA transmit empty event pending<br>1b - Pending; any TCR[TIEn] field is 1 and TSR[TEn] flag is set |
| 4<br>GIRP | MUA General-Purpose Interrupt Pending<br>Indicates that MUB has sent a general-purpose interrupt request.<br>This field becomes 1 when the MUB side sends a general-purpose interrupt request to the MUA side. GSR[GIP0] identifies which general-purpose interrupt request is received.<br>This field becomes 0 when MUA_GSR[GIP0] is cleared, or when MU is reset.<br>0b - No request sent<br>1b - Request sent |
| 3<br>FUP | MUA Flag Update Pending<br>Indicates whether a flag update request is pending. MU generates this request when there is a change to the F*n*[2:0] bits of MUA_FCR.<br>This field becomes 1 when the MUA side sends a flag update request to the MUB side.<br>This field becomes 0 when MU acknowledges this flag update request internally (the flag is updated) from the MUB side, or during MU reset.<br>No flag update changes are allowed when this field is 1. When FUP = 1, a write to the F*n*[2:0] bits of MUA_FCR does not generate a flag update event. The F*n*[2:0] bits do not change.<br>If SR[EP] = 1 (event pending), writing to MUA_FCR does not immediately cause this field to become 1.<br>0b - No pending update flags (initiated by MUA)<br>1b - Pending update flags (initiated by MUA) |
| 2<br>EP | MUA Side Event Pending<br>Indicates a pending side event when the MUA side sends an event update request to the MUB side. An event is any hardware message that the Status register on the MUB side reflects. For example, an event occurs when Transmit register 0 is the target of a write operation. During normal operations, the update mechanism for this field operates automatically.<br>MU clears this field automatically when the event update acknowledgment is received, or when MU resets.<br>To ensure that events are posted to MUB, verify that this field is 0. If it is 1, wait and continue to poll this field until it becomes 0.<br>0b - Not pending<br>1b - Pending |
| 1 | MU Reset Interrupt Pending Flag |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| MURIP | Indicates whether processor B has issued an MU reset.<br>This flag is set after processor B initiates an MU reset by setting MUB_CR[MUR]. If CR[MURIE] = 1, the processor A MU reset interrupt request is issued when processor B writes 1 to MUB_CR[MUR].<br>Clearing this flag also clears the MU reset interrupt request.<br>Only a system reset can reset this flag. MU reset cannot reset this flag.<br>**NOTE**<br>This field behaves differently for register reads and writes.<br>When reading<br>0b - Reset not issued<br>1b - Reset issued<br>When writing<br>0b - No effect<br>1b - Clear the flag |
| 0<br>MURS | MUA and MUB Reset State<br>Indicates the reset state of MUA and MUB.<br>This field becomes 1 during any system reset or MU reset from the MUA or MUB side.<br>This field becomes 0 when the reset sequence on both MUA and MUB sides ends. After issuing any of the aforementioned reset events, verify that this field is 0 before starting any access.<br>0b - Out of reset<br>1b - In reset |

### 39.7.1.6 Core Control 0 (CCR0)

#### Offset

| Register | Offset |
|---|---|
| CCR0 | 10h |

#### Function

Allows MUA to control the processor on the MUB side.

### Diagram

| 3-0<br>RFn | MUA Receive Register Full<br>Indicates whether MUA Receive register (RR*n*) is full, where *n* = 0 to 3.<br>RF*n* becomes 1 when the MUB_TR*n* register is written to on the MUB side.<br>When RF*n* is 1, it indicates to the MUA side that new data in the MUA_RR*n* register is ready for MUA to read it. If MUA_RCR[RIE*n*] = 1, a receive *n* interrupt is issued on the MUA side.<br>RF*n* becomes 0 when the MUA_RR*n* register is read, or when MU is reset.<br>After RF*n* becomes 0, if MUA_RCR[RIE*n*] = 1, the receive *n* interrupt request is cleared on the MUA side.<br>0b - Not full<br>1b - Full |

## 39.7.1.16 Transmit (TR0 - TR3)

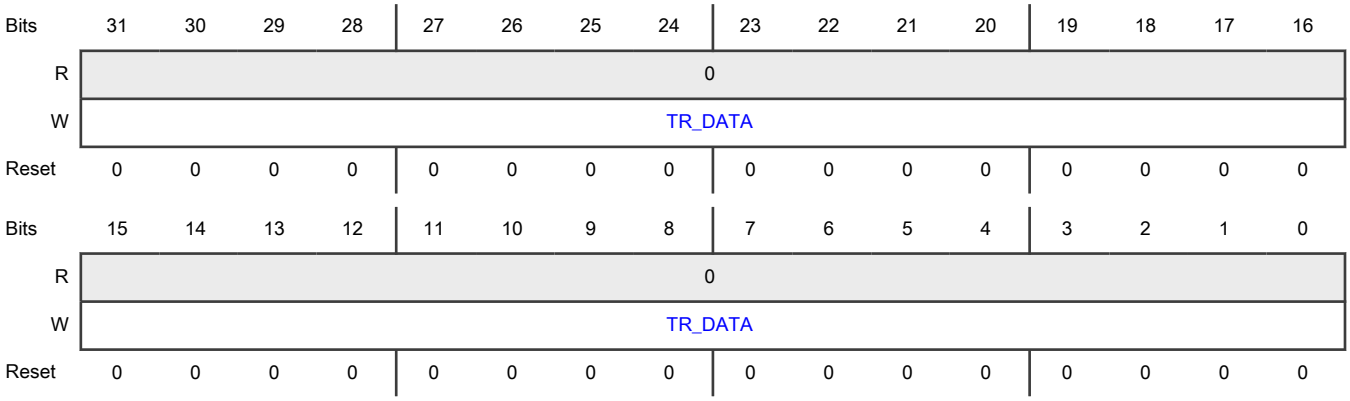
### Offset

| Register | Offset |
|---|---|
| TR0 | 200h |
| TR1 | 204h |
| TR2 | 208h |
| TR3 | 20Ch |

### Function

Contains MUA transmit data.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>TR_DATA | MUA Transmit Data<br>Contains MUA transmit data. MUB_RR*n* reflects the data written to this register.<br>The TR*n* and RR*n* registers are not double-buffered. Writing to MUA_TR*n* overrides the data readable in the MUA_RR*n* register.<br>A write to the Transmit register clears MUA_TSR[TE*n*] on the transmitter side, and sets MUB_RSR[RF*n*] on the receiver side.<br>You can write to this register only when MUA_TSR[TE*n*] = 1.<br>Reading this register returns all zeroes. |

## 39.7.1.17 Receive (RR0 - RR3)

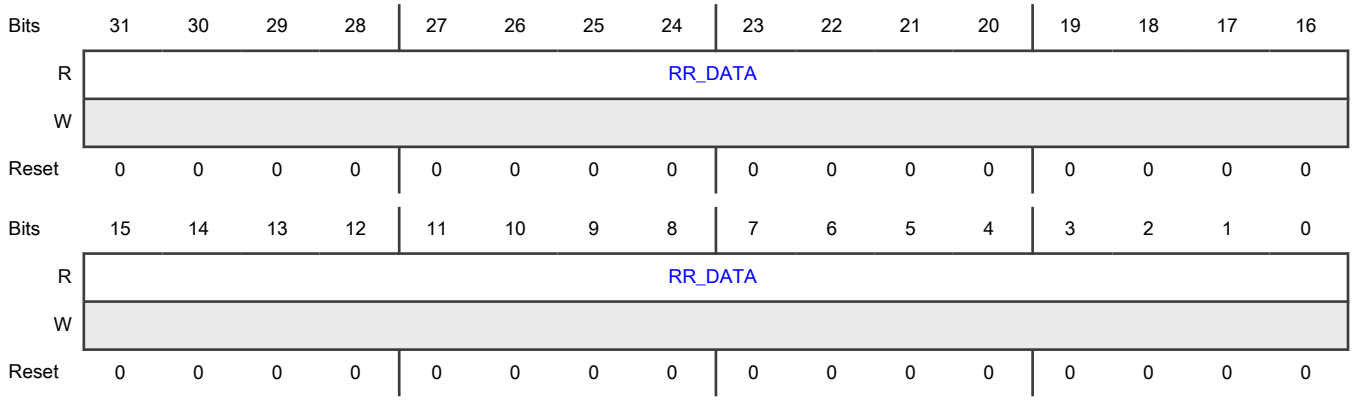
### Offset

| Register | Offset |
|---|---|
| RR0 | 280h |
| RR1 | 284h |
| RR2 | 288h |
| RR3 | 28Ch |

### Function

Contains MUA receive data.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-0<br>RR_DATA | MUA Receive Data<br>Reflects the data written to MUB TR*n*.<br>Reading this register clears MUA_RSR[RF*n*] on the receiver side, and sets MUB_TSR[TE*n*] on the transmitter side.<br>You can read this register only when MUA_RSR[RF*n*] = 1. Reading it before MUA_RSR[RF*n*] becomes 1 may result in reading incorrect data. Poll MUA_RSR[RF*n*] to confirm it is set before reading RR*n*.<br>Writing to this register generates an error response to MUA. |

## 39.7.2 MU register descriptions

This section contains the detailed register descriptions for MUB registers.

**NOTE**

A module transfer error to processor A or processor B is generated when:

- A read or write access is made to an invalid location.
- A write operation is performed on a read-only register on the processor A side or processor B side of MU.

### 39.7.2.1 MU memory map

MU_0.MUB base address: 404E_C000h

MU_1.MUB base address: 4038_C000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Version ID (VER) | 32 | R | 0300_000Fh |
| 4h | Parameter (PAR) | 32 | R | See section |
| 8h | Control (CR) | 32 | RW | 0000_0000h |

*Table continues on the next page...*

*Table continued from the previous page...*

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| Ch | Status (SR) | 32 | RW | See section |
| 10h | Core Control 0 (CCR0) | 32 | R | 0000_0000h |
| 100h | Flag Control (FCR) | 32 | RW | 0000_0000h |
| 104h | Flag Status (FSR) | 32 | R | 0000_0000h |
| 110h | General-Purpose Interrupt Enable (GIER) | 32 | RW | 0000_0000h |
| 114h | General-Purpose Control (GCR) | 32 | RW | 0000_0000h |
| 118h | General-purpose Status (GSR) | 32 | RW | 0000_0000h |
| 120h | Transmit Control (TCR) | 32 | RW | 0000_0000h |
| 124h | Transmit Status (TSR) | 32 | R | 0000_000Fh |
| 128h | Receive Control (RCR) | 32 | RW | 0000_0000h |
| 12Ch | Receive Status (RSR) | 32 | R | 0000_0000h |
| 200h - 20Ch | Transmit (TR0 - TR3) | 32 | RW | 0000_0000h |
| 280h - 28Ch | Receive (RR0 - RR3) | 32 | R | 0000_0000h |

### 39.7.2.2 Version ID (VER)

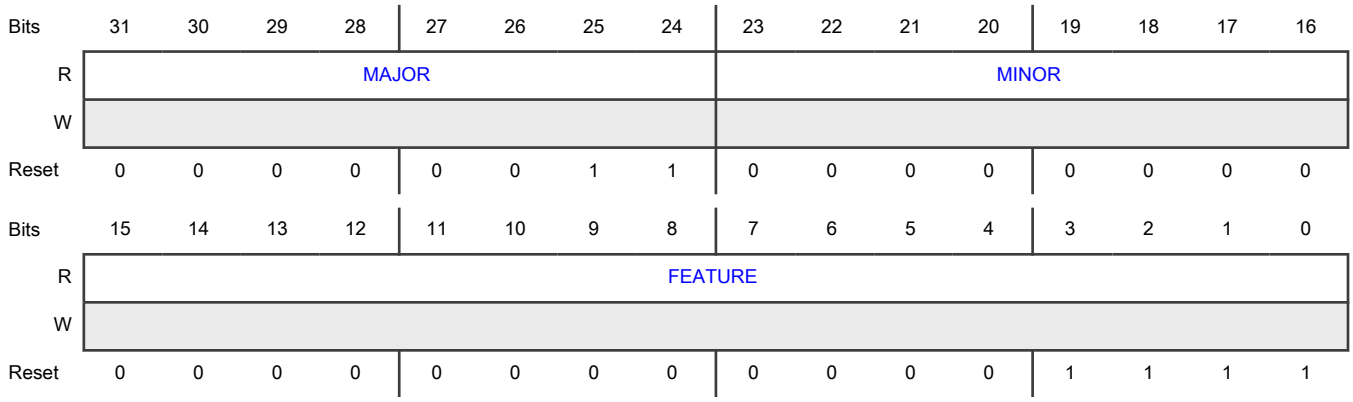
#### Offset

| Register | Offset |
|---|---|
| VER | 0h |

#### Function

Determines the version ID and feature set number of MUB.

#### Diagram



### Fields

| Field | Function |
|---|---|
| 31-24<br>MAJOR | Major Version Number |
| 23-16<br>MINOR | Minor Version Number |
| 15-0<br>FEATURE | Feature Set Number<br>Indicates the feature set number.<br>MU implements:<br>• Standard features<br>• RAIP and RAIE fields<br>• Expanded number of TR*n*/RR*n* registers |

## 39.7.2.3 Parameter (PAR)

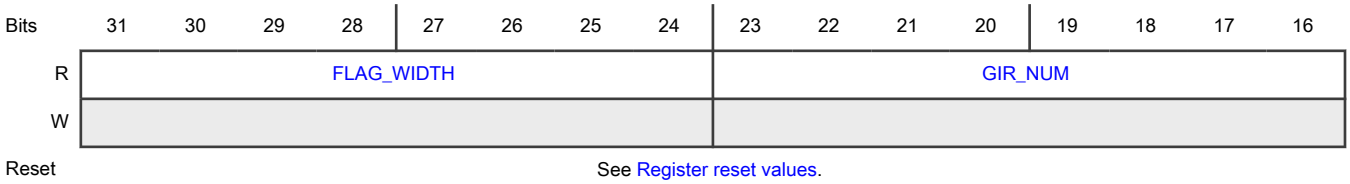
### Offset

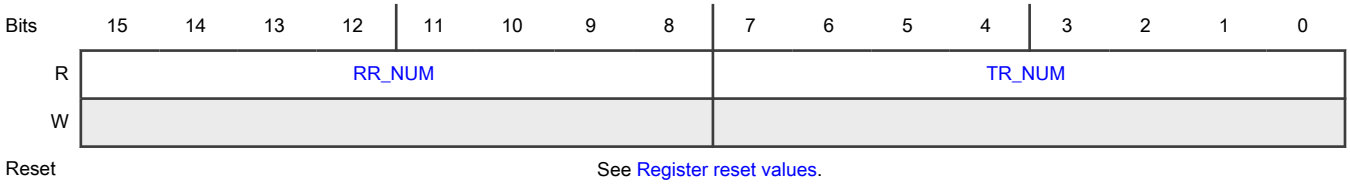
| Register | Offset |
|---|---|
| PAR | 4h |

### Function

Defines the number of flags, transmit registers, receive registers, and general-purpose interrupt requests available for MU.

### Diagram





### Register reset values

| Register | Reset value |
|---|---|
| PAR | MU_0.MUB: 2020_0404h<br>MU_1.MUB: 0301_0404h |

### Fields

| Field | Function |
|---|---|
| 31-24<br>FLAG_WIDTH | Flag Width<br>Specifies the number of flag bits (32) in the Flag Control (FCR) and Flag Status (FSR) registers. |
| 23-16<br>GIR_NUM | General-Purpose Interrupt Request Number<br>Specifies the number of general-purpose interrupt requests available (32). |
| 15-8<br>RR_NUM | Receive Register Number<br>Specifies the number of receive registers (4). |
| 7-0<br>TR_NUM | Transmit Register Number<br>Specifies the number of transmit registers (4). |

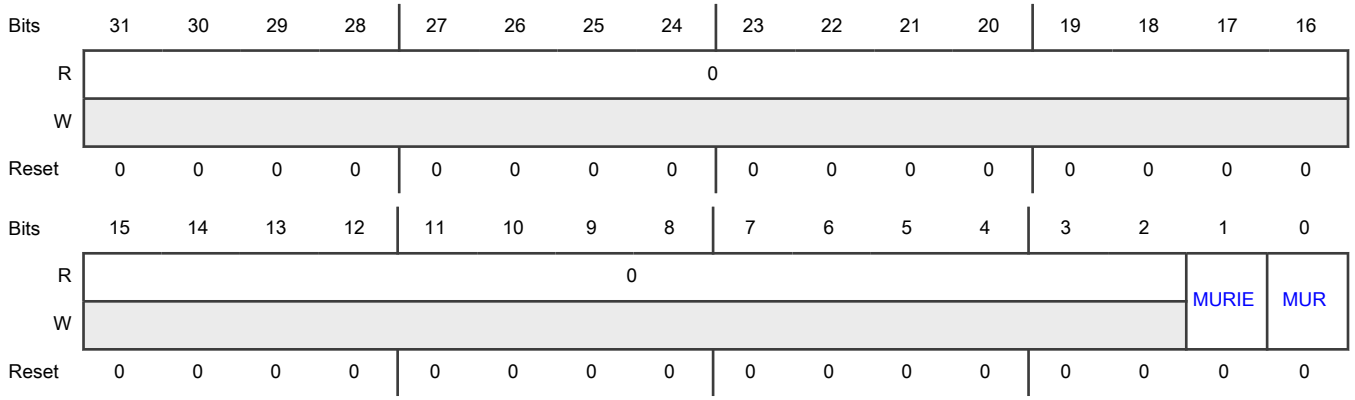
## 39.7.2.4 Control (CR)

### Offset

| Register | Offset |
|---|---|
| CR | 8h |

### Function
Controls MU reset and reset interrupt enable.

### Diagram



**Fields**

| Field | Function |
|---|---|
| 31-2<br>— | Reserved |
| 1<br>MURIE | MUB Reset Interrupt Enable<br>Enables the processor B-side MU reset interrupt request due to MU reset issued by MUA.<br>If the value of this field is 1, an MU reset interrupt request is issued to processor B when MUB_SR[MURIP] = 1.<br>If the value of this field is 0, MU ignores the value of MURIP and issues no MU reset interrupt request.<br>Only a system reset can reset this field. CR[MUR] cannot reset this field.<br>0b - Disable<br>1b - Enable |
| 0<br>MUR | MU Reset<br>Resets MU. Writing 1 to this field resets the MUB and MUA sides. All internal states are cleared. It forces all control and status registers to return to their default values (except in MUB/A_CCR0 registers; MURIE in MUB/A_CR registers; MURIP and MURS in MUB/A_SR registers).<br>Before writing 1 to this field, interrupt processor A because writing 1 to this field may affect the ongoing processor A program.<br>After writing 1 to this field, monitor the value of MUB_SR[MURS] to know when the reset sequence on the processor A-side has ended.<br>This field always reads 0, and it becomes 0 during the MU reset sequence.<br>0b - Idle<br>1b - Reset |

### 39.7.2.5 Status (SR)

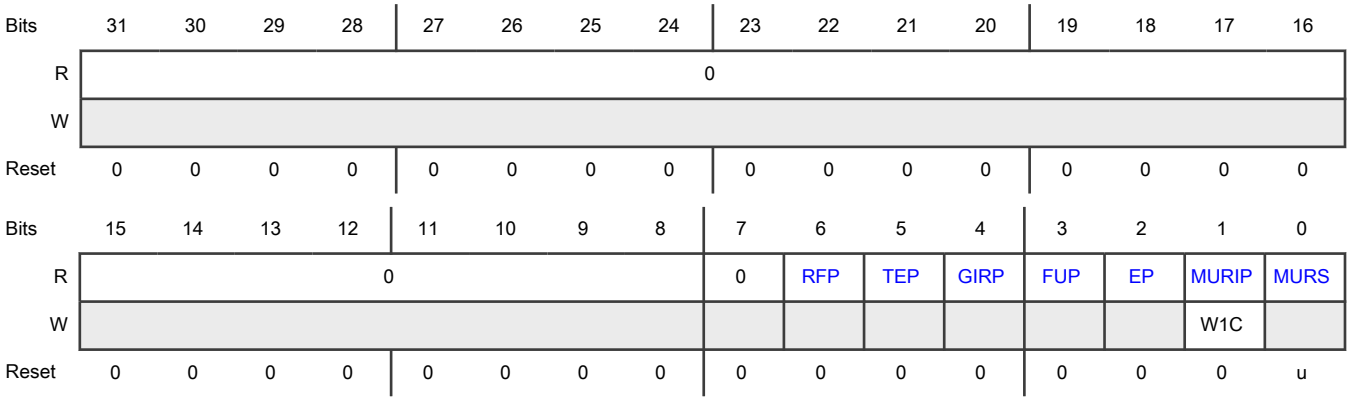
**Offset**

| Register | Offset |
|---|---|
| SR | Ch |

**Function**

Shows the status of MU resets and the status of pending events and requests.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-8<br>— | Reserved |
| 7<br>— | Reserved |
| 6<br>RFP | MUB Receive Full Pending<br>Indicates whether a receive full message is pending.<br>This field becomes 1 when MUA writes to a TR*n* register to send data to MUB. After this field becomes 1, MU checks RSR[RF*n*] to determine whether the data in the Receive register is ready for MUB to read it.<br>This field becomes 0 when all MUB RR*n* registers are read, or when MU is reset.<br>0b - Not pending; MUA is not writing to a Transmit register<br>1b - Pending; MUA is writing to a Transmit register |
| 5<br>TEP | MUB Transmit Empty Pending<br>Indicates whether a transmit empty message is pending.<br>This field becomes 1 when any TCR[TIE*n*] field is 1 and TSR[TE*n*] flag is set. After this field becomes 1, MU checks TSR[TE*n*] to determine whether the data in the Transmit (TR*n*) register is ready for MUB to write to it.<br>This field becomes 0 when write operations to all MUB Transmit (TR*n*) registers where TCR[TIE*n*] = 1 (transfer interrupt enabled) are completed, or when MU is reset.<br>0b - No MUB transmit empty event pending<br>1b - Pending; any TCR[TIEn] field is 1 and TSR[TEn] flag is set |
| 4<br>GIRP | MUB General-Purpose Interrupt Pending<br>Indicates that MUA has sent a general-purpose interrupt request.<br>This field becomes 1 when the MUA side sends a general-purpose interrupt request to the MUB side. GSR[GIP*n*] identifies which general-purpose interrupt request is received. |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | This field becomes 0 when all MUB_GSR[GIP*n*] fields are cleared, or when MU is reset.<br>0b - No request sent<br>1b - Request sent |
| 3<br>FUP | MUB Flag Update Pending<br>Indicates whether a flag update request is pending. MU generates this request when there is a change to the F*n*[31:0] bits of MUB_FCR.<br>This field becomes 1 when the MUB side sends a flag update request to the MUA side.<br>This field becomes 0 when MU acknowledges this flag update request internally (the flag is updated) from the MUA side, or during MU reset.<br>No flag update changes are allowed when this field is 1. When FUP = 1, a write to the F*n*[31:0] bits of MUB_FCR does not generate a flag update event. The F*n*[31:0] bits do not change.<br>If SR[EP] = 1 (event pending), writing to MUB_FCR does not immediately cause this field to become 1.<br>0b - No pending update flags (initiated by MUB)<br>1b - Pending update flags (initiated by MUB) |
| 2<br>EP | MUB Side Event Pending<br>Indicates a pending side event when the MUB side sends an event update request to the MUA side. An event is any hardware message that the Status register on the MUA side reflects. For example, an event occurs when Transmit register 0 is the target of a write operation. During normal operations, the update mechanism for this field operates automatically.<br>MU clears this field automatically when the event update acknowledgment is received, or when MU resets.<br>To ensure that events are posted to MUA, verify that this field is 0. If it is 1, wait and continue to poll this field until it becomes 0.<br>0b - Not pending<br>1b - Pending |
| 1<br>MURIP | MU Reset Interrupt Pending Flag<br>Indicates whether processor A has issued an MU reset.<br>This flag is set after processor A initiates an MU reset by setting MUB_CR[MUR]. If CR[MURIE] = 1, the processor B MU reset interrupt request is issued when processor A writes 1 to MUA_CR[MUR].<br>Clearing this flag also clears the MU reset interrupt request.<br>Only a system reset can reset this flag. MU reset cannot reset this flag.<br>**NOTE**<br>This field behaves differently for register reads and writes.<br>When reading<br>0b - Reset not issued |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | 1b - Reset issued<br>When writing<br>0b - No effect<br>1b - Clear the flag |
| 0<br>MURS | MUA and MUB Reset State<br>Indicates the reset state of MUA and MUB.<br>This field becomes 1 during any system reset or MU reset from the MUA or MUB side.<br>This field becomes 0 when the reset sequence on both MUA and MUB sides ends. After issuing any of the aforementioned reset events, verify that this field is 0 before starting any access.<br>0b - Out of reset<br>1b - In reset |

### 39.7.2.6 Core Control 0 (CCR0)

#### Offset

| Register | Offset |
|---|---|
| CCR0 | 10h |

#### Function

Allows MUB to control the processor on the MUA side.

#### Diagram

### 39.7.2.8 Flag Status (FSR)

#### Offset

| Register | Offset |
|---|---|
| FSR | 104h |

#### Function

Contains flags configured by the values written to MUA_FCR[F*n*].

# Chapter 40
# Power Management

## 40.1 Introduction

The power management system generates, monitors, and controls power supplies and related resets. This chapter describes the system's interaction with other peripherals.

The power management system includes the following modules:

**Table 208. Power management system modules and their functions**

| Part | Function |
|---|---|
| MC_ME | Initiates entry into Low-Power mode |
| MC_PCU | Controls entry into and exit from Low-Power mode |
| PMC | Regulates and monitors power supplies of the Run and the Standby domains |
| MC_RGM | Ensures a clean state and Run domain sanity by controlling the reset sequence |
| FIRC, WKPU, and other chip peripherals | Controls Standby mode wake-up and operations in Run and Standby modes |

Power management system for MCXE315/MCXE316 and MCXE317 represent block diagrams of the power management system for the MCXE31 family.

### 40.1.1 Power management system (for MCXE31B)

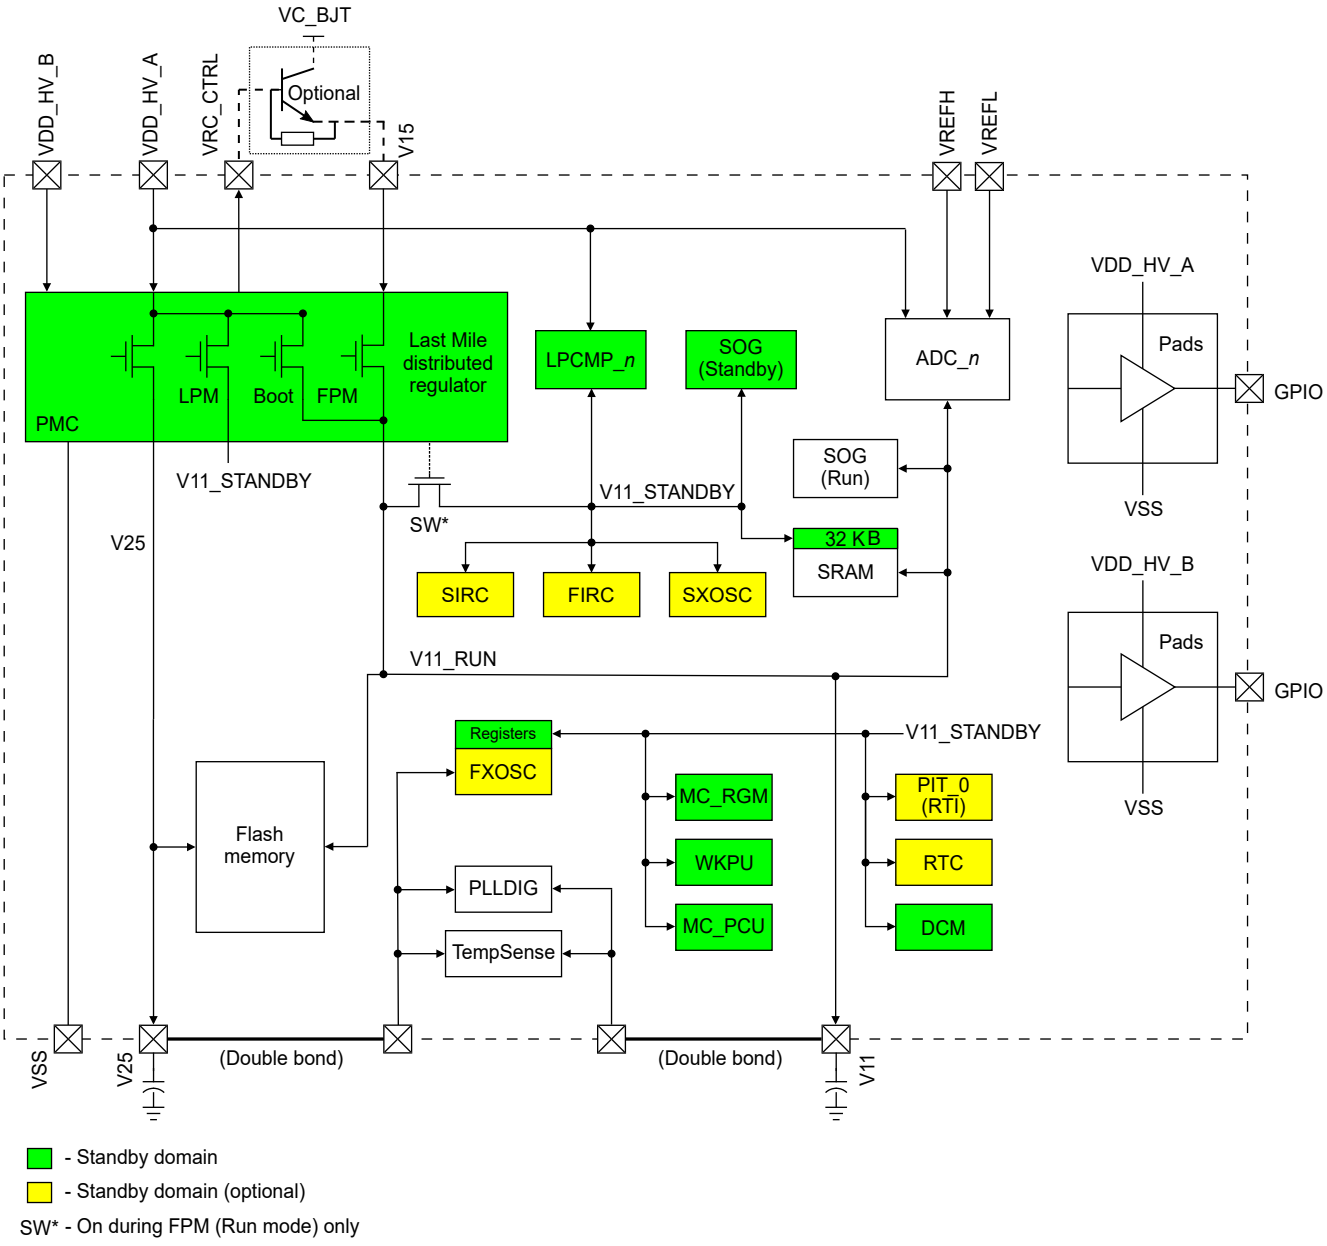

Figure 147. Power management system for MCXE31B

### 40.1.2 Power management system for MCXE315/MCXE316 and MCXE317

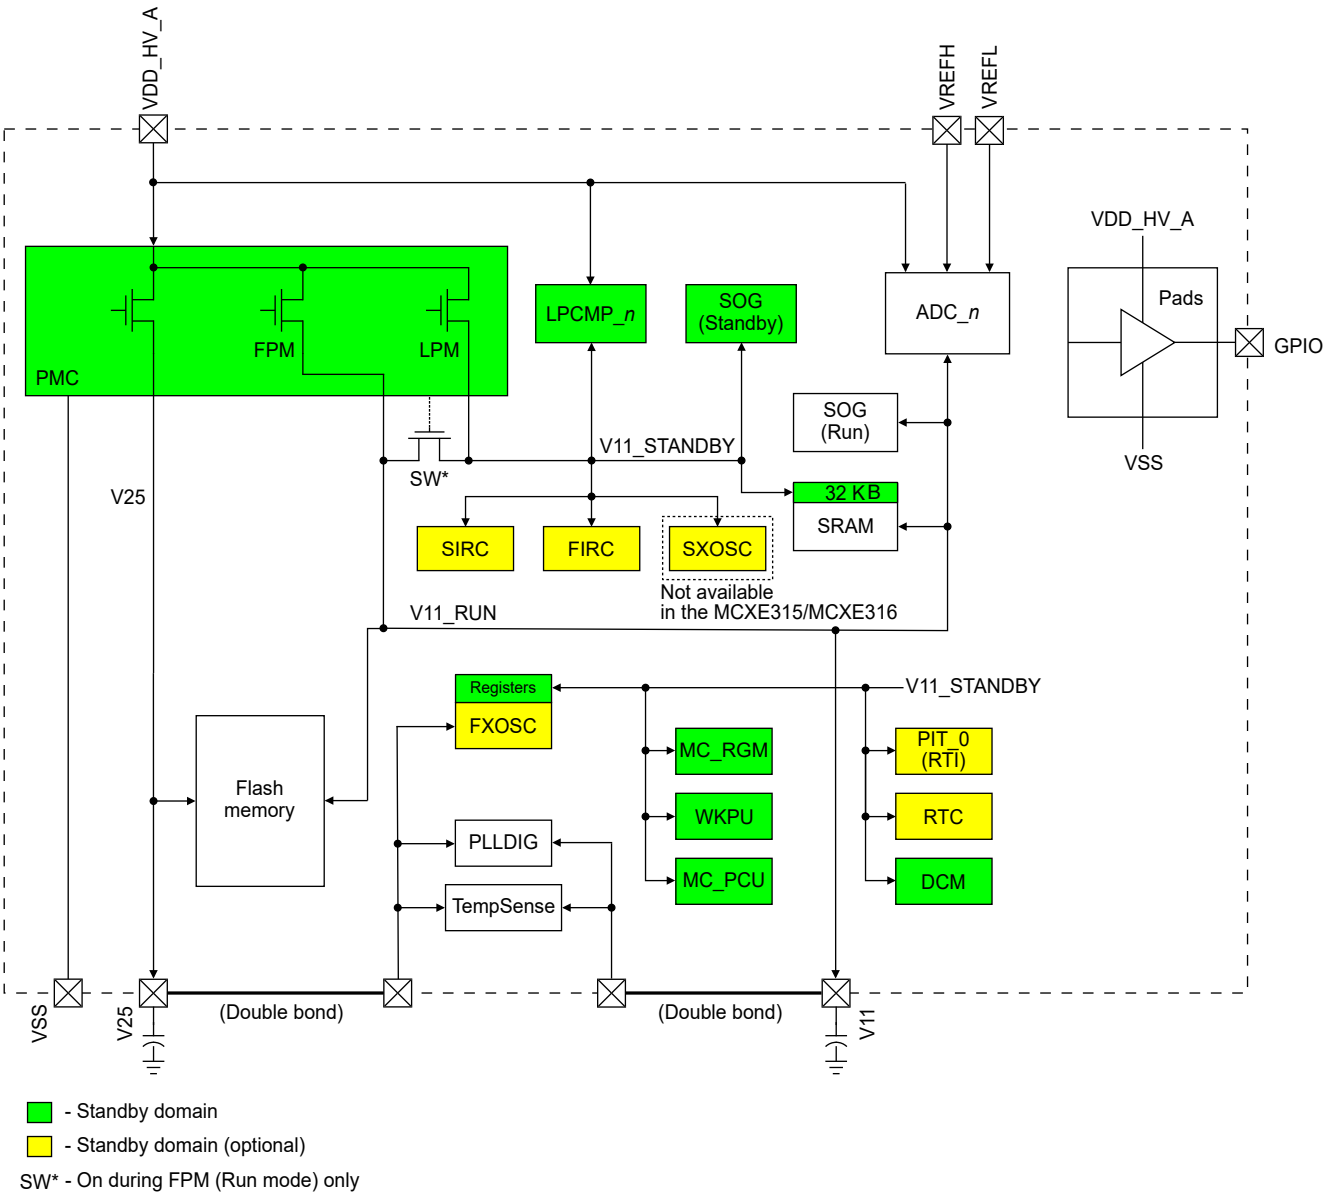

**Figure 148. Power management system for MCXE315/MCXE316 and MCXE317**

### 40.1.3 Features

- For MCXE315, MCXE316, MCXE317, PMC uses VDD_HV_A to generate 1.1 V (nominal) supply for the core logic (V11_RUN)
- For MCXE31B, PMC uses a 1.5 V supply to generate 1.1 V (nominal) supply for the core logic (V11_RUN)
- MCXE31B includes a linear regulator to use an optional external ballast (BJT) and VRC_CTRL output for 1.5 V generation.
- Supports a low-power regulator (LPM) supplying core logic during Standby mode (V11_STANDBY)
- MCXE31B includes 1.1 V FPM regulator options for driving the logic in RUN mode (V11_RUN) from a 1.5V supply:

  - Boot LDO
  - Internal Last-mile
- Supports power switches to isolate voltage islands and configure the chip in Standby mode
- Includes a linear regulator that generates a 2.5 V supply (V25) from VDD_HV_A
- Supports voltage monitors ensuring transitions to a safe state (POR) when a supply is out of a valid range
- Controls power-mode transitions through an interaction with the digital interface
- Offers a padkeeping feature that retains PAD state during standby mode till software boots up
- Separates ADC reference supplies (VREFH and VREFL)

### 40.1.4 Operational power modes

This chip uses two modes:

- Run mode (FPM): Main operation mode having full-chip performance and a higher current consumption as compared to Standby mode.
- Standby mode (LPM): Low-performance mode of the chip in which the Run domain is turned off. Most of the cores and peripherals turn off in this mode.

The boot regulator manages the chip during the booting process except for MCXE315, MCXE316, and MCXE317.

The last-mile regulator is the full-performance regulator, which you enable for running applications. The upcoming sections discuss the sequence to enable or disable the regulator.

The LPM regulator manages the chip in Standby mode.

### 40.1.5 External 1.5 V source (for MCXE31B)

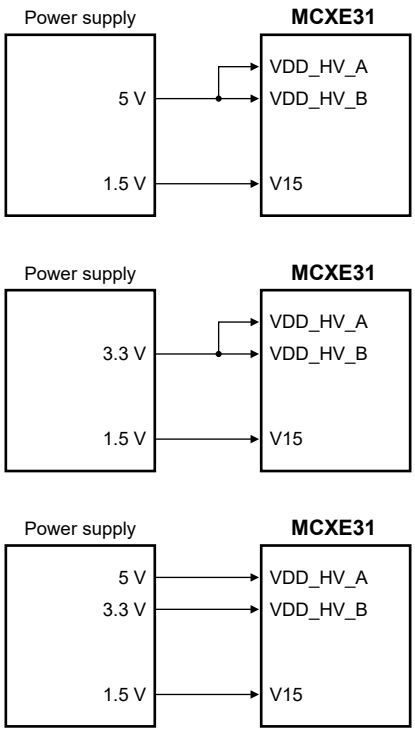

Figure 149. Core supply from external 1.5 V source for MCXE31B

### 40.1.6 Using a BJT for 1.5 V generation (for MCXE31B)

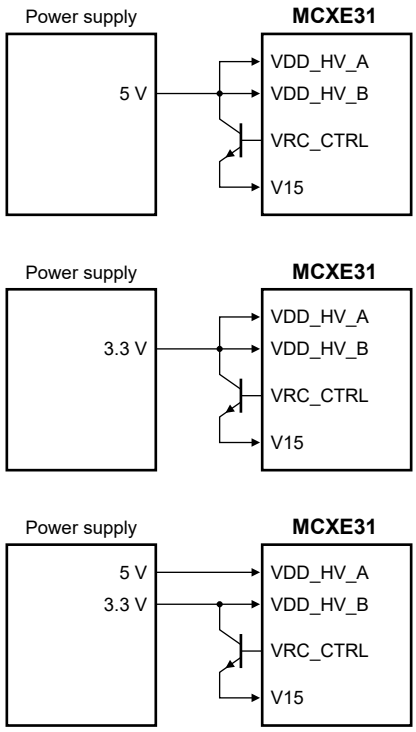

**Figure 150. Using a BJT for 1.5 V generation for MCXE31B**

## 40.2 Power-up sequence

Figure 151 shows the reset sequence for a power-up or Standby mode event. This sequence starts from the POR phase. For the Run domain logic, Standby mode exit operation is same as power-up.

See the Reset Overview chapter for more information about the chip reset sequence.

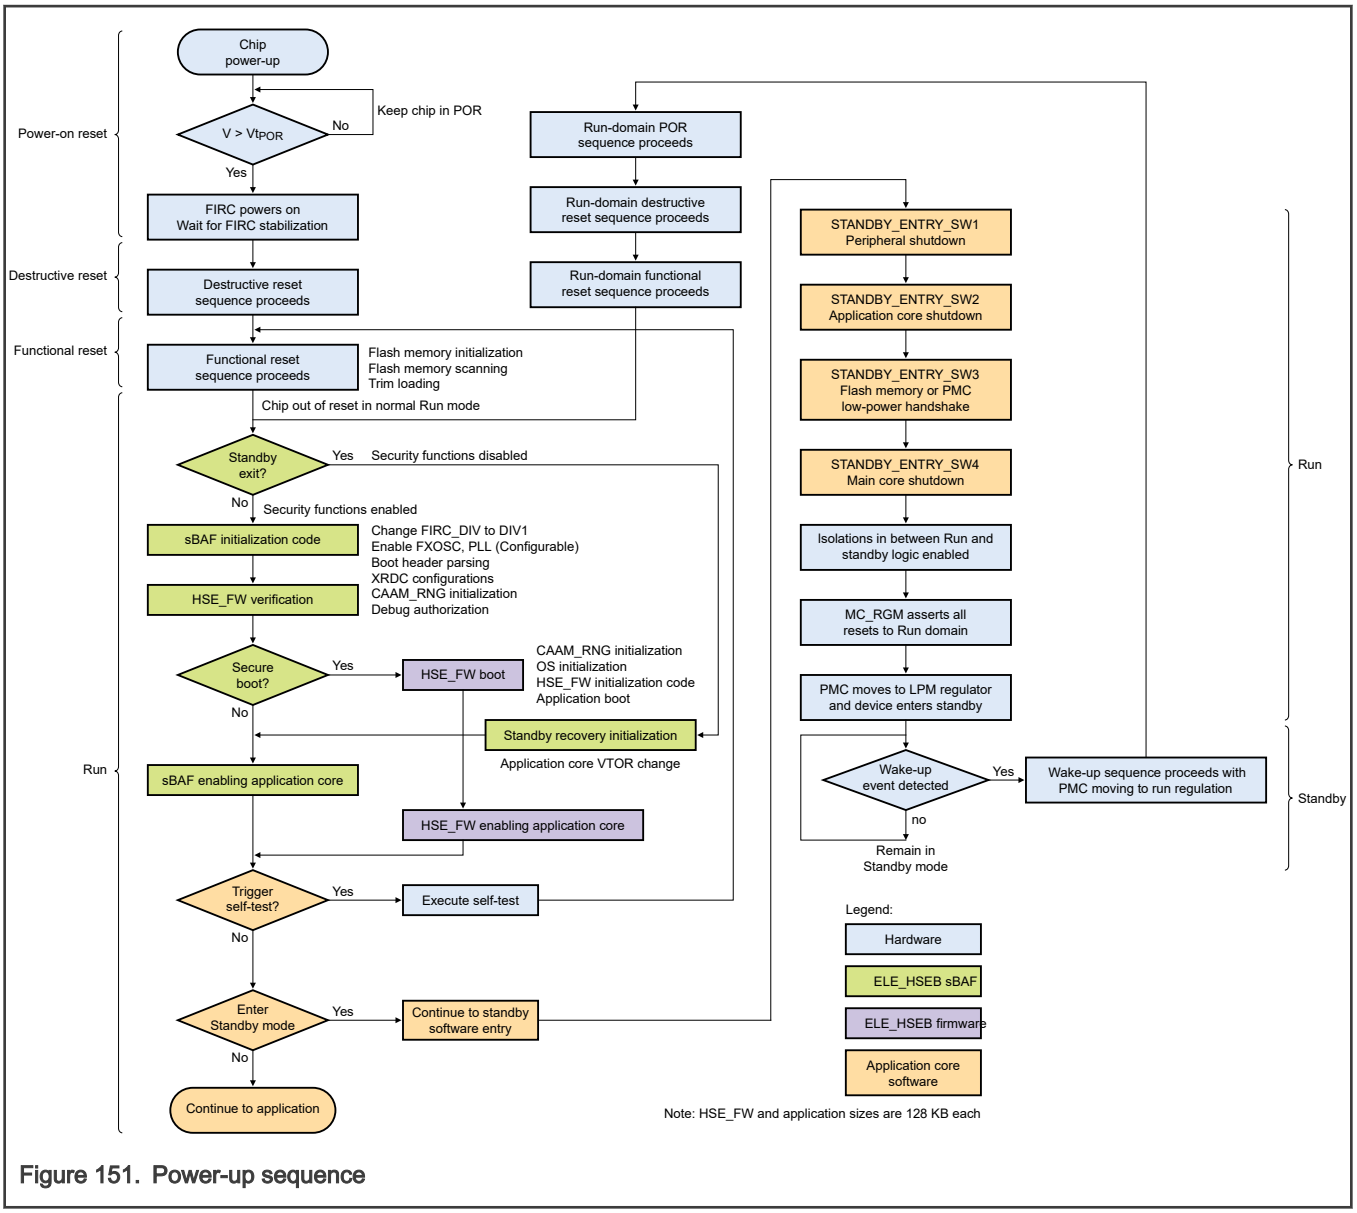

**Figure 151. Power-up sequence**

## 40.3 PMC last-mile regulator auto-enable feature (for MCXE31B)

PMC includes an automatic last-mile auto-enable feature. After starting on boot regulator, this feature allows automatic switch over to last-mile regulator if 1.5 V is present during:

- Chip startup
- Standby mode recovery

You can control the PMC last-mile regulator by appropriately configuring:

- PMC's CONFIG[LMAUTOEN] field
- PMC's CONFIG[LM_EN] field

  For more information, see the descriptions of these fields in PMC's CONFIG register.

**NOTE**

You must write 1 to PMC's CONFIG[LM_EN] field before transtioning to faster clock frequencies irrespective of the setting of PMC's CONFIG[LMAUTOEN] field. This is because of the reduced clock speed when using the boot regulator.

### 40.3.1 Last-mile regulator with 1.5 V from an external source

**Table 209. Last-mile regulator with 1.5 V from an external source**

| Operating condition | Last-mile regulator operation |
|---|---|
| After POR | Boots on boot regulator and then automatically switches to the last-mile regulator |
| After destructive reset | Remains on last-mile regulator<br>**NOTE**<br>If the destructive reset source is low voltage reset on 1.1 V then switchback happens from last-mile to boot regulator for boot. |
| After functional reset | Remains on last-mile regulator |
| After PMC's LVSC[LVD15S] field becomes 1 | Switches, automatically, to the boot regulator to configure clocks for slow speed |

### 40.3.2 Last-mile regulator using a BJT

**Table 210. Last-mile regulator using a BJT**

| Operating condition | Last-mile regulator operation |
|---|---|
| After POR | Boots on boot regulator; switches to the last-mile regulator post reset when the Cortex-M7 core configures the software (post-secure boot) on FIRC (100 ms) |
| After destructive reset | Switches to boot regulator to check reset propagation delay |
| After functional reset | Remains on last-mile regulator |
| After PMC's LVSC[LVD15S] field becomes 1 | Switches, automatically, to boot regulator to configure clocks for slow speed |

## 40.4 Standby mode entry sequence

The Standby mode entry sequence includes three phases of operation:

- Standby mode entry configuration phase or software Standby mode entry sequence
- Standby mode entry handshake phase or hardware Standby mode entry sequence
- Standby mode entry or PMC Standby mode entry

**NOTE**

The Standby mode entry sequence described in this section is the only supported sequence. Contact NXP support if you require an alternate Standby mode entry sequence.

### 40.4.1 Software Standby mode entry sequence

The Standby mode entry sequence discusses chip configuration described in the sections that follow.

Before entering the software Standby mode sequence, the system clock source must be changed to FIRC at 48 MHz because PLLDIG is not available in Standby mode. In this mode, all clock sources can be optionally disabled (including FIRC, which results

in a no-clock, low-power consumption mode). You could use FXOSC, if enabled, when the 2.5 V supply is available by appropriate configuration of PMC's CONFIG[LPM25EN].

The software Standby mode entry sequence consists of four steps:

1. SW1: Module shutdown process
2. SW2: Application core shutdown process
3. SW3: Flash memory low-power handshake and PMC last-mile regulator control
4. SW4: Main core shutdown process

These processes are described in detail in the sections that follow. See Figure 151 that shows the relationship between these four steps in a flow diagram.

#### 40.4.1.1 SW1: Module shutdown process

I/O and module configuration for Standby mode discusses the procedure to configure I/O and the chip modules for Standby mode.

The entry sequence for this mode includes module clock disabling steps (see the "Clocking" chapter for module clock turn on and turn off processes). You must use MC_ME's PRTN*n*_COFB*m*_CLKEN[REQ*p*] fields to enable or disable module clocks.

##### 40.4.1.1.1 Disabling modules

Disable modules by configuring the appropriate fields in their registers for Standby mode operation. See specific module chapters for more information.

The Standby mode entry sequence includes the module clock disabling step, with which you can disable the modules that you do not need for Standby mode operation.

The sequence of disabling modules is shown in I/O and module configuration for Standby mode.

**NOTE**

While enabling or disabling the modules, you must verify that the module is disabled when you read MC_ME's PRTNn_COFBm_STAT register and the module disable field, if applicable. In case of a discrepancy, you must perform proper diagnostic steps.

You must clear the I/O controls for the pads that you do not require in Standby mode (OBE, IBE, and so on). This avoids any unwanted pad keeping settings. See Pad keeping for more information on the chip pad keeping process.

For any standby wake source, if an interrupt occurs it must be disabled before entering into standby and only the wake up event of that source must be enabled. This is to avoid any SW conflict in the interrupt handling for multi application core cases.

The MC_ME's PRTN*n*_COFB*m*_STAT register indicates the status of peripheral clock enable or disable. It may take up to three clock cycles for MC_ME's PRTN*n*_COFB*m*_STAT register to update after MC_ME's PRTN*n*_COFB*m*_CLKEN register is updated.

Once modules are disabled by following above steps:

- Switch to FIRC as the system clock
- Disable FXOSC and wait for clock status
- Configure standby entry

#### 40.4.1.1.2 I/O and module configuration for Standby mode

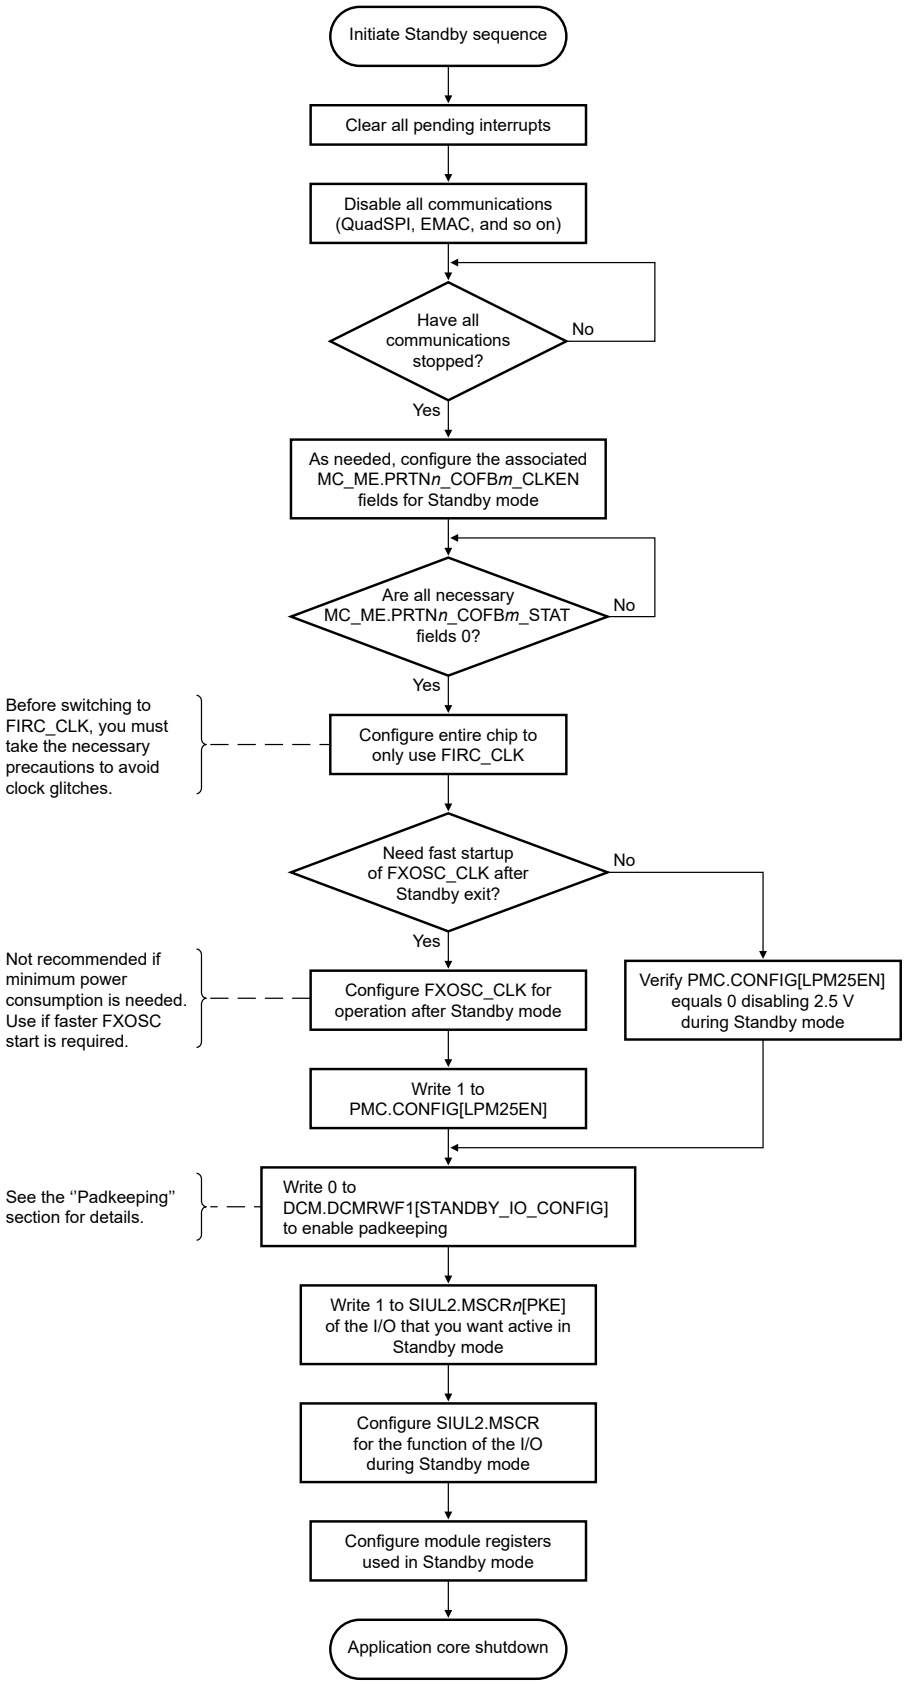

**Figure 152. I/O and module configuration for Standby mode**

#### 40.4.1.2 SW2: Application core shutdown process

The application cores(s) execute a WFI (as opposed to the main core running the Standby mode entry sequence). See the section "Application core shutdown" in the MC_ME chapter for more information.

The main core configuration (programming valid core ID and enabling standby entry process) and wake-up source configuration must also be set in SW2, so that SW4 contains only the main core WFI execution.

#### 40.4.1.3 SW3: Flash memory low-power handshake and PMC last-mile regulator

In this process, you execute a flash memory low-power handshake and disable the PMC last-mile regulator by executing the procedures indicated in Figure 153 and Figure 154 .

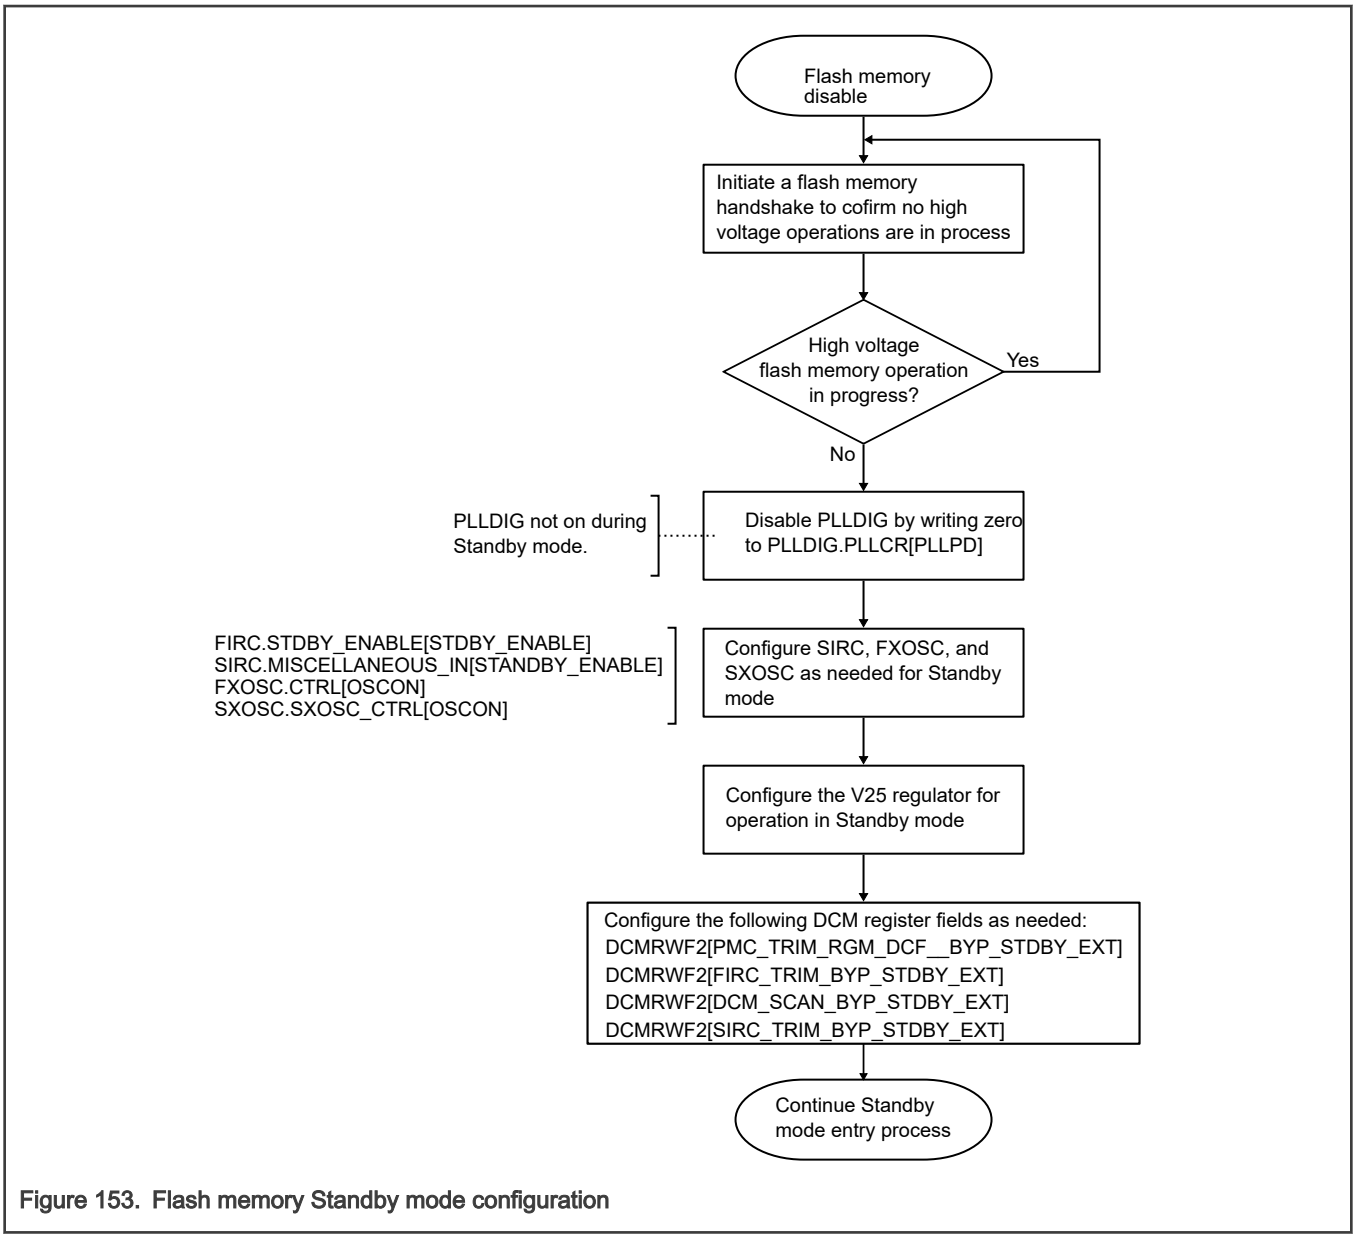

**Figure 153. Flash memory Standby mode configuration**

**NOTE**

Disable the last-mile regulator according to the Last-mile regulator disable sequence (not applicable for MCXE315, MCXE316, and MCXE317).

#### 40.4.1.3.1 Last-mile regulator disable sequence (not applicable for MCXE315, MCXE316, and MCXE317)

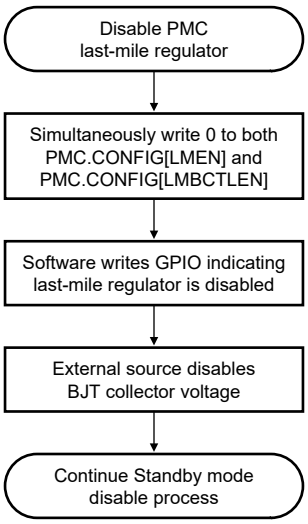

**Figure 154. Last-mile regulator disable sequence**

When exiting Standby mode, the 1.1 V capacitor is charging. You can charge the 1.5 V capacitor during or after the 1.1 V capacitor is charged. If you charge the 1.5 V capacitor sequentially after the 1.1 V capacitor, you will need additional time to complete the overall charging process.

Leaving PMCs CTRL[LMBCTLEN] = 1 saves time when exiting Standby mode and does not draw any additional current during this mode.

### 40.4.1.4 SW4: Main core shutdown process

For information on this process, see these in the "Mode Entry Module (MC_ME)" chapter:

- Figure "Standby entry sequence along with main core shutdown"
- Section "Main core shutdown and Standby mode entry"

You must configure WKPU before disabling interrupts to avoid missing any events as shown in the Standby entry sequence along with main core shutdown flowchart in the MC_ME chapter. You must program WKPU, disable interrupts, and configure MC_ME's Standby mode entry in SW1 (see SW1: Module shutdown process for more information). In SW4, you must perform only the main-core WFI execution.

## 40.4.2 Hardware Standby mode entry sequence

The hardware Standby mode entry sequence consists of handshaking between MC_PCU and MC_ME occuring after Software Standby mode entry sequence completes. The FSM in MC_PCU performs these steps automatically and does not require your intervention (see Power sequence FSM in the Power Control Unit (MC_PCU) chapter for more information).

During the MC_ME and PCU phase, MC_ME and PCU:

- Enable FIRC
- Deassert isolation
- Deassert reset to PD1

## 40.4.3 PMC Standby mode entry

The PMC Standby mode entry sequence starts after Hardware Standby mode entry sequence completes, and consists of these phases:

1. Standby mode entry acknowledgment and initiation of an internal low-power process on receiving Standby mode entry request
2. Disabling of the boot regulator within the PMC low-power process (for MCXE31B)
3. Disabling of the V25 regulator and the FPM LVR monitors
4. Disabling of the V25 regulator (oscillator and flash memory supply) and the LPM monitor, unless it is enabled during Standby mode (see PMC's CONFIG[LPM25EN] field in the "Power management controller (PMC)" chapter for more information)
5. Disabling of the VDD_HV_B LPM monitors (not applicable for MCXE315, MCXE316, and MCXE317)

During PMC phase, after receiving an LPM request, PMC:

- Deasserts FPM ready signal
- Starts the courtesy timer
- When the courtesy timer expires, PMC:
  - Disables the V25 regulator
  - Disables the HP reference blocks
  - Disables the external NMOS
  - Opens the PD0 switch
  - Enables a core LPM request
  - If selected, enables a 2.5 V LPM request
  - Disengages FPM monitors
  - Disables the VDD_HV_B LPM monitor, if present and deselected
- Waits for LPM signal deassertion

## 40.5 Chip status at the end of Standby mode entry sequence

After PMC Standby mode entry completes, the chip completes Standby mode entry as follows:

1. Configures Standby domain peripherals according to SW1 (see SW1: Module shutdown process).
2. Enables pad keeping on pins as described in SW1 (see SW1: Module shutdown process). See Pad keeping for other details.
3. Powers down all memory types except Standby RAM (in SRAM0).
   - The V25 regulator can remain on during Standby mode. However, for maximum power savings, it must remain off in this mode.
4. Isolates Standby and Run domains from each other:
   - Standby domain is functional.
   - Run domain is held in reset.
5. Configures the system clock (FIRC_CLK or PLL_PHI*n*_CLK, depending on their configuration) and other clock sources according to SW3 (see Figure 153 for the procedure details).

   The cores are off and in the Standby domain.
6. Turns off the boot (not applicable for MCXE315, MCXE316, and MCXE317) and FPM regulators
7. Waits for a wake-up event to initiate recovery from Standby mode.

## 40.6 Chip operation in Standby mode

This chip supports the following functionalities in Standby mode:

- STANDBY_RAM content retention during Standby mode.
- Wake-up from up to 60 digital inputs (for details, see the signals WKUP[*n*] functions of WKPU module in the IOMUX file attached to this document). The section WKPU configuration on the chip in the "Wakeup Unit (WKPU)" chapter shows mapping of the wake-up sources.
- Wake-up from up to 16 analog inputs through the Trigger mode functionality (see the signals CMP*n*_IN*m* functions of CMP*n* modules in the IOMUX file attached to this document).
- Wake-up from on-chip timers:
  - RTI (function of PIT[0])
  - SWT0
  - RTC
- Ability to configure the chip clocking modules to optionally enable or disable in Standby mode (FIRC, SXOSC, FXOSC, and SIRC).

## 40.7 Standby mode exit

This chip supports Standby mode exit from a wake-up, functional reset, or destructive reset event. The sources that cause chip Standby mode exit are:

- MC_RGM functional reset event
- MC_RGM destructive reset event
- WKPU wake-up events, WKPU[0]–WKPU[63]. See the WKPU chapter for more information.

After Standby mode exit, the following events occur (for more information, see "Power sequence FSM" in the MC_PCU chapter for MC_PCU FSM transitions during entry into and exit from Standby mode):

1. A wake-up event arrives.
2. FIRC starts powering up (if disabled in Standby mode).
3. PMC starts the transition process to FPM (for example, enables the last-mile regulator and provides V11_RUN supply to the chip).
4. MC_PCU removes the isolation between Run and Standby domains.
5. Run domain reset deasserts (asserts on Standby mode entry) and the chip undergoes a functional reset exit sequence for this domain.
6. The chip enters Run mode of operation.

**NOTE**

A reset event during standby results in pad controls to get reset. Thereby, resulting in unpredictable toggling at GPIO.

### 40.7.1 Faster Standby mode exit

The chip supports an optional configuration for faster recovery from Standby mode on the expense of a higher capacitor recharging current. See the CONFIG[FASTREC] field description in the PMC chapter for more information on faster PMC recovery from Standby mode.

This chip supports an optional feature that bypasses:

- FIRC trimming

- PMC trimming
- DCM scanning

To use the bypass operation, write 1 to DCM.DCMRWF2[5], DCM.DCMRWF2[4], and DCM.DCMRWF2[3] respectively before Standby mode entry. This results in a considerable reduction in Standby mode exit duration. The trim values are retained across Standby mode and bypassing these values does not cause any impact. Even if the FIRC trimming is bypassed, the FIRC must be at 48 MHz before entering Standby mode.

Configuration to achieve the tMODE_STDBYEXIT_FAST as specified in Datasheet

- DCMRWF2[PMC_TRIM_RGM_DCF__BYP_STDBY_EXT] = 1
- DCMRWF2[FIRC_TRIM_BYP_STDBY_EXT] = 1
- DCMRWF2[DCM_SCAN_BYP_STDBY_EXT] = 1

### 40.7.2 Last-mile regulator enable sequence (not applicable for MCXE315, MCXE316, and MCXE317)

After Standby mode exit, you must re-enable the PMC last-mile regulator before transitioning to faster clock frequencies. Figure 155 shows the last-mile regulator enable sequence part of the Standby mode exit process.

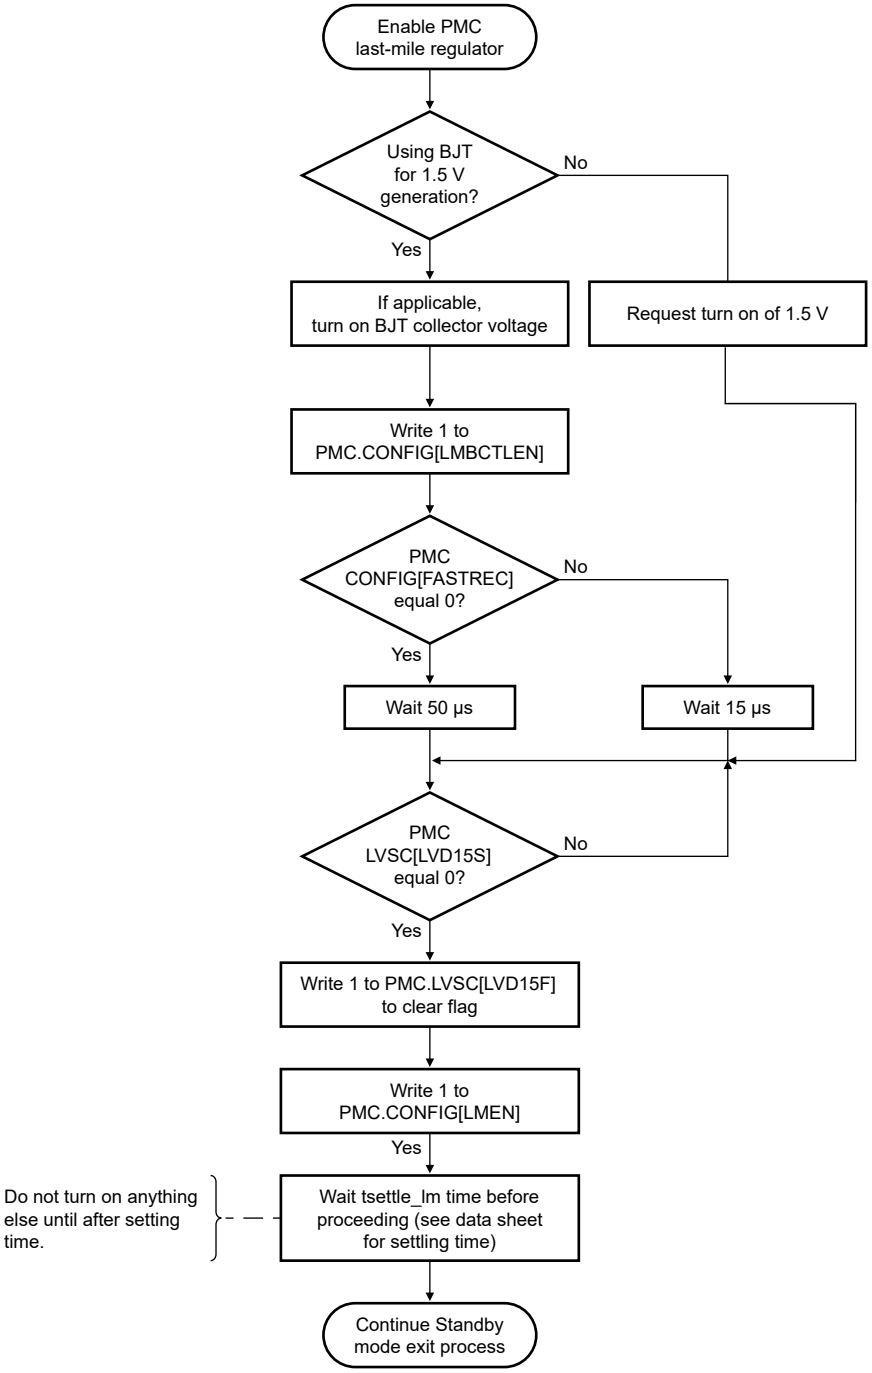

**Figure 155. Last-mile regulator enable sequence**

## 40.8 Chip power domain partitioning

These are the modules in the Standby domain. For more information, see "Peripheral reset status" in the "Reset Overview" chapter.

- FIRC
- FXOSC
- MC_RGM

- DCM
- WKPU
- PIT_0 (RTI)
- LPCMP_[0:2]
- PMC
- SIRC
- SXOSC
- RTC
- SWT_0
- DCF clients

### 40.8.1 Module power status

**Table 211. Module power status**

| PD0 contents | MCXE31B | MCXE317 | MCXE315/MCXE316 |
|---|---|---|---|
| External Pin wakeups | Minimum 60 | Minimum 60 | 33 on 100MQFP & 12 on 48LQFP |
| RTC_API | Yes | Yes | Yes |
| LPCMP0 | Yes | Yes | Yes |
| LPCMP1 | Yes | Yes | No |
| LPCMP2 | Yes | No | No |
| SWT0 | Yes | Yes | Yes |

SWT0 (Cortex-M7_0) resides in the Standby domain and supports a configurable hardware-based timer operation during Standby mode depending on the configuration of SWTs.

All clock sources (excpet PLLDIG) are available in Standby mode. SIRC is present in the Standby domain for low-power wake-up, but can be enabled.

**NOTE**

This chip does not support Stop and Wait modes. The only low-power mode it supports is Standby.

## 40.9 Pad keeping

Pad keeping allows you to return to I/O Run mode configuration settings after using I/O during Standby mode. It eliminates I/O reconfiguration in Run mode.

### 40.9.1 Pad keeping on Run domain pins

The process of entering Standby mode ensures that the chip maintains the Run domain configuration settings. Software Standby mode entry sequence specifies that you must write 0 to DCM's DCMRWF1[STANDBY_IO_CONFIG] before configuring I/O pad keeping. You could consider DCM's DCMRWF1[STANDBY_IO_CONFIG] field as a global enable for all pad keeping purposes during Standby mode. If you are unable to write to this field as described, pad keeping works as explained in this chapter, during Standby mode.

After the chip exits Standby mode, you must write 1 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field (see "Chip specific register descriptions" in the DCM chapter). Writing 1 to this field disables pad keeping and places chip I/O according to its Run mode configuration.

### 40.9.2 Pad keeping on Standby domain pins

The Standby domain pads can have pad keeping enabled or disabled based on pad availability in Standby mode. Writing to SIUL2's MSCR*n*[PKE] field configures Standby mode pad keeping on a selected I/O.

Ensure that DCM's DCMRWF1[STANDBY_IO_CONFIG] = 0 before Standby mode entry for pad keeping on Standby domain pads. Write 0 to the field in case its value is not 0 already.

If a pad is not required during Standby mode, the corresponding MSCR*n*[PKE] field in SIUL2 must be 0.

### 40.9.3 Pad keeping configuration procedure

This procedure specifies how to enable an I/O for pad keeping:

1. Configure SIUL2's MSCR*n* register to control the pad state prior to Standby mode entry (for example, writing 0 to SIUL2's MSCR*n*[OBE], MSCR*n*[IBE], and MSCR[PUE] fields tristates the corresponding I/O).
2. Configure SIUL2's MSCR*n*[PKE] field as needed for an I/O pad keeping state during Standby mode.
3. Write 0 to DCM's DCMRWF1[STANDBY_IO_CONFIG].

   The application core executes WFI, and Standby mode sequence starts.
4. Write 1 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field on Standby mode exit to disable pad keeping. This configures SIUL2 according to its previous settings.

If you write 1 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field before entering Standby mode, the isolation removal hardware removes pad keeping on Standby mode exit. This (writing 1 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field before Standby mode entry) is useful in case of low-power debug because enabling pad keeping does not allow low-power debug protocol to work properly (because the TDO pad is padkept). For low-power debug, you must write 1 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field prior to Standby mode entry.

In case of Standby mode exit by reset, the pad keeping of the reset pin is removed when the chip is reset on Standby mode wake up. See the "GPIO padkeeping enable" signal in Figure 157. The signal corresponds to wake-up via reset event case.

### 40.9.4 Pad keeping waveforms

### 40.9.4.1 Pad keeping when the chip wakes up from Standby mode via an interrupt event

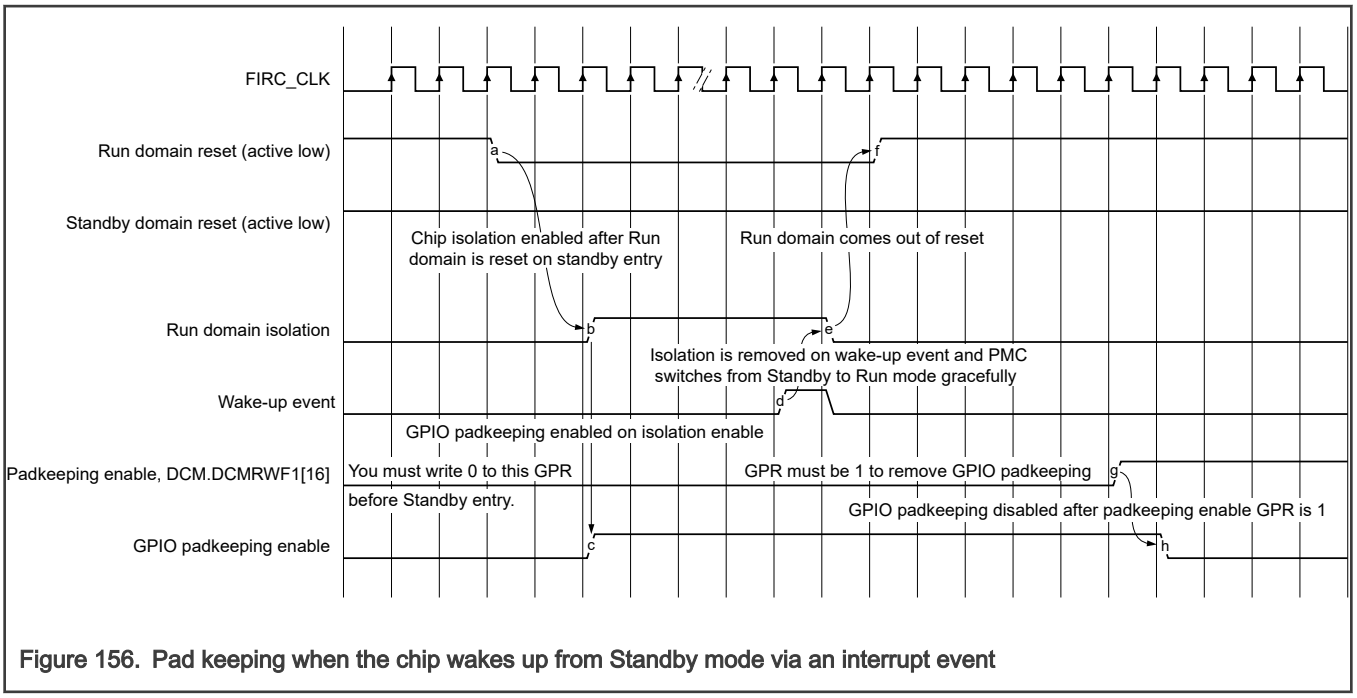

**Figure 156. Pad keeping when the chip wakes up from Standby mode via an interrupt event**

### 40.9.4.2 Pad keeping when the chip wakes up from Standby mode via reset

If the chip exits Standby mode via reset, the reset pad keeping is removed when the chip resets after Standby-mode wake-up. See the figure's "GPIO padkeeping enable" waveform corresponding to wake-up via a reset event.

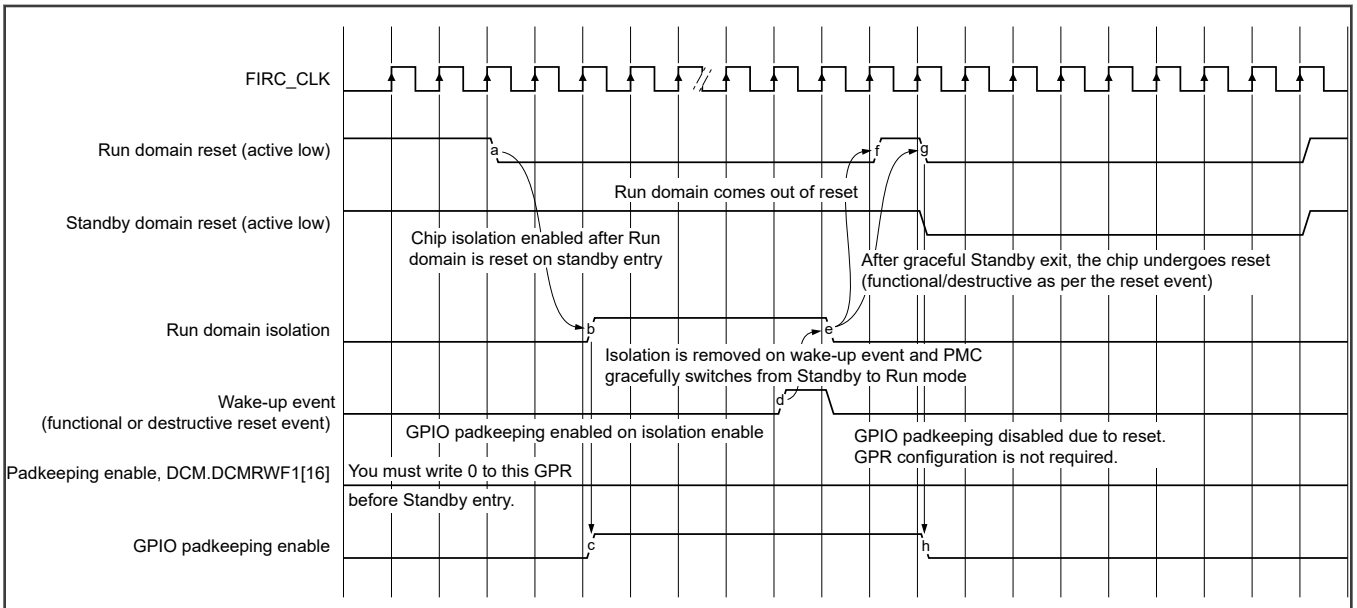

**Figure 157. Pad keeping when the chip wakes up from Standby mode via reset**

## 40.9.5 SIUL2's fields for actively-driven pins in Standby mode

If you use a WKPU pin as a wake-up input, perform these operations on SIUL2's fields:

1. Write 1 to MSCR*x*[IBE].

2. Program MSCR*x*[PUE] and MSCR*x*[PUS] according to the use case.
3. Write 0 to MSCR*x*[PKE].

For the GPIO pins that are driven to high impedance during Standby mode:

1. Write 0 to DCM's DCMRWF1[STANDBY_IO_CONFIG] field.
2. Write 0 to SIUL2's MSCR*x*[SSS] field (GPIO mode).
3. Write 0 to SIUL2's MSCR*x*[IBE] and MSCR*x*[OBE] fields.

Some of the pins are, by default, actively driven in Standby mode. If these pins retain a static value throughout the mode, program the corresponding MSCR*x*[PKE] bits individually.

This table shows the list of pins available in Standby mode along with the functions they perform.

**Table 212. Active pins in Standby mode**

| Pin[1] | Function |
|---|---|
| GPIO_4 | CMP0_OUT |
| GPIO_5 | RESET_b |
| GPIO_9 | CMP2_OUT |
| GPIO_11 | CMP0_RRT |
| GPIO_12 | CLKOUT_STANDBY; CMP1_OUT |

## 40.10 Glossary

**Application core** Core apart from the main core

**Boot regulator** The on chip 1.1 V regulator that is active during startup and entry and exit from Standby mode

**FSM** Finite state machine

**FPM** Full-power mode (Run mode)—uses the last-mile regulator and 1.5 V source to generate the 1.1 V core logic supply during a full-power operation (V11_RUN)

**LPM** Low-power mode (Standby mode)—uses the low-power regulator to generate the 1.1 V core logic supply during low-power operation (V11_STANDBY)

| | |
|---|---|
| **LVR** | Low voltage reset |
| **Main core** | Core initiating the chip Standby mode request (for example, the core corresponding to the "core index" in MC_ME's MAIN_COREID register) |
| **Pad keeping** | Maintains I/O pad configuration during Standby mode, if enabled |
| **V11_STANDBY** | Core logic and clock sources, low-voltage supply to Standby domain |
| **V11_RUN** | Low-voltage supply to Run domain |
| **V15** | High-current input for core or logic supply from either an external BJT or from direct 1.5 V external supply |
| **V25** | Flash memory, FXOSC, and PLLDIG high-voltage supply |
| **VDDA_ADC** | ADC supply voltage |
| **VREFH** | ADC high-voltage reference supply |
| **VREFL** | ADC low-voltage reference supply |
| **VSS** | Core logic ground supply |
| **VDD_HV_A** | Main I/O voltage supply (5 V or 3.3 V) |
| **VDD_HV_B** | Other I/O domain voltage supply (5 V or 3.3 V) |
| **VRC_CTRL** | PMC voltage regulator control output using the BJT option to generate a 1.5 V supply |
| **WFI** | Wait for interrupt software instruction |

# Chapter 41
# Power Management Controller (PMC for MCXE31B)

## 41.1 Introduction

PMC is the power management controller for the MCXE31x family of microcontrollers. It provides multiple power options to allow you to optimize power consumption for the level of functionality needed. It includes internal voltage regulators, POR, and the integrated low/high voltage detect system with reset (brown-out) capability. The voltage regulator requires a 3.3 V or 5 V input to generate all the required secondary supplies.

## 41.2 Features

PMC includes the following features:

- Combination of internal and external voltage regulator options, offering RUN and Standby modes
- Active POR providing brown-out detect
- LVR for all system-relevant power domains
- LVD and HVD as indication for software

## 41.3 Modes of operation

PMC provides two basic modes of operation for the voltage regulators and monitors:

- FPM, which is used on chip-level in RUN modes: For high-current consumption
- LPM, which is used on chip-level for Standby modes: For low-current consumption

## 41.4 Block diagram

The following figure shows the block diagram for this module.

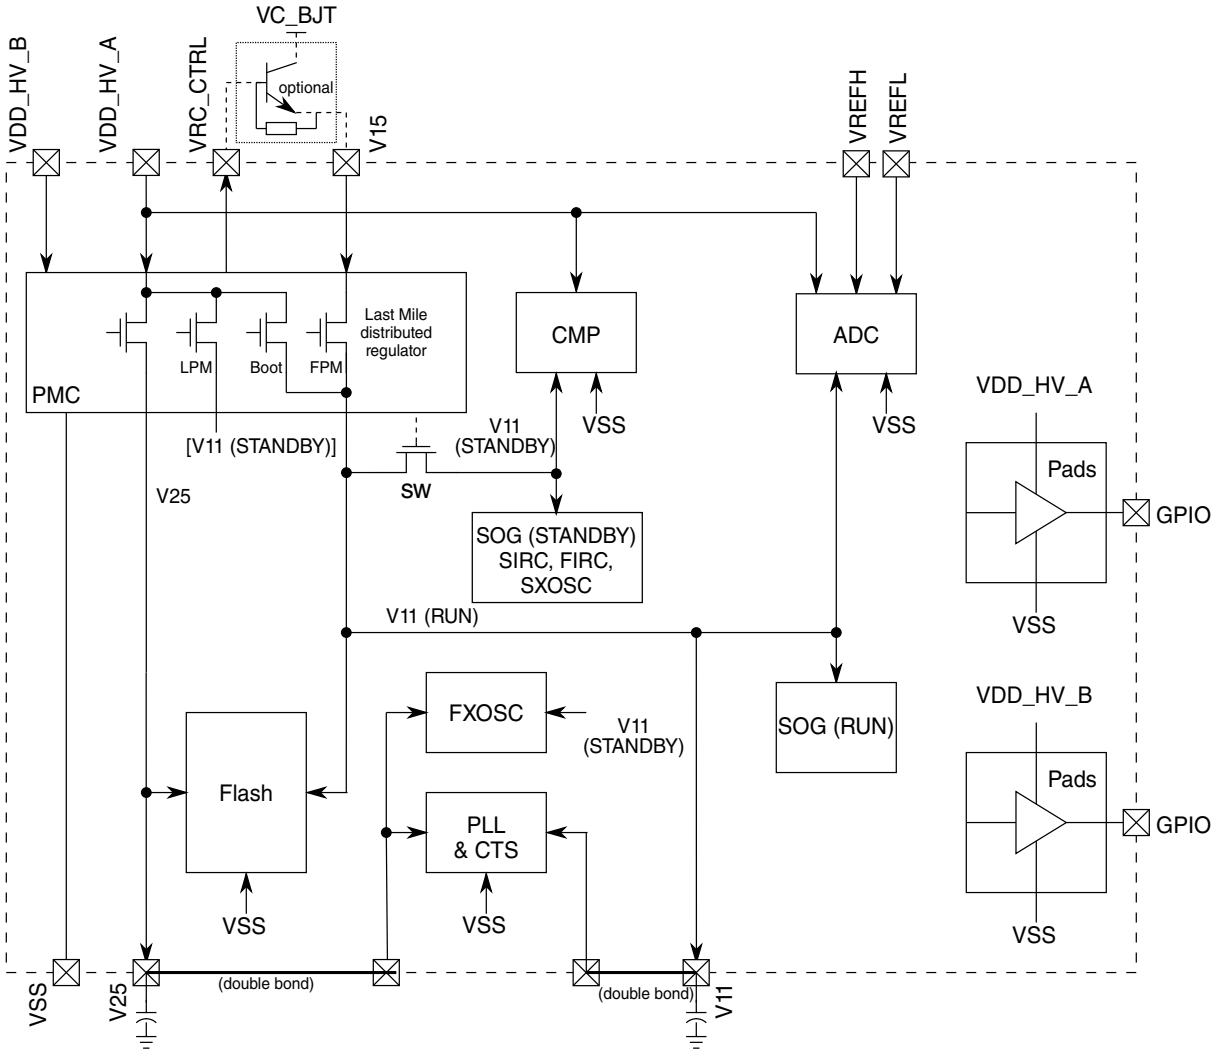

Figure 158. PMC block diagram

## 41.5 Signals

This table describes the PMC module signals.

Table 213. Signal Description

| Signal | I/O | Description |
|---|---|---|
| VDD_HV_A | Supply input | This is the primary high-voltage supply input to PMC. VDD_HV_A is used for the PMC internal precision references. After the VDD_HV_A domain is powered up, it must be kept powered at all times of operation (FPM and LPM). |
| VDD_HV_B[1] | Supply input | This is the secondary high-voltage supply input supervised by the PMC. After the VDD_HV_B domain is powered up, it must be kept powered at all times of operation (FPM and LPM). |

*Table continues on the next page...*

Table 213. Signal Description (continued)

| Signal | I/O | Description |
|---|---|---|
| V25 | Supply output | V25 power supply domain is driven by a fully integrated low-dropout linear voltage regulator. It supplies the Flash memory and (via a double bond) the clock modules. |
| V15[1] | Supply input | This is the high-current input for core/logic supply that can be fed by an external BJT or another source. |
| VRC_CTRL | Output | VRC_CTRL connects to the base of external BJT, if this option is used to generate V15. |
| V11 | Supply output | V11 is the core/logic supply. It is driven by a fully integrated low-dropout linear voltage regulator. |
| VSS | Ground | VSS must be grounded. All VSS Pins need to be externally connected to the same ground node. |

1. VDD_HV_B and V15 not present in MCXE315/MCXE316 and MCXE317.

## 41.6 Functional description

The following sections describe functional details of the PMC.

### 41.6.1 Reset

The POR and all LVRs are combined into one single MCU POR.

After an MCU POR event, it can be determined which power domain caused it, by reading in the PMC_LVSC register, the POR flag, and LVR flags.

After an initial power ramp up of the MCU in the PMC_LVSC register, the POR flag and the LVR flags are all set to 1. The Go/Nogo flags have an arbitrary value.

**NOTE**

After an initial power ramp up, all flags in the LVSC register must be cleared (by writing 0xFFFFFFFF to the LVSC register).

Because the flags are sticky bits, it is required to clear them before usage. So, in case of an unexpected MCU POR, the source of the problem can be tracked and debugged by reading the flags in the LVSC register.

### 41.6.2 Interrupts

PMC includes two interrupt sources:

- HVD interrupt: It combines all HVD monitors into one interrupt source. Interrupt enable is the HVDIE field in the CONFIG register. See the PMC Configuration Register (CONFIG) and Low Voltage Status and Control Register (LVSC) registers for details.
- LVD interrupt: It combines the LVD15 and LVD5A monitors into one interrupt source. Interrupt enable is the LVDIE field in the CONFIG register. See the CONFIG and LVSC registers for details.

## 41.7 PMC register descriptions

### 41.7.1 PMC memory map

This section includes the PMC module memory map and detailed descriptions for all the registers.

PMC base address: 402E_8000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Low Voltage Status and Control Register (LVSC) | 32 | RW | See section |
| 4h | PMC Configuration Register (CONFIG) | 32 | RW | See section |
| Ch | Version ID register (VERID) | 32 | R | 0200_0001h |

## 41.7.2 Low Voltage Status and Control Register (LVSC)

### Offset

| Register | Offset |
|---|---|
| LVSC | 0h |

### Function

This register contains status and control bits to support the low-voltage reset and low- or high-voltage detect function. When the PMC is in LPM, the low- or high-voltage detect systems are disabled.

**NOTE**

For all flags that are not affected by reset (POR flag, all LVR flags, all GNG flags), in case a reset occurs at the same time while trying to clear the flags (by writing 1), the flag value is not defined appropriately. In this case, you need to clear the flag again after exit from reset.

### 41.7.3 PMC Configuration Register (CONFIG)

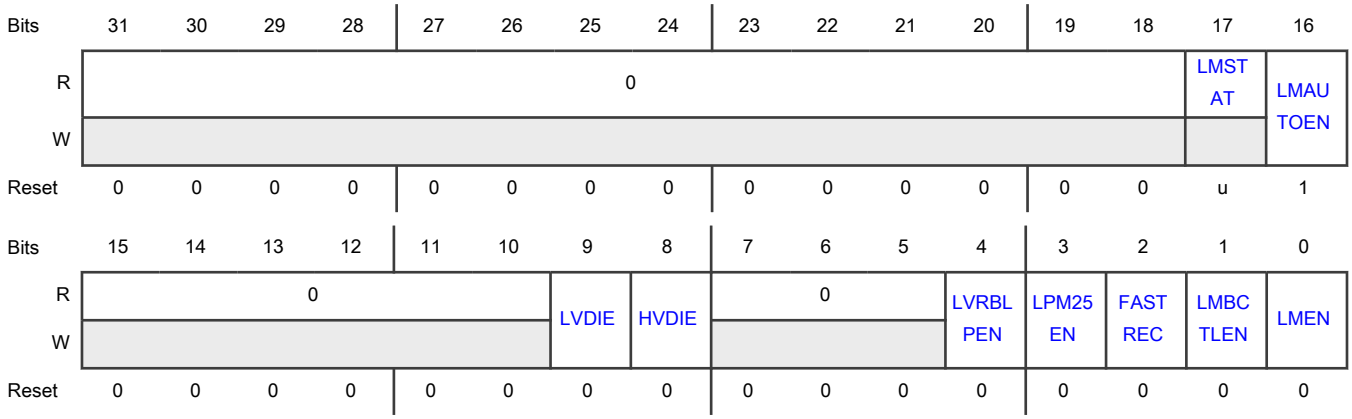
**Offset**

| Register | Offset |
|---|---|
| CONFIG | 4h |

**Function**

If the Last Mile Regulator option is not available on your device ( Version ID register (VERID) register: LMFEAT=0), then the bits LMEN, LMBCTLEN, LMAUTOEN and LMSTAT fields can not be written and read always 0.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-18<br>— | Reserved |
| 17<br>LMSTAT | Last Mile regulator status bit<br>This bits reflects the current status of the Last Mile regulator. This information is required as when auto turn over feature is enabled (LMAUTOEN=1) the PMC will switch automatically between Boot regulator and Last Mile regulator depending on the V15 status (LVD15S).<br>0b - Last Mile Regulator is off<br>1b - Last Mile Regulator is on |
| 16<br>LMAUTOEN | Last Mile regulator auto turn over bit<br>Enables to turn over automatically from Boot Regulator Mode to Last Mile regulator mode and vice versa depending on the V15 voltage status (LVD15S). As long as LMEN=0 software must make sure that the system clock is on FIRC clock or slower. To use higher clock speed software must set LMEN=1.<br>0b - Auto turnover disabled<br>1b - Auto turnover enabled |
| 15-10<br>— | Reserved |
| 9<br>LVDIE | Low voltage detect interrupt enable<br>Enables hardware interrupt requests if any of the following flags is set: LVD5AF, LVD15F. LVD interrupt must be disabled before going into LPM.<br>0b - LVD hardware interrupt is disabled (use polling).<br>1b - Request an LVD hardware interrupt when LVDA5F=1 or LVD15F=1. |
| 8<br>HVDIE | High voltage detect interrupt enable |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | Enables hardware interrupt requests if any of the following flags is set: HVDAF, HVDBF, HVD25F, HVD11F.<br>0b - HVD hardware interrupt is disabled (use polling).<br>1b - Request an HVD hardware interrupt when HVDAF=1, HVDBF=1, HVD25F=1, or HVD11F=1. |
| 7-5<br>— | Reserved |
| 4<br>LVRBLPEN | LVRBLP enable bit during LPM<br>Controls whether the low-voltage reset detection (LVRBLP) on the VDD_HV_B power domain is active or inactive in LPM<br>0b - Low-voltage reset detection is disabled in LPM.<br>1b - Low-voltage reset detection is enabled in LPM. |
| 3<br>LPM25EN | V25 domain enable bit during LPM<br>Controls whether the V25 regulator and low-voltage reset detection (LVR25LP) are active or inactive in LPM<br>0b - V25 regulator and LVR25LP are disabled in LPM.<br>1b - V25 regulator and LVR25LP are enabled in LPM. |
| 2<br>FASTREC | Fast recovery from LPM enable bit<br>Controls the recovery time from LPM to FPM. At recovery from LPM, all the tank capacitors from the secondary supplies have to be recharged. This causes a high-current demand, which might not be met by the supply driving the VDD_HV_A primary domain. When selecting the fast recovery time, the current for recharging is approximately three times higher than that for FASTREC=0. The application must determine from the drive capability of the external VDD_HV_A regulator, the size of tank caps on the secondary supply pins and the selected recovery time if this is sufficient to start up from LPM in time.<br>0b - Normal recovery time from LPM<br>1b - Fast recovery time from LPM |
| 1<br>LMBCTLEN | Last Mile regulator base control enable bit<br>This field must be set to 1 if external BJT between VDD_HV_A and V15 is used on the PCB. The base of this BJT must be connected to the VRC_CTRL pin and is controlled by the PMC to regulate a voltage of 1.5V on V15 pin. After setting LMBCTLEN=1 the software has to wait for 15us (FASTREC=1) respectively 50us (FASTREC=0) before polling LVD15S=0 and then setting LMEN=1. This respects the softstart time of the V15 regulator. If LMAUTOEN=1 then LMBCTLEN can be left enabled when going into LPM, the hardware will turn the regulator off and back on automatically after recovery from LPM.<br>0b - External BCTL regulator for V15 disabled<br>1b - External BCTL regulator for V15 enabled |
| 0<br>LMEN | Last Mile regulator enable bit |

*Table continues on the next page...*

*Table continued from the previous page...*

| Field | Function |
|---|---|
| | Enables the Last Mile regulator, which regulates an external 1.5V voltage on V15 down to the core and logic supply (V11 power domain), which is typically 1.1V. Setting LMEN=1 hands over the V11 voltage generation from the Boot regulator to the Last Mile regulator. The software must ensure that before enabling the Last Mile regulator, the voltage on V15 is sufficiently high as indicated by the LVD15S status field (LVD15S=0). To use external BJT between VDD_HV_A and V15, the LMBCTLEN field must be set before the LMEN field, and the software must wait until 1.5V is up (LVD15S=0). If LMAUTOEN=0 then to disable the Last Mile regulator, LMEN and LMBCTLEN must be cleared simultaneously (single register write). The software must disable (LMEN=0) the Last Mile regulator before going into LPM. After setting LMEN=1, software must wait a minimum time of 1.5us before changing clock rate.<br>0b - Last Mile regulator is disabled.<br>1b - Last Mile regulator is enabled. |

## 41.7.4 Version ID register (VERID)

### Offset

| Register | Offset |
|---|---|
| VERID | Ch |

### Function

This register returns the major and minor version numbers of hardware implementation.

| **XOSC** | External crystal oscillator |

# Chapter 42
# Power Management Controller (PMC for MCXE315, MCXE316, and MCXE317)

## 42.1 Overview

PMC provides multiple power options to allow you to optimize power consumption for the appropriate level of functionality. It includes:

- Internal voltage regulators
- POR
- Integrated low and high voltage detection system with reset (brownout) capability

The voltage regulator requires a 3.3 V or 5 V input to generate all the required secondary supplies.

### 42.1.1 Block diagram

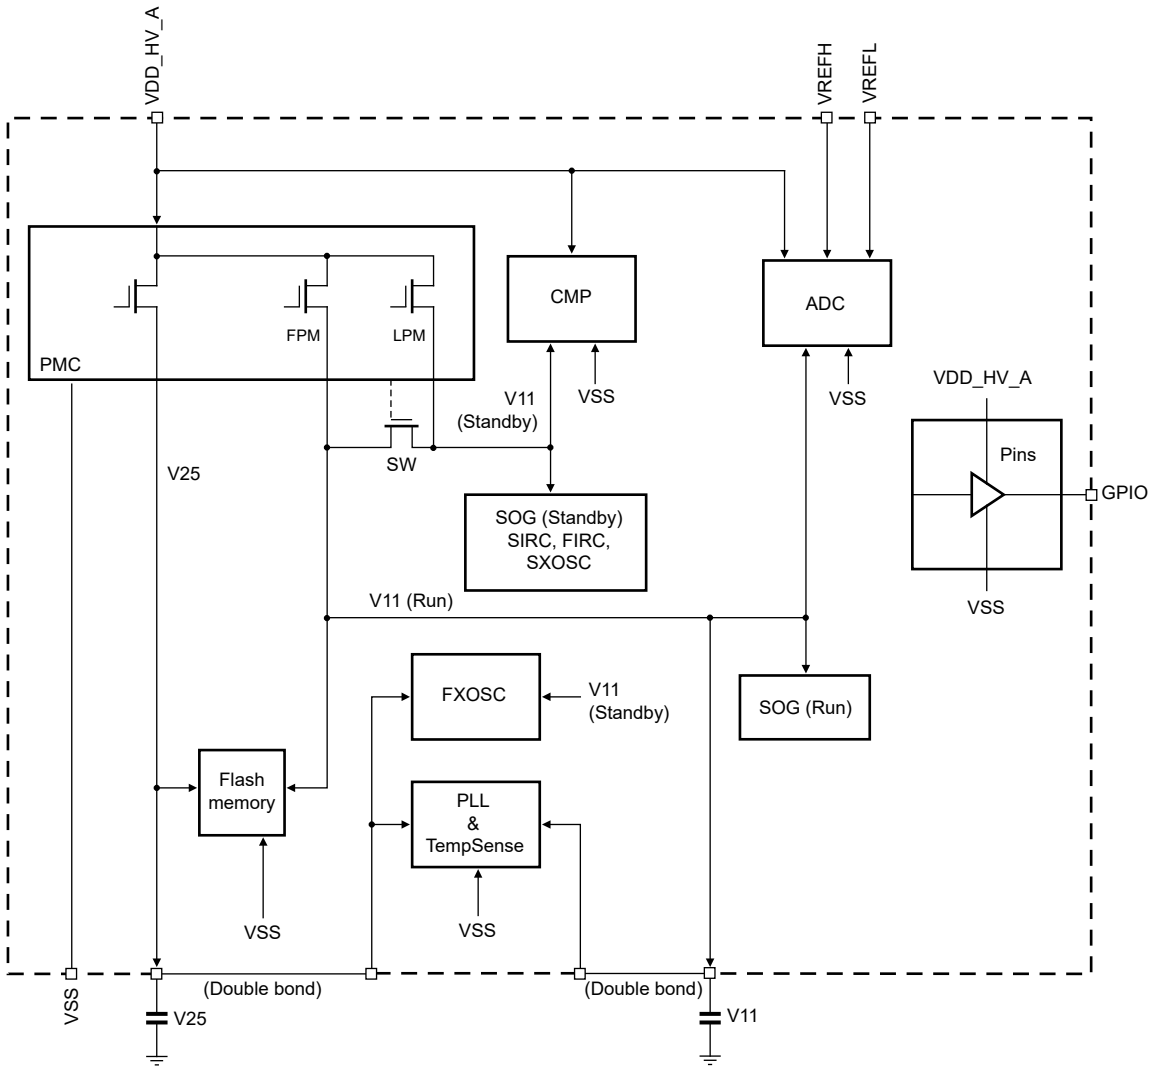

Figure 159. Block diagram

### 42.1.2 Features

- A combination of internal and external voltage regulator options, offering Run and Standby modes
- Active POR, providing brownout detect
- LVR for all system-relevant power domains
- Software-readable Low Voltage Status and Control register that contains flags that indicate low- or high-voltage conditions

## 42.2 Functional description

### 42.2.1 Modes of operation

PMC provides two basic modes of operation for voltage regulators and monitors:

- FPM supports chip run modes that have high current consumption.

- LPM supports chip standby modes that have low current consumption.

### 42.2.2 Reset

The POR and all LVRs combine into one single chip POR.

After a chip POR event, you can determine which power domain caused it by reading the PORF and LVR*x* flags in Low Voltage Status And Control (LVSC).

After an initial power ramp-up of the chip in LVSC, PMC sets the POR and LVR*x* flags. The go/no go flags have an arbitrary value.

**NOTE**

After an initial power ramp-up, you must clear all flags in LVSC by writing FFFF_FFFFh to that register.

Because the flags are sticky bits, you must clear them before using them. That way, if an unexpected chip POR occurs you can track and debug the source of the problem by reading the flags in LVSC.

### 42.2.3 Interrupts

PMC includes two interrupt sources:

- HVD interrupt: Combines all HVD monitors into one interrupt source. CONFIG[HVDIE] enables this interrupt. See PMC Configuration (CONFIG) and Low Voltage Status And Control (LVSC) for details.
- LVD interrupt: The LVD5A monitor is the only interrupt source. CONFIG[LVDIE] enables this interrupt. See PMC Configuration (CONFIG) and Low Voltage Status And Control (LVSC) for details.

## 42.3 Signals

**Table 214. Signals**

| Signal | Type | Description |
|---|---|---|
| VDD_HV_A | Supply input | The primary high-voltage supply input to PMC. VDD_HV_A is used for the PMC internal precision references. After the VDD_HV_A power domain is powered up, it must always be kept powered for both FPM and LPM. |
| V25 | Supply output | A fully integrated low-dropout linear voltage regulator drives the V25 power supply domain. V25 supplies the flash memory and (via a double bond) the clock modules. |
| V11 | Supply output | V11 is the core and logic supply. A fully integrated low-dropout linear voltage regulator drives V11. |
| VSS | Ground | VSS must be grounded. You must connect all VSS pins externally to the same ground node. |

## 42.4 PMC register descriptions

### 42.4.1 PMC memory map

DEFAULT_NICKNAME base address: 0h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Low Voltage Status And Control (LVSC) | 32 | RW | See section |
| 4h | PMC Configuration (CONFIG) | 32 | RW | 0000_0000h |
| Ch | Version ID (VERID) | 32 | R | 0300_0000h |

## 42.4.2 Low Voltage Status And Control (LVSC)

### Offset

| Register | Offset |
|---|---|
| LVSC | 0h |

### Function

Contains status and control fields that support the low-voltage reset and low- or high-voltage detect functions. When PMC is in LPM, the low- or high-voltage detect systems are disabled.

**NOTE**

For all flags that are not affected by reset (POR flag, all LVR flags, all GNG flags), if a reset occurs while trying to clear the flags (by writing 1), the flag value is not defined appropriately. In this case, you must clear the flag again after exiting from reset.

# Chapter 43
# Mode Entry Module (MC_ME)

## 43.1 Chip-specific MC_ME information

### 43.1.1 MC_ME modes

This chip implements these modes:

- Reset
- Run
- Standby

The chip always enters Run mode after exiting Reset mode wherein you can configure the chip to perform its computational and communication functions. In Run mode:

- The chip remains fully powered. The boot core is the only core enabled on Run entry.
- You can enable and disable application cores and peripherals as needed, based on functional and power requirements.
- You can configure the pins and self-test as needed. See "Self-Test programming sequence" section in the STCU2 chapter for the self-test programming sequence to be followed before initiating self-test, in which:
  - Pins are safe-stated.
  - No computational or communication activities are possible.
- The chip automatically enters Reset mode after self-test (BIST) is complete.

### 43.1.2 MC_ME partition mapping of cores and peripherals

MC_ME provides registers and interface signals to support multiple partitions. These MC_ME partitions are different from the chip's LBIST partitions described in the "Safety Overview" chapter. This chip has three MC_ME partitions:

- Partition 0: Contains application cores and the on/off-platform slots on AIPS_0 bridge
- Partition 1: Contains the on/off-platform slots on AIPS_1 bridge
- Partition 2: Contains the on/off-platform slots on AIPS_2 bridge

Table 215 and Table 216 specify the core and peripheral mapping on MC_ME partitions and their associated clock gating possiblities.

MC_ME also provides provisions to control the booting address for application cores, which can be configured to start from a nondefault address location by appropriately configuring PRTN*x*_CORE*n*_ADDR[ADDR].

### 43.1.3 Core clock gating

MC_ME has individual core-clock enable fields that gate the application core clocks, which can also be clock gated by executing Waiting for Interrupt (WFI).

You can enable the application cores by configuring the respective CCE fields. See Application core initialization process and Application core shutdown process for proper initialization and shutdown of application cores. There is no clock control for the ELE_HSEB core. It needs to be only put into WFI if required to be shutdown (for example, in Standby mode).

**Table 215. MC_ME partition core mapping**

| Core | MC_ME partition | MC_ME clock enable register field |
|---|---|---|
| Cortex-M7_0 | 0 | MC_ME.PRTN0_CORE0_PCONF[CCE] |

### 43.1.4 Peripheral clock gating

See Peripheral initialization process and Peripheral shutdown process for proper initialization and shutdown of peripherals. See Table 216 for peripheral clock gating possibilities.

The application core can program the reserved configurations.

**NOTE**

Before accessing the registers of a peripheral to start using it, its clock must be turned on, otherwise, a Hard-Fault event will occur.

**Table 216. MC_ME partition peripheral mapping and clock control**

1. See the memory-map sheet attached to this document for details on available peripherals in different chips.
2. While accessing SELFTEST_GPR space, software must ensure that the STCU2 block has its clock enabled. i.e., MC_ME.PRTN1_COFB3_CLKEN[REQ104] configured as 1'b1. Not ensuring this might result in unpredictable device behaviour.

### 43.1.5 Application core initialization process

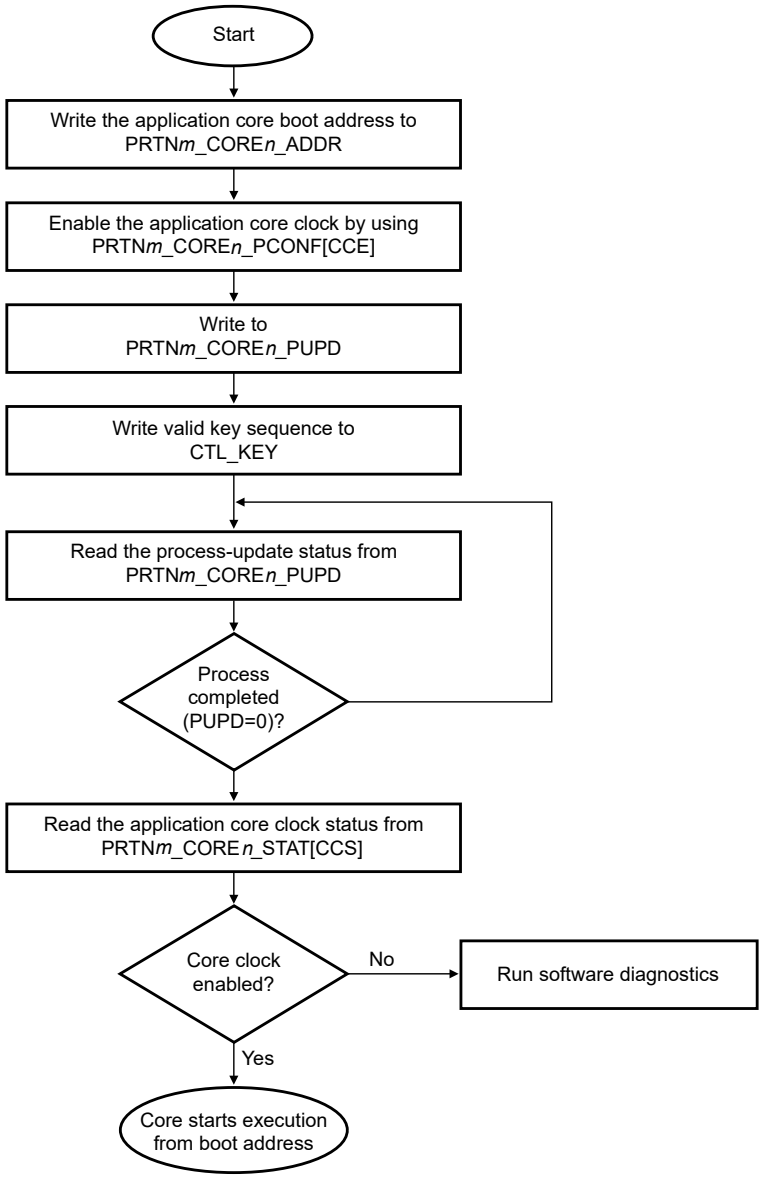

Figure 160. Application core initialization process

### 43.1.6 Application core shutdown process

If a debugger is attached to the chip and application debug is enabled, the application core continues running if you write 0 to MDM_AP.MDMAPCT[CM7_*n*_CORE_ACCESS].

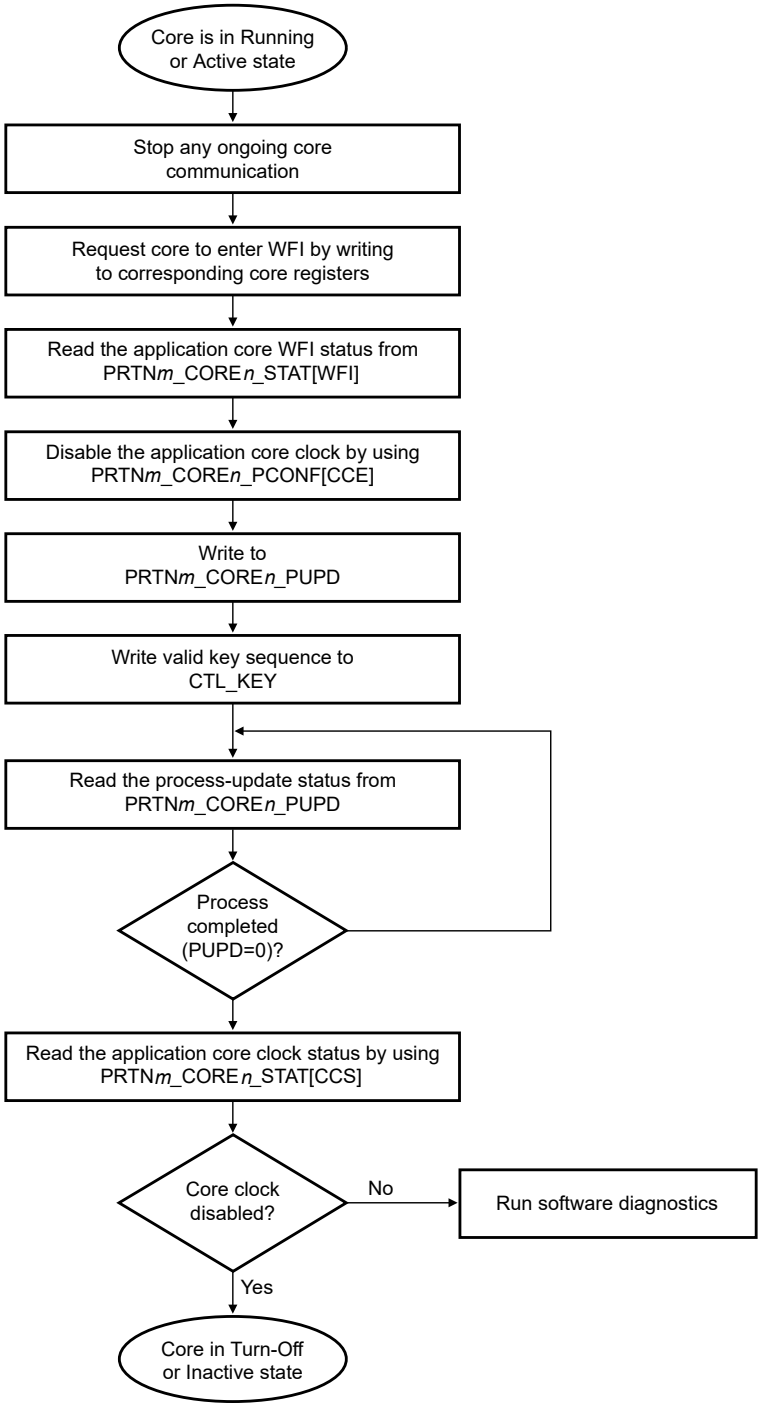

Figure 161. Application core shutdown process

## 43.1.7 Peripheral initialization process

You cannot control all the peripherals. For example, you cannot turn on and turn off the peripherals required for chip functionality across reset or power-up. They always remain on.

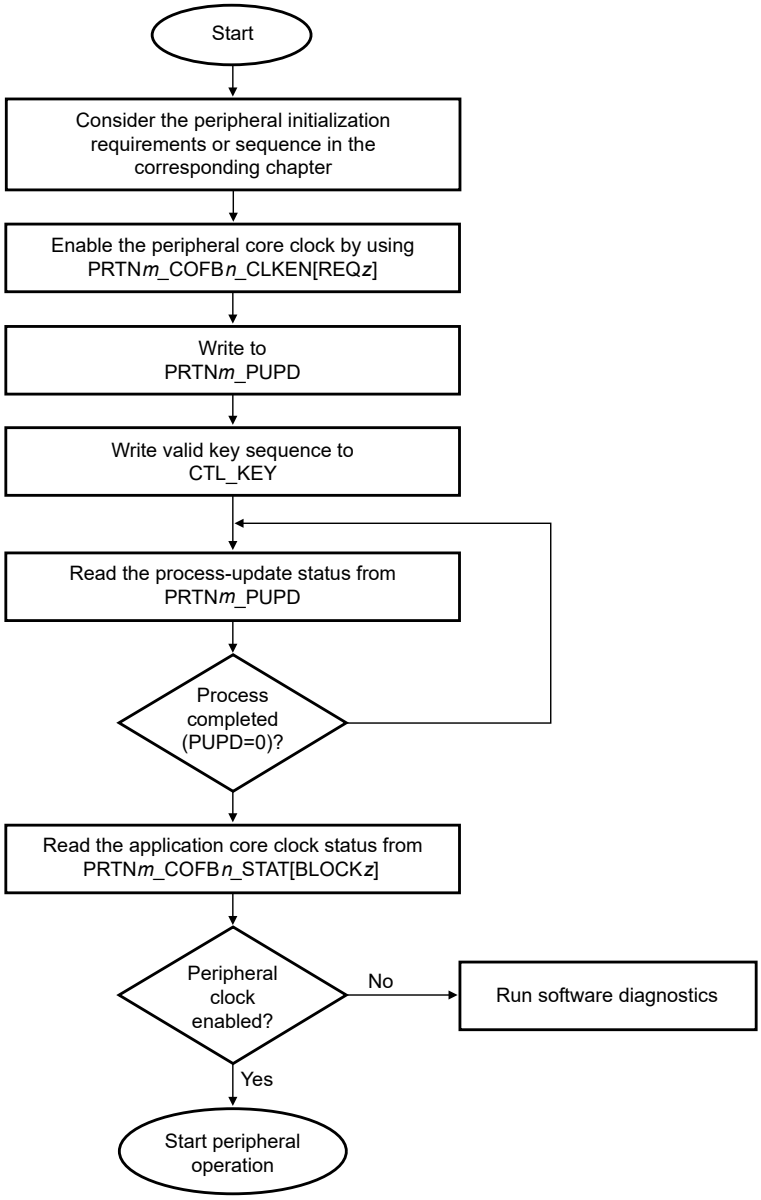

Figure 162. Peripheral initialization process

### 43.1.8 Peripheral shutdown process

You cannot control all the peripherals. For example, you cannot turn on and turn off the peripherals required for chip functionality across reset or power-up. They always remain on.

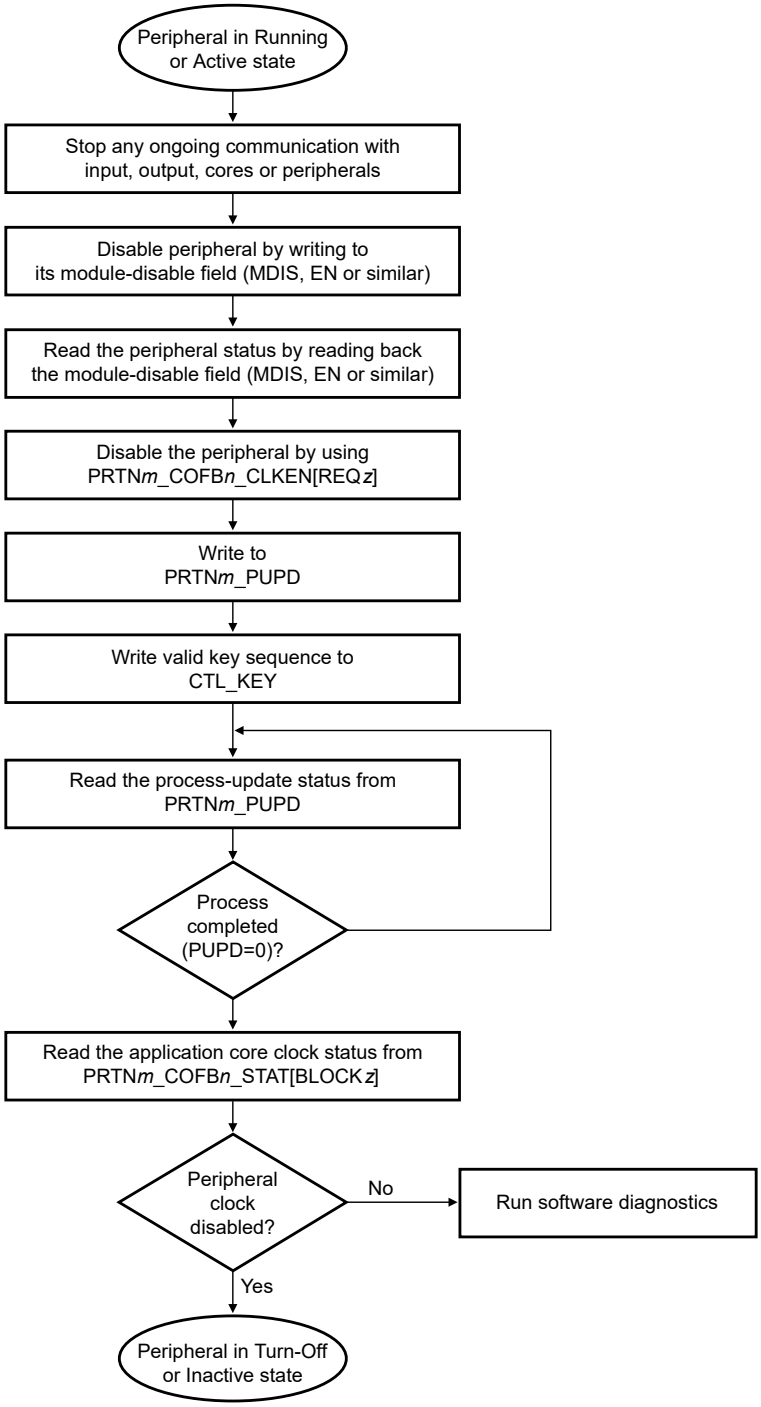

**Figure 163. Peripheral shutdown process**

## 43.2 Introduction

The MC_ME module generates control signals for a set of modules of the SoC. The set of signals are defined in corresponding 'Partition Configuration Registers'. It also implements a software-based mechanism for initiating a functional and destructive reset sequence and standby entry handshake with power management of SoC. See Figure 164 for the MC_ME block diagram.

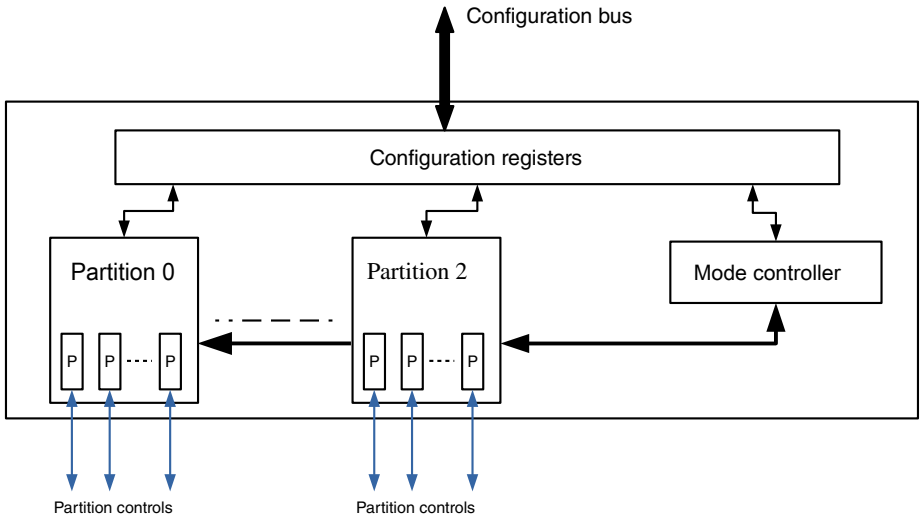

Figure 164. MC_ME block diagram

## 43.3 Features

MC_ME includes the following features:

- 3 logic partitions implementation and their controls
- Core clock controls
- Partition clock control
- Control mechanism for initiating a destructive or functional reset sequence to MC_RGM
- Control mechanism for initiating standby mode entry for SoC

The logic partition inside MC_ME refers to a certain group of on-chip resources (or IP blocks) that are clubbed together to represent a single 'Partition' inside MC_ME. The MC_ME partition can be the same or different than an LBIST partition. Each of the MC_ME partitions implements a certain number of hardware processes. These hardware processes provide a mechanism to regulate various control signals provided to or received from the IP blocks. The corresponding status signals can also be monitored from MC_ME register(s). Each of the hardware processes is bound to finish in 512 cycles of the MC_ME register configuration clocks. Therefore, the hardware processes are non blocking in nature. Mismatch in the expected versus actual status of any hardware process is controlled by a pre-defined software.

## 43.4 Partition processes

Each of the processes inside the partition controls register space and corresponds to a control signal provided to that partition. A partition can include a core, or COFBs, or both. The MC_ME hardware processes provide control and status via signals provided to partitions. Each partition can be assigned a signal for control and a signal for status. Each of the control signals implements functionality for the partition. For example, clock gating and peripheral control.

The hardware process can be triggered and monitored using a set of three registers:

- Configuration register; for example, Partition n Process Configuration register
- Update register; for example, Partition n Process Update register
- Status register; for example, Partition n Status register

Similar registers exist for cores inside the partition.

The process setup and triggering procedure is shown in Figure 165. Each of the processes is independent of others and can be triggered or re-triggered in parallel or sequential to other processes. The triggering or re-triggering mechanism remains the same.

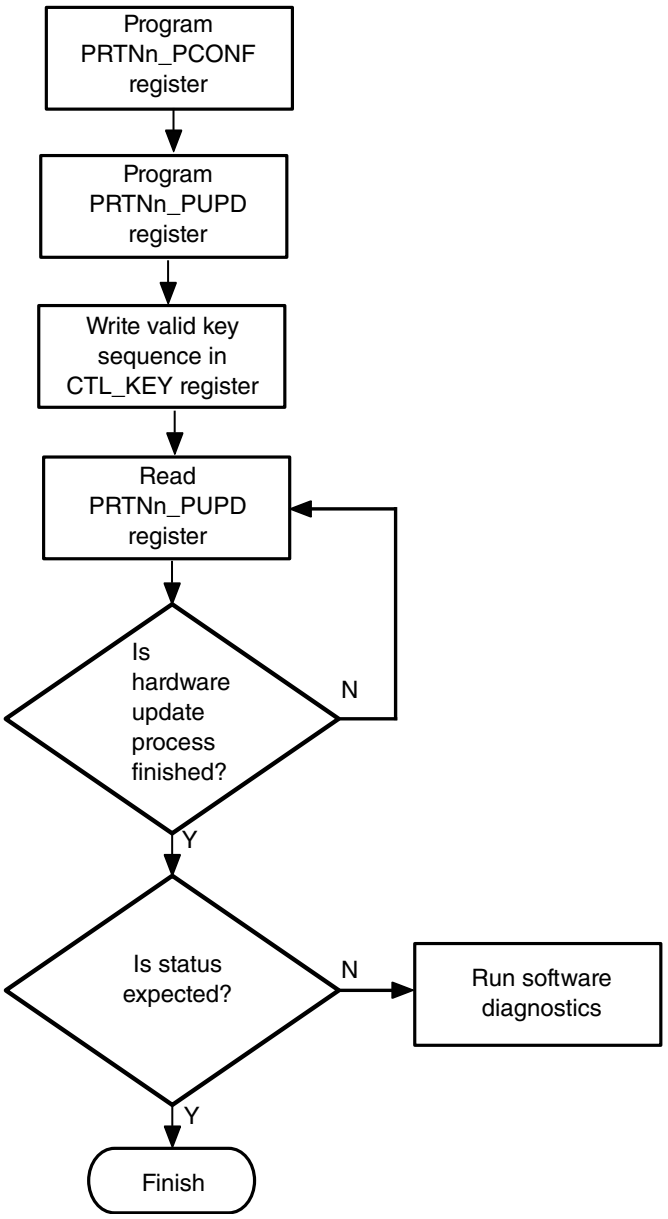

**Figure 165. Partition process setup procedure**

All the hardware processes are bound to finish in 512 cycles of the MC_ME configuration clock. If the actual and the expected status for a process does not match, then the diagnostics is left as a software responsibility. The software diagnostic can include further wait cycles for the status to match.

## 43.5 Mode transition

MC_ME implements a mode transition mechanism, whereby the mode of operation for SoC can be changed. Then module implements a mechanism that can lead to:

- Destructive reset
- Functional reset
- Standby mode entry

Destructive reset and functional reset requests from MC_ME are non-retractable transitions. After it is initiated, the other MC_ME functionality is rendered unusable and bus errors are provided for upcoming access to the MC_ME register until a reset sequence is executed by MC_RGM. Hence, it is vital that MC_RGM should never ignore or gate the reset requests from MC_ME.

For transition into the standby mode, the software should ensure that required IP blocks such as clock sources and I/O communication are in their respective inactive states before initiating a standby mode transition to MC_ME. After MC_ME initiates a power down sequence request, it cannot be retracted. The SoC enters a standby power down sequence and then reenter power-up sequence even for cases where the standby wakeup happens right at the time of initiating a power-down sequence request.

Steps for initiating the MC_ME mode transition:

1. Setup the MODE_CONF register with the corresponding target mode bit set to logic-1.
2. Perform the same update as done in the MODE_CONF register on the CONF_UPD register.
3. Write the valid control key (0x5AF0) on the CTL_KEY register.
4. Write the valid invert control key (0xA50F) on the CTL_KEY register.

Mode transition to MC_ME is initiated, after the sequence mentioned above is completed.

In step 1, if both FUNC_RST and DEST_RST in Mode Configuration Register (MODE_CONF) are 1:

- After step 4 is complete, MC_ME initiates a mode transition to a destructive (not functional) reset.
- After the chip exits reset, MC_RGM records that both MC_ME's destructive reset and MC_ME's functional reset were the reset source.

**NOTE**

Any hardware partition processes setup, along with mode transition, is executed in parallel to the mode transition of MC_ME.

## 43.6 Standby entry

MC_ME provides hardware processes that implement shutdown sequencing of on-chip resources, such as cores and COFBs. The standby entry sequencing can be achieved or implemented using these hardware processes. The order of the hardware process is determined by the software and MC_ME. It requires no restriction in sequencing of the operation. Following is an example sequence for initiating a power-down sequence for entering the standby mode for SoC. The standby entry sequence should include (but not limited to) the following steps:

1. Setting up wakeup lines
2. Shutting down cores and COFBs
3. Switching all MC_CGM muxes to FIRC with PCFS
4. Powering down all clock sources except FIRC
5. Setting up MC_ME using the main core and initiating a standby mode transition
6. Executing WFI instruction on the main core (per Arm specification)

### 43.6.1 Application core shutdown

This section describes a mechanism for shutting down an application core. The sequence proposed here is extendible with the housekeeping tasks required for other IPs. Each of the tasks mentioned in the following sequence, can be further integrated with an SoC-specific task.

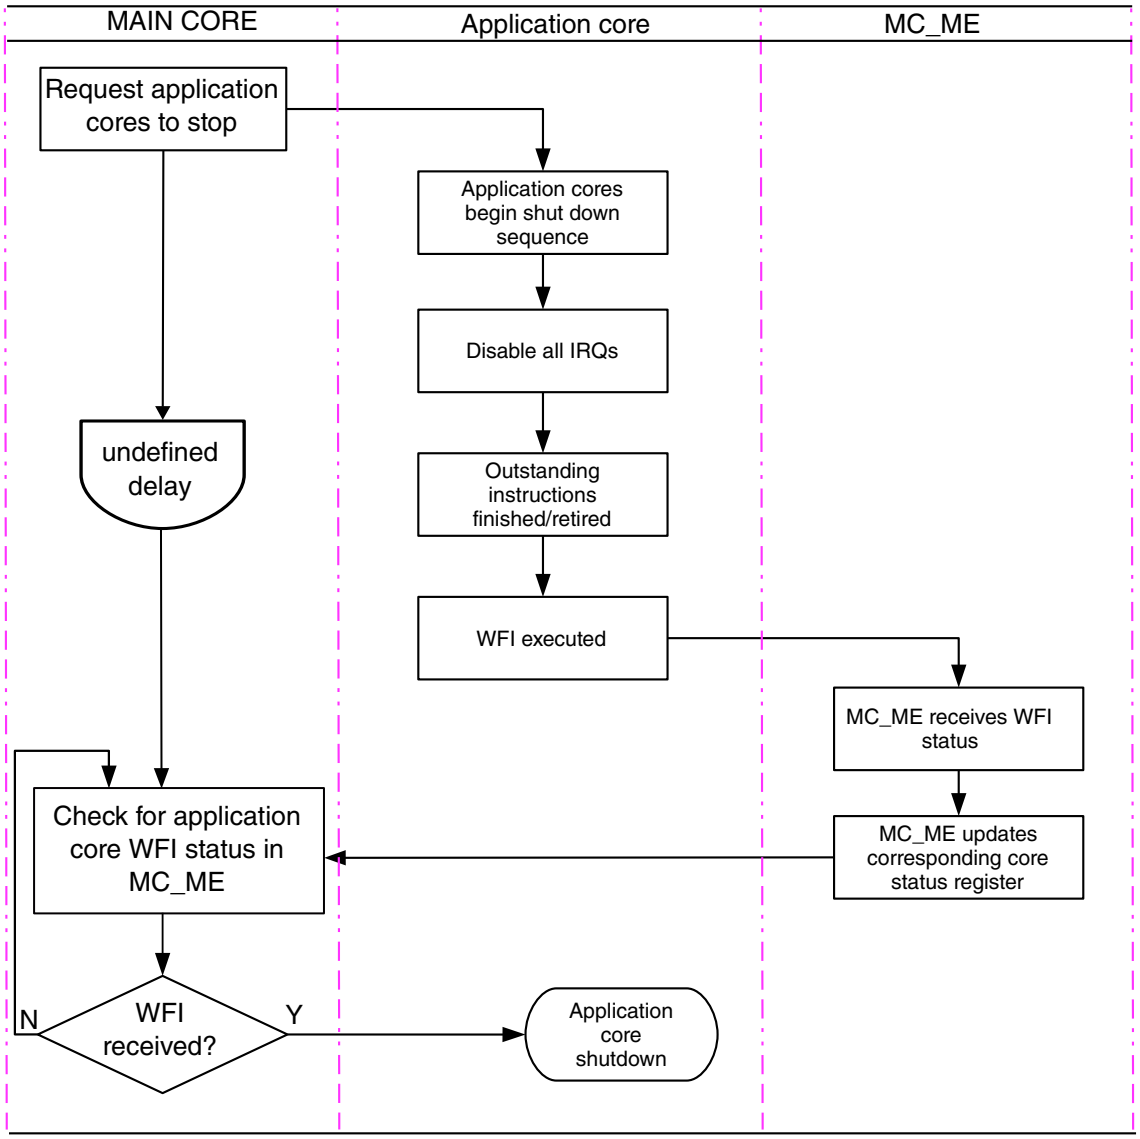

Figure 166. Application core shutdown

After the application core is shutdown, the main core can optionally decide to gate the respective core clock using the corresponding core clock hardware process.

### 43.6.2 Main core shutdown and standby entry

This section describes standby entry sequence along with the main core shutdown. This sequence should only be initiated after SoC is ready for entering standby and has completed all the housekeeping activities. It is necessary that the main core has completed all the operations pertaining to other (application cores) and is the last active core before initiating the standby entry sequence. See Figure 167.

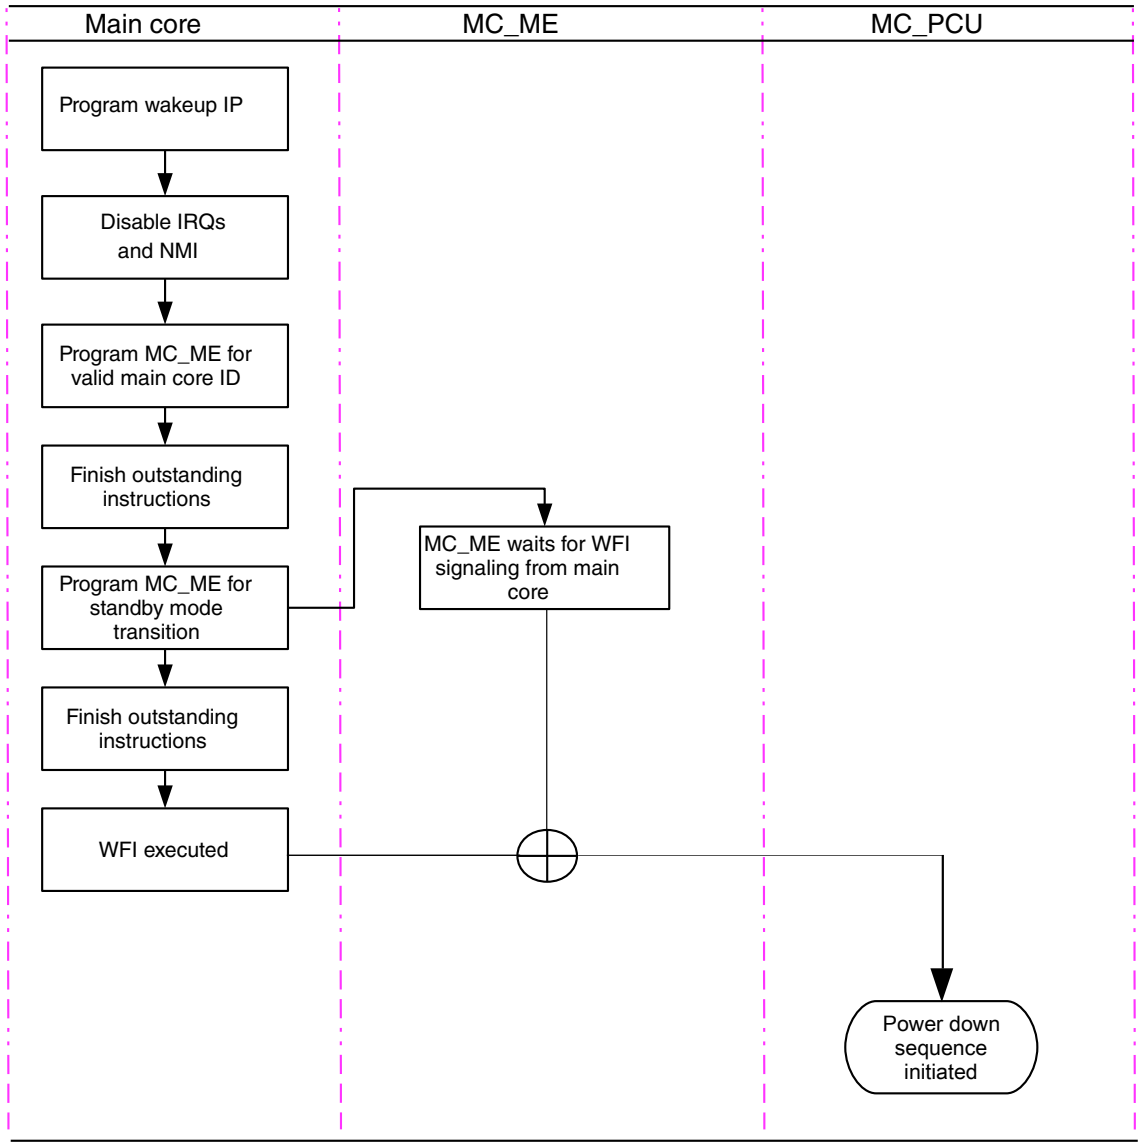

Figure 167. Standby entry sequence along with main core shutdown

**NOTE**

- MC_ME initiates the power sequence to MC_PCU. This enables the main core to remain inactive (WFI state) until it is reset and power-up again at standby exit.

## 43.7 MC_ME register descriptions

MC_ME implements set hardware processes that can be used by the software for changing the mode of operation for a partition. Following are the features of MC_ME registers:

- All registers are 32-bit wide.
- Only 32-bit read and write accesses are supported.
- Read/write accesses of less than 32 bits terminate with an error.
- Writes to read-only register fields in writable registers are ignored and do not provide an error message.

- Writes to read-only registers are aborted with an error message.

### 43.7.1 MC_ME memory map

MC_ME base address: 402D_C000h

| Offset | Register | Width (In bits) | Access | Reset value |
|---|---|---|---|---|
| 0h | Control Key Register (CTL_KEY) | 32 | RW | 0000_5AF0h |

### 43.7.2 Control Key Register (CTL_KEY)

#### Offset

| Register | Offset |
|---|---|
| CTL_KEY | 0h |

#### Function

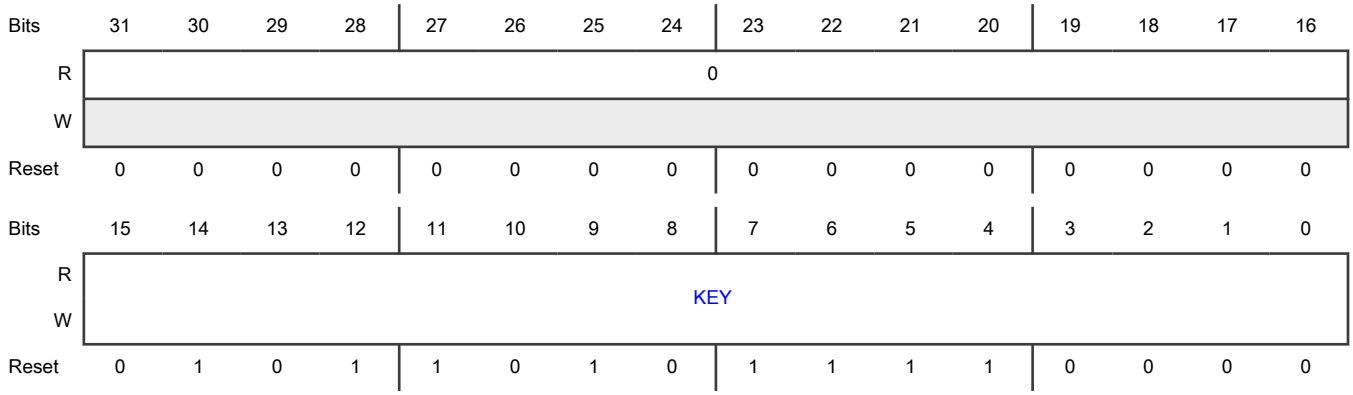
This register provides the mechanism to MC_ME for starting the hardware processes for the partition(s) and standby entry sequence. The hardware processes for partitions are triggered through the corresponding PRTNn_PCONF register. The mechanism to trigger the hardware processes of the respective partitions require two write operations: first time with key and second time with inverted key. The hexadecimal value of key is 0x5AF0 whereas for inverted key is 0xA50F.

For initiating a standby entry sequence, the MODE_CONF register is used for providing a standby entry request along with a valid key combination.

**NOTE**

Reads from this register return a valid key value to be written next.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved<br>This field is reserved and read returns zeros. |
| 15-0<br>KEY | Control key<br>Key for starting the hardware processes. Writes with a value other than key or inverted key are ignored. Reads return bit inverted value corresponding to last write. |

## 43.7.3 Mode Configuration Register (MODE_CONF)

### Offset

| Register | Offset |
|---|---|
| MODE_CONF | 4h |

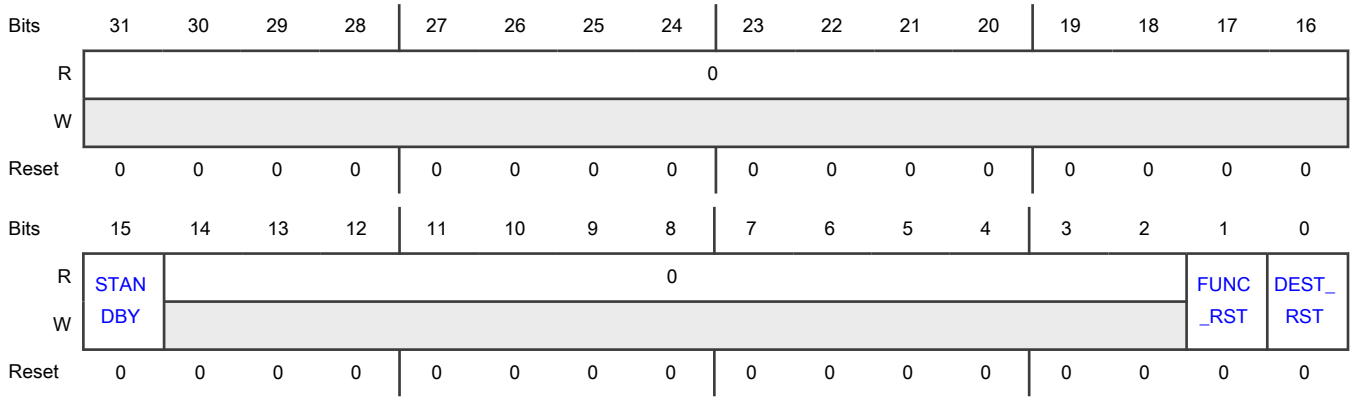
### Function

This register is used for initiating a standby request or a reset event (destructive or functional) for the chip. The functional or destructive events are signaled to MC_RGM for further handling.

**NOTE**

Software must not enable mode entry if the value of multiple fields is 1 in the MODE_CONF register.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-16<br>— | Reserved<br>This field is reserved and read returns zeros. |
| 15<br>STANDBY | Standby request<br>Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a standby entry sequence request to MC_ME. |
| 14-2<br>— | Reserved<br>This field is reserved and read returns zeros. |
| 1<br>FUNC_RST | Functional reset request<br>Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a functional reset event signaling to MC_RGM. |
| 0<br>DEST_RST | Destructive reset request<br>Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a destructive reset event signaling to MC_RGM. |

## 43.7.4 Mode Update Register (MODE_UPD)

### Offset

| Register | Offset |
|---|---|
| MODE_UPD | 8h |

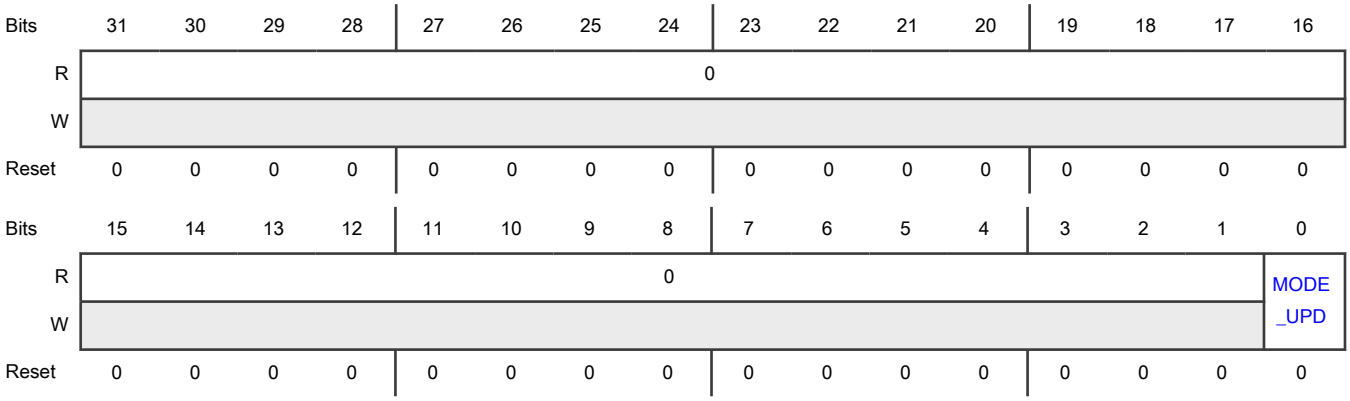
### Function

This register is used for initiating a mode change. Mode change refers to initiating a standby request, or generating a destructive or functional reset event to MC_RGM. Setting mode update field to logic-1, along with programming MODE_CONF registers and then followed by a valid key combination will generate a mode transition request.

**NOTE**

The MODE_UPD register is implemented to make mode transition programming model the same as partition programming model. This is for future expansion inside MC_ME.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved<br>This field is reserved and read returns zeros. |
| 0<br>MODE_UPD | Mode update<br>Writing a logic-1 to this bit, followed by a valid key combination initiates a mode change as per the MODE_CONF register. |

## 43.7.5 Mode Status Register (MODE_STAT)

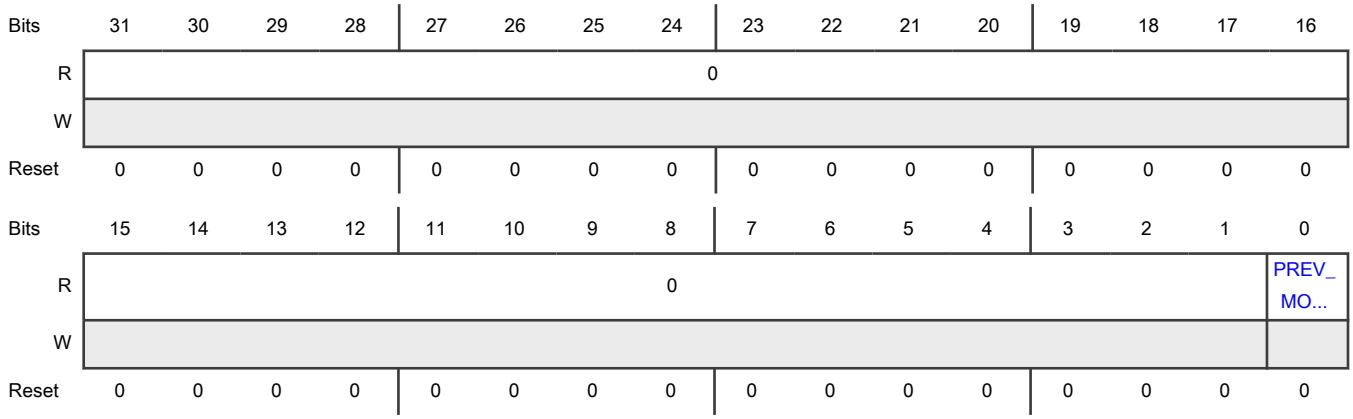
### Offset

| Register | Offset |
|---|---|
| MODE_STAT | Ch |

### Function

This register provides the status of the previous mode. In case of standby exit, if the reset event status register of MC_RGM are set, then contents of this register should be ignored.

### Diagram



### Fields

| Field | Function |
|---|---|
| 31-1<br>— | Reserved<br>This field is reserved and read returns zeros. |
| 0<br>PREV_MODE | Previous mode<br>This bit shows the status of the previous mode.<br>0b - The previous mode was reset (any reset).<br>1b - The previous mode was standby. |

## 43.7.6 Main Core ID Register (MAIN_COREID)

### Offset

| Register | Offset |
|---|---|
| MAIN_COREID | 10h |

### Function

This register provides the ID of the main core sequencing the operation for the standby sequence. Core ID is required for entering in the standby mode, and using this MC_ME locates the WFI instruction execution of the main core. The core ID in this register is specified by the partition index along with the core index.

**NOTE**

Before initiating a standby entry sequence, the contents of this register should point to the correct main core. Providing non-existing or incorrect core ID leads to unpredictable hardware behavior.

### Fields

| Field | Function |
|---|---|
| 31-13<br>— | Reserved<br>This field is reserved and read returns zeros. |
| 12-8<br>PIDX | Partition index<br>Provides the partition index of the main core. Only values 0 - 2 can be written. |
| 7-3<br>— | Reserved<br>This field is reserved and read returns zeros. |
| 2-0<br>CIDX | Core index<br>Provides the core index of the main core inside the partition. |

## 43.7.7 Partition 0 Process Configuration Register (PRTN0_PCONF)

### Offset

| Register | Offset |
|---|---|
| PRTN0_PCONF | 100h |

### Function

This register provides a configuration for the hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_PCONF and PRTN0_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

**NOTE**

The partition clock enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

**NOTE**

See chip-specific MC_ME information to check if this register is implemented on chip.

## 43.7.8 Partition 0 Process Update Register (PRTN0_PUPD)

### Offset

| Register | Offset |
|---|---|
| PRTN0_PUPD | 104h |

### Function

This register provides trigger signaling for the hardware processes corresponding to partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_PCONF register. When the hardware process is finished the corresponding bit in this register is auto-cleared to logic-0.

**NOTE**

See chip-specific MC_ME information to check if this register is implemented on chip.

## 43.7.9 Partition 0 Status Register (PRTN0_STAT)

### Offset

| Register | Offset |
|---|---|
| PRTN0_STAT | 108h |

### Function

This register provides the current status of the control signals from the partition 0.

**NOTE**

See chip-specific MC_ME information to check if this register is implemented on chip.

### Diagram

## 43.7.10 Partition 0 COFB Set 1 Clock Status Register (PRTN0_COFB1_STAT)

### Offset

| Register | Offset |
|---|---|
| PRTN0_COFB1_STAT | 114h |

### Function

This register provides the status of set 1 of COFBs inside partition 0.

**NOTE**

The reset value of this register can vary depending on the availability of active clock pulses inside partition 0.

### 43.7.11 Partition 0 COFB Set 1 Clock Enable Register (PRTN0_COFB1_CLKEN)

#### Offset

| Register | Offset |
|---|---|
| PRTN0_COFB1_CLKEN | 134h |

#### Function

This register provides clock control signaling to the individual COFBs in set 1 inside partition 0. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

**NOTE**

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

## 43.7.12 Partition 0 Core 0 Process Configuration Register (PRTN0_CORE0_PCONF)

### Offset

| Register | Offset |
|---|---|
| PRTN0_CORE0_PCONF | 140h |

### Function

This register provides configurations for the Core 0 hardware processes corresponding to partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_CORE0_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_CORE0_PUPD and PRTN0_CORE0_PCONF registers are used to determine the hardware processes to be executed. These processes are triggered in parallel and are independent of each other. All dependent processes should be requested one after another from the software.

## 43.7.13 Partition 0 Core 0 Process Update Register (PRTN0_CORE0_PUPD)

### Offset

| Register | Offset |
|---|---|
| PRTN0_CORE0_PUPD | 144h |

### Function

This register provides trigger signaling for the core hardware processes corresponding to partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_CORE0_PCONF register. When the hardware process is finished, the corresponding bit in this register is auto-cleared to logic-0.
