1 LPREQPOL	Low-Power Request Output Pin Polarity Control Controls the true polarity of the low-power request output pin. 0b - High 1b - Low
0 LPREQOE	Low-Power Request Output Enable Enables the low-power request output pin. 0b - Disable 1b - Enable

37.7.6 SPC Power Domain Mode Status (PD_STATUS0 - PD_STATUS1)

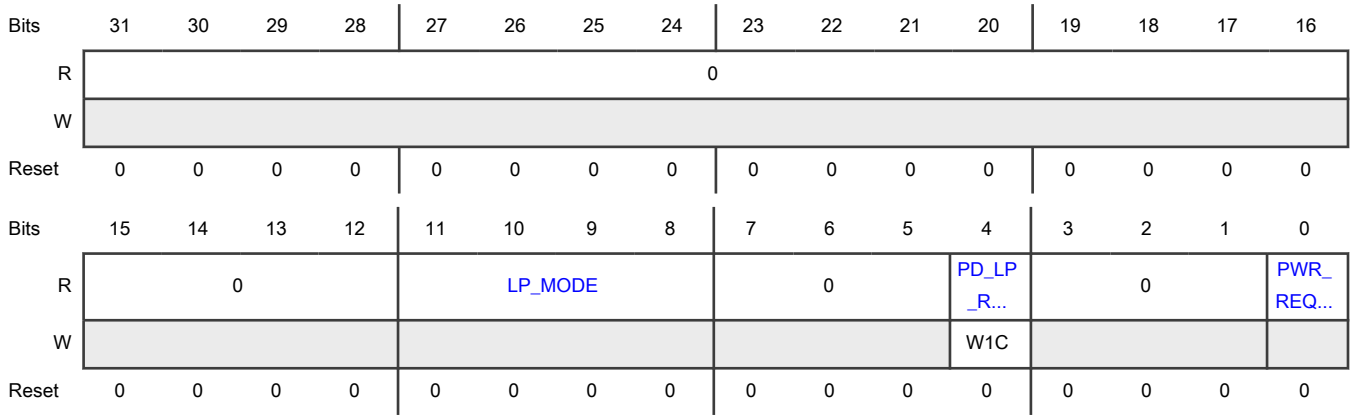
Offset

Register	Offset
PD_STATUS0	30h
PD_STATUS1	34h

Function

Indicates power mode status for each of the SPC power domains. See the chip-specific SPC information to determine which power domains are associated with this register.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-8 LP_MODE	Power Domain Low Power Mode Request Indicates the last low-power mode that the power domain requested. 0000b - SLEEP with system clock running 0001b - DSLEEP with system clock off 0010b - PDOWN with system clock off 0100b - Reserved 1000b - DPDOWN with system clock off
7-5 —	Reserved
4 PD_LP_REQ	Power Domain Low Power Request Flag Set when low power mode was requested by Power Domain since last cleared by software. 0b - Did not request 1b - Requested
3-1 —	Reserved
0 PWR_REQ_STATUS	Power Request Status Flag Indicates whether the power domain requested low-power mode. 0b - Did not request 1b - Requested

37.7.7 SRAM Control (SRAMCTL)

Offset

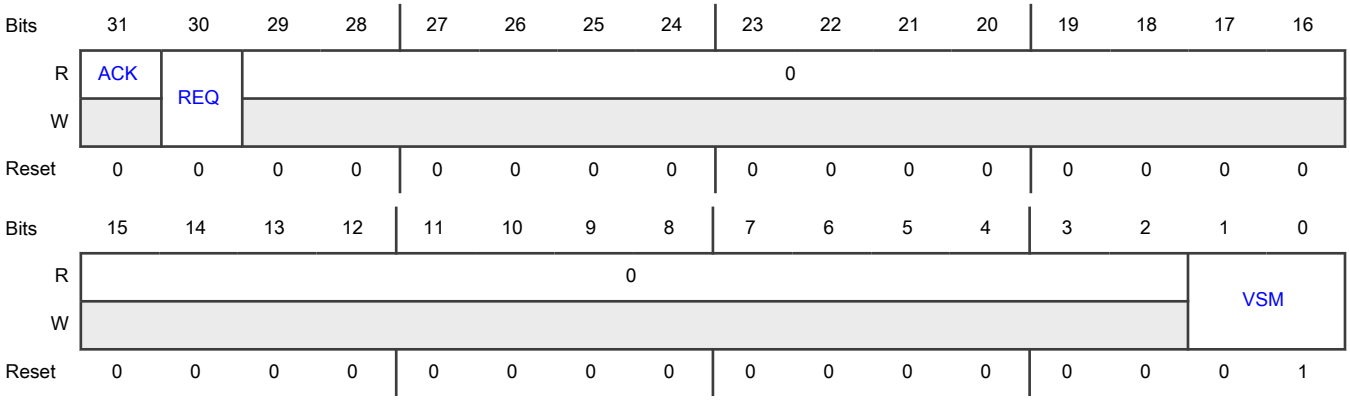
Register	Offset
SRAMCTL	40h

Function

Configures the SRAM timing for different voltage levels.

When transitioning between two voltage levels, you must keep the SRAM timing at the lowest voltage level until the voltage change is complete.

Diagram



Fields

Field	Function
31 ACK	SRAM Voltage Update Request Acknowledge Indicates whether SPC acknowledged the request for an SRAM trim-value change. 0b - Not acknowledged 1b - Acknowledged
30 REQ	SRAM Voltage Update Request Allows you to request an SRAM trim value change. After requesting the change, you must wait for the ACK field to become 1, then write 0 to REQ. 0b - Do not request 1b - Request
29-2 —	Reserved
1-0	Voltage Select Margin

Table continues on the next page...

Table continued from the previous page...

Field	Function
VSM	Specifies the operating voltage for the SRAM's read/write timing margin. 00b - Reserved 01b - 1.0 V 10b - 1.1 V 11b - Reserved

37.7.8 Active Power Mode Configuration (ACTIVE_CFG)

Offset

Register	Offset
ACTIVE_CFG	100h

Function

Controls the SPC regulators settings in the Active and Sleep power mode.

Changes to the drive strength or voltage level for any of the LDOs or DCDC sets the SC[BUSY] flag until SPC changes its state to the new value.

NOTE

The LVDE and HVDE fields reset only with a POR. All other fields reset only with a system reset.

Fields

Field	Function
31-30 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
29 IO_HVDE	IO High-Voltage Detection Enable Enables the IO high-voltage detection. When IO_HVDE = 1, you must write a value to BGMODE that enables the bandgap. Only a POR resets this field. Monitors VDD IO on PORT. For port details, see the chip-specific information. 0b - Disable 1b - Enable
28 SYS_HVDE	System High-Voltage Detection Enable Enables the system high-voltage detection. When SYS_HVDE = 1, you must write a value to BGMODE that enables the bandgap. Only a POR resets this field. 0b - Disable 1b - Enable
27 CORE_HVDE	Core High-Voltage Detection Enable Enables the core high-voltage detection. When CORE_HVDE = 1, you must write a value to BGMODE that enables the bandgap. Only a POR resets this field. 0b - Disable 1b - Enable
26 IO_LVDE	IO Low-Voltage Detection Enable Enables the IO low-voltage detection. When IO_LVDE = 1, you must write a value to BGMODE that enables the bandgap. Only a POR resets this field. Monitors VDD IO on PORT. For port details, see the chip-specific information. 0b - Disable 1b - Enable
25 SYS_LVDE	System Low-Voltage Detection Enable Enables the system low-voltage detection. When SYS_LVDE = 1, you must write a value to BGMODE that enables the bandgap. Only a POR resets this field. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 CORE_LVDE	Core Low-Voltage Detection Enable Enables the core low-voltage detection. When CORE_LVDE = 1, you must write a value to BGMODE that enables the bandgap. Only a POR resets this field. 0b - Disable 1b - Enable
23 VDD_VD_DISABLE	VDD Voltage Detect Disable Disables VDD voltage detect. Mask all LVDs and HVDs when you change the active voltage levels. If this field is 1, it will not mask and allow LVDs and HVDs conditions to generate a system reset or interrupt. If this field is 0, it will mask all LVDs and HVDs when changing the regulator voltage levels during Active mode. 0b - Enable 1b - Disable
22 —	Reserved
21-20 BGMODE	Bandgap Mode Specifies the bandgap mode configuration. BGMODE will be set to 01b to keep the Bandgap enabled if a write to disable Bandgap is detected while keeping any of the regulators in normal drive strength or if any of the LVD/HVDs are kept enabled or if VDD CORE glitch detect are kept enabled. 00b - Bandgap disabled 01b - Bandgap enabled, buffer disabled 10b - Bandgap enabled, buffer enabled 11b - Reserved
19 —	Reserved
18 LPBUFF_EN	CMP Bandgap Buffer Enable Enables the buffer-stored reference voltage to CMP. 0b - Disable 1b - Enable
17-13 —	Reserved
12	Glitch Detect Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
GLITCH_DETECT_DISABLE	Reset on POR only State of GLITCH_DETECT_DISABLE will be ignored if Bandgap is disabled and Glitch Detect hardware will be forced to OFF state. 0b - Low Voltage Glitch Detect enabled 1b - Low Voltage Glitch Detect disabled
11-10 DCDC_VDD_LVL	DCDC VDD Regulator Voltage Level Specifies the DCDC VDD regulator level. When switching the DCDC drive strength from low to normal, ensure that the DCDC high VDD LVL setting is set to the same level that was set prior to switching the DCDC to low drive strength. Otherwise, if the LVDs are enabled, an unexpected LVD can occur. 00b - Reserved 01b - Midvoltage (1.0 V) 10b - Normal voltage (1.1 V) 11b - Overdrive voltage (1.2 V)
9-8 DCDC_VDD_DS	DCDC VDD Drive Strength Specifies the DCDC VDD regulator drive strength. If you specify normal drive strength, you must write a value to ACTIVE_CFG[BGMODE] that enables the bandgap. 01b - Low 10b - Normal All other values are reserved.
7 —	Reserved
6 SYSLDO_VDD_LVL	LDO_SYS VDD Regulator Voltage Level Specifies the LDO_SYS VDD regulator level. You must write 0 to SYS_HVDE before writing 1 to SYSLDO_VDD_LVL. The VDD_SYS voltage can only operate at the overdrive voltage for a limited amount of time for the life of the chip. See the chip data sheet for the maximum voltage and time specifications. This is intended only for programming eFuses. 0b - Normal voltage (1.8 V) 1b - Overdrive voltage (2.5 V)
5 —	Reserved
4	LDO_SYS VDD Drive Strength

Table continues on the next page...

Table continued from the previous page...

Field	Function
SYSLDO_VDD_DS	Specifies the LDO_SYS VDD regulator drive strength If you specify normal drive strength, you must write a value to ACTIVE_CFG[BGMODE] that enables the bandgap. If you have enabled LVDs or HVDs, and attempt to specify low drive strength, SPC ignores the attempt. SPC forces a normal drive strength when SYSLDO_VDD_LVL = 1. 0b - Low 1b - Normal
3-2 CORELDO_VDD_LVL	LDO_CORE VDD Regulator Voltage Level **NOTE** LDO_CORE overdrive voltage level (1.2V) is not supported when LDO_CORE is configured for low drive. Selects the LDO_CORE VDD regulator level. If the CORELDO_VDD_DS fields are set to the same value in both the ACTIVE_CFG and LP_CFG registers, the CORELDO_VDD_LVL's in the ACTIVE_CFG and LP_CFG register must be set to the same voltage level settings. You can change the core VDD levels for the LDO_CORE low power regulator only when CORELDO_VDD_DS=1. When switching CORELDO_VDD_DS from low to normal drive strength, ensure the LDO_CORE high VDD LVL setting is set to the same level that was set prior to switching to the LDO_CORE drive strength (CORELDO_VDD_DS). Otherwise, if the LVDs are enabled, an unexpected LVD can occur. You must specify the same level for both CORELDO_VDD_LVL and DCDC_VDD_LVL, even if LDO_CORE is off. 00b - Reserved 01b - Regulate to mid voltage (1.0 V) 10b - Regulate to normal voltage (1.1 V) 11b - Regulate to overdrive voltage (1.2 V)
1 —	Reserved
0 CORELDO_VDD_DS	LDO_CORE VDD Drive Strength Selects the LDO_CORE VDD regulator drive strength **NOTE** When setting CORELDO_VDD_DS to Normal, BGMODE must be programmed to a value that enables the Bandgap. Writes to set drive strength to Low will be ignored if LVD/HVDs are kept enabled.

Fields

Field	Function
31-30 —	Reserved
29 IO_HVDE	IO High Voltage Detect Enable This field monitors VDD IO on PORT. For port details, see the chip-specific SPC information. This field resets only after a POR, LVD, or HVD event. When IO_HVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
28 SYS_HVDE	System High Voltage Detect Enable This field resets only after a POR, LVD, or HVD event. When SYS_HVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
27 CORE_HVDE	Core High Voltage Detect Enable This field resets only after a POR, LVD, or HVD event. When CORE_HVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
26 IO_LVDE	IO Low Voltage Detect Enable This field monitors VDD IO on PORT. For port details, see the chip-specific SPC information. This field resets only after a POR, LVD, or HVD event. When IO_LVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
25 SYS_LVDE	System Low Voltage Detect Enable This field resets only after a POR, LVD, or HVD event. When SYS_LVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
24 CORE_LVDE	Core Low Voltage Detect Enable This field resets only after a POR, LVD, or HVD event. When CORE_LVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
23 LP_IREFEN	Low-Power IREF Enable You can disable the low-power IREF only in DPDOWN mode. In all other low-power modes, writing 1 to this field has no effect and the low-power IREF is always enabled. See the chip-specific SPC information for the modules that require the low-power IREF to be enabled in DPDOWN mode when you use the module in DPDOWN mode. 0b - Disable for power saving in Deep Power Down mode 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
22 —	Reserved
21-20 BGMODE	Bandgap Mode Specifies the bandgap mode configuration. BGMODE will be set to 01b to keep the Bandgap enabled if a write to disable Bandgap is detected while keeping any of the regulators in normal drive strength or if any of the LVD/HVDs are kept enabled or if VDD CORE glitch detect are kept enabled. 00b - Bandgap disabled 01b - Bandgap enabled, buffer disabled 10b - Bandgap enabled, buffer enabled 11b - Reserved
19 —	Reserved
18 LPBUFF_EN	CMP Bandgap Buffer Enable Enables the buffer-stored reference voltage to CMP. The CMP bandgap buffer is automatically disabled and turned off in DPDOWN mode. 0b - Disable 1b - Enable
17 COREVDD_IVS_EN	CORE VDD Internal Voltage Scaling (IVS) Enable Enables the IVS regulator. When enabled, the IVS regulator scales the external input CORE VDD to a lower voltage level to reduce internal leakage during Power Down mode. COREVDD_IVS_EN is automatically 0 in SLEEP or DPDOWN modes. CORE VDD can only get IVS in PDOWN mode. 0b - Disable 1b - Enable
16 —	Reserved
15-13 —	Reserved
12 GLITCH_DETECT_DISABLE	Glitch Detect Disable This field resets only after a POR, LVD, or HVD event.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If you have disabled the bandgap, SPC ignores the value of GLITCH_DETECT_DISABLE and deactivates the glitch-detect hardware. 0b - Enable 1b - Disable
11-10 DCDC_VDD_LVL	DCDC VDD Regulator Voltage Level Specifies the DCDC VDD regulator level. 00b - Retention voltage (0.7 V) 01b - Mid voltage (1.0 V) 10b - Normal voltage (1.1 V) 11b - Overdrive voltage (1.2 V)
9-8 DCDC_VDD_DS	DCDC VDD Drive Strength Specifies the drive strength of the DCDC VDD regulator. If you specify normal drive strength, you must write a value to LP_CFG[BGMODE] that enables the bandgap. The DCDC regulator is always turned off and disabled in DPDOWN mode. Pulse Refresh mode is invalid in SLEEP mode. SPC ignores writes to reserved values. 00b - Pulse refresh 01b - Low 10b - Normal 11b - Reserved
7 —	Reserved
6-5 —	Reserved
4 SYSLDO_VDD_DS	LDO_SYS VDD Drive Strength Specifies the drive strength of the LDO_SYS VDD regulator. If you specify normal drive strength, you must write a value to LP_CFG[BGMODE] that enables the bandgap. If you have enabled LVDs or HVDs, and attempt to specify low drive strength, SPC ignores the attempt. 0b - Low 1b - Normal
3-2	LDO_CORE VDD Regulator Voltage Level

Table continues on the next page...

Table continued from the previous page...

Field	Function
CORELDO_VDD_LVL	Specifies the LDO_CORE VDD regulator level for low-power sleep modes. **NOTE** LDO_CORE overdrive voltage level (1.2V) is not supported when LDO_CORE is configured for low drive. If the CORELDO_VDD_DS fields are set to the same value in both the ACTIVE_CFG and LP_CFG registers, the CORELDO_VDD_LVL's in the ACTIVE_CFG and LP_CFG register must be set to the same voltage level settings. You can change the core VDD levels for the LDO_CORE low power regulator only when ACTIVE_CFG[CORELDO_VDD_DS] = 1. So, before entering any of the low-power states (DSLEEP, PDOWN, DPDOWN) with LDO_CORE low power regulator selected (LP_CFG[CORELDO_VDD_DS] = 0), you must use CORELDO_VDD_LVL to select the correct regulation level during ACTIVE run mode. Updating CORELDO_VDD_LVL sets the SC[BUSY] flag. That flag remains set for at least the total time delay that Active Voltage Trim Delay (ACTIVE_VDELAY) specifies. Before changing CORELDO_VDD_LVL, you must wait until the SC[BUSY] flag clears before entering the selected low-power sleep mode. This ensures the correct core VDD voltage levels are set after the chip is in the chosen mode. Program CORELDO_VDD_LVL to have the same level as LP_CFG[DCDC_VDD_LVL], even if LDO_CORE is off. 00b - Retention voltage 01b - Mid voltage (1.0 V) 10b - Normal voltage (1.1 V) 11b - Overdrive voltage (1.2 V)
1 —	Reserved
0 CORELDO_VDD_DS	LDO_CORE VDD Drive Strength Specifies the drive strength of the LDO_CORE VDD regulator. The LDO_CORE regulator is forced to disabled in DPDOWN Sleep mode. If you specify normal drive strength, you must write a value to LP[BGMODE] that enables the bandgap. If you have enabled LVDs or HVDs, and attempt to specify low drive strength, SPC ignores the attempt. 0b - Low 1b - Normal

37.7.11 Low Power Mode Configuration 1 (LP_CFG1)

Offset

Register	Offset
LP_CFG1	10Ch

Function

Enables different analog modules in Deep Sleep, Power Down, or Deep Power Down modes.

See the chip-specific SPC information for a list of analog modules that this register controls.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 SOC_CNTRL	Low-Power Configuration Chip Control Provides control bits to the chip to enable analog modules in Low Power mode. Bit combinations with 0: The associated analog modules are disabled. Bit combinations with 1: The associated analog modules are enabled.

37.7.12 Low Power Wake-Up Delay (LPWKUP_DELAY)

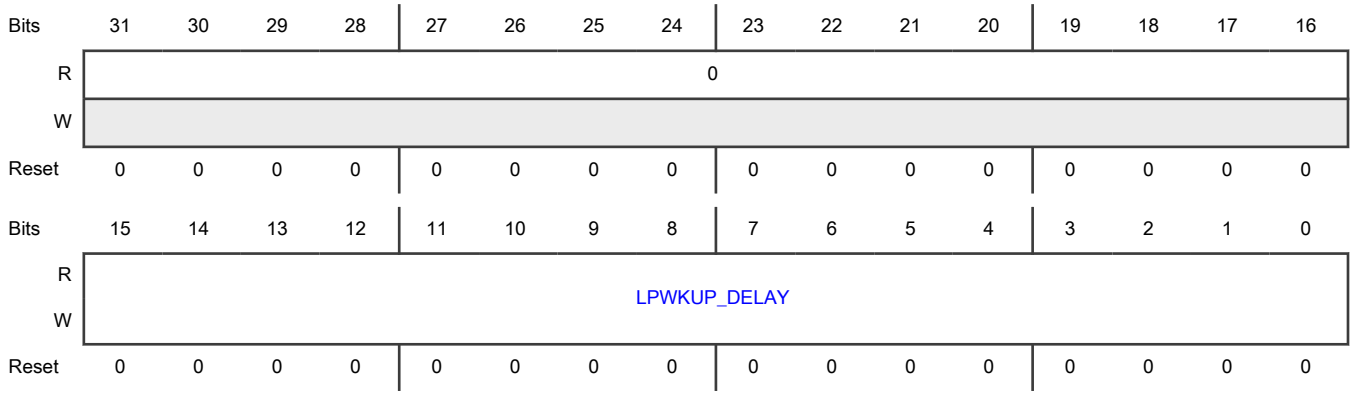
Offset

Register	Offset
LPWKUP_DELAY	120h

Function

Works with the LPREQ pin to extend the wake-up time if the external PMIC or switch needs additional time after wake-up.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 LPWKUP_DELAY	Low-Power Wake-Up Delay Specifies the number of SPC timer clock cycles that SPC waits after exiting low-power modes. This field resets only after a POR, LVD, or HVD event. When voltage levels are not the same between ACTIVE mode and Low Power mode, you must write a nonzero value to this field.

37.7.13 Active Voltage Trim Delay (ACTIVE_VDELAY)

Offset

Register	Offset
ACTIVE_VDELAY	124h

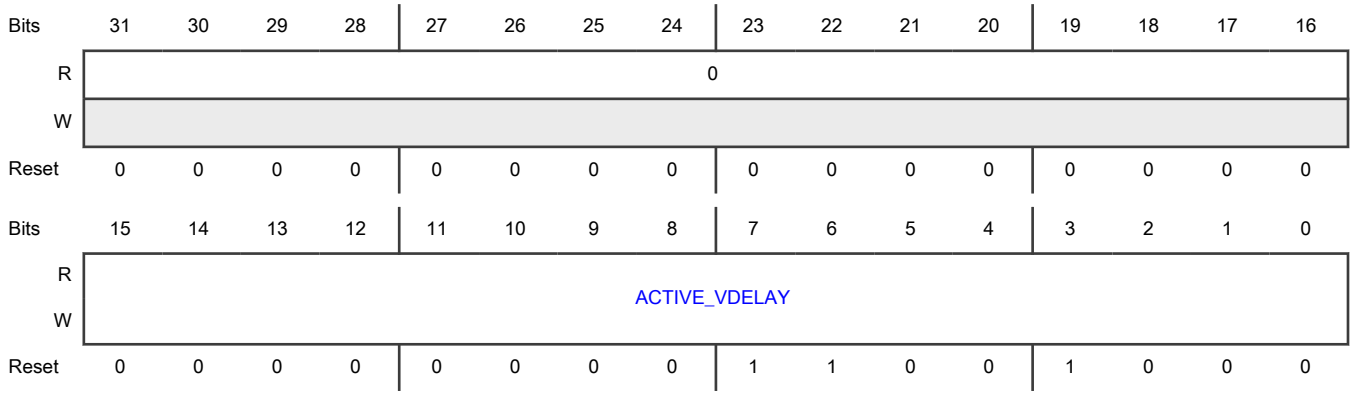
Function

Specifies the delay due to voltage level changes to the regulators in Active mode.

This register resets only after a POR event.

SPC loads the ACTIVE_VDELAY values are loaded from IFR or FUSE after any reset. NXP trims this reset value for the recommended wait time.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 ACTIVE_VDELAY	Active Voltage Delay Specifies the number of SPC timer clock cycles that SPC waits when changing the core-regulator voltage level in Active mode.

37.7.14 Voltage Detect Status (VD_STAT)

Offset

Register	Offset
VD_STAT	130h

Function

Displays the LVD or HVD captured for:

- Core VDD.
- System VDD.
- IO VDD.

This register resets only after a POR event.

Diagram

37.7.15 Core Voltage Detect Configuration (VD_CORE_CFG)

Offset

Register	Offset
VD_CORE_CFG	134h

Function

Provides these functions:

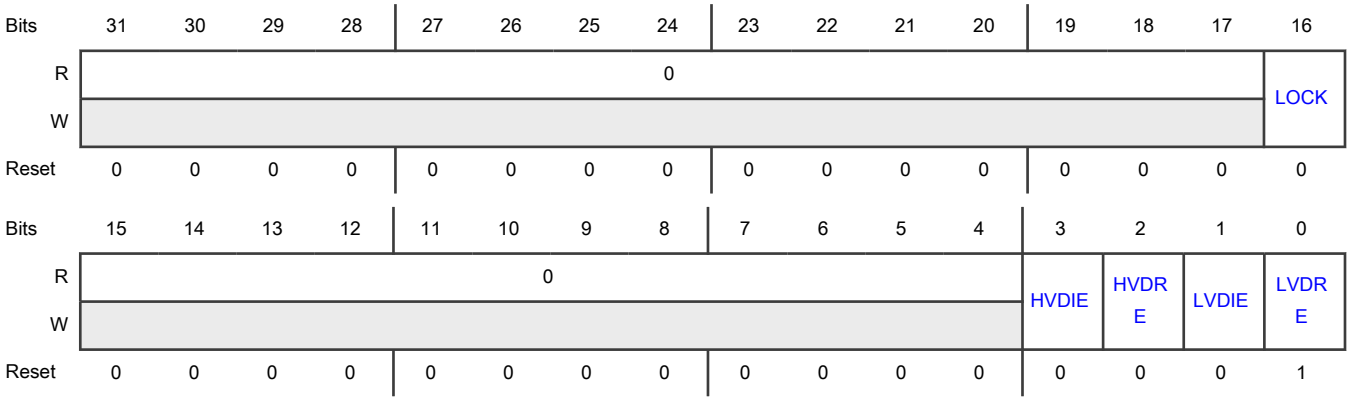
- Configures the low-voltage trip point.
- Enables the core LVD reset and interrupts.

This register resets only after a POR event.

NOTE

If you write 1 to both LVDRE and LVDIE, SPC generates an interrupt after exiting from LVDRE reset. If you don't want this to occur, configure the LVD or HVD so only one is enabled.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 LOCK	Core Voltage Detect Reset Enable Lock Allows writing to the LVDRE and HVDRE fields. 0b - Allow 1b - Deny
15-4 —	Reserved
3 HVDIE	Core VDD HVD Interrupt Enable Enables the Core VDD HVD (COREVDD_HVDF) event to generate a hardware interrupt. If you write 1 to HVDIE with HVD set, SPC automatically generates an HVD interrupt. 0b - Disable 1b - Enable
2 HVDRE	Core VDD HVD Reset Enable Enables the core VDD HVD (COREVDD_HVDF) event to generate a hardware reset. Before writing to this field, you must write 0 to LOCK. 0b - Disable 1b - Enable
1 LVDIE	Core LVD Interrupt Enable Enables the Core LVD (COREVDD_LVDF) event to generate a hardware interrupt. If you write 1 to LVDIE with LVDF set, SPC automatically generates an LVD interrupt.

Table continues on the next page...

0 LVDRE	IO VDD LVD Reset Enable Enables the IO VDD LVD (IOVDD_LVDF) event to generate a hardware reset. Before writing to this field, you must write 0 to LOCK. 0b - Disable 1b - Enable

37.7.18 External Voltage Domain Configuration (EVD_CFG)

Offset

Register	Offset
EVD_CFG	140h

Function

Isolates signals from external voltage domains under certain conditions.

Chip pins supply the external voltage domains. These domains are controlled at the board level. This register allows you to control internal isolations for signals from these domains if either of the following conditions is true:

- They are not powered on the board.
- They are powered off externally in low-power modes (using the SPC_LPREQ pin).

Any logic in the isolated voltage domain also resets, because the voltage domain is assumed to be powered off. This reset does not impact any VDD_CORE internal power domains or registers—only I/O pads, analog components, or both.

This register resets only after a POR event.

Each bit of the EVDISO, EVDLPISO, and EVDSTAT fields corresponds to one of the I/O or analog supplies according to Table 345.

Table 345. Mapping of bits to supplies

Bit position in field	Description
0	VDD
1	VDD_USB
2	VDD_P2
3	VDD_P3
4	VDD_P4/VDD_ANA
5	Reserved

NOTE

Bit 0 VDD should not be set in EVD_CFG[EVDISO] and it should only be set in EVD_CFG[EVDLPISO] when moving to Deep Power Down mode

Fields

Field	Function
31-22 —	Reserved
21-16 EVDSTAT	External Voltage Domain Status Indicates the status of the external voltage domains. See Table 345 for the mapping of each bit of this field. Each bit's value has the following meaning: 0b - Isolated or not powered 1b - Not isolated
15-14 —	Reserved
13-8 EVDLPISO	External Voltage Domain Low-Power Isolation Isolates the external voltage domain in low-power modes. Use this field if you use the SPC_LPREQ pin to power off any voltage domain in low-power modes. See Table 345 for the mapping of each bit of this field. Each bit's value has the following meaning: 0b - Not isolated 1b - Isolated
7-6 —	Reserved
5-0 EVDISO	External Voltage Domain Isolation Isolates the external voltage domain. Use this field if any voltage domain is always powered off on the board, or whenever a voltage domain is powered off under software control.

Table continues on the next page...

37.7.23 DCDC Burst Configuration (DCDC_BURST_CFG)

Offset

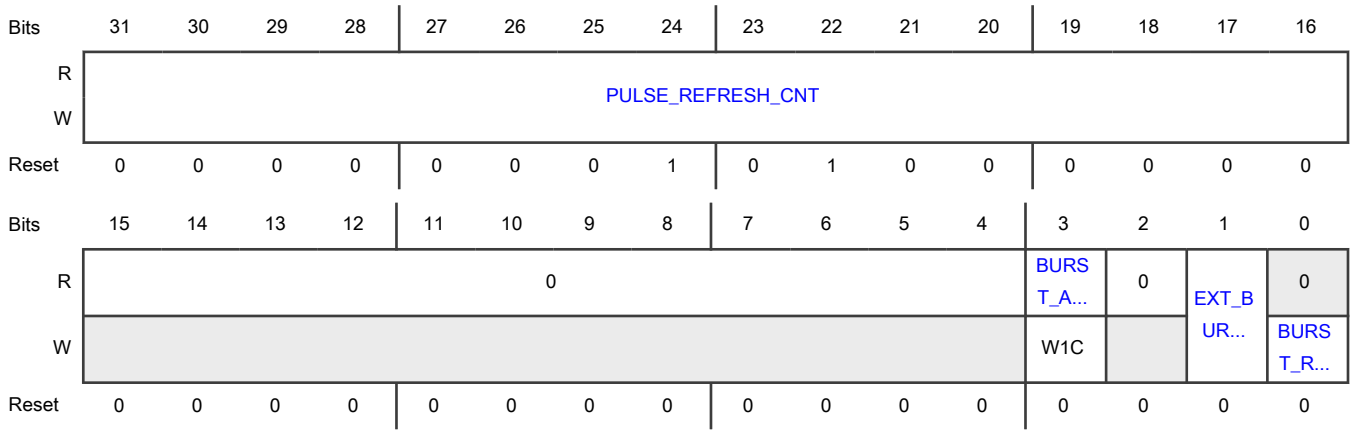
Register	Offset
DCDC_BURST_CFG	504h

Function

Controls the DCDC burst operation.

This register resets only after a POR, LVD, or HVD event.

Diagram



Fields

Field	Function
31-16 PULSE_REFRESH_CNT	Refresh Count Value Controls the DCDC refresh frequency when DCDC is in Pulse Refresh mode. When DCDC is enabled and running in Pulse Refresh mode, PULSE_REFRESH_CNT controls how often the DCDC is pulsed on and off based on a low-power reference clock. You must specify a count value that is long enough to allow a DCDC burst to occur. The pulse duration (time between on and off) is: (reference clock period) × (PULSE_REFRESH_CNT + 2)
15-4 —	Reserved
3 BURST_ACK	Burst Acknowledge Flag Indicates that the DCDC burst completed, and therefore DCDC entered Quiet mode. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Did not complete 1b - Completed When writing 0b - No effect 1b - Clear the flag
2 —	Reserved
1 EXT_BURST_EN	External Burst Request Enable Enables external burst requests. When this field is 1, SPC asserts the output burst trigger DCDC_BURST_TRIG_PULSE after the DCDC burst request has been acknowledged. **NOTE** Enable external bursts before writing 1 to BURST_REQ and after BURST_ACK is 0. 0b - Disable 1b - Enable
0 BURST_REQ	Software Burst Request Generates a software burst request to DCDC. **NOTE** Do not generate a new burst request until the previous burst request has completed and you acknowledged this by clearing the BURST_ACK flag.

Chapter 38
Core Mode Controller (CMC)

38.1 Chip-specific CMC information

Table 346. Reference links to related information

Topic	Related module	Reference
Full description	CMC	CMC
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

38.1.1 Module instances

This device has one instance of CMC module, CMC0.

38.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

38.1.3 SRAMDIS0 register

The Reserved fields in CMC_SRAMDIS0 must be written with zero.

38.2 Overview

CMC provides the sequencing of the CPU and associated logic through the different operating modes.

This chapter describes the available CPU operating modes, including reset, active mode, and low-power modes.

38.2.1 Block diagram

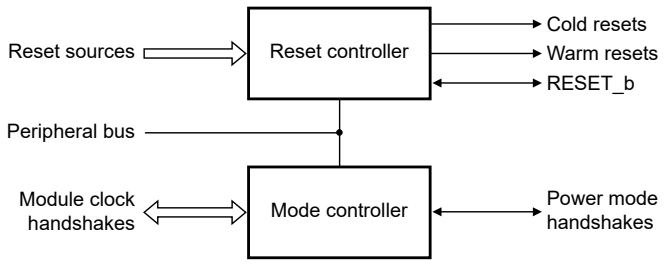

Figure 177. Block diagram

38.2.2 Features

- Configures the low-power mode options including SRAM retention
- Provides reset controller including reset status register and warm reset configuration
- Provides boot mode register and status bits

38.3 Functional description

This section provides the functional description of the block.

38.3.1 Modes of operation

The Arm Cortex-M CPU enters a low-power mode with the execution of a WFI or WFE instruction or via the SLEEPONEXIT mechanism. CMC configures the low-power mode that is entered.

The following table describes the low-power modes available to each core.

Table 347. Operating modes

Mode	Entry	Exit	Description
Reset	POR Warm reset WUU via power down	Active	• Core and peripherals are reset • SRAM optionally retained on power-down wake-up
Active	Reset NVIC WUU	WFI WFE SLEEPONEXIT	Core executing instructions, peripherals optionally active.
Sleep	WFI WFE SLEEPONEXIT	NVIC Reset	• Core waiting for interrupt or event, peripherals optionally active • Core and peripherals retain state. SRAM is active or retained.
Deep Sleep	WFI WFE SLEEPONEXIT	NVIC Reset	• Core waiting for interrupt or event, peripherals optionally active • Core and peripherals retain state, SRAM is retained
Power Down	WFI WFE SLEEPONEXIT	WUU via Active Reset	• Core and peripherals waiting for wakeup • Core and peripherals retain state • SRAM is optionally retained
Deep Power Down	WFI WFE SLEEPONEXIT	WUU via Reset Reset	Core, peripherals, and SRAM not retained.

38.3.2 Active mode

This section describes power options in Active mode.

38.3.2.1 Flash memory

This section describes the Flash Memory Low-Power mode.

You can place the internal flash memory in Low-Power mode under the following conditions:

- Under software control (FLASHCR[FLASHDIS])
- When CPU is sleeping (FLASHCR[FLASHDOZE])
- When the chip enters a low-power mode

When the internal flash memory enters a low-power mode, the wake-up time of the flash memory automatically delays the first access upon exit from Low-Power mode. If there is no access between the internal flash memory exiting Low-Power and subsequent re-entry of Low-Power mode, the wake-up time of the flash memory delays the re-entry.

38.3.2.2 System SRAM

The system SRAM is divided into 32 different power partitions. You can individually power gate these partitions either all the time or only in low-power modes. System SRAM contents in a power gated partition are not retained. You must not access system SRAM partitions when they are power gated.

- Write 1 to SRAMDIS[i] to always power gate system SRAM power partition "i".
- Write 1 to SRAMRET[i] to power gate system SRAM power partition "i" during a low-power mode only.

38.3.3 Low-power modes

This section describes the low-power modes.

38.3.3.1 Low-power entry

The following steps occur during the Low-Power mode entry sequence.

Table 348. Entry sequence

Step	CKMODE (min)	LPMODE (min)	Description
1	0h	0h	Core enters Low-Power mode by WFI/WFE instruction or via SLEEPONEXIT.
2	1h	0h	• Wake-up interrupt controller is enabled. • Core is clock gated.
3	3h	0h	• Request AHB initiators to enter Low-Power mode. • Wait for acknowledge. • AHB initiators are clock gated.
4	3h	0h	• Request AHB peripherals to enter Low-Power mode. • Wait for acknowledge. • AHB peripherals are clock gated.
5	7h	0h	• Request peripherals to enter Low-Power mode. • Wait for acknowledge. • Peripherals are clock gated.
6	Fh	0h	Request power management (regulators, bandgap) to enter Low-Power mode.
7	Fh	1h	• SRAMs enter Low-Power mode (Deep Sleep). • System clocks are gated.
8	Fh	3h	Power domain is placed in Low-Power retention state (Power Down).
9	Fh	7h	Power domain is switched off.
10	Fh	Fh	Regulators are powered off (Deep Power-Down).

38.3.3.2 DMA wakeup

You can configure the DMA to generate a wake-up when a DMA request for configured channel asserts. This is supported when you request the DMA to enter Low-Power mode and retain the DMA state (not in Deep Power-Down).

The DMA wakeup triggers an exit from Low-Power mode for everything except the core, which remains clock gated. Re-enter Low-Power mode after the DMA request negates, and the normal low-power mode entry sequence is followed.

Because a DMA wake-up results in everything except the core from exiting Low-Power mode, you must ensure that other modules not involved in the wakeup remain in a known state. To accomplish this, disable the modules before the initial entry in Low-Power mode or configure the Doze field in selected modules.

If the flash memory is not required during the DMA wakeup, NXP recommends that FLASHCR[FLASHDOZE] = 1.

NOTE

If the DMA request does not negate due to the DMA transfer, the chip remains in a higher power state until an interrupt or other wake-up sources can wakeup the core.

An interrupt that occurs during a DMA wakeup causes an immediate exit from Low-Power mode without affecting the DMA transfer.

38.3.3.3 Power domains

CMC configures Low-Power mode of 2 different power domains when the core enters a low-power mode with CKMODE = Fh. You can configure the different power domains to enter different low-power modes , but you must not configure the WAKE domain to a lower-power mode than any of the other domains.

NOTE

The WAKE domain LPMODE register setting must always be less than or equal to the LPMODE register setting for all other power domains.

CMC controls the following power domains:

- MAIN
- WAKE

The table below lists allowed combinations for MAIN and WAKE.

Table 349. Power Mode Combinations for MAIN and WAKE

CMC PMCTRLMAIN	CMC PMCTRLWAKE
0x0	0x0
0x1	0x1
0x3	0x3
0x3	0x1
0xF	0xF

Configure all power domains to the same Low-Power mode using Global Power Mode Control (GPMCTRL). Alternatively, configure each PMCTRL register to assign an individual low-power mode to each domain.

38.3.3.4 Debug in low-power modes

When the debugger asserts CDBGPWRUPREQ, it requests the debug logic to power up and enable the functionality depending on DBGCTL[SOD].

- When DBGCTL[SOD] = 0, the core clock remains enabled even when the core is sleeping (CKMODE = 0h). CDBGPWRUPACK remains asserted.
- When DBGCTL[SOD] = 1, ignore the debug request when the core sleeps. CDBPWRUPQACK negates when the core is sleeping.

NOTE

Do not attach a debugger when the JTAG/SWD logic is powered down.

38.3.4 Clocks

- The slow bus clock clocks CMC registers and logic.
- clk_1m clock clocks the timeout counters.

38.3.5 Reset

This section describes the sources of reset and the different resets that you can generate.

38.3.5.1 Reset sources

This section describes the different reset sources.

Power-on reset (POR)

When you initially apply power to the MCU or the supply voltage is below the POR falling threshold, the POR circuit triggers the POR condition.

The POR condition asserts a cold reset in all power domains. SRS[POR] and SRS[VD] become 1 on a POR condition.

Voltage detect (VD)

The voltage detect monitors enable by default and keeps the MCU in reset until the supply voltage rises above the LVD rising threshold. Whenever the voltage detect monitors are enabled, they trigger a reset condition if the supply voltage is outside the voltage detect trip point.

SRS[VD] becomes 1 on voltage detect condition. The voltage detect monitors assert a cold reset in all power domains.

Wakeup (WAKEUP)

On a wakeup from Deep-Power Down mode, the power management logic triggers a Wake-up reset in the power domains that had powered off.

The wake-up reset condition asserts a cold reset in all power domains that were powered down. The system power domain, including the RESET_b pin, is unaffected by a wake-up from Deep-Power Down mode (unless another reset source triggers the wake-up). SRS[WAKEUP] becomes 1 on a wake-up reset condition.

External pin reset (RESET_b)

The RESET_b pin is a bidirectional open-drain pin with an internal pull-up resistor. The RESET_b pin function depends on the mode:

- During reset, the RESET_b drives low until the MCU completes initialization, at which point the RESET_b pin is released. If the RESET_b pin asserts externally, then the MCU remains in reset until the RESET_b input is pulled high.
- During active and low-power modes, the RESET_b pin can assert externally to force the MCU into the PIN reset condition.

The RESET_b pin implements a digital filter that you can configure to filter out glitches on the RESET_b pin that are less than 1–32 CMC clock cycles. The filter bypasses in low-power modes when you disable the CMC clock.

The PIN reset condition asserts a warm reset in all power domains. SRS[PIN] and SRS[WARM] become 1 on a PIN reset condition.

Debug access port reset (DAP)

Any debug access port that can initiate a reset request from a connected debugger triggers the DAP reset condition.

The DAP reset condition asserts a warm reset in all power domains. SRS[DAP] and SRS[WARM] become 1 on a DAP reset condition.

Reset timeout (RSTACK)

The reset state machine includes a timeout counter that is triggered by the reset state machine not progressing within 65536 cycles of the clk_1m clock. This triggers the RSTACK reset condition.

The RSTACK reset condition asserts a warm reset in all power domains. SRS[RSTACK], SRS[FATAL], and SRS[WARM] become 1 on an RSTACK reset condition.

Low-power timeout (LPACK)

The low-power entry state machine includes a timeout counter that triggers if a module does not acknowledge entry into Low-Power mode after 65536 cycles of the clk_1m clock. This triggers the LPACK reset condition.

The LPACK reset condition asserts a warm reset in all power domains. SRS[LPACK] and SRS[WARM] become 1 on an LPACK reset condition.

System clock generation (SCG)

The system clock generation includes loss of clock and loss of lock monitors that you can configure to generate a reset, this triggers the SCG reset condition.

The SCG reset condition asserts a warm reset in all power domains. SRS[SCG], SRS[FATAL], and SRS[WARM] become 1 on an SCG reset condition.

Windowed watchdog timer 0 (WWDT0)

The windowed watchdog timer monitors the software by expecting periodic refreshing of the watchdog counter. When this does not occur, it triggers the WWDT0 reset condition.

The WWDT0 reset condition asserts a warm reset in all power domains. SRS[WWDT0] and SRS[WARM] become 1 on a WWDT0 reset condition.

Software (SW)

The software can request a system reset by configuring the system reset request in the Cortex-M33 core, this triggers the software reset condition.

The software reset condition asserts a warm reset in all power domains. SRS[SW] and SRS[WARM] become 1 on a software reset condition.

Lockup (LOCKUP)

The Cortex-M33 core enters Lockup state as a result of certain illegal operations, this triggers the LOCKUP reset condition.

The LOCKUP reset condition asserts an MCU reset in all power domains. SRS[LOCKUP] and SRS[WARM] become 1 on a LOCKUP reset condition.

CPU1 (CPU1)

When CPU1 detects a local reset condition, it triggers the CPU1 reset condition.

The CPU1 reset condition asserts a warm reset in all power domains. SRS[CPU1] and SRS[WARM] becomes 1 on a CPU1 reset condition.

VBAT POR (VBAT)

When VBAT asserts its POR, it triggers the VBAT reset condition.

The VBAT reset condition asserts a warm reset in all power domains. SRS[VBAT] and SRS[WARM] become 1 on a VBAT reset condition.

Windowed watchdog timer 1 (WWDT1)

The windowed watchdog timer monitors the software by expecting periodic refreshing of the watchdog counter. When this does not occur, it triggers the WWDT1 reset condition.

The WWDT1 reset condition asserts a warm reset in all power domains. SRS[WWDT1] and SRS[WARM] become 1 on a WWDT1 reset condition.

Code watchdog (CDOG)

CDOG module helps protect the integrity of software by detecting unexpected changes (faults) in the code execution flow. CDOG module configures to reset or interrupt the processor core when the module detects a fault.

The CDOG0 reset condition asserts a warm reset in all power domains. SRS[CDOG0] and SRS[WARM] become 1 on a CDOG0 reset condition.

The CDOG1 reset condition asserts a warm reset in all power domains. SRS[CDOG1] and SRS[WARM] become 1 on a CDOG1 reset condition.

JTAG reset (JTAG)

When a JTAG instruction places the chip in reset, it triggers the JTAG reset condition.

The JTAG reset condition asserts a warm reset in all power domains. SRS[JTAG]SRS[JTAG], SRS[FATAL]SRS[FATAL], and SRS[WARM] become 1 on a JTAG reset condition.

Security violation (SECVIO)

When a security module detects a security violation, it triggers the SECVIO reset condition.

The SECVIO reset condition asserts a warm reset in all power domains. SRS[SECVIO], SRS[FATAL], and SRS[WARM] become 1 on a SECVIO reset condition.

Tamper detect (TAMPER)

When a tamper detection module detects a tamper event, it triggers the TAMPER reset condition.

The TAMPER reset condition asserts a warm reset in all power domains. The SRS[TAMPER], SRS[FATAL], and SRS[WARM] become 1 on a TAMPER reset condition.

38.3.5.2 Reset types

This section describes the different resets that you can generate.

Cold reset

Each power domain generates a cold reset to reset the debug logic and mode control logic. The cold reset for each power domain can assert as a result of the following events.

- Initial POR of the chip
- Voltage detect monitor (LVD, for example)

- Power domain wake-up from Deep-Power Down (varies per domain)

A cold reset does not guarantee the contents of on-chip SRAM.

Warm reset

- Cold Reset or any of the remaining warm reset sources generates a warm reset.
- A warm reset resets most of the logic in each power domain.
- Warm resets are divided into fatal reset sources and non-fatal reset sources.

You can configure the non-fatal reset sources to generate an interrupt instead of the warm reset. The warm reset averts if you can clear the non-fatal reset source (including status flag) within 65536 cycles of the clk_1m clock. Non-fatal resets retain the contents of on-chip SRAM.

You cannot configure the fatal reset sources to generate an interrupt and do not guarantee the contents of on-chip SRAM.

38.3.5.3 Reset sequence

Power-on reset

Perform the following steps as part of the POR (or voltage detect monitor) sequence:

1. RESET_b pin drives low and internal reset signals asserted.
2. POR or LVD signals negate and clocks are enabled in their default configuration.
3. Internal reset remains asserted for 8 CMC clock cycles.
4. Internal reset to flash memory and fuse controllers negates and their initialization sequences commence.
5. Initialization sequences for flash memory and fuse complete.
6. Internal trim registers are loaded and RESET_b pin is tri-stated.
7. Reset state machine waits for RESET_b pin input to pull high or drive high externally.
8. Internal reset signals negate.
9. Core exits reset and fetches the initial program counter and stack pointer from ROM.

Deep-power down wake-up

Perform the following steps as part of the deep-power down wake-up sequence:

1. Internal reset signals asserted.
2. Wake-up signal negates and clocks are enabled in their default configuration.
3. Internal reset remains asserted for 8 CMC clock cycles.
4. Internal reset to flash memory and fuse controllers negates and commence their initialization sequences.
5. Initialization sequences for flash memory and fuse complete.
6. Internal trim registers are loaded.
7. Internal reset signals negate.
8. Core exits reset and fetches the initial program counter and stack pointer from ROM.

A wake-up from deep-power down via the RESET_b pin follows the warm reset sequence.

Warm reset

Perform the following steps as part of the warm reset sequence:

1. RESET_b pin drives low and internal reset signals asserted.
2. Clocks are enabled in their default configuration.
3. Internal reset remains asserted for 8 CMC clock cycles.
4. Internal reset to flash memory and fuse controllers negates and commence their initialization sequences.
5. Initialization sequences for flash memory and fuse complete.
6. Internal trim registers are loaded and RESET_b pin is tri-stated.
7. Reset state machine waits for RESET_b pin input to pull high or drive high externally.
8. Internal reset signals negate.
9. Core exits reset and fetches the initial program counter and stack pointer from ROM.

38.3.6 Interrupts

CMC generates a single interrupt, which System Reset Interrupt Enable (SRIE) configures.

38.4 External signals

Table 350. External signals

Signal	Description	Direction
RESET_B	Bidirectional open-drain reset pin with pullup that asserts low during warm reset except when waking up from a low-power mode.	Input or output
ISPMODE_n	The input pin is sampled at the end of the RESET_B assertion and stored in Mode (MR0).	Input

38.5 Initialization

By default, the digital glitch filter is disabled on RESET_b pin. To enable the filter, configure:

- RPC[LPFEN], RPC[FILTEN], or both.
- RPC[FILTCFG].

38.6 Application information

To configure for Deep-Power Down Low-Power mode entry:

1. Write Fh to Clock Control (CKCTRL)
2. Write 8h to Power Mode Protection (PMPROT)
3. Write Fh to Global Power Mode Control (GPMCTRL)
4. Execute WFI instruction

To configure for Power-Down Low-Power mode entry:

1. Write Fh to Clock Control (CKCTRL)
2. Write 2h to Power Mode Protection (PMPROT)
3. Write 3h to Global Power Mode Control (GPMCTRL)
4. Execute WFI instruction

To configure for Sleep mode entry:

1. Write 0h or 1h to Clock Control (CKCTRL)
2. Execute WFI instruction

To configure for Deep Sleep Low-Power mode entry:

1. Write Fh to Clock Control (CKCTRL)
2. Write 1h to Power Mode Protection (PMPROT)
3. Write 1h to Global Power Mode Control (GPMCTRL)
4. Execute WFI instruction

To configure for MAIN in power-down and WAKE in Deep Sleep Low-Power mode entry:

1. Write Fh to Clock Control (CKCTRL)
2. Write 3h to Power Mode Protection (PMPROT)
3. Write 3h to PMCTRLMAIN
4. Write 1h to PMCTRLWAKE
5. Execute WFI instruction

38.7 Memory map and register descriptions

This section describes the registers in the CMC module.

38.7.1 CMC register descriptions

NOTE

Different CMC registers reset on different reset types.

NOTE

You must read back the last register written to before executing the WFI instruction. This ensures that before the MCU enters the low power mode, all register writes associated with setting up the low power mode are complete, failure to do this may result in the low power mode not being entered correctly.

38.7.1.1 CMC memory map

CMC0 base address: 4004_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID (VERID)	32	R	0301_0000h
10h	Clock Control (CKCTRL)	32	RW	0000_0000h
14h	Clock Status (CKSTAT)	32	RW	0000_0000h
18h	Power Mode Protection (PMPROT)	32	RW	0000_0000h
1Ch	Global Power Mode Control (GPMCTRL)	32	RW	0000_0000h
20h	Power Mode Control (PMCTRLMAIN)	32	RW	0000_0000h
24h	Power Mode Control (PMCTRLWAKE)	32	RW	0000_0000h

Table continues on the next page...

Table continued from the previous page...

Offset	Register	Width (In bits)	Access	Reset value
80h	System Reset Status (SRS)	32	R	See section
84h	Reset Pin Control (RPC)	32	RW	0000_0000h
88h	Sticky System Reset Status (SSRS)	32	RW	0000_0006h
8Ch	System Reset Interrupt Enable (SRIE)	32	RW	0000_8800h
90h	System Reset Interrupt Flag (SRIF)	32	RW	0000_0000h
9Ch	Reset Count Register (RSTCNT)	32	R	0000_0000h
A0h	Mode (MR0)	32	RW	0000_0000h
B0h	Force Mode (FM0)	32	RW	0000_0000h
C0h	SRAM Disable (SRAMDIS0)	32	RW	0000_0000h
D0h	SRAM Retention (SRAMRET0)	32	RW	0000_0000h
E0h	Flash Control (FLASHCR)	32	RW	0000_0000h
100h	BootROM Status Register (BSR)	32	RW	0000_0000h
10Ch	BootROM Lock Register (BLR)	32	RW	0000_0002h
110h	Core Control (CORECTL)	32	RW	0000_0000h
120h	Debug Control (DBGCTL)	32	RW	0000_0000h

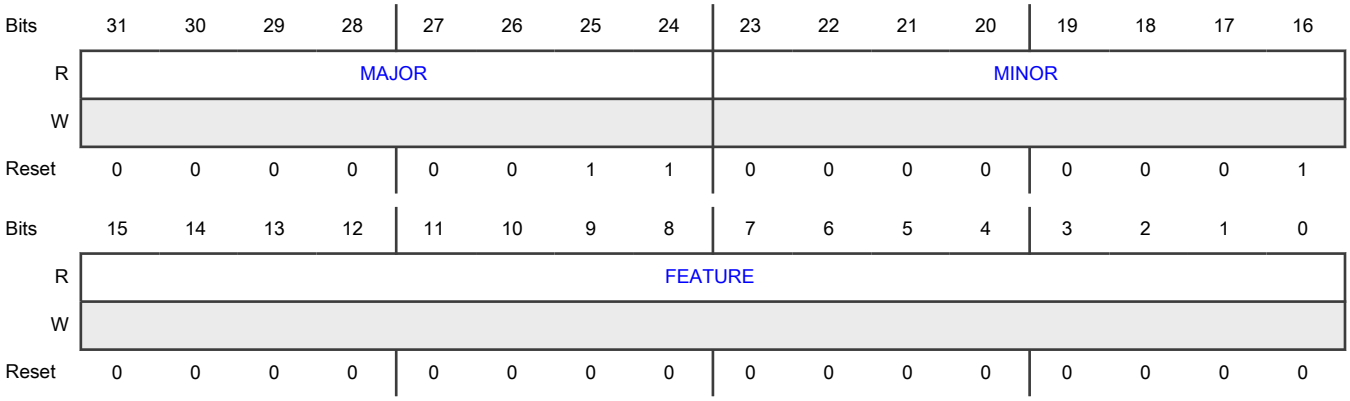
38.7.1.2 Version ID (VERID)

Offset

Register	Offset
VERID	0h

Function
Contains version numbers for module design and feature set.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Returns the major version number for the module specification.
23-16 MINOR	Minor Version Number Returns the minor version number for the module specification.
15-0 FEATURE	Feature Specification Number Returns the feature set number.

38.7.1.3 Clock Control (CKCTRL)

Offset

Register	Offset
CKCTRL	10h

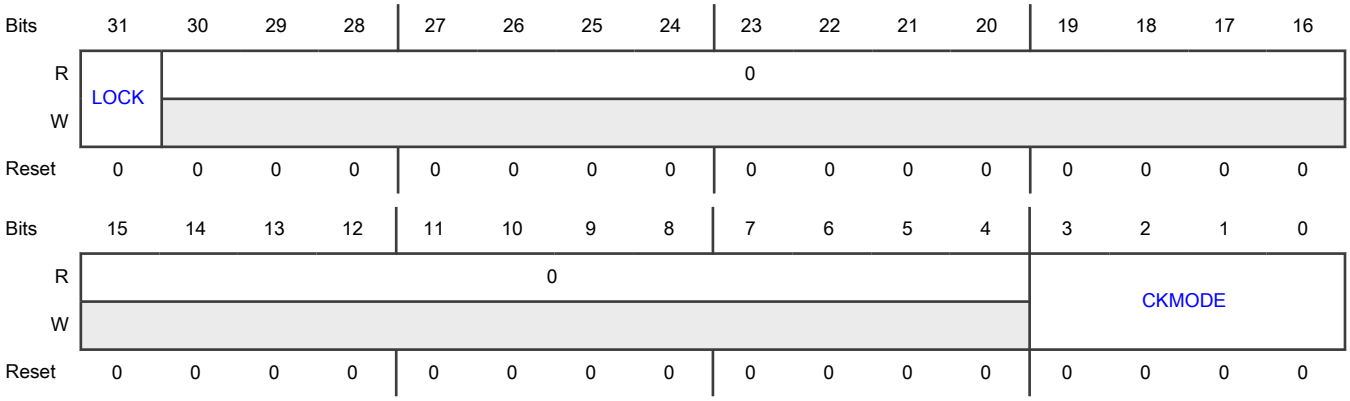
Function

Configures the amount of clock gating when the core asserts sleeping due to WFI, WFE, or SLEEPONEXIT.

NOTE

This register resets on WAKE warm reset.

Diagram



Fields

Field	Function
31 LOCK	Lock Locks the register and blocks writes until the next reset. 0b - Allowed 1b - Blocked
30-4 —	Reserved
3-0 CKMODE	Clocking Mode Configures the amount of clock gating when the core enters a low-power mode because of WFI, WFE or SLEEPONEXIT. Configuring CKMODE > 0 requires the SLEEPDEEP field in the Arm core to become 1. Configuring PMCTRLx[LPMODE] > 0 requires writing Fh to CKMODE. 0000b - Core clock is on 0001b - Core clock is off 1111b - Core, platform, and peripheral clocks are gated, and core enters Low-Power mode.

38.7.1.4 Clock Status (CKSTAT)

Offset

Register	Offset
CKSTAT	14h

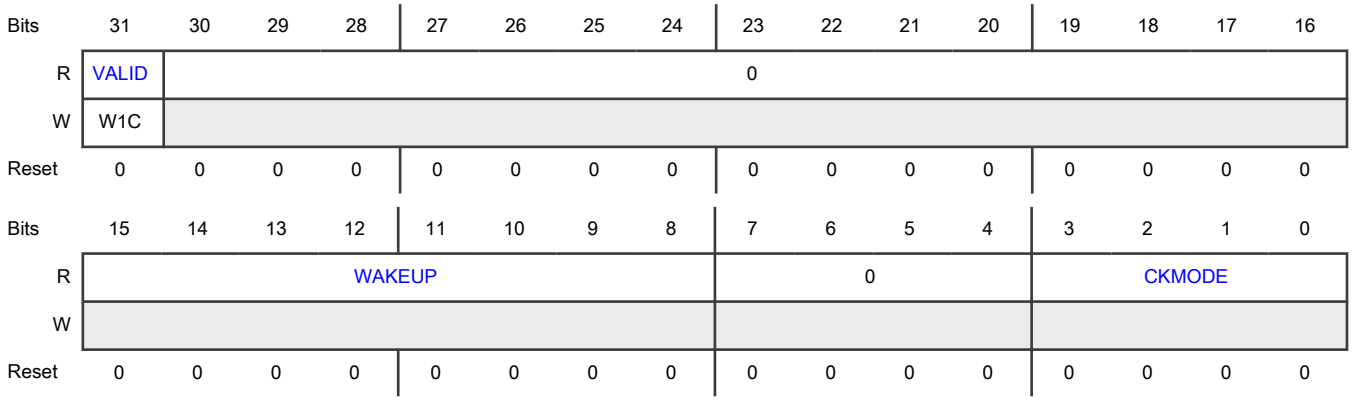
Function

Returns the clock gating status and wake-up source from the previous Low-Power mode entry, provided the core was clock gated. This requires configuring CKCTRL[CKMODE] > 0 and the wake-up event must occur after the core is clock gated. The register contents are only valid when CKSTAT[VALID] = 1.

NOTE

This register resets on WAKE warm reset.

Diagram



Fields

Field	Function
31 VALID	Clock Status Valid Indicates that the core clock was gated since you last wrote 0 to this field. 0b - Core clock not gated 1b - Core clock was gated due to Low-Power mode entry
30-16 —	Reserved
15-8 WAKEUP	Wake-up Source Returns any wake-up sources from the previous Low-Power mode entry. [0] - Wake-up source is reset interrupt or wakeup from Deep Power-Down [1] - Wake-up source is debug request [2] - Wake-up source is interrupt [3] - Wake-up source is DMA wakeup [4] - Wake-up source is WUU request [5] - Wake-up source is USBFS (USB0) [6] - Wake-up source is ITRC [7] - Wake-up source is CPU1 A wakeup from Deep Power-Down writes 1 to WAKEUP[0]. Depending on Low-Power mode, other wake-up bits may not become 1.
7-4 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
3-0 CKMODE	Low Power Status Returns the result of the previous Low-Power mode entry. 0000b - Core clock not gated 0001b - Core clock was gated 1111b - Core, platform, and peripheral clocks were gated, and power domain entered Low-Power mode All other values are reserved.

38.7.1.5 Power Mode Protection (PMPROT)

Offset

Register	Offset
PMPROT	18h

Function

Provides protection for entry in low-power modes, you must allow a low-power mode before configuring any Power Mode Control register (PMCTRLx) to that mode.

NOTE

This register resets on WAKE warm reset.

Diagram

Field	Function
LOCK	Locks the register and blocks writes until the next reset. 0b - Allowed 1b - Blocked
30-4 —	Reserved
3-0 LPMODE	Low-Power Mode Bit 0: When set, allows the PMCTRLx[LPM] field to be configured for Deep Sleep. Bit 1: When set, allows the PMCTRLx[LPM] field to be configured for Power Down. Bit 3: When set, allows the PMCTRLx[LPM] field to be configured for Deep Power Down. 0000b - Not allowed 0001b - Allowed 0010b - Allowed 0011b - Allowed 0100b - Allowed 0101b - Allowed 0110b - Allowed 0111b - Allowed 1000b - Allowed 1001b - Allowed 1010b - Allowed 1011b - Allowed 1100b - Allowed 1101b - Allowed 1110b - Allowed 1111b - Allowed

38.7.1.6 Global Power Mode Control (GPMCTRL)

Offset

Register	Offset
GPMCTRL	1Ch

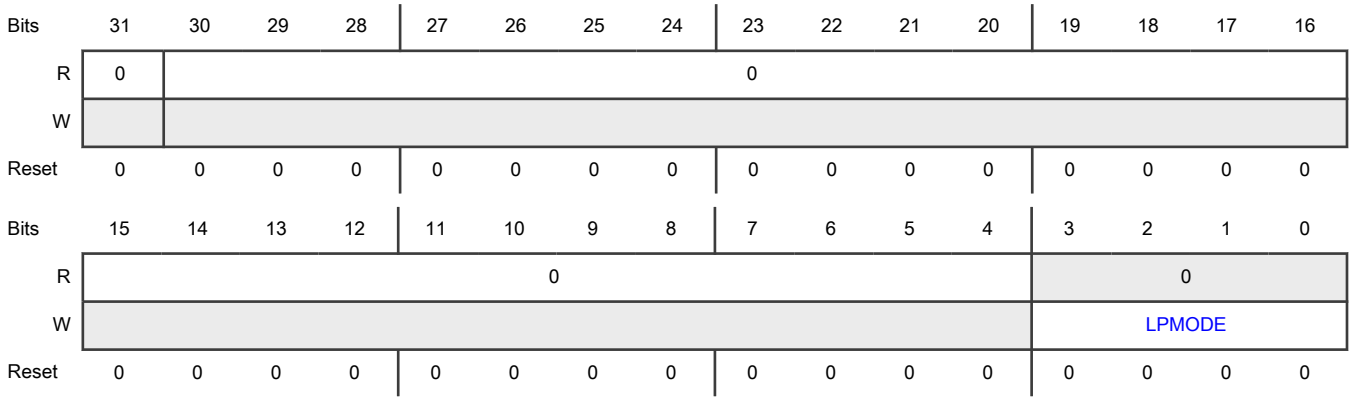
Function

Updates all PMCTRLx registers with the value written.

NOTE

This register resets on WAKE cold reset.

Diagram



Fields

Field	Function
31 —	Reserved
30-4 —	Reserved
3-0 LPMODE	Low-Power Mode Specifies that all PMCTRLx[LPMODE] fields update with the value written.

38.7.1.7 Power Mode Control (PMCTRLMAIN - PMCTRLWAKE)

Offset

Register	Offset
PMCTRLMAIN	20h
PMCTRLWAKE	24h

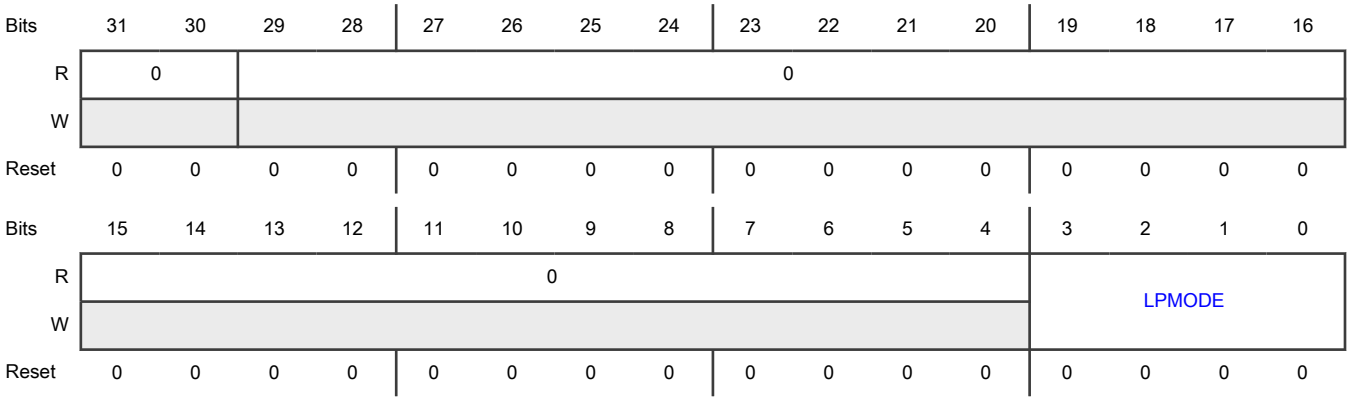
Function

Configures entry into low-power modes for each power domain, provided that the selected power mode is allowed via an appropriate setting of Power Mode Protection (PMPROT), and CKMODE = Fh.

NOTE

This register resets by WAKE cold reset.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-4 —	Reserved
3-0 LPMODE	Low-Power Mode Selects the desired Low-Power mode when a core executes WFI or WFE instruction. Writes to this field are blocked if you have not enabled the protection level using Power Mode Protection (PMPROT). You must not configure this field for the WAKE domain to a lower power mode than any other power domain. **NOTE** See Power domains section for details on allowed combinations. 0000b - Active/Sleep 0001b - Deep Sleep 0011b - Power Down 0111b - Reserved 1111b - Deep-Power Down

38.7.1.8 System Reset Status (SRS)

Offset

Register	Offset
SRS	80h

Function

Updates on every MAIN warm reset to indicate the type/source of the most recent reset.

Diagram

14 SW	Software Reset Indicates a software reset request from the Arm core (SYSRESETREQ) that causes a reset. 0b - Reset not generated 1b - Reset generated
13	Windowed Watchdog 0 Reset

Table continues on the next page...

Table continued from the previous page...

Field	Function
WWDT0	Indicates the WWDT 0 timeout that causes a reset. 0b - Reset is not generated 1b - Reset is generated
12 SCG	System Clock Generation Reset Indicates a loss-of-clock or loss-of-lock event in the SCG that causes a reset. This is a fatal reset source and SRAM contents are not guaranteed. 0b - Reset is not generated 1b - Reset is generated
11 LPACK	Low Power Acknowledge Timeout Reset Indicates a timeout in the Low Power Mode entry logic that causes a reset. This timeout is generated if a peripheral does not acknowledge entry into Low-Power mode within 65536 cycles of clk_1m clock. 0b - Reset not generated 1b - Reset generated
10 RSTACK	Reset Timeout Indicates a timeout or other error condition in the system reset generation logic that causes a reset. This is a fatal reset source, and SRAM contents are not guaranteed. 0b - Reset not generated 1b - Reset generated
9 DAP	Debug Access Port Reset Indicates a reset request from a DAP that causes a reset. 0b - Reset was not generated 1b - Reset was generated
8 PIN	Pin Reset Indicates an external assertion of the RESET_b pin that causes a reset. 0b - Reset was not generated 1b - Reset was generated
7-6 —	Reserved
5 FATAL	Fatal Reset Asserts if the last reset source was a fatal reset source. You cannot guarantee SRAM contents following a fatal reset source.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Reset was not generated 1b - Reset was generated
4 WARM	Warm Reset Asserts if the last reset source was a warm reset source. 0b - Reset not generated 1b - Reset generated
3 —	Reserved
2 VD	Voltage Detect Reset Indicates that an enabled voltage detect monitor causes a reset. 0b - Reset not generated 1b - Reset generated
1 POR	Power-on Reset Indicates the POR detection logic that causes a reset. You cannot guarantee SRAM contents following a POR source. 0b - Reset not generated 1b - Reset generated
0 WAKEUP	Wake-up Reset Indicates a wake-up from Deep-Power Down mode that causes a reset. 0b - Reset not generated 1b - Reset generated

38.7.1.9 Reset Pin Control (RPC)

Offset

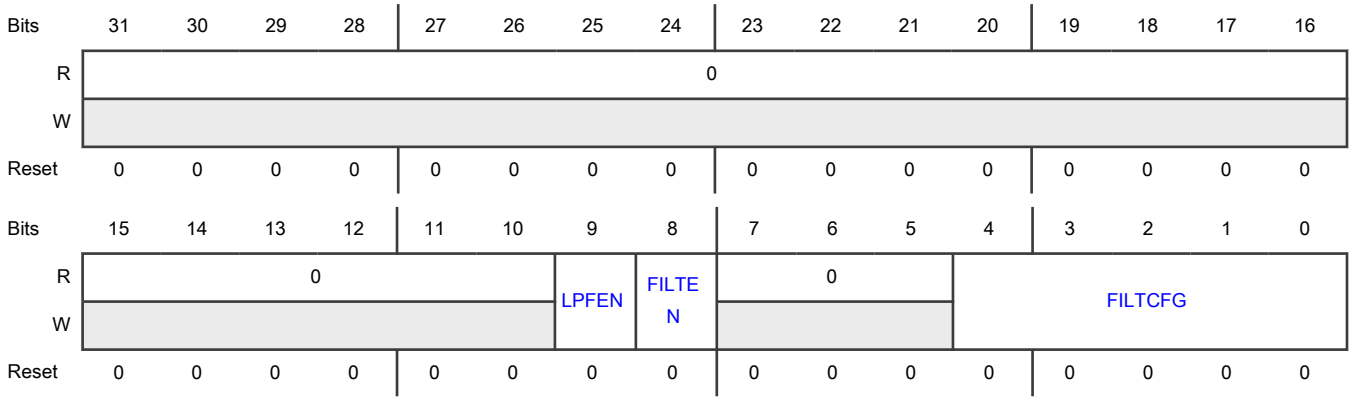
Register	Offset
RPC	84h

Function

NOTE

WAKE cold reset resets this register.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 LPFEN	Low-Power Filter Enable Enables the low-power reset pin filter in both Active and Low-Power modes when this field = 1. The RESET_b pin must assert for more than three clk_1m clock cycles to always propagate through the filter. A glitch less than two clk_1m clock cycles never propagates through the filter. 0b - Disables 1b - Enables
8 FILTEN	Filter Enable Enables the slow clock reset pin filter in Active modes. The RESET_b pin must assert for more than FILTCFG + 1 slow system clock cycles to always propagate through the filter. A glitch less than FILTCFG slow system clock cycles never propagates through the filter. If RPC[LPFEN] also becomes 1, then the filters operate in series. 0b - Disables 1b - Enables
7-5 —	Reserved
4-0 FILTCFG	Reset Filter Configuration Configures the reset pin filter's width from 1 to 32 slow system clock cycles.

38.7.1.10 Sticky System Reset Status (SSRS)

Offset

Register	Offset
SSRS	88h

Function

Stores all sources of system reset that has generated a system reset since the last WAKE cold reset and that you have not cleared. SSRS does not update following a core software reset.

NOTE

This register resets on WAKE cold reset.

Diagram

38.7.1.11 System Reset Interrupt Enable (SRIE)

Offset

Register	Offset
SRIE	8Ch

Function

Delays the assertion of a system reset for 65538 cycles of the clk_1m clock when an interrupt is generated. This allows you to perform a graceful shutdown or to abort the warm reset provided you can clear the pending reset source by resetting the source and then clearing the pending flag. This feature cannot delay a cold or fatal warm reset source. System Reset Status (SRS) updates after the warm reset occurs.

The reset interrupt is not supported in Deep-Power Down mode.

NOTE

This register is reset on WAKE Cold Reset.

38.7.1.12 System Reset Interrupt Flag (SRIF)

Offset

Register	Offset
SRIF	90h

Function

Returns the source of the reset interrupt. You can clear the pending reset source by resetting the source and then clearing the pending flag.

NOTE

This register resets on WAKE warm reset.

Diagram

38.7.1.13 Reset Count Register (RSTCNT)

Offset

Register	Offset
RSTCNT	9Ch

Function

The Reset Count Register returns the number of reset sequences completed since the last WAKE Cold Reset.

NOTE

This register is reset on WAKE Cold Reset.

Diagram

38.7.1.16 SRAM Disable (SRAMDIS0)

Offset

Register	Offset
SRAMDIS0	C0h

Function

Powers off the specific on-chip System SRAM arrays whenever the corresponding register field becomes 1. You must not access the SRAM array and also do not retain the SRAM array contents.

You must configure this register to 0 before entering DS mode.

NOTE

This register resets on MAIN warm reset.

Field	Function
31-0 DISn	SRAM Disable If this field is 1, corresponding SRAM array is disabled. SRAM array is powered off and must not be accessed. If this field is 0, corresponding SRAM array is enabled. **NOTE** See the chip-specific CMC section for register bit details. 0b - Enables 1b - Disables

38.7.1.17 SRAM Retention (SRAMRET0)

Offset

Register	Offset
SRAMRET0	D0h

Function

Configures if the on-chip System SRAM arrays are retained or powered off in low-power modes.

You must configure this register to 0 before entering DS mode.

NOTE

This register resets on WAKE warm reset.

Diagram

Chapter 39
Security overview

39.1 Disclaimer

As system security requirements and the attack surface evolves, it is important for customers to understand the types of attacks (especially advanced physical attacks) which NXP does not claim to protect against, or strongly mitigate, so that appropriate mitigation can be taken by the customer at the system level if necessary.

- This SoC has built-in security event detection features. However, NXP does not guarantee against advanced tamper attempts, including operation of the device beyond the defined specification limits. NXP does not guarantee the protection against semi-invasive and invasive attacks.
- This SoC has several built-in features addressing side channel attacks. However, there is no claim to be completely resistant. The effectiveness of these features has not been independently evaluated. Therefore NXP does not guarantee that the result will meet specific customer requirements.
- This SoC's security trust architecture relies on the strength of cryptographic algorithms and digital signatures. If these are subsequently determined to have inherent flaws, then the impact for each flaw must be evaluated and, in this case, NXP does not guarantee the underlying trust architecture claims.
- This SoC has some built-in access control mechanisms to support the logical separation of executed code. However, NXP does not guarantee that the device completely ensures logical separation by itself. Any vulnerabilities identified in Trusted Execution Environments or Hypervisor software may impact this separation and data integrity, and may require additional mitigations.

NXP recommends customers to implement appropriate design and operating safeguards based on defined threat models, to minimize the security risks associated with their applications and products.

39.2 Overview

This chapter provides an overview of Platform Security features the device implements using following on-chip components.

- ELS security subsystem provides key isolation. It also includes random number generation functionality.
- Physically Unclonable Function (PUF) SRAM controller
- PUF that stores the applications keys, which are provisioned to ELS S50 key store, securely.
- Public-key cryptography accelerator (PKC) .
- OTP controller (OTPC) which supports loading and housing of EFUSE content into shadow registers.
- Code Watch Dog (CDOG) to ensure software integrity by detecting unexpected changes in the code execution flow.
- Intrusion and Tamper Response Controller (ITRC) to configure the response action for an intrusion event detected by an on-chip security sensors.
- Memory Block Checker (MBC) that provides read, write, and execute access control per block of internal flash memory.
- Digital tamper (TDET) to support tamper detection.
- Secure AHB bus and AHB Controller to support secure trusted execution at the system level.
- PRINCE in CTR mode of operation to provide confidentiality protection of the content stored on internal flash.
- FlexSPI providing support of inline Prince Encryption Decryption (IPED) in GCM or CTR mode of operation.
- Digital and analog Glitch Detect (GDET) to provide power supply glitch detection.
- Cyclic Redundancy Check (CRC) that provides error detection for multi-bit errors.

The detailed description of each component can be found in the Security Reference Manual for this chip.

NOTE

The EdgeLock Secure Subsystem (ELS) is also known as EdgeLock Secure Enclave, Core Profile (ELE). This document uses the ELS name, but other materials might refer to this module as EdgeLock Secure Enclave, Core Profile or ELE.

The following figure shows the MCX N security system diagram:

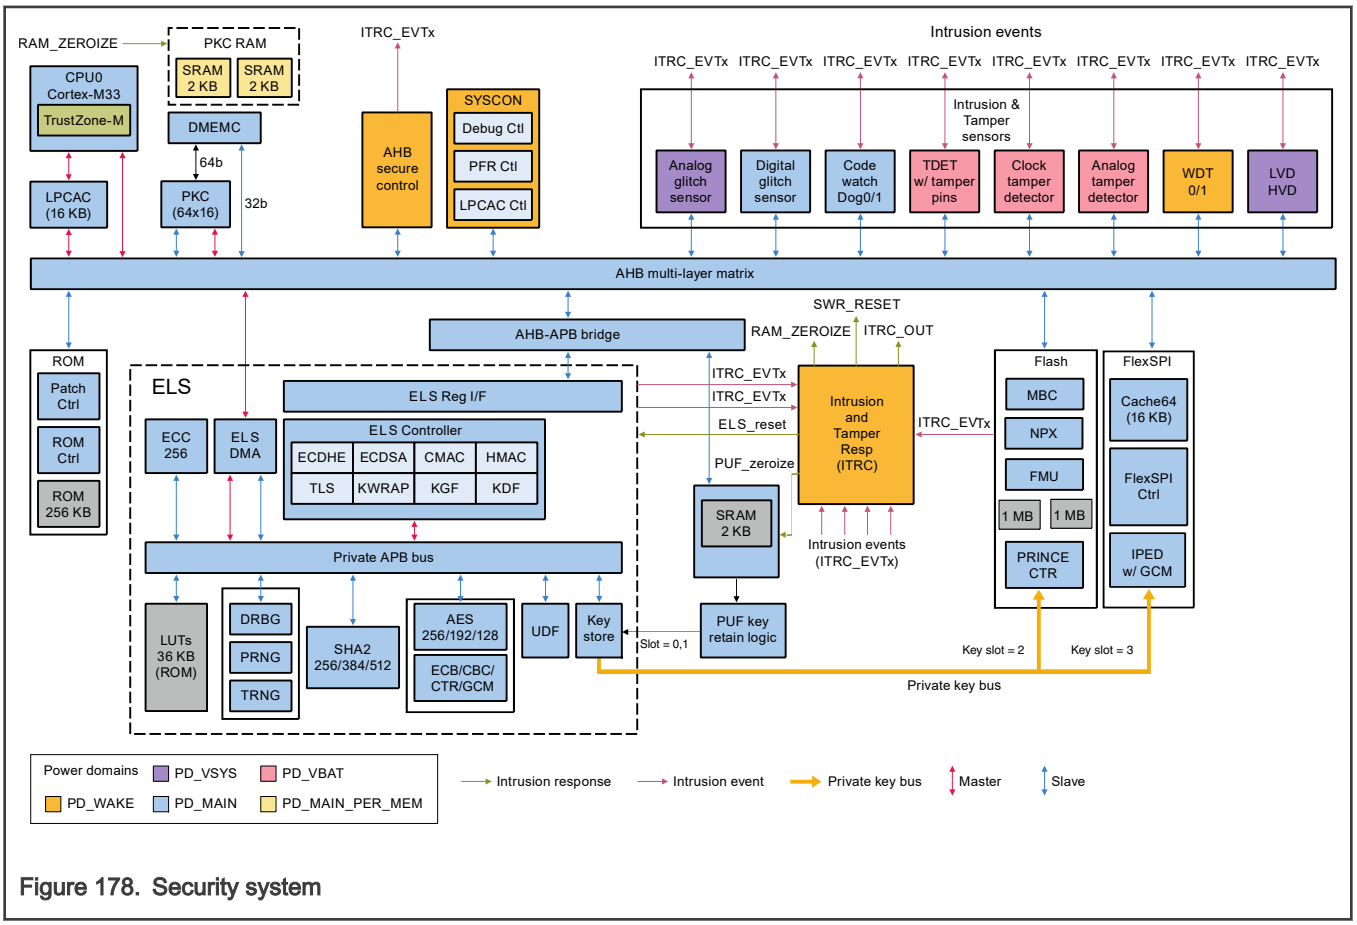

Figure 178. Security system

39.3 Immutable Root of Trust

As defined by Trusted Computing Group, “an Immutable Root of Trust (RoT) is expected to remain identical across all devices within a set of device models based on a defined threat model. It is also expected not to change across time and, therefore, will behave the same during each device’s lifespan.” It consists of truly immutable hardware logic, including analog and digital logic, read-only memory and one-time programmable memory. Immutable RoT is essential for guaranteeing any security feature, including Secure Boot, Secure Debug, Life-cycle Management, and a number of others. In this device, Immutable RoT is embedded in the Boot ROM (immutable bootloader). It uses the device hardware cryptographic functionality for its function.

39.4 Life-cycle management

During its lifespan, a typical device finds itself in various places around the world. It is manufactured in a semiconductor factory, tested and packaged in silicon manufacturer facilities, sold to various distributors, sold further to the Original Equipment Manufacturer (OEM), assembled, tested and provisioned by their Contract Manufacturers and, finally, delivered to the end-customer. In the case of failure, a device is returned to OEM or even back to the silicon manufacturer for further failure analysis.

Device life-cycle state is used to reflect the actual state of the device, which is further used to instruct the device on how exactly to protect the assets a device hosts during specific time. For example, when a device is being tested at a silicon manufacturer facility and no OEM or end-customer assets have been provisioned on it, then access to the device, in terms of debug or test, is less restrictive than when a device is with the end-customer.

Life-cycle state is monotonic, meaning it can only always be increased. Immutable RoT is in charge of life-cycle management and it enforces device access policies accordingly.

39.5 Secure boot

Secure Boot ensures authenticity, integrity and confidentiality of the device bootloader, firmware, and other software during the boot process and ensures that the intended secure life-cycle state is reached. ECDSA P-256 with SHA-256 or ECDSA P-384 with SHA-384 are there to guarantee authenticity and integrity of the firmware image. PRINCE-based memory encryption using a device-unique key derived from PUF can be used to provide code/data confidentiality while the firmware image is stored in internal or external FLASH. Immutable RoT is in charge of enforcing Secure Boot and it does so according to the policies defined by the life-cycle state.

39.6 Secure update

Secure Update is the process used to securely update the firmware image in the field. The firmware image is encrypted using AES-128 or AES-256 and signed using ECDSA P-256 or ECDSA P-384, following the SB3.1 firmware image format. Secure Update guarantees authenticity and confidentiality of the new image. It also ensures that the new image is up-to-date, preventing the rollback to an older image. Running firmware is in charge of receiving and verifying the new firmware image. The follow-up Secure Boot verifies the new firmware image again, making sure the Immutable RoT is still in charge of ensuring authenticity of the latest firmware.

39.7 Secure debug

Secure Debug is the process used to securely access debug, following the policy defined by the life-cycle state. When a debugger wants to debug a device, they indicate that through a so-called debug mailbox and initiate reset. During boot, a device is checking the debug mailbox and starting a full asymmetric-key crypto based challenge-response protocol. A 128-bit random challenge is issued by the device and signed by a debugger. The response is then verified by the device and, if successful, debug is allowed. Immutable RoT is in charge of the whole process.

39.8 IP protection

IP Protection is a set of mechanisms used to protect confidentiality and integrity of valuable code and data stored on the device. During Secure Update, the firmware image is encrypted using AES. While at rest and during Secure Boot, the firmware image can be encrypted using PRINCE. Data or code stored in internal or external memory is encrypted using PRINCE as well. PRINCE encryption is done using a device-unique key, which is derived from PUF by the Immutable RoT. Up to 4 independent memory regions of internal FLASH and up to 4 independent memory regions of external FLASH can be used for protecting IP content from various vendors.

39.9 Secure isolation

Arm TrustZone enables Secure Isolation during run-time by providing four distinct levels of privilege: secure-privilege, secure-user, non-secure-privilege, non-secure-user. Every peripheral is equipped with Peripheral Protection Checker (PPC) that can be programmed to control access to that peripheral, following the Arm TrustZone philosophy. Every memory is equipped with Memory Protection Checker (MPC) that can also be programmed in the same way as the PPC. Secure AHB Controller is in charge of programming all PPC and MPC blocks and only the highest level of privilege, which is secure-privilege, is allowed to do that.

As highlighted by the mechanisms we use for IP Protection, PRINCE-based memory encryption also ensures Secure Isolation between multiple IP vendors. Initial Vector (IV) is derived by secure-privilege and a different value is used for every independent memory region, ensuring the isolation between each other.

39.10 Secure attestation

Secure Attestation is a set of mechanisms used to provide evidence to a remote party on the device’s genuine identity, its software and firmware versions, as well as its integrity and lifecycle state. Device Identity Composition Engine (DICE), as defined by Trusted Computing Group, uses Immutable RoT during boot time to create a unique Device Identity which takes into account Unique Device Secret (UDS), hardware state of the device and its firmware. The DICE feature is implemented using the ELS Runtime

Fingerprint (RTF) in this device. RTF is the NXP-proprietary attestation mechanism, which measures the device's state during boot-time and run-time as well.

39.11 Secure storage

Immutable RoT, including PUF as the source of device-unique master key, is in charge of key derivation and key management. RFC3394 using device-unique key wrapping key is used as a method for securely storing keys. AES GCM using device-unique keys is used for securely storing valuable data. PRINCE memory encryption using device-unique key can be used for storing valuable code in internal and external FLASH.

39.12 Trust provisioning

Trust provisioning is a process used for creation of initial Device Identity keys. Its major objective is to provide a cryptographic proof of the device's origin and to offer a set of tools to OEM for secure provisioning of their own assets. In a nutshell, a device-unique private-public key pair is created on every device, the public portion of which is collected and signed by NXP. That signed public key is installed back onto every device in a form of device-unique certificate, which serves as the actual proof of the device's origin. The corresponding private key, together with other pre-installed key material, is then used for authentication and secure connection to the device, enabling secure provisioning of OEM assets even in a manufacturing environment OEM may not fully trust.

39.13 Secure key management

Secure key management is a process of securing valuable keys and various key material which are essential in maintaining security of the end-user, OEM and NXP assets. The process strongly relies on the Immutable RoT consisting of PUF, hardware logic and ROM. A device-unique master key is provided by PUF and only used for further key derivation. Part of the derivation data is supplied by the Immutable RoT, accurately reflecting the device's state, making sure different keys are derived in different states. For example, different life-cycle state will often yield a different derived key. Similarly, when the debug port is open a different key will be derived than when the debug port is closed. All the platform keys reside within a security subsystem, hidden from the application core at all times.

39.14 Anomaly Detection and Reaction

Anomaly Detection and Reaction describes the processes or algorithms that analyze the device input and output such as sensor data, as well as the software integrity and application operation for abnormal events and, if required, trigger and execute an action. Typically these actions encompass logging the anomaly, issuing a message to the cloud backend, resetting the device, and/or changing a life cycle state.

Chapter 40
Cyclic Redundancy Check (CRC)

40.1 Chip-specific CRC information

Table 351. Reference links to related information

Topic	Related module	Reference
Full description	CRC	CRC

Clocking		Clock distribution
Power management		Power management
Interrupts	NVIC	Interrupts

40.1.1 Module instances

This device has one instance of the CRC module, CRC0.

40.2 Overview

CRC generates 16-bit or 32-bit CRC codes output for error detection. You can calculate these codes for up to 32 bits input data at a time.

CRC provides a programmable polynomial and other parameters to meet 16-bit or 32-bit CRC standards.

40.2.1 Block diagram

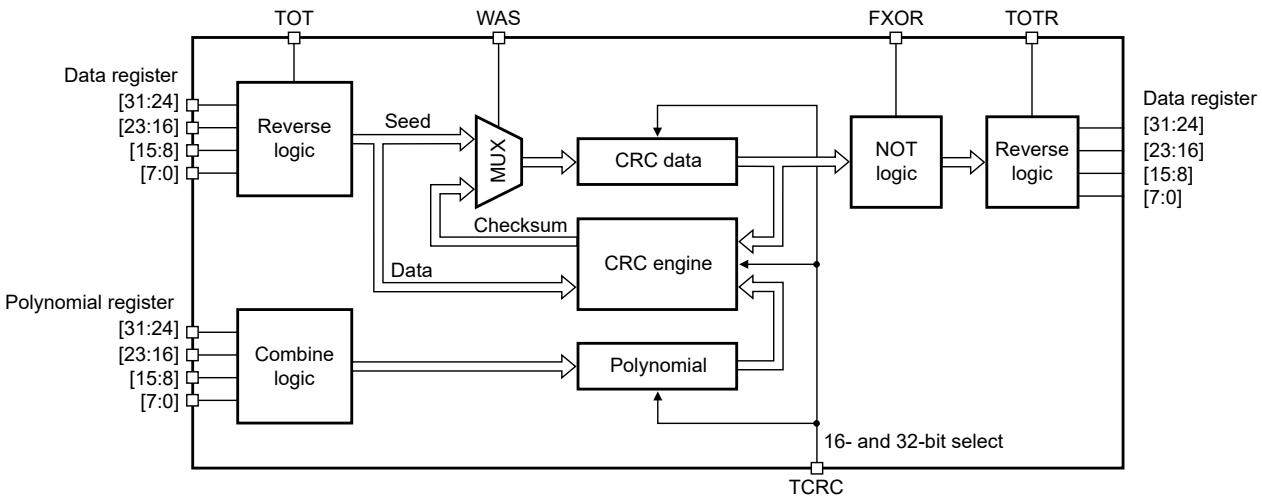

Figure 179. Block diagram

40.2.2 Features

CRC has the following features:

- Hardware CRC generator circuit using 16-bit or 32-bit programmable shift registers

- Programmable initial seed value and polynomial
- Transpose of input or output data (CRC result) in bitwise or bytewise (this option is required for certain CRC standards. You cannot perform a bytewise transpose operation when accessing DATA via 8-bit access.)
- Invert final CRC result
- 32-bit CPU register programming interface

40.3 Functional description

40.3.1 Modes of operation

The following sections describe various modes of operation that affect the functionality of CRC: Run mode and Low power mode.

40.3.1.1 Run mode

Run mode is the basic mode of operation.

40.3.1.2 Low power mode

When the chip enters the lower power mode, the CRC module clock (ipg_clk and ipg_clk_s) is disabled and the in-progress CRC calculation stops. The calculation resumes after the CRC module clock is enabled or the chip exits low power mode via system reset.

40.3.2 CRC calculations

In 16-bit and 32-bit CRC modes, you can program data values as 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes lead to an incorrect CRC calculation.

40.3.2.1 Calculating a 16-bit CRC

Perform these steps to calculate a 16-bit CRC:

1. Write 0 to CTRL[TCRC] to enable 16-bit CRC mode.
2. Program the transpose and complement options in Data (DATA) as required for the CRC calculation.
3. Write a 16-bit polynomial to GPOLY[LOW].

   GPOLY[HIGH] is not usable in 16-bit CRC mode.
4. Write 1 to CTRL[WAS] to program the seed value.
5. Write a 16-bit seed to DATA[LU] and DATA[LL].

   DATA[HU] and DATA[HL] are not used.
6. Write 0 to CTRL[WAS] to start writing data values.
7. Write data values into DATA[LU], and DATA[LL]

   CRC is calculated on every data value write and the intermediate CRC result is stored back into DATA[LU] and DATA[LL]
8. After writing all the data values, read the final CRC result from DATA[LU] and DATA[LL].

CRC is calculated bytewise and two clocks are required to complete one CRC calculation.

The transpose and complement operations are performed on-the-fly when reading or writing values. See Transpose feature and Result complement for details.

40.3.2.2 Calculating a 32-bit CRC

Perform these steps to calculate a 32-bit CRC:

1. Write 1 to CTRL[TCRC] to enable 32-bit CRC mode.

2. Program the transpose and complement options in Control (CTRL) as required for CRC calculation. See Transpose feature and Result complement for details.
3. Write a 32-bit polynomial to GPOLY[HIGH] and GPOLY[LOW] .
4. Write 1 to CTRL[WAS] to program the seed value.
5. Write a 32-bit seed to DATA[HU], DATA[HL], DATA[LU], and DATA[LL].
6. Write 0 to CTRL[WAS] to start writing data values.
7. Write data values into DATA[HU], DATA[HL], DATA[LU], and DATA[LL]

   CRC is computed on every data value write and the intermediate CRC result is stored back into DATA[LU] and DATA[LL]
8. After writing all the values, read the final CRC result from DATA[HU], DATA[HL], DATA[LU], and DATA[LL].

   CRC is calculated bytewise and two clocks are required to complete one CRC calculation.

The transpose and complement operations are performed on-the-fly when reading or writing values. See Transpose feature and Result complement for details.

40.3.3 Transpose feature

Transpose is not enabled by default. However, CRC requires input data and/or final checksum to be transposed. You have an option to configure each transpose operation separately to meet CRC standards. The data is transposed on-the-fly while being read or written.

Some protocols use the little-endian format for data stream to calculateCRC. In this case, transpose flips bits.

40.3.3.1 Types of transpose

CRC provides several types of transpose to flip bits and/or bytes for both writing input data and reading result separately using the CTRL[TOT] and CTRL[TOTR] according to the CRC calculation being used.

The following types of transpose are available for writing to and reading from DATA.

1. CTRL[TOT] or CTRL[TOTR] is 0.

   No transposition occurs.
2. CTRL[TOT] or CTRL[TOTR] is 1.

   Bits in a byte are transposed when bytes are not transposed.

   reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}.

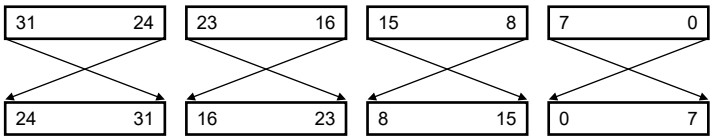

Figure 180. Transpose type 1b

3. CTRL[TOT] or CTRL[TOTR] is 10b.

   Both bits in bytes and bytes are transposed.

   reg[31:0] becomes {reg[0:7], reg[8:15], reg[16:23], reg[24:31]}.

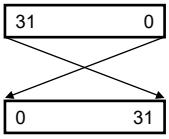

Figure 181. Transpose type 10b

4. CTRL[TOT] or CTRL[TOTR] is 11b.

   Bytes are transposed but bits are not transposed.

   reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}.

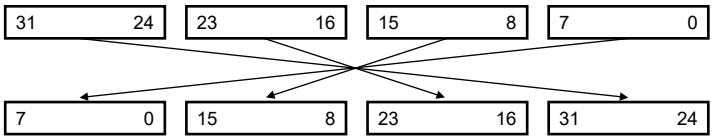

Figure 182. Transpose type 11b

NOTE

For 8-bit and 16-bit write accesses to Data (DATA), the data is transposed with 0s on the unused byte or bytes (taking 32 bits as a whole), but CRC is calculated on the valid byte(s) only. When reading the Data (DATA) for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in DATA[HU] and DATA[HL]. You must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

40.3.4 Result complement

When CTRL[FXOR] = 1, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in Data (DATA) every time Data (DATA) is read. When CTRL[FXOR] = 0,, reading Data (DATA) accesses the raw checksum value.

40.3.5 Clocking

Table 352. CRC clocks

Type of clock	Description
Bus clock (ipg_clk/ipg_clk_s)	ipg_clk_s controls the access to the CRC registers. ipg_clk and ipg_clk_s function the CRC module.

40.3.6 Interrupts

This module has no interrupts.

40.4 External signals

There is no CRC signal that connects off chip.

40.5 Initialization

To enable CRC calculation, you must program:

- CTRL[WAS] .
- Polynomial (GPOLY).

- Parameters for transposition and CRC result inversion in the applicable registers.

Writing 1 to CTRL[WAS] enables you to program the seed value into CRC Data registers.

After writing all the data, you must wait for at least two clock cycles to read the data from CRC Data (DATA) register.

After a CRC calculation completes, you can reinitialize the module for a new CRC computation by again writing 1 to CTRL[WAS] and programming a new, or previously used, seed value. You must set all other parameters before programming the seed value and subsequent data values.

40.6 Use cases

The following tables use the little-endian format.

40.6.1 CTRL programming

The following table shows Control (CTRL) programming for 16-bit CRC.

Table 353. CTRL programming for 16-bit CRC

Algorithm	Polynomial	Seed	Ref in	Ref out	XOR out	CTRL[TOT]	CTRL[TOTR]	CTRL[FXOR]

40.7 Memory map and register descriptions

NOTE

You must reconfigure CRC engine in case an IPS transfer error occurs (ips_xfr_err).

The CRC module generates a transfer error in the following cases:

- Write accesses to the register addresses that are not mapped to the peripherals but included in the address spaces of the peripherals.

40.7.1 CRC register descriptions

8h	Control (CTRL)	32	RW	0000_0000h

40.7.1.2 Data (DATA)

Offset

Register	Offset
DATA	0h

Function

Configures the value of seed, data, and checksum. When CTRL[WAS] = 1, any write to this register is regarded as the seed value. When CTRL[WAS] becomes 0, any write to this register is regarded as data for general CRC calculation.

In 16-bit CRC mode, DATA[HU] and DATA[HL] are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, you can program to write 8 bits, 16 bits, or 32 bits in big endian order, provided all bytes are contiguous.

After writing all data values, you can read the CRC result from DATA register. In 16-bit CRC mode, the CRC result is available in DATA[LU] and DATA[LL]. In 32-bit CRC mode, all fields contain the result. After writing all data, you must wait for at least two clock cycles to read the data from CRC data (DATA) register.

Fields

Field	Function
31-24	Upper Part of High Byte

Table continues on the next page...

Table continued from the previous page...

Field	Function
HU	Generates CRC checksum in both 16-bit and 32-bit CRC modes if CTRL[WAS] = 0. • In 16-bit CRC mode (CTRL[TCRC] = 0), this field is not used for programming a seed value. • In 32-bit CRC mode (CTRL[TCRC] = 1), the values written to this field are part of the seed value when CTRL[WAS] = 1.
23-16 HL	Lower Part of High Byte Generates CRC checksum in both 16-bit and 32-bit CRC modes if CTRL[WAS] = 1. • In 16-bit CRC mode (CTRL[TCRC] = 0), this field is not used for programming a seed value. • In 32-bit CRC mode (CTRL[TCRC] = 1), the values written to this field are part of the seed value when CTRL[WAS] = 1.
15-8 LU	Upper Part of Low Byte Generates CRC checksum when CTRL[WAS] = 0. When CTRL[WAS] = 1,the values written to this field are part of the seed value.
7-0 LL	Lower Part of Low Byte Generates CRC checksum when CTRL[WAS] = 0. When CTRL[WAS] = 0, the values written to this field are part of the seed value.

40.7.1.3 Polynomial (GPOLY)

Offset

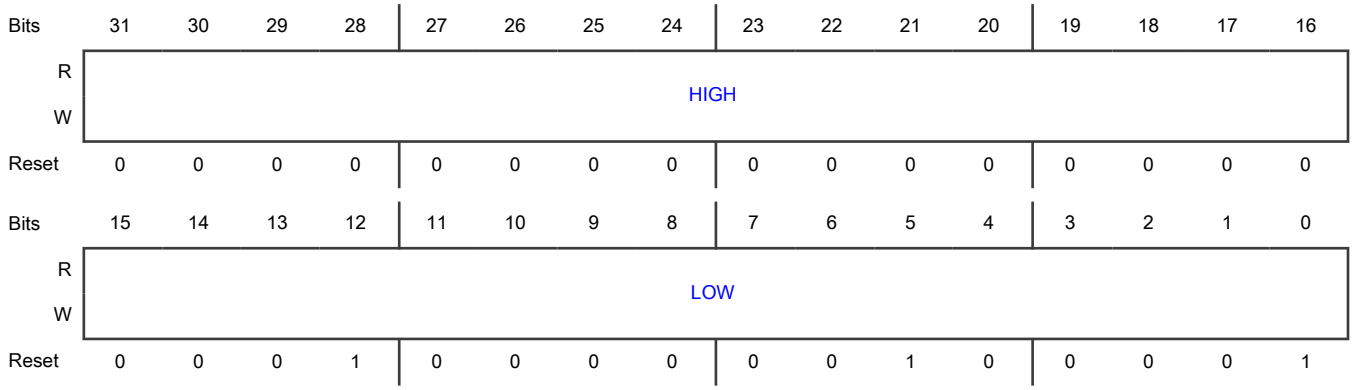
Register	Offset
GPOLY	4h

Function

Configures polynomial value for CRC calculation.

- Sets the upper 16 bits of polynomial that are used only in 32-bit CRC mode. Writes to this field are ignored in 16-bit CRC mode.
- Sets the lower 16 bits of polynomial that are used in both 16-bit and 32-bit CRC modes.

Diagram



Fields

Field	Function
31-16 HIGH	High Half-Word Writable and readable in 32-bit CRC mode (CTRL[TCRC] = 1). You cannot write to this field in 16-bit CRC mode (CTRL[TCRC] = 0).
15-0 LOW	Low Half-Word Writable and readable in both 16-bit and 32-bit CRC modes.

40.7.1.4 Control (CTRL)

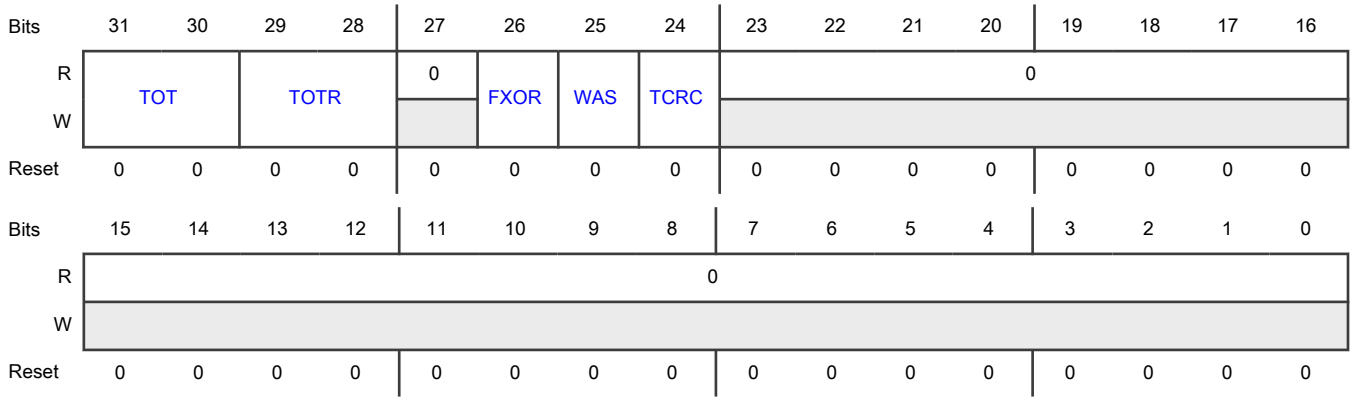
Offset

Register	Offset
CTRL	8h

Function

Sets control for CRC. You must write 1 to the appropriate fields of this register before starting a new CRC calculation, which you can initialize by writing 1 to CTRL[WAS] and then writing the seed into DATA.

Diagram



Fields

Field	Function
31-30 TOT	Transpose Type for Write Sets transpose type for the values written to DATA. See Transpose feature for the available transpose options. 00b - No transposition 01b - Bits in bytes are transposed, but bytes are not transposed. 10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed, no bits in a byte are transposed.
29-28 TOTR	Transpose Type for Read Sets transpose type for the values read from DATA . See Transpose feature for the available transpose options. 00b - No transposition 01b - Bits in bytes are transposed, but bytes are not transposed. 10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed, no bits in a byte are transposed.
27 —	Reserved
26 FXOR	Complement Read of CRC Data Register Enables on-the-fly complementing of read data. Some CRC protocols require the final checksum to be XORed with FFFFFFFFh or FFFFh. 0b - Disables XOR on reading data. 1b - Inverts or complements the read value of the CRC Data.
25 WAS	Write as Seed Specifies whether writes to DATA are data values or seed values. When this field = 1, the value that you write to is considered as seed value. When this field = 0, the value that you write to is considered as data for CRC calculation. 0b - Data values 1b - Seed values
24 TCRC	TCRC Defines the width of CRC. 0b - 16 bits 1b - 32 bits
23-0 —	Reserved

41.1.1 Module instances

This device has two instances of 16-bit ADC, ADC0 and ADC1.

41.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

41.1.3 ADC input connections

41.1.4 ADC voltage reference options

The ADC voltage references are:

- CFG[REFSEL]=00, VREFH reference pin
- CFG[REFSEL]=01, ANA_7(VREFI/VREFO) pin
- CFG[REFSEL]=10, VDD_ANA supply pin

41.1.5 ADC trigger inputs

ADC trigger sources get routed through the Input Multiplexing (INPUTMUX). See the INPUTMUX chapter for available trigger sources.

41.1.6 ADC input clock frequency

See device datasheet to know minimum/maximum ADC input clock frequencies.

41.2 Overview

The 16-bit analog-to-digital converter (ADC) is a dual successive approximation ADC designed for operation within an integrated microcontroller system-on-a-chip.

NOTE

For chip-specific modes of operation, see the power management information for the device.

41.2.1 Block diagram

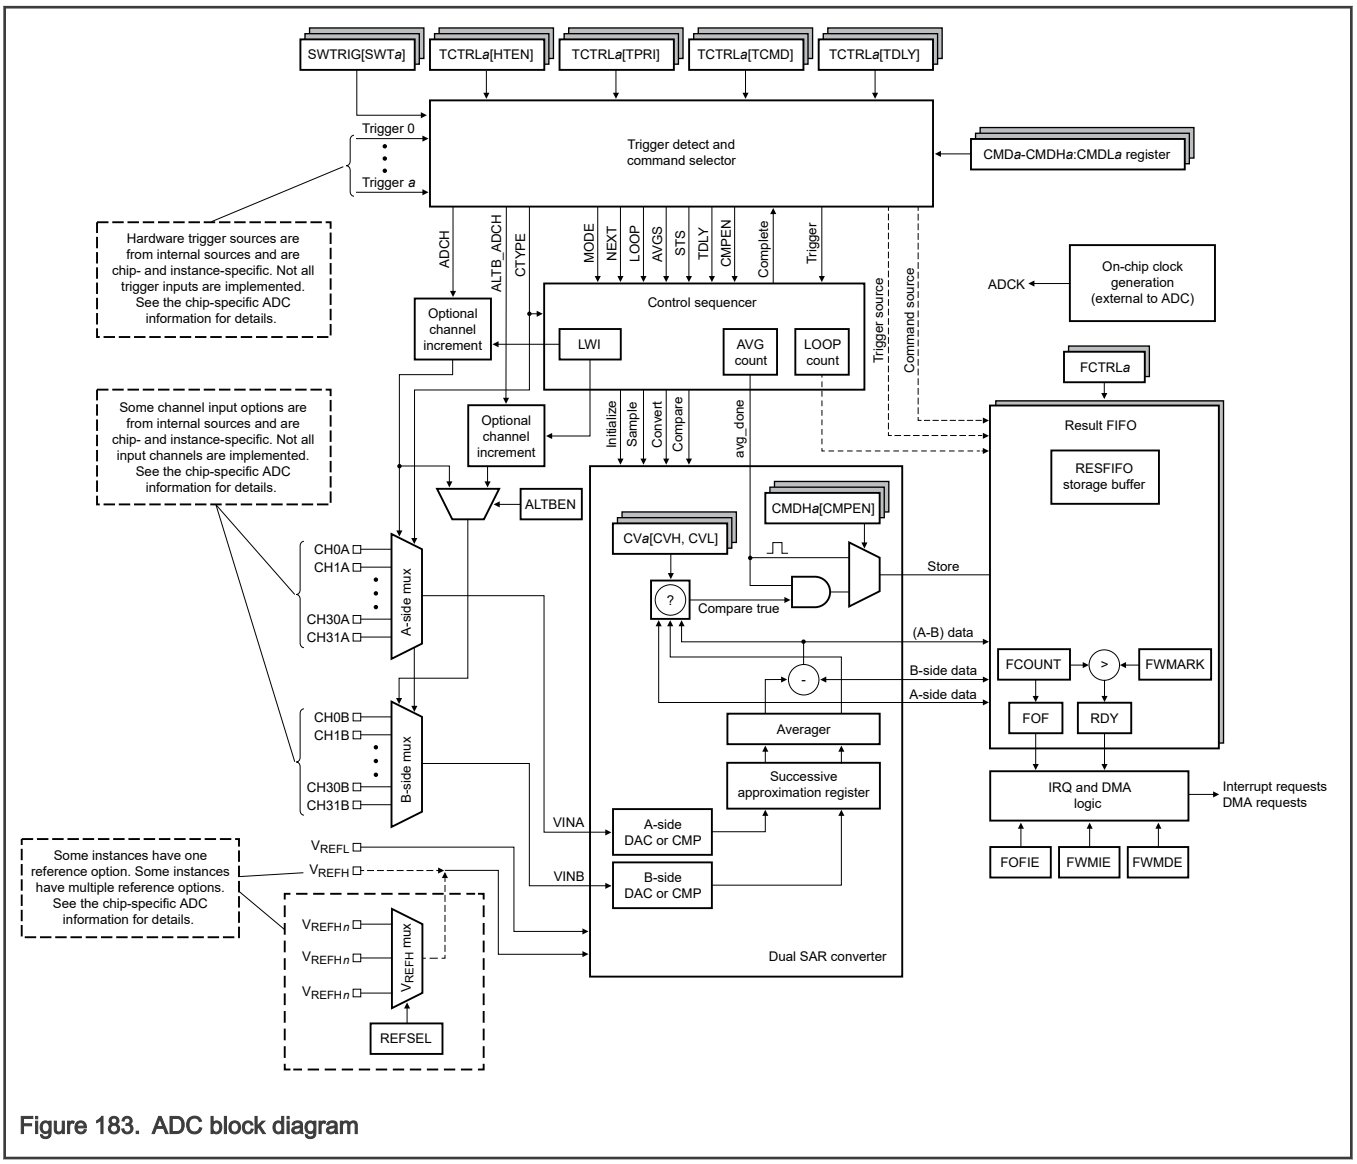

Figure 183. ADC block diagram

41.2.2 Features

ADC has these features:

- Linear successive approximation algorithm
  - Differential operation with 16-bit or 13-bit resolution
  - Single-ended operation with 16-bit or 12-bit resolution
  - Support for two simultaneous single-ended conversions
- Configurable analog input sample time
- Configurable speed options to accommodate operation in low-power modes of SoC
- Trigger detection with up to 4 trigger sources with priority level configuration. Software or hardware trigger option for each.
- 15 command buffers, to allow independent options selection and channel sequence scanning

- Automatic comparisons for less-than, greater-than, within range, or out-of-range with "store on true" and "repeat until true" options
- 2 independent result FIFOs, each containing 16 entries. Each FIFO has configurable watermark and overflow detection.
- Interrupt, DMA, or polled operation
- Linearity and gain adjustment calibration logic

41.3 Functional description

ADC performs analog-to-digital conversions on any of the software-selectable analog input channels via a successive approximation algorithm.

The ADC module can average the result of multiple conversions on a channel before storing the calculated result. The hardware average function is enabled by setting CMDHn[AVGS] to a non-zero value. The function operates in any conversion mode or configuration.

ADC can compare the result of a conversion with the contents of two value registers for less-than, greater-than, inside-range, or outside-range detection. The compare function operates in any conversion mode or configuration.

When the conversion and averaging loops finish, the resulting data is placed in one of 2 available FIFO data buffers . The data includes tag information associated with the result. When the number of stored data words exceeds the setting, a configurable watermark level supports interrupts or DMA requests. Interrupts can also be enabled to indicate when FIFO overflow errors occur.

The module initializes to its lowest power state during reset.

The ADC analog circuits can be pre-enabled to begin conversions sooner at the expense of higher idle currents. Conversions are initiated by selectable trigger events from software or hardware sources.

The trigger-detection logic includes a configurable enable and priority scheme for available trigger sources.

ADC includes multiple command buffers to provide flexibility for channel scanning and independent channel selections for different trigger sources. These command buffers can be configured for:

- Differential or single-ended conversion
- Sample time
- Averaging on a per-channel basis

ADC includes offset and linearity calibration logic. A request for calibration should be made upon reset or power up. Each successive approximation register (SAR) conversion uses calibration data calculated during the calibration routine.

The sequencing of an ADC command is summarized in the flow diagram below.

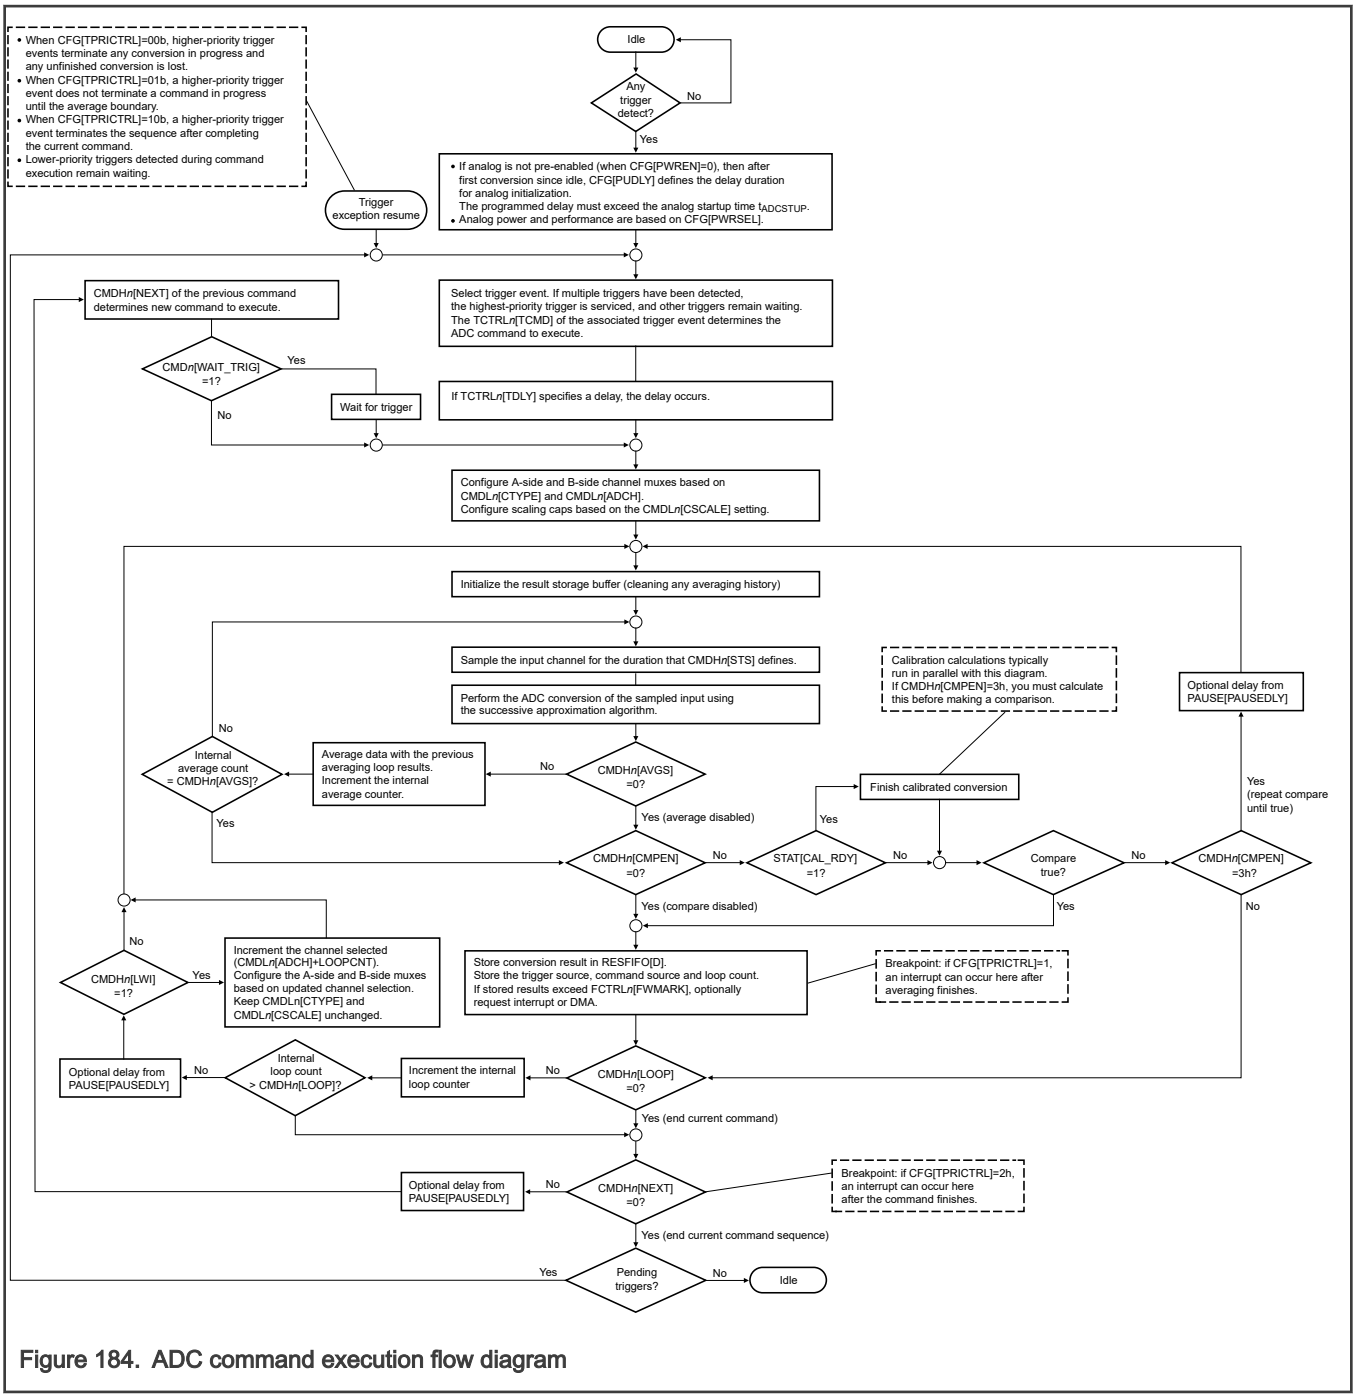

Figure 184. ADC command execution flow diagram

41.3.1 Power control mode

By default, the ADC analog circuits are disabled while ADC is in its idle state. When a trigger is detected and ADC command processing is initiated, the analog circuits are enabled. These circuits require a period of initialization before the first conversion cycle.

The value of CFG[PUDLY] should be set to incur a delay longer than $t_{ADCSTUP}$. The accuracy of initial conversions after activation is degraded if the value of CFG[PUDLY] is too low.

You can achieve faster conversion startup times by setting CFG[PWREN] to pre-enable the analog circuits of ADC. This faster conversion consumes extra power, even while ADC is in an idle state. When CFG[PWREN] is 1, the Power Enable timer is

activated. The timer enforces the minimum time required (configured by CFG[PUDLY]) before detected triggers can initiate ADC conversions.

ADC also has options for controlling power and performance summarized in the table below. See the device data sheet for specification of the available power modes.

Table 359. Power option settings

CFG[PWRSEL]	Description
0xb (Default)	Slow speed and low power
1xb	Fast speed and high power

41.3.2 ADC behavior in low-power mode

ADC supports system-level low-power modes. In low-power modes where ADC can remain functional, CTRL[DOZEN] controls ADC behavior.

When CTRL[DOZEN] = 0, if ADC was configured and enabled before entering low-power mode, ADC can continue operating while the system transitions to the low-power state. Any conversion in progress is not disrupted. External hardware trigger detection and active conversions are operational.

When CTRL[DOZEN] = 1, ADC waits for the current averaging iteration or FIFO storage to complete before acknowledging the low-power entry request.

When entering a low-power mode where ADC cannot remain functional, the module:

- Ignores CTRL[DOZEN].
- Waits for the current averaging iteration or FIFO storage to complete before acknowledging the low-power entry request.

After entering the low-power state, the ADC is kept inactive until the system exits the low-power state. The setting of CFG[PWREN] is ignored and the ADC analog circuits are forced to their lowest-power state. Upon waking from the low-power state, the analog circuits are automatically re-enabled and the power-up delay timer begins, if:

- The analog circuits were pre-enabled before entering Stop mode (CFG[PWREN] = 1), and
- The control registers retained their states in low-power mode.

Any triggered conversion is stalled until the power-up delay associated with CFG[PUDLY] has finished.

41.3.3 Voltage reference

The voltage reference high (V_{REFH}) used by ADC is supplied from either an on-chip voltage reference source or from an off-chip source via external pins. V_{REFL} is always from an external pin and must be at the same voltage as the Analog Power Domain Ground.

This block supports a programmable selection of the Voltage Reference High used for ADC conversions (via CFG[REFSEL]).

See the chip configuration information on the voltage reference options specific to this packaged device.

41.3.4 Trigger detect and command execution

See Figure 184 for a flow diagram of command execution sequencing.

ADC command execution is initiated from up to 4 trigger sources. Each trigger can be software-generated by writing 1b to the corresponding SWTRIG[SWTn] field. Alternatively, asynchronous input sources at the periphery of the module can generate hardware triggers. The number and sources of hardware triggers implemented is device-specific. See the chip-specific ADC information for descriptions of available hardware trigger sources for this device.

Each hardware trigger source is enabled by setting the associated enable field (TCTRLn[HTEN]). Each trigger source is assigned a priority via the associated priority control field (TCTRLn[TPRI]). Each of the trigger sources is associated with a command buffer via the associated command select field (TCTRLn[TCMD]).

When a hardware trigger input is enabled, hardware trigger events are detected on the rising edge of the associated hardware trigger source.

Each trigger source has an associated priority field TCTRLn[TPRI] which allows arbitration between trigger sources. Arbitration selects two things: which trigger sequence to execute next, and how to handle a trigger exception. Trigger exceptions are defined as allowing a higher-priority trigger sequence to interrupt operation of a lower-priority sequence. When a trigger exception occurs, programmable arbitration allows the configurable stop and resume points for low-priority sequences. The fields affecting arbitration are CFG[HPT_EXDI], CFG[TCMDRES], CFG[TRES], and CFG[TPRICTRL].

1. When CFG[HPT_EXDI] = 1b, trigger exceptions are disabled and any higher priority triggers are left pending until the current sequence completes. New triggers are accepted based on priority.
2. When CFG[HPT_EXDI] = 0b (default), exceptions are enabled and the higher-priority sequence begins executing at a user-specified breakpoint.

Breakpoint locations are determined by CFG[TPRICTRL], which affects latency for accepting trigger exceptions.

1. When CFG[TPRICTRL] = 0h, a higher-priority trigger causes an immediate command abort and the new command specified by the trigger is immediately started.
2. When CFG[TPRICTRL] = 1h, the current conversion is allowed to complete (including averaging) before the higher-priority exception starts. In this mode, if the command is running through a series of averages, this series completes. However, there is no requirement to finish the entire command before being interrupted. For example, if the command consists of four loop iterations, there is no requirement to complete all four iterations before the interrupt occurs.
3. When CFG[TPRICTRL] = 2h, a higher-priority trigger begins once the current command is completed. If a command consists of five loop iterations each containing eight averages, then all 40 conversions must be completed before accepting the trigger exception.

CFG[TCMDRES] and CFG[TRES] determine what ADC does after accepting a trigger exception. The module can be programmed to resume commands after returning from a trigger exception.

1. When CFG[TRES] = 0h, commands are not automatically resumed after being stopped by an exception. However, an interrupt is set to indicate that this case has occurred. The flag TSTAT[TEXC_NUM] can be used to resolve which trigger was stopped by the exception.
2. When CFG[TRES] = 1h, ADC automatically resumes commands after they were stopped by an exception.

Using CFG[TRES] with CFG[TCMDRES], the module can be programmed to resume commands at one of two possible locations.

1. When CFG[TCMDRES] = 0h, the trigger which was stopped by an exception is resumed from the beginning of its associated command sequence. Triggers that are waiting to be resumed take the same priority programmed to TCTRLn[TPRI].
2. When CFG[TCMDRES] = 1h, the trigger is resumed from the command that it was executing before being interrupted by an exception.

If a trigger occurs with priority lower than the priority of the currently executing command, trigger detection is left pending until the current command sequence finishes. Lower-priority trigger events cannot be serviced until a higher-priority triggered command (or command sequence) completes.

When a conversion is completed (including hardware averaging when CMDHn[AVGS] is non-zero), the result is placed in a RESFIFO buffer. When an ADC command selects looping (when CMDHn[LOOP] is non-zero) a command stores multiple conversion results to the FIFO during execution of that command.

At the end of command execution, CMDHn[NEXT] selects the next command to be executed. Multiple commands can be executed sequentially by configuring the CMDHn[NEXT] field of each command. Setting the next command to 0h causes conversions to terminate at the completion of the current command. Unending circular command execution is allowed by setting the CMDHn[NEXT] field of the last command in a sequence to the first command in the sequence.

By default, command sequences execute automatically in the order in which CMDHn[NEXT] fields are programmed. However, by using CMDHn[WAIT_TRIG], command execution can be stalled and launched based on trigger inputs. For example, if TRIGGER2 is programmed to start the command sequence CMD1, CMD2, CMD3, then this sequence is run once unconditionally to

completion upon receiving TRIGGER2. If CMDH2[WAIT_TRIG] = 1h, however, the sequence pauses after CMD1 until TRIGGER2 is received again. In this way, sequences can be stalled until a trigger assertion is received.

Disabling ADC by writing 0b to CTRL[ADCEN] terminates any active ADC command processing. Writing 0b to CTRL[ADCEN] causes the current command (or command sequence) to terminate, clears any pending triggers, and sends the ADC module to an idle state.

41.3.5 Pause option

When an application does not require the maximum conversion rate, the effective conversion rate can be reduced:

- By implementing periodic trigger events to initiate ADC conversions, or
- By selecting a reduced-frequency clock as the ADCK source.

Both options are chip-specific and are dependent on ADC triggering and clocking options external to the ADC module. The latency associated with ADC analog power-up delays limits the maximum conversion rate when using periodic triggering.

Conversion rates can also be reduced by inserting a pause of a programmable duration:

- Between loop iterations
- Between commands in a sequence
- Between conversions, when a command is executing in the Compare Until True configuration

When PAUSE[PAUSEEN] = 1, PAUSE[PAUSEDLY] controls the duration of pausing during command execution sequencing. The pause delay is a count of (PAUSE[PAUSEDLY] * 4) ADCK cycles.

NOTE

Do not change the PAUSE register while CTRL[ADCEN] = 1. Writes to the PAUSE register while CTRL[ADCEN] is 1 can lead to metastable operation.

See Figure 184 for the places during command execution sequencing where the pause can be inserted.

41.3.6 Resync functionality

Any software or hardware trigger source can be configured to act as a resync trigger. Trigger-based resync interrupts a running trigger (resync target) and clears the FIFO to which the trigger is writing. Resync can be used either to abort a running sequence, or to restart a running sequence depending on the value of CFG[TRES]. If CFG[TRES] = 1, the target sequence is aborted, the FIFO is cleared, and the sequence is restarted after the resync occurs. If CFG[TRES] = 0, the target sequence is aborted and the FIFO is cleared after the resync occurs. The FIFOs that are cleared are based on the resync targets TCTRLn[FIFO_SEL_A] and TCTRLn[FIFO_SEL_B]. To only clear one FIFO, set TCTRLn[FIFO_SEL_A] = TCTRLn[FIFO_SEL_B]. When the resync occurs, any results are stored in TCTRLn[FIFO_SEL_A] or TCTRLn[FIFO_SEL_B] that are not associated with the resync target are lost.

A resync trigger must have a specific target. The resync only occurs if the resync target is running at the time of the trigger. In the following example, n is the resync trigger number and m is the resync target number. According to these variables, trigger n should resync trigger m. To enable a trigger source to act as a resync trigger, these conditions must be satisfied:

1. The resync trigger TCTRLn[RSYNC] must be set to 1.
2. The resync trigger must have higher priority than the resync target (TCTRLn[TPRI] must be less than TCTRLm[TPRI]).
3. The resync target is specified using TCTRLn[TCMD]. In this case the resync target, m, must be equal to TCTRLn[TCMD].
4. The resync target, m, must be executing commands when the resync trigger, n, is asserted.
5. Trigger m must have at least one conversion remaining to start when trigger n is received.

If a trigger source n has TCTRLn[RSYNC] set to 1, but some of the above conditions are not met, the trigger source n is ignored.

The following figure illustrates a resync trigger sequence. In this example, trigger source 1 is configured to resync trigger source 0.

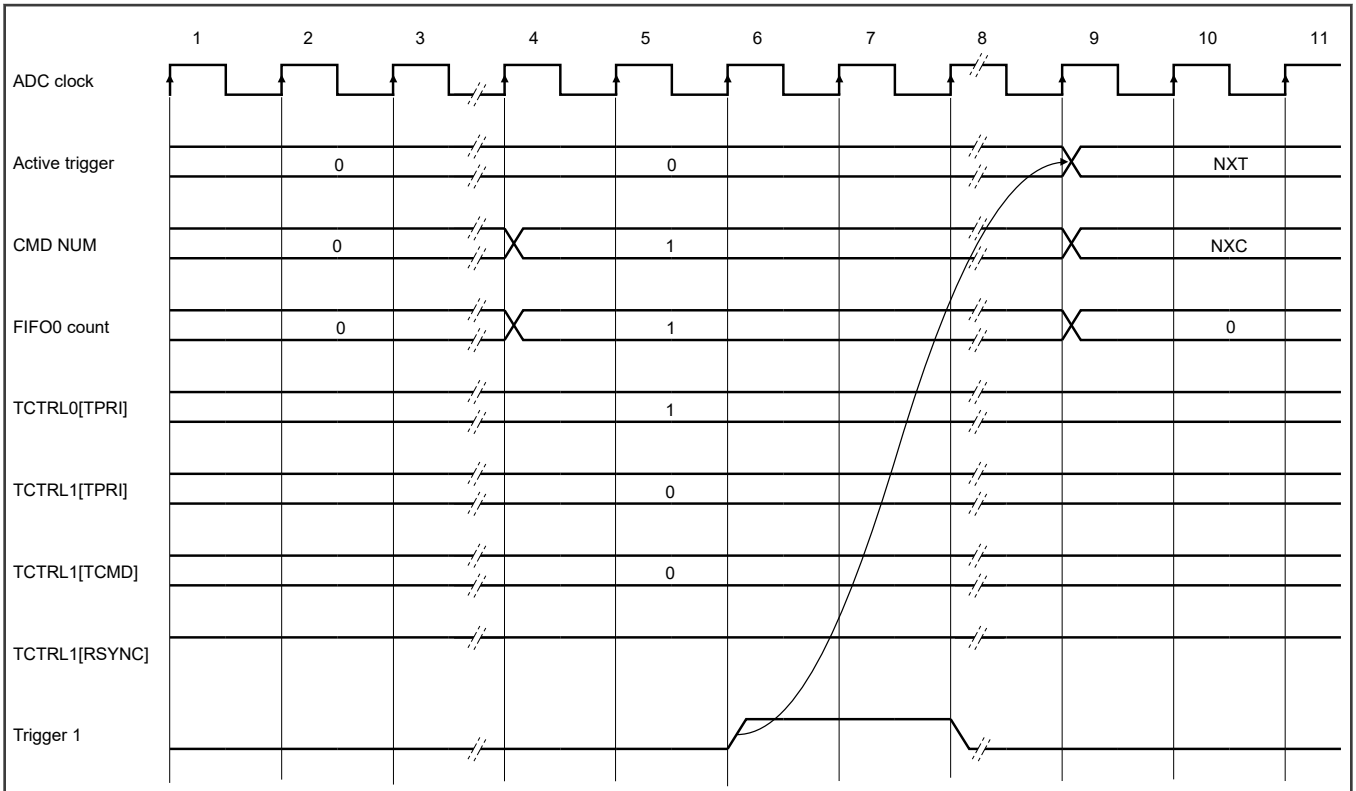

Figure 185. ADC Resync Example

In this figure, trigger source 0 is executing a sequence of commands when trigger source 1 is asserted. Trigger source 0 is stopped when trigger source 1 is asserted after some synchronization delay. In addition, the FIFO being written to by trigger source 0 is cleared (FIFO0 in this example). After the trigger 0 sequence is stopped, ADC runs the next trigger pending with the highest priority. This trigger is marked as NXT, for next trigger. If resume functionality is enabled, and trigger source 0 has the highest priority pending, then NXT = 00h.

41.3.7 Temperature sensor

ADC has a dedicated input channel for an on-chip temperature sensor. See the chip-specific channel definition to determine which channel is connected to the on-chip temperature sensor.

To calculate the temperature, you must first execute a conversion of the temperature sensor channel with configuration requirements. The sequence to convert the temperature sensor channel is:

1. Configure a command buffer register to convert the temperature sensor channel (CMDLn[ADCH]).
2. Program the command buffer with the following parameters:
   - 16b mode (CMDLa[MODE] = 0x1)
   - Differential: CMDLn[CTYPE] = 2h
   - Max averaging: CMDHn[AVGS] = 7h
   - Max sample time: CMDHn[STS] = 7h
   - LOOP set to 1: CMDHn[LOOP] = 1h
   - Loop with increment disabled: CMDHn[LWI] = 0h
   - Compare function disabled: CMDHn[CMPEN] = 0h
3. Configure a trigger control register TCTRLn with the following parameters:

- TCTRLn[TCMD] = command buffer used in steps 2 and 3.
- TCTRLn[FIFO_SEL_A] directs conversion results to FIFO0 orFIFO1

4. Trigger a conversion of the temperature sensor channel. You trigger the conversion by writing 1 to the associated bit in Software Trigger Register (SWTRIG) (that is, the trigger configured in the previous step).

After completing the conversion of the temperature sensor channel, two results are stored in the FIFO selected by TCTRLn[FIFO_SEL_A]. Each result corresponds to a component of the overall temperature value. Read these values from the FIFO and use the following equation to calculate the ambient temperature.

$$\text{Temp} = A\left[\frac{\alpha(\text{Vbe8}-\text{Vbe1})}{\text{Vbe8} + (\alpha(\text{Vbe8}-\text{Vbe1}))}\right] - B$$

Equation 17. Temperature sensor function

In the preceding equation:

- Vbe1 is the first value stored to the FIFO as a result of the temperature sensor channel conversion.
- Vbe8 is the second value stored to the FIFO as a result of the temperature sensor channel conversion.
- A is the slope factor.
- B is the offset factor.
- α is the bandgap coefficient.

A, B, and α are specified constant values from the ADC electrical information in the chip data sheet.

41.3.8 Result FIFO operation

ADC includes 2 16-entry FIFOs in which the result of ADC conversions are stored. In addition, a valid indicator bit, the trigger source, the source command, and the loop count are also stored with the data. FCTRLn[FCOUNT] indicates how many valid data words are stored in each RESFIFO.

A programmable watermark threshold supports configurable notification of data availability. When FCTRLn[FCOUNT] is greater than FCTRLn[FWMARK], the associated RDY flag is asserted. When IE[FWMIEn] = 1, a watermark interrupt request is issued. When DE[FWMDEn] = 1, a DMA request is issued. Reading RESFIFO provides the oldest unread data word entry in the FIFO and decrements FCTRLn[FCOUNT]. When FCTRLn[FCOUNT] falls equal to or below FCTRLn[FWMARK], the RDY flag is cleared.

Each FIFO can be emptied by successive reads of RESFIFOn. When RESFIFOn[VALID] is 1, the associated FIFO entry is valid. Reading RESFIFOn when the FIFO is empty (when RESFIFOn[VALID] = 0 and FCTRLn[FCOUNT] = 0h) provides an undefined data word. All FIFOs are reset by writing 1b to CTRL[RSTFIFOn].

If ADC attempts to store a data word to the FIFO when the FIFO is full, the FIFO overflow flag (FCTRLn[FOF]) is set. When IE[FOFIEn] = 1, an overflow interrupt request is issued. The FOF flag is cleared by writing 1 to STAT[FOFn]. When overflow events occur, no new data is stored and the data associated with the storage event that triggered the overflow is lost.

Conversion results can be steered to any FIFO in the design. TCTRLn[FIFO_SEL_A] and TCTRLn[FIFO_SEL_B] determine into which FIFO the final result is written. Depending on which trigger is executing, the results can be steered to different locations. Depending on the type of conversion selected, the FIFO destination register fields are interpreted differently. During either differential or single-ended mode (CMDLn[CTYPE] != 3h) only one result is produced. The destination during these modes is determined from TCTRLn[FIFO_SEL_A]. In dual-single-ended mode, both TCTRLn[FIFO_SEL_A] and TCTRLn[FIFO_SEL_B] determine the Channel A and Channel B destinations respectively.

41.3.9 Sampling Modes

The ADC module supports three different sampling modes: dual single-ended, single-ended, and differential. The sampling mode is determined by the currently executing command using CMDLn[CTYPE].

When executing a command in dual single-ended mode, two independent conversion results are calculated and stored in selectable FIFO destinations. Command processing, however, is not individually controlled for each independent channel being sampled. When operating in dual single-ended mode both channels are sampled and processed simultaneously.

The selection of Channel B is controlled by CMDLn[ALTBEN].

- When CMDLn[ALTBEN] = 1, the channel for the B-side is selected independently (via the value of CMDLn[ALTB_ADCH]).
- When CMDLn[ALTBEN] = 0, the Channel B selection is controlled by CMDLn[ADCH] and Channel A and Channel B are paired (CH0A/CH0B, CH1A/CH1B, and so on).

If comparisons are enabled in dual single-ended mode, only the A-side channels (CH0A, CH1A, and so on) are used for the comparison. The A-side comparison determines whether both the A-side and B-side results are written to the FIFOs.

- If the A-side comparison passes, both the A-side and B-side results are stored.
- If the A-side comparison fails, A-side and B-side results are not written to the FIFOs.

Single-ended mode is configurable to allow either A-side or B-side channels to be sampled. In single-ended mode, the results from each conversion can be written to a selectable FIFO using TCTRLn[FIFO_SEL_A].

In differential mode, the final SAR calculation is equivalent to V(CHA) - V(CHB). If the result is negative, then the value is stored in sign-extended two's complement format. TCTRLn[FIFO_SEL_A] also determines where differential conversion results are stored.

In dual single-ended mode, however, two independent results are produced. Individual control is provided by using TCTRLn[FIFO_SEL_A] and TCTRLn[FIFO_SEL_B] to select a FIFO destination for both results during this mode. Both single-ended results may be written to the same destination by programming TCTRLn[FIFO_SEL_A] = TCTRLn[FIFO_SEL_B]. In this case, the CH_A result is always stored before the CH_B result.

41.3.10 Compare Function

After the input is sampled and converted and any averaging iterations are performed, CMDHn[CMPEN] determines:

- Whether to use the automatic compare function, storing the conversion result when true.
- Whether to repeat the channel acquisition until the automatic compare function returns a true result.

The command-sequencing options related to the compare function are summarized in the table below.

NOTE

Latency is added to the end of a compare-until-true conversion to resolve the next command or loop in a sequence. This latency is necessary to calibrate the SAR data before resolving the result of a comparison. Delay for this feature is only added when resolving the result of a conversion. Intermediate samples during averaging do not include extra latency; only loop and command boundaries experience this delay. The latency is always less than or equal to five ADC clock cycles.

Table 360. Compare modes

CMDHn[CMPEN]	Compare function	Description
00b	Compare disabled	Do not perform compare operation. Always store the conversion result to the FIFO.
01b	Reserved	
10b	Store on true	Perform compare operation. Store conversion result to FIFO after averaging only when the result of the comparison is true. Regardless of the comparison result, the LOOP setting is considered. The LOOP counter is incremented before deciding whether the current command has completed or additional LOOP iterations are required.
11b	Repeat compare until true	Perform compare operation. Store conversion result to FIFO after averaging only when the result of the comparison is true. Once a comparison is true, the LOOP setting is considered. The LOOP counter is incremented before deciding whether the current command has completed or additional LOOP iterations are required. When a

Table continues on the next page...

Table 360. Compare modes (continued)

CMDHn[CMPEN]	Compare function	Description
		comparison is false, the conversion is repeated without considering the LOOP setting, and the LOOP counter is not incremented.

The compare operation checks the result based on the values of CVn[CVH] and CVn[CVL], as shown in the following table.

Table 361. Compare operations

CVn[CVL] vs. CVn[CVH]	Operation	Description
set CVn[CVL] < CVn[CVH]	Outside range (General form)	True if the result is less than CVn[CVL] **or** greater than CVn[CVH].
set CVn[CVH] to maximum value set CVn[CVL] to compare point	Less than	True if the result is less than CVn[CVL].
set CVn[CVL] to minimum value set CVn[CVH] to compare point	Greater than	True if the result is greater than CVn[CVH].
set CVn[CVL] > CVn[CVH]	Inside range	True if the result is less than CVn[CVL] **and** greater than CVn[CVH].

NOTE

When ADC continues operating in a low-power mode, the compare function can monitor the voltage and wake the device only when the compare condition is met.

41.3.11 Cycles per conversion

The number of ADCK cycles needed to complete a conversion, varies based on the selected resolution (CMDLa[MODE]), the sample time configured, and several other configuration options discussed below.

To calculate the cycle count, first, determine the Base Cycles Count from Table 362. Next, add the Sample Time Adder based on CMDHa[STS] setting as summarized in Table 363. If averaging is enabled (CMDHa[AVGS] does not equal to 0), then the total cycle (Base Cycles Count + Sample Time Adder) should be multiplied by the number of averages configured as summarized in Table 364.

$$CycleCount\ /\ Conversion = [(BaseCycleCount + SampleTimeAdder) * AverageMultiplier]$$

Equation 18. Cycle Count/Conversion

Note that there is latency associated with trigger detection and starting an initial conversion. There is additional latency associated with offset and gain error adjustment of a raw conversion result and storage of a final result to the FIFO. Due to the pipe-lining of conversions when looping or command chaining is configured, the next conversion is immediately started while a raw conversion result is being adjusted and stored and thus the conversion rate is maximized.

The base cycles per conversion are variable depending on CMDLa[MODE] setting as summarized in the following table:

Table 362. Base cycles per conversion

Base ADCK cycles/conversion[1]	
16-bit CMDLa[MODE] = 1	12-bit CMDLa[MODE] = 0
24	19

1. This cycle count includes min sample time of 3.5 ADCK cycles.

In addition to the base cycles per conversion, the configured sample time needs to be considered. The sample time adder is variable depending on CMDHa[STS] setting and is summarized in the following table:

Table 363. Sample time cycle adder

CMDHa[STS] (default 000)	Add ADCK cycles/conversion
000	0
001	2
010	4
011	8
100	16
101	32
110	64
111	128

Table 364. Averaging multiplier

CMDHa[AVGS] (default 0000)	Averaging multiplier
0000	1
0001	2
0010	4
0011	8
0100	16
0101	32
0110	64
0111	128
1000	256
1010	512
1011	1024

When LOOPing is used:

CMDHa[LOOP] allows iteration of a command (that is a channel can be converted multiple times). This feature adds 3 additional cycles between conversions.

NOTE

When commands are chained using CMDHa[NEXT] to execute back-to-back conversions the ADC does not have the 3 stall cycles between commands.

For a command that executes multiple conversions of the same channel using LOOPing the total cycle count is:

$$CycleCount/Command = [(BaseCycleCount + SampleTimeAdder) * AverageMultiplier * (CMDHa[LOOP] + 1)] + (3 * CMDHa[LOOP])$$

Equation 19. Cycle Count/Command

41.3.12 Clocking

ADC uses the ADCK clock input provided by an on-chip clock select block. It is used by the SAR conversion-control sequencing logic and the FIFO storage buffer. The ADCK frequency must be within the specified frequency range for ADCK, and varies based on CFG[PWRSEL]. See the device data sheet for supported frequency ranges.

ADC continues operating in low-power mode as long as CTRL[DOZEN] = 0 and the on-chip clock select block supplies an ADCK clock source.

NOTE

When in low-power mode with CTRL[DOZEN] = 0, the bus clock can be shut off, and asynchronous interrupts and DMA requests can be configured. ADC continues processing commands and writing data to the internal FIFO.

ADC has four sources for asynchronous interrupts during low-power mode: watermark, FIFO overflow, TCOMP, and TEXC. To enable them, configure IE[FWMIEx], IE[FOFIEx], IE[TCOMP_IE], and IE[TEXC_IE] before entering low-power mode.

When CTRL[DOZEN] = 1 in low-power mode, ADC waits for the current averaging iteration or FIFO storage to complete before acknowledging the low-power mode entry. Any pending triggers are dropped when a low-power mode request is made in this mode. ADC is forced into its lowest-power setting after acknowledging the low-power mode request.

41.3.13 Resets

Table 365. ADC Resets

Reset source	Description
Chip reset	The logic and registers for ADC are reset to their default states on a chip reset.
Software reset	ADC implements a software reset field in its control register. CTRL[RST] resets all logic and registers to their default states, except for the CTRL register itself.
FIFO reset	ADC implements write-only control that resets FIFO0 (CTRL[RSTFIFO0]) and FIFO1 (CTRL[RSTFIFO1]). After a FIFO is reset, that FIFO is empty.

41.3.14 Interrupts and DMA requests

ADC includes several sources for interrupts and DMA requests. The table below summarizes these sources.

A programmable watermark threshold supports configurable notification of data availability and can generate either an interrupt exception or a DMA request. When FCTRLn[COUNT] is greater than FCTRLn[FWMARK], the associated STAT[RDYn] flag is asserted. The IE[FWMIEn] and DE[FWMDEn] control fields control the masking for this exception. When STAT[RDYn] becomes 1 and IE[FWMIEn] = 1, a watermark interrupt request is issued. When STAT[RDYn] becomes 1 and DE[FWMDEn] = 1, a DMA request is issued.

The other exception sources can only generate interrupts and do not have a DMA request option. Each source has a mask control field in the IE register and no corresponding field in the DE register.

Table 366. ADC Interrupts and DMA Requests

Status Register (STAT)		Description	Can generate		
Flag	Name		Interrupt?	DMA request?	Low-power wake-up?
RDYn	Result FIFO n Ready Flag	Conversion result data is written to Result FIFO and has a watermark configurable trigger level to generate an exception request as controlled by FCTRLn[FWMARK].	Y	Y	Y
FOFn	Result FIFO n Overflow Flag	Attempting to store data to the FIFO when the FIFO is full is an error condition.	Y	N	Y
TCOMP_INT	Trigger Completion Flag	A trigger sequence has been completed. All associated commands have been run.	Y	N	Y
TEXC_INT	High Priority Trigger Flag	A high priority trigger exception has occurred.	Y	N	Y

41.4 External signals

The ADC module supports analog channel inputs with differential and single-ended conversion options for all channels.

See chip-specific section for supply and ground connections.

Table 367. ADC signal descriptions

Signal	Description	I/O
CHnA - CH0A[1]	A-side Analog Channel Inputs	I
CHnB - CH0B[1]	B-side Analog Channel Inputs	I

1. where n is the maximum channel number supported in the chip. See the chip-specific information for the number of channels supported on your device.

41.4.1 Analog channel inputs (CHnA and CHnB)

CMDLn[ADCH] and CMDLn[CTYPE] control selection of paired or individual input channels. Each ADC command independently makes a channel and conversion type selection. Each CMDLn[ADCH] channel selection has an associated A side and an associated B side input. Each CMDLn[ADCH] pair can be converted in differential mode, but only limited pairs should be converted as differential channels (for example, adjacent pins designed with matched impedance). For the pin pairings available for differential conversions for your device, see the Chip Configuration details.

NOTE

Some input channels from on-chip sources, such as temperature sensors and reference voltage sources, may only be connected to individual instances of ADC. Some input channel options in the field-setting descriptions may not be available for your device. See chip-specific information for the channels supported on this device.

41.5 Initialization

41.5.1 Calibration functions

The ADC module has multiple calibration functions that must be executed as part of ADC setup to achieve the specified accuracy. Calibration must be run after any reset and before a conversion is initiated. Before offset calibration or calibration, the user must configure the clock source and frequency of ADC for the clock source availability and needs of the application. ADC must be

enabled (CTRL[ADCEN] = 1h) before a calibration function runs. If calibration is requested while ADC is actively converting, that sequence completes before starting calibration.

Averaging multiple conversions can achieve improved accuracy during the calibration routines. CTRL[CAL_AVGS] is used during a calibration routine to control how many samples are averaged together. If the application uses ADC in a wide variety of configurations, the configuration for which the highest accuracy is required should be selected. Alternatively, multiple calibrations can be done for the different configurations.

41.5.1.1 Offset calibration

The Offset Trim Register (OFSTRIM) is used to trim for ADC comparator offset voltage. The ADC supports an offset calibration function in which the OFSTRIM register is automatically updated. To perform offset calibration:

1. Configure for the desired averaging via CTRL[CAL_AVGS].
2. Initiate Offset Calibration by setting CTRL[CALOFS].
3. Poll the STAT[CAL_RDY] flag. When STAT[CAL_RDY] is asserted, the offset calibration function has completed, and the OFSTRIM register has updated.

41.5.1.2 ADC Calibration

ADC includes hardware calibration logic in which the A-side and B-side converters are calibrated for gain error and linearity error correction of the raw conversion result. GCR0[GCALR] and the CAL_GAR registers control calibration for the A-side converter. GCR1[GCALR] and the CAL_GBR registers control calibration for the B-side converter. ADC supports a calibration function in which the CAL_GAR and CAL_GBR registers are automatically updated. The calibration function also updates GCC0[GAIN_CAL] (associated with A-side calibration) and GCC1[GAIN_CAL] (associated with B-side calibration). For A-side calibration, a software calculation is required to derive GCR0[GCALR] from GCC0[GAIN_CAL]. For B-side calibration, a corresponding calculation is required to derive GCR1[GCALR] from GCC1[GAIN_CAL].

To complete calibration setup:

1. Execute Offset calibration steps. The Offset Trim Register (OFSTRIM) is used during calibration to trim for comparator offset voltage.
2. Configure the averaging via CTRL[CAL_AVGS].
3. Initiate the calibration routine by writing 1 to CTRL[CAL_REQ]. CTRL[CAL_REQ] remains 1 until the CAL routine has been accepted by the ADC. After acceptance, CTRL[CAL_REQ] automatically becomes 0.
4. The A-side calibration data is updated first. Poll the GCR0[RDY] flag. When it is asserted, the hardware controlled A-side calibration operation is complete, and CAL_GAR and GCC0[GAIN_CAL] registers are updated. The updated value in GCC0[GAIN_CAL] is required for further software processing described in the following steps.
5. Read GCC0[GAIN_CAL] and store for use in the gain_adjustment calculation.
6. Calculate the A-side gain_adjustment: (131072)/(131072-GCC0[GAIN_CAL]). GCC0[GAIN_CAL] is a 16-bit unsigned value. This calculation results in a floating point value between 1 and 2.
7. The integer value of the gain_adjustment calculation is always 1 and can be discarded. The fractional component must be stored to GCR0[GCALR]. Write the fractional component value to GCR0[GCALR].
8. Execute the same calculation for the B-side converter. Poll the GCC1[RDY] flag. When it is asserted, the hardware controlled B-side calibration operation is complete, and CAL_GBR and GCC1[GAIN_CAL] registers are updated. The updated value in GCC1[GAIN_CAL] is needed for further software processing.
9. Read the GCC1[GAIN_CAL] register and store for use in the gain_adjustment calculation.
10. Calculate the B-side gain_adjustment = (131072)/(131072-GCC1[GAIN_CAL]). Formatting for the value is the same as the A-side.
11. Like the A-side, round the fractional component of the B-side gain_adjustment to 16-bits and store it in GCR1[GCALR].

12. Once GCR0[GCALR] and GCR1[GCALR] contain the results from the gain_adjustment calculations, set the GCR0[RDY] and GCR1[RDY] flags to indicate they are valid. It is acceptable for the GCRn[GCALR] and corresponding GCRn[RDY] field to be updated on the same write cycle.

After completing the steps above, the calibration sequence is complete and the STAT[CAL_RDY] flag is set. The STAT[CAL_RDY] flag remains set until the user resets the system or requests a new calibration sequence.

When STAT[CAL_RDY] is set, ADC is configured to run in calibrated mode. Each conversion uses a combination of linearity and gain calibration results to correct SAR data. Calibration conversion latency is required to process each sample. However, due to the pipelined nature of data and control sequences, each conversion can still be initiated without experiencing this calibration delay.

41.5.1.3 Calibration General A-Side and B-Side Widths

The general calibration value registers CAL_GARn and CAL_GBRn have non-uniform widths. The following table defines the bit widths of each register.

Table 368. Calibration General Widths

Element CAL_GxR[N]	Width (Bits)
N = 00h, 20h	11
N = 01h	12
N = 02h–03h	13
N = 0x04–07h	14
N = 0x08–0Fh	15
N = 0x10–1Fh	16

These registers are typically updated automatically during the self-calibration sequence. To reduce the latency associated with ADC setup, the CAL_GxR values from a calibration sequence can be stored in non-volatile memory after an initial calibration. These values can then be written to the CAL_GxR registers via software prior to the first ADC conversion. If these registers are set to values not generated by the calibration function, the linearity error specifications may not be met.

NOTE

These values can only be written in a single access, byte accesses are not supported.

41.6 ADC register descriptions

This section describes the ADC registers.

41.6.1 ADC memory map

ADC0 base address: 4010_D000h

ADC1 base address: 4010_E000h

Fields

Field	Function
31-24 MAJOR	Major Version Number Returns the major version number for the module specification.
23-16 MINOR	Minor Version Number Returns the minor version number for the module specification.
15 —	Reserved
14-12 NUM_FIFO	Number of FIFOs Indicates the number of result FIFOs implemented in the design. 000b - N/A 001b - One 010b - Two 011b - Three 100b - Four

Table continues on the next page...

Table continued from the previous page...

Field	Function
11 NUM_SEC	Number of Single-Ended Outputs Supported Indicates the number of single-ended channels which can be processed simultaneously. 0b - One 1b - Two
10 CALOFSI	Calibration Function Implemented Indicates whether ADC contains hardware calibration functions. When supported, CTRL[CAL_REQ] can be used to request the calibration routine. 0b - Not implemented 1b - Implemented
9 IADCKI	Internal ADC Clock Implemented Indicates whether this implementation of the ADC block includes an internal clock source. 0b - Not implemented 1b - Implemented
8 VR1RNGI	Voltage Reference 1 Range Control Bit Implemented Indicates whether a control bit is implemented to select the input voltage range on Voltage Reference Option 1. 0b - Range control not required. 1b - Range control required.
7 —	Reserved
6-4 CSW	Channel Scale Width Indicates whether channel scaling is supported. When supported, each command buffer has a control field (CMDLn[CSCALE]) for setting input scaling. 000b - Not supported. 001b - Supported with one-bit CSCALE control field. 110b - Supported with six-bit CSCALE control field.
3 MVI	Multiple Vref Implemented Indicates whether multiple voltage reference high (VREFH) inputs are supported. When multiple voltage references are supported, CFG[REFSEL] selects voltage reference high options. 0b - Single VREFH input supported. 1b - Multiple VREFH inputs supported.
2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1 DIFFEN	Differential Supported Indicates whether differential operation is supported. When supported, each command buffer has control fields (CMDLn[CTYPE]) for configuring for differential operation and expanding the number of supported channels from 32 to 64. 0b - Not supported 1b - Supported. CMDLn[CTYPE] controls fields implemented.
0 RES	Resolution Indicates the maximum accuracy supported. 0b - Up to 13-bit differential or 12-bit single-ended resolution supported. 1b - Up to 16-bit differential or 16-bit single-ended resolution supported. CMDLn[MODE] available for selecting the resolution of conversions for the associated command.

41.6.3 Parameter Register (PARAM)

Offset

Register	Offset
PARAM	4h

Function

The Parameter register indicates the size of several variable integration options for this instance on the device.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 CMD_NUM	Command Buffer Number Indicates number of command buffers implemented.
23-16 CV_NUM	Compare Value Number Indicates number of compare value registers implemented.
15-8 FIFOSIZE	Result FIFO Depth Indicates the maximum number of conversion data words that can be stored in the result FIFO before an overflow occurs. 0000_0001b - 2 0000_0100b - 4 0000_1000b - 8 0001_0000b - 16 0010_0000b - 32 0100_0000b - 64
7-0 TRIG_NUM	Trigger Number Number of Triggers implemented.

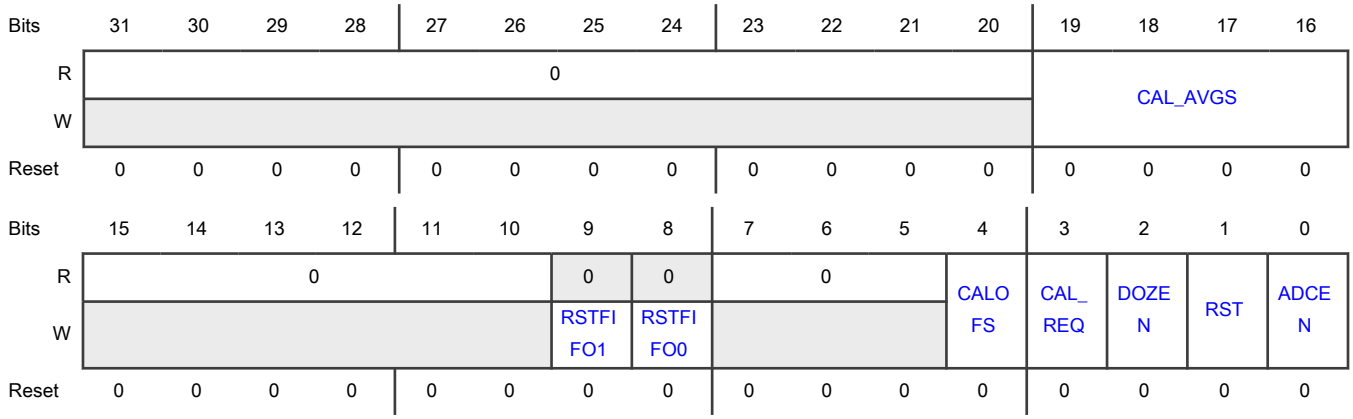
41.6.4 Control Register (CTRL)

Offset

Register	Offset
CTRL	10h

Function
Includes primary control bits.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16 CAL_AVGS	Auto-Calibration Averages Selects how many ADC conversions are averaged to calculate each calibration value. Selecting a higher number of averages will lead to more accurate conversions after completing calibration. The CAL_AVGS bit field applies to both CALOFS and CAL_REQ calibration types. This value should be fixed when requesting and running calibration with CTRL[CAL_REQ] or CTRL[CALOFS]. 0000b - Single conversion. 0001b - 2 conversions averaged. 0010b - 4 conversions averaged. 0011b - 8 conversions averaged. 0100b - 16 conversions averaged. 0101b - 32 conversions averaged. 0110b - 64 conversions averaged. 0111b - 128 conversions averaged. 1000b - 256 conversions averaged. 1001b - 512 conversions averaged. 1010b - 1024 conversions averaged.
15-10 —	Reserved
9 RSTFIFO1	Reset FIFO 1 0b - No effect. 1b - FIFO 1 is reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
8 RSTFIFO0	Reset FIFO 0 0b - No effect. 1b - FIFO 0 is reset.
7-5 —	Reserved
4 CALOFS	Offset Calibration Request Indicates whether a request for a hardware calibration calculation has been made. Writing 1 to this field initiates a hardware offset calibration calculation. Any conversions in progress are completed before launching the offset calibration function. After being accepted, ADC calculates the OFSTRIM[OFSTRIM] value and updates the OFSTRIM register automatically. This field becomes 0 upon completion of the offset calibration calculation. STAT[CAL_RDY] indicates when the offset calibration routine has completed. 0b - Calibration function disabled 1b - Request for offset calibration function
3 CAL_REQ	Auto-Calibration Request Indicates whether a request for the hardware calibration routine has been made. Automatically becomes 0 when the system accepts the hardware calibration request. STAT[CAL_RDY] indicates when this calibration routine has been completed. 0b - No request made. 1b - Request has been made.
2 DOZEN	Doze Enable Controls system transition to low-power modes while ADC is converting. When 0, immediate entries to low-power modes are allowed and ADC conversion functions remain enabled. Any conversion in progress is not disrupted. The selected clock source provided from the on-chip clock source must be able to continue operating. When 1, the ADC waits for the current averaging iteration or FIFO storage to complete before acknowledging the low-power entry request. After entering the low-power state, ADC is kept inactive until the system exits the low-power state. When the system enters a low-power mode in which ADC operation is not supported, the DOZEN bit is ignored and ADC waits for the current transfer to complete any pending operation. 0b - ADC is enabled in low-power mode. 1b - ADC is disabled in low-power mode.
1 RST	Software Reset Resets all internal logic and registers, except the CTRL register. Remains 1 until cleared by software. 0b - ADC logic is not reset. 1b - ADC logic is reset.
0	ADC Enable

Fields

Field	Function
31-28 —	Reserved
27-24 CMDACT	Command Active Indicates the command actively being processed. Commands are only shown here when they are actively being processed by the SAR routine. Use with STAT[ADC_ACTIVE] to determine which conversion is running. 0000b - No command currently in progress. 0001b - Command 1 currently being executed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0010b - Command 2 currently being executed. 0011b-1111b - Associated command number currently being executed.
23-18 —	Reserved
17-16 TRGACT	Trigger Active Indicates the trigger actively being processed. This field can be used to determine which trigger is running through a trigger delay or being converted by the SAR routine. The command associated with this field is running through a conversion when STAT[CMDACT] is not zero. 00b - Command (sequence) associated with Trigger 0 currently being executed. 01b - Command (sequence) associated with Trigger 1 currently being executed. 10b - Command (sequence) associated with Trigger 2 currently being executed. 11b - Command (sequence) associated with Trigger 3 currently being executed.
15-12 —	Reserved
11 ADC_ACTIVE	ADC Active Indicates whether the module is processing a conversion, or has pending triggers to service. 0b - ADC is idle. There are no pending triggers to service and no active commands are being processed. 1b - ADC is processing a conversion, running through the power-up delay, or servicing a trigger.
10 CAL_RDY	Calibration Ready Indicates whether the ADC request for calibration (CTRL[CAL_REQ] or CTRL[CALOFS]) has been completed and the results are ready. This flag is automatically cleared when a new hardware calibration or OFSTRIM request is made. 0b - Calibration is incomplete or has not been run. 1b - ADC is calibrated.
9 TCOMP_INT	Interrupt Flag For Trigger Completion Indicates when a trigger sequence has been completed (all associated commands have been run). IE[TCOMP_IE] must be 1 for the specific trigger source to flag an interrupt upon completion. 0b - Either IE[TCOMP_IE] = 0, or no trigger sequences have run to completion. 1b - Trigger sequence has been completed and all data is stored in the associated FIFO.
8 TEXC_INT	Interrupt Flag For High-Priority Trigger Exception Indicates when a high-priority trigger exception has occurred and CFG[TRES] = 0. This flag only asserts if trigger exception interrupts are enabled (IE[TEXC_IE] = 1h). This flag can be used with TSTAT[TEXC_NUM] to resolve which trigger source was interrupted.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No trigger exceptions have occurred. 1b - A trigger exception has occurred and is pending acknowledgment.
7-4 —	Reserved
3 FOF1	Result FIFO1 Overflow Flag Indicates that more data has been written to the Result FIFO 1 than it can hold. The newer data is not stored and the FIFO holds the original contents. This flag asserts regardless of the value of IE[FOFIE1]. However, an interrupt request is issued only if IE[FOFIE1] is 1. 0b - No result FIFO1 overflow has occurred since the last time that the flag was cleared. 1b - At least one result FIFO1 overflow has occurred since the last time that the flag was cleared.
2 RDY1	Result FIFO1 Ready Flag Indicates when the number of valid data words in the result FIFO 1 is greater than the level set in FCTRL0[FWMARK]. This flag asserts regardless of the value of IE[FWMIE1]. However, an interrupt request or DMA request occurs only when the associated control bit (IE[FWMIE1] and DE[FWMDE1]) is set. This flag is cleared when FCTRL0[FCOUNT] (which decrements on each read of the RESFIFO register) is less than or equal to the level set in FCTRL0[FWMARK]. 0b - Not above watermark 1b - Above watermark
1 FOF0	Result FIFO 0 Overflow Flag Indicates that more data has been written to the Result FIFO 0 than it can hold. The newer data is not stored and the FIFO holds the original contents. This flag asserts regardless of the value of IE[FOFIE0]. However, an interrupt request is issued only if IE[FOFIE0] is 1. 0b - No result FIFO 0 overflow has occurred since the last time that the flag was cleared. 1b - At least one result FIFO 0 overflow has occurred since the last time that the flag was cleared.
0 RDY0	Result FIFO 0 Ready Flag Indicates when the number of valid data words in the result FIFO 0 is greater than the watermark set in FCTRL0[FWMARK]. This flag asserts regardless of the value of IE[FWMIE0]. However, an interrupt request or DMA request occurs only when the associated control field (IE[FWMIE0] and DE[FWMDE0]) is 1. This flag is cleared when the FCTRL0[FCOUNT] (which decrements on each read of the RESFIFO register) is less than or equal to the level set in FCTRL0[FWMARK]. 0b - Not above watermark 1b - Above watermark

41.6.6 Interrupt Enable Register (IE)

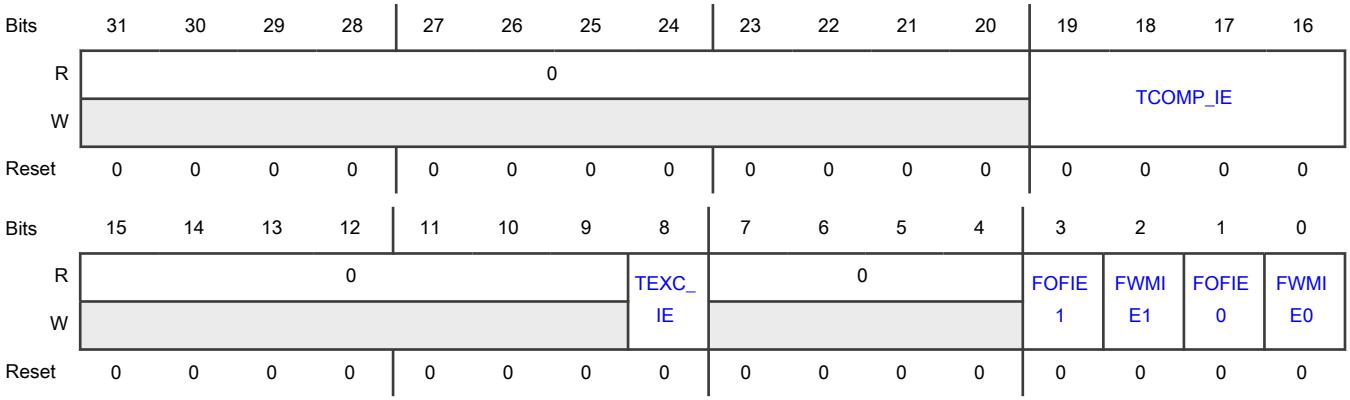
Offset

Register	Offset
IE	18h

Function

Includes system interrupt masking control bits.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16 TCOMP_IE	Trigger Completion Interrupt Enable Enables generation of interrupt requests to indicate when complete trigger command sequences are executed. Each bit in TCOMP_IE corresponds to a trigger source. (TCOMP_IE[0] corresponds to trigger 0, and so on.) All results are stored in the FIFO when a sequence is considered complete. 0000b - All disabled 0001b - Trigger completion interrupts are enabled for trigger source 0 only. 0010b - Trigger completion interrupts are enabled for trigger source 1 only. 0011b-1110b - Associated trigger completion interrupts are enabled. 1111b - All enabled
15-9 —	Reserved
8	Trigger Exception Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TEXC_IE	Enables ADC to assert an interrupt request when a high-priority trigger exception occurs. TSTAT[TEXC_NUM] contains the value of the corresponding trigger affected by the exception. 0b - Disabled 1b - Enabled
7-4 —	Reserved
3 FOFIE1	Result FIFO1 Overflow Interrupt Enable Enables generation of overflow interrupt requests when FOF1 flag is asserted. 0b - Disabled 1b - Enabled
2 FWMIE1	FIFO1 Watermark Interrupt Enable Enables generation of watermark interrupt requests when STAT[RDY1] flag is asserted. 0b - Disabled 1b - Enabled
1 FOFIE0	Result FIFO 0 Overflow Interrupt Enable Enables generation of overflow interrupt requests when FOF flag is asserted. 0b - Disabled 1b - Enabled
0 FWMIE0	FIFO 0 Watermark Interrupt Enable Enables generation of watermark interrupt requests when STAT[RDY0] flag is asserted. 0b - Disabled 1b - Enabled

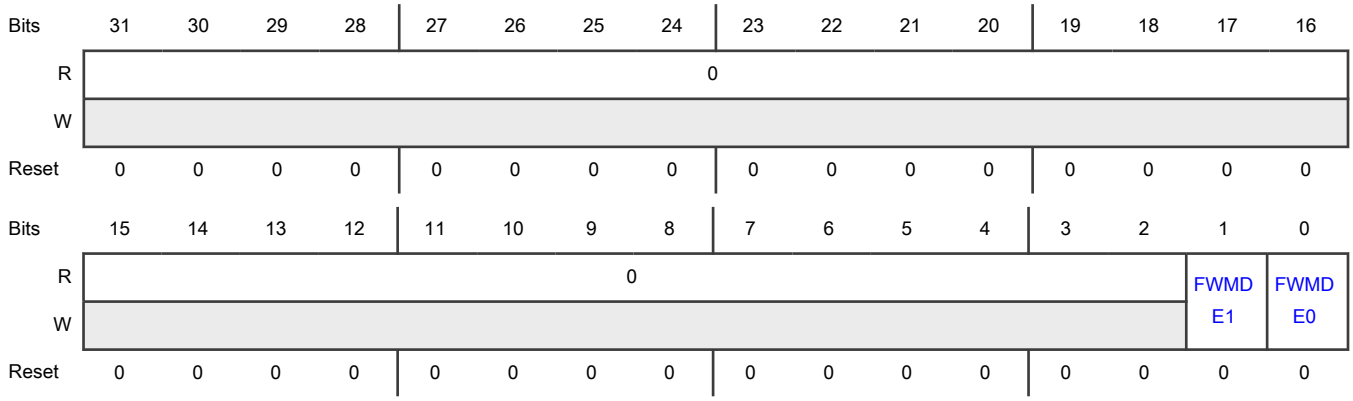
41.6.7 DMA Enable Register (DE)

Offset

Register	Offset
DE	1Ch

Function
Includes DMA request-masking control bits.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 FWMDE1	FIFO1 Watermark DMA Enable Enables generation of DMA requests when STAT[RDY1] flag is asserted. 0b - Disabled 1b - Enabled
0 FWMDE0	FIFO 0 Watermark DMA Enable Enables generation of DMA requests when STAT[RDY0] flag is asserted. 0b - Disabled 1b - Enabled

41.6.8 Configuration Register (CFG)

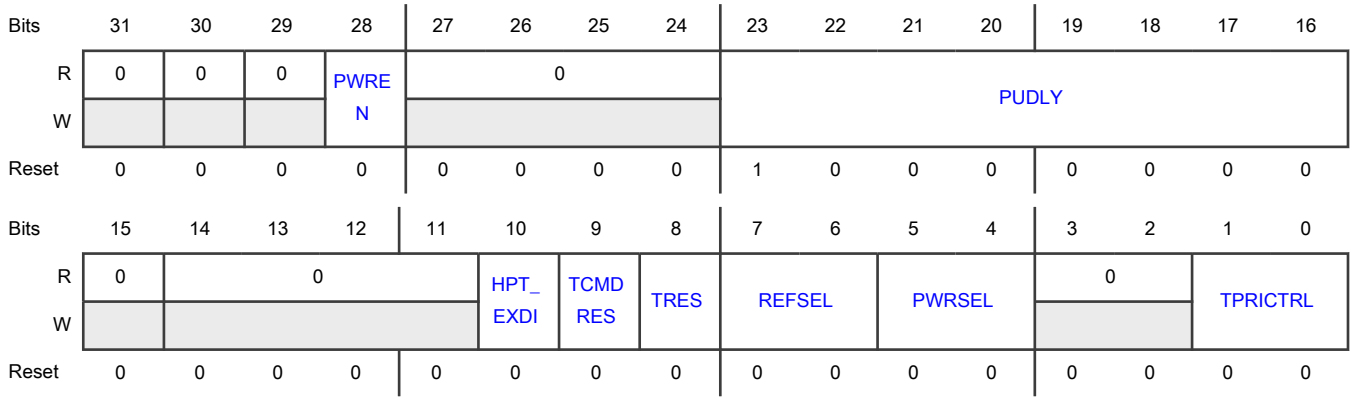
Offset

Register	Offset
CFG	20h

Function

Controls ADC functions common to all commands. When CTRL[ADCEN] = 1, this register cannot be changed and writes to this register are ignored.

Diagram



Fields

Field	Function
31 —	Reserved
30 —	Reserved
29 —	Reserved
28 PWREN	ADC Analog Pre-Enable Enables the ADC analog circuits. When setting this field, user code should delay for a period exceeding the analog startup time of $t_{ADCSTUP}$ before enabling ADC for operation. The module is still operational even when this field is 0, but command execution start is delayed for a period defined by CFG[PUDLY]. See the device data sheet for ADC idle and active power consumption parameters. 0b - ADC analog circuits are only enabled while conversions are active. Analog startup delays affect performance. 1b - ADC analog circuits are pre-enabled and ready to execute conversions without startup delays, at the cost of higher DC current consumption. A single power-up delay (CFG[PUDLY]) is executed immediately once PWREN is set. No detected triggers begin ADC operation until the power-up delay time has passed. After this initial delay expires, the analog circuits remain pre-enabled, and no additional delays are executed.
27-24 —	Reserved
23-16 PUDLY	Power-up Delay Defines the power-up delay executed after an initial trigger wakes ADC from its idle state. Must be programmed to a non-zero value to enable the ADC. Depending on the value of CFG[PWREN], the delay is executed in one of two modes:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• When CFG[PWREN] = 0, the ADC analog circuits are only powered on while the module is active. The power-up delay allows time for the analog circuits to stabilize after being powered on. The startup delay count of (PUDLY * 4) ADCK cycles must result in a longer delay than the analog startup time of $t_{ADCSTUP}$. Accuracy of the initial conversions after activation is degraded if CFG[PUDLY] is set to too small a value. After active conversions, if no subsequent conversions are pending, the ADC analog circuits are automatically reverted to their low-power idle state. When ADC is awakened with a later trigger, the power-up delay runs again. • When CFG[PWREN] = 1 prior to ADC activation, the analog circuits are pre-enabled and the activation delay defined by CFG[PUDLY] is executed immediately. After the delay has been executed, the analog circuits remain enabled regardless of ADC activity. This configuration begins conversions immediately after trigger event detection, at the cost of increased DC power consumption in the analog circuits. **NOTE** ADC does not begin an initial conversion until the power-up delay has executed, regardless of the value of CFG[PWREN].
15 —	Reserved
14-11 —	Reserved
10 HPT_EXDI	High-Priority Trigger Exception Disable Disables high-priority trigger exceptions. See Trigger detect and command execution for a detailed description on trigger exception handling. When 1, exceptions are disabled and CFG[TCMDRES], CFG[TRES], and CFG[TPRICTRL] are ignored. 0b - Enabled 1b - Disabled
9 TCMDRES	Trigger Command Resume Determines where a trigger sequence resumes when interrupted by a high-priority trigger exception. To use this field, CFG[TRES] must be 1. 0b - Trigger sequence automatically restarted. 1b - Trigger sequence resumed from the command that was executed prior to the exception.
8 TRES	Trigger Resume Enable Determines whether trigger sequences interrupted by a high-priority exception are automatically resumed or restarted. If 1, the sequence can be resumed along command boundaries or restarted from the beginning of a sequence, as determined by CFG[TCMDRES]. If 0, interrupted triggers can be resumed via software by monitoring STAT[TEXC_INT] (or via ISR handling for trigger exception interrupt when IE[TEXC_IE] = 1). Software determines which trigger was interrupted

Table continues on the next page...

Table continued from the previous page...

Field	Function
	by reading TSTAT[TEXC_NUM] and restarts the trigger by writing 1 to the corresponding field in the SWTRIG register. 0b - Not automatically resumed or restarted 1b - Automatically resumed or restarted
7-6 REFSEL	Voltage Reference Selection Selects the voltage reference high used for conversions. **NOTE** See the chip-specific ADC information for voltage reference options specific to this packaged device. 00b - Option 1 01b - Option 2 10b - Option 3 11b - Reserved
5-4 PWRSEL	Power Configuration Select Configures the module for power and performance. In the high-power setting, the highest conversion rates are possible. See the device data sheet for power and performance capabilities for each setting. 0xb - Low power 1xb - High power
3-2 —	Reserved
1-0 TPRICTRL	ADC Trigger Priority Control Controls how higher-priority trigger exceptions are handled when they are received during command processing. See Trigger detect and command execution for a detailed explanation of trigger event handling. 00b - Current conversion is aborted and the new command specified by the trigger is started. 01b - Current command is stopped after completing the current conversion. If averaging is enabled, the averaging loop is completed. CMDHn[LOOP] is ignored and the higher-priority trigger is serviced. 10b - Current command is completed (averaging, looping, compare) before servicing the higher-priority trigger. 11b - Reserved

41.6.9 Pause Register (PAUSE)

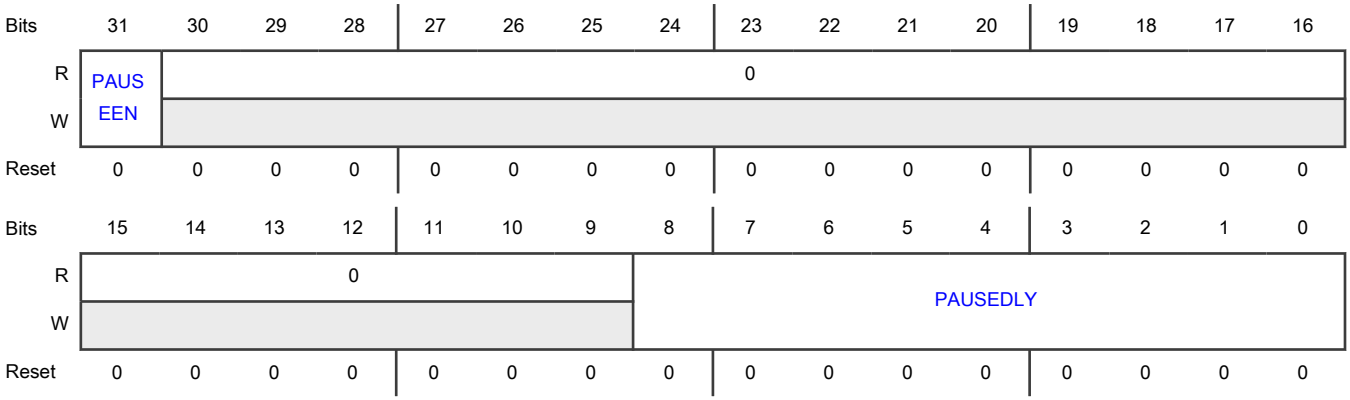
Offset

Register	Offset
PAUSE	24h

Function

Controls the optional inserted delay between conversions. When CTRL[ADCEN] = 1, this register should not be modified.

Diagram



Fields

Field	Function
31 PAUSEEN	Pause Enable Enables the ADC pausing function. When enabled, a programmable delay is inserted during command execution sequencing: • Between LOOP iterations. • Between commands in a sequence. • Between conversions, when a command is executing in compare-until-true configuration. **NOTE** CMDHn[WAIT_TRIG] and PAUSE are mutually exclusive. CMDHn[WAIT_TRIG] takes priority over PAUSE between commands when both are enabled. 0b - Disabled 1b - Enabled
30-9 —	Reserved
8-0 PAUSEDLY	Pause Delay Controls the duration of pauses during command execution sequencing when PAUSE[PAUSEEN] = 1. The pause delay is a count of (PAUSEDLY * 4) ADCK cycles.

41.6.10 Software Trigger Register (SWTRIG)

Offset

Register	Offset
SWTRIG	34h

Function

Initiates software-triggered conversions when written to. Writes to this register are ignored while CTRL[ADCEN] = 0. There is an approximately three ADC-clock-cycle synchronization delay between asserting CTRL[ADCEN] and when SWTRIG can be accepted.

Diagram

Table continued from the previous page...

Field	Function
SWT1	Write 1 to SWT1 generates a trigger 1 event. Writing 1 to SWT1 is ignored while the trigger 1 event is being serviced or is pending. 0b - No trigger 1 event generated. 1b - Trigger 1 event generated.
0 SWT0	Software Trigger 0 Generates a trigger 0 event. Writing 1 to this field is ignored while the trigger 0 event is being serviced or is pending. 0b - No trigger 0 event generated. 1b - Trigger 0 event generated.

41.6.11 Trigger Status Register (TSTAT)

Offset

Register	Offset
TSTAT	38h

Function

Contains status flags to indicate when trigger sequences have been completed or interrupted by a high-priority trigger exception. Each field in this register is set by hardware and cleared by software.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0												TCOMP_FLAG

W													W1C			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-20	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
19-16 TCOMP_FLAG	Trigger Completion Flag Indicates which triggers have been completed. Each bit in this field corresponds to a trigger. When a trigger sequence has completed, the corresponding bit in TCOMP_FLAG is set. For example, if trigger 3 has been completed, then bit 19 is set in the TSTAT register. This register is active only if the corresponding bit in IE[TCOMP_IE] = 1. **NOTE** A synchronization delay may be added to the end of the final conversion in a sequence, prior to this flag being set. This delay can range from two to four ADC CLK cycles. 0000b - No triggers have been completed. Trigger completion interrupts are disabled. 0001b - Trigger 0 has been completed and trigger 0 has enabled completion interrupts. 0010b - Trigger 1 has been completed and trigger 1 has enabled completion interrupts. 0011b-1110b - Associated trigger sequence has completed and has enabled completion interrupts. 1111b - Every trigger sequence has been completed and every trigger has enabled completion interrupts.
15-4 —	Reserved
3-0 TEXC_NUM	Trigger Exception Number Indicates which triggers have been interrupted by exceptions. Each bit in this field corresponds to a trigger. When the corresponding trigger sequence is interrupted by a high-priority trigger exception, the corresponding bit is set. For example, if trigger 3 has been interrupted, then bit 3 is set in this register. This register is active regardless of the value in IE[TEXC_IE]. 0000b - No triggers have been interrupted by a high-priority exception. Or CFG[TRES] = 1. 0001b - Trigger 0 has been interrupted by a high-priority exception. 0010b - Trigger 1 has been interrupted by a high-priority exception. 0011b-1110b - Associated trigger sequence has interrupted by a high-priority exception. 1111b - Every trigger sequence has been interrupted by a high-priority exception.

41.6.12 Offset Trim Register (OFSTRIM)

Offset

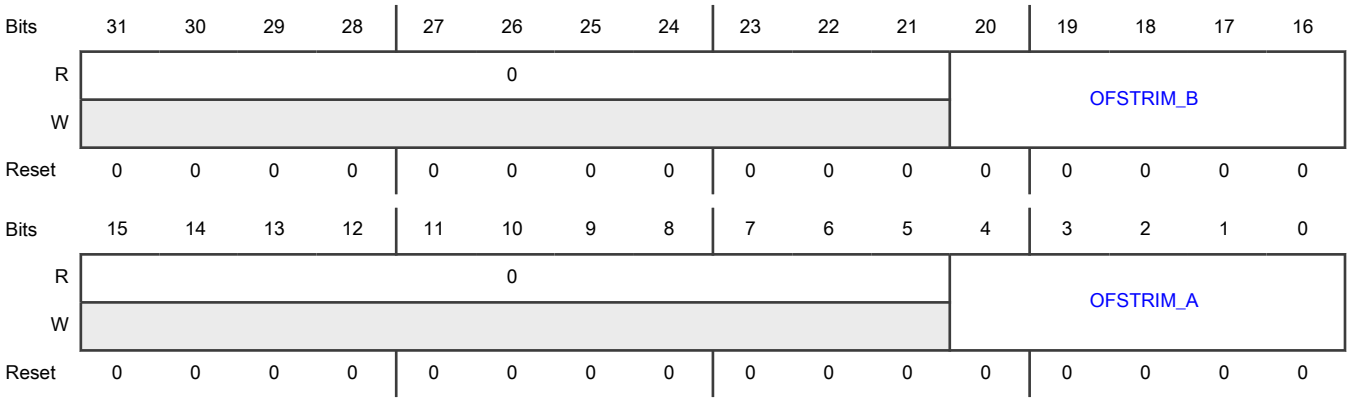
Register	Offset
OFSTRIM	40h

Function

Used to trim for offset. ADC supports a calibration step in which the ADC determines the value needed in the OFSTRIM register.

To determine the value to put in the OFSTRIM register, write 1 to CTRL[CALOFS]. This setting automatically begins a sequence to calculate this value. Once the sequence has completed, the OFSTRIM register is updated with a signed value between -16 and 15. This value is used to minimize offset during normal operation.

Diagram



Fields

Field	Function
31-21 —	Reserved
20-16 OFSTRIM_B	Trim for Offset OFSTRIM is a 5-bit signed value between -16 and 15. This value applies to the ADC B-side conversion results.
15-5 —	Reserved
4-0 OFSTRIM_A	Trim for Offset OFSTRIM_A is a 5-bit signed value between -16 and 15. This value applies to the ADC A-side conversion results.

41.6.13 Trigger Control Register (TCTRL0 - TCTRL3)

Offset

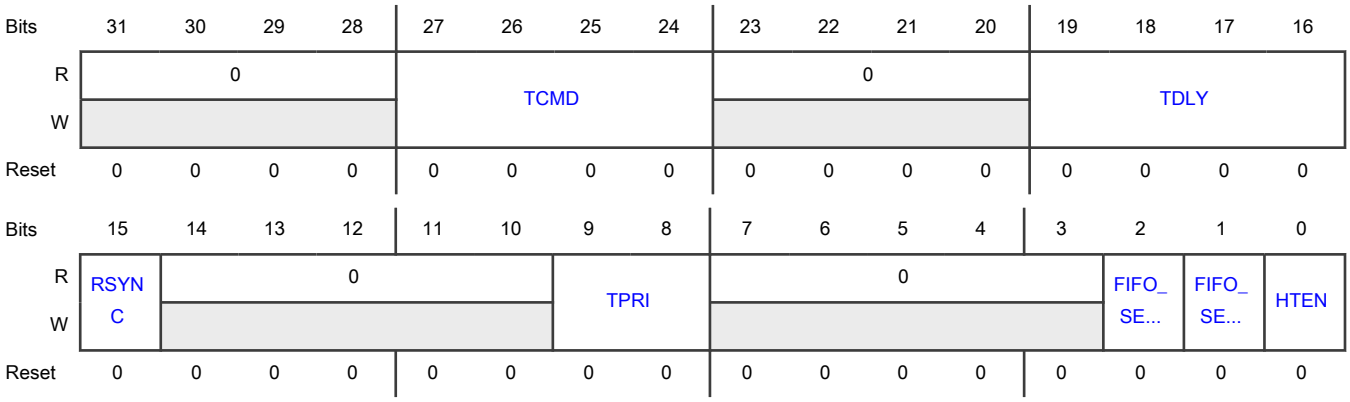
Register	Offset
TCTRL0	A0h
TCTRL1	A4h
TCTRL2	A8h
TCTRL3	ACh

Function

Implements control fields associated with each trigger source. When ADC is executing commands, only one TCTRLn register controls ADC conversions.

Do not update the controlling TCTRLn register while ADC is active. Writing to a TCTRLn register while that trigger control register controls the ADC operation may cause unpredictable behavior.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 TCMD	Trigger Command Select Selects the command from the command buffer to execute upon detection of the associated trigger event. When a higher-priority trigger is received while ADC is converting, the command in this register associated with the new trigger is executed. This execution is done under the control of CFG[TPRICTRL]. See Trigger detect and command execution for details about the relationship between CFG[TPRICTRL] and TCMD. 0000b - Not a valid selection from the command buffer. Trigger event is ignored. 0001b - CMD1 0010b-1110b - Corresponding CMD is executed 1111b - CMD15
23-20 —	Reserved
19-16 TDLY	Trigger Delay Select Selects the trigger delay duration for the start of servicing a trigger event. Each trigger source has an associated programmable delay prior to beginning an initial conversion. When this field is 0, no delay is incurred. When this field is set to a non-zero value, the duration of the delay is 2^{TDLY} ADCK cycles.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 RSYNC	Trigger Resync Enables trigger resync. If 1, this trigger source is used as a resync trigger. A resync trigger can be configured to restart or abort a running trigger sequence (the target). Each resync trigger is configured to have a resync target. When a resync trigger is asserted: • The target sequence is aborted. • The target FIFO destinations are cleared. • The target sequence can be restarted depending on CFG[TRES]. Multiple conditions must be met for a resync trigger to execute properly: • The resync trigger must have higher priority than the resync target. • The resync trigger TCTRLn[RSYNC] must be set to 1b. • The resync target, specified by TCTRLn[TCMD], must be executing when the resync trigger is asserted. See Resync functionality for more information. 0b - Disable 1b - Enable
14-10 —	Reserved
9-8 TPRI	Trigger Priority Setting Sets the priority of the associated trigger source. If two or more triggers have the same priority level, the lower-order trigger event has the higher priority. If Trigger 0 and Trigger 1 are pending triggers and TCTRL0[TPRI] is configured the same as TCTRL1[TPRI], the Trigger 0 command is serviced first. 00b - Highest priority, Level 1 01b-10b - Set to corresponding priority level. 11b - Lowest priority, Level 4
7-3 —	Reserved
2 FIFO_SEL_B	SAR Result Destination for Channel B Indicates the FIFO to which SAR results are written for Channel B. This field is only used in dual single-ended mode (CMDLn[CTYPE] = 11b). In this mode, the SAR result from Channel B is written to the FIFO number specified by this field. See Sampling Modes for more information. 0b - FIFO 0 1b - FIFO 1
1 FIFO_SEL_A	SAR Result Destination for Channel A

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates the FIFO to which SAR results are written for Channel A. This field provides the destination for all single-ended and differential conversions and for all A-side conversions in dual single-ended mode. Conversion results are stored in the FIFO number specified, under the following conditions: • Single-ended mode: CMDLn[CTYPE] = 00b or CMDLn[CTYPE] = 01b. • Differential mode: CMDLn[CTYPE] = 10b. • Dual single-ended mode: CMDLn[CTYPE] = 11b. 0b - FIFO 0 1b - FIFO 1
0 HTEN	Trigger Enable Enables hardware trigger source to initiate conversion on the rising edge of the input trigger source. **NOTE** Enabling the hardware trigger does not disable software triggers. 0b - Disabled 1b - Enabled

41.6.14 FIFO Control Register (FCTRL0 - FCTRL1)

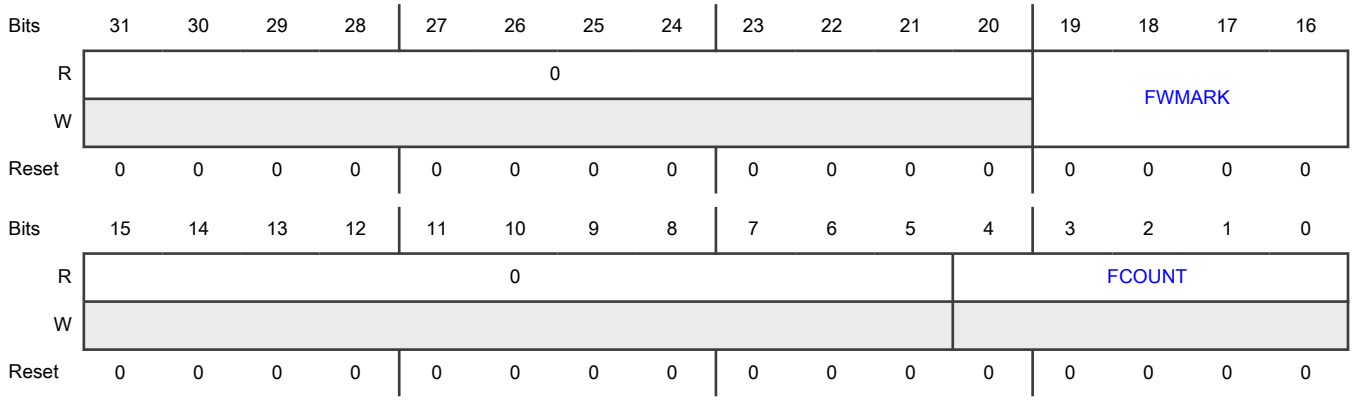
Offset

Register	Offset
FCTRL0	E0h
FCTRL1	E4h

Function

Contains control and status fields for each FIFO in the design. A programmable watermark can be set for each FIFO, which can be used to trigger an interrupt. In addition, the number of entries stored in each FIFO can be monitored by reading FCTRLn[FCOUNT].

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16 FWMARK	Watermark Level Selection Selects the storage threshold for the ADC Result FIFO. When the number of data words stored in the FIFO is greater than this value, the STAT[RDY0] flag is asserted. When IE[FWMIEn] = 1, an interrupt request is generated. When DE[FWMDEn] = 1, a DMA request is generated.
15-5 —	Reserved
4-0 FCOUNT	Result FIFO Counter Indicates the number of data words stored in the result FIFO. This value may be used with PARAM[FIFOSIZE] to calculate how much room is left in the result FIFO. This field is incremented with each storage of new data into the result FIFO and decrements with each read of the result FIFO. The FIFO is reset by writing to CTRL[RSTFIFOn], which initializes FCTRLn[FCOUNT] to 0h.

41.6.15 Gain Calibration Control (GCC0 - GCC1)

Offset

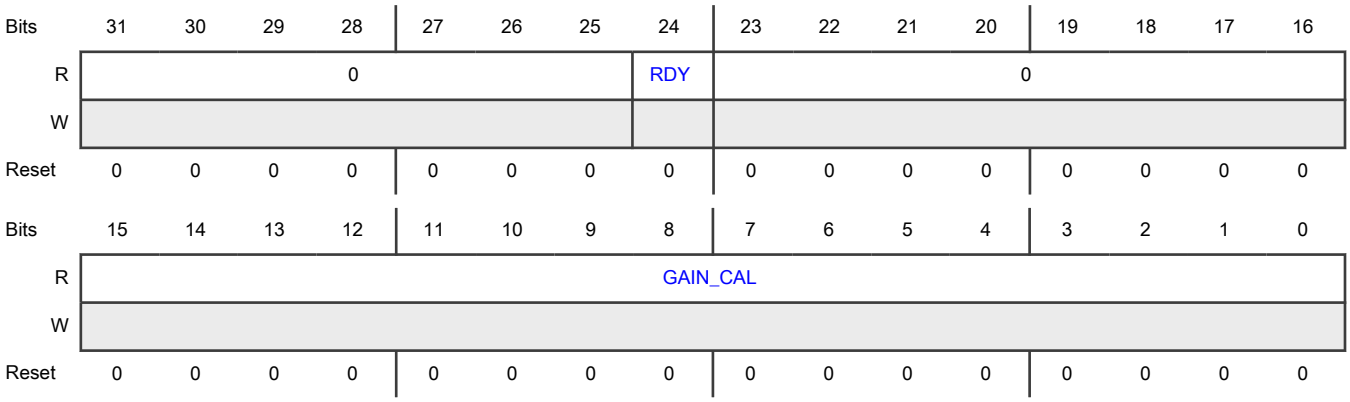
Register	Offset
GCC0	F0h
GCC1	F4h

Function

Holds intermediate values used as part of the calibration steps. GCC0 is associated with the A-side converter and GCC1 is associated with the B-side converter. GCCn[GAIN_CAL] is calculated with hardware and automatically updated during the calibration steps. Once the hardware calibration sequence has updated, GCCn[RDY] is asserted automatically.

Requesting a calibration routine automatically clears the GCCn[RDY] flag until the new GCCn[GAIN_CAL] value is calculated. To complete calibration, further software processing is needed, where GCCn[GAIN_CAL] is used to calculate the gain adjustment. The result is stored to GCRn[GCALR]. See Calibration functions.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 RDY	Gain Calibration Value Valid Indicates whether the data stored in GCCn[GAIN_CAL] is valid and should be used to derive GCRn[GCALR]. If the data in GCCn[GAIN_CAL] is invalid, you can run the hardware calibration routine to correct this issue. 0b - Invalid 1b - Valid
23-16 —	Reserved
15-0 GAIN_CAL	Gain Calibration Value Indicates the calculated value of the gain calibration. As part of the hardware calibration steps, this field is automatically updated with a 16-bit unsigned number. It is used in the gain adjustment calculations to derive the value written to GCRn[GCALR]. See Calibration functions.

41.6.16 Gain Calculation Result (GCR0 - GCR1)

Offset

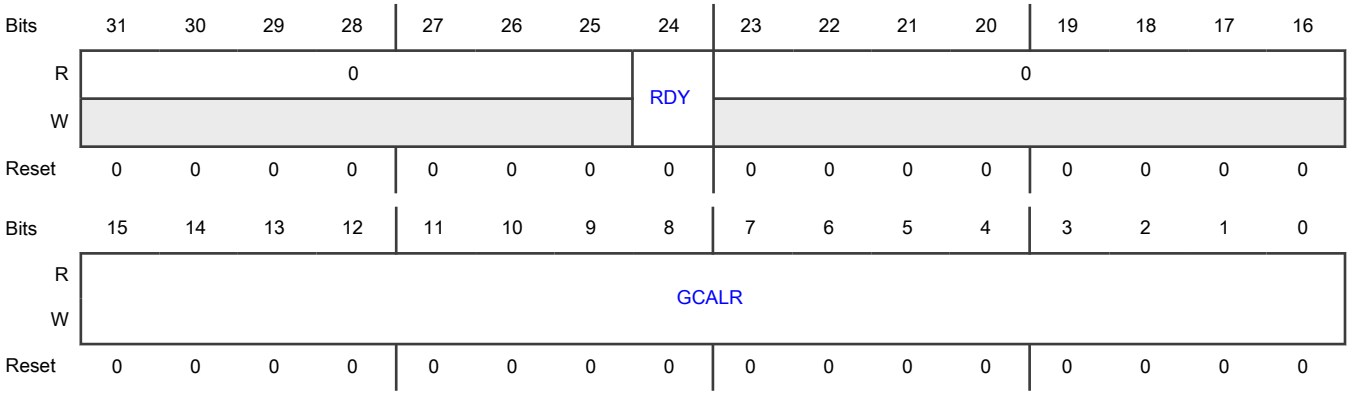
Register	Offset
GCR0	F8h
GCR1	FCh

Function

Used during ADC conversions for automated gain error adjustment. GCR0 is associated with the A-side converter and GCR1 is associated with the B-side converter. Determining the values to store to GCR0[GCALR] and GCR1[GCALR] is the result of software calculations described in setup steps in Calibration functions. Upon writing the GCRn[GCALR] value, the user should also write 1 to GCRn[RDY] to indicate that the gain adjustment result is valid.

A calibration sequence begins by writing 1 to CTRL[CAL_REQ], and the calibration sequence is not complete until GCRn[GCALR] is calculated and GCRn[RDY] is 1. The gain adjustment calculation produces a floating-point value between 1 and 2. GCRn[GCALR] holds the 16-bit fractional component of the gain adjustment calculation. To convert the GCRn[GCALR] value to the gain adjustment value in decimal format, use this formula: 1 + 0.5 * GCRn[15] + 0.25 * GCRn[14] + 0.125 * GCRn[13] + (and so on)

Diagram



Fields

Field	Function
31-25 —	Reserved
24 RDY	Gain Calculation Ready Indicates whether the data stored in GCRn[GCALR] is valid and is used for gain adjustment. GCRn[GCALR] must be written from memory or calculated each time the calibration routine is run. The user must write 1 to this GCRn[RDY] after writing valid data to GCRn[GCALR]. This field becomes 0 automatically when requesting a new calibration sequence. 0b - Invalid 1b - Valid
23-16 —	Reserved
15-0 GCALR	Gain Calculation Result Holds the 16-bit fractional component generated from the gain adjustment calculation during the auto-calibration routine.

41.6.17 Command Low Buffer Register (CMDL1 - CMDL15)

Offset

For a = 1 to 15:

Register	Offset
CMDLa	F8h + (a × 8h)

Function

Controls channel selection and conversion options. There are 15 command buffers (CMDn), each constructed from two 32-bit registers (CMDHn:CMDLn) that can be configured for different channel selection and varying conversion options. Any command buffer is selected and used as the controlling command by association with a trigger event via configuration of TCTRLn[TCMD]. When ADC is executing commands, only one of the CMD buffers controls ADC conversions. Do not update the controlling CMD buffer while ADC is active. A write to a CMD buffer while that CMD buffer controls the ADC operation may cause unpredictable behavior.

NOTE

The 15 command buffers are numbered [CMDH1:CMDL1] through [CMDH15:CMDL15]. In NXP-supplied header files, these buffers are likely to be defined as two 15-element arrays that are indexed from 0. For example, the type declaration would be:

```
unsigned int CMDH[15];
unsigned int CMDL[15];
```

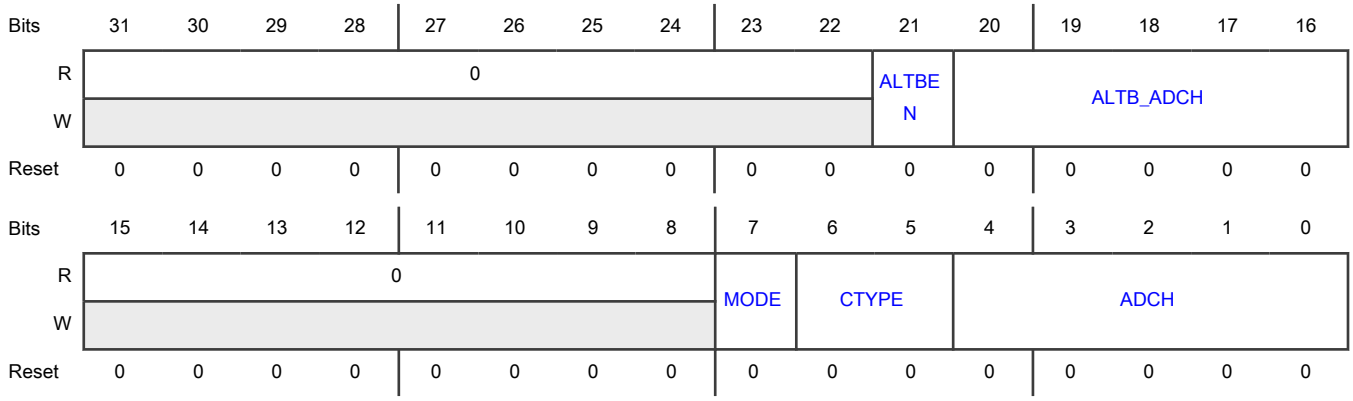
and software would access ADC0 CMDH1 as `ADC0->CMDH[0]` and ADC0 CMDL15 as `ADC0->CMDL[14]`.

The CMDLn[ADCH] and CMDLn[CTYPE] fields control selection of paired or individual input channels. Each ADC command independently makes a channel and conversion type selection. Each ADCH channel selection has an associated A-side and B-side input. Each ADCH pair can be converted in differential mode, but only limited pairs should be converted as differential channels (for example, adjacent pins designed with matched impedance). For the pin pairings available for differential conversions for your device, see the Chip Configuration details.

NOTE

Some input channels are from on-chip sources such as temperature sensors and reference voltage sources and may only be connected to individual instances of ADC. Some input channel options in the field descriptions may not be available for your device. See the chip-specific information for the channels supported on this device.

Diagram



Fields

Field	Function
31-22 —	Reserved
21 ALTBEN	Alternate Channel B Select Enable Enables the ALTB_ADCH to select the input for Channel B independent of ADCH register settings when CTYPE is configured to 01b or 11b. **NOTE** Setting CTYPE to differential (10b) still works but is not recommended. 0b - ALTBEN_ADCH disabled. Channel-A and Channel-B inputs are selected based on ADCH settings. 1b - ALTBEN_ADCH enabled. Channel-A inputs are selected by ADCH setting and Channel-B inputs are selected by ALTB_ADCH setting.
20-16 ALTB_ADCH	Alternate Channel B Input Channel Select When ALTBEN is set, ALTB_ADCH selects the Channel B input when CTYPE is configured to 01b or 11b. **NOTE** Some input channels are from internal resources such as temperature sensors and band gap voltage sources and may only be connected to individual instances of ADC. Some input channel options in field descriptions might not be available for your device. See the chip-specific information for the ADC channel assignments for your device. 0_0000b - Select CH0B 0_0001b - Select CH1B 0_0010b - Select CH2B 0_0011b - Select CH3B 0_0100b-1_1101b - Select corresponding channel CHnB 1_1110b - Select CH30B 1_1111b - Select CH31B
15-8 —	Reserved
7 MODE	Select Resolution of Conversions Selects the ADC resolution. 0b - Standard resolution. Single-ended 12-bit conversion; differential 13-bit conversion with 2's complement output. 1b - High resolution. Single-ended 16-bit conversion; differential 16-bit conversion with 2's complement output.
6-5	Conversion Type

Table continues on the next page...

Table continued from the previous page...

Field	Function
CTYPE	Chooses how a pair of A and B channels are converted. 00b - Single-Ended mode. Only A-side channel is converted. 01b - Single-Ended mode. Only B-side channel is converted. 10b - Differential mode. A-B. 11b - Dual-Single-Ended mode. Both A-side and B-side channels are converted independently.
4-0 ADCH	Input Channel Select Selects the input from one of the channel inputs or one of the input pairs, with CMDLn[CTYPE]. Each ADCH channel selection has an associated A-side and B-side input. **NOTE** Not all pairs should be converted as differential channels. See the chip-specific information for the pin pairings available for differential conversions for your device. **NOTE** Some input channels are from internal resources such as temperature sensors and band gap voltage sources and may only be connected to individual instances of ADC. Some input channel options in field descriptions might not be available for your device. See the chip-specific information for the ADC channel assignments for your device. 0_0000b - CH0A or CH0B or CH0A/CH0B pair. 0_0001b - CH1A or CH1B or CH1A/CH1B pair. 0_0010b - CH2A or CH2B or CH2A/CH2B pair. 0_0011b - CH3A or CH3B or CH3A/CH3B pair. 0_0100b-1_1101b - Select corresponding channel CHnA or CHnB or CHnA/CHnB pair. 1_1110b - CH30A or CH30B or CH30A/CH30B pair. 1_1111b - CH31A or CH31B or CH31A/CH31B pair.

41.6.18 Command High Buffer Register (CMDH1 - CMDH15)

Offset

For a = 1 to 15:

Register	Offset
CMDHa	FCh + (a × 8h)

Function

Controls channel selection and conversion options. There are 15 command buffers (CMDn), each constructed from two 32-bit registers (CMDHn:CMDLn) that can be configured for different channel selection and conversion options. Any command buffer is selected and used as the controlling command by association with a trigger event via configuration of TCTRLn[TCMD]. When ADC is executing commands, only one of the CMD buffers controls ADC conversions. Do not update the controlling CMD buffer while ADC is active. A write to a CMD buffer while that CMD buffer controls the ADC operation may cause unpredictable behavior.

NOTE

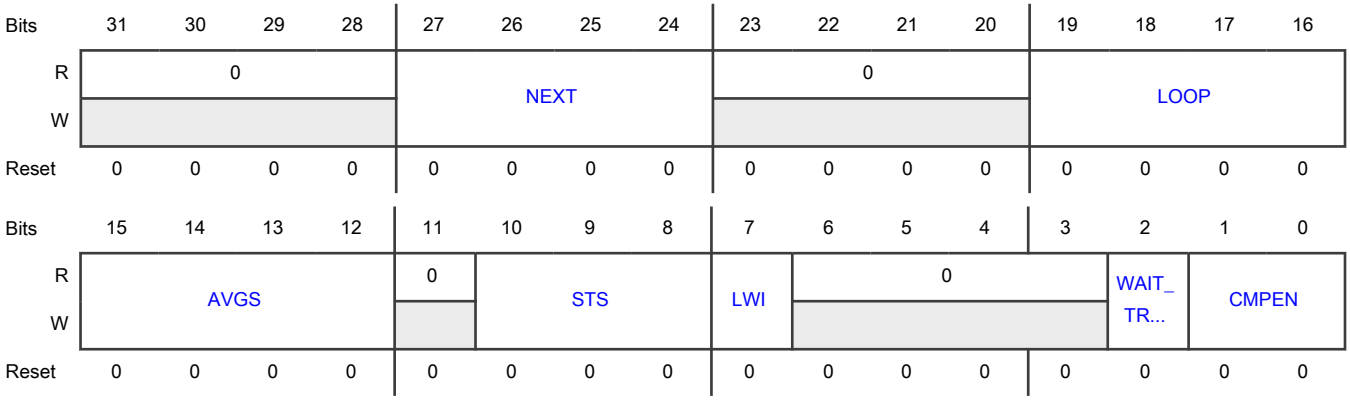
The 15 command buffers are numbered [CMDH1:CMDL1] through [CMDH15:CMDL15]. In NXP-supplied header files, these buffers are likely to be defined as two 15-element arrays that are indexed from 0. For example, the type declaration would be:

```
unsigned int CMDH[15];

unsigned int CMDL[15];
```

and software would access ADC0 CMDH1 as `ADC0->CMDH[0]` and ADC0 CMDL15 as `ADC0->CMDL[14]`.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 NEXT	Next Command Select Selects the next command to be executed after this command completes. Multiple commands can be configured in a scan configuration by linking the next command in a daisy-chain sequence. The command buffer number is not indicative of any particular order. The order of execution is strictly controlled by this field. For example, a sequence of commands could be CMD2 to CMD1 to CMD3. Unending circular command execution can be configured by setting the NEXT field in the last command in a sequence to the first command in the sequence. It is also allowed for a command to set the next command to itself, resulting in a continuous conversion configuration. Setting the next command to 0h causes conversions to terminate at the completion of the command. Lower-priority trigger events cannot be serviced until a higher-priority triggered command (or sequence of commands) completes. 0000b - No next command defined. Terminate conversions at completion of current command. If lower priority trigger pending, begin command associated with lower priority trigger. 0001b - CMD1 0010b-1110b - Select corresponding CMD command buffer register as next command 1111b - CMD15
23-20	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
19-16 LOOP	Loop Count Select Selects the number of times that this command executes (and stores conversion result to RESFIFO) before finishing and transitioning to the next command or idle state. CMDHn[LWI] controls whether a single channel is converted on each iteration or an automatic channel increment results in channel scanning functionality. 0000b - Looping not enabled. Command executes one time. 0001b - Loop one time. Command executes two times. 0010b - Loop two times. Command executes three times. 0011b-1110b - Loop corresponding number of times. Command executes LOOP + 1 times. 1111b - Loop 15 times. Command executes 16 times.
15-12 AVGS	Hardware Average Select Selects how many ADC conversions are averaged to create the ADC result (2^{AVGS}). An internal storage buffer captures temporary results while the averaging iterations are executed. Hardware averaging is a nested loop control and does not extend across LOOP boundaries. See Functional description for usage of AVGS, LOOP, and NEXT fields in command execution sequencing. 0000b - Single conversion 0001b - 2 0010b - 4 0011b - 8 0100b - 16 0101b - 32 0110b - 64 0111b - 128 1000b - 256 1001b - 512 1010b - 1024
11 —	Reserved
10-8 STS	Sample Time Select Selects the total sampling time. When this field contains a non-zero value, the sample time is ($3.5 + 2^{STS}$) ADCK cycles. The shortest sample time maximizes conversion speed for lower-impedance inputs. Extending sample time allows higher-impedance inputs to be sampled accurately. Longer sample times can lower overall power consumption when command looping and sequencing are configured and high conversion rates are not required. 000b - Minimum sample time of 3.5 ADCK cycles.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	001b - 5.5 ADCK cycles. (3.5 + 2^1 ADCK cycles) 010b - 7.5 ADCK cycles. (3.5 + 2^2 ADCK cycles) 011b - 11.5 ADCK cycles. (3.5 + ^{3} ADCK cycles) 100b - 19.5 ADCK cycles. (3.5 + 2^4 ADCK cycles) 101b - 35.5 ADCK cycles. (3.5 + 2^5 ADCK cycles) 110b - 67.5 ADCK cycles. (3.5 + 2^6 ADCK cycles) 111b - 131.5 ADCK cycles. (3.5 + 2^7 ADCK cycles)
7 LWI	Loop with Increment Enables automatic channel incrementing. When 0, the LOOP field selects the number of times the selected channel is converted consecutively. When 1, automatic channel incrementing is enabled and the LOOP field defines how many consecutive channels are converted as part of the command execution. Example 1: LOOP = 8h, LWI = 0b, CMDLn[CTYPE] = 0h, CMDLn[ADCH] = Dh. Convert on channel 13A 9 times. Example 2: LOOP = 8h, LWI = 1b, CMDLn[CTYPE] = 0h, CMDLn[ADCH] = Dh. Run channels 13A-21A each one time. Maximum channel scanning using a single command buffer is defined by the maximum value of the LOOP field (16). 0b - Disabled 1b - Enabled
6-3 —	Reserved
2 WAIT_TRIG	Wait for Trigger Assertion Before Execution Selects whether commands execute automatically or a trigger must be received before execution. When 0, wait states are added before the command until the active trigger is asserted again. When WAIT_TRIG = 0, each command is automatically executed when called. 0b - Command executes automatically. 1b - Active trigger must be asserted again before executing this command.
1-0 CMPEN	Compare Function Enable Enables the automatic compare function. Selects whether to store only when the comparison operation is true, following ADC channel input sampling, conversion, and averaging. When the compare function is enabled, the conversion result is compared to the compare value registers (CVn[CVH] and CVn[CVL]). See Compare Function for details about the options for command sequencing related to the compare function. 00b - Disabled 01b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Enabled. Store on true. 11b - Enabled. Repeat channel acquisition (sample, convert, and compare) until true.

41.6.19 Compare Value Register (CV1 - CV15)

Offset

For a = 1 to 15:

Register	Offset
CVa	1FCh + (a × 4h)

Function

Contains values used to compare the conversion result when the compare function is enabled. This register is formatted like the D field in Data Result FIFO Register (RESFIFO0 - RESFIFO1), which has in different definitions for bit position and value format in different modes. There is a direct association of each compare value register to a specific command buffer register. For example, CV1 is only used during execution of CMD1 command.

When ADC is executing commands, do not update the CVn register associated with the active command (CMDn). Writes to associated CVn register during this time may result in unpredictable behavior.

NOTE

The 15 compare value registers are numbered [CV1] through [CV15]. In NXP-supplied header files, these registers are likely to be defined as a 15-element array indexed from 0. For example, the type declaration would be:

```
unsigned int CV[15];
```

and software would access ADC0 CV1 as `ADC0->CV[0]` and ADC0 CV15 as `ADC0->CV[14]`.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	CVH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CVL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 CVH	Compare Value High Determines the high compare value. The compare function can be configured to check whether the result: • Is less than comparison values • Is greater than comparison values • Falls within a range of two comparison values • Falls outside a range of two comparison values. After the input is sampled and converted and any averaging iterations are performed, CVL and CVH can be used in a compare operation on the result. See Compare Function for a description of CVH usage.
15-0 CVL	Compare Value Low Determines the low compare value. The compare function can be configured to check whether the result: • Is less than comparison values • Is greater than comparison values • Falls within a range of two comparison values • Falls outside a range of two comparison values. After the input is sampled and converted and any averaging iterations are performed, CVL and CVH can be used in a compare operation on the result. See Compare Function for a description of CVL usage.

41.6.20 Data Result FIFO Register (RESFIFO0 - RESFIFO1)

Offset

Register	Offset
RESFIFO0	300h
RESFIFO1	304h

Function

Stores the data result of ADC conversions in a 16-entry FIFO. Several tag fields of source command and trigger information are stored with the data. FCTRLn[FCOUNT] indicates how many valid data words are stored in the RESFIFO. Reading RESFIFO provides the oldest unread data word entry in the FIFO and decrements FCTRLn[FCOUNT]. The FIFO can be emptied by successive reads of RESFIFO. The FIFO is reset by writing 0b1 to CTRL[RSTFIFOn].

The following table describes the format of data in the result FIFO in different modes of operation. The sign bit is the MSB in signed 2's complement modes. For example, when configured for 12-bit single-ended mode, D[15] and D[2:0] become 0. When configured for 13-bit differential mode, D[15] is the sign bit, and D[2:0] becomes 0.

Table 369. Data result register format description

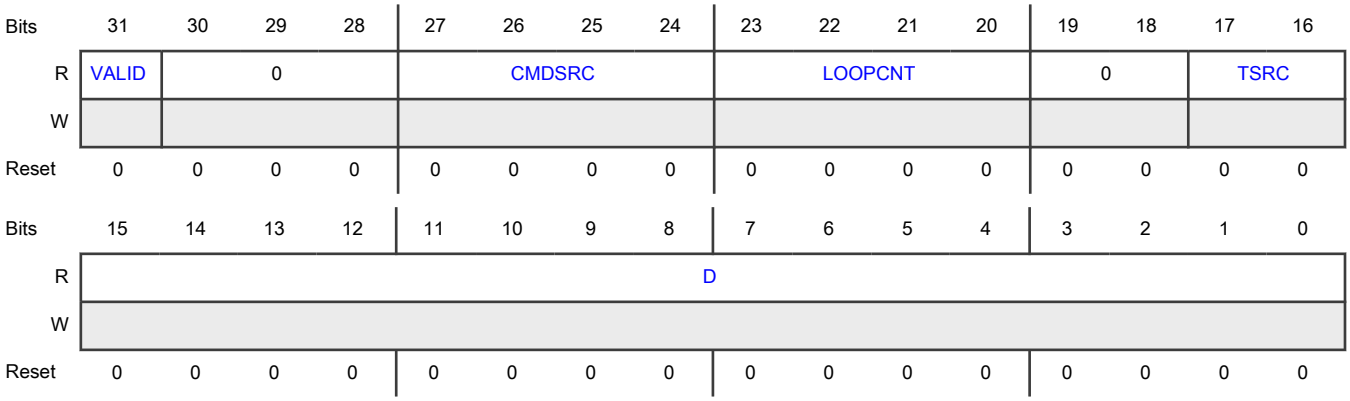
Conversion mode	D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0	Format
16-bit differential	S	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	Signed 2's complement
16-bit single-ended	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	Unsigned, 16-bit magnitude
13-bit differential	S	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	Signed 2's complement, left justified, zero extended
12-bit single-ended	0	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	Unsigned, zero in D[15] and D[2:0]

NOTE

S: Sign bit;

D: Data, 2's complement data when indicated

Diagram



Fields

Field	Function
31 VALID	FIFO Entry is Valid Indicates whether the FIFO entry is valid, which determines what happens to reads from RESFIFO. 0b - FIFO is empty. Discard any read from RESFIFO. 1b - FIFO contains data. FIFO record read from RESFIFO is valid.
30-28 —	Reserved
27-24	Command Buffer Source

Table continues on the next page...

Table continued from the previous page...

Field	Function
CMDSRC	Indicates the executed command buffer that generated this result. 0000b - Not a valid value CMDSRC value for a data word in RESFIFO. 0h is only found in the initial FIFO state, prior to the storage of an ADC conversion result into a RESFIFO buffer. 0001b - CMD1 0010b-1110b - Corresponding command buffer used as control settings for this conversion. 1111b - CMD15
23-20 LOOPCNT	Loop Count Value Indicates the loop count value during the command that generated this result. When CMDHn[LOOP] is non-zero, results are stored multiple times during command execution at the loop boundary. 0000b - Result is from initial conversion in command. 0001b - Result is from second conversion in command. 0010b-1110b - Result is from (LOOPCNT + 1) conversion in command. 1111b - Result is from 16th conversion in command.
19-18 —	Reserved
17-16 TSRC	Trigger Source Indicates the trigger source that initiated a conversion and generated this result. When multiple commands are chained together using CMDHn[NEXT], this field indicates the trigger source that started the command sequence. 00b - Trigger source 0 01b - Trigger source 1 10b - Trigger source 2 11b - Trigger source 3
15-0 D	Data Result Contains the result of an ADC conversion. The formatting for the data in D is summarized in Table 369.

41.6.21 Calibration General A-Side Registers (CAL_GAR0)

Offset

Register	Offset
CAL_GAR0	400h

Function

Corrects for linearity errors of the A-side converter. All 33 A-side general calibration value registers (CAL_GAR0-CAL_GAR32) contain calibration information that is automatically updated during the self-calibration sequence. See Calibration functions for more information on completing ADC calibration steps.

The calibration values in the CAL_GAR registers affect the conversion result by conditionally being subtracted from the conversion before the result is transferred into the FIFOs. Calibration must be run each time ADC is powered down or a hard reset is issued. To reduce the latency required to run calibration, the CAL_GAR values can be stored in non-volatile memory after an initial calibration. These values can be recovered prior to the first ADC conversion. If these registers are set to values not generated by the calibration function, the linearity error specifications may not be met.

The CAL_GAR registers are only read-and-write accessible when ADC is disabled with CTRL[ADCEN] = 0. Access time when writing to these registers is larger than three ADC clock cycles. Wait states are inserted on the bus to meet synchronization timing to the associated CAL_GAR register. The width of each register in this array is non-uniform. The exact width of each register is summarized in Calibration General A-Side and B-Side Widths.

Chapter 42
12-bit Digital-to-Analog Converter (DAC)

42.1 Chip-specific 12-bit DAC information

Table 370. Reference links to related information

Topic	Related module	Reference
Full description	12-bit DAC	12-bit Digital-to-Analog Converter (DAC)
System memory map		Memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing
Input multiplexing	INPUTMUX	See DAC0_TRIG and DAC1_TRIG registers in INPUTMUX

42.1.1 Module instances

This device has two instances of the 12-bit 1Msps DAC module, DAC0, DAC1, with compatible DAC Controller. Set controller FIFO size to 4 (16 words).

42.1.2 12-bit DAC references

- VREFH0 = VDD_ANA
- VREFH1 = VREFO
- VREFH2 = VREFH

42.1.3 12-bit DAC chip-specific initialization

To initialize the 12-bit DAC module:

1. Set the clock divider for the DAC with DACxCLKDIV[DIV] bit in SYSCON register.
2. Enable the clock to the DAC (AHBCLKCTRLn[DACn] = 1) in SYSCON registers. This enables the register interface and the peripheral function clock.
3. Power up the DAC with ACTIVE_CFG1 and LP_CFG1 registers in SPC. See SOC_CNTRL fields.
4. Reset and release the DAC peripheral reset by setting the PRESETCTRLSETn[DACn_RST] bit and then set PRESETCTRLCLRn[DACn_RST] bit.
5. Reset the DAC logic by setting and clearing bit RCR[SWRST]. See Reset Control (RCR).
6. Reset the DAC FIFO by setting and clearing bit RCR[FIFORST].
7. Enable VREF module SOC_CNTRL[VREF_EN] = 1 in ACTIVE_CFG1 register in SPC module. See SOC_CNTRL fields. DAC PTAT and ZTC current sources come from VREF module.
8. If needed, initialize the DAC reference source before selecting the DAC reference with GCR[DACRFS]. See Global Control (GCR)
   - If using VREF_OUT as reference, see Chip-specific VREF information link to VREF_OUT initialization
9. Configure the DAC as described in Initialization.

42.1.4 12-bit DAC trigger inputs

12-bit DAC trigger sources get routed through the INPUTMUX. See the registers DAC0_TRIG and DAC1_TRIG in the INPUTMUX chapter for available trigger sources.

42.2 Overview

The 12-bit general-purpose digital-to-analog converter is a Low-power DAC. The output of the DAC can be placed on an external pin or set as one of the inputs to the analog comparator or ADC.

42.2.1 Block diagram

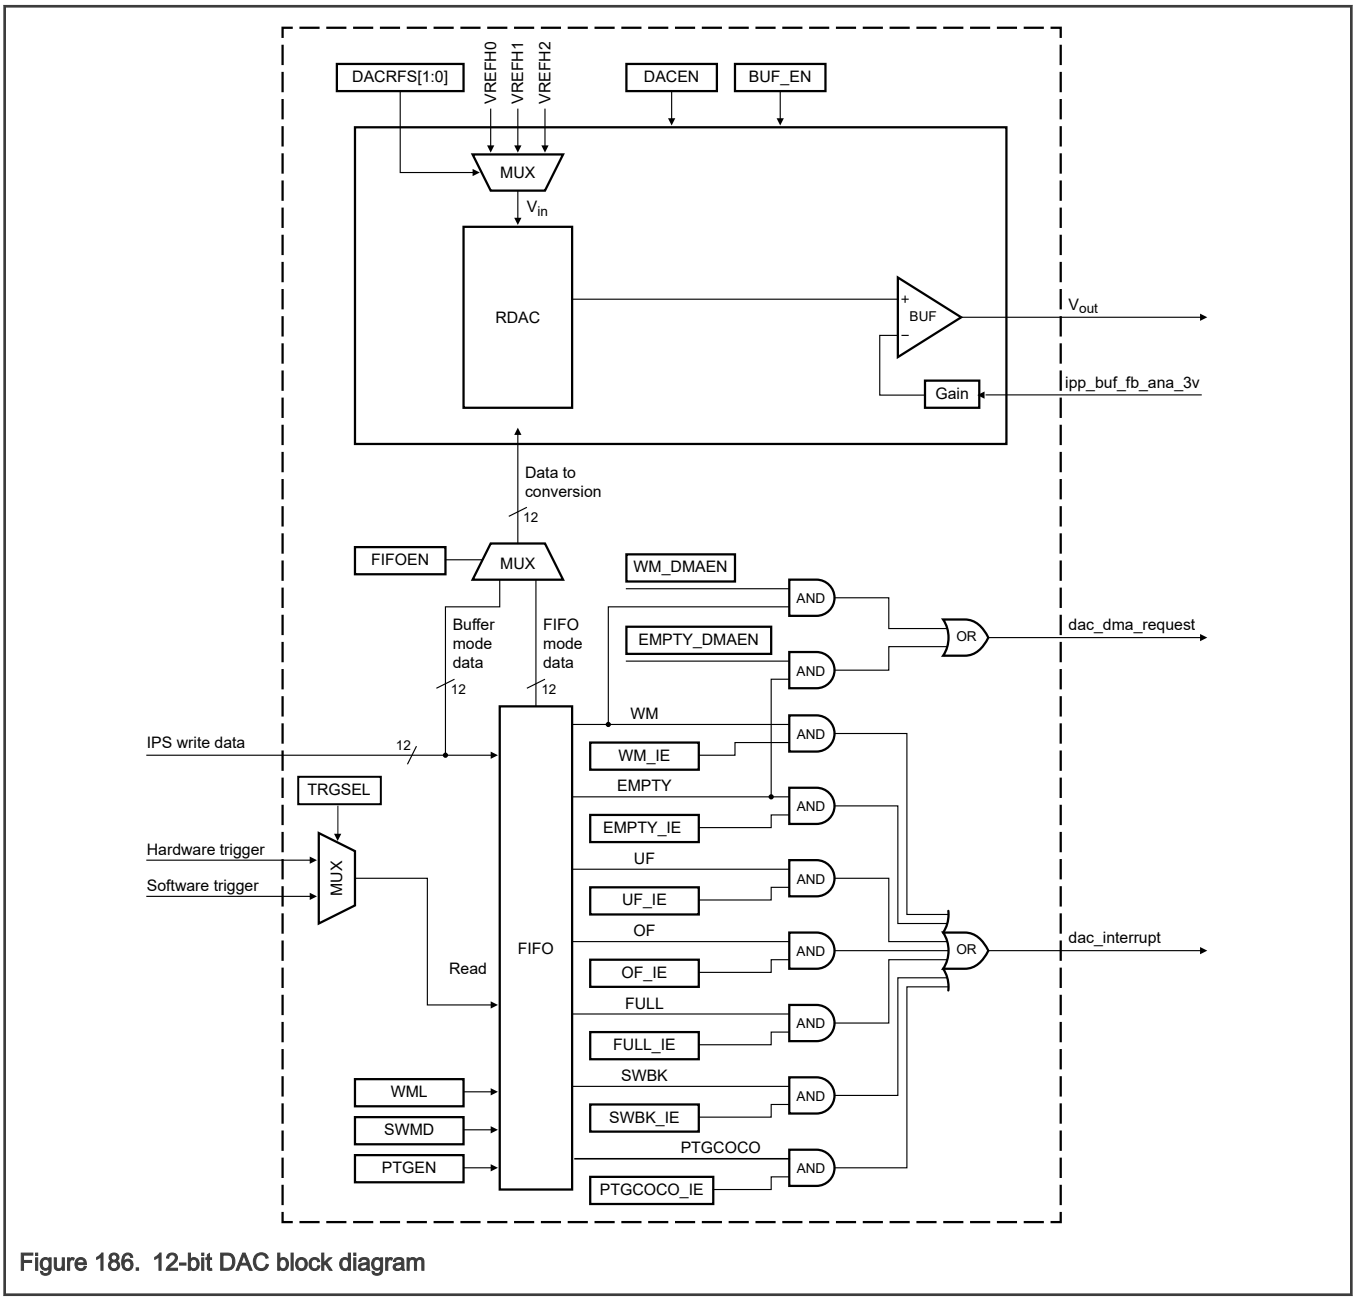

Figure 186. 12-bit DAC block diagram

42.2.2 Features

- Includes an on-chip programmable reference generator output. The voltage output ranges from 1/4096 V_{in} to V_{in}, and the step is 1/4096 V_{in}, where V_{in} is the input reference voltage.
- Selects V_{in} from three reference sources.
- Supports 16-word depth FIFO with the configurable watermark.
- Uses multiple operation modes.
  - Buffer mode
  - FIFO mode
  - Swing Back mode
  - Periodic Trigger mode
- Supports software trigger and hardware trigger.
- Provides selectable performance levels: Low-Power mode(LP) and Lower Low-Power mode(LLP).
- Provides interrupt and DMA support.

42.3 Functional description

12-bit DAC can select one of the three reference inputs: VREFH0, VREFH1, and VREFH2 as the reference voltage, by DACRFS. See the chip-specific 12-bit DAC information to determine the source options for VREFH0, VREFH1, and VREFH2.

12-bit DAC converts a 12-bit data to a stepped analog output voltage when enabled. The output voltage range is from V_{in} to V_{in}/4096, and the step is V_{in}/4096.

You can configure the 12-bit DAC to Buffer mode, FIFO mode, Swing Back mode, or Periodic Trigger mode.

NOTE

You must configure 12-bit DAC before any conversion. During conversion or FIFO write operation, you must not change the configuration or disable DACEN. If you switch to another mode, you must first write a 1 to SWRST to reset 12-bit DAC or write 0 to DACEN.

42.3.1 Buffer mode

You can enable Buffer mode with DACEN.

In Buffer mode, any write to DATA pushes the data to the analog conversion without trigger support.

NOTE

The data write speed must not be higher than the analog conversion speed.

42.3.2 FIFO mode

You can enable FIFO mode with FIFOEN and DACEN.

In FIFO mode, for a 32-/16-bit write to DATA, put the data into the FIFO and the write pointer increments automatically. For an 8-bit write, only if you write both the bytes, the write pointer increases. You must ensure that an 8-bit write is done in pair and write both the upper and lower bytes. There is no priority, which byte to write first.

When a software or hardware trigger comes, the read pointer pointed data in FIFO pushes to the analog conversion, and the read pointer increments automatically. If the trigger comes when FIFO is empty, the data to analog remains unchanged, and an underflow error flag sets.

42.3.3 Swing Back mode

You can enable Swing Back mode with FIFOEN, SWMD, and DACEN.

The read pointer swings between the writer pointer and zero in Swing Back mode. The trigger increases the read pointer till the writer pointer and decreases the read pointer till zero, and so on. EMPTY, FULL, and WM have no meaning and you should ignore them during Swing Back mode.

NOTE

In Swing Back mode, the FIFO should first write at least two data; otherwise, this mode will not work correctly. You should not write the FIFO when Swing Back mode is in progress.

42.3.4 Periodic Trigger mode

You can enable Periodic Trigger mode with FIFOEN, PTGEN, and DACEN.

Due to the trigger (hardware or software) synchronization logic, there is a delay time variation between each conversion. If there is a need to trigger DAC periodically, NXP recommends you to use Periodic Trigger mode.

In Periodic Trigger mode, you only send the first trigger. Then after every [PTG_PERIOD+1] read clock (RCLK) cycle, an internal trigger automatically triggers the DAC. There are [PTG_NUM] internal triggers, therefore, in total [PTG_NUM+1] conversions, including the first trigger that you send. Write 0 to PTGEN to terminate the current conversion queue. Then, after the current conversion completes, the conversion terminates, and the PTGCOCO sets. If PTG_NUM becomes zero, the infinite triggers follow the first hardware/software trigger until you write 0 to PTGEN. In any case, FIFORST or SWRST can terminate the conversion.

During the periodic trigger mode conversion, you can ignore the additional hardware/software triggers. You can start another queue after PTGCOCO becomes 1.

During Periodic Trigger Mode, WM feeds data to FIFO to avoid underflow.

You can combine Periodic Trigger mode with SWMD to periodically trigger DAC and swing back.

42.3.5 Low-power mode operation

If the RCLK remains enabled, 12-bit DAC can be functional with FIFO mode or Swing Back mode or Periodic Trigger mode during Stop and Wait modes, using the hardware trigger initiating the conversion.

42.3.6 DMA

After the corresponding DMA enable register field becomes 1, you can automatically generate DMA requests when WM or EMPTY becomes 1. When you enable DMA, the error flags can only generate an interrupt.

42.3.7 Clocks

12-bit DAC block requires the following clock(s):

- Bus clock for register access and writing data to FIFO or Buffer.
- Read clock to push data from FIFO or Buffer to the analog DAC.

42.3.8 Resets

The following are the 12-bit DAC resets:

1. Global reset fed into the block. This global reset resets everything.
2. SWRST: resets all 12-bit DAC registers and internal logic.
3. FIFORST: resets the FIFO pointers in DAC FIFO Pointer (FPR) and flags in FIFO Status (FSR).

42.3.9 Interrupts

After the corresponding interrupt enable register field becomes 1, warning flags and error flags can generate interrupt. The warning flags are EMPTY, FULL, WM, SWBK, and PTGCOCO. The error flags are OF and UF.

42.4 DAC external signal descriptions

Table 371. DAC external signal descriptions

Signal	Description	I/O
VREFH0	DAC reference high voltage 0	I
VREFH1	DAC reference high voltage 1	I
VREFH2	DAC reference high voltage 2	I
Vout	DAC output	O

42.5 Initialization

To initialize 12-bit DAC:

1. Configure the read clock at chip level.
2. Configure Work mode and GCR enables 12-bit DAC.
3. Configure Interrupt Enable (IER) if required.
4. Configure DMA Enable (DER) if required.
5. Configure Periodic Trigger Control (PCR) if required.
6. Write data to DATA to fill the FIFO, if FIFO mode.
7. Wait analog start-up time
8. Use hardware or software trigger to push data to the analog DAC to convert, if FIFO mode.
9. Write data directly to DATA to push data to the analog DAC to convert, if Buffer mode.

42.6 Application Information

Digital delay

Due to the resynchronization and data latch process, there is a delay between the trigger posedge and analog voltage settling. The delay is (2+ LATCH_CYC)*T to (3+ LATCH_CYC)*T, where T is the RCLK period, and LATCH_CYC*T should not be smaller than 40 ns. So the delay has one T uncertainty. The fast RCLK can achieve a small delay.

RCLK frequency

For discrete conversion, the RCLK frequency has no low limit. But slow RCLK involves large digital delay and uncertainty.

For continuous conversion, the RCLK frequency should be at least 5 times the trigger speed.

For continuous conversion, due to the one cycle uncertainty RCLK, the trigger period should not less than (1000ns + T). Where 1000 ns period means the maximum analog conversion speed 1 Msps.

To achieve the full speed of DAC analog, you must configure to the internal periodic trigger mode.

For Internal Periodic Trigger mode, RCLK frequency should be at least two times the conversion speed. For example, to achieve 1 Msps conversion speed, at least 2 MHz RCLK requires in Periodic Trigger mode.

42.7 Memory map and register definition

All registers are accessible in 8-, 16-, or 32-bit accesses. For efficiency, 32-bit accesses are recommended. Access to an address outside the valid memory map generates a bus error.

42.7.1 12-bit DAC register descriptions

Access to an address outside the valid memory map generates a bus error.

42.7.1.1 DAC memory map

DAC0 base address: 4010_F000h

16-12 —	Reserved
11-8 LATCH_CYC	RCLK Cycles Before Data Latch Configures the DAC sync cycles, which reduces the glitch on the output. The sync time is (LATCH_CYC+1) RCLK cycles. You must configure this register per the RCLK frequency. The recommended sync time is at least 40 ns.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The recommended LATCH_CYC configuration is: Sync time is (LATCH_CYC+1) RCLK cycles, when (25×LATCH_CYC) MHz < RCLK ≤ (25×LATCH_CYC+25) MHz. Example 1, if f_{RCLK} is 48 MHz (period is 20.8 ns), you can configure LATCH_CYC to 0x1 to generate a 41.6 ns sync time. Example 2, if f_{RCLK} is 6 MHz (period is 166.7 ns), you can configure LATCH_CYC to 0x0 to generate a 166.7 ns sync time. See the "Clocking" chapter or chip-specific DAC information for more on the RCLK frequency. **NOTE** 12-bit DAC adds (LATCH_CYC+1) RCLK cycles before the analog starts to set up the output. Therefore, when you write to this field, NXP recommends using the smallest possible value that still meets the requirement of 40 ns sync time.
7 —	Reserved
6 PTGEN	DAC Periodic Trigger Mode Enable Enables Periodic Trigger Mode when FIFOEN becomes 1. 0b - Disables 1b - Enables
5 TRGSEL	DAC Trigger Select Selects the trigger source for FIFO mode. 0b - Hardware trigger 1b - Software trigger
4 SWMD	Swing Back Mode Specifies whether Swing Back mode is enabled. Selects the Swing Back mode when FIFOEN becomes 1. 0b - Disables 1b - Enables
3 FIFOEN	FIFO Enable Selects the FIFO mode or Buffer mode. 0b - Enables FIFO mode and disables Buffer mode. Any data written to DATA[DATA] goes to buffer then goes to conversion. 1b - Enables FIFO mode. Data will be first read from FIFO to buffer and then goes to conversion.
2-1 DACRFS	DAC Reference Select Selects the source of reference voltage high.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - Selects VREFH0 as the reference voltage. 01b - Selects VREFH1 as the reference voltage. 10b - Selects VREFH2 as the reference voltage. 11b - Reserved.
0 DACEN	DAC Enable Enables the DAC system. Starts the programmable reference generator operation. **NOTE** For an 8-bit or 16-bit register write, enable this field after configuring other bytes of GCR. You must configure Periodic Trigger Control (PCR) and DAC FIFO Control (FCR) before enabling this field. 0b - Disables 1b - Enables

42.7.1.6 DAC FIFO Control (FCR)

Fields

Field	Function
31-9 —	Reserved
8 PTGCOCO	Period Trigger Mode Conversion Complete Flag Indicates that PTG mode conversion is completed. This flag becomes 0 by writing a 1 to it.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not completed or not started 1b - Completed
7 UF	FIFO Underflow Flag Specifies that there is a new trigger after EMPTY becomes 1. The FIFO read pointer do not increase in this case and the data sent to DAC analog conversion will not changed. This flag becomes 0 by writing a 1 to it. 0b - No underflow has occurred since the last time the flag was cleared 1b - At least one trigger underflow has occurred since the last time the flag was cleared
6 OF	FIFO Overflow Flag Indicates that data is intended to write into FIFO after FULL becomes 1. The writer pointer do not increase in this case. Do not write the extra data into the FIFO. This flag clears by writing a 1 to it. 0b - No overflow has occurred since the last time the flag was cleared 1b - At least one FIFO overflow has occurred since the last time the flag was cleared
5-4 —	Reserved
3 SWBK	Swing Back One Cycle Complete Flag Indicates that the DAC has completed one period of conversion in Swing Back mode. The read pointer increases to the top (write pointer) once and then decreases to zero. For example, after writing three data to FIFO, the writer pointer is now 3. Then, if continually triggered, the read pointer will swing like: 0-1-2-1-0-1-2-, and so on. After the fourth trigger, the flag sets. Write a 1 to clear this flag. 0b - No swing back cycle has completed since the last time the flag was cleared 1b - At least one swing back cycle has occurred since the last time the flag was cleared
2 WM	FIFO Watermark Status Flag Write 1 to this field if the remaining data in FIFO is less than or equal to WML. By writing data into FIFO by DMA or CPU, this flag clears automatically when the data in FIFO is more than WML. 0b - Data in FIFO is more than watermark level 1b - Data in FIFO is less than or equal to watermark level
1 EMPTY	FIFO Empty Flag Indicates whether the FIFO is empty or not. 12-bit DAC automatically clears this flag when CPU or DMA writes data to the FIFO. 0b - Not empty 1b - Empty
0	FIFO Full Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
FULL	Indicates whether the FIFO is full or not. FIFO read with software trigger or hardware trigger automatically clears this flag. 0b - Not full 1b - Full

42.7.1.9 Interrupt Enable (IER)

Offset

Register	Offset
IER	1Ch

Function

Contains the interrupt enable fields.

Fields

Field	Function
31-3 —	Reserved
2 WM_DMAEN	FIFO Watermark DMA Enable Enables DMA request when data in FIFO is less than or equal to watermark level. 0b - Disables 1b - Enables
1 EMPTY_DMAEN	FIFO Empty DMA Enable Enables DMA request when FIFO is empty. 0b - Disables 1b - Enables
0 —	Reserved

42.7.1.11 Reset Control (RCR)

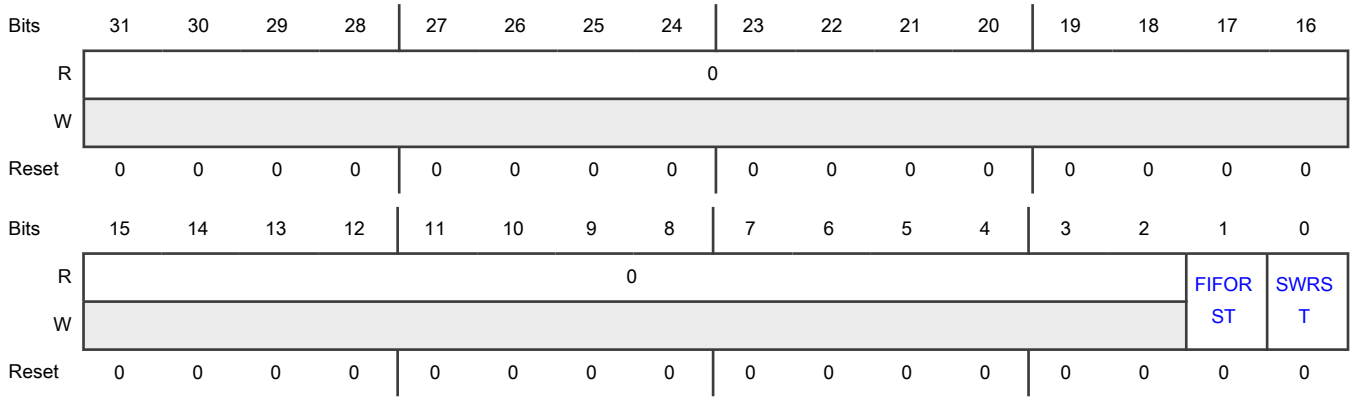
Offset

Register	Offset
RCR	24h

Function

Contains the software reset and FIFO reset fields.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 FIFORST	FIFO Reset Resets the FIFO pointers and flags in FIFO Status (FSR). Remains 1 until you write 0 to it. 0b - No effect 1b - FIFO reset
0 SWRST	Software Reset Resets all DAC registers and internal logic. Remains 1 until you write 0 to it. 0b - No effect 1b - Software reset

42.7.1.12 Trigger Control (TCR)

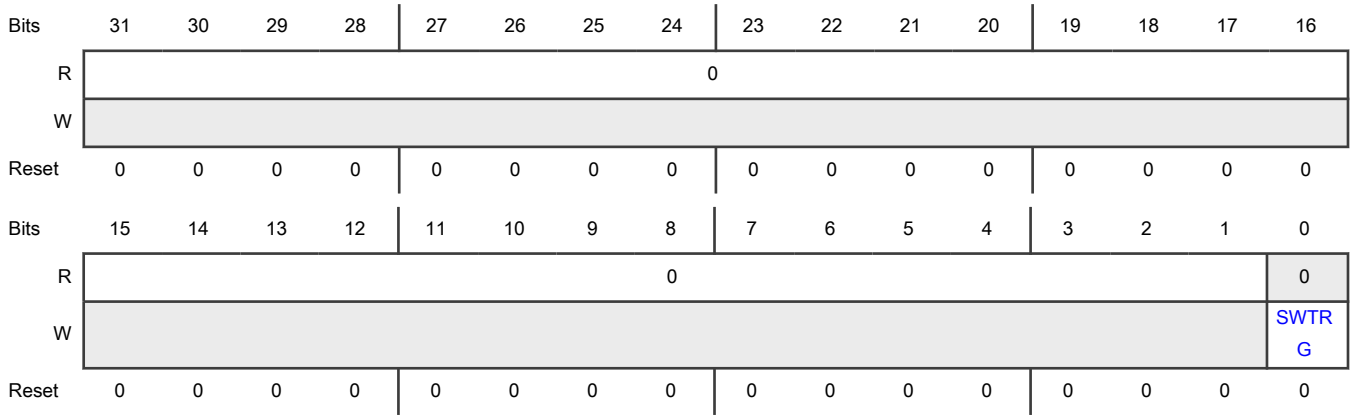
Offset

Register	Offset
TCR	28h

Function

Contains the software trigger field.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 SWTRG	Software Trigger Indicates whether the DAC soft trigger is valid. Active high. This is a write-only field, which always reads 0. If TRGSEL is 1 and FIFO is enabled and not empty, writing 1 to this field advances the FIFO read pointer once. **NOTE** During continuous conversions, do not adopt hardware trigger and software trigger in a mixed use. 0b - Not valid 1b - Valid

42.7.1.13 Periodic Trigger Control (PCR)

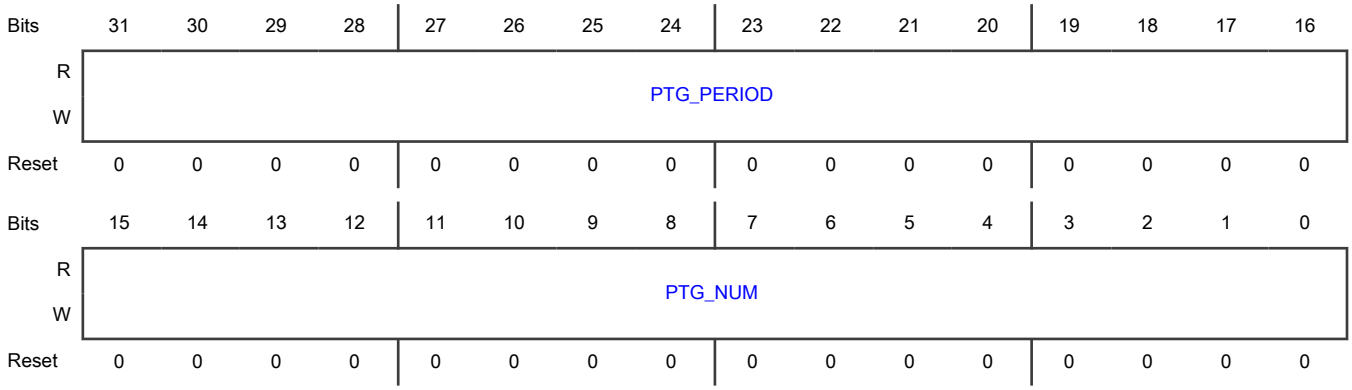
Offset

Register	Offset
PCR	2Ch

Function

Contains the periodic trigger period and periodic trigger number fields.

Diagram



Fields

Field	Function
31-16 PTG_PERIOD	Periodic Trigger Period Width Uses only in Periodic Trigger mode. It controls the periodic trigger frequency. There are [PTG_PERIOD+1] RCLK cycles between each periodic trigger. See the chip-specific DAC information for more on the RCLK frequency. Example 1, if f_{RCLK} is 48 MHz and the conversion speed is 0.5 MHz, there should be 96 RCLK cycles between each periodic trigger. So you must configure the PTG_PERIOD as 0x5F(95). Example 2, if f_{RCLK} is 6 MHz and the conversion speed is 0.5 MHz, there should be 12 RCLK cycles between each periodic trigger. So you must configure the PTG_PERIOD as 0xB(11). **NOTE** The PTG_PERIOD should not be less than 0x1. **NOTE** The periodic trigger frequency should not be larger than the analog conversion speed.
15-0 PTG_NUM	Periodic Trigger Number Uses only in Periodic Trigger mode. There are [PTG_NUM] internal triggers following the first hardware/software trigger. So, there are [PTG_NUM+1] conversions in total. **NOTE** If you write 0 to it, there will be infinite triggers following the first hardware/software trigger, until PTGEN becomes 0.

Chapter 43
14-bit Digital-to-Analog Converter (DAC)

43.1 Chip-specific 14-bit DAC information

Table 372. Reference links to related information

Topic	Related module	Reference
Full description	14-bit DAC	14-bit Digital-to-Analog Converter (DAC)
System memory map		Memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing
Input multiplexing	INPUTMUX	See DAC2_TRIG registers in INPUTMUX

43.1.1 Module instances

This device has one instance of the 14-bit 5 Msps DAC module, DAC2, with compatible DAC Controller. Set controller FIFO size to 5 (32 words).

43.1.2 14-bit DAC references

VIN = VDD_ANA

43.1.3 14-bit DAC chip-specific initialization

To initialize the 14-bit DAC (DAC2) module:

1. Set the clock divider for DAC2 with DACxCLKDIV[DIV] bit in SYSCON.
2. Enable the clock to DAC2 (AHBCLKCTRLn[DACn] = 1) in SYSCON. This enables the register interface and the peripheral function clock.
3. Power up the DAC2 with ACTIVE_CFG1 and LP_CFG1 registers in SPC. See SOC_CNTRL fields.
4. Reset and release the DAC2 peripheral reset by setting the PRESETCTRLSETn[DACn_RST] bit and then set PRESETCTRLCLRn[DACn_RST] bit.
5. Reset the DAC2 logic by setting and clearing bit RCR[SWRST]. See Reset Control (RCR).
6. Reset the DAC2 FIFO by setting and clearing bit RCR[FIFORST].
7. Enable VREF module SOC_CNTRL[VREF_EN] = 1 in ACTIVE_CFG1 register in SPC module. See SOC_CNTRL fields.
8. If needed, initialize the DAC2 reference source before selecting the DAC2 reference with GCR[DACRFS]. See Global Control (GCR)
   - If using VREF_OUT as reference, see Chip-specific VREF information link to VREF_OUT initialization
9. Configure DAC2 as described in section Initialization

43.1.4 14-bit DAC trigger inputs

14-bit DAC (DAC2) trigger sources get routed through the INPUTMUX. See the DAC2_TRIG register in the INPUTMUX chapter for available trigger sources.

43.2 Overview

The 14-bit general-purpose digital-to-analog converter is a High-performance DAC. The output of the DAC can be placed on an external pin or set as one of the inputs to the analog comparator or ADC.

43.2.1 Block diagram

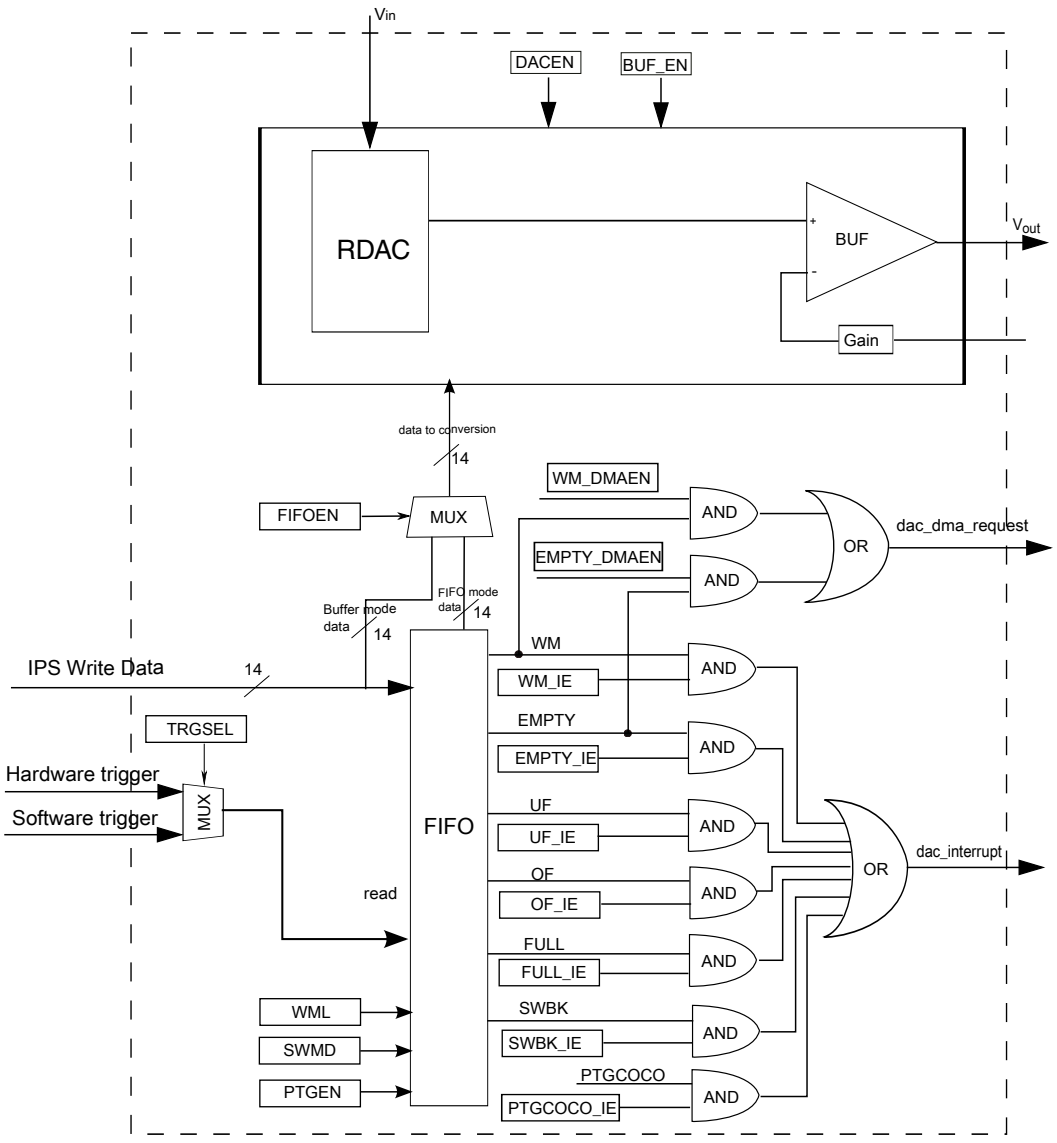


Figure 187. 14-bit DAC block diagram

43.2.2 Features

- Includes an on-chip programmable reference generator output. The voltage output ranges from 1/16384 V_{in} to V_{in}, and the step is 1/16384 V_{in}, where V_{in} is the input reference voltage.
- Supports 32-word depth FIFO with the configurable watermark.
- Uses multiple operation modes.

- Buffer mode
- FIFO mode
- Swing Back mode
- Periodic Trigger mode

- Supports software trigger and hardware trigger.
- Provides interrupt and DMA support.

43.3 Functional description

14-bit DAC converts a 14-bit data to a stepped analog output voltage when enabled. The output voltage range is from V_{in} to $V_{in}/16384$, and the step is $V_{in}/16384$.

You can configure the 14-bit DAC to Buffer mode, FIFO mode, Swing Back mode, or Periodic Trigger mode.

NOTE

You must configure 14-bit DAC before any conversion. During conversion or FIFO write operation, you must not change the configuration or disable DACEN. If you switch to another mode, you must first write a 1 to SWRST to reset 14-bit DAC or write 0 to DACEN.

43.3.1 Buffer mode

You can enable Buffer mode with DACEN.

In Buffer mode, any write to DATA pushes the data to the analog conversion without trigger support.

NOTE

The data write speed must not be higher than the analog conversion speed.

43.3.2 FIFO mode

You can enable FIFO mode with FIFOEN and DACEN.

In FIFO mode, for a 32-/16-bit write to DATA, put the data into the FIFO and the write pointer increments automatically. For an 8-bit write, only if you write both the bytes, the write pointer increases. You must ensure that an 8-bit write is done in pair and write both the upper and lower bytes. There is no priority, which byte to write first.

When a software or hardware trigger comes, the read pointer pointed data in FIFO pushes to the analog conversion, and the read pointer increments automatically. If the trigger comes when FIFO is empty, the data to analog remains unchanged, and an underflow error flag sets.

43.3.3 Swing Back mode

You can enable Swing Back mode with FIFOEN, SWMD, and DACEN.

The read pointer swings between the writer pointer and zero in Swing Back mode. The trigger increases the read pointer till the writer pointer and decreases the read pointer till zero, and so on. EMPTY, FULL, and WM have no meaning and you should ignore them during Swing Back mode.

NOTE

In Swing Back mode, the FIFO should first write at least two data; otherwise, this mode will not work correctly. You should not write the FIFO when Swing Back mode is in progress.

43.3.4 Periodic Trigger mode

You can enable Periodic Trigger mode with FIFOEN, PTGEN, and DACEN.

Due to the trigger (hardware or software) synchronization logic, there is a delay time variation between each conversion. If there is a need to trigger DAC periodically, NXP recommends you to use Periodic Trigger mode.

In Periodic Trigger mode, you only send the first trigger. Then after every [PTG_PERIOD+1] read clock (RCLK) cycle, an internal trigger automatically triggers the DAC. There are [PTG_NUM] internal triggers, therefore, in total [PTG_NUM+1] conversions, including the first trigger that you send. Write 0 to PTGEN to terminate the current conversion queue. Then, after the current conversion completes, the conversion terminates, and the PTGCOCO sets. If PTG_NUM becomes zero, the infinite triggers follow the first hardware/software trigger until you write 0 to PTGEN. In any case, FIFORST or SWRST can terminate the conversion.

During the periodic trigger mode conversion, you can ignore the additional hardware/software triggers. You can start another queue after PTGCOCO becomes 1.

During Periodic Trigger Mode, WM feeds data to FIFO to avoid underflow.

You can combine Periodic Trigger mode with SWMD to periodically trigger DAC and swing back.

43.3.5 Low-power mode operation

If the RCLK remains enabled, 14-bit DAC can be functional with FIFO mode or Swing Back mode or Periodic Trigger mode during Stop and Wait modes, using the hardware trigger initiating the conversion.

43.3.6 DMA

After the corresponding DMA enable register field becomes 1, you can automatically generate DMA requests when WM or EMPTY becomes 1. When you enable DMA, the error flags can only generate an interrupt.

43.3.7 Clocks

14-bit DAC block requires the following clock(s):

- Bus clock for register access and writing data to FIFO or Buffer.
- Read clock (RCLK) to push data from FIFO to the analog DAC.

43.3.8 Resets

The following are the 14-bit DAC resets:

1. Global reset fed into the block. This global reset resets everything.
2. SWRST: resets all 14-bit DAC registers and internal logic.
3. FIFORST: resets the FIFO pointers in DAC FIFO Pointer (FPR) and flags in FIFO Status (FSR).

43.3.9 Interrupts

After the corresponding interrupt enable register field becomes 1, warning flags and error flags can generate interrupt. The warning flags are EMPTY, FULL, WM, SWBK, and PTGCOCO. The error flags are OF and UF.

43.4 DAC external signal descriptions

Table 373. DAC external signal descriptions

Signal	Description	I/O
Vin	DAC reference high voltage	I
Vout	DAC output	O

43.5 Initialization

To initialize 14-bit DAC:

1. Configure the read clock at chip level.
2. Configure Work mode and GCR enables 14-bit DAC.
3. Configure Interrupt Enable (IER) if required.
4. Configure DMA Enable (DER) if required.
5. Configure Periodic Trigger Control (PCR) if required.
6. Write data to DATA to fill the FIFO, if FIFO mode.
7. Wait analog start-up time
8. Use hardware or software trigger to push data to the analog DAC to convert, if FIFO mode.
9. Write data directly to DATA to push data to the analog DAC to convert, if Buffer mode.

43.6 Application Information

Digital delay

Due to the resynchronization, there will be a delay between the trigger posedge and analog voltage settling. The delay is 2T to 3T, where T is the RCLK period. So the delay has one T uncertainty. It is obvious that fast RCLK can achieve small delay.

RCLK frequency

For discrete conversion, the RCLK frequency has no low limit. But slow RCLK involves large digital delay and uncertainty.

For continuous conversion, the RCLK frequency should be at least 5 times the trigger speed.

For continuous conversion, due to the one cycle uncertainty RCLK, the trigger period should not be less than (200ns + T) where 200ns period means the typical analog conversion speed 5 Msps.

To achieve the full speed of DAC analog, you must configure to the internal periodic trigger mode.

For Internal Periodic Trigger mode, RCLK frequency should be at least 1 times the conversion speed. For example, to achieve 5 Msps conversion speed, at least 5 MHz RCLK is required in periodic trigger mode.

43.7 Memory map and register definition

All registers are accessible in 8-, 16-, or 32-bit accesses. For efficiency, 32-bit accesses are recommended. Access to an address outside the valid memory map generates a bus error.

43.7.1 14-bit DAC register descriptions

Access to an address outside the valid memory map generates a bus error.

43.7.1.1 DAC memory map

	data to FIFO, the writer pointer is now 3. Then, if continually triggered, the read pointer will swing like: 0-1-2-1-0-1-2-, and so on. After the fourth trigger, the flag sets. Write a 1 to clear this flag. 0b - No swing back cycle has completed since the last time the flag was cleared 1b - At least one swing back cycle has occurred since the last time the flag was cleared
2 WM	FIFO Watermark Status Flag Write 1 to this field if the remaining data in FIFO is less than or equal to WML. By writing data into FIFO by DMA or CPU, this flag clears automatically when the data in FIFO is more than WML. 0b - Data in FIFO is more than watermark level 1b - Data in FIFO is less than or equal to watermark level
1 EMPTY	FIFO Empty Flag Indicates whether the FIFO is empty or not. 14-bit DAC automatically clears this flag when CPU or DMA writes data to the FIFO. 0b - Not empty 1b - Empty
0 FULL	FIFO Full Flag Indicates whether the FIFO is full or not. FIFO read with software trigger or hardware trigger automatically clears this flag. 0b - Not full 1b - Full

Fields

Field	Function
31-16 PTG_PERIOD	Periodic Trigger Period Width Uses only in Periodic Trigger mode. It controls the periodic trigger frequency. There are [PTG_PERIOD+1] RCLK cycles between each periodic trigger. See the chip-specific DAC information for more on the RCLK frequency. Example 1, if f_{RCLK} is 48 MHz and the conversion speed is 0.5 MHz, there should be 96 RCLK cycles between each periodic trigger. So you must configure the PTG_PERIOD as 0x5F(95). Example 2, if f_{RCLK} is 6 MHz and the conversion speed is 0.5 MHz, there should be 12 RCLK cycles between each periodic trigger. So you must configure the PTG_PERIOD as 0xB(11). **NOTE** The periodic trigger frequency should not be larger than the analog conversion speed.
15-0 PTG_NUM	Periodic Trigger Number Uses only in Periodic Trigger mode. There are [PTG_NUM] internal triggers following the first hardware/software trigger. So, there are [PTG_NUM+1] conversions in total. **NOTE** If you write 0 to it, there will be infinite triggers following the first hardware/software trigger, until PTGEN becomes 0.

Chapter 44
Low-Power Comparator (CMP)

44.1 Chip-specific CMP information

Table 374. Reference links to related information

Topic	Related module	Reference
Full description	CMP	CMP
System memory map		Memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing
Input multiplexing	INPUTMUX	See CMPn_TRIG registers in INPUTMUX

NOTE

See AHB Clock Control 3 (AHBCLKCTRL3) to enable CMP2 clock. Also see Peripheral Reset Control 3 (PRESETCTRL3) for reset control.

44.1.1 Module instances

This chip supports three instances of the CMP module, CMP0, CMP1, and CMP2. Each comparator has an 8-bit DAC.

NOTE

CMP can be functional in low power (LP) mode (including Deep Sleep, Power Down or Deep Power Down mode). To enable CMP in the LP mode, you should enable the CMPn_EN bitfield in the LP_CFG1 register of SPC. When chip enters the LP mode, you must ensure the clock source of the required function is active.

44.1.2 CMP input connections

Table 375. CMP input connections

Index	CMP0_Positive	CMP0_Negative	CMP1_Positive	CMP1_Negative	CMP2_Positive	CMP2_Negative	Description
0	CMP0_IN0P (P1_0)	CMP0_IN0N (P1_0)	CMP1_IN0P (P1_1)	CMP1_IN0N (P1_1)	CMP2_IN0P (P1_2)	CMP2_IN0N (P1_2)	VDD domain

44.1.4 Input references

In the DAC Control Register, when:

- VRSEL=0, VREFH0 is selected, which is VDD
- VRSEL=1, VREFH1 is selected, which is VREFO

44.1.5 Functional clock selection

CCR1[FUNC_CLK_SEL] selects clock sources as follows:

- 00b - Reserved
- 01b - FRO_16K
- 10b - XTAL32K
- 11b - CMPn function clock

44.1.6 Round robin clock selection

RRCR0[RR_CLK_SEL] selects clock sources as follows:

- 00b - Reserved
- 01b - FRO_16K
- 10b - XTAL32K
- 11b - CMPn round robin clock

44.2 Overview

The LPCMP module provides a circuit to compare two analog input voltages. It includes the following:

- A low power comparator (CMP)
- A DAC
- An analog mux (ANMUX)

See Block diagram for more information.

LPCMP can operate across the full range of the supply voltage, known as rail-to-rail operation.

DAC is a 256-tap resistor ladder network that provides a selectable voltage reference for applications requiring a voltage reference. DAC divides the supply reference V_{in} into 256 voltage levels. An 8-bit digital signal input selects the output voltage level, which varies from V_{in} to $V_{in}/256$.

You can select V_{in} from the following voltage sources:

- VREFH0
- VREFH1

See the Chip-specific LPCMP information for more information on source of VREFH0 and VREFH1.

NOTE

The LPCMP's internal DAC output is available as an on-chip internal signal only and is not available for an external chip pin.

ANMUX allows you to select an analog input signal from among eight channel options. One channel option is the DAC output. Other chip resources are connected to the other channels. See the Chip-specific LPCMP information section for more information. ANMUX can operate across the full range of the supply voltage.

44.2.1 Block diagram

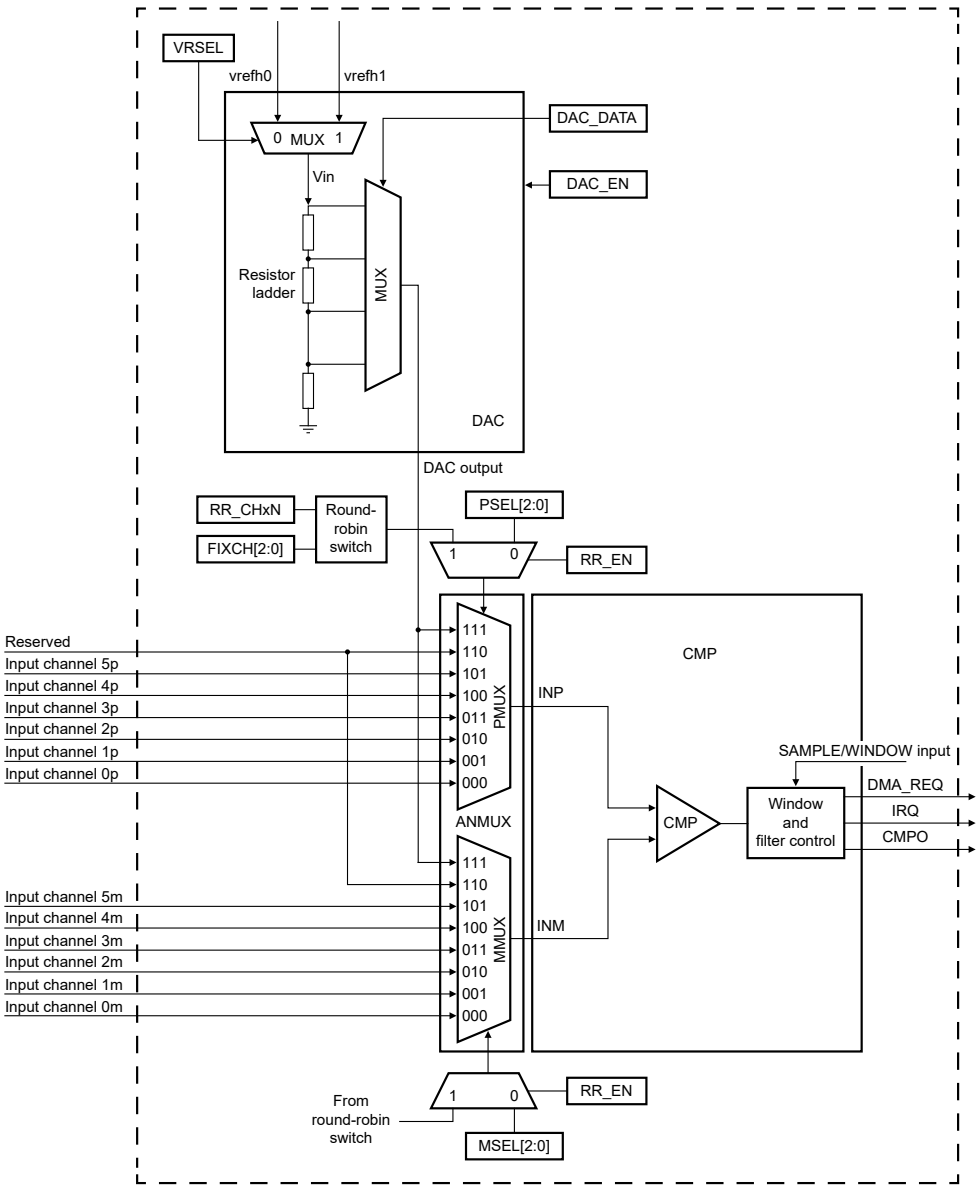

Figure 188. Block diagram

44.2.2 Features

The features of the LPCMP module include：

- Includes two 8-to-1 channel MUXes to select input signal from eight channels
- Supports multiple operation modes to produce a wide range of outputs such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally filtered
- Provides the following advance features for window and sample:

- Window and sample signals can be inverted.
- COUT (comparator output) rising, falling or both edges closes the window.
- COUT level can be defined when window is closed.

- Provides selectable performance levels:
  - Nano-Power mode
  - Low-Power (speed) mode
  - High-Power (speed) mode
- Supports programmable hysteresis control
- Provides a selectable inversion on comparator output
- Uses an external hysteresis at the same time the output filter is used for internal functions
- Provides interrupt and DMA support
- Supports Round Robin Trigger mode
- Includes an 8-bit resolution DAC
- Provides a selectable supply reference source for DAC
- Provides a configurable Low-Power (speed) mode or High-Power (speed) mode for DAC

44.3 Functional description

44.3.1 Functional block diagram

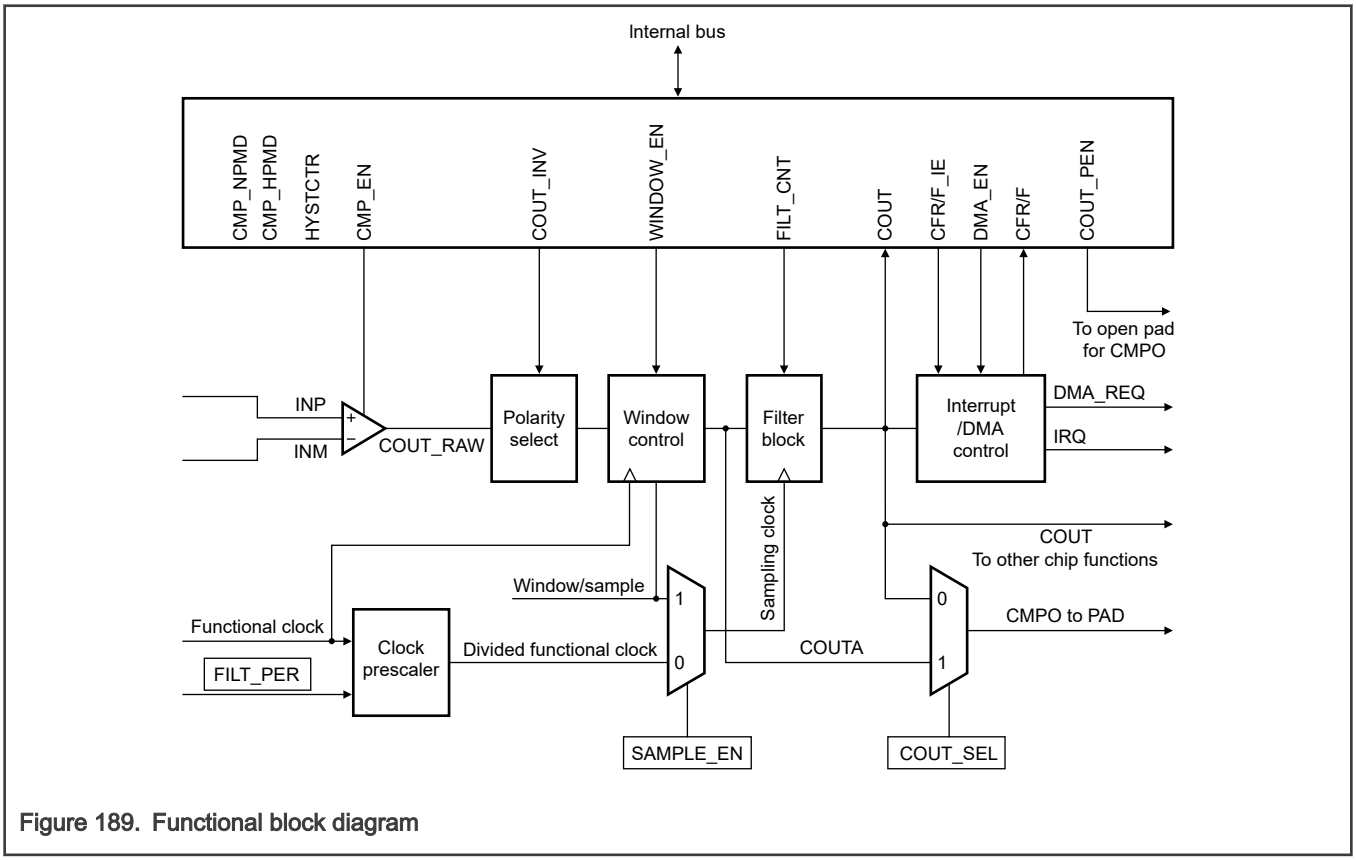

Figure 189. Functional block diagram

As shown in the block diagram, the functions are:

- Compared two analog input voltages applied to INP and INM, COUT_RAW is high when the INP input voltage is greater than the INM input voltage, and COUT_RAW is low when the INP input voltage is less than the INM input voltage.
- The COUT_RAW signal can be inverted by enabling CCR1[COUT_INV].
- The optionally inverted comparator output COUT_RAW is sampled on every functional clock when you enable the CCR1[WINDOW_EN] to generate COUTA. In this case, the comparator output is ignored during time periods when the input voltages are not valid. This is useful when you implement zero-crossing-detection for certain PWM applications.
- The window control block is bypassed when CCR1[WINDOW_EN] is disabled.
- The filter block acts as a simple sampler when CCR1[FILT_CNT] is set to 01h.
- The filter block acts as a filter based on multiple samples when CCR1[FILT_CNT] is set to be greater than 01h.
  - If CCR1[SAMPLE_EN] is set to 1, use the external SAMPLE input as the sampling clock.
  - If CCR1[SAMPLE_EN] is set to 0, use the divided functional clock as the sampling clock.
- Bypasses the filter block when it is not in use.

```
Bypass_Filter_Block = (FILT_CNT == 0x00) |  (~SAMPLE_EN & (FILT_PER == 0x00))
```

- Both COUTA and COUT can be configured as module output CMPO by configuring CCR1[COUT_SEL], and are used for different purposes within the system.
- The optionally filtered COUT can be read directly in CSR[COUT].
- The SAMPLE/WINDOW signal can be inverted by setting CCR1[WINDOW_INV].
- The SAMPLE/WINDOW signal can be closed by COUT's falling edge and/or rising edge by setting CCR1[WINDOW_CLS] in Window mode.
- In Window mode, when window is closed, define the COUTA value as CCR1[COUTA_OW] by setting CCR1[COUTA_OWEN]. If CCR1[COUTA_OWEN] is not set, COUTA holds the last sampled value.

NOTE

See the chip configuration section for the source of SAMPLE/WINDOW input.

44.3.2 Round-robin trigger mode

You can enable Round-Robin Trigger mode by setting RRCR0[RR_EN] to 1. A trigger event initiates a comparison sequence. The next trigger event should not occur before the current sequence completes.

RRCR1[FIXP] and RRCR1[FIXCH] select the reference channel for the plus side mux or the minus side mux. RRCR1[RR_CHnEN] selects active channels.

When a trigger comes, the analog comparator enables. After the comparison sequence completes, the analog comparator disables again. RRCR0[RR_INITMOD] controls the analog stabilization time. Note that RR_INITMOD*round robin clock period must be longer than the initialization delay specified in the Comparator and 8-bit DAC electrical specifications section of LPCMP datasheet.

After the stabilization process completes, the round robin manner comparison sequence begins. Sample the comparison result for the selected active channel after RRCR0[RR_NSAM] defines the configurable number of operation clocks.

There are (RR_SAMPLE_CNT + 1) samples for each channel. With these samples, at least (RR_SAMPLE_THRESHOLD + 1) sampled "1" causes the channel's final sample result to be "1"; otherwise, it is "0". Compare the final result with the pre-programmed value.

After all the active channels are sampled/compared, if the comparison result changes from its pre-programmed state, the corresponding flag in RRSR[RR_CHnF] is set. Write to RRCSR[RR_CHnOUT] to configure the pre-programmed state for each channel. Update RRCSR[RR_CHnOUT] to store the last comparison result for each channel. If any flag in RRSR[RR_CHnF] sets, CSR[RRF] also sets. If IER[RRF_IE] sets, an asynchronous interrupt asserts. Note that these flags do not support generating a DMA transfer event.

The following diagram shows the basic flow of this mode. In the diagram, RRCR1[RR_CH1EN], RRCR1[RR_CH3EN], and RRCR1[RR_CH4EN] are 1, so channels #1, #3, and #4 are selected for round-robin depending on their priority setting. RRCR0[RR_NSAM] sets to 2'b01, so you can sample one clock later the comparison result of the selected channel. After you compare the channel #4, the result is sampled, and round-robin ends. If any of the comparison results from channel #1, #3, or #4 changed from their programmed value (written to RRCSR[RR_CH1OUT], RRCSR[RR_CH3OUT], and RRCSR[RR_CH4OUT]), generates an interrupt . Software can then poll RRSR[RR_CHnF] to see which channel input(s) changed value.

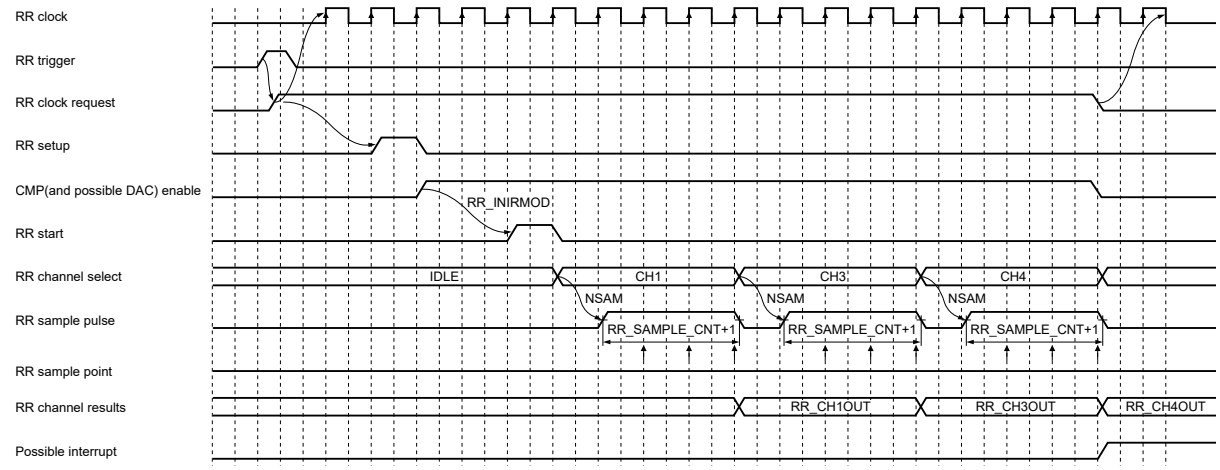

Figure 190. Trigger mode

The table below shows the channel decode in both Functional mode and Trigger mode. Other cases not in the table are illegal.

Table 377. CMP channel decode in functional mode and round-robin trigger mode

Mode	RR_EN	PSEL[2:0]	MSEL[2:0]	FIXP	FIXCH[2:0]	RR_CHxN	INP	INM	CMP Behavior
Functional mode	0	0 to 7	0 to 7	x[1]	x	x	Channel decoded from PSEL[2:0]	Channel decoded from MSEL[2:0]	Compare the channel 0 to 7 with channel 0 to 7[2]
Trigger mode	1	x	x	0	0 to 7	0 to 7	Channel fixed by FIXCH[2:0]	Channel sweep (RR_CHxN)	Sweep the channel 0 to 7 with a fixed channel (0 to 7)
		x	x	1	0 to 7	0 to 7	Channel sweep (RR_CHxN)	Channel fixed by FIXCH[2:0]	Sweep the channel 0 to 7 with a fixed channel (0 to 7)

1. "x" means "don't care"
2. PSEL should not be same as MSEL.

44.3.3 Low-pass filter mode

The low-pass filter mode operates on an unfiltered, optionally inverted comparator output COUTA, and generates the filtered and synchronized output COUT. You can configure both COUTA and COUT as module outputs and use for different purposes within the system.

Synchronization and edge detection determine the bit values of status register. They also apply to COUT for all sampling and windowed modes. You can perform filtering using an internal timebase defined by CCR1[FILT_PER], or use an external sample input to determine sample time.

The need for digital filtering and the amount of filtering depends on your requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, generate a high-frequency oscillations at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

44.3.3.1 Enabling low-pass filter mode

You can enable low-pass filter mode by setting the following:

- CCR1[FILT_CNT] > 01h
- CCR1[FILT_PER] to a nonzero value or writing 1 to CCR1[SAMPLE_EN].

If you use the divided functional clock to drive the low-pass filter, it samples COUTA every CCR1[FILT_PER] functional clock cycle.

If CCR1[SAMPLE_EN] is set to 1, the low-pass filter samples COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive CCR1[FILT_CNT] samples agree that the output value has changed.

44.3.3.2 Latency issues

Program the value of CCR1[FILT_PER] or sample period such that the sampling period is longer than the period of the expected noise, ensuring that a given noise spike corrupts only one sample. You must choose the value of CCR1[FILT_CNT] to reduce the probability of noisy samples causing an incorrect transition to recognize. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CCR1[FILT_CNT].

You must trade off the values of CCR1[FILT_PER] or sample period and CCR1[FILT_CNT] against the need for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CCR1[FILT_CNT].

Table 379 summarizes maximum latency values for the various modes of operation in the absence of noise. Filtering latency restarts each time the noise masks an actual output transition.

44.3.4 Low power mode operation

Below table introduces the mode of operation of lower power.

Table 378. Low power mode operation

Mode of operation	Description
Wait	LPCMP can operate normally with window and filter function.
Deep sleep	LPCMP can operate only in Continuous mode or Round-robin trigger mode.

44.3.5 Functional modes

You can combine the comparator window and filter features as shown in the following table.

Table 379. Functional modes

Mode #	CMP_EN	WINDOW_EN	SAMPLE_EN	FILT_CNT	FILT_PER	Operation	Maximum latency[1]
1	0	X	X	X	X	See the Disabled mode (#1).	N/A

Table continues on the next page...

Table 379. Functional modes (continued)

Mode #	CMP_EN	WINDOW_EN	SAMPLE_EN	FILT_CNT	FILT_PER	Operation	Maximum latency[1]
2A	1	0	X	0x00	X	See the Continuous mode (#2A and #2B).	T_{PD}
2B	1	0	0	X	0x00		
3A	1	0	1	0x01	X	See the Sampled, non-filtered mode (#3A and #3B).	$T_{PD} + T_{SAMPLE} + T_{per}$
3B	1	0	0	0x01	> 0x00		$T_{PD} + (FILT_PER * T_{per}) + T_{per}$
4A	1	0	1	> 0x01	X	See the Sampled, filtered mode (#4A and #4B).	$T_{PD} + (FILT_CNT * T_{SAMPLE}) + T_{SAMPLE}$
4B	1	0	0	> 0x01	> 0x00		$T_{PD} + (FILT_CNT * FILT_PER \times T_{per}) + T_{per}$
5A	1	1	0	0x00	X	See the Windowed mode (#5A and #5B).	$T_{PD} + 2T_{per}$
5B	1	1	0	X	0x00		
6	1	1	0	0x01	> 0x00	See the Windowed/ Resampled mode (#6).	$T_{PD} + (FILT_PER * T_{per}) + 3T_{per}$
7	1	1	0	> 0x01	> 0x00	See the Windowed/ Filtered mode (#7).	$T_{PD} + (FILT_CNT * FILT_PER \times T_{per}) + 3T_{per}$
All other combinations of CMP_EN, WINDOW_EN, SAMPLE_EN, FILT_CNT, and FILT_PER are illegal.							

1. T_{PD} represents the intrinsic delay of the analog component plus the polarity select logic. T_{SAMPLE} is the clock period of the external sample clock. T_{per} is the period of the functional clock.

44.3.5.1 Disabled mode (#1)

In this mode:

- The analog comparator is non-functional and consumes no power.
- CSR[COUT] and CMPO are the same as CCR1[COUT_INV].

44.3.5.2 Continuous mode (#2A and #2B)

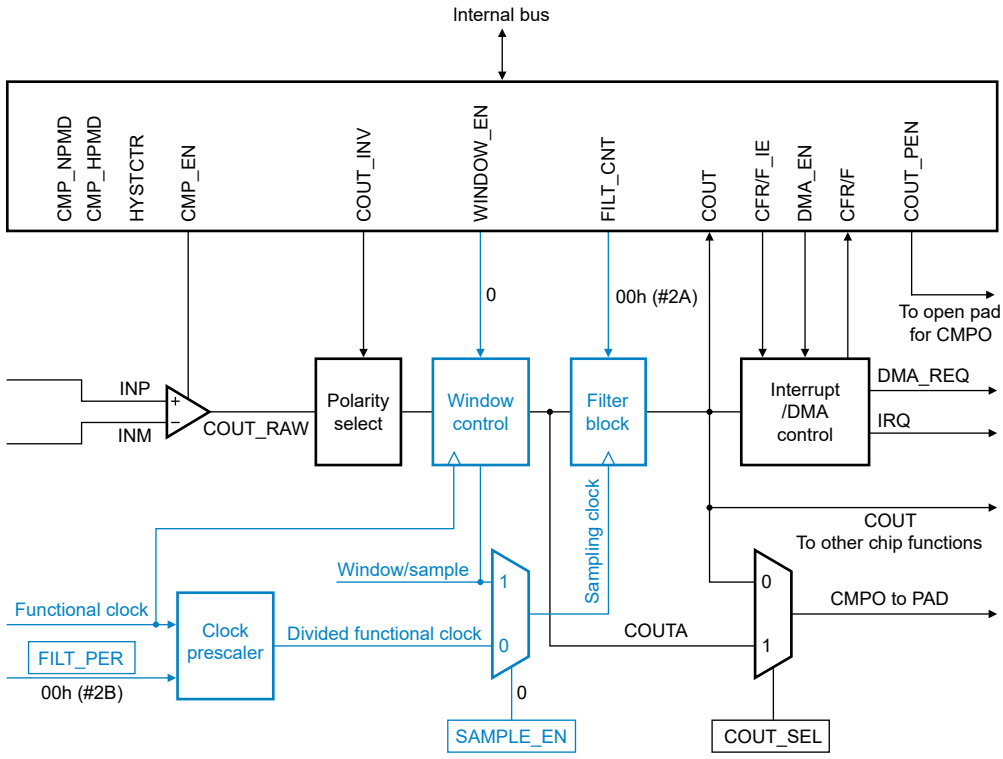

Figure 191. Comparator operation in continuous mode

COUT_RAW is optionally inverted in this mode but is not subject to external sampling or filtering. Both window control and filter blocks bypass completely, and CSR[COUT] updates continuously. The path from comparator input pins to output pins operates in a combinational (unclocked) mode. COUT and COUTA are identical in this mode.

For cases where a comparator drives a fault input, you must configure it to operate in Continuous mode so that an external fault can immediately pass to the target fault circuitry through the comparator.

44.3.5.3 Sampled, non-filtered mode (#3A and #3B)

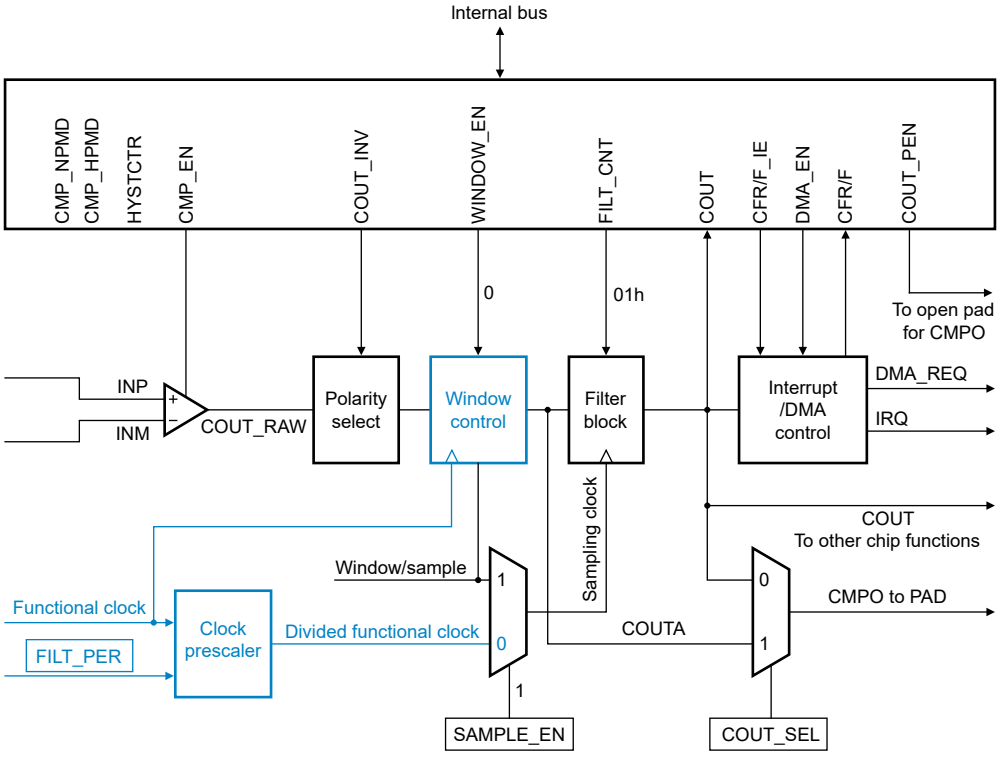

Figure 192. Sampled, non-filtered (#3A): sampling point externally driven

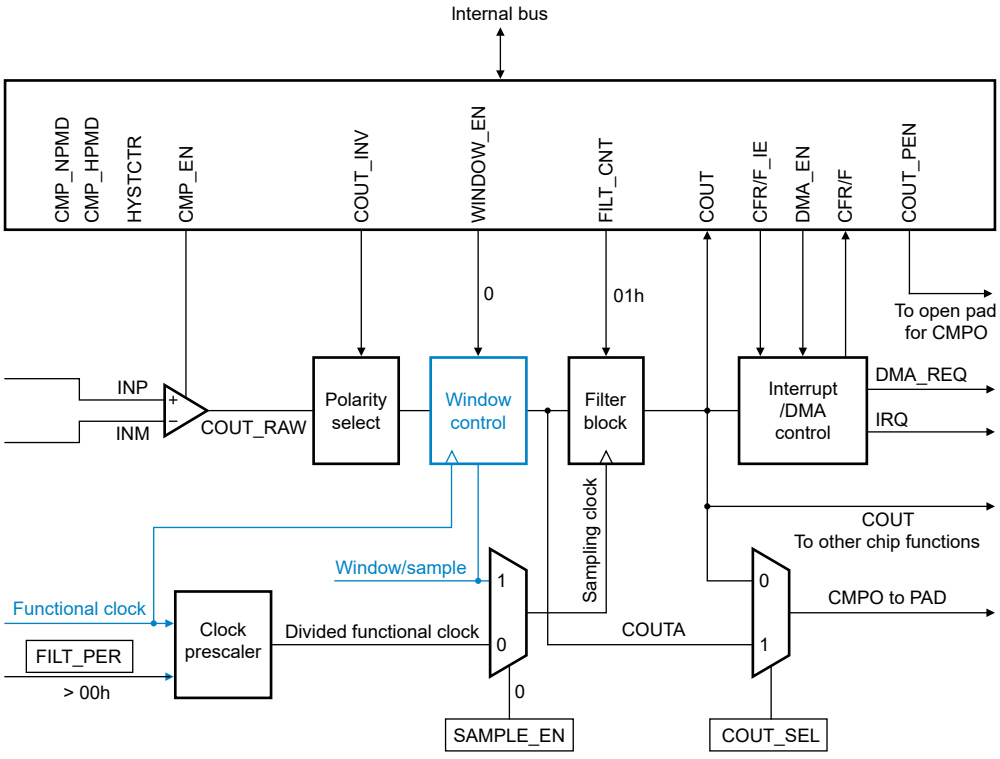

Figure 193. Sampled, Non-Filtered (#3B): sampling interval internally derived

In this mode, the path from analog inputs to COUTA is combinational (unclocked). Windowing control bypasses completely. You can sample COUTA whenever you detect a rising edge on the sampling clock.

The difference in two operation modes (#3A and #3B) of sampled, non-filtered mode is that how you drive the clock to the filter block. In #3A, the clock to filter block drives externally, and in #3B, the clock to filter block drives internally.

The filter block has no other function than sample or hold of the comparator output in this mode.

The following figure shows the comparator operation in this mode, assuming that the polarity select sets to a non-inverting state.

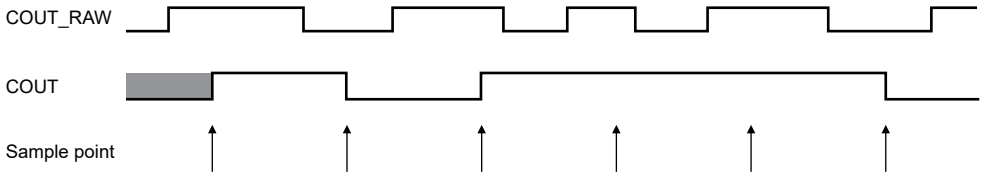

Figure 194. Sampled, Non-Filtered mode timing diagram

44.3.5.4 Sampled, filtered mode (#4A and #4B)

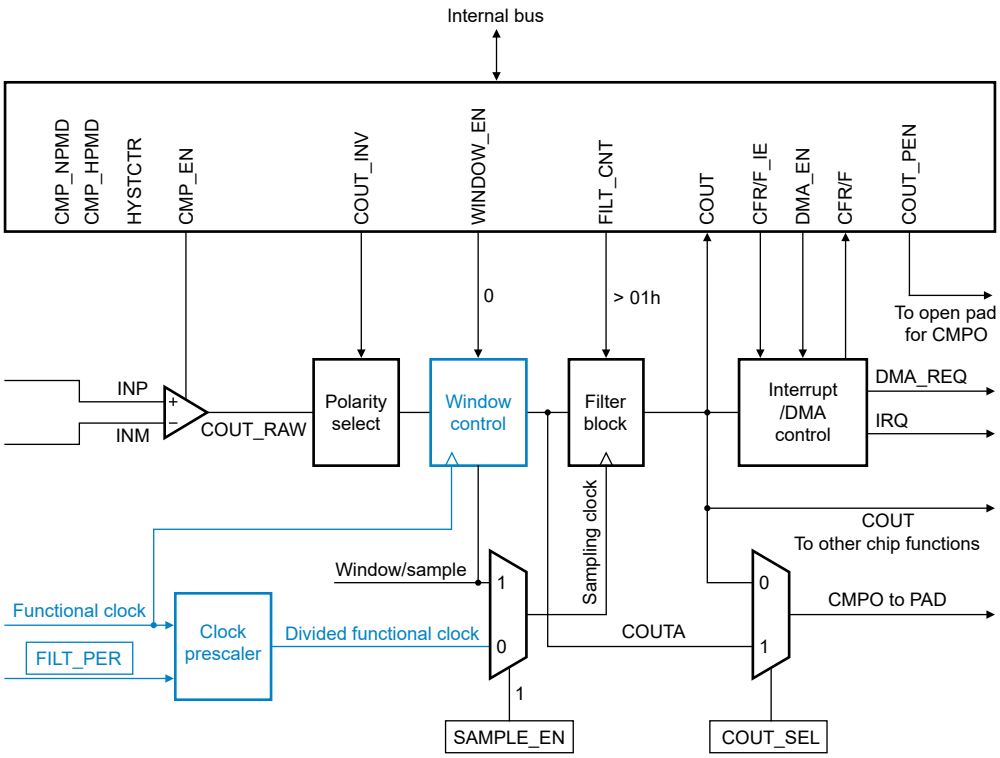

Figure 195. Sampled, filtered (#4A): sampling point externally driven

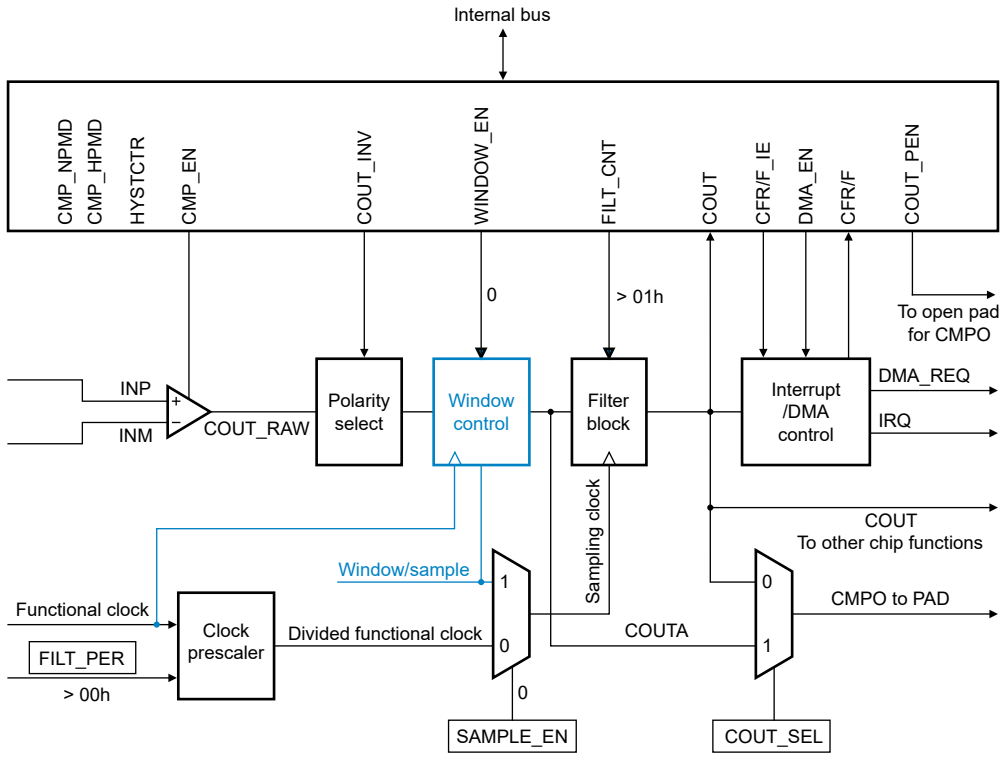

Figure 196. Sampled, filtered (#4B): sampling point internally derived

In this mode, the path from the analog inputs to COUTA is combinational(unclocked). Windowing control bypasses completely. You can sample COUTA whenever you detect a rising edge on the sampling clock.

The only difference in operation between sampled, non-filtered (#3A) mode and sampled, filtered (#4A) mode is that CCR1[FILT_CNT] is larger than 1, which activates filter operation.

The only difference in operation between sampled, non-filtered (#3B) mode and sampled, filtered (#4B) mode is that CCR1[FILT_CNT] is larger than 1, which activates filter operation.

44.3.5.5 Windowed mode (#5A and #5B)

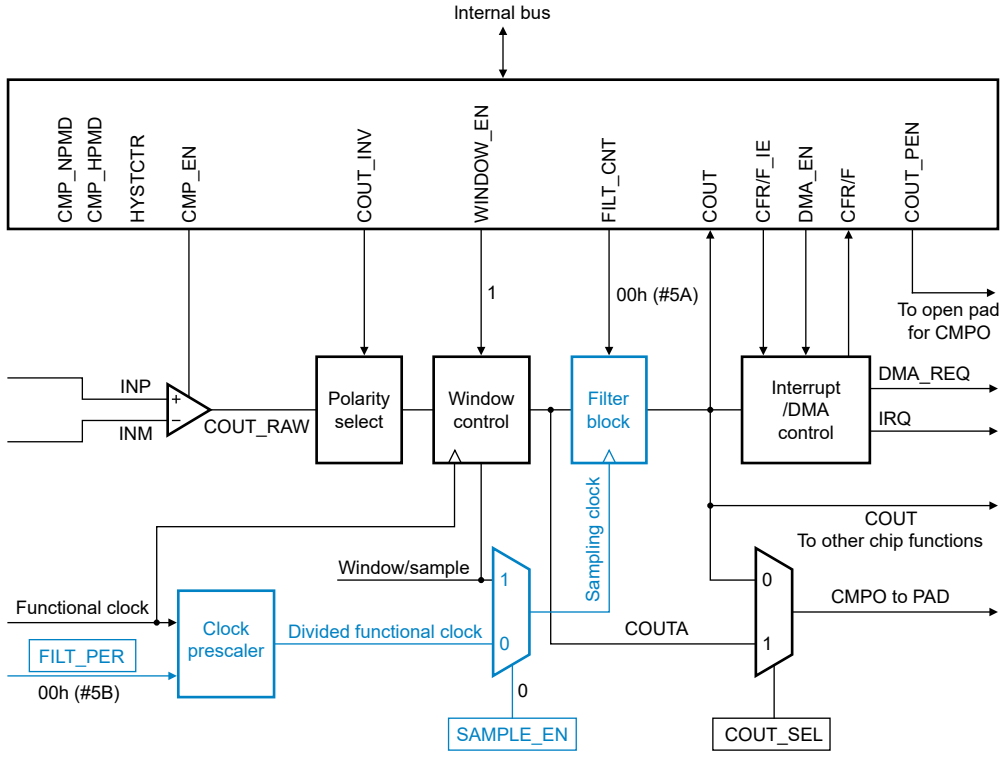

Figure 197. Windowed mode

The functional clock clocks COUTA whenever you enable the window in this mode. The last latched value holds after you disable the window and the filter block is bypassed.

The following figure shows the comparator operation in this mode, ignoring the latency of the analog comparator, polarity select, and window control block. The polarity select sets to a non-inverting state.

COUTA may lag the analog inputs by up to two functional clock cycles plus the combinational path delay through the comparator and polarity select logic in the actual operation.

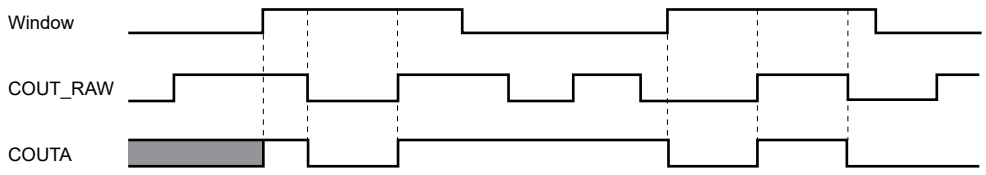

Figure 198. Windowed mode timing diagram

The following figure shows that if CCR1[COUTA_OWEN] becomes 1, you can define COUTA level as CCR1[COUTA_OW], after you closes the window.

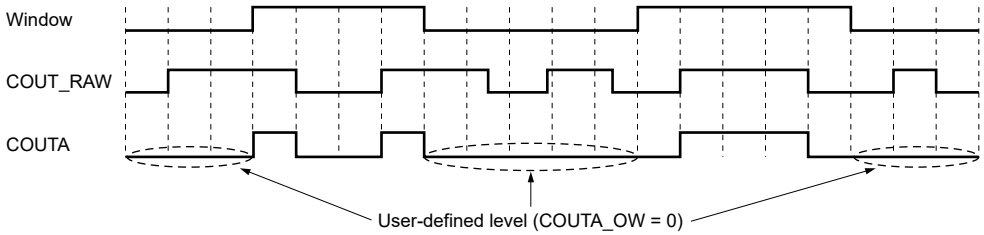

Figure 199. Windowed mode timing diagram with user defined value 0 outside window

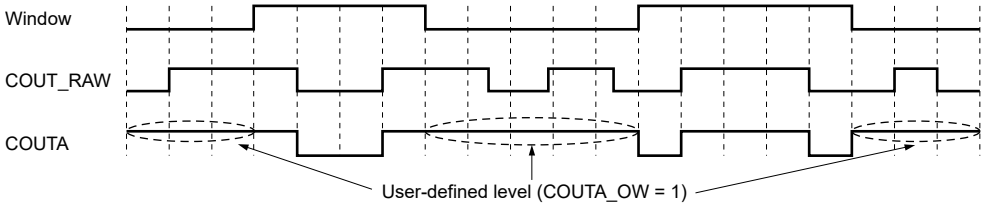

Figure 200. Windowed mode timing diagram with user defined value 1 outside window

If CCR1[WINDOW_CLS] becomes 1, you can define the COUT event (rising edge, falling edge or both edges that CCR1[EVT_SEL] selects) to close the window. The external window signal has to go to zero and back to one to enable the internal window again. The following figure shows an example that COUT rising edge closes the internal window.

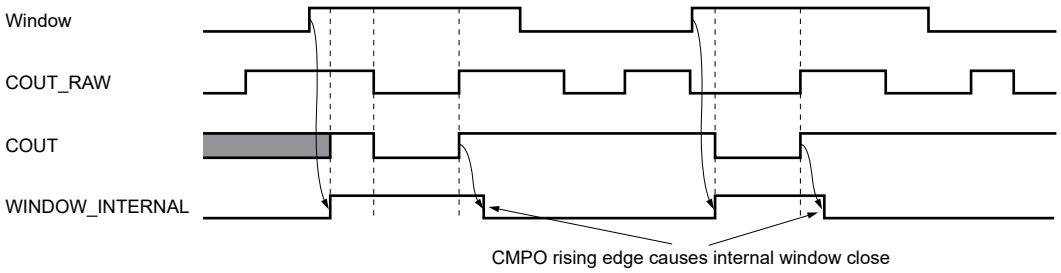

Figure 201. Windowed mode timing diagram with COUT rising edge close window

The following figure shows that if CCR1[WINDOW_INV] becomes 1, you can invert the window signal before you use it.

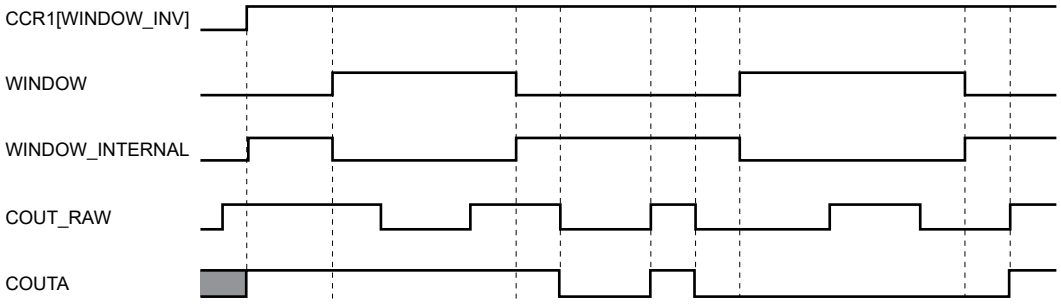

Figure 202. Windowed mode timing diagram with window signal inverted

44.3.5.6 Windowed/Resampled mode (#6)

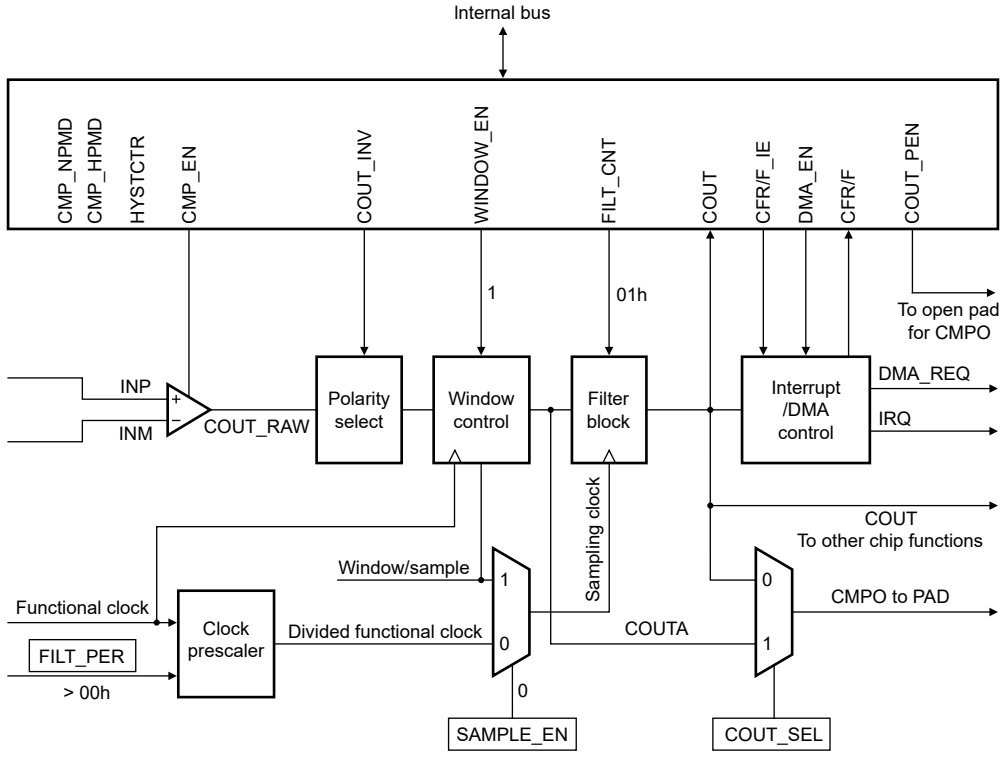

Figure 203. Windowed/Resampled mode

This mode of operation results in an unfiltered string of comparator samples where CCR1[FILT_PER] and the functional clock rate determines the interval between the samples. The following section shows that the configuration for this mode is virtually identical to that for the Windowed/Filtered mode. The only difference is that the value of CCR1[FILT_CNT] must be 1 in this mode.

The following figure uses the same input stimulus shown in Figure 198, and adds resampling of COUTA to generate COUT. The arrows in the figure indicate the time points at which the samples are taken. You can ignore prop delays and latency for clarity.

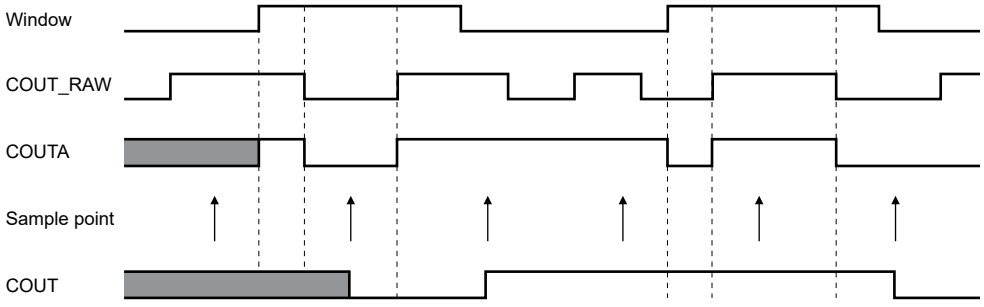

Figure 204. Windowed/Resampled mode operation

This example demonstrates the operation of the comparator in Windowed/Resampled mode, and does not reflect any specific application. Based on the sampling rate and window placement, COUT may not see zero-crossing events that the analog comparator detects. You must carefully consider the sampling period and/or window placement for a given application.

44.3.5.7 Windowed/Filtered mode (#7)

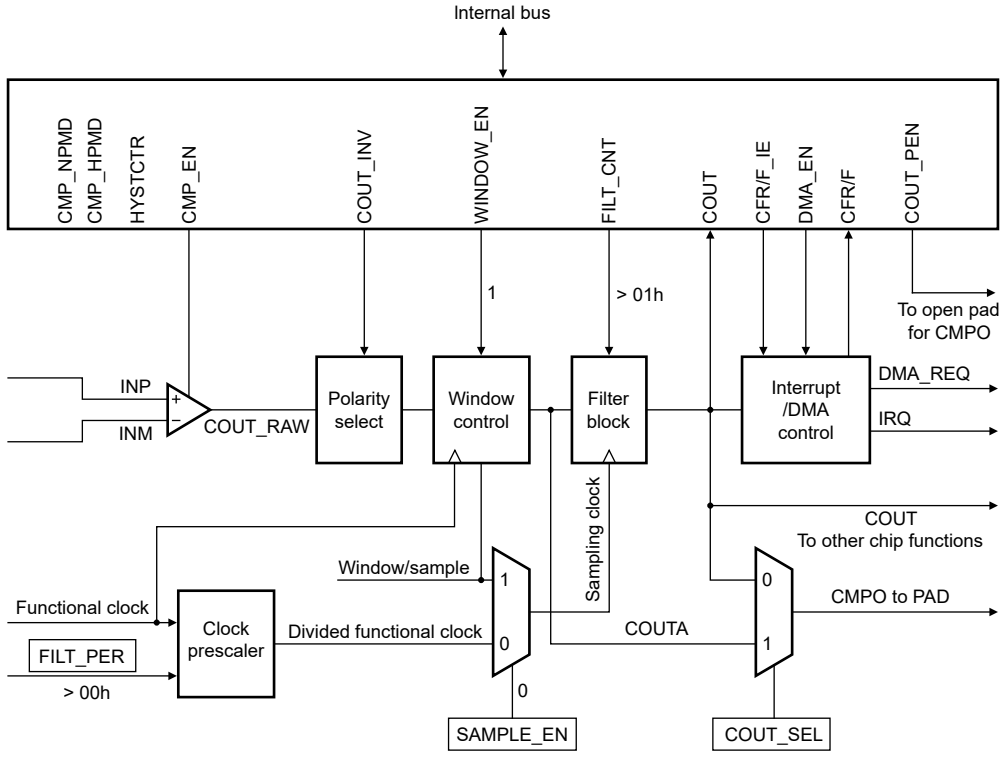

Figure 205. Windowed/Filtered mode

The only difference in operation between Windowed/Resampled mode (#6) and Windowed/Filtered mode (#7) is that CCR1[FILT_CNT] is >1, which activates filter operation.

This mode is the most complex mode of operation for the comparator block, as it utilizes both windowing and filtering features. It also has the highest latency of any of the modes. This is approximately: up to 2 peripheral clock synchronization in the window function + ((CCR1[FILT_CNT] x CCR1[FILT_PER]) + 1) x peripheral clock for the filter function.

44.3.6 DMA

After DMA is enabled by writing 1 to CCR1[DMA_EN] and interrupt is enabled by writing 1 to IER[CFR_IE], IER[CFF_IE], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt. After the DMA completes the transfer, it sends a transfer completing indicator signal that deasserts the DMA transfer request and clears the flags (both CSR[CFR] and CSR[CFF]) to allow a subsequent change on comparator output to occur and forces another DMA request.

A DMA transfer request wakes up the system from Deep sleep mode. After completing the data transfer, the system go back again to Deep sleep mode. See the DMA chapters in this document for more information on the asynchronous DMA function.

44.3.7 Clocking

LPCMP requires the following clocks to operate:

Table 380. LPCMP clocks

Type of clock	Description
Bus	Controls the access to LPCMP registers.

Table continues on the next page...

Table 380. LPCMP clocks (continued)

Type of clock	Description
Functional	Controls window/filter function. LPCMP configures CCR1[FUNC_CLK_SEL] to select one from the four functional clock sources. See the Chip-specific LPCMP information for more on the functional clock source information.
Round-robin clock (RCLK)	Controls Round-robin trigger mode. LPCMP configures CCR1[RR_CLK_SEL] to select one from the four round-robin clock sources. See the Chip-specific LPCMP information for more on the round robin clock source information.

44.3.8 Resets

The global chip reset signal resets LPCMP.

44.3.9 Interrupts

After the corresponding IER becomes 1, CSR[CFR], CSR[CFF], and CSR[RRF] can generate an interrupt, assuming that CCR1[DMA_EN] is not 1. You can clear either the flag or IER to deassert the interrupt.

44.4 External signal descriptions

Below table introduces external signals.

Table 381. External signal descriptions

Signal	Description	I/O
CMPO	Filtered or unfiltered comparator output	O
Input_Analog_Channels	Analog input channels (see the chip-specific information for more on the connections).	I
VREFH_EXT	External reference voltage for the CMP-DAC (see the chip-specific information for more on the connections).	I
RR_ACTIVE	Round-robin trigger mode enabled.	O

44.5 Initialization

You can enable LPCMP by writing 1 to CCR0[CMP_EN], and then configuring the control registers (CCR1, CCR2, DCR, and so on).

To disable LPCMP, write 0 to CCR0[CMP_EN]. Switching operation modes or changing control register fields on-the-fly (when CCR0[CMP_EN] is set to 1) may cause noise on the COUT or COUTA signals. To avoid unwanted signal noise, you must ensure to disable the module before switching modes or changing control fields.

The time required to stabilize COUT is the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function, and filter (see the Comparator and 8-bit DAC electrical specifications section of LPCMP datasheet for more information on propagation delay and power-up delay). Table 379 specifies the delay that the windowing and filter function causes.

During operation, you must always consider the propagation delay of the selected data paths. It can take many functional clock cycles for COUT and CSR[CFR]/CSR[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.

44.6 Application information

44.6.1 Round-robin trigger mode programing recommendation

Configure the Round-robin trigger mode as follows:

1. Configure RRCR0[RR_CLK_SEL] to select the RR clock source.
2. Configure the comparison cycles by RRCR0[RR_NSAM]. Note: It is a mandatory request that the round robin cycling period must set longer than the time that all the active channels complete the specified comparison cycles set by RRCR0[RR_NSAM].
3. Configure CMP initialization delay by RRCR0[RR_INITMOD]. Note: In programming RRCR0[RR_INITMOD], the RR_INITMOD x round robin clock period must be longer than the initialization delay, see the LPCMP datasheet for more information.
4. Configure RRCR0[RR_SAMPLE_CNT] and RRCR0[RR_SAMPLE_THRESHOLD].
5. Configure RRCR0[RR_TRG_SEL] to select the trigger from internal or external.
6. Enable RRCR2[RR_TIMER_EN] and configure RRCR2[RR_TIMER_RELOAD] according to the round robin clock frequency, if using an internal trigger.
7. Configure RRCR1[FIXP] to select the fixed port of CMP and RRCR1[FIXCH] to select the fixed channel.
8. Configure channels for comparison by RRCR1[RR_CHnEN].
9. Write RRCSR[RR_CHnOUT] to define the pre-set state of channel n.
10. Clear channel flags RRSR[RR_CHnF].
11. Enable round robin interrupt by IER[RRF_IE] (disable IER[CFR_IE] and IER[CFF_IE]).
12. Enable round-robin trigger mode by setting RRCR0[RR_EN] to 1.

44.6.2 Round-robin clock (RCLK) frequency requirement

(1) RCLK high frequency limit

RCLK high frequency limit depends on two facts:

1. The analog CMP and DAC initialization time (see the chip data sheet for more information on the initialization time.)
   - RRCR0[RR_INITMOD] provides a maximum 63 RCLK cycles for the analog CMP and DAC initialization.
   - RCLK must be slow to assure: $63 * (1/f_{RCLK}) > T_{initialization}$, where f_{RCLK} is in MHz, and $T_{initialization}$ is in microsecond.
   - so $f_{RCLK} < 63 / T_{initialization}$
   - Example: $T_{initialization}$ = 40 µs, then f_{RCLK} should be smaller than 1.575 MHz.
2. The analog CMP propagation delay (see the Comparator and 8-bit DAC electrical specifications section of LPCMP datasheet for more information on the CMP propagation delay.)
   - RRCR0[RR_NSAM] provides a maximum 4 RCLK cycles for the analog CMP propagation delay.
   - RCLK must be slow to assure: $4 * (1/f_{RCLK}) > T_{propagation}$, where f_{RCLK} is in MHz, and $T_{propagation}$ is in microsecond.
   - $f_{RCLK} < 4 / T_{propagation}$
   - Example: $T_{propagation}$ = 0.1 µs, then f_{RCLK} must be smaller than 40 MHz.

(2) RCLK low frequency limit

In theory, RCLK frequency has no low limit. But the lower the RCLK frequency, the longer the scan time. Therefore, the lower limit of the RCLK frequency depends on the system application.

44.7 LPCMP register descriptions

The memory map comprises of 32-bit aligned registers, which you can access via 8-, 16- or 32-bit reads and 32-bit write. Attempted accesses using unsupported write data sizes, writes to read-only resources, or to reserved spaces terminate with an error. Read access to reserved address generates a transfer error and the read data bus shows all 0s.

44.7.1 LPCMP memory map

CMP0 base address: 4005_1000h

CMP1 base address: 4005_2000h

44.7.2 Version ID (VERID)

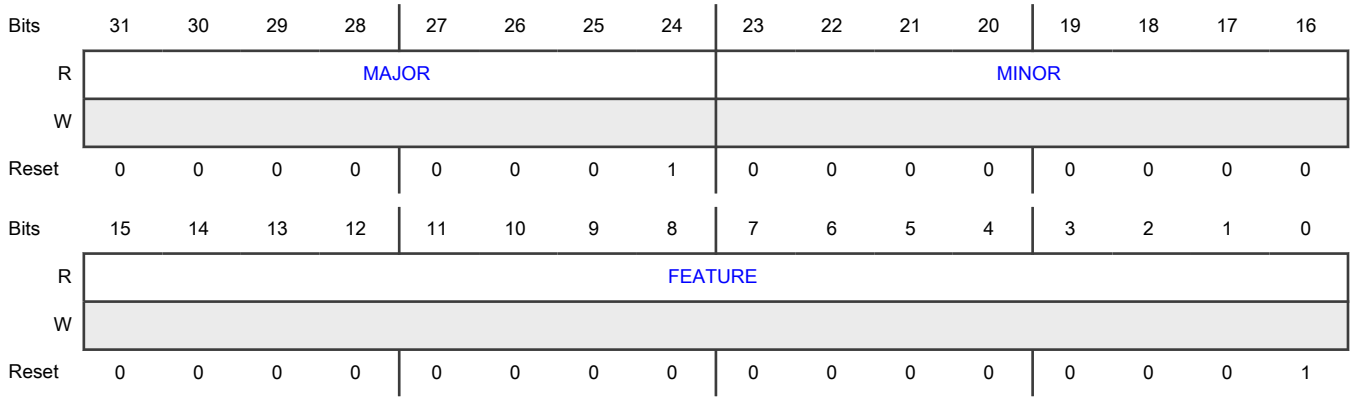
Offset

Register	Offset
VERID	0h

Function

Contains version numbers for the module design and feature set.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Returns the major version number for the module design.
23-16 MINOR	Minor Version Number Returns the minor version number for the module design.
15-0 FEATURE	Feature Specification Number Returns the feature set number. 0000_0000_0000_0001b - Round robin feature

44.7.3 Parameter (PARAM)

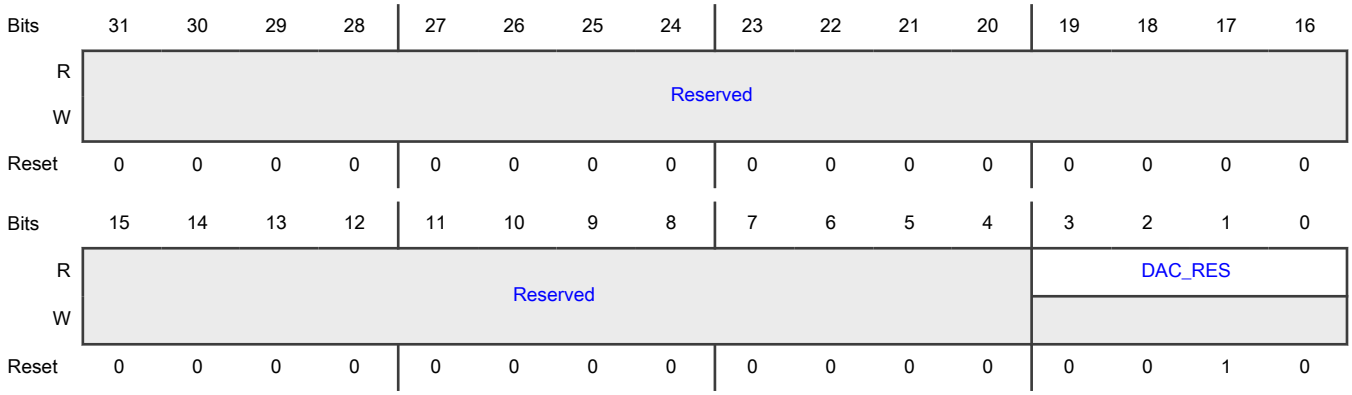
Offset

Register	Offset
PARAM	4h

Function

Contains parameter values that are implemented in the module.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 DAC_RES	DAC Resolution Indicates supported DAC resolutions. **NOTE** All other bit field values are reserved. 0000b - 4-bit DAC 0001b - 6-bit DAC 0010b - 8-bit DAC 0011b - 10-bit DAC 0100b - 12-bit DAC 0101b - 14-bit DAC 0110b - 16-bit DAC

44.7.4 Comparator Control Register 0 (CCR0)

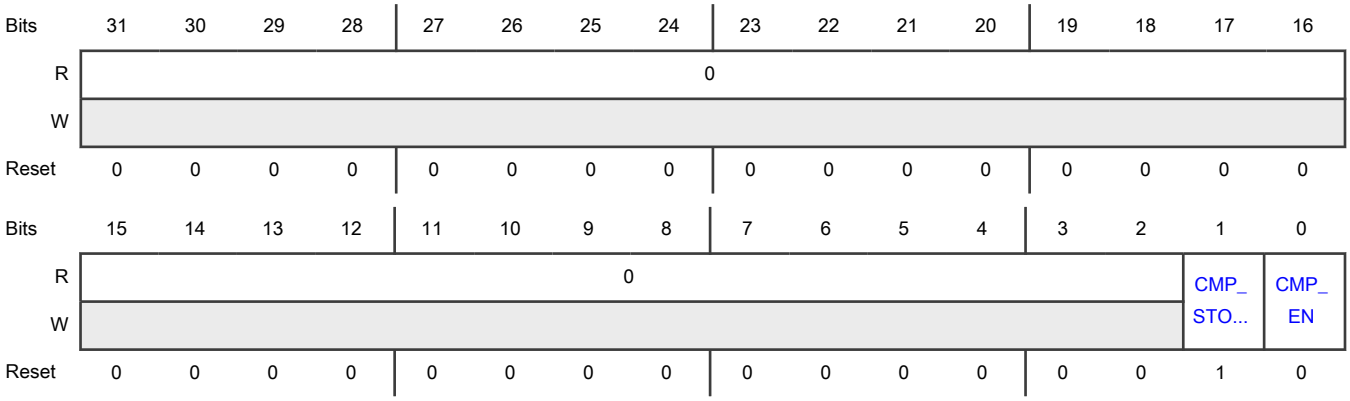
Offset

Register	Offset
CCR0	8h

Function

Contains configuration options for enabling the analog comparator.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 CMP_STOP_EN	Comparator Deep sleep Mode Enable Enables the analog comparator or the DAC when the module is in Deep sleep mode. **NOTE** This field has no effect in Round-robin Trigger mode. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in
CMP0	—	CCR0
CMP1	—	CCR0
CMP2	CCR0	—

0b - Disables the analog comparator regardless of CMP_EN.

1b - Allows CMP_EN to enable the analog comparator.

0 CMP_EN	Comparator Enable Enables the analog comparator. 0b - Disable (The analog logic remains off and consumes no power.) 1b - Enable

44.7.5 Comparator Control Register 1 (CCR1)

Offset

Register	Offset
CCR1	Ch

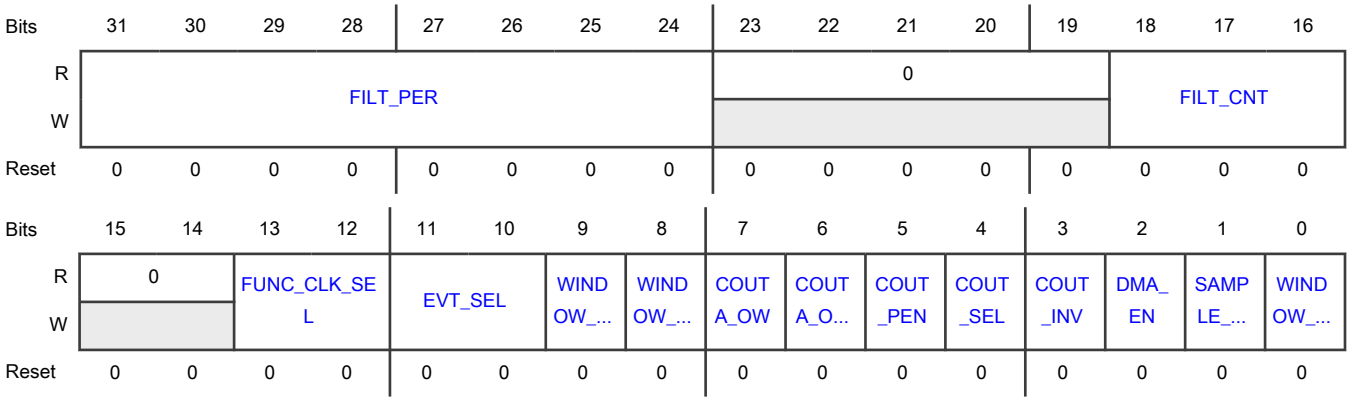
Function

Contains configuration options for the comparator operation, such as enabling Sampling or Windowing mode.

NOTE

You cannot enable Sampling and Windowing modes both at the same time. Sampling mode takes precedence over Windowing mode. If you write 1 to both SAMPLE_EN and WINDOW_EN, only SAMPLE_EN becomes 1.

Diagram



Fields

Field	Function
31-24 FILT_PER	Filter Sample Period Specifies the sampling period (in functional clock cycles) of the comparator output filter. Programming this field to 00h bypasses the filter. See Functional description for more information on filter programming and latency. **NOTE** FILT_PER has no effect in Sampling mode (CCR1[SAMPLE_EN] = 1).
23-19 —	Reserved
18-16 FILT_CNT	Filter Sample Count Specifies the number of consecutive samples that must agree before the comparator output filter accepts the sample as a new valid output state. See Functional description for more information on filter programming and latency.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - Filter is bypassed: COUT = COUTA 001b - 1 consecutive sample (Comparator output is simply sampled.) 010b - 2 consecutive samples 011b - 3 consecutive samples 100b - 4 consecutive samples 101b - 5 consecutive samples 110b - 6 consecutive samples 111b - 7 consecutive samples
15-14 —	Reserved
13-12 FUNC_CLK_SEL	Functional Clock Source Select Selects which clock source is used for the functional clock. See the Chip-specific LPCMP information for more on the functional clock source information. 00b - Select functional clock source 0 01b - Select functional clock source 1 10b - Select functional clock source 2 11b - Select functional clock source 3
11-10 EVT_SEL	COUT Event Select Selects which COUT signal edge (rising, falling, or both) defines a COUT event. **NOTE** Valid only in Windowing mode. 00b - Rising edge 01b - Falling edge 1xb - Both edges
9 WINDOW_CLS	COUT Event Window Close Enables a COUT event (defined as a COUT rising edge, falling edge, or both) to close an active window. See EVT_SEL to configure the COUT event. **NOTE** The WINDOW signal has to go to zero and back to one again to re-activate the window. Valid only in Windowing mode. 0b - COUT event cannot close the window 1b - COUT event can close the window
8	WINDOW/SAMPLE Signal Invert

Table continues on the next page...

Table continued from the previous page...

Field	Function
WINDOW_INV	Inverts the window/sample signal. 0b - Do not invert 1b - Invert
7 COUTA_OW	COUTA Output Level for Closed Window Defines the COUTA signal value when the window is closed. **NOTE** Valid only in Windowing mode and when COUTA_OWEN=1. 0b - COUTA is 0 1b - COUTA is 1
6 COUTA_OWEN	COUTA_OW Enable Enables the COUTA signal value to be defined by COUTA_OW when the window is closed. **NOTE** Valid only in Windowing mode. 0b - COUTA holds the last sampled value. 1b - Enables the COUTA signal value to be defined by COUTA_OW.
5 COUT_PEN	Comparator Output Pin Enable Enables the comparator output to become an available signal option for a selected package pin. 0b - Not available 1b - Available
4 COUT_SEL	Comparator Output Select Selects which comparator output option, COUT or COUTA, to use for CMPO. 0b - Use COUT (filtered) 1b - Use COUTA (unfiltered)
3 COUT_INV	Comparator Invert Selects the polarity of the analog comparator function, affecting the value driven to the COUT output (on both the chip pin and as CSR[COUT]) when CCR0[CMP_EN] is 0. **NOTE** COUT_INV has no effect in Trigger mode. 0b - Do not invert 1b - Invert
2	DMA Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
DMA_EN	Enables DMA transfers triggered from the LPCMP module. After this field and the corresponding interrupt enable field becomes 1, a DMA request is asserted when CFR or CFF becomes 1. 0b - Disable 1b - Enable
1 SAMPLE_EN	Sampling Enable Enables Sampling mode. 0b - Disable 1b - Enable
0 WINDOW_EN	Windowing Enable Enables Windowing mode. **NOTE** Valid only when SAMPLE_EN = 0. 0b - Disable 1b - Enable

44.7.6 Comparator Control Register 2 (CCR2)

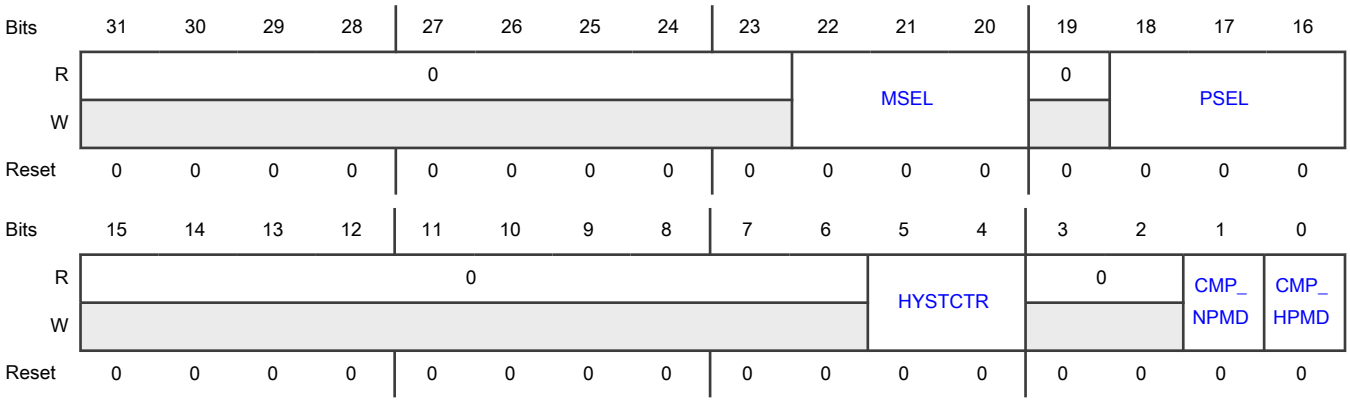
Offset

Register	Offset
CCR2	10h

Function

Contains the configuration options for the comparator operation, such as selecting the plus and minus comparator inputs and the hysteresis levels.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-20 MSEL	Minus Input MUX Select Selects the input used for the negative mux. See the chip-specific LPCMP information for more on connections. **NOTE** MSEL has no effect in Trigger mode. 000b - Input 0m 001b - Input 1m 010b - Input 2m 011b - Input 3m 100b - Input 4m 101b - Input 5m 110b - Reserved 111b - Internal DAC output
19 —	Reserved
18-16 PSEL	Plus Input MUX Select Selects the input used for the positive mux. See the chip-specific LPCMP information for more on connections. **NOTE** PSEL has no effect in Trigger mode. 000b - Input 0p 001b - Input 1p 010b - Input 2p 011b - Input 3p 100b - Input 4p 101b - Input 5p 110b - Reserved 111b - Internal DAC output
15-6 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
5-4 HYSTCTR	Comparator Hysteresis Control Selects the level of internally generated hysteresis for the comparator output. **NOTE** This applies to the comparator hard block. 00b - Level 0: Analog comparator hysteresis 0 mV. 01b - Level 1: Analog comparator hysteresis 10 mV. 10b - Level 2: Analog comparator hysteresis 20 mV. 11b - Level 3: Analog comparator hysteresis 30 mV.
3-2 —	Reserved
1 CMP_NPMD	CMP Nano Power Mode Select Enables Nano Power mode for the comparator. 0b - Disables CMP Nano power mode. CCR2[CMP_HPMD] determines the mode for the comparator. 1b - Enables CMP Nano power mode.
0 CMP_HPMD	CMP High Power Mode Select Selects Low or High Power(Speed) mode for the comparator. **NOTE** Valid only when not in Nano Power mode (CMP_NPMD = 0). 0b - Low power (speed) comparison mode 1b - High power (speed) comparison mode

44.7.7 DAC Control (DCR)

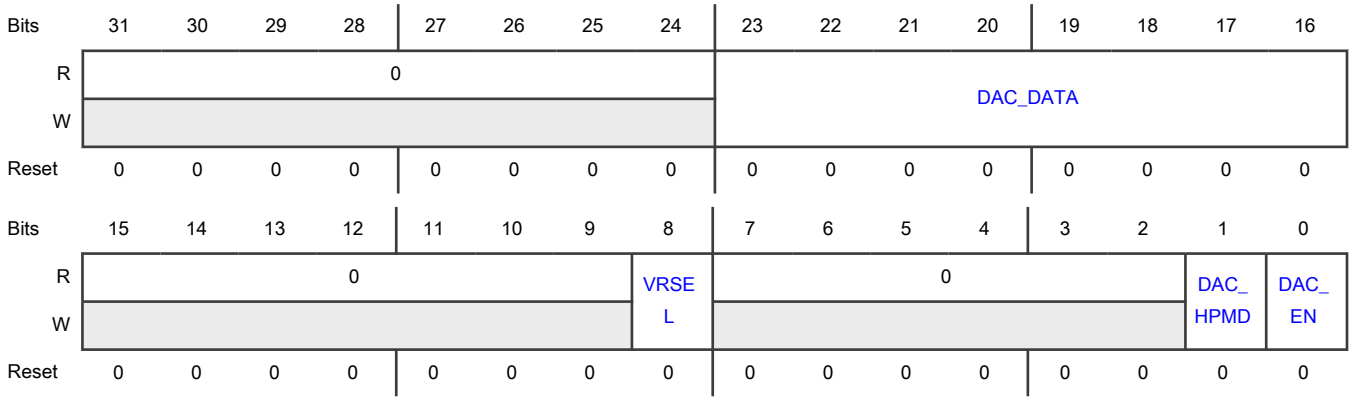
Offset

Register	Offset
DCR	18h

Function

Contains the configuration options to enable the DAC.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 DAC_DATA	DAC Output Voltage Select Selects the DAC output (DACO) voltage from one of 256 distinct levels by configuring the value of DAC_DATA. The DACO ranges from Vin/256 to Vin. **NOTE** DACO = (Vin/256) * (DAC_DATA + 1)
15-9 —	Reserved
8 VRSEL	DAC Reference High Voltage Source Select Selects the high voltage reference source for the Vin supply of the DAC's resistor ladder network. See the chip-specific LPCMP information for the source of vrefh0 and vrefh1. 0b - VREFH0 1b - VREFH1
7-2 —	Reserved
1 DAC_HPMD	DAC High Power Mode Enables the DAC high power mode. 0b - Disable 1b - Enable
0 DAC_EN	DAC Enable Enables the DAC. When disabled, power-down the DAC to conserve power.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable

44.7.8 Interrupt Enable (IER)

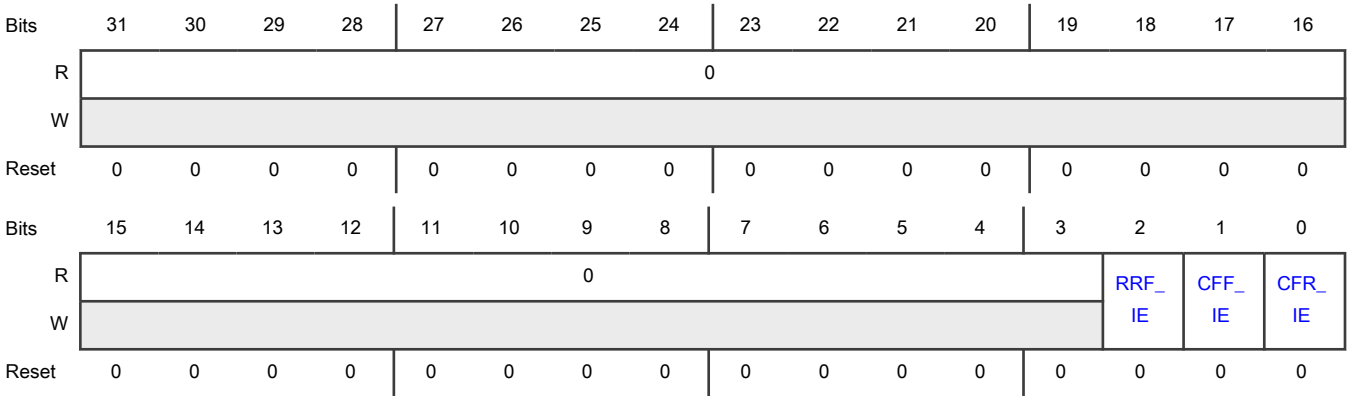
Offset

Register	Offset
IER	1Ch

Function

Provides enable fields for the comparator and round-robin flag interrupts.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 RRF_IE	Round-Robin Flag Interrupt Enable Enables or disables the round-robin flag interrupt. 0b - Disables the round-robin flag interrupt. 1b - Enables the round-robin flag interrupt when the comparison result changes for a given channel.
1	Comparator Flag Falling Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
CFF_IE	Enables or disables the comparator flag falling interrupt. 0b - Disables the comparator flag falling interrupt. 1b - Enables the comparator flag falling interrupt when CFF is set.
0 CFR_IE	Comparator Flag Rising Interrupt Enable Enables or disables the comparator flag rising interrupt. 0b - Disables the comparator flag rising interrupt. 1b - Enables the comparator flag rising interrupt when CFR is set.

44.7.9 Comparator Status (CSR)

Offset

Register	Offset
CSR	20h

Function

Indicates comparator status, including COUT, CFF, CFR, and RRF.

NOTE

LPCMP may output a glitch and affect the value of CSR[CFF] and CSR[CFR] at the moment of enabling CMP. In order to ensure correctness, it is recommended to write one to clear (W1C) CSR[CFF] and CSR[CFR] before further configuring CMP.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-9 —	Reserved
8 COUT	Analog Comparator Output Returns the current value of the analog comparator output when read. This field resets to 0 and reads as CCR1[COUT_INV] after the analog comparator module disables when CCR0[CMP_EN] = 0. Writing to this field is ignored.
7-3 —	Reserved
2 RRF	Round-Robin Flag Detects when any channel's last comparison result is different from the pre-set value in Trigger mode. Write 1 to clear this field. This field clears when CCR0[CMP_EN] or RRCR0[RR_EN] is not 1. 0b - Not detected 1b - Detected
1 CFF	Analog Comparator Flag Falling Detects when a falling edge on COUT occurs. Write 1 to clear this field when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag automatically clears after DMA is done. This field clears when CCR0[CMP_EN] is not 1. 0b - Not detected 1b - Detected
0 CFR	Analog Comparator Flag Rising Detects when a rising edge on COUT occurs. Write 1 to clear this field when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag automatically clears after DMA is done. This field clears when CCR0[CMP_EN] is not 1. 0b - Not detected 1b - Detected

44.7.10 Round Robin Control Register 0 (RRCR0)

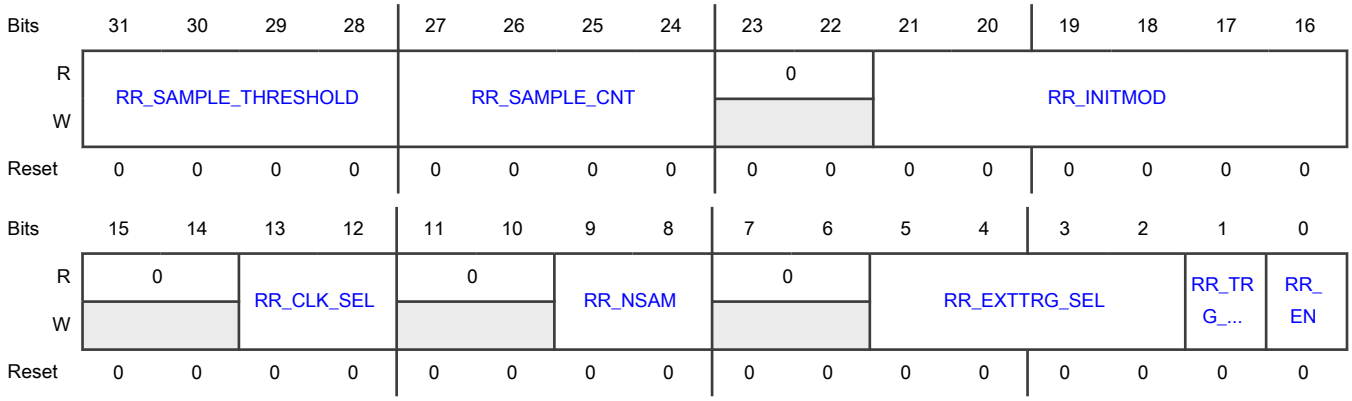
Offset

Register	Offset
RRCR0	24h

Function

Contains configuration options for the round-robin operation, such as enabling it and specifying the initialization delay.

Diagram



Fields

Field	Function
31-28 RR_SAMPLE_THRESHOLD	Sample Time Threshold Specifies that for one channel, when (RR_SAMPLE_THRESHOLD+1) sample results are "1", the final result is "1"; otherwise the final result is "0". **NOTE** This field must not be larger than RRCR0[RR_SAMPLE_CNT]. 0000b - At least 1 sampled "1", the final result is "1" 0001b - At least 2 sampled "1", the final result is "1" 0010b - At least 3 sampled "1", the final result is "1" 0011b - At least 4 sampled "1", the final result is "1" 0100b - At least 5 sampled "1", the final result is "1" 0101b - At least 6 sampled "1", the final result is "1" 0110b - At least 7 sampled "1", the final result is "1" 0111b - At least 8 sampled "1", the final result is "1" 1000b - At least 9 sampled "1", the final result is "1" 1001b - At least 10 sampled "1", the final result is "1" 1010b - At least 11 sampled "1", the final result is "1" 1011b - At least 12 sampled "1", the final result is "1" 1100b - At least 13 sampled "1", the final result is "1" 1101b - At least 14 sampled "1", the final result is "1" 1110b - At least 15 sampled "1", the final result is "1" 1111b - At least 16 sampled "1", the final result is "1"
27-24	Number of Sample for One Channel Specifies the number of samples for one channel.

Table continues on the next page...

44.7.14 Round Robin Control Register 2 (RRCR2)

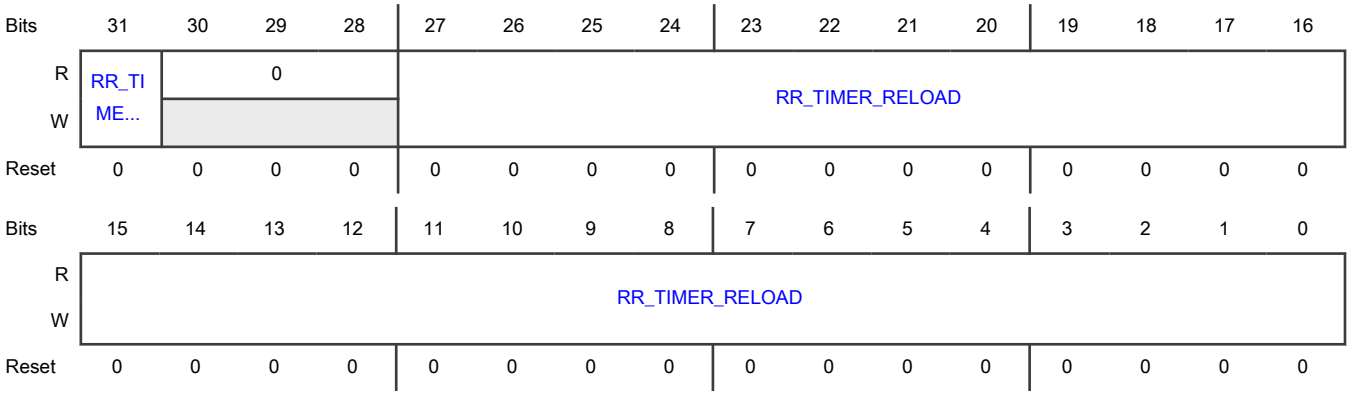
Offset

Register	Offset
RRCR2	38h

Function

Provides the controls for the round-robin internal trigger generation.

Diagram



Fields

Field	Function
31 RR_TIMER_EN	Round-Robin Internal Timer Enable Enables round-robin internal timer. 0b - Disables 1b - Enables
30-28 —	Reserved
27-0 RR_TIMER_RELOAD	Number of Sample Clocks Establishes the repetitive count rate for the round-robin internal timer. Each time the timer counts zero it is reloaded with this value. The round-robin trigger signal generates at a rate of (RR_TIMER_RELOAD + 1) times the round-robin clock period.

Chapter 45
Voltage Reference (VREF)

45.1 Chip-specific VREF information

Table 382. Reference links to related information

Topic	Related module	Reference
Full description	VREF	VREF
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

45.1.1 Module instances

This device has one instance of the VREF module, VREF0.

45.1.2 VREF chip-specific initialization

- Enable the clock to the VREF (AHBCLKCTRL3[VREF] = 1) in SYSCON registers. This enables the register interface and the peripheral function clock.
- Power up the VREF in SPC.ACTIVE_CFG1 register. See SPC.ACTIVE_CFG1[SOC_CNTRL].
- Configure the VREF as described in section Initialization.
  - UTRIM data is automatically loaded with a factory-trimmed after power up. It can also be updated by writing the UTRIM register.

45.1.3 Enabling VREF

To enable reference current, set CSR[LPBGEN] to 1. To enable 1v buffered reference voltage, set CSR[LPBGEN] and CSR[LPBG_BUF_EN].

To use VREF_OUT, set the following bits: CSR[LPBGEN], CSR[HCBGEN], CSR[CHOPEN], CSR[ICOMPEN], CSR[REGEN], CSR[BUF21EN].

45.2 Overview

VREF provides a buffered reference voltage that you can set to levels ranging from 1.0 V to 2.1 V for use as an external reference. When VREF is enabled, the reference voltage, VREF_OUT, is connected to a dedicated output pin. In addition, the buffered reference is available internally for use with on-chip peripherals.

You can trim the VREF voltage output in fine or coarse voltage steps:

- For fine-tuning, use UTRIM[VREFTRIM] to trim the output with (0.05% x VREF_OUT) resolution, where VREF_OUT is the value of the voltage reference output (measured in volts) after using UTRIM[TRIM2V1] to trim the output. For example, after using UTRIM[TRIM2V1] to trim the output VREF_OUT = 1 V, the fine step resolution is : (0.05% x 1) = 0.5 mV.
- For coarse-tuning, use UTRIM[TRIM2V1] to trim the output with 100 mV resolution. For details about possible configurations of the voltage reference, see Table 383

45.2.1 Features

- Programmable User Trim (UTRIM) with 0.5 mV steps in fine-tuning and 100 mV in coarse-tuning. When reset, User Trim (UTRIM) is automatically loaded with a factory-trimmed value.

- Programmable Buffer mode selection:
  - Off
  - Bandgap enabled or standby (output buffer disabled)
  - Low-power (output buffer enabled)
  - High-power (output buffer enabled)
- Low-power bandgap and high-accurate bandgap selection
- Support for a dedicated output pin, VREF_OUT

45.2.2 Block diagram

Figure 206 shows the VREF block diagram.

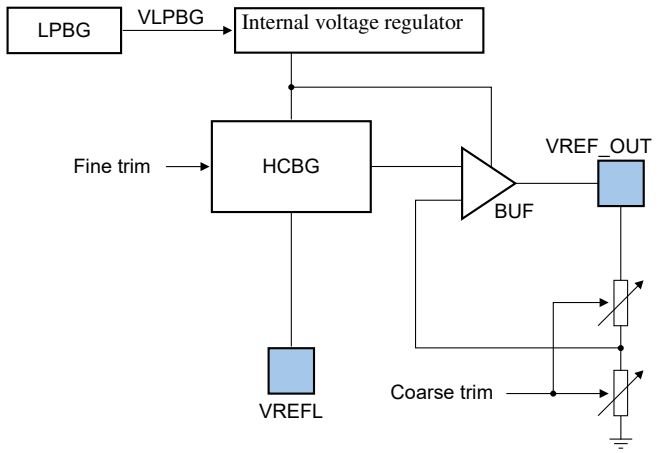


Figure 206. VREF block diagram

45.3 Functional description

VREF is a bandgap buffer system that uses unity gain amplifiers. Both internal and external peripherals use the VREF_OUT signal in Low- and High-Power Buffer modes.

NOTE

When using VREF, a 220 nF capacitor must always be connected between VREF_OUT and Analog Domain Power Supply Ground.

If CSR[HCBGEN] = 1, the voltage reference is enabled, you must set different modes by using CSR[BUF21EN] and CSR[HI_PWR_LV].

The following table shows possible configurations of the voltage reference.

Table 383. VREF_OUT values and related settings

UTRIM[TRIM2V1]	VREF_OUT (V)
0000	1.0
0001	1.1
0010	1.2

Table continues on the next page...

Table 383. VREF_OUT values and related settings (continued)

UTRIM[TRIM2V1]	VREF_OUT (V)
0011	1.3
0100	1.4
0101	1.5
0110	1.6
0111	1.7
1000	1.8
1001	1.9
1010	2.0
1011	2.1
11XX	1.0

45.3.1 Voltage reference disabled

When CSR[LPBGEN] = 0, CSR[HCBGEN] = 0, and CSR[BUF21EN] = 0, the voltage reference is disabled and the VREF bandgap and output buffers are disabled. VREF is in Off mode.

45.3.2 Voltage reference enabled

Enabling voltage reference results into the following main high-level configuration options:

- Write 1 to CSR[LPBGEN]; otherwise, ADC sends a signal to enable the low-power bandgap (LPBG) supply current bias for ADC use.
- Write 1 to CSR[LPBGEN] and CSR[HCBGEN]. This configuration enables the VREF supply voltage on VREF_OUT.

45.3.2.1 CSR[BUF21EN] = 0, CSR[HI_PWR_LV] = X

In Standby mode, the internal VREF bandgap is enabled to generate an accurate 1.0 V output that you can trim by using UTRIM[VREFTRIM]. The bandgap requires time for startup and stabilization. Monitor CSR[VREFST] to determine whether the stabilization and startup are complete when the chop oscillator is not enabled. When chop oscillator is used, the internal bandgap reference voltage settles within the chop oscillator startup time, Tchop_osc_stup.

The output buffer is disabled in this mode, and there is no buffered voltage output. VREF is in Standby mode. If you select this mode first and Low-Power or High-Power Buffer mode is subsequently enabled, there is a delay before the buffer output settles to its final value. This is the buffer startup delay (Tstup), as specified in the appropriate chip data sheet.

45.3.2.2 CSR[BUF21EN] = 1, CSR[HI_PWR_LV] = 1

In Low-Power mode, the internal VREF bandgap is on, and the High-Power Buffer mode is enabled to generate a buffered voltage to VREF_OUT. The available voltage levels range from 1.0 to 2.1 V and can be adjusted in 0.1 V steps using UTRIM[TRIM2V1]. VREF bandgap can also be used as a reference to internal analog peripherals such as an ADC channel or analog comparator input.

If this mode is entered from Standby mode (CSR[BUF21EN] = 0), there is a delay before the buffer output settles to its final value. This is the buffer startup delay (Tstup), as specified in the appropriate device data sheet.

If this mode is entered when VREF is enabled, you must wait longer than Tstup or until CSR[VREFST] = 1 when the chop oscillator is not enabled. If the chop oscillator is being used, wait for the time specified by Tchop_osc_stup (chop oscillator startup time) to ensure that the VREF output has stabilized.

NOTE

In this mode, a 220-nF capacitor is required to connect between the VREF_OUT pin and Analog Domain Power Supply Ground.

45.3.2.3 CSR[BUF21EN] = 1, CSR[HI_PWR_LV] = 0

In High-Power mode, the internal VREF bandgap is on, and the low-power buffer is enabled to generate a buffered voltage to VREF_OUT. The available voltage levels range from 1.0 to 2.1 V and you can adjust them in 0.1 V steps using UTRIM[TRIM2V1]. VREF bandgap can be used as a reference to internal analog peripherals such as an ADC channel or analog comparator input.

If this mode is entered from Standby mode (CSR[BUF21EN] = 0), there is a delay before the buffer output settles to its final value. This is the buffer startup delay (Tstup), as specified in the appropriate chip data sheet.

If this mode is entered when the VREF module is enabled, you must wait longer than Tstup or until CSR[VREFST] = 1 when the chop oscillator is not enabled. If the chop oscillator is being used, wait for the time specified by Tchop_osc_stup (chop oscillator startup time) to ensure that the VREF output has stabilized.

NOTE

In this mode, a 220-nF capacitor connects the VREF_OUT pin and Analog Domain Power Supply Ground.

45.3.3 Internal voltage regulator

VREF contains an internal voltage regulator that you can enable to provide additional supply noise rejection. The module also contains an internal chop oscillator to generate the chop clock. When possible, enable the internal regulator and chop oscillator to attain optimum VREF performance.

When using the chop function, you must also enable the internal voltage regulator. Perform the following procedure when enabling the internal regulator:

1. Enable the internal regulator by writing 1 to CSR[REGEN].
2. Enable the chop oscillator by writing 1 to CSR[CHOPEN].
3. Write 1 to CSR[LPBGEN] and CSR[HCBGEN].

45.3.4 Low-Power modes

VREF can run when the chip is in a low-power mode. To use the VREF regulator and/or the chop oscillator in a low-power mode, the system reference voltage (also known as the bandgap voltage reference) must also be enabled in these modes. See the chip-specific VREF information on how to enable the system reference voltage.

Having the VREF regulator enabled increases the current consumption. Depending on the requirements of the system application, consider disabling the VREF regulator to minimize the current consumption in low-power modes. However, not using the VREF regulator reduces the accuracy of the output voltage by as much as several mV.

45.3.5 Clocking

See the chip-specific VREF information for the required clocking.

45.3.6 Reset

System reset, VREF convert to initial state with buffer cleared and waiting to load new register.

45.3.7 Interrupts

This module has no interrupts.

45.4 External signals

Table 384. External signals

Signal	Description	I/O
VREF_OUT	Internally generated voltage reference output. When the VREF output buffer is disabled, the VREF_OUT signal state is high-impedance.	O

45.5 Initialization

VREF_OUT requires time for startup and stabilization. After writing 1 to CSR[HCBGEN], monitor CSR[VREFST] to determine whether the stabilization and startup are complete when the chop oscillator is not enabled. If the chop oscillator is enabled, Tchop_osc_stup defines the settling time of the internal bandgap reference. You must wait for this time (Tchop_osc_stup) after the internal bandgap is enabled to ensure that the VREF internal reference voltage is stabilized.

After VREF_OUT is enabled and stabilized, changing the value of CSR[HI_PWR_LV] temporarily destabilizes the output voltage at the VREF_OUT pin, even though CSR[VREFST] remains 1. The time it takes for VREF_OUT to settle again is the same as the buffer startup delay (Tstup), as specified in the appropriate device data sheet. Also, applying a step change of the load current to the VREF_OUT pin incurs some time delay to resettle.

To enable the internal 1.75 V VREF regulator, see Internal voltage regulator for the required sequence. When the internal regulator is disabled, the VREF_OUT voltage is more sensitive to supply voltage variation. Use the internal regulator to achieve optimum VREF_OUT performance.

NOTE

You must write 1 to CSR[CHOPEN], CSR[REGEN], and CSR[ICOMPEN] to achieve the performance stated in the device data sheet.

45.6 Register descriptions

45.6.1 VREF register descriptions

45.6.1.1 VREF memory map

VREF0 base address: 4011_1000h

Offset	Register	Width (In bits)	Access	Reset value

Operational Amplifier (OPAMP)

46.1 Chip-specific OPAMP information

Table 385. Reference links to related information

Topic	Related module	Reference
Full description	OPAMP	OPAMP
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing
Input multiplexing	INPUTMUX	See OPAMPn_TRIG registers in INPUTMUX

46.1.1 Module instances

This device contains three instances of the OPAMP module, OPAMP0, OPAMP1, and OPAMP2.

46.1.2 Positive voltage references

The positive voltage reference can be selected using the OPAMP_CTR[PREF] register. The PREF inputs correspond to following signals.

Table 386. PREF inputs

Register bit field value	PREF input[1]	Corresponds to
00b	Input 0	DACx_OUT • DAC0_OUT for OPAMP0 • DAC1_OUT for OPAMP1 • DAC2_OUT for OPAMP2
01b	Input 1	VDD_ANA/2
10b	Input 2	VREFO
11b	Input 3	520 mv. VREFH provides VREF1V, which is divided inside OPAMP to generate 0.52 V.

1. The voltage range is between 0 - VDD_ANA-0.8.

46.1.3 OPAMP_CTR[ADCSW1]

OPAMP_CTR[ADCSW1] can be used to enable negative gain resistor ladder voltage output to ADC and CMP channel. See ADC input connections and CMP input connections for the channel number (OPAMPx_INT).

46.1.4 OPAMP_CTR[ADCSW2]

OPAMP_CTR[ADCSW2] can be used to enable positive gain resistor ladder voltage output to ADC channel. See ADC input connections to check the channel number (OPAMPx_OBS).

46.1.5 OPAMP_CTR[BIASC]

OPAMP_CTR[BIASC] field settings:

- 01b Increase: +12.5%
- 10b decrease: -12.5%
- 11b further decrease: -25%

46.2 Overview

The OPAMP is an advanced amplifier that supports programmable gain (PGA), inverting, non-inverting, buffer mode and standalone mode. Positive and negative inputs of an amplifier connect to internal channels. The module is applicable to the signal-processing stage before ADC.

46.2.1 Block diagram

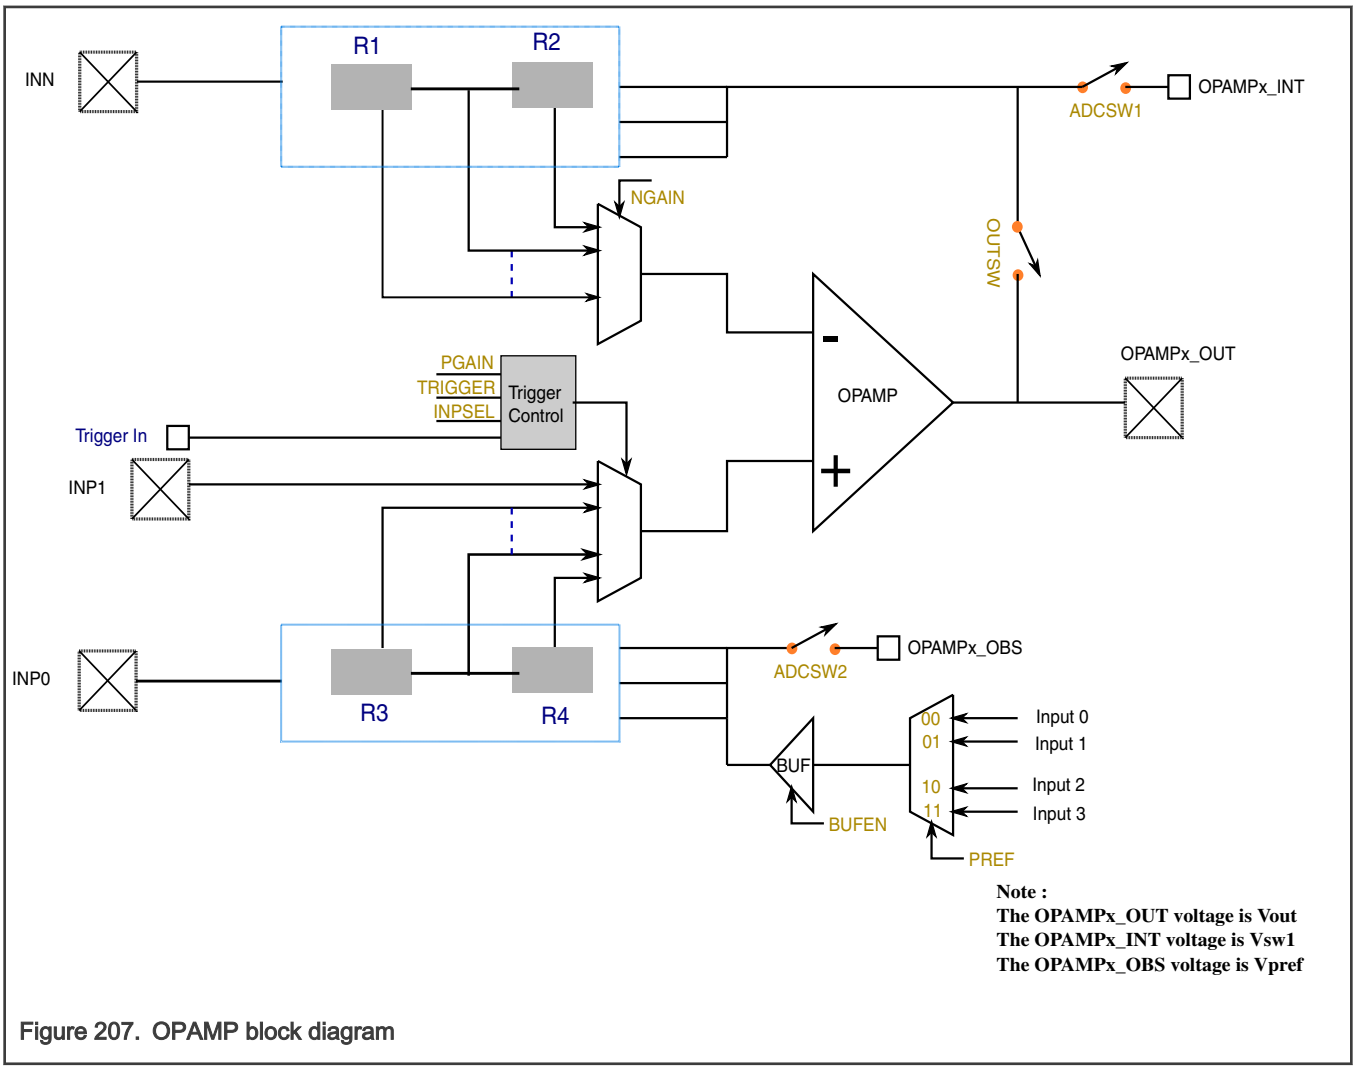

Figure 207. OPAMP block diagram

See chip-specific for supported PREF inputs.

46.2.2 Features

- High performance mode and low power mode

- PGA mode
- Noninverting Amplifier mode
- Inverting Amplifier mode
- Unity gain buffer mode
- Standalone OPAMP mode

46.3 Functional description

This module supports optional gains. See the following table for details where Ngain=R2/R1 and Pgain=R4/R3.

OPAMP_CTR[NGAIN]	Description
000b	Buffer mode
001b	Ngain=1
010b	Ngain=2
011b	Ngain=4
100b	Ngain=8
101b	Ngain=16
110b	Ngain=33
111b	Ngain=64

OPAMP_CTR[PGAIN]	Description
000b	Positive input 1 (INP1)
001b	Pgain=1
010b	Pgain=2
011b	Pgain=4
100b	Pgain=8
101b	Pgain=16
110b	Pgain=33
111b	Pgain=64

NOTE

The actual gain is determined by different usage methods. Some gain calculation examples have been shown in Application Information

46.3.1 Modes

This module supports high performance mode and low power mode selected by configuring OPAMP_CTR[MODE].

The table below shows all supported modes and the related configurations:

Table 387. OPAMP modes configuration

Mode	ADCSW1	OUTSW	ADCSW2	NGAIN	PGAIN	INPSEL	PREF	BUFEN
PGA	ON	ON	ON	x	x	INP0	00b/01b/10b/11b	ON
Noninverting	ON	ON	OFF	x	x	INP0, INP1	-	OFF
Inverting[1]	ON	ON	OFF	x	0	INP1	-	OFF
Standalone	OFF	OFF	OFF	011b	011b	INP0, INP1	-	OFF
Buffer	OFF	OFF	OFF	0	0	INP1	-	OFF

1. Vinp0 must be floating

46.3.1.1 Trigger mode

On the chip, there are up to two pads that can be connected to the OPAMP positive input. In trigger mode, hardware can automatically switch the pad which is connected to OPAMP positive input. It recommends that trigger mode is used when OPAMP is configured to noninverting amplifier. Before enabling trigger mode, the INPSEL bit in the CTR register should be set. Write 0 to BUFEN to disable reference buffer. Configure NGAIN to required gain. After finishing all the configurations, enable the trigger mode. In trigger mode, whenever there is a positive edge of trigger, hardware will switch the pad which is connected to OPAMP positive input. You can read INPF register bit field to monitor which pad is connected to OPAMP positive input in trigger mode.

46.3.1.2 PGA Mode

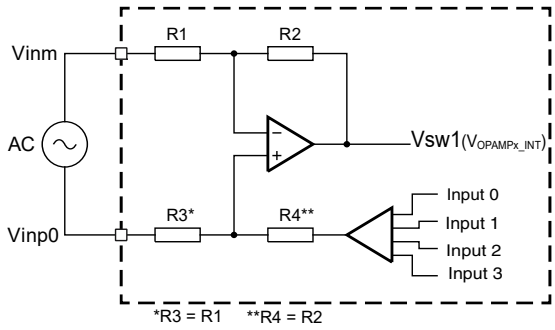

Figure 208. PGA Mode

See chip-specific for supported PREF inputs.

In this mode, configure the registers OPAMP_CTR[NGAIN] and OPAMP_CTR[PGAIN] to select different gains. Enable OPAMP_CTR[BUFEN] and configure the registers OPAMP_CTR[PREF] to select positive reference voltage. Configure OPAMP_CTR[OUTSW] to connect R2 with OPAMP output. Enable OPAMP_CTR[ADCSW1] and OPAMP_CTR[ADCSW2], measure the results from OPAMPx_INT and OPAMPx_OBS by ADC.

46.3.1.3 Noninverting Amplifier mode

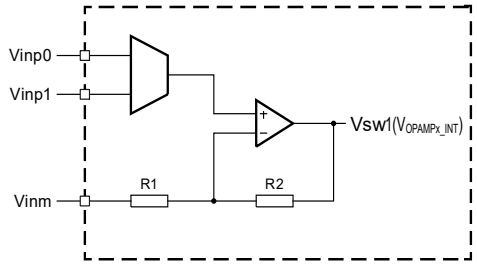

Figure 209. Noninverting Amplifier mode

This mode output a forward gain voltage and the output voltage is connected to the ADC. Configure the registers **OPAMP_CTR[NGAIN]** to select different gains. The positive input can be from Vinp0 or Vinp1. If Vinp1 is used, configure **OPAMP_CTR[PGAIN]** to 0. Configure OPAMP_CTR[BUFEN] to 0 to disable reference buffer. Enable OPAMP_CTR[OUTSW] to connect R2 with OPAMP output (OPAMPx_OUT). Enable OPAMP_CTR[ADCSW1], and measure results from OPAMPx_INT.

46.3.1.4 Inverting Amplifier Mode

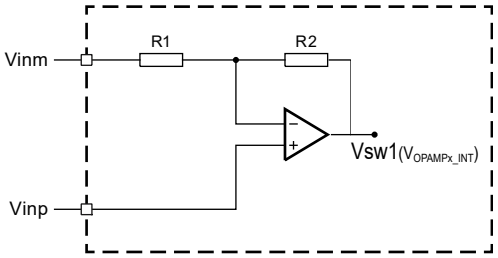

Figure 210. Inverting Amplifier Mode

This mode output a reverse gain voltage and the output voltage is connected to the ADC. Configure the registers **OPAMP_CTR[NGAIN]** to select different gains. The positive input can be either from Vinp1 or reference buffer. Configure **OPAMP_CTR[PGAIN]** to 0 to select Vinp1. Enable reference buffer by **OPAMP_CTR[BUFEN]** to select reference buffer as the source of positive input. Vinp0 must be floating. Enable **OPAMP_CTR[OUTSW]** to connect R2 with OPAMP output (OPAMPx_OUT). Enable **OPAMP_CTR[ADCSW1]**, and measure results from OPAMPx_INT.

46.3.1.5 Standalone OPAMP Mode

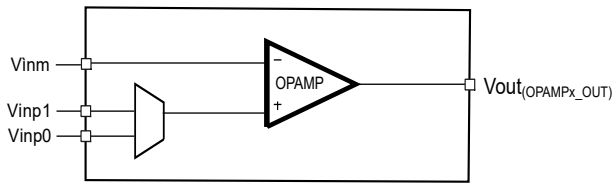

Figure 211. Standalone OPAMP Mode

To use standalone OPAMP mode, disconnect R2 with OPAMP output by disabling **OPAMP_CTR[OUTSW]**. Configure **OPAMP_CTR[NGAIN]=011b** and **OPAMP_CTR[PGAIN]=011b**. Disable reference buffer by **OPAMP_CTR[BUFEN]**. Disconnect ADCSW1 and ADCSW2.

46.3.1.6 Buffer Mode

To select buffer mode, configure the value of registers **OPAMP_CTR[NGAIN]** and **OPAMP_CTR[PGAIN]** to 000b. The output voltage is connected to the **OPAMPx_OUT**. Configure **OPAMP_CTR[BUFEN]** to 0 to disable reference buffer. Enable **OPAMP_CTR[OUTSW]** to connect R2 with OPAMP output. Enable **OPAMP_CTR[ADCSW1]**, and measure results from **OPAMPx_INT**.

46.3.2 Clock

The global clock is used for OPAMP.

46.3.3 Reset

OPAMP is reset by the global chip reset signal.

46.3.4 Interrupts

This module has no interrupts.

46.4 External Signals

Table 388. External Signal Description

Signal	Description	I/O
INN	Analog input channels(Core amplifier negative input channel)	I
INP0	Analog input channels(Core amplifier positive input channel0)	I
INP1	Analog input channels(Core amplifier positive input channel1)	I
V_{OPAMPx_OUT}	Output of the core amplifier	O

46.5 Initialization

This module does not require initialization.

46.6 Application Information

Below is the OPAMP output equation :

$$V_{sw1} = \frac{Ngain+1}{1+\frac{1}{Pgain}} V_{INP0} - Ngain * V_{INN} + \frac{1+Ngain}{1+Pgain} V_{pref}$$

46.6.1 PGA mode Application Information

- Both OUTSW and ADCSW1/2 switches should be on.
- OPAMP_CTR[NGAIN] and OPAMP_CTR[PGAIN] should be set to same value.
- Measurement method:
  - Two steps method
    1. Measure OPAMPx_OBS voltage, defined as Vpref (voltage input selected by PREF bit) first with ADC single end mode, and the measured Vpref will be used in following calculation.

2. Measure OPAMPx_INT voltage, defined as Vsw1 with ADC single end mode real time.

— Differential method

1. Use ADC differential channel measure Vsw1 and Vpref at same time.

- ADCSW1 could be on to fine-tune the results
- Result :

  Recommend Ngain=Pgain,

  — Vsw1 –Vpref = (Vinp0-Vinm) * Ngain

46.6.2 Noninverting mode Application Information

- ADCSW1 should be closed
- Disable the OPAMP_CTR[BUFEN]
- Result

  — Vsw1 + Ngain * Vinm= (1+Ngain) * Vinp

  NXP recommends you to connect Vinm to GND, if you do not need to provide a DC offset, and Vinp is recommended to be connected to Vinp1.

46.6.3 Inverting mode Application Information

- ADCSW1 should be closed
- Disable the OPAMP_CTR[BUFEN]
- Result

  — Vsw1 = (Ngain+1) * Vinp-Ngain * Vinm

- OPAMP_CTR[PGAIN] is recommended to be set to 000b.

  NXP recommends you to connect Vinp to Vinp1. The recommended voltage of Vinp0/1 is half of VDD_ANA. Vinp cannot be 0.

46.6.4 Buffer mode Application Information

- The unity gain buffer mode supports OPAMPx_OUT or OPAMPx_INT as the output, with Vout defined as the voltage.
- Disable the OPAMP_CTR[BUFEN]
- Result :-

  — Vout=Vinp1

  Vinp is recommended to be connected to Vinp1.

46.7 Memory map and register definition

This section includes the OPAMP module memory map and detailed descriptions of all registers. You can select different gains by configuring registers. Registers have options for selecting noninverting and inverting gain application.

46.7.1 OPAMP register descriptions

46.7.1.1 OPAMP memory map

OPAMP0 base address: 4011_0000h

OPAMP1 base address: 4011_3000h

OPAMP2 base address: 4011_5000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID (VERID)	32	R	0000_0000h

47.1.1 Module instances

This device has one instance of the SINC Filter module, SINC0.

47.1.2 SINC output signals

The conversion complete signal is routed into SCT, ADC0/1 and FlexIO via INPUTMUX.

The Break signals are routed into PWM0/1 and EVTG via INPUTMUX. Five break signals are connected using OR into one signal into INPUTMUX.

47.1.3 Wake-up

This chip does not support the Wake-up feature.

47.1.4 SINC pin functions

SINC Filter data input and output pin functions are mapped to various SoC pins and are selected by the Pin Function registers (see Signal multiplexing for more details). The table below lists the SINC Filter data input and output pin functions mapped to the SoC-level pins.

NOTE

Not all SoC pins are pinned out on all packages.

Table 390. SINC data input pin functions

47.1.5 SINC external trigger connections

The SINC Filter external trigger inputs come from various sources within the SoC and are selected by the SINC Filter peripheral input muxes residing at INPUTMUX_BASE address plus offsets 0x520 – 0x530 (see INPUTMUX chapter). The trigger input mux at 0x520 selects the external trigger for channel 0 input source, the trigger input mux at 0x524 selects the external trigger for channel 1 input source, and so on. The table below lists the triggers mapped to the SINC Filter input sources.

47.2 Overview

SINC converts an external ADC sigma-delta modulator bitstream to a data stream. The converters are based on:

- A maximum of 3-order sinc digital decimation filters with FastSinc support.
- A maximum selectable oversampling ratio (OSR) of 2048.

You can combine SINC functionality with additional software-based filtering.

47.2.1 Block diagram

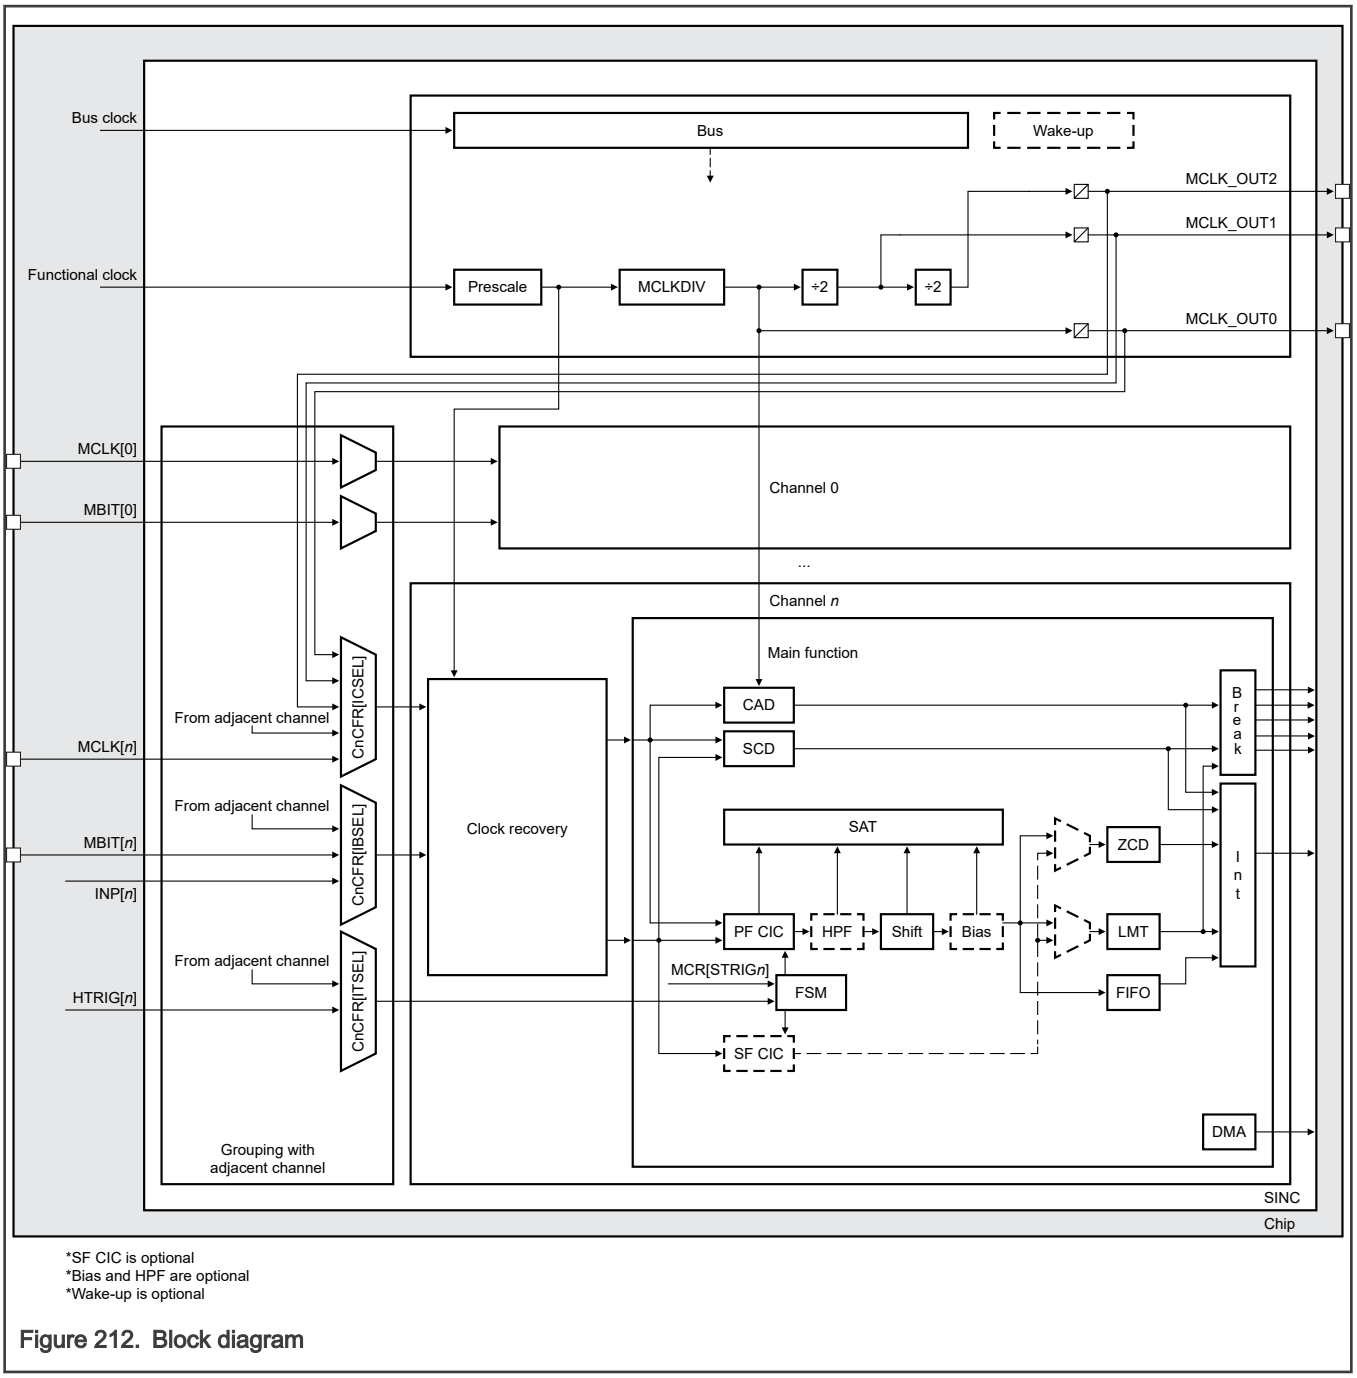

Figure 212. Block diagram

47.2.2 Features

- Filter channels with dedicated modulator clocks, bitstreams, and triggers
- Modulator clock outputs
- One software and one hardware trigger per channel
- One primary filter (PF) for each channel, with a shift and cascaded integrator comb (CIC) filter, for 24-bit precision
- Break signal outputs to turn off the external peripheral when a protection event occurs

- A 8-entry FIFO with watermark support for each channel
- Two DMA requests per channel with various event sources
- Various interrupt sources available for each channel (see Interrupts and breaks)
- Programmable high and low detection limits
- Support for short-circuit detector (SCD), clock-absence detector (CAD), and zero-cross detector (ZCD)
- Programmable shift operations
- Programmable bias (offset) operations
- high-pass filters (HPF) for DC removal
- Support for a Manchester-encoded bitstream

47.3 Functional description

47.3.1 Components

SINC includes the following two main components.

Table 393. Components

Component	Supported functionality
Decimation filter	• A PF per channel • A high-precision 24-bit result with gain scaling • Facility for DC removal using an HPF • Offset bias compensation logic
Digital protection logic	• SCD • Hi-low limit detection (LMT) • CAD • ZCD

47.3.2 Operations

SINC performs operations based on:

- Modulator bitstream sources. See Bitstream source selection for more information.
- Conversion modes. See Modes and behaviors for more information.
- The selected PF. See PF for more information on SINC PF components, and see Calculating ORD and Equation for OSR that define the calculation for ORD and OSR, respectively, of the PF.

47.3.2.1 Calculating ORD

Use the following table to calculate ORD for the PF.

Table 394. Calculating ORD

When C*n*DR[PFORD] is:	ORD is:
0	4
> 0	C*n*DR[PFORD]

47.3.2.2 Equation for OSR

$$OSR = C\mathit{n}DR[PFOSR] + 1$$

Equation 20. Equation for OSR

47.3.2.3 Bitstream source selection

These are SINC's modulator bitstream sources:

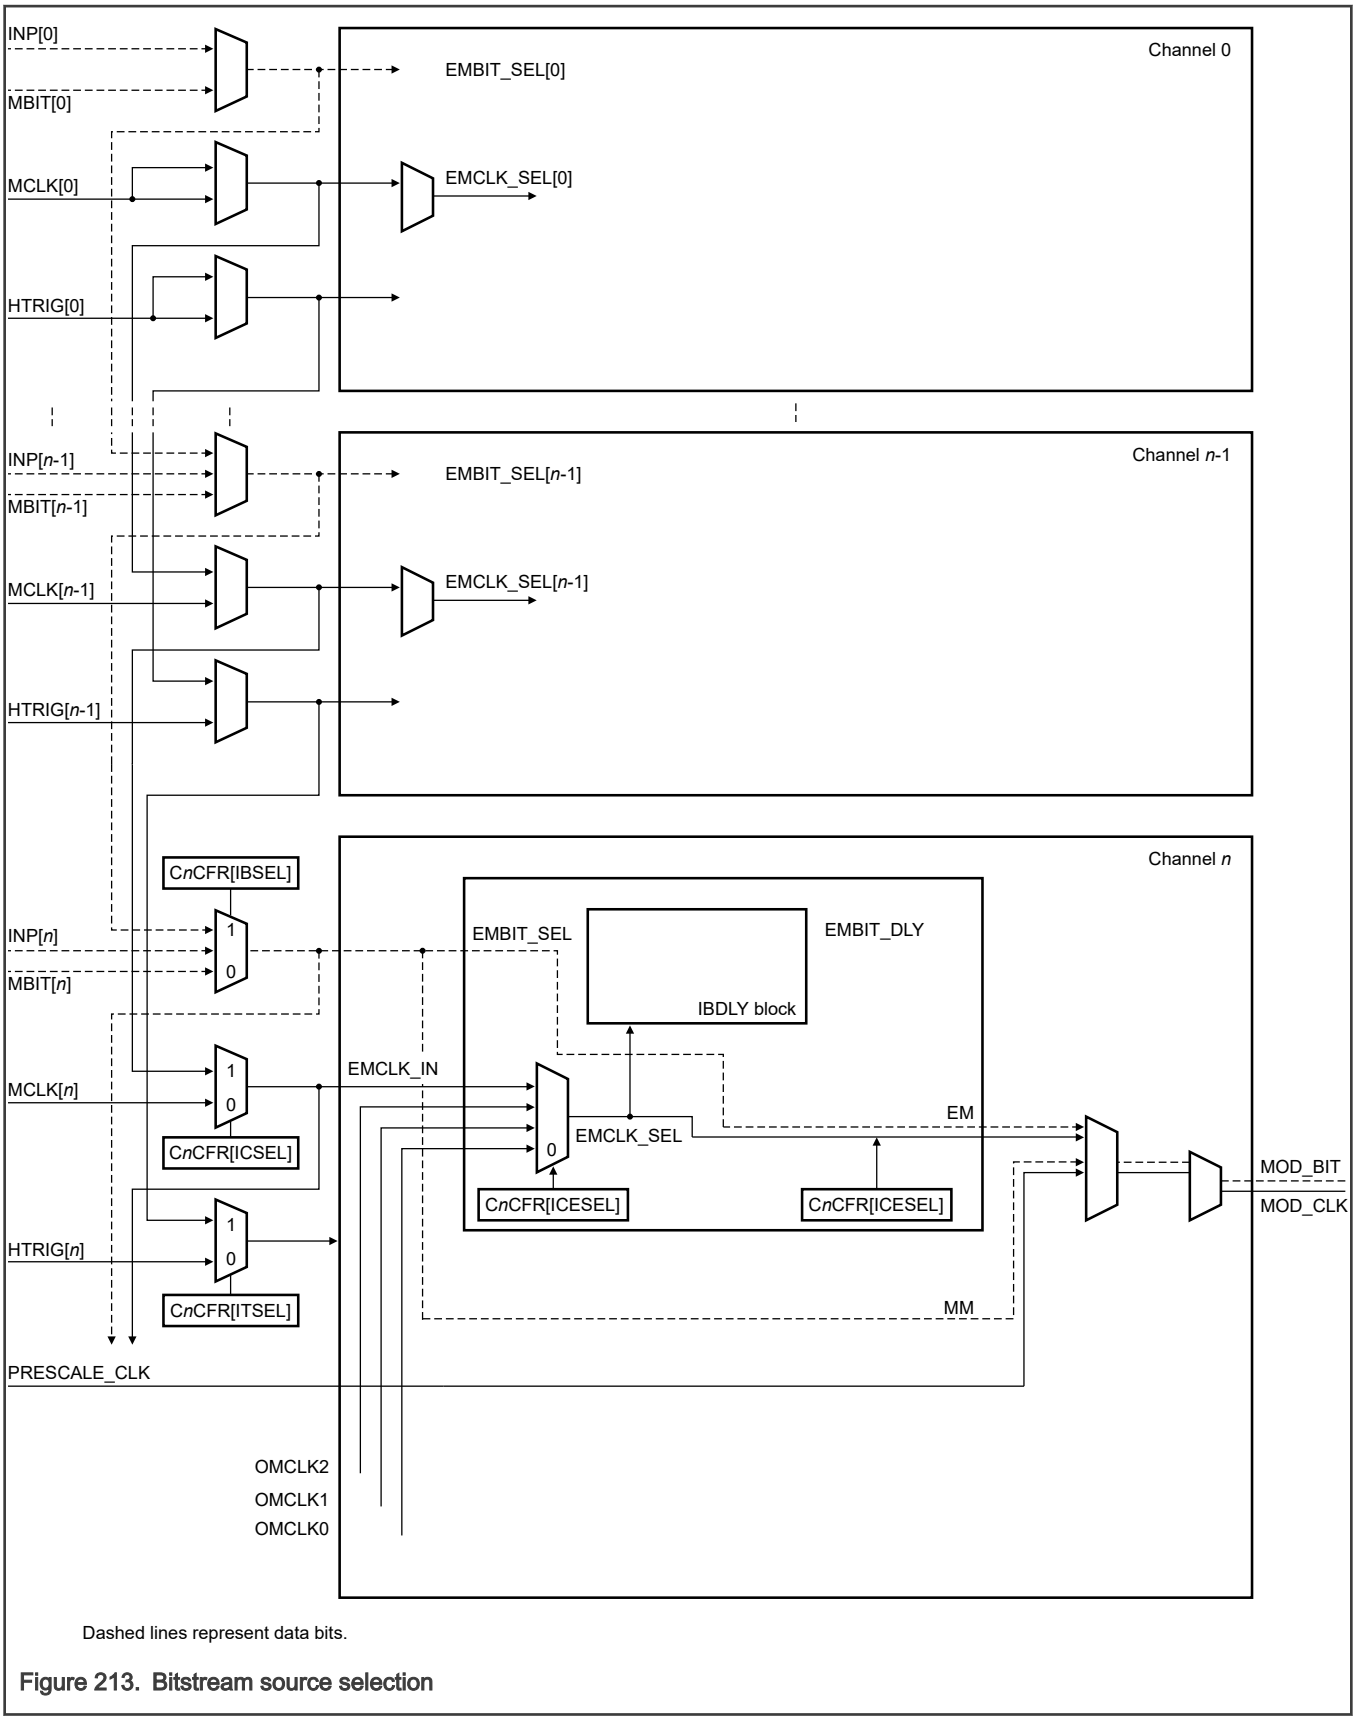
- The MBIT[3:0] signals (see External signals)
- The INP[3:0] signals (see External signals)
- Internal data from registers in Parallel or Serial mode

The following diagram shows MCLK[*n*] and MBIT[*n*] decoder circuits along with these key components:

- External modulator (EM) bitstream (see EM clock input bitstream sampling for EM clock input bitstream sampling)
- Manchester modulator (MM) bitstream (see MM clock input bitstream sampling for MM clock input bitstream sampling)
- Parallel modulator (PM) bitstream (see PM clock input bitstream sampling for PM clock input bitstream sampling)
- Serial modulator (SM) bitstream (see SM clock input bitstream sampling for SM clock input bitstream sampling)

The diagram also illustrates an example of bitstream source selection using:

- An external MCLK[*n*]
- An internal route back clock (OMCLK)
- An internal auto-generated clock for Parallel or Serial mode
- An internal auto-generated clock for Manchester format



Dashed lines represent data bits.

Figure 213. Bitstream source selection

47.3.2.3.1 Modulator bitstream and channel clock selection

Following is the modulator bitstream and clock mux configuration you could perform for each channel.

Table 395. Modulator bitstream and channel clock selection

Use C*n*CFR[IBSEL] to	Use C*n*CFR[ICSEL] to	Use C*n*CFR[ITSEL] to
Select a modulator input bitstream (EMBIT_SEL) for channel *n* that can be either of the following: • A dedicated external modulator bitstream (MBIT[*n*]) if C*n*CFR[IBSEL] = 00b • A dedicated internal modulator bitstream (INP[*n*]) if C*n*CFR[IBSEL] = 01b • A shared group bitstream from an adjacent channel (*n*-1) if C*n*CFR[IBSEL] = 11b	Select a modulator input clock (EMCLK_SEL) for channel *n* that can be either of the following: • A dedicated modulator clock (MCLK[*n*]) if C*n*CFR[ICSEL] = 011b • A shared group clock (MCLK[*n*-1]) from an adjacent channel if C*n*CFR[ICSEL] = 111b • One of the three internal clocks routed to the chip modulator output clock if C*n*CFR[ICSEL] = 000b, 001b, or 010b	Select a modulator input trigger (HTRIG_SEL) for channel *n* that can be either of the following: • A dedicated software trigger (STRIG[*n*]) if C*n*CFR[ITSEL] = 00b • A dedicated hardware trigger (HTRIG[*n*]) if C*n*CFR[ITSEL] = 01b • A shared group hardware trigger (HTRIG[*n*-1]) from an adjacent channel if C*n*CFR[ITSEL] = 11b

47.3.2.3.2 Cross channel modulator bitstreams and clock groups

Following is the modulator bitstream and clock mux configuration you could perform with an adjacent channel.

Table 396. Cross channel modulator bitstreams and clock groups

Write 111b to C*n*CFR[IBSEL] for	Write 111b to C*n*CFR[ICSEL] for	Write 11b to C*n*CFR[ITSEL] for
Combining the adjacent channel modulator bitstreams as groups, which: • Share the same modulator bitstreams and clocks if C*n*CFR[ICSEL] = 111b. • Can be configured to use one channel sample by rising edge and another channel sample by falling edge as a microphone use case. • Can be cascaded.	Combining adjacent channels as groups for the same clock to do either of these: • Reduce the I/O pin number. • Retain channels with the same time sequence. • Cascade, possibly.	Combining adjacent channels as groups for the same hardware trigger to: • Retain channels with the same time sequence. • Share the hardware trigger. • Cascade, possibly.

47.3.2.3.3 Modulator bitstream clock edge selection

Following are the modulator bitstream clock and trigger options you could use for each channel.

Table 397. Modulator bitstream clock edge selection

Use C*n*CFR[ICESEL] to	Use C*n*CFR[ITLVL] to
Select a clock edge and use the selected modulator input clock (EMCLK_SEL) as either of the following:	Select a modulator input trigger event type. The selected modulator input trigger (HTRIG_SEL) can be used as either of the following:

Table continues on the next page...

Table 397. Modulator bitstream clock edge selection

Use CnCFR[ICESEL] to	Use CnCFR[ITLVL] to
• Positive edge (by writing 001b to CnCFR[ICESEL]) • Negative edge (by writing 010b to CnCFR[ICESEL]) • Dual edge (by writing 011b to CnCFR[ICESEL]) • Every other even positive edge (by writing 101b to CnCFR[ICESEL]) • Every other odd negative edge (by writing 110b to CnCFR[ICESEL]) • Every other odd positive edge (by writing 100b to CnCFR[ICESEL]) • Every other even negative edge (by writing 111b to CnCFR[ICESEL])	• A positive edge trigger (by writing 0b to CnCFR[ITLVL]) • A high-level trigger (by writing 1b to CnCFR[ITLVL])

47.3.2.3.4 Modulator bitstream programmed delay

You can write an appropriate value to CnACFR[IBDLY] for the selected modulator bitstream to be delay sampled by the number of prescaled clock cycles. The delay number can be 0 (bypass), and extend to a maximum of 15 clock cycles.

See the following figure for a pictorial representation of the modulator bitstream programmed delay and see Modulator bitstream delay case 0, Modulator bitstream delay case 1, Modulator bitstream delay case 2, Modulator bitstream delay case 3, and Modulator bitstream delay case 4 for delay cases.

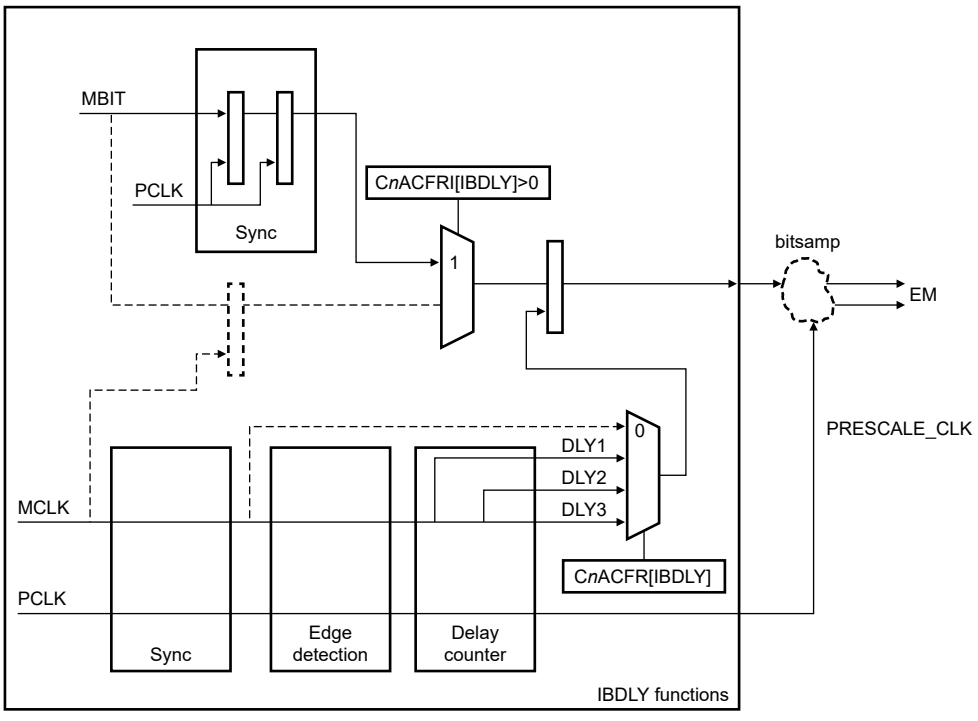


Figure 214. Modulator bitstream programmed delay

47.3.2.3.5 EM clock input bitstream sampling

See EM clock input bitstream sampling: settings for the values you need to write to SINC register fields for EM clock input bitstream sampling and see EM clock input bitstream sampling: diagram for the related bitstream sampling diagram.

47.3.2.3.5.1 EM clock input bitstream sampling: settings

Table 398. EM clock input bitstream sampling: settings

Action	Result
Writing 00b to C*n*CFR[IBFMT]	Selects the CIC filter input from the selected modulator bitstream input (EMBIT_SEL[*n*]), which the EMCLK_SEL[*n*] clock samples to meet the I/O timing requirement and deliver for further decode.
If you write 011b to C*n*CFR[ICSEL]	The selected external clock (EMCLK_SEL) becomes a dedicated modulator clock, MCLK[*n*], for this channel.
If you write 111b to C*n*CFR[ICSEL]	The selected external clock (EMCLK_SEL) becomes a shared group clock from an adjacent channel.
If you write 000b, 001b, or 010b to C*n*CFR[ICSEL]	The selected external clock (EMCLK_SEL) becomes one of the three internal clocks that are routed as modulator clock outputs.

Table continues on the next page...

Table 398. EM clock input bitstream sampling: settings (continued)

Action	Result
If you write 00b to C*n*CFR[IBSEL]	The selected external modulator bitstream (EMBIT_SEL) becomes a dedicated external modulator bitstream (MBIT[*n*]) for this channel.
If you write 01b to C*n*CFR[IBSEL]	The selected external modulator bitstream (EMBIT_SEL) becomes a dedicated internal modulator bitstream (inp[*n*]) for this channel.
If you write 11b to C*n*CFR[IBSEL]	The selected external modulator bitstream (EMBIT_SEL) becomes a shared group bitstream from an adjacent channel, *n*-1.
Writing an appropriate value to C*n*CFR[ICESEL]	Helps you select the type of edge to sample EMBIT_SEL.
Writing an appropriate value to C*n*ACFR[IBDLY]	Helps you select the modulator bitstream delay function.

NOTE

You must configure the prescaler correctly to sample EMCLK_SEL according to C*n*CFR[ICESEL]. If you configure C*n*CFR[ICESEL] as a single-edge sample, you must program the prescaler to be 3x faster than EMCLK_SEL; if you configure C*n*CFR[ICESEL] as a dual-edge sample, you must program the prescaler to be 6x faster than EMCLK_SEL.

See the following for more information:

- Modulator bitstream and channel clock selection
- Modulator bitstream programmed delay
- Bitstream source selection

47.3.2.3.5.2 EM clock input bitstream sampling: diagram

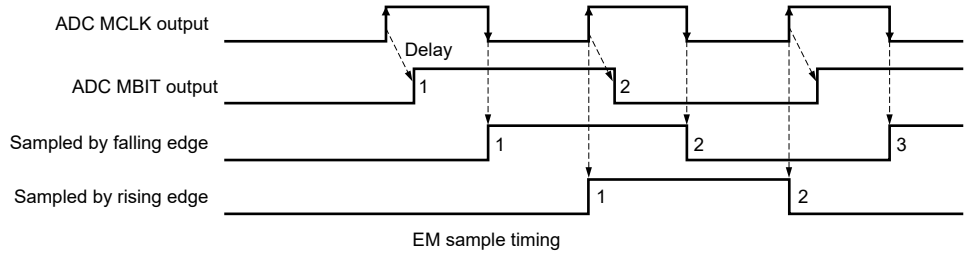

Figure 220. EM clock input bitstream sampling: diagram

47.3.2.3.6 MM clock input bitstream sampling

See MM clock input bitstream sampling: settings for the values you need to write to SINC register fields for MM clock input bitstream sampling and see MM clock input bitstream sampling: diagram for the related bitstream sampling diagram.

47.3.2.3.6.1 MM clock input bitstream sampling: settings

Table 399. MM clock input bitstream sampling: settings

Action	Result
Writing 01b to C*n*CFR[IBFMT]	Helps you select the input bitstream format as external Manchester code. The modulator clock is recovered from the bitstream.
Writing an appropriate value to C*n*CFR[ICESEL]	Helps you select the input clock edge as rising or falling, with only 001b and 010b are valid values (see MM clock input bitstream sampling: diagram).
Writing 00b to C*n*CFR[IBSEL]	Helps you define the selected external modulator bitstream (EMBIT_SEL) as a dedicated external modulator bitstream (MBIT[*n*]) for this channel.
Writing 01b to C*n*CFR[IBSEL]	Helps you define the selected external modulator bitstream (EMBIT_SEL) as a dedicated internal modulator bitstream (INP[*n*]) for this channel.
Writing 11b to C*n*CFR[IBSEL]	Helps you define the selected external modulator bitstream (EMBIT_SEL) as a shared group bitstream from an adjacent channel, *n*-1.
Writing an appropriate value to C*n*MPDATA	Helps you define the correct threshold for the Manchester decoder. The threshold value must lie between the long pulse width and the short pulse width, and the prescaler clock counts this MBIT[*n*] pulse width. As shown in MM clock input bitstream sampling: diagram, if the previous short pulse is not recovered correctly, the first long pulse is considered as the first valid bit used for whole packet synchronization.

For more on the aforementioned settings, see the following:

- Modulator bitstream and channel clock selection
- Bitstream source selection

47.3.2.3.6.2 MM clock input bitstream sampling: diagram

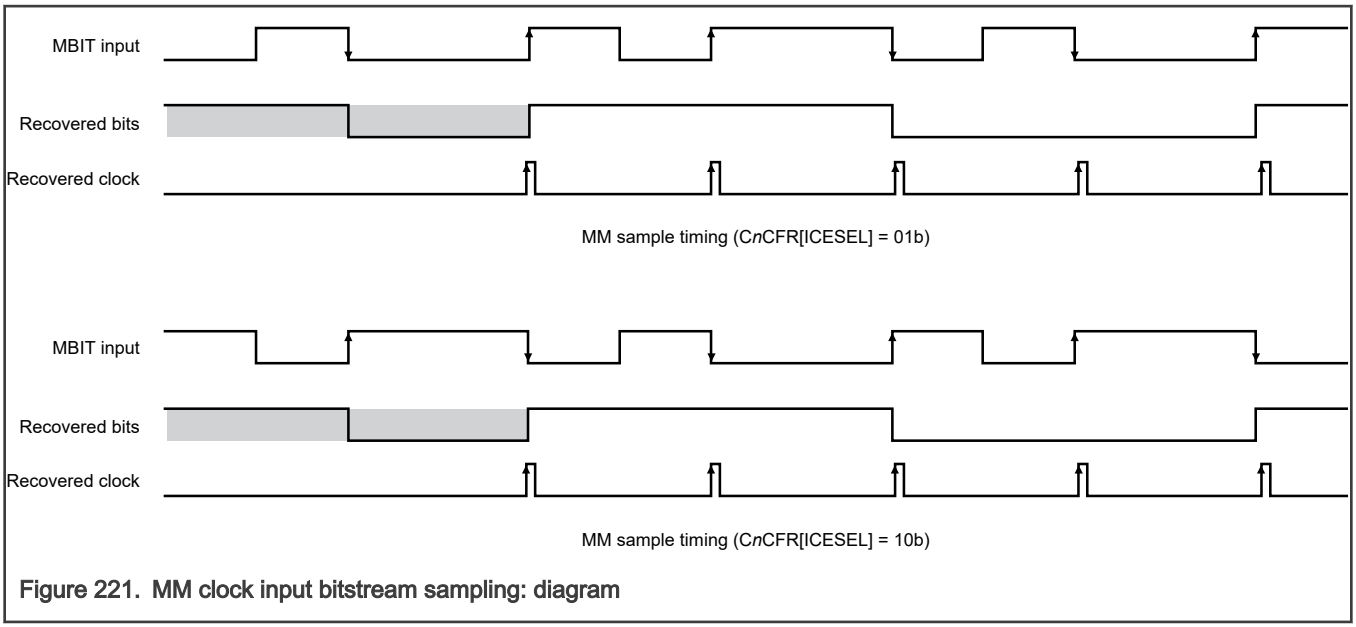

Figure 221. MM clock input bitstream sampling: diagram

47.3.2.3.7 PM clock input bitstream sampling

Table 400. PM clock input bitstream sampling

Action	Result
Writing 10b to CnCFR[IBFMT]	Selects the CIC filter input from Channel n Multipurpose Data (C0MPDATA - C4MPDATA).
Checking the value of CnSR[PSRDY]	Helps you determine if the next write is allowed. CnSR[PSRDY] = 1 indicates that the previously written data is processed and the field is waiting for the next PM write.
Writing to CnCFR[RDFMT]	Selects PM data as signed or unsigned.
Writing to Channel n Multipurpose Data (C0MPDATA - C4MPDATA)	Sends the lower 16 bits to the CIC filter. The PM clock generates automatically after a write event; IMCLK0 decides the clock rate. If a PM write is not allowed (CnSR[PSRDY] = 0 when CnCFR[IBFMT] = 10), writing to Channel n Multipurpose Data (C0MPDATA - C4MPDATA) returns a bus error.

NOTE

Modulator clocks are automatically generated when you write data to Channel n Multipurpose Data (C0MPDATA - C4MPDATA). Because of conversion latency, you must write an extra two dummy data samples to provide extra clocks after the conversion is complete.

47.3.2.3.8 SM clock input bitstream sampling

See SM clock input bitstream sampling: settings for the values you need to write to SINC register fields for SM clock input bitstream sampling and see SM clock input bitstream sampling: diagram for the related bitstream sampling diagram.

47.3.2.3.8.1 SM clock input bitstream sampling: settings

Table 401. SM clock input bitstream sampling: settings

Action	Result
Writing 11b to C*n*CFR[IBFMT]	Selects the CIC filter input from Channel n Multipurpose Data (C0MPDATA - C4MPDATA). The entire 32-bit serial data is shifted to the CIC filter. SM clocks are auto generated after a write event, and IMCLK0 decides the clock rate.
Checking the value of C*n*SR[PSRDY]	Determines if the next SM write is allowed. C*n*SR[PSRDY] = 1 indicates that the previously written data is processed and the field is waiting for the next SM write.
Writing to Channel n Multipurpose Data (C0MPDATA - C4MPDATA) for SM	Returns a bus error if an SM write is not allowed (C*n*SR[PSRDY] = 0), and no bitstream remains to be shifted after conversion finishes (C*n*CFR[IBFMT] = 11b).

NOTE

After conversion, the remaining bits are retained in Channel n Multipurpose Data (C0MPDATA - C4MPDATA). To reset them, you could toggle C*n*CR[CHEN] or MCR[RST].

47.3.2.3.8.2 SM clock input bitstream sampling: diagram

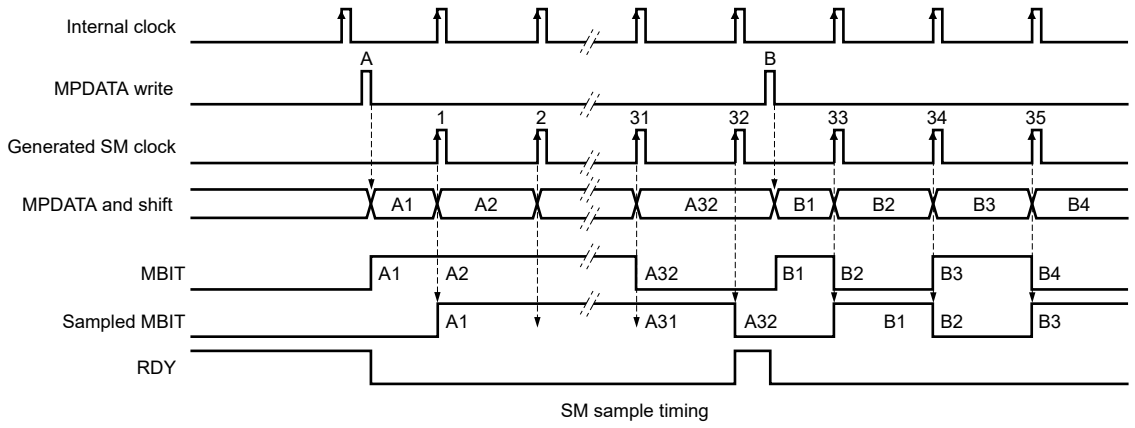

Figure 222. SM clock input bitstream sampling: diagram

47.3.2.4 Conversion process

47.3.2.4.1 Modes and behaviors

After a conversion process triggers:

- The decimation filters are activated.
- NIS[COC*n*] becomes 1 after the conversion completes.

You could use C*n*DR[PFCM] to select one of the conversion modes shown in the following table.

Table 402. Modes and behaviors

Mode	Behavior of the conversion process in this mode
Single (C*n*DR[PFCM] = 00b)	• Each conversion requires a conversion trigger. • A single trigger starts only one conversion.
Continuous (C*n*DR[PFCM] = 01b)	• After a trigger is detected, the conversion process continues until the next trigger event. • The conversion process also continues after the first sample. You can perform a series of conversions at the rate of one sample per decimation clock cycle, which equals the value of C*n*DR[PFOSR] + 1. For details on subsequent samples, see Total conversion time. • The next trigger cancels the current conversion and restarts it.
Always (C*n*DR[PFCM] = 10b)	• After a trigger is detected, the conversion process continues until it is disabled. • Conversions also continue after the first sample. You can perform a series of conversions at the rate of one sample per decimation clock cycle, which equals the value of C*n*DR[PFOSR] + 1. For details on subsequent samples, see Total conversion time. • The next trigger event is ignored.
Fixed-Number (C*n*DR[PFCM] = 11b)	• After a trigger is detected, the conversion process continues until the required conversion number is achieved or until the next trigger event. • The conversion process stops when NIS[CHF*n*] becomes 1, so you can configure C*n*CFR[FIFOWMK] to determine the number of needed conversions. • The conversion process also continues after the first sample. You can perform a series of conversions at the rate of one sample per decimation clock cycle, which equals the value of C*n*DR[PFOSR] + 1. For details on subsequent samples, see Total conversion time. • The next trigger cancels the current conversion and restarts it.

47.3.2.4.2 Completion

Following are some of the events that take place after a conversion completes:

- The new sample value is transferred to the FIFO, and you can get the FIFO content by reading Channel n Result Data (C0RDATA - C4RDATA).
- NIS[COC*n*] becomes 1 and the FIFO data is available.
- NIS[CHF*n*] becomes 1 if the FIFO from the PF channel *n* has overflowed its watermark level and the FIFO data is available.
- A conversion complete and CHF interrupt are asserted if NIE[COCIE*n*] = 1 or NIE[CHFIE*n*] = 1.
- A DMA request and CHF are asserted if C*n*CR[DMAEN] = 1.

Additionally, you can read the current conversion data directly from Channel n Result Data (C0RDATA - C4RDATA) if FIFO is disabled.

47.3.2.4.3 Discontinuation

Conversion involves the following steps:

- CIC calculation
- Shift
- DC removal
- Bias
- Push FIFO and interrupt

You could abort a conversion by using any of these techniques:

- Disable
- Next Trigger
- Stop

This is what you could do to abort conversions, by using different register fields, modes, and triggers:

- To abort a conversion in progress, disable the PF by writing 0 to C*n*CR[PFEN]. However, in case you cancel the CIC filter by using C*n*CR[PFEN], the SCD and CAD blocks can still keep working.
- To abort a conversion along with its subfunctions (PF, CAD, and SCD), disable the channel by writing 0 to C*n*CR[CHEN].
- To abort or disable all the conversions globally, write 0 to MCR[MEN]. The FIFO retains the values of the previous conversion result that had not been read.
- In Single and Continuous conversion modes, if you select an edge trigger, a new trigger aborts the current conversion and restarts a new one.
- If you select a level trigger, a deasserted software or hardware trigger cancels the current conversion.
- In Stop mode, the current conversion is canceled.

If an abort occurs after the CIC filter has performed its function, you could:

- Use the Disable or Stop technique to cancel the current conversion immediately.
- Use the Next Trigger technique for the current conversion to continue the shift and bias operations and save the result to the FIFO. At the same time, the CIC can process the next conversion.

NOTE

For a motor use case, you must calculate the maximum speed (trigger frequency) to ensure that the required conversion number and the next trigger do not overlap. The margin must be at least two modulator clocks.

47.3.2.5 Conversion timing

47.3.2.5.1 Total conversion time

Table 403. Total conversion time

In this mode:	The conversion time is:
Single	The value derived using this formula for a single conversion after the trigger event is over: ORD × OSR × MOD_CLK period
Continuous	The value derived using this formula for the first 24-bit sample after the trigger event is over: ORD × OSR × MOD_CLK period However, the subsequent 24-bit samples are available after the OSR × MOD_CLK period.
Always	
Fixed-Number	

where MOD_CLK period = 1 ÷ the frequency of MOD_CLK.

During a conversion, if you opt to resynchronize the conversion by providing a trigger, the first conversion result is available after the ORD × OSR × MOD_CLK period.

However, if you opt for a run-time phase compensation for a channel, SINC does not support it. You must provide a hardware trigger delay (for example, a PDB block) at the chip level. SINC does not support a software trigger delay.

47.3.2.5.2 Trigger alignment

When a trigger asserts, the recovered modulator clock samples the trigger event (see MOD_CLK in Bitstream source selection). At the same time, the modulator clock samples the MBIT[*n*] signal (see External signals). Therefore, the first valid bitstream to CIC is the clock cycle during which the trigger is asserted.

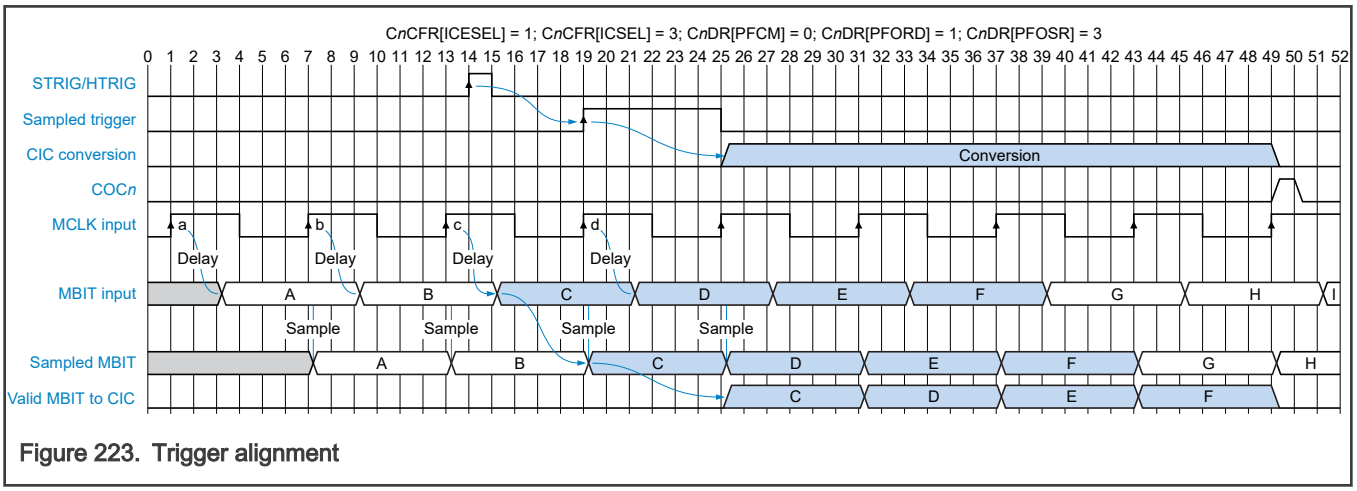

Figure 223. Trigger alignment

47.3.2.6 Trigger timing

47.3.2.6.1 Single mode software edge trigger

As illustrated in the following figure, when a software edge trigger event occurs in Single mode:

- Triggers a and b are ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger c starts conversion C1; trigger d starts conversion D1.
- Trigger e starts conversion e1 and trigger f cancels it before the conversion is complete. Simultaneously, trigger f starts (or resynchronizes) conversion F1.
- Trigger g starts conversion g1 but deassertion of the "Enable" signal cancels it.

See Total conversion time that defines the formula for Single mode conversion time.

NOTE

- The "Enable" signal is a combined AND logic of C*n*CR[PFEN] and SR[CHRDY*n*].
- You write 1 to MCR[STRIG*n*] and SINC writes 0 to this field for a software edge trigger case.

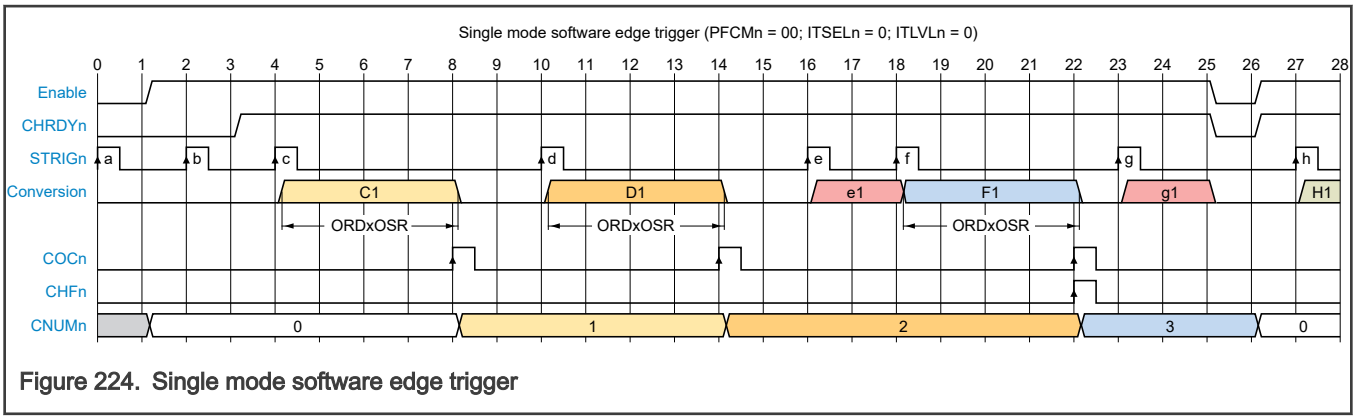

Figure 224. Single mode software edge trigger

47.3.2.6.2 Single mode hardware edge trigger

As illustrated in the following figure, when a hardware edge trigger event occurs in Single conversion mode:

- Triggers a and b are ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger c starts conversion C1; trigger d starts conversion D1.
- Trigger e starts conversion e1, but trigger f cancels it before completion. Simultaneously, trigger f starts (or resynchronizes) conversion F1.
- Trigger g starts conversion g1 but deassertion of the "Enable" signal cancels it.

The external hardware both asserts and deasserts the HTRIG[*n*] signal (see External signals); however, only the rising edge of the signal is accepted as the startup event for conversion. For example, trigger d exists several times, but the fall of trigger g does not cancel conversion D1.

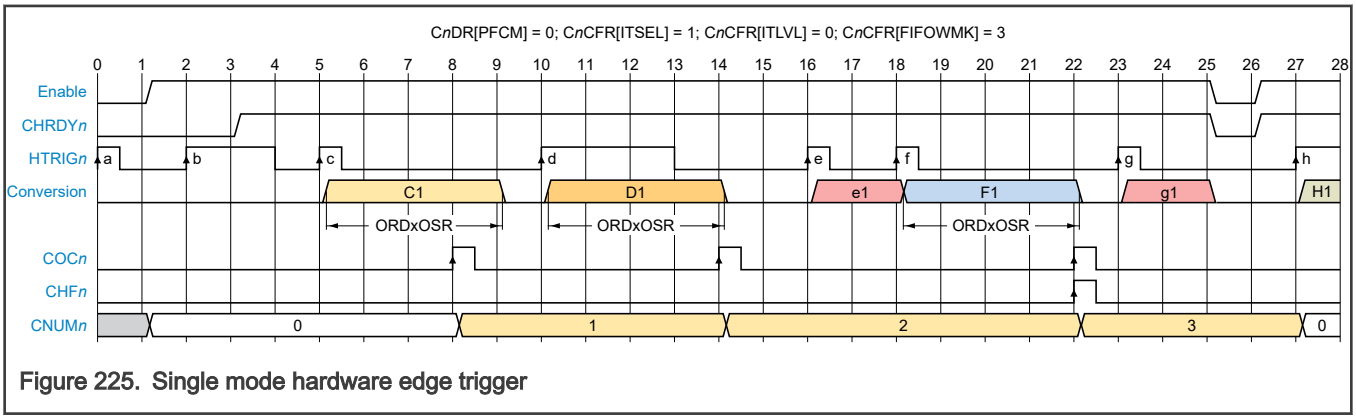

Figure 225. Single mode hardware edge trigger

47.3.2.6.3 Single mode hardware level trigger

As illustrated in the following figure, when a hardware level trigger event occurs in Single mode:

- Trigger a is ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger b starts conversion B1; trigger c starts conversion C1.
- Trigger d starts conversion d1 but the conversion cancels because trigger d deasserts before conversion completion.
- Trigger f starts conversion f1 but the conversion cancels because the "Enable" signal deasserts.

An external hardware asserts and deasserts HTRIG[*n*]. The rising of HTRIG[*n*] starts the conversion and the falling of HTRIG[*n*] cancels the conversion before its completion.

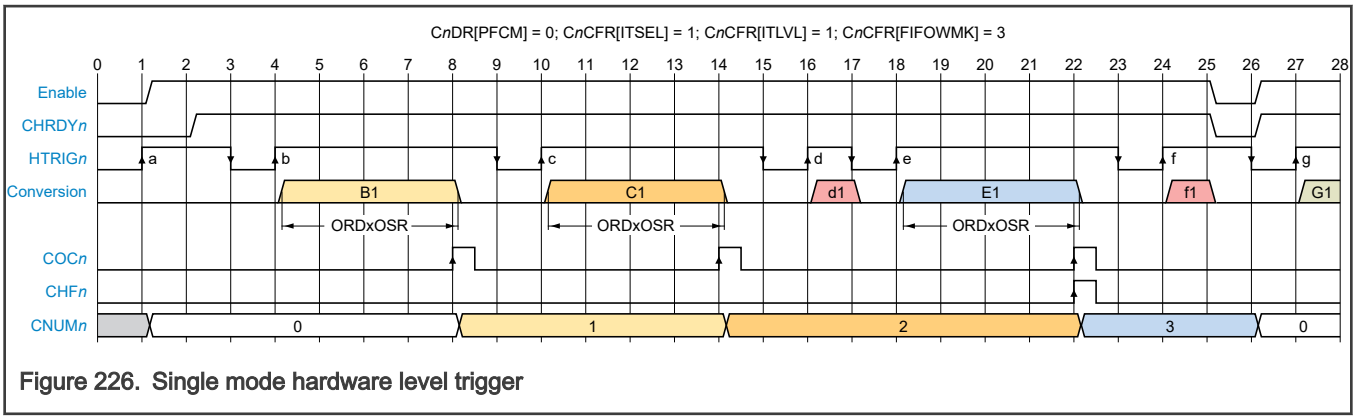

Figure 226. Single mode hardware level trigger

47.3.2.6.4 Continuous mode software edge trigger

In Continuous mode, conversions comprise a set of subconversions and continue until aborted by another event. For example, as shown in the following figure, conversion C comprises subconversions C1, C2, C3, c4, and so on; and conversion D comprises subconversions D1, D2, d3, and so on. When a software edge trigger event occurs in Continuous conversion mode:

- Triggers a and b are ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger c starts conversion C1 and trigger d starts conversion D1.
- The output delay time for C1 is defined as OSR×ORD. When conversion C1 comes to an end, conversion C2 starts automatically.
- The output delay time for C2 is defined as OSR, and so is the output delay time for conversion C3.
- Trigger d cancels conversion c4 and simultaneously resynchronizes conversion D1.
- Writing 0 to C*n*CR[PFEN] cancels conversion d3.

You write 1 to MCR[STRIG*n*] and SINC writes 0 to this field for a software edge trigger event in Continuous mode.

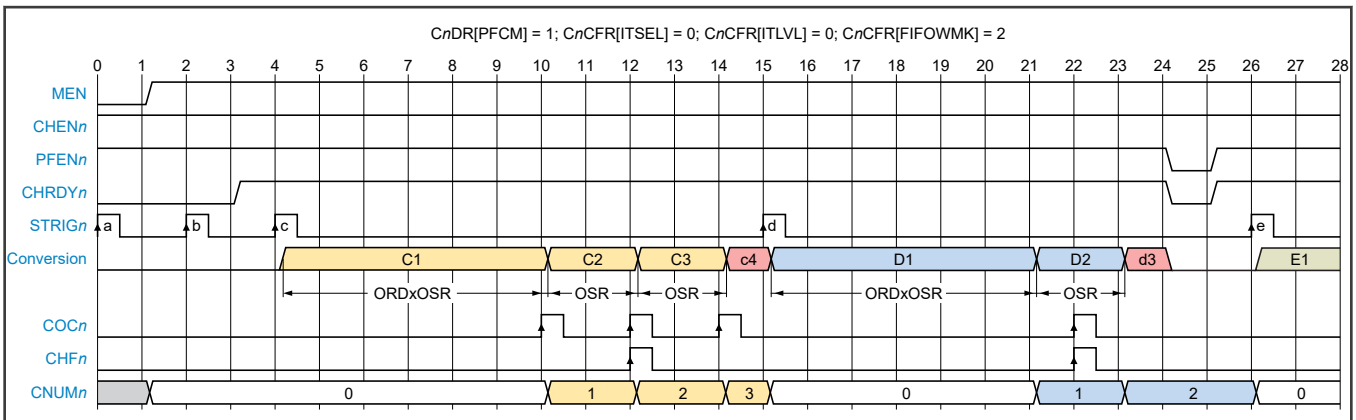

Figure 227. Continuous mode software edge trigger

47.3.2.6.5 Continuous mode hardware edge trigger

As illustrated in the following figure, when a hardware edge trigger event occurs in Continuous mode:

- Triggers a and b are ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger c starts conversion C1, and hardware trigger d starts conversion D1.
- The output delay time for C1 is defined by OSR×ORD. After conversion C1 comes to an end, conversion C2 starts automatically.

- The output delay time for C2 is defined as OSR, and so is the output delay time for C3.
- Trigger d cancels conversion c4 and simultaneously resynchronizes conversion D1.
- Writing 0 to C*n*CR[PFEN] cancels conversion d4.

The external hardware asserts and deasserts HTRIG[*n*]. However, only the rising of HTRIG[*n*] starts the conversion. For example, the hardware trigger d exists several times, but the fall of trigger d does not cancel conversion D1. Hardware trigger b asserts before SR[CHRDY*n*] becomes 1 and remains asserted after SR[CHRDY*n*] becomes 1, but no conversion starts.

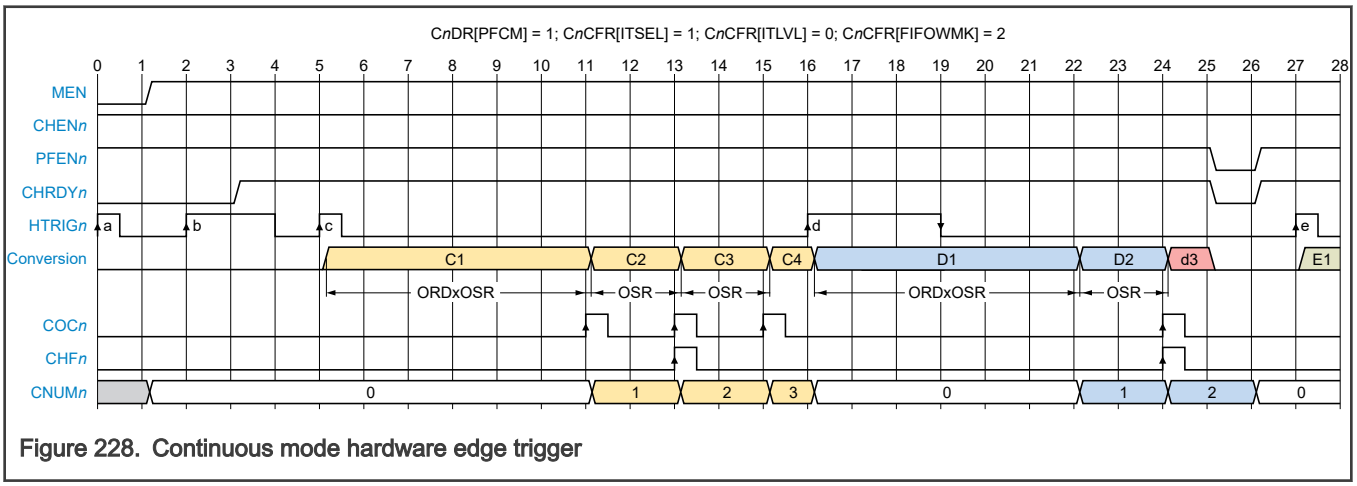

Figure 228. Continuous mode hardware edge trigger

47.3.2.6.6 Continuous mode software level trigger

As illustrated in the following figure, when a software level trigger event occurs in Continuous mode:

- Triggers a and b are ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger c starts conversion C1; trigger d starts conversion D1.
- The output delay time for C1 is defined as OSR×ORD. After conversion C1 comes to an end, conversion C2 starts automatically.
- The output delay time for C2 is defined as OSR, and so is the output delay time for C3.
- Trigger c deassertion cancels conversion c4.
- Signal "Enable" deassertion cancels conversion d3.

For a software level trigger event in Continuous mode, you can write both 1 (to start the conversion process) and 0 (to stop the conversion process) to MCR[STRIG*n*] if SR[CHRDY*n*] is 1. SINC can also write 0 to MCR[STRIG*n*] to cancel the conversion. The following example shows writing 0 to MCR[STRIG*n*] cancels conversion c4.

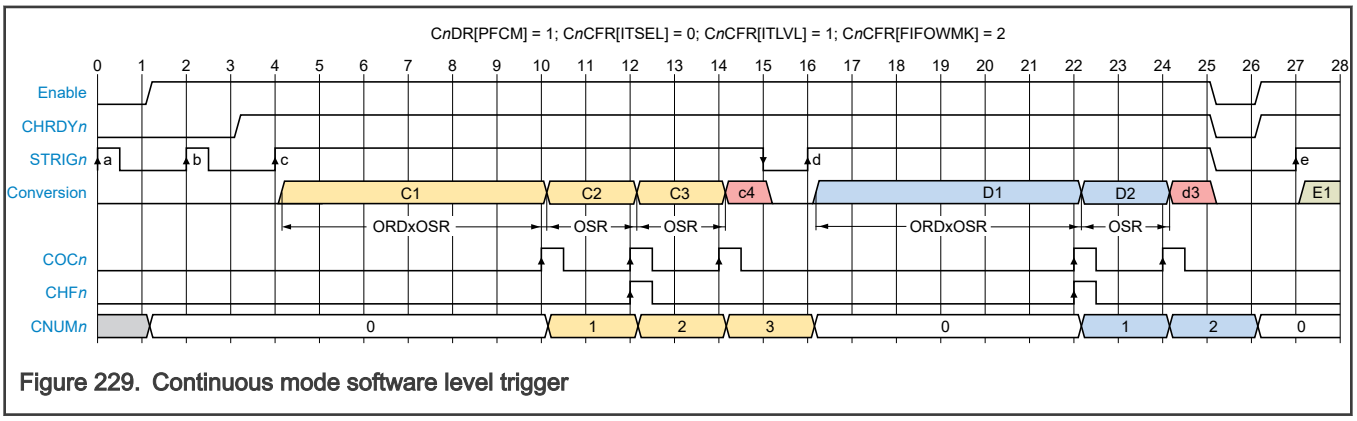

Figure 229. Continuous mode software level trigger

47.3.2.6.7 Continuous mode hardware level trigger

As illustrated in the following figure, when a hardware level trigger event occurs in Continuous mode:

- Triggers a and b are ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger c starts conversion C1; and trigger d starts conversion D1.
- The output delay time for C1 is defined as OSR×ORD. When conversion C1 comes to an end, conversion C2 starts automatically.
- The output delay time for C2 is defined as OSR, and so is the output delay time for conversion C3.
- Trigger c deassertion cancels conversion c4.
- Signal "Enable" deassertion cancels conversion d3.

An external hardware asserts and deasserts HTRIG[*n*]. It asserts HTRIG[*n*] to start the conversion process and deasserts it to stop the conversion process. The following example shows that HTRIG[*n*] deassertion cancels conversion c4.

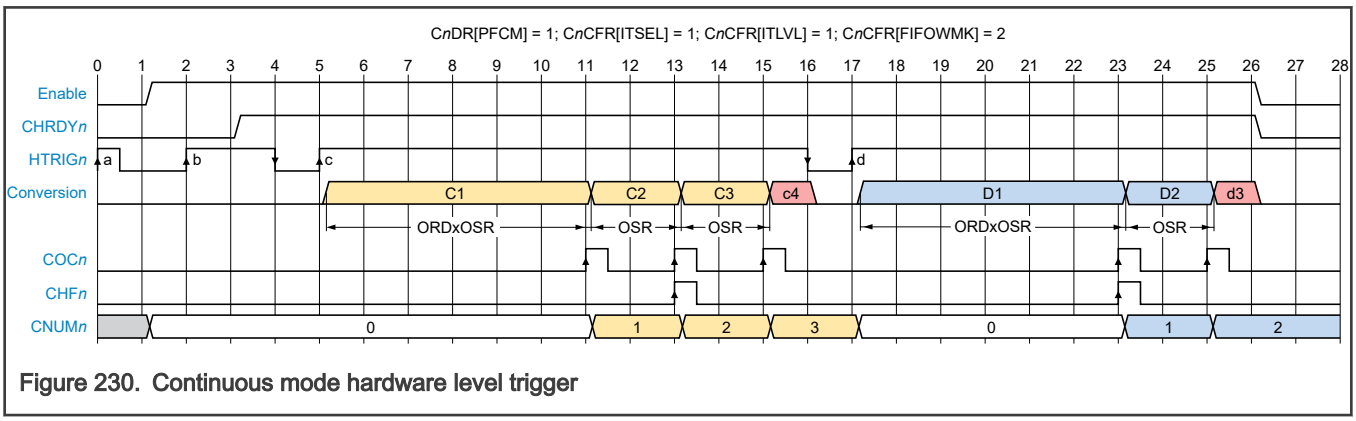

Figure 230. Continuous mode hardware level trigger

47.3.2.6.8 Always mode hardware edge trigger

As illustrated in the following figure, when a hardware edge trigger event occurs in Always mode:

- Triggers a and b are ignored because SR[CHRDY*n*] = 0 (not ready for conversion).
- Trigger c starts conversion C1; trigger e starts conversion D1.
- The output delay time for C1 is defined as OSR×ORD. After conversion C1 comes to an end, conversion C2 starts automatically.
- The output delay time for C2 is defined as OSR, and so is the output delay time for conversion C3.
- Trigger d is ignored.

After the conversion process starts in this mode, the only way to stop it is by writing 0 to MCR[MEN], C*n*CR[CHEN], or C*n*CR[PFEN].

An external hardware both asserts and deasserts HTRIG[*n*].

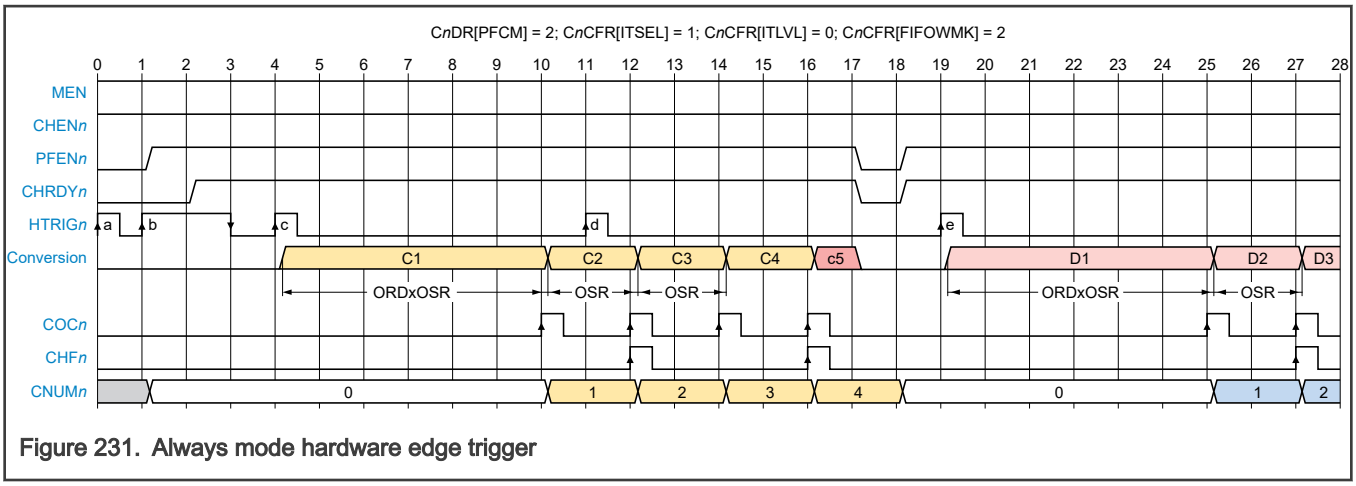

Figure 231. Always mode hardware edge trigger

47.3.2.7 PF

SINC's PF comprises the following:

- A CIC filter
- An optional HPF for DC removal operations
- A shift
- An optional bias

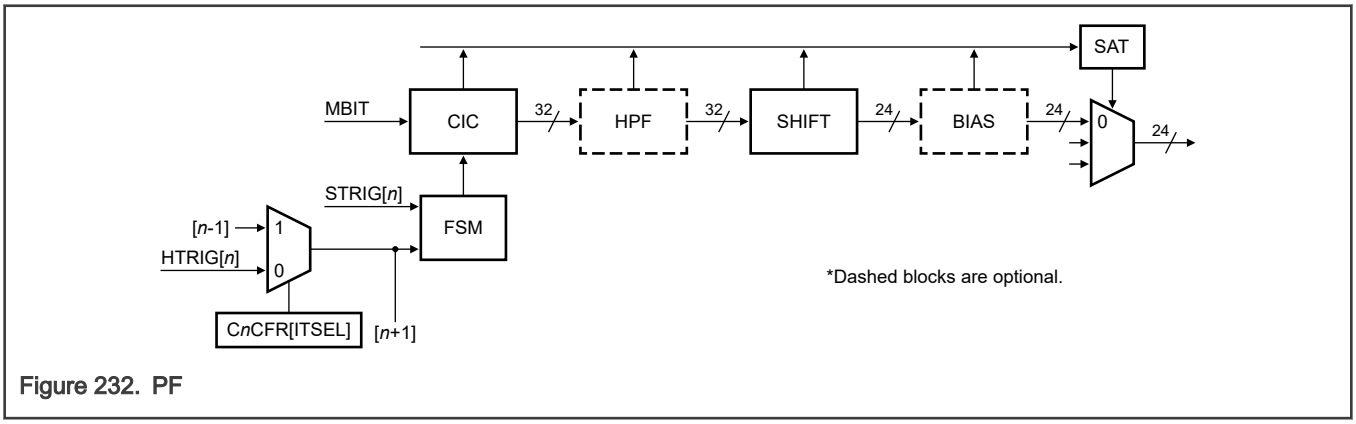

Figure 232. PF

47.3.2.7.1 CIC filter

CIC filters:

- Consist of one or more integrator and comb filter pairs.
- Represent an optimized implementation of low-pass filters (LPFs) with programmable, multiple stages.
- Are widely used because they can be implemented using just adders and subtractors.
- Output raw 32-bit data and deliver it to the HPF (or to the PF shift if HPF is not present).
- Select a CIC filter input, decode modulator bitstream, and decode modulator clock from the recovery block.

The following figure shows the architecture of a three-stage CIC filter, comprising integrator sections followed by comb sections downsampled.

See CnDR[PFORD] for information on PF order and CnDR[PFOSR] for information on PF OSR.

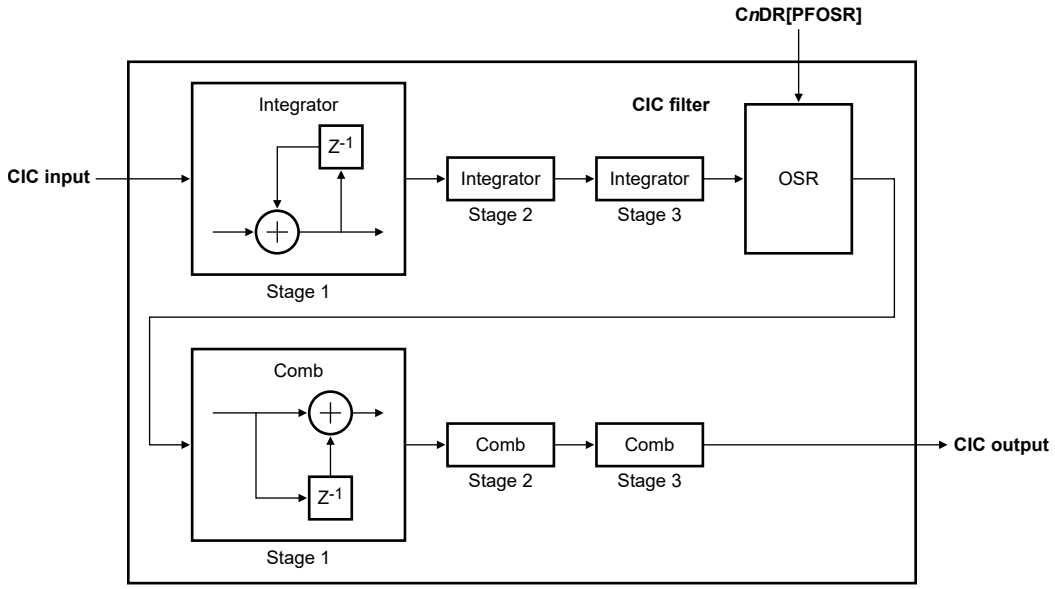

Figure 233. CIC filter

47.3.2.7.1.1 CIC filter transfer function

You can calculate the transfer function of the CIC filter, when C*n*DR[PFORD] is any value except 0, based on the following equation.

$$H(Z) = \frac{Y(Z)}{X(Z)} = \left[\frac{1-Z^{-OSR}}{1-Z^{-1}}\right]^{ORD}$$

Equation 21. CIC filter transfer function

You can see an example of Frequency Response in Frequency response

You can get CIC output effective data width by below equation. Where OSR are described at Equation for OSR.

when C*n*CFR[RDFMT]=0b(signed):

WDITH = log2(OSR^^C*n*DR[PFORD]+1)+1

when C*n*CFR[RDFMT]=1b(unsigned):

WDITH = log2(OSR^^C*n*DR[PFORD]+1)

Equation 22. Equation for CIC effective data width

47.3.2.7.1.2 FastSinc filter transfer function

You can calculate the transfer function of the FastSinc filter, when C*n*DR[PFORD] = 0, based on the following equation.

$$H(Z) = \frac{Y(Z)}{X(Z)} = \left[\frac{1-Z^{-OSR}}{1-Z^{-1}}\right]^{2} * \left[1+Z^{-2*OSR}\right]$$

Equation 23. FastSinc filter transfer function

You can get CIC output effective data width by below equation. Where OSR are described at Equation for OSR

when C*n*CFR[RDFMT]=0b(signed):

WDITH = log2(OSR^^2*2+1)+1

when C*n*CFR[RDFMT]=1b(unsigned):

WDITH = log2(OSR^^2*2+1)

Equation 24. Equation for CIC effective data width

47.3.2.7.1.3 CIC effective data width

You can see an example of Frequency Response in Frequency response

You can get example CIC output effective data width by Table 404. Where OSR are described at Equation for OSR

Table 404. data width vs OSR and ORD

OSR	C*n*CFR[RDFMT]=0b(signed)				C*n*CFR[RDFMT]=1b(unsigned)			
	PFORD=1	PFORD=2	PFORD=0 (fastsinc)	PFORD=3	PFORD=1	PFORD=2	PFORD=0 (fastsinc)	PFORD=3
16	6	10	11	14	5	9	10	13
32	7	12	13	17	6	11	12	16
64	8	14	15	20	7	13	14	19
128	9	16	17	23	8	15	16	22
256	10	18	19	26	9	17	18	25
1291	12	22	23	33(not support)	11	21	22	32
1626	12	23	24	34(not support)	11	22	23	33(not support)

47.3.2.7.2 Trigger events

The following table shows trigger cases based on the configuration of PF conversion modes (C*n*DR[PFCM]), input trigger selection (C*n*CFR[ITSEL]), and input trigger level type (C*n*CFR[ITLVL]).

NOTE

C*n*CFR[ITSEL] = 11b indicates that a grouped trigger shared with an adjacent channel behaves in the same way as a hardware trigger (01b).

Table 405. Trigger events

C*n*DR[PFCM]	C*n*CFR[ITSEL]	C*n*CFR[ITLVL]	Case	Functioning
00	00	0	Single mode software edge trigger	• Writing 1 to MCR[STRIG*n*] starts the conversion process. In case of an ongoing conversion, writing 1 to this field cancels it and starts a new conversion. • MCR[STRIG*n*] automatically becomes 0 after the conversion starts.

Table continues on the next page...

Table 405. Trigger events (continued)

CnDR[PFCM]	CnCFR[ITSEL]	CnCFR[ITLVL]	Case	Functioning
	00	1	Single mode software level trigger	Reserved
	01	0	Single mode hardware edge trigger	• An external hardware trigger rising edge starts the conversion process. • The next trigger during conversion cancels the current conversion and restarts a new one.
	01	1	Single mode hardware level trigger	• An external hardware trigger rising edge starts the conversion process. • The hardware trigger deasserts during conversion and cancels the current conversion.
01	00	0	Continuous mode software edge trigger	• Writing 1 to MCR[STRIGn] starts the conversion process, which continues unless the filter is disabled. In case of an ongoing conversion, writing 1 to this field cancels it and starts a new conversion. • MCR[STRIGn] automatically becomes 0 after the conversion starts.
	00	1	Continuous mode software level trigger	• Writing from 0 to 1 to MCR[STRIGn] starts the conversion process, which continues unless the channel filter is disabled. • Writing 0 to MCR[STRIGn] cancels the current conversion.
	01	0	Continuous mode hardware edge trigger	• An external hardware trigger rising edge starts the conversion process, which continues unless the channel filter is disabled. • The next trigger cancels the current conversion and restarts a new one.
	01	1	Continuous mode hardware level trigger	• An external hardware trigger rising edge starts the conversion process, which continues unless the channel filter is disabled. • The hardware trigger deasserts and cancels the current conversion.

Table continues on the next page...

Table 405. Trigger events (continued)

CnDR[PFCM]	CnCFR[ITSEL]	CnCFR[ITLVL]	Case	Functioning
10	00	0	Always mode software edge trigger	Reserved
	00	1	Always mode software level trigger	Reserved
	01	0	Always mode hardware edge trigger	• An external hardware trigger rising edge starts the conversion process, which continues unless the channel filter is disabled. • The next trigger is ignored.
	01	1	Always mode hardware level trigger	Reserved
11	Any value	1	Always mode hardware level trigger	• Trigger behavior is the same as in Continuous mode for CnCFR[ITSEL] and CnCFR[ITLVL]. • The conversion process automatically stops when the FIFO watermark is asserted.

47.3.2.7.3 HPF transfer function for DC removal

An HPF performs the DC removal function. The CIC filter provides an input to the HPF and outputs 32-bit data, which is sent to the PF shift.

CnACFR[HPFA] specifies the HPF alpha coefficient or disables the HPF when it is 0.

The HPF restarts if CnCR[CHEN] changes from 0 to 1 (in case of a rise event) and the following transfer function specifies the HPF frequency response.

$$H(Z) = \frac{Y(Z)}{X(Z)} = \frac{1\text{-}Z^{-1}}{1\text{-}aZ^{-1}}$$

Equation 25. HPF transfer function for DC removal

NOTE

For DC removal, you can perform HPF gain compensation and use only the signed data format.

47.3.2.7.4 Shift

The CIC filter outputs raw 32-bit data. The higher part of that data is most likely to consist of zeros or sign bits. You must shift this data to attain 24-bit alignment.

If the raw CIC data contains more than 24 bits, then you must shift it right by CnCFR[PFSFT] to fill bits 23–0, and copy the result to data bits 31–8.

If the raw CIC data contains fewer than 24 bits, then you must shift it left by CnCFR[PFSFT] to fill bits 23–0, and copy the result to data bits 31–8.

For right shift, SINC rounds the result up (as if adding 0.5×LSB) before truncation.

Rounding is not necessary for a left shift. If the shift and rounding result is more than 24 bits, the result is saturated and SINC changes the corresponding saturation status field to 1.

47.3.2.7.4.1 Shift right block diagram

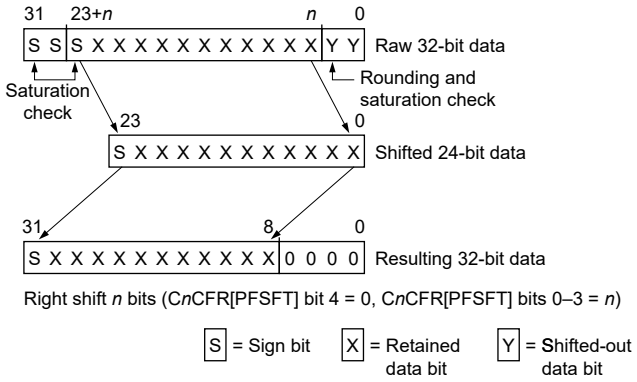

Figure 234. Shift right block diagram

47.3.2.7.4.2 Shift left block diagram

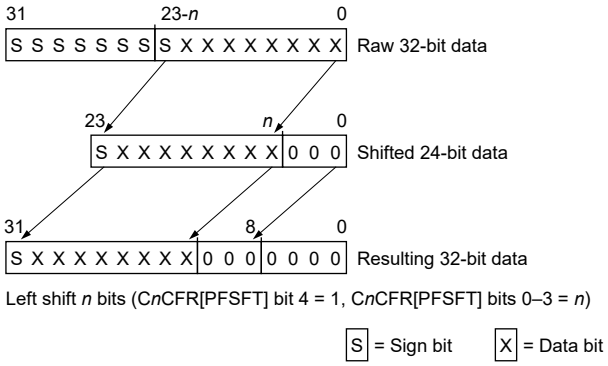

Figure 235. Shift left block diagram

47.3.2.7.5 Bias setting

Channel n Bias (C0BIAS - C4BIAS) specifies a bias offset for PF output, derives input from PF shift, and outputs the final result or value to FIFO and other compare blocks. The valid value is represented in the two's-complement format and the PF subtracts this bias value from the data.

47.3.2.8 SCD operations

An SCD is applied to each channel. Its purpose is to quickly respond if an analog signal is close to its maximum threshold value. The SCD can detect both short-circuit (overcurrent) and open-circuit (overvoltage) errors.

NOTE

An SCD does not support parallel modulator inputs.

Table 406. SCD operations

Using	You can
C*n*CR[SCDEN]	Write 0 to disable the SCD.
EIS[SCD*n*]	Check whether SINC detected a short circuit on filter channel *n*.
Channel n Debug (C0DBGR - C4DBGR) with an appropriate value of C*n*CR[DBGSEL]	Check SCD status anytime. When an SCD event occurs, the SCD continues to count for the same field until a bit toggle occurs and holds the counter for you to read.
EIE[SCDIEn]	Enable and disable the Short Circuit Detected interrupt for filter channel *n*.
C*n*PROT[SCDBK]	Enable and disable the automatic assertion of the BREAK_SCD signal (see External signals).
C*n*PROT[SCDLMT]	Specify the threshold value of the SCD counter. There exists an upcounting counter on each input channel that counts consecutive 0s or 1s on the modulator bitstream. The counter restarts in case of a bit toggle. If this counter reaches a threshold value (C*n*PROT[SCDLMT]), a short-circuit event is invoked.
C*n*PROT[SCDOP]	Program conversion options and control detection of the bit value (0, 1, or both) that increments the SCD counter.
C*n*PROT[SCDCM]	Program conversion modes and control when the SCD operates—when C*n*CR[CHEN] = 1 or when the PF is performing a conversion.

47.3.2.9 CAD operations

A CAD is applied to each channel. You must check the modulator clock input for absence to ensure that the correct conversion process and error detection are in progress.

NOTE

When a clock absence event occurs, the data conversion process and detectors provide incorrect data. You must manage this event and discard the given data when a clock absence is reported.

Table 407. CAD operations

Using field	You can
C*n*CR[CADEN]	Write 0 to disable CAD.
FIFOIS[CAD*n*]	Check whether SINC detected the absence of a clock on filter channel *n*. When a CAD event occurs, CAD continues to count until an overflow occurs and then latches the value until you clear the flag.
FIFOIE[CADIE*n*]	Enable and disable the Clock Absence interrupt for filter channel *n*.

Table continues on the next page...

Table 407. CAD operations (continued)

Using field	You can
C*n*PROT[CADBK]	Enable and disable the automatic assertion of the BREAK_CAD signal (see External signals).
C*n*PROT[CADLMT]	Specify the threshold value of the CAD counter. The internal counters use IMCLK0 (see Function clock); therefore, you must program MCR[PRESCALE] and MCR[MCLKDIV] correctly to ensure that MCLK0_OUT is faster than the expected modulator clock input. However, MCLK0_OUT must not be more than 15 times faster.

47.3.2.10 ZCD operations

A ZCD asserts when a filter channel changes sign. In case of the absence of a threshold register and ripples, the ZCD asserts multiple times.

Table 408. ZCD operations

Using field	You can
C*n*CFR[RDFMT]	Configure the field as signed for the ZCD to work correctly.
C*n*CR[ZCDEN]	Write 0 to disable ZCD.
NIS[ZCD*n*]	Check the status of ZCD.
NIE[ZCDIE*n*]	Enable and disable the Zero Cross Detected interrupt for filter channel *n*.
C*n*CFR[ZCOP]	Select the type of zero crossing—rise, fall, or both.

47.3.2.11 Limit detection operations

Each filter sample is compared to values in the limit registers. This comparison is based on the final conversion value with offset correction applied. C*n*HILMT[HILMT] and C*n*LOLMT[LOLMT] registers contain the corresponding values that are used to compare with the result. C*n*HILMT[HILMT] is used for result comparison with the high limit, and C*n*LOLMT[LOLMT] is used for result comparison with the low limit.

Table 409. Limit detection operations

Using field	You can
C*n*CR[LMTEN]	Write 0 to disable limit checking.
EIS[HLMT*n*], EIS[LLMT*n*], and EIS[WLMT*n*]	Check the status of high limit flag, low limit flag, and window limit flag, respectively.
EIE[HLMTIE*n*], EIE[LLMTIE*n*], and EIE[WLMTIE*n*]	Enable or disable the High Limit interrupt, Low Limit interrupt, and Window Limit Interrupt, respectively.
C*n*ACFR[ADMASEL]	Enable an alternative DMA and select the limit flag that triggers the DMA.
C*n*PROT[HLMTBK], C*n*PROT[LLMTBK], and C*n*PROT[WLMTBK]	Program to assert break signals BREAK_HIGH, BREAK_LOW, and BREAK_WIN, respectively (see External signals).
C*n*PROT[LMTOP]	Program a limit detection option.

47.3.3 FIFO

The FIFO is a first-in, first-out buffer that saves the final filtering results. Each FIFO has a depth of 8 entries, and each entry stores a 24-bit result. Each channel has one FIFO. SINC writes (pushes) data into the FIFO, and you read (pop) data from the FIFO by using Channel n Result Data (C0RDATA - C4RDATA).

The FIFO has a configurable watermark (C*n*CFR[FIFOWMK]). When the amount of data in the FIFO is greater than C*n*CFR[FIFOWMK], SINC requests a DMA, IRQ, or both, depending on NIE[CHFIE*n*] and C*n*CR[DMAEN].

When the FIFO is full, SINC discards a new filtered result and sets the overflow flag (FIFOIS[FOVF*n*]). Similarly, if you attempt a pop operation and the FIFO is empty, SINC does not return any valid data and sets the underflow flag (FIFOIS[FUNF*n*]). When an overflow or underflow occurs, SINC sets the aforementioned flags and can generate an error interrupt you write 1 to the corresponding field in FIFO And CAD Error Interrupt Enable (FIFOIE).

When FIFO is enabled (C*n*CR[FIFOEN] = 1), MCR.MEN = 1, but C*n*CR[CHEN] = 0, you can still read the FIFO to flush it.

When you reset the FIFO by writing 1 to MCR[RST], SINC fills all FIFO entries with zeros and resets the push and pop pointers to their initial position.

Only a PF can serve as the input to a FIFO.

You can use either of the following methods to determine how much data remains in a FIFO:

- Read C*n*SR[FIFOAVIL].
- Write 9d to C*n*CR[DBGSEL], then read Channel n Debug (C0DBGR - C4DBGR).

47.3.4 Wake-up

SINC does not support an asynchronous interrupt to wake up the chip.

47.3.5 Details of debug data

Table 410. Details of debug data

When C*n*CR[DBGSEL] is:	C*n*DBGR[DBGDATA] contains:
0b	Final data from the PF (24 bits)
1b	Offset data (24 bits)
10b	Shifted data from the PF (24 bits)
11b	DC remover (HPF) data (32 bits)
100b	Raw data from the PF's CIC filter
110b	Historical data from short-circuit detection: • Bit 0 indicates the current count bit value. • Bits 1–8 indicate the current count. • Bits 9–16 indicate the previous count. • Bits 17–24 indicate the second-previous count. • Bits 25–31 are reserved.
111b	Data from the Manchester decoder: • Bits 0–7 indicate the number of decode errors (resync) that occurred after you enabled the channel. When this number exceeds 256, SINC resets it to 128.

Table continues on the next page...

Table 410. Details of debug data (continued)

When CnCR[DBGSEL] is:	CnDBGR[DBGDATA] contains:
	• Bits 8–18 indicate how long (in clock cycles) the current bit value has existed. • Bit 19 is the current bit value. • Bits 20–31 are reserved.
1000b	Data from CAD: • Bits 0–3 indicate the number of cycles during which SINC did not detect a modulator clock. SINC resets this number when SINC detects the modulator clock again. If it exceed the CnPROT[CADLMT], it will hold the value until software clear it. The maximum reportable number of clockless cycles is 15d (1111b). If more clockless cycles occur, the value in bits 0–3 remains 15d (1111b). • Bits 4–31 are zero.
1001b	Number of available entries in the FIFO: • Bits 0–7 indicate the number of available entries. • Bits 8–31 are zero.
1010b	Status of the parallel or serial data converter: • Bits 0–5 indicate the number of bits that SINC must still shift out as mod bits, for serial data converter. • Bits 6–7 are reserved. • Bits 8–31 are zero.

47.3.6 Modes of operation

Table 411. Modes of operation

Mode	Description
Normal	Default operational mode in which channels perform filtering operations. An external bitstream from the MBIT[*n*] signal (see External signals) supplies the input data and the MCLK_OUT[*n*] signal (see External signals) delivers the modulator clock to the external ADC.
Low-Power	Mode in which the chip gates the CPU clock, and if MCR[DOZEN] = 1, SINC functions are canceled. If the CPU is in Wait mode, SINC filters and protects the modulator bitstream data and can generate a wake-up event through a synchronous DMA or interrupt, depending on the values of MCR[MEN], CnCR[CHEN], CnCR[PFEN], and other protection block enable fields (CnCR[CADEN], CnCR[SCDEN], or CnCR[ZCDEN]). If the CPU clock enters very low power stop (VLPS) mode, the CPU clock is gated and a peripheral-bus stop acknowledge signal is raised if: • MCR[MEN] = CnCR[CHEN] = 1.

Table continues on the next page...

Table 411. Modes of operation (continued)

Mode	Description
	• Either C*n*CR[PFEN] or the other related protection enable fields (C*n*CR[CADEN], C*n*CR[SCDEN], or C*n*CR[ZCDEN]) are 1. You cannot generate DMAs and interrupts asynchronously to wake up the CPU clock.
Single	Mode in which you can control a typical motor using coils. For more on this mode, see Use case: Motor control with Single mode.
Continuous	Mode in which you can control audio applications and power meters. For more on this mode, see Use case: Audio system with Continuous mode, and Use case: Power meter with Continuous mode.
Fixed-Number	Mode in which you can control a typical motor and enhance this control by using techniques as such: • Adding a compensation filter to achieve better precision. • Flattening the passband. • Improving roll-off. For more on this mode, see Use case: Motor control with Fixed-Number mode.

47.3.7 Clocks

47.3.7.1 Overview

SINC has these types of clocks:

- Bus (see Bus clock)
- Function (see Function clock)
- Modulator (see Modulator clock)

The following sections provide:

- A block diagram of SINC clocks.
- An overview of the functioning and special clocking requirements of SINC clock types.

47.3.7.1.1 Clocks: block diagram

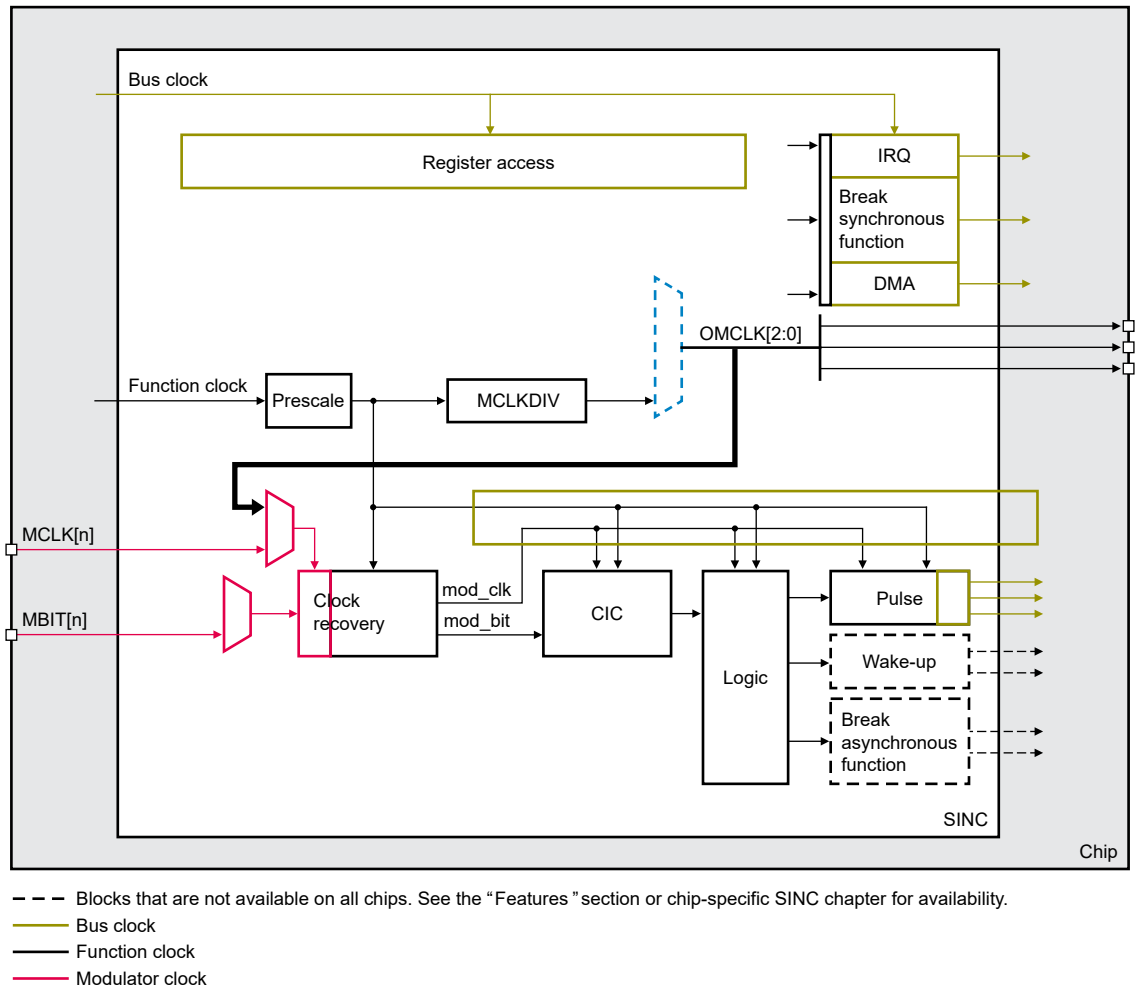

Figure 236. Clocks: block diagram

47.3.7.2 Bus clock

- Provides register access
- Allows control over low-power request signals, DMA, and interrupts

47.3.7.3 Function clock

The chip-provided function clock drives major functions, including:

- The prescaler
- The modulator clock divider (MCLKDIV)

The function clock is prescaled and divided to the correct operating range for SINC.

47.3.7.3.1 Main clock logic

The main clock logic, which is an integral part of the function clock:

- Is shared among all channels.
- Comprises a prescaler, MCLKDIV (divided by 2), and a clock output enable to external clocks.

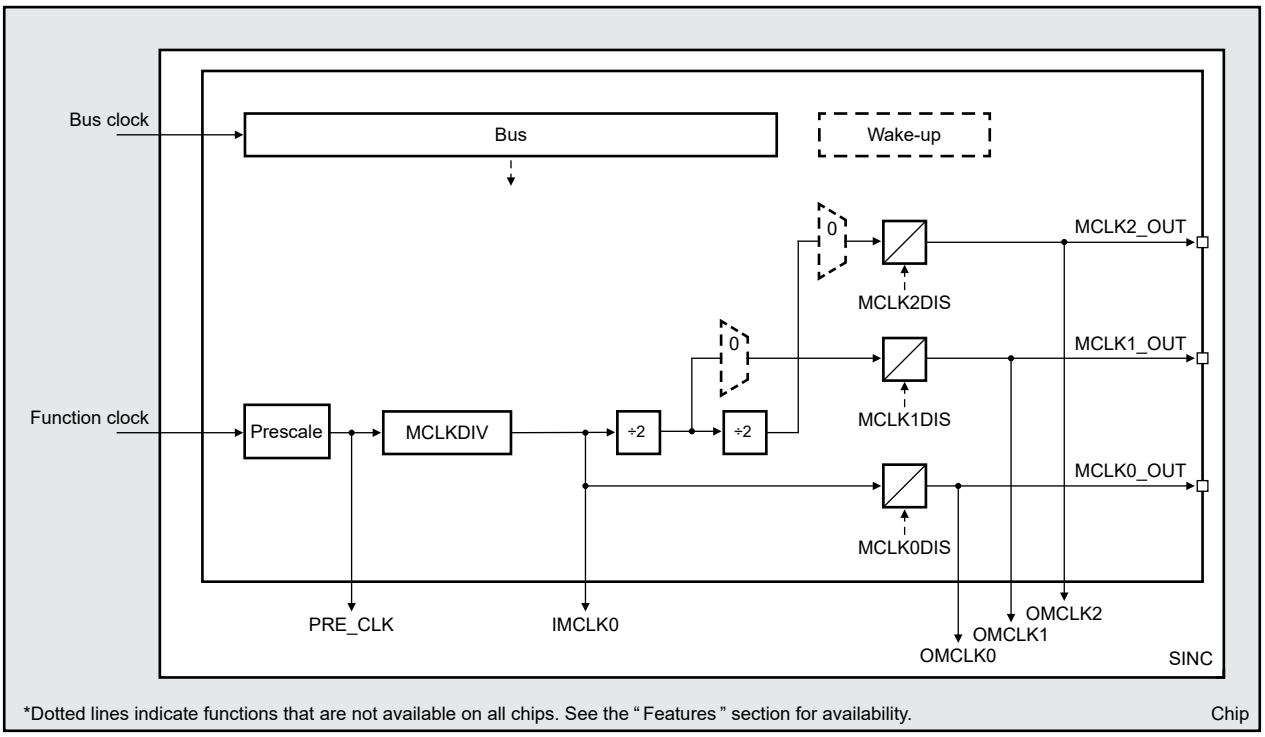

Figure 237. Main clock logic

47.3.7.3.2 Prescaler and output clocks

The prescaler supports power saving. It divides a high-frequency function clock (a major clock for other blocks) with an associated low-frequency clock. The prescaler divides the function clock by using MCR[PRESCALE], and then sends the clock to the divider and other blocks. See Main clock logic.

MCLKDIV sends the following three clocks to the chip for driving an external modulator ADC:

- MCLK_OUT0: Clock arrived at by adding 1 to the value of MCR[MCLKDIV].
- MCLK_OUT1: Clock arrived at by further dividing MCLK_OUT0 by 2.
- MCLK_OUT2: Clock arrived at by further dividing MCLK_OUT1 by 2.

These three aforementioned divided output clocks can be enabled or disabled by using MCR[MCLK0DIS], MCR[MCLK1DIS], and MCR[MCLK2DIS], respectively.

You must write an appropriate value to MCR[MCLKDIV]:

- For the target modulator clock to function properly. In some use cases, the modulator clock frequency must be certain times of the PWM frequency to use SINC's CIC filter.
- To obtain a 50% duty cycle, depending on the requirements of the external modulator ADC.

47.3.7.4 Modulator clock

A modulator clock:

- Is dedicated to each channel.
- Is provided by an external or system source.
- Can generate a digital output bitstream at a high data rate.

The SINC decimation filters reduce the sampling rate of the high-rate modulator output. Because of the latency of the decimation filters, each time a decimation filter is enabled or resynchronized, it takes one to four output samples (depending on the filter order) to reach a steady state producing valid output values.

47.3.7.4.1 Channel clock logic

The channel clock logic, which is a part of the modulator clock:

- Is dedicated to each channel individually.
- Comprises the following:
  - A normal decoder
  - A Manchester decoder
  - A clock source selection for these decoders
  - An MPDATA clock generator
- Includes the following:
  - An input asynchronous MCLK[*n*] selection, sample, or resynchronization
  - An MBIT[*n*] selection or sample
  - Manchester clock recovery
  - A clock select

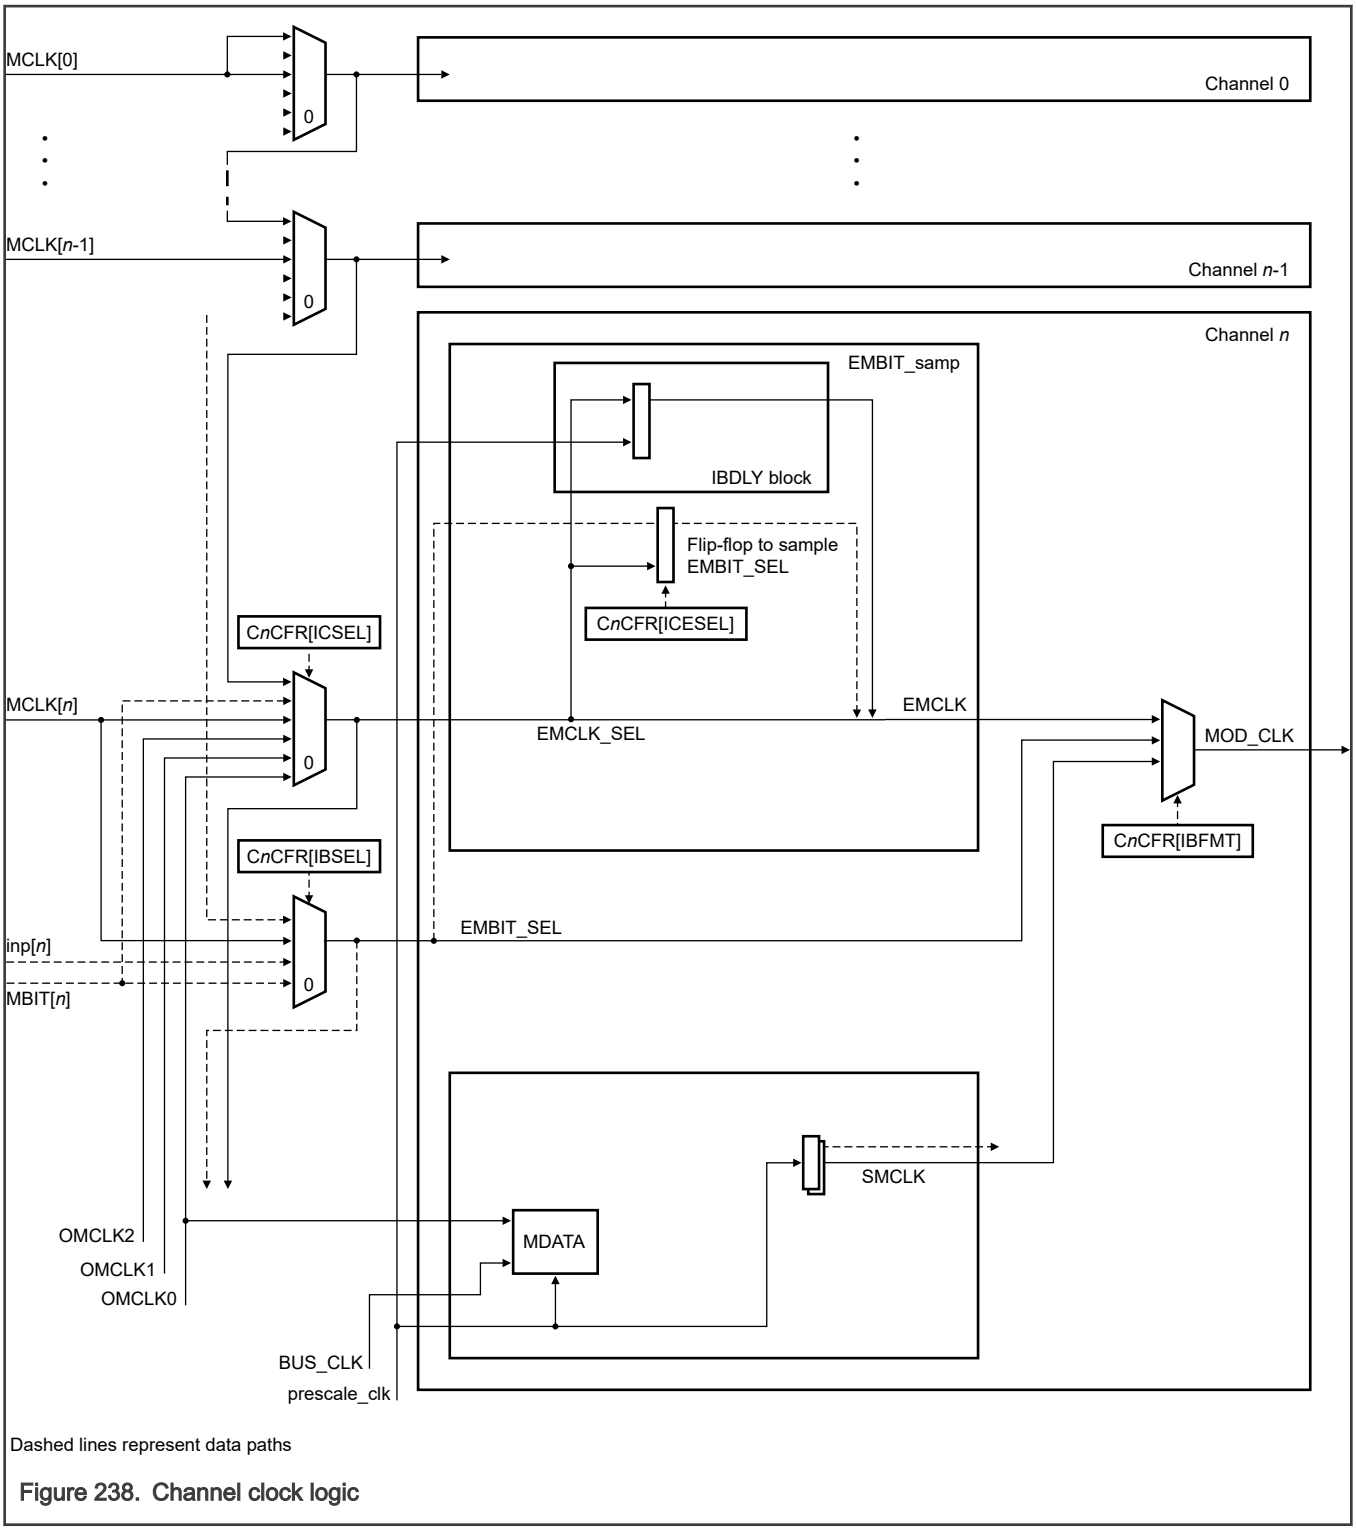

Figure 238. Channel clock logic

47.3.7.4.2 Prescaler considerations

You must program the prescaler to ensure that the predivided clock is:

- At least 3x faster than the MCLK[*n*] input for a single-edge sample.
- 6x faster than the MCLK[*n*] input for a dual-edge sample.

- 6x faster for Manchester coding, else the clock recovery block may function inappropriately.

47.3.7.4.3 Input clock configuration

To configure input clock edges and bitstream formats, you can:

- Write to C*n*CFR[ICSEL] to perform clock source selection and configure C*n*CFR[ICESEL] for the channel modulator clock to be rising edge, falling edge, or dual edge. These clock edges are used to sample the modulator bitstream.
- Write to C*n*CFR[IBFMT] for Manchester coding, when clocks are auto generated.

47.3.7.5 Clock source selection

The selected channel modulator clock input (EMCLK_SEL[*n*]) can be a dedicated external input (MCLK[*n*]), or it could be shared with an adjacent channel (MCLK[*n*-1]), if you write 111b to C*n*CFR[ICSEL]. Additionally, the shared clock can be cascaded between channels (for example, all channels share the same clock, MCLK[0]).

This is what you can do by writing appropriate values to the fields of Channel n Configuration (C0CFR - C4CFR):

- Route the output clocks OMCLK0, OMCLK1, and OMCLK2 as internal clock inputs by writing 000b, 001b, and 010b, respectively, to C*n*CFR[ICSEL]. Thus, SINC can provide output clocks to drive both the external modulator ADC and internal demodulator.
- Recover the manchester clock (MMCLK) by writing 01b to C*n*CFR[IBFMT]. You can use external modulator bitstream selection (EMBIT_SEL), which can be dedicated to each channel (external MBIT[*n*] and internal INP[*n*]) or shared with the adjacent channel (MBIT[*n*-1]), if you write 11b to C*n*CFR[IBSEL].
- Program the Manchester format by writing an appropriate value to C*n*CFR[ICESEL].

See Clock source selection settings for the values you must write to C*n*CFR[ICSEL], C*n*CFR[IBFMT], and C*n*CFR[ICESEL] for clock source selection.

47.3.7.5.1 Clock source selection settings

Table 412. Clock source selection settings

C*n*CFR[ICSEL]	C*n*CFR[IBFMT]	C*n*CFR[ICESEL]	Source	Description
000	00	Any value	OMCLK0	Output clock 0 selected
001	00	Any value	OMCLK1	Output clock 1 selected
010	00	Any value	OMCLK2	Output clock 2 selected
011	00	Any value	MCLK	External modulator clock selected
100	00	Any value	—	—
101	00	Any value	—	Reserved
110	00	Any value		
111	00	Any value	GCLK	Group clock (a previous channel clock selected as clock source)
Any value	01	01	MMCLK_RISE	A manchester clock selected per channel in the Rise format
		10	MMCLK_FALL	A manchester clock selected per channel in the Fall format
		00	Reserved	—
		11		

Table continues on the next page...

Table 412. Clock source selection settings (continued)

CnCFR[ICSEL]	CnCFR[IBFMT]	CnCFR[ICESEL]	Source	Description
Any value	10	Any value	PMCLK	An internal (IMCLK0), auto-generated parallel or serial modulator clock selected for clock source generation when you write a bitstream to Channel n Multipurpose Data (C0MPDATA - C4MPDATA)
	11		SMCLK	

47.3.7.6 Clock edge selection

For clock edge selection, you must program CnCFR[ICESEL] to select when to sample a modulator bitstream (EMBIT_SEL), if CnCFR[IBFMT] = 0.

See Clock edge selection settings for information about which modulator input clock (EMCLK_SEL) and clock edge you must select to sample this modulator bit (EMBIT_SEL), and see Clock edge selection diagram for a pictorial representation of these edge settings.

47.3.7.6.1 Clock edge selection settings

Table 413. Clock edge selection settings

CnCFR[IBFMT]	CnCFR[ICESEL]	Name	Clock edge used to sample the modulator bit (EMBIT_SEL)
00	001	MCLK positive edge	EMCLK_SEL as positive edge sample—SINC uses even-numbered MCLK edges (0, 2, 4, 6, 8, and so on) to sample the selected input data.
	010	MCLK negative edge	EMCLK_SEL as negative edge sample—SINC uses odd-numbered MCLK edges (1, 3, 5, 7, 9, and so on) to sample the selected input data.
	011	MCLK dual edge	EMCLK_SEL as dual edge sample—SINC uses all MCLK edges to sample the selected input data.
	101	MCLK positive edge even	EMCLK_SEL as every other even positive edge sample—SINC uses even-numbered MCLK edges (0, 4, 8, 12, 16, and so on) to sample the selected input data.
	110	MCLK negative edge odd	EMCLK_SEL as every other odd negative edge sample—SINC uses odd-numbered MCLK edges (1, 5, 9, 13, 17, and so on) to sample the selected input data.
	000—111	Reserved	—
01	00		
	01	MMCLK_RISE	A manchester clock per channel in the Rise format—no edge sample options.
	10	MMCLK_FALL	A manchester clock per channel in the Fall format—no edge sample options.
	11	Reserved	—

Table continues on the next page...

47.3.7.6.2 Clock edge selection diagram

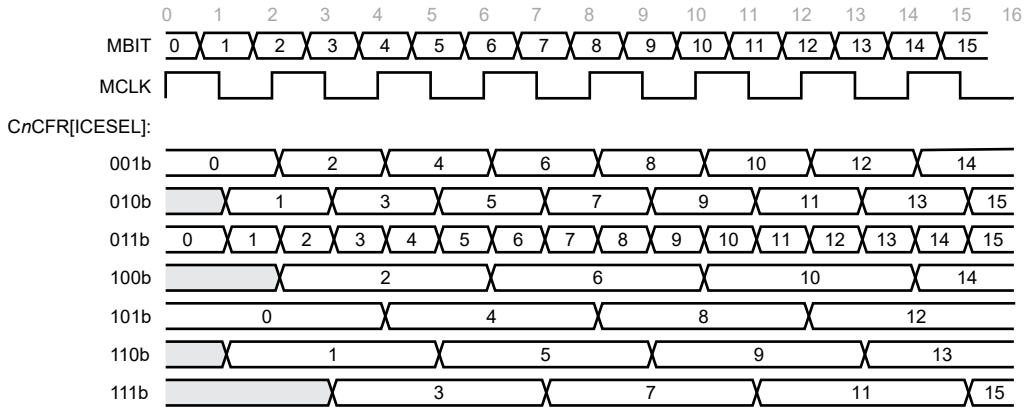

Figure 239. Clock edge selection diagram

47.3.7.7 Modulator clock frequencies and bit rates

The frequency of the function clock provided by the chip determines the minimum and maximum modulator clock frequencies.

47.3.7.7.1 Minimum clock output example

Assume the frequency of the function clock is 133 MHz. At this frequency, the minimum clock output frequency for MCLK_OUT2 is 16 kHz, and an internal or external clock can route it to SINC. Alternatively, an external ADC can divide the clock by 2. Therefore, in this example, the bit rate is 16 kbit/s or 8 bit/s in ideal scenarios.

See Minimum clock output settings for minimum clock output frequency settings of signals at different data rates and the resultant conditions.

47.3.7.7.1.1 Minimum clock output settings

Table 414. Minimum clock output settings

Signal	Minimum frequency	Condition	CnCFR[ICESEL]	Data rate (kbit/s)	Comments
MCLK_OUT0	65 kHz (133 MHz ÷ 8 ÷ 256 = 65 kHz)	Clock routed (CnCFR[ICSEL] = 000b)	001 = positive edge 010 = negative edge	65	—
			011	130	

Table continues on the next page...

Table 414. Minimum clock output settings (continued)

Signal	Minimum frequency	Condition	CnCFR[ICESEL]	Data rate (kbit/s)	Comments
			1xx	32	If ADC divides the clock by 2 but does not connect it
		ADC routes the clock after dividing it by 2 (CnCFR[ICSEL] = 011b)	001 = positive edge 010 = negative edge	32	—
			011	65	
			1xx	16	
MCLK_OUT1	32 kHz (133 MHz ÷ 8 ÷ 256 ÷ 2 = 32 kHz)	Clock routed (CnCFR[ICSEL] = 001b)	001 = positive edge 010 = negative edge	32	
			011	65	
			1xx	16	
		ADC routes the clock after dividing it by 2 (CnCFR[ICSEL] = 011b)	001 = positive edge 010 = negative edge	16	
			011	32	
			1xx	8	
MCLK_OUT2	16 kHz (133 MHz ÷ 8 ÷ 256 ÷ 2 ÷ 2 = 16 kHz)	Clock routed (CnCFR[ICSEL] = 010b)	001 = positive edge 010 = negative edge	16	
			011	32	
			1xx	8	
		ADC routes the clock after dividing it by 2 (CnCFR[ICSEL] = 011b)	001 = positive edge 010 = negative edge	8	
			011	16	
			1xx	4	

47.3.7.7.2 Maximum clock output example

Assume the frequency of the function clock is 133 MHz. At this frequency:

- 66 MHz is the maximum clock output frequency for MCLK_OUT0. The actual frequency depends on the chip I/O timing and the specific use case.

- 44 Mbit/s is the maximum data rate that SINC can support.

Therefore, an external ADC must divide a 66 MHz clock by 2 and route it as 33 MHz. The chip's I/O timing may also limit this high-speed clock.

With an output of 44 MHz, the duty cycle cannot be 50% when the clock is divided by 3. Most external ADCs require a 50% duty cycle. Therefore, 33 MHz is a better choice for the maximum frequency.

See Maximum clock output settings for maximum clock output frequency settings of signals at different data rates and the resultant conditions.

47.3.7.7.2.1 Maximum clock output settings

Table 415. Maximum clock output settings

Signal	Condition	CnCFR[ICESEL]	Maximum frequency (MHz)	Data rate (Mbit/s)	Comments
MCLK_OUT0	Clock routed (CnCFR[ICSEL] = 000b)	001 or 010	33	33	133 MHz ÷ 4 = 33 MHz (50% duty cycle)
			44	44	133 MHz ÷ 3 = 44 MHz (66% duty cycle, depending on the maximum data rate)
		011	22	44	133 MHz ÷ 6 = 22 MHz (depending on the maximum data rate)
		1xx	66	33	133 MHz ÷ 2 = 66 MHz
	ADC routes the clock after dividing it by 2 (CnCFR[ICSEL] = 011b)	001 or 010	66	33	133 MHz ÷ 2 = 66 MHz
		011	33	33	133 MHz ÷ 4 = 33 MHz (50% duty cycle)
			44	44	133 MHz ÷ 3 = 44 MHz (66% duty cycle, depending on the maximum data rate)
		1xx	66	17	133 MHz ÷ 2 = 66 MHz (SINC does not support clock division by 1)
MCLK_OUT1	Clock routed (CnCFR[ICSEL] = 001b)	001 or 010	17	17	133 MHz ÷ 4 ÷ 2 = 17 MHz (assuming you are also using MCLK_OUT0)
			33	33	133 MHz ÷ 2 ÷ 2 = 33 MHz (depending on the maximum output)
		011	17	33	133 MHz ÷ 4 ÷ 2 = 17 MHz (assuming you are also using MCLK_OUT0)
			22	44	133 MHz ÷ 3 ÷ 2 = 22 MHz (depending on the maximum output)
		1xx	17	8	133 MHz ÷ 4 ÷ 2 = 17 MHz (assuming you are also using MCLK_OUT0)
			33	17	133 MHz ÷ 2 ÷ 2 = 33 MHz (depending on the maximum output)
	ADC routes the clock after dividing it by 2 (CnCFR[ICSEL] = 011b)	001 or 010	17	8	133 MHz ÷ 4 ÷ 2 = 16 MHz (assuming you are also using MCLK_OUT0)
			33	17	133 MHz ÷ 2 ÷ 2 = 33 MHz (depending on the maximum output)

Table continues on the next page...

Table 415. Maximum clock output settings (continued)

Signal	Condition	CnCFR[ICESEL]	Maximum frequency (MHz)	Data rate (Mbit/s)	Comments
		011	17	17	133 MHz ÷ 4 ÷ 2 = 16 MHz (assuming you are also using MCLK_OUT0)
			33	33	133 MHz ÷ 2 ÷ 2 = 33 MHz (depending on the maximum output)
		1xx	17	4	133 MHz ÷ 4 ÷ 2 = 17 MHz (assuming you are also using MCLK_OUT0)
			33	8	133 MHz ÷ 2 ÷ 2 = 33 MHz (depending on the maximum output)
MCLK_OUT2	Clock routed (CnCFR[ICSEL] = 010b)	001 or 010	8	8	133 MHz ÷ 4 ÷ 2 ÷ 2 = 8 MHz (assuming you are also using MCLK_OUT0)
			17	17	133 MHz ÷ 2 ÷ 2 ÷ 2 = 17 MHz (depending on the maximum output)
		011	8	17	133 MHz ÷ 4 ÷ 2 ÷ 2 = 8 MHz (assuming you are also using MCLK_OUT0)
			17	33	133 MHz ÷ 2 ÷ 2 ÷ 2 = 17 MHz (depending on the maximum output)
		1xx	8	4	133 MHz ÷ 4 ÷ 2 ÷ 2 = 8 MHz (assuming you are also using MCLK_OUT0)
			17	8	133 MHz ÷ 2 ÷ 2 ÷ 2 = 17 MHz (depending on the maximum output)
	ADC routes the clock after dividing it by 2 (CnCFR[ICSEL] = 011b)	001 or 010	8	4	133 MHz ÷ 4 ÷ 2 ÷ 2 = 8 MHz (assuming you are also using MCLK_OUT0)
			17	8	133 MHz ÷ 2 ÷ 2 ÷ 2 = 17 MHz (depending on the maximum output)
		011	8	8	133 MHz ÷ 4 ÷ 2 ÷ 2 = 8 MHz (assuming you are also using MCLK_OUT0)
			17	17	133 MHz ÷ 2 ÷ 2 ÷ 2 = 17 MHz (depending on the maximum output)
		1xx	8	2	133 MHz ÷ 4 ÷ 2 ÷ 2 = 8 MHz (assuming you are also using MCLK_OUT0)
			17	4	133 MHz ÷ 2 ÷ 2 ÷ 2 = 17 MHz (depending on the maximum output)

47.3.7.7.3 Maximum clock input example

The modulator input clock can be either routed from a SINC output clock or provided by an external ADC (see Block diagram for details).

The maximum input frequency allowed depends on:

- The maximum input data rate and use case.
- The chip's I/O timing.

Assuming that the frequency of the Function clock is 133 MHz, the maximum data rate is 44 Mbit/s (133MHz ÷ 3 = 44 Mbit/s) for a typical use case. For Manchester formats, the maximum allowed clock frequency (recovery from bit) is 22 MHz (133 MHz ÷ 6 = 22 Mbit/s).

The minimum allowed input frequency is not limited if the clock input comes from an external ADC. However, if you select the Manchester format, the limit is 133 MHz ÷ 1024 ÷ 8 = 16 kHz.

NOTE

To calculate the output sample rate, ORD = 3 in Continuous mode.

See Maximum clock input settings for maximum clock input frequency settings of signals at different data rates and the resultant conditions.

47.3.7.7.3.1 Maximum clock input settings

Table 416. Maximum clock input settings

Case	CnCFR[ICESEL]	Maximum frequency (MHz)	Input data rate (Mbit/s)	OSR	Output sample rate	Comments
CnCFR[IBFMT] = 00	001 010	44	44	16	2.7 Mbit/s	44 MHz ÷ 16 = 2.7 Mbit/s; 14-bit CIC
				256	172 kbit/s	44 MHz ÷ 256 = 172 kbit/s; 26-bit CIC
				1290	34 kbit/s	44 MHz ÷ 1290 = 34 kbit/s; 32-bit CIC
	011	22	44	16	2.7 Mbit/s	—
				256	172 kbit/s	
				1290	34 kbit/s	
	1xx	44	22	16	1.4 Mbit/s	
				256	86 kbit/s	
				1290	17 kbit/s	
CnCFR[IBFMT] = 01	Any value	22	22	16	1.4 Mbit/s	For the Manchester format, recovered clocks must be a value smaller than 22 Mbit/s.
				256	86 kbit/s	—
				1290	17 kbit/s	

47.3.7.8 Modulator clock I/O timing

47.3.7.8.1 I/O timing diagram

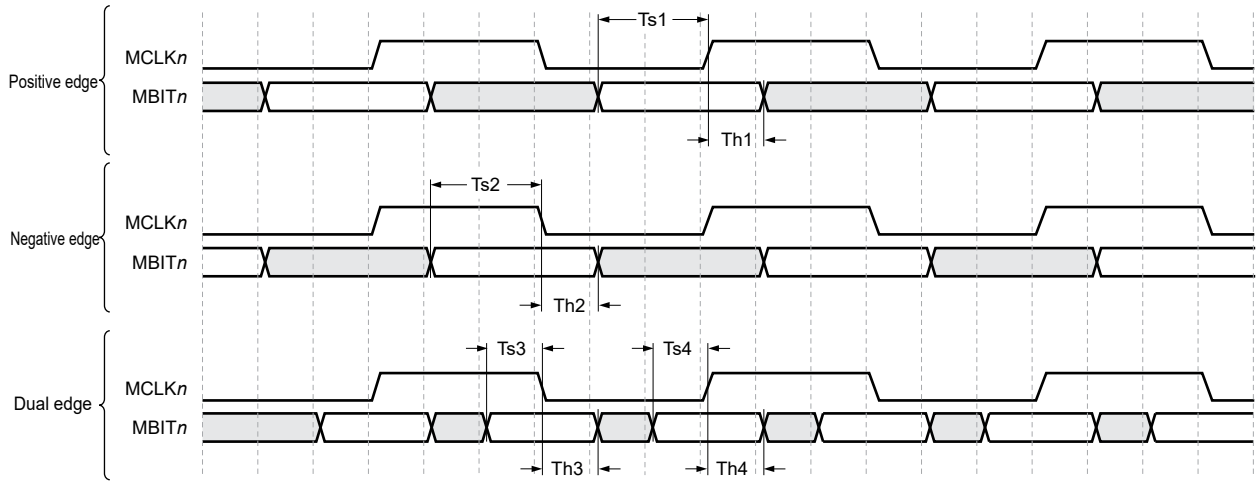

Figure 240. I/O timing diagram

See I/O timing settings for the symbols used in this diagram.

47.3.7.8.2 I/O timing settings

Table 417. I/O timing settings

Symbol	Description	Minimum time (in ns)	Maximum time (in ns)
T_{s1}	Setup time from data valid to clock high	5	—
T_{h1}	Hold time from clock high to data valid	5	—
T_{s2}	Setup time from data valid to clock low	5	—
T_{h2}	Hold time from clock low to data valid	5	—
T_{s3}	Setup time from data valid to clock high	5	—
T_{h3}	Hold time from clock high to data valid	5	—
T_{s4}	Setup time from data valid to clock low	5	—
T_{h4}	Hold time from clock low to data valid	5	—

47.3.8 Reset

This section describes how to reset the SINC module and explains special requirements related to reset.

Writing 1 to MCR[RST] resets the following function blocks and registers:

- All function blocks (such as filters, short-circuit detectors, and so on) except for the clock
- Normal Interrupt Status (NIS)
- Error Interrupt Status (EIS)
- FIFO And CAD Error Interrupt Status (FIFOIS)
- Status (SR)

- MCR[STRIG*n*], together with related functions

47.3.9 Interrupts and breaks

This section describes all the interrupts that SINC generates.

Each channel has several interrupt sources that you can control and check with dedicated register fields.

If NIE[COCIE*n*] = 1, then an interrupt request is used to indicate that one filtering result is available in the corresponding channel's FIFO. You can then read the result in Channel n Result Data (C0RDATA - C4RDATA).

If NIE[CHFIE*n*] = 1, then an interrupt request is used to indicate that the FIFO surpassed its watermark level. In this case, SINC sets the corresponding NIS[CHF*n*] flag.

SINC can also generate an error interrupt request when an unexpected condition such as a FIFO overflow or underflow, a loss of clock, saturation, or exceeded value threshold occurs.

When an error occurs, SINC can assert break signals to deactivate an external peripheral. You control this feature by using Channel n Protection (C0PROT - C4PROT).

Table 418. Interrupts and breaks

Status register	Status field	Enable register	Enable field	Break enable field in C*n*PROT	Description
NIS	COC*n*	NIE	COCIE*n*	—	Conversion complete
	CHF*n*		CHIE*n*	—	Data ready
	ZCS*n*		ZCIE*n*	—	Zero cross detected
EIS	SCD*n*	EIE	SCDIE*n*	SCDBK	Short circuit detected
	WLMT*n*		WLMTIE*n*	WLMTBK	Window limit reached
	LLMT*n*		LLMTIE*n*	LLMTBK	Low limit reached
	HLMT*n*		HLMTIE*n*	HLMKBK	High limit reached
FIFOIS	FUNF*n*	FIFOIE	FUNFIE*n*	—	FIFO underflow
	FOVF*n*		FOVFIE*n*	—	FIFO overflow
	CADF*n*		CADIE*n*	CADBK	Clock absence detected
	SAT*n*		SATIE*n*	—	Saturation

47.3.10 DMA

SINC has two DMAs for each channel:

- Primary DMA exclusively for the FIFO
- Alternate DMA for various sources (see C*n*ACFR[ADMASEL])

If C*n*CR[DMAEN] = 1, you read the FIFO-stored samples through DMA transactions. Each channel has dedicated DMA requests. If the FIFO of each channel reach their watermark the output interface makes a request for DMA transaction.

SINC clears the "data output ready" flags (NIS.CHFn) when a DMA transaction finishes.

SINC supports all the alternate DMA sources mentioned in C*n*ACFR[ADMASEL]. You can select only one source at a time. After an alternate DMA transaction finishes, SINC clears the related flags in Normal Interrupt Status (NIS), Error Interrupt Status (EIS), and FIFO And CAD Error Interrupt Status (FIFOIS).

47.4 External signals

Table 419. External signals

Signal	Used for	Description
BREAK_CAD[4:0]	Output to the chip	CAD-related break signals sent to the chip for turning off other functions
BREAK_HIGH[4:0]	Output to the chip	High-limit break signals sent to the chip for turning off other functions
BREAK_LOW[4:0]	Output to the chip	Low-limit break signal sent to the chip for turning off other functions
BREAK_SCD[4:0]	Output to the chip	SCD-related break signal sent to the chip for turning off other functions
BREAK_WIN[4:0]	Output to the chip	Window-limit-related break signal sent to the chip for turning off other functions
FILT_CC[4:0]	Output to the chip	Signal acting as an output to be used by downstream modules in the signal processing chain that SINC is a component of
HTRIG[4:0]	Input from the chip	Hardware external trigger
INP[4:0]	Input from the chip	Internal modulator bitstream input
MBIT[4:0]	Input from the chip	External modulator bitstream input
MCLK_OUT0	Output to the chip	Modulator clock output 0
MCLK_OUT1	Output to the chip	Modulator clock output 1, which is MCLK_OUT0 divided by 2
MCLK_OUT2	Output to the chip	Modulator clock output 2, which is MCLK_OUT1 divided by 2
MCLK[4:0]	Input from the chip	External modulator clock input
ipi_coc_int[3:0]	Output to the chip	Conversion complete interrupt
ipi_chf_int[3:0]	Output to the chip	Channel (FIFO) output interrupt
ipi_zcs_int[3:0]	Output to the chip	Zero cross interrupt
ipi_scd_int[3:0]	Output to the chip	Short circuit detect interrupt
ipi_low_int[3:0]	Output to the chip	Low limit interrupt
ipi_high_int[3:0]	Output to the chip	High limit interrupt
ipi_win_int[3:0]	Output to the chip	Window limit interrupt
ipi_fund_int[3:0]	Output to the chip	FIFO underflow interrupt
ipi_fover_int[3:0]	Output to the chip	FIFO overflow interrupt
ipi_sat_int[3:0]	Output to the chip	Saturation interrupt
ipi_cad_int[3:0]	Output to the chip	Clock monitor interrupt
ipi_chn_ored_int[3:0]	Output to the chip	ORed together for above interrupt per channel

Table continues on the next page...

Table 419. External signals (continued)

Signal	Used for	Description
ipd_req_sinc[3:0]	Output to the chip	Conversion complete DMA request for SINC
ipd_done_sinc[3:0]	Input from the chip	Handshake signal from chip, indicates that DMA request is processed
ipd_req_alt[3:0]	Output to the chip	Alternative DMA request for SINC
ipd_done_alt[3:0]	Input from the chip	Handshake signal from chip, indicates that DMA request is processed

47.5 Initialization

47.5.1 Starting SINC

By default, SINC is disabled (MCR[MEN] = 0). To start or configure SINC, do this:

1. Configure the shared clock generation logic as described in Configure clocking-related fields before enabling SINC.
2. Configure OSR, ORD, and all other necessary options.
3. Enable the modulator clock output.
4. Enable all the required decimation filters and protection functions.
5. Write 1 to MCR[MEN] to start SINC.

The corresponding clock is generated for both the internal (IMCLK0) and external (MCLK_OUT*n*) signals (see External signals). If MCLK_OUT*n* is enabled, SINC waits for seven clock cycles before the external ADC is stable. SR[MCLKRDY*n*] fields become 1 after that.

This is how SINC behaves during and after starting up:

- For an internal clock source (if C*n*CFR[ICSEL] = 000b, 010b, or 001b), MCLK_OUT*n* checks SR[MCLKRDY*n*]. The field changes into a valid state when it becomes 1.
- If the clock source is external, Manchester, or grouped, all the three SR[MCLKRDY*n*] fields are selected and wait for a certain number of clock cycles before becoming 1.
- If MCLK_OUT*n* is disabled, SINC waits for one clock cycle for the internal logic to be stable.
- After startup, SINC waits for the conversion trigger to start conversion. The enabled channel conversions begin after SINC receives a software or hardware trigger. During startup, SINC ignores this signal.

47.5.2 Configure clocking-related fields before enabling SINC

Before you enable SINC (write 1 to MCR[MEN]), you must configure the following fields:

Table 420. Configure clocking-related fields before enabling SINC

Register	Fields to configure
Main Control (MCR)	MCLK0DIS MCLK1DIS MCLK2DIS MCLKDIV PRESCALE

47.5.3 Configure fields before enabling channels

Before you enable a channel (write 1 to C*n*CR[CHEN]), you must configure the following fields:

Table 421. Configure fields before enabling channels

Register	Fields to configure
Channel n Data Rate (C0DR - C4DR)	All
Channel n Configuration (C0CFR - C4CFR)	All except FIFOWMK
Channel n Protection (C0PROT - C4PROT)	All
Channel n Bias (C0BIAS - C4BIAS)	All
Channel n Low Limit (C0LOLMT - C4LOLMT)	All
Channel n High Limit (C0HILMT - C4HILMT)	All
Channel n Advanced Configuration (C0ACFR - C4ACFR)	All

47.6 Application information

This section describes several ways to use SINC.

47.6.1 Reading asynchronous data safely

1. Write 1 to C*n*SR[SRDS].
2. Wait until SINC changes C*n*SR[SRDS] to 0.
3. Read the data in Channel n Debug (C0DBGR - C4DBGR).

47.6.2 Transferring data between domains safely

To transfer data from the function-clock domain to the bus-clock domain safely, perform this procedure:

1. Choose the type of data that you want (see Details of debug data).
2. Write the corresponding value to C*n*CR[DBGSEL].
3. Write 1 to C*n*SR[SRDS].
4. Wait until C*n*SR[SRDS] becomes 0.
5. Read the data from C*n*DBGR.
6. Ensure that C*n*SR[DBGRS] = 0.

If you skip steps 1 and 2, C*n*DBGR contains the data from the last time you performed the full procedure.

Due to SINC's internal microarchitecture, the returned instantaneous data may be incomplete and invalid. Step 6 ensures that the data you read is valid.

47.6.3 Use case: Motor control with Single mode

47.6.3.1 Overview

This example uses Single mode to control a typical motor with three coils. Six on-chip PWM channels drive those three coils. Three external ADCs measure the coil current, and additional ADCs monitor total current or voltage to trigger critical events (such as overcurrent or short circuit) to shut down the motor.

The ADCs produce a high-speed bitstream and send it to SINC through MBIT signals (see External signals). Then, SINC:

1. Demodulates the bitstream.

2. Decimates the bitstream.
3. Converts the bitstream to a 24-bit result at a lower frequency.
4. Saves the result in a FIFO.

You can then:

1. Read the coil current from the FIFO.
2. Read other information (such as speed and position) from other modules on the chip.
3. Process the data to determine the parameters (on or off, PWM ratio drive strength) for the next coil-drive step.

Schematic shows the motor-control schematic.

Frequency response shows the resulting frequency response of the PF's CIC. In that diagram, pay particular attention to the following:

- Without a compensation filter, there is a drop in the passband, and roll-off (aliasing) occurs in the stop band.
- F_D (346 kHz) is near the 17th harmonic wave of the PWM switch frequency (20 kHz). This example filters out this noise more efficiently.
- A dropoff of –3 dB occurs at F_C (91 kHz). Therefore, the input signal must have a much-lower frequency—1 kHz or lower. If this is not possible, your software must compensate accordingly.

47.6.3.2 Schematic

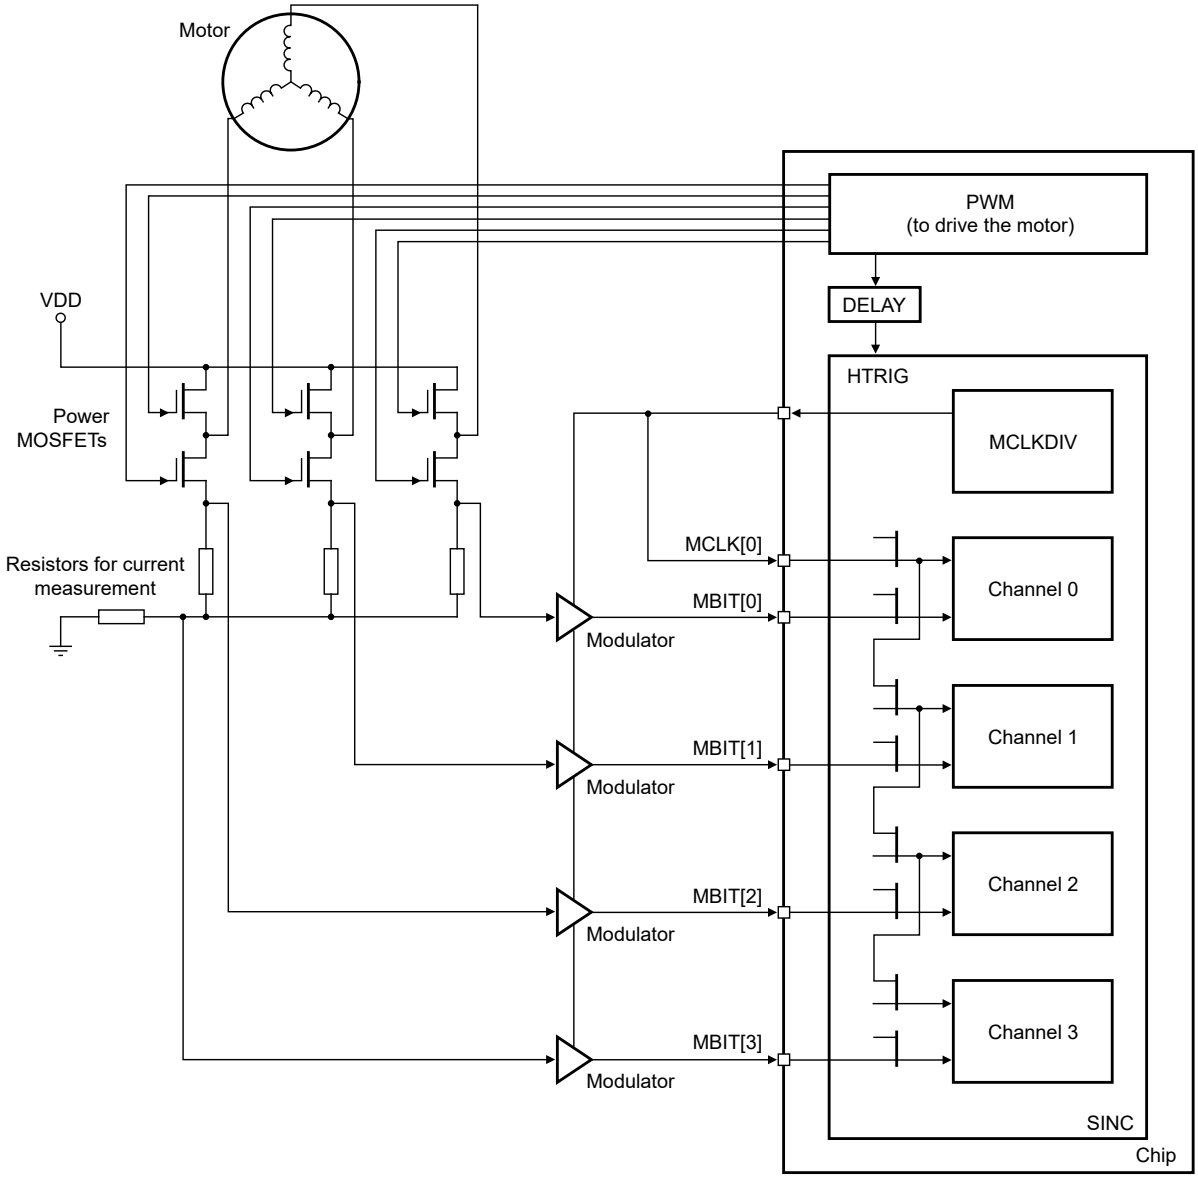

Figure 241. Schematic

47.6.3.3 Assumptions

Table 422. Assumptions

Parameter	Value
SINC function clock	133 MHz
Target external modulator ADC clock (F_S)	22.2 MHz
Motor speed	6000 RPM (100 Hz)

Table continues on the next page...

Table 422. Assumptions (continued)

Parameter	Value
PWM switch frequency (F_P)	20 kHz (corresponding to a 50 µs period, or 200 PWM steps per revolution)
OSR	64
Decimation frequency (F_D)	346 kHz (calculated from target external modulator ADC clock and OSR)
Cutoff frequency (F_C)	91 kHz
Signal-to-noise ratio (SNR)	79 dB
Effective number of bits (ENOB)	Approximately 12.9 (calculated using SNR)
Data width	20 bits (calculated using OSR and ORD)

47.6.3.4 Frequency response

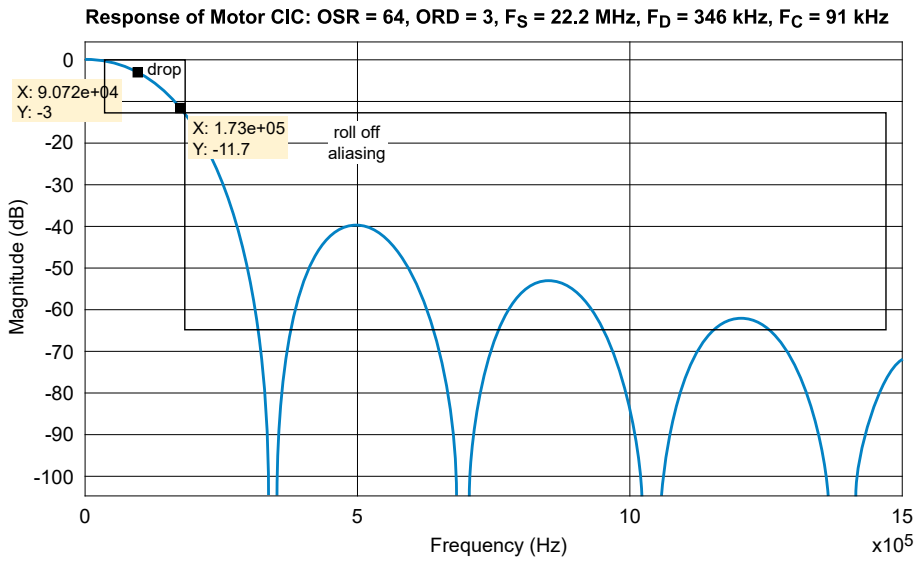

Figure 242. Frequency response

47.6.3.5 Procedure

1. Configure the related PWM and other chip modules to establish the correct pin connection with SINC. In particular, ensure that the PWM event signal connects to SINC as a hardware trigger, so that when PWM starts driving the coil, SINC can start conversion at a specific time.
2. Program the PWM event delay such that when SINC starts conversion, the coil currents are stable, as shown in Measurement time.
3. If the external ADC does not provide a clock, configure the modulator clock output. In this case, MCLK_OUT0 drives all external ADCs. To achieve MCLK_OUT0 = 22.2 MHz:
    a. Write 0 to MCR[PRESCALE].
    b. Write 5d to MCR[MCLKDIV].
4. Configure the data rate for channels 0–2 (*n* = 0–2) as follows:
    a. Write 3d to C*n*DR[PFORD].
    b. Write 63d to C*n*DR[PFOSR] to select OSR = 64.

c. Write 0 to C*n*DR[PFCM] to select Single mode.

5. Configure the data rate for channel 3 (*n* = 3) as follows:
   a. Write 2d to C*n*DR[PFORD] to select the optional fast response.
   b. Write 63d to C*n*DR[PFOSR] to select OSR = 64.
   c. Write 10b to C*n*DR[PFCM] to select Always mode for monitoring total current.
6. Configure fields in Channel n Configuration (C0CFR - C4CFR) for data operation as follows:

Channels (value of *n*)	C*n*CFR field to write	Value to write	Purpose
0–3	ITLVL	0	Select edge triggering
0–2	ITSEL	1	Select hardware triggering
3	ITSEL	0	Select software triggering
0–3	IBSEL IBFMT	0	Select a bitstream from the MBIT signals (see External signals)
0	ICSEL	11b	Select the external modulator clock
1–3	ICSEL	111b	Group the clocks with channel 0
0–3	ICESEL	1b or 10b	Configure the clock edge that you want
0–3	FIFOWMK	0	Set the FIFO watermark
0–3	RDFMT	0	Select the signed data format
0–3	PFSFT	1_0100b	Select a left shift of 4

NOTE

For channels 0–2, the conversion time (calculated using ORD×OSR÷F_S) is 8.6 µs. This is smaller than the PWM period (50 µs) and allows enough margin to adjust sample time that Measurement time requires.

7. Enable SINC features as follows:

Channels (value of *n*)	Register and field to write	Value to write	Purpose
0–3	C*n*CR[PFEN]	1	Enable the PFs
0–3	C*n*CR[CHEN]	1	Enable the channels and their subfunctions
0–3	C*n*CR[FIFOEN]	1	Enable each PF's FIFO transfers
3	C*n*CR[SCDEN]	1	Enable SCD
3	C*n*PROT[SCDOP]	0	Specify that both repeating bit values increment the SCD counter
3	C*n*PROT[SCDBK]	1	Enable the SCD break signal
3	C*n*PROT[SCDLMT]	192d	Specify the SCD limit threshold

8. Optionally enable other subfunctions if you need them.
9. To enable interrupts for all channels (*n* = 0–3), write 1 to NIE[COCIEn].
10. To enable conversion, write 1 to MCR[MEN].

11. Wait until SR[CHRDYn] becomes 1 for all channels (*n* = 0–3).
12. Start PWM.
13. To start conversion for channel 3, write 1 to MCR[STRIG3].
14. Wait until NIS[COC*n*] = 1. This indicates conversion completion.
15. Read the ADC results from the FIFO using Channel n Result Data (C0RDATA - C4RDATA).
16. Process the motor-control data.
17. Reconfigure PWM.
18. Go to step 14 for the next loop.

47.6.3.6 Measurement time

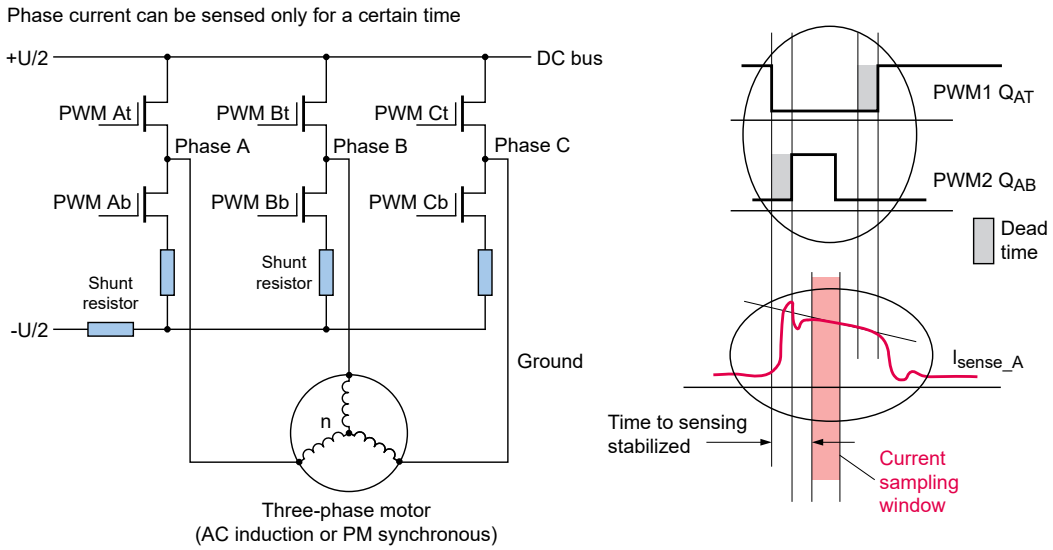

Figure 243. Measurement time

47.6.4 Use case: Motor control with Fixed-Number mode

47.6.4.1 Overview

This example improves on Use case: Motor control with Single mode by adding a compensation filter to achieve better precision, flatten the passband, improve roll-off, and so on. This method requires several samples for each PWM turn to perform filter compensation and sharpening with additional decimation. After the FIFO reaches its watermark, the conversion and filtering processes automatically stop.

NOTE

You can also achieve the same result with Continuous mode. When the FIFO reaches its watermark, you can toggle C*n*CR[PFEN] to abort conversion and wait for another trigger. The problem with this approach is that you must toggle C*n*CR[PFEN] as quickly as possible when SINC sets the corresponding NIS[CHF*n*] flag. If you disable conversion too late, it is hard to identify whether the 13th conversion had completed before you terminated conversion.

47.6.4.2 Assumptions

Table 423. Assumptions

Parameter	Value
SINC function clock	133 MHz
Target external modulator ADC clock (F_S)	22.2 MHz
Motor speed	6000 RPM (100 Hz)
PWM switch frequency (F_P)	20 kHz (corresponding to a 50 µs period, or 200 PWM steps per revolution)
Number of samples per PWM period	12
OSR	64
Decimation frequency (F_D)	346 kHz (calculated using the target external modulator ADC clock and OSR)
Cutoff frequency (F_C)	91 kHz
Additional decimation factor	2, in software
SNR	Approximately 94 dB (see the ADC specifications in the chip data sheet)
ENOB	Approximately 15.4 (calculated using SNR)
Data width	20 bits (calculated using OSR and ORD)

47.6.4.3 Frequency response

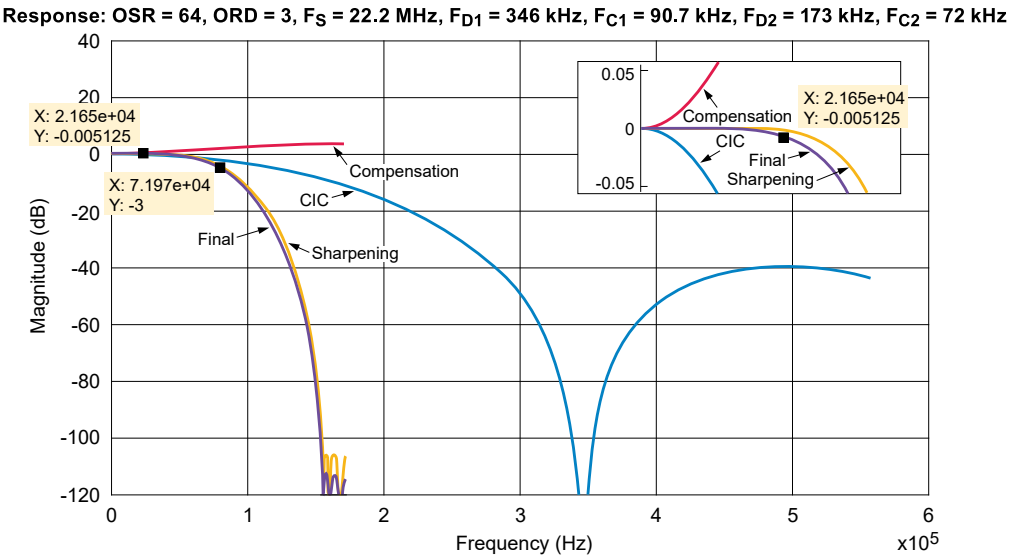

Figure 244. Frequency response

47.6.4.4 Procedure

1. Configure the related PWM and other chip modules to establish the correct pin connection with SINC. In particular, ensure that the PWM event signal connects to SINC as a hardware trigger, so that when PWM starts driving the coil, SINC can start conversion at a specific time.

2. Program the PWM event delay such that when SINC starts conversion, the coil currents are stable, as shown in Measurement time.
3. If the external ADC does not provide a clock, configure the modulator clock output. For this example, MCLK_OUT0 drives all external ADCs. To achieve MCLK_OUT0 = 22.2 MHz:
    a. Write 0 to MCR[PRESCALE].
    b. Write 5d to MCR[MCLKDIV].
4. Configure the data rate for channels 0–2 (*n* = 0–2) as follows:
    a. Write 3d to C*n*DR[PFORD].
    b. Write 63d to C*n*DR[PFOSR] to select OSR = 64.
    c. Write 11b to C*n*DR[PFCM] to select Fixed-Number mode.
5. Configure the data rate for channel 3 (*n* = 3) as follows:
    a. Write 2d to C*n*DR[PFORD] to select the optional fast response.
    b. Write 63d to C*n*DR[PFOSR] to select OSR = 64.
    c. Write 10b to C*n*DR[PFCM] to select Always On mode for monitoring total current.
6. Configure fields in Channel n Configuration (C0CFR - C4CFR) for data operation as follows:

Channels (value of *n*)	C*n*CFR field to write	Value to write	Purpose
0–3	ITLVL	0	Select edge triggering
0–2	ITSEL	1	Select hardware triggering
3	ITSEL	0	Select software triggering
0–3	IBSEL IBFMT	0	Select a bitstream from the MBIT signals (see External signals)
0	ICSEL	11b	Select the external modulator clock
1–3	ICSEL	111b	Group the clocks with channel 0
0–3	ICESEL	1b or 10b	Configure the clock edge that you want
0–3	FIFOWMK	11b	Set the FIFO watermark
0–3	RDFMT	0	Select the signed data format
0–3	PFSFT	1_0100b	Select a left shift of 4

NOTE

For channels 0–2, the conversion time for 12 samples (calculated using {[ORD+11]×OSR]}÷F_S) is 40.3 µs. This is smaller than the PWM period (50 µs) and allows enough margin to adjust sample time that Measurement time requires.

7. Enable SINC features as follows:

Channels (value of *n*)	Register and field to write	Value to write	Purpose
0–3	C*n*CR[PFEN]	1	Enable the PFs

Table continues on the next page...

Table continued from the previous page...

Channels (value of *n*)	Register and field to write	Value to write	Purpose
0–3	C*n*CR[CHEN]	1	Enable the channels and their subfunctions
0–3	C*n*CR[FIFOEN]	1	Enable each PF's FIFO transfers
3	C*n*CR[SCDEN]	1	Enable SCD
3	C*n*PROT[SCDOP]	0	Specify that both repeating bit values increment the SCD counter
3	C*n*PROT[SCDBK]	1	Enable the SCD break signal
3	C*n*PROT[SCDLMT]	192d	Specify the SCD limit threshold

8. Optionally enable other subfunctions if you need them.
9. To enable interrupts for all channels (*n* = 0–3), write 1 to NIE[COCIEn].
10. To enable conversion, write 1 to MCR[MEN].
11. Wait until SR[CHRDYn] becomes 1 for all channels (*n* = 0–3).
12. Start PWM.
13. To start conversion for channel 3, write 1 to MCR[STRIG3].
14. Wait until NIS[CHF*n*] = 1. This indicates conversion completion.
15. Read the ADC results from the FIFO using Channel n Result Data (C0RDATA - C4RDATA).
16. Optionally perform compensation:
    a. CIC gain adjust (divide 40_0000h if necessary) to get a fixed-point decimal between -1.0 and 1.0, than take part in the ADC reference voltage to get the final value in the correct format.
    b. Post-process the ADC result at a low speed, perform filter compensation and sharpening, and decimate the frequency by 2 to get the final ADC result as shown in Frequency response.
    c. If you have enough samples and don't have a hardware-delay feature, optionally perform delay compensation (for example, with a Lagrange polynomial).
17. Process the motor-control data.
18. Reconfigure PWM.
19. Go to step 14 for the next loop.

47.6.5 Use case: Audio system with Continuous mode

47.6.5.1 Overview

You can use SINC for two typical audio applications:

- Stereo recorder, using two SINC channels to sample the left and right audio channels
- Microphone array, using two or more SINC channels to sample a person's voice (based on distance from the person) and a beamforming software compensation to filter out environment noise

Schematic shows the audio schematic.

Waveforms: Audio system illustrates why you need different edges and why one MBIT input goes to two channels.

Frequency response after CIC filter shows the resulting frequency response of the PF's CIC.

Frequency response after HPF shows that HPF response is not linear and does not approach 0 dB.

47.6.5.2 Schematic

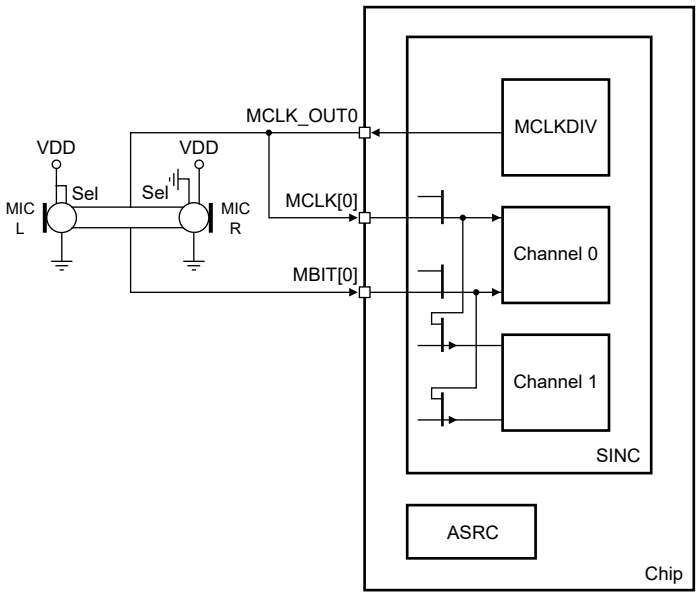

Figure 245. Schematic

47.6.5.3 Assumptions

Table 424. Assumptions

Parameter	Value
SINC function clock	133 MHz
Target external modulator ADC clock	16.6 MHz
Target audio sample rate	44.0 kHz
Data precision	24 bits
OSR	94
Additional decimation factor	4
C*n*ACFR[HPFA]	1
Signal-to-noise ratio	Approximately 118 dB
Equivalent number of bits	Approximately 19.2
Final output frequency	44.22 kHz (calculated using the ADC clock, OSR, and additional decimation)

47.6.5.8 Procedure

This procedure involves only channels 0 and 1 (*n* = 0–1).

1. Configure the chip pin connections so that one MBIT goes to both SINC channels 0 and 1 (containing the left and right bitstreams, respectively).
2. If the external ADC does not provide a clock, configure the modulator clock output. For this use case, MCLK_OUT0 drives all external ADCs. To achieve MCLK_OUT0 = 16.6 MHz:
   a. Write 0 to MCR[PRESCALE].
   b. Write 7d to MCR[MCLKDIV].

3. Configure the data rate as follows:
    a. Write 3d to C*n*DR[PFORD].
    b. Write 93d to C*n*DR[PFOSR] to select OSR = 94.
    c. Write 01b to C*n*DR[PFCM] to select Continuous mode.
4. Configure fields in Channel n Configuration (C0CFR - C4CFR) for data operation as follows:

Channels (value of *n*)	C*n*CFR field to write	Value to write	Purpose
0–1	ITLVL	0	Select edge triggering
0–1	ITSEL	0	Select software triggering
0–1	IBSEL IBFMT	0	Select a bitstream from the MBIT signals (see External signals)
0	ICSEL	11b	Select the external modulator clock
1	ICSEL	111b	Group the clocks with channel 0
0	ICESEL	1	Select the left clock edge
1	ICESEL	10b	Select the right clock edge
0–1	FIFOWMK	7d	Set the FIFO watermark
0–1	RDFMT	0	Select the signed data format
0–3	PFSFT	1_0011b	Select a left shift of 3

5. Enable SINC features:
    - Optionally enable other subfunctions if you need them.

Channels (value of *n*)	Register and field to write	Value to write	Purpose
0–1	C*n*CR[PFEN]	1	Enable the PFs
0–1	C*n*CR[CHEN]	1	Enable the channels and their subfunctions
0–1	C*n*CR[FIFOEN]	1	Enable each PF's FIFO transfers
0–1	C*n*ACFR[HPFA]	1	Select the alpha coefficient

6. Optionally enable other subfunctions if you need them.
7. To enable interrupts for channels 0 and 1, write 1 to CHFIE0 and CHFIE1 in Normal Interrupt Enable (NIE).
8. To enable conversion, write 1 to MCR[MEN].
9. Wait until SR[CHRDYn] becomes 1.
10. To start conversion, write 1 to MCR[STRIGn].
11. Wait until NIS[CHF*n*] = 1. This indicates that the FIFOs are nearly full.
12. Process the audio data. This can include:
    - Adjusting the CIC gain. For example, divide the 24-bit result by OSR^{ORD} (in this case, C_AC78h) to get a fixed-point decimal value between –1.0 and 1.0. Then, account for the ADC reference voltage to get the real value.

- Using your software to perform additional compensation, low-pass filtering (sharpening), and decimation by 4. See Frequency response after LPF and compensation for results.
- Using your software to perform HPF gain compensation. Frequency response after HPF shows that you must compensate by adding 0.1367 dB.
- Using your software or another module (such as a sample-rate converter) to perform asynchronous data-rate conversion. In this use case, the final data rate is 44.22 kHz, but the audio system requires 44.000 kHz.
- Optionally performing delay compensation or beamforming. You can use a Lagrange polynomial for this.

13. Go to step 11 for the next loop.

47.6.6 Use case: Power meter with Continuous mode

47.6.6.1 Overview

You can use SINC for a power meter.

A typical low-cost power meter can achieve a wide dynamic range (approximately 6 mA to 60 A) using:

- A successive approximation register ADC (SAR ADC), with 12- to 16-bit resolution, to measure typical voltages (for example, 220 V or 380 V) that have a stable wave.
- A sigma-delta ADC (SD ADC), with 20- to 24-bit resolution, to measure current.

For a single-phase power meter, use one SINC channel to measure current and one SAR ADC to measure voltage.

For a three-phase power meter, use three or four SINC channels to measure current and three SAR ADCs to measure voltage. If your SAR ADC supports multiplexed channels, you can use one SAR ADC to sample three voltages at different times.

Ideally, voltage and current measurements must occur at the same time. However, in this use case, simultaneous measurement is hard to achieve. You can use SINC's FILT_CC output to synchronize the measurement time between SINC and SAR ADC.

Schematic shows the power-meter schematic.

47.6.6.2 Schematic

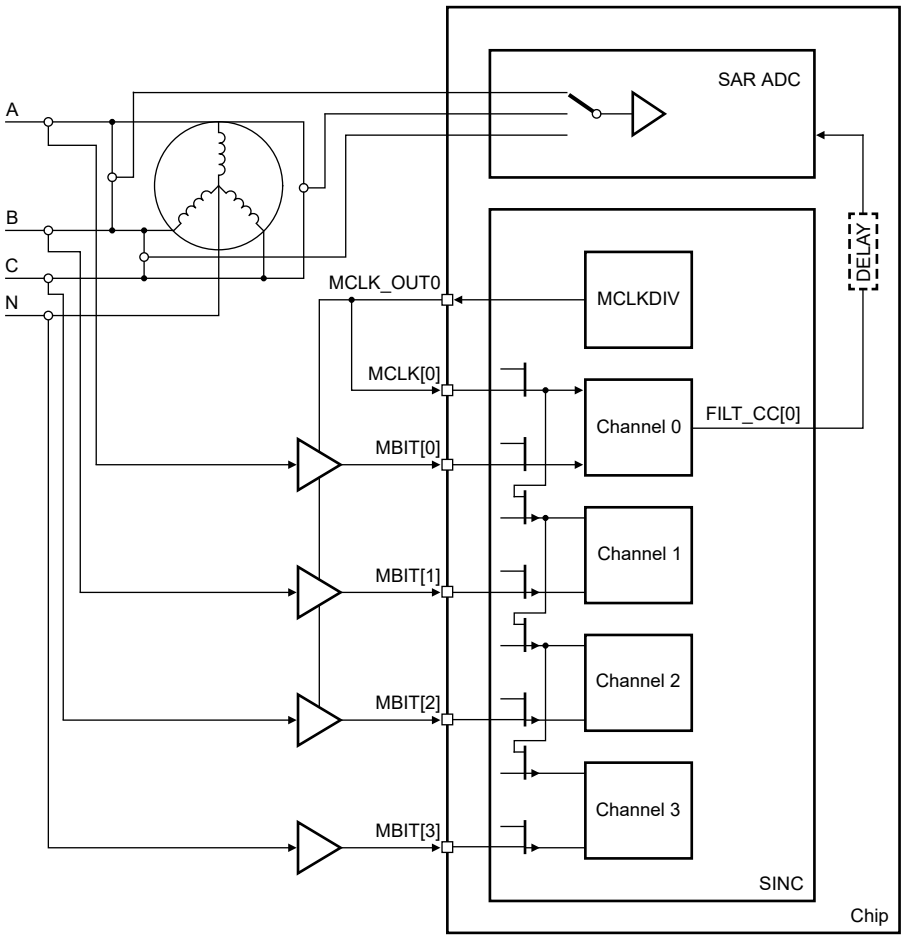

Figure 250. Schematic

47.6.6.3 Considerations

SAR ADC must support switching and must sample three voltage inputs when it receives a trigger.

This use case includes the following delays:

- From the SINC sample time to FILT_CC
- From FILT_CC to the delay block
- From the delay block to the start of SAR ADC's conversion of A in Schematic
- From the end of SAR ADC's conversion of A to the start of conversion B

You can calculate the delay, and you must compensate for that delay.

You can also manage delays by configuring the delay value to be near the SINC sample rate (0.5 × OSR), and ignore SINC's first output. In this case, when SINC completes its second conversion, SAR ADC has also just finished its first sample. Therefore, you can reduce the delay-compensation effort and improve precision by carefully configuring the delay value.

For the exact delay setting, consider SINC's CIC phase response and align it to SAR ADC's analog sample-and-hold time (not including conversion time). CIC phase response is linear, so you can convert it to a delay time, which is about half of OSR in Continuous mode.

47.7 SINC register descriptions

SINC supports a programming model for:

- Configuring the module.
- Storing the FIFO buffer.
- Enabling clock generation.
- Generating triggers.
- Protecting SINC operation.
- Using DMA.

Before you enable SINC or its channels, you must configure certain fields as described in Configure clocking-related fields before enabling SINC and Configure fields before enabling channels.

In the memory map, the following addresses are reserved and do not generate a transfer error if you access them:

- 28h
- 2Ch
- 30h
- 34h

47.7.1 SINC memory map

47.7.2 Version ID (VERID)

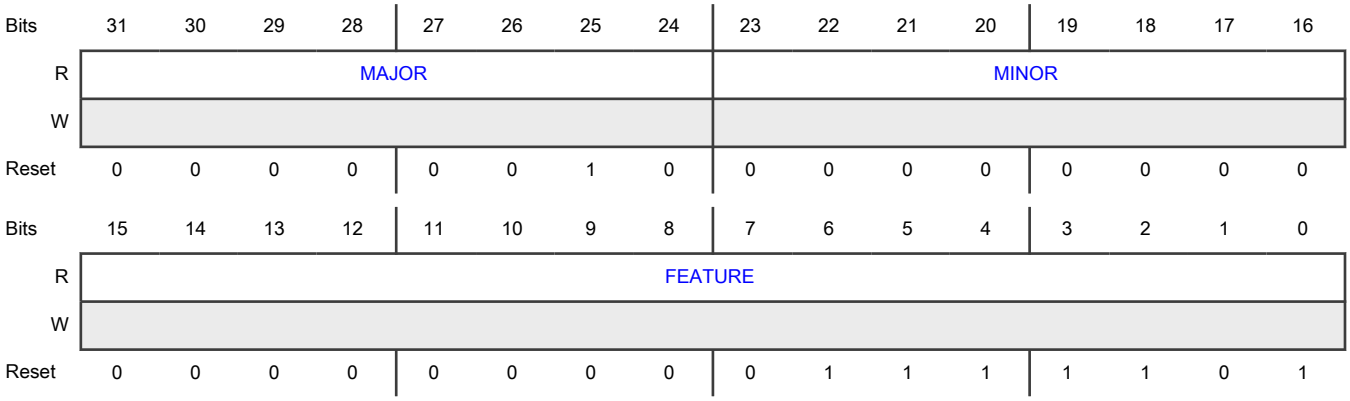
Offset

Register	Offset
VERID	0h

Function

Records the specific SINC version in the chip.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Indicates the major version number of the SINC design. 0000_0001b - 1.x 0000_0010b - 2.x All other values are reserved.
23-16 MINOR	Minor Version Number Indicates the minor version number of the SINC design. 0000_0000b - x.0 All other values are reserved.
15-0 FEATURE	Feature Specification Code Contains a coded value in which each bit represents certain features available in this SINC instance.

Bit position	Feature
0	Feature set
1	Alternate clock selection and divider
2	Asynchronous function clock
4	Reserved
5	Availability of HPF
6	Availability of bias

Field	Function

Bit position	Feature
15–7	Reserved

47.7.3 Parameters (PARAMETER)

Offset

Register	Offset
PARAMETER	4h

Function

Specifies and indicates some of SINC's operating parameters.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 —	Reserved
23-21 —	Reserved
20-16 ZCDn	Zero Cross Detected Flag Indicates whether the resulting data on filter channel *n* crossed zero and therefore changed sign. Use C*n*CFR[ZCOP] to configure the type of zero crossing that sets the Zero Cross Detected flag.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
15-13 —	Reserved
12-8 CHFn	Data Output Ready Flag Indicates whether the FIFO from PF channel *n* has overflowed its watermark level and the data is available in Channel n Result Data (C0RDATA - C4RDATA). This flag contributes to generating an interrupt or DMA request if you enabled these by using NIE[CHFIE*n*] or C*n*CR[DMAEN], respectively. SINC sets this flag according to the watermark level. If you enabled DMA requests, SINC clears the flag after the DMA controller finishes the DMA transaction. In other cases—for example, if you enabled interrupts—you clear the flag by writing 1 to it. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overflow; data not available 1b - Overflow; data available When writing 0b - No effect 1b - Clear the flag
7-5 —	Reserved
4-0 COCn	Conversion Complete Flag Indicates whether one conversion has finished and the data is available in Channel n Result Data (C0RDATA - C4RDATA). **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When reading 0b - Not finished; data not available 1b - Finished; data available When writing 0b - No effect 1b - Clear the flag

47.7.9 Error Interrupt Status (EIS)

Offset

Register	Offset
EIS	1Ch

Function

Contains flags for error-related interrupts on each SINC channel.

Diagram

Field	Function
	Defines the modulate clock edge selection. When selected edge occurs, the modulate bit are sampled for further process. 001b - Positive edge 010b - Negative edge 011b - Both edges 100b - Every other odd positive edge 101b - Every other even positive edge 110b - Every other odd negative edge 111b - Every other even negative edge All other values are reserved.
20-18 ICSEL	Input Clock Select Defines the modulate clock source selection. 000b - MCLK_OUT0 with internal routeback 001b - MCLK_OUT1 with internal routeback 010b - MCLK_OUT2 with internal routeback 011b - External modulator clock dedicated to this channel 111b - Grouped clock shared with an adjacent channel; the adjacent channel's ICSEL field determines the input clock All other values are reserved.
17-16 IBFMT	Input Bit Format Defines the input modulate bit format. 00b - External bitstream from the MBIT[n] signal 01b - External Manchester code; ICESEL selects the rise or fall decoder 10b - Internal 16-bit parallel data from MPDATA 11b - Internal 32-bit serial data from MPDATA
15 —	Reserved
14-13 —	Reserved
12-10 FIFOWMK	FIFO Watermark Specifies the FIFO watermark. When the number of entries in the FIFO exceeds this value, SINC sets the Data Output Ready flag (see NIS[CHF*n*]).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If you enable interrupt requests (write 1 to NIE[CHFIE*n*]), SINC also generates an interrupt request. If you enable DMA (write 1 to C*n*CR[DMAEN]), SINC also generates a DMA request.
9-8 —	Reserved
7 —	Reserved
6 RDFMT	Result Data Format Result data are 24bit width, located at CnRDATA[31:8]. This field controls the signed or unsigned format. If signed format, CnRDATA[31] indicates the negative or positive value. 0b - Left justified, signed 1b - Left justified, unsigned
5 —	Reserved
4-0 PFSFT	PF Shift Shifts the PF data for the correct 24-bit precision. See Shift for details. Bits 0–3 specify the number of bits to shift the data. Bit 4 specifies the shift direction: 0b - Right 1b - Left

47.7.15 Channel n Protection (C0PROT - C4PROT)

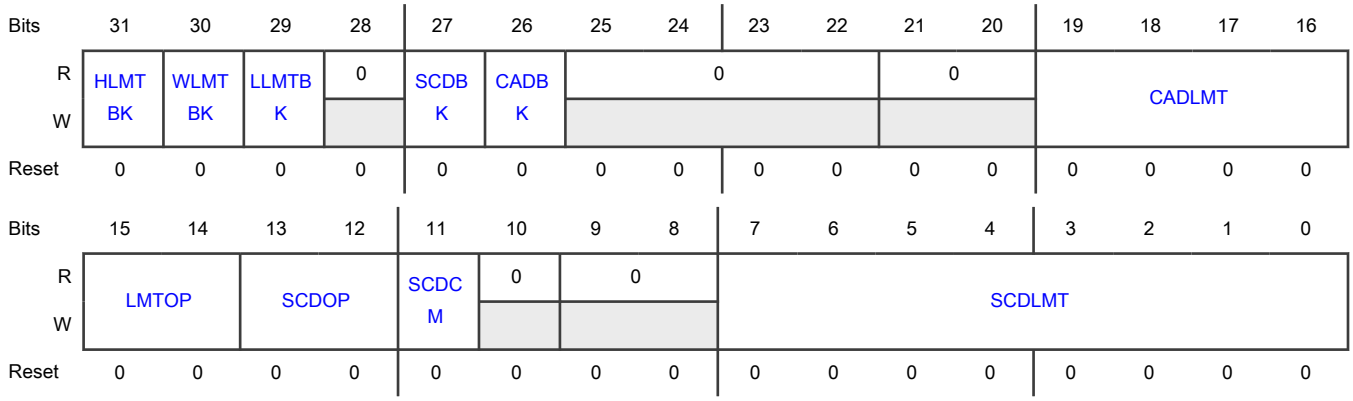
Offset

Register	Offset
C0PROT	44h
C1PROT	74h
C2PROT	A4h
C3PROT	D4h
C4PROT	104h

Function

Configures the SINC functions related to protection (SCD, CAD, and limits).

Diagram



Fields

Field	Function
31 HLMTBK	High Limit Break Signal Enables the automatic assertion of the BREAK_HIGH signal (see External signals) when SINC detects a high-limit event on the associated channel. 0b - Disables 1b - Enables
30 WLMTBK	Window Limit Break Signal Enables the automatic assertion of the BREAK_WIN signal (see External signals) when SINC detects a window-limit event on the associated channel. 0b - Disables 1b - Enables
29 LLMTBK	Low Limit Break Signal Enables the automatic assertion of the BREAK_LOW signal (see External signals) when SINC detects a low-limit event on the associated channel. 0b - Disables 1b - Enables
28 —	Reserved
27 SCDBK	SCD Break Signal Enables the automatic assertion of the BREAK_SCD signal (see External signals) when SINC detects an SCD event on the associated channel. 0b - Disables 1b - Enables
26	CAD Break Signal

Table continues on the next page...

Table continued from the previous page...

Field	Function
CADBK	Enables the automatic assertion of the BREAK_CAD signal (see External signals) when SINC detects a CAD event on the associated channel. 0b - Disables 1b - Enables
25-22 —	Reserved
21-20 —	Reserved
19-16 CADLMT	CAD Limit Threshold Specifies the threshold value for the CAD counter. The CAD counter tracks the number of clock cycles during which SINC does not detect a clock. If that number exceeds CADLMT, a CAD event occurs on the associated channel. You disable CAD by writing 0 to CADLMT. 0000b - Disables CAD All other values - Threshold value
15-14 LMTOP	Limit Detection Option Specifies whether SINC compares the filter sample value to: • The low limit (C*n*LOLMT[LOLMT]) • The high limit (C*n*HILMT[HILMT]) • Both the high and low limits • A window of values between the low and high limits See Limit detection operations for more information. 00b - Both high and low limits 01b - High limit 10b - Low limit 11b - Windowed value
13-12 SCDOP	SCD Option Specifies which repeating bit value increments the SCD counter. 00b - Both 0 and 1 01b - Only 1 10b - Only 0 11b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
11 SCDCM	SCD Conversion Mode Specifies when SCD operates. 0b - Constantly when CnCR[CHEN] = MCR[MEN] = 1 1b - Only when the PF is performing a conversion
10 —	Reserved
9-8 —	Reserved
7-0 SCDLMT	SCD Limit Threshold Specifies the threshold value for the SCD counter. The SCD counter tracks the number of received bits with the same repeating value (always 0 or always 1). If that number exceeds SCDLMT, an SCD event occurs on the associated channel. 0000_0000b-0000_0001b - Disables SCD All other values - Threshold value

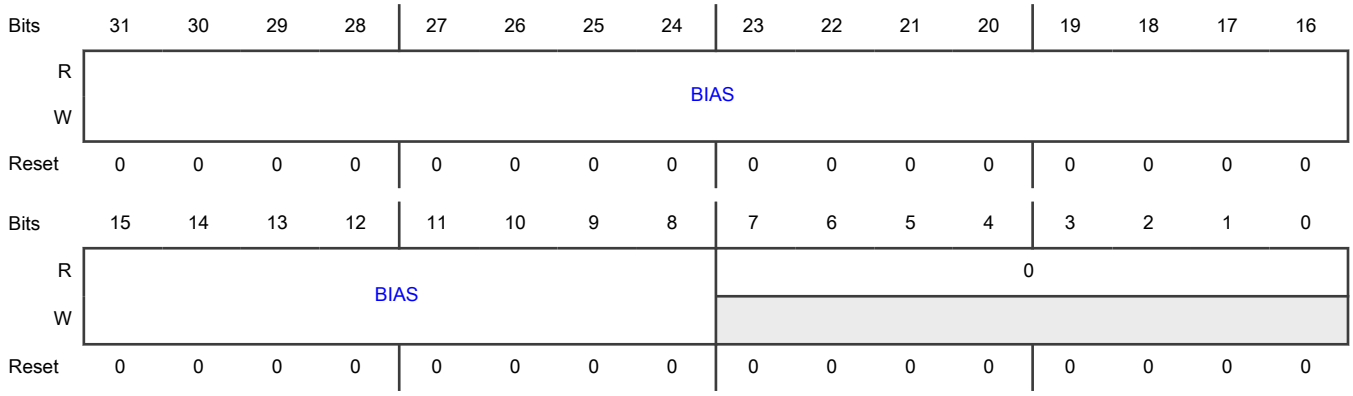
47.7.16 Channel n Bias (C0BIAS - C4BIAS)

Offset

Register	Offset
C0BIAS	48h
C1BIAS	78h
C2BIAS	A8h
C3BIAS	D8h
C4BIAS	108h

Function
Configures the filter bias.

Diagram



Fields

Field	Function
31-8 BIAS	Bias Value Specifies the bias offset for this channel's PF. After the PF shifts its data, the filter subtracts this bias value from the data. Bit 23 of this field (bit 31 within the register) specifies the bias sign: 0b - Positive 1b - Negative
7-0 —	Reserved

47.7.17 Channel n Low Limit (C0LOLMT - C4LOLMT)

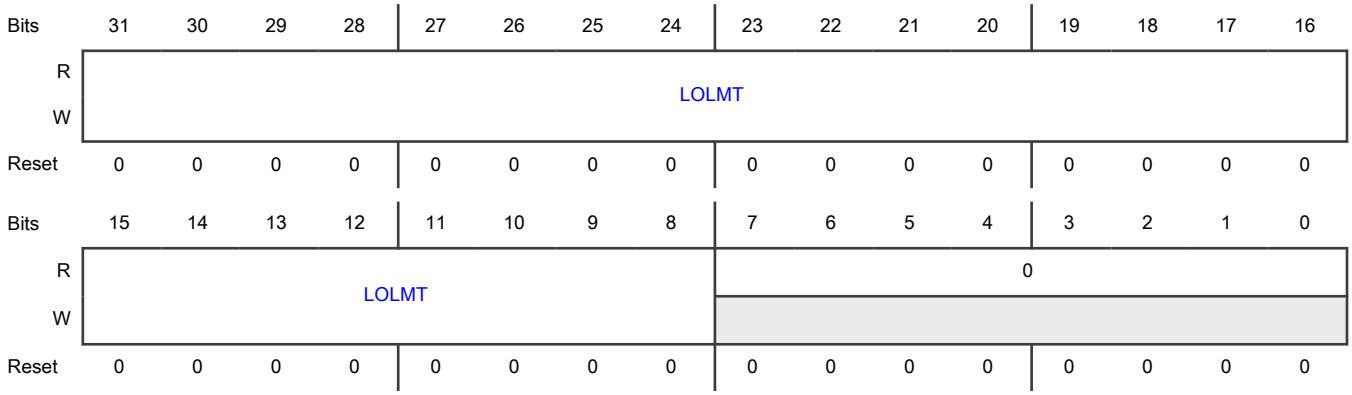
Offset

Register	Offset
C0LOLMT	4Ch
C1LOLMT	7Ch
C2LOLMT	ACh
C3LOLMT	DCh
C4LOLMT	10Ch

Function

Specifies the low-limit threshold value.

Diagram



Fields

Field	Function
31-8 LOLMT	Low Limit Threshold Specifies the low-limit threshold value. When the data exceeds this threshold value, a low-limit event occurs. C*n*CFR[RDFMT] determines the limit threshold format (signed or unsigned). **NOTE** Ensure that LOLMT is lower than C*n*HILMT[HILMT]. Otherwise, the low-limit threshold does not work.
7-0 —	Reserved

47.7.18 Channel n High Limit (C0HILMT - C4HILMT)

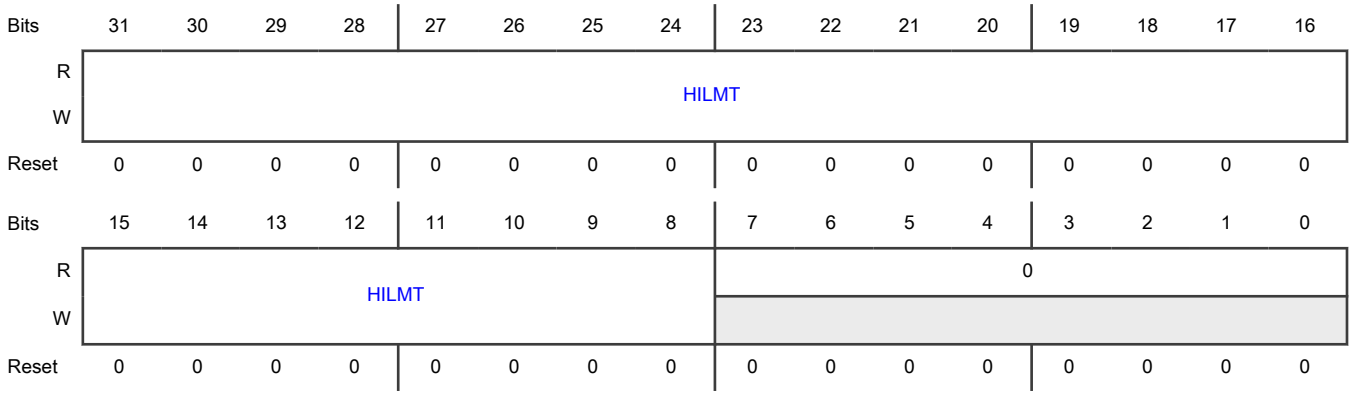
Offset

Register	Offset
C0HILMT	50h
C1HILMT	80h
C2HILMT	B0h
C3HILMT	E0h
C4HILMT	110h

Function

Specifies the high-limit threshold value.

Diagram



Fields

Field	Function
31-8 HILMT	High Limit Threshold Specifies the high-limit threshold value. When the data exceeds this threshold value, a high-limit event occurs. C*n*CFR[RDFMT] determines the limit threshold format (signed or unsigned). **NOTE** Ensure that C*n*LOLMT[LOLMT] is lower than HILMT. Otherwise, the low-limit threshold does not work.
7-0 —	Reserved

47.7.19 Channel n Result Data (C0RDATA - C4RDATA)

Offset

Register	Offset
C0RDATA	54h
C1RDATA	84h
C2RDATA	B4h
C3RDATA	E4h
C4RDATA	114h

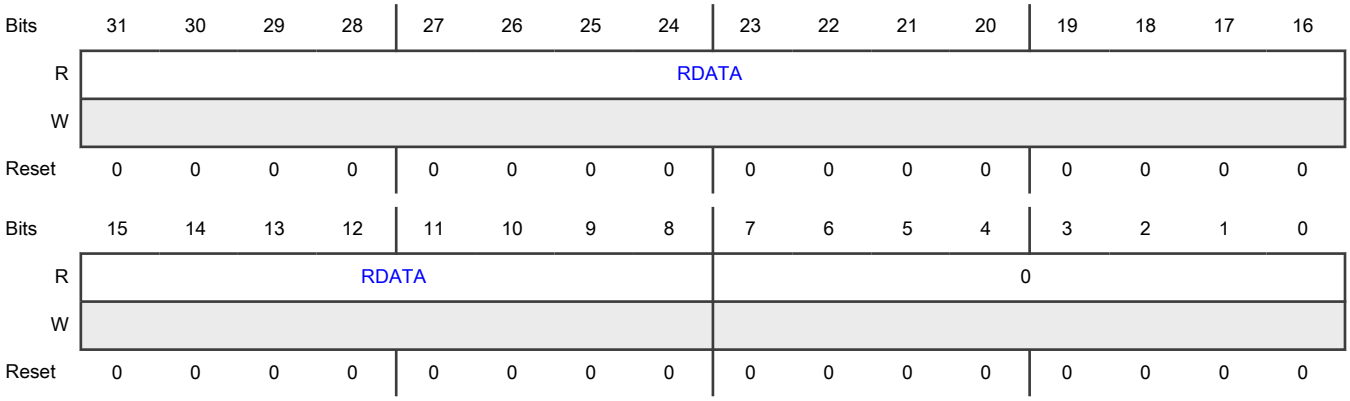
Function

Returns data from the FIFO.

NOTE

NXP recommends that you use a 32-bit access to read this register. If you use a byte access to read this register, you must read the highest byte last, and this increases the FIFO level.

Diagram



Fields

Field	Function
31-8 RDATA	Result Data Contains data from the FIFO. Bit 23 of this field (bit 31 within the register) serves as the sign bit if you specify the signed-data format (C*n*CFR[RDFMT] = 0). When you read this field, be aware of the following circumstances:

Conditions when you read RDATA	Result
SINC has not yet completed the conversion	One of the following occurs: • RDATA contains all zeros. • SINC triggers a FIFO underflow error.
FIFO is disabled (C*n*CR[FIFOEN] = 0)	RDATA contains the last conversion result. You must poll the C*n*SR[SRDS] flag, and if that flag is set after you read RDATA, you must read RDATA again.

7-0 —	Reserved

47.7.20 Channel n Multipurpose Data (C0MPDATA - C4MPDATA)

Offset

Register	Offset
C0MPDATA	58h
C1MPDATA	88h
C2MPDATA	B8h
C3MPDATA	E8h
C4MPDATA	118h

Function

Contains multipurpose data as specified in C*n*CFR[IBFMT].

You can use this register for a parallel bitstream, a serial bitstream, or a Manchester decoder threshold as described in the following table.

Table 425. MPDATA content options

Data type	C*n*CFR[IBFMT]	Description
Manchester	01b	Bits 10–0 contain the Manchester decoder threshold value.
Parallel	10b	Bits 15–0 contain the parallel 16-bit data. You can write to MPDATA only when parallel or serial data is ready (C*n*SR[PSRDY] = 1). Otherwise, a transfer error occurs.
Serial	11b	Bits 31–0 contain the serial data. You can write to MPDATA only when parallel or serial data is ready (C*n*SR[PSRDY] = 1) or MPDATA is not completely full. Otherwise, a transfer error occurs. **NOTE** Allow write MPDATA when C*n*SR[PSRDY] = 0, give you the chance if keep the remain bit for next conversion or overwrite with new data. In this case, the write are only allowed one time. **NOTE** MPDATA are shift out,you can read back for debug. But in corner case, last bit does not shift out while remain bit are zero.

47.7.22 Channel n Status (C0SR - C4SR)

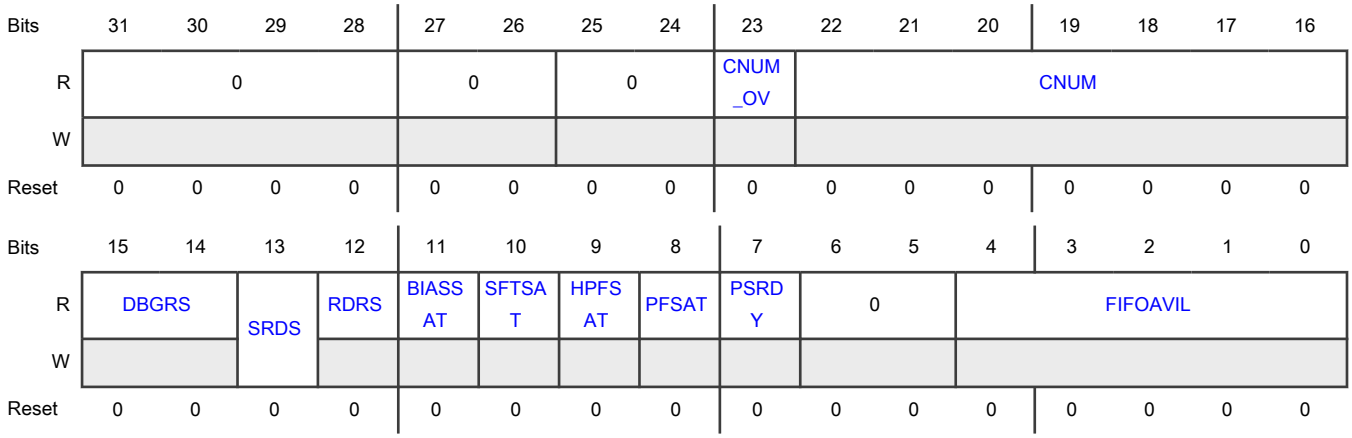
Offset

Register	Offset
C0SR	60h
C1SR	90h
C2SR	C0h
C3SR	F0h
C4SR	120h

Function

Provides channel-status information.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-26 —	Reserved
25-24 —	Reserved
23 CNUM_OV	Overflow In Number Of Conversions Indicates when the number of conversions exceeds 127. When this occurs, SINC changes CNUM_OV to 1. After resynchronization, SINC changes CNUM_OV to 0. 0b - No overflow 1b - Overflow
22-16 CNUM	Number Of Conversions In coordination with CNUM_OV, specifies the number of conversions:

Mode	Event
Continuous	After the start of a trigger
Single	After the enablement of conversion

SINC counts the number of conversions internally and modifies CNUM and CNUM_OV as follows:

When the number of conversions is:	SINC does this:
127 or fewer	Stores the number of conversions in CNUM

Field	Function
	<table><tr><th>When the number of conversions is:</th><th>SINC does this:</th></tr><tr><td>128 or more</td><td>• Stores [(number of conversions) mod 128] in CNUM • Changes CNUM_OV to 1</td></tr></table>
15-14 DBGRS	Debug Data Read Status Indicates whether the debug data is valid. When this value is 0, the CIC, HPF, shift, and offset outputs are all correct. 00b - Valid 01b-11b - Invalid
13 SRDS	Start Read Debug Data Sync Starts the debug data latch procedure and reports the procedure status. When you write 1 to this field, SINC starts the procedure and changes this field to 0. When the field becomes 0 again, you can safely read the debug data (Channel n Debug (C0DBGR - C4DBGR)). **NOTE** This field behaves differently for register reads and writes. When reading 0b - Data valid 1b - Procedure in progress When writing 0b - No effect 1b - Starts the procedure
12 RDRS	Result Data Direct Read Status When you disable the FIFO to read channel data from it, indicates that the data in Channel n Result Data (C0RDATA - C4RDATA) is stable and valid. Before this value is 1, the data may not be stable. Therefore, to obtain stable data, do one of the following: • Wait until the conversion completes, then read C*n*RDATA. • When you read data, ensure that RDRS = 0. 0b - Valid 1b - Invalid
11 BIASSAT	Bias Saturation Flag Indicates whether bias saturation occurred. 0b - Did not occur

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Occurred
10 SFTSAT	Shift Saturation Flag Indicates whether shift saturation occurred. 0b - Did not occur 1b - Occurred
9 HPFSAT	HPF Saturation Flag Indicates whether HPF saturation occurred. 0b - Did not occur 1b - Occurred
8 PFSAT	Primary CIC Saturation Flag Indicates whether primary CIC filter saturation occurred. 0b - Did not occur 1b - Occurred
7 PSRDY	Parallel or Serial Data Ready Indicates whether Channel n Multipurpose Data (C0MPDATA - C4MPDATA) is ready for you to write parallel or serial data. 0b - Not ready 1b - Ready
6-5 —	Reserved
4-0 FIFOAVIL	FIFO Available Data Indicates the number of remaining data entries in the FIFO.

47.7.23 Channel n Debug (C0DBGR - C4DBGR)

Offset

Register	Offset
C0DBGR	64h
C1DBGR	94h
C2DBGR	C4h
C3DBGR	F4h
C4DBGR	124h

Function

Contains the instantaneous debug data and status for debugging each channel's subblocks.

You select the data by writing to C*n*CR[DBGSEL], as shown in Details of debug data. For example:

- If you write 3d to C*n*CR[DBGSEL], SINC offers you 32 bits of data from the DC remover (HPF).
- If you write 4d to C*n*CR[DBGSEL], SINC offers you raw data from the PF's CIC filter.

The instantaneous data is read-only, and the contents are for each subblock.

See Reading asynchronous data safely and Transferring data between domains safely for the procedures to manage data safely.

Chapter 48
Standard Counter/Timers (CTIMER)

48.1 Chip-specific CTIMER information

Table 426. Reference links to related information

Topic	Related module	Reference
Full description	CTIMER	CTIMER
System memory map		Memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing
Input multiplexing	INPUTMUX	See TIMERnTRIG registers in INPUTMUX

This chip includes 5x standard 32-bit capture/match/pwm timers. Each timer has up to 4x capture and 4x match registers with corresponding inputs and outputs.

NOTE

I2S and USB signals to feed into timers at capture inputs.

48.1.1 Module instances

This device has five instances of the CTIMER module, CTIMER0, CTIMER1, CTIMER2, CTIMER3, CTIMER4.

48.1.2 Signals

The tables below give a summary of each of the Timer/Counter related pins and the recommended PORT settings. Also note that different part number and package variations may provide different CTIMER related pin functions.

Table 427. Timer/Counter pin description

Pin	Type	Description
CTIMER0_CAP3:0 CTIMER1_CAP3:0 CTIMER2_CAP3:0 CTIMER3_CAP3:0 CTIMER4_CAP3:0	Input	Capture Signals- A transition on a capture pin can be configured to load one of the Capture Registers with the value in the Timer Counter and optionally generate an interrupt. Capture functionality can be selected from a number of pins. Timer/Counter block can select a capture signal as a clock source instead of the APB bus clock. For more details, see CTCR register.
CTIMER0_MAT3:0 CTIMER1_MAT3:0 CTIMER2_MAT3:0 CTIMER3_MAT3:0 CTIMER4_MAT3:0	Output	External Match Output - When a match register (MR3:0) equals the timer counter (TC) this output can either toggle, go low, go high, or do nothing. The External Match Register (EMR) controls the functionality of this output. Match Output functionality can be selected on a number of pins in parallel.

48.1.3 Initialization

1. Select a clock source for the CTIMER using the CTIMERCLKSEL register.
2. Enable the clock to the CTIMER via CTIMERCLKSELn[SEL]. This enables the register interface and the peripheral function clock.
3. Clear the CTIMER peripheral reset using the Peripheral Reset Control 0 (PRESETCTRL0) and Peripheral Reset Control 1 (PRESETCTRL1) registers.
4. Each CTIMER provides interrupts to the NVIC. See MCR and CCR registers in the CTIMER register section for match and capture events. For interrupt connections, see NVIC interrupt assignments.
5. Select timer pins and pin modes as needed through the relevant PORT registers.
6. The CTIMER DMA request lines are connected to the DMA trigger inputs via the DMAC0_ITRIG_INMUX registers (See INPUTMUX). Note that timer DMA request outputs are connected to DMA trigger inputs.

48.1.4 External global enable

When the timer is enabled by the CTIMER global start register in SYSCON, (CTIMER Global Start Enable (CTIMERGLOBALSTARTEN)), it is equivalent to writing 1 to the TCR[CEN] bit in CTIMER. The external global start register is used to enable multiple timers at the same time. This operation is allowed by writing a 1 to each Timer's TCR[AGCEN] bit. If the Timer control register's CEN bit is already 1, the external global start enable register has no effect (See SYSCON[CTIMERGLOBALSTARTEN]).

For more information refer CTIMER global start enable register (See SYSCON).

48.1.5 Peripheral input multiplexers

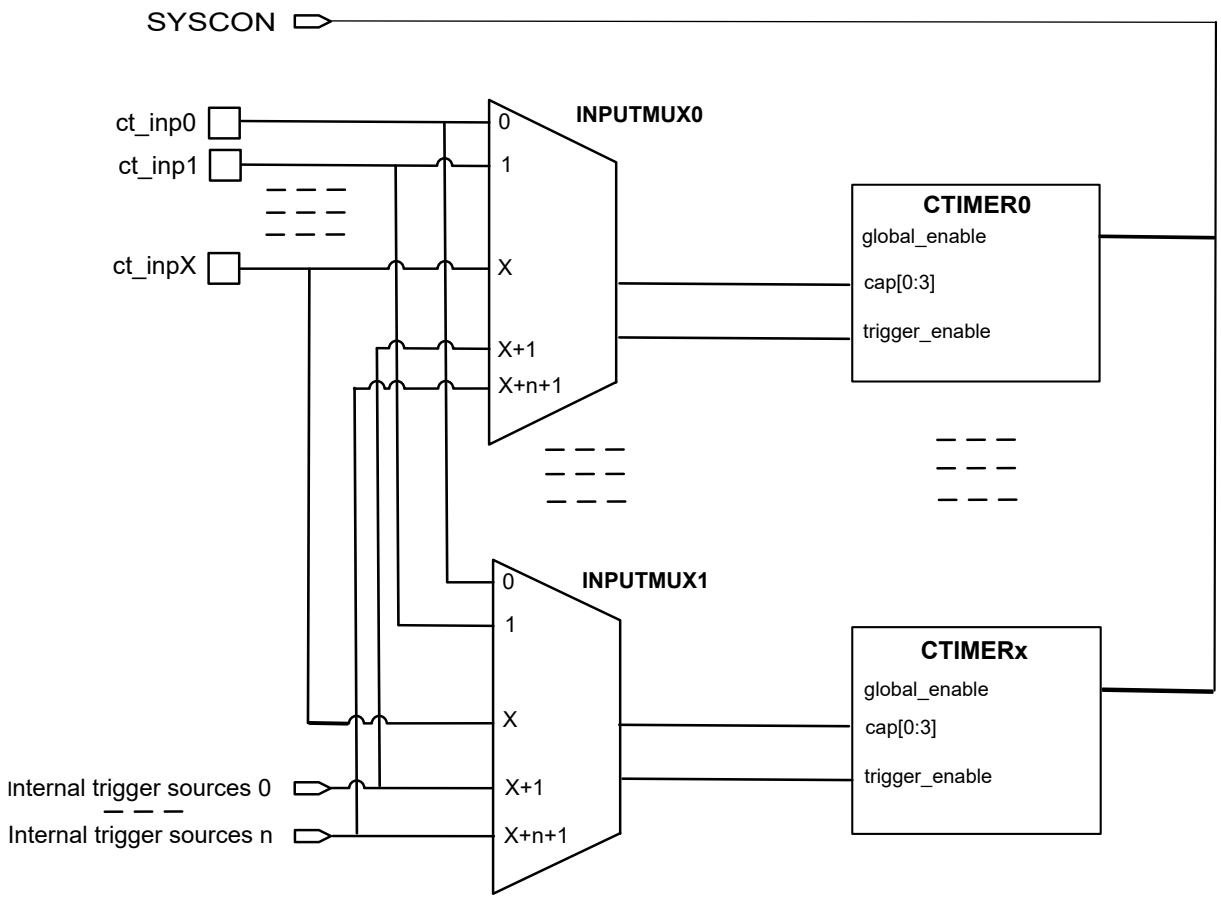

Figure 251. Peripheral input multiplexers for CTIMER

48.2 Overview

Each CTIMER is designed to count cycles of the CTIMER function clock or an externally supplied clock. A CTIMER can optionally generate an interrupt or perform other actions at specified timer values based on the settings of Match (MR0 - MR3). Each CTIMER also includes capture input pins (see Capture mode) to capture the timer value when an input signal transitions, optionally generating an interrupt.

In PWM mode, three match registers can be used to provide a single-edge controlled PWM output on the match output pins. One match register is used to control the PWM cycle length. All match registers can optionally be auto-reloaded from a companion shadow register (see Match Shadow (MSR0 - MSR3)) whenever the counter is reset to zero. This feature permits modifying the match values for the next counter cycle without disrupting PWM waveforms during the current cycle. When enabled, match reload occurs whenever the counter is reset, either because of a match event or by writing 1 to TCR[CRST].

48.2.1 Block diagram

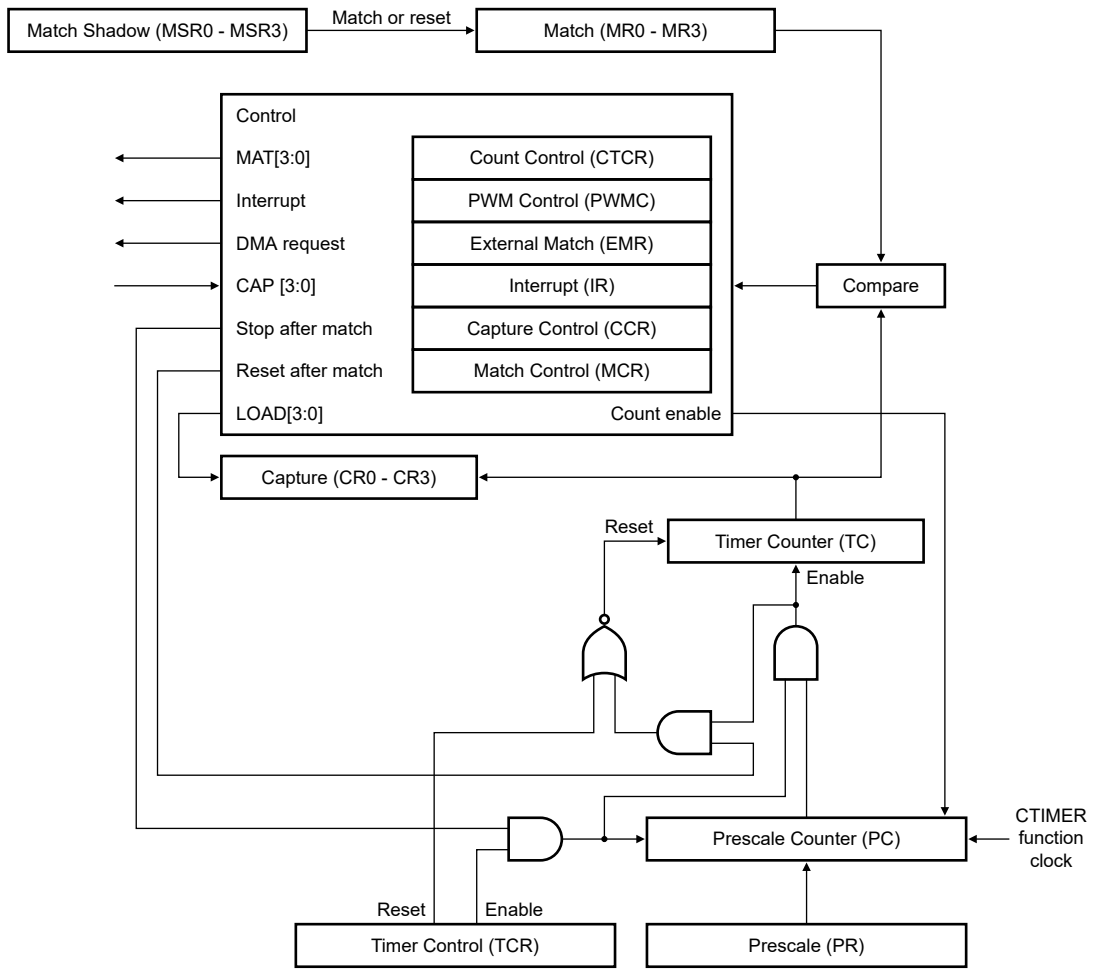

Figure 252. Block diagram

48.2.2 Features

- Contains a 32-bit CTIMER with a programmable 32-bit prescaler (the timers include external capture and match pin connections)
- Contains Timer Control (TCR) and External trigger enable, either of which you can use to enable each timer (you can also use an external global start enable register to globally enable one or more timers)
- Performs counter or timer operations
- Selects the function clocks that may be asynchronous to other system clocks
- Includes up to four 32-bit captures (see Capture mode) to take a snapshot of the timer value when an input signal transitions (a capture event may also optionally generate an interrupt, and the number of capture inputs available for each timer on a chip may vary)
- Enables you to configure the timer and prescaler to be cleared on a designated capture event (this feature permits easy pulse-width measurement by clearing the timer on the leading edge of an input pulse, capturing the timer value on the trailing edge)
- Includes Match (MR0 - MR3) to allow:
  - Continuous operation with optional interrupt generation after a match occurs

  - Optional auto-reload from Match Shadow (MSR0 - MSR3) when the counter is reset
  - Stop timer after a match with optional interrupt generation
  - Reset timer after a match with optional interrupt generation
- Generates up to four external outputs corresponding to Match (MR0 - MR3), for each timer, with the following capabilities (the number of match outputs available for each timer on a chip may vary):
  - Go low when matched
  - Go high when matched
  - Toggle when matched
  - Do nothing
- Enables you to configure up to four match registers for PWM operation, allowing up to three single-edged controlled PWM outputs (the number of match outputs available for each timer on a chip may vary)
- Uses up to two match registers to generate DMA requests

48.3 Functional description

Figure 253 shows a timer configured to reset the count and generate an interrupt after a match. The value of Prescale (PR) is 2 and the value of Match (MR0 - MR3) is 6. At the end of the timer cycle where the match occurs, the timer count is reset and gives a full-length cycle to the match value. The interrupt indicating that a match has occurred is generated in the next clock after the timer reaches the match value.

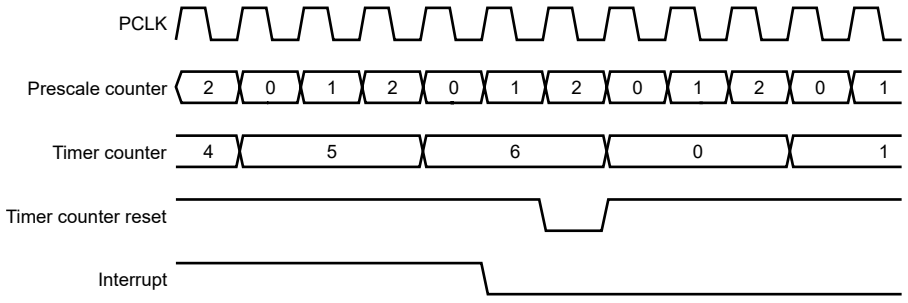

Figure 253. Timer cycle with PR = 2, MR*x* = 6, and both interrupt and reset enabled after match

Figure 254 shows a timer configured to stop and generate an interrupt after a match. The value of Prescale (PR) is 2 and the value of Match (MR0 - MR3) is 6. In the next clock after the timer reaches the match value, TCR[CEN] becomes 0 and the interrupt indicating that a match has occurred is generated.

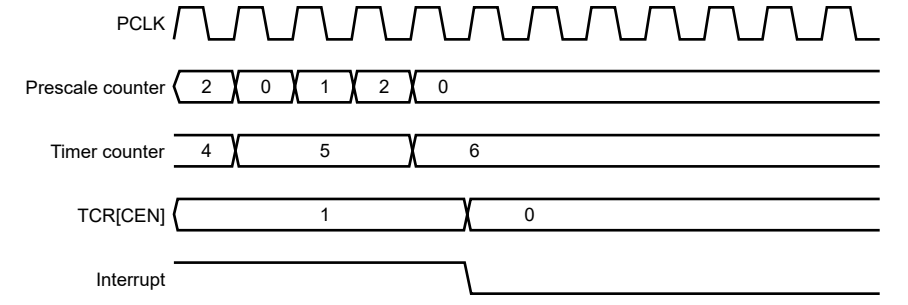

Figure 254. Timer cycle with PR = 2, MR*x* = 6, and both interrupt and stop enabled after match

48.3.1 Operation sections

All single-edge controlled PWM outputs go low at the beginning of each PWM cycle (timer is set to zero) unless their match value is zero.

Each PWM output goes high when its match value is reached. If no match occurs (that is, the match value is greater than the PWM cycle length), the PWM output remains continuously low.

If a match value larger than the PWM cycle length is written to Match (MR0 - MR3), and the PWM signal is already high, the PWM signal is cleared at the start of the next PWM cycle.

If a match register contains the same value as the timer reset value (the PWM cycle length), the PWM output is reset to low on the next clock tick after the timer reaches the match value. Therefore, the PWM output always consists of one clock tick wide positive pulse with a period that the PWM cycle length determines (that is, the timer reload value).

If Match (MR0 - MR3) = 0, the PWM output goes to high the first time the timer goes back to zero, and remains high continuously.

The following figure shows sample PWM waveforms with a PWM cycle length of 100 that MR3 specifies and PWM outputs that PWM Control (PWMC) enables.

NOTE

When you select match outputs to perform as PWM outputs, you must write 0 to MCR[MR*n*R] and MCR[MR*n*S], except to the match register setting the PWM cycle length. For this register, write 1 to MCR[MR*n*R] to enable the timer reset when the timer value matches the value of the corresponding match register.

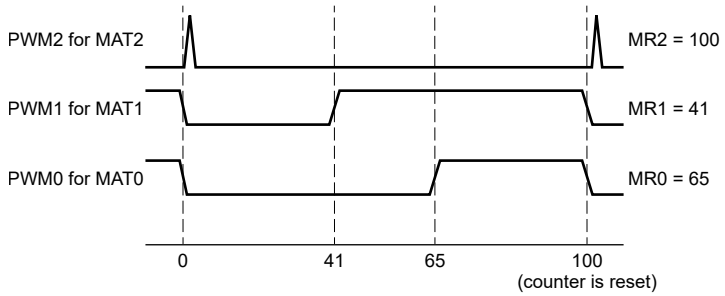

Figure 255. Sample PWM waveforms with a PWM cycle length of 100 (selected by MR3) and MAT3:0 enabled as PWM outputs by the PWM Control register.

48.3.2 Mode sections

48.3.2.1 Capture mode

You can configure a CAP to load Capture (CR0 - CR3) with the value in the counter or timer and optionally generate an interrupt. One of the pins generates the capture signal with a capture function. Each CAP is connected to one capture channel of the timer.

CTIMER can select a CAP as a clock source instead of selecting the APB CTIMER function clock. See Count Control (CTCR) for more information.

48.3.2.2 Match mode

When the value of a match register (Match (MR0 - MR3)) equals that of Timer Counter (TC), the corresponding match output can either toggle, go low, go high, or do nothing. External Match (EMR) and PWM Control (PWMC) control the functionality of this output.

48.3.3 External trigger enable

When trigger_enable is asserted (rising edge), it is equivalent to writing 1 to TCR[CEN]. If TCR[CEN] is already 1, trigger_enable rising edge events have no effect.

48.3.4 Clocking

Table 428. CTIMER clocks

Type of clock	Description
Functional Clock(ctclk)	Asynchronous to the bus clock, provide clock to perform counter or timer operations.
Bus Clock(pclk)	The bus clock is only used for bus accesses to the control and configuration registers.

48.3.5 Reset

TCR[CRST] resets Timer Counter (TC) and Prescale Counter (PC).

48.3.6 Interrupts

This module has capture and match interrupts. See the Interrupt (IR)

48.3.7 DMA

DMA requests are generated when the value of Timer Counter (TC) either matches the value of MR0 or MR1 (see Match (MR0 - MR3) for more information). This DMA request is not connected to the operation of the match outputs (see Match mode) controlled by External Match (EMR). Each match sets a DMA request flag, which is connected to the DMA controller. You must configure the DMA controller correctly.

When a timer is initially set up to generate a DMA request, the request may already be asserted before a match condition occurs. An initial DMA request may be avoided by writing 1 to the interrupt flag location, as if clearing a timer interrupt. See Interrupt (IR) for more information. A DMA request is cleared automatically when the DMA controller manages it.

NOTE

Timer DMA requests are generated whenever the timer value is equal to the related match register value. DMA requests are always generated when the timer is running, unless the match register value is higher than the upper count limit of the timer. It is important not to select and enable timer DMA requests in the DMA block unless you configure the timer correctly to generate valid DMA requests.

48.4 External signals

Table 429. CTIMER pin descriptions

Pin	Type	Description
CTIMER*m*_CAP*n*	Input	Capture signals—You can configure a transition on a capture pin to load one of the capture registers (Capture (CR0 - CR3)) with the value of Timer Counter (TC) and optionally generate an interrupt. You can select the capture functionality for a number of pins. CTIMER can select a capture signal as a clock source instead of the APB bus clock. See Count Control (CTCR) for more information.
CTIMER*m*_MAT*n*	Output	External match output—When the value of a match register (Match (MR0 - MR3)) equals the value of Timer Counter (TC), this output can either toggle, go low, go high, or do nothing. External Match (EMR) controls the functionality of this output. You can select the match output functionality for a number of pins in parallel.

48.4.1 Multiple capture (CAP) and match (MAT) pins

You can configure the pins of the chip to be used for this module. These pins are generally reused, and you can connect several internal module pins selectively. However, you can connect only one internal pin at a time.

NOTE

Match conditions may be used internally without the use of a chip's pin.

48.5 Initialization

See the Chip-specific CTIMER information for the initialization section for more details or steps.

48.6 Application information

CTIMER register descriptions discusses the following:

- Interval timer for counting internal events
- PWM outputs
- Pulse width demodulator via capture inputs
- Free running timer

48.7.2 Interrupt (IR)

Offset

Register	Offset
IR	0h

Function

Provides flags for match interrupts and capture interrupts. If an interrupt is generated, it sets the corresponding flag in this register. Otherwise, the flag remains cleared. Writing 1 to the corresponding IR field resets the interrupt. Writing 0 has no effect. Clearing an interrupt for a timer match also clears any corresponding DMA request. You can write to this register to clear interrupts, and can read this register to identify which interrupt sources are pending.

Field	Function
31-6 —	Reserved
5 ATCEN	Allow Trigger Count Enable Enables the input trigger. If this field is 1, it allows the input trigger_enable = 1 action to take effect (see External trigger enable). If this field is 0, the action is not allowed. 0b - Disable 1b - Enable
4 AGCEN	Allow Global Count Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables the global count. If this field is 1, it allows the input global_enable = 1 action to take effect. If this field = 0, the action is not allowed. 0b - Disable 1b - Enable
3-2 —	Reserved
1 CRST	Counter Reset Enable Enables the counter reset. If this field is 1, Timer Counter (TC) and Prescale Counter (PC) are synchronously reset after the next positive edge of the CTIMER function clock. The counters remain reset until this field becomes 0. If this field is 0, no effect takes place. 0b - Disable 1b - Enable
0 CEN	Counter Enable Enables the counters. If this field is 1, Timer Counter (TC) and Prescale Counter (PC) are enabled. When an external trigger enables the timer or the external global start enable register enables it, this field becomes 1 automatically. 0b - Disable 1b - Enable

48.7.4 Timer Counter (TC)

Offset

Register	Offset
TC	8h

Function

Specifies the timer counter.

This register is incremented when Prescale Counter (PC) reaches its terminal count. Unless it is reset before reaching its upper limit, Timer Counter (TC) counts up through the value FFFF_FFFFh, and then wraps back to the value 0000_0000h. This event does not cause an interrupt, but you can use Match (MR0 - MR3) to detect an overflow if needed.

Timer Counter (TC) is incremented after every Prescale (PR) + 1 cycle of the CTIMER function clock. Timer Control (TCR) controls the functioning of this register.

Diagram

Fields

Field	Function
31-0 PRVAL	Prescale Reload Value Specifies the value of the prescale reload.

48.7.6 Prescale Counter (PC)

Offset

Register	Offset
PC	10h

Function

Controls the division of the CTIMER function clock by some constant value before it is applied to Timer Counter (TC). This allows control of the relationship between the resolution of the timer and the maximum time before the timer overflows.

Prescale Counter (PC) is incremented on every CTIMER function clock. When it reaches the value stored in Prescale (PR), Timer Counter (TC) is incremented and Prescale Counter (PC) is reset on the next CTIMER function clock. This causes Timer Counter (TC) to increment on every CTIMER function clock when Prescale (PR) = 0, every two CTIMER function clocks when Prescale (PR) = 1, and so on.

You can use the bus interface to observe and control Prescale Counter (PC).

0 MR0I	Interrupt on MR0 Generates an interrupt when MR0 matches the value in Timer Counter (TC). 0b - Does not generate 1b - Generates

48.7.8 Match (MR0 - MR3)

Offset

Register	Offset
MR0	18h
MR1	1Ch
MR2	20h
MR3	24h

Function

Continuously compares the value of Match (MR0 - MR3) with the value of TC[TCVAL]. When both the values are equal, actions such as the following can be triggered automatically:

- Generation of an interrupt
- Resetting of Timer Counter (TC)
- Stopping of the timer

The settings defined in Match Control (MCR) control these actions.

If MCR[MRnRL] = 1, Match (MR0 - MR3) is automatically reloaded with the current contents of its corresponding Match Shadow (MSR0 - MSR3) whenever Timer Counter (TC) becomes 0. This transfer takes place on the same clock edge that advances Timer Counter (TC) to 0.

NOTE

Timer Counter (TC) resets in response to an occurrence of a match on MATCH being used to set the cycle counter rate. A reset can also occur if you write 1 to TCR[CRST].

Diagram

Fields

Field	Function
31-0 MATCH	Timer Counter Match Value Triggers an action automatically when the value of this field is the same as that of TC[TCVAL].

48.7.9 Capture Control (CCR)

Offset

Register	Offset
CCR	28h

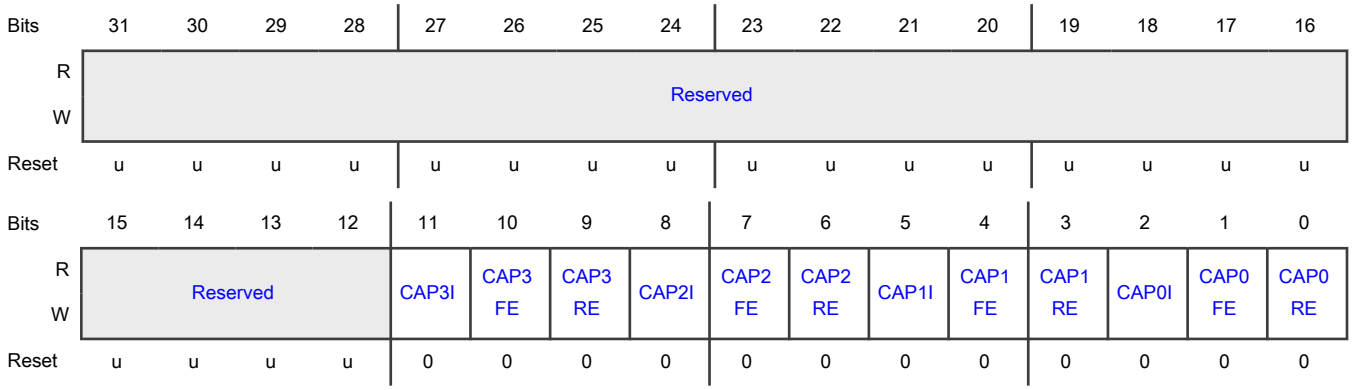
Function

Controls whether one of the capture registers (Capture (CR0 - CR3)) is loaded with the value in Timer Counter (TC) when the capture event occurs. The register also controls whether the capture event generates an interrupt. When you configure both the rising and falling bits at the same time, which is a valid configuration, it results into a capture event for both edges. In the description below, "*n*" represents the timer number, 0 or 1.

NOTE

If you select Counter mode for a particular CAP*n* input in Count Control (CTCR), you must program the fields in this register as 0. You can select both capture and interrupt for the other CAP*n* inputs.

Diagram



Fields

Field	Function
31-12 —	Reserved
11 CAP3I	Generate Interrupt on Channel 3 Capture Event Generates an interrupt on channel 3 capture event using a CR3 load. 0b - Does not generate 1b - Generates
10 CAP3FE	Falling Edge of Capture Channel 3 Loads CR3 with the contents of Timer Counter (TC) when you write 1 and then 0 to this field. 0b - Does not load 1b - Loads

2 CAP0I	Generate Interrupt on Channel 0 Capture Event Generates an interrupt on channel 0 capture event using a CR0 load. 0b - Does not generate 1b - Generates
1 CAP0FE	Falling Edge of Capture Channel 0 Loads CR0 with the contents of Timer Counter (TC) when you write 1 and then 0 to this field. 0b - Does not load 1b - Loads
0 CAP0RE	Rising Edge of Capture Channel 0 Loads CR0 with the contents of Timer Counter (TC) when you write 0 and then 1 to this field. 0b - Does not load 1b - Loads

48.7.10 Capture (CR0 - CR3)

Offset

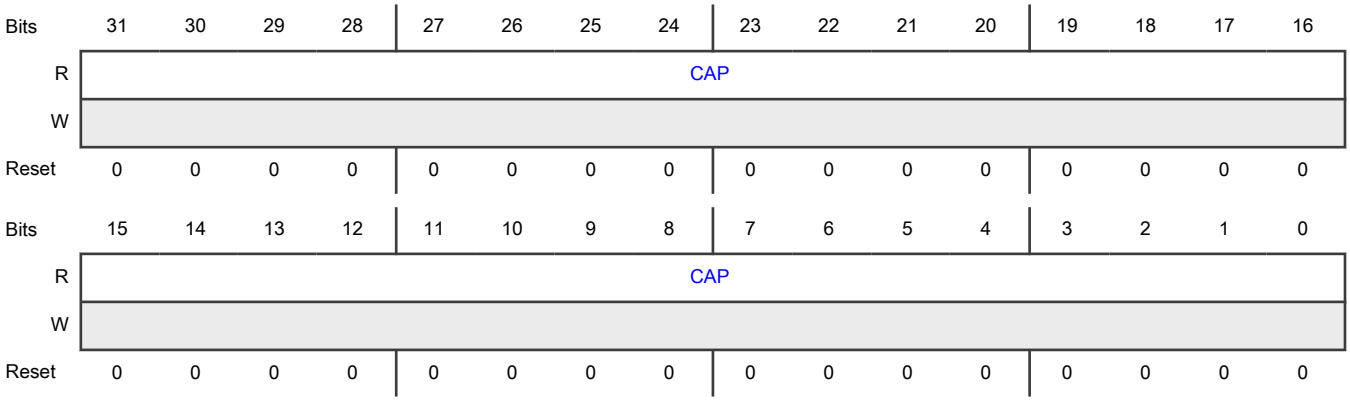
Register	Offset
CR0	2Ch
CR1	30h
CR2	34h
CR3	38h

Function

Works with a capture channel and may load with the value of Timer Counter (TC) when a specified event occurs on the signal defined for that capture channel. The signal could originate from an external pin or an internal source.

This register determines whether the capture function is enabled, and whether a capture event happens on the rising edge, falling edge, or on both edges of the associated signal. The register is loaded with the value of Timer Counter (TC) when there is an event on the CAP*n* input.

Diagram



Fields

Field	Function
31-0 CAP	Timer Counter Capture Value Determines whether the capture function is enabled and defines the edge on which the capture function occurs.

48.7.11 External Match (EMR)

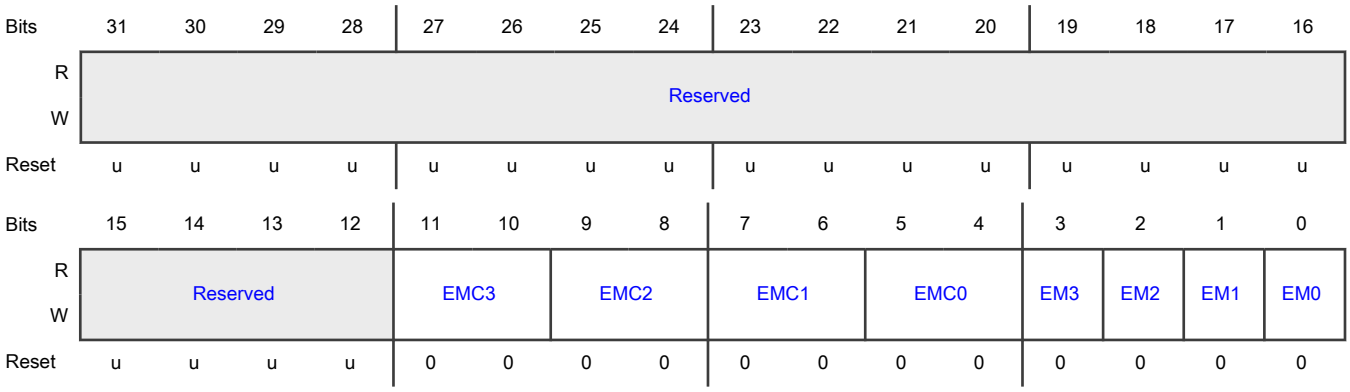
Offset

Register	Offset
EMR	3Ch

Function

Provides both control and status of the external match pins. If the match outputs (see Match mode) are configured as PWM outputs, PWM rules determine the function of this register.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-10 EMC3	External Match Control 3 Determines the functionality of EM3: • If this field is 1, the corresponding external match field or output becomes 0 (if pinned out MAT3 pin is low). • If this field is 10, the corresponding external match field or output becomes 1 (if pinned out MAT3 pin is high). • If this field is 11, it toggles the corresponding external match field or output. 00b - Does nothing 01b - Goes low 10b - Goes high 11b - Toggles
9-8 EMC2	External Match Control 2 Determines the functionality of EM2: • If this field is 1, the corresponding external match field or output becomes 0 (if pinned out MAT2 pin is low). • If this field is 10, the corresponding external match field or output becomes 1 (if pinned out MAT2 pin is high). • If this field is 11, it toggles the corresponding external match field or output. 00b - Does nothing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	do nothing, as selected by EMC2. This field is driven to the MAT pins if the match function is selected via IOPCTL. 0b - Low 1b - High
1 EM1	External Match 1 Reflects the state of output MAT1—whether this output is connected to a pin. If a match occurs between Timer Counter (TC) and MR1 (see Match (MR0 - MR3)), this field can either toggle, go low, go high, or do nothing, as selected by EMC1. This field is driven to the MAT pins if the match function is selected via IOPCTL. 0b - Low 1b - High
0 EM0	External Match 0 Reflects the state of output MAT0—whether this output is connected to a pin. If a match occurs between Timer Counter (TC) and MR0 (see Match (MR0 - MR3)), this field can either toggle, go low, go high, or do nothing, as selected by EMC0. This field is driven to the MAT pins if the match function is selected via IOPCTL. 0b - Low 1b - High

48.7.12 Count Control (CTCR)

Offset

Register	Offset
CTCR	70h

Function

Selects between Timer and Counter mode, and in Counter mode, selects the signal and edges for counting.

When Counter mode is selected as the mode of operation, the CAP input (selected by CINSEL) is sampled on every rising edge of the CTIMER function clock. After comparing two consecutive samples of this CAP input, one of the following four events is recognized:

- Rising edge
- Falling edge
- Either of the edges
- No change in the selected CAP input level

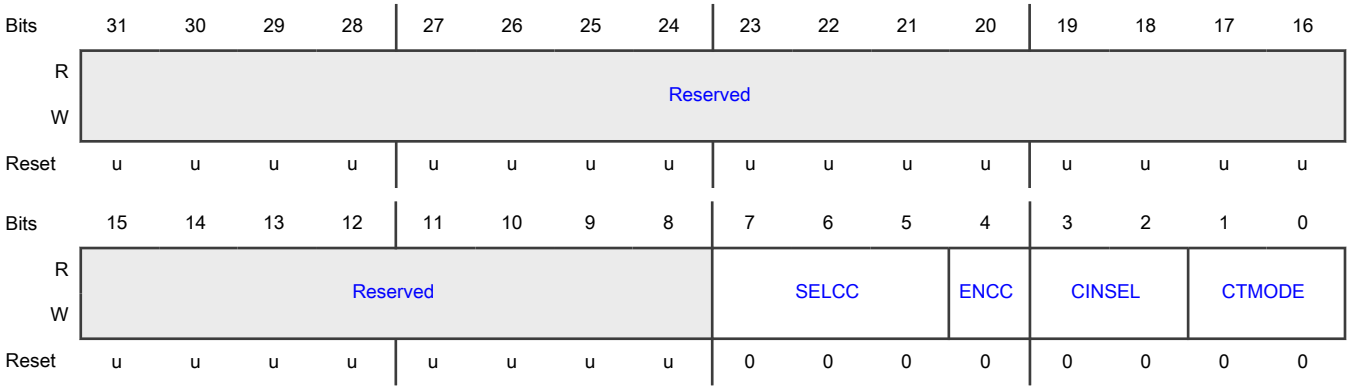
Only if the identified event occurs and the event corresponds to the one selected by CTMODE, Timer Counter (TC) is incremented.

Effective processing of the externally supplied clock to the counter has some limitations:

- Because two successive rising edges of the CTIMER function clock are used to identify only one edge on the CAP selected input, the frequency of the CAP input cannot exceed one half of the CTIMER function clock.
- Consequently, the duration of the high or low levels on the same CAP input in this case cannot be shorter than the CTIMER function clock duration.

You can also use ENCC and SELCC to enable and configure the capture-clears-timer feature. This feature allows for a designated edge on a particular CAP input to reset the timer to all zeros. Using this mechanism to clear the timer on the leading edge of an input pulse and perform a capture on the trailing edge permits direct pulse-width measurement using a single capture input without the need to perform a subtraction operation in software.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-5 SELCC	Edge Select Selects which input edge (rising or falling) causes the timer and prescaler to be cleared, when ENCC is 1. These fields have no effect when ENCC is 0. 000b - Capture channel 0 rising edge 001b - Capture channel 0 falling edge 010b - Capture channel 1 rising edge 011b - Capture channel 1 falling edge 100b - Capture channel 2 rising edge 101b - Capture channel 2 falling edge 110b - Capture channel 3 rising edge 111b - Capture channel 3 falling edge
4 ENCC	Capture Channel Enable Enables capture channel. Writing 1 to this field enables clearing of the timer and the prescaler when the capture-edge event specified in SELCC occurs.

Table continues on the next page...

Table continued from the previous page...

Field	Function
3-2 CINSEL	Count Input Select Selects which CAP pin is sampled for clocking when CTMODE is not 0. **NOTE** If Counter mode is selected for a particular CAP*n* input in Count Control (CTCR), you must program the corresponding fields for that input in Capture Control (CCR) as 0. However, you can select both capture and interrupt for the other three CAP*n* inputs in the same timer. 00b - Channel 0, CAPn[0] for CTIMERn 01b - Channel 1, CAPn[1] for CTIMERn 10b - Channel 2, CAPn[2] for CTIMERn 11b - Channel 3, CAPn[3] for CTIMERn
1-0 CTMODE	Counter Timer Mode Selects between Timer and Counter mode, and in Counter mode, selects the signal and edges for counting: • If this field is 0, every rising CTIMER function clock edge is incremented. • If this field is 1, Timer Counter (TC) is incremented on the rising edges of the CAP input selected by CINSEL. • If this field is 10, Timer Counter (TC) is incremented on the falling edges of the CAP input selected by CINSEL. • If this field is 11, Timer Counter (TC) is incremented on both edges of the CAP input selected by CINSEL. 00b - Timer mode 01b - Counter mode rising edge 10b - Counter mode falling edge 11b - Counter mode dual edge

48.7.13 PWM Control (PWMC)

Offset

Register	Offset
PWMC	74h

Function

Configures match outputs (see Match mode) as PWM outputs. You can independently set each match output to perform either as a PWM output or match output controlled by External Match (EMR).

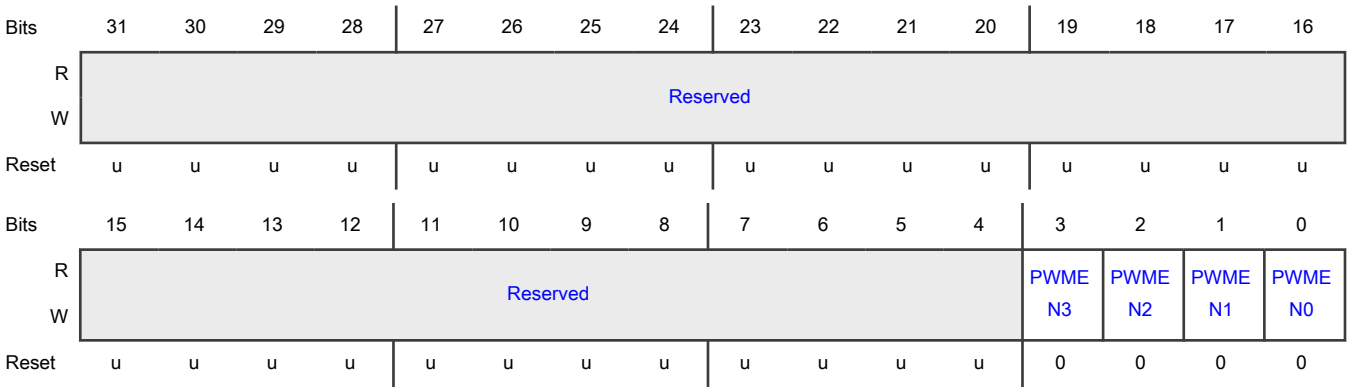
NOTE

Different part numbers and package variations may provide different match output pin functions.

For each timer, you can select a maximum of three single-edge controlled PWM outputs on the MAT*n*[2:0] outputs. One additional match register (see Match (MR0 - MR3)) determines the PWM cycle length. When a match occurs in any of the other match registers, the PWM output is set to high. The match register resets the timer that you can configure to set the PWM cycle length. When the timer is reset to zero, all currently high match outputs configured as PWM outputs are cleared.

This register enables PWM mode for the external match pins.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 PWMEN3	PWM Mode Enable for Channel 3 Enables PWM mode for channel 3. Use match channel 3 to set the PWM cycle length. If this field is 0, EM3 controls CTIMER*n*_MAT3. If this field is 1, PWM mode is enabled for CTIMER*n*_MAT3. 0b - Disable 1b - Enable
2 PWMEN2	PWM Mode Enable for Channel 2 Enables PWM mode for channel 2. If this field is 0, EM2 controls CTIMER*n*_MAT2. If this field is 1, PWM mode is enabled for CTIMER*n*_MAT2. 0b - Disable 1b - Enable
1 PWMEN1	PWM Mode Enable for Channel 1 Enables PWM mode for channel 1. If this field is 0, EM1 controls CTIMER*n*_MAT1. If this field is 1, PWM mode is enabled for CTIMER*n*_MAT1. 0b - Disable 1b - Enable
0	PWM Mode Enable for Channel 0

Table continues on the next page...

Table continued from the previous page...

Field	Function
PWMEN0	Enables PWM mode for channel 0. If this field is 0, EM0 controls CTIMER*n*_MAT0. If this field is 1, PWM mode is enabled for CTIMER*n*_MAT0. 0b - Disable 1b - Enable

48.7.14 Match Shadow (MSR0 - MSR3)

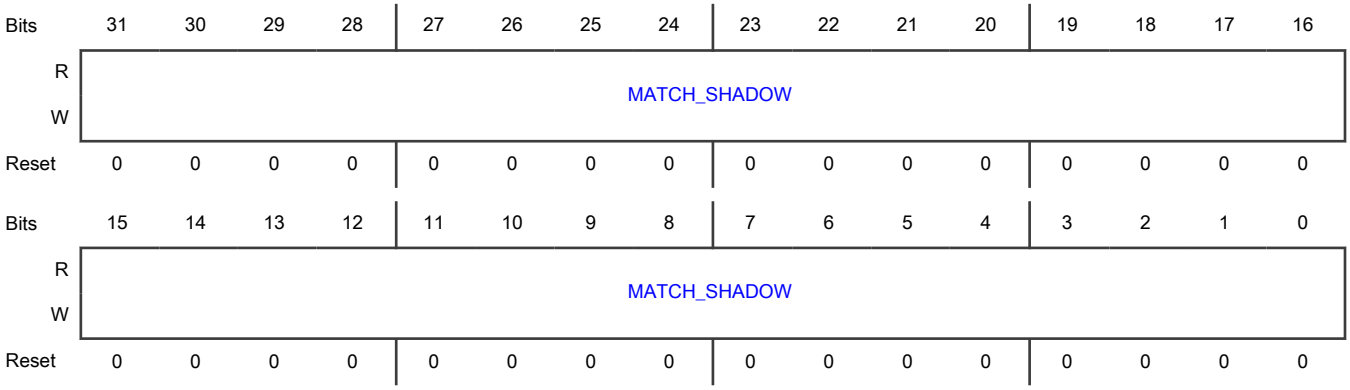
Offset

Register	Offset
MSR0	78h
MSR1	7Ch
MSR2	80h
MSR3	84h

Function

Contains the value that the corresponding Match (MR0 - MR3) are (optionally) reloaded with at the start of each new counter cycle. Typically, the match that causes the counter to be reset (and instigates the match reload) is also programmed to generate an interrupt or DMA request. Software or the DMA engine then has one full counter cycle to modify the contents of this register before the next reload occurs.

Diagram



Fields

Field	Function
31-0 MATCH_SHADOW	Timer Counter Match Shadow Value Reloads automatically with the contents of this register whenever Timer Counter (TC) is reset to zero.

49.1.1 Module instances

This device has one instance of the SCTIMER module, SCT0.

49.2 Overview

SCT is a powerful, flexible timer module capable of creating complex PWM waveforms and performing other advanced timing and control operations with minimal or no CPU intervention. It can operate as a single 32-bit counter or as two independent, 16-bit counters in Unidirectional or Bidirectional modes.

As with most timers, SCT supports:

- A selection of match registers against which you can compare the count value.
- Capture registers where you can record the current count value if a predefined condition is detected.

An additional feature contributing to the versatility of SCT is the concept of events. This module supports multiple separate events that you can define based on some combination of parameters, including all or some of the following:

- A match on one of the match registers
- A transition on one of the SCT inputs or outputs
- The direction of count

Every action that SCT performs occurs in direct response to the events that you define, without any software overhead. You can enable an event to:

- Start, stop, or halt the counter.
- Limit the counter, which refers to clearing the counter in Unidirectional mode, or changing the counter direction in Bidirectional mode.
- Set, clear, or toggle any SCT output.
- Force a capture of the count value into any of the capture registers.
- Generate an interrupt or DMA request.

SCT also allows you to group and filter events. A group of enabled and disabled events can be described as a state, and several states with different sets of enabled and disabled events are allowed. Changing from one state to another is event-driven and can therefore happen without your intervention. By defining these states, SCT provides the means to run state machines in hardware to accomplish complex waveform and timing tasks.

In a simple system such as a classical timer or counter with capture and match capabilities, all events that could cause the timer to capture the timer value or toggle a match output are enabled, and remain enabled, at all times while the counter is running. In this case, no events are filtered and the state that does not change describes the system. This is the default configuration for SCT.

In a more complex system, two states could be set up that allow some events in one state and not in the other. You can use an event that is enabled in both states to move from one state to the other and back while filtering out events in either of the states. In such a two-state system, you can create different waveforms at the SCT output, depending on the event history. Change of states is event-driven and happens without any CPU intervention.

Formally, you can program SCT as a state machine generator. With the unique ability to perform switching between groups of events, you can use SCT as a highly complex state machine engine. Events identify the occurrence of conditions that warrant state changes and determine the next state to move to. This provides you with an extremely powerful control tool—particularly when SCT inputs and outputs are connected to other on-chip resources.

In addition to events and states, SCT provides other enhanced features:

- Four alternative clocking modes including a fully asynchronous mode
- Selection of any SCT input as a clock source or a clock gate
- Ability to define a fractional portion to certain match registers (fractional matching uses a “dither” approach to achieve average resolutions of up to 1/16th of a clock period when generating PWM edges)
- Ability to select a greater-than-or-equal-to match condition for the purpose of event generation

NOTE

In this chapter, the term "bus error" indicates an SCT response that makes the processor take an exception.

49.2.1 Block diagram

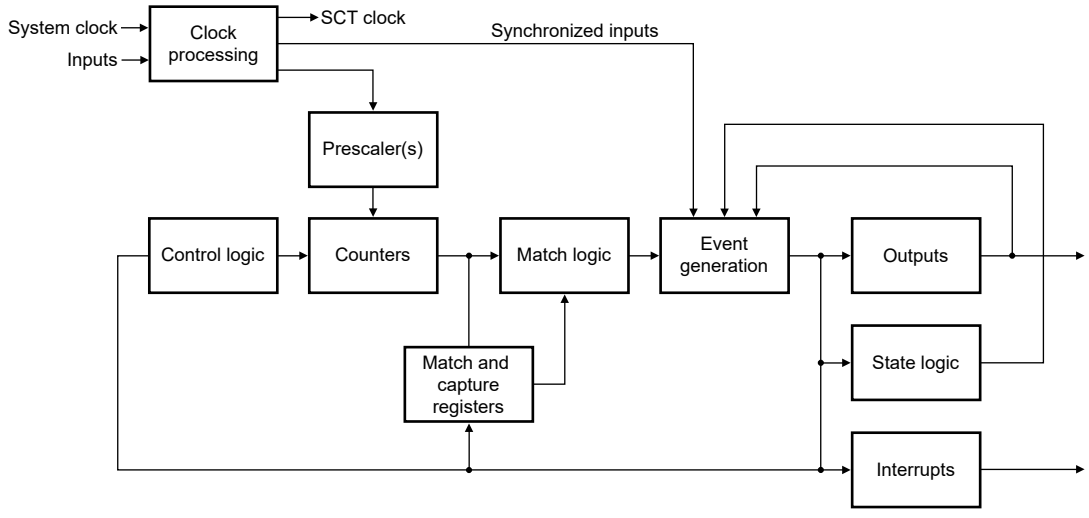

Figure 256. Block diagram

49.2.2 Features

SCT supports:

- 8 inputs

- 10 outputs
- 16 match and capture registers
- 16 events
- 32 states
- 6 dithers

Counter or timer features:

- Configurable as two 16-bit counters or one 32-bit counter (this configuration is possible for each SCT)
- Counters clocked by the system clock or a selected input
- Configurable as up counters or up-down counters
- Configurable number of match and capture registers
- Ability for the counter value to be loaded into capture registers, triggered by a match or I/O toggle
- Event creation possible for the following timer events for match and/or I/O transitions:
  - DMA request
  - Interrupt
  - Stop
  - Limit
  - Halt
  - Change counting direction
  - Toggle outputs
  - Change the state

PWM features:

- Ability to use counters with match registers to toggle outputs and create time-proportioned PWM signals (PWM waveforms can change based on the current state)
- Up to eight single-edge or four dual-edge PWM outputs with an independent duty cycle and a common PWM cycle length

Event creation features:

- Ability to enable events in Bidirectional mode, based on the count direction (the following conditions define an event):
  - A counter match condition
  - An input (or output) condition such as a rising or falling edge or level
  - A combination of match and/or I/O conditions
- Ability for selected events to limit, halt, start, or stop a counter or change direction
- Ability for events to trigger state changes, output transitions, timer captures, interrupts, and DMA transactions
- Ability to use match register 0 as an automatic limit
- Ability to hold match events until another qualifying event occurs

State control features:

- No pre-defined meaning (you determine these states entirely)
- Provision for a mechanism of context switching for SCT, including creation of complex state machines
- Defined by events that can happen in the state while the counter is running
- Ability to transition into another state as a result of an event

- Ability to be assigned to one or more states
- Ability for state variables to allow sequencing across multiple counter cycles

49.3 Functional description

49.3.1 SCT operation

In its simplest, single-state configuration, SCT operates as an event-controlled single or bidirectional counter. You can configure events as:

- Counter match events
- An input or output level
- Transitions on an input or output pin
- Combination of match and I/O behavior

In response to an event, SCT output (or outputs) can transition, or SCT can perform other actions such as creating an interrupt, and starting, stopping, or resetting the counter. You can perform multiple, simultaneous actions for each event. Furthermore, any number of events can trigger a specific SCT action.

A single or multiple SCT actions uniquely define an event. Events that you enable to trigger an SCT action or actions at any stage of the counter define a state, and the events not selected for this state are ignored.

In a multi-state configuration, states change in response to events. A state change is an additional action that SCT can perform when an event occurs. If you configure an event to change the state, the new state defines a new set of events resulting in different SCT actions. Through multiple cycles of the counter, events can change the state multiple times and thus create a large variety of event-controlled transitions on the SCT outputs and/or interrupts.

After configuration, SCT can run continuously, without your intervention, and can generate multiple output patterns entirely under the control of events. See the following sections to perform various SCT actions:

- Configuring SCT for multiple events and states to configure SCT
- Running SCT to start, run, and stop SCT
- Configuring SCT without using states to configure SCT as a simple, event-controlled counter or timer

49.3.2 Configuring SCT without using states

SCT can function as a standard counter or timer with external capture inputs and match outputs, without using the state logic. To use SCT without states, configure SCT as follows:

1. Write 0 to State Variable (STATE) (0 is the default).
2. Write 0 to EV*n*_CTRL[STATELD] and EV*n*_CTRL[STATEV] for each event.
3. Write 0x1 to EV*n*_STATE[STATEMSKn] for each event. This enables the event.

In effect, the event occurs in a single state that never changes when the counter is running.

49.3.3 Configuring SCT for multiple events and states

49.3.3.1 Configure the counter

1. Configure the low (L) and high (H) counters in SCT Configuration (CONFIG) by selecting two independent 16-bit counters (L and H) or one combined 32-bit counter in CONFIG[UNIFY].
2. Select the SCT clock source by using CONFIG[CLKMODE] and CONFIG[CKSEL] from any of the inputs or an internal clock.

49.3.3.2 Configure the match and capture registers

1. Select the number of match and capture registers that the application uses (not more than what is available on this chip), by using Match and Capture Register Mode (REGMODE). For each of the match and capture register pairs, you can select whether the register is used as a match register or capture register.
2. Define match conditions for each selected match register:
   - Each match register (Match Value (MATCH0 - MATCH15)) sets one match value, if a 32-bit counter is used, or two match values, if the L and H 16-bit counters are used.
   - Each match reload register (Match Reload Value (MATCHREL0 - MATCHREL15)) sets a reload value that is loaded into the match register when the counter reaches a limit condition or the value 0.

49.3.3.3 Configure events and event responses

State variables allow SCT control across more than one cycle of the counter. Counter matches, I/O edges, and state values are combined into a set of general-purpose events that can switch outputs, request interrupts, and change state values (see Figure 257). Perform this procedure to configure events and event responses:

1. Define what triggers each event, by using Event n Control (EV0_CTRL - EV15_CTRL) (one register per event):
   - Using EV*n*_CTRL[COMBMODE], select whether the event occurs:
     - On change of an input or output
     - On an input or output level
     - On a match condition of the counter
     - On a combination of match and I/O conditions
   - For a match condition:
     a. Select the match register that contains the match condition for the event to occur. Enter the number of the selected match register in EV*n*_CTRL[MATCHSEL].
     b. Define, by using EV*n*_CTRL[HEVENT], whether the event occurs on matching the L or the H counter (when using L and H counters).
   - For an SCT input or output level or transition:
     a. Select the input number or the output number that is associated with this event, using EV*n*_CTRL[IOSEL] and EV*n*_CTRL[OUTSEL].
     b. Define how the selected input or output triggers the event (edge- or level-sensitive) using EV*n*_CTRL[IOCOND].
2. Define the effect of each event on SCT outputs, by using Output n Set (OUT0_SET - OUT9_SET) or Output n Clear (OUT0_CLR - OUT9_CLR) (up to the maximum number of outputs on this chip, one register per output): For each SCT output, select the events that set or clear this output. More than one event can change the output, and each event can change multiple outputs.
3. Define how each event affects the counter:
   a. Write 1 to the corresponding LIMIT[LIMMSK_H] or LIMIT[LIMMSK_L] for the event to set an upper limit for the counter:
      - When a limit event occurs in Unidirectional mode, the counter is cleared to zero and begins counting up on the next clock edge.
      - When a limit event occurs in Bidirectional mode, the counter begins to count down from the current value on the next clock edge.
   b. Write 1 to the corresponding HALT[HALTMSK_H] or HALT[HALTMSK_L] for the event to halt the counter. If the counter is halted, it stops counting, and no new events can occur. You can restore the counter operation by writing 0 CTRL[HALT_H] and/or CTRL[HALT_L].

c. Write 1 to the corresponding STOP[STOPMSK_H] or STOP[STOPMSK_L] for the event to stop the counter. If the counter is stopped, it stops counting. However, if you configure an event as a transition on an I/O, it can restart the counter.

d. Write 1 to the corresponding START[STARTMSK_H] or START[STARTMSK_L] for the event to restart the counting. Only events that are defined by an input changing can be used to restart the counter.

4. Define the events that contribute to the SCT interrupt: write 1 to the corresponding EVEN[IEN*n*] and EVFLAG[FLAG*n*] to enable the event to contribute to the SCT interrupt.

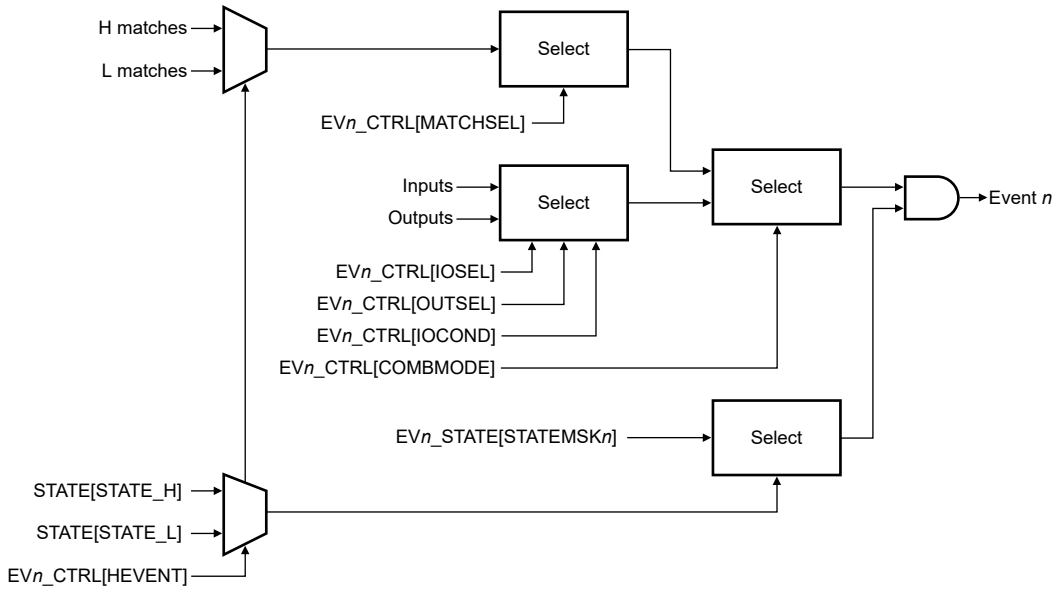

Figure 257. Event selection

49.3.3.4 Configure multiple states

1. Select the state or states (up to two), by using Event n State (EV0_STATE - EV15_STATE), for each event (up to the maximum number of events on this chip—one register per event), in which this event is allowed to occur. You can select each state for more than one event.
2. Determine how the event affects the system state: using Event n Control (EV0_CTRL - EV15_CTRL) (up to the maximum number of events on this chip—one register per event), set the new state value in EV*n*_CTRL[STATEV] for this event. If the event is the highest numbered in the current state, this value is either added to the existing state value or replaces it, depending on the configuration of EV*n*_CTRL[STATELD].

NOTE

If EV*n*_CTRL[STATEV] and EV*n*_CTRL[STATELD] are 0, the state does not change. If there are higher numbered events in the current state, this event cannot change the state.

49.3.3.5 Miscellaneous options

SCT includes a certain (selectable) number of capture registers that you can program to capture the counter contents when one or more events occur.

If the counter is in Bidirectional mode, you can configure Output Counter Direction Control (OUTPUTDIRCTRL) to determine the effect of setting and clearing of an output, based on whether the counter is counting up or down.

49.3.4 State logic

You can configure SCT as a timer or counter with multiple programmable states, which you can define through the events that can be captured in each particular state. A multi-state SCT can change from one state to another when an event that you define triggers a state change through each event's Event n Control (EV0_CTRL - EV15_CTRL) in one of the following ways:

- The event can increment the current state number by a new value.
- The event can write a new state value.

If an event increments the state number beyond the number of available states, SCT enters a locked state where all further events are ignored while the counter is still running. Software must interfere to change out of this state.

Software can capture the counter value (and potentially create an interrupt and write to all outputs) when an event that moves SCT into a locked state, occurs. Later, when SCT is in the locked state, software can read the counter again to record the time passed since the locking event and can also read the state variable to obtain the current state number.

If SCT registers an event that forces an abort, putting SCT in a locked state can be a safe way to record the time that has passed since the abort event when no new events are allowed to occur. Because multiple states (any state number between the maximum implemented state and 31) are locked states, you can define multiple abort or error events, each incrementing the state number by a different value.

49.3.5 Clearing the prescaler

When enabled by a nonzero CTRL[PRE_L] and/or CTRL[PRE_H], the prescaler acts as a clock divider for the counter, like a fractional part of the counter value. The prescaler is cleared whenever the counter is cleared or loaded for any of the following reasons:

- Hardware reset
- When you write to Counter Value (COUNT)
- When you write 1 to CTRL[CLRCTR]
- An event selected by a 1 in the counter limit register when CTRL[BIDIR] = 0

When CTRL[BIDIR] = 0, a limit event caused by an I/O signal can clear a nonzero prescaler. However, a limit event caused by a match clears only a nonzero prescaler in a special case, as described in Match vs. I/O events.

A limit event, when CTRL[BIDIR] = 1, does not clear the prescaler. Instead, it writes 0 to CTRL[DOWN] and decrements the counter on the same clock if the counter is enabled in that clock.

49.3.6 Match vs. I/O events

The prescaler and clock mode 01 make the counter operation complex, in which the SCT clock is the bus clock. However, you can enable the prescaler and counter to count only when a selected edge is detected on a clock input:

- The prescaler is enabled when the clock mode is not 01, or when the input edge that CONFIG[CKSEL] selects is detected.
- The counter is enabled when the prescaler is enabled, and (PRELIM = 0 or the prescaler is equal to the value of PRELIM).

An I/O component of an event can occur in any SCT clock when its counter, CTRL[HALT], is 0. In general, a match component of an event can only occur in an SCT clock when its counter fields, CTRL[HALT] and CTRL[STOP], are both 0 and the counter is enabled.

The following table shows the conditions when various kinds of events can occur.

Table 431. Event conditions

EV*n*_CTRL[COMBMODE]	EV*n*_CTRL[IOCOND]	Event can occur on clock:
I/O	Any	Whenever CTRL[HALT] = 0.

Table continues on the next page...

Table 431. Event conditions (continued)

EV*n*_CTRL[COMBMODE]	EV*n*_CTRL[IOCOND]	Event can occur on clock:
MATCH	Any	When CTRL[HALT] = 0, CTRL[STOP] = 0, and the counter is enabled.
OR	Any	• From the I/O component, whenever CTRL[HALT] = 0. • From the match component, when CTRL[HALT] = 0, CTRL[STOP] = 0, and the counter is enabled.
AND	Low or High	When CTRL[HALT] = 0, CTRL[STOP] = 0, and the counter is enabled.
AND	Rise or Fall	Whenever CTRL[HALT] = 0.

49.3.7 Fractional matches

You can configure the first six match registers from Match Value (MATCH0 - MATCH15) to have a fractional portion to their match values. A higher average resolution is achievable on these registers, with an associated Fractional Match (FRACMAT0 - FRACMAT5), by using a dithering mechanism. The dither engine delays the assertion of a match by one counter clock every *n* (0 to 15) out of 16 counter cycles. The value of *n* is specified in Fractional Match (FRACMAT0 - FRACMAT5), associated with each of the first six match registers.

You can disable dithering on any of the match registers by loading all zeroes (the default value) into its corresponding Fractional Match (FRACMAT0 - FRACMAT5).

49.3.7.1 Dithering

At the start of each new SCT counter cycle (that is, when the counter counts down to zero in Bidirectional mode or is cleared to zero by a limit event), the dither engine determines which matches are to be delayed by one clock during the upcoming counter cycle. Delaying the match effectively adds 1 to the designated match value when up-counting or subtracts 1 when down-counting, during that particular counter cycle.

For each dither-enabled match register, the value that you program in its associated Fractional Match (FRACMAT0 - FRACMAT5) specifies for how many counter cycles, out of every 16 of them, its match is to be delayed. An algorithm applied to the FRACMAT value distributes this number as evenly as possible across the 16 counter cycles. This results in a unique dither pattern for each match register (see Table 432).

Dither Condition (DITHER) (event-mask register) provides you additional control over the dithering process. Typically, the dither engine advances though the match dither patterns at the start of every new SCT counter cycle. Dither Condition (DITHER) allows you to specify that advancement to the next element in the dither patterns occurs only if one or more designated events have happened during the previous cycle of the counter.

The dither algorithm is designed to spread out the cycles in which the matches are delayed as evenly as possible across the 16 counter cycles. The following table shows the dither pattern that is applied for each value of FRACMAT. "D" indicates the counter cycles where a match on the relevant match register is delayed.

Table 432. Dither pattern

	Counter cycle															
FRACMAT	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

49.4 External signals

SCT inputs can come from numerous places and are selected by the SCT input mux.

SCT outputs can be routed to multiple places and can be connected to both a pin and an ADC trigger at the same time.

Table 433. SCT signals

Signal	I/O	Description
SCT_IN*n*	I	SCT input. Signals come from GPIO sources, each from a variety of pins selected via IOPCTL muxing.
SCT_OUT*n*	O	SCT output. Signals go to IOPCTL muxing where they can be (optionally) output onto a selection of GPIO pins.

49.5 Initialization

To initialize SCT:

1. Enable the clock to SCT.
2. Clear the SCT peripheral reset.
3. Configure the interrupts.
4. Connect the SCT outputs to external pins.
5. Configure the DMA request lines to connect to the DMA trigger inputs.

49.6 Application information

49.6.1 Running SCT

1. Initialize SCT (see Initialization).
2. Write to State Variable (STATE) to define the initial state. By default, the initial state is 0.
3. To start SCT, write to SCT Control (CTRL):
    a. Clear the counters.
    b. Write 0 or 1 to CTRL[STOP_L] and/or CTRL[STOP_H].

    NOTE

    The counter starts counting after CTRL[STOP] becomes 0 as well. If CTRL[STOP] = 1, SCT, instead, waits for an event to occur that you can configure to start the counter.

    c. Select Unidirectional or Bidirectional counting mode (CTRL[BIDIR_L] and/or CTRL[BIDIR_H]) for each counter.
    d. Select the prescale factor for the counter clock (CTRL[PRE_L] or CTRL[PRE_H]).
    e. Write 0 to CTRL[HALT_L] and/or CTRL[HALT_H]. By default, the counters halt and no events can occur.
4. Stop or halt the counters at any time by using CTRL[STOP_L] and/or CTRL[STOP_H], or CTRL[HALT_L] and/or CTRL[HALT_H], respectively.
    - After the counters stop, both you and an event configured to write 0 to CTRL[STOP_L] and/or CTRL[STOP_H] can start the counter again.
    - After the counter halts, only writing 0 to CTRL[HALT_L] and/or CTRL[HALT_H] can start the counter again. No events can occur.
    - After the counters halt, you can set any SCT output as high or low by writing directly to the OUT register.

You can read the current SCT state at any time by using State Variable (STATE).

To change the current state (that is, independently of any event occurring), write 1 to CTRL[HALT] and write to State Variable (STATE) to change the state value. You are allowed to write to State Variable (STATE) only when the counter halts (CTRL[HALT_L] and/or CTRL[HALT_H] = 1) and no events can occur.

49.6.2 SCT configuration example

This section discusses SCT configuration by using an example, showing the simple application of SCT with two sets of match events (EV0/1 and EV3/4) to set and clear SCT output 0. The timer automatically resets whenever it reaches the MAT0 match value.

In the initial state 0, match event EV0 sets output 0 to high and match event EV1 clears output 0.

When monitoring SCT input 0:

- If input 0 is low at the next timer reset (EV2), the state changes to state 1, enabling events EV3 and EV4. This leads to the same output but with different match value triggers.
- If input 0 is high at the next timer reset, the associated event (EV5) causes the state to change back to the state enabling events EV0 and EV1.

Figure 258 uses this SCT configuration:

- One input
- One output
- Five match registers
- Six events, and match 0 used with the autolimit function
- Two states

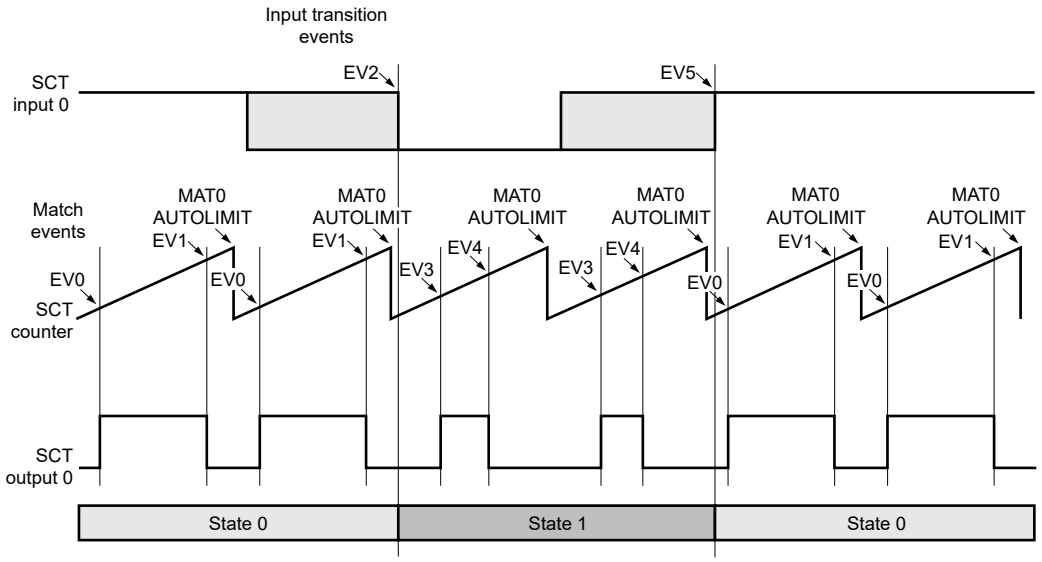

Figure 258. SCT configuration example: pictorial representation

This application of SCT uses the configuration listed in the following table (all register values not listed are their default values):

Table 434. SCT configuration example: settings

Configuration	Register	Setting
Counter	SCT Configuration (CONFIG)	Use a unified counter (CONFIG[UNIFY] = 1).
	SCT Configuration (CONFIG)	Enable the autolimit for MAT0 (CONFIG[AUTOLIMIT_L] = 1).
	SCT Control (CTRL)	Use a unidirectional counter (CTRL[BIDIR_L] = 0).
Clock base	SCT Configuration (CONFIG)	Use the default values for clock configuration.
Match and capture registers	Match and Capture Register Mode (REGMODE)	Configure one match register for each match event by writing 0 to bits 0, 1, 2, 3, and 4 of REGMODE[REGMOD_L*n*].
Define match values	MATCH (0/1/2/3/4)	Set a match value MATCH0/1/2/4_L in each register. The match register 0 serves as an automatic limit event that resets the counter, without using an event. To enable the automatic limit, write 1 to CONFIG[AUTOLIMIT].

Table continues on the next page...

Table 434. SCT configuration example: settings (continued)

Configuration	Register	Setting
Define match reload values	MATCHREL (0/1/2/3/4)	Set a match reload value RELOAD0/1/2/3/4_L in each register (same as the match value in this example).
Define when event 0 occurs	EV0_CTRL	• Set EV*n*_CTRL[COMBMODE] = 0x1. Event 0 uses match condition only. • Set EV*n*_CTRL[MATCHSEL] = 1. Select the match value of match register 1. The match value of MAT1 is associated with event 0.
Define when event 1 occurs	EV1_CTRL	• Set EV*n*_CTRL[COMBMODE] = 0x1. Event 1 uses match condition only. • Set EV*n*_CTRL[MATCHSEL] = 2. Select the match value of match register 2. The match value of MAT2 is associated with event 1.
Define when event 2 occurs	EV2_CTRL	• Set EV*n*_CTRL[COMBMODE] = 0x3. Event 2 uses match condition and I/O condition. • Set EV*n*_CTRL[IOSEL] = 0. Select input 0. • Set EV*n*_CTRL[IOCOND] = 0x0. Input 0 is low. • Set EV*n*_CTRL[MATCHSEL] = 0. This selects match register 0 to qualify the event = 0.
Define how event 2 changes the state	EV2_CTRL	Write 1 to EV*n*_CTRL[STATEV] and EV*n*_CTRL[STATELD]. Event 2 changes the state to state 1.
Define when event 3 occurs	EV3_CTRL	• Set EV*n*_CTRL[COMBMODE] = 0x1. Event 3 uses match condition only. • Set EV*n*_CTRL[MATCHSEL] = 0x3. Select match value of match register 3. The match value of MAT3 is associated with event 3.
Define when event 4 occurs	EV4_CTRL	• Set EV*n*_CTRL[COMBMODE] = 0x1. Event 4 uses match condition only. • Set EV*n*_CTRL[MATCHSEL] = 0x4. Select match value of match register 4. The match value of MAT4 is associated with event 4.
Define when event 5 occurs	EV5_CTRL	• Set EV*n*_CTRL[COMBMODE] = 0x3. Event 5 uses match condition and I/O condition. • Set EV*n*_CTRL[IOSEL] = 0. Select input 0. • Set EV*n*_CTRL[IOCOND] = 0x3. Input 0 is high. • Set EV*n*_CTRL[MATCHSEL] = 0. Chooses match register 0 to qualify the event.
Define how event 5 changes the state	EV5_CTRL	Write 0 to EV*n*_CTRL[STATEV] and 1 to EV*n*_CTRL[STATELD]. Event 5 changes the state to state 0.
Define by which events output 0 is set	OUT0_SET	Set SET0 bits 0 (for event 0) and 3 (for event 3) to one to set the output when these events 0 and 3 occur.
Define by which events output 0 is cleared	OUT0_CLR	Set CLR0 bits 1 (for events 1) and 4 (for event 4) to one to clear the output when events 1 and 4 occur.

Table continues on the next page...

Table 434. SCT configuration example: settings (continued)

Configuration	Register	Setting
Configure states to enable event 0	OUT0_STATE	Set STATEMSK0 bit 0 to 1, enabling event 0 in state 0. Set all other bits to 0.
Configure states to enable event 1	EV1_STATE	Set STATEMSK1 bit 0 to 1, enabling event 1 in state 0. Set all other bits to 0.
Configure states to enable event 2	EV2_STATE	Set STATEMSK2 bit 0 to 1, enabling event 2 in state 0. Set all other bits to 0.
Configure states to enable event 3	EV3_STATE	Set STATEMSK3 bit 1 to 1, enabling event 3 in state 1. Set all other bits to 0.
Configure states to enable event 4	EV4_STATE	Set STATEMSK4 bit 1 to 1, enabling event 4 in state 1. Set all other bits to 0.
Configure states to enable event 5	EV5_STATE	Set STATEMSK5 bit 1 to 1, enabling event 5 in state 1. Set all other bits to 0.

49.7 Memory map and register definition

49.7.1 Register configuration

For most of the SCT registers, the register function depends on the settings of certain other register fields:

- CONFIG[UNIFY] determines whether SCT is used as one 32-bit register (for operation as one 32-bit counter or timer) or as two 16-bit counters or timers named L and H.
  - If CONFIG[UNIFY] = 1, only one register is used (for operation as one 32-bit counter or timer).
  - If CONFIG[UNIFY] = 0, you can access the L and H registers using a 32-bit read or write operation, or you can read or write to them individually.

Typically, you configure CONFIG[UNIFY] by writing to SCT Configuration (CONFIG) before accessing any other registers.

- REGMOD[REGMOD_H*n*] and REGMOD[REGMOD_L*n*] determine whether each set of match and capture registers uses the match or capture functionality:
  - If REGMODE*n* = 0, registers operate as match and reload registers.
  - If REGMODE*n* = 1, registers operate as capture and capture control registers.

49.7.2 Register functional grouping

Most SCT registers either configure an event or select an event for a specific action of the counter (or counters) and outputs. The following figure shows the registers and register fields that you must configure for each event. In Figure 259, the following letters are used to represent the maximum quantity of certain SCT features:

- i = match and captures
- j = events
- k = states
- p = outputs
- q = inputs

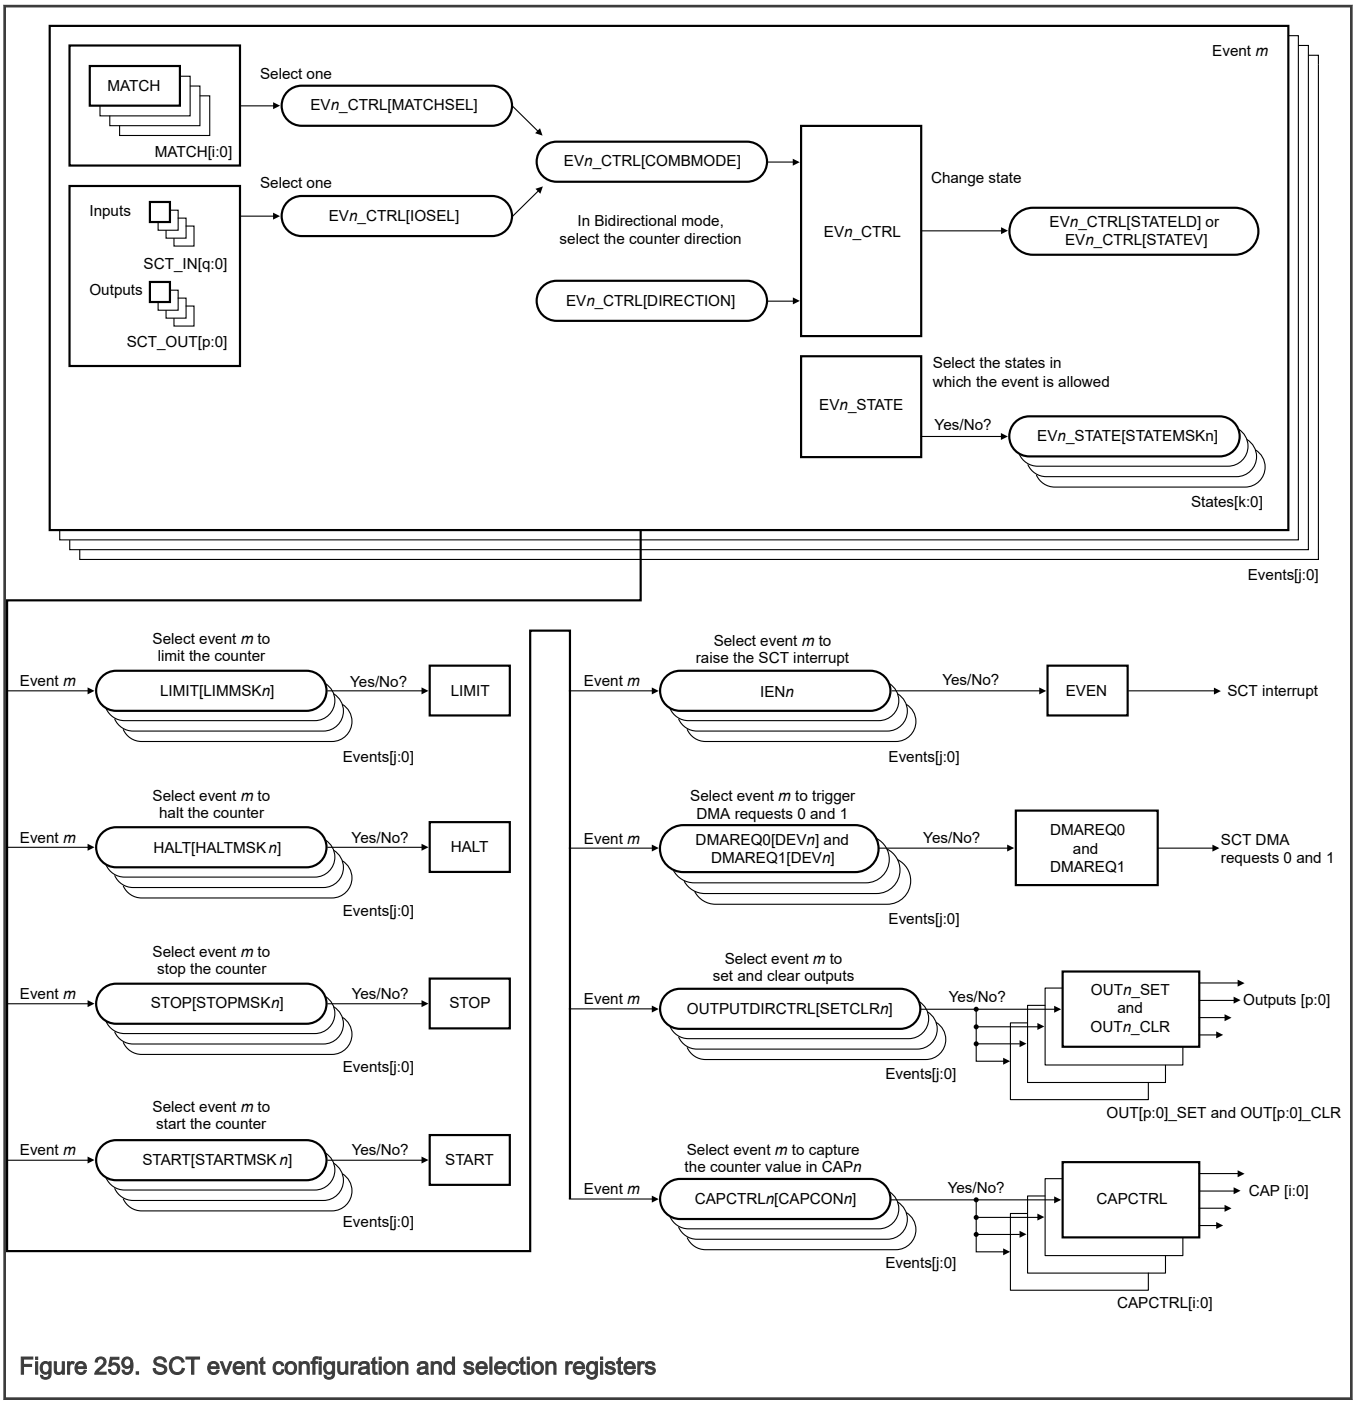

Figure 259. SCT event configuration and selection registers

49.7.2.1 Counter configuration and control registers

SCT contains these registers for configuration, monitoring, and control:

- SCT Configuration (CONFIG) configures SCT in a single, 32-bit counter mode or in dual, 16-bit counter mode. This register helps you perform clocking, clock synchronization, configure automatic limits, and use reload registers.
- SCT Control (CTRL) helps you monitor and set the counter direction. Additionally, using this register, you can clear, start, stop, or halt the 32-bit counter or individual 16-bit counters in Dual-Counter mode.

49.7.2.2 Event configuration registers

Each event is associated with these registers:

- Event n State (EV0_STATE - EV15_STATE) to enable the event
- Event n Control (EV0_CTRL - EV15_CTRL) to define what triggers the event

49.7.2.3 Match and capture registers

SCT includes a set of registers to store the SCT match or capture values:

- Each Match Value (MATCH0 - MATCH15) is associated with a corresponding Match Reload Value (MATCHREL0 - MATCHREL15), which automatically reloads Match Value (MATCH0 - MATCH15) at the beginning of each counter cycle.
- One Match and Capture Register Mode (REGMODE) to configure each match and capture register for either storing a match value or capture value.
- A set of match and capture registers with each register, depending on the setting of Match and Capture Register Mode (REGMODE), for either storing a match value or counter capture value.
- One Capture Control (CAPCTRL0 - CAPCTRL15) for each Capture Value (CAP0 - CAP15).

Figure 260 shows the match logic for SCT.

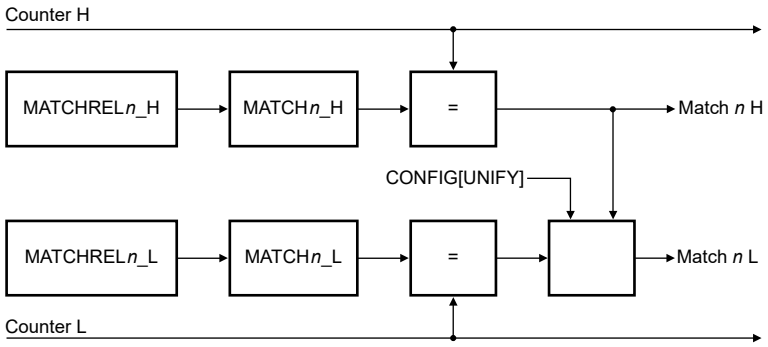

Figure 260. Match logic

Figure 261 shows the capture logic for SCT.

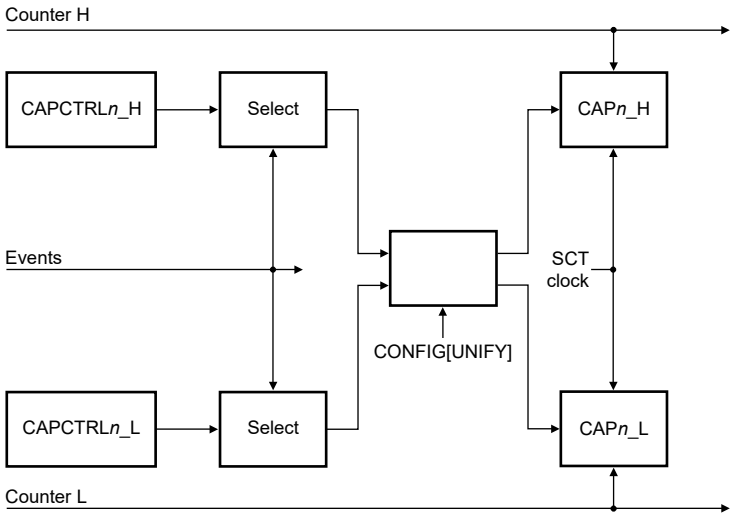

Figure 261. Capture logic

49.7.2.4 Event select registers for counter operations

This group of registers helps you select the events that affect the counter. The counter actions are limit, halt, start, and stop, which apply to the unified counter or to the two 16-bit counters:

- SCT Limit Event Select (LIMIT) selects the events that limit the counter.
- Start Event Select (START) and Stop Event Select (STOP) select the events that start or stop the counter.
- Halt Event Select (HALT) selects the events that halt the counter.
- Counter Value (COUNT) contains the counter value (or values) in the dual-counter setup.

All the aforementioned registers except Start Event Select (START) contain one field per event that selects whether each event limits, stops, starts, or halts the counter (or counters) in Dual-Counter mode. In this mode, you can select the events independently for each counter.

49.7.2.5 Event select registers for setting or clearing outputs

This group of registers helps you select the events that affect the level of each SCT output. Also included in this group are registers to manage conflicts that occur when events try to set or clear the same output:

- One Output n Set (OUT0_SET - OUT9_SET) for each output to select the events that set the output
- One Output n Clear (OUT0_CLR - OUT9_CLR) for each output to select the events that clear the output
- Output Conflict Resolution (RES) that defines an action when multiple events try to control an output at the same time
- Conflict Flag (CONFLAG) and Conflict Interrupt Enable (CONEN) that monitor interrupts arising from "output set and clear conflicts"
- Output Counter Direction Control (OUTPUTDIRCTRL) that interchanges the set and clear output operation caused by an event in Bidirectional mode

Output n Set (OUT0_SET - OUT9_SET) and Output n Clear (OUT0_CLR - OUT9_CLR) contain one field each per event that selects whether the event changes the state for a given output *n*.

In Dual-Counter mode, you can select the events independently for each output.

The following figure shows an SCT output slice.

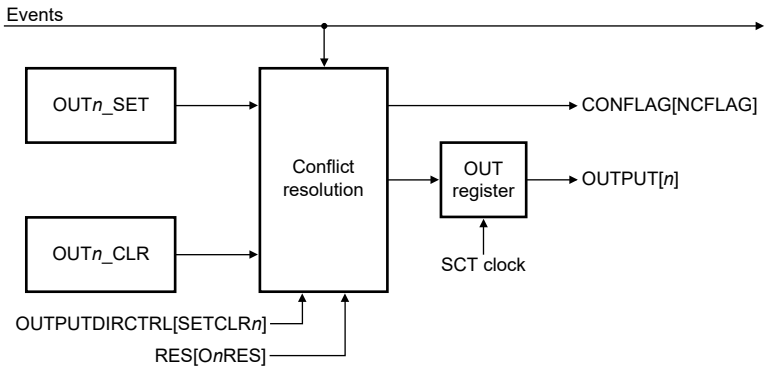

Figure 262. Output slice *n*

49.7.2.6 Event select registers for capturing a counter value

This group of registers helps you select events that capture the counter value and store it in one of Capture Value (CAP0 - CAP15). Each capture register *n* includes an associated Capture Control (CAPCTRL0 - CAPCTRL15), which in turn selects the events to capture the counter value.

49.7.2.7 Event select register for initiating DMA transfers

This register allows each of the two DMA requests to select the events that can generate a DMA request.

DMA Request 0 (DMAREQ0) and DMA Request 1 (DMAREQ1) contain a field for each event that selects whether the event generates a DMA request. An additional field enables the DMA trigger after the match registers are reloaded.

49.7.2.8 Interrupt handling registers

The following registers provide flags that are set by events and select the events that request an interrupt:

- Event Flag (EVFLAG) provides a flag for each event that is set when the event occurs.
- Event Interrupt Enable (EVEN) provides a field for each event to be enabled for the SCT interrupt.

This following figure shows an event triggering SCT to generate an interrupt.

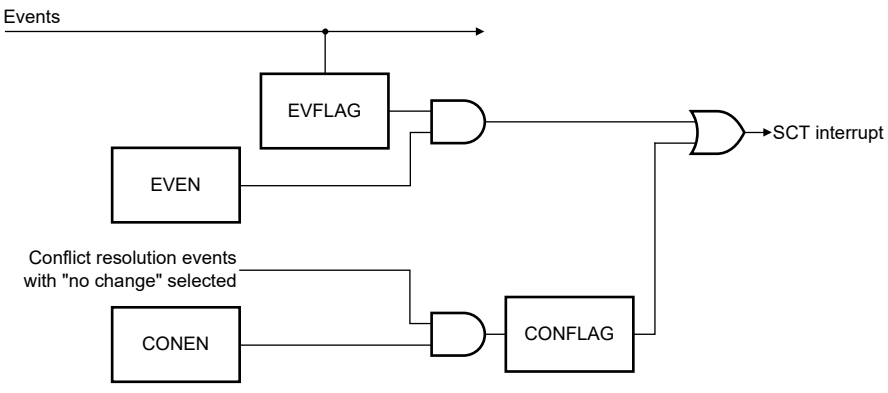

Figure 263. SCT interrupt generation

49.7.2.9 Registers for controlling SCT inputs and outputs

The following registers allow you (as opposed to events) to set SCT input and outputs:

- Input State (INPUT) to read the state of any of the SCT inputs
- Output State (OUTPUT) to set or clear any of the SCT outputs or to read their states

49.7.3.2 SCT Configuration (CONFIG)

Offset

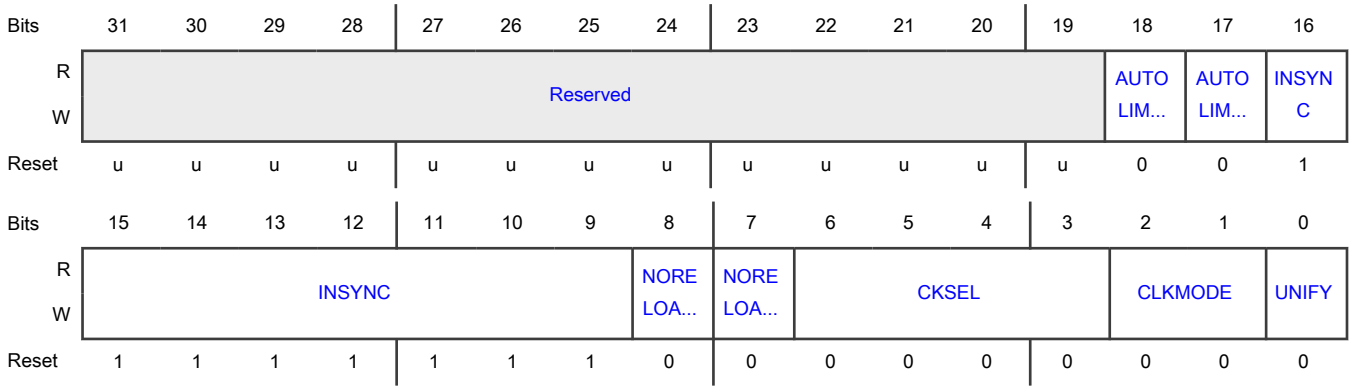
Register	Offset
CONFIG	0h

Function

Configures the overall SCT operation. You must write to this register before writing to any other registers.

Only word writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram



Fields

Field	Function
31-19 —	Reserved
18 AUTOLIMIT_H	Auto Limit Higher Enables the counter to be cleared to zero in Unidirectional mode or to change the direction of count in Bidirectional mode, as with any SCT Limit Event Select (LIMIT) event. You can write to this field at any time, except when CONFIG[UNIFY] = 1. If this field = 1, a match on match register 0 is considered as the limit condition without the need to define an associated event. 0b - Disables 1b - Enables
17 AUTOLIMIT_L	Auto Limit Lower Enables the counter to be cleared to zero in Unidirectional mode or to change the direction of count in Bidirectional mode, as with any SCT Limit Event Select (LIMIT) event. You can write to this field at any time, and the field applies to both the higher and lower registers when CONFIG[UNIFY] = 1. If this field = 1, a match on match register 0 is considered as the limit condition. You need not define an associated event. 0b - Disables 1b - Enables
16-9 INSYNC	Input Synchronization Specifies synchronization for input *n* (bit 9 = input 0, bit 10 = input 1, bit 16 = input 7, and so on). If you write 1 to any of these bits, it subjects the corresponding input to synchronization with the SCT clock, before it is used to create an event. If an input is already known to be synchronous with the SCT clock, you may write 0 to this field for a faster input response.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE SCT clock is the system clock for clock modes 0-2. It is the selected, asynchronous SCT input clock for clock mode 3. This field only affects inputs used for event generation, and does not apply to the clock input specified in CONFIG[CKSEL].
8 NORELOAD_H	No Reload Higher Match Specifies whether higher match registers are reloaded from their respective reload registers. Writing 1 to this field eliminates the need to write to Match Reload Value (MATCHREL0 - MATCHREL15) if the match values are fixed. It prevents the higher match registers to be reloaded from their respective reload registers. You can write to this field at any time, except when CONFIG[UNIFY] = 1. 0b - Reloaded 1b - Not reloaded
7 NORELOAD_L	No Reload Lower Match Specifies whether lower match registers are reloaded from their respective reload registers. Writing 1 to this field eliminates the need to write to Match Reload Value (MATCHREL0 - MATCHREL15) if the match values are fixed. It prevents the lower match registers to be reloaded from their respective reload registers. You can write to this field at any time, and the field applies to both the higher and lower registers when CONFIG[UNIFY] = 1. 0b - Reloaded 1b - Not reloaded
6-3 CKSEL	SCT Clock Select Specifies SCT clock. The specific functionality of the designated input or edge is dependent on the mode you select using CONFIG[CLKMODE]. 0000b - Rising edges on input 0 0001b - Falling edges on input 0 0010b - Rising edges on input 1 0011b - Falling edges on input 1 0100b - Rising edges on input 2 0101b - Falling edges on input 2 0110b - Rising edges on input 3 0111b - Falling edges on input 3 1000b - Rising edges on input 4

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1001b - Falling edges on input 4 1010b - Rising edges on input 5 1011b - Falling edges on input 5 1100b - Rising edges on input 6 1101b - Falling edges on input 6 1110b - Rising edges on input 7 1111b - Falling edges on input 7
2-1 CLKMODE	SCT Clock Mode Specifies SCT clock mode. • If this field = 0, SCT uses System Clock mode. In this mode, the system clock clocks the entire SCT module, including all counters and counter prescalers. • If this field = 1, SCT uses Sampled System Clock mode. In this mode, the system clock clocks the SCT module, but the counter and prescalers are only enabled to count when the designated edge is detected on the input that CONFIG[CKSEL] selects. The minimum pulse width on the selected clock-gate input is 1 bus clock period. This is a high-performance mode. • If this field = 10, SCT uses Input Clock mode. The input or edge that CONFIG[CKSEL] selects clocks the SCT module, including all counters and prescalers, after first being synchronized with the system clock. The minimum pulse width on the clock input is one bus clock period. This is a low-power, sampled-clock mode. • If this field = 11, SCT uses Asynchronous mode. In this mode, the input or edge that CONFIG[CKSEL] selects clocks the entire SCT module. The SCT outputs are switched synchronously to the SCT input clock, and not the system clock. The input clock rate must be at least half the system clock rate and can be the same or faster than the system clock. 00b - System Clock mode 01b - Sampled System Clock mode 10b - SCT Input Clock mode 11b - Asynchronous mode
0 UNIFY	SCT Operation Determines whether SCT is used as a single, unified 32-bit counter or timer or as dual, independent 16-bit counters or timers named low (L) and high (H). You must define the setting of this field before accessing other registers. 0b - Dual counters, COUNTER_L and COUNTER_H 1b - Unified counter

49.7.3.3 SCT Control (CTRL)

Offset

Register	Offset
CTRL	4h

Function

Allows SCT control.

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only the _L fields are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, CTRL_L and CTRL_H. You can read or write to both these registers, individually.

You can write to all fields in this register when the counter is stopped or halted. When the counter is running, the only fields that you can write to are STOP or HALT. You can write to the other fields in a subsequent write, after HALT becomes 1.

NOTE

- If you select CLKMODE = 0x3, wait for at least 12 system clock cycles between a write access to the H, L, or the unified version of this register and the next write access. This restriction does not apply when writing to the HALT field(s) and then writing to this register again to restart the counters (for example, you must update Match Value (MATCH0 - MATCH15), and this is allowed only when the counters are halted).
- If SCT is operating as two 16-bit counters, events can only modify the state of the outputs when no counter is halted. This is true regardless of what triggered the event.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	Reserved				PRE_L							BIDIR_L	CLRCTR_L	HALT_L	STOP_L	DOWN_L
Reset	u	u	u	0	0	0	0	0	0	0	0	0	0	1	0	0

Fields

Field	Function
31-29 —	Reserved
28-21	Prescaler for High Counter

Table continues on the next page...

Table continued from the previous page...

Field	Function
PRE_H	Specifies the factor by which the SCT clock is prescaled to produce the high counter clock, which is clocked at the rate of SCT clock ÷ PREL_H + 1. **NOTE** Clear the counter (by writing 1 to CLRCTR) when changing the value of this field.
20 BIDIR_H	Bidirectional Select High Selects the direction of the high counter. If this field = 0, the high counter counts up to its limit condition, and is then cleared to zero. If this field = 1, the high counter counts up to its limit, and then counts down to a limit condition or to zero. 0b - Up 1b - Up-down
19 CLRCTR_H	Clear Counter High Clears the high counter. Writing 1 to this field clears the high counter. CLRCTR_H always reads as 0.
18 HALT_H	Halt Counter High Halts the high counter. When this field = 1, the H counter does not run and no events can occur. Also, CTRL[STOP_H] clears. You can remove the halt condition when SCT is not running (is in a stop condition), by using a single write to this register, to simultaneously clear the HALT and STOP fields. **NOTE** Once set, HALT_H can only be cleared by software to restore counter operation. HALT_H = 1 on reset. 0b - Disable 1b - Enable
17 STOP_H	Stop Counter High Stops the high counter from running. When STOP_H = 1 and HALT = 0, the H counter does not run but I/O events related to the counter can occur. If such an event matches the mask in Start Event Select (START), CTRL[STOP_H] is cleared and counting resumes. 0b - Disabled 1b - Enabled
16 DOWN_H	Down Counter High Specifies whether the high counter is counting up or down.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Hardware sets DOWN_H when the counter is counting up, a counter limit condition occurs, and BIDIR = 1. Hardware clears DOWN_H when the counter is counting down and a limit condition occurs, or when the counter reaches 0. 0b - Up 1b - Down
15-13 —	Reserved
12-5 PRE_L	Prescaler for Low Counter Specifies the factor by which the SCT clock is prescaled to produce the low or unified counter clock. The counter clock is clocked at the rate of SCT clock ÷ PRE_L + 1. **NOTE** You can clear the counter by writing 1 to CLRCTR when changing the value of this field.
4 BIDIR_L	Bidirectional Select Low Selects the direction of the low or unified counter. If this field = 0, the counter counts up to a limit condition and is then cleared to 0. If this field = 1, the counter counts up to a limit, and then counts down to a limit condition or to 0. 0b - Up 1b - Up-down
3 CLRCTR_L	Clear Counter Low Clears the low or unified counter. Writing 1 to this field clears the low or unified counter. The field always reads 0.
2 HALT_L	Halt Counter Low Specifies whether the L or unified counter is enabled. If this field = 1, the low or unified counter does not run and no events can occur. STOP_L also becomes 0. It is possible to remove the halt condition while SCT is in the stop condition (not running), with a single write to this register, to simultaneously clear the HALT field and set the STOP field. Once set, only software can clear HALT_L to restore counter operation. HALT_L = 1 on reset. 0b - Disabled 1b - Enabled
1 STOP_L	Stop Counter Low Specifies whether the low or unified counter is enabled. If STOP_L = 1 and HALT = 0, the low or unified counter does not run, but I/O events related to the counter can occur. If a designated start event occurs, STOP_L is cleared and counting resumes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
0 DOWN_L	Down Counter Low Specifies whether the low or unified counter is counting up or down. Hardware sets DOWN_L when the counter is counting up, counter limit occurs, and BIDIR = 1. Hardware clears this field when the counter is counting down and a limit condition occurs, or when the counter reaches 0. 0b - Up 1b - Down

49.7.3.4 SCT Limit Event Select (LIMIT)

Offset

Register	Offset
LIMIT	8h

Function

Selects the SCT limit event.

An event can limit a running counter. When any of the events selected in this register occur, the counter is cleared to zero from its current value or changes the counting direction, if it is in Bidirectional mode. Each field of this register is associated with a different event (bit 0 with event 0, and so on). Writing 1 to a field causes its associated event to serve as a LIMIT event, which whenever occurs, resets the counter to zero in Unidirectional mode, or changes the count direction in Bidirectional mode and keeps running. To define the actual limiting event (a match, an I/O pin toggle, and so on), see Event n Control (EV0_CTRL - EV15_CTRL).

NOTE

Counting up to all ones or counting down to zero is always equivalent to a limit event occurring.

In addition to using this register to specify events that serve as limits, it is also possible to automatically cause a limit condition whenever a match register 0 match occurs. This eliminates the need to define an event for the sole purpose of creating a limit. CONFIG[AUTOLIMIT_L] and CONFIG[AUTOLIMIT_H] enable or disable this feature.

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only the _L fields are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, LIMIT_L and LIMIT_H. You can read or write to both the _L and _H registers individually.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	LIMMSK_H															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LIMMSK_L															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 LIMMSK_H	Limit Event Counter High Specifies the counter limit for the high counter. If bit *n* is 1, event *n* is used as a counter limit for the high counter (event 0 = bit 16, event 1 = bit 17, and so on). Number of bits = number of events in this SCT.
15-0 LIMMSK_L	Limit Event Counter Low Specifies the counter limit for the low counter. If bit *n* is 1, event *n* is used as a counter limit for the low or unified counter (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT.

49.7.3.5 Halt Event Select (HALT)

Offset

Register	Offset
HALT	Ch

Function

Halts high and low events.

A halt event can disable (or halt) a running counter. When any of the events selected in this register occur, the counter stops running and all further events are disabled.

Each field of this register is associated with a different event (bit 0 with event 0, and so on). Setting a bit causes the associated event to serve as a HALT event. To define the actual events that cause the counter to halt (a match, an I/O pin toggle, and so on), see Event n Control (EV0_CTRL - EV15_CTRL).

NOTE

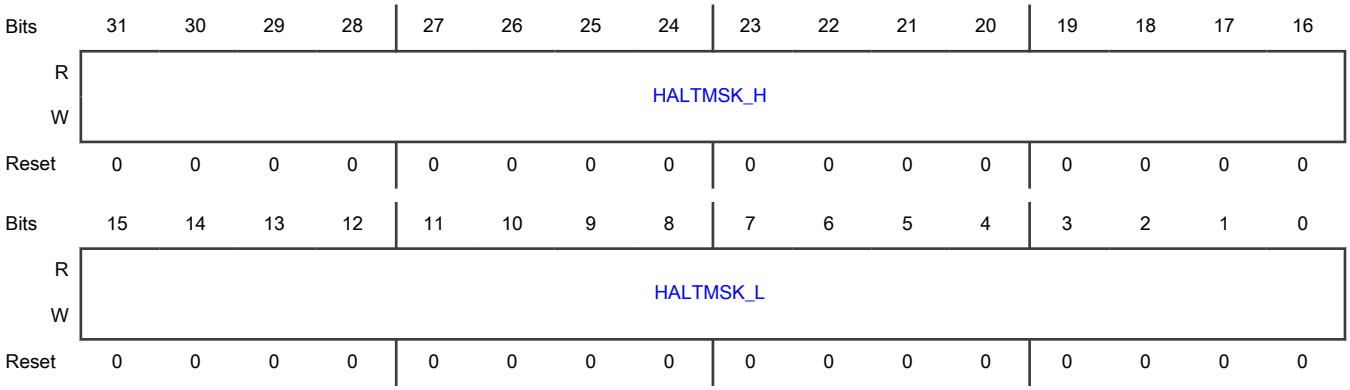
You can remove a HALT condition by clearing CTRL[HALT].

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only the _L fields are used.

- If CONFIG[UNIFY] = 0, you can write to this register as two registers, HALT_L and HALT_H. You can read or write to both the _L and _H registers individually.

Diagram



Fields

Field	Function
31-16 HALTMSK_H	Halt Event High Halts the high event. If bit *n* is 1, event *n* writes 1 to CTRL[HALT_H] (event 0 = bit 16, event 1 = bit 17, and so on). Number of bits = number of events in this SCT.
15-0 HALTMSK_L	Halt Event Low Halts the low event. If bit *n* is 1, event *n* writes 1 to CTRL[HALT_L] (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT.

49.7.3.6 Stop Event Select (STOP)

Offset

Register	Offset
STOP	10h

Function

Stops high and low events.

A stop event can stop a running counter. When any of the events selected in this register occur, counting is suspended. This means that the counter stops running and remains at its current value. Event generation remains enabled, and any event selected in Start Event Select (START), such as an I/O event or an event generated by the other counter, can restart the counter.

This register specifies the events that stop the counter. Each field of the register is associated with a different event (bit 0 with event 0, and so on). Setting a bit causes its associated event to serve as a STOP event. To define the actual event that causes the counter to stop (a match, an I/O pin toggle, and so on), see Event n Control (EV0_CTRL - EV15_CTRL).

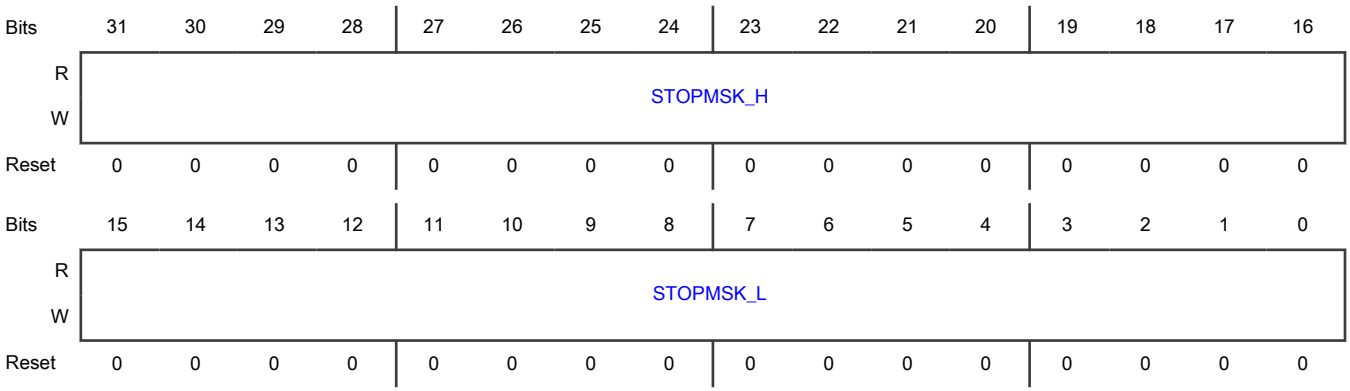
NOTE

You can stop and restart the counter by writing to SCT Control (CTRL).

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only the _L fields are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, STOP_L and STOP_H. You can read or write to both the _L and _H registers individually.

Diagram



Fields

Field	Function
31-16 STOPMSK_H	Stop Event High Stops the high event. If bit *n* is 1, the event *n* writes 1 to CTRL[STOP_H] (event 0 = bit 16, event 1 = bit 17, and so on). Number of bits = number of events in this SCT.
15-0 STOPMSK_L	Stop Event Low Stops the low event. If bit *n* is 1, the event *n* writes 1 to CTRL[STOP_L] (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT.

49.7.3.7 Start Event Select (START)

Offset

Register	Offset
START	14h

Function

Starts high and low events.

A start event can restart a stopped counter.

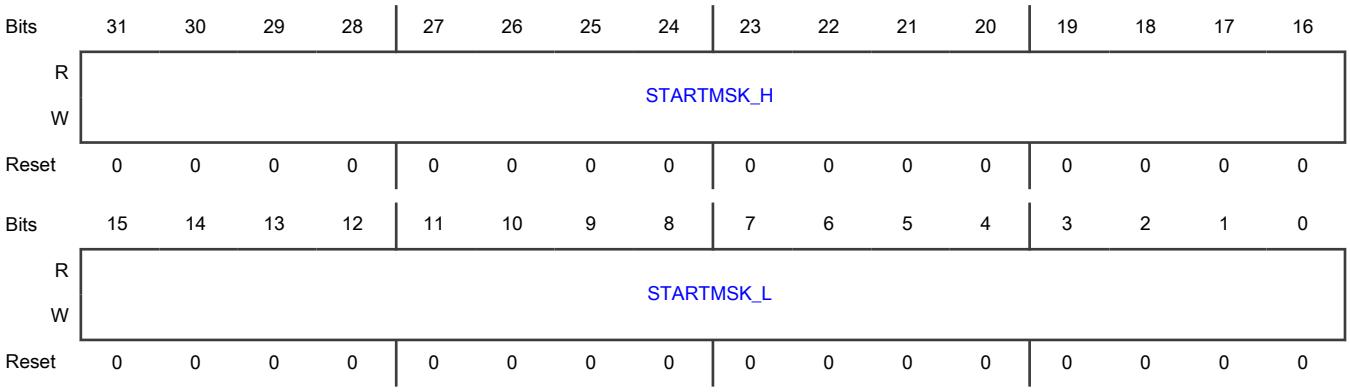
When any of the events selected in Start Event Select (START) occur, counting restarts from the current counter value.

Each field of this register associates with a different event (bit 0 with event 0, and so on). Setting a bit causes the associated event to serve as a START event. When a START event occurs, hardware clears CTRL[STOP]. A START event has no effect on CTRL[HALT]. Only software can remove a HALT condition. To define the actual event that starts the counter (an I/O pin toggle or an event generated by the other running counter in Dual-Counter mode), see Event n Control (EV0_CTRL - EV15_CTRL).

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only the _L fields are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, START_L and START_H. You can read or write to both the _L and _H registers individually.

Diagram



Fields

Field	Function
31-16 STARTMSK_H	Start Event High Starts the high event. If bit *n* is 1, event *n* writes 0 to CTRL[STOP_H] (event 0 = bit 16, event 1 = bit 17, and so on). Number of bits = number of events in this SCT.
15-0 STARTMSK_L	Start Event Low Starts the low event. If bit *n* is 1, event *n* writes 0 to CTRL[STOP_L] (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT.

49.7.3.8 Dither Condition (DITHER)

Offset

Register	Offset
DITHER	18h

Function

Enables the dither engine to advance to the next count in the dither pattern every time the SCT counter reaches zero (that is, at the start of every new SCT counter cycle). Using this register, you can alter this behavior by qualifying the advancement through the dither pattern with designated events. As with the other condition or mask registers (such as Halt Event Select (HALT), Stop Event Select (STOP), and SCT Limit Event Select (LIMIT)), each field of this register corresponds to an event.

Writing 1 to one or more fields in this register causes the dither engine to advance to the next element in the dither pattern (that is, increment the 16-state cycle counter) by only following SCT counter cycles during which one or more of the designated dither events have occurred.

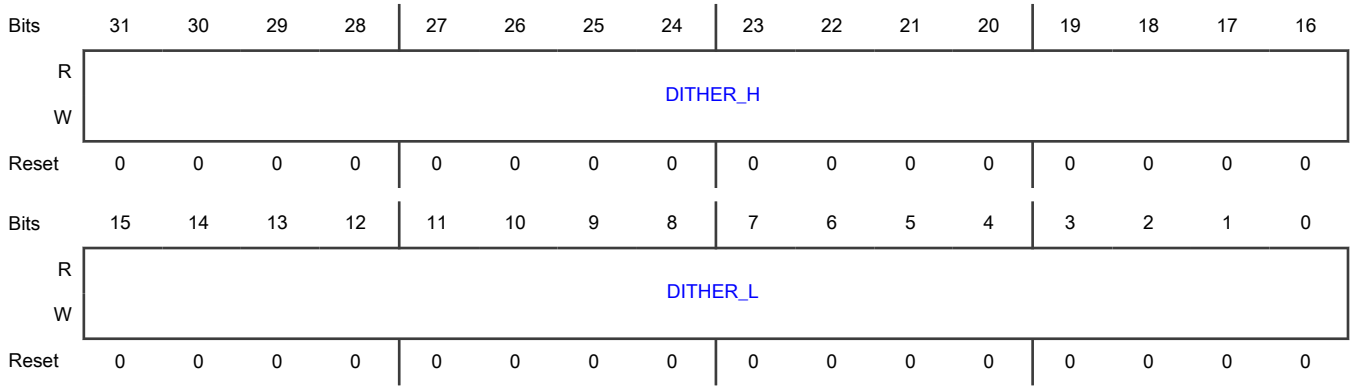
There exists a global dither condition register per 16-bit SCT. This register controls advancement through the dither patterns for all the match registers associated with that half of SCT.

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONGIG[UNIFY] = 1, only the _L bits are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, START_L and START_H. You can read and write to both the _L and _H registers individually or in a single 32-bit read or write operation.

For details on the dither engine and dither pattern, see Dithering.

Diagram



Fields

Field	Function
31-16 DITHER_H	Dither High Dithers high events. If bit *n* is 1, event *n* writes 0 to CTRL[STOP_H] (event 0 = bit 16, event 1 = bit 17, and so on). Number of bits = number of events in this SCT.
15-0 DITHER_L	Dither Low Dithers low events. If bit *n* is 1, event *n* writes 0 to CTRL[STOP_L] (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT.

49.7.3.9 Counter Value (COUNT)

Offset

Register	Offset
COUNT	40h

Function

Defines high and low counters.

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, this register acts as a unified 32-bit register and both the _L and _H fields are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, COUNT_L and COUNT_H. You can read and write to both the _L and _H registers individually. In this case, the _L and _H registers count independently under the control of other registers.

You are allowed to write to COUNT_L, COUNT_H, or the unified register only when the corresponding counter is halted (CTRL[HALT] = 1). In case you attempt to write to the counter when it is not halted, a bus error takes place. However, you can read the counter registers at any time.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	CTR_H															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CTR_L															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 CTR_H	Counter High Allows reads and writes to the upper bits of the unified counter. If CONFIG[UNIFY] = 0, read or write the 16-bit H counter value, and if CONFIG[UNIFY] = 1, read or write the upper 16 bits of the 32-bit unified counter.
15-0 CTR_L	Counter Low Allows reads and writes to the lower bits of the unified counter. If CONFIG[UNIFY] = 0, read or write the 16-bit L counter value, and if CONFIG[UNIFY] = 1, read or write the lower 16 bits of the 32-bit unified counter.

49.7.3.10 State Variable (STATE)

Offset

Register	Offset
STATE	44h

Function

Specifies high and low state variables.

Each group of enabled and disabled events is assigned a number called the state variable. For example, a state variable with a value of 0 could have events 0, 2, and 3 enabled and all other events disabled. A state variable with the value of 1 could have events 1, 4, and 5 enabled and all others disabled.

NOTE

Event n State (EV0_STATE - EV15_STATE) defines the event that is enabled in each group.

You can read the state associated with a counter at any time, and are allowed to write to STATE[STATE_L], STATE[STATE_H], or the unified register only when the corresponding counter is halted (CTRL[HALT_L] and CTRL[HALT_H] = 1).

The state variable is the main feature that distinguishes SCT from other counters, timers, and PWM blocks. Events can be made to occur only in certain states, and these events can, in turn, perform the following actions:

- Set and clear outputs
- Limit, stop, and start the counter
- Cause interrupts and DMA requests
- Modify the state variable

The application completely controls the value of a state variable. If an application does not use states, the value of the state variable remains zero, which is the default value.

You can use a state variable to track and control multiple cycles of the associated counter in any desired operational sequence.

EV*n*_CTRL[STATEV] and EV*n*_CTRL[STATELD] of all defined events set all possible values for the state variable. The change of the state variable during multiple counter cycles reflects how the associated state machine moves from one state to the next.

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only the _L bits are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, STATE_L and STATE_H.

You can read or write to both the _L and _H registers individually.

49.7.3.11 Input State (INPUT)

Offset

Register	Offset
INPUT	48h

Function

Indicates the state and form of SCT inputs.

You can read the state of SCT inputs, in slightly different forms, using this register:

- The AIN fields of this register indicate the state of the inputs captured on the last rising edge of the SCT clock. This corresponds to a nearly direct read-out of the input but can cause spurious fluctuations in case of an asynchronous input signal.
- The SIN fields of this register indicate the form of the inputs used for event detection. This may include additional stages of synchronization, depending on what is specified for that input in CONFIG[INSYNC]:
  - If CONFIG[INSYNC] = 1, the input is triple-synchronized to the SCT clock, resulting in a stable signal that is delayed by three SCT clock cycles.

— If CONFIG[INSYNC] = 0, the value of SIN is identical to the value of AIN.

49.7.3.12 Match and Capture Register Mode (REGMODE)

Offset

Register	Offset
REGMODE	4Ch

Function

Specifies whether each register acts as a match register or capture register. SCT contains multiple match and capture registers, and each register includes an accompanying register that functions as a reload register when the primary register is used as a match or capture-control register.

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only REGMODE[REGMOD_L*n*] is used. REGMODE[REGMOD_H*n*] is used only when CONFIG[UNIFY] = 0.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, REGMODE_L and REGMODE_H. You can read or write to both the _L and _H registers individually. REGMODE[REGMOD_L*n*] controls the lower match and capture registers, and REGMODE[REGMOD_H*n*] controls the higher or upper match and capture registers.

Diagram

Fields

Field	Function
31-16 REGMOD_Hn	Register Mode High Controls match and capture register *n*. If this field = 0, register *n* operates as a match register, and if this field = 1, register *n* operates as a capture register. 0b - Match 1b - Capture
15-0 REGMOD_Ln	Register Mode Low Controls match and capture register *n*. If this field = 0, register *n* operates as a match register, and if this field = 1, register *n* operates as a capture register. 0b - Match 1b - Capture

49.7.3.13 Output State (OUTPUT)

Offset

Register	Offset
OUTPUT	50h

Function

Determines SCT output state.

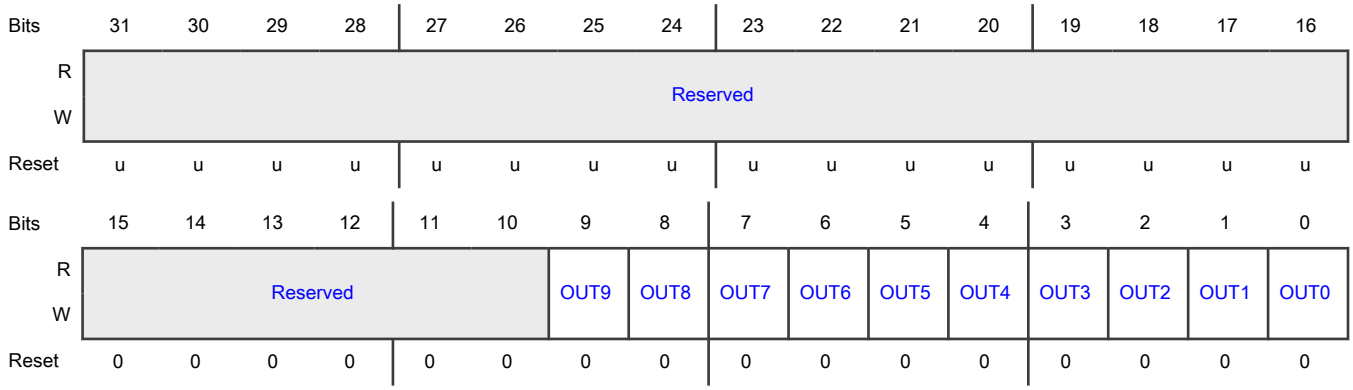
Each SCT output has a corresponding field in this register to allow you to control the output state directly or read its current state.

While the counter is running, only events can set, clear, and toggle these outputs. However, using this register, you can write to any of the output registers when both the counters are halted to control the outputs directly. Writing to the OUT register is only allowed when all counters (L-counter, H-counter, or unified counter) are halted (CTRL[HALT] = 1).

You can read this register at any time to sense the state of the outputs.

Only word writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-10 —	Reserved
9-0 OUTn	Output Low and High Specifies the SCT output state. The number of bits equals the number of outputs in this SCT. 0b - Forces the corresponding output low 1b - Forces the corresponding output high

49.7.3.14 Output Counter Direction Control (OUTPUTDIRCTRL)

Offset

Register	Offset
OUTPUTDIRCTRL	54h

Function

Specifies, for each output, the impact of the counting direction on the meaning of set and clear operations on the output, when using Bidirectional mode. The purpose of this register is to facilitate the creation of center-aligned output waveforms without the need to define additional events.

Only word writes are permitted to this register; attempting to write a halfword value results in a bus error.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

49.7.3.15 Output Conflict Resolution (RES)

Offset

Register	Offset
RES	58h

Function

Specifies the action to be taken if multiple events (or even the same event) dictate that a given output must be both set and cleared at the same time.

To enable an event to toggle an output each time the event occurs, write 1 to the fields for that event in both Output n Set (OUT0_SET - OUT9_SET) and Output n Clear (OUT0_CLR - OUT9_CLR), and write 0x3 to RES[O*n*RES].

Only word writes are permitted to this register. Attempting to write a halfword value results in a bus error.

49.7.3.16 DMA Request 0 (DMAREQ0)

Offset

Register	Offset
DMAREQ0	5Ch

Function

Enables DMA requests to be generated when a particular event occurs or when counter match registers are loaded from the reload registers. SCT includes two DMA request outputs.

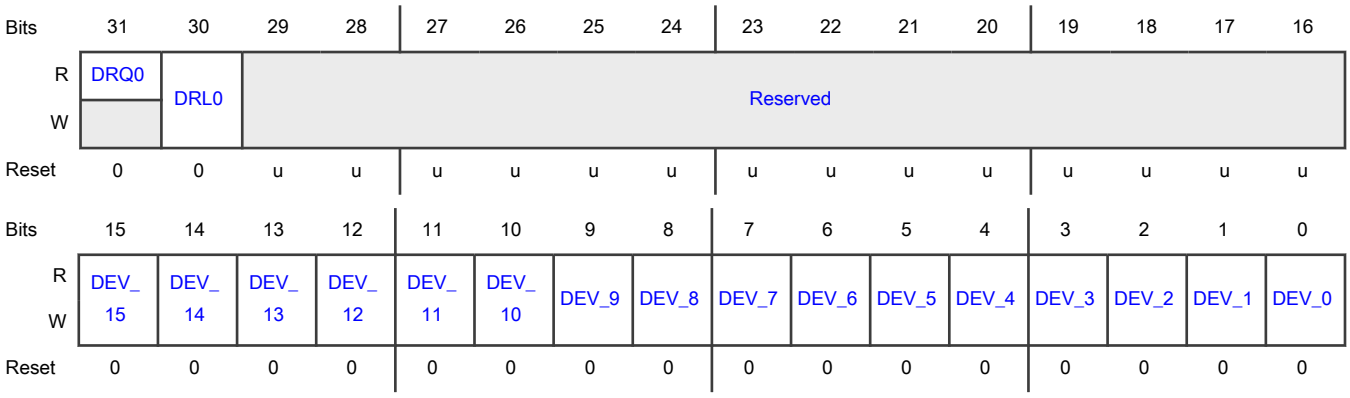
The DMA request registers are word-write only. Attempting to write a halfword value to these registers results in a bus error.

Event-generated DMA requests are particularly useful for launching DMA activity to or from other peripherals under SCT control.

NOTE

In this chip, SCT DMA requests are connected to the DMA trigger inputs, and the DMA trigger input mux registers control them.

Diagram



Fields

Field	Function
31 DRQ0	DMA Request 0 State Indicates the state of DMA request 0. **NOTE** If the related DMA channel is enabled and properly set up, it is unlikely for you to see this flag. The DMA service rapidly clears this field. If the flag remains set, there could be an issue with the DMA setup.
30 DRL0	DMA Request Low 0 Triggers DMA request 0. Writing 1 to this field triggers DMA request 0 when it loads MATCH*n*[MATCH_L] or the unified registers, using MATCHREL*n*[RELOAD_L] or the unified registers.
29-16 —	Reserved
15-0 DEV_n	DMA Request Event Triggers DMA request 0 using event *n*. If bit *n* = 1, event *n* triggers DMA request 0 (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT.

49.7.3.17 DMA Request 1 (DMAREQ1)

Offset

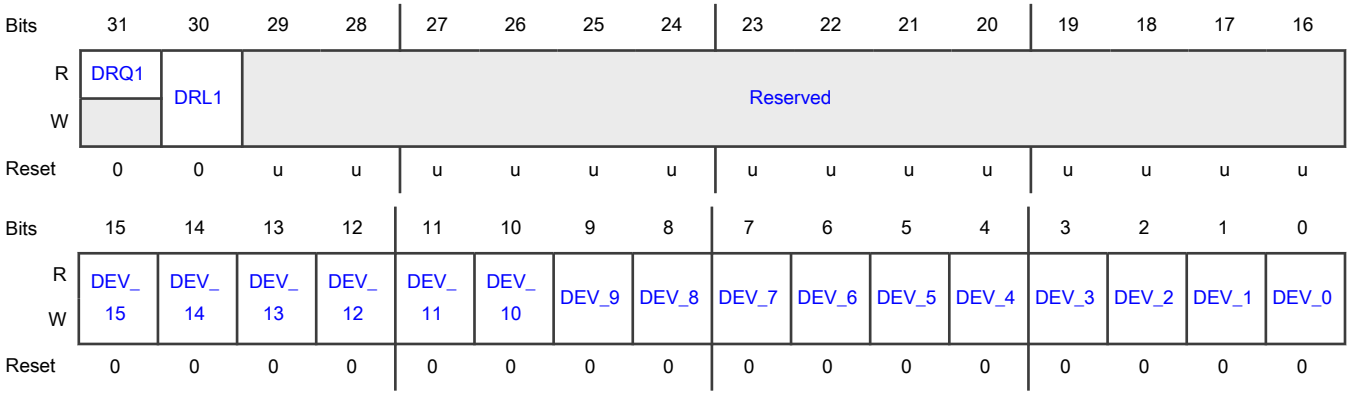
Register	Offset
DMAREQ1	60h

Function

Specifies DMA request 1.

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram



Fields

Field	Function
31 DRQ1	DMA Request 1 State Specifies the state of DMA request 1. **NOTE** If the related DMA channel is enabled and properly set up, it is unlikely for you to see this flag, which the DMA service clears rapidly. If the flag remains set, there could be an issue with the DMA setup.
30 DRL1	DMA Request Low 1 Triggers DMA request 1. Writing 1 to this field triggers DMA request 1 when it loads MATCH*n*[MATCH_L] or the unified registers, using MATCHREL*n*[RELOAD_L] or the unified registers.
29-16 —	Reserved
15-0	DMA Request Event

Table continues on the next page...

Table continued from the previous page...

Field	Function
DEV_n	Triggers DMA request using event *n*. If bit *n* = 1, event *n* triggers DMA request 1 (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT.

49.7.3.18 Event Interrupt Enable (EVEN)

Offset

Register	Offset
EVEN	F0h

Function

Enables flags to request an interrupt if EVFLAG[FLAG*n*] = 1.

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

49.7.3.19 Event Flag (EVFLAG)

Offset

Register	Offset
EVFLAG	F4h

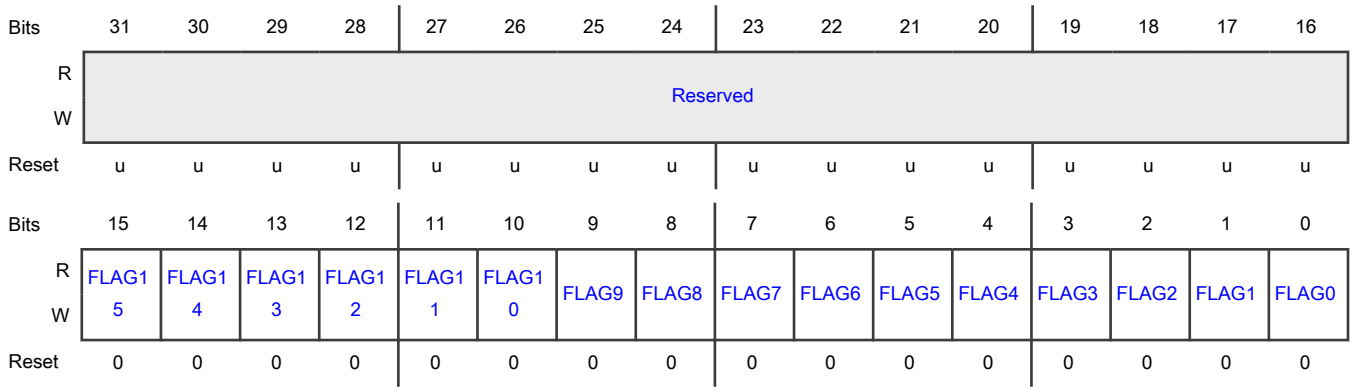
Function

Records events.

Writing 1 to this register clears the corresponding flags and negates the SCT interrupt request if all enabled flags are 0.

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 FLAGn	Event Flag Specifies event flag *n*. Bit *n* is 1 if event *n* has occurred since reset or a 1 was last written to this bit (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT. 0b - No flag 1b - Event n flag

49.7.3.20 Conflict Interrupt Enable (CONEN)

Offset

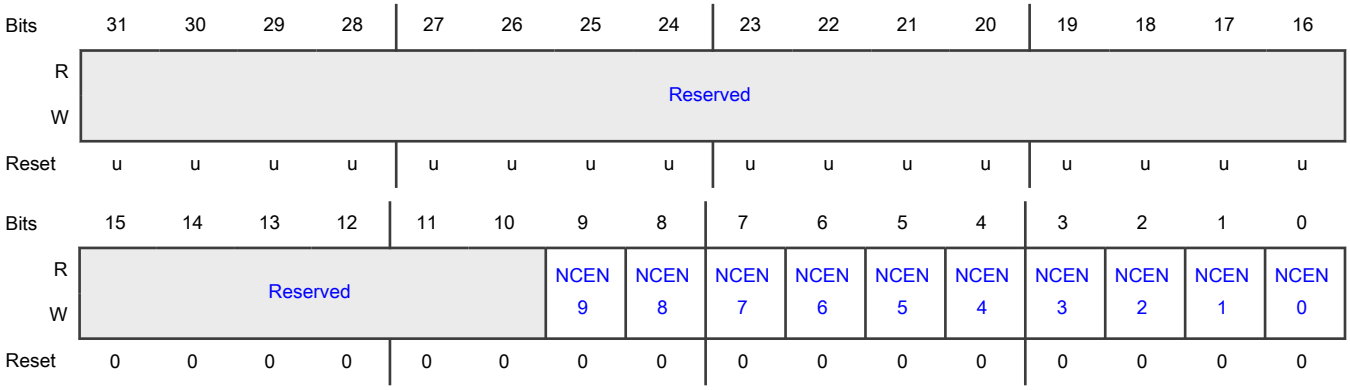
Register	Offset
CONEN	F8h

Function

Enables no-change conflict events specified in Output Conflict Resolution (RES) to generate an interrupt request.

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-0 NCENn	No Change Conflict Event and Interrupt Enable Specifies whether an interrupt is generated. SCT requests an interrupt when bit *n* of this register and Conflict Flag (CONFLAG) are both = 1 (output 0 = bit 0, output 1 = bit 1, and so on). 0b - No interrupt 1b - Interrupt

49.7.3.21 Conflict Flag (CONFLAG)

Offset

Register	Offset
CONFLAG	FCh

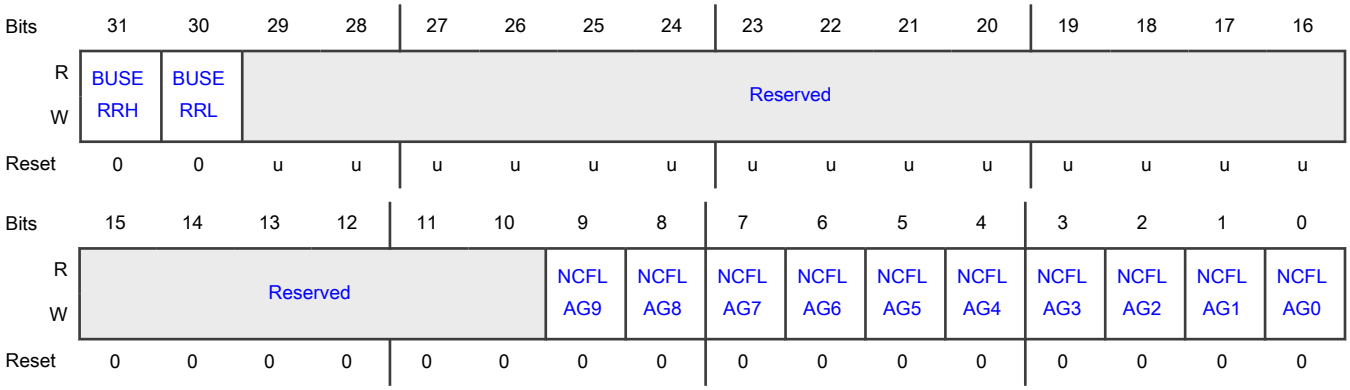
Function

Records a no-change conflict occurrence and also provides details of any bus errors.

Writing 1 to the fields of this register clears the corresponding read bits and negates the SCT interrupt request if all enabled flags are zero.

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram



Fields

Field	Function
31 BUSERRH	Bus Error High Specifies whether the bus error is low or unified. The most recent bus error from this SCT involved writing CTR H, STATE H, MATCH H, or the Output register when the H counter was not halted.
30 BUSERRL	Bus Error Low or Unified Specifies whether the bus error is low or unified. The most recent bus error from this SCT involved writing to CTR L/Unified, STATE L/Unified, MATCH L/Unified, or the Output register when the L/U counter was not halted. A word write to certain L and H registers can be half successful and half unsuccessful.
29-10 —	Reserved
9-0 NCFLAGn	No Change Conflict Event Flag Specifies whether a no-change conflict event occurred. 0b - Did not occur 1b - Occurred

49.7.3.22 Capture Value (CAP0 - CAP15)

Offset

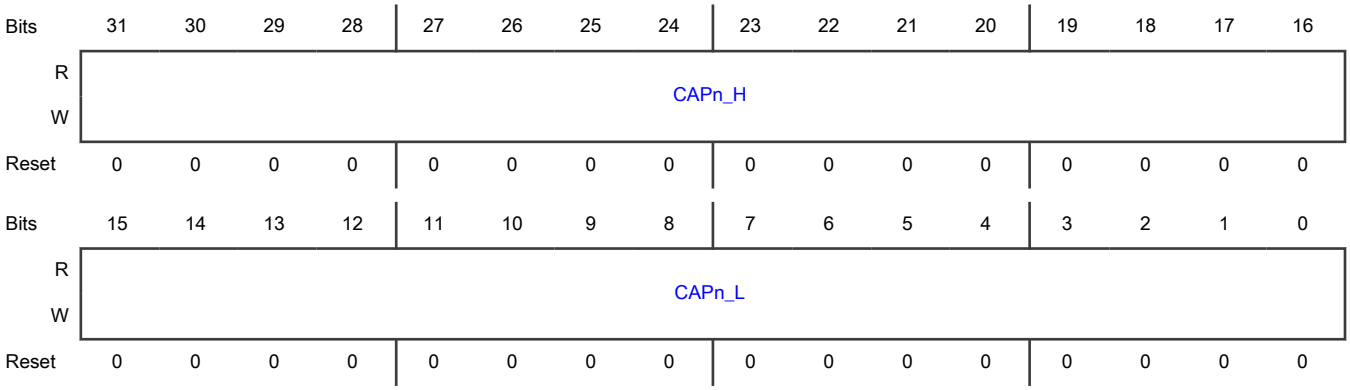
For n = 0 to 15:

Register	Offset
CAPn	100h + (n × 4h)

Function

Allows you to record counter values when the events selected by the corresponding capture control registers occur.

Diagram



Fields

Field	Function
31-16 CAPn_H	Capture High Captures the higher counter value. If CONFIG[UNIFY] = 0, read the 16-bit counter value at which this register was last captured, and if CONFIG[UNIFY] = 1, read the upper 16 bits of the 32-bit value at which this register was last captured.
15-0 CAPn_L	Capture Low Captures the lower counter value. If CONFIG[UNIFY] = 0, read the 16-bit counter value at which this register was last captured, and if CONFIG[UNIFY] = 1, read the lower 16 bits of the 32-bit value where this register was last captured.

49.7.3.23 Match Value (MATCH0 - MATCH15)

Offset

For n = 0 to 15:

Register	Offset
MATCHn	100h + (n × 4h)

Function

Is compared to counters to help create events.

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 0, the L and H registers are independently compared to the L and H counters.
- If CONFIG[UNIFY] = 1, the combined L and H registers hold a 32-bit value that is compared to the unified counter. A match can only occur in a clock for which the counter is running (Stop Event Select (STOP) and Halt Event Select (HALT) are 0).

You can read this register at any time. Writing to MATCH[MATCH*n*_L], MATCH[MATCH*n*_H], or the unified register is only allowed when the corresponding counter is halted (CTRL[HALT_L] and CTRL[HALT_H] are 1). Match events occur in the SCT clock for which the counter is (or would be) incremented to the next value. When a match event limits its counter, the value in this register is the last value of the counter before it is cleared to zero (or decremented if BIDIR is 1).

There is no “write-through” from reload registers to match registers. Before starting a counter, you can write one value to this register, used in the first cycle of the counter, and a different value to the corresponding match reload register used in the second cycle.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	MATCHn_H

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	MATCHn_L															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 MATCHn_H	Match High Compares upper bits to the unified counter. If CONFIG[UNIFY] = 0, read or write the 16-bit value to be compared to the H counter. If CONFIG[UNIFY] = 1, read or write the upper 16 bits of the 32-bit value to be compared to the unified counter.
15-0 MATCHn_L	Match Low Compares lower bits to the unified counter. If CONFIG[UNIFY] = 0, read or write the 16-bit value to be compared to the lower counter. If CONFIG[UNIFY] = 1, read or write the lower 16 bits of the 32-bit value to be compared to the unified counter.

49.7.3.24 Fractional Match (FRACMAT0 - FRACMAT5)

Offset

Register	Offset
FRACMAT0	140h

Table continues on the next page...

Table continued from the previous page...

Register	Offset
FRACMAT1	144h
FRACMAT2	148h
FRACMAT3	14Ch
FRACMAT4	150h
FRACMAT5	154h

Function

Provides a higher average resolution over time by applying a dither pattern as described in Dithering. This dither pattern results in delaying recognition of a match for one counter clock for *n* (0 to 15) out of every 16 counter cycles. You must program the value of *n* in these fractional match registers, which are provided for up to first six of the match registers.

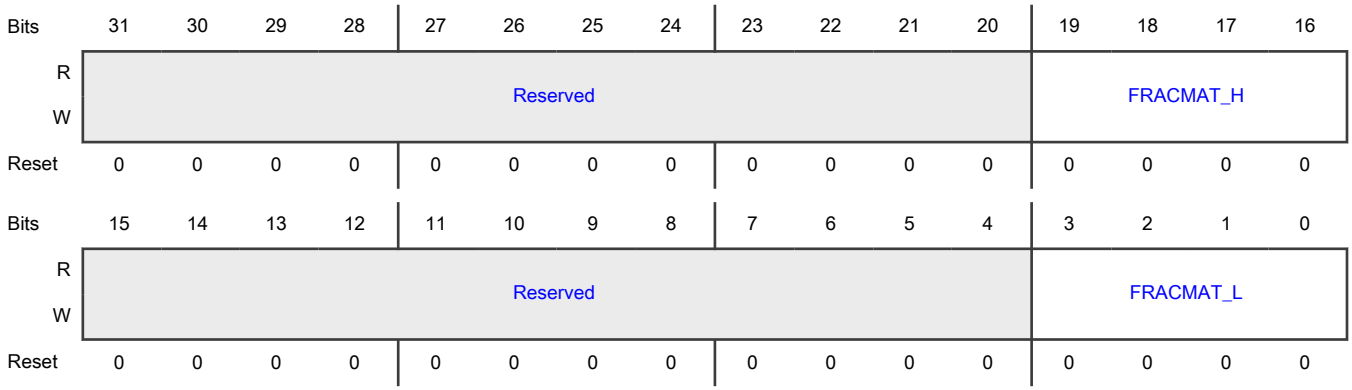
You can read fractional match registers at any time, but can write to FRACMAT*n*[FRACMAT_L], FRACMAT*n*[FRACMAT_H], or the unified register only when the corresponding counter is halted (CTRL[HALT_L] and CTRL[HALT_H] are 1).

Each fractional match register has an associated fractional match reload register. The contents of these reload registers are transferred into the fractional match registers at the start of every new SCT counter cycle unless CONFIG[NORELOAD] = 1 for the appropriate half counter.

You can write to the reload registers at any time, regardless of whether the counter is running.

There is no write-through from the fractional match reload registers to the fractional match registers. Before starting a counter, you can write a value to the fractional match register that is used in the first cycle or period of operation, and a different value to the corresponding fractional match reload register that is used in the second cycle or period.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16	Fractional Match High

Table continues on the next page...

Table continued from the previous page...

Field	Function
FRACMAT_H	Allows reads or writes to upper bits for fractional match. If CONFIG[UNIFY] = 0, read or write a 4-bit value specifying the dither pattern to be applied to the corresponding MATCH*n*[MATCH_H] field (*n* = 0 to 5).
15-4 —	Reserved
3-0 FRACMAT_L	Fractional Match Low Allows reads or writes to lower bits for fractional match. If CONFIG[UNIFY] = 0, read or write a 4-bit value specifying the dither pattern to be applied to the corresponding MATCH*n*[MATCH_L] field (*n* = 0 to 5). If CONFIG[UNIFY] = 1, the value applies to the unified, 32-bit fractional match register.

49.7.3.25 Capture Control (CAPCTRL0 - CAPCTRL15)

Offset

For n = 0 to 15:

Register	Offset
CAPCTRLn	200h + (n × 4h)

Function

Controls the events that cause loading of the corresponding capture register from the counter.

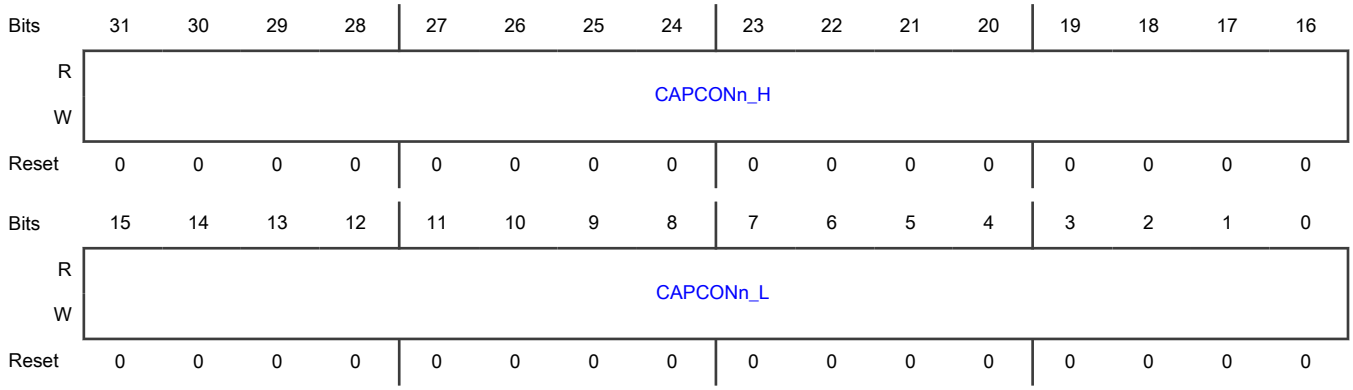
You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only the _L fields are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, CAPCTRL*n*_L and CAPCTRL*n*_H. You can read both or write to the _L and _H registers individually.

Based on a selected event, the capture registers can be loaded with the current counter value when the event occurs.

Each capture control register (L, H, or unified 32-bit) controls which events cause the load of the corresponding capture register from the counter.

Diagram



Fields

Field	Function
31-16 CAPCONn_H	Capture Control High Captures higher bits. If bit *n* = 1, event *n* causes CAP*n*[CAP_H] (CONFIG[UNIFY] = 0) to be loaded (event 0 = bit 16, event 1 = bit 17, and so on). Number of bits = number of match and captures in SCT.
15-0 CAPCONn_L	Capture Control Low Captures lower bits. If bit *n* = 1, event *n* causes CAP*n*[CAP_L] (CONFIG[UNIFY] = 0) or CAP*n* (CONFIG[UNIFY] = 1) to be loaded (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of match and captures in SCT.

49.7.3.26 Match Reload Value (MATCHREL0 - MATCHREL15)

Offset

For n = 0 to 15:

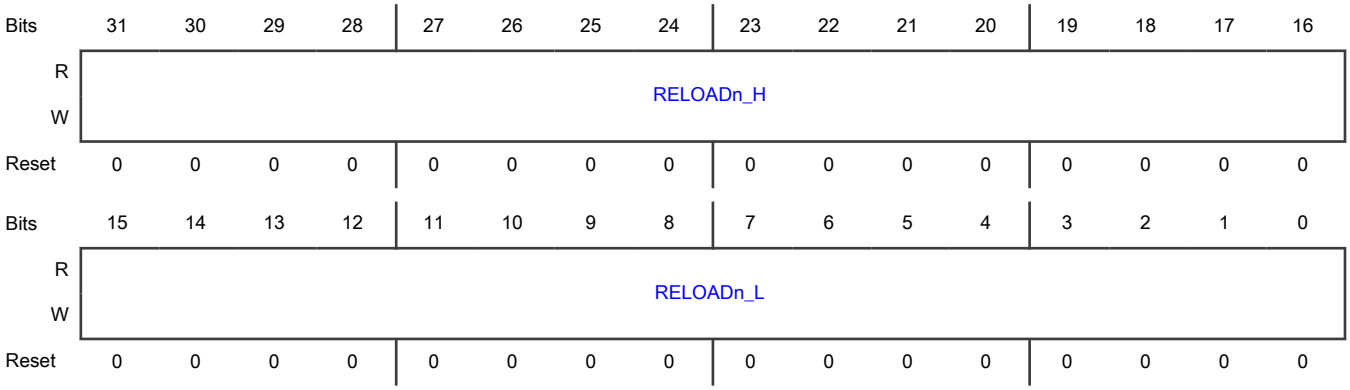
Register	Offset
MATCHRELn	200h + (n × 4h)

Function

Reloads a match register (L, H, or unified 32-bit counter) from its corresponding reload register at the start of each new counter cycle, which is when:

- CTRL[BIDIR_H] and CTRL[BIDIR_L] are 0 and the counter is cleared to zero upon reaching its limit condition.
- CTRL[BIDIR_H] and CTRL[BIDIR_L] are 1 and the counter counts down to 0, unless CONFIG[NORELOAD_H] and CONFIG[NORELOAD_L] are 1.

Diagram



Fields

Field	Function
31-16 RELOADn_H	Reload High Specifies the value to be loaded into MATCH*n*[MATCH_H]. If CONFIG[UNIFY] = 0, this field specifies the 16-bit value to be loaded into MATCH*n*[MATCH_H]. If CONFIG[UNIFY] = 1, the field specifies the upper 16 bits of the 32-bit value to be loaded into MATCH*n*[MATCH_H].
15-0 RELOADn_L	Reload Low Specifies the value to be loaded into MATCH*n*[MATCH_L]. If CONFIG[UNIFY] = 0, this field specifies the 16-bit value to be loaded into MATCH*n*[MATCH_L]. If CONFIG[UNIFY] = 1, the field specifies the lower 16 bits of the 32-bit value to be loaded into MATCH*n*[MATCH_L].

49.7.3.27 Fractional Match Reload (FRACMATREL0 - FRACMATREL5)

Offset

Register	Offset
FRACMATREL0	240h
FRACMATREL1	244h
FRACMATREL2	248h
FRACMATREL3	24Ch
FRACMATREL4	250h
FRACMATREL5	254h

Function

Reloads a fractional match register (_L, _H, or the unified 32-bit counter) from the corresponding fractional match reload register at the start of each new counter cycle.

A fractional match register is loaded from the corresponding fractional match reload register at the start of each new counter cycle, which means when:

- CTRL[BIDIR] = 0 and the counter is cleared to zero upon reaching its limit condition, or when CTRL[BIDIR] = 1 and the counter counts down to 0, unless the appropriate CONFIG[NORELOAD] field = 1.
- CTRL[BIDIR] = 1 and the counter is cleared to zero upon reaching its limit condition, or when CTRL[BIDIR] = 1 and the counter counts down to 0, unless the appropriate CONFIG[NORELOAD] field = 1.

Fields

Field	Function
31-20 —	Reserved
19-16 RELFRAC_H	Reload Fractional Match High Specifies the value to be loaded into FRACMAT*n*[FRACMAT_H]. If CONFIG[UNIFY] = 0, read or write the 4-bit value to be loaded into FRACMAT*n*[FRACMAT_H]. If CONFIG[UNIFY] = 1, read or write the upper 4 bits with the 4-bit value to be loaded into FRACMAT*n*[FRACMAT_H].
15-4 —	Reserved
3-0 RELFRAC_L	Reload Fractional Match Low Specifies the value to be loaded into FRACMAT*n*[FRACMAT_L]. If CONFIG[UNIFY] = 0, read or write the 4-bit value to be loaded into FRACMAT*n*[FRACMAT_L]. If CONFIG[UNIFY] = 1, read or write the lower 4 bits to be loaded into FRACMAT*n*[FRACMAT_L].

49.7.3.28 Event n State (EV0_STATE - EV15_STATE)

Offset

For n = 0 to 15:

Register	Offset
EVn_STATE	300h + (n × 8h)

Function

Specifies event *n* state.

You can enable each event in some contexts (or states) and disable it in others. Each event defined in Event n Control (EV0_CTRL - EV15_CTRL) has an associated Event Interrupt Enable (EVEN) that can enable or disable the event for each available state.

Each event also has an associated Event n State (EV0_STATE - EV15_STATE) that allows this event to happen in one or more states of the counter selected by the corresponding EV*n*_CTRL[HEVENT] field.

An event *n* is disabled when its corresponding Event n State (EV0_STATE - EV15_STATE) contains all zeros because it is masked regardless of the current state.

In simple applications that do not use states, write 0x01 to this register to enable each event in exactly one state. Because the state does not change (which means, the state variable always remains at its reset value of 0), writing 0x01 permanently enables this event.

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram

R W	STATEMSKn															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 STATEMSKn	Event State Mask Specifies the state in which event *n* happens. If bit *m* = 1, event *n* happens in state *m* of the counter selected by the HEVENT field (*n* = event number, *m* = state number; state 0 = bit 0, state 1= bit 1, and so on). Number of bits = number of states in this SCT.

49.7.3.29 Event n Control (EV0_CTRL - EV15_CTRL)

Offset

For n = 0 to 15:

Register	Offset
EVn_CTRL	304h + (n × 8h)

Function

Defines the conditions for an event to occur, based on the counter values or input and output states.

After you configure an event, it can be selected to trigger multiple actions (for example, stopping the counter and toggling an output) unless the event is blocked in the current SCT state, or the counter is halted. To block a particular event from occurring, use Event n State (EV0_STATE - EV15_STATE). To block all events for a given counter, write 1 to CTRL[HALT] or select an event to halt the counter.

An event can be programmed to occur based on a selected input or output edge or level and/or based on its counter value, matching a selected match register. In Bidirectional mode, you can enable events based on the direction of count.

If CONFIG[UNIFY] = 0, each event is associated with a particular counter in EV*n*_CTRL[HEVENT]. An event is permanently disabled when its event state mask register contains all 0s.

Each event can modify its counter STATE value. If more than one event associated with the same counter occurs in a given clock cycle, only the state change specified for the highest-numbered event among them takes place. Other actions dictated by any simultaneously occurring events all take place.

Only word writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved									DIRECTION		MATCHMEM	STATEV			
Reset	u	u	u	u	u	u	u	u	u	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	STATEV	STATELD	COMBMODE		IOCOND		IOSEL				OUTSEL	HEVENT	MATCHSEL			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-23 —	Reserved
22-21 DIRECTION	Direction Specifies the direction for event generation. This field only applies when the counters are operating in BIDIR mode. If CTRL[BIDIR] = 0, SCT ignores this field. 00b - Direction independent (event triggered regardless of the count direction)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - Counting up (event triggered only during up-counting when CTRL[BIDIR] = 1) 10b - Counting down (event triggered only during down-counting when CTRL[BIDIR] = 1) 11b - Reserved
20 MATCHMEM	Match Mem If this field = 1 and EV*n*_CTRL[COMBMODE] specifies a match component to the triggering of this event, a match is considered to be active whenever the counter value is greater than or equal to the value specified in the match register when counting up, and less than or equal to the match value when counting down. If this field = 0, a match is only active during the cycle when the counter is equal to the match value.
19-15 STATEV	State Value Specifies the state value. The state value is loaded into or added to the state that EV*n*_CTRL[HEVENT] selects, depending on EV*n*_CTRL[STATELD], when this event is the highest-numbered event occurring for that state. If both the STATELD and STATEV fields are 0, there is no change to the value of STATE.
14 STATELD	State Load Controls how EV*n*_CTRL[STATEV] modifies the state that EV*n*_CTRL[HEVENT] selects when this event is the highest-numbered event occurring for that state. 0b - Value of STATEV added to that of STATE (the carry out is ignored) 1b - Value of STATEV loaded into that of STATE
13-12 COMBMODE	Combination Mode Selects how the specified match and I/O condition are used and combined. 00b - OR (the event occurs when either the specified match or I/O condition occurs) 01b - MATCH (uses the specified match only) 10b - IO (uses the specified I/O condition only) 11b - AND (the event occurs when the specified match and I/O condition occur simultaneously)
11-10 IOCOND	Input or Output Condition Selects the I/O condition for event *n*. The detection of edges on outputs lags the conditions that switch the outputs by one SCT clock. To guarantee proper edge and state detection, an input must have a minimum pulse width of at least one SCT clock period. 00b - Low 01b - Rise 10b - Fall 11b - High
9-6	Input or Output Signal Select

Table continues on the next page...

Table continued from the previous page...

Field	Function
IOSEL	Selects the input or output signal number associated with this event, if any. Do not select an input in this register if CONFIG[CLKMODE] is 1x. In this case, the clock input is an implicit ingredient of every event.
5 OUTSEL	Input and Output Select Selects the inputs or outputs that EV*n*_CTRL[IOSEL] specifies. 0b - Inputs 1b - Outputs
4 HEVENT	High Event Selects the low and high counters. Do not write 1 to this field if CONFIG[UNIFY] = 1. 0b - Low counter (selects the L state and the L match register that the MATCHSEL field specifies) 1b - High counter (selects the H state and the H match register that the MATCHSEL field specifies)
3-0 MATCHSEL	Match Select Selects the match register associated with this event, if any. A match can occur only when the counter that EV*n*_CTRL[HEVENT] selects is running.

49.7.3.30 Output n Set (OUT0_SET - OUT9_SET)

Offset

For n = 0 to 9:

Register	Offset
OUTn_SET	500h + (n × 8h)

Function

Selects the events that can set each SCT output.

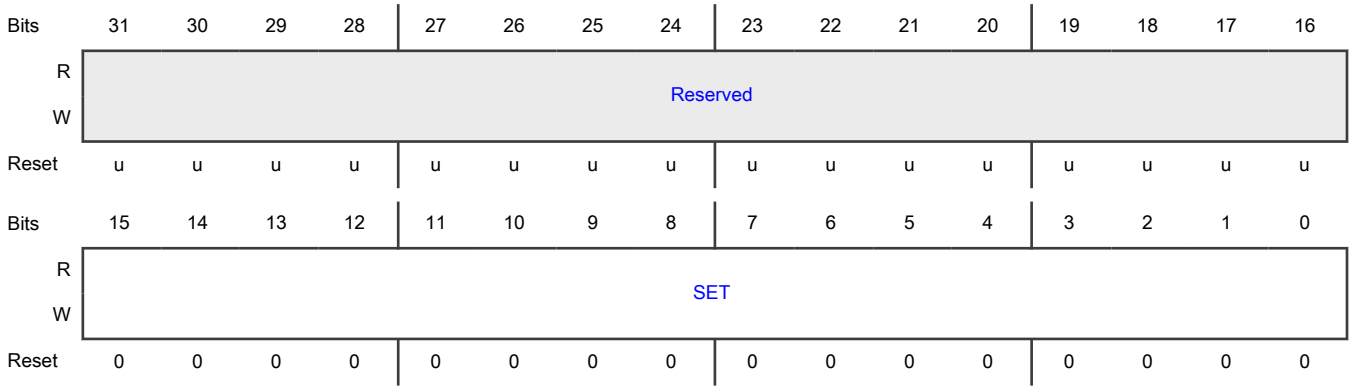
Based on a selected event, each SCT output can be set. There is one output set register for each SCT output. Each bit of an output set register is associated with a different event (bit 0 with event 0, and so on). The selected event can set or clear the output depending on the setting of OUTPUTDIRCTRL[SETCLR*n*]. To define the actual event that sets the output (a match, an I/O pin toggle, and so on), see Event n Control (EV0_CTRL - EV15_CTRL).

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

NOTE

If SCT is operating as two 16-bit counters, events can modify output states only when no counter is halted. This is true regardless of what triggered the event.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 SET	Set Output Selects events to set outputs. If bit *m* = 1, it selects event *m* to set output *n* (or clear it if OUTPUTDIRCTRL[SETCLR*n*] = 0x1 or 0x2). Output 0 = bit 0, output 1 = bit 1, and so on. Number of bits = number of events in this SCT. If the counter is used in Bidirectional mode, it is possible to reverse the action that the output set and clear registers specify when counting down (see Output Counter Direction Control (OUTPUTDIRCTRL) for more information).

49.7.3.31 Output n Clear (OUT0_CLR - OUT9_CLR)

Offset

For n = 0 to 9:

Register	Offset
OUTn_CLR	504h + (n × 8h)

Function

Selects the events that can clear each SCT output.

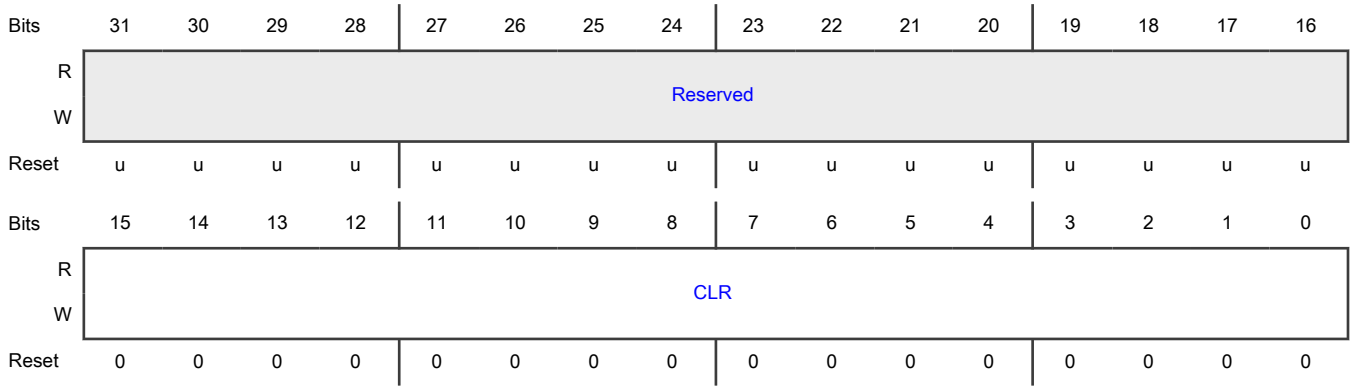
Based on a selected event, each SCT output can be cleared. There is one register for each SCT output that selects which events can clear that output. Each bit of an output clear register is associated with a different event (bit 0 with event 0, and so on). A selected event can clear or set the output depending on the setting of OUTPUTDIRCTRL[SETCLR*n*]. To define the actual event that clears the output (a match, an I/O pin toggle, and so on), see Event n Control (EV0_CTRL - EV15_CTRL).

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

NOTE

If SCT is operating as two 16-bit counters, events can modify output states only when no counter is halted. This is true regardless of what triggered the event.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CLR	Clear Output Selects events to clear outputs. If bit *m* = 1, it selects event *m* to clear output *n* (or set it if OUTPUTDIRCTRL[SETCLR*n*] = 0x1 or 0x2). Event 0 = bit 0; event 1 = bit 1, and so on. Number of bits = number of events in this SCT. If the counter is used in Bidirectional mode, it is possible to reverse the action specified by the output set and clear registers when counting down (see Output Counter Direction Control (OUTPUTDIRCTRL) for more information).

Chapter 50
Multi-Rate Timer (MRT)

50.1 Chip-specific MRT information

Table 435. Reference links to related information

Topic	Related module	Reference
Full description	MRT	MRT
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

50.1.1 Module instances

This device has one instance of the MRT module, MRT0.

50.1.2 Chip-specific MRT initialization

To initialize the MRT module:

1. Enable the clock to MRT via MRT field in AHB Clock control 1 AHBCLKCTRL1 register in SYSCON.
2. Deassert the MRT reset via MRT_RST field in the Peripheral reset control 1 PRESETCTRL1 register in SYSCON.
3. Ensure that the MRT can issue an interrupt in the chip. See registers for SmartDMA arch B inputs (SMARTDMAARCHB_INMUX0 - SMARTDMAARCHB_INMUX7) in INPUTMUX.

50.2 Overview

MRT provides a repetitive interrupt timer with 4 channels.

50.2.1 Block diagram

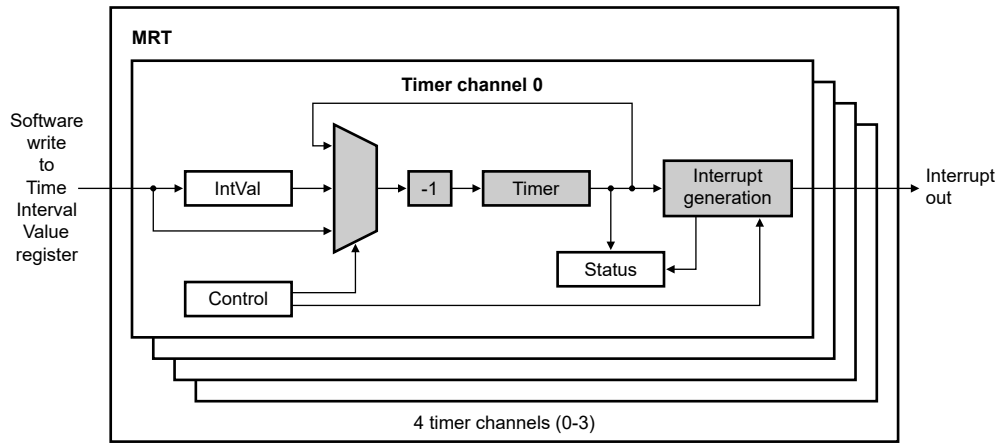


Figure 264. Block diagram

50.2.2 Features

- 24-bit interrupt timer.
- There are 4 channels independently counting down from individually set values.
- Repeat Interrupt, One-Shot Interrupt, and One-Shot Stall modes.
- You can program individual time intervals for each channel.
- Each channel operates independently of the other channels.

50.3 Functional description

The following sections discuss various modes that affect the functionality of MRT.

50.3.1 Operating modes

MRT has the following three operating modes:

- Repeat Interrupt mode
- One-Shot Interrupt mode
- One-Shot Stall mode

50.3.1.1 Repeat Interrupt mode

• Generates repeated interrupts after a selected time interval.

• Gets used for application-based Pulse Width Modulation (PWM) or Pulse Position Modulation (PPM).

When TIMER*n* is in idle state, writing a nonzero value (IVALUE) to INTVAL*n* immediately loads the time interval value (IVALUE -1). Then the timer begins to count down from this value.

After the timer reaches 0

- an interrupt is generated.
- the value in INTVAL*n* (IVALUE -1) is automatically reloaded, and
- the timer starts to count down again.

When the timer is running in Repeat Interrupt mode, you can perform various interval timer actions (change or stop):

Table 436. Possible actions in Repeat Interrupt mode

Action	To perform action	Timer does this	Interrupt
Change the interval value on the next interval timer cycle.	• Write new value (>0) to INTVAL*n*. • Write 0 to LOAD.	On the next cycle, the timer counts down from the new value.	An interrupt is generated when the timer reaches 0.
Change the interval value immediately (also called "change on-the-fly") in the interval timer.	• Write new value (>0) to INTVAL*n*. • Write 1 to LOAD.	The timer immediately starts to count down from the new timer interval value.	An interrupt is generated when the timer reaches 0.
Stop the interval timer at the end of the time interval.	• Write 0 to INTVAL*n*. • Write 0 to LOAD.	The timer stops at the end of the time interval.	An interrupt is generated when the timer reaches 0.
Stop the interval timer immediately.	• Write 0 to INTVAL*n*. • Write 1 to LOAD.	The timer stops immediately.	No interrupt is generated when INTVAL*n* is written.

50.3.1.2 One-Shot Interrupt mode

• In this mode, the timer generates one interrupt after a one-time count.

• This mode allows you to generate an interrupt at any time.

• Using this mode, you can introduce a specific delay in a software task.

When the timer is in an idle state, writing a nonzero value (IVALUE) to INTVAL*n* immediately loads the time interval value (IVALUE -1), and the timer starts to count down. As soon as the timer reaches 0, the timer stops and an interrupt is generated (and then enters the idle state).

When the timer is running in One-Shot Interrupt mode, you can perform the following interval timer actions (load or stop):

Table 437. Possible actions in One-Shot Interrupt mode

Action	To perform action	Timer does this	Interrupt
Load a timer interval value.	• Write a new time interval value (>0) to INTVAL*n*. • Write 1 to LOAD.	The timer immediately reloads the new time interval, and starts counting down from the new value.	An interrupt is generated when the timer reaches 0.
Stop the interval timer.	• Write a 0 to INTVAL*n*. • Write 1 to LOAD.	The timer immediately stops counting and moves to the idle state.	No interrupt is generated when INTVAL*n* is updated.

50.3.1.3 One-Shot Stall mode

• Used for very short delays (for example, when the delay needed is less than the time it takes to arrive at an interrupt service routine).

• Designed for very low software overhead that requires only a single write to INTVAL*n* (if the channel is already configured for One-Shot stall mode). MRT counts the requested delay when stalling the bus write operation, and then concluding the write operation when the delay has finished. No interrupt or status polling is needed.

Use this mode:

- when a short delay is needed between two software-controlled events.
- when a delay is expected before your application can continue.

The CPU consumes a minimum amount of power during One-Shot Stall mode, because no bus transactions occur during that period.

One-Shot Stall mode provides a minimum amount of time between the execution of the instruction that performs the write to INTVAL*n* and the time that your software resumes execution. Other system events, such as interrupts or other bus masters accessing the APB bus where MRT resides, can cause the delay to be longer.

50.3.2 Clocking

Table 438. MRT clocks

Type of clock	Description
Bus clock (vpb_clk)	Controls the access to the MRT registers and functions the MRT module.

50.3.3 Interrupts

A channel provides 3 different interrupts modes listed below and can select the interrupt mode individually per channel. This interrupt can be programmed with an independent time interval.

- Repeat interrupt

- Shot interrupt
- Shot bus stall interrupt

50.4 External signals

This module has no external signals.

50.5 Initialization

To initialize:

1. Enable the clock to MRT.
2. Deassert MRT reset.
3. Ensure that MRT can issue an interrupt in the chip.

See the Chip-specific section for more details.

50.6 Memory map and register descriptions

50.6.1.2 Time Interval Value (INTVAL0 - INTVAL3)

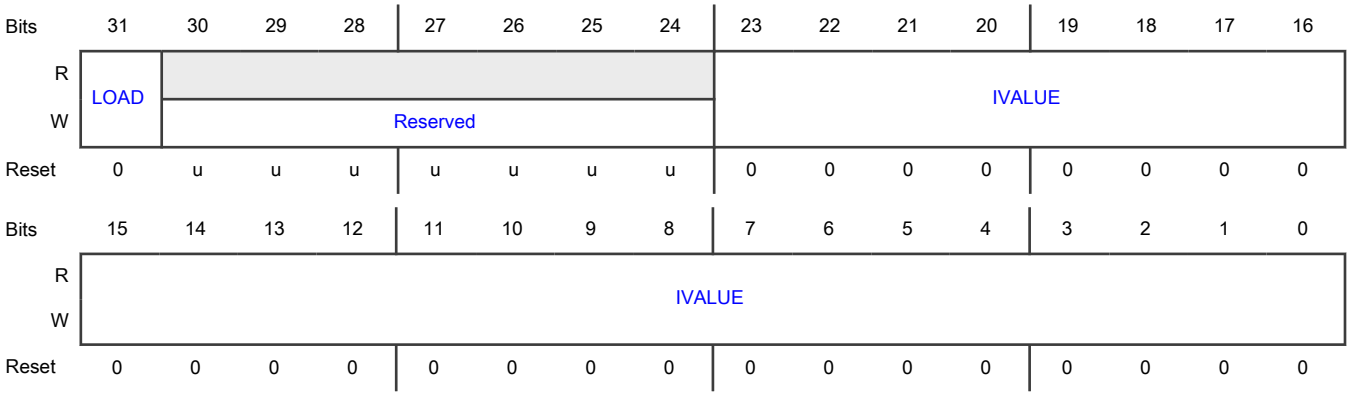
Offset

Register	Offset
INTVAL0	0h
INTVAL1	10h
INTVAL2	20h
INTVAL3	30h

Function

Contains MRT load value and controls how the timer is reloaded. The load value is IVALUE -1.

Diagram



Fields

Field	Function
31 LOAD	Force Load Enable Determines how the timer interval value (IVALUE -1) is loaded into the TIMER*n*.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	LOAD is write only. Reading LOAD always returns 0. If the repeat mode is selected, the load from the INTVAL*n* to the TIMER*n* is processed at the end of the time interval. The INTVAL*n* interval value (IVALUE -1) is immediately loaded into the TIMER*n* when it is running. 0b - No force load 1b - Force load
30-24 —	Reserved Reserved. Read value is undefined; only 0 should be written.
23-0 IVALUE	Time Interval Load Value. INTVAL*n*[IVALUE] is loaded into TIMER*n*, and MRT channel *n* starts counting down from IVALUE -1. If the timer is idle, then writing a nonzero value to INTVAL*n*[IVALUE] starts the timer immediately. If the timer is running, then writing a 0 to INTVAL*n*[IVALUE] does the following: if LOAD = 1, then the timer stops immediately; if LOAD = 0, then the timer stops at the end of the time interval.

50.6.1.3 Timer (TIMER0 - TIMER3)

Offset

Register	Offset
TIMER0	4h
TIMER1	14h
TIMER2	24h
TIMER3	34h

Function

Holds the current timer value (the TIMER*n* reads the value of the down counter). TIMER*n* registers are read only.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								VALUE

Reset	u	u	u	u	u	u	u	u	1	1	1	1	1	1	1	1

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	VALUE															
W																
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Fields

Field	Function
31-24 —	Reserved Reserved. Read value is undefined; only 0 should be written.
23-0 VALUE	Current Timer Value Holds the current timer value of the down counter. The initial value of TIMER*n* is loaded as (IVALUE -1) from INTVAL*n*, either at the end of the time interval or immediately in the following cases: INTVAL*n* is updated in the idle state or INTVAL*n* is updated with LOAD = 1. When the timer is in an idle state, reading TIMER*n*[VALUE] fields returns -1 (00FF FFFFh).

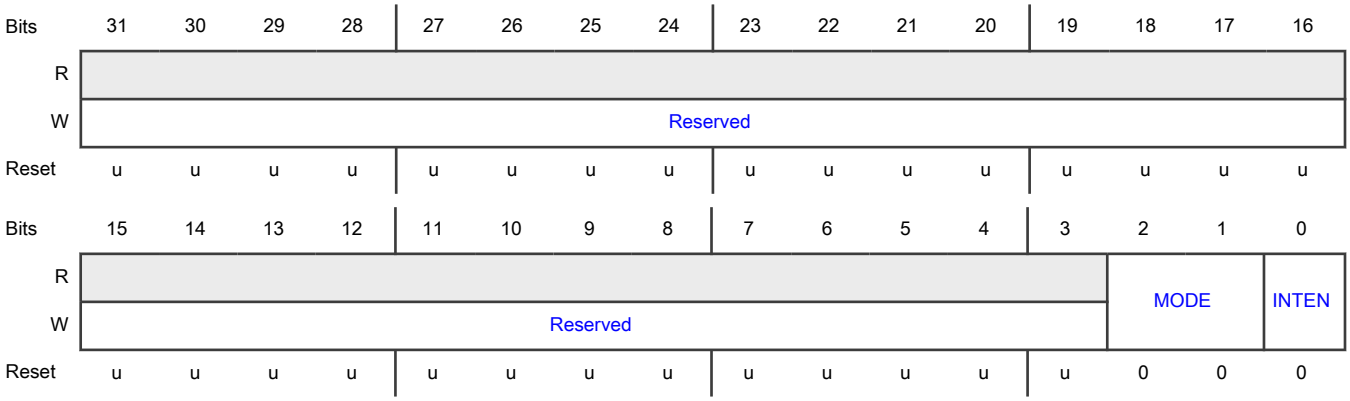
50.6.1.4 Control (CTRL0 - CTRL3)

Offset

Register	Offset
CTRL0	8h
CTRL1	18h
CTRL2	28h
CTRL3	38h

Function
Controls the modes and enables the interrupt for each MRT.

Diagram



Fields

Field	Function
31-3	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
2-1 MODE	MRT Operating mode Selects the timer mode. 00b - Repeat Interrupt mode 01b - One-Shot Interrupt mode 10b - One-Shot Stall mode 11b - Reserved
0 INTEN	Interrupt request Enables the TIMER*n* interrupt. 0b - Disabled 1b - Enabled

50.6.1.5 Status (STAT0 - STAT3)

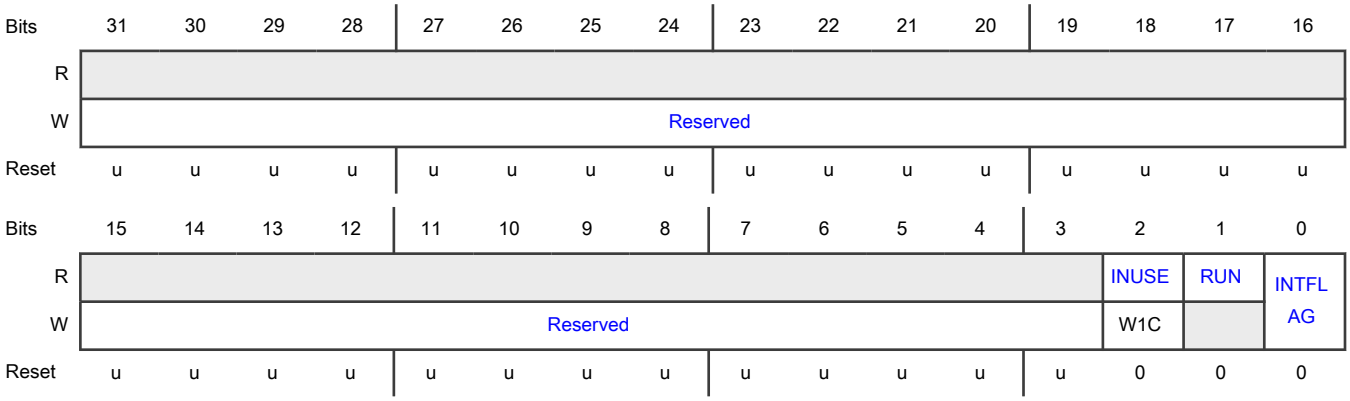
Offset

Register	Offset
STAT0	Ch
STAT1	1Ch
STAT2	2Ch
STAT3	3Ch

Function

Indicates the status of each MRT timer channel.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 INUSE	Channel-In-Use flag Affects the use of Idle Channel (IDLE_CH); the operating details depend on the operating mode bit in MODCFG[MULTITASK]. Writing 1 to this bit clears the status. 0b - This timer channel is not in use. 1b - This timer channel is in use.
1 RUN	Timer n State Indicates the state of TIMER*n*. STAT*n*[RUN] is read only. TIMER*n* stops in idle state and runs in running state. 0b - Idle state. 1b - Running.
0 INTFLAG	Interrupt Flag Monitors the interrupt flag. If the INTEN bit in the CONTROLn is also set to 1, then the interrupt for timer channel n and the global interrupt are generated. Writing a 1 to INTFLAG bit clears the interrupt request. 0b - No pending interrupt. 1b - Pending interrupt.

50.6.1.6 Module Configuration (MODCFG)

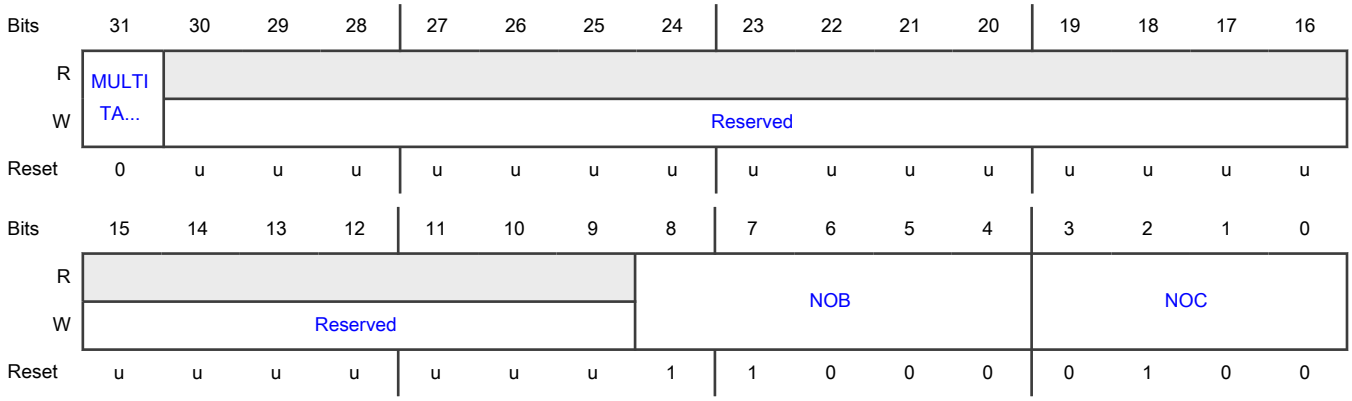
Offset

Register	Offset
MODCFG	F0h

Function

Provides information about this particular MRT instance. It also allows selecting an overall mode for the idle channel feature. MODCFG[MULTITASK] provides the configuration (number of channels and timer width) for this MRT. A reset of the INUSE(n) flags for all channels happens in Hardware Status mode.

Diagram



Fields

Field	Function
31 MULTITASK	MULTITASK Selects the operating mode for STAT*n*[INUSE] and Idle Channel (IDLE_CH). 0b - Hardware status mode. 1b - Multitask mode
30-9 —	Reserved Read value is undefined; only 0 should be written.
8-4 NOB	Number of Bits Identifies the number of timer bits in this MRT (24 bits on this chip).
3-0 NOC	Number of Channels Identifies the number of channels in this MRT.

50.6.1.7 Idle Channel (IDLE_CH)

Offset

Register	Offset
IDLE_CH	F4h

Function

Returns the number of the first Idle Channel.

Use Idle Channel (IDLE_CH) for finding available channels in MRT. This allows you more flexibility when using MRT—no fixed channel assignments are required, and you do not need to search for an available channel. Generally, Idle Channel (IDLE_CH) returns the lowest available channel number.

MODCFG[MULTITASK] allows you to use Idle Channel (IDLE_CH) in two ways. MODCFG[MULTITASK] affects both the functions of Idle Channel (IDLE_CH), and the function of STAT*n*[INUSE] for each MRT channel:

- MULTITASK = 0: Hardware status mode. The STAT*n*[INUSE] for all MRT channels are reset. Idle Channel (IDLE_CH) returns the lowest idle channel number. A channel is considered idle if its RUN flag = 0, and there is no interrupt pending for that channel.
- MULTITASK = 1: Multitask mode. In Multitask mode, the STAT*n*[INUSE] allow more control over when MRT channels are released for further use. When Idle Channel (IDLE_CH) is read, returning a channel number of an idle channel, the STAT*n*[INUSE] for that channel is set by hardware. That channel is not considered idle until its RUN flag = 0, and there is no interrupt pending, and its INUSE flag = 0. This allows reserving an MRT channel with a single register read, and there is no need to start the channel before that channel is no longer considered idle by Idle Channel (IDLE_CH). It also allows you to identify a specific MRT channel. Then you can use that channel more than once without releasing it, removing the need to ask for an available channel for every use.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								CHAN				Reserved			
W																
Reset	u	u	u	u	u	u	u	u	0	0	0	0	u	u	u	u

Fields

Field	Function
31-8 —	Reserved
7-4 CHAN	Idle Channel Helps in reading IDLE_CH[CHAN] and returns the lowest idle timer channel. The number is positioned so that you can use it as an offset from MRT base address. This provides access to the registers for the allocated channel. If all timer channels are running, then CHAN = Fh.
3-0 —	Reserved

50.6.1.8 Global Interrupt Flag (IRQ_FLAG)

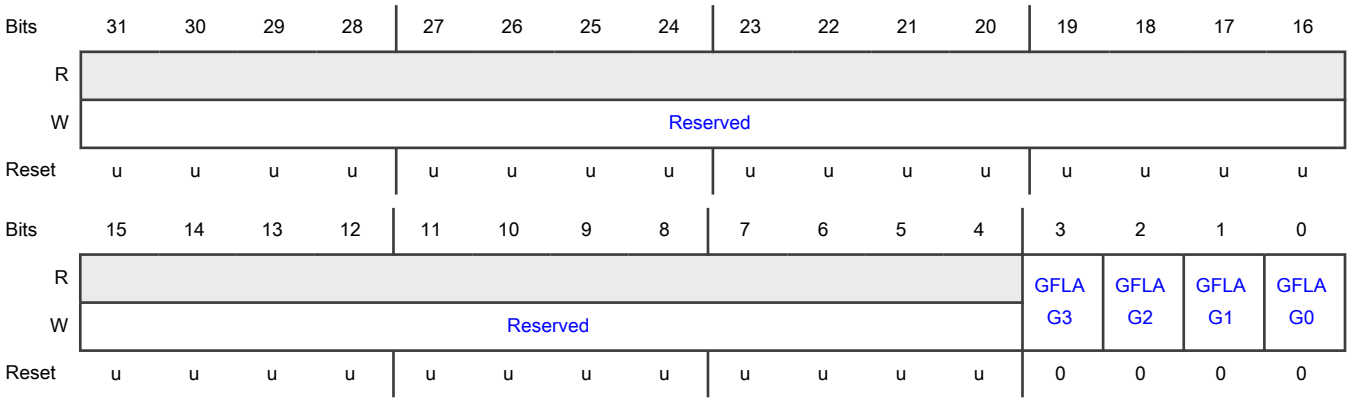
Offset

Register	Offset
IRQ_FLAG	F8h

Function

Combines the interrupt flags from the individual timer channels into one register. Setting and clearing each flag behaves in the same way as setting and clearing STAT*n*[INTFLAG] in each of the STATUS*n* registers.

Diagram



Fields

Field	Function
31-4 —	Interrupt Flag Reserved. Read value is undefined; only 0 should be written.
3 GFLAG3	Interrupt Flag Monitors the interrupt flag of TIMER3 and acts similar to channel 0.
2 GFLAG2	Interrupt Flag Monitors the interrupt flag of TIMER2 and acts similar to channel 0.
1 GFLAG1	Interrupt Flag Monitors the interrupt flag of TIMER1 and acts similar to channel 0.
0 GFLAG0	Interrupt Flag Monitors the interrupt flag of TIMER0. Writing 0 is equivalent to no operation. In the pending interrupt state, Timer (TIMER0 - TIMER3) has reached the end of the time interval. If CTRL*n*[INTEN] in CONTROL*n* also gets 1, then there is a timer channel *n* interrupt and a global interrupt. Writing 1 to IRQ_FLAG[GFLAG0] clears the interrupt request. 0b - No pending interrupt. 1b - Pending interrupt

Chapter 51
Windowed Watchdog Timer (WWDT)

51.1 Chip-specific WWDT information

Table 439. Reference links to related information

Topic	Related module	Reference
Full description	WWDT	WWDT
System memory map		Memory map
Clocking		Clock distribution
Power management		Power management

NOTE

A watchdog reset resets the chip. See WWDT for details.

51.1.1 Module instances

This device has two instances of the WWDT module, WWDT0 and WWDT1.

51.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

51.1.3 MOD[LOCK] behavior

When MOD[LOCK] is set, the write accesses to SYSCON registers are blocked.

- WWDT0: After MOD[LOCK] is set to one and a Watchdog feed is performed, hardware prevents changes to the Watchdog Clock Divider,WDT0 Clock Divider (WDT0CLKDIV), register. MOD[LOCK] can be set once by software and is only cleared by any reset.
- WWDT1: After MOD[LOCK] is set to one and a Watchdog feed is performed, hardware prevents changes to the Watchdog clock divider, WDT1 Function Clock Divider (WDT1CLKDIV), register or WDT1 clock mux select, WDT1 Clock Selection (WDT1CLKSEL), register. MOD[LOCK] can be set once by software and is only cleared by any reset.

51.2 Overview

WWDT helps you reset or interrupt a microcontroller within a programmable time, if the microcontroller (or core) is stuck in an infinite loop or is executing an unintended code. If an application fails to reload or feed a watchdog (WDOG) timer within the predefined duration of time, it generates a watchdog reset (if enabled).

51.2.1 Block diagram

In the following WWDT block diagram, the synchronization logic (APB bus clock to WDCLK) is not shown. See the chip-specific WWDT information section or clocking chapter for more details.

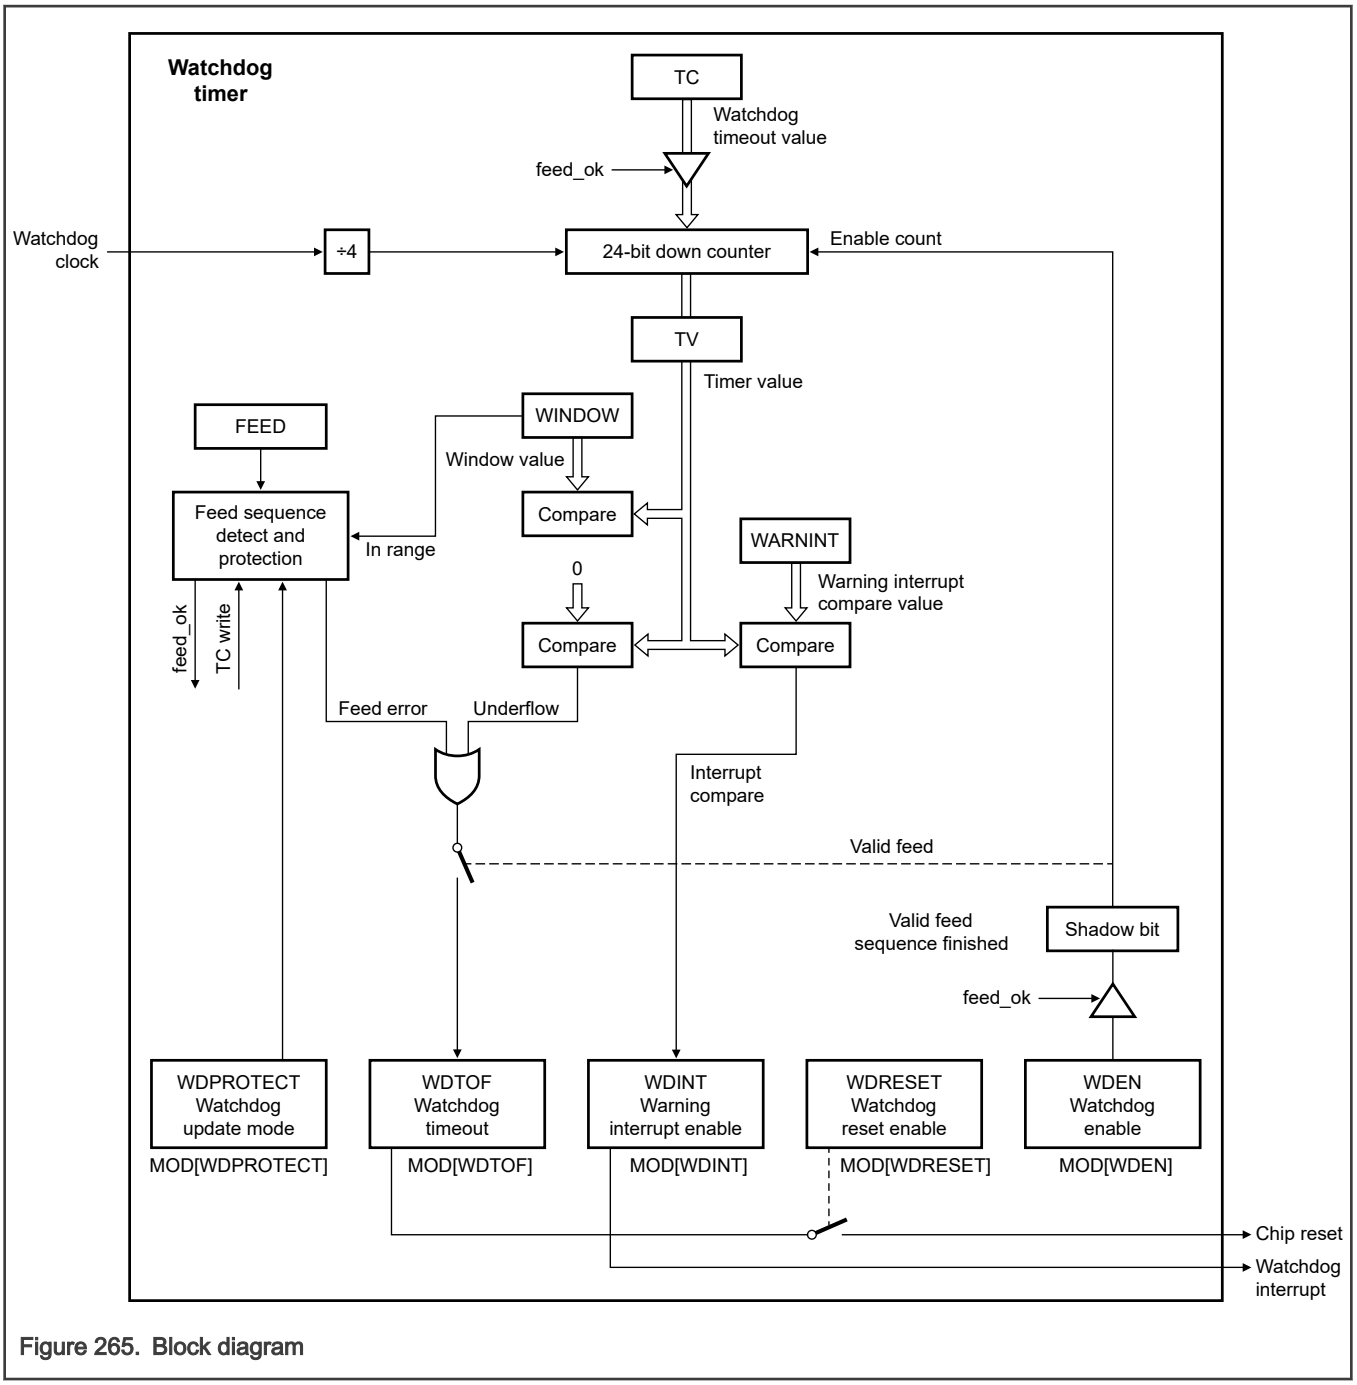


Figure 265. Block diagram

51.2.2 Features

- Can reset or interrupt the microcontroller within a programmable time
- Watchdog reset indication flag
- Clocking features:
  - Programmable 24-bit timer with an internal fixed (divided by 4) prescaler
  - Selectable time period in increments of four watchdog clocks: From 1024 watchdog clocks (T_{WDCLK} x 256 x 4) to over 67 million watchdog clocks (T_{WDCLK} x 2^{24} x 4)

  - Watchdog clock (WDCLK) source having a selectable frequency in the range of 6 kHz to 1.5 MHz (see the chip-specific information section and the Clocking chapter for detailed setting in this device)
- Can be configured to run in Low-Power mode (see the chip-specific information section and the Power Management chapter for detailed setting in this device)
- Other configurable features:
  - Windowed operation requiring a watchdog reload to occur between a programmable minimum and maximum timeout period
  - Generation of a warning interrupt at a programmable time before watchdog timeout
  - Protection of the watchdog reload value so that you can change it only after the warning interrupt time is reached

51.3 Functional description

When you program a watchdog window (a timing window), an early watchdog reload is also treated as a watchdog event, which prevents situations where a system failure may still reload the watchdog timer. For example, the application code could be stuck in an interrupt service that contains a watchdog reload (feed). You must set the timing window in a way that this situation causes an early watchdog timer reload, which generates a watchdog event, and then enables the system to recover from this situation.

WWDT consists of a fixed (divided by 4) prescaler and a 24-bit counter. The minimum value of the counter is FFh; if you write a value lower than FFh, the counter automatically loads with the value FFh.

- Minimum watchdog interval is (T_{WDCLK} X 256 X 4).
- Maximum watchdog interval is (T_{WDCLK} X 2^{24} X 4) in multiples of (T_{WDCLK} X 4).

51.3.1 Operating modes

This section describes all functional operating modes of the WWDT module: Disabled, Watchdog Interrupt, and Watchdog Reset.

Table 440. Watchdog operating modes selection

MOD[WDEN]	MOD[WDRESET]	Mode	Mode description
0	X (0 or 1)	Disabled	Debugs or operates without the watchdog running.
1	0	Watchdog Interrupt	Generates a watchdog warning interrupt but does not enable the watchdog reset. A watchdog counter equal to the value of WARNINT[WARNINT] sets MOD[WDINT] and generates a watchdog interrupt request.
1	1	Watchdog Reset	Enables both the watchdog interrupt and watchdog reset: • A watchdog counter equal to the value of WARNINT[WARNINT] sets MOD[WDINT] and generates a watchdog interrupt request. • A watchdog counter equal to 0 resets the microcontroller. • A watchdog feed before reaching the value of WINDOW[WINDOW] also causes a watchdog reset.

51.3.2 Example timing diagrams to show WWDT in operation

A feed is correct when both of the following conditions are true:

- A valid feed sequence completes, writing AAh followed by 55h to FEED[FEED].
- The value of TV[COUNT] is not greater than the value of WINDOW[WINDOW].

If either of these conditions is not true, a feed error occurs.

In the correct watchdog feed with Windowed mode enabled, the sequence of writing AAh followed by 55h occurs when the counter value (11FCh) is not greater than the value of WINDOW[WINDOW] (1200h). It is a correct feed (reload) event. After the correct feed event occurs, the watchdog counter reloads with the TC[COUNT] value (2000h).

In addition to the above two conditions, when MOD[WDPROTECT] = 1, the watchdog counter must not be greater than the value of WARNINT[WARNINT] for a correct feed to occur. See the following figure for a pictorial representation.

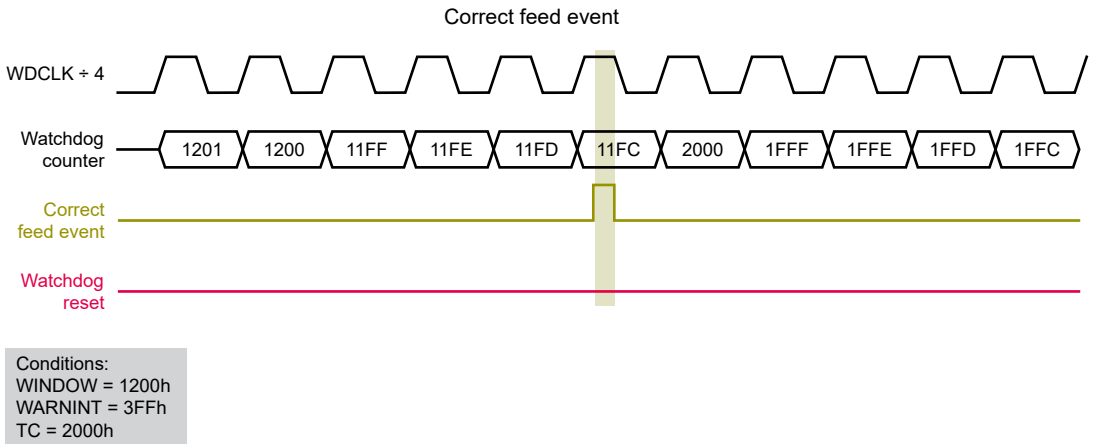

Figure 266. Correct watchdog feed with Windowed mode enabled

A correct feed sequence can only occur when the value of TV[COUNT] is not greater than the value of WINDOW[WINDOW] (1200h). Otherwise, a feed error occurs.

The following figure shows a reset trigger when you feed the watchdog too early.

An early feed event occurs if the feed sequence occurs when the watchdog counter value (1257h) is greater than the value of WINDOW[WINDOW] (1200h). This feed error can generate a reset if MOD[WDRESET] = 1.

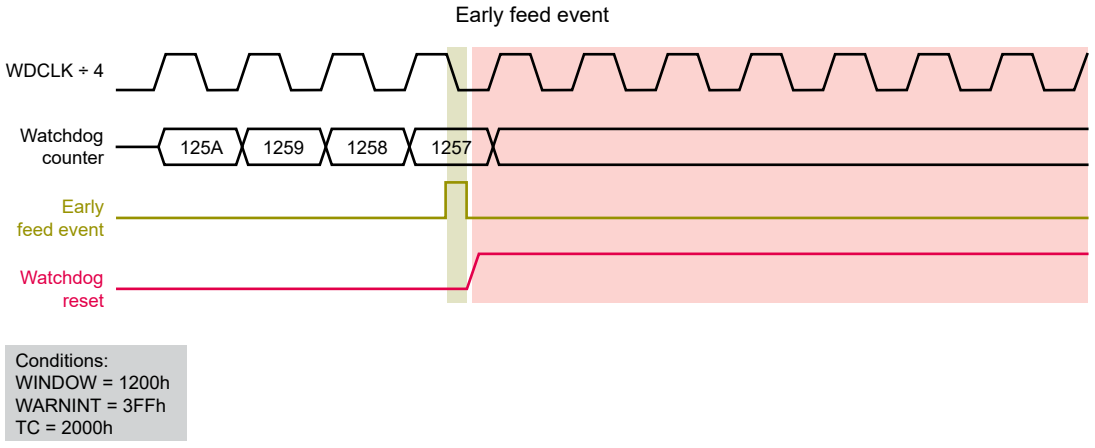

Figure 267. Early watchdog feed with Windowed mode enabled

The following figure shows WWDT generating a warning.

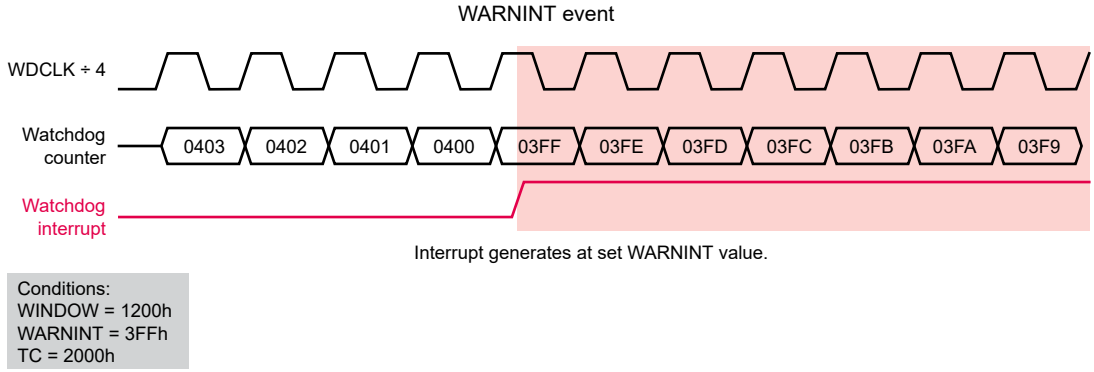

Figure 268. Watchdog warning interrupt

51.3.3 Clocking

WWDT uses two clocks: APB bus clock and WDCLK.

- The system clock derives the APB bus clock that is used for APB accesses to the watchdog registers.
- The watchdog oscillator derives WDCLK that is used for watchdog timer counting.

The synchronization logic between the two clock domains works as follows:

- When updating Mode (MOD) and Timer Constant (TC), the new value takes effect in three WDCLK cycles on the logic in the WDCLK clock domain.
- When the watchdog timer is counting on WDCLK, the synchronization logic first locks the value of the counter on WDCLK and then synchronizes it with the APB bus clock, so that the CPU can read Timer Value (TV).

NOTE

Because of the synchronization step, you must add a delay of three WDCLK clock cycles between the feed sequence and the time that you take to enable the functionality of MOD[WDPROTECT]. The length of the delay depends on the selected watchdog clock, WDCLK.

51.3.4 Using the WWDT lock

WWDT supports lock features to ensure continuous operation. These features prevent:

- The disabling of the WWDT clock source.
- The changing of the WWDT reload value.

51.3.4.1 Preventing the disabling of the WWDT clock source

If MOD[LOCK] = 1, the WWDT clock source is locked. You cannot disable the clock source when entering Sleep or Deep-Sleep modes. Therefore, enable the watchdog oscillator for each Power mode before writing 1 to MOD[LOCK].

51.3.4.2 Preventing the changing of the WWDT reload value

If MOD[WDPROTECT] = 1, then any attempt to change the value of TC[COUNT] with a feed sequence, before the watchdog counter value becomes less than the values of WARNINT[WARNINT] and WINDOW[WINDOW], sets MOD[WDTOF] and causes a watchdog reset.

Any type of reset disables the reload overwrite lock mechanism.

51.4 External signals

This module has no external signals.

51.5 Initialization

Perform the following steps to initialize WWDT:

1. Enable and configure the watchdog oscillator.
2. Set the watchdog timer constant reload value using TC[COUNT].
3. Set the watchdog timer operating mode using MOD[WDPROTECT].
4. Set a value for the watchdog window time using WINDOW[WINDOW], if the windowed operation is desired.
5. Set a value for the watchdog warning interrupt using WARNINT[WARNINT] and configure the system interrupt controller, if a warning interrupt is desired.
6. Enable the watchdog by writing AAh followed by 55h to FEED[FEED].

To prevent a watchdog event, you must feed or reload WWDT again before the watchdog counter reaches 0. If you set a value for the watchdog window time, then the feed or reload must also occur after the watchdog counter passes the value of WINDOW[WINDOW].

After you configure WWDT in a way that a watchdog event causes a reset (MOD[WDRESET] = 1), or when the counter reaches 0 (it causes a reset), then the microcontroller (or core) is also reset (loading the stack pointer and program counter from the vector table, just like the way it happens for an external reset).

51.6 Memory map and register definition

This section includes the WWDT module memory map and detailed descriptions of all registers.

51.6.1 WWDT register descriptions

51.6.1.1 WWDT memory map

WWDT0 base address: 4001_6000h

WWDT1 base address: 4001_7000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Mode (MOD)	32	RW	0000_0000h
4h	Timer Constant (TC)	32	RW	0000_00FFh
8h	Feed Sequence (FEED)	32	W	See section
Ch	Timer Value (TV)	32	R	0000_00FFh
14h	Warning Interrupt Compare Value (WARNINT)	32	RW	0000_0000h
18h	Window Compare Value (WINDOW)	32	RW	00FF_FFFFh

51.6.1.2 Mode (MOD)

Offset

Register	Offset
MOD	0h

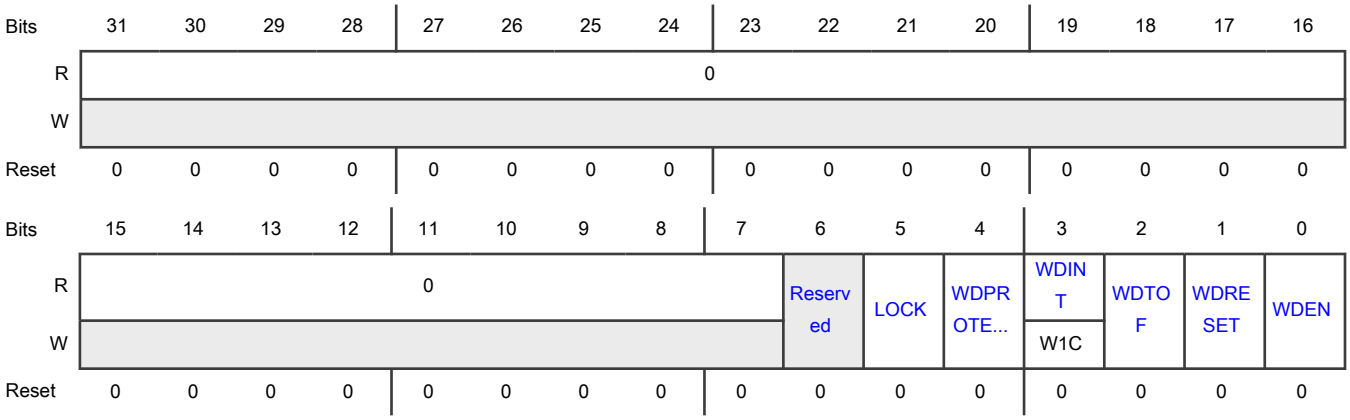
Function

Controls the operation of WWDT. You must perform a watchdog feed before any changes to this register take effect.

NOTE

After you write 1 to MOD[WDEN], MOD[WDPROTECT], or MOD[WDRESET], you can return those fields to 0 only with an external reset or a WWDT reset. Until those resets occur, writing 0 to the aforementioned fields has no effect.

Diagram



Fields

Field	Function
31-7 —	Reserved
6 —	Reserved
5 LOCK	Lock Prevents disabling or powering down of the watchdog oscillator after you write 1 to this field and perform a watchdog feed. You can write 1 to this field, which can become 0 only with a reset. 0b - No Lock 1b - Lock
4 WDPROTECT	Watchdog Update Mode Protects the value of TC[COUNT] from changing at any time. In Flexible mode (when this field is 0), you can change the value of TC[COUNT] at any time. In Threshold mode (when this field is 1), you can change the value of TC[COUNT] only after the counter is less than the individual values of WARNINT[WARNINT] and WINDOW[WINDOW]. Any attempt to change the value of TC[COUNT] with a feed sequence, before the watchdog counter value becomes less than the values of WARNINT[WARNINT] and WINDOW[WINDOW], sets MOD[WDTOF] and causes a watchdog reset. You can write 1 to this field, which can become 0 only with a reset (see the note in MOD register).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Flexible 1b - Threshold
3 WDINT	Warning Interrupt Flag Sets the flag when the timer is at or below the value defined in WARNINT[WARNINT]. Note that you cannot clear this flag while the value of WARNINT[WARNINT] is equal to the value of TV[COUNT]. This can occur if the value of both WARNINT[WARNINT] and MOD[WDRESET] is 0 when TV[COUNT] decrements to 0. When you configure WWDT to generate a warning interrupt, the interrupt occurs when the counter is no longer greater than the value defined by WARNINT[WARNINT]. If a feed sequence occurs when the watchdog counter value is greater than the value of WINDOW[WINDOW], this flag is set. Any reset clears this flag. 0b - No flag 1b - Flag
2 WDTOF	Watchdog Timeout Flag The bit could be set if: • Watchdog timer timeout has occurred • Feed error has occurred You must clear this flag by writing 0 to it. An external reset or POR clears this flag too. 0b - Watchdog event has not occurred. 1b - Watchdog event has occurred (causes a chip reset if WDRESET = 1).
1 WDRESET	Watchdog Reset Enable Allows a watchdog timeout to cause a chip reset, if this field = 1. After you write 1 to this field, you cannot write 0 to it (see the note in MOD register). 0b - Interrupt 1b - Reset
0 WDEN	Watchdog Enable Enables or disables the watchdog timer. After writing 1 to this field, perform a watchdog feed (reload) to enable the watchdog timer. After you write 1 to this field, you cannot write 0 to it (see the note in MOD register). 0b - Timer stopped 1b - Timer running

51.6.1.3 Timer Constant (TC)

Offset

Register	Offset
TC	4h

Function

Specifies the desired timeout value. Transferring the value of this register into the watchdog counter requires a feed sequence. The register resets to 00_00FFh. Writing a value below FFh causes 00_00FFh to load into the register. Therefore, the minimum timeout interval is T_{WDCLK} X 256 X 4.

If MOD[WDPROTECT] = 1, then any attempt to change the value of this register with a feed sequence, before the watchdog counter value becomes less than the individual values of WARNINT[WARNINT] and WINDOW[WINDOW], sets MOD[WDTOF] and causes a watchdog reset.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 —	Reserved
23-0 COUNT	Watchdog Timeout Value Specifies the desired timeout value for WWDT.

51.6.1.4 Feed Sequence (FEED)

Offset

Register	Offset
FEED	8h

Function

Reloads the watchdog timer with the TC[COUNT] value, if you write AAh followed by 55h to FEED[FEED]. This operation also starts WWDT, if the watchdog timer is enabled by writing 1 to MOD[WDEN].

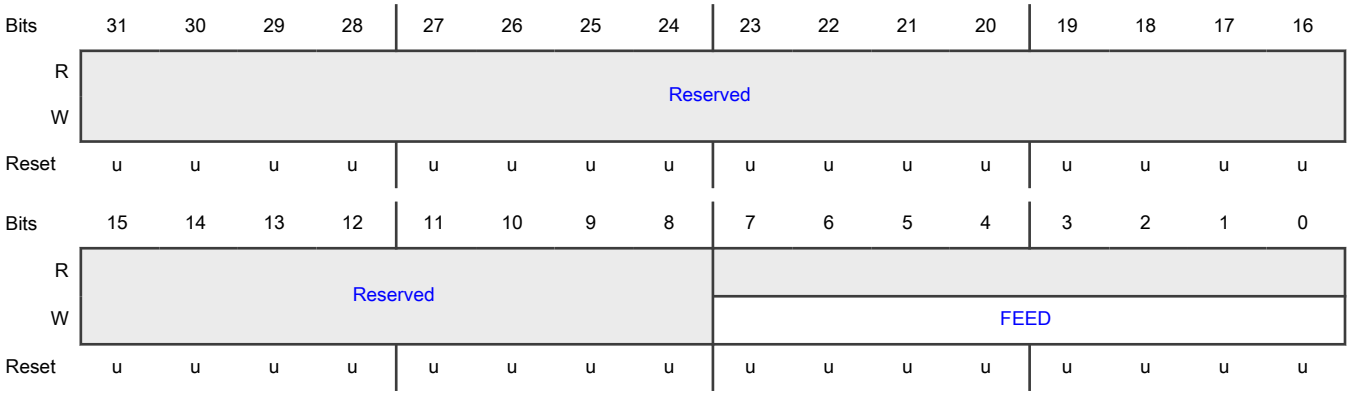
However, writing 1 to MOD[WDEN] is not sufficient to enable WWDT. Before the watchdog can generate a reset, MOD[WDEN] must be 1, followed by a valid feed sequence that completes itself. Until then, the watchdog ignores feed errors.

After writing AAh to FEED[FEED], access to any watchdog register other than writing 55h to FEED[FEED] causes an immediate reset or interrupt when WWDT is enabled and sets MOD[WDTOF]. An incorrect access to a watchdog register during a feed sequence generates the reset during the second APB bus clock.

To avoid an unintended interrupt, it is a good practice to disable interrupts around a feed sequence. Disable interrupts if they may result in rescheduling processor control away from the current task in the middle of the feed, and then lead to some other access to WWDT before control returns to the interrupted task.

If the value of WINDOW[WINDOW] is less than the default value, it may limit the time for which a watchdog feed is allowed.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 FEED	Feed Value Specifies feed value. The value must be AAh followed by 55h.

51.6.1.5 Timer Value (TV)

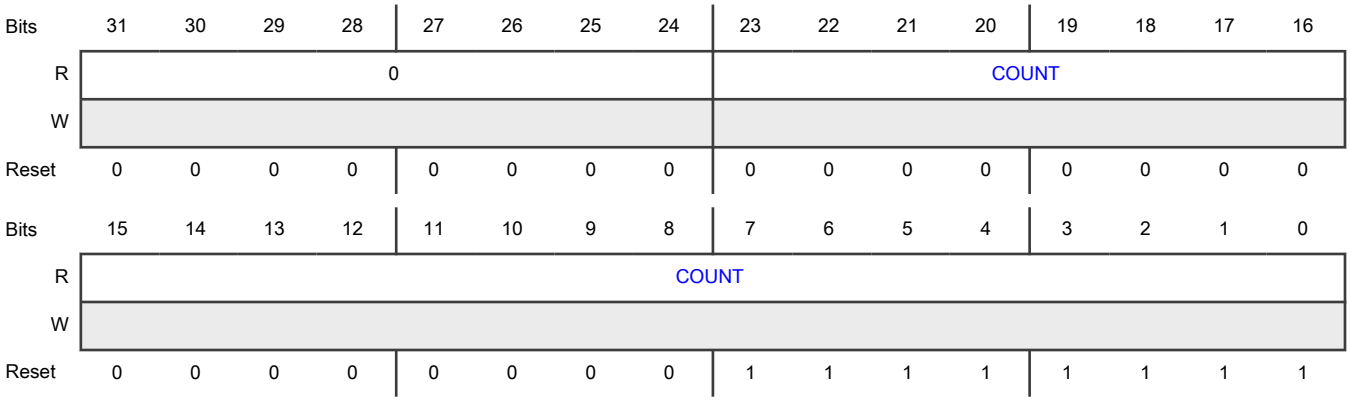
Offset

Register	Offset
TV	Ch

Function

Contains the current value of the WWDT counter. When the core (or CPU) reads this register, the value of this register is older than the actual value of the timer. Reading the timer using the lock and synchronization procedure takes up to six WDCLK cycles plus six APB bus clock cycles.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 COUNT	Counter Timer Value Specifies the current value of the watchdog timer.

51.6.1.6 Warning Interrupt Compare Value (WARNINT)

Offset

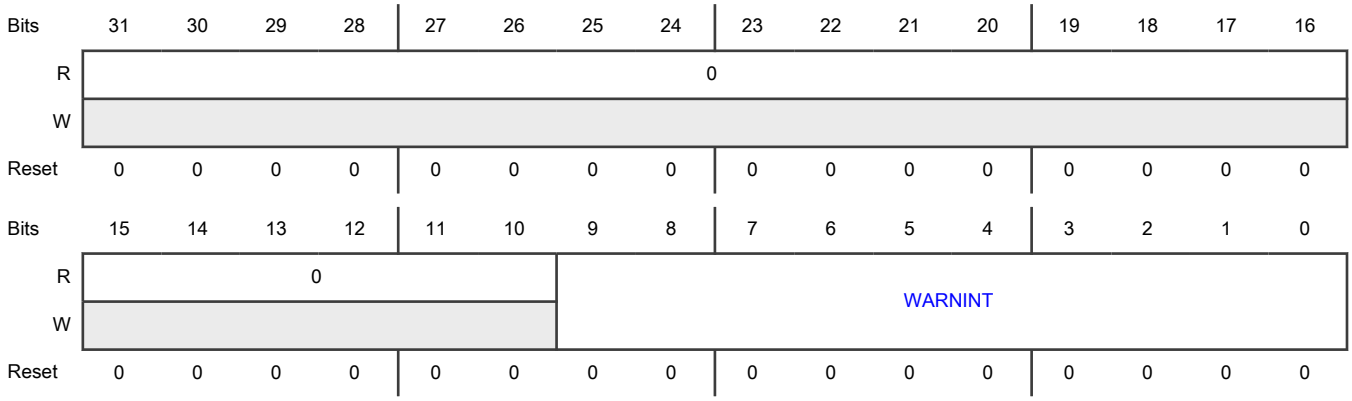
Register	Offset
WARNINT	14h

Function

Determines the value of TV[COUNT] that generates a watchdog interrupt. When this value is less than or equal to the value defined by WARNINT, an interrupt generates after the subsequent WDCLK.

A match of the WWDT counter to WARNINT occurs when the lower 10 bits of the timer counter have the same value as the lower 10 bits of WARNINT, and the remaining upper bits of the counter are all 0. This gives a maximum time of 1023 watchdog timer counts (4096 watchdog clocks) for the interrupt to occur before a watchdog event. If WARNINT is 0, then the interrupt occurs at the same time as the watchdog event.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-0 WARNINT	Watchdog Warning Interrupt Compare Value Specifies a timer value that generates a warning interrupt.

51.6.1.7 Window Compare Value (WINDOW)

Offset

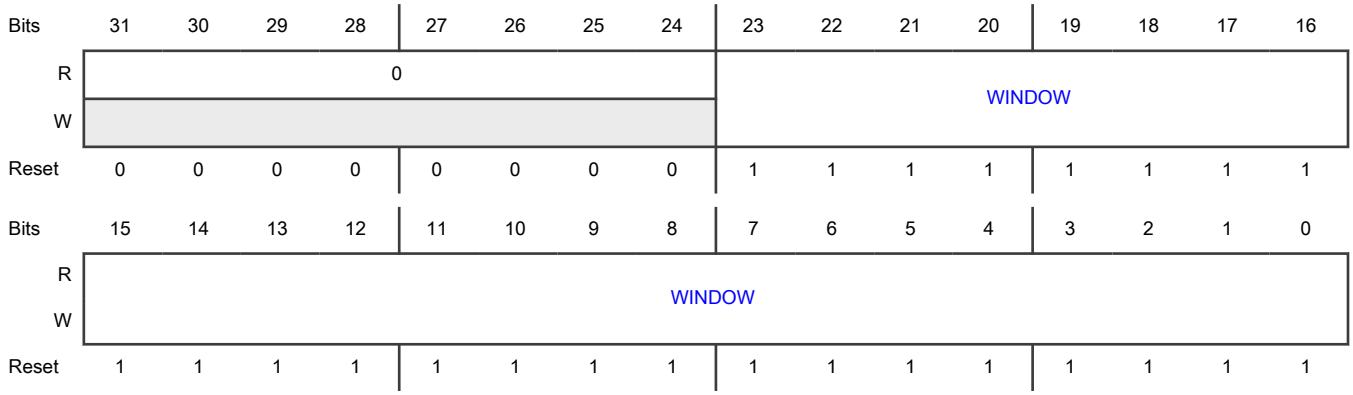
Register	Offset
WINDOW	18h

Function

Determines the highest timer value (TV[COUNT]) allowed during a watchdog feed. If a feed sequence occurs when the value of TV[COUNT] is greater than the value in WINDOW[WINDOW], a watchdog event occurs.

WINDOW[WINDOW] resets to the maximum value of TV[COUNT], where windowing is not in effect.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 WINDOW	Watchdog Window Value Specifies the highest timer value in which a watchdog feed can occur.

Chapter 52
Micro-Tick Timer (UTICK)

52.1 Chip-specific UTICK information

Table 441. Reference links to related information

Topic	Related module	Reference
Full description	UTICK	UTICK

Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

52.1.1 Module instances

This device has one instance of the UTICK module, UTICK0.

52.1.2 UTICK clock

Enable the Watchdog oscillator that provides the Micro-Tick Timer clock via UTICK field in AHB Clock Control 1 AHBCLKCTRL1[UTICK] register.

See UTICK clocking.

52.2 Overview

UTICK is a 31-bit timer that counts down to 0 and then generates an interrupt. Thus, it provides a fixed time interval between interrupts. This is a simple, ultra-low-power timer that can run and wake up the chip from Low-power mode. See chip specific information for low power modes UTICK can wakeup.

52.2.1 Block diagram

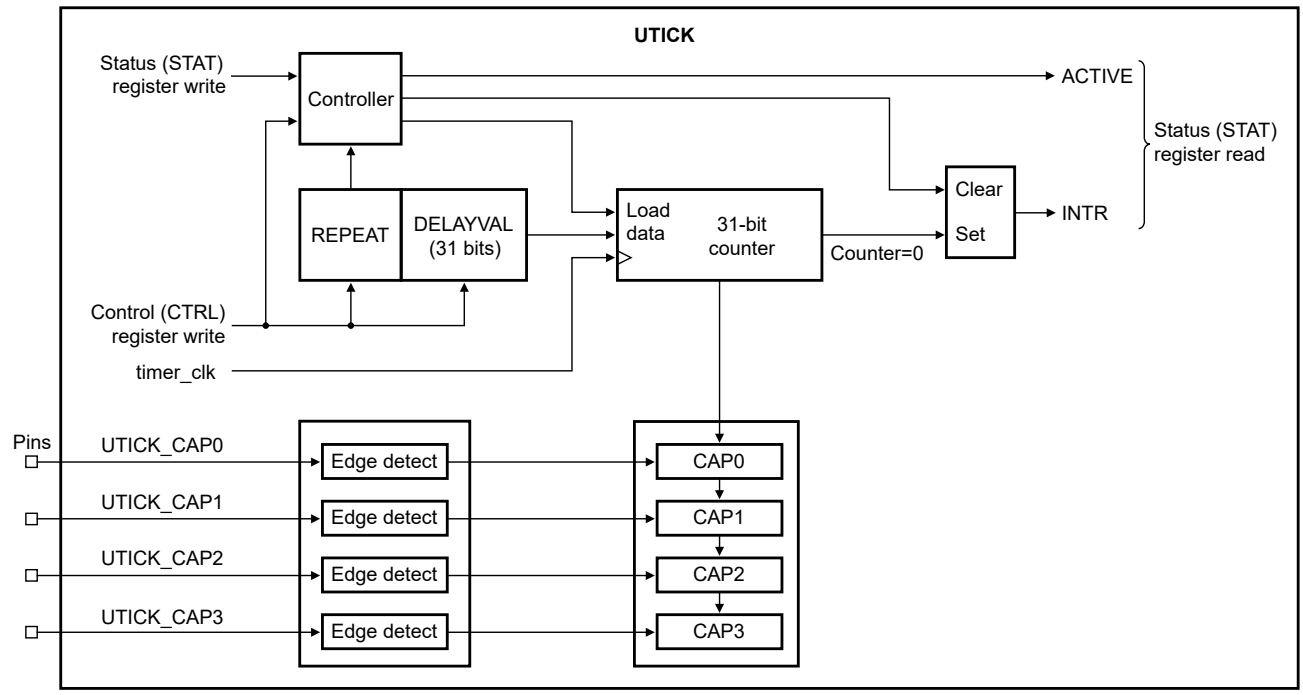

Figure 269. Block diagram

52.2.2 Features

- Wakes up the chip from Low-power mode.
- Starts with a nonzero value written to CTRL[DELAYVAL].
- Operates using interrupt or software polling mode.
- Includes Capture (CAP0 - CAP3) registers that use external pin transitions as a trigger.

52.3 Functional description

52.3.1 Operations

Perform the following procedure before using UTICK:

1. Configure CTRL[REPEAT] to either perform a one-time delay or continuous delay.
2. Configure CTRL[DELAYVAL] to specify the delay time value in terms of the timer clock.
3. Configure CFG[CAPEN*n*] to decide the number of events to capture (the maximum is four).
4. Configure CFG[CAPPOL*n*] to capture the polarity (whether to capture on a positive or negative edge of a signal).

52.3.2 Clocking

The UTICK clock is selectable from the following clock inputs:

Table 442. Clocking

Clock	Description
Global functional clock (timer_clk)	This clock is supposed to be on during normal operation. This clock is treated as asynchronous to pclk. **NOTE** See the Chip specific section for more details on UTICK clock.
System bus clock (pclk)	This clock is used only for register reads and writes.

52.3.3 Interrupts

The interrupt is generated when the tick_count reaches 1h so that on the next rising edge of timer_clk, it doesn't trigger again automatically. Its associated status field is STAT[INTR].

52.4 External signals

Signal	I/O	Description
UTICK_CAP0, UTICK_CAP1, UTICK_CAP2, UTICK_CAP3	I	Capture inputs. Configure the selected transition on a capture pin to load Capture (CAP0 - CAP3) with the counter value.

52.5 Initialization

To initialize UTICK:

1. Enable the clock to the UTICK register interface.
2. Enable UTICK interrupts for waking up from Low-power mode, configure Control (CTRL) register.
3. Configure Capture Configuration (CFG) register to enable UTICK capture functions and selects the polarity of capture triggers.
4. Enable the oscillator that provides the UTICK clock, after writing values corresponding registers UTICK timer works normally.

52.6 UTICK register descriptions

52.6.1 UTICK memory map

UTICK0 base address: 4001_2000h

Offset	Register	Width (In bits)	Access	Reset value

53.1.1 Module instances

This device has one instance of the OSTIMER module, OSTIMER0.

53.2 Overview

OSTIMER includes a shared 42-bit timer and separate 42-bit match and capture functions for the Cortex-M33 core.

53.2.1 Block diagram

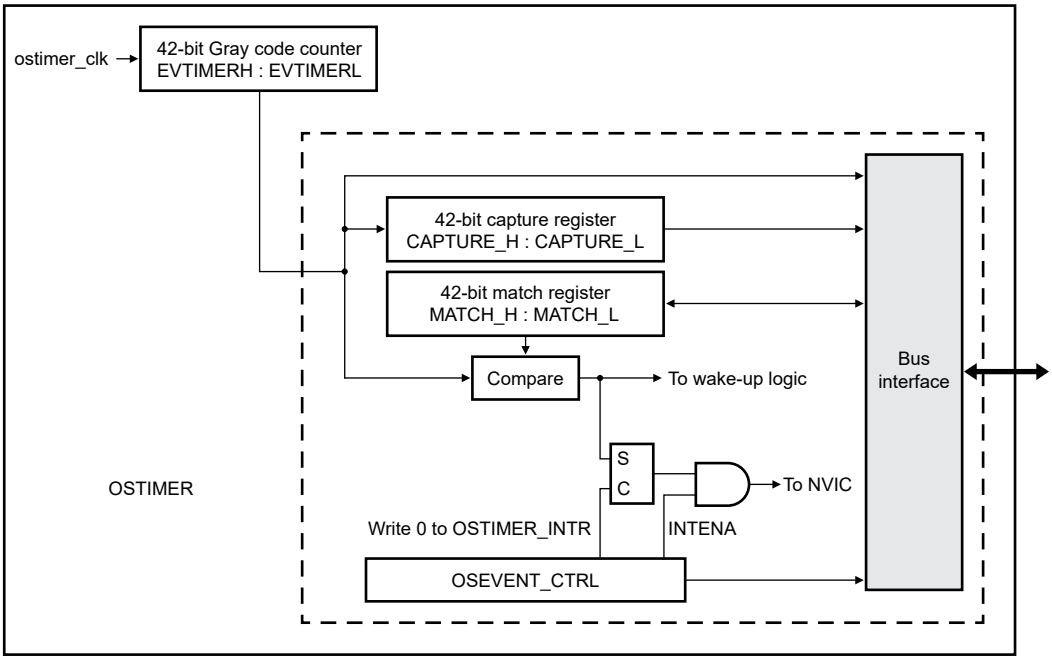

Figure 270. Block diagram

53.2.2 Features

- Provides a 42-bit Gray code counter (known as central EVTimer). Using Gray code means that the timer can run at a frequency unrelated to any CPU clock and can still be read by a CPU without a synchronization delay. Gray code is a reflected binary code that changes in a single-bit position for each increment.
- Supports separate functions for each CPU:
  - A capture register can copy the main counter value when triggered by a CPU request.
  - A match register can be compared to the main counter and can optionally generate an interrupt or wake-up event.

53.3 Functional description

The following sections describe the functional details of this module.

53.3.1 Shared event or timestamp timer

The 42-bit shared EVTimer initializes after chip power-up and then counts up continuously. The typical clock for this timer is the 1 MHz low-power oscillator.

This timer is implemented as a Gray code counter that enables the counter to be read asynchronously by any of the processing domains or captured by a capture register running on an asynchronous clock. The output of this shared EVTimer is connected to the processor-specific submodules.

53.3.2 CPU-specific match, capture, and interrupt generation

The submodules associated with each CPU include:

- A separate bus interface.
- 42 bits of capture values, available in CAPTURE_L and CAPTURE_H.
- 42 bits of match values, available in MATCH_H and MATCH_L.
- A control register, which includes an interrupt request flag and an interrupt enable field.

Capture registers	42 bits of capture values are available in CAPTURE_L and CAPTURE_H for each CPU. When the CPU issues a capture command, capture registers store the current value of the central EVTimer.
Match registers and interrupt request	42 bits of match values are available in MATCH_H and MATCH_L for each bus interface. The EVTimer output is compared against this combined value for interrupt or wake-up generation. A match to this register pair sets OSEVENT_CTRL[OSTIMER_INTRFLAG], which you can enable to generate an interrupt or wake-up request. You must write values to the match registers in Gray code. OSEVENT_CTRL[MATCH_WR_RDY] must be 0 before you write to the match registers. When you write a new value to the match registers, you must write to MATCH_L before the write to MATCH_H.

53.3.3 Clocking

The OSTIMER uses three clock signals: hclk, capture_clk, and ostimer_clk.

1. Hclk is the IPS interface clock for both the Arm and DSP sub-module, being used in all the registers and write/read operations.
2. Ostimer_clk is the counter clock, being used in the timer itself and in the intr_wakeup signals. It is expected to be running in a low frequency (~1MHz).
3. capture_clk is the Arm and DSP clock, it is used to register the capture signal “capture_load”.

53.3.4 Reset

For OSTIMER, the reset function is more complicated as compared to most other functions.

- Only the POR and software reset can reset the shared EVTimer. "Software reset" refers to a complete reset of the module.
- The capture and match registers are reset by a system reset. "System reset" refers to a reset from the RESET*n* pin, SYSRESETREQ from the CPU, a POR, or any other internal low-voltage resets.
- The control register (OSEVENT_CTL) is reset by the system reset or by software reset. However, the MATCH_WR_RDY bit can only be reset by system reset.

The following table shows a list of resets for OSTIMER registers.

Table 444. OSTIMER registers and their corresponding resets

Registers	POR	Software reset
EVTIMERL and EVTIMERH	Yes	Yes
CAPTURE_L and CAPTURE_H	Yes	No
OSEVENT_CTRL	Yes	Yes

53.3.5 Interrupts

If the interrupt request is enabled (i.e., OSEVENT_CTRL[OSTIMER_INTENA]= 1), the OSTIMER will generate interrupt when the central 42-bit EVTimer and the value programmed in MATCH_L and MATCH_H matches.

No interrupt generates if the interrupt request is disabled (i.e., OSEVENT_CTRL[OSTIMER_INTENA]= 0).

53.4 External signals

This module has no external signals.

53.5 Initialization

Perform this procedure to initialize OSTIMER:

1. Enable the OSTIMER clock. This enables the register interface and the peripheral function clock.
2. Select a clock source for OSTIMER.
3. Clear the OSTIMER peripheral reset.
4. Enable the interrupt that OSTIMER provides to the interrupt controller (set OSEVENT_CTRL[OSTIMER_INTRFLAG]= 1). This allows the chip to wake up from Deep Sleep mode.

53.6 Memory map and register definition

This section includes the module's memory map and detailed descriptions of all registers.

53.6.1 OSTIMER register descriptions

53.6.1.1 OSTIMER memory map

OSTIMER0 base address: 4004_9000h

Offset	Register	Width (In bits)	Access	Reset value
0h	EVTIMER Low (EVTIMERL)	32	R	0000_0000h
4h	EVTIMER High (EVTIMERH)	32	R	0000_0000h
8h	Local Capture Low for CPU (CAPTURE_L)	32	R	0000_0000h
Ch	Local Capture High for CPU (CAPTURE_H)	32	R	0000_0000h

14h	Local Match High for CPU (MATCH_H)	32	RW	FFFF_FFFFh
1Ch	OSTIMER Control for CPU (OSEVENT_CTRL)	32	RW	0000_0000h

53.6.1.2 EVTIMER Low (EVTIMERL)

Offset

Register	Offset
EVTIMERL	0h

Function

Contains the immediate value of the central EVTimer. This is a Gray encoded counter register that is not synchronized with the bus clock.

Because two 32-bit reads are required to retrieve the entire counter value, it is possible for the counter to roll over between the reads of EVTIMERL and EVTIMERH. Gray encoding ensures that even if this roll over occurs, the value read represents either the counter value immediately preceding or immediately following the rollover, if the bus clock rate is at least twice the module's clock rate (nominally 1 MHz), or if the bus is clocked by the same 1 MHz LP oscillator that provides the clock to the module.

Diagram

Fields

Field	Function
31-0 EVTIMER_COUNT_VALUE	EVTimer Count Value Specifies the current value of the lower 32 bits of the central 42-bit EVTimer when you read this register. **NOTE** Only one physical EVTimer exists and is readable from all domains.

53.6.1.3 EVTIMER High (EVTIMERH)

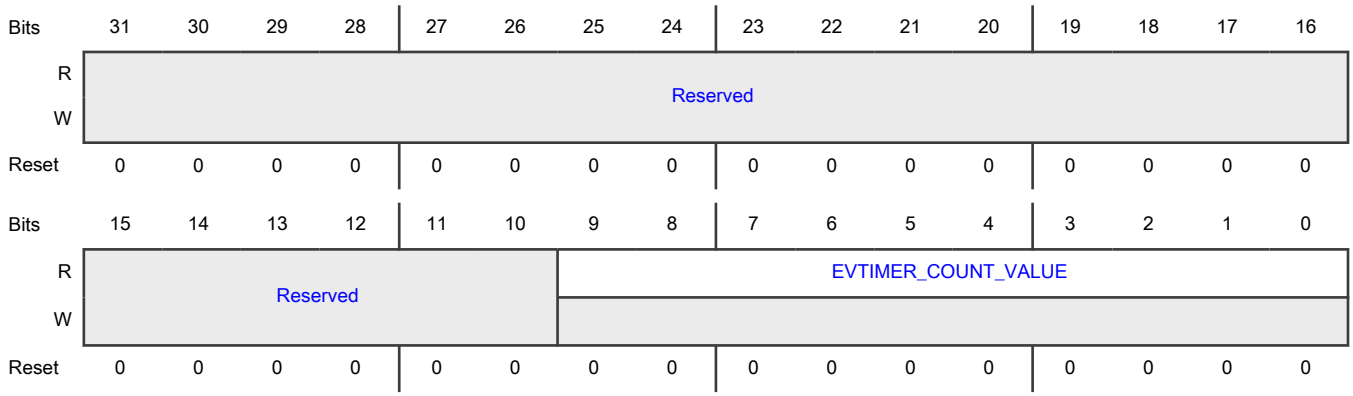
Offset

Register	Offset
EVTIMERH	4h

Function

Contains the higher value of the central EVTimer. This register resets only after POR or a software reset.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-0 EVTIMER_COUNT_VALUE	EVTimer Count Value Specifies the current value of the upper 10 bits of the central 42-bit EVTimer when you read this register. **NOTE** Only one physical EVTimer exists and is readable from all domains.

53.6.1.4 Local Capture Low for CPU (CAPTURE_L)

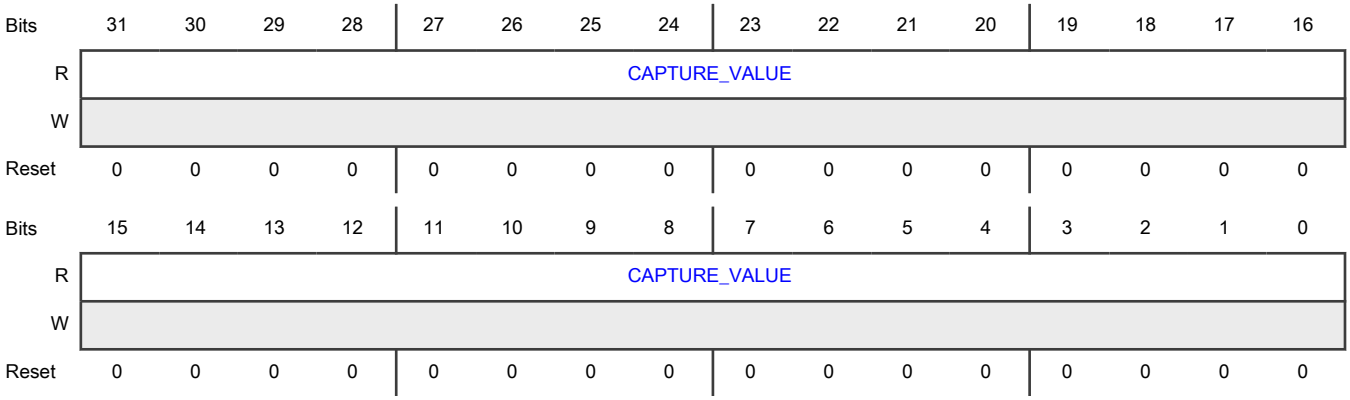
Offset

Register	Offset
CAPTURE_L	8h

Function

Contains the value of the central EVTimer when captured by the CPU. This register is Gray encoded to match EVTimer. You must not execute a new capture command between reading CAPTURE_L and CAPTURE_H, to avoid retrieving incoherent results.

Diagram



Fields

Field	Function
31-0 CAPTURE_VALUE	EVTimer Capture Value Specifies the value of the lower 32 bits of the central 42-bit EVTimer when you read this register, at the time that the CPU generated the last capture signal. A separate pair of CAPTURE_L and CAPTURE_H is implemented for each CPU. Each CPU reads its own capture value at the same pair of addresses.

53.6.1.5 Local Capture High for CPU (CAPTURE_H)

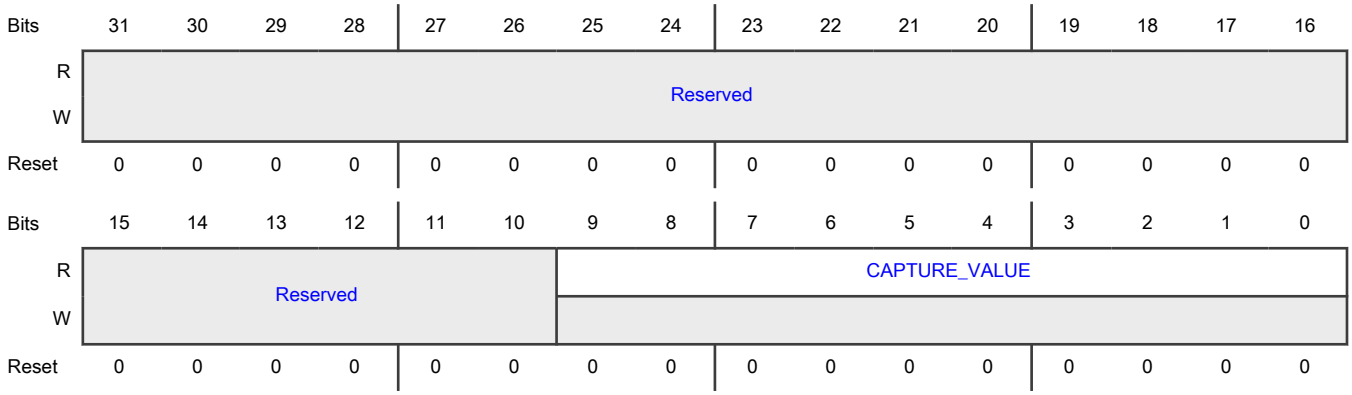
Offset

Register	Offset
CAPTURE_H	Ch

Function

Contains the value of the central EVTimer when captured by the CPU. This register is Gray encoded to match EVTimer. You must not execute a new capture command between reading CAPTURE_L and CAPTURE_H, to avoid retrieving incoherent results.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-0 CAPTURE_VALUE	EVTimer Capture Value Specifies the value of the upper 10 bits of the central 42-bit EVTimer when you read this register, at the time the CPU generated the last capture signal (using CMSIS C function "__SEV();").

53.6.1.6 Local Match Low for CPU (MATCH_L)

Offset

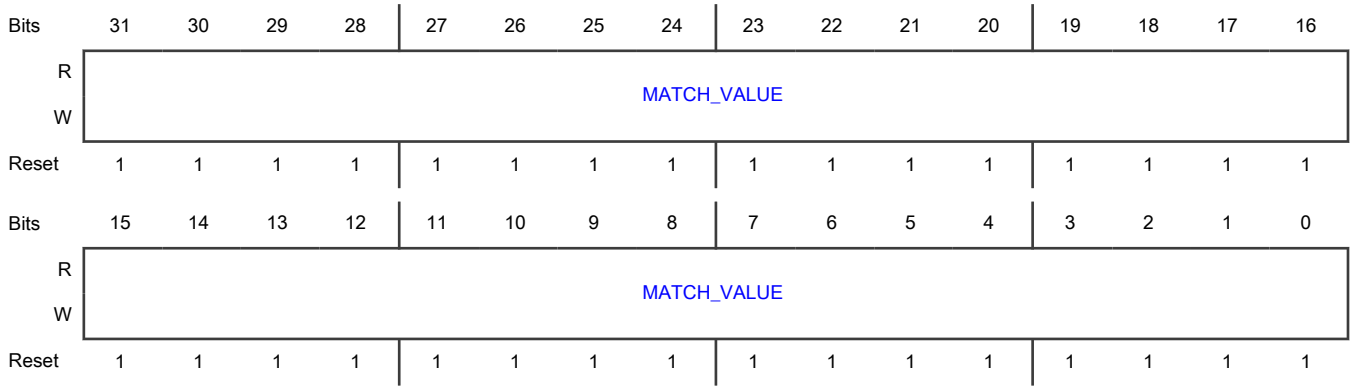
Register	Offset
MATCH_L	10h

Function

Compares the match value with the central EVTimer value. This register is Gray encoded to match EVTimer. The value in this pair of registers is stable, so there is no need for multiple reads. When writing to the match register pair, you must write to MATCH_L first, followed by the write to MATCH_H.

You must not initiate a second write to the match register pair until the first write is complete (which is a minimum of three bus clocks followed by a write to MATCH_H). OSEVENT_CTRL[MATCH_WR_RDY] indicates when it is safe to reload the match registers. You do not need to read OSEVENT_CTRL[MATCH_WR_RDY] if an interrupt has already occurred because of the previous match value, or the required time period has elapsed.

Diagram



Fields

Field	Function
31-0 MATCH_VALUE	EVTimer Match Value Compares the value (lower 32 bits) of the MATCH_L and MATCH_H register pair with the central EVTimer value. If both the values match, the CPU generates an interrupt request if the interrupt is enabled. A separate pair of MATCH_L and MATCH_H is implemented for each CPU reading its own local value at the same pair of addresses.

53.6.1.7 Local Match High for CPU (MATCH_H)

Offset

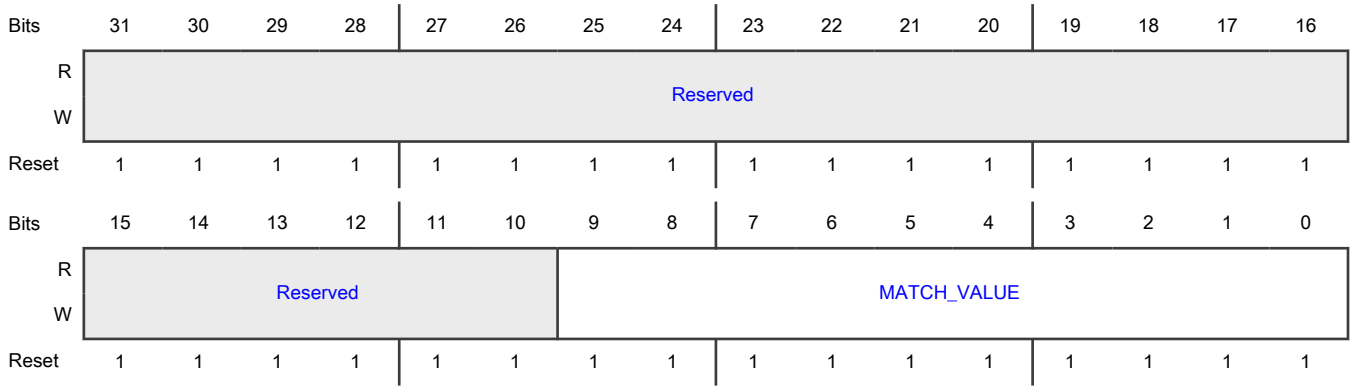
Register	Offset
MATCH_H	14h

Function

Compares the match value with the central EVTimer value. This register is Gray encoded to match EVTimer. The value in this pair of registers is stable, so there is no need for multiple reads. When writing to the match register pair, you must write to MATCH_L first, followed by the write to MATCH_H.

You must not initiate a second write to the match register pair until the first write is complete (which is a minimum of three bus clocks followed by a write to MATCH_H). OSEVENT_CTRL[MATCH_WR_RDY] indicates when it is safe to reload the match registers. You do not need to read OSEVENT_CTRL[MATCH_WR_RDY] if an interrupt has already occurred because of the previous match value, or the required time period has elapsed.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-0 MATCH_VALUE	EVTimer Match Value Compares the value (upper 10 bits) of the MATCH_L and MATCH_H register pair with the central EVTimer value. If both the values match, the CPU generates an interrupt request if the interrupt is enabled.

53.6.1.8 OSTIMER Control for CPU (OSEVENT_CTRL)

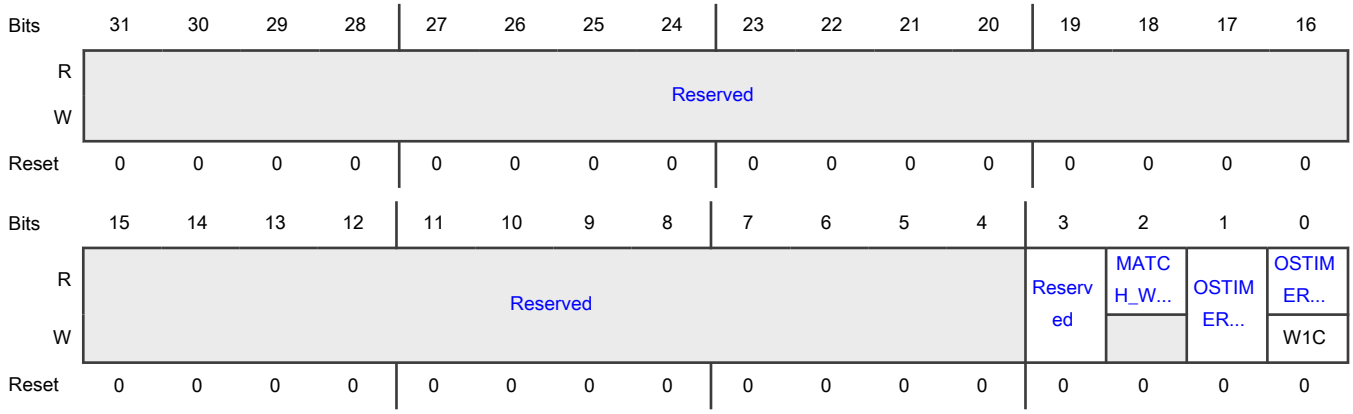
Offset

Register	Offset
OSEVENT_CTRL	1Ch

Function

Provides the interrupt flag and interrupt enable signals for each CPU. A separate OSEVENT_CTRL register is implemented for each CPU. Each CPU reads its own local value at the same address.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 —	Reserved
2 MATCH_WR_RDY	EVTimer Match Write Ready Specifies that when this field is low, it is safe to reload (write) to the match registers. In typical applications, it is not necessary to read this field. The 42-bit match register value is transferred from a pair of shadow registers to the active match registers after you write to MATCH_H. You must not initiate a second write to MATCH_L and MATCH_H until after this transfer completes. This field becomes 0 after the transfer completes. It is not necessary to read this status field, if an interrupt has already occurred because of the first match value, or if it is certain (via some other means) that the required period of time (3 bus clocks) has elapsed.
1 OSTIMER_INTENA	Interrupt or Wake-Up Request This bit is to enable/disable interrupt request. If the value is 1, then this field asserts an interrupt or wake-up request to the domain processor. Otherwise, the interrupt or wake-up requests are blocked. 0b - Interrupts blocked 1b - Interrupts enabled
0 OSTIMER_INTRFLAG	Interrupt Flag Sets an interrupt flag when a match occurs between the central 42-bit EVTimer and the value programmed in the MATCH_L and MATCH_H register pair for the associated CPU. Writes to clear this field are asynchronous. You must write 1 to this field before writing a new match value into MATCH_L and MATCH_H.

Enhanced Flex Pulse Width Modulator (PWM)

54.1 Chip-specific PWM information

Table 445. Reference links to related information

Topic	Related module	Reference
Full description	PWM	PWM
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing
Input multiplexing	INPUTMUX	See FlexPWMn_SMn_EXTAn registers in INPUTMUX

NOTE

PWM uses system_clk.

54.1.1 Module instances

This device has two instances of the PWM module, PWM0 and PWM1. Neither instance of the module supports the NanoEdge placement feature. Fine edge control is simulated by a dithering process.

54.1.2 PWM pins and signals information

In this device, PWMn_EXTB input is not used; only PWMn_EXTA input is used.

54.1.3 Reset value of Fault Status Register (FSTS0)

The reset value of FST0 register on this device is 0x0F0F.

54.2 Overview

The Pulse Width Modulator (PWM) module contains PWM submodules, each of which can be used to control a single half-bridge power stage. Fault channel support is provided.

This module generates various switching patterns, including highly sophisticated waveforms. It is ideal for controlling different Switched Mode Power Supplies (SMPS) topologies.

54.2.1 Block diagram

The following figure shows the PWM block diagram.

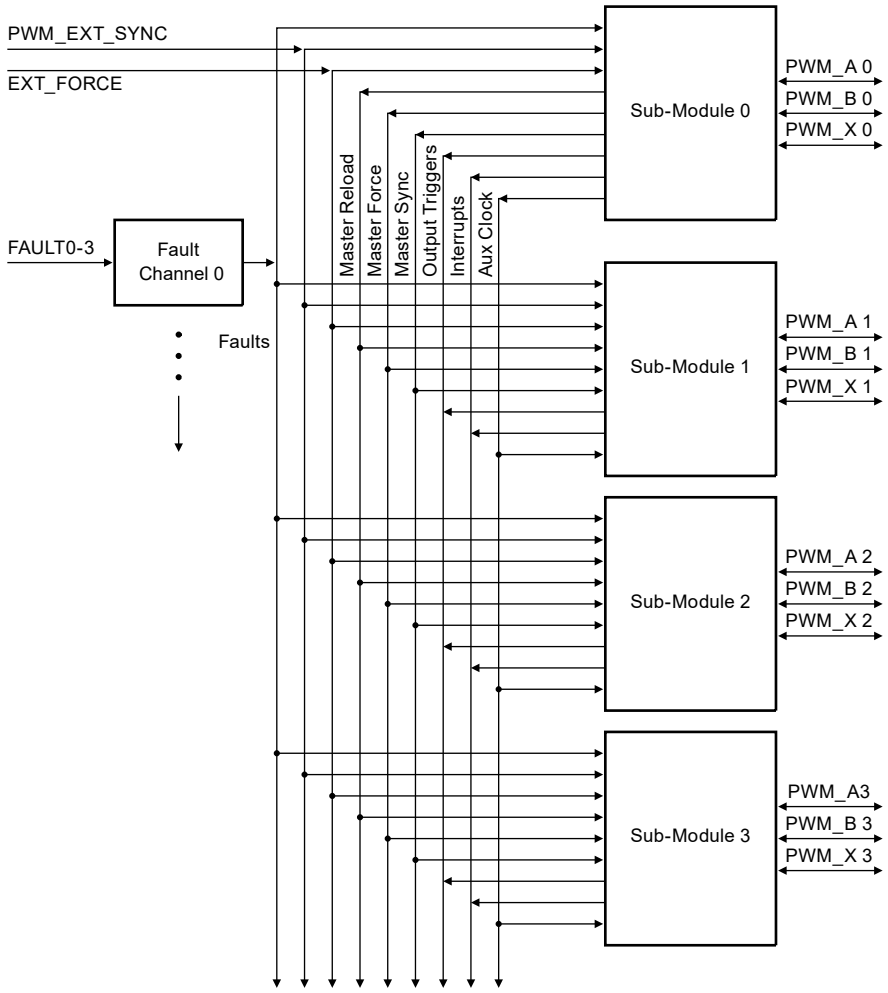

Figure 271. PWM block diagram

54.2.2 Features

Following are the features of PWM:

- 16-bit resolution for center, edge-aligned, and asymmetrical PWMs
- Dithering to simulate enhanced resolution when fine edge placement is not available
- PWM outputs that can operate as complementary pairs or independent channels
- Ability to accept signed numbers for PWM generation
- Independent control of both edges of each PWM output
- Support for synchronization to external hardware or other PWM
- Double buffered PWM registers
  - Integral reload rates from 1 to 16
  - Half cycle reload capability
- Multiple output trigger events can be generated per PWM cycle via hardware
- Support for double switching PWM outputs
- Fault inputs can be assigned to control multiple PWM outputs

- Programmable filters for fault inputs
- Independently programmable PWM output polarity
- Independent top and bottom deadtime insertion
- Each complementary pair can operate with its own PWM frequency and deadtime values
- Individual software control for each PWM output
- All outputs can be programmed to change simultaneously via a FORCE_OUT event
- PWM_X pin can optionally output a third PWM signal from each submodule
- Channels not used for PWM generation can be used for buffered output compare functions and for input capture functions
- Enhanced dual edge capture functionality

54.3 Functional description

54.3.1 PWM submodule

The following figure shows the PWM Submodule Block Diagram.

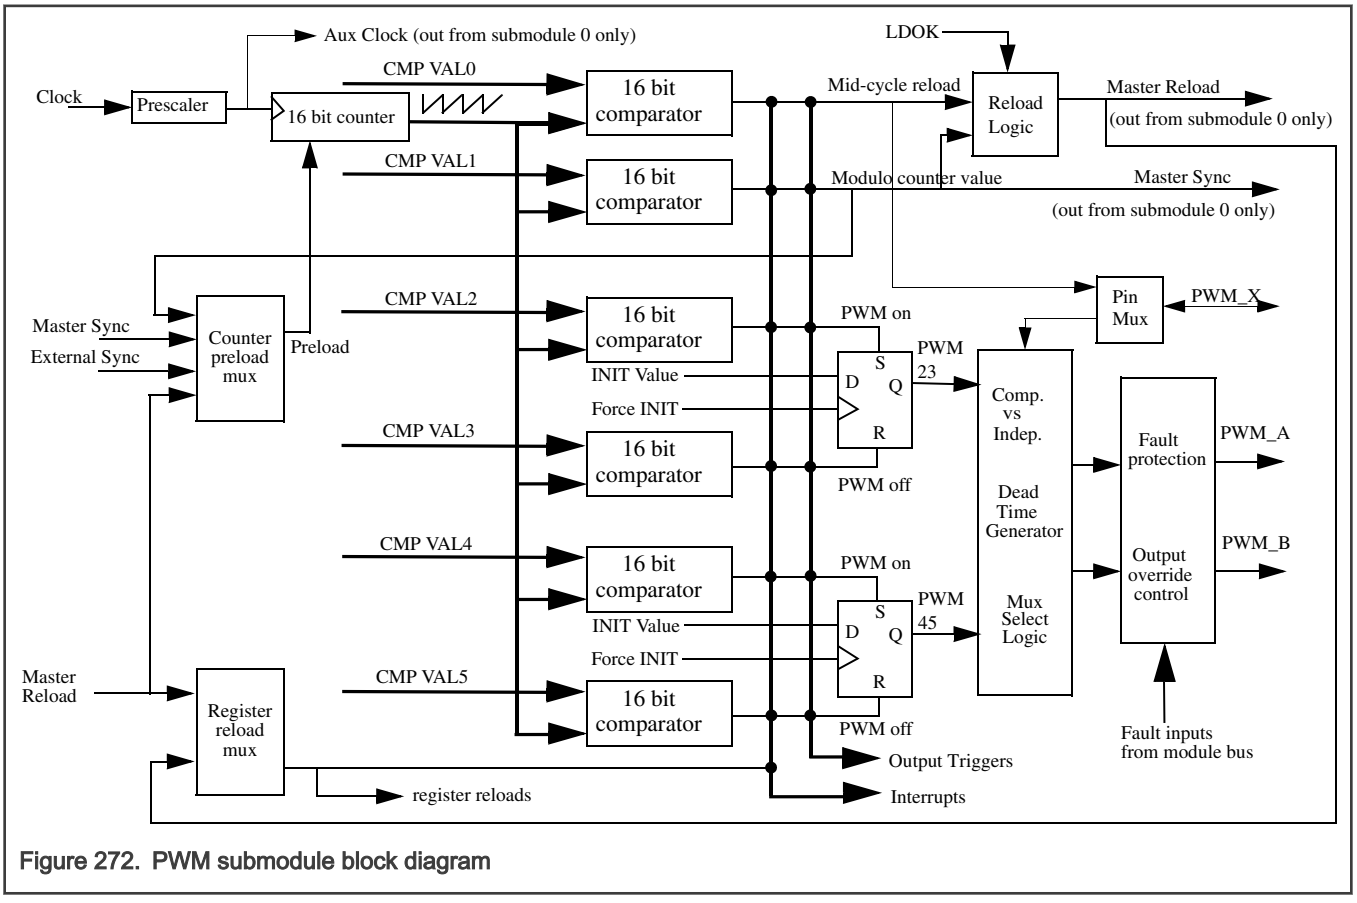

Figure 272. PWM submodule block diagram

54.3.2 PWM capabilities

This section describes some capabilities of the PWM module.

54.3.2.1 Center aligned PWMs

Each submodule has its own timer that is capable of generating PWM signals on two output pins. The edges of each of these signals are controlled independently as shown in Figure 273.

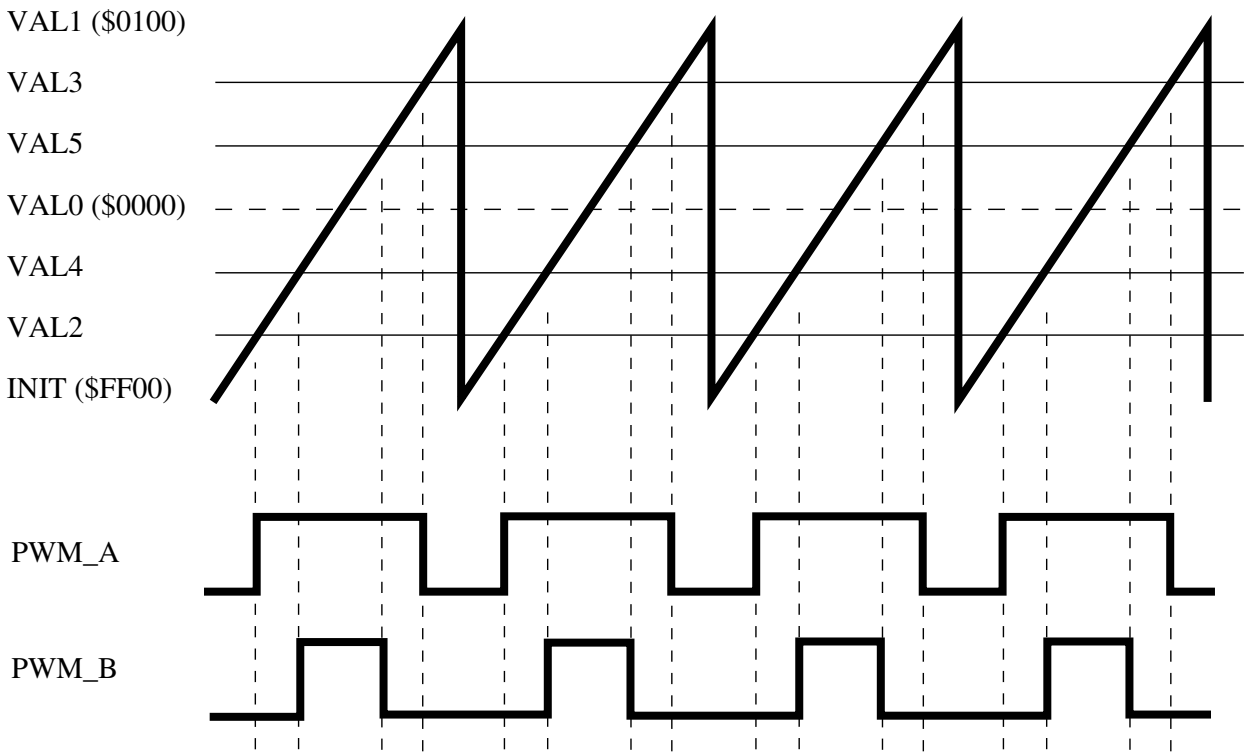

Figure 273. Center aligned PWM example

The submodule timers only count in the up direction and then reset to the INIT value. Instead of having a single value that determines pulse width, there are two values that must be specified: the turn-on edge and the turn-off edge. This double-action edge generation provides the user control over the pulse width and also the relative alignment of the signal. As a result, there is no need to support separate PWM alignment modes since the PWM alignment mode is inherently a function of the turn-on and turn-off edge values.

Figure 273 also illustrates an additional enhancement to the PWM generation process. When the counter resets, it is reloaded with a user-specified value, which may or may not be zero. If the value chosen happens to be the 2's complement of the modulus value, then the PWM generator operates in "signed" mode. This means if each PWM's turn-on and turn-off edge values are same in numbers but different in their sign, the "on" portion of the output signal is centered around a count value of zero. Therefore, only one PWM value is calculated in software and then this value and its negative are provided to the submodule as the turn-off and turn-on edges respectively. This technique results in a pulse width consists of an odd number of timer counts. If all PWM signal edge calculations follow this convention, then the signals will be center aligned with each other, which is the goal. The center alignment between the signals is not restricted to symmetry around the zero count value, as any other number would also work. However, centering on zero provides the greatest range in signed mode and also simplifies the calculations.

54.3.2.2 Edge aligned PWMs

Figure 274 shows the results of edge aligned operation when the turn-on edge for each pulse is specified to be the INIT value. Therefore, only the turn-off edge value needs to be periodically updated to change the pulse width.

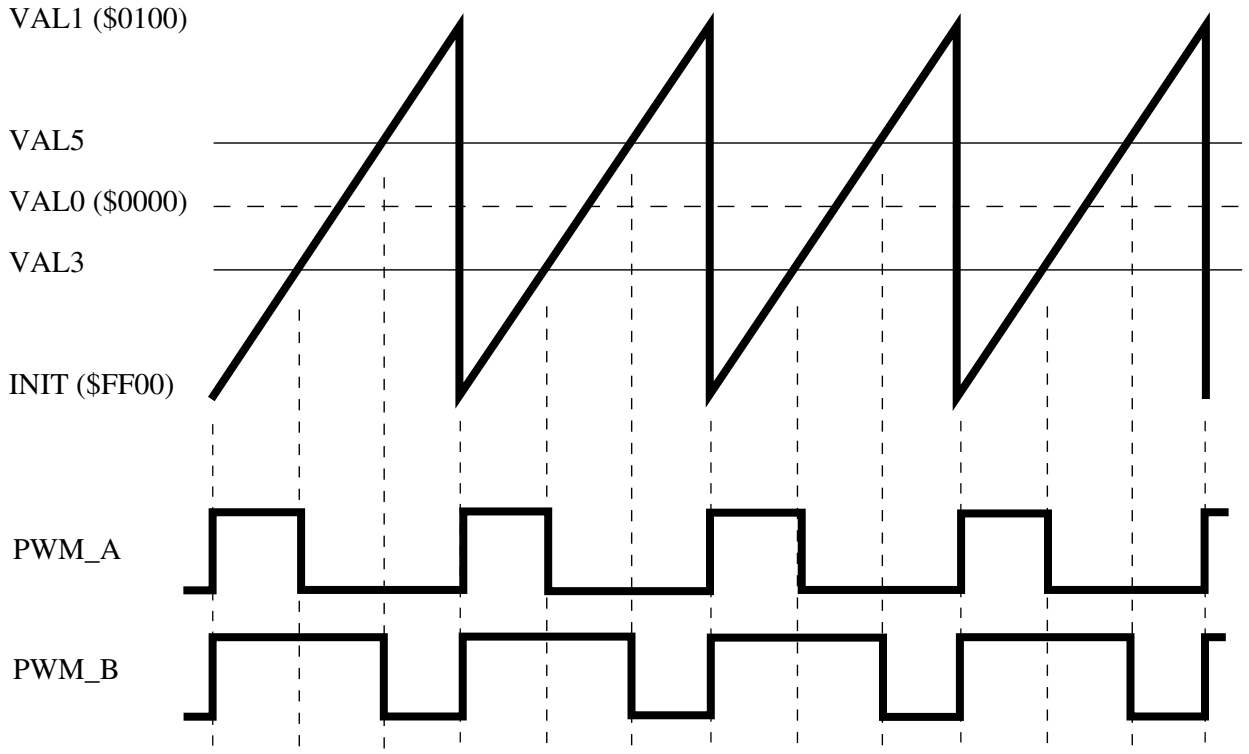

Figure 274. Edge aligned example (INIT=VAL2=VAL4)

With edge aligned PWMs, another example of the benefits of signed mode can be seen. Use "bipolar" PWMs to drive an H-bridge, where a 50% duty cycle results in zero volts on the load. Duty cycles less than 50% generate negative load voltages and duty cycles greater than 50% generate positive load voltages. If the module is set to signed mode operation (the INIT and VAL1 values are the same number with opposite signs), then there is a direct proportionality between the PWM turn-off edge value and the motor inverter voltage, including the sign. Therefore, signed mode of operation simplifies the software interface to the PWM module since no offset calculations are required to translate the output variable control algorithm to the voltage on an H-Bridge load.

54.3.2.3 Phase shifted PWMs

In the previous sections, the benefits of the signed mode of operation were discussed in the context of simplifying the required software calculations by eliminating the requirement to bias up signed variables before applying them to the module. However, if numerical biases are applied to the turn-on and turn-off edges of different PWM signals, the signals will be phase shifted to each other, as shown in Figure 275. This results in certain advantages when applied to a power stage. For example, when operating a multi-phase inverter at a low modulation index, all of the PWM switching edges from the different phases occur at the same time. This can be troublesome from a noise standpoint, especially if ADC readings of the inverter must be scheduled near those times. Phase shifting the PWM signals can open up timing windows between the switching edges to allow a signal to be sampled by the ADC. However, phase shifting does not affect the duty cycle so average load voltage is not affected.

If the outputs of submodules 1 - 3 need to be delayed from the output of submodule 0 (and from each other), instead of just creating a phase delay by adding an offset to the turn on and turn off times of the different submodules, another method is to use the PHASEDLY registers for submodules 1 - 3 to indicate their delay from the submodule 0 timing. This method can be used when the master sync signal from submodule 0 is selected as the initialization source (CTRL2[INIT_SEL]==b10). This method allows all of the submodules to be programmed with the same turn on and turn off time but submodules 1 - 3 can still be delayed the time from submodule 0.

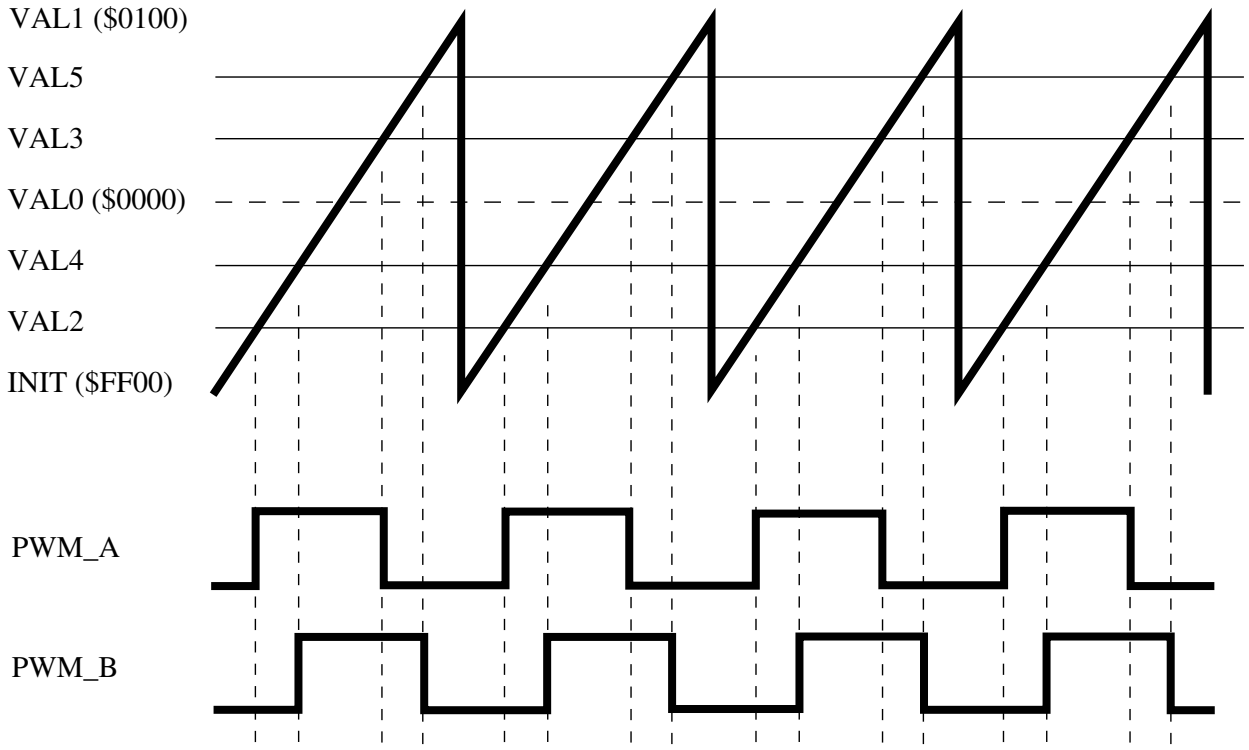

Figure 275. Phase shifted outputs - example for 1 submodule

An additional benefit of phase shifted PWMs is shown in Figure 276. In this case, an H-Bridge circuit is driven by 4 PWM signals to control the voltage waveform on the primary of a transformer. Both left and right side PWMs are configured to generate a square wave with 50% duty cycle. This works for the H-Bridge since no narrow pulse widths are generated reducing the high frequency switching requirements of the transistors. The RMS value of this waveform is directly controlled by the amount of phase shift of the square waves. Regardless of the phase shift, no DC component appears in the load voltage as long as the duty cycle of each square wave remains at 50% suitable for transformer loads. As a result, this topology is frequently used in industrial welders to adjust the amount of energy delivered to the weld arc.

NOTE

The square wave on the right side of the H-Bridge is phase shifted compared to the left side of the H-Bridge. As a result, the transformer primary sees the bottom waveform across its terminals.

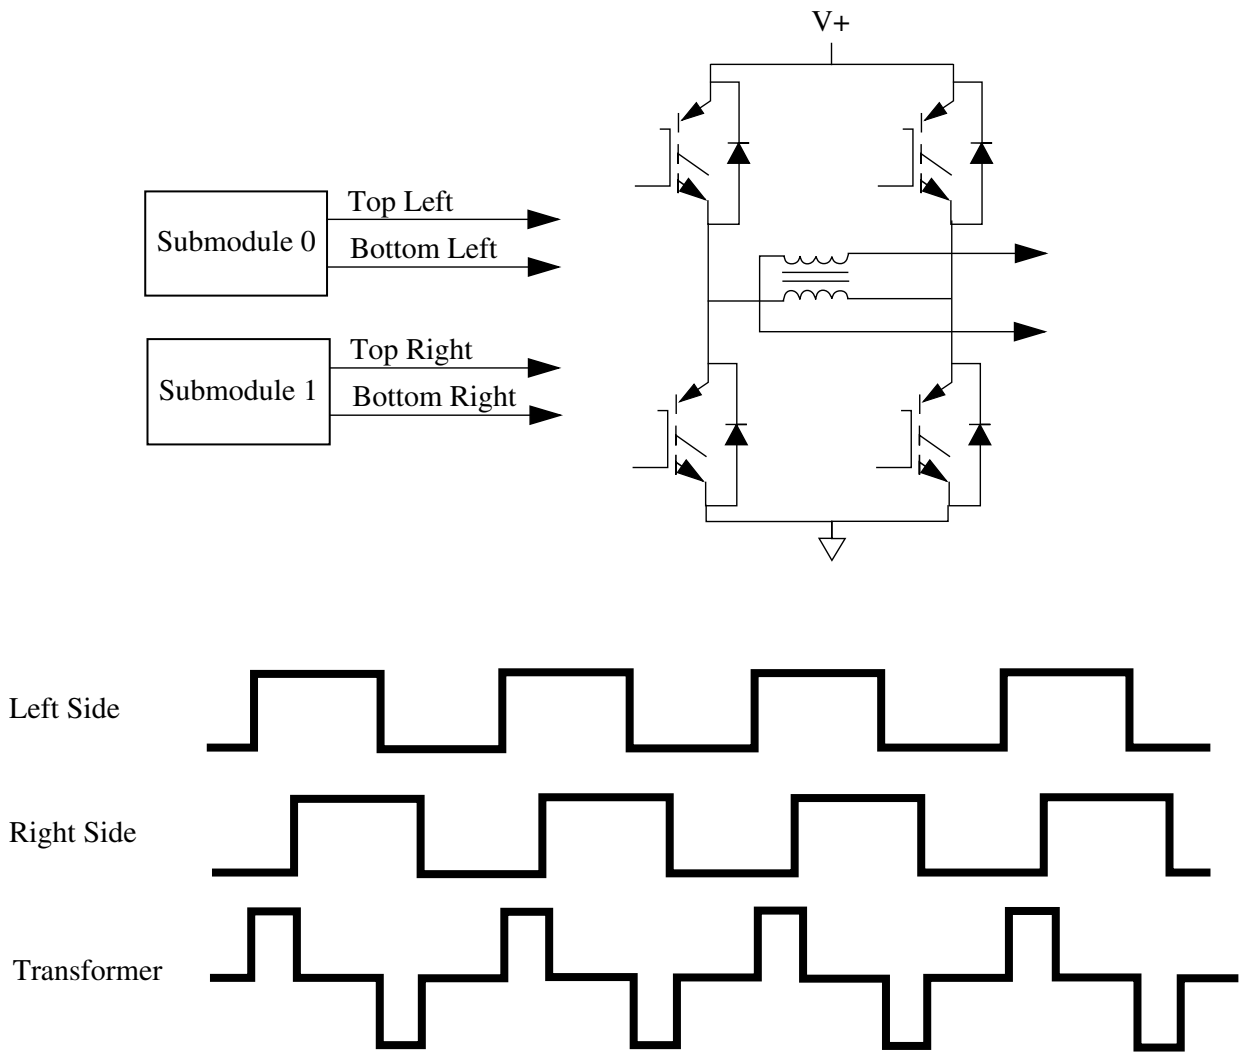

Figure 276. Phase Shifted PWMs Applied to a Transformer Primary

54.3.2.4 Double switching PWMs

Double switching PWM output is supported to aid in single shunt current measurement and three-phase reconstruction. This method supports two independent rising edges and two independent falling edges per PWM cycle. The VAL2 and VAL3 registers are used to generate the even channel (labeled as PWM_A in Figure 277) while VAL4 and VAL5 are used to generate the odd channel. The two channels (PWM23 or PWM_A and PWM45 or PWM_B from force out logic) are combined using XOR logic (force out logic) as the following figure shows. The DBLPWM signal can be run through the deadtime insertion logic.

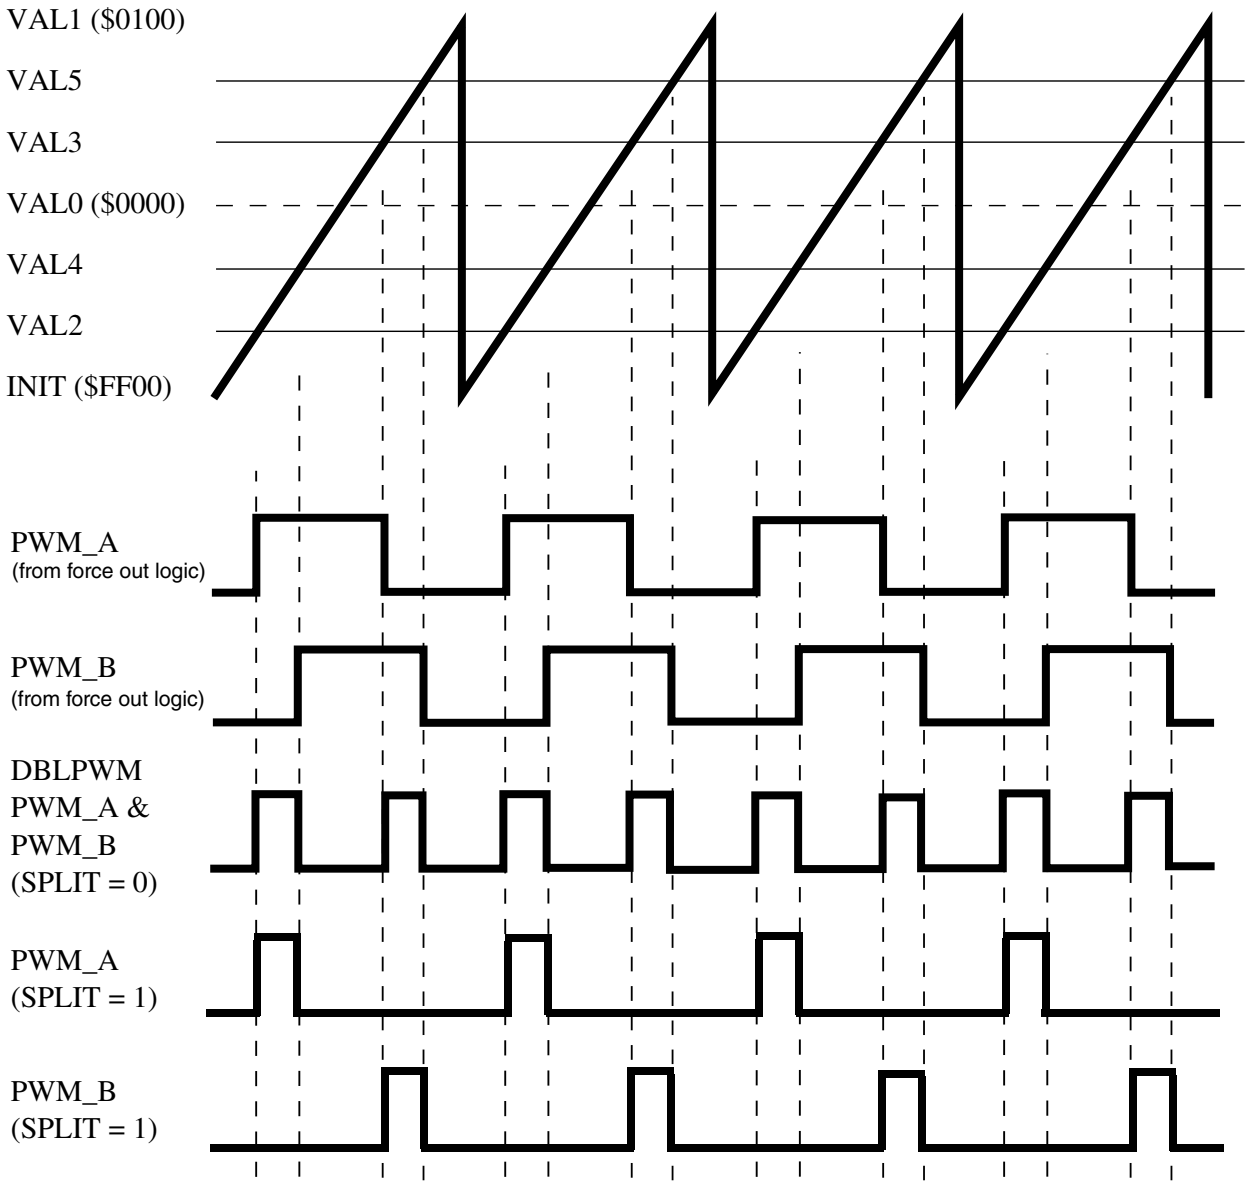

Figure 277. Double switching output example

54.3.2.5 ADC triggering

In cases where the timing of the ADC triggering is critical, it must be scheduled as a hardware event instead of software activated. With this PWM module, multiple ADC triggers can be generated in hardware per PWM cycle without the requirement of another timer module. Figure 278 shows how this is accomplished. When specifying a complementary mode of operation, only two edge comparators are required to generate the output PWM signals for a given submodule. This means the other comparators are free to perform other functions. In this example, the software does not need to quickly respond after the first conversion to set up other conversions that must occur in the same PWM cycle.

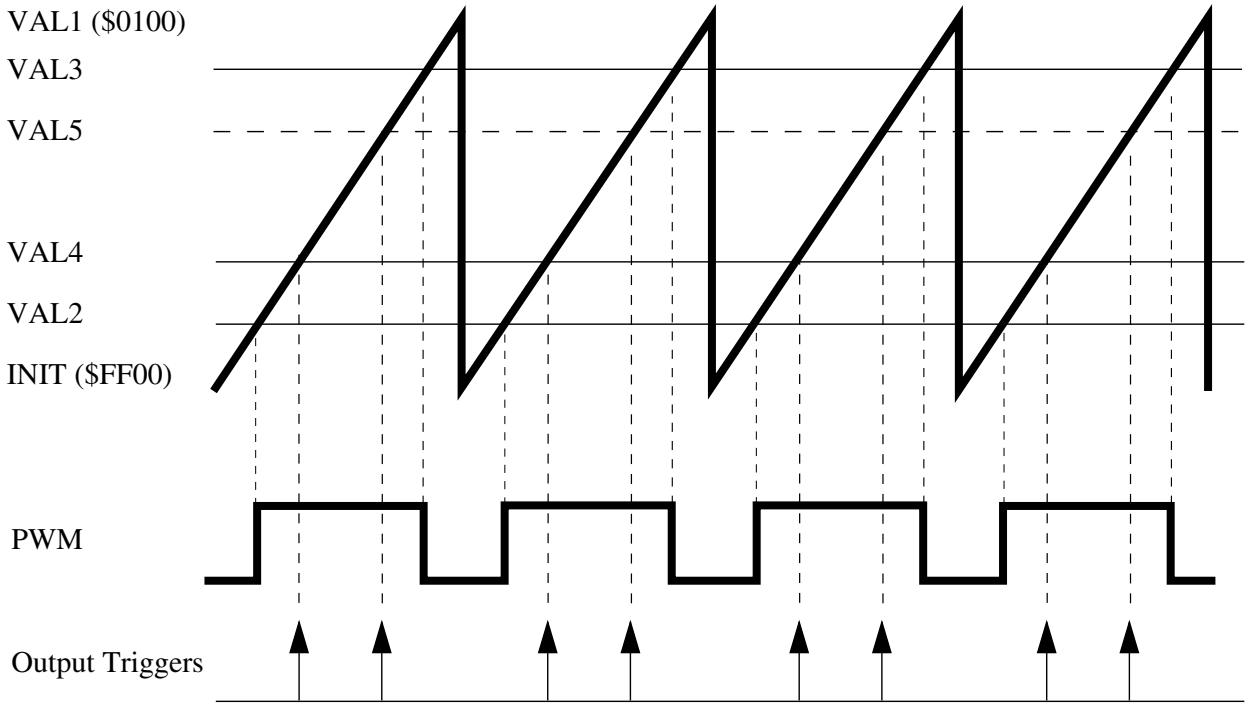

Figure 278. Multiple output trigger generation in hardware

Because each submodule has its own timer, it is possible for each submodule to run at a different frequency. One of the options possible with this PWM module is to have one or more submodules running at a lower frequency, but still synchronized to the timer in submodule0. Figure 279 shows how this feature can be used to schedule ADC triggers over multiple PWM cycles. You can use the lower-frequency submodule to control the sampling frequency of the software control algorithm where multiple ADC triggers can now be scheduled over the entire sampling period. In Figure 279, *all* submodule comparators are shown being used for ADC trigger generation.

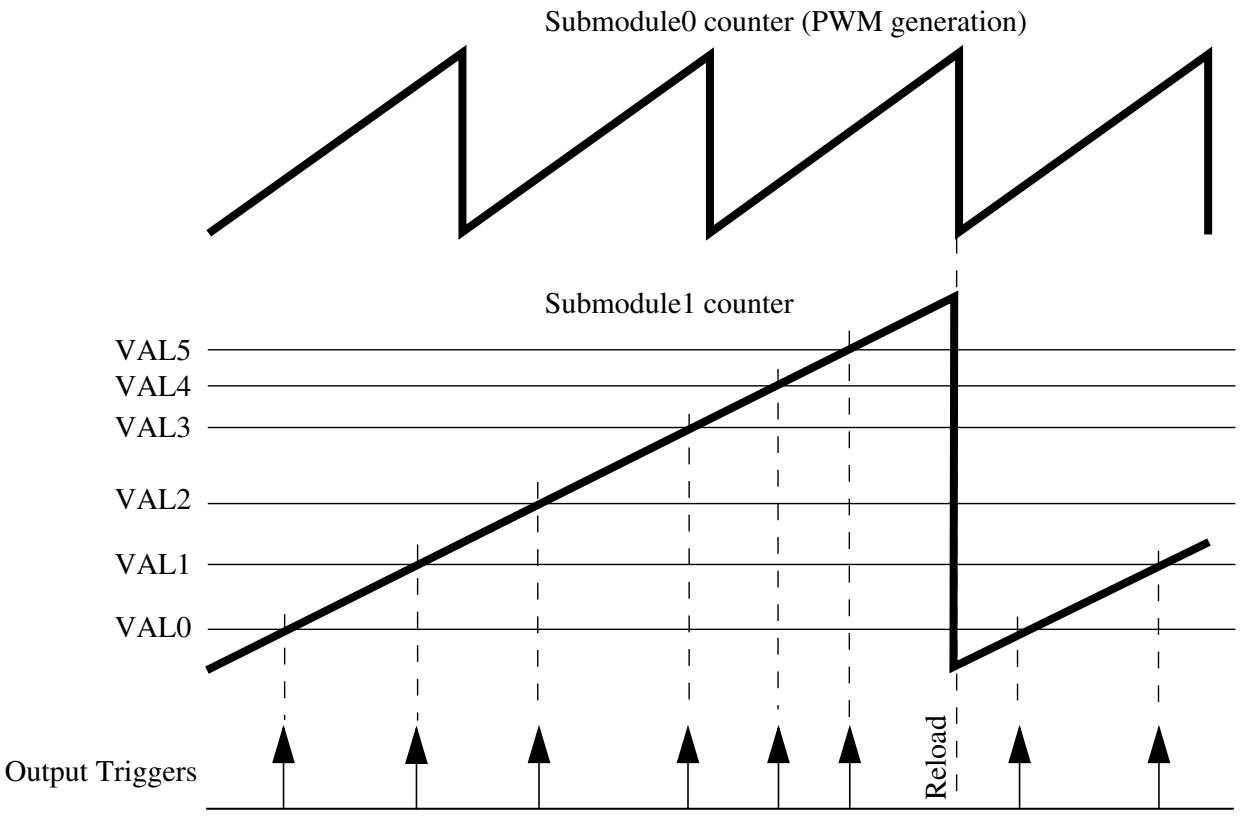

Figure 279. Multiple output triggers over several PWM cycles

54.3.2.6 Enhanced capture capabilities (E-Capture)

When a PWM pin is not used for PWM generation, it can be used to perform input captures. For PWM generation, both edges of the PWM signals are specified via separate compare register values. When programmed for input capture, both of these registers work on the same pin to capture multiple edges, toggling from one to the other in either a free running or one-shot fashion. Programming the desired edge of each capture circuit, period, and pulse width of an input signal can easily be measured without the requirement to re-arm the circuit. In addition, each edge of the input signal can clock an 8-bit counter where the counter output is compared to a user specified value (EDGCMP). When the counter output equals EDGCMP, the value of the submodule timer is captured and the counter is automatically reset. This feature counts a specified number of edge events and then performs a capture and interrupt. The following figure illustrates some of the functionality of the E-Capture circuit.

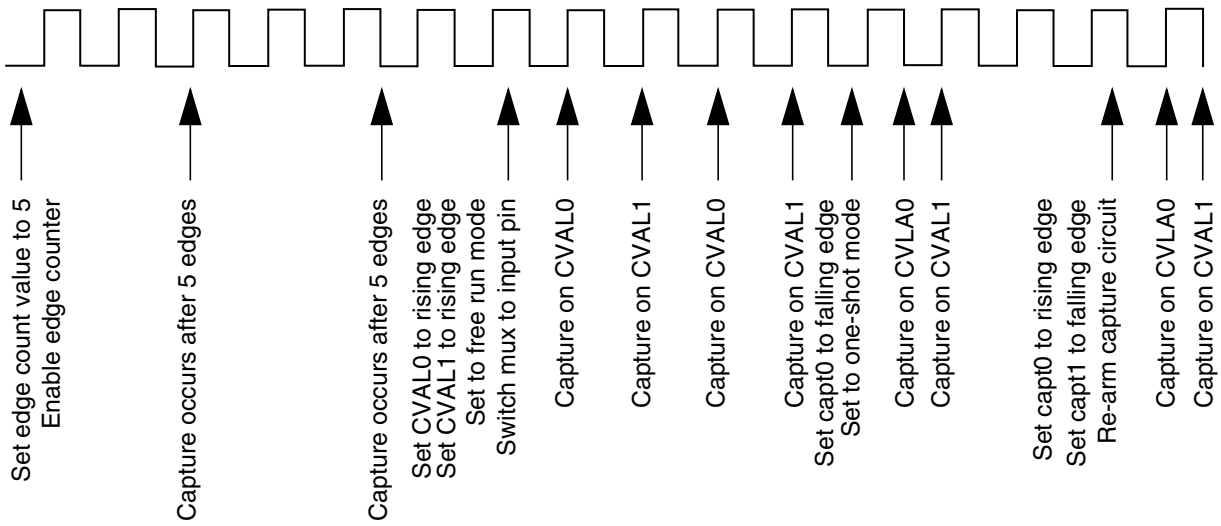

Figure 280. Capture capabilities of the E-Capture circuit

When a submodule is used for PWM generation, its timer counts up to the modulus value used to specify the PWM frequency and then is re-initialized. Therefore, using this timer for input captures on one of the other pins (for example, PWM_X) has limited utility since it does not count through all of the numbers and the timer reset represents a discontinuity in the 16-bit number range. However, when measuring a signal that is synchronous to the PWM frequency, the timer modulus range is suited for the application. As shown in Figure 281, the output of a PWM power stage is connected to the PWM_X pin that is configured for free running input captures. Specifically, the CVAL0 capture circuitry is programmed for rising edges and the CVAL1 capture circuitry is set for falling edges. This results in new load pulse width data acquired every PWM cycle. To calculate the pulse width, subtract the CVAL0 register value from the CVAL1 register value. This measurement is beneficial when performing deadtime distortion correction on a half bridge circuit driving an inductive load. Also, these values can be directly compared to the VALx registers responsible for generating the PWM outputs to obtain a measurement of system propagation delays. For details, refer to the separate discussion of deadtime distortion correction.

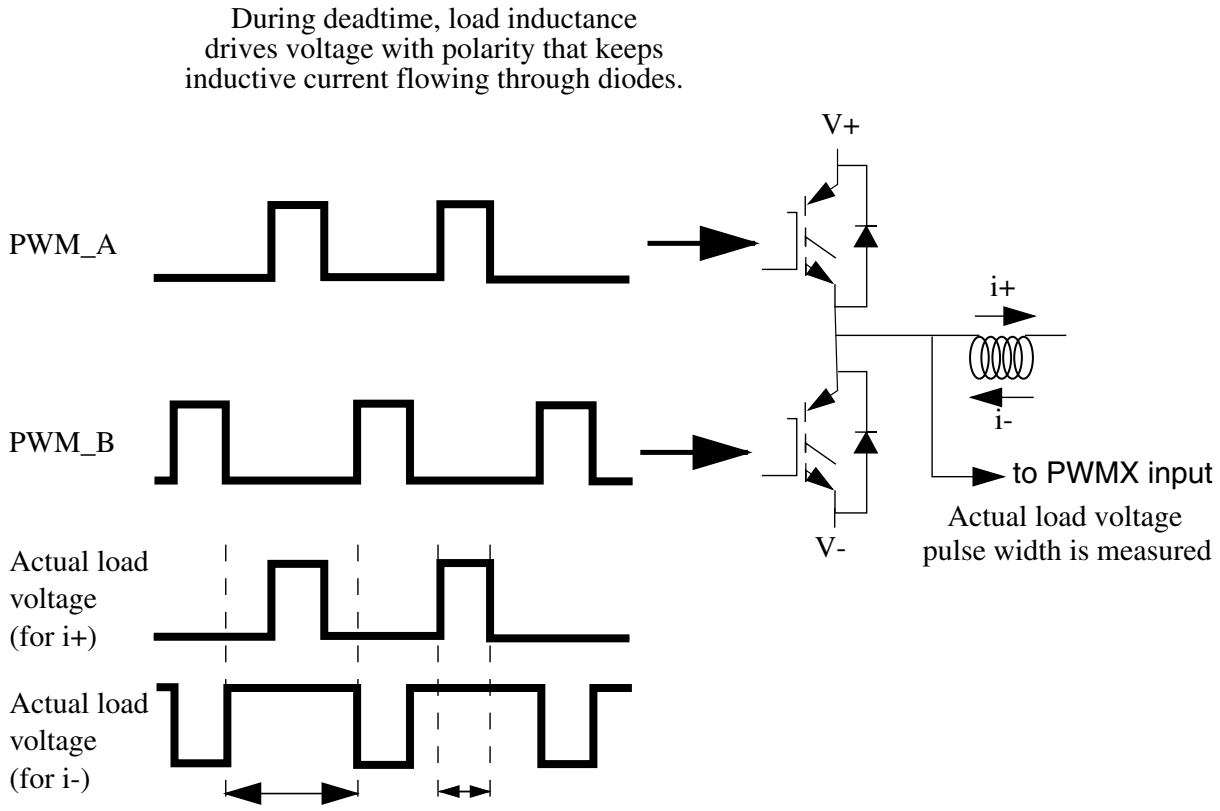

Figure 281. Output pulse width measurement possible with the E-capture circuit

54.3.2.7 Synchronous switching of multiple outputs

Before the PWM signals are routed to the output pins, they are processed by a hardware block that permits all submodule outputs to be switched synchronously. This feature is useful in commutated motor applications where the next commutation state can be laid in ahead of time and then immediately switched to the outputs when the appropriate condition or time is reached. All the changes occur immediately after the trigger event occurs eliminating any interrupt latency and also the changes occurs synchronously on all submodule outputs.

The synchronous output switching is accomplished via a signal called FORCE_OUT. This signal originates from the local FORCE bit within the submodule, from submodule0, or from external to the PWM module, and in most cases, is supplied from an external timer channel configured for output compare. In a typical application, software sets up the desired states of the output pins in preparation for the next FORCE_OUT event. This selection lays dormant until the FORCE_OUT signal transitions and then all outputs are switched simultaneously. The signal switching is performed upstream from the deadtime generator so that any abrupt changes that occur do not violate deadtime on the power stage when in complementary mode.

Figure 282 shows an application that can benefit from this feature. On a brushless DC motor in many cases, it is required to spin the motor without need of hall-effect sensor feedback. Instead, the back EMF of the motor phases is monitored and this information is used to schedule the next commutation event. The top waveforms of Figure 282 represent these back EMF signals. Timer compare events (represented by the long vertical lines in the diagram) are scheduled based on the zero crossings of the back-EMF waveforms. The PWM module is configured via software ahead of time with the next state of the PWM pins in anticipation of the compare event. When it happens, the output compare of the timer drives the FORCE_OUT signal which immediately changes the state of the PWM pins to the next commutation state with no software latency.

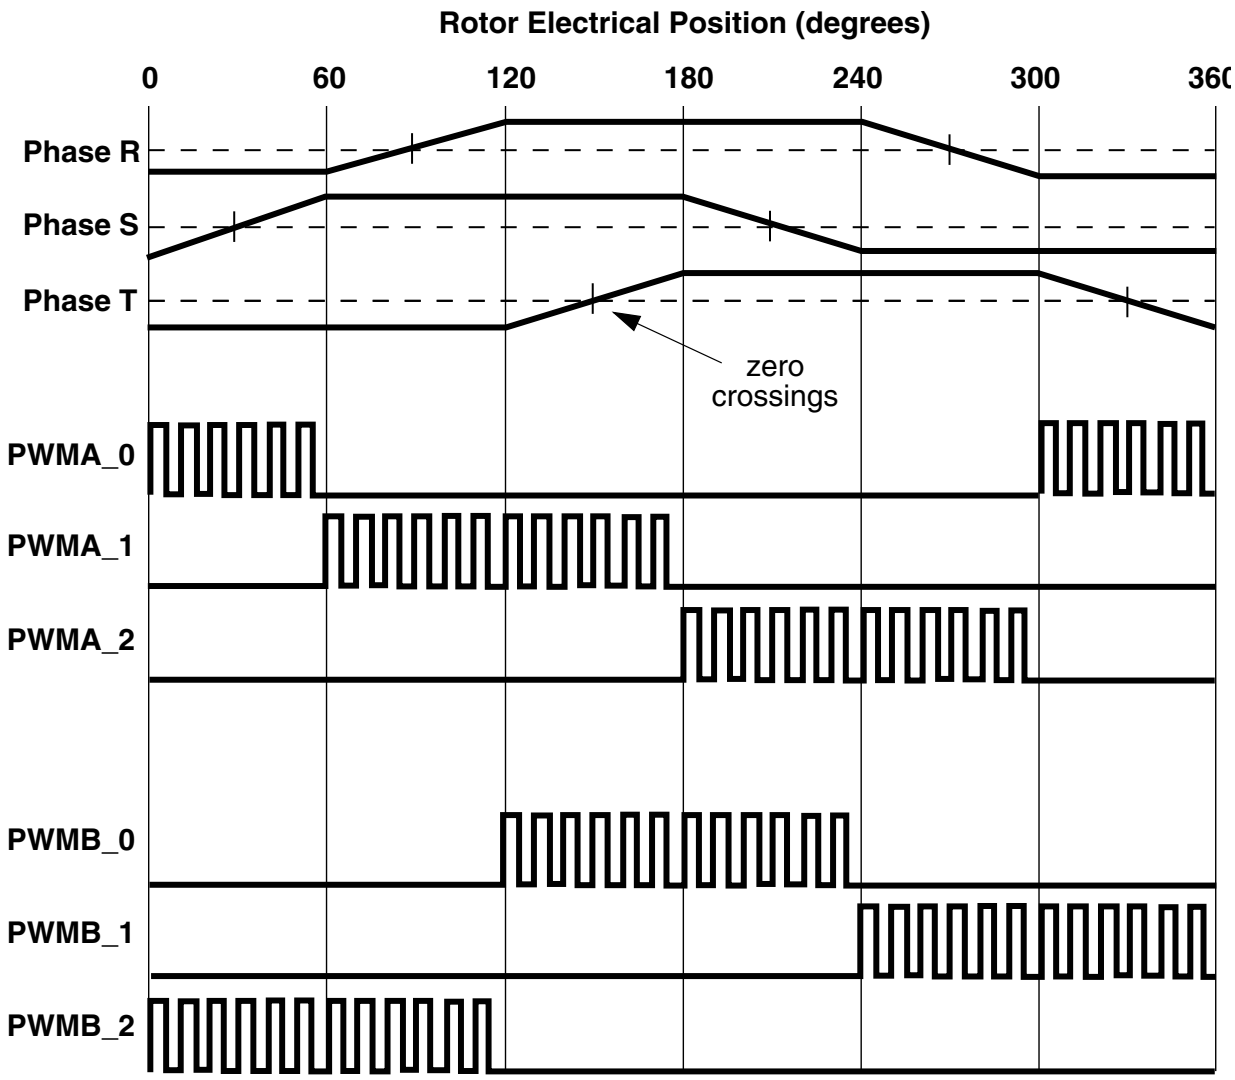

Figure 282. Sensorless BLDC commutation using the force out function

54.3.3 Operation

This section describes the implementation of various sections of the PWM in detail.

The following figure is a high-level block diagram of output PWM generation.

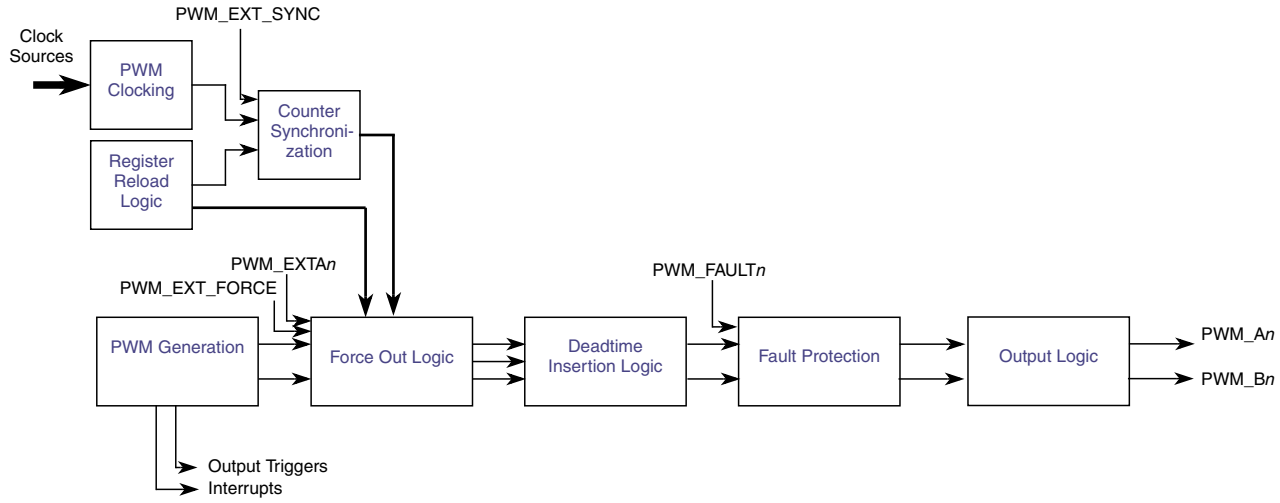

Figure 283. High-level output PWM generation block diagram

54.3.3.1 Register reload logic

The register reload logic is used to determine when the outer set of registers for all double buffered register pairs will be transferred to the inner set of registers. The register reload event can be scheduled to occur every "n" PWM cycles using CTRL[LDFQ] and CTRL[FULL], which is defined by VAL1 register. A half cycle reload option is also supported (CTRL[HALF]) where the reload can take place in the middle of a PWM cycle. The half cycle point is defined by the VAL0 register and does not have to be exactly in the middle of the PWM cycle.

As shown in Figure 284 the reload signal from submodule0 can be broadcast as the Master Reload signal allowing the reload logic from submodule0 to control the reload of registers in other submodules.

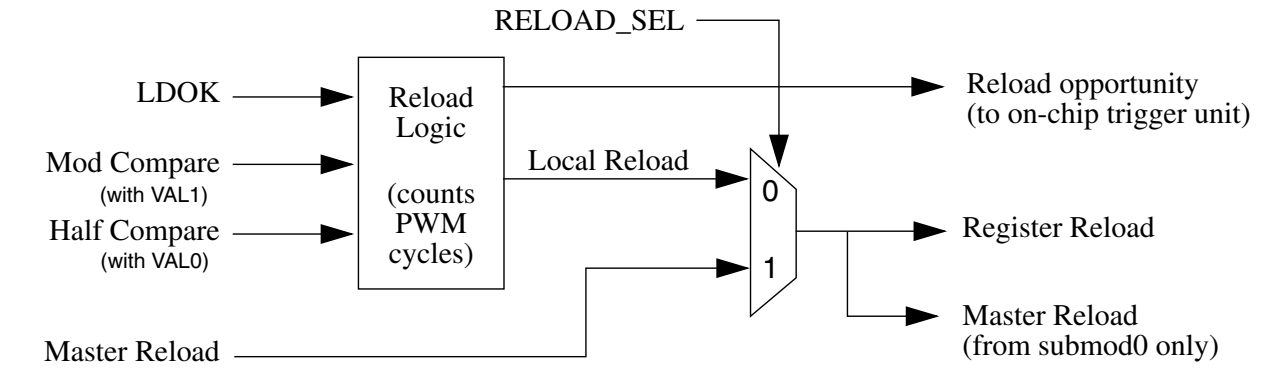

Figure 284. Register reload logic of each submodule

54.3.3.2 Counter synchronization

As shown in Figure 285, the 16-bit counter counts up until its output equals VAL1 which is used to specify the counter modulus value. The resulting compare causes a rising edge to occur on the Local Synchronization signal which is one of four possible sources used to cause the 16-bit counter to be initialized with INIT. If Local Synchronization is selected as the counter initialization signal, VAL1 within the submodule effectively controls the timer period (and then the PWM frequency generated by that submodule), and everything operates or functions at a local level.

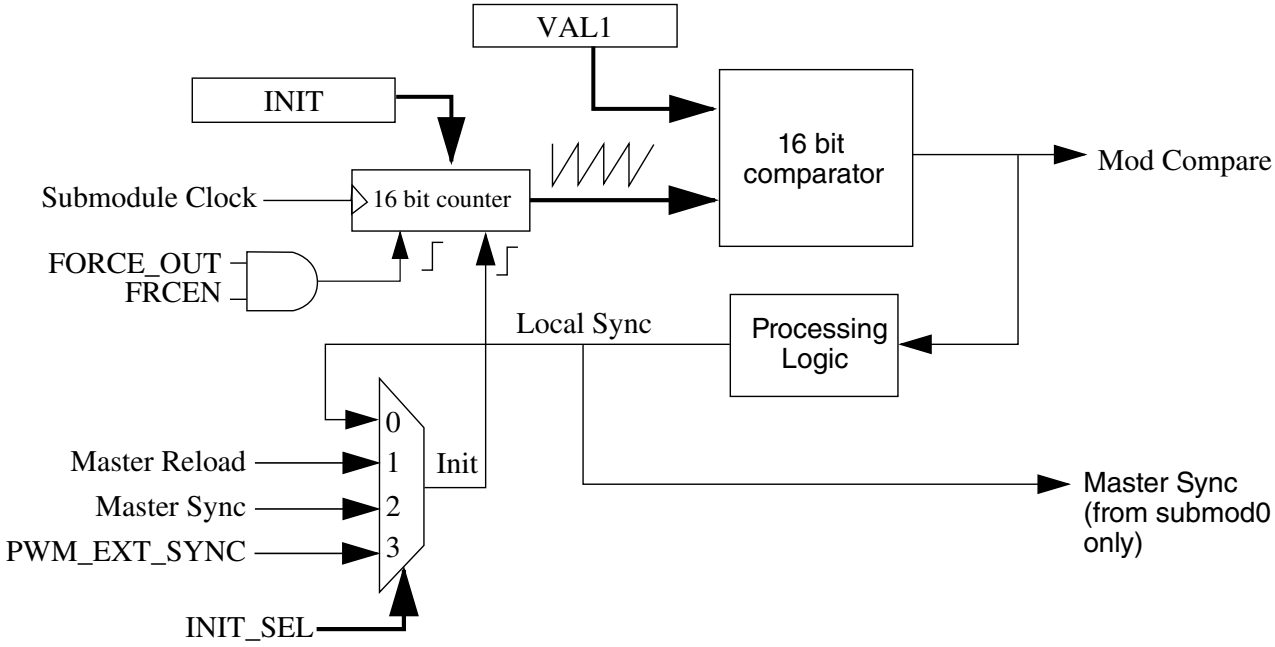

Figure 285. Counter synchronization for each submodule

The Master Synchronization signal originates as the Local Sync from submodule0. If configured to do so, the timer period of any submodule can be locked to the period of the timer in submodule0.

The PWM_EXT_SYNC signal originates on chip or off chip depending on the system architecture. This signal may be selected as the source for counter initialization so that an external source can control the period of all submodules.

If the Master Reload signal is selected as the source for counter initialization, then the period of the counter will be locked to the register reload frequency of submodule0. Since the reload frequency is commensurate to the sampling frequency of the software control algorithm, the submodule counter period is equal the sampling period. As a result, this timer can be used to generate output compares or output triggers over the entire sampling period which may consist of several PWM cycles. The Master Reload signal can only originate from submodule0.

The counter can optionally initialize upon the assertion of the FORCE_OUT signal assuming that CTRL2[FRCEN] is set. As shown in Figure 285, this constitutes a second initialization input into the counter, which causes the counter to initialize regardless of which signal is selected as the counter initialization signal. A forced initialization causes a register reload if MCTRL[LDOK] is set.

The counter can be initialized by FORCE_OUT signal only when MCTRL[RUN] = 1 or CTLR2[CLK_SEL] = 2 which chooses auxiliary clock from SM0.

The FORCE_OUT signal is provided mainly for commutated applications. When PWM signals are commutated on an inverter controlling a brushless DC motor, it is necessary to restart the PWM cycle at the beginning of the commutation interval. This action effectively resynchronizes the PWM waveform to the commutation timing. Otherwise, the average voltage applied to a motor winding integrated over the entire commutation interval will be a function of the timing between the asynchronous commutation event for the PWM cycle. The effect is more critical at higher motor speeds where each commutation interval may consist of only a few PWM cycles. If the counter is not initialized at the start of each commutation interval, the result is an oscillation caused by the beating between the PWM frequency and the commutation frequency.

54.3.3.3 PWM generation

Figure 286 illustrates how PWM generation is accomplished in each submodule. In each case, two comparators and associated VALx registers are utilized for each PWM output signal. One comparator and VALx register are used to control the turn-on edge, while a second comparator and VALx register control the turn-off edge.

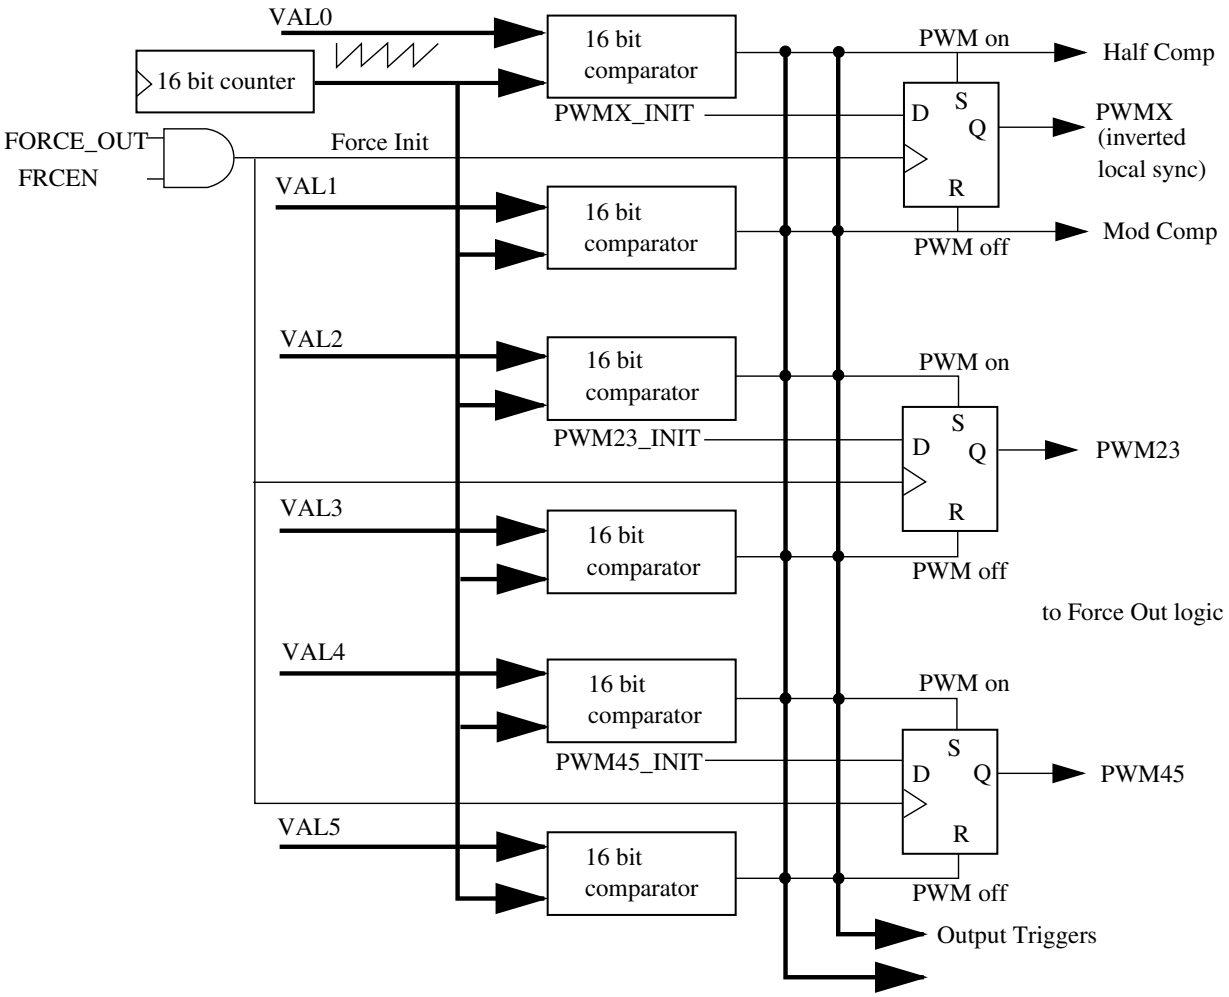

Figure 286. PWM Generation Hardware of each submodule

The generation of the Local Synchronization signal is performed exactly the same way as the other PWM signals in the submodule. While comparator 0 causes a falling edge of the Local Synchronization signal, comparator 1 generates a rising edge. Comparator 1 is also hardwired to the reload logic to generate the full cycle reload indicator.

If VAL1 is controlling the modulus of the counter and VAL0 is half of the VAL1 register minus the INIT value, then the half cycle reload pulse occurs exactly half way through the timer count period and the Local Synchronization will have a 50% duty cycle. On the other hand, if the VAL1 and VAL0 registers are not required for register reloading or counter initialization, they can be used to modulate the duty cycle of the Local Synchronization signal, effectively turning it into an auxiliary PWM signal (PWM_X) assuming that the PWM_X pin is not being used for another function such as input capture or deadtime distortion correction. Including the Local Synchronization signal, each submodule is capable of generating three PWM signals where software has complete control over each edge of each of the signals.

If the comparators and edge value registers are not required for PWM generation, they can be used for other functions such as output compares, generating output triggers, or generating interrupts at timed intervals.

The 16-bit comparators shown in Figure 286 are "equal to" comparators. In addition, if both the set and reset of the flip-flop are asserted, then the flop output goes to 0.

54.3.3.4 Output compare capabilities

By using the VALx registers in conjunction with the submodule timer and 16-bit comparators, buffered output compare functionality can be achieved with no additional hardware required. Specifically, the following output compare functions are possible:

- An output compare sets the output high
- An output compare sets the output low
- An output compare generates an interrupt
- An output compare generates an output trigger

In PWM generation, an output compare is initiated by programming a VALx register for a timer compare, which in turn causes the output of the D flip-flop to either set or reset. For example, if an output compare is desired on the PWM_A signal that sets it high, VAL2 would be programmed with the counter value where the output compare should take place. However, to prevent the D flip-flop from being reset again after the compare has occurred, the VAL3 register must be programmed to a value out of the modulus range of the counter. Therefore, a comparison that would result in resetting the D flip-flop output would never occur. Conversely, if an output compare is desired on the PWM_A signal that sets it low, the VAL3 register is programmed with the appropriate count value and the VAL2 register is programmed with a value out of the counter modulus range. Regardless of whether a high compare or low compare is programmed, an interrupt, or output trigger can be generated when the compare event occurs.

54.3.3.5 Force out logic

For each submodule, the software can select between eight signal sources for the FORCE_OUT signal depending on the chip architecture:

1. Local CTRL2[FORCE]
2. Master Force signal from submodule0
3. Local Reload signal
4. Master Reload signal from submodule0
5. Local Synchronization signal
6. Master Synchronization signal from submodule0
7. EXT_SYNC signal from on or off chip
8. EXT_FORCE signal from on or off chip

The local signals are used to change the signals on the output pins of the submodule without regard for synchronization with other submodules. However, if it is required that all signals on all submodule outputs change at the same time, the Master, EXT_SYNC, or EXT_FORCE signals must be selected.

Figure 287 illustrates the Force logic. The SEL23 and SEL45 fields each choose from one of four signals that can be supplied to the submodule outputs: the PWM signal, the inverted PWM signal, a binary level specified by software via the OUT23 and OUT45 bits, or the PWM_EXTA alternate external control signals. The selection can be determined ahead of time, and when a FORCE_OUT event occurs, these values are presented to the signal selection mux that immediately switches the requested signal to the output of the mux for further processing downstream.

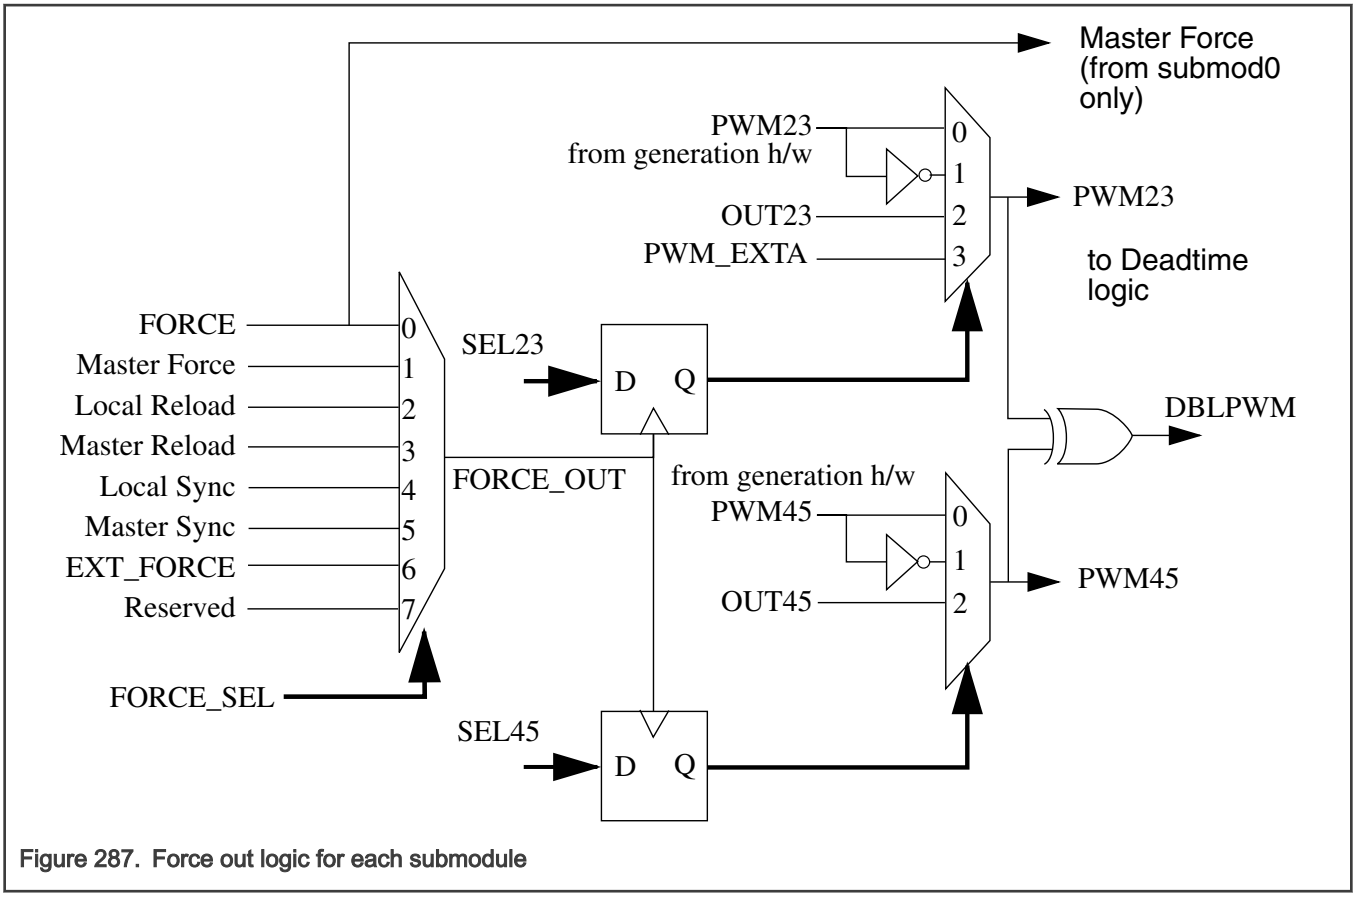

Figure 287. Force out logic for each submodule

The local CTRL2[FORCE] signal of submodule0 can be broadcast as the Master Force signal to other submodules. This feature allows the CTRL2[FORCE] of submodule0 to synchronously update all of the submodule outputs at the same time. The EXT_FORCE signal originates from outside the PWM module from a source such as a timer or digital comparators in the Analog-to-Digital Converter.

54.3.3.6 Independent or complementary channel operation

Writing a logic one to CTRL2[INDEP] configures the pair of PWM outputs as two independent PWM channels. Each PWM output is controlled by its own VALx pair operating independently of the other output.

Writing a logic zero to CTRL2[INDEP] configures the PWM output as a pair of complementary channels. The PWM pins are paired as shown in Figure 3-16 in complementary channel operation. The signal that is connected to the output pin (PWM23 or PWM45) is determined by MCTRL[IPOL].

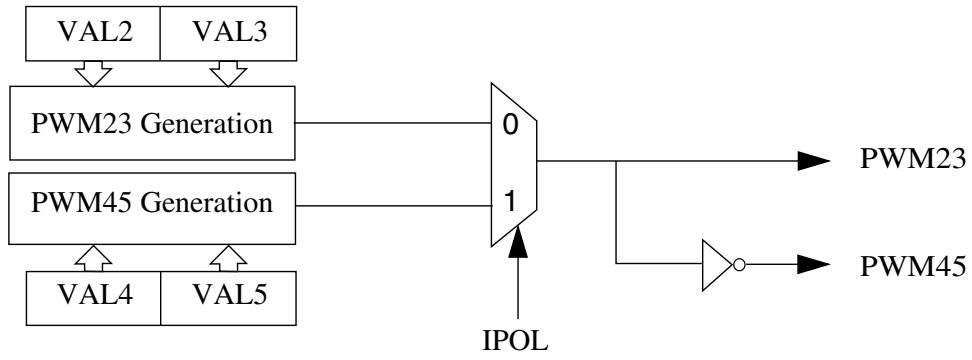

Figure 288. Complementary channel pair for each submodule

The complementary channel operation is for driving top and bottom transistors in a motor drive circuit, as shown in Figure 289.

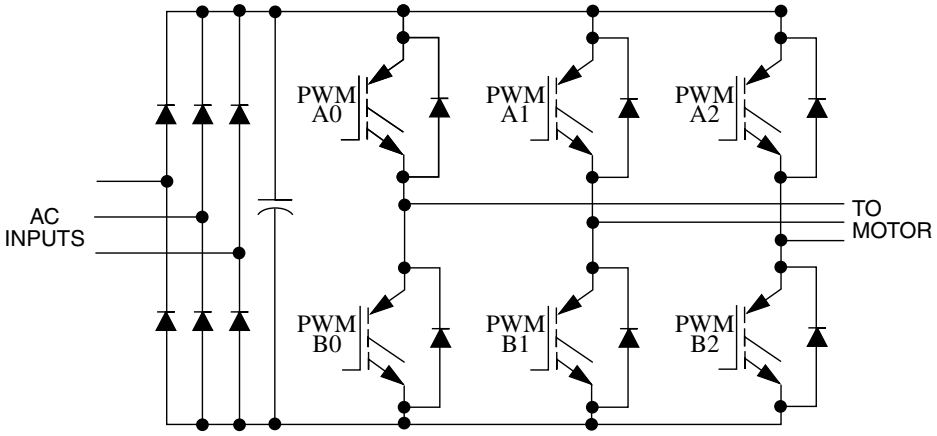

Figure 289. Typical 3 phase AC motor drive

The complementary operation allows the use of the deadtime insertion feature.

54.3.3.7 Deadtime insertion logic

The following figure shows the deadtime insertion logic of each submodule which is used to create non-overlapping complementary signals when not in independent mode.

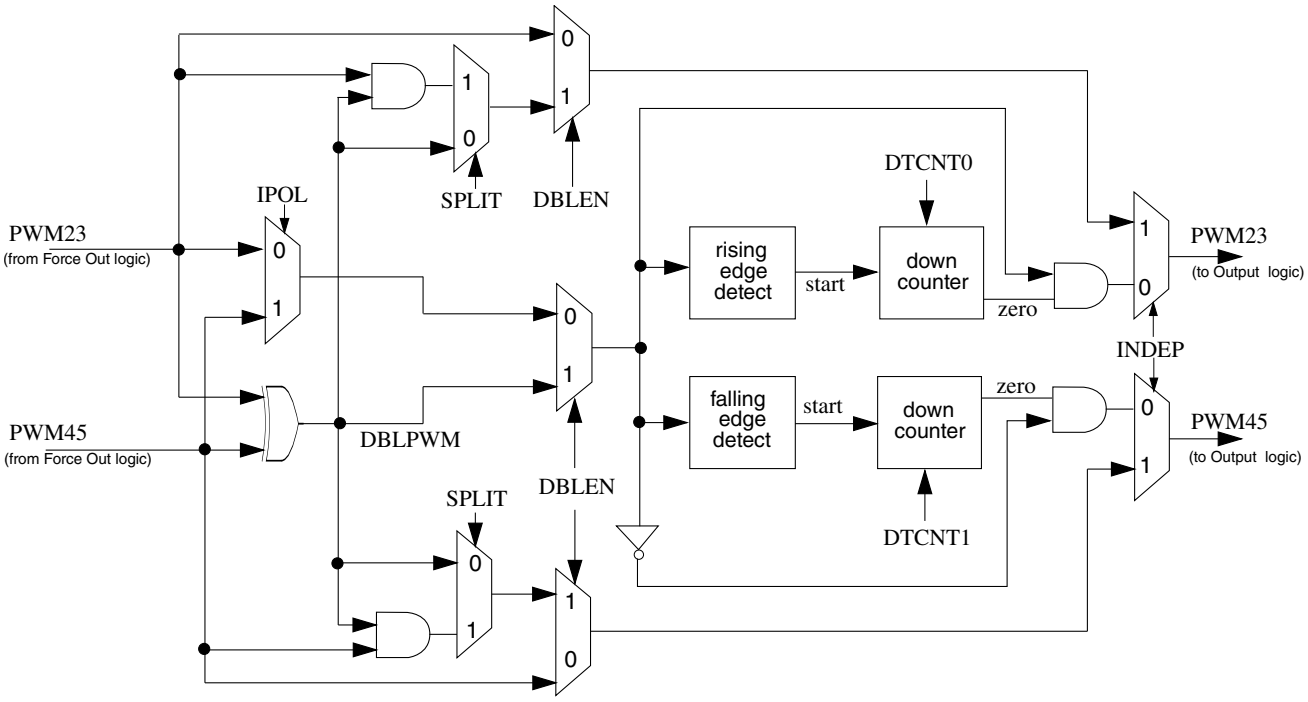

Figure 290. Deadtime Insertion Logic for each submodule

While in the complementary mode, a PWM pair can be used to drive top/bottom transistors, as shown in the figure. When the top PWM channel is active, the bottom PWM channel is inactive, and vice versa.

NOTE

To avoid short-circuiting the DC bus and endangering the transistor, there must be no overlap of conducting intervals between the top and bottom transistors. But the transistor's characteristics make its switching-off time longer than switching-on time. To avoid the conducting overlap of top and bottom transistors, deadtime needs to be inserted in the switching period, as shown in Figure 291.

The deadtime generators automatically insert software-selectable activation delays into the pair of PWM outputs. The deadtime registers (DTCNT0 and DTCNT1) specify the number of IPBus clock cycles to use for deadtime delay. Every time the deadtime generator inputs change state, deadtime is inserted. Deadtime forces both PWM outputs in the pair to the inactive state.

When deadtime is inserted in complementary PWM signals connected to an inverter driving an inductive load, the PWM waveform on the inverter output will have a different duty cycle than what appears on the output pins of the PWM module. This results in a distortion in the voltage applied to the load. A method of correcting this, adding to or subtracting from the PWM value used, is discussed next.

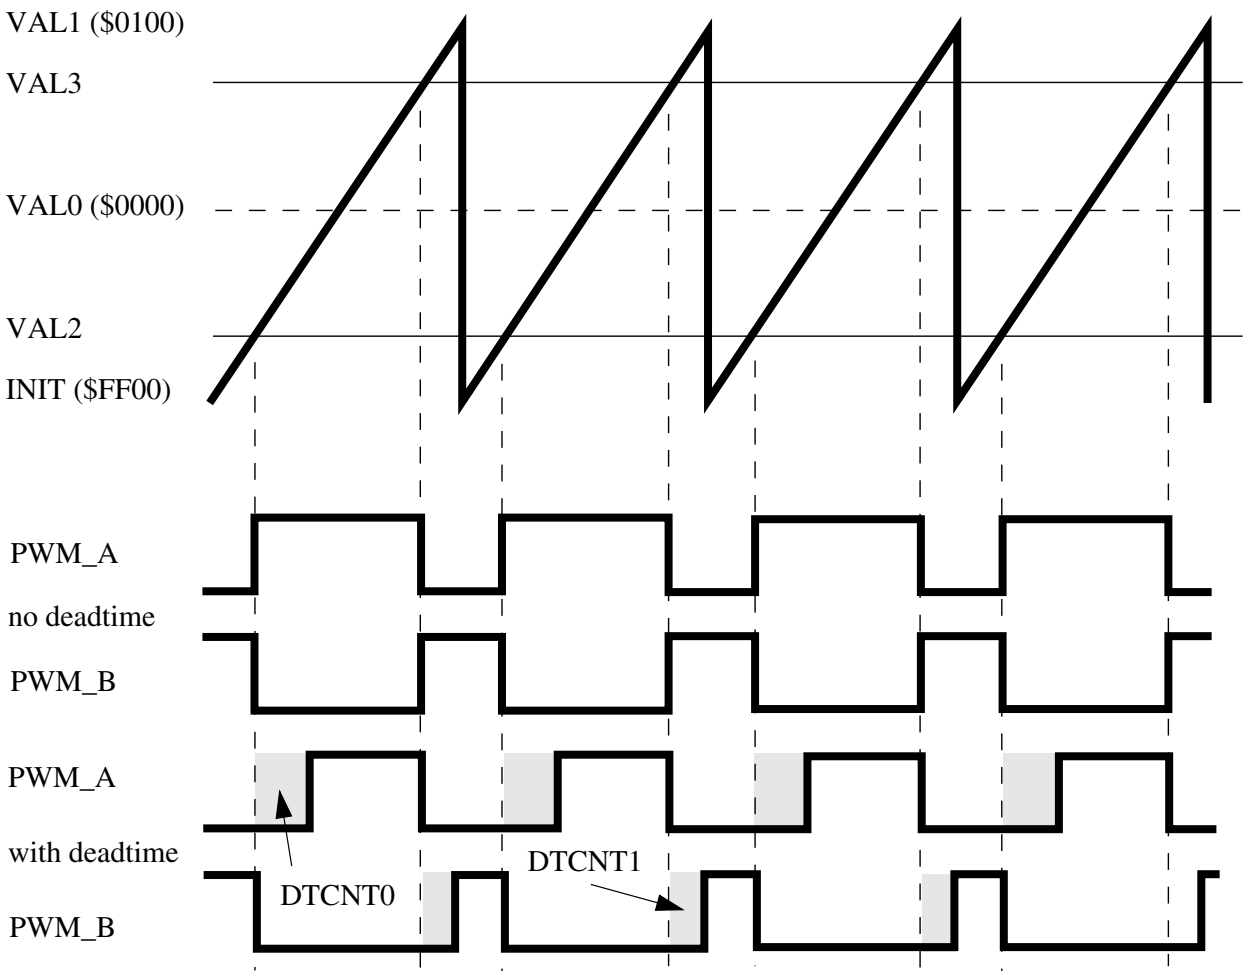

Figure 291. Deadtime insertion

54.3.3.7.1 Top/Bottom correction

In complementary mode, either the top or the bottom transistor controls the output voltage. However, deadtime has to be inserted to avoid overlap of conducting interval between the top and bottom transistor. Both transistors in complementary mode are off during deadtime, allowing the output voltage to be determined by the current status of load and introducing distortion in the output voltage, as shown in Figure 292. On AC induction motors running open-loop, the distortion typically manifests itself as poor low-speed performance, such as torque ripple and rough operation.

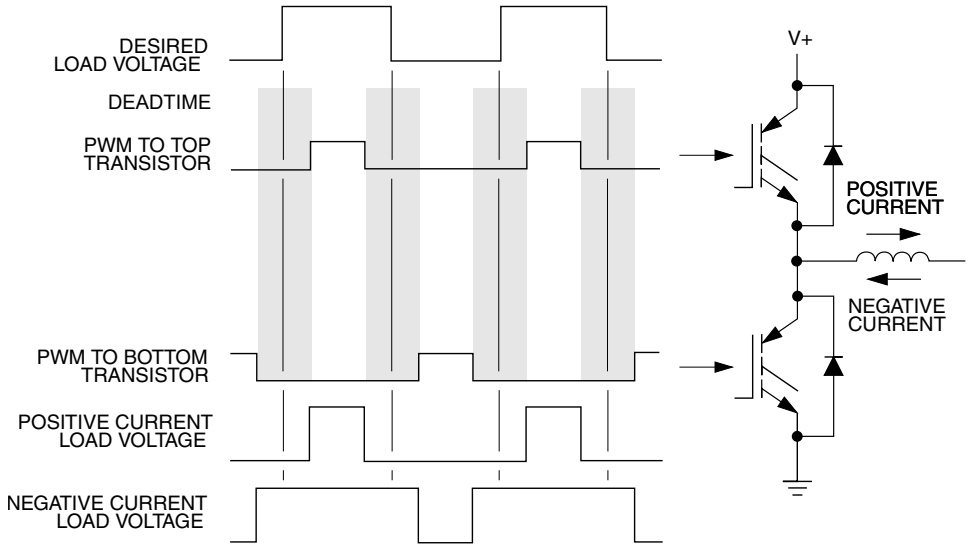

Figure 292. Deadtime distortion

During deadtime, load inductance distorts output voltage by keeping current flowing through the diodes. This deadtime current flow creates a load voltage that varies with the current direction. With a positive current flow, the load voltage during deadtime is equal to the bottom supply, putting the top transistor in control. With a negative current flow, the load voltage during deadtime is equal to the top supply putting the bottom transistor in control.

Remembering that the original PWM pulse widths were shortened by deadtime insertion, the averaged sinusoidal output is less than the desired value. However, when deadtime is inserted, it distorts in the motor current waveform inverter outputs. This distortion is aggravated by different turn-on and turn-off delays of each of the transistors. By giving the PWM module information on which transistor is controlling at a given time this distortion can be corrected.

For a typical circuit in complementary channel operation, only one of the transistors is effective in controlling the output voltage at any given time. This depends on the direction of the motor inverter current for that pair, as shown in Figure 292. To correct distortion one of two different factors must be added to the desired PWM value, depending on whether the top or bottom transistor is controlling the output voltage. Therefore, the software is responsible for calculating both compensated PWM values prior to placing them in the VALx registers. Either the VAL2/VAL3 or the VAL4/VAL5 register pair controls the pulse width at any given time. For a given PWM pair, whether the VAL2/VAL3 or VAL4/VAL5 pair is active depends on either:

- The state of the current status pin, PWMX, for that driver
- The state of the odd/even correction bit, MCTRL[IPOL], for that driver

To correct deadtime distortion, the software can decrease or increase the value in the appropriate VALx register.

- In edge-aligned operation, decreasing or increasing the PWM value by a correction value equal to the deadtime typically compensates for deadtime distortion.
- In center-aligned operation, decreasing or increasing the PWM value by a correction value equal to one-half the deadtime typically compensates for deadtime distortion.

54.3.3.7.2 Manual correction

To detect the current status, the voltage on each PWMX pin is sampled twice in a PWM period, at the end of each deadtime. The value is stored in CTRL[DT]. CTRL[DT] is a timing marker indicating when to toggle between PWM value registers. The software can then set MCTRL[IPOL] to switch between VAL2/VAL3 and VAL4/VAL5 register pairs according to CTRL[DT] values.

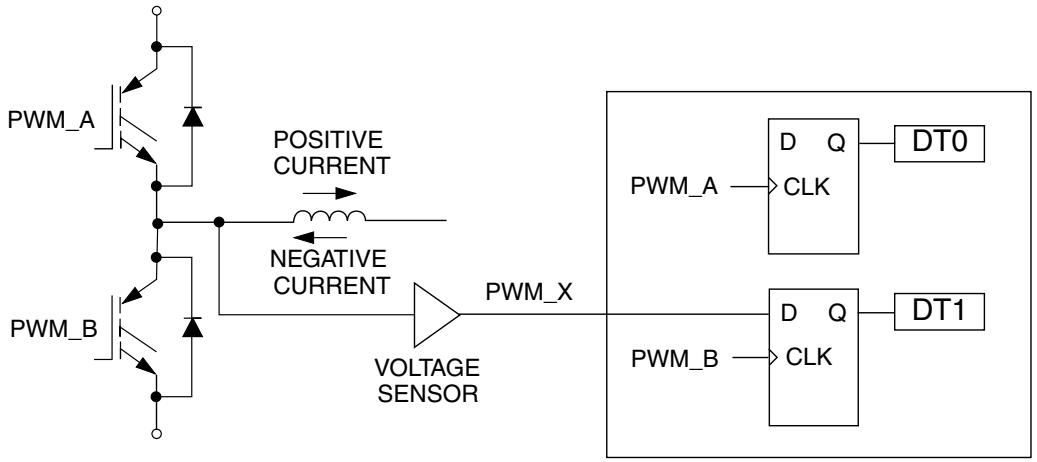

Figure 293. Current-status sense scheme for deadtime correction

Both D flip-flops latch low, CTRL[DT] = 00, during deadtime periods if the current is large and flowing out of the complementary circuit. See the preceding figure. Both D flip-flops latch the high, CTRL[DT] = 11, during deadtime periods if the current is also large and flowing into the complementary circuit.

However, under low-current, the output voltage of the complementary circuit during deadtime is between the high and low levels. The current cannot free-wheel through the opposition anti-body diode, regardless of polarity, giving additional distortion when the current crosses zero. Sampled results are CTRL[DT] = b10. Thus, the best time to change one PWM value register to another is just before the current zero crossing.

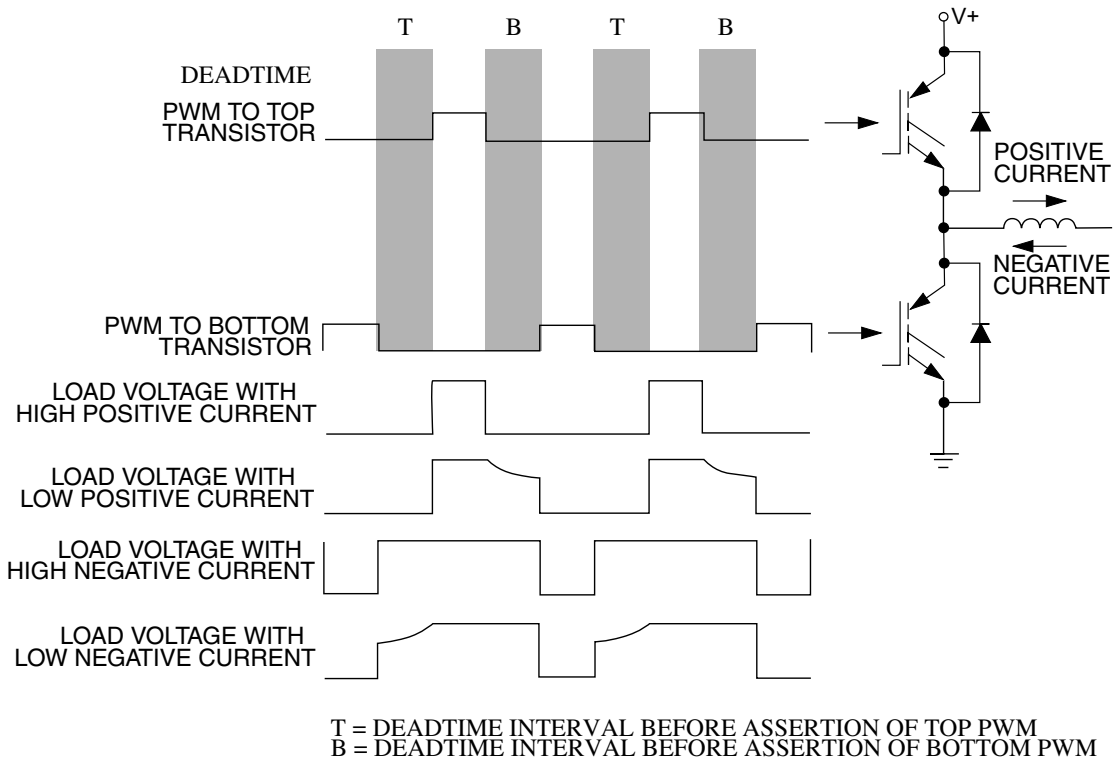

Figure 294. Output voltage waveforms

54.3.3.8 Fractional delay logic

For applications where more resolution than a single IPBus clock period is needed, the fractional delay logic can be used to achieve fine resolution on the rising and falling edges of the PWM_A and PWM_B outputs. Enable the use of the fractional delay logic by setting FRCTRL[FRACx_EN]. The FRACVALx registers act as a fractional clock cycle addition to the turn-on and turn-off count specified by the VAL2, VAL3, VAL4, or VAL5 registers. The FRACVAL1 register acts as a fractional increase in the PWM period as defined by VAL1. If FRACVAL1 is programmed to a non-zero value, then the largest value for the VAL1 register is 0xFFFE for unsigned usage or 0x7FFE for signed usage. This limit is required to avoid counter rollovers when accumulating the fractional additional period.

Both the fractional enables (1, 23, 45) and the fractional values (1-5) are double buffered and reloaded at the same time as the value registers.

Each PWM cycle, the value compare point is increased by 1 when there is overflow on the double buffered value of the fractional register plus the 5-bit accumulated fractional value. The accumulated fractional value starts at zero, so it is impossible to overflow the first PWM cycle.

At the end of each PWM cycle, if the corresponding fractional enable is set then the accumulated fractional value increments by the fractional value (double buffered value). The accumulated fractional value is 5-bits, so in the case of overflow only the remainder is kept. If the corresponding fractional enable is clear, then the accumulated fractional value is reset. This is the only way to reset the accumulated fractional value.

The accumulated fractional values are not accessible to software.

To fine-tune the PWM period using the FRACVAL1 register, if you want a period of 100.25 clock cycles, program VAL1 with 0x0064 and FRACVAL1 with 0x4000. The fractional value will accumulate so that every 4 PWM cycles will be 1 clock cycle longer (101 instead of 100). The rising and falling edges of the PWM outputs will also use the accumulated fraction to delay their edges and maintain a consistent 100.25 cycles spacing between corresponding edges from one cycle to the next.

The results of the fractional delay logic depend on whether or not the PWM submodule has an analog NanoEdge placer block available. With fractional delay enabled, PWM works in digital dithering mode: the value of FRACVALx is accumulated in each PWM period; when the accumulated value of FRACVALx overflows, VALx increments one in the next PWM period.

54.3.3.8.1 Fractional delay logic without NanoEdge placement block

For submodules that are not supported by the NanoEdge placer, the PWM can use dithering to simulate fine edge control. Enable this feature by setting the FRCTRL[FRAC1_EN], FRCTRL[FRAC23_EN], and FRCTRL[FRAC45_EN] bits. The PWM period or the PWM edges will dither from the nearest whole number values to achieve an average value that is equivalent to the programmed fractional value. The added cycles are based on the accumulation of the fractional component. For example, if you want the PWM period to be 50.25 clock cycles, then program VAL1 with 0x0032 and FRACVAL1 with 0x4000. The PWM period will be 50 cycles long most of the time, but will occasionally be 51 cycles long to achieve a long-term average of 50.25 cycles.

In submodules that are not supported by a NanoEdge placer, the clock frequency is not required to be any specific value to achieve proper operation.

54.3.3.9 Output logic

The following figure shows the output logic of each submodule including how each PWM output has individual fault disabling, polarity control, and output enable. This allows for maximum flexibility when interfacing with the external circuitry.

The PWM23 and PWM45 signals which are output from the deadtime logic (as shown in Figure 295) are positive true signals. In other words, a high level on these signals should result in the corresponding transistor in the PWM inverter being turned ON. The voltage level required at the PWM output pin to turn the transistor ON or OFF is a function of the logic between the pin and the transistor. Therefore, it is imperative that the user program OCTRL[POLA] and OCTRL[POLB] before enabling the output pins. A fault condition can result in the PWM output being put in a high-impedance state, forced to a logic 1 state, or forced to a logic 0 state, depending on the values programmed into the OCTRL[PWMxFS] fields.

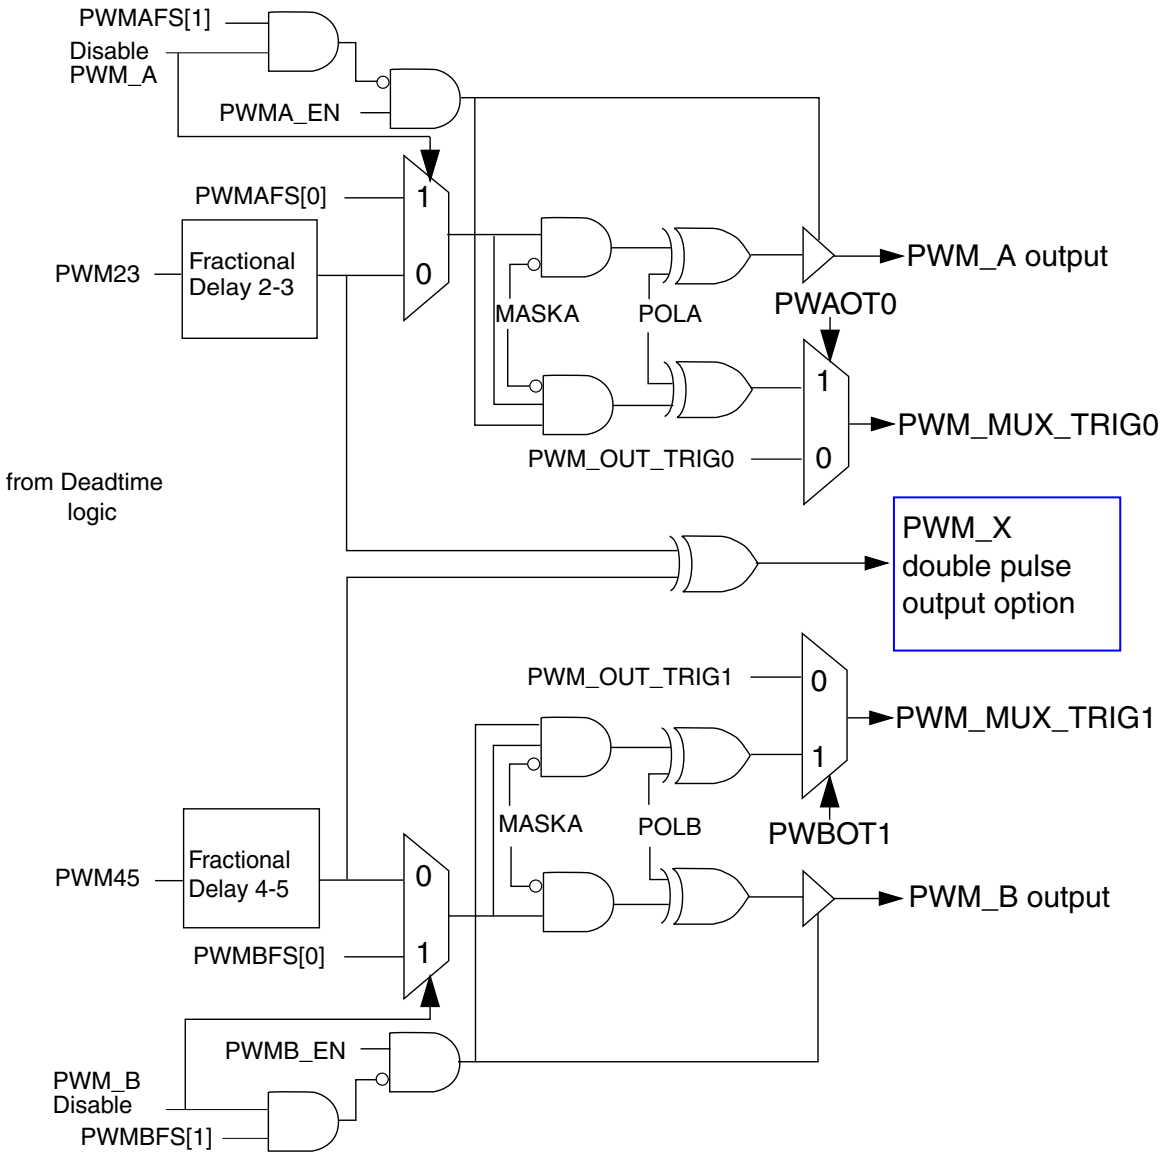

Figure 295. Output logic for each submodule

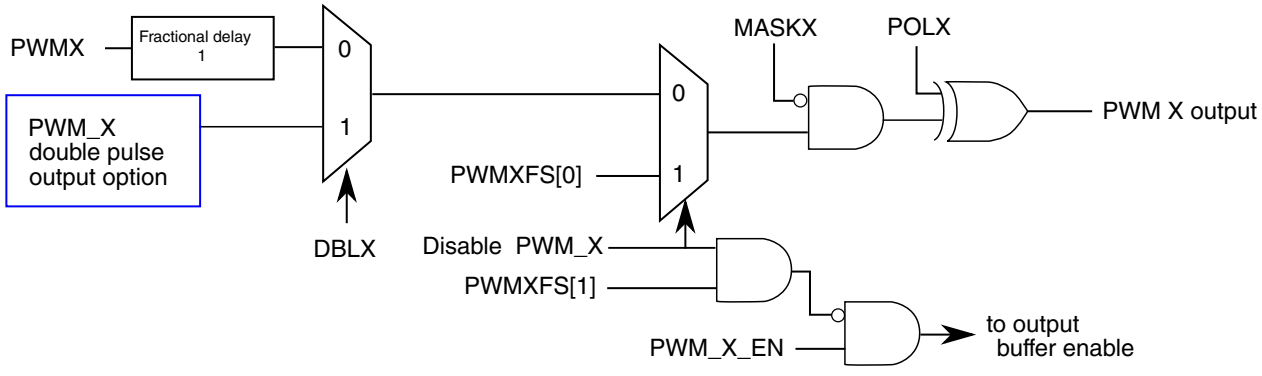

Figure 296. Output logic continued

54.3.3.10 E-Capture

The Enhanced Capture (E-Capture) logic is designed to measure both edges of an input signal. As a result, when a submodule pin is configured for input capture, the CVALx registers associated with that pin are used to record the edge values.

The following figure shows block diagram of the E-Capture circuit. Upon entering the pin input, the signal is split into two paths. One goes straight to a mux input where software can select to pass the signal directly to the capture logic for processing. The other path connects the signal to an 8-bit counter which counts both the rising and falling edges of the signal. The output of this counter is compared to an 8-bit value that is specified by the user (EDGCMPx) and when the two values are equal, the comparator generates a pulse that resets the counter. This pulse is also supplied to the mux input where software can select it to be processed by the capture logic. This feature permits the E-Capture circuit to count up to 256 edge events before initiating a capture event. This feature is useful for dividing down high frequency signals for capture processing so that capture interrupts do not overwhelm the CPU. Also, this feature can be used to generate an interrupt after "n" events have been counted.

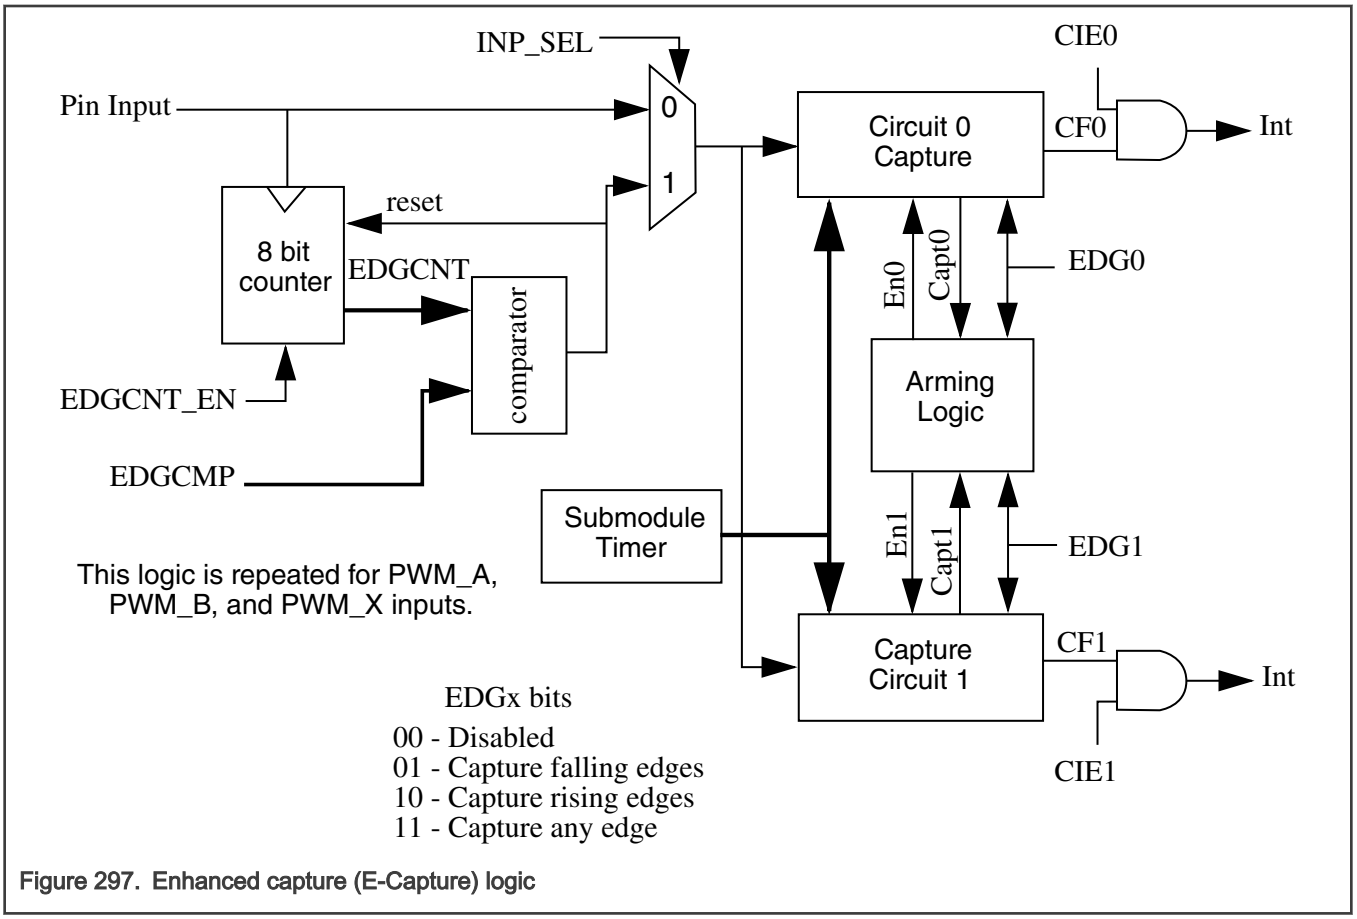

Figure 297. Enhanced capture (E-Capture) logic

Based on the mode selection, the mux selects either the pin input or the compare output from the count/compare circuit to be processed by the capture logic. The selected signal is routed to two separate capture circuits which work in tandem to capture sequential edges of the signal. The type of edge to be captured by each circuit is determined by CAPTCTRLx[EDGx1] and CAPTCTRLx[EDGx0], whose functionality is listed in the above figure. Also, controlling the operation of the capture circuits is the arming logic which allows captures to be performed in a free running (continuous) or one shot mode. In free running mode, the capture sequences will be performed indefinitely. If both capture circuits are enabled, they will work together in a ping-pong style where a capture event from one circuit leads to the arming of the other and vice versa. In one shot mode, only one capture sequence will be performed. If both capture circuits are enabled, capture circuit 0 is first armed and when a capture event occurs, capture circuit 1 is armed. Once the second capture occurs, further captures are disabled until another capture sequence is initiated. Both capture circuits are also capable of generating an interrupt to the CPU.

54.3.3.11 Fault protection

Fault protection can control any combination of PWM output pins. Faults are generated by a logic one on any of the FAULTx pins. This polarity can be changed via FCTRL[FLVL]. Each FAULTx pin can be mapped arbitrarily to any of the PWM outputs. When fault protection hardware disables PWM outputs, the PWM generator continues to run, only the output pins are forced to logic 0, logic 1, or high impedance depending on the values of OCTRL[PWMxFS].

The fault decoder disables PWM pins selected by the fault logic and the disable mapping (DISMAPn) registers. The following figure shows an example of the fault disable logic. Each bank of bits in DISMAPn control the mapping for a single PWM pin. See the following table.

The fault protection is enabled even when the PWM module is not enabled. Therefore, a fault is latched in and must be cleared to prevent an interrupt when the PWM is enabled.

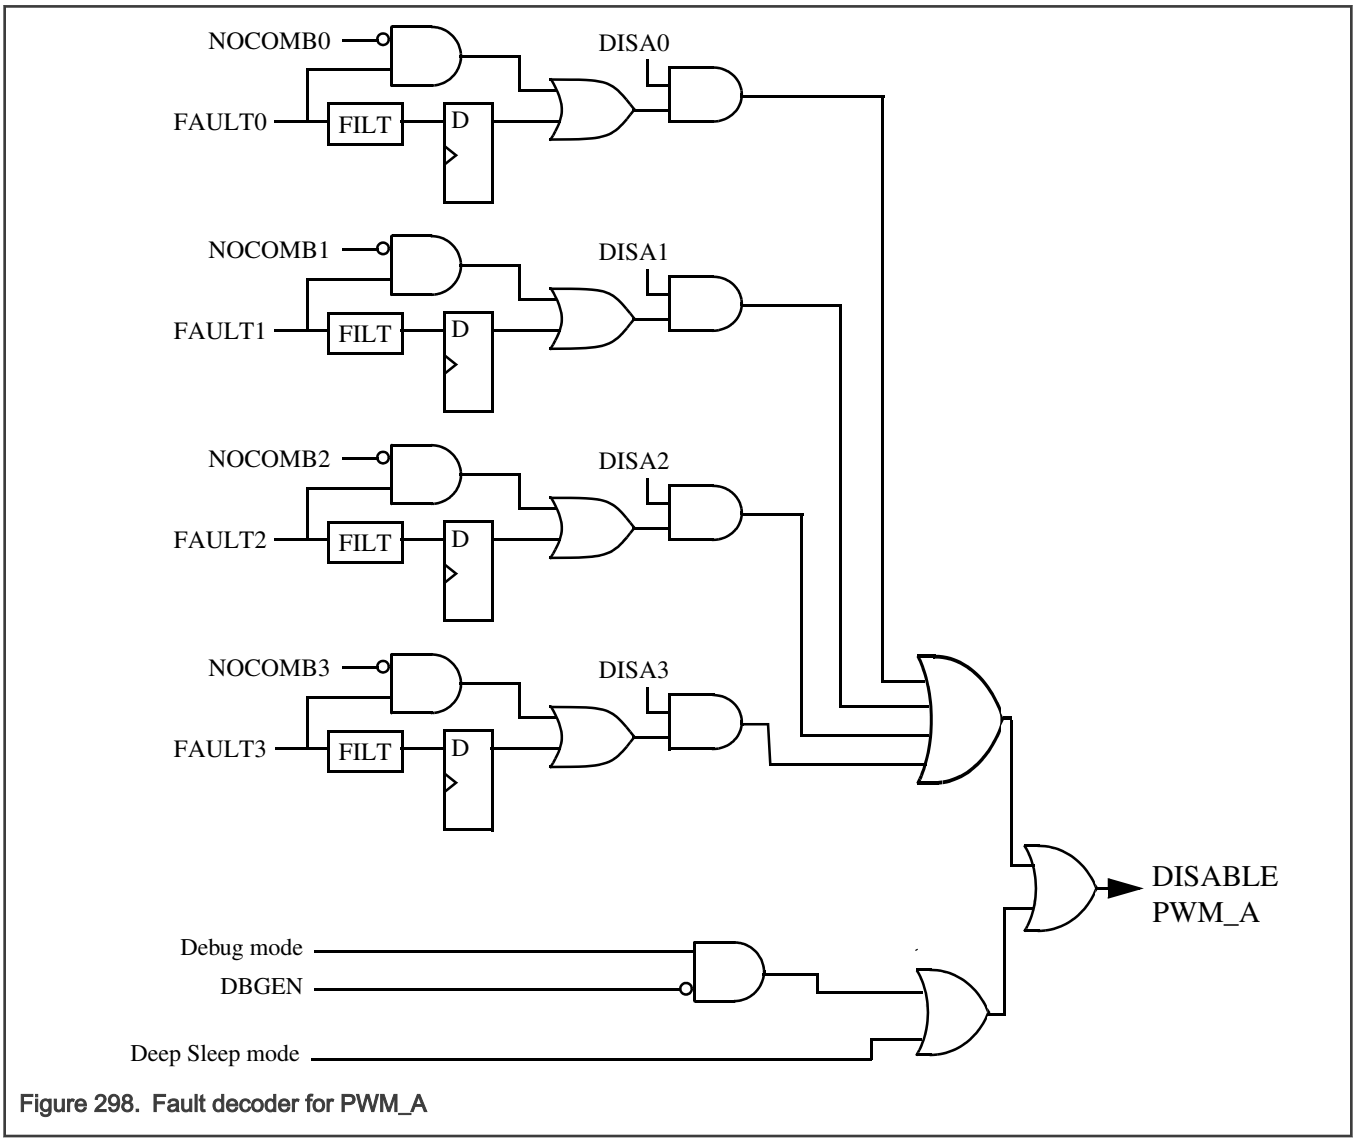

Figure 298. Fault decoder for PWM_A

Table 446. Fault Mapping

PWM Pin for 1 submodule	Controlling Register Bits
PWM_A	DISMAP0[DIS0A]

Table continues on the next page...

Table 446. Fault Mapping (continued)

PWM Pin for 1 submodule	Controlling Register Bits
PWM_B	DISMAP0[DIS0B]
PWM_X	DISMAP0[DIS0X]

54.3.3.11.1 Fault pin filter

Each fault pin has a programmable filter that can be bypassed. The sampling period of the filter can be adjusted with FFILT[FILT_PER]. The number of consecutive samples that must agree before an input transition is recognized can be adjusted using FFILT[FILT_CNT]. Setting FFILT[FILT_PER] to all 0 disables the input filter for a given FAULTx pin.

Upon detecting a logic 0 on the filtered FAULTx pin (or a logic 1 if FCTRL[FLVLx] is set), the corresponding FSTS[FFPINx] and FSTS[FFLAGx] bits are set. FSTS[FFPINx] remains set as long as the filtered FAULTx pin is zero. Clear FSTS[FFLAGx] by writing a logic 1 to FSTS[FFLAGx].

If the FIEx, FAULTx pin interrupt enable bit is set, FSTS[FFLAGx] generates a CPU interrupt request. The interrupt request latch remains set until:

- Software clears FSTS[FFLAGx] by writing a logic one to the bit
- Software clears the FIEx bit by writing a logic zero to it
- A reset occurs

Even with the filter enabled, there is a combinational path from the FAULTx inputs to the PWM pins, which in turn bypasses the filter when FCTRL20[NOCOMBx] = 0. This logic is also capable of holding a fault condition in the event of loss of clock to the PWM module.

54.3.3.11.2 Automatic fault clearing

Setting an automatic clearing mode bit, FCTRL[FAUTOx] configures faults from the FAULTx pin for automatic clearing.

When FCTRL[FAUTOx] is set, disabled PWM pins are enabled when the FAULTx pin returns to logic one and a new PWM full or half cycle begins. See the following figure. If FSTS[FFULLx] is set and the fault condition on FAULTx disappears, then the disabled PWM pins are enabled at the start of next full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle. Clearing FSTS[FFLAGx] does not affect disabled PWM pins when FCTRL[FAUTOx] is set.

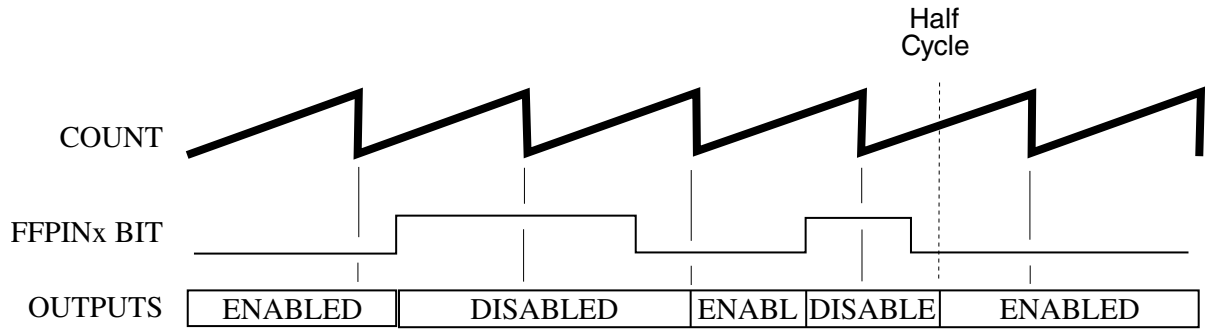

Figure 299. Automatic fault clearing

54.3.3.11.3 Manual fault clearing

Clearing the automatic clearing mode bit, FCTRL[FAUTOx], configures faults from the FAULTx pin for manual clearing:

- If the fault safety mode bits FCTRL[FSAFEx] are clear, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FSTS[FFLAGx] flag

— The pins are enabled when the next PWM full or half cycle begins regardless of the logic level detected by the filter at the FAULTx pin, as shown in Figure 300. If FSTS[FFULLx] is set, then the disabled PWM pins are enabled at the start of a full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle.

- If the fault safety mode bits FCTRL[FSAFEx] are set, then PWM pins disabled by the FAULTx pins are enabled when:
  — Software clears the corresponding FSTS[FFLAGx] flag
  — The filter detects a logic zero on the FAULTx pin at the start of the next PWM full or half cycle boundary, as shown in Figure 301. If FSTS[FFULLx] is set, then the disabled PWM pins are enabled at the start of a full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle.

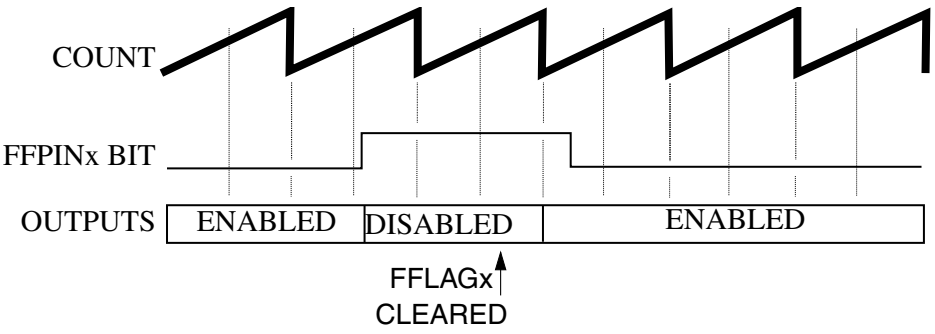

Figure 300. Manual fault clearing (FCTRL[FSAFEx] = 0, FSTS[FFULLx] = 1)

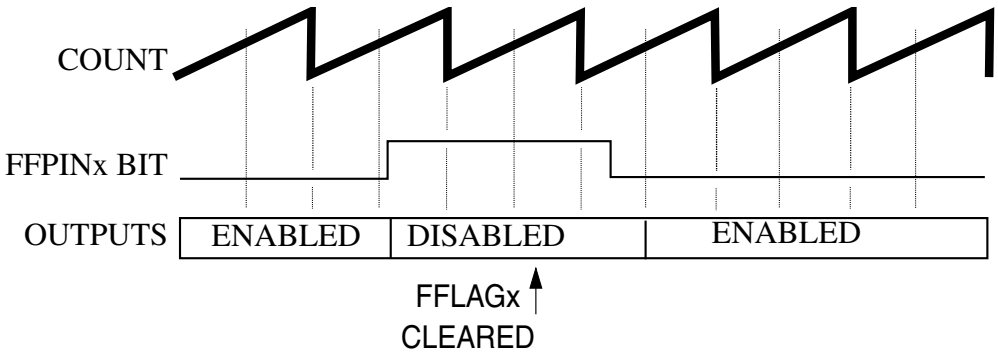

Figure 301. Manual fault clearing (FCTRL[FSAFEx] = 1, FSTS[FHALFx] = 1)

NOTE

Fault protection also applies during software output control when the SEL23 and SEL45 fields are set to select OUT23 and OUT45 bits or PWM_EXTA. Fault clearing still occurs at half or full PWM cycle boundaries while the PWM generator is engaged, MCTRL[RUN] equals one. But the OUTx bits can control the PWM pins while the PWM generator is off, MCTRL[RUN] equals zero. Thus, fault clearing occurs at IPBus cycles while the PWM generator is off and at the start of PWM cycles when the generator is engaged.

54.3.3.11.4 Fault testing

FTST[FTEST] is used to simulate a fault condition on each of the fault inputs within that fault channel.

54.3.3.12 PWM generator loading

54.3.3.12.1 Load enable

MCTRL[LDOK] enables loading of the following PWM generator parameters.

- The prescaler divisor: from CTRL[PRSC]

- The PWM period and pulse width: from the INIT, FRACVALx, and VALx registers

MCTRL[LDOK] allows the software to finish calculating all of these PWM parameters so they can be synchronously updated. The CTRL[PRSC], INIT, and VALx registers are loaded by software into a set of outer buffers. When MCTRL[LDOK] is set, these values are transferred to an inner set of registers at the beginning of the next PWM reload cycle to be used by the PWM generator when CTRL[LDMOD] is cleared. These values can be transferred to the inner set of registers immediately upon setting MCTRL[LDOK] if CTRL[LDMOD] is set. Set MCTRL[LDOK] by reading it when it is a logic zero and then writing a logic one to it. After loading, MCTRL[LDOK] is automatically cleared.

54.3.3.12.2 Load frequency

CTRL[LDFQ] selects an integral loading frequency of one to 16 PWM reload opportunities. CTRL[LDFQ] takes effect at every PWM reload opportunity, regardless of the state of MCTRL[LDOK]. CTRL[HALF] and CTRL[FULL] control reload timing. If CTRL[FULL] is set, a reload opportunity occurs at the end of every PWM cycle when the count equals VAL1. If CTRL[HALF] is set, a reload opportunity occurs at the half cycle when the count equals VAL0. If both CTRL[HALF] and CTRL[FULL] are set, a reload opportunity occurs twice per PWM cycle when the count equals VAL1 and when it equals VAL0.

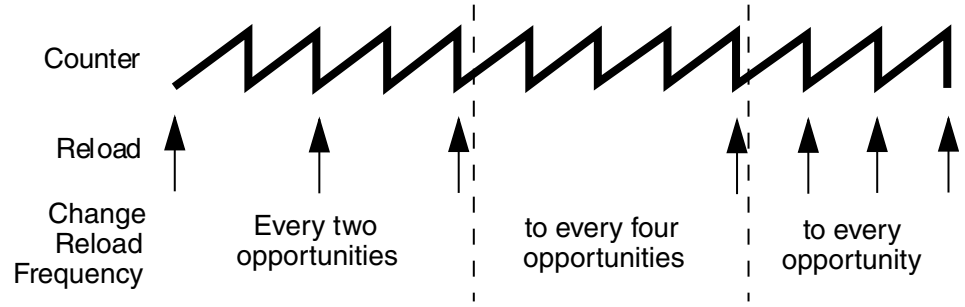

Figure 302. Full cycle reload frequency change

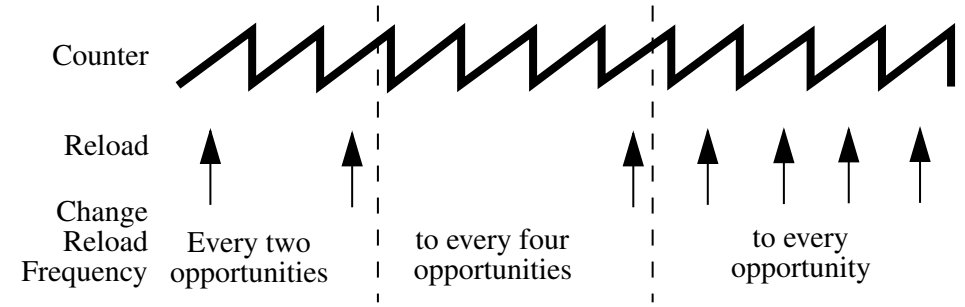

Figure 303. Half cycle reload frequency change

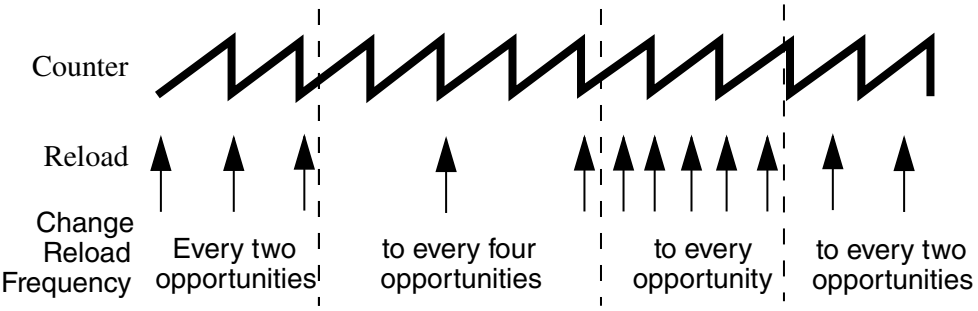

Figure 304. Full and half cycle reload frequency change

54.3.3.12.3 Reload flag

At every reload opportunity the PWM Reload Flag (STS[RF]) is set. Setting STS[RF] happens even if an actual reload is prevented by MCTRL[LDOK]. If the PWM reload interrupt enable bit INTEN[RIE] is set, the STS[RF] flag generates CPU interrupt requests allowing software to calculate new PWM parameters in real time. When INTEN[RIE] is not set, reloads still occur at the selected reload rate without generating CPU interrupt requests.

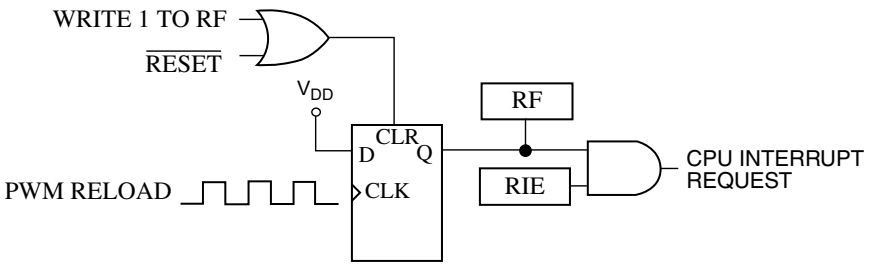

Figure 305. PWMF reload interrupt request

54.3.3.12.4 Reload errors

When one of the INIT, VALx, FRACVALx, or CTRL[PRSC] registers is updated (written by software), the STS[RUF] flag is set to indicate the data in the set of double buffered registers is not coherent. STS[RUF] is cleared by a successful reload which consists of the reload signal while MCTRL[LDOK] is set. If STS[RUF] is set and MCTRL[LDOK] is clear when the reload signal occurs, a reload error takes place and STS[REF] is set. If STS[RUF] is clear when a reload signal asserts, then the data is coherent and no error is flagged.

54.3.3.12.5 Initialization

Initialize all registers and then set MCTRL[LDOK] before setting MCTRL[RUN].

NOTE

If MCTRL[LDOK] is not set, setting MCTRL[RUN] also sets the STS[RF] flag. To prevent a CPU interrupt request, clear INTEN[RIE] before setting MCTRL[RUN].

The PWM generator uses the last values loaded if MCTRL[RUN] is cleared and then set while MCTRL[LDOK] equals zero.

When MCTRL[RUN] is cleared:

- The STS[RF] flag and pending CPU interrupt requests are not cleared
- All fault circuitry remains active
- Software/external output control remains active
- Deadtime insertion continues during software/external output control

54.3.4 Power modes

Be careful when using this module in Deep Sleep, Sleep, and Debug operating modes.

CAUTION

Some applications require regular software updates for proper operation. Failure to provide regular software updates could result in destroying the hardware setup.

To accommodate this situation, PWM outputs are placed in their inactive states in Deep Sleep mode, and they can optionally be placed in inactive states in Sleep and Debug modes. PWM outputs are reactivated (assuming they were active beforehand) when these modes are exited.

Table 447. Modes when PWM operation is restricted

Mode	Description
Deep Sleep	PWM outputs are inactive.
Debug	PWM outputs are driven or inactive as a function of CTRL2[DBGEN].

54.3.5 Clocking

Figure 306 shows the logic used to generate the main counter clock. Each submodule can select between three clock signals: the IPBus clock, EXT_CLK, and AUX_CLK. The EXT_CLK goes to all of the submodules. The AUX_CLK signal is broadcast from submodule0 and can be selected as the clock source by other submodules so that the 8-bit prescaler and MCTRL[RUN] from submodule0 can control all of the submodules.

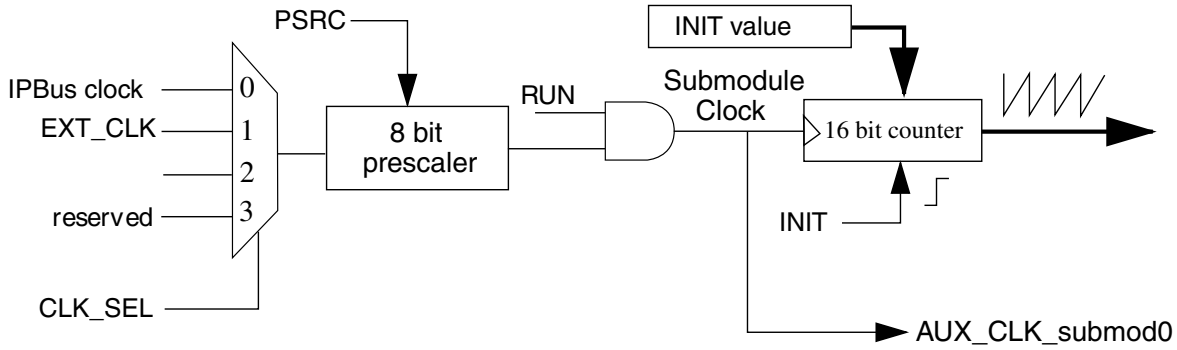

Figure 306. Clocking Block Diagram for PWM Submodule 0

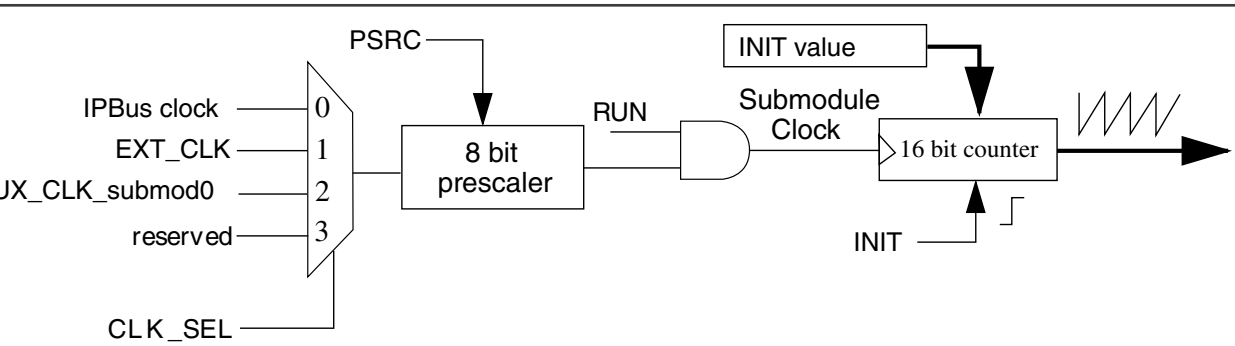

Figure 307. Clocking Block Diagram for all other PWM Submodules

To permit lower PWM frequencies, the prescaler produces the PWM clock frequency by dividing the IPBus clock frequency by 1-128. The prescaler bits, CTRL[PRSC], select the prescaler divisor. This prescaler is buffered and will not be used by the PWM generator until MCTRL[LDOK] is set and a new PWM reload cycle begins or CTRL[LDMOD] is set.

54.3.6 Resets

All PWM registers are reset to their default values upon any system reset.

The reset forces all registers to their reset states and tristates the PWM outputs.

54.3.7 Interrupts

Each of the submodules within the eFlexPWM module can generate an interrupt from several sources. The fault logic can also generate interrupts. The interrupt service routine (ISR) must check the related interrupt enables and interrupt flags to determine the actual cause of the interrupt.

Table 448. Interrupt Summary

Core Interrupt	Interrupt Flag	Interrupt Enable	Name	Description
PWM_CMP0	SM0STS[CMPF]	SM0INTEN[CMPIE]	Submodule 0 compare interrupt	Compare event has occurred
PWM_CAP0	SM0STS[CFA1], SM0STS[CFA0], SM0STS[CFB1], SM0STS[CFB0], SM0STS[CFX1], SM0STS[CFX0]	SM0INTEN[CFA1IE], SM0INTEN[CFA0IE], SM0INTEN[CFB1IE], SM0INTEN[CFB0IE], SM0INTEN[CFX1IE], SM0INTEN[CFX0IE]	Submodule 0 input capture interrupt	Input capture event has occurred
PWM_RELOAD0	SM0STS[RF]	SM0INTEN[RIE]	Submodule 0 reload interrupt	Reload event has occurred
PWM_CMP1	SM1STS[CMPF]	SM1INTEN[CMPIE]	Submodule 1 compare interrupt	Compare event has occurred
PWM_CAP1	SM1STS[CFA1], SM1STS[CFA0], SM1STS[CFB1], SM1STS[CFB0], SM1STS[CFX1], SM1STS[CFX0]	SM1INTEN[CFA1IE], SM1INTEN[CFA0IE], SM1INTEN[CFB1IE], SM1INTEN[CFB0IE], SM1INTEN[CFX1IE], SM1INTEN[CFX0IE]	Submodule 1 input capture interrupt	Input capture event has occurred
PWM_RELOAD1	SM1STS[RF]	SM1INTEN[RIE]	Submodule 1 reload interrupt	Reload event has occurred
PWM_CMP2	SM2STS[CMPF]	SM2INTEN[CMPIE]	Submodule 2 compare interrupt	Compare event has occurred
PWM_CAP2	SM2STS[CFA1], SM2STS[CFA0], SM2STS[CFB1], SM2STS[CFB0], SM2STS[CFX1], SM2STS[CFX0]	SM2INTEN[CFA1IE], SM2INTEN[CFA0IE], SM2INTEN[CFB1IE], SM2INTEN[CFB0IE], SM2INTEN[CFX1IE], SM2INTEN[CFX0IE	Submodule 2 input capture interrupt	Input capture event has occurred
PWM_RELOAD2	SM2STS[RF]	SM2INTEN[RIE]	Submodule 2 reload interrupt	Reload event has occurred

Table continues on the next page...

Table 448. Interrupt Summary (continued)

Core Interrupt	Interrupt Flag	Interrupt Enable	Name	Description
PWM_CMP3	SM3STS[CMPF]	SM3INTEN[CMPIE]	Submodule 3 compare interrupt	Compare event has occurred
PWM_CAP3	SM3STS[CFA1], SM3STS[CFA0], SM3STS[CFB1], SM3STS[CFB0], SM3STS[CFX1], SM3STS[CFX0]	SM3INTEN[CFA1IE], SM3INTEN[CFA0IE], SM3INTEN[CFB1IE], SM3INTEN[CFB0IE], SM3INTEN[CFX1IE], SM3INTEN[CFX0IE	Submodule 3 input capture interrupt	Input capture event has occurred
PWM_RELOAD3	SM3STS[RF]	SM3INTEN[RIE]	Submodule 3 reload interrupt	Reload event has occurred
PWM_RERR	SM0STS[REF]	SM0INTEN[REIE]	Submodule 0 reload error interrupt	Reload error has occurred
	SM1STS[REF]	SM1INTEN[REIE]	Submodule 1 reload error interrupt	
	SM2STS[REF]	SM2INTEN[REIE]	Submodule 2 reload error interrupt	
	SM3STS[REF]	SM3INTEN[REIE]	Submodule 3 reload error interrupt	
PWM_FAULT	FSTS[FFLAG]	FCTRL[FIE]	Fault input interrupt	Fault condition has been detected

54.3.8 DMA

Each submodule can request a DMA read access for its capture FIFOs and a DMA write request for its double buffered registers.

Table 449. DMA summary

DMA request	DMA enable	Name	Description
Submodule 0 read request	SM0DMAEN[CX0DE]	SM0 Capture FIFO X0 read request	SM0CVAL0 contains a value to be read
Submodule 0 read request	SM0DMAEN[CX1DE]	SM0 Capture FIFO X1 read request	SM0CVAL1 contains a value to be read
Submodule 0 read request	SM0DMAEN[CA0DE]	SM0 Capture FIFO A0 read request	SM0CVAL2 contains a value to be read
Submodule 0 read request	SM0DMAEN[CA1DE]	SM0 Capture FIFO A1 read request	SM0CVAL3 contains a value to be read

Table continues on the next page...

Table 449. DMA summary (continued)

DMA request	DMA enable	Name	Description
Submodule 0 read request	SM0DMAEN[CB0DE]	SM0 Capture FIFO B0 read request	SM0CVAL4 contains a value to be read
Submodule 0 read request	SM0DMAEN[CB1DE]	SM0 Capture FIFO B1 read request	SM0CVAL5 contains a value to be read
Submodule 0 read request	SM0DMAEN[CAPTDE]	SM0 Capture FIFO read request source select	Selects source of submodule0 read DMA request
Submodule 0 write request	SM0DMAEN[VALDE]	SM0VALx write request	SM0VALx and SM0FRACVALx registers need to be updated
Submodule 1 read request	SM1DMAEN[CX0DE]	SM1 Capture FIFO X0 read request	SM1CVAL0 contains a value to be read
Submodule 1 read request	SM1DMAEN[CX1DE]	SM1 Capture FIFO X1 read request	SM1CVAL1 contains a value to be read
Submodule 1 read request	SM1DMAEN[CA0DE]	SM1Capture FIFO A0 read request	SM1CVAL2 contains a value to be read
Submodule 1 read request	SM1DMAEN[CA1DE]	SM1 Capture FIFO A1 read request	SM1CVAL3 contains a value to be read
Submodule 1 read request	SM1DMAEN[CB0DE]	SM1 Capture FIFO B0 read request	SM1CVAL4 contains a value to be read
Submodule 1 read request	SM1DMAEN[CB1DE]	SM1 Capture FIFO B1 read request	SM1CVAL5 contains a value to be read
Submodule 1 read request	SM1DMAEN[CAPTDE]	SM1 Capture FIFO read request source select	Selects source of submodule1 read DMA request
Submodule 1 write request	SM1DMAEN[VALDE]	SM1VALx write request	SM1VALx and SM1FRACVALx registers need to be updated
Submodule 2 read request	SM2DMAEN[CX0DE]	SM2 Capture FIFO X0 read request	SM2CVAL0 contains a value to be read
Submodule 2 read request	SM2DMAEN[CX1DE]	SM2 Capture FIFO X1 read request	SM2CVAL1 contains a value to be read
Submodule 2 read request	SM2DMAEN[CA0DE]	SM2 Capture FIFO A0 read request	SM2CVAL2 contains a value to be read
Submodule 2 read request	SM2DMAEN[CA1DE]	SM2 Capture FIFO A1 read request	SM2CVAL3 contains a value to be read
Submodule 2 read request	SM2DMAEN[CB0DE]	SM2 Capture FIFO B0 read request	SM2CVAL4 contains a value to be read

Table continues on the next page...

Table 449. DMA summary (continued)

DMA request	DMA enable	Name	Description
Submodule 2 read request	SM2DMAEN[CB1DE]	SM2 Capture FIFO B1 read request	SM2CVAL5 contains a value to be read
Submodule 2 read request	SM2DMAEN[CAPTDE]	SM2 Capture FIFO read request source select	Selects source of submodule2 read DMA request
Submodule 2 write request	SM2DMAEN[VALDE]	SM2VALx write request	SM2VALx and SM2FRACVALx registers need to be updated
Submodule 3 read request	SM3DMAEN[CX0DE]	SM3 Capture FIFO X0 read request	SM3CVAL0 contains a value to be read

Submodule 3 read request	SM3DMAEN[CB1DE]	SM3 Capture FIFO B1 read request	SM3CVAL5 contains a value to be read
Submodule 3 read request	SM3DMAEN[CAPTDE]	SM3 Capture FIFO read request source select	Selects source of submodule3 read DMA request
Submodule 3 write request	SM3DMAEN[VALDE]	SM3VALx write request	SM3VALx and SM3FRACVALx registers need to be updated

54.4 External signals

The PWM has pins named PWM_An, PWM_Bn, PWM_Xn, FAULTn, EXT_SYNC, EXT_FORCE, and PWMn_EXTA. The PWM also has an on-chip input called EXT_CLK and output signals called PWMn_OUT_TRIGx and PWMn_MUX_TRIGx.

54.4.1 PWM_An and PWM_Bn - External PWM output pair

These pins are the output pins of the PWM channels. These pins can be independent PWM signals or a complementary pair. When not needed as an output, they can be used as inputs to the input capture circuitry.

54.4.2 PWM_Xn - Auxiliary PWM output signal

These pins are the auxiliary output pins of the PWM channels. They can be independent PWM signals. When not needed as an output, they can be used as inputs to the input capture circuitry or used to detect the polarity of the current flowing through the complementary circuit at deadtime correction.

54.4.3 FAULTn - Fault Inputs

These are input pins for disabling selected PWM outputs.

54.4.4 EXT_SYNC - External synchronization signal

These input signals allow a source external to the PWM to initialize the PWM counter. Therefore, the PWM can be synchronized to external circuitry.

54.4.5 EXT_FORCE - External output force signal

This input signal allows a source external to the PWM to force an update of the PWM outputs. Therefore, the PWM can be synchronized to external circuitry.

54.4.6 PWMn_EXTA - Alternate PWM control signals

These pins allow an alternate source to control the PWM_An and PWM_Bn outputs. Typically, the PWMn_EXTA input (depending on the state of MCTRL[IPOL]) is used for the generation of a complementary pair. Typical control signals include ADC conversion high/low limits, TMR outputs, GPIO inputs, and comparator outputs.

For pin input details, see chip-specific eFlexPWM information.

54.4.7 PWMn_OUT_TRIG0 and PWMn_OUT_TRIG1 - Output triggers

These outputs allow the PWM submodules to control timing of ADC conversions. See the description of the SMnTCTRL[OUT_TRIG_EN] for information about how to enable these outputs and how the compare registers match up to the output triggers.

54.4.8 PWM[n]_MUX_TRIG0 and PWM[n]_MUX_TRIG1 - Output triggers

These outputs can be either PWMn_OUT_TRIG0/PWMn_OUT_TRIG1 signals or PWM_A/PWM_B signals from output logic. See the description of the PWAOT0 and PWBOT1 bits in the Output Trigger Control Register for information about how to enable these outputs.

54.4.9 EXT_CLK - External clock signal

This signal allows a source external to the PWM (typically a timer or an off-chip source) to control the PWM clocking. Therefore, the PWM can be synchronized to the timer, or multiple chips can be synchronized to each other.

54.5 PWM register descriptions

The address of a register is the sum of a base address and an address offset. The base address is defined at the core level, and the address offset is defined at the module level. The PWM module has a set of registers for each PWM submodule, for the configuration logic, and for each fault channel.

NOTE

While the registers are 16-bit wide, they can be accessed in pairs as 32-bit registers, if the pairs are word-aligned.

Submodule registers are repeated for each PWM submodule. To designate which submodule that they are in, register names are prefixed with SMx(x=0,1...). The base address of submodule 0 is the same as the base address for the PWM module as a whole. The base address of submodule 1 is offset 0x60 from the base address for the PWM module as a whole. This 0x60 offset is based on the number of registers in a submodule. The base address of submodule 2 is equal to the base address of submodule 1 plus this same 0x60 offset. The pattern repeats for the base address of submodule 3.

The base address of the configuration registers is equal to the base address of the PWM module as a whole plus an offset of 0x180.

54.5.1 PWM memory map

PWM0 base address: 400C_E000h

PWM1 base address: 400D_0000h

54.5.2 Counter Register (SM0CNT - SM3CNT)

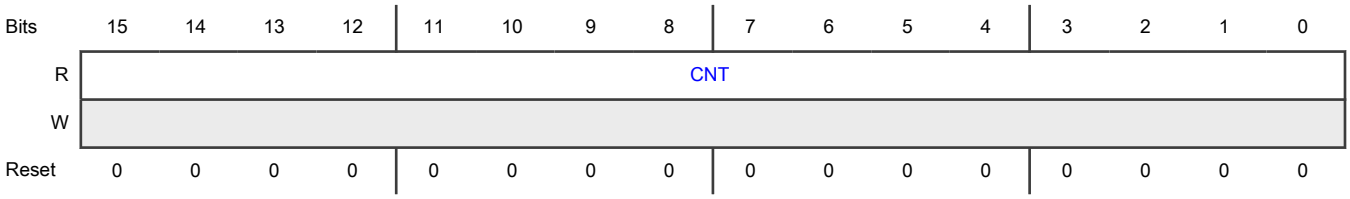
Offset

Register	Offset
SM0CNT	0h
SM1CNT	60h
SM2CNT	C0h
SM3CNT	120h

Function

This field displays the state of the signed 16-bit submodule counter. This register is not byte accessible. Writing this register generates bus transfer error.

Diagram



Fields

Field	Function
15-0 CNT	Counter Register Bits

54.5.3 Initial Count Register (SM0INIT - SM3INIT)

Offset

Register	Offset
SM0INIT	2h
SM1INIT	62h
SM2INIT	C2h
SM3INIT	122h

Function

The 16-bit signed value in this buffered register defines the initial count value for the PWM in PWM clock periods. This is the value loaded into the submodule counter when local sync, master sync, or master reload is asserted (based on the value of CTRL2[INIT_SEL]) or when CTRL2[FORCE] is asserted and force init is enabled. For PWM operation, the buffered contents of this register are loaded into the counter at the start of every PWM cycle. This register is not byte accessible.

NOTE

The INIT register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. This register cannot be written when MCTRL[LDOK] is set. Reading INIT reads the value in a buffer and not necessarily the value the PWM generator is currently using.

W										FORCE						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15 DBGEN	Debug Enable When set to one, the PWM continues to run while the chip is in Debug mode. If the device enters Debug mode and this bit is zero, then the PWM outputs are disabled until Debug mode is exited. At that point, the PWM pins resume operation as programmed in the PWM registers.
14 —	Reserved
13 INDEP	Independent or Complementary Pair Operation This bit determines if the PWM_A and PWM_B channels are independent PWMs or a complementary PWM pair. 0b - PWM_A and PWM_B form a complementary PWM pair. 1b - PWM_A and PWM_B outputs are independent PWMs.
12 PWM23_INIT	PWM23 Initial Value This bit determines the initial value for PWM23 and the value to which it is forced when FORCE_INIT is asserted.
11 PWM45_INIT	PWM45 Initial Value This bit determines the initial value for PWM45 and the value to which it is forced when FORCE_INIT is asserted.
10 PWMX_INIT	PWM_X Initial Value This bit determines the initial value for PWM_X and the value to which it is forced when FORCE_INIT is asserted.

Table continues on the next page...

Table continued from the previous page...

Field	Function
9-8 INIT_SEL	Initialization Control Select These bits control the source of the INIT signal which goes to the counter. 00b - Local sync (PWM_X) causes initialization. 01b - Master reload from submodule 0 causes initialization. This setting should not be used in submodule 0 as it forces the INIT signal to logic 0. The submodule counter will only re-initialize when a master reload occurs. 10b - Master sync from submodule 0 causes initialization. This setting should not be used in submodule 0 as it forces the INIT signal to logic 0. 11b - EXT_SYNC causes initialization.
7 FRCEN	Force Enable This bit allows the CTRL2[FORCE] signal to initialize the counter without regard to the signal selected by CTRL2[INIT_SEL]. This is a software controlled initialization. A forced initialization will also assert the register reload if MCTRL[LDOK] is set. 0b - Initialization from a FORCE_OUT is disabled. 1b - Initialization from a FORCE_OUT is enabled.
6 FORCE	Force Initialization If CTRL2[FORCE_SEL] is set to 000, writing a 1 to this bit results in a FORCE_OUT event. This causes the following actions to be taken: • The PWM_A and PWM_B output pins assume values based on DTSRCSEL[SMxSEL23] and DTSRCSEL[SMxSEL45]. • If CTRL2[FRCEN] is set, the counter value is initialized with the INIT register value only when the submodule MCTRL[RUN] = 1 or CTRL2[CLK_SEL] = 2.
5-3 FORCE_SEL	Force Select This bit determines the source of the FORCE OUTPUT signal for this submodule. 000b - The local force signal, CTRL2[FORCE], from this submodule is used to force updates. 001b - The master force signal from submodule 0 is used to force updates. This setting should not be used in submodule 0 as it holds the FORCE OUTPUT signal to logic 0. 010b - The local reload signal from this submodule is used to force updates without regard to the state of LDOK. 011b - The master reload signal from submodule0 is used to force updates if LDOK is set. This setting should not be used in submodule0 as it holds the FORCE OUTPUT signal to logic 0. 100b - The local sync signal from this submodule is used to force updates. 101b - The master sync signal from submodule0 is used to force updates. This setting should not be used in submodule0 as it holds the FORCE OUTPUT signal to logic 0. 110b - The external force signal, EXT_FORCE, from outside the PWM module causes updates. 111b - The external sync signal, EXT_SYNC, from outside the PWM module causes updates.

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 RELOAD_SEL	Reload Source Select This bit determines the source of the RELOAD signal for this submodule. When this bit is set, MCTRL[LDOK[0]] for submodule 0 should be used since the local MCTRL[LDOK] will be ignored. 0b - The local RELOAD signal is used to reload registers. 1b - The master RELOAD signal (from submodule 0) is used to reload registers. This setting should not be used in submodule 0 as it forces the RELOAD signal to logic 0.
1-0 CLK_SEL	Clock Source Select These bits determine the source of the clock signal for this submodule. 00b - The IPBus clock is used as the clock for the local prescaler and counter. 01b - EXT_CLK is used as the clock for the local prescaler and counter. 10b - Submodule 0's clock (AUX_CLK) is used as the source clock for the local prescaler and counter. This setting should not be used in submodule 0 as it forces the clock to logic 0. 11b - Reserved

54.5.5 Control Register (SM0CTRL - SM3CTRL)

Offset

Register	Offset
SM0CTRL	6h
SM1CTRL	66h
SM2CTRL	C6h
SM3CTRL	126h

Function
Includes control settings for timing, loading, and buffering.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LDFQ				HALF	FULL	DT		COMP MODE	PRSC			SPLIT	LDMOD	DBLX	DBLEN
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-12 LDFQ	Load Frequency These buffered bits select the PWM load frequency. Reset clears LDFQ, selecting loading every PWM opportunity. A PWM opportunity is determined by HALF and FULL. The register bits are write-protected by MCTRL2[WRPROT] bits. **NOTE** LDFQ takes effect when the current load cycle is complete, regardless of the state of MCTRL[LDOK]. Reading LDFQ reads the buffered values and not necessarily the values currently in effect. 0000b - Every PWM opportunity 0001b - Every 2 PWM opportunities 0010b - Every 3 PWM opportunities 0011b - Every 4 PWM opportunities 0100b - Every 5 PWM opportunities 0101b - Every 6 PWM opportunities 0110b - Every 7 PWM opportunities 0111b - Every 8 PWM opportunities 1000b - Every 9 PWM opportunities 1001b - Every 10 PWM opportunities 1010b - Every 11 PWM opportunities 1011b - Every 12 PWM opportunities 1100b - Every 13 PWM opportunities 1101b - Every 14 PWM opportunities 1110b - Every 15 PWM opportunities 1111b - Every 16 PWM opportunities
11 HALF	Half Cycle Reload This bit enables half-cycle reloads. A half cycle is defined by when the submodule counter matches the VAL0 register and does not have to be halfway through the PWM cycle. This bit is write-protected by MCTRL2[WRPROT] bits.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Half-cycle reloads disabled. 1b - Half-cycle reloads enabled.
10 FULL	Full Cycle Reload This bit enables full-cycle reloads. A full cycle is defined by when the submodule counter matches the VAL1 register. Either CTRL[HALF] or CTRL[FULL] must be set to move the buffered data into the registers used by the PWM generators or CTRL[LDMOD] must be set. If both CTRL[HALF] and CTRL[FULL] are set, then reloads can occur twice per cycle. This bit is write-protected by MCTRL2[WRPROT] bits. 0b - Full-cycle reloads disabled. 1b - Full-cycle reloads enabled.
9-8 DT	Deadtime These bits reflect the sampled values of the PWM_X input at the end of each deadtime. Sampling occurs at the end of deadtime 0 for DT[0] and the end of deadtime 1 for DT[1]. Reset clears these bits. The register bits are write-protected by MCTRL2[WRPROT] bits.
7 COMPMODE	Compare Mode This bit controls how comparisons are made between the VAL* registers and the PWM submodule counter. This bit can be written one time after which it requires a reset to release the bit for writing again. 0b - The VAL* registers and the PWM counter are compared using an "equal to" method. This means that PWM edges are only produced when the counter is equal to one of the VAL* register values. This implies that a PWM_A output that is high at the end of a period maintains this state until a match with VAL3 clears the output in the following period. 1b - The VAL* registers and the PWM counter are compared using an "equal to or greater than" method. This means that PWM edges are produced when the counter is equal to or greater than one of the VAL* register values. This implies that a PWM_A output that is high at the end of a period could go low at the start of the next period if the starting counter value is greater than (but not necessarily equal to) the new VAL3 value.
6-4 PRSC	Prescaler These buffered bits select the divide ratio of the PWM clock frequency selected by CTRL2[CLK_SEL]. **NOTE** Reading CTRL[PRSC] reads the buffered values and not necessarily the values currently in effect. CTRL[PRSC] takes effect at the beginning of the next PWM cycle and only when the load okay bit MCTRL[LDOK] is set, or CTRL[LDMOD] is set. This field cannot be written when MCTRL[LDOK] is set. 000b - Prescaler 1. PWM clock frequency = f_{clk} 001b - Prescaler 2. PWM clock frequency = f_{clk} /2 010b - Prescaler 4. PWM clock frequency = f_{clk} /4 011b - Prescaler 8. PWM clock frequency = f_{clk} /8

Table continues on the next page...

Table continued from the previous page...

Field	Function
	100b - Prescaler 16. PWM clock frequency = f_{clk} /16 101b - Prescaler 32. PWM clock frequency = f_{clk} /32 110b - Prescaler 64. PWM clock frequency = f_{clk} /64 111b - Prescaler 128. PWM clock frequency = f_{clk} /128
3 SPLIT	Split the DBLPWM signal to PWM_A and PWM_B This bit is used in independent mode when DBLEN is set. This bit allows the two PWM pulses generated by DBLEN to be split with one pulse on PWM_A and one on PWM_B. The two pulses within the same PWM period are created by an XOR function of the PWM_A and PWM_B sources. The splitting function causes PWM_A to output the pulse that occurs when the PWM_A source is 1 and the PWM_B source is 0. The PWM_B output occurs when the PWM_B source is 1 and the PWM_A source is 0. (See Double switching PWMs .) This bit is write-protected by MCTRL2[WRPROT] bits. 0b - DBLPWM is not split. PWM_A and PWM_B each have double pulses. 1b - DBLPWM is split to PWM_A and PWM_B.
2 LDMOD	Load Mode Select This bit selects the timing of loading the buffered registers for this submodule. This bit is write-protected by MCTRL2[WRPROT] bits. 0b - Buffered registers of this submodule are loaded and take effect at the next PWM reload if MCTRL[LDOK] is set. 1b - Buffered registers of this submodule are loaded and take effect immediately upon MCTRL[LDOK] being set. In this case, it is not necessary to set CTRL[FULL] or CTRL[HALF].
1 DBLX	PWM_X Double Switching Enable This bit enables the double switching behavior on PWM_X. When this bit is set, the PWM_X output shall be the exclusive OR combination of PWM_A and PWM_B prior to polarity and masking considerations. This bit is write-protected by MCTRL2[WRPROT] bits. 0b - PWM_X double pulse disabled. 1b - PWM_X double pulse enabled.
0 DBLEN	Double Switching Enable This bit enables the double switching PWM behavior (See Double switching PWMs). This bit is write-protected by MCTRL2[WRPROT] bits. 0b - Double switching disabled. 1b - Double switching enabled.

54.5.6 Value Register 0 (SM0VAL0 - SM3VAL0)

Offset

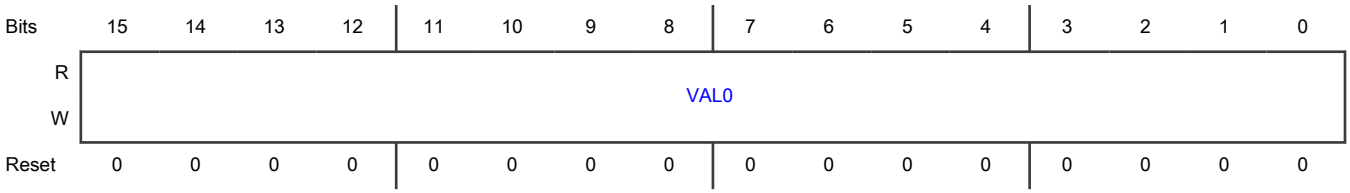
Register	Offset
SM0VAL0	Ah
SM1VAL0	6Ah
SM2VAL0	CAh
SM3VAL0	12Ah

Function

NOTE

The VAL0 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL0 cannot be written when MCTRL[LDOK] is set. Reading VAL0 reads the value in a buffer. It is not necessarily the value that the PWM generator is currently using.

Diagram



Fields

Field	Function
15-0 VAL0	Value 0 The 16-bit signed value in this buffered register defines the mid-cycle reload point for the PWM in PWM clock periods. This value also defines when the PWM_X signal is set and the local sync signal is reset. This register is not byte accessible. **NOTE** The actual behavior takes effect when counter equal VAL0+1.

54.5.7 Fractional Value Register 1 (SM0FRACVAL1 - SM3FRACVAL1)

Offset

Register	Offset
SM0FRACVAL1	Ch
SM1FRACVAL1	6Ch

Table continues on the next page...

Table continued from the previous page...

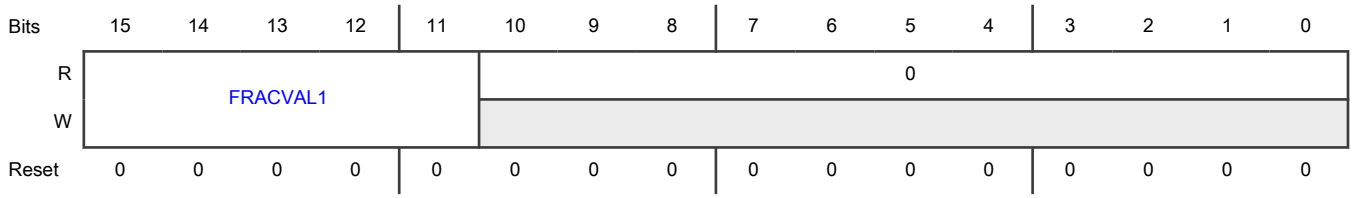
Register	Offset
SM2FRACVAL1	CCh
SM3FRACVAL1	12Ch

Function

NOTE

The FRACVAL1 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. FRACVAL1 cannot be written when MCTRL[LDOK] is set. Reading FRACVAL1 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Diagram



Fields

Field	Function
15-11 FRACVAL1	Fractional Value 1 These bits act as a fractional addition to the value in the VAL1 register which controls the PWM period. With fractional delay enabled, PWM works in digital dithering mode. The PWM period is computed in terms of IPBus clock cycles. This fractional portion is accumulated at the end of every cycle until an additional whole IPBus cycle is reached. At this time the value being used for VAL1 is temporarily incremented, and the PWM period is extended by one clock to compensate for the accumulated fractional values.
10-0 —	Reserved

54.5.8 Value Register 1 (SM0VAL1 - SM3VAL1)

Offset

Register	Offset
SM0VAL1	Eh
SM1VAL1	6Eh
SM2VAL1	CEh
SM3VAL1	12Eh

Function

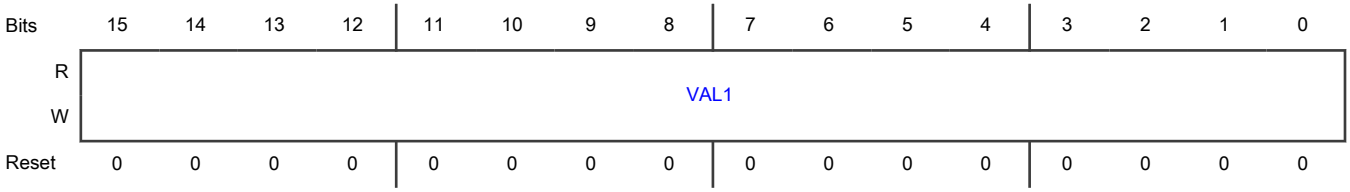
NOTE

The VAL1 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL1 cannot be written when MCTRL[LDOK] is set. Reading VAL1 reads the value in a buffer. It is not necessarily the value that the PWM generator is currently using.

When using FRACVAL1, limit the maximum value of VAL1 to 0xFFFE for unsigned applications or to 0x7FFE for signed applications, to avoid counter rollovers caused by accumulating the fractional period defined by FRACVAL1.

If the VAL1 register defines the timer period (Local Sync is selected as the counter initialization signal), a 100% duty cycle cannot be achieved on the PWM_X output. After the count reaches VAL1, the PWM_X output is low for a minimum of one count every cycle. When the Master Sync signal (only originated by the Local Sync from submodule 0) is used to control the timer period, the VAL1 register can be free for other functions such as PWM generation without the duty cycle limitation.

Diagram



Fields

Field	Function
15-0 VAL1	Value 1 The 16-bit signed value written to this buffered register defines the modulo count value (maximum count) for the submodule counter. When reaching this count value, the counter reloads itself with the contents of the INIT register and asserts the local sync signal while resetting PWM_X. This register is not byte accessible. **NOTE** The actual behavior takes effect when the counter equals VAL1+1.

54.5.9 Fractional Value Register 2 (SM0FRACVAL2 - SM3FRACVAL2)

Offset

Register	Offset
SM0FRACVAL2	10h
SM1FRACVAL2	70h
SM2FRACVAL2	D0h
SM3FRACVAL2	130h

Function

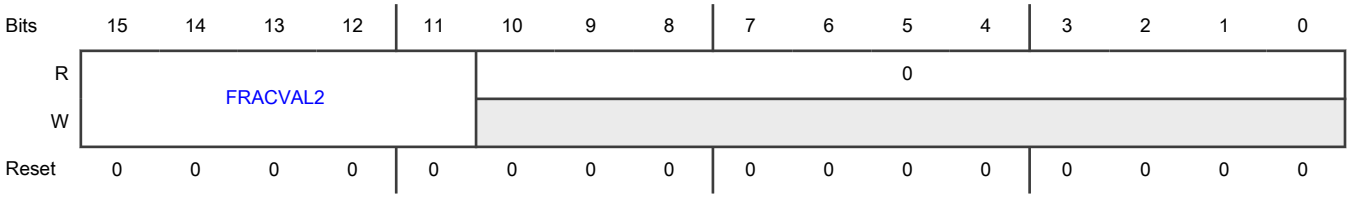
NOTE

The FRACVAL2 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. FRACVAL2 cannot be written when MCTRL[LDOK] is set. Reading FRACVAL2 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

NOTE

FRCTRL[FRAC23_EN] should be set to 0 when the values of VAL2 and VAL3 cause the high or low time of the PWM output to be 3 cycles or less.

Diagram



Fields

Field	Function
15-11 FRACVAL2	Fractional Value 2 These bits act as a fractional addition to the value in the VAL2 register which controls the PWM_A turn on timing. It is also used to control the fractional addition to the turn off delay of PWM_B when MCTRL[IPOLx]=0 in complementary mode, CTRL2[INDEP]=0. With fractional delay enabled, PWM works in digital dithering mode. The PWM_A turn on delay is computed in terms of IPBus clock cycles. This fractional portion is accumulated at the end of every cycle until an additional whole IPBus cycle is reached. At this time the value being used for VAL2 is temporarily incremented, and the PWM_A turn on delay is extended by one clock to compensate for the accumulated fractional values.
10-0 —	Reserved

54.5.10 Value Register 2 (SM0VAL2 - SM3VAL2)

Offset

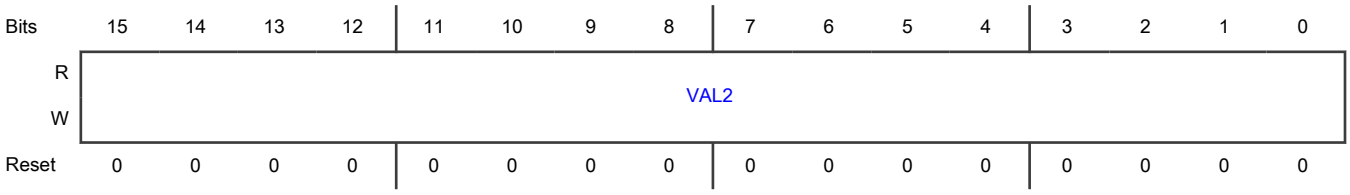
Register	Offset
SM0VAL2	12h
SM1VAL2	72h
SM2VAL2	D2h
SM3VAL2	132h

Function

NOTE

The VAL2 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL2 cannot be written when MCTRL[LDOK] is set. Reading VAL2 reads the value in a buffer and not necessarily the value that the PWM generator is currently using.

Diagram



Fields

Field	Function
15-0 VAL2	Value 2 The 16-bit signed value in this buffered register defines the count value to set PWM23 high. This register is not byte accessible. **NOTE** The actual behavior takes effect when the counter equals VAL2+1.

54.5.11 Fractional Value Register 3 (SM0FRACVAL3 - SM3FRACVAL3)

Offset

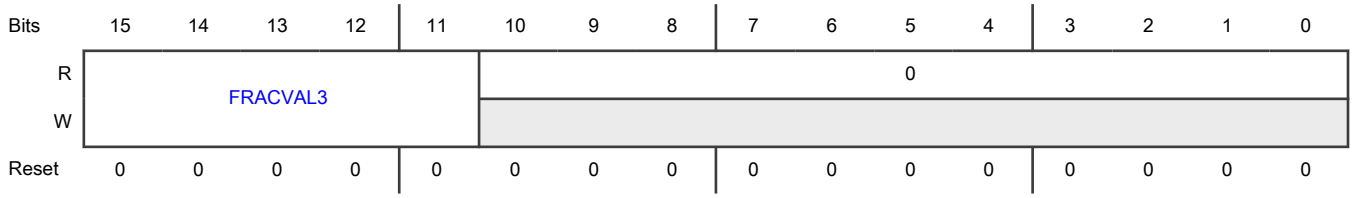
Register	Offset
SM0FRACVAL3	14h
SM1FRACVAL3	74h
SM2FRACVAL3	D4h
SM3FRACVAL3	134h

Function

NOTE

The FRACVAL3 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. FRACVAL3 cannot be written when MCTRL[LDOK] is set. Reading FRACVAL3 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Diagram



Fields

Field	Function
15-11 FRACVAL3	Fractional Value 3 These bits act as a fractional addition to the value in the VAL3 register which controls the PWM_A turn off timing. It is also used to control the fractional addition to the turn on delay of PWM_B when MCTRL[IPOLx]=0 in complementary mode, CTRL2[INDEP]=0. **NOTE** FRCTRL[FRAC23_EN] should be set to 0 when the values of VAL2 and VAL3 cause the high or low time of the PWM output to be 3 cycles or less. With fractional delay enabled, PWM works in digital dithering mode. The PWM_A turn off delay is computed in terms of IPBus clock cycles. This fractional portion is accumulated at the end of every cycle until an additional whole IPBus cycle is reached. At this time the value being used for VAL3 is temporarily incremented, and the PWM_A turn off delay is extended by one clock to compensate for the accumulated fractional values.
10-0 —	Reserved

54.5.12 Value Register 3 (SM0VAL3 - SM3VAL3)

Offset

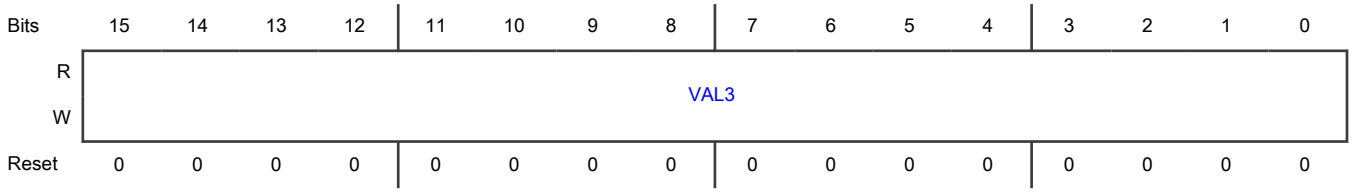
Register	Offset
SM0VAL3	16h
SM1VAL3	76h
SM2VAL3	D6h
SM3VAL3	136h

Function

NOTE

The VAL3 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL3 cannot be written when MCTRL[LDOK] is set. Reading VAL3 reads the value in a buffer and not necessarily the value that the PWM generator is currently using.

Diagram



Fields

Field	Function
15-0 VAL3	Value 3 The 16-bit signed value in this buffered register defines the count value to set PWM23 low. This register is not byte accessible. **NOTE** The actual behavior takes effect when the counter equals VAL3+1.

54.5.13 Fractional Value Register 4 (SM0FRACVAL4 - SM3FRACVAL4)

Offset

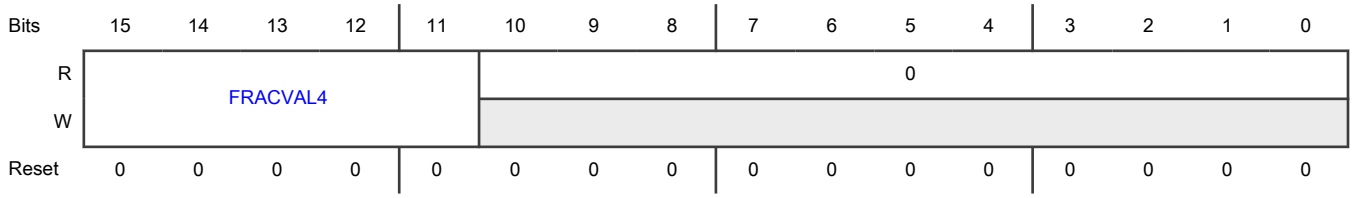
Register	Offset
SM0FRACVAL4	18h
SM1FRACVAL4	78h
SM2FRACVAL4	D8h
SM3FRACVAL4	138h

Function

NOTE

The FRACVAL4 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. FRACVAL4 cannot be written when MCTRL[LDOK] is set. Reading FRACVAL4 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Diagram



Fields

Field	Function
15-11 FRACVAL4	Fractional Value 4 These bits act as a fractional addition to the value in the VAL4 register which controls the PWM_B turn on timing. It is also used to control the fractional addition to the turn off delay of PWM_A when MCTRL[IPOLx]=1 in complementary mode, CTRL2[INDEP]=0. **NOTE** FRCTRL[FRAC45_EN] should be set to 0 when the values of VAL4 and VAL5 cause the high or low time of the PWM output to be 3 cycles or less. With fractional delay enabled, PWM works in digital dithering mode. The PWM_B turn on delay is computed in terms of IPBus clock cycles. This fractional portion is accumulated at the end of every cycle until an additional whole IPBus cycle is reached. At this time the value being used for VAL4 is temporarily incremented, and the PWM_B turn on delay is extended by one clock to compensate for the accumulated fractional values.

54.5.14 Value Register 4 (SM0VAL4 - SM3VAL4)

Offset

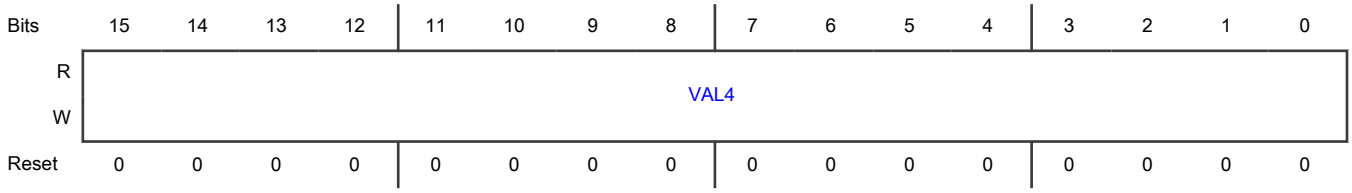
Register	Offset
SM0VAL4	1Ah
SM1VAL4	7Ah
SM2VAL4	DAh
SM3VAL4	13Ah

Function

NOTE

The VAL4 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL4 cannot be written when MCTRL[LDOK] is set. Reading VAL4 reads the value in a buffer and not necessarily the value that the PWM generator is currently using.

Diagram



Fields

Field	Function
15-0 VAL4	Value 4 The 16-bit signed value in this buffered register defines the count value to set PWM45 high. This register is not byte accessible. **NOTE** The actual behavior takes effect when the counter equals VAL4+1.

54.5.15 Fractional Value Register 5 (SM0FRACVAL5 - SM3FRACVAL5)

Offset

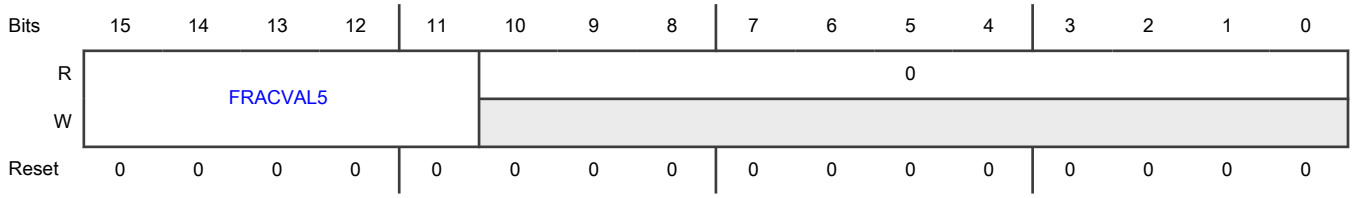
Register	Offset
SM0FRACVAL5	1Ch
SM1FRACVAL5	7Ch
SM2FRACVAL5	DCh
SM3FRACVAL5	13Ch

Function

NOTE

The FRACVAL5 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. FRACVAL5 cannot be written when MCTRL[LDOK] is set. Reading FRACVAL5 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Diagram



Fields

Field	Function
15-11 FRACVAL5	Fractional Value 5 These bits act as a fractional addition to the value in the VAL5 register which controls the PWM_B turn off timing. It is also used to control the fractional addition to the turn on delay of PWM_A when MCTRL[IPOLx]=1 in complementary mode, CTRL2[INDEP]=0. **NOTE** FRCTRL[FRAC45_EN] should be set to 0 when the values of VAL4 and VAL5 cause the high or low time of the PWM output to be 3 cycles or less. With fractional delay enabled, PWM works in digital dithering mode. The PWM_B turn off delay is computed in terms of IPBus clock cycles. This fractional portion is accumulated at the end of every cycle until an additional whole IPBus cycle is reached. Offset

Register	Offset
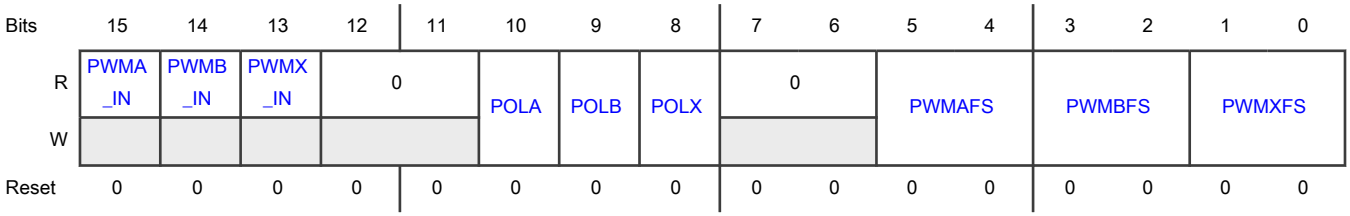
SM0OCTRL	22h
SM1OCTRL	82h
SM2OCTRL	E2h
SM3OCTRL	142h

Function

Contains output controls for fault states. This register is write-protected by MCTRL2[WRPROT] bits.

Diagram



Fields

Field	Function
15 PWMA_IN	PWM_A Input This bit shows the logic value currently being driven into the PWM_A input. The reset state is undefined.
14 PWMB_IN	PWM_B Input This bit shows the logic value currently being driven into the PWM_B input. The reset state is undefined.
13 PWMX_IN	PWM_X Input This bit shows the logic value currently being driven into the PWM_X input. The reset state is undefined.
12-11 —	Reserved
10 POLA	PWM_A Output Polarity This bit inverts the PWM_A output polarity. 0b - PWM_A output not inverted. A high level on the PWM_A pin represents the "on" or "active" state. 1b - PWM_A output inverted. A low level on the PWM_A pin represents the "on" or "active" state.
9 POLB	PWM_B Output Polarity This bit inverts the PWM_B output polarity. 0b - PWM_B output not inverted. A high level on the PWM_B pin represents the "on" or "active" state. 1b - PWM_B output inverted. A low level on the PWM_B pin represents the "on" or "active" state.
8 POLX	PWM_X Output Polarity This bit inverts the PWM_X output polarity. 0b - PWM_X output not inverted. A high level on the PWM_X pin represents the "on" or "active" state. 1b - PWM_X output inverted. A low level on the PWM_X pin represents the "on" or "active" state.
7-6 —	Reserved
5-4	PWM_A Fault State

Table continues on the next page...

Table continued from the previous page...

Field	Function
PWMAFS	These bits determine the fault state for the PWM_A output during fault conditions and Deep Sleep mode. It may also define the output state during Debug mode depending on the setting of CTRL2[DBGEN]. 00b - Output is forced to logic 0 state prior to consideration of output polarity control. 01b - Output is forced to logic 1 state prior to consideration of output polarity control. 10b,11b - Output is put in a high-impedance state.
3-2 PWMBFS	PWM_B Fault State These bits determine the fault state for the PWM_B output during fault conditions and Deep Sleep mode. It may also define the output state during Debug mode depending on the setting of CTRL2[DBGEN]. 00b - Output is forced to logic 0 state prior to consideration of output polarity control. 01b - Output is forced to logic 1 state prior to consideration of output polarity control. 10b,11b - Output is put in a high-impedance state.
1-0 PWMXFS	PWM_X Fault State These bits determine the fault state for the PWM_X output during fault conditions and Deep Sleep mode. It may also define the output state during Debug mode depending on the setting of CTRL2[DBGEN]. 00b - Output is forced to logic 0 state prior to consideration of output polarity control. 01b - Output is forced to logic 1 state prior to consideration of output polarity control. 10b,11b - Output is put in a high-impedance state.

54.5.19 Status Register (SM0STS - SM3STS)

Offset

Register	Offset
SM0STS	24h
SM1STS	84h
SM2STS	E4h
SM3STS	144h

Function
Contains Compare and Capture flag status.

Fields

Field	Function
15 —	Reserved
14 RUF	Registers Updated Flag This bit is set when one of the INIT, VALx, FRACVALx, or CTRL[PRSC] registers has been written, which indicates potentially non-coherent data in the set of double buffered registers. Clear this bit by a proper reload sequence consisting of a reload signal while MCTRL[LDOK] = 1. Reset clears this bit. 0b - No register update has occurred since last reload. 1b - At least one of the double buffered registers has been updated since the last reload.
13 REF	Reload Error Flag This bit is set when a reload cycle occurs while MCTRL[LDOK] is 0 and the double buffered registers are in a non-coherent state (STS[RUF] = 1). Clear this bit by writing a logic one to this location. Reset clears this bit. 0b - No reload error occurred. 1b - Reload signal occurred with non-coherent data and MCTRL[LDOK] = 0.
12 RF	Reload Flag This bit is set at the beginning of every reload cycle regardless of the state of MCTRL[LDOK]. Clear this bit by writing a logic one to this location when DMAEN[VALDE] is clear (non-DMA mode). This bit can also be cleared by the DMA done signal when DMAEN[VALDE] is set (DMA mode) . Reset clears this bit. 0b - No new reload cycle since last STS[RF] clearing 1b - New reload cycle since last STS[RF] clearing
11 CFA1	Capture Flag A1 This bit is set when a capture event occurs on the Capture A1 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CA1DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CA1DE] is set (DMA mode) . Reset clears this bit.
10 CFA0	Capture Flag A0 This bit is set when a capture event occurs on the Capture A0 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CA0DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CA0DE] is set (DMA mode) . Reset clears this bit.
9	Capture Flag B1

Table continues on the next page...

Table continued from the previous page...

Field	Function
CFB1	This bit is set when a capture event occurs on the Capture B1 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CB1DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CB1DE] is set (DMA mode) . Reset clears this bit.
8 CFB0	Capture Flag B0 This bit is set when a capture event occurs on the Capture B0 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CB0DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CB0DE] is set (DMA mode) . Reset clears this bit.
7 CFX1	Capture Flag X1 This bit is set when a capture event occurs on the Capture X1 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CX1DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CX1DE] is set (DMA mode) . Reset clears this bit.
6 CFX0	Capture Flag X0 This bit is set when a capture event occurs on the Capture X0 circuit . This bit is cleared by writing a one to this bit position if DMAEN[CX0DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CX0DE] is set (DMA mode) . Reset clears this bit.
5-0 CMPF	Compare Flags These bits are set when the submodule counter value matches the value of one of the VALx registers. Clear these bits by writing a 1 to a bit position. 00_0000b - No compare event has occurred for a particular VALx value. 00_0001b - A compare event has occurred for a particular VALx value.

54.5.20 Interrupt Enable Register (SM0INTEN - SM3INTEN)

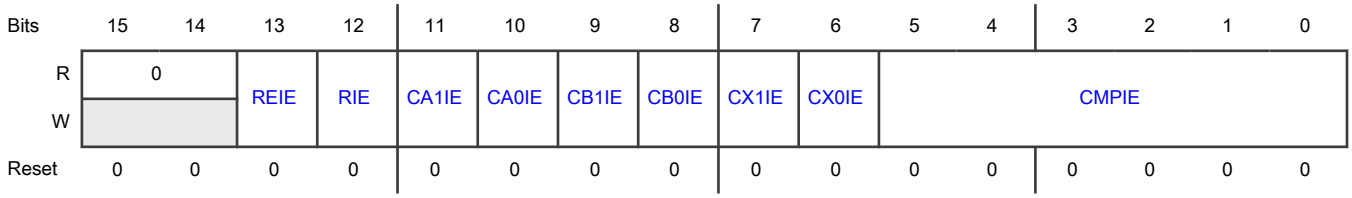
Offset

Register	Offset
SM0INTEN	26h
SM1INTEN	86h
SM2INTEN	E6h
SM3INTEN	146h

Function

Contains Compare and Capture interrupt enables.

Diagram



Fields

Field	Function
15-14 —	Reserved
13 REIE	Reload Error Interrupt Enable This bit enables the reload error flag, STS[REF], to generate CPU interrupt requests. Reset clears this bit. 0b - STS[REF] CPU interrupt requests disabled 1b - STS[REF] CPU interrupt requests enabled
12 RIE	Reload Interrupt Enable This bit enables the reload flag, STS[RF], to generate CPU interrupt requests. Reset clears this bit. 0b - STS[RF] CPU interrupt requests disabled 1b - STS[RF] CPU interrupt requests enabled
11 CA1IE	Capture A 1 Interrupt Enable This bit allows the STS[CFA1] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CA1DE]. 0b - Interrupt request disabled for STS[CFA1] 1b - Interrupt request enabled for STS[CFA1]
10 CA0IE	Capture A 0 Interrupt Enable This bit allows the STS[CFA0] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CA0DE]. 0b - Interrupt request disabled for STS[CFA0]. 1b - Interrupt request enabled for STS[CFA0].
9 CB1IE	Capture B 1 Interrupt Enable This bit allows the STS[CFB1] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CB1DE]. 0b - Interrupt request disabled for STS[CFB1]. 1b - Interrupt request enabled for STS[CFB1].
8	Capture B 0 Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
CB0IE	This bit allows the STS[CFB0] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CB0DE]. 0b - Interrupt request disabled for STS[CFB0]. 1b - Interrupt request enabled for STS[CFB0].
7 CX1IE	Capture X 1 Interrupt Enable This bit allows the STS[CFX1] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CX1DE]. 0b - Interrupt request disabled for STS[CFX1]. 1b - Interrupt request enabled for STS[CFX1].
6 CX0IE	Capture X 0 Interrupt Enable This bit allows the STS[CFX0] flag to create an interrupt request to the CPU. Do not set this bit and DMAEN[CX0DE]. 0b - Interrupt request disabled for STS[CFX0]. 1b - Interrupt request enabled for STS[CFX0].
5-0 CMPIE	Compare Interrupt Enables These bits enable the STS[CMPF] flags to cause a compare interrupt request to the CPU. 00_0000b - The corresponding STS[CMPF] bit will not cause an interrupt request. 00_0001b - The corresponding STS[CMPF] bit will cause an interrupt request.

54.5.21 DMA Enable Register (SM0DMAEN - SM3DMAEN)

Offset

Register	Offset
SM0DMAEN	28h
SM1DMAEN	88h
SM2DMAEN	E8h
SM3DMAEN	148h

Function

Contains controls for DMA. This register is write-protected by MCTRL2[WRPROT] bits.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0						VALDE	FAND	CAPTDE		CA1DE	CA0DE	CB1DE	CB0DE	CX1DE	CX0DE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-10 —	Reserved
9 VALDE	Value Registers DMA Enable This bit enables DMA write requests for the VALx and FRACVALx registers when STS[RF] is set. Reset clears this bit. 0b - DMA write requests disabled 1b - Enabled. DMA write requests for the VALx and FRACVALx registers enabled
8 FAND	FIFO Watermark AND Control This bit works in conjunction with the DMAEN[CAPTDE] field when it is set to watermark mode (DMAEN[CAPTDE] = 01). While DMAEN[CAxDE], DMAEN[CBxDE], and DMAEN[CXxDE] determine which FIFO watermarks the DMA read request is sensitive to. This bit determines if the selected watermarks are AND'ed together or OR'ed together to create the request. 0b - Selected FIFO watermarks are OR'ed together. 1b - Selected FIFO watermarks are AND'ed together.
7-6 CAPTDE	Capture DMA Enable Source Select These bits select the source of enabling the DMA read requests for the capture FIFOs. Reset clears these bits. 00b - Read DMA requests disabled. 01b - Exceeding a FIFO watermark sets the DMA read request. This requires at least one of DMAEN[CA1DE], DMAEN[CA0DE], DMAEN[CB1DE], DMAEN[CB0DE], DMAEN[CX1DE], or DMAEN[CX0DE] to be set to determine which watermark(s) the DMA request is sensitive. 10b - A local synchronization (VAL1 matches counter) sets the read DMA request. 11b - A local reload (STS[RF] being set) sets the read DMA request.
5 CA1DE	Capture A1 FIFO DMA Enable This bit enables DMA read requests for the Capture A1 FIFO data when STS[CFA1] is set. Reset clears this bit. Do not set this bit and INTEN[CA1IE].
4 CA0DE	Capture A0 FIFO DMA Enable This bit enables DMA read requests for the Capture A0 FIFO data when STS[CFA0] is set. Reset clears this bit. Do not set both this bit and INTEN[CA0IE].

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 CB1DE	Capture B1 FIFO DMA Enable This bit enables DMA read requests for the Capture B1 FIFO data when STS[CFB1] is set. Reset clears this bit. Do not set both this bit and INTEN[CB1IE].
2 CB0DE	Capture B0 FIFO DMA Enable This bit enables DMA read requests for the Capture B0 FIFO data when STS[CFB0] is set. Reset clears this bit. Do not set both this bit and INTEN[CB0IE].
1 CX1DE	Capture X1 FIFO DMA Enable This bit enables DMA read requests for the Capture X1 FIFO data when STS[CFX1] is set. Reset clears this bit. Do not set both this bit and INTEN[CX1IE].
0 CX0DE	Capture X0 FIFO DMA Enable This bit enables DMA read requests for the Capture X0 FIFO data when STS[CFX0] is set. Reset clears this bit. Do not set both this bit and INTEN[CX0IE].

54.5.22 Output Trigger Control Register (SM0TCTRL - SM3TCTRL)

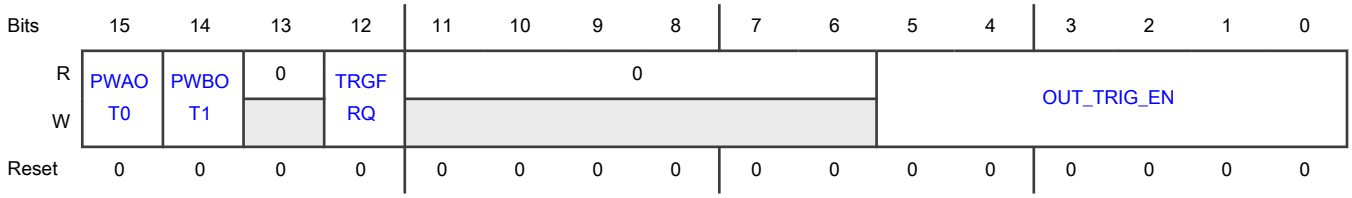
Offset

Register	Offset
SM0TCTRL	2Ah
SM1TCTRL	8Ah
SM2TCTRL	EAh
SM3TCTRL	14Ah

Function

Contains trigger controls.This register is write-protected by MCTRL2[WRPROT] bits.

Diagram



Fields

Field	Function
15 PWAOT0	Mux Output Trigger 0 Source Select This bit selects which signal to bring out on the PWM's PWM_MUX_TRIG0 port. 0b - Route the PWM_OUT_TRIG0 signal to PWM_MUX_TRIG0 port. 1b - Route the PWM_A output to the PWM_MUX_TRIG0 port.
14 PWBOT1	Mux Output Trigger 1 Source Select This bit selects which signal to bring out on the PWM's PWM_MUX_TRIG1 port. 0b - Route the PWM_OUT_TRIG1 signal to PWM_MUX_TRIG1 port. 1b - Route the PWM_B output to the PWM_MUX_TRIG1 port.
13 —	Reserved
12 TRGFRQ	Trigger Frequency This bit allows control over the frequency of the trigger outputs when using non-zero values of CTRL[LDFQ]. 0b - Trigger outputs are generated during every PWM period even if the PWM is not reloaded every period due to CTRL[LDFQ] being non-zero. 1b - Trigger outputs are generated only during the final PWM period prior to a reload opportunity when the PWM is not reloaded every period due to CTRL[LDFQ] being non-zero.
11-6 —	Reserved
5-0 OUT_TRIG_EN	Output Trigger Enables These bits enable the generation of PWM_OUT_TRIG0 and PWM_OUT_TRIG1 outputs based on the counter value matching the value in one or more of the VAL0-5 registers. **NOTE** Due to delays in creating the PWM outputs, the output trigger signals lead the PWM output edges by 2-3 clock cycles depending on the fractional cycle value being used. 1x_xxxxb - PWM_OUT_TRIG1 will set when the counter value matches the VAL5 value. x1_xxxxb - PWM_OUT_TRIG0 will set when the counter value matches the VAL4 value.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	xx_1xxxb - PWM_OUT_TRIG1 will set when the counter value matches the VAL3 value. xx_x1xxb - PWM_OUT_TRIG0 will set when the counter value matches the VAL2 value. xx_xx1xb - PWM_OUT_TRIG1 will set when the counter value matches the VAL1 value. xx_xxx1b - PWM_OUT_TRIG0 will set when the counter value matches the VAL0 value.

54.5.23 Fault Disable Mapping Register 0 (SM0DISMAP0 - SM3DISMAP0)

Offset

Register	Offset
SM0DISMAP0	2Ch
SM1DISMAP0	8Ch
SM2DISMAP0	ECh
SM3DISMAP0	14Ch

Function

This register determines which PWM pins are disabled by the fault protection inputs. Reset sets all of the bits in the fault disable mapping register. This register is write-protected by MCTRL2[WRPROT] bits.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Fields

Field	Function
15-12 —	Reserved
11-8 DIS0X	PWM_X Fault Disable Mask 0 Each of the four bits of this field is one-to-one associated with the four FAULTx inputs of fault channel 0. The PWM_X output is turned off if there is a logic 1 on a FAULTx input and a 1 in the corresponding bit of this field. DIS0X[0] is associated with FAULT0. DIS0X[1] is associated with FAULT1. DIS0X[2] is associated with FAULT2. DIS0X[3] is associated with FAULT3.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	A reset sets all bits in this field.
7-4 DIS0B	PWM_B Fault Disable Mask 0 Each of the four bits of this field is one-to-one associated with the four FAULTx inputs of fault channel 0. The PWM_B output is turned off if there is a logic 1 on a FAULTx input and a 1 in the corresponding bit of this field. DIS0B[0] is associated with FAULT0. DIS0B[1] is associated with FAULT1. DIS0B[2] is associated with FAULT2. DIS0B[3] is associated with FAULT3. A reset sets all bits in this field.
3-0 DIS0A	PWM_A Fault Disable Mask 0 Each of the four bits of this field is one-to-one associated with the four FAULTx inputs of fault channel 0. The PWM_A output is turned off if there is a logic 1 on a FAULTx input and a 1 in the corresponding bit of this field. DIS0A[0] is associated with FAULT0. DIS0A[1] is associated with FAULT1. DIS0A[2] is associated with FAULT2. DIS0A[3] is associated with FAULT3. A reset sets all bits in this field.

54.5.24 Deadtime Count Register 0 (SM0DTCNT0 - SM3DTCNT0)

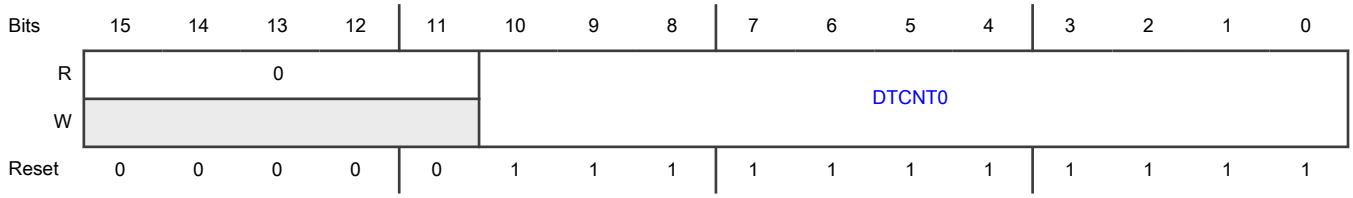
Offset

Register	Offset
SM0DTCNT0	30h
SM1DTCNT0	90h
SM2DTCNT0	F0h
SM3DTCNT0	150h

Function

Deadtime operation applies only to complementary channel operation. The values written to the DTCNTx registers are in terms of IPBus clock cycles regardless of the setting of CTRL[PRSC] and/or CTRL2[CLK_SEL]. Reset sets the deadtime count registers to a default value of 0x07FF, selecting a deadtime of 2047 IPBus clock cycles, when fractional delay is not enabled. The DTCNTx registers are not byte accessible.

Diagram



Fields

Field	Function
15-11 —	Reserved
10-0 DTCNT0	Deadtime Count Register 0 This field is used to control the deadtime during 0 to 1 transitions of the PWM_A output (assuming normal polarity).

54.5.25 Deadtime Count Register 1 (SM0DTCNT1 - SM3DTCNT1)

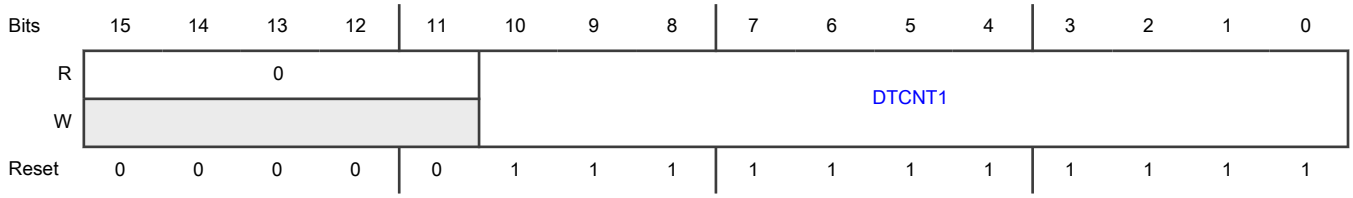
Offset

Register	Offset
SM0DTCNT1	32h
SM1DTCNT1	92h
SM2DTCNT1	F2h
SM3DTCNT1	152h

Function

Deadtime operation applies only to complementary channel operation. The values written to the DTCNTx registers are in terms of IPBus clock cycles regardless of the setting of CTRL[PRSC] and/or CTRL2[CLK_SEL]. Reset sets the deadtime count registers to a default value of 0x07FF, selecting a deadtime of 2047 IPBus clock cycles, when fractional delay is not enabled. The DTCNTx registers are not byte accessible.

Diagram



Fields

Field	Function
15-11 —	Reserved
10-0 DTCNT1	Deadtime Count Register 1 This field is used to control the deadtime during 0 to 1 transitions of the complementary PWM_B output.

54.5.26 Capture Control A Register (SM0CAPTCTRLA)

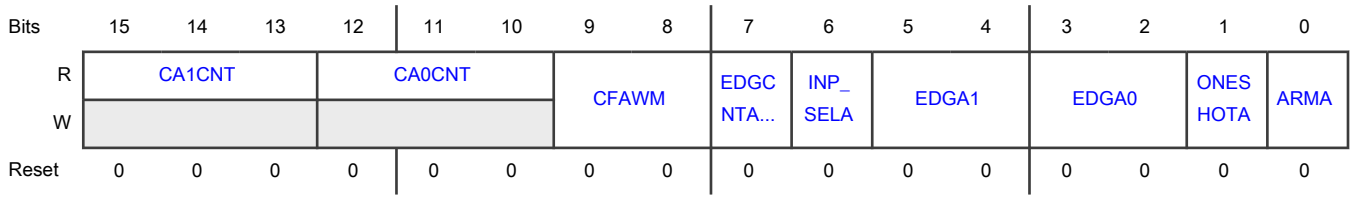
Offset

Register	Offset
SM0CAPTCTRLA	34h

Function

Contains capture controls for mode A. This register is write-protected by MCTRL2[WRPROT] bits.

Diagram



Fields

Field	Function
15-13 CA1CNT	Capture A1 FIFO Word Count This field reflects the number of words in the Capture A1 FIFO. (FIFO depth is 1.)
12-10 CA0CNT	Capture A0 FIFO Word Count This field reflects the number of words in the Capture A0 FIFO. (FIFO depth is 1.)

Table continues on the next page...

Table continued from the previous page...

Field	Function
9-8 CFAWM	Capture A FIFOs Water Mark This field represents the water mark level for capture A FIFOs. The capture flags, STS[CFA1] and STS[CFA0], are not set until the word count of the corresponding FIFO is greater than this water mark level. (FIFO depth is 1.)
7 EDGCNTA_EN	Edge Counter A Enable This field enables the edge counter which counts rising and falling edges on the PWM_A input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELA	Input Select A This field selects between the raw PWM_A input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_A input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. When this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLA[EDGA0] and CAPTCTRLA[EDGA1] fields are ignored. The software must place a value other than 00 in either or both of the CAPTCTLRA[EDGA0] and/or CAPTCTRLA[EDGA1] fields to enable one or both of the capture registers.
5-4 EDGA1	Edge A 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGA0	Edge A 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTA	One Shot Mode A This bit selects between free running and one shot mode for the input capture circuitry. 0b - Free Running. Free running mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLA[ARMA] is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is

Table continues on the next page...

Table continued from the previous page...

Field	Function
	disarmed, and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1b - One Shot. One shot mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLA[ARMA] is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and CAPTCTRLA[ARMA] is cleared. No further captures are performed until CAPTCTRLA[ARMA] is set again. If only one of the capture circuits is enabled, then a single capture occurs on the enabled capture circuit and CAPTCTRLA[ARMA] is then cleared.
0 ARMA	Arm A Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event. 0b - Input capture operation is disabled. 1b - Input capture operation as specified by CAPTCTRLA[EDGAx] is enabled.

54.5.27 Capture Compare A Register (SM0CAPTCOMPA)

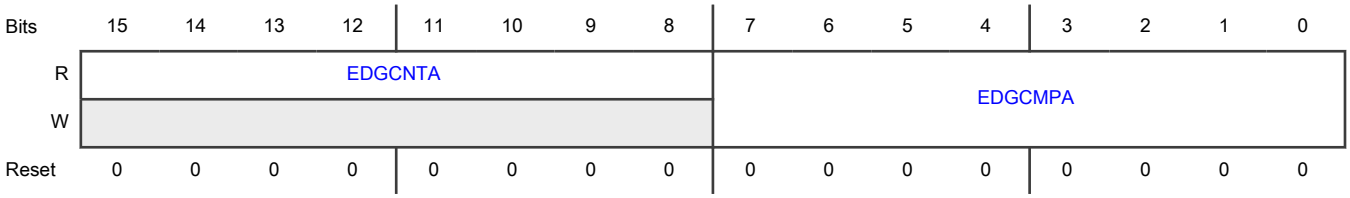
Offset

Register	Offset
SM0CAPTCOMPA	36h

Function

Contains capture and compare values for mode A.This register is write-protected by MCTRL2[WRPROT] bits.

Diagram



Fields

Field	Function
15-8 EDGCNTA	Edge Counter A This field contains the edge counter value for the PWM_A input capture circuitry.
7-0 EDGCMPA	Edge Compare A This field is the compare value associated with the edge counter for the PWM_A input capture circuitry.

54.5.28 Capture Control B Register (SM0CAPTCTRLB)

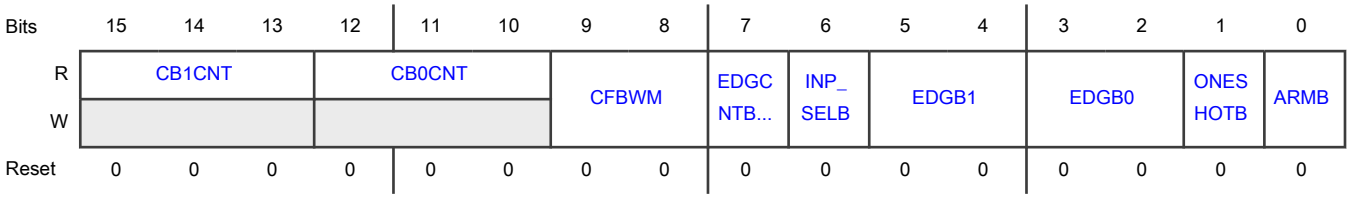
Offset

Register	Offset
SM0CAPTCTRLB	38h

Function

Contains capture controls for mode B. This register is write-protected by MCTRL2[WRPROT] bits.

Diagram



Fields

Field	Function
15-13 CB1CNT	Capture B1 FIFO Word Count This field reflects the number of words in the Capture B1 FIFO. (FIFO depth is 1.)
12-10 CB0CNT	Capture B0 FIFO Word Count This field reflects the number of words in the Capture B0 FIFO. (FIFO depth is 1.)
9-8 CFBWM	Capture B FIFOs Water Mark This field represents the water mark level for capture B FIFOs. The capture flags, STS[CFB1] and STS[CFB0], will not be set until the word count of the corresponding FIFO is greater than this water mark level. (FIFO depth is 1.)
7 EDGCNTB_EN	Edge Counter B Enable This field enables the edge counter which counts rising and falling edges on the PWM_B input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELB	Input Select B This field selects between the raw PWM_B input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_B input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. When this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the

54.5.44 Capture PWM_A Input Filter Register (SM0CAPTFILTA - SM3CAPTFILTA)

Offset

Register	Offset
SM0CAPTFILTA	5Ah
SM1CAPTFILTA	BAh
SM2CAPTFILTA	11Ah
SM3CAPTFILTA	17Ah

Function

Input filter considerations include:

- The CAPTA_FILT_PER value should be set such that the sampling period is larger than the period of the expected noise. This way a noise spike will only corrupt one sample. The CAPTA_FILT_CNT value should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the CAPTA_FILT_CNT+3 power.
- The values of CAPTA_FILT_PER and CAPTA_FILT_CNT must be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting CAPTA_FILT_PER to a non-zero value) introduces a latency of ((CAPTA_FILT_CNT+4) x CAPTA_FILT_PER x IPBus clock period).

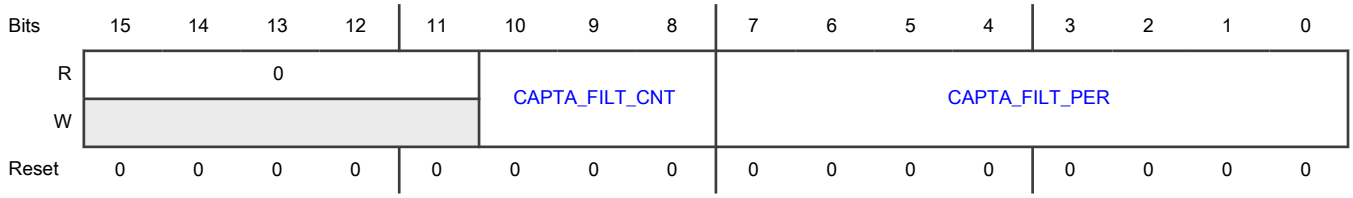
NOTE

When the filter is enabled, there is a combinational path to disable the PWM outputs to ensure rapid response to input capture conditions if the PWM module loses its clock. The latency induced by the filter will be seen in the time to set FSTS[FFLAG] and FSTS[FFPIN].

This register is not byte accessible

This register is write-protected by MCTRL2[WRPROT] bits.

Diagram



Fields

Field	Function
15-11 —	Reserved
10-8 CAPTA_FILT_CNT	Input Capture Filter Count This field represents the number of consecutive samples that must agree prior to the input filter accepting an input transition. The number of samples is the decimal value of this field plus three: the bit field value of 0-7 represents 3-10 samples, respectively. The value of CAPTA_FILT_CNT affects the input latency.
7-0 CAPTA_FILT_PER	Input Capture Filter Period This field applies universally to all capture inputs. These bits represent the sampling period (in IPBus clock cycles) of the input capture pin input filter. Each input is sampled multiple times at the rate specified by this field. If CAPTA_FILT_PER is 0x00 (default), then the input filter is bypassed. The value of CAPTA_FILT_PER affects the input latency. **NOTE** When changing values for CAPTA_FILT_PER from one non-zero value to another non-zero value, first write a value of zero to clear the filter.

54.5.45 Capture PWM_B Input Filter Register (SM0CAPTFILTB - SM3CAPTFILTB)

Offset

Register	Offset
SM0CAPTFILTB	5Ch
SM1CAPTFILTB	BCh
SM2CAPTFILTB	11Ch

54.5.65 Phase Delay Register (SM1PHASEDLY - SM3PHASEDLY)

Offset

Register	Offset
SM1PHASEDLY	B8h
SM2PHASEDLY	118h
SM3PHASEDLY	178h

Function

The 16-bit unsigned value in this buffered register defines the delay from the master sync signal of submodule 0 to the time that this submodule recognizes the master sync in PWM clock periods. CTRL2[INIT_SEL] must be set to 10b to select the master sync signal as the source for initialization when using this register. Setting this register with a non-zero value and using the master sync signal as the initialization source, allows the output of this submodule to be a fixed number of cycles delayed from submodule 0. For PWM operation, the buffered contents of this register are updated at the start of every PWM cycle. This field is not byte accessible.

NOTE

The PHASEDLY register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. This register cannot be written when MCTRL[LDOK] is set. Reading PHASEDLY reads the value in a buffer and not necessarily the value that the PWM generator is currently using. Also, the value of this register should not be set to a value larger than the period defined in submodule 0.

7 EDGCNTX_EN	Edge Counter X Enable This bit enables the edge counter which counts rising and falling edges on the PWM_X input signal. 0b - Edge counter disabled and held in reset 1b - Edge counter enabled
6 INP_SELX	Input Select X This bit selects between the raw PWM_X input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWM_X input signal selected as source. 1b - Edge Counter. Output of edge counter/compare selected as source. When this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLX[EDGX0] and CAPTCTRLX[EDGX1] fields are ignored. The software must place a value other than 00 in either or both of the CAPTCTLRX[EDGX0] and/or CAPTCTRLX[EDGX1] fields to enable one or both of the capture registers.
5-4 EDGX1	Edge X 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2	Edge X 0

Table continues on the next page...

Table continued from the previous page...

Field	Function
EDGX0	These bits control the input capture 0 circuitry by determining which input edges cause a capture event. 00b - Disabled 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTX	One Shot Mode Aux This field selects between free running and one shot mode for the input capture circuitry. 0b - Free Running. Free running mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1b - One Shot. One shot mode is selected if both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed, and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed, and the ARMX bit is cleared. No further captures are performed until the ARMX bit is set again. If only one of the capture circuits is enabled, then a single capture occurs on the enabled capture circuit and the ARMX bit is then cleared.
0 ARMX	Arm X Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event. 0b - Input capture operation is disabled. 1b - Input capture operation as specified by CAPTCTRLX[EDGXx] is enabled.

54.5.71 Capture Compare X Register (SM2CAPTCOMPX)

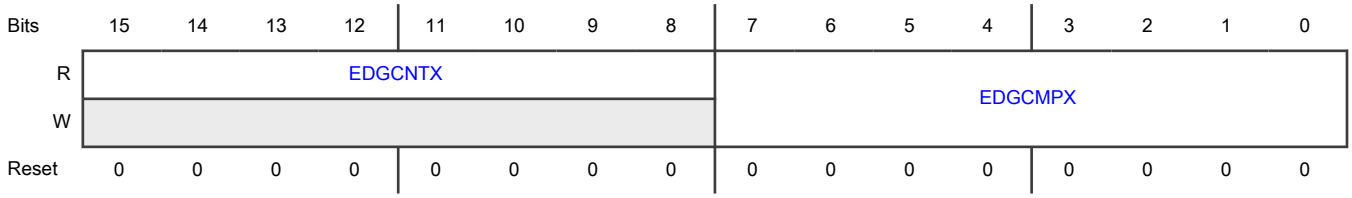
Offset

Register	Offset
SM2CAPTCOMPX	FEh

Function

Contains capture and control values for mode X. This register is write-protected by MCTRL2[WRPROT] bits.

Diagram



Fields

Field	Function
15-8 EDGCNTX	Edge Counter X This field contains the edge counter value for the PWM_X input capture circuitry.
7-0 EDGCMPX	Edge Compare X This field is the compare value associated with the edge counter for the PWM_X input capture circuitry.

54.5.72 Capture Value 0 Register (SM2CVAL0)

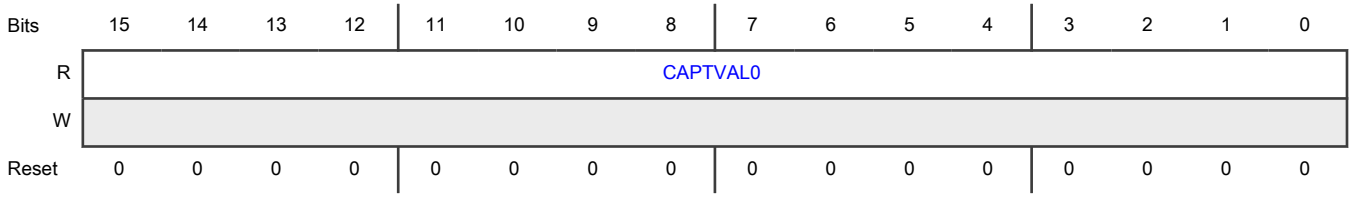
Offset

Register	Offset
SM2CVAL0	100h

Function

Writing this register generates bus transfer error.

Diagram



Fields

Field	Function
15-0 CAPTVAL0	Capture Value 0 This field stores the value captured from the submodule counter. Exactly when this capture occurs is defined by CAPTCTRLX[EDGX0]. Each capture increases the value of CAPTCTRLX[CX0CNT] by 1 until the maximum value is reached. Each read of this field decreases the value of CAPTCTRLX[CX0CNT] by 1 until 0 is reached. This field is not byte accessible.

Fields

Field	Function
15-0 CAPTVAL5	Capture Value 5 This field stores the value captured from the submodule counter when this capture occurs is defined by CAPTCTRLB[EDGB1]. Each capture increases the value of CAPTCTRLB[CB1CNT] by 1 until the maximum value is reached. Each read of this field decreases the value of CAPTCTRLB[CB1CNT] by 1 until 0 is reached. This field is not byte accessible.

54.5.101 Capture Value 5 Cycle Register (SM3CVAL5CYC)

Offset

Register	Offset
SM3CVAL5CYC	176h

Function
Writing this register generates bus transfer error.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												CVAL5CYC			
W

Fields

Field	Function
15-12 —	Reserved
11-8 PWMA_EN	PWM_A Output Enables

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field enables the PWM_A outputs of submodules 3 - 0, respectively. Set these bits to 0 (output disabled) when a PWM_A pin is being used for input capture. • 0b0 PWM_A output disabled. • 0b1 PWM_A output enabled.
7-4 PWMB_EN	PWM_B Output Enables This field enables the PWM_B outputs of submodules 3 - 0, respectively. Set these bits to 0 (output disabled) when a PWM_B pin is being used for input capture. • 0b0 PWM_B output disabled. • 0b1 PWM_B output enabled.
3-0 PWMX_EN	PWM_X Output Enables This field enables the PWM_X outputs of submodules 3 - 0, respectively. Set these bits to 0 (output disabled) when a PWM_X pin is being used for input capture or deadtime correction. • 0b0 PWM_X output disabled. • 0b1 PWM_X output enabled.

54.5.103 Mask Register (MASK)

Offset

Register	Offset
MASK	182h

Function

MASK is double buffered and does not take effect until a FORCE_OUT event occurs within the appropriate submodule. Reading MASK reads the buffered values and not necessarily the values currently in effect. This double buffering can be overridden by setting the UPDATE_MASK bits.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R					MASKA				MASKB				MASKX			
W	UPDATE_MASK															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-12 UPDATE_MASK	Update Mask Bits Immediately This field masks or unmasks the PWM_X (X = A, B, or X) outputs of submodules 3 - 0 respectively by forcing the MASK* (* = A, B or X) bits to be immediately updated within submodules 3 - 0, respectively without waiting for a FORCE_OUT event. These self-clearing bits always read as zero. Software may write to any or all of these bits and may set these bits in the same write operation that updates the MASKA, MASKB, and MASKX fields of this register. • 0b0 Normal operation. MASK* bits within the corresponding submodule are not updated until a FORCE_OUT event occurs within the submodule. • 0b1 Immediate operation. MASK* bits within the corresponding submodule are updated on the following clock edge after setting this bit. For example: • UPDATE_MASK[3]=1 updates the mask bits MASKA[3], MASKB[3], and MASKX[3]. • UPDATE_MASK[3:0]=0101 updates the mask bits MASKA[2], MASKA[0], MASKB[2], MASKB[0], MASKX[2], and MASKX[0].
11-8 MASKA	PWM_A Masks This field masks the PWM_A outputs of submodules 3 - 0, respectively by forcing the output to logic 0 prior to consideration of the output polarity. • 0b0 PWM_A output normal. • 0b1 PWM_A output masked. MASKA[3:0] masks PWM_A_3 through PWM_A_0
7-4 MASKB	PWM_B Masks This field masks the PWM_B outputs of submodules 3 - 0, respectively by forcing the output to logic 0 prior to consideration of the output polarity. • 0b0 PWM_B output normal. • 0b1 PWM_B output masked. MASKB[3:0] masks PWM_B_3 through PWM_B_0
3-0 MASKX	PWM_X Masks This field masks the PWM_X outputs of submodules 3 - 0, respectively by forcing the output to logic 0 prior to consideration of the output polarity.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• 0b0 PWM_X output normal. • 0b1 PWM_X output masked. MASKX[3:0] masks PWM_X_3 through PWM_X_0

54.5.104 Software Controlled Output Register (SWCOUT)

Offset

Register	Offset
SWCOUT	184h

Function

These bits are double buffered and do not take effect until a FORCE_OUT event occurs within the appropriate submodule. Reading these bits reads the buffered value and not necessarily the value currently in effect.

54.5.106 Master Control Register (MCTRL)

Offset

Register	Offset
MCTRL	188h

Function

In every 4-bit field in this register, each bit acts on a separate submodule. Accordingly, the description of every bit field refers to the effect of an individual bit.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	IPOL				RUN				0				LDOK			
W									CLDOK							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-12 IPOL	Current Polarity This field corresponds to submodules 3 - 0, respectively. Each bit selects between PWM23 and PWM45 as the source for the generation of the complementary PWM pair output for the corresponding submodule. MCTRL[IPOL] is ignored in independent mode. MCTRL[IPOL] does not take effect until a FORCE_OUT event takes place in the appropriate submodule. Reading MCTRL[IPOL] reads the buffered value and not necessarily the value currently in effect. 0000b - PWM23 is used to generate complementary PWM pair in the corresponding submodule. 0001b - PWM45 is used to generate complementary PWM pair in the corresponding submodule.

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-8 RUN	Run This field enables the clocks to the PWM generator of submodules 3 - 0, respectively. The corresponding MCTRL[RUN] bit must be set for each submodule that is using its input capture functions or is using the local reload as its reload source. When this bit equals zero, the submodule counter is reset, and PWM outputs are held. A reset clears this field. 0000b - PWM counter is stopped, but PWM outputs hold the current state. 0001b - PWM counter is started in the corresponding submodule.
7-4 CLDOK	Clear Load Okay This field corresponds to submodules 3 - 0, respectively. Each write-only bit is used to clear the corresponding bit of MCTRL[LDOK]. Write a 1 to CLDOK to clear the corresponding MCTRL[LDOK] bit. If a reload occurs within a submodule with the corresponding MCTRL[LDOK] bit set at the same time that MCTRL[CLDOK] is written, then the reload in that submodule will not be performed and MCTRL[LDOK] will be cleared. CLDOK bit is self-clearing and always reads as a 0.
3-0 LDOK	Load Okay This field corresponds to submodules 3 - 0, respectively. Each read/set bit loads CTRL[PRSC] and the INIT, FRACVALx, and VALx registers of the corresponding submodule into a set of buffers. The buffered prescaler divisor, submodule counter modulus value, and PWM pulse width take effect at the next PWM reload if CTRL[LDMOD] is clear or if CTRL[LDMOD] is set. Set the corresponding MCTRL[LDOK] bit by reading it when it is logic zero and then writing a logic one to it. The VALx, FRACVALx, INIT, and CTRL[PRSC] registers of the corresponding submodule cannot be written while the corresponding MCTRL[LDOK] bit is set. In Master Reload Mode (CTRL2[RELOAD_SEL]=1), it is necessary to set the LDOK bit corresponding to submodule0; however, it is recommended to also set the LDOK bit of the slave submodules, to prevent unwanted writes to the registers in the slave submodules. The MCTRL[LDOK] bit is automatically cleared after the new values are loaded, or it can be manually cleared before a reload by writing a logic 1 to the appropriate MCTRL[CLDOK] bit. LDOK bits cannot be written with a zero. MCTRL[LDOK] can be set in DMA mode when the DMA indicates that it has completed the update of all CTRL[PRSC], INIT, FRACVALx, and VALx registers in the corresponding submodule. Reset clears LDOK field. 0000b - Do not load new values. 0001b - Load prescaler, modulus, and PWM values of the corresponding submodule.

54.5.107 Master Control 2 Register (MCTRL2)

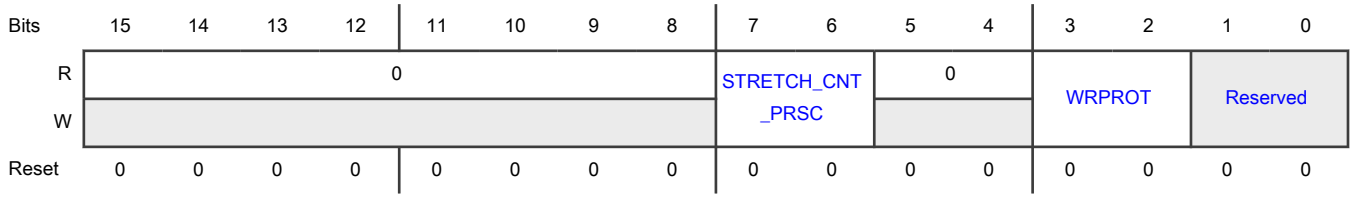
Offset

Register	Offset
MCTRL2	18Ah

Function

Includes control for monitoring the PLL state and write protection of some configuration registers.

Diagram



Fields

Field	Function
15-8 —	Reserved
7-6 STRETCH_CNT_PRSC	Stretch IPBus clock count prescaler for mux0_trig/mux1_trig/out0_trig/out1_trig/pwma_trig/pwmb_trig If user config eFlexPWM work in fast clk mode(use SoC level register, eFlexPWM input signal fast_clk_mode is high), then user can use these bits to stretch output signals mux0_trig/mux1_trig/out0_trig/out1_trig/pwma_trig/pwmb_trig. 00b - Stretch count is zero, no stretch. 01b - Stretch mux0_trig/mux1_trig/out0_trig/out1_trig/pwma_trig/pwmb_trig for 2 IPBus clock period. 10b - Stretch mux0_trig/mux1_trig/out0_trig/out1_trig/pwma_trig/pwmb_trig for 4 IPBus clock period. 11b - Stretch mux0_trig/mux1_trig/out0_trig/out1_trig/pwma_trig/pwmb_trig for 8 IPBus clock period.
5-4 —	Reserved
3-2 WRPROT	Write protect Enable write protection of some configuration registers of eFlexPWM. 00b - Write protection off (default). 01b - Write protection on. 10b - Write protection off and locked until chip reset. 11b - Write protection on and locked until chip reset.
1-0 —	Reserved

54.5.108 Fault Control Register (FCTRL0)

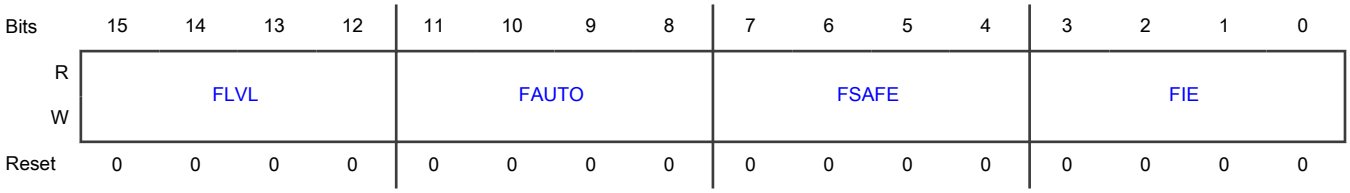
Offset

Register	Offset
FCTRL0	18Ch

Function

For every 4-bit field in this register, the bits act on the fault inputs in order. For example, FLVL bits 15-12 act on faults 3-0, respectively. This register is write-protected by MCTRL2[WRPROT] bits.

Diagram



Fields

Field	Function
15-12 FLVL	Fault Level This field selects the active logic level of the individual fault inputs 3-0, respectively. A reset clears this field. 0000b - A logic 0 on the fault input indicates a fault condition. 0001b - A logic 1 on the fault input indicates a fault condition.
11-8 FAUTO	Automatic Fault Clearing This field selects automatic or manual clearing of faults 3-0, respectively. A reset clears this field. 0000b - Manual fault clearing. PWM outputs disabled by this fault are not enabled until FSTS[FFLAGx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL]. If neither FFULL nor FHALF is set, then the fault condition cannot be cleared. This is further controlled by FCTRL[FSAFE]. 0001b - Automatic fault clearing. PWM outputs disabled by this fault are enabled when FSTS[FFPINx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL] without regard to the state of FSTS[FFLAGx]. If neither FFULL nor FHALF is set, then the fault condition cannot be cleared.
7-4 FSAFE	Fault Safety Mode This field selects the safety mode during manual fault clearing. A reset clears this field. FSTS[FFPINx] may indicate that a fault condition still exists even though the actual fault signal at the FAULTx pin is clear due to the fault filter latency.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0000b - Normal mode. PWM outputs disabled by this fault are not enabled until FSTS[FFLAGx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL] without regard to the state of FSTS[FFPINx]. If neither FHALF nor FFULL is set, then the fault condition cannot be cleared. The PWM outputs disabled by this fault input will not be re-enabled until the actual FAULTx input signal de-asserts since the fault input will combinationally disable the PWM outputs (as programmed in DISMAPn). 0001b - Safe mode. PWM outputs disabled by this fault are not enabled until FSTS[FFLAGx] is clear and FSTS[FFPINx] is clear at the start of a half cycle or full cycle depending on the states of FSTS[FHALF] and FSTS[FFULL]. If neither FHLAF nor FFULL is set, then the fault condition cannot be cleared.
3-0 FIE	Fault Interrupt Enables This field enables CPU interrupt requests generated by the FAULTx pins. A reset clears this field. **NOTE** The fault protection circuit is independent of the FIEx bit and is always active. If a fault is detected, the PWM outputs are disabled according to the disable mapping register. 0000b - FAULTx CPU interrupt requests disabled. 0001b - FAULTx CPU interrupt requests enabled.

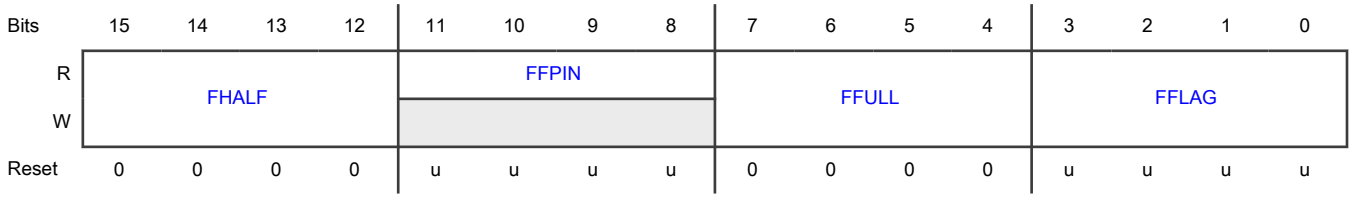
54.5.109 Fault Status Register (FSTS0)

Offset

Register	Offset
FSTS0	18Eh

Function
Includes controls related to fault conditions.

Diagram



Fields

Field	Function
15-12 FHALF	Half Cycle Fault Recovery This field is used to control the timing for re-enabling the PWM outputs after a fault condition. These bits apply to both automatic and manual clearing of a fault condition. These register bits are write-protected by MCTRL2[WRPROT] bits. **NOTE** Both FHALF and FFULL can be set so that the fault recovery occurs at the start of a full cycle and at the start of a half cycle (as defined by VAL0). If neither FHALF nor FFULL is set, then no fault recovery is possible. 0000b - PWM outputs are not re-enabled at the start of a half cycle. 0001b - PWM outputs are re-enabled at the start of a half cycle (as defined by VAL0).
11-8 FFPIN	Filtered Fault Pins These read-only bits reflect the current state of the filtered FAULTx pins converted to high polarity. A logic 1 indicates that a fault condition exists on the filtered FAULTx pin. A reset has no effect on this field. After the system reset de-asserts, these are the possible values of FFPIN: If FCTRL[FLVL] = 0 and FAULTx = 0, then FFPIN is set to 1. If FCTRL[FLVL] = 0 and FAULTx = 1, then FFPIN is kept as 0. If FCTRL[FLVL] = 1 and FAULTx = 0, then FFPIN is kept as 0. If FCTRL[FLVL] = 1 and FAULTx = 1, then FFPIN is set to 1.
7-4 FFULL	Full Cycle This field is used to control the timing for re-enabling the PWM outputs after a fault condition. These bits apply to both automatic and manual clearing of a fault condition. These register bits are write-protected by MCTRL2[WRPROT] bits. **NOTE** Both FHALF and FFULL can be set so that the fault recovery occurs at the start of a full cycle and at the start of a half cycle (as defined by VAL0). If neither FHALF nor FFULL is set, then no fault recovery is possible. 0000b - PWM outputs are not re-enabled at the start of a full cycle 0001b - PWM outputs are re-enabled at the start of a full cycle
3-0	Fault Flags

Table continues on the next page...

Table continued from the previous page...

Field	Function
FFLAG	These read-only flags are set within two CPU cycles after a transition to active on the FAULTx pin. Clear this bit by writing a logic one to it. A reset clears this field. While the reset value is 0, these bits may be set to 1 by the time they can be read depending on the state of the fault input signals. After the system reset de-asserts, these are the possible values of FFLAG: If FCTRL[FLVL] = 0 and FAULTx = 0, then FFLAG is set to 1. If FCTRL[FLVL] = 0 and FAULTx = 1, then FFLAG is kept as 0. If FCTRL[FLVL] = 1 and FAULTx = 0, then FFLAG is kept as 0. If FCTRL[FLVL] = 1 and FAULTx = 1, then FFLAG is set to 1. 0000b - No fault on the FAULTx pin. 0001b - Fault on the FAULTx pin.

54.5.110 Fault Filter Register (FFILT0)

Offset

Register	Offset
FFILT0	190h

Function

The settings in this register are shared among each of the fault input filters within the fault channel.

Input filter considerations include:

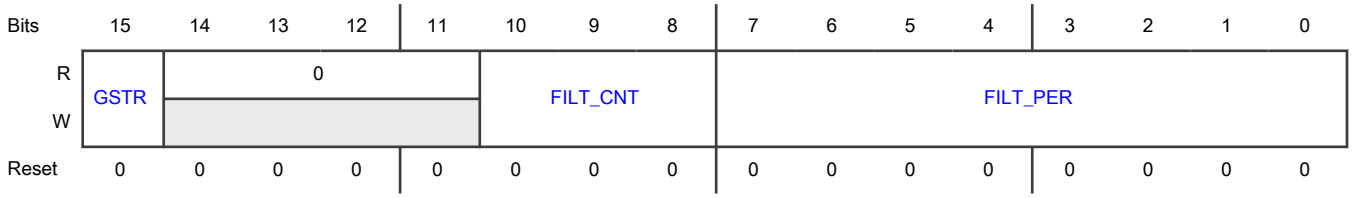
- Set the FILT_PER value such that the sampling period is larger than the period of the expected noise. This way a noise spike corrupts one sample. Select the FILT_CNT value to reduce and recognize the probability of noisy samples causing an incorrect transition. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the FILT_CNT+3 power.
- The values of FILT_PER and FILT_CNT must be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT_PER to a non-zero value) introduces a latency of ((FILT_CNT+4) x FILT_PER x IPBus clock period).

NOTE

When the filter is enabled, there is a combinational path to disable the PWM outputs to ensure rapid response to fault conditions, and fault response if the PWM module loses its clock. The latency induced by the filter will be seen in the time to set FSTS[FFLAG] and FSTS[FFPIN].

This register is write-protected by MCTRL2[WRPROT] bits.

Diagram



Fields

Field	Function
15 GSTR	Fault Glitch Stretch Enable This field is used to enable the fault glitch-stretching logic. This logic ensures that narrow fault glitches are stretched to be at least 2 IPBus clock cycles wide. In some cases, a narrow fault input can cause problems due to the short PWM output shutdown/re-activation time. The stretching logic ensures that a glitch on the fault input, when the fault filter is disabled, will be registered in the fault flags. 0b - Fault input glitch stretching is disabled. 1b - Input fault signals are stretched to at least 2 IPBus clock cycles.
14-11 —	Reserved
10-8 FILT_CNT	Fault Filter Count These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. The number of samples is the decimal value of this field plus three: the bit field value of 0-7 represents 3-10 samples, respectively. The value of FILT_CNT affects the input latency.
7-0 FILT_PER	Fault Filter Period This 8-bit field applies universally to all fault inputs. These bits represent the sampling period (in IPBus clock cycles) of the fault pin input filter. Each input is sampled multiple times at the rate specified by this field. If FILT_PER is 0x00 (default), then the input filter is bypassed. The value of FILT_PER affects the input latency. **NOTE** When changing values for FILT_PER from one non-zero value to another non-zero value, first write a value of zero to clear the filter.

54.5.111 Fault Test Register (FTST0)

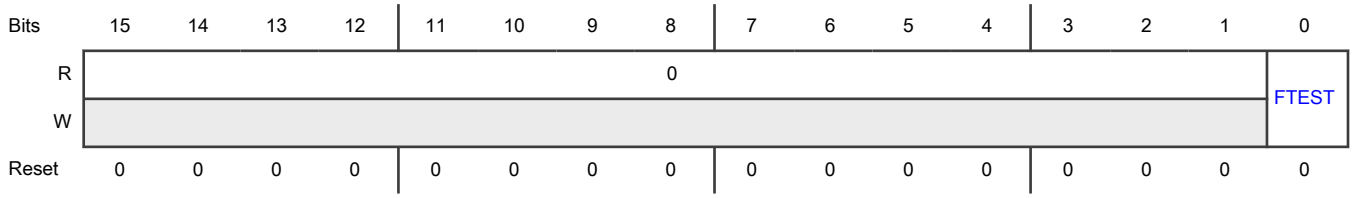
Offset

Register	Offset
FTST0	192h

Function

Contains FTEST field for fault simulation.

Diagram



Fields

Field	Function
15-1 —	Reserved
0 FTEST	Fault Test This field is used to simulate a fault condition. Setting this bit causes a simulated fault to be sent into all of the fault filters. The condition propagates to the fault flags and possibly the PWM outputs depending on the DISMAPn settings. Clearing this bit removes the simulated fault condition. This register bit is write-protected by MCTRL2[WRPROT] bits. 0b - No fault 1b - Cause a simulated fault

54.5.112 Fault Control 2 Register (FCTRL20)

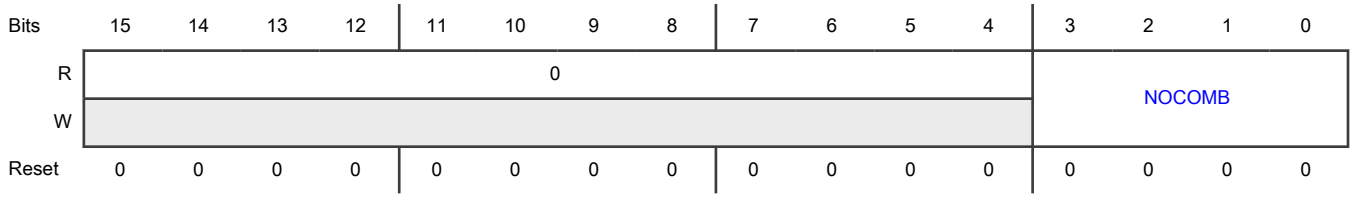
Offset

Register	Offset
FCTRL20	194h

Function

Controls combinational link from fault inputs to PWM outputs. This register is write-protected by MCTRL2[WRPROT] bits.

Diagram



Fields

Field	Function
15-4	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
3-0 NOCOMB	No Combinational Path From Fault Input To PWM Output This field is used to control the combinational path from the fault inputs to the PWM outputs. When these bits are low (default), the corresponding fault inputs have a combinational path to the PWM outputs that are sensitive to these fault inputs (as defined by DISMAP0). This combinational path is a safety feature that ensures the output is disabled even if the SOC has a failure of its clocking system. The combinational path also means that a pulse on the fault input can cause a brief disable of the PWM output even if the fault pulse is not wide enough to get through the input filter and be latched in the fault logic. Setting these bits removes the combinational path and uses the filtered and latched fault signals as the fault source to disable the PWM outputs. This eliminates fault glitches from creating PWM output glitches but also increases the latency to respond to a real fault. 0000b - There is a combinational link from the fault inputs to the PWM outputs. The fault inputs are combined with the filtered and latched fault signals to disable the PWM outputs. 0001b - The direct combinational path from the fault inputs to the PWM outputs is disabled and the filtered and latched fault signals are used to disable the PWM outputs.

Chapter 55
Quadrature Decoder (QDC)

55.1 Chip-specific QDC information

Table 450. Reference links to related information

Topic	Related module	Reference
Full description	QDC	QDC
System memory map		Memory map
Clocking		Clock distribution
Power management		Power management
Input multiplexing	INPUTMUX	See QDC0_TRIG and QDC1_TRIG registers in INPUTMUX

NOTE

QDC uses system_clk. See QDC0_TRIG and QDC1_TRIG registers in INPUTMUX chapter to see QDC input trigger connections.

55.1.1 Module instances

This device has two instances of the QDC module: QDC0 and QDC1.

55.2 Overview

ENC interfaces to position and speed sensors used in industrial motor control applications. ENC uses the following five input signals from those position and speed sensors to decode shaft position, revolution count, and speed:

- PHASEA
- PHASEB
- INDEX
- TRIGGER
- HOME

55.2.1 Block diagram

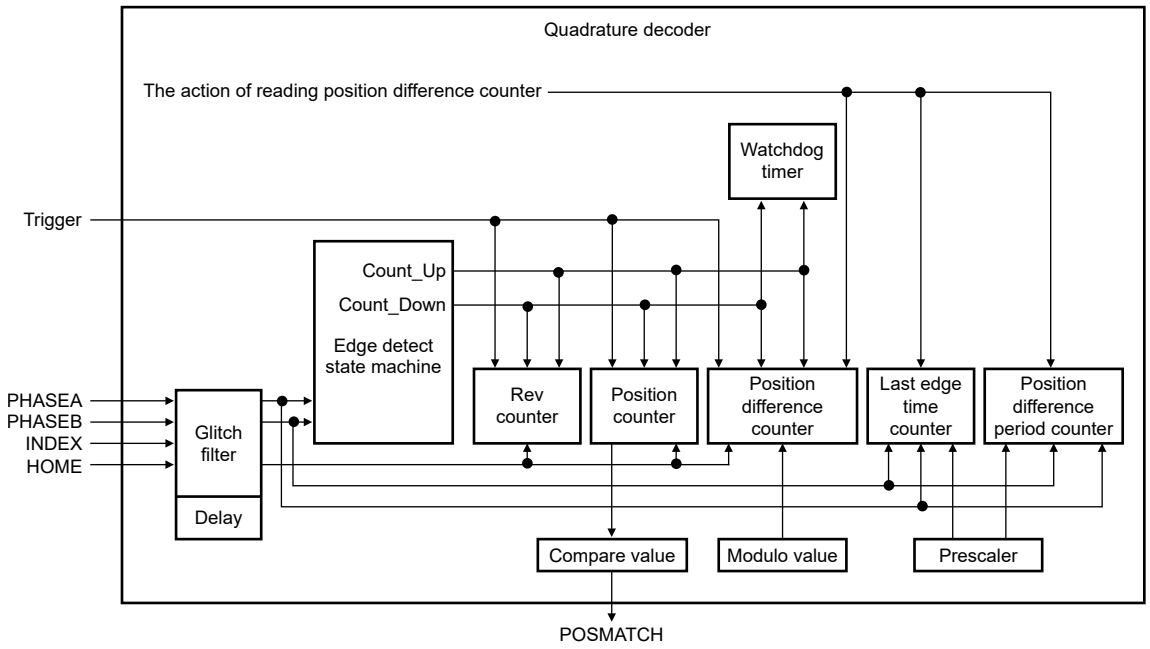


Figure 308. ENC block diagram

55.2.2 Features

- Logic to decode quadrature signals
- Inputs that you could connect to a general purpose timer to perform low-speed velocity measurements
- Digital filter for inputs that you could configure according to your requirements
- Quadrature decoder filter that can be bypassed
- 32-bit position counter capable of modulo counting
- Position counter that you, or external events, could initialize
- 16-bit position difference register
- Compare function to indicate when the shaft has reached a defined position
- Watchdog timer to detect a non-rotating shaft condition
- 16-bit revolution counter that could be preloaded
- Maximum count frequency that equals the peripheral clock rate
- Availability of an optional interrupt when both PHASEA and PHASEB inputs change in the same cycle

55.3 Functional description

The following timing diagram shows the basic operation of an incremental position ENC.

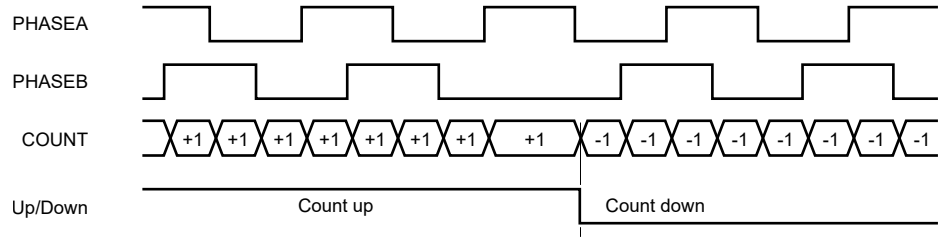

Figure 309. ENC signals

55.3.1 Positive versus negative direction

A typical quad encoder has three outputs: PHASEA signal, PHASEB signal, and INDEX pulse (not shown).

- If PHASEA leads PHASEB, then motion is in the positive direction.
- If PHASEA trails PHASEB, then motion is in the negative direction.

You can integrate the transitions on these phases to yield position or differentiate to yield velocity. Design the ENC to perform these functions in hardware.

55.3.2 Speed measurement method

This section explains the speed measurement method. It includes a speed measurement algorithm.

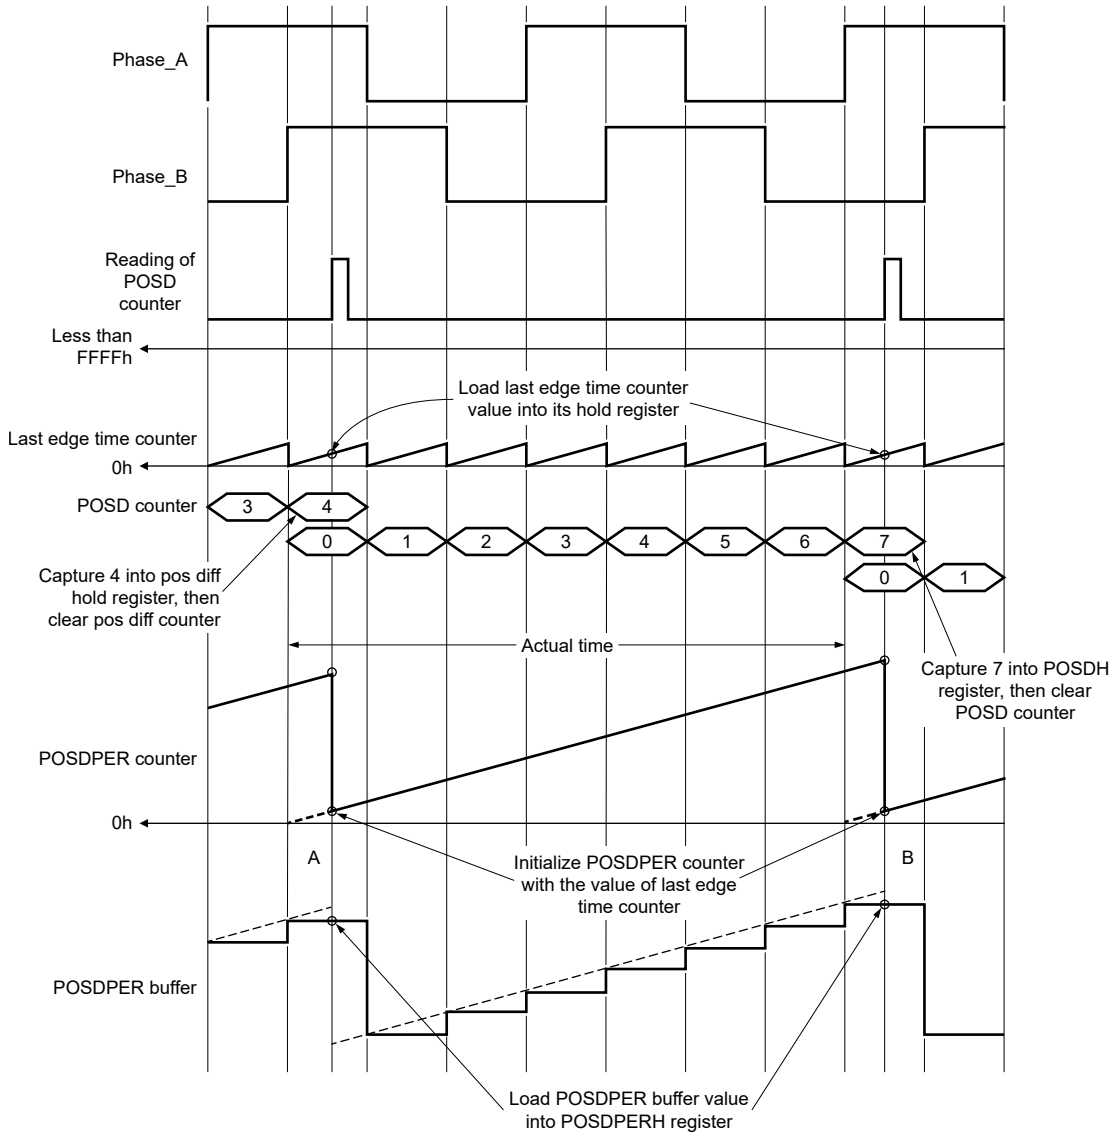

Figure 310. Counters behavior and updating mechanism

Reading of Position Difference Counter (POSD) occurs at time point A and time point B. “Actual time” represents the time duration between the first phase_a/b edges right before time points A and B. At time point B, after reading Position Difference Counter (POSD), Position Difference Period Hold (POSDPERH) contains the time length of “Actual time” and Position Difference Hold (POSDH) includes the value of phase_a/b pulses within that “Actual time”. You can calculate the speed based on Position Difference Period Hold (POSDPERH) and Position Difference Hold (POSDH). The following figure shows a visualized explanation of speed measurement with this method:

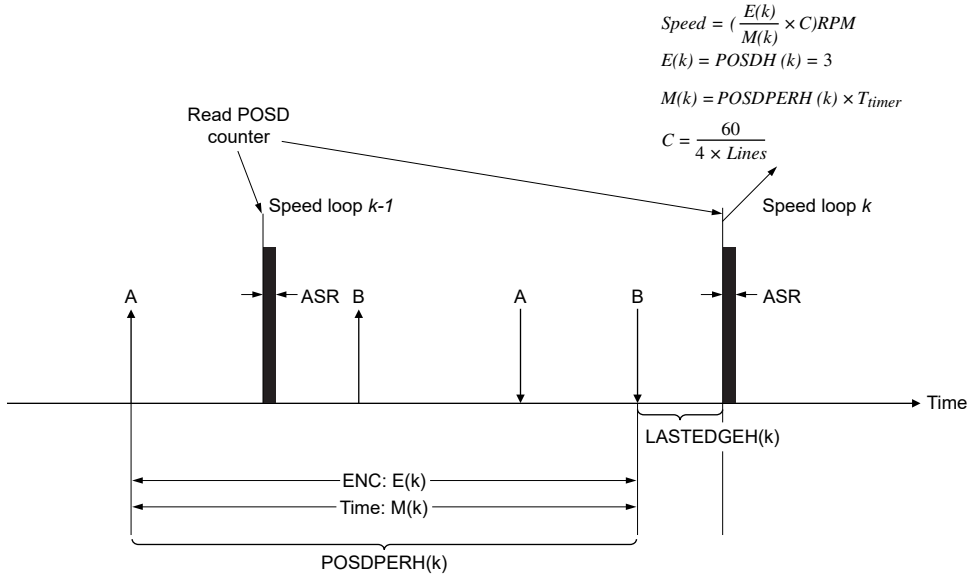

Figure 311. High speed measurement with method

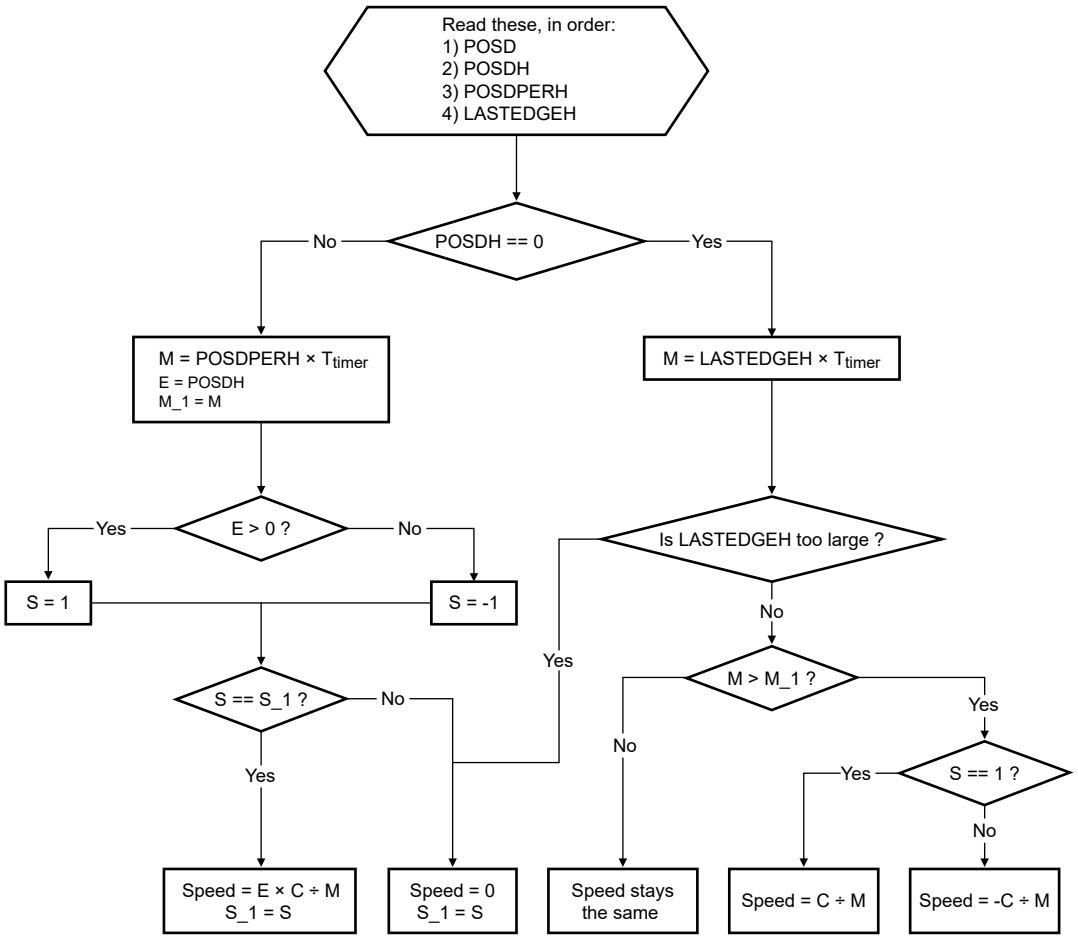
Speed calculation algorithm

However, to cover all the cases in real applications, a simple speed measurement algorithm is necessary. The following figure shows the speed measurement algorithm.



S: Indicates whether E = 0 in this POSD reading operation. If E = 0, then S = -1. If E > 0, then S = 1.
S_1: Indicates whether E = 0 in the previous POSD reading operation. If E=0, then S = -1. If E > 0, then S=1.
M: Indicates the M value in this POSD reading operation.
M_1: Indicates the M value in the previous POSD reading operation.

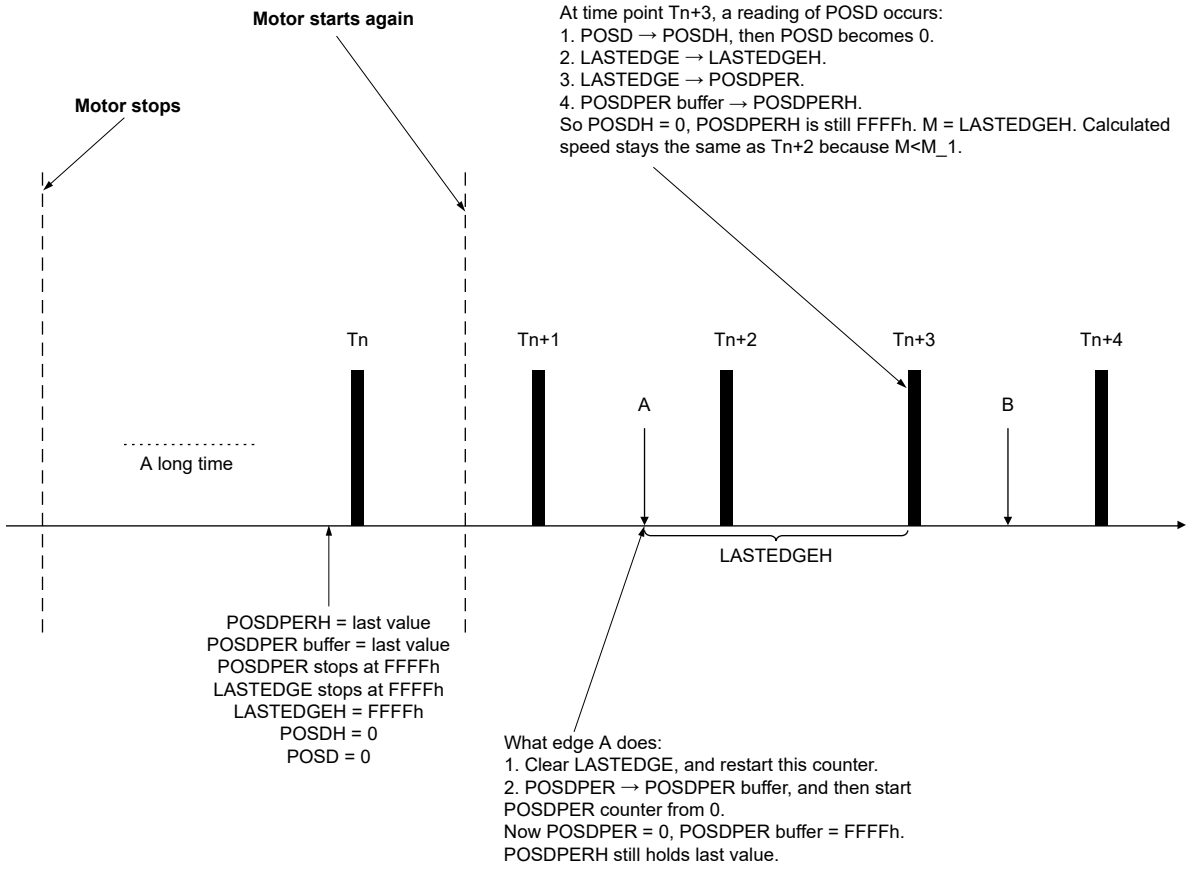

Figure 320. Speed measurement at time point Tn+3

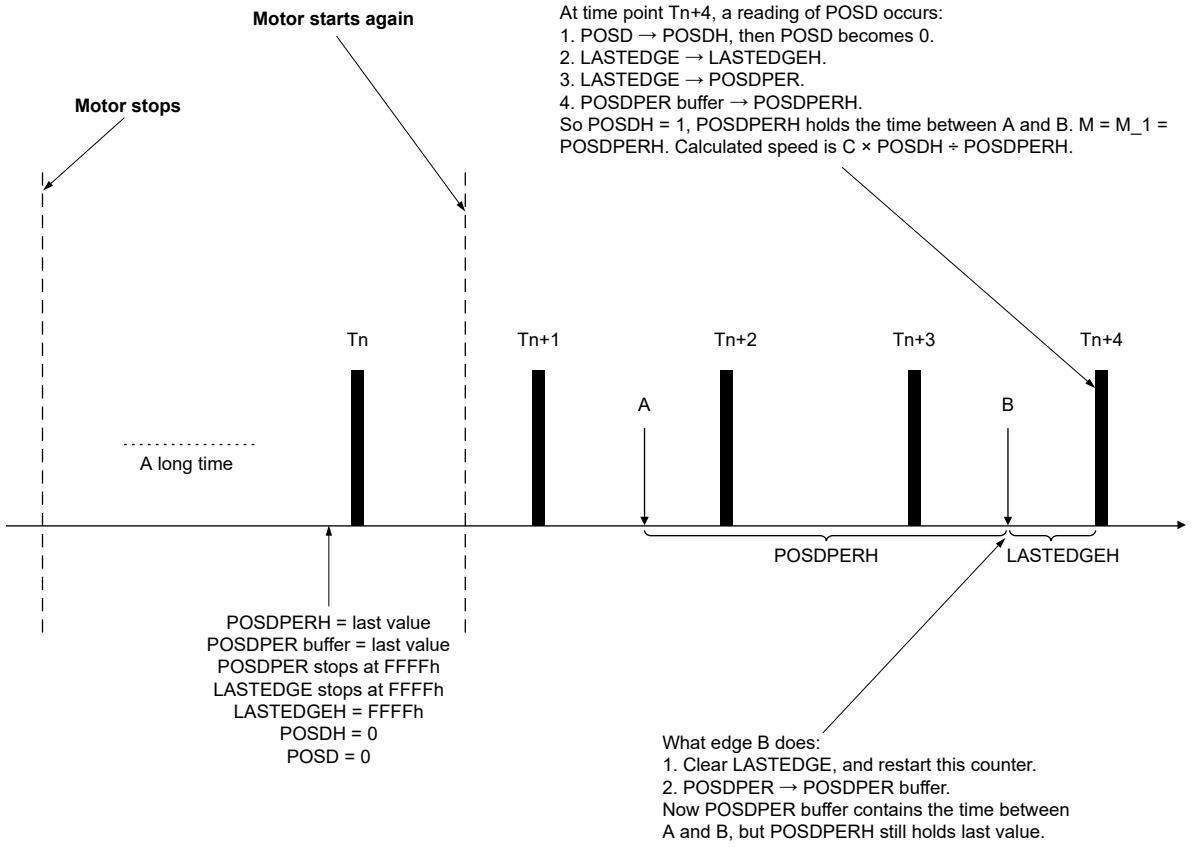

Figure 321. Speed measurement at time point Tn+4

55.3.3 Glitch filter

The quadrature decoder logic must sense signal transitions, and the signal inputs first run through a glitch filter. This glitch filter has a digital delay line, which samples multiple time points on the signal and verifies a stable new signal state before outputting this new signal state to the internal quadrature decoder logic. To adapt to a variety of signal bandwidths, the sample rate of this delay line is programmable.

55.3.4 Edge detect state machine

The edge detect state machine looks for changes in the four possible states of the filtered PHASEA and PHASEB inputs, which calculates the direction of motion. Format this information as Count_Up and Count_Down signals. Each counter includes its hold register. These signals route into up to three up/down counters:

- Position counter
- Revolution counter
- Position difference counter

55.3.5 Counter registers and hold registers, and how to initialize

Hold registers are associated with the following 4 types of counters:

- Position
- Position difference
- Revolution

- Rising edge of trigger event when CTRL2[UPDHLD] is 1

When you read any counter registers, write the contents of each counter register to the corresponding hold register. Taking a snapshot of the counters' values allows a consistent view of a system's position and the velocity to attain. If CTRL3[PMEN] is 1, then Position Difference Hold (POSDH) updates only when you read the POSD counter and not when other counters are read. To capture a time stamp of when these registers are read, use the POSMATCH output with a timer channel.

The position counter is 32 bits wide. To ensure that the position counter can reliably initialize with two 16-bit accesses, two registers (Upper Initialization (UINIT) and Lower Initialization (LINIT)) are provided. You must load Upper Initialization (UINIT) and Lower Initialization (LINIT) with the desired value. Then write 1 to CTRL[SWIP] to load the position counter. Alternatively, CTRL[XIP] or CTRL[HIP] can enable the position counter to initialize in response to a HOME or INDEX signal transition.

55.3.5.1 Position counter

The 32-bit position counter calculates up or down on every count pulse, which the difference between PHASEA and PHASEB generates. The position counter acts as integration information, whose count value is proportional to position. Count_Up and Count_Down signals determine the direction of the count. You may initialize the position counters to a predetermined value by one of 4 different methods:

- Software-triggered event
- INDEX signal transition
- HOME signal transition
- Rising edge of a trigger event

You can program the INDEX and HOME signals to interrupt the processor. Whenever you read the position counters (Upper Position Counter (UPOS) or Lower Position Counter (LPOS)), a snapshot of the following counters are placed into their respective hold registers:

- Position counter
- Position difference counter (only if CTRL3[PMEN] is 0)
- Revolution counter

55.3.5.2 Position difference counter

The 16-bit position difference counter contains the position difference value occurring between each read of the position register. The position register counts up or down on every count pulse. The position difference counter acts as a differentiator whose count value is proportional to the change in position since the last time the position counter was read.

When you read the position registers, the position difference counter, or the revolution counter, the contents of Position Difference Counter (POSD) are copied into Position Difference Hold (POSDH), and the position difference counter becomes 0.

If CTRL3[PMEN] is 1, a read of the position difference counter, and not a read of the revolution counter or position counters, updates the position difference counter and its hold register.

55.3.5.3 Position difference counter hold

Position Difference Hold (POSDH) stores a copy of the position difference counter when you read the position register. When you read the position register, the position difference counter, or the revolution counter, the position difference counter's contents are copied into Position Difference Hold (POSDH), and the position difference counter becomes 0.

If CTRL3[PMEN] is 1, a read of the position difference counter, and not a read of the revolution counter or position counters, updates Position Difference Hold (POSDH).

55.3.5.4 Revolution counter

The 16-bit up/down revolution counter counts or integrate revolutions by counting index pulses. Determine the direction of the count by the Count_Up and Count_Down signals, determined by the Phase A and B inputs. A different count direction on the rising and falling edges of the index pulse indicates that the quad encoder changed direction on the index pulse.

55.3.5.5 Watchdog timer

The watchdog timer ensures that the algorithm indicates motion in the shaft. Two successive counts indicate proper operation and reset the timer.

- The timeout value is programmable.
- When a timeout occurs, you can generate an interrupt to the processor.

55.3.5.6 Pulse accumulator functionality

You can program the logic to integrate only selected transitions of the PHASEA signal. This way, you can use the position counter as a pulse accumulator.

- The count direction is up.
- The INDEX input can optionally initialize the pulse accumulator.

55.3.5.7 Last edge time counter

The 16-bit last edge time counter contains the time since the last edge on PHASEA or PHASEB. The last edge time counter counts up on every prescaled clock pulse.

When you read the position difference counter, copy the content of LASTEDGE[LASTEDGE] into Last Edge Time Hold (LASTEDGEH).

55.3.5.8 Position difference period counter

The position difference period counter:

- Contains the accumulated time from the last time you read the position difference counter.
- Counts up on every prescaled clock pulse.
- Loads from the last edge time counter whenever you read the position difference register.

55.3.6 Prescaler for slow or fast speed measurement

- For applications with a fast-moving shaft encoder, to compute the speed, calculate the change in the position counter per unit time, or read Position Difference Counter (POSD) and calculate the speed.
- The timer module enables high-resolution velocity measurements by measuring the time period between quad phases for applications with slow motor speeds and low line count quad encoders.
  - The timer module uses a 16-bit free running counter operated from a prescaled version of the IPBus clock.
  - The prescaler divides the IPBus clock by values ranging from 1 to 128. A 60 MHz IPBus clock frequency, yields a resolution from 17 ns to 2.1 µs and a maximum count period from 1.09 ms to 140 ms. For example, with a 1000-tooth decoder, you can calculate speeds down to 0.11 rpm using a prescaler.

55.3.7 Resets

There are no special requirements. Any system reset resets this module.

55.3.8 Clocks

This module requires only the IPBus clock in normal operation.

55.3.9 Interrupts

Table 451. Interrupt summary

Core interrupt	Interrupt flag	Interrupt enable	Description
ipi_int_home	CTRL[HIRQ]	CTRL[HIE]	HOME signal transition interrupt
ipi_int_index	CTRL[XIRQ]	CTRL[XIE]	INDEX signal transition interrupt or roll-over/ under interrupt
	CTRL2[ROIRQ]	CTRL2[ROIE]	
	CTRL2[RUIRQ]	CTRL2[RUIE]	
ipi_int_wdog	CTRL[DIRQ]	CTRL[DIE]	Watchdog timeout interrupt
ipi_int_cmp	CTRL[CMPIRQ]	CTRL[CMPIE]	Compare match interrupt
ipi_int_sab	CTRL2[SABIRQ]	CTRL2[SABIE]	Simultaneous PHASEA and PHASEB change interrupt

55.4 External signals

Four external signals are multiplexed to the following four pins of a quad timer module:

- PHASEA
- PHASEB
- INDEX
- HOME

You can connect the following two internal signals to other chip resources:

- TRIGGER
- POSMATCH

Table 452. Signal descriptions

Signal		Description
PHASEA	Phase A input	You can connect the PHASEA input to one of the phases from a two-phase shaft quad encoder output. ENC uses PHASEA and PHASEB to indicate a decoder increment has passed and to calculate its direction. • When you use ENC as a single phase pulse accumulator, you can also use PHASEA as the single input. • The PHASEA input can be an input capture channel for one of the timer modules (in the chip), which you can connect to using a crossbar switch. Direction for two-phase shaft quad encoder output: • PHASEA is the leading phase for a shaft rotating in the positive direction. • PHASEA is the trailing phase for a shaft rotating in the negative direction.
PHASEB	Phase B input	You can connect the PHASEB input to the other phase from a two-phase shaft quad encoder output.

Table continues on the next page...

Table 452. Signal descriptions (continued)

Signal		Description
		• The PHASEB input can be an input capture channel for one of the timer modules (in the chip), which you can connect to using a crossbar switch. Direction for two-phase shaft quad encoder output: • PHASEB is the trailing phase for a shaft rotating in the positive direction. • PHASEB is the leading phase for a shaft rotating in the negative direction.
INDEX	Index input	• Normally connected to the index pulse output of a quad encoder, the INDEX pulse can optionally reset the position counter and the pulse accumulator of ENC. The INDEX pulse also causes a change of state on the revolution counter. Calculate the direction of this state change (increment or decrement) from the PHASEA and PHASEB inputs. • The INDEX input can be an input capture channel for one of the timer modules (in the chip), which you can connect to using a crossbar switch.
HOME	Home switch input	ENC and the timer module can use the HOME input. • You can use the HOME input to trigger the initialization of the position counters (Upper Position Counter (UPOS) and Lower Position Counter (LPOS)). Often the HOME signal is connected to a sensor on the motor or machine, sending a notification that it has reached a defined home position. • You can connect the HOME signal to the timer module (in the chip) using a crossbar switch.
TRIGGER	Trigger input	You can use the TRIGGER input to: • Write 0 to the position counters (Upper Position Counter (UPOS) and Lower Position Counter (LPOS)). • Take a snapshot of POS, Revolution Counter (REV), and Position Difference Counter (POSD). • Indicate an elapsed time period by connecting the TRIGGER input signal to a periodic pulse generator or timer.
POSMATCH	Position match output	• To record the time at which the shaft position matches a user-defined compare value (COMP), The POSMATCH output can trigger a timer channel. • Alternatively, to record the time at which you read the position information (when you read the position counters (Upper Position Counter (UPOS) and Lower Position Counter (LPOS), Revolution Counter (REV), or Position Difference Counter (POSD)) the POSMATCH output can trigger a timer channel.

55.5 Memory map and registers

This section describes the module memory map and registers.

55.5.1 ENC register descriptions

The address of a register is the sum of a base address and an address offset.

- Base address is defined at the MCU level
- Address offset is defined at the module level

For the base address, see the chip-specific documentation. All memory locations base and offsets are given in hex.

55.5.1.1 ENC memory map

QDC0 base address: 400C_F000h

QDC1 base address: 400D_1000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control (CTRL)	16	RW	0000h
2h	Input Filter (FILT)	16	RW	0000h
4h	Watchdog Timeout (WTR)	16	RW	0000h
6h	Position Difference Counter (POSD)	16	RW	0000h
8h	Position Difference Hold (POSDH)	16	R	0000h
Ah	Revolution Counter (REV)	16	RW	0000h
Ch	Revolution Hold (REVH)	16	R	0000h
Eh	Upper Position Counter (UPOS)	16	RW	0000h
10h	Lower Position Counter (LPOS)	16	RW	0000h
12h	Upper Position Hold (UPOSH)	16	R	0000h
14h	Lower Position Hold (LPOSH)	16	R	0000h
16h	Upper Initialization (UINIT)	16	RW	0000h
18h	Lower Initialization (LINIT)	16	RW	0000h
1Ah	Input Monitor (IMR)	16	R	0000h
1Ch	Test (TST)	16	RW	0000h
1Eh	Control 2 (CTRL2)	16	RW	0000h
20h	Upper Modulus (UMOD)	16	RW	0000h
22h	Lower Modulus (LMOD)	16	RW	0000h
24h	Upper Position Compare (UCOMP)	16	RW	FFFFh
26h	Lower Position Compare (LCOMP)	16	RW	FFFFh
28h	Last Edge Time (LASTEDGE)	16	R	FFFFh
2Ah	Last Edge Time Hold (LASTEDGEH)	16	R	FFFFh
2Ch	Position Difference Period Counter (POSDPER)	16	R	FFFFh
2Eh	Position Difference Period Buffer (POSDPERBFR)	16	R	FFFFh
30h	Position Difference Period Hold (POSDPERH)	16	R	FFFFh
32h	Control 3 (CTRL3)	16	RW	0000h

55.5.1.2 Control (CTRL)

Offset

Register	Offset
CTRL	0h

Function

Controls basic functions on HOME and INDEX signals and part of basic functions.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HIRQ	HIE	HIP	HNE	0	REV	PH1	XIRQ	XIE	XIP	XNE	DIRQ	DIE	WDE	CMPIRQ	CMPIE
W	W1C				SWIP			W1C				W1C			W1C	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15 HIRQ	HOME Signal Transition Interrupt Request Specifies whether a transition has occurred on the HOME signal. This field becomes 1 when a HOME signal transitions, according to CTRL[HNE]. If this field and CTRL[HIE] are 1, then a HOME interrupt occurs. 0b - Not occurred 1b - Occurred
14 HIE	HOME Interrupt Enable Enables or disables HOME signal interrupts. 0b - Disable 1b - Enable
13 HIP	Enable HOME to Initialize Position Counters UPOS and LPOS Enables the position counter, which the HOME signal initializes. 0b - No action 1b - HOME signal initializes the position counter
12 HNE	Use Negative Edge of HOME Input Selects using the positive and negative edge of the HOME input. 0b - Use positive-going edge-to-trigger initialization of position counters UPOS and LPOS 1b - Use negative-going edge-to-trigger initialization of position counters UPOS and LPOS

Table continues on the next page...

Table continued from the previous page...

Field	Function
11 SWIP	Software-Triggered Initialization of Position Counters UPOS and LPOS Specifies that writing 1 to this field transfers the Upper Initialization (UINIT) and Lower Initialization (LINIT) contents to Upper Position Counter (UPOS) and Lower Position Counter (LPOS) (thereby initializing those counters). 0b - No action 1b - Initialize position counter
10 REV	Enable Reverse Direction Counting Selects the direction of the count (how you interpret the quadrature signal). 0b - Counts normally 1b - Counts in the reverse direction
9 PH1	Enable Signal Phase Count Mode Bypasses or uses the quadrature decoder logic. 0b - Uses the standard quadrature decoder, where PHASEA and PHASEB represent a two-phase quadrature signal. 1b - Bypasses the quadrature decoder. A positive transition of the PHASEA input generates a count signal. PHASEB input and CTRL[REV] controls the counter direction. If the value of CTRL[REV] and PHASEB are identical; then count is up. If the value of CTRL[REV] and PHASEB is different, then count is down.
8 XIRQ	INDEX Pulse Interrupt Request Specifies whether the INDEX pulse has occurred. This field becomes 1 when a transition on the INDEX signal occurs, according to the use negative edge of CTRL[XNE]. If this field and CTRL[XIE] become 1, then an INDEX interrupt occurs. 0b - Not occurred 1b - Occurred
7 XIE	INDEX Pulse Interrupt Enable Enables or disables INDEX pulse interrupts. 0b - Disable 1b - Enable
6 XIP	INDEX Triggered Initialization of Position Counters UPOS and LPOS Enables or disables the position counter that the INDEX pulse initializes. 0b - Does not initialize 1b - Initializes
5 XNE	Select Positive and Negative Edge of INDEX Pulse Selects the positive and negative edge of the INDEX pulse.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Use positive edge 1b - Use negative edge
4 DIRQ	Watchdog Timeout Interrupt Request Specifies whether the watchdog timeout interrupt has occurred. This field also becomes 0 when CTRL[WDE] = 0. 0b - Not occurred 1b - Occurred
3 DIE	Watchdog Timeout Interrupt Enable Enables or disables the watchdog timeout interrupts. 0b - Disable 1b - Enable
2 WDE	Watchdog Enable Enables or disables the watchdog timer that monitors the PHASEA and PHASEB inputs for motor movement. 0b - Disable 1b - Enable
1 CMPIRQ	Compare Interrupt Request Specifies whether the COMP match has occurred. This field becomes 1 when the counter matches the COMP value. 0b - No match has occurred 1b - COMP match has occurred
0 CMPIE	Compare Interrupt Enable Enables the compare interrupt. 0b - Disable 1b - Enable

55.5.1.3 Input Filter (FILT)

Offset

Register	Offset
FILT	2h

Function

Specifies:

- The input filter sample period.
- The filter prescaler.
- The filter sample count.

FILT[FILT_PRSC] prescales the IPBus clock according to the following equation:

$$FILT\ clock\ frequency = \frac{IPBus\ clock\ frequency}{2^{FILT_PRSC}}$$

Figure 322. FILT clock frequency

Choose FILT[FILT_PER] such that the sampling period is larger than the period of the expected noise. Doing this means that a noise spike will only corrupt one sample.

Choose FILT[FILT_CNT] to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of FILT_CNT+3.

You must also trade off the values of FILT[FILT_PER] and FILT[FILT_CNT] against the need for minimal latency in recognizing valid input transitions. Turning on the input filter (write a non-zero value to FILT[FILT_PER]) introduces a latency of ((FILT[FILT_CNT] + 3)×FILT[FILT_PER]) FILT clock cycles + 2 IPBus clock periods.

You can measure the filter latency:

- Drive the quadrature decoder inputs (PHASEA, PHASEB, INDEX, HOME).
- Monitor the filtered output in Input Monitor (IMR).
- Determine how many IPBus clock cycles it takes before the output shows up, using the following equations, where f is FILT[FILT_PER], and s is FILT[FILT_CNT].
  - DELAY = f×(s+3)(FILT clock cycles) + 1 (IPBus clock cycles)(to read the filtered output)
  - DELAY = f×(s+3)(FILT clock cycles) + 2 (IPBus clock cycles) (to monitor the output in the IMR)

One additional IPBus clock cycle is required to read the filtered output, and two more IPBus clock cycles are required to monitor the filtered output in Input Monitor (IMR). The sample rate sets when it reaches the number f. The following examples use the preceding equations:

- Example: when f = 0, the filter is bypassed: DELAY = 1 or 2 clock cycles.
- Example: when f = 5 and s = 2: DELAY = 5×(2+3) FILT clock cycles + (1 or 2) IPBus clock cycles

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	FILT_PRSC			0		FILT_CNT			FILT_PER							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-13	Prescaler Divide IPBus Clock to FILT Clock

Table continues on the next page...

Table continued from the previous page...

Field	Function
FILT_PRSC	Prescales the IPBus clock to FILT clock. A value of 2^{FILT_PRSC} prescales the IPBus clock, which means that the prescaler logic can divide the clock by a minimum of 1 and a maximum of 128. So FILTER can filter lower frequency noise.
12-11 —	Reserved
10-8 FILT_CNT	Input Filter Sample Count Represents the number of consecutive samples that must agree, before the input filter accepts an input transition. • A value of 0h represents three samples • A value of 7h represents ten samples The value of this field affects the input latency.
7-0 FILT_PER	Input Filter Sample Period Represents the decoder input signals' sampling period (in IPBus clock cycles). Sample each input multiple times at the rate this field specifies. • If FILT_PER is 00h, then the input filter is bypassed. Bypassing the digital filter enables the position/ position difference counters to operate with count rates up to the IPBus frequency. • The value of this field affects the input latency. • When you change the value of this field from a non-zero value to another non-zero value, write 0 first to clear the filter.

55.5.1.4 Watchdog Timeout (WTR)

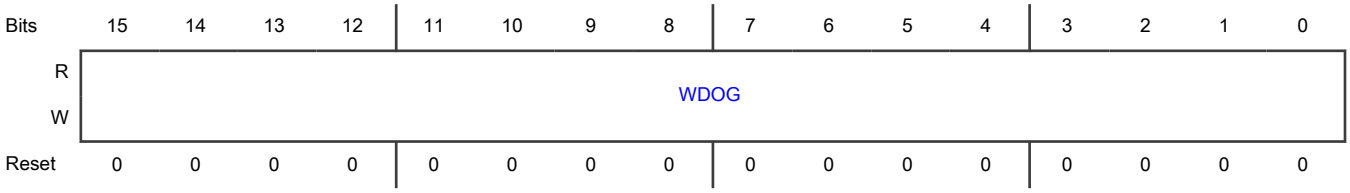
Offset

Register	Offset
WTR	4h

Function

Stores the timeout count for the quadrature decoder module watchdog timer. This quadrature decoder module watchdog timer is different from any other watchdog timer(s) that may also be present in the chip.

Diagram



Fields

Field	Function
15-0 WDOG	WDOG Represents the number of clock cycles, plus one clock cycle that the watchdog timer counts before timing out (and optionally generating an interrupt).

55.5.1.5 Position Difference Counter (POSD)

Offset

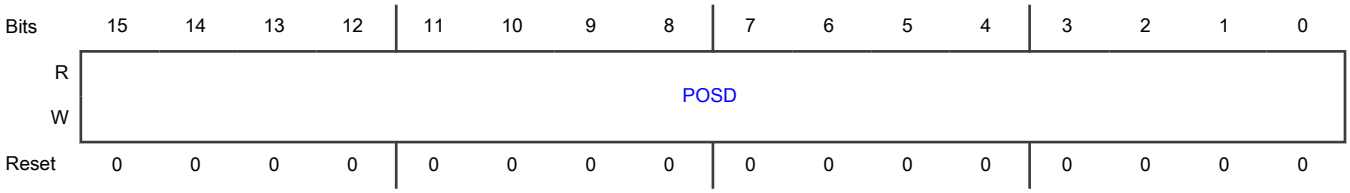
Register	Offset
POSD	6h

Function

Contains the position change in value occurring between each read of the position register. You can use the value of this register to calculate velocity.

- This register computes up or down on every count pulse.
- This register acts as a differentiator, whose count value is proportional to the change in position since the last time you read the position counter.
- When you read this register, its contents are copied into Position Difference Hold (POSDH) and this register becomes 0.

Diagram



Fields

Field	Function
15-0 POSD	POSD Specifies the position change in value between each read of the position register.

55.5.1.6 Position Difference Hold (POSDH)

Offset

Register	Offset
POSDH	8h

Function

Contains a snapshot of the value of Position Difference Counter (POSD). You can use the value of this register to calculate velocity.

Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-0 INIT	INIT Contains the value to initialize Lower Position Counter (LPOS).

55.5.1.15 Input Monitor (IMR)

Offset

Register	Offset
IMR	1Ah

Function

Contains the values of the raw and filtered PHASEA, PHASEB, INDEX, and HOME input signals. The reset value depends on the values of the raw and filtered values of PHASEA, PHASEB, INDEX, and HOME input signals:

- If you connect these input pins to a pullup, then bits 0–7 of this register are all ones.
- If you connect these input pins to a pulldown device, then bits 0–7 of this register are all zeros.
- If no pullup or pulldown is connected to these input pins, then the reset value of the 8 lower bits of this register are all unknown.

7 FPHA	FPHA Specifies the filtered version of PHASEA input.
6 FPHB	FPHB Specifies the filtered version of PHASEB input.
5 FIND	FIND Specifies the filtered version of INDEX input.
4 FHOM	FHOM Specifies the filtered version of HOME input.
3 PHA	PHA Specifies the raw PHASEA input.
2 PHB	PHB Specifies the raw PHASEB input.
1 INDEX	INDEX Specifies the raw INDEX input.
0 HOME	HOME Specifies the raw HOME input.

55.5.1.16 Test (TST)

Offset

Register	Offset
TST	1Ch

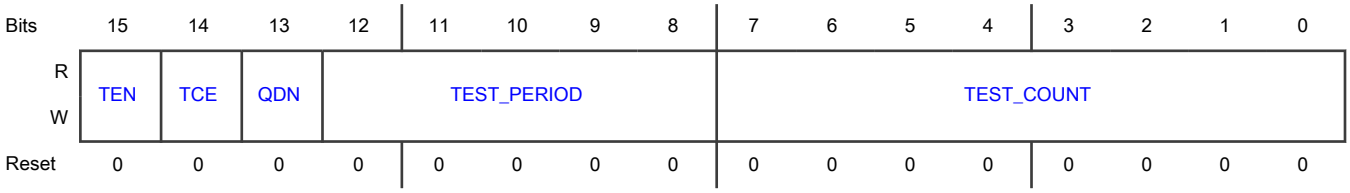
Function

Controls and sets the frequency of a quadrature signal generator; it provides a quadrature test signal to the inputs of the quadrature decoder module.

- The TEST_COUNT value is counted down to zero when TST[TEN] and TST[TCE] are 1.
- Each count value of one represents a single quadrature cycle, which the position counter (Upper Position Counter (UPOS) and Lower Position Counter (LPOS)) interprets as a count of one if enabled (TST[TEN] and TST[TCE] are 1).
- Repeated writing of new values to TEST_COUNT can cause an extra phase transition and, therefore an extra count by the Position Counter.
- The period field determines each quadrature cycle phase's length (in IPBus clock cycles).

This register is a factory test feature; however, you may find it helpful during your software development and testing.

Diagram



Fields

Field	Function
15 TEN	Test Mode Enable Connects the test module to inputs of the quadrature decoder module. 0b - Disable 1b - Enable
14 TCE	Test Counter Enable Connects the test counter to inputs of the quadrature decoder module. 0b - Disable 1b - Enable
13 QDN	Quadrature Decoder Negative Signal Selects whether a negative or positive quadrature decoder signal is generated. 0b - Positive quadrature decoder signal 1b - Negative quadrature decoder signal
12-8 TEST_PERIOD	TEST_PERIOD Specifies the period of the quadrature phase in IPBus clock cycles.
7-0 TEST_COUNT	TEST_COUNT Specifies the number of quadrature advances to generate.

55.5.1.17 Control 2 (CTRL2)

Offset

Register	Offset
CTRL2	1Eh

Function

Specifies the status of interrupts, interrupt enable, and part of basic functions.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W					W1C				W1C		W1C					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-13 —	Reserved
12 INITPOS	Initialize Position Registers Has multiple functions: • When this field is 1, it allows the TRIGGER input to initialize the position counter with Upper Initialization (UINIT) and Lower Initialization (LINIT). • When this field is 0, Upper Position Counter (UPOS) and Lower Position Counter (LPOS) are not initialized on the rising edge of TRIGGER input. Do not write 1 to this field when you use Last Edge Time (LASTEDGE) and Position Difference Period Counter (POSDPER) to measure speed. 0b - Don't initialize position counter 1b - Initialize position counter
11 SABIRQ	Simultaneous PHASEA and PHASEB Change Interrupt Request Indicates that the PHASEA and PHASEB inputs changed simultaneously (within a single clock period). This event typically indicates an error condition, because quadrature coding requires only one of these inputs to change at a time. 0b - No simultaneous change has occurred 1b - A simultaneous change has occurred
10 SABIE	Simultaneous PHASEA and PHASEB Change Interrupt Enable Enables simultaneous PHASEA and PHASEB change interrupts when CTRL2[SABIRQ] becomes 1. 0b - Disable 1b - Enable
9 OUTCTL	Output Control Controls the pulsing of the POSMATCH output signal. This can control when a timer channel captures a timestamp. 0b - POSMATCH pulses when a match occurs between the position counters (POS) and the corresponding compare value (COMP) 1b - POSMATCH pulses when the UPOS, LPOS, REV, or POSD registers are read

Table continues on the next page...

Table continued from the previous page...

Field	Function
8 REVMOD	Revolution Counter Modulus Enable Selects how Revolution Counter (REV) increments or decrements. By default, Revolution Counter (REV) is controlled based on the count direction and the INDEX pulse. As an option, you can control the revolution counter using the roll-over/under detection during modulo counting. 0b - Use INDEX pulse 1b - Use modulus counting roll-over or roll-under
7 ROIRQ	Roll-over Interrupt Request Indicates when the position counter (POS) rolls over from the MOD value to the INIT value or from FFFF_FFFFh to 0000_0000h. 0b - Did not occur 1b - Occurred
6 ROIE	Roll-over Interrupt Enable Enables roll-over interrupts when CTRL2[ROIRQ] is 1. This roll-over interrupt combines with the index interrupt signal. 0b - Disable 1b - Enable
5 RUIRQ	Roll-under Interrupt Request Indicates when the position counter (POS) rolls under from the INIT value to the MOD value or from 0000_0000h to FFFF_FFFFh. 0b - No roll-under has occurred 1b - Roll-under has occurred
4 RUIE	Roll-under Interrupt Enable Enables roll-under interrupts when CTRL2[RUIRQ] is 1. This roll-under interrupt combines with the index interrupt signal. 0b - Disable 1b - Enable
3 DIR	Count Direction Flag Indicates the direction of the last count. 0b - Down direction 1b - Up direction
2 MOD	Enable Modulo Counting Has multiple functions:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• When this field is 1, it allows Upper Position Counter (UPOS) and Lower Position Counter (LPOS) to count in a modulo fashion, using MOD and INIT as the upper and lower bounds of the counting range. During modulo counting: — When you indicate a "count up" and the position counter is equal to MOD, then the position counter reloads with the value of INIT. — When you indicate a "count down" and the position counter is equal to INIT, then the position counter reloads with the value of MOD. • When this field is 0, then the values of MOD and INIT are ignored, and the position counter wraps to zero when counting up from FFFF_FFFFh, or wraps to FFFF_FFFFh when counting down from 0. 0b - Disable 1b - Enable
1 UPDPOS	Update Position Registers Has multiple functions: • When this field is 1, it allows the TRIGGER input to write 0 to Position Difference Counter (POSD), Revolution Counter (REV), Upper Position Counter (UPOS), and Lower Position Counter (LPOS). • When this field is 0, Position Difference Counter (POSD), Revolution Counter (REV), Upper Position Counter (UPOS), and Lower Position Counter (LPOS) ignore the TRIGGER input. • If this field and CTRL2[INITPOS] are 1, Upper Position Counter (UPOS) and Lower Position Counter (LPOS) initialize to Upper Initialization (UINIT) and Lower Initialization (LINIT) on the rising edge of the TRIGGER input. Do not write 1 to this field when you use Last Edge Time (LASTEDGE) and Position Difference Period Counter (POSDPER) to measure speed. 0b - No action 1b - Clear
0 UPDHLD	Update Hold Registers Has multiple functions: • When this field is 1, it allows the TRIGGER input to update Position Difference Hold (POSDH), Revolution Hold (REVH), Upper Position Hold (UPOSH), and Lower Position Hold (LPOSH). • When this field is 0, the TRIGGER input does not update the hold registers (Position Difference Hold (POSDH), Revolution Hold (REVH), Upper Position Hold (UPOSH), and Lower Position Hold (LPOSH)). Do not write 1 to this field when you use Last Edge Time (LASTEDGE) and Position Difference Period Counter (POSDPER) to measure speed. Updating Position Difference Hold (POSDH) causes Position Difference Counter (POSD) to become 0. 0b - Disable 1b - Enable

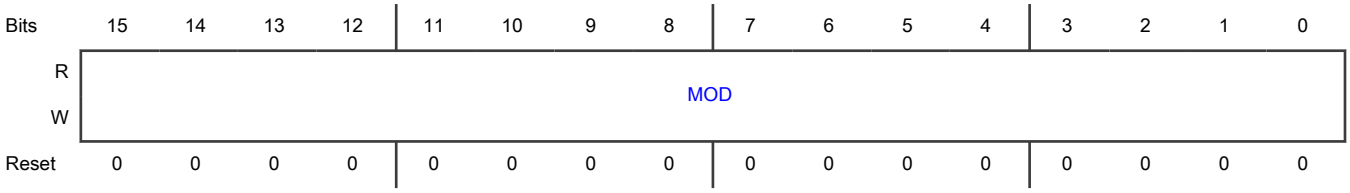
55.5.1.18 Upper Modulus (UMOD)

Offset

Register	Offset
UMOD	20h

Function
Contains the upper (most significant) half of the modulus register.

Diagram



Fields

Field	Function
15-0 MOD	MOD Specifies the upper (most significant) half of the modulus register. This field acts as the upper bound during modulo counting and as the upper reload value when rolling over from the lower bound.

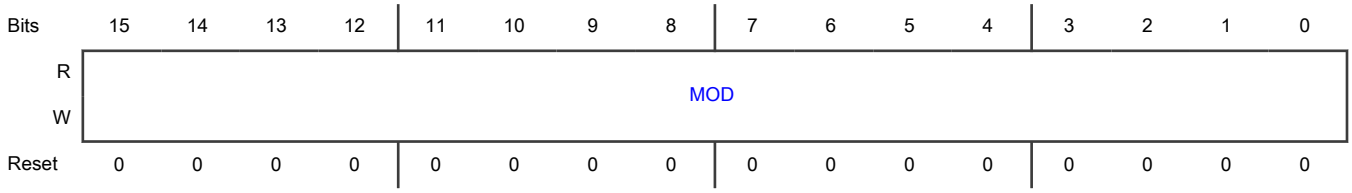
55.5.1.19 Lower Modulus (LMOD)

Offset

Register	Offset
LMOD	22h

Function
Contains the lower (least significant) half of the modulus register.

Diagram



Fields

Field	Function
15-0 MOD	MOD Specifies the lower (least significant) half of the modulus register. This field acts as the upper bound during modulo counting and as the upper reload value when rolling over from the lower bound.

55.5.1.20 Upper Position Compare (UCOMP)

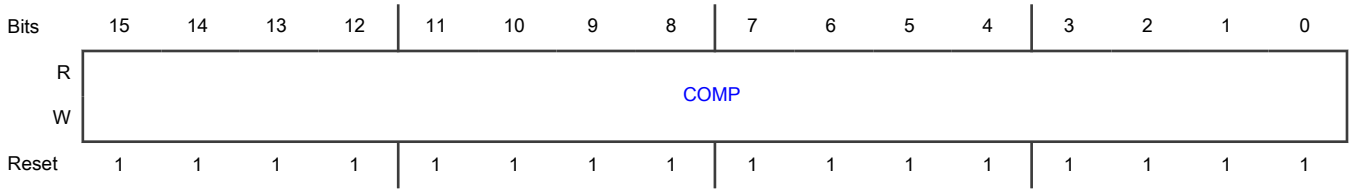
Offset

Register	Offset
UCOMP	24h

Function

Specifies the upper (most significant) half of the position compare register. When the value of the position counter (POS) matches the value of the position compare register (COMP), CTRL[CMPIRQ] becomes 1, and the POSMATCH output is asserted.

Diagram



Fields

Field	Function
15-0 COMP	COMP Specifies the upper (most significant) half of the position compare register.

55.5.1.21 Lower Position Compare (LCOMP)

Offset

Register	Offset
LCOMP	26h

Function

Contains the lower (least significant) half of the position compare register. When the value of the position counter (POS) matches the value of the position compare register (COMP), CTRL[CMPIRQ] becomes 1 and the POSMATCH output is asserted.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Fields

Field	Function
15-0 COMP	COMP Specifies the lower (least significant) half of the position compare register.

55.5.1.22 Last Edge Time (LASTEDGE)

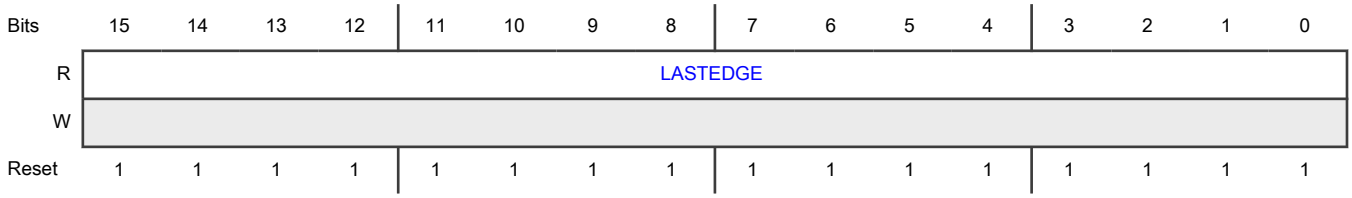
Offset

Register	Offset
LASTEDGE	28h

Function

Represents the time after the last edge occurred on PHASEA or PHASEB.

Diagram



Fields

Field	Function
15-0 LASTEDGE	Last Edge Time Counter Represents the time after the last edge occurred on PHASEA or PHASEB. This field counts up using the peripheral clock that CTRL3[PRSC] prescales. Any edge on PHASEA or PHASEB resets this field to 0 and starts counting. If the LASTEDGE count reaches FFFFh, the counting stops to prevent an overflow. Counting continues when an edge occurs on PHASEA or PHASEB.

55.5.1.23 Last Edge Time Hold (LASTEDGEH)

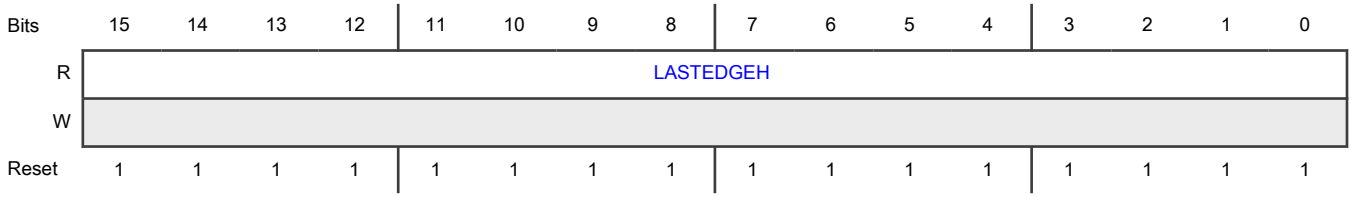
Offset

Register	Offset
LASTEDGEH	2Ah

Function

Holds register for the Last Edge Time (LASTEDGE) value.

Diagram



Fields

Field	Function
15-0 LASTEDGEH	Last Edge Time Hold Holds the Last Edge Time (LASTEDGE) value when you read Position Difference Counter (POSD).

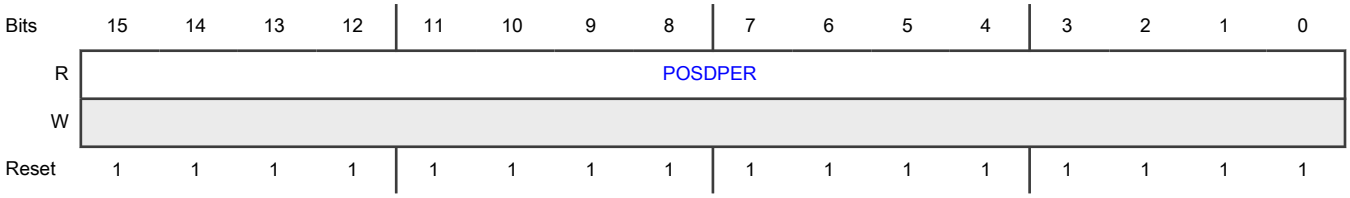
55.5.1.24 Position Difference Period Counter (POSDPER)

Offset

Register	Offset
POSDPER	2Ch

Function
Indicates the position-difference period.

Diagram



Fields

Field	Function
15-0 POSDPER	Position difference period Counts up using the peripheral clock that CTRL3[PRSC] prescales. Reading Position Difference Counter (POSD) loads the value of Last Edge Time (LASTEDGE) into Position Difference Period Counter (POSDPER). If Position Difference Period Counter (POSDPER) count reaches FFFFh, the counting stops to prevent an overflow. Counting continues when an edge occurs on PHASEA or PHASEB.

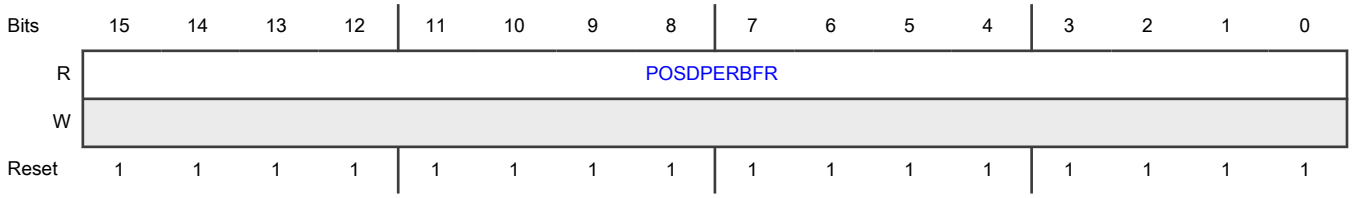
55.5.1.25 Position Difference Period Buffer (POSDPERBFR)

Offset

Register	Offset
POSDPERBFR	2Eh

Function
Buffers the value of Position Difference Period Counter (POSDPER).

Diagram



Fields

Field	Function
15-0 POSDPERBFR	Position difference period buffer Updates with Position Difference Period Counter (POSDPER) value when any edge occurs on PHASEA or PHASEB.

55.5.1.26 Position Difference Period Hold (POSDPERH)

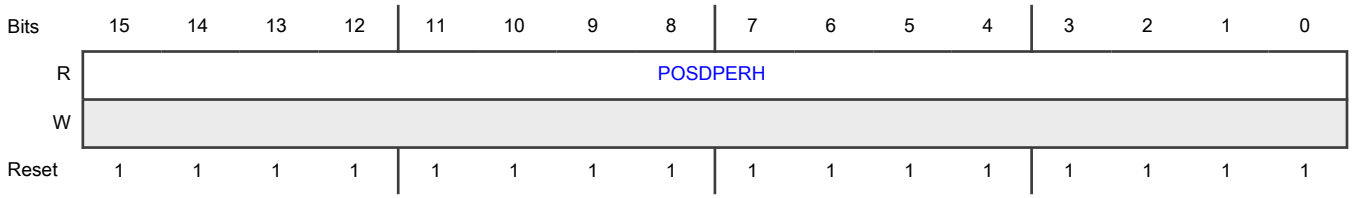
Offset

Register	Offset
POSDPERH	30h

Function

Holds register for Position Difference Period Counter (POSDPER) value.

Diagram



Fields

Field	Function
15-0 POSDPERH	Position difference period hold Updates with Position Difference Period Buffer (POSDPERBFR) value when you read Position Difference Counter (POSD).

55.5.1.27 Control 3 (CTRL3)

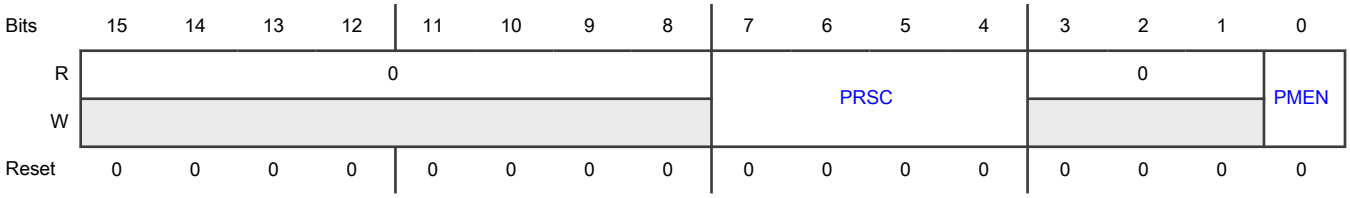
Offset

Register	Offset
CTRL3	32h

Function

Specifies prescaler values for the period clock divider and period measurement function.

Diagram



Fields

Field	Function
15-8 —	Reserved
7-4 PRSC	Prescaler Prescales the peripheral clock that LASTEDGE[LASTEDGE] and POSDPER[POSDPER] use. The resulting prescale clock value is 2^{PRSC}. The prescaler logic can divide the clock by a minimum of 1 and a maximum of 32,768.
3-1 —	Reserved
0 PMEN	Period Measurement Function Enable Specifies that the period-measurement functions of the following registers are used: • Last Edge Time (LASTEDGE) • Last Edge Time Hold (LASTEDGEH) • Position Difference Period Counter (POSDPER) • Position Difference Period Buffer (POSDPERBFR) • Position Difference Period Hold (POSDPERH) If this field is 0, Position Difference Counter (POSD) is loaded to Position Difference Hold (POSDH) and then becomes 0 whenever you read Position Difference Counter (POSD), Upper Position Counter (UPOS), Lower Position Counter (LPOS), or Revolution Counter (REV). If this field is 1, Position Difference Counter (POSD) is loaded to Position Difference Hold (POSDH) and then becomes 0 only when you read Position Difference Counter (POSD).

Chapter 56
Real-Time Clock Subsystem (RTC_SUBSYSTEM)

56.1 Chip-specific RTC_SUBSYSTEM information

Table 453. Reference links to related information

Topic	Related module	Reference
Full description	RTC_SUBSYSTEM	RTC_SUBSYSTEM
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

56.1.1 Module instances

This device has one instance of the RTC_SUBSYSTEM, RTC_SUBSYSTEM0.

56.1.2 Power domain and clock

The RTC_SUBSYSTEM has three main components — the RTC, sub-second counter, and wake timer. The sub-second counter is implemented in the CORE_MAIN power domain, while the wake timer and critical portions of RTC are in the VBAT power domain.

The RTC_SUBSYSTEM receives FRO_16K and XTAL32K clock inputs. The RTC module's CTRL[CLK_SEL] register selects between the two clocks, and the selected clock is routed to the sub-second counter and wake timer.

56.2 Overview

RTC_SUBSYSTEM includes subsecond and wake timer features. The 16-bit subsecond up counter is clocked by the lp_osc input clock, which you must first enable (see Subsecond counter for more information). Either a 1 kHz or 0.5 kHz clock—which is the output of WAKE_TIMER_CTRL[OSC_DIV_ENA] (the clock divider of the lp_osc clock source)—clocks the wake timer.

56.2.1 Block diagram

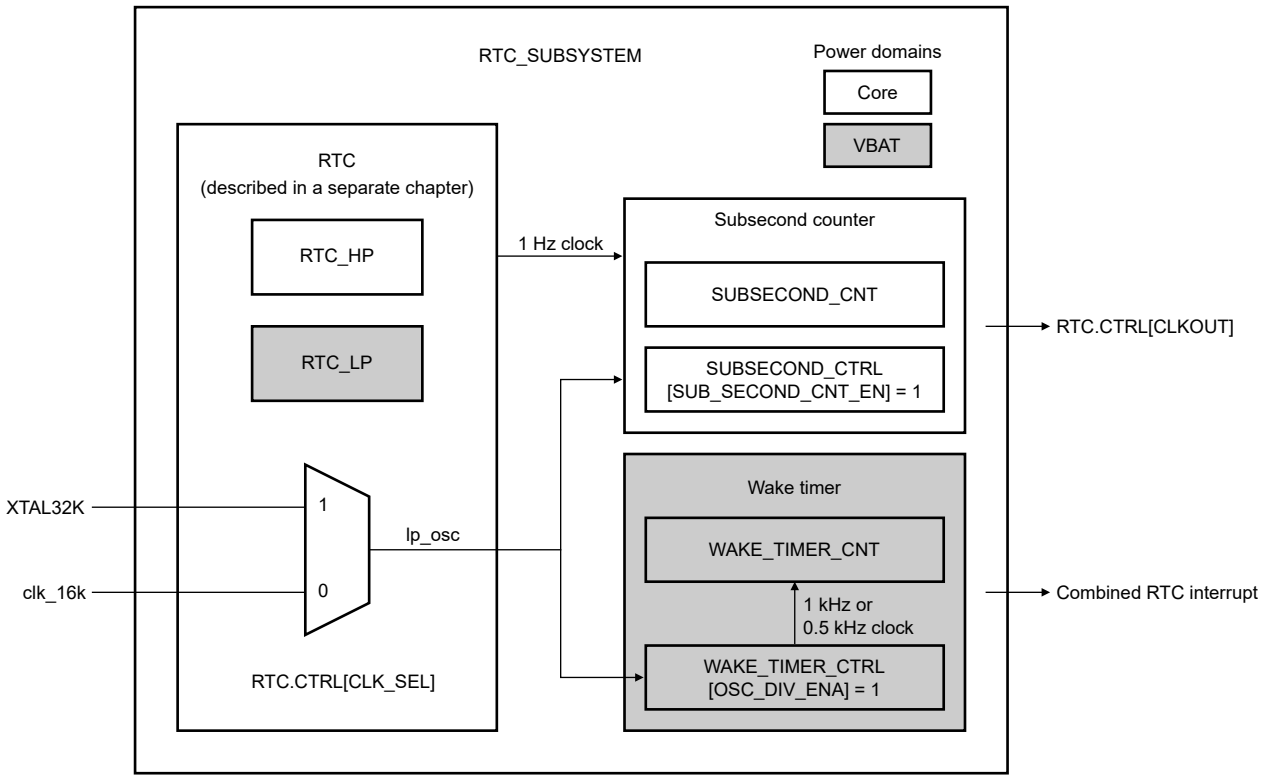

Figure 323. Block diagram

56.2.2 Features

- 16-bit subsecond counter function support in real-time application
- 32-bit wake-up timer counter in the VBAT domain to wake up the chip

56.3 Functional description

RTC_SUBSYSTEM includes a real-time clock (RTC), a subsecond counter, and a wake-up timer.

56.3.1 RTC

RTC handles the following:

- Basic clock functions
- Interrupts and alarms
- Time and calendaring functions and
- Clock compensation logic

See the "Real-Time Clock (RTC)" chapter for more information.

56.3.2 Subsecond counter

You must read the state of this counter through the bus and combine it with the 1-second RTC counter for a more precise time reading. The subsecond counter does not contribute to the alarm, interrupt, or wake-up generation.

SUBSECOND_CNT[SUBSECOND_CNT] is disabled when you reset RTC or disable the main RTC 1 Hz counter.
You must independently enable the field by writing 1 to SUBSECOND_CTRL[SUB_SECOND_CNT_EN] after enabling RTC.CTRL[CLKOUT] (see chip-specific RTC_SUBSYSTEM for more information) to select the 1 Hz clock output. After being enabled, the counter waits until the start of the next 1-second interval. Then, the counter begins incrementing at the lp_osc clock rate. As long as the counter remains enabled, SUBSECOND_CNT rolls over to 0 and resumes counting at the start of each 1-second interval.

56.3.3 Wake timer

The time interval required for many applications, including waking up the part from a low-power mode, often demands a greater degree of resolution than the 1-second minimum interval that the main RTC counter provides. For these applications, you can use a higher-frequency secondary timer that is an independent, standalone wake-up timer for intervals up to 64 s with approximately 1 ms of resolution.

Wake timer is a 16-bit down counter that clocks at 1 kHz after you enable it. If the frequency of the lp_osc clock source is 16 kHz, then the wake timer clocks at a rate of 0.5 kHz. Writing a nonzero value to this timer automatically enables the counter and launches a countdown sequence. When you use the counter as a wake timer, this write can occur prior to entering a low-power mode.

After a starting count value loads, the wake timer turns on, counts from the pre-loaded value down to 0, generates an interrupt and a wake command, and then turns itself off until a subsequent software write relaunches it.

56.3.4 Clocking

Table 454. Clocking

Clock	Description
lp_osc	Clock output from RTC.CTRL[CLOCK_SEL], which selects between the CLK_16K and XTAL32K inputs as the clock source.

56.4 External signals

This module has no external signals.

56.5 Initialization

This module does not require initialization.

56.6 RTC_SUBSYSTEM register descriptions

56.6.1 RTC_SUBSYSTEM memory map

RTC_SUBSYSTEM0 base address: 4004_C000h

Offset	Register	Width (In bits)	Access	Reset value
800h	Subsecond Control (SUBSECOND_CTRL)	32	RW	0000_0000h
804h	Subsecond Counter (SUBSECOND_CNT)	32	R	0000_0000h
C00h	Wake Timer Control (WAKE_TIMER_CTRL)	32	RW	0000_0000h

56.6.2 Subsecond Control (SUBSECOND_CTRL)

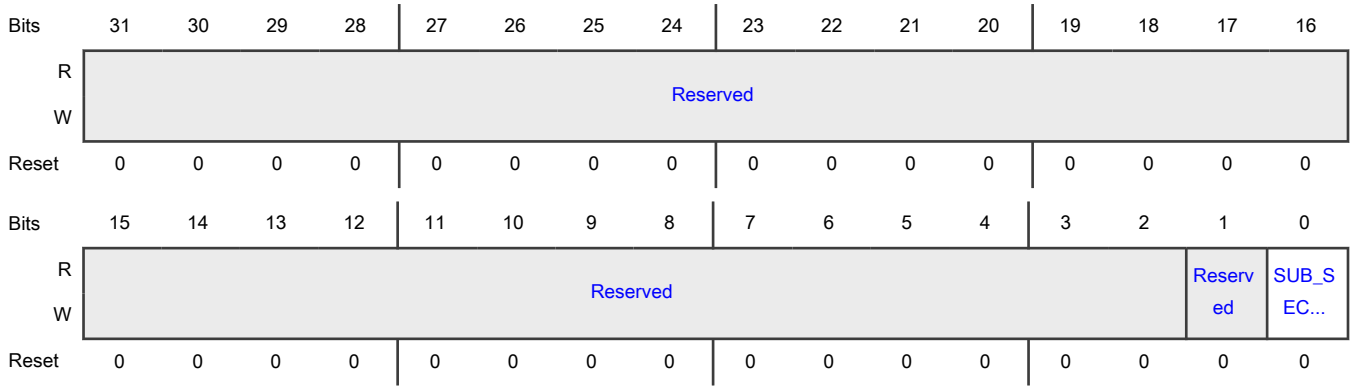
Offset

Register	Offset
SUBSECOND_CTRL	800h

Function

Controls Subsecond Counter (SUBSECOND_CNT).

Diagram



Fields

Field	Function
31-2 —	Reserved
1 —	Reserved
0 SUB_SECOND_CNT_EN	Subsecond Counter Enable **NOTE** Write 1 to RTC.CTRL[CLKOUT] to select the 1 Hz clock output for the subsecond counter to synchronize with the RTC_SECONDS counter. See the chip-specific RTC_SUBSYSTEM for more information. 0b - Disable 1b - Enable

56.6.3 Subsecond Counter (SUBSECOND_CNT)

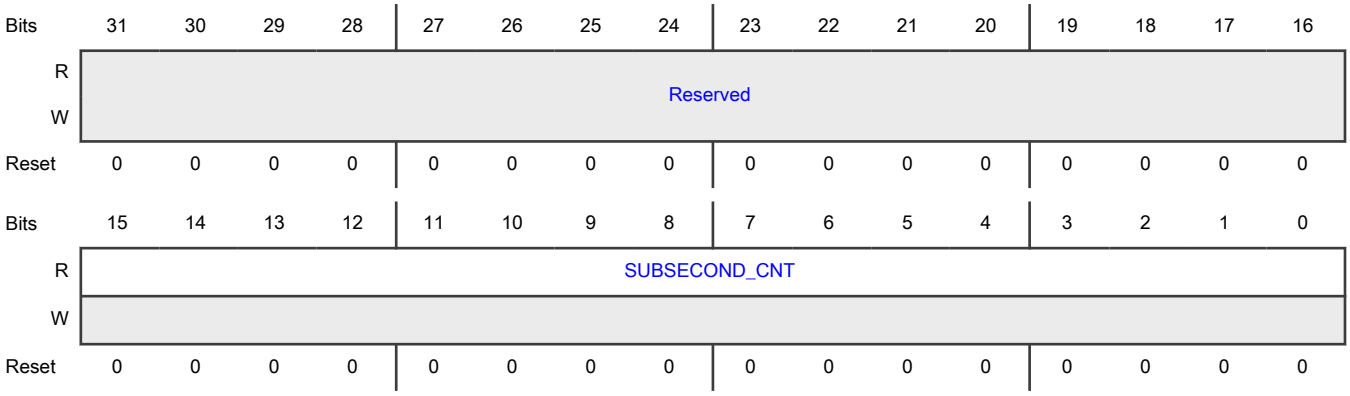
Offset

Register	Offset
SUBSECOND_CNT	804h

Function

Contains the subsecond counter value. The 32 kHz clock input clocks this 16-bit subsecond counter.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 SUBSECOND_CNT	Current Subsecond Counter Value Contains the current subsecond counter value. Because of clock domain crossing, you must read the register twice in succession and confirm whether the two values are the same. In case they are not, repeat the procedure until the values become the same.

56.6.4 Wake Timer Control (WAKE_TIMER_CTRL)

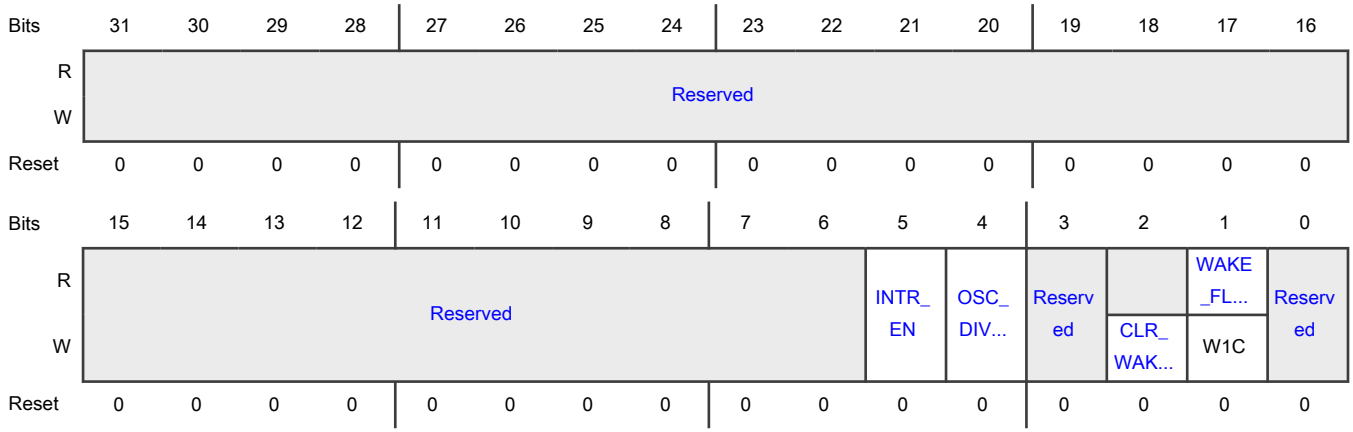
Offset

Register	Offset
WAKE_TIMER_CTRL	C00h

Function

Controls Wake Timer Counter (WAKE_TIMER_CNT). Either a 1 kHz or 0.5 kHz clock—which is the output of the 5-bit ripple counter with the lp_osc clock as the clock source—clocks the wake timer.

Diagram



Fields

Field	Function
31-6 —	Reserved
5 INTR_EN	Enable Interrupt Enables an interrupt when you write 1 to WAKE_TIMER_CTRL[WAKE_FLAG]. 0b - Disable 1b - Enable
4 OSC_DIV_ENA	OSC Divide Enable Enables the clock divider to divide down the lp_osc input clock source to generate either a 1 kHz or 0.5 kHz clock for the wake timer. Write 1 to OSC_DIV_ENA for the wake timer to run. 0b - Disable 1b - Enable
3 —	Reserved
2 CLR_WAKE_TIMER	Clear Wake Timer Clears the wake timer and halts the operation until a new count value is loaded. **NOTE** Reading this field always returns 0. 0b - No effect 1b - Clear the wake timer counter
1 WAKE_FLAG	Wake Timer Status Flag Specifies whether the wake timer has timed out.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not timed out 1b - Timed out
0 —	Reserved

56.6.5 Wake Timer Counter (WAKE_TIMER_CNT)

Offset

Register	Offset
WAKE_TIMER_CNT	C0Ch

Function

Contains the current value of the wake timer. Do not write to this register while counting is in progress.

Diagram

Fields

Field	Function
31-0 WAKE_CNT	Wake Counter Contains the current value of the wake timer. Because of clock domain crossing, you must read the register twice in succession and confirm whether the two values are the same. In case they are not, repeat the procedure until the values become the same. A write to this field preloads a start-count value into the timer and starts a countdown sequence.

Chapter 57
Real-Time Clock (RTC)

57.1 Chip-specific RTC information

Table 455. Reference links to related information

Topic	Related module	Reference
Full description	RTC	RTC
System memory map		Memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

57.1.1 Module instances

This device has one instance of the RTC module, RTC0.

57.1.2 VBAT wakeup via WAKEUP_b pin

An RTC interrupt asserts the VBAT.STATUS[IRQ2_DET]. This interrupt can optionally be configured as a source to assert the WAKEUP_b pin. When the device is operating in the VBAT power mode, you can transition the device back to active mode by configuring an external circuitry to recognize the WAKEUP_b assertion and request for a system power on. See the VBAT chapter for more details.

57.2 Overview

Real Time Clock (RTC) is a low-power module that provides time keeping and calendaring functions, protection against spurious memory/register updates. It can also compensate the 1 Hz clock against variations in 32 kHz or 16 kHz clock in oscillator due to crystal or temperature.

57.2.1 Block diagram

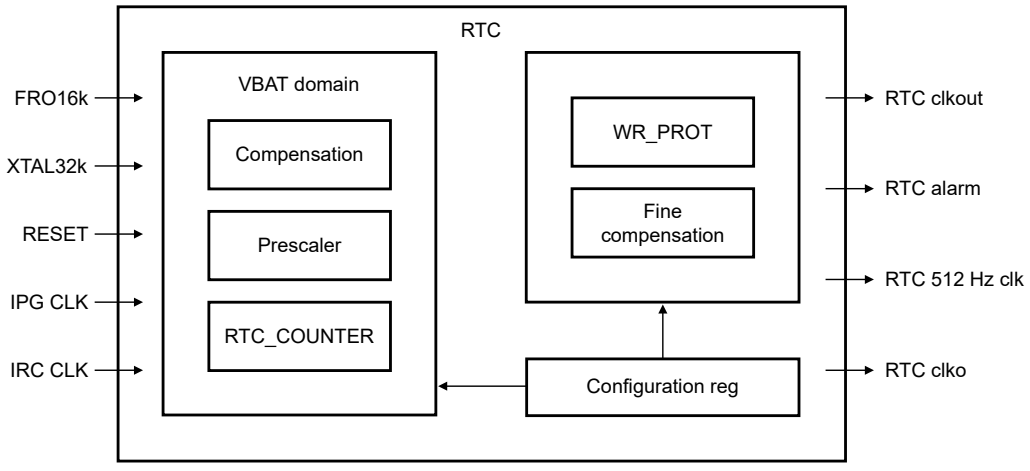

Figure 324. RTC block diagram

57.2.2 Features

RTC includes the following features:

- Designed for low power
  - Time and date counters are interleaved to prevent simultaneous toggling
- Basic clock functions
  - Separate counters for days, hour, minutes, and seconds
  - Calendaring support—Separate counters for year, month, and day of the week
    - Automatic adjustment for daylight saving with user-defined parameters
    - Automatic adjustment for month and leap year
  - External clock support to run the counters if you choose to provide an externally-compensated 1Hz clock
- Time zone offset—RTC uses local time which implicitly contains the time zone offset
- Programmable alarm with interrupt—Alarm is output from RTC in case the MCU uses it as a wake up event
- Periodic interrupts (sampling timer interrupts)
- Hardware compensation—Compensates 1 Hz clock (to the counters) against frequency variations in oscillator clock due to temperature changes or crystal characteristics. Programmable correction factor calculated by firmware.
- 16-bit CPU register programming interface with protection against runaway code
- Option to output the buffered 32.768 or 16.384 kHz clock or the compensated 1 Hz clock.

57.3 Functional description

57.3.1 Modes of Operation

This section describes the RTC modes of operation.

57.3.1.1 Wait mode/Power Down mode

RTC is fully operational in Wait mode (called Wait mode or Power Down mode depending on the device series). RTC runs off a 32.768 or 16.384 kHz clock that is not gated in Wait mode. This means the timekeeping functions (and other functions) that depend on the 32.768 or 16.384 kHz clock continue to operate independent of the CPU. Only the register block's clock is gated and no register contents are lost.

57.3.1.2 Stop mode/Deep Power Down mode

In Stop mode (called Stop mode or Deep Power Down mode depending on the device series), RTC is fully operational and behaves in the same way as it does when in Wait mode. If CPU power (VDD) is removed in Stop mode, RTC switches its power supply source to battery supply (VBAT) and isolates itself from the powered off domains.

NOTE

If the system bus clock is off in Stop mode, no read happens on RTC registers. When the system bus clock is switched on again, synchronization takes time. During the synchronization time, no write is allowed and any read to the RTC register returns FFFEh as the code to indicate the clock domains are synchronizing.

57.3.1.3 VBAT mode

Because it runs off a 32.768 or 16.384 kHz clock, RTC is fully operational in VBAT mode. The 32.768 or 16.384 kHz clock is not gated in VBAT mode and RTC's timekeeping functions (and other functions) that depend on the clock continue to operate independent of the CPU. Only the register block's clock is gated and no register contents are lost. After coming out of VBAT mode, the register content is not accessible for two osc_clk cycles due to synchronization.

57.3.2 Design overview

RTC provides basic timekeeping functions through counters for seconds, minutes, and hours, and calendaring functions via date, day-of-week, month, and year counters, including automatic adjustments for leap years and daylight saving time. Reading these counters indicates the current date and time and writing to these registers sets the date and time as provided by the user.

The alarm is set for a specific hour, minute, and second. If the alarm interrupt is enabled, an interrupt to CPU is generated when the time counters match the configured alarm hour, minute, and second settings. The alarm can also be configured to match a specific day, month, and year to generate an interrupt. The alarm signal is output to an MCU pin to allow wake up or control of external devices on board.

RTC also provides sampling timer interrupts.

A frequency compensation module is integrated into the RTC to correct any error in the 1 Hz clock due to variations in the 32.768/16.384 kHz clock which could be caused by crystal inaccuracy, board variations, or change in temperature. The combined compensation value for both crystal and temperature variation is determined by software and the correction is done in hardware.

The registers in RTC are configured via the CPU register programming interface. A protection mechanism is built into RTC to protect its registers against unintended writes by any runaway code. The protection mechanism requires the CPU to write a specific sequence of codes to the STATUS[7:6] bits to allow write access to the registers. After updating the registers, the CPU can write 10 to STATUS[7:6] bits to enable the write protection. After unlocking the registers, the CPU has a window of two seconds in which to update the register space. Following power-on reset, a window of 15 seconds is allowed for the CPU to configure the RTC, after which the registers are locked. Any updates beyond the unlock window require the CPU to unlock the registers, again.

For detailed description on the complete functionality of RTC, see Time and calendaring functions.

57.3.3 Clocking

The 32.768 kHz clock input from the oscillator is divided to generate a 512 Hz and a 1 Hz clock in RTC.

Table 456. Clocking

Signal name	Description	Direction
rtc_clk_out	1 Hz, 16 kHz, or 32.768 kHz clock output. Option for selecting compensated 1 Hz clock or buffered 32.768 kHz or 16 KHz clock is available in Control (CTRL).	Output
rtc_clko_s	Gated 32.768 kHz or 16 kHz clock output to other peripherals. Controlled by CTRL[CLKO_DIS].	Output
rtc_osc_32k_in_clk_hp	32.768 kHz clock input from oscillator, used in HP domain.	Input
rtc_osc_32k_in_clk_lp	32.768 kHz clock input from oscillator, used in LP domain.	Input
rtc_osc_16k_in_clk_hp	16.384 kHz clock input from FRO16, used in HP domain.	Input
rtc_osc_16k_in_clk_lp	16.384 kHz clock input from FRO16, used in LP domain.	Input
ipg_clk_hp_s	Gated system bus clock used for register read or write for high power or the CPU domain.	Input
ipg_clk_lp_s	Gated system bus clock used for register read or write for low power or the battery domain.	Input
ipg_clk_hp	System bus clock used to synchronize the oscillator 32.768 kHz or FRO 16 kHz clock to the ipg_clk domain (free running clock), used in HP domain.	Input
ipg_clk_lp	System bus clock used to synchronize the oscillator 32.768 kHz or FRO 16 kHz clock to the ipg_clk domain (free running clock), used in LP domain.	Input
rtc_irc_clk	Mhz clock used to fine compensate the oscillator clock.	Input

RTC has a 32.768 kHz clock input from the oscillator and a 16 kHz clock input from the FRO. You can select which clock to use by setting CTRL[CLK_SEL]. The clock becomes the output to the peripherals and divided to generate a 512 Hz clock and a 1 Hz clock. The 512 Hz clock becomes the output to peripherals and the 1 Hz clock is the input of the counter.

The 1 Hz clock is subject to variations in speed due to temperature changes or crystal irregularities. The input clock rtc_irc_clk runs in cycles of MHz and compensates for these variations by making precise adjustments to the 1 Hz clock.

RTC has one system bus clock used to synchronize the oscillator 32.768 kHz or 16 kHz clock to the ipg_clk domain.

Writing to CTRL[CLKOUT] configures either the clock input (32.768 kHz or 16 kHz) or the 1 Hz clock as the output from the SOC for use outside RTC. Writing to CTRL[CLKO_DIS] determines if the selected clock outputs to other peripherals.

57.3.4 Interrupts

Write one to IER[ALM_IE] to enable the alarm interrupt. The alarm interrupt is asserted when the programmed alarm value matches the counter values and the ISR[ALM_IS] bit is set. The status bit and interrupt are cleared by writing one. The status register is also cleared on software reset, except for the tamper status which remains unaffected. The counters matched for the alarm interrupt are selected based on the alarm type set in CTRL[ALM_MATCH].

There are eight periodic, sampling timer interrupts. When the clock generation counter counts to the programmed value, the corresponding bit in the status register is set. The status bits are cleared either by writing one or by software reset.

57.3.5 Time and calendaring functions

RTC performs and controls all the chronological functions listed below.

- Implements all counters for date and time and the related control logic
- Calculates leap year and adjusts the day count accordingly
- Increments or decrements counters to adjust for leap seconds
- Tracks the number of days in a month
- Automatically adjusts for daylight saving time
- Generates alarm with selectable matching of different counters.

Dynamic modifications to the date counters are done based on leap year, month, and daylight saving. Additionally, the user software can add or subtract a second to adjust for leap seconds. All changes are controlled by hardware and triggered by software.

A leap year is defined as a year in which the year value is divisible by 4 and 400 and has an extra day in February. Daylight saving is implemented in different regions of the world to shift the local time according to the summer or winter seasons. Time is shifted at a pre-defined time decided by the regional conditions and programmed by the user software. RTC automatically adjusts the time using hardware alarms for daylight saving. The day counter is also adjusted for months which have 28, 29, 30, or 31 days.

Alarm generation is done by the RTC block. Matching the counters is controlled by CTRL[ALM_MATCH] to give various alarm options for daily, monthly, yearly, or one-time alarms.

NOTE

Setting an hour alarm value that coincides with the daylight saving start hour value will not generate an alarm because the hour counter is incremented by two (instead of one) when daylight saving comes into effect. For example, setting ALM_HOURMIN to 0x1500 (hour alarm value = 15 or 3 PM) when DST_HOUR = 0x1411 (DST start hour value = 14 or 2 PM) will cause the hour counter to go from 14 to 16. The hour counter will not equal 15 and therefore the alarm which was set for 15 (or 3 PM) will not trigger. User software must take daylight saving changes into account when setting alarm values.

NOTE

User software must program an alarm time equal to the daylight saving end time (fallback time). The user software must write 0 to CTRL[DST_EN] when the alarm interrupt occurs, otherwise the correct operation might not take place.

57.3.6 RTC compensation logic

The compensation logic supports temperature and frequency compensation and provides an accurate and wide range of compensation suitable for many crystals. It can correct a wide range of crystal offsets from as low as 0.119 PPM.

There are two important components in the compensation logic: coarse compensation and fine compensation. The coarse compensation provides an accurate clock to RTC's internal time and date counters, and fine compensation generates an accurate 1 Hz clock output (via MCU pin) with high resolution clock edge placement (up to 0.88 ppm) and near 50 percent duty cycle.

Enabling the required compensation logic

Coarse compensation is enabled by writing to CTRL[COMP_EN] and fine compensation is enabled by writing to CTRL[FINEEN]. However, when FINEEN = 1, COMP_EN must be equal to 1. Setting both bits to 0 disables all compensation. This is the default state out of reset.

Compensation parameters need to be provided to allow required compensation logic to run. The parameters are provided by writing to the COMPEN register.

NOTE

If CTRL[FINEEN] = 0, then compensation must be disabled using CTRL[COMP_EN] before changing COMPEN for the first time. Successive changes can be done without disabling compensation.

If FINEEN = 1, then there are two options:

- Either clear previously accumulated fractional compensation value by disabling compensation from the CTRL register, program new values, and re-enable compensation and start a fresh
- Or, overwrite the current values leading to the addition of previously accumulated fractional compensation value to programmed fractional compensation value.

The integer part is always overwritten

Compensation parameters

Compensation logic requires the user software to provide compensation parameters in the COMPEN register in order to generate an accurate 1 Hz clock. These parameters are defined depending on the type of compensation enabled.

The compensation parameters (when FINEEN = 0) are defined as:

- **Compensation correction value:** Compensation correction value is a two's complement value by which the 1 Hz Clock is modified (during its generation) by either adding or removing RTC oscillator clock cycles.
- **Compensation interval:** Compensation interval is the duration in seconds over which the correction is applied. This is the time in which the addition or removal of 32.768 or 16.384 kHz clock cycles is done, thereby ensuring that the compensation interval is close to the interval obtained with an ideal 1 Hz clock.

The compensation parameters (when FINEEN = 1) are defined as:

- **Integral compensation value:** This is a two's complement value of the integer part of correction or compensation value that has to be adjusted in every 1 second period. This value is expressed in terms of the number of clock cycles of the RTC oscillator clock.
- **Fraction compensation value:** This is the fractional part of the correction or compensation value that has to be adjusted. This value is expressed as the number of clock cycles of a fixed 4.194304 MHz clock that have to be added. This value is always a positive number.

NOTE

When FINEEN = 1, the compensation interval is by default set to 1, indicating that the compensation will be done at every second.

Coarse compensation logic

Coarse compensation logic provides the accurate 1 Hz clock pulses to the time and date counters and the coarse 1 Hz clock to the fine compensation logic.

When FINEEN = 0: RTC compensates the clock over the provided compensation interval. The addition or removal of clocks is done in a single 1 Hz period, leaving the other 1 Hz periods of the compensation interval the same. This addition or removal of RTC oscillator clock cycles adjusts the 1 Hz clock in a way that keeps the overall compensation interval time close to the same interval being measured with an ideal clock.

When FINEN = 1: The integer part of the compensation (or correction) value is added or removed every 1 Hz period and the fraction part is accumulated and adjusted when the accumulated value equals 1 RTC oscillator clock cycle period.

To perform crystal offset compensation, the user software computes the compensation parameters external to RTC and, using details about the crystal characteristics (aging, drift, and so on), computes the correction factor. The user software then programs it in the two's complement format in the compensation register (COMPEN). Based on the values written in the COMPEN register, the compensation is performed.

To perform temperature compensation, the user software can maintain a lookup table in its memory which lists the change in frequency of 32.768 or 16.384 kHz crystal clock for each degree change in temperature. The CPU wakes up periodically to measure the external temperature via a temperature sensor connected to an A/D converter. The user software uses the lookup table to determine the compensation factor and writes the value to be compensated (in terms of number of 32.768 or 16.384 kHz clock cycles in two's complement format) in the compensation register (COMPEN). Based on the new values written, the compensation logic adjusts the clock from the next compensation interval.

The user software must compute a common compensation factor if it detects a variation in 32.768 or 16.384 kHz clock due to both temperature and crystal characteristics.

Vital statistics

- Range of compensation interval: 1 second to 255 seconds. If FINEEN = 0, writing a 0 disables compensation. If FINEEN = 1, this interval is always 1 second.
- Range of compensation: -128 to +127 (number of 32.768 or 16.384 kHz clock cycles)
- Selection criteria: Compensation is done only when enabled by user software. User software can disable compensation by writing a 0 compensation interval or setting CTRL[COMPEN] = 0.

Fine compensation logic

The fine compensation logic takes the coarse 1 Hz clock (from coarse compensation block) and generates accurate 1 Hz clock output with accurate clock edge placement and near 50 percent duty cycle.

The fine compensation runs when FINEEN = 1 and uses the MCU's IRC clock to adjust the fractional part of the compensation value every 1 Hz period. This provides an accurate edge placement on the 1 Hz clock.

The fine compensation module automatically adjusts the fractional compensation value for any variation in the IRC clock.

NOTE

Because the IRC clock is generated on MCU, this clock will be disabled when MCU power is OFF or in certain low power modes. In this case, the coarse 1 Hz clock is output from the MCU. The coarse 1 Hz clock is not a 50 percent duty cycle clock.

57.3.7 Write protection mechanism

The write protection mechanism protects the RTC registers from any unexpected updates that can happen from a runaway code. This logic monitors the values written to STATUS[WE]. By default, unconditional write access is allowed to these bits only. For writing the locking and unlocking sequence, 8-bit access should be configured in STATUS[7:0].

To enable write protection, write 10 to these bits. To disable write protection, write the following sequence to those bits: 00, 01, 11, 10.

After a power-on reset, the write protection mechanism is disabled, allowing the user software to configure the RTC block. After configuration is complete, the user code can enable the write protection mode. If this is not done by the user software, the registers are put into write protect mode 15 seconds after power-on. If the write protection mode is unlocked to update registers and not locked again by the user software, the write protection mode is automatically enabled after two seconds.

Any write access made to the registers when write protection is enabled (that is, registers are locked) will cause the transfer error signal to be asserted. Reads are allowed at all times.

NOTE

1. Always check STATUS[WRITE_PROT_EN] after running unlocking and locking sequences and re-run the sequence if STATUS[WRITE_ PROT_EN] is not in the required state.
2. Two consecutive unlocking sequences will lock the registers. After they are unlocked, running an unlock sequence before the timeout will lock RTC registers.

57.4 External Signals

Table 457. External signals

Signal	Description	Direction
RTC_CLKOUT	Output clock to external devices on the board.	Output

57.5 Memory map and registers

57.5.1 RTC register descriptions

The register address is the sum of the base address and the address offset. The base address is defined at the chip level. The address offset is defined at the module level.

NOTE

A 32.768 kHz or 16 kHz clock is needed to initialize the RTC. This clock can later be gated when programming the RTC registers.

NOTE

Use valid dates to configure registers. For example, do not configure a value like February 30, 2024, because there is no 30th in February 2024.

57.5.1.1 RTC memory map

57.5.1.2 Year and Month Counters (YEARMON)

Offset

Register	Offset
YEARMON	0h

Function

Stores the value of the month and year counters. The year field stores the offset in years from a hardcoded base year (2112), not the actual year value. This is a signed value that ranges from -128 to +127. The actual year value can be calculated by adding the base year (2112) and the offset in the YEARMON[15:8] register, meaning the range of years supported is 1984 (2112 - 128) to 2239 (2112 + 127). For example, if the current year is 2007, then it will be represented in this register as 105 or 0x97. Software should program the offset from the base year into this register.

For year calculation:

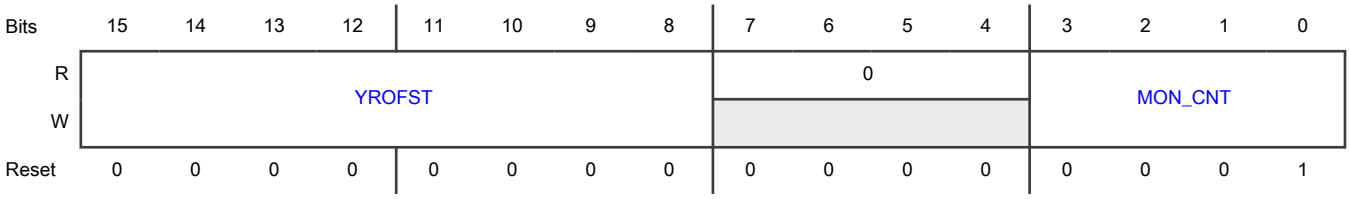
Actual Year = Base Year (for example, 2112) + Offset Year

The month field stores the count value of the months register. Writing to this register loads the months counter with this new value. The valid values are shown in table below.

User software should first determine the state of STATUS[INVAL_BIT] to determine if the counters are stable before a value can be read or changed. The assertion of STATUS[INVAL_BIT] ensures that no operation is done at the boundary of a second when counters change value.

Both month and year are unaffected by software reset.

Diagram



Fields

Field	Function
15-8 YROFST	Year Offset Count Value Indicates the offset in years from the base year (hard coded as 2112) and does not show the actual year value. This is a signed value. Valid values are -128 to 127. The base year is 2112 and if the value of YEAR field is 0x10, the actual year is 2112 + 16 = 2128.
7-4 —	Reserved
3-0 MON_CNT	Month Counter Provides the value of the Months Counter. Valid Values are: 0000b,1101b,1110b,1111b - Illegal Value 0001b - January 0010b - February 0011b - March 0100b - April 0101b - May 0110b - June 0111b - July 1000b - August 1001b - September 1010b - October 1011b - November 1100b - December

57.5.1.3 Days and Day-of-Week Counters (DAYS)

Offset

Register	Offset
DAYS	2h

Function

Shows the current value of the day-of-week counter and the days counter. Reading this register returns the latest value of the counters. Writing to this register loads the value to the day-of-week and days counters, and the counters continue to count from this new value. The day-of-week is not calculated automatically and should be written by CPU. This register is unaffected by software reset.

User software should first determine the state of STATUS[INVAL_BIT] to determine if the counters are stable before their value can be read or changed. The assertion of STATUS[INVAL_BIT] ensures that no operation is done at the boundary of a second when counters change value.

57.5.1.4 Hours and Minutes Counters (HOURMIN)

Offset

Register	Offset
HOURMIN	4h

Function

Used to program the hours and minutes counter. The register can be read anytime to get the current value of the counters. The hours counter can be set to anything between 0 and 23. The minutes counter can be set to anything between 0 and 59. This register is unaffected by software reset. Only power-on reset can reset this register.

User software should first determine the state of the STATUS[INVAL_BIT] to determine if the counters are stable before their value can be read or changed. The assertion of STATUS[INVAL_BIT] ensures that no operation is done at the boundary of a second when counters change value.

57.5.1.6 Year and Months Alarm (ALM_YEARMON)

Offset

Register	Offset
ALM_YEARMON	8h

Function

Used to configure the months and year setting of the alarm. The alarm setting can be read or written anytime. Alarm interrupt bit is set when all values of alarm seconds, minutes, hours, days, month, and year match their respective counter values. This register is reset to its default state on software reset.

User software can configure the alarm type by using the CTRL[ALM_MATCH].

57.5.1.9 Seconds Alarm (ALM_SECONDS)

Offset

Register	Offset
ALM_SECONDS	Eh

Function

Used to configure the seconds setting of the alarm. The alarm setting can be read or written anytime. This register is reset to default value on software reset.

User software has the option of using bits 9:8 to perform a correction on the seconds counter to compensate for leap seconds. Writing to these bits adds or subtracts 1 from the seconds counter and read returns zeros.

User software should first determine the state of STATUS[INVAL_BIT] to determine if the counters are stable before they can be incremented or decremented. The assertion of STATUS[INVAL_BIT] ensures that no operation is done at the boundary of a second when counters change value.

User software can configure alarm type using CTRL[ALM_MATCH].

0 FINEEN	Fine Compensation Enable 0b - Fine compensation is disabled 1b - Fine compensation is enabled.

57.5.1.11 Status (STATUS)

Offset

Register	Offset
STATUS	12h

Function

Indicates the status of various processes occurring inside the RTC. Also helps the user software to read time or date register when the values are stable and not changing. Compensation Done bit and Bus Error bit are cleared by writing 1. Software reset resets the whole register to its default state.

All memory mapped registers are protected against spurious updates by the write protect mechanism. To unlock the registers, a specific pattern (as mentioned in the table above) has to be written in the write enable bits (WE[1:0]) to enable or disable write protection. The WE[1:0] bits are the only bits that are freely writeable by user software. The write enable bits are self-clearing bits that always return zeros on read.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Fields

Field	Function
15-12 —	Reserved
11 CMP_DONE	Compensation Done Indicates that the current compensation cycle is complete. This field is cleared by writing 1. This bit is asserted seven 32.768 or 16.384 kHz clock cycles before the actual compensation interval completes so that back-to-back compensation can be enabled. 0b - Compensation busy or not enabled 1b - Compensation completed
10 —	Reserved
9 —	Reserved
8 BUS_ERR	Bus Error Indicates that a read or write cycle was initiated by software when the STATUS[INVAL_BIT] = 1. Write access to time or date registers is nullified (terminate normally) and no register value is changed. Reading when STATUS[INVAL_BIT] is asserted returns 0xFFFF. No transfer error is asserted. This bit is cleared by writing 1. 0b - Read and write accesses are normal. 1b - Read or write accesses occurred when STATUS[INVAL_BIT] was asserted.
7-6 WE	Write Enable Controls entry into and exit from the write protection mode. Both registers are protected by the write protection mechanism. These are self-clearing bits. Reads will return zeros. Disable write protection by writing this sequence: 00b, 01b, 11b, 10b. See Write protection mechanism for more information. **NOTE** When the registers are unlocked, they remain in this unlocked state for a time of 2 seconds, after which they are locked automatically. After power-on reset, the registers are unlocked and then are locked automatically after 15 seconds.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Enable Write Protection - Registers are locked.
5 CMP_INT	Compensation Interval Asserted for a time equal to compensation interval seconds as configured by the user. Used by the MCU to calculate the interrupts serviced during this interval and performs corrections in case of deviations (calibration). This bit toggles on at the start of every new compensation interval and is either 0 or 1 during the entire duration. This bit will not toggle if compensation logic has been disabled by MCU.
4 —	Reserved
3-2 —	Reserved
1 WRITE_PROT_EN	Write Protect Enable Status Indicates that registers are in locked mode and writing to them is disabled. Any write access made to the register space when write protection is enabled (that is, when they are in locked mode) will cause the transfer error signal to be asserted. 0b - Registers are unlocked and can be accessed. 1b - Registers are locked and in read-only mode.
0 INVAL_BIT	Invalidate CPU Read/Write Access Indicates the time and date counters are invalid or changing and therefore should not be read or written to. This bit is asserted for one oscillator clock cycle before and after the 1 Hz (seconds clock) boundary edge. Write access to time and date registers is nullified (terminate normally) and no register value is changed. Reading when STATUS[INVAL_BIT] is asserted returns 0xFFFF. No transfer error is asserted. 0b - Time and date counters can be read or written. Time and date is valid. 1b - Time and date counter values are changing or time and date is invalid and cannot be read or written.

57.5.1.12 Interrupt Status (ISR)

Offset

Register	Offset
ISR	14h

Function

NOTE

For the sampling timer interrupt status bits [14:6], see the chip configuration chapter for the applicable sampling timer frequencies.

Indicates the status of the various real-time clock interrupts. When an event of the types included in this register occurs, the bit will be set in this register regardless of the status of its corresponding interrupt enable bit. The status bits and interrupts are cleared by writing a value of 1. Interrupts may occur when the system clock is idle or in Standby mode. When the system enters the active power mode, an interrupt is indicated to the CPU. The first event of the Sampling Timer interrupts after power-on reset should not be used to qualify any periodic interval. However, the correct periodic interval (that is, 512 Hz or 256 Hz, and so on) should be determined using two sampling timer interrupts. The time between two interrupts should always be the correct time period.

This register is cleared on software reset.

NOTE

Sampling interrupts from 512 Hz to 2 Hz are generated using uncompensated clock. Only 1 Hz is compensated.

57.5.1.13 Interrupt Enable (IER)

Offset

Register	Offset
IER	16h

Function

NOTE

For the sampling timer interrupt enable bits [14:6], see the chip configuration chapter for the applicable sampling timer frequencies.

Enables and disables the various real-time clock interrupts. De-asserting an interrupt enable bit has no effect on the assertion of its corresponding status bit.

Alarm interrupt is asserted on counters matching the alarm setting done in the memory map. The counters matched for the alarm interrupt are selected based on the alarm type set in CTRL[3:2]. The various types of alarms available are shown in the following table. Only one alarm type can be used at a time.

Table 458. Alarm Match Table

ALM_MATCH[1:0] (CTRL[3:2])	Counters Matched	Alarm Type
00	Seconds, Minutes, and Hours	Daily
01	Seconds, Minutes, Hours, and Days	Monthly
10	Seconds, Minutes, Hours, Days, and Months	Yearly
11	Seconds, Minutes, Hours, Days, Months, and Year	One Time

RTC generates a common interrupt. The user software should read the status register in the interrupt service routine to determine which interrupt has occurred.

57.5.1.14 Sub Second Counter (RTC_TEST2)

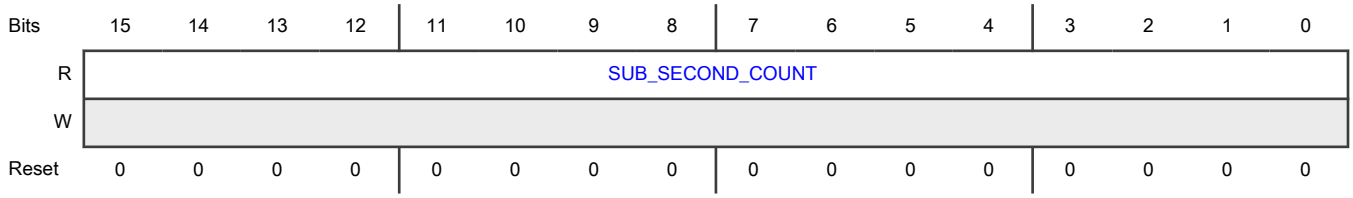
Offset

Register	Offset
RTC_TEST2	1Ch

Function

The RTC_TEST2 counter is used as a subsecond counter.

Diagram



Fields

Field	Function
15-0	Sub Second Counter Value

Table continues on the next page...

Field	Function
SUB_SECOND_COUNT	This counter is used as a sub second counter. Actually it counts the 32 kHZ/16 kHZ clk cycles and auto clear every second.

57.5.1.15 Daylight Saving Hour (DST_HOUR)

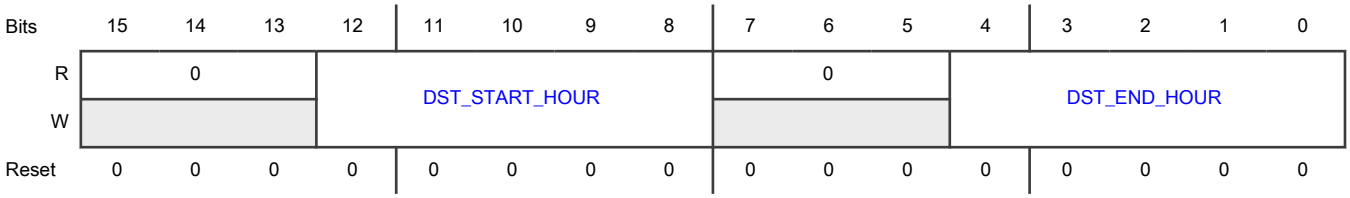
Offset

Register	Offset
DST_HOUR	22h

Function

Stores the time in hours when daylight saving has to be applied or reversed. This register is programmable when CTRL[DST_EN] = 0. When CTRL[DST_EN] = 1, the contents of this register cannot be changed. The user software should program the correct hour value (0-23) per the regional settings. For example, if daylight saving starts at 2:00 AM on March 25 and ends at 2:00 AM on October 28 in 2007 then the time at which the RTC advances or falls back is actually 1:59 AM. Therefore, the user software should program one, not two, for the hour count value (that is, write 0x0101) in this register. A 59-minute count is automatically checked inside RTC and not required to be programmed. This register has no effect on software reset.

Diagram



Fields

Field	Function
15-13 —	Reserved
12-8 DST_START_HOUR	Daylight Saving Time (DST) Hours Start Value The hour value for the time when DST comes into effect. Same as hours counter value in the Hours and Minutes Counters (HOURMIN).
7-5 —	Reserved
4-0 DST_END_HOUR	Daylight Saving Time (DST) Hours End Value The hour value for the time when DST is reversed. Same as hours counter value in the Hours and Minutes Counters (HOURMIN).

57.5.1.16 Daylight Saving Month (DST_MONTH)

Offset

Register	Offset
DST_MONTH	24h

Function

Stores the month when the daylight saving needs to be applied or reversed. This register is programmable when CTRL[DST_EN] = 0. When CTRL[DST_EN] = 1, the contents of this register cannot be changed. The CPU should program the correct month value (1-12) per the regional settings. For example, if daylight saving starts on March 25 and ends on October 28 in 2007, then CPU should write 0x030A in this register. This register has no effect on software reset.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				DST_START_MONTH				0				DST_END_MONTH			
W

Fields

Field	Function
15-12 —	Reserved
11-8 DST_START_MONTH	Daylight Saving Time (DST) Month Start Value The month value for the time when DST comes into effect. See Year and Month Counters (YEARMON).
7-4 —	Reserved
3-0 DST_END_MONTH	Daylight Saving Time (DST) Month End Value The month value for the time when DST is reversed. See Year and Month Counters (YEARMON).

57.5.1.17 Daylight Saving Day (DST_DAY)

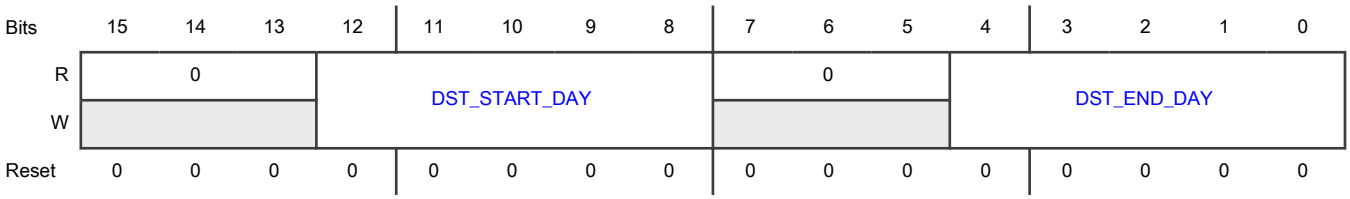
Offset

Register	Offset
DST_DAY	26h

Function

Stores the day when the daylight saving needs to be applied or reversed. This register is programmable when CTRL[DST_EN] = 0. When CTRL[DST_EN] = 1, the contents of this register cannot be changed. The CPU should program the correct day value (1-31) per the regional settings. For example, if the Daylight Saving starts at March 25 and ends at October 28 in 2007, then the CPU should write 0x191C in this register. This register is unaffected by software reset.

Diagram



Fields

Field	Function
15-13 —	Reserved
12-8 DST_START_DAY	Daylight Saving Time (DST) Day Start Value The day value for the time when DST comes into effect.

4-0 DST_END_DAY	Daylight Saving Time (DST) Day End Value The day value for the time when DST is reversed.

57.5.1.18 Compensation (COMPEN)

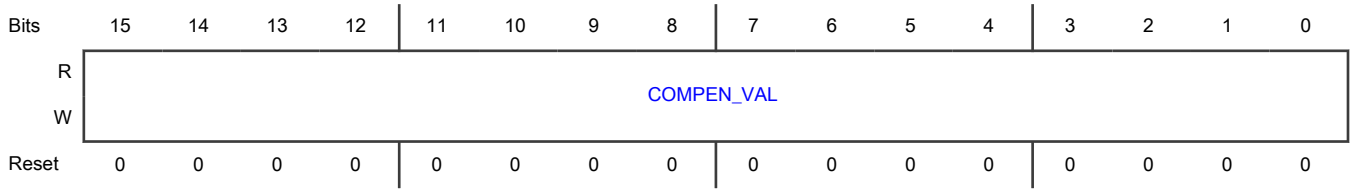
Offset

Register	Offset
COMPEN	28h

Function

Stores the compensation value to be used by the compensation block to correct the 1 Hz clock.

Diagram



Fields

Field	Function
15-0 COMPEN_VAL	Compensation Value Stores the compensation parameters. The definition of this field is dependent on the setting of CTRL[FINEEN]. If CTRL[FINEEN] = 0: • Compensation or Correction Value (COMPEN[7:0]) — Compensation or correction value is a two's complement value that modifies the 1 Hz clock (during its generation) by either adding or removing RTC oscillator clock cycles. • Compensation Interval (COMPEN[15:8]) — Compensation interval is the duration in seconds over which the correction is applied. This is the time in which the addition or removal of 32.768 or 16.384 kHz clock cycles occurs, thereby ensuring that the compensation interval is close to the interval obtained with an ideal 1 Hz clock. If CTRL[FINEEN] = 1 • Integral Compensation Value (COMPEN[15:12]) — This is a two's complement value of the integer part of correction or compensation value that has to be adjusted in every 1 second period. This value is expressed in terms of number of clock cycles of the RTC oscillator clock. • COMPEN[11:7] — Should be zero • Fraction Compensation Value (COMPEN[6:0]) — This is the fractional part of the correction or compensation value that has to be adjusted. This value is expressed as number of clock cycles of a fixed IRC_CLK. This value is always a positive number.

Chapter 58
Frequency Measurement (FREQME)

58.1 Chip-specific Frequency Measurement information

Table 459. Reference links to related information

Topic	Related module	Reference
Full description	FREQME	Frequency Measurement
System memory map		Memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing
Input multiplexing	INPUTMUX	See FREQMEAS_REF and FREQMEAS_TAR registers in INPUTMUX for a list of clocks that can be selected as inputs to the frequency measurement circuit.

58.1.1 Module instances

This device has one instance of the Frequency Measurement module, FREQME0.

58.2 Overview

FREQME accurately measures the frequency of an on- or off-chip target clock signal using a selectable on-chip reference clock. For example, it can accurately determine the frequency of a low-power oscillator that varies depending on process and temperature.

58.2.1 Block diagram

Figure 325. Block diagram

See the chip-specific FREQME information for the target and reference clock selection options.

58.2.2 Features

- High-accuracy Frequency Measurement mode for on- and off-chip clocks
- Pulse Width Measurement (PWM) mode
- Reference and target clock inputs selectable from among various chip-specific options
- Optional measurement complete interrupt
- Result out-of-range detection with optional interrupt

58.3 Functional description

The following sections describe FREQME functional details.

58.3.1 Frequency Measurement mode

In Frequency Measurement mode (CTL_W[PULSE_MODE] = 0), FREQME counts the number of target clock cycles that occur during a specified number of cycles from a reference clock that has a known frequency. You can then calculate the target clock frequency based on the frequency of the reference clock, the number of reference clock cycles, and the number of target clock cycles (see Equation 26).

The frequency measurement circuit is based on two 31-bit counters—one clocked by the selected reference clock and one by the selected target clock. You can only read the target clock counter. FREQME synchronizes the clocks at the start and end of each count sequence during preparation for the next count sequence. A count sequence consists of incrementing the target clock counter for each target clock pulse that occurs during the time defined by $2^{CTRL_W[REF_SCALE]}$ periods of the reference clock.

After selecting reference and target clocks, you initiate a measurement cycle by writing 1 to CTRL_W[MEASURE_IN_PROGRESS]. You can then poll this same field, which automatically transitions to 0 when the measurement operation completes. Alternatively, the completion of the measurement operation can generate an interrupt.

The measurement cycle terminates when the reference counter equals the value $2^{CTRLSTAT[REFSCALE]}$. If CTRLSTAT[REFSCALE] = 0, the reference counter counts to one and stops. You can use this feature to measure the frequency of a fast target clock using a slow reference clock such as the 32 kHz clock without taking much time for the measurement to complete. The penalty is reduced accuracy in the measurement.

When the counting operation completes, the state of the target counter is loaded into CTRL_R[RESULT], and the CTRL_W[MEASURE_IN_PROGRESS] field is 0. You can then read the value and calculate the target frequency as follows, with the frequencies given in MHz.

$$F_{target} = (CTRL_R[RESULT] - 2) \times F_{reference} \div 2^{CTRLSTAT[REFSCALE]}$$

Equation 26. Calculating the target clock frequency

58.3.1.1 Accuracy

The Frequency Measurement mode can measure the frequency of any on-chip (or off-chip) clock (referred to as the target clock) with a high degree of accuracy by using an on-chip clock of known frequency as a reference clock.

Uncertainty in the reference clock (for example a ±1 % accuracy of the clock) adds to the measurement error of the target clock. In general, though, this additional error is less than the uncertainty of the reference clock.

58.3.2 Pulse Measurement mode

When you write 1 to CTRL_W[PULSE_MODE] and write 1 to CTRL_W[MEASURE_IN_PROGRESS] to start a measurement cycle, FREQME counts target clock pulses while the reference clock is in a specific state (high or low), selected by writing to CTRL_W[PULSE_POL]. See the description of these fields for more details.

58.3.3 Clocking

The clock inputs are as follows:

- Reference clock (REF_CLK_IN). This clock has a known frequency.
- Target clock (TARGET_CLK_IN). This clock frequency can be calculated based on the reference clock.

NOTE

These clocks can be all synchronous.

See the chip-specific FREQME information for the target and reference clock selection options.

58.3.4 Interrupts

The following interrupts can optionally be generated at the completion of a frequency measurement cycle.

Table 460. Interrupts

Condition	Interrupt enable field	Interrupt status field
Result is ready to read	CTRL_W[RESULT_READY_INT_EN]	CTRLSTAT[RESULT_READY_INT_EN]
Result is greater than MAX[MAX_VALUE]	CTRL_W[GT_MAX_INT_EN]	CTRLSTAT[GT_MAX_INT_EN]
Result is less than MIN[MIN_VALUE]	CTRL_W[LT_MIN_INT_EN]	CTRLSTAT[LT_MIN_INT_EN]

58.4 External signals

Table 461. External signals

Signal	Description	Direction
REF_CLK_IN	Reference clock. On-chip clock with known frequency chosen as reference.	Input
TARGET_CLK_IN	Target clock. On- or off-chip clock to be measured by FREQME.	Input

58.5 Initialization

Initialize FREQME by performing the following steps:

1. Enable the clock that drives FREQME in the chip-level clock control register. This step enables the register interface and the peripheral function clock.
2. Clear the FREQME peripheral reset in the chip-level reset control register.
3. If measuring an external clock, use the Input/Output pin configuration registers to connect the FREQME target clock input (TARGET_CLK_IN) to an external pin.
4. Ensure that the reference and target clocks are enabled.
5. Select the reference and target clocks.

58.6 Memory map and register definition

This section includes the FREQME memory map and detailed descriptions of all registers.

58.6.1 FREQME register descriptions

58.6.1.1 FREQME memory map

FREQME0 base address: 4001_1000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control (in Read mode) (CTRL_R)	32	R	0000_0000h
0h	Control (in Write mode) (CTRL_W)	32	W	0000_0000h
4h	Control Status (CTRLSTAT)	32	RW	0000_0000h
8h	Minimum (MIN)	32	RW	0000_0000h
Ch	Maximum (MAX)	32	RW	7FFF_FFFFh

58.6.1.2 Control (in Read mode) (CTRL_R)

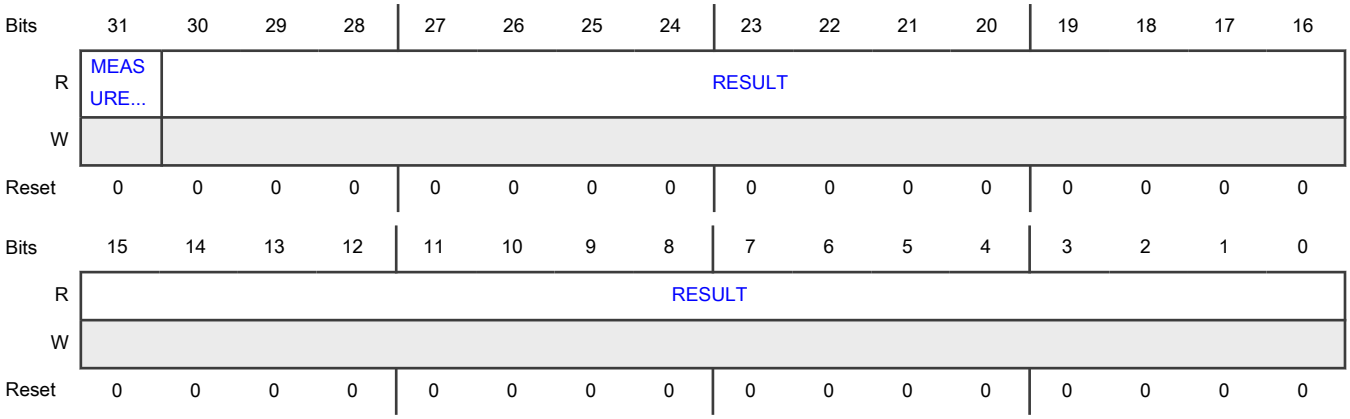
Offset

Register	Offset
CTRL_R	0h

Function

Contains different fields depending on whether you are performing a read or a write. Reading this register provides the measurement results and the status of the measurement cycle.

Diagram



Fields

Field	Function
31 MEASURE_IN_PROGRESS	Measurement In Progress Indicates whether measurement is in progress or complete. If complete, you can read the result from RESULT. 0b - Complete 1b - In progress
30-0 RESULT	Indicates the measurement result—either the target clock counter value (for Frequency Measurement mode) or pulse width measurement (for Pulse Width Measurement mode). This field is valid only when MEASURE_IN_PROGRESS = 0, In Continuous mode (CTRL_W[CONTINUOUS_MODE_EN] = 1), the value is the result from the most-recently completed measurement.

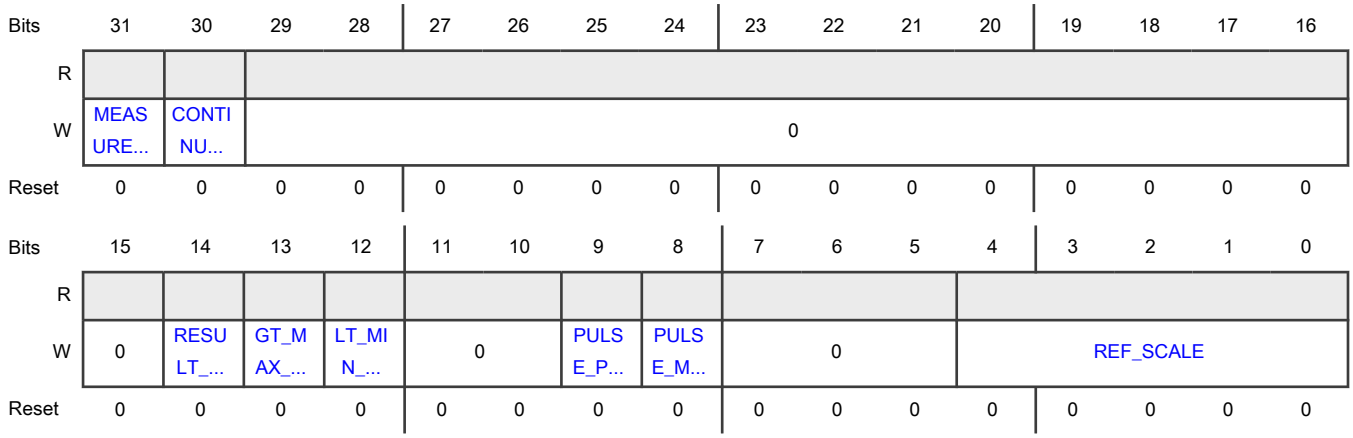
58.6.1.3 Control (in Write mode) (CTRL_W)

Offset

Register	Offset
CTRL_W	0h

Function
Writes to this register control and configure the measurement cycle.

Diagram



Fields

Field	Function
31 MEASURE_IN_PROGRESS	Measurement In Progress Initiates a frequency measurement cycle or terminates a measurement cycle that is in progress. Writing 1 to this field initiates a frequency or pulse width measurement process. Hardware automatically writes 0 to the MEASURE_IN_PROGRESS field when the measurement cycle completes. If there is an active measurement in progress, a new measurement starts. Writing 0 to this field forces the termination of any measurement cycle currently in progress and resets CTRL_R[RESULT] or just resets CTRL_R[RESULT] if idle. 0b - Terminates measurement 1b - Initiates measurement
30 CONTINUOUS_MODE_EN	Continuous Mode Enable When you write 1 to both MEASURE_IN_PROGRESS and this field, measurement is performed continuously. The result for the most-recently completed measurement is available in CTRL_R[RESULT]. When the result is out of range (that is, CTRLSTAT[GT_MAX_STAT] = 1 or CTRLSTAT[LT_MIN_STAT] = 1), this field automatically transitions to 0 and the continuous measurement is suspended. After clearing both status bits, you must write 1 to both MEASURE_IN_PROGRESS and this field restart measurement in continuous mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
29-15 —	Reserved
14 RESULT_READY_INT_EN	Result Ready Interrupt Enable Generates interrupt when a measurement completes and the result is ready (CTRLSTAT[RESULT_READY_STAT] = 1). 0b - Disable 1b - Enable
13 GT_MAX_INT_EN	Greater Than Maximum Interrupt Enable Generates an interrupt when the result is greater than MAX[MAX_VALUE] (CTRLSTAT[GT_MAX_STAT] = 1). 0b - Disable 1b - Enable
12 LT_MIN_INT_EN	Less Than Minimum Interrupt Enable Generates an interrupt when the result is less than MIN[MIN_VALUE] (CTRLSTAT[LT_MIN_STAT] = 1). 0b - Disable 1b - Enable
11-10 —	Reserved
9 PULSE_POL	Pulse Polarity Specifies whether a pulse width (high period or low period) of the reference clock is measured in the Pulse Width Measurement mode. **NOTE** PULSE_POL is valid only in the Pulse Width Measurement mode. • A high period measurement is triggered by the rising edge on the reference clock input. • A low period measurement is triggered by the falling edge on the reference clock input. 0b - High period 1b - Low period
8 PULSE_MODE	Pulse Width Measurement Mode Select Selects the measurement mode—either Frequency Measurement mode or Pulse Width Measurement mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In Frequency Measurement mode, measurement begins at the rising edge of the selected reference clock and continues until a count of 2^{REF_SCALE} reference clock pulses is reached. In Pulse Width Measurement mode, the counter starts incrementing when the selected trigger edge (rising edge for high period measurement or falling edge for low period) occurs, and stops at the next edge (falling edge for a high period measurement or rising edge for a low period measurement). Select high or low period measurement by writing the desired value to PULSE_POL. 0b - Frequency Measurement mode 1b - Pulse Width Measurement mode
7-5 —	Reserved
4-0 REF_SCALE	Reference Clock Scaling Factor Specifies the reference clock scaling factor in Frequency Measurement mode. The reference count cycle is 2^{REF_SCALE}. A higher number provides better accuracy but consumes more processing time. This field is valid only in Frequency Measurement mode.

58.6.1.4 Control Status (CTRLSTAT)

Offset

Register	Offset
CTRLSTAT	4h

Function

Contains the current CTRL_W register configuration fields.

Chapter 59
Low-Power Timer (LPTMR)

59.1 Chip-specific LPTMR information

Table 462. Reference links to related information

Topic	Related module	Reference
Full description	LPTMR	LPTMR
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

59.1.1 Module instances

This device has two instances of the LPTMR module, LPTMR0 and LPTMR1.

59.1.2 LPTMR clocks

The prescaler and glitch filter of the LPTMR module (the module functional clock) can be clocked from one of four sources determined by LPTMRx_PSR[PCS]. The following table shows the clock assignments for this field.

NOTE

The chosen clock must remain enabled if the LPTMR is to continue operating in all required low-power modes. Refer Module operation in low-power modes to see low power modules of LPTMR.

The LPTMR allows the maximum clock frequency of 25 MHz.

Table 463. LPTMRn prescaler/glitch filter clocking options

LPTMRn_PSR[PCS]	Prescaler/glitch filter clock number	Chip clock
00	0	FRO_12M - Free Running Oscillator - 12 MHz clock source.
01	1	FRO_16K - Free Running Oscillator - 16 K clock source.
10	2	32K_CLK - Selectable clock output from the Battery Backed domain produced by either the OSC_32K or the FRO_32K.
11	3	OSC_SYS - Crystal Oscillator - System - Clock frequency must be less than 25 MHz to be used as a clock for LPTMR.

59.1.3 LPTMR pulse counter input options

LPTMRn_CSR[TPS] configures the input source used in pulse counter mode. The following table shows the input assignments for this field.

Table 464. LPTMRn (n=0,1) pulse counter input options

LPTMRn_CSR[TPS]	Pulse counter input number	Chip input
00	0	CMP0_OUT
01	1	CMP1_OUT
10	2	LPTMRn_Alt2
11	3	LPTMRn_Alt3

59.2 Overview

You can configure LPTMR to operate as a time counter with an optional prescaler, or as a pulse counter with an optional glitch filter, across all power modes, including low-power modes. It is reset only on VSYS warm reset, allowing it to be used as a time-of-day counter.

59.2.1 Block diagram

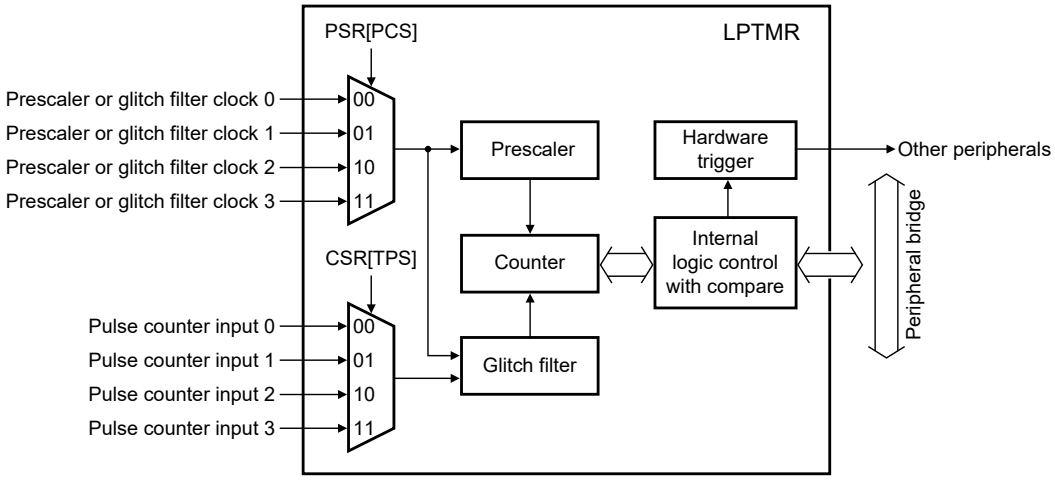

Figure 326. Block diagram

59.2.2 Features

- 32-bit time counter or pulse counter with compare:
  - Optional interrupt that can generate an asynchronous wake-up from any low-power mode
  - Hardware trigger output
  - Counter that supports a free-running mode or reset on compare
- Configurable clock source for prescaler and glitch filter
- Configurable input source for pulse counter (rising-edge or falling-edge)

59.3 Functional description

59.3.1 Low-power modes

In low-power modes, LPTMR continues to operate normally. You can configure LPTMR to exit a low-power mode by generating either an interrupt or a DMA request.

59.3.2 Clocks

The LPTMR prescaler and glitch filter can be clocked by one of the clocks that you configure by using PSR[PCS]. You must enable the clock source before you enable LPTMR.

In Pulse Counter mode, with the glitch filter bypassed, the selected input source directly clocks Counter (CNR), and no other clock source is required. To minimize power in this case, configure the glitch filter clock source for a clock that is disabled.

NOTE

- You may need to configure the clock source that you select in PSR[PCS] for it to remain enabled in low-power modes. Otherwise, LPTMR does not operate in low-power modes.
- The clock source or pulse input source selected for LPTMR must not exceed the maximum frequency of f_{LPTMR} defined in the chip data sheet.

59.3.3 Reset

LPTMR is reset only on VSYS warm reset. When configuring LPTMR registers, you must initially write to Control Status (CSR) with LPTMR disabled, before configuring Prescaler and Glitch Filter (PSR) and Compare (CMR). Then, you must write 1 to CSR[TEN] as the last step in the initialization. Doing so ensures that LPTMR is configured correctly and the LPTMR counter is reset to zero following a VSYS warm reset.

59.3.4 Prescaler and glitch filter

The LPTMR prescaler and glitch filter share the same logic, which operates as a prescaler in Time Counter mode and as a glitch filter in Pulse Counter mode.

NOTE

You must not alter the prescaler and glitch filter configuration when LPTMR is enabled.

59.3.4.1 Prescaler enabled

In Time Counter mode, when the prescaler is enabled, the output of the prescaler directly clocks Counter (CNR). When LPTMR is enabled, CNR increments every 2^1 to 2^{16} prescaler clock cycles. After LPTMR is enabled, the first increment of CNR takes an additional one or two prescaler clock cycles because of the synchronization logic.

59.3.4.2 Prescaler bypassed

In Time Counter mode, when the prescaler is bypassed, the selected prescaler clock increments Counter (CNR) on every clock cycle. When LPTMR is enabled, the first increment takes an additional one or two prescaler clock cycles because of the synchronization logic.

59.3.4.3 Glitch filter enabled

In Pulse Counter mode, when the glitch filter is enabled, the output of the glitch filter directly clocks Counter (CNR). When LPTMR is first enabled, the output of the glitch filter is asserted, that is, logic 1 for active-high and logic 0 for active-low. The following table shows the change in glitch filter output with the selected input source.

Table 465. Glitch filter output with the selected input source

If	Then
The selected input source remains deasserted for at least 2^1 to 2^{15} consecutive prescaler clock rising edges	The glitch filter output also deasserts.
The selected input source remains asserted for at least 2^1 to 2^{15} consecutive prescaler clock rising edges	The glitch filter output also asserts.

NOTE

The input is sampled only on the rising clock edge.

The value of CNR increments each time the glitch filter output asserts. In Pulse Counter mode, the maximum rate at which CNR can increment is once every 2^2 to 2^{16} glitch filter clock edges. When first enabled, the glitch filter waits for an additional one or two glitch filter clock edges because of the synchronization logic.

59.3.4.4 Glitch filter bypassed

In Pulse Counter mode, when the glitch filter is bypassed, the selected input source increments the value of Counter (CNR) every time it asserts. Before LPTMR is first enabled, the selected input source is forced to be asserted. This prevents CNR from incrementing if the selected input source is already asserted when LPTMR is first enabled.

59.3.5 Counter

The value of Counter (CNR) increments by 1 on every:

- Prescaler clock in Time Counter mode, with prescaler bypassed.
- Prescaler output in Time Counter mode, with prescaler enabled.
- Input source assertion in Pulse Counter mode, with glitch filter bypassed.
- Glitch filter output in Pulse Counter mode, with glitch filter enabled.

CNR is reset when LPTMR is disabled or if the counter register overflows. If CSR[TFC] = 0, then CNR is also reset whenever CSR[TCF] = 1.

When the core is halted in Debug mode:

- CNR continues incrementing if configured for Pulse Counter mode.
- CNR stops incrementing if configured for Time Counter mode.

You cannot initialize CNR but can read it at any time. On each read of CNR, you must first write a value to it. This synchronizes and registers the current value of CNR into a temporary register. The contents of the temporary register are returned on each read of CNR.

When reading CNR, the bus clock must be at least two times faster than the rate at which the LPTMR counter is incrementing; otherwise, incorrect data may be returned.

59.3.6 Compare

After the next Counter (CNR) increment (when its value is equal to that of Compare (CMR)), the following events occur:

- CSR[TCF] is read as 1b.
- LPTMR generates an interrupt if CSR[TIE] is 1 as well.
- LPTMR generates a hardware trigger.
- LPTMR writes 0 to CNR if CSR[TFC] is 0.

When LPTMR is enabled, you can modify the value of CMR only when CSR[TCF] is 1. When updating CMR, you must write to it and clear CSR[TCF] before the LPTMR counter increments past the new LPTMR compare value.

NOTE

When LPTMR is enabled in Time Counter mode, the first increment takes an additional one or two clock cycles because of the synchronization logic. This results in the first compare (and therefore interrupt and hardware trigger) occurring slightly later. A faster prescaler clock or larger prescaler value minimizes this impact.

59.3.7 Interrupt

LPTMR generates an interrupt whenever CSR[TIE] and CSR[TCF] are 1. CSR[TCF] is cleared by disabling LPTMR or writing a logic 1 to it.

You can modify the value of CSR[TIE] and write 1 to CSR[TCF] when LPTMR is enabled.

LPTMR generates an interrupt asynchronously to the system clock. The interrupt can be used to generate a wake-up from any low-power mode, provided LPTMR is enabled as a wake-up source.

59.3.8 Hardware trigger

The LPTMR hardware trigger asserts at the same time CSR[TCF] is set and can be used to trigger hardware events in other peripherals without your intervention. The hardware trigger is always enabled.

Table 466. Hardware trigger

When	Then
CMR[COMPARE] and CSR[TFC] are 0	The LPTMR hardware trigger asserts on the first compare and does not deassert.
CMR[COMPARE] is set to a nonzero value, or if CSR[TFC] = 1	The LPTMR hardware trigger asserts on each compare and deasserts on the following increment of Counter (CNR).

59.4 External signals

Table 467. External signals

Signal	Description		Direction
LPTMR_ALT*n*	Pulse Counter Input LPTMR can select one of the input pins to be used in Pulse Counter mode.		Input
	State meaning	Assertion—If configured for Pulse Counter mode with an active-high input, assertion causes Counter (CNR) to increment. Deassertion—If configured for Pulse Counter mode with an active-low input, deassertion causes CNR to increment.	
	Timing	Assertion or deassertion may occur at any time; input may assert asynchronously to the bus clock.	

59.5 Initialization

Perform the following procedure to initialize LPTMR:

1. Configure Control Status (CSR) for the selected mode and pin configuration, when CSR[TEN] is 0. This resets the counter and clears the flag.
2. Configure Prescaler and Glitch Filter (PSR) with the selected clock source and prescaler or glitch filter configuration.
3. Configure Compare (CMR) with the selected compare point.
4. Write 1 to CSR[TEN] to enable LPTMR.

59.6 Application information

59.6.1 Application 1: Generate an interrupt every 100 ms using 32.768 kHz clock source

1. Disable LPTMR by writing 0 to CSR[TEN].
2. Select a 32.768 kHz clock source by configuring PSR[PCS].
3. Bypass the prescaler and glitch filter by writing 1 to PSR[PBYP].
4. Assert an interrupt every 3277 cycles by configuring CMR[COMPARE] = 0CCCh.
5. Enable LPTMR by writing 1 to CSR[TEN].
6. Enable the LPTMR interrupt by writing 1 to CSR[TIE].

NOTE

This is just an example. See the chip-specific LPTMR information for the clocks supported on a given chip.

59.6.2 Application 2: Generate an interrupt once a minute using 32.768 kHz clock source

1. Disable LPTMR by writing 0 to CSR[TEN].
2. Select a 32.768 kHz clock source by configuring PSR[PCS].
3. Select the prescaler to divide the prescaler clock by 32768 to increment the counter once a second by configuring PSR[PRESCALE] = 0Eh.
4. Assert an interrupt every 60 seconds by configuring CMR[COMPARE] = 003Bh.
5. Enable LPTMR by writing 1 to CSR[TEN].
6. Enable the LPTMR interrupt by writing 1 to CSR[TIE].

NOTE

This is just an example. See the chip-specific LPTMR information for the clocks supported on a given chip.

59.7 Memory map and register definition

NOTE

The LPTMR registers are reset only on VSYS warm reset. See Reset for more information.

59.7.1 LPTMR register descriptions

59.7.1.1 LPTMR memory map

LPTMR0 base address: 4004_A000h

LPTMR1 base address: 4004_B000h

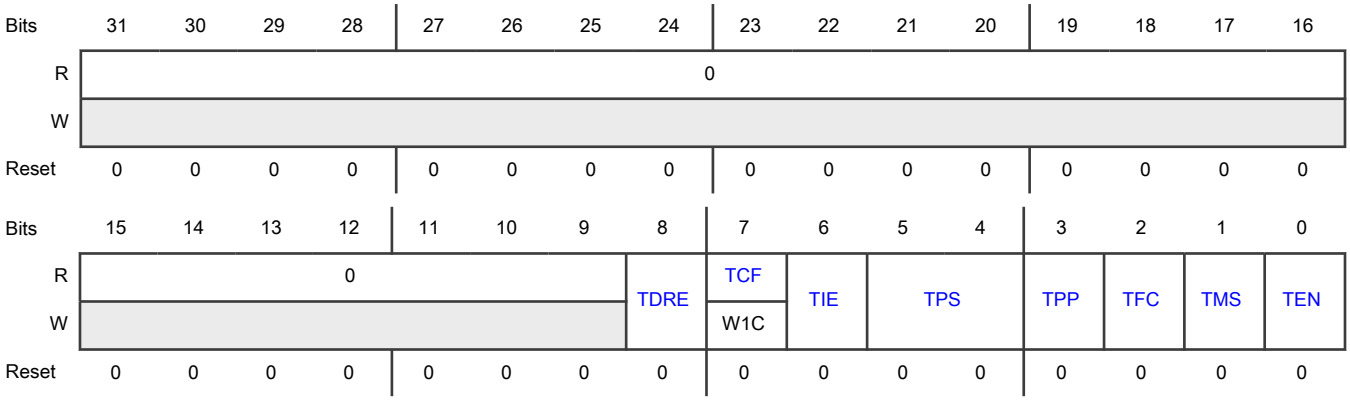
Diagram



Fields

Field	Function
31-9 —	Reserved
8 TDRE	Timer DMA Request Enable Enables the timer DMA request. When TDRE is 1, the LPTMR DMA request is generated whenever CSR[TCF] is also set. Then, CSR[TCF] is cleared after the DMA controller completes execution. 0b - Disable 1b - Enable
7 TCF	Timer Compare Flag Compares the timer. TCF sets on the next Counter (CNR) increment when LPTMR is enabled and Counter (CNR) equals Compare (CMR). TCF is cleared when LPTMR is disabled or a logic 1 is written to it. **NOTE** You must clear this flag before enabling the timer interrupt or DMA request. **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When reading 0b - CNR ≠ (CMR + 1) 1b - CNR = (CMR + 1) When writing 0b - No effect 1b - Clear the flag
6 TIE	Timer Interrupt Enable Enables the timer interrupt. If TIE is 1, then LPTMR generates an interrupt if CSR[TCF] is 1 as well. 0b - Disable 1b - Enable
5-4 TPS	Timer Pin Select Configures the input source to be used in Pulse Counter mode. The input connections vary by chip. For details, see the chip configuration information about connections to these inputs. You must modify this field only when LPTMR is disabled. 00b - Input 0 01b - Input 1 10b - Input 2 11b - Input 3
3 TPP	Timer Pin Polarity Configures the polarity of the input source in Pulse Counter mode. If TPP is 0, then the pulse counter input source is active-high, and Counter (CNR) increments on the rising edge. If TPP is 1, then the pulse counter input source is active-low, and CNR increments on the falling edge. You must modify this field only when LPTMR is disabled. 0b - Active-high 1b - Active-low
2 TFC	Timer Free-Running Counter Specifies when the counter resets. If TFC is 0, Counter (CNR) resets on the count cycle following Counter (CNR) becoming equal to Compare (CMR). If TFC is 1, CNR resets on overflow. In both cases, CSR[TCF] sets to 1 on the cycle after CNR and CMR match. You must modify this field only when LPTMR is disabled. 0b - Reset when TCF asserts 1b - Reset on overflow
1	Timer Mode Select Configures the mode of LPTMR.

Table continues on the next page...

Chapter 60
External Watchdog Monitor (EWM)

60.1 Chip-specific EWM information

Table 468. Reference links to related information

Topic	Related module	Reference
Full description	EWM	EWM
System memory map		Memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

60.1.1 Module instances

This device has one instance of the EWM module, EWM0.

60.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

60.1.3 CLKPRESCALER register implementation

The CLKPRESCALER register is used for prescaling the clock frequency of low power clock source where:

Prescaled clock frequency = low power clock source frequency / (1 + CLK_DIV).

60.1.4 Low power clock sources

For this device, the EMW's LPO_CLK options are connected as shown in the table below. See EWM clocking for details.

Table 469. LPO_CLK connections

EWM LPO_CLK	SoC clock
LPO_CLK[0]	EWM LPO CLK
LPO_CLK[1]	Not connected/Do not use
LPO_CLK[2]	Not connected/Do not use
LPO_CLK[3]	Not connected/Do not use

60.2 Overview

For safety purposes, a redundant watchdog system, EWM, is designed to monitor external circuits and the MCU software flow. This provides a backup mechanism to the internal watchdog that resets the MCU's CPU and peripherals.

The internal watchdog is used to monitor the flow and execution of the embedded software within the MCU. It consists of a counter that, if allowed to overflow, forces an internal, asynchronous reset to all on-chip peripherals. The counter also optionally asserts the RESET_B pin to reset external devices and circuits. The watchdog counter must not overflow if the software code works well and services the watchdog to restart the actual counter.

The EWM does not reset the MCU's CPU and peripherals, making it different from internal watchdog. The EWM module provides an independent ewm_out_b signal that, when asserted, resets or places an external circuit into a safe mode. The ewm_out_b signal asserts upon EWM counter timeout. An optional external input, ewm_in, allows additional control when asserting the ewm_out_b signal.

60.2.1 Block diagram

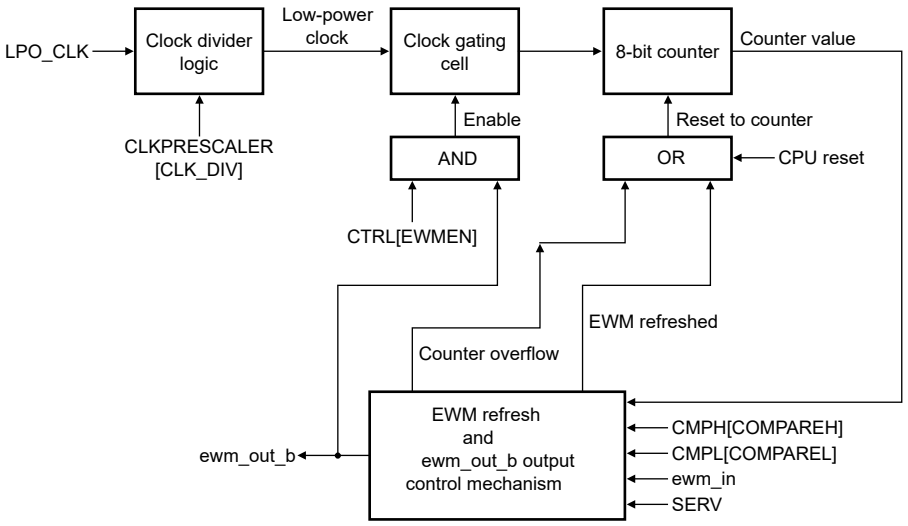

Figure 327. Block diagram

60.2.2 Features

- Independent LPO_CLK source
- Programmable timeout period, specified in terms of the number of EWM LPO_CLK cycles
- Windowed refresh option that provides:
  - A robust check to confirm that the program flow is faster than expected.
  - A programmable window.
  - Refresh outside the window, leading to assertion of the ewm_out_b signal.
- Robust refresh mechanism:
  - Write values of B4h and 2Ch to Service (SERV) within 15 peripheral bus clock cycles.
- One output port, ewm_out_b, which when asserted is used to reset or place the external circuit into Safe mode
- One input port, ewm_in, which allows an external circuit to control the assertion of the ewm_out_b signal

60.3 Functional description

The following sections discuss these aspects of EWM:

- Functional details
- Operating modes

NOTE

If the BUS_CLK is lost, EWM does not generate the ewm_out_b signal and no refresh operation is possible.

60.3.1 Modes of operation

60.3.1.1 Stop mode

When EWM is in Stop mode, the CPU cannot refresh EWM. After entering Stop mode, the EWM counter freezes.

Following are the possible ways to exit Stop mode:

- Through a reset: EWM remains disabled in this case.
- Through an interrupt: EWM is re-enabled and the counter continues to be clocked from the same value as prior to Stop mode entry.

NOTE

Consider the following if EWM enters Stop mode during the CPU refresh mechanism:

- While exiting Stop mode through an interrupt, the refresh mechanism starts from the previous state. That is, if you write the refresh command correctly and EWM enters Stop mode immediately, you must write the next command in *15* peripheral bus clocks after exiting Stop mode.
- You must mask all interrupts before executing the EWM refresh instructions.

60.3.1.2 Debug mode

EWM remains unimpacted when entering Debug mode:

- If EWM is enabled before entering Debug mode, it remains enabled.
- If EWM is disabled before entering Debug mode, it remains disabled.

60.3.2 Using the EWM counter

EWM uses an 8-bit ripple counter that is fed by a clock source independent of the peripheral bus clock source. As the preferred timeout is between 1 ms and 100 ms, the actual clock source must be in the kHz range.

The counter is reset to 0 in these conditions:

- After CPU reset
- After the EWM refresh action completes
- At counter overflow

The CPU cannot access the counter value.

60.3.3 Using compare registers

You can write to Compare Low (CMPL) and Compare High (CMPH) only once after a CPU reset and you cannot modify them until another CPU reset occurs. These registers are used to create a refresh window for the EWM module.

You cannot program Compare Low (CMPL) and Compare High (CMPH) with the same value. In case of any attempt, the ewm_out_b signal asserts as soon as the counter reaches the value of Compare Low (CMPL) + 1.

NOTE

- You must update Compare Low (CMPL) and Compare High (CMPH) before enabling EWM. Therefore, you must provide a reasonable time after POR for the external monitoring circuit to stabilize. You must also ensure that the ewm_in pin is deasserted.
- Service should be requested after 1 clock period of slowest clock frequency while updating Compare Low (CMPL) register.

60.3.4 Using the refresh mechanism

Other than the initial configuration of EWM, the CPU can access EWM only through Service (SERV). The CPU must access this register by correctly writing unique data within the windowed time frame, as determined by Compare Low (CMPL) and Compare High (CMPH) for the correct EWM refresh operation. The following table describes conditions that exist and the refresh mechanisms that apply to those conditions.

Table 470. Refresh mechanisms

Condition	Mechanism
The EWM refresh action completes when the value of Compare Low (CMPL) ≤ the counter value ≤ the value of Compare High (CMPH).	The software behaves as expected and the EWM counter resets to 0. The ewm_out_b output signal remains in Deasserted state if, during the EWM refresh action, the ewm_in input is in Deasserted state.
The EWM refresh action completes when the counter value < the value of Compare Low (CMPL).	The software refreshes EWM before the windowed time frame, the counter resets to 0, and the ewm_out_b output signal asserts no matter what the value of the ewm_in input signal is.
The counter value becomes greater than the value of Compare High (CMPH) prior to completion of the EWM refresh action.	The software does not refresh EWM. The EWM counter resets to 0 and the ewm_out_b output signal asserts no matter what the value of the ewm_in input signal is.

See Service (SERV) for more on the refresh mechanism.

60.3.5 Interrupt

When the ewm_out_b signal asserts, an interrupt request can be generated to indicate the assertion of the EWM reset out signal. The interrupt is enabled when CTRL[INTEN] = 1. Writing 0 to this field clears the interrupt request but does not affect the ewm_out_b signal, which can be deasserted only by forcing a system reset.

60.3.6 Clocking

The following table shows EWM clocks.

Table 471. EWM Clocks

Clock	Description
IPG_CLK	This is the system clock and should be turned on for EWM to be able to work properly. During low power modes in which the core is powered down, this clock is disabled,
IPG_CLK_S	This is the IPS clock and is synchronous with IPG_CLK. It is disabled except during IPS write accesses. it is enabled with EWM's IPS_MODULE_EN
LPO_CLOCK[3:0]	EWM can have 4 different clock sources for running its EWM counter and one of them can be selected by EWM_CLKCTRL [CLK_SEL]. This clock is gated when EWM is disabled or when EWM_out is asserted.

60.3.7 Selecting the EWM counter clock

You can program CLKCTRL[CLKSEL] to select from the available low-power clock sources for the EWM counter.

60.3.8 Using the counter clock prescaler

You can program CLKPRESCALER[CLK_DIV] to divide the EWM counter clock source. This divided clock is used to run the EWM counter.

NOTE

The divided clock used to run the EWM counter must not exceed half the frequency of the bus clock.

60.4 External signals

EWM includes external signals and internal options for the counter clock sources, as shown in the following table.

NOTE

All active-low signals are represented with the suffix "_b" throughout the chapter.

Table 472. Signal descriptions

Signal	Description	I/O
ewm_in	EWM's input for the safety status of external safety circuits. You can program the polarity of ewm_in by using CTRL[ASSIN]. The default polarity is active-low.	I
ewm_out_b	EWM's reset out signal	O
lpo_clk[3:0]	Low-power clock sources for the running counter	I

60.4.1 Using the ewm_out_b signal

The ewm_out_b signal is a digital output signal used to gate an external circuit (application-specific) that controls critical safety functions.

The ewm_out_b signal remains deasserted when the CPU regularly refreshes EWM within the programmable refresh window, indicating that the application code is executing as expected.

The ewm_out_b signal asserts in any of the following conditions:

- An EWM refresh action occurs when the counter value is less than the value of Compare Low (CMPL).
- The EWM counter value becomes greater than the value of Compare High (CMPH) and no EWM refresh occurs.
- The functionality of the ewm_in pin is enabled and the ewm_in pin asserts when refreshing EWM.
- After any reset.

The ewm_out_b signal asserts after any reset by the virtue of the external pulldown mechanism on the ewm_out_b pin. To deassert the ewm_out_b signal, write 1 to CTRL[EWMEN] to enable EWM.

If the ewm_out_b signal shares its pad with a digital I/O pin, this actual pad defers to being an input signal on reset. The ewm_out_b signal controls the pad state only after CTRL[EWMEN] enables EWM.

NOTE

The ewm_out_b pad must be in Pulldown state when the EWM functionality is being used and EWM is under reset.

60.4.2 Using the ewm_out_b pin state in low-power modes

During Wait, Stop, and Power-Down modes, the ewm_out_b pin enters a high-impedance state. You have the option to control the logic state of the pin by using an external pull device or by configuring the internal pull device. When the CPU enters Run mode from Wait or Stop mode recovery, the pin resumes its previous state before entering Wait or Stop mode. When the CPU enters Run mode after exiting Power-Down mode, the pin returns to its reset state.

60.4.3 Using the ewm_in signal

The ewm_in signal is a digital input signal for the safety status of external safety circuits. This signal allows an external circuit to control the assertion of the ewm_out_b signal. For example, in the application, an external circuit monitors a critical safety function, and if there is a fault with the safety function, the external circuit can actively initiate the ewm_out_b signal, which controls the gating circuit.

The ewm_in signal is ignored if EWM is disabled, or if CTRL[INEN] = 0 after any reset.

After you enable EWM (by writing 1 to CTRL[EWMEN]) and the ewm_in functionality (by writing 1 to CTRL[INEN]), the ewm_in signal must be in Deasserted state before the CPU starts refreshing EWM. This ensures that the ewm_out_b signal stays in Deasserted state; otherwise, the ewm_out_b output signal asserts.

60.5 Memory map and register definitions

This section contains the module memory map and registers.

NOTE

EWM supports only 8-bit register accesses; 16-bit and 32-bit accesses are not supported.

60.5.1 EWM register descriptions

60.5.1.1 EWM memory map

EWM0 base address: 400C_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control (CTRL)	8	RW	00h
1h	Service (SERV)	8	RW	00h
2h	Compare Low (CMPL)	8	RW	00h
3h	Compare High (CMPH)	8	RW	FFh
4h	Clock Control (CLKCTRL)	8	RW	00h
5h	Clock Prescaler (CLKPRESCALER)	8	RW	00h

60.5.1.2 Control (CTRL)

Offset

Register	Offset
CTRL	0h

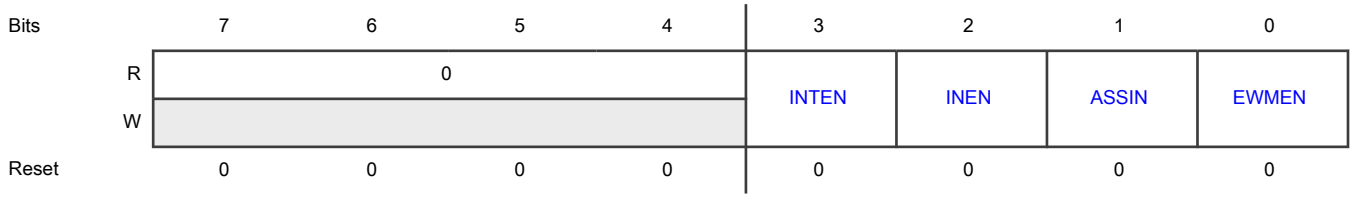
Function

Controls the functionality of EWM.

NOTE

You can write to CTRL[INEN], CTRL[ASSIN], and CTRL[EWMEN] only once after a CPU reset. Modifying these fields more than once generates a bus transfer error.

Diagram



Fields

Field	Function
7-4 —	Reserved
3 INTEN	Interrupt Enable Enables interrupt request generation. If this field = 1 and the ewm_out_b signal is asserted, an interrupt request is generated. To deassert interrupt requests, write 0 to this field. 0b - Deasserts interrupt requests 1b - Generates interrupt requests
2 INEN	Input Enable Enables the ewm_in port. When this field = 1, it enables the ewm_in port. 0b - Disables 1b - Enables
1 ASSIN	Assertion State Select Specifies the asserted state of the ewm_in signal. By default, the asserted state of the ewm_in signal is logic 0 (active-low), which is when this field = 0. When this field = 1, the ewm_in asserted state is logic 1 (active-high). You can use this field to change the expected polarity of the ewm_in signal. 0b - Logic 0 1b - Logic 1
0 EWMEN	EWM Enable Enables the EWM module. If this field = 1, it enables the EWM module, and if the field = 0, it disables the EWM module. You cannot re-enable this field until the next reset because of its write-once nature. 0b - Disables 1b - Enables

60.5.1.3 Service (SERV)

Offset

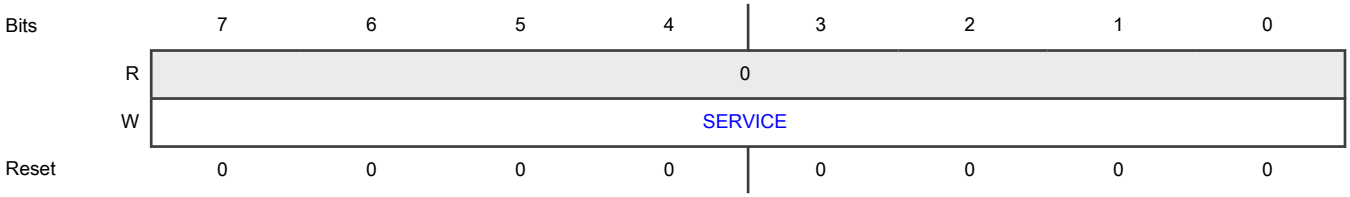
Register	Offset
SERV	1h

Function

Provides an interface from the CPU to the EWM module.

Attempted reads of this register return 0.

Diagram



Fields

Field	Function
7-0 SERVICE	Service Provides an interface from the CPU to the EWM module. The EWM refresh mechanism requires the CPU to write these values to this field: a first data byte of B4h, followed by a second data byte of 2Ch. The EWM refresh action is invalid if either of the following conditions is true: • The first or second data byte is not written correctly. • The second data byte is not written within a fixed number of peripheral bus cycles of the first data byte, known as EWM_refresh_time. The number of peripheral bus clock cycles required for EWM_refresh_time is 15.

60.5.1.4 Compare Low (CMPL)

Offset

Register	Offset
CMPL	2h

Function

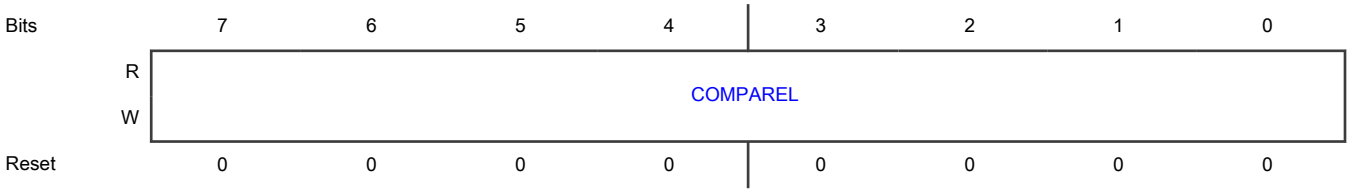
Determines the lower value of the windowed time frame for the correct EWM refresh operation.

This register is reset to 0 after a CPU reset. This provides no minimum time for the CPU to refresh the EWM counter.

NOTE

You can write to this register only once after a CPU reset. Writing to the register more than once generates a bus transfer error.

Diagram



Fields

Field	Function
7-0 COMPAREL	Compare Low Configures the minimum counter value when refreshes are allowed. If a refresh is attempted while the counter value is lower than COMPAREL, then the ewm_out_b signal is asserted. To prevent runaway code from changing the value of this field, you must write to this field after a CPU reset even if the (default) minimum refresh time is required.

60.5.1.5 Compare High (CMPH)

Offset

Register	Offset
CMPH	3h

Function

Determines the higher value of the windowed time frame for the correct EWM refresh operation.

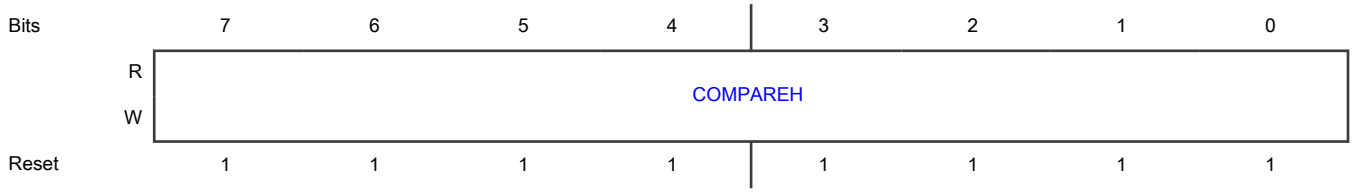
This register is reset to FFh after a CPU reset. This provides a maximum time of up to 256 clocks for the CPU to refresh the EWM counter.

NOTE

You can write to this register only once after a CPU reset. Writing to the register more than once generates a bus transfer error.

The valid values for this register are up to FEh because the EWM counter never expires when the value of COMPAREH = FFh. The expiration happens only if the EWM counter is greater than the value of COMPAREH.

Diagram



Fields

Field	Function
7-0 COMPAREH	Compare High Configures the maximum counter value till when refreshes are allowed. If a refresh is not attempted while the counter value is greater than COMPAREH, then the ewm_out_b signal is asserted. To prevent runaway code from changing the value of this field, you must write to this field after a CPU reset.

60.5.1.6 Clock Control (CLKCTRL)

Offset

Register	Offset
CLKCTRL	4h

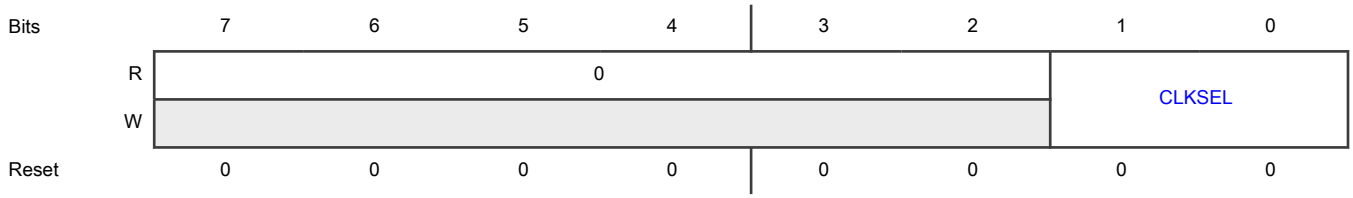
Function

Provides a selection mechanism for low-power clock sources to run the EWM counter.

NOTE

You can write to this register only once after a CPU reset. Writing to the register more than once generates a bus transfer error. You must select the required low-power clock before enabling EWM.

Diagram



Fields

Field	Function
7-2 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
1-0 CLKSEL	Clock Select Provides a selection mechanism for low-power clock sources to run the EWM counter. EWM has the following available low-power clock sources for running the EWM counter. Write an appropriate value to this field to select one of the clock sources. • 00 - lpo_clk[0] • 01 - lpo_clk[1] • 10 - lpo_clk[2] • 11 - lpo_clk[3] See the chip-specific information for low power clock sources used in your device.

60.5.1.7 Clock Prescaler (CLKPRESCALER)

Offset

Register	Offset
CLKPRESCALER	5h

Function

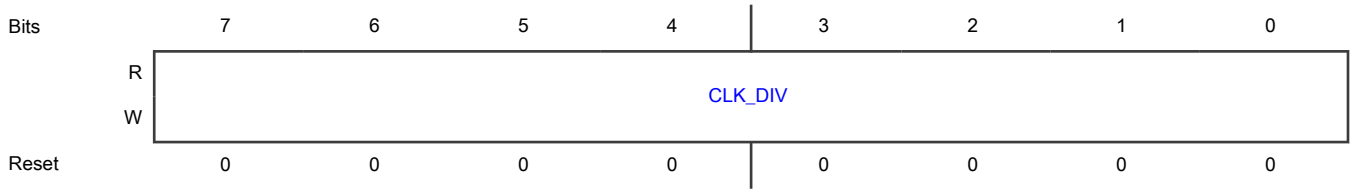
Prescales the EWM counter clock source by a clock divider.

This register is reset to 00h after a CPU reset.

NOTE

You can write to this register only once after a CPU reset. Writing to the register more than once generates a bus transfer error. You must write the required prescaler value before enabling EWM.

Diagram



Fields

61.1.1 Module instances

This device has one instance of the USBFS module, USBFS0.

61.2 Overview

USBFS comprises an On-The-Go (OTG) dual-role subsystem with OTG protocol support. The OTG implementation in this module provides a device solution for a full-speed compliant peripheral and limited host functionality for implementing a USB 2.0 full-speed/low-speed compliant embedded host. The OTG logic implements features, which *On-The-Go and Embedded Host Supplement to the USB 2.0 Specification* requires.

In this subsystem, the USB full-speed controller interfaces to a USB FS/LS transceiver and Memory map and register definitions also includes configuration controls for that transceiver.

In Device mode, the USBFS subsystem working with the SCG module can use the FIRC to generate a 48 MHz USB controller clock tuned using the incoming host USB data for crystal-less operation. Memory map and register definitions also include the registers necessary for configuration controls and status signals of the USB portion of this crystal-less operation.

61.2.1 Block diagram

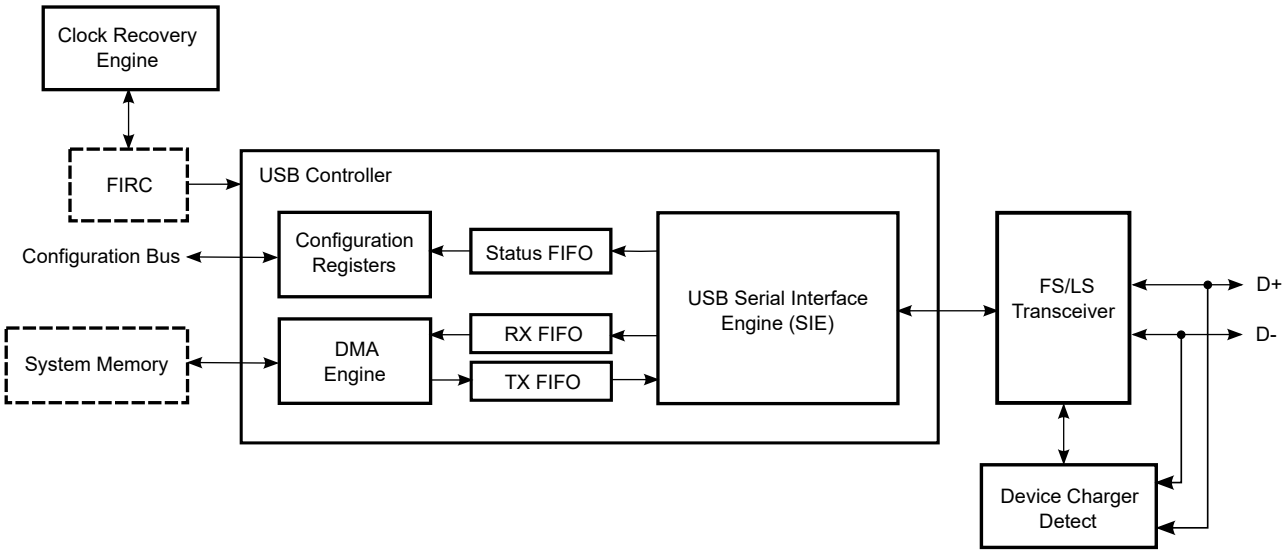

Figure 328. USB FS/LS subsystem overview

61.2.2 Features

- Includes a dual-role USB OTG-capable controller that supports Full-Speed (FS) device or FS/LS embedded host operation. The controller operates with DMA or FIFO data stream interfaces and supports up to 16 bidirectional endpoints. The module complies with the USB 2.0 specification.
- Supports a USB transceiver that includes internal 15 kΩ pulldowns on the D+ and D- lines for Host mode functionality and a 1.5 kΩ pullup on the D+ line for Device mode functionality.
- Supports a USB device charger detection module with USB battery charging 1.2 detection and signaling features (see the "USB DCD" chapter in this Reference Manual for more information).
- Includes FIRC with clock recovery block to eliminate the need for a clock from a 48 MHz crystal. The USB frequency tuning feature is available only for USB device mode operation (see the SCG chapter in this Reference Manual for more information).
- Keep Alive mode allows operation in Sleep mode for certain USB low-traffic situations without needing to restart the USB session after exiting Low-Power mode. In this mode, the USBFS subsystem can respond to IN tokens with NAK replies and initiate wakeup for SETUP or software-assigned tokens.
- A configurable connection allows any one of the LPUART transmit and receive pins to be connected to the Full Speed USB physical layer.
- Supports lane reversal feature to allow switching the roles of package USB0_DM and USB0_DP pins providing additional flexibility for PC board layout.

61.2.3 USB interface general overview

The USB is a cable bus that supports data exchange between a host computer and a wide range of simultaneously accessible peripherals. The bus allows peripherals to be attached, configured, used, and detached when the host and other peripherals operate. The attached peripherals share USB bandwidth through a host-scheduled, token-based protocol.

USB software provides a uniform system view for all application software, hiding implementation details to make application software more portable. It manages the dynamic attaching and detaching of peripherals.

There is only one host in any USB system. The USB interface to the host computer system is referred to as the host controller.

Any system may have multiple USB devices, such as human interface devices, speakers, printers, etc. USB devices present a standard USB interface regarding comprehension, response, and standard capability.

The host initiates transactions to specific peripherals, whereas the device responds to control transactions. The device sends and receives data to and from the host using a standard USB data format. USB 2.0 full-speed/low-speed peripherals operate at 12 Mbit/s or 1.5 Mbit/s.

See the USB 2.0 specification for more information.

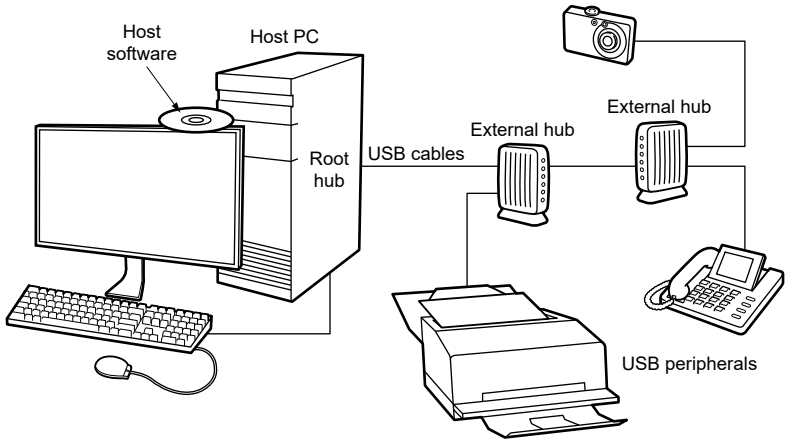

Figure 329. Example USB 2.0 system configuration

61.2.4 USB On-The-Go

USB is a popular standard for connecting peripherals and portable consumer electronic devices such as digital cameras and tablets to host PCs. The OTG Supplement to the USB Specification extends USB to peer-to-peer applications. Using USB OTG technology, consumer electronics, peripherals, and portable devices can connect to exchange data. For example, a digital camera can connect directly to a printer, or a keyboard can connect to a tablet to exchange data.

With the USB OTG product, you can develop a fully USB-compliant peripheral device that can also assume the role of a USB host. The software determines the role of the device based on hardware signals. It then initializes the device in the appropriate mode of operation (host or peripheral) based on how it is connected. After connecting, the devices can negotiate using the OTG protocols to assume the role of host or peripheral based on the task.

See the *On-The-Go and Embedded Host Supplement to the USB 2.0 Specification* for more information.

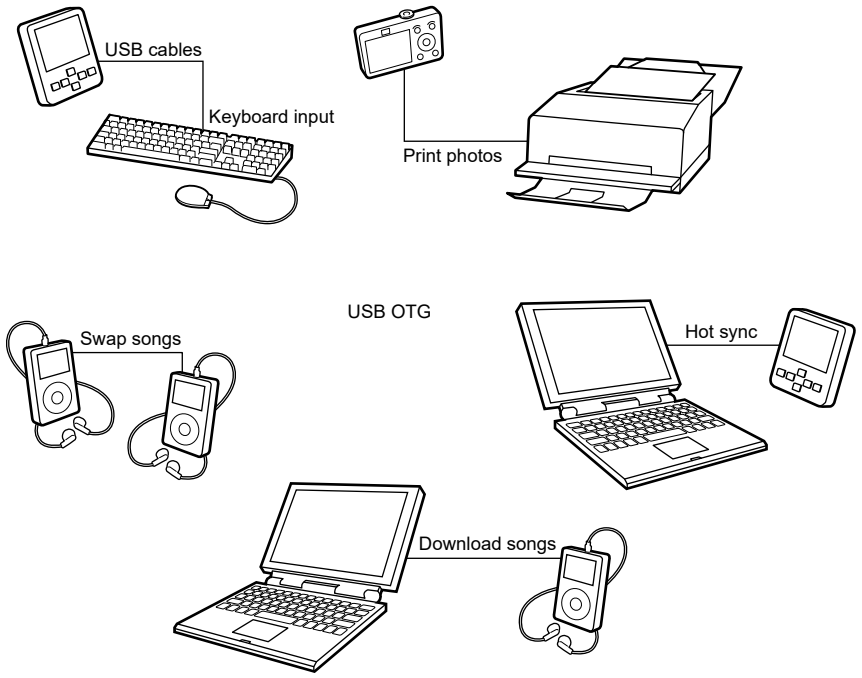

Figure 330. Example USB 2.0 On-The-Go configurations

61.3 Functional description

61.3.1 On-chip transceiver required external components

USB system operation requires external components to ensure that you have met the driver output impedance, eye diagram, and VBUS cable fault tolerance requirements. DM and DP I/O pads must connect through series resistors (approximately 33 Ω each) to the USB connector on the application printed circuit board (PCB). Additionally, signal quality optimizes when you mount these 33 Ω resistors closer to the processor than the USB board-level connector. The USB transceiver includes the following:

- An internal 1.5 kΩ pullup resistor on the USB_DP line for the full-speed device (CONTROL[DPPULLUPNONOTG] or OTGCTL[DPHIGH] controls).
- Internal 15 kΩ pulldown resistors on the USB_DP and USB_DM signals, primarily intended for Host mode operation, are also useful in Device mode, as explained below.

NOTE

For device operation, you must enable the internal 15 kΩ pulldowns to keep the DP and DM ports in a known quiescent state when the VBUS detection software determines that the USB connection is not activated. It also includes cases when no cable to a host is present or the USB port is not used. USBCTRL[PDE] must control the internal 15 kΩ pulldowns in this case.

For host operation, the internal 15 kΩ pulldowns enable automatically, as the USB 2.0 specification requires when CTL[HOSTMODEEN] is asserted high.

The following diagrams provide overviews of device-only, host-only, and dual-role connections. See *Kinetis Peripheral Module Quick Reference (KQRUG)*, available on www.nxp.com, for more information.

61.3.2 Programmer interface

USBFS communicates with the processor core through status registers, control registers, and data structures in memory. This section discusses the major components of the programming model for USBFS.

61.3.2.1 Buffer descriptor table (BDT)

The device operation's function is to transfer a request in the memory image to and from the USB. USBFS implements a BDT to manage USB endpoint communications in system memory efficiently.

- The BDT resides on a 512-byte boundary in system memory and is pointed to by the BDT page registers.
- Every endpoint direction requires two 8-byte buffer descriptor (BD) entries.

Therefore, a system with 16 fully bidirectional endpoints requires 512 bytes of system memory to implement the BDT. The two BD entries allow for an EVEN BD and ODD BD entry for each endpoint direction, which enables the microprocessor to process one BD while USBFS is processing the other BD. Double buffering BDs allow USBFS to transfer data easily at the maximum throughput provided by USB.

You must manage buffers for USBFS by updating the BDT when needed. This allows USBFS to efficiently manage data transmission and reception while the microprocessor performs communication overhead processing and other function-dependent applications.

Because the buffers are shared between the microprocessor and USBFS, a simple semaphore mechanism distinguishes who is allowed to update the BDT and buffers in system memory. A semaphore (the OWN field) becomes 0 when the microprocessor owns the BD entry.

- When OWN = 0, the microprocessor is allowed read and write access to the BD entry and the buffer in system memory.
- When OWN = 1, USBFS owns the BD entry and the buffer in system memory. USBFS now has full read and write access, and the microprocessor must not modify the BD or its corresponding data buffer.

The BD also contains indirect address pointers where the actual buffer resides in system memory. The following diagram shows this indirect address mechanism.

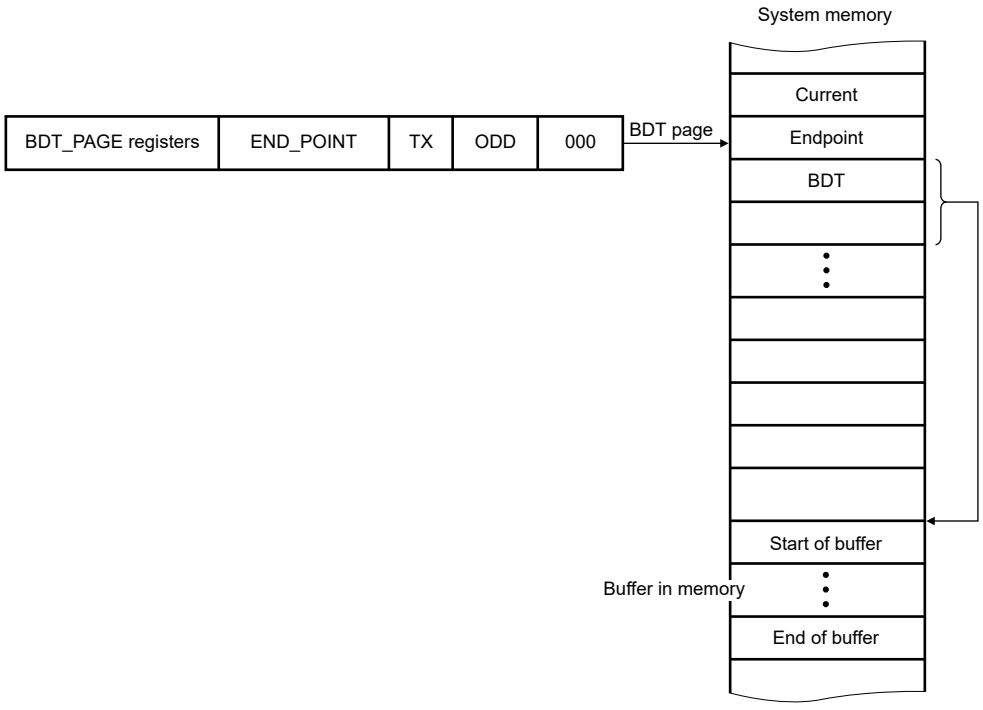

Figure 334. Buffer descriptor table

61.3.2.2 Addressing BDT entries

An understanding of the addressing mechanism of BDT is useful when accessing endpoint data via USBFS or microprocessor:

- The BDT occupies up to 512 bytes of system memory.
- You can support 16 bidirectional endpoints with a full BDT of 512 bytes.
- 16 bytes are needed for each USB endpoint direction.
- Applications with fewer than 16 endpoints require less RAM to implement the BDT.
- The BDT page registers (BDT_PAGE) point to the starting location of the BDT.
- You must locate the BDT on a 512-byte boundary in system memory.
- All enabled transit and receive endpoint BD entries are indexed into the BDT to allow easy access via USBFS or MCU core.

When you receive a USB token on an enabled endpoint, USBFS uses its integrated DMA controller to interrogate the BDT. USBFS reads the corresponding endpoint BD entry to determine whether it (USBFS) owns the BD and corresponding buffer in system memory.

To compute the entry point into the BDT, the BDT_PAGE registers are concatenated with the current endpoint and the TX and ODD fields to form a 32-bit address. This following tables show this address mechanism:

Table 474. BDT address calculation

31:24	23:16	15:9	8:5	4	3	2:0
BDT_PAGE_03	BDT_PAGE_02	BDT_PAGE_01[7:1]	Endpoint	TX	ODD	000

Table 475. BDT address calculation fields

Field	Description
BDT_PAGE	BDT_PAGE registers in the control register block
ENDPOINT	ENDPOINT field from the USB TOKEN
TX	1 for transmit transfers; 0 for receive transfers
ODD	It corresponds to the buffer currently in use; the buffers are used in a ping-pong fashion. Maintained within the USBFS SIE.

61.3.2.3 Buffer descriptors (BDs)

A buffer descriptor provides endpoint buffer control information for USBFS and the processor. The BDs have different meanings, depending on whether USBFS or the processor reads the BD in memory.

The USBFS controller uses the data stored in the BDs to determine:

- Who owns the buffer in system memory
- Data0 or Data1 PID
- Whether to release ownership upon packet completion
- No address increment (FIFO mode)
- Whether data toggle synchronization is enabled
- How much data to transmit or receive
- Where the buffer resides in system memory

The processor uses the data stored in the BDs to determine:

- Who owns the buffer in system memory
- Data0 or Data1 PID
- The received TOKEN PID
- How much data was transmitted or received
- Where the buffer resides in system memory

The format for the BD is shown in the following table.

Table 476. Buffer descriptor format

31:26	25:16	15:8	7	6	5	4	3	2	1	0
RSVD	BC (10 bits)	RSVD	OWN	DATA0/1	KEEP/ TOK_PID[3]	NINC/ TOK_PID[2]	DTS/ TOK_PID[1]	BDT_STALL/ TOK_PID[0]	0	0
Buffer Address (32 bits)										

Table 477. Buffer descriptor fields

Field	Description
31–26 RSVD	Reserved
25–16 BC	Byte Count Represents the 10-bit byte count. USBFS SIE changes this field upon completing a receive transfer with the byte count of the data received.
15–8 RSVD	Reserved
7 OWN	Determines whether the processor or USBFS currently owns the buffer. Except when KEEP = 1, the SIE hands ownership back to the processor after completing the token by writing 0 to this field. This must always be the last byte of the BD that the processor updates when it initializes a BD. 0 The processor has access to the BD. USBFS ignores all other fields in the BD. 1 USBFS has access to the BD. When USBFS owns the BD, the processor must not modify any other fields in the BD.
6 DATA0/1	Defines whether you transmit or receive a DATA0 field (DATA0/1=0) or a DATA1 (DATA0/1=1) field. It is unchanged by USBFS.
5 KEEP/ TOK_PID[3]	Has two functions (KEEP or TOK_PID[3]): • KEEP—When written by the processor, it serves as the KEEP bit. Typically, this bit is 1 with ISO endpoints feeding a FIFO. The microprocessor is not informed that a token has been processed. Transfer the data to or from the FIFO. When KEEP becomes 1, the NINC field usually becomes 1 to prevent address increment.

Table continues on the next page...

Table 477. Buffer descriptor fields (continued)

Field	Description
	0 Allows USBFS to release the BD when a token has been processed. 1 This field is unchanged by USBFS. Bit 3 of the current token PID is written back to the BD by USBFS. • TOK_PID[3]—If the OWN field also becomes 1, then the BD remains owned by USBFS indefinitely; when written by USB, it serves as TOK_PID[3]. Typically, this field is 1 with ISO endpoints feeding a FIFO. The microprocessor is not informed that a token has been processed. Transfer the data to or from the FIFO. When KEEP becomes 1, the NINC field usually becomes 1 to prevent address increment. 0 or 1 USBFS writes back bit 3 of the current token PID to the BD.
4 NINC/ TOK_PID[2]	No Increment (NINC) Disables the DMA engine address increment. This forces the DMA engine to read or write from the same address. This is useful for endpoints when data is *read from* or *written to* a single location (such as a FIFO). Typically this field becomes 1 with the KEEP field for ISO endpoints that are interfacing to a FIFO. 0 USBFS writes bit 2 of the current token PID to the BD. 1 This bit is unchanged by USBFS.
3 DTS/ TOK_PID[1]	Enables USBFS to perform data toggle synchronization when you write 1 to this field. • If KEEP = 0, then bit 1 of the current token PID is written back to the BD. • If KEEP = 1, then this field is unchanged by USBFS. 0 Data toggle synchronization is disabled. 1 Enables USBFS to perform data toggle synchronization.
2 BDT_STALL TOK_PID[0]	Causes USBFS to issue a STALL handshake if the SIE receives a token that uses the BDT in this location when you write 1 to this field. The SIE does not consume the BDT (the OWN field remains 1 and the rest of the BDT is unchanged) when a BDT_STALL field becomes 1. • If KEEP = 0, write back bit 0 of the current token PID to the BD. • If KEEP = 1, then this field is unchanged by USBFS. 0 No stall issued. 1 The SIE does not consume the BDT (the OWN field remains 1, and the rest of the BDT is unchanged). Writing 1 to BDT_STALL also causes the corresponding USB_ENDPTn[EPSTALL] to become 1. This causes USB OTG to issue a STALL handshake for both directions of the associated endpoint. To clear the stall condition: 1. Write 0 to the associated USB_ENDPTn[EPSTALL]. 2. Write the BDT to clear OWN and BDT_STALL.
TOK_PID[n]	Bits [5:2] can also represent the current token PID. When a transfer completes, USBFS writes back the current token PID into the BD. The values written back are the token PID values from the USB specification:

Table continues on the next page...

Table 477. Buffer descriptor fields (continued)

Field	Description
	• 1h for an OUT token. • 9h for an IN token. • Dh for a SETUP token. In Host mode, this field reports the last returned PID or a transfer status indication. The possible values returned are: • 3h: DATA0 • Bh: DATA1 • 2h: ACK • Eh: STALL • Ah: NAK • 0h: Bus timeout • Fh: Data error
1–0 Reserved	Reserved
ADDR[31:0]	Address Represents the 32-bit buffer address in system memory; this address must also be 32-bit aligned. USBFS does not change this field.

61.3.2.4 USB transaction

When USBFS transmits or receives data, it computes the BDT address using the address generation shown in Addressing BDT entries.

If OWN = 1, then the following process occurs:

1. USBFS reads the BDT.
2. The SIE transfers the data via the DMA to or from the buffer pointed to by Address (ADDR) of the BD.
3. When the TOKEN completes, USBFS updates the BDT, and if KEEP = 0, then USBFS changes the OWN field to 0.
4. Update the STAT register, and the TOK_DNE interrupt occurs.
5. When the processor processes the TOK_DNE interrupt, it reads from the status register all the information required to process the endpoint.
6. At this point, the processor allocates a new BD so that you can transmit or receive the additional USB data for that endpoint and then processes the last BD.

The following figure shows how a typical USB token is processed after the BDT is read and OWN = 1.

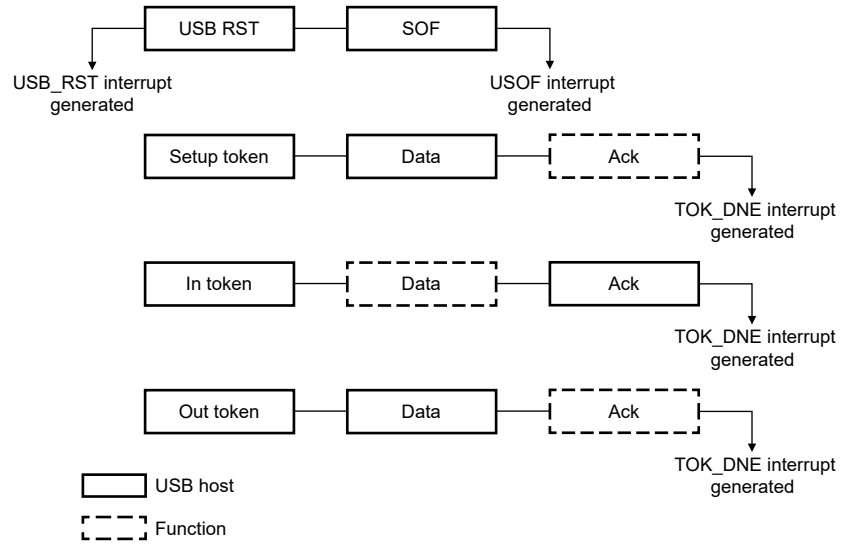

Figure 335. USB token transaction

USB has two sources for the DMA overrun error:

- **Memory latency:** The memory latency may be too high and cause the receive FIFO to overflow. This is predominantly a hardware performance issue, usually caused by transient memory access issues.
- **Oversized packets:** The packet received may be larger than the negotiated MaxPacket size. Typically, a software bug causes this. The USB specification is ambiguous for DMA overrun errors due to oversized data packets because it assumes correct software drivers on both sides. NAKing the packet can result in the retransmission of the already oversized packet data. Therefore, in response to oversized packets, the USB core continues ACKing the packet for non-isochronous transfers.

Table 478. USB responses to DMA overrun errors

Errors due to memory latency	Errors due to oversized packets
Non-acknowledgment (NAK) or bus timeout (BTO) — See bit 4 in Error Interrupt Status (ERRSTAT) as appropriate for the class of transaction.	Continues acknowledging (ACKing) the packet for non-isochronous transfers.
—	Clip the data written to memory to the MaxPacket size so as not to corrupt system memory.
ERRSTAT[DMAERR] becomes 1 for Host mode and Device mode of operation. Depending on the INTENB and ERRENB register's values, the core may assert an interrupt to notify the processor of the DMA error.	Asserts ERRSTAT[DMAERR], which can trigger an interrupt and ISTAT[TOKDNE] fires. The TOK_PID field of the BDT is not 1111 because the DMAERR is not due to latency.
• In Host mode: Generate ISTAT[TOKDNE] and the TOK_PID field of the BDT is 1111 to indicate the DMA latency error. Host mode software can decide to retry or move to next scheduled item. • In Device mode: The BDT is not written back nor ISTAT[TOKDNE] triggered because it is assumed that a second attempt is queued and will succeed in the future.	The packet length field written back to the BDT is the MaxPacket value representing the length of the clipped data written to memory.
From here, you can decide an appropriate course of action for future transactions, such as stalling the endpoint, canceling the transfer, disabling the endpoint, and others.	

61.3.3 Operations

61.3.3.1 Device mode FIRC operation

The following are the FIRC initialization code steps for USB crystal-less Device mode operation:

1. Enable the FIRC nominal 48 MHz clock by ensuring that the FIRCCSR[FIRCEN] and FIRCTCFG[TRIMSRC] fields in the SCG registers have the correct values for crystal-less FS USB Device mode operation.
2. Enable the USB clock recovery tuning by writing 1 to CLK_RECOVER_CTRL[CLOCK_RECOVER_EN].
3. Complete the configuration of the USB clock recovery logic by writing 1 to CLK_RECOVER_IRC_EN[IRC_EN].
4. This chip does not have alternate USB input clock sources from clock muxes, so no additional 48 MHz clock path configuration is required.

61.3.3.2 USB and VREGIN pin status detection

This device does not have a dedicated VBUS detect pin. Still, it does have the capability through CONTROL[SESS_VLD] to report the status of VBUS using one of two monitoring methods with different package pins. The choice between the two VBUS monitoring methods is made with CONTROL[VBUS_SOURCE_SEL]. For VBUS detection, use a specified GPIO pin for both bus-powered and self-powered USB cases. If the GPIO pins on this device do not directly support a 5 V input, use an external resistive voltage divider to keep the input voltage within the valid range if you use the GPIO pin method for VBUS detection. The voltage status of the VDD_LDO_USB pin is passed internally from the USB VREG to the USB FS subsystem, so no additional board connections are required if you choose the VBUS detection method.

For this chip, the specified GPIO package pin for VBUS monitoring is PTB6 configured in mux mode ALT2.

This device does not have a dedicated OTG ID detect pin. For OTG ID pin detection, if needed, use one of the GPIO pins connected to the WUU configured as an input pin with pullup enabled.

61.3.3.3 LPUART over USB capability

This device supports a connection whereby any LPUART may connect to the FS USB physical layer (and the USB controller disconnected) to allow simple debugging capabilities for applications that do not have direct physical access to other LPUART Tx/Rx pins.

When you write 1 to USBCTRL[UARTSEL], the selected LPUART connects to the FS USB physical layer. This configures the FS USB0_DP/DM signals to configure as normal LPUART signals, which do not operate in differential mode. When USBCTRL[UARTCHLS] becomes 0, FS USB0_DP/DM signal pins are configured for LPUART Tx/Rx functions respectively. When USBCTRL[UARTCHLS] becomes 1, FS USB0_DP/DM signal pins are configured for LPUART Rx/Tx functions.

61.3.3.4 Lane reversal feature

This device supports lane reversal for the USB0_DP and USB0_DM pins for flexibility in PC board design depending on the USB receptacle type and location choices.

USBCTRL[DPDM_LANE_REVERSE] controls the lane reversal. After USBCTRL[DPDM_LANE_REVERSE] becomes 0, the USB0_DP and USB0_DM external package pins have their normal roles. After USBCTRL[DPDM_LANE_REVERSE] becomes 1, the I/O pin roles are switched so that the USB0_DP external package pin operates as USB_DM and the USB0_DM external package pin operates as USB_DP.

Lane reversal impacts all USB standard data communication functions along with battery charging detection and signaling. Lane reversal does **not** impact LPUART over USB mode selections for USB0_DP/DM pin functions because there is already a pin configuration for that mode using USBCTRL[UARTCHLS].

61.3.4 Modes of operation

USBFS includes the following main modes of operation:

- Active mode

- Low-Power mode
- Keep-Alive mode

61.3.4.1 Active mode

This is the basic mode of operation. The USBFS core uses software control to switch between two modes of operation:

- USB peripheral device
- USB host

In either mode, the USB host or USB peripheral device uses the same data paths and BDs for the transmission and reception of data. For this reason, use a USBFS core-centric nomenclature to describe the direction of the data transfer between the USBFS core and USB:

- Receive (or "Rx") describes transfers that move data from USB to memory.
- Transmit (or "Tx") describes transfers that move data from memory to USB.

The following table shows how the data direction corresponds to the USB token type in host and peripheral device applications.

Table 479. Data direction for USB host or USB peripheral device

	Rx	Tx
Device	OUT or SETUP	IN
Host	IN	OUT or SETUP

61.3.4.2 Low-Power mode

The USB controller supports Sleep mode, Deep Sleep mode, and Power Down mode to save power consumption.

When the USB subsystem detects no activity on the USB bus for more than 3 ms, ISTAT[SLEEP] becomes 1. This field can cause an interrupt, and you decide on the appropriate action.

Waking from a Sleep Low-Power mode when the USB subsystem is powered occurs through an asynchronous interrupt triggered by activity on the USB bus. Writing 1 to USBTRC0[USBRESMEN] enables this function.

The following wakeup features are also supported:

- In Active and Sleep modes, the USB controller can generate an interrupt on VREGIN detection using MISCCTRL[VFEDG_EN], MISCCTRL[VREDG_EN], USBTRC0[VFEDG_DET], and USBTRC0[VREDG_DET].
- In Deep Sleep and Power Down modes, VDD_LDO_USB is an input pin to WUU, and a transition on it can generate a wakeup.
- In Deep Sleep and Power Down modes, USB0_DP and USB0_DM are input pins to WUU, and a transition on those pins can generate a wake-up provided the USB subsystem is powered and in Host mode.
- In Deep Sleep and Power Down modes, the GPIO pins chosen to detect VBUS and OTG ID are also input to WUU, so transitions on them can generate a wakeup.

In Deep Power Down mode, the pads become isolated, and USB bus activity cannot wake the system.

61.3.4.3 Keep-Alive mode

Keep Alive mode is for the chips operating with Device-only USB use cases.

NOTE

The address range 48010000h to 480101FFh consists of 512 bytes of on-chip USB RAM, which is available in Active or Sleep modes. This allows the USB core to access the USB RAM in Keep Alive Mode.

When entering Keep Alive Mode, you must place the BDT entries and all USB buffers accessed during Keep Alive mode in the USB RAM space.

Keep Alive mode keeps USB basic response functionality active in the Sleep low-power mode, so there is no need to re-enumerate the USB device after exiting that Low-Power mode. When connected to the host and when there is no data to transfer, to save power, the software can power down the system bus and the CPU, keeping only the USB power on. In Keep Alive mode, only the USB 48 MHz functional clock is required by the USB controller; the rest of the device can transition to Sleep mode. When the SETUP token or a software-assigned token is received, the USB core wakes up, but it responds with NAK to all other types of packets.

Because the USB core must access the BDT in Keep Alive mode, use the on-chip USB RAM for the BDT and small data packets during Keep Alive mode. Place the BDT into this RAM in Keep Alive mode and changes all OWN fields to 0 (except the SETUP endpoint). You can do this by writing 1 to KEEP_ALIVE_CTRL[OWN_OVERRD_EN].

61.3.4.3.1 Entering Keep-Alive mode

To enter Keep-Alive mode:

1. **To configure the USB subsystem for Keep-Alive mode before entering Sleep mode:**
   - Initialize the BDT in USB RAM, including writing 0 to the OWN field within each BDT entry for every endpoint except for EP0. You must configure the buffer address for EP0 to an address within the USB SRAM, ensuring that you place received data within the USB SRAM. The USB FS subsystem cannot access other memory locations in USB Keep-Alive mode.
   - Configure KEEP_ALIVE_WKCTRL[WAKE_ON_THIS] appropriately to configure what received token generates the wakeup from Keep-Alive mode.
   - Enable the wakeup interrupt by writing 1 to KEEP_ALIVE_CTRL[WAKE_INT_EN].
   - Enable Keep-Alive mode operation by writing 1 to KEEP_ALIVE_CTRL[KEEP_ALIVE_EN].
2. **Enter Sleep mode, ensuring that the USB 48 MHz functional clock source remains enabled:**
   - If the 48 MHz clock is not configured for USB crystal-less operation, follow Device mode FIRC operation instructions.
   - The software then enters Sleep mode, and the USB subsystem is in Keep-Alive mode.
   - Follow the procedures described in the "Power Management" and "System Power Control (SPC)" chapters of this document to reduce power consumption in Sleep mode for extraneous modules.

61.3.4.3.2 Exiting Keep-Alive mode

Any enabled interrupt generates a wakeup from Sleep mode; this causes an exit from USB Keep Alive mode. You can also configure the USB to generate an interrupt when it receives a particular token (for example, SETUP), as configured by KEEP_ALIVE_WKCTRL[WAKE_ON_THIS]. Other USB interrupts can also remain enabled and are generated in USB Keep-Alive mode.

61.3.5 Clocking

This section describes clocks and special clocking requirements of USBFS.

Table 480. Clocking

Clock name	Description
Bus clock	The bus clock is system-dependent. It must be greater than 24 MHz.
Function clock	USB 48 MHz functional clock

61.3.6 Reset

Chip reset

The logic and registers for USBFS reset to their default states on a chip reset.

Software reset

USBFS implements a software reset field in its control register. See USBTRC0[USBRESET] for more information.

61.3.7 Interrupts

The following table illustrates the status flags that can generate USBFS interrupts.

Table 481. Interrupts

Flag	Description	Low-power wakeup
ONEMSEC	One millisecond timer timeout flag	No
LINE_STATE_CHG	Line state change flag	No
STALL	Stall handshake flag	No
ATTACH	Attach flag	No
RESUME	Resume flag	No
SLEEP	Sleep flag	No
TOKDNE	Token processing done flag	No
SOFTOK	SOF token flag	No
ERROR	Error flag	No
USBRST	USB reset flag	No
BTSERR	Bit stuff error flag	No
OWNERR	BD unavailable error flag	No
DMAERR	DMA access error flag	No
BTOERR	Bus turnaround timeout error flag	No
DFN8	Data field bit width error flag	No
CRC16	CRC16 error flag	No
CRC5EOF	EOF error flag	No
PIDERR	PID error flag	No
USB_RESUME_INT	Asynchronous resume wakeup flag	Yes
VFEDG_DET	VREGIN falling edge flag	Yes
VREDG_DET	VREGIN rising edge flag	Yes
WAKE_INT_STS	Wakeup interrupt flag in Keep-Alive mode	No
OVF_ERROR	Frequency trim adjustment flag	No

61.3.8 DMA

USBFS provides an integrated DMA controller that transfers the packet data to and from memory. The DMA controller allows USB endpoint data to transfer very efficiently, limiting processor involvement.

61.4 External signals

This section describes clocks and special clocking requirements of USBFS.

Table 482. External signals

Signal	Description
USB0_DP	USB D+ pin
USB0_DM	USB D- pin
VDD_USB	3.3 V power supply for USB transceiver

61.5 Initialization

For Host mode initialization, see Host mode operation examples.

For Device mode initialization, see Device mode operation examples.

61.6 Application information

61.6.1 OTG and Host mode operation

The Host mode logic allows portable, mobile, and other devices using this chip to function as a USB-embedded host (EH) controller. The OTG logic adds an interface to allow the OTG host negotiation and session request protocols (HNP and SRP) to implement in software.

Host mode is used in handheld-portable devices to connect simple HID class devices like printers and keyboards easily. It is not intended to perform the functions of a full OHCI or UHCI-compatible host controller found on PC motherboards. Host mode allows bulk, isochronous, interrupt, and control transfers. Perform bulk data transfers at nearly the total USB interface bandwidth. Support is provided for ISO transfers, but the number of ISO streams you can practically support is affected by the interrupt latency of the processor servicing the Token Done interrupts from the SIE. You must write custom drivers to support host mode operation.

The USBFS core can only operate as a peripheral device or in Host mode; the USBFS core cannot operate simultaneously in both peripheral device and Host modes. Writing 1 to CTL[HOSTMODEEN] enables Host mode. When Host mode is enabled, use the endpoint zero only. You must disable all other endpoints.

61.6.2 Host mode operation examples

The following sections list the steps to perform USB host functions using the USBFS core. See the *Universal Serial Bus Specification, Revision 2.0*, "Chapter 9 USB Device Framework" for more information.

To enable Host mode and discover a connected device:

1. Enable Host Mode (CTL[HOSTMODEEN] = 1).
   - Enable the pulldown resistors and disable the pullup resistors.
   - SOF generation begins.
   - USBFS initializes the SOF counter to 12,000 (corresponding to an interval of 1 ms between SOF frames).
   - To eliminate noise on the USB, write 0 to CTL[USBENSOFEN] to disable SOF packet generation.
2. Enable the ATTACH interrupt (INTEN[ATTACHEN] = 1).
3. Wait for the ATTACH interrupt (ISTAT[ATTACH]), which is signaled by a USB peripheral device pullup resistor changing the state of DPLUS or DMINUS from 0 to 1 (CTL[SE0] to J or K state).
4. Check the state of CTL[JSTATE] and CTL[SE0]. If the connecting device is low speed (CTL[JSTATE] is 0), then:
   - Write 1 to ADDR[LSEN].
   - Write 1 to ENDPT0[HOSTWOHUB].
5. Enable RESET (CTL[RESET] = 1) for 10 ms.
6. Enable SOF packet to keep the connected device from going suspended (CTL[USBENSOFEN] = 1).

7. Send the appropriate commands to the default control pipe of the connected device, to enumerate the attached device.

To complete a control transaction to a connected device:

1. Complete all the steps to discover a connected device.
2. Set up the endpoint control register for bidirectional control transfers: ENDPT0[4:0] = 0dh.
3. Place a copy of the device framework setup command in a memory buffer.
4. Initialize current even or odd TX EP0 BDT to transfer the 8 bytes of command data for a device framework command (for example, get a device descriptor).
   - Write 0008_0080h to the BDT command word –Byte count to 8, and write 1 to OWN.
   - Set the BDT buffer address field (see Table 476) buffer address field to the start address of the 8-byte command buffer.
5. Set the USB device address of the peripheral device in the address register (ADDR[ADDR]). After the USB bus reset, the chip's USB address is zero. The set address device framework command writes 1 to the chip USB address.
6. Write Token (TOKEN) with a SETUP to Endpoint 0, the peripheral device default control pipe (TOKEN = D0h).
   - This initiates a setup token on the bus, followed by a data packet.
   - After completing the packets, return the device handshake in the BDT PID field.
   - When you write the BDT, assert a Token Done (ISTAT[TOKDNE]) interrupt. This completes the setup phase of the setup transaction.
7. To initiate the data phase of the setup transaction (that is, to get the data for the GET DEVICE DESCRIPTOR command), set up a buffer in memory for the data to be transferred.
8. Initialize the current even or odd TX EP0 BDT to transfer the data.
   - Write 0040_00C0h to the BDT command word – BC to 64 (the byte count of the data buffer, in this case), write 1 to OWN field, and set Data toggle to Data1.
   - Set the BDT buffer address field to the start address of the data buffer.
9. Write Token (TOKEN) with an IN or OUT token to Endpoint 0 (the peripheral device default control pipe), and write an IN token for a GET DEVICE DESCRIPTOR command (TOKEN = 0x90). This initiates an IN token on the bus, followed by a data packet from the device to the host.

   After the data packet completes, write the BDT and assert a Token Done interrupt (ISTAT[TOKDNE]). For control transfers with a single packet data phase, this completes the data phase of the setup transaction.
10. To initiate the status phase of the setup transaction, set up a buffer in memory to receive or send the zero length status phase data packet.
11. Initialize the current even or odd TX EP0 BDT to transfer the status data.
    - Write 0000_00C0h to the BDT command word – BC to 0 (the byte count of the data buffer in this case), write 1 to the OWN field, and set the Data toggle to Data1.
    - Set the BDT buffer address field to the start address of the data buffer.
12. Write Token (TOKEN) with an IN or OUT token to Endpoint 0 (the peripheral device default control pipe), and write an OUT token for a GET DEVICE DESCRIPTOR command (TOKEN = 10h). This initiates an OUT token on the bus, followed by a *zero-length* data packet from the host to the device.

    After the data packet completes, write the BDT with the handshake from the device, and assert a Token Done (ISTAT[TOKDNE]) interrupt. This completes the data phase of the setup transaction.

To send a full speed bulk data transfer to a peripheral device:

1. Complete all steps to discover and configure a connected device. Write Address (ADDR) with the address of the peripheral device. Typically, there is only one other device on the USB bus in Host mode, so it is expected that the address is 01h and must remain constant.
2. Write 1Dh to Endpoint Control (ENDPT0 - ENDPT15) to enable transmit and receive transfers with handshaking enabled.
3. Set up the even TX EP0 BDT to transfer up to 64 bytes.
4. Set the USB device address of the peripheral device in the address register (ADDR[ADDR]).
5. Write Token (TOKEN) with an OUT token to the desired endpoint. The write to Token (TOKEN) triggers the USBFS transmit state machines to begin transmitting the token and the data.
6. Set up the odd TX EP0 BDT to transfer up to 64 bytes.
7. Write Token (TOKEN) with an OUT token, as in 5. To achieve maximum throughput, you can queue two tokens simultaneously to allow the packets to be double-buffered.
8. Wait for ISTAT[TOKDNE] interrupt. This indicates that one of the BDTs has been released back to the processor and that the transfer has completed.
   - If the peripheral device asserts NAKs, then USBFS continues to retry the transfer indefinitely without processor intervention (unless ENDPT0[RETRYDIS] is 1).
   - If ENDPT0[RETRYDIS] becomes 1, then return the handshake (ACK, NAK, STALL, or ERROR (fh)) in the BDT PID field.
   - If a stall interrupt occurs, then you must de-queue the pending packet and you must clear the error condition in the peripheral device.
   - If a Reset interrupt occurs (CTL[SE0] for more than 2.5 µs), the peripheral device detaches.
9. After ISTAT[TOKDNE] interrupt occurs, return to step 2 to examine the BDTs and queue the next data packet.

61.6.3 Device mode operation examples

The following sections list the steps required to perform USB device functions using the USBFS core.

To enable Device mode and discover a connected USB host:

1. Disable Host Mode (CTL[HOSTMODEEN] = 0).
2. Pullup DP (CONTROL[DPPULLUPNONOTG] = 1b).
3. Disable weak pulldown on DP and DM (USBCTRL[PDE] = 0b).
4. Disable suspend (USBCTRL[SUSP] = 1'b0).
5. Clear status flags.
6. Enable USBRST interrupt (INTEN[USBRSTEN] = 1b).
7. Enable USBFS (CTL[USBENSOFEN] = 1'b1).
8. Wait for reset request from USB host (ISTAT[USBRST] = 1b).
9. Detect USBRST interrupt, device connected to USB host.

To complete a packet transfer:

1. Complete all the steps to discover a connected USB host.
2. Set up the endpoint control register for packet transfer (ENDPT0[4:0] = 0dh).
3. Enable TOKDNE interrupt (INTEN[TOKDNEEN] = 1b).
4. Initialize the endpoint BDT in USB RAM including setting OWN = 1b.
5. Clear TXD_SUSPEND flag (write 1 to clear CTL[TXSUSPENDTOKENBUSY]).

6. Wait packet transfer to complete (ISTAT[TOKDNE] = 1b).
7. Detect TOKDNE interrupt, check BDT and status flags.

61.6.4 OTG operation

The USB-OTG core provides sensors and controls to enable On-The-Go (OTG) operation. The OTG driver software uses these sensors to implement the host negotiation protocol (HNP) and session request protocol (SRP) and to give access to the OTG protocol control signals. The following state machines show the OTG operations involved with HNP and SRP protocols from either end of the USB cable.

61.6.4.1 OTG dual role A device operation

A device is considered the A device:

- According to the type of cable attached.
- If you plug in the USB Type Standard-A or Micro-A plug into the device.

The following flow diagram and state description table show how a *dual role* A device operates:

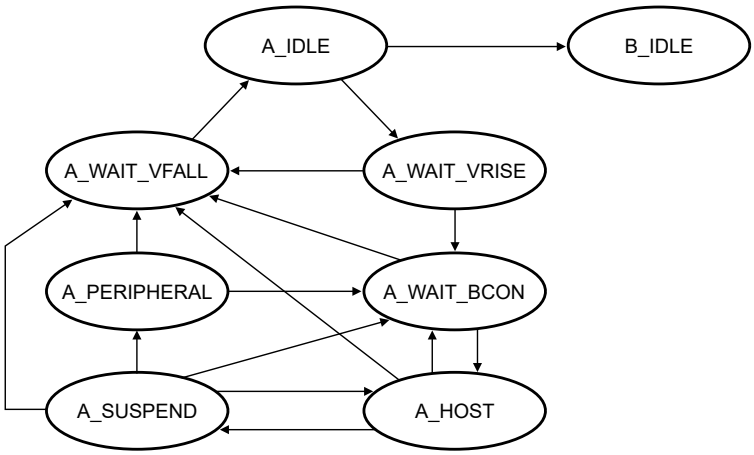

Figure 336. Dual role A device flow diagram

Table 483. State descriptions for the dual role A device flow

State	Possible events in this state	Event response
A_IDLE	An ID interrupt[1] occurs, indicating that the cable has been unplugged, or a Type B cable is attached. The device now acts as a Type B device.	Go to B_IDLE.
	The A application wants to use the bus or the B device is doing an SRP (as A_SESS_VLD interrupt or Attach or Port status change interrupt indicates).	Go to A_WAIT_VRISE. Turn on DRV_VBUS. Check the data line for 5-10 ms pulsing.
A_WAIT_VRISE	An ID interrupt[1] occurs or if A_VBUS_VLD is false after 100 msec, indicating that the cable is changed or the A device cannot support the current required from the B device.	Go to A_WAIT_VFALL. Turn off DRV_VBUS.
	An A_VBUS_VLD interrupt occurs	Go to A_WAIT_BCON.

Table continues on the next page...

Table 483. State descriptions for the dual role A device flow (continued)

State	Possible events in this state	Event response
A_WAIT_BCON	200 ms pass without an Attach or ID interrupt[1] (this could wait forever if desired)	Go to A_WAIT_FALL. Turn off DRV_VBUS.
	An A_VBUS_VLD interrupt occurs and a B device attaches	Go to A_HOST. Enter Host mode.
A_HOST	Enumerate the device to determine OTG support. Then one of the following occurs:	
	• An A_VBUS_VLD interrupt occurs. • A device has finished its session and does not need the bus anytime soon. • The B device disconnects.	Go to A_WAIT_VFALL. Exit Host mode. Turn off DRV_VBUS.
	One of the following occurs: • The A device finishes its session. • The A device relinquishes the bus to the B device.	Go to A_SUSPEND.
	An ID interrupt[1] occurs or if the B device disconnects.	Go to A_WAIT_BCON.
A_SUSPEND	An ID interrupt[1] occurs, or if a 150 ms B disconnect timeout occurs (this timeout value could be longer), or if an A_VBUS_VLD interrupt occurs.	Go to A_WAIT_VFALL. Turn off DRV_VBUS.
	HNP is enabled, and B disconnects in 150 ms, then B device becomes the host.	Go to A_PERIPHERAL. Exit Host mode.
	The A device wants to start another session.	Go to A_HOST.
A_PERIPHERAL	An ID interrupt[1] or A_VBUS_VLD interrupt occurs.	Go to A_WAIT_VFALL. Turn off DRV_VBUS.
	The bus is idle for 3–200 ms.	Go to A_WAIT_BCON. Enter Host mode.
A_WAIT_VFALL	An ID interrupt[1] occurs or (A_SESS_VLD or a B device connects)	Go to A_IDLE.

1. ID interrupt is triggered due to a detected change in the resistance between the local USB connector ID pin and ground.

61.6.4.2 OTG dual role B device operation

A device is considered a B device if you connect it to the bus with a USB type Standard-B, Mini-B, or Micro-B plug inserted into the local USB receptacle. The type Mini-B plug and receptacle are now only allowed for dedicated peripheral devices and not allowed for a dual role or OTG devices.

The following flow diagram and state description table show how a *dual role* B device operates:

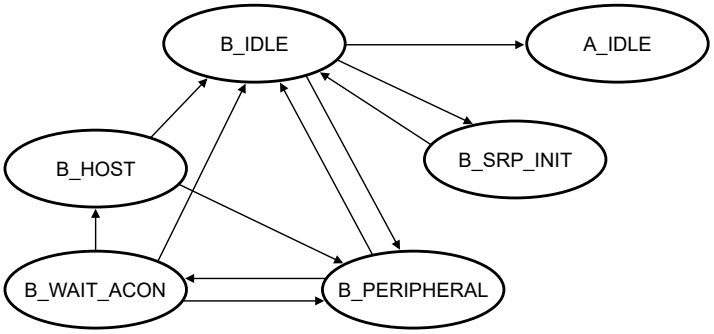

Figure 337. Dual role B device flow diagram

Table 484. State descriptions for the dual role B device flow

State	Possible events in this state	Event response
B_IDLE	An ID interrupt[1] occurs, indicating that a Type A cable is plugged in. The device must now respond as a type A device.	Go to A_IDLE.
	A B_SESS_VLD interrupt occurs, and the A device has turned on VBUS and begins a session.	Go to B_PERIPHERAL. Turn on DP_HIGH.
	A B application wants the bus and the bus is idle for 2 ms, and B_SESS_END becomes 1, then the B device can perform an SRP.	Go to B_SRP_INIT. Pulse CHRG_VBUS Pulse. DP_HIGH 5-10 ms.
B_SRP_INIT	One of the following occurs: • An ID interrupt[1] • The B device completes initiating SRP	Go to B_IDLE.
B_PERIPHERAL	HNP is enabled and the bus is suspended, and the B device wants the bus, B can become the host.	Go to B_WAIT_ACON. Turn off DP_HIGH.
B_WAIT_ACON	An A device connects, and an attach interrupt is received.	Go to B_HOST. Exit Host Mode.
	An ID interrupt[1] or B_SESS_VLD interrupt occurs. The cable changes or VBUS goes away, the host does not support it.	Go to B_IDLE.
	3.125 ms expires or a Resume occurs	Go to B_PERIPHERAL.
B_HOST	An ID interrupt[1] or B_SESS_VLD interrupt occurs. The cable changes or if VBUS goes away, then the host does not support it.	Go to B_IDLE.
	B application is done or the A device disconnects.	Go to B_PERIPHERAL.

1. An ID interrupt is triggered due to a detected change in the resistance between the local USB connector ID pin and ground.

61.7 Memory map and register definitions

This section provides the memory map and detailed descriptions of all USBFS interface registers.

NOTE

OTG Control (OTGCTL), Control (CTL), USB Control (USBCTRL), and USB OTG Control (CONTROL) have similar names but these are all separate registers.

61.7.1 USBFS memory mapping

In addition to the address space occupied by the USBFS registers, 512 bytes of embedded RAM are required for use in Keep Alive mode. On this chip the starting address of the USB RAM block is 4801_0000h.

You can use this USB RAM in Active power mode for BDT entries, USB data buffers, or other purposes.

61.7.2.6 OTG Interrupt Status (OTGISTAT)

Offset

Register	Offset
OTGISTAT	10h

Function

Records changes to the state of the 1-millisecond timer and line state stable logic.

You can read this register to determine the event that triggers an interrupt.

Only fields that have changed since the last read becomes 1.

Diagram

Bits	7	6	5	4	3	2	1	0
R	Reserved	ONEMSEC	LINE_ST...	0	Reserved	Reserved	0	Reserved
W	W1C	W1C	W1C		W1C	W1C		W1C

Fields

Field	Function
7 —	Reserved
6 ONEMSEC	One Millisecond Timer Timeout Flag Specifies the status of the 1 millisecond timer. This field becomes 1 when the 1 millisecond timer expires. To avoid losing 1 ms counts, service the interrupt every millisecond. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not timed out 1b - Timed out When writing 0b - No effect 1b - Clear the flag
5	Line State Change Interrupt Flag Detects Reset, Resume, Connect, and Data Line Pulse signaling.

Table continues on the next page...

Table continued from the previous page...

Field	Function
LINE_STATE_CHG	• This field becomes 1 when the USB line state (CTL [SE0] and CTL [JSTATE]) are stable without change for 1 ms, and the value of the line state varies from the last time when the line state was stable. • This field is 1 on transitions between CTL[SE0] and CTL[JSTATE], CTL[SE0] and K-state, and CTL[JSTATE] and K-state. Changes in CTL[JSTATE] when CTL[SE0] is true and do not cause an interrupt. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag

61.7.2.8 OTG Status (OTGSTAT)

Offset

Register	Offset
OTGSTAT	18h

Function

Displays the actual value from the 1 millisecond timer and line state stable logic.

Diagram

Bits	7	6	5	4	3	2	1	0
R	0	ONEMSEC	LINESTA...	0				
W								
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7 —	Reserved
6 ONEMSEC	Reserved for 1 ms count
5 LINESTATESTABLE	Line State Stable Indicates that the internal signals that control OTGISTAT[LINE_STATE_CHG] are stable for at least 1 ms. This field provides hardware debounce of the linestate in detecting connect, disconnect, and resume signaling. First read OTGISTAT[LINE_STATE_CHG] and then read this field. If OTGISTAT[LINE_STATE_CHG] reads as 1, you can consider the value of OTGISTAT[LINE_STATE_CHG] stable. 0b - Unstable 1b - Stable
4-0 —	Reserved

61.7.2.9 OTG Control (OTGCTL)

Offset

Register	Offset
OTGCTL	1Ch

Function

Controls the operation of data line termination resistors.

Diagram

Bits	7	6	5	4	3	2	1	0
R W	DPHIGH	Reserved	DPLOW	DMLOW	Reserved	OTGEN	Reserved	
Reset	0	0	0	0	0	0	0	0

6 —	Reserved
5 DPLOW	D+ Data Line pulldown Resistor Enable If you write 1 to this field, ensure that you also write 1 to OTGCTL[DMLOW]. 0b - Disable 1b - Enable
4 DMLOW	D– Data Line Pulldown Resistor Enable 0b - Disable 1b - Enable
3 —	Reserved
2 OTGEN	On-The-Go Pullup and Pulldown Resistor Enable Enables OTG pullup and pulldown resistor. 0b - If USBENSOFEN is 1 and HOSTMODEEN is 0 in the Control Register (CTL), then the D+ Data line pullup resistors are enabled. If HOSTMODEEN is 1, then the D+ and D– Data line pulldown resistors are engaged. 1b - Uses the pullup and pulldown controls in this register.
1-0 —	Reserved

61.7.2.10 Interrupt Status (ISTAT)

Offset

Register	Offset
ISTAT	80h

Function

Contains flag fields for each of the interrupt sources within USBFS. Each of these fields is qualified with their respective interrupt enable fields.

All fields of this register are logically OR'd together, along with OTG Status (OTGSTAT), to form a single interrupt source for the processor's interrupt controller.

Diagram

Bits	7	6	5	4	3	2	1	0
R	STALL	ATTACH	RESUME	SLEEP	TOKDNE	SOFTOK	ERROR	USBRST
W	W1C	W1C	W1C	W1C	W1C	W1C	W1C	W1C
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7 STALL	Stall Interrupt Flag In Device mode, becomes 1 when SIE sent a STALL handshake. In Host mode, USBFS changes this field to 1 when USBFS detects a STALL acknowledge during the handshake phase of a USB transaction. This interrupt can determine whether the last USB transaction was completed successfully or stalled. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
6 ATTACH	Attach Interrupt Flag Indicates when USBFS detects an attach of a USB device. This field is only meaningful if CTL[HOSTMODEEN] = 1. This field signifies that a peripheral is now present and must be configured. Asserts if no transitions occur on the USB for 2.5 µs and the current bus state is not CTL[SE0].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
5 RESUME	Resume Flag Indicates when a K-state is observed on the DP or DM signals for 2.5 µs. You must disable this interrupt when not in Suspend mode. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
4 SLEEP	Sleep Flag Indicates when USBFS detects a constant idle on the USB bus for 3 ms. Activity on the USB bus resets the sleep timer. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
3 TOKDNE	Current Token Processing Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates when the current token being processed has completed. The processor must immediately read Status (STAT) to determine the EndPoint and BD used for this token. Clearing this flag causes one of the following events: • STAT becomes 0. • USBFS loads the STAT holding register into Status (STAT). **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not processed 1b - Processed When writing 0b - No effect 1b - Clear the flag
2 SOFTOK	Start Of Frame (SOF) Token Flag Indicates when USBFS receives a SOF token. In Host mode, this field becomes 1 when either of the following events occur. After that, you can prepare for the next SOF. • The SOF threshold is reached (MISCCTRL[SOFBUSSET] = 0). • The SOF counter reaches 0 (MISCCTRL[SOFBUSSET] = 1). **NOTE** This field behaves differently for register reads and writes. When reading 0b - Did not receive 1b - Received When writing 0b - No effect 1b - Clear the flag
1 ERROR	Error Flag Indicates when any of the error conditions within Error Interrupt Status (ERRSTAT) occur. The processor must then read Error Interrupt Status (ERRSTAT) to determine the source of the error. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Error did not occur 1b - Error occurred When writing 0b - No effect 1b - Clear the flag
0 USBRST	USB Reset Flag Indicates when USBFS detects a valid USB reset. This informs the processor that it must write 00h into the address register and enable endpoint 0. This field becomes 1 after a USB reset is detected for 2.5 µs. This field does not become 1 again until the USB reset condition is removed and the USB reset condition is reasserted. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag

61.7.2.11 Interrupt Enable (INTEN)

Offset

Register	Offset
INTEN	84h

Function

Enables interrupt sources within USBFS. Writing 1 to any of these fields enables the respective interrupt source in Interrupt Status (ISTAT).

Diagram

Bits	7	6	5	4	3	2	1	0
R W	STALLEN	ATTACHEN	RESUMEEN	SLEEPEN	TOKDNEEN	SOFTOKEN	ERROREN	USBRSTEN
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7 STALLEN	STALL Interrupt Enable Enables the STALL interrupt. 0b - Disable 1b - Enable
6 ATTACHEN	ATTACH Interrupt Enable Enables the ATTACH interrupt. 0b - Disable 1b - Enable
5 RESUMEEN	RESUME Interrupt Enable Enables the RESUME interrupt. 0b - Disable 1b - Enable
4 SLEEPEN	SLEEP Interrupt Enable Enables the SLEEP interrupt. 0b - Disable 1b - Enable
3 TOKDNEEN	TOKDNE Interrupt Enable Enables the TOKDNE interrupt. 0b - Disable 1b - Enable
2 SOFTOKEN	SOFTOK Interrupt Enable Enables the SOFTOK interrupt. 0b - Disable 1b - Enable
1 ERROREN	ERROR Interrupt Enable Enables the ERROR interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
0 USBRSTEN	USBRST Interrupt Enable Enables the USBRST interrupt. 0b - Disable 1b - Enable

61.7.2.12 Error Interrupt Status (ERRSTAT)

Offset

Register	Offset
ERRSTAT	88h

Function

Enables interrupt error sources within USBFS. Each of these fields are qualified with their respective error enable fields.

All fields of this register are logically OR'ed together and the result placed in ISTAT[ERROR].

Each field becomes 1 as soon as you detect the error condition; therefore, the interrupt does not typically correspond with the end of a token being processed.

Diagram

Bits	7	6	5	4	3	2	1	0
R	BTSERR	OWNERR	DMAERR	BTOERR	DFN8	CRC16	CRC5EOF	PIDERR
W	W1C	W1C	W1C	W1C	W1C	W1C	W1C	W1C
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7 BTSERR	Bit Stuff Error Flag Indicates when a bit stuff error is detected. If this field is 1, then the corresponding packet is rejected due to the error. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Packet not rejected due to the error 1b - Packet rejected due to the error When writing 0b - No effect 1b - Clear the flag
6 OWNERR	BD Unavailable Error Flag Indicates when USBFS operates in Peripheral mode (CTL[HOSTMODEEN] = 0). This field becomes 1 if USBFS requires a new BD for SETUP, ISO IN, or ISO OUT transfer when a new BD is not available. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
5 DMAERR	DMA Access Error Flag Indicates if USBFS has requested a DMA access to read a new BDT, but has not been given the bus before it needs to receive or transmit data. • If processing a transit transfer, this causes a transmit data underflow condition. • If processing a receive transfer, this causes a receive data overflow condition. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
4 BTOERR	Bus Turnaround Timeout Error Flag Indicates when a bus turnaround timeout error occurs. USBFS contains a bus turnaround timer that keeps track of the amount of time elapsed between the token and data phases of a SETUP or OUT TOKEN or the data and handshake phases of a IN TOKEN. A bus turnaround timeout error occurs if more than 16 bit times are counted from the previous EOP before a transition from IDLE.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Not timed out 1b - Timed out When writing 0b - No effect 1b - Clear the flag
3 DFN8	Data Field Not 8 Bits Flag Indicates if the data field received was not 8 bits in length. USB Specification 1.0 requires that data fields be an integer number of bytes. If the data field is not an integer number of bytes, then this field becomes 1. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Integer number of bytes 1b - Not an integer number of bytes When writing 0b - No effect 1b - Clear the flag
2 CRC16	CRC16 Error Flag Indicates when a data packet is rejected due to a CRC16 error. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not rejected 1b - Rejected When writing 0b - No effect 1b - Clear the flag
1 CRC5EOF	CRC5 Error or End of Frame Error Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When USBFS operates in Peripheral mode (CTL[HOSTMODEEN] = 0), this interrupt detects CRC5 errors in the token packets generated by the host. If this field is 1, then the token packet is rejected because of a CRC5 error. When USBFS operates in Host mode (CTL[HOSTMODEEN] = 1), this interrupt detects End Of Frame (EOF) error conditions. This type of error occurs when USBFS transmits or receives data and the SOF counter reaches zero. This interrupt is useful when developing USB packet scheduling software to ensure that no USB transactions cross the start of the next frame. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
0 PIDERR	PID Error Flag Indicates when the PID check field fails. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Did not fail 1b - Failed When writing 0b - No effect 1b - Clear the flag

61.7.2.13 Error Interrupt Enable (ERREN)

Offset

Register	Offset
ERREN	8Ch

Function
Enables the error interrupt sources within USBFS.

Writing 1 to any of these fields enables the respective interrupt source in ERRSTAT.

Each field becomes 1 as soon as the error condition is detected; therefore, the interrupt does not typically correspond with the end of a token processed.

Diagram

Bits	7	6	5	4	3	2	1	0
R W	BTSERREN	OWNERREN	DMAERREN	BTOERREN	DFN8EN	CRC16EN	CRC5EOF...	PIDERREN
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7 BTSERREN	BTSERR (Bit Stuff Error) Interrupt Enable 0b - Disable 1b - Enable
6 OWNERREN	OWNERR Interrupt Enable This field is valid when USBFS operates in Peripheral mode (CTL[HOSTMODEEN] = 0). 0b - Disable 1b - Enable
5 DMAERREN	DMAERR Interrupt Enable 0b - Disable 1b - Enable
4 BTOERREN	BTOERR (Bus Timeout Error) Interrupt Enable 0b - Disable 1b - Enable
3 DFN8EN	DFN8 (Data Field Not Integer Number of Bytes) Interrupt Enable 0b - Disable 1b - Enable
2 CRC16EN	CRC16 Interrupt Enable 0b - Disable 1b - Enable
1 CRC5EOFEN	CRC5/EOF Interrupt Enable 0b - Disable 1b - Enable
0 PIDERREN	PIDERR Interrupt Enable 0b - Disable 1b - Enable

61.7.2.14 Status (STAT)

Offset

Register	Offset
STAT	90h

Function

Reports the transaction status within USBFS.

When the processor's interrupt controller receives ISTAT[TOKDNE], you must read Interrupt Status (ISTAT) to determine the status of the previous endpoint communication. The data in this register is valid when the TOKDNE interrupt is asserted. This register is a read window into a group FIFO that USBFS maintains. After USBFS uses a BD, it updates this register.

If you perform another USB transaction before servicing the TOKDNE interrupt, then USBFS stores the status of the next transaction in the STAT FIFO. Thus, STAT is a 4-byte FIFO that allows the processor core to process one transaction when the SIE processes the next transaction. Writing 0 to ISTAT[TOKDNE] causes the SIE to update this register with the contents of the next STAT value. If the data in the STAT holding register is valid, then the SIE immediately reasserts to TOKDNE interrupt.

Diagram

Bits	7	6	5	4	3	2	1	0
R	ENDP				TX	ODD	0	
W								
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7-4 ENDP	Endpoint address Encodes the endpoint address that receives or transmits the previous token. This allows the processor core to determine the BDT entry that the last USB transaction update.
3 TX	Transmit Indicator Indicates whether the most recent transaction was a receive or transmit operation. 0b - Receive 1b - Transmit
2 ODD	Odd Bank Indicates whether the last BD that you updated is in the odd bank of the BDT. 0b - Not in the odd bank 1b - In the odd bank
1-0 —	Reserved

61.7.2.15 Control (CTL)

Offset

Register	Offset
CTL	94h

Function
Provides various control and configuration information for USBFS.

Diagram

Bits	7	6	5	4	3	2	1	0
R	JSTATE	SE0	TXSUSPE...	RESET	HOSTMOD...	RESUME	ODDRST	USBENSO...
W								
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7 JSTATE	Live USB Differential Receiver JSTATE Signal Specifies that the current state of ADDR[LSEN] affects the polarity of this signal.
6 SE0	Live USB Single-Ended Zero signal
5 TXSUSPENDTOKENBUSY	TXD Suspend And Token Busy In Device mode, disables packet transmission and reception. SIE writes 1 to this field to disable this functionality. SIE does this when a SETUP token is received. This allows you to dequeue any pending packet transactions in the BDT before resuming token processing. Write 0 to this field to allow SIE to continue. In Host mode, USBFS writes 1 to this field when USBFS is busy executing a USB token. When this field is 1, you must not write more token commands to Token (TOKEN). Before writing any tokens to TOKEN, wait until this field becomes 0 to ensure that token commands are not lost.
4 RESET	Reset Signaling Enable Enables USBFS to generate USB reset signaling for resetting USB peripherals. This field is meaningful only in Host mode (CTL[HOSTMODEEN] = 1). You must write 1 to this field for the duration of reset signaling, then write 0 to this field to end reset signaling. 0b - Disable 1b - Enable
3 HOSTMODEEN	Host Mode Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - USBFS operates in Device mode. 1b - USBFS operates in Host mode. In Host mode, USBFS performs USB transactions under the programmed control of the host processor.
2 RESUME	Resume Enables USBFS to execute resume signaling when this field becomes 1. This allows USBFS to perform remote wake-up. You must write 1 to this field for the required time and then write 0 to this field. If CTL[HOSTMODEEN] becomes 1, USBFS appends a low-speed end-of-packet to the Resume signaling when this field becomes 0.
1 ODDRST	Odd Reset Resets all the BDT ODD ping/pong fields to 0 when you write 1 to this field, which specifies the EVEN BDT bank.
0 USBENSOFEN	USB Enable When Device mode is enabled, writing 1 to this field enables USBFS to operate. Writing 0 to this field disables USBFS. Writing 1 to this field causes the SIE to reset all of its STAT[ODD] to the BDTs and also resets most of the logic in the SIE. When Host mode is enabled, writing 0 to this field causes the SIE to stop sending SOF tokens. 0b - Disable 1b - Enable

61.7.2.16 Address (ADDR)

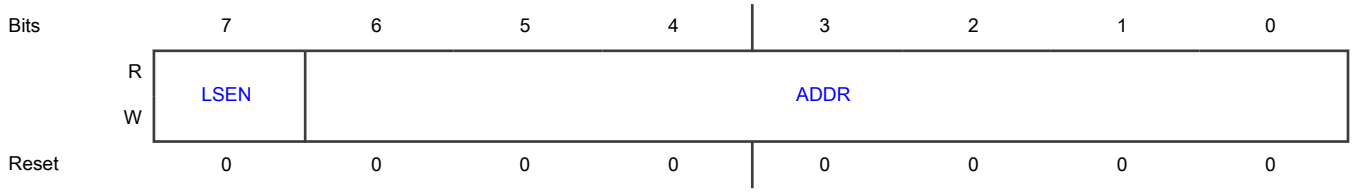
Offset

Register	Offset
ADDR	98h

Function

- In Peripheral mode (CTL[HOSTMODEEN] = 0), this register holds the unique USB address that USBFS decodes. In Host mode (CTL[HOSTMODEEN] = 1), USBFS transmits this USB address with a TOKEN packet. This enables USBFS to uniquely address any USB peripheral. In both Peripheral or Host mode: CTL[USBENSOFEN] must be 1.
- After the reset input becomes active or USBFS decodes a USB reset signal, this register resets to 00h. This action initializes this register to decode address 00h, as required by the USB specification.

Diagram



Fields

Field	Function
7 LSEN	Low Speed Enable Informs USBFS that you must perform the next token command written to Token (TOKEN) at low-speed. This enables USBFS to perform the preamble required for low-speed data transmissions.
6-0 ADDR	USB Address Defines the USB address that USBFS decodes in Peripheral mode, or that USBFS transmits when in Host mode.

61.7.2.17 BDT Page 1 (BDTPAGE1)

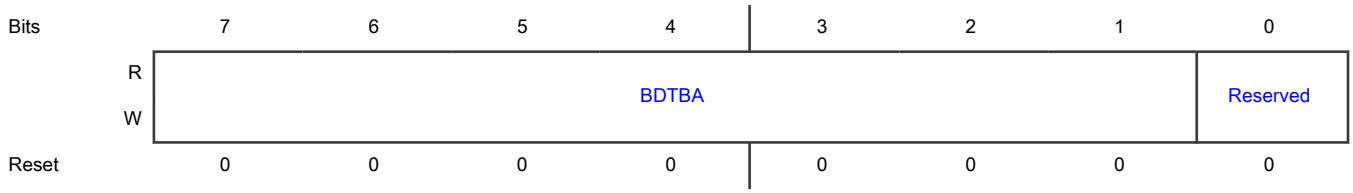
Offset

Register	Offset
BDTPAGE1	9Ch

Function

Provides address bits 15 through 9 of the base address where the current BDT resides in system memory. See Buffer descriptor table (BDT) for more information. The 32-bit BDT base address is always aligned on 512-byte boundaries, so bits 8 through 0 of the base address are always zero.

Diagram



Fields

Field	Function
7-1 BDTBA	BDT Base Address Provides address bits 15 through 9 of the BDT base address.

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 —	Reserved

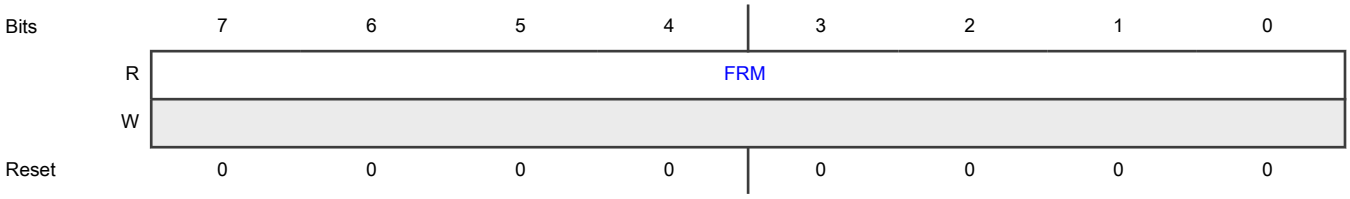
61.7.2.18 Frame Number Register Low (FRMNUML)

Offset

Register	Offset
FRMNUML	A0h

Function
Works with Frame Number Register High (FRMNUMH) to indicate the 11-bit frame number that determines the address of the BDT in system memory. When you receive ISTAT[SOFTOK], update these registers with the current frame number.

Diagram



Fields

Field	Function
7-0 FRM	Frame Number, Bits 0-7

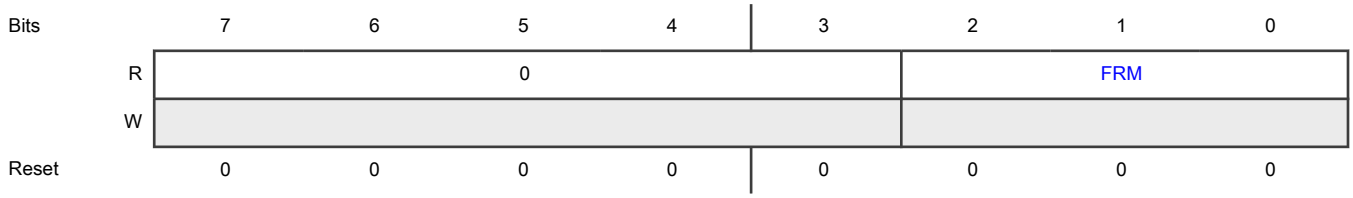
61.7.2.19 Frame Number Register High (FRMNUMH)

Offset

Register	Offset
FRMNUMH	A4h

Function
Works with Frame Number Register Low (FRMNUML) to indicate the 11-bit frame number that determines the address of the BDT in system memory. These registers are updated with the current frame number when you receive ISTAT[SOFTOK].

Diagram



Fields

Field	Function
7-3 —	Reserved
2-0 FRM	Frame Number, Bits 8-10

61.7.2.20 Token (TOKEN)

Offset

Register	Offset
TOKEN	A8h

Function

Initiates USB transactions when in Host mode (CTL[HOSTMODEEN] = 1).

When you execute a USB transaction to a peripheral, it writes the TOKEN type and endpoint to Token (TOKEN). After you wrote to Token (TOKEN), USBFS begins the specified USB transaction to the address contained in the address register.

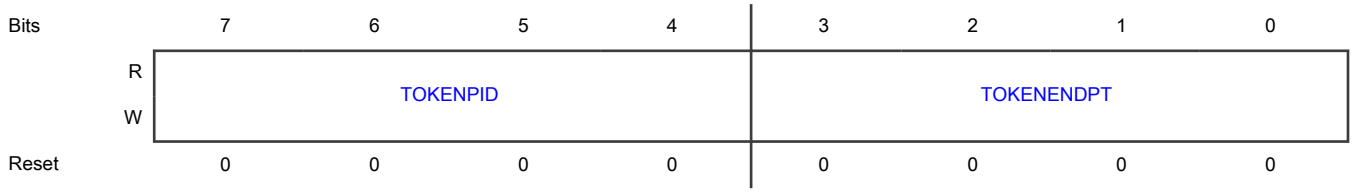
Before writing to Token (TOKEN), the processor core must always check that the TOKEN_BUSY in the control register is not 1. This ensures that the token commands are not overwritten before you can execute them.

Use Address (ADDR) and Endpoint Control (ENDPT0 - ENDPT15) when performing a token command and must write before Token (TOKEN).

Address (ADDR) selects the USB peripheral address, which the token command transmits.

Endpoint Control (ENDPT0 - ENDPT15) determines the handshake and retries policies used during the transfer.

Diagram



Fields

Field	Function
7-4 TOKENPID	Token Type Specifies the token type that USBFS executes. 0001b - OUT token. USBFS performs an OUT (TX) transaction. 1001b - IN token. USBFS performs an IN (RX) transaction. 1101b - SETUP token. USBFS performs a SETUP (TX) transaction
3-0 TOKENENDPT	Token Endpoint Address Specifies the endpoint address for the token command. The 4-bit value written must be a valid endpoint.

61.7.2.21 SOF Threshold (SOFTHLD)

Offset

Register	Offset
SOFTHLD	ACh

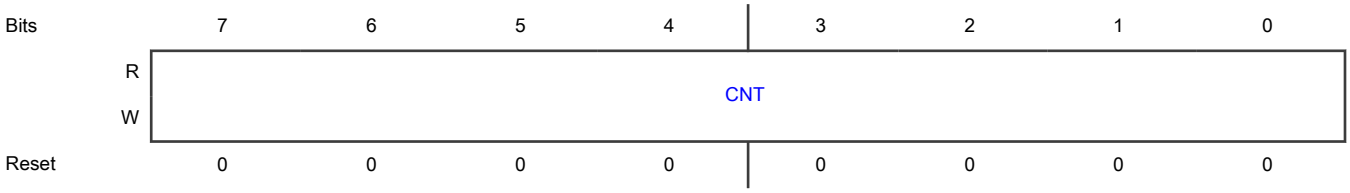
Function

This register is used only in Host mode (CTL[HOSTMODEEN] = 1). The 14-bit SOF counter counts the interval between SOF frames when in Host mode. You must transmit the SOF every 1 ms, so load the SOF counter with a value of 12000. When the SOF counter reaches zero, a SOF token is transmitted. This register programs the number of USB byte times when MISCCTRL[SOFDYNTHLD] = 0 (or 8-byte times when MISCCTRL[SOFDYNTHLD] = 1), before the SOF stops initiating token packet transactions.

Write a value to SOFTHLD[CNT] that ensures that other packets are not actively transmitted when the SOF time counts to zero. After the SOF counter reaches the threshold value, no more tokens are transmitted until after the SOF has been transmitted. The value programmed into the threshold register must reserve enough time to ensure that the worst-case transaction finishes. In general, the worst-case transaction is an IN token, followed by a data packet from the peripheral device and the host's response. The actual time required is a function of the maximum packet size on the bus. Typical values for the SOF threshold are:

- 74 for 64-byte packets
- 42 for 32-byte packets
- 26 for 16-byte packets
- 18 for 8-byte packets

Diagram



Fields

Field	Function
7-0 CNT	SOF Count Threshold Represents the SOF count threshold in byte times when MISCCTRL[SOFDYNTHLD] = 0, or 8-byte times when MISCCTRL[SOFDYNTHLD] = 1.

61.7.2.22 BDT Page 2 (BDTPAGE2)

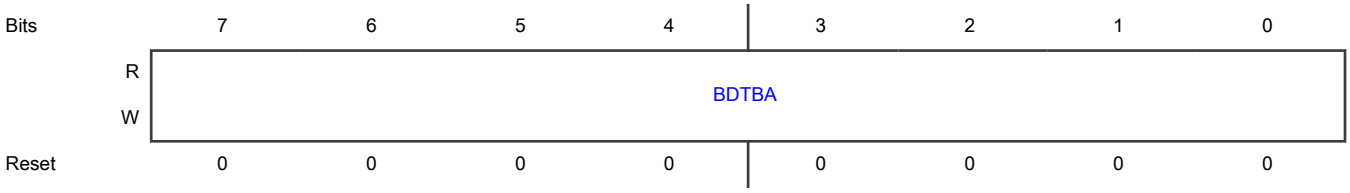
Offset

Register	Offset
BDTPAGE2	B0h

Function

Works with BDT Page 3 (BDTPAGE3) to specify address where the current BDT resides in system memory. See Buffer descriptor table (BDT) for more information.

Diagram



Fields

Field	Function
7-0 BDTBA	BDT Base Address Provides address bits 23 through 16 of the BDT base address in system memory.

61.7.2.23 BDT Page 3 (BDTPAGE3)

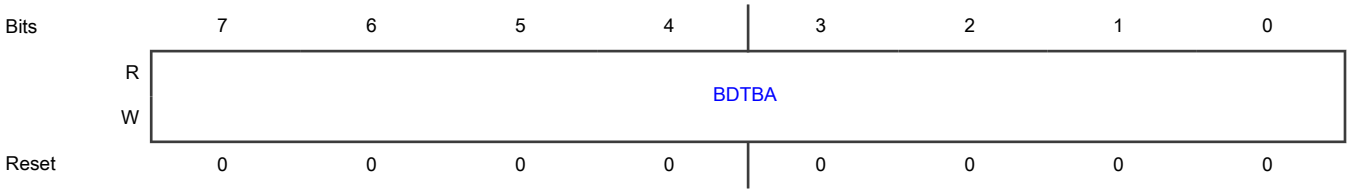
Offset

Register	Offset
BDTPAGE3	B4h

Function

Works with BDT Page 2 (BDTPAGE2) to specify the address where the current BDT resides in system memory. See Buffer descriptor table (BDT) for more information.

Diagram



Fields

Field	Function
7-0 BDTBA	BDT Base Address Provides address bits 31 through 24 of the BDT base address in system memory.

61.7.2.24 Endpoint Control (ENDPT0 - ENDPT15)

Offset

For a = 0 to 15:

Register	Offset
ENDPTa	C0h + (a × 4h)

Function

Contains the endpoint control fields for each of the 16 endpoints available within USBFS for a decoded address. The format for these registers is shown in the following figure.

- Endpoint 0 (ENDPT0) is associated with control pipe 0, which is required for all USB functions. Therefore, after a USBRST interrupt occurs, the processor core must write 1 to ENDPT0 to contain 0Dh. In Host mode, ENDPT0 determines the handshake, retry, and low-speed characteristics of the host transfer. For ENDPT0 in Host mode, common values are 4Dh for control, bulk, and interrupt transfers and 4Ch for isochronous transfers.
- For control, bulk, and interrupt transfers, ENDPTn[EPHSHK] = 1. For isochronous transfers, ENDPTn[EPHSHK] = 0.
- ENDPTn[EPCTLDIS], ENDPTn[EPRXEN], and ENDPTn[EPTXEN] define if an endpoint is enabled and the endpoint's direction. The endpoint enables and direction control is defined in the following table.

Table 485. Endpoint enable and direction control

EPCTLDIS	EPRXEN	EPTXEN	Endpoint enable and direction control
X	0	0	Disable endpoint
X	0	1	Enable endpoint for transit transfers only
X	1	0	Enable endpoint for receive transfers only
1	1	1	Enable endpoint for receive and transit transfers
0	1	1	Enable endpoint for receive and transit as well as control (SETUP) transfers.

Diagram

Bits	7	6	5	4	3	2	1	0
R	HOSTWOH...	RETRYDIS	0	EPCTLDIS	EPRXEN	EPTXEN	EPSTALL	EPHSHK
W								
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7 HOSTWOHUB	Host Without A Hub Specifies whether a low-speed device connects to the host using a hub. This field: • Is meaningful only in Host mode. • Exists only in endpoint 0, and is reserved and read-only for all other ENDPT*n* registers. 0b - Connected using a hub (USBFS generates PRE_PID as required) 1b - Connected directly to host without a hub, or was used to attach
6 RETRYDIS	Retry Disable Specifies whether the host retries the NAK'ed transactions. This field: • Is meaningful only in Host mode. • Exists in only in ENDPT0, and is reserved and read-only for all other ENDPTn registers. When the host attempts to poll an interrupt endpoint, this field must be 1. 0b - Retried NAK'ed transactions in hardware. 1b - Do not retry NAK'ed transactions. When a transaction is NAK'ed, the BDT PID field is updated with the NAK PID, and the TOKEN_DNE interrupt becomes 1.
5 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 EPCTLDIS	Control Transfer Disable Disables control (SETUP) transfers. When this field is 0, control transfers are enabled only if ENDPTn[EPRXEN] and ENDPTn[EPTXEN] are both 1. See Table 485. 0b - Enable 1b - Disable
3 EPRXEN	Endpoint for RX transfers enable Enables the endpoint for RX transfers. See Table 485.
2 EPTXEN	Endpoint for TX transfers enable Enables the endpoint for TX transfers. See Table 485.
1 EPSTALL	Endpoint Stalled Indicates that the endpoint is stalled. • This field has priority over all other control fields in this register, but this field is only valid if ENDPTn[EPTXEN] = 1 or ENDPTn[EPRXEN] = 1. • Any access to this endpoint causes USBFS to return a STALL handshake. • After an endpoint is stalled, the host controller must intervene.
0 EPHSHK	Endpoint Handshaking Enable Enables an endpoint to perform handshaking during a transaction to this endpoint when this field becomes 1. This field is generally 1 unless the endpoint is isochronous.

61.7.2.25 USB Control (USBCTRL)

Offset

Register	Offset
USBCTRL	100h

Function

Configures:

- The USB FS transceiver
- LPUART over USB pin mode
- DP and DM lane reversal

Diagram

Bits	7	6	5	4	3	2	1	0
R	SUSP	PDE	UARTCHLS	UARTSEL	HOST_LS...	DPDM_LA...	0	
W								
Reset	1	1	0	0	0	0	0	0

Fields

Field	Function
7 SUSP	Suspend Places the USB transceiver into Suspend state. 0b - Not in Suspend state 1b - In Suspend state
6 PDE	Pulldown Enable Enables the weak pulldowns on the USB transceiver. 0b - Disable on D+ and D– 1b - Enable on D+ and D–
5 UARTCHLS	UART Signal Channel Select Selects the UART signal channel. This field is valid only when you select to use USB signals as UART signals. 0b - USB DP and DM signals are used as UART TX/RX. 1b - USB DP and DM signals are used as UART RX/TX.
4 UARTSEL	UART Select Selects USB external package pins to be used as UART signals. You must not change this field when USB data communication is active. 0b - USB DP and DM external package pins are used for USB signaling. 1b - USB DP and DM external package pins are used for UART signaling.
3 HOST_LS_EOP	Host-Mode-Only Low-Speed Device EOP Signaling Specifies whether the host drives resume End of Packet (EOP) signaling for a full-speed device or a directly-connected low-speed device. Host mode resumes the EOP signaling setting for a low-speed device. Use this field only during Host mode. 0b - Full-speed device or a low-speed device through a hub 1b - Directly-connected low-speed device
2 DPDM_LANE_REVERSE	DP and DM Lane Reversal Control Specifies an external USB DP and DM package pin assignment configuration for your flexibility in board design.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	You must not change this field when USB data communication is active. 0b - Standard USB DP and DM package pin assignment 1b - Reverse roles of USB DP and DM package pins
1-0 —	Reserved

61.7.2.26 USB OTG Observe (OBSERVE)

Offset

Register	Offset
OBSERVE	104h

Function

Indicates the state of the pullups and pulldowns at the transceiver, which is useful when interfacing with an external OTG control module via a serial interface.

Diagram

Bits	7	6	5	4	3	2	1	0
R	DPPU	DPPD	0	DMPD	0			
W								
Reset	0	1	0	1	0	0	0	0

Fields

Field	Function
7 DPPU	D+ Pullup Indicates the state of the D+ pullup enable at the USB transceiver. 0b - Disabled 1b - Enabled
6 DPPD	D+ Pulldown Indicates the state of the D+ pulldown enable at the USB transceiver. 0b - Disabled 1b - Enabled
5	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
4 DMPD	D- Pulldown Indicates the state of the D- pulldown enable at the USB transceiver. 0b - Disabled 1b - Enabled
3-0 —	Reserved

61.7.2.27 USB OTG Control (CONTROL)

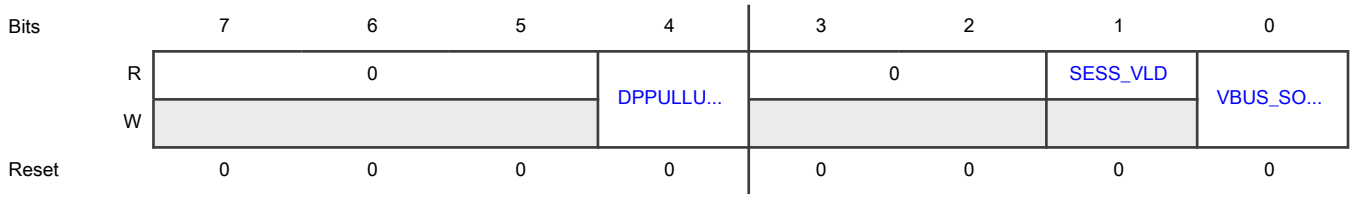
Offset

Register	Offset
CONTROL	108h

Function

Controls VBUS monitoring and the Device-mode DP pullup in the USBFS transceiver.

Diagram



Fields

Field	Function
7-5 —	Reserved
4 DPPULLUPNONOTG	DP Pullup in Non-OTG Device Mode Provides control of the DP pullup in USB OTG, if you configure USB in a non-OTG device mode. 0b - Disable 1b - Enabled
3-2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1 SESS_VLD	VBUS Session Valid status Indicates whether the VBUS monitoring method reports that VBUS is above or below the session-valid threshold. CONTROL[VBUS_SOURCE_SEL] specifies which of the following options USBFS uses to monitor the VBUS voltage: • The input to the 3.3-5 V USB regulator • A resistive divider between VBUS and the ground connected to a GPIO pin 0b - Below 1b - Above
0 VBUS_SOURCE_SEL	VBUS Monitoring Source Select Specifies the source of the VBUS monitoring signal. This source determines the value of CONTROL[SESS_VLD]. 0b - Reserved 1b - Resistive divider attached to a GPIO pin

61.7.2.28 USB Transceiver Control 0 (USBTRC0)

Offset

Register	Offset
USBTRC0	10Ch

Function

Controls the following operational aspects that the USB Full-Speed Controller registers do not provide:

- Basic operation of the on-chip USB full-speed transceiver
- USB data connection

Diagram

Bits	7	6	5	4	3	2	1	0
R		VREGIN_...	USBRESM...	VFEDG_D...	VREDG_D...	USB_CLK...	SYNC_DET	USB_RES...
W	USBRESET							
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7 USBRESET	USB Reset Generates a hard reset to USB OTG. After this field becomes 1 and the reset occurs, this field becomes 0 automatically. **NOTE** **This field always reads 0. After writing 1 to this field, wait for 2 USB clock cycles before accessing other USB register fields.** 0b - Normal USBFS operation 1b - Returns USBFS to its reset state
6 VREGIN_STS	VREGIN Status Indicates the VREGIN status.
5 USBRESMEN	Asynchronous Resume Interrupt Enable Enables the USB asynchronous wake-up from Suspend mode. When this field becomes 1, after detection of resume signaling on the USB bus, it allows USBFS to send an asynchronous wake-up event to the MCU. The MCU then re-enables clocks to USBFS. This is used for low-power Suspend mode when USB module clocks are stopped or when the USB transceiver is in Suspend mode. Async wake-up only works in Device mode. • The asynchronous resume interrupt differs from the synchronous resume interrupt in that it asynchronously detects K-state using the unfiltered state of the D+ and D– pins. • You must only enable the asynchronous resume interrupt after you suspend the transceiver. 0b - Disable 1b - Enable
4 VFEDG_DET	VREGIN Falling Edge Interrupt Detect Detects the VREGIN falling edge interrupt. To enable this field, use USB *x* _MISCCTRL[VFEDG_EN]. 0b - Not detected 1b - Detected
3 VREDG_DET	VREGIN Rising Edge Interrupt Detect Detects the VREGIN rising edge interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	To enable this field, use USB *x* _MISCCTRL[VREDG_EN]. 0b - Not detected 1b - Detected
2 USB_CLK_RECOVERY_INT	Combined USB Clock Recovery interrupt status The read-only USB_CLK_RECOVERY_INT field will be set to 1'b1 when any of USB clock recovery interrupt conditions are detected and those interrupts are unmasked. • The only unmasked USB clock recovery interrupt condition results from an overflow of the frequency trim setting values, indicating that the frequency trim calculated is out of the adjustment range of the FIRC output clock. • To clear USB_CLK_RECOVERY_INT bit after it has been set, write 0xFF to register USB_CLK_RECOVER_INT_STATUS.
1 SYNC_DET	Synchronous USB Interrupt Detect Detects the synchronous USB interrupt. 0b - Not detected 1b - Detected
0 USB_RESUME_INT	USB Asynchronous Interrupt Indicates whether the interrupt is generated. 0b - Not generated 1b - Generated because of the USB asynchronous interrupt

61.7.2.29 Frame Adjust (USBFRMADJUST)

Offset

Register	Offset
USBFRMADJUST	114h

Function

Allows adjustment of frame counting interval for the Host mode operation.

Diagram

Bits	7	6	5	4	3	2	1	0
R	ADJ							
W								
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7-0 ADJ	Frame Adjustment Specifies that in Host mode, the frame adjustment is a two's complement number that adjusts the period of each USB frame in 12 MHz clock periods. A SOF is normally generated every 12,000 cycles of a 12 MHz clock. Frame Adjust (USBFRMADJUST) can adjust this by -128 to +127, to compensate for inaccuracies in the USB 48 MHz clock. Changes to this field take effect at the start of the next frame.

61.7.2.30 Keep Alive Mode Control (KEEP_ALIVE_CTRL)

Offset

Register	Offset
KEEP_ALIVE_CTRL	124h

Function

Configures and monitors the keep-alive feature for low-power Device mode applications.

Diagram

Bits	7	6	5	4	3	2	1	0
R	WAKE_IN...	KEEP_AL...	0	WAKE_IN...	WAKE_RE...	STOP_AC...	OWN_OVE...	KEEP_AL...
W	W1C							
Reset	0	0	0	0	1	0	0	0

Fields

Field	Function
7 WAKE_INT_STS	Wakeup Interrupt Status Flag Becomes 1 if KEEP_ALIVE mode is enabled and you receive a SETUP token or software assigned token only after the token is processed and the USB state is IDLE. **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
6 KEEP_ALIVE_STS	Keep Alive Status Indicates if USB is in Keep Alive mode. 0b - Not in Keep Alive mode 1b - In Keep Alive mode
5 —	Reserved
4 WAKE_INT_EN	Wakeup Interrupt Enable Enables KEEP_ALIVE_CTRL[WAKE_INT_STS] when you write 1 to this field.
3 WAKE_REQ_EN	Wakeup Request Enable Enables the USB bus wakeup request. During KEEP_ALIVE mode, bus access by the USB controller to a memory location outside the USB SRAM causes the bus access to stall until KEEP_ALIVE mode exits. When this field becomes 1, bus access by the USB controller to a memory location outside the USB SRAM generates a wakeup, allowing the bus access to complete. After the bus access finishes, the USB reenters the KEEP_ALIVE mode if no other wakeups are detected. **NOTE** An interrupt is not generated as a result of the wakeup request. 0b - Disable 1b - Enable
2 STOP_ACK_DLY_EN	Stop Acknowledge Delay Enable Has multiple functions: • When this field becomes 1, then the module responds to the ipg_stop when the USB core state is idle and there is no AHB transfer. • When this becomes 0, then the module responds to the ipg_stop when there is no AHB transfer. 0b - Enter KEEP_ALIVE mode immediately when there is no USB AHB transfer. 1b - Enter KEEP_ALIVE mode until the USB core is idle and there is no USB AHB transfer.
1	OWN Bit Override Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
OWN_OVERRD_EN	Enables OWN field override. During KEEP_ALIVE mode, when this field becomes 1, and if the received token is not SETUP, the OWN field of current BD is forced to 0, so the USB core responds with NAK.
0 KEEP_ALIVE_EN	Keep Alive Mode Enable Enables USB_KEEP_ALIVE mode. 0b - Everything remains same as before. 1b - USB shall enter USB_KEEP_ALIVE mode after asserting ipg_stop.

61.7.2.31 Keep Alive Mode Wakeup Control (KEEP_ALIVE_WKCTRL)

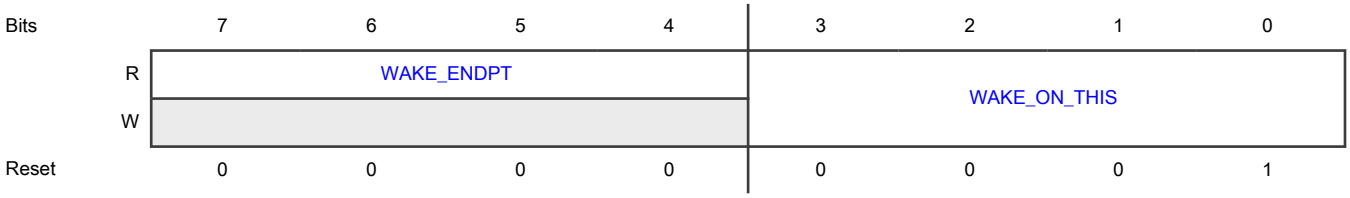
Offset

Register	Offset
KEEP_ALIVE_WKCTRL	128h

Function

Provides additional configuration and status fields for Keep Alive mode.

Diagram



Fields

Field	Function
7-4 WAKE_ENDPT	Endpoint address for the wakeup request Indicates which endpoint causes the wakeup interrupt.
3-0 WAKE_ON_THIS	Token PID for the wakeup request Specifies which token can wakeup USB during KEEP_ALIVE mode. 0001b - Wake up after receiving OUT or SETUP token packet. 1101b - Wake up after receiving SETUP token packet. All other values are reserved.

61.7.2.32 Miscellaneous Control (MISCCTRL)

Offset

Register	Offset
MISCCTRL	12Ch

Function

Provides additional controls for the USBFS subsystem.

Diagram

Bits	7	6	5	4	3	2	1	0
R	STL_ADJ...	Reserved		VFEDG_EN	VREDG_EN	OWNERRI...	SOFBUSS...	SOFDYNT...
W								
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7 STL_ADJ_EN	USB Peripheral Mode Stall Adjust Enable Specifies that this field is valid only in Peripheral mode (CTL[HOSTMODEEN] = 0). By default (STL_ADJ_EN = 0), when you stall an endpoint (ENDPTn[END_STALL] = 1), both IN and OUT directions of the endpoint are stalled. If this field is 1, then when an endpoint is stalled (ENDPTn[END_STALL] = 1), then the USBx_STALL_xx_DIS registers can control which endpoint direction(s) are affected. 0b - If ENDPTn[END_STALL] = 1, both IN and OUT directions for the associated endpoint stalls. 1b - If ENDPTn[END_STALL] = 1, the STALL_xx_DIS registers control which directions for the associated endpoint stalls.
6-5 —	Reserved
4 VFEDG_EN	VREGIN Falling Edge Interrupt Enable Enables VREGIN falling edge interrupt. 0b - Disable 1b - Enable
3 VREDG_EN	VREGIN Rising Edge Interrupt Enable Enables VREGIN rising edge interrupt. 0b - Disable 1b - Enable
2	OWN Error Detect for ISO IN and ISO OUT Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
OWNERRISODIS	Disables OWN error detect for ISO IN, and ISO out. This field is only valid for Peripheral mode (CTL[HOSTMODEEN] = 0). 0b - Enable 1b - Disable
1 SOFBUSSET	SOF_TOK Interrupt Generation Mode Select Specifies the behavior that causes the SOF_TOK interrupt to become 1. This field is meaningful only in Host mode (CTL[HOSTMODEEN] = 1). 0b - According to the SOF threshold value 1b - When the SOF counter reaches 0
0 SOFDYNTHLD	Dynamic SOF Threshold Compare mode Specifies the behavior that causes the SOF_TOK interrupt to become 1. This field is meaningful only in Host mode (CTL[HOSTMODEEN] = 1). 0b - When the byte-times SOF threshold is reached 1b - When 8 byte-times SOF threshold is reached or overstepped

61.7.2.33 Peripheral Mode Stall Disable for Endpoints 7 to 0 in IN Direction (STALL_IL_DIS)

Offset

Register	Offset
STALL_IL_DIS	130h

Function

Meaningful only in Peripheral mode (CTL[HOSTMODEEN] = 0) and when MISCCTRL[STL_ADJ_EN] = 1.

When you stall an endpoint (ENDPTn[END_STALL] = 1), the fields in this register enable or disable stalling of the IN direction of the endpoints 7 to 0.

Diagram

Bits	7	6	5	4	3	2	1	0

61.7.2.37 USB Clock Recovery Control (CLK_RECOVER_CTRL)

Offset

Register	Offset
CLK_RECOVER_CTRL	140h

Function

Controls the crystal-less USB clock mode in which the internal FIRC oscillator is tuned to match the clock extracted from the incoming USB data stream.

You must configure the FIRC internal oscillator module in the SCG module and enable SOF frequency tuning in this register and FIRC Oscillator Enable (CLK_RECOVER_IRC_EN) for this mode.

Diagram

Bits	7	6	5	4	3	2	1	0
R	CLOCK_R...	RESET_R...	RESTART...	0	TRIM_IN...	Reserved	Reserved	Reserved
W								
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7 CLOCK_RECOVER_EN	Crystal-Less USB Enable Enables the frequency trimming logic for the FIRC module to generate clocks for crystal-less FS USB Device mode operation. You must initialize the FIRCCSR[FIRCEN] and FIRCTCFG[TRIMSRC] to enable the FIRC module itself. Then this field and CLK_RECOVER_IRC_EN[IRC_EN] must become 1 before using the crystal-less USB clock configuration. **NOTE** **You must not write 1 to this field for USB Host mode or OTG operation.** 0b - Disable 1b - Enable
6 RESET_RESUME_ROUGH_EN	Reset or Resume to Rough Phase Enable Indicates that the clock recovery block tracks the FIRC to get an accurate 48 MHz clock. It has 2 phases after you enable CLK_RECOVER_CTRL[CLOCK_RECOVER_EN], rough phase and tracking phase. The step to fine-tune the FIRC by adjusting the trim fine value differs during these 2 phases. The rough step-in phase is larger than that in the tracking phase. Switch back to the rough stage whenever a USB bus reset or bus resume occurs. 0b - Always works in tracking phase after the first time rough phase, to track transition. 1b - Go back to rough stage whenever a bus reset or bus resume occurs.
5	Restart from IFR Trim Value

Table continues on the next page...

Table continued from the previous page...

Field	Function
RESTART_IFR TRIM_EN	FIRC has a default trim fine value whose default value is factory trimmed (the IFR trim value). The clock recover block tracks the clock's accuracy at 48 MHz and keeps updating the trim fine value accordingly. 0b - Trim fine adjustment always works based on the previous updated trim fine value. 1b - Trim fine restarts from the IFR trim value whenever you detect bus_reset or bus_resume or deassert module enable.
4 —	Reserved
3 TRIM_INIT_VAL _SEL	Selects the source for the initial FIRC trim fine value used after a reset. 0b - Mid-scale 1b - IFR
2 —	Reserved Do not modify the value of this field.
1 —	Reserved
0 —	Reserved

61.7.2.38 FIRC Oscillator Enable (CLK_RECOVER_IRC_EN)

Offset

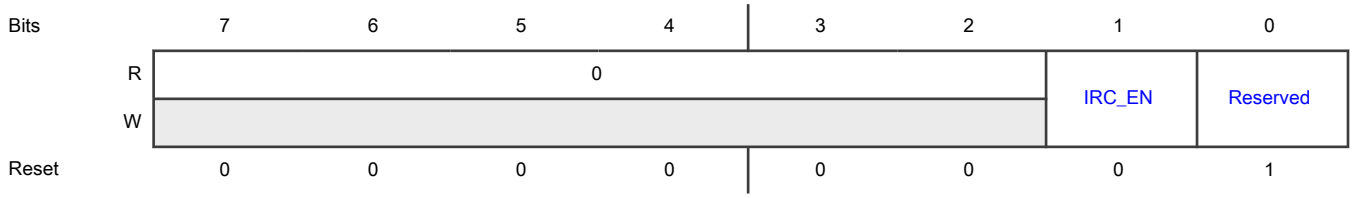
Register	Offset
CLK_RECOVER_IRC_E N	144h

Function

Controls the USB-specific frequency trimming behavior for the on-chip FIRC module used to produce nominal 48 MHz clocks for USB crystal-less operation and other functions.

See the FIRC operation in the "Clock Distribution" section in the SCG chapter for more information.

Diagram



Fields

Field	Function
7-2 —	Reserved
1 IRC_EN	Fast IRC enable Configures the frequency trimming logic for the FIRC module to generate clocks for crystal-less FS USB Device mode operation. You must initialize FIRCCSR[FIRCEN] and FIRCTCFG[TRIMSRC] for the SCG module to enable the FIRC module itself. Then this field and CLK_RECOVER_CTRL[CLOCK_RECOVER_EN] must become 1 before using the crystal-less USB clock configuration. 0b - Disable 1b - Enable
0 —	Reserved

61.7.2.39 Clock Recovery Combined Interrupt Enable (CLK_RECOVER_INT_EN)

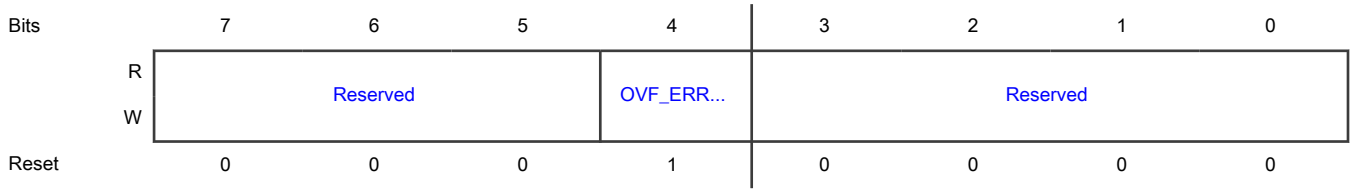
Offset

Register	Offset
CLK_RECOVER_INT_EN	154h

Function

Enables or masks the individual interrupt flags, which are logically OR'ed together, to produce the combined interrupt indication at USBTRC0[USB_CLK_RECOVERY_INT] if you detect the indicated conditions in the USB clock recovery algorithm operation.

Diagram



Fields

Field	Function
7-5 —	Reserved
4 OVF_ERROR_EN	Overflow error interrupt enable Determines whether the OVF_ERROR condition signal is used in generation of USB_CLK_RECOVERY_INT. 0b - The interrupt is masked 1b - The interrupt is enabled
3-0 —	Reserved

61.7.2.40 Clock Recovery Separated Interrupt Status (CLK_RECOVER_INT_STATUS)

Offset

Register	Offset
CLK_RECOVER_INT_STATUS	15Ch

Function

Contains flags for clock-recovery interrupts.

Diagram

Bits	7	6	5	4	3	2	1	0
R	Reserved			OVF_ERR...	Reserved			
W	W1C			W1C	W1C			
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7-5 —	Reserved
4 OVF_ERROR	Overflow Error Interrupt Status Flag Indicates that the USB clock recovery algorithm detects that the frequency trim adjustment needed for the FIRC output clock is outside the available TRIM_FINE adjustment range for FIRC. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Unmasked interrupt occurred When writing 0b - No effect 1b - Clear the flag

Universal Serial Bus 2.0 High-Speed Integrated PHY (USBHS_PHY)

62.1 Chip-specific USBHS_PHY information

Table 486. Reference links to related information

Topic	Related module	Reference
Full description	USBHS_PHY	USBHS_PHY
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

NOTE

See AHB Clock Control 2 (AHBCLKCTRL2) to enable USBHS_PHY clock. Also see Peripheral Reset Control 2 (PRESETCTRL2) for reset control.

62.1.1 Module instances

This device has one instance of USBHS_PHY module.

62.1.2 USBHS_PHY operation modes

USBHS_PHY is functional only in SD and OD modes. It is non-functional in MD mode. Configure SPC.ACTIVE_CFG[DCDC_VDD_LVL] = SPC.ACTIVE_CFG[CORELDO_VDD_LVL] >= 0x2 for correct operation of the module.

62.2 Overview

This chip contains a USBPHY macrocell capable of operating in either:

- Device mode: In this mode, the USB physical layer can connect to USB host systems at the USB high-speed (HS) rate of 480 Mbit/s or full-speed (FS) rate of 12 Mbit/s.
- Host mode: In this mode, USBPHY can connect to peripheral devices operating at HS, FS, or the USB 2.0 low-speed (LS) rate of 1.5 Mbit/s.

USBPHY communicates with the USB HS controller using a standard UTMI+ interface. The module includes the following for configuration and status reporting:

- 480 MHz PLL
- UTMI digital logic and state machines
- Analog transceiver circuits
- IPS bus interface

The USB_DP and USB_DM pins connect directly to a USB connector.

See the "USB Device Charger Detection module (USBDCD)" chapter for the digital and analog portions that USBPHY contains and the module functions it performs. USBPHY also supports features for detection and signaling described in *USB Battery Charging Specification, Revision 1.2*. Also see descriptions for Charger Detect (USB1_CHRG_DETECT) and Charger Detect Status (USB1_CHRG_DET_STAT) for a better insight into USBPHY's charger detection functions.

62.2.1 Block diagram

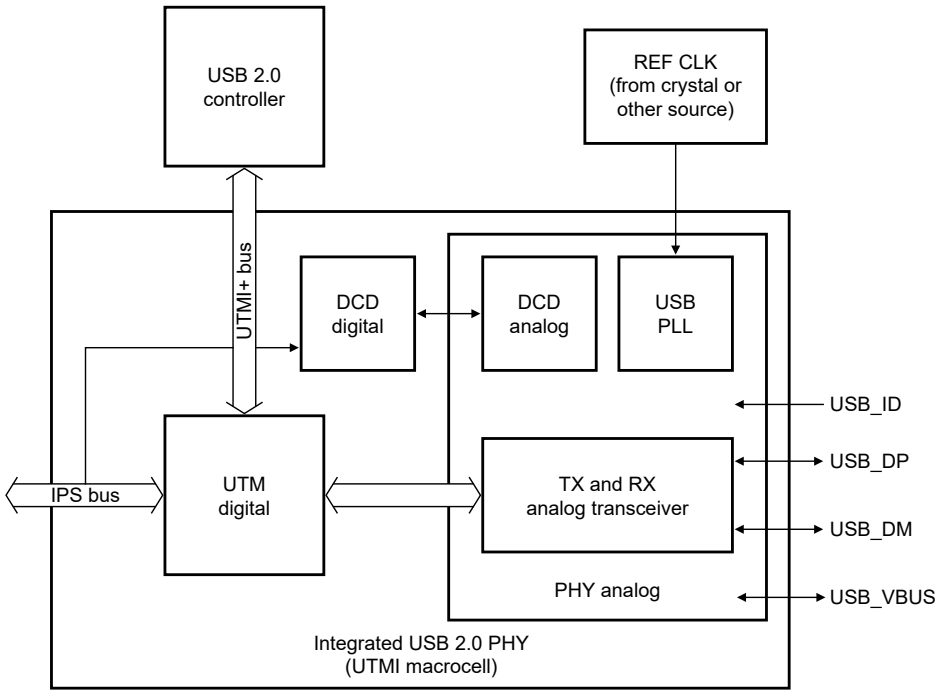

Figure 338. Block diagram

62.2.2 Features

- Supports HS and FS in Device mode
- Supports HS, FS, and LS in Host mode
- Complies with the UTMI+ standard with a 16-bit data interface to the USB controller
- Provides an integrated 480 MHz PLL
- Supports USBDCD with features for detection and signaling described in *USB Battery Charging Specification, Revision 1.2*
- Supports a programmable phase fractional divider (PFD) output clock

62.3 Functional description

62.3.1 Operation

UTMI provides a 16-bit interface to the USB controller. This interface is clocked at 30 MHz to match the controller instance on the chip:

- The digital portion of USBPHY includes:
  - UTMI interface and control and status logic
  - Digital transmitter
  - Digital receiver
  - Programmable registers
- The analog transceiver section includes the following for all three USB 2.0 signaling speeds, as shown in Figure 340:

— Analog receiver

— Analog transmitter

62.3.1.1 UTMI interface and control and status logic

The UTMI interface and control and status logic handle the UTMI+ interface signals, line_state bits, reset buffering, some suspend and resume functions, transceiver speed selection, and transceiver termination selection.

The PLL in USBPHY supplies a 480 MHz clock to the USBPHY's digital section, and the UTMI interface and control and status logic divide the clock to generate the 30 MHz clock used in the UTMI+ interface.

This 480 MHz clock is also the input to the PFD hardware module. The PFD can generate the PFD output clock frequency by using the following formula: 480 MHz × 18 ÷ *n*, where *n* = 18–35. The mux is shown in the following figure (see PFDA[PFD0_FRAC] and PFDA[PFD_CLK_SEL]).

NOTE

The maximum programmable frequency allowed for the PFD output clock, USB1PFDCLK, is chip-specific.

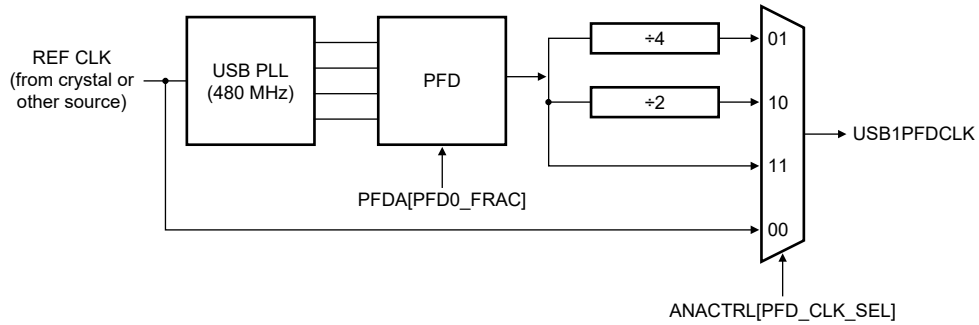

Figure 339. USB1PFDCLK generation diagram

62.3.1.2 Digital transmitter

The digital transmitter receives a 16-bit transmit data from the USB controller and handles the tx_valid, tx_validh, and tx_ready handshakes.

In addition, it contains the transmit serializer that converts the 16-bit parallel words at 30 MHz to a single bit stream at 480 Mbit/s for HS, 12 Mbit/s for FS, or 1.5 Mbit/s for LS. The digital transmitter does this conversion while implementing the bit-stuffing algorithm and the NRZI encoder that you use to remove the DC component from the serial bit stream. The output of this encoder is sent to the LS, FS, or HS differential drivers (see LS or FS differential driver and HS differential driver) in the transmitter block of the analog transceiver section.

62.3.1.3 Digital receiver

The digital receiver, when operating at HS, receives the 480 MHz, 9X oversampled data from the combination of HS differential receiver and 9X oversample module. When operating at LS or FS, it receives the raw serial bit stream from LS or FS differential receiver. Within the digital receiver, the LS or FS serial bit stream is oversampled 5X for the appropriate signaling rate. The oversampled data streams go to separate HS DLL and LS DLL or FS DLL circuits used for data recovery.

As the phase of the USB remote transmitter shifts relative to the local PLL, the HS DLL, LS DLL, or FS DLL tracks these changes to give a reliable sample of the incoming bit stream. Because this sample point shifts relative to the PLL phase used by the digital logic, a rate-matching elastic buffer is provided to cross this clock domain boundary. When the received data bit stream is in the local clock domain, an NRZI decoder and bit unstuffer restore the original payload data bit stream and pass it to a deserializer and holding register.

The RX state machine handles the rx_valid and rx_validh handshakes with the USB controller. If the handshakes are not interlocked, then there is no rx_ready signal from the controller. The controller must take each 16-bit value that the USBPHY

presents. The RX state machine provides an rx_active signal to the controller that indicates when it is inside a valid packet (SYNC detected, and so on).

62.3.1.4 Analog receiver

The analog receiver comprises five differential receivers, two single-ended receivers, and a 9X, 480 MHz HS data sampling module , as shown in Figure 340 and described further in this section.

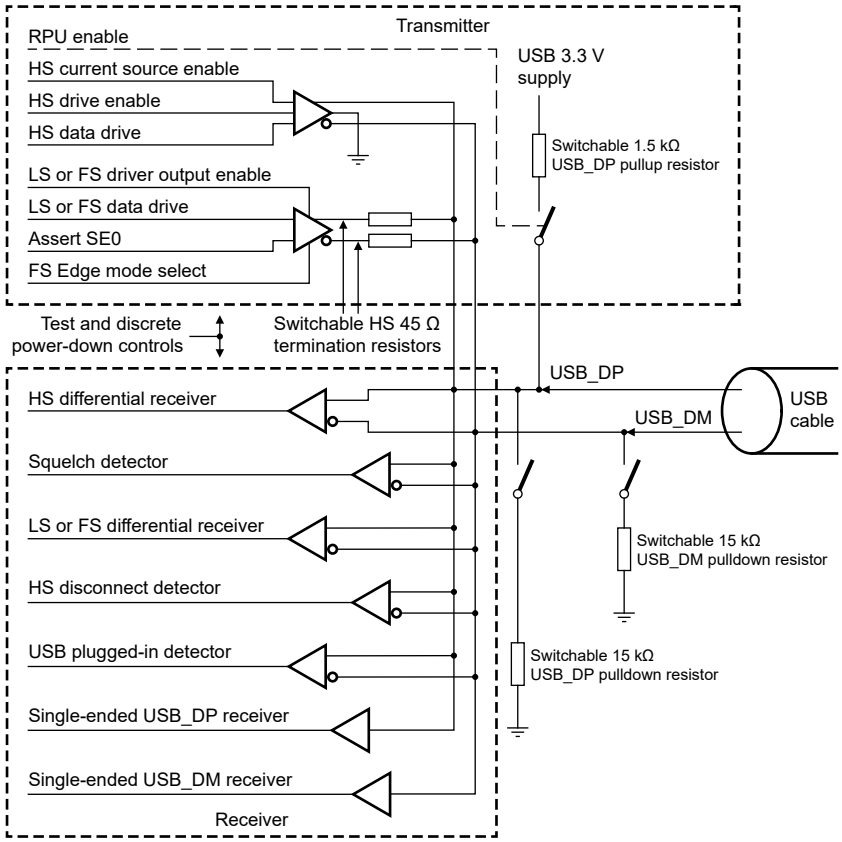

Figure 340. Analog transceiver block diagram

62.3.1.4.1 HS differential receiver

The HS differential receiver is optimized to work with the low-amplitude, ground-referenced signaling used during the HS USB operation. If the received signal voltage on the USB_DP pin is greater than the signal voltage on the USB_DM pin, the output of the receiver is high (1b). Otherwise, its output is low (0b). The purpose of the HS differential receiver is to discriminate the ± 400 mV differential voltage resulting from the current flow of high-speed drivers into the dual 45 Ω terminations found on each pin of the differential pair.

The squelch detector (see Squelch detector) ensures that the differential signal has sufficient magnitude to be valid. The HS differential receiver tolerates up to 500 mV of the common-mode offset.

62.3.1.4.2 Squelch detector

The squelch detector (also called envelope detector) is a differential analog receiver and threshold comparator. If the differential magnitude is less than a nominal 100 mV threshold, its output is high (1b). Otherwise, its output is low (0b). The purpose of the squelch detector is to invalidate HS differential receiver when the incoming signal is too low to be received reliably.

62.3.1.4.3 LS or FS differential receiver

The LS or FS differential receiver is optimized for the LS or FS signaling crossover voltage range of 1.3 V to 2.0 V. It must have an input sensitivity of better than 200 mV over a common-mode range of 0.8 V to 2.5 V.

If the signal voltage on the USB_DP pin is higher than the signal voltage on the USB_DM pin, the output of the receiver is high (1b). Otherwise, its output is low (0b). The digital receiver (see Digital receiver) decodes this output data of the receiver into J or K states, depending on the speed.

62.3.1.4.4 HS disconnect detector

The HS disconnect detector (also called the host disconnect detector) is a differential analog receiver and threshold comparator. If the differential magnitude between the USB_DP and USB_DM pins is greater than a nominal 575 mV threshold, its output is high (1b). Otherwise, its output is low (0b). The HS disconnect detector is only used in Host mode. The output of the detector is sampled during the long end-of-packet (EOP) that occurs at the end of the HS start-of-frame (SOF) packet, as enabled by CTRL[ENHOSTDISCONDETECT].

62.3.1.4.5 USB plugged-in detector

When operating in Device mode, USBPHY provides the following methods for the local USB device to detect the attachment of a cable that is also attached to a remote USB host or hub. Enable only one of these methods at a time when waiting to identify the cable attachment event, and disable all of them during USB data communication:

- Data contact detect: This is the preferred standards-based method to use the function as per *USB Battery Charging Specification, Revision 1.2*. The use of this method is described in the "USB Device Charger Detection Module (USBDCD)" chapter.
- USB plugged-in (cable attach) detector: This method looks for both USB_DP and USB_DM to be high. There is a pair of large on-chip switchable pullup resistors (200 kΩ). This pair holds both USB_DP and USB_DM high when the USB cable is not attached. The USB plugged-in detector signals a 0 in this case. When operating in Device mode, the upstream port in the remote host or hub interface contains a 15 kΩ pulldown resistor, which could easily override the 200 kΩ pullup resistor. When the cable attachment event occurs, at least one signal in the pair is low, which forces the plugged-in detector output to be high. The USB plugged-in detector is controlled through CTRL[ENDEVPLUGINDETECT] and the results are observable through STATUS[DEVPLUGIN_STATUS].

62.3.1.4.6 Single-ended USB_DP receiver

The single-ended USB_DP receiver output is high (1b) whenever the USB_DP input is above its nominal 1.4 V threshold. Otherwise, its output is low (0b).

62.3.1.4.7 Single-ended USB_DM receiver

The single-ended USB_DM receiver output is high (1b) whenever the USB_DM input is above its nominal 1.4 V threshold. Otherwise, its output is low (0b).

62.3.1.4.8 9X oversample module

The 9X oversample module uses nine identically spaced phases of the 480 MHz clock to sample the HS received bit data. The squelch signal is sampled only at 1X.

62.3.1.5 Analog transmitter

The analog transmitter comprises two differential drivers: one for HS signaling and another for LS or FS signaling. It also contains the switchable 45 Ω termination resistors (see Switchable 45 Ω termination resistors), 1.5 kΩ Device mode pullup resistor, and the switchable 15 kΩ Host mode pulldown resistors (see Figure 341).

62.3.1.5.1 Switchable 45 Ω termination resistors

The HS current-mode differential signaling requires a 90 Ω differential termination at each end of the USB cable. This results from switching in 45 Ω terminating resistors from each signal line to ground at each end of the cable.

Because each signal is terminated in parallel with 45 Ω at each end, each HS driver sees a 22.5 Ω DC load. This load impedance is too low for LS or FS signaling levels, generating the need for switchable HS terminating resistors. Selectable trimming resistors are provided to tune the actual termination resistance of each output pin, as shown in Figure 341. For example, TX[TXCAL45DP] allows one of the 16 trimming resistor values to be placed in parallel with the 45 Ω termination on the USB_DP signal.

These termination resistors are integrated with LS or FS differential driver and the same resistors also serve as the 45 Ω source series terminations required for LS or FS signaling.

62.3.1.5.2 LS or FS differential driver

The LS or FS differential drivers are essentially a pair of low-impedance pullup and pulldown devices that are switched in Differential mode for most LS or FS signaling. One output is driven high when the other output is driven low to signal the J or K state. Both outputs are driven low for the LS or FS SE0 states. Both the USB_DP and USB_DM LS or FS pulldown drivers are also turned on simultaneously for HS signaling. This effect causes switching in both 45 Ω terminating resistors.

62.3.1.5.3 HS differential driver

The HS differential driver receives a 17.78 mA current from the constant current source (Iref) and essentially steers it down either the USB_DP signal or USB_DM signal, or alternatively to the ground.

This current produces approximately a 400 mV drop across the 22.5 Ω termination that the driver sees when it is steered onto one of the signal lines. The approximately 17.78 mA current source is referenced back to the integrated voltage bandgap (Vbg) circuit.

62.3.1.5.4 Switchable 1.5 kΩ USB_DP pullup resistor

USBPHY provides a switchable 1.5 kΩ pullup resistor on the USB_DP signal. This resistor is switched on to indicate to the host or hub controller that an FS-capable device is on the USB cable, powered on, and ready. This resistor is switched off at POR, so the host does not recognize a USB device until the processor software enables the announcement of an FS device.

62.3.1.5.5 Switchable 15 kΩ USB_DP and USB_DM pulldown resistors

USBPHY provides switchable 15 kΩ pulldown resistors on both USB_DP and USB_DM signals. They are enabled in Host mode to indicate to the device controller on the far end of the USB connection that a host is present. These resistors are also used during certain battery charging detector functions.

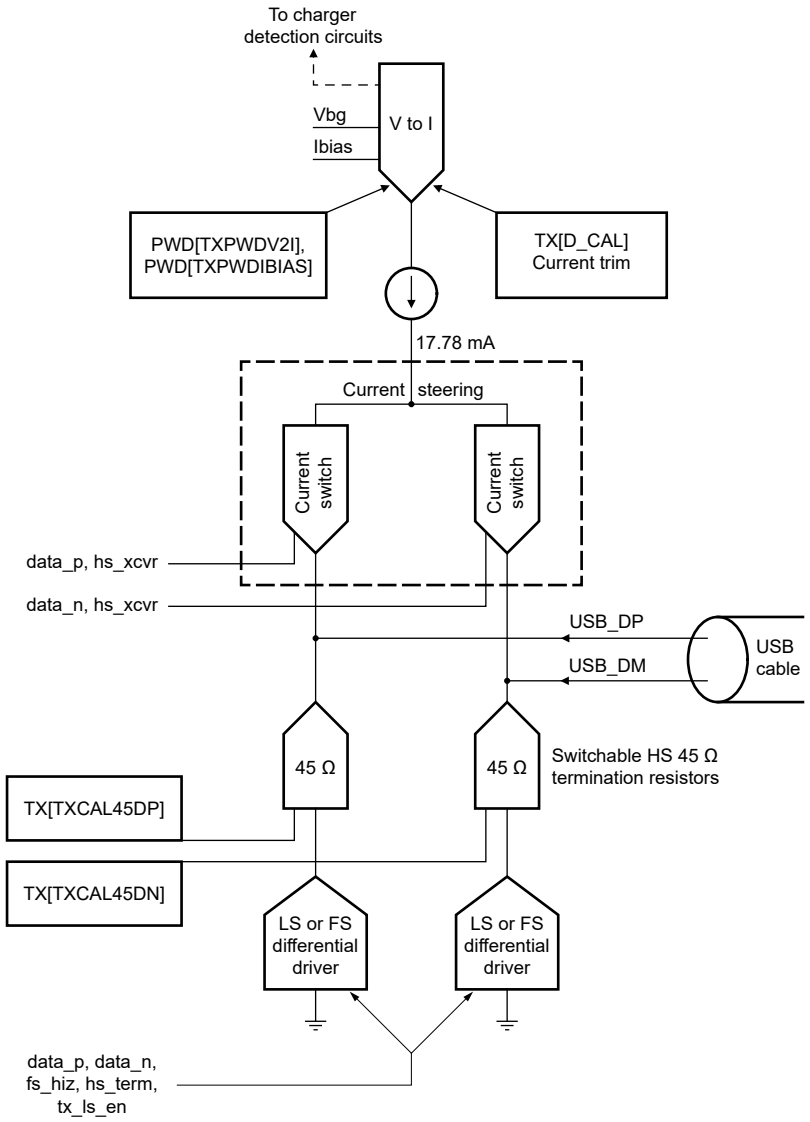

Figure 341. USBPHY transmitter block diagram

62.3.2 Low-Power mode

USBPHY includes Low-Power mode (Suspend mode) to save power consumption. When the USB bus is idle, you can place the transceiver in this mode, after which you can stop the clocks on USBPHY. The 32 kHz low-power clock must remain active as it is needed for wake-up detection.

The USB HS controller controls entry and exit into Low-Power mode:

- If USB.PORTSC1[SUSPEND] is 1, the UTMI interface is driven to the FS or LS state.
- If USB.PORTSC1[PHCD] is 1, the UTMI signal, SuspendM, goes low.
- If CTRL[ENAUTOCLR_PHY_PWD] and CTRL[ENAUTOCLR_CLKGATE] are 1, the utmi_clk and PHY transmitter are automatically enabled when the SuspendM signal goes high.
- If PLL_SIC[MISC2_CONTROL0] is 1, the PLL is powered down automatically when in Suspend mode. The PLL is automatically enabled when the SuspendM signal goes high. After the PLL is locked, USBPHY uses the PLL clock again.

Low-Power mode is always entered under the control of the driver software. See the "Universal Serial Bus Controller (USB)" chapter for details.

62.3.3 Clocking

Table 487. Input clocks

Clock	Description
ipg_clk	Free-running IPS bus clock for configuring registers
clk_xtal	24 MHz crystal clock for the PLL source
ckil_32k	32 kHz clock, which is used during Suspend mode if you need USB as a wake-up source

Table 488. Output clocks

Clock	Description
ref_pfd	PLL PFD clock that you can use as a system clock source
utmi_clk	30 MHz clock to the USB controller

62.3.4 Reset

Table 489. Resets

Reset	Description
Chip	Resets the logic and registers in USBPHY to their default states
UTMI	Resets the UTMI state machines, FIFO, and so on
Software	Soft-resets (SFTRST) USBPHY's Power Down (PWD), TX Control (TX), RX Control (RX), General Purpose Control (CTRL), STATUS[OTGID_STATUS], Debug 0 (DEBUG0), and IP Block (IP), when you write 1 to CTRL[SFTRST], along with resetting state machines in USBPHY Write 0 to CTRL[SFTRST] to release USBPHY from reset. **NOTE** A soft-reset can take multiple clock periods to complete; therefore, do not write 1 to CTRL[CLKGATE] when writing 1 to CTRL[SFTRST]. The reset process gates the clocks automatically.

62.3.5 Interrupts

Table 490. Interrupts

Flag or event	Interrupt enable	Description
CTRL[DEVPLUGIN_IRQ]	CTRL[ENIRQDEVPLUGIN]	Indicates nonstandard resistive plugged-in detection
CTRL[RESUME_IRQ]	CTRL[ENIRQRESUMEDETECT]	Indicates that the host is sending resume signaling after a Suspend signal
CTRL[WAKEUP_IRQ]	CTRL[ENIRQWAKEUP]	Indicates that the USB controller has stopped driving the SuspendM signal in its active-low state to USBPHY
CTRL[OTG_ID_CHG_IRQ]	CTRL[ENOTG_ID_CHG_IRQ]	Indicates that the value of the OTG ID pin has changed

Table continues on the next page...

Table 490. Interrupts (continued)

Flag or event	Interrupt enable	Description
CTRL[HOSTDISCONDETECT_IRQ]	CTRL[ENIRQHOSTDISCON]	Indicates that the host has detected USB device disconnection in HS mode
USBDCD interrupt	USBDCD interrupt enable	See the "Interrupts" section in the "USB Device Charger Detection Module (USBDCD)" chapter for details.

62.4 External signals

Table 491. USBPHY signals

Signal	Description	Direction
USB_DP	D+ pin	I/O
USB_DM	D– pin	I/O
USB_ID	ID Pin	Input
USB_VBUS	VBUS pin	Power

62.5 Initialization

To initialize this module, USBPHY is designed for minimal configuration while retaining significant programmability.

Table 492. USBPHY's configuration procedure

Step	Purpose	Programming
1	Release USBPHY from reset.	Write 0 to CTRL[SFTRST].
2	Run clocks.	Write 0 to CTRL[CLKGATE].
3	Reset the fields in Power Down (PWD).	Write 0 to the fields in Power Down (PWD).
4	Enable the UTMI+ level.	Write 1 to CTRL[ENUTMILEVEL2] and CTRL[ENUTMILEVEL3].
5	Enable other fields in General Purpose Control (CTRL) as needed.	Write 1 to CTRL[ENAUTOCLR_PHY_PWD], CTRL[ENAUTOCLR_CLKGATE], CTRL[AUTORESUME_EN], and so on.
6	Enable the reference clock system oscillator for the USB PLL.	Configure the reference clock system oscillator.
7	Control the USB PLL feedback loop divider.	Configure PLL_SIC[PLL_DIV_SEL] according to the system oscillator frequency.
8	Enable the USBPHY PLL regulator.	Write 1 to PLL_SIC[PLL_REG_ENABLE].
9	Clear the bypass feature.	Write 0 to PLL_SIC[PLL_BYPASS].
10	Configure other fields in PLL SIC (PLL_SIC) as needed.	Write to PLL SIC (PLL_SIC).
11	Power up the PLL.	Write 1 to PLL_SIC[PLL_POWER].
12	Enable the USB 3.3 V and 1.8 V monitors.	Write 1 to ANACTRL[LVI_EN].

Table continues on the next page...

Table 492. USBPHY's configuration procedure (continued)

Step	Purpose	Programming
13	Wait for the PLL clock lock.	Poll PLL_SIC[PLL_LOCK].
14	Enable the USB clock.	Write 1 to PLL_SIC[PLL_EN_USB_CLKS].

62.6 Application information

62.6.1 VBUS detector

USBPHY has three separate VBUS detectors, which you can individually power on or off using USB1_VBUS_DETECT[VBUSVALID_PWRUP_CMPS]. For power efficiency, align the USB software to the desired use case and either enable only one detector (if an internal detector is desired) or none of them (if an external detector is desired).

All three detectors have observable status fields in VBUS Detect Status (USB1_VBUS_DET_STAT), and to accomplish software overrides. Use the usb_vbusvalid_ext signal as a hardware override.

USB1_VBUS_DET_STAT[VBUS_VALID] is often used in Host mode; it is the most accurate and has a programmable threshold that USB1_VBUS_DETECT[VBUSVALID_THRESH] defines.

A session valid detector is often used in Device mode and may be useful in systems using nonstandard VBUS voltages.

You can use USB1_VBUS_DET_STAT[VBUS_VALID_3V] in Host mode, which has a lower threshold for the voltage on the USB1_VBUS pin than either the session valid detector or USB1_VBUS_DET_STAT[VBUS_VALID]. It may be useful for applications that provide a nonstandard VBUS voltage to USBPHY.

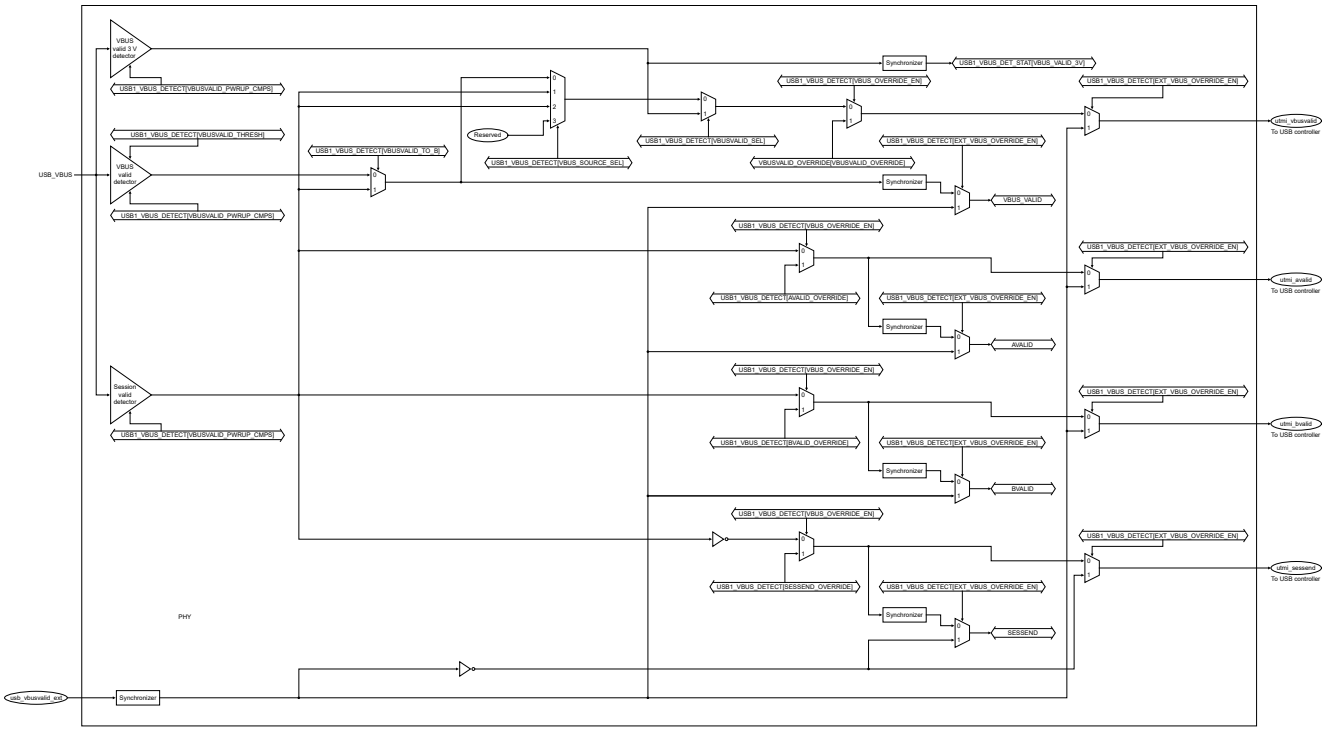

Figure 342. VBUS detectors and control registers

62.6.2 Recommended register configuration for USB certification

USBPHY has the programmability to adjust several transceiver parameters. You can:

- Adjust the TX HS driver termination impedance, FS driver output impedance, and HS driver output currents by using TX Control (TX). You can disable the ability to override the default parametric trim fields using TX Control (TX) by writing 0 to TRIM_OVERRIDE_EN[TX_CAL45DM_OVERRIDE], TRIM_OVERRIDE_EN[TX_CAL45DP_OVERRIDE], and TRIM_OVERRIDE_EN[TX_D_CAL_OVERRIDE].
- Adjust the HS RX thresholds for Squelch detector and HS disconnect detector by using RX Control (RX).

The default values of the transceiver parametric trim fields are centered, with no changes needed for USB certification testing when the chip is used with boards optimized for signal integrity on the HS USB port.

In other cases, such as when external components are inserted between the USB_DP or USB_DM pins and the USB connector, or other compromises are made on the USB_DP or USB_DM signal routing, changes to the parametric trim fields may be useful.

62.7.2 Power Down (PWD)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
PWD	0h	Power Down
PWD_SET	4h	Writing 1 to a bit in this register ensures that the corresponding bit in PWD is 1
PWD_CLR	8h	Writing 1 to a bit in this register ensures that the corresponding bit in PWD is 0
PWD_TOG	Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in PWD

Function

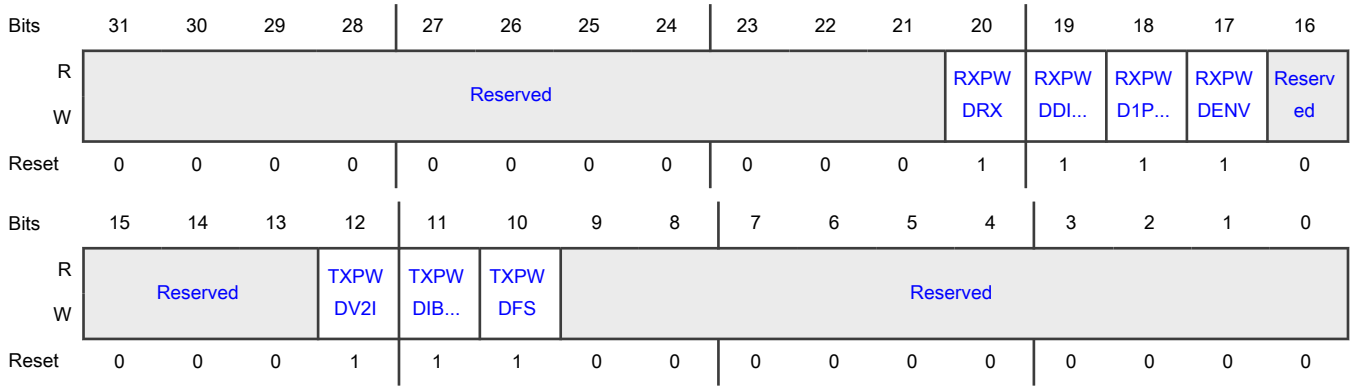
Provides overall control and status indication of the USBPHY power state.

The fields in this register have autopower-down writing of 1 and 0, depending on the configuration of fields in other registers. These features are intended to reduce the amount of software interaction needed when entering and leaving the Suspend bus state.

You must enable USBPHY's main reference bias generator separately, including the specific bias circuits required for the PLL and those controlled with this register. See PLL_SIC[REFBIAS_PWD] and PLL_SIC[REFBIAS_PWD_SEL] for information regarding how the main reference bias is controlled.

Before programming this register, you must enable the USBPHY clocks in USBPHY's General Purpose Control (CTRL) and PLL SIC (PLL_SIC).

Diagram



Fields

Field	Function
31-21 —	Reserved
20 RXPWDRX	Power Down USBPHY Receiver Circuits Disables the RX circuits except the FS differential comparator, such as the HS RX differential receiver, HS envelope detector, and HS host disconnect comparator, along with their RX current mirror bias circuits. The overall control of the RX current bias hardware module is shared with the battery charge circuit, but this field powers down the other aforementioned RX circuits unconditionally. If a wake-up event exists when USB is suspended and CTRL[ENAUTOCLR_PHY_PWD] is 1, this field becomes 0 automatically. This field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Enable 1b - Disable or power down
19 RXPWDDIFF	Power Down USB HS Differential Receiver Disables the USB HS RX differential receiver that is used for data reception in HS operation. If a wake-up event exists when USB is suspended and CTRL[ENAUTOCLR_PHY_PWD] is 1, this field becomes 0 automatically. This field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Enable 1b - Disable or power down
18 RXPWD1PT1	Power Down USB FS Differential Receiver Disables the USB FS RX differential receiver that is used for data reception in both FS and LS operations. This field does not affect the bias and operation of the FS differential receiver.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If a wake-up event exists when USB is suspended and CTRL[ENAUTOCLR_PHY_PWD] is 1, this field becomes 0 automatically. This field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Enable 1b - Disable or power down
17 RXPWDENV	Power Down USB HS RX Envelope Detector Disables the USB HS RX envelope detector and host disconnect comparator. The USB HS RX envelope detector generates the squelch signal used to qualify the HS RX data. The host disconnect comparator is used in Host mode to check for a disconnection from the remote device. If a wake-up event exists when USB is suspended and CTRL[ENAUTOCLR_PHY_PWD] is 1, this field becomes 0 automatically. This field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Enable 1b - Disable or power down
16-13 —	Reserved
12 TXPWDV2I	Power Down USBPHY TX V-I Converter and Current Mirror Disables the USBPHY TX V-I converter and current mirror. The V-I converter provides the currents used in the HS TX drivers and depends on both USBPHY's bias module and the bias current block. If a wake-up event exists when USB is suspended and CTRL[ENAUTOCLR_PHY_PWD] is 1, this field becomes 0 automatically. This field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Enable 1b - Disable or power down
11 TXPWDIBIAS	Power Down USBPHY TX Current Bias Block Disables the USBPHY current bias block for the TX that provides mirrored currents to track USBPHY's bias module reference current generator for several functions in the TX, RX, and detector sections. Control of the current bias block is shared with the battery charge circuit. Writing 1 to this field does not power down the circuit unless the corresponding field in the battery charge control is also 1 for power down. The field must be 1 only when the USB is in the Suspend bus state. This effectively powers down the entire USB transmit path. If a wake-up event exists when USB is suspended and CTRL[ENAUTOCLR_PHY_PWD] is 1, this field becomes 0 automatically. This field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Enable 1b - Disable or power down
10 TXPWDFS	Power Down USB FS TX Drivers Disables the USB FS TX drivers that must have their bias enabled during USB data communication, including resume and bus reset signaling. They are used in HS, FS, and LS because the pulldown of the FS TX drivers provides local HS termination. If this field is 1, configure them to high-impedance state. If a wake-up event exists when USB is suspended and CTRL[ENAUTOCLR_PHY_PWD] is 1, this field becomes 0 automatically. This field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Provide bias to enable 1b - Disable or power down
9-0 —	Reserved

62.7.3 TX Control (TX)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
TX	10h	TX Control
TX_SET	14h	Writing 1 to a bit in this register ensures that the corresponding bit in TX is 1
TX_CLR	18h	Writing 1 to a bit in this register ensures that the corresponding bit in TX is 0
TX_TOG	1Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in TX

Function

Allows adjustment of transmit circuit parameters.

Diagram

Fields

Field	Function
31-29 —	Reserved
28-26 —	The value of this reserved bit must remain 100b.
25 —	The value of this reserved bit must remain 0b.
24 —	The value of this reserved bit must remain 0b.
23-22 —	Reserved
21 —	The value of this reserved bit must remain 0b.
20 —	Reserved
19-16 TXCAL45DP	DP Series Termination Resistance Trim Specifies the trim value of the 45 Ω DP series termination resistance. Decode to trim the nominal 45 Ω series termination resistance to the USB_DP output pin. When TRIM_OVERRIDE_EN[TX_CAL45DP_OVERRIDE] is 1, the values in this field are used to trim the termination resistance. When TRIM_OVERRIDE_EN[TX_CAL45DP_OVERRIDE] is 0, the resistance trim values in TRIM_OVERRIDE_EN[USBPHY_TX_CAL45DP] are used instead. Maximum resistance is at value 0000b, minimum resistance is at value 1111b, and resistance is centered at value 0111b. For this USBPHY, each incrementally increasing trim value decreases the target resistance by about 3.5% compared to the next lower value.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Trimming this resistance impacts both the overshoot and undershoot of the FS TX output and the amplitude of the HS TX output.
15-14 —	Reserved
13 —	The value of this reserved bit must remain 0b.
12 —	Reserved
11-8 TXCAL45DN	DM Series Termination Resistance Trim Specifies the trim value of the 45 Ω DM series termination resistance. Decode to trim the nominal 45 Ω series termination resistance to the USB_DM output pin. When TRIM_OVERRIDE_EN[TX_CAL45DM_OVERRIDE] is 1, the values in this field are used to trim the termination resistance. When TRIM_OVERRIDE_EN[TX_CAL45DM_OVERRIDE] is 0, the resistance trim values in TRIM_OVERRIDE_EN[USBPHY_TX_CAL45DN] are used instead. Maximum resistance is at value 0000b, minimum resistance is at value 1111b, and resistance is centered at value 0111b. For this USBPHY, each incrementally increasing trim value decreases the target resistance by about 3.5% compared to the next lower value. Trimming this resistance impacts both the overshoot and undershoot of the FS TX output and the amplitude of the HS TX output.
7-4 —	Reserved
3-0 D_CAL	HS TX Output Current Trim Specifies the trim value of the HS TX output current. Decode to trim the nominal 17.78 mA current source for the HS TX drivers on USB_DP and USB_DM. This output current is directly proportional to the amplitude of the HS TX eye diagram. When TRIM_OVERRIDE_EN[TX_D_CAL_OVERRIDE] is 1, the values in this field are used to trim the output current. When TRIM_OVERRIDE_EN[TX_D_CAL_OVERRIDE] is 0, the current trim values in TRIM_OVERRIDE_EN[USBPHY_TX_D_CAL] are used instead. 0000b - Maximum current, approximately 19% above nominal 0111b - Nominal 1111b - Minimum current, approximately 19% below nominal

62.7.4 RX Control (RX)

Offset

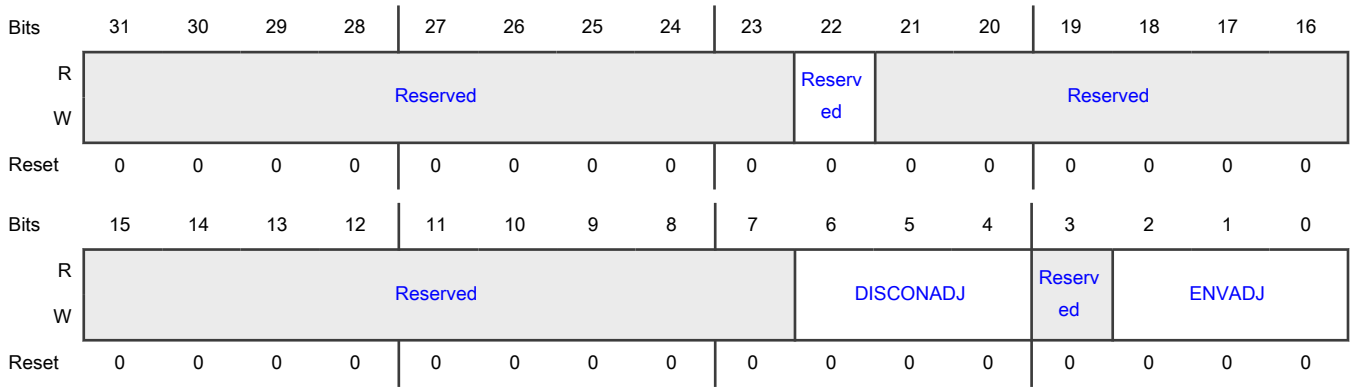
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
RX	20h	RX Control
RX_SET	24h	Writing 1 to a bit in this register ensures that the corresponding bit in RX is 1
RX_CLR	28h	Writing 1 to a bit in this register ensures that the corresponding bit in RX is 0
RX_TOG	2Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in RX

Function

Handles receive path controls.

Diagram



Fields

Field	Function
31-23 —	Reserved
22 —	The value of this reserved bit must remain 0b.
21-7 —	Reserved
6-4 DISCONADJ	Disconnect Detector Trip Point Adjusts the trip point (trip-level voltage) for HS disconnect detector used in Host mode. 000b - 0.56875 V 001b - 0.55000 V

Table continues on the next page...

Table continued from the previous page...

Field	Function
	010b - 0.58125 V 011b - 0.60000 V 1xxb - Reserved
3 —	Reserved
2-0 ENVADJ	Envelope Detector Trip Point Adjusts the trip point (trip-level voltage) for the envelope detector used for HS squelch (see Squelch detector). The following values are nominal DC values to indicate the effect of changing this field. AC values measured during compliance testing are higher. 000b - 0.1000 V 001b - 0.1125 V 010b - 0.1250 V 011b - 0.0875 V 1xxb - Reserved

62.7.5 General Purpose Control (CTRL)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
CTRL	30h	General Purpose Control
CTRL_SET	34h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL is 1
CTRL_CLR	38h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL is 0
CTRL_TOG	3Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in CTRL

Function

Handles OTG and host controls.

This register also includes interrupt enables, connectivity detect enables, and results.

Fields

Field	Function
31 SFTRST	Software Reset Soft-resets USBPHY's Power Down (PWD), TX Control (TX), RX Control (RX), General Purpose Control (CTRL), STATUS[OTGID_STATUS], Debug 0 (DEBUG0), and IP Block (IP), along with resetting state machines in USBPHY. Write 0 to this field to release USBPHY from reset. 0b - Release from reset 1b - Soft-reset
30 CLKGATE	UTMI Clock Gate Gates UTMI clocks. Write 1 to this field to save power when USB is not actively used. The configuration state of this field is retained when the clock is gated. If a wake-up event exists when USB is suspended and CTRL[ENAUTOCLR_CLKGATE] is 1, this field becomes 0 automatically. This field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Run clocks 1b - Gate clocks
29 UTMI_SUSPENDM	UTMI Suspend Indicates a power-down state. If all power-down fields in USBPHY's Power Down (PWD) are 1, this field is forced to 0. Otherwise, this field reflects a synchronized version of the SuspendM signal from the USB controller to USBPHY. UTMI_SUSPENDM is negative logic because the UTMI specification requires it to be. 0b - Not suspended 1b - Suspended
28	The value of this reserved bit must remain 0b.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
27 OTG_ID_VALUE	OTG ID Value Indicates the results of the ID pin status for the USB cable plugged into the local micro- or mini-AB receptacle. If this field is 0, the ID resistance to ground is less than Ra_Plug_ID, indicating the host (A) side. If this field is 1, the ID resistance is greater than Rb_Plug_ID, indicating the device (B) side. You can use this field to reflect the status of USBPHY's internal USB_ID pin detector, or either of the local or external ID pin overrides depending on the configuration of USB1_VBUS_DETECT[ID_OVERRIDE_EN] and USB1_VBUS_DETECT[EXT_ID_OVERRIDE_EN]. The function of this field is very similar to that of STATUS[OTGID_STATUS], but this field has additional debounce and system clock synchronization logic to filter the glitches on the USB_ID pin. 0b - Host 1b - Device
26 —	This field has no function on this chip.
25 —	This field has no function on this chip.
24 —	The value of this reserved bit must remain 0b.
23 —	This field has no function on this chip.
22 —	This field has no function on this chip.
21 —	This field has no function on this chip.
20 ENAUTOCLR_PHY_PWD	PHY PWD Autoclear Enable Enables automatic writing of 0 to the fields in USBPHY's Power Down (PWD) if there is a wake-up event when USB is suspended. If wake-up is required automatically without software interaction, you must write 1 to this field. Recognizing the rising edge of the UTMI_SUSPENDM signal driven from the USB controller to USBPHY triggers the wake-up event for this feature. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
19 ENAUTOCLR_CLKGATE	Autoclear Clock Gate Enable Enables automatic writing of 0 to CLKGATE if there is a wake-up event when USB is suspended. If wake-up is required automatically without software interaction, you must write 1 to this field. Recognizing the rising edge of the UTMI_SUSPENDM signal driven from the USB controller to USBPHY triggers the wake-up event for this feature. 0b - Disable 1b - Enable
18 AUTORESUME_EN	Autoresume Enable Enables the autoresume feature. When this field is 1, USBPHY uses a 32 kHz clock to send resume signaling to respond to the device remote wake-up (for Host mode only). This feature is useful when the USB PLL is off and the reference clock is also powered down. 0b - Disable 1b - Enable
17 WAKEUP_IRQ	Wake-Up Interrupt Specifies that the USB controller has stopped driving the SuspendM signal in its active-low state to USBPHY. If ENIRQWAKEUP is 1, the state of this field is passed to USBPHY's combined interrupt output signal. Reset this field by writing 1 to the SCT clear address space, and not by a general write.
16 ENIRQWAKEUP	Wake-Up Interrupt Enable Enables WAKEUP_IRQ detection results to affect USBPHY's combined interrupt output signal. 0b - Disable 1b - Enable
15 ENUTMILEVEL3	UTMI Level 3 Enable Enables the UTMI+ level 3 operation for USBPHY. If an embedded host use case must support an external FS hub with an LS device connected, you must write 1 to this field. 0b - Disable 1b - Enable
14 ENUTMILEVEL2	UTMI Level 2 Enable Enables the UTMI+ level 2 operation for USBPHY. If an embedded host use case must support an LS device, you must write 1 to this field. 0b - Disable 1b - Enable
13	APB Clock Switch Option

Table continues on the next page...

Table continued from the previous page...

Field	Function
DATA_ON_LRADC	Specifies an APB clock switch option. This is one of the fields that affects muxing and the behavior of the APB clock used in USBPHY. On some chips, changes to the value of this field may be required to allow programming of registers during the USB Suspend state or for proper recognition of wake-up and disconnect. To avoid unexpected USB behavior, do not change the value of this field without a specific recommendation from NXP.
12 DEVPLUGIN_IRQ	Device Plug-In Interrupt Specifies the device connected indicator for nonstandard resistive plugged-in detection and that the USB cable attachment status between the device and host has changed. Only if ENDEVPLUGINDETECT is 1, the value of this field is valid. If ENIRQDEVPLUGIN is 1, the state of this field is passed to USBPHY's combined interrupt output signal. Reset this field by writing 1 to the SCT clear address space, and not by a general write.
11 ENIRQDEVPLUGIN	Enable Interrupt for Nonstandard Resistive Plugged-In Detection Enables the detection results in DEVPLUGIN_IRQ to affect USBPHY's combined interrupt output signal. 0b - Disable 1b - Enable
10 RESUME_IRQ	Resume Interrupt Specifies whether the host is sending a Resume signal after a Suspend signal. This field also becomes 1 after a bus reset during the Suspend state. Use this field to wake up from this state for either the resume or the reset case. If ENIRQRESUMEDETECT is 1, the state of this field is passed to USBPHY's combined interrupt output signal. Reset this field by writing 1 to the SCT clear address space or by a general register write. The value of RESUMEIRQSTICKY also affects the behavior of this field and its IRQ signal. 0b - No resume interrupt 1b - Resume interrupt
9 ENIRQRESUMEDETECT	Resume Detection Interrupt Enable Enables the detection results in RESUME_IRQ to affect USBPHY's combined interrupt output signal. You must write 1 to this field only after the device has entered the Suspend state. 0b - Disable 1b - Enable
8 RESUMEIRQSTICKY	Resume Interrupt Sticky Specifies until when RESUME_IRQ remains 1. 0b - During the resume or reset state signaling period

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Until you write 0 to it
7 ENOTGIDDETECT	Enable Internal OTG ID Detector Enables the circuit to detect the resistance of the USB_ID pin when monitoring the cable plugged into the micro- or mini-AB receptacle. On some chips, the USB controller provides an alternate method to enable the pullup for the USB_ID pin. Either of the two USB_ID pullup enable methods is used. To avoid extra power consumption, this field must remain 0 whenever USB_ID pin monitoring is not required. 0b - Disable 1b - Enable
6 OTG_ID_CHG_IRQ	OTG ID Change Interrupt Specifies whether the value of the OTG ID pin is changed. If ENOTG_ID_CHG_IRQ is 1, the state of this field is passed to USBPHY's combined interrupt output signal. Reset this field by writing 1 to the SCT clear address space, and not by a general write. 0b - No ID change interrupt 1b - ID change interrupt
5 DEVPLUGIN_POLARITY	Device Plug-In Polarity Specifies the device plug-in polarity interrupt configuration for nonstandard resistive plugged-in detection. For Device mode, if this field is 0, the interrupt is tripped when the USB cable from the host to the device is plugged in. If this field is 1, the interrupt is tripped when the USB cable from the host to the device is unplugged. 0b - Plugged in 1b - Unplugged
4 ENDEVPLUGINDETECT	Enable Nonstandard Resistive Plugged-In Detection Enables connection of nominal 200 kΩ pullup resistors to both the USB_DP and USB_DM pins as a method of detecting when a USB cable is attached in Device mode. This field must remain 0 for normal USB data communication or when using USBHSDCD for battery charger detection, according to *USB Battery Charger Specification Revision 1.2*, or any other detection mechanism for USB cable plug-in. When this field is 1, all methods for enabling the local 15 kΩ pulldown resistors, such as ANACTRL[DEV_PULLDOWN], must be 0. STATUS[DEVPLUGIN_STATUS] reports the results of this detection method. 0b - Disable 1b - Enable
3 HOSTDISCONDETECT_IRQ	Host Disconnect Detection Interrupt Specifies whether the host has detected USB device disconnection in HS mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If CTRL[HOSTDISCONDETECT_IRQ] is 1, the state of this field is passed to USBPHY's combined interrupt output signal. Reset this field by writing 1 to the SCT clear address space, and not by a general write. 0b - Connected 1b - Disconnected
2 ENIRQHOSTDISCON	Enable Interrupt for Host Disconnect Enables the detection results in HOSTDISCONDETECT_IRQ to affect USBPHY's combined interrupt output signal. This field becomes 1 in Host mode for HS operation after software recognizes that a USB device connection has occurred and after writing 1 to ENHOSTDISCONDETECT. 0b - Disable 1b - Enable
1 ENHOSTDISCONDETECT	Host Disconnect Detection Enable Enables HS disconnect detector for Host mode. This field must be 1 to allow the UTMI controller to observe the results of the HS disconnect detector, which is sampled at an appropriate time, after the host sends an SOF packet. After recognizing that an HS device is connected, you must write 1 to this field. The state of this detector is observed using STATUS[HOSTDISCONDETECT_STATUS]. 0b - Disable 1b - Enable
0 ENOTG_ID_CHG_IRQ	OTG ID Change Interrupt Enable Enables the detection results in OTG_ID_CHG_IRQ to affect USBPHY's combined interrupt output signal. 0b - Disable 1b - Enable

62.7.6 Status (STATUS)

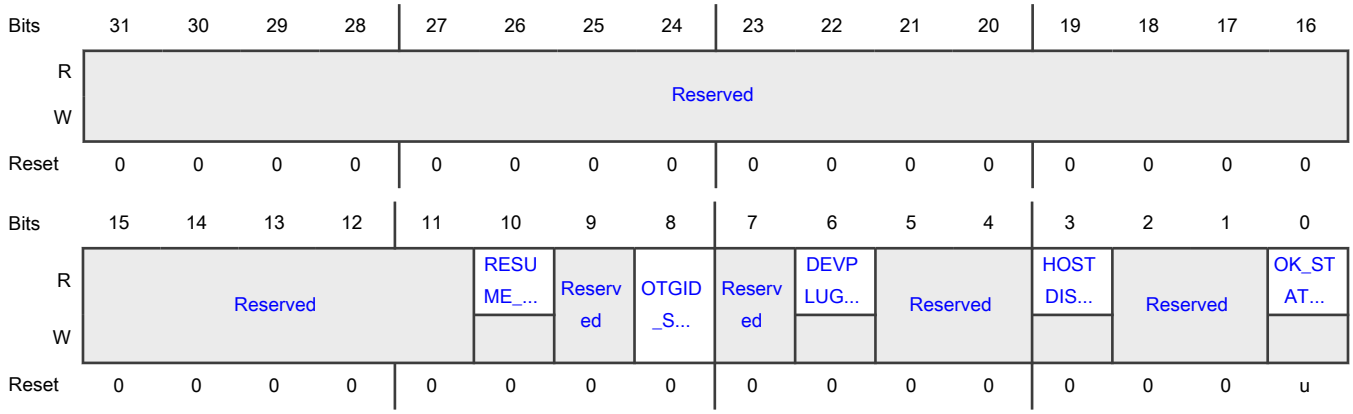
Offset

Register	Offset
STATUS	40h

Function

Holds results of IRQ and other detects.

Diagram



Fields

Field	Function
31-11 —	Reserved
10 RESUME_STATUS	Resume Status Indicates that the host is sending a wake-up request after the Suspend state and has triggered an interrupt. This field only provides a valid indication to resume when operating in FS or HS, after being in the Suspend bus state. The status field may toggle during USB data packet communication. Also, it does not indicate resume status when operating as a host that is directly attached to an LS device.
9 —	Reserved
8 OTGID_STATUS	OTG ID Status Specifies the results of the ID pin status for the USB cable plugged into the local micro- or mini-AB receptacle. The value of this field is also used for the IDDIG signal sent from USBPHY to the USB controller. You can use this field to reflect the status of USBPHY's internal USB_ID pin detector or either of the local or external ID pin overrides, depending on the configuration of USB1_VBUS_DETECT[ID_OVERRIDE_EN] and USB1_VBUS_DETECT[EXT_ID_OVERRIDE_EN]. If this field is 0, the ID resistance to ground is less than Ra_Plug_ID, indicating the host (A) side. If this field is 1, the ID resistance is greater than Rb_Plug_ID, indicating the device (B) side. 0b - Host 1b - Device
7 —	Reserved
6	Status Indicator for Nonstandard Resistive Plugged-In Detection

Table continues on the next page...

Table continued from the previous page...

Field	Function
DEVPLUGIN_STATUS	Indicates whether the device is connected on the USB_DP and USB_DM lines using the nonstandard resistive plugged-in detection method that CTRL[ENDEVPLUGINDETECT] controls. When a USB cable attached to a remote host is attached to the local device, the 15 kΩ host pulldowns override the high value resistors used in this detection method. 0b - No attachment detected 1b - Cable attachment detected
5-4 —	Reserved
3 HOSTDISCONDETECT_STATUS	Host Disconnect Status Indicates whether the USB cable disconnect is detected at the local host (downstream) port when in HS mode. 0b - Not detected 1b - Detected
2-1 —	Reserved
0 OK_STATUS_3V	USB 3.3 V and 1.8 V Supply Status Indicates the power status of USBPHY's noncore supply domains. The operation of this field depends on the state of ANACTRL[LVI_EN]. When ANACTRL[LVI_EN] is 1, this field is only 1 if both the USB 1.8 V and USB 3.3 V power rails are in their valid ranges. If this field is 0, one or both of the 1.8 V and 3.3 V supplies to USBPHY are not powered. 0b - Not powered 1b - Powered

62.7.7 Debug 0 (DEBUG0)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
DEBUG0	50h	Debug 0
DEBUG0_SET	54h	Writing 1 to a bit in this register ensures that the corresponding bit in DEBUG0 is 1
DEBUG0_CLR	58h	Writing 1 to a bit in this register ensures that the corresponding bit in DEBUG0 is 0

Table continues on the next page...

Table continued from the previous page...

Register	Offset	Description
DEBUG0_TOG	5Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in DEBUG0

Function

Controls debug features of USBPHY for testing and characterization. Some fields in this register also allow additional configurability for the 15 kΩ pulldown resistors and the behavior of the signals related to the OTG ID detection.

Diagram

15-13 —	Reserved
12 —	The value of this reserved bit must remain 0b.
11-8 —	The value of this reserved bit must remain 0000b.
7-6 —	Reserved
5-4 ENHSTPULLDOWN	Enable Host Pulldown Overdrive Mode Enables Host Pulldown Overdrive mode. Write 1b to bit 5 to override the control of the USB_DP 15 kΩ pulldown, which the USB controller normally performs. Write 1b to bit 4 to override the control of the USB_DM 15 kΩ pulldown, which the USB controller normally performs. Write 00b to both bits to disable Host Pulldown Overdrive mode and return the control of the pulldown resistors to the USB controller. When in Host Pulldown Overdrive mode, HSTPULLDOWN further controls the connection of the individual pulldown resistors. Both pulldown resistors are also unconditionally enabled when ANACTRL[DEV_PULLDOWN] is 1, without considering the value of this field. 00b - Disable 01b - Enable
3-2 HSTPULLDOWN	Host Pulldown Overdrive Mode Selects whether to connect pulldown resistors on the USB_DP and USB_DM pins if the Host Pulldown Overdrive mode is enabled through ENHSTPULLDOWN. Write 1b to bit 3 to connect the 15 kΩ pulldown on the USB_DP line. Write 1b to bit 2 to connect the 15 kΩ pulldown on the USB_DM line. Write 00b to both bits to disconnect the resistors in Host Pulldown Override mode. 00b - Disconnect 01b - Connect
1 —	This field performs no function on this chip.
0	Hold OTG_ID

Table continues on the next page...

Table continued from the previous page...

Field	Function
OTGIDPIOLOCK	Holds the OTG ID value after the OTG_ID state from STATUS[OTGID_STATUS] is sampled. This provides power savings for the detection circuit that is used to determine the ID pin status by allowing the USB_ID pin detector to be disabled. The value of this field affects the value of STATUS[OTGID_STATUS] but does not affect the value of CTRL[OTG_ID_VALUE].

62.7.8 Version (VERSION)

Offset

Register	Offset
VERSION	80h

Function

Indicates the version of USBPHY.

Fields

Field	Function
31-24 MAJOR	Major Indicates the major field of the RTL version.
23-16 MINOR	Minor Indicates the minor field of the RTL version.
15-0 STEP	Step Indicates the stepping of the RTL version.

62.7.9 IP Block (IP)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
IP	90h	IP Block
IP_SET	94h	Writing 1 to a bit in this register ensures that the corresponding bit in IP is 1
IP_CLR	98h	Writing 1 to a bit in this register ensures that the corresponding bit in IP is 0
IP_TOG	9Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in IP

Function

Contains patch and debug fields that modify digital operation.

Fields

Field	Function
31-25 —	Reserved
24-23 —	The value of this reserved bit must remain 00b.
22-21 —	This field has no function on this chip.
20-19	The value of this reserved bit must remain 00b.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
18 —	The value of this reserved bit must remain 1b.
17 —	The value of this reserved bit must remain 1b.
16 —	The value of this reserved bit must remain 0b.
15-3 —	Reserved
2 —	The value of this reserved bit must remain 0b.
1 —	Do not change the value of this field without a specific recommendation from NXP.
0 POWER_CONTROL_SUSPEND_OPTION	Power Control Suspend Option Specifies the power control suspend option. This is one of the fields that affects muxing and the behavior of the APB clock used in USBPHY. On some chips, changes to the value of this field may be required to allow programming of registers during the USB Suspend state or for proper recognition of wake-up and disconnect. To avoid unexpected USB behavior, do not change the value of this field without a specific recommendation from NXP.

62.7.10 PLL SIC (PLL_SIC)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
PLL_SIC	A0h	PLL SIC
PLL_SIC_SET	A4h	Writing 1 to a bit in this register ensures that the corresponding bit in PLL_SIC is 1
PLL_SIC_CLR	A8h	Writing 1 to a bit in this register ensures that the corresponding bit in PLL_SIC is 0
PLL_SIC_TOG	ACh	Writing 1 to a bit in this register inverts the value of the corresponding bit in PLL_SIC

Function

Configures the operation of USBPHY's 480 MHz PLL and observes its lock status. Use this register to control USBPHY's main reference bias generator used for PLL, transceiver, and detector circuits. Additional fields in the register are used to configure power mode switching features.

Fields

Field	Function
31 PLL_LOCK	USB PLL Lock Status Indicator Indicates whether the USB PLL is locked. This field becomes 1 after some delay when the PLL is powered up. USBPHY clears this field during the change in PLL software configuration settings, including PLL_POWER and PLL_DIV_SEL. If the PLL is configured for autopowerdown and USBPHY enters the Suspend bus state, this field becomes 0. 0b - Not locked 1b - Locked
30 PLL_PREDIV	PLL Pre-Divider Pre-divide selector between /1 or /2 to expand the range of the USB PLL input clock. USBPHY's PLL has a configurable internal pre-divider for its reference clock input. The pre-divider mux either passes the reference clock input directly to the PLL or uses a divide-by-two circuit between the module's reference clock input and the PLL loop. This feature allows support of 38.4, 40, 48, 60, or 64 MHz system reference clocks with the USB PLL. 0b - Uses the undivided reference clock for PLL loop 1b - Divides the reference clock by two for PLL loop
29-27 —	The value of this reserved bit must remain 000b.
26 —	The value of this reserved bit must remain 0b.

Table continues on the next page...

Table continued from the previous page...

Field	Function
25 —	The value of this reserved bit must remain 0b.
24-22 PLL_DIV_SEL	PLL Divider Value Configuration Controls the USB PLL feedback loop divider and allows use of different frequency signals for the PLL reference clock input connected to the OSCCLK signal from the system oscillator. USBPHY's PLL produces a 480 MHz output clock. When TRIM_OVERRIDE_EN[DIV_SEL_OVERRIDE] is 1, use the values in this field to control the PLL divider. When TRIM_OVERRIDE_EN[DIV_SEL_OVERRIDE] is 0, the PLL divider values in TRIM_OVERRIDE_EN[PLL_CTRL0_DIV_SEL] are used instead. If this field is 111b, it may give marginal jitter results. The input clock frequency used for the PLL reference clock input is the output of the pre-divider stage controlled by PLL_SIC[PLL_PREDIV] bit field. For most SOCs the pre-divider would not be enabled but this feature might be used if an SOC had a very high frequency but still stable system reference clock. 000b - Configure for a 32 MHz input clock (divide by 15) 001b - Configure for a 30 MHz input clock (divide by 16) 010b - Configure for a 24 MHz input clock (divide by 20) 011b - Reserved, not usable for USB operation (divide by 22) 100b - Configure for a 20 MHz input clock (divide by 24) 101b - Configure for a 19.2 MHz input clock (divide by 25) 110b - Configure for a 16 MHz input clock (divide by 30) 111b - Configure for a 12 MHz input clock (divide by 40)
21 PLL_REG_ENABLE	Enable PLL Regulator Enables the USB PLL regulator. The USB PLL operates in a voltage domain powered by a local regulator within USBPHY. Use this field to control the PLL regulator. The USB software stack must write 1 to this field. Then, at least 15 µs later, write 1 to PLL_POWER to avoid glitches on the PLL output clocks. You must power up USBPHY's main reference bias generator for the PLL regulator to operate. See REFBIAS_PWD and REFBIAS_PWD_SEL for information on how the main reference bias is controlled. 0b - Disable 1b - Enable
20 REFBIAS_PWD	Power Down Reference Bias Disables or powers down the main reference bias in direct power control mode. You must enable USBPHY's main reference bias circuits for the other bias circuits in USBPHY to operate, including the bias circuits required for the PLL and those controlled with Power Down (PWD).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field allows direct enable of the main reference bias circuits, independent of whether the USBPHY is in the Suspend bus state, but is only effective when REFBIAS_PWD_SEL is 1. The USB software stack must write 0 to this field together with writing 1 to REFBIAS_PWD_SEL to enable the needed bias circuits when performing battery charger detection or when using the VBUS_VALID comparator, if USBPHY is in the Suspend bus state with the USB PLL powered down. 0b - Enable 1b - Disable or power down
19 REFBIAS_PWD_SEL	Reference Bias Power Control Determines the method used to enable and disable USBPHY's main reference bias circuits. You must enable the main reference bias circuits for the other bias circuits in USBPHY to operate, including the bias circuits required for the PLL and those controlled using Power Down (PWD). The USB software stack must write 1 to this field together with writing 0 to REFBIAS_PWD to allow direct enable for the needed bias circuits when performing battery charger detection or when using the VBUS_VALID comparator, if USBPHY is in the Suspend bus state with the USB PLL powered down. For CLN40ULP PHY, it is recommended to write 1 to this field together with writing 0 to REFBIAS_PWD and writing 1 to MISC2_CONTROL0 to allow automatic power control when USBPHY is entering and leaving the Suspend bus state. 0b - PLL_POWER internal state signal 1b - REFBIAS_PWD
18 —	This field performs no function on this chip.
17 —	The value of this reserved bit must remain 0b.
16 PLL_BYPASS	Bypass USB PLL Controls the clock mux for the PLL main output used in USBPHY. The output clock signal is selected either from the 480 MHz output required for USB data communication or the PLL's reference input clock. Because the default state of this field is 1, you must write 0 to this field during the USB initialization routine. 0b - 480 MHz output clock 1b - Input reference clock
15-14 —	This field performs no function on this chip.
13 PLL_ENABLE	PLL Output Clock Enable Enables the main 480 MHz single-phase clock output from the USB PLL to the UTMI logic. This field works with MISC2_CONTROL0 to perform a PLL operation. You must power up the USB PLL using PLL_POWER first, before the clock output is enabled using this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
12 PLL_POWER	USB PLL Powerup Control Allows the 480 MHz USB PLL to be powered up. This field, when 0, forces powerdown of the USB PLL and safestates all of its output clocks. USBPHY controls the internal PLL power-up state signal. When appropriately configured with other register fields, USBPHY can power down the PLL when USBPHY is in the Suspend bus state and the PLL clocks are not needed, and restart the PLL when exiting Suspend. In this Auto-Powerup or Auto-Powerdown mode, the USB software stack must write 1 to PLL_POWER when initializing the PLL and USBPHY. The value of this field reflects what you write to the register and it does not toggle as the autopowerup or autopowerdown conditions change. See REFBIAS_PWD_SEL, REFBIAS_PWD, PLL_REG_ENABLE, and MISC2_CONTROL0 to understand their influence on the USB PLL behavior and operation of its bias circuits. 0b - Power down 1b - Allow powerup
11 —	The value of this reserved bit must remain 0b.
10 —	The value of this reserved bit must remain 0b.
9 —	The value of this reserved bit must remain 0b.
8 —	The value of this reserved bit must remain 0b.
7 —	The value of this reserved bit must remain 0b.
6 PLL_EN_USB_CLKS	PLL Multi-Phase Clock Outputs Enable Enables the 480 MHz multiple-phase clock outputs from the USB PLL to the UTMI logic and HS RX data recovery circuits. This field works with MISC2_CONTROL0 to perform a PLL operation. You must power up the USB PLL by using PLL_POWER first, before the clock outputs are enabled using this field. 0b - Disable 1b - Enable
5	Miscellaneous Control

Table continues on the next page...

Table continued from the previous page...

Field	Function
MISC2_CONTROL0	Determines USB PLL operation status during the Suspend state. This field, together with PLL_POWER, determines when USBPHY's 480 MHz PLL is powered up. When this field is 0, the PLL is powered up depending on whether PLL_POWER is 1. When MISC2_CONTROL0 is 1, the PLL is powered up if PLL_SIC[PLL_POWER] is 1 and the value of CTRL[UTMI_SUSPENDM] from the USB controller is 1, but PLL is powered down when in the Suspend bus state, if CTRL[UTMI_SUSPENDM] is 0. For the CLN40ULP PHY, it is recommended to write 1 to this field together with writing 0 to REFBIAS_PWD and writing 1 to REFBIAS_PWD_SEL to allow automatic power control when USBPHY is entering and leaving the Suspend bus state. 0b - Power up PLL 1b - Power down PLL
4-2 —	The value of this reserved bit must remain 000b.
1 —	The value of this reserved bit must remain 0b.
0 —	The value of this reserved bit must remain 0b.

62.7.11 VBUS Detect (USB1_VBUS_DETECT)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
USB1_VBUS_DETECT	C0h	VBUS Detect
USB1_VBUS_DETECT_SET	C4h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_VBUS_DETECT is 1
USB1_VBUS_DETECT_CLR	C8h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_VBUS_DETECT is 0
USB1_VBUS_DETECT_TOG	CCh	Writing 1 to a bit in this register inverts the value of the corresponding bit in USB1_VBUS_DETECT

Function

Defines controls for several methods of USB VBUS detection and some additional out-of-band signaling functions.

Diagram

Fields

Field	Function
31 —	Reserved
30-28 —	Reserved
27 —	Reserved
26 DISCHARGE_VBUS	VBUS Discharge Resistor Enables (controls) a nominal 22 kΩ resistor between the USB1_VBUS pin and ground. You can use this field to accelerate the fall of the VBUS signal at the end of a session. 0b - Disable 1b - Enable
25-23 —	Reserved
22-20 VBUSVALID_PWRUP_CMPS	VBUS_VALID Comparator Enable Enables (powerups) the VBUS detection comparators. There are three different VBUS detection comparators or detectors included in USBPHY. This field allows any combination of those circuits to be enabled or powered down. Usually, not all of the VBUS detection methods are needed for a particular use case. The USB software stack must reset the individual fields to 0 for any VBUS detection methods that are not used to save power. To understand how to configure the VBUS detection comparators and observe their results, see the other fields in VBUS Detect (USB1_VBUS_DETECT) and VBUS Detect Status (USB1_VBUS_DET_STAT). Bit 20 of this field controls the VBUS_VALID comparator that is often used in Host mode. Bit 21 of this field controls the session valid detector that is often used in Device mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Bit 22 of this field controls the VBUS_VALID_3V detector that you can use in Host mode if a nonstandard VBUS voltage signal is connected to the USB1_VBUS pin. 0xxb - Disable or power down the VBUS_VALID_3V detector 1xxb - Enable the VBUS_VALID_3V detector x0xb - Disable or power down the session valid detector x1xb - Enable the session valid detector xx0b - Disable or power down the VBUS_VALID comparator xx1b - Enable the VBUS_VALID comparator
19 — 	Reserved
18 VBUSVALID_TO_B	VBUS_VALID Comparator Selection Selects the comparator used for VBUS_VALID. This field helps you select, between the VBUS_VALID comparator and session valid detector, the comparator used to report the VBUS_VALID results in USB1_VBUS_DET_STAT[VBUS_VALID]. The VBUS_VALID comparator is the most accurate and has a programmable threshold that VBUSVALID_THRESH defines. The session valid detector may be useful in systems using nonstandard VBUS voltages. The mux selection using this field happens before any VBUS_VALID selection controlled by VBUS_SOURCE_SEL and VBUSVALID_SEL, and it has an impact only if the VBUS overrides are not enabled and USB1_VBUS_DETECT[VBUSVALID_SEL] is 0. If this field is 0, use the VBUS_VALID comparator for the VBUS_VALID results. If this field is 1, use the session valid detector for the VBUS_VALID results. The session valid threshold is ≥ 0.8 V and ≤ 4.0 V. 0b - VBUS_VALID comparator 1b - Session valid detector
17-15 — 	Reserved
14 EXT_VBUS_OVERRIDE_EN	External VBUS Override Enable Enables the external VBUS override using a value supplied from outside USBPHY. USBPHY has an input to allow VBUS detection status to be supplied from an external digital signal in use cases where the USBPHY's internal detection method or software local overrides are not used. The connection of this external VBUS signal is chip-specific. When this field is 0, the VBUS status signals reported in USB1_VBUS_DET_STAT[VBUS_VALID], USB1_VBUS_DET_STAT[AVALID], USB1_VBUS_DET_STAT[BVALID], and USB1_VBUS_DET_STAT[SESSEND] and the VBUS_VALID,

Table continues on the next page...

Table continued from the previous page...

Field	Function
	AVALID, BVALID, and SESSEND signals are sent to the USB controller. The VBUS detection method configuration determines this, as described for other fields in this register, including VBUS_OVERRIDE_EN. When this field is 1, the VBUS status signals reported in USB1_VBUS_DET_STAT[VBUS_VALID], USB1_VBUS_DET_STAT[AVALID], and USB1_VBUS_DET_STAT[BVALID] and the VBUS_VALID, AVALID, and BVALID signals sent to the USB controller reflect the value on the external VBUS override signal. The VBUS status signal reported in USB1_VBUS_DET_STAT[SESSEND] and the SESSEND signal sent to the USB controller reflect the inverse of the value on the external VBUS override signal. 0b - Internal detector or local override 1b - External VBUS_VALID value
13 EXT_ID_OVERRIDE_EN	External ID Override Enable Enables the external ID pin status override using a value supplied from outside USBPHY. USBPHY has an input to allow OTG ID pin detection status to be supplied from an external digital signal in use cases where the USBPHY's internal detector methods or software local override are not used. The connection of this external ID pin status signal is chip-specific. When this field is 0, the ID pin status signal reported in STATUS[OTGID_STATUS] and the IDDIG signal sent to the USB controller are determined by the USBPHY's ID pin detection method or the local override value that ID_OVERRIDE and ID_OVERRIDE_EN configure. When this field is 1, the ID pin status signal reported in the following fields, along with the IDDIG signal sent to the USB controller, reflect the value of the external ID pin signal: • STATUS[OTGID_STATUS] • USB1_VBUS_DET_STAT[EXT_ID] 0b - Internal detector or local override 1b - External ID signal value
12 ID_OVERRIDE	ID Pin Status Local Override Specifies the ID pin status local override value. If the USB use case does not use USBPHY's dedicated USB_ID detection pin, this field provides an alternate method to reflect the ID pin status. If ID_OVERRIDE_EN is 1 and EXT_ID_OVERRIDE_EN is 0, then the value written in this field is used for the IDDIG signal and also reported in STATUS[OTGID_STATUS]. This field has no impact if either ID_OVERRIDE_EN or EXT_ID_OVERRIDE_EN is 0. See STATUS[OTGID_STATUS] to understand the state assignment convention of the ID pin value.
11 ID_OVERRIDE_EN	Enable Local ID Pin Status Override Enables (allows) local ID pin status override. If the USB use case does not use USBPHY's dedicated USB_ID detection pin, this field enables an alternate method to reflect the ID pin status. When this field is 1, the value of ID_OVERRIDE is used for the reported ID pin status. This field has an impact only if EXT_ID_OVERRIDE_EN is 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Use ID pin detector or external override 1b - Allow local override of ID pin detection status
10-9 VBUS_SOURCE_SEL	VBUS_VALID Source Selection Selects the source of the VBUS_VALID signal reported to the USB subsystem. If this field is 0, use the VBUS_VALID comparator results for the signal reported to the USB subsystem. If this field is 1 or 10, use the session valid comparator results for the signal reported to the USB subsystem. This is one of the fields that selects the source of the VBUS_VALID signal output from USBPHY for the rest of the USB subsystem. The way the output signal is connected to other portions of the USB subsystem, including the USB controller, is chip-specific. The VBUS_VALID source selections in this field takes effect only if VBUSVALID_SEL, VBUS_OVERRIDE_EN, and EXT_VBUS_OVERRIDE_EN are 0. This field does not impact the VBUS_VALID value reported in USB1_VBUS_DET_STAT[VBUS_VALID]. 00b - VBUS_VALID comparator result 01b - Session valid comparator result 10b - Session valid comparator result 11b - Reserved
8 VBUSVALID_SEL	VBUS_VALID Selection Selects the source of the VBUS_VALID signal reported to the USB subsystem. If this field is 0, use the VBUS_VALID comparator results for the signal reported to the USB subsystem. If this field is 1, use the VBUS_VALID_3V comparator results for the signal reported to the USB subsystem. This is one of the fields that selects the source of the VBUS_VALID signal output from USBPHY for the rest of the USB subsystem. The way the output signal is connected to other portions of the USB subsystem, including the USB controller is, chip-specific. The VBUS_VALID source selection in this field takes effect only if VBUS_OVERRIDE_EN and EXT_VBUS_OVERRIDE_EN are 0. This field does not impact the VBUS_VALID value reported in USB1_VBUS_DET_STAT[VBUS_VALID]. 0b - VBUS_VALID comparator result 1b - VBUS_VALID_3V comparator result
7 VBUSVALID_OVERRIDE	Override Value for the VBUS_VALID Signal Provides a value for the VBUS_VALID signal output from USBPHY to the rest of the USB subsystem if VBUS_OVERRIDE_EN is 1 and EXT_VBUS_OVERRIDE_EN is 0. The way the output signal is connected to other portions of the USB subsystem, including the USB controller, is chip-specific. The value of this field does not affect the VBUS_VALID value reported in USB1_VBUS_DET_STAT[VBUS_VALID].
6	Override Value for A-Device Session Valid

Table continues on the next page...

Table continued from the previous page...

Field	Function
AVALID_OVERRIDE	Provides the value for USB1_VBUS_DET_STAT[AVALID] and the UTMI AVALID signal output from USBPHY to the USB controller if VBUS_OVERRIDE_EN is 1 and EXT_VBUS_OVERRIDE_EN is 0.
5 BVALID_OVERRIDE	Override Value for B-Device Session Valid Provides the value for USB1_VBUS_DET_STAT[BVALID] and the UTMI BVALID signal output from USBPHY to the USB controller if VBUS_OVERRIDE_EN is 1 and EXT_VBUS_OVERRIDE_EN is 0.
4 SESSEND_OVERRIDE	Override Value for SESSEND Provides the value for USB1_VBUS_DET_STAT[SESSEND] and the UTMI SESSEND signal output from USBPHY to the USB controller if VBUS_OVERRIDE_EN is 1 and EXT_VBUS_OVERRIDE_EN is 0.
3 VBUS_OVERRIDE_EN	VBUS Detect Signal Local Override Enable Allows you to override the results from the VBUS_VALID and session valid comparators using the values in VBUSVALID_OVERRIDE, AVALID_OVERRIDE, BVALID_OVERRIDE, and SESSEND_OVERRIDE. This field has an impact only when EXT_VBUS_OVERRIDE_EN is 0. If this field is 0, use the results of the internal VBUS_VALID and session valid comparators for VBUS_VALID, AVALID, BVALID, and SESSEND. If this field is 1, use the override values for VBUS_VALID, AVALID, BVALID, and SESSEND. The VBUS_VALID, AVALID, BVALID, and SESSEND signals sent from USBPHY to the USB controller are affected by these bit selections. The values reported for VBUSVALID_OVERRIDE, AVALID_OVERRIDE, BVALID_OVERRIDE, and SESSEND_OVERRIDE are also affected, but the value of USB1_VBUS_DET_STAT[VBUS_VALID_3V] is not affected. This override method may be useful if VBUS detection is not done by using USBPHY's internal VBUS_VALID or session valid comparators. 0b - Results of VBUS_VALID and session valid comparators for VBUS_VALID, AVALID, BVALID, and SESSEND 1b - Override values for VBUS_VALID, AVALID, BVALID, and SESSEND
2-0 VBUSVALID_THRESH	VBUS Comparator Threshold Sets the threshold for the VBUS_VALID comparator, which is the most accurate method to determine the presence of a 5 V VBUS connection and includes hysteresis to minimize the need for software debounce of the detection. This comparator has ~50 mV of hysteresis to prevent chattering at the comparator trip point. 000b - 4.0 V 001b - 4.1 V 010b - 4.2 V 011b - 4.3 V 100b - 4.4 V 101b - 4.5 V 110b - 4.6 V

62.7.12 VBUS Detect Status (USB1_VBUS_DET_STAT)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

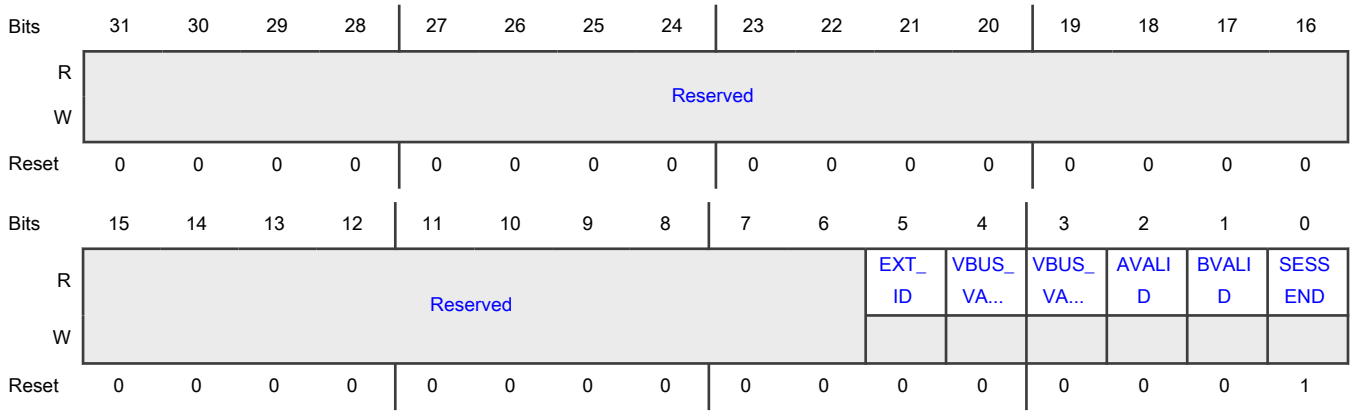
Register	Offset	Description
USB1_VBUS_DET_STAT	D0h	VBUS Detect Status
USB1_VBUS_DET_STAT_SET	D4h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_VBUS_DET_STAT is 1
USB1_VBUS_DET_STAT_CLR	D8h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_VBUS_DET_STAT is 0
USB1_VBUS_DET_STAT_TOG	DCh	Writing 1 to a bit in this register inverts the value of the corresponding bit in USB1_VBUS_DET_STAT

Function

Allows observation of status for several different types of USB VBUS detect functions.

This register also has a field to observe the external override signal for the OTG ID pin status.

Diagram



Fields

Field	Function
31-6	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
5 EXT_ID	OTG ID External Override Status Reflects the value of the ID pin status for the external override input to USBPHY. This value is only valid when USB1_VBUS_DETECT[EXT_ID_OVERRIDE_EN] is 1. Because the function of this field is limited, it may be more useful to observe the ID pin status using CTRL[OTG_ID_VALUE] or STATUS[OTGID_STATUS] instead. To understand the state assignment convention of the ID pin value, see STATUS[OTGID_STATUS].
4 VBUS_VALID_3V	VBUS_VALID_3V Detector Status Reflects the output of USBPHY's VBUS_VALID_3V detector when USB1_VBUS_DETECT[VBUSVALID_PWRUP_CMPS] enables that detector. You cannot override this value. If this field is 0, the VBUS voltage is below the VBUS_VALID_3V threshold. If this field is 1, the VBUS voltage is above the VBUS_VALID_3V threshold. The internal VBUS_VALID_3V detector in USBPHY has a lower threshold for the voltage on the USB1_VBUS pin than either the session valid detector or the VBUS_VALID comparator. This signal may be useful for applications that provide a nonstandard VBUS voltage to USBPHY. 0b - Below threshold 1b - Above threshold
3 VBUS_VALID	VBUS Voltage Status Indicates the result of USBPHY's internal VBUS_VALID detection for the USB1_VBUS pin or external VBUS_VALID override. If this field is 0, the VBUS voltage is below the comparator threshold. If this field is 1, the VBUS voltage is above the comparator threshold. USB1_VBUS_DETECT[VBUSVALID_TO_B] selects the VBUS_VALID comparator used. The values of USB1_VBUS_DETECT[VBUSVALID_OVERRIDE] and USB1_VBUS_DETECT[VBUS_OVERRIDE_EN] do not affect the VBUS_VALID status reported, but you can overwrite it if USB1_VBUS_DETECT[EXT_VBUS_OVERRIDE_EN] is 1. The detection method used for VBUS_VALID in this status field depends on the value of USB1_VBUS_DETECT[VBUSVALID_TO_B]. 0b - Below threshold 1b - Above threshold
2 AVALID	A-Device Session Valid Status Reflects the output of the session valid detector in USBPHY when USB1_VBUS_DETECT[VBUSVALID_PWRUP_CMPS] enables that detector and you cannot override the value. If this field is 0, the VBUS voltage is below the session valid threshold.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 1, the VBUS voltage is above the session valid threshold. For local overrides, you can overwrite this field using USB1_VBUS_DETECT[VBUS_OVERRIDE_EN] and USB1_VBUS_DETECT[AVALID_OVERRIDE]. Besides, for external overrides, overwrite this field using USB1_VBUS_DETECT[EXT_VBUS_OVERRIDE_EN] and the external VBUS_VALID override input signal to USBPHY. 0b - Below threshold 1b - Above threshold
1 BVALID	B-Device Session Valid Status Reflects the output of the session valid detector in USBPHY when USB1_VBUS_DETECT[VBUSVALID_PWRUP_CMPS] enables that detector and you cannot override the value. If this field is 0, the VBUS voltage is below the session valid threshold. If this field is 1, the VBUS voltage is above the session valid threshold. For local overrides, you can overwrite this field using USB1_VBUS_DETECT[VBUS_OVERRIDE_EN] and USB1_VBUS_DETECT[BVALID_OVERRIDE]. Besides, for external overrides, overwrite this field using USB1_VBUS_DETECT[EXT_VBUS_OVERRIDE_EN] and the external VBUS_VALID override input signal to USBPHY. 0b - Below threshold 1b - Above threshold
0 SESSEND	Session End Indicator Reflects the inverse of the output of the session valid detector in USBPHY when USB1_VBUS_DETECT[VBUSVALID_PWRUP_CMPS] enables that detector and you cannot override the value. If this field is 0, the VBUS voltage is below the session valid threshold. If this field is 1, the VBUS voltage is above the session valid threshold. For local overrides, you can overwrite this field using USB1_VBUS_DETECT[VBUS_OVERRIDE_EN] and USB1_VBUS_DETECT[SESSEND_OVERRIDE]. Besides, for external overrides, overwrite this field using USB1_VBUS_DETECT[EXT_VBUS_OVERRIDE_EN] and the external VBUS_VALID override input signal to USBPHY. 0b - Above threshold 1b - Below threshold

62.7.13 Charger Detect (USB1_CHRG_DETECT)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
USB1_CHRG_DETECT	E0h	Charger Detect
USB1_CHRG_DETECT_SET	E4h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_CHRG_DETECT is 1
USB1_CHRG_DETECT_CLR	E8h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_CHRG_DETECT is 0
USB1_CHRG_DETECT_TOG	ECh	Writing 1 to a bit in this register inverts the value of the corresponding bit in USB1_CHRG_DETECT

Function

Enables USB battery charging (BC) v1.2 functions, including device mode charger detection and host mode charging port advertisement. You can control several of the USBPHY analog circuits for BC v1.2 functions by either using this register or the embedded USBHSDCD module, which has autosequencing state machines and a separate register space.

You must first enable USBPHY's main reference bias circuits for BC v1.2 functions by using either of the control methods (see MISC[REFBIAS_PWD] and MISC[REFBIAS_PWD_SEL]).

See the "USB High-Speed Device Charger Detection (USBHSDCD)" chapter for USBHSDCD module operation.

Fields

Field	Function
31 DCDSEL	DCD Selection Selects the control source for battery charging detection and advertisement circuits. If this field is 0, Charger Detect (USB1_CHRG_DETECT) controls the BC 1.2 functionality. If this field is 1, fields and state machines in the USBHSDCD module control the BC 1.2 functionality. You can control several of the USBPHY analog circuits associated with the USB BC v1.2 functions by either using control fields in this register or by using registers in the USBHSDCD module. Use of USBHSDCD is recommended for software simplification, for device mode charger detection because USBHSDCD can autosequence through the detection states. The USBHSDCD module is also recommended if charging port host advertisement is needed with this USBPHY.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Fields in USB1_CHRG_DETECT 1b - Fields and state machines in the USBHSDCD module
30-24 —	Reserved
23 —	Do not change the value of this field without a specific recommendation from NXP.
22-21 —	Reserved
20 EN_B	Selection of BC v1.2 Function Enable Enables the selection of the BC v1.2 functions depending on other fields. If this field is 0, the BC v1.2 functions, when controlled by this register, are enabled. If this field is 1, the BC v1.2 functions, when controlled by this register, are disabled. This field serves as a qualifier for CHK_CHRG_B, CHK_CONTACT, and DETECT_SEC when DCDSEL is 0. You must disable the charger detection operation prior to the start of a normal USB data communication. 0b - Enable 1b - Disable
19 CHK_CHRG_B	BC Charger Detection Function Enable Enables the BC v1.2 primary detection function for charger detect depending on other fields. If this field is 0, the BC charger detection functions, when controlled by this register, are enabled. If this field is 1, the BC charger detection functions, when controlled by this register, are disabled. A device uses primary detection to distinguish whether it is connected to a standard downstream port or a charging port. This field has an impact only when both DCDSEL and EN_B are 0. The results of this detection are observed in USB1_CHRG_DET_STAT[CHRG_DETECTED]. 0b - Enable 1b - Disable
18 CHK_CONTACT	BC Data Contact Detect Function Enable Enables the BC v1.2 data contact detect function for charger detect depending on other fields. If this field is 0, the BC data contact detect functions, when controlled by this register, are disabled. If this field is 1, the BC data contact detect functions, when controlled by this register, are enabled. A device uses the BC v1.2 method of data contact detection to discover attachment to a host port or dedicated charging port.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field has an impact only when both DCDSEL and EN_B are 0. The results of this detection are observed in USB1_CHRG_DET_STAT[PLUG_CONTACT]. 0b - Disable 1b - Enable
17-5 —	Reserved
4 VDM_SRC_ENABLE	VDM_SRC Function Enable Enables the BC v1.2 charging downstream port (CDP) advertisement signaling for charger detect depending on other fields. If this field is 0, the CDP advertisement signaling VDM_SRC functions, when controlled by this register, are disabled. If this field is 1, the CDP advertisement signaling VDM_SRC functions, when controlled by this register, are enabled. You must only use this signaling in embedded host mode according to the BC v1.2 specification. This field only affects when DCDSEL, EN_B, and DETECT_SEC are 0, and CHK_CHRG_B is 1. 0b - Disable 1b - Enable
3 —	The value of this reserved bit must remain 0b.
2 PULLUP_DP	DP Pullup Resistor Enable Override Control Enables the pullup resistor on the USB_DP pin required for FS Device mode operation, which is normally controlled using the UTMI bus signals sent to USBPHY from the USB controller. If this field is 0, the DP pullup resistor is controlled only with UTMI bus signals. If this field is 1, the DP pullup resistor is force enabled. If this field is 1, the pullup resistor is enabled independently of the UTMI signals to USBPHY. The USB software stack uses this capability during charger type detection, according to the obsolete *USB Battery Charging Specification, Revision 1.1*. For *USB Battery Charging Specification, Revision 1.2* detection and normal USB data communication, this field must remain 0. 0b - Disable 1b - Enable
1 DETECT_SEC	Secondary Detection Function Enable Enables the BC v1.2 secondary detection function for charger detect depending on other fields. If this field is 0, the BC secondary detection functions, when controlled by this register, are disabled. If this field is 1, the BC secondary detection functions, when controlled by this register, are enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	After a device determines that it is connected to a charging port during primary detection, you can use secondary detection to determine whether the remote port is a charging downstream port or a dedicated charging port. This field has an impact only when DCDSEL and EN_B are 0. The results of this detection are observed in USB1_CHRG_DET_STAT[SECDET_DCP]. 0b - Disable 1b - Enable
0 —	The value of this reserved bit must remain 0b to avoid interference with USB battery charging detection.

62.7.14 Charger Detect Status (USB1_CHRG_DET_STAT)

Offset

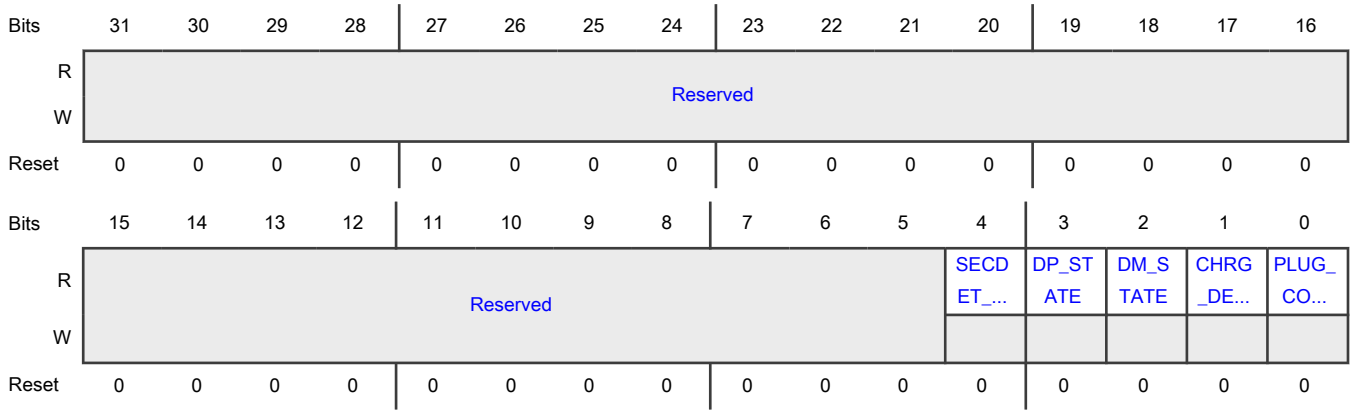
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
USB1_CHRG_DET_STAT	F0h	Charger Detect Status
USB1_CHRG_DET_STAT_SET	F4h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_CHRG_DET_STAT is 1
USB1_CHRG_DET_STAT_CLR	F8h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_CHRG_DET_STAT is 0
USB1_CHRG_DET_STAT_TOG	FCh	Writing 1 to a bit in this register inverts the value of the corresponding bit in USB1_CHRG_DET_STAT

Function

Allows observation of status for USB charger detection functions.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 SECDET_DCP	Battery Charging Secondary Detection Phase Output Indicates the type of charging port (charging downstream port (CDP) or downstream charging port (DCP)) detected during the secondary detection phase, according to *USB Battery Charging Specification, Revision 1.2*, using either Charger Detect (USB1_CHRG_DETECT) or the USBHSDCD module. 0b - CDP detected 1b - DCP detected
3 DP_STATE	DP Voltage Indicates the single-ended receiver output from charger detection circuits for the USB_DP pin. 0b - USB_DP pin voltage is ≤ 0.8 V 1b - USB_DP pin voltage is ≥ 2.0 V
2 DM_STATE	DM Voltage Indicates the single-ended receiver output from charger detection circuits for the USB_DM pin. 0b - USB_DM pin voltage is ≤ 0.8 V 1b - USB_DM pin voltage is ≥ 2.0 V
1 CHRG_DETECTED	Battery Charging Primary Detection Phase Output Indicates whether a standard downstream port (SDP) or a charging port is detected during the USB battery charging primary detection phase using either Charger Detect (USB1_CHRG_DETECT) or the USBHSDCD module. If a charging port is detected, this field reverts to 0 when primary detection ends and secondary detection starts. 0b - SDP detected

	1b - Charging port detected
0 PLUG_CONTACT	Battery Charging Data Contact Detection Phase Output Indicates whether an attached USB cable is detected between the remote host and the local device during the data contact detection phase, according to *USB Battery Charging Specification, Revision 1.2*, using either Charger Detect (USB1_CHRG_DETECT) or the USBHSDCD module. 0b - Not detected 1b - Detected

62.7.15 Analog Control (ANACTRL)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
ANACTRL	100h	Analog Control
ANACTRL_SET	104h	Writing 1 to a bit in this register ensures that the corresponding bit in ANACTRL is 1
ANACTRL_CLR	108h	Writing 1 to a bit in this register ensures that the corresponding bit in ANACTRL is 0
ANACTRL_TOG	10Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in ANACTRL

Function

Includes fields for:

- Analog control functions.
- Enabling the host pulldowns on the USB_DP and USB_DM pins when not in Host mode.
- Allowing control of an LVI detector.
- Configuring the PFD clock output. The PFD input clock comes from the 480 MHz USB PLL, and you use the PFD output clock (pfd_clk) to generate the USB1PFDCLK for use outside USBPHY.

Field	Function
3-2 PFD_CLK_SEL	PFD Clock Selection Selects the frequency relationship between the local pfd_clock and USB1PFDCLK outputs exported from USBPHY. See PFD A (PFDA) for other configuration information for the PFD clock. If this field is 00b, USB1PFDCLK has the same frequency as the USB PLL reference clock. If this field is 01b, the USB1PFDCLK frequency is pfd_clk divided by 4. If this field is 10b, the USB1PFDCLK frequency is pfd_clk divided by 2. If this field is 11b, USB1PFDCLK is the same as the pfd_clk frequency. 00b - USB1PFDCLK = USB PLL reference clock 01b - USB1PFDCLK = pfd_clk ÷ 4 10b - USB1PFDCLK frequency = pfd_clk ÷ 2 11b - USB1PFDCLK = pfd_clk
1 LVI_EN	Internal Low Voltage Detector Enable Enables an internal low-voltage detector for USBPHY's 3.3 V and 1.8 V power inputs. The low-voltage detector is used for status monitoring and isolation logic. See STATUS[OK_STATUS_3V] for more information. Writing 1 to this field enables this low-voltage detector. **NOTE** You must write 1 to this field for the CLN40ULP PHY. 0b - Disable 1b - Enable
0 —	The value of this reserved bit must remain 0b.

62.7.16 Trim (TRIM_OVERRIDE_EN)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
TRIM_OVERRIDE_EN	130h	Trim
TRIM_OVERRIDE_EN_SET	134h	Writing 1 to a bit in this register ensures that the corresponding bit in TRIM_OVERRIDE_EN is 1
TRIM_OVERRIDE_EN_CLR	138h	Writing 1 to a bit in this register ensures that the corresponding bit in TRIM_OVERRIDE_EN is 0
TRIM_OVERRIDE_EN_TOG	13Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in TRIM_OVERRIDE_EN

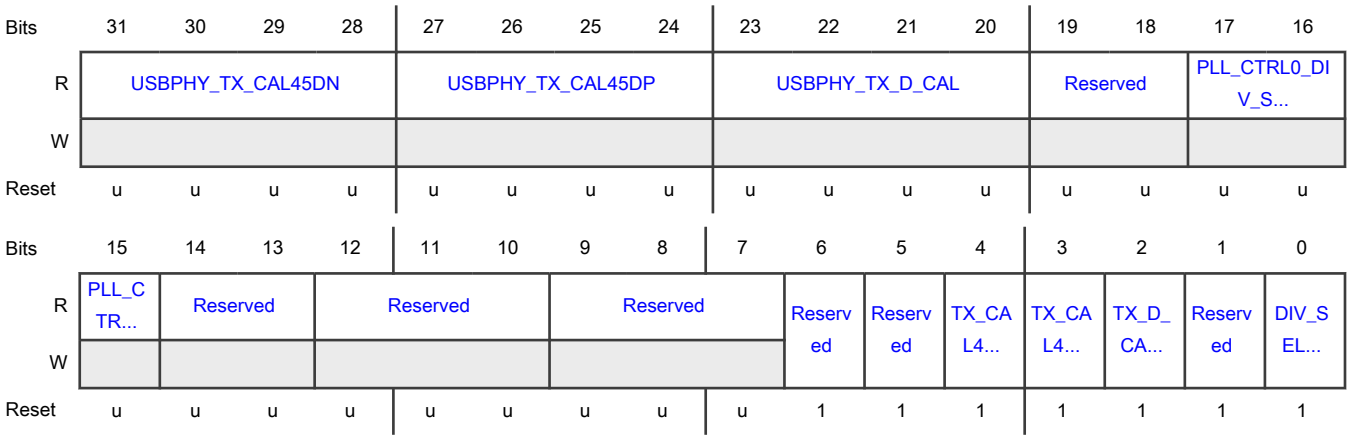
Function

Allows observation of the default nonvolatile settings of USBPHY parameter controls for USBPHY_TX_CAL45DN, USBPHY_TX_CAL45DP, USBPHY_TX_D_CAL, and PLL_CTRL0_DIV_SEL.

Additional fields also determine whether those values are overridden by using the settings defined in USBPHY's TX Control (TX) and PLL SIC (PLL_SIC). The default behavior is to use the values in TX Control (TX) and PLL SIC (PLL_SIC) instead of this register.

The method used to load the read-only values into this register during reset and boot is chip-specific. The values observed in the read-only fields after boot may vary from the reset values shown.

Diagram



Fields

Field	Function
31-28 USBPHY_TX_CAL45DN	DM Series Termination Resistance Trim Bits from Outside USBPHY Decodes to trim the nominal 45 Ω series termination resistance to the USB_DM output pin, with values loaded using signals outside USBPHY. When TX_CAL45DM_OVERRIDE is 1, the values in this field are used to trim the termination resistance. When TX_CAL45DM_OVERRIDE is 0, the resistance trim values in USBPHY_TX_CAL45DN are used instead. The methods used to load the read-only values into this field during reset and boot are chip-specific. Maximum resistance is at value 0000b, minimum resistance is at value 1111b, and resistance is centered at value 0111b. For this USBPHY, each incrementally increasing trim value decreases the target resistance by about 3.5% compared to the next lower value. Trimming this resistance impacts both the overshoot and undershoot of the FS TX output and the amplitude of the HS TX output. The methods used to load the read-only values into this register during reset and boot are chip-specific.
27-24 USBPHY_TX_CAL45DP	DP Series Termination Resistance Trim Bits from Outside USBPHY Decodes to trim the nominal 45 Ω series termination resistance to the USB_DP output pin, with values loaded using signals outside USBPHY. When TX_CAL45DP_OVERRIDE is 1, the values in this field are used to trim the termination resistance. When TX_CAL45DP_OVERRIDE is 0, the resistance trim values in USBPHY_TX_CAL45DP are used instead. The methods used to load the read-only values into this field during reset and boot are chip-specific.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Maximum resistance is at value 0000b, minimum resistance is at value 1111b, and resistance is centered at value 0111b. For this USBPHY, each incrementally increasing trim value decreases the target resistance by about 3.5% compared to the next lower value. Trimming this resistance impacts both the overshoot and undershoot of the FS TX output and the amplitude of the HS TX output.
23-20 USBPHY_TX_D_CAL	HS TX Output Current Trim Bits from Outside USBPHY Decodes to trim the nominal 17.78 mA current source for the HS TX drivers on USB_DP and USB_DM, with values loaded using signals from outside USBPHY. This output current is directly proportional to the amplitude of the HS TX eye diagram. When TX_D_CAL_OVERRIDE is 1, the values in this field are used to trim the output current. When TX_D_CAL_OVERRIDE is 0, the current trim values in TX[D_CAL] are used instead. The methods used to load the read-only values into this field during reset and boot are chip-specific. 0000b - Maximum current, approximately 19% above nominal 0111b - Nominal 1111b - Minimum current, approximately 19% below nominal
19-18 —	The values observed for this field may vary.
17-15 PLL_CTRL0_DIV_SEL	PLL Divider Value Configuration Bits from Outside USBPHY Controls the USB PLL feedback loop divider and allows the use of different frequency signals for the PLL reference clock input connected to the OSCCLK signal from the system oscillator, with values loaded from outside USBPHY. USBPHY's PLL produces a 480 MHz output clock. When DIV_SEL_OVERRIDE is 1, the values in this field are used to control the PLL divider. When DIV_SEL_OVERRIDE is 0, the PLL divider values in PLL_SIC[PLL_DIV_SEL] are used instead. See the field value descriptions for PLL_SIC[PLL_DIV_SEL] to understand the available input frequency settings. The methods used to load the read-only values into this field during reset and boot are chip-specific. The input clock frequency used for the PLL reference clock input is the output of the pre-divider stage controlled by PLL_SIC[PLL_PREDIV] bit field. For most SOCs the pre-divider would not be enabled but this feature might be used if an SOC had a very high frequency but still stable system reference clock.
14-13 —	The values observed for this field may vary.
12-10 —	The values observed for this field may vary.
9-7 —	Reserved
6	The value of this reserved bit must remain 1b.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
5 —	The value of this reserved bit must remain 1b.
4 TX_CAL45DM_OVERRIDE	Override Enable for USB_DM Series Termination Trim Determines whether the values of USBPHY_TX_CAL45DN or TX[TXCAL45DN] are used for the DM output resistance adjustment. If this field is 0, use the values from Trim (TRIM_OVERRIDE_EN) for the bandgap voltage trim. If this field is 1, use the values of TX Control (TX) for DM resistance trim. 0b - TRIM_OVERRIDE_EN 1b - TX
3 TX_CAL45DP_OVERRIDE	Override Enable for USB_DP Series Termination Trim Determines whether the values of USBPHY_TX_CAL45DP or TX[TXCAL45DP] are used for the DP output resistance adjustment. If this field is 0, use the values from Trim (TRIM_OVERRIDE_EN) for DP resistance trim. If this field is 1, use the values of TX Control (TX) for DP resistance trim. 0b - TRIM_OVERRIDE_EN 1b - TX
2 TX_D_CAL_OVERRIDE	Override Enable for HS TX Output Current Trim Determines whether the values of USBPHY_TX_D_CAL or TX[D_CAL] are used for the HS TX current adjustment. If this field is 0, use the values from Trim (TRIM_OVERRIDE_EN) for DP resistance trim. If this field is 1, use the values of TX Control (TX) for DP resistance trim. 0b - TRIM_OVERRIDE_EN 1b - TX
1 —	The value of this reserved bit must remain 1b.
0 DIV_SEL_OVERRIDE	Override Enable for PLL Divider Value Determines whether the values of PLL_CTRL0_DIV_SEL or PLL_SIC[PLL_DIV_SEL] are used for the USB PLL feedback loop divider. If this field is 0, use the values from Trim (TRIM_OVERRIDE_EN) for the PLL divider value. If this field is 1, use the values of PLL SIC (PLL_SIC) for the PLL divider value. 0b - TRIM_OVERRIDE_EN 1b - PLL_SIC

62.7.17 PFD A (PFDA)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
PFDA	140h	PFD A
PFDA_SET	144h	Writing 1 to a bit in this register ensures that the corresponding bit in PFDA is 1
PFDA_CLR	148h	Writing 1 to a bit in this register ensures that the corresponding bit in PFDA is 0
PFDA_TOG	14Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in PFDA

Function

Includes fields for the PFD output clock.

The PFD input clock comes from the 480 MHz USB PLL, and uses the PFD output clock (pfd_clk) to generate USB1PFDCLK for use outside USBPHY.

There is 1 set of PFD controls and PFD output clock on this chip.

ANACTRL[PFD_CLK_SEL] affects the PFD output clock behavior.

To configure the PFD clock:

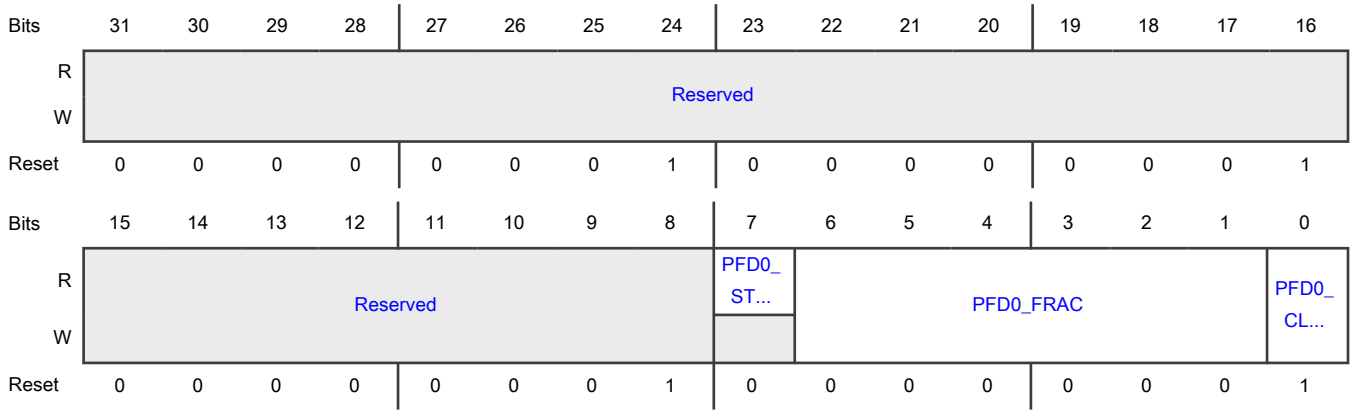
1. Wait until PLL_SIC[PLL_LOCK] becomes 1.
2. Configure ANACTRL[PFD_CLK_SEL] to select the PFD clock source.
3. Configure PFD*x*_FRAC to select the PFD clock frequency.
4. Write 0 to PFD*x*_CLKGATE to ungate the PFD clock.
5. Wait until PFD*x*_STABLE becomes 1.

Now you can use the PFD clock for system functions.

NOTE

If you want to change the value of PFD*x*_FRAC, gate the PFD clock (write 1 to PFD*x*_CLKGATE) and reset the PLL, that is, write 0 to PLL_SIC[PLL_POWER] and then write 1 to it again. After the reset, follow the aforementioned steps to reconfigure PFD*x*_FRAC.

Diagram



Fields

Field	Function
31-8 —	Reserved
7 PFD0_STABLE	PFD0 Stable Signal Allows PFD output clock frequency changes without forcing the relock of the USBPHY PLL. This field has an initial value of 0 after reset and transitions to a value of 1, indicating that the PFD clocks have stabilized following a logic path-settling interval after PFD0_FRAC is updated to change the fractional divider value. The value of this field continues to invert each time PFD0_FRAC is changed without resetting the PLL. This is a debug and diagnostic field that must not be used in the USB software stack because the PFD clock output becomes stable very quickly after the fractional divider value is changed. 0b - Not stable 1b - Stable
6-1 PFD0_FRAC	PFD0 Fractional Divider Selects the pfd_clk output frequency. Changing this field causes pfd_update to be toggled. The pfd_clk output frequency is: 480 MHz × 18 ÷ *n*, where *n* = 18–35 Valid values of PFD0_FRAC range from 0010_0110_1010b to 0010_0111_1011b; other values may cause undefined results.
0 PFD0_CLKGATE	PFD0 Clock Gate Controls clock gating (disabling) for the PFD pfd_clk output for power savings when the PFD is not used. Write 1 to this field to gate the output of the PFD. If the PFD reference clock is not stable, the USB PLL is not locked, or the USB PLL is not enabled, this gating is also enabled. This field must be reset to 0 to enable the specified pfd_clk output. 0b - Enable 1b - Disable

62.8 Register macro usage

A read-modify-write (RMW) operation involves updating one field without disturbing the contents of the remaining fields in the register. In this operation, the CPU reads the register, modifies the target field, and then writes the results back to the register. Because of the initial register read, this is an expensive operation in terms of CPU cycles.

To address this issue, you can implement some USBPHY registers as a group, including registers that can be used to either set, clear, or toggle (SCT) individual fields of the primary register. When writing to an SCT register, all fields that are 1 perform the associated operation on the primary register, while all fields that are 0 are not affected. The SCT registers always read back 0 and must have the write-only access type. If the primary register is read-only, you cannot implement SCT registers.

With this architecture, you can update one or more fields using only register writes. First, a write to the associated clear register clears all bits of the target fields, and then the desired value of the target fields is written to the set register. This sequence of two writes is referred to as a clear-set (CS) operation.

A CS operation does have a potential drawback—whenever a field is modified, USBPHY sees a value of 0 before you write the final value. For most fields, passing through the 0 state is not a problem. Nonetheless, this behavior is something to consider when performing a CS operation.

Also, you do not require a CS operation for fields that are 1-bit wide. When the CS operation works in this case, it is more efficient to simply set or clear the target bit (that is, one write instead of two). A simple set or clear operation is also atomic, whereas a CS operation is not.

All macros for SCT are atomic. For registers that do not provide hardware support for this functionality, these macros are implemented as a sequence of RMW operations. When an atomic operation is required, you must remember this, because if an interrupt occurs during a critical update sequence, unexpected behavior may take place.

Chapter 63
USB Device Charger Detection Module (USBDCD)

63.1 Chip-specific USBDCD information

Table 493. Reference links to related information

Topic	Related module	Reference
Full description	USBDCD	USBDCD
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing
Interrupts	NVIC	Interrupts **NOTE** For USBFSDCD, the interrupt is same as USBFS, and for USBHSDCD, it is same as USB HS PHY.

63.1.1 Module instances

This chip includes two USBDCD blocks.

- USBDCD is used for control of device charger detect for USB FS/LS DCD function on USB0 port.
- USBHSDCD is used for control of device charger detect for USB HS/FS/LS DCD function on USB1 port.

63.1.2 Reset control

- USBDCD: Reset control is same as USBFS.
- USBHSDCD: Reset control is same as USB HS PHY.

See Peripheral Reset Control 1 (PRESETCTRL1) and Peripheral Reset Control 2 (PRESETCTRL2).

63.1.3 AHB clock control

- USBDCD: Clock control is same as USBFS.
- USBHSDCD: Clock control is same as USB HS PHY.

See AHB Clock Control 1 (AHBCLKCTRL1) and AHB Clock Control 2 (AHBCLKCTRL2).

63.2 Overview

USBDCD works with the USB transceiver to detect whether the USB device is attached to a Charging Port, either a Dedicated Charging Port (DCP) or a Charging Downstream Port (CDP). System software coordinates the detection activities of the module and controls an off-chip integrated circuit that performs the battery charging.

The use of the term "USB transceiver" in this module documentation applies to the USB physical layer instance on the chip, whether it is an Full Speed (FS)/Low Speed (LS) only transceiver or an High Speed (HS)/FS/LS capable PHY.

63.2.1 Block diagram

The following figure is a high-level block diagram of the module.

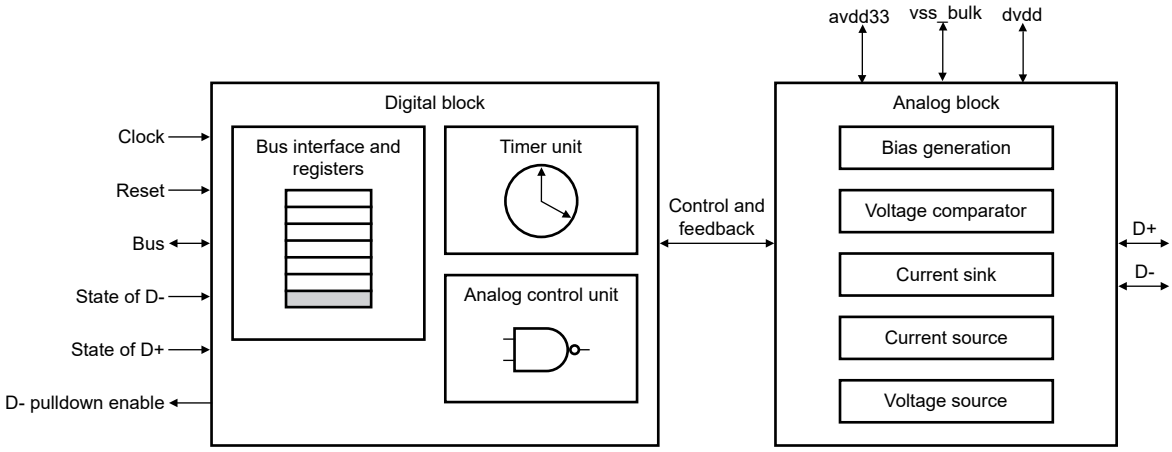

Figure 343. Block diagram

USBDCD consists of two main blocks:

- A Digital block provides the programming interface (memory-mapped registers) and includes the Timer unit and the Analog control unit.
- An Analog block provides the circuitry for the physical detection of the charger that includes the Bias generation, Voltage source, Current source, Current sink, and Voltage comparator circuitry. This block also contains necessary muxes between the source/sink circuits and the D- and D+ pins.

63.2.2 Features

- Compliant with the latest industry-standard specifications: *USB Battery Charging Specification, Revisions 1.1 and 1.2*
- Supports programmable timing parameters:
  - By default set to values required by the industry standards to allow easy configuration. You only need to set the clock frequency before enabling the module.
  - Updates of the standards are programmable.

63.3 Functional description

Several hardware components are involved in the sequence of detecting the presence of the charging port and type of the charging port. System software coordinates this activity. This collection of interacting hardware and software is called USB battery charging subsystem. The following figure shows USBDCD as a component of the subsystem.

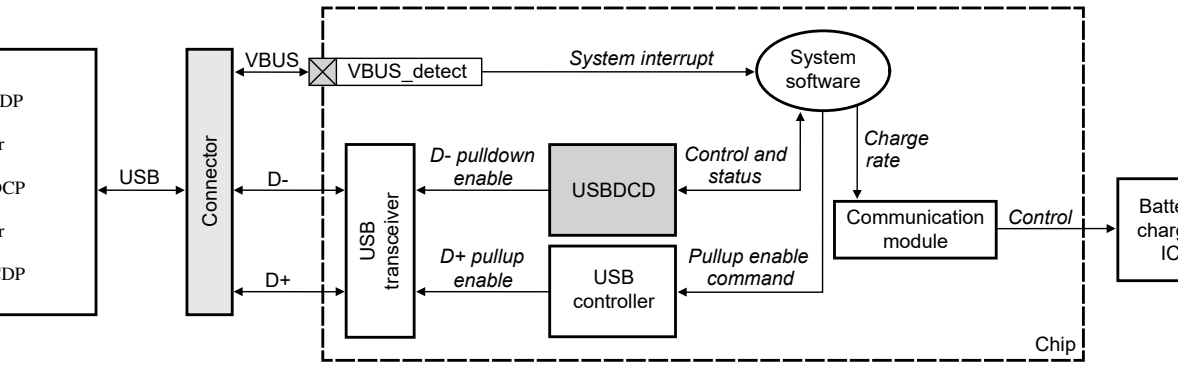

Figure 344. USB battery charging subsystem

The following table describes the components.

Table 494. USB battery charger subsystem components

<table>
<tr><th>Component</th><th>Description</th></tr>
<tr><td>Battery Charger IC</td><td>The external battery charger IC regulates the charge rate to the rechargeable battery. System software is responsible for communicating the appropriate charge rates.
<table>
<tr><th>Charger</th><th>Maximum current drawn</th></tr>
<tr><td>Standard Downstream Port (SDP)</td><td>up to 500 mA (I_{CFG_MAX})[1]</td></tr>
<tr><td>CDP</td><td>up to 1500 mA (I_{DEV_CHG})</td></tr>
<tr><td>DCP</td><td>up to 1500 mA (I_{DEV_CHG})</td></tr>
</table>
1. If a USB SDP host has suspended the USB device, the current drawn by the device has to follow the rules of the Dead Battery Provision in the USB Battery Charging Specification, Rev. 1.2.</td></tr>
<tr><td>Comm Module</td><td>A communications module on the device can be used to control the charge rate of the battery charger IC.</td></tr>
<tr><td>System software</td><td>Coordinates the detection activities of the subsystem.</td></tr>
<tr><td>USB Controller</td><td>The D+ pullup enable control signal plays a role during the charger type detection phase. System software must issue a command to the USB controller to assert this signal. After this pullup is enabled, the device is considered to be connected to the USB bus. The host then attempts to enumerate it.
NOTE
In general, the USB controller is used only for USB device applications when using most features of USBDCD. The exception is for USB host applications which need to advertise CDP capability. See Host Mode CDP advertisement signaling. Otherwise, USBDCD must be disabled in host mode.</td></tr>
<tr><td>USB Transceiver</td><td>The USB transceiver contains the pullup resistor for the USB D+ signal and the pulldown resistors for the USB D+ and D– signals. The D+ pullup and the D– pulldown are both used during the charger detection sequence in BC1.1, but it is not used during charger detection in BC1.2. The USB transceiver also outputs the digital state of the D+ and D– signals from the USB bus.
The pullup and pulldown enable signals are controlled by other modules during the charger detection sequence in BC1.1: The D+ pullup enable is output from the USB controller and is under software control. USBDCD controls the D– pulldown enable.</td></tr>
<tr><td>USBDCD</td><td>Detects whether the device has been plugged into either an SDP, a CDP, or a DCP.</td></tr>
<tr><td>VBUS_detect</td><td>This interrupt pin connected to the USB VBUS signal detects when the device has been plugged into or unplugged from the USB bus. If the system requires waking up from a low-power mode on being plugged into the USB port, this interrupt should also be a low-power wakeup source. If this pin multiplexes other functions, such as GPIO, the pin can be configured as an interrupt so that the USB plug or unplug event can be detected.</td></tr>
</table>

63.3.1 Modes of operation

The operating modes of the USBDCD module are shown in the following table.

Table 495. Module modes and their conditions

Module mode	Description	Conditions when used
Enabled for Charger Detection	The module performs the charger detection sequence.	System software must enable the module only if all of the following conditions are true: • The system is using a rechargeable battery or is otherwise capable of being powered up by an SDP or a Charging Port. • The device is being used in a USB device application. • The device is attached to the USB cable.
Enabled for Signal Overrides	Module bias circuits are enabled for special signaling on DP/DM pins.	See SIGNAL_OVERRIDE[PS].
Disabled	The module is not active and is held in a low-power state.	System software must disable the module when either of the following conditions is true: • The charger detect sequence is complete. • The conditions for being enabled are not met.
Powered Off	The digital supply voltage dvdd is removed.	Low system performance requirements allow putting the device into a very low-power stop mode.

Operating mode transitions are shown in the following table.

Table 496. Entering and exiting module modes

Module mode	Entering	Exiting	Mode after exiting
Enabled	Set CONTROL[START].	Set CONTROL[SR]. [1]	Disabled
Disabled	Take *either* of the following actions: • Set CONTROL[SR].[1] • Reset the module. By default, the module is disabled.	Set CONTROL[START].	Enabled
Powered Off	Perform the following actions: 1. Put the device into very low-power stop mode. 2. Adjust the supply voltages.	Perform the following actions: 1. Restore the supply voltages. 2. Take the device out of very low-power stop mode.	Disabled

1. The effect of setting the CONTROL[SR] field is immediate; that is, the module is disabled even if the sequence has not completed.

63.3.2 The charger detection sequence

The following figure illustrates the charger detection sequence in a simplified timing diagram based on the *USB Battery Charging Specification, Rev. 1.2*.

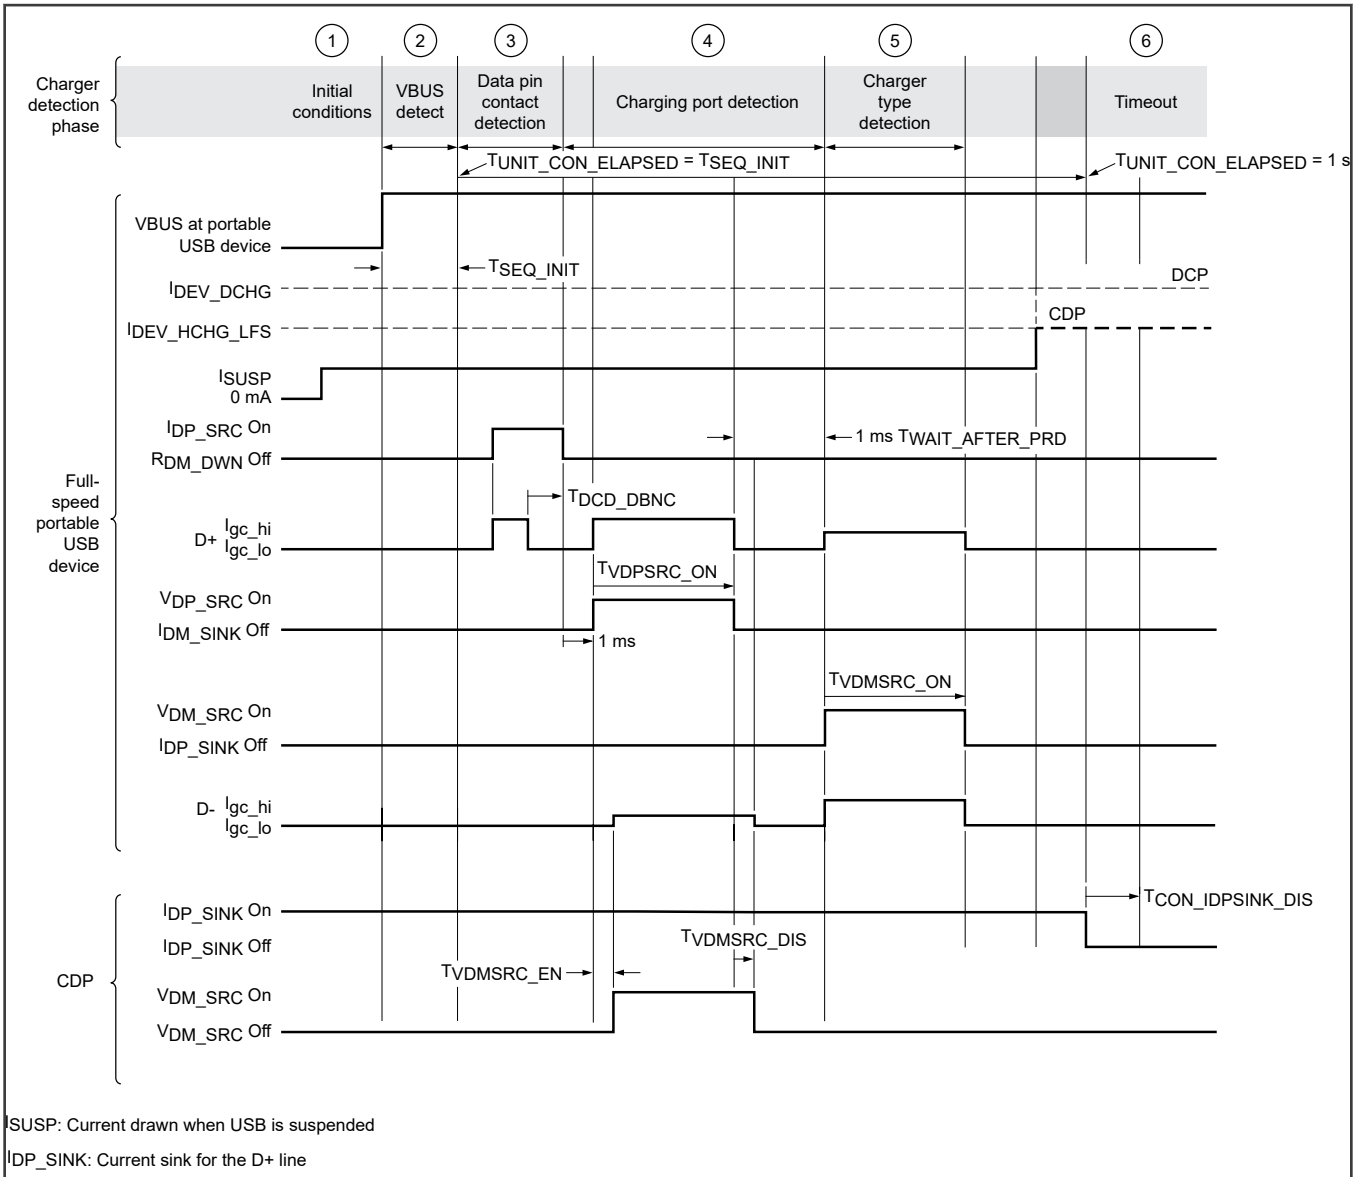

Figure 345. FS charger detection timing for BC1.2

Timing parameter values used in this module for BC1.2 are listed in the following table.

Table 497. Timing parameters for the charger detection sequence for BC1.2

Parameter	USB Battery Charging Spec	Module default	Module programmable range
T_{DCD_DBNC} [1]	10 ms min (no max)	10 ms	0– 1023 ms
T_{VDPSRC_ON} [1]	40 ms min (no max)	40 ms	0 –1023 ms
$T_{WAIT_AFTER_PRD}$	N/A	1 ms	0– 1023 ms
T_{VDMSRC_ON}	40 ms	40 ms	0 –1023 ms

Table continues on the next page...

Table 497. Timing parameters for the charger detection sequence for BC1.2 (continued)

Parameter	USB Battery Charging Spec	Module default	Module programmable range
T_{SEQ_INIT}	N/A	16 ms	0 –1023 ms
T_{UNIT_CON} [1]	1 s	N/A	N/A
T_{VDMSRC_EN} [1]	1– 20 ms	From the USB host	N/A
T_{VDMSRC_DIS} [1]	0 – 20 ms	From the USB host	N/A
$T_{CON_IDPSINK_DIS}$ [1]	0 – 10 ms	From the USB host	N/A

1. This parameter is defined by the *USB Battery Charging Specification, Rev. 1.2*.

The following figure illustrates the charger detection sequence in a simplified timing diagram based on the *USB Battery Charging Specification, Rev. 1.1*.

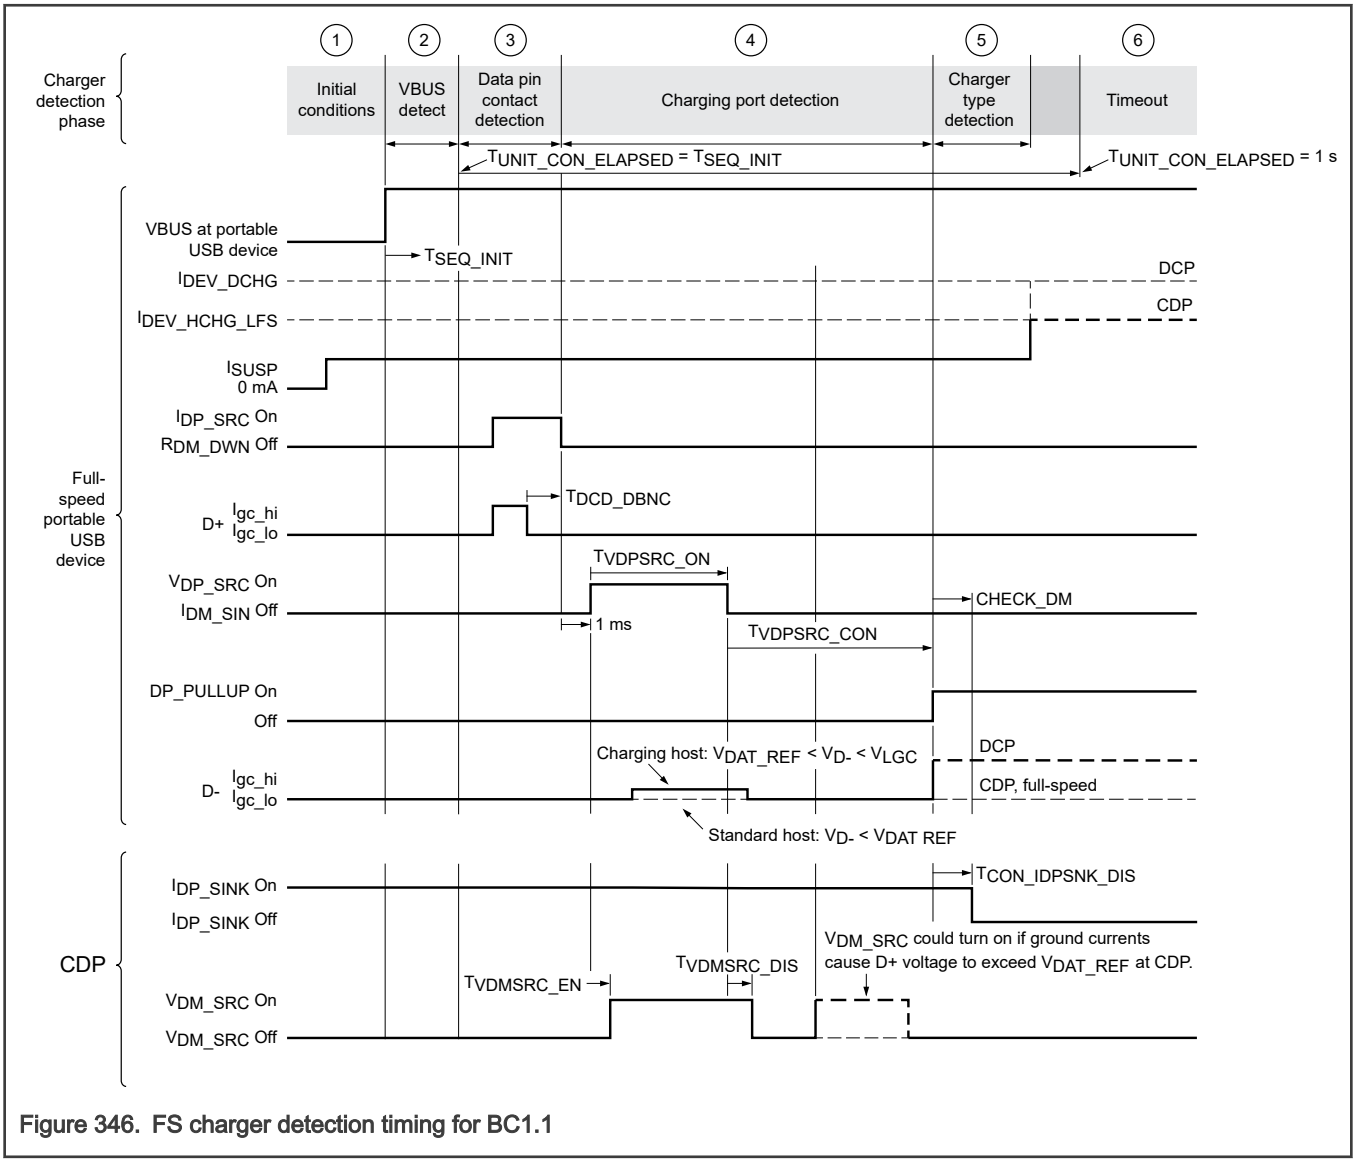

Figure 346. FS charger detection timing for BC1.1

Timing parameter values used in this module for BC1.1 are listed in the following table.

Table 498. Timing parameters for the charger detection sequence for BC1.1

Parameter	USB Battery Charging Spec	Module default	Module programmable range
T_{DCD_DBNC} [1]	10 ms min (no max)	10 ms	0– 1023 ms
T_{VDPSRC_ON} [1]	40 ms min (no max)	40 ms	0 –1023 ms
T_{VDPSRC_CON} [1]	40 ms min (no max)	40 ms	0 –1023 ms
CHECK_DM	N/A	1 ms	0– 15 ms
T_{SEQ_INIT}	N/A	16 ms	0 –1023 ms
T_{UNIT_CON} [1]	1 s	N/A	N/A
T_{VDMSRC_EN} [1]	1– 20 ms	From the USB host	N/A
T_{VDMSRC_DIS} [1]	0 –20 ms	From the USB host	N/A
$T_{CON_IDPSINK_DIS}$ [1]	0– 20 ms	From the USB host	N/A

1. This parameter is defined by the *USB Battery Charging Specification, Rev. 1.1*.

The following table provides an overview description of the charger detection sequence shown in the preceding figure.

Table 499. Overview of the charger detection sequence

Phase		Overview description	Full description
1	Initial conditions	Initial system conditions that need to be met before the detection sequence is initiated.	Initial system conditions
2	VBUS detection	System software detects contact of the VBUS signal with the system interrupt pin VBUS_detect.	VBUS contact detection
3	Data pin contact detection	The USBDCD module detects that the USB data pins D+ and D– have made contact with the USB port.	Data pin contact detection
4	Charging port detection	The USBDCD module detects if the port is an SDP or either type of charging port, that is CDP or DCP.	Charging port detection
5	Charger type detection	The USBDCD module detects the type of charging port, if applicable.	Charger type detection
6	Sequence timeout	The USBDCD module did not finish the detection sequence within the timeout interval. The sequence will continue until halted by software.	Charger detection sequence timeout

63.3.2.1 Initial system conditions

The USBDCD module is intended for use with USB device applications using a rechargeable battery. The module does not have support for interfacing with ACA or ACA-Dock equipment as defined in the *USB Battery Charging Specification,*

Revision 1.2. It cannot be used with USB applications that are embedded host or OTG, except as indicated in Host Mode CDP advertisement signaling.

In addition, before the USBDCD module's charger detection sequence can be initiated, the system must be:

- Powered-up and in run mode. The USBDCD instantiation of this module for the High-Speed port does not directly depend on the VBUS voltage and can operate as long as the avdd33 supply is in a valid range.
- Recently plugged into a USB port.
- Drawing not more than 2.5 mA total system current from the USB bus, except as allowed by the *USB 2.0 Connect Timing Update ECN*.

Examples of allowable precursors to this set of initial conditions include:

- A powered-down device is subsequently powered-up upon being plugged into the USB bus.
- A device in a low-power mode subsequently enters run mode upon being plugged into the USB bus.

63.3.2.2 VBUS contact detection

Once the device is plugged into a USB port, the VBUS_detect system interrupt is triggered. System software must do the following to initialize the module and start the charger detection sequence:

1. Restore power if the module is powered-off.
2. Set CONTROL[SR] to initiate a software reset.
3. Configure the USBDCD module by programming the CLOCK register and the timing parameters as needed.
4. Set CONTROL[IE] to enable interrupts, or clear CONTROL[IE] if the software polling method is used.
5. Program CONTROL[BC12] based on which revision of the USB Battery Charging Specification is needed.
6. Set CONTROL[START] to start the charger detection sequence.

63.3.2.3 Data pin contact detection

The module must ensure that the data pins have made contact because the detection sequence depends upon the state of the USB D+ and D- signals. USB plugs and receptacles are designed such that when the plug is inserted into the receptacle, the power pins make contact before the data pins make contact. See the following figure.

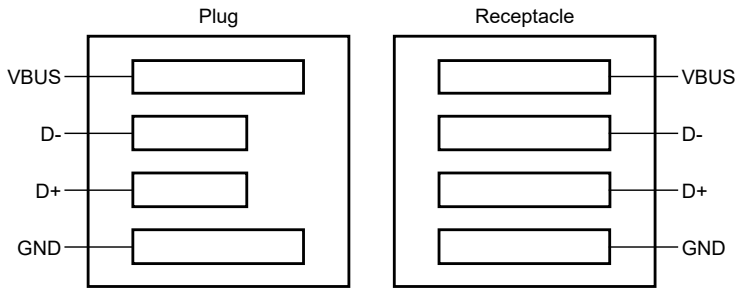

Figure 347. Relative pin positions in USB plugs and receptacles

As a result, when a portable USB device is attached to an upstream port, the portable USB device detects VBUS before the data pins have made contact. The time between power pins and data pins making contact depends on how fast the plug is inserted into the receptacle. Delays of several hundred milliseconds are possible.

63.3.2.3.1 Debouncing the data pin contact

When system software has initiated the charger detection sequence, as described in Initial system conditions, the USBDCD module turns on the I_{DP_SRC} current source and enables the R_{DM_DWN} pulldown resistor. If the data pins have not made contact, the D+ line remains high. After the data pins make contact, the D+ line goes low and debouncing begins.

After the D+ line goes low, the module continuously samples the D+ line over the duration of the T_{DCD_DBNC} debounce time interval. By default, T_{DCD_DBNC} is 10 ms, but it can be programmed in the TIMER0[TDCD_DBNC] field. See the description of TIMER0 for details.

When it has remained low for the entire interval, the debouncing is complete. However, if the D+ line returns high during the debounce interval, the module waits until the D+ line goes low again to restart the debouncing. This cycle repeats until either of the following happens:

- The data pin contact has been successfully debounced (see Success in detecting data pin contact (phase completion)).
- A timeout occurs (see Charger detection sequence timeout).

63.3.2.3.2 Success in detecting data pin contact (phase completion)

After successfully debouncing the D+ state, the module does the following:

- Updates the STATUS register to reflect phase completion (See Table 505 for field values.)
- Directly proceeds to the next step in the sequence: detection of a charging port (See Charging port detection.)

63.3.2.4 Charging port detection

After it detects that the data pins have made contact, the module waits for a fixed delay of 1 ms, and then attempts to detect whether it is plugged into a charging port. The module connects the following analog units to the USB D+ or D– lines during this phase:

- The voltage source V_{DP_SRC} connects to the D+ line
- The current sink I_{DM_SINK} connects to the D– line
- The voltage comparator connects to the USB D– line, comparing it to the voltage V_{DAT_REF}.

After a time of T_{VDPSRC_ON}, the module samples the D– line. The T_{VDPSRC_ON} parameter is programmable and defaults to 40 ms. After sampling the D– line, the module disconnects the voltage source, current sink, and comparator.

The next steps in the sequence depend on the voltage on the D– line as determined by the voltage comparator. See the following table.

Table 500. Sampling D– in the charging port detection phase

If the voltage on D- is...	Then...	See...
Below V_{DAT_REF}	The port is an SDP that does not support using charging currents above I_{CFG_MAX}.	SDP
Above V_{DAT_REF} but below V_{LGC}	The port is a charging port.	Charging port
Above V_{LGC}	This is an error condition.	Error in charging port detection

63.3.2.4.1 SDP

As part of the charger detection handshake with a standard USB host, the module does the following without waiting for the interval ($T_{WAIT_AFTER_PRD}$ or T_{VDPSRC_CON}) to elapse:

- Updates the STATUS register to reflect that an SDP is detected with SEQ_RES = 01b. See Table 505 for field values.
- Sets CONTROL[IF].

- Generates an interrupt if enabled in CONTROL[IE].

At this point, control is passed to system software via the interrupt. The rest of the sequence, which detects the type of charging port, is not applicable, so software must perform the following steps:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.
5. Communicate the appropriate charge rate to the external battery charger IC; see Table 494.

63.3.2.4.2 Charging port

As part of the charger detection handshake with any type of USB host, the module waits until the interval ($T_{WAIT_AFTER_PRD}$ or T_{VDPSRC_CON}) has elapsed before it does the following:

For *USB Battery Charging Specification, Rev. 1.2*:

- Enables V_{DM_SRC}.
- Updates the STATUS register to reflect that a charging port is detected with SEQ_RES = 10b. See Table 505 for field values.
- At this point the detection sequence progresses to Charger type detection without needing software interaction.

For *USB Battery Charging Specification, Rev. 1.1*:

- Updates the STATUS register to reflect that a charging port is detected with SEQ_RES = 10b. See Table 505 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].
- At this point, control is passed to system software via the interrupt. Software must:
  1. Read the STATUS register.
  2. Set CONTROL[IACK] to acknowledge the interrupt.
  3. Issue a command to the USB controller to pullup the USB D+ line.
  4. Wait for the module to complete the final phase of the sequence. See Charger type detection.

63.3.2.4.3 Error in charging port detection

For this error condition, the module does the following:

- Updates the STATUS register to reflect the error with SEQ_RES = 00b. See Table 505 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

Note that in this case the module does not wait for the interval ($T_{WAIT_AFTER_PRD}$ or T_{VDPSRC_CON}) to elapse.

At this point, control has been passed to system software via the interrupt. The rest of the sequence (detecting the type of charging port) is not applicable, so software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.

63.3.2.5 Charger type detection

For *USB Battery Charging Specification, Rev. 1.2*:

After the USBDCD module enables the V_{DM_SRC}, the module starts the T_{VDMSRC_ON} timer counting down the time interval programmed into the TIMER2[T_{VDMSRC_ON}] field.

Once the T_{VDMSRC_ON} timer is elapsed, the module samples the USB D+ line to determine the type of charger. See the following table.

Table 501. Sampling D+ in the charger type detection phase (BC1.2)

If the voltage on D+ is...	Then...	See...
High (D+>V_{DAT_REF})	The port is a DCP. [1]	DCP
Low (D+<V_{DAT_REF})	The port is a CDP. [2]	CDP

1. In a DCP, the D+ and D– lines are shorted together through a small resistor.
2. In a CDP, the D+ and D– lines are not shorted.

For *USB Battery Charging Specification, Rev. 1.1*:

After software enables the D+ pullup resistor, the module is notified automatically (via internal signaling) to start the CHECK_DM timer counting down the time interval programmed in the TIMER2[CHECK_DM] field.

After the CHECK_DM time is elapsed, the module samples the USB D– line to determine the type of charger. See the following table.

Table 502. Sampling D– in the charger type detection phase (BC1.1)

If the voltage on D– is...	Then...	See...
High	The port is a DCP. [1]	DCP
Low	The port is a CDP. [2]	CDP

63.3.2.5.1 DCP

For a DCP, the module does the following:

- Updates the STATUS register to reflect that a dedicated charging port is detected with SEQ_RES = 11b. See Table 505 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE] field.

The *USB Battery Charging Specification, Rev. 1.2* indicates that additionally if the detection sequence determines an attachment to a DCP, then the USB device should signal on the D+ pin by either enabling the D+ pullup resistor or enabling V_{DP_SRC}.

At this point, control has been passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Disable the USB controller to prevent transitions on the USB D+ or D– lines from causing spurious interrupt or wakeup events to the system.
3. Set CONTROL[IACK] to acknowledge the interrupt.
4. Set CONTROL[SR] to issue a software reset to the module.
5. Disable the module.

6. Enable signaling on the D+ pin. This can be done by enabling the Transceiver D+ pullup resistor through configuration of the register fields in the USB controller instance for this USB port. For USBHSDCD instantiation of USBDCD, this signaling can alternatively be done by enabling V_{DP_SRC} through setting the SIGNAL_OVERRIDE[PS] field to a value of 010b.
7. Communicate the appropriate charge rate to the external battery charger IC; see Table 494.

63.3.2.5.2 CDP

For a CDP, the module does the following:

- Updates the STATUS register to reflect that a CDP is detected with SEQ_RES = 10b. See Table 505 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

At this point, control is passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.
5. Communicate the appropriate charge rate to the external battery charger IC; see Table 494.

63.3.2.6 Charger detection sequence timeout

The maximum time allowed to connect according to the *USB Battery Charging Specification* is one second. If the Unit Connection Timer reaches the one second limit and the sequence is still running as indicated by the STATUS[ACTIVE] field, the module does the following:

- Updates the STATUS register to reflect that a timeout error has occurred. See Table 505 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].
- The detection sequence continues until explicitly halted by software setting CONTROL[SR].
- The Unit Connection Timer continues counting. See the description of TIMER0.

At this point, control is passed to the system software via the interrupt, which has two options: ignore the interrupt and allow more time for the sequence to complete, or halt the sequence. To halt the sequence, software must:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.

This timeout function is also useful in case software does not realize that the USB device is unplugged from USB port during the charger detection sequence. If the interrupt occurs but the V_{BUS_DETECT} input is low, software can disable and reset the module.

System software might allow the sequence to run past the timeout interrupt under these conditions:

1. The USB Battery Charging Spec is amended to allow more time. In this case, software should poll TIMER0[$T_{UNITCON}$] periodically to track elapsed time after 1s; or
2. For debug purposes.

Note that the $T_{UNITCON}$ register field will stop incrementing when it reaches its maximum value so it will not roll over to zero and start counting up again.

63.3.2.7 Dead Battery Provision signaling

If the system needs to operate under the Dead Battery Provision of the *USB Battery Charging Specification, Revision 1.2*, the USBDCD module must be configured to signal V_{DP_SRC} on the USB_DP pin.

For information on Dead Battery Provision conditions and signaling, see the Dead or weak battery later in this chapter.

63.3.2.8 Host Mode CDP advertisement signaling

If the system is configured in Embedded Host mode, and the system hardware external to the SOC is capable of serving as a CDP, this capability can be signaled by the USBDCD module.

As indicated in the *USB Battery Charging Specification, Revision 1.2*, one way that the CDP can behave for this case is to signal V_{DM_SRC} on the USB_DM pin while there is not a remote device connected to the host, and then disable V_{DM_SRC} shortly after a connection event.

The V_{DM_SRC} signaling can be enabled through setting the SIGNAL_OVERRIDE[PS] field to 100b.

If this feature is used, the USB subsystem software must control this field upon detecting USB connect and disconnect events.

63.3.3 Clocking

The following table describes the clock sources for the USBDCD module. Refer to the chip's clocking chapter for clock setting, configuration, and gating information.

Note these clocks share same name with the USB PHY.

Table 503. USBDCD clocks

Clock name	Description
MODULE_CLK	Peripheral clock
MODULE_CLK_S	Peripheral access clock

63.3.4 Resets

There are two ways to reset various register contents in this module: hardware resets and a software reset.

63.3.4.1 Hardware resets

Hardware resets originate at the system or device level and propagate down to the individual module level. They include start up reset, low-voltage reset, and all other hardware reset sources.

Hardware resets cause the register contents to be restored to their default state as listed in the register descriptions.

63.3.4.2 Software reset

A software reset re-initializes the module's status information, but leaves configuration information unchanged. The software reset allows software to prepare the module without needing to reprogram the same configuration each time the USB device is plugged into a USB port.

Setting CONTROL[SR] initiates a software reset. The following table shows all register fields that are reset to their default values by a software reset.

Table 504. Software reset and register fields affected

Register	Fields affected	Fields not affected
CONTROL[1]	IF	IE, START
STATUS	All	None
CLOCK	None	All
TIMER*n*	TUNITCON	All other

1. CONTROL[SR] and CONTROL[IACK] are self-clearing.

A software reset also returns all internal logic, timers, and counters to their reset states. If the module is already active (STATUS[ACTIVE] = 1b), a software reset stops the sequence.

NOTE

Software must always initiate a software reset before starting the sequence to ensure the module is in a known state.

63.3.5 Interrupts

The USBDCD module has an interrupt to alert system software of certain events, which are listed in the following table. All events except the Phase Complete event for the Data Pin Detection phase can trigger an interrupt.

Table 505. Events triggering an interrupt by sequence phase

Sequence phase	Event	Event description	STATUS fields [1]	Phase description
Data Pin Detection	Phase Complete	The module has detected data pin contact. *No interrupt occurs*: CONTROL[IF] = 0b.	ERR = 0b SEQ_STAT = 01b SEQ_RES = 00b TO = 0b	VBUS contact detection
Charging Port Detection	Phase Complete	The module has completed the process of identifying if the USB port is a charging port or not. **NOTE:** An interrupt is triggered at completion of this phase for BC 1.1 operation whether an SDP or a Charging port is detected. For BC 1.2 operation, if an SDP is detected an interrupt is triggered but if a Charging port is detected the sequence goes directly to the Charger Type Detection phase.	ERR = 0b SEQ_STAT = 10b SEQ_RES = 01b or 10b TO = 0b	Charging port detection
	Error	The module cannot identify the type of port because the D– line is above the USB's VLGC threshold.	ERR = 1b SEQ_STAT = 10b SEQ_RES = 00b TO = 0b	Error in charging port detection

Table continues on the next page...

Table 505. Events triggering an interrupt by sequence phase (continued)

Sequence phase	Event	Event description	STATUS fields [1]	Phase description
Charger Type Detection	Phase Complete	The module has completed the process of identifying the charger type detection. **NOTE:** The ERR flag always reads zero because no known error conditions are checked during this phase.	ERR = 0b SEQ_STAT = 11b SEQ_RES = 11b or 10b TO = 0b	Charger type detection
Sequence Timeout	Error	The timeout interval from the time the USB device attaches to a USB port until it connects has elapsed.	ERR = 1b SEQ_STAT = last value [2] SEQ_RES = last value [2] TO = 1b	Charger detection sequence timeout

1. See the description of the Status register for register information.
2. The SEQ_STAT and SEQ_RES fields retain the values held at the time of the timeout error.

63.3.5.1 Interrupt handling

Software reads which event caused the interrupt from the STATUS register during the interrupt service routine.

An interrupt is generated only if CONTROL[IE] is set. The CONTROL[IF] field is always set under interrupt conditions, even if CONTROL[IE] is cleared. In this case, software can poll CONTROL[IF] to determine if an interrupt condition is pending.

Writes to CONTROL[IF] are ignored. To reset CONTROL[IF], set CONTROL[IACK] to acknowledge the interrupt. Writing to CONTROL[IACK] when CONTROL[IF] is cleared has no effect.

63.4 External signals

This section describes the module signals. The following table shows a summary of module signals that interface with the pins of the device.

Table 506. Signal descriptions

Signal	Description	I/O
USB_DM	USB D– analog data signal. The analog block interfaces directly to the D– signal on the USB bus.	I/O
USB_DP	USB D+ analog data signal. The analog block interfaces directly to the D+ signal on the USB bus.	I/O
avdd33 [1]	3.3 V regulated analog supply	POWER
vss_bulk	Digital/Analog ground	POWER
dvdd	Core voltage digital supply	POWER

1. Voltage must be 3.3 V ± 10% for full functionality of the module. That is, the charger detection function does not work when this voltage is below 3.0 V, and the CONTROL[START] field should not be set.

NOTE

The transceiver module also interfaces to the USB_DM and USB_DP signals. Both modules and the USB host/hub use these signals as bidirectional, tristate signals.

Information about the signal integrity aspects of the lines including shielding, isolated return paths, input or output impedance, packaging, suggested external components, ESD, and other protections can be found in the USB 2.0 Specification and in Application information.

63.5 Initialization

This module is designed for minimal configuration while retaining significant programmability. To initialize USBDCD:

1. Initialize the CLOCK register to the actual system clock frequency, unless the default value already matches the system requirements.
2. Reset ANACTRL[DEV_PULLDOWN] to 0b when this module is in use for the proper operation of the USBHSDCD instantiation of USBDCD.

   For more information, see the "USB PHY Analog Control Register (ANACTRL)" section of the "Universal Serial Bus 2.0 Integrated PHY (USB-PHY)" chapter.
3. Do not modify other registers, as they default to the values that comply with the USB Battery Charging Specification.
4. Configure timing parameters to obtain flexibility as per the requirements of a specific system.

All module configuration must occur *before* initiating the charger detection sequence. Configuration changes made *after* setting CONTROL[START] result in undefined behavior.

63.6 Application information

This section provides application information.

63.6.1 External pullups

Any external pullups applied to the USB D+ or D- data lines must be capable of being disabled to prevent incorrect pullup values or incorrect operation of the USB subsystem.

63.6.2 Dead or weak battery

According to the *USB Battery Charging Specification, Revision 1.2*, a USB device with a dead or weak battery that is attached to an SDP can draw charging current from VBUS without connecting for several minutes, until the battery is charged to the point that the USB device can connect. The conditions for this operation are referred to as the Dead Battery Provision.

The *USB Battery Charging Specification, Revision 1.2* limits this charging condition to 100 mA for a duration of 45 minutes. The later *USB 2.0 Connect Timing Update ECN* modifies this charging condition to 500 mA for a duration of 2 minutes. Customers designing systems to take advantage of the Dead Battery Provision should study both specifications closely.

The USBDCD module is compatible with systems that do not check the strength of the battery. Therefore, this module assumes that the battery is good, so the USB device must immediately connect to the USB bus by pulling the USB_DP pin high after the USBDCD module has determined that the device is attached to an SDP or CDP. (By definition, a DCP does not support connection but still requires a signaling event, see DCP.)

The module is also compatible with systems that have other circuitry to check the strength of the battery. In these systems, if it is known that the battery is weak or dead, software can delay connecting to the USB while charging using the Dead Battery Provision. Once the battery is charged to the good battery threshold, software must then connect to the USB host by pulling the USB_DP pin high.

While using the Dead Battery Provision, the USB_DP pin must signal by enabling V_{DP_SRC}. On this product that signaling can be done most simply by setting the SIGNAL_OVERRIDE[PS] field to value 10b.

63.6.3 Handling unplug events

If the device is unplugged from the USB bus during the charger detection sequence, the contents of the STATUS register must be ignored and the USBDCD module must get a Software Reset, as described in Software reset.

63.7 USBDCD register descriptions

63.7.1 USBDCD memory map

USBDCD0 base address: 400D_C000h

USBHS1_PHY_DCD base address: 4010_A800h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control (CONTROL)	32	RW	0003_0000h
4h	Clock (CLOCK)	32	RW	0000_0061h
8h	Status (STATUS)	32	R	0000_0000h
Ch	Signal Override (SIGNAL_OVERRIDE)	32	RW	0000_0000h
10h	TIMER0 (TIMER0)	32	RW	0010_0000h
14h	TIMER1 (TIMER1)	32	RW	000A_0028h
18h	TIMER2_BC11 (TIMER2_BC11)	32	RW	0028_0001h
18h	TIMER2_BC12 (TIMER2_BC12)	32	RW	0001_0028h

63.7.2 Control (CONTROL)

Offset

Register	Offset
CONTROL	0h

Function

Controls various global functions, such as software reset, initiating the charger detection sequence, BC12 compatibility, and interrupt enablement.

Diagram

7-3 —	Reserved
2-0 PS	Phase Selection Enables specified voltage and current source circuits on the USB_DP and USB_DM pins. Use of the override values below enables the charger detection bias circuits without needing to set CONTROL[START].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Customers may set this field to 010b for required signaling if attached to a Dedicated Charging Port, or during operation under the Dead Battery Provision. Customers may set this field to 100b in Embedded Host use case for signaling Charging Downstream Port advertisement. 000b - No overrides. Field must remain at this value during normal USB data communication to prevent unexpected conditions on USB_DP and USB_DM pins. (Default) 001b - Reserved, not for customer use. 010b - Enables VDP_SRC voltage source for the USB_DP pin and IDM_SINK current source for the USB_DM pin. 011b - Reserved, not for customer use. 100b - Enables VDM_SRC voltage source only. 101b - Reserved, not for customer use. 110b - Reserved, not for customer use. 111b - Reserved, not for customer use.

63.7.6 TIMER0 (TIMER0)

Offset

Register	Offset
TIMER0	10h

Function
Represents the system latency in ms using the TSEQ_INIT field.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0								TSEQ_INIT							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				TUNITCON											
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-26 —	Reserved
25-16 TSEQ_INIT	Sequence Initiation Time TSEQ_INIT represents the system latency (in ms) measured from the time VBUS goes active to the time system software initiates the charger detection sequence in the USBDCD module. When software sets CONTROL[START], the Unit Connection Timer (TUNITCON) is initialized with the value of TSEQ_INIT. Valid values are 0-1023, but the USB Battery Charging Specification requires the entire sequence, including TSEQ_INIT, to be completed in 1 s or less. 00_0000_0000b-11_1111_1111b - 0 ms - 1023 ms
15-12 —	Reserved
11-0 TUNITCON	Unit Connection Timer Elapse (in ms) Displays the amount of elapsed time since the event of setting CONTROL[START] plus the value of TSEQ_INIT. The timer is automatically initialized with the value of TSEQ_INIT before starting to count. This timer enables compliance with the maximum time allowed to connect T_{UNIT_CON} under the USB Battery Charging Specification. If the timer reaches the one second limit, the module triggers an interrupt and sets the error flag STATUS[ERR]. The timer continues counting throughout the charger detection sequence, even when control has been passed to software. As long as the module is active, the timer continues to count until it reaches the maximum value of FFFh (4095 ms). The timer does not roll over to zero. A software reset clears the timer.

63.7.7 TIMER1 (TIMER1)

Offset

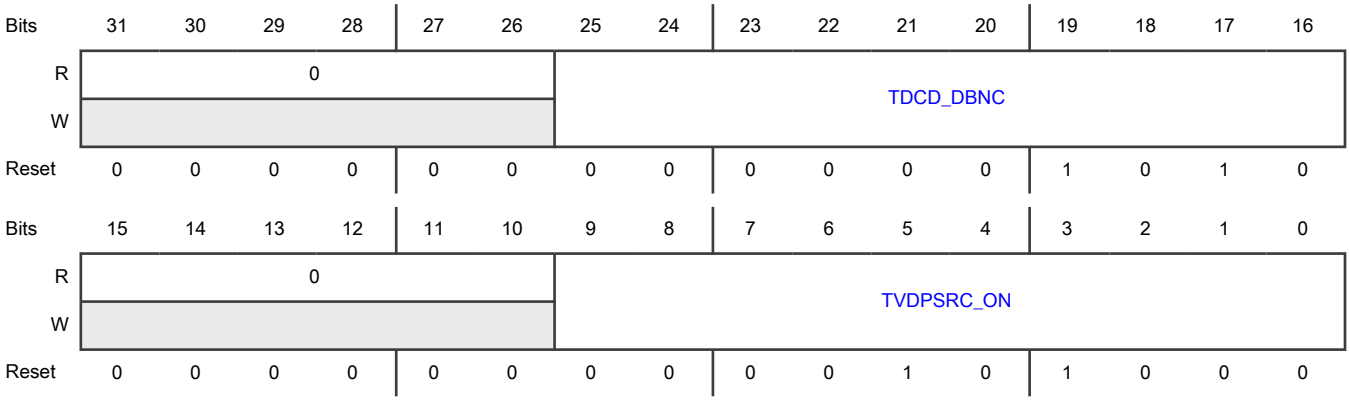
Register	Offset
TIMER1	14h

Function
Contains timing parameters.

NOTE

Register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 TDCD_DBNC	Time Period to Debounce D+ Signal Sets the time period (ms) to debounce the D+ signal during the data pin contact detection phase. See Debouncing the data pin contact. Valid values are 1-1023, but the USB Battery Charging Specification requires a minimum value of 10 ms. 00_0000_0001b-11_1111_1111b - 1 ms - 1023 ms
15-10 —	Reserved
9-0 TVDPSRC_ON	Time Period Comparator Enabled This timing parameter is used after detection of the data pin. See Charging port detection. Valid values are 1-1023, but the USB Battery Charging Specification requires a minimum value of 40 ms. 00_0000_0001b-11_1111_1111b - 1 ms - 1023 ms

63.7.8 TIMER2_BC11 (TIMER2_BC11)

Offset

Register	Offset
TIMER2_BC11	18h

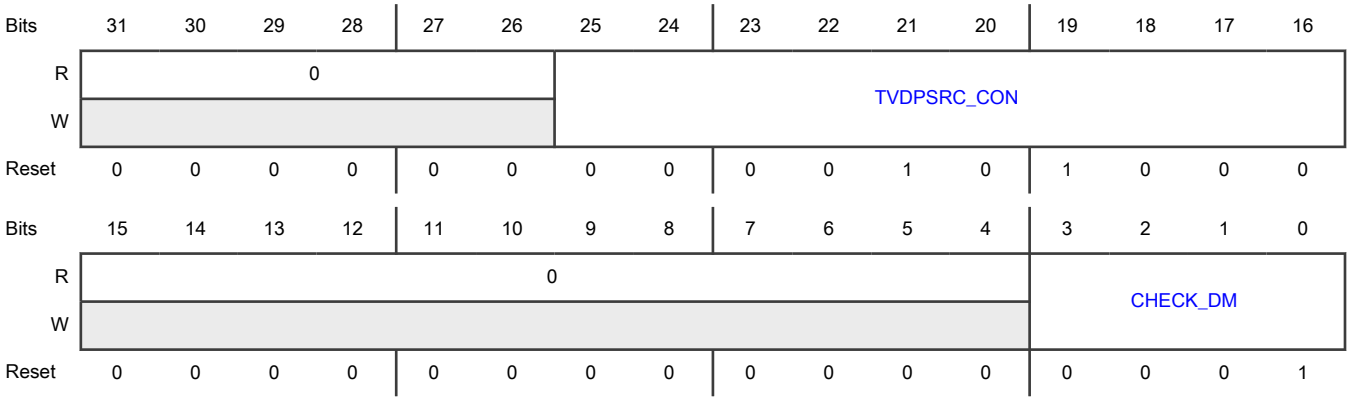
Function

TIMER2_BC11 contains timing parameters for *USB Battery Charging Specification, Rev 1.1.*

NOTE

Register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 TVDPSRC_CON	Time Period Before Enabling D+ Pullup Sets the time period (ms) that the module waits after charging port detection before system software must enable the D+ pullup to connect to the USB host. Valid values are 1-1023, but the USB Battery Charging Specification requires a minimum value of 40 ms. 00_0000_0001b-11_1111_1111b - 1 ms - 1023 ms
15-4 —	Reserved
3-0 CHECK_DM	Time Before Check of D- Line Sets the amount of time (in ms) that the module waits after the device connects to the USB bus until checking the state of the D- line to determine the type of charging port. See Charger type detection. Valid values are 1-15 ms. 0001b-1111b - 1 ms - 15 ms

63.7.9 TIMER2_BC12 (TIMER2_BC12)

Offset

Register	Offset
TIMER2_BC12	18h

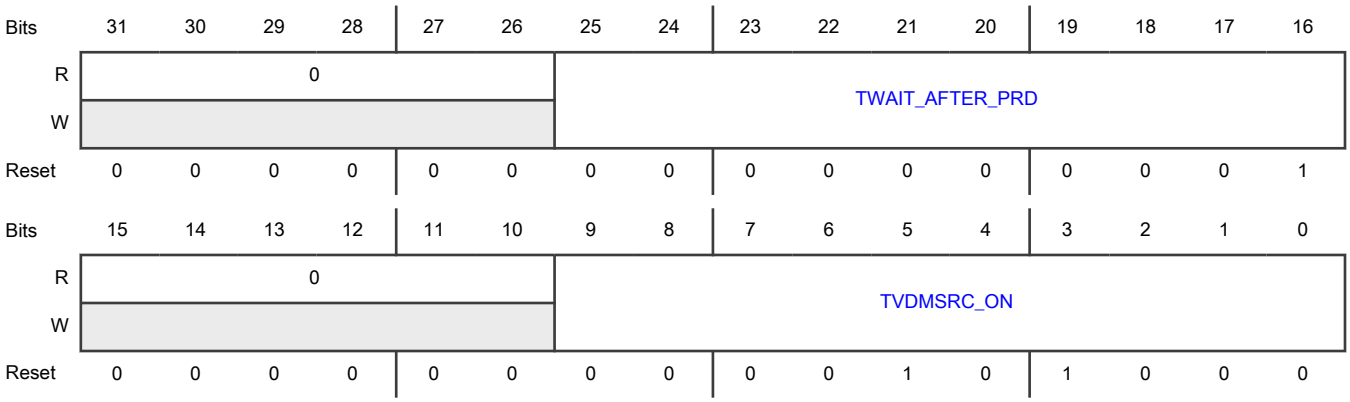
Function

Contains timing parameters for *USB Battery Charging Specification, Rev 1.2*.

NOTE

Register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 TWAIT_AFTER_PRD	TWAIT_AFTER_PRD Sets the amount of time (in ms) that the module waits after primary detection before start to secondary detection. Valid values are 1-1023ms. 00_0000_0001b-11_1111_1111b - 1 ms - 1023 ms
15-10 —	Reserved
9-0 TVDMSRC_ON	TVDMSRC_ON Sets the amount of time (in ms) that the module enables the V_{DM_SRC}. Valid values are 0-40ms. 00_0000_0000b-00_0010_1000b - 0 ms - 40 ms

Chapter 64
Universal Serial Bus High-Speed Controller (USBHS)

64.1 Chip-specific USBHS information

Table 507. Reference links to related information

Topic	Related module	Reference
Full description	USBHS	USBHS
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

NOTE

See AHB Clock Control 2 (AHBCLKCTRL2) for clock control. Also see Peripheral Reset Control 2 (PRESETCTRL2) for reset control.

64.1.1 Module instances

This device has one instance of the USBHS module.

64.1.2 USBHS operation modes

USBHS is functional only in SD and OD modes. It is non-functional in MD mode. Configure SPC.ACTIVE_CFG[DCDC_VDD_LVL] = SPC.ACTIVE_CFG[CORELDO_VDD_LVL] >= 0x2 for correct operation of the module.

64.2 Overview

The USB controller block provides high performance USB functionality that conforms to the *Universal Serial Bus Specification*, Rev. 2.0 (Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips; 2000), and the *On-The-Go and Embedded Host Supplement to the USB Revision* 2.0 Specification (Hewlett-Packard Company, Intel Corporation, LSI Corporation, Microsoft Corporation, Renesas Electronics Corporation, ST-Ericsson; 2012).

The USB controller consists of one independent USB controller core: On-The-Go (OTG) controller core. Each controller core supports UTMI interface. See Features for more details. The controller core is single-port core. For the OTG core, there is only one port. The port can be used as either a downstream or an upstream port.

64.2.1 Block diagram

The following figure is a block diagram of USB.

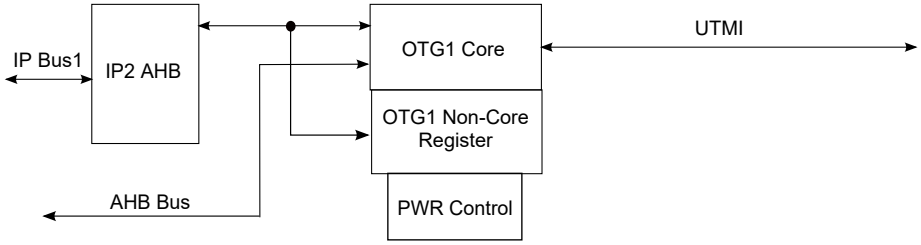


Figure 348. USB block diagram

64.2.2 Features

There is one USB 2.0 controller core in this chip:

- Controller Core 0 is also named 'OTG1 Core'; its connected port is named 'OTG1 port'.

The following list provides features of each controller core.

- USB 2.0 Controller Core 0
  - High-Speed/Full-Speed/Low-Speed OTG core
  - HS/FS/LS UTMI compliant interface
  - High Speed, Full Speed and Low Speed operation in HOST mode (with UTMI transceiver)
  - High Speed, and Full Speed operation in Peripheral mode (with UTMI transceiver)
  - Hardware support for OTG signaling, session request protocol, and host negotiation protocol
  - 8 bidirectional endpoints
  - Support charger detection
- Low-power mode with local and remote wake-up capability
- Embedded DMA controller in each core

64.3 Functional description

These sections describe the functionality of the various building blocks of the USB.

64.3.1 USB 2.0 Controller Core 0

The USB 2.0 Controller 0 is an instantiation of an EHCI-compatible core which supports high-, full-, and low-speed operation.

In Host mode, this controller core supports high-, full-, and low-speed operation. In Device mode, it supports high- and full-speed operation.

64.3.1.1 Host mode

The controller supports direct connection of a HS/FS/LS device with on-chip UTMI transceiver. Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a USB 2.0 high speed hub has been implemented within the DMA and protocol engine blocks to support connection to full and low speed devices.

64.3.1.2 Peripheral (device) mode

- 8 bidirectional endpoints

- High/full-speed operation
- Support of HNP, and SRP
- Remote wake-up capability

64.3.2 Modes of operation

The USB has two main modes of operation: normal mode and low power mode .

Each USB OTG controller core can operate in High Speed operation (480 Mbps), Full Speed operation (12 Mbps) and Low Speed operation (1.5 Mbps).

This chapter explains the operation modes.

64.3.2.1 Normal mode

The OTG controller core can operate in Host mode and Device (Peripheral) mode.

The USB controller core has its corresponding port, which can work in one or more interface modes.

NOTE

The USB controller supports only the interface type listed below. Selecting a different interface type in the PORTSC_PTS field results in unpredictable behavior and may cause the system to hang.

- OTG1 port
  - This port supports on-chip UTMI transceiver only.

64.3.2.2 Low-power mode

The USB controller core has a low-power mode (Suspend mode) to save power consumption.

As described in the USB 2.0 specification, the device can go into the Suspend state after it sees a constant Idle state on the upstream facing port. The OTG controller core enters the Suspend mode after 3 ms of inactivity on the port when it is in Device Operation mode. The host controllers, including the OTG controller in Host mode, do not suspend automatically but can be placed in the Suspend mode by software.

Either the local Arm platform or the remote USB Host/Peripheral can initiate a wake-up sequence to resume USB communication. For details about Suspend/Resume, see Power control.

64.3.2.2.1 Power control

The USB controller supports suspend and wake-up functionality.

The power control block allows for placing the transceiver in USB low power mode when USB bus is IDLE, and supports local and remote wake-up to bring the transceiver out of USB low power mode when needed. Additionally, the power control block can wake-up the Arm platform from core sleep mode by generating an interrupt.

64.3.2.2.1.1 Entering low power suspend mode

In Host operation mode, low power suspend mode is entered as follows:

1. Clear the ASE and PSE bits in USB_USBCMD, and wait until the AS and PS bits in USB_USBSTS become "0".
2. Set the "SUSPEND" bit in USB_PORTSC1
3. Set VBUSVALID_TO_SESSVALID in USBPHYx_USB1_VBUS_DETECT
4. Set the "PHCD" bit in USB_PORTSC1
5. Set all PWD bits in USBPHYx_PWD
6. Set CLKGATE in USBPHYx_CTRL

NOTE

Step 4,5,6 shall be done in atomic operation. That is, interrupt should be disabled during these three steps.

For device operation mode, low power suspend mode is entered as follows:

1. After Host drive is IDLE for 3ms, an SLI interrupt is issued (the "DCSUSPEND" or "SLI" bit in USB_USBSTS)
2. Set VBUSVALID_TO_SESSVALID in USBPHYx_USB1_VBUS_DETECT
3. Set the "PHCD" bit on USB_PORTSC1
4. Set all PWD bits in USBPHYx_PWD
5. Set CLKGATE in USBPHYx_CTRL

NOTE

Step 3,4,5 shall be done in atomic operation. That is, interrupt should be disabled during these three steps.

64.3.2.2.1.2 Wake-up events

The power control block monitors the USB bus when the USB core is in the USB suspend state.

Depending on whether the core is on Host or Device mode, a number of wake-up conditions are monitored. Upon detection of a wake-up condition, an interrupt will be generated to Arm platform if the related wake-up interrupt enable bit is set.

USB wake-up interrupt also re-activates the Arm platform clocks if they were stopped during the suspend.

64.3.2.2.1.2.1 Host mode events

The host controller wakes up on the following events:

- Remote Wake-up Request

A peripheral can request the host to reactivate the bus by driving wake-up signaling on the DM/DP lines. The power control block sends a wake-up request to the USB core when a J-K transition on DM/DP line is detected.

- Wake-Up On Overcurrent

If Wake-Up On Overcurrent is enabled (WKOC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when an overcurrent event is detected.

- Wake-Up On Disconnect

If Wake-Up On Disconnect is enabled (WKDC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when a disconnection event is detected (J-SE0/K-SE0 transition on DM/DP line).

- Wake-Up On Connect

If a Wake-Up On Connect is enabled (WKCN bit in the USB core register PORTSC1 is set '1'), the power control sub-block sends a wake-up request to the USB core when the connection event is detected (SE0-J/SE0-K transition on DM/DP line).

For a detailed description of register bits WKOC, WKDC, WKCN, see USB_nPORTSC1.

64.3.3 Interrupts

64.3.3.1 USB core interrupts

Each USB core uses one dedicated vector in the Interrupt Table. The vector numbers associated with each of the cores can be found in the Interrupt section.

With the exception of the wake-up interrupts, all of the interrupt sources are controlled in the USB Cores. Refer to the USB_nUSBINTR for details.

64.3.3.2 USB wake-up interrupts

Each USB Core has an associated wake-up interrupt. The wake-up interrupts are generated outside of the USB controller cores, but using the same vector as the corresponding USB controller cores interrupt.

These interrupts are generated by the Power Control blocks which run on the 32 kHz standby clock. The wake-up interrupt is designed to work even when the USB and Arm platform clocks are disabled, such that a wake-up condition on the USB bus can re-activate the Arm platform clocks.

Because the wake-up interrupt is generated and cleared on a 32 kHz clock, this interrupt request responds very slowly to clear actions. For this reason, the software must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously as this is clocked by the Arm platform clock. The software should wait for at least three 32 kHz clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. Because this interrupt is only used during low power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to entering the USB suspend mode.

64.3.3.3 Interrupts - host operational model

For detailed information about interrupt capability that the EHCI host controller hardware provides, see the "Interrupts" section in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

64.3.3.4 Servicing interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

64.3.3.4.1 High-frequency interrupts

High frequency interrupts in particular should be handled in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

The table below describes the High frequency interrupt events.

Table 508. High Frequency Interrupt Events

Execution Order	Interrupt	Action
1a	USB Interrupt - USB.ENDPTSETUPSTATUS	Copy contents of setup buffer and acknowledge setup packet (as indicated in Figure 352 shows the End Point Queue Head). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.
1b	USB Interrupt[1] - USB.ENDPTCOMPLETE	Handle completion of dTD as indicated in Figure 352 shows the End Point Queue Head.
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

64.3.3.4.2 Low-frequency interrupts

The low frequency interrupts can be handled in any order because they do not occur often in comparison to the high-frequency interrupts.

The table below shows the Low frequency interrupt events.

Table 509. Low Frequency Interrupt Events

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

64.3.3.4.3 Error interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

The following table shows the error interrupt events.

Table 510. Error Interrupt Events

Interrupt	Action
USB Error Interrupt	This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ USB.ENDPTCOMPLETE).
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

64.3.4 Clocks

The following table describes the clock sources for USB. See the clock control chapter for clock setting, configuration and gating information.

Table 511. USB Clocks

Clock	Description
ipg_ahb_clk	AHB bus clock
ipg_clk_s	Peripheral access clock

64.4 External signals

The table below lists the external signals of USB.

Table 512. USB External Signals

Signal	Description	Direction

64.5 Initialization

64.5.1 Host controller initialization

For detailed information, see the "Host Controller Initialization" section in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

64.5.2 Device controller initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs.

Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

- Set Controller Mode in the USB.USBMODE register to device mode.

  NOTE

  Transitioning from host mode to device mode requires a device controller reset before modifying USB.USBMODE.

- Allocate and Initialize device queue heads in system memory.
  - Minimum: Initialize device queue heads 0 Tx & 0 Rx.

    NOTE

    All device queue heads for control endpoints must be initialized before the endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

  - For information on device queue heads, refer to section Device data structures.
- Configure USB.ENDPOINTLISTADDR Pointer.
  - For additional information on USB.ENDPOINTLISTADDR, refer to the register table.
- Enable the microprocessor interrupt associated with the USB core.
  - Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend.
  - For a list of available interrupts refer to the USB_nUSBINTR and the USB_nUSBSTS register tables.
- Set Run/Stop bit to Run Mode.
  - After the Run bit is set and the device is connected to a host, a Bus Reset will be issued by host downstream port. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the Port State and Control section below.

    NOTE

    Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register.

It is also not necessary to prime Endpoint 0 initially because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

64.6 Application information

This section describes the detailed application knowledge for OTG1 port.

64.6.1 Register interface

Configuration, control and status registers are divided into three categories, identification, capability and operational registers.

NOTE

USB controller registers support only DWORD (32-bit) access.

- Identification registers are used to declare the slave interface presence along with the complete set of the hardware configuration parameters.
- Static, read only capability registers define the software limits, restrictions, and capabilities of the host/device controller.
- Operational registers are dynamic control or status registers that may be read only, read/write, or read/write-to-clear. The following sections define the use of these registers.

EHCI registers are listed alongside device registers to show the complementary nature of host and device control.

The following table describes the Interface register sets.

Table 513. Interface Register Sets

Offset	Register Set	Explanation
000h-07Ch	Identification Registers	Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.
100h-124h	Capability Registers	Capability registers specify the limits, restrictions, and capabilities of a host/device controller implementation. These values are used as parameters to the host/device controller driver.
080h-0FCh 140h-1FCh	Operational Registers	Operational registers are used by the system software to control and monitor the operational state of the host/device controller.

64.6.1.1 Configuration, control and status register set

The following table describes the Device/Host capability registers.

NOTE

Depending on implementation, "*x*" can have the following values: UOG1.

Table 514. Device/Host Capability Registers

Offset	Size (Bytes)	Mnemonic	Register Name	Device Mode	Host Mode
000h	4	USB_*x*_ID	Identification Register	O	O
004h	4	USB_*x*_HWGENERAL	General Hardware Parameters	O	O
008h	4	USB_*x*_HWHOST	Host Hardware Parameters	X	O

1C4 ... 1DCh		USB_*x*_ENDPTCTRL1 .... USB_*x*_ENDPTCTRL7			

NOTE

"O" means the register is available in host/device operation mode;

"X" means the register is reserved in host/device operation mode

64.6.1.2 Identification registers

Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.

64.6.1.3 OTG operations

64.6.1.3.1 Register bits

In the previous section, the Register interface has behaviors described for device mode and behaviors described for host mode. However, for OTG operations it is necessary to perform tasks independent of the controller mode.

NOTE

The only way to transit the controller mode out of host or device mode is with the controller reset bit. Therefore, it is also necessary for the OTG tasks to be performed independent of a controller reset as well as independent of the controller mode.

The following figure shows the controller mode.

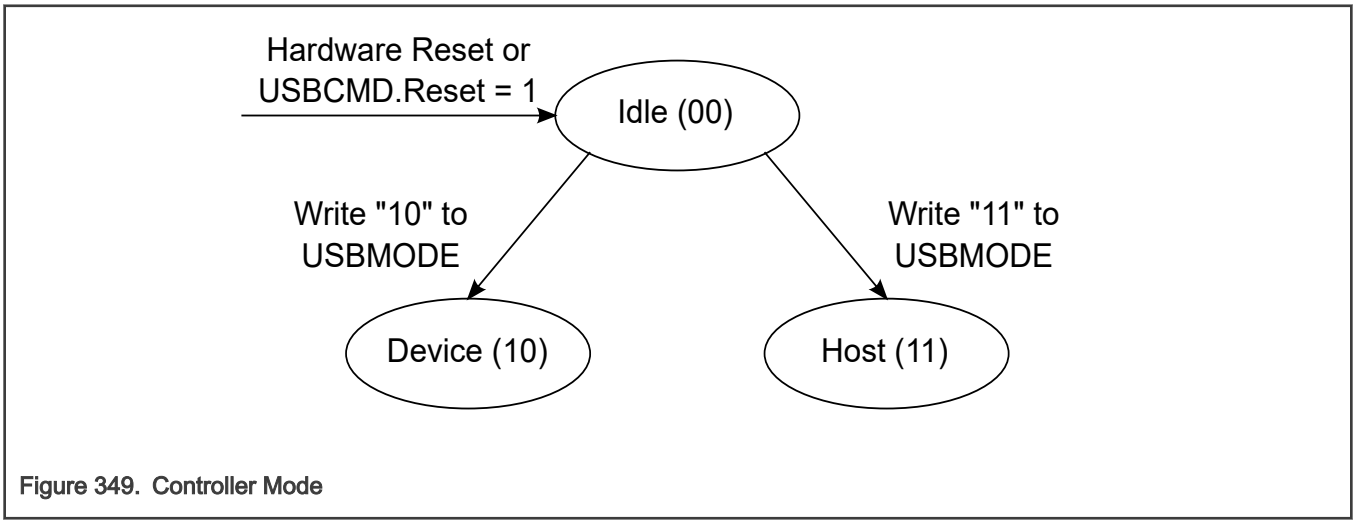

Figure 349. Controller Mode

To this end, listed below are the register bits that are used for OTG operations, which are independent of the controller mode and are also not affected by a write to the reset bit in the USBCMD register:

All Identification Registers

All Device/Host Capability Registers

OTGSC: All bits

PORTSC1:

- Physical Interface Select
- Physical Interface Serial Select
- Physical Interface Data Width
- Physical Interface Low Power
- Physical Interface Wake Signals
- Port Indicators
- Port Power

64.6.2 Host data structures

For detailed information, see the "Data Structures" chapter in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

64.6.3 Host operational model

For detailed information, see the "Operational Model" chapter in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

64.6.4 EHCI deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specification. Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com. Device operation & On-The-Go operation is not specified in the EHCI and thus the implementation supported in this core is proprietary.

The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator - Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation - In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface - This core does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation - This design includes an On-The-Go controller for Port #1.

64.6.4.1 Embedded transaction translator function

The OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

64.6.4.1.1 Discovery-EHCI deviation

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation.

The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, Chirp completes successfully).

Because this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in USB.PORTSCx.

Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in the following table.

Table 515. Summary of EHCI

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X. [where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (i.e. Split target hub)]	FS and LS device can be either downstream from a HS hub with HubAddr = X [HubAddr > 0] or directly attached [where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (i.e. Split target hub is the root hub)]

64.6.4.1.2 Operational model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specification. Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. http://www.usb.org) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

64.6.4.1.2.1 Micro- frame pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the micro-frame pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

64.6.4.1.2.2 Split state machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator.

Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. The following table summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

Table 516. Summary of the Conditions of Handshakes[1]

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full.	NAK
Start-Split: All periodic buffers full.	ERR
Start-Split: Success for start of Async. Transaction.	ACK
Start-Split: Start Periodic Transaction.	No Handshake (OK)
Complete-Split: Failed to find transaction in queue.	Bus Time Out
Complete-Split: Transaction in Queue is Busy.	NYET
Complete-Split: Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

1. The unshaded cells represent Start-Splits and the shaded cells represent Complete-Splits

64.6.4.1.2.3 Asynchronous transaction scheduling and buffer management

USB 2.0 specification items	Implementation in the embedded transaction translator
11.17.3	Sequencing is provided and a packet length estimator ensures that no FS or LS packet babbles exist in the SOF time
11.17.4	Transaction tracking happens for two data pipes

64.6.4.1.2.4 Periodic transaction scheduling and buffer management

USB 2.0 specification items	Implementation in the embedded transaction translator
11.18.6.[1-2]	• Abort of pending start-split conditions: — End of frame (EOF), and not started in six microframes — Idle for more than four microframes • Abort of pending complete-split conditions:

Table continues on the next page...

Table continued from the previous page...

USB 2.0 specification items	Implementation in the embedded transaction translator
	— EOF — Idle for more than four microframes
11.18.[7-8]	• Transaction tracking for up to 16 data pipes • Complete-split transaction searching **NOTE** There is no data schedule mechanism for these transactions other than the microframe pipeline. The embedded TT assumes that the number of packets scheduled in a frame does not exceed the frame duration (1 ms); else, it results in an undefined behavior.

64.6.4.1.2.5 Multiple transaction translators

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N_TT field in the HCSPARAMS register.

64.6.4.2 Device operation

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

64.6.4.2.1 USB_USBMODE register

Given that the dual-role controller is initialized in neither host nor device mode, the USB_nUSBMODE register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

64.6.4.2.2 Non-zero fields the register file

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode .

64.6.4.2.3 SOF interrupt

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for host mode.

EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See USB_nUSBSTS and USB_nUSBINTR registers.

64.6.4.3 Embedded design interface

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

64.6.4.3.1 Frame adjust register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of micro-frames are timed precisely to 125 us using the transceiver clock as a reference clock. That is, a 60 MHz transceiver clock for 8-bit physical interfaces & full-speed serial interfaces or 30 MHz transceiver clock for 16-bit physical interfaces.

64.6.4.4 Miscellaneous variations from EHCI

64.6.4.4.1 Programmable physical interface behaviour

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes. Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase. The control bits for selecting the Physical Interface operating mode have been added to the USB_nPORTSC1 register providing a capability that is not defined by EHCI.

64.6.4.4.2 Discovery

64.6.4.4.2.1 Port reset

The port connect methods specified by EHCI require setting the port reset bit in the USB_nPORTSC1 register for a duration of 10 ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10 ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to reset the device.
- Software shall write a '0' to reset the device after 10 ms.
  - This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress, the write will simple be ignored and the reset will continue until completion.
- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device in now operational and at this point the port speed has been determined.

64.6.4.4.2.2 Port speed detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation, which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices.

Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.
- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed - *This information is redundant with the 2-bit Port Speed indicator above.*

64.6.4.4.3 Port test mode

Port Test Control mode behaves fully as described in EHCI. An alternate host controller driver procedure is not necessary or supported.

64.6.5 Device data structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller.

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

NOTE

Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/ writable fields. The device controller must preserve the read-only fields on all data structure writes.

The figure below shows the organization of the EndPoint Queue Head.

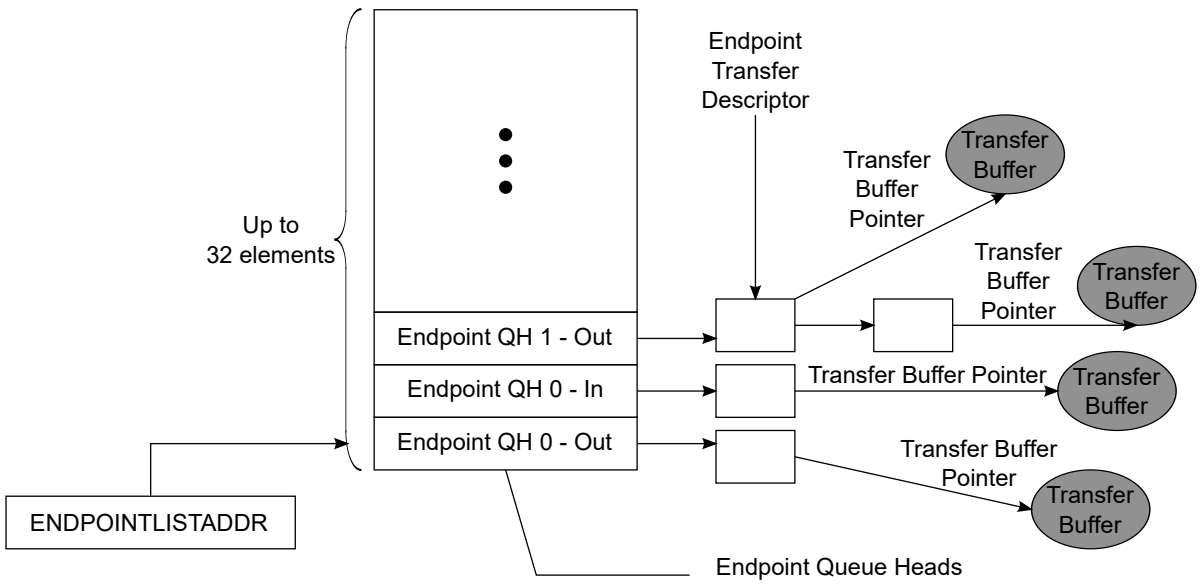

Figure 350. EndPoint Queue Head Organization

Endpoint queue heads are arranged in an array in a continuous area of memory pointed to by the USB.ENDPOINTLISTADDR pointer. The even-numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). That is, the device queue heads in the list with even offset support receiver endpoints (OUT) and the queue heads in the list with odd offset are used for transmit endpoint(IN). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

NOTE

The Endpoint Queue Head List must be aligned to a 2k boundary.

64.6.5.1 Endpoint Queue Head (dQH)

The device Endpoint Queue Head (dQH) is where all transfers for a given endpoint are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries.

During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD status

DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

Table 517. Endpoint Queue Head (dQH)

Host Controller Read/Write Host Controller Read Only

64.6.5.1.1 Endpoint capabilities/characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not attempt to modify this information while the corresponding endpoint is enabled.

Table 518 describes the endpoint capabilities.

Table 518. Endpoint Capabilities/Characteristics

Bit	Description
31-30	Mult. This field is used to indicate the number of packets executed per transaction description as given by the following: 00 - Execute N Transactions as demonstrated by the USB variable length packet protocol where N is computed using the Maximum Packet Length (dQH) and the Total Bytes field (dTD) 01 Execute 1 Transaction. 10 Execute 2 Transactions. 11 Execute 3 Transactions. **NOTE** Non-ISO endpoints must set Mult="00". ISO endpoints must set Mult="01", "10", or "11" as needed.
29	Zero Length Termination Select. This bit is used to indicate when a zero length packet is used to terminate transfers where to total transfer length is a multiple . This bit is not relevant for Isochronous 0 - Enable zero length packet to terminate transfers equal to a multiple of the Maximum Packet Length. (default). 1 - Disable the zero length packet on transfers that are equal in length to a multiple Maximum Packet Length.
28-27	Reserved. These bit reserved for future use and should be set to zero.
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	Interrupt On Setup (IOS). This bit is used on control type endpoints to indicate if USBINT is set in response to a setup being received.
14-0	Reserved. Bits reserved for future use and should be set to zero.

64.6.5.1.2 Transfer overlay-endpoint queue head

The seven DWords in the overlay area represent a transaction working space for the device controller.

The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See dTD for a description of the overlay fields.

64.6.5.1.3 Current dTD pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

The following table describes the dTD Pointer.

Table 519. Next dTD Pointer

Bit	Description

Table continues on the next page...

Table 519. Next dTD Pointer (continued)

31-5	Current dTD. This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.
4-0	Reserved. Bit reserved for future use and should be set to zero.

64.6.5.1.4 Set-up buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

NOTE

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

The following table describes the Multiple Mode Control.

Table 520. Multiple Mode Control (HCCPARAMS)

DWord	Bits	Description
1	31-0	Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.
2	31-0	Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

64.6.5.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/received for a given transfer.

The DCD should not attempt to modify any field in an active dTD except the Next Like Pointer, which should only be modified as described in section Managing transfers with transfer descriptors.

Table below shows the Endpoint Transfer Descriptor (dTD).

Table 521. Endpoint Transfer Descriptor (dTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 521. Endpoint Transfer Descriptor (dTD) (continued)

Buffer Pointer (Page 4)	Reserved

Host Controller Read/Write  Host Controller Read Only

The following table describes the dTD Pointer.

Table 522. Next dTD Pointer

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved. Bits reserved for future use and should be set to zero.
0	Terminate (T). 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

The following table describes the dTD Token.

Table 523. dTD Token

Bit	Description
31	Reserved. Bit reserved for future use and should be set to zero.
30-16	Total Bytes. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction. The maximum value software may store in the field is 5*4K (5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K (4000H). If the value of the field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for IN transfers that Total Bytes To Transfer be an even multiple of *Maximum Packet Length*. If software builds such a transfer descriptor for an IN transfer, the last transaction will always be less that *Maximum Packet Length*.
15	Interrupt On Complete (IOC). This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.
14-12	Reserved. Bits reserved for future use and should be set to zero.
11-10	Multiplier Override (MultO). This field can be used for transmit ISO's (i.e. ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO. Example:

Table continues on the next page...

Table 523. dTD Token (continued)

	if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 0 [default] Three packets are sent: {Data2(8); Data1(7); Data0(0)} if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 2 Two packets are sent: {Data1(8); Data0(7)} For maximal efficiency, software should compute MultO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultO should be 1. Note: Non-ISO and Non-TX endpoints must set MultO = "00".
9-8	Reserved. Bits reserved for future use and should be set to zero.
7-0	Status. This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are: Bit Status Field Description 7 Active. 6 Halted. 5 Data Buffer Error. 3 Transaction Error. 4, 2, 0 Reserved.

The table below describes the dTD Buffer Page Pointer List.

Table 524. dTD Buffer Page Pointer List

Bit	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
0,11-0	Current Offset. Offset into the 4kb buffer where the packet is to begin.
1,10-0	Frame Number. Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.

64.6.6 Device operational model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus.

Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

64.6.6.1 Port state and control

After receiving a reset on the bus, the port will enter the *defaultFS or defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0.

The following state diagram depicts the state of a USB 2.0 device.

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'.

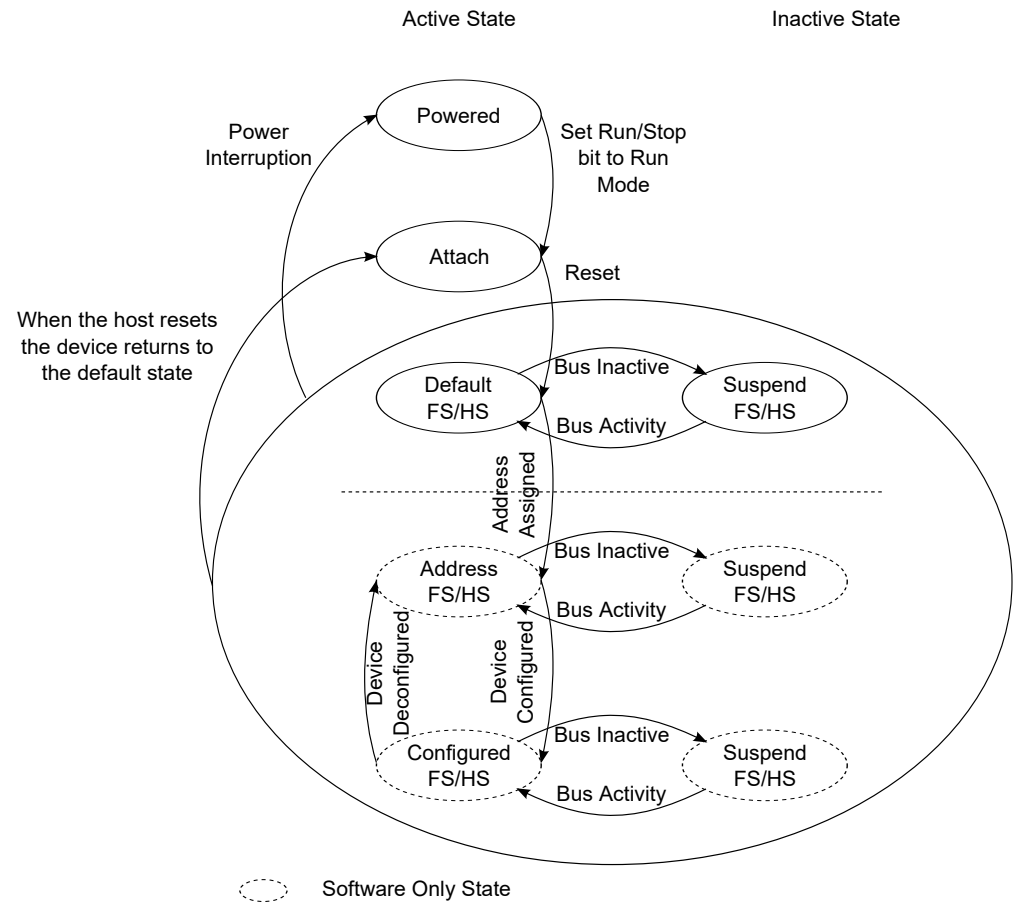

Figure 351. Device State Diagram

States *powered, attach, defaultFS/HS, suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits:

The following table describes the Device Controller State Information Bits.

Table 525. Device Controller State Information Bits

Bit	Register
DCSuspend	USBSTS
USB Reset Received	USBSTS
Port Change Detect	USBSTS
High-Speed Port	PORTSC1

It is the responsibility of the DCD to maintain a state variable to differentiate between the *DefaultFS/HS* state and the *Address/Configured* states. Change of state from *Default* to *Address* and the *Configured* states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the *Address* state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the *Configured* indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the USB_UOG_ENDPTCTRLx registers and initializing the associated queue heads.

64.6.6.1.1 Bus reset

A bus reset is used by the host to initialize downstream devices.

When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the USB_nENDPTSTAT register and writing the same value back to the USB_nENDPTSTAT register.

Clear all the endpoint complete status bits by reading the USB_nPTCOMPLETE register and writing the same value back to the USB_nENDPTCOMPLETE register.

Cancel all primed status by waiting until all bits in the USB_nENDPTPRIME are 0 and then writing 0xFFFFFFFF to USB_nENDPTFLUSH.

Read the reset bit in the USB_nPORTSC1 register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare.)

- A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the USB_nPORTSC1 to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9 - Device Framework.

NOTE

The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

64.6.6.1.2 Suspend and resume

Suspend state: operational model	Resume state: operational model
To conserve power, USB devices automatically enter the Suspended state when the device observes no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. The attached devices must be prepared to suspend at any time they are powered, regardless of whether they are assigned a nondefault address, are configured, or neither of the two	If the device controller is suspended, its operation is resumed when an active signal is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port by writing 1 to PORTSC1[FPR] while the device is in the Suspend state. Sending resume signal to an upstream port must cause the host to issue resume signaling and bring the suspended bus segment (one more device) back to the active condition.

Table continues on the next page...

Suspend state: operational model	Resume state: operational model
conditions exist. Bus activity may cease because of the host entering a Suspend mode of its own. In addition, a USB device must enter the Suspended state when the hub port it is attached to is disabled. A USB device exits Suspend mode when there is bus activity. It may also request the host to exit Suspend mode or selective suspend by using electrical signaling to indicate remote wake-up. The ability of a device to signal remote wake-up is optional. If the USB device is capable of remote wake-up signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wake-up signaling must be disabled. The device controller moves into the Suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the Suspend state, an interrupt notifies the DCD (assuming that PORTSC1[SUSP] is 1, which means, the device controller is suspended). The DCD response, when the device controller is suspended, is application-specific and may involve switching to a low-power operation. See the USB 2.0 specification for information about bus power limits in Suspend state. **NOTE** Review system level clocking issues defined in Clocking section for the clocking requirements of a suspended device controller.	**NOTE** The host must enable resume signaling, by using the set feature command defined in the device framework (chapter 9 of the USB 2.0 specification), before using it.

64.6.6.2 Managing endpoints

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device.

The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a *control* type data channel used for device discovery and enumeration. Other types of endpoints support by USB include *bulk, interrupt*, and *isochronous*. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

The USB OTG device controller hardware supports up to 8 endpoint numbers.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a *queue head* allocated in memory. To support the 8 endpoint numbers, 16 *queue heads* are required. The operation of an endpoint and use of *queue heads* are described later in this document.

64.6.6.2.1 Endpoint initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the USB_UOG_ENDPTCTRLx register.

Each 32-bit USB_UOG_ENDPTCTRLx is split into an upper and lower half. The lower half of USB_UOG_ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the USB_UOG_ENDPTCTRLx register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization. The following table shows the fields and values for the Device Controller Endpoint initialization.

Table 526. Device Controller Endpoint Initialization

Field	Value
Data Toggle Reset	1
Data Toggle Inhibit	0
Endpoint Type	00 Control 01 Isochronous 10 Bulk 11 Interrupt
Endpoint Stall	0

64.6.6.2.2 Stalling

There are two occasions where the device controller may need to return to the host a STALL.

The first occasion is the functional stall, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the USB_UOG_ENDPTCTRLx register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A protocol stall, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the USB_UOG_ENDPTCTRLx register can ensure that both stall bits are set at the same instant.

NOTE

Any write to the USB_UOG_ENDPTCTRLx register during operational mode must preserve the endpoint type field (that is, perform a read-modify-write).

The following table shows the response matrix for the Device Controller Stall.

Table 527. Device Controller Stall Response Matrix

USB Packet	Endpoint Stall Bit.	Effect on STALL bit.	USB Response
SETUP packet received by a non-control endpoint.	N/A	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'1'	None.	STALL

Table continues on the next page...

Table 527. Device Controller Stall Response Matrix (continued)

IN/OUT/PING packet received by a non-control endpoint.	'0'	None.	ACK/ NAK/ NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1'	None	STALL
IN/OUT/PING packet received by a control endpoint.	'0'	None.	ACK/ NAK/ NYET

64.6.6.2.3 Data toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe.

For more information on data toggle, refer to the USB 2.0 specification.

64.6.6.2.3.1 Data toggle reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the USB_UOG_ENDPTCTRLx register.

This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

64.6.6.2.3.2 Data toggle inhibit

NOTE

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

64.6.6.2.3.3 Priming transmit endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH).

After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the USB_UOG_ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Because only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. More information about FIFO sizing is presented in section .

64.6.6.2.3.4 Priming receive endpoints

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

64.6.6.3 Operational model for packet transfers

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification.

At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1 transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "priming" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term "flushing" is used to describe the action of clearing a packet that was queued for execution.

64.6.6.3.1 Interrupt/Bulk endpoint operational model

The behaviors of the device controller for interrupt and bulk endpoints are identical.

All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

N = INT(Number Of Bytes/Max. Packet Length) + 1

With Zero Length Termination (ZLT) = 1

N = MAXINT(Number Of Bytes/Max. Packet Length)

Table 528. Variable Length Transfer Protocol Example (ZLT = 0)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3

Table continues on the next page...

Table 528. Variable Length Transfer Protocol Example (ZLT = 0) (continued)

511	256	2	256	255	
512	256	3	256	256	0
512	512	2	512	0	

Table 529. Variable Length Transfer Protocol Example (ZLT = 1)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	2	256	256	
512	512	1	512		

NOTE

The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. *** Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. *** Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. *** This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). *** This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

NOTE

All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

64.6.6.3.1.1 Interrupt/Bulk endpoint bus response matrix

The table below shows the response matrix for Interrupt/Bulk Endpoint Bus.

Table 530. Interrupt/Bulk Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow

Table continues on the next page...

Table 530. Interrupt/Bulk Endpoint Bus Response Matrix (continued)

Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

NOTE

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

64.6.6.3.2 Control endpoint operation model

This section details the setup phase, data phase, status phase, and the control endpoint bus response matrix.

64.6.6.3.2.1 Setup phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

The setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted be an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

- Disable Setup Lockout by writing 1 to Setup Lockout Mode (SLOM) in USB_nUSBMODE. (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

NOTE

Leaving the Setup Lockout Mode As 0 will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting UBS_nENDSETUPSTAT to determine that a setup packet was received on a particular pipe:
  1. Write 1 to clear corresponding bit UBS_nENDSETUPSTAT.
  2. Write 1 to Setup Tripwire (SUTW) in USB_nUSBCMD register.
  3. Duplicate contents of dQH.SetupBuffer into local software byte array.
  4. Read Setup TripWire (SUTW) in USB_nUSBCMD register. (if set - continue; if cleared - go to 2)
  5. Write 0 to clear Setup Tripwire (SUTW) in USB nUSBCMD register.
  6. Process setup packet using local software byte array copy and execute status/handshake phases.

NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

64.6.6.3.2.2 Data phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the USB.ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the USB_nENDPTPRIME register is zero and the associated bit in the USB_nENDPTSTAT register is a one. If a prime fails, i.e. The USB_nENDPTPRIME bit goes to zero and the USB_nENDPTSTAT bit is not set, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status (USB_nENDPTSTAT) to enforce data coherency with the setup packet.

NOTE

- The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

64.6.6.3.2.3 Status phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase.

The DCD must also perform the same checks of the USB.ENDPTSETUPSTAT as described above in the data phase.

NOTE

- The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

64.6.6.3.2.4 Control endpoint bus response matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

The table below shows the response matrix for the Control Endpoint Bus.

Table 531. Control Endpoint Bus Response Matrix

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSERR	
In	STALL	NAK	Transmit	BS Error	N/A	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A

Table continues on the next page...

Table 531. Control Endpoint Bus Response Matrix (continued)

Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

64.6.6.3.3 Isochronous endpoint operational model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes.

Real time delivery by the device controller will be accomplished by the following:

- Exactly MULT Packets per (micro) Frame are transmitted/received. Note: MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets are sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro) frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the *Transaction Error* bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
  - MULT counter reaches zero.
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT

NOTE

For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
  - MULT counter reaches zero.
  - Non-MDATA Data PID is received**
    - ** Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
  - Overflow Error:
    - Packet received is > maximum packet length. [*Buffer Error* bit is set]
    - Packet received exceeds total bytes allocated in dTD. [*Buffer Error* bit is set]
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT
  - CRC Error [*Transaction Error* bit is set]

NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

64.6.6.3.3.1 Isochronous pipe synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the (micro) frame number (USB_UOG_FRINDEX register) can be used as a marker.

To cause a packet transfer to occur at a specific (micro) frame number [N], the DCD should interrupt on SOF during frame N-1. When the USB_UOG_FRINDEX=N-1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro) frame N-1 so that the device controller will execute delivery during (micro) frame N.

NOTE

Priming an endpoint towards the end of (micro) frame N-1 will not guarantee delivery in (micro) frame N. The delivery may actually occur in (micro) frame N+1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

64.6.6.3.3.2 Isochronous endpoint bus response matrix

The following table shows the response matrix for the Isochronous Endpoint Bus.

Table 532. Isochronous Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL Packet	NULL Packet	Transmit	BS Error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. BS Error = Force Bit Stuff Error

   NULL Packet = Zero Length Packet

64.6.6.4 Managing queue heads

The following figure shows the End Point Queue Head.

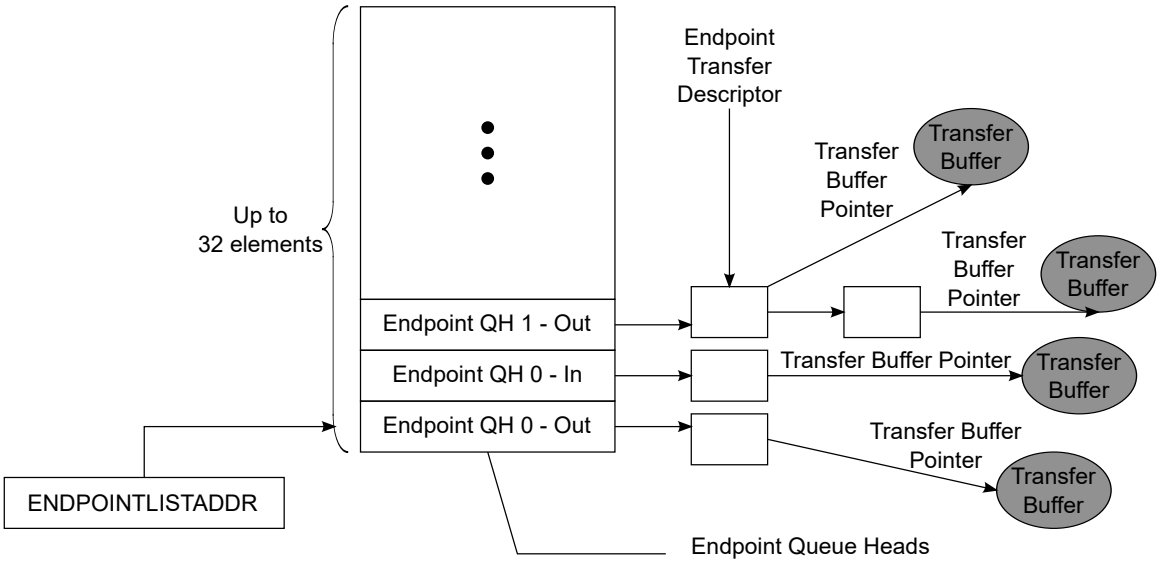

Figure 352. End Point Queue Head Diagram

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTD). An area of memory pointed to by USB.ENDPOINTLISTADDR contains a group of all dQH's in a sequential list as shown in Figure 352. The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers will no longer exist within the queue head once the dTD is retired (see section Software link pointers).

In addition to the current and next pointers and the dTD overlay examined in section Operational model for packet transfers, the dQH also contains the following parameters for the associated endpoint: Multiplier, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

64.6.6.4.1 Queue head initialization

One device queue head must be initialized for each active endpoint.

To initialize a device queue head:

- Write the wMaxPacketSize field as required by the USB Chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1,2, or 3 as required bandwidth and in conjunction with the USB Chapter 9 protocol.

NOTE

In FS mode, the multiplier field can only be 1 for ISO endpoints.

- Write the next dTD Terminate bit field to 1.
- Write the Active bit in the status field to 0.
- Write the Halt bit in the status field to 0.

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTD's.

64.6.6.4.2 Operational model for setup transfers

As discussed in section Control endpoint operation model, setup transfer requires special treatment by the DCD. A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a "1" to the corresponding bit in ENDPTSETUPSTAT.

NOTE

- The acknowledge must occur before continuing to process the setup packet.
- After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH - RX. Only the local software copy should be examined.

3. Check for pending data or status dTD's from previous control transfers and flush if any exist as discussed in section Flushing/De-priming an endpoint.
4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

NOTE

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

64.6.6.5 Managing transfers with transfer descriptors

These sections detail how to build, execute, and complete transfers with transfer descriptors.

64.6.6.5.1 Software link pointers

It is necessary for the DCD software to maintain head and tail pointers to the for the linked list of dTDs for each respective queue head.

This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list. The following figure shows the Software Link Pointers.

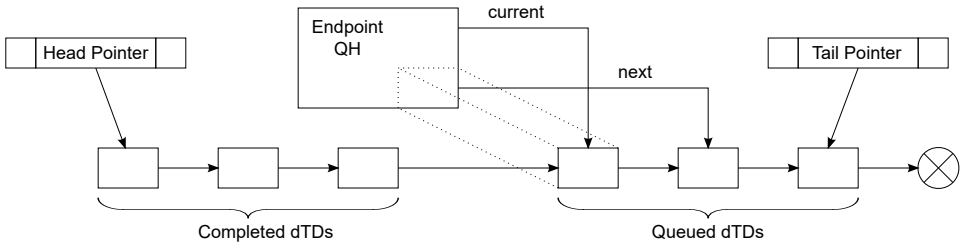

Figure 353. Software Link Pointers

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

64.6.6.5.2 Building a transfer descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer.

Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to "00000"

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to 1.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to 1 and all remaining status bits set to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

64.6.6.5.3 Executing a transfer descriptor

To safely add a dTD, the DCD must be follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty: Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding).

- Case 1: Link list is empty
    1. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
    2. Clear active & halt bit in dQH (in case set from a previous error).
    3. Prime endpoint by writing 1 to correct bit position in ENDPTPRIME. Software should check that the dTD/dQH content in external memory is updated before setting the bit in ENDPTPRIME register.
- Case 2: Link list is not empty
    1. Add dTD to end of linked list.
    2. Read correct prime bit in ENDPTPRIME - if 1 DONE.
    3. Set ATDTW bit in USBCMD register to 1.
    4. Read correct status bit in ENDPTSTAT. (store in tmp. variable for later)
    5. Read ATDTW bit in USBCMD register.
        - If 0 go to 3.
        - If 1 continue to 6.
    6. Write ATDTW bit in USBCMD register to 0.
    7. If status bit read in (3) is 1 DONE.
    8. If status bit read in (3) is 0 then go to Case 1: Step 1.

64.6.6.5.4 Transfer completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

NOTE

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the Device error matrix.

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

64.6.6.5.5 Flushing/De-priming an endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer.

There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in ENDPTFLUSH.
2. Wait until all bits in ENDPTFLUSH are '0'.
   - Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.
3. Read ENDPTSTAT register to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:
   - Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using ENDPTFLUSH register. A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush be repeating steps 1-3 until each endpoint is successfully flushed.

64.6.6.5.6 Device error matrix

The following table summarizes packet errors that are not automatically handled by the Device Controller.

Table 533. Device Error Matrix

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow **	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated. The table below describes the errors.

Table 534. Error Descriptions

Error	Description
Overflow	Number of bytes received exceeded max. packet size or total buffer length. ** This error will also set the Halt bit in the dQH and if there are dTDs remaining in the linked list for the endpoint, then those will not be executed.
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.
ISO Fulfillment Error	Host failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the "dead" (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.

64.7 USB non-core memory map/register definition

64.7.1 USBNC register descriptions

There are two kinds of registers in the USB module: The USB core registers and USB non-core registers. The USB core registers are used to control USB core functions and are more independent of USB features. The USB controller core has its own core registers. The USB non-core registers are additional to USB core registers and are more dependent on the USB features. The USB non-core registers support the 32,16, and 8-bit register access.

This section describes only the USB non-core registers. For detailed descriptions of the USB core registers, see Register interface.

NOTE

For reserved bits, preserve the value when writing (read its reset value, then write this value back).

64.7.1.1 USBNC memory map

USBHS1.USBNC base address: 4010_B200h

Offset	Register	Width (In bits)	Access	Reset value
0h	USB OTG Control 1 (CTRL1)	32	RW	3000_1000h
4h	USB OTG Control 2 (CTRL2)	32	RW	5F00_0000h
10h	USB Host HSIC Control (HSIC_CTRL)	32	RW	1000_4084h

64.7.1.2 USB OTG Control 1 (CTRL1)

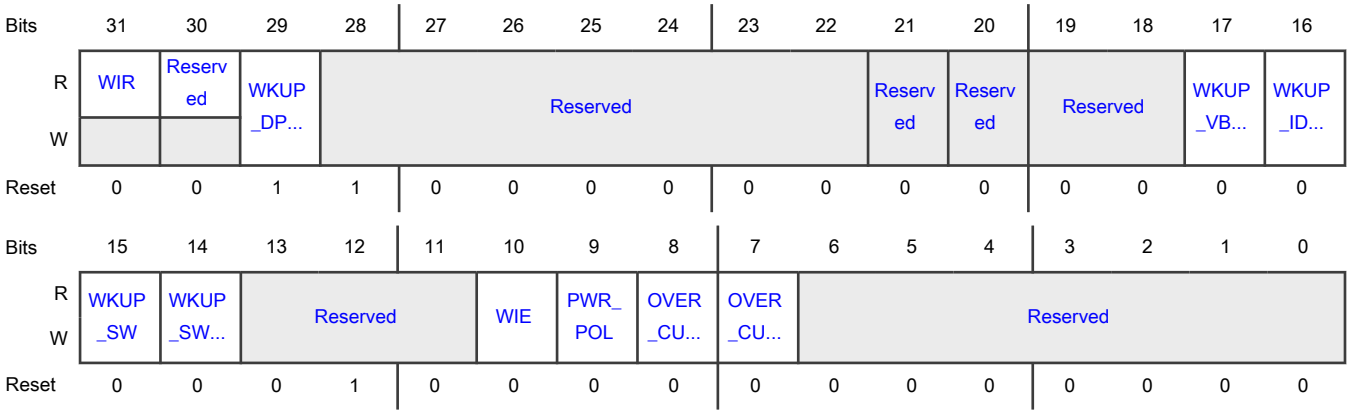
Offset

Register	Offset
CTRL1	0h

Function

Controls the integration specific features of the USB OTG1 module. These features are not directly related to the USB functionality, but control special features, interfacing on the USB ports, as well as power control and wake-up functionality.

Diagram



Fields

Field	Function
31 WIR	Wake-up Interrupt Request Indicates that a wake-up interrupt request is received on the OTG1 port. This bit is cleared by disabling the wake-up interrupt (clearing bit "OWIE"). 0b - No request received 1b - Request received
30 —	Reserved
29 WKUP_DPDM_EN	Wake-up on DPDM Change Enable 0b - DPDM changes wake-up to be disabled only when VBUS is 0 1b - DPDM changes wake-up to be enabled, it is for device only

64.8.1.6 TX Buffer Hardware Parameters (HWTXBUF)

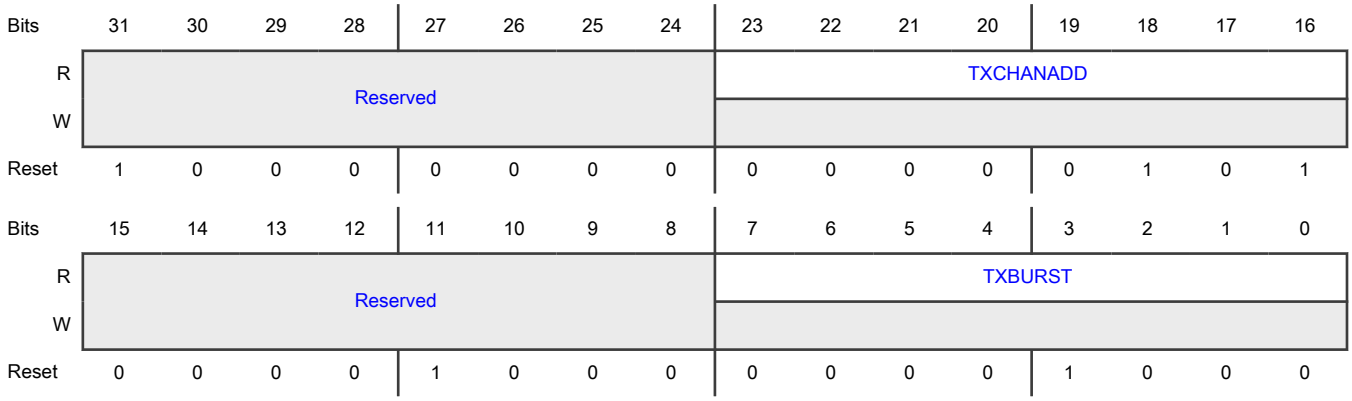
Offset

Register	Offset
HWTXBUF	10h

Function

Indicates TX buffer hardware parameters such as burst size, FIFO buffer size, and so on.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 TXCHANADD	TX FIFO Buffer size is: (2^TXCHANADD) * 4 Bytes These bits are set to '08h', so buffer size is 256*4 Bytes. For the OTG controller operating in device mode, this is the FIFO buffer size per endpoint. As the OTG controller has 8 TX endpoint, there are 8 of these buffers. For the OTG controller operating in host mode, or for Host-only controller, the entire buffer memory is used as a single TX buffer. Therefore, there is only 1 of this buffer.
15-8 —	Reserved
7-0 TXBURST	Default burst size for memory to TX buffer transfer This is reset value of TXPBURST bits in USB core register USB_n_BURSTSIZE. See BURSTSIZE.

64.8.1.7 RX Buffer Hardware Parameters (HWRXBUF)

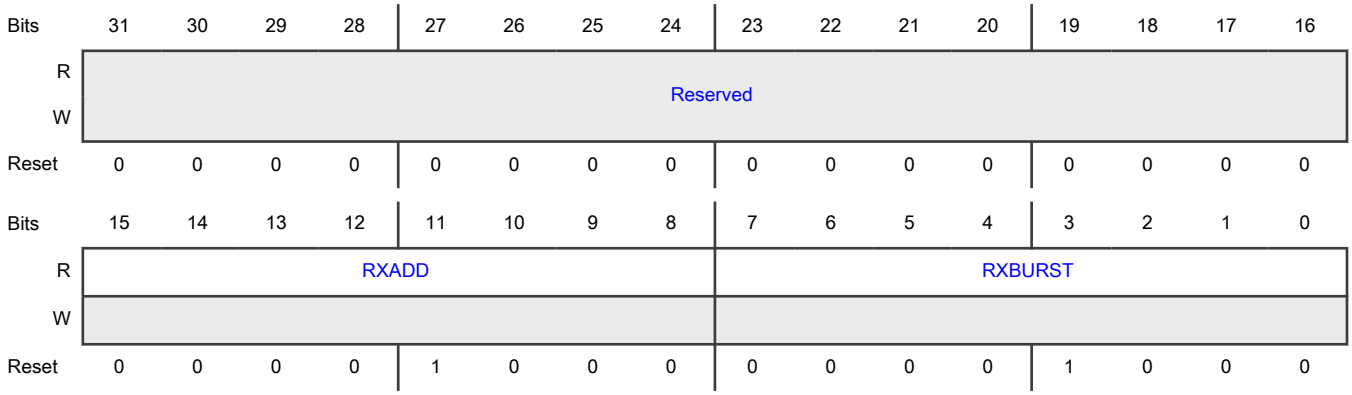
Offset

Register	Offset
HWRXBUF	14h

Function

Indicates RX buffer hardware parameters such as burst size, FIFO buffer size, and so on.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 RXADD	Buffer total size for all receive endpoints is (2^RXADD) RX Buffer size is: (2^RXADD) * 4 Bytes. These bits are set to '08h', so buffer size is 256*4 Bytes. There is a single Receive FIFO buffer in the USB controller. The buffer is shared for all endpoints for the OTG controller in device mode.
7-0 RXBURST	Default burst size for memory to RX buffer transfer This is reset value of RXPBURST bits in USB core register USB_n_BURSTSIZE. See BURSTSIZE.

64.8.1.8 General Purpose Timer #0 Load (GPTIMER0LD)

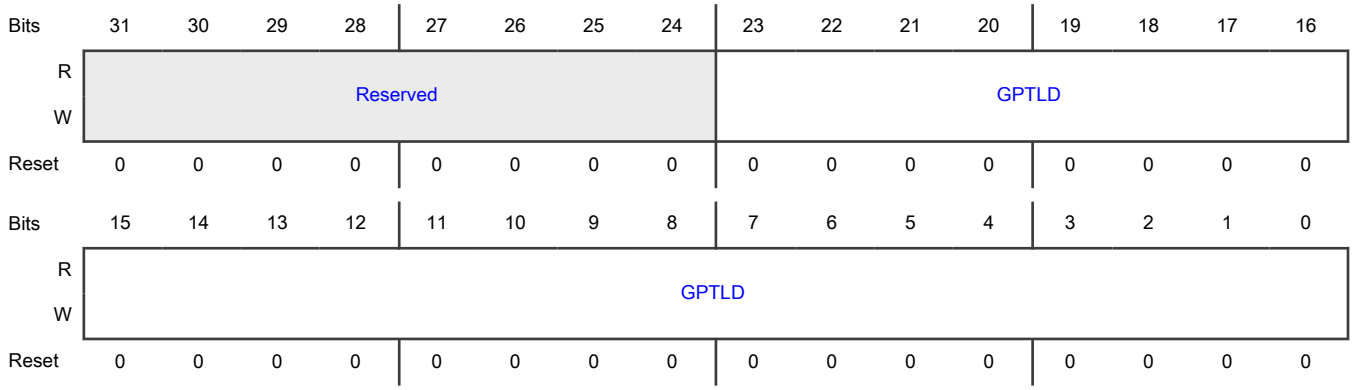
Offset

Register	Offset
GPTIMER0LD	80h

Function

Controls load value of the count timer in register n_GPTIMER0CTRL. See GPTIMER0CTRL.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 GPTLD	General Purpose Timer Load Value These bit fields are loaded to GPTCNT bits when GPTRST bit is set '1b'. This value represents the time in microseconds minus 1 for the timer duration. Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. **NOTE** Max value is 0xFFFFFF or 16.777215 seconds.

64.8.1.9 General Purpose Timer #0 Controller (GPTIMER0CTRL)

Offset

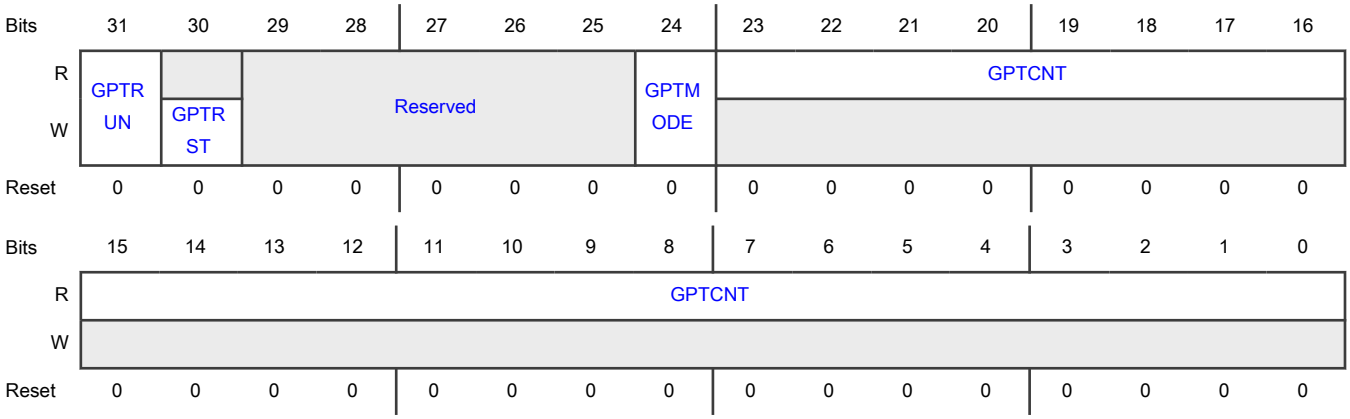
Register	Offset
GPTIMER0CTRL	84h

Function

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI0 bit in n_USBSTS register (See USBSTS), interrupt enable bit is TIE0 bit in n_USBINTR register. (See USBINTR .)

Diagram



Fields

Field	Function
31 GPTRUN	General Purpose Timer Run GPTCNT bits are not effected when setting or clearing this bit. 0b - Stop counting 1b - Run
30 GPTRST	General Purpose Timer Reset 0b - No action 1b - Load counter value from GPTLD bits in n_GPTIMER0LD
29-25 —	Reserved
24 GPTMODE	General Purpose Timer Mode In one shot mode, the timer will count down to zero, generate an interrupt, and stop until the counter is reset by software; In repeat mode, the timer will count down to zero, generate an interrupt and automatically reload the counter value from GPTLD bits to start again. 0b - One Shot Mode 1b - Repeat Mode
23-0 GPTCNT	General Purpose Timer Counter This field is the count value of the countdown timer.

64.8.1.10 General Purpose Timer #1 Load (GPTIMER1LD)

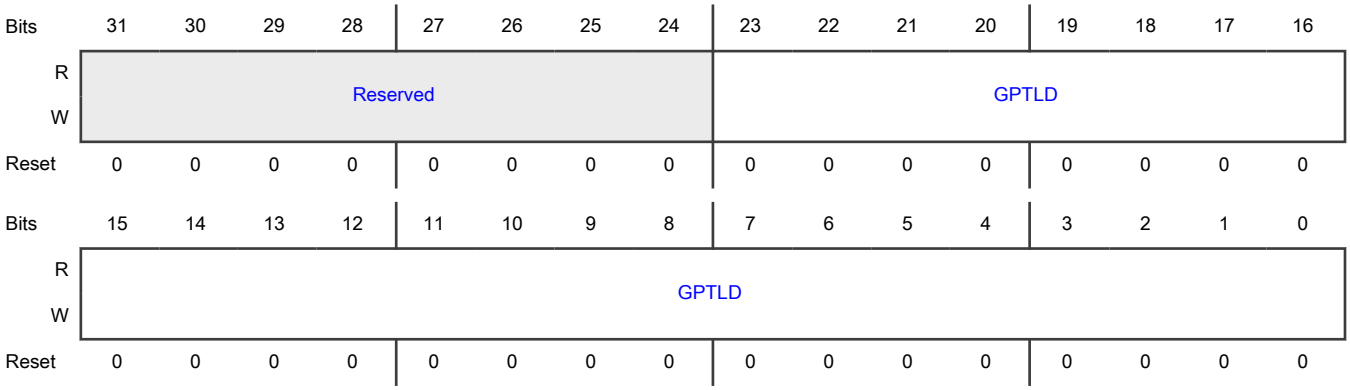
Offset

Register	Offset
GPTIMER1LD	88h

Function

This register controls load value of the count timer in register n_GPTIMER1CTRL. See GPTIMER1CTRL .

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 GPTLD	General Purpose Timer Load Value These bit fields are loaded to GPTCNT bits when GPTRST bit is set '1b'. This value represents the time in microseconds minus 1 for the timer duration. Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. **NOTE** Max value is 0xFFFFFF or 16.777215 seconds.

64.8.1.11 General Purpose Timer #1 Controller (GPTIMER1CTRL)

Offset

Register	Offset
GPTIMER1CTRL	8Ch

Function

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI1 bit in USB_n_USBSTS register (See USBSTS), interrupt enable bit is TIE1 bit in n_USBINTR register (See USBINTR).

23-0 GPTCNT	General Purpose Timer Counter This field is the count value of the countdown timer.

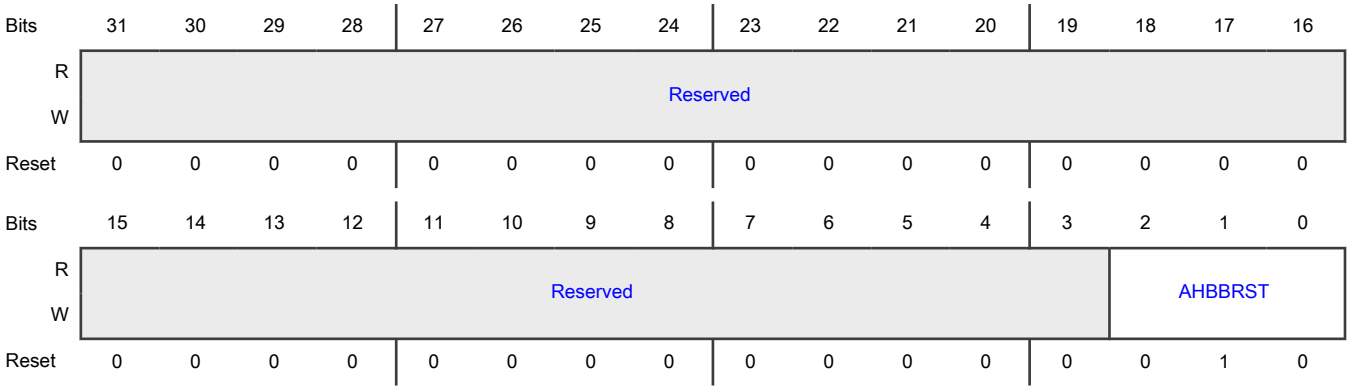
64.8.1.12 System Bus Config (SBUSCFG)

Offset

Register	Offset
SBUSCFG	90h

Function
This register defines the system bus configuration.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 AHBBRST	AHB master interface Burst configuration These bits control AHB master transfer type sequence (or priority). **NOTE** This register overrides n_BURSTSIZE register when its value is not zero. 000b - Incremental burst of unspecified length only 001b - INCR4 burst, then single transfer 010b - INCR8 burst, INCR4 burst, then single transfer 011b - INCR16 burst, INCR8 burst, INCR4 burst, then single transfer 100b - Reserved, don't use 101b - INCR4 burst, then incremental burst of unspecified length 110b - INCR8 burst, INCR4 burst, then incremental burst of unspecified length 111b - INCR16 burst, INCR8 burst, INCR4 burst, then incremental burst of unspecified length

64.8.1.13 Capability Registers Length (CAPLENGTH)

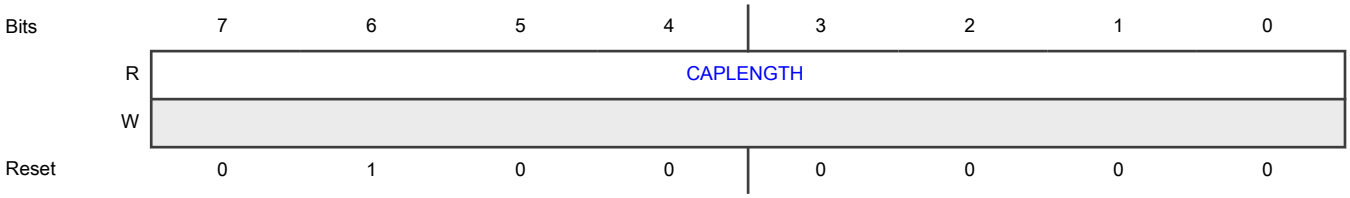
Offset

Register	Offset
CAPLENGTH	100h

Function

The Capability Registers Length register contains the address offset to the Operational registers relative to the CAPLENGTH register.

Diagram



Fields

Field	Function
7-0 CAPLENGTH	These bits are used as an offset to add to register base to find the beginning of the Operational Register. Default value is '40h'.

64.8.1.14 Host Controller Interface Version (HCIVERSION)

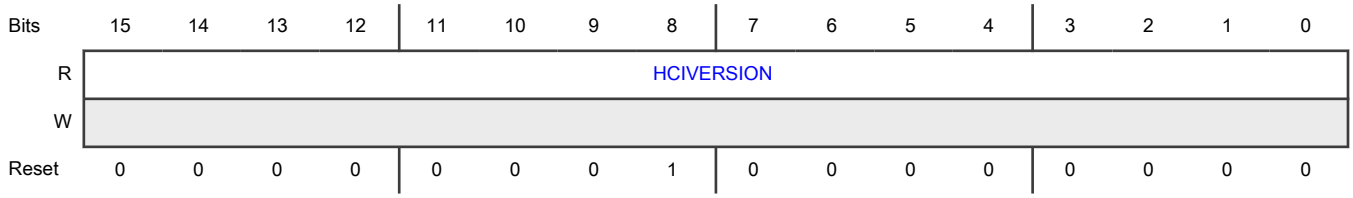
Offset

Register	Offset
HCIVERSION	102h

Function

This is a 2-byte register containing a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision.

Diagram



Fields

Field	Function
15-0 HCIVERSION	Host Controller Interface Version Number Default value is '10h', which means EHCI rev1.0.

64.8.1.15 Host Controller Structural Parameters (HCSPARAMS)

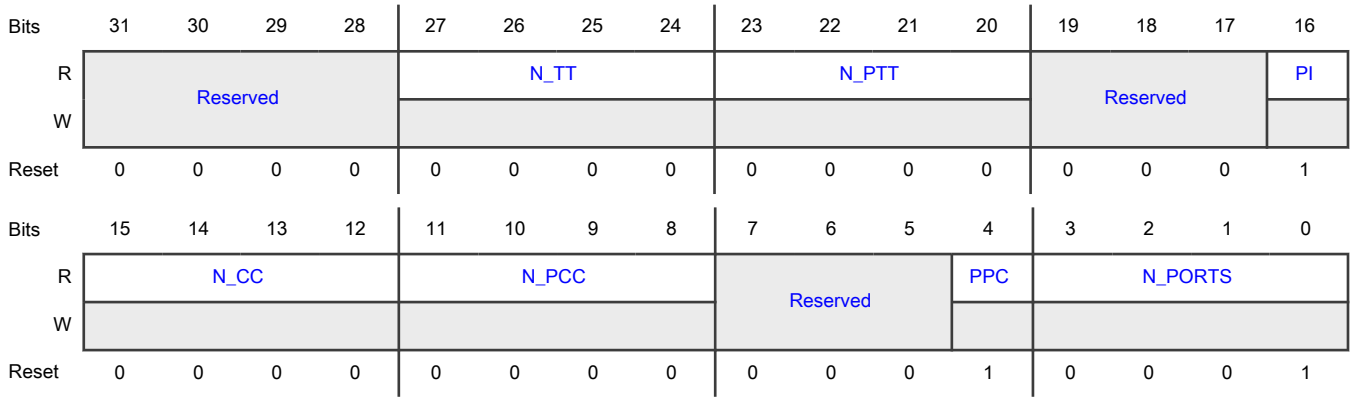
Offset

Register	Offset
HCSPARAMS	104h

Function

The following figure shows the port steering logic capabilities of Host Control Structural Parameters (n_HCSPARAMS).

Diagram



Fields

Field	Function
31-28 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
27-24 N_TT	Number of Transaction Translators This field indicates the number of embedded transaction translators associated with the USB2.0 host controller. These bits would be set to '0001b' for Multi-Port Host, and '0000b' for Single-Port Host.
23-20 N_PTT	Number of Ports per Transaction Translator This field indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. These bits would be set to equal N_PORTS for Multi-Port Host, and '0000b' for Single-Port Host.
19-17 —	Reserved
16 PI	Port Indicators (P INDICATOR) This bit indicates whether the ports support port indicator control. When set to one, the port status and control registers include a read/writeable field for controlling the state of the port indicator. This bit is "1b" in all controller core.
15-12 N_CC	Number of Companion Controller This field indicates the number of companion controllers associated with this USB2.0 host controller. These bits are '0000b' in all controller core. 0000b - There is no internal Companion Controller and port-ownership hand-off is not supported 0001b - There are internal companion controller(s) and port-ownership hand-offs is supported
11-8 N_PCC	Number of Ports per Companion Controller This field indicates the number of ports supported per internal Companion Controller. It is used to indicate the port routing configuration to the system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC. These bits are '0000b' in all controller core.
7-5 —	Reserved
4 PPC	Port Power Control This field indicates whether the host controller implementation includes port power control. A one indicates the ports have port power switches. A zero indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each port status and control register

Table continues on the next page...

Table continued from the previous page...

Field	Function
3-0 N_PORTS	Number of Downstream Ports This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register. Valid values are in the range of 1h to Fh. A zero in this field is undefined. These bits are always set to '0001b' because all controller cores are Single-Port Host.

64.8.1.16 Host Controller Capability Parameters (HCCPARAMS)

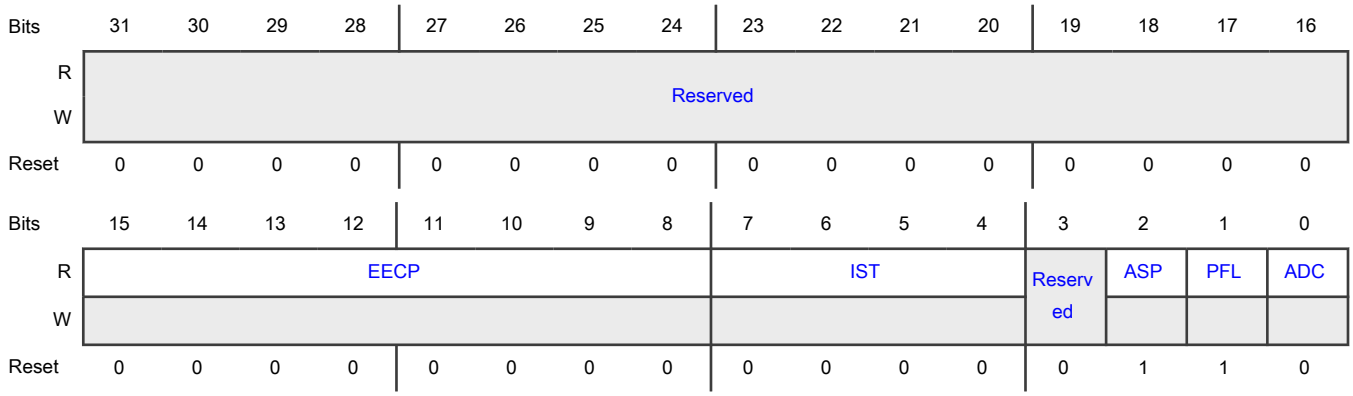
Offset

Register	Offset
HCCPARAMS	108h

Function

This register identifies multiple mode control (time-base bit functionality), addressing capability.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 EECP	EHCI Extended Capabilities Pointer This field indicates the existence of a capabilities list. A value of 00h indicates no extended capabilities are implemented. A non-zero value in this register indicates the offset in PCI configuration space of the first EHCI extended capability. The pointer value must be 40h or greater if implemented to maintain the consistency of the PCI header defined for this class of device.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE These bits are set '00h' in all controller core.
7-4 IST	Isochronous Scheduling Threshold This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. These bits are set '00h' in all controller core.
3 —	Reserved
2 ASP	Asynchronous Schedule Park Capability If this bit is set to a one, then the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the Asynchronous Schedule Park Mode Enable and Asynchronous Schedule Park Mode Count fields in the USBCMD register. **NOTE** ASP bit reset value: '00b' for OTG controller core, '11b' for Host-only controller core.
1 PFL	Programmable Frame List Flag If this bit is set to zero, then the system software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero. If set to a one, then the system software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous. This bit is set '1b' in all controller core.
0 ADC	64-bit Addressing Capability This bit is set '0b' in all controller core, no 64-bit addressing capability is supported.

64.8.1.17 Device Controller Interface Version (DCIVERSION)

Offset

Register	Offset
DCIVERSION	120h

Function

This register indicates the two-byte BCD encoding of the device controller interface version number.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	1	1	0	0	0	1	0	0	0

Fields

Field	Function
31-9 —	Reserved
8 HC	Host Capable When this bit is 1, this controller is capable of operating as an EHCI compatible USB 2.0 host controller.
7 DC	Device Capable When this bit is 1, this controller is capable of operating as a USB 2.0 device.
6-5 —	Reserved
4-0 DEN	Device Endpoint Number This field indicates the number of endpoints built into the device controller. If this controller is not device capable, then this field will be zero. Valid values are 0 - 15.

64.8.1.19 USB Command (USBCMD)

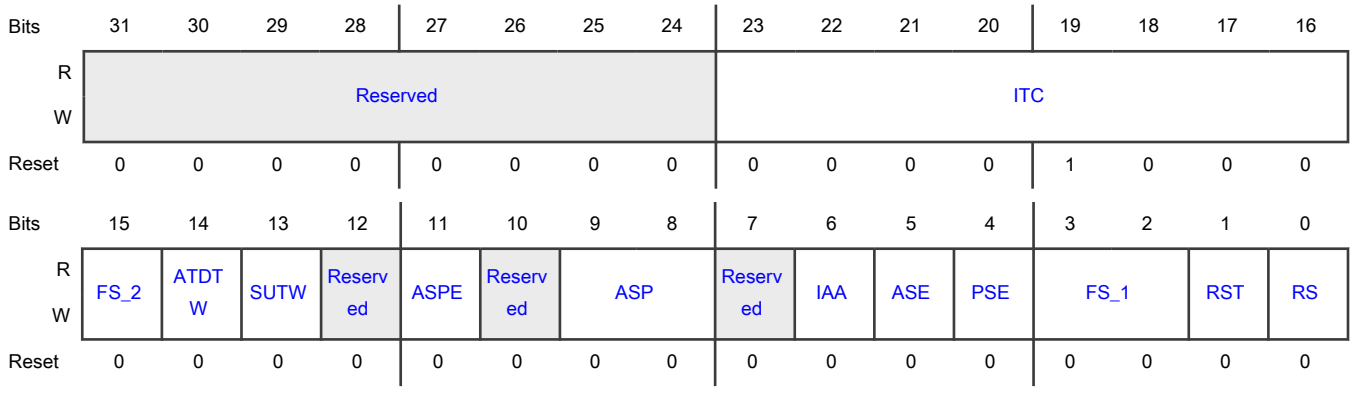
Offset

Register	Offset
USBCMD	140h

Function

The Command Register indicates the command to be executed by the serial bus host/device controller. Writing to the register causes a command to be executed.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 ITC	Interrupt Threshold Control The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 0000_0000b - Immediate (no threshold) 0000_0001b - 1 micro-frame 0000_0010b - 2 micro-frames 0000_0100b - 4 micro-frames 0000_1000b - 8 micro-frames 0001_0000b - 16 micro-frames 0010_0000b - 32 micro-frames 0100_0000b - 64 micro-frames
15 FS_2	Frame List Size [host mode only] This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. Specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. This field defines bit 2 of the following values. USBCMD[FS_1] defines bits 1:0. 000b - 1024 elements (4096 bytes) 001b - 512 elements (2048 bytes) 010b - 256 elements (1024 bytes) 011b - 128 elements (512 bytes) 100b - 64 elements (256 bytes) 101b - 32 elements (128 bytes) 110b - 16 elements (64 bytes) 111b - 8 elements (32 bytes)
14 ATDTW	Add dTD TripWire[device mode only] This bit is used as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software. This bit would also be cleared by hardware when state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized.

Table continues on the next page...

Table continued from the previous page...

Field	Function
13 SUTW	Setup TripWire [device mode only] This bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by the DCD without being corrupted. If the setup lockout mode is off (SLOM bit in USB core register n_USBMODE, see USBMODE) then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software. This bit would also be cleared by hardware when a hazard detected.
12 —	Reserved
11 ASPE	Asynchronous Schedule Park Mode Enable If the Asynchronous Park Capability bit in the HCCPARAMS register is a one, then this bit defaults to a 1h and is R/W. Otherwise the bit must be a zero and is RO. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. **NOTE** ASPE bit reset value: '0b' for OTG controller .
10 —	Reserved
9-8 ASP	Asynchronous Schedule Park Mode Count If the Asynchronous Park Capability bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is Read-Only. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when Park Mode Enable is a one as this will result in undefined behavior. This field is set to 3h in all controller core.
7 —	Reserved
6 IAA	Interrupt on Async Advance Doorbell This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results.
5 ASE	Asynchronous Schedule Enable This bit controls whether the host controller skips processing the Asynchronous Schedule. Only the host controller uses this bit. 0b - Do not process the Asynchronous Schedule 1b - Use the ASYNCLISTADDR register to access the Asynchronous Schedule
4 PSE	Periodic Schedule Enable This bit controls whether the host controller skips processing the Periodic Schedule. Only the host controller uses this bit. 0b - Do not process the Periodic Schedule 1b - Use the PERIODICLISTBASE register to access the Periodic Schedule
3-2 FS_1	Frame List Size Specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. This field defines bits 1:0 of the following values. USBCMD[FS_2] defines bit 2. 000b - 1024 elements (4096 bytes) 001b - 512 elements (2048 bytes) 010b - 256 elements (1024 bytes) 011b - 128 elements (512 bytes) 100b - 64 elements (256 bytes) 101b - 32 elements (128 bytes) 110b - 16 elements (64 bytes) 111b - 8 elements (32 bytes)
1 RST	Controller Reset Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host operation mode: When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior. Device operation mode:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Writing a one to this bit when the device is in the attached state is not recommended, because the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints should be flushed and the USBCMD Run/Stop bit should be set to 0.
0 RS	Run/Stop Host operation mode: When set to '1b', the Controller proceeds with the execution of the schedule. The Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the controller is in the Halted state (that is, HCHalted in the USBSTS register is a one). Device operation mode: Writing a one to this bit will cause the controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the controller has been properly initialized. Writing a 0 to this will cause a detach event. 0b - Stop 1b - Run

64.8.1.20 USB Status (USBSTS)

Offset

Register	Offset
USBSTS	144h

Function

This register indicates various states of the Host/Device Controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-26 —	Reserved
25 TI1	General Purpose Timer Interrupt 1 (GPTINT1) This bit is set when the counter in the GPTIMER1CTRL register transitions to zero, writing a one to this bit will clear it.
24 TI0	General Purpose Timer Interrupt 0 (GPTINT0) This bit is set when the counter in the GPTIMER0CTRL register transitions to zero, writing a one to this bit clears it.
23-17 —	Reserved
16 NAKI	NAK Interrupt Bit This bit is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when all Enabled TX/RX Endpoint NAK bits are cleared.
15 AS	Asynchronous Schedule Status This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
14 PS	Periodic Schedule Status This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately

Table continues on the next page...

Table continued from the previous page...

Field	Function
	disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
13 RCL	Reclamation This is a read-only status bit used to detect an empty asynchronous schedule. Only used in the host operation mode.
12 HCH	HCHalted This bit is a zero whenever the Run/Stop bit is a one. The Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Controller hardware (for example, an internal error). Only used in the host operation mode. Default value is '0b' for OTG core . This is because OTG core is not operating as host in default. See CM bit in USB_n_USBMODE register. **NOTE** HCH bit reset value: '0b' for OTG controller core .
11 —	Reserved
10 ULPII	ULPI Interrupt This bit will be set '1b' by hardware when there is an event completion in ULPI viewport. This bit is usable only if the controller support UPLI interface mode.
9 —	Reserved
8 SLI	DCSuspend When a controller enters a suspend state from an active state, this bit will be set to a one. The device controller clears the bit upon exiting from a suspend state. Only used in device operation mode.
7 SRI	SOF Received When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1 ms in device FS mode and every 125 µs in HS mode and will be synchronized to the actual SOF that is received. Because the device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to connect and chirp.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In host mode, this bit will be set every 125 µs and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it.
6 URI	USB Reset Received When the device controller detects a USB Reset and enters the default state, this bit will be set to a one. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used in device operation mode.
5 AAI	Interrupt on Async Advance System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the n_USBCMD register. This status bit indicates the assertion of that interrupt source. Only used in host operation mode.
4 SEI	System Error This bit is will be set to '1b' when an Error response is seen to a read on the system interface.
3 FRI	Frame List Rollover The Host Controller sets this bit to a one when the Frame List Index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USB_n_USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FHINDEX [12] toggles. Only used in host operation mode.
2 PCI	Port Change Detect The Host Controller sets this bit to a one when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively.
1 UEI	USB Error Interrupt (USBERRINT) When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set. The device controller detects resume signaling only.
0 UI	USB Interrupt (USBINT) This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.

64.8.1.21 Interrupt Enable (USBINTR)

Offset

Register	Offset
USBINTR	148h

Function

The interrupts to software are enabled with this register. An interrupt is generated when a bit is set and the corresponding interrupt source is active. The USB Status register (n_USBSTS) still shows interrupt sources even if they are disabled by the n_USBINTR register, allowing polling of interrupt events by the software.

19 UPIE	USB Host Periodic Interrupt Enable When this bit is one, and the UPI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
18 UAIE	USB Host Asynchronous Interrupt Enable When this bit is one, and the UAI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
17 —	Reserved
16 NAKE	NAK Interrupt Enable When this bit is one and the NAKI bit in n_USBSTS register is a one the controller will issue an interrupt.
15-11 —	These bits are reserved and should be set to zero.
10 —	Reserved
9 —	Reserved
8 SLE	Sleep Interrupt Enable When this bit is one and the SLI bit in n_n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
7 SRE	SOF Received Interrupt Enable When this bit is one and the SRI bit in n_USBSTS register is a one the controller will issue an interrupt.
6 URE	USB Reset Interrupt Enable When this bit is one and the URI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
5 AAE	Async Advance Interrupt Enable When this bit is one and the AAI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
4 SEE	System Error Interrupt Enable When this bit is one and the SEI bit in n_USBSTS register is a one the controller will issue an interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Only used in host operation mode.
3 FRE	Frame List Rollover Interrupt Enable When this bit is one and the FRI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
2 PCE	Port Change Detect Interrupt Enable When this bit is one and the PCI bit in n_USBSTS register is a one the controller will issue an interrupt.
1 UEE	USB Error Interrupt Enable When this bit is one and the UEI bit in n_USBSTS register is a one the controller will issue an interrupt.
0 UE	USB Interrupt Enable When this bit is one and the UI bit in n_USBSTS register is a one the controller will issue an interrupt.

64.8.1.22 USB Frame Index (FRINDEX)

Offset

Register	Offset
FRINDEX	14Ch

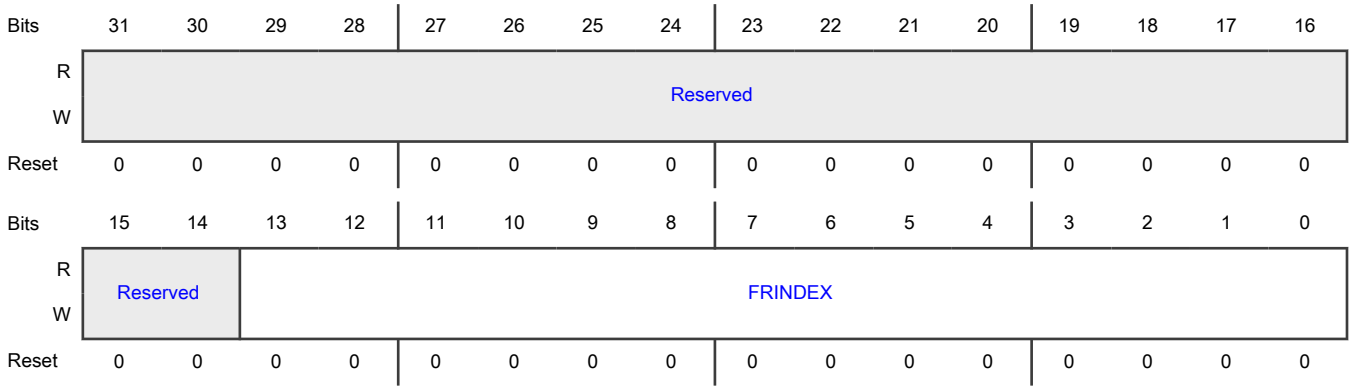
Function

This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the n_USBCMD register.

This register must be written as a DWord. Byte writes produce undefined results. This register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit. A write to this register while the Run/Stop hit is set to a one produces undefined results. Writes to this register also affect the SOF value.

In device mode this register is read only and, the device controller updates the FRINDEX [13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX [13:3] will be checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] will be set to the SOF value and FRINDEX [2:0] will be set to zero (that is, SOF for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] will be increment (that is, SOF for 125 us micro-frame.).

Diagram



Fields

Field	Function
31-14 —	Reserved
13-0 FRINDEX	Frame Index The value, in this register, increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. This means that each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode. USBCMD [Frame List Size] Number Elements N In device mode the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode bits 2:0 indicate the current microframe. The bit field values description below is represented as (Frame List Size) Number Elements N. 00_0000_0000_0000b - (1024) 12 00_0000_0000_0001b - (512) 11 00_0000_0000_0010b - (256) 10 00_0000_0000_0011b - (128) 9 00_0000_0000_0100b - (64) 8 00_0000_0000_0101b - (32) 7 00_0000_0000_0110b - (16) 6 00_0000_0000_0111b - (8) 5

64.8.1.23 Device Address (DEVICEADDR)

Offset

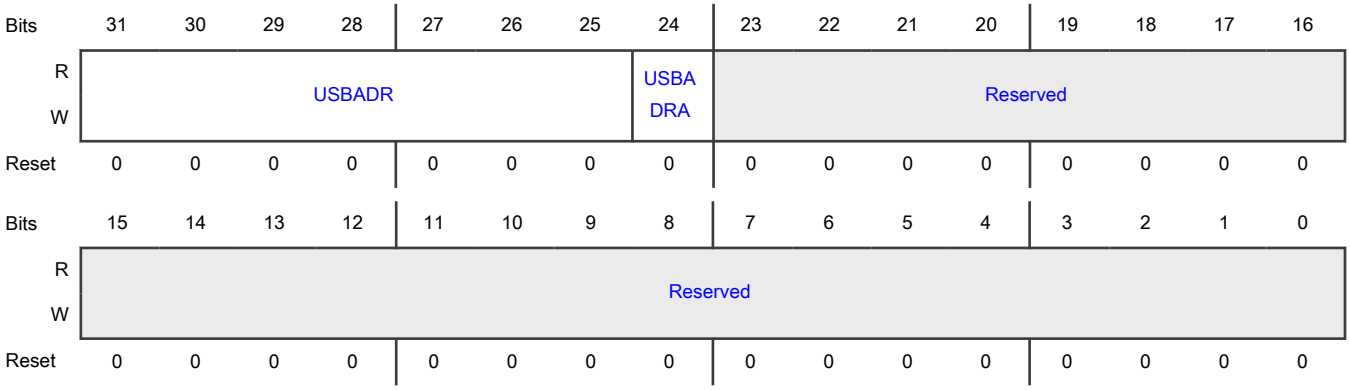
Register	Offset
DEVICEADDR	154h

Function

Device Controller only

The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS descriptor.

Diagram



Fields

Field	Function
31-25 USBADR	Device Address These bits correspond to the USB device address
24 USBADRA	Device Address Advance When this bit is '0', any writes to USBADR are instantaneous. When this bit is written to a '1' at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: • IN is ACKed to endpoint 0. (USBADR is updated from staging register). • OUT/SETUP occur to endpoint 0. (USBADR is not updated). • Device Reset occurs (USBADR is reset to 0).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
23-0 —	- Reserved

64.8.1.24 Frame List Base Address (PERIODICLISTBASE)

Offset

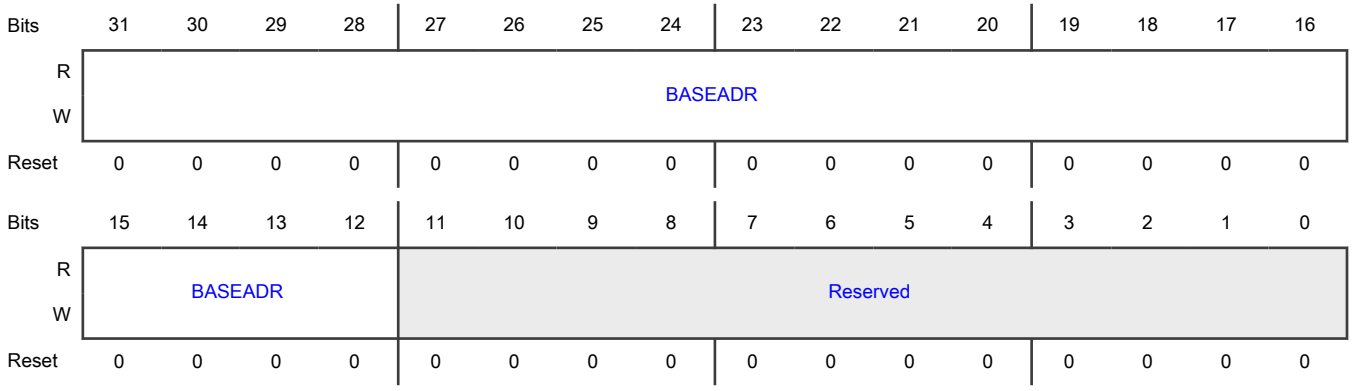
Register	Offset
PERIODICLISTBASE	154h

Function

Host Controller only

This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (USB_n_FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.

Diagram



Fields

Field	Function
31-12 BASEADR	Base Address (Low) These bits correspond to memory address signals [31:12], respectively. Only used by the host controller.
11-0 —	- Reserved

64.8.1.25 Next Asynch. Address (ASYNCLISTADDR)

Offset

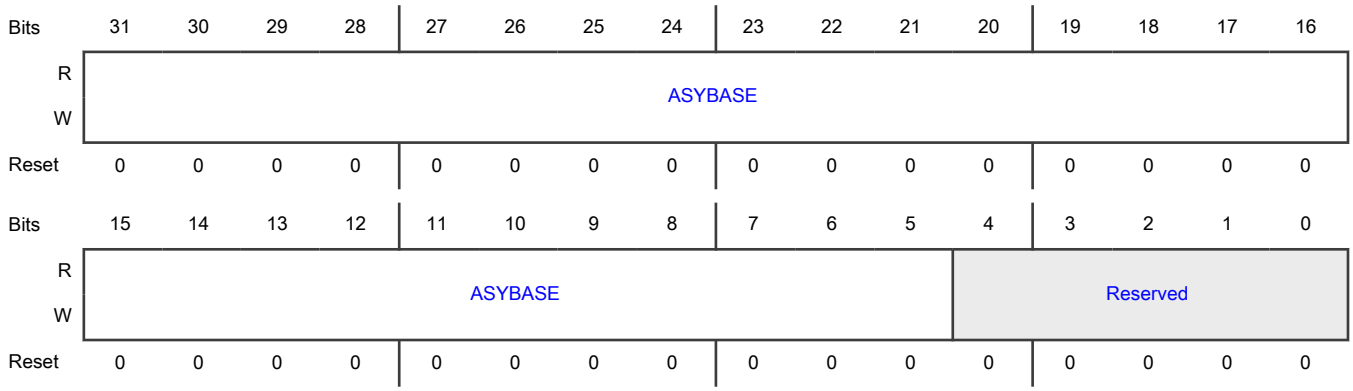
Register	Offset
ASYNCLISTADDR	158h

Function

Host Controller only

This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Bits [4:0] of this register cannot be modified by the system software and will always return a zero when read.

Diagram



Fields

Field	Function
31-5 ASYBASE	Link Pointer Low (LPL) These bits correspond to memory address signals [31:5], respectively. This field may only reference a Queue Head (QH). Only used by the host controller.

64.8.1.27 Programmable Burst Size (BURSTSIZE)

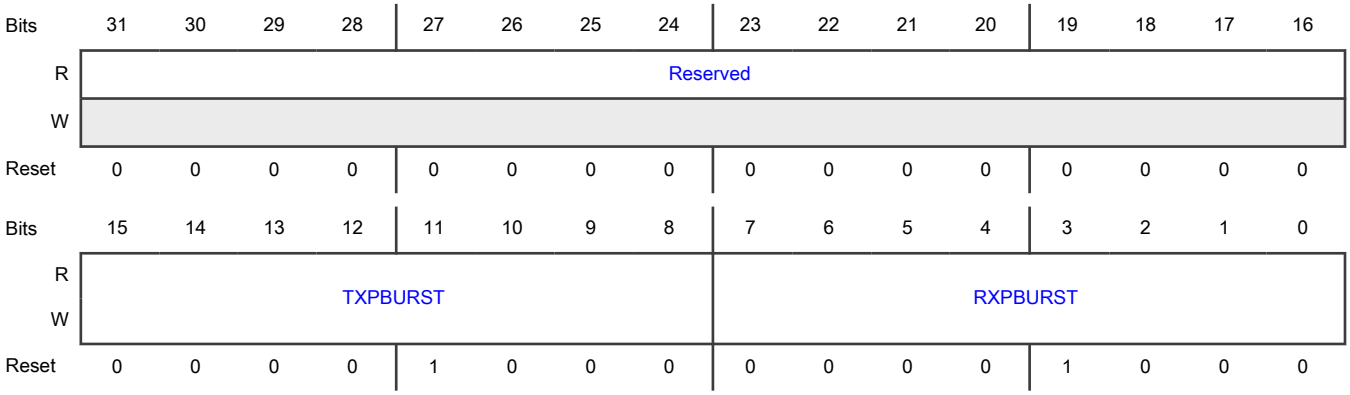
Offset

Register	Offset
BURSTSIZE	160h

Function

This register is used to control the burst size used during data movement on the AHB master interface. This register is ignored if AHBBRST bits in SBUSCFG register is non-zero value.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 TXPBURST	Programmable TX Burst Size Default value is determined by TXBURST bits in n_HWTXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from system memory to the USB bus.
7-0 RXPBURST	Programmable RX Burst Size Default value is determined by TXBURST bits in n_HWRXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from the USB bus to system memory.

64.8.1.28 TX FIFO Fill Tuning (TXFILLTUNING)

Offset

Register	Offset
TXFILLTUNING	164h

Function

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Definitions:

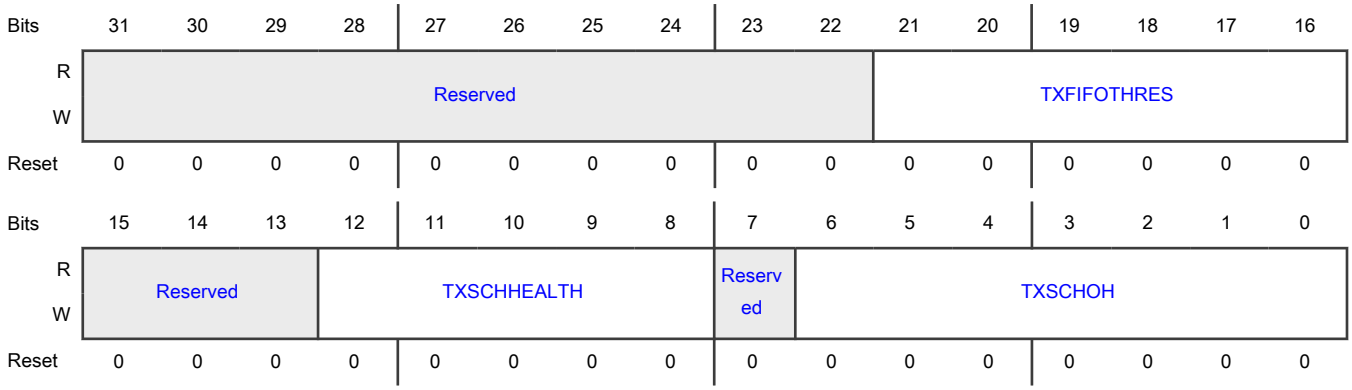
- T_0 = Standard packet overhead
- T_1 = Time to send data payload
- T_{ff} = Time to fetch packet into TX FIFO up to specified level.
- T_s = Total Packet Flight Time (send-only) packet
- $T_s = T_0 + T_1$
- T_p = Total Packet Time (fetch and send) packet
- $T_p = T_{ff} + T_0 + T_1$

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure T_p remains before the end of the [micro]frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro]frame is < T_s then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a mark will be made the scheduler health counter to note the occurrence of a "back-off" event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Back-offs can be minimized with use of the n_TSCHHEALTH (T_{ff}) described below.

NOTE

The reset value could vary from instance to instance. See the detail in bit field description and ignore reset value in summary table in this case!

Diagram



Fields

Field	Function
31-22 —	Reserved
21-16 TXFIFOTHRES	FIFO Burst Threshold This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USB_n_USBMODE register is set.
15-13 —	Reserved
12-8 TXSCHHEALTH	Scheduler Health Counter This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31.
7 —	Reserved
6-0 TXSCHOH	Scheduler Overhead This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267us when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333us when a device is connected in Low/Full Speed Mode. Default value is '08h' for OTG controller core .

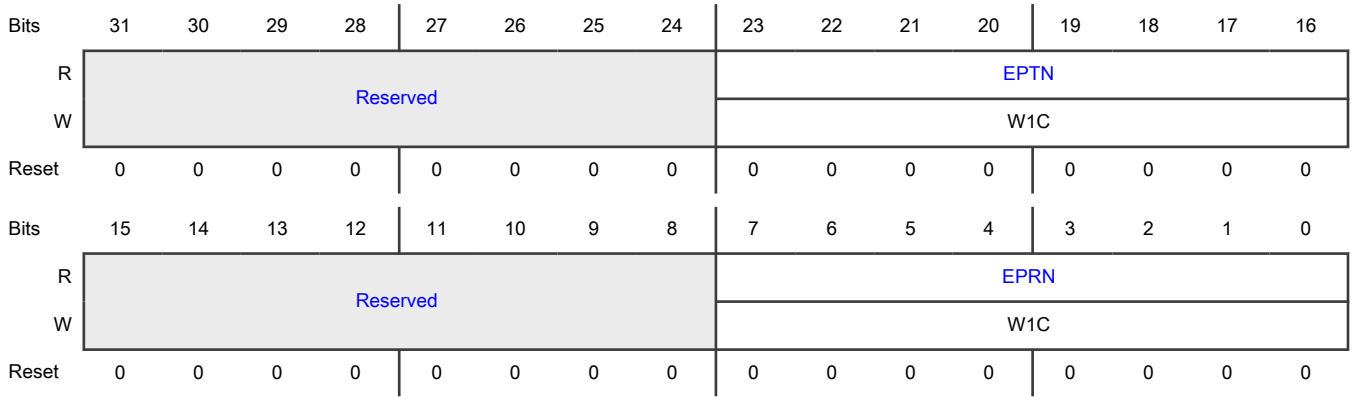
64.8.1.29 Endpoint NAK (ENDPTNAK)

Offset

Register	Offset
ENDPTNAK	178h

Function
Configures RX and TX endpoint NAKs.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 EPTN	TX Endpoint NAK Each TX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received IN token for the corresponding endpoint. Bit [N] - Endpoint #[N], N is 0-7
15-8 —	Reserved
7-0 EPRN	RX Endpoint NAK Each RX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received OUT or PING token for the corresponding endpoint. Bit [N] - Endpoint #[N], N is 0-7

64.8.1.30 Endpoint NAK Enable (ENDPTNAKEN)

Offset

Register	Offset
ENDPTNAKEN	17Ch

Function

Enables RX and TX endpoint NAKs.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

23-16 EPTNE	TX Endpoint NAK Enable Each bit is an enable bit for the corresponding TX Endpoint NAK bit. If this bit is set and the corresponding TX Endpoint NAK bit is set, the NAK Interrupt bit is set. Bit [N] - Endpoint #[N], N is 0-7
15-8 —	Reserved
7-0 EPRNE	RX Endpoint NAK Enable Each bit is an enable bit for the corresponding RX Endpoint NAK bit. If this bit is set and the corresponding RX Endpoint NAK bit is set, the NAK Interrupt bit is set. Bit [N] - Endpoint #[N], N is 0-7

64.8.1.31 Configure Flag (CONFIGFLAG)

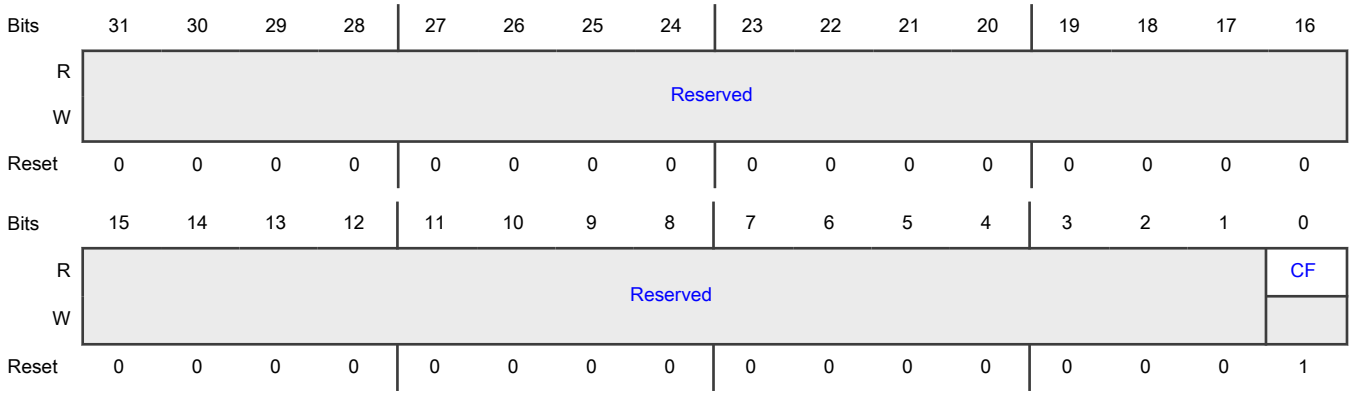
Offset

Register	Offset
CONFIGFLAG	180h

Function

Controls port-routing control logic.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 CF	Configure Flag Host software sets this bit as the last action in its process of configuring the Host Controller. This bit controls the default port-routing control logic. 0b - Port routing control logic default-routes each port to an implementation dependent classic host controller 1b - Port routing control logic default-routes all ports to this host controller

64.8.1.32 Port Status & Control (PORTSC1)

Offset

Register	Offset
PORTSC1	184h

Function

Host Controller

A host controller could implement one to eight port status and control registers. The number is determined by N_PORTs bits in HWSPARAMs register (see HCSPARAMS). Software could read this parameter register to determine how many ports need service.

All controller cores on this product are Single-Port, so there is only one port status and control register for each controller core.

This register is only reset by power on reset or controller core reset. The initial conditions of a port are:

- No device connected
- Port disabled

If the port supports power control, this state remains until port power is supplied (by software).

Device Controller

A controller operating in device mode has only port register one (PORTSC1) and it does not support power control in that mode. Port control in device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

Diagram

Fields

Field	Function
31-30 PTS_1	Parallel Transceiver Select Parallel Transceiver Select (bit25, bit31, bit30). For OTG core, it's Read-Only. For Host1/Host2/Host3 core, it's Read/Write. **NOTE** All USB port interface modes are listed in this field description, but not all are supported. For detail feature of each controller core, see Features . The behaviour is unknown when unsupported interface mode is selected. Bit field {bit25, bit31, bit30}: This field defines bits 1:0 of the following values. PORTSC1[PTS_2] defines bit 2. 000b - UTMI/UTMI+ 001b - Reserved 010b - ULPI 011b - Parallel Transceiver Select 100b - HSIC
29 STS	Serial Transceiver Select Serial Interface Engine can be used in combination with UTMI+/ULPI physical interface to provide FS/LS signaling instead of the parallel interface signals. When this bit is set '1b', serial interface engine will be used instead of parallel interface signals. This bit has no effect unless PTS bits is set to select UTMI+/ULPI interface.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The Serial/USB1.1 PHY/IC-USB will use the serial interface engine for FS/LS signaling regardless of this bit value. 0b - Parallel Interface signals is selected 1b - Serial Interface Engine is selected
28 PTW	Parallel Transceiver Width - Read/Write Parallel Transceiver Width This bit has no effect if serial interface engine is used. 0b - Select the 8-bit UTMI interface [60 MHz] 1b - Select the 16-bit UTMI interface [30 MHz]
27-26 PSPD	Port Speed This register field indicates the speed at which the port is operating. 00b - Full Speed 01b - Low Speed 10b - High Speed 11b - Undefined
25 PTS_2	Parallel Transceiver Select See description at bits 31-30 Bit field {bit25, bit31, bit30}: This field defines bit 2 of the following values. PORTSC1[PTS_1] defines bits 1:0. 000b - UTMI/UTMI+ 001b - Reserved 010b - ULPI 011b - Parallel Transceiver Select 100b - HSIC
24 PFSC	Port Force Full Speed Connect When this bit is set to '1b', the port will be forced to only connect at Full Speed, It disables the chirp sequence that allows the port to identify itself as High Speed. 0b - Normal operation 1b - Forced to full speed
23 PHCD	PHY Low Power Suspend - Clock Disable (PLPSCD) When this bit is set to '1b', the PHY clock is disabled. Reading this bit will indicate the status of the PHY clock.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The PHY clock cannot be disabled if it is being used as the system clock. In device mode, The PHY can be put into Low Power Suspend when the device is not running (USBCMD Run/Stop=0b) or the host has signalled suspend (PORTSC1 SUSPEND=1b). PHY Low power suspend will be cleared automatically when the host initials resume. Before forcing a resume from the device, the device controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend when the downstream device has been put into suspend mode or when no downstream device is connected. Low power suspend is completely under the control of software. 0b - Enable PHY clock 1b - Disable PHY clock
22 WKOC	Wake on Over-current Enable (WKOC_E) Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if Port Power (PORTSC1) is zero.
21 WKDC	Wake on Disconnect Enable (WKDSCNNT_E) Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if Port Power (PORTSC1) is zero or in device mode.
20 WKCN	Wake on Connect Enable (WKCNNT_E) Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if Port Power (PORTSC1) is zero or in device mode.
19-16 PTC	Port Test Control Refer to Port test mode for the operational model for using these test modes and the USB Specification Revision 2.0, Chapter 7 for details on each test mode. The FORCE_ENABLE_FS and FORCE ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_{HS/FS/LS} values will force the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE will allow the port state machines to progress normally from that point. **NOTE** Low speed operations are not supported as a peripheral device. Any other value than zero indicates that the port is operating in test mode. Value Specific Test 0000b - TEST_MODE_DISABLE 0001b - J_STATE 0010b - K_STATE 0011b - SE0 (host) / NAK (device)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0100b - Packet 0101b - FORCE_ENABLE_HS 0110b - FORCE_ENABLE_FS 0111b - FORCE_ENABLE_LS 1000b-1111b - Reserved
15-14 PIC	Port Indicator Control Writing to this field has no effect if the P_INDICATOR bit in the HCSPARAMS register is a zero. Refer to the USB Specification Revision 2.0 for a description on how these bits are to be used. This field is zero if Port Power (PORTSC1) is zero. 00b - Port indicators are off 01b - Amber 10b - Green 11b - Undefined
13 PO	Port Owner This bit unconditionally goes to a 0 when the configured bit in the CONFIGFLAG register makes a 0 to 1 transition. This bit unconditionally goes to 1 whenever the Configured bit is zero System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that an internal companion controller owns and controls the port. Port owner handoff is not supported in all controller cores, therefore this bit will always be 0.
12 PP	Port Power The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: • PPC = 0b, PP = 1b (Read Only) - Host controller does not have port power control switches. Each port is hard-wired to power. • PPC = 1b, PP = 1b/0b (Read/Write) - OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (that is, PP equals a 0), the port is non-functional and will not report attaches, detaches, etc. When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitional by the host controller driver from a one to a zero (removing power from the port). This feature is implemented in all controller cores (PPC = 1).
11-10 LS	Line Status These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In host mode, the use of linestate by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of linestate by the device controller driver is not necessary. 00b - SE0 01b - K-state 10b - J-state 11b - Undefined
9 HSP	High-Speed Port When the bit is one, the host/device connected to the port is in high-speed mode and if set to zero, the host/device connected to the port is not in a high-speed mode. **NOTE** HSP is redundant with PSPD(bit 27, 26) but remained for compatibility.
8 PR	Port Reset In Host Mode: Read/Write. When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver. In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. This field is zero if Port Power (PORTSC1) is zero. 0b - Port is not in reset 1b - Port is in reset
7 SUSP	Suspend In Host Mode: Read/Write. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State • 0x Disable • 10 Enable • 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the Force Port Resume bit to zero. The host controller ignores a write of zero to this bit. If host software sets this bit to a one when the port is not enabled (that is, Port enabled bit is a zero) the results are undefined. This field is zero if Port Power (PORTSC1) is zero in host mode. In Device Mode: Read Only. In device mode this bit is a read only status bit. 0b - Port not in suspend state 1b - Port in suspend state
6 FPR	Force Port Resume In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver. Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation, clear the bit the port control state switches to HS or FS idle. This field is zero if Port Power (PORTSC1) is zero in host mode. This bit is not-EHCI compatible. In Device mode: After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit will be cleared because a K-to-J transition detected, the Port Change Detect bit in the USBSTS register is also set to one. 0b - No resume (K-state) detected/driven on port 1b - Resume detected/driven on port
5 OCC	Over-current Change This bit is set '1b' by hardware when there is a change to Over-current Active. Software can clear this bit by writing a one to this bit position.

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 OCA	Over-Current Active This bit will automatically transition from one to zero when the over current condition is removed. 0b - This port does not have an over-current condition 1b - This port currently has an over-current condition
3 PEC	Port Enable/Disable Change In Host Mode: For the root hub, this bit is set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if Port Power (PORTSC1) is zero. In Device mode: The device port is always enabled, so this bit is always '0b'. 0b - No change 1b - Port enabled/disabled status has changed
2 PE	Port Enabled/Disabled In Host Mode: This bit is reset to '0b'. Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. **NOTE** The bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is zero if Port Power (PORTSC1) is zero in host mode. In Device Mode: The device port is always enabled, so this bit is always '1b'. 0b - Disable 1b - Enable
1 CSC	Connect Status Change In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the

Table continues on the next page...

Table continued from the previous page...

Field	Function
	changed condition, hub hardware will be 'setting' an already-set bit (that is, the bit will remain set). Software clears this bit by writing a one to it. This field is zero if Port Power (PORTSC1) is zero in host mode. In Device Mode: This bit is undefined in device controller mode. 0b - No change 1b - Change in current connect status
0 CCS	Current Connect Status In Host Mode: This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set. This field is zero if Port Power (PORTSC1) is zero in host mode. In Device Mode: A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended. 0b - In Host mode: No device is present. In Device mode: Not attached 1b - In Host mode: Device is present on port. In Device mode: Attached

64.8.1.33 On-The-Go Status & Control (OTGSC)

Offset

Register	Offset
OTGSC	1A4h

Function

This register is available only in OTG controller core. It has four sections:

- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)
- OTG Controls (Read/Write)

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms does not cause an update of the status input register, or cause an OTG interrupt.

See also USBMODE register.

22 DPIS	Data Pulse Interrupt Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC1(0)[PP] = 0. Software must write a one to clear this bit.
21 STATUS_1MS	1 Millisecond Timer Interrupt Status This bit is set once every millisecond. Software must write a one to clear this bit.
20 BSEIS	B Session End Interrupt Status This bit is set when VBus has fallen below the B session end threshold. Software must write a one to clear this bit.
19 BSVIS	B Session Valid Interrupt Status This bit is set when VBus has either risen above or fallen below the B session valid threshold. Software must write a one to clear this bit.
18 ASVIS	A Session Valid Interrupt Status This bit is set when VBus has either risen above or fallen below the A session valid threshold. Software must write a one to clear this bit.
17 AVVIS	A VBus Valid Interrupt Status This bit is set when VBus has either risen above or fallen below the VBus valid threshold on an A device. Software must write a one to clear this bit.
16 IDIS	USB ID Interrupt Status This bit is set when a change on the ID input has been detected. Software must write a one to clear this bit.
15 —	Reserved
14 DPS	Data Bus Pulsing Status A '1' indicates data bus pulsing is being detected on the port.
13 TOG_1MS	1 Millisecond Timer Toggle This bit toggles once per millisecond.
12 BSE	B Session End Indicates VBus is below the B session end threshold.
11 BSV	B Session Valid Indicates VBus is above the B session valid threshold.

Table continues on the next page...

Table continued from the previous page...

Field	Function
10 ASV	A Session Valid Indicates VBus is above the A session valid threshold.
9 AVV	A VBus Valid Indicates VBus is above the A VBus valid threshold.
8 ID	USB ID 0b - A device 1b - B device
7-6 —	Reserved
5 IDPU	ID Pullup This bit provide control over the ID pull-up resistor; When this bit is 0, the ID input will not be sampled. 0b - Off 1b - On
4 DP	Data Pulsing Setting this bit causes the pullup on DP to be asserted for data pulsing during SRP.
3 OT	OTG Termination This bit must be set when the OTG device is in device mode, this controls the pulldown on DM.
2 —	Reserved
1 VC	VBUS Charge Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP.
0 VD	VBUS Discharge Setting this bit causes VBus to discharge through a resistor.

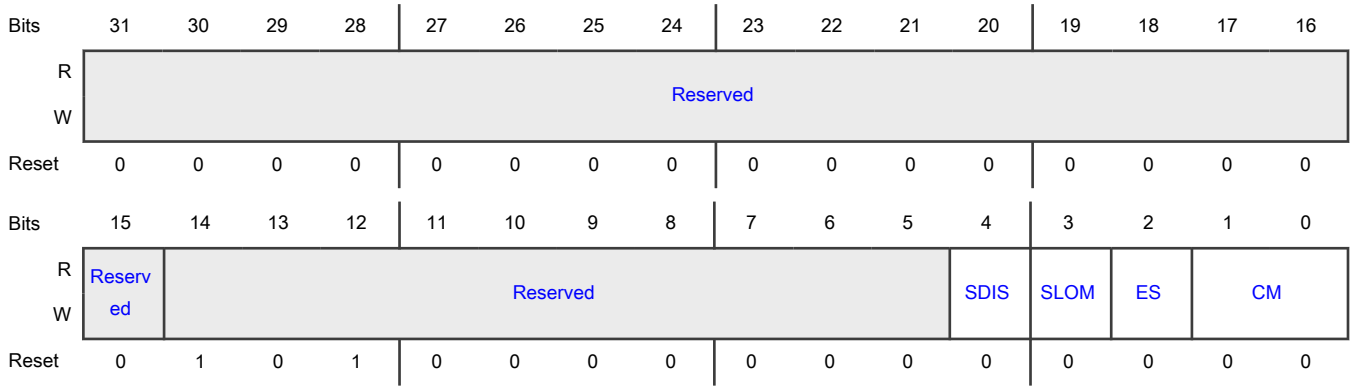
64.8.1.34 USB Device Mode (USBMODE)

Offset

Register	Offset
USBMODE	1A8h

Function
Configures USB device operation mode.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 —	Reserved
14-5 —	Reserved
4 SDIS	Stream Disable Mode Device Mode: Setting to a '1' disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. **NOTE** In High Speed Mode, all packets received are responded to with a NYET handshake when stream disable is active. Host Mode: Setting to a '1' ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB. **NOTE** Time duration to pre-fill the FIFO becomes significant when stream disable is active. See TXFILLTUNING and TXTTFILLTUNING [MPH Only] to characterize the adjustments needed for the scheduler when using this feature. **NOTE** The use of this feature substantially limits of the overall USB performance that can be achieved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Inactive 1b - Active
3 SLOM	Setup Lockout Mode In device mode, this bit controls behavior of the setup lock mechanism. See Control endpoint operation model. 0b - Setup Lockouts On (default); 1b - Setup Lockouts Off. DCD requires use of Setup Data Buffer Tripwire in USBCMD.
2 ES	Endian Select This bit can change the byte alignment of the transfer buffers to match the host microprocessor. The bit fields in the microprocessor interface and the data structures are unaffected by the value of this bit because they are based upon the 32-bit word. 0b - Little Endian 1b - Big Endian
1-0 CM	Controller Mode Controller mode is defaulted to the proper mode for host only and device only implementations. For those designs that contain both host & device capability, the controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. For combination host/device controllers, this register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the RESET bit in the USBCMD register before reprogramming this register. For OTG controller core, reset value is '00b'. 00b - Idle [Default for combination host/device] 01b - Reserved 10b - Device Controller [Default for device only controller] 11b - Host Controller [Default for host only controller]

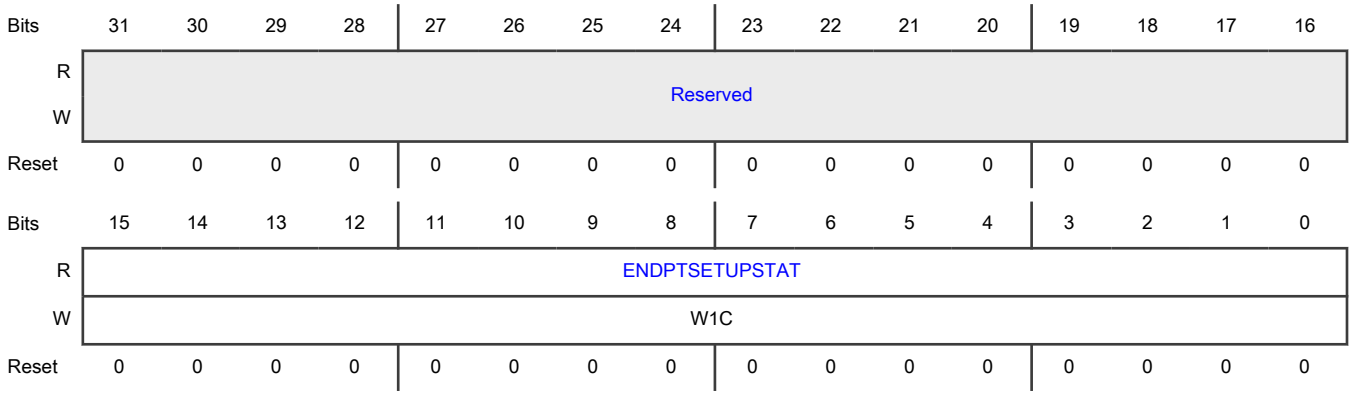
64.8.1.35 Endpoint Setup Status (ENDPTSETUPSTAT)

Offset

Register	Offset
ENDPTSETUPSTAT	1ACh

Function
Indicates endpoint setup status.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 ENDPTSETUPSTAT	Setup Endpoint Status For every setup transaction that is received, a corresponding bit in this register is set to one. Software must clear or acknowledge the setup transfer by writing a one to a respective bit after it has read the setup data from Queue head. The response to a setup packet as in the order of operations and total response time is crucial to limit bus time outs while the setup lock our mechanism is engaged. See Managing endpoints in the Device Operational Model. This register is only used in device mode.

64.8.1.36 Endpoint Prime (ENDPTPRIME)

Offset

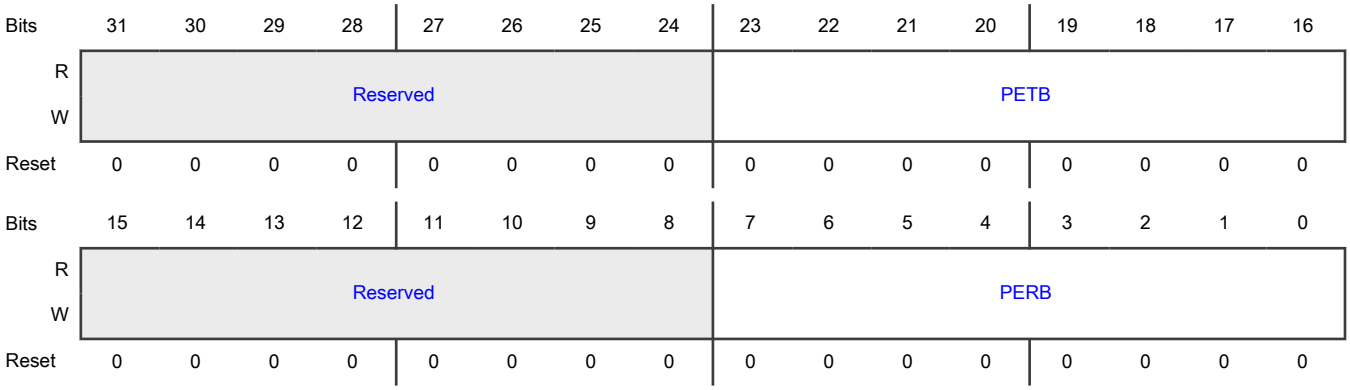
Register	Offset
ENDPTPRIME	1B0h

Function

This register is only used in device mode.

When software sets the prime bit for a given endpoint, the device controller loads the transfer descriptor, pointed to by the queue head, such that the endpoint is ready to transmit or receive when the host sends a request (IN/OUT token). The endpoint will NAK all requests from the host until the endpoint is primed. The controller will automatically re-prime the endpoint with a new transfer descriptor when one is found via the next_dtd pointer of the current transfer descriptor. Hence, the prime bit must only be set by software when a descriptor is added to the queue head.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 PETB	Prime Endpoint Transmit Buffer For each endpoint a corresponding bit is used to request that a buffer is prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction. Software should write a one to the corresponding bit when posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed. **NOTE** These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. PETB[N] - Endpoint #N, N is in 0..7
15-8 —	Reserved
7-0 PERB	Prime Endpoint Receive Buffer For each endpoint, a corresponding bit is used to request a buffer prepare for a receive operation for when a USB host initiates a USB OUT transaction. Software should write a one to the corresponding bit whenever posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed. **NOTE** These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. PERB[N] - Endpoint #N, N is in 0..7

64.8.1.37 Endpoint Flush (ENDPTFLUSH)

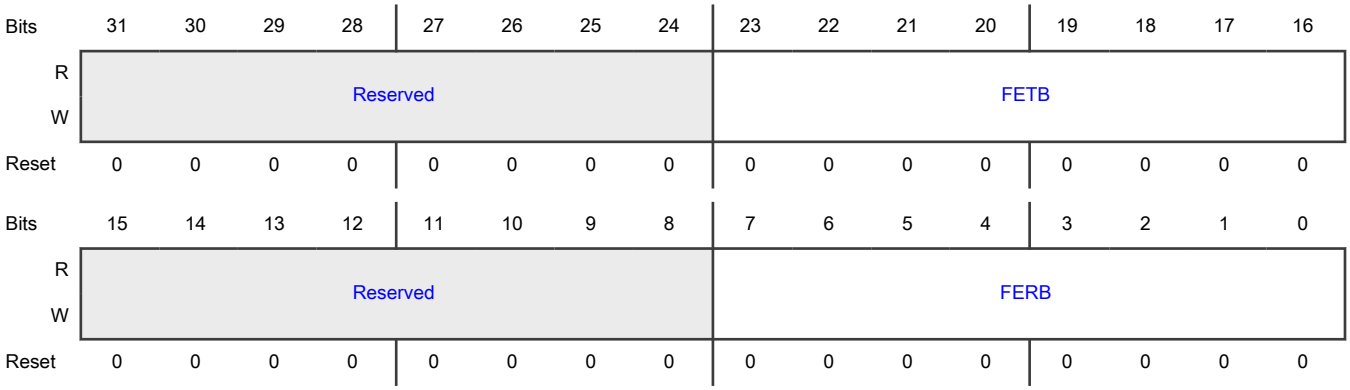
Offset

Register	Offset
ENDPTFLUSH	1B4h

Function

This register is only used in device mode.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 FETB	Flush Endpoint Transmit Buffer Writing one to a bit(s) in this register causes the associated endpoint(s) to clear any primed buffers. If a packet is in progress for one of the associated endpoints, then that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FETB[N] - Endpoint #N, N is in 0..7
15-8 —	Reserved
7-0 FERB	Flush Endpoint Receive Buffer Writing one to a bit(s) causes the assocUOGiated endpoint(s) to clear any primed buffers. If a packet is in progress for one of the associated endpoints, then that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FERB[N] - Endpoint #N, N is in 0..7\

64.8.1.38 Endpoint Status (ENDPTSTAT)

This control will continue to STALL until this bit is either cleared by software or automatically cleared as above for control endpoints. **NOTE** [CONTROL ENDPOINT TYPES ONLY]: there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. However, should the DCD observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a new setup has been received by checking the associated endptsetupstat bit. 0b - Endpoint OK 1b - Endpoint stalled
15-8 —	Reserved
7 RXE	RX Endpoint Enable An endpoint should be enabled only after it has been configured. 0b - Disabled 1b - Enabled
6 RXR	RX Data Toggle Reset (WS) Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the host and device. 1b - Reset PID sequence

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 RXI	RX Data Toggle Inhibit This bit is only used for test and should always be written as zero. Writing a one to this bit causes this endpoint to ignore the data toggle sequence and always accept data packet regardless of their data PID. 0b - Disabled 1b - Enabled
4 —	Reserved
3-2 RXT	RX Endpoint Type 00b - Control 01b - Isochronous 10b - Bulk 11b - Interrupt
1 RXD	RX Endpoint Data Sink Should always be written as zero. 0b - Dual Port Memory Buffer/DMA Engine
0 RXS	RX Endpoint Stall This bit is set automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint and this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. This control will continue to STALL until this bit is either cleared by software or automatically cleared as above for control endpoints. **NOTE** [CONTROL ENDPOINT TYPES ONLY]: there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. However, should the DCD observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a new setup has been received by checking the associated endptsetupstat bit. 0b - Endpoint OK 1b - Endpoint stalled

64.8.1.44 Endpoint Control 4 (ENDPTCTRL4)

Offset

Register	Offset
ENDPTCTRL4	1D0h

Function

This is endpoint control register for endpoint 4 in device operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

Chapter 65
Ultra Secured Digital Host Controller (uSDHC)

65.1 Chip-specific uSDHC information

Table 535. Reference links to related information

Topic	Related module	Reference
Full description	uSDHC	uSDHC
Clocking		Clock distribution [1]
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

1. lp_osc is connected as the low power clock, in this device.

NOTE

See AHB Clock Control 2 (AHBCLKCTRL2) for clock control. Also see Peripheral Reset Control 2 (PRESETCTRL2) for reset control.

65.1.1 Module instances

This device has one instance of the uSDHC module, uSDHC0.

65.2 Overview

uSDHC provides the interface between the host system and the eMMC, SD card, and SDIO as shown in Figure 355. The module acts as a bridge, passing host bus transactions to the eMMC, SD card, and SDIO by sending commands and performing data accesses to/from the cards. It handles the SD card/SDIO/eMMC protocols at the transmission level.

65.2.1 Block diagram

The following figure illustrates the block diagram for uSDHC. Dual port SRAM is FIFO for write/read. For more information, see Data buffer.

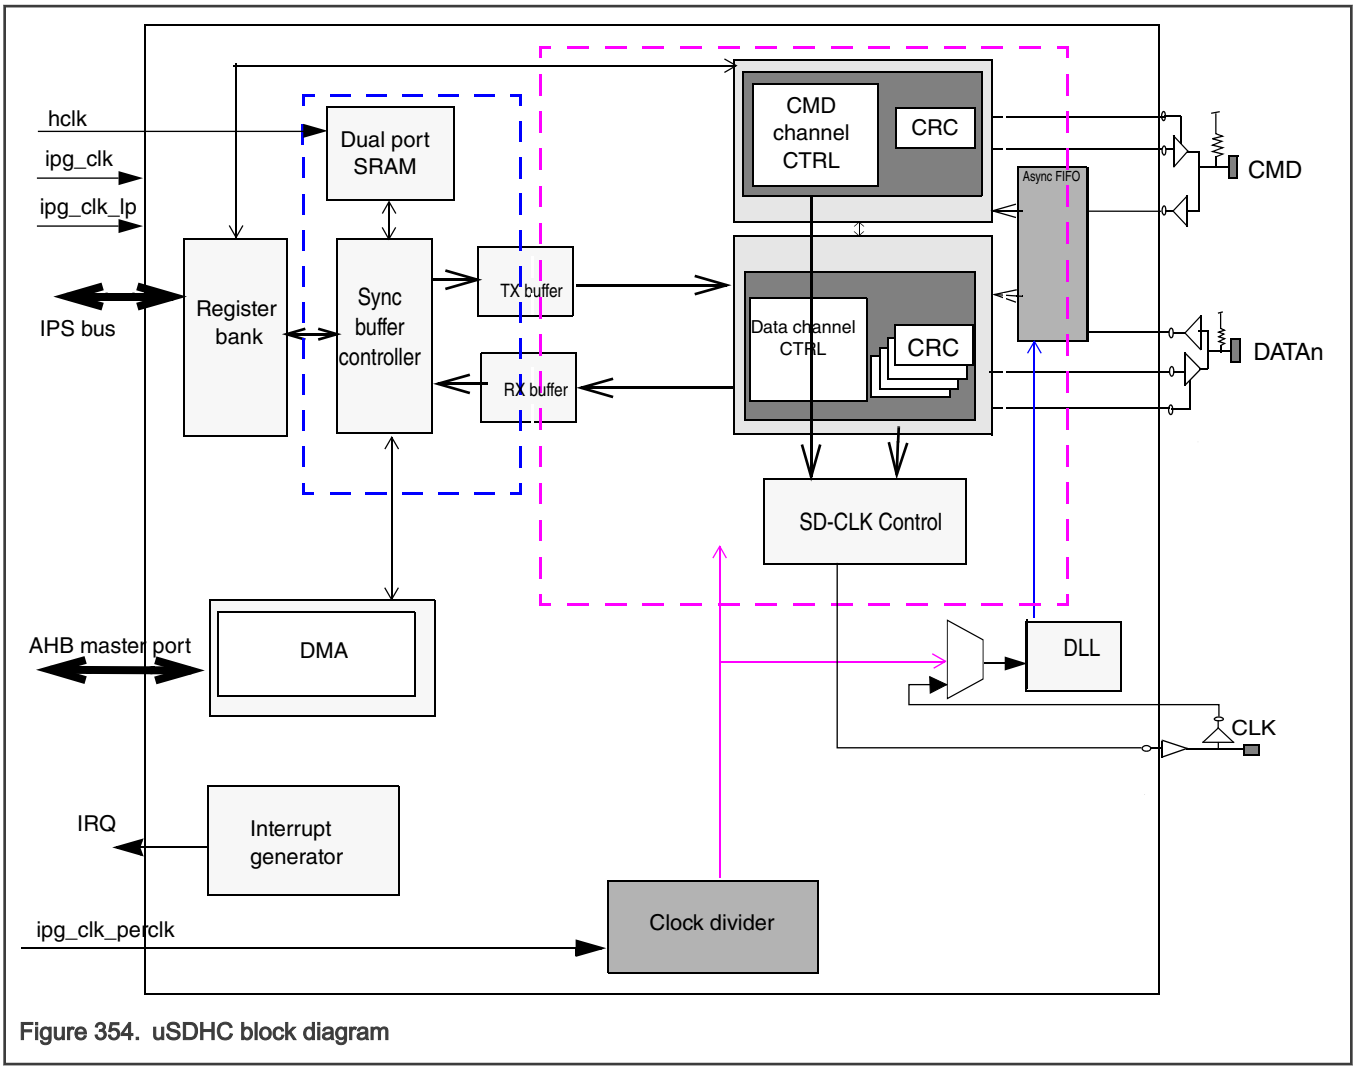

Figure 354. uSDHC block diagram

The figure below shows the System connection of uSDHC:

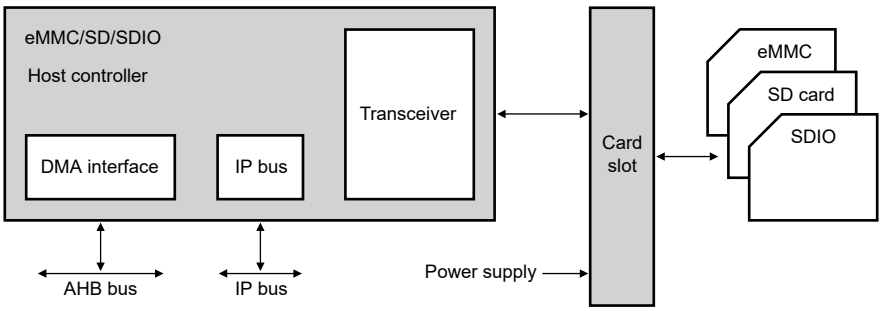

Figure 355. System connection of uSDHC

The following are brief descriptions of the cards supported by uSDHC:

- The Embedded MultiMediaCard (eMMC) is a universal low-cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous eMMC were based on a 7-pin serial bus with a single data pin, while the new high speed eMMC communication is based on an advanced 11-pin serial bus designed to operate in the low-voltage range.

- The Secure Digital Card (SD) is an evolution of the old eMMC technology. It is specifically designed to meet the security, capacity, performance, and environmental requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment, and data transfer protocol are backward compatible with the old eMMC (with some additions).
- Under the SD protocol, system connection can be categorized into memory card, I/O card, and combo card, which have both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI (Secure Digital Music Initiative) standard. The I/O card, which is also known as SDIO, provides high-speed data I/O with low-power consumption for mobile electronic devices.

65.2.2 Features

The list given below shows the features of the uSDHC module:

- Conforms to the SD Host Controller Standard Specification version 2.0/3.0
- Compatible with the eMMC System Specification version 4.2/4.3/4.4/4.41
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Specification version 2.0/3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, eMMC, MMC plus, and MMC RS cards
- For card bus clock frequency: See the product Data Sheet for the clock frequency of each supported mode.
- Supports 1-bit/4-bit SD and SDIO modes, and 1-bit/4-bit/8-bit eMMC modes
  - Up to 832 Mbps of data transfer for SDIO using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDIO using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 832 Mbps of data transfer for SDXC cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDXC card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 416 Mbps of data transfer for eMMC using eight parallel data lines in the Single Data Rate (SDR) mode
  - Up to 832 Mbps of data transfer for eMMC using eight parallel data lines in the Dual Data Rate (DDR) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes; also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal DMA capabilities
- Supports voltage selection by configuring vendor-specific register bit
- Supports Advanced DMA to perform linked memory access

NOTE

This block can support all the above-listed speed mode and maximum data throughput. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

65.3 Functional description

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock and reset manager, and clock generator.

65.3.1 Modes and operations

65.3.1.1 Data transfer modes

The uSDHC module can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- eMMC 1-bit
- eMMC 4-bit
- eMMC 8-bit
- Identification mode (up to 400 kHz)
- eMMC full-speed mode (up to 26 MHz)
- eMMC high-speed mode (up to 52 MHz)
- eMMC DDR mode (52 MHz both edges)
- SD card or SDIO full-speed mode (up to 25 MHz)
- SD card or SDIO high-speed mode (up to 50 MHz)
- SD card or SDIO UHS-I mode (up to 208 or 100 MHz in SDR mode, up to 50 MHz in the DDR mode)

NOTE

This block can support all the above listed speed mode and maximum clock frequency. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

65.3.2 Data buffer

The uSDHC module uses one configurable data buffer to transfer data between the system bus (IP bus or advanced high-performance bus (AHB) bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock). The buffer is used as a temporary storage for transferring data between the host system and the card. The watermark levels for read and write are both configurable and can range between 1 to 128 words. The burst lengths for read and write are also configurable and can range between 1 to 31 words. The next figure provides the uSDHC buffer scheme as buffer control and buffer RAM wrapper.

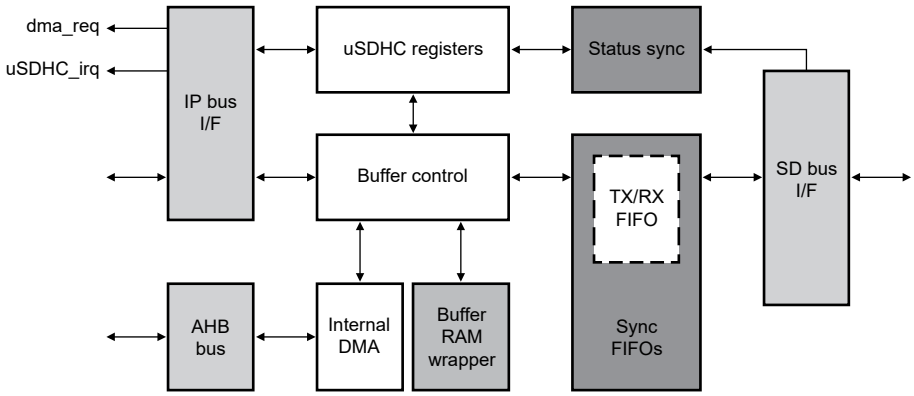

Figure 356. uSDHC buffer scheme

Here are 2 transfer modes to access the data buffer:

- CPU polling mode:
  - For a host-read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, by polling the BRR bit, the host driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar. For more information on the process of writing operation, see Write operation sequence.
- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AHB bus.

For a read operation, when there are more words in the buffer than the amount set in WTMK_LVL[RD_WML], the internal DMA starts fetching data over the AHB bus. Except for INCR4 and INCR8, the burst type is always the INCR mode and the burst length depends on the shortest of the following factors:

- Burst length configured in the burst length field of the Watermark Level register
- Watermark level boundary
- Block size boundary
- Data boundary configured in the current descriptor (if the ADMA is active)
- 1 KB address boundary defined in the AHB protocol

The Write operation functions in a similar manner—sequential and contiguous access is necessary to ensure that the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, the byte order is swapped after the data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, the byte order is swapped before the data is stored in the buffer.

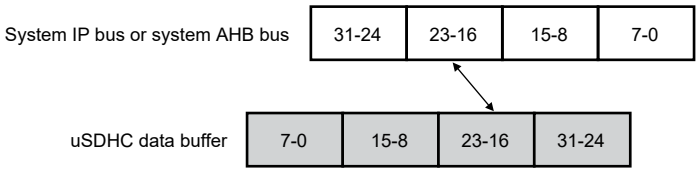

Figure 357. Data swap between system bus and uSDHC data buffer in the byte little endian mode

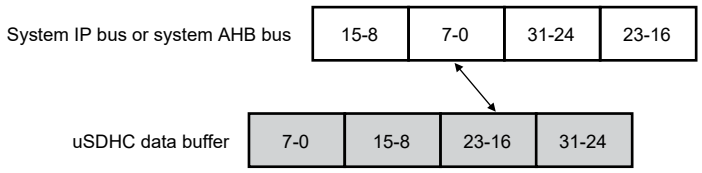

Figure 358. Data swap between system bus and uSDHC data buffer in half word big endian mode

65.3.2.1 Write operation sequence

There are 2 ways to write data into the buffer when the user transfers data to the card:

- Processor core polling through the BWR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, the DMAEN bit in the Transfer Type register is not set when the command is sent, uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in WTMK_LVL[WR_WML] and is ready for receiving new data. At the same time, uSDHC sets the BWR bit. The buffer write ready interrupt is generated if it is enabled by software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the write operation from that address. It is recommended that a software reset for Data be applied before the transfer is restarted.

The uSDHC module does not start data transmission until the buffer has been filled with the number of words set in the WR_WML register. If the buffer is empty and the host system does not write data in time, uSDHC stops the CLK to avoid the data buffer underrun situation.

65.3.2.2 Read operation sequence

There are 2 ways to read data from the buffer when the data is received from the card:

- Processor core polling through the BRR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, which is available and ready for system fetching data. At the same time, uSDHC sets the BRR bit. The buffer read ready interrupt is generated if it is enabled by the software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the read operation from that address. It is recommended that a software reset (in register RSTD) for data be applied before the transfer is restarted.

For any read transfer mode, uSDHC does not start data transmission until the number of words set in the RD_WML register are in buffer. If the buffer is full and the host system does not read data in time, uSDHC stops the CLK to avoid the data buffer overrun situation.

65.3.2.3 Data buffer and block size

In the uSDHC module, the data buffer can hold up to 128 words (32-bit) and the watermark levels for write and read can be configured accordingly. The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. For both read and write, the watermark level can range between 1 to 128 words. For both read and write,

the burst length can range between from 1 to 31 words. The host driver may configure the value according to the system and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes). That means, the largest block size is 512 bytes.

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned), stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the software side must write twice for each block. For each block, the ending byte is abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

65.3.2.4 Dividing large data transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in multiples of block size. If the total data length cannot be divided evenly into a multiple of the block size, then there are two options to transfer the data. These two options depend on the function and the card design. Option 1 is for the host driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data. Only for write, uSDHC sends data to the card.

See Figure 359 for an example showing the division of large data transfers, assuming a kind of WLAN SDIO that only supports a block size of up to 64 bytes. Although uSDHC supports a block size of up to 4096 bytes, SDIO can only accept a block size of less than 64 bytes, so the data must be divided (see the example below).

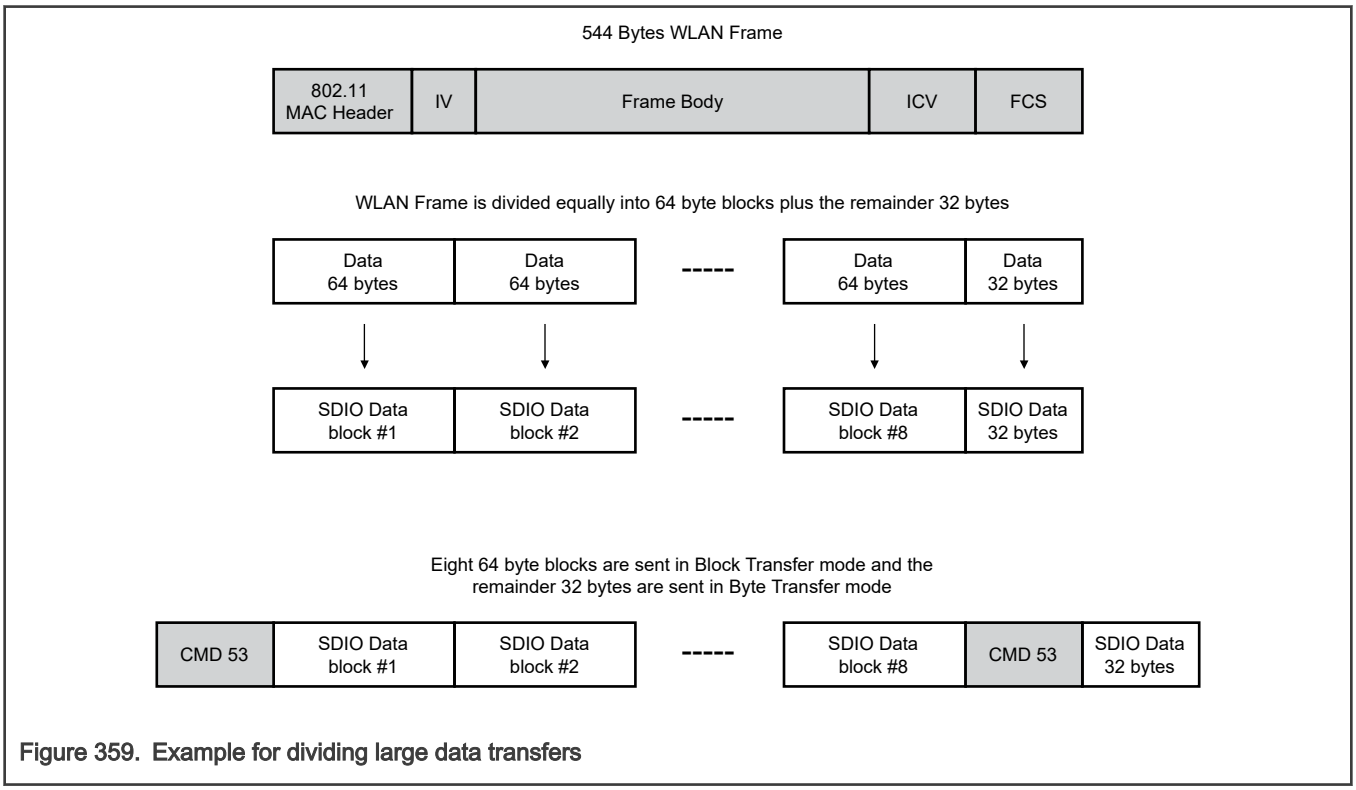

Figure 359. Example for dividing large data transfers

65.3.3 DMA AHB interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, but the BWR and BRR bits are set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register. See Figure 360 for an illustration of the DMA AHB interface block.

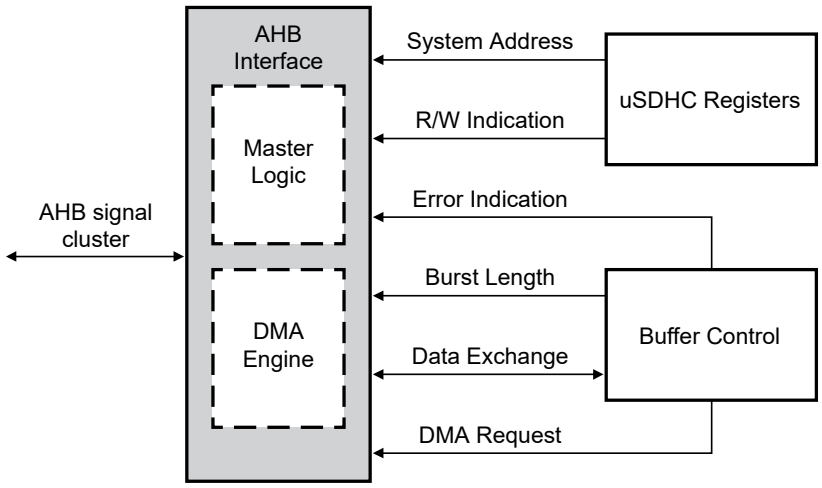

Figure 360. DMA AHB interface block

65.3.3.1 Internal DMA request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the data buffer block sends a DMA request to AHB interface.

The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The data buffer de-asserts the request if the data buffer space (for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of the current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always automatically set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to six words (24 bytes). After the first burst transfer, if there are greater than or equal to two words in the buffer, which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to transfer for the current block is ceiling((31 - 6 * 4) / 4) = 2. The uSDHC module reads two words out of the buffer, with seven valid bytes and one stuffed byte.

65.3.3.2 DMA burst length

Just like a CPU polling access, the DMA burst length for the internal DMA engine can range between 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block. See the example in Internal DMA request. After six words are read, the burst length is two words, then the next burst length is six words. This is because the next block starts, which is 31 bytes, more than six words. The host driver may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length is the same.

65.3.3.3 AHB master interface

It is possible that the internal AHB DMA engine could fail during the data transfer. Upon detection of an AHB bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register is generated to host CPU to report a bus error condition.

After the DMAE interrupt is received, the software sends a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and restart the transfer from this address to recover the corrupted block.

65.3.3.4 ADMA engine

In the SD host controller standard, a new DMA transfer algorithm called the Advanced DMA (ADMA) is defined. For simple DMA, after the page boundary is reached, a DMA interrupt is generated and the new system address is programmed by the host driver. The ADMA defines the programmable descriptor table in the system memory. The host driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized because the host MCU intervention is not be needed during long DMA-based data transfers.

There are two types of ADMA in host controller: ADMA1 and ADMA2. ADMA1 can support data transfer of 4KB aligned data in system memory, and ADMA2 eliminates the restriction so that the data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors defined in SD host controller Standard, and if the "End" flag is detected in the descriptor, ADMA stops after this descriptor is processed.

65.3.3.4.1 ADMA concept and descriptor format

ADMA1 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Set data length descriptor
- Set data address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA2 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Rsv descriptor (new in ADMA2)
- Set data length and address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA starts read/write operation after it reaches the tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last set type descriptor before the tran type descriptor. Every tran type descriptor triggers a transfer, and the transfer data length is extracted from the most recent set type descriptor. If there is no set type descriptor after the previous Trans descriptor, the data length is the value for previous transfer, or 0 if no set descriptor is ever met.

For ADMA2, the tran type descriptor contains both data length and transfer data address, so the tran type descriptor itself can start a data transfer.

See Figure 361 for the format of the descriptor table for ADMA1.

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 361. Format of the ADMA1 descriptor table

See Figure 362 for the concept and access method of the descriptor table for ADMA1.

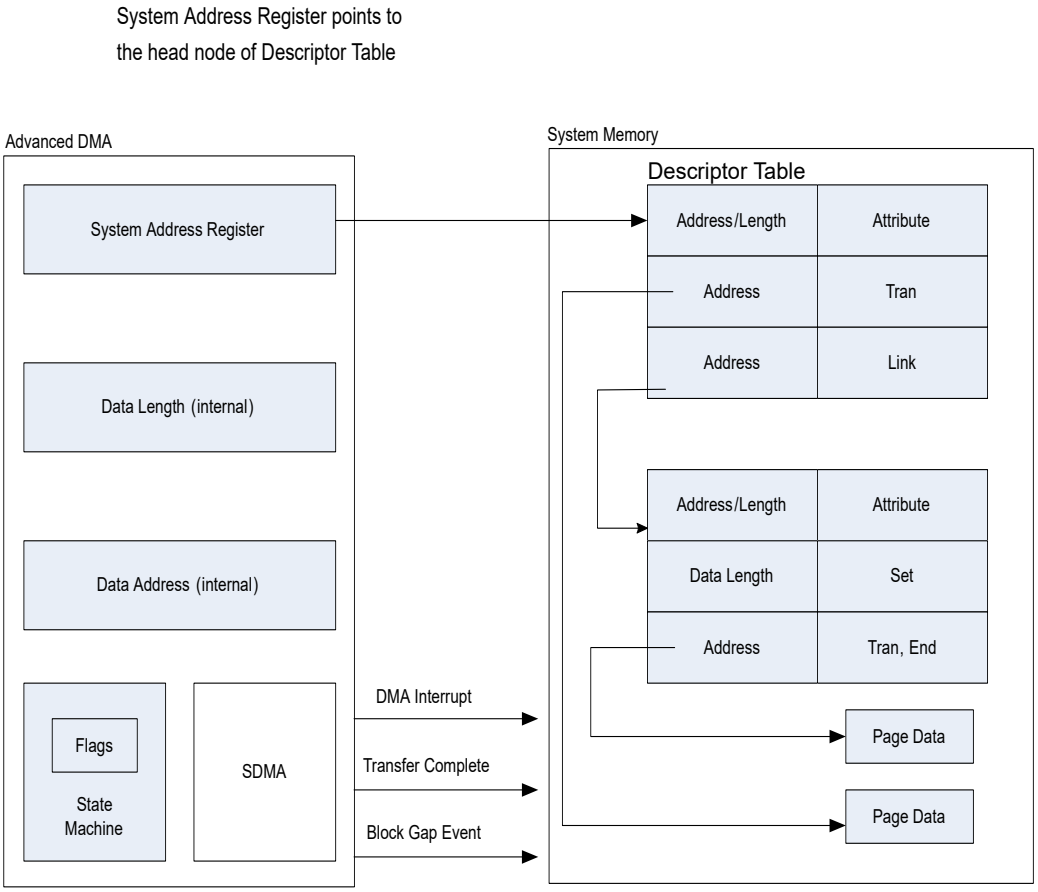

Figure 362. Concept and access method of the ADMA1 descriptor table

The figure below explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it ignores the higher 32-bit. The Address field should be set to word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 363. Format of the ADMA2 descriptor table

See Figure 364 for the concept and access method of the descriptor table for ADMA2.

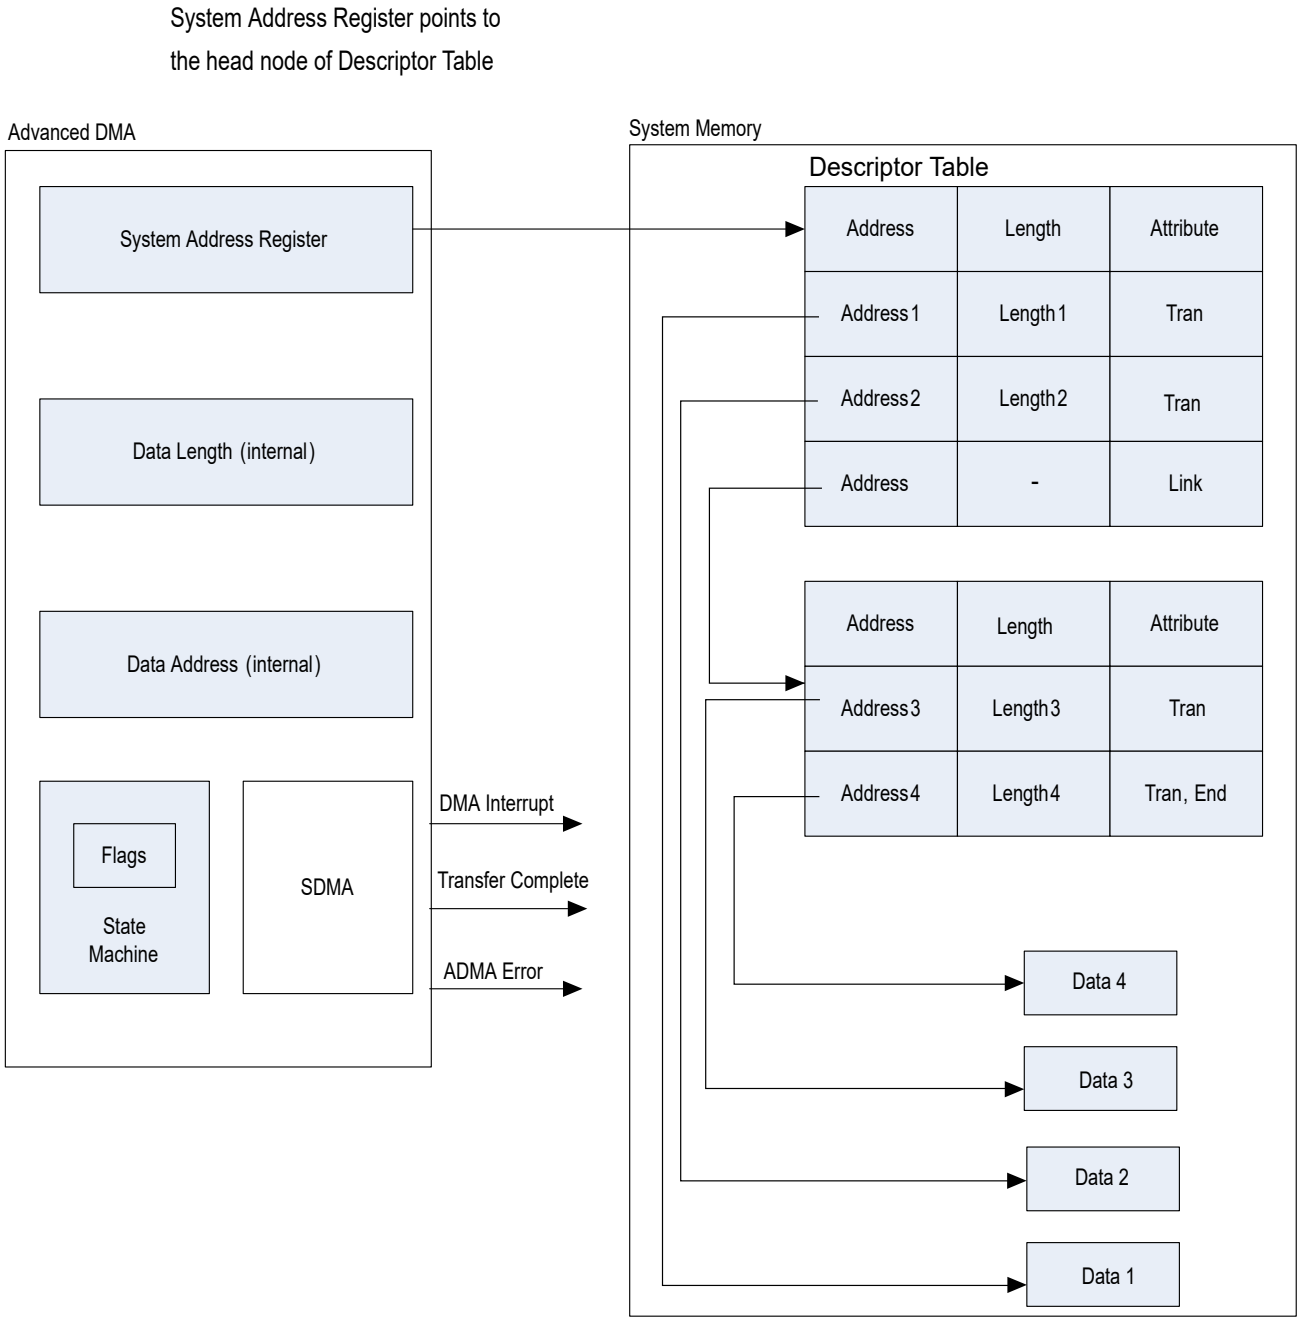

Figure 364. Concept and access method of the ADMA2 descriptor table

65.3.3.4.2 ADMA interrupt

If the interrupt flag descriptor is set, ADMA generates an interrupt according to various types of descriptors.

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.

- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

65.3.3.4.3 ADMA error

The ADMA stops whenever an error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

An ADMA descriptor error is generated when it fails to detect a "valid" flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the "Interrupt" flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in register BLK_ATT must be equal to the whole data length set in descriptor, otherwise data length mismatch error is generated.

When BLKCNTEN bit is not set, then the whole data length set in descriptor is a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors occur.

65.3.4 Register bank with IP bus interface

Register accesses through the IP bus interface are on the register bank. See Figure 365 for the block diagram.

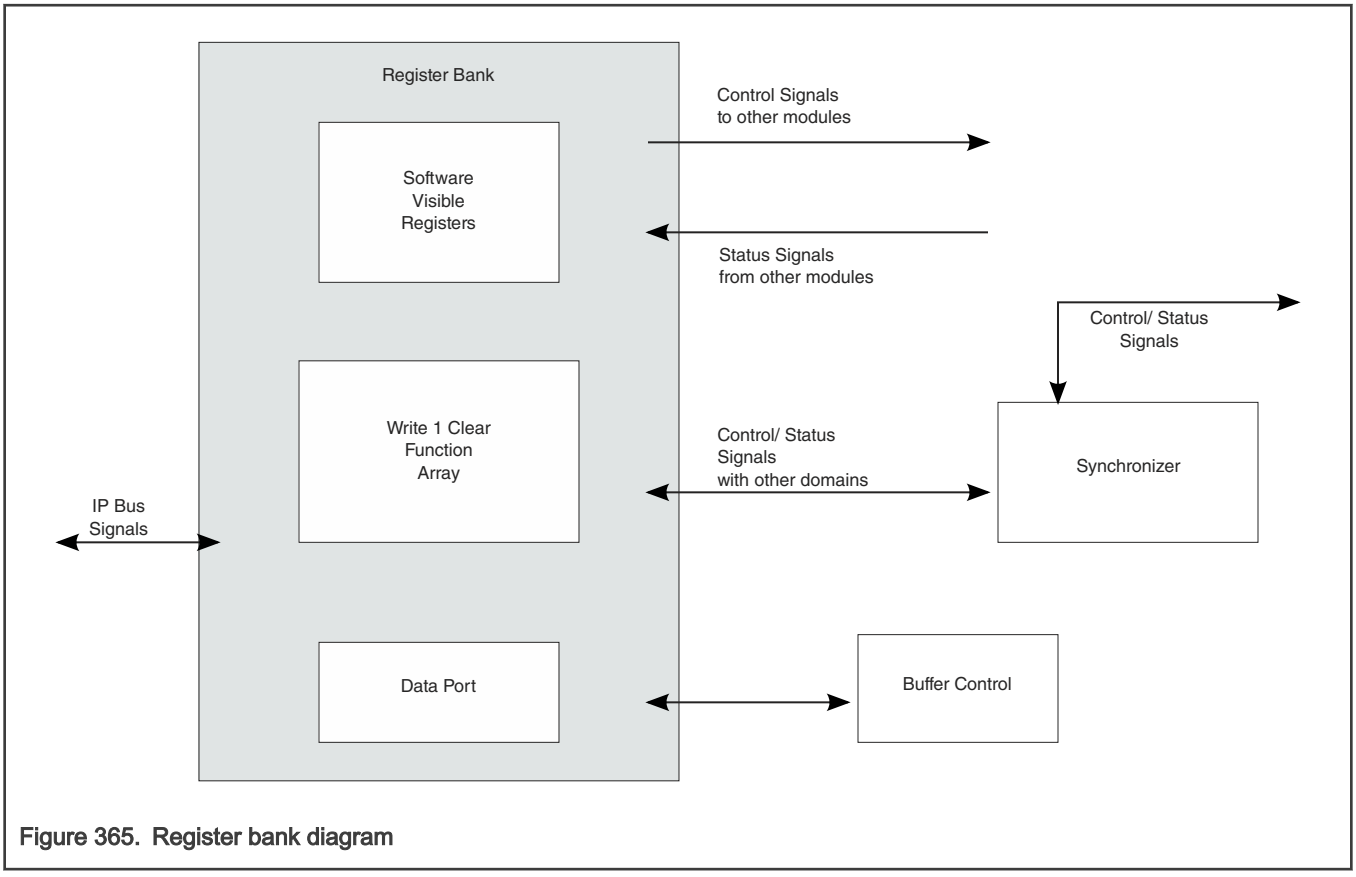

Figure 365. Register bank diagram

Only a 32-bit access is allowed, and no partial read/write is supported; therefore, all accesses are word aligned.

Access to an unimplemented address within the register memory map space does not generate a transfer error.

65.3.4.1 SD protocol unit

The SD protocol unit deals with all SD protocol affairs.

The SD protocol unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from SDIO
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status

The SD protocol unit consists of four sub-modules:

- SD control misc
- Command control
- Data control
- Clock control

65.3.4.2 SD control miscellaneous

In the SD control miscellaneous unit:

- The card detection (including DATA3 for card detection) and card interrupt are implemented.
- The module monitors the signal level on all the eight data lines and the command lines. It directly routes the level values into the register bank.

65.3.4.3 SD clock control

If the internal data buffer is near full (for read) or near empty (for write), the SD clock must be gated off to avoid buffer over/under-run. This module asserts the gate of the output SD clock to shut the clock off. After the buffer has space (for read) or has data (for write), the clock gate of this module opens, and the SD clock is active again.

65.3.4.4 Command control

The Command Control module deals with the transactions on the CMD line.

See Figure 366 for an illustration of the structure for the Command CRC shift register.

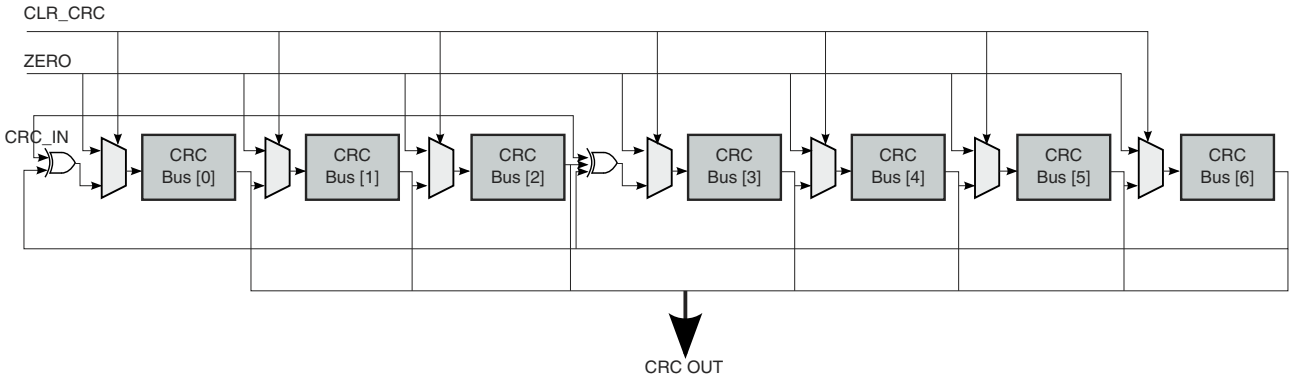

Figure 366. Command CRC shift register

The CRC polynomials for the CMD are as follows:

```
Generator polynomial: G(x) = x^7 + x^3 + 1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[6:0] = Remainder [(M(x) * x^7) / G(x)]
```

65.3.4.5 Data control

The data agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line and generates the read wait state by the request from the transceiver.

The CRC polynomials for the data are as follows:

```
Generator polynomial: G(x) = x^16 + x^12 + x^5 +1

M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0

CRC[15:0] = Remainder [(M(x) * x^16) / G(x)]
```

65.3.5 Card insertion and removal detection

The uSDHC module uses the DATA3 pin to detect card insertion or removal. It is controlled by SoC pad or other logic. When there is no card on the eMMC/SD bus, the DATA3 is pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt.

65.3.6 Power management and wakeup events

When there is no operation between uSDHC and the card through the SD bus, the user can completely disable the peripheral clock and base clock in the chip-level clock control module to save power. When the user needs to use uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to uSDHC are disabled, for instance, when the system is in low-power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC module can generate these interrupts even when there are no clocks enabled. The three interrupts that can be used as wakeup events are these:

- Card removal interrupt
- Card insertion interrupt

- Interrupt from SDIO (not available in multiple block data transfers)

These three wakeup events (or wakeup interrupts) can also be used to wakeup the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to uSDHC are disabled or when the entire system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (PROT_CTRL) for more information on the uSDHC Protocol Control register.

65.3.6.1 Setting wakeup events

For uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters the sleep mode. Before the software disables the host clock, it should ensure that all the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- Internal data buffer is empty

65.3.7 eMMC fast boot

The Embedded MultiMediaCard (eMMC4.3 or later) specification adds a fast boot feature that requires hardware support. There are two types of fast boot modes in the eMMC4.3 or later specification: boot operation and alternative boot operation. Each type also has with-acknowledge and without-acknowledge modes.

In the boot operation mode, the master (eMultiMediaCard host) can read boot data from the slave (eMMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for slave), before issuing CMD1.

NOTE

For the eMMC4.3 setting, please see the eMMC4.3 specification.

65.3.7.1 Boot operation

If the CMD line is held low for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after the CMD line goes low, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line low to read all of the boot data.

NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes low. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode with the CMD line high.

The boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal eMMC initialization sequence by sending CMD1.

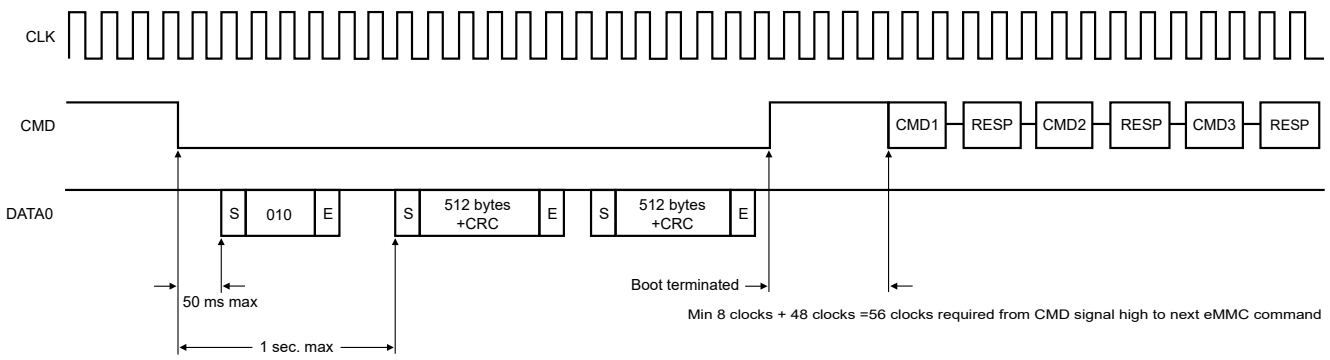

Figure 367. Embedded MultiMediaCard state diagram (normal boot mode)

65.3.7.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after CMD0 with the argument of 0xFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave must send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode by issuing CMD0 (Reset).

Boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal eMMC initialization sequence by sending CMD1.

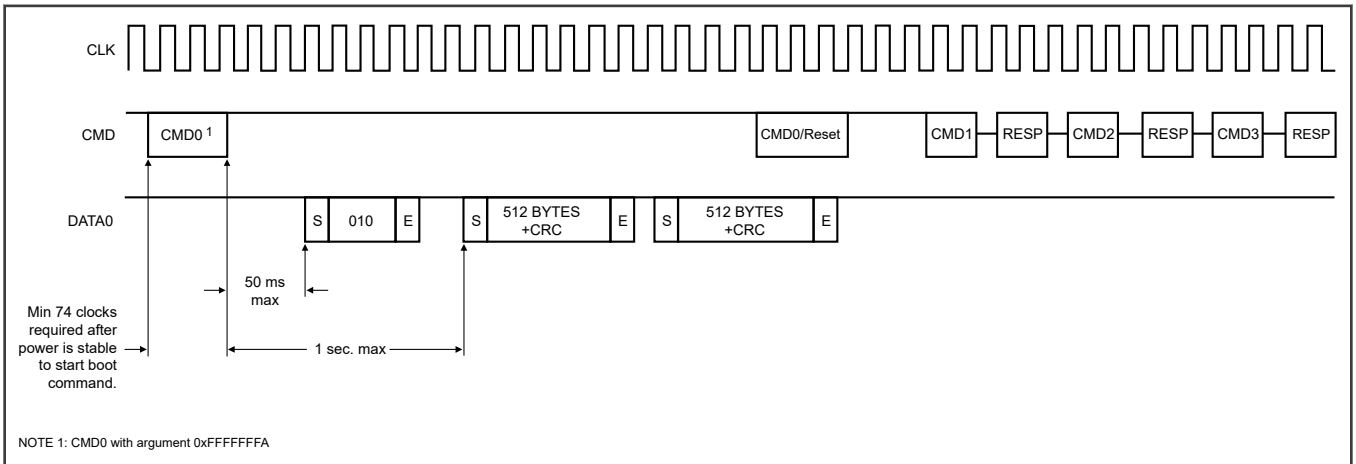

Figure 368. Embedded MultiMediaCard state diagram (alternative boot mode)

65.3.8 Commands for SD card, SDIO, and eMMC

A table containing the list of commands for the eMMC/SD card/SDIO is provided here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the SD card, SDIO, and eMMC:

- Broadcast commands (bc), no response
- Broadcast commands with response (bcr), response from all cards simultaneously
- Addressed (point-to-point) commands (ac), no data transfer on the DATA
- Addressed (point-to-point) data transfer commands (adtc)

Response: A response is a token that is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

Table 536. Commands for eMMC/SD card/SDIO

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all eMMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all eMMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO in idle state to send them operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The

Table continues on the next page...

Table 536. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
		[23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set			Embedded MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.

Table continues on the next page...

Table 536. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	adtc	[31:0] reserved bits(all 0)	R1	SEND_TUNING_BLOCK	64 bytes tuning pattern is sent for SDR50 and SDR104.
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21	Reserved				
CMD22	Reserved				
CMD23	ac	[31] reliable write request [30:16] set to 0 [15:0] number of blocks	R1	SET_BLOCK_COUNT	Defines the number of blocks (read/write) and the reliable writer parameter (write) for a block read or write command.
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command is issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write

Table continues on the next page...

Table 536. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
					protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command

Table continues on the next page...

Table 536. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
					accesses application dependent registers which are not defined in the eMMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather than a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 is used to read and write these registers.

Table continues on the next page...

Table 536. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62-63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block).
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on DATA3 of the card.
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for eMMC and SD cards. For eMMC, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed eMMC and high-speed SD cards. Command SWITCH_FUNC is for high-speed SD cards.
3. Command SWITCH is for high speed eMMC. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 537.
4. ACMDs is preceded with the APP_CMD command. Commands listed are used for SD only, other SD commands not listed are not supported on this module.

The access bits for the EXT_CSD access modes are listed in the following table.

Table 537. EXT_CSD access modes

Bits	Access name	Operation
00	Command set	The command set is changed according to the Cmd Set field of the argument.
01	Set bits	The bits in the pointed byte are set, according to the bits set to 1 in the Value field.
10	Clear bits	The bits in the pointed byte are cleared, according to the bits set to 1 in the Value field.
11	Write byte	The Value field is written into the pointed byte.

65.3.9 SDIO interrupt

Information on interrupts in 1-bit mode, interrupts in 4-bit mode, and card interrupt handling are detailed in the sections below.

65.3.9.1 Interrupts in 1-bit mode

In this case, the DATA1 pin provides the interrupt function. An interrupt is asserted by pulling the DATA1 low from SDIO, until the interrupt service is finished to clear the interrupt.

65.3.9.2 Interrupt in 4-bit mode

As the interrupt and data line 1 share pin 8 in a 4-bit mode, an interrupt is only sent by the card and recognized by the host during a specific time. This is known as the interrupt period. The uSDHC module only provides samples the level on pin 8 during the interrupt period. At all other times, the host treats it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in a 4-bit mode, there is only a limited period of time that the interrupt period can be active because of the limited period of data line availability between the multiple blocks of data. This requires stricter definition of the interrupt period. For this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line holds low for one clock cycle, then pulls high for the next clock cycle . On completion of the interrupt period, the card releases the DATA1 line into the high Z state. The uSDHC module provides sample of the DATA1 during the interrupt period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Specification v1.10 for further information about the SDIO interrupt.

65.3.9.3 Card interrupt handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, uSDHC clears the interrupt request to the host system. The host driver should clear this bit before servicing the SDIO interrupt, and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from SDIO does not clear, this bit is set again. To clear this bit, it is required to reset the interrupt source from the external card followed by writing 1 to this bit. In a 1-bit mode, uSDHC detects the SDIO interrupt with or without the SD clock (to support wakeup). In a 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from SDIO and the interrupt to the Host System Interrupt Controller. When the SDIO status is set and the host driver needs to service this interrupt, the SDIO bit in the Interrupt Control Register of SDIO is cleared. This is required to clear the SDIO interrupt status latched in uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1 and uSDHC starts sampling the interrupt signal again.

See Figure 369 for an illustration of the SDIO interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

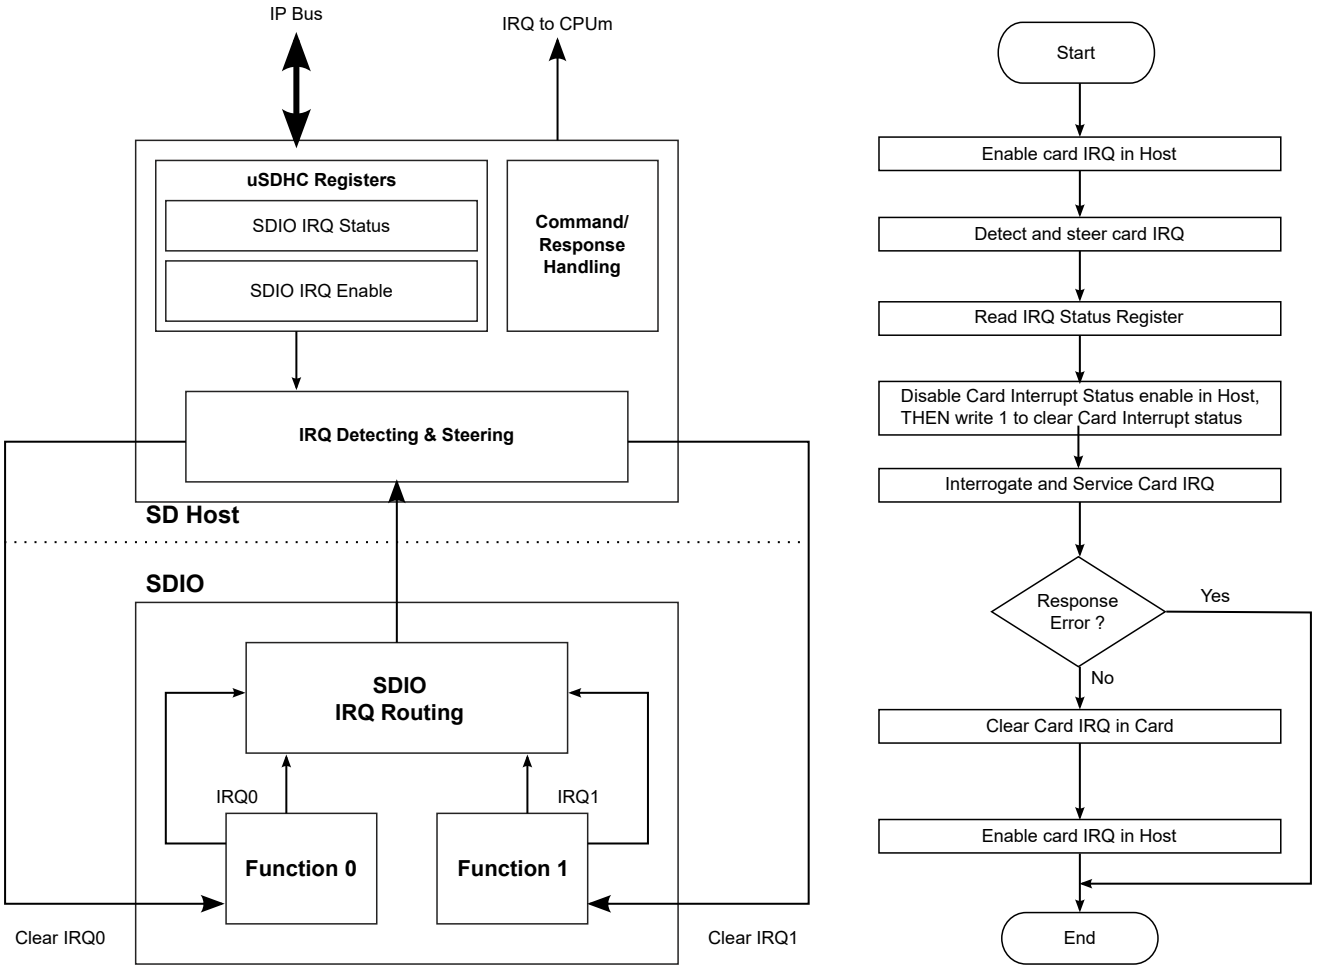

Figure 369. Card interrupt scheme, card interrupt detection, and handling procedure

65.3.10 Software restrictions

65.3.10.1 Initialization active

The driver cannot set INITA bit in System Control register when any of the command line or data lines are active, so the driver must ensure both CDIHB and CIHB bits are cleared.

65.3.10.2 Software polling procedure

For polling read or write, after the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in the Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block. For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

65.3.10.3 Suspend operation

To suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by SDIO, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such a 'suspend' command, uSDHC treats the current transfer is aborted and change the BLKCNT register to its original value, instead of retaining the remaining number of blocks.

65.3.10.4 Data length setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

ADMA1 is 4KB aligned.

65.3.10.5 (A)DMA address setting

To configure the ADMA1/ADMA2/DMA address register, when TC bit is set, the register always updates itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring the ADMA1/ADMA2/DMA address register.

65.3.10.6 Data port access

Data port does not support parallel access. For example, during an internal DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or internal DMA. Otherwise the data is corrupted inside the uSDHC buffer.

65.3.10.7 Change clock frequency

The uSDHC module does not automatically gate off the card clock when the host driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing the clock divisor value (SDCLKFS or DVS in System Control Register) or setting the RSTA bit.

Also, before changing the clock divisor value, the host driver should make sure that the SDSTB bit is high.

65.3.10.8 Multi-block read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for eMMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode. In this case, the card may not respond to this extra abort command and uSDHC gets response timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

65.3.11 Clocking

The table found here describes the clock sources for uSDHC. For more information on clocking, see the Clocking chapter.

Table 538. Clocks

Clock name	Description
hclk	Bus clock
ipg_clk	Peripheral clock
ipg_clk_perclk	Base clock
ipg_clk_lp	Low power clock

65.3.11.1 Clock and reset manager

This module controls all four kinds reset signals within uSDHC:

- Hardware reset
- Software reset for all logic
- Software reset for the data logic
- Software reset for the command logic

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

65.3.11.2 Clock generator

The clock generator generates the card CLK by peripheral source clock in two stages. The clock divisor can be configured through register SYS_CTRL[SDCLKFS] for prescaler configuration while the [DVS] for divisor configuration. Details can be found in the register function description. See the following figure for the structure of the divider. The term "Base" represents the frequency of peripheral source clock (see ipg_clk_perclk in Table 538).

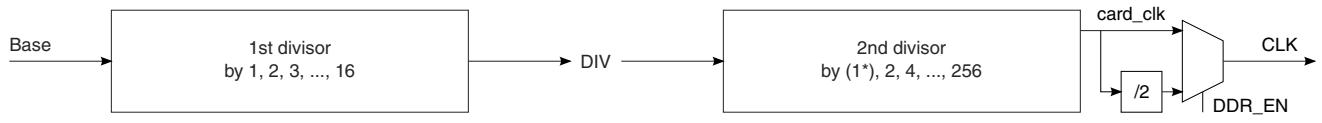

Figure 370. Two stages of the clock divider

The first stage outputs an intermediate clock (DIV) that can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler and outputs the actual internal working clock (card_clk). This clock is the driving clock for all the sub modules of the SD protocol unit, and helps in syncing FIFOs (see Figure 356) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage can be DIV, DIV/2, DIV/4,..., or DIV/256. Therefore, the highest frequency of the card_clk is base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of the base clock is 50%, the duty cycle of card_clk is also 50%, even when the compound divisor is an odd value.

NOTE

CLK is different for the SDR and DDR modes.

- In the SDR mode, CLK is equal to the internal working clock (card_clk).

$$f_{card_clk} = \frac{f_{Base}}{SYS_CTRL[DVS] \times SYS_CTRL[SDCLKFS]}$$

$$f_{CLK} = f_{card_clk}$$

Equation 27. Equation for f_{card_clk} in SDR mode

$$f_{card_clk} = \frac{400MHz}{1x(2)} = 200MHz$$

$$f_{CLK} = f_{card_clk} = 200\ MHz$$

- In the DDR mode, CLK is equal to card_clk/2

$$f_{card_clk} = \frac{f_{Base}}{SYS_CTRL[DVS] \times (SYS_CTRL[SDCLKFS]/2)}$$

$$f_{CLK} = \frac{f_{card_clk}}{2}$$

Equation 28. Equation for f_{card_clk} in DDR mode

$$f_{card_clk} = \frac{400MHz}{1x(2/2)} = 400MHz$$

$$f_{CLK} = \frac{f_{card_clk}}{2} = \frac{400MHz}{2} = 200MHz$$

65.4 External signals

The following table describes the uSDHC external signals:

Table 539. uSDHC external signals

Signal	Description	Direction
CLK	Is an Internally generated clock used to drive the eMMC, SD card, and SDIO.	O
CMD	Is used to send commands and receive responses to and from the card.	I/O
DAT7	DAT7 line in the 8-bit mode — Not used in other modes	I/O
DAT6	DAT6 line in the 8-bit mode — Not used in other modes	I/O
DAT5	DAT5 line in the 8-bit mode — Not used in other modes	I/O
DAT4	DAT4 line in the 8-bit mode — Not used in other modes	I/O
NOTE If uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.		
DAT3	DAT3 line in the 4/8-bit mode or configured as card detection pin. The bit may be configured as card detection pin in the 1-bit mode.	I/O
DAT2	DAT2 line or Read Wait in the 4-bit mode Read Wait in 1-bit mode	I/O
DAT1	DAT1 line in the 4/8-bit mode Also, used to detect interrupt in 1/4-bit mode	I/O
DAT0	DAT0 line in all the modes Also, used to detect busy state	I/O

65.5 Application information

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, and ALL_SEND_CID. In the Broadcast mode, eMMC are in the open-drain mode to avoid bus contention. See Commands for SD card, SDIO, and eMMC for the commands of bc and bcr categories.

After the broadcast command CMD3 is issued, the cards enter the standby mode. Addressed type commands are used from this point. In this mode, for eMMC, the CMD/DATA I/O pads turns to the push-pull mode to have the driving capability for maximum frequency operation. See Commands for SD card, SDIO, and eMMC for the commands of ac and adtc categories.

A uSDHC FIFO control problem exists with a software reset for a single block read. See MIX_CTRL[DTDSEL] for more information.

65.5.1 Command send and response receive basic operation

Assuming that the data type WORD is an unsigned 32-bit integer, the flow indicated below presents a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)

{

    WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner

    wCmd = (<cmd_index> & 0x3f) << 24; // set the first 8 bits as '00'+<cmd_index>

    set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL according to the command index;

    if (internal DMA is used) wCmd |= 0x1;

    if (multi-block transfer) {

        set MSBSEL bit;

        if (finite block number) {

            set BCEN bit;

            if (auto12 command is to use) set AC12EN bit;

        }

    }

    write_reg(CMDARG, <cmd_arg>); // configure the command argument

    write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command

}

wait_for_response(cmd_index)

{

    while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set

    read IRQ Status register and check if any error bits about Command are set
```

```
    if (any error bits are set) report error;

    write 1 to clear CC bit and all Command Error bits;

}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure that the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and move to the Standby state no response to the Host when CMD2 is sent. The host driver deals with "fake" errors like this with caution.

65.5.2 Card identification mode

When a card is inserted to the socket or the card is reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for eMMC.

65.5.2.1 Card detect

See Figure 371 for a flow diagram showing the detection of SD card and SDIO using uSDHC.

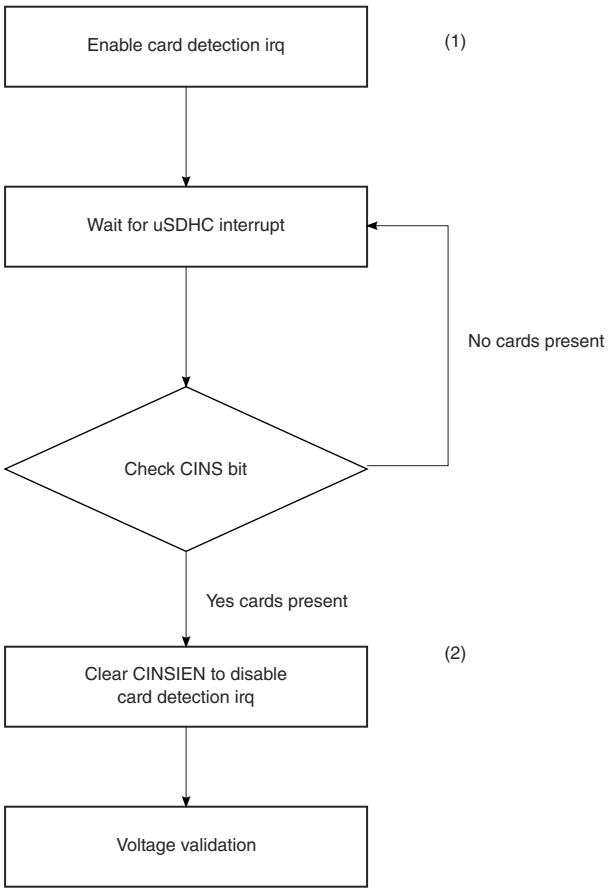

Figure 371. Flow diagram for card detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt.

- When an interrupt from uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion.
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards.

65.5.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) that is driven by Power On Reset (POR).
- Software reset (Host only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the host controller, respectively.
- Card reset (Card only): The command, "Go_Idle_State" (CMD0), is the software reset command for all types of eMMC and SD memory cards. This command sets each card into the idle state regardless of the current card state. For an SDIO, CMD52 is used to write an I/O reset in CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both uSDHC and the card.

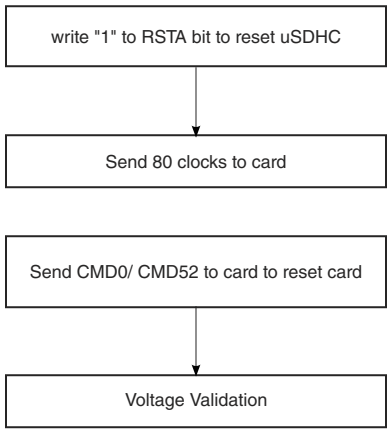

Figure 372. Flow chart for resetting uSDHC and SD card or SDIO

```
software_reset() {
    set_bit(SYSCTRL, RSTA); // software reset the Host set DTOCV and SDCLKFS fields to get the CLK of
    //frequency around 400kHz
    //configure IO pad to set the power voltage of external card to around 3.0V
    //poll bits CIHB and CDIHB
    //bits of PRSSTAT to wait both fields are cleared
    set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
    send_command(CMD_GO_IDLE_STATE, <other parameter>); // reset the card with CMD0 or
    send_command(CMD_IO_RW_DIRECT, <other parameter>);
}
```

65.5.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for VDD are defined in the Operation Conditions Register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer VDD conditions. This means that if the host and card have non-common VDD ranges, the card is neither able to complete the identification cycle nor able to send CSD data.

Therefore, special commands Send_Op_Cont (CMD1 for eMMC), SD_Send_Op_Cont (ACMD41 for SD Memory), and IO_Send_Op_Cont (CMD5 for SD I/O) are used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards that do not match the VDD range(s) desired by the host. This is accomplished when the host sends the desired VDD voltage window as the operand of this command. Cards that cannot perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive state. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive state. This query should be used if the host is able to select a common voltage range or if a notification is sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_argument) {
    label the card as UNKNOWN;
    send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO operation
voltage, command argument is zero
    if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
        if (0 < number of IO functions) {
            label the card as SDIO;
            IORDY = 0;
            while (!(IORDY in IO OCR response)) { // set voltage range for each IO function
                send_command(IO_SEND_OP_COND, <voltage range>, <other parameter>);
                wait_for_response(IO_SEND_OP_COND);
            } // end of while ...
        } // end of if (0 < ...
        if (memory part is present inside SDIO)
            Label the card as SDCombo; //this is an SD-Combo card
    } // end of if (RESP_TIMEOUT ...
    if (the card is labeled as SDIO)
        return; // card type is identified and voltage range is set, so exit the function;
    send_command(APP_CMD, 0x0, <other parameter>); // CMD55, Application specific CMD prefix
    if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
        send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage range for
memory part or SD card
        wait_for_response(SD_APP_OP_COND); // voltage range is set
        if (card type is UNKNOWN)
           label the card as SD;
        return; //
    } // end of if (no error ...
    else if (errors other than time-out occur) { // command/response pair is corrupted
        deal with it by program specific manner;
    } // of else if (response time-out
    else { // CMD55 is refuse, it must be eMMC
        if (card is already labeled as SDCombo) { // change label
            re-label the card as SDIO;
            ignore the error or report it;
            return; // card is identified as SDIO
        } // end of if (card is ...
        send_command(SEND_OP_COND, <voltage range>, <...>);
        if(RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
            either label the card as UNKNOWN;
            return;
        } // end of if (RESP_TIMEOUT ...
    } // end of else
}
```

65.5.2.4 Card registry

This section briefly describes the registry flow. For details, please refer to the card specifications. Card registry for the eMMC and SD/SDIO/SD combo cards are different. For the SD card, the identification process starts at a clock rate lower than 400

kHz and the power voltage higher than 2.7 V (as defined by the card spec). Currently, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host requests the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command is sent to all the new cards in the system. Incompatible cards are put into the Inactive state. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready state), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification state.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA is used to address the card for future data transfer operations. After the RCA is received, the card changes its state to the Standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in the system.

For eMMC operation, the host starts the card identification process in the open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line to allow parallel card operation during card identification. After the bus is activated, the host requests the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired AND " operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive state. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in the Ready state) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. As the CID is unique for each card, only one card can be successfully sent its full CID to the host. This card then goes into the Identification state. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign a relative card address (RCA) to the card. After the RCA is received, the state of the card changes to standby, and the card does not react in further identification cycles. Also, its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

The following steps show how to perform an operation using eMMC:

```
card_registry() {
    do { // decide RCA for each card until response time-out
        if(card is labelled as SDCombo or SDIO) { // for SDIO like device
            send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO to publish its RCA
            retrieve RCA from response;
        } // end if (card is labelled as SDCombo ...
        else if (card is labelled as SD) { // for SD card
            send_command(ALL_SEND_CID, <...>);
            if(RESP_TIMEOUT == wait_for_response(ALL_SEND_CID))
                break;
            send_command(SET_RELATIVE_ADDR, <...>);
            retrieve RCA from response;
        } // else if (card is labelled as SD ...
        else if (card is labelled as eMMC) {
            send_command(ALL_SEND_CID, <...>);
            rca = 0x1; //arbitrarily set RCA, 1 here for example
            send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper 16 bits
        } // end of else if (card is labelled as eMMC...
    } while (response is not time-out);
}
```

65.5.3 Card access

Information about Block Write, Block Read, Suspense Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

65.5.3.1 Block write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

65.5.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card indicates that the failure on the DATA line. The transferred data is discarded and not written, and all further transmitted blocks (in multiple block write mode) are ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write-protected area.

For eMMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and does not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO at any time, and the card responds with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby state and release the DATA line without interrupting the write operation. When re-selecting the card, it reactivates the busy indication by pulling data to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card that incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other methods (CPU polling status with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

65.5.3.1.2 DDR write

uSDHC supports the dual data rate mode.

The software flow to write to a card in the DDR mode is described as below:

1. Check the card status and wait until the card is ready for data.

NOTE

For eMMC, block length only can be set to 512byte.

2. Set the uSDHC number block register (NOB), where nob is 5, for instance.
3. Set the eMMC, SD card, or SDIO to high-speed mode and use SWITCH(CMD6).
4. Set the eMMC bus or SD with 4-bit/8-bit DDR mode and use SWITCH(CMD6).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred or another error that occurred during the auto12 command sending and response receiving.

65.5.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the Stop At Block Gap Request (SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Similar to the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status and wait until the card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred or some another error that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The host driver reads the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible that the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is the end of the transfer. These types of requests are ignored, the driver should treat these as a non-pause transfer, and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the host system is not stopped, and the transfer is active until the data buffer is full. Because of this, it is recommended to avoid using the Suspend command for SDIO. This is because when such a command is sent, uSDHC interprets the system that switches to another function on SDIO and flush the data buffer. uSDHC takes the Resume command as a normal command with data transfer, and it is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC module automatically sends a CMD12 to mark the end of the multi-block transfer.

65.5.3.2 Block read

Information about Normal read, DDR read, Read with Pause, and Delay Line (DLL) in Read Path are detailed in the sections below.

65.5.3.2.1 Normal read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer state. For multi blocks read, data blocks are continuously transferred until a stop command is issued.

The software flow to read from a card that incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other methods (CPU polling status with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status and wait until card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer read ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

65.5.3.2.2 DDR read

The uSDHC module supports dual data rate mode.

The software flow to write to a card in the DDR mode is described below:

1. Check the card status and wait until the card is ready for data.

   NOTE

   For eMMC, block length can be set to only 512 bytes.

2. Set the uSDHC number block register (NOB) where nob is 5, for instance.
3. Set the eMMC, SD card, or SDIO to high-speed mode and use SWITCH (CMD6).
4. Set the eMMC bus or SD with 4-bit /8-bit DDR mode and use SWITCH(CMD6).
5. Disable the buffer write ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.

6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

65.5.3.2.3 Read with Pause

The read operation is not generally able to pause. Only SDIO (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If SDIO supports Read Wait (SRW bit in CCCR register is 1), the host driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. Before setting the SABGREQ bit, ensure that the RWCTL bit in the Protocol Control register is set, otherwise uSDHC does not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit after the Read Wait capability of SDIO is recognized.

Similar to the flow described in Normal read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on SDIO to confirm that the card supports the Read Wait mode.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
5. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
6. Set the uSDHC number block register (NOB), where nob is 5, for instance.
7. Disable the buffer read ready interrupt, configure the DMA setting, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

Similar to the Write operation, it is possible to meet the ending block of the transfer when paused. In this case, uSDHC ignores the Stop At Block Gap Request and treats it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause is transferred to the host system. No matter if the Suspend command is sent or not, the internal data buffer is not flushed.

If the Suspend command is sent and the transfer is later resumed by means of a Resume command, uSDHC takes the command as a normal one accompanied with data transfer. It is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the uSDHC automatically sends CMD12 to mark the end of multi-block transfer.

65.5.3.2.4 Delay Line (DLL) in read path

The DLL is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage, and temperature (PVT).

The reasons why DLL is needed for uSDHC are these:

- The path of read data traveling from card to host varies.
- In the eMMC and SD cards DDR mode, the minimum input setup and hold time are both at 2.5 ns.

The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in the override mode. The override value set is the number of delay cells. In the override mode, there is no need to set the DLL_enable. Another DLL mode is target value mode. In this mode, the DLL automatically adjusts the number of delay cells according to the target value set by the user and PVT changes. Be aware that the target value is in units of 1/32 of the clock reference period. If the card_clk is 100Mhz, then the reference clock period is 10ns; setting target value of 16 means 5ns =(16/32)*10ns. The software can disable automatic update by the setting dll_gate_update bit.

As you might change the frequency of card_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card_clk) is changed. If DLL is to be used, make sure SDCLKFS is used (at least be set to divided by 2) so that the REF_CLK generated are the same frequency as card_clk. There are two DLLs, PARTS DLL and STROBE DLL.

Step 1: Set the DLL_CTRL_RESET and DLL_CTRL_ENABLE fields

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: Clear the DLL_CTRL_RESET field

Step 5: Wait until both the DLL_STS_SLV_LOCK and DLL_STS_REF_LOCK are asserted

Step 6: Set the DLL_CTRL_SLV_FORCE_UPD

Step 7: Clear the DLL_CTRL_SLV_FORCE_UPD

NOTE

The software should make sure that the DLL_CTRL_SLV_FORCE_UPD lasts for at least one card_clk. So, the software may need to add some delay between step 6 and step 7.

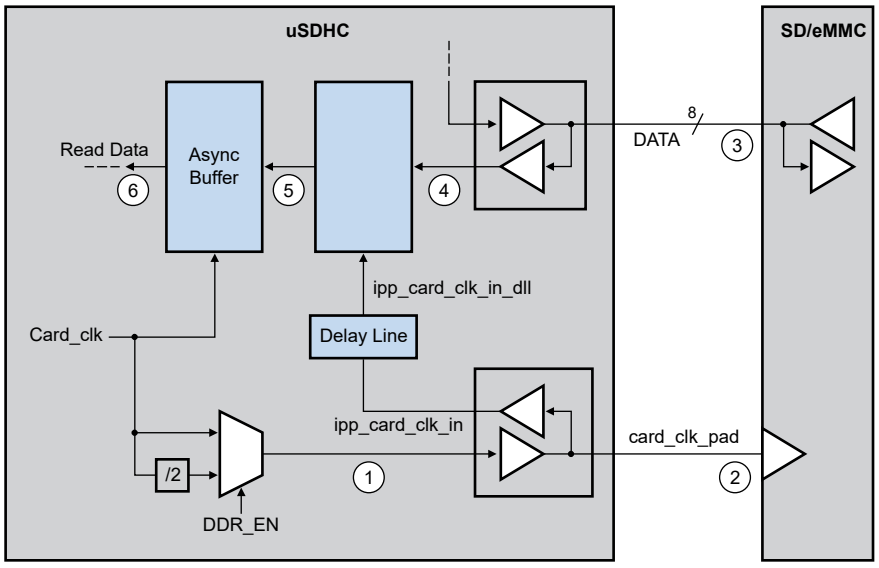

Figure 373. DLL in read path

65.5.3.3 Suspend Resume

The uSDHC module supports the Suspend Resume operations of SDIO, although slightly different than the suggested implementation of Suspend in the SDIO specification.

65.5.3.3.1 Suspend

After setting the SABGREQ bit, the host driver may send a Suspend command to switch to another function of SDIO. The uSDHC module does not monitor the content of the response, so it does not know if the Suspend command succeeded or not. Accordingly, it does not de-assert Read Wait for read pause. To solve this problem, the host driver does not mark the Suspend command as "Suspend", (that is, setting the CMDTYP bits to 01). Instead, the driver sends this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform uSDHC that the current transfer is suspended. Here is the sequence for the Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, uSDHC stops driving DATA2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on SDIO.

65.5.3.3.2 Resume

To resume the data transfer, a Resume command is issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation.
2. Send the Resume command: In the Transfer Type register, all the bit fields are set to the value as if this were another ordinary data transfer instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer is resumed.

65.5.3.4 ADMA usage

To use the ADMA in a data transfer, the host driver must prepare the correct descriptor chain prior to sending the read/write command. The steps to prepare the correct descriptor chain are these:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4KB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors matches the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.

7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

65.5.3.5 Transfer error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 errors are detailed in the sections below.

65.5.3.5.1 CRC error

It is possible at the end of a block transfer that a write CRC status error or read CRC error occurs. For this type of error, the latest block received is discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one. For a multi-block transfer, the host driver issues a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 is sent by uSDHC. In this case, the host driver re-sends or re-obtains the last block with a single block transfer.

65.5.3.5.2 Internal DMA error

During the data transfer with internal Simple DMA, if the DMA engine encounters an error on the AHB bus, the DMA operation is aborted, and the DMA error interrupt is sent to the host system. When acknowledged by such an interrupt, the host driver calculates the start address of data block in which the error occurs. The start address can be calculated by either:

- Reading the DMA System Address register: The error occurs during the previous burst. Considering the block size, the previous burst length and the start address of the next burst transfer, it is straight forward to obtain the start address of the corrupted block.
- Reading the BLKCNT field of the Block Attribute register: Considering the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined.To use this method, MIX_CTRL[BCEN] bit has to be set to enable Block Attribute register update.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

65.5.3.5.3 Transfer ADMA error

There are three kinds of possible ADMA errors: The AHB transfer, invalid descriptor, and data-length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the host driver should recover the error as shown below and re-transfer from the place of interruption.

- AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or to the next block if no block is corrupted.
- Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and recreate the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
- Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

65.5.3.5.4 Auto CMD12 error

After the last block of the multi-block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, uSDHC automatically sends a CMD12 to the card to stop the transfer. When errors with this command occur, it is recommended to the host driver to deal with the situations in the following manner:

- Auto CMD12 response time-out: It is not certain whether the command is accepted by the card or not. The host driver clears the auto CMD12 error status bits and re-send CMD12 until it is accepted by the card.
- Auto CMD12 response CRC error: As the card responds to CMD12, it aborts the transfer. The host driver may ignore the error and clear the error status bit.
- Auto CMD12 conflict error or not sent: The command is not sent; therefore, the host driver sends a CMD12 manually.

65.5.3.6 Card interrupt

The external cards can inform the host controller by means of some special signals. For SDIO, it can be the low-level on the DATA1 line during some special period. The uSDHC module only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by uSDHC, and the host system is informed by uSDHC asserting the uSDHC interrupt line, the interrupt service from the host driver is called.

As the interrupt source is controlled by the external card, the interrupt from SDIO must be serviced before the CINT bit is cleared. Refer to Card interrupt handling for the card interrupt handling flow.

65.5.4 Switch function

A switch command is issued by the host driver to enable new features added to the eMMC and SD cards. The eMMC and SD cards can transfer data at bus widths other than 1-bit. Different speed modes are also defined. To enable these features, a switch command is issued by the host driver.

For SDIO, the high-speed mode /DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed as high. For SD cards, the high-speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For eMMC, the high-speed mode is queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit, and DDR8-bit width of eMMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO, it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudo-code examples do not show current capability check, which is recommended in the function switch process.

65.5.4.1 Query, enable, and disable SDIO high-speed mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report SDIO does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of the desired value below 25MHz;
(data transactions like normal peers)
}
```

65.5.4.2 Query, enable, and disable SD high-speed mode/DDR50 /SDR50 /SDR104

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;(high speed
mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
      send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of around 50MHz for high speed mode, 100MHz for SDR50, 200MHz for SDR104, 50MHz for DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

65.5.4.3 Query, enable, and disable eMMC high-speed mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of eMMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the eMMC does not support high speed mode and return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of eMMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this eMMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of eMMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report eMMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of eMMC;
check if HS_TIMING byte (byte number 185) is 0;
```

```
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

65.5.4.4 Set eMMC bus width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of eMMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the eMMC does not support multiple bit width and return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-bit,
x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

65.5.5 ADMA operation

Here are the codes for the ADMA1 and ADMA2 operations.

65.5.5.1 ADMA1 operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

65.5.5.2 ADMA2 operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

65.5.6 Fast boot operation

65.5.6.1 Normal fast boot flow

Here are the steps for normal fast boot flow:

1. Software must configure the SYS_CTRL[INITA] bit to make sure that 74 card clocks are finished.
2. Software must configure the eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode. If the data is sent through the DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set Data Transfer Width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN retain the default value, where DPSEL bit is set to 1, DTDSEL is set to 1 and MSBSEL is set to 1.
7. DMAEN should be configured as 0 in the polling mode and if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
8. When step 6 is configured, the boot process begins. The software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt is triggered, and the software must configure eMMC Boot Register to bit 6 to 0 to disable boot. This makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.

9. If there is no timeout, software needs to determine when the data read is finished and then configure eMMC Boot Register bit 6 to 0 to disable boot. This render CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin the normal initialization process.
10. You must reset the host and begin the normal process.

65.5.6.2 Alternative fast boot flow

Here are the steps for alternative fast boot flow:

1. Software needs to configure SYS_CTRL[INITA] to make sure 74 card clocks are finished.
2. Software needs to configure eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through the DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in the DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the data transfer width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with the 0xFFFFFFFA argument. In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. Note DMAEN should be configured as 0 in the polling mode, and if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in the DDR fast boot mode, DDR_EN needs to be set to 1.
7. When step 6 is configured, the boot process begins. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host sends out the interrupt and the software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process.
8. If there is no time out, the software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the eMMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. You must reset the host and begin the normal process.

65.5.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during eMMC fast boot.

In fast boot, the host can use Advanced DMA2 (ADMA2) with two destinations.

The detailed flow is described below:

1. The software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure that 74 card clocks are finished.
2. The software needs to configure the eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the first time, so that the host stops at the block gap when the uSDHC controller gets VAULE1 blocks from the device. Also, configure bits[3-0] to select the ack timeout value according to the SD clock frequency.

3. The software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hffff).
4. The software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
6. The software needs to set at least three pairs of ADMA2 descriptor in boot memory (that is, in IRAM, at least six words). The first pair descriptor defines the start address (that is, IRAM) and data length (that is,512byte*VALUE1) of the first part boot code. The software also needs to set the second pair descriptor, the second start address (any value that is writable), and data length is suggested to set 1~2word (record as VALUE2). Note that the second couple desc also transfers useful data even at lease 1 word, because our ADMA2 cannot support 0 data_length data transfer descriptor.
7. The software needs to configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot and do not need to be set in normal fast boot.
8. The software needs to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. DMAEN is configured as 1 in the DMA mode. And, if BCEN is configured as 1, then configure blk no in Bock Attributes Register to the max value. And, if in the DDR fast boot mode, DDR_EN needs to be set to 1.
9. When step 8 is configured, boot process begins, the first VALUE1 block number data gets transferred. The software needs to poll the TC bit (bit1 in Interrupt Status Register) to determine first transfer is ended. Also, the software needs to polling the BGE bit (bit2 in Interrupt Status Register) to determine if the first transfer stops at the block gap.
10. When TC and BGE bits are set to 1, the software can analyze the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of the boot code (VALUE3, the remain boot code block). Remember to set the last descriptor with END.
11. The software needs to configure the eMMC Boot Register (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the ack mode or not. In the DMA mode, configure bit 7 to 1 for enabling the automatically stop at block gap feature. Also, configure bit31-bit16 to set the (BLK_CNT - (VALUE1+1+VALUE3)), that host stops at block gap when the uSDHC controller gets (VALUE1+1+VALUE3)) blocks from device totally include the blocks received in step 9. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequency. Note that the software does not need to configure the BLK_CNT again, because it is counted down automatically by the uSDHC controller.
12. The software needs to clear the TC and BGE bits and the software needs to clear SABGREQ (bit 16 in the Protocol control register) and set CREQ (bit17 in the Protocol control register) to 1 to resume the data transfer. Host transfers the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. The software needs to do poll BGE bit to determine if the fast boot is over.

Note:

- When ADMA boot flow starts, for uSDHC, it is like a normal ADMA read operation. So, set ADMA2 descriptor as the normal ADMA2 transfer.
- Need a few words length memory to keep descriptor.
- For the 1~2-word data in second descriptor setting, it is a useful data, so the software needs to deal the data because of the application case.

65.6 uSDHC memory map and register definition

65.6.1 uSDHC register descriptions

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map of uSDHC. All these registers only support 32-bit accesses.

NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

65.6.1.1 uSDHC memory map

uSDHC0 base address: 4010_9000h

Offset	Register	Width (In bits)	Access	Reset value
0h	DMA System Address (DS_ADDR)	32	RW	0000_0000h

65.6.1.2 DMA System Address (DS_ADDR)

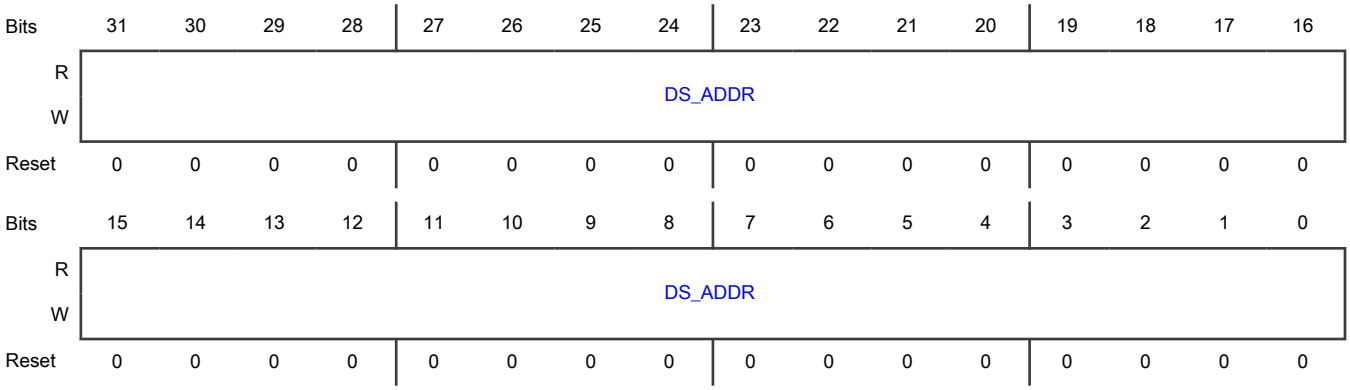
Offset

Register	Offset
DS_ADDR	0h

Function

This register contains the physical system memory address used for DMA transfers.

Diagram



Fields

Field	Function
31-0 DS_ADDR	System address **DMA system address / argument 2** When ACMD23_ARGU2_EN is set to 0, SDMA uses this register as system address and supports only 32-bit addressing mode. Auto CMD23 cannot be used with SDMA. When ACMD23_ARGU2_EN is set to 1, SDMA uses ADMA System Address register (05Fh – 058h) instead of this register to support both ADMA1 and ADMA2. This register is used only for Argument2 and SDMA may use Auto CMD23. 1. **SDMA system address**

Table continues on the next page...

Field	Function
	Because the address must be word (4 bytes) aligned, the least two bits are reserved and always set to 0. When uSDHC stops a DMA transfer, this register points out the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operation during transfers may return an invalid value. The host driver initializes this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The host driver waits until the DLA field in the Present State register is cleared, before writing to this register. The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, uSDHC automatically changes SEQ burst type to NSEQ. Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions. 2. **Argument 2** This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.

65.6.1.3 Block Attributes (BLK_ATT)

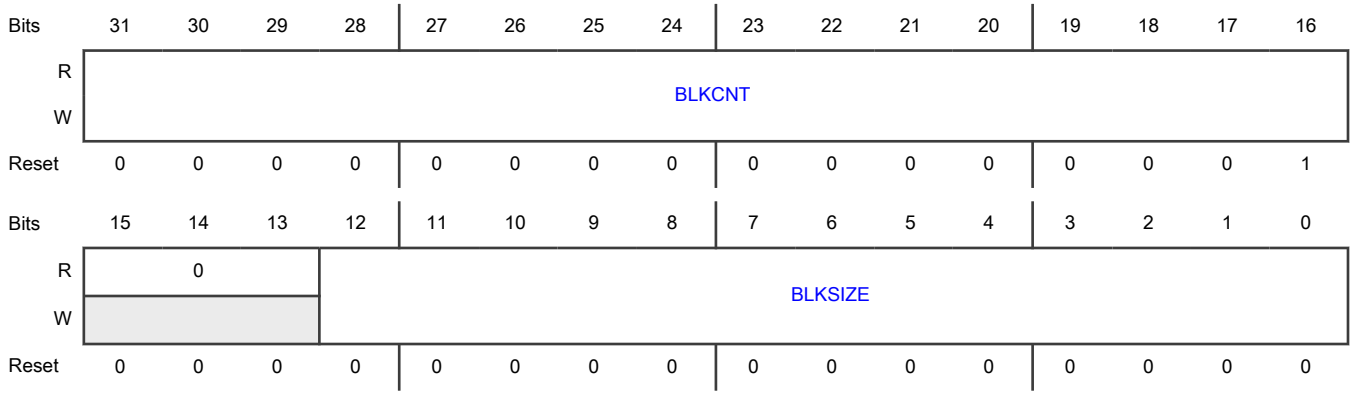
Offset

Register	Offset
BLK_ATT	4h

Function

This register is used to configure the number of data blocks and the number of bytes in each block.

Diagram



Fields

Field	Function
31-16 BLKCNT	Blocks count for current transfer This field is enabled when the Block Count Enable field in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this field always reads as 1. The host driver sets this field to a value between 1 and the maximum block count. The uSDHC module decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to zero results in no data blocks being transferred. This field should be accessed only when no transaction is executing (that is, after transactions are stopped). During data transfer, read operations on this field may return an invalid value and write operations are ignored. When saving transfer content because of a Suspend command, the number of blocks yet to be transferred can be determined by reading this field. The reading of this field should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when the Suspend command is sent out, uSDHC treats the current transfer as aborted and change the BLKCNT field back to its original value instead of keeping the dynamical indicator of the remaining block count. When restoring transfer content prior to issuing a Resume command, the host driver restores the previously saved block count. **NOTE** Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL field is indicating a single block transfer, the read value of BLKCNT is always 1. 0000_0000_0000_0000b - Stop count 0000_0000_0000_0001b - 1 block 0000_0000_0000_0010b - 2 blocks 1111_1111_1111_1111b - 65535 blocks
15-13 —	Reserved
12-0 BLKSIZE	Transfer block size This field specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations are ignored. 0_0000_0000_0000b - No data transfer 0_0000_0000_0001b - 1 byte 0_0000_0000_0010b - 2 bytes 0_0000_0000_0011b - 3 bytes 0_0000_0000_0100b - 4 bytes 0_0001_1111_1111b - 511 bytes

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0_0010_0000_0000b - 512 bytes 0_1000_0000_0000b - 2048 bytes 1_0000_0000_0000b - 4096 bytes

65.6.1.4 Command Argument (CMD_ARG)

Offset

Register	Offset
CMD_ARG	8h

Function

This register contains the SD/eMMC command argument.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CMDARG															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 CMDARG	Command argument The SD/eMMC command argument is specified as bits 39-8 of the command format in the SD or eMMC specification. This field is write protected when the Command Inhibit (CMD) field in the Present State register is set.

65.6.1.5 Command Transfer Type (CMD_XFR_TYP)

Offset

Register	Offset
CMD_XFR_TYP	Ch

Function

This register is used to control the operation of data transfers. The host driver sets this register before issuing a command followed by a data transfer or before issuing a Resume command. To prevent data loss, uSDHC prevents writing to the bits, which are involved in the data transfer of this register, when data transfer is active. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver checks the Command Inhibit DAT field (PRES_STATE[CDIHB]) and the Command Inhibit CMD field (PRES_STATE[CIHB]) in the Present State register before writing to this register. When the CDIHB field in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB field is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as a single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC ignores the sending of this command and do nothing.

If the commands with data transfer do not receive the response in 64 clock cycles, that is, if response time-out happens, uSDHC treats the external device, does not accept the command, and aborts the data transfer. In this scenario, the driver should issue the command again to retry the transfer. It is also possible that for some reason the card responds to the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

Table 540. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, regarding the Response Type bits as well as the name of the response type.

Table 541. Relationship between parameters and the name of the response type

Response type	Index check enable	CRC check enable	Name of response type
00	0	0	No response
01	0	1	R2
10	0	0	R3, R4

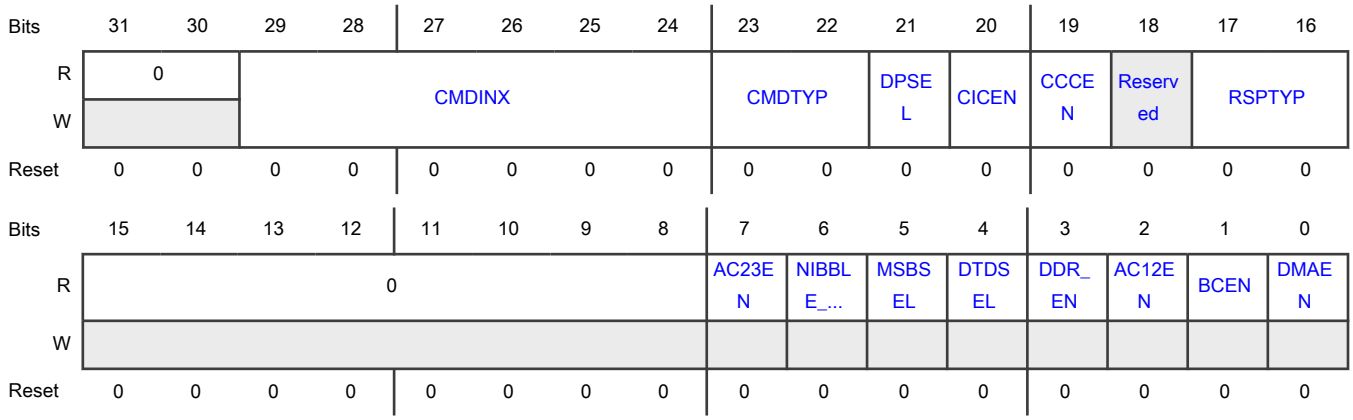
Table continues on the next page...

Table 541. Relationship between parameters and the name of the response type (continued)

Response type	Index check enable	CRC check enable	Name of response type
10	1	1	R1, R5, R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification, but R5b is defined in this specification to specify that uSDHC checks the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command is used with R5b.
- The CRC fields for R3 and R4 are expected to be all 1 bits. The CRC check is disabled for these response types.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 CMDINX	Command index These fields are set to the command number that is specified in bits 45-40 of the command-format in the SD Memory Card Physical Layer Specification and SDIO Specification.
23-22 CMDTYP	Command type There are three types of special commands: Suspend, Resume, and Abort. These fields are set to 00b for all other commands. • Suspend command: If the Suspend command succeeds, uSDHC assumes that the card bus has been released and that it is possible to issue the next command that uses the DATA line. Because uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the host driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform uSDHC that a Suspend command was successfully issued. See Suspend Resume for more details. After the end bit of command is sent, uSDHC deasserts Read Wait for read transactions and stops checking busy for

Table continues on the next page...

Table continued from the previous page...

Field	Function
	write transactions. In a 4-bit mode, the interrupt cycle starts. If the Suspend command fails, uSDHC maintains its current state, and the host driver restarts the transfer by setting the Continue Request field in the Protocol Control register. • Resume command: The host driver re-starts the data transfer by restoring the registers saved before sending the Suspend command and then sends the Resume command. The uSDHC module checks for a pending busy state before starting write transfers. • Abort command: If this command is set when executing a read transfer, uSDHC stops reads to the buffer. If this command is set when executing a write transfer, uSDHC stops driving the DATA line. After issuing the Abort command, the host driver should issue a software reset (Abort Transaction). 00b - Normal other commands 01b - Suspend CMD52 for writing bus suspend in CCCR 10b - Resume CMD52 for writing function select in CCCR 11b - Abort CMD12, CMD52 for writing I/O Abort in CCCR
21 DPSEL	Data present select This field is set to 1 to indicate that data is present and is transferred using the DATA line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52) • Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b (for example, CMD38)) **NOTE** In resume command, this field is set, and other bits in this register is set the same as when the transfer was initially launched. When this field is set, while the DTDSEL field is 0, writes to the register Transfer Type are ignored. 0b - No data present 1b - Data present
20 CICEN	Command index check enable If this field is set to 1, uSDHC checks the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this field is set to 0, the Index field is not checked. 0b - Disable command index check 1b - Enables command index check
19 CCCEN	Command CRC check enable If this field is set to 1, uSDHC checks the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this field is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. See RSPTYP[1:0] and Command Transfer Type (CMD_XFR_TYP).

Table continued from the previous page...

Field	Function
	0b - Disables command CRC check 1b - Enables command CRC check
18 —	Reserved
17-16 RSPTYP	Response type select 00b - No response 01b - Response length 136 10b - Response length 48 11b - Response length 48, check busy after response
15-8 —	Reserved
7 AC23EN	AC23EN This field is read when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is tied to '0'. When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register. 0b - Disable 1b - Enable
6 NIBBLE_POS	NIBBLE_POS This field indicates the nibble position in the DDR 4-bit mode. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'. 0b - Disable 1b - Enable
5 MSBSEL	MSBSEL This field enables multiple block DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP). 0b - Disable 1b - Enable
4 DTDSEL	DTDSEL This field defines the direction of DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If a CMD with the response data size cannot be divided by 64 bytes, is given without a STOP CMD, and is followed by a software reset, then you must write a 0 to DTDSEL before inserting a software reset. This is necessary to avoid any issue during the SD card reinitialization. Read multiple blocks will not be affected as it is required to have a STOP CMD. 0b - Disable 1b - Enable
3 DDR_EN	DDR_EN Dual data rate mode selection. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. 0b - Disable 1b - Enable
2 AC12EN	AC12EN Multiple block transfers for memory require a CMD12 to stop the transaction. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0b - Disable 1b - Enable
1 BCEN	BCEN This field is used to enable the Block Count register, which is only relevant for multiple block transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0b - Disable 1b - Enable
0 DMAEN	DMAEN This field enables DMA functionality. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register. 0b - Disable 1b - Enable

65.6.1.6 Command Response0 (CMD_RSP0)

Offset

Register	Offset
CMD_RSP0	10h

Function

This register is used to store part 0 of the response bits from the card.

65.6.1.9 Command Response3 (CMD_RSP3)

Offset

Register	Offset
CMD_RSP3	1Ch

Function

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD bus to Command Response registers for each response type. In this table, R[ ] refers to a bit range within the response data as transmitted on the SD bus.

Table 542. Response bit definition for each response type

Response type	Meaning of response	Response field	Response register
R1,R1b (normal response)	Card status	R[39:8]	CMDRSP0
R1b (auto CMD12 response)	Card status for auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (publish RCA)	New published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, uSDHC only stores part of the response data in the Command Response registers. This enables the host driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by uSDHC (as specified by the Command Index Check Enable and the

Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, uSDHC checks R[47:1], and if the response length is 136 the uSDHC checks R[119:1].

Because uSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows uSDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

65.6.1.10 Data Buffer Access Port (DATA_BUFF_ACC_PORT)

Offset

Register	Offset
DATA_BUFF_ACC_PORT	20h

Function

The Buffer Data Port register is for 32-bit data access by the Arm platform. When the internal DMA is enabled, any write to this field is ignored, and any read from this field always yields 0s.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Function
31-0 DATCONT	Data content This field is used to access the internal buffer.

65.6.1.11 Present State (PRES_STATE)

Offset

Register	Offset
PRES_STATE	24h

Function

The host driver can get status of uSDHC from this 32-bit read only register.

The host driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands are issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

NOTE

The reset value of Present State register depends on board connectivity.

Fields

Field	Function
31-24 DLSL	DATA[7:0] line signal level This field is used to check the DATA line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up. 0000_0001b - Data 0 line signal level 0000_0010b - Data 1 line signal level 0000_0100b - Data 2 line signal level 0000_1000b - Data 3 line signal level 0001_0000b - Data 4 line signal level 0010_0000b - Data 5 line signal level 0100_0000b - Data 6 line signal level 1000_0000b - Data 7 line signal level
23 CLSL	CMD line signal level This field is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this field after reset is 1'b1, when the command line is pulled up.
22-20 —	Reserved
19 —	Reserved
18 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
17 —	Reserved
16 CINST	Card inserted This field indicates whether a card has been inserted. The uSDHC module debounces this signal so that the host driver does not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not affect this field. The Software Reset For All in the System Control register does not affect this field. A software reset does not affect this field. 0b - Power on reset or no card 1b - Card inserted
15 TSCD	Tap select change done This field indicates the delay setting is effective after write CLK_TUNE_CTRL_STATUS register. 0b - Delay cell select change is not finished. 1b - Delay cell select change is finished.
14-13 —	Reserved
12 RTR	Re-Tuning Request (only for SD3.0 SDR104 mode) Host controller may request host driver to execute re-tuning sequence by setting this field when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data. This field is cleared when a command is issued with setting Execute Tuning field in MIX_CTRL register. Changing of this field from 0 to 1 generates Re-Tuning Event. See Interrupt status registers for more detail. This field isn't set to 1 if Sampling Clock Select in the MIX_CTRL register is set to 0 (using fixed sampling clock). 0b - Fixed or well tuned sampling clock 1b - Sampling clock needs re-tuning
11 BREN	Buffer read enable This status field is used for non-DMA read transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this field is high, valid data greater than the watermark level exist in the buffer. A change of this field from 1 to 0 occurs when some reads from the buffer (read DATPORT (Base + 0x20)) are made and the buffer hasn't valid data greater than the watermark level. A change of this field from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled. 0b - Read disable 1b - Read enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
10 BWEN	Buffer write enable This status field is used for non-DMA write transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this field is 1, valid data greater than the watermark level can be written to the buffer. A change of this field from 1 to 0 occurs when some writes to the buffer (write DATPORT (Base + 0x20)) are made and the buffer hasn't valid space greater than the watermark level. A change of this field from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled. 0b - Write disable 1b - Write enable
9 RTA	Read transfer active This status field is used for detecting completion of a read transfer. This field is set for either of the following conditions: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer A transfer complete interrupt is generated when this field changes to 0. This field is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the System, that is, all data are read away from uSDHC internal buffer. • When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent because of the Stop At Block Gap Request being set to 1. 0b - No valid data 1b - Transferring data
8 WTA	Write transfer active This status field indicates a write transfer is active. If this field is 0, it means no valid write data exists in uSDHC. This field is set in either of the following cases: • After the end field of the write command • When writing 1 to the Continue Request field in the Protocol Control register to restart a write transfer This field is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple) • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request During a write transaction, a Block Gap Event interrupt is generated when this field is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the host driver in determining when to issue commands during Write Busy state.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No valid data 1b - Transferring data
7-4 —	Reserved
3 SDSTB	SD clock stable This status field indicates that the internal card clock is stable. This field is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON field in System Control register to remove glitches on the card clock when the frequency is changing. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. 0b - Clock is changing frequency and not stable. 1b - Clock is stable.
2 DLA	Data line active This status field indicates whether one of the DATA lines on the SD bus is in use. In the case of read transactions: This status indicates if a read transfer is executing on the SD bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer This field is cleared in either of the following cases: • When the end field of the last data block is sent from the SD bus to uSDHC. • When the Read Wait state is stopped by a Suspend command and the DATA2 line is released. The uSDHC module waits at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait to use the suspend / resume function. This field remains 1 during Read Wait. In the case of write transactions: This status indicates that a write transfer is executing on the SD bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the write command • When writing to 1 to the Continue Request field in the Protocol Control register to continue a write transfer This field is cleared in either of the following cases:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• When the SD card releases Write Busy of the last data block, uSDHC also detects if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, uSDHC assumes the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and because of a Stop At Block Gap Request. In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This field is cleared when the DATA0 line is released. 0b - DATA line inactive 1b - DATA line active
1 CDIHB	Command Inhibit Data (DATA) This status field is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this field is 0, it indicates that uSDHC can issue the next SD / eMMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register. **NOTE** The SD host driver can save registers for a suspend transaction after this field has changed from 1 to 0. 0b - Can issue command that uses the DATA line 1b - Cannot issue command that uses the DATA line
0 CIHB	Command inhibit (CMD) If this status bit is 0, it indicates that the CMD line is not in use and uSDHC can issue a SD / eMMC command using the CMD line. This field is set also immediately after the Transfer Type register is written. This field is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, commands using only the CMD line can be issued if this field is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If uSDHC cannot issue the command because of a command conflict error (see Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this field remains 1 and the Command Complete is not set. The Status of issuing an auto CMD12 does not show on this field. 0b - Can issue command using only CMD line 1b - Cannot issue command

65.6.1.12 Protocol Control (PROT_CTRL)

Offset

Register	Offset
PROT_CTRL	28h

Function

This register controls three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether uSDHC issues a Suspend command or the SD card accepts the Suspend command.

- If the host driver does not issue a Suspend command, the Continue request is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card accepts it, a Resume command is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card does not accept it, the Continue request is used to restart the transfer.

Any time stop at block gap request stops the data transfer, the host driver waits for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the host driver clears the Stop At Block Gap Request before or simultaneously.

Fields

Field	Function
31 —	Reserved Always write as 0
30 NON_EXACT_BLK_RD	Non-exact block read Current block read is non-exact block read. It is only used for SDIO. 0b - The block read is exact block read. Host driver does not need to issue abort command to terminate this multi-block read. 1b - The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read.
29-27 BURST_LEN_EN	BURST length enable for INCR, INCR4 / INCR8 / INCR16, INCR4-WRAP / INCR8-WRAP / INCR16-WRAP This field is used to enable or disable the burst length for the external AHB2AXI bridge. It is useful especially for INCR transfer because without burst length indicator, the AHB2AXI bridge does not know the burst length in advance. Without burst length indicator, AHB INCR transfers can only be converted to SINGLEs on the AXI side. 1xxb - Burst length is enabled for INCR4-WRAP / INCR8-WRAP / INCR16-WRAP.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	x1xb - Burst length is enabled for INCR4 / INCR8 / INCR16. xx1b - Burst length is enabled for INCR.
26 WECRM	Wakeup event enable on SD card removal This field enables a wakeup event, via a card removal, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Removal Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Removal Status and uSDHC interrupt. 0b - Disables wakeup event enable on SD card removal 1b - Enables wakeup event enable on SD card removal
25 WECINS	Wakeup event enable on SD card insertion This field enables a wakeup event, via a card insertion, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Insertion Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Insertion Status and uSDHC interrupt. 0b - Disable wakeup event enable on SD card insertion 1b - Enable wakeup event enable on SD card insertion
24 WECINT	Wakeup event enable on card interrupt This field enables a wakeup event, via a card interrupt, in the Interrupt Status register. This field can be set to 1 if FN_WUS (Wakeup Support) in CIS is set to 1. When this field is set, the Card Interrupt Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Interrupt Status and uSDHC interrupt. 0b - Disables wakeup event enable on card interrupt 1b - Enables wakeup event enable on card interrupt
23-21 —	Reserved Always write as 3'b100
20 RD_DONE_NO_8CLK	Read performed number 8 clock According to the SD/eMMC spec, for read data transaction, 8 clocks are needed after the end field of the last data block. So, by default(RD_DONE_NO_8CLK=0), eight clocks are active after the end field of the last read data transaction. However, these 8 clocks should not be active if user wants to use stop at block gap (include the auto stop at block gap in boot mode) feature for read and the RWCTL field (bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid these 8 clocks. Otherwise, the device might send extra data to uSDHC while uSDHC ignores these data. In a summary, this field should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.
19	Interrupt at block gap

Table continues on the next page...

Table continued from the previous page...

Field	Function
IABG	This field is valid only in 4-bit mode, of SDIO, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If SDIO cannot signal an interrupt during a multiple block transfer, this field should be set to 0 to avoid an inadvertent interrupt. When the host driver detects an SDIO insertion, it sets this field according to the CCCR of the card. 0b - Disables interrupt at block gap 1b - Enables interrupt at block gap
18 RWCTL	Read wait control The read wait function provided by this field is optional for SDIO. If the card supports read wait, set this field to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise, uSDHC has to stop the SD clock to hold read data, which restricts commands generation. When the host driver detects an SDIO insertion, it sets this field according to the CCCR of the card. If the card does not support read wait, this field should never be set to 1; otherwise, DATA line conflicts might occur. If this field is set to 0, stop at block gap during read operation is also supported, but uSDHC stops the SD clock to pause reading operation. 0b - Disables read wait control and stop SD clock at block gap when SABGREQ field is set 1b - Enables read wait control and assert read wait without stopping SD clock at block gap when SABGREQ field is set
17 CREQ	Continue request This field is used to restart a transaction which was stopped using the stop at block gap request. When a suspend operation is not accepted by the card, it is also by setting this field to restart the paused transfer. To cancel stop at the block gap, set stop at block gap request to 0 and set this field to 1 to restart the transfer. The uSDHC module automatically clears this field, therefore it is not necessary for the host driver to set this field to 0. If both stop at block gap request and this field are 1, the continue request is ignored. 0b - No effect 1b - Restart
16 SABGREQ	Stop at block gap request This field is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the transfer complete is set to 1, indicating a transfer completion, the host driver leaves this field set to 1. Clearing both the stop at block gap request and continue request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC module supports the stop at block gap request for write transfers, but for read transfers it requires that SDIO support read wait. Therefore, the host driver does not set this field during read transfers unless SDIO supports Read Wait and has set the read wait control to 1; otherwise, uSDHC stops the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the host driver writes data to the Data Port register, the host driver sets this field after all block data is written. If this field is set to 1, the host driver does not write data to the Data Port register after a block is sent. Once this field is set, the host driver does not clear this field before the Transfer Complete field in Interrupt Status register is set, otherwise uSDHC's behavior is undefined. This field effects read transfer active, write transfer active, DATA Line Active and Command Inhibit (DATA) in the Present State register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Transfer 1b - Stop
15-10 —	Reserved
9-8 DMASEL	DMA select This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00b - No DMA or simple DMA is selected. 01b - ADMA1 is selected. 10b - ADMA2 is selected. 11b - Reserved
7 —	Reserved
6 —	Reserved
5-4 EMODE	Endian mode This field supports all three endian modes in data transfer. See Data buffer for more details. 00b - Big endian mode 01b - Half word big endian mode 10b - Little endian mode 11b - Reserved
3 D3CD	DATA3 as card detection pin If this field is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 might set the card into the SPI mode, which uSDHC does not support. 0b - DATA3 does not monitor card insertion 1b - DATA3 as card detection pin
2-1 DTW	Data transfer width This field selects the data width of the SD bus for a data transfer. The host driver sets it to match the data width of the card. Possible data transfer width is 1-bit, 4-bits or 8-bits. 00b - 1-bit mode 01b - 4-bit mode 10b - 8-bit mode

Fields

Field	Function
31-29 —	Reserved
28 RSTT	Reset tuning When set this field to 1, it resets tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning field in AUTOCMD12_ERR_STATUS also sets this field to 1 to reset tuning circuit
27 INITA	Initialization active

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is set, 80 SD-clocks are sent to the card. After the 80 clocks are sent, this field is self cleared. This field is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this field is already 1 has no effect. Writing 0 to this field at any time has no effect. When either of the CIHB and CDIHB fields in the Present State register are set, writing 1 to this field is ignored (that is, when command line or data lines are active, write to this field is not allowed). On the other-hand, when this field is set, that is, during initialization active period, it is allowed to issue command, and the command bit stream appears on the CMD pad after all 80 clock cycles are done. So, when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs to send 80 cycles to the card and does not want to wait till this field is self cleared.
26 RSTD	Software reset for data line Only part of the data circuit is reset. DMA circuit is also reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Data Port register — Buffer is cleared and initialized • Present State register — Buffer read enable — Buffer write enable — Read transfer active — Write transfer active — DATA line active — Command Inhibit (DATA) • Protocol Control register — Continue request • Interrupt Status register — Buffer read ready — Buffer write ready — DMA interrupt — Block gap event — Transfer complete **NOTE** When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0b - No reset 1b - Reset
25	Software reset for CMD line

Table continues on the next page...

Table continued from the previous page...

Field	Function
RSTC	Only part of the command circuit is reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Present State Register — Command Inhibit (CMD) • Interrupt Status Register — Command Complete 0b - No reset 1b - Reset
24 RSTA	Software reset for all This reset affects the entire host controller except for the card detection circuit. RSTA resets all the registers that can be reset by RSTC/RSTD. During its initialization, the host driver is set this field to 1 to reset uSDHC. The uSDHC module resets this field to 0 when the capabilities registers are valid and the host driver can read them. Additional use of Software Reset For All does not affect the value of the capabilities registers. After this field is set, it is recommended that the host driver reset the external card and re-initialize it. After this field is set, the software should wait for self-clear. In tuning process, after every CMD19 is finished, this field is set to retest uSDHC. **NOTE** When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0b - No reset 1b - Reset
23 IPP_RST_N	Hardware reset This field's value is output to card through pad directly to hardware reset pin of the card if the card supports this feature.
22 RST_FIFO	Reset the async FIFO Reset the async FIFO between card interface and the internal logic. After this field is set, the software waits for self-clear.
21 —	Reserved
20 —	Reserved
19-16 DTOCV	Data timeout counter value This value determines the interval by which DAT line timeouts are detected. See the Data Timeout Error field in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency is generated by dividing the base clock SDCLK value by this value.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The host driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events. 0000b - SDCLK x 2^{32} 0001b - SDCLK x 2^{33} 0010b - SDCLK x 2^{18} 0011b - SDCLK x 2^{19} 1101b - SDCLK x 2^{29}, recommend to use for supported speed modes except SDR104 mode 1110b - SDCLK x 2^{30}, recommend to use for SDR104 mode
15-8 SDCLKFS	SDCLK frequency select This field is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this field holds the prescaler (of this register) and divisor (next register) of the Base Clock Frequency register. In Single Data Rate mode (DDR_EN field of MIXERCTRL is '0') Only the following settings are allowed: 80h) Base clock divided by 256 40h) Base clock divided by 128 20h) Base clock divided by 64 10h) Base clock divided by 32 08h) Base clock divided by 16 04h) Base clock divided by 8 02h) Base clock divided by 4 01h) Base clock divided by 2 00h) Base clock divided by 1 While in Dual Data Rate mode (DDR_EN field of MIXERCTRL is '1') Only the following settings are allowed: 80h) Base clock divided by 512 40h) Base clock divided by 256 20h) Base clock divided by 128 10h) Base clock divided by 64 08h) Base clock divided by 32 04h) Base clock divided by 16 02h) Base clock divided by 8 01h) Base clock divided by 4 00h) Base clock divided by 2

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When the software changes the DDR_EN field, SDCLKFS might need to be changed also. In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / (prescaler x divisor) For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h yields 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD clock after reset is 375 kHz. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. If setting SDCLKFS and DVS can generate the same clock frequency,(for example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.), SDCLKFS is highly recommended. For SDR104 mode, if DLL is to be used, make sure SDCLKFS is used so that REF_CLK, generated for PARTS DLL, is at the same frequency as SD_CLK.
7-4 DVS	Divisor This field is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle. Before changing clock divisor value (SDCLKFS or DVS), Host driver should make sure the SDSTB field is high. The settings are as follows: 0000b - Divide-by-1 0001b - Divide-by-2 1110b - Divide-by-15 1111b - Divide-by-16
3-0 —	Reserved Always write as 1.

65.6.1.14 Interrupt Status (INT_STATUS)

Offset

Register	Offset
INT_STATUS	30h

Function

An interrupt is generated when the normal interrupt signal enable is enabled and at least one of the status fields is set to 1. For all fields, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For card interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the card driver services the interrupt condition; otherwise, the CINT field is asserted again.

The table below shows the relationship between the command timeout error and the command complete.

Table 543. uSDHC status for command timeout error/command complete bit combinations

Command complete	Command timeout error	Meaning of the status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the transfer complete and the data timeout error.

Table 544. uSDHC status for data timeout error/transfer complete bit combinations

Transfer complete	Data timeout error	Meaning of the status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data transfer complete

The table below shows the relationship between the command CRC error and command timeout error.

Table 545. uSDHC status for command CRC error/command timeout error bit combinations

Command CRC error	Command timeout error	Meaning of the status
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Fields

Field	Function
31 —	Reserved
30-29 —	Reserved
28 DMAE	DMA error Occurs when an Internal DMA transfer has failed. This field is set to 1, when some error occurs in the data transfer. This error can be caused by either simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Because any error corrupts the whole data block, the host driver restarts the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 0b - No error 1b - Error
27 —	Reserved
26 TNE	Tuning error: (only for SD3.0 SDR104 mode) This field is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, host driver needs to abort a command executing and perform tuning. This field is relevant in combination with the bus error only and must be cleared prior to all the write and read transactions.
25 —	Reserved
24 AC12E	Auto CMD12 error

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Occurs when detecting that one of the fields in the Auto CMD12 Error Status register has changed from 0 to 1. This field is set to 1, not only when the errors in Auto CMD12 occur, but also, when the Auto CMD12 is not executed due to the previous command error. 0b - No error 1b - Error
23 —	Reserved
22 DEBE	Data end bit error Occurs either when detecting 0 at the end field position of read data that uses the DATA line, or at the end field position of the CRC. This field is not asserted in tuning process. 0b - No error 1b - Error
21 DCE	Data CRC error Occurs when detecting a CRC error when transferring read data that uses the DATA line, or when detecting the Write CRC status having a value other than 010. This field is not asserted in tuning process. 0b - No error 1b - Error
20 DTOE	Data timeout error Occurs when detecting one of following time-out conditions. • Busy time-out for R1b, R5b type • Busy time-out after Write CRC status • Read Data time-out. This field is not asserted in tuning process. 0b - No error 1b - Time out
19 CIE	Command index error Occurs if a command index error occurs in the command response. This field is not asserted in tuning process. 0b - No error 1b - Error
18	Command end bit error

Table continues on the next page...

Table continued from the previous page...

Field	Function
CEBE	Occurs when detecting that the end field of a command response is 0. This field is not asserted in tuning process. 0b - No error 1b - End bit error generated
17 CCE	Command CRC error Command CRC Error is generated in two cases. • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this field is set when detecting a CRC error in the command response. • The uSDHC module detects a CMD line conflict by monitoring the CMD line when a command is issued. If uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then uSDHC aborts the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error should also be set to 1 to distinguish CMD line conflict. This field is not asserted in tuning process. 0b - No error 1b - CRC error generated
16 CTOE	Command timeout error Occurs only if no response is returned within 64 SDCLK cycles from the end field of the command. If uSDHC detects a CMD line conflict, in which case a Command CRC Error is also be set (as shown in Interrupt Status (INT_STATUS)), this field is set without waiting for 64 SDCLK cycles. This is because the command is aborted by uSDHC. This field is not asserted in tuning process. 0b - No error 1b - Time out
15 ERR_INT_STATUS	Error Interrupt Status This bit is set when any of the error status bit DMAE, AC12E, DEBE, DCE, DTOE, CIE, CEBE, CCE and CTOE is set.
14 TP	Tuning pass:(only for SD3.0 SDR104 mode) Current CMD19 transfer is done successfully. That is, current sampling point is correct.
13 —	Reserved
12 RTE	Re-tuning event: (only for SD3.0 SDR104 mode) This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. host controller requests host driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Re-tuning is not required. 1b - Re-tuning should be performed.
11 —	Reserved
10-9 —	Reserved
8 CINT	Card interrupt This status field is set when an interrupt signal is detected from the external card. In 1-bit mode, uSDHC detects the Card Interrupt without the SD clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from SDIO and the interrupt to the host system. Writing this field to 1 can clear this field, but as the interrupt source from SDIO does not clear, this field is set again. to clear this field, it is required to reset the interrupt source from the external card followed by a writing 1 to this field. When this status has been set, and the host driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the host system. After completion of the card interrupt service (It should reset the interrupt sources in SDIO and the interrupt signal might not be asserted), write 1 to clear this field, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again. 0b - No card interrupt 1b - Generate card interrupt
7 CRM	Card removal This status field is set if the Card Inserted field in the Present State register changes from 1 to 0. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if no card is inserted. to leave it cleared, clear the Card Removal Status Enable field in Interrupt Status Enable register. 0b - Card state unstable or inserted 1b - Card removed
6 CINS	Card insertion This status field is set if the Card Inserted field in the Present State register changes from 0 to 1. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if a card is inserted. to leave it cleared, clear the Card Inserted Status Enable field in Interrupt Status Enable register. 0b - Card state unstable or removed 1b - Card inserted

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 BRR	Buffer read ready This status field is set if the Buffer Read Enable field, in the Present State register, changes from 0 to 1. See the Buffer Read Enable field in the Present State register for additional information. This field indicates that cmd19 is finished in tuning process. 0b - Not ready to read buffer 1b - Ready to read buffer
4 BWR	Buffer write ready This status field is set if the Buffer Write Enable field, in the Present State register, changes from 0 to 1. See the Buffer Write Enable field in the Present State register for additional information. 0b - Not ready to write buffer 1b - Ready to write buffer
3 DINT	DMA interrupt Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this field does not be set. Instead, the DMAE field is set. Either Simple DMA or ADMA finishes data transferring, this field is set. 0b - No DMA interrupt 1b - DMA interrupt is generated.
2 BGE	Block gap event If the Stop At Block Gap Request field in the Protocol Control register is set, this field is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this field is not set to 1. In the case of a Read Transaction: This field is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD bus timing). The Read Wait must be supported to use this function. In the case of Write Transaction: This field is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). 0b - No block gap event 1b - Transaction stopped at block gap
1 TC	Transfer complete This field is set when a read or write transfer is completed. In the case of a Read Transaction: This field is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the host system). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request field in the Protocol Control register (after valid data has been read to the host system). In the case of a Write Transaction: This field is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as

Table continues on the next page...

Table continued from the previous page...

Field	Function
	specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request field in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released). In the case of a command with busy, this field is set when busy is deasserted. This field is not asserted in tuning process. 0b - Transfer does not complete 1b - Transfer complete
0 CC	Command complete This field is set when you receive the end field of the command response (except auto CMD12). See the Command Inhibit (CMD) in the Present State register. This field is not asserted in tuning process. 0b - Command not complete 1b - Command complete

65.6.1.15 Interrupt Status Enable (INT_STATUS_EN)

Offset

Register	Offset
INT_STATUS_EN	34h

Function

Setting any bit in this register to 1 enables the corresponding interrupt status be requested to the system. If any bit is set to 0, the corresponding interrupt request gets blocked.

- Depending on IABG field setting, uSDHC might be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There are some delays on the Card Interrupt, asserted from the card, to the time the host system is informed.
- To detect a CMD line conflict, the host driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

65.6.1.16 Interrupt Signal Enable (INT_SIGNAL_EN)

Offset

Register	Offset
INT_SIGNAL_EN	38h

Function

This register is used to select which interrupt status is indicated to the host system as the interrupt. These status fields all share the same interrupt lines. Setting any of these fields to 1 enables interrupt generation. The corresponding Status register field generates an interrupt when the corresponding interrupt signal enable field is set.

Diagram

65.6.1.17 Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS)

Offset

Register	Offset
AUTOCMD12_ERR_STATUS	3Ch

Function

When the Auto CMD12 Error Status field in the Status register is set, the host driver checks this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in field 04-01. This register is valid only when the Auto CMD12 Error status field is set.

The table below shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 546. Relationship between command CRC error and command timeout error for auto CMD12

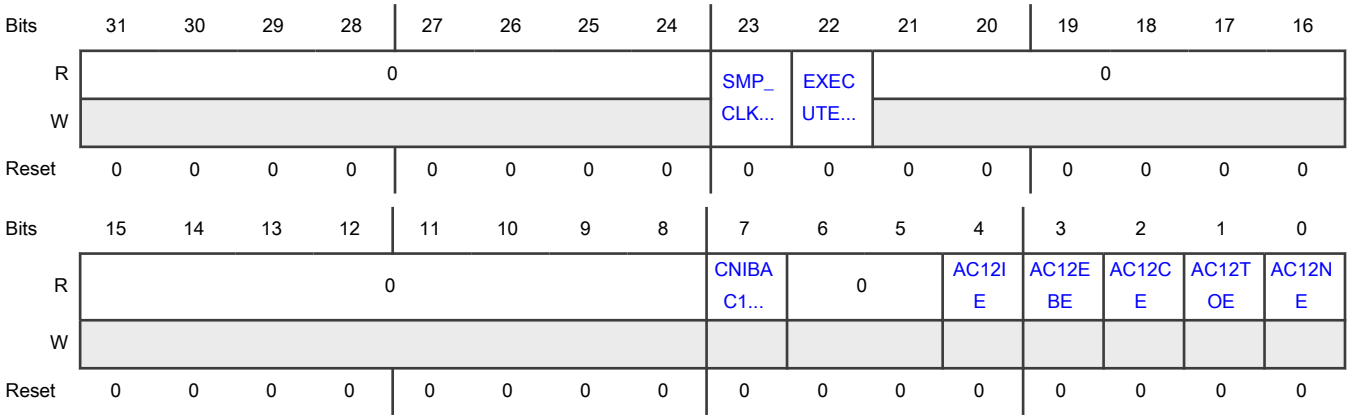
Auto CMD12 CRC error	Auto CMD12 timeout error	Type of error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

- When uSDHC is going to issue an Auto CMD12
  - Set field 0 to 1 if the Auto CMD12 cannot be issued due to an error in the previous command
  - Set field 0 to 0 if the Auto CMD12 is issued
- At the end field of an Auto CMD12 response
  - Check errors correspond to fields 1-4
  - Set fields 1-4 corresponding to detected errors
  - Clear fields 1-4 corresponding to detected errors
- Before reading the Auto CMD12 Error Status field 7
  - Set field 7 to 1 if there is a command that can't be issued
  - Clear field 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, field 7 is sampled when the driver is not writing to the Command register. So, it is suggested to read this register only when the AC12E field in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error fields (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 SMP_CLK_SEL	Sample clock select This field is used to select sampling clock to receive CMD and DATA. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is controlled by re-tuning procedure and is valid after the tuning procedure is complete (AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=0). A value of '1' means that tuning has been completed successfully and a value of '0' implies the tuning has failed. Writing '1' to this field is meaningless and ignored when the tuning has failed. The tuning circuit is reset by writing '0' to this field. This field can be cleared by setting AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=1. Once the tuning circuit is reset, it takes time to complete tuning sequence. Therefore, host driver should keep this field as 1 to perform

Table continues on the next page...

Table continued from the previous page...

Field	Function
	the re-tuning sequence in a short time. This field cannot be changed while the Host controller is receiving response or a read data block. 0b - Fixed clock is used to sample data 1b - Tuned clock is used to sample data
22 EXECUTE_TUNING	Execute tuning This field is used to start the tuning procedure. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is set to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to AUTOCMD12_ERR_STATUS[SMP_CLK_SEL]. 0b - Tuning procedure is aborted 1b - Start tuning procedure
21-8 —	Reserved
7 CNIBAC12E	Command not issued by Auto CMD12 error Setting this field to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 error (D04-D01) in this register. 0b - No error 1b - Not issued
6-5 —	Reserved
4 AC12IE	Auto CMD12 / 23 index error Occurs if the command index error occurs in response to a command. 0b - No error 1b - Error, the CMD index in response is not CMD12/23
3 AC12EBE	Auto CMD12 / 23 end bit error Occurs when detecting that the end field of command response is 0 which should be 1. 0b - No error 1b - End bit error generated
2 AC12CE	Auto CMD12 / 23 CRC error Occurs when detecting a CRC error in the command response. 0b - No CRC error 1b - CRC error met in Auto CMD12/23 response
1	Auto CMD12 / 23 timeout error

Table continues on the next page...

Table continued from the previous page...

Field	Function
AC12TOE	Occurs if no response is returned within 64 SDCLK cycles from the end field of the command. If this field is set to1, the other error status fields (2-4) have no meaning. 0b - No error 1b - Time out
0 AC12NE	Auto CMD12 not executed If memory multiple block data transfer is not started, due to a command error, this field is not set because it is not necessary to issue an Auto CMD12. Setting this field to 1 means uSDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this field is set to 1, other error status fields (1-4) have no meaning. 0b - Executed 1b - Not executed

65.6.1.18 Host Controller Capabilities (HOST_CTRL_CAP)

Offset

Register	Offset
HOST_CTRL_CAP	40h

Function

This register provides the host driver with information specific to uSDHC implementation. The value in this register is the power-on-reset value and does not change with a software reset.

Diagram

SDR50_SUPPORT	

65.6.1.19 Watermark Level (WTMK_LVL)

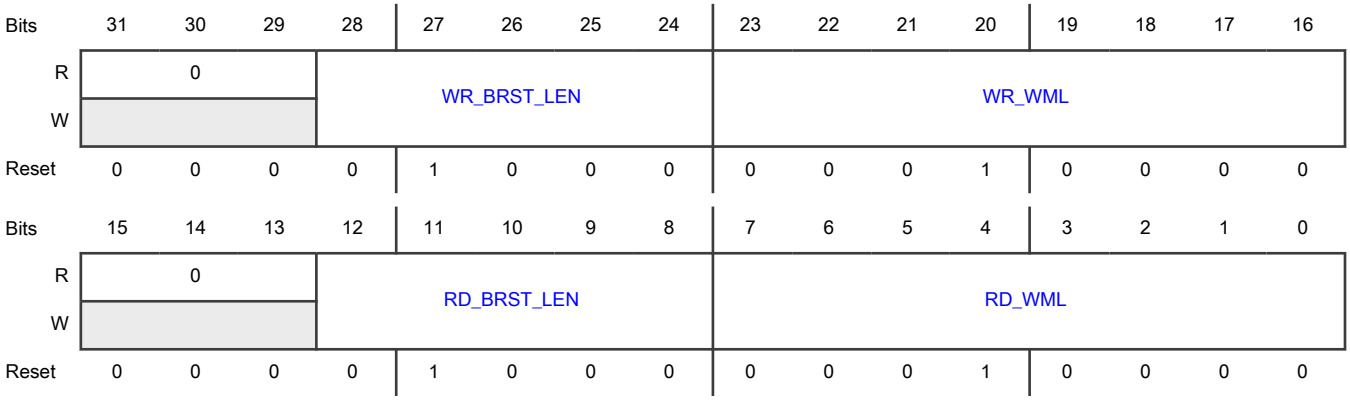
Offset

Register	Offset
WTMK_LVL	44h

Function

This register indicates configurability of write and read watermark levels (FIFO threshold). Their value can range from 1 to 128 words. Both write and read burst lengths are also configurable. Their value can range from 1 to 31 words.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-24 WR_BRST_LEN	Write burst length due to system restriction, the actual burst length might not exceed 16 This field indicates the number of words uSDHC writes in a single burst. The write burst length must be less than or equal to the write watermark level, and all bursts within a watermark level transfer is in back-to-back mode. On reset, this field is 8. Writing 0 to this field results in '01000' (that is, it is not able to clear this field).
23-16 WR_WML	Write watermark level

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also, the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.
15-13 —	Reserved
12-8 RD_BRST_LEN	Read burst length due to system restriction, the actual burst length might not exceed 16 This field indicates the number of words uSDHC reads in a single burst. The read burst length must be less than or equal to the read watermark level, and all bursts within a watermark level transfer is in back-to-back mode. On reset, this field is 8. Writing 0 to this field results in '01000' (that is, it is not able to clear this field).
7-0 RD_WML	Read watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also, the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.

65.6.1.20 Mixer Control (MIX_CTRL)

Offset

Register	Offset
MIX_CTRL	48h

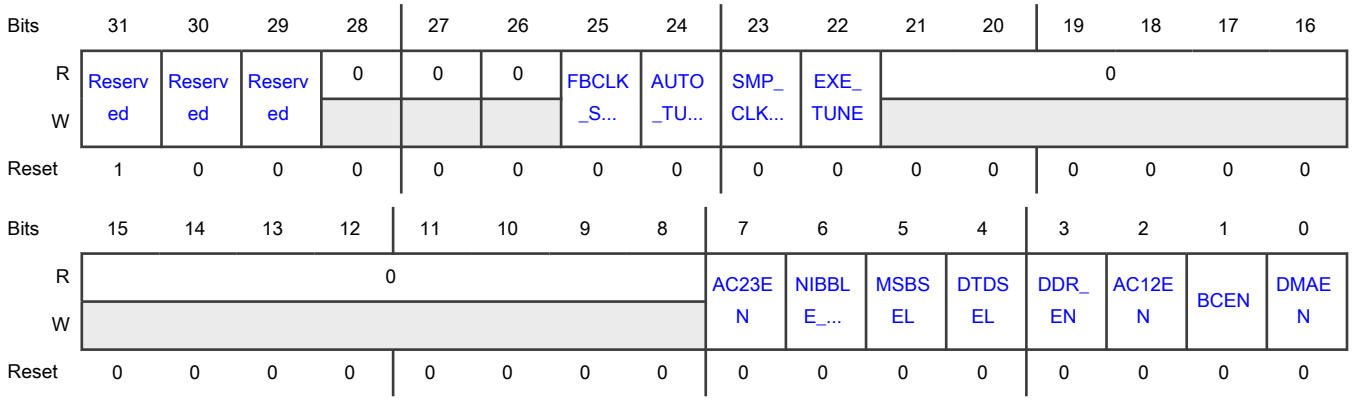
Function

This register is used to DMA and data transfer. To prevent data loss, the software should check if data transfer is active before writing this register. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

Table 547. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

Diagram



Fields

Field	Function
31 —	Reserved Always write as 1.
30 —	Reserved Always write as 0.
29 —	Reserved Always write as 0.
28 —	Reserved
27 —	Reserved
26 —	Reserved
25 FBCLK_SEL	Feedback clock source selection (Only used for SD3.0, SDR104 mode) 0b - Feedback clock comes from the loopback CLK 1b - Feedback clock comes from the ipp_card_clk_out
24 AUTO_TUNE_EN	Auto tuning enable (Only used for SD3.0, SDR104 mode) 0b - Disable auto tuning 1b - Enable auto tuning
23 SMP_CLK_SEL	Clock selection When TUNING_CTRL[STD_TUNING_EN] is 0, this field is used to select Tuned clock or Fixed clock to sample data / cmd (Only used for SD3.0, SDR104 mode)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Fixed clock is used to sample data / cmd 1b - Tuned clock is used to sample data / cmd
22 EXE_TUNE	Execute tuning: (Only used for SD3.0, SDR104 mode) When TUNING_CTRL[STD_TUNING_EN] is 0, this field is set to 1 to indicate the host driver is starting tuning procedure. Tuning procedure is aborted by writing 0. 0b - Not tuned or tuning completed 1b - Execute tuning
21-8 —	Reserved
7 AC23EN	Auto CMD23 enable This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register.
6 NIBBLE_POS	Nibble position indication This field indicates the nibble position in the DDR 4-bit mode. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single block select This field enables multiple block DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP). 0b - Single block 1b - Multiple blocks
4 DTDSEL	Data transfer direction select This field defines the direction of DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands. If a CMD with the response data size cannot be divided by 64 bytes, is given without a STOP CMD, and is followed by a software reset, then you must write a 0 to DTDSEL before inserting a software reset. This is necessary to avoid any issue during the SD card reinitialization. Read multiple blocks will not be affected as it is required to have a STOP CMD. 0b - Write (Host to card) 1b - Read (Card to host)
3	Dual data rate mode selection

Table continues on the next page...

Table continued from the previous page...

Field	Function
DDR_EN	This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only.
2 AC12EN	Auto CMD12 enable Multiple block transfers for memory require a CMD12 to stop the transaction. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0b - Disable 1b - Enable
1 BCEN	Block count enable This field is used to enable the Block Count register, which is only relevant for multiple block transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0b - Disable 1b - Enable
0 DMAEN	DMA enable This field enables DMA functionality. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register. 0b - Disable 1b - Enable

65.6.1.21 Force Event (FORCE_EVENT)

Offset

Register	Offset
FORCE_EVENT	50h

Function

This register is not a physically implemented register. Rather, it is an address at which the Interrupt Status register can be written if the corresponding field of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register sets the corresponding field of Interrupt Status register. A read from this register always results in 0's. to change the corresponding status fields in the Interrupt Status register, make sure to set IPGEN field in System Control Register so that peripheral clock is always active.

Forcing a card interrupt generates a short pulse on the DATA1 line, and the driver might treat this interrupt as a normal interrupt. The interrupt service routine might skip polling the card interrupt factor as the interrupt is self cleared.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0 FEVTAC12NE	Force event auto command 12 not executed Forces the AC12NE field in the Auto Command12 Error Status register to be set

65.6.1.22 ADMA Error Status (ADMA_ERR_STATUS)

Offset

Register	Offset
ADMA_ERR_STATUS	54h

Function

When an ADMA Error Interrupt has occurred, the ADMA error sates field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the host driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.
- ST_CADR: This state is never set because it only increments the descriptor pointer and does not generate an ADMA error.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.

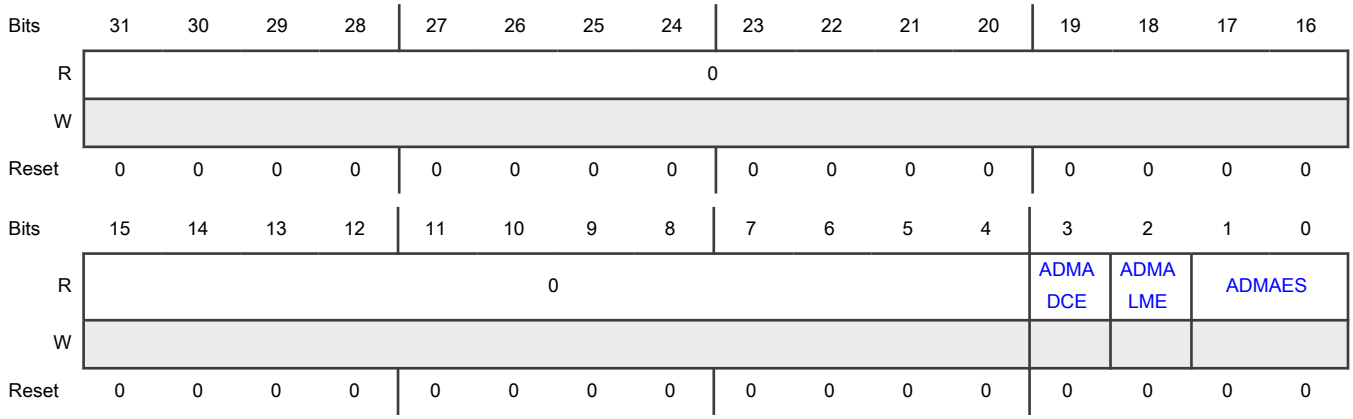
In case of a write operation, the host driver should use the ACMD22 to get the number of the written block, rather than using this information, because unwritten data might exist in the host controller.

The host controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The host driver can distinguish this error by reading the Valid field of the error descriptor.

Table 548. ADMA error state coding

D01-D00	ADMA error state (when error has occurred)	Contents of ADMA System Address register
00	ST_STOP (Stop DMA)	Holds the address of the next executable descriptor command
01	ST_FDS (Fetch descriptor)	Holds the valid descriptor address
10	ST_CADR (Change address)	No ADMA error is generated
11	ST_TFR (Transfer data)	Holds the address of the next executable descriptor command

Diagram



Fields

Field	Function
31-4 —	Reserved
3 ADMADCE	ADMA descriptor error This error occurs when invalid descriptor fetched by ADMA. 0b - No error 1b - Error
2 ADMALME	ADMA length mismatch error This error occurs in the following two cases: • While the block count enable is being set, the total data length specified by the descriptor table is different from that specified by the block count and block length. • Total data length cannot be divided by the block length. 0b - No error 1b - Error
1-0 ADMAES	ADMA error state (when ADMA error is occurred) This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. See ADMA Error Status (ADMA_ERR_STATUS) for more details.

65.6.1.23 ADMA System Address (ADMA_SYS_ADDR)

Offset

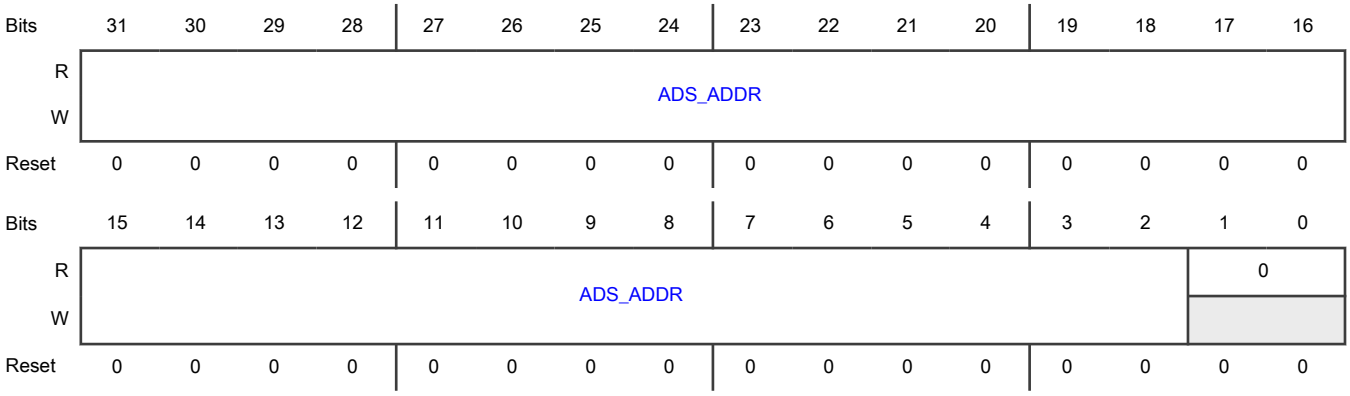
Register	Offset
ADMA_SYS_ADDR	58h

Function

This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the host driver sets the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register holds the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned.

Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions.

Diagram



Fields

Field	Function
31-2 ADS_ADDR	ADMA system address This field contains the physical system memory address used for ADMA transfers.
1-0 —	Reserved

65.6.1.24 DLL (Delay Line) Control (DLL_CTRL)

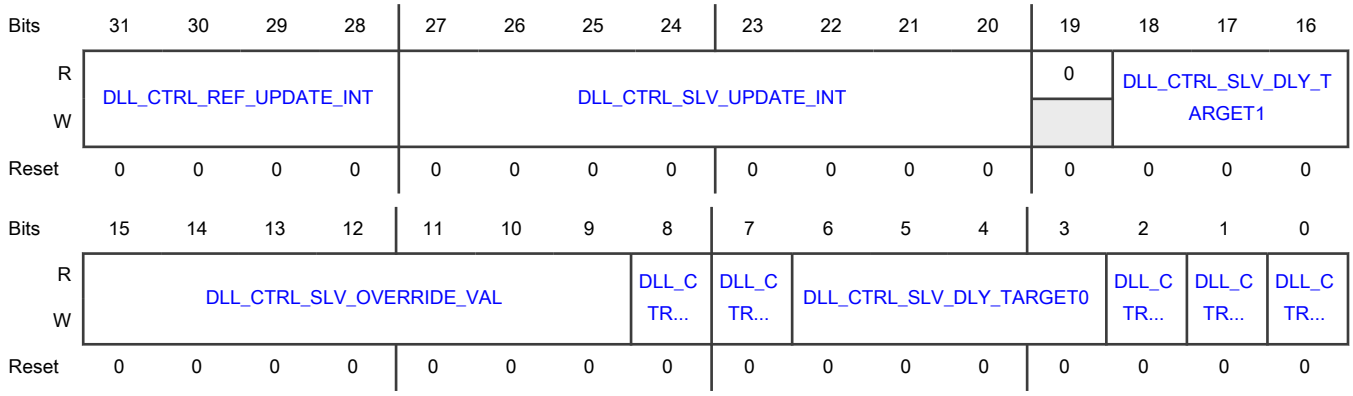
Offset

Register	Offset
DLL_CTRL	60h

Function

This register contains control fields for DLL.

Diagram



Fields

Field	Function
31-28 DLL_CTRL_REF_UPDATE_INT	DLL control loop update interval The interval cycle is (2 + REF_UPDATE_INT) * REF_CLOCK. By default, the DLL control loop updates every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20 DLL_CTRL_SLV_UPDATE_INT	Slave delay line update interval If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19 —	Reserved
18-16 DLL_CTRL_SLV_DLY_TARGET1	DLL slave delay target1 See DLL_CTRL_SLV_DLY_TARGET0 below.
15-9 DLL_CTRL_SLV_OVERRIDE_VAL	DLL slave override val When SLV_OVERRIDE = 1, this field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.
8 DLL_CTRL_SLV_OVERRIDE	DLL slave override Set this field to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0
7	DLL gate update

Table continues on the next page...

Table continued from the previous page...

Field	Function
DLL_CTRL_GATE_UPDATE	Set this field to 1 to prevent the DLL from updating (because when clock_in exists, glitches might appear during DLL updates). This field might be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6-3 DLL_CTRL_SLV_DLY_TARGET0	DLL slave delay target0 The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. The delay is (({DLL_CTRL_SLV_DLY_TARGET1,DLL_CTRL_SLV_DLY_TARGET0} +1)* REF_CLOCK / 2) / 16 So the input read-clock can be delayed relative input data from (REF_CLOCK / 2) / 16 to REF_CLOCK * 4. **NOTE** For the restrictions of delay cell implementation, the delay target must be set between REF_CLOCK/16 and REF_CLOCK*2 when REF_CLOCK is running at 200 MHz. When REF_CLOCK frequency is slower than 100 MHz, the maximum delay target might not reach REF_CLOCK*2.
2 DLL_CTRL_SLV_FORCE_UPD	DLL slave delay line Setting this field to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line updates automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1 DLL_CTRL_RESET	DLL reset Setting this field to 1 force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, so to create a subsequent reset, RESET must be taken low and then asserted again.
0 DLL_CTRL_ENABLE	DLL and delay chain Set this field to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

65.6.1.25 DLL Status (DLL_STATUS)

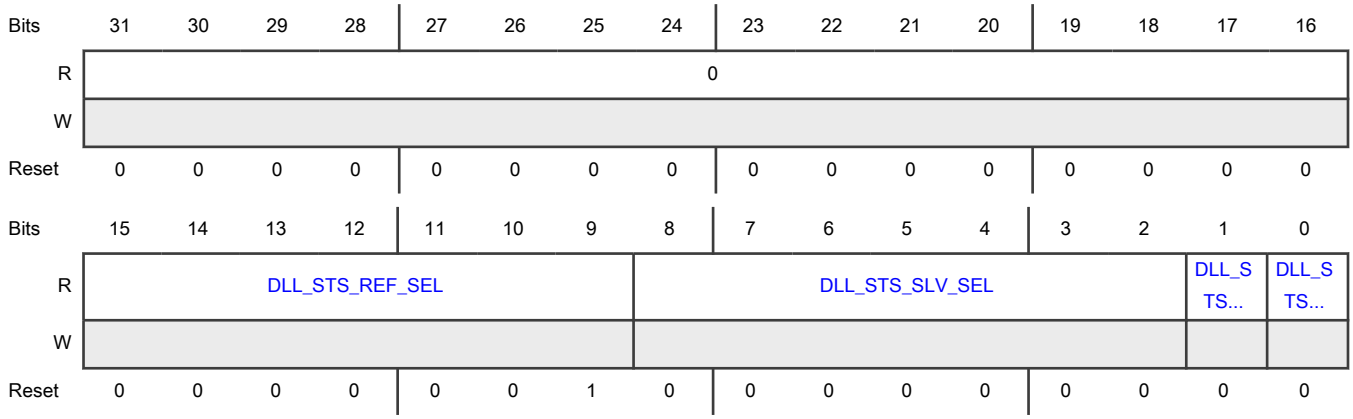
Offset

Register	Offset
DLL_STATUS	64h

Function

This register contains the DLL status information. All fields are read only and reads the same as the power-reset value.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-9 DLL_STS_REF_SEL	Reference delay line select taps This is encoded by 7 fields for 127 taps.
8-2 DLL_STS_SLV_SEL	Slave delay line select status This is the instant value generated from reference chain. Because the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Slave delay-line lock status This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

65.6.1.26 CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS)

Offset

Register	Offset
CLK_TUNE_CTRL_STATUS	68h

Function

This register contains the Clock Tuning Control status information. This register is added to support SD3.0 UHS-I SDR104 mode.

Fields

Field	Function
31 PRE_ERR	PRE error PRE error which means the number of delay cells added on the feedback clock is too small. It is valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
30-24 TAP_SEL_PRE	TAP_SEL_PRE Reflects the number of delay cells added on the feedback clock between the feedback clock and CLK_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is disabled, TAP_SEL_PRE is always equal to DLY_CELL_SET_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is enabled, TAP_SEL_PRE is updated automatically according to the status of the auto tuning circuit to adjust the sample clock phase.
23-20 TAP_SEL_OUT	Delay cells added on the feedback clock between CLK_PRE and CLK_OUT Reflects the number of delay cells added on the feedback clock between CLK_PRE and CLK_OUT.
19-16 TAP_SEL_POST	Delay cells added on the feedback clock between CLK_OUT and CLK_POST Reflects the number of delay cells added on the feedback clock between CLK_OUT and CLK_POST.
15 NXT_ERR	NXT error NXT error which means the number of delay cells added on the feedback clock is too large. It's valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
14-8 DLY_CELL_SET_PRE	delay cells on the feedback clock between the feedback clock and CLK_PRE Set the number of delay cells on the feedback clock between the feedback clock and CLK_PRE.

Table continues on the next page...

66.1.1 Module instances

This chip has ten instances of LP_FLEXCOMM module, LP_FLEXCOMM0,1,2,3,4,5,6,7,8,9.

Each instance supports LPUART, LPSPI, and LPI2C functions. Each LPI2C, LPSPI, and LPUART instance is integrated within an LP_FLEXCOMM instance. Configure the LP_FLEXCOMM instance for I2C, SPI, and UART operation before using the corresponding LPI2C, LPSPI, and LPUART instance.

66.1.2 LP_FLEXCOMM configuration

When configured for LPSPI, LP_FLEXCOMM supports 8x32 bit FIFOs. When configured for LPI2C/LPUART, two 8x16 FIFOs are supported, one for each module. In any one of the ten instances, UART and I2C can be used simultaneously with limited functionality. All LP_FLEXCOMM instances support modbus and DMA End of Packet (EOP). There are two separate interrupts. The DMA requests and the trigger inputs/outputs are shared.

66.2 LP_FLEXCOMM

66.2.1 Overview

Each LP_FLEXCOMM interface provides one peripheral communications function from a choice of several, chosen by software. This chapter describes the overall LP_FLEXCOMM interface and how to choose the communications function. See the corresponding communications module chapter for details on each function provided.

66.2.1.1 Block diagram

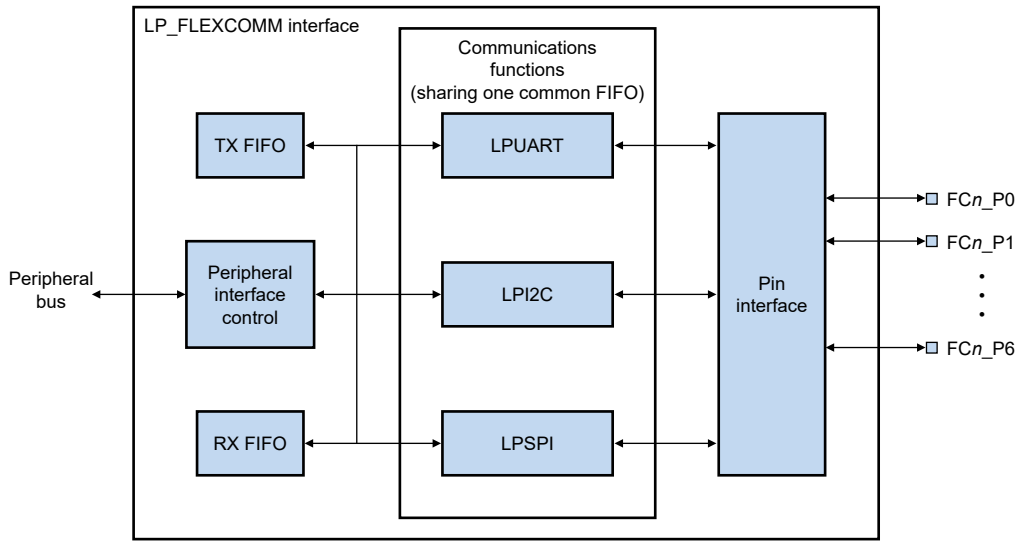

Figure 374. LP_FLEXCOMM interface block diagram

66.2.1.2 Features

Each LP_FLEXCOMM interface provides a choice of peripheral communications functions. You must choose one of them before you can configure and use the function.

- LPUART with asynchronous transmit and receive
- LPSPI controller or subordinate, with up to four peripheral chip selects
- LPI2C with separate controller and subordinate functions

LPUART and LPI2C can be selected at the same time with reduced interface.

A FIFO of 8 words is shared between the different interfaces. The LPI2C subordinate does not support a FIFO.

66.2.2 Functional description

The following sections describe the functional details of LP_FLEXCOMM.

66.2.2.1 Modes

This section describes the modes present in LP_FLEXCOMM.

66.2.2.1.1 Operating modes

Some communication options might not be available on a particular LP_FLEXCOMM interface. Reading PSELID shows which communication functions are available. You can select a specific supported function by writing the appropriate value to PSELID[PERSEL].

66.2.2.1.2 Low-power modes

The LP_FLEXCOMM interface follows the low-power mode operation of the selected communications module.

66.2.2.1.3 Debug mode

When the LP_FLEXCOMM interface is configured as LPSPI or LPI2C, you can configure it not to initiate a new transaction when the CPU is halted.

66.2.2.2 Clocking

The LP_FLEXCOMM interface requires a bus interface clock for the register interface of the selected communications module. It also requires a functional clock which generates the clocking for the peripheral communications interface. The clocks for unselected functions are internally gated.

66.2.2.3 Reset

The LP_FLEXCOMM interface receives a single reset that returns the entire module to its reset state. Out of reset, no peripheral communications function is selected, and the lock bit is clear.

66.2.2.4 Interrupts

The LP_FLEXCOMM interface generates a single interrupt from the configured peripheral communications function(s). When the LP_FLEXCOMM interface is configured for both LPUART and LPI2C functions, you can read the source of the interrupt from ISTAT.

66.2.2.5 DMA

The LP_FLEXCOMM interface generates two DMA requests:

- Transmit DMA Request
- Receive DMA Request (with End Of Packet support)

When the LP_FLEXCOMM interface is configured for both LPUART and LPI2C functions, you must enable DMA requests for only one of them.

66.2.2.6 Triggers

The LP_FLEXCOMM interface receives a single input trigger that is routed to all internal modules. When configured for both LPUART and LPI2C functions, you must enable the input trigger for only one of them.

The LP_FLEXCOMM interface generates 4 output triggers:

Output	LPSPI	LPUART	LPI2C	LPUART+LPI2C
Trigger 0	Frame	TX Word	Controller EOP	Controller EOP
Trigger 1	Word	RX Word	Subordinate EOP	Subordinate EOP
Trigger 2	—	RX Idle	Controller Busy	RX Idle
Trigger 3	—	TX Data	Bus Busy	TX Data

66.2.3 External signals

This table describes the LP_FLEXCOMM interface module signals. Pin usage for a specific communications function is described in the corresponding chapter of each communications module.

Signal	LPSPI	LPUART	LPI2C	LPUART+LPI2C
FC_P0	SDO/DATA[0]	RXD	SDA	SDA
FC_P1	SCK	TXD	SCL	SCL
FC_P2	SDI/DATA[1]	RTS_b	SCLS	TXD
FC_P3	PCS[0]	CTS_b	SDAS	RXD
FC_P4	PCS[3]/DATA[3]	DSR_b	HREQ_b	CTS_b
FC_P5	PCS[2]/DATA[2]	DTR_b	—	RTS_b
FC_P6	PCS[1]/HREQ	DCD_b	—	HREQ_b

66.2.4 Initialization

To initialize a LP_FLEXCOMM interface:

1. Enable the bus interface clock for the LP_FLEXCOMM interface.
2. Select a clock source for the functional clock of the selected communications module.
3. Select the function by writing the appropriate value to PSELID[PERSEL].
4. See the specific communications module chapter to complete the configuration.

66.2.5 Application information

LP_FLEXCOMM interface applications mirror those of the selected communications module.

66.2.6 Memory Map and register definition

This section includes the LP_FLEXCOMM interface module memory map and detailed descriptions of all registers.

The LP_FLEXCOMM interface supports 8-bit, aligned 16-bit, and aligned 32-bit register accesses, unless otherwise noted in the register description of the selected peripheral function.

66.2.6.1 LP_FLEXCOMM register descriptions

66.3 Low-Power Inter-Integrated Circuit (LPI2C)

66.3.1 Overview

LPI2C supports an efficient interface to an I2C bus as a controller and target:

- Implements logic support for Standard, Fast, Fast+, HS-mode (target only) and Ultra-Fast modes of operation
- Uses little CPU overhead, with DMA offloading of FIFO register accesses

LPI2C also complies with the System Management Bus (SMBus) Specification, version 3. The SMBus is a single-ended simple two-wire bus, which is typically used for low-bandwidth communications.

The Inter-Integrated Circuit (I^2C) serial bus is multi-controller, multi-target, packet-switched, and single-ended, and is often used to attach microcontroller ICs to lower-speed peripheral ICs.

NOTE

Terminology in this chapter has been updated to align with I^2C-bus specification, Rev. 7.0, as shown in Table 550.

Table 550. Updated terms

Updated term	Deprecated term
Controller	Master
Target	Slave

66.3.1.1 Block diagram

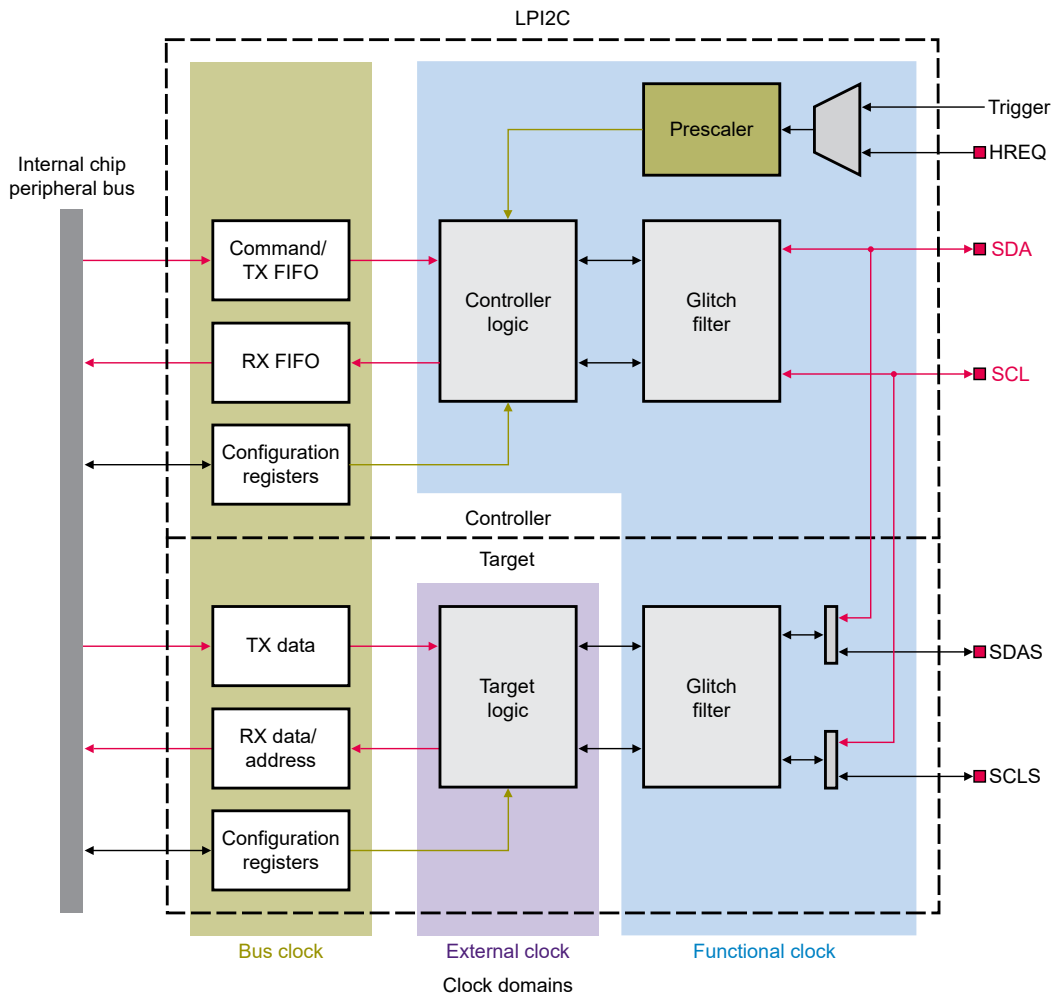

Figure 375. Block diagram

66.3.1.2 Features

LPI2C supports:

- Standard, Fast, Fast+ and Ultra Fast modes
- HS mode in target mode
- Multicontroller, including synchronization and arbitration, means that any number of controller nodes can be present. Also, controller and target roles can be changed between messages (after a Stop signal is sent).
- Clock stretching. Used on the SCL line, as an I2C flow control mechanism.
- Arbitration for when the system has more than one controller. When used on the SDA line, ensures that there is only one I2C transmitter at a time.
- General call, seven-bit addressing, and ten-bit addressing
- Software reset, Start byte, and device ID (also require software support)

The LPI2C controller supports:

- Command and transmit FIFO of 8 words (8-bit transmit data + 3-bit command)

- Receive FIFO of 8 words (8-bit receive data).
- Command FIFO waiting for an I2C idle bus before initiating a transfer
- Initiation of repeated Start and Stop conditions and one or more controller-receiver transfers by command FIFO
- Stop condition generation from command FIFO, or automatic generation of Stop condition when the transmit FIFO is empty
- Host request input to control the start time of an I2C bus transfer
- Interrupt generation on data match and unwanted data rejection, via flexible receive data match
- Flags and optional interrupt signals at repeated Start condition, Stop condition, loss of arbitration, unexpected NACK, and command word errors
- Configurable bus idle timeout and pin-stuck-low timeout

The LPI2C target supports:

- Separate I2C target registers to minimize software overhead because of controller or target switching
- 7-bit or 10-bit addressing, address range, SMBus alert, and general call address.
- Transmit data register that supports interrupt or DMA requests
- Receive data register that supports interrupt or DMA requests
- Software-controllable ACK or NACK, with optional clock stretching on ACK or NACK field
- Configurable clock stretching, to avoid transmit-FIFO-underrun and receive-FIFO-overrun errors
- Flags and optional interrupt at end of packet, Stop condition, or bit error detection

66.3.2 Functional description

66.3.2.1 Controller mode

The LPI2C controller logic operates independently from the target logic to perform all controller-mode transfers on the I2C bus.

66.3.2.1.1 Transmit and Command FIFO commands

The transmit FIFO stores command data to initiate various I2C operations. The following operations can be initiated through commands in the transmit FIFO:

- Start or repeated Start condition with address byte, expecting ACK or NACK.
- Transmit data. This operation is the default for zero-extended-byte writes to the transmit FIFO.
- Receive 1-256 bytes of data. You can configure this operation to discard received data and not to store it in the receive FIFO.
- Stop condition. You can configure this operation to send a Stop condition when the transmit FIFO is empty.

Multiple transmit and receive commands can be inserted between the Start and Stop conditions. To comply with the I2C specification, transmit and receive commands must not be interleaved. The receive data command and the receive data and discard commands can be interleaved. This interleaving ensures that only the desired received data is stored in the receive FIFO (or compared with the data match logic).

The LPI2C controller automatically transmits a NACK on the last byte of a receive data command. It transmits the NACK unless the next command in the FIFO is also a receive data command. If the transmit FIFO is empty when a receive data command completes, a NACK is also automatically transmitted.

The LPI2C controller supports 10-bit addressing via a (repeated) Start condition, followed by a transmit data byte containing the second address byte, followed by any number of data bytes with the controller transmit data.

A Start or repeated Start condition expecting a NACK (for example, HS mode controller code) must be followed by a Stop or (repeated) Start condition.

66.3.2.1.2 Controller operations

When LPI2C is enabled, it monitors the I2C bus to detect when the I2C is idle (MSR[BBF]). If either SCL or SDA are low, the I2C bus is no longer considered idle. The bus becomes idle if a Stop condition is detected or if a bus idle timeout is detected (as configured by MCFGR2[BUSIDLE]). After the bus is idle, if the transmit FIFO is not empty and the host request is asserted or disabled, the LPI2C controller initiates a transfer on the bus. This transfer involves the following steps:

1. Wait the bus idle time equal to (MCCR0[CLKLO] + 1) multiplied by the prescaler (MCFGR1[PRESCALE]).
2. Transmit a Start condition and address byte using the timing configuration in Controller Clock Configuration 0 (MCCR0). If an HS mode transfer is configured, the timing configuration from Controller Clock Configuration 1 (MCCR1) is used instead.
3. Perform controller transmit or controller receive transfers, as configured by the transmit FIFO.
4. Transmit NACK on the last byte of a controller receive transfer. This action is performed unless the next command in the transmit FIFO is also a receive data command and the transmit FIFO is not empty.
5. Transmit a repeated Start or Stop condition as configured by the transmit FIFO or MCFGR1[AUTOSTOP]. A repeated Start can change which timing configuration register is used.

When MCFGR0[RELAX] is 1, the LPI2C controller does not wait for the I2C bus to be idle before starting a transfer. It also relaxes some restrictions on the order of FIFO commands. For example, it allows a Stop command when it is idle to generate a Start condition, followed by one SCL clock pulse, and then a Stop condition.

When the LPI2C controller is disabled, LPI2C continues emptying the transmit FIFO until a Stop condition is transmitted. (The controller could be disabled due to MCR[MEN] being 0, or automatically due to mode entry.) However, LPI2C no longer stalls the I2C bus by waiting for the transmit or receive FIFO. After the transmit FIFO is empty, LPI2C generates a Stop condition automatically.

The LPI2C controller can stall the I2C bus under certain conditions. This stalling results in SCL pulled low continuously on the first bit of a byte, until these conditions change:

- The LPI2C controller is enabled and busy, the transmit FIFO is empty, and MCFGR1[AUTOSTOP] is 0. The LPI2C controller continues to stall the bus until the transmit FIFO is loaded with more data.
- The LPI2C controller is enabled and receiving data, receive data is not being discarded (due to command or receive data match), and the receive FIFO is full. The LPI2C controller continues to stall the I2C bus until the receive FIFO is emptied.

The LPI2C controller aborts the existing transfer when MCFGR0[ABORT] becomes 1. This action causes the LPI2C controller to complete the existing word and then transmit a Stop condition. If the receive FIFO is full when the receive operation is aborted, the last received data is discarded. A new transfer does not start while MCFGR0[ABORT] is 1.

66.3.2.1.3 Receive FIFO and data matching

The receive FIFO stores receive data during controller-receiver transfers. You can configure the LPI2C controller to discard received data instead of storing it in the receive FIFO. This option is configured via the command word in the transmit FIFO.

Received data supports a receive data match function that can match received data against one of two bytes, or against a masked data byte. You can configure the data match function to compare only the first one or two data words received since the last (repeated) Start condition. Received data that is already discarded due to the command word cannot cause a data match. It delays the match on the first data word received until after the discarded data is received.

You can configure the receiver match function to discard all received data until a data match is detected, using MCFGR0[RDMO]. Following a data match, write 0 to MCFGR0[RDMO] before writing 0 to MSR[DMF] to allow all subsequent data to be received.

66.3.2.1.4 Timing parameters

The LPI2C controller can configure the following timing parameters. Parameters are configured separately for HS mode (Controller Clock Configuration 1 (MCCR1)) and other modes (Controller Clock Configuration 0 (MCCR0)). This separation allows the HS mode controller code to be sent using regular timing parameters. Then it allows a switch to HS mode timing (following a repeated Start) until the next STOP condition.

Configure the LPI2C controller timing parameters, measured in LPI2C functional clock cycles, as shown in Table 551. You must configure these parameters to meet the I2C timing specification for the required mode.

Table 551. Timing parameters

I2C specification timing parameter	I2C specification timing symbol	LPI2C timing parameter (in LPI2C functional clock cycles)
SCL clock period	tSCL	(CLKHI + CLKLO + 2 + SCL_LATENCY) × (2 ^ PRESCALE)
Hold time (repeated) Start condition	tHD:STA	(SETHOLD +1) × (2 ^ PRESCALE)
Low period of the SCL clock	tLOW	(CLKLO + 1) × (2 ^ PRESCALE)
High period of the SCL clock	tHIGH	(CLKHI + 1 + SCL_LATENCY) × (2 ^ PRESCALE)
Setup time for a repeated Start condition or Stop condition	tSU:STA, tSU:STO	(SETHOLD + 1 + SCL_LATENCY) × (2 ^ PRESCALE)
Data hold time	tHD:DAT	(DATAVD + 1) × (2 ^ PRESCALE)
Data setup time	tSU:DAT	(SDA_LATENCY + 1) × (2 ^ PRESCALE)
Bus free time between a Stop and Start condition	tBUF	(CLKLO + 1 + SDA_LATENCY) × (2 ^ PRESCALE)
Data valid time, data valid acknowledge time	tVD:DAT, tVD:ACK	(DATAVD + 1) × (2 ^ PRESCALE)

Table 552 defines the latency parameters. These parameters assume that the risetime is less than one LPI2C functional clock cycle. The risetime depends on a number of factors, including the I/O propagation delay, the I2C bus loading, and the external pullup resistor sizing. A larger risetime increases the number of cycles that the signal takes to propagate through the synchronizer (and glitch filter), which increases the latency.

Table 552. Synchronization latency

Timing parameter	Timing definition
SCL_LATENCY	ROUNDDOWN ((2 + FILTSCL + SCL_RISETIME) ÷ (2 ^ PRESCALE))
SDA_LATENCY	ROUNDDOWN ((2 + FILTSDA + SDA_RISETIME) ÷ (2 ^ PRESCALE))

The following timing restrictions must be enforced to avoid unexpected Start or Stop conditions on the I2C bus. These restrictions also avoid unexpected Start or Stop conditions detected by the LPI2C controller. The timing restrictions can be summarized as "SDA cannot change when SCL is high outside a transmitted (repeated) Start or Stop condition."

Table 553. LPI2C timing parameter restrictions

Timing parameter	Minimum	Maximum	Comment
CLKLO	03h	—	CLKLO x (2 ^ PRESCALE) > SCL_LATENCY
CLKHI	01h	—	Configure CLKHI to meet the duty cycle requirements in the I2C specification
SETHOLD	02h	—	SETHOLD × (2 ^ PRESCALE) > SDA_LATENCY

Table continues on the next page...

Table 553. LPI2C timing parameter restrictions (continued)

Timing parameter	Minimum	Maximum	Comment
DATAVD	01h	CLKLO – SDA_LATENCY – 1	Configure DATAVD to meet the data hold requirement in the I2C specification
FILTSCL	00h	[CLKLO × (2 ^ PRESCALE)] – 3	FILTSCL and FILTSDA are the only parameters not multiplied by (2 ^ PRESCALE)
FILTSDA	FILTSCL	[CLKLO × (2 ^ PRESCALE)] – 3	Configuring FILTSDA greater than FILTSCL can delay the SDA input to compensate for board level skew
BUSIDLE	(CLKLO + SETHOLD + 2) × 2	—	Must also be greater than (CLKHI + 1)

See the UM10204, *I2C-bus specification and user manual*.

See Application information for example LPI2C timing configurations.

66.3.2.1.5 Error conditions

The LPI2C controller monitors errors while it is active. The following conditions generate an error flag and block a new Start condition from being sent, until the flag is cleared by software:

- A Start or Stop condition is detected and is not generated by the LPI2C controller (MSR[ALF] becomes 1).
- Transmitting data on SDA and different values are received (MSR[ALF] becomes 1). LPI2C controller stops driving SDA immediately, but continues to drive SCL for the remainder of the byte.
- NACK is detected when transmitting data, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- NACK is detected and is expecting ACK for the address byte, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- ACK is detected and is expecting NACK for the address byte, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- Transmit FIFO is requesting to transmit or receive data without a Start condition (MSR[FEF] becomes 1). This restriction is ignored when MCFGR0[RELAX] is 1.
- SCL (or SDA if MCFGR1[TIMECFG] is 1) is low for (MCFGR2[TIMELOW] × 256) prescaler cycles without a pin transition (MSR[PLTF] becomes 1).

You must respond to MSR[PLTF] to terminate the existing command. You can terminate the command cleanly by writing 0 to MCR[MEN], or you can terminate it abruptly by writing 1 to MCR[RST].

You can use MCFGR0[RELAX] to attempt to recover a target with SDA stuck low. If MCFGR0[RELAX] is 1, the LPI2C controller does not wait for the I2C bus to be idle before starting a transfer. Initiating a Start command with address FFh, then the Stop condition, should generate sufficient SCL clock edges to cause the target to release SDA.

You can use MCFGR2[BUSIDLE] to force the I2C bus to be considered idle when SCL and SDA remain high for (BUSIDLE + 1) prescaler cycles. The bus is considered idle when the LPI2C controller is first enabled. When BUSIDLE is configured greater than zero, then SCL or SDA must be high for (BUSIDLE + 1) prescaler cycles before the I2C bus is considered idle.

66.3.2.1.6 DMA support

For efficient DMA transfers to the transmit and command FIFO, two alias regions support incrementing 8-bit, 16-bit, or 32-bit write accesses to that FIFO.

- Controller Transmit Command Burst (MTCBR0 - MTCBR127) is a 512-byte region that supports pushing CMD and DATA into the transmit FIFO.

- Transmit Data Burst (MTDBR0 - MTDBR252) is a 1024-byte region that supports pushing zero extended DATA into the transmit FIFO.

The two regions are contiguous. A DMA transfer can start in the MTCBR region to initialize the transfer including START condition with address. The same transfer can complete in the MTDBR region with the data to transmit without changing the transfer size.

The transmit FIFO prevents writes that overflow the FIFO, but this prevention does not signal an error. Do not perform 32-bit writes to the MTDBR unless there are four empty slots in the transmit FIFO. Do not perform 16-bit writes to the MTDBR unless there are two empty slots in the transmit FIFO.

66.3.2.1.7 Pin configuration

Configuration	Description
Open-drain support	The LPI2C controller defaults to open-drain configuration of the SDA and SCL pins. Support for true open drain depends on the specific device, and requires the pins where LPI2C pins are muxed to support true open drain.
HS mode support	Support for HS mode depends on the specific device. This mode requires the SCL pin to support the current source pullup required in the I2C specification.
Ultra-Fast mode support	The LPI2C controller supports the output-only push-pull function required for I2C Ultra-Fast mode using the SDA and SCL pins. Support for Ultra-Fast mode also requires MCFGR1[IGNACK] to be 1.
Push-pull two-wire support	A push-pull two-wire configuration is available to the LPI2C controller. If LPI2C is the only controller and all I2C pins on the bus are at the same voltage, this configuration may support a partial HS mode. A partial HS mode, not a full HS mode, because this configuration actively drives high rather than enabling a current service pull-up. This configuration sets the SCL pin as push-pull for every clock except the first clock pulse, to allow HS-mode-compatible targets to perform clock stretching. In this mode, the SDA pin is tristated for controller-receive data bits and controller-transmit ACK/NACK bits, and is configured as push-pull at other times. To avoid the risk of contention when SDA is push-pull, configure the pin for open-drain operation, as part of the device-specific configuration.
Push-pull four-wire support	The push-pull four-wire configuration separates the SCL input data and output data into separate pins. It also separates the SDA input data and output data into separate pins. The SCL/SDA pins are used for input data; the SCLS/SDAS pins are used for output data, with configurable polarity. This configuration simplifies external connections when connecting the LPI2C to the I2C bus through external level shifters or discrete components. When using this four-wire configuration, the LPI2C controller logic and LPI2C target logic cannot connect to separate I2C buses.

66.3.2.2 Target mode

To perform all target mode transfers on the I2C bus, the LPI2C target logic operates independently from the LPI2C controller logic.

66.3.2.2.1 Address matching

You can configure the LPI2C target:

- To match one of two addresses, using either 7-bit or 10-bit addressing modes for each address.
- To match a range of addresses in either 7-bit or 10-bit addressing modes.
- To match the general call address and generate appropriate flags.
- To match the SMBus alert address and generate appropriate flags.
- To detect the HS mode controller code address, and to disable the digital filters and output valid delay time until the next Stop condition is detected.

After a valid address is matched, the LPI2C target automatically performs target-transmit or target-receive transfers until:

- A NACK is detected (unless SCFGR1[IGNACK] becomes 1).
- A bit error is detected (the LPI2C target is driving SDA, but a different value is sampled).
- A (repeated) Start or Stop condition is detected.

When SCFGR1[RXALL] is 1, the LPI2C target receives all addresses and data on the I2C bus. Unless the address is matched, it never drives the SDA pin. Configure the LPI2C target to match only on 7-bit address mode when this feature is enabled. Software can support 10-bit address mode. This option is intended for debugging the contents of an I2C transfer between another controller and target. Likewise, SCFGR1[SDCFG] and SCFGR1[RSCFG] configure the Stop or repeated Start flags to assert on all Stop or repeated Start conditions, even when there is no address match.

66.3.2.2.2 Transmit and receive data

Target Transmit Data (STDR) and Target Receive Data (SRDR) are double-buffered and only update during a target-transmit and target-receive transfer, respectively.

You can configure the target address that was received to be read from SRDR (for example, when using DMA to transfer data) or from Target Address Status (SASR).

You can configure STDR to request data only after a target-transmit transfer is detected. You can also configure it to request new data whenever STDR is empty.

Write to STDR only when SSR[TDF] is set.

Read SRDR only when SSR[RDF] is set, or when SSR[AVF] is set and SCFGR1[RXCFG] = 1.

Read SASR only when SSR[AVF] is set.

66.3.2.2.3 Read request

The LPI2C target generates a read request when the I2C bus is idle and you write 1 to SCFGR0[RDREQ]. This occurrence causes the LPI2C target to pull the SDA pin low until either the first SCL falling edge or SCFGR0[RDREQ] becomes 0. Following the next Stop condition or a software timeout, you can proceed as follows:

- If the LPI2C target is accessed at the correct address, the read request is acknowledged, and you must write 0 to SCFGR0[RDREQ].
- If SCFGR0[RDACK] is 1, the read request is acknowledged by a Start followed by one SCL pulse followed by a STOP condition. You must write 0 to SCFGR0[RDREQ].
- If neither of the first two cases occurred, the read request is not acknowledged. You must write 0 and then 1 to SCFGR0[RDREQ] after an appropriate delay, provided the I2C bus is idle.
- If a software timeout occurs, the read request is not acknowledged, and you should write 0 to SCFGR0[RDREQ]. Another request can be generated after an appropriate delay.

Writing to SCFGR0[RDREQ] when the I2C bus is busy results in a logic 0 being written. Write 1 to SCFGR0[RDREQ], then confirm that the register is written to correctly. If the register does not update correctly, the I2C bus is no longer idle and the read request must be attempted later.

66.3.2.2.4 Clock stretching

The LPI2C target supports many configurable options for clock stretching. You can configure these conditions to perform clock stretching:

- SSR[AVF] is set during the ninth clock pulse of the address byte.
- SSR[TDF] is set during the ninth clock pulse of a target-transmit transfer.
- SSR[RDF] is set during the ninth clock pulse of a target-receive transfer.
- SSR[TAF] is set during the eighth clock pulse of an address byte or a target-receive transfer. In HS mode, this option is disabled.

- Clock stretching can be extended for a number of cycles equal to the value of SCFGR2[CLKHOLD] cycles. This stretching allows additional setup time to sample the SDA pin externally. In HS mode, this option is disabled.

When clock stretching is enabled, clock stretching extends for one peripheral bus clock cycle after SDA updates, unless extended by the SCFGR2[CLKHOLD] configuration.

66.3.2.2.5 Timing parameters

The LPI2C target can configure the following timing parameters:

- SDA data valid time from SCL negation to SDA update
- SCL hold time when clock stretching is enabled to increase setup time when sampling SDA externally
- SCL glitch filter time
- SDA glitch filter time

These parameters are disabled when SCR[FILTEN] is 0, when SCR[FILTDZ] is 1 in Doze mode, and when LPI2C target detects HS mode. When disabled, the LPI2C target is clocked directly from the I2C bus. In this case, the target may not satisfy all timing requirements of the I2C specification (such as SDA minimum hold time in Standard/Fast mode).

The LPI2C target places the following restrictions on the timing parameters:

- You must configure SCFGR2[FILTSDA] to be greater than or equal to SCFGR2[FILTSCL] (unless compensating for board level skew between SDA and SCL).
- You must configure SCFGR2[DATAVD] to be less than the minimum SCL low period.

66.3.2.2.6 Error conditions

The LPI2C target can flag the following error conditions:

- SSR[BEF] is set when the LPI2C target is driving SDA but it samples a different value than what is expected.
- SSR[FEF] is set due to a transmit data underrun or a receive data overrun. To eliminate the possibility of underrun and overrun, enable clock stretching. When SCFGR1[RXNACK] is 1, the LPI2C target generates a NACK on a receive data overrun.
- SSR[FEF] is also set due to an address overrun, but only when SCFGR1[RXCFG] is 1. To eliminate the possibility of overrun, enable clock stretching. When SCFGR1[RXNACK] is 1, the LPI2C target generates a NACK on an address overrun regardless of the value of SCFGR1[RXCFG].

The LPI2C target does not implement a timeout due to SCL or SDA being stuck low. If this detection is required, use the LPI2C controller logic so you can reset the LPI2C target when this condition is detected.

66.3.2.3 Low-power modes

LPI2C remains functional during low-power modes, if MCR[DOZEN] = 0 and LPI2C uses an external or internal clock source that remains enabled. LPI2C can generate an interrupt or DMA request to cause a wake-up from low-power modes.

You can configure LPI2C to be disabled in low-power modes when MCR[DOZEN] = 1. In this case, LPI2C waits for the current transfer to complete any pending operation.

NOTE

See the chip-specific information for low-power modes available on your chip.

66.3.2.4 Debug mode

Table 554. Debug mode

Mode	LPI2C operation
Debug	If MCR[DBGEN] = 1, can continue operating in Debug mode.

66.3.2.5 Peripheral triggers

The connection of the LPI2C peripheral triggers to other peripherals depends upon the specific device being used.

Table 555. LPI2C triggers

Trigger	Description
Controller output trigger	Generates an output trigger that can be connected to other peripherals on the device. The controller output trigger asserts on either a repeated Start or a Stop condition. The trigger remains asserted for one cycle of the LPI2C functional clock divided by MCFGR1[PRESCALE].
Target output trigger	Generates an output trigger that can be connected to other peripherals on the device. The target output trigger asserts on either a repeated Start or a Stop condition that occurs after a target address match. The target output trigger remains asserted until the next target SCL pin negation.
Input trigger	To control the start of a LPI2C bus transfer, the LPI2C input trigger can be selected instead of the HREQ input. The input trigger is synchronized. To be detected, the input trigger must assert for at least two cycles of the LPI2C functional clock divided by the value of MCFGR1[PRESCALE]. When LPI2C is busy, the HREQ input (and therefore the input trigger) is ignored.

66.3.2.6 Clocking

Table 556. LPI2C clocks

Clock	Description
LPI2C functional clock	The LPI2C functional clock is asynchronous to the bus clock. It can remain enabled in low-power modes to support I2C bus transfers by the LPI2C controller. The functional clock is also used by the LPI2C target to support digital filter and data hold time configurations. The LPI2C controller divides the functional clock by a prescaler (MCFGR1[PRESCALE]) and the resulting frequency must be at least eight times faster than the I2C bus bandwidth.
External clock	The LPI2C target logic is clocked directly from the external pins. These pins are SCL and SDA, or SCLS and SDAS if the controller and target are implemented on separate pins). This clocking allows the LPI2C target to remain operational, even when the LPI2C functional clock is disabled. **NOTE** If the LPI2C functional clock is disabled, the LPI2C target digital filter must be disabled. This condition can affect compliance with some timing parameters of the I2C specification, such as data hold time.
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPI2C controller and target registers.

For chip-specific clocking information, see the Clocking chapter.

66.3.2.7 Reset

Table 557. LPI2C resets

Reset	Description
Chip reset	The logic and registers for the LPI2C controller and target are reset to their default states after a chip reset.
Software reset	The LPI2C controller implements a software reset field in its control register. MCR[RST] resets all controller logic and registers to their default states, except for Controller Control (MCR) itself. The LPI2C target implements a software reset field in its control register. SCR[RST] resets all target logic and registers to their default states, except for Target Control (SCR) itself.
FIFO reset	The LPI2C controller implements write-only control fields that reset the transmit FIFO (MCR[RTF]) and receive FIFO (MCR[RRF]). After a FIFO is reset, that FIFO is empty. The LPI2C target implements write-only control fields that reset the transmit data register (SCR[RTF]) and receive data register (SCR[RRF]). After a data register is reset, that data register is empty.

66.3.2.8 Interrupts and DMA requests

Depending on the configuration, interrupts and DMA requests can be combined:

- LPI2C controller and target interrupts
- LPI2C controller and target transmit DMA requests
- LPI2C controller and target receive DMA requests

66.3.2.8.1 Controller mode

Table 558 lists the Controller mode sources that can generate LPI2C controller interrupts and LPI2C controller transmit and receive DMA requests.

Table 558. Controller interrupts and DMA requests

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
Transmit Data Flag (MSR[TDF])	Data can be written to transmit FIFO, as configured by MFCR[TXWATER].	Y	TX	Y
Receive Data Flag (MSR[RDF])	Data can be read from the receive FIFO, as configured by MFCR[RXWATER].	Y	RX	Y
End Packet Flag (MSR[EPF])	Controller has transmitted a repeated Start or Stop condition.	Y	N	Y
Stop Detect Flag (MSR[SDF])	Controller has transmitted a Stop condition (and the LPI2C controller is idle, if MCFGR1[STOPCFG] = 1) .	Y	N	Y
NACK Detect Flag (MSR[NDF])	During an address byte, the controller expects an ACK but detects a NACK. During an address byte, the controller expects a NACK but detects an ACK.	Y	N	Y

Table continues on the next page...

Table 558. Controller interrupts and DMA requests (continued)

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
	During a controller-transmitter data byte, the controller detects a NACK.			
Arbitration Lost Flag (MSR[ALF])	The controller lost arbitration due to a Start or Stop condition detected at the wrong time, or the controller was transmitting data but received data different from the data that was transmitted.	Y	N	Y
FIFO Error Flag (MSR[FEF])	The controller expects a Start condition in the command FIFO, but the next entry in the command FIFO is not a Start condition.	Y	N	Y
Pin Low Timeout Flag (MSR[PLTF])	Pin low timeout is enabled and SCL (or SDA, if configured) is low for longer than the configured timeout.	Y	N	Y
Data Match Flag (MSR[DMF])	The received data matches the configured data match, but the received data is not discarded due to a command FIFO entry.	Y	N	Y
Start Detect Flag (MSR[STF])	A Start condition is detected on the I2C bus (and the LPI2C controller is idle, if MCFGR1[STARTCFG] = 1).	Y	N	Y
Controller Busy Flag (MSR[MBF])	LPI2C controller is busy transmitting or receiving data.	N	N	N
Bus Busy Flag (MSR[BBF])	LPI2C controller is enabled and activity is detected on the I2C bus, but no Stop condition is detected and no bus idle timeout (if enabled) occurred.	N	N	N

66.3.2.8.2 Target mode

Table 559 lists the target mode sources that can generate LPI2C target interrupts and LPI2C target transmit and receive DMA requests.

Table 559. Target interrupts and DMA requests

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
Transmit Data Flag (SSR[TDF])	Data can be written to Target Transmit Data (STDR).	Y	TX	Y
Receive Data Flag (SSR[RDF])	Data can be read from Target Receive Data (SRDR).	Y	RX	Y

Table continues on the next page...

Table 559. Target interrupts and DMA requests (continued)

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
Address Valid Flag (SSR[AVF])	Address can be read from Target Address Status (SASR).	Y	RX	Y
Transmit ACK Flag (SSR[TAF])	ACK or NACK can be written to Target Transmit ACK (STAR).	Y	N	Y
Repeated Start Flag (SSR[RSF])	Target has detected an address match followed by a repeated Start condition.	Y	RX	Y
Stop Detect Flag (SSR[SDF])	Target has detected an address match followed by a Stop condition.	Y	RX	Y
Bit Error Flag (SSR[BEF])	Target was transmitting data, but received data is different from what was transmitted.	Y	N	Y
FIFO Error Flag (SSR[FEF])	This flag is set by: • Transmit data underrun • Receive data overrun • Address status overrun when SCFGR1[RXCFG] = 1 This flag can only be set when clock stretching is disabled.	Y	N	Y
Address Match 0 Flag (SSR[AM0F])	Target detected an address match SAMR[ADDR0].	Y	N	N
Address Match 1 Flag (SSR[AM1F])	Target detected an address match with SAMR[ADDR1] or using an address range.	Y	N	N
General Call Flag (SSR[GCF])	Target detected an address match with the general call address.	Y	N	N
SMBus Alert Response Flag (SSR[SARF])	Target detected an address match with the SMBus alert address.	Y	N	N
Target Busy Flag (SSR[SBF])	LPI2C target is busy receiving an address byte or is transmitting or receiving data.	N	N	N
Bus Busy Flag (SSR[BBF])	LPI2C target is enabled and a Start condition is detected on I2C bus, but no Stop condition detected.	N	N	N

66.3.2.8.3 End-of-packet DMA transfer

End-of-packet functionality serves serial interfaces where the transfer size may not be known in advance and the data is pushed by an external device. Examples include UART receive, I2C Target mode, and SPI Target mode. End-of-packet processing is intended to ensure that data does not become stranded in either the receive FIFO or DMA receive buffer. Support for end-of-packet processing must be implemented in both the serial interfaces and DMA controller.

The condition that signals the end of packet differs for each serial interface but is processed by the serial peripheral and DMA in the same way. For example:

- UART end of packet is signaled by an idle line condition.

- I2C end of packet is signaled by Stop or repeated Start condition.
- SPI end of packet is signaled by PCS negation.

When the serial peripheral is configured to signal an end-of-packet condition to the DMA and the serial interface detects an end-of-packet condition, it asserts the DMA request for the receive FIFO regardless of the watermark configuration. For larger watermark configurations, this behavior ensures that the last few words of the transfer are first flushed from the receive FIFO.

The DMA then reads the contents of the receive FIFO, depending on the first word in the FIFO:

- If the receive FIFO is empty, the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, but the first word in the FIFO starts a new packet, data is not pulled from the receive FIFO. Also, the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, and the first word in the FIFO does not start a new packet, the DMA transfers data as normal.

Because the DMA may transfer multiple words per request, the end-of-packet condition persists until the DMA minor loop finishes and no additional data is pulled from the FIFO. The status flag that triggered the end-of-packet condition is cleared when the minor loop completes after the end of packet is signaled to the DMA controller.

When the DMA detects the end-of-packet condition, it writes all received words up to the end of packet into system memory. It also saves the destination address for the word after the last valid data. The DMA then terminates the channel as if the major loop completed, including final offsets and optional interrupts, channel linking, and scatter-gather. The final destination address can be saved to system memory or is available in the destination address register.

Because the DMA terminates the major loop, the receive FIFO is not serviced until the DMA is reconfigured. You can perform this reconfiguration through software or hardware (for example, channel linking or scatter-gather). Minimize this delay to avoid receiver FIFO overrun. Automatic DMA end-of-packet processing is not recommended when there are only a few words transferred between end-of-packet conditions. In this case, the DMA spends more time processing the end of packet than transferring the data. For example, to avoid an excessive number of idle conditions, increase the UART idle line length as needed.

66.3.3 External signals

Table 560. External signals

Signal	Name	Two-wire scheme	Four-wire scheme	Direction
SCL	LPI2C clock line	SCL	In Four-Wire mode, this pin is the SCL input pin.	Input or output
SDA	LPI2C data line	SDA	In Four-Wire mode, this pin is the SDA input pin.	Input or output
SCLS	Secondary I2C clock line	Not used	In Four-Wire mode, this pin is the SCLS output pin. If LPI2C controller/target are configured to use separate pins, then this pin is the LPI2C target SCL pin.	Input or output
SDAS	Secondary I2C data line	Not used	In Four-Wire mode, this pin is the SDAS output pin. If LPI2C controller/target are configured to use separate pins, then this pin is the LPI2C target SDA pin.	Input or output
HREQ	Host request	When configured for controller (input), if host request is asserted and the I2C bus is idle, it initiates a transfer. When configured for target (output), it asserts while valid data is present in Target Transmit Data (STDR).		Input or output

Table continues on the next page...

66.3.4 Initialization

To initialize the LPI2C controller:

1. Configure Controller Configuration 0 (MCFGR0)–Controller Configuration 3 (MCFGR3) as required by the application.
2. Configure Controller Clock Configuration 0 (MCCR0) and Controller Clock Configuration 1 (MCCR1) to satisfy the timing requirements of the I2C mode supported by the application.
3. Enable controller interrupts and DMA requests as required by the application.
4. Enable the LPI2C controller by writing 1 to MCR[MEN].

To initialize the LPI2C target:

1. Configure Target Address Match (SAMR) with the I2C address of the target location on the I2C bus.
2. Configure Target Configuration 0 (SCFGR0) and Target Configuration 1 (SCFGR1) as required by the application.
3. Configure Target Configuration 2 (SCFGR2) to satisfy the timing requirements of the I2C mode supported by the application.
4. Enable target interrupts and DMA requests as required by the application.
5. Enable the LPI2C target by writing 1 to SCR[SEN].

66.3.5 Application information

Configure the I2C timing parameters to meet the requirements of the I2C specification. This configuration depends on the supported mode and LPI2C functional clock frequency. When switching between two modes using different clock configuration registers (for example, Fast mode and HS mode), MCFGR1[PRESCALE] must remain constant between the modes.

Table 561. Example timing configurations

I2C mode	Clock frequency	Baud rate	PRESCALE	FILTSCL / FILTSDA	SETHOLD	CLKLO	CLKHI	DATAVD
Standard	8 MHz	100 kbit/s	0h	0h/0h	24h	28h	24h	02h
Standard	48 MHz	100 kbit/s	2h	1h/1h	37h	3Fh	37h	03h

66.3.6 Memory map and registers

66.3.6.1 LPI2C register descriptions

Writing to a read-only register or reading from a write-only register can cause bus errors. This module does not check whether programmed values in the registers are correct; you must ensure that valid programmed values are written to the registers.

66.3.6.1.1 LPI2C memory map

LPI2C0 base address: 4009_2800h

LPI2C1 base address: 4009_3800h

Fields

Field	Function
31-24 MAJOR	Major Version Number Returns the major version number for the module design specification.
23-16 MINOR	Minor Version Number Returns the minor version number for the module design specification.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-0 FEATURE	Feature Specification Number Returns the feature set number. 0000_0000_0000_0010b - Controller only, with standard feature set 0000_0000_0000_0011b - Controller and target, with standard feature set

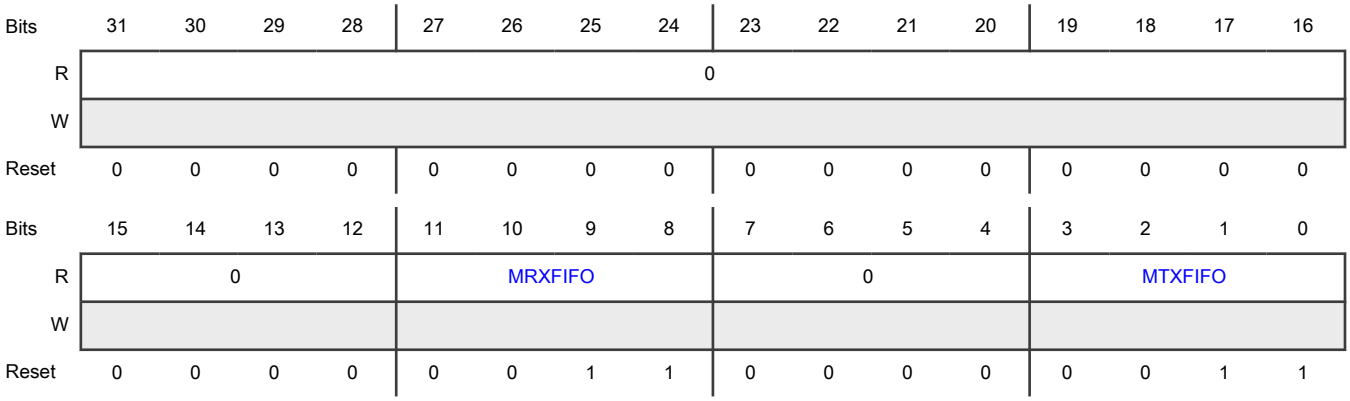
66.3.6.1.3 Parameter (PARAM)

Offset

Register	Offset
PARAM	4h

Function
Contains parameter values implemented in the module.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-12 —	Reserved
11-8 MRXFIFO	Controller Receive FIFO Size Configures the number of words in the controller receive FIFO to $2^{MRXFIFO}$.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-4 —	Reserved
3-0 MTXFIFO	Controller Transmit FIFO Size Configures the number of words in the controller transmit FIFO to $2^{MTXFIFO}$.

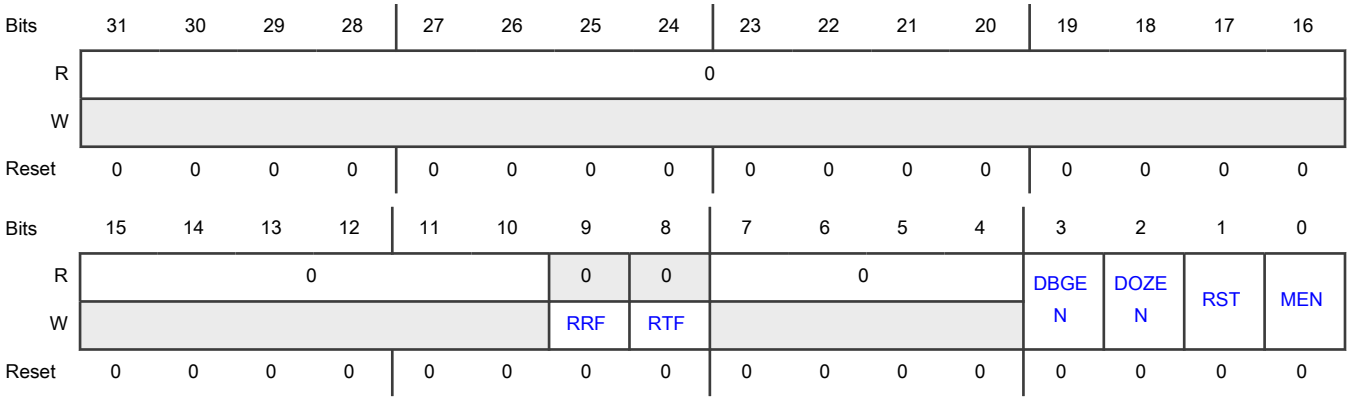
66.3.6.1.4 Controller Control (MCR)

Offset

Register	Offset
MCR	10h

Function
Contains resets, debug enable, and other controller control settings.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RRF	Reset Receive FIFO Resets the receive FIFO. 0b - No effect 1b - Reset receive FIFO

Table continues on the next page...

Table continued from the previous page...

Field	Function
8 RTF	Reset Transmit FIFO Resets the transmit FIFO. 0b - No effect 1b - Reset transmit FIFO
7-4 —	Reserved
3 DBGEN	Debug Enable Enables the controller in Debug mode. 0b - Disable 1b - Enable
2 DOZEN	Doze Mode Enable Enables the controller in Doze mode. 0b - Enable 1b - Disable
1 RST	Software Reset Resets all internal controller logic and registers except Controller Control (MCR). This field remains 1 (enabled) until you write 0 to it. The reset takes effect immediately and remains asserted until negated by software. There is no minimum delay required before clearing the software reset. 0b - No effect 1b - Reset
0 MEN	Controller Enable Enables the controller logic. 0b - Disable 1b - Enable

66.3.6.1.5 Controller Status (MSR)

Offset

Register	Offset
MSR	14h

Function
Contains status flags for transmit and receive data, for start and stop conditions, and for bus and controller busy or idle status.

Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Fields

Field	Function
31-26 —	Reserved
25 BBF	Bus Busy Flag Specifies whether the I2C bus is busy. 0b - Idle 1b - Busy
24 MBF	Controller Busy Flag Specifies whether the I2C controller is busy. 0b - Idle 1b - Busy
23-16 —	Reserved
15 STF	Start Flag Specifies whether a Start condition is detected on the bus when the bus is idle. When MCFGR1[STARTCFG] is 0, this field becomes 1 only if the LPI2C controller is also idle. When MCFGR1[STARTCFG] is 1, STF becomes 1 for any Start condition when the I2C bus is idle. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Start condition not detected 1b - Start condition detected When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clear the flag
14 DMF	Data Match Flag Indicates whether the received data matches MDMR[MATCH0] or MDMR[MATCH1] (as configured by MCFGR1[MATCFG]). Received data discarded due to MTDR[CMD] does not cause this flag to set. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Matching data not received 1b - Matching data received When writing 0b - No effect 1b - Clear the flag
13 PLTF	Pin Low Timeout Flag Indicates whether pin low timeout has occurred. Sets when the SCL or SDA input is low for more than the number of PINLOW cycles defined by MCFGR3[PINLOW], even when the LPI2C controller is idle. You must resolve the pin low condition via software. PLTF cannot be cleared as long as the pin low timeout continues. Before LPI2C can initiate a Start condition, you must clear this flag. See MCFGR1[TIMECFG] for the SCL and/or SDA timeout settings. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Pin low timeout did not occur 1b - Pin low timeout occurred When writing 0b - No effect 1b - Clear the flag
12 FEF	FIFO Error Flag Detects the LPI2C controller's attempt to send or receive data without first generating a (repeated) Start condition. This error can occur when the transmit FIFO underflows when MCFGR1[AUTOSTOP] = 1. When this flag is set, the LPI2C controller sends a Stop condition (if busy). The controller does not initiate a new Start condition until the flag is cleared. **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When reading 0b - No FIFO error 1b - FIFO error When writing 0b - No effect 1b - Clear the flag
11 ALF	Arbitration Lost Flag Indicates whether arbitration is lost. Either of these conditions sets this flag: • The LPI2C controller transmits a logic 1 and detects a logic 0 on the I2C bus. • The LPI2C controller detects a Start or Stop condition when the LPI2C controller is transmitting data. When ALF is set, the LPI2C controller releases the I2C bus (goes idle), and the LPI2C controller does not initiate a new Start condition until the ALF is cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Controller did not lose arbitration 1b - Controller lost arbitration When writing 0b - No effect 1b - Clear the flag
10 NDF	NACK Detect Flag Indicates whether an unexpected NACK has been detected. This flag is set when the LPI2C controller detects a NACK it was not expecting when transmitting an address or data. When set, the controller does not initiate a new Start condition until this flag is cleared. If a NACK is expected for a given address (as configured by the command word), this flag is set if a NACK is not generated. When this flag is set, the LPI2C controller automatically transmits a Stop condition if MCFGR1[AUTOSTOP] = 1, or if the transmit FIFO is not empty. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No unexpected NACK detected 1b - Unexpected NACK detected When writing 0b - No effect

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Clear the flag
9 SDF	Stop Detect Flag Indicates whether the LPI2C controller has generated a Stop condition. When MCFGR1[STOPCFG] = 0, this flag is set for any Stop condition. When MCFGR1[STOPCFG] = 1, this flag is set only when the LPI2C controller is also idle (transmit FIFO is empty). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stop condition generated 1b - Stop condition generated When writing 0b - No effect 1b - Clear the flag
8 EPF	End Packet Flag Indicates whether the LPI2C controller has generated a repeated Start condition or a Stop condition. When the controller first generates a Start condition, this flag is not set. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stop or repeated Start generated 1b - Stop or repeated Start generated When writing 0b - No effect 1b - Clear the flag
7-2 —	Reserved
1 RDF	Receive Data Flag Indicates whether the receive data is ready. This flag is set when the number of words in the receive FIFO is greater than MFCR[RXWATER]. 0b - Receive data not ready 1b - Receive data ready
0 TDF	Transmit Data Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates whether transmit data is requested. This flag is set when the number of words in the transmit FIFO is equal or less than MFCR[TXWATER]. 0b - Transmit data not requested 1b - Transmit data requested

66.3.6.1.6 Controller Interrupt Enable (MIER)

Offset

Register	Offset
MIER	18h

Function

Contains enables for:

- Transmit and receive data interrupts
- Start, Stop, and NACK detection interrupts
- DMA interrupts

R	0						RDMO	CIRFIFO	0				HRDIR	HRSEL	HRPOL	HREN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-18	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
17 ABORT	Abort Transfer Determines whether the LPI2C controller completes the existing byte and then sends a Stop condition. A new transfer does not start while this field is 1. 0b - Normal transfer 1b - Abort existing transfer and do not start a new one
16 RELAX	Relaxed Mode Specifies the type of transfer. If this field is 1, the LPI2C controller relaxes several transfer restrictions. Transfers start when the bus is busy and FIFO commands are not checked for errors. You can use this mode to attempt recovery of a stuck I2C target by toggling the SCL pin. 0b - Normal transfer 1b - Relaxed transfer
15-10 —	Reserved
9 RDMO	Receive Data Match Only Determines whether all received data that does not set MSR[DMF] is discarded. After MSR[DMF] is set, the RDMO configuration is ignored. When disabling RDMO, write 0 to this field before writing 0 to MSR[DMF] to ensure that no receive data is lost. 0b - Received data is stored in the receive FIFO 1b - Received data is discarded unless MSR[DMF] is set
8 CIRFIFO	Circular FIFO Enable Enables the transmit FIFO read pointer to be saved to a temporary register. The transmit FIFO empties as normal. After the LPI2C controller is idle and the transmit FIFO is empty, the read pointer value is restored from the temporary register. This setting causes the contents of the transmit FIFO to be cycled through repeatedly. If MCFGR1[AUTOSTOP] is 1, then a Stop condition is sent whenever the transmit FIFO is empty and the read pointer is restored. 0b - Disable 1b - Enable
7-4 —	Reserved
3 HRDIR	Host Request Direction Configures the direction of the HREQ pin. When this field is 1, the LPI2C target drives the HREQ output pin and the pin becomes 1 when there is data in the target transmit data register. For proper operation when this field is 1, write 1 to SCFGR1[TXCFG].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - HREQ pin is input (for LPI2C controller) 1b - HREQ pin is output (for LPI2C target)
2 HRSEL	Host Request Select Selects the source of the host request input. When host request is enabled, this field must not change. 0b - Host request input is pin HREQ 1b - Host request input is input trigger
1 HRPOL	Host Request Polarity Configures the polarity of the host request input. When host request is enabled, this field must not change. HRPOL sets the polarity for both the HREQ pin and the input trigger. • When HRPOL=0, the polarity is configured for active low, so host request is asserted if the HREQ pin or input trigger are logic 0. • When HRPOL=1, the polarity is configured for active high, so host request is asserted if the HREQ pin or input trigger are logic 1. 0b - Active low 1b - Active high
0 HREN	Host Request Enable Enables host request. When enabled, the LPI2C controller only initiates a Start condition if the host request input is asserted and the bus is idle. A repeated Start condition is not affected by the host request. 0b - Disable 1b - Enable

66.3.6.1.9 Controller Configuration 1 (MCFGR1)

Offset

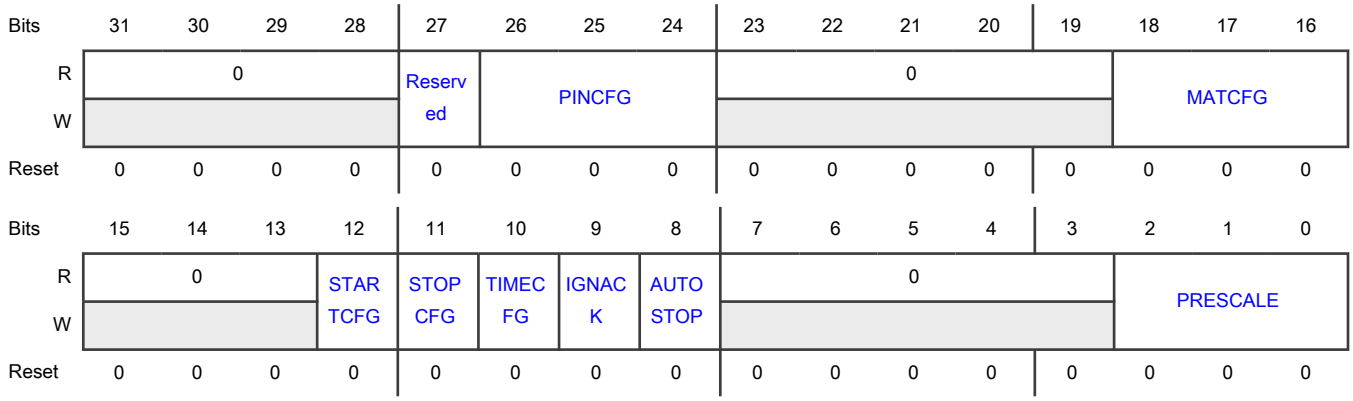
Register	Offset
MCFGR1	24h

Function

Contains controls for pin configuration, clock prescaler, and various other control settings.

Write to this register only when the I2C controller is disabled.

Diagram



Fields

Field	Function
31-28 —	Reserved
27 —	Reserved
26-24 PINCFG	Pin Configuration Configures the pin mode for LPI2C. 000b - Two-pin open drain mode. SCL/SDA pins: Bidirectional open drain for controller and target. SCLS/SDAS pins: Not used. 001b - Two-pin output only mode (Ultra-Fast mode). SCL/SDA pins: Output-only (Ultra-Fast mode) open drain for controller and target. SCLS/SDAS pins: Not used. 010b - Two-pin push-pull mode. SCL/SDA pins: Bidirectional push-pull for controller and target. SCLS/SDAS pins: Not used. 011b - Four-pin push-pull mode. SCL/SDA pins: Input only for controller and target. SCLS/SDAS pins: Output-only push-pull for controller and target. 100b - Two-pin open-drain mode with separate LPI2C target. SCL/SDA pins: Bidirectional open drain for controller. SCLS/SDAS pins: Bidirectional open drain for target. 101b - Two-pin output only mode (Ultra-Fast mode) with separate LPI2C target. SCL/SDA pins: Output-only (Ultra-Fast mode) open drain for controller. SCLS/SDAS pins: Output-only open drain for target. 110b - Two-pin push-pull mode with separate LPI2C target. SCL/SDA pins: Bidirectional push-pull for controller. SCLS/SDAS pins: Bidirectional push-pull for target. 111b - Four-pin push-pull mode (inverted outputs). SCL/SDA pins: Input only for controller and target. SCLS/SDAS pins: Inverted output-only push-pull for controller and target.
23-19 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
18-16 MATCFG	Match Configuration Configures the condition that sets MSR[DMF]. See Controller Data Match (MDMR). 000b - Match is disabled 001b - Reserved 010b - Match is enabled: first data word equals MDMR[MATCH0] OR MDMR[MATCH1] 011b - Match is enabled: any data word equals MDMR[MATCH0] OR MDMR[MATCH1] 100b - Match is enabled: (first data word equals MDMR[MATCH0]) AND (second data word equals MDMR[MATCH1) 101b - Match is enabled: (any data word equals MDMR[MATCH0]) AND (next data word equals MDMR[MATCH1) 110b - Match is enabled: (first data word AND MDMR[MATCH1]) equals (MDMR[MATCH0] AND MDMR[MATCH1]) 111b - Match is enabled: (any data word AND MDMR[MATCH1]) equals (MDMR[MATCH0] AND MDMR[MATCH1])
15-13 —	Reserved
12 STARTCFG	Start Configuration Configures the conditions that set MSR[STF] when a Start condition occurs. When this field is 0, MSR[STF] is set on a Start condition when both the I2C bus and LPI2C are idle. In other words, any nonrepeated Start condition is initiated by any controller on the bus except the LPI2C controller. When this field is 1, MSR[STF] is set on a Start condition when the I2C bus is idle. In other words, any nonrepeated Start condition is initiated by any controller on the bus including the LPI2C controller. 0b - Sets when both I2C bus and LPI2C controller are idle 1b - Sets when I2C bus is idle
11 STOPCFG	Stop Configuration Configures the conditions that set MSR[SDF]. When this field is 0, any Stop condition generated by the LPI2C controller sets SDF. When this field is 1, the last Stop condition before the LPI2C controller is idle sets SDF. In this case, the transmit FIFO is empty at the time of the Stop condition. 0b - Any Stop condition 1b - Last Stop condition
10 TIMECFG	Timeout Configuration Configures which signals must be low for longer than the configured timeout to set MSR[PLTF]. When this field is 0, MSR[PLTF] is set when SCL is low for longer than the configured timeout.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - SCL 1b - SCL or SDA
9 IGNACK	Ignore NACK Determines whether the LPI2C controller ignores a received NACK and treats it as an ACK. In this case, MSR[NDF] is never set. This field must be 1 in Ultra-Fast mode. 0b - No effect 1b - Treat a received NACK as an ACK
8 AUTOSTOP	Automatic Stop Generation Determines whether a Stop condition is generated when the LPI2C controller is busy and the transmit FIFO is empty. A Stop condition can also be generated using a transmit FIFO command. When this field is 1, a Stop condition is automatically generated when the transmit FIFO is empty and the LPI2C controller is busy. 0b - No effect 1b - Stop automatically generated
7-3 —	Reserved
2-0 PRESCALE	Prescaler Configures the clock prescaler used for all LPI2C controller logic except the digital glitch filters. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128

MCFGR2	28h

Function

Contains the configuration for the bus idle timeout and glitch filters for SDA and SCL.

Write to this register only when the I2C controller is disabled.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0				BUSIDLE											
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 —	Reserved
27-24 FILTSDA	Glitch Filter SDA Configures the I2C controller digital glitch filters for the SDA input. The latency through the glitch filter is equal to the number of cycles defined by this field. The value of this field must be less than the minimum SCL low or high period. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. Writing 0 to this field disables the glitch filter. MCFGR1[PRESCALE] does not affect the glitch filter cycle count. It is automatically bypassed in HS mode.
23-20 —	Reserved
19-16 FILTSCL	Glitch Filter SCL Configures the I2C controller digital glitch filters for SCL input. The latency through the glitch filter is equal to the number of cycles defined by this field. The value of this field must be less than the minimum SCL low or high period. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. These cycles are based on the functional clock. Writing 0 to this field disables the glitch filter. MCFGR1[PRESCALE] does not affect the glitch filter cycle count. It is automatically bypassed in HS mode.
15-12 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-0 BUSIDLE	Bus Idle Timeout Configures the bus idle timeout period, in clock cycles. If both SCL and SDA are high for longer than the number of cycles defined by this field, the I2C bus is assumed to be idle and the controller can generate a Start condition. Writing 0 to this field disables the bus idle timeout.

66.3.6.1.11 Controller Configuration 3 (MCFGR3)

Offset

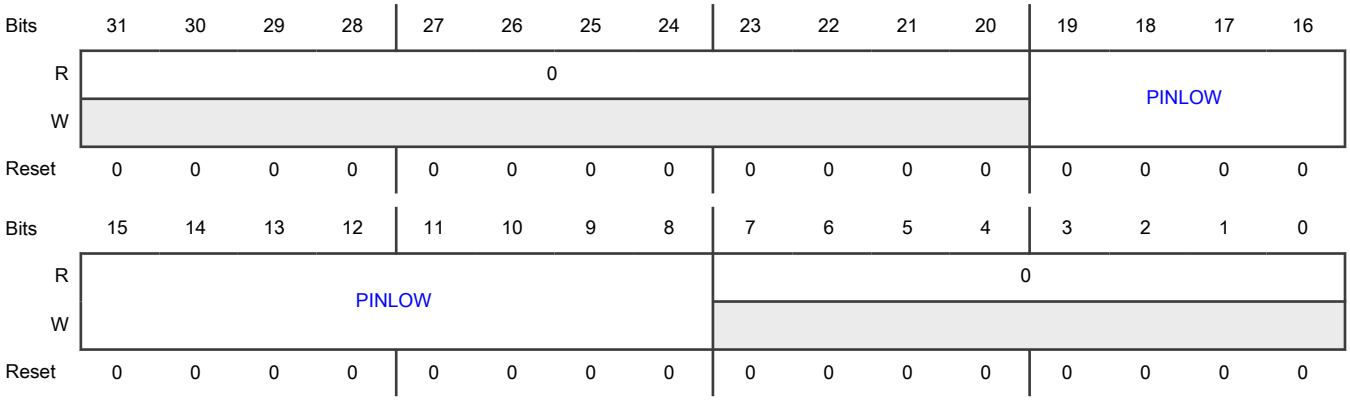
Register	Offset
MCFGR3	2Ch

Function

Configures the threshold value for the pin low timeout flag.

Write to this register only when the I2C controller is disabled.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-8 PINLOW	Pin Low Timeout Configures the threshold value, in clock cycles, that sets MSR[PLTF].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If SCL or SDA (selected by MCFGR1[TIMECFG]) is low for longer than (PINLOW × 256) cycles, MSR[PLTF] is set. When this field is 0, the pin low timeout feature is disabled.
7-0 —	Reserved

66.3.6.1.12 Controller Data Match (MDMR)

Offset

Register	Offset
MDMR	40h

Function

Contains data match values.

Write to this register only when the I2C controller is disabled or idle.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 —	Reserved
23-16 MATCH1	Match 1 Value Specifies match 1 value that is compared to the received data when receive data match is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 —	Reserved
7-0 MATCH0	Match 0 Value Specifies match 0 value that is compared to the received data when receive data match is enabled.

66.3.6.1.13 Controller Clock Configuration 0 (MCCR0)

Offset

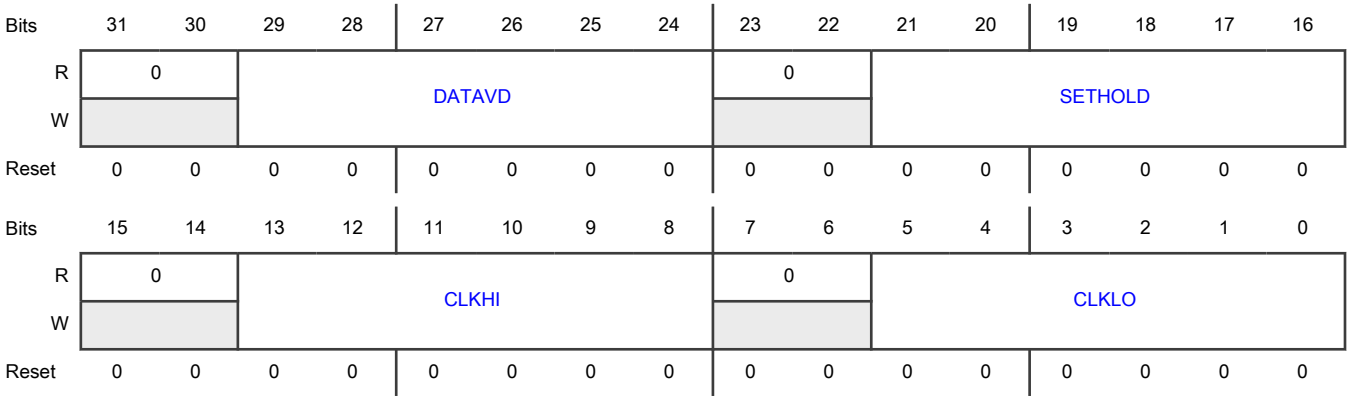
Register	Offset
MCCR0	48h

Function

Configures various clock controls.

You cannot make changes to this register when the I2C controller is enabled and is used for standard, fast, fast-mode plus, and ultra-fast transfers.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 DATAVD	Data Valid Delay

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Specifies the minimum number of cycles (minus one) used as the data hold time for SDA. This value must be less than the minimum SCL low period.
23-22 —	Reserved
21-16 SETHOLD	Setup Hold Delay Specifies the minimum number of cycles (minus one) used by the controller for these conditions: • Hold time for a Start • Setup and hold time for a repeated Start • Setup time for a Stop The setup time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
15-14 —	Reserved
13-8 CLKHI	Clock High Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock high. The SCL high time is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
7-6 —	Reserved
5-0 CLKLO	Clock Low Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock low. This value is also used for the minimum bus free time between a Stop and a Start condition. This period is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.

66.3.6.1.14 Controller Clock Configuration 1 (MCCR1)

Offset

Register	Offset
MCCR1	50h

Function

Configures various clock controls.

You cannot makes changes to this register when the I2C controller is enabled and is used for HS mode transfers. The separate clock configuration for HS mode allows arbitration to take place in Fast mode (with timing configured by Controller Clock Configuration 0 (MCCR0)), before switching to HS mode (with timing configured by MCCR1).

	any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
7-6 —	Reserved
5-0 CLKLO	Clock Low Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock low. This value is also used for the minimum bus free time between a Stop and a Start condition. This period is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.

66.3.6.1.15 Controller FIFO Control (MFCR)

Offset

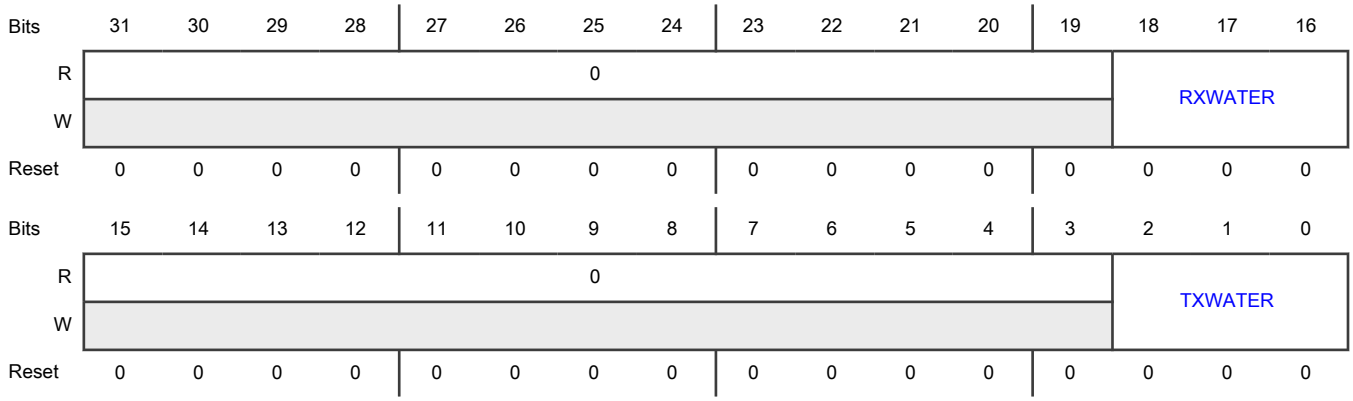
Register	Offset
MFCR	58h

Function

Controls the receive and transmit FIFO watermark values.

This register is used only in Stop mode, when this register is static (not changing).

Diagram



Fields

Field	Function
31-19	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
18-16 RXWATER	Receive FIFO Watermark Determines the watermark for setting SSR[RDF]. That flag is set when the number of words in the receive FIFO is greater than the value of this field. Writing a value equal to or greater than the FIFO size truncates the value.
15-3 —	Reserved
2-0 TXWATER	Transmit FIFO Watermark Determines the watermark for setting SSR[TDF]. That flag is set when the number of words in the transmit FIFO is equal or less than the value of this field. Writing a value equal to or greater than the FIFO size truncates the value.

66.3.6.1.16 Controller FIFO Status (MFSR)

Offset

Register	Offset
MFSR	5Ch

Function
Specifies the number of words in the transmit and receive FIFOs.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Function
31-20 —	Reserved
19-16 RXCOUNT	Receive FIFO Count Specifies the number of words in the receive FIFO.
15-4 —	Reserved
3-0 TXCOUNT	Transmit FIFO Count Specifies the number of words in the transmit FIFO.

66.3.6.1.17 Controller Transmit Data (MTDR)

Offset

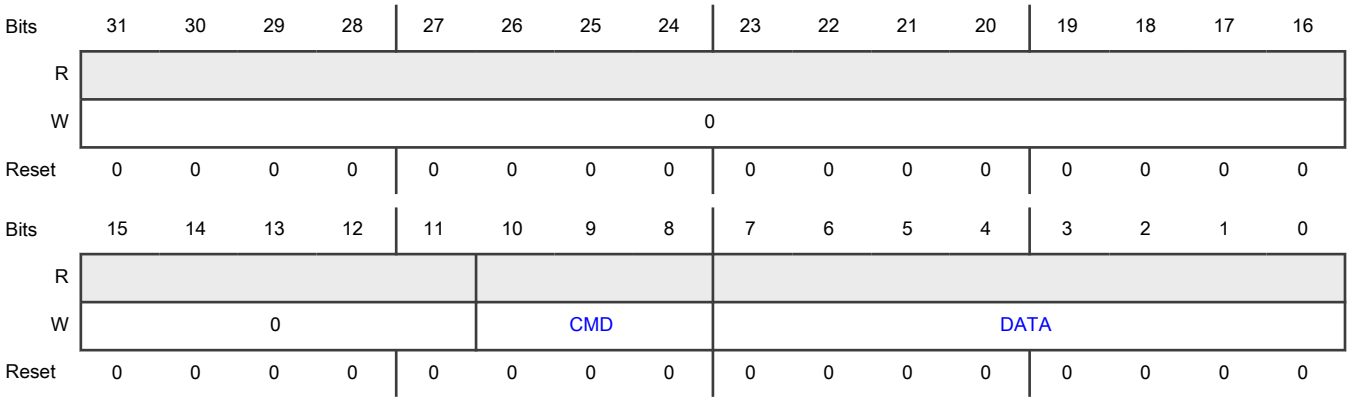
Register	Offset
MTDR	60h

Function

Configures transmit data:

- An 8-bit write to MTDR[CMD] is ignored and does not increment the FIFO write pointer.
- An 8-bit write to MTDR[DATA] zero-extends the value of MTDR[CMD] and increments the FIFO write pointer.
- A 16-bit or 32-bit write operation writes to both MTDR[CMD] and MTDR[DATA] and increments the FIFO write pointer.

Diagram



Fields

Field	Function
31-11 —	Reserved
10-8 CMD	Command Data Selects command transmitted by controller. 000b - Transmit the value in DATA[7:0] 001b - Receive (DATA[7:0] + 1) bytes. DATA[7:0] is used as a byte counter. Receive that many bytes and check each for a data match (if configured) before storing the received data in the receive FIFO. 010b - Generate Stop condition on I2C bus 011b - Receive and discard (DATA[7:0] + 1) bytes. DATA[7:0] is used as a byte counter. Receive that many bytes but do not check for a data match or store those bytes in the receive FIFO. 100b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] 101b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] (this transfer expects a NACK to be returned) 110b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] using HS mode 111b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] using HS mode (this transfer expects a NACK to be returned)
7-0 DATA	Transmit Data Contains data used by the commands listed in MTDR[CMD]. Performing an 8-bit write to this field zero-extends the value of MTDR[CMD].

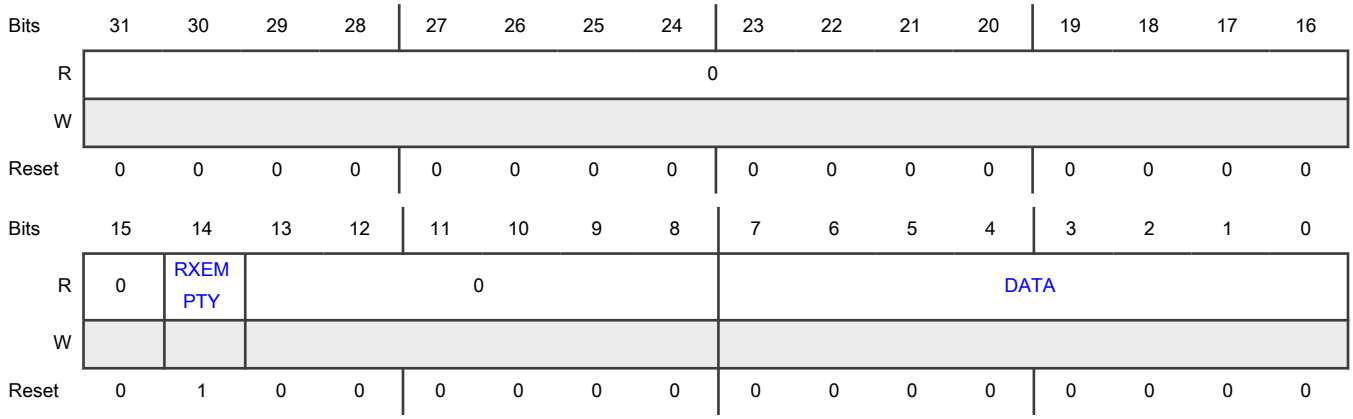
66.3.6.1.18 Controller Receive Data (MRDR)

Offset

Register	Offset
MRDR	70h

Function
Contains the status of the receive FIFO and the data received by the I2C controller that has not been discarded.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 RXEMPTY	Receive Empty Indicates whether the controller receive data FIFO is empty. 0b - Not empty 1b - Empty
13-8 —	Reserved
7-0 DATA	Receive Data Contains data received by the I2C controller that has not been discarded. Received data can be discarded due to the command in MTDR[CMD], or the controller can be configured to discard nonmatching data.

66.3.6.1.19 Controller Receive Data Read Only (MRDROR)

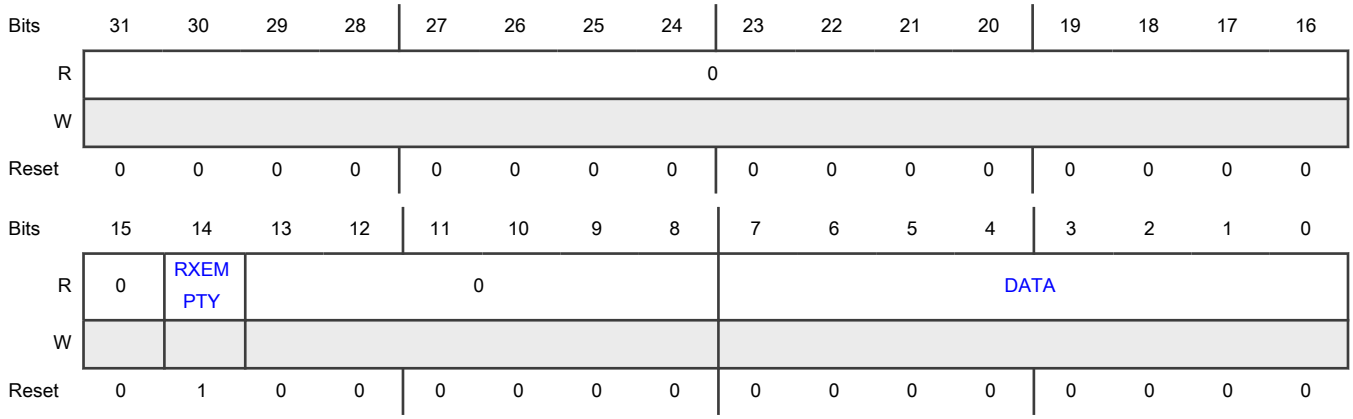
Offset

Register	Offset
MRDROR	78h

Function

Contains the status of the receive FIFO and returns the data received by the I2C controller, but does not pull the data from the FIFO.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 RXEMPTY	RX Empty Indicates whether the receive data FIFO is empty. 0b - Not empty 1b - Empty
13-8 —	Reserved
7-0 DATA	Receive Data

66.3.6.1.20 Target Control (SCR)

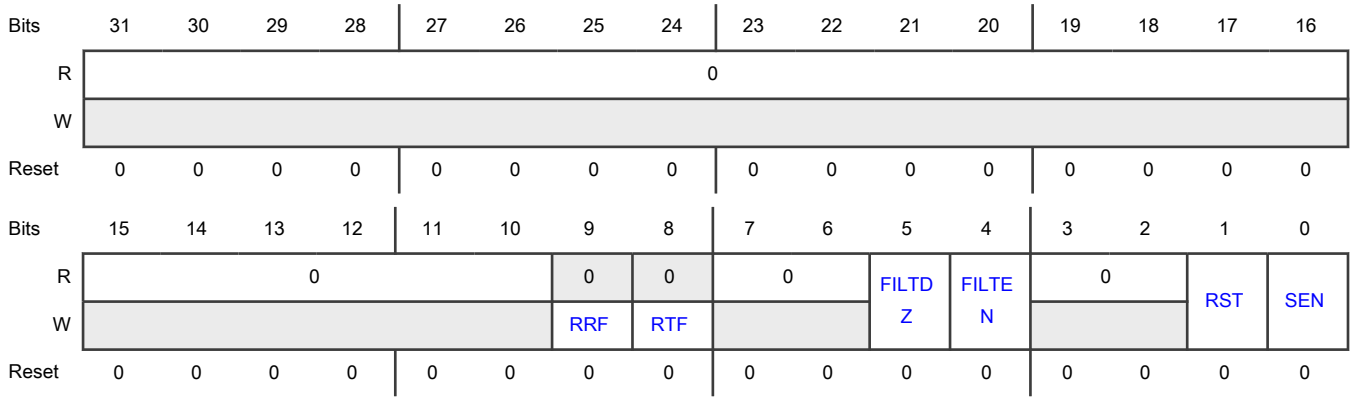
Offset

Register	Offset
SCR	110h

Function

Contains resets and other target control settings.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RRF	Reset Receive FIFO Empties the receive FIFO in Target Receive Data (SRDR). 0b - No effect 1b - SRDR is now empty
8 RTF	Reset Transmit FIFO Empties the transmit FIFO in Target Transmit Data (STDR). 0b - No effect 1b - STDR is now empty
7-6 —	Reserved
5 FILTDZ	Filter Doze Enable Enables filter in Doze mode. Update this field only when the I2C target is disabled. 0b - Enable 1b - Disable
4 FILTEN	Filter Enable Enables digital filter and output delay counter for target mode. Update this field only when the I2C target is disabled. 0b - Disable 1b - Enable
3-2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1 RST	Software Reset Resets target mode logic. The reset takes effect immediately. The value of this field remains 1 until you write 0 to it. There is no minimum delay required before clearing the software reset. 0b - Not reset 1b - Reset
0 SEN	Target Enable Enables I2C Target mode. 0b - Disable 1b - Enable

66.3.6.1.21 Target Status (SSR)

Offset

Register	Offset
SSR	114h

Function

Contains status flags for transmit and receive data, for error conditions, and for bus and target busy or idle status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-26 —	Reserved
25 BBF	Bus Busy Flag Indicates whether an I2C bus is idle or busy. 0b - Idle 1b - Busy
24 SBF	Target Busy Flag Indicates whether an I2C target is idle or busy. 0b - Idle 1b - Busy
23-16 —	Reserved
15 SARF	SMBus Alert Response Flag Indicates whether an SMBus alert response has been detected. You can clear this flag by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - Disabled or not detected 1b - Enabled and detected
14 GCF	General Call Flag Indicates whether a target has detected the general call address. You can clear this flag by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - General call address disabled or not detected 1b - General call address detected
13 AM1F	Address Match 1 Flag Indicates whether the received address matches the value in ADDR1, or it falls within the ADDR0 to ADDR1 range as configured by SCFGR1[ADDRCFG]. This flag is cleared by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - Matching address not received 1b - Matching address received
12	Address Match 0 Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
AM0F	Indicates whether the received address matches the ADDR0 field, as configured by SCFGR1[ADDRCFG]. This flag is cleared by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - ADDR0 matching address not received 1b - ADDR0 matching address received
11 FEF	FIFO Error Flag Indicates whether there is a FIFO error. This flag can only be set when clock stretching is disabled. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No FIFO error 1b - FIFO error When writing 0b - No effect 1b - Clear the flag
10 BEF	Bit Error Flag Indicates whether the LPI2C target has transmitted a logic 1 and detects a logic 0 on the I2C bus. The target ignores the rest of the transfer until the next (repeated) Start condition. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No bit error occurred 1b - Bit error occurred When writing 0b - No effect 1b - Clear the flag
9 SDF	Stop Detect Flag Indicates whether the LPI2C target detects a Stop condition, and if the LPI2C target matched the last address byte. When SCFGR1[SDCFG] = 1, this flag is set on any Stop condition. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No Stop detected 1b - Stop detected When writing 0b - No effect 1b - Clear the flag
8 RSF	Repeated Start Flag Indicates whether the LPI2C target detects a repeated Start condition and if the LPI2C target matched the last address byte. When SCFGR1[RSCFG] = 1, this flag is set on any repeated Start condition. This flag is not set when the target first detects a Start condition. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No repeated Start detected 1b - Repeated Start detected When writing 0b - No effect 1b - Clear the flag
7-4 —	Reserved
3 TAF	Transmit ACK Flag Indicates whether a transmit ACK or NACK is required. You can clear this flag by writing to Target Transmit ACK (STAR). 0b - Not required 1b - Required
2 AVF	Address Valid Flag Indicates whether the contents of Target Address Status (SASR) are valid. You can clear this flag by reading SASR. When SCFGR1[RXCFG] = 1, this flag is also cleared by reading Target Receive Data (SRDR). 0b - Not valid 1b - Valid
1 RDF	Receive Data Flag Indicates whether receive data is ready. You can clear this flag by reading Target Receive Data (SRDR). When SCFGR1[RXCFG] = 1, this flag is not cleared when reading Target Receive Data (SRDR) if SSR[AVF] = 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not ready 1b - Ready
0 TDF	Transmit Data Flag Indicates whether transmit data has been requested. This flag is cleared by writing to Target Transmit Data (STDR). When SCFGR1[TXCFG] = 0, if a NACK, repeated Start, or Stop condition is detected, this flag is also cleared. 0b - Transmit data not requested 1b - Transmit data is requested

66.3.6.1.22 Target Interrupt Enable (SIER)

Offset

Register	Offset
SIER	118h

Function

Contains transmit and receive data interrupt enables, start and stop detect interrupt enables, and other target interrupt enables.

Diagram

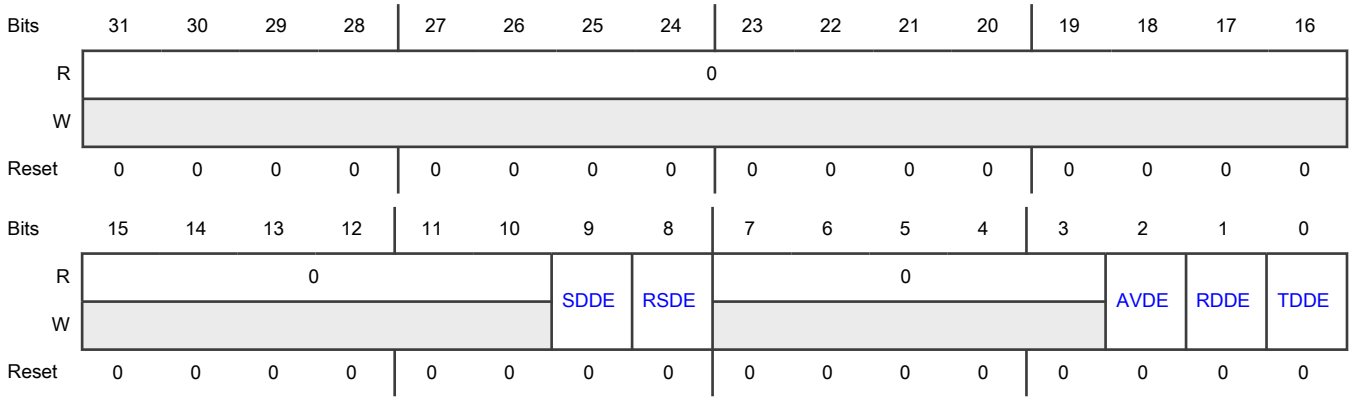
66.3.6.1.23 Target DMA Enable (SDER)

Offset

Register	Offset
SDER	11Ch

Function
Contains the transmit, request, and receive enables for DMA.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 SDDE	Stop Detect DMA Enable Enables DMA end-of-packet processing on stop detection. Reading Target Receive Data (SRDR) when it is empty: • Generates a DMA end-of-packet response. • Returns 0000_40FFh. • Writes 0 to MSR[SDF]. 0b - Disable 1b - Enable
8 RSDE	Repeated Start DMA Enable Enables DMA end-of-packet processing on repeated start. Reading Target Receive Data (SRDR) when it is empty: • Generates a DMA end-of-packet response. • Returns 0000_40FFh. • Writes 0 to MSR[RDF]. 0b - Disable 1b - Enable
7-3 —	Reserved
2 AVDE	Address Valid DMA Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables address valid DMA request. The address valid DMA request is shared with the receive data DMA request. If both are enabled, write 1 to SCFGR1[RXCFG] to allow the DMA to read the address from Target Receive Data (SRDR). 0b - Disable 1b - Enable
1 RDDE	Receive Data DMA Enable Enables receive data for DMA. 0b - Disable DMA request 1b - Enable DMA request
0 TDDE	Transmit Data DMA Enable Enables transmit data for DMA. 0b - Disable 1b - Enable

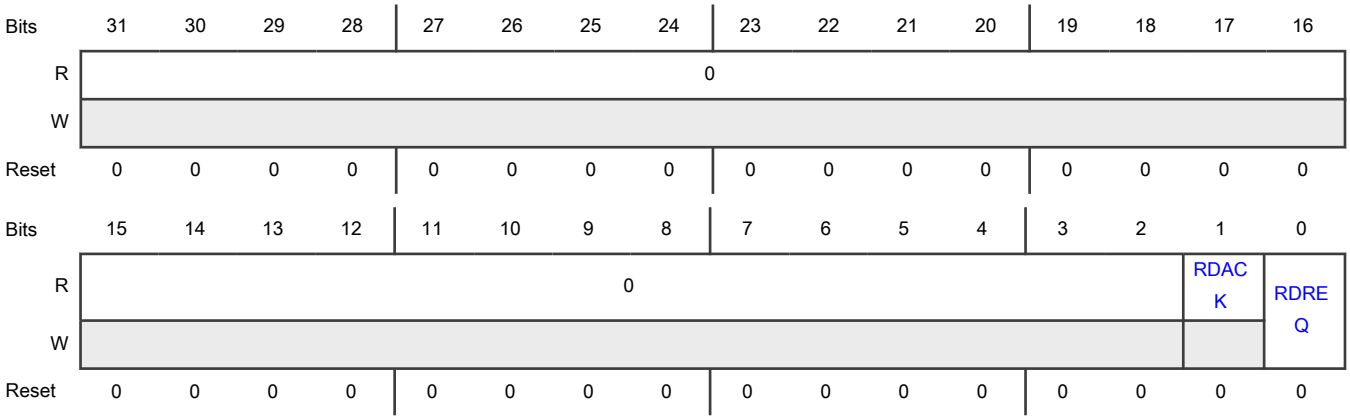
66.3.6.1.24 Target Configuration 0 (SCFGR0)

Offset

Register	Offset
SCFGR0	120h

Function
Configures the read request feature.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RDACK	Read Acknowledge Flag Indicates whether a Start then Stop sequence with one SCL pulse between them acknowledged the read request while SCFGR0[RDREQ] = 1. You can clear this flag by writing 0 to SCFGR0[RDREQ]. 0b - Read Request not acknowledged 1b - Read Request acknowledged
0 RDREQ	Read Request Enables read request. When the I2C bus is idle, writing 1 to this field causes the LPI2C target to drive SDA low, triggering a Start condition. The LPI2C target releases SDA on the next falling edge of SCL or when you write 0 to this field. To initiate a second read request (for example, following I2C bus activity that did not acknowledge the request), write 0 then 1 to this field. When the I2C bus is busy, writing to this register always writes 0 to this field. 0b - Disable 1b - Enable

66.3.6.1.25 Target Configuration 1 (SCFGR1)

Offset

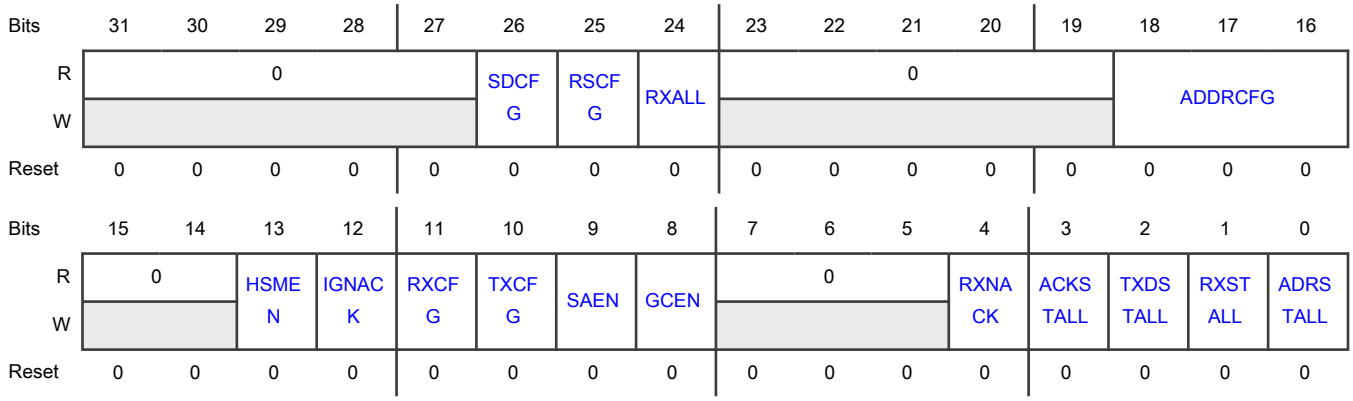
Register	Offset
SCFGR1	124h

Function

Configures various aspects of the target.

Write to this register only when the I2C target is disabled.

Diagram



Fields

Field	Function
31-27 —	Reserved
26 SDCFG	Stop Detect Configuration Configures the conditions that set MSR[SDF]. 0b - Any Stop condition following an address match 1b - Any Stop condition
25 RSCFG	Repeated Start Configuration Configures the conditions that set MSR[STF]. 0b - Any repeated Start condition following an address match 1b - Any repeated Start condition
24 RXALL	Receive All Enables receive-all functionality. When enabled, the LPI2C target stores all addresses on the I2C bus in Target Address Status (SASR) and all data on the I2C bus in Target Receive Data (SRDR). However, the LPI2C target does not drive SDA (for ACK or target-transmit transfer) unless there is an address match. The LPI2C target can drive SCL if clock stretching is enabled. When this field is 1, the LPI2C target only supports 7-bit addressing modes (you must configure SCFGR1[ADDRCFG] for 7-bit address match). Software can support 10-bit addresses, however. The first byte of a 10-bit address is saved to Target Address Match (SAMR). The second byte is saved as the first data byte in Target Receive Data (SRDR). Use this field to aid debugging of the I2C bus by saving all data on the bus without altering the state of the bus. When this field is 1, it is recommended to also write 1 to SCFGR1[RSCFG] and SCFGR1[SDCFG] so you can track the full state of the I2C bus. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-19 —	Reserved
18-16 ADDRCFG	Address Configuration Configures the condition that causes an address to match. 000b - Address match 0 (7-bit) 001b - Address match 0 (10-bit) 010b - Address match 0 (7-bit) or address match 1 (7-bit) 011b - Address match 0 (10-bit) or address match 1 (10-bit) 100b - Address match 0 (7-bit) or address match 1 (10-bit) 101b - Address match 0 (10-bit) or address match 1 (7-bit) 110b - From address match 0 (7-bit) to address match 1 (7-bit) 111b - From address match 0 (10-bit) to address match 1 (10-bit)
15-14 —	Reserved
13 HSMEN	HS Mode Enable Enables detection of the HS mode controller code of target address 0000_1XX, but does not cause an address match on this code. When this field is 1 and any HS mode controller code is detected, SCR[FILTEN] and SCFGR1[ACKSTALL] are ignored until the next Stop condition is detected. 0b - Disable 1b - Enable
12 IGNACK	Ignore NACK Determines whether the target ends transfer when a NACK condition is detected. When this field is 1, the LPI2C target continues transfers after a NACK is detected. This field is required to be 1 in Ultra-Fast mode. 0b - End transfer on NACK 1b - Do not end transfer on NACK
11 RXCFG	Receive Data Configuration Configures which data is returned and which flags are cleared when reading Target Receive Data (SRDR). When this field is 0, reading SRDR returns received data and clears MSR[RDF]. When this field is 1, reading SRDR: • Returns the value of Target Address Status (SASR) and clears SSR[AVF] when SSR[AVF] is set. • Returns received data and clears MSR[RDF] when SSR[AVF] is not set. 0b - Return received data, clear MSR[RDF]

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Return SASR and clear SSR[AVF] when SSR[AVF] is set, return received data and clear MSR[RDF] when SSR[AFV] is not set
10 TXCFG	Transmit Flag Configuration Determines which conditions set MSR[TDF]. This field always becomes 1 before a NACK is detected at the end of a target-transmit transfer. This change can cause an extra word to be written to the transmit data FIFO. When this field is 0, Target Transmit Data (STDR) is automatically emptied when a target-transmit transfer is detected. MSR[TDF] is set when a target-transmit transfer is detected, and MSR[TDF] is cleared at the end of the target-transmit transfer. When this field is 1, MSR[TDF] is set when STDR is empty, and MSR[TDF] is cleared when STDR is full. This setting allows STDR to be filled before a target-transmit transfer is detected. However, it can cause STDR to be written before a NACK is detected on the last byte of a target-transmit transfer. 0b - MSR[TDF] is set only during a target-transmit transfer when STDR is empty 1b - MSR[TDF] is set whenever STDR is empty
9 SAEN	SMBus Alert Enable Enables a match on an SMBus alert. 0b - Disable 1b - Enable
8 GCEN	General Call Enable Enables a general call address. 0b - Disable 1b - Enable
7-5 —	Reserved
4 RXNACK	Receive NACK Determines whether to override the setting of STAR[TXNACK] when the LPI2C receives a matching address during an overrun. When this field is 1, the LPI2C target responds with a NACK under the following conditions: • SSR[AVF] would be set due to matching an address, but that flag is already 1 (address overrun). • SSR[RDF] would be set due to receiving data, but that flag is already 1 (receive data overrun). 0b - ACK or NACK always determined by STAR[TXNACK] 1b - NACK always generated on address overrun or receive data overrun, otherwise ACK or NACK is determined by STAR[TXNACK]
3	ACK SCL Stall

Table continues on the next page...

Table continued from the previous page...

Field	Function
ACKSTALL	Enables SCL clock stretching during target-transmit address bytes and target-receiver address and data bytes, so you can write to Target Transmit ACK (STAR) before the ACK or NACK is transmitted. Clock stretching occurs when transmitting the ninth bit, and is therefore not compatible with HS mode. If this field is 1: • You do not need to write 1 to SCFGR1[RXSTALL] or SCFGR1[ADRSTALL]. • When there is an address match on the first byte of a 10-bit address, SSR[AVF] is set, allowing you to read the received address before writing to Target Transmit ACK (STAR). 0b - Disable 1b - Enable
2 TXDSTALL	Transmit Data SCL Stall Enables SCL clock stretching when SSR[TDF] = 1 during a target-transmit transfer. Clock stretching occurs following the ninth bit, and is therefore compatible with HS mode. 0b - Disable 1b - Enable
1 RXSTALL	RX SCL Stall Enables SCL clock stretching when SSR[RDF] = 1 during a target-receive transfer. Clock stretching occurs following the ninth bit, and is therefore compatible with HS mode. 0b - Disable 1b - Enable
0 ADRSTALL	Address SCL Stall Enables SCL clock stretching when SSR[AVF] = 1. Clock stretching only occurs following the ninth bit, and is therefore compatible with HS mode. 0b - Disable 1b - Enable

66.3.6.1.26 Target Configuration 2 (SCFGR2)

Offset

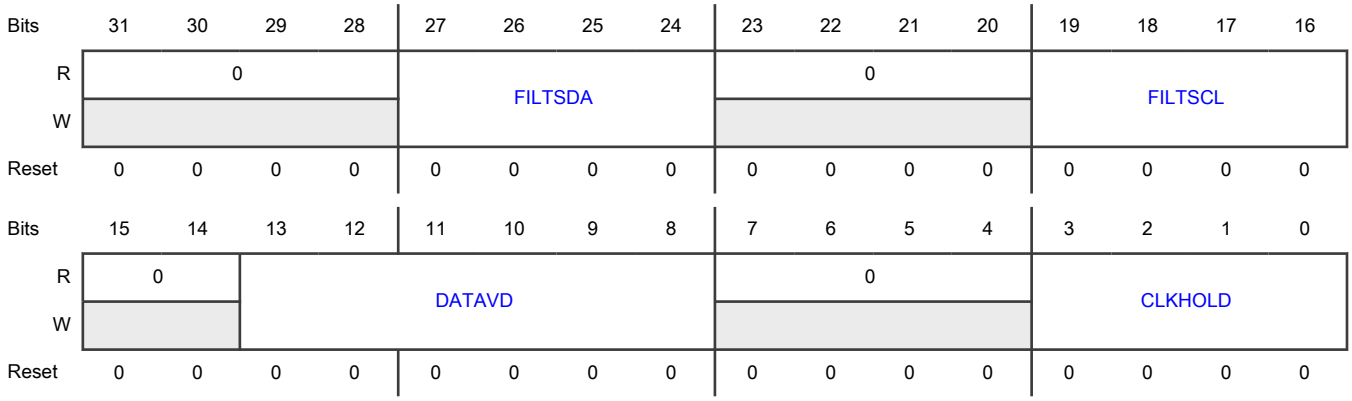
Register	Offset
SCFGR2	128h

Function

Configures data valid delay, clock hold time, and glitch filters for SDA and SCL.

Write to this register only when the I2C target is disabled.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 FILTSDA	Glitch Filter SDA Configures the I2C target digital glitch filters for SDA input. Writing 0 to this field disables the glitch filter. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. The latency through the glitch filter is equal to the number of cycles defined by this field + 3. The latency must be configured to be less than the minimum SCL low or high period. MCFGR1[PRESCALE] does not affect the glitch filter cycle count, and the glitch filter cycle count is disabled in HS mode.
23-20 —	Reserved
19-16 FILTSCL	Glitch Filter SCL Configures the I2C target digital glitch filters for SCL input. Writing 0 to this field disables the glitch filter. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. The latency through the glitch filter is equal to the number of cycles defined by this field + 3. The latency must be configured to be less than the minimum SCL low or high period. MCFGR1[PRESCALE] does not affect the glitch filter cycle count, and the glitch filter cycle count is disabled in HS mode.
15-14 —	Reserved
13-8	Data Valid Delay

Table continues on the next page...

Table continued from the previous page...

Field	Function
DATAVD	Configures the SDA data valid delay time for the I2C target, which is equal to FILTSCL + DATAVD + 3 cycles. The data valid delay must be configured to be less than the minimum SCL low period. MCFGR1[PRESCALE] does not affect the I2C target data valid delay time, and the I2C target data valid delay time is disabled in HS mode.
7-4 —	Reserved
3-0 CLKHOLD	Clock Hold Time Configures the minimum clock hold time for the I2C target, when clock stretching is enabled. The minimum hold time is equal to the number of cycles defined by this field + 3. MCFGR1[PRESCALE] does not affect the I2C target clock hold time, and the I2C target clock hold time is disabled in HS mode.

66.3.6.1.27 Target Address Match (SAMR)

Offset

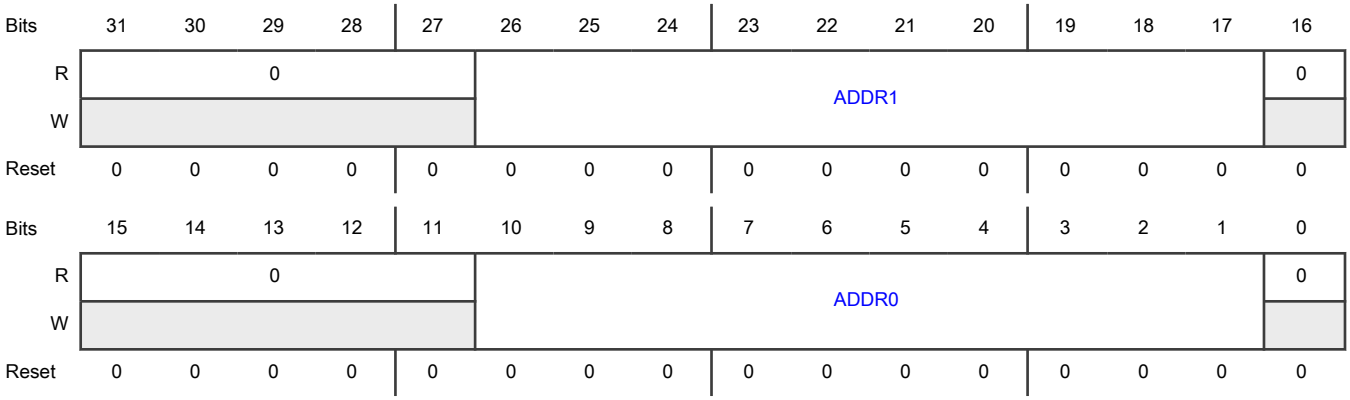
Register	Offset
SAMR	140h

Function

Contains address values for received target match comparison.

Write to this register only when the I2C target is disabled.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-17 ADDR1	Address 1 Value Contains the value of address 1, which is compared to the received address to detect the target address. In 10-bit mode, the first address byte is compared to {11110, ADDR1[26:25]} and the second address byte is compared to ADDR1[24:17]. In 7-bit mode, the address is compared to ADDR1[23:17].
16-11 —	Reserved
10-1 ADDR0	Address 0 Value Contains the value of address 0, which is compared to the received address to detect the target address. In 10-bit mode, the first address byte is compared to {11110, ADDR0[10:9]} and the second address byte is compared to ADDR0[8:1]. In 7-bit mode, the address is compared to ADDR0[7:1].
0 —	Reserved

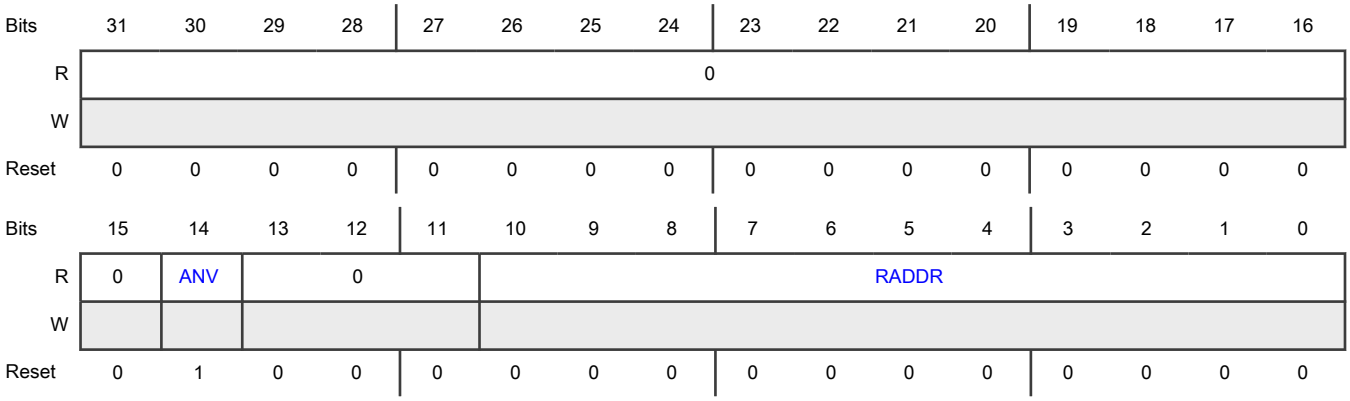
66.3.6.1.28 Target Address Status (SASR)

Offset

Register	Offset
SASR	150h

Function
Contains the received address and its validity.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 ANV	Address Not Valid Indicates whether SASR[RADDR] is valid. 0b - Valid 1b - Not valid
13-11 —	Reserved
10-0 RADDR	Received Address Contains the received address. Updates whenever SSR[AM0F] or SSR[AM1F] is set. Reading Target Address Status (SASR) clears SSR[AM0F] and SSR[AM1F]. In 7-bit mode, the address byte is stored in RADDR[7:0]. In 10-bit mode, the first address byte is {11110, RADDR[10:9], RADDR[0]} and the second address byte is RADDR[8:1]. The Read-or-Write bit is therefore always stored in RADDR[0]. When SCFGR1[ACKSTALL] = 1, if the first address byte matches in 10-bit mode, the first address byte is stored in RADDR[7:0] so you can read this field before writing the Transmit ACK. If the second address byte matches, this field is then updated with the full 10-bit address.

66.3.6.1.29 Target Transmit ACK (STAR)

Offset

Register	Offset
STAR	154h

Function

Configures choice of ACK or NACK on each received word.

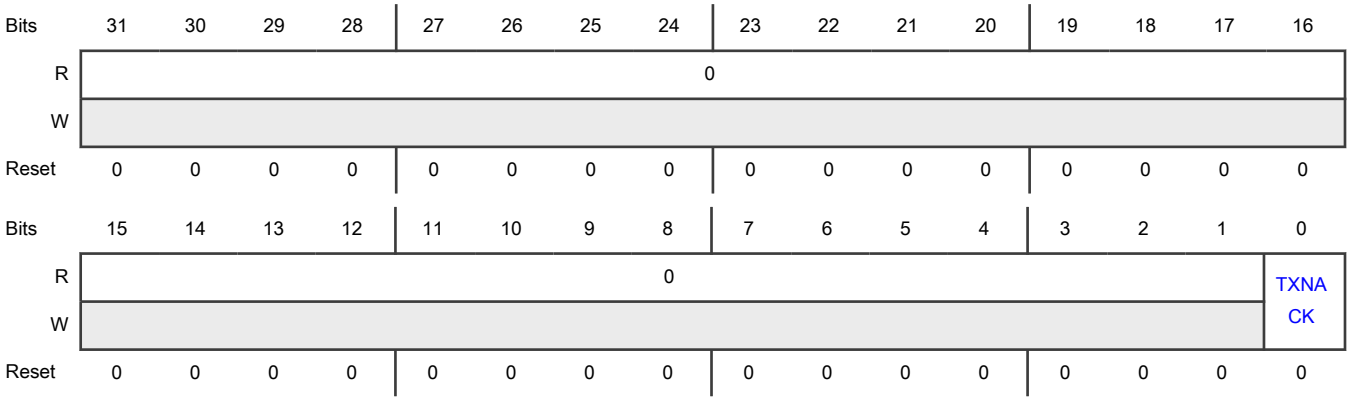
You can write to this register only when SCFGR1[ACKSTALL] = 1.

SCFGR1[ACKSTALL] enables clock stretching during the ACK-or-NACK bit slot. During this time, you can write to this register.

The logic ensures that the clock stretching continues for at least one bus clock cycle after this register is updated.

This clock stretching time can be extended via SCFGR2[CLKHOLD].

Diagram



Fields

Field	Function
31-1 —	Reserved
0 TXNACK	Transmit NACK Selects whether transmit ACK (logic 0) or NACK (logic 1) is returned on the bus by the I2C target after receiving each word. • When SCFGR1[ACKSTALL] = 1, a transmit NACK signal must be written once for each matching address byte and each received word. SCFGR1[ACKSTALL] must be 1, because that setting stalls the data transfer until software reads the received word (and determines whether to respond with an ACK or NACK). • To configure the default (ACK or NACK), you can write to this field when LPI2C target is disabled or idle. 0b - Transmit ACK 1b - Transmit NACK

66.3.6.1.30 Target Transmit Data (STDR)

Offset

Register	Offset
STDR	160h

Function

Contains the I2C target data to transmit.

Clock stretching (enabled or disabled) affects when the transmit data is transferred. SCFGR1[TXDSTALL] enables clock stretching during the first data bit of a target-transmit transfer.

If clock stretching is enabled (SCFGR1[TXDSTALL] = 1), the transmit data transfer is stalled until this register is updated. Clock stretching is extended by at least 1 bus clock cycle after this register is updated. Clock stretching can be delayed further by using SCFGR2[CLKHOLD].

If clock stretching is disabled (SCFGR1[TXDSTALL] = 0), the transmit data must be written before the start of the target-transmit transfer, otherwise SSR[FEF] is set.

10-8 RADDR	Received Address Contains address received by the LPI2C target. When both SCFGR1[RXCFG] and SSR[AVF] are 1, bits [10:8] of SASR[RADDR] are returned. Otherwise, this field returns zero.
7-0 DATA	Receive Data Contains data received by the LPI2C target. When both SCFGR1[RXCFG] and SSR[AVF] are 1, bits [7:0] of SASR[RADDR] are returned.

66.3.6.1.33 Controller Transmit Command Burst (MTCBR0 - MTCBR127)

Offset

For n = 0 to 127:

Register	Offset
MTCBRn	200h + (n × 4h)

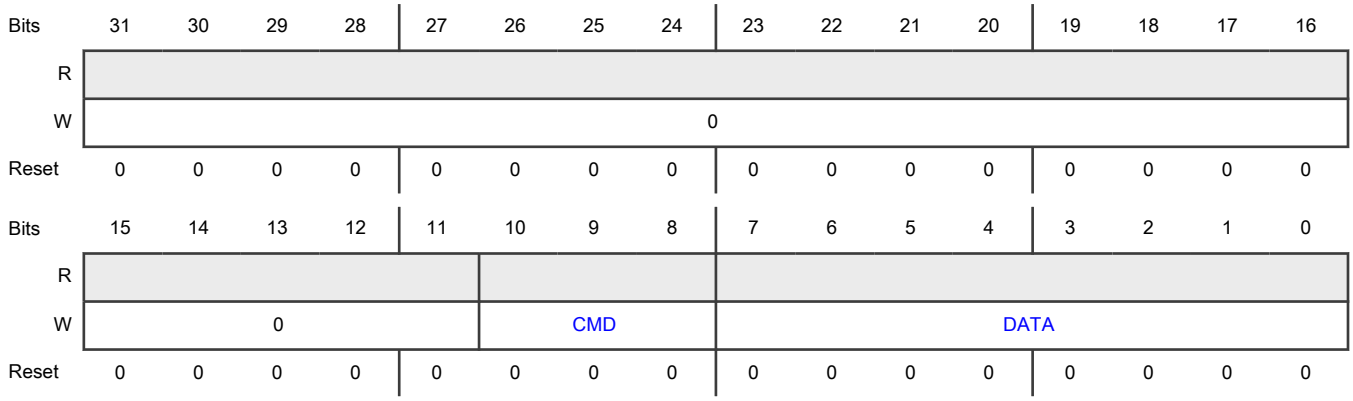
Function

Contains transmit Command and Data fields to support burst transfers.

Is an alias of the Controller Transmit Data Register designed to support incrementing burst transfers to the transmit FIFO by a DMA controller using aligned 8-bit, 16-bit, or 32-bit writes. The size of the Controller Transmit Data Burst Register is 512-bytes.

- An aligned 32-bit write in this region pushes one entry into the transmit FIFO.
- An aligned 16-bit write in this region to MTCBRn[15:0] pushes one entry into the transmit FIFO.
- An 8-bit write in this region to MTCBRn[7:0] updates DATA[7:0], but does not push the data into the transmit FIFO.
- An 8-bit write in this region to MTCBRn[15:8] pushes the data written to CMD[2:0] plus the previously written DATA[7:0] into the transmit FIFO.
- An 8-bit or 16-bit write in this region to MTXBRn[31:16] is ignored.

Diagram



Fields

7-0 DATA	Data Data is written to the Controller Transmit Data Register.

66.3.6.1.34 Transmit Data Burst (MTDBR0 - MTDBR252)

Offset

For n = 0 to 252:

Register	Offset
MTDBRn	400h + (n × 4h)

Function

Contains transmit Data fields to support burst transfers.

Is an alias of the Transmit Data Register designed to support incrementing burst transfers to the transmit FIFO by a DMA controller using 8-bit, 16-bit, or 32-bit writes. The CMD field is always zero-extended for transmit data. The size of the Transmit Data Burst Register is 1012 bytes.

- An aligned 32-bit write in this region pushes four zero-extended DATA entries into the transmit FIFO (DATA0 byte first). Note that the register access is extended by 3 wait states.
- An aligned 16-bit write in this region to either half of a 32-bit word pushes two zero-extended DATA entries into the transmit FIFO (DATA0 or DATA2 first). Note that the register access is extended by 1 wait state.
- An 8-bit write in this region pushes one zero-extended DATA entry into the transmit FIFO.

66.4 Low-Power Serial Peripheral Interface (LPSPI)

66.4.1 Overview

LPSPI provides an efficient interface (either as a master or slave) to an SPI bus, which is a synchronous serial communication interface used in embedded systems. It is typically used to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing with secure digital cards and LCD displays.

66.4.1.1 Block diagram

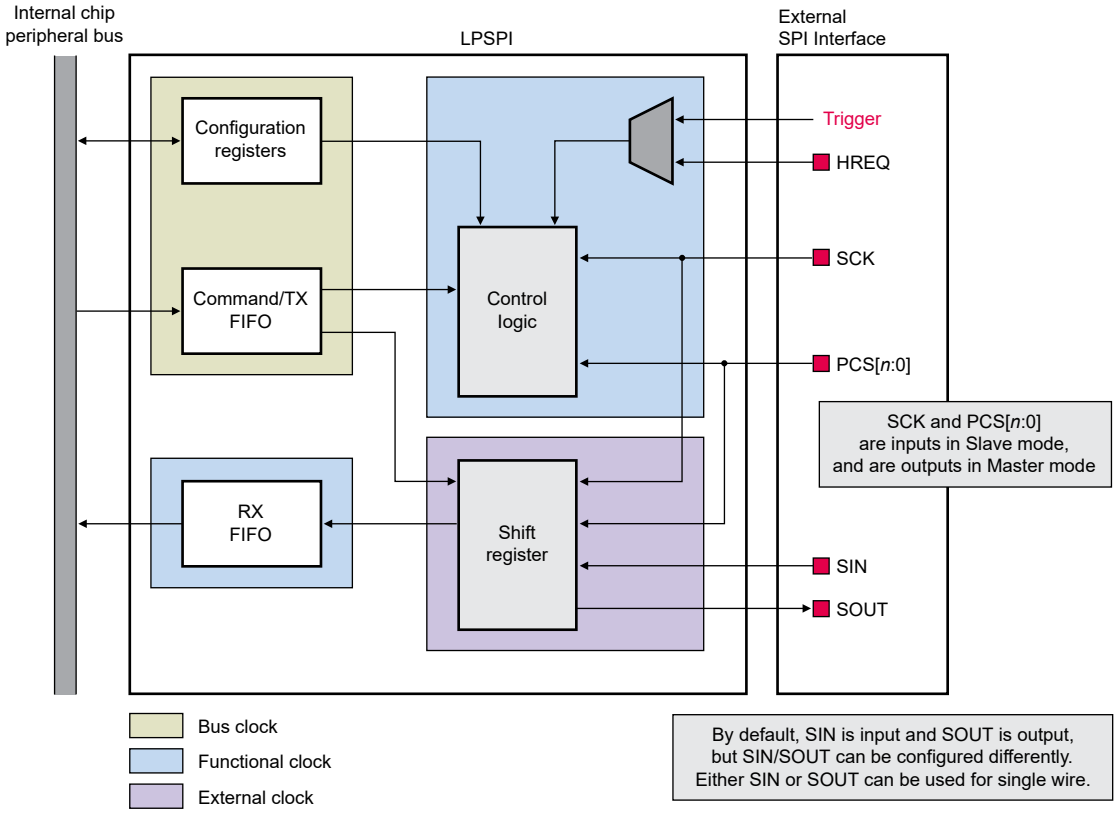

Figure 378. Block diagram

66.4.1.2 Features

- Minimal CPU overhead, with DMA transmit and receive requests supporting FIFO register accesses
- Operation continues in Deep Sleep mode, if configured to do so and an appropriate clock is available
- Support available for 32-bit word size
- Configurable clock polarity and phase
- Support available for 4 peripheral chip selects in Master mode
- Support available for Slave mode
- 8-word transmit and command FIFO
- 8-word receive FIFO
- Flexible timing parameters in Master mode, including SCK frequency and duty cycle, and delays between PCS and SCK edges
- Continuous transfer option to keep PCS asserted across multiple frames
- Full-duplex transfers that support 1-bit transmit and receive on each clock edge
- Half-duplex transfers that support:
  - 1-bit transmit or receive on each clock edge
  - 2-bit transmit or receive on each clock edge
  - 4-bit transmit or receive on each clock edge

- Option to use host request to control the start of an SPI bus transfer
- Receive data match logic that discards nonmatching data and interrupt on data match

66.4.2 Functional description

66.4.2.1 Master mode

66.4.2.1.1 Transmit and command FIFO commands

The transmit and command FIFO is a combined FIFO that includes both transmit data words and command words. You store:

- Transmit data words in the transmit and command FIFO, by writing to Transmit Data (TDR).
- Command words in the transmit and command FIFO, by writing to Transmit Command (TCR).

When a command word is at the top of the transmit and command FIFO, the actions that can occur depend on whether LPSPI is busy or between frames (see TCR[CONT] and TCR[CONTC]). See Table 562 for conditions and possible corresponding actions when a command word is at the top of the transmit and command FIFO.

Table 562. Possible actions when a command word is at the top of the transmit and command FIFO

Condition	Action
LPSPI is enabled and idle.	The command word is pulled from the FIFO, and this command word controls all subsequent transfers.
LPSPI is busy and TCR[CONTC] is 0.	The SPI frame completes at the end of the existing word, ignoring TCR[FRAMESZ]. The command word is then pulled from the FIFO and that command word controls all subsequent transfers (or until the next update to the command word). Note that a command word with TCR[CONTC] = 0 always terminates the existing transfer regardless of the previous TCR[CONT] value.
LPSPI is busy; the existing TCR[CONT] value is 1 and the new TCR[CONTC] value is 1.	The command word must be updated at the frame boundary. The command word is pulled from the FIFO during the last SCK pulse of the existing frame (based on the value of FRAMESZ), and the frame continues using the new command value for the rest of the frame (or until the next update to the command word). When TCR[CONTC] = 1, only the lower 24 bits of the command word are updated. If the command word is updated at a word boundary, then the transfer halts (stops) after that word. TCR[CONTC] is ignored when not at a frame boundary, so the frame ends prematurely.

TCR[CONT] = 1 keeps PCS asserted at end of frame, allowing the transfer to continue.

TCR[CONTC] = 1 specifies that this command word must not terminate the existing frame, and the transfer can continue using the new command word.

TCR[CONTC] = 1 is restricted in the sense that the new command must load on a frame boundary, and the only way for a transfer to continue from a frame boundary is when the previous command has TCR[CONT] = 1.

You can read the current state of the existing command word from Transmit Command (TCR). It requires at least three LPSPI functional clock cycles for Transmit Command (TCR) to update after you write to it (assuming an empty FIFO), and LPSPI must be enabled (CR[MEN] = 1).

Writing to Transmit Command (TCR) does not initiate an SPI bus transfer, unless TCR[TXMSK] = 1. When TCR[TXMSK] = 1, a new command word is not loaded until the end of the existing frame (based on the value of TCR[FRAMESZ]); at the end of the transfer, TCR[TXMSK] transitions to 0.

In Master mode, the LPSPI command word in Transmit Command (TCR) controls SPI attributes based on the selections in register fields. See Table 563 for TCR fields and associated functionality related to data transfer.

Table 563. Command word in Master mode

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
CPOL	Clock polarity	Specifies the polarity of the SCK pin. Any change of CPOL value causes a transition on the SCK pin.	N
CPHA	Clock phase	Specifies the clock phase of the transfer.	N
PRESCALE	Prescaler value	Specifies a prescaler used to divide the LPSPI functional clock, to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS enables LPSPI to connect to different slave devices at different frequencies.	N
PCS	Peripheral chip select	Specifies which PCS pin asserts for the transfer; the polarity of PCS is static and specified by CFGR1[PCSPOL]. If CFGR1[PCSCFG] = 1, do not select PCS[3:2].	N
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.	Y
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing with devices that organize data as big-endian.	Y
CONT	Continuous transfer	Configures LPSPI for a continuous transfer that keeps PCS asserted between frames (as specified by FRAMESZ). You must write a new command word to cause PCS to negate. Also, this field supports changing the command word at frame size boundaries.	Y
CONTC	Continuing command	Indicates that this is a new command word for the existing continuous transfer. When CONTC = 1, the command word must only be written to the transmit and command FIFO on a frame boundary.	Y
RXMSK	Receive data mask	Masks the receive data and does not store the masked receive data in the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.	Y
TXMSK	Transmit data mask	Masks the transmit data; masked transmit data is not pulled from the transmit FIFO, and the output data pin is 3-stated (unless otherwise configured by CFGR1[OUTCFG]). This option is useful for half-duplex transfers.	Y
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse: • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing with QuadSPI memory devices, and either TXMSK or RXMSK must also be 1.	Y
FRAMESZ	Frame size	Configures the frame size in number of bits equal to (FRAMESZ + 1):	Y

Table continues on the next page...

Table 563. Command word in Master mode (continued)

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
		• The minimum frame size is 8 bits. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remaining bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits.	

66.4.2.1.1.1 SPI bus transfers

LPSPI initiates an SPI bus transfer when all these conditions are true:

- Data is written to the transmit FIFO.
- The HREQ pin is asserted (or the HREQ function is disabled).
- LPSPI is enabled.

To perform the SPI bus transfer, LPSPI uses the attributes configured in Transmit Command (TCR) and the timing parameters defined in Clock Configuration (CCR).

The SPI bus transfer ends after the number of bits indicated by the value of FRAMESZ have been transferred (provided CONT = 0), or at the end of a word when a new transmit command word is at the top of the transmit and command FIFO. When LPSPI is disabled, the SPI bus transfers end after the transmit FIFO is empty and LPSPI is idle.

The HREQ input is only checked when PCS is negated.

66.4.2.1.1.2 Circular FIFO

The transmit and command FIFO supports a circular FIFO feature. This feature enables the LPSPI master to (periodically) repeat a short data transfer that fits within the transmit and command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled (CFGR0[CIRFIFO] = 1), the current state of the FIFO read pointer is saved and the status flags are not updated. After the FIFO is empty and LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit and command FIFO are not permanently pulled from the FIFO when Circular FIFO mode is enabled.

66.4.2.1.2 Receive FIFO and data match

The receive FIFO stores received data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of being stored in the receive FIFO:

- Received data is written to the receive FIFO when the last bit of the word is sampled.
- If the transmit FIFO is empty during a multiple-word or continuous transfer, then the receive data is written to the receive FIFO before the transfer stalls (assuming CFGR1[NOSTALL] = 0) while waiting for new transmit data or for a command word to be written.

LPSPI provides a receive data match function that can match received data against one of the two words in DMR0 and DMR1, or against a masked data word. You can also configure the received data match function to compare only the first one or two received data words since the start of the frame:

- Received data that is already discarded because of TCR[RXMSK] cannot cause the data match flag to set, and delays the receive data match on the first received data word, until all discarded data is received.

- You can configure the receive data match function to discard all received data until a data match is detected, using CFGR0[RDMO].
- After a receive data match, to allow all subsequent data to be received, write 0 to CFGR0[RDMO], and then write 0 to SR[DMF].

66.4.2.1.3 Timing parameters

The timing parameters that are used for all SPI bus transfers are relative to the LPSPI functional clock divided by the selection specified in TCR[PRESCALE]. Although you cannot change Clock Configuration (CCR) when LPSPI is busy, to support interfacing with different slave devices at different frequencies, you can change the TCR[PRESCALE] selection between SPI bus transfers by using Transmit Command (TCR).

NOTE

The minimum value shown in Table 564 is the minimum counter value, but the values of Clock Configuration (CCR) must also satisfy the data sheet specs based on the LPSPI functional clock frequency and prescaler value.

Table 564. Timing parameters

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Minimum value	Maximum value
Field	Name			
SCKSET	SCK setup phase	Configures the SCK setup phase to (SCKSET + 1) cycles. The setup phase is the SCK high period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK low period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
SCKHLD	SCK hold phase	Configures the SCK hold phase to (SCKHLD + 1) cycles. The hold phase is the SCK low period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK high period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
PCSPCS	PCS-to-PCS delay	Configures the minimum delay between PCS negation and the next PCS assertion to (PCSPCS + PCSPCS + 2) cycles. When the command word is updated between transfers, there is a minimum of (PCSPCS + 1) cycles between the command word update and any change on PCS pins.	0 (2 cycles)	255 (512 cycles)
SCKSCK	SCK-to-SCK delay	Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (SCKSCK + 1) cycles. This is useful when the external slave requires a large delay between different words of an SPI bus transfer.	0 (1 cycle)	255 (256 cycles)

Table continues on the next page...

Table 564. Timing parameters (continued)

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Minimum value	Maximum value
Field	Name			
PCSSCK	PCS-to-SCK delay	Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles.	0 (1 cycle)	255 (256 cycles)
SCKPCS	SCK-to-PCS delay	Configures the minimum delay between the last SCK edge and the PCS negation to (SCKPCS + 1) cycles.	0 (1 cycle)	255 (256 cycles)

Figure 379 shows the timing settings controlled by:

- TCR[CPHA]
- TCR[CPOL]
- CCR[SCKPCS]
- CCR[PCSSCK]
- CCR1[SCKSET]
- CCR1[SCKHLD]

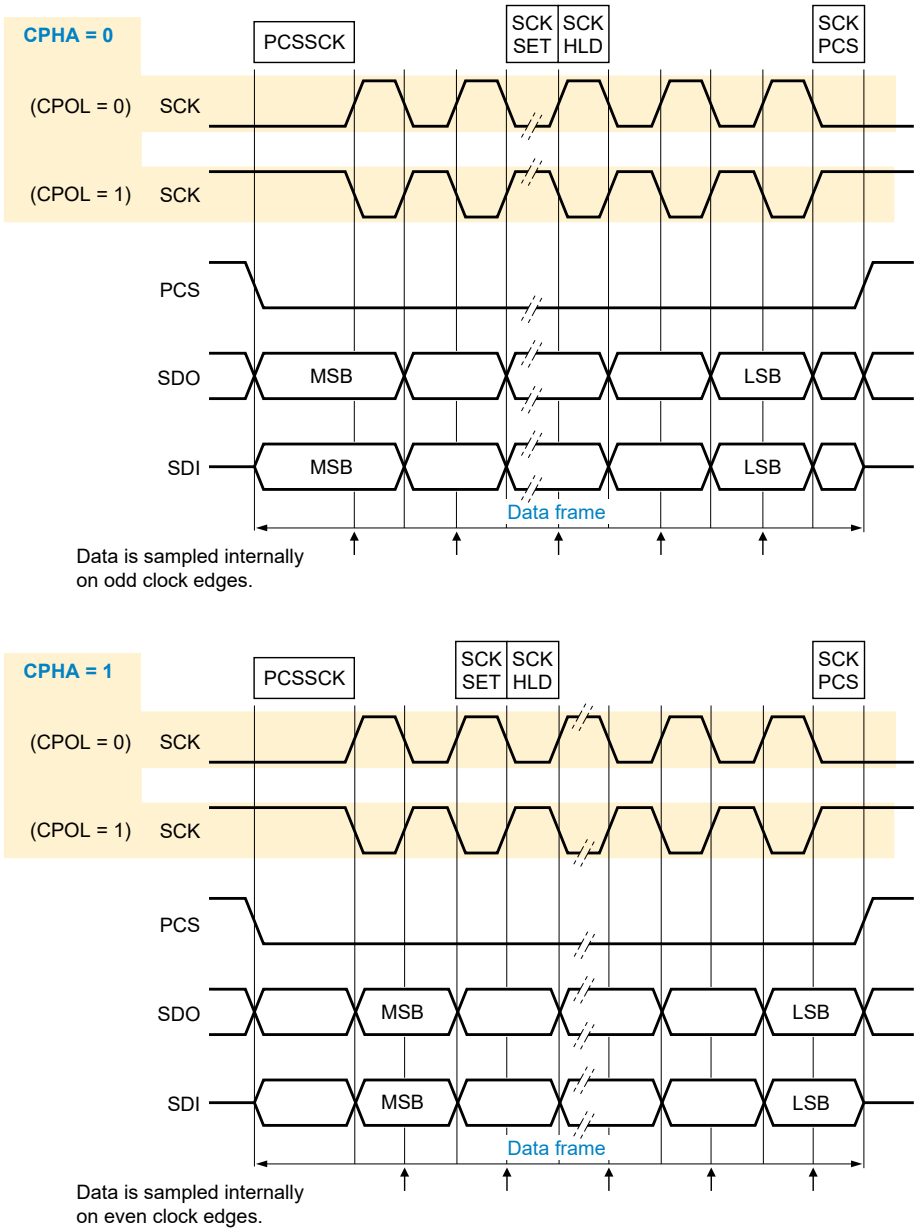

Figure 379. Clock phase (TCR[CPHA]) timing diagram example

To configure for a baud rate of 10 MHz with 50/50 duty cycle and with a functional clock frequency of 100 MHz, use the following settings:

- CCR1[SCKSET] = 0x4 (5 cycles)
- CCR1[SCKHLD] = 0x4 (5 cycles)
- CCR1[PCSPCS] = 0x8 (10 cycles)
- CCR1[SCKSCK] = 0x4 (5 cycles)
- CRR[PCSSCK] = 0x4 (5 cycles)
- CRR[SCKPCS] = 0x4 (5 cycles)
- TCR[PRESCALE] = 0x0 (divide by 1)

66.4.2.1.4 Pin configuration

Following are the pin configuration settings for half-duplex transfers:

- To swap directions or to support half-duplex transfers on the same pin, you can configure the SIN and SOUT pins using CFGR1[PINCFG].
- To specify whether an output data pin (SOUT, for example) 3-states when PCS is negated, or if the output data pin retains the last value, use CFGR1[OUTCFG].
- When configuring half-duplex transfers, you must configure the output data pins to 3-state when PCS is negated (CFGR1[OUTCFG] = 1).
- When performing half-duplex 2-bit transfers, you can write any value to CFGR1[PCSCFG].
- When performing half-duplex 4-bit transfers, you must write 1h to CFGR1[PCSCFG].

66.4.2.1.5 Clock loopback
