NXP Semiconductors
Reference Manual

Document identifier: MCXNP184M150F70RM
Rev. 7, 2025-10-10

MCX N Reference Manual

Supports MCX N94, N54, N53, N52 and N24

Contents

Chapter 1 About This Manual..... 15
1.1 About This Document..... 15

Chapter 2 Introduction..... 18
2.1 Overview..... 18
2.2 Target applications..... 19
2.3 Block diagram..... 21
2.4 System bus priority and arbitration..... 22
2.5 Functional overview..... 23

Chapter 3 Core Overview..... 36
3.1 Introduction..... 36
3.2 CPU0 and CPU1 Cortex-M33 Code and System buses..... 36
3.3 Nested Vectored Interrupt Controller (NVIC)..... 37
3.4 Implementation Defined Attribution Unit (IDAU)..... 44

Chapter 4 Memory..... 45
4.1 Memory architecture..... 45
4.2 System memory map..... 45
4.3 Cache..... 48
4.4 SRAM..... 48
4.5 Read Only Memory (ROM)..... 51
4.6 Internal flash..... 51
4.7 External memory..... 53
4.8 Peripheral Bridge (PBRG)..... 53

Chapter 5 Low-Power Cache Controller (LPCAC)..... 62
5.1 Chip-specific LPCAC information..... 62
5.2 Overview..... 63
5.3 Functional description..... 63
5.4 Signal descriptions..... 64
5.5 Memory regions and input control description..... 65

Chapter 6 CACHE64 Controller (CACHE64_CTRL)..... 67
6.1 Chip-specific CACHE64_CTRL information..... 67
6.2 Overview..... 68
6.3 Functional description..... 68
6.4 External signals..... 74
6.5 Initialization..... 74
6.6 Memory map and registers..... 75

Chapter 7 CACHE64 Policy Select (CACHE64_POLSEL)..... 83
7.1 Chip-specific CACHE64_POLSEL information..... 83
7.2 Overview..... 83
7.3 Functional description..... 84

7.4 Application information..... 85
7.5 Memory map and register definition..... 86

Chapter 8 Flash Memory Module (FMU)..... 90
8.1 Chip-specific FMU information..... 90
8.2 Overview.....91
8.3 Functional description.....92
8.4 External signals..... 108
8.5 Initialization.....108
8.6 Memory map and registers.....109
8.7 Glossary..... 121

Chapter 9 Flash Controller (FMC).....123
9.1 Chip-specific FMC information..... 123
9.2 Overview.....123
9.3 Functional description.....124
9.4 External signals..... 126
9.5 Initialization and application information.....126

Chapter 10 FlexSPI.....127
10.1 Chip-specific FlexSPI information.....127
10.2 Overview.....128
10.3 Functional description.....130
10.4 External signals..... 182
10.5 Initialization.....183
10.6 Application information..... 183
10.7 Memory map and register definition..... 201
10.8 AHB memory map definition.....274

Chapter 11 Performance Monitor (CMX_PERFMON)..... 275
11.1 Chip-specific CMX_PERFMON information..... 275
11.2 Overview.....276
11.3 Functional description.....277
11.4 External signals..... 278
11.5 Initialization.....278
11.6 Memory map and register definition..... 278

Chapter 12 Signal Multiplexing..... 284
12.1 Introduction.....284
12.2 Pinout..... 284

Chapter 13 ROM API..... 317
13.1 Overview.....317
13.2 Functional description.....317

Chapter 14 In-System Programming (ISP)..... 376
14.1 Overview.....376
14.2 Functional description.....376

14.3 ISP protocol....378
14.4 Bootloader packet types....379
14.5 Bootloader command set....386
14.6 Bootloader status error codes....407
14.7 UART ISP....414
14.8 I2C ISP....416
14.9 SPI ISP....418
14.10 USB ISP....422
14.11 CAN ISP....424

Chapter 15 Boot ROM....426
15.1 Overview....426
15.2 Functional description....426
15.3 Boot modes....433
15.4 External memory support....460
15.5 eFuse definitions....469

Chapter 16 Debug....470
16.1 Introduction....470
16.2 Test and debug port connectivity....471
16.3 Debug ROM table....474
16.4 Cortex-M33 core debug....474
16.5 In-system programming access port (ISP-AP)....475
16.6 CTI....475
16.7 Low-power debug....476
16.8 Debug authentication....477

Chapter 17 System Controller (SYSCON)....478
17.1 Chip-specific SYSCON information....478
17.2 Overview....478
17.3 Signals....479
17.4 Memory map and register definition....479

Chapter 18 PowerQuad DSP Coprocessor and Accelerator (PowerQuad)....639
18.1 Chip-specific PowerQuad information....639
18.2 Overview....639
18.3 Functional description....640
18.4 External signals....654
18.5 Initialization....654
18.6 Application information....655
18.7 Memory map and register definition....670

Chapter 19 SmartDMA Controller....695
19.1 Chip-specific SmartDMA Controller information....695
19.2 Overview....698
19.3 Functional description....699
19.4 Memory map....700

Chapter 20 Neural Processing Unit (NPU)....701

20.1 Chip-specific NPU information....701
20.2 Overview....701
20.3 Functional description....704
20.4 Memory map and register definitions....706

Chapter 21 CoolFlux BSP32 Subsystem....707
21.1 Chip-specific CoolFlux BSP32 information....707
21.2 Overview....707
21.3 Functional description....709
21.4 External signals....710
21.5 Initialization....710
21.6 Application information....710
21.7 Physical memory map....710
21.8 CoolFlux BSP32 register descriptions....711

Chapter 22 Inter-CPU Mailbox (MAILBOX)....723
22.1 Chip-specific MAILBOX information....723
22.2 Overview....723
22.3 Functional description....724
22.4 Signals....724
22.5 Memory map and register definition....724

Chapter 23 Enhanced Direct Memory Access (eDMA) Controller....731
23.1 Chip-specific eDMA information....731
23.2 Overview....740
23.3 Functional description....742
23.4 External signals....747
23.5 Initialization....747
23.6 Memory map/register definition....759

Chapter 24 Wakeup Unit (WUU)....831
24.1 Chip-specific WUU information....831
24.2 Overview....833
24.3 Functional description....835
24.4 External signals....836
24.5 Initialization....836
24.6 Application information....837
24.7 Memory map and register definition....837

Chapter 25 Event Generator (EVTG)....881
25.1 Chip-specific EVTG information....881
25.2 Overview....881
25.3 Functional description....882
25.4 External signals....887
25.5 Application information....887
25.6 Memory map and register definition....888

Chapter 26 Input Multiplexing (INPUTMUX)....903
26.1 Chip-specific INPUTMUX information....903

26.2 Overview....903
26.3 Functional description....904
26.4 External signals....904
26.5 Memory map and register definition....904

Chapter 27 Semaphores2 (SEMA42)....1124
27.1 Chip-specific SEMA42 information....1124
27.2 Overview....1124
27.3 Functional description....1125
27.4 Memory map/register definition....1128
27.5 External signals....1132
27.6 Initialization....1132

Chapter 28 Interrupt Monitor (INTM)....1133
28.1 Chip-specific INTM information....1133
28.2 Overview....1133
28.3 Functional description....1134
28.4 External signals....1134
28.5 Initialization....1134
28.6 INTM register descriptions....1134

Chapter 29 Error Injection Module (EIM)....1142
29.1 Chip-specific EIM information....1142
29.2 Overview....1143
29.3 Functional description....1145
29.4 Initialization....1145
29.6 EIM register descriptions....1145

Chapter 30 Error Recording Module (ERM)....1158
30.1 Chip-specific ERM information....1158
30.2 Overview....1159
30.3 Functional description....1160
30.4 Initialization....1161
30.5 ERM register descriptions....1162

Chapter 31 Programmable Logic Unit (PLU)....1179
31.1 Chip-specific PLU information....1179
31.2 Overview....1179
31.3 Functional description....1180
31.4 External signals....1182
31.5 Initialization....1182
31.6 Memory Map and register definition....1183

Chapter 32 Reset....1192
32.1 Overview....1192
32.2 Power reset sources....1192
32.3 External reset sources....1193
32.4 Internal reset sources....1194
32.5 Reset type....1195

Chapter 33 Clocking..... 1198
33.1 Configuring the main clock and system clock.....1198
33.2 Clock generation.....1198
33.3 Module clocking.....1205
33.4 Set up PLL0.....1216
33.5 Set up PLL1.....1216

Chapter 34 System Clock Generator (SCG).....1217
34.1 Chip-specific SCG information..... 1217
34.2 Overview.....1218
34.3 Functional description.....1220
34.4 External signals..... 1238
34.5 Initialization.....1239
34.6 Application information..... 1239
34.7 Memory map and register definition..... 1243

Chapter 35 Power Management.....1311
35.1 Introduction.....1311
35.2 Power domains.....1311
35.3 Power modes.....1315
35.4 Module operation in low-power modes.....1317
35.5 Power supply configurations.....1322
35.6 Power optimization..... 1324

Chapter 36 VBAT.....1327
36.1 Chip-specific VBAT information.....1327
36.2 Overview.....1328
36.3 Functional description.....1329
36.4 External signals..... 1331
36.5 Initialization.....1332
36.6 Application information..... 1332
36.7 Memory map and register definition..... 1333

Chapter 37 System Power Control (SPC).....1373
37.1 Chip-specific SPC information.....1373
37.2 Overview.....1376
37.3 Functional description.....1377
37.4 External signals..... 1384
37.5 Initialization.....1384
37.6 Application information..... 1384
37.7 SPC register descriptions..... 1385

Chapter 38 Core Mode Controller (CMC)..... 1427
38.1 Chip-specific CMC information..... 1427
38.2 Overview.....1428
38.3 Functional description.....1428
38.4 External signals..... 1436
38.5 Initialization.....1436
38.6 Application information..... 1436
38.7 Memory map and register descriptions..... 1437

Chapter 39 Security overview....1470
39.1 Disclaimer....1470
39.2 Overview....1470
39.3 Immutable Root of Trust....1471
39.4 Life-cycle management....1471
39.5 Secure boot....1472
39.6 Secure update....1472
39.7 Secure debug....1472
39.8 IP protection....1472
39.9 Secure isolation....1472
39.10 Secure attestation....1472
39.11 Secure storage....1473
39.12 Trust provisioning....1473
39.13 Secure key management....1473
39.14 Anomaly Detection and Reaction....1473

Chapter 40 Cyclic Redundancy Check (CRC)....1474
40.1 Chip-specific CRC information....1474
40.2 Overview....1474
40.3 Functional description....1475
40.4 External signals....1477
40.5 Initialization....1477
40.6 Use cases....1478
40.7 Memory map and register descriptions....1480

Chapter 41 Analog-to-Digital Converter (ADC)....1485
41.1 Chip-specific ADC information....1485
41.2 Overview....1487
41.3 Functional description....1489
41.4 External signals....1500
41.5 Initialization....1500
41.6 ADC register descriptions....1502

Chapter 42 12-bit Digital-to-Analog Converter (DAC)....1553
42.1 Chip-specific 12-bit DAC information....1553
42.2 Overview....1554
42.3 Functional description....1555
42.4 DAC external signal descriptions....1557
42.5 Initialization....1557
42.6 Application Information....1557
42.7 Memory map and register definition....1558

Chapter 43 14-bit Digital-to-Analog Converter (DAC)....1574
43.1 Chip-specific 14-bit DAC information....1574
43.2 Overview....1575
43.3 Functional description....1576
43.4 DAC external signal descriptions....1577
43.5 Initialization....1578
43.6 Application Information....1578
43.7 Memory map and register definition....1578

Chapter 44 Low-Power Comparator (CMP)....1594
44.1 Chip-specific CMP information....1594
44.2 Overview....1596
44.3 Functional Description....1598
44.4 External signal descriptions....1611
44.5 Initialization....1611
44.6 Application information....1612
44.7 LPCMP register descriptions....1613

Chapter 45 Voltage Reference (VREF)....1635
45.1 Chip-specific VREF information....1635
45.2 Overview....1635
45.3 Functional description....1636
45.4 External signals....1638
45.5 Initialization....1639
45.6 Register descriptions....1639

Chapter 46 Operational Amplifier (OPAMP)....1645
46.1 Chip-specific OPAMP information....1645
46.2 Overview....1646
46.3 Functional description....1647
46.4 External Signals....1650
46.5 Initialization....1650
46.6 Application Information....1650
46.7 Memory map and register definition....1651

Chapter 47 SINC Filter....1658
47.1 Chip-specific SINC information....1658
47.2 Overview....1661
47.3 Functional description....1663
47.4 External signals....1707
47.5 Initialization....1708
47.6 Application information....1709
47.7 SINC register descriptions....1724

Chapter 48 Standard Counter/Timers (CTIMER)....1769
48.1 Chip-specific CTIMER information....1769
48.2 Overview....1771
48.3 Functional description....1773
48.4 External signals....1775
48.5 Initialization....1776
48.6 Application information....1776
48.7 CTIMER register descriptions....1776

Chapter 49 SCTIMER....1796
49.1 Chip-specific SCTIMER information....1796
49.2 Overview....1796
49.3 Functional description....1799
49.4 External signals....1804
49.5 Initialization....1804

49.6 Application information..... 1805
49.7 Memory map and register definition..... 1808

Chapter 50 Multi-Rate Timer (MRT)..... 1857
50.1 Chip-specific MRT information..... 1857
50.2 Overview..... 1857
50.3 Functional description..... 1858
50.4 External signals..... 1860
50.5 Initialization..... 1860
50.6 Memory map and register descriptions..... 1860

Chapter 51 Windowed Watchdog Timer (WWDT)..... 1869
51.1 Chip-specific WWDT information..... 1869
51.2 Overview..... 1869
51.3 Functional description..... 1871
51.4 External signals..... 1873
51.5 Initialization..... 1874
51.6 Memory map and register definition..... 1874

Chapter 52 Micro-Tick Timer (UTICK)..... 1882
52.1 Chip-specific UTICK information..... 1882
52.2 Overview..... 1882
52.3 Functional description..... 1883
52.4 External signals..... 1884
52.5 Initialization..... 1884
52.6 UTICK register descriptions..... 1884

Chapter 53 OS Event Timer (OSTIMER)..... 1891
53.1 Chip-specific OSTIMER information..... 1891
53.2 Overview..... 1891
53.3 Functional description..... 1892
53.4 External signals..... 1893
53.5 Initialization..... 1893
53.6 Memory map and register definition..... 1893

Chapter 54 Enhanced Flex Pulse Width Modulator (PWM)..... 1901
54.1 Chip-specific PWM information..... 1901
54.2 Overview..... 1901
54.3 Functional description..... 1903
54.4 External Signals..... 1935
54.5 PWM register descriptions..... 1936

Chapter 55 Quadrature Decoder (QDC)..... 2062
55.1 Chip-specific QDC information..... 2062
55.2 Overview..... 2062
55.3 Functional description..... 2063
55.4 External signals..... 2076
55.5 Memory map and registers..... 2077

Chapter 56 Real-Time Clock Subsystem (RTC_SUBSYSTEM)..... 2104
56.1 Chip-specific RTC_SUBSYSTEM information..... 2104
56.2 Overview..... 2104
56.3 Functional description..... 2105
56.4 External signals..... 2106
56.5 Initialization..... 2106
56.6 RTC_SUBSYSTEM register descriptions..... 2106

Chapter 57 Real-Time Clock (RTC)..... 2111
57.1 Chip-specific RTC information..... 2111
57.2 Overview..... 2111
57.3 Functional description..... 2112
57.4 External Signals..... 2117
57.5 Memory map and registers..... 2117

Chapter 58 Frequency Measurement (FREQME)..... 2140
58.1 Chip-specific Frequency Measurement information..... 2140
58.2 Overview..... 2140
58.3 Functional description..... 2140
58.4 External signals..... 2142
58.5 Initialization..... 2142
58.6 Memory map and register definition..... 2142

Chapter 59 Low-Power Timer (LPTMR)..... 2151
59.1 Chip-specific LPTMR information..... 2151
59.2 Overview..... 2152
59.3 Functional description..... 2152
59.4 External signals..... 2155
59.5 Initialization..... 2155
59.6 Application information..... 2155
59.7 Memory map and register definition..... 2156

Chapter 60 External Watchdog Monitor (EWM)..... 2163
60.1 Chip-specific EWM information..... 2163
60.2 Overview..... 2163
60.3 Functional Description..... 2164
60.4 External signals..... 2167
60.5 Memory Map..... 2168

Chapter 61 USB Full-Speed Host and Device Controller (USBFS)..... 2175
61.1 Chip-specific USBFS information..... 2175
61.2 Overview..... 2175
61.3 Functional description..... 2178
61.4 External signals..... 2190
61.5 Initialization..... 2191
61.6 Application information..... 2191
61.7 Memory map and register definitions..... 2197

Chapter 62 Universal Serial Bus 2.0 High-Speed Integrated PHY (USBHS_PHY)..... 2250
62.1 Chip-specific USBHS_PHY information..... 2250
62.2 Overview..... 2250
62.3 Functional description..... 2251
62.4 External signals..... 2258
62.5 Initialization..... 2258
62.6 Application information..... 2259
62.7 USBPHY register descriptions..... 2260
62.8 Register macro usage..... 2310
62.9 References..... 2310

Chapter 63 USB Device Charger Detection Module (USBDCD)..... 2311
63.1 Chip-specific USBDCD information..... 2311
63.2 Overview..... 2311
63.3 Functional description..... 2312
63.4 External signals..... 2325
63.5 Initialization..... 2326
63.6 Application information..... 2326
63.7 USBDCD register descriptions..... 2327

Chapter 64 Universal Serial Bus High-Speed Controller (USBHS)..... 2338
64.1 Chip-specific USBHS information..... 2338
64.2 Overview..... 2338
64.3 Functional description..... 2339
64.4 External signals..... 2343
64.5 Initialization..... 2344
64.6 Application information..... 2345
64.7 USB non-core memory map/register definition..... 2375
64.8 USB core memory map/register definition..... 2380

Chapter 65 Ultra Secured Digital Host Controller (uSDHC)..... 2465
65.1 Chip-specific uSDHC information..... 2465
65.2 Overview..... 2465
65.3 Functional description..... 2468
65.4 External signals..... 2493
65.5 Application information..... 2494
65.6 uSDHC memory map and register definition..... 2511

Chapter 66 Low-Power Flexible Communications Interface (LP_FLEXCOMM) 2583
66.1 Chip-specific LP_FLEXCOMM information..... 2583
66.2 LP_FLEXCOMM..... 2583
66.3 Low-Power Inter-Integrated Circuit (LPI2C)..... 2590
66.4 Low-Power Serial Peripheral Interface (LPSPI)..... 2661
66.5 Low-Power Universal Asynchronous Receiver/Transmitter (LPUART)..... 2709

Chapter 67 Synchronous Audio Interface (SAI)..... 2780
67.1 Chip-specific SAI information..... 2780
67.2 Overview..... 2781

67.3 Functional description....2782
67.4 External signals....2789
67.5 Initialization....2790
67.6 Memory map and register definition....2790

Chapter 68 Flexible Controller Area Network (FlexCAN)....2830
68.1 Chip-specific CAN information....2830
68.2 Overview....2830
68.3 Functional description....2833
68.4 External signal descriptions....2883
68.5 Initialization and application information....2883
68.6 Memory map and register definition....2884

Chapter 69 EMVSIM....2980
69.1 Chip-specific EMVSIM information....2980
69.2 Overview....2980
69.3 Functional description....2982
69.4 External signals....2994
69.5 Initialization....2994
69.6 Application information....2996
69.7 Memory map and registers....2999

Chapter 70 Ethernet QoS (ENET)....3031
70.1 Chip-specific ENET information....3031
70.2 Overview....3031
70.3 Functional description....3033
70.4 Signals....3099
70.5 Memory Map and register definition....3100

Chapter 71 Flexible Input/Output (FlexIO)....3320
71.1 Chip-specific FlexIO information....3320
71.2 Overview....3324
71.3 Functional description....3326
71.4 External signals....3336
71.5 Initialization....3336
71.6 Application information....3336
71.7 Memory map and registers....3356

Chapter 72 Improved Inter-Integrated Circuit (I3C)....3403
72.1 Chip-specific I3C information....3403
72.2 Overview....3403
72.3 Functional description....3405
72.4 External signals....3418
72.5 Initialization....3418
72.6 Application information....3420
72.7 I3C register descriptions....3422

Chapter 73 General Purpose Input/Output (GPIO)....3524
73.1 Chip-specific GPIO information....3524

73.2 Overview....3525
73.3 Functional description....3526
73.4 External signals....3528
73.5 Initialization....3529
73.6 Application information....3529
73.7 Memory map and register definition....3529

Chapter 74 Pin Interrupt and Pattern Match (PINT)....3551
74.1 Chip-specific PINT information....3551
74.2 Overview....3552
74.3 Functional description....3552
74.4 External signals....3555
74.5 Initialization....3555
74.6 Application information....3555
74.7 Memory map and register definition....3558

Chapter 75 Port Control (PORT)....3573
75.1 Chip-specific PORT information....3573
75.2 Overview....3574
75.3 Functional description....3574
75.4 Initialization....3576

Chapter 1
About This Manual

1.1 About This Document

1.1.1 Audience

This manual is intended for the board-level product designers and product software developers. This manual assumes that the reader has a background in computer engineering and/or software engineering and understands the concepts of the digital system design, microprocessor architecture, Input/Output (I/O) devices, industry standard communication, and device interface protocols.

1.1.2 Organization

This document is organized into two main sets of chapters.

1. First set covers the chip at a system level and provides an architectural overview. It also covers the system memory map, system-level interrupt events, clock, reset and system controller.
2. Chapters in the second set provides a technical description of individual modules along with chip-specific contents at the beginning of each chapter.

1.1.3 Suggested Reading

This section lists the additional resources that provide background for the information in this manual, as well as general information about the architecture.

1.1.3.1 General Information

The following documentation provides useful background information about the Arm® Cortex® processor.

For information about the Arm Cortex processor see:

- **http://infocenter.arm.com**

Refer Security Primitives: Requirements in (I)IoT Systems document to familiarize with NXP's security nomenclature.

1.1.3.2 Related Documentation

For a current list of documentation, refer to **http://www.nxp.com**.

1.1.4 Conventions

This document uses the following notational conventions:

cleared / set	When a bit has a value of zero, it is said to be cleared; when it has a value of one, it is said to be set.
mnemonics	Instruction mnemonics are shown in lowercase bold.
italics	Italics indicate variable command parameters, for example, **bcctr***x*. The book titles in the text are set in italics.
15	An integer in decimal.
0x	the prefix to denote a hexadecimal number.
0b	The prefix to denote a binary number. Binary values of 0 and 1 are written without a prefix.
n'H4000CA00	The n-bit hexadecimal number.

BLK_REG_NAME	The register names are all uppercase. The block mnemonic is prepended with an underscore delimiter (_).
BLK_REG[FIELD]	The fields within registers appear in brackets. For example, ESR[RLS] refers to the Receive Last Slot field of the ESAI Status Register.
BLK_REG[*n*]	The bit number *n* within the BLK.REG register.
BLK_REG[*l:r*]	The register bit ranges. The ranges are indicated by the left-most bit number *l* and the right-most bit number *r*, separated by a colon (:). For example, ESR[15:0] refers to the lower half word in the ESAI Status Register.
x, U	In some contexts, such as signal encodings, an unitalicized x indicates a "don't care" or "uninitialized". The binary value can be 1 or 0.
x	An italicized *x* indicates an alphanumeric variable.
n, m	Italicized *n or m* represent integer variables.
!	Binary logic operator NOT.
&&	Binary logic operator AND.
||	Binary logic operator OR.
^ or <O+>	Binary logic operator XOR. For example, A <O+> B.
|	Bit-wise OR. For example, 0b0001 | 0b1000 yields the value of 0b1001.
&	Bit-wise AND. For example, 0b0001 and 0b1000 yields the value of 0b0000.
{A,B}	Concatenation, where the *n*-bit value A is prepended to the *m*-bit value B to form an (*n*+*m*)-bit value. For example, {0, REG*m* [14:0]} yields a 16-bit value with 0 in the most significant bit.
- or grey fill	Indicates a reserved bit field in a register. Although these bits can be written to with ones or zeros, they always read zeros.
>>	Shift right logical one position.
<<	Shift left logical one position.
<=	Assignment.
==	Compare equal.
!=	Compare not equal.
>	Greater than.
<	Less than.

1.1.5 Register Access

1.1.5.1 Register Diagram Field Access Type Legend

This figure provides the interpretation of the notation used in the register diagrams for a number of common field access types:

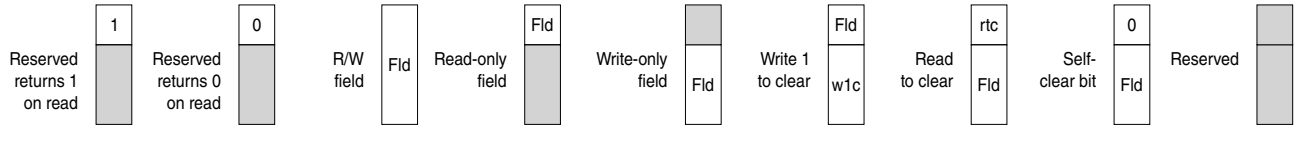

Figure 1. Register Field Conventions

NOTE

For reserved register fields, the software should mask off the data in the field after a read (the software can't rely on the contents of data read from a reserved field) and always write all zeros.

1.1.5.2 Register Macro Usage

A common operation is to update one field without disturbing the contents of the remaining fields in the register. Normally, this requires a read-modify-write (RMW) operation, where the CPU reads the register, modifies the target field, then writes the results back to the register. This is an expensive operation in terms of CPU cycles, because of the initial register read.

To address this issue, some hardware registers are implemented as a group, including registers that can be used to either set, clear, or toggle (SCT) individual bits of the primary register. When writing to an SCT register, all the bits set to 1 perform the associated operation on the primary register, while the bits set to 0 are not affected. The SCT registers always read back 0 and should be considered write-only. The SCT registers are not implemented if the primary register is read-only.

With this architecture, it is possible to update one or more fields using only register writes. First, all bits of the target fields are cleared by a write to the associated clear register, then the desired value of the target fields is written to the set register. This sequence of two writes is referred to as a clear-set (CS) operation.

A CS operation does have one potential drawback. Whenever a field is modified, the hardware sees a value of 0 before the final value is written. For most fields, passing through the 0 state is not a problem. Nonetheless, this behavior is something to consider when using a CS operation.

Also, a CS operation is not required for fields that are one-bit wide. While the CS operation works in this case, it is more efficient to simply set or clear the target bit (that is, one write instead of two). A simple set or clear operation is also atomic, while a CS operation is not.

Note that not all macros for set, clear, or toggle (SCT) are atomic. For registers that do not provide hardware support for this functionality, these macros are implemented as a sequence of read-modify-write operations. When an atomic operation is required, the developer should pay attention to this detail, because unexpected behavior might result if an interrupt occurs in the middle of the critical section comprising the update sequence.

A set of SCT registers is offered for registers in many modules on this device, as described in this manual.
In a module memory map table, the suffix _SET, _CLR, or _TOG is added to the base name of the register.
For example, the CCM_ANALOG_PLL_ARM register has three other registers called CCM_ANALOG_PLL_ARM_SET, CCM_ANALOG_PLL_ARM_CLR, and CCM_ANALOG_PLL_ARM_TOG.

In the sub-section that describes one of these sets of registers, a short-hand convention is used to denote that a register has the SCT register set. There is an italicized *n* appended to the end of the short register name. Using the above example, the name used for this register is CCM_ANALOG_PLL_ARM*n*. When you see this designation, there is a SCT register set associated with the register, and you can verify this by checking it in the memory map table. The address offset for each of these registers is given in the form of the following example:

Address: 20C_8000h base + 0h offset + (4d × i), where i=0d to 3d

In this example, the address for each of the base registers and their three SCT registers can be calculated as:

Register	Address
CCM_ANALOG_PLL_ARM	20C_8000h
CCM_ANALOG_PLL_ARM_SET	20C_8004h
CCM_ANALOG_PLL_ARM_CLR	20c_8008h
CCM_ANALOG_PLL_ARM_TOG	20C_800Ch

Chapter 2
Introduction

2.1 Overview

The MCX N dual-core microcontroller series combines two Arm Cortex-M33 cores with a Neural Processing Unit (NPU) Neutron1-16, a CoolFlux BSP32, a PowerQuad DSP Co-processor, TrustZone capabilities, and multiple high-speed connectivity options running at 150 MHz. To support a wide variety of applications, the MCX N series includes advanced serial peripherals, timers, high-precision analog, and state-of-the-art security features like secure user code, data, and communications. All MCX N dual-core products include dual-bank flash which supports read while write operation from internal flash. They also support large external serial memory configurations. The MCX N dual-cores series are as follows:

- **N52:** Mainstream MCU with a second M33 core, CoolFlux BSP32 programmable for PLC connectivity, PowerQuad, advanced timers, analog, high-speed connectivity (including Hi-Speed USB), and FlexIO which can be programmed as an LCD controller.
- **N53:** Mainstream MCU with a second M33 core, Edge AI-ready NPU, PowerQuad, advanced timers, analog, high-speed connectivity (including Hi-Speed USB), audio, and FlexIO which can be programmed as an LCD controller.
- **N54**: Mainstream MCU with a second M33 core, Edge AI-ready NPU, PowerQuad, advanced timers, analog, high-speed connectivity (including Hi-Speed USB), 10/100 Ethernet, and FlexIO which can be programmed as an LCD controller.
- **N94**: Integration CPU, NPU, DSP, advanced timers, high precision analog, high-speed connectivity including Hi-Speed USB, CAN 2.0, 10/100 Ethernet, and FlexIO which can be programmed as an LCD controller.

The MCX N single-core series microcontrollers combine the Arm Cortex-M33 TrustZone® core with multiple high-speed connectivity options running at 150 MHz. To support a wide variety of applications, the MCX N series includes advanced serial peripherals, timers, high-precision analog, and state-of-the-art security features like secure user code, data, and communications. All MCX N products include dual-bank flash which supports read while write operation from internal flash. The MCX N single-core series are general purpose MCUs with advanced peripherals and a range of serial, analog, and high-speed connectivity. The MCX N single-core series are as follows:

- **N24:** General purpose MCU with advanced peripherals and a range of serial, analog and high-speed connectivity including 10/100Mbps Ethernet. It integrates up to 2MB of flash memory and 512kB of SRAM alongside motor control and graphics capabilities.

The chip includes these key features:

Table 1. Key features

Function	Features
Security	• TrustZone for Armv8M • Secure boot, firmware update, and debug authentication using ROM • EdgeLock® secure subsystem (ELS) • Public-key cryptography (PKC) • External and internal flash memory interface with on-the-fly PRINCE decryption and encryption • Physically Unclonable Function (PUF) hardware options • Factory Root of Trust (RoT) programming • Tamper detection • Analog and digital glitch detection

Table continues on the next page...

Table 1. Key features (continued)

Function	Features
	• Code Watchdog (CDOG) • Intrusion and Tamper Response Controller (ITRC)
Industrial strength	• Industrial temperature rating • Industrial communication protocol support (CAN-FD) • High-resolution mixed signal analog • BLDC and PMSM motor control support • Integrated sensor interfaces: I3C, I2C, SPI, and UART • 15-year longevity • Configurable RAM ECC • Ethernet (ENET) with QoS
Power-efficient operating modes	• Down to 57 µA/MHz (3.3 V, @25 ℃) in OD Active Mode (while(1) executing from flash, DC/DC enabled) • 170 µA in Deep Sleep mode (full 512 KB SRAM retention, 3.3 V, @25 ℃) • 5.2 µA in Power Down mode (full 512 KB SRAM retention, 3.3 V, @25 ℃) • Down to 2.0 µA in Deep Power Down mode, 5.3 ms wake-up (RTC enabled 8 KB RAM and Reset pin enabled, @25 ℃)

2.2 Target applications

- **Industrial**
  - Energy Storage and Management System
  - Smart Metering
  - Power Line Communication
  - Factory Automation
  - Industrial HMI
  - Mobile Robotics Ecosystem
  - Motion Control and Robotics
  - Motor Drives
  - Brushless DC Motor (BLDC) Control Permanent Magnet Synchronous Motor (PMSM)
  - Edge AI/ML Anomaly Detection and Predictive Maintainance
- **Smart Home**
  - Home Control Panel
  - Home Security and Surveillance
  - Home Security and Surveillance
  - Major Home Appliances
  - Robotic Appliance

- Smart Speaker
- Soundbar
- Gaming Accessories
- Smart Lighting
- Smart Power Socket and Light Switch
- Edge AI/ML Vision and Voice Detection / Recognition

2.3 Block diagram

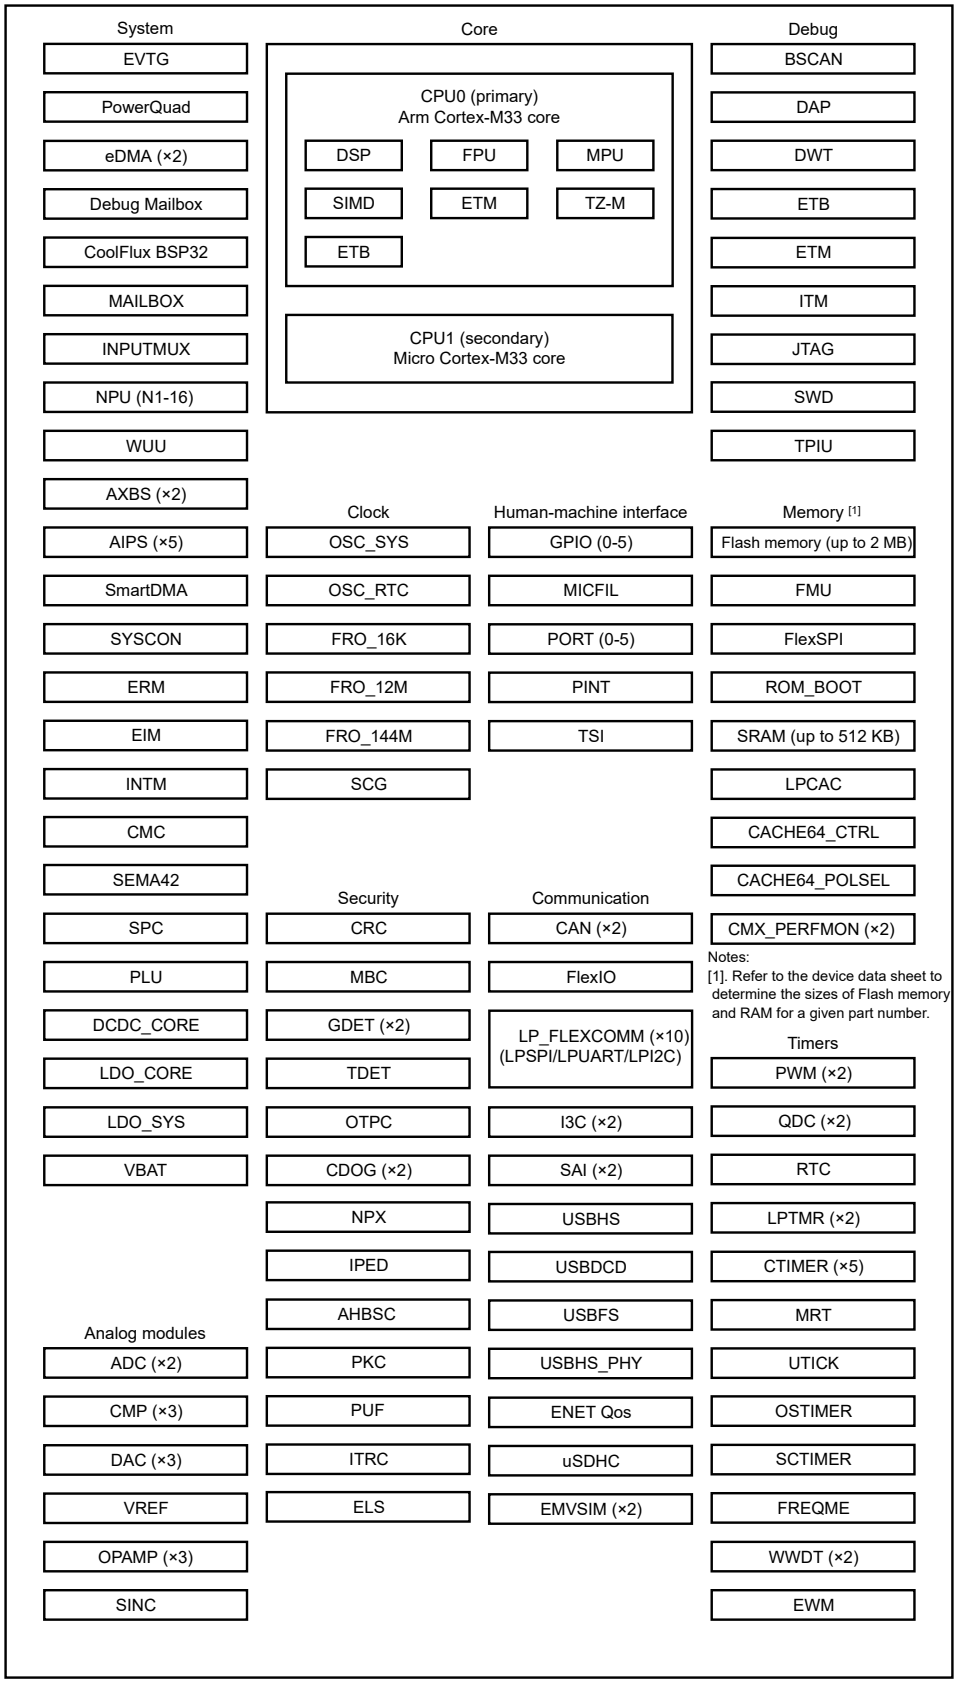

Figure 2. Features block diagram

NOTE

See the datasheet for information on peripheral availability and quantity for the specific part number and package.

Figure 3 shows the chip's block diagram, including bus connections.

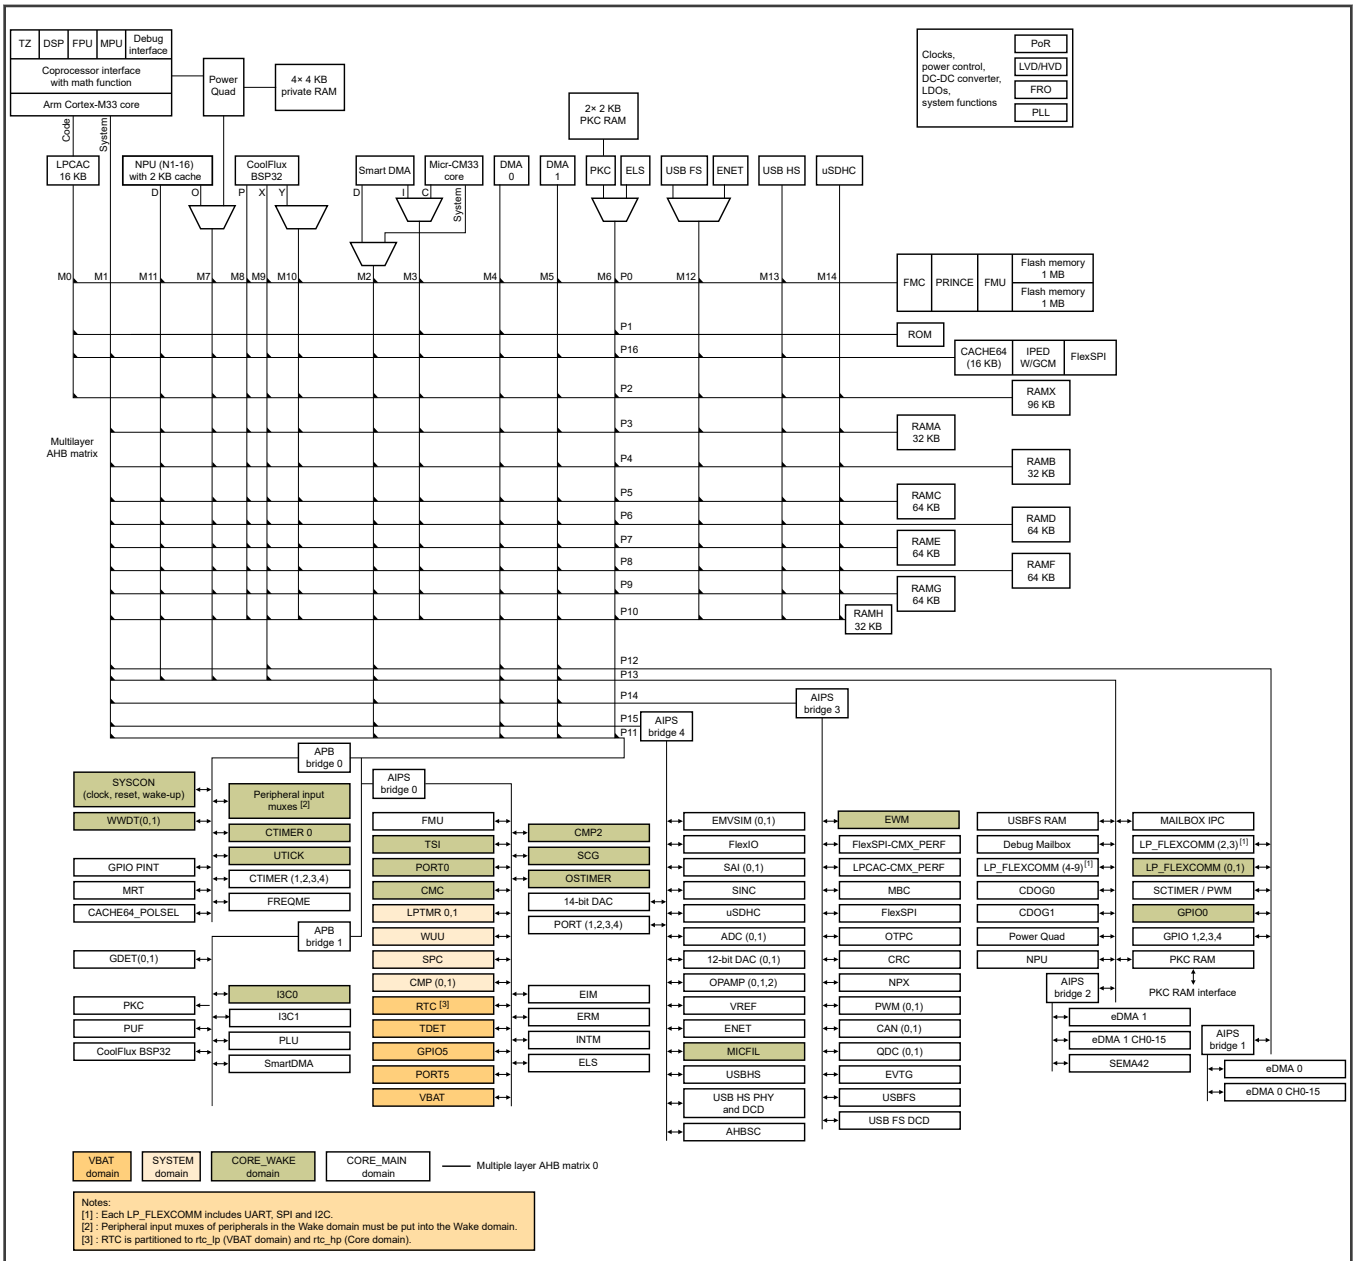

Figure 3. Bus matrix block diagram

NOTE

See the datasheet for information on peripheral availability and quantity for the specific part number and package.

2.4 System bus priority and arbitration

As shown in Figure 3 , this device includes a number of masters that can access the various slave ports. The multilayer AHB matrix allows for concurrent accesses when multiple masters are attempting to access different slave ports. If multiple masters attempt an access to the same slave port at the same time then arbitration is required.

The SYSCON_AHBMATPRIO register is where the programmable priorities for each of the master ports can be configured. Masters are assigned a priority value between zero and three with three being the highest priority. If two ports have the same priority, then the lowest port number is given priority.

There are some master ports that are shared between two masters. Where the port is shared, only one of the masters can have an active access at a time. The priority between two masters sharing a port uses a fixed arbitration scheme. The table below lists the master or masters for each of the ports. In the case where the port is shared, the high-priority master is specified:

Table 2. AHB bus matrix ports

Master port	Master	Accessible slave ports	Inaccessible slave ports	AHB ID
M0	CPU0 (CM33) code bus	P0 - P2 and P16	P3 - P15	0
M1	CPU0 (CM33) system bus	P3 - P16	P0 - P2	1
M2	CPU1 (Micr-CM33) code bus (low-priority)	P0 and P2 - P16	P1	2
	SmartDMA data bus (high-priority)			3
M3	CPU1 (Micr-CM33) system bus (low-priority)	P0 - P10 and P16	P11 - P15	4
	SmartDMA instruction bus (high-priority)			5
M4	DMA0	P0 - P16	None	6
M5	DMA1	P0 and P2 - P16	P1	7
M6	PKC (low-priority)	P0 - P11 and P16	P12 - P15	8
	ELS (high-priority)			9
M7	PowerQuad (low-priority)	P0, P2 - P10, P13, and P16	P1, P11 - P12, and P14 - P15	10
	NPU operand bus (high-priority)			11
M8	CoolFlux BSP32 program memory bus	P0, P2 - P10, and P16	P1 and P11 - P15	12
M9	CoolFlux BSP32 X-data memory bus	P0, P2 - P10, P12 - P13, and P16	P1, P11, and P14 - P15	13
M10	CoolFlux BSP32 Y-data memory bus	P0, P2 - P10, and P16	P1 and P11 - P15	14
M11	NPU data bus	P0, P2 - P10, P13, and P16	P1, P11 - P12, and P14 - P15	16
M12	USBFS (low-priority)	P0, P2 - P10, and P16	P1 and P11 - P15	17
	Ethernet (high-priority)			18
M13	USBHS	P0, P2 - P10, and P16	P1 and P11 - P15	19
M14	uSDHC	P2 - P10	P0 - P1 and P11 - P16	20

2.5 Functional overview

Table 3 shows the chip modules organized by functional category.

Table 3. Module functional categories

Module category	Description
Core	• The Arm Cortex®-M33 is part of the Cortex-M Series of processors targeting microcontroller cores focused on cost-sensitive, deterministic, and interrupt-driven environments. • The Cortex-M33 processor is based on the Armv8-M Architecture and ThumbR-2 ISA and is upward compatible with the Cortex-M7, M4, M3, M1, M0, and M0+.
System	• PowerQuad DSP Coprocessor and Accelerator (PowerQuad) • Debug Mailbox • SmartDMA Controller • Neural Processing Unit (NPU N1-16) • CoolFlux BSP32 • Inter-CPU Mailbox (MAILBOX) • Enhanced Direct Memory Access (eDMA) • Wake-Up Unit (WUU) • Event Generator (EVTG) • AHB Cross-Bar Switch (AXBS) Lite • Peripheral Inputmux • Semaphore (SEMA42) • Interrupt Monitor (INTM) • Error Injection Module (EIM) • Error Reporting Module (ERM) • Programmable Logic Unit (PLU) • System Power Controller (SPC) • Core Mode Controller (CMC)
Memory	• ROM-BOOT and ROM-CODE • Static Random Access Memory (SRAM) • AHB Low Power Cache Controller (LPCAC) • CACHE64 Controller (CACHE64_CTRL) • CACHE64 Policy Select (CACHE64_POLSEL) • Flash Management Unit (FMU) • Flash Memory Controller (FMC) supporting counter mode PRINCE • Flexible Serial Peripheral Interface (FlexSPI) supporting IPED with GCM. FlexSPI also supports Octal and Quad memory interfaces. • Performance Monitor (CMX_PERFMON)

Table continues on the next page...

Table 3. Module functional categories (continued)

Module category	Description
Clock	• VBAT — Crystal Oscillator - Real Time Clock (OSC_RTC) — 16 K Free Running Oscillator (FRO_16K) • System Clock Generator (SCG) — Crystal Oscillator - System (OSC_SYS) — 144 M Free Running Oscillator (FRO_144M) — 12 M Free Running Oscillator (FRO_12M) — PLL and USB PLL
Security	• EdgeLock Secure Subsystem (ELS) • Public Key Cryptography (PKC) • Physical Unclonable Function (PUF) • Cyclic Redundancy Check (CRC) • PRINCE encryption/decryption • Digital tamper (TDET) • Code Watchdog (CDOG) • Digital and analog Glitch Detect (GDET) • OTP Controller (OTPC) • Intrusion and Tamper Response Controller (ITRC) • AHB Secure Controller (AHBSC) • Memory Block Checker (MBC) • TrustZone
Analog	• 16/12-bit Analog-to-Digital Converter (ADC) • 14-bit Digital-to-Analog Converter (DAC) • 12-bit Digital-to-Analog Converter • Low Power Comparator (LPCMP) • Voltage Reference (VREF) • Operational Amplifier (OPAMP) • Sigma-Delta Modulator (SINC)
Timer	• Standard Counter/Timer (CTIMER) • SCTimer • Multi Rate Timer (MRT) • Windowed Watchdog Timer (WWDT) • Micro-Tick (UTICK) Timer

Table continues on the next page...

Table 3. Module functional categories (continued)

Module category	Description
	• OS Event Timer (OSTIMER) • Enhanced Flex Pulse Width Modulator (PWM) • Quadrature Decoder (QDC) • Real Time Clock (RTC) • Frequency Measurement (FREQME) • Low-power Timer (LPTMR) • External Watchdog Monitor (EWM)
Communication	• Universal Serial Bus - Full Speed (USBFS) and Transceiver • USB High-Speed (USBHS) Controller and Physical Layer Interface (PHY) • Universal Serial Bus - Device Charger Detect (USBDCD) • Ultra Secured Digital Host Controller (uSDHC) • LP_FLEXCOMM with Low Power Inter-Integrated Circuit (LPI2C), Low Power Serial Peripheral Interface (LPSPI), and Low Power Universal Asynchronous Receive/Transmit (LPUART) support • Serial Audio Interface (SAI) • FlexCAN with Flexible Data rate (FlexCAN FD) • Euro, MasterCard, and Visa Subscriber Identification Module (EMVSIM) • Ethernet QoS (ENET) • Flexible Input/Output (FlexIO) • Improved Inter-Integrated Circuit (I3C)
Human Machine Interface (HMI)	• General Purpose Input/Output (GPIO) • Port Control (PORT) • Pin Interrupt and Pattern Match (PINT) • PDM Microphone Interface (MICFIL) • Touch Sense Interface (TSI)

2.5.1 Core

The following core modules are available on this chip.

Table 4. Core modules

Module	Description
CPU0	An Arm Cortex-M33 processor that runs at a frequency of up to 150 MHz (device revision 1B only). The configuration of this instance includes MPU, FPU, DSP, ETM, TrustZone, and coprocessor interface.

Table continues on the next page...

Table 4. Core modules (continued)

Module	Description
CPU1	An Arm Cortex-M33 coprocessor that runs at a frequency of up to 150 MHz (device revision 1B only). The configuration of this instance supports system tick timer but does not include MPU, FPU, DSP, ETM, and TrustZone.
Digital Signal Processing Extensions (DSP)	The Cortex-M33 processor features extended single-cycle Multiply Accumulate (MAC) instructions, optimized Single Instruction Multiple Data (SIMD) arithmetic, and saturating arithmetic instructions.
Floating Point Unit (FPU)	Provides single-precision floating point computation, compliant to the IEEE Standard for Floating-Point Arithmetic (IEEE 754).
Memory Protection Unit (MPU)	Provides support for eight unified protection regions, overlapping protection regions with ascending region priority, and access permissions. MPU mismatches and permission violations invoke the HardFault handler.
Nested Vectored Interrupt Controller (NVIC)	The Armv8M exception model and Nested-Vectored Interrupt Controller (NVIC) implement a relocatable vector table supporting external interrupts, a single non-maskable interrupt (NMI), and priority levels.
System Tick Timer (SysTick)	See the *Armv8M Architecture Reference Manual* for more information about this system timer.

2.5.2 Debug

The following debug modules are available on this chip.

Table 5. Debug modules

Module	Description
Boundary Scan (BSCAN)	Allows external circuitry testing of a chip. The serial scan chain also permits the system signals flowing into and out of the system logic to be sampled and examined without causing interference with the normal device operation.
Cross Trigger Interface (CTI)	Enables the debug logic of the chip to interact with each other (cross-trigger).
Data Watchpoint and Trace (DWT)	A generic name for modules that allow debug access of the Cortex-M33. The DWT consists of the Debug Watchpoint and Trace (DWT) module and the Flash Patch and Breakpoint (FPB) unit.
Debug Access Port (DAP)	Enables real-time access to the chip registers from an external debugger without halting the processor cores.
Embedded Trace Buffer (ETB)	On-chip memory used to store real-time trace instruction and data trace information from the Embedded Trace Macrocell (ETM).
Embedded Trace Macrocell (ETM)	Real-time trace module providing real-time instruction and data tracing of a processor core.

Table continues on the next page...

Table 5. Debug modules (continued)

Module	Description
Instruction Trace Macrocell (ITM)	Provides a memory-mapped register interface that applications can use to write logging or event words for profiling software.
Joint Test Action Group (JTAG)	Implements serial communication protocol for communicating with the Test Access Port (TAP).
Serial Wire Debug (SWD)	A serial communication interface used for debugging devices with multiple cores while only requiring a single external interface.
Trace Port Interface Unit (TPIU)	Acts as a bridge between the on-chip trace data from the modules (such as ETM or ITM which have separate system IDs) to the external world.

2.5.3 System

The following system modules are available on this chip.

Table 6. System modules

Module	Description
Power Quad	Hardware accelerator targeting common calculations in DSP applications.
Debug mailbox	Supports Arm Serial Wire Debug mode.
SmartDMA	Supports unique reduced instruction sets and performs event- and IO-driven handling to offload the work from the Arm processor.
CoolFlux BSP32	Dual-Harvard, dual-multiplier processor based on the ultra-low power CoolFlux architecture. Supports 16-bit and 32-bit scalar operations, as well as complex SIMD operations and data types.
Inter-CPU Mailbox (MAILBOX)	Provides simple communication and resource allocation between CPUs.
Event Generator (EVTG)	Supports the generation of a configurable number of EVENT signals. EVTG includes two AND/OR/INVERT (AOI) modules and one configurable flip-flop.
AHB Cross-Bar Switch (AXBS) Lite	Connects bus masters and bus slaves. This allows the bus masters to access different bus slaves simultaneously and provides arbitration among the bus masters when they access the same slave.
Peripheral Bridge(AIPS_Lite)	Converts an AMBA AHB interface to a peripheral interface that allows the Peripheral Bridge2 (PBRIDGE2) controller to interface to multiple peripherals. This device has five peripheral bridges.
System Controller (SYSCON)	Provides controls and configurations of the system and peripherals for the multiple functions.

Table continues on the next page...

Table 6. System modules (continued)

Module	Description
Core Mode Controller (CMC)	Provides control and protection on entry and exit to each power mode, control for the System Power Controller (SPC), and reset entry and exit for the complete device.
Enhanced Direct Memory Access (eDMA)	Performs source and destination address calculations and data-movement operations. Capable of performing complex data transfers with minimal intervention from a host processor.
NPU	A Neural Network processing accelerator. It is a configurable architecture comprising weight compression, compute engine, and data canvas.
Wake-up Unit (WUU)	Allows selection of external pins and internal modules as interrupt wake-up sources from Power Down and Deep Power Down modes.
Peripheral Input Multiplexing (INPUTMUX)	Allows the trigger output of one peripheral to be connected to the trigger input of a second peripheral.
Semaphore (SEMA42)	A memory-mapped module that provides the robust hardware support needed in multi-core systems for implementing semaphores. It provides a simple mechanism to achieve lock and unlock operations via a single write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.
Interrupt monitor (INTM)	Provides a mechanism to monitor the latency of the responses on interrupt requests.
Error Injection Module (EIM)	Provides a method for diagnostic coverage of internal memories (for example, system RAM, cache RAMs, and peripheral memories).
Error Reporting Module (ERM)	Provides information and optional interrupt notification on memory error events associated with error correction code (ECC) and parity.
System Power Controller (SPC)	Provides control over the operation and configuration of the system power generation modules to optimize power consumption for the level of functionality needed.
Direct Current/Direct Current Converter - Core (DCDC_CORE)	A voltage converter for generating the core voltage for the chip.
Low Drop Out Regulator - Core (LDO_CORE)	A voltage regulator for generating the core voltage for the chip.
Low Drop Out Regulator - System (LDO_SYS)	A voltage regulator for generating the system voltage for the chip.
Programmable Logic Unit (PLU)	Monitors the state of input devices and makes decisions based on a custom program to control the state of output devices.

2.5.4 Memory

The following memory modules are available on this chip.

Table 7. Memory modules

Module	Description
Static Random Access Memory (SRAM)	Internal system SRAM memory. Each individual block of SRAM can be configured to be retained in low-power modes.
AHB Low Power Cache Controller (LPCAC)	A processor-local level 1 (L1) bus cache controller for use with cores using AMBA-AHB input/output buses.
CACHE64 Controller (CACHE64_CTRL)	Includes cache memory controller (CACHE64), which is a general purpose AMBA AHB bus protocol cache.
CACHE64 Policy Select (CACHE64_POLSEL)	Monitors incoming AHB addresses to define the policy that the cache controller (CACHE64_CTRL) uses.
Flash Management Unit (FMU)	Manages the interface between the chip and the on-chip flash memory.
Flash Memory Controller (FMC)	A programmable, non-volatile flash memory that can store executable program code or data.
Flexible Serial Peripheral Interface (FlexSPI)	Interfaces with external serial flash devices.
Performance Monitor (CMX_PERFMON)	Contains counters which can be configured to count events in order to calculate performance of a CPU, cache, or memory.

2.5.5 Clock

The following clock modules are available on this chip.

Table 8. Clock sources

Module	Description
Crystal Oscillator - Real Time Clock (OSC_RTC)	Generates, in conjunction with an external 32 kHz crystal, a 32 kHz reference clock for the RTC that can also be used by the chip.
Free Running Oscillator - 16 K (FRO_16K)	An ultra low-power internal 16.384 kHz clock source. It is functional down to VBAT mode. The FRO_16K is trimmed to +/- 6% accuracy over the entire voltage and temperature range.
System Clock Generator (SCG)	Provides you with access to the configuration control registers for the system level clock sources.
Crystal Oscillator - System (OSC_SYS)	Generates, in conjunction with an external crystal or resonator, a reference clock for the chip.
Free Running Oscillator - 144 MHz (FRO_144M)	An internal clock source that generates a 144 MHz reference clock for the RTC that can also be used by the chip.
Free Running Oscillator - 12 MHz (FRO_12M)	An internal clock source that generates a 12 MHz frequency for use by the chip.

Table continues on the next page...

Table 8. Clock sources (continued)

Module	Description
PLL and USB PLL	PLL0 and PLL1 allow the chip operation up to the maximum CPU rate without the need for a high-frequency external clock. PLL0 and PLL1 can run from the internal FRO_144M, the 40 MHz OSC, or the 32.768 kHz RTC oscillator. Both support fractional division and spread-spectrum. There is a PLL in USBHS PHY to provide 480 MHz clock for USBHS. USB PLL uses external 16 MHz, 19.2 MHz, 20 MHz, 24 MHz, or 32 MHz as a reference clock. The USB PLL clock can be used as a system clock source.

2.5.6 Security

The following security modules are available on this chip.

Table 9. Security modules

Module	Description
ELS	Security subsystem ensuring key isolation.
PKC	Public-key cryptography accelerator
Physically Unclonable Function (PUF) SRAM controller/Quiddikey	Includes PUFs that are virtually impossible to duplicate or clone and consequently helps in secure key generation and storage and device authentication.
PUF subsystem	Stores the applications keys, which are provisioned to ELS key store, securely.
Cyclic Redundancy Check (CRC)	Provides error detection for all single and double errors, and many multi-bit errors.
PRINCE	Ensures confidentiality protection of the content stored on internal flash. Also ensures both confidentiality and integrity protection of the content stored on external flash. Run-time code integrity protection is ensured during execution from external flash.
Digital Tamper (TDET)	Supports tamper detection.
Code Watchdog Timer (CDOG)	Helps protect the integrity of software by detecting unexpected changes (faults) in the code execution flow.
Digital and analog Glitch Detect (GDET)	A fully digital detector connected to the supply lines to provide glitch detection.
OTPC w 4kb Fuse	An on-chip EFUSE OTP controller from TSMC which supports loading and housing of EFUSE content into shadow registers.
Intrusion and Tamper Response Controller (ITRC)	Provides mechanism to configure the response action for an intrusion event detected by an on-chip security sensor.

Table continues on the next page...

Table 9. Security modules (continued)

Module	Description
Secure AHB bus and AHB Controller (AHBSC)	The device implements a second layer of protection with secure AHB Bus to support secure trusted execution at the system level. The secure AHB Controller provides access policies for all the bus slaves via checker functions.
Memory Block Checker (MBC)	Provides read, write, and execute access control per block to internal flash memory.
TrustZone - M (TZM)	Is an Arm security feature related to hardware-enforced access control mechanisms.

2.5.7 Timer

The following timer modules are available on this chip.

Table 10. Timer modules

Module	Description
Standard Counter/Timer (CTIMER)	Each Counter/timer is designed to count cycles of the CTIMER function clock.
SCTIMER	A powerful and flexible timer module capable of creating complex PWM waveforms with minimal or no CPU intervention.
Multi Rate Timer (MRT)	Provides a repetitive 24-bit interrupt timer with four channels.
Windowed Watchdog Timer (WWDT)	Helps reset or interrupt an erroneous microcontroller within a programmable time.
Micro-Tick (UTICK) Timer	A 31-bit timer that provides a fixed time interval between interrupts.
OS Event Timer (OSTIMER)	A 42-bit Gray code counter.
Enhanced Flex Pulse Width Modulator (PWM)	Generates various switching patterns, including highly sophisticated waveforms, and controls different Switched Mode Power Supplies (SMPS) topologies.
Quadrature Decoder (QDC)	Interfaces to position and speed sensors that are used in industrial motor control applications.
Real Time Clock Subsystem (RTC_SUBSYSTEM)	Supports subsecond and wake timer features.
Real Time Clock (RTC)	Provides time keeping and calendaring functions and additionally provides protection against spurious memory and register updates and battery operation.
Frequency Measurement (FREQME)	Provides high-accuracy frequency measurement function for on-chip and off-chip clocks.
Low-power Timer (LPTMR)	A 16-bit timer or pulse counter with compare feature.

Table continues on the next page...

Table 10. Timer modules (continued)

Module	Description
External Watchdog Monitor (EWM)	Monitors external circuits, as well as the MCU software flow. Also provides a backup mechanism to the internal watchdog that resets the MCU's CPU and peripherals.

2.5.8 Communication

The following communication modules are available on this chip.

Table 11. Communication modules

Module	Description
Universal Serial Bus Full Speed Host and Device Controller (USBFS)	Supports OTG protocol. The OTG implementation in this module provides a device solution for a full speed compliant peripheral along with limited host functionality for implementing a USB 2.0 full speed/low speed compliant embedded host.
Universal Serial Bus 2.0 High-Speed Integrated Physical Layer Interface (USBHS_PHY)	This chip contains USB 2.0 PHY macrocells capable of connecting to USB host/device systems at the USB low-speed (LS) rate of 1.5 Mbits/s, full-speed (FS) rate of 12 Mbits/s, or at the USB 2.0 high-speed (HS) rate of 480 Mbits/s. The USB PHY supports USB Battery Charger Specification Revision 1.2.
Universal Serial Bus - Device Charger Detect (USBDCD)	Monitors the USB data lines to detect attachment to a USB charging port meeting the USB Battery Charging Specification Rev1.2.
Universal Serial Bus - High Speed Controller (USBHS)	Provides high performance USB functionality that conforms to the Universal Serial Bus Specification, Rev. 2.0.
Ultra Secured Digital Host Controller (uSDHC)	Provides the interface between the host system and the SD/SDIO/MMC cards.
Low-power Flexible Communications Interface (LP_FLEXCOMM)	Provides an option to choose one peripheral function from a choice of several peripherals, such as Low Power Inter-Integrated Circuit (LPI2C), Low Power Serial Peripheral Interface (LPSPI), and Low Power Universal Asynchronous Receive/Transmit (LPUART).
Serial Audio Interface (SAI)	A full-duplex, serial port that allows the chip to communicate with serial devices that implement the Inter-IC sound bus (I2S) and the Intel® AC97 standards.
FlexCAN with FD	A communication controller implementing the Controller Area Network (CAN) protocol according to the ISO 11898-1 standard and CAN 2.0 B protocol specifications.
Smart Card Interface Module (EMVSIM)	Facilitates communication to Smart Cards compatible with the EMV v4.3 standard (Book 1) and Smart Cards compatible with ISO/IEC 7816-3 Standard.

Table continues on the next page...

Table 11. Communication modules (continued)

Module	Description
Ethernet QoS	Enables a host to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2008 standard.
Flexible Input/Output (FlexIO)	Emulation of a variety of serial/parallel communication protocols. Flexible 16-bit timers with support for a variety of trigger, reset, enable and disable conditions.
Improved Inter-Integrated Circuit (I3C)	An extension of the I2C bus protocol supporting higher speeds.

2.5.9 Human Machine Interface (HMI)

The following HMI modules are available on this chip.

Table 12. HMI modules

Module	Description
General Purpose Input/Output (GPIO)	All GPIO pins support interrupt and DMA request generation.
Port Control (PORT)	Provides support for pad control functions.
Pin Interrupt and Pattern Match (PINT)	Pins with configurable functions can serve as external interrupts or inputs to the pattern match engine. Uses standard GPIO functions as inputs.
PDM Microphone Interface (MICFIL)	Supports audio delivery from microphones to the processor in several applications, such as mobile telephones.
Touch Sense Interface (TSI)	Provides touch sensing detection on capacitive touch sensors.

2.5.10 Analog

The following analog modules are available on this chip.

Table 13. Analog modules

Module	Description
Analog-to-Digital Converter (ADC)	A dual 16-bit successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.
14-bit Digital-to-Analog Converter (DAC)	A high performance, 14-bit general-purpose DAC the output of which can be placed on an external pin or set as one of the inputs to the analog comparator or ADC.
12-bit Digital-to-Analog Converter	A low power, 12-bit general-purpose DAC the output of which can be placed on an external pin or set as one of the inputs to the analog comparator or ADC.
Low Power Comparator (LPCMP)	Provides a circuit for comparing two analog input voltages.

Table continues on the next page...

Table 13. Analog modules (continued)

Module	Description
Voltage Reference (VREF)	Supplies an accurate voltage output that can be used by internal or external peripherals.
Operational Amplifier (OPAMP)	Supports more than 100 dB amplifier gain.
SINC Filter	Converts external ADC sigma-delta modulator bit stream to data stream.

Chapter 3
Core Overview

3.1 Introduction

This section covers the core modules included in this chip.

NOTE

This chapter is also repeated in the MCX N Security Reference Manual, with differences only in the Peripheral Bridge memory map tables in Peripheral Bridge (PBRG). The sections in the Reference Manual does not show the security relevant information in it.

3.2 CPU0 and CPU1 Cortex-M33 Code and System buses

CPU0 is the primary Cortex-M33 (ver r0p4-00rel0) processor, which supports TrustZone-M, Floating Point Unit (FPU), and Memory Protection Unit (MPU).

The MCX N device also includes a second instance of Cortex-M33, CPU1, which is the secondary Mirco-CM33 intended to offload the main processor to support special dedicated applications. The configuration of this instance does not include MPU, FPU, DSP, ETM, Trustzone-M, Secure Attribution Unit (SAU) or co-processor interface. SYSTICK is supported on both cores.

Cortex-M33 implements a modified Harvard memory architecture using two 32-bit bus interfaces: the Code and System buses. The bus interfaces are activated by address range and can include both instruction fetches and operand data references on a given bus port. (A traditional Harvard architecture strictly separates instruction fetches and operand data references onto specific bus ports regardless of access address.) The Code bus is typically used for instruction fetching and data accesses of PC-relative data, while the system bus is typically used for operand data references to the on-chip and off-chip memories and peripheral accesses. The bus structure fully supports concurrent instruction fetch and data accesses, but the Cortex-M33 implementations can generate both types of references on each bus.

NOTE

It is recommended that performance critical code be located such that it fetches from the Code bus interface as defined by addresses < 0x2000_0000.

3.2.1 Code Bus access

CPU0 and CPU1 code bus can access memory as shown in Bus matrix block diagram . CPU0 code bus access is routed to Low Power Cache (LPCAC) controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable accesses or forwarding the cache write-through and cache miss accesses to the downstream memories through the master port of this cache controller.

3.2.2 System bus access

All System bus accesses are routed to the target address in destination memories through multilayer AHB matrix slave port. See Bus matrix block diagram .

3.2.3 Access control

CPU0 Code and System Bus accesses are checked by the core access control logic, that is, IDAU/SAU and MPU. All requests that miss or bypass the cache are checked by downstream secure AHB bus logic. The caches include protection control signals (HPROT[3:0], which is defined in Arm AHB protocol) and processing domain bits as part of the tags. If a fetch address hits the cache but the protection control and/or domain bits are different, the cache controller forces a miss with the allocate location the same as the address hit location in the cache. This policy allows all the downstream checks to take place, and this new miss is loaded in the cache with the updated protection control and domain bits overwriting the line with the same address. This keeps the cache coherent while always checking accesses that need to see the downstream checks.

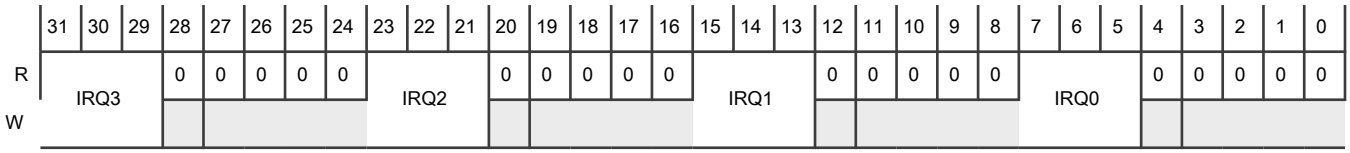
CPU1 access is controlled by secure AHB control.

Read, write, and execute access control to on-chip flash is controlled by Memory Block Checker (MBC). See MBC chapter in MCX N Security Reference Manual.

3.3 Nested Vectored Interrupt Controller (NVIC)

3.3.1 Interrupt priority levels

This device supports 8 priority levels for interrupts. Therefore, in the NVIC each source in the IPR registers contains 3 bits. For example, IPR0 is shown below:



3.3.2 Non-Maskable Interrupt (NMI) configuration

The Non-Maskable Interrupt (NMI) enable bit and source selection bits are implemented for each core in SYSCON NMI Source Select register.

3.3.3 Interrupt channel assignments

The interrupt source assignments are defined in the following table.

- Vector number - the value stored on the stack when an interrupt is serviced.
- IRQ number - non-core interrupt source count, which is the vector number minus 16.

The IRQ number is used within Arm's NVIC documentation.

Table 15. Interrupt Vector Assignments

Address	Vector	IRQ	NVIC non-IPR register number	NVIC IPR register number	Alias	Source Description
0000_0000	0	-	-	-	Cortex-M33	Initial Stack Pointer
0000_0004	1	-	-	-	Cortex-M33	Initial Program Counter
0000_0008	2	-	-	-	Cortex-M33	Non-Maskable Interrupt (NMI)
0000_000C	3	-	-	-	Cortex-M33	Hard Fault
0000_0010	4	-	-	-	Cortex-M33	MemManage Fault
0000_0014	5	-	-	-	Cortex-M33	Bus Fault
0000_0018	6	-	-	-	Cortex-M33	Usage Fault

3.4 Implementation Defined Attribution Unit (IDAU)

MCX N implements a simple attribution unit that divides whole memory map into secure or non-secure regions. All peripherals and memories are aliased at two locations.

- Address 0x0000_0000 to 0x1FFF_FFFF
  - Non-Secure always
- Address 0x2000_0000 to 0xFFFF_FFFF
  - If Address Bit_28 = 0 Non-Secure
  - If Address Bit_28 = 1 Secure

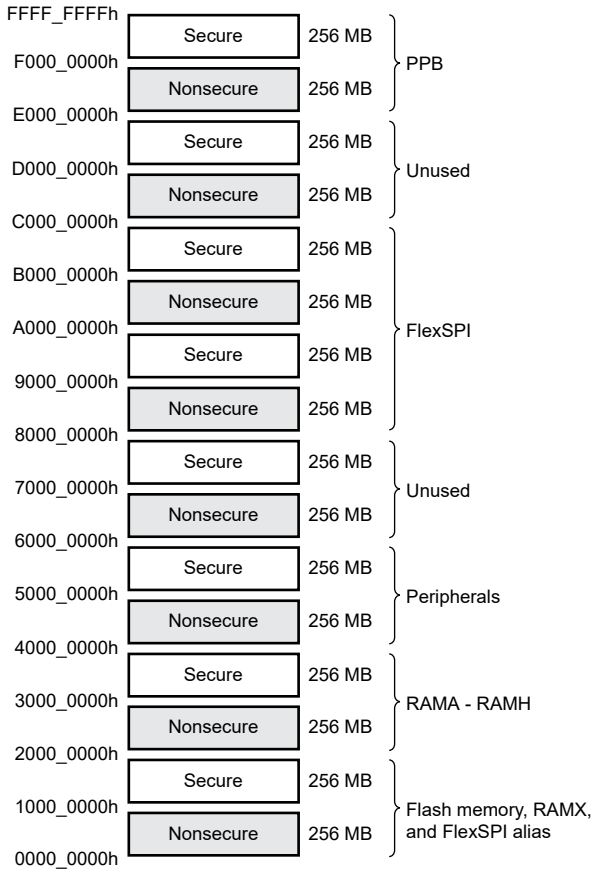

Figure 4. IDAU implementation

Chapter 4
Memory

4.1 Memory architecture

The memory architecture supports a wide range of target applications and maximizes performance while maintaining low power consumption. The memory system of the device includes SRAM, ROM, internal flash, and external memory.

4.2 System memory map

The following table shows the chip's high-level memory map.

Additionally, the various sections are split into "Secure" and "Non-Secure" apertures for each IP. Although these apertures address the same IP, access through the "Secure" aperture can only be performed by code with the appropriate security settings.

NOTE

The secure space is the alias of the non-secure region.

Table 16. System memory map (continued)

Start address	End address	TZ-M State[1]	Description	Size	Cached
E010_0000	FFFF_FFFF		Reserved	—	—

1. This is the default Targeted Security Attribute for the memory region at reset. It is set by the IDAU and the SAU configuration. The attribute listed is the intended use case for users of TrustZone-M (TZM) security function.
2. On device part numbers that support optional ECC, RAMG and RAMH can be used to provide ECC data for other RAM blocks. RAMG and RAMH are not accessible as regular memory when used for ECC, so their availability in the memory map depends on the selected ECC configuration.
3. On device part numbers that support optional ECC, RAMB and RAMX ECC is enabled by default. This means that RAMH is used to provide ECC and is not accessible as regular RAM by default.

NOTE

For detailed connection between masters and slaves, see Bus matrix block diagram.

4.3 Cache

To help increase system performance, there are several caches included in the device.

The 16 KB Low Power Cache Controller (LPCAC) is connected to the Code bus of the primary CM33 core. Contents of this cache are only visible to the CM33 core. The LPCAC can be used to cache CM33 access to the program flash (0x0000_0000-0x001F_FFFF and 0x1000_0000-0x101F_FFFF) and FlexSPI (0x0800_0000-0x0FFF_FFFF and 0x1800_0000-0x1FFF_FFFF) code bus memory regions. The LPCAC chapter provides the functional description of the cache, but the SYSCON LPCAC Control (LPCAC_CTRL) register is used to control operation of the cache.

The Flash controller includes a small (64 byte) cache. Because the cache is a part of the memory controller, an access from any master to the flash can potentially be cached. The SYSCON NVM Control (NVM_CTRL) register is used to control and enable the FMC cache.

The 16 KB cache controller (CACHE64) is interfaced directly to the FlexSPI memory controller. Because the CACHE64 is integrated at the controller, an access from any master to the FlexSPI can be cached as long as the corresponding address is configured as cacheable. The CACHE64_POLSEL module is used to define the cache policy (non-cacheable, write-thru cacheable, or write-back cacheable) for up to three regions in the FlexSPI. The CACHE64_POLSEL and CACHE64 use a remapping scheme to map the FlexSPI system memory map regions (0x0800_0000-0x0FFF_FFFF, 0x1800_0000-0x1FFF_FFFF, 0x8000_0000-0x8FFF_FFFF, 0x9000_0000-0x9FFF_FFFF, 0xA000_0000-0xAFFF_FFFF, and 0xB000_0000-0xBFFF_FFFF) to a single, contiguous 512 Mbyte region used to access the FlexSPI. Refer to Table 35 for details on the remapping.

4.4 SRAM

Devices in this family support up to 512 KB of on-chip RAM (with ECC disabled). Refer to the device data sheet to determine the RAM size for a given part number. Refer to Table 17 for the RAM configurations.

RAMX (up to 96 KB) is connected to the CM33 Code buses. RAMX is the preferred RAM block to use for code storage.

RAMA which is always four 8 KB banks (32 KB total) is the preferred RAM block to use for data retention. The RAMA banks can be retained in device low-power modes. It can also optionally be powered from VBAT using LDO_RAM. To optimize power consumption, RAMA is split into 4 banks, where the low-power mode and VBAT retention for each bank is individually programmable. Low power configuration (LDO_RAM enable/disable and bank retention) are controlled by the VBAT module.

The other RAM blocks and partitions (other than RAMA) all have independent power switches that can be turned on/off depending on the application's RAM needs. CMC_SRAMDIS0 can be used to completely power gate a RAM partition (applies for all power modes). CMC_SRAMRET0 can be used to turn off the periphery of RAM partitions while retaining the contents of those RAMs during Power Down mode.

4.4.1 RAM ECC

RAMA always supports software configurable ECC (enabled by default). Each 8 KB RAM bank support 32+7 ECC, which provides one bit correction and two bits detection capability.

Depending on the specific device part number, ECC might be supported for the other RAM blocks. Refer to the device datasheet to determine if a given part number supports ECC for RAMs other than RAMA. For non-RAMA blocks, the ECC bits are provided by re-purposing RAMG and/or RAMH sub-blocks to provide ECC. RAMG and RAMH are used for ECC bits even for devices that don't support the full 512 KB of RAM, where RAMG and RAMH are not available as normal RAM memory. For devices with less than 512 KB of total RAM, other RAM blocks are disabled as ECC is enabled to keep the total amount of RAM being used including ECC blocks balanced. Therefore, enabling optional ECC will decrease the overall available memory as RAMG, RAMH, or other memory blocks become inaccessible.

NOTE

The SYSCON_ECC_ENABLE_CTRL bits must be set sequentially starting with bit 0 and working up to bit 3. Enabling ECC for RAMA and RAMB/RAMX is allowed. It is not legal to enable ECC for RAMA and RAMD/RAMC and leave ECC disabled on RAMB/RAMX (setting bit 0 and bit 2 but skipping bit 1).

The SYSCON's ECC_ENABLE_CTRL register is used to configure ECC functionality. ECC is always enabled by default for RAMA. RAMX/RAMB ECC is enabled, by default, for part numbers that support ECC. Other RAM blocks default to ECC disabled, even on ECC enabled part numbers.

Refer to the table below for details on the RAM configurations.

Table 17. RAM configurations

RAM Block	Start Address	End Address	Sub-Block	Size (KB)	Memory block availability based on device total memory size		ECC RAM	SYSCON ECC_ENABLE_CTRL	CMC SRAMDIS0/ SRAMRET0[1]
					352 KB (no ECC)/288 KB (with ECC)	512 KB (no ECC)/416 KB (with ECC)			
RAMX	0400_0000	0400_7FFF	RAMX0	32	Y	Y	RAMH1	bit 1	bit 0
	0400_8000	0400_FFFF	RAMX1	32	Y	Y			bit 1

	2005_8000	2005_BFFF	RAMG2	16	ECC[5]	Y[4]			bit 13
	2005_C000	2005_FFFF	RAMG3	16	ECC[5]	Y[4]			
RAMH	2006_0000	2006_1FFF	RAMH0	8	ECC[5]	Y			bit 14
	2006_2000	2006_7FFF	RAMH1	24	ECC[5]	Y[4]			

1. See SRAMDIS0 register and SRAMRET0 register.
2. Block becomes inaccessible when RAMD and RAMC ECC is enabled (SYSCON_ECC_ENABLE_CTRL[RAMD_RAMC_ECC_ENABLE] = 1).
3. Block becomes inaccessible when RAMB and RAMX ECC is enabled (SYSCON_ECC_ENABLE_CTRL[RAMB_RAMX_ECC_ENABLE] = 1).
4. Block is not accessible if ECC is enabled for its pair.
5. Block is not accessible as part of main memory but is used if ECC is enabled for its pair.

NOTE

For parts that support ECC on RAM blocks other than RAMA, ECC is enabled by default for the RAMB and RAMX blocks. This means the RAMH block is not accessible by default.

NOTE

While the RAMA-RAMH blocks are implemented as contiguous regions in the system memory map, each of the RAM blocks uses a different physical AHB slave port for access. This means that misaligned or burst accesses across the boundary from one RAM block to another are not allowed.

4.4.2 RAM ECC Error

The Error Recording Module (ERM) provides information and optional interrupt notification on SRAM error events associated with ECC. The syndrome and error address information is captured along with error event in ERM registers.

The Error Injection Module (EIM) can be used to induce artificial errors in the RAM ECC. EIM can inject single-bit and multi-bit inversions on data. Injecting faults on memory accesses can be used to exercise the SEC-DED ECC function of the related system.

4.4.3 RAM clock gating

To reduce power consumption, the RAM blocks support an auto clock gating feature. When auto clock gating is enabled, if the RAM block is not accessed for 16 bus clocks, then the clock to the RAM block is automatically gated off. If the clock is off, then there is a one bus cycle delay for the next access to the RAM block.

The auto clock gating feature is configurable on a per RAM block basis. The auto clock gating function is configured by the SYSCON's AUTOCLKGATEOVERRIDE and AUTOCLKGATEOVERRIDEC registers. By default, auto clock gating is enabled for the RAMX and RAMA blocks. The auto clock gating feature should be disabled, for RAM blocks that are used for code and data sections that require time-critical or deterministic execution.

In addition to the auto clock gating, the clock for each RAM block other than RAMX and RAMA can be manually disabled if the RAM block is not used or not used in a particular mode. The clock gate controls for the RAM blocks are found in the SYSCON_AHBCLKCTRL0 register. By default, the clocks are disabled for most RAM blocks; however, the ROM will enable the clock for all RAM blocks when booting.

NOTE

If ECC is enabled for blocks other than RAMA, then the clock for the corresponding ECC RAM must be enabled.

4.5 Read Only Memory (ROM)

The internal ROM memory is used to store the boot code and time-critical software library routines. After a reset, the Cortex-M33 processor starts its code execution from this memory.

4.5.1 ROM size

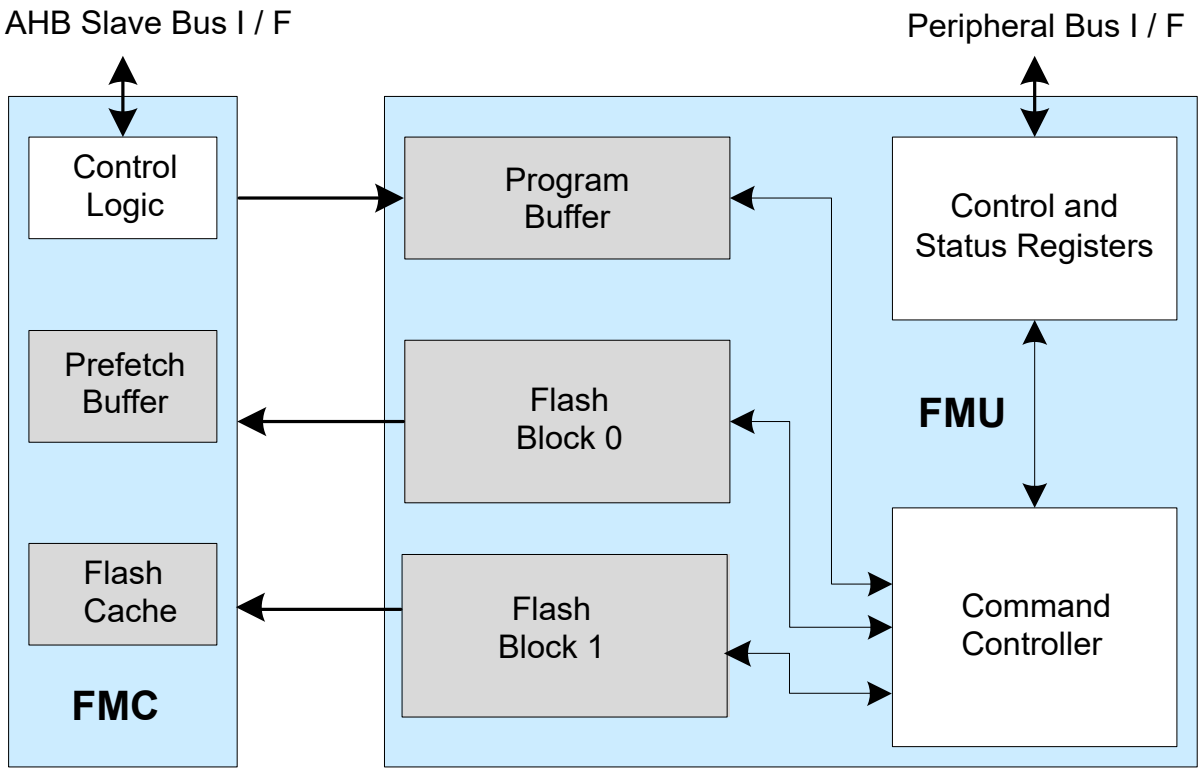
The Boot ROM of this device is 256 KB.

4.6 Internal flash

This device embeds up to 2 MB of flash. It is implemented as 2 x 1MB flash block instances.

Refer to the device datasheet to determine the flash size of a given part number.

The following figure shows the high-level block diagram of the on-chip flash.



4.6.1 Flash memory controller

The Flash Memory Controller (FMC) manages accesses performed by the bus masters of the system to the flash memory. The FMC accelerates flash memory transfers to allow program code execution at higher clock frequency than flash memory.

The FMC provides two separate mechanisms for accelerating read operations to the flash memory:

- A 128-bit prefetch buffer, which can prefetch the next 128-bit flash memory location.
- A 64-Byte cache organized as a one set, four-way associative cache with 128-bit (or 16-Byte) size entries.

Note the FMC and its cache and buffers has no visibility into flash memory erase and program cycles because the Flash Memory module manages them directly.

The speculation logic is tuned to work with the flash cache enabled. If the flash cache is present, the speculation logic assumes it may immediately request the next sequential flash phrase as soon as any access hits the speculation buffer since this will cause the phrase to be loaded in the flash cache. If the flash cache is present and disabled, the speculation logic may move to the next flash phrase before the current flash phrase in the speculation buffer is fully accessed, causing degradation in the speculation logic performance. For best performance on implementation which have both flash cache and speculation logic options available, enable the flash cache whenever the speculation logic is enabled.

4.6.1.1 Prefetch buffer

When speculative reads are enabled, the FMC immediately requests the next sequential address after a read completes. The next 128-bit memory location is read. The speculative prefetch mechanism improves performance by reducing or even eliminating wait states when accessing sequential code and/or data.

The FMC provides invalidation control for the prefetch buffer but the SYSCON's NVM_CTRL register is used to enable and configure speculative prefetching.

While NVM_CTRL[DIS_DATA_SPEC] and NVM_CTRL[DIS_FLASH_SPEC] are cleared by default, the operation of these fields interacts with the NVM_CTRL[DIS_MBECC_ERR_DATA] and NVM_CTRL[DIS_MBECC_ERR_INST].

NVM_CTRL[DIS_MBECC_ERR_DATA] is set by default which disables the flash speculation even though NVM_CTRL[DIS_FLASH_SPEC] is cleared. For best performance, NVM_CTRL[DIS_MBECC_ERR_DATA] should be cleared early on in startup code.

4.6.1.2 Flash cache

Cache memory stores already fetched data. This code is immediately available for repeated execution without any wait states, if needed.

The FMC provides controls for flash replacement algorithm, lock per way, and invalidation per way. The ways are numbered 0-3, and the sets are numbered 0-3. The cache supports Least Recently Used (LRU) replacement algorithm per set across all 4 ways. The SYSCON's NVM_CTRL register is used to enable/disable the cache and set other configurations. The flash cache is enabled by default.

The cache entries, both data and tag/valid, can be read at any time.

Software is required to maintain memory coherence when any segment of the flash cache is programmed. For example, all buffer data associated with the reprogrammed flash should be invalidated. Accordingly, cache program visible writes must occur after a programming or erase event is completed and before the new memory image is accessed.

The access to on-chip flash is checked in the Memory Block Controller (MBC).

4.7 External memory

This device has one FlexSPI subsystem supporting Octal and Quad SPI memory devices. The FlexSPI instance is primarily intended for code execution from off-chip SPI NOR and NAND flash memory. The FlexSPI interfaces also support HyperFlash, HyperRAM and Xccela memory types.

The FlexSPI interface supports execute-in-place and on-the-fly decryption using the IPED with GCM module. The FlexSPI interface includes a 16 KB cache with a CACHE64 AHB-cache controller. The CACHE64_POLSEL module is provided at the CACHE64 interface to enable different caching policies for different address regions. These policies include:

- Write-back
- Write-through
- Non-cached

4.8 Peripheral Bridge (PBRG)

The Peripheral Bridge (PBRG) is the portion of the bus fabric that connects the peripherals to the processor elements. Each peripheral has a base address where the processor elements can access them. The following sections provide the memory map of the peripherals connected to each of the Peripheral Bridges.

4.8.1 Peripheral Bridge 0 (PBRG0) memory map

Table 18. Peripheral bridge 0

Chapter 5
Low-Power Cache Controller (LPCAC)

5.1 Chip-specific LPCAC information

Table 23. Reference links to related information

Topic	Related module	Reference
Full description	LPCAC	LPCAC
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

NOTE

See SYSCON LPCAC Control (LPCAC_CTRL) description for the LPCAC controls.

5.1.1 Module instances

This device has one instance of the LPCAC module.

5.1.2 LPCAC cacheable memory range

The LPCAC module has no registers. All configuration for the LPCAC module is handled through the SYSCON's LPCAC_CTRL register.

The 16 KB LPCAC is connected to the Code bus of the primary CM33 core. Contents of this cache are only visible to the CM33 core. The cacheable memory range are shown in table below. For details, refer to System memory map.

Table 24. LPCAC cacheable memory range

Start address	End address	TZ-M State	Description	Size	Cached
0000_0000	001F_FFFF	Non-Secure	Program flash **Note:** Program flash has two flash memory arrays/banks of up to 1 MB each.	2 MB	LPCAC
0800_0000	0FFF_FFFF	Non-Secure	Flexible Serial Peripheral Interface (FlexSPI) **Note:** The 128 MB FlexSPI at address 0x0800_0000 is aliased to FlexSPI at address 0x8000_0000 ~0x87FF_FFFF.	128 MB	LPCAC/ CACHE64
1000_0000	101F_FFFF	Secure	Program flash	2 MB	LPCAC
1800_0000	1FFF_FFFF	Secure	Flexible Serial Peripheral Interface (FlexSPI)	128 MB	LPCAC/ CACHE64

5.1.3 LPCAC reset

A system reset would reset the LPCAC on this device. LPCAC is disabled after the reset.

5.1.4 Parity error check

LPCAC supports parity checking on its RAM. Any parity errors that are detected are reported through the Error Recording Module (ERM). See the ERM chapter.

5.2 Overview

LPCAC provides low-latency access to instructions or data. This decouples processor performance from system memory performance, increasing bus availability for other modules and improving system performance.

LPCAC has a 32-bit data path AMBA-AHB input bus and a 32-bit data path AMBA-AHB output bus.

5.2.1 Block diagram

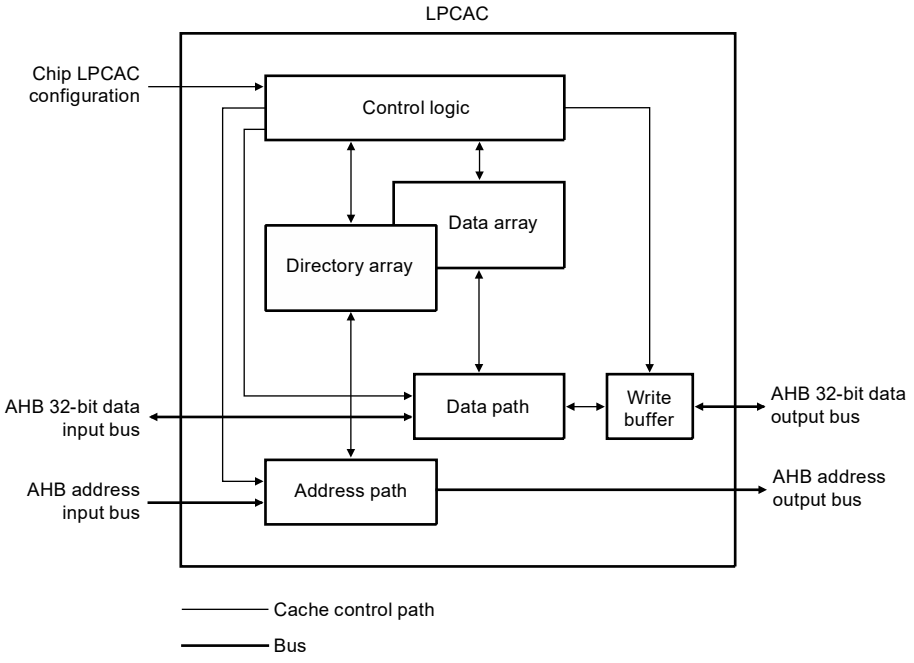

Figure 5. Block diagram

5.2.2 Features

LPCAC supports the following features:

- Nonblocking and write-through cache mode
- 16 KB total cache size
- Cache organization as an 8-way, 8-set-associative design based on 256-byte superpages
- Each way or superpage contains up to sixteen sequential 16-byte pages
- Cache supports optional odd parity with one bit of odd parity per 4 bytes of cache data.
  - Cache can recover and scrub data parity errors by forcing miss on parity error and reloading data

5.3 Functional description

This section provides further information on the LPCAC module operation.

A reset signal clears and enables this module.

LPCAC examines every valid AHB input access. If the access hits the cache memory region and the cache is enabled, the access goes to the cache portion of the module. If the access is not cacheable, the access is passed directly to the AHB output bus.

The LPCAC cache has a 256-byte line subdivided into sixteen 16-byte sublines:

- Cache read accesses that are cache misses perform an aligned 16-byte subline-size burst cache read miss to the module's AHB output bus. Then the cache loads the needed data in the cache’s data storage. The cache miss uses a 4-beat (32 bits per beat), wrapped burst bus access to fetch the cache miss data.
- Cache read accesses that are cache hits return the desired read data from the cache.
- Cache write accesses that are cache misses perform the desired write operation only to the module's AHB output bus (for write-through mode accesses, LPCAC has a no allocation on write-miss policy).
- Cache write accesses that are cache hits perform the desired write operation to the cache and the module's AHB output bus.

LPCAC has a one entry write buffer. When LPCAC is enabled and available, cache write accesses with a bufferable attribute use the buffer, which allows write from the processor to receive an immediate (zero wait state) bus termination.

5.3.1 Cache functional description

The LPCAC cache is an 8-way, 8-set-associative, 256-byte per line write-through design. It supports a total cache capacity of 16 KB for a 32-bit wide cache miss data path.

5.3.1.1 Cache controls

This module has controls to enable, disable, and clear the cache.

The cache control inputs are as follows:

- clr_lpcac: clear lpcac
- dis_lpcac: disable lpcac
- dis_lpcac_wtbf: disable write buffer
- lim_lpcac_wtbf: limit write buffer
- frc_no_alloc: force no allocation
- parity_miss_en: enable parity, miss on parity error
- parity_fault_en: enable parity error reporting

See chip-specific section for more information on how these signals are connected or controlled on a given device.

5.3.2 Clocks

The core clock domain defines the module's clock domain.

5.3.3 Reset

A reset signal clears and enables this module. See the chip-integration information for the resets that affect LPCAC.

5.3.4 Interrupts

This module has no interrupts.

5.4 Signal descriptions

This module has no external signals.

5.5 Memory regions and input control description

5.5.1 Memory regions

LPCAC decodes cacheable address regions. The cache memory region may be composed of one or more disjointed memory regions and the total size may be larger than the cache storage.

Any address not in the cacheable memory region is in the pass-through memory region. All accesses to the pass-through memory regions are non-cacheable. For all accesses to the cacheable memory regions, the access is cacheable if the attributes of the access indicate that it can be cached, else the access is non-cacheable.

See the System Memory Map for cache memory range information.

5.5.2 Input controls

The LPCAC does not have a module-resident programming model. An external block supplies the needed LPCAC control inputs.

Table 25. Control inputs for LPCAC

Function	Control input	Description
clear lpcac	clr_lpcac	One cycle active-high pulse clears the lpcac.
disable lpcac	dis_lpcac	• 0 = lpcac enabled (reset configuration) • 1 = lpcac disabled, all cacheable accesses pass from LPCAC input to output bus
disable write buffer	dis_lpcac_wtbf	• 0 = write buffer enabled • 1 = write buffer disabled
limit write buffer	lim_lpcac_wtbf	• 0 = If write buffer is enabled, buffer all writes to spaces that are bufferable • 1 = If write buffer is enabled, buffer all writes to spaces that are both bufferable and cacheable
force no allocation	frc_no_alloc	When frc_no_alloc is asserted and the cache is enabled, all accesses to the cache search the cache. If they hit a valid entry that was loaded before frc_no_alloc was asserted, they operate normally. That is, read hits return cache data without going through the cache and write hits update cache data and write through the cache. If they miss, they bypass the cache (that is, even though a read access is to a cacheable space, it does not allocate on a cache miss). This control input is useful for debug. If there is a software breakpoint, halting the processor. Then, using the debug port, cacheable memory and other address spaces are accessed. These debug accesses go through the processor, through the cache, and to the rest of the system. The idea is during the debug accesses the cache is placed on frc_no_alloc mode. In this way, debug access through the core and then through the cache do not disturb the state of the cache. Before restarting the processor, frc_no_alloc mode is negated. When the processor restarts, the cache state is the same or at least very similar as the cache state when the breakpoint was hit. • 0 = normal allocation on cache miss • 1 = no allocation on cache miss

Table continues on the next page...

Table 25. Control inputs for LPCAC (continued)

Function	Control input	Description
parity miss enable	parity_miss_en	Enables miss on parity to scrub the parity error and to reload the data line that had the parity error. • 0 = do not take a miss on a parity error • 1 = force a miss on a parity error
parity enable	parity_fault_en	Enables and disables parity error report. • 0 = disable • 1 = enable

Chapter 6
CACHE64 Controller (CACHE64_CTRL)

6.1 Chip-specific CACHE64_CTRL information

Table 26. Reference links to related information

Topic	Related module	Reference
Full description	CACHE64_CTRL	CACHE64_CTRL
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	NA

NOTE

The CACHE64_CTRL module works in conjunction with the CACHE64_POLSEL module. The CACHE64_POLSEL determines the cache policy to be applied for a given AHB address and passes this information to the CACHE64_CTRL.

6.1.1 Module instances

This device has one instance of the CACHE64 controller module, CACHE64_CTRL0.

6.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by non-secure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

6.1.3 FlexSPI regions mapping to CACHE64_CTRL

The CACHE64_CTRL module is used to cache FlexSPI accesses. There are multiple FlexSPI regions in the system memory map, but these are remapped to create a single contiguous 512 Mbyte region (0x8000_0000-0x9FFF_FFFF), where accesses to some system regions are aliased into a single region for the cache. The table below shows how the FlexSPI system regions are mapped to the CACHE64_CTRL:

Table 27. FlexSPI regions mapping to CACHE64_CTRL

System start address (hex)	System End address (hex)	Size	CACHE64_CTRL start address	CACHE64_CTRL end address	Access
0x0800_0000	0x0FFF_FFFF	128 MB	0x8000_0000	0x87FF_FFFF	Non-secure
0x1800_0000	0x1FFF_FFFF	128 MB	0x8000_0000	0x87FF_FFFF	Secure
0x8000_0000	0x8FFF_FFFF	256 MB	0x8000_0000	0x8FFF_FFFF	Non-secure
0x9000_0000	0x9FFF_FFFF	256 MB	0x8000_0000	0x8FFF_FFFF	Secure
0xA000_0000	0xAFFF_FFFF	256 MB	0x9000_0000	0x9FFF_FFFF	Non-secure
0xB000_0000	0xBFFF_FFFF	256 MB	0x9000_0000	0x9FFF_FFFF	Secure

6.2 Overview

A cache is a block of high-speed memory locations that contains address information (commonly known as a tag) and its associated data. It decreases the average time of a memory access. CACHE64_CTRL includes cache memory controller (CACHE64), which is a general purpose AMBA AHB bus protocol cache.

6.2.1 Block diagram

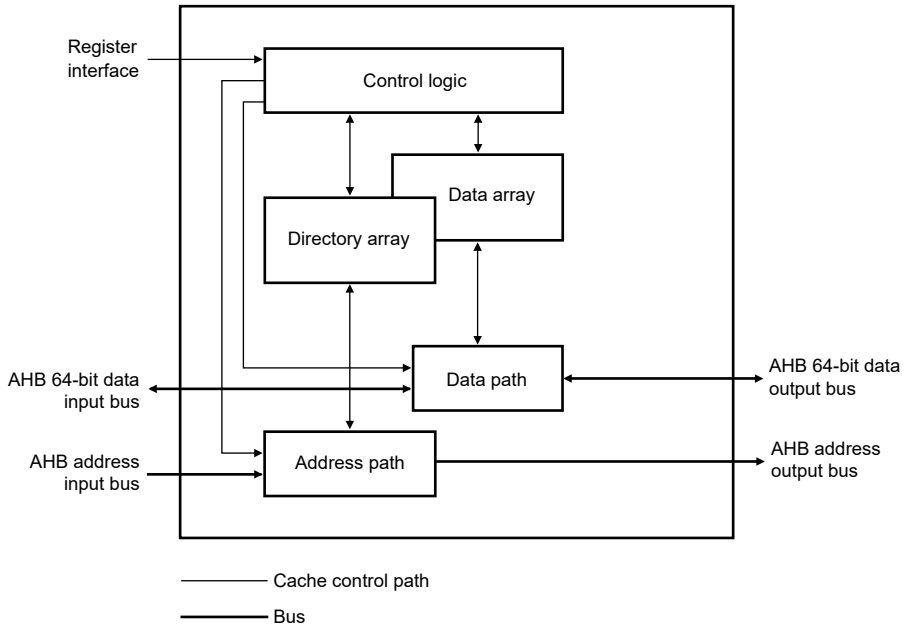

Figure 6. Block diagram

6.2.2 Features

CACHE64_CTRL is designed to work with AMBA AHB bus systems. It includes:

- An input (Controller) AHB bus that you can access using Cache mode attributes for cacheable copyback, cacheable write-through, or noncacheable mode operation and write bufferable mode operation on an access-by-access basis.
- An output (Target) 64-bit data path AHB bus for downstream cache read miss, cache write-through write, and noncacheable accesses.
- A peripheral interface for accessing the cache's program model.

6.3 Functional description

A cache operates on two principles of locality:

- Spatial locality — Access to one location possibly follows an access from adjacent locations (for example, sequential instruction execution or usage of a data structure).
- Temporal locality — Access to an area of memory possibly repeats within a short period of time (for example, execution of a code loop).

To minimize the quantity of control information stored, the spatial locality property groups several locations together, under the same tag. This logical block is known as a cache line.

You achieve temporal locality by retaining recently accessed lines in the cache.

When data loads into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are known as cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the bus controller wants to access a cacheable location, the cache is checked. If the access is a cache hit, the access occurs immediately. Otherwise, a location is allocated, and the cache line is loaded from memory. Different cache topologies and access policies are possible. However, they must comply with the memory coherency model of the underlying architecture.

Caches introduce a number of potential problems, mainly because of:

- Memory accesses occurring at times other than when the programmer would normally expect them.
- The existence of multiple physical locations where a data item can be held.

6.3.1 Submodules

- Cache_apb — This sub-module is responsible for CACHE64_CTRL configuration of related registers.
- Cache_cam — This sub-module contains address information (commonly known as a tag) and its associated data. This sub-module asserts TAG parity fault.
- Cache_pipe — This sub-module is responsible for AHB bus access.

6.3.2 Operations

6.3.2.1 Cache configuration

CACHE64_CTRL receives manager bus requests on the manager (M) bus.

You can access the cache programming model via the cache controller's AMBA AHB bus.

CACHE64_CTRL then processes the cacheable accesses as needed, when bypassing the noncacheable, cache write-through, cache miss, and cache maintenance accesses to its subordinate bus.

The cache on this chip has a 2-way set associative cache structure with a total size of 16 KB. The cache has a 32-bit address, 64-bit data paths, and a 32-byte line size. The cache tags and data storage use single-port, synchronous RAMs.

For this 16 KB cache, each cache TAG function uses two 256 x 21-bit RAM arrays, and the cache DATA function uses two 1024 x 64-bit RAM arrays. The cache TAG entries store 19 bits of the upper address as well as a modified and valid bit per cache line. The cache DATA entries store eight bytes of code or data.

All normal cache accesses use physical addresses. This leads to the use of the following cache address:

CACHE - 16 KB size = (256 sets) x (32-byte lines) x (2-way set associative)

Table 28. Tag cache address use

Tag cache address use	Cache
Tag hit address range	Address[31:13]
Tag set select address range	Address[12:5] used to select 1 of 256 sets
Not used	Address[4:0]

Table 29. Data cache address use

Data cache address use	System cache
Not used	Address[31:13]
Data set select address range	Address[12:5] used to select one of 256 sets
64-bit word select	Address[4:3] used to select one of four 64-bit words within a set
Byte select	Address[2:0] used to select the byte within the 64-bit word

6.3.2.2 Cache control

The cache is disabled at reset. Cache tag and data arrays are not cleared at reset. Therefore, to enable and configure the cache, you must clear the cache commands and initialize the required tag array.

6.3.2.2.1 Cache set commands

The cache set commands may operate on one of the following:

- All of way 0
- All of way 1
- All of both ways (complete cache)

Cache set commands are specified using the upper bits in Cache Control (CCR). Cache set commands perform their operation on the cache independent of CCR[ENCACHE].

You initiate a cache set command by writing 1 to CCR[GO]. This field also acts as a busy bit for set commands. The field remains 1 when the command is active, and the module writes 0 to it after the set command completes.

Supported cache set commands are provided in Table 30. Following are the set commands:

- Invalidate — Unconditionally clears valid and modify bits of a cache entry.
- Push — Pushes a cache entry if it is valid and modified, then clears the modify bit. If the entry is not valid or not modified, leave it as is.
- Clear — Pushes a cache entry if it is valid and modified, then clears the valid and modify bits. If the entry is not valid or not modified, clear the valid bit.

Table 30. Cache set commands

Cache Control (CCR)[27:24]				Command
PUSHW1	INVW1	PUSHW0	INVW0	
0	0	0	0	No operation (NOP)
0	0	0	1	Invalidate all of way 0
0	0	1	0	Push all of way 0
0	0	1	1	Clear all of way 0
0	1	0	0	Invalidate all of way 1
0	1	0	1	Invalidate all of way 1 and way 0 (invalidate complete cache)
0	1	1	0	Invalidate all of way 1; push all of way 0
0	1	1	1	Invalidate all of way 1; clear all of way 0
1	0	0	0	Push all of way 1
1	0	0	1	Push all of way 1; invalidate all of way 0
1	0	1	0	Push all of way 1 and way 0 (push complete cache)
1	0	1	1	Push all of way 1; clear all of way 0
1	1	0	0	Clear all of way 1
1	1	0	1	Clear all of way 1; invalidate all of way 0
1	1	1	0	Clear all of way 1; push all of way 0
1	1	1	1	Clear all of way 1 and way 0 (clear complete cache)

After a reset, complete an invalidate cache command before using the cache. It is possible to combine the cache invalidate command with the cache enable. That is, writing 8500_0003h to Cache Control (CCR) invalidates the cache and enables the cache and write buffer.

6.3.2.2.2 Cache line commands

Cache line commands operate on a single line in the cache at a time. You can perform these commands using a physical or cache address that consists of a set address and a way select. The line command acts on the specified cache line.

Cache line commands with physical addresses first search both ways of the cache set specified by the following physical address bits. If they hit, the commands perform their action on the hit way: For cache- [12:5].

You specify cache line commands using the upper bits in Cache Line Control (CLCR). Cache line commands perform their operation on the cache independent of CCR[ENCACHE]. Using a cache address, the command can be completely specified using Cache Line Control (CLCR). Using a physical address, the command must also use Cache Search Address (CSAR) to specify the physical address.

You can initiate a line cache command by writing 1 to CLCR[LGO] or CSAR[LGO]. This field also acts as a busy bit for line commands. The field remains 1 when the command is active and CACHE64_CTRL writes 0 to it after the set command completes.

Table 31. Cache line commands

Cache Line Control (CLCR)[27:24]			Command
CLCR[LACC]	CLCR[LADSEL]	CLCR[LCMD]	
0	0	00	Search by cache address and way
0	0	01	Invalidate by cache address and way
0	0	10	Push by cache address and way
0	0	11	Clear by cache address and way
0	1	00	Search by physical address
0	1	01	Invalidate by physical address
0	1	10	Push by physical address
0	1	11	Clear by physical address
1	0	00	Write by cache address and way
1	0	01	NOP
1	0	10	NOP
1	0	11	NOP
1	1	*xx*	NOP

6.3.2.2.2.1 Executing a series of line commands using cache addresses

You can perform a series of line commands with incremental cache addresses by writing to Cache Line Control (CLCR):

1. Place the command in Cache Line Control (CLCR)[27:24].
2. Write 1 to CLCR[WSEL] and CLCR[TDSEL] as needed.
3. Place the cache address in CLCR[CACHEADDR].
4. Write 1 to CLCR[LGO].
5. Wait for the command to complete (CLCR[LGO] becomes 0).
6. Increment the cache address (at bit 3 to step through data or at bit 5 to step through lines).

7. Write 1 to CLCR[LGO].
8. Wait for the command to complete (CLCR[LGO] becomes 0).
9. Repeat steps 5 - 8 as needed.

6.3.2.2.2.2 Executing a series of line commands using physical addresses

You can perform a series of line commands with incremental physical addresses using the following steps:

1. Write to Cache Line Control (CLCR):
   a. Place the command in Cache Line Control (CLCR) [27:24].
   b. Write 1 to CLCR[TDSEL].
2. Place the physical address in CSAR[PHYADDR] and write 1 to CSAR[LGO].
3. Wait for the command to complete (CLCR[LGO] becomes 0).
4. Increment the physical address (at bit 3 to step through data or at bit 5 to step through lines).
5. Write 1 to CLCR[LGO].
6. Wait for the command to complete (CLCR[LGO] becomes 0).
7. Repeat steps 3 - 6 as needed.

Cache Line Control (CLCR) and Cache Search Address (CSAR) both contain a field called LGO, and this field has the same functionality. Therefore, you can complete the above steps in a single write to Cache Search Address (CSAR).

6.3.2.2.2.3 Line command results

At completion of a line command, Cache Line Control (CLCR) contains information on the initial state of the line targeted by the command. For line commands with cache addresses, read this information before performing a line command action from the targeted cache line. For line commands with physical addresses, read this information on a hit before the line command action is performed from the hit cache line. In the cache, for line commands with a physical address miss, CLCR[LCIVB] becomes 0, and no line command action is performed. In general, if CLCR[LCIVB] becomes 0, the targeted line is invalid at the start of the line command and no line operation is performed.

Table 32. Line command results

Cache Line Control (CLCR)[22:20]			For cache address commands	For physical address commands
CLCR[LCWAY]	CLCR[LCIMB]	CLCR[LCIVB]		
0	0	0	Way 0 line is invalid	No hit
0	0	1	Way 0 valid and not modified	Way 0 valid and not modified
0	1	0	Way 0 line is invalid	No hit
0	1	1	Way 0 valid and modified	Way 0 valid and modified
1	0	0	Way 1 line is invalid	No hit
1	0	1	Way 1 valid and not modified	Way 1 valid and not modified
1	1	0	Way 1 line is invalid	No hit
1	1	1	Way 1 valid and modified	Way 1 valid and modified

On completion of a line command other than a write, Cache Read/Write Value (CCVR) contains information on the initial state of the line tag or data targeted by the command. For line commands, CLCR[TDSEL] selects between tag and data. If the line command used a physical address and missed, the data is don't care. For write commands, Cache Read/Write Value (CCVR) holds the write data.

The cache does not have line lock capability.

6.3.3 Modes of operation

Table 33. Modes of operation

Mode	Description
Write-Through	Access to address spaces with this cache mode are cacheable: • If all cacheable spaces are read-only spaces, then cache contains read-only data and all writes to the cache cause a fault. See the chip-specific cacheable space information. • A read miss on the input bus causes a line read on the output bus of a 32-byte-aligned memory address that contains the desired address. A read miss data loads into the cache and marks as valid and not modified. • A read hit to a valid cache location returns data from the cache with no output bus accesses. • A write miss bypasses the cache and writes to the output bus (no allocation on write-miss policy for Write-Through mode spaces). • A write hit updates the cache hit line with the write data and writes to the output bus. • The caches are bus-controller-local and do not support hardware cache coherency. If the bus controller accesses write-through regions and another bus controller that can access the same target memory, without going through the cache (such as DMA), must update these regions, you must first perform explicit cache clears to ensure all modified cache lines update their associated memories, before they are modified by external controllers and subsequent cache bus controller accesses get the updated memory.
Write-Back	Access to address spaces with this cache mode are cacheable: • A read miss on the input bus causes a line read on the output bus of a 32-byte-aligned memory address that contains the desired address. This miss data loads into the cache and marks it as valid and not modified. • A read hit to a valid cache location returns data from the cache with no output bus access. • A write miss performs a read-to-write (executes write-miss policy for Write-Back mode spaces). You perform a line read on the output bus of a 32-byte-aligned memory address containing the desired write address. This miss data is loaded into the cache and marked as valid and modified. Then the write data updates the appropriate cache data locations.

Table continues on the next page...

Table 33. Modes of operation (continued)

Mode	Description
	• A write hit updates the cache hit line with the write data and marks the line as modified. • Caches do not support hardware cache coherency. If the cache's bus controller has written to write-back regions, and another bus controller that can access the same target memory without going through the cache must see these updates, you must perform explicit cache pushes to any needed cache memory range to ensure that all modified cache lines update their associated memories before being this controller reads them. Likewise, if the cache's bus controller has accessed write-back regions, and another bus controller that can access the same target memory without going through the cache must update these regions, you must first perform explicit cache clears to any needed cache memory range to ensure that all modified cache lines update their associated memories before this controller modifies them, and subsequent cache controller bus accesses get the updated memory.
Noncacheable	Access to address spaces with this cache mode are not cacheable. These accesses bypass the cache and access the output bus.

6.3.4 Clocking

Caches use the AHB manager bus clock.

6.3.5 Reset

Caches are disabled at reset. However, cache tag and data arrays are not cleared at reset. See Initialization and Cache control for more information regarding cache initialization and configuration.

6.3.6 Interrupts

CACHE64_CTRL has no interrupts.

6.4 External signals

There are no external signals for CACHE64_CTRL.

6.5 Initialization

Perform this procedure to initialize cache:

1. Write 1 to CCR[INVW1] and CCR[INVW0].
2. Write 1 to CCR[GO].
3. Write 1 to CCR[ENWRBUF] and CCR[ENCACHE].

NOTE

Steps 1, 2 and 3 can be done simultaneously. That is, writing 8500_0003h to Cache Control (CCR) invalidates the cache and enables the cache and write buffer.

6.6 Memory map and registers

The cache programmer's model provides a variety of registers for configuring and controlling the cache, as well as indirect access paths to all cache tag and data storage.

NOTE

The cache registers are accessible in Supervisor mode only.

6.6.1 CACHE64_CTRL register descriptions

6.6.1.1 CACHE64_CTRL memory map

CACHE64_CTRL0 base address: 4001_B000h

Offset	Register	Width (In bits)	Access	Reset value
800h	Cache Control (CCR)	32	RW	0000_0000h
804h	Cache Line Control (CLCR)	32	RW	0000_0000h
808h	Cache Search Address (CSAR)	32	RW	0000_0000h
80Ch	Cache Read/Write Value (CCVR)	32	RW	0000_0000h

6.6.1.2 Cache Control (CCR)

Offset

Register	Offset
CCR	800h

Function

Enables the cache and write buffer. This register also contains the fields used for commands specified in Cache set commands.

Table continued from the previous page...

Field	Function
—	
3 FRCNOALLC	Forces No Allocation On Cache Misses 0b - Allocation on cache misses 1b - Forces no allocation on cache misses (FRCWT must be asserted)
2 FRCWT	Force Write Through Mode Specifies whether all cacheable spaces to write through are forced. 0b - Does not force 1b - Force
1 ENWRBUF	Enable Write Buffer Enables the write buffer. 0b - Disables 1b - Enables
0 ENCACHE	Cache Enable Enables the cache. 0b - Disables 1b - Enables

6.6.1.3 Cache Line Control (CLCR)

Offset

Register	Offset
CLCR	804h

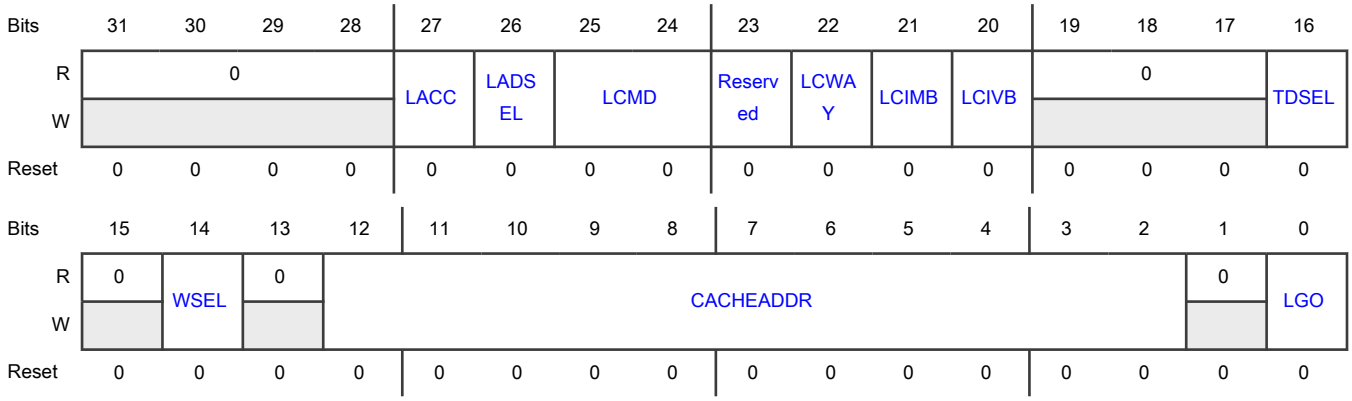
Function

Defines the commands specified in Cache line commands that you must perform using a specific cache line address or physical address.

If you specify the physical address, you can search cache in both the ways, and the command only performs on the way that hits.

You can write to CLCR[LCWAY], CLCR[LCIMB], and CLCR[LCIVB]; however, the values that you write to these fields have no functional purpose.

Diagram



Fields

Field	Function
31-28 —	Reserved
27 LACC	Line Access Type Specifies the operation that you must perform (read or write) after a hit, when performing a search command. **NOTE** Only used for search commands (CLCR[LCMD] = 00). 0b - Read 1b - Write
26 LADSEL	Line Address Select Specifies the address (cache or physical). When using the cache address (specified in CLCR[WSEL] and CLCR[CACHEADDR]), the way must also be specified in CLCR[WSEL]. When using the physical address (specified in Cache Search Address (CSAR)), both ways are searched and the command is performed only after a hit. 0b - Cache 1b - Physical
25-24 LCMD	Line Command Performs one of the four commands after a cache hit. CLCR[LACC] determines whether the operation is a read or write. 00b - Search and read or write 01b - Invalidate 10b - Push 11b - Clear

Table continues on the next page...

Table continued from the previous page...

Field	Function
23 —	Reserved
22 LCWAY	Line Command Way Indicates the way that the line command uses. Applies only if CLCR[LCIVB] = 1. 0b - Way 0 1b - Way 1
21 LCIMB	Line Command Initial Modified Bit Shows the initial state of the modified bit. If this field = 0, and the command uses cache address and way, this field shows the initial state of the modified bit, which is 0. If the command uses physical address and a hit, this field shows the initial state of the modified bit, which is 0. If the command uses physical address and is a miss, this field reads 0. If this field = 1, and the command uses cache address and way, this field shows the initial state of the modified bit, which is 1. If the command uses physical address and way, this field shows the initial state of the modified bit, which is 1. If a miss, this field reads 0. 0b - Initial state 0 1b - Initial state 1
20 LCIVB	Line Command Initial Valid Bit Shows the initial state of the valid bit. If this field = 0, and the command uses cache address and way, this field shows the initial state of the valid bit, which is 0. If the command uses physical address and a hit, this field shows the initial state of the valid bit, which is 0. If the command uses physical address and is a miss, this field reads 0. If this field = 1, and the command uses cache address and way, this field shows the initial state of the valid bit, which is 1. If the command uses physical address and way, this field shows the initial state of the modified bit, which is 1. If a miss, this field reads 0. 0b - Initial state 0 1b - Initial state 1
19-17 —	Reserved
16 TDSEL	Tag Or Data Select Selects tag or data for search and read or write commands. 0b - Data 1b - Tag
15	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
14 WSEL	Way Select Selects the way for line commands. 0b - Way 0 1b - Way 1
13 —	Reserved
12-2 CACHEADDR	Cache Address Represents bits [12:2] of the cache address: CLCR[12:5] accesses the tag arrays. CLCR[12:3] accesses the data arrays. CLCR[2] specifies which half of the 64 bits of data to place in Cache Read/Write Value (CCVR).
1 —	Reserved
0 LGO	Initiate Cache Line Command Initiates the cache command that CLCR[LCMD], CLCR[LADSEL], and CLCR[LACC] indicate, if you write 1 to this field. Reading this field indicates whether a cache command is active. **NOTE** • This field remains 1 until the command completes. Writing 0 has no effect. • This field is shared with CSAR[LGO]. You can write either register address bit[0] interchangeably. This saves cache writes (helps performance), when performing cache operations. Cache line operations start when you write to Cache Line Control (CLCR) with CLCR[LGO] being 1 or the cache search address can be changed and a search is started by writing to Cache Search Address (CSAR) with CSAR[LGO] being 1. 0b - Write: no effect; Read: no line command active 1b - Write: initiate line command; Read: line command active

6.6.1.4 Cache Search Address (CSAR)

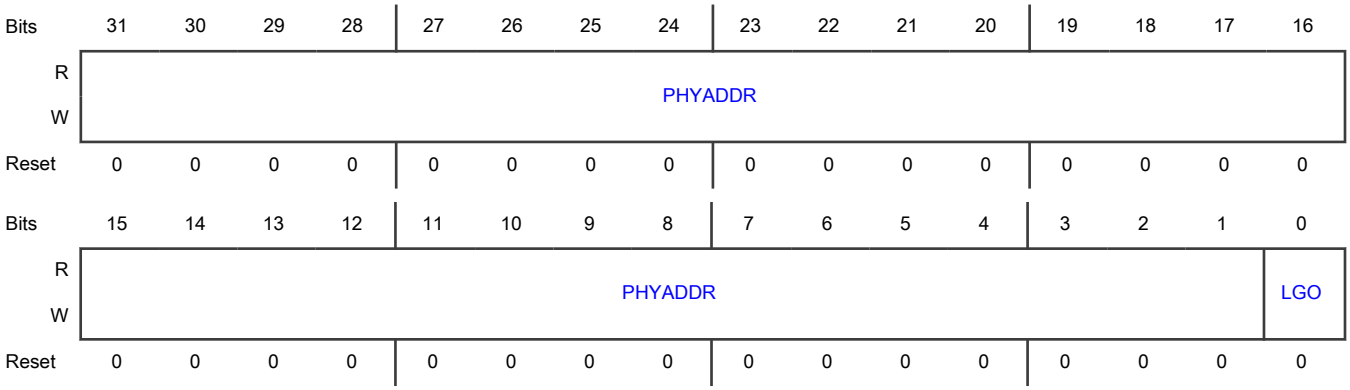
Offset

Register	Offset
CSAR	808h

Function

Defines the physical address for cache line commands, when CLCR[LADSEL] = 1.

Diagram



Fields

Field	Function
31-1 PHYADDR	Physical Address Represents bits [31:1] of the system address: CSAR[31:13] is used for tag compare. CSAR[12:5] accesses the tag arrays. CSAR[12:3] accesses the data arrays. CSAR[2] specifies which half of the 64 bits of data to place in Cache Read/Write Value (CCVR). CSAR[1] is not used. Writes to this bit are allowed, and the read value is the previously written value. This bit is not functionally used.
0 LGO	Initiate Cache Line Command Initiates the cache command that CSAR[PHYADDR] indicates, if you write 1 to this field. Reading this field indicates whether a cache command is active. **NOTE** • This field remains 1 until the command completes. Writing 0 has no effect. • This field is shared with CLCR[LGO]. 0b - Write: no effect; Read: no line command active 1b - Write: initiate line command; Read: line command active

6.6.1.5 Cache Read/Write Value (CCVR)

Offset

Register	Offset
CCVR	80Ch

Function

Sources write data or return read data when a search line command is requested (CLCR[LCMD] = 00). CLCR[LACC] determines whether the access is a read or write, and CLCR[TDSEL] determines whether the access is to the data or tag arrays.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CACHE64 Policy Select (CACHE64_POLSEL)

7.1 Chip-specific CACHE64_POLSEL information

Table 34. Reference links to related information

Topic	Related module	Reference
Full description	CACHE64_POLSEL	CACHE64_POLSEL
System memory map		Memory map
Clocking		Clock distribution

7.1.1 Module instances

This device has one instance of the CACHE64_POLSEL module, CACHE64_POLSEL0.

7.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

7.1.3 FlexSPI regions mapping to CACHE64_POLSEL

The CACHE64_POLSEL block is responsible for defining the memory regions and cache polices to use for each region within the CACHE64 controller. Because the CACHE64 is integrated at the FlexSPI slave port, the cacheable regions are the FlexSPI regions in the system memory map. The upper address lines are ignored when setting cache policies, so that the three regions supported by CACHE64_POLSEL are applied across all of the FlexSPI address regions.

There are multiple FlexSPI regions in the system memory map, but these are remapped to create a single contiguous 512 Mbyte region (0x8000_0000-0x9FFF_FFFF), where accesses to some system regions are aliased into a single region for the cache. The table below shows how the FlexSPI system regions are mapped to the CACHE64_POLSEL:

Table 35. FlexSPI regions mapping to CACHE64_POLSEL

System start address (hex)	System End address (hex)	Size	CACHE64_POLSEL start address	CACHE64_POLSEL end address	Access
0x0800_0000	0x0FFF_FFFF	128 MB	0x8000_0000	0x87FF_FFFF	Non-secure
0x1800_0000	0x1FFF_FFFF	128 MB	0x8000_0000	0x87FF_FFFF	Secure
0x8000_0000	0x8FFF_FFFF	256 MB	0x8000_0000	0x8FFF_FFFF	Non-secure
0x9000_0000	0x9FFF_FFFF	256 MB	0x8000_0000	0x8FFF_FFFF	Secure
0xA000_0000	0xAFFF_FFFF	256 MB	0x9000_0000	0x9FFF_FFFF	Non-secure
0xB000_0000	0xBFFF_FFFF	256 MB	0x9000_0000	0x9FFF_FFFF	Secure

7.2 Overview

CACHE64_POLSEL monitors incoming AHB addresses to define the policy that the cache controller (CACHE64_CTRL) uses. Both CACHE64_POLSEL and the cache controller work in tandem with each other.

7.2.1 Features

- Provides cache policy information to the cache controller.
- Supports up to three regions, each with a programmable cache policy:
  - Each region can be independently designated as noncache, write-through cache, and write-back cache.
  - User-defined boundaries are supported between the three regions with 1 KB granularity.

7.3 Functional description

CACHE64_POLSEL permits dividing the memory space that the cache controller accesses into three contiguous regions and applies one of these three cache policies to each region:

- First region (region 0) starts at the bottom (lowest address) in the target address space and goes up to the top of the 1 KB boundary designated in REG0_TOP.
- Second region (region 1) starts at the next address and extends to the top of the boundary designated in REG1_TOP.
- Third region starts at the address after that and continues to the top of the memory space accessed via the cache controller.

7.3.1 Region mapping

CACHE64_POLSEL controls the cache policy for memory between the base address and end address. Within the CACHE64_POLSEL memory area, you can define up to three contiguous memory regions, with each region having independently programmable cache policy settings.

As shown in the following figure, REG0_TOP and REG1_TOP control the boundaries between the regions. These registers provide bits 26-11 of the address and the lower 10 bits are always 1s. For example, if REG0_TOP is 0001_0000h, then region 0 ends at BASE_ADDRESS + 0001_03FFh. Region 1 starts at 0001_0400h.

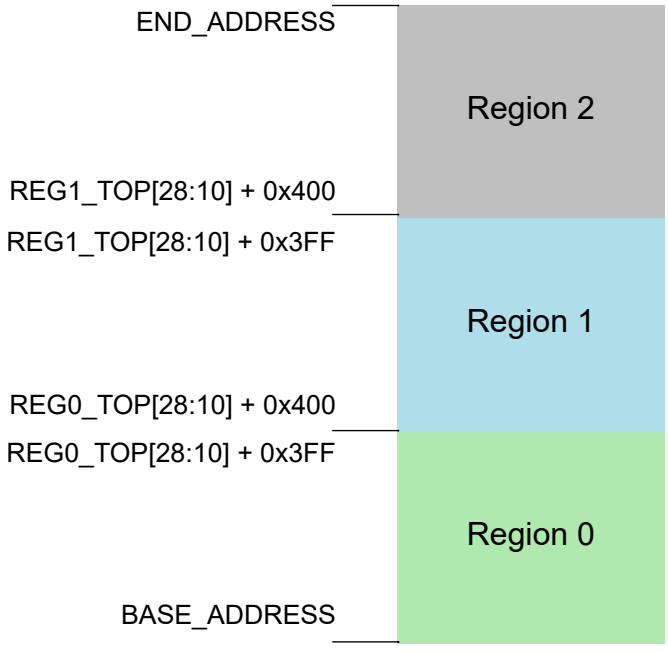

Figure 7. Cache memory regions

For CACHE64_POLSEL implementations that have multiple memory regions (more than one base address and end address), the regions are aliased across all of the memory regions. Therefore, the configured cache policies are also aliased across all of the memory regions.

7.3.2 Region priority

When you access an address, CACHE64_POLSEL attempts to match it to one of the regions in a sequential order that starts with region 0. In pseudocode, the region hit logic does this:

```
if (address < REG0_TOP + 0x3FF)
  address hits in Region 0;
else
  if (address < REG1_TOP + 0x3FF)
    address hits in Region 1;
  else
    address hits in Region 2;
```

NOTE

If you configure REG0_TOP and REG1_TOP to create overlapping regions, then the lowest number region in which the address hits, is used.

7.4 Application information

This section provides an example CACHE64_POLSEL configuration. The example assumes:

- The MCU has two memory regions mapped to CACHE64_POLSEL:
  - Nonsecure region: BASE_ADDRESS = 0800_0000h, END_ADDRESS = 0FFF_FFFFh
  - Secure region: BASE_ADDRESS = 1800_0000h, END_ADDRESS = 1FFF_FFFFh
- Region 0: 56 MB is configured as write-through.
- Region 1: 8 MB is configured as noncacheable.
- Region 2: The remaining memory region is unused and configured as invalid.

The following register settings are used to achieve this configuration:

- REG0_TOP = 037F_FC00h
- REG1_TOP = 03FF_FC00h
- POLSEL = 0000_0031h

The following figure shows the resulting memory configuration.

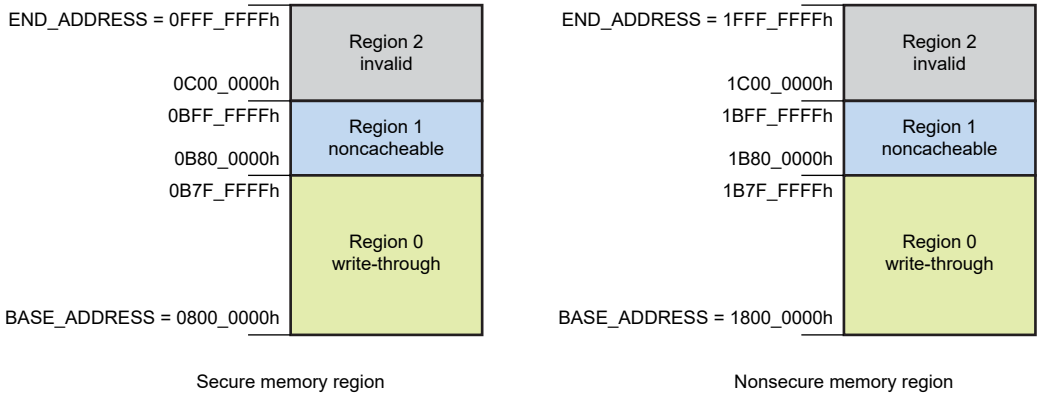

Figure 8. CACHE64_POLSEL configuration example

7.5 Memory map and register definition

The CACHE64_POLSEL registers are included in the register space of the CACHE64 module, utilizing addresses that CACHE64 does not use internally.

7.5.1 CACHE64_POLSEL register descriptions

7.5.1.1 CACHE64_POLSEL memory map

CACHE64_POLSEL0 base address: 4001_B000h

Offset	Register	Width (In bits)	Access	Reset value
14h	Region 0 Top Boundary (REG0_TOP)	32	RW	0AAA_A800h
18h	Region 1 Top Boundary (REG1_TOP)	32	RW	1555_5400h
1Ch	Policy Select (POLSEL)	32	RW	0000_0000h

7.5.1.2 Region 0 Top Boundary (REG0_TOP)

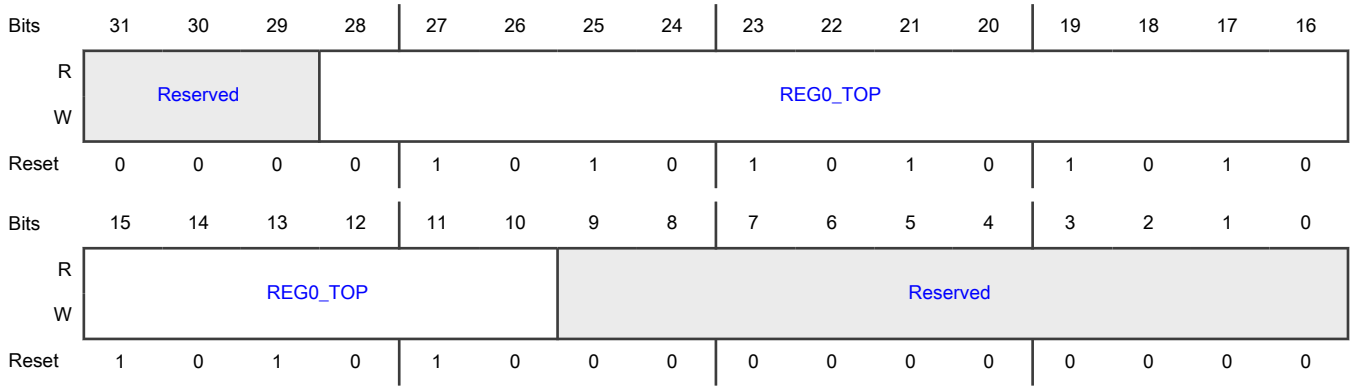
Offset

Register	Offset
REG0_TOP	14h

Function

Provides bits 28-10 of the region 0 compare address. The actual granularity implemented is 1 KB.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-10 REG0_TOP	Upper Limit Of Region 0 Provides bits 28-10 of the region 0 compare address. The value provided here is concatenated with 3FFh to create the full compare address. For example, if REG0_TOP[28:10] = 0b00000000000_111111, the region 0 end address is BASE_ADDRESS + 0000_FFFFh (64 KB).
9-0 —	Reserved

7.5.1.3 Region 1 Top Boundary (REG1_TOP)

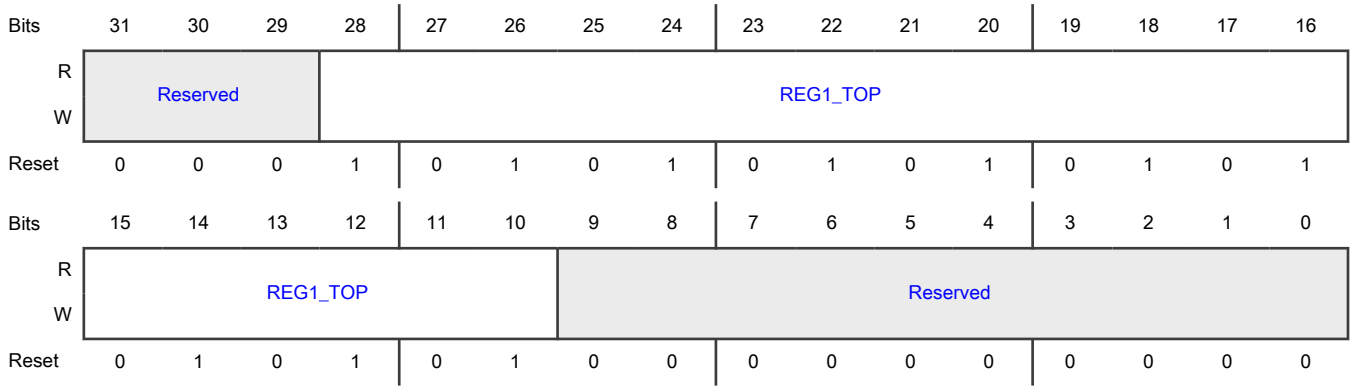
Offset

Register	Offset
REG1_TOP	18h

Function

Provides bits 28-10 of the region 1 compare address. The actual granularity implemented is 1 KB.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-10 REG1_TOP	Upper Limit Of Region 1 Provides bits 28-10 of the region 1 compare address. The value provided here is concatenated with 3FFh to create the full compare address. For example, if REG1_TOP[28:10] = 0b00000000000_111111, the region 0 end address is BASE_ADDRESS + 0000_FFFFh (64 KB).
9-0 —	Reserved

7.5.1.4 Policy Select (POLSEL)

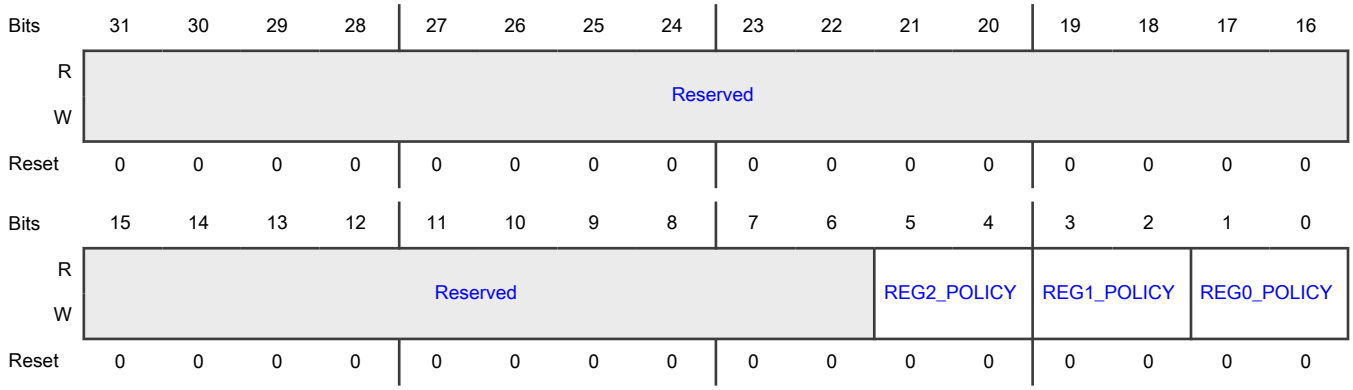
Offset

Register	Offset
POLSEL	1Ch

Function

Specifies the policy to be applied to all addresses falling within the designated space.

Diagram



Fields

Field	Function
31-6 —	Reserved
5-4 REG2_POLICY	Policy Select For Region 2 Specifies the policy to be applied to all addresses falling within the space designated as region 2. 00b - Noncacheable 01b - Write-through 10b - Write-back 11b - Invalid
3-2 REG1_POLICY	Policy Select For Region 1 Specifies the policy to be applied to all addresses falling within the space designated as region 1. 00b - Noncacheable 01b - Write-through 10b - Write-back 11b - Invalid
1-0 REG0_POLICY	Policy Select For Region 0 Specifies the policy to be applied to all addresses falling within the space designated as region 0. 00b - Noncacheable 01b - Write-through 10b - Write-back 11b - Invalid

Chapter 8
Flash Memory Module (FMU)

8.1 Chip-specific FMU information

Table 36. Reference links to related information

Topic	Related module	Reference
Full description	FMU	Flash Memory Module
System memory map		Memory map
Clocking		Clock distribution

8.1.1 Module instances

This device contains one instance of the FMU module, FMU0.

8.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

8.1.3 Key terms

- Flash page — 128 bytes of flash main memory; represents the largest portion of the flash memory that can be programmed in one operation.
- Flash phrase — 16 bytes of flash main memory; represents the smallest portion of the flash memory that can be programmed in one operation.
- Flash sector — 8 KB flash main memory; represents the smallest portion of the flash memory that can be erased in one operation.

8.1.4 Internal flash

See Internal flash.

8.1.5 Salvage feature

The salvage feature is enabled in this MCU. Salvage involves using ECC to pass erase verify, allowing single-bit faults per phrase verified. See description of FSTAT[SALV_USED] for more details.

8.1.6 Register reset value

The reset value of the FSTAT and FCCOB0 registers might change depending on the device's BootROM settings.

8.1.7 FCTRL[RWSC] configuration

The configuration of Read Wait-State Control (RWSC) field of Flash Control Register (FCTRL) is shown in below table.

Table 37. FCTRL[RWSC] configuration in different run modes and speed

OD mode	SD Mode	MD Mode	RWSC
101-150 MHz	—	—	0011 (default value)
65-100 MHz, includes 100 MHz	65-100 MHz, includes 100 MHz	—	0010
37-64 MHz, includes 64 MHz	37-64 MHz, includes 64 MHz	25-50 MHz	0001
<= 36 MHz	<= 36 MHz	<= 24 MHz	0000

8.2 Overview

The flash module includes the following accessible memory regions:

- Program flash memory for vector space and code store
- Separate flash memory for parameter store

Flash memory is ideal for single-supply applications, permitting in-the-field erase and reprogramming operations without the need for any external high voltage power sources.

The flash module includes a command controller that executes commands to modify flash memory contents. An erased bit reads '1' and a programmed bit reads '0'. The programming operation is unidirectional; it can only move bits from the '1' state (erased) to the '0' state (programmed). Only the erase operation restores bits from '0' to '1'; bits cannot be programmed from a '0' to a '1'.

CAUTION

A flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a flash phrase or page is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

The standard shipping condition for flash memory is erased. Data loss over time may occur due to degradation of the erased ('1') states and/or programmed ('0') states. Therefore, it is recommended that flash memory be re-erased immediately prior to factory programming to ensure that the full data retention capability is achieved.

8.2.1 Block diagram

The block diagram of the flash module is shown in the following figure.

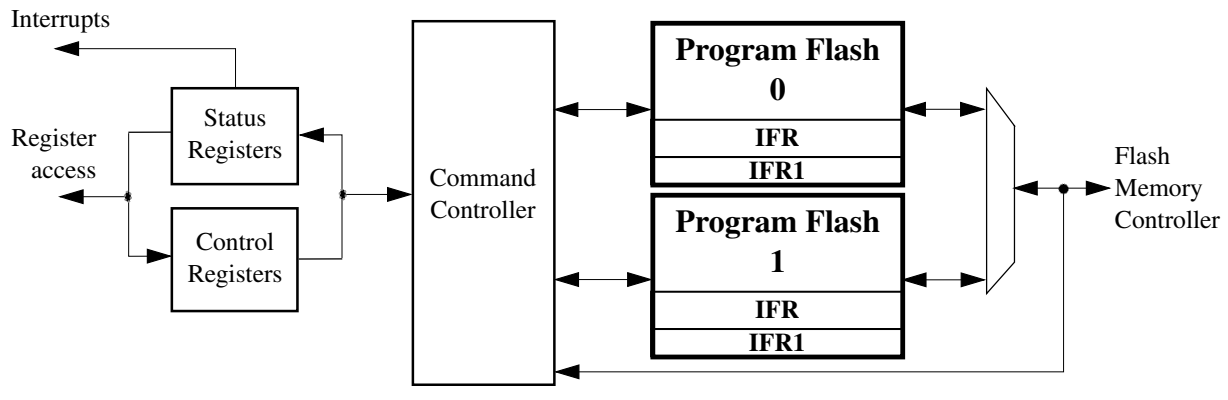


Figure 9. Flash block diagram

8.2.2 Features

The flash memory module provides the following features:

- Sector size of 8 Kbytes
- Single-bit error correction and double-bit error detection for each flash or IFR phrase
- Read-while-write flash access
- Command-based flash program, erase, and verify operations
- Internal high-voltage supply generator for flash program and erase operations
- Optional interrupt generation upon flash command completion
- Optional interrupt generation upon double-bit error detection during flash reads from the FMC

NOTE

See the chip configuration details for the exact amount of flash memory available.

8.3 Functional description

The following sections describe functional details of the flash module.

8.3.1 Operations

Operations are typically used to modify flash memory contents. The next sections describe:

- Command write sequence used to set flash command parameters and launch execution
- Available flash commands
- Commands impacted by Block Checker and FMC access protection
- Read-while-write capability

8.3.1.1 Command write sequence

Flash commands are accomplished using a command write sequence illustrated in Figure 10. The command controller monitors the transaction protection level on writes during the command write sequence, performs various checks on the command (FCCOB) content, and continues with command execution if all requirements are fulfilled.

Before launching a command, the ACCERR, PVIOL, and CMDABT flags in the FSTAT register must be zero and the CCIF flag must be one to verify that any previous command has completed. The FAIL flag in the FSTAT register is cleared by the command controller when a command is launched unless the FAIL flag was set during initialization due to FMU parameters not being loaded from IFR1. If CCIF is clear, the previous command execution is still active, a new command write sequence cannot be started, and all writes to the FCCOB registers are ignored.

8.3.1.1.1 Load the FCCOB Registers

The user must load the FCCOB registers with all parameters required by the specific flash command. The contents of any FCCOB register not used by the specific flash command are ignored except for FCCOB1 (command options) where undefined bits should be cleared. The individual registers that make up the FCCOB data set can be written in any order. All writes to the FCCOB registers in a command write sequence must occur at the same transaction protection level. Any write to the FCCOB registers that violates this rule will be ignored.

Addresses loaded into FCCOB registers assume the flash and IFR spaces start at 0000_0000h. For multi-block configurations, flash space is concatenated and IFR space is concatenated (see IFR description).

8.3.1.1.2 Launch the Command by Clearing CCIF

Once all relevant command parameters have been loaded, the user launches the command by clearing the FSTAT[CCIF] bit by writing a '1' to it. The write to clear CCIF must occur at the same transaction protection level as the writes used to load

the FCCOB registers. Any write to clear CCIF that violates this rule will be ignored. The CCIF flag remains clear until the flash command completes.

The FSTAT register contains a blocking mechanism which prevents a new flash command from launching (unable to clear CCIF) if the previous command resulted in the setting of an access error (ACCERR), protection violation (PVIOL), or active command abort flag (CMDABT). In error scenarios, two writes to FSTAT are required to initiate the next command: the first write to clear these flags, the second write to clear CCIF. The write to clear these flags can occur at any transaction protection level.

8.3.1.1.3 Command Execution and Error Reporting

Flash command processing contains the following steps:

1. The command controller performs a series of parameter checks, if applicable, which are unique to each command. If the parameter check fails, the FSTAT[ACCERR] flag is set. ACCERR reports invalid instruction codes or options, out of bounds or misaligned addresses, or missing FMU parameters. In the case FMU parameters were not loaded from IFR1 during initialization, the ACCERR flag sets and the FSTAT[FAIL] flag remains set. Command processing never proceeds to execution when the parameter check fails. Instead, command processing is terminated after setting the FSTAT[CCIF] flag. Note that for program and erase operations, PEWEN will not set if FMU parameters were not loaded and PERDY will not set if program or erase related writes to flash or IFR space violate command requirements.
2. If necessary, the command controller performs a protection check to see if the command is allowed to execute on the requested memory space. If the protection check fails, the FSTAT[PVIOL] flag is set. Command processing never proceeds to execution when the protection check fails. Instead, command processing is terminated after setting the FSTAT[CCIF] flag.
3. If the parameter and protection checks pass, the command proceeds to execution. Run-time errors, such as failure to verify, may occur during the execution phase and are reported in the FAIL flag. A flash command may have access errors, protection violations, and run-time errors, but the run-time errors are not seen until all access errors and protection violations have been corrected.
4. If FCTRL[ABTREQ] sets during command execution, the operation will abort with the FSTAT[CMDABT] flag set.
5. Command execution results, if applicable, are reported back to the user via the FCCOB registers.
6. The command controller sets FSTAT[CCIF] signifying that the command has completed.

CAUTION

If the FAIL flag is set along with ACCERR, FMU parameters were not loaded from IFR1 during initialization. In this case, it is recommended that the flash module be reinitialized. If the issue persists, flash commands will continue to set the ACCERR and FAIL flags.

The flow for a generic command write sequence is illustrated in the following figure.

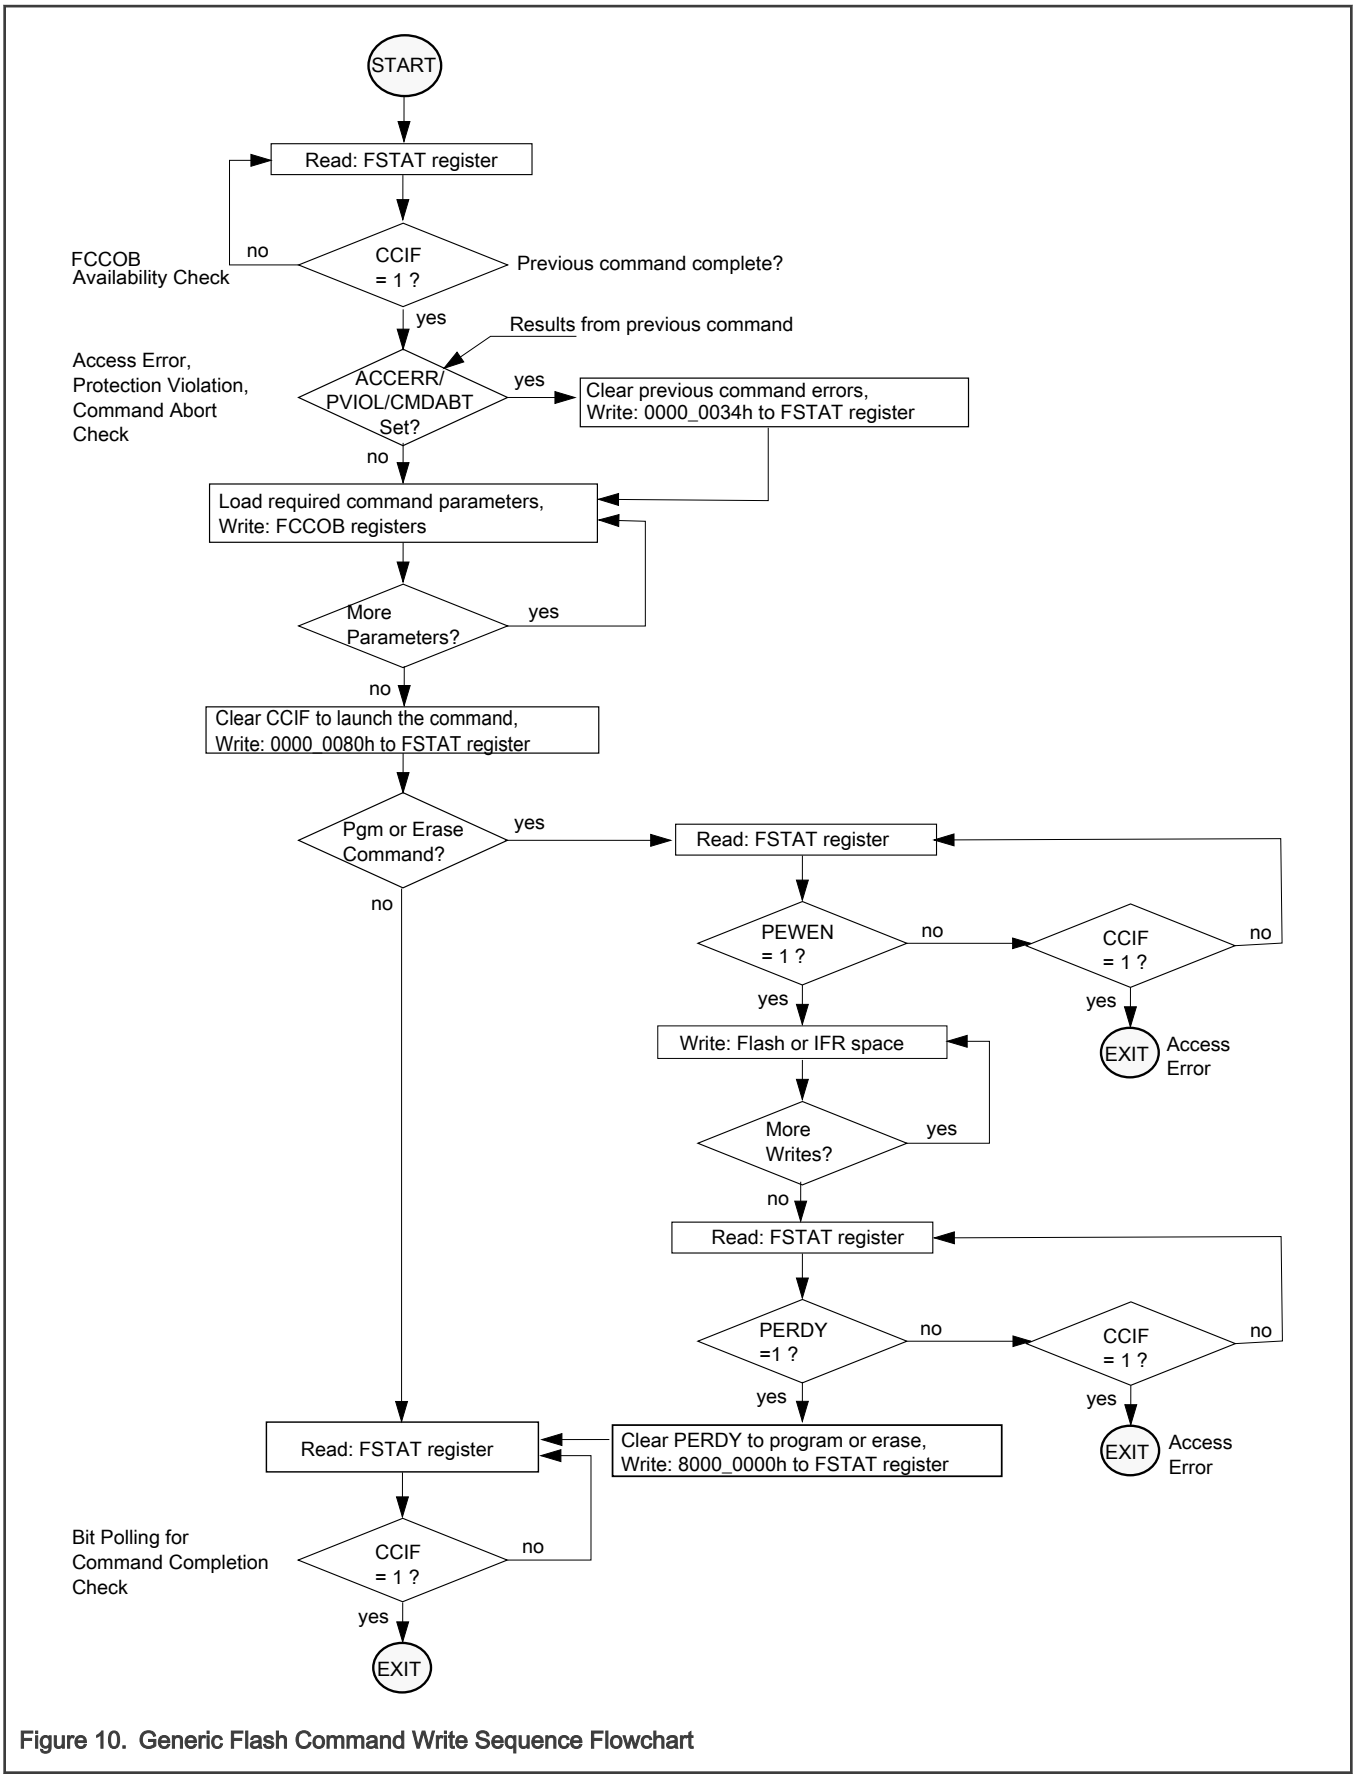

Figure 10. Generic Flash Command Write Sequence Flowchart

8.3.1.1.4 Aborting a Command Write Sequence or Command Operation

FSTAT[CMDP] sets at the start of a command write sequence, typically by writing to one of the FCCOB registers. With CMDP set, setting the FCTRL[ABTREQ] bit allows a user to abort a command write sequence and take control over a new command write sequence. The ABTREQ bit can only be set by a user with the same domain ID as indicated by FSTAT[CMDDID] and at the same or higher security/privilege protection level when compared to FSTAT[CMDPRT], the current owner of the command write sequence. While ABTREQ is set, CCIF cannot be cleared to launch a command.

If FSTAT[CCIF] is high when ABTREQ is set, the command write sequence will abort and ownership transferred to the user setting the ABTREQ bit. The FSTAT[CWSABT] flag will set and the CMDPRT field will be updated based on the write transaction that set the ABTREQ bit. The ABTREQ bit will then be cleared automatically.

If CCIF is low when ABTREQ is set, the command controller will abort execution of the current command operation, set FSTAT[CMDABT], and set CCIF. The CMDPRT field will be updated based on the write transaction that set the ABTREQ bit. The ABTREQ bit will then be cleared automatically. While CMDABT is set, CCIF cannot be cleared to launch a command. Aborting a program or erase operation may leave the flash or IFR space being modified in an indeterminate state.

NOTE

Aborting certain flash commands may take longer to abort than to execute. See the device data sheet for flash command timing specifications.

8.3.1.2 Flash commands

The following table summarizes the function of all flash commands. If any column is marked with an 'X', the flash command is relevant to that particular memory resource.

FCMD	Command	Program flash 0	IFR	Program flash 1[1]	Function
00h	Read 1s All (RD1ALL)	x	x	x	Verify that all flash and IFR space is erased
01h	Read 1s Block (RD1BLK)	x		x	Verify that a flash block is erased
02h	Read 1s Sector (RD1SCR)	x		x	Verify that a flash sector is erased
03h	Read 1s Page (RD1PG)	x		x	Verify that a flash page is erased
04h	Read 1s Phrase (RD1PHR)	x		x	Verify that a flash phrase is erased
05h	Read into MISR (RDMISR)	x		x	Generate MISR signature for range of flash pages
12h	Read 1s IFR Sector (RD1ISCR)		x		Verify that an IFR sector is erased
13h	Read 1s IFR Page (RD1IPG)		x		Verify that an IFR page is erased
14h	Read 1s IFR Phrase (RD1IPHR)		x		Verify that an IFR phrase is erased

Table continues on the next page...

[1] For module with dual flash blocks.

Table continued from the previous page...

FCMD	Command	Program flash 0	IFR	Program flash 1[1]	Function
15h	Read IFR into MISR (RDIMISR)		x		Generate MISR signature for range of IFR pages
23h	Program Page (PGMPG)	x	x	x	Program data to a flash or IFR page
24h	Program Phrase (PGMPHR)	x	x	x	Program data to a flash or IFR phrase
40h	Erase All (ERSALL)	x	x	x	Erase all flash and IFR space if enabled
42h	Erase Sector (ERSSCR)	x	x	x	Erase a flash sector

8.3.1.3 Flash commands impacted by Block Checker and FMC access protection

The following flash commands are impacted by Block Checker and FMC access protection:

- Program Phrase (PGMPHR)
- Program Page (PGMPG)
- Erase Sector (ERSSCR)

During execution of these flash commands, a sequence of AHB writes to flash or IFR space are required with validity checked by the Block Checker or FMC. When writes are enabled by the FMU, violations detected by the FMC are reported as an access error in the FMU. The other violations are handled by the Block Checker or FMC.

Table 38. Flash Write Access Checks

Flash Write Violation Condition	Block Checker	FMC	FMU
Flash or IFR address out-of-range	X		
Flash or IFR write permission check fails	X		
Write to IFR1 space		X	
Write width not 32-bit		X	
Writes not enabled by FSTAT[PEWEN]		X	
First write in sequence not properly aligned per FSTAT[PEWEN]			X
Non-sequential write after first aligned write in sequence			X
Bus permissions for the AHB write do not match the bus permissions of the APB write that launched the flash command			X

8.3.1.4 Read-while-write (RWW)

The following simultaneous accesses are allowed:

[1] For module with dual flash blocks.
[1] For module with dual flash blocks.

- The user may read from one program flash memory block while a command is active in another program flash memory block.

8.3.2 Flash command descriptions

This section describes all flash commands that can be launched by a valid command write sequence. The flash module sets the FSTAT[ACCERR] bit and aborts the command execution if any of the following illegal conditions occur:

- There is an unrecognized command code in the FCCOB FCMD field.
- There is an error in an FCCOB field for the specific command. Refer to the error handling table provided for each command.

The ACCERR, PVIOL, and CMDABT flags in the FSTAT register should be cleared prior to starting a command write sequence. As described in Launch the Command by Clearing CCIF, a new command cannot be launched while these flags are set.

Do not attempt to read a flash block while a flash command is running (CCIF = 0) on that same block. The flash module may return a transfer error to the FMC resulting in a bus fault. The exception to this rule is during program operations where the flash block is still readable after the command is launched up until the time the FSTAT[PERDY] flag is cleared.

CAUTION

Flash data must be in the erased state before being programmed. Cumulative programming of bits (adding more zeros) is not allowed.

8.3.2.1 Read 1s All Command

The Read 1s All command checks if all flash and IFR space are in the erased state.

Table 39. Read 1s All Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	00h (RD1ALL)

Upon clearing CCIF to launch the Read 1s All command, the command controller:

- verifies that all flash and IFR space are in the erased state

If all flash and IFR space are not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s All operation completes.

Table 40. Read 1s All Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

8.3.2.2 Read 1s Block Command

The Read 1s Block command checks if a flash block is in the erased state.

Table 41. Read 1s Block Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	01h (RD1BLK)
2	Block address

Upon clearing CCIF to launch the Read 1s Block command, the command controller:

- verifies that the selected flash block is in the erased state

If the selected flash block is not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s Block operation completes.

Table 42. Read 1s Block Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Address is not block aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

8.3.2.3 Read 1s Sector Command

The Read 1s Sector command checks if a flash sector is in the erased state.

Table 43. Read 1s Sector Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	02h (RD1SCR)
2	Sector address

Upon clearing CCIF to launch the Read 1s Sector command, the command controller:

- verifies that the selected flash sector is in the erased state

If the selected flash sector is not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s Sector operation completes.

Table 44. Read 1s Sector Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Address is not sector aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

8.3.2.4 Read 1s Page Command

The Read 1s Page command checks if a flash page is in the erased state.

Table 45. Read 1s Page Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	03h (RD1PG)
2	Page address

Upon clearing CCIF to launch the Read 1s Page command, the command controller:

- verifies that the selected flash page is in the erased state

If the selected flash page is not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s Page operation completes.

Table 46. Read 1s Page Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Address is not page aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

8.3.2.5 Read 1s Phrase Command

The Read 1s Phrase command checks if a flash phrase is in the erased state.

Table 47. Read 1s Phrase Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	04h (RD1PHR)
2	Phrase address

Upon clearing CCIF to launch the Read 1s Phrase command, the command controller:

- verifies that the selected flash phrase is in the erased state

If the selected flash phrase is not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s Phrase operation completes.

Table 48. Read 1s Phrase Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Address is not phrase aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

8.3.2.6 Read into MISR command

The Read into MISR operation generates a signature based on the contents of the selected flash memory using an embedded MISR.

Table 49. Read into MISR Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	05h (RDMISR) [7:0]
2	Starting flash page address
3	Ending flash phrase address
4	Word 0 of MISR seed
5	Word 1 of MISR seed
6	Word 2 of MISR seed
7	Word 3 of MISR seed
Returned values	
4	Word 0 of MISR signature
5	Word 1 of MISR signature
6	Word 2 of MISR signature
7	Word 3 of MISR signature

Upon clearing CCIF to launch the Read into MISR command, the command controller:

1. initializes the MISR with the seed provided
2. processes flash data starting with the starting flash page address provided
3. continues until the ending flash phrase address has been processed (must be the last phrase in a page)
4. returns the resulting signature into the FCCOB register bank unless an uncorrectable ECC fault is detected

The CCIF flag sets after the Read into MISR operation completes. If the operation is aborted by setting FCTRL[ABTREQ], a signature will not be returned if the abort occurs prior to the operation writing the signature.

MISR polynomial is $X^{128} + X^{126} + X^{101} + X^{99} + 1$.

Table 50. Read into MISR Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Starting address is not flash page aligned	FSTAT[ACCERR]
Ending address is not flash phrase aligned	FSTAT[ACCERR]
Ending address is not the last phrase in a page	FSTAT[ACCERR]
Starting address is larger than the ending address	FSTAT[ACCERR]
Requested range crosses a flash block boundary	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]

Table continues on the next page...

7	Word 3 of MISR seed
Returned values	
4	Word 0 of MISR signature
5	Word 1 of MISR signature
6	Word 2 of MISR signature
7	Word 3 of MISR signature

Upon clearing CCIF to launch the Read IFR into MISR command, the command controller:

1. initializes the MISR with the seed provided
2. processes IFR data starting with the starting IFR page address provided
3. continues until the ending IFR phrase has been processed (must be the last phrase in a page)
4. returns the resulting signature into the FCCOB register bank unless an uncorrectable ECC fault is detected

The CCIF flag sets after the Read IFR into MISR operation completes. If the operation is aborted by setting FCTRL[ABTREQ], a signature will not be returned if the abort occurs prior to the operation writing the signature.

MISR polynomial is $X^{128} + X^{126} + X^{101} + X^{99} + 1$.

Table 58. Read IFR into MISR Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Starting address is not IFR page aligned	FSTAT[ACCERR]
Ending address is not IFR phrase aligned	FSTAT[ACCERR]
Ending address is not the last phrase in a page	FSTAT[ACCERR]
Starting address is larger than the ending address	FSTAT[ACCERR]
Requested range crosses the IFR block boundary	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Uncorrectable ECC error is detected	FSTAT[FAIL]

8.3.2.11 Program Page command

The Program Page operation programs 32 words of data to a previously erased flash or IFR page.

CAUTION

The page must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a page is not allowed.

Table 59. Program Page Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	23h (PGMPG) [7:0]

Upon clearing CCIF to launch the Program Page command, the command controller:

1. sets FSTAT[PEWEN] to enable writes to the flash and IFR space in the system memory map
2. waits for the user to write 32 consecutive words to the flash or IFR space with the first write being page aligned
3. clears FSTAT[PEWEN] field
4. sets FSTAT[PERDY]
5. waits for the user to clear FSTAT[PERDY]
6. programs the data into the targeted page written to in step 2
7. verifies bits to be programmed are programmed to the program verify level

The CCIF flag sets after the Program Page operation completes. The Program Page operation can be aborted by setting FCTRL[ABTREQ]. If the operation is aborted, the operation terminates with the FSTAT[CMDABT] flag set. Once CCIF is set, the Program Page command may be repeated (same addresses, same data) to complete the program operation without erasing the sector containing the targeted page. Invalid writes to flash or IFR space based on Block Checker or FMC access protection are trapped outside of the flash module.

Table 60. Program Page Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Protection level of the writes to flash or IFR space do not match the protection level of the command write sequence	FSTAT[ACCERR]
Initial address is not page aligned and subsequent addresses phrase aligned	FSTAT[ACCERR]
Number of writes to flash or IFR space is more than expected	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

8.3.2.11.1 Page programming

The standard process of programming one or more flash or IFR pages is as follows:

1. If required, launch the Erase Sector command to erase the flash or IFR sector to be programmed (repeat for additional sectors).
2. Launch the Program Page command to enable writes to the flash space.
3. After the command controller sets FSTAT[PEWEN], write 32 consecutive words to the flash space with the first word page aligned. The data written to the flash space is not readable until the program operation has successfully completed.
4. After the flash page has been written, the command controller will stall and set FSTAT[PERDY].

5. Clear PERDY allowing the command controller to resume and program the 32 words into the flash or IFR space written to in step 3.
6. Wait for CCIF to set indicating the program operation has completed.
7. To program additional flash or IFR pages in previously erased flash memory, repeat steps 2 through 6.

8.3.2.12 Program Phrase command

The Program Phrase operation programs 4 words of data to a previously erased flash or IFR phrase.

CAUTION

The phrase must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a phrase is not allowed.

Table 61. Program Phrase Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	24h (PGMPHR) [7:0]

Upon clearing CCIF to launch the Program Phrase command, the command controller:

1. sets FSTAT[PEWEN] to enable writes to the flash and IFR space in the system memory map
2. waits for the user to write 4 consecutive words to the flash or IFR space with the first write being phrase aligned
3. clears FSTAT[PEWEN] field
4. sets FSTAT[PERDY]
5. waits for the user to clear FSTAT[PERDY]
6. programs the data into the targeted phrase written to in step 2.
7. verifies bits to be programmed are programmed to the program verify level

The CCIF flag sets after the Program Phrase operation completes. The Program Phrase operation can be aborted by setting FCTRL[ABTREQ]. If the operation is aborted, the operation terminates with the FSTAT[CMDABT] flag set. Once CCIF is set and the CMDABT flag is cleared, the Program Phrase command may be repeated (same addresses, same data) to complete the program operation without erasing the sector containing the targeted phrase. Invalid writes to flash or IFR space based on Block Checker or FMC access protection are trapped outside of the flash module.

Table 62. Program Phrase Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Protection level of the writes to flash or IFR space do not match the protection level of the command write sequence	FSTAT[ACCERR]
Address is not phrase aligned	FSTAT[ACCERR]
Number of writes to flash or IFR space is more than expected	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

8.3.2.12.1 Phrase programming

The standard process of programming one or more flash or IFR phrases is as follows:

1. If required, launch the Erase Sector command to erase the flash or IFR sector to be programmed (repeat for additional sectors).
2. Launch the Program Phrase command to enable writes to the flash and IFR space.
3. After the command controller sets FSTAT[PEWEN], write 4 consecutive words to the flash or IFR space with the first word phrase aligned. The data written to the flash or IFR space is not readable until the program operation has successfully completed.
4. After the flash or IFR phrase has been written, the command controller will stall the operation and set FSTAT[PERDY].
5. Clear PERDY allowing the command controller to resume and program the 4 words into the flash or IFR space written to in step 3.
6. Wait for CCIF to set indicating the program operation has completed.
7. To program additional flash or IFR phrases in previously erased flash memory, repeat steps 2 through 6.

8.3.2.13 Erase All command

The Erase All operation erases all flash and IFR space if enabled by the MCU. If salvage is enabled, the erase operation will not fail due to detected single-bit ECC faults.

Table 63. Erase All Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	40h (ERSALL) [7:0]

Upon clearing CCIF to launch the Erase All command, the command controller:

1. erases flash block 1 sector-by-sector
2. verifies that flash block 1 is erased; if not, skips IFR space in block 1 and all of block 0
3. erases IFR space in block 1 sector-by-sector
4. verifies IFR space in block 1 is erased; if not, skips all of block 0
5. erases flash block 0 sector-by-sector
6. verifies flash block 0 is erased; if not, skips IFR space in block 0
7. erases IFR space in block 0 sector-by-sector
8. verifies IFR space in block 0 is erased
9. clears FSTAT[CMDP] flag

The CCIF flag sets after the Erase All operation completes. If either the flash or IFR space is not in the erased state, FSTAT[FAIL] sets.

Table 64. Erase All Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Command is disabled by the MCU	FSTAT[PVIOL]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

8.3.2.14 Erase Sector command

The Erase Sector operation erases the IFR sector to prepare the sector for programming.

Table 65. Erase Sector Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	42h (ERSSCR) [7:0]

Upon clearing CCIF to launch the Erase Sector command, the command controller:

1. sets FSTAT[PEWEN] to enable writes to the flash and IFR space in the system memory map
2. waits for the user to write 4 consecutive words to the flash or IFR space with the first write being phrase (or sector) aligned
3. clears FSTAT[PEWEN] field
4. sets FSTAT[PERDY]
5. waits for the user to clear FSTAT[PERDY]
6. erases the selected flash or IFR sector
7. verifies the selected flash or IFR sector is erased

If the selected flash or IFR sector is not in the erased state, FSTAT[FAIL] is set. The CCIF flag sets after the Erase Sector operation completes. The Erase Sector operation can be aborted by setting FCTRL[ABTREQ]. If the operation is aborted, the operation terminates with the FSTAT[CMDABT] flag set. Once CCIF is set, the Erase Sector command may be repeated to complete the erase operation. Invalid writes to flash or IFR space based on Block Checker or FMC access protection are trapped outside of the flash module.

Table 66. Erase Sector Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Protection level of the writes to flash or IFR space do not match the protection level of the command write sequence	FSTAT[ACCERR]
Address is not flash or IFR phrase aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
IFR Sector is protected (see FCNFG register)	FSTAT[PVIOL]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

8.3.3 Mass Erase

If enabled by the MCU, MCU resources can be used to launch a mass erase operation without accessing the flash registers. If salvage is enabled, the erase operation will not fail due to detected single-bit ECC faults.

To know how to enable/disable mass erase for your device, refer the chip-specific section.

The status of the mass erase request is reflected in the FCNFG[ERSREQ] bit. When launched, the mass erase operation occurs regardless of the state of the CMDP, ACCERR, PVIOL, or CMDABT flags in the FSTAT register but requires FSTAT[CCIF] to be set and the MCU to enable mass erase. When mass erase is launched with CCIF set, the CMDP, CCIF, CWSABT, PVIOL, and CMDABT flags in the FSTAT register clear. The ACCERR and FAIL flags also clear unless the FMU parameters were not loaded from IFR1 during initialization in which case the mass erase operation terminates without performing any erase of flash memory.

Upon successful launch of the mass erase operation, the command controller (same steps as the Erase All command):

1. erases flash block 1 sector-by-sector
2. verifies that flash block 1 is erased; if not, skips IFR space in block 1 and all of block 0
3. erases IFR space in block 1 sector-by-sector
4. verifies IFR space in block 1 is erased; if not, skips all of block 0
5. erases flash block 0 sector-by-sector
6. verifies flash block 0 is erased; if not, skips IFR space in block 0
7. erases IFR space in block 0 sector-by-sector
8. verifies IFR space in block 0 is erased

The CCIF flag sets and the ERSREQ bit clears once the operation completes and the FSTAT[FAIL] flag sets if any verify step fails during the mass erase operation. This method of erasing the flash memory cannot be aborted by setting FCTRL[ABTREQ].

8.3.4 Modes

8.3.4.1 Sleep mode

If the CPU enters sleep mode while a flash command is executing, the flash module can wake the CPU via the command complete interrupt (see Interrupts).

8.3.4.2 Non-Active Power mode

If a flash command is active (CCIF = 0) when the MCU requests a non-active power mode, the command execution completes before the MCU is allowed to enter the non-active power mode.

8.3.5 Clocking

This module has no clocking considerations.

8.3.6 Interrupts

The flash module can generate interrupt requests to the MCU upon the occurrence of various flash module events. These interrupt events and their associated status and control bits are shown in the following table.

Table 67. Flash Module Interrupt Sources

Flash Event	Readable Status Bit	Interrupt Enable Bit
Flash Command Complete	FSTAT[CCIF]	FCNFG[CCIE]
Flash ECC Fault Detected	FSTAT[DFDIF]	FCNFG[DFDIE]

NOTE

Vector addresses and their relative interrupt priority are determined at the MCU level.

8.4 External signals

The flash module contains no signals that connect off-chip.

8.5 Initialization

On each reset, the command controller initializes the following based on IFR1 content:

1. FCTRL[RWSC]
2. FMU Parameters (FMUPARM)

The FSTAT[CCIF] flag is cleared throughout the initialization flow. The flash module also holds off all access to flash registers and flash memory during initialization. Completion of the initialization flow is marked by setting FSTAT[CCIF]. If an uncorrectable ECC error is detected during initialization, the FSTAT[FAIL] flag sets. The FAIL flag also sets if FMU parameters are not loaded from IFR1 during initialization. In this case, attempts to launch a flash command terminate with the ACCERR and FAIL flags set. The recommendation is to refrain from launching flash commands if the FAIL flag sets after initialization.

If a reset occurs while any flash command is in progress, that command is immediately aborted. The state of the flash memory or IFR space being programmed or erased is not guaranteed. Command operations do not automatically resume after exiting reset.

8.6 Memory map and registers

This section describes the flash memory map for IFR/IFR1 space and registers. See the MCU system memory map for the location of all flash memory space and registers. Data read from unimplemented memory space in the flash module is undefined.

8.6.1 IFR description

Each flash block contains IFR space separate from the main flash memory. IFR space is memory mapped (see the MCU system memory map). IFR space is divided into IFR pages programmable using the Program Page command. IFR pages are further divided into IFR phrases programmable using the Program Phrase command. Once programmed, IFR phrases can be reprogrammed after a successful erase using the Erase Sector command operation unless the IFR sector is protected by the FCNFG register.

Table 68. IFR map

Offset Byte Address	IFR Field Size (Bytes)
Block 0 IFR Sector 0	
0000h-1FFFh	8,192
Block 0 IFR Sector 1	
2000h-3FFFh	8,192
Block 0 IFR Sector 2	
4000h-5FFFh	8,192
Block 0 IFR Sector 3	
6000h-7FFFh	8,192
Block 1 IFR Sector 0	
8000h-9FFFh	8,192
Block 1 IFR Sector 1	
A000h-BFFFh	8,192
Block 1 IFR Sector 2	
C000h-DFFFh	8,192
Block 1 IFR Sector 3	
E000h-FFFFh	8,192

Each flash block also contains IFR1 space separate from the main flash memory. IFR1 space in program flash block 0 is memory mapped for read-only access (see the MCU system memory map). IFR1 space cannot be erased or programmed by the user.

Table 69. IFR1 map

Offset Byte Address	IFR1 Field Size (Bytes)
Block 0 IFR1 Sector	
0000h-15FFh	5,632
1600h-16FFh	256
1700h-1FFFh	2,304
Block 1 IFR1 Sector	
2000h-3FFFh	8,192

8.6.2 Register descriptions

The flash module contains a set of memory-mapped control and status registers.

NOTE

While a command is running (FSTAT[CCIF]=0), register writes are allowed to FSTAT[PERDY,DFDIF,CWSABT], FCNFG, and FCTRL[ABTREQ,FDFD,RWSC].

8.6.2.1 Flash register descriptions

8.6.2.1.1 Flash memory map

FMU0.MSF1 base address: 4004_3000h

Offset	Register	Width (In bits)	Access	Reset value

8.6.2.1.2 Flash Status Register (FSTAT)

Offset

Register	Offset
FSTAT	0h

Function

The FSTAT register reports the operational status of the flash module.

NOTE

When set, ACCERR, PVIOL, and CMDABT flags prevent the launch of any more commands until the flag is cleared (by writing a one to it).

CAUTION

When clearing the DFDIF flag, be careful not to use read-modify-write on the entire FSTAT register and inadvertently clear CCIF to launch a command.

Diagram

Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	u

Fields

Field	Function
31 PERDY	Program-Erase Ready Control/Status Flag The PERDY flag is set by the command controller when a program or sector erase command operation has successfully completed the write phase. The command controller will stall the command operation until the user clears the PERDY flag by writing a 1 to PERDY. Failure to clear PERDY will leave the command controller stalled but the flash or IFR space targeted by the command operation will remain readable by the FMC. If FCTRL[ABTREQ] is set while the PERDY flag is set, the command controller will clear PERDY, abort the command operation, and set both CCIF and CMDABT. 0b - Program or sector erase command operation not stalled 1b - Program or sector erase command operation ready to execute

Table continues on the next page...

Table continued from the previous page...

Field	Function
30-26 —	Reserved
25-24 PEWEN	Program-Erase Write Enable Control During program or sector erase command operations, writes are enabled to flash or IFR space in the system memory map. For phrase programming or sector erase, writes are enabled for 4 consecutive words (16 bytes) with address phrase aligned. For page programming, writes are enabled for 8 consecutive phrases (128 bytes) with address page aligned. For programming, data written to erased flash or IFR space for program commands is not available until the program operation has successfully completed. PEWEN will not assert if FMU parameters were not loaded from IFR1 during initialization. 00b - Writes are not enabled 01b - Writes are enabled for one flash or IFR phrase (phrase programming, sector erase) 10b - Writes are enabled for one flash or IFR page (page programming) 11b - Reserved
23-18 —	Reserved
17 SALV_USED	Salvage Used for Erase operation This flag indicates salvage was used during the last Erase Sector, Erase All, or Mass Erase operation and is valid at the end of the operation. Salvage involves using ECC to pass erase verify allowing single-bit faults per phrase verified. This flag remains valid until any flash command or Mass Erase operation launches at which time the flag clears. Use of salvage does not guarantee that the erase operation succeeds but only that salvage was used on at least one phrase. 0b - Salvage not used during last operation 1b - Salvage used during the last erase operation
16 DFDIF	Double Bit Fault Detect Interrupt Flag The DFDIF flag indicates an uncorrectable ECC fault was detected during a valid flash read access from the FMC. The DFDIF flag is cleared by writing a 1 to DFDIF. Writing a 0 to DFDIF has no effect. 0b - Double bit fault not detected during a valid flash read access 1b - Double bit fault detected (or FCTRL[FDFD] is set) during a valid flash read access
15-12 CMDDID	Command domain ID While the CMDP flag is set, the CMDDID bits reflect the domain ID of the write transaction controlling a command write sequence or aborting a command operation. Writes to load an FCCOB register, clear CCIF, or clear PERDY must have the same domain ID as the write transaction that started the command write sequence. The CMDDID bits persist after the CMDP flag clears until the CMDP flag sets again at the start of a new command write sequence. Writes to clear the CWSABT, ACCERR, PVIOL, or CMDABT flags are not influenced by the state of the CMDDID bits.
11	Command protection status flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
CMDP	The CMDP flag sets when a command write sequence starts with a write to load an existing FCCOB register or clear CCIF while ACCERR, PVIOL, and CMDABT are clear. Clearing the CWSABT, ACCERR, PVIOL, or CMDABT flags as part of a command write sequence will not set the CMDP flag. While the CMDP flag is set, the protection level of any subsequent write transaction to load an FCCOB register, clear CCIF, or clear PERDY must match the CMDPRT bits and the domain ID must match the CMDDID bits. The CMDP flag remains set until cleared when CCIF is set after a command operation or Power Down recovery completes unless the CMDABT flag is set. The CMDP flag is cleared even if the operation ends with ACCERR or PVIOL set. When the CMDP flag is cleared, the CMDPRT and CMDDID bits remain unchanged. The CMDP flag is also cleared by a mass erase request with CCIF set. 0b - Command protection level and domain ID are stale 1b - Command protection level (CMDPRT) and domain ID (CMDDID) are set
10 —	Reserved
9-8 CMDPRT	Command protection level While the CMDP flag is set, the CMDPRT bits reflect the secure/privilege protection level of the write transaction controlling a command write sequence or aborting a command operation. Writes to load an existing FCCOB register, clear CCIF, or clear PERDY must occur with the same protection level as indicated by the CMDPRT bits. Writes to clear the CWSABT, ACCERR, PVIOL, or CMDABT flags are not influenced by the state of the CMDPRT bits. If FCTRL[ABTREQ] is set while CCIF is high or low, the CMDPRT bits will change to reflect the security/ privilege protection level of the write transaction that set the ABTREQ bit. 00b - Secure, normal access 01b - Secure, privileged access 10b - Nonsecure, normal access 11b - Nonsecure, privileged access
7 CCIF	Command Complete Interrupt Flag The CCIF flag indicates that a flash command has completed. The CCIF flag is cleared by writing a 1 to CCIF to launch a flash command. The CCIF flag stays low until the command completes. The CCIF flag is cleared by a mass erase request with CCIF set. The CCIF flag is also cleared upon entry into Deep Sleep, Power Down, and Deep Power Down modes and stays low until the end of recovery from these non-active power modes. The CCIF flag is reset to 0 but is set to 1 at the end of flash initialization. 0b - Flash command, initialization, or power mode recovery in progress 1b - Flash command, initialization, or power mode recovery has completed
6 CWSABT	Command Write Sequence Abort Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The CWSABT flag indicates whether a request to abort a command write sequence prior to command launch has been granted. If FCTRL[ABTREQ] is set while CCIF is high, the CWSABT flag will get set. Once CWSABT is set, ABTREQ will get cleared. While the CWSABT flag is set, ABTREQ cannot be set. The CWSABT flag is cleared by writing a 1 to CWSABT while CCIF is set or clear and ABTREQ is clear. Writing a 0 to the CWSABT flag has no effect. The CWSABT flag is cleared by a mass erase request with CCIF set. 0b - Command write sequence not aborted 1b - Command write sequence aborted
5 ACCERR	Command Access Error Flag The ACCERR flag indicates an illegal attempt was made to launch a flash command due to a violation of the command write sequence or by providing invalid command parameters. The ACCERR flag also sets during command execution if FMU parameters were not loaded from IFR1 during initialization. While the ACCERR flag is set, the CCIF flag cannot be cleared to launch a command. The ACCERR flag is cleared by writing a 1 to ACCERR while CCIF is set. Writing a 0 to the ACCERR flag has no effect. The ACCERR flag is cleared by a mass erase request with CCIF set but is not cleared during Power Down recovery. 0b - No access error detected 1b - Access error detected
4 PVIOL	Command Protection Violation Flag The PVIOL flag indicates an attempt was made to modify a protected area of flash memory during a command operation. While the PVIOL flag is set, the CCIF flag cannot be cleared to launch a command. The PVIOL flag is cleared by writing a 1 to PVIOL while CCIF is set. Writing a 0 to the PVIOL flag has no effect. The PVIOL flag is cleared by a mass erase request with CCIF set but is not cleared during Power Down recovery. 0b - No protection violation detected 1b - Protection violation detected
3 —	Reserved
2 CMDABT	Command Abort Flag The CMDABT flag indicates FCTRL[ABTREQ] was set during a command operation while CCIF was clear. This event will result in the termination of the operation unless it occurs during the exit routine of the operation. Once CMDABT is set, ABTREQ will get cleared. While the CMDABT flag is set, ABTREQ cannot be set and the CCIF flag cannot be cleared to launch a command. The CMDABT flag is cleared by writing a 1 to CMDABT while CCIF is set and ABTREQ is clear. Writing a 0 to the CMDABT flag has no effect. The CMDABT flag is cleared by a mass erase request with CCIF set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No command abort detected 1b - Command abort detected
1 —	Reserved
0 FAIL	Command Fail Flag The FAIL flag is set if an error is detected during execution of a flash command, mass erase operation, or flash initialization. If the FAIL flag sets along with ACCERR after launching a flash command or mass erase operation, FMU parameters were not loaded from IFR1 during initialization and a clean POR where FMU parameters are successfully loaded is required to clear the FAIL flag. As a status flag, this bit cannot (and need not) be cleared by the user like some of the other flags in this register. The value of the FAIL flag for "command-N" is valid only at the end of the "command-N" execution when CCIF=1 and before the next command has been launched. At some point during the execution of "command-N+1," the FAIL flag is cleared unless FMU parameters were not loaded from IFR1 during initialization. The FAIL flag is cleared by a mass erase request with CCIF set unless FMU parameters were not loaded from IFR1 during initialization. The FAIL flag is not cleared during Power Down recovery. 0b - Error not detected 1b - Error detected

8.6.2.1.3 Flash Configuration Register (FCNFG)

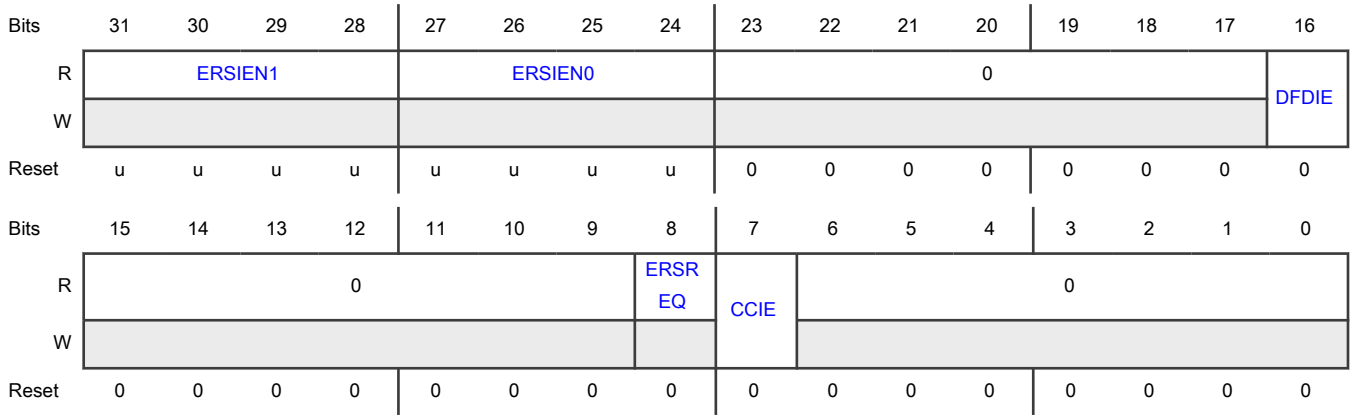
Offset

Register	Offset
FCNFG	4h

Function

This register provides information on the current functional state of the flash module.

Diagram



Fields

Field	Function
31-28 ERSIEN1	Erase IFR Sector Enable - Block 1 (for dual block configs) This field controls the ability to erase the IFR sectors in block 1 using the ERSSCR command. These bits are loaded from sideband signals during initialization. Note: These bits have no effect on single block configurations. Note: The ERSALL command and MCU mass erase request do not adhere to these restrictions. X equals 0, 1, 2, or 3. Any and all bits in the field are independently configured. 0000b - Block 1 IFR Sector X is protected from erase by ERSSCR command 0001b - Block 1 IFR Sector X is not protected from erase by ERSSCR command
27-24 ERSIEN0	Erase IFR Sector Enable - Block 0 This field controls the ability to erase the IFR sectors in block 0 using the ERSSCR command. These bits are loaded from sideband signals during initialization. Note: The ERSALL command and MCU mass erase request do not adhere to these restrictions. X equals 0, 1, 2, or 3. Any and all bits in the field are independently configured. 0000b - Block 0 IFR Sector X is protected from erase by ERSSCR command 0001b - Block 0 IFR Sector X is not protected from erase by ERSSCR command
23-17 —	Reserved
16 DFDIE	Double Bit Fault Detect Interrupt Enable The DFDIE bit controls interrupt generation when an uncorrectable ECC fault is detected during a valid flash read access from the platform flash controller. 0b - Double bit fault detect interrupt disabled 1b - Double bit fault detect interrupt enabled. An interrupt request is generated whenever the FSTAT[DFDIF] flag is set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-9 —	Reserved
8 ERSREQ	Mass Erase Request This bit indicates whether a sideband request has been received by the command controller to execute the Mass Erase operation. ERSREQ is not directly writable but sets when a Mass Erase request is received by the flash module while CCIF is set. ERSREQ is cleared by the command controller when the operation completes. 0b - No request or request complete 1b - Request to run the Mass Erase operation
7 CCIE	Command Complete Interrupt Enable The CCIE bit controls interrupt generation when a flash command completes. 0b - Command complete interrupt disabled 1b - Command complete interrupt enabled. An interrupt request is generated whenever the FSTAT[CCIF] flag is set.
6-0 —	Reserved

8.6.2.1.4 Flash Control Register (FCTRL)

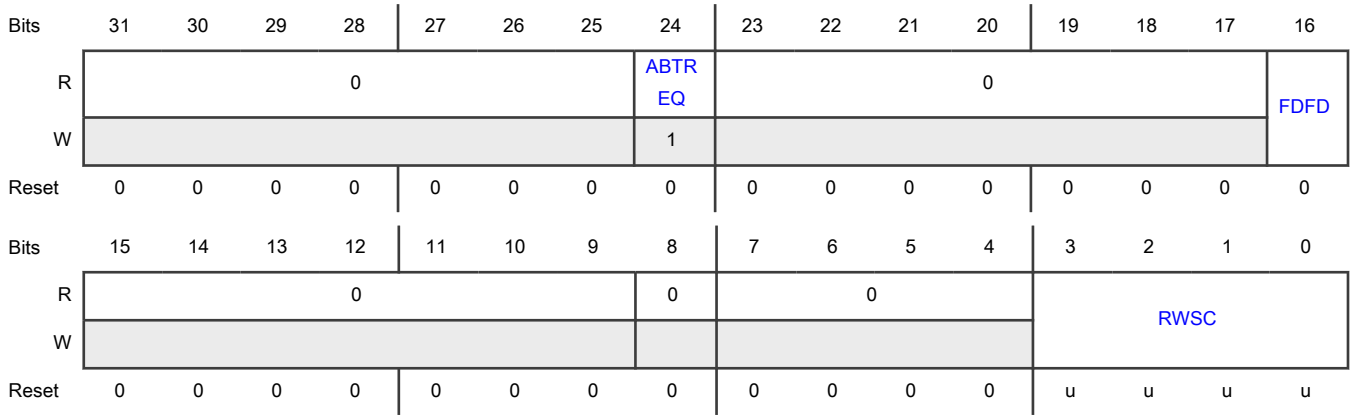
Offset

Register	Offset
FCTRL	8h

Function

The flash control register controls activity associated with flash memory reads and command operations.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 ABTREQ	Abort Request With FSTAT[CMDP] set, setting the ABTREQ bit allows a user to abort a command write sequence or command operation. The ABTREQ bit can only be set by a user with the same domain ID as indicated by FSTAT[CMDDID] and the same or higher security/privilege protection level than is indicated by FSTAT[CMDPRT]. While ABTREQ is set, CCIF cannot be cleared to launch a command. If FSTAT[CCIF] is high when ABTREQ is set, the command write sequence will abort and ownership transferred to the user setting the ABTREQ bit. The FSTAT[CWSABT] flag will set and the CMDPRT field will be updated based on the write transaction that sets the ABTREQ bit. The ABTREQ bit will then be cleared automatically. If FSTAT[CCIF] is low when ABTREQ is set, the command operation will abort and ownership transferred to the user setting the ABTREQ bit. The FSTAT[CMDABT] flag will set and the CMDPRT field will be updated based on the write transaction that sets the ABTREQ bit. The ABTREQ bit will then be cleared automatically. While CWSABT or CMDABT are high, writes to ABTREQ will be ignored. 0b - No request to abort a command write sequence 1b - Request to abort a command write sequence
23-17 —	Reserved
16 FDFD	Force Double Bit Fault Detect The FDFD bit enables the user to emulate the setting of the FSTAT[DFDIF] flag to check the associated interrupt routine. The FDFD bit is cleared by writing a 0 to FDFD. 0b - FSTAT[DFDIF] sets only if a double bit fault is detected during a valid flash read access from the platform flash controller

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - FSTAT[DFDIF] sets during any valid flash read access from the platform flash controller. An interrupt request is generated if the DFDIE bit is set.
15-9 —	Reserved
8 —	Reserved
7-4 —	Reserved
3-0 RWSC	Read Wait-State Control These bits control the number of wait-states added to account for the ratio of system clock period to flash access time during full speed power mode. Ratios greater than one require non-zero settings for the RWSC field for proper flash accesses. The required settings are documented in the device data sheet. 0h - no additional wait-states are added (single cycle access) 1h - 1 additional wait-state is added 2h - 2 additional wait-states are added ... Fh - 15 additional wait-states are added These bits are loaded from IFR1 during initialization. **NOTE** The default FCTRL[RWSC] is set to a value appropriate for the chip's max operating frequency. Refer to the chip-specific section for the default value.

8.6.2.1.5 Flash Common Command Object Registers (FCCOB0 - FCCOB7)

Offset

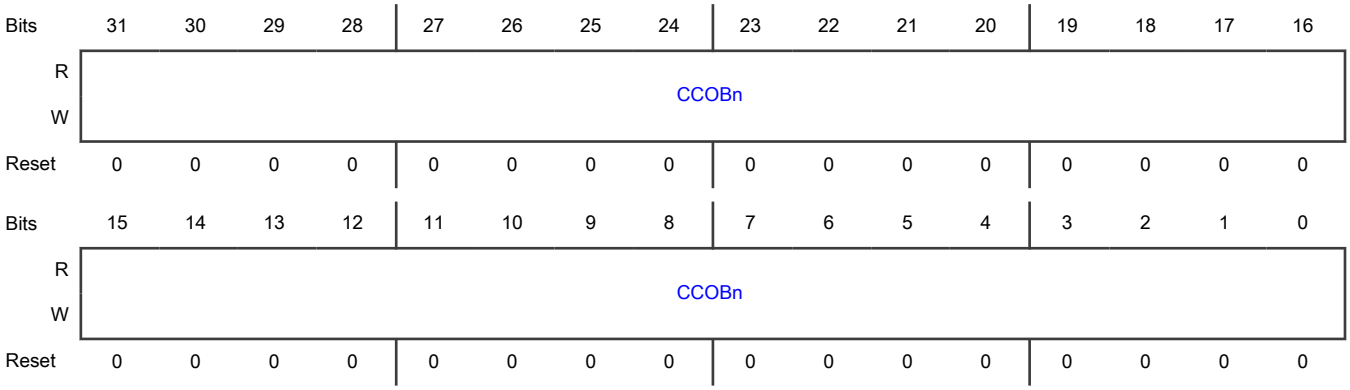
For a = 0 to 7:

Register	Offset
FCCOBa	10h + (a × 4h)

Function

The FCCOB register group provides fields for command codes and parameters. The individual words within the set append a 0-7 hex identifier to the FCCOB register name: FCCOB0, FCCOB1, ..., FCCOB7.

Diagram



Fields

Field	Function
31-0 CCOBn	CCOBn The FCCOB register group provides a command code and relevant parameters to the command controller. The individual registers that compose the FCCOB data set can be written in any order, but you must provide all needed values, which vary from command to command. First, set up all required FCCOB fields and then initiate the command execution by writing a 1 to the FSTAT[CCIF] bit. This clears the CCIF bit, which locks all FCCOB parameter fields and they cannot be changed by the user until the command completes (CCIF returns to 1). No command buffering or queueing is provided; the next command can be loaded only after the current command completes. Some commands return information to the FCCOB registers. Any values returned to FCCOB are available for reading after the FSTAT[CCIF] flag returns to 1. The following table shows a generic flash command format. The first FCCOB register, FCCOB0, always contains the command code. This 8-bit value defines the command to be executed. The command code is followed by the parameters required for this specific flash command, typically an address and/or data values.

NOTE

The command parameter table is written in terms of FCCOB Number (which is equivalent to the word number). This number is a reference to the FCCOB register name and is not the register address.

FCCOB Number[1]	Typical Command Parameter Contents [31:0]
0	FCMD [7:0] (flash command code, bits [31:8] are not writable)
1	FCMDOPT [7:0] (flash command options, bits [31:8] are not writable)
2	Flash address 1 (start)
3	Flash address 2 (end)
4	Data Word 0
5	Data Word 1
6	Data Word 2

Field	Function	
	FCCOB Number[1]	Typical Command Parameter Contents [31:0]
	7	Data Word 3
	1. Refers to FCCOB register name, not register address	

8.7 Glossary

Block Checker — MCU IP that provides a mechanism to set access rights to the flash memory for read and write operations.

Command write sequence — A series of MCU writes to the Flash FCCOB register group and FSTAT[CCIF] that initiates and controls the execution of flash algorithms that are built into the flash module.

Endurance — The number of times that an aligned flash or IFR phrase can be erased and reprogrammed.

FCCOB (Flash Common Command Object Block) — A group of flash registers that are used to pass command, address, data, and any associated parameters to the command controller.

Flash block — A macro within the flash module which provides the nonvolatile memory storage with an aligned block address being the first address in the block.

Flash module — All flash blocks plus a flash management unit providing command control and an interface to MCU buses.

Flash page — 128 bytes of flash main memory with an aligned page having byte-address[6:0] = 00h; represents the largest portion of the flash memory that can be programmed in one operation.

Flash phrase — 16 bytes of flash main memory with an aligned phrase having byte-address[3:0] = 0000b; represents the smallest portion of the flash memory that can be programmed in one operation.

Flash sector — 8 Kbytes of flash main memory with an aligned sector having byte-address[12:0] = 0000h; represents the smallest portion of the flash memory that can be erased in one operation.

FLW — The Flash Logical Window module allows a specific logical address range to access a programmable physical address range in the flash memory with programmable FLW default settings stored in IFR space.

FMC — Flash Memory Controller module manages flash memory reads and writes.

IFR — Information flash region separate from the main flash memory array. Each flash block has 32 Kbytes of user IFR space. Sometimes referred to as IFR0.

IFR1 — Information flash region separate from the main memory array reserved for array trim, MCU trim, and test. Each flash array has 8 Kbytes of IFR1 space.

IFR page — 128 bytes of IFR or IFR1 space with an aligned IFR page having byte-address[6:0] = 00h; represents the largest portion of IFR space that can be programmed.

IFR phrase — 16 bytes of IFR or IFR1 space with an aligned IFR phrase having byte-address[3:0] = 0000b; represents the smallest portion of IFR space that can be programmed in one operation.

IFR sector — 8 Kbytes of IFR or IFR1 space with an aligned IFR sector having byte-address[12:0] = 0000h; represents the smallest portion IFR space that can be erased.

MISR — Multiple-input signature register used to generate a signature based on flash memory contents read.

MSF — Microcontroller Secure Flash.

NVM — Nonvolatile memory. The flash block is an NVM using NOR-type flash memory technology.

Program flash — Program flash memory provides nonvolatile storage for vectors and code store.

Retention — The length of time that data (erased or programmed) can be kept in the NVM without experiencing errors upon readout.

RWW — Read-While-Write. The ability to simultaneously read from one flash memory resource while flash command operations are active in another flash memory resource.

Security/Privilege protection levels — The Flash module supports 4 levels of security/privilege protection for flash commands:

1. Secure (Trusted) / Privileged
2. Secure (Trusted) / User
3. Non-secure (Non-Trusted) / Privileged
4. Non-secure (Non-Trusted) / User

Chapter 9
Flash Controller (FMC)

9.1 Chip-specific FMC information

Table 70. Reference links to related information

Topic	Related module	Reference
Full description	FMC	FMC
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

See NVM Control (NVM_CTRL) for details on flash speculation and flash cache control.

NOTE

The Flash Controller module includes an optional PRINCE encryption/decryption features that is not described here. For details on this feature, refer to the MCX N Security RM.

9.1.1 ECC error check

The flash includes ECC checks on the memory contents. Any correctable, single-bit errors are automatically corrected. Non-correctable, double-bit errors are reported through the Error Recording Module (ERM). See the ERM chapter.

9.2 Overview

The Flash Memory Controller (FMC) is a memory interface and acceleration unit providing:

- An interface between the device and the nonvolatile memory
- Buffers that can accelerate flash memory transfers
  - A flash-phrase-sized buffer (128 bits) holds the most recently accessed flash phrase.
  - An optional flash-phrase-sized speculation buffer can prefetch the next flash phrase.
  - An optional 4-way, set-associative cache can store previously accessed flash phrases.

The FMC manages the interface between the device and the flash memory. The FMC receives status information describing the configuration of the memory and uses this information to ensure a proper interface. The following table shows the supported read and write operations.

Flash memory type	Read	Write
Program, IFR, IFR1 flash memory	8-bit, 16-bit, and 32-bit reads	16-byte and 128-byte writes

The FMC is controlled by a programmer's model external to the FMC module; see the chip-specific FMC information for details. The FMC's programming model provides a very configurable, high performance flexible memory controller, which can be optimized for the runtime characteristics of specific applications.

NOTE

Program the FMC's controls only while the flash controller is idle. Changing the configuration settings while a flash access is in progress can cause non-deterministic, unpredictable behavior.

9.2.1 Features

- Interface between the device and the flash memory:
  - The FMC's input bus supports 8-bit, 16-bit, and 32-bit read operations to flash memory.
  - The FMC's flash memory interface fetches a 128-bit flash phrase.
  - For input read requests, the FMC fetches a flash phrase with the desired read data from flash memory.
  - The flash memory interface can write aligned 16-byte flash write phrases or aligned 128-byte flash write pages to flash memory.
  - The FMC has a 16-byte aligned write buffer. This buffer is used once for aligned 16-byte flash write phrases or eight times for aligned 128-byte flash write pages.
  - The FMC's input bus supports 32-bit write operations for flash memory writes to fill the FMC's write buffer.
  - For input write requests, the FMC must receive the 4-word write of an aligned phrase in order.
- Acceleration of data transfer from flash memory to the device:
  - A flash-phrase-sized buffer that holds the current decrypted flash phrase fetched due to a FMC read request. Subsequent FMC read requests *that hit in the current buffer* return data with no wait states.
  - A flash-phrase-sized prefetch speculation buffer with controls for prefetching on instructions and/or data reads. When prefetching is enabled, idle FMC-to-flash interface cycles are used to fetch the next sequential flash phrase and hold it in the prefetch buffer. Subsequent FMC read requests *that hit in the speculation buffer* return data with no wait states.
  - Input controls:
    - to disable data type speculation
    - to disable all speculation
    - to invalidate the current and speculation buffers

    See the chip-specific section for details about controls.
  - The flash cache has input controls:
    - to disable instruction caching
    - to disable operand caching
    - to disable all caching
    - to clear the cache

    See the chip-specific section for details about controls.
  - The size of the flash cache in bytes is calculated as follows:

    flash cache size = [number of ways] × [number of sets] × [flash phrase size (in bytes)]

    For example, a flash cache with 4 ways, 1 set, and a 128-bit flash phrase (= 16 bytes) has a total flash cache size = 64 bytes

    (4 ways) × (1 set) × (16 bytes per flash phrase) = 64 bytes, the size of the flash cache

    NOTE

    Clear the speculation buffer and flash cache before accessing recently modified flash addresses. The flash cache has a specific clear control bit. To clear the speculation buffer, first disable then re-enable the speculation via other modules.

9.3 Functional description

The FMC is a flash interface and acceleration unit, with flexible buffers for user configuration.

- The FMC's input bus can operate faster than the flash memory.
- The FMC-to-flash interface has flow control to add wait states as needed (for input bus reads that need flash accesses).
- The FMC also contains various configurable buffers that hold recent flash accesses. If an input bus read hits a valid buffer, then that access will complete with no wait states.

9.3.1 Modes of operation

The FMC only operates when a bus master accesses the flash memory.

For any device power mode where the flash memory cannot be accessed, FMC is disabled automatically.

9.3.2 Default configuration

After system reset, the FMC is configured to provide a significant level of buffering for transfers from the flash memory. For all banks:

- The current and speculation buffers are cleared by reset.
- Prefetch support for data and instructions is enabled.
- The cache is cleared by reset.
- The cache is configured for data or instruction replacement.

9.3.3 Configuration options

The default configuration provides a high degree of flash acceleration, but advanced users may want to customize the FMC buffer configurations to maximize throughput for their use cases. When reconfiguring the FMC for custom use cases, do not program the FMC's control registers while the flash memory is being accessed. Instead, change the control registers with a routine executing from RAM in Supervisor mode.

The FMC's cache and buffering controls allow other modules to tune resources to suit specific application requirements. The cache and buffer are each controlled individually. The controls enable buffering and prefetching per memory bank and access type (instruction fetch or data reference).

See the chip-specific section for details about the registers used to configure FMC.

As an application example: if both instruction fetches and data references are accessing flash memory, then control is available to send instruction fetches, data references, or both to the cache or the single-entry buffer. Likewise, speculation can be enabled or disabled for either type of access.

In another application example, the cache can be configured for replacement from bank 0, while the single-entry buffer can be enabled for bank 1 only. This configuration is ideal for applications that use bank 0 for program space and bank 1 for data space.

For best performance, the FMC cache and speculation buffering should be enabled for instruction, data fetching, or both. The following is recommended for best performance:

- If the speculation buffer is enabled for both instruction and data speculation, enable the flash cache for both instruction and data caching.
- If the speculation buffer is enabled for instruction speculation only, enable the flash cache for at least instruction caching.

9.3.4 Wait states

Because the core, crossbar switch, and bus masters can be clocked at a higher frequency than the flash clock, flash memory accesses that do not hit in the speculation buffer or cache usually require wait states.

FMC does not allow the configuration of wait states directly. Wait states can be controlled via FMU FCTRL[RWSC].

9.3.5 Speculative reads

The FMC has a single buffer that reads ahead to the next phrase in the flash memory if there is an idle cycle. Speculative prefetching is programmable for instruction and data accesses. Because many code accesses are sequential, using the speculative prefetch buffer improves performance in most cases.

See the chip-specific section for information about controlling speculative reads.

When speculative reads are enabled, the FMC immediately requests the next sequential phrase address after a read completes. By requesting the next phrase immediately, speculative reads can help to reduce or even eliminate wait states when accessing sequential code and/or data.

9.3.6 Interrupts

This module has no interrupts.

9.4 External signals

The FMC has no external signals.

9.5 Initialization and application information

The FMC does not require user initialization. Flash acceleration features are enabled by default.

The FMC has no visibility into flash memory erase and program cycles because the Flash Memory module manages them directly. To prevent the possibility of returning stale data when an application is executing flash memory commands, disable and/or flush FMC's current buffer, speculation buffer, and cache. While you can disable these features individually, we recommend disabling all of them when executing flash memory commands.

See the chip-specific section for details about the registers used to disable features.

Chapter 10
FlexSPI

10.1 Chip-specific FlexSPI information

Table 71. Reference links to related information

Topic	Related module	Reference
Full description	FlexSPI	FlexSPI
System memory map		Memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

10.1.1 Module instances

This device has one instance of the FlexSPI module, FLEXSPI0.

NOTE

The FlexSPI module includes an optional IPED GCM feature that is not described here. For details on this feature, refer to the MCX N Security RM.

10.1.2 FlexSPI AHB regions

There are multiple FlexSPI regions in the system memory map, but the data accessed is aliased across the multiple regions. Refer to System memory map to see FlexSPI AHB spaces on this device. Also, refer to FlexSPI regions mapping to CACHE64_CTRL and CACHE64_POLSEL.

10.1.3 Controller ID allocation

The Controller ID (MSTRID) values used for the FlexSPI module are same as the AHB bus matrix port numbers. Refer to Table 2 to find the controller port/MSTRID value used for each controller.

10.1.4 FlexSPI connection modes

The table below shows details about the Parallel and Individual modes for flash memory.

Table 72. Relation between modes and bus size for FlexSPI instances

Mode	Effective Bus Size	Data Signals	Function	Devices Attached to Bus	Chip Selects
INDIVIDUAL	4 bit	A_DATA0- A_DATA3	Single QSPI chip support(1b,2b,4b)	Up to 2	A_SS0_B, A_SS1_B
INDIVIDUAL	4 bit	B_DATA0- B_DATA3	Single QSPI chip support(1b,2b,4b)	Up to 2	B_SS0_B, B_SS1_B
INDIVIDUAL	8 bit	A_DATA0-	Single Octal/	Up to 2	A_SS0_B,

Table continues on the next page...

Table 72. Relation between modes and bus size for FlexSPI instances (continued)

Mode	Effective Bus Size	Data Signals	Function	Devices Attached to Bus	Chip Selects
		A_DATA7	Hyperbus/Xccela chip support(1x8b)		A_SS1_B
INDIVIDUAL	8 bit	B_DATA0- B_DATA7	Single Octal/ Hyperbus/Xccela chip support(1x8b)	Up to 2	B_SS0_B, B_SS1_B
PARALLEL	8 bit	A_DATA0- A_DATA3 | B_DATA0- B_DATA3	Two QSPI chips in parallel(2x4b)	2 parallel chips x2 = up to 4	(A_SS0_B | B_SS0_B), (A_SS1_B | B_SS1_B)
PARALLEL	16 bit	A_DATA0- A_DATA7 | B_DATA0- B_DATA7	Two Octal/ Hyperbus/Xccela chips in parallel(2x8b)	2 parallel chips x2 = up to 4	(A_SS0_B | B_SS0_B), (A_SS1_B | B_SS1_B)

10.2 Overview

FlexSPI supports two SPI channels and up to four external devices. Each channel supports Single/Dual/Quad/Octal mode data transfer (1/2/4/8 bidirectional data lines).

The FlexSPI configuration depends on the chip configuration. See the system-level section for boot information and pinmux for chip-specific information regarding the modes and number of devices supported.

FlexSPI supports communication with both serial flash memory and serial RAM devices. While many of the descriptions, registers, and fields specifically reference flash memory, almost all information can also be applied to serial RAM. Flash memory is used as an example in the tables and figures in this chapter.

NOTE

Terminology in this chapter has been updated to align with JEDEC standard *Expanded Serial Peripheral Interface (xSPI) for Non Volatile Memory Devices, Version 1.0*.

Table 73. Updated terms

Updated term	Deprecated term
Controller	Master
Target	Slave

10.2.1 Block diagram

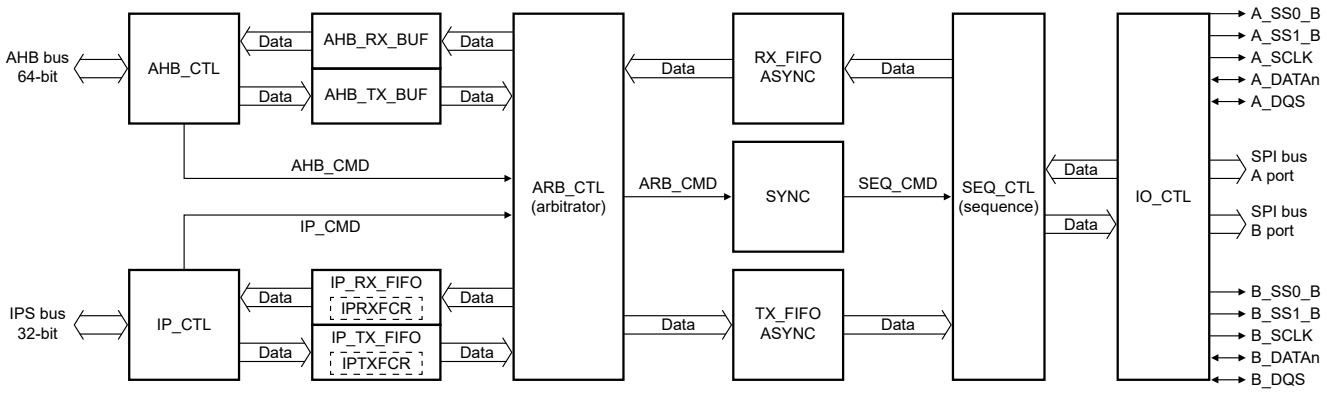


Figure 11. Block diagram

10.2.2 Features

FlexSPI supports:

- Flexible sequence engine (lookup table) to support various vendor devices
  - Serial NOR flash memory and other devices with SPI protocol similar to serial NOR flash memory
  - Serial NAND flash memory
  - HyperBus devices (HyperFlash/HyperRAM)
  - XCCELA devices
  - FPGA devices
- Flash memory access modes
  - Single, Dual, Quad, Octal mode
  - Single Data Transfer Rate (SDR) and Double Data Transfer Rate (DDR) mode
  - Individual/Parallel mode
- Sampling clock mode
  - Internal dummy read strobe looped back internally
  - Internal dummy read strobe looped back from pad
  - SCLK clock output looped back from pad
  - Flash-memory-provided read strobe
- Automatic data learning to select the correct sample clock phase
- Memory mapped read and write access by AHB bus
  - AHB receive buffer implemented to reduce read latency. Total AHB receive buffer size: 1024 bytes.
  - 16 AHB controllers with programmable priority for read access from each
  - 8 flexible and configurable buffers in AHB receive buffer
  - AHB transmit buffer implemented to buffer all write data from one AHB burst. AHB transmit buffer size is 64 bytes.

NOTE

All AHB controllers share this AHB transmit buffer. There is no AHB controller number limitation for write access.

- Software-triggered flash memory read and write access by IP bus
  - IP receive FIFO implemented to buffer all read data from external devices. FIFO size: 1024 bytes
  - IP transmit FIFO implemented to buffer all write data to external devices. FIFO size: 1024 bytes
  - DMA support to read IP receive FIFO
  - DMA support to fill IP transmit FIFO
  - SCLK stops when IP receive FIFO is full during reading flash memory data
  - SCLK stops when IP transmit FIFO is empty during writing flash memory data

10.3 Functional description

10.3.1 Flash connection

There are two FlexSPI interface ports (port A and port B). Each port supports up to two flash devices by providing two chip select outputs.

NOTE

FlexSPI configuration depends on the chip configuration. See the chip-specific FlexSPI information regarding the number of devices supported.

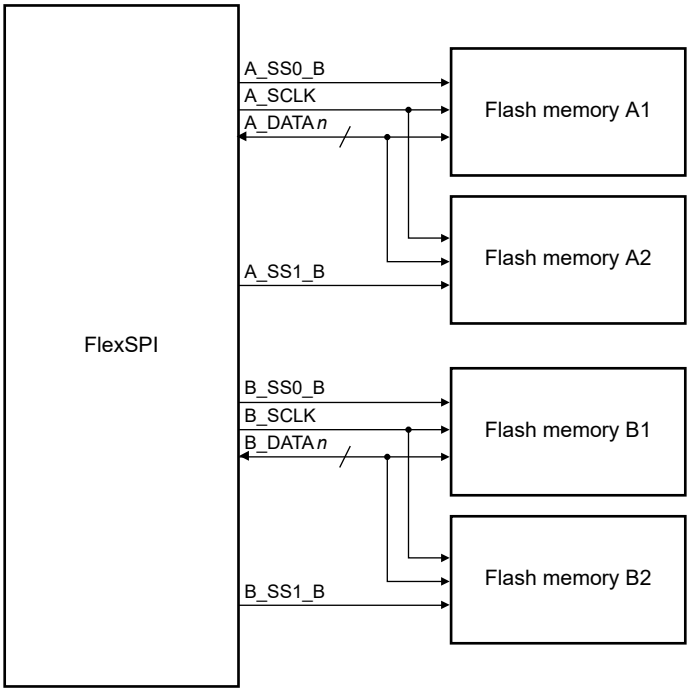

Figure 12. FlexSPI connection diagram with four devices.

NOTE

- Flash A1 and Flash A2 can be two flash chip packages or two flash dies in the same package. There is no difference to FlexSPI. This statement is also true for Flash B1 and Flash B2.
- Flash A1 and Flash B1 can be accessed in parallel, using parallel mode. FlexSPI merges or splits the flash read and program data automatically. This statement is also true for Flash A2 and Flash B2.
- In parallel mode, Flash A1 and Flash A2 cannot be accessed at the same time. This statement is also true for Flash B1 and Flash B2.
- In individual mode, flash devices cannot be accessed at the same time. But these four devices can be accessed separately.

There is a combination mode (MCR0[COMBINATIONEN] = 1) used to provide octal flash memory support by combining Port A (A_DATA[3:0]) and Port B (B_DATA[3:0]) together. Normal mode can also support Octal mode by using all eight data lines from Port A or Port B. Figure 13 shows the connection diagram for combination mode.

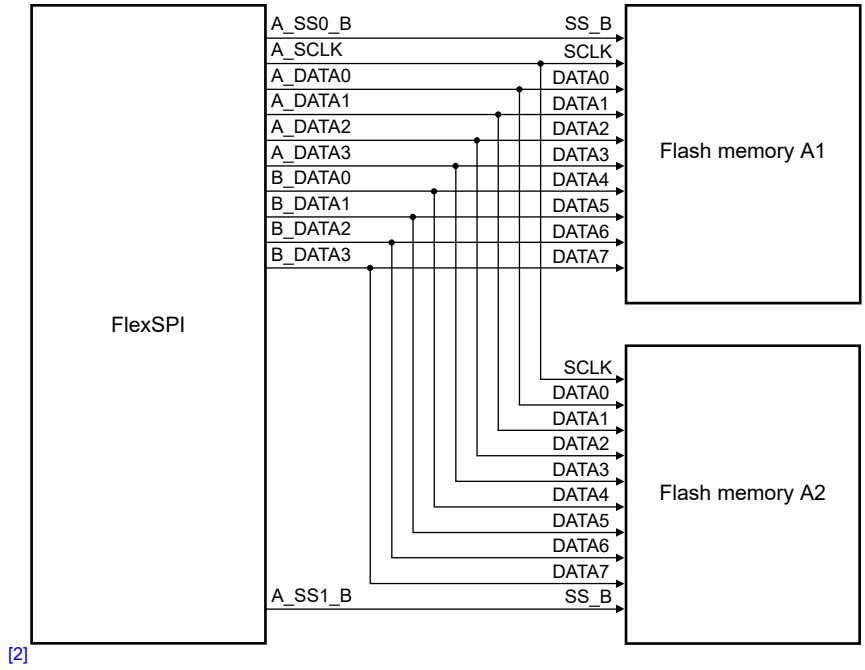

Figure 13. FlexSPI connection diagram for combination mode

10.3.2 Flash memory access mode

10.3.2.1 SPI clock mode

FlexSPI only supports SPI clock mode 0: clock polarity (CPOL) = 0 and clock phase (CPHA) = 0. When the SPI bus is idle, SCLK stays at a logic low state.

10.3.2.2 Individual mode and Parallel mode

In individual mode, read and write data are received and transmitted on port A or port B.

In parallel mode, read and write data are received and transmitted on port A and port B in parallel. FlexSPI merges or splits the read and program data automatically (READ/WRITE instruction). Only read and program data is merged or split (READ/WRITE

[2] Parallel mode access is not available in combination mode.

instruction). For other instructions (such as Command, Address, Mode, and Data size), the same associated information is transmitted to the devices connected to port A and port B. For more details, see Executing instructions on SPI interface.

IPCR1[IPAREN] (for IP command) or AHBCR[APAREN] (for AHB command) statistically determines Individual and Parallel mode.

NOTE

FlexSPI does not support 16-bit read and write for the SPI interface.

10.3.2.3 SDR mode and DDR mode

In SDR mode, flash memory receives data on the rising edge of SCLK and transmits data on the falling edge of SCLK.

In DDR mode, flash memory receives and transmits data on both the rising and falling edges of SCLK.

The instruction (opcode) in the LUT sequence dynamically determines SDR and DDR modes. There is no static configuration register field setting for SDR and DDR modes. See FlexSPI input timing and FlexSPI output timing for details about input and output timing.

10.3.2.4 Single, Dual, Quad, and Octal mode

In Single mode, FlexSPI transmits and receives data on one data pin (DATA0 for transmitting, DATA1 for receiving).

In Dual mode, FlexSPI transmits and receives data on two data pins (DATA0–DATA1 for both transmitting and receiving).

In Quad mode, FlexSPI transmits and receives data on four data pins (DATA0–DATA3 for both transmitting and receiving).

In Octal mode, FlexSPI transmits and receives data on eight data pins (DATA0–DATA7 for both transmitting and receiving).

Instruction (num_pads) in the LUT sequence dynamically determine Single, Dual, Quad, and Octal modes. There is no static configuration register field setting for Single, Dual, Quad, and Octal modes.

10.3.3 Modes of operation

FlexSPI operates with these modes.

Table 74. Operating modes

Mode	Description
Module Disable	This mode is a low-power mode for FlexSPI. In Module Disable mode, the AHB clock and serial clock domains are gated off internally, but the IPS bus clock domain is not gated off. Read and write access to the control and status register are available, but the LUT, IP receive FIFO, and IP transmit FIFO cannot be accessed. Serial memory access is also not available. Write 1 to MCR0[MDIS] to enter this mode. Write 0 to MCR0[MDIS] to exit this mode.
Doze	This mode is a low-power mode for the chip. When the chip requires FlexSPI to enter Doze mode and MCR0[DOZEEN] = 1, FlexSPI enters Doze mode after all transactions are completed (STS0[ARBIDLE] = 1). In Doze mode, the AHB clock and serial clock domains are gated off internally, but the IPS bus clock is not gated off. Read and write access to the control and status register are available, but the LUT, IP receive FIFO, the IP transmit FIFO cannot be accessed. Serial memory access is also not available. This mode is entered via system request, and exited by deasserting this system request.
Stop	This mode is a low-power mode for the chip.

Table continues on the next page...

Table 74. Operating modes (continued)

Mode	Description
	When the chip requires the FlexSPI to enter Stop mode, FlexSPI waits for all transactions to complete (STS0[ARBIDLE] = 1) and return ACK handshake to the system. After the ACK handshake is returned, FlexSPI gates off the AHB clock and serial clock domains internally. The system can gate off the AHB bus clock, IPS bus clock, and serial clock at the system level. This mode is entered via system request. This mode is exited by deasserting this system request, and the ACK handshake message is also deasserted immediately.
Normal	No clock is gated off internally. Normal register access and serial memory access are available.

10.3.4 AHB access memory map

FlexSPI allocates AHB memory space for each memory device starting from the FlexSPI region base address of the system memory map. The FLSHxCR0[FLSHSZ] field determines the amount of memory allocated for each memory device in KB, Fx_SIZE. The memory is then allocated sequentially and contiguously.

NOTE

The maximum flash size supported for each device is 512 MB. The maximum total flash size supported (for all four devices) is also 512 MB.

When MCR2[SAMEDEVICEEN] = 1:

- FA1_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB
- FA2_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB
- FB1_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB
- FB2_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB

When MCR2[SAMEDEVICEEN] = 0:

- FA1_SIZE = FLSHSZ × 1 KB
- FA2_SIZE = FLSHA2CR0[FLSHSZ] × 1 KB
- FB1_SIZE = FLSHB1CR0[FLSHSZ] × 1 KB
- FB2_SIZE = FLSHB2CR0[FLSHSZ] × 1 KB

Flash B1 and Flash B2 size settings are ignored in parallel mode (FLSHB1CR0[FLSHSZ], FLSHB2CR0[FLSHSZ]). To execute in parallel mode, Flash B1 should be the same device as Flash A1, and Flash B2 should be the same device as Flash A2.

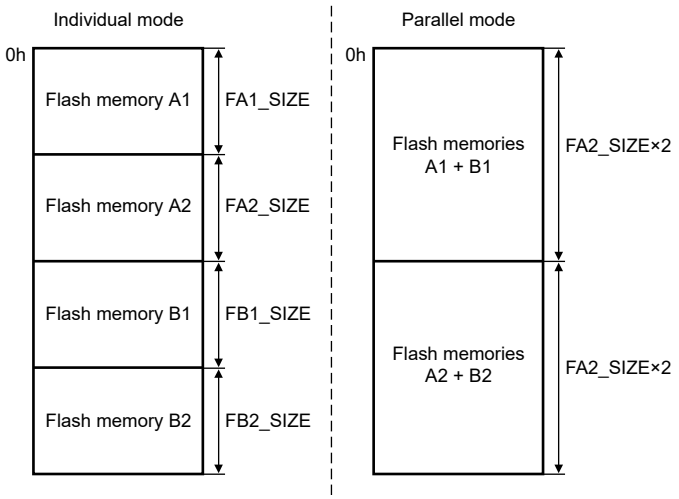

Figure 14. AHB access memory map in individual and parallel mode

AHB access memory map in individual mode:

- Flash A1 address range: 0000_0000h to FA1_SIZE
- Flash A2 address range: FA1_SIZE to (FA1_SIZE + FA2_SIZE)
- Flash B1 address range: (FA1_SIZE + FA2_SIZE) to (FA1_SIZE + FA2_SIZE + FB1_SIZE)
- Flash B2 address range: (FA1_SIZE + FA2_SIZE + FB1_SIZE) to (FA1_SIZE + FA2_SIZE + FB1_SIZE + FB2_SIZE)

AHB access memory map in parallel mode:

- Flash A1+B1 address range: 0000_0000h to FA1_SIZE × 2
- Flash A2+B2 address range: FA1_SIZE × 2 to (FA1_SIZE × 2 + FA2_SIZE × 2)

NOTE

The address used in Figure 14 and equations in this topic is the address presented to the memory. The base address for FlexSPI in the system memory map has already been removed, so it not used or shown here.

10.3.4.1 Dual image use case using HADDRSTART, HADDREND, and HADDROFFSET registers

The FlexSPI controller has a remap feature that supports the storage of dual images in memory. The HADDRSTART and HADDREND registers can be used to configure an address range to which an offset (that the HADDROFFSET register configures) is applied. This feature allows a single system bus address range to be mapped to two different memory ranges: the range that is remapped or the range that is not remapped. You can enable and disable the remapping to switch between accessing the two images at the same system memory address. This feature is used for booting.

NOTE

- Remapping in this table includes the REMAP register (HADDRSTART[0]) and SWAP register (HADDRSTART[2]).
- The swap function impacts both the AHB and IPS address remapping with the same mechanism. The remap function only impacts the AHB address.

Table 75. FlexSPI address translation

	AHB or IPS address	Memory address	Description
Enable remap			

Table continues on the next page...

Table 75. FlexSPI address translation (continued)

	AHB or IPS address	Memory address	Description
AHB WR	ADDR	ADDR + OFFSET	The remap function is available if HADDRSTART <= ADDR < HADDREND, otherwise no change in address.
AHB RD	ADDR	ADDR + OFFSET	The remap function is available if HADDRSTART <= ADDR <HADDREND, otherwise no change in address.
Disable remap			
AHB WR	ADDR	ADDR	No change in address.
AHB RD	ADDR	ADDR	No change in address.

NOTE

- HADDRSTART[0] is used to enable the remap feature.
- The ADDR above is the address from the IPS or AHB interface. The OFFSET is same as the HADDROFFSET register.

10.3.4.2 Flash address sent to flash memory devices

The AHB address (AHB command) or IPCR0[SFAR] (IP command) determines the flash memory access start address. See Flash memory access via AHB command and Flash memory access via IP command for more details.

For AHB commands, the FlexSPI controller removes the flash memory base address automatically when sending flash addresses to flash devices. The flash address is sent to devices in two parts: row address and column address. For flash devices that do not support the column address, set FLSHxCR1[CAS] to 0. This setting causes all flash address bits to be sent to flash devices as row addresses.

For word-addressable flash devices, the last bit of the address is not needed, because flash memory is read and programmed in terms of two bytes. For parallel mode, Flash A1 and Flash B1 (or Flash A2 and Flash B2) are accessed in parallel. As a result, the flash memory address sent to flash devices should be divided by 2. Table 76 indicates the relationship of row address, column address, and flash address (FA).

Table 76. Flash address, row address, and column address

Parallel mode	Word-addressable	Row address	Column address	Comment
0	0	FA[31:CAS]	FA[CAS-1:0]	There is no limitation on FA and data size alignment.
0	1	FA[31:CAS+1]	FA[CAS:1]	FA and data size should be two-byte aligned.
1	0	FA[31:CAS+1]	FA[CAS:1]	FA and data size should be two-byte aligned.
1	1	FA[31:CAS+2]	FA[CAS+1:2]	FA and data size should be four-byte aligned.

NOTE

- FA is the flash address without base address.
- If the bit number of the row or column flash address is more than the valid value, the high position bits are supplemented with zero. See Programmable sequence engine for details about row or column address instructions.

When parallel mode is enabled or word-addressable flash memory is used, there are limitations on the flash memory start address and data size. You can address this requirement by aligning the AHB bus access address (for AHB command) or IP command address IPCR0[SFAR] (for IP command) in software. There are two ways to avoid these limitations in the specified case.

1. For AHB Read Command only:

   When AHBCR[READADDROPT] and AHBCR[PREFETCHEN] are both 1, FlexSPI guarantees the start address and data size for the flash memory access are eight-byte aligned by hardware.

   When AHBCR[READADDROPT] is 1, FlexSPI fetches redundant data to guarantee the flash memory start address is eight-byte aligned. When prefetch is enabled (AHBCR[PREFETCHEN] is 1), the size of the eight-byte-aligned AHB receive buffer determines the flash memory read data size.

2. For AHB Write Command and Individual Mode only:

   By default, FlexSPI guarantees the flash memory write access start address and data size are two-byte aligned when using DQS as write mask (FLSHCR4[WMENB or WMENA] = 1).

   This feature is not applied in parallel mode and must be used if the external device supports write mask feature.

   For example, for odd start address:

   - To write 6 bytes, FlexSPI sends 8 bytes, the first and last byte are both masked.
   - To write 7 bytes, FlexSPI sends 8 bytes, only the first byte is masked.
   - To write 8 bytes, FlexSPI sends 10 bytes, the first and last byte are both masked.

   For even start address:

   - To write 6 bytes, FlexSPI sends 6 bytes, no bytes are masked.
   - To write 7 bytes, FlexSPI sends 8 bytes, last byte is masked.
   - To write 8 bytes, FlexSPI sends 8 bytes, no bytes are masked.

10.3.5 Lookup table (LUT)

The LUT is an internal memory that preserves a number of preprogrammed sequences. Each sequence consists of up to eight instructions which are executed sequentially. When an IP command or an AHB command triggers a flash memory access, the FlexSPI controller:

1. Fetches the sequence from LUT (sequence index or number).
2. Executes the flash memory access to generate a valid flash transaction on the SPI interface.

Figure 15 shows the LUT structures, sequences, and instructions.

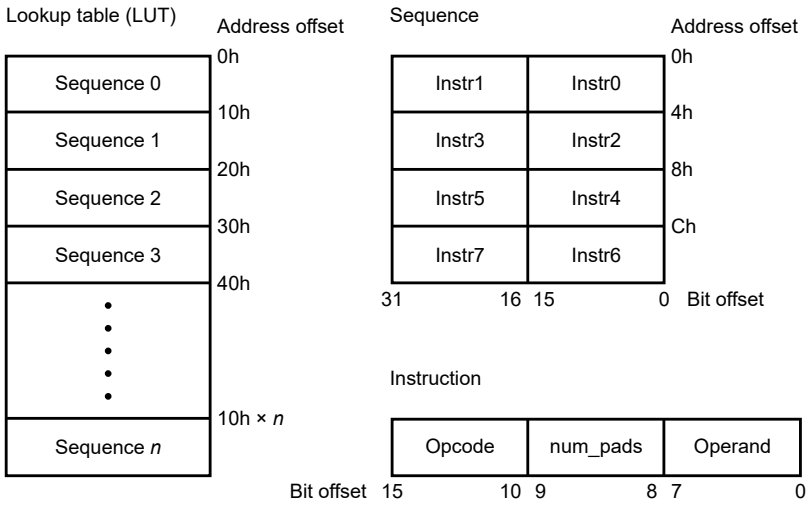

Figure 15. LUT structure, sequences, and instructions

NOTE

If the number of instructions needed for a flash transaction is less than eight, the STOP instruction (code 0000_0000h) must be programmed for unneeded instructions.

For IP and AHB write commands, the FlexSPI controller always executes from instruction pointer 0. For AHB read commands, the FlexSPI controller executes from a saved instruction start pointer. The FlexSPI controller saves the instruction start pointers separately for each flash device. All these saved instruction pointers are zero before the JMP_ON_CS instruction is executed. When the JMP_ON_CS instruction is executed, the operand in the JMP_ON_CS instruction is saved as instruction start pointer. See Execute-In-Place (XIP) enhanced mode.

The reset value of the LUT is unknown because it is implemented as internal memory. The LUT must be programmed according to the connected device. To protect its contents during a code runover, the LUT can be locked or unlocked to prevent unwanted changes after the LUT has been configured. The key to lock or unlock the LUT is **5AF05AF0h**.

To lock the LUT:

1. Write the key (5AF05AF0h) to LUT Key (LUTKEY).
2. Write 1 to LUTCR[LOCK] and write 0 to LUTCR[UNLOCK]. When there is another register write access to FlexSPI between these two write accesses, this LUT is not successfully locked.

To unlock the LUT:

1. Write the key (5AF05AF0h) to the LUT Key Register LUT Key (LUTKEY).
2. Write 0 to LUTCR[LOCK] and write 1 to LUTCR[UNLOCK]. When there is another register write access to FlexSPI between these two write accesses, this LUT is not successfully locked.

The lock status of the LUT can be read from LUTCR[LOCK] and LUTCR[UNLOCK].

10.3.6 Programmable sequence engine

The FlexSPI controller implements a programmable sequence engine that executes the sequence from the LUT. The FlexSPI controller executes the instructions sequentially, and generates flash transactions on the SPI interface accordingly. Table 77 is a complete list of the supported instructions.

Table 77. Instruction set

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
CMD_SDR	00_0001h	00h - one pad (Single mode) 01h - two pads (Dual mode) 02h - four pads (Quad mode) 03h - eight pads (Octal mode)	Transmit command code to flash memory	Command code: Operand[7:0]	Bit number: 8
CMD_DDR	00_0021h				
RADDR_SDR	00_0002h		Transmit row address to flash memory See Flash address sent to flash memory devices	Row_Address[31:0] Row_Address comes from AHB bus (AHB command) or IPCR0[SFAR] (IP command).	Bit number: operand[7:0] Value of operand determines number of bits sent in Row_Address.
RADDR_DDR	00_0022h				
CADDR_SDR	00_0003h		Transmit column address to flash memory. See Flash address sent to flash memory devices.	Column_Address[31:0] Column_Address comes from AHB bus (AHB command) or IPCR0[SFAR] (IP command).	Bit number: operand[7:0] Value of operand determines number of bits sent in Column_Address.
CADDR_DDR	00_0023h				
MODE1_SDR	00_0004h		Transmit mode bits to flash memory	Mode bits: Operand[0]	Bit number: 1
MODE1_DDR	00_0024h				
MODE2_SDR	00_0005h			Mode bits: Operand[1:0]	Bit number: 2
MODE2_DDR	00_0025h				
MODE4_SDR	00_0006h			Mode bits: Operand[3:0]	Bit number: 4
MODE4_DDR	00_0026h				
MODE8_SDR	00_0007h			Mode bits: Operand[7:0]	Bit number: 8
MODE8_DDR	00_0027h				
WRITE_SDR	00_0008h		Transmit program data to flash device	Program data in IP_TX_FIFO or AHB_TX_BUF	AHB burst size and burst type (AHB command) or IPCR1[IDATSZ] (IP command) determines byte number (data size). For details about flash read or program data size, see Flash memory access via AHB command and Flash memory access via IP command.
WRITE_DDR	00_0028h				
READ_SDR	00_0009h		Receive read data from flash device Read data is put into AHB_RX_BUF or IP_RX_FIFO.	-	
READ_DDR	00_0029h				
DATSZ_SDR	00_000Bh		Transmit read or program data size	Internal logic	Bit number: operand[7:0]
DATSZ_DDR	00_002Bh				

Table continues on the next page...

Table 77. Instruction set (continued)

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
			(byte number) to flash device	Read or program data size for current command sequence	Never set operand to zero or greater than 64 for DATSZ instruction.
DUMMY_SDR	00_000Ch		Leave data lines undriven by FlexSPI controller. Turnaround cycles are provided from host driving to device driving. num_pads determines number of pads in input mode.	-	Dummy cycle number (in serial root clock): Operand[7:0] Dummy cycle (N), described in data sheet of flash device, is in number of SCLK cycles. This number may be configurable. In SDR mode, SCLK cycle is same as serial root clock. Operand value must be set to N. In DDR mode, SCLK cycle is double serial root clock cycle. Operand value must be set to 2N, 2N-1 or 2N+1 depending on definition of dummy in data sheet of flash device. See Flash memory access sequence examples and dummy cycle definition in data sheet of external memory.
DUMMY_DDR	00_002Ch				
DUMMY_RWDS_SDR	00_000Dh		Similar to DUMMY_SDR/ DUMMY_DDR instruction. Difference is in dummy cycle number. DQS pin is called RWDS in HyperBus specification. See Dummy instruction for details. **Set operand to "Latency count" for HyperBus devices.**	-	For read command, dummy cycle number (in serial root clock): (operand[7:0] × 4 - 1) if RWDS (DQS pin) is high; (operand[7:0] × 2 - 1) if RWDS (DQS pin) is low; For write command, dummy cycle number (in serial root clock): (operand[7:0] × 4 - 2) if RWDS (DQS pin) is high; (operand[7:0] × 2 - 2) if RWDS (DQS pin) is low;
DUMMY_RWDS_DDR	00_002Dh				

Table continues on the next page...

Table 77. Instruction set (continued)

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
LEARN_SDR	00_000Ah	00h - one pad (Single mode) 01h - two pads (Dual mode) 02h - four pads (Quad mode) 03h - eight pads (Octal mode)	Receive read data or preamble bit from flash device FlexSPI controller compares data line bits with the DLPR register to determine a correct sampling clock phase.	-	Bit number: operand[7:0] Never set operand to zero for LEARN instruction. Value of operand indicates number of bits to receive and compare to DLPR value. For example, 8-bit pattern 5Ah on each data line must set operand to 8.
LEARN_DDR	00_002Ah				
JMP_ON_CS	00_001Fh	Num_pads setting ignored.	Stop execution, deassert CS and save operand[7:0] as instruction start pointer for next sequence. Normally this instruction is used to support Execute-In-Place enhanced mode. See Execute-In-Place (XIP) enhanced mode. This instruction is only allowed for AHB read commands. When using this instruction in IP command or AHB write command, interrupt status flag set (INTR[IPCMDERR] or INTR[AHBCMDERR]).	-	No transaction on SPI interface.
STOP	00_0000h		Stop execution and deassert CS. Next command sequence (to same flash device) starts from instruction pointer 0.	-	

The programmable sequence engine allows configuration of the LUT according to the connected external serial device. The flexible LUT structure easily adapts to new command or protocol changes from different vendors.

The DDR sequence is a flash memory access sequence that contains DDR instructions other than DUMMY_DDR, and may contain SDR instructions. The output and input timing on FlexSPI differs for SDR and DDR sequences. When included as part of a DDR sequence, SDR instructions execute differently from SDR instructions in an SDR sequence. See FlexSPI input timing and FlexSPI output timing.

10.3.6.1 Executing instructions on SPI interface

This section describes the execution of instructions on the SPI interface. For all instructions that receive bits from or transmit bits to flash devices:

- The bit order in one byte is higher on DATA7 than DATA0.
- The bit order is higher on port B than port A.

This order is shown in Figure 16.

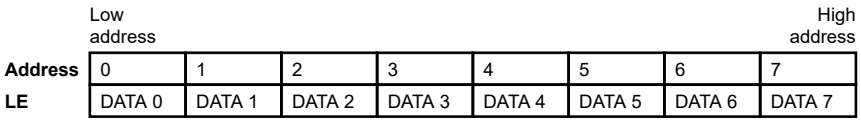

Figure 16. Bus bit order

Table 78. SPI instructions

Instructions	Description
Command (CMD_SDR, CMD_DDR)	Normally used to transmit a command code to the external device. The command code is the 8-bit operand in the instructions. Command code is sent to both port A and port B in parallel mode. See Flash memory access sequence examples.
Address (RADDR_SDR, RADDR_DDR, CADDR_SDR, CADDR_DDR)	Normally used to send the flash memory access start address (row address or column address) to an external device. FlexSPI determines the bits of the row address or column address according to the AHB access address or IP command address. See Flash address sent to flash memory devices. The operand value in the instruction code represents the number of address bits to send. The bits in the row address or column address are sent to both port A and port B in parallel mode. For example, when NUM_PADSn = 8, a memory reading the flash memory address on four SCK edges requires the sum of bits in CADDR and RADDR instructions to be 32. Otherwise, FlexSPI does not generate four SCK edges of address phase. See Flash memory access sequence examples.
Mode (MODEx_SDR, MODEx_DDR)	Normally used to send mode bits to external devices. Mode bits are the lower bits of an operand. For example, the bit number is 1 for MODE1_SDR and MODE1_DDR, 2 for MODE2_SDR and MODE2_DDR, 4 for MODE4_SDR and MODE4_DDR, and 8 for MODE8_SDR and MODE8_DDR. The pad number should not be greater than the mode bit number. For example, you cannot set NUM_PADSn to 11b (Octal mode) for MODE4_* instructions. Mode bits are sent to both port A and port B in parallel mode. See Flash memory access sequence examples for more details.
Data Size (DATSZ_SDR, DATSZ_DDR)	Used to send the size of program data or read data (byte number) to external devices. This instruction is normally used in FPGA applications where the memory space in external device acts like a FIFO. The external device requires data size information to determine how much

Table continues on the next page...

Table 78. SPI instructions (continued)

Instructions	Description
	data are popped from or pushed into the internal FIFO. The operation value in the data size instructions is the bit number. Data size is sent to both port A and port B in parallel mode. See Flash memory access sequence examples.
Write (WRITE_SDR, WRITE_DDR)	Normally used to send program data to external device. Programming data is fetched from IP_TX_FIFO (IP Command) or AHB_TX_Buffer (AHB command). For details about flash program data size, see Flash memory access via AHB command and Flash memory access via IP command. The byte order for program data is always from low to high. Odd bytes are sent on port A and even bytes are sent on port B in parallel mode. See Flash memory access sequence examples for more details.
Read (READ_SDR, READ_DDR)	Normally used to receive flash memory data from external devices. Received data is put into IP_RX_FIFO (IP Command) or AHB_RX_Buffer (AHB command). For information about flash memory read data size, see Flash memory access via AHB command and Flash memory access via IP command. The byte order for reading data is always from low to high. Odd bytes are received from port A and even bytes are received from port B in parallel mode. See Flash memory access sequence examples.
Dummy (DUMMY_SDR, DUMMY_DDR, DUMMY_RWDS_SDR, DUMMY_RWDS_DDR)	Used to provide turnaround cycles on the SPI interface. During dummy instruction, the FlexSPI controller and external devices do not drive the SPI interface. See Programmable sequence engine for details about dummy cycle number. DUMMY_RWDS_DDR can be used for a HyperBus device that uses RWDS pin to indicate whether extra latency is needed. DUMMY_RWDS_SDR is reserved. The FlexSPI controller checks the DQS pin input level at the fourth cycle after SCLK output toggling is enabled. The DQS pin is called RWDS in HyperBus specification. See Flash memory access sequence examples. **NOTE** FlexSPI releases the bus after at least one cycle. To avoid data contention, the NUM_PADSn value for the dummy commands should be configured to match the number of data lines used for the external memory.
Learn (LEARN_SDR, LEARN_DDR)	Used to determine the correct sample clock phase for flash memory read data sampling. External device drives read data (or data learning pattern) bits on the FlexSPI interface. The FlexSPI controller compares the data line bits to the DLPR register to determine a correct sampling clock phase. Clock phase selection is automatically updated after executing learn instructions. See Data learning for more details. The operand value in learn instructions is the byte number. FlexSPI checks the same data pattern on each data line. The byte order is byte 0, byte 1, byte 2, byte 3, byte0, byte 1, and so on. • Byte 0 is DLPR register bits 7–0. • Byte 1 is DLPR register bits 15–8. • Byte 2 is DLPR register bits 23–16. • Byte 3 is DLPR register bit 31–24. The bit order is from high to low in each byte. See Flash memory access sequence examples.

10.3.6.2 Flash memory access sequence examples

Diagrams below all assume MCR0[SERCLKDIV] = 0.

Figure 17 shows an example SDR single I/O read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.

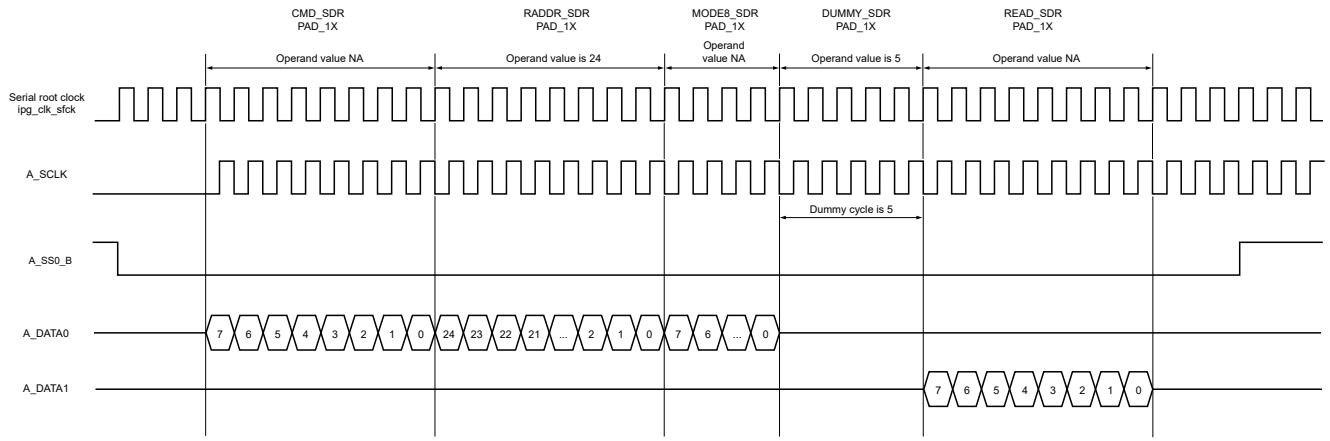

Figure 17. Flash memory access sequence example (SDR single I/O read sequence)

NOTE

- FlexSPI dummy instruction starts and ends at the rising edge of serial root clock.
- Device dummy cycle starts and ends at the falling edge of SCLK (on Cypress S25FS512S data sheet).

Figure 18 shows an example SDR quad I/O read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.

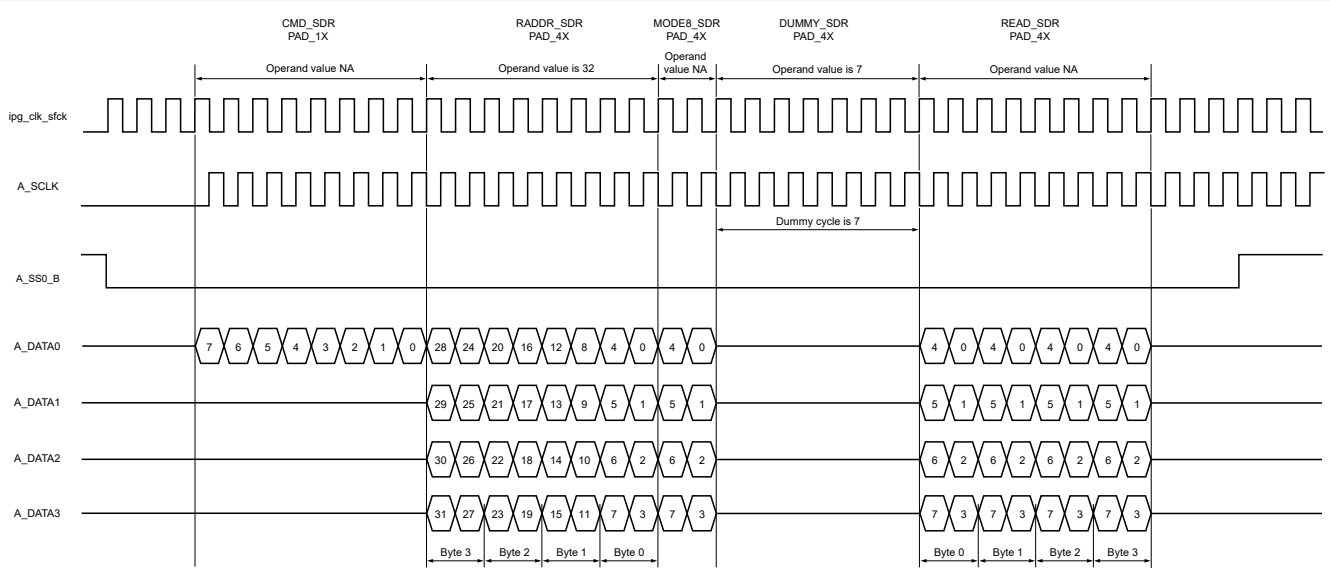

Figure 18. Flash memory access sequence example (SDR quad I/O read sequence)

NOTE

- FlexSPI dummy instruction starts and ends at the rising edge of serial root clock.
- Device dummy cycle starts and ends at the falling edge of SCLK (on Cypress S25FS512S data sheet).

Figure 19 shows an example DDR quad I/O read sequence (Cypress Serial Nor Flash S25FS512S) in parallel mode.

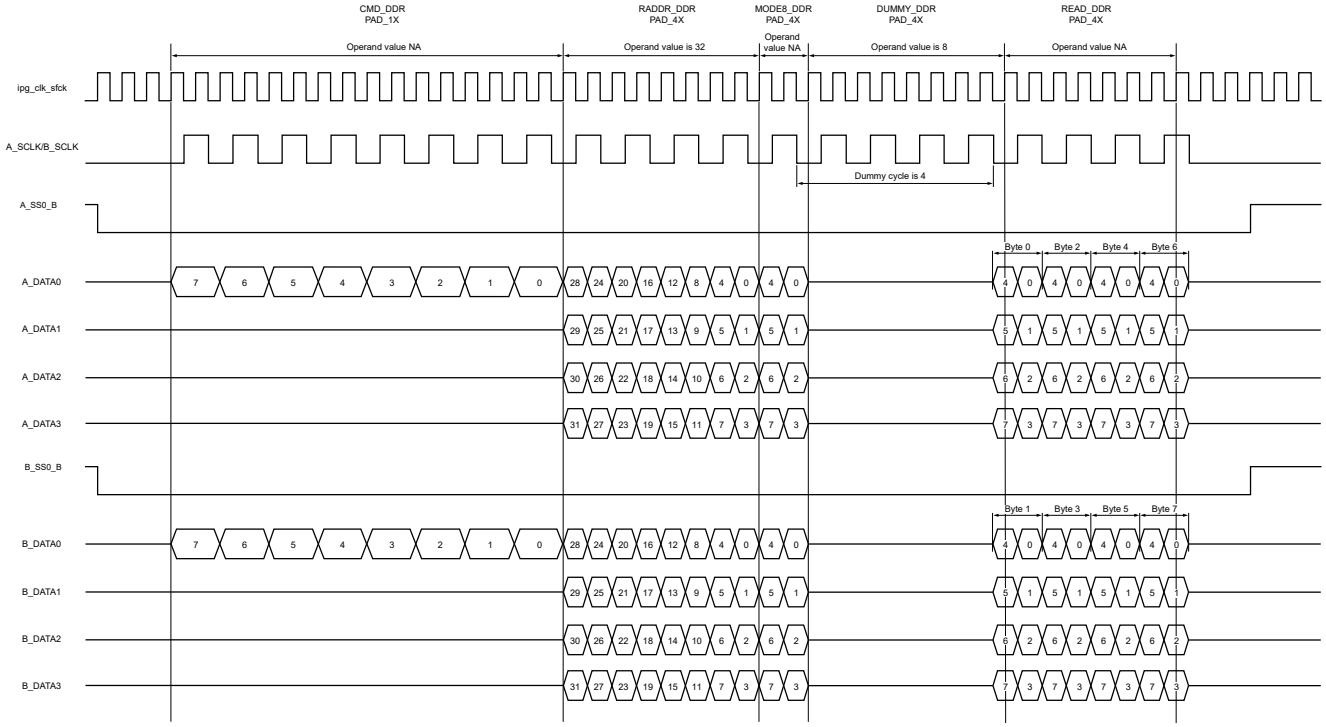

Figure 19. Flash memory access sequence example (DDR quad I/O read sequence)

Figure 20 shows an example learn instruction (not for a specified flash device) in individual mode.

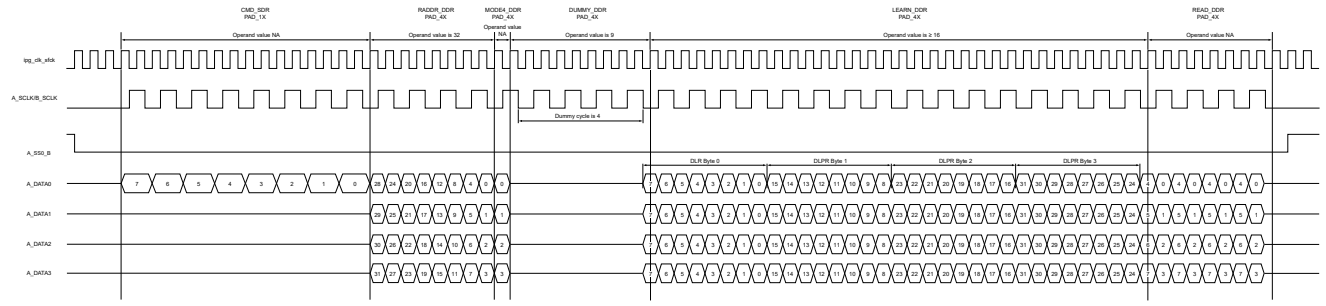

Figure 20. Flash memory access sequence example (data learning)

NOTE

- FlexSPI dummy instruction starts and ends at the rising edge of serial root clock.
- Device dummy cycle starts and ends at the falling edge of SCLK.
- The operand value of DUMMY_DDR instruction is odd because the total cycle number before DUMMY_DDR cycle is odd.

Figure 21 shows an example HyperBus device read transaction (single latency count) in individual mode.

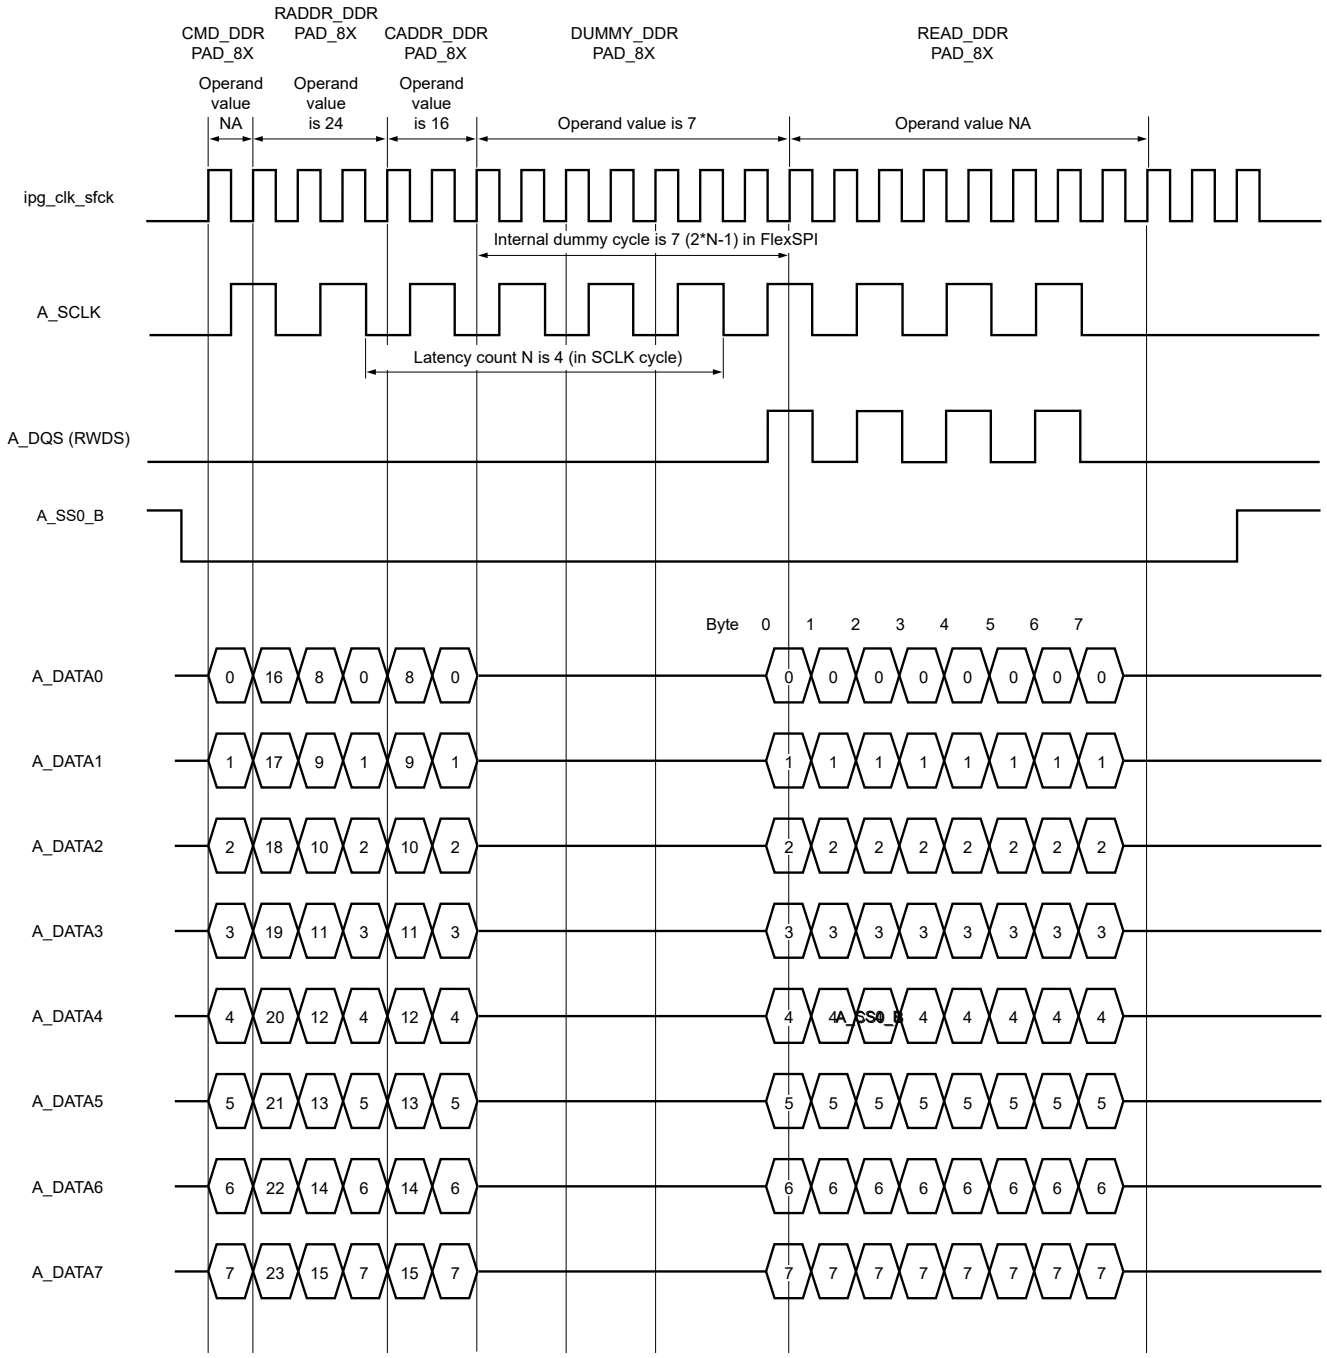

Figure 21. HyperBus device read transaction with single latency count

NOTE

FlexSPI continues to drive the clock until it has latched all of the read data it is expecting. On-chip delay for the data to reach FlexSPI can increase the number of SCK clock pulses.

Figure 22 shows an example HyperBus device read transaction (additional latency count) in individual mode.

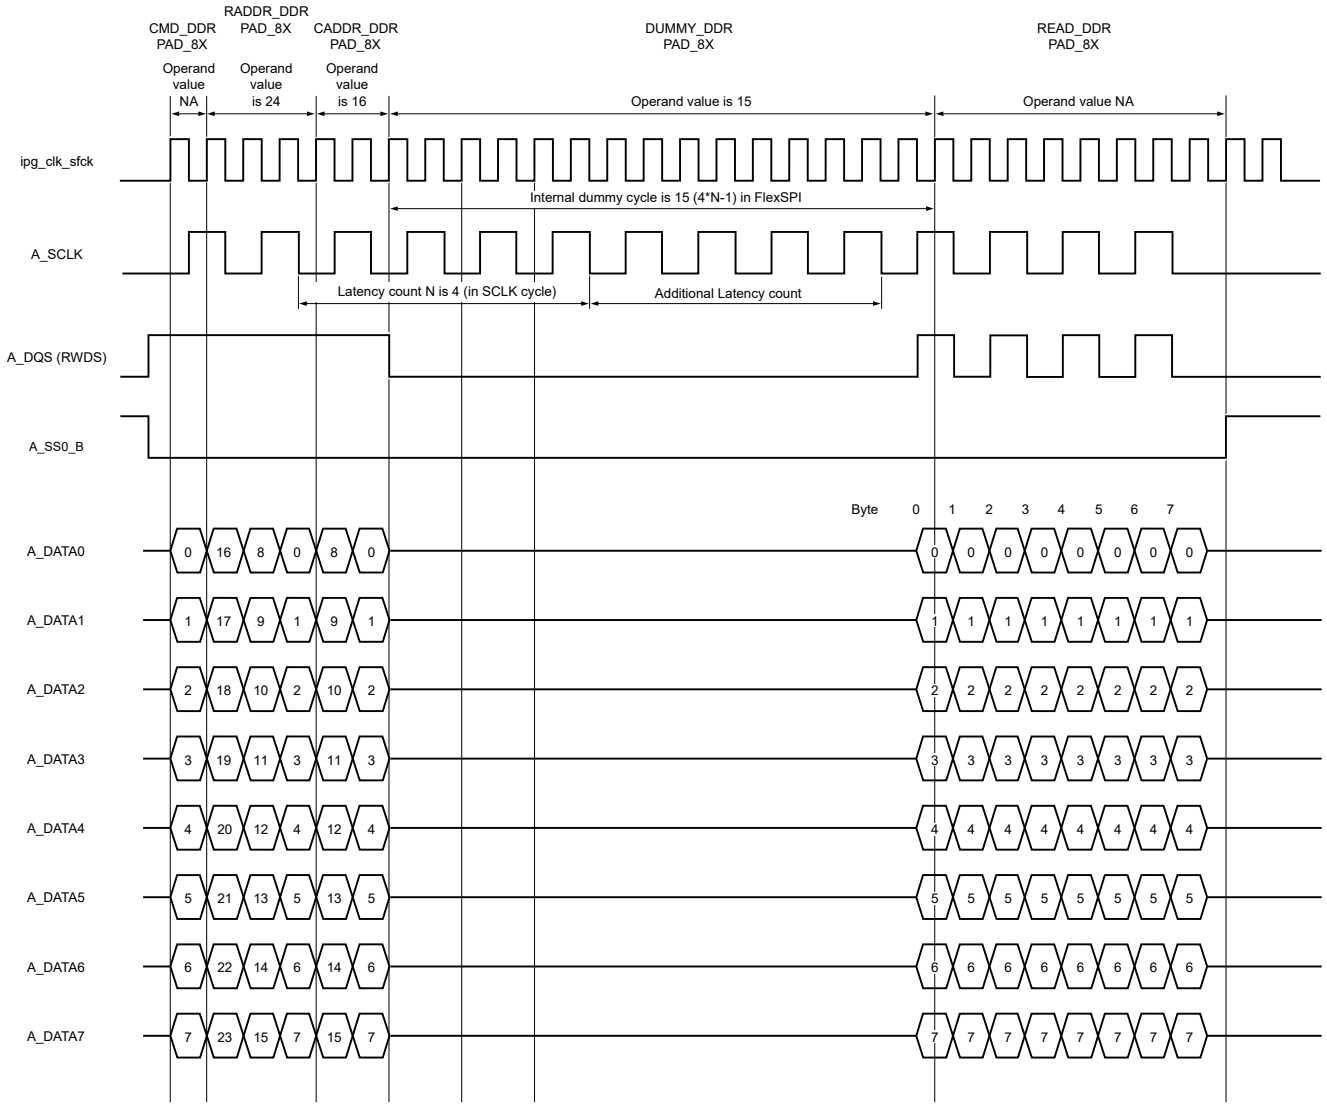

Figure 22. HyperBus device read transaction with additional latency count

Figure 23 shows an example HyperBus device write transaction (single latency count) in individual mode.

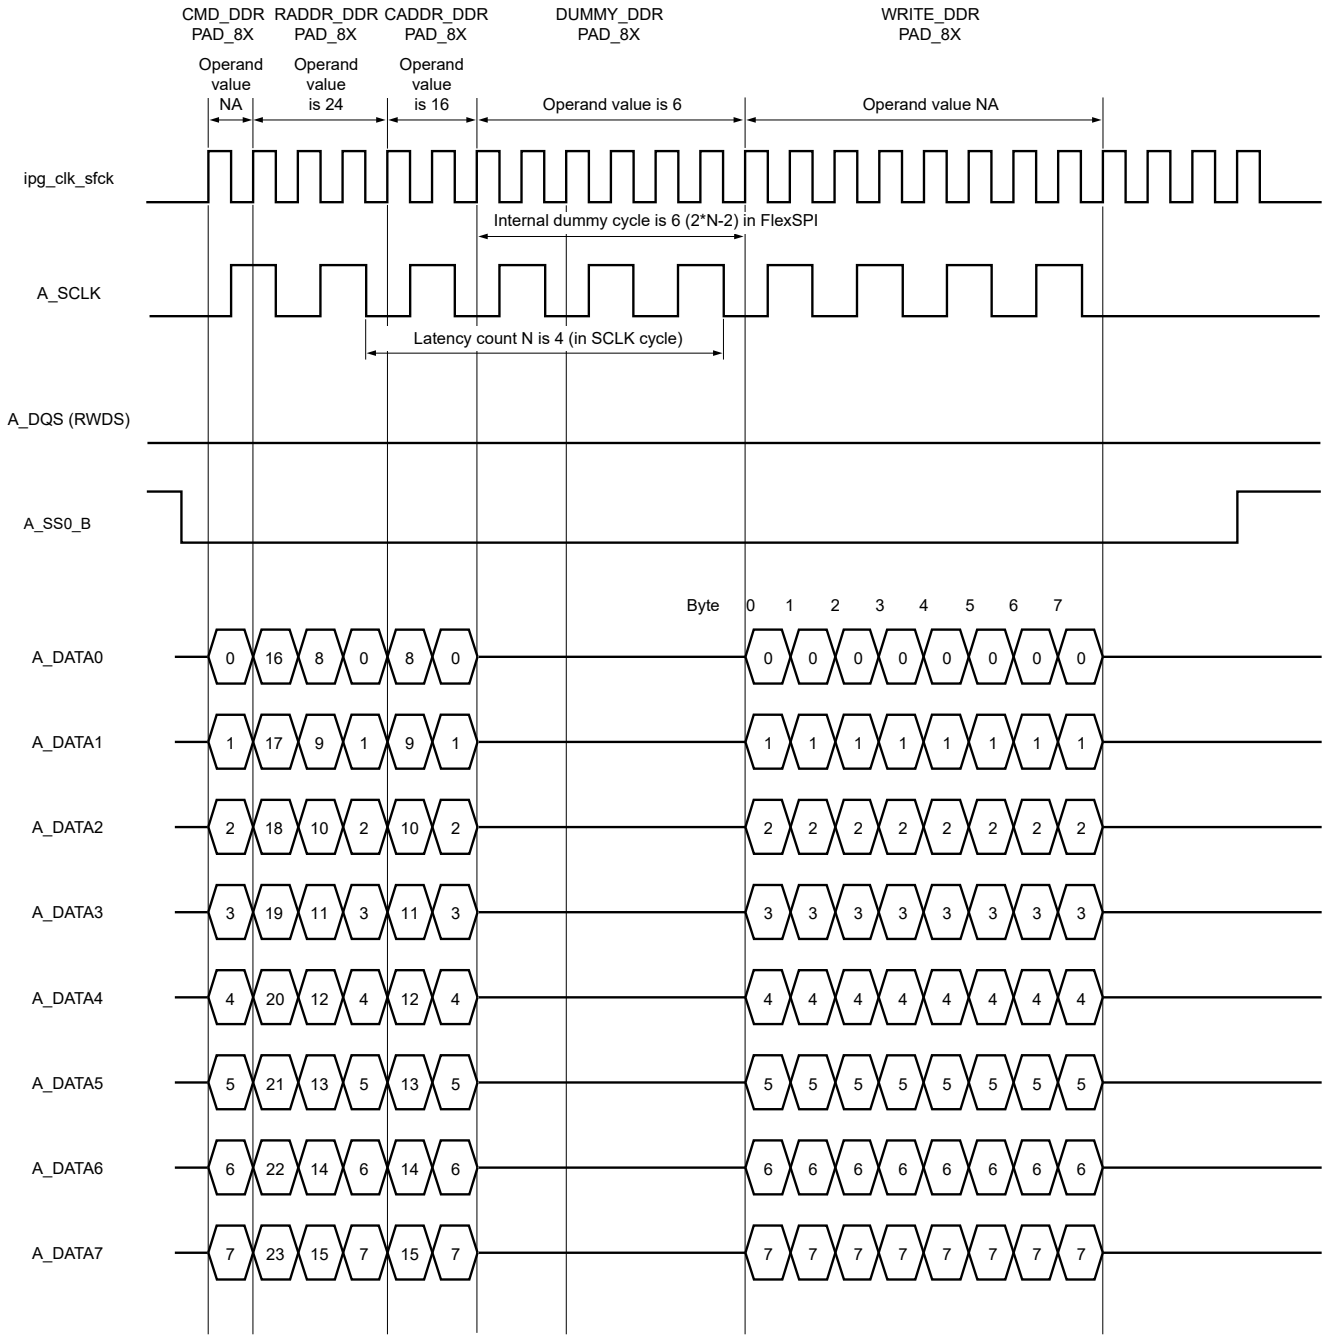

Figure 23. HyperBus device write transaction with single latency count

Figure 24 shows an example HyperBus device write transaction (additional latency count) in individual mode.

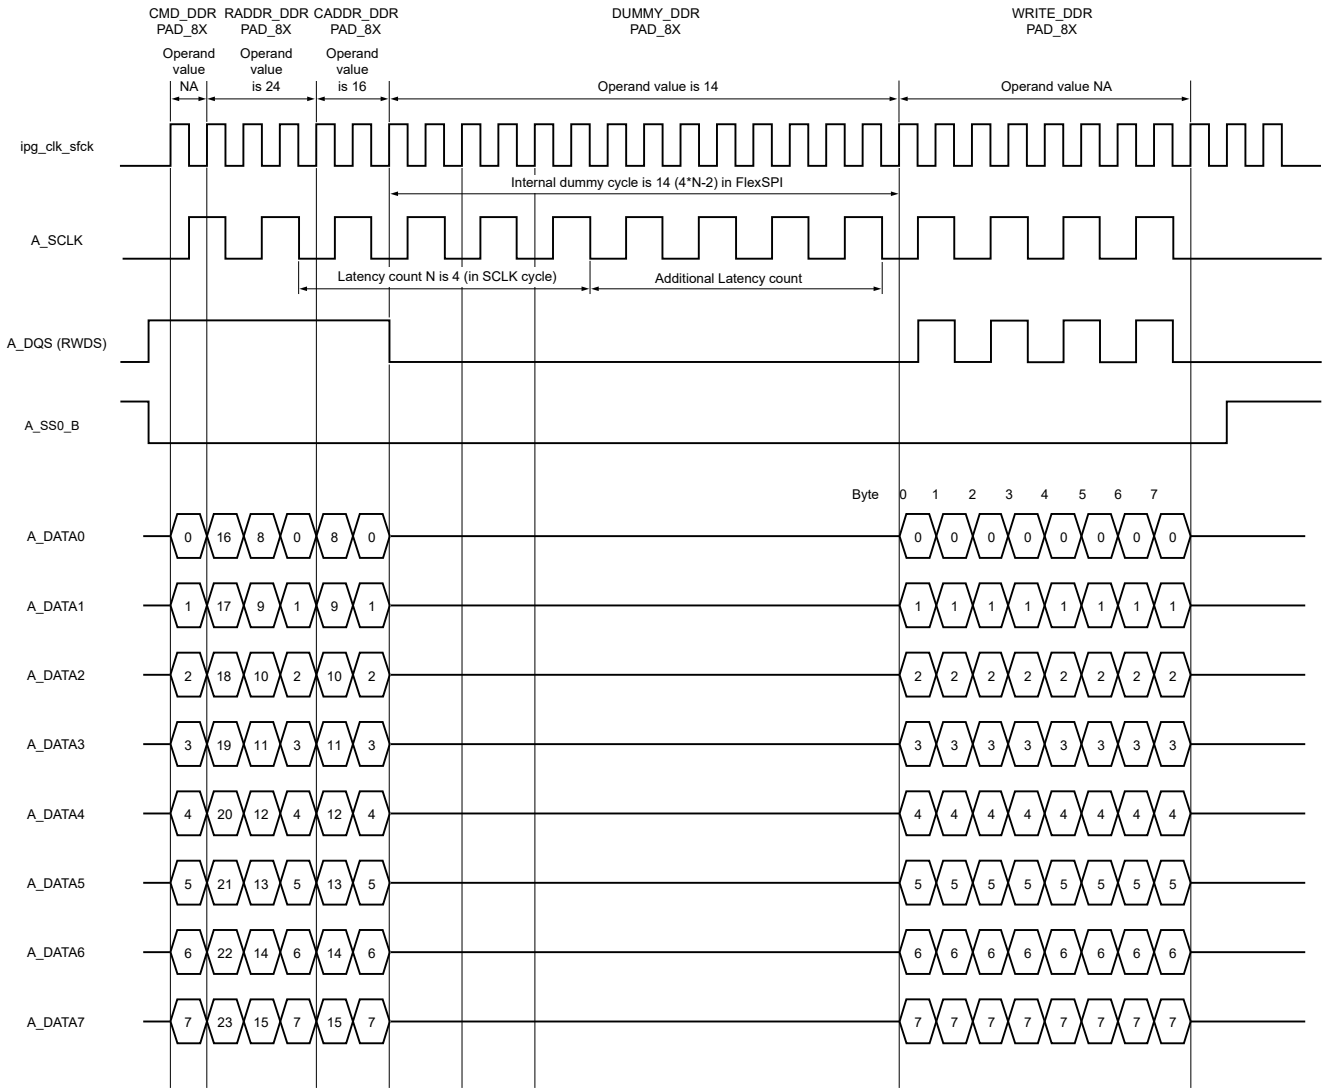

Figure 24. HyperBus device write transaction with additional latency count

10.3.7 Clocking

This section describes FlexSPI clocks and special clocking requirements.

Table 79. Clock usage

Clock name	Description	Comment
serial clock root (ipg_clk_sfck)	Root clock for Serial domain	FlexSPI core clock, used to generate the serial clock output. The clock is optionally divided using MCR0[SERCLKDIV] to obtain the SCLK.

Table continues on the next page...

Table 79. Clock usage (continued)

Clock name	Description	Comment
		Its frequency is same as SPI SCK frequency in SDR mode if MCR0[SERCLKDIV] = 0.
ahb clock (hclk)	AHB bus clock	hclk frequency is higher than 1/4 of serial root clock, so internal async FIFO is never full. This clock is used for internal logic in FlexSPI.
ipg clock (ipg_clk)	IPS bus clock	Register access clock. ipg_clk must be equal to hclk or an integer division of hclk. For example, ipg_clk = hclk/2.
SCLK	FlexSPI serial clock. Output clock on SCLK pin	Half clock frequency of serial clock root in DDR mode, and same frequency as serial clock root in SDR mode. Clock output toggles during the entire flash memory access sequence.
DQS_OUT	Dummy Read Strobe output	Same frequency as SCLK. Clock output toggles during READ and LEARN instructions. The DQS ensures that the data can be strobed correctly. It is only used for data strobe, instead of command or address strobe. The data includes useful read data and data learning patterns.
DQS_IN	Sample clock for receive data	Same frequency as SCLK. Sample clock comes from looped-back dummy read strobe, looped-back SCLK, or flash-memory-provided read strobe.

10.3.8 Interrupts

Table 80 describes all interrupts that FlexSPI generates.

Table 80. Flash memory address, row address, and column address

Interrupt	Enable	Condition
IP command done	INTEN[IPCMDDONEEN]	An IP command is finished.
IP command grant error	INTEN[IPCMDGEEN]	An IP command grant timeout occurs (bus not granted after MCR0[IPGRANTWAIT] × 1024 AHB clock cycles). See Overview of error categories, flags, and triggered sources.
AHB command grant error	INTEN[AHBCMDGEEN]	An AHB command grant timeout occurs (bus not granted after MCR0[AHBGRANTWAIT] × 1024 AHB

Table continues on the next page...

Table 80. Flash memory address, row address, and column address (continued)

		clock cycles). See Overview of error categories, flags, and triggered sources.
IP command error	INTEN[IPCMDERREN]	A command check error or a command execution error for an IP command occurs. See Overview of error categories, flags, and triggered sources.
AHB command error	INTEN[AHBCMDERREN]	A command check error or a command execution error for AHB command occurs. See Overview of error categories, flags, and triggered sources.
IP_RX_FIFO watermark available	INTEN[IPRXWAEN]	The fill level of IP_RX_FIFO reaches the watermark level (IPRXFCR[RXWMRK]).
IP_TX_FIFO watermark empty	INTEN[IPTXWEEN]	The empty level of IP_TX_FIFO reaches the watermark level (IPTXFCR[TXWMRK]).
Data learning failed	INTEN[DATALEARNFAILEN]	No valid sample clock phase found after LEARN instruction is executed. See Overview of error categories, flags, and triggered sources.
Sequence execution timeout	INTEN[SEQTIMEOUTEN]	A sequence execution time exceeds the timeout wait time (MCR1[SEQWAIT]). For example, the following flash memory read command sequence lasts about 800_0000h cycles (ipg_clk_sfck). If SEQWAIT is set to FFFFh, a sequence timeout interrupt is generated. • IP command triggers timeout. • Flash memory read data size is 100_0000h bytes. • Flash memory accesses in single mode and SDR mode.
AHB bus timeout	INTEN[AHBBUSTIMEOUTEN]	AHB bus response timeout occurs. For example, AHB read sequence is not configured properly in LUT (such as without a READ instruction). No data is read from an external device. As a result, FlexSPI cannot reach the read data in AHB_RX_Buffers for the AHB read command. See Overview of error categories, flags, and triggered sources.
Write command stops SCLK	INTEN[SCKSTOPBYWREN]	IP_TX_FIFO is empty while executing a write command sequence. FlexSPI stops SCLK output clock toggling and waits for write data filling.

Table continues on the next page...

Table 80. Flash memory address, row address, and column address (continued)

Read command stops SCLK	INTEN[SCKSTOPBYRDEN]	IP_RX_FIFO is full while executing a read command sequence. FlexSPI stops SCLK output clock toggling and waits to read the data from IP_RX_FIFO.
IP command security violation	INTEN[IPCMDSECUREVIOEN]	A non-secure controller requests an IP command sequence to an address outside the non-secure areas that IPSNSZSTARTn and IPSNSZENDn define.

10.3.9 Inline PRINCE encryption and decryption (IPED) CTR

IPED is a PRINCE-based encryption-decryption IP with a 64-bit block cipher and 128-bit key. FlexSPI supports automatic encryption on IP and AHB write commands, and automatic decryption on AHB read commands.

NOTE

The read or write access address sent to IPED.i_data is always 64 bits (eight bytes).

- For read operations, the start address and fetch size are always eight-byte-aligned. FlexSPI guarantees this condition.
- For write operations, software should manage any partial write that is not eight-byte-aligned. For example, before performing page erase and page program operations, the eight-byte boundary data should be read back.

Changing the register setting of IPEDCTRL changes the behavior of IPED.

To use IPED, apply these settings:

- AHBCR[READADDROPT] = 1
- AHBCR[PREFETCHEN] = 1 or AHBCR[READSZALIGN] = 1

FlexSPI supports a maximum of 7 address ranges for different 64-bit IPED.i_iv to encrypt or decrypt data.

The IPEDCTXnSTART and IPEDCTXnEND registers control the 7 ranges. There must be no overlap among these 7 ranges. Otherwise behavior of IP is undefined. Any single read or write request to flash memory must not cross one context boundary. For AHB read and write operations, hardware can automatically keep the boundary by writing 1 to AHBCR[ALIGNMENT]. Software must maintain the IP command write boundary. Any read or write request across context boundary leads to wrong data to or from the external device.

IPED context control 0 (IPEDCTXCTRL0) and IPED context control 1 (IPEDCTXCTRL1) control the write ability of IPEDCTXnSTART and IPEDCTXnEND. By default, IPEDCTXnSTART and IPEDCTXnEND cannot be modified after reset is enabled. Table 81 lists details.

Table 81. IPEDCTXnSTART and IPEDCTXnEND write ability

IPEDCTXCTRL0[CTXn_FREEZE0]	IPEDCTXCTRL1[CTXn_FREEZE1]	CTXn_FREEZE0 and CTXn_FREEZE1 writable	IPEDCTXnSTART and IPEDCTXnEND writable
10b	10b	yes	yes
01b (default)	10b (default)	yes	no
don't care	00b or 01b or 11b	no	no
00b or 11b	don't care	no	no

10.3.10 Flash memory access via IP command

Follow these steps to trigger a flash memory access via IP command.

1. If this command is a programing command, fill the IP transmit FIFO with programming data (for instance, programming flash data and flash memory status registers.)
2. Write the flash memory access start address to IPCR0[SFAR].
3. Write the read or program data size to IPCR1[IDATSZ]. Write the sequence index to IPCR1[ISEQID]. Write the sequence number to IPCR1[ISEQNUM].
4. Write 1 to IPCMD[TRG] to trigger a flash memory access command.
5. Wait for the INTR[IPCMDDONE] flag to set or for the IP command done interrupt to fire, indicating the command has completed on the FlexSPI interface.

NOTE

- The IP transmit FIFO can be filled before or after writing the IPCR0, IPCR1, and IPCMD registers. If the SFM command starts with the IP transmit FIFO empty, FlexSPI stops SCLK toggling to wait for transmit data ready automatically.
- The IPCMD register must be written after writing the IPCR0 and IPCR1 registers.
- One IP command can issue up to eight command sequences.
- You cannot issue another IP command before the previous IP command is finished. Performing this action results in unknown behavior.

If this command is a read command, all read data from flash memory is put into the IP receive FIFO. Software must read data from the IP receive FIFO via AHB bus or IP bus. When the IP receive FIFO is full and the flash device still contains data to read, FlexSPI stops SCLK toggling until the FIFO has free space. See SCLK stop.

A triggered serial flash command contains:

- A flash memory access start address. IPCR0[SFAR] determines this address.
- A flash chip select. The flash memory access address and flash memory size setting (FLSHxCR0[FLSHSZ]) determine the chip select.
- A flash command sequence index and sequence number. FlexSPI sequentially executes the sequences indexed from IPCR1[ISEQID] to (IPCR1[ISEQID] + IPCR1[ISEQNUM]) in LUT.
- Flash individual/parallel memory access mode:

  Determined by IPCR1[IPAREN].
- The flash memory read or program data size, in bytes.
  - If the value of IPCR1[IDATSZ] is nonzero, the data size is IPCR1[IDATSZ].
  - If the value of IPCR1[IDATSZ] is zero, the operand value in the read or write instruction determines the data size.

NOTE

- Software must ensure that the last sequence index never exceeds the LUT sequence number. That is, IPCR1[ISEQID] + IPCR1[ISEQNUM] must be less than 16.
- For sequence numbers greater than one, the data size is applied to every command sequence.
- If there is no write or read instruction in the command sequence, the data size is ignored.

The IP command request is sent to the arbitrator after software triggers it. It is not executed on the FlexSPI interface until the arbitrator grants it. See Command arbitration.

10.3.10.1 Reading data from IP receive FIFO

FlexSPI puts read data from the external device into the IP receive FIFO for IP commands.

The data stored in the IP receive FIFO can be read using IPS and register transactions:

- 400C8100h–400C817Ch (by IPS bus)

FlexSPI pushes read data into the IP receive FIFO in sets of 64 bits each time it receives 64 bits of data from an external device. When the number of read data bits is not 64-bit-aligned, FlexSPI pushes additional zero bits into the IP receive FIFO for the last push.

The processor or DMA can read the IP receive FIFO.

10.3.10.1.1 Reading via processor

To read data from the IP receive FIFO via processor, configure the items below.

- Write 0 to IPRXFCR[RXDMAEN].
- Write the watermark level to IPRXFCR[RXWMRK]. The watermark level is (IPRXFCR[RXWMRK] + 1) × 8 bytes.
- Write 1 to INTEN[IPRXWAEN] to enable the IP receive FIFO watermark available interrupt (optional).

The processor must poll INTR[IPRXWA] or wait for the IP receive FIFO watermark available interrupt before reading data from the FIFO. Waiting ensures that a watermark level amount of data is filled in the IP receive FIFO before reading.

After reading a watermark level amount of data from the FIFO, software must set the INTR[IPRXWA] flag to pop that data from the FIFO.

Figure 25 shows the reading flow from the IP receive FIFO via processor.

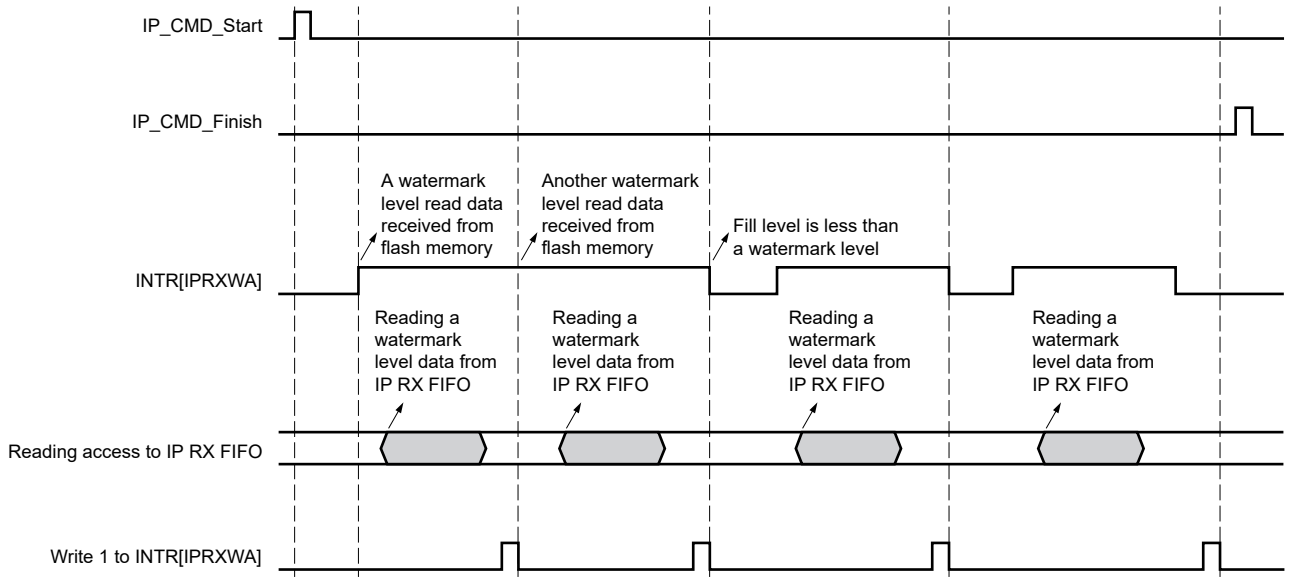

Figure 25. Reading IP receive FIFO via processor

NOTE

- The processor must read a watermark level of data from the IP receive FIFO before setting the INTR[IPRXWA] flag.
- The total flash read or program data size is not required to be a multiple of the watermark level. When the reading data size from the FIFO is less than a watermark level for the last time, software polls IPRXFSTS[FILL], not INTR[IPRXWA]. After all data from the FIFO are copied and all command sequences to flash memory are finished (INTR[IPCMDDONE] = 1), software sets IPRXFCR[CLRIPRXF] to clear the FIFO. If the FIFO is not cleared, the reading data will be incorrect for the next reading command to flash memory.
- Setting the INTR[IPRXWA] flag pops the IP receive FIFO data. Each read access to the FIFO does not pop the data.

10.3.10.1.2 Reading via DMA

To read data from the IP receive FIFO via DMA, configure the items below.

- Write 1 to IPRXFCR[RXDMAEN].
- Write the watermark level to IPRXFCR[RXWMRK]. The watermark level is (IPRXFCR[RXWMRK] + 1) × 8 bytes.
- Configure the DMA transfer minor loop size to match the watermark level.

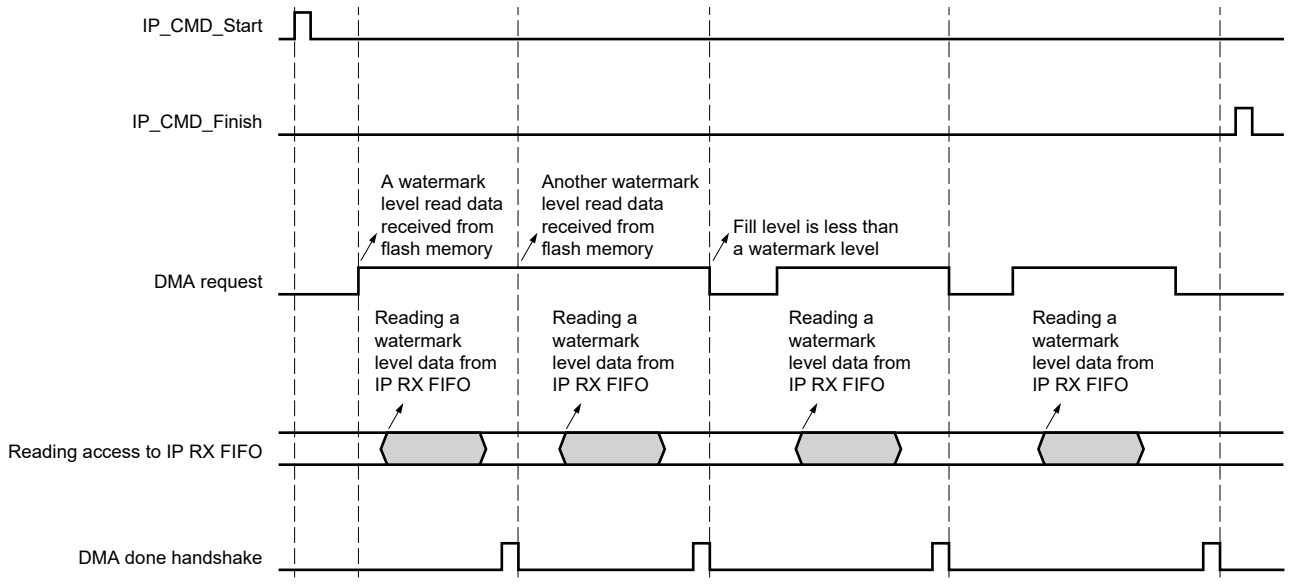

Figure 26. Reading from IP receive FIFO via DMA

NOTE

- When the fill level of the FIFO meets or exceeds the watermark level, a DMA request is generated. This request is level-valid, not pulse-valid.
- DMA reads a watermark level amount of data from the IP receive FIFO each time. (Configure the minor loop size to match the watermark level).
- DMA must return a done handshake (pulse valid) to FlexSPI each time it finishes reading a watermark level amount of data.
- The DMA done handshake (not each read access) pops the IP receive FIFO data.
- The total read and write data size (major loop size) must be a multiple of the watermark level. The DMA does not know when the data is ready for the last reading. When the data size is not a multiple of the watermark level, it is too complex for the DMA driver to poll IPRXFSTS[FILL].

10.3.10.2 Writing data to IP transmit FIFO

The programming data is put into the IP transmit FIFO, then FlexSPI transmits it to the flash memory. IPS can write it:

- 400C_8180h–400C_81FCh (via IP bus)

When FlexSPI fetches data to transmit, 64 bits of data from the IP transmit FIFO are popped. If the programming data size is not a multiple of 64 bits, the number of last popped valid bits is less than 64 bits. No error occurs; these invalid bits are not transmitted to the flash memory.

The processor or DMA can fill the IP transmit FIFO with programming data.

10.3.10.2.1 Writing via processor

To write data into the IP transmit FIFO via processor, configure the items below.

- Write 0 to IPTXFCR[TXDMAEN].
- Write the watermark level to IPTXFCR[TXWMRK]. The watermark level is (IPTXFCR[TXWMRK] + 1) × 8 bytes.
- Write 1 to INTEN[IPTXWEEN] to enable the IP transmit FIFO watermark available interrupt (optional).

The processor must poll INTR[IPTXWE] or wait for the IP transmit FIFO watermark empty interrupt before writing data to the FIFO. Waiting ensures that a watermark level amount of data is available in the IP transmit FIFO before writing.

After writing a watermark level amount of data to the FIFO, software must set the INTR[IPTXWE] flag to push that data into the FIFO. (The write pointer is incremented.)

NOTE

Setting the INTR[IPTXWE] flag pushes the IP transmit FIFO data. Each write access to the FIFO does not push the data.

Figure 27 shows the writing flow to the IP transmit FIFO via processor.

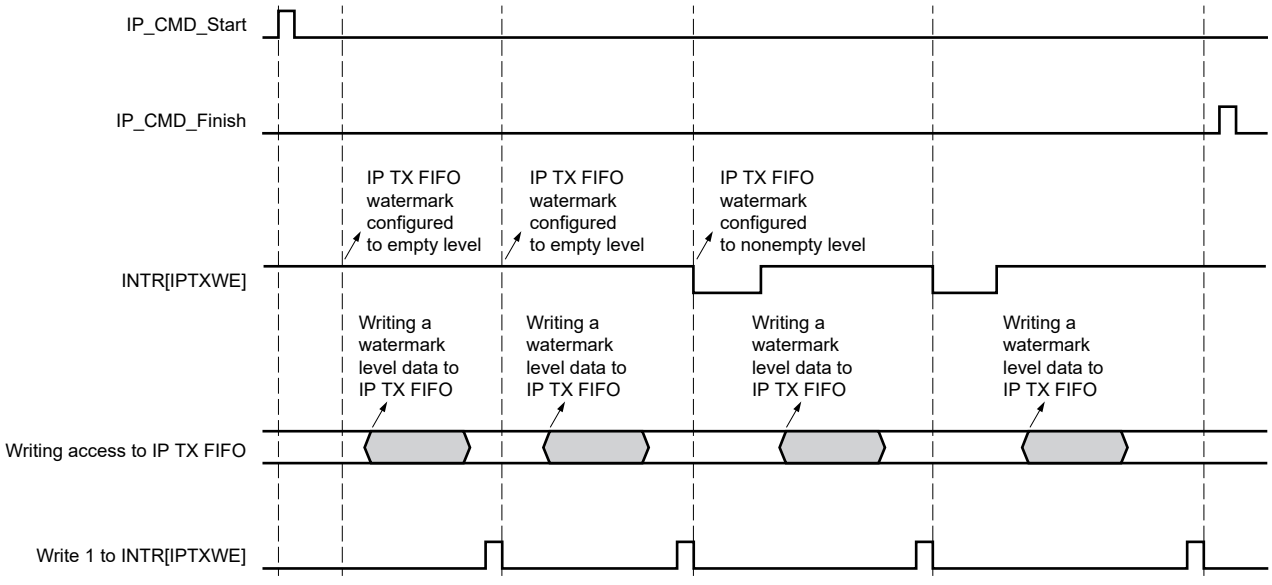

Figure 27. Writing to IP transmit FIFO via processor

NOTE

- The processor must write a watermark level amount of data into the IP transmit FIFO each time.
- The total flash write data size is not required to be a multiple of the watermark level. In this case, the writing data size to the FIFO is less than a watermark level for the last time. After all data to the FIFO are written and all command sequences to flash memory are finished (INTR[IPCMDDONE] = 1), the processor sets IPTXFCR[CLRIPTXF] to clear the FIFO. If the FIFO is not cleared, the programming data will be incorrect for the next programming command to flash memory.

10.3.10.2.2 Writing via DMA

To write data into the IP transmit FIFO via DMA, configure the items below.

- Write 1 to IPTXFCR[TXDMAEN].
- Write the watermark level to IPTXFCR[TXWMRK]. The watermark level is (IPTXFCR[TXWMRK] + 1) × 8 bytes.
- Configure the DMA transfer minor loop size to match the watermark level.

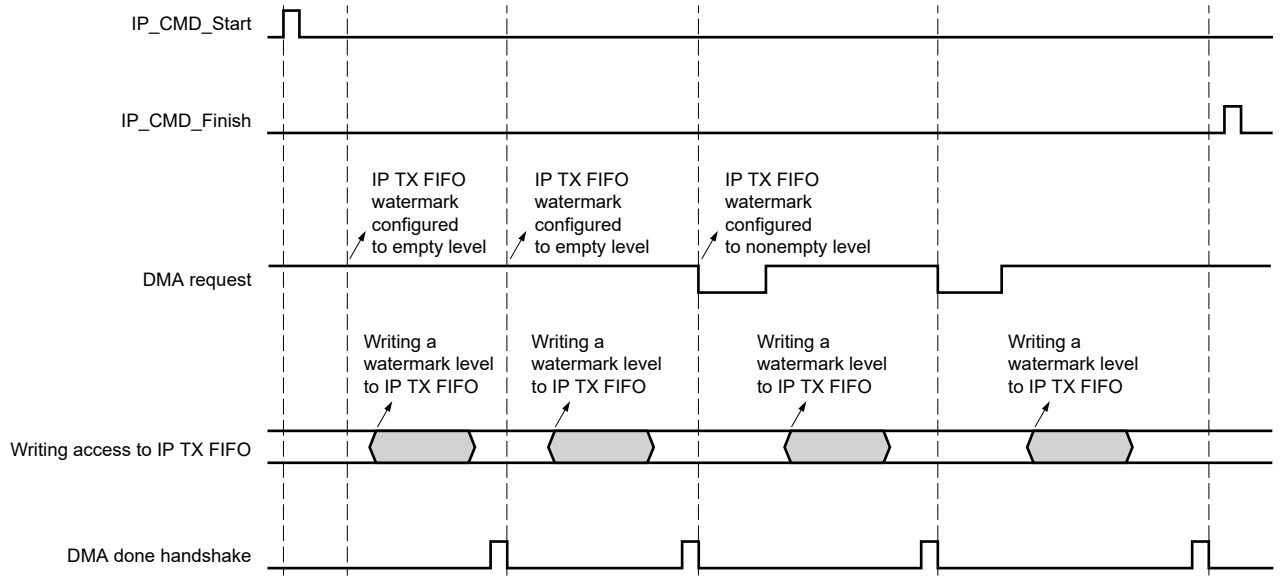

Figure 28. Writing into IP transfer FIFO via DMA

NOTE

- When there is empty space in the IP transmit FIFO greater than the watermark level, a DMA request is generated. This request is level-valid, not pulse-valid.
- DMA writes a watermark level amount of data into the FIFO each time. (Configure the minor loop size to match the watermark level.
- DMA returns a done handshake (pulse valid) to FlexSPI each time it finishes writing a watermark level amount of data.
- The DMA done handshake (not each write access) pushes the IP transmit FIFO data.
- The total program data size (major loop size) is not required to be a multiple of the watermark level. After writing all data into the IP transmit FIFO and all command sequences to flash memory are finished (INTR[IPCMDDONE] = 1), write 1 to IPTXFCR[CLRIPTXF] to clear the FIFO. Failure to clear the FIFO results in incorrect programming data for the next programming command to flash memory.

10.3.11 Flash memory access via AHB command

Flash memory can be accessed via AHB bus directly on the AHB address space. See chip-specific section for details about the AHB address space. This address space is mapped to serial flash memory in FlexSPI. AHB bus accesses to this address space trigger flash memory access command sequences as needed.

For AHB read access to serial flash memory, FlexSPI fetches data from flash memory into the AHB receive buffer, then returns the data on the AHB bus. For AHB write access to serial flash memory, FlexSPI buffers AHB bus write data into the AHB transmit buffer, then transmits the data to serial flash memory.

No software configuration or polling is needed for AHB commands, except for FlexSPI initialization. As with a normal AHB target, the AHB controller accesses the external flash device transparently.

AHB commands are normally used to access serial flash memory space. IP commands must be used to access the control and status registers or other spaces, such as a one-time programmable (OTP) space in an external flash device.

The AHB commands for read and write access are discussed in detail below.

10.3.11.1 AHB write access to flash memory

For AHB write access to flash memory, FlexSPI buffers the write data from the AHB bus into the internal AHB transmit buffer. FlexSPI then transmits the data to flash memory. FlexSPI only buffers write data for one AHB burst. Figure 29 shows the hardware operation in response to an AHB write access to flash memory.

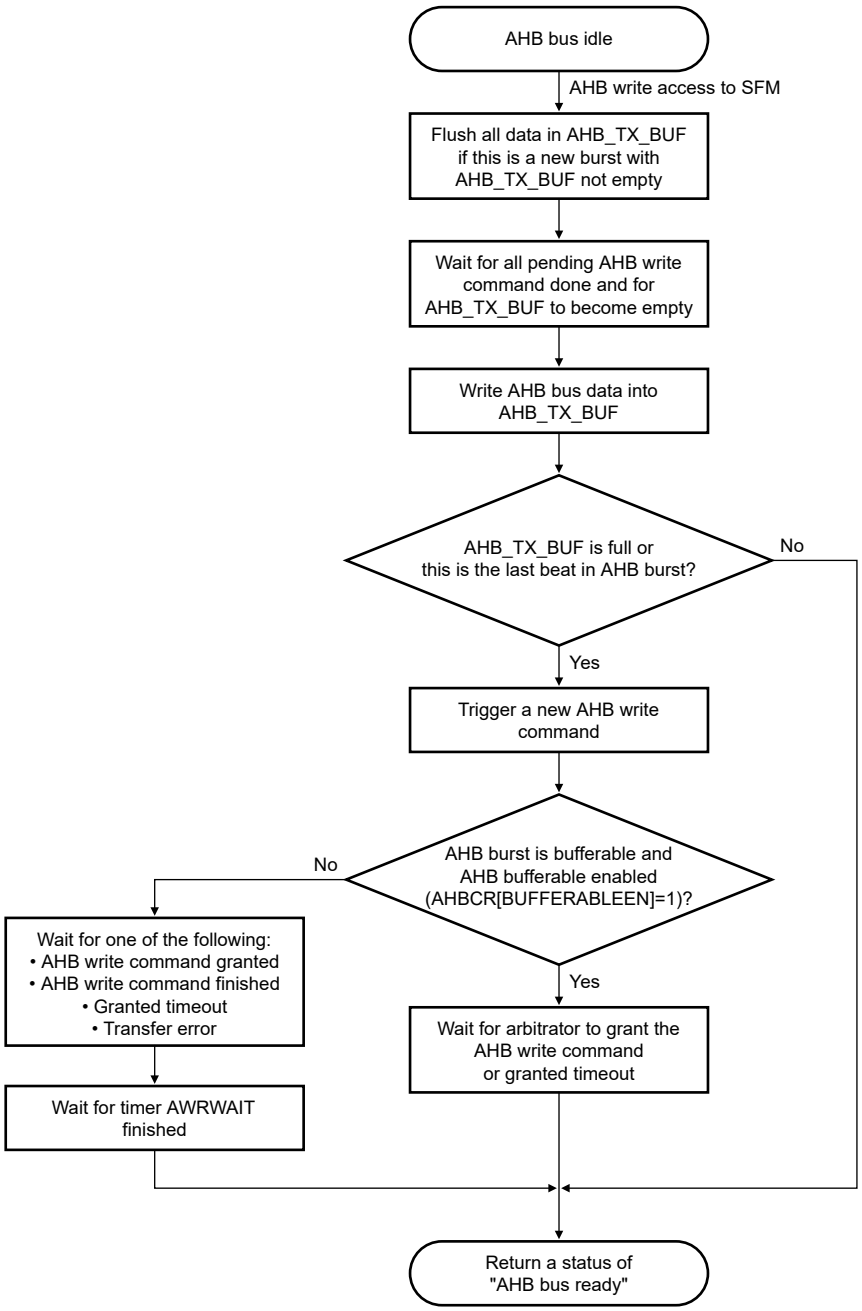

Figure 29. Hardware operation in response to AHB write access to flash memory

NOTE

1. If previous AHB burst is INCR write burst, AHB transmit buffer may not be empty when AHB bus is idle or new burst arrives. A new AHB write command is triggered to flush all data in AHB transmit buffer to external flash device. The new burst is held until this AHB write command finishes.
2. If the current access is bufferable, when the AHB write command is triggered, AHB ready is returned after the write command is granted. If the current access is non-bufferable, AHB ready is returned after the write command finishes.

FlexSPI triggers a new AHB write command in these cases:

- This beat is the last one in the current AHB burst, for any burst type except INCR.

- AHB transmit buffer is full after the current beat data is buffered.
- AHB bus becomes idle or a new burst arrives with the AHB transmit buffer not empty.

Table 82 describes the details of a triggered AHB write command.

Table 82. Triggered AHB write command

Item	Description
Flash memory access start address	Determined by AHB burst address. FlexSPI records the start address for the data in AHB transmit buffer, which is used as flash memory access start address.
Flash memory chip select	FlexSPI uses the settings of the flash memory access start address and flash memory size to determine the chip selection.
Flash memory command sequence index	Determined by FLSHxCR2[AWRSEQID].
Flash memory command sequence number	Determined by FLSHxCR2[AWRSEQNUM]. If AWRSEQNUM is not zero, multiple flash memory access command sequences are triggered every time for an AHB write command. The sequences indexed from AWRSEQID to (AWRSEQID + AWRSEQNUM) in LUT are executed sequentially.
Flash memory access mode (Individual/ Parallel)	Determined by AHBCR[APAREN].
Flash memory data size	Determined by byte number of buffered data in AHB transmit buffer.

The following examples indicate internal logic for AHB write access to flash memory, where AHB_TX_BUF is 64 bytes :

- AHB INCR 64-bit bufferable burst with address sequence 8h, 10h, 18h, 20h, ..., 50h (10 beats total).

  Two AHB write commands are triggered: the first command with flash memory start address 8h and data size 40h; the second command with flash memory start address 48h and data size 10h. See Figure 30.

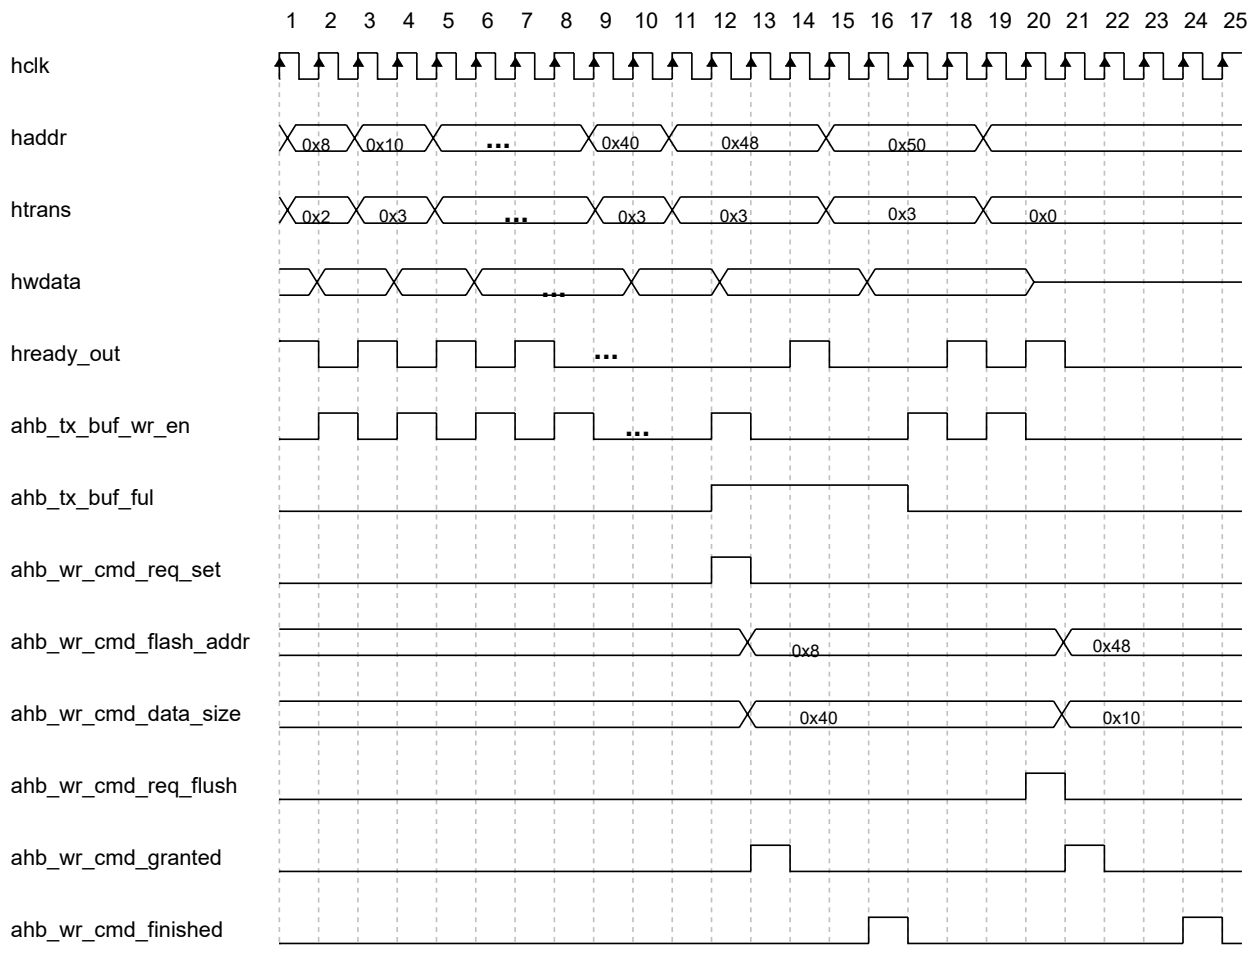

Figure 30. AHB write access (INCR, 64-bit, bufferable)

- AHB WRAP8 64-bit bufferable burst with address sequence 28h, 30h, 38h, 0h, 8h, 10h, 18h, 20h.

  One AHB write command is triggered with flash memory start address 0h and data size 40h. See Figure 31.

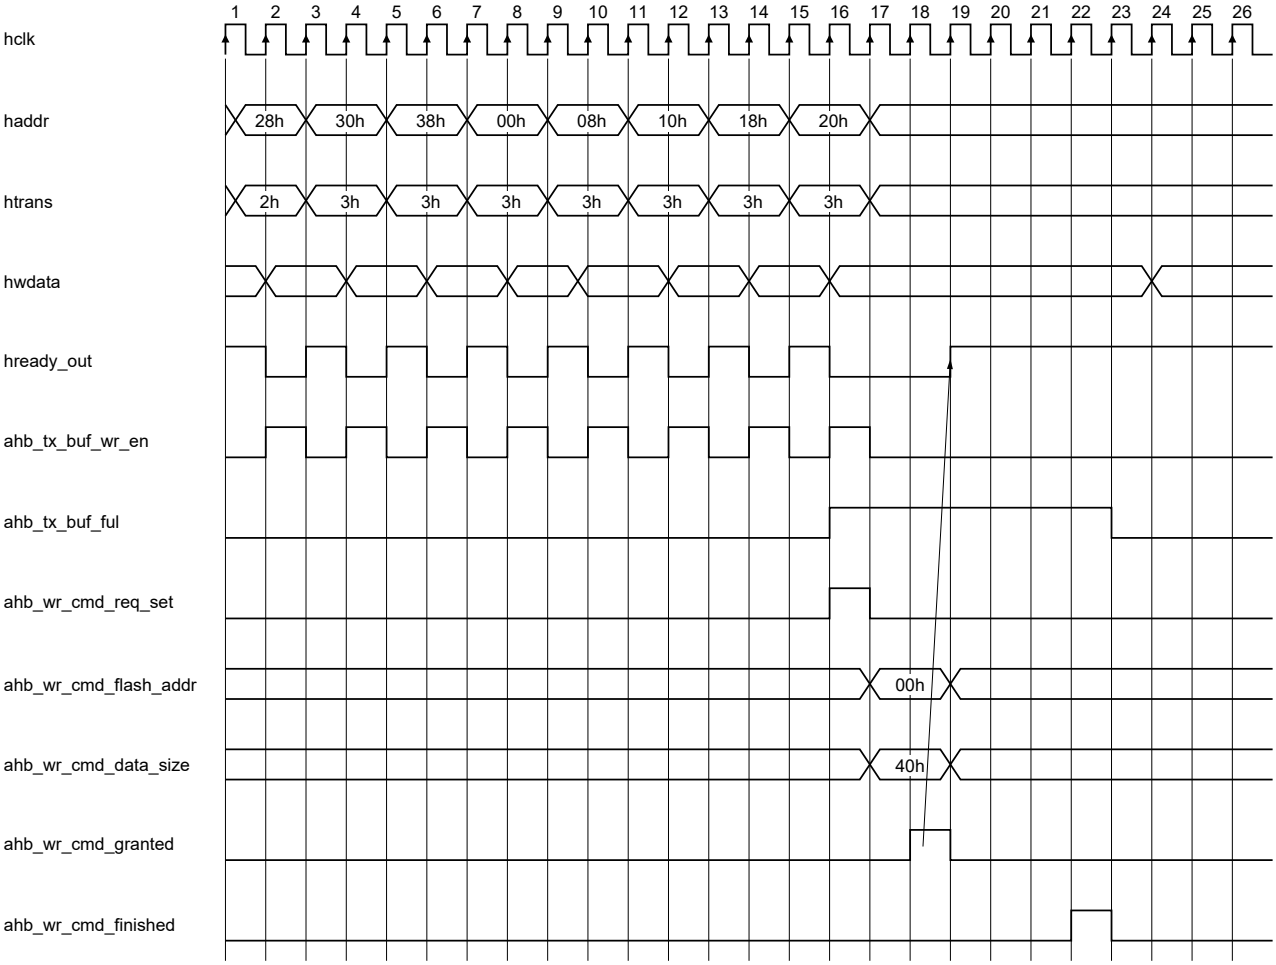

Figure 31. AHB write access (WRAP8, 64-bit, bufferable)

- AHB WRAP8 64-bit non-bufferable burst with address sequence 28h, 30h, 38h, 0h, 8h, 10h, 18h, 20h.

  One AHB write command is triggered with flash memory start address 0h and data size 40h.

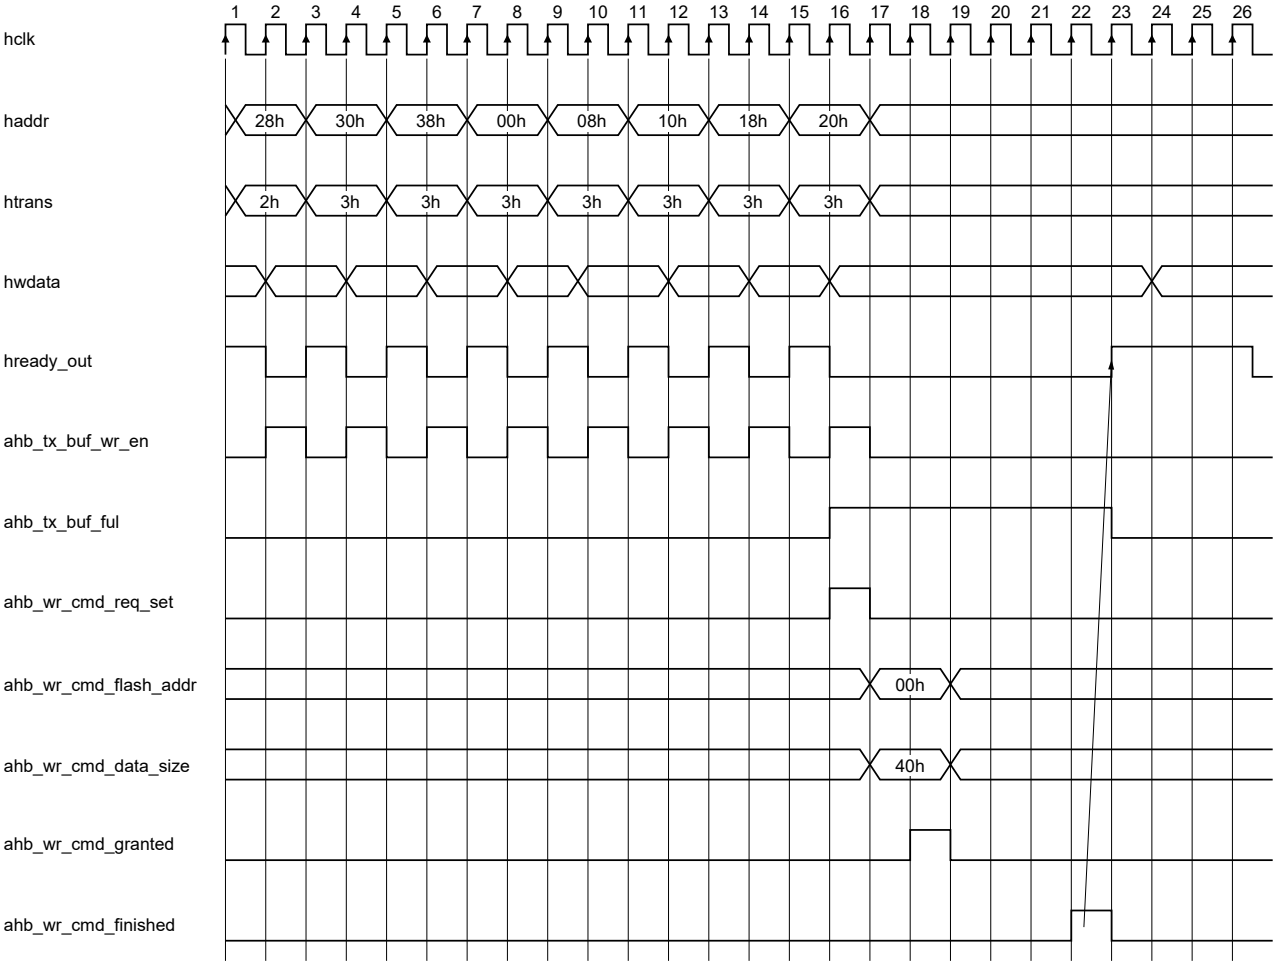

Figure 32. AHB write access (WRAP8, 64-bit, non-bufferable)

NOTE

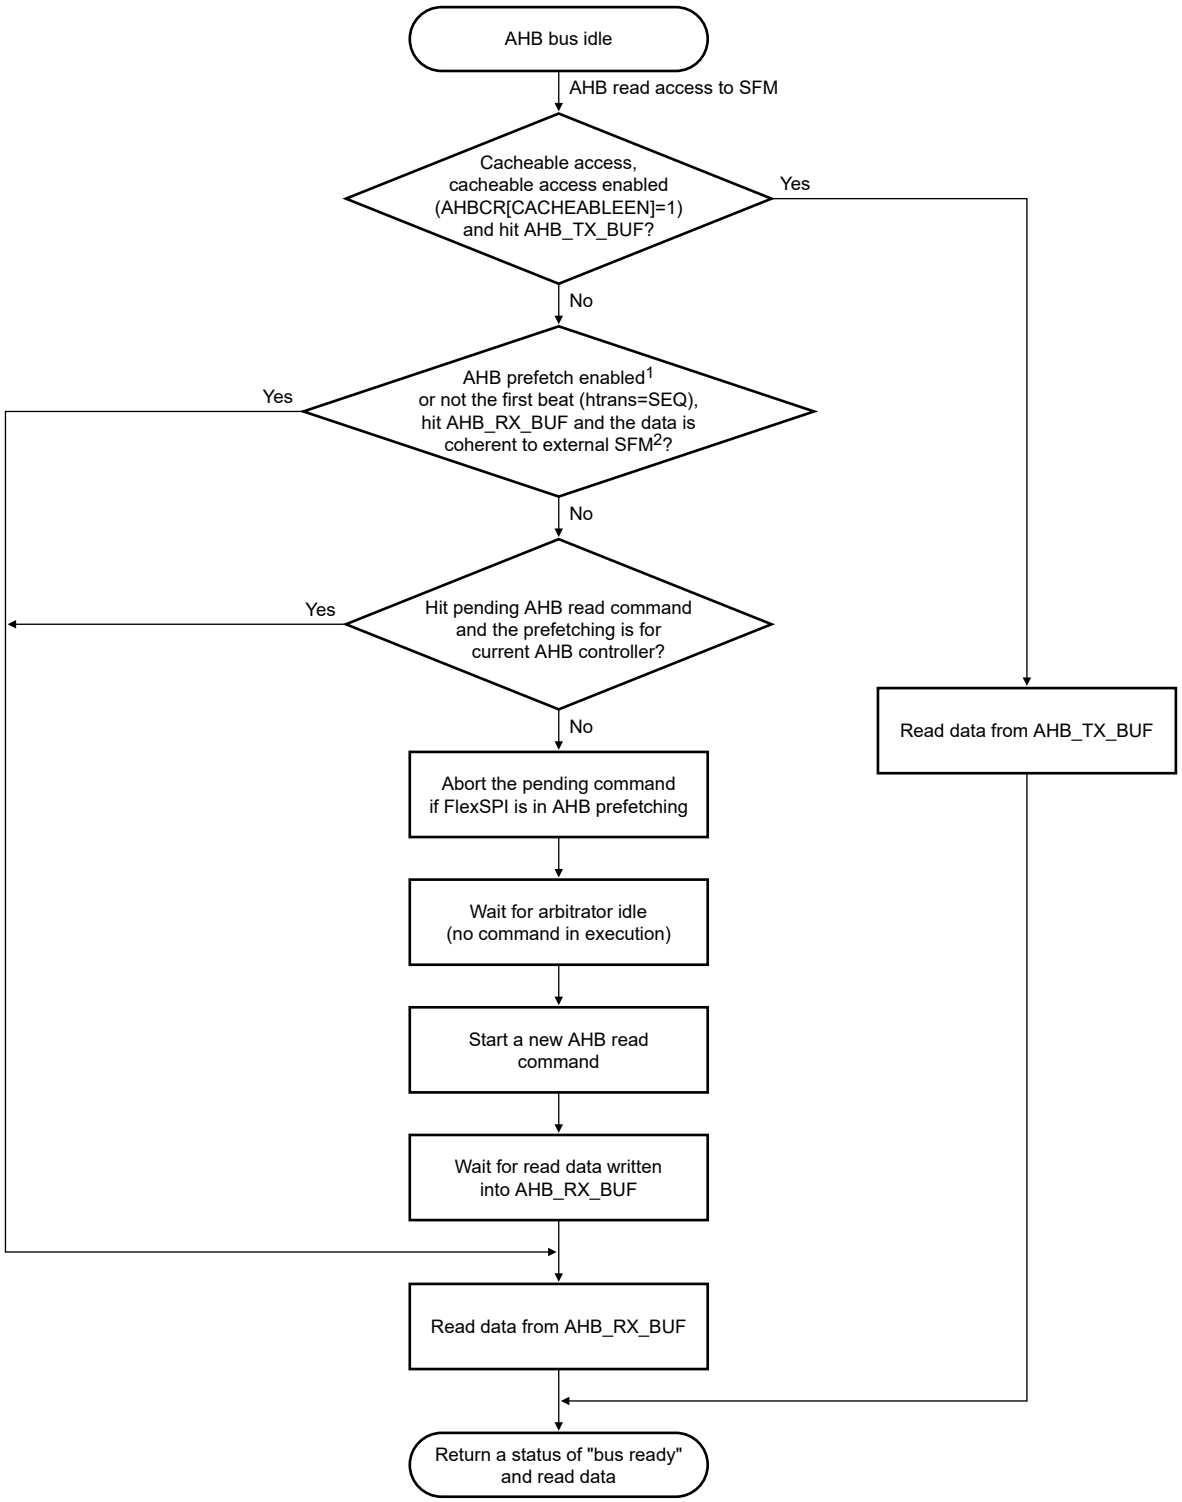
If the burst data size (in bytes) is greater than the AHB transmit buffer size, wrapper burst is not supported. For example, if AHB_TX_BUF is 64 bytes, AHB WRAP16 (16 × 64 bits = 128 bytes) write burst access is not supported.

10.3.11.2 AHB read access to flash memory

For AHB read access to flash memory, FlexSPI checks the burst access type and register setting to determine whether to access these locations:

- The AHB transmit buffer
- The AHB receive buffer
- A pending AHB read command

If all of these options are missed, FlexSPI triggers a new AHB read command to fetch data from flash memory. Figure 33 shows the hardware operation in response to AHB read access to flash memory.



Notes:
1) AHB prefetch is enabled when both AHBCR[PREFETCHEN]=1 and AHBRXBUFxCR0[PREFETCHEN]=1 (x is the AHB RX buffer ID for the current AHB controller).
2) The AHB RX buffer holds the data read from flash memory. This data may become incoherent if AHB writes to the same flash-memory address.

Figure 33. Hardware operation in response to AHB read access to flash memory

Table 83 describes the details of a triggered AHB read command.

Table 83. Triggered AHB read command

Item	Description
Flash memory access start address and data size	Determined by AHB address, burst type, and burst size. FlexSPI fetches read data from the start address for the current burst or beat. See Table 84 for details.
Flash memory chip select	FlexSPI uses the settings of the flash memory access start address and flash memory size to determine the chip select.
Flash memory command sequence index	Determined by FLSHxCR2[AWRSEQID].
Flash memory command sequence number	Determined by FLSHxCR2[AWRSEQNUM]. If AWRSEQNUM is not zero, multiple flash memory access command sequences are triggered every time for an AHB read command. The sequences indexed from AWRSEQID to (AWRSEQID + AWRSEQNUM) in LUT are executed sequentially.
Flash memory access mode (Individual/ Parallel)	Determined by AHBCR[APAREN].

NOTE

- FlexSPI automatically determines which ARDSEQNUM and ARDSEQID fields that the flash device uses as sequence ID for chip selection. See MCR2[SAMEDEVICEEN].
- FlexSPI determines which AHB receive buffer to use for the current AHB read access by controller ID. For details about the AHB receive buffer ID and AHB controller ID mapping, see AHB receive buffer management.
- You cannot allocate the size of the AHB receive buffer to be less than the AHB Burst size. This allocation results in unknown behavior.

Table 84. AHB read command flash memory start address and data size

Prefetch enable	Cross flash boundary	Burst type	Flash memory start address [28:0]	Data size
0	Never cross flash boundary, because AHB burst never crosses 1 KB boundary.	SINGLE, INCR4, INCR8, INCR16	hbeat_start_address	(hburst_end_address-hbeat_start_address)
		INCR	hbeat_start_address	byte size of current beat For INCR burst with prefetch disabled, each beat is handled same as SINGLE burst.
		WRAP4, WRAP8, WRAP16	hburst_start_address	(hburst_end_address-hburst_start_address)
1	No	INCR, SINGLE, INCR4, INCR8, INCR16	hbeat_start_address	ahb_rx_buf_sz
	No	WRAP4, WRAP8, WRAP16	hburst_start_address	ahb_rx_buf_sz

Table continues on the next page...

Table 84. AHB read command flash memory start address and data size (continued)

Prefetch enable	Cross flash boundary	Burst type	Flash memory start address [28:0]	Data size
	Yes	INCR, SINGLE, INCR4, INCR8, INCR16	hbeat_start_address	(flash_top_address-hbeat_start_address)
	Yes	WRAP4, WRAP8, WRAP16	hburst_start_address	(flash_top_address-hburst_start_address)

NOTE

- hbeat_start_address is HADDR input from the AHB controller for current beat.
- hburst_start_address (for example 00h) is the lowest address for current burst. hburst_end_address (for example 10h) is the highest address in current burst plus 1. For example, WRAP4 burst with HADDR 8h, Ch, 0h, 4h.
- ahb_rx_buf_sz is the buffer size in bytes of AHB receive buffer that the current AHB controller uses.
- flash_top_address is the top address of currently accessed flash memory.

10.3.11.3 AHB receive buffer management

There are 8 buffers (Buffer 0–7) in the AHB receive buffer. These buffers are transparent to AHB controllers. FlexSPI fetches flash memory data and returns it on the AHB bus automatically. No status register polling is needed for AHB read access to Serial Flash Memory (SFM).

The total size of AHB receive buffers is 1 KB. Use AHBRXBUF0CR0[BUFSZ]–AHBRXBUFCR7[BUFSZ] to configure the buffer size of each AHB receive buffer. The buffer size for Buffer 0 to Buffer 7 could be set to 0. If the buffer size is set to 0, FlexSPI ignores the related setting of AHBRXBUFxCR0[MSTRID]. Buffer 7 is used for all AHB controllers not assigned to Buffer 0–6. FlexSPI ignores the Buffer 7 size setting field (AHBRXBUF7CR0[BUFSZ]). Its buffer size is: (AHB receive buffer total size) - (the sum of the sizes of Buffer 0–6).

When an AHB read access to serial flash memory occurs, FlexSPI determines which buffer to use via this method:

1. If the controller ID equals AHBRXBUF0CR0[MSTRID] and AHBRXBUF0CR0[BUFSZ] is not zero, Buffer 0 is used.
2. If the controller ID equals AHBRXBUF1CR0[MSTRID] and AHBRXBUF1CR0[BUFSZ] is not zero, Buffer 1 is used.
3. If the controller ID equals AHBRXBUF2CR0[MSTRID] and AHBRXBUF2CR0[BUFSZ] is not zero, Buffer 2 is used.
4. If the controller ID equals AHBRXBUF3CR0[MSTRID] and AHBRXBUF3CR0[BUFSZ] is not zero, Buffer 3 is used.
5. If the controller ID equals AHBRXBUF4CR0[MSTRID] and AHBRXBUF4CR0[BUFSZ] is not zero, Buffer 4 is used.
6. If the controller ID equals AHBRXBUF5CR0[MSTRID] and AHBRXBUF5CR0[BUFSZ] is not zero, Buffer 5 is used.
7. If the controller ID equals AHBRXBUF6CR0[MSTRID] and AHBRXBUF6CR0[BUFSZ] is not zero, Buffer 6 is used.
8. If all the above cases are not met, Buffer 7 is used.

NOTE

- Software must ensure that the size of each buffer is not less than the maximum burst size of an AHB read access from the AHB controller using this buffer. Otherwise, the behavior is undefined. The minimum buffer size request depends on the chip implementation. For example, if the capability of the chip to send out a maximum burst is 64 bytes, the minimum AHB receive buffer is 64 bytes.
- Assigning multiple buffers to a single AHB controller is not supported, unless the prefetch buffer enhancement feature is being used (see Prefetch buffer enhancement).
- When AHB read prefetch is enabled (AHBCR[PREFETCHEN] = 1), the size of the buffer determines the prefetch data size. If it does not cross the flash boundary, FlexSPI fetches data from the external flash device with that buffer size.
- The priority setting of AHB controller (AHBRXBUFxCR0[PRIORITY] = 1) is used only for suspending control of AHB prefetching. See Command abort and suspend.

10.3.11.3.1 Prefetch buffer enhancement

If a given controller frequently accesses memory at multiple address areas (non-sequential accesses), then the prefetch buffer can become less effective. For example, if the CPU is executing task A at a given address, then switches to task B at a different address, then when the CPU switches to task B (FLEXSPI receives request for an access that does not hit in the prefetch buffer), then the prefetch buffer will be flushed and a new prefetch will start at the task B address. When the CPU switches back to task A (task A addresses now miss in the prefetch buffer, because the buffer holds task B addresses instead), then the prefetch buffer will be flushed again and start prefetching at the task A address.

If the switches between task A and task B happen frequently, then FLEXSPI can end up re-reading items it had previously stored in the prefetch buffer as the buffer ends up being flushed often due to the task switches.

To increase the efficiency of FLEXSPI in situations like those described in the example above, the prefetch buffer enhancement feature can be enabled. When prefetch buffer enhancement is enabled (AHBRXBUFnCR0[REGIONEN]=1), then multiple prefetch buffers can be assigned to the same controller with an address range (AHBBUFREGIONSTARTn/ENDn) used as an additional filter to determine which buffer is used.

FLEXSPI compares the controller ID along with corresponding address range of each buffer to select one buffer. Other buffers are not impacted. This way, the AHB controller can prefetch the data from multiple address ranges in each of the buffers.

Program sequence:

- Configure AHBBUFREGIONSTARTn and AHBBUFREGIONENDn with the desired address ranges. Note that the addresses here use the AHB address including the system base address, not the serial flash address with the base address removed
- END must be larger than START
- Set AHBRXBUFnCR0[REGIONEN] = 1
- Set AHBRXBUFnCR0[MSTRID] with the MSTRID corresponding to the controller that will own multiple buffers, for example 4'b0011

NOTE

- This function is only meaningful when prefetch is enabled.
- Only Buffer 0 - 3 support this enhancement when REGIONEN=1, other buffers work like before. Buffer 0 - 3 with REGIONEN=0 works like before.

Prefetch buffer enhancement example:

The core in the system uses MSTRID = 0. The core will frequently switch between task A at 0x8000_1000-0x8000_1FFF and task B at 0x8000_2000-0x8000_2FFF, so dedicated prefetch buffers will be used for these tasks. The core will access other addresses in the FLEXSPI region using a third prefetch buffer.

To achieve this configuration:

- AHBBUFREGIONSTART0 = 0x8000_1000 and AHBBUFREGIONEND0 = 0x8000_2000. Configure Buffer 0 to the address range used by task A.
- AHBBUFREGIONSTART1 = 0x8000_2000 and AHBBUFREGIONEND1 = 0x8000_3000. Configure Buffer 1 to the address range used by task B.
- AHBRXBUF0CR0 = 0xC000_0004. Buffer 0 is a 256 bytes buffer assigned to the core (MSTRID = 0) with the prefetch buffer enhancement feature enabled (REGIONEN = 1), so only task A addresses will use buffer 0.
- AHBRXBUF1CR0 = 0xC000_0004. Buffer 1 is a second 256 bytes buffer assigned to the core (MSTRID = 0) with the prefetch buffer enhancement feature enabled (REGIONEN = 1), so only task B addresses will use buffer 1.
- AHBRXBUF4CR0 = 0x8000_0004. Buffer 4 is a third 256 bytes buffer assigned to the core (MSTRID = 0). The prefetch buffer enhancement feature will not be used for this buffer (and is not available for buffer 4 anyway). Core accesses that do not hit in Buffer 0 or Buffer 1 will use Buffer 4.

10.3.12 Command arbitration

There are four flash memory access command sources:

1. AHB command, that AHB write access to serial flash memory space triggers
2. AHB command, that AHB read access to serial flash memory space triggers
3. IP command, that writing IPCMD[TRG] triggers
4. Suspended command, an AHB read prefetch sequence which is suspended

An AHB bus access never triggers a write command and a read command at the same time.

The AHB prefetch sequence is an AHB command sequence triggered via AHB read access when AHB prefetch is enabled. After all read data is fetched for the current AHB read burst, FlexSPI prefetches more data to reduce read latency for the next AHB read access. An AHB command for a read operation is never aborted while fetching read data for the current AHB read burst. However, a new IP command or AHB command request while prefetching data (not for the current read burst) can abort an AHB read command.

When the arbitrator is idle (STS0[ARBIDLE] = 1), the granted priority of these command sources is:

1. AHB command (read or write)
2. IP command
3. Suspended command

NOTE

When the arbitrator is idle and there is no AHB or IP command request, a suspended command is not granted immediately. The arbitrator waits MCR2[RESUMEWAIT] AHB clock cycle idle states before resuming the suspended command to avoid AHB prefetch sequence being resumed and suspended frequently.

If the arbitrator is busy executing AHB or IP commands (not suspended commands), no new command requests are granted. If the grant times out, an AHB or IP command granted error occurs.

If a new AHB or IP command request comes while arbitrator is executing AHB read prefetch sequence, AHB read prefetch sequence is aborted (but not immediately). Arbitrator grants the AHB or IP command request after AHB read prefetch sequence is aborted on the FlexSPI interface and saved all internal data pointers.

10.3.12.1 Command abort and suspend

Table 85 describes the command abort and suspend mechanism.

Table 85. Command abort and suspend

Action	Description
Aborting a command	As mentioned above, if a new AHB or IP command request arrives, an AHB read prefetch sequence can be aborted.
Suspending a command	When an AHB read prefetch sequence is aborted on the FlexSPI interface, FlexSPI saves this suspended sequence in the cases listed below. FlexSPI resumes this sequence after the arbitrator has been idle for enough time. • There is no valid suspended command (AHBSPNDSTS[ACTIVE] = 0). This condition can occur when no command is suspended or when the suspended command is resumed. • The priority of aborted AHB read prefetch sequence is higher than the active suspend sequence. **NOTE** FlexSPI ignores and never resumes the original suspended sequence.
Activating a suspended command	The suspended command (internal status) becomes active when an AHB prefetch command is aborted and suspended. It becomes inactive in the following cases: • The arbitrator resumes the suspended command. • The AHB controller triggers a new AHB read command request using the same AHB receive buffer (buffer ID). **NOTE** MCR0[SWRESET] can be used to clear any suspended command. The saved suspended command is dropped and no resuming occurs. The suspended command must be cleared after the flash page program or erase. Otherwise, another command may lead to a period in which the flash memory cannot support a read command.

Figure 34 shows an example of the flow of command abort, suspend, or resume.

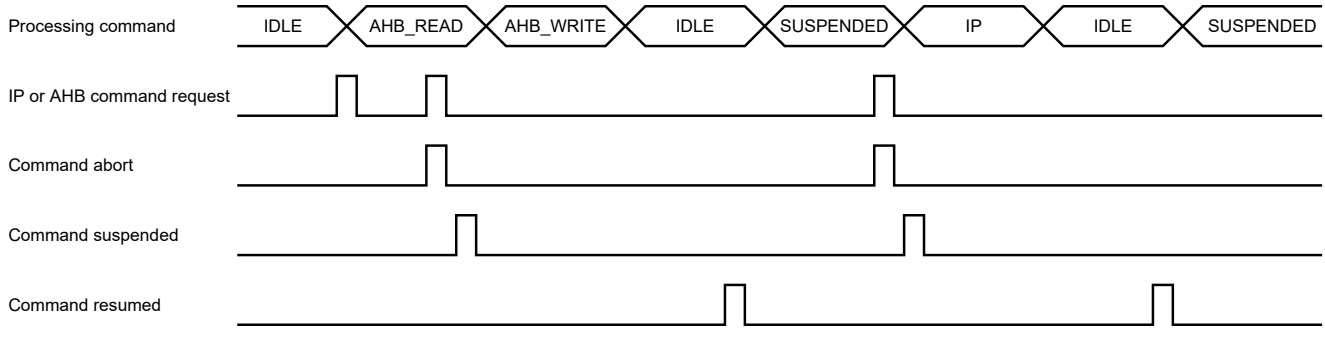


Figure 34. Command instruction execution on FlexSPI interface

NOTE

- The AHB prefetch sequence is aborted, suspended, or resumed twice in Figure 34. A new AHB write command request aborts the sequence the first time, and a new IP command request aborts the sequence the second time.
- The suspended sequence is resumed after a wait time of idle state. If there are frequent IP or AHB command requests and the wait time is not set reasonably, the suspend and resume activities may be triggered frequently.

10.3.13 SCLK stop

FlexSPI stops SCLK output toggling:

- When programming data is not ready for a programming command sequence.
- When an internal FIFO has no space to receive data for reading command sequence.

Certain devices may not support the stopping of SCLK during a command sequence (chip select is valid). SCLK stopping can be avoided via the methods described below.

- For flash memory reading that an IP command triggers:
  - Never trigger a read command with data size larger than IP receive FIFO size.
  - Internal asynchronous FIFO for flash memory reading should never be full.

    FlexSPI pops 64 bits of data per AHB clock cycle from this FIFO, and receives data from FlexSPI interface on the serial root clock. The flash memory access mode (Single, Dual, Quad, or Octal mode and Individual or Parallel mode) determines the receiving speed. For example, in Octal mode and Parallel mode, FlexSPI receives 16 bits per serial root clock cycle. If the AHB clock frequency is faster than 1/4 of the serial root clock, this asynchronous FIFO is never full.
- For flash memory programming that an IP command triggers:
  - Never trigger a program command with data size larger than the IP transmit FIFO size. Write all programming data into the IP transmit FIFO before triggering the IP command.
  - The internal asynchronous FIFO for flash memory programming must never be empty.

    FlexSPI fetches 64 bits of programming data per AHB clock cycle into this FIFO, and transmits data to the FlexSPI interface on the serial root clock. The flash memory access mode (Single, Dual, Quad, or Octal mode and Individual or Parallel mode) determines the transmitting speed. For example, in Octal mode and Parallel mode, FlexSPI transmits 16 bits per serial root clock cycle. If the AHB clock frequency is faster than 1/4 of the serial root clock, this asynchronous FIFO is never empty.
- For flash memory reading or programming that an AHB command triggers:
  - The internal asynchronous FIFO for flash memory reading and programming must never be full or empty. The frequency ratio limitation is same as it is for flash memory reading or flash memory programming that an IP command triggers.

NOTE

- FlexSPI never triggers an AHB read command with data size larger than the internal AHB receive buffer size.
- FlexSPI never triggers an AHB program command with data size larger than the internal AHB transmit buffer size.
- All programming data is buffered into the AHB transmit buffer before triggering an AHB program command in FlexSPI.

10.3.14 FlexSPI output timing

10.3.14.1 Output timing between data and SCLK

This section describes the output timing relationship of data (on A_DATA and B_DATA) and SCLK. There are three cases.

- **SDR instruction in SDR sequence**

  An SDR sequence contains only SDR instructions. In this case, all data bits last one serial root clock cycle on the FlexSPI interface. Figure 35 shows the relationship between the serial root clock, data, and SCLK:

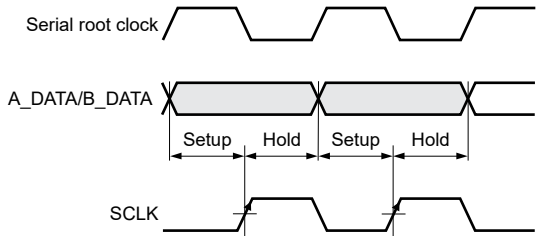

Figure 35. SDR instruction in SDR sequence

- **SDR instructions in a DDR sequence**

  A DDR sequence is a flash memory access command sequence that contains DDR instructions other than DUMMY_DDR. It may contain SDR instructions. If there are SDR instructions in a DDR sequence, all data bits last for two serial root clock cycles on the FlexSPI interface. Figure 36 shows the relationships between the serial root clock, data, and SCLK.

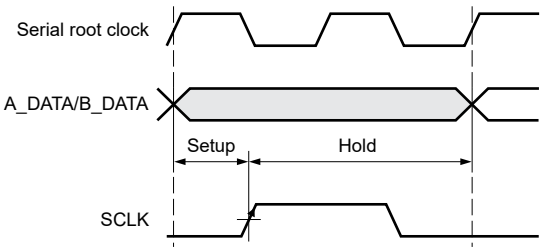

Figure 36. SDR instruction in DDR sequence

- **DDR instructions in a DDR sequence**

  For DDR instructions in a DDR sequence, all data bits last one serial root clock cycle on the FlexSPI interface. Figure 37 shows the relationships between the serial root clock, data, and SCLK.

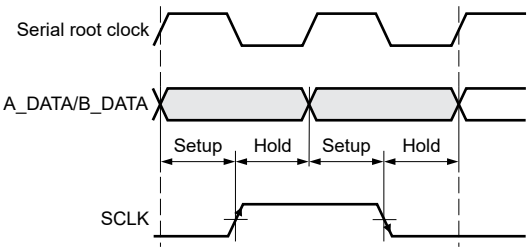

Figure 37. DDR instruction in DDR sequence

10.3.14.2 Output timing between chip select and SCLK

This section describes the output timing relationship between chip select (on A_SS0_B , A_SS1_B, B_SS0_B, and B_SS1_B) and SCLK. The timing relationship for the SDR sequence differs a little from the timing relationship for the DDR sequence.

- **Chip select timing in SDR sequence**

For an SDR sequence, the delay from chip select assertion to the SCLK rising edge is (FLSHxCR1[TCSS] + 0.5) cycles of the serial root clock. The delay from SCLK falling edge to chip select deassertion is FLSHxCR1[TCSH] cycles of serial root clock. Figure 38 shows the timing relationship between the chip select and SCLK.

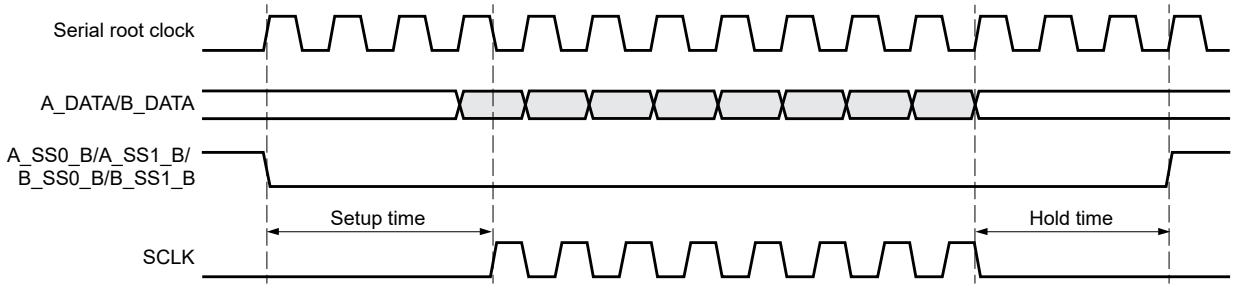

Figure 38. Chip select output timing for SDR sequence

- **Chip select timing in DDR sequence**

  For a DDR sequence, the delay from chip select assertion to the SCLK rising edge is **(FLSHxCR1[TCSS] + 0.5)** cycles of the serial root clock. The delay from the SCLK falling edge to chip select deassertion is **(FLSHxCR1[TCSH] + 0.5)** cycles of serial root clock.

  NOTE

  When AHB receive prefetch is enabled, and prefetch can be aborted, configure TCSH to 1 or greater. Configuring TCSH in this way guarantees a positive chip select hold time after the SCLK falling edge.

  Figure 39 shows the timing relationship between chip select and SCLK.

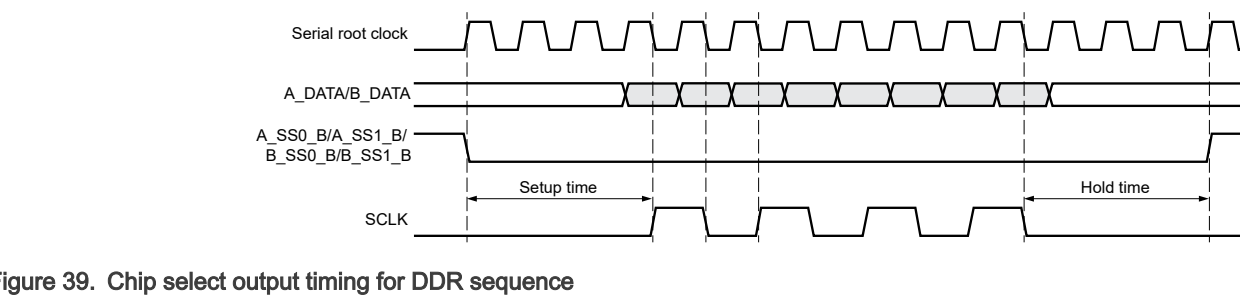

Figure 39. Chip select output timing for DDR sequence

For devices such as an FPGA device, a minimum chip select negation time (time between two chip select assertions) may be required. If the value of FLSHxCR1[CSINTERVAL] is nonzero, FlexSPI ensures a delay between chip select valid assertions. The delay time is CSINTERVAL × 256 cycles of serial root clock for an SDR or DDR sequence. If the external device has no limitation, configure the value of this field to zero. Figure 40 shows the timing of the chip select interval.

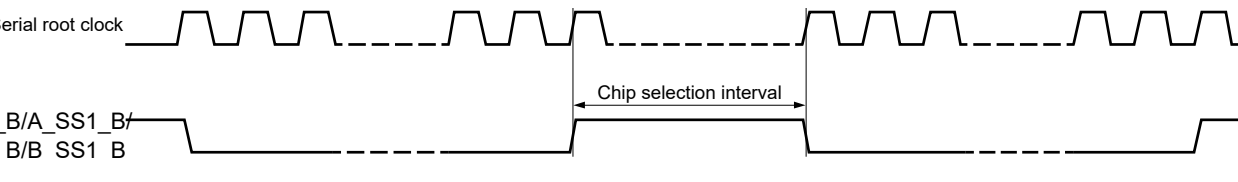

Figure 40. Chip select valid interval

10.3.15 FlexSPI input timing

This section describes the input timing of FlexSPI.

10.3.15.1 Receiving block

This section describes the receiving block in FlexSPI.

FlexSPI decodes instruction code to determine SDR mode or DDR mode. It also determines whether both the rising and falling edges are used for flash data sampling. FlexSPI samples the data line for learn instructions and read instructions.

MCR0[RXCLKSRC] selects the clock source from these four sources for the sampling clock:

- Internal dummy read strobe and looped back internally
- Internal dummy read strobe and looped back from DQS pad
- SCK output and looped back from SCK pad
- Flash-memory-provided read strobe

For details about DLL configuration, see DLL configuration for sampling.

Figure 41 shows the sampling block in FlexSPI.

FlexSPI uses both rising and falling edges to sample data from flash_A and flash_B. Two muxes with four clock source inputs generate the signals ipp_ind_io_fa, ipp_ind_io_fb. See Receive clock source features. ipp_ind_io_fa_int and ipp_ind_io_fb_int are reversed from ipp_ind_io_fa and ipp_ind_io_fb. Both sampling flip-flops are used when FlexSPI is in DDR mode. Only the falling edge sampling flip-flop is used in SDR mode.

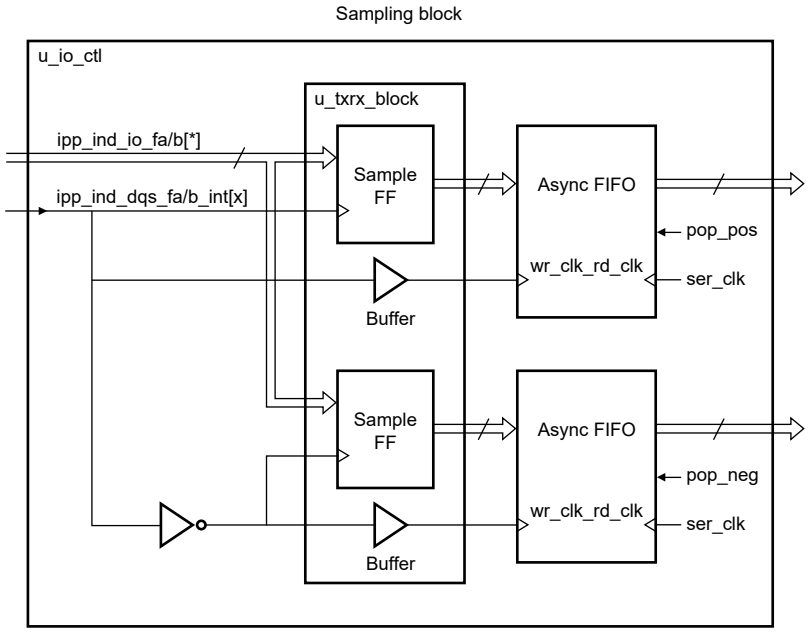

Figure 41. Sampling block in FlexSPI

Figure 42 is the receiving block diagram for data learning.

There are 16 clock phases for sampling data. An internal delay chain delays the clock phases.

See Data learning.

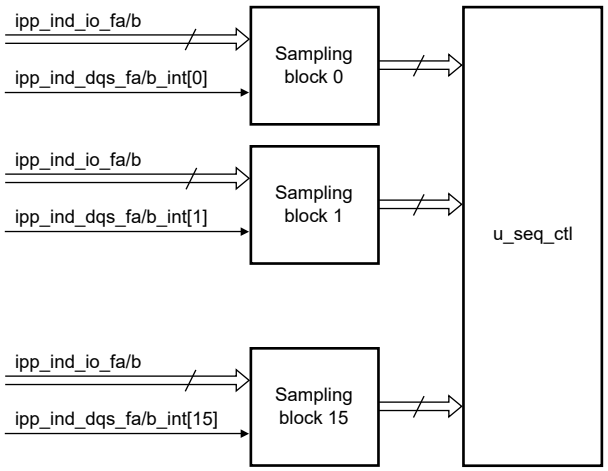

Figure 42. Sampling blocks for data learning

FlexSPI does not support read operations with a zero-turnaround cycle for direction switching on I/O pins. This read operation often occurs in QuadSPI configuration register reads. In Figure 43 and Figure 44, SIO[3:0] is an output from FlexSPI in the CMD phase, and is an input to FlexSPI in the DATA phase. No time remains for FlexSPI to switch the direction. This kind of read is not supported. FlexSPI and flash memory drive the I/O pins at the same time, which may cause a problem. To avoid this behavior on I/O pins, using SPI mode or reading with dummy cycles is required.

NOTE

The cycle numbers are not accurate in the examples below. See the device spec for accurate cycle numbers.

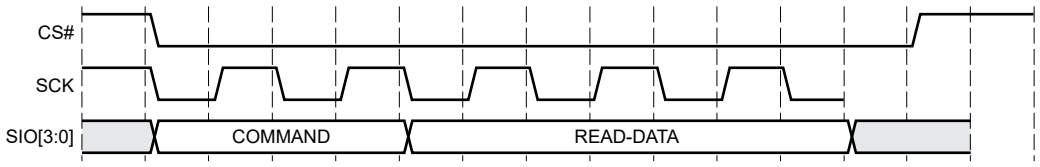

Figure 43. Unsupported read behavior

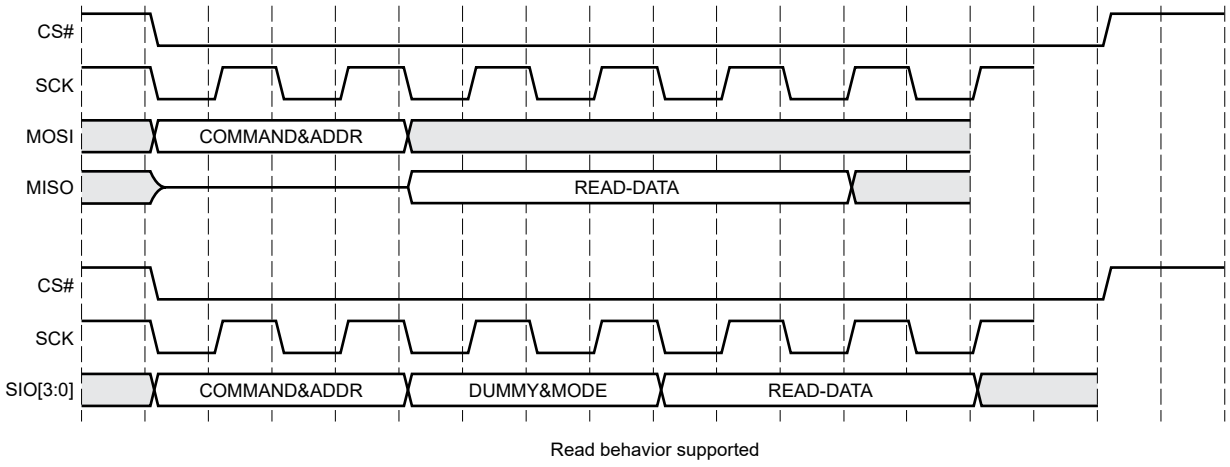

Figure 44. Supported read behavior

10.3.15.2 Receive clock source features

FlexSPI uses a read strobe to sample incoming data. There are several options for generating the read clock strobe that MCR0[RXCLKSRC] selects. Using the receive clock source method has implications for the board connections and can affect the maximum frequency that the interface supports. See the device data sheet for details on the maximum frequency supported for each RXCLKSRC option.

Table 86. RXCLKSRC options

MCR0[RXCLKSRC]	Description	Board connection	Max Frequency
0	Internal dummy read strobe and internal loopback	DQS pin is not used. The DQS pin can be configured for an alternate signal function.	Lowest
1	Internal dummy read strobe and loopback from DQS pad	FlexSPI uses the DQS pin, and it must be configured for its FlexSPI function. The internally generated read strobe is sent to the DQS pin and is sampled at the pin to match more closely the data pin timings. The DQS pin is typically left floating. External capacitance can be added to adjust timing.	Medium
2	SCK output and loopback from SCK pad	SCK is used as the read strobe. FlexSPI uses the signal looped back from the SCK pad as the read strobe to match more closely the data pin timings. DQS pin is not used and can be configured for an alternate signal function.	Medium
3	Flash-memory-provided read strobe	DQS pin is connected to the DQS or RWDS signal that the memory provides.	Highest

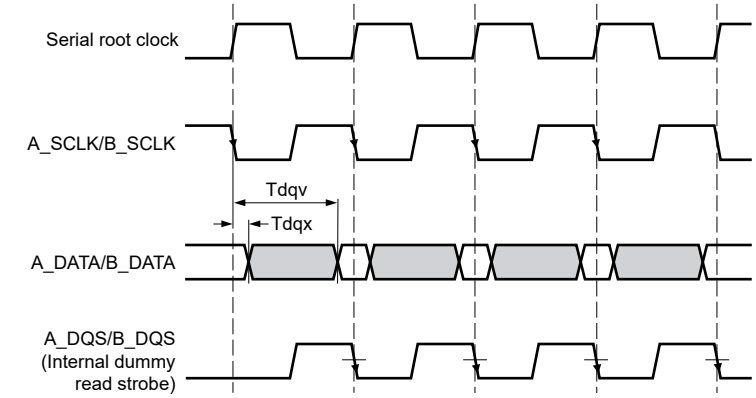
10.3.15.3 Input timing for sampling with dummy read strobe

This section describes the input timing when sampling with the internal dummy read strobe (MCR0[RXCLKSRC] = 0 or 1). The timing for sampling with an internal dummy read strobe loopback is very similar to the timing for loopback from pad. Sampling with a dummy read strobe loopback from the DQS pad can achieve a higher read frequency. It compensates for the delay of the SCLK output path and data pin input path.

The input timing is different for SDR mode and DDR mode.

- **Input timing for sampling with dummy read strobe in SDR mode**

  For SDR read or learn instructions, FlexSPI samples input data pins with the falling edge of the dummy read strobe. Figure 45 shows the input timing for sampling with dummy read strobe in SDR mode.



Tdqv is the setup time from SCLK to the next valid data.
Tdqx is the hold time from SCLK to the current valid data.

Figure 45. Input timing for sampling with dummy read strobe in SDR mode

- **Input timing for sampling with dummy read strobe in DDR mode**

  For DDR read or learn instructions, FlexSPI samples input data pins on rising and falling edges of the dummy read strobe. Figure 46 shows the input timing for sampling with dummy read strobe in DDR mode.

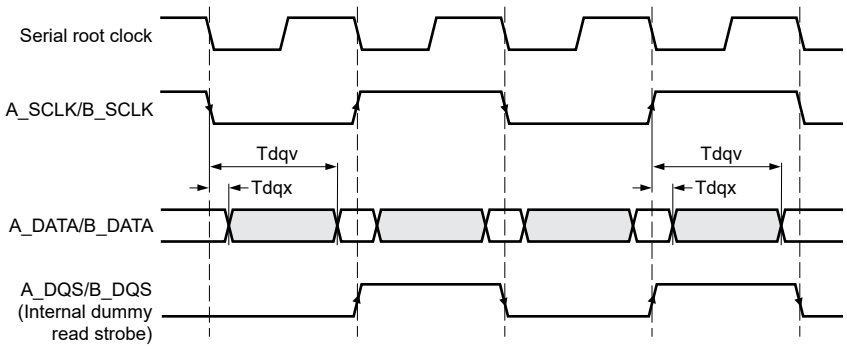


Figure 46. Input timing for sampling with dummy read strobe in DDR mode

10.3.15.4 Input timing for sampling with SCK output looped back from SCK pad

This section describes the input timing when sampling with the SCK output looped back from the SCK pad (MCR0[RXCLKSRC] = 2). The input timing is similar to sampling with a dummy read strobe. SCK output toggles for all types of instructions, but internal dummy strobe only toggles for read and learn instructions. In this case, FlexSPI receives more data bits when sampling with SCK output. FlexSPI automatically ignores the redundant data bits sampled.

10.3.15.5 Input timing for sampling with flash-memory-provided read strobe

This section describes the input timing when sampling with flash-memory-provided read strobe (MCR0[RXCLKSRC] = 3). The input timing is different for SDR mode and DDR mode.

NOTE

There are no known devices that provide a read strobe and support SDR mode operation.

- **Flash-memory-provided read strobe with SCLK**

  Certain flash devices provide both read data and read strobes with SCLK. Then the read strobe edge is aligned with the read data change. The FlexSPI controller delays the read strobe for one half cycle of the serial root clock (with DLL), then samples

read data with the delayed strobe. See DLL configuration for sampling. Figure 47 and Figure 48 show the input timing for sampling with flash memory read strobe in SDR mode and DDR mode.

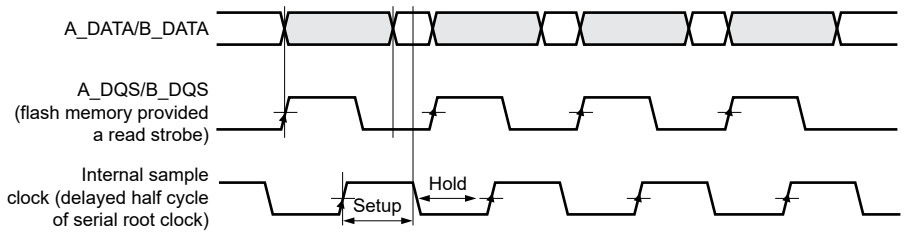

Figure 47. Input timing 2 for flash-memory-provided read strobe in SDR mode

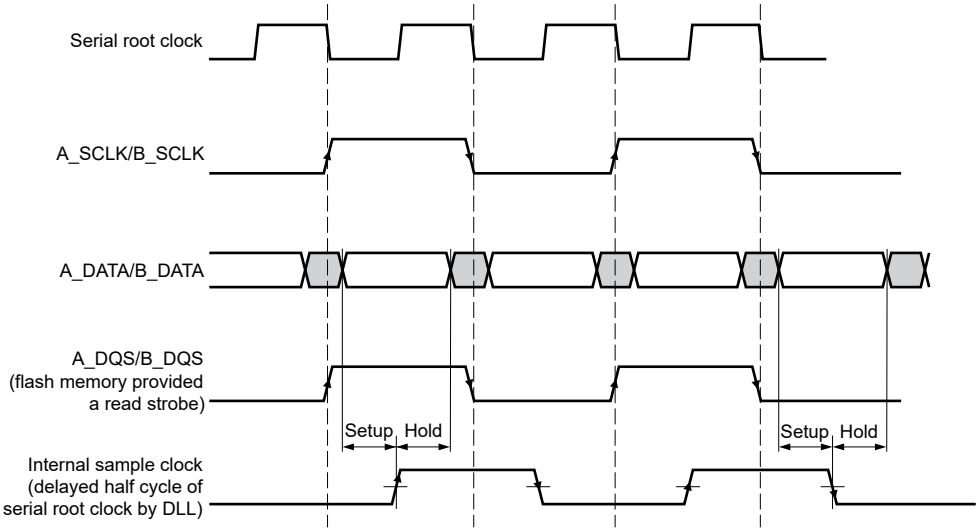

Figure 48. Input timing 2 for flash-memory-provided read strobe in DDR mode

10.3.15.6 DLL configuration for sampling

For the four sampling clock sources described previously, the input timing differs depending on the DLLxCR register configuration, according to the sampling clock source mode. The DLL is a delay-line chain that can be set to a fixed number of delay cells. It can also be auto-adjusted to lock on a certain phase delay to the reference clock.

- DLLxCR must be set to 0000_0100h (one fixed delay cell in DLL delay chain) in the following cases:
  - Sampling data with dummy read strobe looped back internally (MCR0[RXCLKSRC] = 0h)
  - Sampling data with dummy read strobe looped back from DQS pad (MCR0[RXCLKSRC] = 1h)
  - Sampling data with SCLK output looped back from SCLK pad (MCR0[RXCLKSRC] = 2h)
- When data is sampled with a flash-memory-provided read strobe (MCR0[RXCLKSRC] = 3h) and flash memory provides the read strobe with SCLK, DLL must be configured as follows (when serial root clock is over 100 Mhz. These settings ensure a lock of the reference clock (serial root clock).
  - DLLxCR[SLVDLYTARGET] is up to flash parameters used.
  - DLLxCR[REFPHASEGAP] = 2h
  - DLLxCR[DLLEN] = 1h
  - DLLxCR[OVRDEN] = 0h
  - Other fields in DLLxCR must be kept at their reset values (all zeroes).

After the register settings above are completed, set the DLL with following steps.

1. Reset the DLL(DLLxCR[DLLRESET] or MCR0[SWRESET]).
2. Wait for STS2[xREFLOCK] and STS2[xSLVLOCK] being asserted.
3. Wait for equal or more than 512 serial root clock cycles.
4. Start read or write operation.

NOTE

If the serial root clock is slower than 100 MHz, DLL cannot lock on a half cycle of serial root clock. The delay cell number is limited in the delay chain. DLL must be configured as follows instead:

- DLLxCR[OVRDEN] = 1
- DLLxCR[OVRDVAL] = N

  Each delay cell in DLL is about 75 ps to 225 ps. The delay of DLL delay chain is (N × Delay_cell_delay). N is set based on the maximum DDR frequency (N ≤ equation). This value is calculated based on the MAX_DDR_FREQ parameter. N = 34. This value is a recommended value. If a failure occurs, the value might require adjustment in a real application.

  You can calculate the delay of one delay cell and obtain the value of N. If the serial root clock is lower than 100 MHz, the delay chain can't lock with DLLxCR[SLVDLYTARGET] = 0xF (half cycle of root clock delay). You need to set DLLxCR[SLVDLYTARGET] as 0xE (15/32 cycle delay) or less. When DLL is locked (read STS2[AREFLOCK] and STS2[ASLVLOCK]), the delay cell number = STS2[ASLVSEL] +1 and the delay value (one delay cell) = (total delay)/(delay cell number). Based on delay value, the N can be easily calculated.
- Other fields in DLLxCR must be kept at their reset values (all zeroes).

10.3.16 Data learning

The FlexSPI controller generates 16 clock phases (Phase 0–15) via delay cell line (DCL) with the selected sample clock. Clock phase 0 is the selected sample clock (DQS_IN) with no delay cell. 16 sampling blocks are implemented for both Port A and 16 sampling blocks are implemented for Port B.

During a learn instruction, FlexSPI compares the sampled data bits with the internal data learn pattern in the Data Learning Pattern (DLPR) register and determines the correct sampling clock phase. The phase selection is automatically updated after a learn instruction and applied to subsequent read instructions or sequences.

When data learning is disabled (MCR0[LEARNEN] = 0), FlexSPI always uses clock phase 0 to sample FlexSPI data lines. Attempting to execute a learn instruction results in an error flag (INTR[IPCMDERR] or INTR[AHBCMDERR]).

FlexSPI supports data learning in both SDR mode and DDR mode. Data learning is not supported if the sampling clock source is a flash-memory-provided read strobe (MCR0[RXCLKSRC] = 3h).

Data learning can achieve high read frequency, but the flash memory input timing still limits the highest frequency. Flash memory must receive the command code and flash address bits.

When data learning is enabled, FlexSPI uses clock phase 0 after reset and before executing a learn instruction. The clock phase selection is updated after FlexSPI executes the learn instruction. The selected sample clock phase can be polled via STS0[DATALEARNPHASEA] and STS0[DATALEARNPHASEB]. When data learning fails, the INTR[DATALEARNFAIL] interrupt flag is set, and the previous clock phase selection is kept. You can write 1 to MCR2[CLRLEARNPHASE] to reset the internal clock phase selection to clock phase 0.

10.3.16.1 Data learning with flash-memory-provided preamble bit

Certain flash devices support driving with preamble bits before driving read data in each read command sequence. Preamble bits are also called the data-learning pattern (DLP). The DLP is programmable via configuration register in the flash device.

For the specified read command sequence, flash memory returns preamble bits after dummy cycles and before returning read data.

For these flash devices, the operation flow with data learning is:

1. Configure the data learning pattern in Data Learning Pattern (DLPR) register.
2. Configure the same data learning pattern in the flash device by triggering an IP command.
3. Enable data learning in the flash device by triggering an IP command.
4. Configure LUT sequence with valid read command sequence containing the learn instruction.
5. Trigger a flash memory read command via AHB or IP command as normal.

NOTE

The first four steps are executed only once. They are not needed for every flash memory read command.

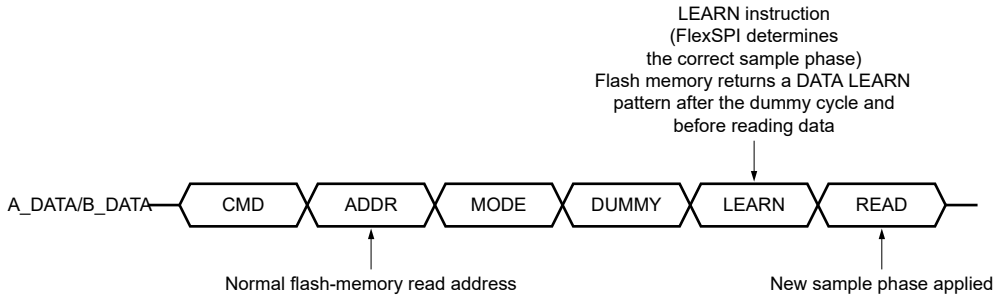

Figure 49. Data learning flow with flash-memory-provided preamble bit

10.3.16.2 Data learning without flash-memory-provided preamble bit

For flash devices that do not provide a preamble bit, the DLP cannot be returned automatically for each read command sequence. For these flash devices, the data learning sequence is:

1. Set data learning pattern in Data Learning Pattern (DLPR) register.
2. Reserve a certain flash memory area and program data (according to data learning pattern and flash memory access mode) to this area via IP command.
3. Configure LUT sequence with read sequence using a learn instruction instead of a read instruction. Trigger the read sequence to the reserved flash memory area via IP command.
4. Trigger the flash memory read command via AHB or IP command as normal. No learn instruction is needed in this read sequence.

NOTE

- The first three steps are executed only once. They are not needed for every flash memory read command.
- Step 4 should be executed with a certain interval to ensure that the internal sampling clock phase is adjusted in time.

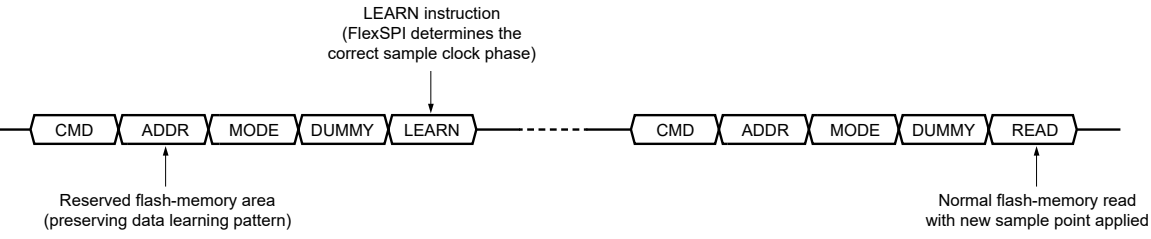

Figure 50. Data learning flow without flash-memory-provided preamble bit

NOTE

- For flash devices that do not provide a preamble bit, software overhead is required to read the reserved flash memory area at the interval.

These items determine the preprogramming data:

- Data Learning Pattern (DLPR register setting)
- DLP bit length
- Individual or Parallel mode for read command
- Octal, Quad, Dual, or Single mode for read command

Figure 51 shows a preprogramming data example where the DLPR value is 43h, eight bits, and flash memory is read in Quad mode and Parallel mode.

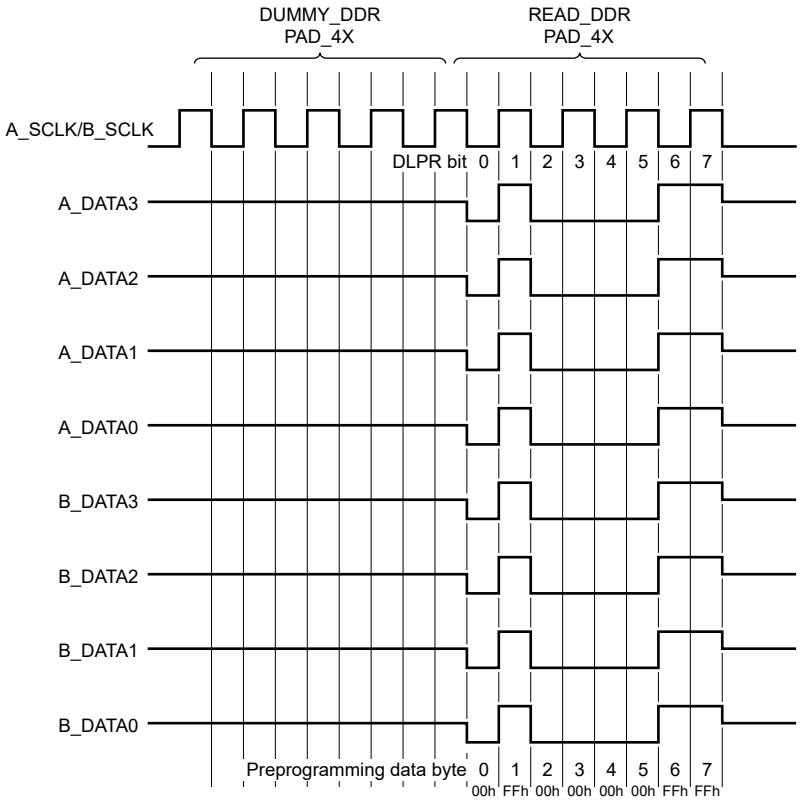

Figure 51. Preprogramming data for data learning

10.3.17 Execute-In-Place (XIP) enhanced mode

FlexSPI always supports XIP, regardless of whether external devices provide XIP enhanced mode. To support XIP, put program codes on an external device, then read or execute these codes directly via AHB read access to serial flash memory space. There is no configuration or status polling needed during AHB read access to the memory of the external device. The AHB receive buffer is fully transparent to software.

Certain devices provide XIP enhanced mode to improve code execution. In this mode, the command code is only sent in the first read instruction. It saves many cycles for command instructions and improves code execution. Devices enter or exit XIP enhanced mode via a special sequence that external devices specify. See the external device data sheet for more details.

Normally, a device enters XIP enhanced mode via this sequence:

1. Enable XIP enhanced mode in external flash device via IP command.

2. Send the first read sequence to external flash device with correct mode bits. Command code is included in this read sequence.
3. Send the subsequent read sequences to external flash device with correct mode bits. Command code is not included in these read sequences. Mode bits must be sent according to the flash specified; otherwise, the flash exits XIP enhanced mode.

The instruction JMP_ON_CS in FlexSPI must be used to support XIP enhanced mode in external devices. This instruction is only allowed in the AHB read command; otherwise, the instruction generates an IPCMDERR or AHBCDMERR interrupt (when the interrupt is enabled). When external devices do not support XIP enhanced mode, JMP_ON_CS must never be used. To support XIP enhanced mode:

- The first instruction in the read sequence must be the command instruction.
- The last valid instruction must be JMP_ON_CS (with operand 1h).

For the first AHB read command triggered, FlexSPI executes the instructions from the instruction pointer 0 in the sequence (which is the command instruction). After this sequence is executed, FlexSPI saves the operand in the JMP_ON_CS instruction as the start pointer for the next command to current device internally. For the next AHB read command triggered, FlexSPI executes from the instruction pointer 1h, bypassing the command instruction.

After XIP enhanced mode is started, it is possible to access flash via other commands like program commands. You must, however, use a special sequence to exit enhanced XIP mode before you can run a different command. Figure 52 indicates XIP operation with Flash XIP enhanced mode.

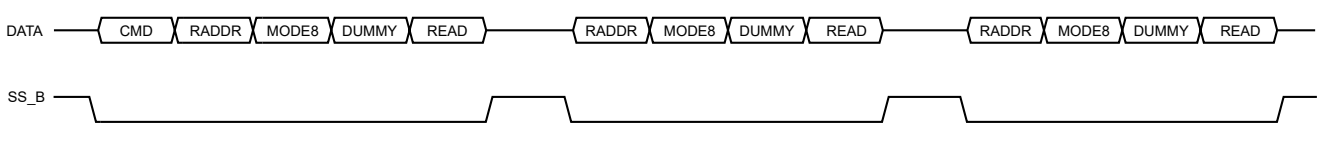

Figure 52. XIP Enhanced Mode Operation

10.3.18 AHB bus blocking

FlexSPI can temporarily block some or all AHB transactions. This feature is useful when IP commands are in progress that could cause a potential conflict with an AHB request. Examples of situations where IP bus blocking would be used are:

- Avoiding RWW (read while write). While programming or erasing flash, reads are not allowed. AHB bus blocking can prevent the AHB bus from requesting a read while IP write commands are in progress.
- Decrypting while encrypting. The IPED of FlexSPI cannot support simultaneous encryption and decryption. Partial AHB bus blocking can prevent AHB reads from IPED regions while IP writes to encrypted block are in progress.

To block all AHB transactions:

1. Configure blocking for all AHB transactions by writing 1 to IPCR2[IPBLKALLAHB].
2. Request AHB bus blocking by writing 1 to IPCR2[IPBLKAHBREQ].
3. Wait for the AHB bus blocking request to be acknowledged (IPCR2[IPBLKAHBACK] = 1).
4. Perform IP write commands as needed.
5. Request normal operation by writing 0 to IPCR2[IPBLKAHBREQ].
6. Wait for AHB blocking request clear to be acknowledged (IPCR2[IPBLKAHBACK] = 0).

To block AHB transactions to IPED regions only, while allowing AHB transactions to unencrypted areas:

1. Configure blocking for AHB transactions to IPED areas by writing 0 to IPCR2[IPBLKALLAHB].
2. Request AHB bus blocking by writing 1 to IPCR2[IPBLKAHBREQ].
3. Wait for the AHB bus blocking request to be acknowledged (IPCR2[IPBLKAHBACK] = 1).

4. Perform IP write commands as needed.
5. Request normal operation by writing 0 to IPCR2[IPBLKAHBREQ].
6. Wait for AHB blocking request clear to be acknowledged (IPCR2[IPBLKAHBACK] = 0).

NOTE

AHB bus blocking can only be used to prevent conflicts between AHB and IP transactions. Software must handle conflicts between multiple AHB transactions.

10.3.19 Domain control

FLEXSPI supports two kinds of protection modes to manage nonsecure controller IP command access:

- IP command trigger
- LUT write

The chip must maintain domain control of the AHB region.

10.3.19.1 IP command domain control

Two pairs of start and end registers can be configured to specify the regions that allow nonsecure controller IP command access: IPSNSZSTARTn and IPSNSZENDn. Only secure controllers can write to these registers. Nonsecure controllers cannot configure or change the regions where IP commands can be used. Any addresses outside the nonsecure regions are treated as secure.

NOTE

The end address must be larger than the start address. The start address must be the flash memory address.

Once the address range of these registers becomes valid (start address < end address), any IP command issued by nonsecure controller targeting a secure region is blocked. No IP command is triggered. The INTR[IPCMDSECUREVIO] interrupt is set instead.

The program sequence is:

1. Write start address to IPSNSZSTART0 and end address to IPSNSZEND0.
2. Write start address to IPSNSZSTART1 and end address to IPSNSZEND1.

After the IPSNSZSTARTn and IPSNSZENDn registers are configured, FlexSPI responds to IP commands (IPCMD[TRG] = 1) as shown in Table 87.

Table 87. IPS access

Secure type: ips_nonsecure = 0 and ips_supervisor_access = 1	IPCR0[SFAR] address located within NSZ range	IPCMD successfully triggered
	IPCR0[SFAR] address outside NSZ range	IPCMD successfully triggered
Nonsecure type: ips_nonsecure = 1 or ips_supervisor_access = 0	IPCR0[SFAR] address located within NSZ range	IPCMD successfully triggered
	IPCR0[SFAR] address located outside NSZ range	IPCMD failed to trigger, INTR[IPCMDSECUREVIO] set

10.3.19.2 LUT write protection

LUTCR[PROTECT] controls LUT write protection. By default, no protection is applied on the LUT Control (LUTCR) register and LUT memory, and any controller can access the LUT freely.

When LUTCR[PROTECT] = 1, only a secure controller can change the value of LUTCR and the content of the LUT table. Unless hardware resets FlexSPI to return to the LUT write-protection-disabled state, nonsecure controllers cannot write to the LUT table or LUTCR register.

No error or interrupt occurs if a non-secure controller attempts to write to the protected LUT; the write operation is ignored.

10.4 External signals

This section provides the external signal information for the FlexSPI module.

Table 88. External Signal List

Signal name	Function	Direction	Description
A_SS0_B	Peripheral Chip Select Flash A1	O	Chip select for the serial flash device A1
A_SS1_B	Peripheral Chip Select Flash A2	O	Chip select for the serial flash device A2
B_SS0_B	Peripheral Chip Select Flash B1	O	Chip select for the serial flash device B1
B_SS1_B	Peripheral Chip Select Flash B2	O	Chip select for the serial flash device B2
A_SCLK	Serial Clock Flash A	O	Serial clock output to the serial flash device A. This clock runs at half the frequency of serial clock root in DDR mode, and at the same frequency as serial clock root in SDR mode. Clock output toggles during the entire flash memory access sequence.
B_SCLK	Serial Clock Flash B	O	Serial clock output to the serial flash device B. This clock runs at half the frequency of serial clock root in DDR mode, and at the same frequency as serial clock root in SDR mode. Clock output toggles during the entire flash memory access sequence. **NOTE** B_SCLK may be used as the differential clock output of A_SCLK by writing 1 to MCR2[SCKBDIFFOPT].
A_DATAn	Serial I/O Flash A	I/O	Data I/O lines to and from the serial flash device A
B_DATAn	Serial I/O Flash B	I/O	Data I/O lines to and from the serial flash device B
A_DQS	Data Strobe Signal Flash A	I/O	Data strobe signal for port A. This signal has three functions: • Driven with read strobe by external device. Some flash devices provide the read strobe signal together with read data. In this case, if the external device drives this pad only

Table continues on the next page...

Table 88. External Signal List (continued)

Signal name	Function	Direction	Description
			when reading flash memory data, this pad may require a **pull-down** resistor. • Driven with latency information by external device. Some devices use this pin to indicate the dummy cycles needed (before program or read data transfer) such as HyperRAM or HyperFlash. • Loopback dummy read strobe. The FlexSPI controller provides internal dummy read strobe for flash memory read data. Higher read frequency can be achieved by looping back this dummy read strobe from the pad. This pin can be floated or have some capacitive load added at the board level to compensate for load on DATA or SCLK pins.
B_DQS	Data Strobe Signal Flash B	I/O	Similar to A_DQS

10.5 Initialization

The FlexSPI controller initialization sequence is:

1. Enable controller clocks (AHB clock, IP bus clock, or serial root clock) at system level.
2. To enter module stop mode, write 1 to MCR0[MDIS].
3. Configure module control registers: MCR0, MCR1, and MCR2. Do not change MCR0[MDIS].
4. When AHB commands are used, configure AHB Bus Control (AHBCR) and AHB Receive Buffer Control (AHBRXBUFxCR0) registers.
5. Configure flash control registers (FLSHxCR0, FLSHxCR1, or FLSHxCR2) according to external device type.
6. Configure DLL control register (DLLxCR) according to sample clock source selection.
7. To exit module stop mode, write 0 to MCR0[MDIS].
8. Configure LUT as needed for AHB command or IP command.
9. Optionally, to reset controller, write 1 to MCR0[SWRESET].

External devices must be configured via IP command normally after initialization. For example, the WRITE STATUS command performs device configuration for most serial NOR flash memory.

10.6 Application information

This section describes applications that FlexSPI supports.

10.6.1 Application on serial NOR flash device

This section provides the example LUT instruction sequences for serial NOR flash device (Cypress Flash S25FS128S).

10.6.1.1 Write enable command

Table 89 shows the WRITE ENABLE command sequence.

Table 89. WRITE ENABLE command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h	06h	Command name: WREN
1-7	STOP (00h)	0h	00h	

10.6.1.2 Write registers command

Table 90 shows the Write Registers command sequence.

Table 90. Write Registers command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	01h	Command name: WRR
1	WRITE_SDR	0h (Single)	1h or 2h	Data size is 1 byte or 2 bytes. Byte 0 is write data for Status Register 1; Byte 1 is write data for Configuration Register 1. IPCR1[IDATSZ] can override this value.
2-7	STOP (00h)	0h	00h	

10.6.1.3 Page Program command

Table 91 shows Page Program command sequence.

Table 91. PAGE PROGRAM command (Cypress serial NOR flash)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	02h or 12h	Command name: PP or 4PP PP is 3-byte address mode. 4PP is 4-byte address mode.
1	ADDR_SDR	0h (Single)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	WRITE_SDR	0h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default programming data size. This value is ignored for AHB command.
3-7	STOP (00h)	0h	00h	

Table 92 shows Page Program command sequence (QPI mode).

Table 92. PAGE PROGRAM (QPI mode) command (Cypress serial NOR flash)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	2h (Quad)	02h or 12h	Command name: PP or 4PP PP is 3-byte address mode. 4PP is 4-byte address mode.
1	ADDR_SDR	2h (Quad)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	WRITE_SDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default programming data size. This value is ignored for AHB command.
3-7	STOP (00h)	0h	00h	

10.6.1.4 Read Status 1 command

Table 93 shows READ STATUS 1 command sequence.

Table 93. READ STATUS 1 command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	05h	Command name: RDSR1
1	READ_SDR	0h (Single)	1h	1 byte for Status register 1
2-7	STOP (00h)	0h	00h	

10.6.1.5 Read command

Table 94 shows READ command sequence.

Table 94. READ command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	03h or 13h	Command name: READ or 4READ READ is 3-byte address mode. 4READ is 4-byte address mode.
1	ADDR_SDR	0h (Single)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	READ_SDR	0h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
3-7	STOP (00h)	0h	00h	

10.6.1.6 Fast Read command

Table 95 shows Fast Read command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[3:0] = 8h.

Table 95. FAST_READ command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	0Bh or 0Ch	Command name: FAST_READ or 4FAST_READ FAST_READ is 3-byte address mode. 4FAST_READ is 4-byte address mode.
1	ADDR_SDR	0h (Single)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	DUMMY_SDR	0h (Single)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
3	READ_SDR	0h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
4-7	STOP (00h)	0h	00h	

10.6.1.7 Dual IO Fast Read command

Table 96 shows Dual IO FAST_READ command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[3:0] = 8h, Continuous Read mode.

Table 96. Dual IO FAST_READ command (Continuous Read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	BBh or BCh	Command name: DIOR or 4DIOR DIOR is 3-byte address mode. 4DIOR is 4-byte address mode.
1	ADDR_SDR	1h (Dual)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	MODE8_SDR	1h (Dual)	Axh	Enter continuous read mode or remain in continuous read mode.
3	DUMMY_SDR	1h (Dual)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
4	READ_SDR	1h (Dual)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.

Table continues on the next page...

Table 96. Dual IO FAST_READ command (Continuous Read mode) (continued)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
5	JMP_ON_CS	0h (or Don't care)	01h	CMD instruction is bypassed after the first read access.
6-7	STOP (00h)	0h	00h	

Table 97 shows Dual IO FAST_READ command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[3:0] = 8h, Noncontinuous Read mode.

Table 97. Dual IO FAST_READ command (Noncontinuous Read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	BBh or BCh	Command name: DIOR or 4DIOR DIOR is 3-byte address mode. 4DIOR is 4-byte address mode.
1	ADDR_SDR	1h (Dual)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	MODE8_SDR	1h (Dual)	Any value other than Axh	Exit continuous read mode or remain in noncontinuous read mode.
3	DUMMY_SDR	1h (Dual)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
4	READ_SDR	1h (Dual)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
5-7	STOP (00h)	0h	00h	

10.6.1.8 Quad IO Fast Read command

Table 98 shows Quad IO FAST_READ command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[6] = 0, CR2V[3:0] = 8h, Non-QPI mode, Noncontinuous read mode.

Table 98. Quad IO FAST_READ command (Non-QPI mode, Noncontinuous read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	EBh or ECh	Command name: QIOR or 4QIOR QIOR is 3-byte address mode. 4QIOR is 4-byte address mode.
1	ADDR_SDR	2h (Quad)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.

				data size. This value is ignored for AHB command.
5-7	STOP (00h)	0h	00h	

10.6.3 Application on Serial NAND flash device

This section provides example LUT instruction sequences for serial NAND flash device (Micron Flash MT29 series). The operation of serial NAND flash is similar to serial NOR flash.

The read operation sequence is:

- Page read. Transfer the data from the NAND flash array to the cache register.
- Get feature to read the status.
- Random data read

Table 109 shows the page read command sequence.

Table 109. Page Read command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	13h	Command code: 13h
1	RADDR_SDR	1h (Single)	18h	Row address: 24 bit
2-7	STOP (0h)	0h	00h	

Table 110 shows Get Feature command sequence.

Table 110. Get Feature command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	0Fh	Command code: 0Fh
1	CMD_SDR	1h (Single)	C0h	Status register address (C0h)
2	READ_SDR	0x1 (Single)	02h	2 bytes read data
3-7	STOP (0h)	0h	00h	

Table 111 shows Random Data Read command sequence.

Table 111. Read from Cache x4 command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	6Bh	Command code: 6Bh
1	MODE4_SDR	1h (Single)	0h or 1h	If plane selection is one, software should decode the flash address and write 1h to mode bits. If plane selection

Table continues on the next page...

Table 111. Read from Cache x4 command (continued)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
				is zero, software should write 0h to mode bits. Plane selection bit is 18th bit of flash address. If NAND flash size is less than 4 Gbit, plane selection is always zero.
2	CADDR_SDR	1h (Single)	0Ch	Column address: 12 bit
3	DUMMY_SDR	2h (Quad)	08h	Dummy cycle number: 8 (serial root clock)
4	READ_SDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size.
5-7	STOP (0x0)	0x0	0x00	

The program operation sequence is:

- Write enable
- Program Load. Transfer the write data to the cache register.
- Program Execute
- Get Feature to read the status.

Table 112 shows Program Load command sequence.

Table 112. Program Load command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	02h	Command code: 02h
1	MODE4_SDR	1h (Single)	0h or 1h	If plane selection is one, software should decode the flash address and write 1h to mode bits. If plane selection is zero, software should write 0h to mode bits. Plane selection bit is 18th bit of flash address. If NAND flash size is less than 4 Gbit, plane selection is always zero.
2	CADDR_SDR	1h (Single)	0Ch	Column address: 12 bit
3	WRITE_SDR	1h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default writing data size.
4-7	STOP (0h)	0h	00h	

Table 113 shows Program Execute command sequence.

Table 113. Program Execute command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	10h	Command code: 10h
1	RADDR_SDR	1h (Single)	18h	Row Address: 24 bit
2-7	STOP (0h)	0h	00h	

10.6.4 Application on FPGA device

An FPGA device can be accessed via both AHB and IP commands. All AHB accesses to FPGA are transparent to the software driver (no software intervention). An FPGA device may have some special requirements.

Table 114. Special requirements for FPGA devices

Condition	How to manage the condition
Device type may be different on A1, A2, B1, or B2.	Write 0 to MCR2[SAMEDEVICEEN] and configure the FLSHxCR0 and FLSHxCR1 registers separately for up to four external devices.
Device requires different wait cycle for programming.	The AHB write wait cycle number can be set separately for these four external devices (via FLSHxCR2[AWRWAIT]). Software can configure the sequences in LUT with different dummy instructions (operand determines dummy cycle). FlexSPI holds the AHB bus ready for this wait time; AHB bus performance may decrease when this wait time is very long.
Device requires different wait cycle for reading.	The AHB read sequence index and sequence number can be set separately for these four external devices (via FLSHxCR2[ARDSEQID] and FLSHxCR2[ARDSEQNUM]). Software can configure the sequences in LUT with different dummy instructions (operand determines dummy cycle).
Device may be sensitive to read instruction clock cycle number.	If its internal memory is implemented similar to a FIFO, the device is sensitive to the read instruction clock cycle number. Software can send the data size information to the external device via DATSZ instruction. The FPGA device decodes the data size information and determines how many data bytes must be popped.
Device may require interval time between chip select valid.	This interval can be managed via FLSHxCR1[CSINTERVAL].
Device may use SCLK as reference clock for its internal PLL.	SCLK must be free-running and the clock frequency must be stable. To achieve this configuration, write 1 to MCR0[SCKFREERUNEN] and only use SDR sequences.

10.6.5 Overview of error categories, flags, and triggered sources

Table 115 provides an overview of the categories, flags, and triggered sources of errors in FlexSPI.

Table 115. Error category, triggered sources, and flags

Error Category	Triggered Sources	Description	Error Flags
Command grant error	AHB write command	Command grant timeout	INTR[AHBCMDGE] is set AHB bus error response

Table continues on the next page...

Table 115. Error category, triggered sources, and flags (continued)

Error Category	Triggered Sources	Description	Error Flags
	AHB read command		INTR[AHBCMDGE] is set AHB bus error response
	IP command		INTR[IPCMDGE] is set
Command check error	AHB write command	• AHB write command with JMP_ON_CS instruction used in the sequence • Unknown instruction opcode in the sequence • Instruction DUMMY_SDR or DUMMY_RWDS_SDR used in DDR sequence • Instruction DUMMY_DDR or DUMMY_RWDS_DDR used in SDR sequence	INTR[AHBCMDERR] is set Command is not executed when an error is detected in command check
	AHB read command	• Unknown instruction opcode in the sequence • Instruction DUMMY_SDR or DUMMY_RWDS_SDR used in DDR sequence • Instruction DUMMY_DDR or DUMMY_RWDS_DDR used in SDR sequence	INTR[AHBCMDERR] is set Command is not executed when an error is detected in command check
	IP command	• IP command with JMP_ON_CS instruction used in the sequence • Unknown instruction opcode in the sequence • Instruction DUMMY_SDR or DUMMY_RWDS_SDR used in DDR sequence • Instruction DUMMY_DDR or DUMMY_RWDS_DDR used in SDR sequence • Flash boundary across	INTR[IPCMDERR] is set Command is not executed when an error is detected in command check
Command execution error	AHB write command	Command timeout during execution	INTR[AHBCMDERR] is set INTR[SEQTIMEOUT] is set An AHB bus error response

Table continues on the next page...

Table 115. Error category, triggered sources, and flags (continued)

Error Category	Triggered Sources	Description	Error Flags
			occurs, except in following cases: • Flush triggers AHB write command (INCR burst ended with AHB_TX_BUF not empty) • AHB bufferable write access and bufferable enabled (AHBCR[BUFFERABLEEN] = 1)
	AHB read command		INTR[AHBCMDERR] is set INTR[SEQTIMEOUT] is set AHB bus error response
	IP command		INTR[IPCMDERR] is set INTR[SEQTIMEOUT] is set
AHB bus timeout	AHB write command	AHB bus timeout (no bus ready return)	INTR[AHBBUSTIMEOUT] is set AHB bus error response
	AHB read command		
Data learning failed	Any command	No valid sample clock phase found after learn instruction is executed	INTR[DATALEARNFAIL] is set
Security error	IP command	Nonsecure controller requests IP command access to a secure region	INTR[IPCMDSECUREVIO] is set

10.7 Memory map and register definition

This section includes the FlexSPI module memory map and detailed descriptions of all registers.

10.7.1 Register access

All registers can be accessed with 8-bit, 16-bit, and 32-bit width operations. Never change the values of reserved fields in control registers. Changing the values of reserved fields may impact the normal functioning of the controller.

NOTE

When FlexSPI can access sensitive memory contents, the FlexSPI controller should protect those contents using resource isolation such as XRDC or TrustZone, or equivalent partition control via SCFW. Ensure that only trusted software is allowed to access the FlexSPI controller register interface.

10.7.2 FlexSPI register descriptions

10.7.2.1 FlexSPI memory map

FLEXSPI0 base address: 400C_8000h

Offset	Register	Width (In bits)	Access	Reset value

Fields

Field	Function
31-24 AHBGRANTWAIT	Timeouts Wait Cycle for AHB command Grant Sets duration of timeout wait cycle for AHB commands. If the arbitrator does not grant the AHB-triggered command, it times out after (AHBGRANTTIMEOUT × 1024) AHB clock cycles. When the pending

Table continues on the next page...

Table continued from the previous page...

Field	Function
	command sequence is IP-triggered and the read or write data size is too large, this grant timeout may occur. When an AHB command grant timeout occurs, an INTR[AHBCMDGE] interrupt is generated. When INTEN[AHBCMDGEEN] = 1, the arbitrator ignores AHB commands. **NOTE** This field is for debugging only. Do not change the value from its default.
23-16 IPGRANTWAIT	Timeout Wait Cycle for IP Command Grant Sets duration of timeout wait cycle for IP commands. If the arbitrator does not grant the IP-triggered command, it times out after (IPGRANTTIMEOUT × 1024) AHB clock cycles. When the pending command sequence is AHB-triggered and the read or write data size is too large, this grant timeout may occur. When IP command grant timeout occurs, an INTR[IPCMDGE] interrupt is generated. When INTEN[IPCMDGEEN] = 1, the arbitrator ignores IP commands. **NOTE** This field is for debugging only. Do not change the value from its default.
15 LEARNEN	Data Learning Enable Enables data learning feature. When data learning is disabled, the sampling clock phase 0 is always used for receive data sampling, even when a learn instruction is correctly executed. See Data learning. 0b - Disable 1b - Enable
14 SCKFREERUNEN	SCLK Free-running Enable Enables free-running SCLK output. For FPGA applications, the external device may use SCLK as a reference clock to its internal PLL. If SCLK free-running is enabled, data sampling with loopback clock from SCLK pad is not supported (MCR0[RXCLKSRC] = 2). 0b - Disable 1b - Enable
13 COMBINATIONEN	Combination Mode Enable Enables combination mode, which supports flash Octal mode access. When Port A and Port B data are four bits wide, this mode combines Port A and B Data pins (A_DATA[3:0] and B_DATA[3:0]). When Port A and Port B data are eight bits wide, combination mode is not supported; write 0 to this field in this case. 0b - Disable 1b - Enable
12 DOZEEN	Doze Mode Enable Enables Doze mode. When enabled, AHB clock and serial clock are gated off when there is a Doze-mode request from the system. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
11 HSEN	Half Speed Serial Flash Memory Access Enable Enables the clock divider to provide a half-speed clock to external serial flash devices (A_SCLK/ B_SCLK) for all commands in SDR and DDR mode. Write 1 to MCR0[MDIS] before changing the value of this field. Failure to do so may cause issues in the internal logic or state machine. 0b - Disable 1b - Enable
10-8 SERCLKDIV	Serial Root Clock Divider Sets divider value for serial root clock. The serial root clock can be divided inside FlexSPI . See Clocking. **NOTE** Do not modify this field while FlexSPI is active (MCR0[MDIS] = 0). 000b - Divided by 1 001b - Divided by 2 010b - Divided by 3 011b - Divided by 4 100b - Divided by 5 101b - Divided by 6 110b - Divided by 7 111b - Divided by 8
7 —	Reserved
6 —	Reserved
5-4 RXCLKSRC	Sample Clock Source for Flash Reading Selects sampling clock source for flash memory reading. See Receive clock source features. 00b - Dummy Read strobe that FlexSPI generates, looped back internally 01b - Dummy Read strobe that FlexSPI generates, looped back from DQS pad 10b - SCLK output clock and looped back from SCLK pad 11b - Flash-memory-provided read strobe and input from DQS pad
3-2 —	Reserved
1	Module Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
MDIS	Disables FlexSPI module. When the module is disabled, AHB and serial clock are gated off internally to save power. Only register access is allowed, except for the LUT, IP receive FIFO, and IP transmit FIFO. 0b - No impact 1b - Module disable
0 SWRESET	Software Reset Resets the internal FlexSPI state machine and aborts any transactions in progress. Hardware automatically writes 0 to this field after software reset is done. Configuration registers are not reset. 0b - No impact 1b - Software reset

10.7.2.3 Module Control 1 (MCR1)

Offset

Register	Offset
MCR1	4h

Function

Controls basic functions of FlexSPI module

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	AHBBUSWAIT															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Fields

Field	Function
31-16	Command Sequence Wait

Table continues on the next page...

Table continued from the previous page...

Field	Function
SEQWAIT	Sets wait time for command sequence. Command sequence execution times out and aborts after (SEQWAIT × 1024) serial root clock cycles. When this timeout occurs, if the interrupt is enabled (INTEN[SEQTIMEOUTEN] = 1), an INTR[SEQTIMEOUT] interrupt is generated. Also, the arbitrator ignores AHB commands. **NOTE** You cannot write 0 to this field.
15-0 AHBBUSWAIT	AHB Bus Wait Sets wait time for AHB bus. When data is not received from or transmitted to serial flash memory space after (AHBBUSWAIT × 1024) AHB clock cycles, the read or write access times out. When this timeout occurs, the AHB bus receives an error response, and an interrupt is generated (INTR[AHBBUSTIMEOUT]). When INTR[AHBBUSTIMEOUT] = 1, the arbitrator ignores AHB commands. **NOTE** You cannot write 0 to this field.

10.7.2.4 Module Control 2 (MCR2)

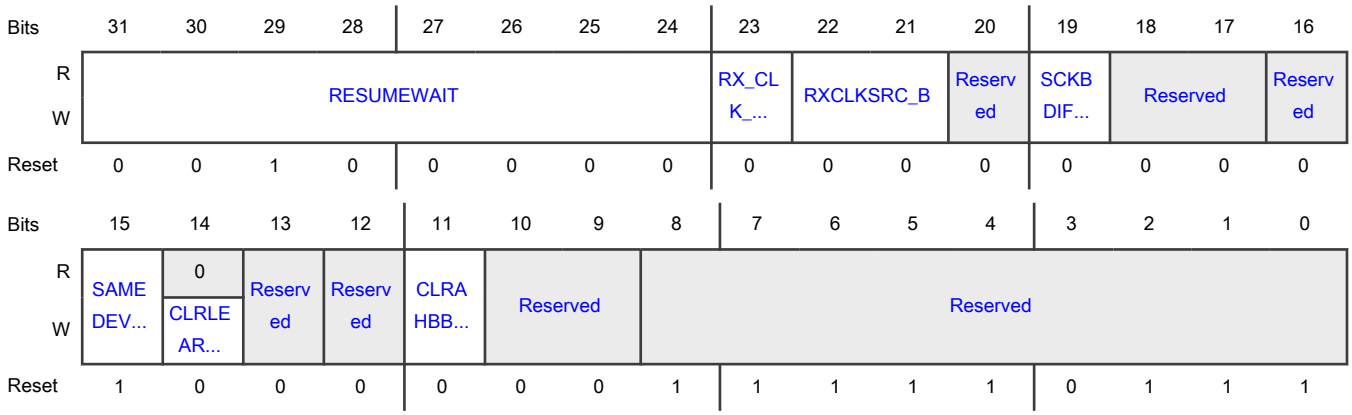
Offset

Register	Offset
MCR2	8h

Function

Controls basic functions of FlexSPI module.

Diagram



Fields

Field	Function
31-24 RESUMEWAIT	Resume Wait Duration Determines duration (in AHB clock cycles) to remain in idle state before suspended command sequence is resumed. See Command abort and suspend.
23 RX_CLK_SRC_DIFF	Sample Clock Source Different Selects whether to use the same clock source or a different clock source for Port A and Port B. 0b - Use MCR0[RXCLKSRC] for Port A and Port B. MCR2[RXCLKSRC_B] is ignored and MCR0[RXCLKSRC] selects the Sample Clock source for Flash Reading of both ports A and B. 1b - Use MCR0[RXCLKSRC] for Port A, and MCR2[RXCLKSRC_B] for Port B. MCR0[RXCLKSRC] selects the Sample Clock source for Flash Reading of port A (A_SCLK) and MCR2[RXCLKSRC_B] selects the Sample Clock source for Flash Reading of port B (B_SCLK).
22-21 RXCLKSRC_B	Port B Receiver Clock Source Selects Port B sample clock source selection for flash memory reading. 00b - Dummy read strobe that FlexSPI generates, looped back internally. 01b - Dummy read strobe that FlexSPI generates, looped back from DQS pad. 10b - SCLK output clock and looped back from SCLK pad 11b - Flash-memory-provided read strobe and input from DQS pad
20 —	Reserved
19 SCKBDIFFOPT	SCLK Port B Differential Output Controls whether to use B_SCLK pad as the Port B SCLK output. Alternatively, B_SCLK pad can be used as A_SCLK differential clock output (inverted clock to A_SCLK). Before changing the value of this field, write 1 to MCR0[MDIS]. After changing the value of this field, write 1 to MCR0[SWRESET]. 0b - Use B_SCLK pad as port B SCLK clock output. Port B flash memory access is available. 1b - Use B_SCLK pad as port A SCLK inverted clock output (Differential clock to A_SCLK). Port B flash memory access is not available.
18-17 —	Reserved
16 —	Reserved
15 SAMEDEVICEEN	Same Device Enable Sets all external devices (A1, A2, B1, and B2) to be the same devices (in type and in size).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - In Individual mode, FLSHA1CRx and FLSHA2CRx, FLSHB1CRx and FLSHB2CRx settings are applied to Flash A1, A2, B1, B2 separately. In Parallel mode, FLSHA1CRx register setting is applied to Flash A1 and B1, FLSHA2CRx register setting is applied to Flash A2 and B2. FLSHB1CRx and FLSHB2CRx register settings are ignored. 1b - FLSHA1CR0, FLSHA1CR1, and FLSHA1CR2 register settings are applied to Flash A1, A2, B1, B2. FLSHA2CRx, FLSHB1CRx, and FLSHB2CRx settings are ignored.
14 CLRLEARNPHASE	Clear Learn Phase Selection Resets the sampling clock phase selection to 0. When 1 is written to this field, it becomes 0 again immediately. 0b - No impact 1b - Reset sample clock phase selection to 0
13 —	Reserved
12 —	Reserved
11 CLRAHBBUFOPT	Clear AHB Buffer Determines whether AHB receive and transmit buffers are cleared automatically when FlexSPI returns Stop mode ACK. If an AHB receive buffer or transmit buffer will be powered off in Stop mode, software should write 1 to this field. Otherwise, an AHB read access after exiting Stop mode may hit either buffer, but their data entries are invalid. 0b - Not cleared automatically 1b - Cleared automatically
10-9 —	Reserved
8-0 —	Reserved

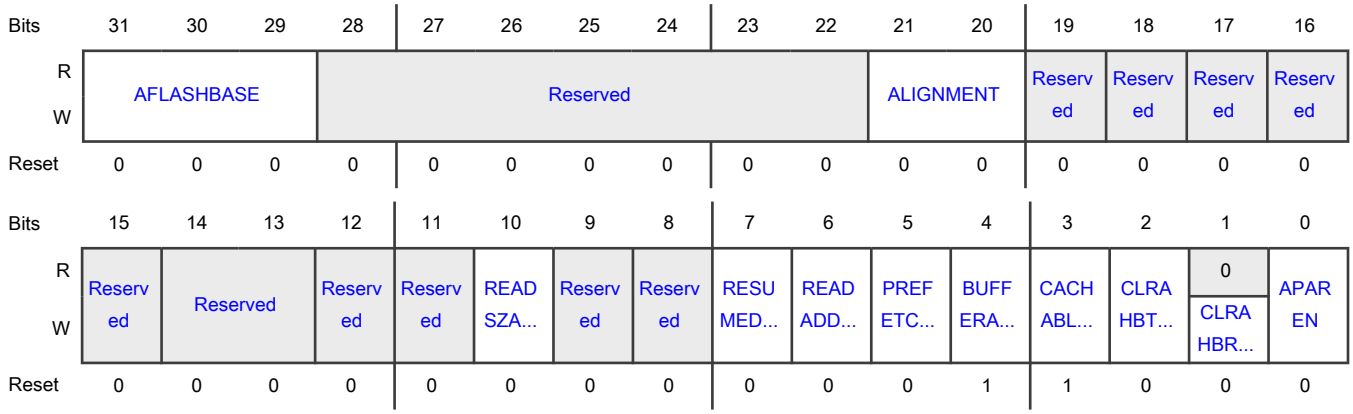
10.7.2.5 AHB Bus Control (AHBCR)

Offset

Register	Offset
AHBCR	Ch

Function
Controls AHB bus interface functions.

Diagram



Fields

Field	Function
31-29 AFLASHBASE	AHB Memory-Mapped Flash Base Address
28-22 —	Reserved
21-20 ALIGNMENT	AHB Boundary Alignment Configures the size of AHB read and write boundary. All accesses that cross the boundary are divided into smaller sub accesses. 00b - No limit 01b - 1 KB 10b - 512 bytes 11b - 256 bytes
19 —	Reserved
18 —	Reserved
17 —	Reserved
16 —	Reserved
15 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
14-13 —	Reserved
12 —	Reserved
11 —	Reserved
10 READSZALIGN	AHB Read Size Alignment Configures how AHB read size is determined. See Table 84. 0b - Register settings such as PREFETCH_EN determine AHB read size. 1b - AHB read size to up size to 8 bytes aligned, no prefetching
9 —	Reserved
8 —	Reserved
7 RESUMEDISABLE	AHB Read Resume Disable Disables the resumption of AHB read prefetch. 0b - Suspended AHB read prefetch resumes when AHB is IDLE. 1b - Suspended AHB read prefetch does not resume once aborted.
6 READADDROPT	AHB Read Address Option Removes AHB burst start address alignment limitation. When the FlexSPI controller is used for FPGA application, this field may be required for FlexSPI to fetch the exact byte number as an AHB burst. In this case, FPGA device should be non-word-addressable and this field must be 0. 0b - AHB read burst start address alignment is limited when flash memory is accessed in parallel mode or flash is word-addressable. 1b - AHB read burst start address alignment is not limited. FlexSPI fetches more data than the AHB burst requires for address alignment.
5 PREFETCHEN	AHB Read Prefetch Enable Enables AHB read prefetch. When enabled, FlexSPI fetches more flash read data than the current AHB burst requires. This action reduces the read latency for next AHB read access. **NOTE** AHB read prefetch is enabled only when both this field and AHBRXBUFnCR0[PREFETCHEN] are 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
4 BUFFERABLEEN	Bufferable Write Access Enable Enables AHB bus bufferable write access. This field affects the last beat of an AHB write access. See AHB write access to flash memory. 0b - Disabled. For all AHB write accesses (bufferable or nonbufferable), FlexSPI returns AHB Bus Ready after transmitting all data and finishing command. 1b - Enabled. For AHB bufferable write access, FlexSPI returns AHB Bus Ready when the arbitrator grants the AHB command. FlexSPI does not wait for the AHB command to finish.
3 CACHABLEEN	Cacheable Read Access Enable Enables AHB bus cacheable read access. 0b - Disabled. When an AHB bus cacheable read access occurs, FlexSPI does not check whether it hit the AHB transmit buffer. 1b - Enabled. When an AHB bus cacheable read access occurs, FlexSPI first checks whether the access hit the AHB transmit buffer.
2 CLRAHBTXBUF	Clear AHB Transmit Buffer Clears status and pointers of AHB transmit buffer. When the clear operation completes, this field clears automatically, so it always reads as 0. 0b - No impact. 1b - Enable clear operation.
1 CLRAHBRXBUF	Clear AHB Receive Buffer Clears status and pointers of AHB receive buffer. When the clear operation completes, this field clears automatically, so it always reads as 0. 0b - No impact. 1b - Enable clear operation.
0 APAREN	AHB Parallel Mode Enable Enables Parallel mode for AHB-triggered read and write commands. 0b - Flash is accessed in Individual mode. 1b - Flash is accessed in Parallel mode.

10.7.2.6 Interrupt Enable (INTEN)

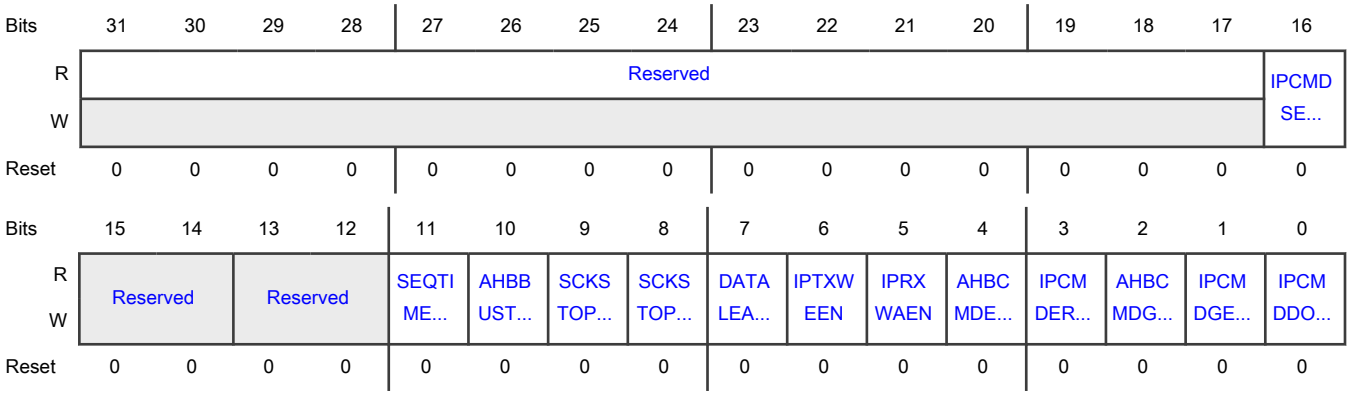
Offset

Register	Offset
INTEN	10h

Function

Includes AHB error response, IPS error response, and ECC error interrupt enables. See Interrupts.

Diagram



Fields

Field	Function

10.7.2.8 LUT Key (LUTKEY)

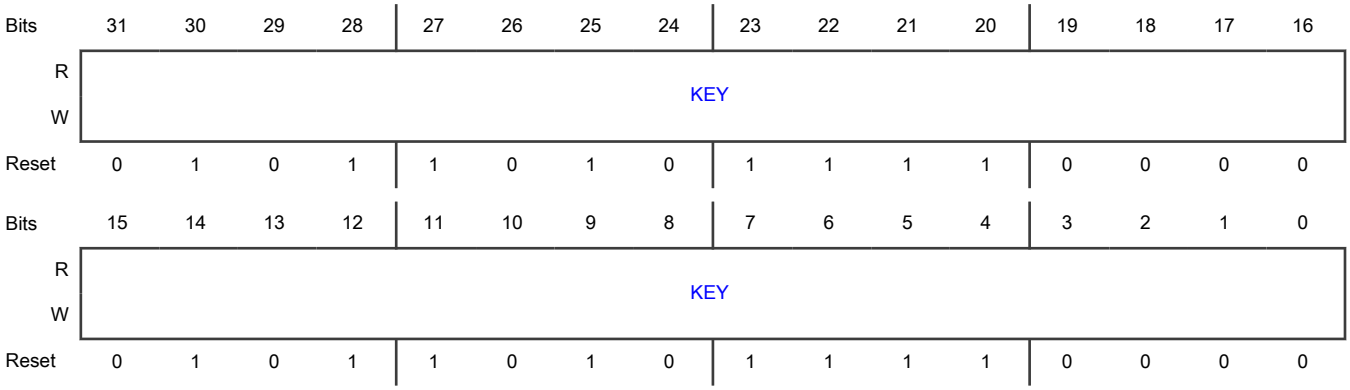
Offset

Register	Offset
LUTKEY	18h

Function

Contains the key to lock and unlock LUT. See Lookup table (LUT).

Diagram



Fields

Field	Function
31-0 KEY	LUT Key Contains key to lock or unlock LUT. The key is 5AF05AF0h. Read value is always 5AF05AF0h.

10.7.2.9 LUT Control (LUTCR)

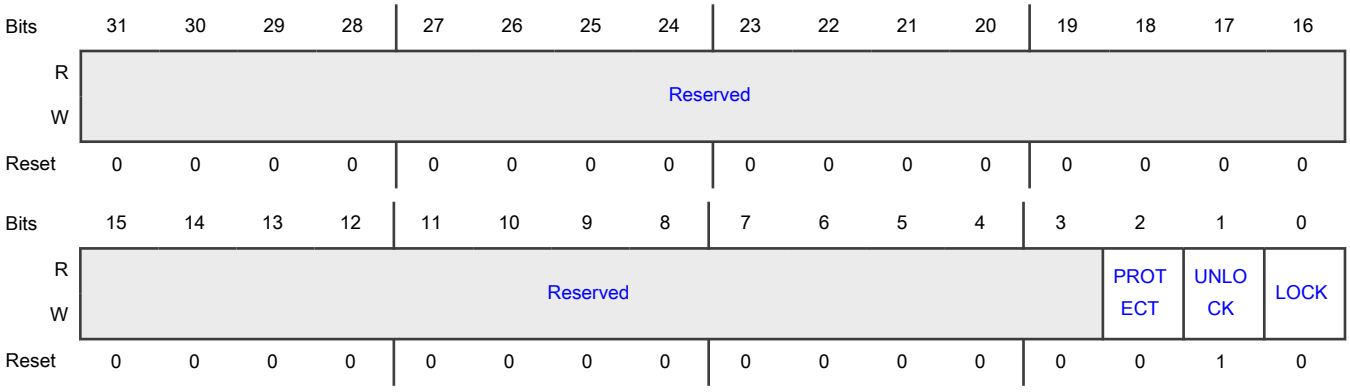
Offset

Register	Offset
LUTCR	1Ch

Function

Used with LUTKEY register to lock or unlock LUT. For the lock or unlock operation to be successful, this register must be written immediately after writing 5AF05AF0h to the LUTKEY register. See Lookup table (LUT) for details on locking and unlocking LUT. You cannot write 00 or 11 to the LOCK and UNLOCK fields.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 PROTECT	LUT Protection Controls lookup table protection. 0b - Not protected. All IPS controllers can access LUTCR and LUT memory. 1b - Protected. Only secure IPS controller can change the value of LUTCR and write to LUT memory.
1 UNLOCK	Unlock LUT 0b - LUT is locked (LUTCR[LOCK] must be 1) 1b - LUT is unlocked and can be written
0 LOCK	Lock LUT 0b - LUT is unlocked (LUTCR[UNLOCK] must be 1) 1b - LUT is locked and cannot be written

10.7.2.10 AHB Receive Buffer n Control 0 (AHBRXBUF0CR0 - AHBRXBUF7CR0)

Offset

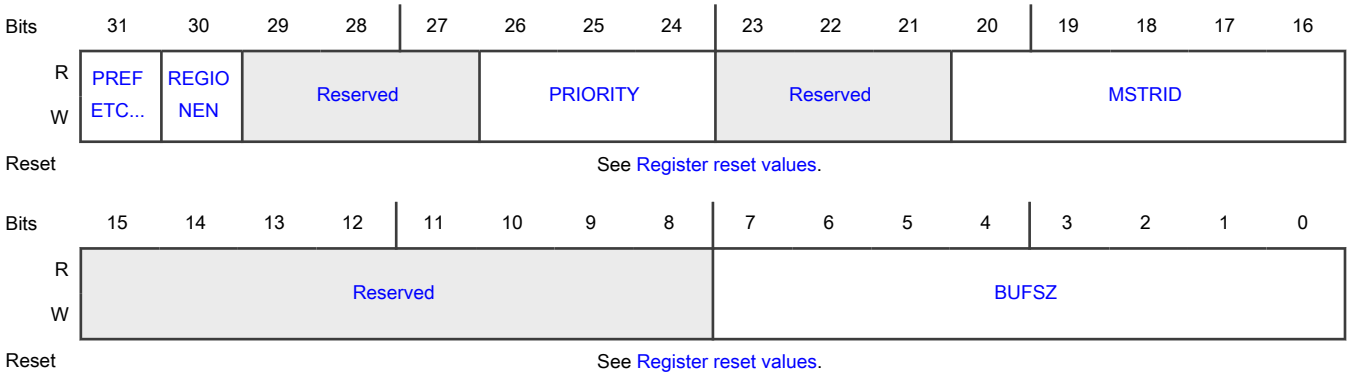
For n = 0 to 7:

Register	Offset
AHBRXBUFnCR0	20h + (n × 4h)

Function

Stores the read data from the SPI interface.

Diagram



Register reset values

Register	Reset value
AHBRXBUF0CR0	8000_0010h
AHBRXBUF1CR0	8001_0010h
AHBRXBUF2CR0	8002_0010h
AHBRXBUF3CR0	8003_0010h
AHBRXBUF4CR0	8004_0010h
AHBRXBUF5CR0	8005_0010h
AHBRXBUF6CR0	8006_0010h
AHBRXBUF7CR0	8007_0010h

Fields

Field	Function
31 PREFETCHEN	AHB Read Prefetch Enable Enables AHB read prefetch for the controller corresponding to the current AHB receive buffer. The prefetch feature is disabled when AHBCR[PREFETCHEN] is 0. You can use this field to enable or disable prefetch separately for each controller. 0b - Disabled 1b - Enabled when AHBCR[PREFETCHEN] is enabled.
30 REGIONEN	AHB Receive Buffer Address Region Enable Enable prefetch buffer enhancement. See Prefetch buffer enhancement. **NOTE** Only AHBRXBUF 0-3 have this function. 0b - Disabled. The buffer hit is based on the value of MSTRID only. 1b - Enabled. The buffer hit is based on the value of MSTRID and the address within AHBBUFREGIONSTARTn and AHBREGIONENDn.
29-27 —	Reserved
26-24 PRIORITY	AHB Controller Read Priority Configure the priority for the AHB Controller Read to which this AHB receive buffer is assigned. 7 is the highest priority, 0 the lowest. See Command abort and suspend.
23-21 —	Reserved
20-16	AHB Controller ID

Table continues on the next page...

Table continued from the previous page...

Field	Function
MSTRID	Configures the ID of the AHB controller to which this AHB receive buffer is assigned. See AHB receive buffer management.
15-8 —	Reserved
7-0 BUFSZ	AHB Receive Buffer Size Configures the size of the AHB receive buffer in multiples of 64 bits. See AHB receive buffer management.

10.7.2.11 Flash Control 0 (FLSHA1CR0 - FLSHB2CR0)

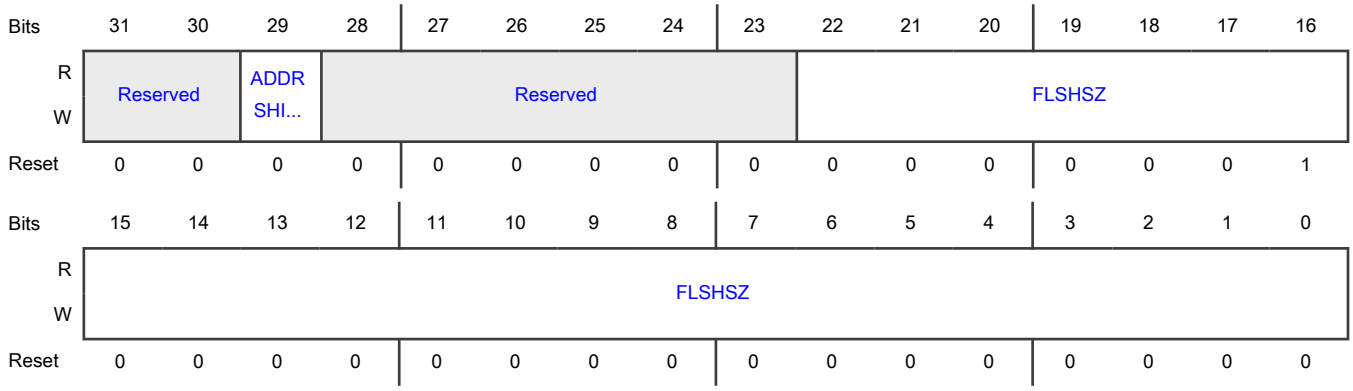
Offset

Register	Offset
FLSHA1CR0	60h
FLSHA2CR0	64h
FLSHB1CR0	68h
FLSHB2CR0	6Ch

Function

Contains flash memory size setting. FlexSPI determines which device is accessed (Chip Select) via this register.

Diagram



Fields

Field	Function
31-30	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
29 ADDRSHIFT	AHB Address Shift Function control Used to left-shift five bits for the flash address to support ISSI quad PSRAM. 0b - Disabled 1b - Enabled
28-23 —	Reserved
22-0 FLSHSZ	Flash Size in KB Configures the maximum flash memory size. For AHB access: Maximum flash size supported for each device is 512 MB. When the value of this field is greater than the maximum size, the device flash size is interpreted as the maximum. The maximum flash size is the largest flash size supported for a single device. It is also the maximum total flash size supported for all devices (up to four). If the total flash size is larger than the maximum size, only the maximum flash size address space is accessible. For IPS access, The maximum flash size supported for each device is 4 GB. When the value of this field is greater than 400000h, the device flash size is taken as 4 GB. The max total flash size supported (for all 4 devices) is also 4 GB. If the total flash size is larger than 4 GB, only 4 GB of address space is accessible.

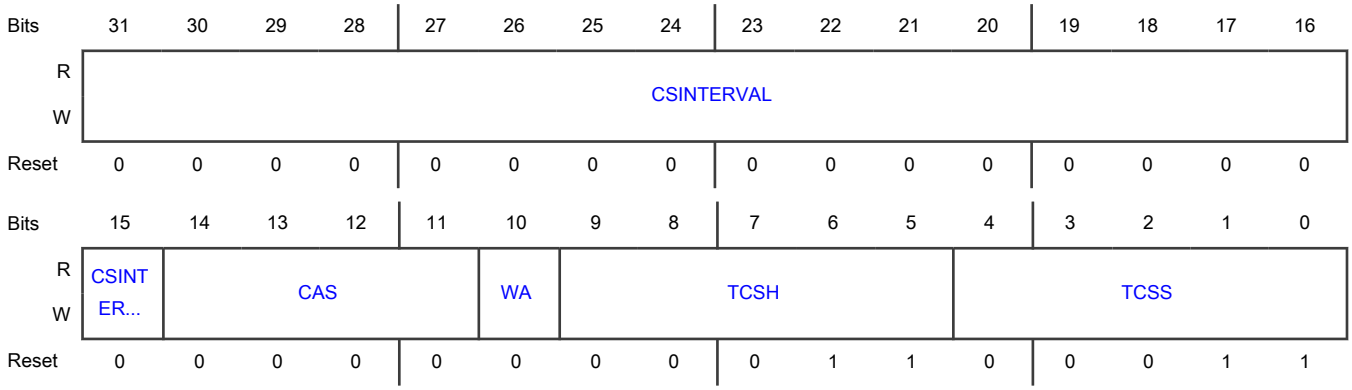
10.7.2.12 Flash Control 1 (FLSHA1CR1 - FLSHB2CR1)

Offset

Register	Offset
FLSHA1CR1	70h
FLSHA2CR1	74h
FLSHB1CR1	78h
FLSHB2CR1	7Ch

Function
Contains settings for flash device-specific timings and flash internal address space.

Diagram



Fields

Field	Function
31-16 CSINTERVAL	Chip Select Interval Configures the minimum interval between flash device chip select deassertion and chip select assertion. If the external flash device has a limitation on the interval between command sequences, configure this field accordingly. If there is no limitation, write 0h to this field. When CSINTERVALUNIT = 0, the chip select invalid interval is: CSINTERVAL × 1 serial clock cycle; When CSINTERVALUNIT = 1, the chip select invalid interval is: CSINTERVAL × 256 serial clock cycles. **NOTE** The minimum chip select interval is 2 cycles, even when the value of CSINTERVAL is less than 2.
15 CSINTERVALUNIT	Chip Select Interval Unit Configures the interval unit for chip select. 0b - 1 serial clock cycle 1b - 256 serial clock cycles
14-11 CAS	Column Address Size When external flash memory has a separate address field for rows and columns, this field configures the flash column address bit width. FlexSPI automatically splits a flash-mapped address into row address and column address according to the values of this field and the WA field. When the external flash memory does not support column address, write 0 to this field. FlexSPI transmits all flash address bits as Row address. For flash address mapping, see Flash address sent to flash memory devices.
10 WA	Word-Addressable Configures whether external flash memory is word-addressable or byte-addressable. If flash memory is word-addressable, it should be accessed in multiples of 16 bits. Currently, FlexSPI does not transmit flash address bit 0 to external flash memory. For flash address mapping, see Flash address sent to flash memory devices.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Byte-addressable 1b - Word-addressable
9-5 TCSH	Serial Flash CS Hold Time Used to meet flash TCSH timing requirement. Serial flash CS Hold time that FlexSPI promises is: (TCSH + 1/2) serial clock cycles for DDR mode, and TCSH serial clock cycles for SDR mode. See Output timing between chip select and SCLK.
4-0 TCSS	Serial Flash CS Setup Time Used to meet flash TCSS timing requirement. Serial flash CS Setup time that FlexSPI promises is: (TCSS + 1/2) serial root clock cycles for SDR and DDR mode. See Output timing between chip select and SCLK.

10.7.2.13 Flash Control 2 (FLSHA1CR2 - FLSHB2CR2)

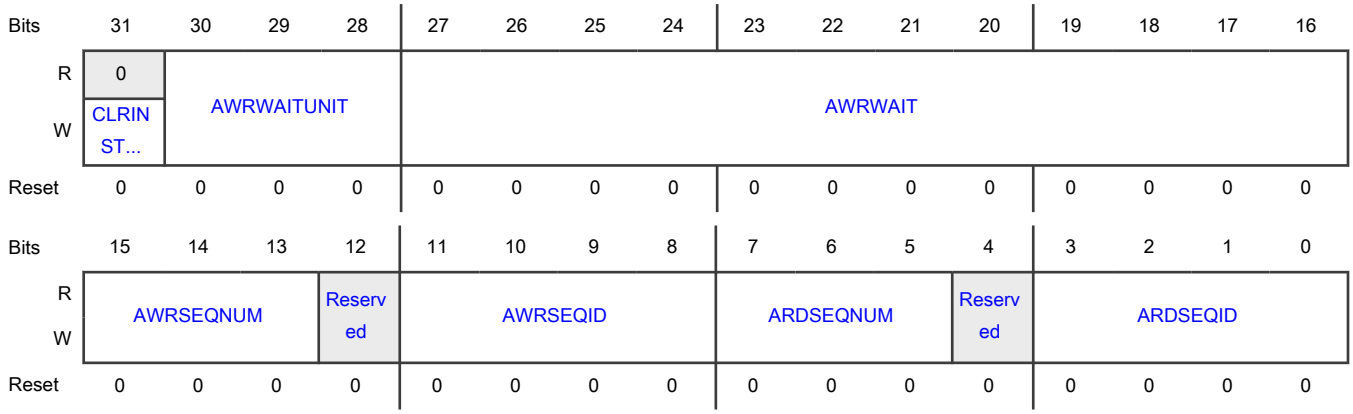
Offset

Register	Offset
FLSHA1CR2	80h
FLSHA2CR2	84h
FLSHB1CR2	88h
FLSHB2CR2	8Ch

Function

Contains fields to configure AHB bus access. If the four external devices are different types, AHB read and write commands may use different command sequences; AHB bus ready wait time may also differ.

Diagram



Fields

Field	Function
31 CLRINSTRPTR	Clear Instruction Pointer Clears the instruction pointer, which is the pointer that JMP_ON_CS saves internally. See Programmable sequence engine. This field is used for AHB read access to external flash memory supporting Execute-In-Place (XIP) mode.
30-28 AWRWAITUNIT	AWRWAIT Unit Configures the unit of AHB write wait time, as the value of AWRWAIT determines, in terms of AHB clock cycles. 000b - 2 001b - 8 010b - 32 011b - 128 100b - 512 101b - 2048 110b - 8192 111b - 32768
27-16 AWRWAIT	AHB Write Wait Configures AHB write wait time, with the AWRWAITUNIT field. Certain devices (such as FPGA) require time to write data into internal memory after the command sequences finished on the FlexSPI interface. If another read command sequence arrives before the current programming finishes internally, the read data may be wrong. This field is used to hold the AHB bus ready for AHB write access, waiting until the programming is finished in the external device. This hold ensures that no AHB read command is triggered before the programming finishes in the external device. The wait cycle between an AHB-triggered command sequence finishing on FlexSPI and the AHB return bus being ready is: AWRWAIT × AWRWAITUNIT.
15-13 AWRSEQNUM	Sequence Number for AHB Write-Triggered Command Configures the sequence number of an AHB read-triggered command. For certain flash devices (for example, HyperFlash, HyperRam, and Serial NAND flash), a flash programming access is done via several command sequences. An AHB write command triggers (AWRSEQNUM + 1) command sequences to external flash memory each time. FlexSPI executes the sequences in LUT incrementally. **NOTE** • Software should ensure that the last sequence index never exceeds LUT sequence numbers: AWRSEQID + AWRSEQNUM < 16 • Software must ensure that the AWRSEQNUM and LUT fields are configured correctly according to the external device specification. FlexSPI does not check the sequence; it executes the sequences one by one.
12 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-8 AWRSEQID	Sequence Index for AHB Write-Triggered Command
7-5 ARDSEQNUM	Sequence Number for AHB Read-Triggered Command Configures the sequence number of an AHB read-triggered command in the lookup table. For certain flash devices (for example, HyperFlash, HyperRam, and Serial NAND flash), a flash read access is done via several command sequences. An AHB read command triggers (ARDSEQNUM + 1) command sequences to external flash memory each time. FlexSPI executes the sequences in LUT incrementally. **NOTE** • Software should ensure that the last sequence index never exceeds LUT sequence numbers: ARDSEQID + ARDSEQNUM ≤ 16. • Software must ensure that the ARDSEQNUM and LUT fields are configured correctly according to the external device specification. FlexSPI does not check the sequence; it executes the sequences one by one.
4 —	Reserved
3-0 ARDSEQID	Sequence Index for AHB Read-Triggered Command in LUT

10.7.2.14 Flash Control 4 (FLSHCR4)

Offset

Register	Offset
FLSHCR4	94h

Function

Provides configuration for all external devices.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Function
31-12 —	Reserved
11-9 —	Reserved
8-6 —	Reserved
5 —	Reserved
4 —	Reserved
3 WMENB	Write Mask Enable for Port B Enables write mask for flash device on port B. 0b - Disabled. When writing to external device, DQS(RWDS) pin is not driven. 1b - Enabled. When writing to external device, FlexSPI drives DQS(RWDS) pin as write mask output.
2 WMENA	Write Mask Enable for Port A Enables write mask for flash device on port A. 0b - Disabled. When writing to external device, DQS(RWDS) pin is not driven. 1b - Enabled. When writing to external device, FlexSPI drives DQS(RWDS) pin as write mask output.
1 WMOPT2	Write Mask Option 2 When using AP memory, used to remove AHB or IP write burst minimum length limitation. When using this field, FLSHCR4[WMOPT1] should be 1. 0b - When writing to an external device, DQS pin is used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst length is not limited. 1b - When writing to an external device, DQS pin is not used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst length is limited. The minimum write burst length should be 4.
0 WMOPT1	Write Mask Option 1 Used to remove AHB and IP write burst start address alignment limitation. 0b - When writing to an external device, DQS pin is used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst start address alignment is not limited. 1b - When writing to an external device, DQS pin is not used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst start address alignment is limited.

10.7.2.15 IP Control 0 (IPCR0)

Offset

Register	Offset
IPCR0	A0h

Function

Provides all configuration required for IP commands. Provides the start address for the flash device, instead of the chip address, to be accessed for IP command. FlexSPI determines the chip select automatically according to this start address.

NOTE

- You cannot issue an IP command that crosses flash device boundaries. If you do so, it generates an IPCMDERR interrupt.
- Configure this register before an IP command is triggered.
- Do not change the values in this register while an IP command is in progress.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	SFAR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SFAR	Serial Flash Address Configures the serial flash address for IP commands. The address should be the address of the flash device without the base address.

10.7.2.16 IP Control 1 (IPCR1)

Offset

Register	Offset
IPCR1	A4h

Function

Provides all configuration required for IP commands. Provides the flash read and program data size, sequence index in LUT, sequence number and individual/parallel mode settings for IP commands.

NOTE

- Configure this register before an IP command is triggered.
- Do not change the values in this register while an IP command is in progress.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 IPAREN	Parallel Mode Enable for IP Commands 0b - Disabled. Flash memory is accessed in Individual mode. 1b - Enabled. Flash memory is accessed in Parallel mode.
30-27 —	Reserved
26-24 ISEQNUM	Sequence Number for IP command: ISEQNUM+1.
23-20 —	Reserved
19-16 ISEQID	Sequence Index in LUT for IP command.
15-0 IDATSZ	Flash Read/Program Data Size (in bytes) for IP command.

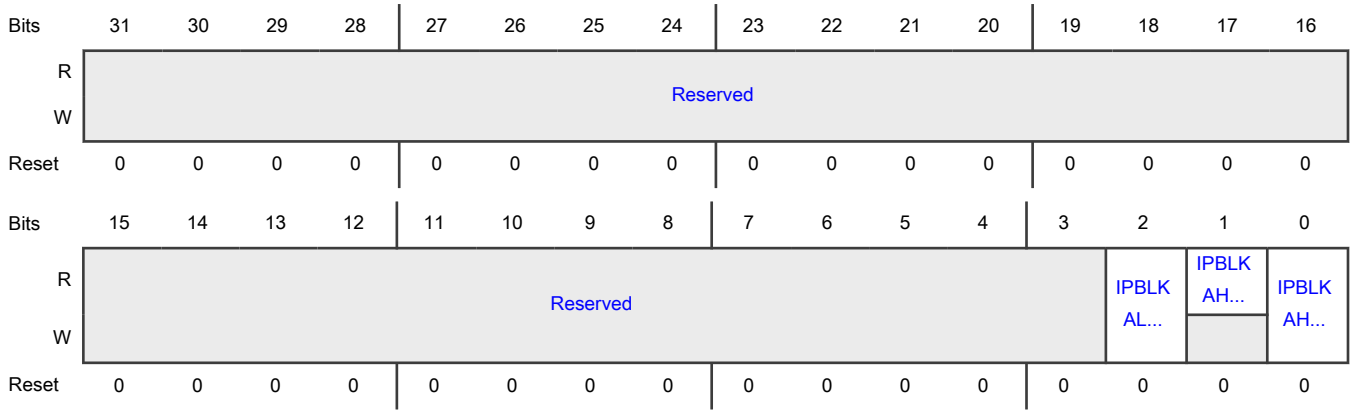
10.7.2.17 IP Control 2 (IPCR2)

Offset

Register	Offset
IPCR2	A8h

Function
Configures whether IP commands can block AHB commands.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 IPBLKALLAHB	IP Command Blocking All AHB Command Enable 0b - IP commands only block AHB commands that affect the IPED region. 1b - IP commands block all AHB commands.
1 IPBLKAHBACK	IP Command Blocking AHB Command Acknowledgment Enable 0b - IP commands do not block AHB command acknowledgment. 1b - IP commands block AHB command acknowledgment.
0 IPBLKAHBREQ	IP Command Blocking AHB Command Request Enable 0b - IP commands do not block AHB command requests. 1b - IP commands block AHB command requests.

10.7.2.18 IP Command (IPCMD)

Offset

Register	Offset
IPCMD	B0h

Function

Used to trigger an IP command to access external flash device. When the arbitrator grants the IP command, the command is executed on the FlexSPI interface.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved															0
W																TRG
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-1 —	Reserved
0 TRG	Command Trigger Triggers an IP command. This field clears automatically after it has been written and always reads as 0. **NOTE** You cannot trigger another IP command before the previous IP command finishes on the FlexSPI interface. Software must poll INTR[IPCMDDONE] or wait for this interrupt. 0b - No action 1b - Start the IP command that the IPCR0 and IPCR1 registers define.

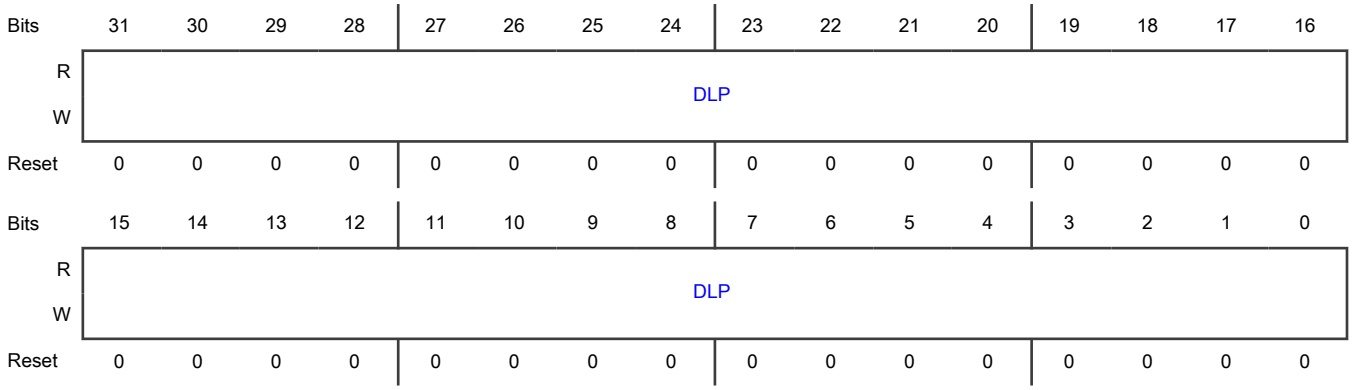
10.7.2.19 Data Learning Pattern (DLPR)

Offset

Register	Offset
DLPR	B4h

Function
Provides the pattern to be used during Data Learning in FlexSPI.

Diagram



Fields

Field	Function
31-0 DLP	Data Learning Pattern The operand in the LEARN_SDR or LEARN_DDR instruction code determines the data learning pattern bit number. This number never exceeds 32 bits. If the operand in the instruction code is greater than 32, a 32-bit pattern is used. See Data learning.

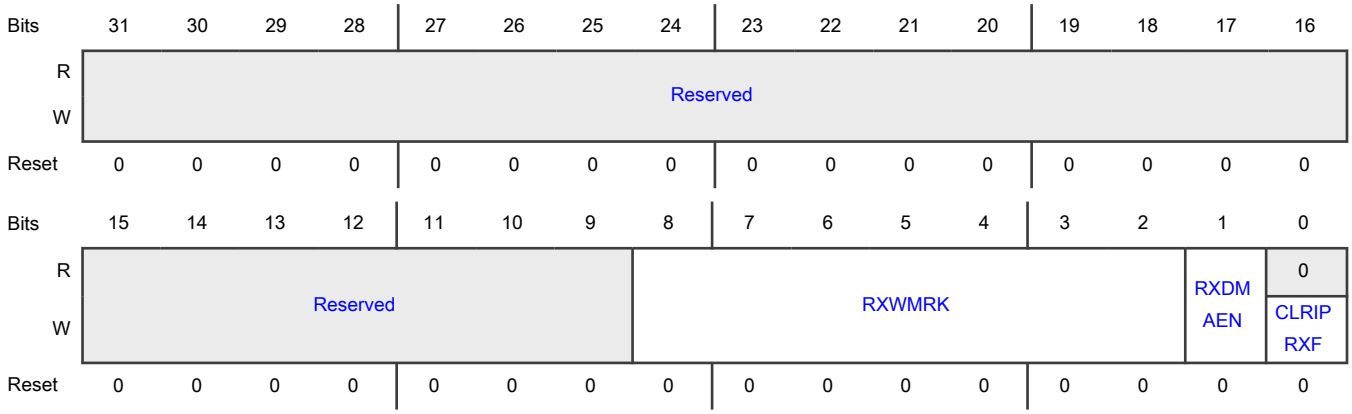
10.7.2.20 IP Receive FIFO Control (IPRXFCR)

Offset

Register	Offset
IPRXFCR	B8h

Function
Provides the configuration fields for IP receive FIFO management.

Diagram



Fields

Field	Function
31-9 —	Reserved
8-2 RXWMRK	IP Receive FIFO Watermark Level Configures the watermark level for the IP receive FIFO. The watermark level is (RXWMRK + 1) × 64 bits. The INTR[IPRXWA] interrupt is set when FlexSPI fills the IP receive FIFO ≥ the watermark level. A DMA request occurs when the fill level is ≥ the watermark level and IPRXFCR[RXDMAEN] = 1. When the fill level is ≥ the watermark level and INTEN[IPRXWAEN] = 1, an INTR[IPRXWA] interrupt is generated. **NOTE** After writing 1 to INTR[IPRXWA] to clear it, the read address should be rolled back to the start address (memory mapped).
1 RXDMAEN	IP Receive FIFO Reading by DMA Enable 0b - Disabled. The processor reads the FIFO. 1b - Enabled. DMA reads the FIFO.
0 CLRIPRXF	Clear IP Receive FIFO Clears all valid data entries in IP receive FIFO. Resets the read and write pointers in IP receive FIFO. 0b - No function 1b - A clock cycle pulse clears all valid data entries in IP receive FIFO.

10.7.2.21 IP Transmit FIFO Control (IPTXFCR)

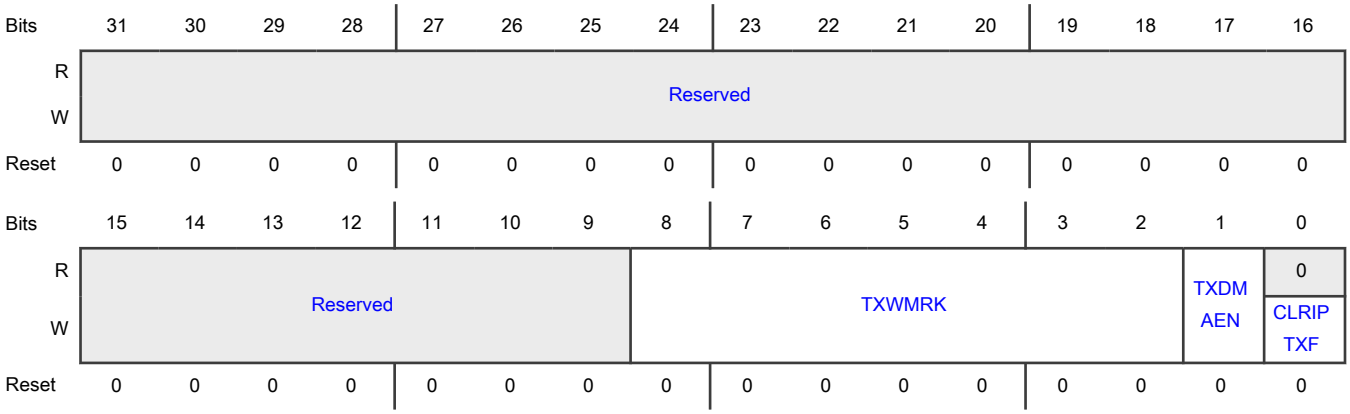
Offset

Register	Offset
IPTXFCR	BCh

Function

Provides the configuration fields for IP transmit FIFO management.

Diagram



Fields

Field	Function
31-9 —	Reserved
8-2 TXWMRK	Transmit Watermark Level Sets the transmit watermark level. The watermark level is (TXWMRK + 1) × 64 bits. INTR[IPTXWE] is set when FlexSPI empties the IP transmit FIFO ≥ the watermark level. When the empty level ≥ the watermark level and IPTXFCR[TXDMAEN] = 1, a DMA request occurs. When the empty level ≥ the watermark level and INTEN[IPTXWEEN] = 1, an INTR[IPTXWE] interrupt is generated. **NOTE** • The watermark level should not be larger than the write window. • The watermark level should not be larger than the IP transmit FIFO size. • The write address to the IP receive FIFO should roll back to the start address of the write window. After pushing the IP transmit fifo, you should write 1 to INTR[IPTXWE] to clear it, which will perform the rollback.
1 TXDMAEN	Transmit FIFO DMA Enable Selects whether DMA or processor fills IP transmit FIFO. 0b - Processor 1b - DMA
0 CLRIPTXF	Clear IP Transmit FIFO Clears all valid data entries in IP transmit FIFO. The read and write pointers in IP transmit FIFO are reset. 0b - No function 1b - A clock cycle pulse clears all valid data entries in the IP transmit FIFO.

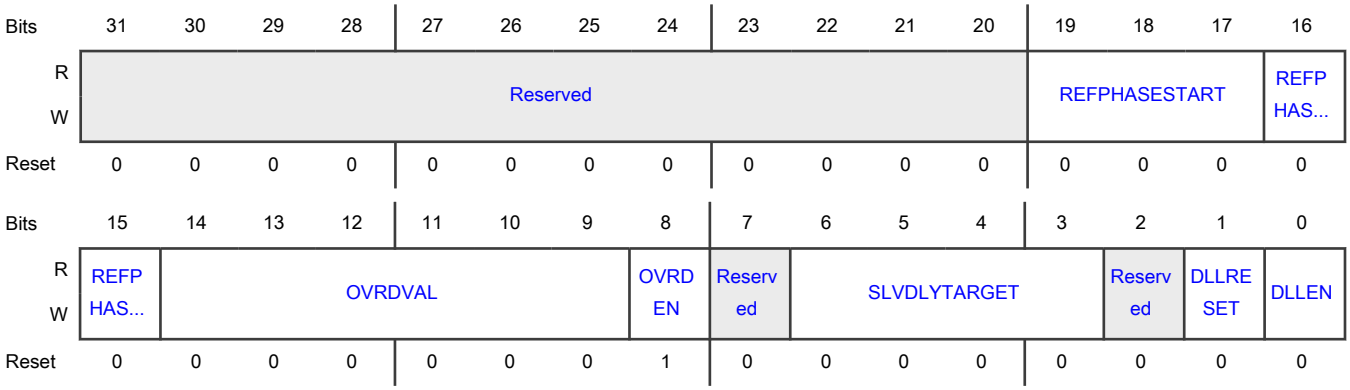
10.7.2.22 DLL Control 0 (DLLACR - DLLBCR)

Offset

Register	Offset
DLLACR	C0h
DLLBCR	C4h

Function
Configures Flash A and B sample clock DLL.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-17 REFPHASESTART	Reference Clock Delay Line Start Phase If the DLL does not lock well when DLLxCR[DLLEN] is enabled, update the register value of REFPHASESTART. 7h is recommended value. Note that DLLxCR[DLLRESET] is required to be triggered after REFPHASESTART is updated.
16-15 REFPHASEGAP	Reference Clock Delay Line Phase Adjust Gap. REFPHASEGAP setting of 2h is recommended if DLLEN is set.
14-9 OVRDVAL	Target Clock Delay Line Override Value Configures the override value for the target clock line delay cell number. When OVRDEN = 1, the delay cell number in DLL is OVRDVAL + 1. See DLL configuration for sampling.
8 OVRDEN	Target Clock Delay Line Override Value Enable Enables the override value for the target clock line delay cell number.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
7 —	Reserved
6-3 SLVDLYTARGET	Target Delay Line Configures the target delay line for the target. The delay target for target delay line is: ((SLVDLYTARGET+1) × 1/32 × clock cycle of reference clock (serial root clock). If serial root clock is ≥ 100 MHz, DLLEN is set to 1, OVRDEN is set to 0, then SLVDLYTARGET setting is up to flash parameters used.
2 —	Reserved
1 DLLRESET	DLL reset Forces a DLL reset. The forced reset causes the DLL to lose lock and recalibrate to detect a ref_clock half-period phase shift. The reset action is edge-triggered, so software must write 0 to this field after writing 1 to it (no delay limitation). 0b - No function 1b - Force DLL reset.
0 DLLEN	DLL Calibration Enable Enables DLL calibration. When DLL calibration is disabled, the delay cell number in the target delay line is always 1. When DLLxCR[OVRDEN] = 1, the target delay line is overridden and this field is ignored. 0b - Disable 1b - Enable

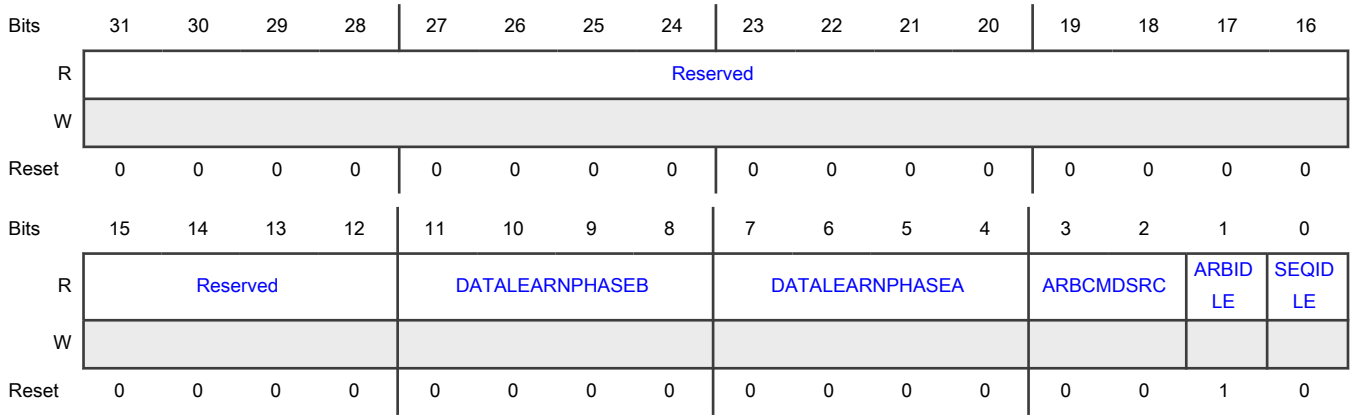
10.7.2.23 Status 0 (STS0)

Offset

Register	Offset
STS0	E0h

Function
Indicates the status of the internal state machine.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-8 DATALEARNPHASEB	Data Learning Phase Selection on Port B Indicates the sampling clock phase selection on Port B after data learning. This field is similar to STS0[DATALEARNPHASEA]. The sampling clock phase is chosen separately for Port A and Port B.
7-4 DATALEARNPHASEA	Data Learning Phase Selection on Port A Indicates the sampling clock phase selection on Port A after data learning. There are 16 clock phases for the sampling clock that the delay cell line generates. When data learning is not enabled, the default clock phase 0 is used to sample flash read data. When data learning is enabled and a LEARN_SDR or LEARN_DDR instruction has executed correctly, FlexSPI determines the correct clock phase to sample read data. See Data learning.
3-2 ARBCMDSRC	ARB Command Source Indicates the trigger source of current command sequence that the arbitrator has granted. When ARB_CTL is not busy (STS0[ARBIDLE] = 1), the value of this field does not matter. 00b - Trigger source is AHB read command. 01b - Trigger source is AHB write command. 10b - Trigger source is IP command (by writing 1 to IPCMD[TRG]). 11b - Trigger source is a suspended command that has resumed.
1 ARBIDLE	ARB_CTL State Machine Idle Indicates whether the state machine in ARB_CTL is idle, or a command sequence that the arbitrator granted has not finished on the FlexSPI interface. When idle, no transaction is occurring on the FlexSPI interface (STS0[SEQIDLE] = 1). When waiting for the FlexSPI controller to become idle, poll this field instead of STS0[SEQIDLE]. 0b - Not idle

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Idle
0 SEQIDLE	SEQ_CTL State Machine Idle Indicates whether the state machine in SEQ_CTL is idle, or a command sequence is executing on the FlexSPI interface. 0b - Not idle 1b - Idle

10.7.2.24 Status 1 (STS1)

Offset

Register	Offset
STS1	E4h

Function
Indicates the error code of the AHB or IPS interface error response.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7-2 ASLVSEL	Flash A Sample Clock Target Delay Line Delay Cell Number Indicates the sample clock target delay line delay cell number for Flash A. There are 0-63 phases. • 000001b - Indicates lock phase 0. • 100000b - Indicates lock phase 63.
1 AREFLOCK	Flash A Sample Clock Reference Delay Line Locked 0b - Not locked 1b - Locked
0 ASLVLOCK	Flash A Sample Target Delay Line Locked 0b - Not locked 1b - Locked

10.7.2.26 AHB Suspend Status (AHBSPNDSTS)

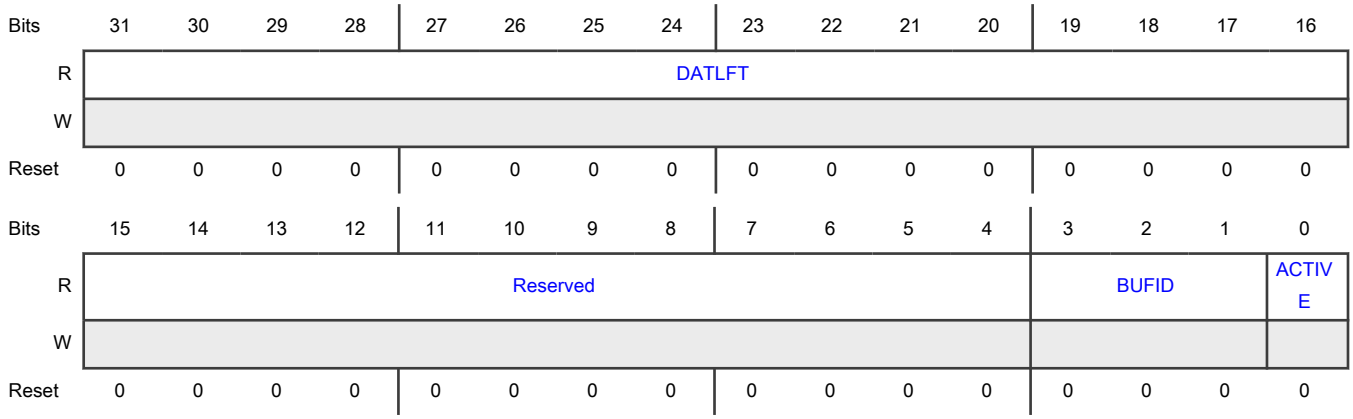
Offset

Register	Offset
AHBSPNDSTS	ECh

Function

Indicates the status of suspended AHB read prefetch command sequence. When an IP or AHB command is triggered while the arbitrator processes an AHB read sequence (prefetching additional data not for current AHB burst), the prefetch sequence is suspended. When there are no longer transactions on FlexSPI, the prefetch sequence may be resumed. FlexSPI saves only one AHB prefetch sequence. When a new prefetch sequence is suspended with an active sequence already suspended, the previous suspended sequence is removed and never resumed. See Command abort and suspend.

Diagram



Fields

Field	Function
31-16 DATLFT	Data Left Contains the data size remaining (in bytes) for a suspended command sequence.
15-4 —	Reserved
3-1 BUFID	AHB Receive Buffer ID for Suspended Command Sequence
0 ACTIVE	Active AHB Read Prefetch Suspended Indicates whether an AHB read prefetch command sequence has been suspended. 0b - No suspended AHB read prefetch command. 1b - An AHB read prefetch command sequence has been suspended.

10.7.2.27 IP Receive FIFO Status (IPRXFSTS)

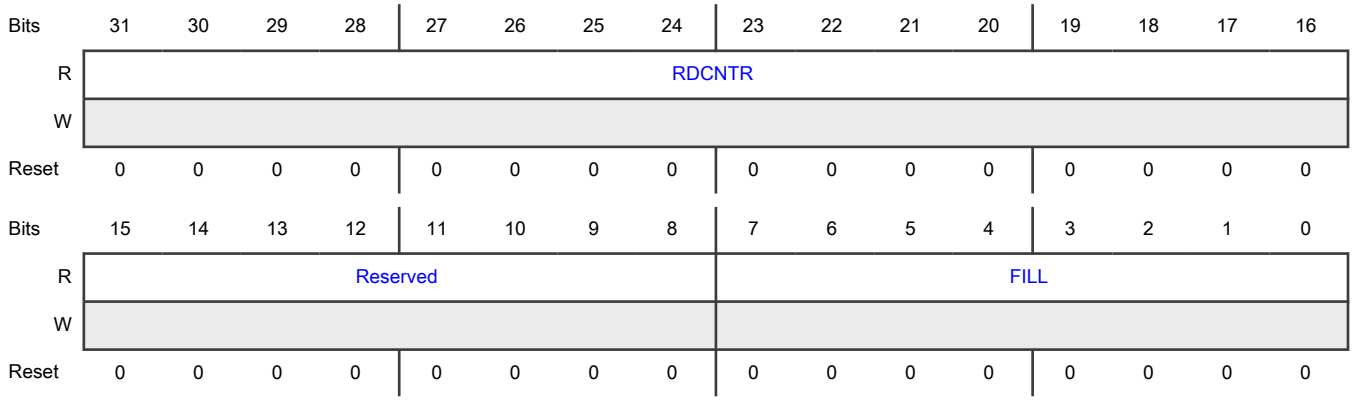
Offset

Register	Offset
IPRXFSTS	F0h

Function

Indicates the status of IP receive FIFO.

Diagram



Fields

Field	Function
31-16 RDCNTR	Read Data Counter Contains counter for total data read. The data read is the value of this field × 64 bits.
15-8 —	Reserved
7-0 FILL	Fill Level of IP Receive FIFO Indicates how full the IP receive FIFO is. The fill level is the value of this field × 64 bits.

10.7.2.28 IP Transmit FIFO Status (IPTXFSTS)

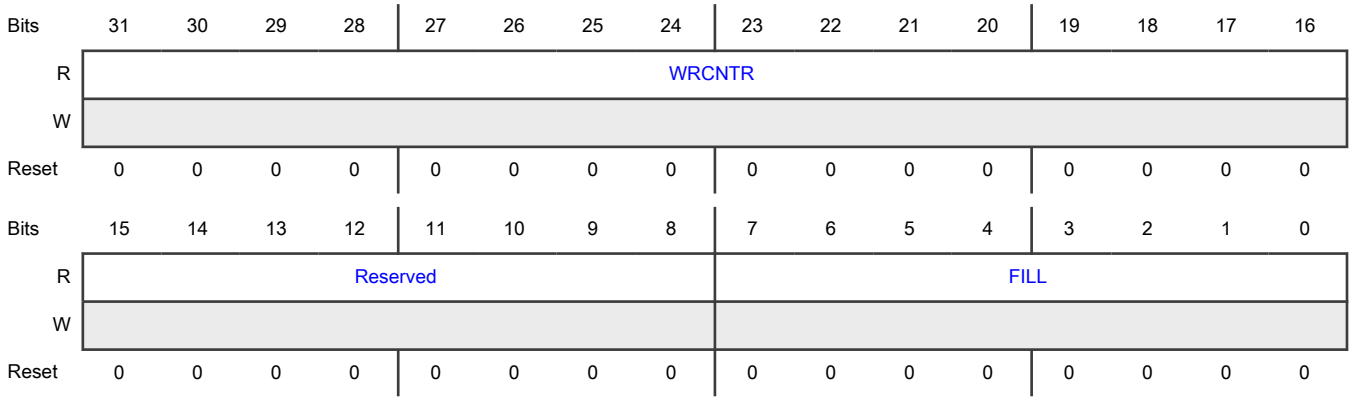
Offset

Register	Offset
IPTXFSTS	F4h

Function

Indicates the status of IP transmit FIFO.

Diagram



Fields

Field	Function
31-16 WRCNTR	Write Data Counter Contains counter for total data written. The data written is the value of this field × 64 bits.
15-8 —	Reserved
7-0 FILL	Fill Level of IP Transmit FIFO Indicates how full the IP transmit FIFO is. The fill level is the value of this field × 64 bits.

10.7.2.29 IP Receive FIFO Data a (RFDR0 - RFDR31)

Offset

For a = 0 to 31:

Register	Offset
RFDRa	100h + (a × 4h)

Function

Provides read access to IP receive FIFO via IPS bus. The read value is unknown for read access to invalid entries in the IP receive FIFO.

NOTE

RFDR is implemented as memory, so the reset value is unknown.

Diagram

Fields

Field	Function
31-0 TXDATA	Transmit Data Contains transmit data. See Writing data to IP transmit FIFO.

10.7.2.31 Lookup Table a (LUT0 - LUT63)

Offset

For a = 0 to 63:

Register	Offset
LUTa	200h + (a × 4h)

Function

Contains a lookup table for command sequences. Software should set the sequence index before triggering an IP command or AHB command. FlexSPI fetches the command sequence from LUT when an IP or AHB command is triggered. There are 16 command sequences in LUT. See Lookup table (LUT) and Programmable sequence engine.

NOTE

LUT is implemented as memory, so the reset value is unknown.

7-0 OPERAND0	OPERAND0

10.7.2.32 HADDR REMAP Start Address (HADDRSTART)

Offset

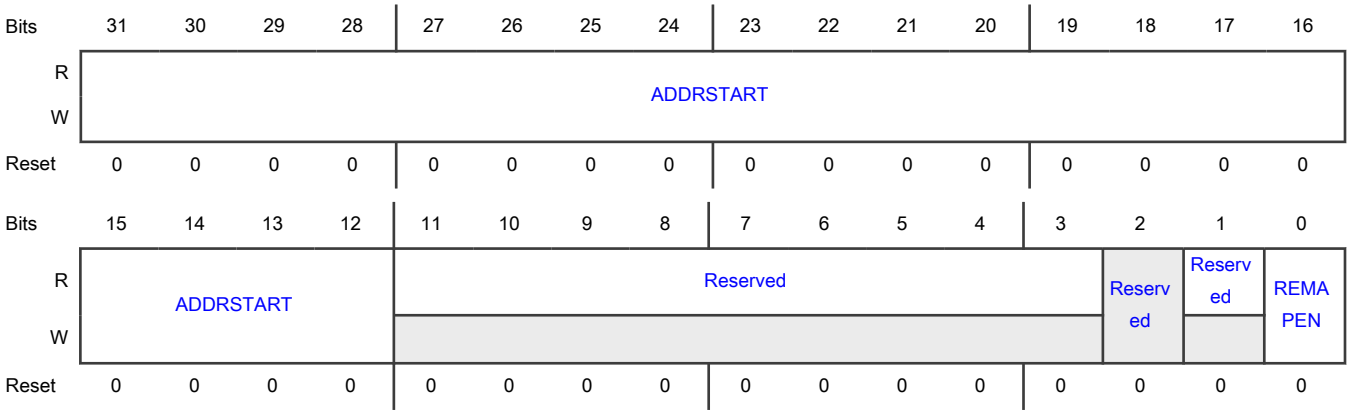
Register	Offset
HADDRSTART	420h

Function

Used to configure options for the dual-image remap feature.

See Dual image use case using HADDRSTART, HADDREND, and HADDROFFSET registers.

Diagram



Fields

Field	Function
31-12	HADDR Start Address

Table continues on the next page...

Table continued from the previous page...

Field	Function
ADDRSTART	Contains the start address of the HADDR remap range, aligned to 4 KB.
11-3 —	Reserved
2 —	Reserved
1 —	Reserved
0 REMAPEN	AHB Bus Address Remap Enable 0b - HADDR REMAP Disabled 1b - HADDR REMAP Enabled

10.7.2.33 HADDR REMAP END ADDR (HADDREND)

Offset

Register	Offset
HADDREND	424h

Function

Used to configure options for the dual-image remap feature.

See Dual image use case using HADDRSTART, HADDREND, and HADDROFFSET registers.

Diagram

Fields

Field	Function
31-12 ENDSTART	End Address of HADDR Remap Range Contains the end address of the HADDR remap range, aligned to 4 KB.
11-0 —	Reserved

10.7.2.34 HADDR Remap Offset (HADDROFFSET)

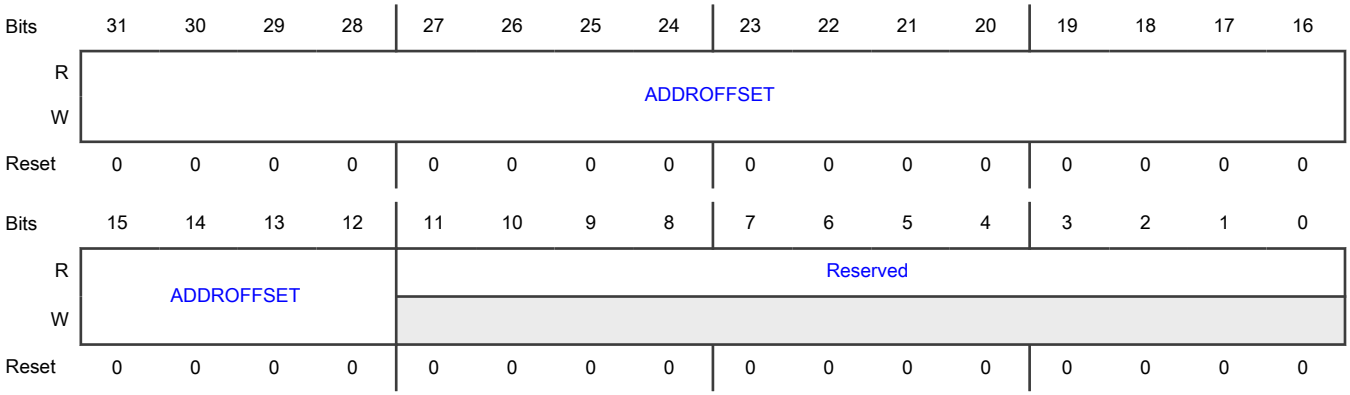
Offset

Register	Offset
HADDROFFSET	428h

Function
Used to configure options for the dual-image remap feature.

See Dual image use case using HADDRSTART, HADDREND, and HADDROFFSET registers.

Diagram



Fields

Field	Function
31-12 ADDROFFSET	HADDR Offset Contains the offset for HADDR. The remapped address is ADDR[31:12] = ADDR_original[31:12] + ADDROFFSET.
11-0 —	Reserved

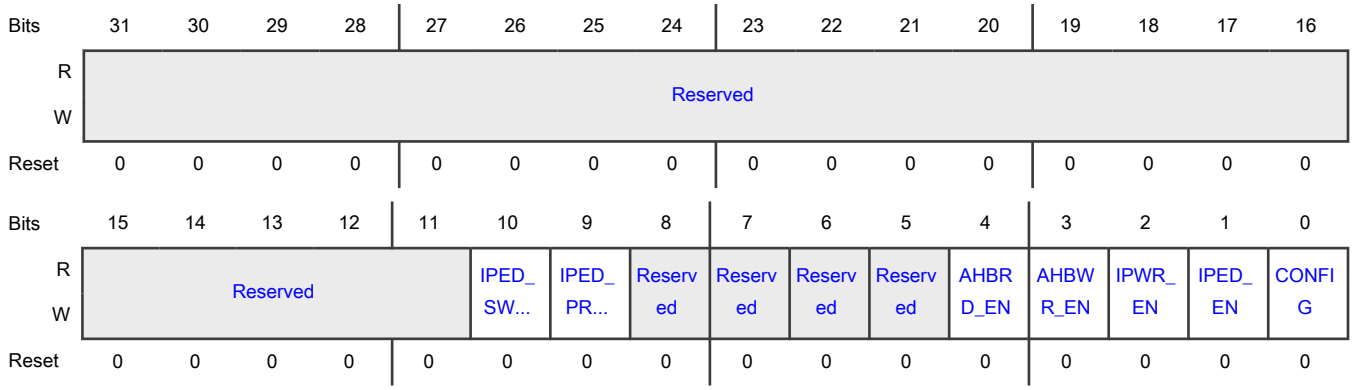
10.7.2.35 IPED Function Control (IPEDCTRL)

Offset

Register	Offset
IPEDCTRL	42Ch

Function
Selects IPED mode for encryption and decryption.

Diagram



Fields

Field	Function
31-11 —	Reserved
10 IPED_SWRESET	Abort Current Decryption or Encryption 0b - No function. 1b - Aborts current decryption or encryption and waits for the next start operation.
9 IPED_PROTECT	IPED Protection Can be used to limit access to IPED configuration registers. 0b - No restrictions 1b - Only privileged controllers can write IPED registers.
8 —	Reserved
7 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 —	Reserved
5 —	Reserved
4 AHBRD_EN	AHB Read IPED CTR Mode Decryption Enable 0b - Disable 1b - Enable
3 AHBWR_EN	AHB Write IPED CTR Mode Encryption Enable. 0b - Disable 1b - Enable
2 IPWR_EN	IP Write IPED CTR Mode Encryption Enable 0b - Disable 1b - Enable
1 IPED_EN	IPED Encryption and Decryption Enable 0b - Disable 1b - Enable
0 CONFIG	IPED Mode Select Configures whether encryption and decryption are fully pipelined. 0b - Fully pipelined 1b - Not fully pipelined

10.7.2.36 IPS Nonsecure Region a Start Address (IPSNSZSTART0 - IPSNSZSTART1)

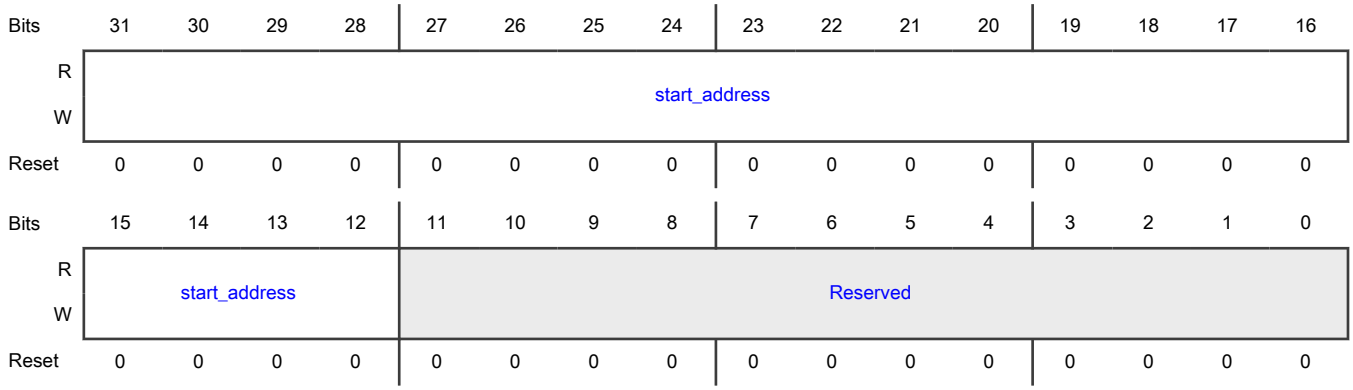
Offset

Register	Offset
IPSNSZSTART0	430h
IPSNSZSTART1	438h

Function

Indicates the start address of IPS nonsecure address region.

Diagram



Fields

Field	Function
31-12 start_address	Start Address of Nonsecure Region Indicates start address. Must be at least four-KB aligned. The address used here is the flash memory address that is compared with IPCR0[SFAR] to determine whether an IP command occurs in the region. Only a secure controller can write to this register. See Domain control.
11-0 —	Reserved

10.7.2.37 IPS Nonsecure Region a End Address (IPSNSZEND0 - IPSNSZEND1)

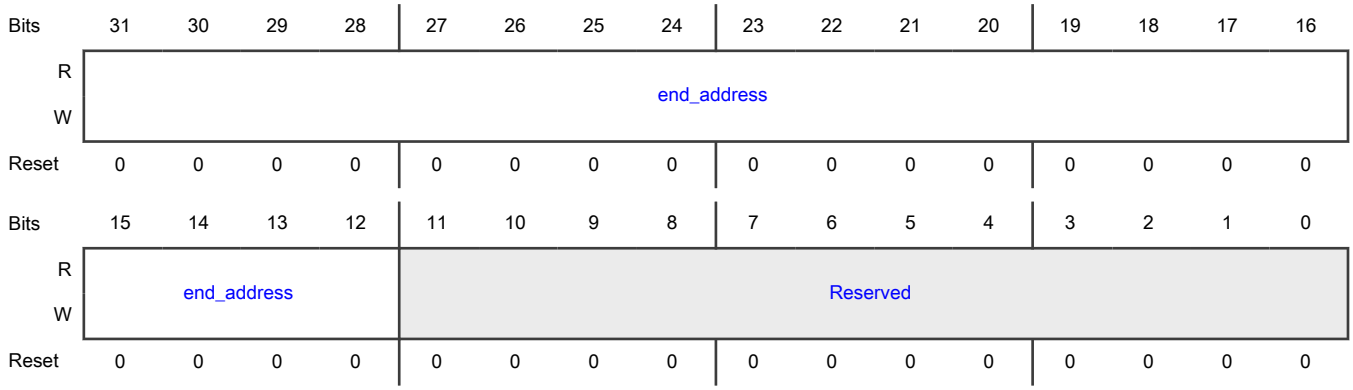
Offset

Register	Offset
IPSNSZEND0	434h
IPSNSZEND1	43Ch

Function

Indicates the end address of IPS nonsecure address region.

Diagram



Fields

Field	Function
31-12 end_address	End Address of Nonsecure Region Indicates end address. Must be at least four-KB aligned. The address used is the flash memory address compared with IPCR0[SFAR] to determine if an IP command hits in the region. Only a secure controller can write to this register. See Domain control.
11-0 —	Reserved

10.7.2.38 Receive Buffer Start Address of Region a (AHBBUFREGIONSTART0 - AHBBUFREGIONSTART3)

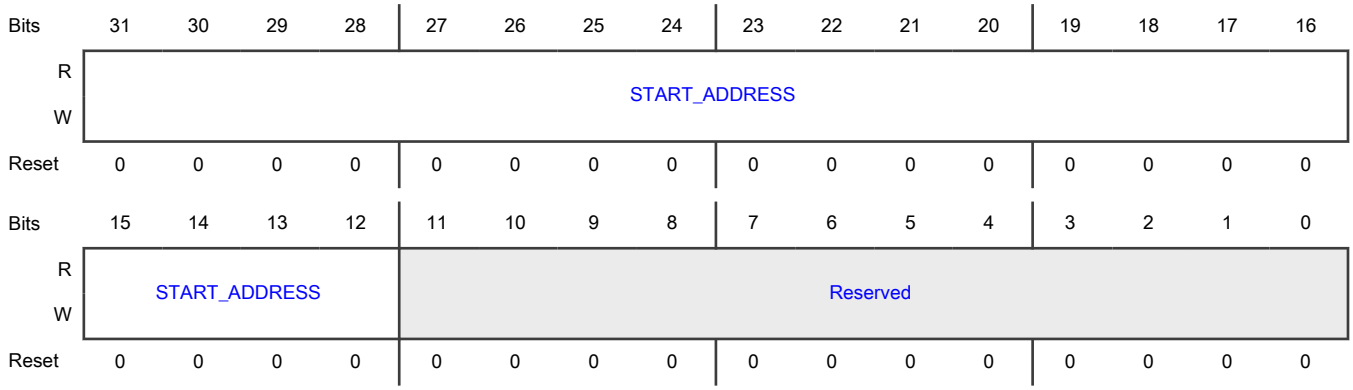
Offset

Register	Offset
AHBBUFREGIONSTART0	440h
AHBBUFREGIONSTART1	448h
AHBBUFREGIONSTART2	450h
AHBBUFREGIONSTART3	458h

Function

Indicates the start address of AHB receive buffer address region.

Diagram



Fields

Field	Function
31-12 START_ADDRESS	Start Address of Prefetch Sub-Buffer Region Indicates start address. The start address must be at least four-KB aligned. The address used here is the AHB address that is compared with the system bus address to determine if an AHB read hits in the region. See Prefetch buffer enhancement.
11-0 —	Reserved

10.7.2.39 Receive Buffer Region a End Address (AHBBUFREGIONEND0 - AHBBUFREGIONEND3)

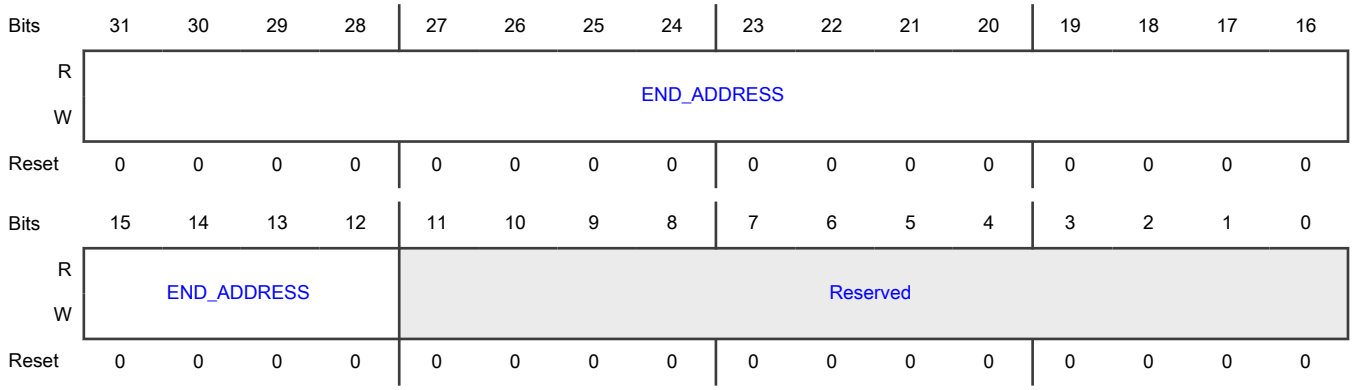
Offset

Register	Offset
AHBBUFREGIONEND0	444h
AHBBUFREGIONEND1	44Ch
AHBBUFREGIONEND2	454h
AHBBUFREGIONEND3	45Ch

Function

Indicates the end address of AHB receive buffer address region.

Diagram



Fields

Field	Function
31-12 END_ADDRESS	End Address of Prefetch Sub-Buffer Region Indicates end address. The end address must be at least four-KB aligned. The address used here is the AHB address that is compared with the system bus address to determine if an AHB read hits in the region. See Prefetch buffer enhancement.
11-0 —	Reserved

10.7.2.40 IPED context control 0 (IPEDCTXCTRL0)

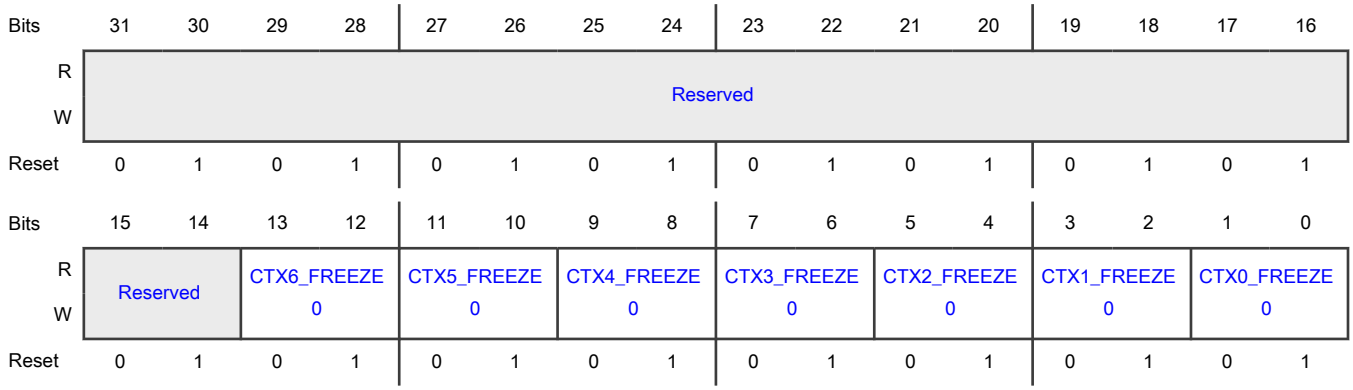
Offset

Register	Offset
IPEDCTXCTRL0	500h

Function

Freezes the IPEDCTXnSTART and IPEDCTXnEND registers. If bit1 and bit0 of the CTXn_FREEZE0 field are different, and IPEDCTXCTRL1[CTXn_FREEZE1] = 10b, CTXn_FREEZE0 is writable. See Inline PRINCE encryption and decryption (IPED) CTR.

Diagram



Fields

Field	Function
31-14 —	Reserved
13-12 CTX6_FREEZE0	Context Register Freeze for Region 6 Controls the read and write properties of this field and region 6 context registers (IPEDCTX6xxxx). This field freezes the IPEDCTX6START and IPEDCTX6END registers. If bit1 and bit0 of CTX6_FREEZE0 field are different, and IPEDCTXCTRL1[CTX6_FREEZE1] = 10b, CTX6_FREEZE0 is writable.
11-10 CTX5_FREEZE0	Context Register Freeze for Region 5 Controls the read and write properties of this field and region 5 context registers (IPEDCTX5xxxx). This field freezes the IPEDCTX5START and IPEDCTX5END registers. If bit1 and bit0 of CTX5_FREEZE0 field are different, and IPEDCTXCTRL1[CTX5_FREEZE1] = 10b, CTX5_FREEZE0 is writable.
9-8 CTX4_FREEZE0	Context Register Freeze for Region 4 Controls the read and write properties of this field and region 4 context registers (IPEDCTX4xxxx). This field freezes the IPEDCTX4START and IPEDCTX4END registers. If bit1 and bit0 of CTX4_FREEZE0 field are different, and IPEDCTXCTRL1[CTX4_FREEZE1] = 10b, CTX4_FREEZE0 is writable.
7-6 CTX3_FREEZE0	Context Register Freeze for Region 3 Controls the read and write properties of this field and region 3 context registers (IPEDCTX3xxxx). This field freezes the IPEDCTX3START and IPEDCTX3END registers. If bit1 and bit0 of CTX3_FREEZE0 field are different, and IPEDCTXCTRL1[CTX3_FREEZE1] = 10b, CTX3_FREEZE0 is writable.
5-4 CTX2_FREEZE0	Context Register Freeze for Region 2 Controls the read and write properties of this field and region 2 context registers (IPEDCTX2xxxx). This field freezes the IPEDCTX2START and IPEDCTX2END registers. If bit1 and bit0 of CTX2_FREEZE0 field are different, and IPEDCTXCTRL1[CTX2_FREEZE1] = 10b, CTX2_FREEZE0 is writable.
3-2 CTX1_FREEZE0	Context Register Freeze for Region 1 Controls the read and write properties of this field and region 1 context registers (IPEDCTX1xxxx). This field freezes the IPEDCTX1START and IPEDCTX1END registers. If bit1 and bit0 of CTX1_FREEZE0 field are different, and IPEDCTXCTRL1[CTX1_FREEZE1] = 10b, CTX1_FREEZE0 is writable.

Table continues on the next page...

Table continued from the previous page...

Field	Function
1-0 CTX0_FREEZE0	Context Register Freeze for Region 0 Controls the read and write properties of this field and region 0 context registers (IPEDCTX0xxxx). This field freezes the IPEDCTX0START and IPEDCTX0END registers. If bit1 and bit0 of CTX0_FREEZE0 field are different, and IPEDCTXCTRL1[CTX0_FREEZE1] = 10b, CTX0_FREEZE0 is writable.

10.7.2.41 IPED context control 1 (IPEDCTXCTRL1)

Offset

Register	Offset
IPEDCTXCTRL1	504h

Function

Freezes the IPEDCTXnSTART and IPEDCTXnEND registers. If bit1 and bit0 of the CTXn_FREEZE0 field are different, and IPEDCTXCTRL1[CTXn_FREEZE1] = 10b, CTXn_FREEZE1 is writable. See Inline PRINCE encryption and decryption (IPED) CTR.

10.8 AHB memory map definition

This section describes FlexSPI module AHB memory map in detail.

10.8.1 AHB memory map for serial flash memory and RAM access

AHB read and write access for serial flash and RAM memory are mapped to a specific address range. See the system memory map for specific address ranges supported.

AHB bus features supported for serial flash and RAM memory reading:

- Cacheable and non-cacheable access
- Prefetch enable and disable
- Burst size: 8, 16, 32, 64 bits
- All burst types: types: SINGLE, INCR, WRAP4, INCR4, WRAP8, INCR8, WRAP16, INCR16

AHB bus features for Serial RAM writing:

- Bufferable and Non-Bufferable access
- Burst size: 8, 16, 32, 64 bits
- All burst types: SINGLE, INCR, WRAP4, INCR4, WRAP8, INCR8, WRAP16, INCR16

See Flash memory access via AHB command for details about AHB access to serial flash memory and RAM.

Chapter 11
Performance Monitor (CMX_PERFMON)

11.1 Chip-specific CMX_PERFMON information

Table 116. Reference links to related information

Topic	Related module	Reference
Full description	CMX_PERFMON	CMX_PERFMON
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

11.1.1 Module instances

This device has two instances of the CMX_PERFMON module. Two performance monitors are used in this device; one is for monitoring LPCAC that maps to CMX_PERFMON0, and another one is for FlexSPI that maps to CMX_PERFMON1.

11.1.2 Perfmon Counters

The following table describes the countable events for the LPCAC and FlexSPI performance monitors.

Table 117. Perfmon Counters

Event Encoding	Mnemonic	CMX_PERFMON Note: Same event encodings are used for CMX_PERFMON0 and CMX_PERFMON1 except cac_wb_push.	Notes
AHB nonTCM ("cache") Transfers			
0b100_0000	cac_if	YES	Cached instruction fetches
0b100_0100	cac_if_stalls	YES	Stalled cached instruction fetches
0b100_0001	cac_opr	YES	Cached operand reads
0b100_0101	cac_opr_stalls	YES	Stalled cached operand reads
0b100_0010	cac_opw	YES	Cached operand writes
0b100_0110	cac_opw_stalls	YES	Stalled cached operand writes
0b100_0011	cac_opx	YES	Cached operand reads plus writes
0b100_0111	cac_opx_stalls	YES	Stalled cached operand reads plus writes
0b100_1000	cac_wt_opw	YES	Cache writethrough operand writes

Table 117. Perfmon Counters (continued)

Event Encoding	Mnemonic	CMX_PERFMON Note: Same event encodings are used for CMX_PERFMON0 and CMX_PERFMON1 except cac_wb_push.	Notes
0b100_1100	cac_wt_opw_stalls	YES	Stalled writethrough operand writes
0b101_0000	cac_if_miss	YES	Instruction fetch miss (for CMX_PERFMON1 - number of times FlexSPI signalled miss)
0b101_0001	cac_opr_miss	YES	Operand read miss
0b101_0010	cac_opw_miss	YES	Operand write miss
0b101_0011	cac_opx_miss	YES	Operand read plus write miss
0b101_1000	cac_wb_push	YES for CMX_PERFMON1, NO for CMX_PERFMON0	Cache writeback line pushes

11.2 Overview

CMX_PERFMON contains counters that you can configure to count events used to calculate the performance of a CPU, cache, or memory. You can configure CMX_PERFMON to select the events to be counted for each counter.

Block diagram provides an overview of CMX_PERFMON, which includes three event counters.

11.2.1 Block diagram

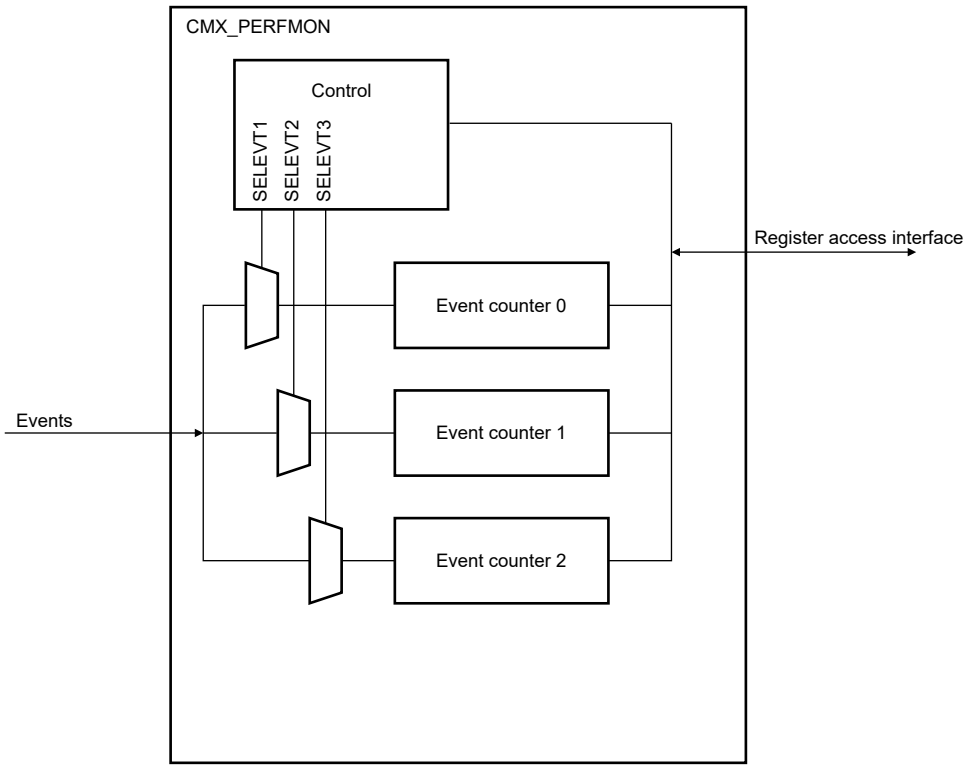

Figure 53. Block diagram

11.2.2 Features

- Three 40-bit event counters
- Programmable event select
- Countable events that include cache, branch fetches, and stalls
- Memory mapped performance monitor that counts instructions, cache, branch, IPS, and TCM stats
- Count filter based on privilege level

11.3 Functional description

11.3.1 Operations

See the chip-specific CMX_PERFMON information for details about the countable events for the performance counters per CMX_PERFMON instance on this chip.

CMX_PERFMON has 3 programmable counters to count CPU events. The event to be counted is configured using the PMCR0 register.

Each counter is a 40-bit register that tracks the number of occurrences of the selected event.

The counters can be programmed to take one of the 3 states:

- At idle state, the counters are in idle and do not perform any operation.

- At local start state, the counters are actively listening to CPU and cache and start incrementing when the selected events are observed.
- At local stop state, the counters stop listening to all components. The 3 event counter can be independently cleared by writing to PMCR0[RECTR*n*], where *n* denotes the counter instance.

11.3.2 Operating modes

The following table shows:

- The operating modes that you can specify for CMX_PERFMON.
- The PMCR0[CMODE] value that you must specify to count events in each mode.

Table 118. Operating modes

Mode	Description	CMODE value (binary)
Privileged	If supported, only counts events in Privilege mode.	11
User	If supported, only counts events in User mode.	10
Both Privileged and User	Counts events in both Privilege and User mode.	00

Use PMCR0[SSC] to start and stop the counters.

11.3.3 Clocking

This module has no clocking considerations.

11.3.4 Interrupts

This module has no interrupts.

11.4 External signals

CMX_PERFMON has no external signals.

11.5 Initialization

To initialize CMX_PERFMON:

1. Program PMCR0[SELEVT*n*] to select the specific CPU event to be counted by this counter, where *n* denotes the counter instance.
2. Set PMCR0[CMODE] to filter each counter for the selected event while the CPU is in privilege, user, or either mode.
3. Set PMCR0[SSC] to program the counter to be in one of idle, local start, or local stop states.
4. Set PMCR0[RECTR*n*] to clear the counters independently where *n* denotes the counter instance.

11.6 Memory map and register definition

11.6.1 CMX_PERFMON register descriptions

11.6.1.1 CMX_PERFMON memory map

CMX_PERFMON0 base address: 400C_1000h

CMX_PERFMON1 base address: 400C_2000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Performance Monitor Control (PMCR)	32	RW	0000_0000h
18h	Performance Monitor Event Counter (PMECTR1_HI)	8	R	00h
1Ch	Performance Monitor Event Counter (PMECTR1_LO)	32	R	0000_0000h
20h	Performance Monitor Event Counter (PMECTR2_HI)	8	R	00h
24h	Performance Monitor Event Counter (PMECTR2_LO)	32	R	0000_0000h
28h	Performance Monitor Event Counter (PMECTR3_HI)	8	R	00h
2Ch	Performance Monitor Event Counter (PMECTR3_LO)	32	R	0000_0000h

11.6.1.2 Performance Monitor Control (PMCR)

Offset

Register	Offset
PMCR	0h

Function

Specifies:

- The events that the PMECTR*n*HI and PMECTR*n*LO count.
- The count mode.
- The start and stop control.
- The enables for the counters.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-25 SELEVT3	Select Event 3 Selects the event to be counted in PMECTR3. See the chip-specific CMX_PERFMON information to select which event PMECTR3 counts.
24-18 SELEVT2	Select Event 2 Selects the event to be counted in PMECTR2. See the chip-specific CMX_PERFMON information to select which event PMECTR2 counts.
17-11 SELEVT1	Select Event 1 Selects the event to be counted in PMECTR1. See the chip-specific CMX_PERFMON information to select which event PMECTR1 counts.
10 RECTR3	Reset Event Counter 3 Specifies whether the counter runs normally or the counter value resets at the end of the cycle. Write 1 to this field to clear this counter. This field does not return to 0 automatically, so if you want to restart the counter after clearing it, write 0 to this field. 0b - Run normally 1b - Reset
9 RECTR2	Reset Event Counter 2 Specifies whether the counter runs normally or the counter value resets at the end of the cycle. Write 1 to this field to clear this counter. This field does not return to 0 automatically, so if you want to restart the counter after clearing it, write 0 to this field. 0b - Run normally 1b - Reset
8 RECTR1	Reset Event Counter 1 Specifies whether the counter runs normally or the counter value resets at the end of the cycle. Write 1 to this field to clear this counter. This field does not return to 0 automatically, so if you want to restart the counter after clearing it, write 0 to this field. 0b - Run normally 1b - Reset
7 —	Reserved
6 —	Reserved
5-4	Count Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
CMODE	Determines whether events are counted for Privileged mode, User mode, or both Privileged and User modes. This setting affects the operation of all event counters. 00b - Counted in both User and Privileged modes 01b - Reserved 10b - Reserved 11b - Reserved
3-1 SSC	Start and Stop Control Provides a three-phase mechanism to start and stop the counters. It includes a prioritized scheme with the following relative priorities: local start > local stop The start or stop affects all performance monitor event counters concurrently, so that the counters are coherent. 000b - Idle or no-op 001b - Local stop 010b,011b - Local start 100b - Reserved 101b - Reserved 110b,111b - Reserved
0 MENB	Module Is Enabled Indicates whether CMX_PERFMON is enabled. Enabling CMX_PERFMON does not start the counters. To start the counters, write a nonzero value to PMCR0[SSC]. 0b - Disabled 1b - Enabled

11.6.1.3 Performance Monitor Event Counter (PMECTR1_HI - PMECTR3_HI)

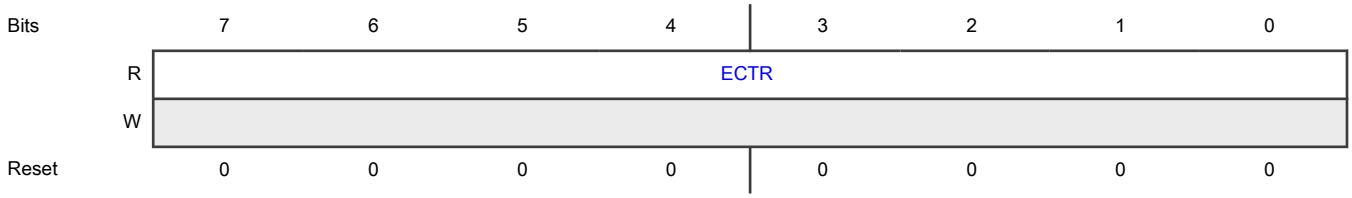
Offset

Register	Offset
PMECTR1_HI	18h
PMECTR2_HI	20h
PMECTR3_HI	28h

Function

Provides part of a 40-bit event counter that you configure with PMCR0[SELEVT*n*].

Diagram



Fields

Field	Function
7-0 ECTR	Event Counter Specifies the upper 8 bits of the event[*n*] counter.

11.6.1.4 Performance Monitor Event Counter (PMECTR1_LO - PMECTR3_LO)

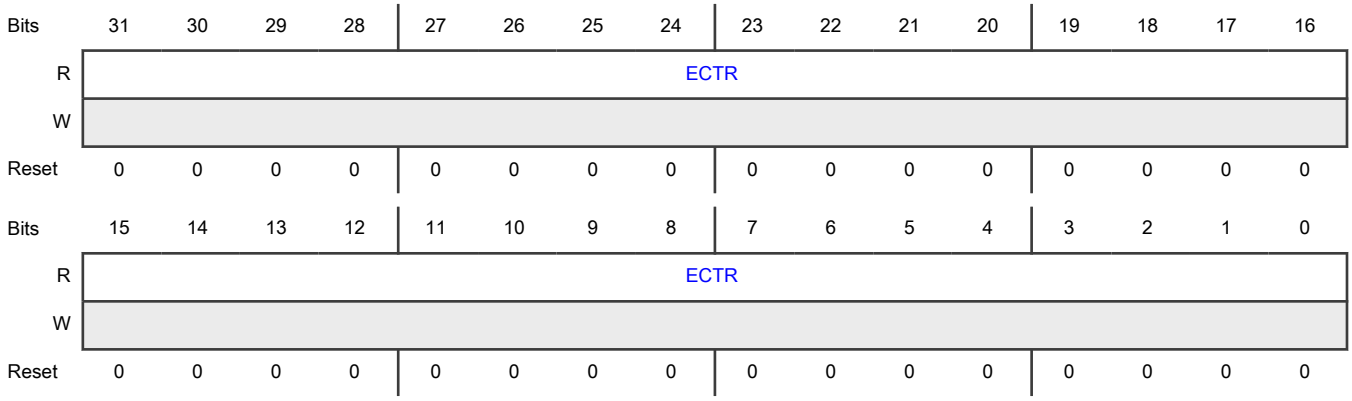
Offset

Register	Offset
PMECTR1_LO	1Ch
PMECTR2_LO	24h
PMECTR3_LO	2Ch

Function

Provides part of a 40-bit event counter that you configure with PMCR0[SELEVT*n*].

Diagram



Fields

Field	Function
31-0	Event Counter

Table continues on the next page...

Field	Function
ECTR	Specifies the lower 32 bits of the event[*n*] counter. The 40-bit counter value increments each time the event selected in [SELEVT*n*] occurs.

Chapter 12
Signal Multiplexing

12.1 Introduction

Pins have several functions available via signal multiplexing to optimize functionality in small packages. This chapter illustrates which device's signals are multiplexed on which external pin.

See the pinout table (also in the attached spreadsheet) to know how the pins available on this device are configured. The attached spreadsheet also provides the available device packages and pinout diagrams.

12.1.1 Signal multiplexing constraints

- A given module signal must be assigned to a maximum of one package pin. Do not program the same function to more than one pin.
- To ensure the best signal timing for a given peripheral's interface, choose the pins in closest proximity to each other.

12.2 Pinout

See the following table for pinout details, also in the attached MCXNP184M150F70_Pinout.xlsx

12.2.1 Pinmux view

NOTE

- For BGA package, all balls with same name are shorted together on BGA package.
- VSS_ANA and VSS_P4 are shorted together on package.
- +I3C in Pad Type means strong pull up resistor is implemented on the pin. PV bit is implemented in the Pin Control register of the pin.
- +I2C in Pad Type represents I2C filter is implemented on the pin. PFE bit is implemented in the Pin Control register of the pin.
- DIS in default column means the pin's input buffer is disabled by default.
- AON and RST pads support passive filter. PFE bit is implemented in the Pin Control register of the pin.
- PE, PS, SRE, and DSE are supported in the Pin Control register of all types of IO.

Chapter 13
ROM API

13.1 Overview

This section provides an introduction to the ROM API in this device.

NOTE

This chapter is also available in the *MCX N Security Reference Manual*, with differences related to security functionality. The chapter in the Reference Manual does not show the security relevant information in it.

13.1.1 Features

- The ROM API supports programming both the Programmable FLASH region (store application code and data) and the CFPA and CMPA Regions (store device configurations, boot configuration, in-field programmable data).
- The ROM API enables the Serial NOR FLASH programming via the FlexSPI Flash Driver API.
- The ROM API supports OTP-eFuse read and programming.
- The ROM API provides native support for Nboot API in the user application.
- The ROM API supports In-application-programming functionality by the IAP API, via the unified memory interface or the Sbloader API.

13.2 Functional description

This section introduces the ROM API structure first, then describes the FLASH API, OTP API, FLEXSPI NOR API, IAP API and NBOOT APIs. This section also demonstrates the typical usage of each API.

- The primary purpose of the FLASH API is to update the programmable FLASH area and specify the parameters in the CMPA and the CFPA.
- The FLEXSPI FLASH API eases the support of various Serial NOR devices in the market.
- OTP API provides the functionality to advance lifecycle; program/read critical one-time programmable parameters and some general-purpose one-time programmable FUSE field.
- IAP API enables the flexibility of doing in-application-programming by the memory interface or the dedicated SBloader API.

NOTE

All ROM APIs are callable from secure world only. Therefore, all function pointers use secure address aliases. Applications should switch to secure mode and then call ROM API or create NSC veneers for ROM APIs.

13.2.1 ROM API structure

The ROM API table locates at address 0x1303fc00. See Figure 54.

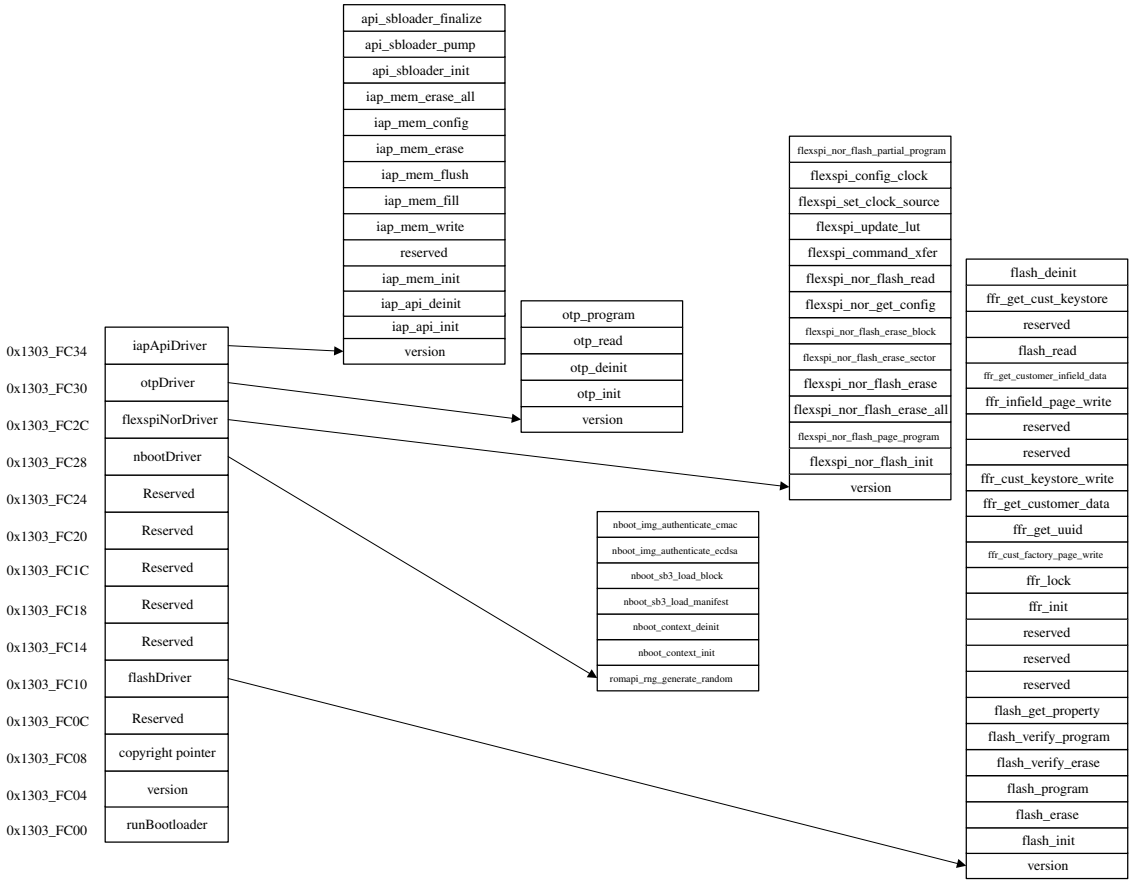

Figure 54. ROM API structure

13.2.2 FLASH APIs

The FLASH API set enables the following features:

- Initialize FLASH controller
- Erase and verify the specified FLASH area
- Program and verify the specified FLASH page
- Retrieve FLASH properties
- Initialize or Lock the CMPA and CFPA Regions
- Program and Read CMPA
- Program and Read CFPA

The FLASH APIs are organized in the FLASH Driver API Interface structure. See the API layout and API prototypes from the following data structure. The whole FLASH API wrapper is available in the SDK release package.

The bootloader API prototypes are:

```
typedef struct FLASHDriverInterface
{
    standard_version_t version; /* flash driver API version number */
```

```
    /* FLASH driver */
    status_t (*flash_init)(flash_config_t *config);
    status_t (*flash_erase)(flash_config_t *config, uint32_t start, uint32_t lengthInBytes, uint32_t
key);
    status_t (*flash_program)(flash_config_t *config, uint32_t start, uint8_t *src, uint32_t
lengthInBytes);
    status_t (*flash_verify_erase)(flash_config_t *config, uint32_t start, uint32_t lengthInBytes);
    status_t (*flash_verify_program)(flash_config_t *config, uint32_t start, uint32_t lengthInBytes,
const uint8_t *expectedData, uint32_t *failedAddress, uint32_t *failedData);
    status_t (*flash_get_property)(flash_config_t *config, flash_property_tag_t whichProperty,
uint32_t *value);
    uint32_t reserved0[3];

    /* FLASH FFR driver */
    status_t (*ffr_init)(flash_config_t *config);
    status_t (*ffr_lock)(flash_config_t *config);
    status_t (*ffr_cust_factory_page_write)(flash_config_t *config, uint8_t *page_data, bool
seal_part);
    status_t (*ffr_get_uuid)(flash_config_t *config, uint8_t *uuid);
    status_t (*ffr_get_customer_data)(flash_config_t *config, uint8_t *pData, uint32_t offset,
uint32_t len);
    status_t (*ffr_cust_keystore_write)(flash_config_t *config, ffr_key_store_t *pKeyStore);
    status_t reserved1;
    status_t reserved2;
    status_t (*ffr_infield_page_write)(flash_config_t *config, uint8_t *page_data, uint32_t
valid_len);
    status_t (*ffr_get_customer_infield_data)(flash_config_t *config, uint8_t *pData, uint32_t
offset, uint32_t len);
    status_t (*flash_read)(flash_config_t *config, uint32_t start, uint8_t *dest, uint32_t
lengthInBytes);
    status_t reserved3;
    status_t (*flash_get_cust_keystore)(flash_config_t *config, uint8_t *pData, uint32_t offset,
uint32_t len);
    status_t (*flash_deinit)(flash_config_t *config);
}
flash_driver_interface_t;
```

Each FLASH API depends on a common FLASH context structure named *flash_config_t* to perform the proper FLASH operation. See the structure details below.

```

/*! @brief FLASH driver state information.
*
* An instance of this structure is allocated by the user of the flash driver and
* passed into each of the driver APIs.
*/
typedef struct
{
    uint32_t PFlashBlockBase;  /*!< A base address of the first PFlash block */
    uint32_t PFlashTotalSize;  /*!< The size of the combined PFlash block. */
    uint32_t PFlashBlockCount; /*!< A number of PFlash blocks. */
    uint32_t PFlashPageSize;   /*!< The size in bytes of a page of PFlash. */
    uint32_t PFlashSectorSize; /*!< The size in bytes of a sector of PFlash. */
    flash_ffr_config_t ffrConfig;
    uint32_t reserved0[5];
    uint32_t *nbootCtx;
    bool useAhbRead;
}
flash_config_t;
```

The flash_ffr_config_t is defined as below:

```
/*! @brief FLASH controller paramter config. */

typedef struct
{
    uint32_t ffrBlockBase;
    uint32_t ffrTotalSize;
    uint32_t ffrPageSize;
    uint32_t sectorSize;
    uint32_t cfpaPageVersion;
    uint32_t cfpaPageOffset;
}
flash_ffr_config_t;
```

flash_ffr_config_t is managed by the FFR_Init API call, the user application doesn't need to touch it.

The ffr_key_store_t and flash_ffr_config_t definitions are:

```
#define FLASH_FFR_KETBLOB_SIZE (0x30u)
typedef struct
{
    uint8_t reserved[1][FLASH_FFR_KETBLOB_SIZE];
}
ffr_key_store_t;
typedef enum
{
    kFLASH_PropertyPflashSectorSize = 0x00U, /*!< Pflash sector size property.*/
    kFLASH_PropertyPflashTotalSize = 0x01U, /*!< Pflash total size property.*/
    kFLASH_PropertyPflashBlockSize = 0x02U, /*!< Pflash block size property.*/
    kFLASH_PropertyPflashBlockCount = 0x03U, /*!< Pflash block count property.*/
    kFLASH_PropertyPflashBlockBaseAddr = 0x04U, /*!< Pflash block base address property.*/
    kFLASH_PropertyPflashPageSize = 0x30U, /*!< Pflash page size property.*/
    kFLASH_PropertyPflashSystemFreq = 0x31U, /*!< System Frequency property.*/
    kFLASH_PropertyFfrSectorSize = 0x40U, /*!< FFR sector size property.*/
    kFLASH_PropertyFfrTotalSize = 0x41U, /*!< FFR total size property.*/
    kFLASH_PropertyFfrBlockBaseAddr = 0x42U, /*!< FFR block base address property.*/
    kFLASH_PropertyFfrPageSize = 0x43U, /*!< FFR page size property.*/
}
flash_property_tag_t;
```

13.2.2.1 Version

The "version" field in the FLASH API table indicates the current FLASH API version in the ROM bootloader.

Prototype :

```
standard_version_t version;
```

Table 120. Definition of the version field

Parameter	Description
standard_version_t	Pointer to version structure to store current FLASH driver version information uint8_t bugfix; /* bugfix version [7:0] */ uint8_t minor; /* minor version [15:8] */ uint8_t major; /* major version [23:16] */ char name; /* character name is "F", where "F" stands for Flash and character version cannot be changed, it is fixed */

Example:

```
#define ROM_API_TREE ((uint32_t*)0x1303fc00)
#define FLASH_API_TREE ((flash_driver_interface_t*)ROM_API_TREE[4])
uint32_t FlashDriverVersion = FLASH_API_TREE-> version;
```

In this SoC, the FLASH Driver version is "0x46010100", it means the FLASH driver version is 1.1.0.

13.2.2.2 flash_init

This API initializes the FLASH default parameters and related FLASH clock for the FLASH and FMC. The *flash_init* API should be called before all the other FLASH APIs.

Prototype :

```
status_t (*flash_init)(flash_config_t *config);
```

Table 121. Parameters used for flash_init API

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.

Example :

```
flash_config_t flashConfig;
uint32_t status = FLASH_API_TREE->flash_init (&flashConfig);
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means flash has been inited successfully.

13.2.2.3 flash_erase

This API erases the internal FLASH region specified by the parameters. This API must be called after the flash_init.

Prototype :

```
status_t (*flash_erase)(flash_config_t *config, uint32_t start, uint32_t lengthInBytes, uint32_t key);
```

Table 122. Parameters used in flash_erase API

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
start	The start address of the required flash memory to be erased. The start address must be sector size aligned (that is, a multiple of 8 KB).
lengthInBytes	The length, given in bytes (not words or long words) to be erased. Must be sector size aligned.
key	Key is used to validate erase operation. Must be set to “kFLASH_ApiEraseKey”. kFLASH_ApiEraseKey = (((‘k’) << 24) | ((‘e’) << 16) | ((‘f’) << 8) | ((‘l’)))

Example :

```
uint32_t start = 0x0 ;
uint32_t lengthInBytes = 0x2000 ;
#define ERASE_KEY 0x6b65666b
uint32_t status = FLASH_API_TREE->flash_erase (&flashConfig, start, lengthInBytes, ERASE_KEY);
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means the FLASH region 0x0 – 0x2000 has been erased.

13.2.2.4 flash_program

This API programs the data into the internal flash page specified by input parameters. The required "start" and "lengthInBytes" parameters must be page-size aligned. This API must be called after the flash_init. Flash must be erased before programming.

Prototype :

```
status_t (*flash_program)(flash_config_t *config, uint32_t start, uint8_t *src, uint32_t
lengthInBytes);
```

Table 123. Parameters used in flash_program API

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
start	The start address of the required flash memory to be programmed. The start address must be 128 bytes-aligned.
src	Pointer to the source buffer of data that is to be programmed into flash.
lengthInBytes	The length in bytes (not words or long words) to be programmed; the length must also be 128 bytes-aligned.

Example:

```
uint8_t programBuffer[512];
for (uint32_t i=0; i<sizeof(programBuffer); i++)
{
```

```
    programBuffer[i] = (uint8_t)(i & 0xFF);
}status = FLASH_API_TREE->flash_program(&flashConfig, 0x0, programBuffer, sizeof(programBuffer);)
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means the specified data has been programmed into the FLASH region.

13.2.2.5 flash_verify_erase

This API checks whether the specified FLASH area is in the erasure state.

This API must be called after the flash_init.

Prototype :

```
status_t (*flash_verify_erase)(flash_config_t *config, uint32_t start, uint32_t lengthInBytes);
```

Table 124. Parameters used in flash_verify_erase API

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
start	The start address of the required flash memory to be verified. Must be page-aligned.
lengthInBytes	The length, given in bytes (not words or long words) to be verified. Must be page-aligned.

Example:

```
uint32_t start = 0x0 ;
uint32_t lengthInBytes = 0x1000 ;
uint32_t status = FLASH_API_TREE->flash_verify_erase (&flashConfig, start, lengthInBytes);
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means the internal FLASH region 0x0 – 0x1000 is erased.

13.2.2.6 flash_verify_program

This API checks whether the data in the specified area is identical to the data supposed to be programmed. This API must be called after the flash_init.

Prototype :

```
status_t (*flash_verify_program)(flash_config_t *config,
uint32_t start,
uint32_t lengthInBytes,
const uint8_t *expectedData,
uint32_t *failedAddress,
uint32_t *failedData);
```

Table 125. Parameters used in flash_verify_program API

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
start	The start address of the required flash memory to be verified.
lengthInBytes	The length, given in bytes (not words or long words) to be verified.
expectedData	Pointer to the expected data that is to be verified against.
failedAddress	Pointer to returned first failing address.
failedData	Pointer to return failing data.

Example:

```
uint32_t start = 0x0 ;
uint32_t lengthInBytes = sizeof(expected_buffer) ;
uint32_t failedAddress, failedData;
uint32_t status = FLASH_API_TREE->flash_verify_erase (&flashConfig, start, lengthInBytes, (const
uint8_t *) expected_buffer, & failedAddress, & failedData);
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means the expected data same as the programed data in the specific FLASH region.

13.2.2.7 flash_get_property

This API returns the requested FLASH property. This API must be called after the flash_init and ffr_init.

Prototype :

```
status_t (*flash_get_property)(flash_config_t *config, flash_property_tag_t whichProperty, uint32_t
*value);
```

Table 126. Parameters used in flash_get_property API

Parameter	whichProperty	Description
config		Pointer to flash_config_t data structure in memory to store driver runtime state.
whichProperty		Pointer to the which flash property need to get.
value		Pointer to the returned flash property value.
Property definition		
kFLASH_PropertyPflashTotalSize	0x01	Pflash total size property.
kFLASH_PropertyPflashBlockSize	0x02	Pflash Block size property.

Table continues on the next page...

Table 126. Parameters used in flash_get_property API (continued)

Parameter	whichProperty	Description
kFLASH_PropertyPflashBlockCount	0x03	Pflash Block Count size property.
kFLASH_PropertyPflashBlockBaseAddr	0x04	flash block base address.
kFLASH_PropertyPflashPageSize	0x30	Pflash page size property.
kFLASH_PropertyFfrTotalSize	0x41	FFR total size property.
kFLASH_PropertyFfrBlockBaseAddr	0x42	FFR block base address property.
kFLASH_PropertyFfrPageSize	0x43	FFR page size property.

Example:

```
flash_property_tag_t whichProperty = kFLASH_PropertyPflashTotalSize;
uint32_t value = 0;
uint32_t status = FLASH_API_TREE->flash_get_property(&flashConfig, whichProperty, &value);
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means the flash property get successfully, and will return the property value if needed.

13.2.2.8 ffr_init

This API is used for initializing the FFR controller and the *flash_ffr_config* context. It must be called before calling other FFR APIs.

NOTE

flash_init must be called before calling the ffr_init API. Before calling other flash_driver_interface_t APIs, especially flash_verify_erase and flash_verify_program, it is necessary to call the flash_init and ffr_init APIs.

Prototype :

```
status_t (*ffr_init)(flash_config_t *config);
```

Table 127. Parameters used in ffr_init API

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.

Example:

```
uint32_t status = FLASH_API_TREE-> ffr_init (&flashConfig);
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means the FFR parameters has been configured.

13.2.2.9 ffr_lock

This API is used to enable the firewall for all FLASH banks, including enabling FLASH protection for three IFR banks and disabling write access to the FLASHBENKENABLE register. ffr_lock unconditionally locks writing to the CFPA and CMPA flash areas. Subsequent writes are inhibited unless a power-on reset (POR) or brown-out detect (BOD) reset occurs.

Prototype :

```
status_t (*ffr_lock)(flash_config_t *config);
```

Table 128. Parameters used in ffr_lock

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.

Example:

```
uint32_t status = FLASH_API_TREE-> ffr_lock (&flashConfig);
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means the FFR regions has been locked.

13.2.2.10 ffr_cust_factory_page_write

The API is used for writing the CMPA data into the CMPA region, and the API should be called after the flash_init and ffr_init.

Prototype :

```
status_t (*ffr_cust_factory_page_write)(flash_config_t *config, uint8_t *page_data, bool seal_part);
```

Table 129. Parameters used in ffr_cust_factory_page_write API

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
page_data	Pointer to value address that will be written to the destination address.
seal_part	If set as true or the page_data includes the non-zero CMAC data, the CMPA CMAC will be calculated and programed into the CMPA region.

Example:

```
uint32_t cmpa_buffer [ffr_page_size] = {0, 2, 3, 4};
uint32_t status = FLASH_API_TREE-> ffr_cust_factory_page_write (&flashConfig, (uint8_t *)cmpa_buffer,
false);
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means the cmpa_buffer data has been programed into the CMPA region.

13.2.2.11 ffr_get_uuid

The API is used for getting the UUID data of the device, and the API should be called after the flash_init and ffr_init.

Prototype :

```
status_t (*ffr_get_uuid)(flash_config_t *config, uint8_t *uuid);
```

Table 130. Parameters used in ffr_get_uuid API

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
uuid	Pointer to value address, the value is read back from the Bank0_IFR1 0x0110_0000 – 0x0110_0010.

Example:

```
uint32_t uuid_buffer [4];
uint32_t status = FLASH_API_TREE-> ffr_get_uuid(&flashConfig, (uint8_t *)uuid_buffer);
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means the uuid data has been got from the UUID of the device.

13.2.2.12 ffr_get_customer_data

This API is used to read data stored in CMPA, and the API should be called after the flash_init and ffr_init.

Prototype :

```
status_t (*ffr_get_customer_data)(flash_config_t *config, uint8_t *pData, uint32_t offset, uint32_t
len);
```

Table 131. Parameters used in ffr_get_customer_data API

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
pData	Point to the destination buffer that stores data read from CMPA.
offset	Point to the offset value based on the CMPA start address(0x0100_4000) of the device.
len	The length in bytes to be read back. The offset + len <= 512B.

Example:

```
uint32_t cmpa_buffer[4];
uint32_t offset = 0;
uint32_t status = FLASH_API_TREE->ffr_get_customer_data(&flashConfig, (uint8_t *)cmpa_buffer, offset,
sizeof(cmpa_buffer));
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means the CMPA data has been got from the CMPA region and stored into the cmpa_buffer.

13.2.2.13 ffr_cust_keystore_write

The API is used for programing the customer key store data into the customer key store region (0x0100_4160 - 0x0100_418f), and the API should be called after the flash_init and ffr_init.

Prototype :

```
status_t (*ffr_cust_keystore_write)(flash_config_t *config, ffr_key_store_t *pKeyStore);
```

Table 132. . Parameters used in ffr_cust_keystore_write API

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
pKeyStore	Pointer to the customer key store data buffer, which will be programed into the customer key store region.

Example:

```
uint32_t status = FLASH_API_TREE->ffr_cust_keystore_write(&flashConfig, (ffr_key_store_t *)
cust_keystore_buffer);
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means customer key store data has been programed into the customer key store region.

13.2.2.14 ffr_infield_page_write

The API is used for programing the CFPA data into the CFPA inactive page and the API should be called after the flash_init and ffr_init.

Prototype :

```
status_t (*ffr_infield_page_write)(flash_config_t *config, uint8_t *page_data, uint32_t valid_len);
```

Table 133. . Parameters used in ffr_infield_page_write API

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
page_data	Pointer to the source buffer of data that is to be programed into the in-field page.
valid_len	The length in bytes to be programmed, the length must equal the page size.

Example:

```
uint32_t cfpa_buffer [128];
uint32_t status = FLASH_API_TREE-> ffr_infield_page_write (&flashConfig, (uint8_t *) cfpa_buffer,
sizeof(cfpa_buffer));
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means the CFPA data has been programed into the CFPA Scratch region.

13.2.2.15 ffr_get_customer_infield_data

The API is used for getting the CFPA data from the FFR CFPA region, and the API should be called after the flash_init and ffr_init.

Prototype :

```
status_t (*ffr_get_customer_infield_data)(flash_config_t *config, uint8_t *pData, uint32_t offset,
uint32_t len);
```

Table 134. Parameters used in ffr_get_customer_infield_data API

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
pData	Point to the destination buffer of data that stores data read from customer In-field page.
offset	Pointer to the offset value based on the CFPA address (Ping page: 0x01000000, Pong page: 0x01002000) of the device.
len	Point to the length of data to read, and the offset + len <= 8192B.

Example:

```
uint32_t cfpa_buffer[4];
uint32_t offset = 0;
uint32_t status = FLASH_API_TREE->ffr_get_customer_infield_data (&flashConfig, (uint8_t *)
cfpa_buffer, offset, sizeof(cfpa_buffer ));
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means the CFPA data has been got from the CFPA region and stored into the cfpa_buffer.

13.2.2.16 flash_read

The API is used for getting internal flash data, including the FLASH and FFR data, and the API should be called after the flash_init.

Prototype :

```
status_t (*flash_read)(flash_config_t *config, uint32_t start, uint8_t *dest, uint32_t lengthInBytes);
```

Table 135. Parameters used in flash_read API

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
start	Point to the start address where data will be read.
dest	Pointer to the buffer used for storing the read data.
lengthInBytes	Point to the read data length

Example:

```
uint32_t start_addr = 0x1000;
uint8_t read_buffer[512] = {0};
uint32_t length = 512;
uint32_t status = FLASH_API_TREE-> flash_read(&flashConfig, start_addr, (uint8_t *) read_buffer,
length);
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means the expected read region has been loaded into the read_buffer.

13.2.2.17 flash_get_cust_keystore

The API is used for getting the customer key store data from the customer key store region (0x0100_4160 - 0x0100_418f), and the API should be called after the flash_init and ffr_init.

Prototype:

```
status_t (*flash_get_cust_keystore)(flash_config_t *config, uint8_t *pData, uint32_t offset, uint32_t
len);
```

Table 136. Parameters used in flash_get_cust_keystore API

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
pData	Pointer to the customer key store data buffer, which got from the customer key store region.
offset	Point to the offset value based on the customer key store address (0x01004160)of the device.
len	Point to the length of the expected get customer key store data, and the offset + len <= 512B.

Example:

```
uint8_t cust_keystore_buffer[512] = {0};
uint32_t offset = 0;
uint32_t length = 512;
uint32_t status = FLASH_API_TREE-> flash_get_cust_keystore (&flashConfig, (uint8_t *)
cust_keystore_buffer, offset, length);
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means the customer key store data has been got from the customer key store region and stored into the cust_keystore_buffer.

13.2.2.18 flash_deinit

This API deinitializes the FLASH default parameters and related FLASH clock for the FLASH and FMC. The flash_deinit API should be called after all the other FLASH APIs.

Prototype :

```
status_t (*flash_deinit)(flash_config_t *config);
```

Table 137. Parameters used in flash_deinit API

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.

Example:

```
flash_config_t flashConfig;
uint32_t status = FLASH_API_TREE->flash_deinit (&flashConfig);
```

See the possible status codes in Table 138. If the status is kStatus_FLASH_Success return value, it means FLASH has been deinited successfully.

13.2.2.19 Possible return codes of the FLASH APIs

Table 138. Return codes for FLASH APIs

Return code	Value	Description
kStatus_FLASH_Success	0	API is executed successfully
kStatus_FLASH_InvalidArgument	4	An invalid argument is provided
kStatus_FlashAlignmentError	101	Address or length does not meet the required alignment.
kStatus_FlashAddressError	102	Address or length is outside addressable memory.
kStatus_FLASH_CommandFailure	105	The FMU_FSTAT[FAIL] bit is set.
kStatus_FlashUnknownProperty	106	Unknown Flash property.
kStatus_FlashEraseKeyError	107	The key provided does not match the programmed flash key.
kStatus_FlashRegionExecuteOnly	108	The area of flash is protected as execute-only.
kStatus_FLASH_CommandNotSupported	111	Flash API is not supported
kStatus_FLASH_ReadOnlyProperty	112	The flash property is read-only
kStatus_FLASH_InvalidPropertyValue	113	The flash property value is out of range
kStatus_FLASH_EccError	116	A correctable or uncorrectable error during command execution
kStatus_FLASH_CompareError	117	Destination and source memory contents do not match
kStatus_FLASH_InvalidWaitStateCycles	119	The wait state cycle set to r/w mode is invalid

Table continues on the next page...

Table 138. Return codes for FLASH APIs (continued)

kStatus_FLASH_OutOfDateCfpaPage	132	CFPA page version is out of date
kStatus_FLASH_BlankIfrPageData	133	Blank page cannot be read
kStatus_FLASH_EncryptedRegionsEraseNotDoneAtOnce	134	Encrypted flash subregions are not erased at once
kStatus_FLASH_SealedFfrRegion	137	The FFR region is sealed
kStatus_FLASH_FfrRegionWriteBroken	138	The FFR Spec region is not allowed to be written discontinuously
kStatus_FLASH_NmpaAccessNotAllowed	139	The NMPA region is not allowed to be read/ written/erased
kStatus_FLASH_CmpaCfgDirectEraseNotAllowed	140	The CMPA Cfg region is not allowed to be erased directly
kStatus_FLASH_FfrBankIsLocked	141	The FFR bank region is locked
kStatus_FLASH_CfpaScratchPageInvalid	148	CFPA Scratch Page is invalid
kStatus_FLASH_CfpaVersionRollbackDisallowed	149	CFPA version rollback is not allowed

13.2.2.20 Flash APIs Example

The section provides examples to introduce the Flash APIs usage.

Example 1 (program the image data or specific data into internal flash region):

```
#define ROM_API_TREE ((uint32_t*)0x1303fc00)
#define FLASH_API_TREE ((flash_driver_interface_t*)ROM_API_TREE[4])
flash_config_t flashConfig;
status_t status = kStatus_Success;
uint32_t load_address = 0x10000;
uint32_t erase_size = 0x800;
uint32_t s_buffer[512];
for (uint32_t i = 0; i < 512; i++)
{
    s_buffer[i] = i;
}
uint32_t FlashDriverVersion = FLASH_API_TREE->version;
debug_printf("Flash version= %x\r\n", FlashDriverVersion);
status = FLASH_API_TREE->flash_init(&flashConfig);
debug_printf("flash_init version= %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
status = FLASH_API_TREE->ffr_init(&flashConfig);
debug_printf("ffr_init version= %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
```

```
status = FLASH_API_TREE->flash_erase(&FlashConfig, load_address, erase_size, kFLASH_ApiEraseKey);
debug_printf("flash_erase status = %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
/* call the flash_verify_erase api to check whether the flash region has been erased */
status = FLASH_API_TREE->flash_verify_erase(&FlashConfig, load_address, erase_size);
debug_printf("flash_verify_erase status = %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
/* here s_buffer data can also be replaced by the image data that is used for dual image boot */
status = FLASH_API_TREE->flash_program(&FlashConfig, load_address, (uint8_t *)s_buffer,
sizeof(s_buffer);
debug_printf("flash_program status = %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
/* call the flash_verify_program api to check whether the s_buffer data has been loaded into the
flash region */
uint32_t failedAddress, failedData;
status = FLASH_API_TREE->flash_verify_program (&FlashConfig, load_address, sizeof(s_buffer), (const
uint8_t *)s_buffer, &failedAddress, &failedData);
debug_printf("flash_verify_program status = %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
```

Example 2 (update the ffr data and get the data from the ffr region):

```

#define ROM_API_TREE ((uint32_t*)0x1303fc00)
#define FLASH_API_TREE ((flash_driver_interface_t*)ROM_API_TREE[4])
flash_config_t flashConfig;
uint32_t pflashBlockBase = 0;
uint32_t cmpa_key_store_address = 0x0100_4000;
uint8_t pData[512];
uint8_t pData1[512] ;
uint8_t uuid[16];
uint32_t ffr_buffer_len = 512 ;
status_t status = kStatus_Success;
status = FLASH_API_TREE->flash_init(&flashConfig);
debug_printf("flash_init version= %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
status = FLASH_API_TREE->ffr_init(&flashConfig);
debug_printf("ffr_init version= %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
status = FLASH_API_TREE->flash_get_property(&FlashConfig, kFLASH_PropertyPflashBlockBaseAddr,
&pflashBlockBase);
debug_printf("kFLASH_PropertyPflashBlockBaseAddr = %x\r\n", pflashBlockBase);
```

```
if (status != kStatus_FLASH_Success)
{
    return status;
}
/* call ffr_infield_page_write to load CfpaData into the CFPA inactive region; CfpaData is provided
by user; the version of CfpaData should be larger than or same as before */
status = FLASH_API_TREE->ffr_infield_page_write(&FlashConfig, (uint8_t *)&CfpaData, FFR_BUFFER_LEN);
debug_printf("ffr_infield_page_write status = %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
status = FLASH_API_TREE->ffr_get_customer_infield_data(&FlashConfig, (uint8_t *)pData, 0,
ffr_buffer_len);
debug_printf("ffr_get_customer_infield_data status = %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
/* call ffr_cust_factory_page_write to load CmpaData into the CMPA region; CMpaData is provided by
user */
status = FLASH_API_TREE->ffr_cust_factory_page_write(&FlashConfig, (uint8_t *)CmpaData, false);
debug_printf("ffr_cust_factory_page_write status = %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
status = FLASH_API_TREE->ffr_get_customer_data(&FlashConfig, (uint8_t *)pData, 0, ffr_buffer_len);
debug_printf("ffr_get_customer_data status = %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
status = FLASH_API_TREE->ffr_get_uuid(&FlashConfig, uuid);
debug_printf("ffr_get_uuid status = %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
/* call ffr_keystore_write to load CMPA_KeyStore into the CMPA key_store region; CMPA_KeyStore is
provided by user */
status = FLASH_API_TREE->ffr_keystore_write(&FlashConfig, (ffr_key_store_t *)CMPA_KeyStore);
debug_printf("ffr_keystore_write status = %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
status = FLASH_API_TREE->flash_get_cust_keystore(&FlashConfig, (uint8_t *)pData, 0, ffr_buffer_len);
debug_printf("flash_get_cust_keystore status = %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
status = FLASH_API_TREE->flash_read(&FlashConfig, cmpa_key_store_address, (uint8_t *)pData1,
ffr_buffer_len);
debug_printf("flash_read status = %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
```

```
status = memcmp((const void*) pData, (const void*) pData1, ffr_buffer_len);
debug_printf("cmpa key_store read data compare status = %x\r\n", status);
if (status != 0)
{
    return status;
}
/* call ffr_lock to lock the ffr region; the ffr region can not be accessed until the next reset;
call the flash_init  and the ffr_init APIs */
status = FLASH_API_TREE->ffr_lock(&FlashConfig);
debug_printf("ffr_lock status = %x\r\n", status);
if (status != kStatus_FLASH_Success)
{
    return status;
}
```

13.2.3 runBootloader API

The ROM bootloader provides an API for the user application to enter the ISP mode based on the designated ISP interface mode.

Prototype

```
void (*runBootloader)(void *arg);
```

Table 139. runBootloader API arg fields

Field	Offset	Description	
Tag	[31:24]	Fixed value: 0xEB (Enter Boot)	
Boot Mode	[23:20]	0 - Master boot mode	
		1 - Enter ISP mode	
ISP Interface	[19:16]	**ISP boot mode**	**Master boot mode**
		0 - Auto detection	0 – Internal flash boot
		1 - UART	2 – FlexSPI flash boot
		2 - SPI	Reserved
		3 - I2C	Reserved
		4 - USB FS HID	
		5 - USB HS HID	
		6 - CAN	
Instance	[15:12]	FlexSPI port selection 0: PortA 1: PortB	
Image Index	[11:08]	Boot image index selection in the dual image mode	
Reserved	[07:00]		

Example:

In the application image boot process, regardless of whether the ISP pin is connected to the high level, the device will directly enter the ISP mode through the UART interface according to the parameter ISP Interface in arg.

```
#define ROM_API_TREE ((uint32_t*)0x1303fc00)
#define RUN_BOOTLOADER_API_TREE ((void (*)(void *)) ROM_API_TREE[0])
uint32_t arg = 0xEB120000;   /*0xEB: represents Enter Boot; 0x12: represents enter ISP mode by UART
only */
RUN_BOOTLOADER_API_TREE->runBootloader(&arg);
```

After the application image, which calls the above runBootloader API, has booted successfully, the device will only allow the UART interface to be connected to transfer the data with the host.

13.2.4 FLEXSPI FLASH Driver APIs

The FLEXSPI NOR Driver API set consists of APIs that can simplify external FLASH support. The API set provides the following features:

- Recognize an external Serial NOR FLASH device based on the JESD216 or above revision
- Probe the Octal Serial NOR FLASH via simplified option
- Program data to or read data from an external Serial NOR FLASH device
- Partially or fully erase an external Serial NOR FLASH device.
- Support for most Serial NOR FLASH devices

13.2.4.1 General description

The FlexSPI FLASH APIs are organized in the flexspi_nor_flash_driver_t structure. See the details in data structure below. See the details of each API in the subsequent sections.

```
typedef struct
{
    uint32_t version;
    status_t (*init)(uint32_t instance, flexspi_nor_config_t *config);
    status_t (*page_program)(uint32_t instance, flexspi_nor_config_t *config, uint32_t dstAddr, const
uint32_t *src);
    status_t (*erase_all)(uint32_t instance, flexspi_nor_config_t *config);
    status_t (*erase)(uint32_t instance, flexspi_nor_config_t *config, uint32_t start, uint32_t
length);
    status_t (*erase_sector)(uint32_t instance, flexspi_nor_config_t *config, uint32_t address);
    status_t (*erase_block)(uint32_t instance, flexspi_nor_config_t *config, uint32_t address);
    status_t (*get_config)(uint32_t instance, flexspi_nor_config_t *config,
serial_nor_config_option_t *option);
    status_t (*read)(uint32_t instance, flexspi_nor_config_t *config, uint32_t *dst, uint32_t start,
uint32_t bytes);
    status_t (*xfer)(uint32_t instance, flexspi_xfer_t *xfer);
    status_t (*update_lut)(uint32_t instance, uint32_t seqIndex, const uint32_t *lutBase, uint32_t
numberOfSeq);
    status_t (*set_clock_source)(uint32_t clockSrc);
    void (*config_clock)(uint32_t instance, uint32_t freqOption, uint32_t sampleClkMode);
    status_t (*partial_program)(uint32_t instance, flexspi_nor_config_t *config, uint32_t dstAddr,
const uint32_t *src, uint32_t length);
} flexspi_nor_flash_driver_t;
```

Each FLEXSPI FLASH API depends on a common *flexspi_nor_config_t* parameter to perform the proper operation. The *flexspi_nor_config_t* data structure is defined as below. See the details of the flexspi_nor_config_t in FlexSPI FLASH Driver APIs.

```
/* Serial NOR configuration block */

typedef struct _flexspi_nor_config
{
    flexspi_mem_config_t memConfig; /* Common memory configuration info via FlexSPI */
    uint32_t pageSize;              /* Page size of Serial NOR */
    uint32_t sectorSize;            /* Sector size of Serial NOR */
    uint8_t ipcmdSerialClkFreq;     /* Clock frequency for IP command */
    uint8_t isUniformBlockSize;     /* Sector/Block size is the same */
    uint8_t isDataOrderSwapped;     /* Data order (D0, D1, D2, D3) is swapped (D1,D0, D3, D2) */
    uint8_t reserved0[1];           /* Reserved for future use */
    uint8_t serialNorType;          /* Serial NOR FLASH type: 0/1/2/3 */
    uint8_t needExitNoCmdMode;      /* Need to exit NoCmd mode before other IP command */
    uint8_t halfClkForNonReadCmd;   /* Half the Serial Clock for non-read command: true/false */
    uint8_t needRestoreNoCmdMode;   /* Need to Restore NoCmd mode after IP commmand execution */
    uint32_t blockSize;             /* Block size */
    uint32_t flashStateCtx;         /* FLASH State Context */
    uint32_t reserved2[10];         /* Reserved for future use */
} flexspi_nor_config_t;
```

13.2.4.2 version

This field indicates the FlexSPI FLASH driver version number.

Prototype :

```
uint32_t version;
```

Example:

```
#define ROM_API_TREE ((uint32_t*)0x1303fc00)
#define FLEXSPI_FLASH_API_TREE ((flexspi_nor_flash_driver_t *)ROM_API_TREE[11])
uint32_t FlexSPIFLASHDriverVersion = FLEXSPI_FLASH_API_TREE -> version;
```

In this device, the FlexSPI FLASH Driver version is “0x00010802”, it means the FLEXSPI FLASH API version is 1.8.2.

13.2.4.3 flexspi_nor_flash_init

The API is used for initializing the FlexSPI controller based on the parameters. It requires a full flexspi_nor_config_t data structure to initialize the FLEXSPI controller, clocks, FLASH etc. The data structure can be generated via flexspi_nor_get_config API or in other manners.

Prototype :

```
status_t (*init)(uint32_t instance, flexspi_nor_config_t *config);
```

Table 140. Parameters used in the flexspi_nor_flash_init API

Parameter	Description
instance	Point to the FlexSPI FLASH controller instance. Only instance 0 is supported on this device.
config	This parameter includes the first parameter flexspi_mem_config_t pointing to the flash configuration block(FCB) and related external FLASH device parameters, which consists of arguments related to an external FLASH device, for example, flash size, page size, sector size. See the details of the flexspi_nor_config_t in FlexSPI FLASH Driver APIs.

Example:

```
#define FLEXSPI_INSTANCE (0)
flexspi_nor_config_t flashConfig;
// get the valid flashConfig data here
// Call the API with proper flashConfig parameter
uint32_t status = FLEXSPI_FLASH_API_TREE->init (FLEXSPI_INSTANCE, &flashConfig);
```

See the possible status codes in Table 154. If the status is kStatus_Success return value, it means FlexSPI FLASH driver initialization is completed successfully.

13.2.4.4 flexspi_nor_flash_page_program

The API is used for programming the page data into the Serial NOR FLASH, and the API should be called after the *flexspi_nor_flash_init* API call.

Prototype :

```
status_t (*page_program)(uint32_t instance, flexspi_nor_config_t *config, uint32_t dstAddr, const
uint32_t *src);
```

Table 141. Parameters used in flexspi_nor_flash_page_program API

Parameter	Description
instance	Point to the FlexSPI controller instance, only support 0
config	This parameter points to the flash configuration block(FCB), consisting of arguments related to an external FLASH device, such as flash size, page size, and sector size. See the details of the flexspi_nor_config_t in FlexSPI FLASH Driver APIs.
dstAddr	The start address of the required FLASH memory to be programmed.
src	Pointer to the source buffer of data that is to be programmed into FLASH. The src address must be 32-bit aligned

Example:

```
uint32_t dstAddr = 0x1000 ;
uint8_t programBuffer[256];
for (uint32_t i=0; i<sizeof(programBuffer); i++)
{
    programBuffer[i] = (uint8_t)(i & 0xFF);
```

```
}
status = FLEXSPI_FLASH_API_TREE->page_program(FLEXSPI_INSTANCE, &flashConfig, dstAddr,
&programBuffer);
```

See the possible status codes in Table 154. If the status is kStatus_Success return value, it means the data has been written into the specified region of the FLASH. It cannot guarantee the data has been successfully programmed into the FLASH device.

13.2.4.5 flexspi_nor_flash_erase_all

The API is used for erasing the entire external FLASH region, and the API should be called after the *flexspi_nor_flash_init* API call.

Prototype :

```
status_t (*erase_all)(uint32_t instance, flexspi_nor_config_t *config);
```

Table 142. Parameters used in flexspi_nor_flash_erase_all API

Parameter	Description
instance	Point to the FlexSPI controller instance, only support 0
config	This parameter points to the flash configuration block(FCB) which consists of arguments related to an external FLASH device, for example, flash size, page size, sector size. See the details of the flexspi_nor_config_t in FlexSPI FLASH Driver APIs.

Example:

```
status = FLEXSPI_FLASH_API_TREE-> erase_all (FLEXSPI_INSTANCE, &flashConfig);
```

See the possible status codes in Table 154. If the status is kStatus_Success return value, it means that the chip erase operation is completed on the FLASH side.

13.2.4.6 flexspi_nor_flash_erase

The API is used for erasing the specified region of the external FlexSPI FLASH region, and the API should be called after the *flexspi_nor_flash_init* API call.

Prototype :

```
status_t (*erase)(uint32_t instance, flexspi_nor_config_t *config, uint32_t start, uint32_t length);
```

Table 143. Parameters used in flexspi_nor_flash_erase API

Parameter	Description
instance	Point to the FlexSPI controller instance, only support 0
config	This parameter points to the flash configuration block(FCB) which consists of arguments related to an external FLASH device, for example, flash size, page size, sector size. See the details of the flexspi_nor_config_t in FlexSPI FLASH Driver APIs.

Table continues on the next page...

Table 143. Parameters used in flexspi_nor_flash_erase API (continued)

Parameter	Description
start	The start offset address of the required flash memory to be erased. The start address must be page-aligned (that is, a multiple of page of the specific FlexSPI Flash).
lengthInBytes	The length, given in bytes (not words or long words) to be erased. Must be page-aligned.

Example:

```
uint32_t offset = 0x1000 ;
uint832_t lengthInBytes = 0x1000 ;
status = FLEXSPI_FLASH_API_TREE-> erase (FLEXSPI_INSTANCE, &flashConfig, offset, lengthInBytes);
```

See the possible status codes in Table 154. If the status is kStatus_Success return value, it means the external FlexSPI FLASH region (0x80001000 – 0x80002000) has been erased successfully.

13.2.4.7 flexspi_nor_flash_erase_sector

The API is used for erasing the specified sector of the external FlexSPI FLASH, and the API should be called after the *flexspi_nor_flash_init* API call.

Prototype :

```
status_t (*erase_sector)(uint32_t instance, flexspi_nor_config_t *config, uint32_t address);
```

Table 144. Parameters used in flexspi_nor_flash_erase_sector

Parameter	Description
instance	Point to the FlexSPI controller instance, only support 0
config	This parameter points to the flash configuration block(FCB) which consists of arguments related to an external FLASH device, for example, flash size, page size, sector size. See the details of the flexspi_nor_config_t in FlexSPI FLASH Driver APIs.
start	The parameter specifies the offset address of the sector to be erased.

Example:

```
uint32_t offset = 0x0 ;
status = FLEXSPI_FLASH_API_TREE-> erase_sector (FLEXSPI_INSTANCE, &flashConfig, offset);
```

See the possible status codes in Table 154. If the status is kStatus_Success return value, it means the specified sector region of the external FlexSPI FLASH region has been erased successfully.

13.2.4.8 flexspi_nor_flash_erase_block

The API is used for erasing the specified block region of the external FlexSPI FLASH, and the API should be called after the *flexspi_nor_flash_init* API call.

Prototype :

```
status_t (*erase_block)(uint32_t instance, flexspi_nor_config_t *config, uint32_t address);
```

Table 145. Parameters used in flexspi_nor_flash_erase_block

Parameter	Description
instance	Point to the FlexSPI controller instance, only support 0
config	This parameter points to the flash configuration block(FCB) which consists of arguments related to an external FLASH device, for example, flash size, page size, sector size. See the details of the flexspi_nor_config_t in FlexSPI FLASH Driver APIs.
start	The parameter specifies the offset address of the block to be erased.

Example:

```
uint32_t offset = 0x0 ;
status = FLEXSPI_FLASH_API_TREE-> erase_block (FLEXSPI_INSTANCE, &flashConfig, offset);
```

See the possible status codes in Table 154. If the status is kStatus_Success return value, it means the specified block region of the external FlexSPI FLASH has been erased successfully.

13.2.4.9 flexspi_nor_get_config

The API is used for getting the FlexSPI NOR configuration block based on specified option. It can probe the FLASH type and generate the flexspi_nor_config_t for later full initialization. Typically, the flexspi_nor_flash_init will be performed with the flexspi_nor_config_t parameter probed by the flexspi_nor_get_config API.

Note:

This FlexSPI Flash API only support the Quad FlexSPI Flash type.

Prototype :

```
status_t (*get_config)(uint32_t instance, flexspi_nor_config_t *config, serial_nor_config_option_t
*option);
```

Table 146. Parameters used in flexspi_nor_get_config API

Parameter	Description
instance	Point to the FlexSPI controller instance, only support 0
config	This parameter points to the flash configuration block(FCB) which consists of arguments related to an external FLASH device, for example, flash size, page size, sector size. See the details of the flexspi_nor_config_t in FlexSPI FLASH Driver APIs.
option	This parameter provides a simplified option for the FlexSPI driver to probe the FLASH and get the FLASH parameters later. See the details of the flexspi_nor_config_t in FLEXSPI FLASH Driver APIs. Definitions of this block as below.

Table continues on the next page...

Parameter	Description

```
typedef struct _serial_nor_config_option
{
    union
    {
        struct
        {
            uint32_t max_freq : 4;              //!< Maximum supported Frequency
            uint32_t misc_mode : 4;            //!< miscellaneous mode
            uint32_t quad_mode_setting : 4;   //!< Quad mode setting
            uint32_t cmd_pads : 4;           //!< Command pads
            uint32_t query_pads : 4;        //!< SFDP read pads
            uint32_t device_type : 4;      //!< Device type
            uint32_t option_size : 4;     //!< Option size, in terms of uint32_t,size = (option_size
+ 1)* 4
            uint32_t tag : 4;            //!< Tag, must be 0x0E
        } B;
        uint32_t U;
    } option0;

    union
    {
        struct
        {
            uint32_t dummy_cycles : 8;    //!< Dummy cycles before read
            uint32_t status_override : 8; //!< Override status register value during device mode
configuration
            uint32_t pinmux_group : 4;    //!< The pinmux group selection
            uint32_t dqs_pinmux_group : 4; //!< The DQS Pinmux Group Selection
            uint32_t drive_strength : 4;   //!< The Drive Strength of FlexSPI Pads
            uint32_t flash_connection : 4; //!< FLASH connection option: 0 - Single FLASH connected
to port A, 1 - Reserved, 2 - Single FLASH connected to Port B
        } B;
        uint32_t U;
    } option1;

} serial_nor_config_option_t;
```

Table 147. serial_nor_config_option_t option

Offset	Field	Description
0	Option0	See option0 definition for more details
4	Option1	Optional, effective only if the option Size field in Option0 is non-zero See option1 definition for more details.

Table 148. option0 definition

Field	Bits	Description
tag	31:28	The tag of the config option, fixed to 0x0C

Table continues on the next page...

Table 148. option0 definition (continued)

Field	Bits	Description
option_size	27:24	Size in bytes = (Option Size + 1) * 4 It is 0 if only option0 is required
device_type	23:20	Device Detection Type 0 - Read SFDP for SDR commands 1 - Read SFDP for DDR Read commands 2 - HyperFLASH 1V8 3 - HyperFLASH 3V 4 - Macronix Octal DDR 6 - Micron Octal DDR 8 - Adesto EcoXiP DDR
query_pad	19:16	Data pads during Query command (read SFDP or read MID) 0 - 1 2 - 4 3 – 8
cmd_pad	15:12	Data pads during FLASH access command 0 - 1 2 - 4 3 – 8
quad_mode_setting	11:8	Quad Mode Enable Setting 0 - Not configure 1 - Set bit 6 in Status Register 1 2 - Set bit 1 in Status Register 2 3 - Set bit 7 in Status Register 2 4 - Set bit 1 in Status Register 2 via 0x31 command **NOTE** This field will be effective only if the device is compliant with JESD216 only 5 - (9 longword SDFP table)
misc_mode	7:4	Miscellaneous Mode 0 - Not enabled 1 - Enable 0-4-4 mode for High Random Read performance

Table continues on the next page...

Table 148. option0 definition (continued)

Field	Bits	Description
		3 - Data Order Swapped mode (for MXIC OctaFLASH only) 5 - Select the FlexSPI data sample source as internal loop back; see FlexSPI usage for more details 6 - Configure the FlexSPI NOR flash memory running at stand SPI mode **NOTE** Experimental feature only. Do not use in production: keep it as 0 for normal usage.
max_freq	3:0	Max FLASH Operation speed 0 - Don't change the FlexSPI clock setting

Table 149. option1 definition

Field	Bits	Description
flash_connection	31:28	FLASH connection option: • 0 - Single FLASH connected to port A • 1 - Reserved • 2 - Single FLASH connected to Port B
Reserved	27:24	**NOTE** This field does not have any effect in this device.
dqs_pinmux_group	23:20	The DQS Pinmux Group Selection
pinmux_group	19:16	The pinmux group selection
status_override	15:8	Override status register value during device mode configuration
dummy_cycles	7:0	Dummy cycles for a read command • 0 - Use detected dummy cycle • Others - dummy cycles provided in the flash datasheet

Typical Option configurations are as below:

- QUAD NOR - Quad SDR Read: option0 = 0xc0000004 (75MHz)
- QUAD NOR - Quad DDR Read: option0 = 0xc0100003 (60MHz)

Example:

```
#define FLASH_OPTION_QSPI_SDR 0xc0000001
serial_nor_config_option_t flashConfigOption = { .option0 = { .U = FLASH_OPTION_QSPI_SDR } };
status = FLEXSPI_FLASH_API_TREE-> get_config(FLEXSPI_INSTANCE, &flashConfig, &flashConfigOption);
```

See the possible status codes in Table 154. If the status is kStatus_Success return value, it means the FlexSPI FLASH config block has been configured based on the provided option successfully.

13.2.4.10 flexspi_nor_flash_read

The API is used for getting the FlexSPI NOR Flash data and the API should be called only after the FLEXSPI IP has been properly configured.

Prototype :

```
status_t (*read)(uint32_t instance, flexspi_nor_config_t *config, uint32_t *dst, uint32_t start,
uint32_t bytes);
```

Table 150. Parameters used in flexspi_nor_flash_read API

Parameter	Description
instance	Point to the FlexSPI controller instance, only support 0
config	This parameter points to the flash configuration block(FCB) which consists of arguments related to an external FLASH device, for example, flash size, page size, sector size. See the details of the flexspi_nor_config_t in FlexSPI FLASH Driver APIs.
dst	Pointer to the buffer used for storing the read data. The dst address must be 32-bit aligned
start	The offset address of the required flash memory to be read.
lengthInBytes	The length, given in bytes (not words or long words) to be read. Must be page-aligned.

Example:

```
uint32_t start_offset = 0x1000;
uint32_t read_buffer[512] = {0};
status = FLEXSPI_FLASH_API_TREE->read(FLEXSPI_INSTANCE, &flashConfig, & read_buffer, start_offset,
sizeof(read_buffer));
```

See the possible status codes in Table 154. If the status is kStatus_Success return value, it means the FlexSPI FLASH (0x80001000 – 0x80001800) has been read and stored the data into the read_buffer successfully.

13.2.4.11 flexspi_command_xfer

The API is used for performing the FlexSPI command, this API should be called only when the FLEXSPI IP is properly configured.

Prototype :

```
typedef enum _FlexSPIOperationType
{
    // FlexSPI operation: Only command, both TX and RX buffer are ignored.
    kFlexSpiOperation_Command,
    // FlexSPI operation: Configure device mode, the TX FIFO size is fixed in LUT.
    kFlexSpiOperation_Config,
    // FlexSPI operation: Write,  only TX buffer is effective
    kFlexSpiOperation_Write,
    // FlexSPI operation: Read, only Rx Buffer is effective.
    kFlexSpiOperation_Read,
```

```
    kFlexSpiOperation_End,
} flexspi_operation_t;

//!@brief FlexSPI Transfer Context
typedef struct _FlexSpiXfer
{
    flexspi_operation_t operation; // FlexSPI operation
    uint32_t baseAddress;          // FlexSPI operation base address
    uint32_t seqId;                // Sequence Id
    uint32_t seqNum;               // Sequence Number

    bool Reserved;     // This field does not have any effect in the ROM boot flow.
    const uint32_t *txBuffer;      // Tx buffer
    uint32_t txSize;               // Tx size in bytes
    uint32_t *rxBuffer;            // Rx buffer
    uint32_t rxSize;               // Rx size in bytes
} flexspi_xfer_t;

status_t flexspi_command_xfer(uint32_t instance, flexspi_xfer_t *xfer);
```

Table 151. Parameters used in flexspi_command_xfer API

Parameter	Description
instance	Point to the FlexSPI controller instance, only support 0
xfer	This parameter pointer to FlexSPI Transfer Context which consists of arguments related to FlexSPI operation, sequence, TX and RX related parameters.

Example:

```
uint32_t start_offset = 0x1000;
uint32_t read_buffer[512] = {0};
flexspi_xfer_t flashXfer;
flashXfer.operation = kFlexSpiOperation_Read;
flashXfer.seqNum = 1;
flashXfer.seqId = NOR_CMD_LUT_SEQ_IDX_READ;
while (sizeof(read_buffer))
{
    uint32_t readLength = bytes > 65535 ? 65535 : bytes;
    flashXfer.baseAddress = start_offset;
    flashXfer.rxBuffer = read_buffer;
    flashXfer.rxSize = readLength;
    status = FLEXSPI_FLASH_API_TREE->flexspi_command_xfer (instance, &flashXfer);
    if (status != kStatus_Success)
    {
        return status;
    }
    bytes -= readLength;
    start_offset += readLength;
    read_buffer += readLength / sizeof(uint32_t);
}
return status;
```

See the possible status codes in Table 154. If the status is kStatus_Success return value, it means the FlexSPI FLASH command_xfer has executed the read command successfully, and the read data (0x80001000 – 0x80001800) has been load into the read_buffer array.

NOTE

This API relies on the valid LUT to perform the supported operations. If the LUT is invalid, the result is unpredictable.

13.2.4.12 flexspi_update_lut

The API is used for configuring the FlexSPI Lookup table before calling the flexspi_command_xfer API. This API should be called only when the FLEXSPI IP is properly configured.

Prototype :

```
status_t (*update_lut)(uint32_t instance, uint32_t seqIndex, const uint32_t *lutBase, uint32_t
numberOfSeq);
```

Table 152. Parameters used in flexspi_update_lut API

Parameter	Description
instance	Point to the FlexSPI controller instance, only support 0
seqIndex	This parameter pointer to FlexSPI Dedicated LUT Sequence Index for IP Command.
lutBase	This parameter pointer to FlexSPI Lookup table , which holds FLASH command sequences
numberOfSeq	This parameter points to FlexSPI Sequence Number

Example:

```
// Program Pattern
const uint32_t probe_pattern[4] = { 0x33221100, 0x77665544, 0xbbaa9988, 0xffeeddcc };
flexspi_xfer_t flashXfer;
flashXfer.baseAddress = sizeof(flexspi_nor_config_t);
flashXfer.seqId = NOR_CMD_LUT_SEQ_IDX_PAGEPROGRAM;
flashXfer.operation = kFlexSpiOperation_Write;
flashXfer.txBuffer = (uint32_t *)probe_pattern;
flashXfer.txSize = sizeof(probe_pattern);
flexspi_update_lut(instance,NOR_CMD_LUT_FOR_IP_CMD,&flashConfig-
>memConfig.lookupTable[4*flashXfer.seqId], flashXfer.seqNum);
flashXfer.seqId = NOR_CMD_LUT_FOR_IP_CMD;
status = flexspi_command_xfer(instance, &flashXfer);
```

See the possible status codes in Table 154. If the status is kStatus_Success return value, it means the flexspi_update_lut has execute successfully, and the probe_pattern data has been load into the (baseAddress + 0x80000000) region.

13.2.4.13 flexspi_set_clock_source

The API is used for configuring the FlexSPI clock source. This API should be called before calling the flexspi_not_get_config. This API should be called only when the FlexSPI IP is properly configured. This API only changes the FLEXSPI clock selector in the SYSCON register if the user needs to use it.

Prototype:

```
status_t (*set_clock_source)(uint32_t clockSrc);
```

Parameter	Description
clockSrc	Point to the FlexSPI select clock source Flexspi clock select: • 0000 - No clock • 0001 - PLL0 clock • 0010 - No clock • 0011 - FRO_HF • 0100 - No clock • 0101 - PLL1 clock • 0110 - USB PLL clock

Example:

```
uint32_t flexspi_clock_source = 0x0;
status = FLEXSPI_FLASH_API_TREE-> set_clock_source (flexspi_clock_source);
```

See the possible status codes in Table 194. If the status is kStatus_Success return value, it means the set_clock_source has execute successfully, and the FlexSPI has configure the clock source from the configured clock before.

13.2.4.14 flexspi_config_clock

The API is used for configuring the FlexSPI clock. This API should be called only when the FLEXSPI IP is properly configured. flexspi_set_clock_source only changes the clock selector in SYSCON, flexspi_clock_config can configure the clock frequency of the FLEXSPI root clock and clock source.

Prototype:

```
void (*config_clock)(uint32_t instance, uint32_t freqOption, uint32_t sampleClkMode);
```

Parameter	Description
instance	Point to the FlexSPI controller instance, only support 0
freqOption	This parameter pointer to FlexSPIFlexSPI flash serial clock frequency: kFlexSpiSerialClk_30MHz (1U) kFlexSpiSerialClk_50MHz (2U) kFlexSpiSerialClk_60MHz (3U) kFlexSpiSerialClk_75MHz (4U) kFlexSpiSerialClk_100MHz (5U)

sampleClkMode	This parameter pointer to configure the FlexSPI clock configuration type.
	kFlexSpiClk_SDR (0U) //!< Clock configure for SDR mode
	kFlexSpiClk_DDR (1U) //!< Clock configure for DDR mode

Example:

```
uint32_t flexspi_freqOption = 0x1;
uint32_t flexspi_sampleClkMode = 0x0;
status = FLEXSPI_FLASH_API_TREE-> config_clock(FLEXSPI_INSTANCE, flexspi_freqOption,
flexspi_sampleClkMode);
```

See the possible status codes in Table 194. If the status is kStatus_Success return value, it means the config_clock has execute successfully, and the FlexSPI flash clock will be configured with the provided parameter.

13.2.4.15 flexspi_nor_flash_partial_program

The API is used for partially programming the data into the specified address of FlexSPI FLASH, and the API should be called after the *flexspi_nor_flash_init* API call.

Prototype :

```
status_t (*partial_program)(uint32_t instance, flexspi_nor_config_t *config, uint32_t dstAddr, const
uint32_t *src, uint32_t length);
```

Table 153. Parameters used in the flexspi_nor_flash_partial_program API

Parameter	Description
instance	Point to the FlexSPI controller instance, only support 0
config	This parameter points to the flash configuration block(FCB) which consists of arguments related to an external FLASH device, for example, flash size, page size, sector size. See the details of the flexspi_nor_config_t in FlexSPI FLASH Driver APIs.
dstAddr	The start address of the required FlexSPI flash memory to be programmed.
src	Pointer to the source buffer of data that is to be programmed into FlexSPI flash.
length	The program size of the source buffer.

Example:

```
uint32_t flashAhbAddr = 0x80001000UL;
uint32_t flashAhbBase = 0x80000000UL;
uint32_t flashOffset = flashAhbAddr - flashAhbBase;
uint32_t programBuffer[256 / sizeof(uint32_t)];
uint8_t *buf_u8 = (uint8_t*)programBuffer;
for (uint32_t i=0; i<sizeof(programBuffer); i++)
{
    *buf_u8++ = (uint8_t)(i & 0xFFU);
}
status = FLEXSPI_FLASH_API_TREE->partial_program(FLEXSPI_INSTANCE, &flashConfig, flashOffset,
&programBuffer, sizeof(programBuffer));
```

See the possible status codes in Table 154. If the status is kStatus_Success return value, it means the data has been written into the FlexSPI FLASH.

13.2.4.16 Possible return codes for FLEXSPI FLASH driver APIs

Table 154. Return codes for FLEXSPI FLASH APIs

Error Code	Value	Description
kStatus_Success	0	Operation succeeded without error.
kStatus_Fail	1	The operation failed with a generic error.
kStatus_Invalidargument	4	The requested command's argument is undefined.
kStatus_FLEXSPI_SequenceExecutionTimeout	6000	The FLEXSPI Sequence Execution timeout
kStatus_FLEXSPI_InvalidSequence	6001	The FLEXSPI LUT sequence invalid
kStatus_FLEXSPI_DeviceTimeout	6002	The FLEXSPI device timeout
kStatus_FLEXSPINOR_ProgramFail	20100	Page programming failure
kStatus_FLEXSPINOR_EraseSectorFail	20101	Sector Erase failure
kStatus_FLEXSPINOR_EraseAllFail	20102	Chip Erase failure
kStatus_FLEXSPINOR_WaitTimeout	20103	The execution time out
kStatus_FlexSPINOR_WriteAlignmentError	20105	Address alignment error
kStatus_FlexSPINOR_CommandFailure	20106	Erase/Program Verify Error
kStatus_FlexSPINOR_SFDP_NotFound	20107	SFDP table was not found call
kStatus_FLEXSPINOR_Unsupported_SFDP_Version	20108	Unrecognized SFDP version
kStatus_FLEXSPINOR_FLASH_NotFound	20109	Flash detection failure
kStatus_FLEXSPINOR_DTRRead_DummyProbeFailed	20110	DDR Read dummy probe failure

13.2.4.17 FlexSPI Flash APIs Example

The section will provide the example to introduce All the FlexSPI Flash APIs usage and help users understand and use more deeply. Example(Program the image or specific data into the FlexSPI Flash region):

```
#define ROM_API_TREE ((uint32_t*)0x1303fc00)
#define FLEXSPI_FLASH_API_TREE ((flexspi_nor_flash_driver_t *)ROM_API_TREE[11])
#define FLEXSPI_INSTANCE 0
#define FLEXSPI_PROGRAM_OFFSET (0x1000u)
#define FLEXSPI_ERASE_SIZE (0x2000u)
#define MAX_PAGE_SIZE 512
flexspi_nor_config_t flashConfig;
```

```
uint32_t FlexSPIFLASHDriverVersion = FLEXSPI_FLASH_API_TREE->version;
debug_printf("FlexSPIFLASHDriverVersion version= %x\r\n", FlexSPIFLASHDriverVersion);

// choose the Quad SDR FlexSPI Flash type as the example

serial_nor_config_option_t flashConfigOption = { .option0 = { .U = 0xc0000001}};
status = FLEXSPI_FLASH_API_TREE->get_config(FLEXSPI_INSTANCE, &flashConfig, &flashConfigOption);
debug_printf("flexspi_nor_get_config API status=%d!\n",status);
if (status != kStatus_Success)
{
    return status;
}

//Init the FlexSPI Flash base on the flashConfig, which is configured from the get_config API
status = FLEXSPI_FLASH_API_TREE->init(FLEXSPI_INSTANCE, &flashConfig);
debug_printf("flexspi_nor_flash_init returned error:%d\n", status);
if (status != kStatus_Success)
{
    return status;
}

status = FLEXSPI_FLASH_API_TREE->erase(FLEXSPI_INSTANCE, &flashConfig, FLEXSPI_PROGRAM_OFFSET,
FLEXSPI_ERASE_SIZE)
debug_printf ("flexspi_nor_flash_erase returned status:%d\n", status);;
if (status != kStatus_Success)
{
    return status;
}

// Create the specific data programBuffer to program the data into the FlexSPI Flash, also the data
can be replaced by image data provided by user
uint32_t programBuffer[MAX_PAGE_SIZE / sizeof(uint32_t)];
uint8_t *pBuffer = (uint8_t *)&programBuffer[0];
for (uint32_t i = 0; i < sizeof(programBuffer); i++)
{
    *pBuffer++ = (uint8_t)(i & 0xFF);
}

status = FLEXSPI_FLASH_API_TREE->page_program(FLEXSPI_INSTANCE, &flashConfig, FLEXSPI_PROGRAM_OFFSET,
programBuffer);
debug_printf("flexspi_nor_flash_page_program returned error:%d\n", status);
if (status != kStatus_Success)
{
    return status;
}

uint32_t readBuffer[MAX_PAGE_SIZE];
status = FLEXSPI_FLASH_API_TREE->read(FLEXSPI_INSTANCE, &flashConfig, readBuffer,
FLEXSPI_PROGRAM_OFFSET,
flashConfig.pageSize);
debug_printf("flexspi_nor_flash_read status = %d\n", status);

if (status != kStatus_Success)
{
    return status;
}
else
{
    if (memcmp(readBuffer, programBuffer, flashConfig.pageSize) == 0)
    {
```

```
    debug_printf ("Verify programming by IP read: PASSED\n");
    }
}

status = FLEXSPI_FLASH_API_TREE->erase(FLEXSPI_INSTANCE, &flashConfig, FLEXSPI_PROGRAM_OFFSET,
FLEXSPI_ERASE_SIZE)
debug_printf ("flexspi_nor_flash_erase returned status:%d\n", status);;
if (status != kStatus_Success)
{
    return status;
}
```

13.2.5 OTP-eFuse APIs

13.2.5.1 Version

This fields indicates the version number of the OTP API in this device.

Prototype :

```
standard_version_t version;
```

Table 155. Definition of the version Field in OTP API tree

Parameter	Description
standard_version_t	Pointer to version structure to store current eFuse driver version information uint8_t bugfix; /* bugfix version [7:0] */ uint8_t minor; /* minor version [15:8] */ uint8_t major; /* major version [23:16] */ char name; /* character name is "E", where "E" stands for eFuse. Character name and version are fixed */

Example:

```
#define ROM_API_TREE ((uint32_t*)0x1303fc 00)
#define OTP_API_TREE ((efuse_driver_t *)ROM_API_TREE[12])
uint32_t otpDriverVersion = OTP_API_TREE-> version;
```

In this device, the OTP driver version is "0x45010100", it means the OTP driver version is 1.1.0.

Following is the efuse_driver_t definition:

```
/* @brief EFUSE driver API Interface */
typedef struct
{
    standard_version_t version; /* efuse driver API version number */
    status_t (*init)(void);
    status_t (*deinit)(void);
    status_t (*p_efuse_read)(uint32_t addr, uint32_t *data);
    status_t (*p_efuse_program)(uint32_t addr, uint32_t data);
```

```
} efuse_driver_t;
```

13.2.5.2 otp_init

The API is used for initializing the OTP clock. The *otp_init* API should be called before all the other OTP APIs.

Prototype :

```
status_t (*init)(void);
```

Example :

```
uint32_t status = OTP_API_TREE->init ();
```

See the possible status codes in Table 158. If the status is kStatus_Success return value, it means OTP driver initialization completed successfully.

13.2.5.3 otp_deinit

This API is used to disable OTP controller APB clock.

Prototype :

```
status_t (*deinit)(void);
```

Example :

```
uint32_t status = OTP_API_TREE->deinit ();
```

See the possible status codes in Table 158. If the status is kStatus_Success return value, it means OTP driver deinitialization completed successfully.

13.2.5.4 otp_read

This API is used to read data from OTP-eFuse controller.

Prototype :

```
status_t (*p_efuse_read)(uint32_t addr, uint32_t *data);
```

Table 156. Parameters used in otp_read API

Parameter	Description
addr	Pointer to the eFuse index that specifies the EFUSE word to be read out. The index 0 read data: 0 - 127 bits one word data (which 32bits word data in the 128bits will be changed to a byte) The index 1 read data: 128 - 255 bits one word data (which 32bits word data in the 128bits will be changed to a byte)

Table continues on the next page...

Table 156. Parameters used in otp_read API (continued)

Parameter	Description
	The index 2 read data: 256 - 383 bits one word data (which 32bits word data in the 128bits will be changed to a byte) The index 3 read data: 800 - 831 bits (one word data) The following index return data will follow the index 3, each word will increase the index by one.
data	Pointer to the buffer used for storing the read 32 bit data.

Example :

```
#define EFUSE_INDEX (0x0)
uint32_t eFuseData;
uint32_t status = OTP_API_TREE-> p_efuse_read (EFUSE_INDEX, & eFuseData);
```

See the possible status codes in Table 158. If the status is kStatus_Success return value, it means the OTP data read completed successfully.

13.2.5.5 otp_program

This API is used to program data to specified OTP Word.

Prototype :

```
status_t (*p_efuse_program)(uint32_t addr, uint32_t data);
```

Table 157. Parameters used in the otp_program API

Parameter	Description
addr	Pointer to the eFuse index that specifies the EFUSE word to be programmed
data	Pointer to the 32-bit source data used for programming into the eFuse region.

Example:

```
#define EFUSE_INDEX (43)  /* represents CUST Efuse Index */
uint32_t eFuseData = 0x01010101;
uint32_t status = OTP_API_TREE-> p_efuse_program (EFUSE_INDEX, & eFuseData);
```

See the possible status codes in Table 158. If the status is kStatus_Success return value, it means the data 0x01010101 has been programmed into the eFuse index 43 region.

13.2.5.6 Possible return codes of OTP API

Table 158. Return codes for OTP APIs

Error Code	Value	Description

Table continues on the next page...

Table 158. Return codes for OTP APIs (continued)

kStatus_Success	0	Operation succeeded without error.
kStatus_Fail	1	The operation failed with a generic error.
kStatus_ReadOnly	2	Requested value cannot be changed because it is read-only.
kStatus_OutOfRange	3	Requested value is out of range.
kStatus_InvalidArgument	4	The requested command's argument is undefined.
kStatus_Timeout	5	A timeout occurred.

13.2.5.7 OTP-eFuse APIs Example

This section provides an example of OTP API usage.

NOTE

The OTP-eFuse program is only-program-once, user need to make sure the program data is valid value.

Example:

```
#define ROM_API_TREE ((uint32_t*)0x1303fc00)
#define OTP_API_TREE ((efuse_driver_t *)ROM_API_TREE[12])
#define EFUSE_CUST_TEST_INDEX 43 /* The efuse read will return the efuse bit 2080 - 2111 bits data in
the efusemap file */

#define EFUSE_CMPA_CRC_INDEX 1
uint32_t otpDriverVersion = OTP_API_TREE->version;
debug_printf("otpDriverVersion version= %x\r\n", otpDriverVersion);
uint32_t status = OTP_API_TREE->init();
debug_printf("efuse init status= %x\r\n", status);
if (status != kStatus_Success)
{
    return status;
}

/* The otp efuse value program should not program invalid data into the efuse region, otherwise the
device can boot fail and not behave as expected */

uint32_t fuseLCVal = 0;
status_t status = OTP_API_TREE->efuse_program(EFUSE_CUST_TEST_INDEX, fuseLCVal);
debug_printf("efuse_program LC state status= %x\r\n", status);
if (status != kStatus_Success)
{
    return status;
}

/* Here crc value of the cmpa is just the example data, user needs to set the valid crc data of the
cmpa */

uint32_t fuseCMPACRCVal = 0x12345678;
status_t status = OTP_API_TREE->efuse_program(EFUSE_CMPA_CRC_INDEX, fuseCMPACRCVal);
debug_printf("efuse_program crc value of the CMPA status= %x\r\n", status);
if (status != kStatus_Success)
{
```

```
    return status;
}
uint32_t fuseLCVal1;
uint32_t fuseCMPACRCVal1;
status_t status = OTP_API_TREE->efuse_read(EFUSE_LC_STATE_INDEX, &fuseLCVal1);
debug_printf("efuse_read LC state status = %x \r\n", status);
if (status != kStatus_Success)
{
    return status;
}
status_t status = OTP_API_TREE->efuse_read(EFUSE_CMPA_CRC_INDEX, & fuseCMPACRCVal1);
debug_printf("efuse_program crc value of the CMPA status= %x \r\n", status,);
if (status != kStatus_Success)
{
    return status;
}
status_t status = OTP_API_TREE->deinit();
debug_printf("efuse deinit status= %x\r\n", status);
if (status != kStatus_Success)
{
    return status;
}
```

13.2.6 IAP APIs

13.2.6.1 General description

IAP is in–application–programming. The general IAP APIs call and execution flow is shown in Figure 55.

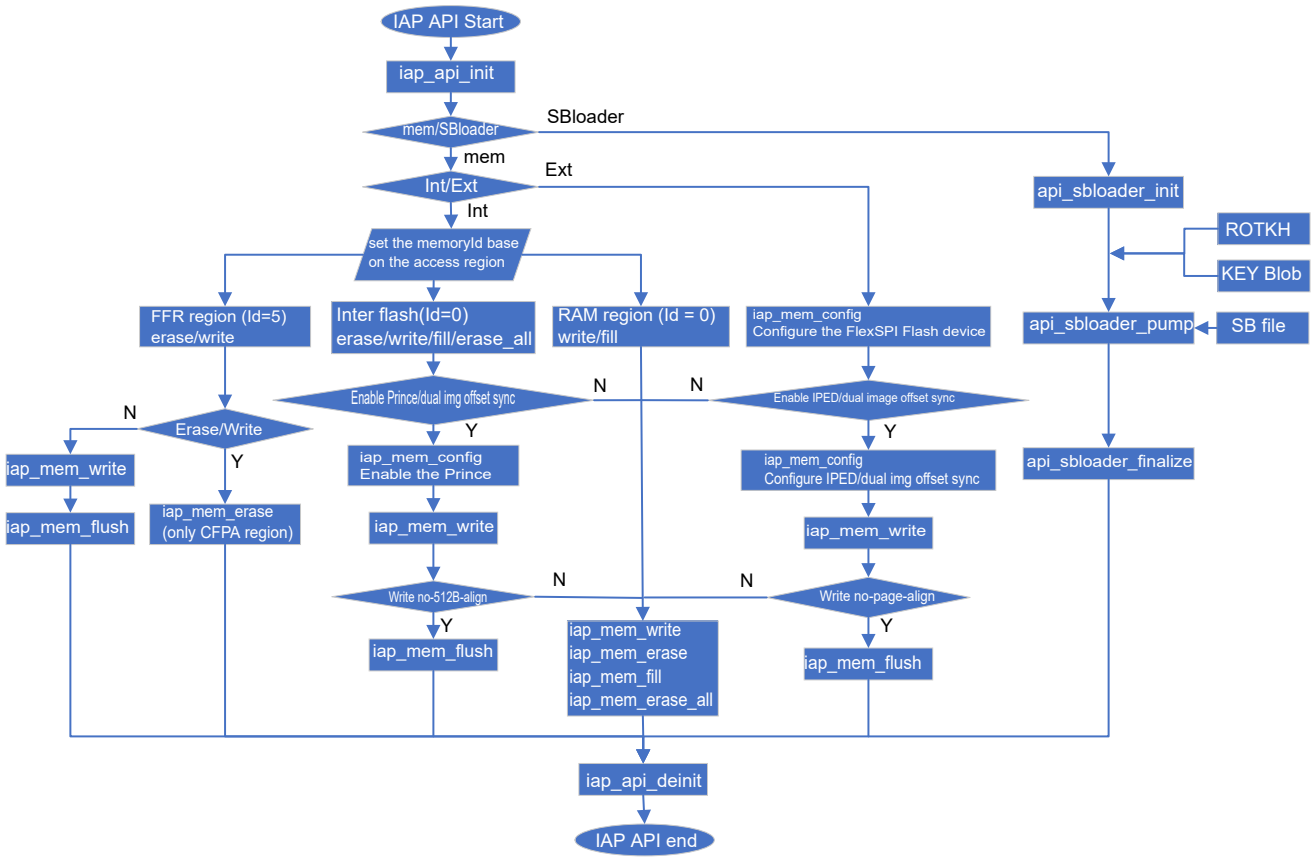

Figure 55. IAP API call flow

The bootloader IAP APIs are organized in the iap_api_interface_t structure, see the details from the below data structure. See the details of each API in the subsequent sections.

```
typedef struct iap_api_interface_struct
{
    standard_version_t version; /* IAP API version number */
    status_t (*api_init)(api_core_context_t *coreCtx, const kp_api_init_param_t *param);
    status_t (*api_deinit)(api_core_context_t *coreCtx);
    status_t (*mem_init)(api_core_context_t *ctx);
    status_t (*mem_read)(api_core_context_t *ctx, uint32_t addr, uint32_t len, uint8_t *buf, uint32_t
memoryId);
    status_t (*mem_write)(api_core_context_t *ctx, uint32_t addr, uint32_t len, const uint8_t *buf,
uint32_t memoryId);
    status_t (*mem_fill)(api_core_context_t *ctx, uint32_t addr, uint32_t len, uint32_t pattern,
uint32_t memoryId);
    status_t (*mem_flush)(api_core_context_t *ctx);
    status_t (*mem_erase)(api_core_context_t *ctx, uint32_t addr, uint32_t len, uint32_t memoryId);
    status_t (*mem_config)(api_core_context_t *ctx, uint32_t *buf, uint32_t memoryId);
    status_t (*mem_erase_all)(api_core_context_t *ctx, uint32_t memoryId);
    status_t (*sbloader_init)(api_core_context_t *ctx);
    status_t (*sbloader_pump)(api_core_context_t *ctx, uint8_t *data, uint32_t length);
    status_t (*sbloader_finalize)(api_core_context_t *ctx);
} iap_api_interface_t;
```

Each IAP API depends on the common context named api_core_context_t. The detail of the context is defined as below:

```
/* @brief The API context structure */

typedef struct api_core_context
{
uint32_t reserved0[10];
    uint32_t reserved1[3];
    flash_config_t flashConfig;
    flexspi_nor_config_t flexspinorCfg;
    uint32_t reserved2[2];
    uint32_t reserved3[1];
    nboot_context_t *nbootCtx;
    uint8_t *sharedBuf;
    uint32_t reserved4[8];

} api_core_context_t;
```

The kp_api_init_param_t is defined as below:

```
typedef struct kb_api_parameter_struct
{
    uint32_t allocStart;
    uint32_t allocSize;
} kp_api_init_param_t;
```

The nboot_context_t is defined as below:

```
typedef struct _nboot_context
{
    uint32_t buffer[0x2e8/sizeof(uint32_t)];
} nboot_context_t;
```

The IAP APIs require a dedicated RAM region as the buffer for each operation. The user application needs to prepare an unused RAM region organized as the *kp_api_init_param_t* structure, and pass this structure to the iap_api_init API. The allocSize in the iap_api_init API call is used to store the different flash context which is used in the api_core_context_t. The minimum size can be set to at least the size of (api_core_context_t).

These fields are managed by api_core_context_t parameter, the user application doesn't need to touch it.

NOTE

Before IAP APIs are used, caller needs to make sure that ELS clocks are enabled. This is required for correct operation of sbloader and iap_mem API on devices with security subsystem.

13.2.6.2 version

The version field indicates the IAP API version number in the device.

Prototype :

```
standard_version_t version;
```

Table 159. Definition of the version in IAP API tree

Parameter	Description

standard_version_t	Pointer to version structure to store current FLASH driver version information
	uint8_t bugfix; //!< bugfix version [7:0]
	uint8_t minor; //!< minor version [15:8]
	uint8_t major; //!< major version [23:16]
	char name; //!< character name is 0x4B = "K".

Example:

```
#define ROM_API_TREE ((uint32_t*)0x1303fc00)
#define IAP_API_TREE ((iap_api_interface_t*)ROM_API_TREE[13])
uint32_t IAPVersion = IAP_API_TREE-> version;
```

In this SoC, the version of IAP Driver is “0x4B030100”, it means the API version is 1.0.0.

13.2.6.3 iap_api_init

The API is used for initializing the IAP API context for the other IAP APIs, this API must be called prior to other IAP APIs.

Prototype :

```
status_t (*api_init)(api_core_context_t *coreCtx, const kp_api_init_param_t *param);
```

Table 160. Parameters used in iap_api_init API

Parameter	Description
coreCtx	Pointer to IAP API core context structure.
param	Pointer to IAP API initialization data structure, used for storing the data during execute the IAP APIs.

Example:

```
api_core_context_t apiCoreCtx;
const kp_api_init_param_t apiInitParam = { .allocStart = 0x30010000, .allocSize = 0x6000 };
uint32_t status = IAP_API_TREE->api_init(&apiCoreCtx, &apiInitParam);
```

See the possible status codes in Table 172. If the status is kStatus_Success return value, it means the IAP API operating environment has been init successfully.

13.2.6.4 iap_api_deinit

The API is used for deinitializing the IAP API context.

Prototype :

```
status_t (*api_deinit)(api_core_context_t *coreCtx);
```

Table 161. Parameters used in iap_api_deinit API

Parameter	Description
coreCtx	Pointer to IAP API core context structure.

Example:

```
uint32_t status = IAP_API_TREE->api_deinit(&apiCoreCtx);
```

See the possible status codes in Table 172. If the status is kStatus_Success return value, it means the IAP API operating environment has been freed and cannot call the other IAP APIs.

13.2.6.5 iap_mem_init

The API is used for initializing the memory interface, including the internal FLASH, RAM, FLEXSPI FLASH.

Prototype :

```
status_t (*iap_mem_init)(api_core_context_t *coreCtx);
```

Table 162. Parameters used in the iap_mem_init API

Parameter	Description
coreCtx	Pointer to IAP API core context structure.

Example:

```
uint32_t status = IAP_API_TREE->iap_mem_init(&apiCoreCtx);
```

See the possible status codes in Table 172. If the status is kStatus_Success return value, it means the IAP API memory interfaces have been init successfully.

NOTE

The mem_init will also be called in the api_init API, so the mem_init no need to be called again after calling the api_init.

13.2.6.6 iap_mem_write

The API is used for programing the data into the internal FLASH, RAM or the external FlexSPI FLASH based on the parameters, such as start address and memoryId, and this API must be called after the iap_api_init API.

Prototype :

```
status_t iap_mem_write(api_core_context_t *coreCtx, uint32_t start, uint32_t lengthInBytes, const
uint8_t *buf, uint32_t memoryId)
```

Table 163. Parameters used in iap_mem_write API

Parameter	Description
coreCtx	Pointer to IAP API core context structure.
start	Points to the program address.
lengthInBytes	Program data size in bytes. If the data size is less than 512 bytes or not an even multiple of 512 bytes, then the iap_mem_flush command must be called to write the remaining bytes.
buf	Pointer to source buffer data that will be programed.

memoryId	Points to the memory id of the different memory regions.
	#define kMemoryID_Internal (0x0U) //!< Internal FLASH/RAM ID
	#define kMemoryID_FFR (0x5U) //!< FFR region ID
	#define kMemoryID_FlexspiNor (0x9U) //!< FlexSPI NOR ID

Example 1:

```
uint32_t start1 = 0x10000 ;
uint8_t programBuffer[512];
for (uint32_t i=0; i<sizeof(programBuffer); i++)
{
    programBuffer[i] = (uint8_t)(i & 0xFF);
}
uint32_t status = IAP_API_TREE->mem_write(&apiCoreCtx, start1, sizeof(programBuffer), (uint8_t *)
programBuffer, 0);
```

Example 2:

```
uint32_t start2 = 0x80001000 ;
uint8_t programBuffer[512];
for (uint32_t i=0; i<sizeof(programBuffer); i++)
{
    programBuffer[i] = (uint8_t)(i & 0xFF);
}
uint32_t status = IAP_API_TREE->mem_write(&apiCoreCtx, start2, sizeof(programBuffer), (uint8_t *)
programBuffer, 9);
```

See the possible status codes in Table 172. If the status is kStatus_Success return value, it means the programBuffer data has been programed into the FLASH region in the example1 and programed into the external FlexSPI FLASH in the example2.

NOTE

- Before calling the mem_write API, the internal flash should be erased first by calling the iap_mem_erase.
- Before calling the mem_write API to program the data into the external FlexSPI FLASH, the external flash should be configured first by calling the iap_mem_config.
- If the programBufferis not 512 alignment or program the data into the ffr region, need to call the iap_mem_flush to program the last less than 512 data into the memory region.

NOTE

If the iap_mem_write used for the FlexSPI Flash data program, the program data should be padded page-alignment to use the iap_mem_flush API to load the expect program data.

13.2.6.7 iap_mem_fill

The API is used for filling the specified pattern data into the memory region with the specific data length. This API is mainly for filling the FLASH configuration option related words into the internal RAM. This API must be called after the iap_api_init API.

Prototype :

```
status_t iap_mem_fill(api_core_context_t *coreCtx, uint32_t start, uint32_t lengthInBytes, uint32_t
pattern, uint32_t memoryId)
```

Table 164. Parameters used in iap_mem_fill API

Parameter	Description
coreCtx	Pointer to IAP API core context structure.
start	Points to the program address.
lengthInBytes	Points to the program data size. Date size must be a multiple of 4 because the pattern is 32-bit.
pattern	Points to 32-bit data pattern that will be programed.

memoryId	Points to the memory id of the different memory regions.
	#define kMemoryID_Internal (0x0U) //!< Internal FLASH/RAM ID
	#define kMemoryID_FFR (0x5U) //!< FFR region ID
	#define kMemoryID_FlexspiNor (0x9U) //!< FlexSPI NOR ID

Example:

```
uint32_t start = 0x10000 ;
uint32_t pattern = 0xa5a55a5a;
uint32_t status = IAP_API_TREE->mem_fill(&apiCoreCtx, start, 0x2000, pattern, 0);
```

See the possible status codes in Table 172. If the status is kStatus_Success return value, it means the pattern data has been programed into the FLASH region (0x10000 – 0x12000).

13.2.6.8 iap_mem_erase

The API is used for erasing the internal FLASH region, FLEXSPI FLASH region via the memory interface. This API should be called after the iap_api_init API.

Prototype :

```
status_t iap_mem_erase(api_core_context_t *coreCtx, uint32_t start, uint32_t lengthInBytes, uint32_t
memoryId)
```

Table 165. Parameters used in iap_mem_erase API

Parameter	Description
coreCtx	Pointer to IAP API core context structure.
start	Points to the erase address.
lengthInBytes	Points to the erase size. The erase size must be 8KB alignment.

memoryId	Points to the memory id of the different memory regions.
	#define kMemoryID_Internal (0x0U) //!< Internal FLASH/RAM ID
	#define kMemoryID_FFR (0x5U) //!< FFR region ID
	#define kMemoryID_FlexspiNor (0x9U) //!< FlexSPI NOR ID

Example:

```
uint32_t start = 0x10000 ;
uint32_t lengthInBytes = 0x2000;
uint32_t status = IAP_API_TREE->mem_erase(&apiCoreCtx, start, lengthInBytes, 0);
```

See the possible status codes in Table 172. If the status is kStatus_Success return value, it means the FLASH region (0x10000 – 0x12000) has be erased.

13.2.6.9 iap_mem_erase_all

The API is used for erasing the entire internal FLASH or FLEXSPI FLASH based on the memoryId parameter. This API should be called after the iap_api_init API.

Prototype :

```
status_t iap_mem_erase_all(api_core_context_t *coreCtx, uint32_t memoryId)
```

Table 166. Parameters used in iap_mem_erase_all API

Parameter	Description
coreCtx	Pointer to IAP API core context structure.

memoryId	Points to the memory id of the different memory regions.
	#define kMemoryID_Internal (0x0U) //!< Internal FLASH/RAM ID
	#define kMemoryID_FlexspiNor (0x9U) //!< FlexSPI NOR ID

Example:

```
uint32_t status = IAP_API_TREE->mem_erase_all(&apiCoreCtx, 0);
```

See the possible status codes in Table 172. If the status is kStatus_Success return value, it means the FLASH region has be erased all.

13.2.6.10 iap_mem_config

The API is used for configuring the PRINCE for internal FLASH, IPED for the FlexSPI FLASH; it is also used for configuring the FLexSPI FLASH and enabling the dual image start address synchronization feature. The SWAP flash feature updates the dual image without considering whether the current active image is running in the bank0 or bank1. This API should be called after the iap_api_init API.

Prototype :

```
status_t iap_mem_config(api_core_context_t *coreCtx, uint32_t *config, uint32_t memoryId)
```

Table 167. Parameters used in iap_mem_config API

Parameter	Description
coreCtx	Pointer to IAP API core context structure.
config	Pointer to the configuration data which will be used for configuring the memory region with the specific encrypt feature based on the memory id.

memoryId	Points to the memory id of the different memory regions.
	#define kMemoryID_Internal (0x0U) //!< Internal FLASH/RAM ID
	#define kMemoryID_FlexspiNor (0x9U) //!< FlexSPI NOR ID

Example 1:

```
prince_prot_region_arg_t flashConfigOptionPrince = { .option = { .tag = 0x50 }, .start =
0x00010000, .length = 0x2000 };
uint32_t status = IAP_API_TREE->mem_config(&apiCoreCtx, (uint32_t *)&flashConfigOptionPrince, 0);
```

Example 2:

```
#define FLASH_OPTION_QSPI_SDR 0xc0000001
flexspi_iped_region_arg_t flashConfigOptionIped = { .option = { .tag = 0x49 }, .start =
0x80001000, .end = 0x80001800 };
uint32_t status = IAP_API_TREE->mem_config(&apiCoreCtx, (uint32_t *)& flashConfigOptionIped, 9);
serial_nor_config_option_t flashConfigOption = { .option0 = { .U = FLASH_OPTION_QSPI_SDR } };
status = IAP_API_TREE->mem_config(&apiCoreCtx, (uint32_t *)& flashConfigOption, 9);
```

Example 3:

```
typedef struct
{
    uint32_t reserved : 24;
    uint32_t tag : 8; // Fixed to 0x52 ('R')
} dual_image_update_option_t;
dual_image_update_option_t dualImgUpdateOption = { .tag = 0x52 };
uint32_t status = IAP_API_TREE->mem_config(&apiCoreCtx, (uint32_t *)& dualImgUpdateOption, 0);
```

See the possible status codes in Table 172. If the status is kStatus_Success return value, it means:

- The internal FLASH region 0x10000 – 0x12000 has been enable the PRINCE feature

- The external FlexSPI FLASH has been configured with the QSPI SDR mode and enable the region 0x80001000 – 0x80001800 IPED feature.
- The dual image start address synchronization feature has been enabled when using the dual image boot feature, the access address will be processed with the remap offset to access the actual address.

13.2.6.11 iap_mem_flush

The API is used after iap_mem_write for flushing the data stored in the memory buffer into the destination memory region. This API should be called after the iap_api_init API.

Prototype :

```
status_t iap_mem_flush(api_core_context_t *coreCtx);
```

Table 168. Parameters used in iap_mem_flush API

Parameter	Description
coreCtx	Pointer to IAP API core context structure.

Example:

```
uint32_t cfpastart = 0x0100_0000 ;
uint8_t cfpaBuffer[512];
for (uint32_t i=0; i<sizeof(cfpaBuffer); i++)
{
    cfpaBuffer [i] = (uint8_t)(i & 0xFF);
}
uint32_t status = IAP_API_TREE->mem_write(&apiCoreCtx, cfpastart, sizeof(cfpaBuffer), (uint8_t *)
cfpaBuffer, 5);
if (status != kStatus_Success)
{
    return status;
}
uint32_t status = IAP_API_TREE->mem_flush(&apiCoreCtx);
```

See the possible status codes in Table 172. If the status is kStatus_Success return value, it means the cfpaBuffer data has been programed into the CFPA region. In the process of the FFR program and when the data of programed into the internal and external FLASH region is not page-align, user need to call the iap_mem_flush after the iap_mem_write to store the data into the actual memory region.

13.2.6.12 api_sbloader_init

This API is used for initializing the sbloader state machine before calling the api_sbloader_pump. This API should be called after the iap_api_init API.

Prototype :

```
status_t api_sbloader_init(api_core_context_t *ctx);
```

Table 169. Parameters used in api_sbloader_init API

Parameter	Description
ctx	Pointer to IAP API core context structure.

Example:

```
uint32_t status = IAP_API_TREE-> sbloader_init (&apiCoreCtx);
```

See the possible status codes in Table 172. If the status is kStatus_Success return value, it means the sbloader runtime environment has been initialized successfully.

13.2.6.13 api_sbloader_pump

This API is used for handling the secure binary (SB3.1 format) data stream, which is used for image update, lifecycle advancing, etc. This API should be called after the iap_api_init and api_sbloader_init APIs.

Prototype :

```
status_t api_sbloader_pump(api_core_context_t *ctx, uint8_t *data, uint32_t length);
```

Table 170. Parameters used in api_sbloader_pump API

Parameter	Description
ctx	Pointer to IAP API core context structure.
data	Pointer to source data that is the sb file buffer data.
length	Points to the size of the process buffer data.

NOTE

If the api_sbloader_pump is used for the FlexSPI Flash data program, the program data should be padded to page-alignment and add additional few data (one Byte) to load the expect program data successfully.

If the api_sbloader_pump is used for internal flash operation, both the flash prefetch buffer and cache should be disabled before calling this API.

Example:

```
/* load the SB file chunk-by-chunk into chunk_processing_buffer */

get_chunk_from_SB_file(uint8_t * chunk_processing_buffer, uint8_t * SBfile_incoming_chunk, uint32_t
chunk_size);
status = IAP_API_TREE-> sbloader_pump(context, & chunk_processing_buffer, chunk_size);
```

See the possible status codes in Table 172. If the status is kStatus_Success return value, it means the sb data has been processed successfully.

13.2.6.14 api_sbloader_finalize

The API is used for finalizing the sbloader operations.

Prototype :

```
status_t api_sbloader_finalize(api_core_context_t *ctx)
```

Table 171. Parameters used in api_sbloader_finalize API

Parameter	Description
ctx	Pointer to IAP API core context structure.

Example:

```
status = IAP_API_TREE-> sbloader_finalize (context);
```

See the possible status codes in Table 172. If the status is kStatus_Success return value, it means the last sb data has programed successfully.

13.2.6.15 Possible return codes for IAP driver APIs

Table 172. Return and Error codes for IAP APIs

Error Code	Value	Description
kStatus_IAP_Success	0	IAP API execution succeeded
kStatus_IAP_Fail	1	IAP API execution failed
kStatus_IAP_InvalidArgument	100001	Invalid argument detected during API execution
kStatus_IAP_OutOfMemory	100002	The Heap size is not enough during API execution
kStatus_IAP_ReadDisallowed	100003	The read memory operation is disallowed during API execution
kStatus_IAP_CumulativeWrite	100004	The FLASH region to be programmed is not empty
kStatus_IAP_EraseFailure	100005	Erase operation failed
kStatus_IAP_CommandNotSupported	100006	The specific command is not supported
kStatus_IAP_MemoryAccessDisabled	100007	Memory access is disabled, typically occurred on the FLEXSPI NOR if it is not configured properly
kStatus_Success	0	Operation succeeded without error.
kStatus_Fail	1	The operation failed with a generic error.
kStatus_Invalidargument	4	The requested command's argument is undefined.
kStatusRomLdrSectionOverrun	10100	means reached the end of the sb file processing
kStatusRomLdrSignature	10101	the signature or version are incorrect

Table continues on the next page...

Table 172. Return and Error codes for IAP APIs (continued)

Error Code	Value	Description
kStatusRomLdrSectionLength	10102	the bootOffset/ new section count is out of range
kStatusRomLdrEOFReached	10104	the end of the image file is reached
kStatusRomLdrChecksum	10105	The checksum of a command tag block is invalid.
kStatusRomLdrCrc32Error	10106	The CRC-32 of the data for a load command is incorrect.
kStatusRomLdrUnknownCommand	10107	An unknown command was found in the SB file.
kStatusRomLdrIdNotFound	10108	There was no bootable section found in the SB file.
kStatusRomLdrDataUnderrun	10109	The SB state machine is waiting for more data.
kStatusRomLdrJumpReturned	10110	The function that was jumped to by the SB file has returned.
kStatusRomLdrCallFailed	10111	The call command in the SB file failed.
kStatusRomLdrKeyNotFound	10112	A matching key was not found in the SB file's key dictionary to unencrypt the section.
kStatusRomLdrSecureOnly	10113	The SB file sent is unencrypted, and security on the target is enabled.
kStatusRomLdrResetReturned	10114	The SB file reset operation has unexpectedly returned.
kStatusRomLdrRollbackBlocked	10115	An Image version rollback event detected
kStatusRomLdrInvalidSectionMacCount	10116	Invalid Section MAC count detected in the SB file
kStatusRomLdrUnexpectedCommand	10117	The command tag in the sb-file is unexpected
kStatusRomLdrBadSBKEK	10118	Bad SBKEK detected

13.2.6.16 IAP API examples

The section will provide the example to introduce all the IAP APIs usage and help users understand and use more deeply.

Example 1 (program the image or specific data into internal Prince enable region and update ffr region):

```
#define ROM_API_TREE ((uint32_t*)0x1303fc00)
#define IAP_API_TREE ((iap_api_interface_t*)ROM_API_TREE[13])
#define FLASH_BUFFER_LEN 0x500
#define CFPA_SCRATCH_ADDRESS 0x3dc00U
#define CMPA_ADDRESS 0x3e200U
#define CMPA_KEY_STORE_ADDRESS 0x3e400U
#define FLASH_PROGRAM_ADDRESS 0x10000;
#define FLASH_ERASE_LEN 0x2000;
#define flashMemId 0
#define ffrMemId 5

uint32_t s_buffer[FLASH_BUFFER_LEN];
```

```
for (uint32_t i = 0; i < FLASH_BUFFER_LEN; i++)
{
    s_buffer[i] = i;
}

uint32_t IAPVersion = IAP_API_TREE->version;
debug_printf("IAPVersion = %x\r\n", IAPVersion);
uint32_t status = kStatus_Success;
api_core_context_t apiCoreCtx;

/* User needs to provide the apiInitParam, which is used as the RAM region for the IAP APIs call */

const kp_api_init_param_t apiInitParam = { .allocStart = 0x30010000, .allocSize = 0x6000 };
status = IAP_API_TREE->api_init(&apiCoreCtx, &apiInitParam);

debug_printf("IAP API api_init return status=%d!\n",status);
if (status != kStatus_Success)
{
    return status;
}

/* config the internal flash region 0x10000 - 0x12000 with the prince feature to encrypt the data in
the region */

prince_prot_region_arg_t flashConfigOptionPrince = { .option = { .tag = 0x50 }, .start =
FLASH_PROGRAM_ADDRESS, .length = FLASH_ERASE_LEN };
status = IAP_API_TREE->mem_config(&apiCoreCtx, (uint32_t *)&flashConfigOptionPrince, flashMemId);
debug_printf("iap_mem_config prince status = %d\n", status);
if (status != kStatus_Success)
{
    return status;
}

status = IAP_API_TREE->mem_erase(&apiCoreCtx, FLASH_PROGRAM_ADDRESS, FLASH_ERASE_LEN, flashMemId);

debug_printf("iap_mem_erase return status=%d!\n",status);
if (status != kStatus_Success)
{
    return status;
}
status = IAP_API_TREE->mem_write(&apiCoreCtx, FLASH_PROGRAM_ADDRESS, sizeof(s_buffer), (uint8_t
*)s_buffer, flashMemId);
debug_printf("iap_mem_write status = %d\n", status);
if (status != kStatus_Success)
{
    return status;
}

/* If load data is not 512B-aligned, user needs to call mem_flush to program the last remaining data
that is not 512B-aligned */

status = IAP_API_TREE->mem_flush(&apiCoreCtx);
debug_printf("iap_mem_flush status = %d\n", status);
if (status != kStatus_Success)
{
    return status;
}

/* Here CfpaData is provided by the user and the version should be larger than the current cfpa
version */
```

```
status = IAP_API_TREE->mem_write(&apiCoreCtx, CFPA_SCRATCH_ADDRESS, sizeof(CfpaData), (uint8_t
*)&CfpaData, ffrMemId);
debug_printf("iap_mem_write cfpa data return status = %d\n", status);
if (status != kStatus_Success)
{
    return status;
}

/* User should always call mem_flush after mem_write to program the ffr data */

status = IAP_API_TREE->mem_flush(&apiCoreCtx);
debug_printf("iap_mem_flush cfpa data status = %d\n", status);
if (status != kStatus_Success)
{
    return status;
}

/* Here the CmpaData is provided by the user */

status = iap_mem_write(&apiCoreCtx, CMPA_ADDRESS, sizeof(CmpaData), (uint8_t *)&CmpaData, ffrMemId);
debug_printf("iap_mem_write status = %d\n", status);
if (status != kStatus_Success)
{
    return status;
}

/* User should always call mem_flush after mem_write to program the ffr data */

status = IAP_API_TREE->mem_flush(&apiCoreCtx);
debug_printf("iap_mem_flush cfpa data status = %d\n", status);
if (status != kStatus_Success)
{
    return status;
}

status = iap_api_deinit(&apiCoreCtx);
debug_printf("iap_api_deinit status = %x!\n", status);
if (status != kStatus_Success)
{
    return status;
}
```

Example 2 (FlexSPI Flash with IPED):

```

#define ROM_API_TREE ((uint32_t*)0x1303fc00)
#define IAP_API_TREE ((iap_api_interface_t*)ROM_API_TREE[13])
#define FLASH_OPTION_SEL 0xc0000001     /* Choose the QSPI SDR FlexSPI Flash option */
#define FLEXSPI_BASE_ADDR (0x80000000u) /* Flash Base Addresss for AHB access */
#define FLEXSPI_START_OFFSET (0x1000u)  /* Test address for IP access */
#define FLEXSPI_START_ADDR (FLEXSPI_BASE_ADDR + FLEXSPI_START_OFFSET) /* Test addresss for AHB access
*/
#define FLEXSPI_ERASE_SIZE (0x2000u)   /* Erase size in the demo */

uint32_t status = kStatus_Success;

api_core_context_t apiCoreCtx;

/* User needs to provide apiInitParam, which is used as the RAM region for the IAP APIs call */
```

```
const kp_api_init_param_t apiInitParam = { .allocStart = 0x30010000, .allocSize = 0x6000 };
status = IAP_API_TREE->api_init(&apiCoreCtx, &apiInitParam);

debug_printf("IAP API api_init return status=%d!\n",status);
if (status != kStatus_Success)
{
    return status;
}

/* Configure the FlexSPI flash region 0x80001000 - 0x80001800 with IPED feature */

uint32_t flexspiMemId = 9;
flexspi_iped_region_arg_t flashConfigOptionIped = { .option = { .tag = 0x49 }, .start =
0x80001000, .end = 0x80001800 };
status = IAP_API_TREE->mem_config(&apiCoreCtx, (uint32_t *)&flashConfigOptionIped, flexspiMemId);
debug_printf("iap_mem_config iped status = %d\n", status);
if (status != kStatus_Success)
{
    return status;
}

/* Configure the FlexSPI flash device with the selected option */

serial_nor_config_option_t flashConfigOption = { .option0 = { .U = FLASH_OPTION_SEL}};
status = IAP_API_TREE->mem_config(&apiCoreCtx, (uint32_t *)&flashConfigOption, flexspiMemId);
debug_printf("iap_mem_config status = %d\n", status);
if (status != kStatus_Success)
{
    return status;
}

status = IAP_API_TREE->mem_erase(&apiCoreCtx, FLEXSPI_START_ADDR, FLEXSPI_ERASE_SIZE, flexspiMemId);
debug_printf("iap_mem_erase returned status:%d\n", status);
if (status != kStatus_Success)
{
    return status;
}

/* Here the programBuffer data can also be replaced by the image data for app to boot in the FlexSPI
Flash boot mode */
uint32_t programBuffer[FLEXSPI_ERASE_SIZE / sizeof(uint32_t)];
uint8_t *pBuffer = (uint8_t *)&programBuffer[0];
for (uint32_t i = 0; i < sizeof(programBuffer); i++)
{
    *pBuffer++ = (uint8_t)(i & 0xFF);
}
status = IAP_API_TREE->mem_write(&apiCoreCtx, FLEXSPI_START_ADDR, sizeof(programBuffer),
(const uint8_t *)programBuffer, flexspiMemId);
debug_printf("iap_mem_write returned status:%d\n", status);
if (status != kStatus_Success)
{
    return status;
}
status = iap_api_deinit(&apiCoreCtx);
debug_printf("iap_api_deinit status = %x!\n", status);
if (status != kStatus_Success)
{
```

```
    return status;
}
```

Example 3 (update the dual-image into the internal flash):

```

#define ROM_API_TREE ((uint32_t*)0x1303e000)
#define IAP_API_TREE ((iap_api_interface_t*)ROM_API_TREE[13])
#define FLASH_PROGRAM_ADDRESS 0x0;
#define FLASH_ERASE_LEN 0x2000;
#define flashMemId 0

typedef struct
{
    uint32_t reserved : 24;
    uint32_t tag : 8; // Fixed to 0x52 ('R')
} dual_image_update_option_t;

uint32_t status = kStatus_Success;

api_core_context_t apiCoreCtx;

/* User needs to provide apiInitParam, which is used as the RAM region for the IAP APIs call */

const kp_api_init_param_t apiInitParam = { .allocStart = 0x30010000, .allocSize = 0x6000 };
status = IAP_API_TREE->api_init(&apiCoreCtx, &apiInitParam);

debug_printf("IAP API api_init return status=%d!\n",status);
if (status != kStatus_Success)
{
    return status;
}

/* Configure the dual-image update into specific lower version image region */

dual_image_update_option_t dualImgUpdateConfigOption = { .tag = 0x52 };
uint32_t flashMemId = 0x0U;
status = iap_mem_config(&apiCoreCtx, (uint32_t *)&dualImgUpdateConfigOption, flashMemId);
debug_printf("iap_mem_config status = %d\n", status);
if (status != kStatus_Success)
{
    return status;
}

/* The erase address will be processed with the remap offset to access the actual address; if the
lower version image is stored in the 0x0, the erase address will be 0; if the lower version image is
stored in the remap offset region, the erase address will be 0x0 + remap_offset; User does not need
to set the erase address, which is just processed by API. */

status = IAP_API_TREE->mem_erase(&apiCoreCtx, FLASH_PROGRAM_ADDRESS, FLASH_ERASE_LEN, flashMemId);

debug_printf("iap_mem_erase return status=%d!\n",status);
if (status != kStatus_Success)
{
    return status;
}

/* The write address will be processed with the remap offset to access the actual address; if the
lower version image is stored in the 0x0, the write address will be 0; if the lower version image is
```

```
stored in the remap offset region, the erase address will be 0x0 + remap_offset. User does not need
to set the write address, which is just processed by API. */

status = IAP_API_TREE->mem_write(&apiCoreCtx, FLASH_PROGRAM_ADDRESS, sizeof(s_buffer), (uint8_t
*)s_buffer, flashMemId);
debug_printf("iap_mem_write status = %d\n", status);
if (status != kStatus_Success)
{
    return status;
}

/* If the load data is not 512B-aligned, user needs to call mem_flush to program the last remaining
data that is not 512B-aligned */

status = IAP_API_TREE->mem_flush(&apiCoreCtx);
debug_printf("iap_mem_flush status = %d\n", status);
if (status != kStatus_Success)
{
    return status;
}
```

13.2.6.17 SBloader APIs

This section uses the SBloader APIs demo to introduce the SBloader APIs usage and helps the user to know how to use the APIs. In addition, the section uses the practical application scenarios to introduce the convenience, flexibility, and practicality of the SBloader APIs. The flow diagram of the SBloader APIs call demo is as follow:

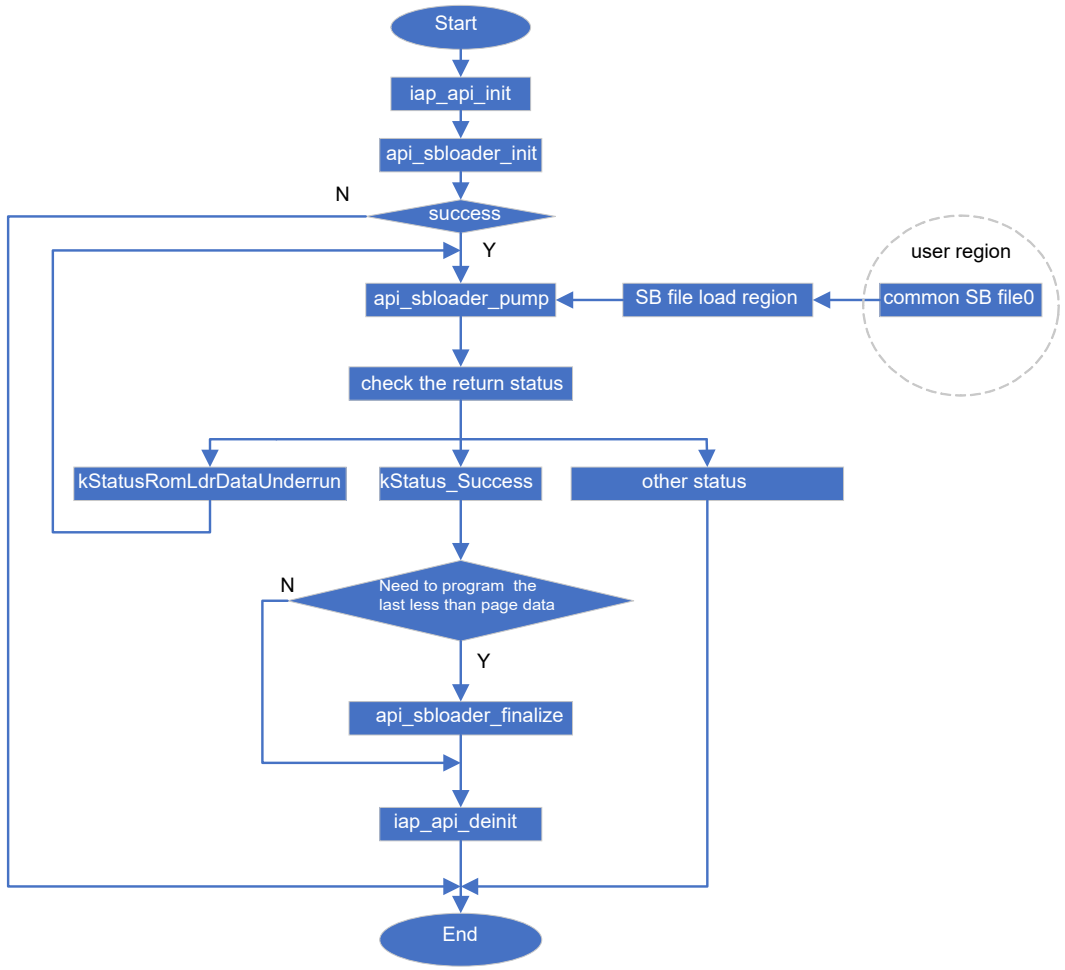

Figure 56. Flow diagram of the SBloader APIs call demo

The above flow diagram mainly introduces the SBloader APIs call flow. When the valid SB3.1 file has been generated and the necessary running environment (ROKTH and KeyBlob) has been setup up, the details can be found in Secure Boot ROM chapter. From the flow diagram, the iap_api_init will be called first to initialize and configure the IAP API core context. And then call the api_sbloader_init to initialize the loader state machine. If the api_sbloader_init return status is success, then the api_sbloader_pump will be called to process the SB file data stream, which is transferred from the user region (internal flash region, external flash region and RAM region apart from the reserved RAM region, list in the following).

1. 0x20008000 - 0x2000ffff
2. 0x30008000 - 0x3000ffff
3. 0x20010000 - 0x20017fff
4. 0x30010000 - 0x30017fff
5. 0x20060000 - 0x20067fff
6. 0x30060000 - 0x30067fff

In the running process of the api_sbloader_pump function, the return status includes three kinds of the results, which can be referred to in Table 172.Return and Error codes for IAP APIs. If the return status is kStatusRomLdrDataUnderrun, more data in the common SB_file0 should be transferred to the api_sbloader_pump to process, and the process has not reached the end of the SB file data. When the kStatus_Success has been received, common SB_file0 has been completely received and processed so

as to update the firmware in the SB_file0 successfully. The other status indicates that api_sbloader_pump API failed to execute. The iap_api_deinit will be executed to clear the IAP APIs context parameters.

In addition, in the process of executing the SB file in the api_sbloader_pump, only the load address of the SB file data will be transferred to the api_sbloader_pump, the data of the SB file is executed with the packet chunk. Users should get and load the packet chunk of the SB file into the ram region like the following function get_data_from_sbfile(), and then call the api_sbloader_pump to process the ram data repeatedly until to the end of the SB file. In transferring the SB file chunk to the device, the user can use different channels to receive the chunk data like UART, SPI, I2C, or USB interface.

Example:

```
#define ROM_API_TREE ((uint32_t*)0x1303e000)
#define IAP_API_TREE ((iap_api_interface_t*)ROM_API_TREE[13])
api_core_context_t apiCoreCtx = { .flashConfig.modeConfig.sysFreqInMHz = 96 };
const kp_api_init_param_t apiInitParam = { .allocStart = 0x30010000, .allocSize = 0x6000 };
uint32_t status = IAP_API_TREE->api_init(&apiCoreCtx, &apiInitParam);
if (status != kStatus_Success)
{
    return status;
}
uint32_t status = IAP_API_TREE->sbloader_init(&apiCoreCtx);
if (status != kStatus_Success)
{
    return status;
}
uint8_t user_buf[1024];
uint32_t size;
while ((status = get_data_from_sbfile(&buffer, &size)) == kStatus_Success)
{
    status = IAP_API_TREE->sbloader_pump(context, &buffer, size);
    if (status == kStatusRomLdrDataUnderrun)
    {
        /* continue to receive the data from SB file for processing */
        debug_printf("Warning: Success to execute ROM API erase, but need more data \n");
    }
    else if (status == kStatus_Success)
    {
        debug_printf("Completed: Success to execute ROM API erase\n");
        break;   /* finish the SB file firewarre update and break */
    }
    else if (status != kStatus_Success)
    {
        debug_printf("Error: Failed to run API kb_execute, status is hex(%x) \n", (uint32_t)status);
        return status;   /* return the fail status or other actions */
    }
}
status = IAP_API_TREE->sbloader_finalize (context);
if (status != kStatus_Success)
{
    debug_printf("Error: Failed to sbloader_finalize\n");
    return status;
}
```

Chapter 14
In-System Programming (ISP)

14.1 Overview

This chip includes ISP functions to support image programming from the serial interface (UART, I^2C, SPI, CAN) and USB HID.

NOTE

This chapter is also available in the *MCX N Security Reference Manual*, with differences related to security functionality. The version of this chapter in the reference manual does not include the security-relevant information.

14.1.1 Features

- Peripheral interfaces:
  - UART
  - I^2C
  - SPI
  - CAN
  - USB
- Automatic detection of the active peripheral
- UART peripheral implements auto-baud detection
- CAN peripheral implements auto-baud detection for predefined baud rates:
  - 1 Mbit/s
  - 500 kbit/s
  - 250 kbit/s
  - 125 kbit/s
- A common packet-based protocol for all peripherals
- Packet error detection and retransmission
- Flash-resident configuration options (in CMPA)
- RAM protection used by the bootloader while it is running
- Retrieval of the device properties, such as flash memory and RAM size
- Multiple options for executing the bootloader, either at system startup or under application control at runtime
- Support for internal flash memory access
- Support for encrypted image downloading
- External flash memory access
- In CMPA, user can use blhost tool command 'write-memory' to program or update the CMPA

14.2 Functional description

14.2.1 Bootloader

ISP stores the boot code in internal ROM. After a reset, the Arm processor starts its code execution from this memory. ISP executes the bootloader code every time the part is powered on, reset, or woken up from a deep power-down, low-power mode.

The bootloader provides a flash memory and OTP-eFuse programming utility that operates over a serial connection on the MCUs. It enables quick and easy programming of MCUs through the entire product lifecycle, including application development, final product manufacturing, and beyond. Host-side command line and GUI tools are available to communicate with the bootloader. Users can use host tools to upload and download application code and to perform manufacturing via the bootloader.

For information on bootloader operation and boot pin, see Overview.

14.2.2 In-system programming (ISP)

Serial booting and other related functions are supported in several different ways:

- ISP protocol
- Bootloader packet types
- Bootloader command set
- UART ISP
- I^2C ISP
- SPI ISP
- USB ISP
- CAN ISP

14.2.3 Memory map after reset

The boot ROM is located in the memory region beginning with the address 1300_0000h. Both the ISP and IAP software use parts of the on-chip RAM. Use of the RAM is described in ISP interrupt and SRAM use.

Based on the DEFAULT_ISP_MODE settings or ISP pin settings, the ROM enters ISP mode and can auto-detect activity on these interfaces:

- CAN
- I^2C
- SPI
- UART
- USB HID

The auto-detect looks for activity on these interfaces and selects the appropriate interface when a properly formed frame is received. If an invalid frame is received, the data is discarded and scanning resumes. Communications for these interfaces are described in In-System programming protocol and Bootloader packet types.

14.2.4 ISP interrupt and SRAM use

14.2.4.1 Interrupts during IAP

When the user application code starts executing, the interrupt vectors from the SRAM are active. Before making an IAP call, you must disable the interrupts. The IAP code does not use or disable interrupts.

14.2.4.2 RAM used by the ISP command handler

ISP reserves the regions designated below for bootloader use when the bootloader is running.

Table 173. RAM used by ROM during ROM execution

RAM region	Purpose
2000_8000h–2001_7FFFh 2001_8000h–2001_9FFFh	• BSS • RW • Stack • Heap 2001_8000h–2001_9FFFh (For the recovery sb loader file handling only)

14.2.5 ISP boot flow

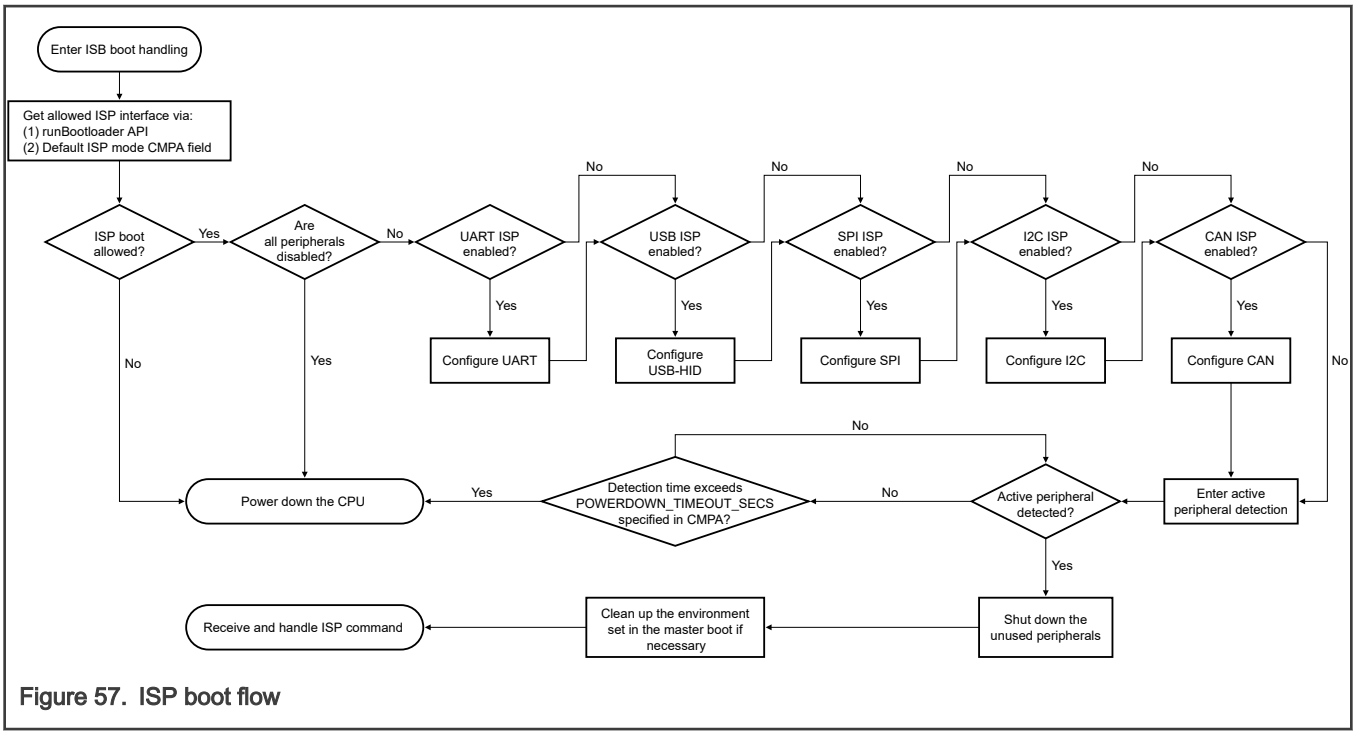

Figure 57. ISP boot flow

14.3 ISP protocol

This section explains the general protocol for packet transfers between the host and the bootloader. The description includes the transfer of packets for different transactions, such as commands with no data phase and commands with an incoming or outgoing data phase. The next section describes various packet types used in a transaction.

Each command sent from the host is replied to with a response command.

Commands can include an optional data phase:

- If the data phase is incoming (from the host to the bootloader), it is part of the original command.
- If the data phase is outgoing (from the bootloader to host), it is part of the response command.

14.3.1 Command with no data phase

The protocol for a command with no data phase contains:

1. Command packet (from the host).

2. GenericResponse command packet (to host).

The ACK sent in response to a command or a data packet can arrive at any time before, during, or after the command or data packet has been processed. See the diagrams in the Bootloader command set section.

14.3.2 Command with incoming data phase

The protocol for a command with incoming data phase contains:

1. Command packet (from host) (kCommandFlag_HasDataPhase set).
2. GenericResponse command packet (to host).
3. Incoming data packets (from the host).
4. GenericResponse command packet to host.

Note:

- The host may not send any further packets while it is waiting for the response to a command.
- The data phase is aborted if the GenericResponse packet, prior to the start of the data phase, does not have a status of kStatus_Success.
- Data phases may be aborted by the receiving side by sending the final GenericResponse early with a status of kStatus_AbortDataPhase. The host may abort the data phase early by sending a zero-length data packet.
- The final GenericResponse packet sent after the data phase includes the status of the entire operation.

14.3.3 Command with outgoing data phase

The protocol for a command with an outgoing data phase contains:

1. Command packet (from the host).
2. ReadMemory Response command packet (to host) (kCommandFlag_HasDataPhase set).
3. Outgoing data packets (to host).
4. GenericResponse command packet (to host).

- The data phase is considered part of the response command for the outgoing data phase sequence.
- The host may not send any further packets while the host is waiting for the response to a command.
- The data phase is aborted if the ReadMemory Response command packet, prior to the start of the data phase, does not contain the kCommandFlag_HasDataPhase flag.
- Data phases may be aborted by the device sending the final GenericResponse early with a status of kStatus_AbortDataPhase. The sending side may abort the data phase early by sending a zero-length data packet.
- The final GenericResponse packet sent after the data phase includes the status of the entire operation.

14.4 Bootloader packet types

14.4.1 Introduction

The bootloader device works in slave mode. All data communications are initiated by a host, which is either a PC or an embedded host. The bootloader device is the target, which receives a command or data packet. All data communications between host and target are packetized.

There are six types of packets used:

- Ping packet
- Ping response packet
- Framing packet

- Command packet
- Data packet
- Response packet

All fields in the packets are in little-endian byte order.

14.4.2 Ping packet

The ping packet is the first packet sent from a host to the target to establish a connection on the selected peripheral in order to run autobaud detection. The ping packet can be sent from host to target at any time that the target is expecting a command packet. If the selected peripheral is UART, a ping packet must be sent before any other communications. For other serial peripherals, it is optional.

In response to a ping packet, the target sends a ping response packet, discussed in the later sections.

Table 174. Ping packet format

Byte #	Value	Name
0	5Ah	Start byte
1	A6h	Ping

14.4.3 Ping response packet

The target sends a ping response packet back to the host after receiving a ping packet. If communication is over a UART peripheral, the target uses the incoming ping packet to determine the baud rate before replying with the ping response packet. After the ping response packet is received by the host, the connection is established, and the host starts sending commands to the target.

Table 175. Ping response packet format

Byte	Value	Parameter
0	5Ah	Start byte
1	A7h	Ping response code
2	00h	Protocol bugfix
3	03h	Protocol minor
4	01h	Protocol major
5	50h	Protocol name = 'P' (50h)
6	00h	Options low
7	00h	Options high
8	fbh	CRC16 low
9	40h	CRC16 high

To run autobaud for the UART peripheral, the ping response packet must be sent by the host when a connection is first established. For other serial peripherals, it is optional but recommended to determine the serial protocol version. The version number is in the same format as the bootloader version number returned by the GetProperty command.

14.4.4 Framing packet

The framing packet is used for flow control and error detection for the communications links that do not have such features built in. The framing packet structure sits between the link layer and the command layer. It wraps command and data packets as well.

Every framing packet containing data sent in one direction results in a synchronizing response framing packet in the opposite direction.

The framing packet described in this section is used for serial peripherals including the UART, CAN, I^2C, and SPI. The USB HID peripheral does not use framing packets. Instead, the packetization inherent in the USB protocol itself is used.

Table 176. Framing packet format

Byte	Value	Parameter	Description
0	5Ah	Start byte	—
1		PacketType	—
2		Length_low	Length is a 16-bit field that specifies the entire command or data packet size in bytes. —
3		Length_high	
4		Crc16_low	This is a 16-bit field. The CRC16 value covers entire framing packet, including the start byte and command or data packets, but does not include the CRC bytes. See CRC16 algorithm.
5		Crc16_high	
6....*n*		Command or Data packet payload	—

A special framing packet that contains only a start byte and a packet type is used for synchronization between the host and target.

Table 177. Special framing packet format

Byte	Value	Parameter
0	5Ah	Start byte
1	A*n*h	packetType

The Packet Type field specifies the type of packet from one of the defined types (below):

Table 178. Packet type field

Packet type	Name	Description
A1h	kFramingPacketType_Ack	The previous packet was received successfully; the sending of more packets is allowed.

Table continues on the next page...

Table 178. Packet type field (continued)

Packet type	Name	Description
A2h	kFramingPacketType_Nak	The previous packet was corrupted and must be re-sent.
A3h	kFramingPacketType_AckAbort	Data phase is being aborted.
A4h	kFramingPacketType_Command	The framing packet contains a command packet payload.
A5h	kFramingPacketType_Data	The framing packet contains a data packet payload.
A6h	kFramingPacketType_Ping	Sent to verify the other side is alive. Also used for UART autobaud.
A7h	kFramingPacketType_PingResponse	A response to ping. It contains the framing protocol version number and options.

14.4.5 CRC16 algorithm

The CRC is computed over each byte in the framing packet header, excluding the CRC16 field itself, and all of the payload bytes. The CRC algorithm is the XMODEM variant of CRC16.

The characteristics of the XMODEM variants are:

Table 179. CRC16 algorithm

Width	16
Polynomial	1021h
Init value	0000h
Reflect in	False
Reflect out	False
Xor out	0000h
Check result	31C3h

The check result is computed by running the ASCII character sequence "123456789" through the algorithm.

```
uint16_t crc16_update(const uint8_t * src, uint32_t lengthInBytes)
{
    uint32_t crc = 0;
    uint32_t j;
    for (j=0; j < lengthInBytes; ++j)
        {
            uint32_t i;
            uint32_t byte = src[j];
            crc ^= byte << 8;
            for (i = 0; i < 8; ++i)
                {
```

```
                    uint32_t temp = crc << 1;
                    if (crc & 8000h)
                        {
                            temp ^= 1021h;
                        }
                    crc = temp;
                }
        }
    return crc;
}
```

14.4.6 Command packet

The command packet carries a 32-bit command header and a list of 32-bit parameters.

Table 180. Command packet format

Command packet format (32 bytes)										
Command header (4 bytes)				28 bytes for Parameters (Max 7 parameters)						
Tag	Flags	Rsvd	Param Count	Param 1 (32-bit)	Param 2 (32-bit)	Param 3 (32-bit)	Param 4 (32-bit)	Param 5 (32-bit)	Param 6 (32-bit)	Param 7 (32-bit)

Table 181. Command header format

Byte #	Command header field	Description
0	Command or Response tag	The command header is 4 bytes long with these fields.
1	Flags	
2	Reserved. Must be 00h.	
3	ParameterCount	

The header is followed by 32-bit parameters up to the value of the ParameterCount field specified in the header. Because a command packet is 32 bytes long, only seven parameters can fit into the command packet.

- **Flags:** Each command packet contains a flag byte. Only bit 0 of the flag byte is used. If bit 0 of the flag byte is set to 1, then data packets follow the command sequence. The number of bytes that are transferred in the data phase is determined by a command-specific parameter in the parameters array.
- **ParameterCount:** The number of parameters included in the command packet.
- **Parameters:** The parameters are word-length (32 bits). With the default maximum packet size of 32 bytes, a command packet can contain up to seven parameters.

Command packets are also used by the target to send responses back to the host. As mentioned previously, command packets and data packets are embedded into framing packets for all transfers.

Table 182. Command tags

Command tag	Name	Description
01h	FlashEraseAll	The command tag specifies which command is supported by the bootloader. The valid command tags for the bootloader are listed here.[1]
02h	FlashEraseRegion	
03h	ReadMemory	
04h	WriteMemory	
05h	FillMemory	
06h	Reserved	
07h	GetProperty	
08h	ReceiveSbFile	
09h	Execute	
0Ah	Call	
0Bh	Reset	
0Ch	SetProperty	
0Dh	Reserved	
0Eh	eFuseProgram/FlashProgramOnce	
0Fh	eFuseRead/FlashReadOnce	
10h	Reserved	
11h	ConfigureMemory	
12h	Reserved	
13h	Reserved	
14h	Reserved	
15h	Reserved	
16h	TrustProvisioning	

1. The GetProperty, Reset, TrustProvisioning, SetProperty, and ReceiveSbFile are allowed in limited ISP mode.

Table 183. Response tags

Response tag	Name	Description
A0h	GenericResponse	The response tag specifies which of the responses the bootloader (target) returns to the host. The valid response tags are listed here.
A3h	ReadMemoryResponse	
A7h	GetPropertyResponse (used for sending responses to GetProperty command only)	
A3h	ReadMemoryResponse (used for sending responses to ReadMemory command only)	
AFh	FlashReadOnceResponse (used for sending responses to FlashReadOnce command only)	
B6h	TrustProvisioningResponse(used for sending response to TrustProvisioning command only)	

14.4.7 Response packet

The responses are carried using the same command packet format wrapped with framing packet data. Types of responses include:

- GenericResponse
- GetPropertyResponse
- ReadMemoryResponse
- FlashReadOnceResponse
- TrustProvisioningResponse

GenericResponse: After the bootloader has processed a command, the bootloader sends a generic response with status and command tag information to the host. GenericResponse is the last packet in the command protocol sequence. The GenericResponse packet contains the framing packet data and the command packet data (with GenericResponse tag = A0h) and a list of parameters (defined in the next section). The parameter count field in the header is always set to 2, for status code and command tag parameters.

Table 184. GenericResponse parameters

Byte #	Parameter	Description
0–3	Status code	Bootloader status error codes are errors encountered during the execution of a command by the target. If a command succeeds, then a kStatus_Success code is returned.
4–7	Command tag	The Command tag parameter identifies the response to the command sent by the host.

GetPropertyResponse: The GetPropertyResponse packet is sent by the target in response to the host query that uses the GetProperty command. The GetPropertyResponse packet contains the framing packet data and the command packet data, with the command or response tag set to a GetPropertyResponse tag value (A7h).

The parameter count field in the header is set to greater than 1, to always include the status code and one or many property values.

Table 185. GetPropertyResponse parameters

Byte #	Value	Parameter
0–3		Status code
4–7		Property value
. . .		. . .
		There can be up to a maximum of 6 property values, limited to the size of the 32-bit command packet and property type.

ReadMemoryResponse: The ReadMemoryResponse packet is sent by the target in response to the host sending a ReadMemory command. The ReadMemoryResponse packet contains the framing packet data and the command packet data, with the command or response tag set to a ReadMemoryResponse tag value (A3h), and the flags field set to kCommandFlag_HasDataPhase (1).

The parameter count is set to 2 for the status code and the data byte count parameters shown below.

Table 186. ReadMemoryResponse parameters

Byte #	Parameter	Description
0–3	Status code	The status of the associated Read Memory command.
4–7	Data byte count	The number of bytes sent in the data phase.

FlashReadOnceResponse: The FlashReadOnceResponse packet is sent by the target in response to the host sending a FlashReadOnce command. The FlashReadOnceResponse packet contains the framing packet data and the command packet data, with the commanresponse tag set to a FlashReadOnceResponse tag value (AFh), and the flags field set to 0. The parameter count is set to 2 plus the number of words requested to be read in the FlashReadOnceCommand.

Table 187. FlashReadOnceResponse parameters

Byte #	Value	Parameter
0–3		Status code
4–7		Byte count to read
. . .		. . .
		Can be up to 20 bytes of requested read data.

TrustProvisioningResponse: The TrustProvisioningResponse packet is sent by the target in response to the host sending a TrustProvisioning command. The TrustProvisioningResponse packet contains the framing packet data and command packet data, with the command or response tag set to a TrustProvisioningResponse tag value (B6h), and the flags field set to 0. The parameter count varies for different operations.

14.5 Bootloader command set

14.5.1 Introduction

All bootloader commands follow the command packet format wrapped by the framing packet as explained in previous sections.

For a list of status codes returned by bootloader see Bootloader status error codes.

14.5.2 GetProperty command

The GetProperty command is used to query the bootloader about various properties and settings. Each supported property has a unique 32-bit tag associated with it. The tag occupies the first parameter of the command packet. The target returns a GetPropertyResponse packet with the property values for the property identified with the tag in the GetProperty command.

Properties are the defined units of data that can be accessed with the GetProperty or SetProperty commands. Properties may be read-only or read-write. All read-write properties are 32-bit integers, so they can easily be carried in a command parameter.

The 32-bit property tag is the only parameter required for GetProperty command.

Table 188. Parameters for GetProperty Command

Byte #	Parameter
0 - 3	Property tag (which can be received from the GetProperty 0 command)
4 - 7	External Memory Identifier (only applies to GetProperty for external memory, or status identifier if the property tag is equal to 8).

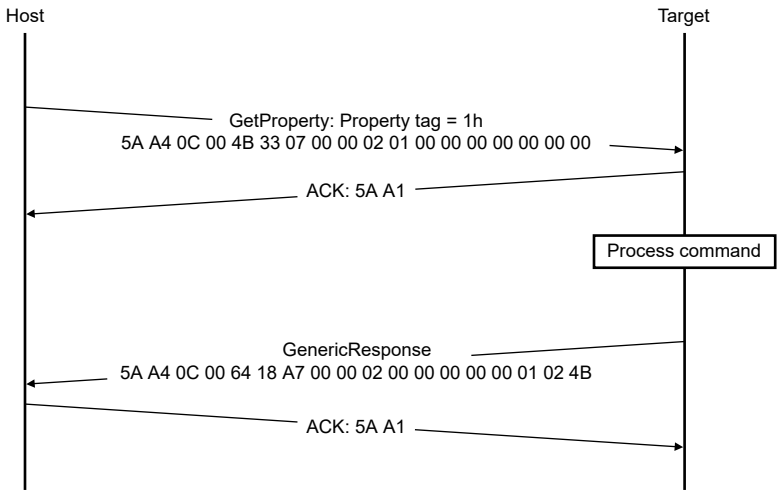

Figure 58. Protocol sequence for GetProperty command

Table 189. GetProperty command packet format (example)

GetProperty	Parameter	Value
Framing packet	Start byte	5Ah
	PacketType	A4h, kFramingPacketType_Command
	Length	0Ch 00h
	Crc16	4Bh 33h

Table 190. GetProperty command packet format (example)

GetProperty	Parameter	Value
Command packet	CommandTag	07h—GetProperty
	Flags	00h
	Reserved	00h
	ParameterCount	02h
	PropertyTag	0000_0001h—CurrentVersion
	Memory ID	0000_0000h—Internal Flash

The GetProperty command has no data phase.

Response: In response to a GetProperty command, the target sends a GetPropertyResponse packet with the response tag set to A7h. The parameter count indicates the number of parameters sent for the property values, with the first parameter showing status code 0, followed by the property value(s). Table 191 shows an example of a GetProperty response packet.

Table 191. GetProperty response packet format (example)

GetPropertyResponse	Parameter	Value
Framing packet	Start byte	5Ah
	PacketType	A4h, kFramingPacketType_Command
	Length	0Ch 00h (12 bytes)
	Crc16	07h 7Ah
Command packet	ResponseTag	A7h
	Flags	00h
	Reserved	00h
	ParameterCount	02h
	Status	0000_0000h
	PropertyValue	0000_014Bh—CurrentVersion

14.5.3 SetProperty command

The SetProperty command is used to change or alter the values of the properties or options of the bootloader. The command accepts the same property tags used with the GetProperty command. However, only some properties are writable. If an attempt to write a read-only property is made, an error is returned indicating the property is read-only and cannot be changed.

The property tag and the new value to set are the two parameters required for the SetProperty command.

Table 192. Parameters for SetProperty command

Byte #	Command
0—3	Property tag
4—7	Property value

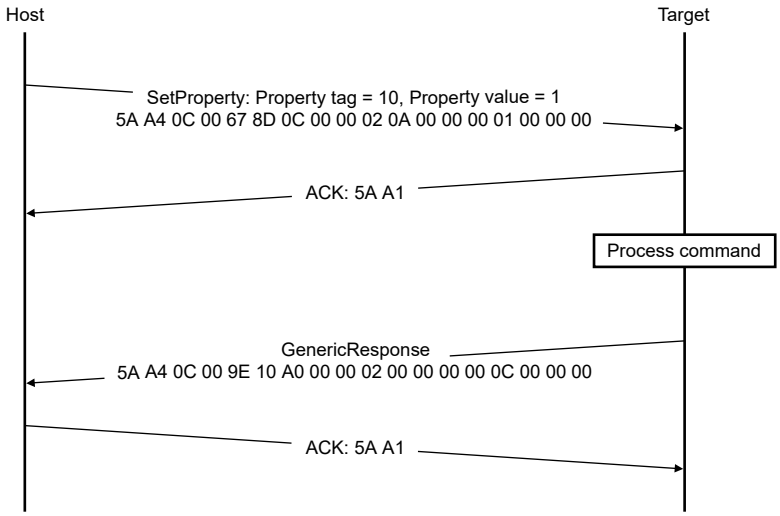

Figure 59. Protocol sequence for SetProperty Command

Table 193. SetProperty command packet format (example)

SetProperty	Parameter	Value
Framing packet	Start byte	5Ah
	PacketType	A4h, kFramingPacketType_Command
	Length	0Ch 00h
	Crc16	67h 8Dh
Command packet	CommandTag	0Ch—SetProperty with property tag 10
	Flags	00h
	Reserved	00h
	ParameterCount	02h
	PropertyTag	0000_000Ah—VerifyWrites
	PropertyValue	0000_0001h

The SetProperty command has no data phase.

Response: The target returns a GenericResponse packet with one of the following status codes:

Table 194. SetProperty response status codes

Status code
kStatus_Success
kStatus_ReadOnly
kStatus_UnknownProperty
kStatus_InvalidArgument

14.5.4 FlashEraseAll command

The FlashEraseAll command performs an erase of the entire flash memory (excluding IFR region). If any flash regions are protected, then the FlashEraseAll command fails and returns an error status code. The command tag for FlashEraseAll command is 01h set in the commandTag field of the command packet.

The FlashEraseAll command requires memory ID. If memory ID is not specified, the internal flash (memory ID = 0) is selected as default.

Table 195. Parameter for FlashEraseAll command

Byte #	Parameter	Value	Description
0-3	Memory ID	000h	Internal Flash
		09h	FlexSPI NOR
		110h	Serial NOR / EEPROM through SPI

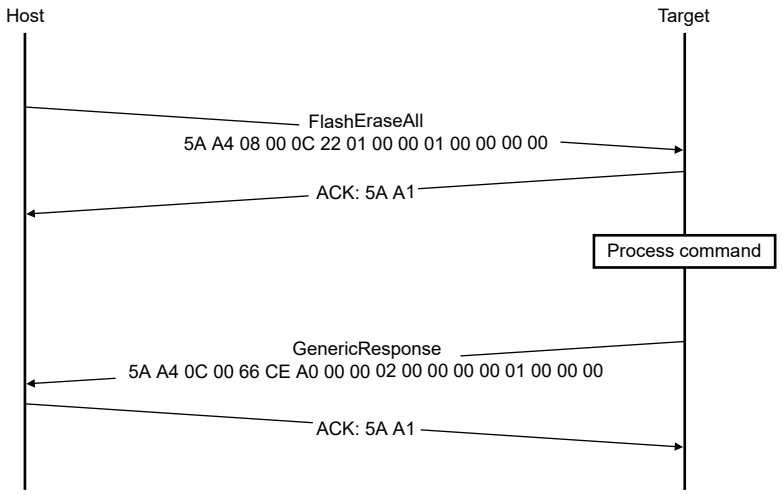

Figure 60. FlashEraseAll command

Table 196. FlashEraseAll command packet format (example)

FlashEraseAll	Parameter	Value
Framing packet	Start byte	5Ah
	PacketType	A4h, kFramingPacketType_Command
	Length	08h 00h
	Crc16	0Ch 22h
Command packet	CommandTag	01h—FlashEraseAll
	Flags	00h
	Reserved	00h
	ParameterCount	01h
	Memory ID	See the above table.

The FlashEraseAll command has no data phase.

Response: The target returns a GenericResponse packet with status code either set to kStatus_Success for successful execution of the command or set to an appropriate error status code.

14.5.5 FlashEraseRegion command

The FlashEraseRegion command performs an erase of one or more sectors of the flash memory.

The start address and number of bytes are the two parameters required for the FlashEraseRegion command. The start address and byte count parameters must be 4-byte aligned ([1:0] = 00), or the FlashEraseRegion command fails and returns kStatus_FlashAlignmentError (101). If the region specified does not fit in the flash memory space, the FlashEraseRegion command fails and returns kStatus_FlashAddressError (102). If any part of the region specified is protected, the FlashEraseRegion command fails and returns kStatus_MemoryRangeInvalid (10200).

Table 197. Parameter for FlashEraseRegion command

Byte #	Parameter
0–3	Start address
4–7	Byte count
8–11	Memory ID

The FlashEraseRegion command has no data phase.

Response: The target returns a GenericResponse packet with one of the following error status codes.

Table 198. FlashEraseRegion response status codes

Status code
kStatus_Success (0).

Table continues on the next page...

Table 198. FlashEraseRegion response status codes (continued)

Status code
kStatus_MemoryRangeInvalid (10200).
kStatus_FlashAlignmentError (101).
kStatus_IFlashAddressError (102).
kStatus_FlashAccessError (103).
kStatus_FlashProtectionViolation (104).
kStatus_FlashCommandFailure (105).

14.5.6 ReadMemory command

The ReadMemory command returns the contents of memory at the given address, for a specified number of bytes. This command can read any region of memory that is accessible by the CPU and not protected by security.

The start address and the number of bytes are the two parameters required for the ReadMemory command. The memory ID is optional. Internal memory is selected as the default if memory ID is not specified.

Table 199. Parameter for read memory command

Byte #	Parameter	Description
0–3	Start address	Start address of memory to read from
4–7	Byte count	Number of bytes to read and return to the caller
8–11	Memory ID	Internal or external memory identifier

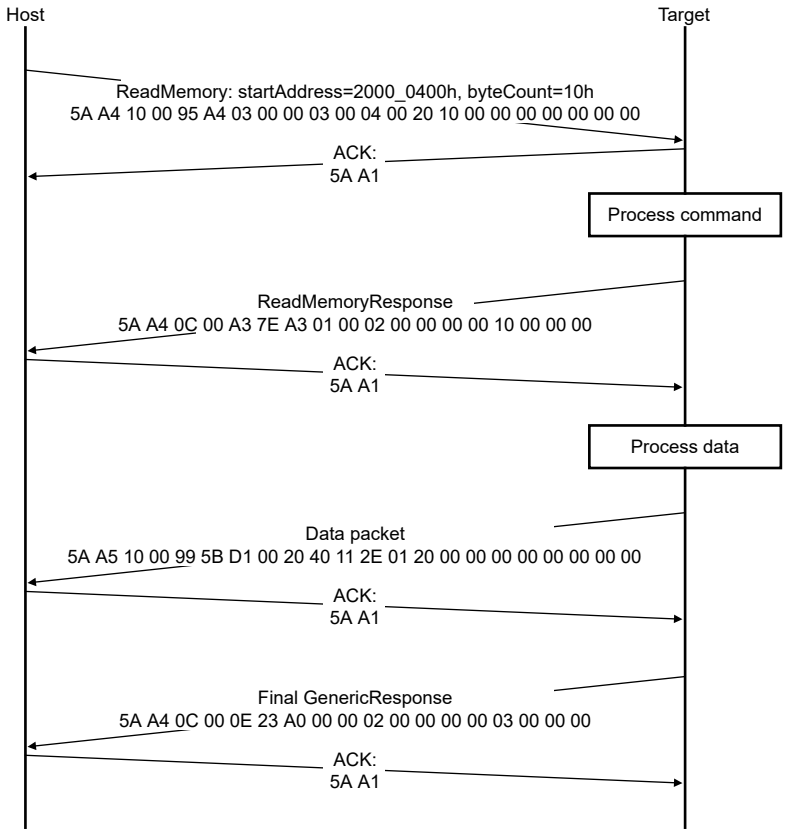

Figure 61. Command sequence for ReadMemory

Table 200. ReadMemory command packet format (example)

ReadMemory	Parameter	Value
Framing packet	Start byte	5Ah
	PacketType	A4h, kFramingPacketType_Command
	Length	10h 00h
	Crc16	F4h 1Bh
Command packet	CommandTag	03h—ReadMemory
	Flags	00h
	Reserved	00h
	ParameterCount	03h
	StartAddress	2000_0400h
	ByteCount	0000_0064h
	Memory ID	0h

Data phase: The ReadMemory command has a data phase. Because the target works in slave mode, the host needs to pull data packets until it has received the number of bytes of data specified in the byteCount parameter of the ReadMemory command.

Response: The target returns a GenericResponse packet with a status code either set to kStatus_Success (upon successful execution of the command) or set to an appropriate error status code.

14.5.7 WriteMemory command

The WriteMemory command writes data that is provided in the data phase to a specified range of bytes in memory (flash memory or RAM). However, if flash memory protection is enabled, then writes to protected sectors fail.

Consider the following information when you write to flash memory:

- First, any flash sector you write to must have been previously erased with a FlashEraseAll or FlashEraseRegion command.
- Writing to flash memory requires the start address to be page-aligned.
- The byte count is rounded up to a page size, and trailing bytes are filled with the flash erase pattern (FFh).
- If the VerifyWrites property is set to true, then writes to flash memory also perform a flash memory verify program operation.

When writing to RAM, the start address does not need to be aligned, and the data is not padded.

The two parameters required for the WriteMemory command are the start address and the number of bytes. The memory ID is optional. Internal memory is selected as the default if memory ID is not specified.

Table 201. Parameters for WriteMemory command

Byte #	Command
0–3	Start address
4–7	Byte count
8–11	Memory ID

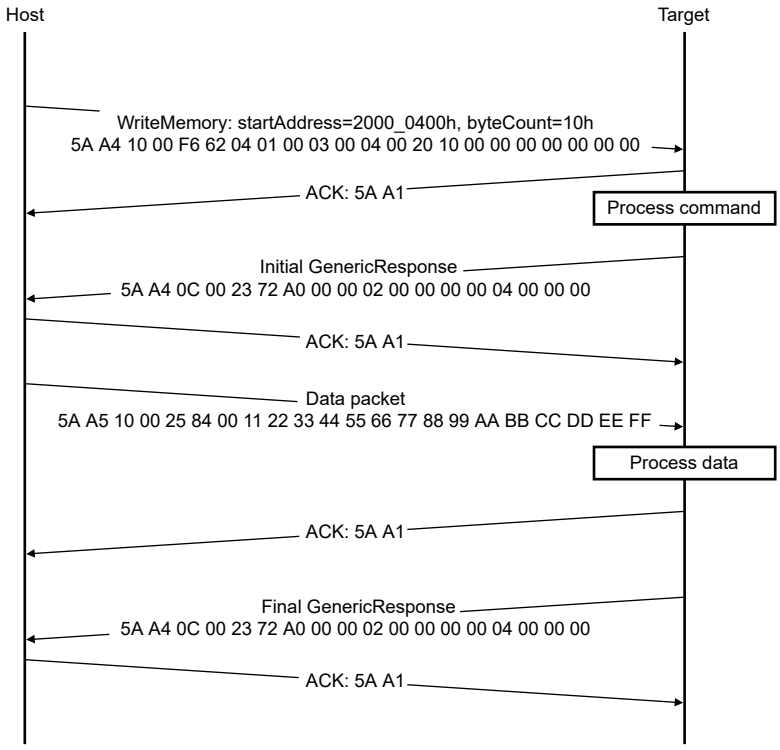

Figure 62. Protocol sequence for WriteMemory command

Table 202. WriteMemory command packet format (example)

WriteMemory	Parameter	Value
Framing packet	Start byte	5Ah
	PacketType	A4h, kFramingPacketType_Command
	Length	10h 00h
	Crc16	97h DDh
Command packet	CommandTag	04—WriteMemory
	Flags	01h
	Reserved	00h
	ParameterCount	03h
	StartAddress	2000_0400h
	ByteCount	0000_0064h
	Memory ID	0h

Data phase: The WriteMemory command has a data phase: the host sends data packets until the target has received the number of bytes of data specified in the byteCount parameter of the WriteMemory command.

Response: The target returns a GenericResponse packet with a status code set to kStatus_Success (upon successful execution of the command), or to an appropriate error status code.

14.5.8 FillMemory command

The FillMemory command fills a range of bytes in memory with a data pattern. It follows the same rules as the WriteMemory command. The difference between FillMemory and WriteMemory is that the FillMemory command parameter includes a data pattern. Also, there is no data phase for the FillMemory command, but WriteMemory does have a data phase.

Table 203. Parameters for FillMemory command

Byte #	Command
0–3	Start address of memory to fill
4–7	Number of bytes to write with the pattern • The start address must be 32-bit aligned. • The number of bytes must be evenly divisible by 4.
8–11	32-bit pattern

- To fill with a byte pattern (8-bit), the byte must be replicated four times in the 32-bit pattern.
- To fill with a short pattern (16-bit), the short value must be replicated two times in the 32-bit pattern.

For example, to fill a byte value with FEh, the word pattern is FEFE_FEFEh; to fill a short value 5AFEh, the word pattern is 5AFE_5AFEh.

Consider the following information when you write to flash memory:

- First, any flash memory sector you write to must have been previously erased with a FlashEraseAll or FlashEraseRegion command.
- Writing to flash memory requires the start address to be 4-byte aligned ([1:0] = 00).
- If the VerifyWrites property is set to true, then writes to flash memory also perform a flash memory verify program operation.

When writing to RAM, the start address does not need to be aligned, and the data is not padded.

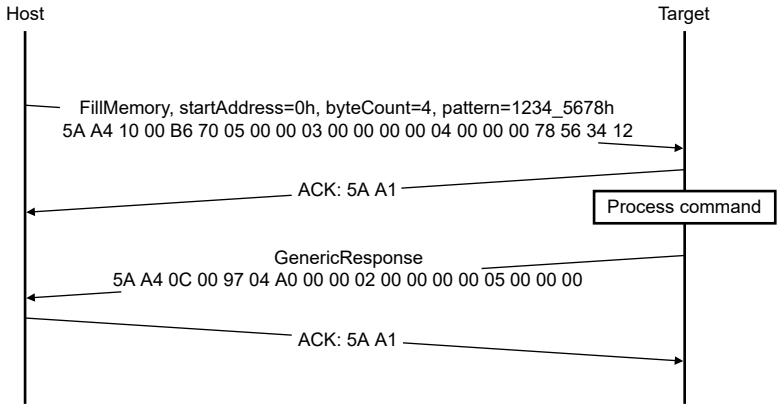

Figure 63. Protocol sequence for FillMemory command

Table 204. FillMemory command packet format (example)

FillMemory	Parameter	Value
Framing packet	Start byte	5Ah
	PacketType	A4h, kFramingPacketType_Command
	Length	10h 00h
	Crc16	E4h 57h
Command packet	CommandTag	05h—FillMemory
	Flags	01h
	Reserved	00h
	ParameterCount	03h
	StartAddress	0000_7000h
	ByteCount	0000_0800h
	PatternWord	1234_5678h

The FillMemory command has no data phase.

Response: The target (bootloader) returns a GenericResponse packet with a status code set to kStatus_Success (upon successful execution of the command), or to an appropriate error status code.

14.5.9 Execute command

The Execute command results in the bootloader setting of each of these items:

- The program counter to the code at the provided jump address
- R0 to the provided argument
- A stack pointer to the provided stack pointer address

Prior to the jump, the system returns to the Reset state.

The Execute command requires these parameters:

- Jump address
- Function argument pointer
- Stack pointer

If the stack pointer is set to zero, the called code is responsible for setting the processor stack pointer before using the stack.

Table 205. Parameters for Execute command

Byte #	Command
0–3	Jump address

Table continues on the next page...

Table 205. Parameters for Execute command (continued)

Byte #	Command
4–7	Argument word
8–11	Stack pointer address

The Execute command has no data phase.

Response: Before executing the Execute command, the target validates the parameters and returns a GenericResponse packet with a status code, set to either kStatus_Success or to an appropriate error status code.

14.5.10 Reset command

The Reset command results in the bootloader resetting the chip.

The Reset command requires no parameters.

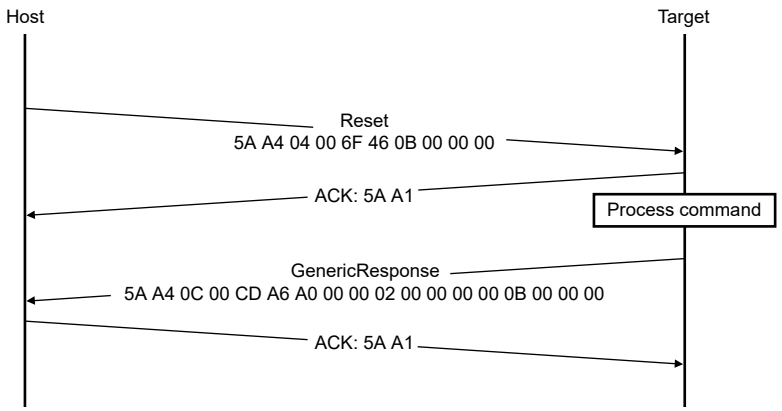

Figure 64. Protocol sequence for Reset command

Table 206. Reset command packet format (example)

Reset	Parameter	Value
Framing packet	Start byte	5Ah
	PacketType	A4h, kFramingPacketType_Command
	Length	04h 00h
	Crc16	6Fh 46h
Command packet	CommandTag	0Bh—reset
	Flags	00h
	Reserved	00h
	ParameterCount	03h

The Reset command has no data phase.

Response: Before resetting the chip, the target returns a GenericResponse packet with status code set to kStatus_Success.

You can also use the Reset command to switch boot from flash memory after successful flash image provisioning via the ROM bootloader. After issuing the Reset command, allow five seconds for the user application to start running from flash memory.

14.5.11 eFuseProgramOnce/FlashProgramOnce command

The FlashProgramOnce command writes data (provided in a command packet) to a specified range of bytes in the program-once field.

Consider the following information when you write to the program-once field:

- The program-once field only supports programming once, so any attempt to reprogram a program-once field generates an error response.
- Writing to the program-once field requires the byte count to be 4-byte aligned or 8-byte aligned.

The FlashProgramOnce command uses three parameters:

- Index 2
- byteCount
- Data

Table 207. Parameters for FlashProgramOnce command

Byte #	Command
0–3	Index of program-once field
4–7	Byte count (must be evenly divisible by 4)
8–11	Data

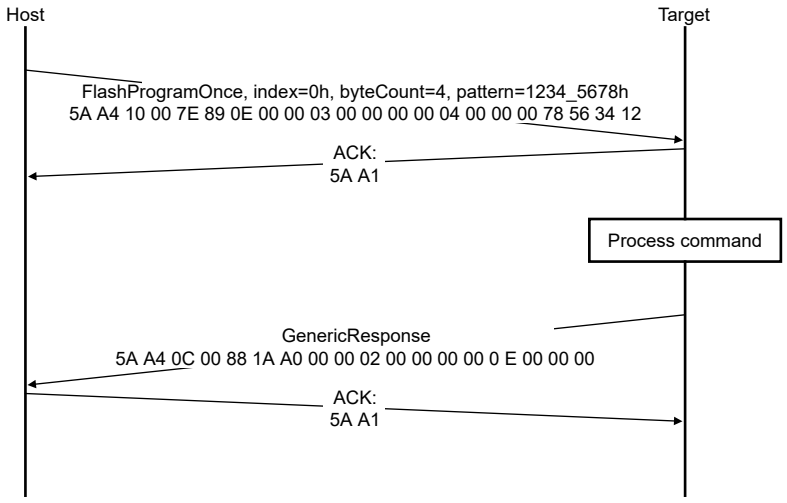

Figure 65. Protocol sequence for FlashProgramOnce command

Table 208. FlashProgramOnce command packet format

FlashProgramOnce	Parameter	Value
Framing packet	start byte	5Ah
	packetType	A4h, kFramingPacketType_Command
	length	10h 00h
	crc16	7E4h 89h
Command packet	commandTag	0Eh—FlashProgramOnce
	flags	0
	reserved	0
	parameterCount	3
	index	0000_0051h (the customer last efuse index)
	byteCount	0000_0004h
	Data	1234_5678h

Response: The target (MCX bootloader) returns a GenericResponse packet with a status code set to kStatus_Success (upon successful execution of the command), or to an appropriate error status code.

14.5.12 eFuseReadOnce / FlashReadOnce command

The FlashReadOnce command returns the contents of the program-once field by providing the given index and byte count.

The FlashReadOnce command uses two parameters: Index and byteCount. The eFuseReadOnce command uses only one parameter: Index.

Table 209. Parameters for FlashReadOnce command

Byte #	Parameter	Description
0–3	Index	Index of the program-once field (to read from)
4–7	byteCount	Number of bytes to read and return to the caller

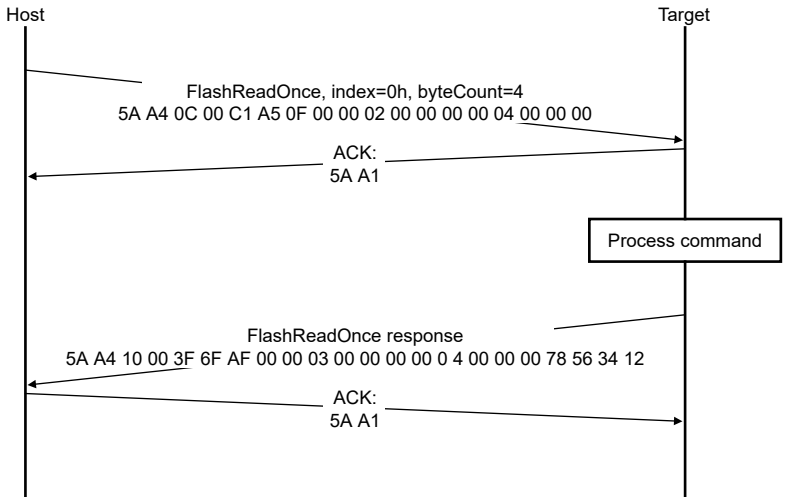

Figure 66. Protocol sequence for FlashReadOnce command

Table 210. FlashReadOnce command packet format

FlashReadOnce	Parameter	Value
Framing packet	start byte	5Ah
	packetType	A4h
	Length	0Ch 00h
	Crc	C1h A5h
Command packet	commandTag	0Fh—FlashReadOnce
	Flags	00h
	Reserved	00h
	parameterCount	02h
	Index	0000_0000h
	byteCount	0000_0004h

Table 211. FlashReadOnce response format

FlashReadOnce response	Parameter	Value
Framing packet	start byte	5Ah
	packetType	A4h
	Length	10h 00h

Table continues on the next page...

Table 211. FlashReadOnce response format (continued)

FlashReadOnce response	Parameter	Value
	CRC	3Fh 6Fh
Command packet	commandTag	AFh
	Flags	00h
	Reserved	00h
	parameterCount	03h
	Status	0000_0000h
	byteCount	0000_0004h
	Data	1234_5678h

Response: Upon successful execution of the command, the target returns:

- A FlashReadOnceResponse packet with a status code set to kStatus_Success
- A byte count
- A corresponding data read from the program-once field

If the execution was not successful, then the target returns a status code set to an appropriate error status and a byte count set to 0.

14.5.13 ConfigureMemory command

The ConfigureMemory command configures an internal or external memory device using a preprogrammed configuration block. The parameters passed in the command are:

- The memory ID
- The memory address from which the configuration data can be loaded

One case for loading the data could be a scenario where the configuration data is written to a RAM or flash memory location. This command would then direct the bootloader to use the data at that location for configuration of the external memory device.

Table 212. Parameters for ConfigureMemory command

Byte #	Command
0–3	Memory ID
4–7	Configuration block address

Response: The target (bootloader) returns a GenericResponse packet with a status code either set to kStatus_Success (upon successful execution of the command) or set to an appropriate error code.

The following table shows the supported memory IDs.

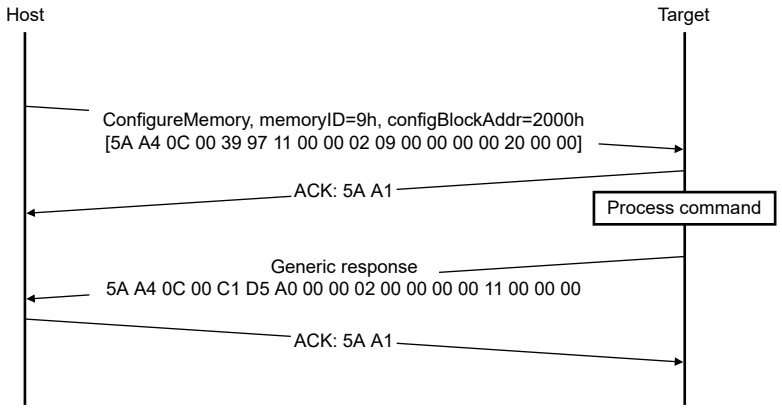

Figure 67. Protocol sequence for ConfigureMemory command

Table 213. Supported memory IDs

Memory ID	Description
0	Internal RAM/FLASH (used for the PRINCE configuration).
9h	External FlexSPI device. See Serial NOR Flash through FlexSPI.
110h	External 1-bit SPI NOR FLASH device. See 1-bit Serial NOR flash through SPI.

14.5.14 ReceiveSBFile command

The Receive SB File command (ReceiveSbFile) starts the transfer of an SB file to the target. This command only specifies the size in bytes of the SB file that is sent in the data phase. The SB file is processed as it is received by the bootloader.

Table 214. Parameters for Receive SB File command

Byte #	Command
0–3	Byte count

Data phase: The Receive SB file command has a data phase. The host sends data packets until the target has received the number of bytes specified in the byteCount parameter of the Receive SB File command.

Response: The target returns a GenericResponse packet with a status code set to the kStatus_Success (upon successful execution of the command) or set to an appropriate error code.

14.5.15 GetProperty/SetProperty command properties

This section lists the properties of the GetProperty and SetProperty commands.

Table 215. Properties used by GetProperty and SetProperty commands, sorted by value

Property	Writable	Tag value	Size	Description
CurrentVersion	No	01h	4	Current bootloader version
AvailablePeripherals	No	02h	4	The set of peripherals supported on this chip

Table continues on the next page...

Table 215. Properties used by GetProperty and SetProperty commands, sorted by value (continued)

Property	Writable	Tag value	Size	Description
FlashStartAddress	No	03h	4	Start address of program flash memory
FlashSizeInBytes	No	04h	4	Size in bytes of program flash memory
AvailableCommands	No	07h	4	The set of commands supported by the bootloader
Check Status	No	08h	4	Return the status based on the specified status identifier 0—CRC status 32-bit return value for CRC check 10401—Application CRC check failed 10402—Application CRC check is inactive 10403—Application CRC check invalid 1—Last Error See details of the last error in GetLastError property.
MaxPacketSize	No	0Bh	4	Maximum supported packet size for currently active peripheral interface.
ReservedRegions	No	0Ch	8 x *n*	List of memory regions reserved by bootloader. Returned as value pairs (<start-address-of-region>,<end-address-of-region>). If HasDataPhase flag is not set, then the response packet parameter count indicates the number of pairs. If HasDataPhase flag is set, then the second parameter is the number of bytes in the data phase. *n* indicates the number of memory region pairs.
SystemDeviceId	No	10h	4	Value from SYSCON's Device ID (DEVICE_ID0) and Chip Revision ID and Number (DIEID) registers.
LifeCycleState	No	11h	4	The life cycle of the device. 5AA5_5AA5h—Device is in development life cycle C33C_C33Ch—Device is in deployment life cycle
UniqueDevice/UUID	No	12h	16	Unique device identification.
Target ROM Version	No	18h	4	Target build version number.
ExternalMemoryAttributes	No	19h	24	List of attributes supported by the specified memory ID (110h = SPINOR FLASH). See description of the return value in ExternalMemoryAttributes property.
IrqNotifierPin	Yes	1ch	4	IRQ Notifier Pin setting: • bit[7:0]: GPIO pin • bit[15:8]: GPIO port • bit [30:16]: Reserved

Table continues on the next page...

Table 215. Properties used by GetProperty and SetProperty commands, sorted by value (continued)

Property	Writable	Tag value	Size	Description
				• bit[31]: Enable flag 0: disable, 1: enable

14.5.15.1 Property definitions

14.5.15.1.1 CurrentVersion property

The value of this property is a 4-byte structure containing the current version of the bootloader.

Table 216. CurrentVersion property fields

Bit	[31:24]	[23:16]	[15:8]	[7:0]
Field	Name = 'K' (4Bh)	Major version	Major version	Bugfix version

14.5.15.1.2 AvailablePeripherals property

The value of this property is the peripherals supported by the bootloader, and the hardware on which it runs.

Table 217. Peripheral bits

Bit	[31:7]	[6]	[5]	[4]	[3]	[2]	[1]	[0]
Field	Reserved	Reserved	Reserved	USB HID	CAN	SPI slave	I2C slave	LPUART

If the peripheral is available, then the corresponding bit is set in the property value. All reserved bits must = 0.

14.5.15.1.3 AvailableCommands property

This property value is a bit field that indicates the commands enabled in the bootloader. Only commands that can be sent from the host to the target are listed in the bit field. Response commands such as GenericResponse are excluded.

The bit number that identifies whether a command is present is the command's tag value minus 1. The value 1 is subtracted from the command tag because the lowest command tag value is 01h. To determine the bit mask for a given command, use this expression: mask = 1 << (tag – 1).

Table 218. Command bits

Bit	[Others]	[20]	[16]	[15]	[14]	[13]	[12]	[11]	[10]	[9]	[8]	[7]	[6]	[5]	[4]	[3]	[2]	[1]	[0]
Command																			

14.5.15.1.4 ExternalMemoryAttributes property

The value that this property returns is a 24-byte data structure containing available external memory attributes:

- Start address
- Total size (in KB)
- Page size
- Sector size
- Block size

Below is the breakdown of the 24-byte structure.

Table 219. Fields of ExternalMemoryAttributes property

Field offset	Field Description
0–3	The value returned is a bitmap showing the supported attributes for the external memory, with the corresponding bit field set. 0000_0001h—start address 0000_0002h—total size 0000_0004h—page size 0000_0008h—sector size 0000_0010h—block size
4–7	Start address of external memory
8–11	Total size of external memory in KB
12–15	Page size of external memory in bytes
16–19	Sector size of external memory in bytes
20–23	Block size of external memory in bytes

14.5.15.1.5 GetLastError property

The following table lists the response words and corresponding error conditions.

Table 220. Response word and error description

Response word	Error	Description
0B37_F300h	kLog_Auth_ImageTypeCheck_Fail	When checking the image type pass, the image type did not meet the authentication condition.
0B32_F300h	kLog_Auth_ReadKeyStore_Fail	The read of the keystore part from the RAM image or another keystore region failed.
0B34_F300h	kLog_Auth_VerifyHMAC_Fail	Failed to verify the mac key.
0B35_F300h	kLog_Auth_ImageEntryCheck_Fail	Application entry point is invalid or stack address is invalid.
0B36_F300h	kLog_Auth_Auth_Fail	The authentication of the image failed.
0B36_F301h	kLog_Auth_Auth_Fail_Time	The authentication failed, and the cost time has been loaded into the log data.
0B37_F300h	kLog_Auth_CrcCheck_Fail	CRC checksum is wrong.
0B37_F301h	kLog_Auth_CrcCheck_Fail_Time	The image CRC check failed and the cost time has been loaded into the log data.
0B37_FC00h	kLog_Auth_CrcCheck_Invalid	Either the image type or the image length = 0 did not meet the requirement of the CRC image.
0B38_F300h	kLog_Auth_Dice_Fail	Dice calculation failed.
0C00_F300h	kLog_Jump_Fail	The image jump failed.

Table 221. Response word and error description

Response word	Error	Description
0C00_F500h	kLog_Jump_Fail_Fatal	Failed to jump to application.
0702_F301h	kLog_Recoveryboot_Fail_Reason	Recovery boot failed.
0501_F300h	kLog_Masterboot_Init_Fail	The master boot initialization failed.
0801_F300h	kLog_Ispboot_Init_Fail	The ISP boot initialization failed, meaning there are no available ISP peripherals.
0901_F300h	kLog_BootDevice_Init_Fail	The boot device initialization failed.
0902_F300h	kLog_BootDevice_Read_Fail	The master boot failed to read the initial image.
0A20_F300h	kLog_ImgLoad_InitLoad_Fail	The master boot failed to load the image header part.
0A21_F300h	kLog_ImgLoad_RemainingLoad_Fail	Image header and configuration data loaded successfully; the remaining portion of the image failed to load.
0B30_DC00h	kLog_Auth_SecureBootDisabled	The secure boot has been disabled—no need to do authentication.

14.6 Bootloader status error codes

Table 222 describes the status error codes that the bootloader returns to the host.

Table 222. Bootloader status error codes, sorted by value

Error code	Value	Description
kStatus_Success	0	Operation succeeded without error
kStatus_Fail	1	Operation failed with generic error
kStatus_ReadOnly	2	Requested value is read-only and cannot be changed
kStatus_OutOfRange	3	Requested value is out of range
kStatus_InvalidArgument	4	Requested command's argument is undefined
kStatus_Timeout	5	Timeout occurred
kStatus_NoTransferInProgress	6	No send in progress
kStatus_FLASH_Success	0	API executed successfully
kStatus_FLASH_InvalidArgument	4	Invalid argument was provided
kStatus_FlashSizeError	100	Not used
kStatus_FlashAlignmentError	101	Address or length does not meet required alignment

Table continues on the next page...

Table 222. Bootloader status error codes, sorted by value (continued)

Error code	Value	Description
kStatus_FlashAddressError	102	Address or length is outside addressable memory.
kStatus_FLASH_CommandFailure	105	INT_STATUS[FAIL] = 1
kStatus_FlashUnknownProperty	106	Unknown flash memory property
kStatus_FlashEraseKeyError	107	Provided key does not match programmed flash memory key
kStatus_FlashRegionExecuteOnly	108	Area of flash memory is protected as execute-only
kStatus_FLASH_ExecuteInRamFunctionNotReady	109	Execute-in-RAM function is not available
kStatus_FLASH_CommandNotSupported	111	Flash memory API is not supported
kStatus_FLASH_ReadOnlyProperty	112	Flash memory property is read-only
kStatus_FLASH_InvalidPropertyValue	113	Flash memory property value out of range
kStatus_FLASH_InvalidSpeculationOption	114	Flash memory prefetch speculation option is invalid
kStatus_FLASH_EccError	116	A correctable or uncorrectable error occurred during command execution
kStatus_FLASH_CompareError	117	Destination and source memory contents do not match
kStatus_FLASH_RegulationLoss	118	Loss of regulation during read
kStatus_FLASH_InvalidWaitStateCycles	119	Wait state cycle set to read/write mode is invalid
kStatus_FLASH_OutOfDateCfpaPage	132	CFPA page version is out of date
kStatus_FLASH_BlankIfrPageData	133	Blank page cannot be read
kStatus_FLASH_EncryptedRegionsEraseNotDoneAtOnce	134	Encrypted flash memory subregions not erased at once
kStatus_FLASH_ProgramVerificationNotAllowed	135	Program verification not allowed when encryption enabled
kStatus_FLASH_HashCheckError	136	Hash check of page data failed
kStatus_FLASH_SealedFfrRegion	137	FFR region sealed

Table continues on the next page...

Table 222. Bootloader status error codes, sorted by value (continued)

Error code	Value	Description
kStatus_FLASH_FfrRegionWriteBroken	138	FFR spec region not allowed to be written discontinuously
kStatus_FLASH_NmpaAccessNotAllowed	139	NMPA region not allowed to be read, written, or erased
kStatus_FLASH_CmpaCfgDirectEraseNotAllowed	140	CMPA configuration region cannot be erased directly
kStatus_FLASH_FfrBankIsLocked	141	FFR bank region locked
kStatus_FLASH_CfpaScratchPageInvalid	148	CFPA scratch page invalid
kStatus_FLASH_CfpaVersionRollbackDisallowed	149	CFPA version rollback not allowed
kStatus_FLASH_ReadHidingAreaDisallowed	150	Flash memory hiding read not allowed
kStatus_FLASH_ModifyProtectedAreaDisallowed	151	Flash firewall page locked Erase and program are not allowed
kStatus_FLASH_CommandOperationInProgress	152	Flash memory state busy Flash memory command is in progress
kStatus_FLASH_IFR1_AccessNotAllowed	153	Access out of the IFR flash region
kStatus_FLASH_EraseVerifyFailed	154	The flash verify erase fail, indicate that flash is not erased
kStatus_UnknownCommand	10000	Command not recognized
kStatus_SecurityViolation	10001	Security violation happened when receiving disallowed commands
kStatus_AbortDataPhase	10002	Sender requested data phase termination
kStatus_Ping	10003	Ping command received from host
kStatus_NoResponse	10004	No response from host
kStatus_NoResponseExpected	10005	Expected no response from host
kStatus_CommandUnsupported	10006	Unsupported command received
kStatusRomLdrSectionOverrun	10100	Reached the end of SB file processing
kStatusRomLdrSignature	10101	Signature or version is incorrect
kStatusRomLdrSectionLength	10102	The bootOffset or new section count is out of range

Table continues on the next page...

Table 222. Bootloader status error codes, sorted by value (continued)

Error code	Value	Description
kStatusRomLdrUnencryptedOnly	10103	Unencrypted image disabled
kStatusRomLdrEOFReached	10104	End of image file has been reached
kStatusRomLdrChecksum	10105	Checksum of command tag block is invalid
kStatusRomLdrCrc32Error	10106	CRC-32 of the data for a load command is incorrect
kStatusRomLdrUnknownCommand	10107	Unknown command was found in SB file
kStatusRomLdrIdNotFound	10108	No bootable section found in SB file
kStatusRomLdrDataUnderrun	10109	SB state machine waiting for more data
kStatusRomLdrJumpReturned	10110	The function jumped to by the SB file has returned
kStatusRomLdrCallFailed	10111	Call command in SB file failed
kStatusRomLdrKeyNotFound	10112	Matching key to unencrypt the section not found in SB file's key dictionary
kStatusRomLdrSecureOnly	10113	SB file sent is unencrypted Security on the target is enabled
kStatusRomLdrResetReturned	10114	SB file reset operation has unexpectedly returned
kStatusRomLdrRollbackBlocked	10115	Image version rollback event detected
kStatusRomLdrInvalidSectionMacCount	10116	Invalid section MAC count detected in SB file
kStatusRomLdrUnexpectedCommand	10117	Command tag in SB file is unexpected
kStatusRomLdrBadSBKEK	10118	Bad SBKEK detected
kStatusRomLdrPendingJumpCommand	10119	Jump command pending Actual jump implemented in sbloader_finalize()
kStatusMemoryRangeInvalid	10200	Requested address range does not match an entry, or the length extends past the matching entry's end address
kStatusMemoryReadFailed	10201	Memory read failed
kStatusMemoryWriteFailed	10202	Memory write failed

Table continues on the next page...

Table 222. Bootloader status error codes, sorted by value (continued)

Error code	Value	Description
kStatusMemoryCumulativeWrite	10203	Cumulative write occurred due to a write to an unerased flash memory region
kStatusMemoryNotConfigured	10205	Memory was not configured before access
kStatusMemoryAlignmentError	10206	Alignment error during memory access
kStatusMemoryVerifyFailed	10207	Verifying operation failed after erasing or programming flash memory
kStatusMemoryWriteProtected	10208	Memory to be written is protected
kStatusMemoryAddressError	10209	Memory address is invalid or wrong
kStatusMemoryBlankCheckFailed	10210	Check of blank memory failed
kStatusMemoryBlankPageReadDisallowed	10211	Memory is blank Read command is disallowed
kStatusMemoryProtectedPageReadDisallowed	10212	Memory is protected Read command is disallowed
kStatusMemoryFfrSpecRegionWriteBroken	10213	Write operation to FFR region broken
kStatusMemoryUnsupportedCommand	10214	Memory command not supported
kStatus_UnknownProperty	10300	Requested property value undefined
kStatus_ReadOnlyProperty	10301	Requested property value cannot be written
kStatus_InvalidPropertyValue	10302	Specified property value invalid
kStatus_AppCrcCheckPassed	10400	CRC check valid and passed
kStatus_AppCrcCheckFailed	10401	CRC check valid but failed
kStatus_AppCrcCheckInactive	10402	CRC check inactive
kStatus_AppCrcCheckInvalid	10403	CRC check invalid because BCA invalid, or CRC parameters unset (all FFh bytes)
kStatus_AppCrcCheckOutOfRange	10404	CRC check valid, but addresses out of range
kStatus_RomApiExecuteCompleted	0	ROM successfully processed complete SB file or boot image
kStatus_RomApiNeedMoreData	10801	ROM needs more data to continue processing boot image

Table continues on the next page...

Table 222. Bootloader status error codes, sorted by value (continued)

Error code	Value	Description
kStatus_RomApiBufferSizeNotEnough	10802	User buffer not large enough for use by Kboot during execution
kStatus_RomApiInvalidBuffer	10803	User buffer not acceptable for sbloader or authentication
kStatus_FLEXSPI_SequenceExecutionTimeout	6000	FLEXSPI sequence execution timed out
kStatus_FLEXSPI_InvalidSequence	6001	FLEXSPI LUT sequence invalid
kStatus_FLEXSPI_DeviceTimeout	6002	FLEXSPI device timed out
kStatus_FLEXSPINOR_ProgramFail	20100	Page programming failure
kStatus_FLEXSPINOR_EraseSectorFail	20101	Sector erase failure
kStatus_FLEXSPINOR_EraseAllFail	20102	Chip erase failure
kStatus_FLEXSPINOR_WaitTimeout	20103	Execution timeout
kStatus_FlexSPINOR_NotSupported	20104	Page size overflow
kStatus_FlexSPINOR_WriteAlignmentError	20105	Address alignment error
kStatus_FlexSPINOR_CommandFailure	20106	Erase or Program verify error
kStatus_FlexSPINOR_SFDP_NotFound	20107	Timeout occurred during the API call
kStatus_FLEXSPINOR_Unsupported_SFDP_Version	20108	Unrecognized SFDP version
kStatus_FLEXSPINOR_FLASH_NotFound	20109	Flash memory detection failure
kStatus_FLEXSPINOR_DTRRead_DummyProbeFailed	20110	DDR read dummy probe failure
kStatus_IAP_Success	0	IAP API execution succeeded
kStatus_IAP_Fail	1	IAP API execution failed
kStatus_IAP_InvalidArgument	100001	Invalid argument detected during API execution
kStatus_IAP_OutOfMemory	100002	Heap size not large enough during API execution
kStatus_IAP_ReadDisallowed	100003	Read memory operation disallowed during API execution
kStatus_IAP_CumulativeWrite	100004	Flash memory region to be programmed is not empty

Table continues on the next page...

Table 222. Bootloader status error codes, sorted by value (continued)

Error code	Value	Description
kStatus_IAP_EraseFailuire	100005	Erase operation failed
kStatus_IAP_CommandNotSupported	100006	Specific command not supported
kStatus_IAP_MemoryAccessDisabled	100007	Memory access disabled **NOTE** Typically occurs on FLEXSPI NOR if it is not configured properly
kStatus_NBOOT_Success	5A5A_5A5Ahu	Operation successful in NBOOT functions
kStatus_NBOOT_Fail	5A5A_A5A5hu	Operation failed in NBOOT functions
kStatus_NBOOT_InvalidArgument	5A5A_A5F0hu	Invalid argument passed to function in NBOOT functions
kStatus_NBOOT_RequestTimeout	5A5A_A5E1hu	Operation timed out in NBOOT functions.
kStatus_NBOOT_KeyNotLoaded	5A5A_A5E2hu	Requested key not loaded in NBOOT functions
kStatus_NBOOT_AuthFail	5A5A_A5E4hu	Authentication failed in NBOOT functions
kStatus_NBOOT_OperationNotAvaialable	5A5A_A5E5hu	Operation not available on this hardware in NBOOT functions
kStatus_NBOOT_KeyNotAvailable	5A5A_A5E6hu	Key not available in NBOOT functions
kStatus_NBOOT_IvCounterOverflow	5A5A_A5E7hu	Overflow of IV counter (PRINCE/IPED) in NBOOT functions
kStatus_NBOOT_SelftestFail	5A5A_A5E8hu	FIPS self-test failure in NBOOT functions
kStatus_NBOOT_InvalidDataFormat	5A5A_A5E9hu	Invalid data format for example antipole in NBOOT functions
kStatus_NBOOT_IskCertUserDataTooBig	5A5A_A5EAhu	Size of user data in ISK certificate greater than 96 bytes in NBOOT functions
kStatus_NBOOT_IskCertSignatureOffsetTooSmall	5A5A_A5EBhu	Signature offset in ISK certificate smaller than expected in NBOOT functions
kStatus_NBOOT_MemcpyFail	5A5A_845Ahu	Unexpected error detected during nboot_memcpy() in NBOOT functions
kStatus_SKBOOT_Success	5AC3_C35Ahu	Operation successful in SKBOOT functions
kStatus_SKBOOT_Fail	C35A_C35Ahu	Operation failed in SKBOOT functions
kStatus_SKBOOT_InvalidArgument	C35A_5AC3hu	Return invalid argument status in SKBOOT functions
kStatus_MKBOOT_Success	0000_C35Ahu	Operation successful in master KBOOT
kStatus_MKBOOT_Fail	0000_C3C3hu	Operation failed in master KBOOT.

Table continues on the next page...

Table 222. Bootloader status error codes, sorted by value (continued)

Error code	Value	Description
kStatus_MKBOOT_InvalidArgument	0000_5AC3hu	Return Invalid argument status in Master KBOOT

NOTE

In UART, I2C, CAN, and SPI ISP modes, the ROM expects posted responses to be read by the host within (20 ms x number of bytes)—otherwise the ROM reports the terminate command. Because an ACK from the ROM is only two bytes, the host must read those bytes within 40 ms of the ROM posting.

14.7 UART ISP

14.7.1 Introduction

The bootloader integrates an autobaud detection algorithm for the UART peripheral, thereby providing flexible baud rate choices.

Autobaud feature: If you use UART*n* to connect to the bootloader, then you must keep the UART*n*_RX pin high and not left floating during the detection phase. You perform this action to comply with the autobaud detection algorithm. After the bootloader detects the ping packet (5Ah A6h) on UART*n*_RX, the bootloader firmware executes the autobaud sequence.

If the bootloader successfully detects the baud rate, then it sends a ping packet response [(5Ah A7h), protocol version (4 bytes), protocol version options (2 bytes), and crc16 (2 bytes)] at the detected baud rate. The bootloader then enters a loop, waiting for bootloader commands via the UART peripheral.

NOTE

The data bytes of the ping packet must be sent continuously (with no more than 80 ms between bytes) in a fixed UART transmission mode (8-bit data, no parity bit, and 1 stop bit). If the bytes of the ping packet are sent one by one with more than 80 ms delay between them, then the autobaud detection algorithm may calculate an incorrect baud rate. In this instance, the autobaud detection state machine should be reset.

The baud rate is closely related to the chip core and system clock frequencies. The typical supported baud rates are:

- 9600
- 19200
- 38400
- 57600
- 115200
- 230400
- 460800
- 1000000

Packet transfer: After autobaud detection succeeds, bootloader communications can take place over the UART peripheral:

- Figure 68 shows how the host detects an ACK from the target.
- Figure 69 shows how the host detects a ping response from the target
- Figure 70 shows how the host detects a command response from the target

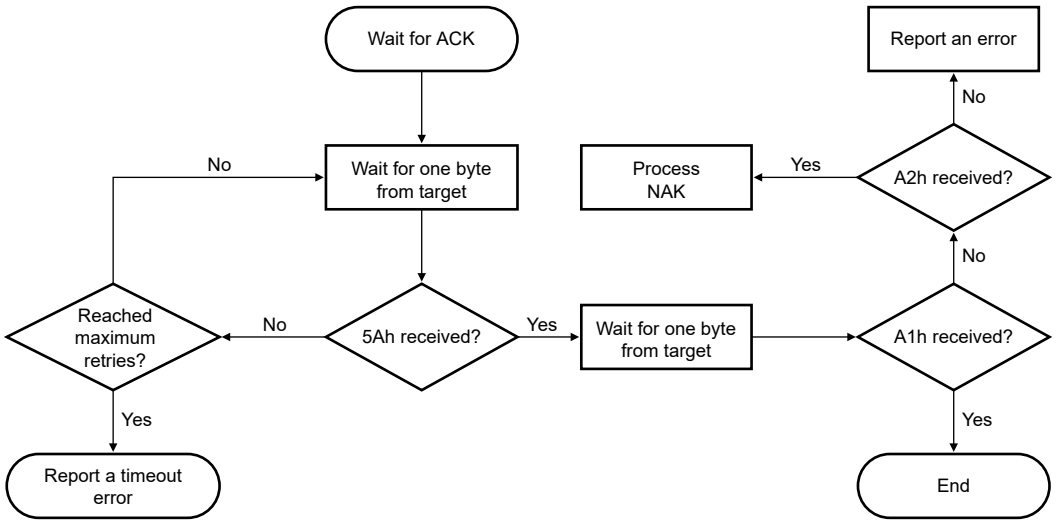

Figure 68. Host reads an ACK from target via UART

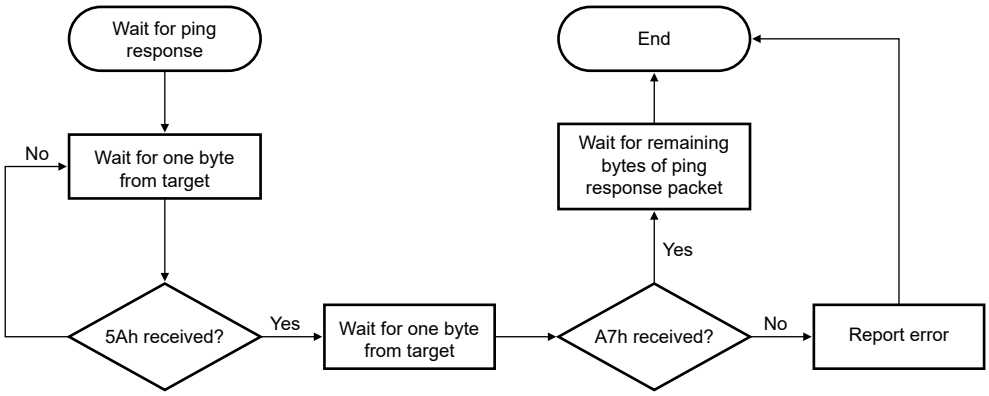

Figure 69. Host reads a ping response from target via UART

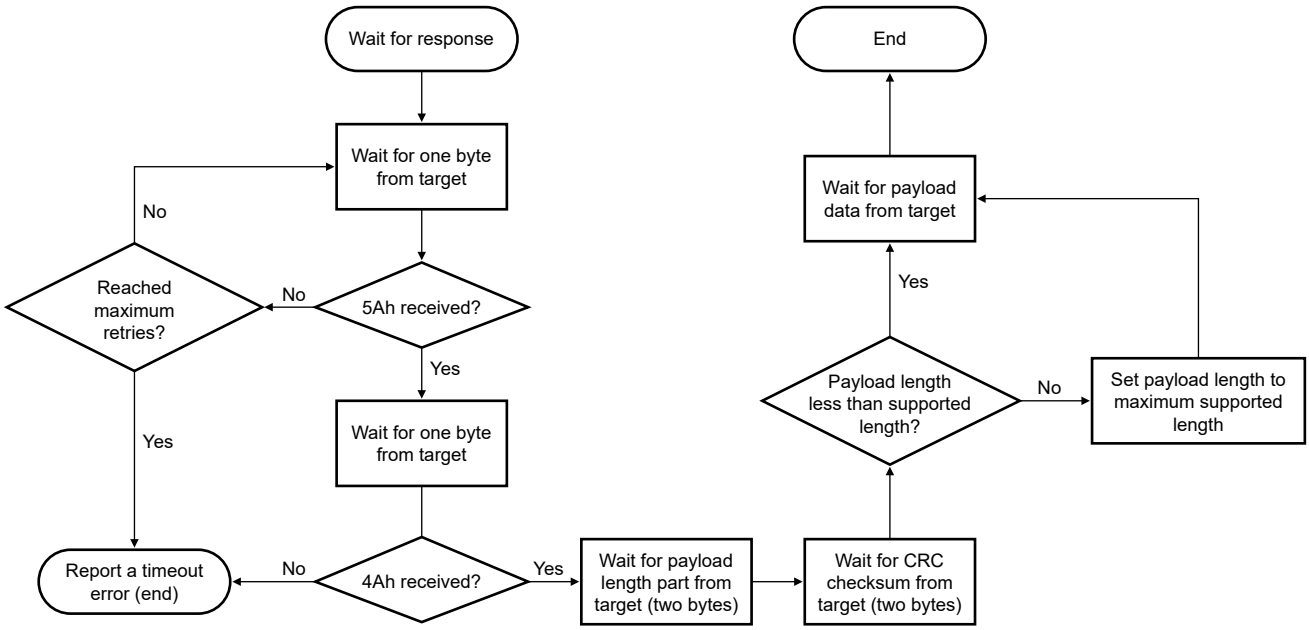

Figure 70. Host reads a command response from target via UART

For more information on UART ISP command, response, and data formats, see Bootloader packet types. For information on UART ISP commands, see Command packet.

14.8 I²C ISP

14.8.1 Introduction

The bootloader supports loading data into flash memory via the I²C peripheral, where the I²C peripheral serves as the I²C target. The transfer uses a 7-bit target address. The bootloader uses 10h as the I²C target address and supports up to 400 kbit/s as the I²C baud rate. You can also reconfigure the I2C slave address with the value from CMPA[I2C_SLAVE_ADDR](0x0100403C[7:0]).

The maximum supported I²C baud rate depends on the core clock frequency when the bootloader is running. The typical baud rate is 400 kbit/s with factory settings.

Because the I²C peripheral serves as an I²C target device, the host must start each transfer and fetch each outgoing packet:

- The host sends an incoming packet with a selected I²C target address, and the direction bit is set as write.
- The host reads an outgoing packet with a selected I²C target address, and the direction bit is set as read.
- If the target is busy with processing or preparing data, then the target sends 00h as the response to the host.

The following flowcharts show the communication flow of the host reading the ping and ACK packets, and the corresponding responses from the target.

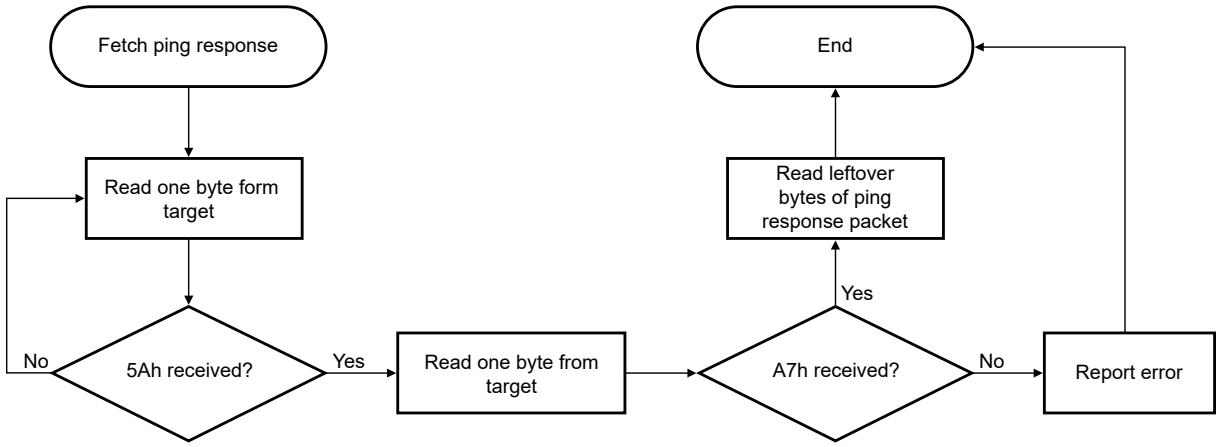

Figure 71. Host reads ping response from target via I²C

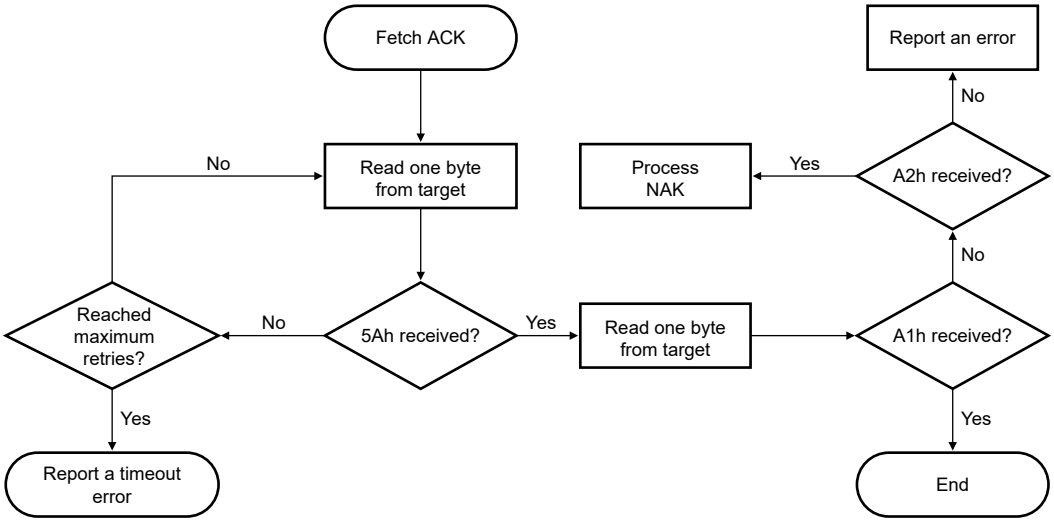

Figure 72. Host reads ACK packet from target via I²C

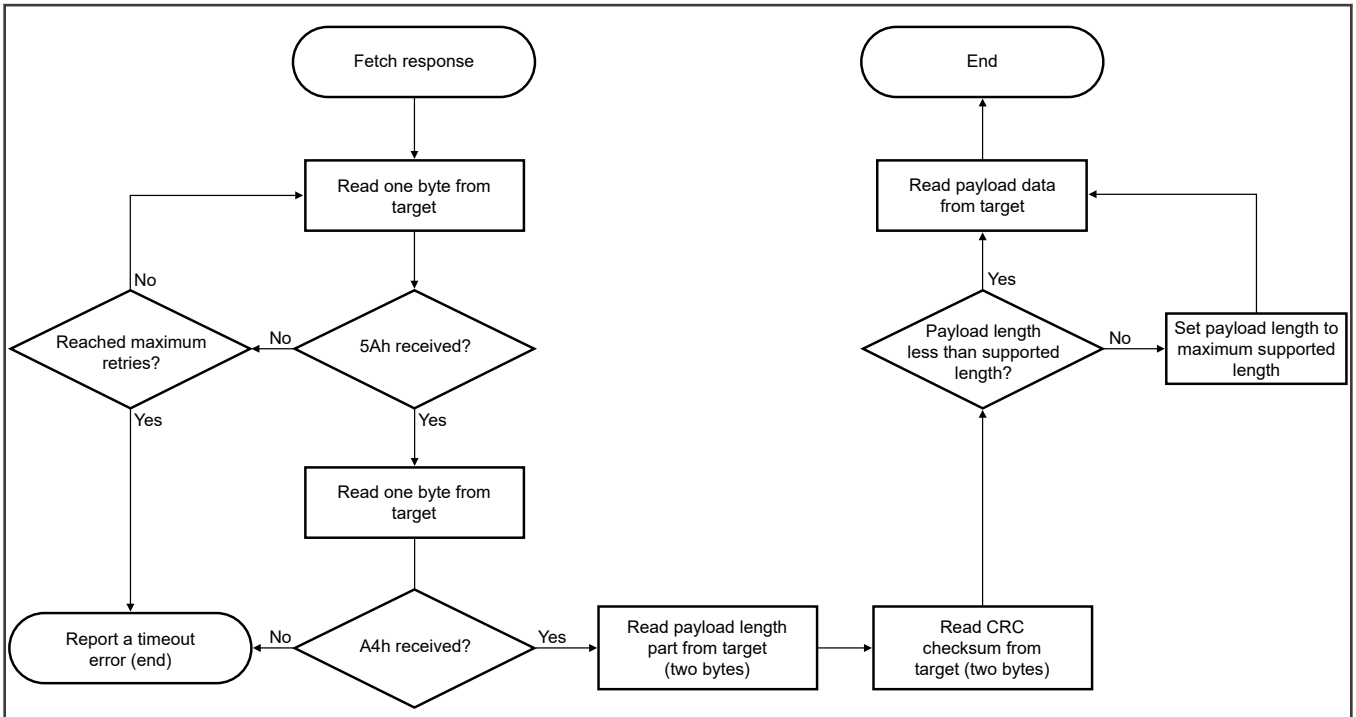

Figure 73. Host reads response from target via I²C

For more information on I²C ISP command, response, and data formats, see Bootloader packet types.

For more information on I²C ISP commands, see Bootloader command set.

14.9 SPI ISP

14.9.1 Introduction

The bootloader supports loading data into flash memory via the SPI peripheral, where the SPI peripheral serves as an SPI target. The SPI transfer should be in SPI mode 3 with 8 data bits.

The maximum supported baud rate of the SPI depends on the core clock frequency when the bootloader is running. The typical baud rate is 2000 kbit/s with the factory settings. The actual baud rate is lower or higher than 2000 kbit/s, depending on the actual value of the core clock.

Because the SPI peripheral serves as an SPI target device, the host must start each transfer and must fetch each outgoing packet.

The transfer on SPI is slightly different from I²C:

- The host receives 1 byte after it sends out any byte.
- Received bytes must be ignored when the host is sending out bytes to the target.
- The host starts reading bytes by sending 00h to the target.

The target sends the byte 00h as a response to the host if the target is under the following conditions:

- Processing incoming packet
- Preparing outgoing data
- Received invalid data

The bootloader also supports the active notification pin (nIRQ pin) to notify the host processor that it is busy or ready for new commands or data.

To accelerate the SPI transfer between the host and the bootloader, the bootloader provides the nIRQ pin, which you enable with the SetProperty command. After you enable it, the host must wait until it sees a negative edge on the nIRQ pin before reading any data from the bootloader. It must also wait until the nIRQ pin is high before sending any data to the bootloader.

See the figure below for the typical physical connection between the host and the bootloader device.

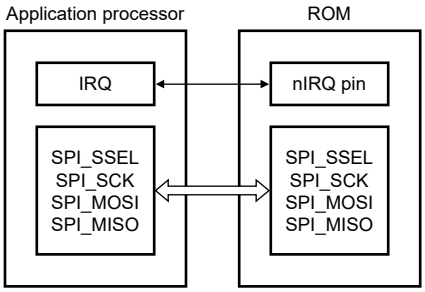

Figure 74. Physical interface for SPI ISP

The following flowcharts show how the host reads a ping response, an ACK, and a command response from the target via SPI, without the nIRQ pin enabled.

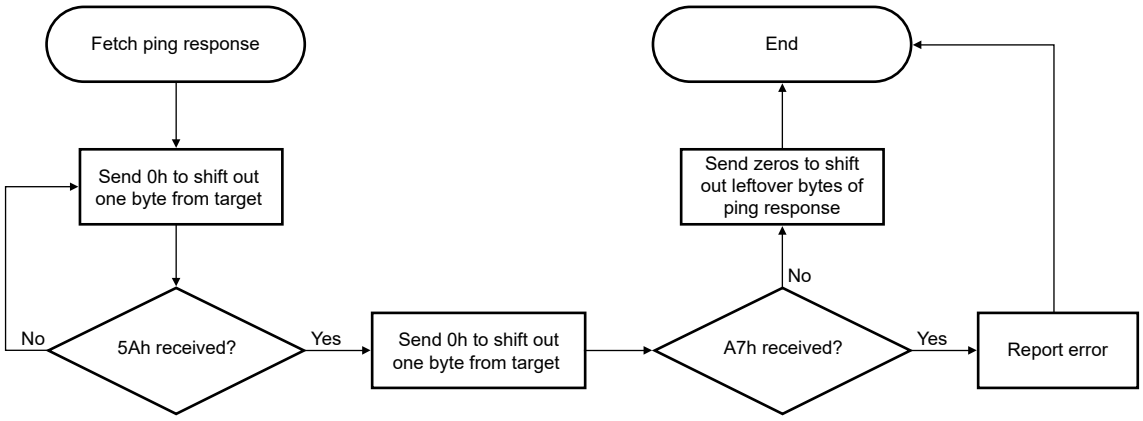

Figure 75. Host reads ping packet from target via SPI

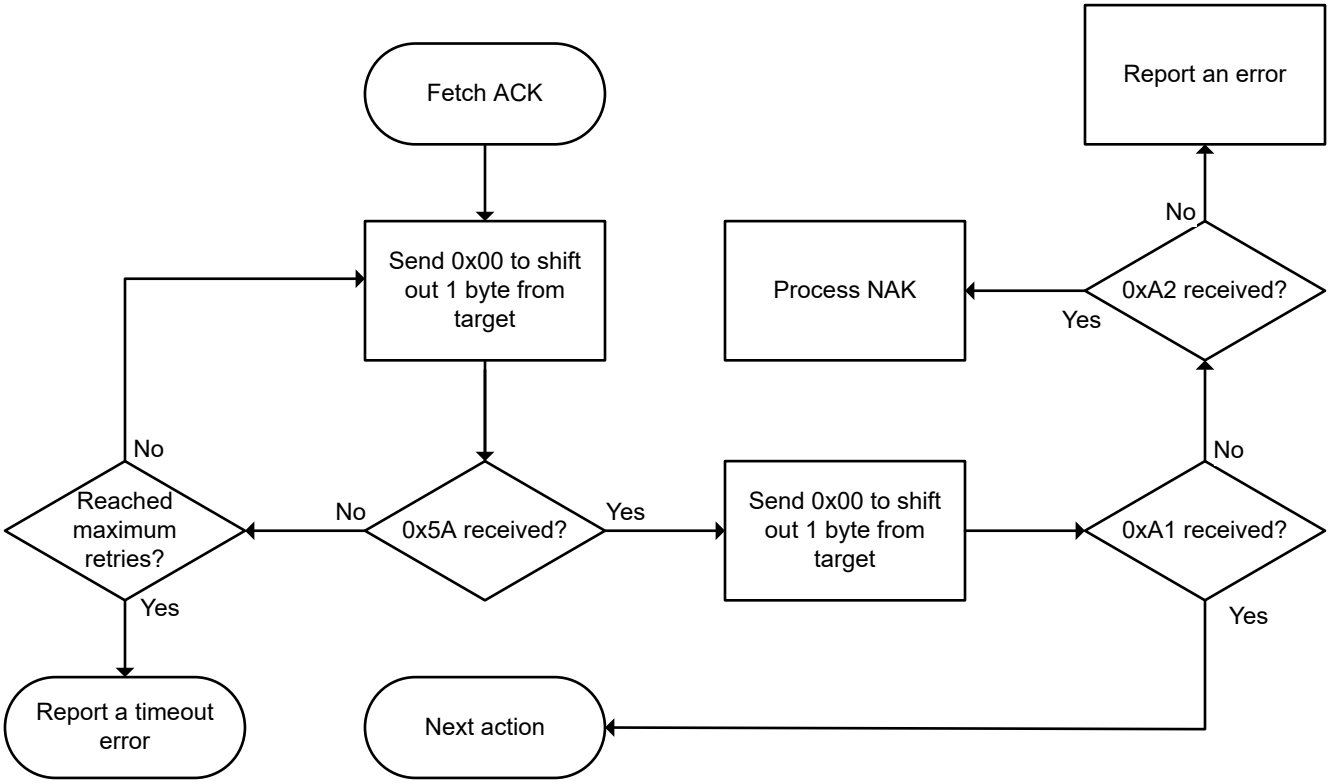

Figure 76. Host reads ACK from target via SPI

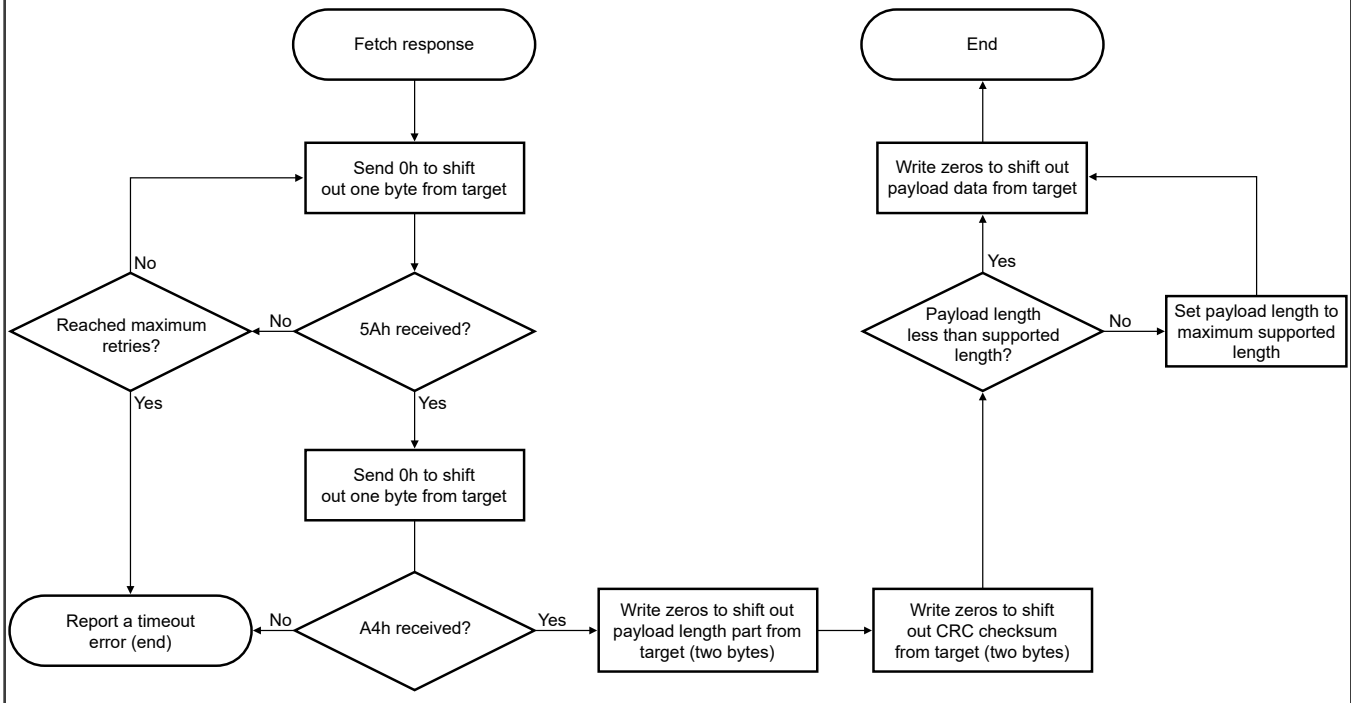

Figure 77. Host reads response from target via SPI

For more information on the command, response, and data formats of SPI ISP, see Bootloader packet types.

For more information on SPI ISP commands, see Bootloader command set.

14.9.2 Host read ACK(5Ah, A1h) packet timing restriction

If the ISP protocol does not use the IRQ pin, then the host must use the data-fetching timing for ACK from the chip:

- After sending out the command, the host must wait for at least 100 µs before polling the start byte 5Ah of the ACK packet sent by the chip. If the fetched data is not 5Ah, delay 100 µs and poll to reread 5Ah.
- For the ACK packet (5Ah, A1h): After the host receives 5Ah, you must add a 50 µs delay before fetching the A1h from the chip.

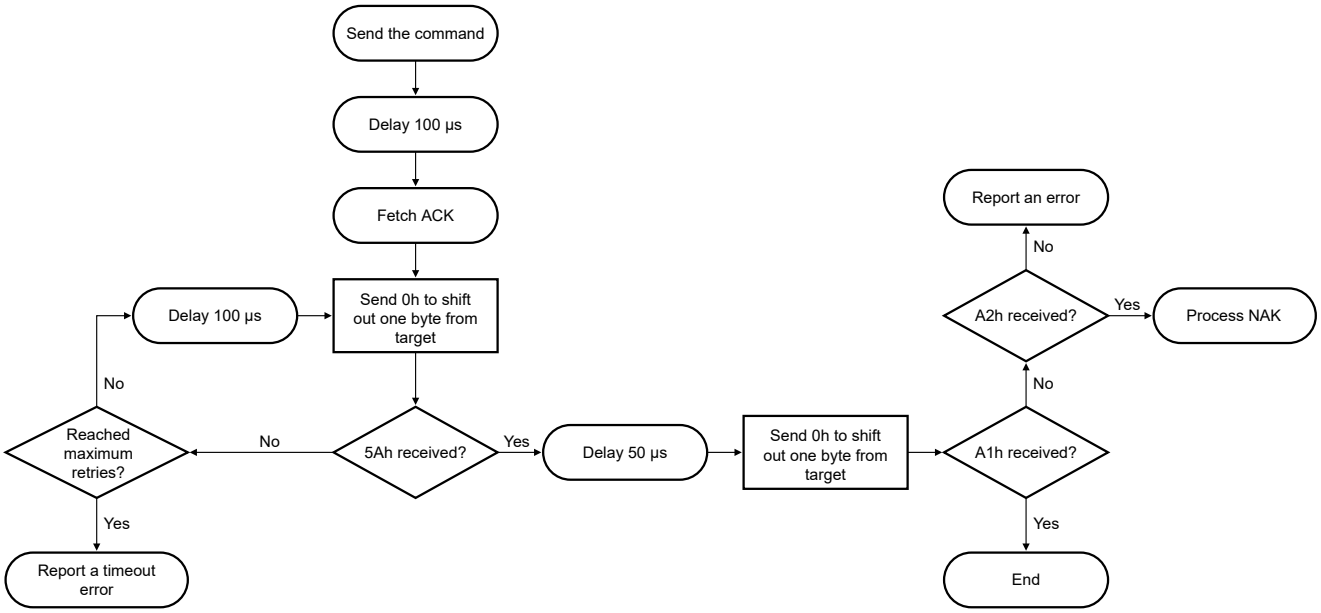

Figure 78. Host read ACK(5Ah, A1h) packet timing restriction flow

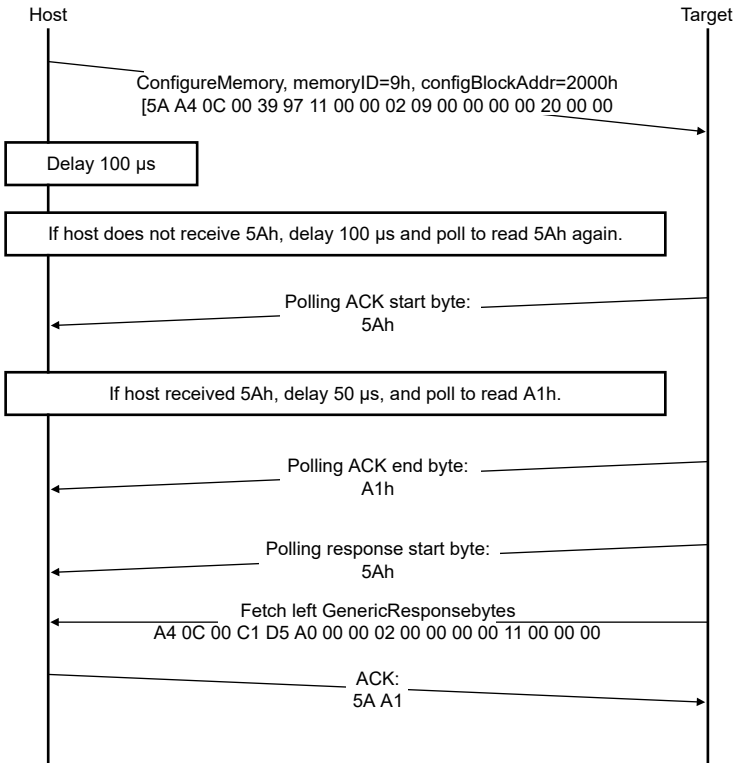

Figure 79. Host read ACK(5Ah, A1h) packet timing restriction

14.10 USB ISP

14.10.1 Introduction

The bootloader supports ISP using the USB peripheral. The target is implemented as a USB human interface device (HID) class.

USB HID does not use framing packets when transferring data through the USB HID class. Instead, USB HID uses the packetization inherent in the USB protocol itself. The chip's ability to NAK out transfers (until they can be received) provides the required flow control. The built-in CRC of each USB packet provides the required error detection.

14.10.1.1 Device descriptor

The bootloader configures the default USB VID, PID, and strings as follows:

Default VID and PID:

- VID = 1FC9h
- PID = 014fh

Default strings:

- Manufacturer [1] = "NXP SEMICONDUCTOR INC"
- Product [2] = "USB COMPOSITE DEVICE"

You can customize the USB VID, PID, and strings using the CMPA of the flash memory. For example, you can customize the USB VID and PID by writing:

- The new VID to the CMPA location 0100_4034h in flash memory
- The new PID to the usbPid field of the CMPA in flash memory

14.10.1.2 Endpoints

The HID peripheral uses three endpoints:

- Control (0)
- Interrupt IN (1)
- Interrupt OUT (2)

The interrupt OUT endpoint is optional for HID class devices. The chip bootloader uses the interrupt OUT endpoint as a pipe, where the firmware can NAK send requests from the USB host.

14.10.1.3 HID Reports

The bootloader USB HID peripheral defines and uses four HID reports. The report ID determines the direction and type of packet sent in the report—otherwise, the contents of all reports are the same.

Table 223. HID reports assigned for the bootloader

Report ID	Packet type	Direction
1	Command	OUT
2	Data	OUT
3	Command	IN
4	Data	IN

Each report has a maximum size of 60 bytes. The maximum payload size is 56 bytes. In addition, there is a 4-byte report header that indicates the length (in bytes) of the payload and a report ID sent to the packet.

The actual data sent in all reports uses the following format:

Table 224. Data format sent in USB HID packet

Report ID	Data
0	Report ID
1	Padding
2	Packet length LSB
3	Packet length MSB
4	Packet[0]
5	Packet[1]
6	Packet[2]
...	...
N+4-1	Packet[N-1]

If the HID report descriptor defines more than one report, the report ID must be included in the data. The actual data sent and received has a maximum length of 35 bytes. The packet length header is in little-endian format and it is set to the size (in bytes)

of the packet sent in the report. This size does not include the report ID or the packet length header itself. During a data phase, a packet size of 0 indicates a data phase abort request from the receiver.

For more information on USB ISP command and response formats, see Command packet.

For more information on USB ISP data format, see Response packet.

For more information on USB ISP commands, see Bootloader command set.

14.11 CAN ISP

The bootloader supports loading data into flash through the CAN peripheral. It supports four predefined auto-detect speeds on CAN transferring:

- 125 KHz
- 250 KHz
- 500 KHz
- 750 KHz
- 1 MHz

The current CAN IP can support up to 1 MHz using the ROM ISP feature, so the default baud rate is set to 1 MHz.

In host applications, you can specify the baud rate for CAN by writing one of the values in the following list to (0100_4028[31:28]) in CMPA:

- 0000: Auto baud detection (125 KHz, 250 KHz, 500 KHz, 750 KHz, 1 MHz)
- 0001: 125 kbit/s
- 0010: 250 kbit/s
- 0011: 500 kbit/s
- 0100: 750 kbit/s
- 0101 and above: 1000 kbit/s and auto baud detection

Initially, the bootloader enters the listen mode with the default speed of 1 MHz. After the host sends a ping to a specific node, it generates traffic on the CAN bus. Because the bootloader is in a listen mode, it can check whether the local node speed is correct by detecting errors. If there is an error, some traffic is visible, but it may not be at the right speed to read the correct data. If this happens, the speed setting changes and checks for errors again. No errors indicates that the speed is correct.

The settings change back to the normal receiving mode to check if there is a package for this node. It then stays in this speed until another host using another speed tries to communicate with any node. It repeats the process to detect a correct speed before sending host time-out and aborting the request.

The host side should have a reasonable time tolerance during the auto-speed detection period. If it sends a time-out signal, that indicates either there is no response from the specific node, or there is a real error and it must report the error to the application.

This flowchart demonstrates the communication flow for how the host reads the ping packet, ACK, and response from the target.

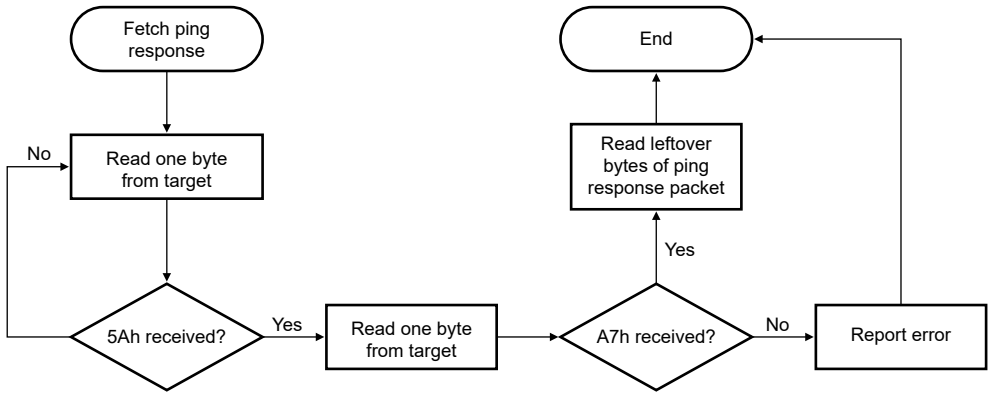

Figure 80. Host reads ping response from target via CAN

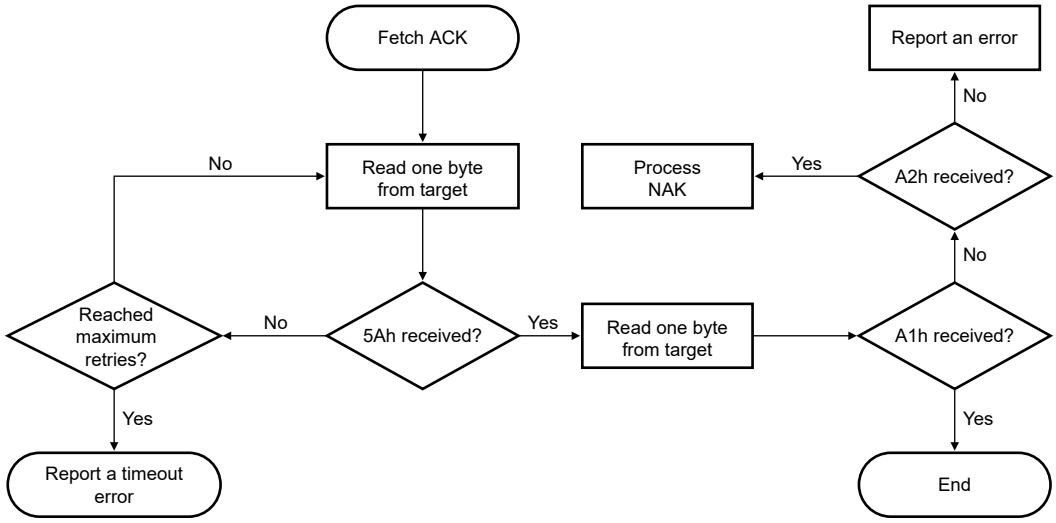

Figure 81. Host reads ACK packet from target via CAN

Chapter 15
Boot ROM

15.1 Overview

This chip supports both on-chip flash memory image boot and external NOR flash memory image boot via the FlexSPI interface.

You can use the boot ROM to erase, program, and read the on-chip or external flash memory, which means you can use the boot ROM to download the boot image into the on-chip or external flash memory via the ISP interfaces.

Following are the boot modes available for the boot ROM:

- Master boot mode
- ISP boot mode
- Recovery boot mode

The boot ROM uses the ISP pins or CMPA configuration to select Master boot mode for on-chip flash memory boot and FlexSPI boot (see Table 226 for more information).

Also, the boot ROM takes responsibility of the boot flow. It selects whether to boot from on-chip flash memory, external flash memory, or ISP mode. It even supports secure boot such as image authentication by ECDSA (P256, P384) or CMAC (128 bits).

There are many boot-related parameters in customer manufacturing/factory programmable area (CMPA) and customer in-field programmable area (CFPA). You can use the boot ROM to update these settings in ISP mode or by using ROM API.

For all details related to CMPA and CFPA, including their fields and address settings, see the IFR map file MCXNP184M150F70_IFR_Fusemap.xlsx, attached to this document.

NOTE

This chapter is also available in the *MCX N Security Reference Manual*, with differences related to security functionality. The chapter in the Reference Manual does not show the security relevant information in it.

15.1.1 Features

The boot ROM (256 KB on-chip with bootloader) allows various boot options and APIs. It supports:

- Automatic booting from internal flash memory, based on ISP pins or the CMPA setting in the PFR.
- In-application programming (IAP) calls (see IAP APIs for more information).
- Flash memory API for programming internal and external FlexSPI NOR flash memory. See the following for more information:
  - FLASH APIs
  - FLEXSPI FLASH Driver APIs
- SPI flash memory recovery boot from 1-bit SPI flash memory devices (see SPI flash memory recovery for more information).

15.2 Functional description

15.2.1 Boot mode and ISP download modes based on the ISP pin

The internal boot ROM memory stores the boot code. After a reset, the Arm processor starts its code execution from this memory. You must execute the bootloader code every time the part is powered on, reset, or wakes up from a deep power-down mode.

Images must be stored in the flash memory or in the serial NOR flash memory connected to the FlexSPI controller. The code is then validated, and the boot ROM vectors to on-chip or off-chip flash memory.

Depending on the values of the CMPA fields, ISP pins, and image header type definition, the bootloader decides whether to boot from flash memory, off-chip flash memory, or run into ISP mode. The boot ROM reads the status of the ISP pins to determine the boot source. See Table 225 for details.

Table 225. Boot mode and ISP download modes based on the ISP pin

Boot mode	ISPMODE_N (P0_6 pin)	Description
Flash memory boot	High	The boot ROM looks for a valid image in the flash memory. If it does not find a valid image, it looks for one in the recovery boot device, if the recovery boot is enabled (9:8, word 0 in CMPA). If it still fails to find a valid image, the boot ROM enters ISP boot mode based on the ISP_BOOT_IF bits defined in Table 226.
ISP boot	Low	One of the serial interfaces (UART, I^2C, SPI, USBFS0, or USBHS1) is used to download the image from the host into the flash memory. The first valid probe message on UART, I^2C, SPI, CAN, or USB becomes inactive on that interface.

NOTE

For the default USB HS ISP mode, you require crystal 24 MHz that you can configure in CMPA. For USB FS ISP mode, the boot ROM uses FRO.

15.2.2 ISP download mode based on the ISP_BOOT_IF CMPA bits

Table 226. ISP download mode based on the ISP_BOOT_IF CMPA bits (word0[6:4])

ISP boot mode	ISP_MODE_2	ISP_MODE_1	ISP_MODE_0	Functionality
Auto ISP	0	0	0	The boot ROM probes the active peripheral from one of the following serial interfaces and downloads the image from the probed peripherals: • UART • I^2C • SPI • CAN • USBFS0 • USBHS1
UART ISP	0	0	1	UART is used to download the image.
SPI ISP	0	1	0	The SPI slave is used to download the image.
I^2C slave ISP	0	1	1	The I^2C slave is used to download the image.
USB0 slave ISP	1	0	0	The USB HID class is used to download the image of the USB0 port.
USB1 slave ISP	1	0	1	The USB HID class is used to download the image of the USB1 port.

Table continues on the next page...

15.2.4 Image header

Top-level boot flow shows the top-level boot process, which starts after the reset is released.

The CPU clock has a default frequency of 48 MHz, based on 144 MHz FRO by default. You can set this frequency to 72 MHz, 144 MHz, or 150 MHz by using the BOOT_SPEED setting in CMPA. When the Cortex-M33 core starts the bootloader, the SWD access is disabled; and therefore, the debugger cannot connect to the CPU during this period. The boot ROM determines the boot mode based on the reset state of the ISP pins.

After completing boot mode detection, the bootloader starts validating the vector table and image header if the image is present in the boot media (internal or external flash memory).

The boot ROM does the following for image validity check:

- Validates the image using header and CMPA settings when secure boot is enabled. See the "Secure Boot ROM" chapter in the *Security Reference Manual* for details.
- Validates the image using CRC32 when secure boot is not enabled, if the CRC check is present in the image header.
- Validates whether SP and PC are valid RAM and NVM addresses of the chip.
- Validates the TZ-M image type if the aforementioned image checks pass.

The beginning of the image follows the format described in Table 228. The bootloader begins scanning for user images by examining the image type marker located at offset 24h. If the value matches any supported image type markers, the image header's validation begins, and after its completion, the qualification continues by examining the TZM "imageType" field:

- If it is a CRC image, you use the "image length" field value as the length to perform a CRC calculation based on the image in the flash memory (see Table 228 for more). The CRC calculation begins at offset 0h from the beginning of the image sector and continues up to the number of bytes specified by the image length, which does not include the "offsetToExtendedHeader" field that makes up the CRC value field. This means that the calculated CRC skips the CRC value field. The result is then compared to the "offsetToExtendedHeader" entry in the structure and the image is considered valid if a match exists; otherwise, the image is considered invalid. The CRC calculation is not performed if the image is not a CRC image.
- If it is a signed image, the "image length" field value is used as the length to perform authentication (ECDSA and CMAC), which is performed on the image in the internal or external flash memory. The authentication begins at offset 0h from the beginning of the image sector, and continues up to the number of bytes specified by the image length. The "offsetToExtendedHeader" field value points to the offset that holds the certificates.

Table 228. Image header

Offset (hex)	Size (bytes)	Symbol	Description
00	4	Initial SP	Stack pointer
04	4	Initial PC	Application's first execution instruction
08	24	Vector table	Cortex-M33 core's vector table entries
20	4	image length	Length of the current image (total length, including the signature), which is set to the actual image length if the image type is another value
24	4	imageType	Image type, bit[7:0]: • 0h: Plain image • 2h: Plain image with CRC • 4h: Signed image • 5h: Plain image with CRC • 6h: SB4 manifest Load_to_RAM image: The image has a nonzero image_load_address and image_length in the image header. Other values are reserved. Bit[10]: Indicates whether the image version is included in ImageType[31:16]: • 0: Image version is not included in "imageType." • 1: Image version is included in "Image Type," applicable to the internal flash memory XIP use case only. Bit[13]: Indicates whether the image includes TZM preset data: • 0: Image does not contain TZM preset data. • 1: Image contains TZM preset data. Bits[31:16]: Image version (for on-chip flash memory) when bit[10] = 1
28	4	offsetToExtendedHeader	Offset to extended header: • For a signed image (imageType = 4h), this is the offset to the certificate header block • For a CRC image (imageType = 2h or 5h), this is the crcChecksum value
2C	8	Vector table	Cortex-M33 core's vector table entries
34	4	imageExecutionAddress	The execution address of the image is: • Set to 0 if image type is XIP

Table continues on the next page...

Table 228. Image header (continued)

Offset (hex)	Size (bytes)	Symbol	Description
			• Set to actual image execution address if the image type is loaded to RAM
38	—	Vector table	Cortex-M33 core's vector table entries

15.2.5 Top-level boot flow

The following figure shows the top-level boot process, which begins after the reset is released.

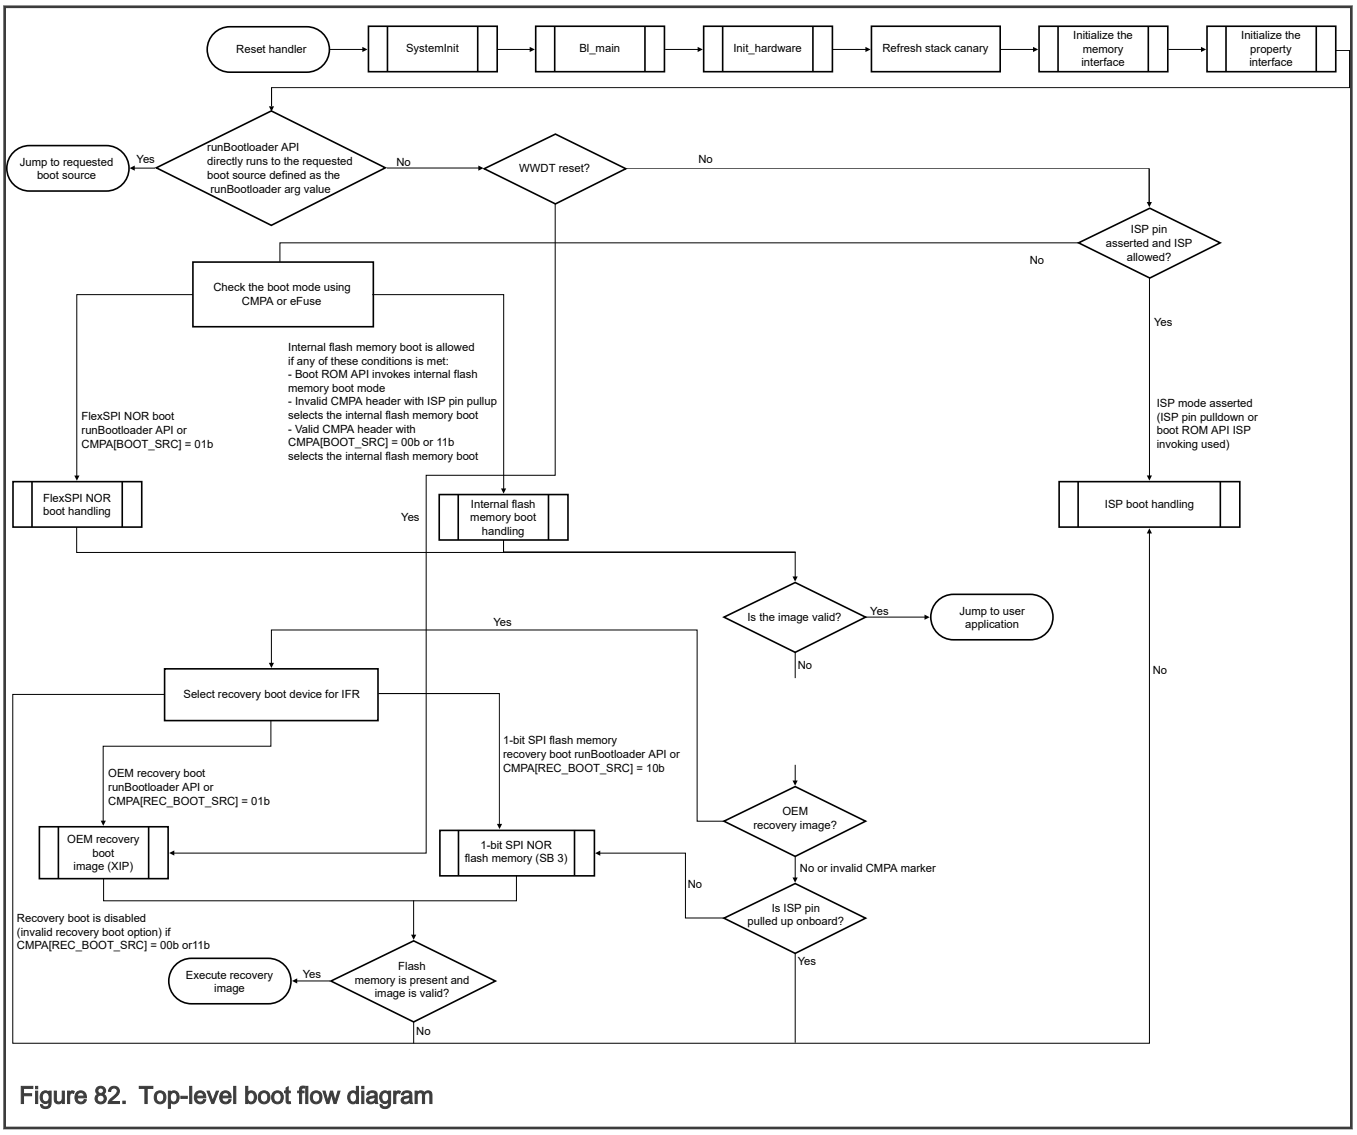

Figure 82. Top-level boot flow diagram

15.2.6 SPI flash memory recovery

Support is provided for a recovery boot from an external 1-bit SPI flash memory device in which the SB3.1 image is stored. The SB3.1 file is an encrypted and signed command script file that supports programming flash memory, IFR, and other configuration commands. You can implement this feature during OTA using a recovery media model in which an external SPI flash memory is

used to store a factory image in the SB3.1 format. If the image in the main flash memory is corrupted, the boot ROM attempts to recover the chip by booting or executing the SB3.1 file that is present on the external flash memory device.

See the "ROM firmware update using SB file" section in the "Secure Boot ROM" chapter in the MCX N Security Reference Manual for details related to the SB3.1 file format.

When booting from an internal or external flash memory using FlexSPI, if the flash memory image is deemed invalid, the chip checks REC_BOOT_SRC (bits 9:8) in the CMPA BOOT_CFG field (0100_4000h) to determine whether SPI flash memory recovery is selected.

The SB file can program the image into internal flash memory. The following commands are available for SB file recovery mode:

```
#define SBLOADER_V3_CMD_SET_IN_REC_MODE \\
    ((1u << kSB3_CmdErase) | (1u << kSB3_CmdLoad) | (1u << kSB3_CmdExecute) |
 (1u << kSB3_CmdProgramFuse) |      \\
    (1u << kSB3_CmdProgramIFR) | (1u << kSB3_CmdCopy) | (1u << kSB3_CmdLoadKeyBlob) |
 (1u << kSB3_CmdConfigMem) | \\
    (1u << kSB3_CmdFillMem))| (1u << kSB3_CmdFwVerCheck))
```

Code Listing 1. Commands for SB file recovery mode

See 1-bit serial NOR flash memory through SPI for more information.

15.3 Boot modes

15.3.1 Master boot mode

Master boot mode supports the following boot devices:

- Internal flash memory boot
- FlexSPI NOR flash memory boot
- SPI 1-bit NOR recovery boot
- Secondary bootloader boot (SBL)
- Bank1_IFR0 recovery boot (OEM_REC)

Table 229. Image offsets for different boot media

Boot media	Image offset
Internal flash memory boot	0h
FlexSPI NOR flash memory boot	1000h
SPI 1-bit NOR recovery boot	0h
Secondary bootloader boot	0h
Bank1_IFR0 recovery boot	0h

15.3.1.1 Internal flash memory boot

The CPU clock is set to the boot speed (that the BOOT_SPEED field specifies) in the CMPA region and boots directly from the internal flash memory or external FlexSPI NOR flash memory based on the BOOT_SRC settings in CMPA. After you select the internal flash memory boot as the boot media, the boot ROM tries to find a valid boot image in the internal flash memory. For more information, see Boot flow.

15.3.1.1.1 Boot flow

Figure 83 shows internal flash memory boot flow:

- The CMPA[FLASH_REMAP_SIZE] field specifies the second image in terms of size. If the field is 0, it indicates that the second image is not present.
- The Secure_FW_Version field [31:0], word 2 in CFPA specifies the minimum allowed image version.
- If the image version flag at imageType[10] is set, the image version can be found at imageType[31:16]; otherwise, the image version is treated as 0.
- In the image list, the newer one is image 0, and the older one is image 1. If the image version information is missing or equal, the image starting from address 0 is treated as image 0, and the image that FLASH_REMAP_SIZE specifies is treated as image 1, which starts from the second bank of the flash memory when the flash memory swap is enabled.

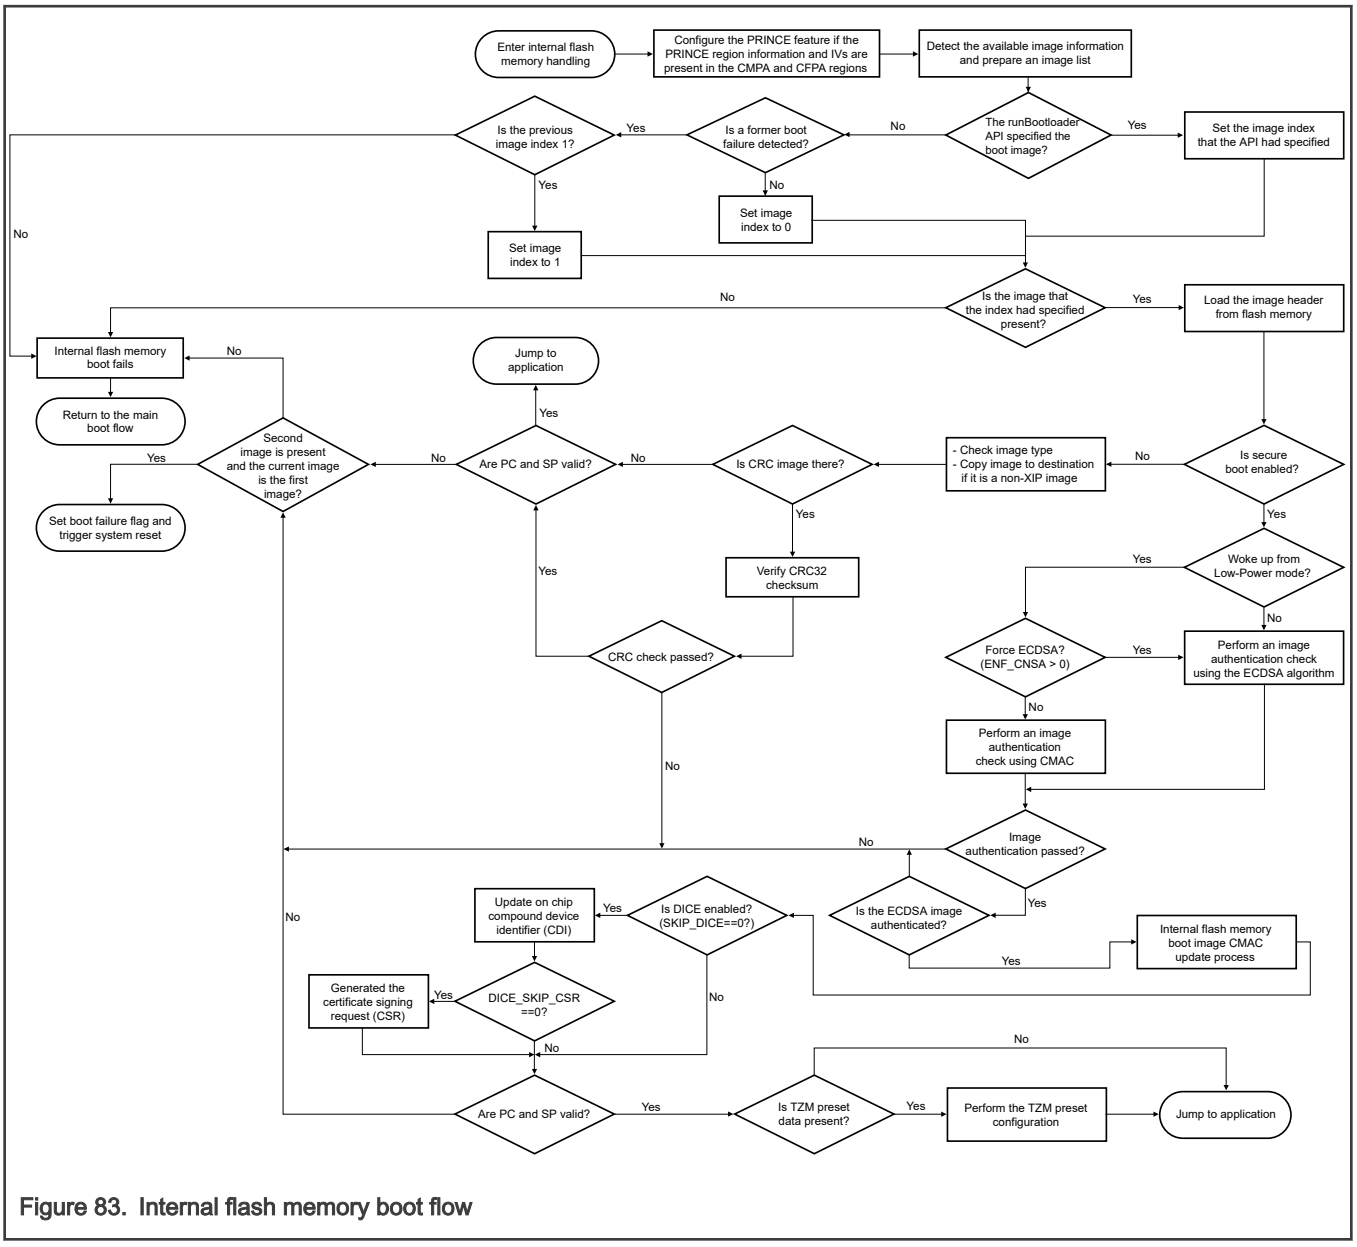

Figure 83. Internal flash memory boot flow

15.3.1.1.2 Internal flash memory dual image boot

The boot ROM supports dual image boot for internal flash memory. This means that two boot images can be placed in the flash memory region. The boot ROM decides which image to boot first based on the image version. It boots the one with the newer image version first, and in case of a failure, it boots the older one. The image version is the image header offset, 24h (see Table 228). Bit 10 shows whether the image contains the image version; if bit 10 is 0, it means that the image has no image version. In this case, the boot ROM considers the image version as 0.

Table 230. Internal flash memory boot image version (image header offset: 24h)

image_type	Field name	Field description
Bits 31–16	Image version	Active when the remap feature is enabled (remap offset and remap size are not zero in CMPA)
Bit 10	IMG_VER_INCLUDED_IN_IMG_TYPE	If this field is 0, the image has no version. If this field is 1, the image has a version in the dual image boot.

15.3.1.1.2.1 Remap feature

The following figure shows the internal flash memory controller remap function. When FLASH_REMAP_SIZE is a nonzero value in CMPA, the internal flash memory AHB access changes the access address based on the current active flash memory bank number. For example, when FLASH_REMAP_SIZE = 2h, and the remap size is 96 KB ((2h + 1) × 32 KB), access to 0h is remapped to flash memory bank1 start offset 0 when the bank1 image is active. The boot ROM can implement a dual image boot with two images via this feature. You set the remap size of the image in the CMPA and eFuse regions.

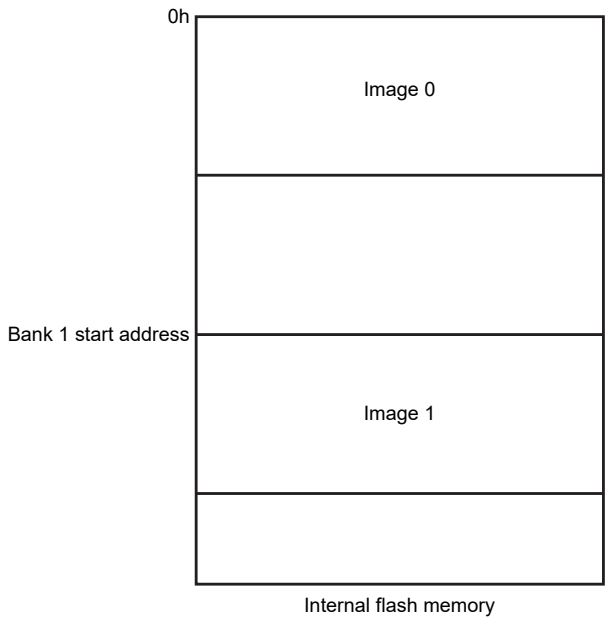

Figure 84. Internal flash memory dual image layout

15.3.1.1.2.2 Remap settings

The following table shows the internal flash memory dual image boot remap setting in CMPA. You must perform the settings defined in this table in CMPA to let the boot ROM know where the second image is placed. You can, then, enable dual image boot by setting the dual image boot image version in the image header, according to the information provided in the aforementioned sections. For more information about the internal flash memory boot flow, see Boot flow.

Table 231. Boot image 1 remap size

Region	Address	Word name	Description
CMPA	0100_4004h	FLASH_REMAP_SIZE	Indicates the flash memory remap size from the flash memory bank1 address, 0h, to the boot ROM.
eFuse	Index: 25	FLASH_REMAP_SIZE[4:0]	Indicates the flash memory remap size from the flash memory bank1 address, 0h, to the boot ROM. Also, nonzero FLASH_REMAP_SIZE[4:0] in eFuse replaces the FLASH_REMAP_SIZE[4:0] data in the CMPA field.

15.3.1.1.2.3 XOM access control settings

In some scenarios, you may need to set some internal flash memory regions as execute-only-memory (XOM) or read-only memory (ROM), or hide flash memory regions to protect the code.

For example, if ACL_SEC_0 = 2, it means that the first sector (32 KB) of the flash memory global access control (GLBAC*n*) index is 2. As shown in Table 232, this sector is set as ROM.

Table 232. Flash memory MBC setting index

GLBAC*n* index	Read	Write	Execute	Lock	Description
0	1	1	1	0	Default flash memory behavior (R/W/X unlocked)
1	1	1	0	1	Data flash memory with this setting: R/W + locked
2	1	0	1	1	ROM with this setting: RX + locked
3	1	0	0	1	Data read-only memory (DROM) with this setting: R + locked
4	1	0	1	0	ROM with this setting: RX unlocked
5	0	0	1	0	XOM with this setting: XOM unlocked
6	0	0	1	1	XOM with this setting: XOM + locked
7	0	0	0	1	Hidden (no access + locked)

Follow below rules to change the ACL_SEC_*n* fields.

- After you select a locked access level, the subsequent updates of this field can be done with higher lock level only.
  - If current sector ACL value (GLBAC*n* index) is greater than the new value, then it is permitted except if the current value is 4 or 5.
    - 7 (___L) > 6 (__XL) > 3 (R__L) > 2 (R_XL) > 1 (RW_L) > 0 (RWX_)
  - If current sector ACL value is 0, 4, or 5 then any new value is permitted.

The boot ROM supports setting flash memory attributes in the CFPA region. Before jumping into the user code, the boot ROM loads the settings of access control for the flash memory sector that you specify in CFPA. Table 233 shows access control settings for flash memory in CFPA.

Table 233. Access control settings for the flash memory sector

CFPA word	Flash memory address (hex)	Word name	Description
Word48	0100_00C0	FLASH_ACL_0_7	Selects the flash memory MBC setting index. See Table 232 for more information.
Word49	0100_00C4	FLASH_ACL_8_15	Same as above
Word50	0100_00C8	FLASH_ACL_16_23	Same as above
Word51	0100_00CC	FLASH_ACL_24_31	Same as above
Word52	0100_00E0	FLASH_ACL_32_39	Same as above
Word53	0100_00E4	FLASH_ACL_40_47	Same as above
Word54	0100_00E8	FLASH_ACL_48_55	Same as above
Word55	0100_00EC	FLASH_ACL_55_63	Same as above

15.3.1.1.2.4 CMPA settings with PRINCE enabled

The following figure shows CMPA settings for internal flash dual image boot with PRINCE enabled.

Table 234. Remapping settings for dual image

CMPA word	Flash memory address	Word name	Value	Details
WORD1	0100_4004h	FLASH_REMAP_SIZE	1h	Remap size: 10000h

After all settings are updated, the boot ROM follows dual image boot as the boot flow progresses.

15.3.1.2 FlexSPI NOR flash memory boot

The boot ROM supports access to different Quad and Octal SPI NOR flash memory chips from various vendors via the FlexSPI interface using 1-bit, 4-bit (Quad), or 8-bit (Octal) mode. It uses the flash memory configuration block (FCB) located at offset 400h on the flash memory chip or flash memory auto-probe feature that CMPA specifies:

- If FLEXSPI_AUTO_PROBE_EN is blown, the bootloader performs the flash memory auto-probe sequence using parameters blown in:
  - The FLEXSPI_PROBE_TYPE field that defines the flash memory auto-probe type.
  - The FLEXSPI_PROBE_TYPE and FLEXSPI_FLASH_TYPE fields that define the flash memory type.
  - The FLEXSPI_FREQUENCY field that defines the flash memory access speed.

  The auto-probe feature is used for detecting the external flash FCB information automatically. When FLEXSPI_AUTO_PROBE_EN is blown, and the preceding necessary fields are programmed, the boot ROM tries to identify the external flash information. If the identification is successful, it obtains a self-identifying FCB configuration block. If the recognition fails, it continues to attempt to read the user FCB configuration block to obtain external flash information.

  When FLEXSPI_AUTO_PROBE_EN=1, which is only supported on chips that are JESD216-compliant, the boot ROM is able to detect the flash memory information via the read SFDP (5Ah) command. The ROM uses the SFDP information to construct an FCB instead of using one from the application image.

- If FLEXSPI_AUTO_PROBE_EN is not blown, the bootloader looks at offset 400h on the flash memory chip; if data at offset 400h is equal to 4246_4346h, the bootloader reads the whole 512-byte FCB into the on-chip SRAM and configures the FlexSPI controller using this FCB accordingly.

  After performing the aforementioned operation, the bootloader starts performing the normal boot flow. See Figure 85 for more information.

Table 235. FlexSPI FCB settings

Field	Offset (hex)	Size (bytes)	Description
tag	000	4	Configuration block tag Setting: 4246_4346h
version	004	4	Configuration block that the boot ROM uses internally Setting: 5601_0400h
Reserved	008	4	Reserved for future use
readSampleClkSrc	00C	1	Read sampling clock source options: 0 – Internal sampling 1 – Loopback from DQS pad 2 – Loopback from SCK pad 3 – External DQS signal
csHoldTime	00D	1	CS hold time in terms of flash memory clock cycles Recommended value is 3.
csSetupTIme	00E	1	CS set up time in terms of flash memory clock cycles The recommended value is 3.
columAddressWidth	00F	1	Column address width: • Is set to 3 for HyperFlash NOR flash memories. • Is set to 0 for other flash memory chips.
deviceModeCfgEnable	010	1	Enables the chip mode configuration sequence: 1 – Enable 0 – Disable
deviceModeType	011	1	Argument for Device mode configuration For example, Quad enable setting in Status Register2 for some Quad SPI flash memory devices: 0 – No mode change 1 – Quad enable (switch from SPI to Quad mode) 2 – Spi2Xpi (switch from SPI to DPI, QPI, or OPI mode) 3 – Xpi2Spi (switch from DPI, QPI, or OPI to SPI mode)

Table continues on the next page...

Table 235. FlexSPI FCB settings (continued)

Field	Offset (hex)	Size (bytes)	Description
waitTimeCfgCommands	012	2	Wait time (in terms of 100 µs) for Device mode configuration command
deviceModeSeq	014	4	Device mode configuration sequence: Byte 0 – Number of required sequences Byte 1 – Sequence index
deviceModeArg	018	4	Argument for Device mode configuration For example, Quad enable setting in Status Register2 for some Quad SPI flash memory devices
configCmdEnable	01C	1	Configuration command enable: 0 – Ignores configuration command 1 – Enables configuration command
configModeType	01D	3	Configuration command type that supports up to three types; each type is combined with a configuration command sequence
configCmdSeqs	020	12	Configuration command that supports up to three sequences
Reserved	02C	4	Reserved for future use
configCmdArgs	030	12	Configuration command that supports up to three arguments
Reserved	03C	4	Reserved for future use
controllerMiscOption	040	4	Miscellaneous controller configuration options: Bit 0 – Differential clock enable: set to 1 for HyperFlash NOR flash memory 1V8 device and set to 0 for other devices Bit 3 – WordAddressableEnable: set to 1 for HyperFlash NOR flash memory and set to 0 for other devices Bit 4 – SafeConfigFreqEnable: set to 1 if expecting to configure the chip with a safe frequency Bit 6 – DDR mode enable: set to 1 if DDR read is expected Other bits – Reserved; set to 0
deviceType	044	1	Device type 1 – Serial NOR flash memory
sflashPadType	045	1	Data pad used in Read command: 1 – Single pad 2 – Dual pads 4 – Quad pads

Table continues on the next page...

Table 235. FlexSPI FCB settings (continued)

Field	Offset (hex)	Size (bytes)	Description
			8 – Octal pads
serialClkFreq	046	1	Serial clock frequency SDR: 1 – 30MHz 2 – 50MHz 3 – 60MHz 4 – 75MHz 5 – 100MHz DDR: 1 – 30MHz 2 – 50MHz
lutCustomSeqEnable	047	1	LUT customization enable—required when you cannot perform the program and erase operations using one LUT sequence (currently, only one is applicable to HyperFlash NOR flash memory)
Reserved	048	8	Reserved for future use
sflashA1Size	050	4	Size of flash memory connected to A1
sflashA2Size	054	4	Size of flash memory connected to A2
sflashB1Size	058	4	Size of flash memory connected to B1
sflashB2Size	05C	4	Size of flash memory connected to B2
csPadSettingOverride	060	4	Pad override value for CS pin Use this value (if nonzero) to configure the CS pin; otherwise, use the default boot ROM setting
sclkPadSettingOverride	064	4	Serial clock pad setting override value
dataPadSettingOverride	068	4	Data pad setting override value
dqsPadSettingOverride	06C	4	DQS pad setting override value
timeoutInMs	070	4	Timeout value (in terms of ms) to terminate the busy check
commandInterval	074	4	CS deselect interval between two commands
dataValidTime	078	4	Clock edge to data valid time
busyOffset	07C	2	Busy offset, valid value: 0-31

Table continues on the next page...

Table 235. FlexSPI FCB settings (continued)

Field	Offset (hex)	Size (bytes)	Description
busyBitPolarity	07E	2	Busy flag polarity: 0 – Busy flag is 1 when the flash memory device is busy 1 – Busy flag is 0 when the flash memory device is busy
lookupTable	080	256	16 LUT sequences—each sequence consists of four words (see the FlexSPI chapter for more information)
lutCustomSeq	180	48	Customizable LUT sequences
Reserved	1B0	16	Reserved for future use
pageSize	1C0	4	Page size of flash memory
sectorSize	1C4	4	Sector size of flash memory
ipcmdSerialClkFreq	1C8	1	Serial clock frequency for IP commands: 0 – The same with read command Others – The same definition as that of the serial clock frequency
isUniformBlockSize	1C9	1	Indicates whether the sector size is the same as the block size: 0 – No 1 – Yes
isDataOrderSwapped	1CA	1	Data order (D0, D1, D2, D3) is swapped with (D1, D0, D3, D2)
Reserved	1CB	1	Reserved for future use
serialNorType	1CC	1	Serial NOR flash memory type: 0, 1, 2, and 3
needExitNoCmdMode	1CD	1	Exits NoCmd mode before other IP commands
halfClkForNonReadCmd	1CE	1	Half serial clock for nonread command: true or false
needRestoreNoCmdMode	1CF	1	Restores NoCmd mode after IP command execution
blockSize	1D0	4	Flash memory block size
flashStateCtx	1D4	4	Flash memory state context
Reserved	1D8	40	Reserved for future use

15.3.1.2.1 Reset

During FlexSPI boot, the boot process requires the FlexSPI flash memory device to be in a certain mode, for example, 1-bit SPI compatible mode. The flash memory device is, by default, in this mode after a POR reset. That is because the power-up sequence resets it along with the boot ROM device. However, the flash memory device does not remain in 1-bit SPI compatible mode if you configure it in DPI, QPI, or Octal mode when any non-POR resets happen (for example, watchdog timer and external pin reset).

In such a case, the boot process requires special processing to restore the flash memory device to 1-bit SPI compatible mode before accessing it. You can achieve this by using a GPIO to assert a reset pin on the flash memory device. The bootloader can perform the reset process and reset the flash memory device to 1-bit SPI compatible mode if the FLEXSPI_RESET_ENABLE field is a nonzero value in CMPA, using the GPIO that the FLEXSPI_RESET_GPIO_PORT and FLEXSPI_RESET_GPIO_PIN fields specify in combination.

NOTE

For Octal flash memory, after the boot ROM boots up, the flash memory is configured to Octal mode. The boot ROM cannot reset the NOR flash memory from Octal mode to standard SPI mode if it is a pin or soft reset causing reboot fail. The only way to solve this is to use a GPIO to reset the Octal NOR flash memory during reboot. There is no such problem in case of Quad SPI flash memory.

Table 236. FlexSPI boot configurations in CMPA WORD32(0100_4010h)(FLEXSPI_BOOT_CFG[0])

Field name	Enum name	Description	Offset	Width	Value (binary)
FLEXSPI_AUTO_PROBE_EN	—	Quad SPI or Octal SPI flash memory auto-probe feature enable	0	1	—

15.3.1.2.2 Boot flow

Figure 85 illustrates the FlexSPI NOR flash memory boot flow. It shows details related to normal image load and authentication flow:

- The FLEXSPI_BOOT_CFG[0] and FLEXSPI_BOOT_CFG[1] fields in CMPA specify the second image in terms of offset and size. If both are 0, it means the second image is not present.
- If the image version at each flash memory offset 600h is valid, use the image version; otherwise, the image version is treated as 0.
- In the image list, the newer one is image 0, and the older one is image 1. If the image version information is missing or equal, the image starting from address 0 is treated as image 0, and the image that the FLEXSPI_BOOT_CFG[0] and FLEXSPI_BOOT_CFG[1] fields specify is treated as image 1.

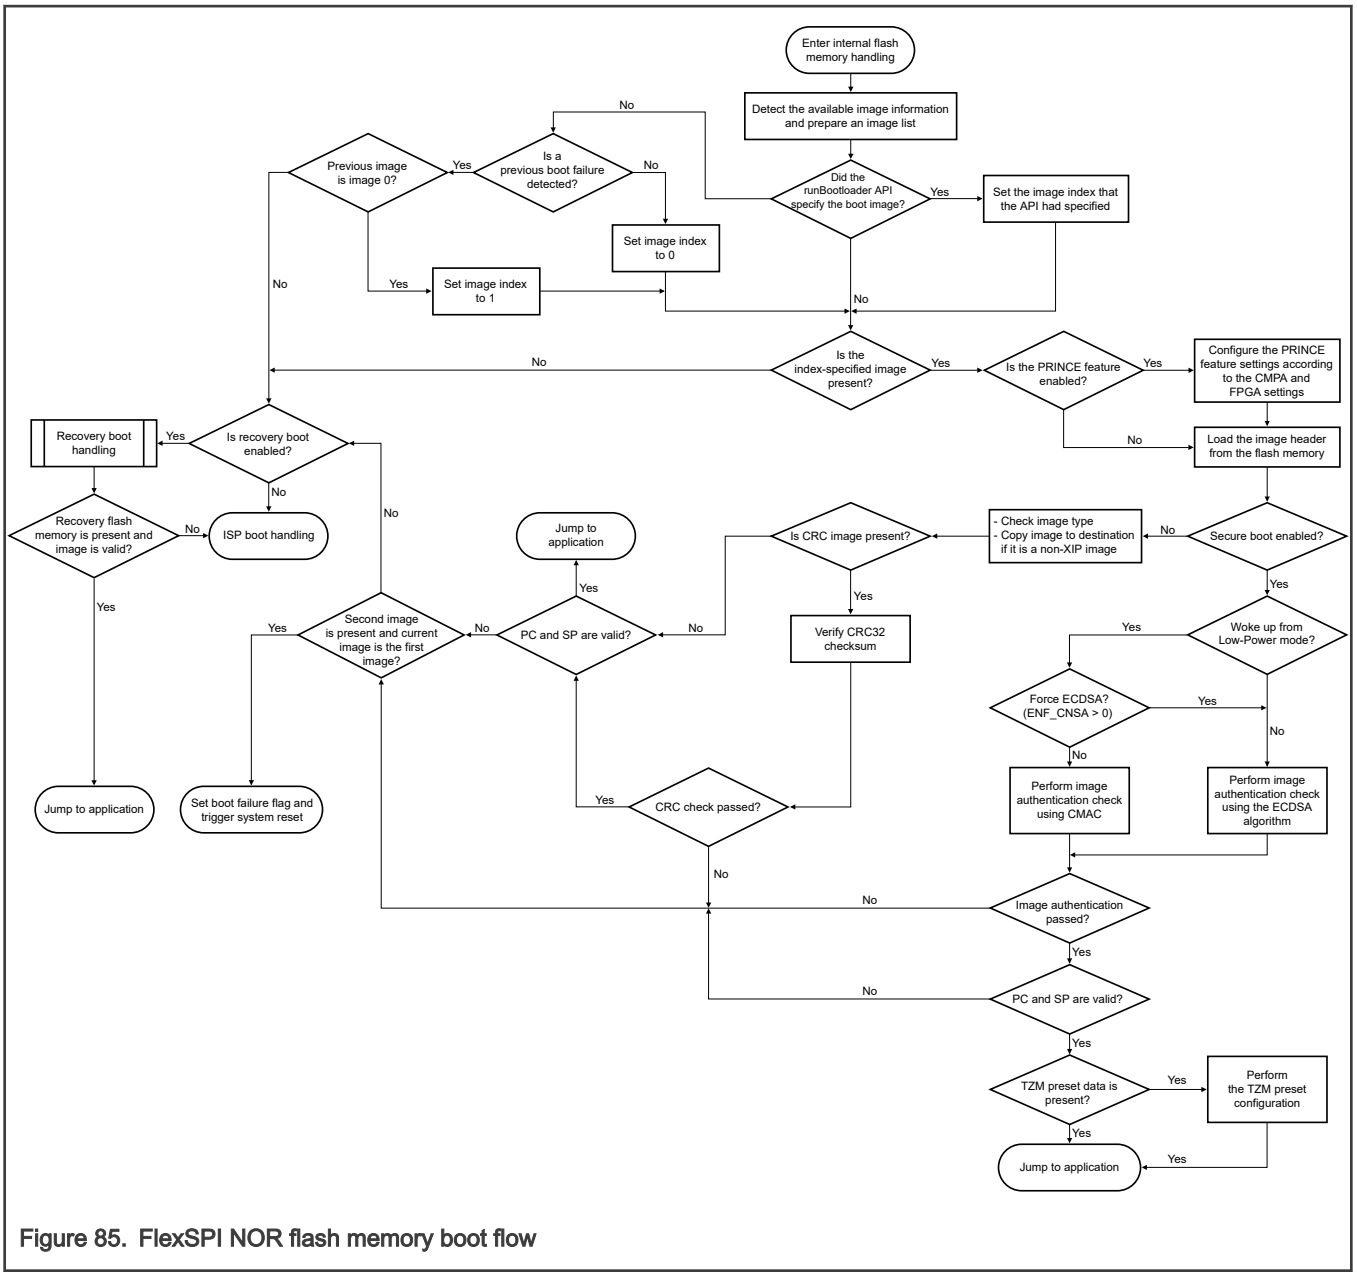

Figure 85. FlexSPI NOR flash memory boot flow

15.3.1.2.3 Dual image ping-pong boot

The FlexSPI controller supports the remap function, which can remap the AHB accessing the address of the serial NOR flash memory to another address with the same offset. In this way, FlexSPI boot supports the second image boot when the first image boots fails.

For dual image ping-pong boot, each of the boot images has its image version, which the boot ROM uses to first select the latest boot image. If the latest image boot fails, the boot ROM uses the old image to boot again.

15.3.1.2.4 Basic remapping function

The following figure shows the basic FlexSPI remap function. When the remap offset is set, FlexSPI memory access changes the access address, adding the offset, as shown in this figure. For example, when the offset is set to 2 MB (200000h), the access to 8000_0000h via FlexSPI is remapped to 8020_0000h. Using this remap feature, the boot ROM can implement a dual image boot with two images. You must set the offset and remap size of the image in the CMPA region.

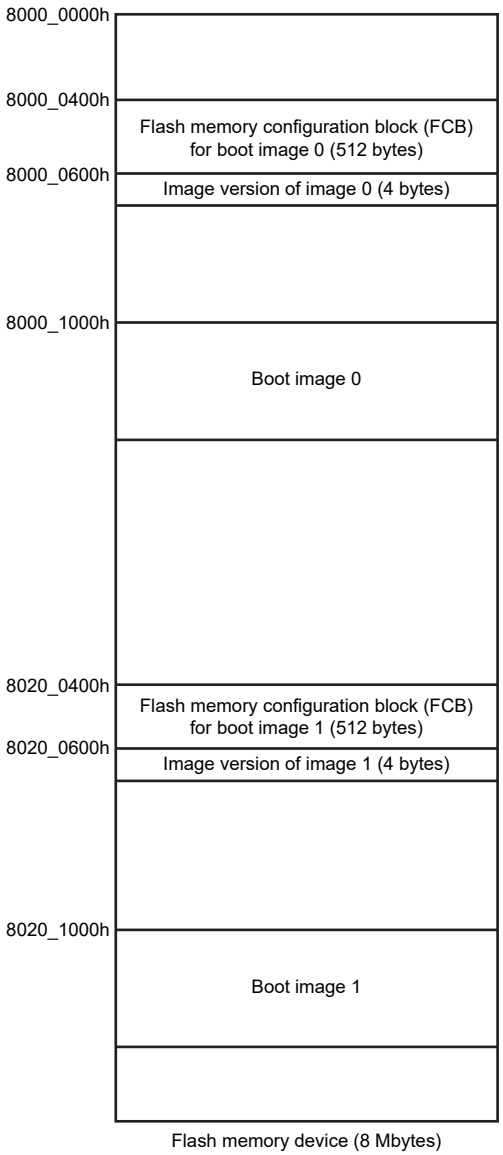

Figure 86. FlexSPI image remap (offset = 200000h)

15.3.1.2.5 Image remap offset and size configuration

The configurations related to FlexSPI dual image boot are allocated in CMPA word5 (0100_4014h) "FLEXSPI_BOOT_CFG [1]" word. See the following table and CMPA in the IFR table for details.

Table 237. Boot image 1 remap offset (CMPA: 0100_4014h)

Name that is filled	Bit offset	Width	Value	Description
FLEXSPI_IMAGE_OFFSET	7	10	*x*	*x* multiplied by 256 KB

Table 238. Boot Image size (FLEXSPI_BOOT_CFG [1])

Name that is filled	Bit offset	Width	Value	Description
FLEXSPI_REMAP_IMAGE_SIZE	17	4	0	Same size as that of the second image offset
			13	256 KB
			14	512 KB
			15	768 KB
			x	*x* multiplied by 1 MB

NOTE

FlexSPI remap size cannot exceed the start address of boot image 1.

15.3.1.2.6 Boot image version

Each boot image version is placed at offset 600h of the FlexSPI boot device (see Basic remapping function).

The image version uses 4 bytes—the lower 2 bytes are the real image version number, and the upper 2 bytes are the invert value of the lower 2 bytes of the image version. All other values that do not follow this rule are regarded as invalid values—if the boot image version is not valid, the boot ROM does not boot that image at all.

However, if the image version is all FFFF_FFFFh (the condition in which you do not program the image version), it is also considered as a valid value. When one of the image versions is FFFF_FFFFh and the other one is a valid image version, the boot ROM always first boots the image with the valid value, and not the one with image version as FFFF_FFFFh. If both image versions are FFFF_FFFFh, the boot ROM always boots the first image residing at the lower address in the FlexSPI NOR flash memory device.

A valid image version must always start from 1, which is FFFE_0001h.

The following table shows some examples of the boot image version.

Table 239. Boot image settings

Image version	Validity	Version number
FFFE_0001h	Valid	1
FFFD_0002h	Valid	2
0000_0003h	Invalid	Does not follow the image version rules
FFFF_FFFFh	Valid	Lower boot sequence
0000_FFFFh	Valid	Largest version, FFFFh

15.3.1.2.7 Ping-Pong boot flow

For FlexSPI boot, the boot ROM always tries to find the latest boot image to boot. If boot fails, the boot ROM tries to find an old boot image. If the boot still fails, it enters ISP boot mode. The following flowchart shows Ping-Pong boot flow.

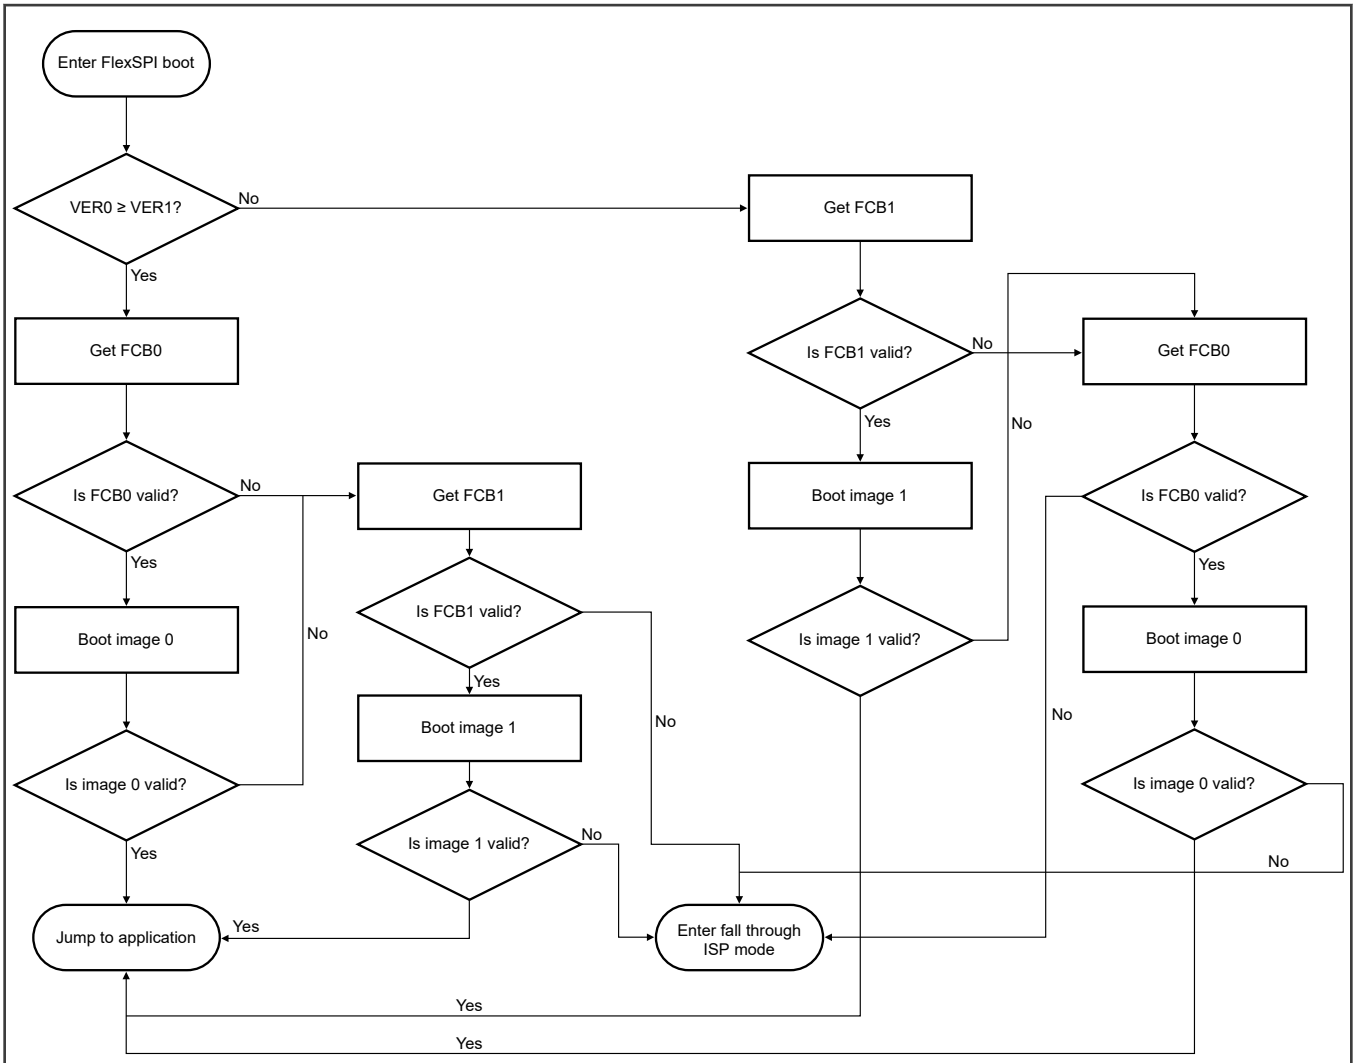

Figure 87. FlexSPI Ping-Pong boot flow

15.3.1.2.8 Configuring the FlexSPI NOR flash memory device

The boot ROM supports the booting of the image from an external FlexSPI NOR flash memory device. This section describes how to use the "blhost" tool to program the image into an external nonvolatile memory for booting. The "blhost" tool uses UART, SPI, I^2C, USB HID, and FlexCAN to communicate with the ROM code via ROM ISP mode.

See Table 227 for FlexSPI pin assignments of NOR flash memory connections.

15.3.1.2.8.1 Boot image programming

The boot ROM supports booting from different types of NOR flash memories such as Quad SPI, Octal SPI, and HyperFlash, which connect to FlexSPI pins that the boot ROM uses. For FlexSPI NOR boot, you must program FCB at offset 8000_0400h, and the boot image at offset 8000_1000h. The following sections provide information on how to configure and program the boot image into NOR flash memory for common NOR flash memory types.

15.3.1.2.8.2 Configuration options, settings, and parameters

15.3.1.2.8.2.1 Options

Table 240. FlexSPI serial NOR flash memory configuration options

Offset	Field	Description
0	Option0	See Table 241 for details.
4	Option1	Optional; effective only if the "option_size" field in option0 configuration is a nonzero value. See Table 242 for more information.

15.3.1.2.8.2.2 Option 0 field descriptions

Table 241. Option 0 field descriptions

Field	Bits	Description
tag	31:28	Tag of the configuration option, fixed to 0Ch
option_size	27:24	Size in bytes = (option size + 1) × 4 It is 0 only if option0 is required.
device_type	23:20	Device detection type: 0 – Read SFDP for SDR commands 1 – Read SFDP for DDR read commands 2 – Reserved 3 – HyperFlash 3V 4 – Macronix Octal DDR 6 – Micron Octal DDR 8 – Adesto EcoXiP DDR
query_pad	19:16	Data pads during Query command: (read SFDP or read MID) 0 – 1 2 – 4 3 – 8
cmd_pad	15:12	Data pads during flash memory access command: 0 – 1 2 – 4 3 – 8
quad_mode_setting	11:8	Quad SPI mode enable setting: 0 – Not configured 1 – Set bit 6 in Status register 1

Table continues on the next page...

Table 241. Option 0 field descriptions (continued)

Field	Bits	Description
		2 – Set bit 1 in Status register 2 3 – Set bit 7 in Status register 2 4 – Set bit 1 in Status register 2 by using the 0x31 command You use this setting to configure flash memory when it enters Quad SPI mode. You must reset the flash memory into stand SPI mode after the chip is reset because the boot ROM does not do that. **NOTE** This field is effective only if the chip is compliant with JESD216 (9 longword SFDP table).
misc_mode	7:4	Miscellaneous mode setting: 0 – Disabled 1 – Enable 0-4-4 mode for high random read performance 3 – Data Order Swapped mode (for MXIC OctaFlash memory only) 5 - Select the FlexSPI data sample source as internal loop back; see FlexSPI usage for more details 6 - Configure the FlexSPI NOR flash memory running at stand SPI mode **NOTE** Experimental feature only. Do not use in production: keep it as 0 for normal usage.
max_freq	3:0	Maximum flash memory operation speed: For SDR: 0 – 30 MHz (default) 1 – 50 MHz 2 – 60 MHz 3 – 75 MHz 4 – 100 MHz For DDR: 0 – 30 MHz 1 – 50 MHz

15.3.1.2.8.2.3 Option 1 field descriptions

Table 242. Option 1 field descriptions

Field	Bits	Description
Reserved	31:8	Reserved for future use

Table continues on the next page...

Table 242. Option 1 field descriptions (continued)

Field	Bits	Description
dummy_cycles	7:0	Dummy cycles for the Read command: 0 – Use detected dummy cycle Others – Use dummy cycles provided in the flash memory data sheet

15.3.1.2.8.2.4 Option settings

The following table shows typical FlexSPI serial NOR flash memory configuration option settings.

Table 243. FlexSPI serial NOR flash memory configuration option settings

FlexSPI mode name	Access type	Setting
Quad SPI NOR	Quad SPI SDR read	Option0 = C000_0002h (60 MHz)
Quad SPI NOR	Quad SPI DDR read	Option0 = C010_0002h (60 MHz)
HyperFlash 3V0	—	Option0 = C033_3002h (60 MHz)
MXIC OPI DDR (OPI DDR enabled by default)	—	C043_3001h (30 MHz)
Micron Octal DDR	—	Option0 = C060_0002h (60 MHz)
Micron OPI DDR	—	Option0 = C060_3002h (60 MHz)
Micron OPI DDR (DDR read enabled by default)	—	Option0 = C063_3002h (60 MHz)
Adesto OPI DDR	—	Option0 = C080_3002h (60 MHz)

15.3.1.2.8.2.5 Configuration parameters

```
                typedef struct _serial_nor_config_option
                {
          union

            struct
            {
              uint32_t max_freq : 4;           // Maximum supported Frequency
              uint32_t misc_mode : 4;          // miscellaneous mode
              uint32_t quad_mode_setting : 4;  // Quad mode setting
              uint32_t cmd_pads : 4;           // Command pads
              uint32_t query_pads : 4;         // SFDP read pads
              uint32_t device_type : 4;        // Device type
              uint32_t option_size : 4;        // Option size, in terms of uint32_t, size =
(option_size + 1)
              uint32_t tag : 4;                     // Tag, must be 0x0C
            } B;
            uint32_t U;
          } option0;

          union
          {
            struct
```

```
            {
              uint32_t dummy_cycles : 8;     // Dummy cycles before read
              uint32_t status_override : 8;   // Override status register value during device mode
configuration
              uint32_t pinmux_group : 4;      // The pinmux group selection
              uint32_t dqs_pinmux_group : 4;  // The DQS Pinmux Group Selection
              uint32_t drive_strength : 4;    // The Drive Strength of FlexSPI Pads
              uint32_t flash_connection : 4;   // Flash connection option: 0 - Single Flash
connected to port A,  2 - Single Flash connected to Port B

            } B;
            uint32_t U;
          } option1;

               } serial_nor_config_option_t;
```

Code Listing 2. FlexSPI NOR flash memory device configuration parameters

15.3.1.2.8.3 Configuring, erasing, and programming via blhost

15.3.1.2.8.3.1 Configure via blhost

To configure a FlexSPI NOR flash memory device, the configuration parameter must be stored in RAM first. Consider Macronix MX25L25645G, which connects to the FlexSPI interface, as an example. The following figure shows the configuration parameter for FlexSPI, which is C000_0001h. You select a configuration parameter according to the flash memory type.

```
C:\blhost>blhost.exe -p com4 fill-memory 0x2000f000 4 0xc0000001
Ping responded in 1 attempt(s)
Inject command 'fill-memory'
Successful generic response to command 'fill-memory'
Response status = 0 (0x0) Success.
```

Code Listing 8. Reading the boot image back via the blhost tool

15.3.1.2.8.3.3 Generate and program FCB via blhost

Generate and program the FlexSPI NOR FCB into the flash memory for FlexSPI boot, with an FCB at offset 8000_0400h. You use this FCB to configure the FlexSPI interface when booting the image from an external NOR flash memory via the FlexSPI interface. You can generate the FCB using the previous FlexSPI configuration parameter (C000_0002h). Store the configured FCB and program parameter into RAM (see Code Listing 9). The boot ROM uses these in the next step to automatically generate and program the FCB into flash memory at offset 8000_0400h (see Code Listing 10).

```
C:\blhost>blhost.exe -p com4 fill-memory 0x2000f000 4 0xf000000f
Ping responded in 1 attempt(s)
Inject command 'fill-memory'
Successful generic response to command 'fill-memory'
Response status = 0 (0x0) Success.
```

Code Listing 11. Reading the FCB back via the blhost tool

15.3.1.2.8.4 Typical configuration parameters

You require different configuration parameters for different FlexSPI NOR flash memory types. The following table shows some typical flash memory configuration parameters.

Table 244. Typical NOR flash memory configuration parameters

Device vendor	Device type	Flash memory type	Configuration parameter	Flash memory mode	Comment
Adesto	Octal SPI flash memory	ATXP032	C080_3001h	DDR	• ATXP032 has three versions, REV A, REV B, and REV C. For REV A, the boot ROM only supports auto probe boot, the OTP fuse word. • You must configure FLEXSPI_BOOT_CFG[0] as 7h, with no need to configure FCB.
Cypress	HyperFlash memory	S26KS512S	C023_3001h	DDR	For HyperFlash boot, you must configure FLEXSPI_BOOT_CFG[0] as 20h before boot.
Macronix	Quad SPI flash memory	MX25L25645G	C000_0001h	SDR	—
Macronix	Quad SPI flash memory	MX25L25645G	C010_0001h	DDR	—
Macronix	Octal SPI flash memory	MX25UM51345G	C040_3001h	DDR	—
Micron	Octal SPI flash memory	MT35XL512ABA	C060_3001h	DDR	—

15.3.1.2.9 Programming the boot image into the flash memory

The following table lists the procedure and corresponding commands to program the boot image into the external flash memory with all data encrypted (see Configuring the FlexSPI NOR flash memory device for more information).

Table 245. FlexSPI NOR flash memory configuration

Step number	Step	Command to perform the step
1	Fill in the flash configuration parameter.	`blhost.exe -p com4 fill-memory 0x20020000 4 0xc0000001`
2	Enable the flash memory.	`blhost.exe -p com4 configure-memory 0x9 0x20020000`
3	Fill in the FCB generation parameters.	`blhost.exe -p com4 fill-memory 0x20020004 4 0xf000000f`
4	Program FCB at flash memory offset 8000_0400h.	`blhost.exe -p com4 configure-memory 0x9 0x20020004`
5	Erase the flash memory region from 8000_0000h to 8001_0000h.	`blhost.exe -p com4 flash-erase-region 0x80001000 0x10000`
6	Program the boot image into the flash memory from offset 8000_1000h.	`blhost.exe -p com4 write-memory 0x80001000 image.bin`

15.3.2 Secondary bootloader mode

Secondary boot mode can be enabled by setting CMPA[BOOT_SRC] as 2. The image loaded in the Bank1_IFR0 region (0x0100_8000 to 0x0100_FFFF) will be set as the primary boot mode, and the secondary boot image will be boot first after the device is reset. The secondary boot image can be plain, crc or signed image, but cannot be set as the SB file.

Also, the Bank1_IFR0 region (0x0100_8000 to 0x0100_FFFF) can be used as the Bank1_IFR0 recovery Boot area by setting the CMPA[REC_BOOT_SRC] as 1, then the Bank1_IFR0 region image will be set as the recovery boot image to boot when the primary image boot fail.

When the Bank1_IFR0 image is larger than the 32KB, user can also use the specific memory of the internal flash for the Bank1_IFR0 image usage based on the CMPA[REC_IMG_EXTn] corresponding bits, and each bit represent 32KB internal flash size. After the Bank1_IFR0 image boot, the specific memory of the internal flash and Bank1_IFR0 region will also be configured with the specific MBC as the bellow table. Suggest to use the last memory blocks of the internal flash for the Bank1_IFR0 image usage.

Based on the CMPA[OEM_BANK1_IFR0_PROT] setting, after the secondary boot image boot, the Bank1_IFR0 region will be configured with the settings as below.

Lifecycle	Boot mode			
	CMPA[OEM_BANK1_IFR0_PROT]	Secondary boot mode(SBL) & Internal flash(CMPA[REC_IMG_EXTn] corresponding block) MBC setting	Bank1_IFR0 recovery boot(OEM_REC) & Internal flash(CMPA[REC_IMG_EXTn] corresponding block) MBC setting	Not Secondary boot mode(SBL) and not Bank1_IFR0 recovery boot(OEM_REC)
Develop (0x3)	NA	GLBAC0	GLBAC0	GLBAC 0
Develop2 (0x7),	0	GLBAC4	GLBAC4	GLBAC 4
In-field (0xF),	1	GLBAC4		

Table continues on the next page...

Table continued from the previous page...

Lifecycle	Boot mode			
	CMPA[OEM_BANK1_IFR0_PROT]	Secondary boot mode(SBL) & Internal flash(CMPA[REC_IMG_EXTn] corresponding block) MBC setting	Bank1_IFR0 recovery boot(OEM_REC) & Internal flash(CMPA[REC_IMG_EXTn] corresponding block) MBC setting	Not Secondary boot mode(SBL) and not Bank1_IFR0 recovery boot(OEM_REC)
In-field Locked (0xCF), Field Return OEM (0x1F)	2	GLBAC2		
	3	GLBAC6		
	4	GLBAC4		
	5	Not allowed to set		GLBAC 2
	6			GLBAC 6
	7			GLBAC 7

Example 1: Under the LC = 7, when the Bank1_IFR0 region is used for the Secondary boot mode(CMPA[BOOT_SRC] as 2), the REC_IMG_EXT1[31] is set as 1 means the internal flash corresponding last block 32K (0x1F_8000 – 0x1F_FFFF) will be used for Secondary boot mode image usage. And set the CMPA[OEM_BANK1_IFR0_PROT] as 2, then the Bank1_IFR0 region and internal flash last block 32K (0x1F_8000 – 0x1F_FFFF) will be configured with GLBAC2 after the SBL boot.

Example 2: Under the LC = 7, when the Bank1_IFR0 region is used for the Bank1_IFR0 recovery boot mode(CMPA[REC_BOOT_SRC] as 1), and under the LC = 7 the REC_IMG_EXT1[31] is set as 1 means the internal flash corresponding last block 32K (0x1F_8000 – 0x1F_FFFF) will be used for Bank1_IFR0 recovery boot image usage, then the Bank1_IFR0 region and internal flash last block 32K (0x1F_8000 – 0x1F_FFFF) will be configured with GLBAC4 after the Bank1_IFR0 recovery boot.

15.3.3 ISP boot mode

The boot ROM supports an ISP which is mainly used for:

- Downloading the image (initial or updated) into the internal or external flash memory from the host.
- Provisioning the chip during production (configuring Secure mode or programming key data, ISP fall-through mode, and lock settings).

There are a number of conditions that can cause the boot ROM to enter ISP mode. By default, all entry methods are allowed, but CMPA fields can be used to restrict which ISP entry methods are allowed.

Table 246. ISP entry methods

ISP entry method	Description	CMPA field to allow/disallow
Boot fail	If the boot ROM does not locate a valid image, then the ROM can fall-through to ISP mode.	ISP_FT_ENTRY
API	The runBootloader API can be called from an application to request ISP mode entry.	ISP_API_ENTRY

Table continues on the next page...

Table 246. ISP entry methods (continued)

ISP entry method	Description	CMPA field to allow/disallow
Debug mailbox	The debug mailbox includes an Enter ISP mode command which can be used to request ISP entry from the debug port.	ISP_DM_ENTRY and ISP_CMD_EN[1]
ISP pin	If the ISP pin is asserted at reset, then the boot ROM can go straight to ISP mode without attempting to find a boot image.	ISP_PIN_ENTRY

1. ISP_CMD_EN is a field within the SOCU configuration. The combination of the fused DCFG_CC_SOCU plus the CFPA's DCFG_CC_SOCU and CMPA's CC_SOCU determine the access rights for debug commands including the Debug Mailbox Enter ISP mode command. The Debug Mailbox chapter is present in MCX N Security Reference Manual.

NOTE

The ISP_DISABLE fuse field can also be used to restrict ISP entry methods. For an ISP entry to work, it must be enabled by both the CMPA and fuse settings.

In ISP mode, the boot ROM can communicate over a variety of serial interfaces. By default, the device UART, I2C, SPI, CAN, and USB HID are supported. The CMPA's ISP_BOOT_IF can be used to select a specific serial interface to be used, or it can be left in the default Auto ISP mode which will scan all the available interfaces looking for activity. There are also fuses that can be used to disable ISP mode on specific interfaces:

- ISP_CAN_Dis
- ISP_USB1_Dis
- ISP_USB0_Dis
- ISP_I2C_Dis
- ISP_SPI_Dis
- ISP_UART_Dis

For ISP mode to work, the interface selected by ISP_BOOT_IF must be allowed by the ISP_xxx_Dis fuses. See the In-System Programming (ISP) chapter for more details on ISP protocol, packet types, commands, and operation for each serial communication type.

15.3.4 Recovery boot mode

The boot ROM supports a recovery boot from an external 1-bit SPI flash memory device or an image loaded into IFR0 (0x0100_8000 to 0x0100_FFFF). The table below summarizes the recovery boot options.

Table 247. Recovery boot options

Recovery boot type	Selected by	Image format
External 1-bit SPI flash	• CMPA REC_BOOT_SRC = 0b10 • Floating ISP pin	• SB3.1 image • Load-to-RAM image
Bank1_IFR0 recovery boot(OEM_REC) (0x0100_8000 to 0x0100_FFFF)	CMPA REC_BOOT_SRC = 0b01	XIP image

See SPI flash memory recovery for more information.

NOTE

The default pins used for 1-bit SPI flash recovery boot overlap with the FlexSPI pins. This was done intentionally to allow a memory to be used as a recovery device and also to be used for FlexSPI operation later.

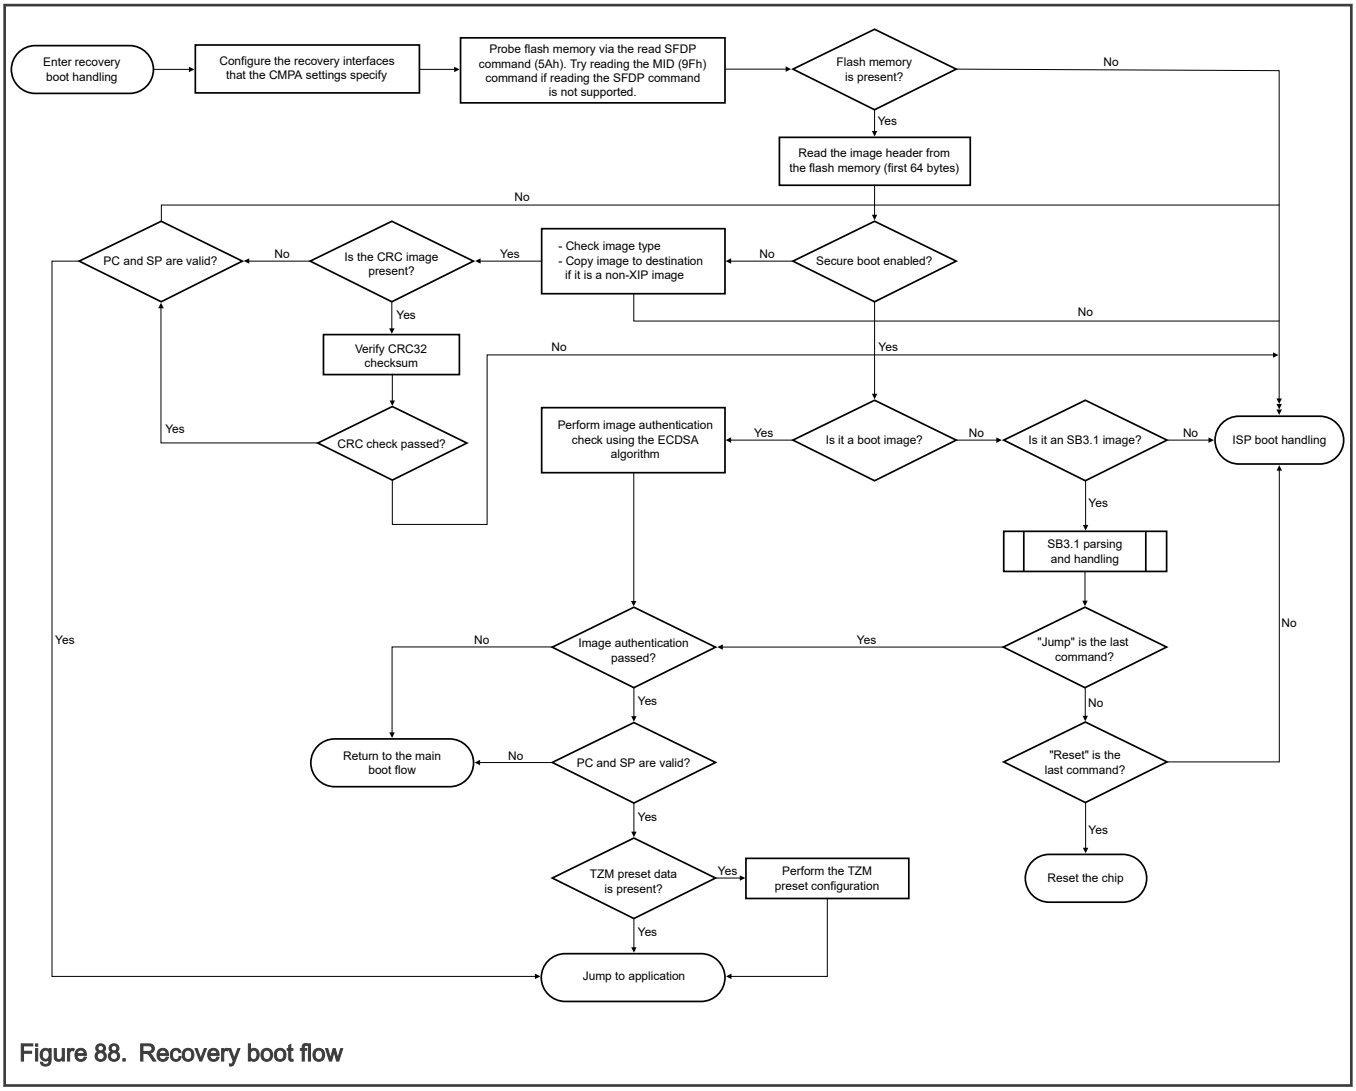

Figure 88. Recovery boot flow

15.4 External memory support

The following table describes the external memory devices, with their memory identifiers, that the boot ROM ISP command supports.

To use an external memory device correctly, the boot ROM enables specific external memory devices, with their corresponding configuration profiles, using a preassigned memory identifier. Without enabling these external memory devices, you cannot access them using the boot ROM ISP command.

Table 248. Memory IDs for external memory devices

Memory identifier	External memory device
09h	Serial NOR over the FlexSPI module
110h	Serial NOR and EEPROM over the SPI module

15.4.1 Serial NOR flash memory through FlexSPI

15.4.1.1 FlexSPI NOR FCB

The boot ROM supports the read, write, and erase functions for external serial NOR flash memory devices via FlexSPI. Before accessing these devices, you must configure the FlexSPI module properly, using a simplified FlexSPI NOR configuration block or a complete 512-byte FlexSPI NOR configuration block. See Table 249 for settings.

The boot ROM can generate the 512-byte FlexSPI NOR configuration block based on the simplified flash memory configuration option block for most serial NOR flash memory devices in the market.

To customize the lookup table (LUT) sequence for a specific chip, you must enable the “lutCustomSeqEnable” field and fill in the corresponding “lutCustomSeq” field. See Table 250 for the predefined LUT index for serial (SPI) NOR.

Table 249. FlexSPI NOR FCB

Field	Offset (hex)	Size (bytes)	Description
tag	000	4	Configuration block tag Must be set to 4246_4346h
version	004	4	Configuration block that the boot ROM uses internally; its value is fixed to 5601_0400h
Reserved	008	4	Reserved for future use
readSampleClkSrc	00C	1	Read sampling clock source option: 0 – Internal sampling 1 – Loopback from DQS pad 2 – Loopback from SCK pad 3 – External DQS signal
csHoldTime	00D	1	CS hold time in terms of flash memory clock cycles Recommended value is 3.
csSetupTIme	00E	1	CS set up time in terms of flash memory clock cycles Recommended value is 3.
columAddressWidth	00F	1	Column address width: • 3 for HyperFlash • 0 for other flash memory devices
deviceModeCfgEnable	010	1	Enables the Device mode configuration sequence
deviceModeType	011	1	Argument for Device mode configuration For example, Quad enable setting in Status register 2 for some Quad SPI flash memory devices
waitTimeCfgCommands	012	2	Wait time in terms of 100 µs for the Device mode configuration command

Table continues on the next page...

Table 249. FlexSPI NOR FCB (continued)

Field	Offset (hex)	Size (bytes)	Description
deviceModeSeq	014	4	Device mode configuration sequence: Byte 0 – Number of required sequences Byte 1 – Sequence index
deviceModeArg	018	4	Argument for Device mode configuration For example, Quad enable setting in Status register 2 for some Quad SPI flash memory devices
configCmdEnable	01C	1	Configuration command enable: 0 – Ignores configuration command 1 – Enables configuration Command
configModeType	01D	3	Configuration command types; supports up to three types Each type is combined with a configuration command sequence.
configCmdSeqs	020	12	Configuration command types; supports up to three sequences
Reserved	02C	4	Reserved for future use
configCmdArgs	030	12	Configure command argument; supports up to three arguments
Reserved	03C	4	Reserved for future use
controllerMiscOption	040	4	Miscellaneous controller configuration options: Bit 0 – Differential clock enable; set to 1 for the HyperFlash 1V8 device, and set to 0 for other devices Bit 3 – WordAddressableEnable; set to 1 for HyperFlash and set to 0 for other devices Bit 4 – SafeConfigFreqEnable; set to 1 for configuring the device with a safe frequency Bit 6 – DDR mode enable; set to 1 if DDR read is expected Other bits – Reserved; set to 0
deviceType	044	1	Device type: 1 - Serial NOR
sflashPadType	045	1	Data pad used in Read command: 1 – Single pad 2 – Dual pads

Table continues on the next page...

Table 249. FlexSPI NOR FCB (continued)

Field	Offset (hex)	Size (bytes)	Description
			4 – Quad pads 8 – Octal pads
serialClkFreq	046	1	SDR: 0 – 30 MHz 1 – 50 MHz 2 – 60 MHz 3 – 75 MHz 4 – 100 MHz DDR: 0 – 30MHz 1 – 50MHz
lutCustomSeqEnable	047	1	LUT customization enable that is required if you cannot perform the program or erase operations using one LUT sequence (currently only applicable to HyperFlash)
Reserved	048	8	Reserved for future use
sflashA1Size	050	4	Size of flash memory connected to A1
sflashA2Size	054	4	Size of flash memory connected to A2
sflashB1Size	058	4	Size of flash memory connected to B1
sflashB2Size	05C	4	Size of flash memory connected to B2
csPadSettingOverride	060	4	Pad override value for CS pin Use this value (if nonzero) to configure the CS pin; otherwise use the default ROM setting
sclkPadSettingOverride	064	4	Serial clock pad setting override value
dataPadSettingOverride	068	4	Data pad setting override value
dqsPadSettingOverride	06C	4	DQS pad setting override value
timeoutInMs	070	4	Timeout value in terms of ms to terminate the busy check
commandInterval	074	4	CS deselect interval between two commands
dataValidTime	078	4	Clock edge to data valid time
busyOffset	07C	2	Busy offset; valid value: 0–31

Table continues on the next page...

Table 249. FlexSPI NOR FCB (continued)

Field	Offset (hex)	Size (bytes)	Description
busyBitPolarity	07E	2	Busy flag polarity: 0 – Indicates that the busy flag is set to 1 when the flash memory device is busy 1 – Indicates that the busy flag is set to 0 when the flash memory device is busy
lookupTable	080	256	16 LUT sequences Each sequence consists of four words (see the "FlexSPI" chapter for more information).
lutCustomSeq	180	48	Customizable LUT sequences
Reserved	1b0	16	Reserved for future use
pageSize	1C0	4	Page size of flash memory
sectorSize	1C4	4	Sector size of flash memory
ipcmdSerialClkFreq	1C8	1	Serial clock frequency for IP command: 0 – The same with Read command Others – The same definition as serialClkFreq
isUniformBlockSize	1C9	1	Indicates whether the sector size is the same as block size: 0 – No 1 – Yes
isDataOrderSwapped	1CA	1	Indicates whether the data order (D0, D1, D2, D3) is swapped (D1, D0, D3, D2)
Reserved	1CB	1	Reserved for future use
serialNorType	1CC	1	Serial NOR flash memory type: 0, 1, 2, or 3
needExitNoCmdMode	1CD	1	Exit NoCmd mode before other IP commands as needed
halfClkForNonReadCmd	1CE	1	Half the serial clock for nonread command: true or false
needRestoreNoCmdMode	1CF	1	Restore NoCmd mode after IP command execution as needed
blockSize	1D0	4	Flash memory block size
flashStateCtx	1D4	4	Flash memory state context

Table continues on the next page...

Table 249. FlexSPI NOR FCB (continued)

Field	Offset (hex)	Size (bytes)	Description
Reserved	1D8	40	Reserved for future use

15.4.1.2 LUT index pre-assignment for FlexSPI NOR

Table 250. LUT index pre-assignment for FlexSPI NOR

Name	Index in LUT	Description
Read	0	Read command sequence
ReadStatus	1	Read status command
ReadStatusXpi	2	Read status command under OPI mode
WriteEnable	3	Write enable command sequence
WriteEnableXpi	4	Write enable command under OPI mode
EraseSector	5	Erase sector command
EraseBlock	8	Erase block command
PageProgram	9	Page program command
ChipErase	11	Full chip erase
ExitNoCmd	15	Exit no command mode as needed
Reserved	6, 7, 10, 12, 13, 14	All reserved indexes can be freely used for other purposes

15.4.2 FlexSPI NOR configuration option block settings

The FlexSPI NOR configuration option block is organized by a 4-bit unit and is expandable (see Table 251 and Table 252 for the current definitions of the block).

The boot ROM detects FCB via reading an SFDP command, which most JESD216(A/B)-compliant flash memory devices support. However, JESD216A/B only defines the dummy cycles for Quad SPI SDR read. To get the dummy cycles for DDR or DTR read mode, the boot ROM supports auto-probing by writing test patterns to offset 200h on the external flash memory devices. For optimal timing, readSampleClkSrc is set to 1 for flash memory devices that do not support externally provided DQS pad inputs. It is set to 3 for flash memory devices that support externally provided DQS pad inputs such as Octal SPI flash memory or HyperFlash NOR flash memory. The FlexSPI_DQS pad is not used for other purposes.

Table 251. FlexSPI NOR configuration option 0 block

Field: Option0 | Offset: 0 Details							
Tag[31:28]	Option size[27:24]	Device detection type[23:20]	Query CMD pad(s) [19:16]	CMD pads(s) [15:12]	Quad SPI enable type[11:8]	Misc mode[7: 4]	Max freq[3:0]
Ch (fixed)	Size in bytes = (option size + 1) × 4 (provides scalability for future use)	Software-defined device types used for configuration block auto-detection 0: Quad SPI SDR 1: Quad SPI DDR 2: HyperFlash 1V8 3: HyperFlash 3V 4: MXIC OPI DDR 6: Micron OPI DDR 7: Micron Octal SDR 8: Adesto OPI DDR 9: Adesto EcoXiP SDR	Command pads (1, 4, and 8) for the SFDP command 0: 1 2: 4 3: 8	Command pads (1, 4, and 8) for the flash memory device 0: 1 2: 4 3: 8	Quad enable sequence 1: QE bit is bit 6 in StatusReg1 2: QE bit is bit 1 in StatusReg2 3: QE bit is in bit 7 in StatusReg2 4: QE bit is bit 1 in StatusReg2; enable command is 0x31	Miscellaneous mode for the selected flash memory types **NOTE** Experimental feature only. Do not use in production: keep it as 0 for normal usage. 0: Not enabled 1: Enable 0-4-4 mode for high random read performance 3: Data orders wrapped mode (for MXIC OctaFlash only) 5: Select the FlexSPI data sample source as internal loop back; see FlexSPI usage for more 6: Configure the FlexSPI NOR flash memory running at stand SPI mode	Maximum flash memory operation speed 0: Don't change the FlexSPI clock setting

Table 252. FlexSPI NOR configuration option 1 block (optional)

Field: Option1 (optional) | Offset: 4 Details			
flash_connection[31:28]	Reserved[27:16]	status_override[15:8]	Dummy cycle[7:0]
Flash connection option (FlexSPI port A or B) 0: Single flash memory connected to port A 2: Single flash memory connected to port B		Override status register value used for Device mode configuration	Dummy cycles for SDR and DDR read commands 0: Use detected dummy cycles Other values: Use dummy cycles provided in the flash memory data sheet

NOTE

CMD pad(s) value is:

- Always 0h for devices that work under 1-1-4, 1-4-4, 1-1-8, or 1-8-8 mode.
- 2 for devices that only support 4-4-4 mode for high performance.
- 3 for devices that only support 8-8-8 mode for high performance.

15.4.3 Typical use cases for the FlexSPI NOR configuration block

Table 253. Use cases for the FlexSPI NOR configuration block

FlexSPI mode name	Access type	Setting
Quad SPI NOR	Quad SDR read	Option0 = C000_0002h (60 MHz)
Quad SPI NOR	Quad DDR read	Option0 = C010_0002h (60 MHz)
HyperFlash 3V0	—	Option0 = C033_3002h (60 MHz)
MXIC OPI DDR	OPI DDR enabled by default	Option0 = C043_3002h (60 MHz)
Micron Octal DDR	DDR read	Option0 = C060_0002h (60 MHz)
Micron OPI DDR	DDR read	Option0 = C060_3002h (60 MHz)
Micron OPI DDR	DDR read enabled by default	Option0 = C063_3002h (60 MHz)
Adesto OPI DDR	DDR read	Option0 = C080_3002h (60 MHz)

15.4.4 Programming a serial NOR flash memory device using the FlexSPI NOR configuration option

The boot ROM supports generating the complete FCB using the configure-memory command. It also supports programming the generated FCB at the start of the flash memory by using a specific option, "0xF000000F." The following table shows an example of how to configure and access HyperFlash (assuming it is a blank HyperFlash device). See Configuring the FlexSPI NOR flash memory device for more information.

Table 254. Programming a serial NOR flash memory device using the FlexSPI NOR configuration option

Step number	Step	Command to perform the step
1	Write the option block to SRAM address 2002_000h.	`blhost -u <PID,VID> - fill-memory 0x20020000 0x04 0xc0333007`
2	Configure HyperFlash using the option block.	`blhost -u <PID,VID> - configure-memory 0x09 0x20020000`
3	Write specific option to SRAM address 2002_000h.	`blhost -u <PID,VID> - fill-memory 0x20020000 0x04 0xf000000f`
4	Program FCB to the offset 400h of the HyperFlash device.	`blhost -u <PID,VID> - configure-memory 0x09 0x20020000`
5	Erase the HyperFlash device from address of specified size.	`blhost -u <PID,VID> – flash-erase-region <addr> <size>`
6	Write the image to the address.	`blhost -u <PID,VID> - write-memory <addr> image.bin`

15.4.5 1-bit serial NOR flash memory through SPI

15.4.5.1 Manual and Auto configuration methods

The boot ROM supports programming 1-bit SPI NOR flash memory devices that support a 3-byte address read, 03h, or 4-byte address read, 13h, via the flash memory configuration option block. It defines the SPI clock frequency as 48 MHz.

The boot ROM supports either a manually configured option or an auto-detected option. When using the manually configured option, you must specify all the flash memory information (flash size, sector size, page size, and so on) in the option block. When using the auto-detected option, which is only supported on devices that are JESD216 compliant, the boot ROM is able to detect the flash memory information via the read SFDP (5Ah) command. Using this command, you can set all the flash memory information to zeros. Table 255 shows details required for configuring the SPI NOR flash memory by using these methods. The read page (03h) is used for the default read command. If the flash memory size is greater than 16 MB (detected by the read SFDP command), the 13h command is used for the page read. If the SFDP command is not supported, the boot ROM uses the read MID (9Fh) to detect whether a device is connected to it.

15.4.5.2 SPI NOR configuration option block settings

Table 255. SPI NOR configuration option block settings (Option0 field settings)

Tag[31:28]	Reserved[27:16]	Flash memory info set[15:12]	Flash memory size[11:8]	Sector size[7:4]	Page size[3:0]
Fixed at Ch		Memory type used to configure and access the NOR flash memory: 0 – Manual (selects flash memory parameter via the flash memory data sheet) 2 – Auto (detects flash memory parameter via the SFDP table)	Memory capacity of the NOR flash memory device: 1 – 1 MB 2 – 2 MB 3 – 4 MB 4 – 8 MB 5 – 16 MB 6 – 32 MB 7 – 64 MB 8 – 64 MB 9 – 128 MB 10 – 256 MB	Sector size of the NOR flash memory device: 0 – 4 KB 1 – 8 KB 2 – 32 KB 3 – 64 KB 4 – 128 KB 5 – 256 KB	Page size of the NOR flash memory device: 0 – 256 bytes 1 – 512 bytes 2 – 1 KB 3 – 128 KB

See Table 256 for information about how to program a 1-bit serial NOR flash memory device via the SPI NOR configuration option block.

15.4.5.3 Programming via the SPI NOR configuration option block

The boot ROM supports programming the serial NOR flash device via the SPI interface using the SPI NOR configuration option block. The following table shows an example of how to configure or program the option block. Before writing the configuration option block, you select the SPI peripheral index by writing the value C070_2000h. (SPI index is the SPI interface used to access serial NOR flash memory.)

Table 256. Programming a 1-bit serial NOR flash memory device via the SPI NOR configuration option block

Step number	Step	Command to perform the step
1	Write the option block to SRAM address 2002_0000h; the SPI instance is 7.	`blhost -p comxx - fill-memory 0x20020000 0x04 0xc0702000`
2	Configure serial NOR flash memory using the option block.	`blhost -p comxx - configure-memory 0x110 0x20020000`
3	Erase the serial NOR flash memory device from address of specified size.	`blhost -p comxx - flash-erase-region <addr> <size> 0x110`
4	Write the recovery boot image or SB3 file to the address in the external 1-bit flash memory.	`blhost -p comxx - write-memory <addr> image.bin 0x110`

15.5 eFuse definitions

The boot ROM supports the fuse block and defines the logical fuse layout provided in the following table, with exported APIs for fuse read and program.

Chapter 16
Debug

16.1 Introduction

This chapter describes the debug architecture of this chip. See Figure 89.

16.1.1 Features

- Supports Joint Test Access Group (JTAG) and Serial Wire Debug (SWD); the primary CM33 CPU supports ETB with 2 KB RAM
- Is based on the Arm CoreSight™ architecture that is adapted for software tracing and debugging
- Implements SWD and Debug Access Port (DAP) to support debugger tools
- Supports the following for the subsystem that uses the Cortex-M33 core:
  - Instrumentation Trace Macrocell (ITM)
  - Data Watchpoint and Trace (DWT)
  - Breakpoint Unit (BPU)
  - Software trace and full instruction trace
- Provides a 4-bit trace port interface unit (TPIU) and 1-bit SWO trace port to efficiently access the Cortex-M33 core's trace information from the system
- Supports cross-triggered interface (CTI). One Cortex-M33 core can halt or restart the other one. The primary Cortex-M33 core's CTI channel input has connections with ETB debug halt, Baseband Signal Processor (BSP) with 32-bit data path and 32-bit data memories (BSP32) restart, and BSP32 break signals.

16.1.2 Architecture

The following figure shows the system level debug architecture.

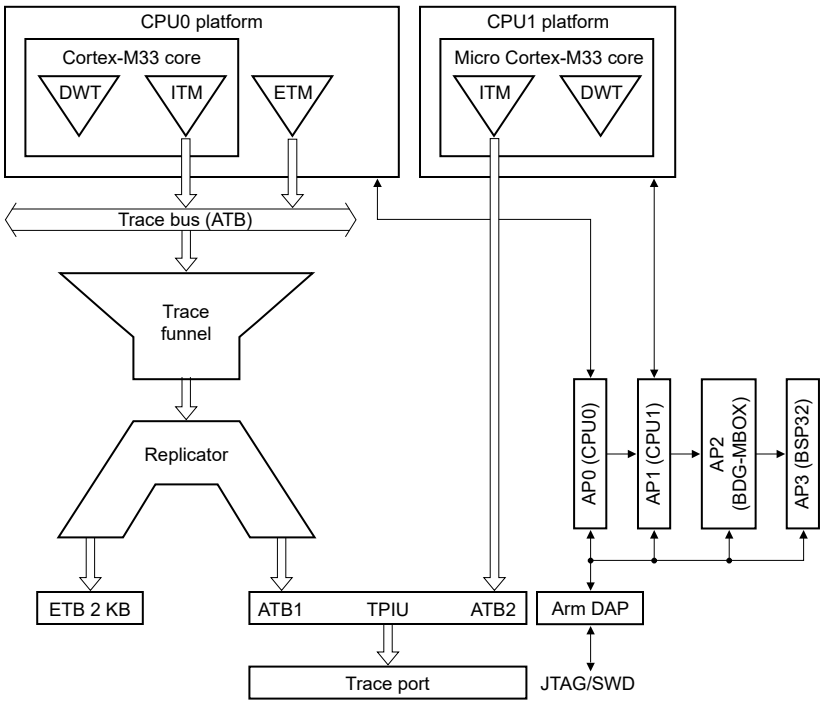

Figure 89. Debug architecture

16.2 Test and debug port connectivity

The following figure shows the connectivity of TAP and DAP on this device.

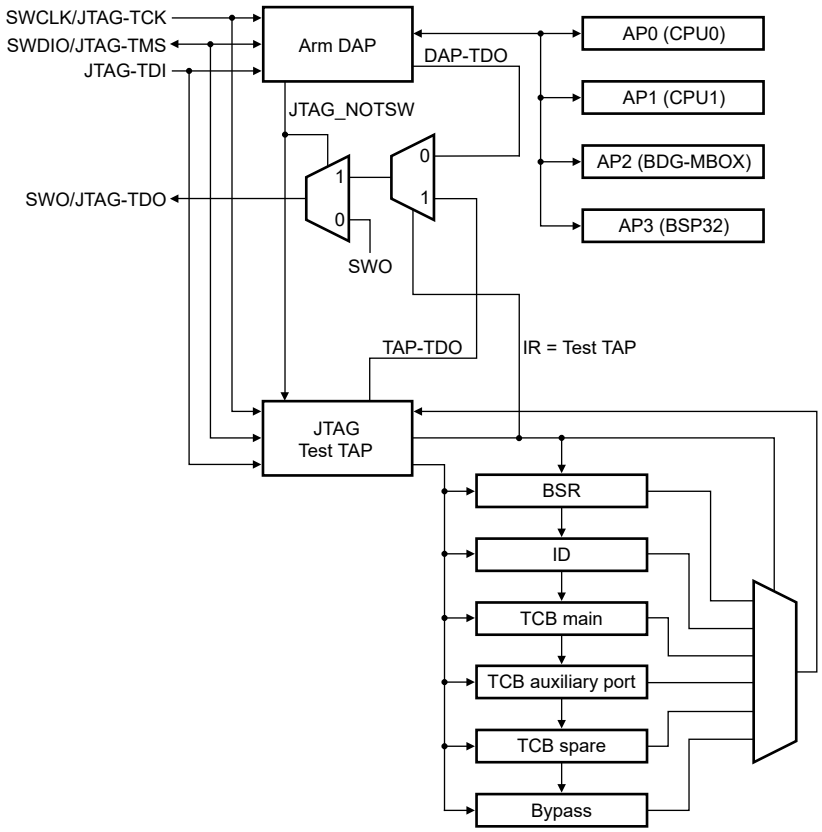

Figure 90. TAP and DAP connectivity

The following table summarizes the JTAG and SWD signals.

Table 257. JTAG and SWD signals description

Pin name	JTAG		SWD		Internal pullup or pulldown
	Type	Description	Type	Description	
TMS or SWDIO	I/O	Mode selection	I/O	Data	Pullup
TCLK or SWCLK	I	Clock	I	Clock	Pulldown
TDI	I	Data input	--	--	Pullup
TDO	O	Data output	--	--	N/A

16.2.1 JTAG

16.2.1.1 Instruction registers

JTAG TAP connects to the Arm DAP controller in parallel, that is, the JTAG-DP port of the DAP. The length of the instruction register (IR) is 4-bits. The JTAG TAP IR codes overlay the DAP controller IR codes. JTAG TAP uses 12 instructions, and the DAP uses the remaining four instructions. The TAP (TDO) outputs are multiplexed based on the selected IR code. This design is fully JTAG compliant and appears to the JTAG chain as a single TAP.

The following table provides a list of IR codes for the system JTAG controller.

Table 258. JTAG TAP

Code	JTAG IR
0000b	IR_EXTEST
0001b	SAMPLE/PRELOAD
0010b	IR_HIGHZ
0011b	IR_CLAMP
0100b	IR_IDCODE
0101b	Reserved
0110b	Reserved
0111b	Reserved
1000b	ARM-DAP IR_ABORT
1001b	Reserved
1010b	ARM-DAP IR_DPACC
1011b	ARM-DAP IR_APACC
1100b	Reserved
1101b	Reserved
1110b	ARM-DAP IR_DAP_ID
1111b	ARM-DAP BYPASS

16.2.1.2 Switching JTAG mode to SWD mode

JTAG mode is the default connection of the JTAG/SWD port. The following sequence of events switch the debug port to SWD mode:

1. Send more than 50 TCLK cycles with TMS/SWDIO = 1.
2. Send the 16-bit sequence on TMS/SWDIO = 0111_1001_1110_0111 (MSB transmitted first).
3. Send more than 50 TCLK cycles with TMS/SWDIO = 1.

16.2.2 DAP

DAP is a standard Arm CoreSight component that provides multiple master driving ports, all accessible and controlled through a single external interface port to provide system-wide debug. The following table lists the DAP IR codes:

Table 259. DAP IR Codes

Code	DAP IR
1000b	ABORT
1010b	DPACC
1011b	APACC
1110b	IDCODE

The DAP offers AHB and APB master interfaces to access system buses. It also exports the internal DAP bus to extend the access ports as per the system requirement. It offers JTAG AP to add auxiliary JTAG TAPs. For more information on DAP or JTAG chips under JTAG AP, see *Arm Debug Interface v5 Architecture Specification* on arm.com

The AHB AP's AHB transfers are burst size of 1 only with no out-of-order transactions and no multiple outstanding accesses. Use the APB AP to access debug components of the system trace such as TPIU and ETB.

Use the exported DAP bus to host AHB AP (integrated as part of the Cortex-M33 core integrations). Select different access ports in the DAP based on the APSEL value set in the SELECT register of SWJ-DP.

The following figure shows the DAP configuration on this chip.

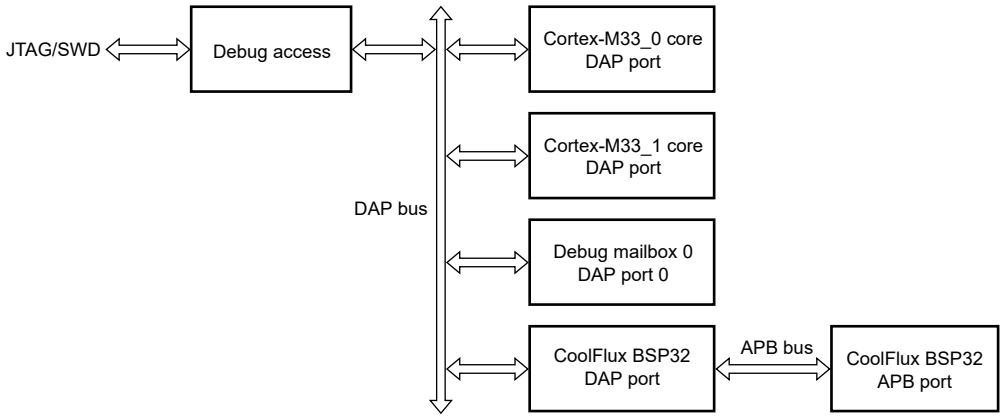

Figure 91. DAP configuration

16.3 Debug ROM table

The debug ROM table holds information about different debug components and help identify them. In this chip, this table resides in the CM33 core and contains entries for CM33 debug components.

Table 260. Debug ROM table

Processor		Start address
CPU0 ROM		E00FE000h
	Cortex-M33 core processor ROM	E00FF000h
	TPIU	E0040000h
	Trace funnel	E0044000h
	ETB	E0045000h
CPU1 ROM		E00FF000h

NOTE

Both CPU0 and CPU1 share the same TPIU inside CPU0 at E0040000h, which only CPU0 can program via its Private Peripheral Bus (PPB).

16.4 Cortex-M33 core debug

This section discusses the debug mechanisms associated with the Cortex-M33 core processor.

16.4.1 Software debug and trace

See Figure 89 for more details on the data flow of software debug and trace information for the Cortex-M33 core on this chip.

16.4.2 DWT

The Cortex-M33 core's DWT module generates trace information in the core. You can program the module's four independent watchpoints for comparing data, address, or program counter (PC) to trigger ETM or to function as a hardware watchpoint. You can configure DWT to generate PC samples at defined intervals and generate interrupt event information. DWT also provides periodic requests for protocol synchronization to the ITM and TPIU.

16.4.3 BPU

The Cortex-M33 core's BPU module consists of up to eight instruction address comparators. It provides breakpoint functionality on all instructions fetched across the entire address range in which you can locate the code.

16.4.4 ITM

ITM generates trace information as packets, and there are multiple sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The sources in decreasing order of priority are as follows:

- Software trace: Your software can write console messages directly to ITM stimulus ports and output them to the host as trace packets.
- Hardware trace: DWT generates these packets, and the ITM outputs them.
- Timestamping: ITM can generate timestamp packets that are inserted into the trace stream to help the host debugger to figure out the timing of events. Timestamp generation occurs relative to packets. ITM contains a 21-bit counter to generate the timestamp.

Trace data from ITM is forwarded to either the TPIO or SWO and streamed out via the trace port.

16.4.5 ETM

Instruction trace, also known as ETM trace, is a continuously collected sequence of every executed instruction for a selected portion of the application. ETM generates trace packets and sends them to the trace bus. It does not output every address or instruction that the processor has executed; it generates compressed information about the program flow and outputs full addresses as per requirement (for example, if a branch takes place). Because the debugger knows the application code image, the debugger can then reconstruct the full instruction sequence from the trace data.

16.5 In-system programming access port (ISP-AP)

ISP-AP provides a useful interface between the debugger and the core, and thus it controls the debug information.

16.6 CTI

The following table defines CTI input triggers.

Table 261. CTI input triggers

Signal	Description	Connection	Acknowledge, handshake
CTITRIGIN[7]	--	ETM to CTI	Pulsed
CTITRIGIN[6]	--		
CTITRIGIN[5]	ETM event output 1		

Table continues on the next page...

Table 261. CTI input triggers (continued)

Signal	Description	Connection	Acknowledge, handshake
CTITRIGIN[4]	ETM event output 0 or comparator output 3	ETM or processor to CTI	
CTITRIGIN[3]	DWT comparator output 2	Processor to CTI	
CTITRIGIN[2]	DWT comparator output 1		
CTITRIGIN[1]	DWT comparator output 0		
CTITRIGIN[0]	Processor halted		

The following table defines CTI output triggers. The Cortex-M33 cores support CTI. One Cortex-M33 core can halt or restart the other one. The CPU0 CTI channel input has connections with ETB debug halt, BSP32 restart, and BSP32 break signals:

- CPU0 CTICHIN = {CPU1 CTICHOUT[1], ETB debug halt, BSP32 restart, BSP32 break}
- CPU1 CTICHIN = {CPU0 CTICHOUT[1], 000}

Table 262. CTI output triggers

Signal	Description	Connection	Acknowledge, handshake
CTITRIGOUT[7]	ETM event input 3	CTI to ETM	Pulsed
CTITRIGOUT[6]	ETM event input 2		
CTITRIGOUT[5]	ETM event input 1 or MTB trace stop	CTI to ETM or MTB	
CTITRIGOUT[4]	ETM event input 0 or MTB trace stop		
CTITRIGOUT[3]	Interrupt request 1	CTI to system	Acknowledged by writing to the CTIINTACK register in ISR
CTITRIGOUT[2]	Interrupt request 0		
CTITRIGOUT[1]	Processor restart	CTI to processor	Processor restarted
CTITRIGOUT[0]	Processor debug request		Acknowledged by the debugger writing to the CTIINTACK register in ISR

16.7 Low-power debug

CMC.DBGCTL[SOD] controls low-power debug. Writing 1 disables the debugger (debug power-up acknowledge negates) when the Cortex-M33 core sleeps, and the chip fully enters Low-Power mode. When CMC.DBGCTL[SOD] = 0, the Cortex-M33 clocks remain enabled while the Cortex-M33 core sleeps. In this condition, the debug powerup request is asserted to maintain the debug connection. The chip does not enter Low-Power mode completely. Your software can modify the value of DBGCTL[SOD] before each low-power entry. Supported modes include:

- Clock-Gated mode
- Power-Gated mode

16.7.1 Clock-Gated mode

If the SWJDAP debug powerup request is high, and CMC.DBGCTL[SOD] = 0, when the system attempts to enter STOP mode, the DAP clock and the FCLK continue to run to support core register access and trace. This happens when the system attempts to enter STOP mode. In this case, the debug module has access to core registers but not to modules that are clock-gated.

16.7.2 Power-Gated mode

You must implement SWJDP in Wake domain and can retain the JTAG/SWD status when the chip enters Deep Sleep or Power-Down mode. In this way, the debugger remains attached to the SWD/JTAG, but the debug powerup acknowledge remains negated to indicate that the debugger cannot connect to any of the debug registers in the Cortex-M33 core. When the chip enters Deep Power-Down mode, JTAG/SWD is reset. Debug access is disabled on every warm reset and remains disabled until the completion of boot ROM execution. This includes a wake-up from Power-Down or Deep Power-Down mode. When wake-up from Power-Down or Deep Power-Down mode occurs, the boot ROM supports either normal boot flow or low-power wake-up flow. In normal boot flow, boot ROM can configure debug based on either debug authentication results or fuse life cycle bit configuration. In low-power wake-up flow, boot ROM configures debug only based on life cycle bit configuration. See the ROM chapters on how to configure debug.

16.8 Debug authentication

The Armv8-M processor implements debug authentications using the CoreSight signals, such as DBGEN, NIDEN, SPIDEN, and SPNIDEN. This chip implements debug authentication to control the state of SPIDEN and SPNIDEN signals from Arm using the ROM and debug mailbox (DM). A 2-bit field in the protected flash region (called either IFR or PFR) specifies the secure debug enable control, and the field values perform the following functions:

- 00: Enables secure debug always (factory default state)
- 01: Enables secure debug using "image authentication", but does not write lock the register before entering the user code
- 10: Enables secure debug using "image authentication" and write locks the register before entering the user code (a blank or corrupted flash memory disables secure debug until the next POR)
- 11: Disables secure debug and write locks the register

Chapter 17
System Controller (SYSCON)

17.1 Chip-specific SYSCON information

Table 263. Reference links to related information

Topic	Related module	Reference
Full description	SYSCON	SYSCON
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

NOTE

The reset values of some registers may change depending on the device's boot settings.

17.1.1 Module instances

This device has one instance of SYSCON module, SYSCON0.

NOTE

The SYSCON module includes some security functionality that is not described here. Refer to the MCX N Security RM for more details.

17.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

17.1.3 Configuration

Configure the SYSCON block as follows:

- No clock configuration is needed. The clock to the SYSCON block is always enabled.
- The SYSCON block controls use of the CLKOUT pin, which must also be configured through Port control module.

17.2 Overview

The SYSCON module provides controls and configurations on the system and peripherals for the multiple functions.

17.2.1 Features

The SYSCON module supports the following features and configurations:

- System and bus configuration
  - AHB matrix priority
  - CPUs control and status
  - CPU and DSP debug access
  - CPU LPCAC control

  - NMI source select
  - Calibrate system tick timer
  - Boot control
- System/Peripherals - clock select and control
  - Allows enabling and selection of clocks to individual peripherals and memories
  - Allows configuration of clock dividers
- Memory configuration
  - ROM access
  - RAM ECC
  - FLASH cache, bus error
- Gray-2-Binary converter
  - Allows decoding gray value coming from OS Event Timer
- Peripherals configuration
  - SmartDMA interrupt hijack
  - PWM0/1 control
  - Ethernet PHY selection and flow control
  - CTIMER global start
- Security configuration
  - Security control - ELS, GDET0/1
  - Security boot
  - Security attestation
- Reset control
  - Monitors and release resets to individual peripherals
- Device ID register

17.3 Signals

Table 264. SYSCON pin description

Function	Type	Pin	Description
CLKOUT	O	PIO0_6, PIO2_2, PIO3_6	CLKOUT clock output. Refer to the Pinouts information.

17.4 Memory map and register definition

This section includes the SYSCON module memory map and detailed descriptions of all registers.

17.4.1 SYSCON register descriptions

17.4.1.1 SYSCON memory map

17.4.1.2 AHB Matrix Priority Control (AHBMATPRIO)

Offset

Register	Offset
AHBMATPRIO	10h

Function

The Multilayer AHB Matrix arbitrates between masters, when they attempt to access the same matrix slave port at the same time. The priority values are 3 = highest, 0 = lowest. When the priority is the same, the master with the lower master number is given priority.

NOTE

Be careful when modifying this register as improper settings can seriously degrade the performance.

17.4.1.3 Secure CPU0 System Tick Calibration (CPU0STCKCAL)

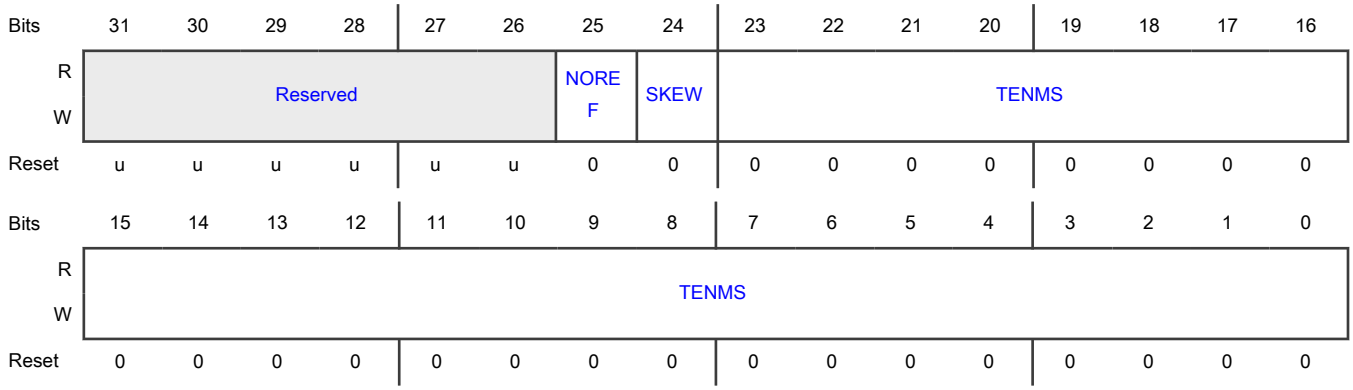
Offset

Register	Offset
CPU0STCKCAL	38h

Function

The CPU0STCKCAL register allows software to set up a default value for the SYST_CALIB register (refer to Arm documentation) in the System Tick Timer of secure part of the CPU0.

Diagram



Fields

Field	Function
31-26 —	Reserved
25 NOREF	Whether the device provides a reference clock to the processor. 0b - Reference clock is provided 1b - No reference clock is provided
24 SKEW	Whether the TENMS value is exact. 0b - TENMS value is exact 1b - TENMS value is not exact or not given
23-0 TENMS	Reload value for 10 ms (100 Hz) timing, subject to system clock skew errors. If the value reads as zero, the calibration value is not known.

17.4.1.4 Non-Secure CPU0 System Tick Calibration (CPU0NSTCKCAL)

Offset

Register	Offset
CPU0NSTCKCAL	3Ch

Function

The CPU0NSTCKCAL register allows software to set up a default value for the SYST_CALIB register in the System Tick Timer of non-secure part of the CPU0.

Diagram

29-16 —	Reserved
15-8 IRQCPU1	The IRQ number of the interrupt that acts as the Non-Maskable Interrupt (NMI) for CPU1, if enabled by NMIENCPU1.
7-0 IRQCPU0	The IRQ number of the interrupt that acts as the Non-Maskable Interrupt (NMI) for CPU0, if enabled by NMIENCPU0.

17.4.1.7 Peripheral Reset Control 0 (PRESETCTRL0)

Offset

Register	Offset
PRESETCTRL0	100h

Function

The PRESETCTRL0 register allows software to reset specific peripherals. Writing a 0 to any assigned bit in this register clears the reset and allows the specified peripheral to operate. Writing a 1 asserts the reset.

NOTE

When modifying the PRESETCTRL registers, use the related PRESETCTRLSET and PRESETCTRLCLR registers to avoid setting or clearing bits unintentionally.

17.4.1.8 Peripheral Reset Control 1 (PRESETCTRL1)

Offset

Register	Offset
PRESETCTRL1	104h

Function

The PRESETCTRL1 register allows software to reset specific peripherals. Writing a 0 to any assigned bit in this register clears the reset and allows the specified peripheral to operate. Writing a 1 asserts the reset.

NOTE

When modifying the PRESETCTRL registers, use the related PRESETCTRLSET and PRESETCTRLCLR registers to avoid setting or clearing bits unintentionally.

17.4.1.11 Peripheral Reset Control Set (PRESETCTRLSET0 - PRESETCTRLSET3)

Offset

Register	Offset
PRESETCTRLSET0	120h
PRESETCTRLSET1	124h
PRESETCTRLSET2	128h
PRESETCTRLSET3	12Ch

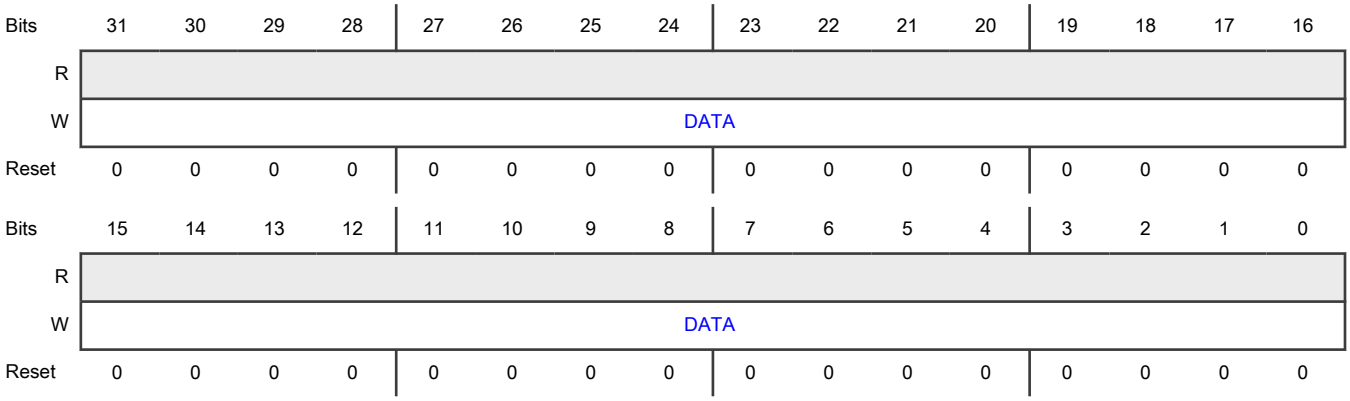
Function

Writing a 1 to a bit position in a write-only PRESETCTRLSETn register sets the corresponding position in PRESETCTRLn.

NOTE

To reset RTC correctly, you must write 1 to RTC.CTRL[SWR] when writing 1 to PRESETCTRL1[RTC_RST], and write 0 to RTC.CTRL[SWR] after writing 0 to PRESETCTRL1[RTC_RST].

Diagram



Fields

Field	Function
31-0 DATA	Data array value, refer to corresponding position in PRESETCTRLn.

17.4.1.12 Peripheral Reset Control Clear (PRESETCTRLCLR0 - PRESETCTRLCLR3)

Offset

Register	Offset
PRESETCTRLCLR0	140h
PRESETCTRLCLR1	144h
PRESETCTRLCLR2	148h
PRESETCTRLCLR3	14Ch

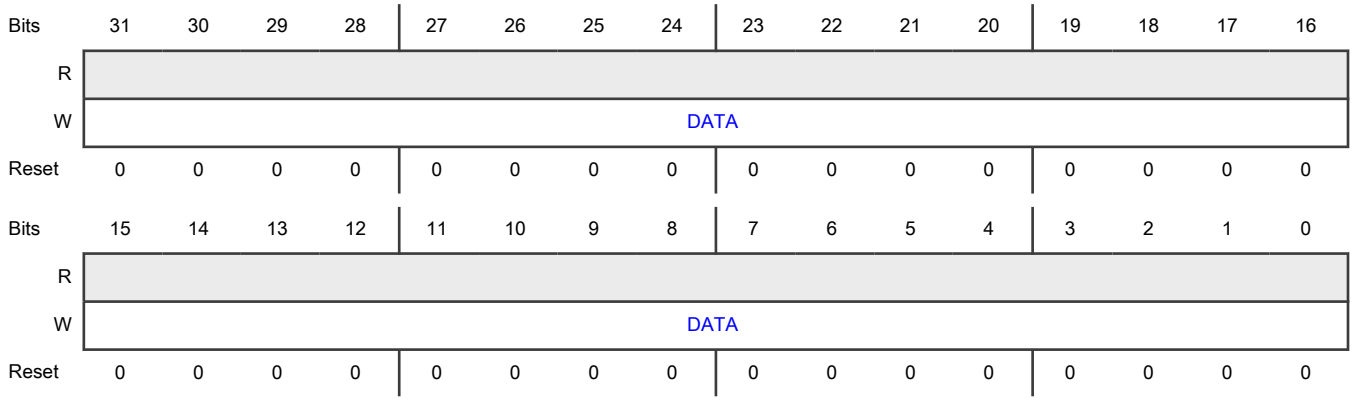
Function

Writing a 1 to a bit position in a write-only PRESETCTRLCLRn register clears the corresponding position in PRESETCTRLn.

NOTE

To reset RTC correctly, you must write 1 to RTC.CTRL[SWR] when writing 1 to PRESETCTRL1[RTC_RST], and write 0 to RTC.CTRL[SWR] after writing 0 to PRESETCTRL1[RTC_RST].

Diagram



Fields

Field	Function
31-0 DATA	Data array value, refer to corresponding position in PRESETCTRLn.

17.4.1.13 AHB Clock Control 0 (AHBCLKCTRL0)

Offset

Register	Offset
AHBCLKCTRL0	200h

Function

The AHBCLKCTRLn registers enable the clocks of the individual modules.

NOTE

When modifying the AHBCLKCTRL registers, use the related AHBCLKCTRLSET and AHBCLKCTRLCLR registers to avoid setting or clearing bits unintentionally.

Diagram

28-8 —	Reserved
7-0 DIV	Clock divider value The divider value = (DIV + 1)

17.4.1.45 PLL1 Clock 1 Divider (PLL1CLK1DIV)

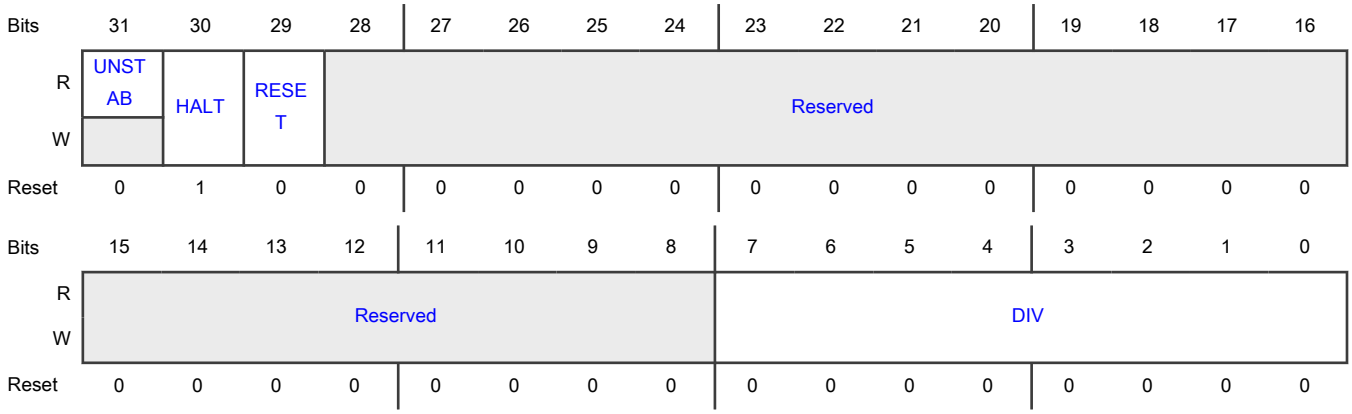
Offset

Register	Offset
PLL1CLK1DIV	3E8h

Function

This register is used to generate pll1_clk1 clock from pll1_clk clock.

Diagram



Fields

Field	Function
31 UNSTAB	Divider status flag 0b - Divider clock is stable 1b - Clock frequency is not stable
30 HALT	Halts the divider counter 0b - Divider clock is running 1b - Divider clock is stopped
29 RESET	Resets the divider counter 0b - Divider is not reset 1b - Divider is reset
28-8 —	Reserved
7-0 DIV	Clock divider value The divider value = (DIV + 1)

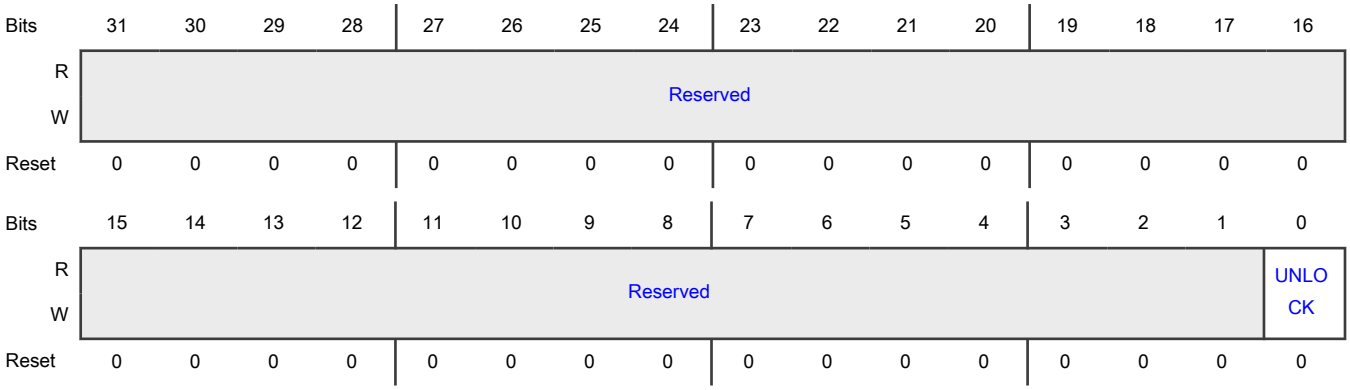
17.4.1.46 Clock Configuration Unlock (CLKUNLOCK)

Offset

Register	Offset
CLKUNLOCK	3FCh

Function
This register controls access to the clock select and divider configuration registers.

Diagram



Fields

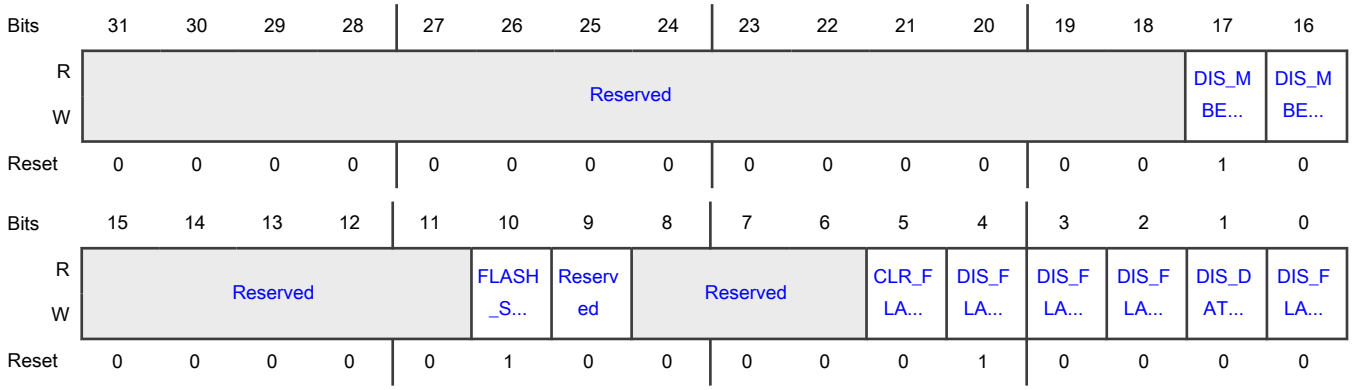
Field	Function
31-1 —	Reserved
0 UNLOCK	Controls clock configuration registers access (for example, xxxDIV, xxxSEL) 0b - Updates are allowed to all clock configuration registers 1b - Freezes all clock configuration registers update

17.4.1.47 NVM Control (NVM_CTRL)

Offset

Register	Offset
NVM_CTRL	400h

Diagram



Fields

Field	Function
31-18 —	Reserved
17 DIS_MBECC_ERR_DATA	Bus error on data multi-bit ECC error control 0b - Enables bus error on multi-bit ECC error for data 1b - Disables bus error on multi-bit ECC error for data
16 DIS_MBECC_ERR_INST	Bus error on instruction multi-bit ECC error control 0b - Enables bus error on multi-bit ECC error for instruction 1b - Disables bus error on multi-bit ECC error for instruction
15-11 —	Reserved
10 FLASH_STALL_EN	FLASH stall on busy control 0b - No stall on FLASH busy 1b - Stall on FLASH busy
9 —	Reserved Keep the default value.
8-6 —	Reserved
5 CLR_FLASH_CACHE	Clear flash cache control 0b - No clear flash cache 1b - Clears flash cache
4	Flash data cache control

Table continues on the next page...

Table continued from the previous page...

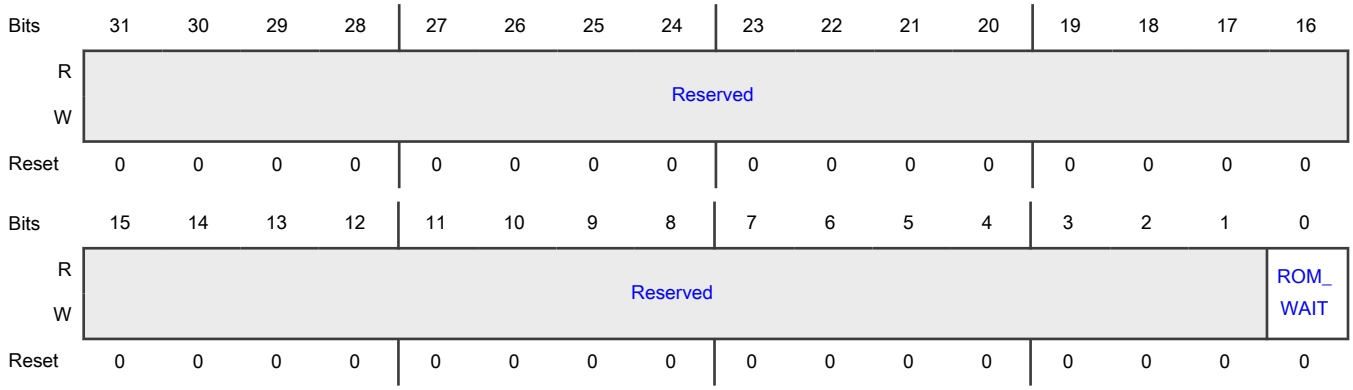
Field	Function
DIS_FLASH_DATA	0b - Enables flash data cache when DIS_FLASH_CACHE=0 1b - Disables flash data cache
3 DIS_FLASH_INST	Flash instruction cache control 0b - Enables flash instruction cache when DIS_FLASH_CACHE=0 1b - Disables flash instruction cache
2 DIS_FLASH_CACHE	Flash cache control 0b - Enables flash cache 1b - Disables flash cache
1 DIS_DATA_SPEC	Flash data speculation control **NOTE** If DIS_MBECC_ERR_DATA and/or DIS_MBECC_ERR_INST are set, then speculation will not be enabled, even if this bit is cleared. 0b - Enables data speculation 1b - Disables data speculation
0 DIS_FLASH_SPEC	Flash speculation control **NOTE** If DIS_MBECC_ERR_DATA and/or DIS_MBECC_ERR_INST are set, then speculation will not be enabled, even if this bit is cleared. 0b - Enables flash speculation 1b - Disables flash speculation

17.4.1.48 ROM Wait State (ROMCR)

Offset

Register	Offset
ROMCR	404h

Diagram



Fields

Field	Function
31-1 —	Reserved
0 ROM_WAIT	ROM waiting Arm core and other masters for one cycle 0b - Disabled 1b - Enabled

17.4.1.49 SmartDMA Interrupt Hijack (SmartDMAINT)

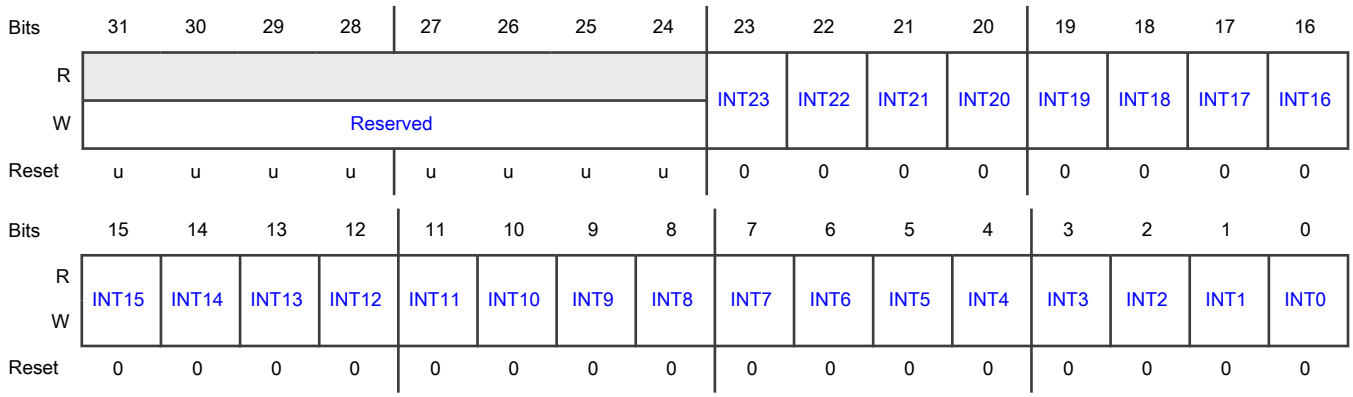
Offset

Register	Offset
SmartDMAINT	414h

Function

Bits directly control the SmartDMA hijacking the system interrupts.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 INT23	SmartDMA hijack NVIC IRQ77 0b - Disable 1b - Enable
22 INT22	SmartDMA hijack NVIC IRQ67 0b - Disable 1b - Enable

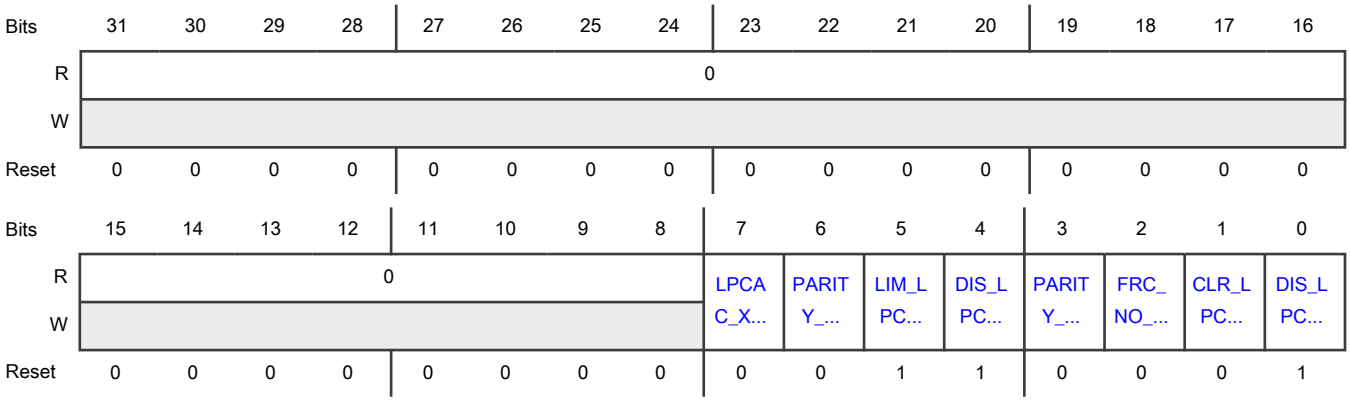
17.4.1.98 LPCAC Control (LPCAC_CTRL)

Offset

Register	Offset
LPCAC_CTRL	824h

Diagram



Fields

Field	Function
31-8 —	Reserved
7 LPCAC_XOM	LPCAC XOM(eXecute-Only-Memory) attribute control Controls if the instruction fetch attribute is used as part of the address input to the LPCAC. When XOM regions in the internal flash are not configured at the MBC, then this option should be disabled so that instructions and data can be stored within the same cache line. This provides the best cache efficiency for non-XOM applications. When XOM areas in the internal flash are configured at the MBC, then this bit must be set so that instructions and data are cached using separate lines within the LPCAC. 0b - Disabled. 1b - Enabled.
6 PARITY_FAULT_EN	Enable parity error report. 0b - Disables parity error report 1b - Enables parity error report
5 LIM_LPCAC_WTBF	Limit LPCAC Write Through Buffer. 0b - Write buffer enabled when transaction is bufferable. 1b - Write buffer enabled when transaction is cacheable and bufferable
4 DIS_LPCAC_WTBF	Disable LPCAC Write Through Buffer. 0b - Enables write through buffer 1b - Disables write through buffer
3 PARITY_MISS_EN	Enables parity miss. 0b - Disabled 1b - Enables parity, miss on parity error
2 FRC_NO_ALLOC	Forces no allocation. 0b - Forces allocation 1b - Forces no allocation
1 CLR_LPCAC	Clears the cache function. 0b - Unclears the cache 1b - Clears the cache
0 DIS_LPCAC	Disables/enables the cache function. 0b - Enabled 1b - Disabled

17.4.1.123 Control Automatic Clock Gating (AUTOCLKGATEOVERRIDE)

Offset

Register	Offset
AUTOCLKGATEOVERRIDE	E04h

Function

This register allows selectively disabling automatic clock gating for device SRAMs. By default, automatic clock gating turns off clocks to each internal SRAM after 16 bus clocks with no activity. This saves power when the SRAMs are not used for a period of time. When turned off due to automatic clock gating, there is a 1 clock delay for the next access to an SRAM. Automatic clock gating may be disabled for time-critical code, which may typically give a 1 or 2% speed improvement.

18.1.1 Module instances

This device has one instance of the PowerQuad module, POWERQUAD0.

18.2 Overview

PowerQuad is a DSP Accelerator, designed to assist Cortex-M, working within the Arm ecosystem. The PowerQuad hardware module is designed to accelerate some general DSP computing tasks, such as math, matrix, filter, and transform functions including Fast Fourier Transforms (FFT). Because hardware executes the computing tasks outside the Arm core, tasks run faster and save CPU time.

As technology evolves, so does the need for smarter and lower-power IoT nodes, so the computational performance requirements for local analysis of data is growing. This requirement poses some challenges for the Cortex-M architecture, designed for low power and real-time control. That strength allows a very light layer of software to be able to control I/O and peripherals in a tightly coupled deterministic manner. This same architecture that is advantageous for MCU control, is not optimal for the task of handling vast amounts of data. The purpose of the PowerQuad hardware accelerator is to assist the Cortex-M33 (CM33) core with the handling of digital signal processing.

PowerQuad is a hardware accelerator for common calculations in DSP applications. PowerQuad includes seven internal computation engines:

- Transform
- Transcendental function
- Trigonometry function
- Dual Biquad infinite impulse response (IIR) filter
- Matrix accelerator
- Finite impulse response (FIR) filter
- Coordinate rotation digital computer (CORDIC)

By significantly reducing the runtime and the energy requirements of signal processing algorithms, PowerQuad allows you to run more accurate, elaborate algorithms in an energy-efficient manner.

18.2.1 Block diagram

PowerQuad is a digital signal coprocessing companion to the CM33 core. You can access PowerQuad through the coprocessor interface, the memory mapped interface, or through the CORDIC interface address space.

PowerQuad is primarily based on a quad floating-point multiply accumulator (MAC) compute block. This four-way MAC implements almost all functions supported by the accelerator. The other compute elements in PowerQuad are the FFT radix-8 butterfly engine (for FFT/DCT calculations) and the CORDIC for inverse trigonometric functions (arctan, arctanh).

Since the main compute engine is natively in floating-point format, this simplifies operations that are not tightly bound in terms of input data or result. Having a floating-point format ensures that a certain resolution can be achieved without the need for saturating the checking and/or implementing logic.

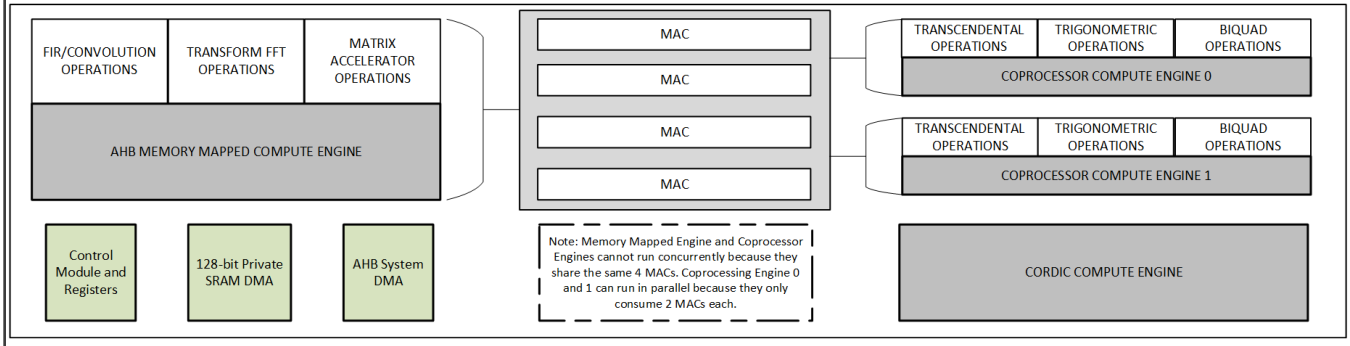

Figure 92. PowerQuad block diagram

18.2.2 Features

The key features of PowerQuad are:

- Communication interfaces:
  - Coprocessor interface from the CM33 core, a register-to-register interaction.
  - AHB as a subordinate interface, use to configure the PowerQuad registers.
  - AHB as a manager interface for PowerQuad to fetch or write data to and from the system memory, when required.
  - 128-bit wide RAM controller that can access up-to 4 RAM banks simultaneously to fetch or write data as needed.
- Four single-precision floating-point multiply accumulator (MAC) units
- Coprocessor engines for tightly coupled opcodes: sin(x), cos(x), ln(x), e^(x), e^(-x), 1/(x), 1/sqrt(x), sqrt(x), biquad(x). Using two MACs, you can run two opcodes in parallel
- Memory-mapped
  - FFT/iFFT/DCT/iDCT operations
  - Matrix operations: add, sub, dot, prod, mult, inverse, transpose, scale
  - Convolution/Correlation/FIR
- Arctan/Arctanh (these operations can be used as the base to compute any CORDIC function)

With the assistance of PowerQuad, the CM33 core is free to perform other tasks. While PowerQuad executes an assigned computation task, the CM33 core can prepare the next PowerQuad task, resulting in a pipeline of PowerQuad tasks.

18.3 Functional description

In a conventional MCU without PowerQuad, the main CPU performs all of the computation work. When using the PowerQuad, work is accelerated and depending on the operation in progress the main CPU can continue to work on other tasks while the PowerQuad finishes processing the operation. For example, transcendental functions are now essentially assembly instructions

for the CM33 core. Other larger functions (such as FFT, or matrix calculations) can be considered as a kind of DMA job, where the core can start them and receive an interrupt or event when the job completes.

Using PowerQuad, you can treat PowerQuad as a coprocessor, performing multiple tasks by rearranging them and reducing the branching to speed up computational processing. The PowerQuad engines compute the assigned functions faster than using the CM33 core alone.

The aim of the PowerQuad coprocessor is to serve the following purposes:

- Provide significant energy reduction for the execution of digital signal processing algorithms
- Significantly accelerate digital signal processing operations compared to the Cortex-M core alone
- Provide hardware acceleration for common DSP functions (mainly from the CMSIS-DSP library)

After applying the clock to PowerQuad, based on the requested operation, one of the computation engines activates. All PowerQuad operations fall into one of three access types. Access PowerQuad through either:

- The coprocessor engines(CP)
- The AHB memory mapped engine (AHB).
- The CORDIC engine

18.3.1 Coprocessor interface

18.3.1.1 Introduction

The ARMv8-M architecture (CM33) introduces a coprocessor interface, which allows PowerQuad access through opcodes:

- MCR (Move from coprocessor to Register)
- MRC (Move from Register to coprocessor)

When accessing PowerQuad through the coprocessor interface, executing a correctly formatted coprocessor instruction launches the operation. Executing a second coprocessor instruction retrieves the result. The coprocessor is self-stalling, which means that if you perform a read from a result register, the access stalls until the computation is complete. These take 2 MACS out of the 4 to implement, allowing you to run two operations in parallel.

To achieve the best performance, use vectorized forms of the coprocessor instructions. These typically handle the work at function calls and follow the timing as shown in the figure below. These vectorized forms are already coded by NXP to achieve timing as shown (note that the figure shows just 2 calculations. In the vectorized functions, we perform 4 of these in a row (that is, 8 calculations).

When submitting the data and/or opcodes to a coprocessor, the CM33 core can continue executing other tasks while the coprocessor computes in parallel. This parallel work ensures that the CM33 core and PowerQuad are not left idle, maximizing the performance of the work done.

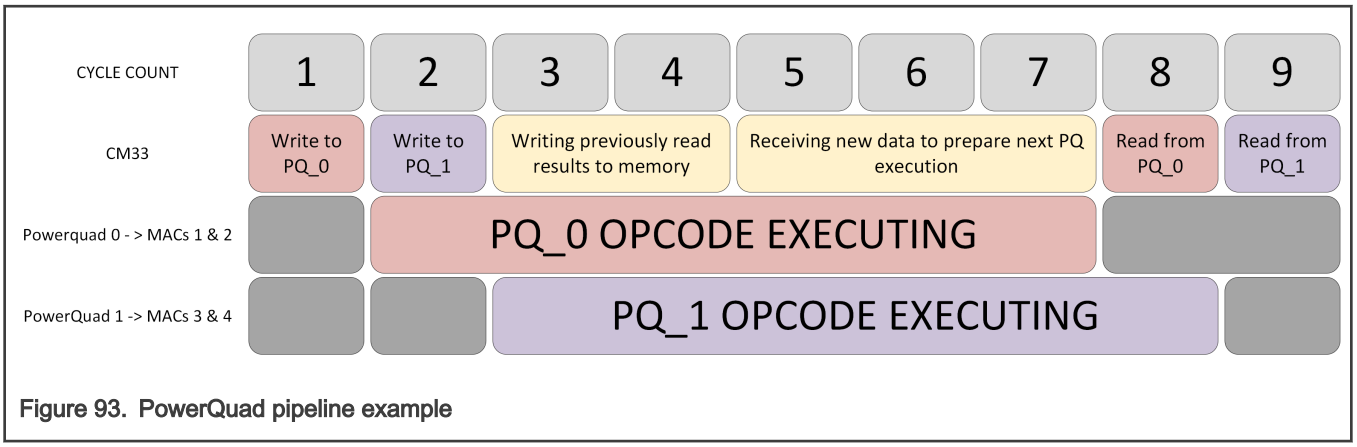

Figure 93. PowerQuad pipeline example

In PowerQuad, this interface uses short (several cycles) operations, for which the CM33 core provides data from one of its registers. The result is stored back in the CM33 register. The above diagram represents a snippet in time where the CM33 core and PowerQuad work in parallel. The CM33 core requests that PowerQuad 0 begin to execute an opcode provided. In the following cycle the CM33 core requests that PowerQuad 1 also begin to execute an opcode. Meanwhile, PowerQuad is fully loaded and the CM33 core takes this time to write back any data previously received from PowerQuad. The CM33 core also uses this time to prepare the next PowerQuad requests. Once PowerQuad 0 finishes, the CM33 core fetches the data by reading back the result in one cycle. Then in the next cycle reads back the result from PowerQuad 1. You can repeat this pipelined effort continuously to optimize the workload on the CM33 core while PowerQuad is busy.

When the data comes to PowerQuad in fixed-point or floating-point format, internally PowerQuad handles the data as floating point. The conversion from fixed-point to floating-point format occurs automatically. Prescaling and postscaling options are available to allow fixed-point numbers with fractional precision.

Results of PowerQuad operations can be either fixed-point or floating-point format (conversion from floating-point to fixed-point format, if needed).

The functions handled in this way are:

- Transcendental: ln(x), e^(x), e^(-x), 1/(x), 1/sqrt(x), sqrt(x), x1/x2
- Trigonometric: sin(x), cos(x)
- Biquad: biquad(x)

For PowerQuad Coprocessing interface examples, see Construct coprocessor interface operations.

18.3.1.2 Transcendental

In mathematics, a transcendental function is a type of function that you cannot express algebraically. A possible solution to simplify the implementation of these algorithms is to create a lookup table. Lookup tables can help to simplify or speed up an inefficient process, however lookup tables take extra space in the memory of the device. A key advantage of PowerQuad is that there is no need for lookup tables, so you do not waste RAM for transcendental functions. All of this work is taken care of by the hardware module.

Another advantage of transcendental function implementation for PowerQuad is that they become actual instructions in the CM33 core. The functions give high precision in a matter of a handful of cycles.

Since PowerQuad can execute 2 of these functions in parallel, the number of cycles consumed matches the number of cycles the CM33 core requires to bring in more data for PowerQuad and write out the results. Therefore, you can fully pipeline PowerQuad running in parallel with the CM33 core and achieve almost single-cycle effective performance for the calculations.

PowerQuad supports the following transcendental functions:

- ln(x)
- $e^{(x)}$
- $e^{(-x)}$
- 1/(x)
- 1/sqrt(x
- sqrt(x)
- x1/x2

18.3.1.2.1 Requirements

Input and output data support float, INT16, and INT32.

18.3.1.2.2 Performance

Table 266. Performance using CM33 alone versus with PowerQuad

Function	API	Using CM33 (s)	Using PowerQuad (s)	Improved Performance	Conditions
Transcendental	PQ_LnF32	15.0E-6	80.0E-9	187.6	Frequency 150 MHz IAR 9.30.1 SDK 2.13.0 Running on Flash Optimization O3 Speed Note, the math functions running on CM33 are only supported on math.h
	PQ_SqrtF32	4.2E-6	93.3E-9	45.3

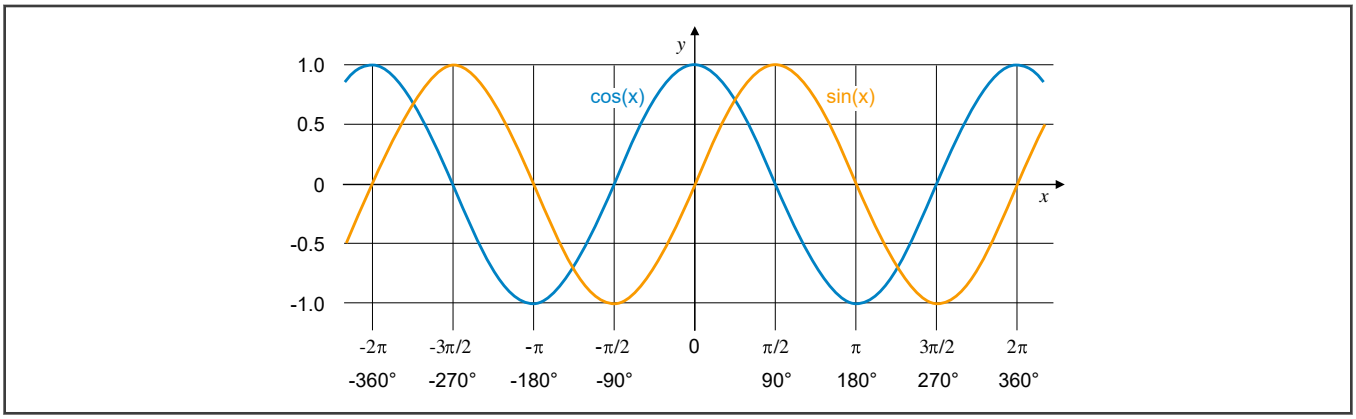
	PQ_EtonxFixed	19.4E-6	73.3E-9	264.3	

18.3.1.3 Trigonometry

The trigonometric functions most widely used in modern mathematics are the sine, the cosine, and the tangent. In embedded applications, trigonometric functions are used in robotics, motor control, signal processing among others. It is essential to process data quickly to benefit from the timing aspects of each application.

The Taylor series of sin(x) and cos(x) centered about 0 have the property of having best convergence (fewest terms) when closest to 0. By partitioning the angular space into half-quadrants (that is π/2 or 45 degrees), you can reuse the basic Taylor series for the sin(x) and cos(x) in the range [0, π/2].



Tangent can be calculated using the equation:

$$\tan(x) = \frac{\sin(x)}{\cos(x)} = \frac{\sin(x)}{\sqrt{1 - sin^2(x)}}$$

The tangent function is not directly mapped as a PowerQuad function. To calculate the tangent of a given value, you can perform a sine and cosine function in parallel and then perform the division of those results. In addition, you could also do sine and inverse square root, however, this method would consume more cycles than the first option.

18.3.1.3.1 Requirements

Input and output floating-point data support radian units, Q15 and Q31 fixed-point data support normalized values.

For fixed-point inputs, the input value is normalized to range -1 to 1 which represents -pi to pi.

For floating-point inputs, the input value is in radians. This function calculates -pi to pi.

18.3.1.3.2 Performance

Table 267. Performance using CM33 alone versus with PowerQuad

Function	API	Using CM33 (s)	Using PowerQuad (s)	Improved Performance	Conditions
Trigonometry	PQ_SinF32	686.7E-9	206.7E-9	3.3	Frequency 150 MHz IAR 9.30.1 SDK 2.13.0 Running on Flash Optimization O3 Speed

	PQ_SinQ15	413.3E-9	286.7E-9	1.4	
	PQ_CosQ15	453.3E-9	233.3E-9	1.9	
	PQ_SinQ31	493.3E-9	233.3E-9	2.1	
	PQ_CosQ31	480.0E-9	226.7E-9	2.1	

18.3.1.4 Dual Biquad IIR

In signal processing, a digital Biquad filter is a second order recursive linear filter, containing two poles and two zeros.

$$H(z) = \frac{b_0 + b_1 z^{-1} + b_2 z^{-2}}{a_0 + a_1 z^{-1} + a_2 z^{-2}}$$

The coefficients are often normalized such that $a_0 = 1$:

$$H(z) = \frac{b_0 + b_1 z^{-1} + b_2 z^{-2}}{1 + a_1 z^{-1} + a_2 z^{-2}}$$

High-order IIR filters can become unstable due to quantization of the coefficients. Typically higher-order filters are implemented in cascaded Biquad portions. PowerQuad can execute cascaded filters by saving the internal states of each run and restoring the states as the data is processed.

The Biquad engine uses the coprocessor interface. Use the APIs provided in the SDK, as executing a Biquad filter is composed of several steps. The MCR and MRC opcodes are used sequentially depending on the order of the filter used. A second order recursive digital filter is shown below.

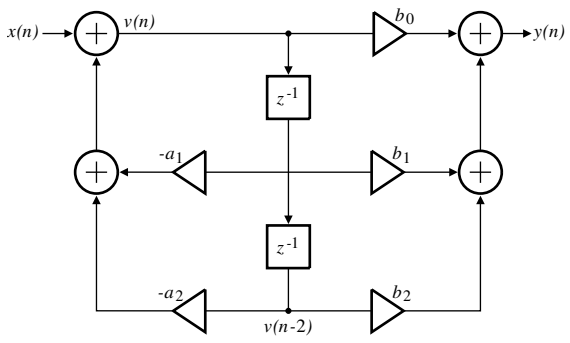

Figure 94. Second-order IIR filter

18.3.1.4.1 Requirements

Input and output data support float, INT16, and INT32.

For single Biquad computations, Biquad state 0 is used.

For cascade Biquad computations, the data flow is input -> Biquad state 1 -> Biquad state 0 -> output.

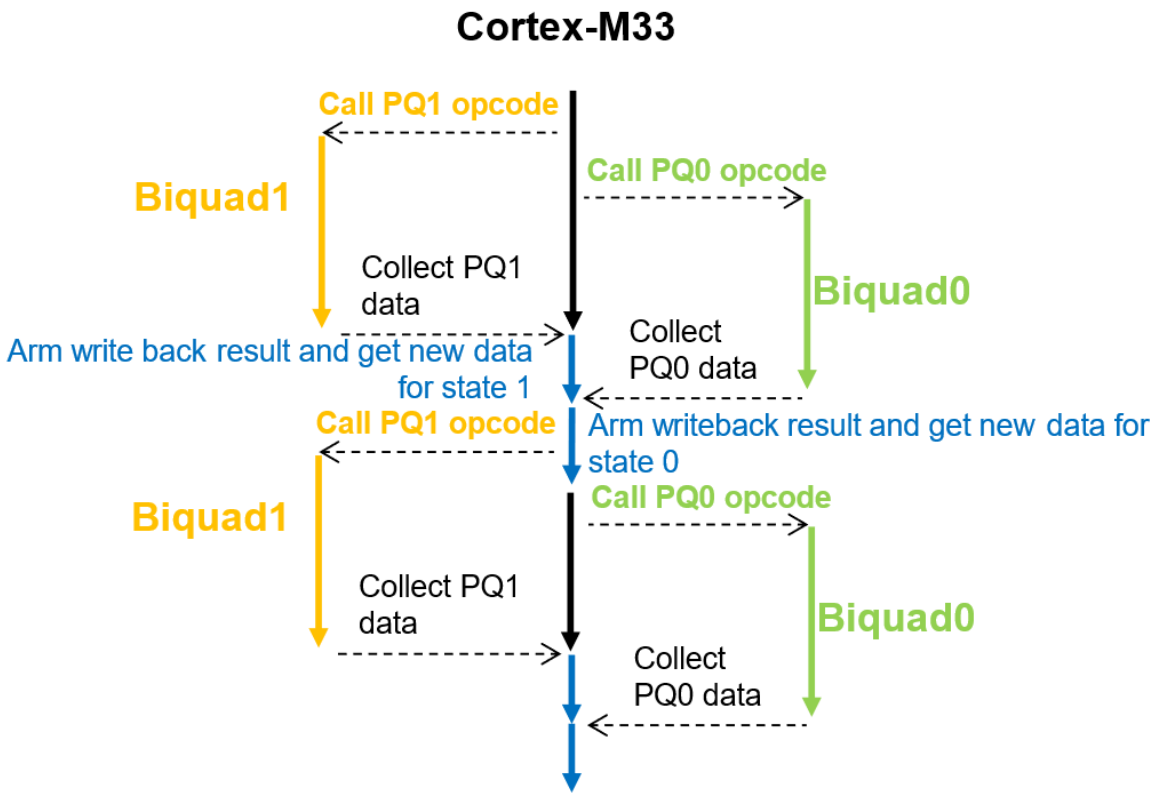

Figure 95. Biquad pipeline example

	BiquadCascadeF32	89.7E-6	

18.3.2 AHB memory-mapped engine

18.3.2.1 Introduction

PowerQuad handles large data operations in a memory-mapped fashion. To access PowerQuad through this method, write to Control (CONTROL) to launch a memory-mapped operation. When the result is ready, an event or interrupt generates to inform the CM33 core that the result is ready. Alternatively, the CM33 core can also poll CONTROL[INST_BUSY]. Retrieve results through one or more AHB reads from the PowerQuad's private RAM or the system's memory.

Some operations must use system memory for intermediate operations or to save context while using the PowerQuad for another operation. Handle these operations through the 32-bit AHB bus. Most memory-mapped operations use the private 128-bit wide memory. Use both the AHB bus and private memory if possible. That is, have one operand coming from system memory and one from private memory, such that you maximize bandwidth and performance. Move operands into private memory by choosing private memory as the result destination pointer. The private memory always keeps the data in the native format (which is floating point in all cases except for FFT, which uses fixed point). In FFT, we recommend that you use private memory for the intermediate calculations, as a temporary region. For other calculations, the recommendation is that one side comes from AHB (system) and the other from private memory. In order to get the operand into private memory, use a matrix scale operation (scale by 1.0) and have an address in private memory as the destination.

PowerQuad is natively 32-bit floating-point, so temporary results in private memory can only be in the same format. The only exception is the FFT engine, which uses fixed-point data. The 4-region memory model configures these parameters:

- Scaling and data format for the operands
- Temporary results
- Final result to fixed-point or floating-point format

With PowerQuad, you can change the format, prescale, or postscale the data on the fly, which is a huge advantage, saving cycles to increase performance.

The CM33 core writes to the control registers of PowerQuad to:

- Select the function
- Provide 4 memory regions with source destination addresses
- Save a temporary scratch address for intermediate results (where applicable such as with FFT and Matrix Inversion)

Poll completion in CONTROL[INST_BUSY] (cleared to ‘0’), or generate an interrupt/event from the PowerQuad.

The functions handled in this way are:

- Matrix (add, sub, scale, invert, transpose, multiply, dot, product)
- FFT/IFFT/DCT/IDCT (note that DCT is partial in PowerQuad and requires some adjustments)
- FIR/Convolution/Correlation

For PowerQuad AHB memory-mapped interface examples, see Construct AHB interface operations .

For any given function where PowerQuad interacts with data (from AHB system memory or private RAM), a user set configuration for 4 regions gives the addressing and the interface for interacting with the data.

The regions are:

- Output
- Temp
- Input A
- Input B

The PowerQuad control registers allow the user to choose the base address for each of the regions used in the function. Apart from a base address for each region, the user can also choose the format for the data on the inside and the outside. For example, you can configure Input A as INT16 fixed-point input but use it as floating point by PowerQuad. The format in or out can only be chosen if the region used is in AHB space. All data written to or read from private RAM does not undergo any conversion.

The internal or external formats can be any of the following:

- Int16 Fixed point
- Int32 Fixed point
- Floating point

In addition to formatting the input and output, you can also choose a scaling factor for the fixed-point inputs and outputs.

18.3.2.2 Memory Handling

PowerQuad has four memory pointer regions:

Input A pointer	Stores the argument A for the algorithm
Input B pointer	Stores the argument B for algorithm (optional)
Temp pointer	Area used for intermediate calculations
Output pointer	Where the result is stored

Each of the memory regions may be configured in the following manner:

Origin data	32-bit fixed, 16-bit fixed, or 32-bit float
Data used in PowerQuad	All data must be float except in the FFT engine which are fixed.
Scaling	PowerQuad can do scaling by power of 2 for input or output.

Each of these regions may reside in internal memory or may reside in private memory. PowerQuad accesses and collects the data accordingly. It is able to access AHB memory space for the entire address space, except for the range E000_0000h – EFFF_FFFFh. The address space starting with E000_0000h is that through which, PowerQuad can access its private RAM. It is recommended to make use of private memory as this region is only accessible by PowerQuad.

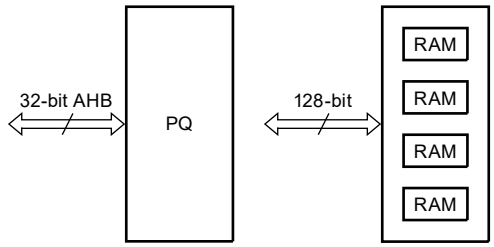

Figure 96. PowerQuad using private RAM as the 128-bit wide scratch pad

18.3.2.3 Transform

PowerQuad provides discrete Fourier transforms and discrete cosine transforms, implemented with a Radix-8 Butterfly structure Fast Fourier Transform (FFT) engine using fixed-point arithmetic at a resolution of 24 bits. The Radix-8 butterfly structure of the engine is shown below. This implementation both reduces the number of memory accesses and makes full use of the four MACs available in PowerQuad.

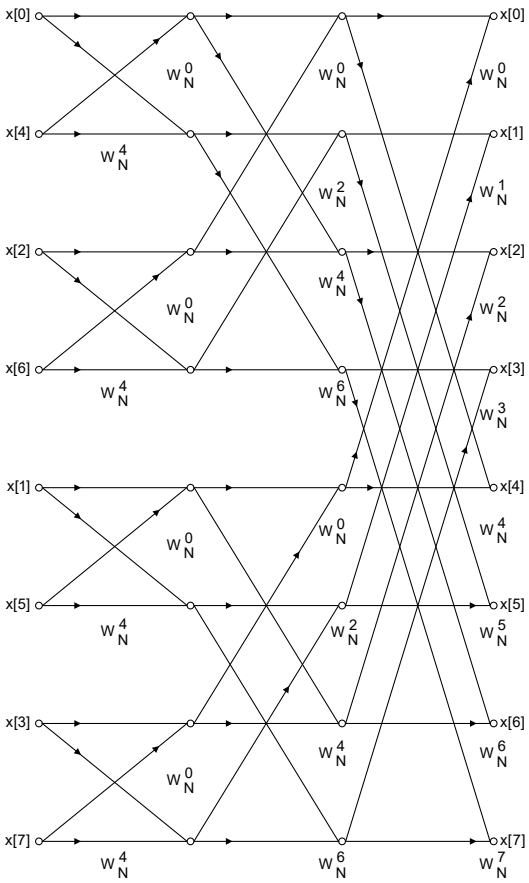

Figure 97. Radix-8 butterfly structure

The discrete Fourier transform (DFT) transforms a sequence of N complex numbers:

$$\{x_n\} := x_0, x_1, \ldots, x_{N-1}$$

Into another sequence of complex numbers:

$$\{X_k\} := X_0, X_1, \ldots, X_{N-1}$$

Defined by:

$$X_k = \frac{1}{N} \sum_{n=0}^{N-1} x_n \bullet e^{-i2\pi kn/N}$$

With the inverse transform defined as:

$$x_n = \frac{1}{N} \sum_{k=0}^{N-1} X_k \bullet e^{i2\pi kn/N}$$

The discrete cosine transform is similar to the discrete Fourier transform but uses only real numbers. It transforms a sequence of N real numbers:

$$\{x_n\} := x_0, x_1, \ldots, x_{N-1}$$

into another sequence of real numbers:

$$\{X_k\} := X_0, X_1, \ldots, X_{N-1}$$

Defined by:

$$X_k = \sum_{n=0}^{N-1} x_n cos\left[\frac{\pi}{N}\left(n+\frac{1}{2}\right)k\right], where\ k = 0, \ldots, N-1$$

And the inverse defined by:

$$X_k = \frac{1}{2}x0 + \sum_{n=1}^{N-1} x_n cos\left[\frac{\pi}{N}n\left(k+\frac{1}{2}\right)\right], where\ k = 0, \ldots, N-1$$

FFT and IFFT are fully performed by PowerQuad. In the case of DCT, PowerQuad only performs odd/even mirroring of the original input before performing an FFT on the input. For example, input of [0 1 2 3 4 5 6 7] gets odd/even mirroring that results in [0 2 4 6 7 5 3 1] before entering FFT. To reach a final DCT value, ARM is required to multiply the resulting spectrum with a rotating phasor. For IDCT, ARM needs to multiply the input by a phasor. The PowerQuad IDCT machine then performs an inverse FFT and then the reverse of the odd/even mirroring done by the transform.

18.3.2.3.1 Requirements

Input and output data support INT16 and INT32.

Important aspects of the input data for the FFT engine are:

- Only considers the bottom 27 bits of the input word, therefore prescaling must not exceed this limit to avoid saturation.
- Always scales the input data by 1/N when computing. If an unscaled result is necessary, the input data (in the INPUT A region) must first be multiplied by N. The inverse FFT is also scaled by 1/N, but is correct per the formula, so no scaling treatment is needed.
- Achieves scaling (that is, multiplying by N) at no cost by configuring the prescaling for the input into FFT.
- Supports these lengths for DCT and DFT are N = 16, 32, 64, 128, 256, 512.

NOTE

PowerQuad can perform scaling by N on the way in with no impact to performance.

Real number sequences must be arranged in memory such that if a sequence is as follows:

$$\{x_n\} := x_0, x_1, \ldots, x_{N-1}$$

Then the input array in memory is:

$$x[N] = \{x_0, x_1, \ldots, x_{N-1}\}$$

Complex number sequences must be arranged in memory such that if a sequence is as follows:

$$\{x_n\} := x_0, x_1, \ldots, x_{N-1}, where\ x_n = x_{nreal} + x_{nim}$$

Then the input array in memory is:

$$x[N] = \{x_0 real, x_0 im, x_1 real, x_1 im, \ldots, x_{N-1} real, x_{N-1} im\}$$

For the output sequence, the array is always made up of complex numbers, where the imaginary parts are zero for real number operations.

	cfft_q31	830.4E-6	22.2E-6	37.4	
	ifft_q15	675.5E-6	22.1E-6	30.5	
	ifft_q31	854.4E-6	22.1E-6	38.6	

18.3.2.4 Matrix

The matrix accelerator engine supports the following operations:

- Addition
- Subtraction
- Multiplication
- Vector Dot-Product
- Inversion
- Transpose
- Scaling

Matrices are composed in the following manner:

In the example matrices below, Matrix A, is composed of 2 rows and 3 columns. Matrix B is composed of 2 rows and 2 columns. Depending on the required matrix operation, the number of rows and columns of each matrix determines if it is possible to proceed.

$A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}$ $B = \begin{bmatrix} 5 & 6 \\ 7 & 8 \end{bmatrix}$

Adds/Subtracts/product of two matrices:

The number of rows in Matrix A must match the rows in Matrix B. The same applies to the columns of each matrix.

Multiplication of two matrices:

The number of columns in Matrix A must match the number of rows in Matrix B.

Scaling of a matrix:

A matrix is scaled using a floating-point scaler number.

[R] = k * [M], where each element in the matrix is scaled by k. The floating-point scaler number is loaded into the Miscellaneous (MISC) register.

Transpose of a matrix:

The transpose of a matrix is an operator that flips a matrix over its diagonal, that is, it switches the row and column indexes of the matrix by producing another matrix denoted as A^T.

Let A be an m × n matrix. The transpose of A, denoted A^T, is the n × m matrix whose columns are the respective rows of A.

Inversion of a matrix:

Matrix inversion is supported only for square matrices. A square matrix is singular only when its determinant is exactly zero. The implementation needs some scratch area in the AHB space. We are not using any of private RAM for this function.

Vector Dot Product:

The dot product is the sum of the products of the corresponding entries of the two sequences of numbers (vectors). The result is one number.

18.3.2.4.1 Requirements

Input and output data support float, INT16, and INT32.

The Length (LENGTH) register is remapped when using the matrix engine. It is composed of the concatenation of the columns in matrix_B, the columns in matrix_A, and the rows in matrix_A.

- LENGTH[31:0] = Cols_B[20:16] | Cols_A[12:8] | Rows_A[4:0]

Matrix operations have a maximum dimension as shown below:

Table 270. Matrix operation dimensions

Operation	Maximum size
Addition	16 x 16
Subtraction	
Hadamard Product	
Product	
Transpose	
Scaling	
Inversion	9 x 9
Vector Dot-Product	256 elements

18.3.2.5 FIR

In digital signal processing, an Nth order discrete time FIR filter does not have feedback, which makes it a very stable filter. However, this type of filter requires many more coefficients to meet a similar outcome of an IIR filter. Due to this requirement, the time it takes to execute a FIR filter is much longer as each coefficient introduces another multiplication in the system. Having PowerQuad as an accelerator of the same operation greatly reduces the impact of having a high-order FIR filter.

The signal flow graph for the general, causal, length N = M + 1, finite-impulse-response (FIR) digital filter is shown below.

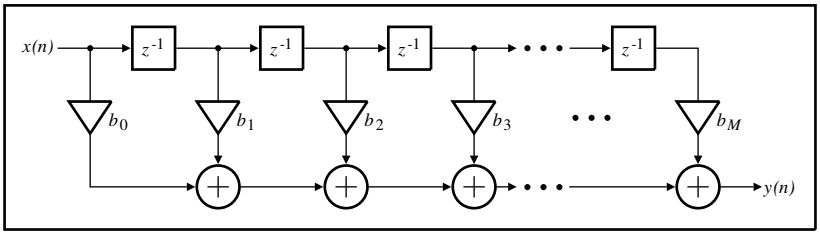

Figure 98. FIR signal flow

This filter implements the difference equation:

$$y[n] = \sum_{i=0}^{M} b_i x[n-i], \text{ where } n = 0, \ldots, M$$

Here x[n] is the input signal, y[n] is the output signal, and M is the filter order. An Mth-order filter has (M + 1) filter taps.

The PowerQuad FIR engine run 4 MAC operations in parallel.

18.3.2.5.1 Requirements

Input and output data support float, INT16, and INT32.

Length (LENGTH) is remapped when using the FIR engine. It is composed of the concatenation of the number of filter taps and the number of samples in the input sequence.

- LENGTH[31:0] = numTaps[31:16] | numSamples[15:0]

Configuring the FIR incremental operations uses the offset from the base address that the FIR operation uses. FIR incremental operation may only be used after FIR operation is used. Prescaling and postscaling the data can be a huge advantage for these operations.

- PQ_FIR(POWERQUAD, pSrcA, srcALen, pSrcB, srcBLen, pDst, op_type);
- PQ_FIRIncremental(POWERQUAD, srcALen, srcBLen, offset);

For full API examples, check the SDK PowerQuad drivers provided at mcuxpresso.nxp.com.

See the MCUXpresso SDK API Reference Manual included in the SDK document folder SDK.zip/docs.

18.3.2.5.2 Performance

Table 272. Performance using CM33 alone versus with PowerQuad

Function	API	Using CM33 (s)	Using PowerQuad (s)	Improved Performance	Conditions
Filter	fir_q15	20.5E-6	1.9E-6	10.6	Frequency 150 MHz IAR 9.30.1 SDK 2.13.0 Running on Flash Optimization O3 Speed

	correl_f32	4.2E-6	1.4E-6	3.0	

18.3.3 CORDIC engine

CORDIC, also known as Volder's algorithm, is a simple and efficient algorithm to calculate many different functions including trigonometric, hyperbolic, and logarithmic functions; and real and complex multiplications.

CORDIC is helpful in accelerating computations in various applications such as graphics in human-machine interfaces and field-oriented control. PowerQuad adds to the advantages of using CORDIC by accelerating the iterations per cycle.

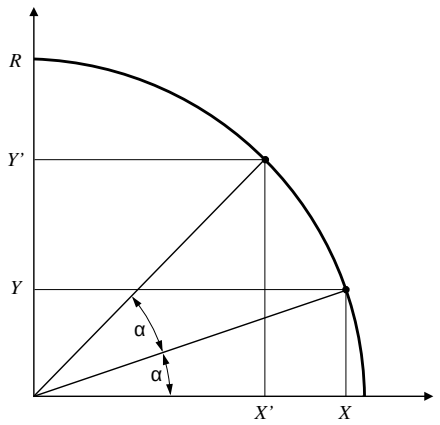

Figure 99. Rotation and vectoring mode of the CORDIC algorithm

In PowerQuad, the CORDIC engine can be directly used for inverse tangent and inverse hyperbolic tangent functions.

CORDIC hardware implements 2 iterations per cycle. The number of iterations is programmable. Although the iterations may be programmable, there is a tradeoff of speed vs. accuracy. CORDIC also allows use cases like calculating phase and magnitude from a real/imaginary pair simultaneously with 2 bits of convergence of output accuracy per cycle. In addition, the CORDIC engine stalls the CPU until the result is ready. Therefore, it is not necessary to poll for events or interrupts.

Functions that can use CORDIC:

- Arctan (x) : 12 cycles for 24-bit accuracy
- Arctanh (x) : 12 cycles for 24-bit accuracy

For PowerQuad CORDIC interface examples, see CORDIC API examples.

18.3.3.1 Requirements

Input and output data support INT16 and INT32.

18.3.3.2 Performance

Table 273. Performance using CM33 alone versus with PowerQuad

Function	API	Using CM33 (s)	Using PowerQuad (s)	Improved Performance	Conditions
CORDIC	PQ_ArctanFixed	19.3E-6	486.7E-9	39.7	Frequency 150 MHz IAR 9.30.1 SDK 2.13.0 Running on Flash Optimization O3 Speed Note, the math functions running on CM33 are only supported on math.h
	PQ_ArctanhFixed	28.1E-6	453.3E-9	62.0	

18.3.4 Clocking

Enable the PowerQuad clock through an AHB Clock Control register in the system control of your chip.

See PowerQuad chip-specific clocking.

18.3.5 Interrupts

Events and Interrupts are enabled in the PowerQuad registers for AHB operations. PowerQuad informs the Cortex-M33 core, based on event or interrupt, upon completion of the chosen algorithm. Events and interrupts are enabled in the PowerQuad registers for AHB interface operations, they cannot be enabled for coprocessor interface operations. PowerQuad informs the CM33 core through the AHB bus, based on an event or interrupt, upon completion of a chosen algorithm.

18.4 External signals

This module has no external signals.

18.5 Initialization

See PowerQuad chip-specific initialization.

1. Enable the PowerQuad clock in the system configuration of your chip.
2. Reset the PowerQuad peripheral in the system configuration of your chip.
3. Enable events and interrupts.

18.6 Application information

This section explores relevant examples for both the coprocessor and AHB interface operations.

18.6.1 Construct coprocessor interface operations

MCR and MRC opcodes are constructed below for each of the supported algorithms in the coprocessor mechanism. The APIs in the SDK drivers internally use the MCR and MRC opcodes. Use these APIs, which are provided in the SDK drivers. To understand how the opcodes are constructed refer to the examples below. The API reference manual can be found in the docs folder of the downloadable SDK package provided at mcuxpresso.nxp.com.

MCR and MRC opcodes have several elements that are defined below. The table describes the inputs from the PowerQuad module for each element.

Table 274. MCR and MRC opcodes

Opcode	Parameters
coproc	CP_PQ
opc1	PQ_INV, PQ_LN, PQ_SQRT, PQ_INVSQRT, PQ_ETOX, PQ_ETONX, PQ_DIV, PQ_SIN, PQ_COS, PQ_BIQ0_CALC, PQ_BIQ1_CALC
Rt	(x) – the input value
CRn	PQ_FLOAT32, PQ_FIXEDPT, PQ_COMP0_ONLY, PQ_COMP1_ONLY
CRm	0
opc2	PQ_TRANS, PQ_TRIG, PQ_BIQUAD, PQ_TRANS, PQ_TRIG_FIXED, PQ_BIQUAD_FIXED

Table 275. Parameter descriptions

Parameters	Description
CP_PQ	PowerQuad Module
PQ_INV	Inverse function, 1/x
PQ_LN	Natural logarithm, ln(x)
PQ_SQRT	Square root, sqrt(x)
PQ_INVSQRT	Inverse square root, 1/sqrt(x)
PQ_ETOX	Exponential function, e^(x)
PQ_ETONX	Inverse Exponential function, e^-(x)
PQ_DIV	Division, x1/x2
PQ_SIN	Sine, sin(x)
PQ_COS	Cosine, cos(x)

Table continues on the next page...

Table 275. Parameter descriptions (continued)

Parameters	Description
PQ_BIQ0_CALC	IIR filter for state 0, biquad0(x)
PQ_BIQ1_CALC	IIR filter for state 1, biquad1(x)
PQ_FLOAT32	Floating point data
PQ_FIXEDPT	Fixed-point data
PQ_COMP0_ONLY	Computation Block 0
PQ_COMP1_ONLY	Computation Block 1
PQ_TRANS	Transcendental engine used for floating-point data
PQ_TRIG	Trigonometric engine used for floating-point data
PQ_BIQUAD	Dual Biquad IIR engine used for floating-point data
PQ_TRANS_FIXED	Transcendental engine used for fixed-point data
PQ_TRIG_FIXED	Trigonometric engine used for fixed-point data
PQ_BIQUAD_FIXED	Dual Biquad IIR engine used for fixed-point data

18.6.1.1 Writing to PowerQuad

Coprocessing operations begin when the MCR operation is executed. Since MCR is an Arm operation, Arm assembler instructions are used directly in the application code. Each type of operation contains different elements to execute properly. See below the different operation types and how they are constructed. APIs have already been defined in the SDK for each of the supported mathematical functions. The following is only for reference.

Table 276. Commands

sin(x)
Floating point: __arm_mcr(CP_PQ, PQ_SIN, (uint32_t)(x), PQ_FLOAT32 | PQ_COMP0_ONLY, 0, PQ_TRIG)
Fixed point: __arm_mcr(CP_PQ, PQ_SIN, (uint32_t)(x), PQ_FIXEDPT | PQ_COMP0_ONLY, 0, PQ_TRIG_FIXED)
cos(x)
Floating point: __arm_mcr(CP_PQ, PQ_COS, (uint32_t)(x), PQ_FLOAT32 | PQ_COMP0_ONLY, 0, PQ_TRIG)
Fixed point: __arm_mcr(CP_PQ, PQ_COS, (uint32_t)(x), PQ_FIXEDPT | PQ_COMP0_ONLY, 0, PQ_TRIG_FIXED)
ln(x)
Floating point: __arm_mcr(CP_PQ, PQ_LN, (uint32_t)(x), PQ_FLOAT32 | PQ_COMP0_ONLY, 0, PQ_TRANS)
Fixed point:

18.6.1.2 Reading from PowerQuad

To read back the result produced by the above algorithms, use the following MRC opcodes:

Table 277. Read back commands

Floating point:
__arm_mrc(CP_PQ, 0, PQ_FLOAT32 | PQ_COMP0_ONLY, 0, 0) __arm_mrc(CP_PQ, 1, PQ_FLOAT32 | PQ_COMP0_ONLY, 0, 0)
Fixed point:
__arm_mrc(CP_PQ, 0, PQ_FIXEDPT | PQ_COMP0_ONLY, 0, 0) __arm_mrc(CP_PQ, 1, PQ_FIXEDPT | PQ_COMP0_ONLY, 0, 0)

18.6.1.3 Coprocessor API example

18.6.1.3.1 Sinusoidal example

Using a sinusoidal equation as an example, let's build the coprocessing operation to accelerate the time it takes to execute, sin(3.0).

In this first example, the input and output values are floating-point numbers. The input value of 3.0 is in radians.

```
float input = 3.0;
float referenceOutput = 0.141120;
```

As mentioned above, the SDK already provides ready to use APIs for the different mathematical operations. In the case of a sine wave, there are three options that are compatible with CMSIS-DSP operations.

```
arm_sin_f32(float x)
arm_sin_q31(q31_t x)
arm_sin_q15(q15_t x)
```

For floating-point values, the `arm_sin_f32` option is used. This then uses the API from the PowerQuad drivers. The extra variable seen below is used for integer-float conversion during the operation.

```
float32_t arm_sin_f32(float32_t x)
 {
     float tmp;

     PQ_SinF32(&x, &tmp);
     return tmp;
 }
```

Inside the PowerQuad function, we can see that the floating-point variable is converted to an unsigned 32-bit integer, which is what the MCR operation uses to process the input. This is done by using a simple union structure that defines the equivalent

floating-point and integer variable. The blue arrow is the defined function call to the MCR operation constructed in Writing to PowerQuad.

```
static inline void PQ_SinF32(float *pSrc, float *pDst)
 {
      pq_float_t val;

       val.floatX = *pSrc;
      _pq_sin0(val.integerX);
      val.integerX = _pq_readAdd0();
      *pDst       = val.floatX;
 }
```

```
#define _pq_sin0(x) __arm_mcr(CP_PQ, PQ_SIN, (uint32_t)(x), PQ_FLOAT32 | PQ_COMP0_ONLY, 0, PQ_TRIG)
```

The blue arrow in the following image is the defined function to the MRC operation constructed in Reading from PowerQuad. This function reads back the result and converts the value back to floating point before storing in the `*pDst` pointer.

```
static inline void PQ_SinF32(float *pSrc, float *pDst)
 {
      pq_float_t val;

       val.floatX = *pSrc;
      _pq_sin0(val.integerX);
      val.integerX = _pq_readAdd0();
      *pDst       = val.floatX;
 }
```

```
#define _pq_readAdd0() __arm_mrc(CP_PQ, 1, PQ_FLOAT32 | PQ_COMP0_ONLY, 0, 0)
```

18.6.1.3.2 Tangent example

Writing to PowerQuad demonstrates that the mapped coprocessing functions for trigonometric applications are sine and cosine. However, using simple math, and other mapped mathematical functions we can build the tangent equation.

Although there are several ways to come to the same tangent solution, note that the chosen equations affect the number of cycles required for the same result. Consider the following three equations:

$$\tan x = \frac{\sin x}{\cos x} \qquad \tan x = \frac{\sin x}{\sqrt{1 - sin^2\ x}} \qquad \tan x = \frac{\cos x}{\sqrt{1 - cos^2\ x}}$$

All three equations provide the same result. However, the two on the right take longer to execute than the one on the left because of the number of cycles required to execute them. Keep in mind that the two on the right are still much faster than doing the same sequence of events without PowerQuad enabled.

For the option on the left, sine and cosine can be done in parallel since these functions use 2 MACs each. Once the values are ready, perform a division. For the two options on the right, square either sine or cosine first, then do the subtraction. Next take the square root, then finally do a division. All of these steps consume many more cycles than the option on the left. Therefore, to realize the full potential of PowerQuad, choose the simplest route when building a new math function based on the available functions.

Since PowerQuad does not natively support the tangent function and we now know which functions to use for efficiency, we can build the code to run on PowerQuad. We want to run two coprocessor functions in parallel, so we must send the MCR opcodes. One uses computation block 0 and the second uses computation block 1. These are already provided in the SDK API, fsl_powerquad.h header file.

```
#define _pq_readAdd0() __arm_mrc(CP_PQ, 1, PQ_FLOAT32 | PQ_COMP0_ONLY, 0, 0)
```

For the purposes of this example, Calculate the tangent of pi/4, which gives us a result of 1, if done correctly. In addition, we use floating-point values as our input and output.

```
float input = (double)(MATH_PI/4.0f);

float finalResult;
```

We use the union structure to convert easily between floating-point and integer values, one for each function. Since the input is the same for the sine and cosine functions used to calculate the tangent, the same value is assigned to both structures.

```
pq_float_t val0, val1, div;

val0.floatX = input;
val1.floatX = input;
```

Then send the commands for each of the opcodes that run on PowerQuad, and the opcodes that read from the resulting registers.

```
_pq_sin0(val0.integerX);
_pq_cos1(val1.integerX);
val0.integerX = _pq_readAdd0();
val1.integerX = _pq_readAdd1();
```

Since the division is done using the intermediate integer values retrieved from both the sine and cosine, they can be used immediately to construct the input of the division and execute the opcode.

```
uint64_t inputDiv = (uint64_t)(val1.integerX) | ((uint64_t)(val0.integerX) << 32U);
_pq_div0(inputDiv);
```

Then read from the resulting register and convert to floating point for the final result.

```
div.integerX = _pq_readMult0();
finalResult = X1.floatX;
```

At this point, the result is 1 for a correctly executed tangent function.

18.6.1.3.3 Biquad cascade example

Having a dual biquad engine allows us to use two different biquad states to execute a chain of second order biquad stages. Where each stage has the same format as described in Dual Biquad IIR. For this example, a 3-stage biquad cascade is shown.

A structure is created to initialize each of the coefficients in each biquad stage. The values vary from application to application, in this case we have the following data. Initialize the COMPREG register with zero, because the register is used for intermediate operations. Importantly, if COMREG has other values, those values can corrupt the result of the operation.

```
pq_biquad_state_t state[3] = {
    {
        .compreg = 0,
        .param =
            {
                .v_n_1 = 0.0f,
                .v_n   = 0.0f,
                .a_1   = 0.2514f,
                .a_2   = 0.5028f,
                .b_0   = 0.2514f,
                .b_1   = -0.1712f,
                .b_2   = 0.1768f,
            },
    },
    {
        .compreg = 0,
        .param =
            {
                .v_n_1 = 0.0f,
                .v_n   = 0.0f,
                .a_1   = 0.2514f,
                .a_2   = 0.5028f,
                .b_0   = 0.2514f,
                .b_1   = -0.1712f,
                .b_2   = 0.1768f,
            },
    },
    {
        .compreg = 0,
        .param =
            {
                .v_n_1 = 0.0f,
                .v_n   = 0.0f,
                .a_1   = 0.2514f,
                .a_2   = 0.5028f,
                .b_0   = 0.2514f,
                .b_1   = -0.1712f,
                .b_2   = 0.1768f,
            },
    },
};
```

The data for the biquad in this example is:

```
float dataForBiquad[16] = {1024.0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0};
```

There are two possible routes to take when executing a cascaded biquad. The first is to calculate all results at once. The second option is to do incremental calculations.

For the first option, the API provided is:

```
pq_biquad_cascade_df2_instance instance;
PQ_BiquadCascadeDf2Init(&instance, stage, state);
PQ_BiquadCascadeDf2F32(&instance, dataForBiquad, biquadResult, 15);
```

The PQ_BiquadCascadeDf2Init function simply assigns the values for the number of stages in this cascade sequence and the structure of the coefficients for each of those stages. The PQ_BiquadCascadeDf2F32 function takes the input data for the filter and the block size, the result is stored in the output pointer provided.

Internally this function restores and backups the intermediate results produced from each of the states, and performs a biquad operation on each state. This function is done multiple times until all stages have been processed. The Restore and BackUp functions use the GPREG and COMPREG registers for intermediate values.

```
if((stage & 0x01U) == 0x01U)
{
        PQ_BiquadRestoreInternalState(POWERQUAD, 0, states);

        PQ_VectorBiquadDf2F32(pSrc, pDst, (int32_t)blockSize);

        PQ_BiquadBackUpInternalState(POWERQUAD, 0, states);

        states++;
        stage--;
}

while(stage > 0U)
{
        PQ_BiquadRestoreInternalState(POWERQUAD, 1, states);
        states++;
        PQ_BiquadRestoreInternalState(POWERQUAD, 0, states);

        PQ_VectorBiquadCascadeDf2F32(pDst, pDst, (int32_t)blockSize);

        states--;
        PQ_BiquadBackUpInternalState(POWERQUAD, 1, states);
        states++;
        PQ_BiquadBackUpInternalState(POWERQUAD, 0, states);

        states++;
        stage -= 2U;
}
```

When the stage is higher than 0, the operation executed is the PQ_VectorBiquadCascadeDf2F32. This function uses both of the Biquad states. As described in Dual Biquad IIR, a cascade biquad operation uses state 1, then state 0 provides the result. If the stage is 1, then a single biquad operation uses only biquad state 0.

For the incremental option, the function is done with the following APIs:

```
PQ_BiquadCascadeDf2Init(&instance, stage, state);

PQ_BiquadCascadeDf2F32(&instance, dataForBiquad, biquadResult, 8);
PQ_BiquadCascadeDf2F32(&instance, &dataForBiquad[8], &biquadResult[8], 7);
```

The function used for the incremental option is the same as the one used in the full calculation. However, the block size is smaller and partitioned in two segments, with the second function starting where the last one left off. This partitioning is beneficial when you must separate operations and use the PowerQuad for another purpose. You must save the intermediate results to return and run the biquad operation without corrupting the data.

For more details on the internal operations of the biquad filter, review the example code provided in the SDK.

18.6.2 Construct AHB interface operations

Below are some examples demonstrating how registers are configured for some of the supported algorithms in the AHB mechanism. The APIs used in the SDK drivers internally use these configurations, so you do not need to use these configurations directly. To understand how to configure the registers, refer to the examples below. The API reference manual can be found in the docs folder of the downloadable SDK package provided at mcuxpresso.nxp.com.

Understanding the math behind the operation, which needs to be accelerated, facilitates the construction of the AHB interface operation. First, it is necessary to know which algorithm to use, before selecting the correct engine and the proper configurations. In addition to the settings for the algorithm chosen, you must write to the CONTROL register to enable the execution. Writing to the CONTROL register indicates to PowerQuad that it can begin processing the information, therefore write to the CONTROL register last. The CONTROL register is composed of three elements:

INST_BUSY	0: Not Busy 1: Busy

Table continues on the next page...

Table continued from the previous page...

DECODE_MACHINE	1: CP_MTX – Matrix Engine 2: CP_FFT – Transform Engine 3: CP_FIR – Filter Engine 5: CP_CORDIC – Cordic Engine
DECODE_OPCODE	Opcode specific to decode_machine: Matrix: PQ_MTX_SCALE, PQ_MTX_MULT, PQ_MTX_ADD, PQ_MTX_INV, PQ_MTX_PROD, PQ_MTX_SUB, PQ_MTX_DOTP, PQ_MTX_TRANS Transform: PQ_TRANS_CFFT, PQ_TRANS_IFFT, PQ_TRANS_CDCT, PQ_TRANS_IDCT, PQ_TRANS_RFFT, PQ_TRANS_RDCT Filter: PQ_FIR_FIR, PQ_FIR_CONVOLUTION, PQ_FIR_CORRELATION, PQ_FIR_INCREMENTAL Cordic : CORDIC_ARCTAN, CORDIC_ARCTANH, CORDIC_ITER, CORDIC_MIU, CORDIC_T

The following sections describe different AHB interface operations and how they are constructed individually. Each type of operation can use the same registers but in a different manner.

18.6.2.1 Matrix API example

A simple matrix example is the addition of two matrices. Matrix data is stored in memory row-by-row, arranged like standard C arrays.

So, if two 2x2 integer matrices A and B are:

$A = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$ $B = \begin{bmatrix} 5 & 6 \\ 7 & 8 \end{bmatrix}$

Then the input data is stored in memory arrays as follows:

- int data_A15[4] = {1, 2, 3, 4};
- int data_B15[4] = {5, 6, 7, 8};

In the same manner, we can expect that our resulting matrix has the same format. In matrix addition, the size of the resulting matrix is the same size as the input matrices.

- int Result[4] = {0};

The SDK drivers provide a structure to help organize the matrices. This structure contains key elements of the matrix. It has the number of rows, columns, and the pointer to where the matrix data is stored.

```
typedef struct
{
   uint16_t numRows;    /**< number of rows of the matrix.     */
   uint16_t numCols;    /**< number of columns of the matrix.  */
   q15_t  *pData;       /**< points to the data of the matrix. */
   arm_matrix_instance_q15;
}
```

Using this structure the three matrices that are needed can be initialized. Since the rows and columns are the same for all of them, we can reuse the variable. The initialization shown below simply assigns the value of the columns and rows to their respective variable in the structure, and points the matrix data to the pointer of the structure.

```
srcRows    = MATRIX_ROWS;
srcColumns = MATRIX_COL;
arm_mat_init_q15(&addMatrixA15, srcRows, srcColumns, A15);
arm_mat_init_q15(&addMatrixB15, srcRows, srcColumns, B15);
arm_mat_init_q15(&addMatrixR, srcRows, srcColumns, Result);
```

For compatibility, we can use the CMSIS-DSP function call directly, which calls the PowerQuad APIs when enabled. It uses the three matrices that are needed for the addition operation.

```
arm_mat_add_q15(&addMatrixA15, &addMatrixB15, &addMatrixR);
```

This example uses fixed-point 16-bit inputs and outputs. For this we must configure the OUTFORMAT, INAFORMAT, INBFORMAT, and TMPFORMAT registers. The drivers facilitate this configuration by providing a defined framework.

```
#define PQ_SET_FIX16_CONFIG                                                                                \
    POWERQUAD->OUTFORMAT = ((uint32_t)(0) << 8U) | ((uint32_t)kPQ_16Bit << 4U) | (uint32_t)kPQ_Float; \
    POWERQUAD->INAFORMAT = ((uint32_t)(0) << 8U) | ((uint32_t)kPQ_16Bit << 4U) | (uint32_t)kPQ_Float; \
    POWERQUAD->INBFORMAT = ((uint32_t)(0) << 8U) | ((uint32_t)kPQ_16Bit << 4U) | (uint32_t)kPQ_Float; \
    POWERQUAD->TMPFORMAT = ((uint32_t)(0) << 8U) | ((uint32_t)kPQ_Float << 4U) | (uint32_t)kPQ_Float; \
    POWERQUAD->TMPBASE   = 0xE0000000U
```

All of the FORMAT registers are configured in the same manner. No scaler is necessary. The output format is fixed 16-bit data and the internal engine format is handled using floating point. Also, the TMPBASE is defined as 0xE000_0000, which is the reference for private RAM.

Next, it is necessary to define the value of LENGTH. As described in Requirements, LENGTH is remapped depending on the operation. In this case, we need the number of columns for matrix B15 and both the columns and rows for matrix A15.

- LENGTH[31:0] = Cols_B[20:16] | Cols_A[12:8] | Rows_A[4:0]

So, LENGTH = 0x40404;

As described above, the CMSIS-DSP function, internally calls the PowerQuad function.

```
arm_status arm_mat_add_q15(const arm_matrix_instance_q15 *pSrcA,
                           const arm_matrix_instance_q15 *pSrcB,
                           arm_matrix_instance_q15 *pDst)

{
    assert(NULL != pSrcA);
    assert(NULL != pSrcB);
    assert(NULL != pDst);

    arm_status status;
    uint32_t length;

    PQ_SET_FIX16_CONFIG;

    length = POWERQUAD_MAKE_MATRIX_LEN(pSrcA->numRows, pSrcA->numCols, pSrcB->numCols);

    PQ_MatrixAddition(POWERQUAD, length, pSrcA->pData, pSrcB->pData, pDst->pData);

    /* Wait for the completion */
    PQ_WaitDone(POWERQUAD);

    status = ARM_MATH_SUCESS;

    /* Return to application */
    return status;
}
```

The API that configures the registers for matrix addition is as follows:

- PQ_MatrixAddition(POWERQUAD, length, data_A, data_B, result);

Table 278. PQ_MatrixAddition parameters

Parameter	Description
POWERQUAD	Base address for the PowerQuad hardware module in the device
length	Composed of the length of the M2 column, M1 row and column. When M1 and M2 are matrix A and B respectively. Length = (length[23:16] = M2 columns | length [15:8] = M1 columns | length [7:0] = M1 rows);
data_A	Base address where the first matrix is located
data_B	Base address where the second matrix is located
result	Base address where the result matrix is expected to be located

The register configurations are set as shown below:

- PowerQuad[OUTBASE] = address of Result;
- PowerQuad[INABASE] = address of A15;
- PowerQuad[INBBASE] = address of B15;
- PowerQuad[LENGTH] = length;
- PowerQuad[CONTROL] = (CP_MTX << 4U) | PQ_MTX_ADD;

Lastly, it is important that the EVENTEN register is enabled to trigger when execution is completed. Events and Interrupts are generally set up during initialization of PowerQuad.

```
arm_status arm_mat_add_q15(const arm_matrix_instance_q15 *pSrcA,
                const arm_matrix_instance_q15 *pSrcB,
                arm_matrix_instance_q15 *pDst)

{
        assert(NULL != pSrcA);
        assert(NULL != pSrcB);
        assert(NULL != pDst);

        arm_status status;
        uint32_t length;

        PQ_SET_FIX16_CONFIG;

        length = POWERQUAD_MAKE_MATRIX_LEN(pSrcA->numRows, pSrcA->numCols, pSrcB->numCols);

        PQ_MatrixAddition(POWERQUAD, length, pSrcA->pData, pSrcB->pData, pDst->pData);

        /* Wait for the completion */
        PQ_WaitDone(POWERQUAD);

        status = ARM_MATH_SUCESS;

        /* Return to application */
        return status;
}
```

The PQ_WaitDone API polls the INST_BUSY flag to know when the result is ready. During the busy period, the main core is sleeping and wakes once the event arrives. Use the event trigger to save cycles instead of an interrupt trigger that services ISR.

```
/* wait for the completion */
while ((base->CONTROL & INST_BUSY) == INST_BUSY)
{
        _WFE();
}
```

At this point, the result can be read from the Result matrix that we initialized at the beginning of the example.

18.6.2.2 FFT API example

The Complex Fast Fourier Transform(CFFT) is a different AHB interface example that uses the transform engine. There are certain requirements and details that must be considered when using the FFT engine. See Requirements for more details.

This example uses fixed 32-bit format data. The input data is taken by using PowerQuad functions and using sine and cosine waves. The input data can be generated from many different sources. For ease of use, the example uses the PowerQuad module.

```
/* Two full period sin wave. */
for (uint32_t i = 0; i < CFFT_INPUT_LEN / 2;  i++)
{
        input[i * 2]     = (arm_sin_q31(i * (0x80000000 / (CFFT_INPUT_LEN / 2))) / 2) >> 5;
        input[i * 2 + 1] = (arm_cos_q31(i * (0x80000000 / (CFFT_INPUT_LEN / 2))) / 2) >> 5;
}
```

Once the input data is ready, PowerQuad must be configured accordingly. For compatibility we can use the CMSIS-DSP function call directly, which calls the PowerQuad APIs when enabled.

```
arm_cfft_q31(&instance, input, 0, 1);
```

This example uses fixed-point 32-bit inputs and outputs. For this we must configure the OUTFORMAT, INAFORMAT, INBFORMAT, and TMPFORMAT registers. The drivers facilitate this configuration by providing a defined framework.

```
#define PQ_SET_FFT_Q31_CONFIG                                                   \
    POWERQUAD->OUTFORMAT = ((uint32_t)(0) << 8U) | ((uint32_t)kPQ_32Bit << 4U) | (uint32_t)kPQ_32Bit; \
    POWERQUAD->INAFORMAT = ((uint32_t)(0) << 8U) | ((uint32_t)kPQ_32Bit << 4U) | (uint32_t)kPQ_32Bit; \
    POWERQUAD->INBFORMAT = ((uint32_t)(0) << 8U) | ((uint32_t)kPQ_32Bit << 4U) | (uint32_t)kPQ_32Bit; \
    POWERQUAD->TMPFORMAT = ((uint32_t)(0) << 8U) | ((uint32_t)kPQ_32Bit << 4U) | (uint32_t)kPQ_32Bit; \
    POWERQUAD->TMPBASE   = 0xE0000000U
```

All of the FORMAT registers are configured in the same manner. There is no scaler necessary. The output format is fixed 32-bit data and the internal engine format is handled using fixed point as well. Also, the TMPBASE is defined as 0xE000_0000, which is the reference for private RAM.

As described above, the CMSIS-DSP function, internally calls the PowerQuad function.

```
void arm_cfft_q31(const arm_cfft_instance_q31 *S, q31_t *p1, uint8_t ifftFlag, uint8_t bitReverseFlag)
{
    assert(bitReverseFlag == 1U);

    q31_t *pIn     = p1;
    q31_t *pOut    = p1;
    uint32_t length = S->fftLen;

    PQ_SET_FFT_Q31_CONFIG;

    if (ifftFlag == 1U)
    {
        PQ_TransformIFFT(POWERQUAD, length, pIn, pOut);
    }
    else
    {
        PQ_TransformCFFT(POWERQUAD, length, pIn, pOut);
    }

    PQ_WaitDone(POWERQUAD);
}
```

The API that configures the registers for CFFT is as follows:

- PQ_TransformCFFT(POWERQUAD, N, inputData, cfftResult);

Table 279. PQ_TransformCFFT parameters

Parameter	Description
POWERQUAD	Base address for the PowerQuad hardware module in the device
N	Length for FFT and DCT, the supported lengths are 16, 32, 64, 128, 256, and 512
inputData	Base address where the input array is located
cfftResult	Base address where the result matrix is expected to be located

The register configurations are set as shown below:

- PowerQuad[OUTBASE] = address of Result;
- PowerQuad[INABASE] = address of input;
- PowerQuad[LENGTH] = N;
- PowerQuad[CONTROL] = (CP_FFT << 4U) | PQ_TRANS_CFFT;

Lastly, it is important that the EVENTEN register is enabled to trigger when execution is completed. Events and Interrupts are generally set up in the initialization of the PowerQuad.

```
void arm_cfft_q31(const arm_cfft_instance_q31 *S, q31_t *p1, uint8_t ifftFlag, uint8_t bitReverseFlag)
{
        assert(bitReverseFlag == 1U);

        q31_t *pIn   = p1;
        q31_t *pOut   = p1;
        uint32_t length = S->fftLen;

        PQ_SET_FFT_Q31_CONFIG;

        if (ifftFlag == 1U)
        {
                PQ_TransformIFFT(POWERQUAD, length, pIn, pOut);
        }
        else
        {
                PQ_TransformCFFT(POWERQUAD, length, pIn, pOut);
        }

        PQ_WaitDone(POWERQUAD);
}
```

The PQ_WaitDone API polls the INST_BUSY flag to know when the result is ready. During the busy period, the main core is sleeping and wakes once the event arrives. Use the event trigger to save cycles instead of an interrupt trigger that services ISR.

```
/* wait for the completion */
 while ((base->CONTROL & INST_BUSY) == INST_BUSY)
{
        _WFE();
}
```

At this point, the result can be read from the Result matrix that we initialized at the beginning of the example.

18.6.2.3 FIR API example

The FIR engine can compute different processes. One of these signal processing mechanisms is convolution. Convolution is one of the most important and fundamental concepts in signal processing and analysis.

Shown here is the mathematical definition of convolution in a discrete time domain.

$$pDst[n] = pSrcA[n] * pSrcB[n] = \sum_{k=-\infty}^{\infty} pSrcA[k] \bullet pSrcB[n-k]$$

Where `pSrcA [n]` is the input signal, `pSrcB[n]` is the impulse response, and `y[n]` is the output.

For this example, the data used is defined as floating-point values, however this example uses 32-bit fixed-point data.

```
static const float pSrcA[] = {0.01f, 0.02f, 0.03f, 0.04f, 0.05f};
static const float pSrcB[] = {0.02f, 0.04f, 0.06f, 0.08f, 0.10f};
```

The drivers in the SDK provide an easy API to convert from floating-point to fixed-point 32-bit data.

```
inputA[i] = FLOAT_2_Q31(pSrcA[i]);
inputB[i] = FLOAT_2_Q31(pSrcB[i]);
```

Once the input data is defined, the PowerQuad must be configured accordingly. For compatibility, we can use the CMSIS-DSP function call directly, which calls the PowerQuad APIs when enabled.

```
arm_conv_q31(inputA, CONV_A_LEN, inputB, CONV_B_LEN, result);
```

The data uses fixed-point 32-bit inputs and outputs. For this, we must configure the OUTFORMAT, INAFORMAT, INBFORMAT, and TMPFORMAT registers. The drivers facilitate this configuration by providing a defined framework.

```
#define PQ_SET_Q31_CONFIG                                                   \
        POWERQUAD->OUTFORMAT = ((uint32_t)(-31) << 8U) | ((uint32_t)kPQ_32Bit << 4U) | (uint32_t)kPQ_Float; \
        POWERQUAD->INAFORMAT = ((uint32_t)(0) << 8U) | ((uint32_t)kPQ_32Bit << 4U) | (uint32_t)kPQ_Float;   \
        POWERQUAD->INBFORMAT = ((uint32_t)(0) << 8U) | ((uint32_t)kPQ_32Bit << 4U) | (uint32_t)kPQ_Float;   \
        POWERQUAD->TMPFORMAT = ((uint32_t)(0) << 8U) | ((uint32_t)kPQ_Float << 4U) | (uint32_t)kPQ_Float;   \
        POWERQUAD->TMPBASE   = 0xE0000000U
```

All of the FORMAT registers are configured in the same manner, except OUTFORMAT and TMPFORMAT. The output format is scaled for 32 bits. In addition, the output and the input formats are fixed 32-bit data. The internal engine format is handled using floating point. The temporary format remains floating point throughout its use. Also, the TMPBASE is defined as 0xE000_0000, which is the reference for private RAM.

As described above, the CMSIS-DSP function, internally calls the PowerQuad function.

```
void arm_conv_q31(const q31_t *pSrcA, uint32_t srcALen, const q31_t *pSrcB, uint32_t srcBLen, q31_t *pDst)
{
    assert(NULL != pSrcA);
    assert(NULL != pSrcB);
    assert(NULL != pDst);

    PQ_SET_Q31_CONFIG;

    PQ_FIR(POWERQUAD, pSrcA, (int32_t)srcALen,  pSrcB, (int32_t)srcBLen, pDst,  PQ_FIR_CONVOLUTION);
    PQ_WaitDone(POWERQUAD);
}
```

The API that configures the registers for FIR is as follows:

- PQ_FIR(POWERQUAD, pSrcA, srcALen, pSrcB, srcBLen, pDst, op_type);

Table 280. PQ_FIR parameters

Parameter	Description
POWERQUAD	Base address for the PowerQuad hardware module in the device
pSrcA	Base address where the input signal is located
srcALen	Length of the input signal
pSrcB	Base address where the impulse response signal is located
srcBLen	Length of the impulse response
pDst	Base address where the result is expected to be located
op_type	Filter operation that is the computer

The register configurations are set as shown below:

- PowerQuad[OUTBASE] = address of pDst;

- PowerQuad[INABASE] = address of pSrcA;
- PowerQuad[INBBASE] = address of pSrcB;
- PowerQuad[LENGTH] = (srcBLen << 16) | srcALen;
- PowerQuad[CONTROL] = (CP_FIR << 4U) | PQ_FIR_CONVOLUTION;

Enable the EVENTEN register to trigger when execution is completed. Set up Events and Interrupts during PowerQuad initialization.

```
void arm_conv_q31(const q31_t *pSrcA, uint32_t srcALen, const q31_t *pSrcB, uint32_t srcBLen, q31_t *pDst)
{
        assert(NULL != pSrcA);
        assert(NULL != pSrcB);
        assert(NULL != pDst);

        PQ_SET_Q31_CONFIG;

        PQ_FIR(POWERQUAD, pSrcA, (int32_t)srcALen,  pSrcB, (int32_t)srcBLen, pDst,  PQ_FIR_CONVOLUTION);
        PQ_WaitDone(POWERQUAD);
}
```

The PQ_WaitDone API polls the INST_BUSY flag to know when the result is ready. During the busy period, the main core is sleeping and wakes once the event arrives. Use the event trigger to save cycles instead of an interrupt trigger that services ISR.

```
/* wait for the completion */
 while ((base->CONTROL & INST_BUSY) == INST_BUSY)
{
        _WFE();
}
```

The results are read from the result pointer, initialized in the configuration registers.

18.6.3 CORDIC API examples

The inverse trigonometric functions are implemented using a CORDIC. PowerQuad implements two-iteration per cycle CORDIC. The return value is in the range of -2^27 to 2^27, which represents -pi to pi. The sum of data_A and data_B should not exceed the range of INT32.

This example demonstrates the arctangent of 0.5. Larger input numbers gets higher output accuracy, the result of PQ_ArctanFixed(POWERQUAD, 200000, 100000, kPQ_Iteration_24) is more accurate than PQ_ArctanFixed(POWERQUAD, 2, 1, kPQ_Iteration_24).

The PowerQuad functions can be used directly as there is not support for the arctangent function in the CMSIS-DSP library. The input and output data are handled as 32-bit fixed-point data.

```
PQ_ArctanFixed(DEMO_POWERQUAD, 20000000, 10000000, kPQ_Iteration_24);
```

In this example, the FORMAT registers are not used. Instead we directly provide the inputs to the CORDIC registers of the Powerquad. CORDIC_X contains the dividend and CORDIC_Y contains the divisor. CORDIC_Z contains the result once the execution has finished. To initialize this register write 0.

```
int32_t pq_arctan(int32_t x int32_t y)
{
int32_t result = PQ_ArctanFixed(DEMO_POWERQUAD, x, y, kPQ_Iteration_24);
        result += (y<0 && x<0 )? 0xf8000000;
                  (y>=0 && x<0 )? 0x08000000;

return (result);
}
```

The API that configures the registers for arctan using CORDIC is as follows:

- PQ_ArctanFixed(POWERQUAD, data_A, data_B, iteration);

Table 281. PQ_ArctanFixed parameters

Parameter	Description
POWERQUAD	Base address for the PowerQuad hardware module in the device
data_A	Base address where the value of the opposite side
data_B	Base address where the value of the adjacent side
iteration	Value of iterations for rotations in the calculation can be 8, 16, or 24

The register configurations are set as shown below:

- PowerQuad[CORDIC_X] = data_A;
- PowerQuad[CORDIC_Y] = data_B;
- PowerQuad[CORDIC_Z] = 0;
- PowerQuad[CONTROL] = (CP_CORDIC << 4U) | CORDIC_ARCTAN | CORDIC_ITER(iteration);

Enable the EVENTEN register to trigger when execution is completed. Set up Events and Interrupts during PowerQuad initialization.

```
int32_t PQ_ArctanFixed(POWERQUAD_Type *base, int32_t x, int32_t y, pq_cordic_iter_t iteration)
{
    base->CORDIC_X = (uint32_t)x;
    base->CORDIC_Y = (uint32_t)y;
    base->CORDIC_Z = 0U;
    base->CONTROL  = (CP_CORDIC << 4U) | CORDIC_ARCTAN | CORDIC_ITER(iteration);

    PQ_WaitDone(base);
    return (int32_t)base->CORDIC_Z;
}
```

The PQ_WaitDone API polls the INST_BUSY flag to know when the result is ready. During the busy period, the main core is sleeping and wakes once the event arrives. Use the event trigger to save cycles instead of an interrupt trigger that services ISR.

```
/* wait for the completion */
while ((base->CONTROL & INST_BUSY) == INST_BUSY)
{
        _WFE();
}
```

The result can be read from the CORDIC Input Z (CORDIC_Z) register.

18.7 Memory map and register definition

This section includes the PowerQuad module memory map and detailed descriptions of all registers.

NOTE

This module does not generate transfer errors when accessing unimplemented registers in its register space.

18.7.1 PowerQuad register descriptions

18.7.1.1 PowerQuad memory map

POWERQUAD0 base address: 400B_F000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Output Base (OUTBASE)	32	RW	0000_0000h
4h	Output Format (OUTFORMAT)	32	RW	0000_0000h
8h	Temporary Base (TMPBASE)	32	RW	0000_0000h
Ch	Temporary Format (TMPFORMAT)	32	RW	0000_0000h

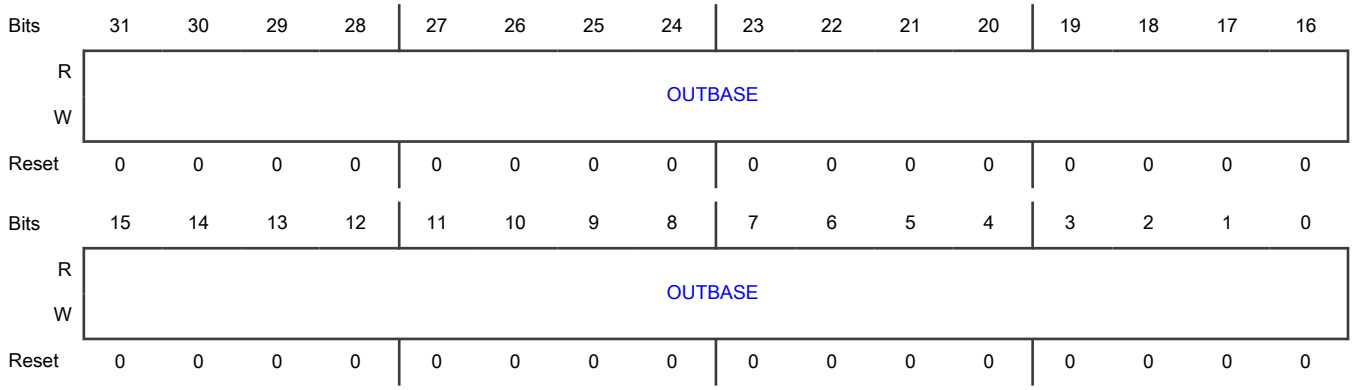
18.7.1.2 Output Base (OUTBASE)

Offset

Register	Offset
OUTBASE	0h

Function
Contains the base address, which points to a location in memory where you want to store the result of the operation.

Diagram



Fields

Field	Function
31-0 OUTBASE	Output Region Base Address 32-bit register that contains the base address where the result is stored upon completion of the AHB operation.

18.7.1.3 Output Format (OUTFORMAT)

Offset

Register	Offset
OUTFORMAT	4h

Function

Used to define the format of the data inside the engine and outside the engine in the OUTBASE location. The scaling factor can also be chosen for fixed-point output.

NOTE

The format definitions can only be used when data regions are in AHB space. Data written to or read from private RAM space does not undergo conversion.

18.7.1.4 Temporary Base (TMPBASE)

Offset

Register	Offset
TMPBASE	8h

Function

Used to define the location in which temporary data can be stored while operations are being executed. PowerQuad uses its own private RAM for this purpose. The base address for this area is 0xE000_0000.

NOTE

Inverse matrix operations do not use the private RAM area. The TMPBASE address must point to a scratch area in AHB space.

Diagram

Fields

Field	Function
31-0 TMPBASE	Base Address for the Temporary Region Contains the base address for the temporary data stored during some operations.

18.7.1.5 Temporary Format (TMPFORMAT)

Offset

Register	Offset
TMPFORMAT	Ch

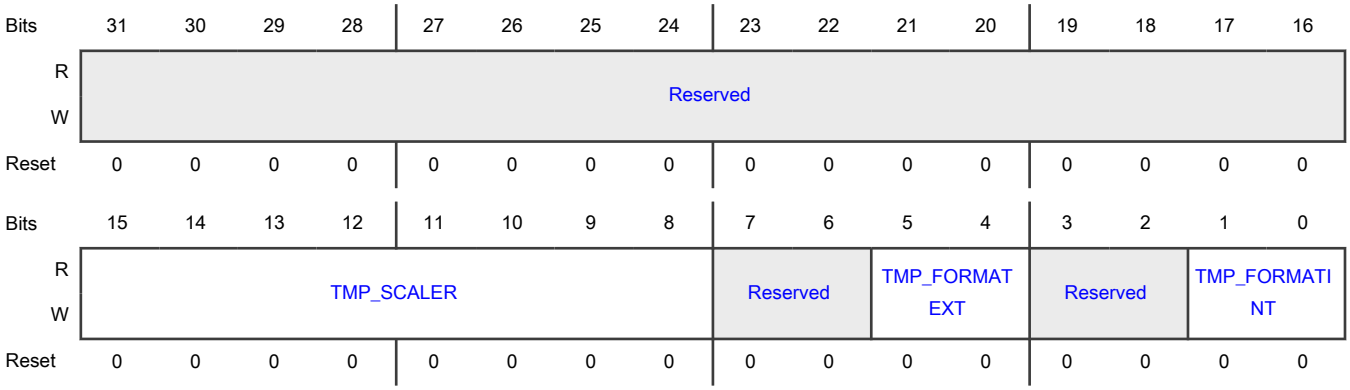
Function

Used to define the format of the data inside the engine and outside the engine in the TMPBASE location. The scaling factor can also be chosen for fixed-point output.

NOTE

The format definitions can only be used when data regions are in AHB space. Data written to or read from private RAM space does not undergo conversion.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 TMP_SCALER	Scaling Value for Temporary Data. 8-bit scaling value used when converting from floating-point to fixed-point Q15 or Q31 formats.
7-6 —	Reserved
5-4 TMP_FORMAT EXT	Temporary External Format Format of temporary data, converted when exiting the engine. **NOTE** This conversion can only be used for temporary data in AHB space, it cannot be used for temporary data stored in private RAM. 00b - Q15 16-bit fixed-point integer 01b - Q31 32-bit fixed-point integer 10b - F32 32-bit floating-point format 11b - Reserved

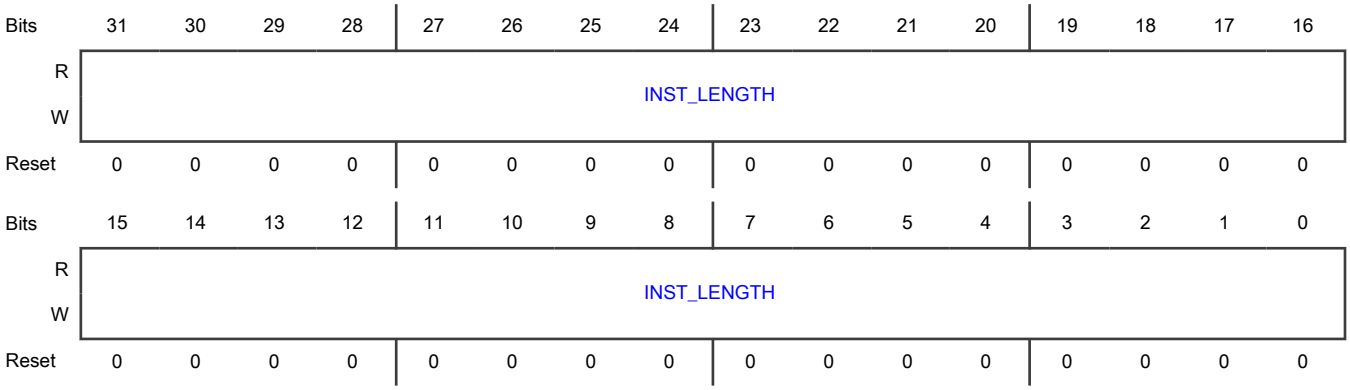
18.7.1.11 Length (LENGTH)

Offset

Register	Offset
LENGTH	104h

Function
Length register

Diagram



Fields

Field	Function

31-0
INST_LENGTH
	Instruction length
	The INST_LENGTH field is remapped according to the operating engine in use. The value of this field provides the dimensions of the operands.
	For Matrix Operations:
	`LENGTH[31:0] = Cols_B[20:16] | Cols_A[12:8] | Rows_A[4:0]`
	For FIR Operations:
	`LENGTH[31:0] = numTaps[31:16] | numSamples[15:0]`
	For other operations:
	`LENGTH[31:0] is the value of size of the input operand.`
	NOTE
	Maximum row/column is 16 by 16, regardless of 5-bit allowance.
	For vector operations, the maximum size is 256 (vector operations have only one dimension for length).

18.7.1.12 Coprocessor Prescale (CPPRE)

Offset

Register	Offset
CPPRE	108h

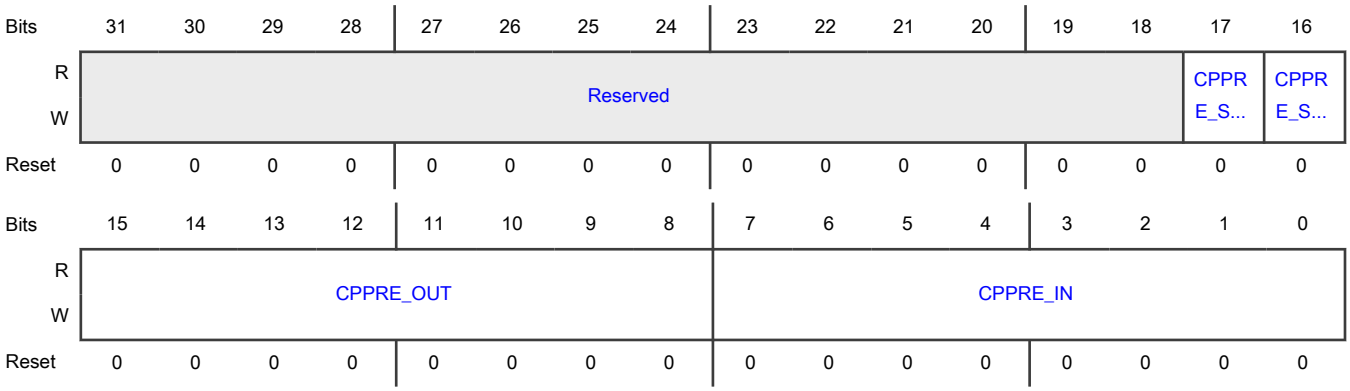
Function

Used to define the format of the input and output data used via the coprocessor bus interface. In addition, you can set the saturation for the output.

NOTE

CPPRE does not affect data used via the AHB bus interface.

Diagram



Fields

Field	Function
31-18 —	Reserved
17 CPPRE_SAT8	Saturation 8 Output value saturation is applied at 'n' bits, when 'n' is either 8 bits or 16 bits. 0b - 8 bits 1b - 16 bits
16 CPPRE_SAT	Saturation Sub-32 bit saturation. Enforces saturation for the output data. If enabled, CPPRE_SAT8 defines saturation. 0b - No saturation 1b - Forces sub-32 bit saturation
15-8 CPPRE_OUT	Postscaling Output Contains the coprocessor postscaling value for fixed-point output data with fractional precision.
7-0 CPPRE_IN	Prescaling Input Contains the coprocessor scaling value for fixed-point input data with fractional precision.

18.7.1.13 Miscellaneous (MISC)

Offset

Register	Offset
MISC	10Ch

Function

Used to store the scaling value used for matrix scale operations. Each element of the matrix scales by the value of this register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 INST_MISC	Scaling Factor 32-bit value that scales the elements of a matrix.

18.7.1.14 Cursory (CURSORY)

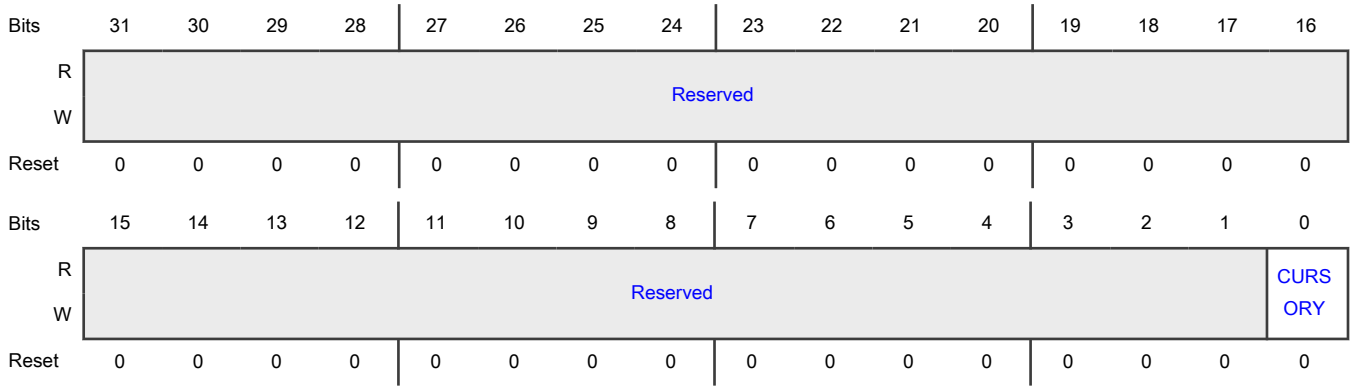
Offset

Register	Offset
CURSORY	110h

Function

Enables PowerQuad to reduce the resolution of results by zeroing out the LSB bits of the input and output of the floating-point MACs. Reducing the resolution reduces power consumption. Use when PowerQuad does not require greater accuracy.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 CURSORY	Cursory Mode Cursory mode allows control of the input and output resolution to the MACs used by PowerQuad engines. 0b - Disable cursory mode, full floating-point accuracy (24-bit mantissa + 2 bits before rounding). 1b - Enable cursory Mode, 16-bit mantissa (bottom bits are zeroed for inputs and outputs of MACs).

18.7.1.15 CORDIC Input X (CORDIC_X)

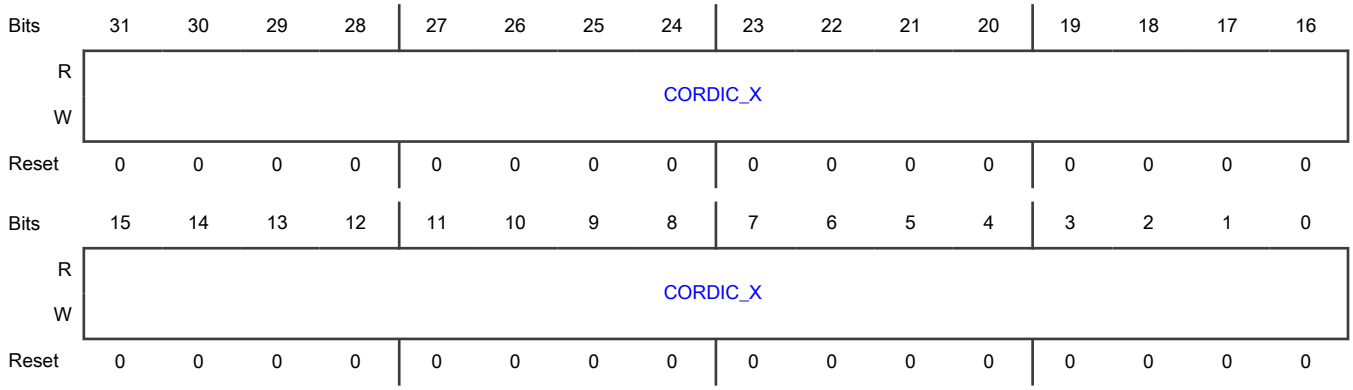
Offset

Register	Offset
CORDIC_X	180h

Function

Used for CORDIC-based algorithms. Contains the value of the first operand in the operation.

Diagram



Fields

Field	Function
31-0 CORDIC_X	CORDIC Input X Fixed-point operand, X, for CORDIC-based operations.

18.7.1.16 CORDIC Input Y (CORDIC_Y)

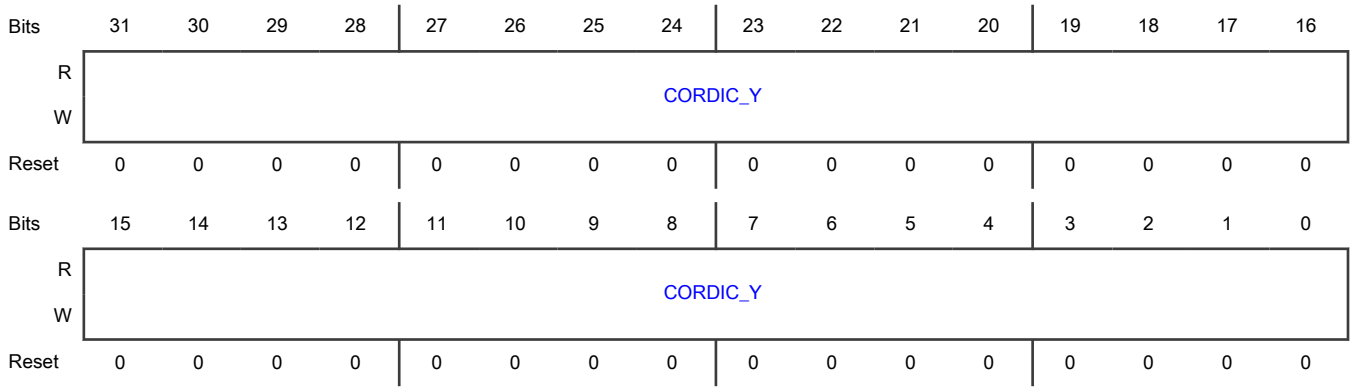
Offset

Register	Offset
CORDIC_Y	184h

Function

Used for CORDIC-based algorithms. Contains the value of the second operand in the operation.

Diagram



Fields

Field	Function
31-0 CORDIC_Y	CORDIC Input Y Fixed-point operand, Y, for CORDIC-based operations.

18.7.1.17 CORDIC Input Z (CORDIC_Z)

Offset

Register	Offset
CORDIC_Z	188h

Function

Used for CORDIC-based algorithms. Contains the value of the result in the operation.

Diagram

Fields

Field	Function
31-0 CORDIC_Z	CORDIC Input Z Fixed-point result data, Z, for CORDIC-based operations.

18.7.1.18 Error Status (ERRSTAT)

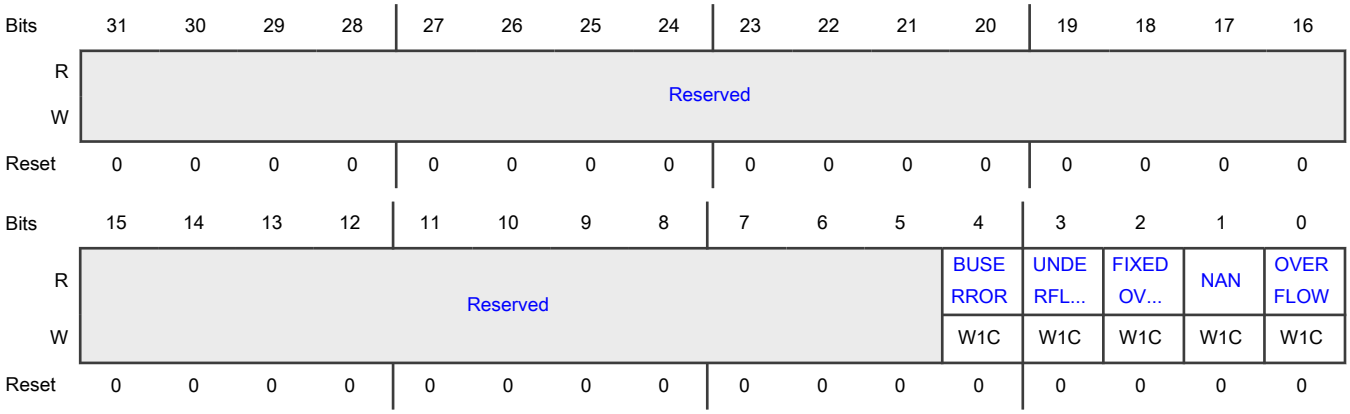
Offset

Register	Offset
ERRSTAT	18Ch

Function

Provides 5 sticky status bits that capture an error during a PowerQuad operation. All bits are 'Write 1 to Clear'(W1C).

Diagram



Fields

Field	Function
31-5 —	Reserved
4 BUSERROR	Bus Error An AHB master interface bus error has occurred. 0b - No error 1b - Error on bus
3 UNDERFLOW	Underflow Error occurs when the input is so small that it has been truncated to 0. 0b - No error 1b - Error on underflow
2 FIXEDOVERFLOW	Fixed-point Overflow Error occurs when there is more data than can be processed. This bit refers to fixed-point values. 0b - No error 1b - Error on fixed-point overflow
1 NAN	Floating-Point Not-a-Number (NaN) Error occurs when the data has been corrupted or is illegal. 0b - No error 1b - Error on floating-point NaN
0	Floating-point Overflow

Table continues on the next page...

Table continued from the previous page...

Field	Function
OVERFLOW	Error occurs when there is more data than can be processed. This bit refers to floating-point values. 0b - No error 1b - Error on floating-point overflow

18.7.1.19 Interrupt Enable (INTREN)

Offset

Register	Offset
INTREN	190h

Function

Determines which conditions trigger an interrupt, based on the set status of the ERRSTAT register and on successful completion of operation.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-8 —	Reserved
7 INTR_COMP	Interrupt on Instruction Completion 0b - Disable interrupt 1b - Enable interrupt
6-5 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 INTR_BERR	Interrupt on AHBM Bus Error 0b - Disable interrupt 1b - Enable interrupt
3 INTR_UFLOW	Interrupt on Underflow 0b - Disable interrupt 1b - Enable interrupt
2 INTR_FIXED	Interrupt on Fixed-point Overflow 0b - Disable interrupt 1b - Enable interrupt
1 INTR_NAN	Interrupt Floating-point NaN 0b - Disable interrupt 1b - Enable interrupt
0 INTR_OFLOW	Interrupt Floating-point Overflow 0b - Disable interrupt 1b - Enable interrupt

18.7.1.20 Event Enable (EVENTEN)

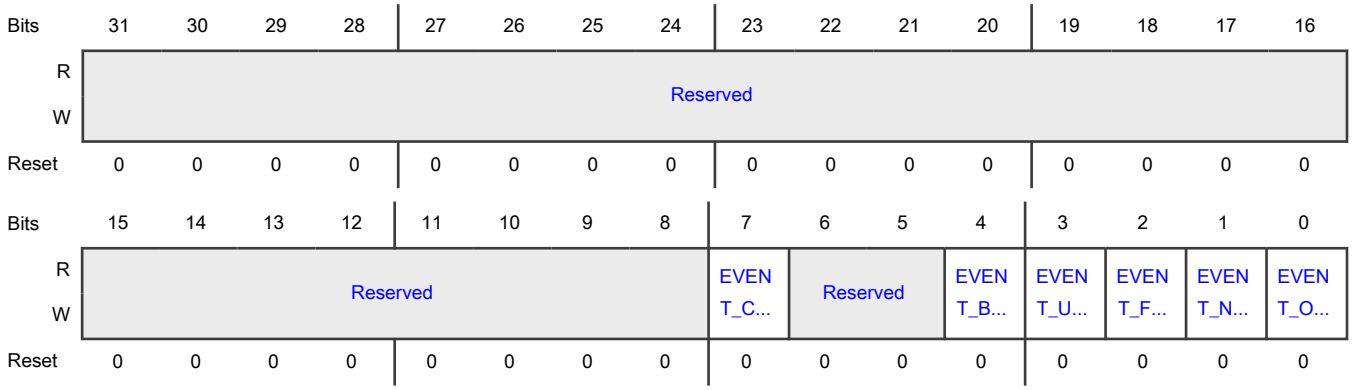
Offset

Register	Offset
EVENTEN	194h

Function

Determines which conditions trigger an event based on the set status of the ERRSTAT register and on successful completion of operation.

Diagram



Fields

Field	Function
31-8 —	Reserved
7 EVENT_COMP	Event Trigger on Instruction Completion 0b - Disable event trigger 1b - Enable event trigger
6-5 —	Reserved
4 EVENT_BERR	Event Trigger on AHBM Bus Error 0b - Disable event trigger 1b - Enable event trigger
3 EVENT_UFLOW	Event Trigger on Underflow 0b - Disable event trigger 1b - Enable event trigger
2 EVENT_FIXED	Event Trigger on Fixed-point Overflow 0b - Disable event trigger 1b - Enable event trigger
1 EVENT_NAN	Event Trigger on Floating-Point NaN 0b - Disable event trigger 1b - Enable event trigger
0 EVENT_OFLOW	Event Trigger on Floating-point Overflow 0b - Disable event trigger 1b - Enable event trigger

18.7.1.21 Interrupt Status (INTRSTAT)

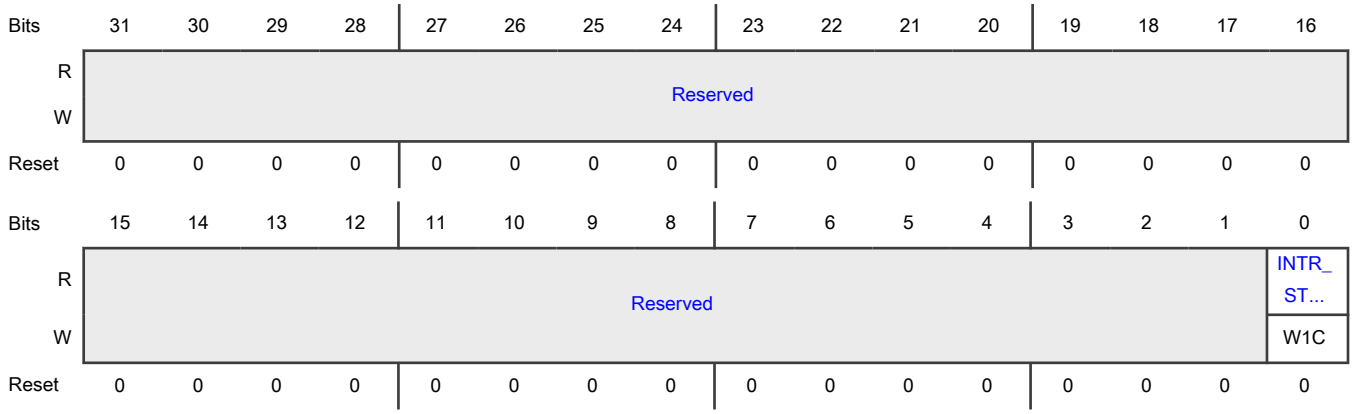
Offset

Register	Offset
INTRSTAT	198h

Function

Notifies on asserted trigger condition. A write of any value clears the Interrupt Status bit.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 INTR_STAT	Interrupt Status 0b - No new interrupt 1b - Interrupt captured

18.7.1.22 General Purpose Register Bank n (GPREG0 - GPREG15)

Offset

For n = 0 to 15:

Register	Offset
GPREGn	200h + (n × 4h)

Function

The General Purpose Register Bank is n x 32 bits. Used within the PowerQuad MAC engines. The values seen here are the staging and result registers of the adders and multipliers. These banks are made accessible so that you can back up the registers, when needed, to use PowerQuad for a different thread, then restore these saved values.

These registers are used by the Dual Biquad IIR engine and the Transform engine for intermediate data.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	GPREG															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	GPREG															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 GPREG	General Purpose Bank Intermediate staging and result data can be pulled and restored as needed. However, it is important to consider when data is being manipulated, because it can corrupt the results of an operation.

18.7.1.23 Compute Register Bank n (COMPREG0 - COMPREG7)

Offset

For n = 0 to 7:

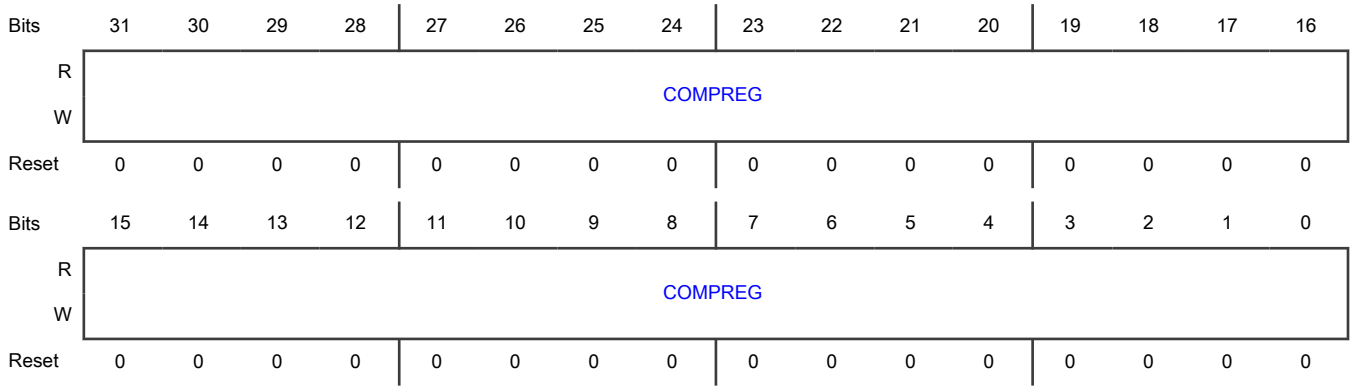
Register	Offset
COMPREGn	240h + (n × 4h)

Function

The Compute Register Bank is n x 32 bits. Used within the PowerQuad MAC engines. The values seen here are the staging or intermediate data used in FFT or Biquad operations. These banks are made accessible so that you can back up the registers, when needed, to use PowerQuad for a different thread. Then restore these saved values.

These registers are only used by the Dual Biquad IIR engine.

Diagram



Fields

Field	Function
31-0 COMPREG	Compute bank Intermediate staging and result data can be pulled and restored as needed. However it is important to consider when data is being manipulated, because it can corrupt the results of an operation.

19.1.1 Clock

The SmartDMA clock can be enabled or disabled by setting the SmartDMA field in the AHBCLKCTRL1 register.

19.1.2 Reset

The SmartDMA module can be reset by setting the corresponding field in the PRESETCTRL1 register. Clear the SmartDMA peripheral reset using the PRESETCTRLCLR1 register before using SmartDMA.

19.1.3 Interrupts

SmartDMA interrupt number is 53 (SmartDMA_IRQ).

19.1.4 Triggers

SmartDMA has 71 input sources in total in this chip. The following table lists the trigger sources of SmartDMA:

Table 284. SmartDMA trigger sources

Input	Function

1. SYS_IRQ combines the CDOG IRQ, WWDT IRQ, MBC secure violation IRQ, Secure AHB Matrix secure violation IRQ, GDET IRQ, ELS S50 error IRQ, PKC error IRQ, and VBAT IRQ using the logical OR operation.

19.1.5 Memory map

The priority of AHB bus masters can be adjusted by using the SYSCON[AHBMATPRIO] register.

19.2 Overview

SmartDMA is a core that supports unique, reduced instruction sets. It works in a similar way to the Arm core. Being the controller of AHB matrix, SmartDMA can access:

- All its targets.
- The GPIO peripheral control and data registers.

The purpose of SmartDMA is to perform event- and I/O-driven handling to offload the Arm processor in the system.

19.2.1 Block diagram

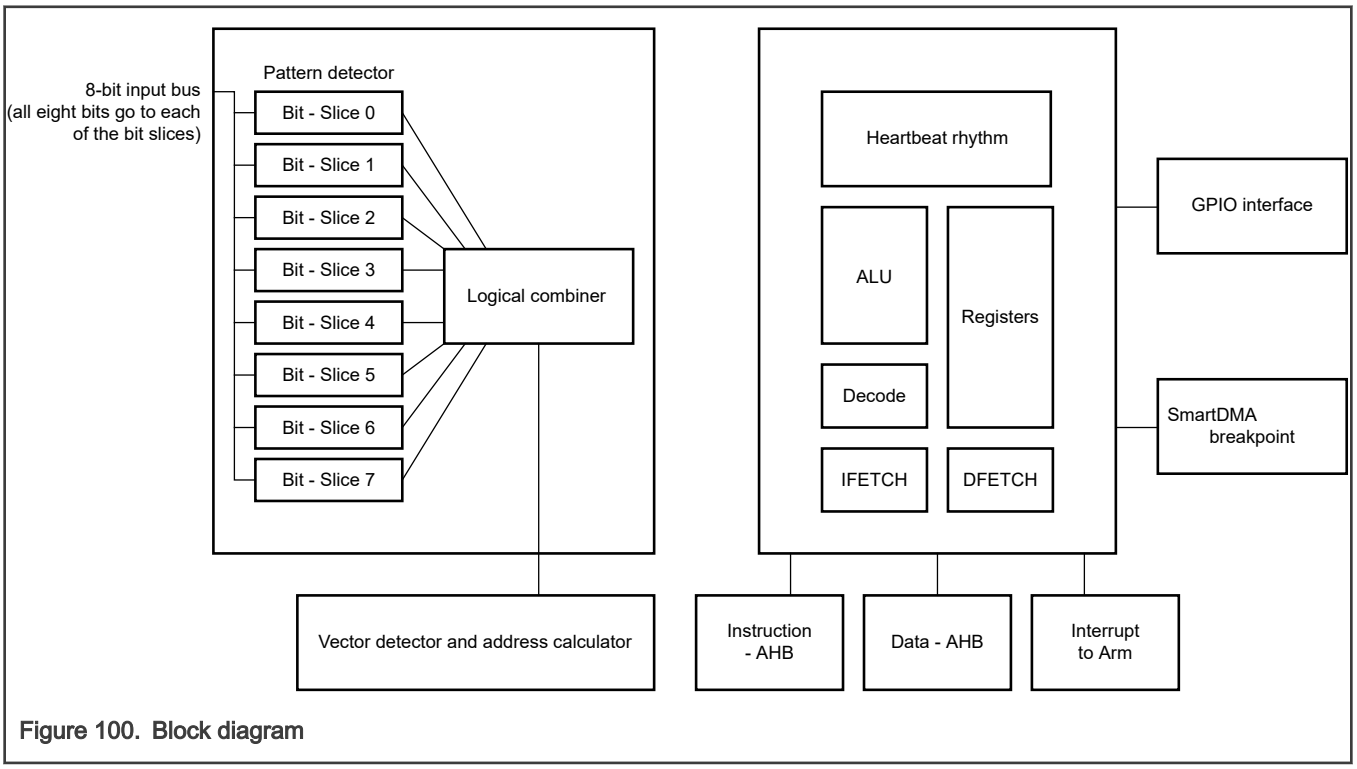

Figure 100. Block diagram

19.2.2 Features

SmartDMA is designed to deliver an optimal performance for the following purposes:

- State machine control
- Boolean detection
- Tedious or repetitive simple tasks
- DMA function
- Interrupt load reduction on Arm
- Streaming GPIO
- General I/O handling
- Protocol emulation over I/O, such as parallel camera and LCD interfaces
- Shift-based algorithm calculation
- Large-scale data manipulation

19.3 Functional description

19.3.1 Clocking

SmartDMA uses the same system clock as the Arm core does. You can enable or disable the SmartDMA clock by configuring the appropriate register field (see the chip-specific section for details). However, you must enable the clock for SmartDMA before setting the SmartDMA controller and SmartDMA program execution.

19.3.2 Reset

You can reset the SmartDMA module by configuring the corresponding register field. See the chip-specific section for details.

19.3.3 Interrupts

You can enable the Arm interrupt for SmartDMA via nested vectored interrupt controller (NVIC). See the chip-specific section for details.

19.3.4 Pin description

SmartDMA can access and manipulate a maximum of 32 I/O pins that are selected as “SmartDMA function”. You can configure “SmartDMA function” by using signal multiplexing.

SmartDMA includes dedicated GPIO control registers through which it can quickly access I/O ports. See the chip-specific section for details.

19.3.5 Requests and triggers

In general, SmartDMA requests set the pace of execution to match what the peripheral (including its FIFO if it has one) could do. For example,

- USART issues a transmit SmartDMA request when its transmit FIFO is not full, and a receive SmartDMA request when its receive FIFO is not empty.
- The GPIO pin issues a data storage SmartDMA request when its rising edge is detected.
- The timer event issues a PWM output SmartDMA request when the counter reaches zero.
- ADC issues a result reading SmartDMA request after the conversion is complete.

SmartDMA includes a number of channels connected to external input sources. See the chip-specific section for details.

19.3.6 Setting and power consumption in different modes

In Sleep mode, SmartDMA:

- Is active.
- Can operate and access all enabled peripherals and memories.
- Can wake up the Arm core from Sleep mode.

In Power-Down and Deep Power-Down modes, SmartDMA:

- Is inactive.
- Is configurable for low-power consumption by:
  - Disabling the SmartDMA clock when not in use.
  - Placing SmartDMA into the reset state.
  - Holding the SmartDMA core by using some opcodes.
  - Slowing down the frequency of SmartDMA execution.

19.4 Memory map

SmartDMA includes two AHB bus master interfaces. You can adjust the priority of AHB bus masters to achieve the desired system performance. See the chip-specific section for details.

Clock speed of the NPU is derived directly from the system_clk.

20.2 Overview

This chapter provides information on the features supported by the eIQ® Neutron N1-16 NPU. For enablement details and constraints, see the documentation that is part of eIQ Toolkit at http://nxp.com/eiq.

The NPU is an on-chip hardware accelerator that provides efficient processing of machine-learning workloads. It works in conjunction with the chip's CPU to deliver higher performance and lower power consumption for neural network (NN) inference.

In addition to managing Multiply-Accumulate (MAC) compute blocks throughput, NPU also:

- Optimizes arrangement of weights
- Manages memory accesses
- Provides rescaling, activation, and pooling functions

Enablement support for the eIQ Neutron N1-16 NPU is provided with the eIQ Toolkit and eIQ Machine Learning (ML) Software Development Environment. Some of the features and operators listed in this chapter may not be enabled in eIQ software. See References for links to eIQ documentation that lists the features and operators enabled in the latest eIQ software.

You can import your trained and quantized NN into eIQ Toolkit. The eIQ tooling generates an NPU-optimized model that can be integrated into an ML application running on the target device.

20.2.1 Block diagram

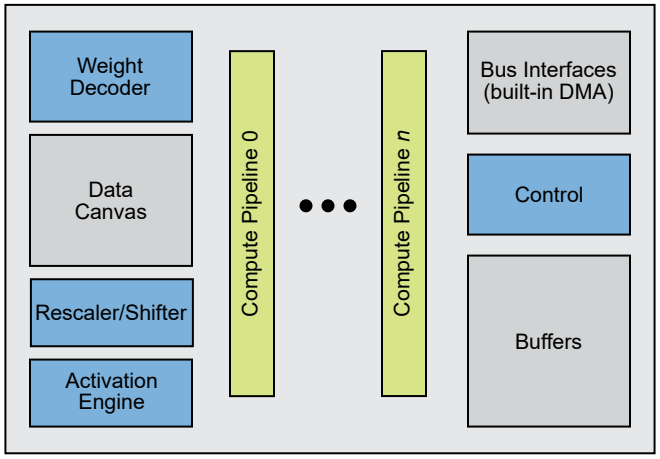

Figure 101. eIQ Neutron NPU architecture

Table 286.

Component	Description
Activation Engine	Provides activation functions. See the list of supported activation functions.
Buffers	Data buffers for pipeline input data and MAC results.
Bus Interfaces	Provide Interconnect fabric designed for efficient data transfer between memories and compute blocks.
Control	Provides control and status functions.
Data Canvas	Provides 2D circular data buffer that enables data reuse among compute pipelines.
Rescaler/Shifter	Provides post-scaling of MAC compute block results. See Rescale support.
Weight Decoder	Manages decompression, if necessary, for weight fetches. See Weight decode support.

20.2.2 Features

- Performance:
  - Up to 16 MACs/cycle for 8-bit × 8-bit operations
- Supported data types:
  - Input data:
    - 8-bit unsigned asymmetric
    - 8-bit signed asymmetric
    - 8-bit signed symmetric
  - Weights:
    - 8-bit signed symmetric
    - 8-bit unsigned symmetric
  - Arithmetic operations:
    - 8-bit data × 8-bit weight

  - Activation × Activation (transformers, for example):
    - 8-bit symmetric × 8-bit symmetric (signed or unsigned)
  - Bias:
    - Custom FP16 format (1-bit sign, 5-bit up-shift, 10 bits significant value)
  - Results:
    - 32-bit symmetric signed
    - 16-bit symmetric signed/unsigned
    - 8-bit symmetric/asymmetric signed/unsigned
- Supported operators: see Operator summary.
- Constraints for Spatial Compute (Convolution, for example):
  - Padding. Individually selectable for Top/Bottom/Left/Right; maximum padding is 4 pixels.
  - Stride. 1 or 2 pixels (horizontal and vertical).
  - Dilation. 1 or 2 pixels (horizontal and vertical).
  - Kernel size. Maximum weight matrix row length = 64 k.
  - Kernel height. Maximum = 8 pixels (Includes pixels skipped due to dilation).
  - Kernel width. Maximum = 64 pixels (Includes pixels skipped due to dilation).

NOTE

Larger kernel-shapes, stripes, and so on, can be achieved through cascading multiple layers.

- Accumulation support:

  eIQ Neutron N1-16 NPU uses a 32-bit accumulation scheme, which prevents saturation—even in large neural networks—for 8-bit × 8-bit computations.
- Weight decode support:
  - 8-bit weights direct (no decode)
  - Mini-weights (<8 bits) through sign extension
  - Mini-weights (≤6 bits). Weights are translated using a codebook. You can use weight clustering to have fewer used 8-bit values and then encode the chosen values by using an index table. NPU uses the weights as indices to select appropriate 8-bit values as the weights are loaded into compute.
- Rescale support:

  Rescales 32-bit accumulator results.
  - In a typical case in which the quantizer can rely on the integer precision dynamic range to perform the ReLU clipping and max value clipping, this function scales values to the desired 8-bit or 16-bit output directly.
  - Rescaling is also used to scale the accumulator result so it can be presented as 16-bit data to NPU's Activation Engine.

  The general form of the rescaling stage is:

```
Output = Round((accumulator × scaleFactor)>>downshiftFactor)
```

  eIQ Neutron N1-16 NPU supports the following rescaling scheme:
  - 16-bit rescale factor: 10-bit scaler, 6-bit downshift factor
- Activation Engine:

eIQ Neutron N1-16 NPU provides built-in activation functions and a hardware engine to perform activation. The Activation Engine works on 16-bit signed data produced by rescaling.

The activation functions are executed “in-pipeline” together with the computation preceding it. No extra cycles are consumed and there is no need for spilling higher precision data into memory than the activated data size.

Activation engine accuracy is 8-bit precision, except for ReLu, which essentially has no modification to values, and exp(x), which is output as 16-bit data.

The supported built-in activation functions are:

- 8-bit:
  - ReLU
  - ReLUx
  - Sigmoid
  - Tanh
  - LeakyReLU (limited to Alpha = 0.25, 0.125, and 0.0625)

20.3 Functional description

20.3.1 Operator summary

Table 287. Operator summary

Operator[1]	TFLite operator	Data size (bits)		Notes
		Input[2]	Output[3]	
Absolute	ABS	8	8	
Add Tensor-Tensor	ADD	8	8	Includes scaling to match quantization scales; both inputs must be of equal bit width
Add Tensor + Constant	ADD	8	8	
Average Pooling	AVERAGE_POOL_2D	8	8	
Concatenate Tensors	CONCATENATE	8	8	
Convolution 2D/1D	CONV_2D	8	8	
Depthwise Convolution 2D/1D	DEPTHWISE_CONV_2D	8	8	
Expand Dimensions	EXPAND_DIMS			Supported by Activate Function Interpolator
Fully Connected / Dense / Linear	FULLY_CONNECTED	8	8	Support for 8- or 16-bit weights and data of 8- or 16-bit data
Leaky-ReLU	LEAKY_RELU	8	8	• As fused activation function or TFLite operator LEAKY_RELU • 8-bit precision for scaling LeakyReLU data
Logistic / Sigmoid	LOGISTIC	8	8	As fused activation or TFLite operator LOGISTIC

Table continues on the next page...

Table 287. Operator summary (continued)

Operator[1]	TFLite operator	Data size (bits)		Notes
		Input[2]	Output[3]	
Maximum	MAXIMUM	8	8	
Max-Pooling	MAX_POOL_2D	8	8	
Mean / Average	MEAN	8	8	
Minimum	MINIMUM	8	8	
Multiplication	MUL, BatchMatMul	8	8	• Support for all types of multiplications—batched, non-batched, dot-product matrix-matrix, matrix-scalar, transpose matrix-matrix, Hadamard • 8-bit data × 8-bit weight
Packing	PACK	8	8	
Padding	PAD	8	8	Implicit with compute
Re-Quantize	QUANTIZE	8	8	• To change INT quantization scale and zero point • Integer input, integer output
RELU	RELU	8	8	As fused activation or TFLite operator RELU
RELU6	RELU6	8	8	• As fused activation or TFLite operator RELU6 • Supports min-max clipping factors other than (0, 6)
RELU	RELU_N1_TO_1	8	8	As fused activation or TFLite operator RELU_N1_TO_1
Reshape Tensor	RESHAPE	8	8	
Resize Bilinear	RESIZE_BILINEAR	8	8	Constraint: Only 2×2. Larger resize factors can be achieved by cascading multiple 2×2 resize layers.
Resize Nearest Neighbor	RESIZE_NEAREST_NEIGHBOR	8	8	Constraint: Only 2×2. Larger resize factors can be achieved by cascading multiple 2×2 resize layers.
Shape	SHAPE	N/A		No operation is performed by NPU hardware
Slice Tensor	SLICE, STRIDED_SLICE	8	8	

Table continues on the next page...

Table 287. Operator summary (continued)

Operator[1]	TFLite operator	Data size (bits)		Notes
		Input[2]	Output[3]	
Split Tensor	SPLIT, SPLIT_V	8	8	
Squeeze Tensor	SQUEEZE			Operation is not performed by NPU hardware
Strided Slice	STRIDED_SLICE	8	8	
Subtract Tensor-Tensor	SUB	8	8	• Includes scaling to match quantization scales • 8-bit data × 8-bit weight
Subtract Tensor-Constant	SUB	8	8	• Includes scaling to match quantization scales • 8-bit data × 8-bit weight
Tanh / hyperbolic tangent function	TANH	8	8	As fused activation or TFLite operator TANH
Transpose Convolution 2D	TRANSPOSE_CONV	8	8	Includes possibility of upsampling input (zero-filled) before operation
Unidirectional LSTM	UNIDIRECTIONAL_SEQUENCE_LSTM	8	8	
Unpack Tensor	UNPACK			No operation is performed by NPU hardware

1. Some of the operators in listed in this table may not be enabled in eIQ software. See References for links to eIQ documentation that lists the operators enabled in the latest eIQ software.
2. Inputs are always 8-bit.
3. Output can be 8-,16-, or 32-bit. Note that this is a format—it does not imply 32-bit precision, but output can be generated in int32 format with whatever data is generated. This can be useful if you want to run, for example, a convolution with the intent of running activation outside of Neutron. It is also sometimes useful to export results as 16-bit data to have symmetric data instead of 8-bit asymmetric data.

20.4 Memory map and register definitions

eIQ Neutron NPU does not have any user-configurable registers. All NPU configuration and control functions must be performed using NXP's eIQ Toolkit software. See References for links.

Chapter 21
CoolFlux BSP32 Subsystem

21.1 Chip-specific CoolFlux BSP32 information

Table 288. Reference links to related information

Topic	Related module	Reference
Full description	CoolFlux BSP32	CoolFlux BSP32
System memory map		Memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

21.1.1 Module instances

This device has one instance of the CoolFlux BSP32 module, BSP32_0.

21.1.2 RAM

CoolFlux program memory interface can access flash and FlexSPI also along with RAMX, RAMA ~ RAMH. CoolFlux X data memory interface can also access mailbox and Powerquad RAM.

21.1.3 Compiler options

Due to long memory paths from data memory output directly to data memory address, the maximum frequency that can be obtained is limited. The compiler should disable the sequence that consists of a data memory load to a pointer register, followed in the next cycle by a memory access using that same pointer.

21.2 Overview

The CoolFlux BSP32 is a programmable digital signal processor, where BSP stands for Baseband Signal Processor and the 32 indicates that is has a 32-bit data path and 32-bit data memories. It is dual Harvard, dual multiplier processor based on the ultra-low power CoolFlux architecture. It supports 16 and 32-bit scalar operations as well as complex and SIMD operations and data types. CoolFlux BSP32 is fully programmable in C and comes with an optimizing compiler and tool suite.

More information about the CoolFlux BSP32 can be received from the NXP CoolFlux team (coolflux.support@nxp.com). Documentation on the tools (compiler, simulator, linker, ...) as well as documentation on the architecture and instruction set architecture are available as well. Training on programming the CoolFlux BSP32 processor can also be requested using the same channel and email address.

This module has a dedicated clock and reset signal.

21.2.1 Block diagram

The following figure shows the block diagram of the CoolFlux BSP32 subsystem.

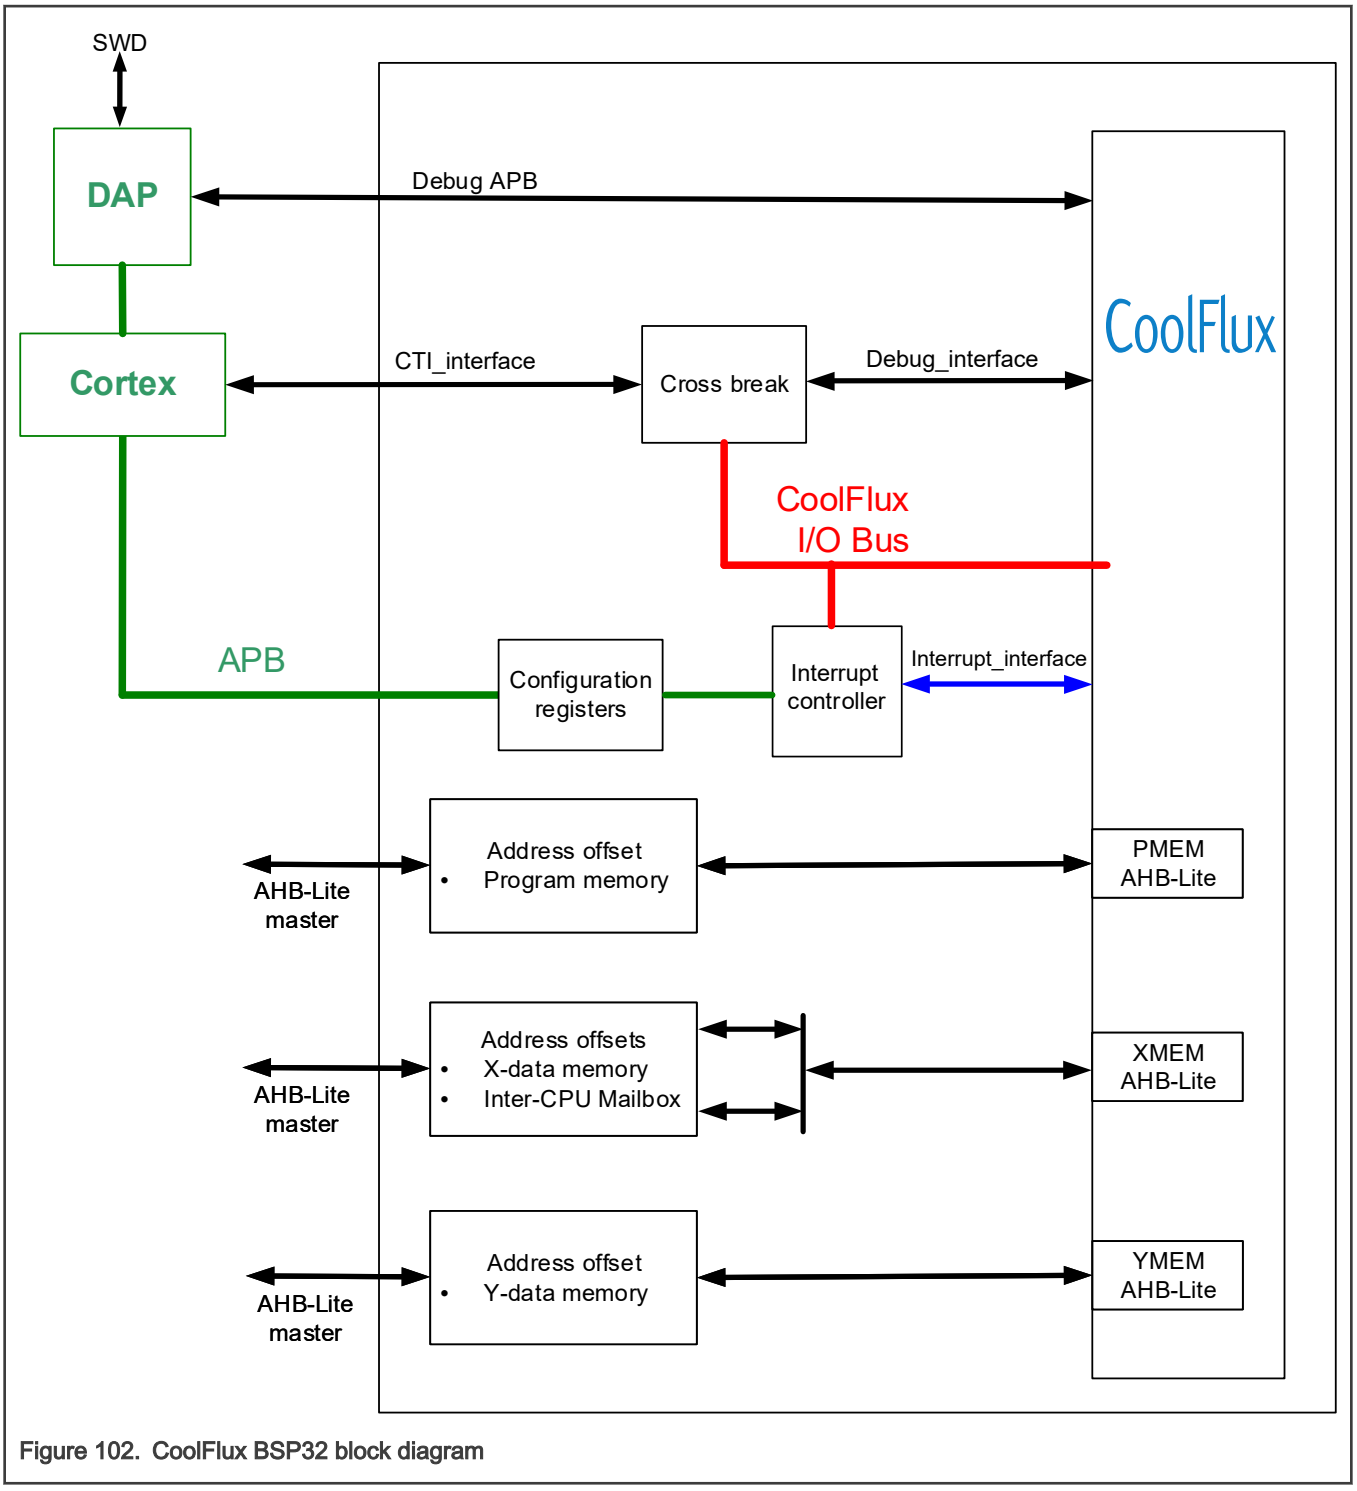

Figure 102. CoolFlux BSP32 block diagram

21.2.2 Features

- CoolFlux BSP32 32-bit processor, developed especially for audio, sensor or modem applications
- AHB-Lite interface towards program memory
- Two AHB-Lite interfaces towards on-chip data memory
- Serial Wire Debug (shared with Cortex-M33 Control Domain CPU).

21.3 Functional description

The CoolFlux BSP32 subsystem is built around the CoolFlux BSP32 processor as the main building blocks. This is a fully (C) programmable architecture that is able to execute a wide range of different algorithms. All other modules within the subsystem are meant to control this processor or to enable external communication towards the CoolFlux BSP32.

The interrupt controller can be used to interrupt the CoolFlux BSP32 based upon external events. In the other direction, the CoolFlux BSP32. also has the ability to send interrupts externally which allow inter-processor communication.

A cross-break module is available which allows common debugging between the Cortex processor and CoolFlux BSP32. This cross-break is able to transfer break events between both processors which allow a processor to (conditionally) enter debug mode at the moment the other one does.

A range of programmable registers (within the APB addressing space) is to configure and initialize the CoolFlux BSP32. This includes setting memory offset registers and inter-processor communication registers as will be explained later in the register definition chapter.

21.3.1 Security

CoolFlux BSP32 does not include any mechanism for supporting system security of the type implemented by the Cortex-M33.

21.3.2 APB programming interface

The CoolFlux BSP32 subsystem has an APB programming interface that is used to configure the subsystem. It is used to set the memory offset registers, program the internal FIFO’s, set the boot address, and generate an interrupt towards CoolFlux BSP32. Most of these registers must be set before the subsystem is pulled out of reset.

21.3.3 Cross break

The CoolFlux BSP32 subsystem contains a programmable cross break module that makes it possible to do co-debugging between CoolFlux BSP32 and Cortex M33. It can, for instance, be used to stop one processor when the other one hits a breakpoint.

21.3.4 Inter-CPU communications

CoolFlux BSP32 and CM33 can communicate with each other via various means. Shared memory that is accessible to both processors makes it possible to work on shared buffers. The mailbox can be used to send messages from one processor to the other. Finally, both processors can generate interrupts on the other one.

21.3.5 Operations and modes

The CoolFlux BSP32 is a programmable architecture that is initialized through a range of programmable registers in APB addressing space. It always executes its program via program memory and accesses the data within X or Y memory space. Hence it has no different operations or modes.

21.3.6 Clocking

The CoolFlux BSP32 has a single clock input pin called "clk". Only the rising edge of this clock is used. Note that the APB programming interface and the APB debug interface have their own APB clock signals, called "apb_pclk" and "apb_pclk_debug" respectively, both asynchronous and active low.

21.3.7 Reset

The CoolFlux BSP32 is held in reset after a device reset. Before CoolFlux BSP32 begins execution, the Cortex-M33 must load code into the memories accessible by the CoolFlux BSP32, configure CoolFlux BSP32 configuration registers (for instance, the memory offset values), and release the CoolFlux BSP32 from reset. The reset input signal is called "reset" and is asynchronous, active high. Note that the APB programming interface and the APB debug interface have their own APB reset signals, called "apb_presetn" and "apb_presetn_debug" respectively, both asynchronous and active low.

21.3.8 Interrupts

CoolFlux BSP32 has 32 external interrupt inputs. An internal interrupt controller maps these 32 interrupt sources to any of the three CoolFlux interrupt routines. Each interrupt can be enabled or disabled individually and routed to any interrupt routine. The interrupts are handled in software by the processor itself using edge detection. Whenever an interrupt is received on the CoolFlux BSP32, the corresponding interrupt routine is executed.

More explanation on the usage of interrupts can be found in the CoolFlux documentation that can be obtained from the CoolFlux team (coolflux.support@nxp.com).

The CoolFlux BSP32 subsystem can generate an external interrupt. This interrupt can be routed towards the Cortex M33 to facilitate inter-processor communication.

21.4 External signals

This section explains the external signals. The CoolFlux BSP32 subsystem has the following interface groups

External signals:

- Clock, reset and test signals
- APB programming interface
- APB debug interface
- Cross-trigger interface
- Interrupt interface
- Sleep mode indication
- Program memory AHB-Lite interface
- X-data memory AHB-Lite interface
- Y-data memory AHB-Lite interface

21.5 Initialization

Before the CoolFlux BSP32 subsystem can be used, it must be initialized. This involves the following.

Initialization:

- The three memories (P,X,Y) must be loaded with the correct program and data
- The four IVT registers (registers ivt0, ivt1, ivt2, ivt3) must be initialized
- The APB configuration registers must be initialized (e.g. offset registers to be able to access the memories)
- Clock must be enabled
- Reset must be de-asserted

From this moment onwards, the CoolFlux BSP32 will start executing the code as placed inside the program memory.

21.6 Application information

The CoolFlux BSP32 subsystem is built around the CoolFlux BSP32 processor. As this is a fully C-programmable processor, it can be used to execute different sorts of applications. These can be audio application, baseband algorithms, ultra-wide band applications. It is optimized to efficiently run integer, fix-point and complex data types in an ultra-low power manner.

21.7 Physical memory map

The general features of the CoolFlux BSP32 physical memory map are discussed in the following sections.

The CoolFlux BSP32 includes three AHB-Lite bus master interfaces. The priority of this and other AHB bus masters can be adjusted to achieve system performance needed by an application by using the SYSCON[AHBMATPRIO] register.

21.7.1 RAM

The CoolFlux BSP32 AHB-Lite program memory interface can access the SRAM X memory as well as SRAM A … SRAM H memory.

The X and Y CoolFlux BSP32 AHB-Lite data memory interfaces can access the SRAM A … SRAM H memories. These data memories also have access to the PowerQuad addressing space.

21.7.2 AHB and APB peripherals

The CoolFlux BSP32 processor access to peripherals is limited to the Inter-CPU mailbox attached to the AHB bus. This way, it is possible to communicate through short messages and interrupts between the CoolFlux BSP32 and the Cortex M33. Refer to the Inter-CPU Mailbox chapter for more information.

21.8 CoolFlux BSP32 register descriptions

Different registers to control the CoolFlux BSP32 subsystem. Before using the CoolFlux BSP32 subsystem it must be initialized using the APB interface. Communication between the CoolFlux BSP32 subsystem and the Cortex subsystem also uses this interface.

31-1 —	Reserved
0 val	Interrupt status register

21.8.8 CoolFlux BSP32 gating override (cf_gating_override)

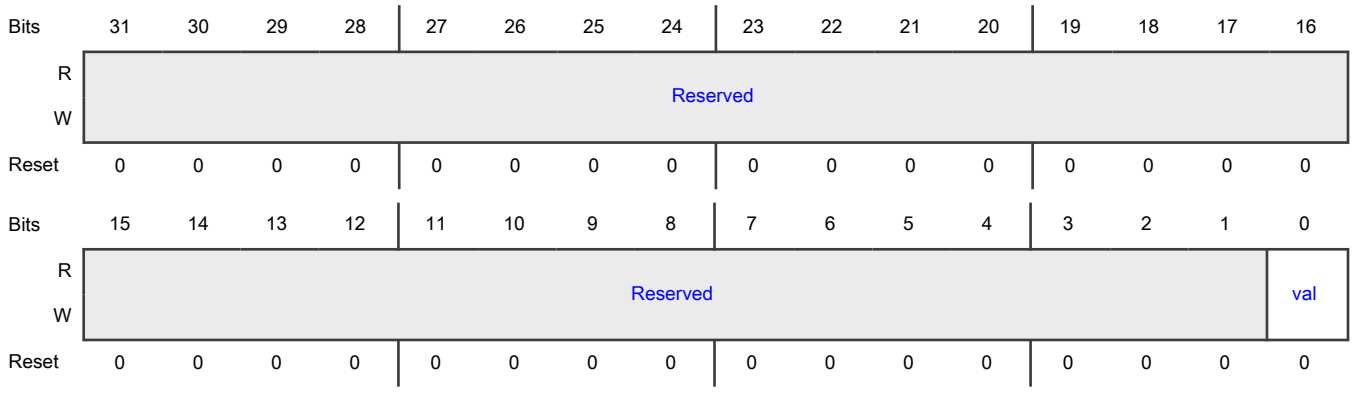
Offset

Register	Offset
cf_gating_override	18h

Function

By default, the clock towards the CoolFlux BSP32 is switched off when the processor enters sleep mode. This can be overruled by setting this bit. When set, the clock towards the CoolFlux BSP32 keeps running when it enters sleep mode. This will have a negative impact on power.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 val	CoolFlux BSP32 gating override

21.8.9 CoolFlux BSP32 IVT offset register (ivt_offset)

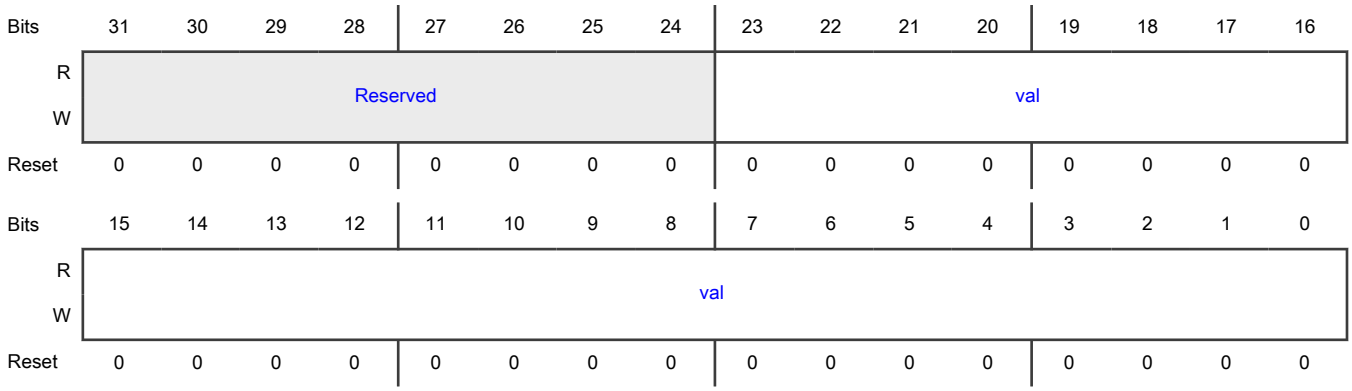
Offset

Register	Offset
ivt_offset	1Ch

Function

The Interrupt Vector Table (IVT) of the CoolFlux BSP32 is used to determine the addresses of the reset vector and interrupt vectors. By default, the IVT table starts from program memory address 0 from a CoolFlux point of view, which means that the IVT start address is defined by the "offset address for program memory" register. The IVT offset register can be used to re-locate the IVT table of the CoolFlux BSP32 program, thereby placing the IVT table in a different location in program memory. For more information about the IVT table, please refer to the CoolFlux BSP32 C Programmer's manual that can be obtained from the CoolFlux team (coolflux.support@nxp.com).

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 val	CoolFlux BSP32 IVT offset register

21.8.10 CoolFlux BSP32 sleep mode register (sleep_mode)

Offset

Register	Offset
sleep_mode	20h

Function

Register indicating whether the CoolFlux BSP32 is in sleep mode (1) or not (0). The CoolFlux BSP32 will enter sleep mode when the eop (End-Of-Program) instruction is executed and is thus fully under software control. It will exit from sleep mode in case of an interrupt request, debug request or a full reset. Sleep mode is used in an application to save power while waiting on a particular event (mostly an interrupt as mentioned above). In this sleep mode, power consumption is reduced as most of the clocks will be switched off (automatically done in hardware).

21.8.14 CoolFlux BSP32 IVT register 3 content (ivt3)

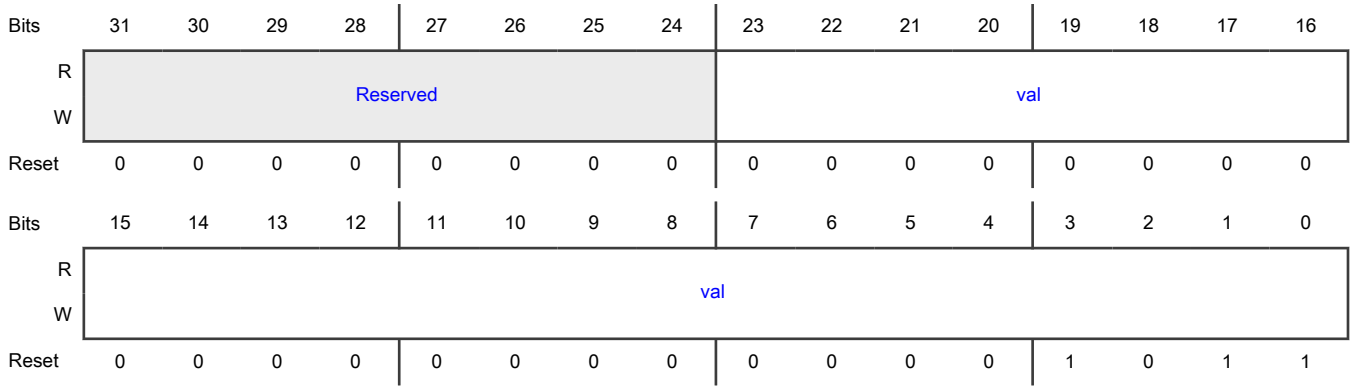
Offset

Register	Offset
ivt3	30h

Function

Content of IVT register 3 (interrupt line 2 vector). This needs to be written explicitly before the processor is pulled out of reset. The content of this register is used as the target address of a "goto" instruction.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 val	CoolFlux BSP32 IVT register 3 content

21.8.15 CoolFlux BSP32 IVT disable register (ivt_disable)

Offset

Register	Offset
ivt_disable	34h

Function

Before using the CoolFlux BSP32, the four IVT registers (registers ivt0, ivt1, ivt2, ivt3) must be initialized. These writes can be omitted by writing to this register. In that case, the four IVT registers are not used and their data is read directly from program memory instead. As this leads to longer timing paths, the maximum allowed frequency of the CoolFlux BSP32 is reduced. Its usage was deprecated in newer version and therefore, writing a "1" to this register is strongly disadvised.

Diagram

Chapter 22
Inter-CPU Mailbox (MAILBOX)

22.1 Chip-specific MAILBOX information

Table 289. Reference links to related information

Topic	Related module	Reference
Full description	MAILBOX	MAILBOX
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

This block is a AHB slave peripheral with a single clock domain and reset. This device supports two mailboxes, where each mailbox has three 32-bit registers. Each mailbox has one mutex register and one peripheral ID register. For each mailbox, the corresponding interrupt line intr[i] is set if MBOX_REG[i] is not 0 and cleared if it is 0.

22.1.1 Module instances

This device has one instance of the Inter-CPU Mailbox module, MAILBOX0.

22.2 Overview

MAILBOX provides simple communication and resource allocation between CPUs by using two mechanisms:

The first mechanism helps you send an interrupt, along with a simple message, to another CPU. To generate an interrupt to another CPU, you can set any one of the interrupt flags (up to 32) by using Cortex-M33 (CPU0) Interrupt Set (IRQ0SET) and CoolFlux (CPU1) Interrupt Set (IRQ1SET). The other CPU reads Cortex-M33 (CPU0) Interrupt Set (IRQ0SET) and CoolFlux (CPU1) Interrupt Set (IRQ1SET) to determine the action it needs to perform. If more than one IRQ*n* field is 1, the CPU receiving the interrupts reads all of them. After completing the requested service or operation, the CPU that receives the interrupt requests writes 1 to one or more fields in Cortex-M33 (CPU0) Interrupt Clear (IRQ0CLR) and CoolFlux (CPU1) Interrupt Clear (IRQ1CLR) to clear them.

To check whether the operation is complete, the CPU sending the request can check IRQ*n*, or the CPU receiving the original interrupt can use the same mechanism on the reverse to notify the requesting CPU.

You can determine the use of each bit in Cortex-M33 (CPU0) Interrupt (IRQ0) and CoolFlux (CPU1) Interrupt (IRQ1) and also provide additional information to each request bit. For example, both the CPUs can use predefined memory locations to hold detailed information about the interrupt requests.

The second mechanism is based on a single-bit resource allocation request. MUTEX[EX] defines the mutual exclusion request, and reading it provides the current status of the resource. If the resource is available, it is reserved for the process that reads the register. You define the resource control, and after getting access to the resource, you must write 1 to MUTEX[EX] to clear the field after it has used the resource. For more information, see MUTEX[EX].

22.2.1 Block diagram

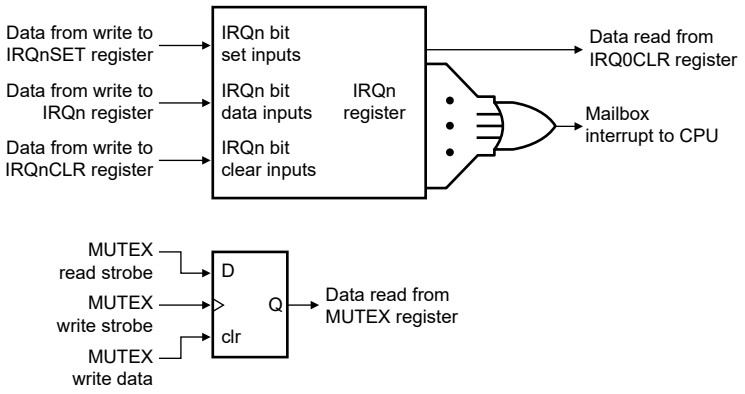

Figure 103. Block diagram

22.2.2 Features

- Provides inter-processor communication, allowing multiple CPUs to share resources and communicate with each other in a simple manner.
- Enables each CPU to generate up to 32 user-defined interrupts.
- Enables each CPU to claim a shared resource if the resource is available.

22.3 Functional description

22.3.1 Clocks

SYSCON.AHBCLKCTRL0[MAILBOX] controls this module's bus clock.

22.3.2 Reset

SYSCON.PRESETCTRL0[MAILBOX_RST] resets this module.

22.4 Signals

This module has no configurable pins.

22.5 Memory map and register definition

This section includes this module's memory map and detailed descriptions of all registers.

22.5.1 MAILBOX register descriptions

22.5.1.1 MAILBOX memory map

MAILBOX0 base address: 400B_2000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Cortex-M33 (CPU0) Interrupt (IRQ0)	32	RW	0000_0000h
4h	Cortex-M33 (CPU0) Interrupt Set (IRQ0SET)	32	W	See section
8h	Cortex-M33 (CPU0) Interrupt Clear (IRQ0CLR)	32	W	See section
10h	CoolFlux (CPU1) Interrupt (IRQ1)	32	RW	0000_0000h
14h	CoolFlux (CPU1) Interrupt Set (IRQ1SET)	32	W	See section
18h	CoolFlux (CPU1) Interrupt Clear (IRQ1CLR)	32	W	See section
F8h	Mutual Exclusion (MUTEX)	32	RW	0000_0001h

22.5.1.2 Cortex-M33 (CPU0) Interrupt (IRQ0)

Offset

Register	Offset
IRQ0	0h

Function

Allows other CPUs to send interrupt requests to Cortex-M33 (CPU0).

This register allows communication between CPUs. For example, a CPU can handle certain peripherals, along with signaling another CPU, when data is available. Each bit of this register can be configured differently, based on your requirements.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	INTREQ															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 INTREQ	Interrupt Request Sends interrupt requests to the Cortex-M33 (CPU0) interrupt controller, if you write 1 to any of the bits.

22.5.1.3 Cortex-M33 (CPU0) Interrupt Set (IRQ0SET)

Offset

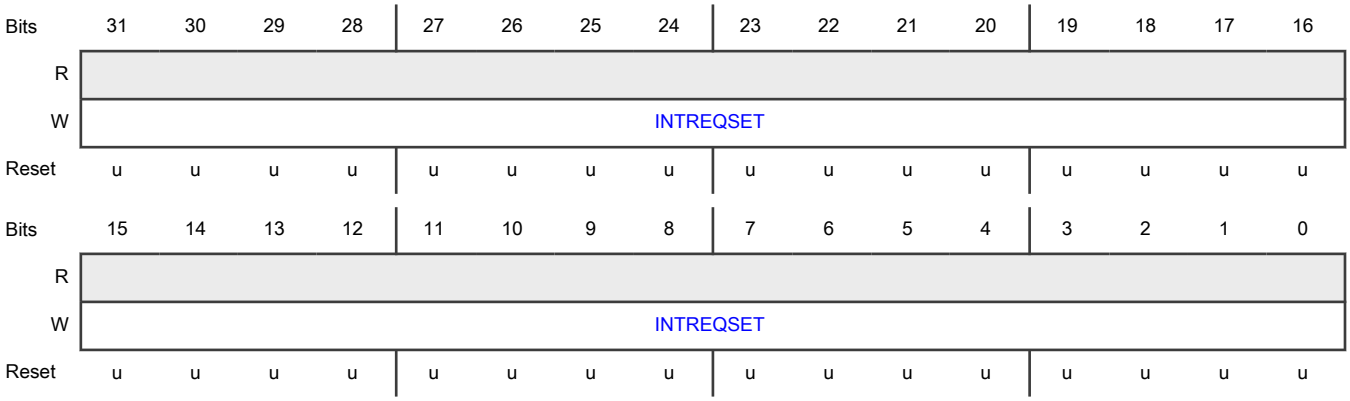
Register	Offset
IRQ0SET	4h

Function

Generates interrupt requests for Cortex-M33 (CPU0).

Writing 1 to any bit of this register writes 1 to the corresponding bit of Cortex-M33 (CPU0) Interrupt (IRQ0). You can generate more than one interrupt by writing 1 to multiple bits of this register.

Diagram



Fields

Field	Function
31-0 INTREQSET	Interrupt Request Set 0 Generates interrupt requests for Cortex-M33 (CPU0).

22.5.1.4 Cortex-M33 (CPU0) Interrupt Clear (IRQ0CLR)

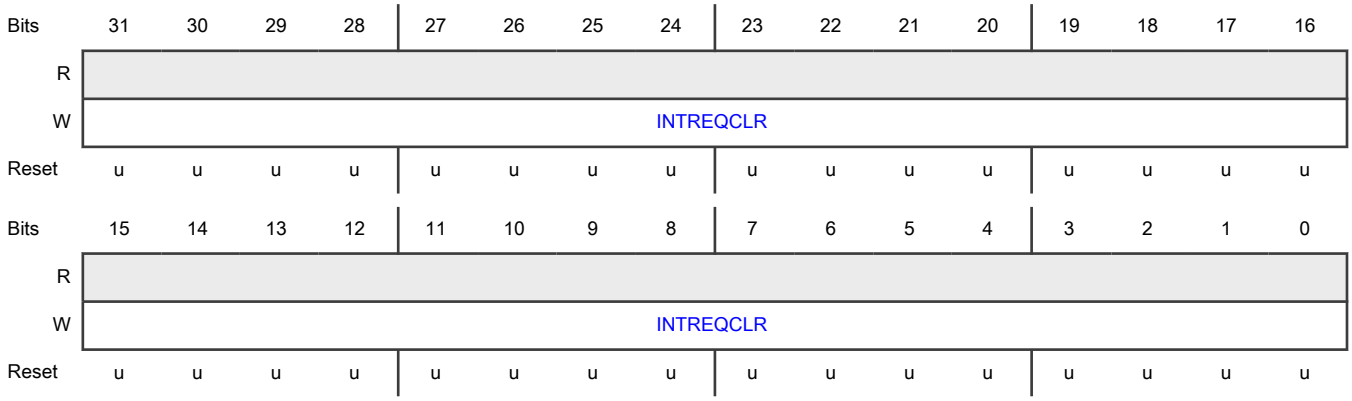
Offset

Register	Offset
IRQ0CLR	8h

Function

Clears interrupts for Cortex-M33 (CPU0) after the requested service or operation is complete. Writing 1 to any bit of this register writes 0 to the corresponding bit of Cortex-M33 (CPU0) Interrupt (IRQ0).

Diagram



Fields

Field	Function
31-0 INTREQCLR	Interrupt Request Clear 0 Clears interrupt requests for Cortex-M33 (CPU0).

22.5.1.5 CoolFlux (CPU1) Interrupt (IRQ1)

Offset

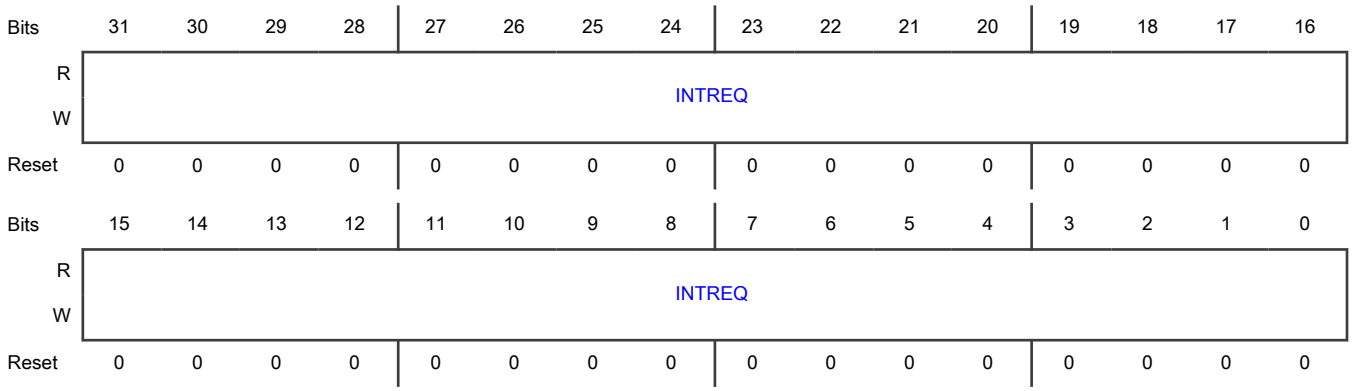
Register	Offset
IRQ1	10h

Function

Allows other CPUs to send interrupt requests to CoolFlux (CPU1).

This register allows communication between CPUs. For example, a CPU can handle certain peripherals, along with signaling another CPU, when data is available. Each bit of this register can be configured differently, based on your requirements.

Diagram



Fields

Field	Function
31-0 INTREQ	Interrupt Request Sends interrupt requests to the CoolFlux (CPU1) interrupt controller, if you write 1 to any of the bits.

22.5.1.6 CoolFlux (CPU1) Interrupt Set (IRQ1SET)

Offset

Register	Offset
IRQ1SET	14h

Function

Generates interrupt requests for CoolFlux (CPU1).

Writing 1 to any bit of this register writes 1 to the corresponding bit of CoolFlux (CPU1) Interrupt (IRQ1). You can generate more than one interrupt by writing 1 to multiple bits of this register.

Diagram

Fields

Field	Function
31-0 INTREQSET	Interrupt Request Set 1 Generates interrupt requests for CoolFlux (CPU1).

22.5.1.7 CoolFlux (CPU1) Interrupt Clear (IRQ1CLR)

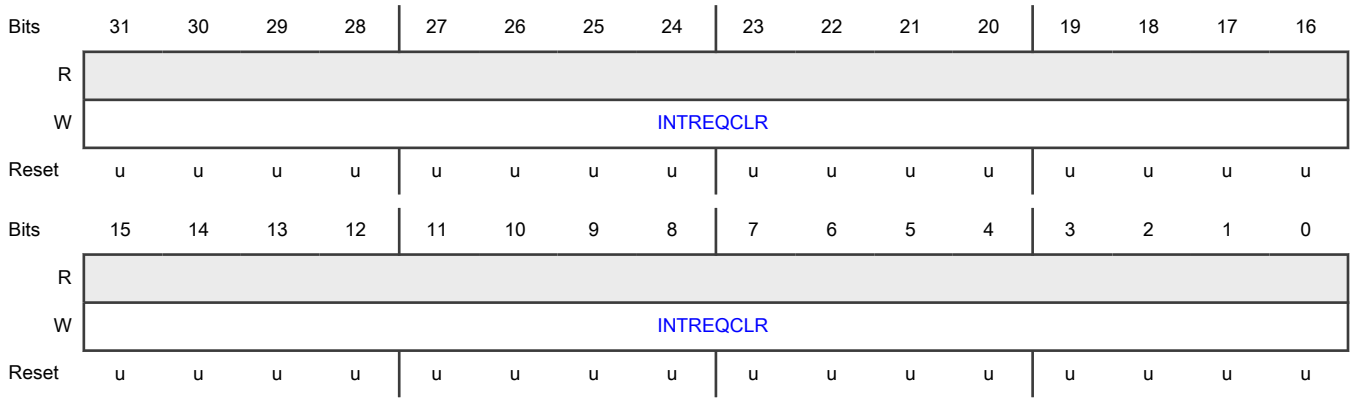
Offset

Register	Offset
IRQ1CLR	18h

Function

Clears interrupts for CoolFlux (CPU1) after the requested service or operation is complete. Writing 1 to any bit of this register writes 0 to the corresponding bit of CoolFlux (CPU1) Interrupt (IRQ1).

Diagram



Fields

Field	Function
31-0 INTREQCLR	Interrupt Request Clear 1 Clears interrupt requests for CoolFlux (CPU1).

22.5.1.8 Mutual Exclusion (MUTEX)

Offset

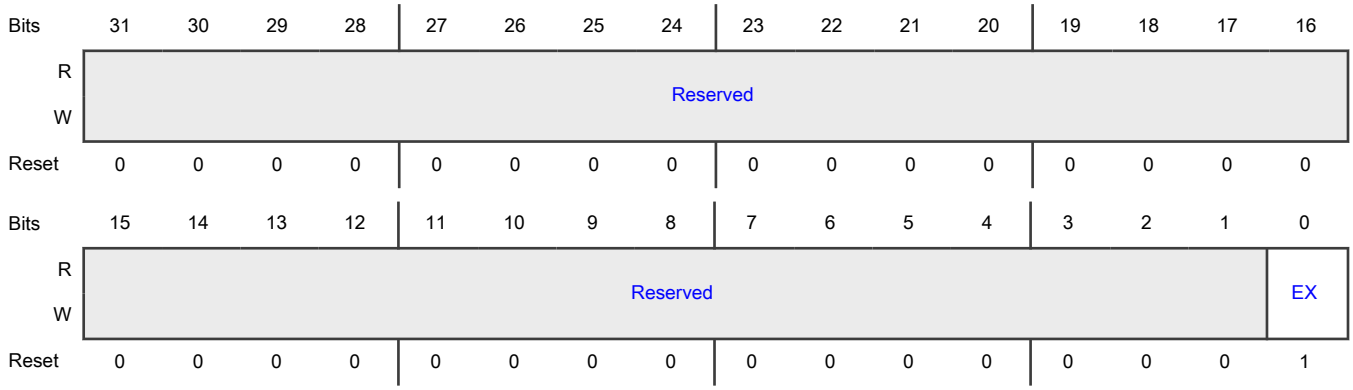
Register	Offset
MUTEX	F8h

Function

Provides an inter-processor communication handshake.

This register provides a resource allocation handshake between two CPUs. To access a shared resource (possibly a resource allocation table in memory), a CPU reads this register. If the CPU reads 1, it has control over the shared resource allocation. After making the required changes, the CPU writes to the register. As a result, MUTEX[EX] becomes 1 again, making the shared resource allocation available to another CPU. If the CPU reads 0, it must wait for MUTEX[EX] to become 1 before accessing the shared resource allocation information.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 EX	Mutual Exclusion Request Provides resource allocation handshake between two CPUs. This field indicates the availability of a shared resource. When read for any reason, the field returns the current value and becomes 0. The field becomes 1 again following any write. 0b - Resource unavailable 1b - Resource available

23.1.1 Module instances

This device has two 16 channel eDMA controllers.

23.1.2 Direct Memory Access Multiplexer (DMAMUX)

The peripheral request line for each channel of the Direct Memory Access Controller (DMA) is driven from a Direct Memory Access Multiplexer (DMAMUX). This is a flexible configuration that allows the user to select the appropriate peripheral to connect to each channel of the DMA Controller. The DMAMUX for this device allows up to 128 DMA request signals (6 unused signals are reserved) to be mapped to each channel. Because of the mux, there is not a correlation between any of the DMA request sources and a specific DMA channel.

The DMAMUX is an integrated component of the DMA Controller. This allows each DMA channel and DMA Multiplexer to configured as secure or non-secure on initial configuration of the device and not be changed without the correct permissions.

23.1.3 DSPI

DSPI is external to the DMA and is only referred as an example of DMA hardware request usage.

23.1.4 Security considerations

When TrustZone-M is used, the following configurations are recommended for eDMA usage:

- Use strict checking (AHBSC.MISC_CTRL_REG[DISABLE_STRICT] = 01b). Strict mode enabled is also the default configuration.
- Configure both eDMAs for secure and privileged level in the AHBSC's MASTER_SEC_LEVEL and MASTER_SEC_ANTI_POL_REG registers (**note**: this is not the default setting).
- Enable the eDMA master ID replication feature for all DMA channels. The master ID replication feature is enabled globally by setting MP_CSR[GMRC], and then is enabled on a per channel basis by setting CHn_SBR[EMI].
- AHBSC peripheral slots and CHn_SBR[PAL, SEC] for each DMA channel need to be preconfigured for secure/non-secure and privileged/non-privileged based on the intended usage of each channel. This allows masters of each type to configure allocated channels. Unused DMA channels should be configured for secure and privileged access to prevent misuse.

When the settings above are followed, the master ID is captured when the TCDn_CSR is written according to the configuration of the master that wrote TCDn_CSR. The final DMA channel access security level can be downgraded from secure to non-secure depending on the source and destination addresses. See the "Master Security Wrapper (MSW)" section of the device Security Reference Manual.

NOTE

DMA scatter/gather operations must use an address matching the configuration of the DMA channel. Secure channels must access a secure memory address to load new TCDs. Non-secure channels must access a non-secure memory address to load new TCDs.

23.2 Overview

The enhanced direct memory access (eDMA) controller is capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 16 channels

23.2.1 Block diagram

Figure 104 illustrates the components of the eDMA system, including the eDMA module (engine).

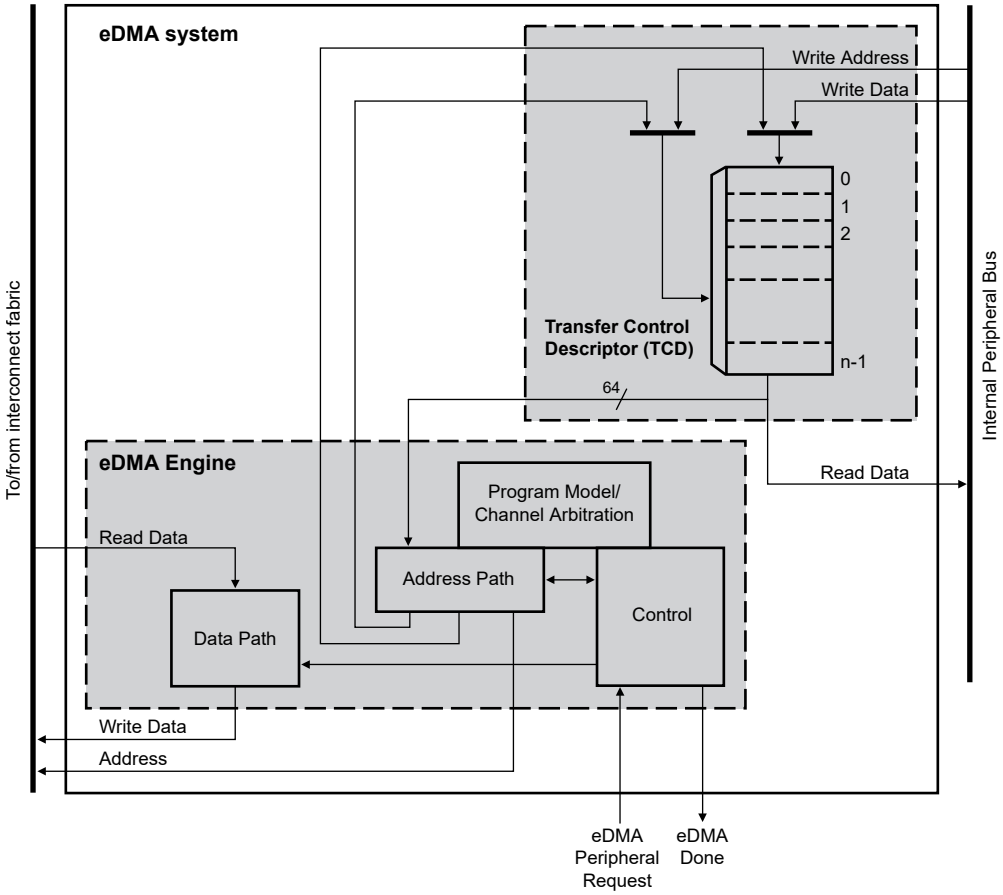

Figure 104. Block diagram

23.2.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 293. eDMA engine submodules

Submodule	Function
Address path	This block: • Implements a primary channel and secondary (preempt) channel • Manages all master bus-address calculations All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the primary channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by CH*n*_PRI[ECP]) where a large data transfer can be preempted to minimize the time another channel is blocked from execution. When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of a new TCD*n* from memory as part of a scatter/gather operation. See Dynamic scatter/gather for more details.
Data path	This block implements the bus master read/write data path. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), and the data path module implements the second stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has been moved from the source to the destination. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, the eDMA performs two reads, then one 32-bit write.

The transfer control descriptor local memory is further partitioned into:

Table 294. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, and manages accesses from the eDMA engine as well as references from the internal peripheral bus. In simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

23.2.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and is not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for complex address calculations
- 16-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage for all transfers
  - Connections to the crossbar switch for bus mastering the data movement
- TCD organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel that are logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module, *n* is used to reference the channel number.

23.3 Functional description

The operation of eDMA is described in the following subsections.

23.3.1 Modes of operation

The eDMA operates in the following modes:

Table 295. Modes of operation

Mode	Description
Normal	In Normal mode, eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the TCD. The minor loop is the sequence of read-write operations that transfers these NBYTES per service

Table continues on the next page...

Table 295. Modes of operation (continued)

Mode	Description
	request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	eDMA operation is configurable in Debug mode via the control register: • If CSR[EDBG] is cleared to 0, eDMA continues to operate. • If CSR[EDBG] is set to 1, eDMA stops transferring data. If Debug mode is entered when a channel is active, eDMA continues operation until the channel retires.

23.3.2 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

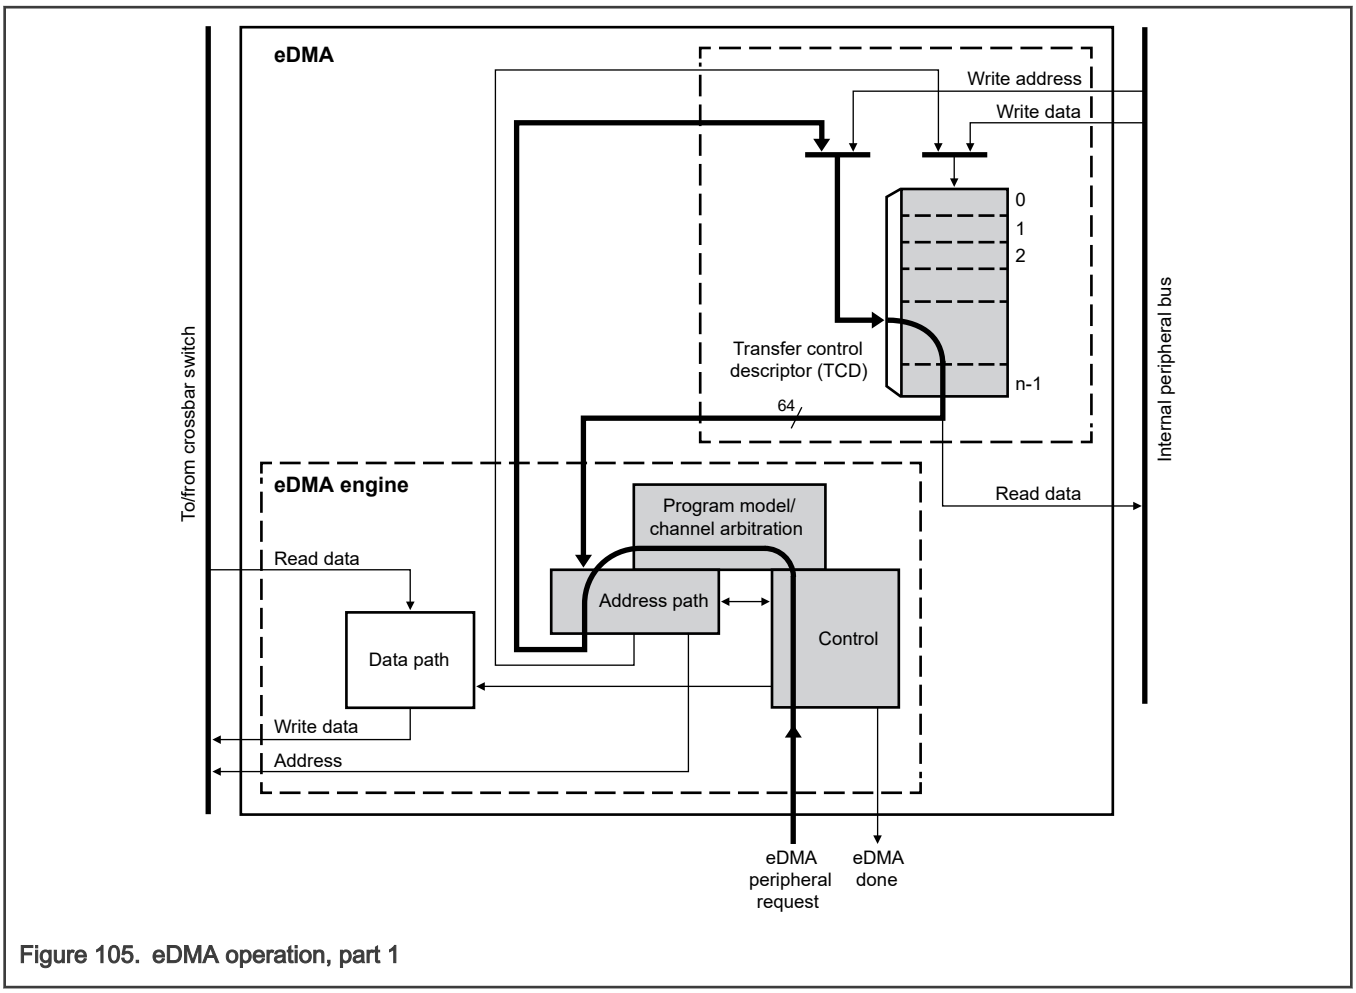

Figure 105. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] field follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration.

In the next cycle, the channel arbitration begins using fixed-priority plus the optional round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the

local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor is read from the local memory and then loaded into the eDMA engine address path's primary or secondary channel execution registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path registers.

The following diagram illustrates the second part of the basic data flow:

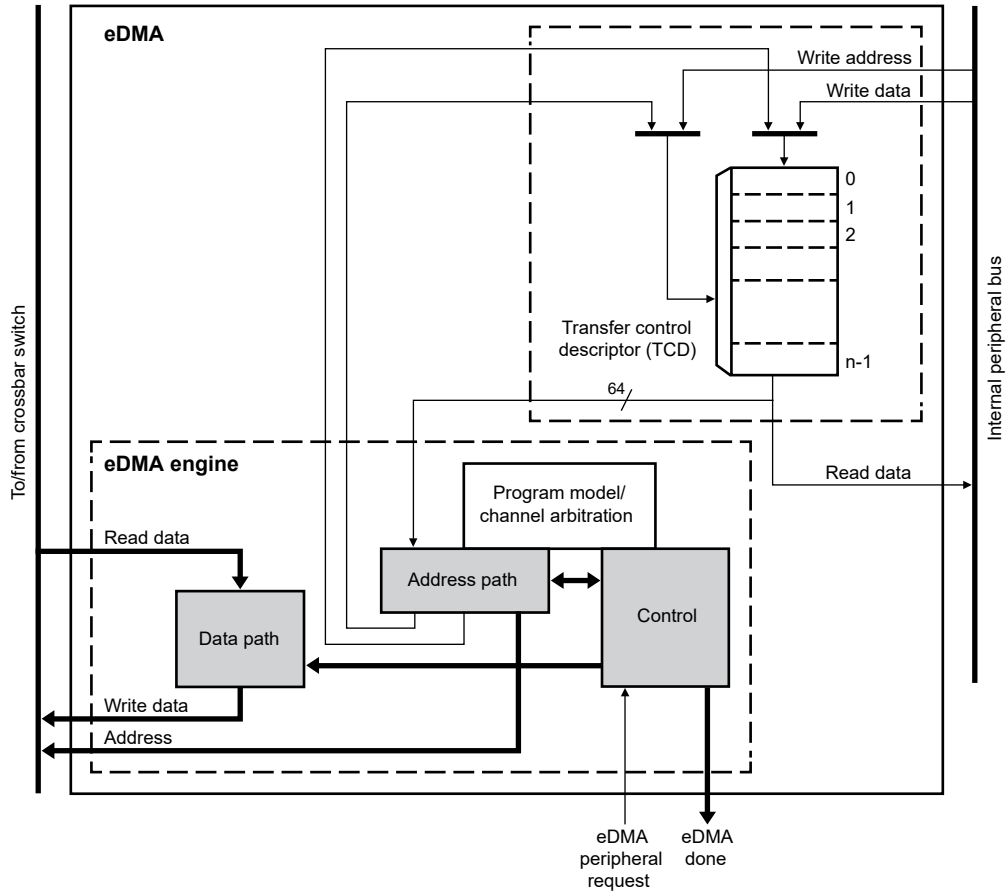

Figure 106. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) go through the required sequence of source reads and destination writes to perform the actual data movement. The source reads are initiated, and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the byte count, NBYTES, has been transferred.

After NBYTES of data has been moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD (for example, SADDR, DADDR, CITER). If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER field. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

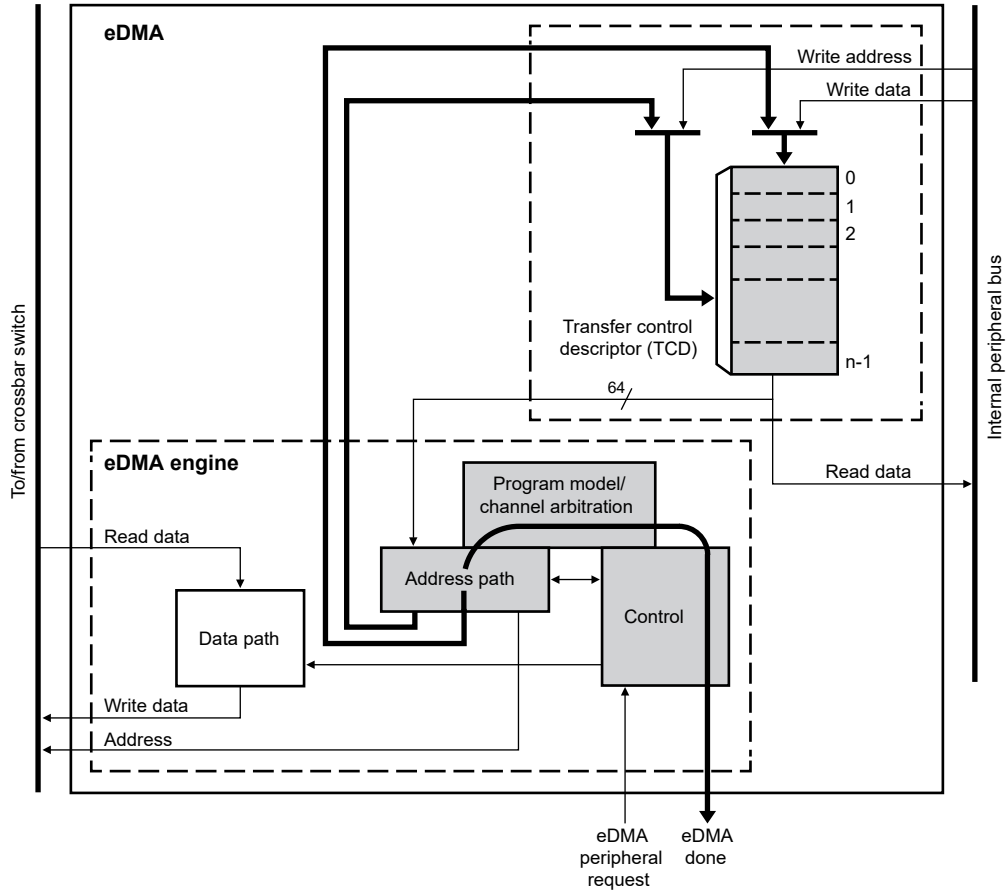

Figure 107. eDMA operation, part 3

23.3.3 Fault reporting and handling

Channel errors are reported in the Error Status register (CHn_ES) and can be caused by any of the following:

- A configuration error, which is an illegal setting in the transfer control descriptor
- An active channel canceled via a "cancel transfer with error" hardware or software request
- An error termination to a bus master read or write cycle

A configuration error is reported when an inconsistent state is represented by one of these factors:

- Starting source or destination address
- Source or destination offsets
- Minor loop byte count
- Transfer size

Each of these possible causes is detailed below:

- The addresses and offsets must be aligned on zero-modulo-transfer-sized boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size.

NOTE

To aid in debugging, set the Halt After Error field in the DMA's Control Status register, CSR[HAE]. Upon any error condition, the DMA is halted after the error is recorded. The DMA remains halted and does not process any channel service requests. After the error is fixed, the DMA may be enabled again by clearing the Halt field, CSR[HALT].

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (TCDn_DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[ELINK] field does not equal the TCDn_BITER[ELINK] field.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, are reported as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion if properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel field in the eDMA error register is set to 1. At the same time, the details of the error condition are loaded into the Error Status register (CHn_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag, and the possible assertion of an interrupt request are not affected when an error is detected.

After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

The error status fields are read-only. These error indicators are sticky and cannot be cleared. They show the last recorded error until the DMA is reset. CHn_ES[ERR] is used to determine if a new error condition exists. This field is the logical OR of each channel's error interrupt field (ERR).

After the software has resolved all errors and cleared all of the error interrupt fields, the MP_ES[VLD] is cleared to 0 but the cause of the last error is still indicated.

23.3.4 Channel preemption

The eDMA uses a priority vector value to determine the highest priority channel requesting service.

The priority vector is a combination of:

1. the channel's group priority, CHn_GRPRI
2. the channel's priority level, CHn_PRI[APL]

It can be considered a number composed of these concatenated priority levels: CHn_GRPRI : CHn_PRI[APL]

Priority vector = ((CHn_GRPRI << 8) + (CHn_PRI[APL] << 5) + CHn_*)

A channel requesting service with the highest priority vector value will receive the next execution slot.

An execution slot is available:

1. immediately if the eDMA is idle
2. when an active channel retires
3. when valid preemption conditions exist

NOTE

Preemption is strictly priority based. Preemption is not bound by a specific group number as defined by CHn_GRPRI.

Channel preemption is enabled on a per-channel basis by setting the CHn_PRI[ECP] field. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher-priority channel. After the preempting channel has completed all of its minor loop data transfers, the preempted channel is restored and resumes execution.

After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended, and the higher-priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted.

A channel's ability to preempt another channel can be disabled by setting CHn_PRI[DPA] to 1. When a channel's preempt ability is disabled, that channel cannot suspend a lower-priority channel's data transfer, regardless of the lower-priority channel's ECP setting. This allows for a pool of low-priority, large-data-moving channels to be defined.

You can configure these low-priority channels to not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true high-priority channel. When you enable round-robin channel arbitration mode (CSR[ERCA] is set to 1), any channel with a priority level equal to 0 (CHn_PRI[APL] = 0) has preemption disabled and cannot preempt another channel.

23.3.5 Clocking

This module has no clocking considerations.

23.3.6 Interrupts

Software can enable the interrupt for each channel for the following events:

1. The major loop is half complete (INTHALF)
2. The major loop is complete (INTMAJOR)
3. A configuration error occurs (EEI)

23.4 External signals

This module has no external signals.

23.5 Initialization

The following sections discuss initialization of the eDMA and programming considerations.

23.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the MP_CSR if a configuration other than the default is wanted.
2. Write the channel priority levels to the CHn_PRI registers and group priority levels to the CHn_GRPRI registers if a configuration other than the default is wanted.
3. Enable error interrupts in the CHn_CSR[EEI] registers if they are wanted.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the CHn_CSR[ERQ] registers.
6. Request channel service via either:
   - Software: setting TCDn_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in Table 296, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, defined by TCDn_SADDR, to the destination, defined by TCD_DADDR, continue until the number of bytes specified by TCDn_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCDn_SADDR, TCDn_DADDR, and TCDn_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, then eDMA executes further post-processing, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 296. TCD control and status (TCDn_CSR) fields

TCDn_CSR field name	Description
START	Control field to start the channel explicitly when using a software-initiated DMA service (automatically cleared by hardware)
EEOP	Control field to enable end-of-packet processing
ESDA	Control field to enable storing of the destination address to system memory after the major loop completes
DREQ	Control field to disable hardware-initiated DMA service requests after major loop completion
BWC	Control field for throttling the bandwidth control of a channel
ESG	Control field to enable the scatter-gather feature
INTHALF	Control field to enable interrupt when major loop is half-complete
INTMAJOR	Control field to enable interrupt when major loop completes

Table 297. Channel control and status (CHn_CSR) fields

CHn_CSR field name	Description
ACTIVE	Status field indicating the channel is currently in execution
DONE	Status field indicating major loop completion (cleared by software when a channel begins execution)
EEI	Control field to enable error interrupts
EARQ	Control field to enable external, asynchronous wakeup event in conjunction with the ERQ field
ERQ	Control field to enable hardware service requests

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

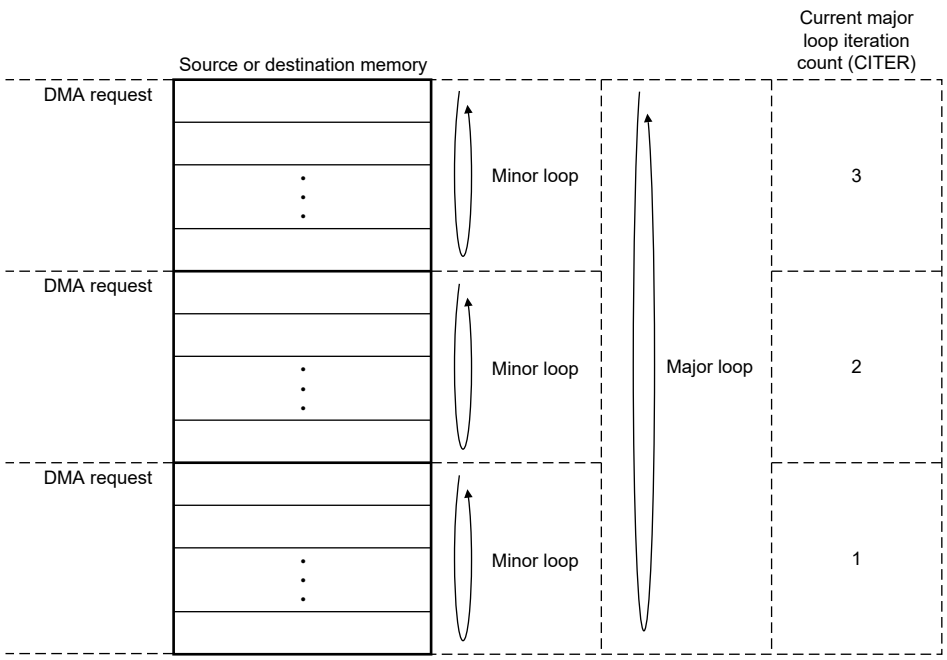

Figure 108. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings are related.

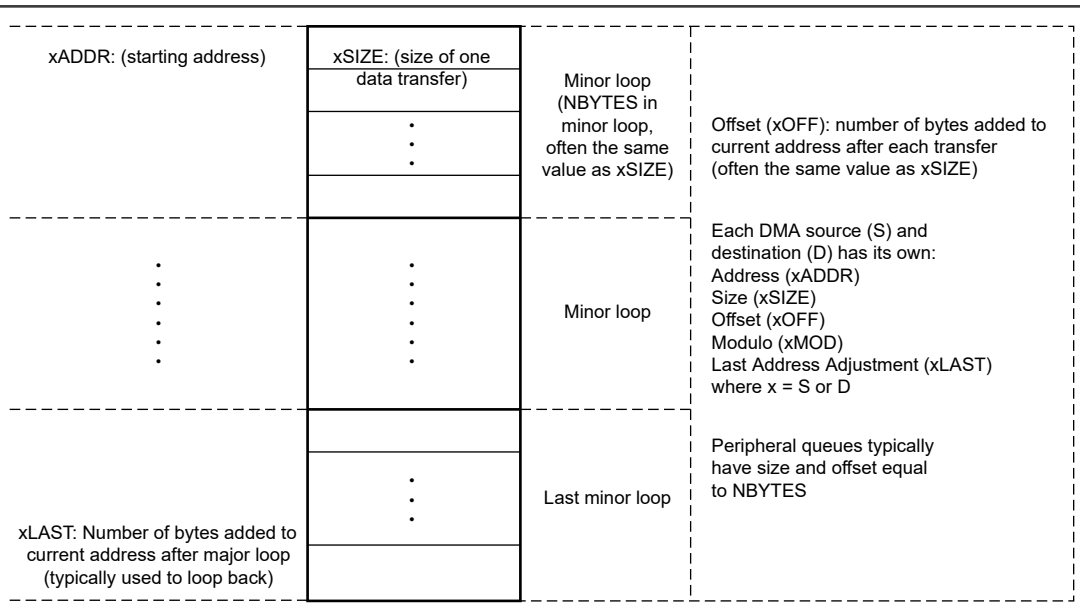

Figure 109. Memory array terms

23.5.2 eDMA arbitration

The eDMA uses a layered arbitration scheme composed of multiple priority levels. The eDMA uses a fixed-priority arbitration scheme with optional round-robin arbitration under specific conditions. The priorities are evaluated in the following order:

Table 298. eDMA arbitration priorities

Priority	Scheme	Description
1 (Highest)	Arbitration group priority	Each channel is assigned an arbitration group via the CHn_GRPRI registers. Priority is given to the highest value (31 being the highest possible value) down to the lowest value (zero, the default).
2	Channel priority	Each channel is assigned a channel priority level via the CHn_PRI registers. The channel priority is a relative priority level within an arbitration group. Priority is given to the highest value (seven being the highest possible value) down to the lowest value (zero, the default). Channel priorities within each arbitration group need not be unique. If multiple channels have the same channel priority level, the channel number will be used to determine priority as defined in row three.
3	Channel number	When two or more channels have the same arbitration group priority and channel priority, the channel number (CHn_NUM) is used to determine the highest priority. Priority is given to the highest channel number. Lowest priority is channel 0. The channel numbers are static and cannot be changed in the programmer's model.
4 (Lowest)	Round-robin	When round-robin is enabled, any channel configured for round-robin operation has lowest priority within an arbitration group. Round-robin is enabled by setting the MP_CSR[ERCA] field to 1. After being enabled, channels with a channel priority of zero (CHn_PRI=0) will use round-robin arbitration. Round-robin arbitration will rotate the channel selection among the channels requesting service with CHn_PRI=0 within the arbitration group. Any non-zero channel within the arbitration group will continue to use fixed-priority arbitration, and if requesting service will be selected over any round-robin channels.

For fixed arbitration, the overall priority can be considered a number composed of three concatenated priority levels: CHn_GRPRI:CHn_PRI:CH_NUM. The largest number has the highest priority and the lowest number has the lowest priority.

For round-robin arbitration, the priority number is CHn_GRPRI:0:X. The module rotates through the CHn_PRI=0 channels requesting service without regard to priority among these channels. Any channel within the arbitration group for which CHn_PRI is greater than 0 will be serviced before the round-robin channels.

23.5.3 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data.

The channel number causing the error is recorded in the Error Status register (CHn_ES). If the error source is not removed before the next activation of the problematic channel, the error is detected and recorded again. Setting the halt after error field, CSR[HAE], will halt the DMA and prevent recurrence of the error.

23.5.4 Arbitration mode considerations

This section discusses arbitration considerations for eDMA.

23.5.4.1 Fixed group arbitration, fixed channel arbitration

In this mode, eDMA selects for execution the channel service request from the highest-priority channel in the highest-priority group. If eDMA is programmed so that the channels within a high-priority group have a high number of requests or large data transfers, that group may consume all the bandwidth of the eDMA controller. That is, no lower-priority groups are serviced if there is always at least one DMA request pending on a channel in the highest-priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly.

23.5.4.2 Fixed group arbitration, round-robin channel arbitration

The highest-priority group with a request is serviced. Lower-priority groups are serviced if no pending requests exist in the higher-priority groups.

Within each group, channels are serviced starting with the highest non-zero channel priority. For all channels with a channel priority programmed to 0, selection begins with the highest channel number requesting service and then rotates through to the lowest channel number requesting service. The round-robin channel arbitration can provide a fairness mechanism to lower-priority channels.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, fixed channel arbitration, but all the channels in the highest-priority group will be serviced. Service latency is short on the highest-priority group, but could potentially be very much longer as the group priority decreases.

23.5.5 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

23.5.5.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the CH*n*_CSR[DONE] field is set to 1 and an interrupt is generated if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte-wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source, and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
```

```
TCDn_DLAST_SGA= -16
TCDn_CSR[INTMAJ] = 1
TCDn_CSR[START] = 1 (should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] field requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes:
   - CH*n*_CSR[DONE] = 0
   - TCD*n*_CSR[START] = 0
   - CH*n*_CSR[ACTIVE] = 1
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

23.5.5.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop, transferring 16 bytes per iteration. After the channel's hardware requests are enabled via the CHn_CSR[ERQ] register field, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:

a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
h. Write 32 bits to location 0x200C → last iteration of the minor loop.

6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0.
8. The channel retires, which concludes one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware (eDMA peripheral) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: Channel TCD data from local memory to internal register file.
13. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
    b. Write 32 bits to location 0x2010 → first iteration of the minor loop.
    c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
    d. Write 32 bits to location 0x2014 → second iteration of the minor loop.
    e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
    f. Write 32 bits to location 0x2018 → third iteration of the minor loop.
    g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
    h. Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).
15. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
16. The channel retires, which concludes with the major loop complete. The eDMA goes idle or services the next channel.

23.5.5.3 Using the modulo feature

The modulo feature of the eDMA allows implementation of a circular data queue in which the size of the queue is a power of 2. xMOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature. Modulo addressing applies to cases where the minor loop offset is enabled; that is, the upper address bits remain the same after the minor loop offset is added to the source or destination address.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value but the 28 upper address bits (0x1234567*x*) retain their original value. In this example, the source address is set to 0x12345670, the offset is set to four bytes, and the MOD field is set to four, which allows for a 2^4 byte (16 byte) queue size.

Table 299. Modulo example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

23.5.6 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

23.5.6.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software-initiated service requests.

1. The first method is to read the TCDn_CITER field and test for a change.
2. The second method, extracted from the sequence shown below, is to test the TCDn_CSR[START] field and the CHn_CSR[ACTIVE] field. The minor-loop-complete condition is indicated by both fields reading 0 after TCDn_CSR[START] is set to 1. Polling the CHn_CSR[ACTIVE] field only may be inconclusive because the active status may be missed if the channel execution is short in duration.

The CHn_CSR and TCDn_CSR status fields execute the following sequence for a software-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	1	0	0	Initiate channel service request via software.
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

The best method to test for minor-loop completion when using hardware-initiated (that is, peripheral-initiated) service requests is to read the TCDn_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status fields execute the following sequence for a hardware-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	0	0	0	Initiate channel service request via hardware (peripheral request asserted).
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

For both activation types, the major-loop-complete status is explicitly indicated via the CHn_CSR[DONE] field.

The TCDn_CSR[START] field is cleared to 0 automatically when the channel begins execution, regardless of how the channel activates.

23.5.6.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCDn_SADDR, TCDn_DADDR, and TCDn_NBYTES values if they are read when a channel executes. The true values of SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file, and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES (which decrements to zero as the transfer progresses), can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

23.5.6.3 Checking channel preemption status

A preemptive situation is one in which a preempt-enabled channel is executing and a higher-priority request becomes active. When round-robin channel arbitration mode is enabled, all channels with their channel priority set to 0 lose their preempt ability. Channel priorities of 0 are treated as equal, that is, they are constantly rotating, when round-robin arbitration mode is enabled.

The CHn_CSR[ACTIVE] field for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended when the preempting channel executes one major loop iteration. If two CHn_CSR[ACTIVE] fields are set simultaneously in the global TCD map, a higher-priority channel is actively preempting a lower-priority channel.

23.5.7 Channel linking

Channel linking (or chaining) is a mechanism in which one channel sets the TCDn_CSR[START] field of another channel (or itself), thus initiating a service request for that channel. When properly enabled, the eDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCDn_CITER[ELINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, using an initial field setting of:

```
MP_CSR[GCLC] = 1
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJORELINK] = 1
TCDn_CSR[MAJORLINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] field
2. Minor loop done → set TCD12_CSR[START] field
3. Minor loop done → set TCD12_CSR[START] field
4. Minor loop done, major loop done→ set TCD7_CSR[START] field

When minor loop linking is enabled (TCDn_CITER[ELINK] = 1), the TCDn_CITER[CITER] field uses a nine-bit vector to form the current iteration count. When minor loop linking is disabled (TCDn_CITER[ELINK] = 0), the TCDn_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCDn_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

NOTE

The TCDn_CITER[ELINK] field and the TCDn_BITER[ELINK] field must be equal — if they are not, a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop halfway done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, that is, use another channel's TCD, at the end of a loop.

Table 300. Channel linking parameters

Wanted link behavior	TCD control field name	Description
Link at end of minor loop	TCDn_CITER[ELINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	TCDn_CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of major loop	TCDn_CSR[MAJORELINK]	Enable channel-to-channel linking on major loop completion
	TCDn_CSR[MAJORLINKCH]	Link channel number when linking at end of major loop

23.5.8 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

23.5.8.1 Dynamically changing the channel priority

To change group or channel priority levels:

1. Halt the DMA by writing 1 to the CSR[HALT] field.
2. Change the group or channel priorities as wanted.
3. Enable normal DMA operations by writing 0 to the CSR[HALT] field.

23.5.8.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCDn_CSR[MAJORELINK] field during channel execution (see the diagram in TCD structure). This field is read from the TCD local memory at the end of channel execution, thus allowing you to enable the feature during channel execution.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic channel link by enabling the TCDn_CSR[MAJORELINK] field at the same time the eDMA engine is retiring the channel. TCDn_CSR[MAJORELINK] would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

We recommend that you use the following coherency model when executing a dynamic channel link request.

1. Write 1 to the TCDn_CSR[MAJORELINK] field.
2. Read back the TCDn_CSR[MAJORELINK] field.
3. Test the TCDn_CSR[MAJORELINK] request status:
   - If TCDn_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
   - If TCDn_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCDn_CSR[MAJORELINK] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field is set to 1, indicating the major loop is complete.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing to the TCDn_CSR[MAJORELINK] field. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution.

23.5.8.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in the eDMA programmer's model, thus replacing the current descriptor.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic scatter/gather operation by enabling the TCDn_CSR[ESG] field at the same time the eDMA engine is retiring the channel. The TCDn_CSR[ESG] field would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods are recommended for executing a dynamic scatter/gather request. Whenever the TCDn_CSR is written, the TCD local memory controller forces the TCDn_CSR[ESG] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field has been set to 1, indicating the major loop is complete. If attempting to set the ESG, ensure the DONE field is cleared to 0.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing the TCDn_CSR[MAJORELINK] or TCDn_CSR[ESG] fields. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution and is set to 1 upon major loop completion.

23.5.8.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCDn_CSR[MAJORELINK] field is 0, the TCDn_CSR[MAJORLINKCH] field is not used by the eDMA. In this case, the TCDn_CSR[MAJORLINKCH] bits may be used for other purposes. This method uses the TCDn_CSR[MAJORLINKCH] field as a TCDn_CSR identification (ID).

When the descriptors are built, write a unique TCDn_CSR ID in the TCDn_CSR[MAJORLINKCH] field for each TCDn_CSR associated with a channel using dynamic scatter/gather.

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the TCDn_CSR[DREQ] field to 1 will prevent future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the 16-bit TCDn_CSR control/status field.
5. Test the TCDn_CSR[ESG] request status and TCDn_CSR[MAJORLINKCH] value:

- If ESG = 1, the dynamic scatter/gather attempt was successful.
- If ESG = 0 and the MAJORLINKCH (ID) did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
- If ESG = 0 and the MAJORLINKCH (ID) changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

23.5.8.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCDn_DLAST_SGA field as a TCD identification (ID).

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the DREQ field to 1 will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the TCDn_CSR[ESG] field.
5. Test the TCDn_CSR[ESG] request status:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0, read the 32-bit TCDn_DLAST_SGA field.
   - If ESG = 0 and the TCDn_DLAST_SGA did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the TCDn_DLAST_SGA changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

23.5.9 Suspend/resume a DMA channel with active hardware service requests

The DMA allows you to move data from memory or peripheral registers to another location in memory or to peripheral registers without CPU interaction. After the DMA and peripherals are configured and active, it is rare but supported to suspend a peripheral's service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For coherency, you must follow a specific procedure. This section provides guidance on how to coherently suspend and resume a Direct Memory Access (DMA) channel when the DMA is triggered by a slave module such as the Serial Peripheral Interface (DSPI), Sigma Delta Analog to Digital Convertor (SDADC), or other module.

23.5.9.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check the DMA's Hardware Request Status (MP_HRS) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ field to 0 on the appropriate DMA channel.

For example, assume the DSPI is set as a master for transmitting data via a DMA service request when the TXFIFO has an empty slot. The DMA will transfer the next command and data to the TXFIFO upon the request. If you need to suspend the DMA/DSPI transfer loop, perform the following steps:

1. Disable the DMA service request at the source by writing 0 to DSPI_RSER[TFFF_RE]. Confirm that DSPI_RSER[TFFF_RE] is 0.
2. Ensure there is no DMA service request from the DSPI by verifying that MP_HRS[HRS] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ field to 0. If a service request is present, wait until the request has been processed and the HRS field reads 0.

23.5.9.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting its ERQ field to 1.
2. Enable the DMA service request at the peripheral.

23.6 Memory map/register definition

The eDMA programming model is partitioned into three parts:

1. The first part defines a number of registers providing overall control functions and is known as the management page.
2. The second part corresponds to the channel (CH) control, status, and configuration.
3. The third part corresponds to the local TCD memory.

TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the data movement operation. Each TCDn definition is presented as 11 registers of 16 or 32 bits. See DMA TCD register descriptions for details.

TCD initialization

Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

TCD structure

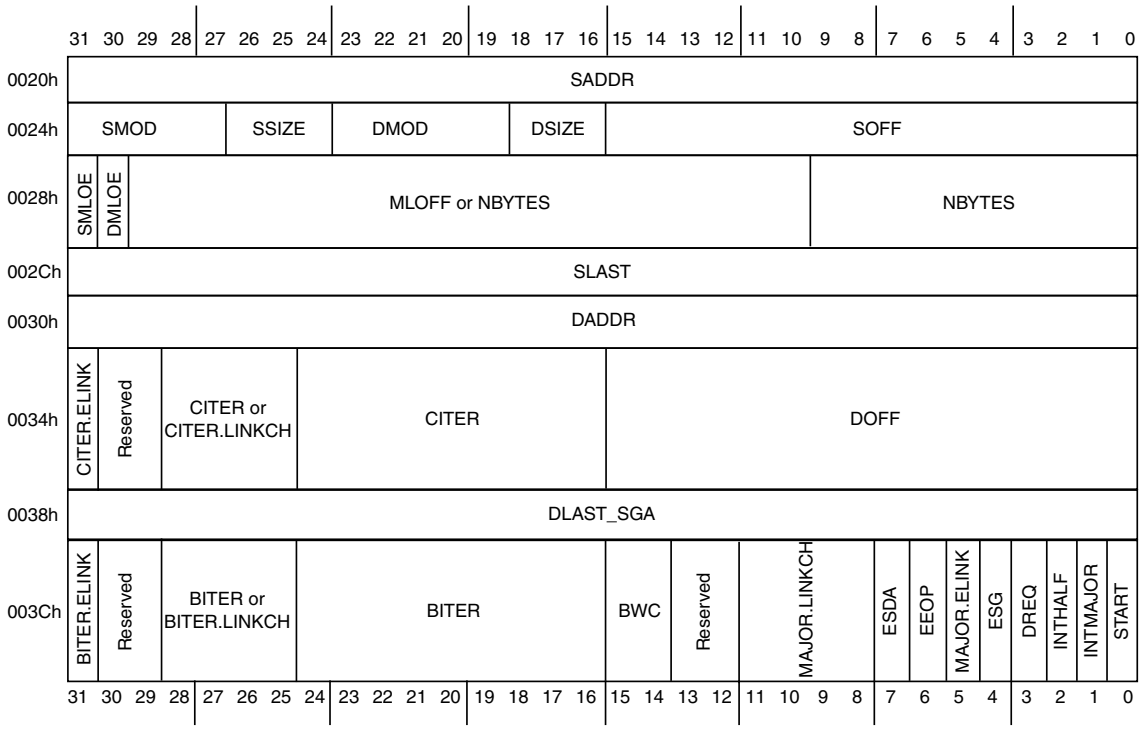

Figure 110. TCD structure

Accesses to reserved memory and fields

- Reading reserved fields in a register returns the value of zero.
- Writes to reserved fields in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

23.6.1 DMA MP register descriptions

23.6.1.1 MP memory map

eDMA_0_MP base address: 4008_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Management Page Control (MP_CSR)	32	RW	0031_0000h
4h	Management Page Error Status (MP_ES)	32	R	0000_0000h

Ch	Management Page Hardware Request Status (MP_HRS)	32	R	0000_0000h
100h - 13Ch	Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI)	32	RW	0000_0000h

23.6.1.2 Management Page Control (MP_CSR)

Offset

Register	Offset
MP_CSR	0h

Function

The Management Page Control register defines the basic operating configuration of the DMA.

Arbitration uses a two-tier priority system; group and channel priority. The eDMA assigns each channel to a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed priority and may be configured to use a selective round-robin scheme for specified channels within each priority group. For fixed-priority arbitration, eDMA selects for execution the highest priority channel requesting service in the highest priority arbitration group.

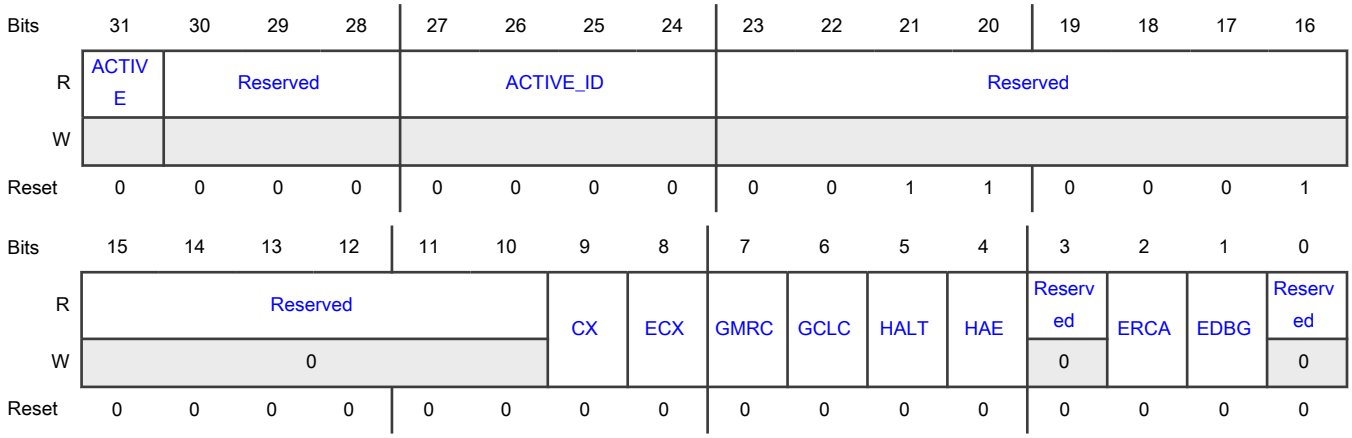
The channel priority registers assign the relative priorities within each arbitration group; see CHn_PRI. All channels with a non-zero CHn_PRI value use fixed-priority arbitration.

When you enable round-robin arbitration, all channels with channel priority set to zero do not have a priority and, of those channels requesting service, are cycled through (from high to low channel number) without regard to priority relative to each other within the same priority group. Any channel with a non-zero CHn_PRI value automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI).

NOTE

For correct operation, changes to the MP_CSR[ERCA, GCLC, GMRC] fields must be performed when the DMA channels are inactive; that is, when the MP_CSR[ACTIVE] field is 0.

Diagram



Fields

Field	Function
31 ACTIVE	DMA Active Status 0b - eDMA is idle 1b - eDMA is executing a channel
30-28 —	Reserved
27-24 ACTIVE_ID	Active Channel ID This field identifies the channel number that is executing when the ACTIVE bit is 1.
23-16 —	Reserved
15-10 —	Reserved
9 CX	Cancel Transfer When set to 1, this field cancels the remaining data transfer, stops the executing channel, and forces the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. CX clears itself to 0 after the cancel has been honored. This cancel retires the channel normally as if the minor loop had been completed. 0b - Normal operation 1b - Cancel the remaining data transfer
8 ECX	Cancel Transfer With Error Cancellation of the remaining data transfer is similar to that of the CX field. Execution of the channel is stopped and the minor loop is forced to finish. The cancellation takes effect after the last write of the current read/write sequence. The ECX field clears itself to 0 after the cancel is honored. In addition to

0 —	Reserved

23.6.1.3 Management Page Error Status (MP_ES)

Offset

Register	Offset
MP_ES	4h

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus master read or write cycle
- An uncorrectable error that occurred when the device was accessing the TCD SRAM
- A "cancel transfer with error" request was made via the corresponding cancel transfer field or input signal

Upon any error condition, the software must initialize the TCD of the channel that contains the error, as it is in an incomplete state after an error. See Fault reporting and handling for more details.

30-28 —	Reserved
27-24 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error or last recorded error-canceled transfer.
23-9 —	Reserved
8 ECX	Transfer Canceled The ECX operation is a management page function. When employed, the targeted channel's CHn_ES register reports an unspecified error; that is, only the CHn_ES[ERR] field is set to 1. The management page has full view of the error condition. 0b - No canceled transfers 1b - Last recorded entry was a canceled transfer by the error cancel transfer input
7 SAE	Source Address Error When this field is 1, it indicates that TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error When this field is 1, it indicates that TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error When this field is 1, it indicates that TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error When this field is 1, it indicates that TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3	NBYTES/CITER Configuration Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
NCE	This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - The last recorded error was NBYTES equal to zero or a CITER not equal to BITER error. Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was a bus error on a source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was a bus error on a destination write

23.6.1.4 Management Page Interrupt Request Status (MP_INT)

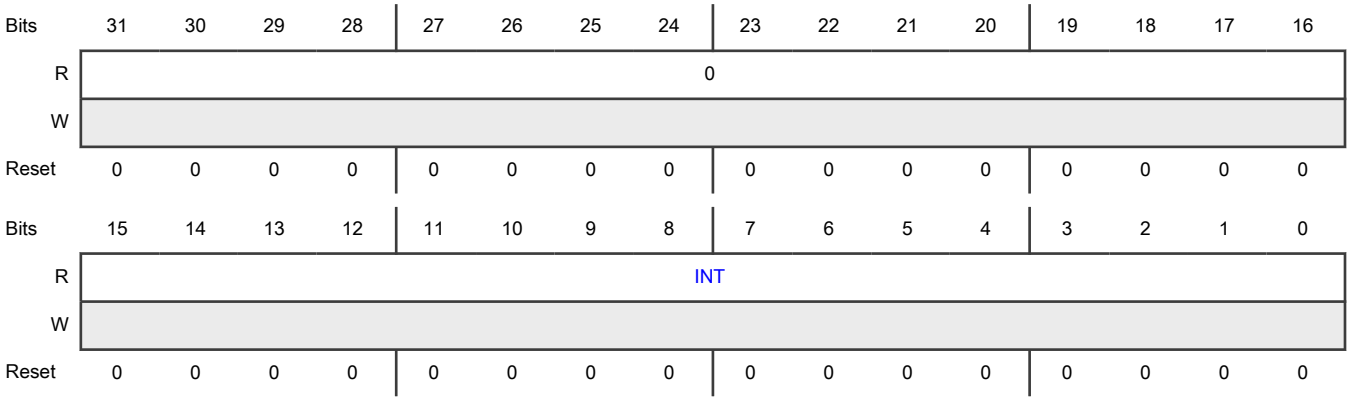
Offset

Register	Offset
MP_INT	8h

Function

This register shows the current state of the interrupt service requests for all eDMA channels.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 INT	Interrupt Request Status The INT register presents the interrupt request status for each eDMA channel. Depending on the appropriate field setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion or an error condition. The eDMA routes channel interrupt requests to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate field in the channel’s interrupt request register, CHn_INT, thus negating the interrupt request. 0b - Interrupt request for corresponding channel not present 1b - Interrupt request for corresponding channel present

23.6.1.5 Management Page Hardware Request Status (MP_HRS)

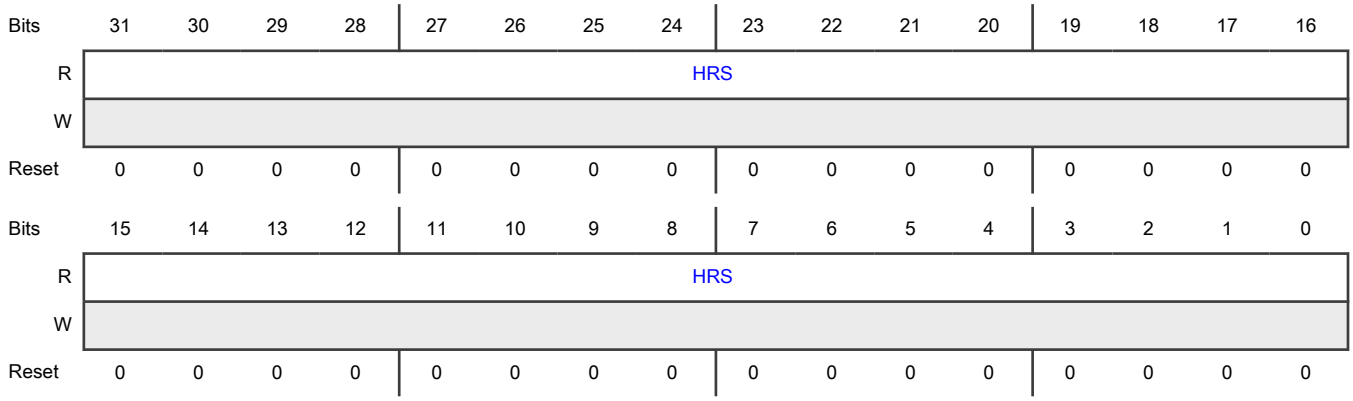
Offset

Register	Offset
MP_HRS	Ch

Function

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by eDMA's arbitration logic.

Diagram



Fields

Field	Function
31-0 HRS	Hardware Request Status The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel. 0b - Hardware service request for corresponding channel is not present 1b - Hardware service request for corresponding channel is present

23.6.1.6 Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI)

Offset

For n = 0 to 15:

Register	Offset
CHn_GRPRI	100h + (n × 4h)

Function

The contents of this register define the arbitration group associated with each channel. Using a fixed-priority group arbitration scheme, eDMA evaluates the arbitration group priorities by numeric value from highest group number to lowest; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. The range of the group priority values is limited to the values of 0 through 31. Within each arbitration group, the channel priority assignment CH*n*_PRI determines the highest-priority channel.

Diagram

23.6.2.2 Management Page Control (MP_CSR)

Offset

Register	Offset
MP_CSR	0h

Function

The Management Page Control register defines the basic operating configuration of the DMA.

Arbitration uses a two-tier priority system; group and channel priority. The eDMA assigns each channel to a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed priority and may be configured to use a selective round-robin scheme for specified channels within each priority group. For fixed-priority arbitration, eDMA selects for execution the highest priority channel requesting service in the highest priority arbitration group.

The channel priority registers assign the relative priorities within each arbitration group; see CHn_PRI. All channels with a non-zero CHn_PRI value use fixed-priority arbitration.

When you enable round-robin arbitration, all channels with channel priority set to zero do not have a priority and, of those channels requesting service, are cycled through (from high to low channel number) without regard to priority relative to each other within the same priority group. Any channel with a non-zero CHn_PRI value automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI).

NOTE

For correct operation, changes to the MP_CSR[ERCA, GCLC, GMRC] fields must be performed when the DMA channels are inactive; that is, when the MP_CSR[ACTIVE] field is 0.

Fields

Field	Function
31 VLD	Valid Logical OR of all CHn_ES[ERR] status fields. 0b - No CHn_ES[ERR] fields are set to 1 1b - At least one CHn_ES[ERR] field is set to 1, indicating a valid error exists that software has not cleared
30-28 —	Reserved
27-24 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error or last recorded error-canceled transfer.
23-9 —	Reserved
8 ECX	Transfer Canceled The ECX operation is a management page function. When employed, the targeted channel's CHn_ES register reports an unspecified error; that is, only the CHn_ES[ERR] field is set to 1. The management page has full view of the error condition. 0b - No canceled transfers 1b - Last recorded entry was a canceled transfer by the error cancel transfer input
7 SAE	Source Address Error When this field is 1, it indicates that TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6	Source Offset Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
SOE	When this field is 1, it indicates that TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error When this field is 1, it indicates that TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error When this field is 1, it indicates that TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - The last recorded error was NBYTES equal to zero or a CITER not equal to BITER error. Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was a bus error on a source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was a bus error on a destination write

23.6.2.4 Management Page Interrupt Request Status (MP_INT)

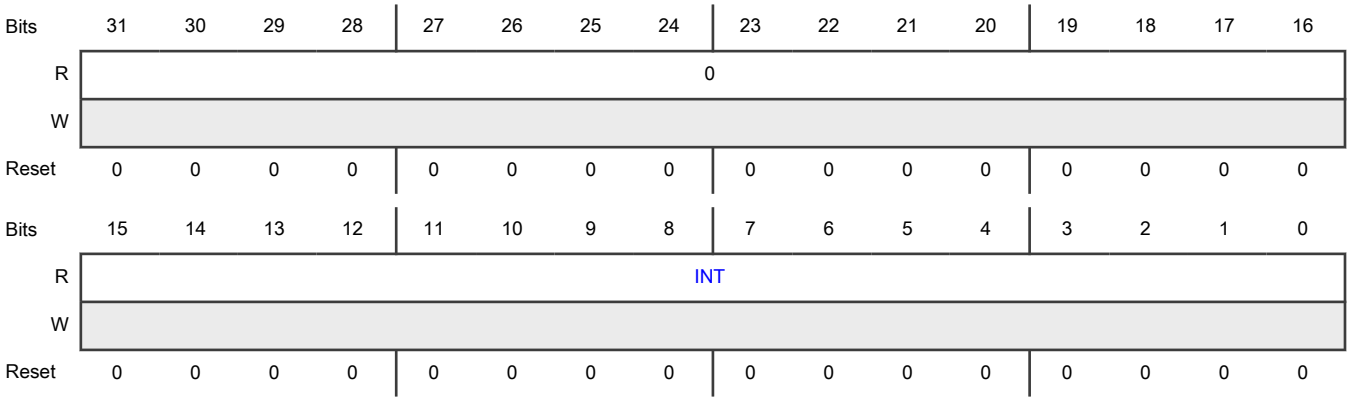
Offset

Register	Offset
MP_INT	8h

Function

This register shows the current state of the interrupt service requests for all eDMA channels.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 INT	Interrupt Request Status The INT register presents the interrupt request status for each eDMA channel. Depending on the appropriate field setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion or an error condition. The eDMA routes channel interrupt requests to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate field in the channel's interrupt request register, CHn_INT, thus negating the interrupt request. 0b - Interrupt request for corresponding channel not present 1b - Interrupt request for corresponding channel present

23.6.2.5 Management Page Hardware Request Status (MP_HRS)

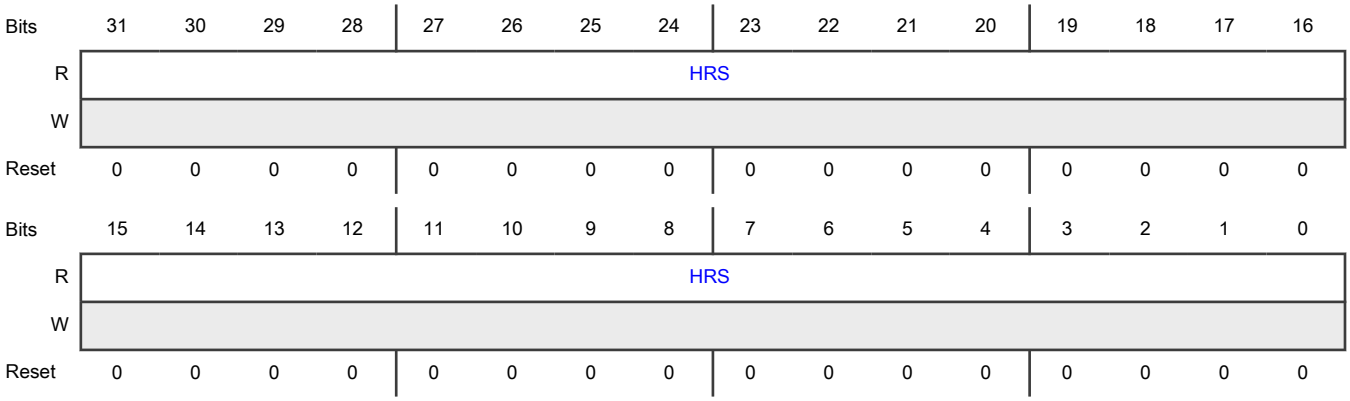
Offset

Register	Offset
MP_HRS	Ch

Function

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by eDMA's arbitration logic.

Diagram



Fields

Field	Function
31-0 HRS	Hardware Request Status The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel. 0b - Hardware service request for corresponding channel is not present 1b - Hardware service request for corresponding channel is present

23.6.2.6 Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI)

Offset

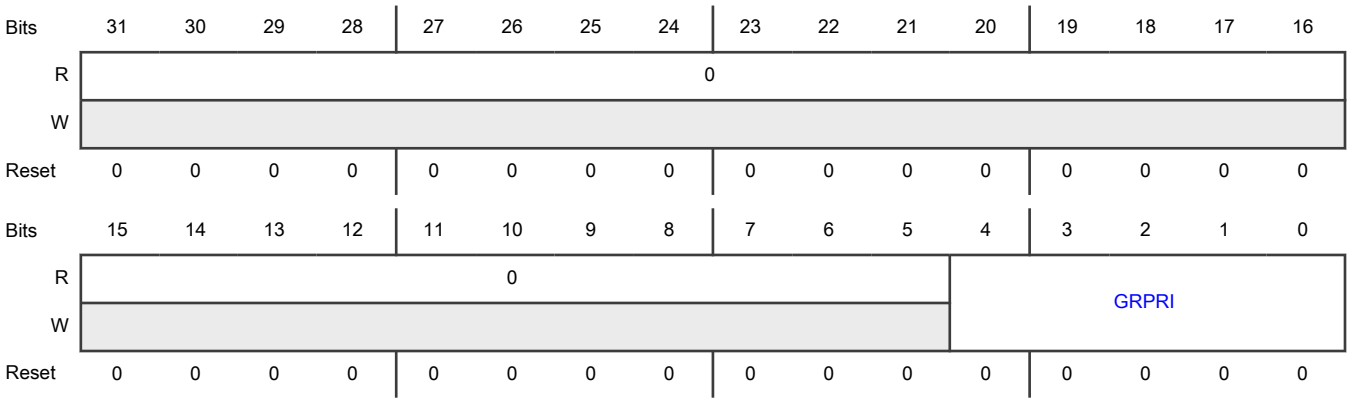
For n = 0 to 15:

Register	Offset
CHn_GRPRI	100h + (n × 4h)

Function

The contents of this register define the arbitration group associated with each channel. Using a fixed-priority group arbitration scheme, eDMA evaluates the arbitration group priorities by numeric value from highest group number to lowest; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. The range of the group priority values is limited to the values of 0 through 31. Within each arbitration group, the channel priority assignment CH*n*_PRI determines the highest-priority channel.

Diagram



Fields

Field	Function
31-5 —	Reserved
4-0 GRPRI	Arbitration Group For Channel n Fixed-priority arbitration group number.

23.6.3.2 Channel Control and Status (CH0_CSR - CH15_CSR)

Offset

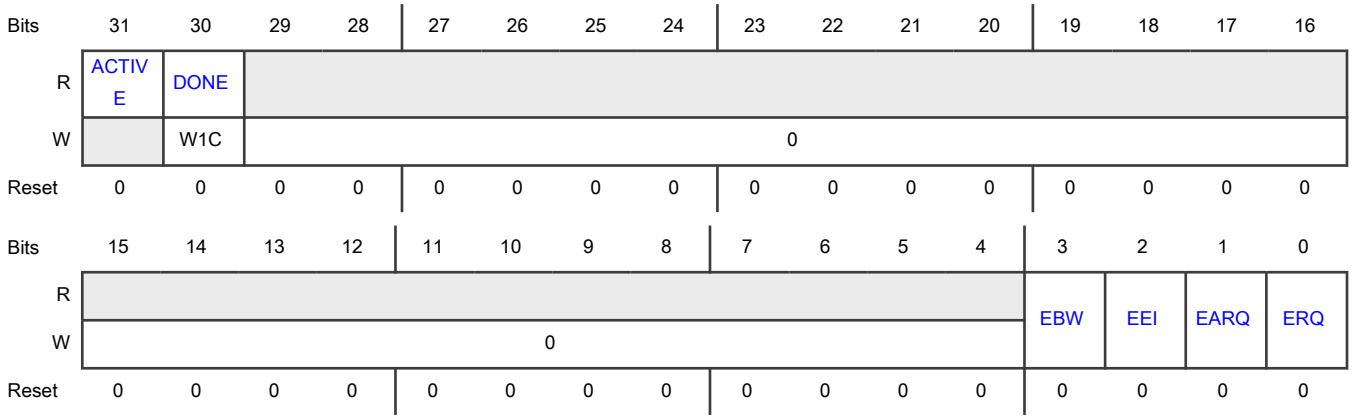
For n = 0 to 15:

Register	Offset
CHn_CSR	0h + (n × 1000h)

Function

This register contains several fields related to hardware and interrupt requests, configuration, and status for the given channel.

Diagram



Fields

Field	Function
31 ACTIVE	Channel Active The ACTIVE field indicates the channel was selected by arbitration and is executing the prescribed transfers. The eDMA sets it to 1 when channel service begins, and clears it to 0 as the minor loop completes or when any error condition is detected. Except for dynamic scatter/gather or dynamic channel linking, you must not modify the transfer control descriptor when a channel is active.
30 DONE	Channel Done The DONE field indicates the eDMA has completed the major loop. The eDMA engine sets this field as the CITER count reaches zero. If enabled, the eDMA generates an interrupt request corresponding to this completed channel. The software clears it, or the hardware clears it when the channel is activated. **NOTE** This field must be cleared to 0 before writing the MAJORELINK or ESG fields.
29-4 —	Reserved
3 EBW	Enable Buffered Writes When buffered writes are enabled, all writes except for the last write sequence of the minor loop are signaled by the eDMA as bufferable. 0b - Buffered writes on system bus disabled. Buffered writes on system bus disabled 1b - Buffered writes on system bus enabled. Bufferable write signal asserted on all system bus writes except during last write sequence
2 EEI	Enable Error Interrupt The EEI field enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller. 0b - Error signal for corresponding channel does not generate error interrupt

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Assertion of error signal for corresponding channel generates error interrupt request
1 EARQ	Enable Asynchronous DMA Request The enable asynchronous DMA request field (EARQ) does not affect DMA operations. When set to 1, this field allows the hardware service request enable field (ERQ) to propagate out of the DMA to the power controller. When cleared to 0, this field masks the hardware service request enable field to the power controller. 0b - Disable asynchronous DMA request for the channel 1b - Enable asynchronous DMA request for the channel
0 ERQ	Enable DMA Request Disable a channel's hardware service request at the source before clearing the channel's ERQ field. The DMA hardware request input signal and the enable request field (ERQ) must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request field does not affect a channel service request made explicitly through software or channel linking. The state of the ERQ field does not affect the channel's START field. 0b - DMA hardware request signal for corresponding channel disabled 1b - DMA hardware request signal for corresponding channel enabled

23.6.3.3 Channel Error Status (CH0_ES - CH15_ES)

Offset

For n = 0 to 15:

Register	Offset
CHn_ES	4h + (n × 1000h)

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus master read or write cycle

The ERR field signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the CHn_CSR[EEI] field, then logically summed across all channels to form an error interrupt request, which may be routed to the interrupt controller. In addition, this enabled error status is logically OR'd onto the channel done interrupt, CHn_INT[INT], thus forming a done or error interrupt on a per channel basis.

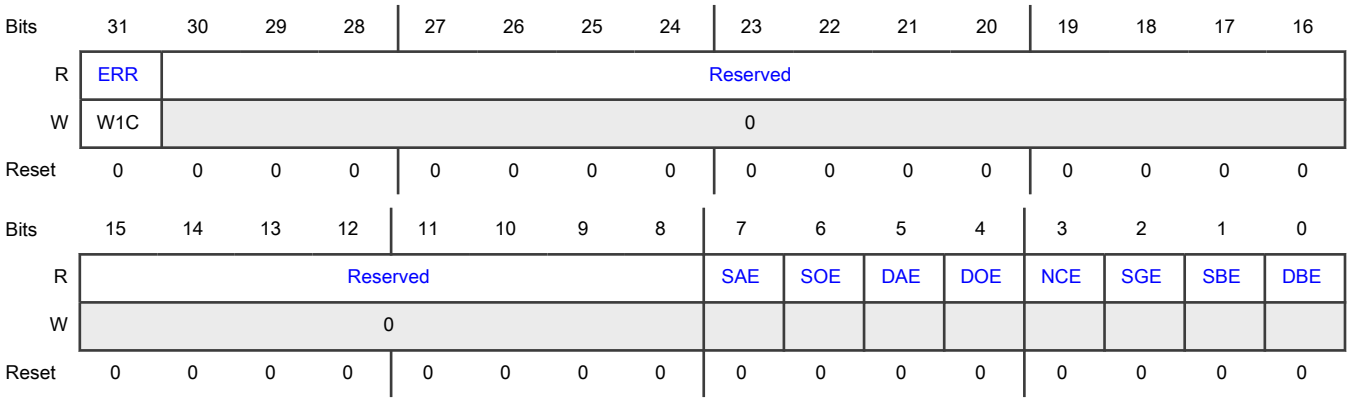
During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when eDMA detects an error. The contents of this ERR register field can also be polled because a non-zero value indicates the presence of a channel error, regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing a 1 to the ERR field clears the channel's error status, and writing a 0 has no effect.

An unspecified error, where only the ERR field is set to 1, indicates that either a transfer was cancelled with an error. The Management Page Error Status register has full view of the error condition.

See Fault reporting and handling for more details.

Diagram



Fields

Field	Function
31 ERR	Error In Channel 0b - An error in this channel has not occurred 1b - An error in this channel has occurred
30-8 —	Reserved
7 SAE	Source Address Error TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 DOE	Destination Offset Error TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG]is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was bus error on source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was bus error on destination write

23.6.3.4 Channel Interrupt Status (CH0_INT - CH15_INT)

Offset

For n = 0 to 15:

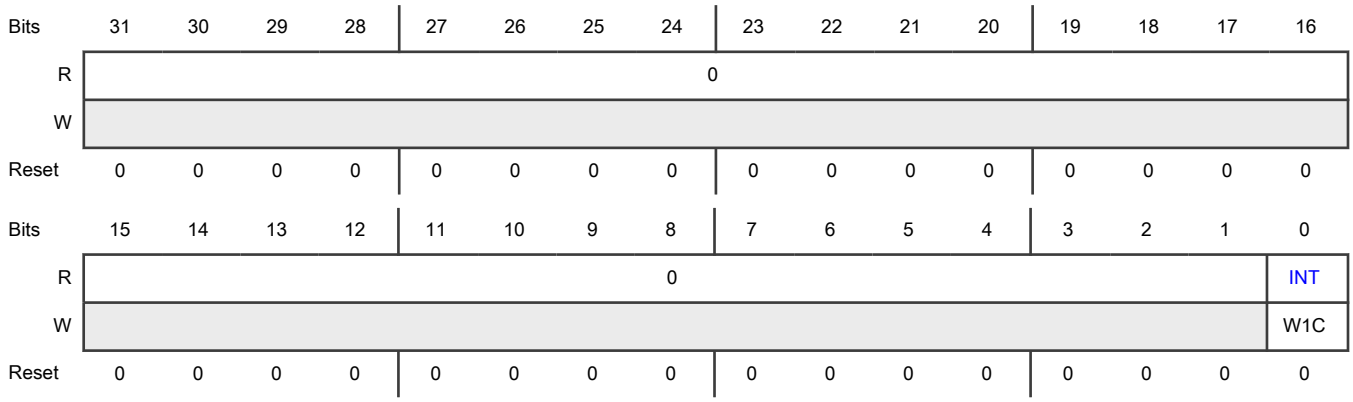
Register	Offset
CHn_INT	8h + (n × 1000h)

Function

The INT field signals the presence of an interrupt request for the channel. Depending on the appropriate bit setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion or an error condition.

The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. On writes to INT, a 1 clears the channel's interrupt request. A zero has no effect on the channel's current interrupt status.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 INT	Interrupt Request 0b - Interrupt request for corresponding channel cleared 1b - Interrupt request for corresponding channel active

23.6.3.5 Channel System Bus (CH0_SBR - CH15_SBR)

Offset

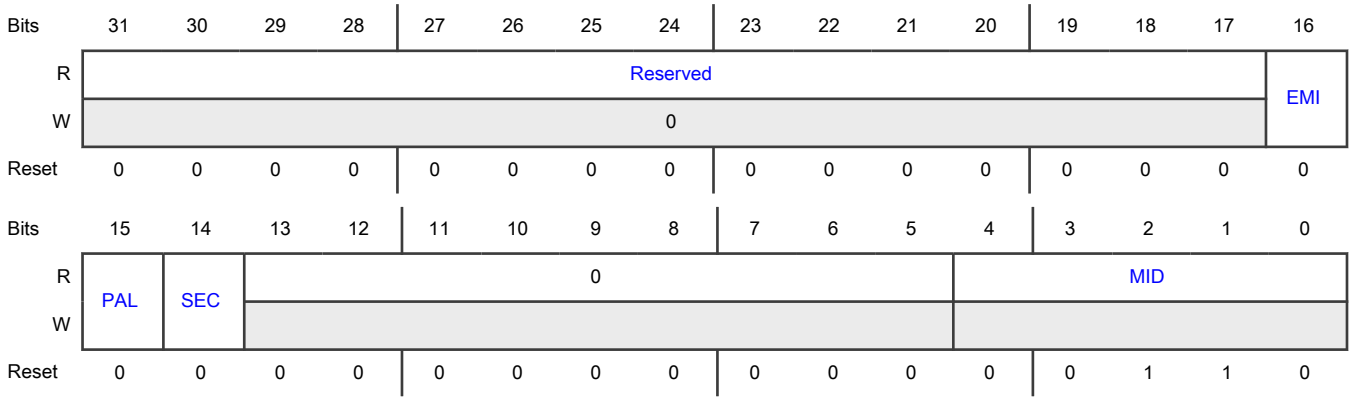
For n = 0 to 15:

Register	Offset
CHn_SBR	Ch + (n × 1000h)

Function

The Channel System Bus register places identification and attribute information on the system bus interface for the eDMA.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 EMI	Enable Master ID Replication The eDMA master ID replication field allows the eDMA to use the same protection level and system bus ID of the master programming the eDMA's TCD. When enabled, the eDMA uses the master ID and protection level stored in the CHn_SBR registers, instead of the eDMA's default values. When a master (for example a core) programs a TCD, its master ID is captured when the TCD*n*_CSR control attributes are written. A scatter/gather operation does not affect the CHn_SBR registers. You can write the EMI only if MP_CSR[GMRC] = 1, which means Global Master ID Replication Control is enabled; otherwise, the EMI is forced to zero. **NOTE** If master ID replication is disabled, the nonsecure, user protection level for DMA transfers is used. 0b - Master ID replication is disabled 1b - Master ID replication is enabled
15 PAL	Privileged Access Level This field controls DMA's protection level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - User protection level for DMA transfers 1b - Privileged protection level for DMA transfers
14 SEC	Security Level DMA's security level on the system bus when the channel is active.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - Nonsecure protection level for DMA transfers 1b - Secure protection level for DMA transfers
13-5 —	Reserved
4-0 MID	Master ID This field controls the DMA's master ID on the system bus when the channel is active. **NOTE** The ID captured in this register reflects the master ID of the core or other master writing the channel's security attributes, TCD*n*_SBR[SEC].

23.6.3.6 Channel Priority (CH0_PRI - CH15_PRI)

Offset

For n = 0 to 15:

Register	Offset
CHn_PRI	10h + (n × 1000h)

Function

The contents of these registers define unique priorities associated with each channel within the same channel group. Channel grouping is programmed via Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI).

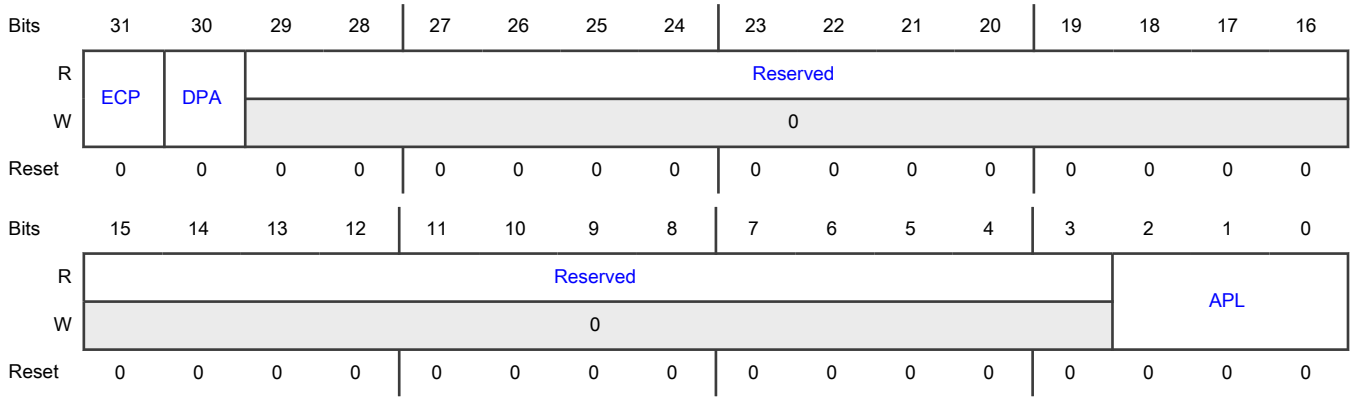
The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, channel numbers with the same, non-zero value, will be selected based on channel number with the higher channel number having higher priority.

If more than one channel in a group has an arbitration priority level value of zero, then the arbitration mode field MP_CSR[ERCA] is used to determine the arbitration scheme for all channels with APL=0 within a group.

When you enable round-robin channel arbitration (MP_CSR[ERCA] = 1), all channels with APL=0 within a group will use a round-robin arbitration scheme, which rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group.

When you enable fixed-priority channel arbitration (MP_CSR[ERCA] = 0), eDMA selects channels with APL=0 based on channel number, with the higher channel number having higher priority.

Diagram



Fields

Field	Function
31 ECP	Enable Channel Preemption 0b - Channel cannot be suspended by a higher-priority channel's service request 1b - Channel can be temporarily suspended by a higher-priority channel's service request
30 DPA	Disable Preempt Ability 0b - Channel can suspend a lower-priority channel 1b - Channel cannot suspend any other channel, regardless of channel priority
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Channel priority level for arbitration within the assigned arbitration group.

23.6.3.7 Channel Multiplexor Configuration (CH0_MUX - CH15_MUX)

Offset

For n = 0 to 15:

Register	Offset
CHn_MUX	14h + (n × 1000h)

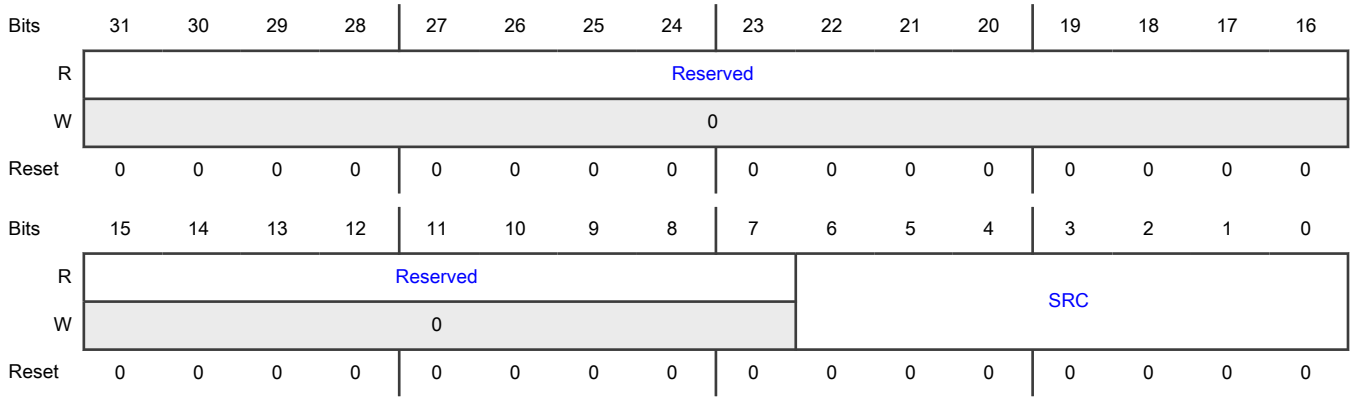
Function

Each of the DMA channels can be independently associated with various peripherals in the system. The Channel Multiplexor Configuration register selects the peripheral assigned to each channel. Service requests from the peripheral should be disabled when configuring a channel to a peripheral source.

Each channel must have a unique value when selecting a peripheral slot in the channel mux configuration. The only value that may overlap is source 0. If there is an attempt to write a mux configuration value that is already consumed by any channel, a mux configuration of 0 (SRC = 0) will be written.

All channels will default to source 0. When a particular peripheral is needed, the channel's mux configuration is set to that source number. When the peripheral is no longer needed, the mux configuration for that channel should be written to 0, thus releasing the resource.

Diagram



Fields

Field	Function
31-7 —	Reserved
6-0 SRC	Service Request Source Hardware service request source for the channel. **NOTE** With the exception of 0, attempts to write a value already in use will be forced to 0.

23.6.3.8 TCD Source Address (TCD0_SADDR - TCD15_SADDR)

Offset

For n = 0 to 15:

Register	Offset
TCDn_SADDR	20h + (n × 1000h)

Function

This register contains the address for the read transactions.

Diagram

Field	Function
15-0 SOFF	Source Address Signed Offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

23.6.3.10 TCD Transfer Attributes (TCD0_ATTR - TCD15_ATTR)

Offset

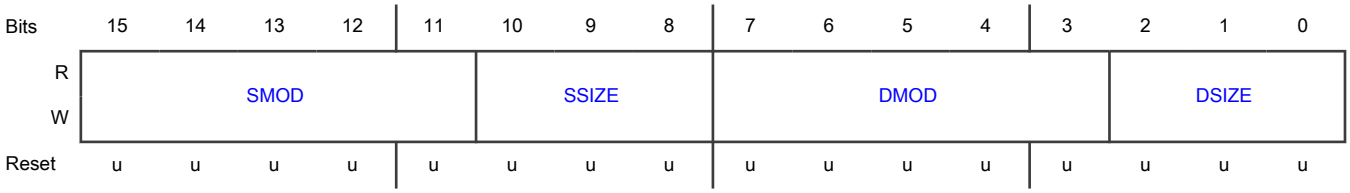
For n = 0 to 15:

Register	Offset
TCDn_ATTR	26h + (n × 1000h)

Function

This register contains size and option modulo addressing information for source and destination addresses.

Diagram



Fields

Field	Function
15-11 SMOD	Source Address Modulo This field defines a specific address range, which is the value after the SADDR + SOFF calculation is performed on the original register value. Setting this field makes it easy to implement a circular data queue. For data queues requiring power-of-2-sized bytes, the queue must start at a 0-modulo-size address and the SMOD field must be set to the appropriate value for the queue, freezing the required number of upper address bits. The value programmed into this field specifies the number of lower address bits that are allowed to change. For a circular queue application, you typically set TCDn_SOFF[SOFF] to the transfer size to implement post-increment addressing, with the SMOD function constraining the addresses to a 0-modulo-size range. 0_0000b - Source address modulo feature disabled 0_0001b - Source address modulo feature enabled for any non-zero value [1-31]
10-8 SSIZE	Source Data Transfer Size 000b - 8-bit 001b - 16-bit 010b - 32-bit 011b - 64-bit 100b - 16-byte 101b - 32-byte 110b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
	111b - Reserved
7-3 DMOD	Destination Address Modulo See the SMOD definition.
2-0 DSIZE	Destination Data Transfer Size See the SSIZE definition.

23.6.3.11 TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD15_NBYTES_MLOFFNO)

Offset

For n = 0 to 15:

Register	Offset
TCDn_NBYTES_MLOFFNO	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR), or destination address (TCDn_DADDR), upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. When minor loop offsets are enabled, the minor loop offset value (TCDn_NBYTES_MLOFFYES[MLOFF]) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both, prior to the addresses being written back to the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (SMLOE or DMLOE is 1), TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is redefined. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is used to specify multiple fields:

- A source enable bit (SMLOE) to specify the minor loop offset must be applied to the source address (TCDn_SADDR) upon minor loop completion
- A destination enable bit (DMLOE) to specify the minor loop offset must be applied to the destination address (TCDn_DADDR) upon minor loop completion
- The sign extended minor loop offset value (MLOFF)

The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

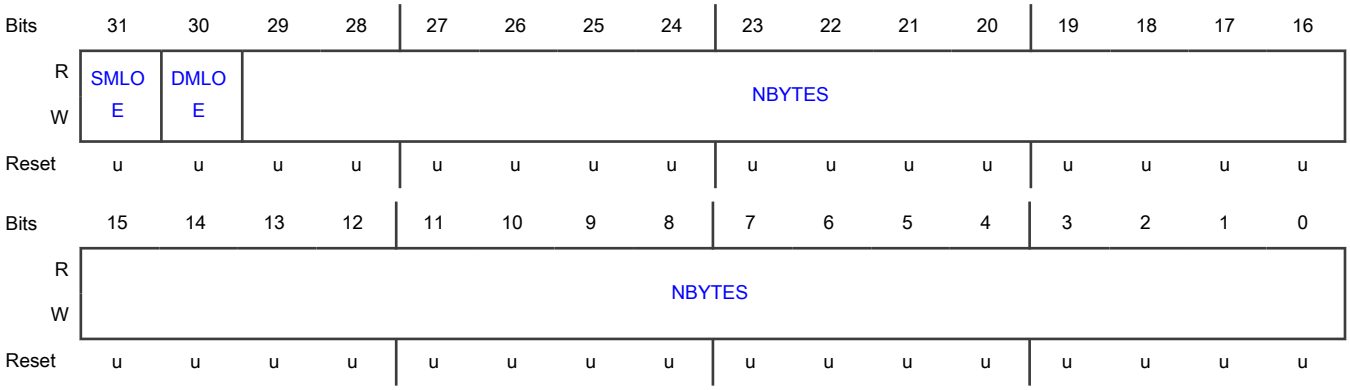
One of two register profiles (this register or TCDn_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is defined as follows:

- If SMLOE = 0 and DMLOE = 0, then see the TCDn_NBYTES_MLOFFNO register description.

- If either SMLOE or DMLOE is 1, then see the TCDn_NBYTES_MLOFFYES register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-0 NBYTES	Number of Bytes To Transfer Per Service Request Number of bytes to be transferred for each service request of the channel. When a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the byte transfer count has been reached. This process is normally an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the byte count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is complete, additional processing is performed.

23.6.3.12 TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD15_NBYTES_MLOFFYES)

Offset

For n = 0 to 15:

Register	Offset
TCDn_NBYTES_MLOFFYES	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offset is an address offset value added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion occurs when the channel has finished the service request and has transferred NBYTES. Minor loop offsets are enabled by setting either the source enable bit (SMLOE) or the destination enable bit (DMLOE).

The source enable bit (SMLOE) specifies the minor loop offset value (MLOFF) that is to be applied to the source address (TCDn_SADDR) upon minor loop completion. The destination enable bit (DMLOE) specifies the minor loop offset (MLOFF) that is to be applied to the destination address (TCDn_DADDR) upon minor loop completion.

If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

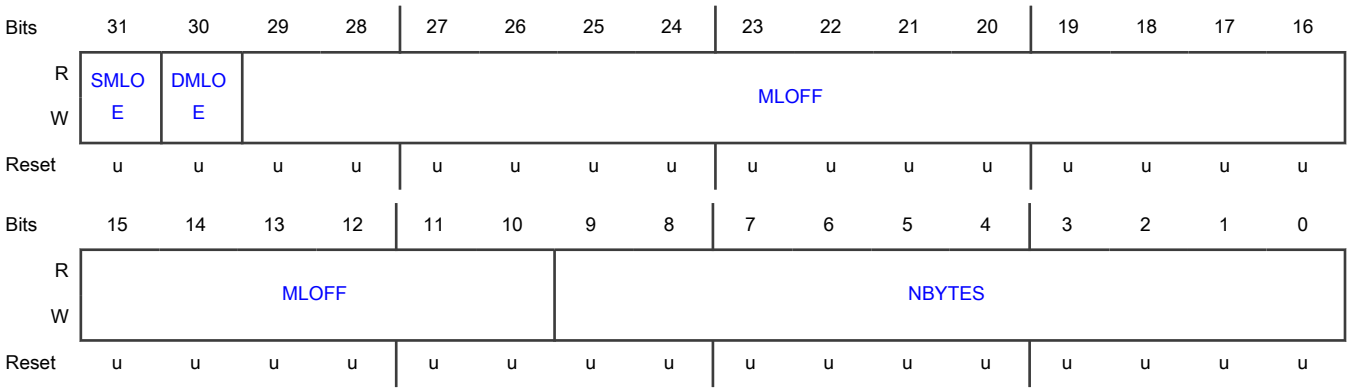
When you enable the minor loop offset overlay (either SMLOE or DMLOE is 1), eDMA redefines TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES specifies the sign-extended minor loop offset value (MLOFF). The same offset value (MLOFF) applies to both source and destination minor loop offsets. When the minor loop offset is enabled, you must align it to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFNO) defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFYES is defined as follows:

- If either minor loop offset is enabled (SMLOE or DMLOE = 1), then see the TCDn_NBYTES_MLOFFYES register description.
- If SMLOE and DMLOE are both 0, then see the TCDn_NBYTES_MLOFFNO register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-10 MLOFF	Minor Loop Offset If SMLOE or DMLOE is 1, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
9-0 NBYTES	Number of Bytes To Transfer Per Service Request The number of bytes to be transferred in each service request of the channel. As a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the minor byte transfer count has been reached. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is complete, additional processing is performed.

23.6.3.13 TCD Last Source Address Adjustment / Store DADDR Address (TCD0_SLAST_SDA - TCD15_SLAST_SDA)

Offset

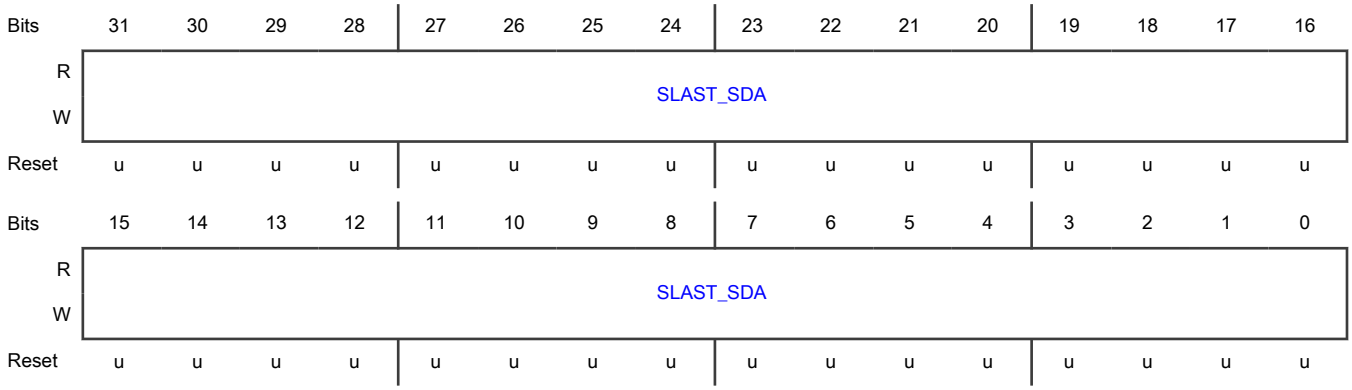
For n = 0 to 15:

Register	Offset
TCDn_SLAST_SDA	2Ch + (n × 1000h)

Function

This register contains the value added to the source address when the major loop is complete. When the store destination address option is enabled, this field provides a pointer to memory for storing the final destination address.

Diagram



Fields

Field	Function
31-0 SLAST_SDA	Last Source Address Adjustment / Store DADDR Address Source last address adjustment or the system memory address for destination address (DADDR) storage. If (TCDn_CSR[ESDA] = 0), then: • Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero.

23.6.3.14 TCD Destination Address (TCD0_DADDR - TCD15_DADDR)

Offset

For n = 0 to 15:

Register	Offset
TCDn_DADDR	30h + (n × 1000h)

Function

This register contains the address for the write transactions.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Fields

Field	Function
31-0 DADDR	Destination Address Memory address pointing to the destination data.

23.6.3.15 TCD Signed Destination Address Offset (TCD0_DOFF - TCD15_DOFF)

Offset

For n = 0 to 15:

Register	Offset
TCDn_DOFF	34h + (n × 1000h)

Function

This register contains the sign-extended value added to Destination Address register after each write transaction.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DOFF															
W																
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Fields

Field	Function
15-0 DOFF	Destination Address Signed Offset Sign-extended offset that is applied to the current destination address to form the next-state value as each destination write is completed.

23.6.3.16 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD15_CITER_ELINKNO)

Offset

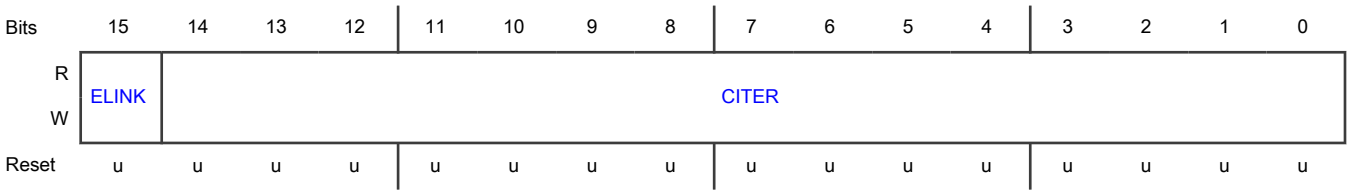
For n = 0 to 15:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 0, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel to 1. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

23.6.3.17 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD15_CITER_ELINKYES)

Offset

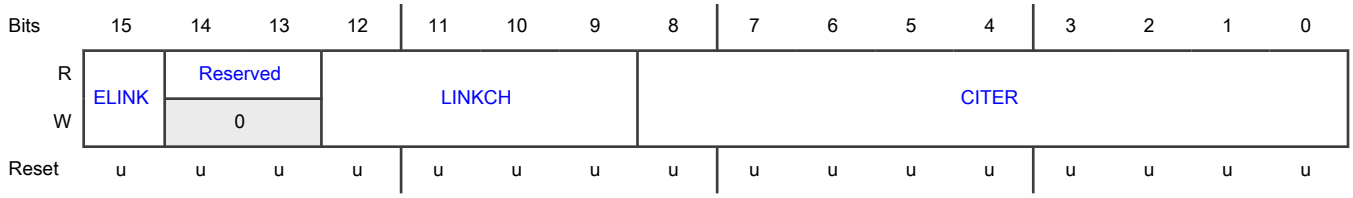
For n = 0 to 15:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 1, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. When enabled, an internal mechanism sets the TCDn_CSR[START] field of the specified channel (LINKCH) upon minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-13 —	Reserved
12-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted the eDMA engine initiates a channel service request to the channel defined by this field by writing that channel's TCDn_CSR[START] field to 1.
8-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

23.6.3.18 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD15_DLAST_SGA)

Offset

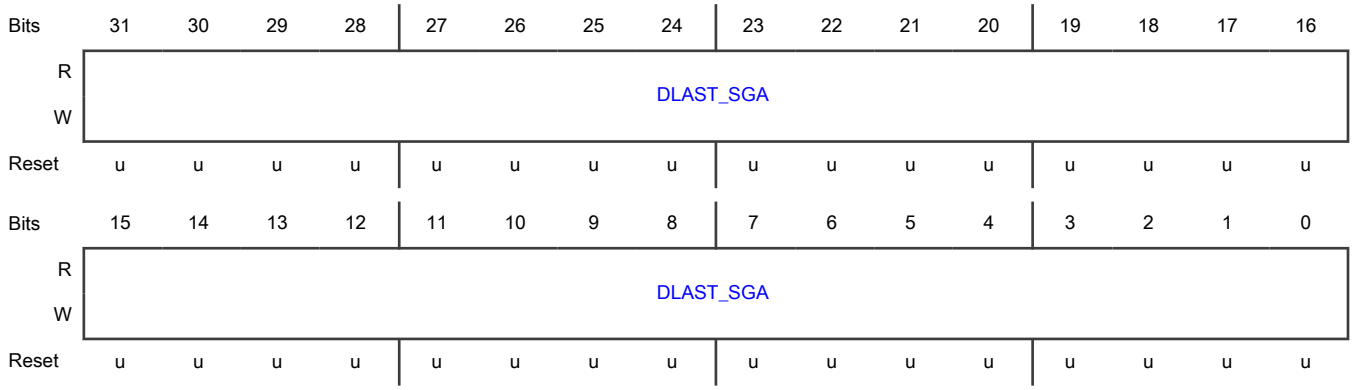
For n = 0 to 15:

Register	Offset
TCDn_DLAST_SGA	38h + (n × 1000h)

Function

This register contains the value added to the destination address when the major loop is complete. When the Scatter/Gather option is enabled, this field provides a pointer to memory for fetching a transfer control descriptor to reprogram the channel.

Diagram



Fields

Field	Function
31-0 DLAST_SGA	Last Destination Address Adjustment / Scatter Gather Address Adjustment of the last destination address or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value is added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo 32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo 32-byte, or else a configuration error is reported.

23.6.3.19 TCD Control and Status (TCD0_CSR - TCD15_CSR)

Offset

For n = 0 to 15:

Register	Offset
TCDn_CSR	3Ch + (n × 1000h)

Function

This register is used to enable optional features.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BWC				MAJORLINKCH				ESDA	EEOP	MAJORELINK	ESG	DREQ	INTHALF	INTMAJOR	START
W			0													
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	0

Fields

Field	Function
15-14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces eDMA to stall after the completion of each read/write access, to control the bus request bandwidth seen by the system bus interconnect. **NOTE** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00b - No eDMA engine stalls 01b - Reserved 10b - eDMA engine stalls for 4 cycles after each R/W 11b - eDMA engine stalls for 8 cycles after each R/W
13-12 —	Reserved
11-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field to 1.
7 ESDA	Enable Store Destination Address As the channel completes the major loop by either the current iteration counter (CITER) decrementing to 0, or by receiving an enabled end-of-packet signal, this field enables writing the destination address (DADDR) to the address stored in the SLAST_SDA field. The value written to system memory is the last DADDR value prior to the DLAST_SGA offset being applied, or overwritten by an enabled scatter/gather operation. When the ESDA bit is 1, SLAST_SDA contains the write pointer instead of the final source address offset. Because this is a pointer and not a final offset, a last source address offset of zero is applied to SADDR instead of the SLAST_SGA value. 0b - Ability to store destination address to system memory disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Ability to store destination address to system memory enabled
6 EEOP	Enable End-Of-Packet Processing When enabled by the EEOP field, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel, and to treat the shutdown as the major-loop-completed event. If the EEOP field is 1, the end-of-packet signal from supported peripherals is accepted. If the EEOP field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA-saved destination address), minus the software-saved initial address (DADDR), reflects the total amount of data transferred. 0b - End-of-packet operation disabled 1b - End-of-packet hardware input signal enabled
5 MAJORELINK	Enable Link When Major Loop Complete As the channel completes the major loop, this flag enables linking to another channel defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses TCDn_DLAST_SGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure, which is loaded as the transfer control descriptor into local memory. **NOTE** To support the dynamic scatter/gather coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Current channel's TCD is normal format 1b - Current channel's TCD specifies scatter/gather format.
3 DREQ	Disable Request If this flag is 1, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches 0. 0b - No operation. Channel's ERQ field not affected 1b - Clear the ERQ field to 0 upon major loop completion, thus disabling hardware service requests. Channel's ERQ field cleared to 0 when major loop complete
2	Enable Interrupt If Major Counter Half-complete

Table continues on the next page...

Table continued from the previous page...

Field	Function
INTHALF	If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use INTHALF; use INTMAJOR instead. 0b - Halfway point interrupt disabled 1b - Halfway point interrupt enabled
1 INTMAJOR	Enable Interrupt If Major count complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count (CITER) reaches 0. 0b - End-of-major loop interrupt disabled 1b - End-of-major loop interrupt enabled
0 START	Channel Start If this flag is 1, the channel is requesting service. The eDMA hardware automatically clears this flag to 0 after the channel begins execution. 0b - Channel not explicitly started 1b - Channel explicitly started via a software-initiated service request

23.6.3.20 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD15_BITER_ELINKNO)

Offset

For n = 0 to 15:

Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is 0, the TCDn_BITER register is defined as follows.

Diagram

Fields

Field	Function
15 ELINK	Enables Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

23.6.3.21 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD15_BITER_ELINKYES)

Offset

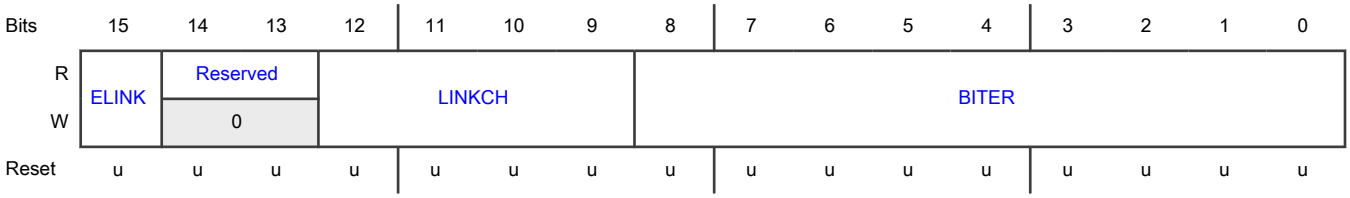
For n = 0 to 15:

Register	Offset
TCDn_BITER_ELINKYES	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is set, the TCDn_BITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-13 —	Reserved
12-9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field.
8-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

23.6.4.2 Channel Control and Status (CH0_CSR - CH15_CSR)

Offset

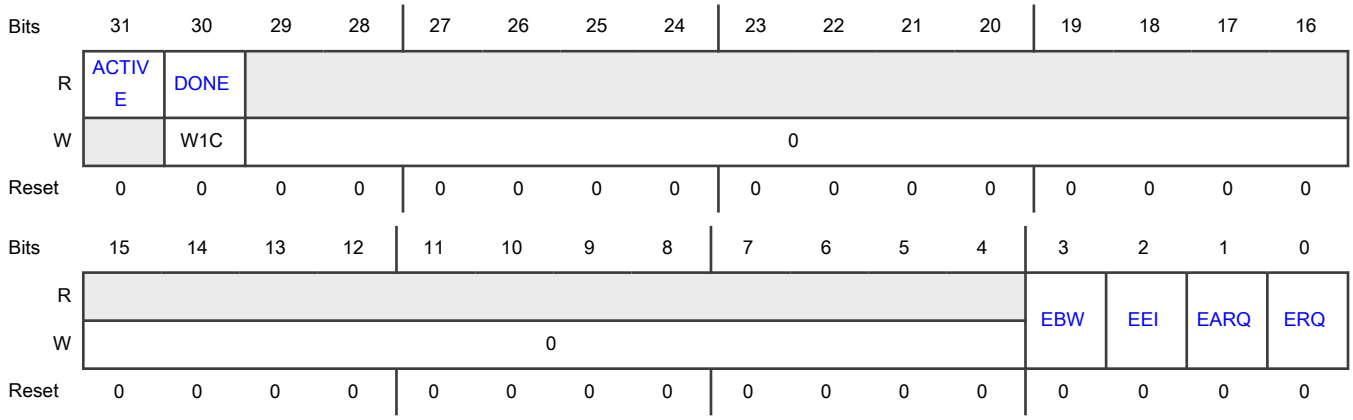
For n = 0 to 15:

Register	Offset
CHn_CSR	0h + (n × 1000h)

Function

This register contains several fields related to hardware and interrupt requests, configuration, and status for the given channel.

Diagram



Fields

Field	Function
31 ACTIVE	Channel Active The ACTIVE field indicates the channel was selected by arbitration and is executing the prescribed transfers. The eDMA sets it to 1 when channel service begins, and clears it to 0 as the minor loop completes or when any error condition is detected. Except for dynamic scatter/gather or dynamic channel linking, you must not modify the transfer control descriptor when a channel is active.
30 DONE	Channel Done The DONE field indicates the eDMA has completed the major loop. The eDMA engine sets this field as the CITER count reaches zero. If enabled, the eDMA generates an interrupt request corresponding to this completed channel. The software clears it, or the hardware clears it when the channel is activated. **NOTE** This field must be cleared to 0 before writing the MAJORELINK or ESG fields.
29-4 —	Reserved
3 EBW	Enable Buffered Writes When buffered writes are enabled, all writes except for the last write sequence of the minor loop are signaled by the eDMA as bufferable. 0b - Buffered writes on system bus disabled. Buffered writes on system bus disabled 1b - Buffered writes on system bus enabled. Bufferable write signal asserted on all system bus writes except during last write sequence
2 EEI	Enable Error Interrupt

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The EEI field enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller. 0b - Error signal for corresponding channel does not generate error interrupt 1b - Assertion of error signal for corresponding channel generates error interrupt request
1 EARQ	Enable Asynchronous DMA Request The enable asynchronous DMA request field (EARQ) does not affect DMA operations. When set to 1, this field allows the hardware service request enable field (ERQ) to propagate out of the DMA to the power controller. When cleared to 0, this field masks the hardware service request enable field to the power controller. 0b - Disable asynchronous DMA request for the channel 1b - Enable asynchronous DMA request for the channel
0 ERQ	Enable DMA Request Disable a channel's hardware service request at the source before clearing the channel's ERQ field. The DMA hardware request input signal and the enable request field (ERQ) must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request field does not affect a channel service request made explicitly through software or channel linking. The state of the ERQ field does not affect the channel's START field. 0b - DMA hardware request signal for corresponding channel disabled 1b - DMA hardware request signal for corresponding channel enabled

23.6.4.3 Channel Error Status (CH0_ES - CH15_ES)

Offset

For n = 0 to 15:

Register	Offset
CHn_ES	4h + (n × 1000h)

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus master read or write cycle

The ERR field signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the CHn_CSR[EEI] field, then logically summed across all channels to form an error interrupt request, which may be routed to the interrupt controller. In addition, this enabled error status is logically OR'd onto the channel done interrupt, CHn_INT[INT], thus forming a done or error interrupt on a per channel basis.

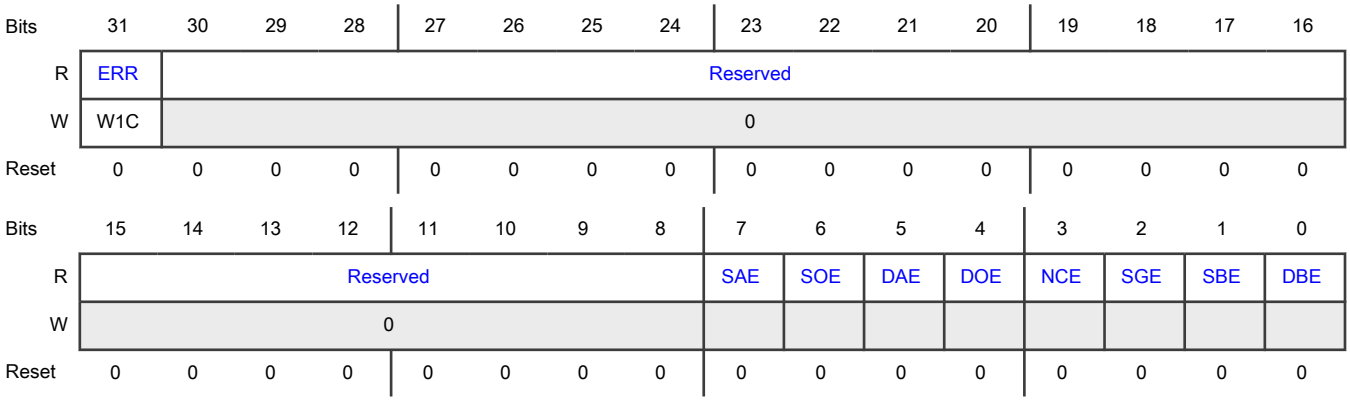
During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when eDMA detects an error. The contents of this ERR register field can also be polled because a non-zero value indicates the presence of a channel error, regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing a 1 to the ERR field clears the channel's error status, and writing a 0 has no effect.

An unspecified error, where only the ERR field is set to 1, indicates that either a transfer was cancelled with an error. The Management Page Error Status register has full view of the error condition.

See Fault reporting and handling for more details.

Diagram



Fields

Field	Function
31 ERR	Error In Channel 0b - An error in this channel has not occurred 1b - An error in this channel has occurred
30-8 —	Reserved
7 SAE	Source Address Error TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 DAE	Destination Address Error TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG]is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was bus error on source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was bus error on destination write

23.6.4.4 Channel Interrupt Status (CH0_INT - CH15_INT)

Offset

For n = 0 to 15:

Register	Offset
CHn_INT	8h + (n × 1000h)

Function

The INT field signals the presence of an interrupt request for the channel. Depending on the appropriate bit setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion or an error condition.

The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. On writes to INT, a 1 clears the channel's interrupt request. A zero has no effect on the channel's current interrupt status.

23.6.4.5 Channel System Bus (CH0_SBR - CH15_SBR)

Offset

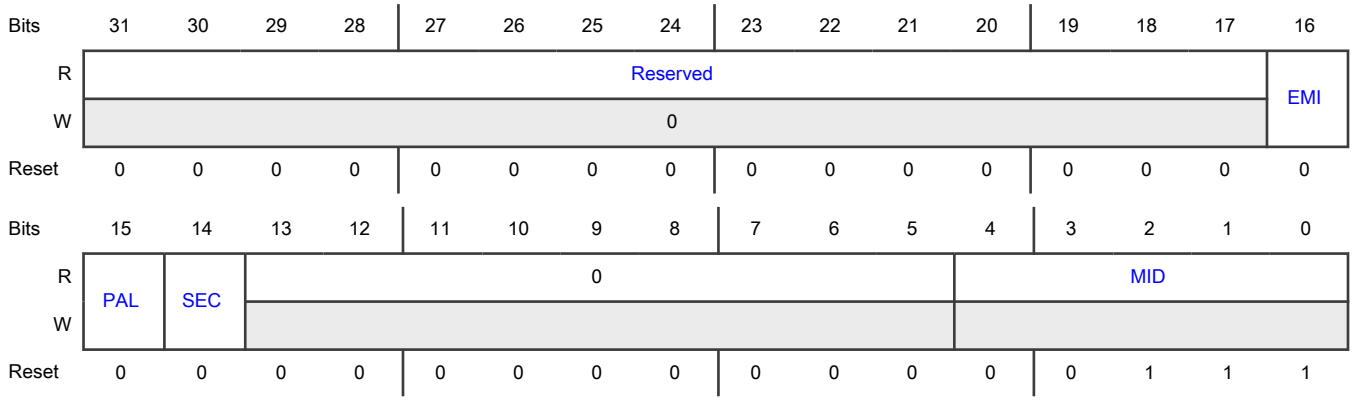
For n = 0 to 15:

Register	Offset
CHn_SBR	Ch + (n × 1000h)

Function

The Channel System Bus register places identification and attribute information on the system bus interface for the eDMA.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 EMI	Enable Master ID Replication The eDMA master ID replication field allows the eDMA to use the same protection level and system bus ID of the master programming the eDMA's TCD. When enabled, the eDMA uses the master ID and protection level stored in the CHn_SBR registers, instead of the eDMA's default values. When a master (for example a core) programs a TCD, its master ID is captured when the TCD*n*_CSR control attributes are written. A scatter/gather operation does not affect the CHn_SBR registers. You can write the EMI only if MP_CSR[GMRC] = 1, which means Global Master ID Replication Control is enabled; otherwise, the EMI is forced to zero. **NOTE** If master ID replication is disabled, the nonsecure, user protection level for DMA transfers is used. 0b - Master ID replication is disabled 1b - Master ID replication is enabled
15 PAL	Privileged Access Level This field controls DMA's protection level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - User protection level for DMA transfers 1b - Privileged protection level for DMA transfers
14 SEC	Security Level DMA's security level on the system bus when the channel is active.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - Nonsecure protection level for DMA transfers 1b - Secure protection level for DMA transfers
13-5 —	Reserved
4-0 MID	Master ID This field controls the DMA's master ID on the system bus when the channel is active. **NOTE** The ID captured in this register reflects the master ID of the core or other master writing the channel's security attributes, TCD*n*_SBR[SEC].

23.6.4.6 Channel Priority (CH0_PRI - CH15_PRI)

Offset

For n = 0 to 15:

Register	Offset
CHn_PRI	10h + (n × 1000h)

Function

The contents of these registers define unique priorities associated with each channel within the same channel group. Channel grouping is programmed via Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI).

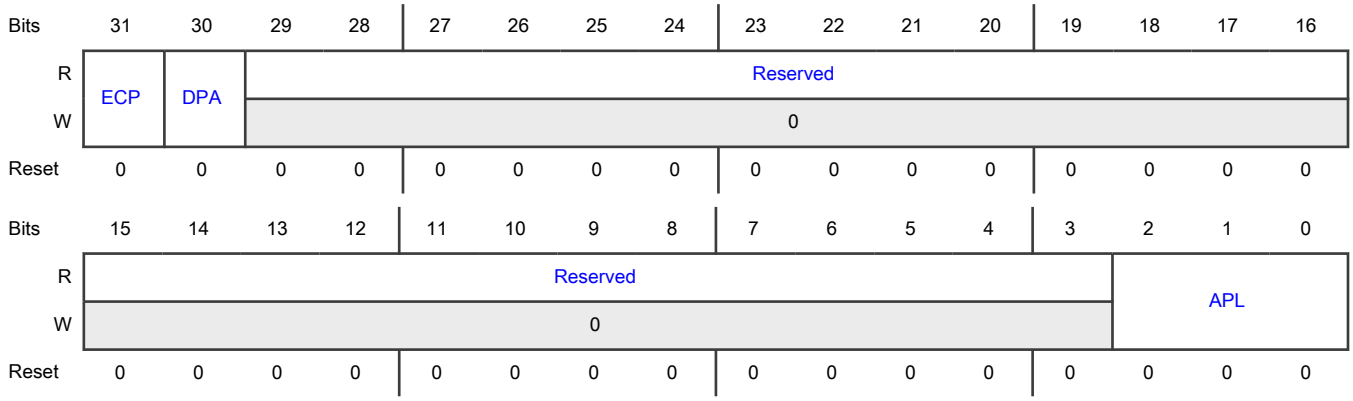
The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, channel numbers with the same, non-zero value, will be selected based on channel number with the higher channel number having higher priority.

If more than one channel in a group has an arbitration priority level value of zero, then the arbitration mode field MP_CSR[ERCA] is used to determine the arbitration scheme for all channels with APL=0 within a group.

When you enable round-robin channel arbitration (MP_CSR[ERCA] = 1), all channels with APL=0 within a group will use a round-robin arbitration scheme, which rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group.

When you enable fixed-priority channel arbitration (MP_CSR[ERCA] = 0), eDMA selects channels with APL=0 based on channel number, with the higher channel number having higher priority.

Diagram



Fields

Field	Function
31 ECP	Enable Channel Preemption 0b - Channel cannot be suspended by a higher-priority channel's service request 1b - Channel can be temporarily suspended by a higher-priority channel's service request
30 DPA	Disable Preempt Ability 0b - Channel can suspend a lower-priority channel 1b - Channel cannot suspend any other channel, regardless of channel priority
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Channel priority level for arbitration within the assigned arbitration group.

23.6.4.7 Channel Multiplexor Configuration (CH0_MUX - CH15_MUX)

Offset

For n = 0 to 15:

Register	Offset
CHn_MUX	14h + (n × 1000h)

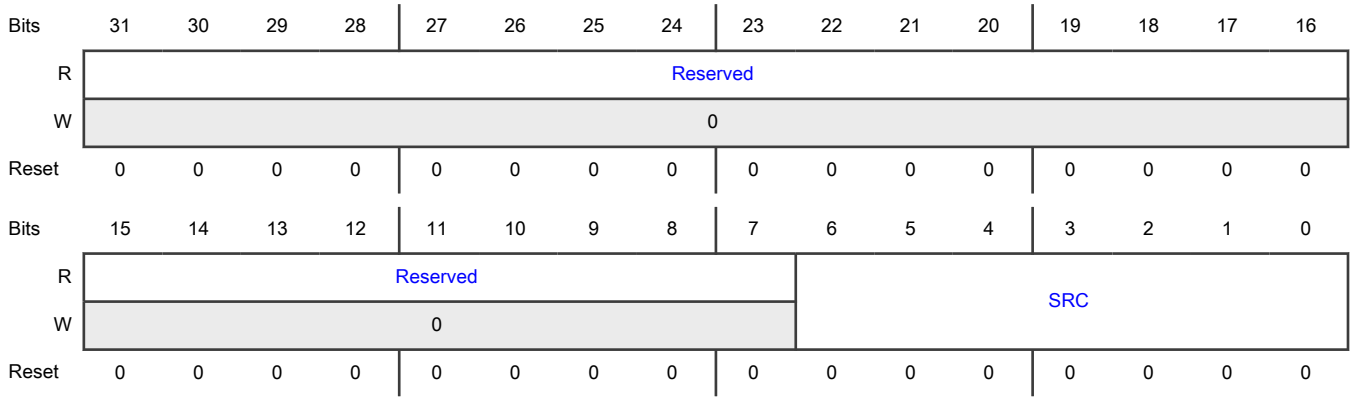
Function

Each of the DMA channels can be independently associated with various peripherals in the system. The Channel Multiplexor Configuration register selects the peripheral assigned to each channel. Service requests from the peripheral should be disabled when configuring a channel to a peripheral source.

Each channel must have a unique value when selecting a peripheral slot in the channel mux configuration. The only value that may overlap is source 0. If there is an attempt to write a mux configuration value that is already consumed by any channel, a mux configuration of 0 (SRC = 0) will be written.

All channels will default to source 0. When a particular peripheral is needed, the channel's mux configuration is set to that source number. When the peripheral is no longer needed, the mux configuration for that channel should be written to 0, thus releasing the resource.

Diagram



Fields

Field	Function
31-7 —	Reserved
6-0 SRC	Service Request Source Hardware service request source for the channel. **NOTE** With the exception of 0, attempts to write a value already in use will be forced to 0.

23.6.4.8 TCD Source Address (TCD0_SADDR - TCD15_SADDR)

Offset

For n = 0 to 15:

Register	Offset
TCDn_SADDR	20h + (n × 1000h)

Function

This register contains the address for the read transactions.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
15-0 SOFF	Source Address Signed Offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

23.6.4.10 TCD Transfer Attributes (TCD0_ATTR - TCD15_ATTR)

Offset

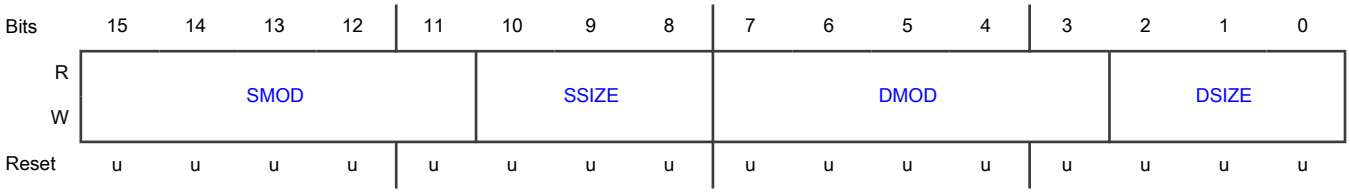
For n = 0 to 15:

Register	Offset
TCDn_ATTR	26h + (n × 1000h)

Function

This register contains size and option modulo addressing information for source and destination addresses.

Diagram



Fields

Field	Function
15-11 SMOD	Source Address Modulo This field defines a specific address range, which is the value after the SADDR + SOFF calculation is performed on the original register value. Setting this field makes it easy to implement a circular data queue. For data queues requiring power-of-2-sized bytes, the queue must start at a 0-modulo-size address and the SMOD field must be set to the appropriate value for the queue, freezing the required number of upper address bits. The value programmed into this field specifies the number of lower address bits that are allowed to change. For a circular queue application, you typically set TCDn_SOFF[SOFF] to the transfer size to implement post-increment addressing, with the SMOD function constraining the addresses to a 0-modulo-size range. 0_0000b - Source address modulo feature disabled 0_0001b - Source address modulo feature enabled for any non-zero value [1-31]
10-8 SSIZE	Source Data Transfer Size 000b - 8-bit 001b - 16-bit 010b - 32-bit 011b - 64-bit 100b - 16-byte 101b - 32-byte 110b - Reserved

Table continued from the previous page...

Field	Function
	111b - Reserved
7-3 DMOD	Destination Address Modulo See the SMOD definition.
2-0 DSIZE	Destination Data Transfer Size See the SSIZE definition.

23.6.4.11 TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD15_NBYTES_MLOFFNO)

Offset

For n = 0 to 15:

Register	Offset
TCDn_NBYTES_MLOFFNO	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR), or destination address (TCDn_DADDR), upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. When minor loop offsets are enabled, the minor loop offset value (TCDn_NBYTES_MLOFFYES[MLOFF]) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both, prior to the addresses being written back to the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (SMLOE or DMLOE is 1), TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is redefined. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is used to specify multiple fields:

- A source enable bit (SMLOE) to specify the minor loop offset must be applied to the source address (TCDn_SADDR) upon minor loop completion
- A destination enable bit (DMLOE) to specify the minor loop offset must be applied to the destination address (TCDn_DADDR) upon minor loop completion
- The sign extended minor loop offset value (MLOFF)

The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

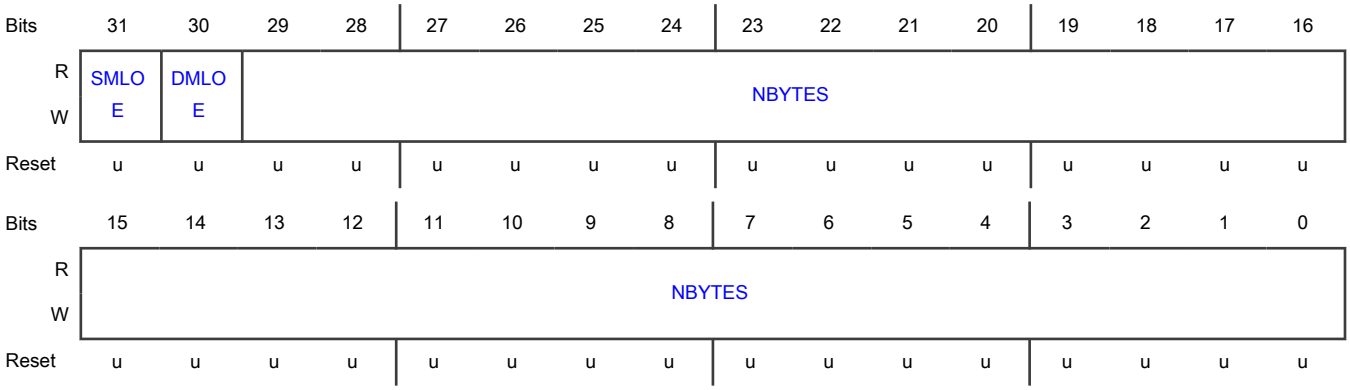
One of two register profiles (this register or TCDn_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is defined as follows:

- If SMLOE = 0 and DMLOE = 0, then see the TCDn_NBYTES_MLOFFNO register description.

- If either SMLOE or DMLOE is 1, then see the TCDn_NBYTES_MLOFFYES register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-0 NBYTES	Number of Bytes To Transfer Per Service Request Number of bytes to be transferred for each service request of the channel. When a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the byte transfer count has been reached. This process is normally an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the byte count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is complete, additional processing is performed.

23.6.4.12 TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD15_NBYTES_MLOFFYES)

Offset

For n = 0 to 15:

Register	Offset
TCDn_NBYTES_MLOFFYES	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offset is an address offset value added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion occurs when the channel has finished the service request and has transferred NBYTES. Minor loop offsets are enabled by setting either the source enable bit (SMLOE) or the destination enable bit (DMLOE).

The source enable bit (SMLOE) specifies the minor loop offset value (MLOFF) that is to be applied to the source address (TCDn_SADDR) upon minor loop completion. The destination enable bit (DMLOE) specifies the minor loop offset (MLOFF) that is to be applied to the destination address (TCDn_DADDR) upon minor loop completion.

If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

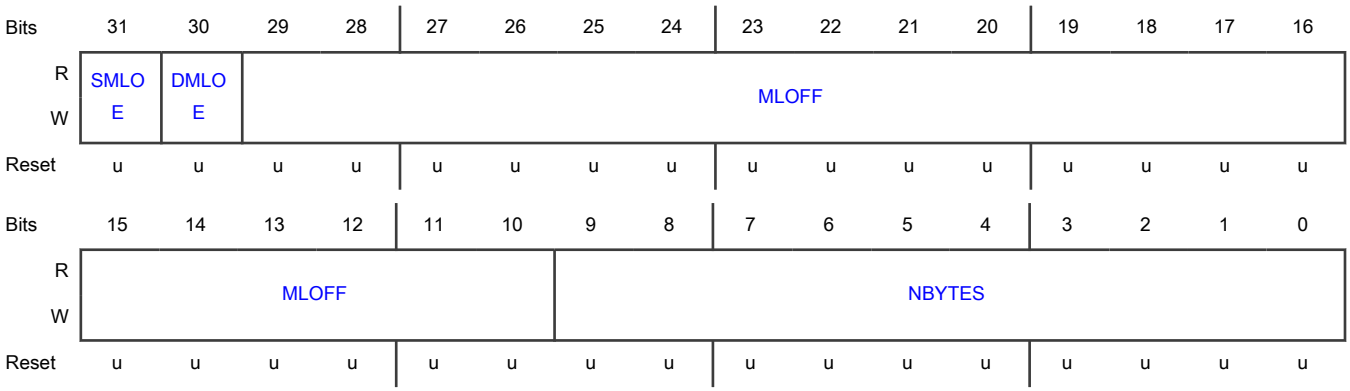
When you enable the minor loop offset overlay (either SMLOE or DMLOE is 1), eDMA redefines TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES specifies the sign-extended minor loop offset value (MLOFF). The same offset value (MLOFF) applies to both source and destination minor loop offsets. When the minor loop offset is enabled, you must align it to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFNO) defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFYES is defined as follows:

- If either minor loop offset is enabled (SMLOE or DMLOE = 1), then see the TCDn_NBYTES_MLOFFYES register description.
- If SMLOE and DMLOE are both 0, then see the TCDn_NBYTES_MLOFFNO register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-10 MLOFF	Minor Loop Offset If SMLOE or DMLOE is 1, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
9-0 NBYTES	Number of Bytes To Transfer Per Service Request The number of bytes to be transferred in each service request of the channel. As a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the minor byte transfer count has been reached. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is complete, additional processing is performed.

23.6.4.13 TCD Last Source Address Adjustment / Store DADDR Address (TCD0_SLAST_SDA - TCD15_SLAST_SDA)

Offset

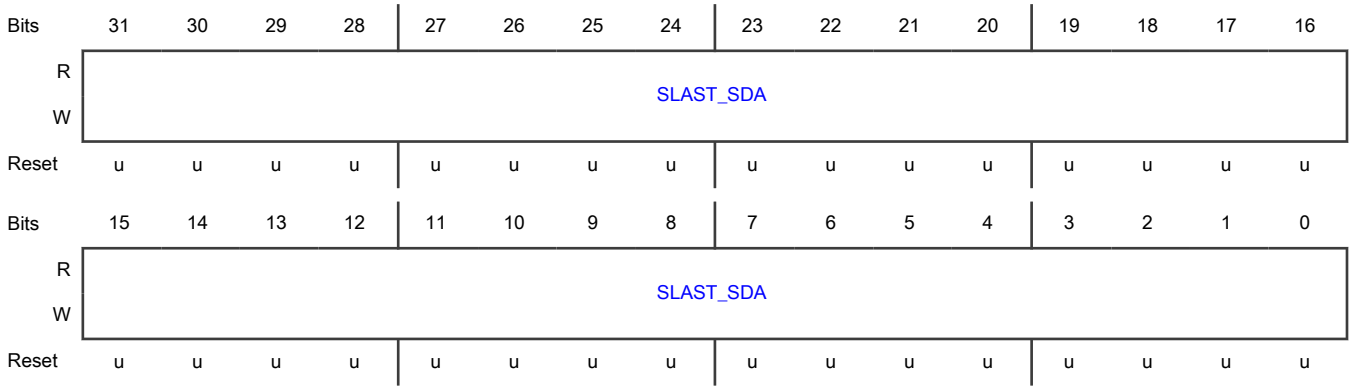
For n = 0 to 15:

Register	Offset
TCDn_SLAST_SDA	2Ch + (n × 1000h)

Function

This register contains the value added to the source address when the major loop is complete. When the store destination address option is enabled, this field provides a pointer to memory for storing the final destination address.

Diagram



Fields

Field	Function
31-0 SLAST_SDA	Last Source Address Adjustment / Store DADDR Address Source last address adjustment or the system memory address for destination address (DADDR) storage. If (TCDn_CSR[ESDA] = 0), then: • Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero.

23.6.4.14 TCD Destination Address (TCD0_DADDR - TCD15_DADDR)

Offset

For n = 0 to 15:

Register	Offset
TCDn_DADDR	30h + (n × 1000h)

Function

This register contains the address for the write transactions.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Fields

Field	Function
31-0 DADDR	Destination Address Memory address pointing to the destination data.

23.6.4.15 TCD Signed Destination Address Offset (TCD0_DOFF - TCD15_DOFF)

Offset

For n = 0 to 15:

Register	Offset
TCDn_DOFF	34h + (n × 1000h)

Function

This register contains the sign-extended value added to Destination Address register after each write transaction.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DOFF															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Fields

Field	Function
15-0 DOFF	Destination Address Signed Offset Sign-extended offset that is applied to the current destination address to form the next-state value as each destination write is completed.

23.6.4.16 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD15_CITER_ELINKNO)

Offset

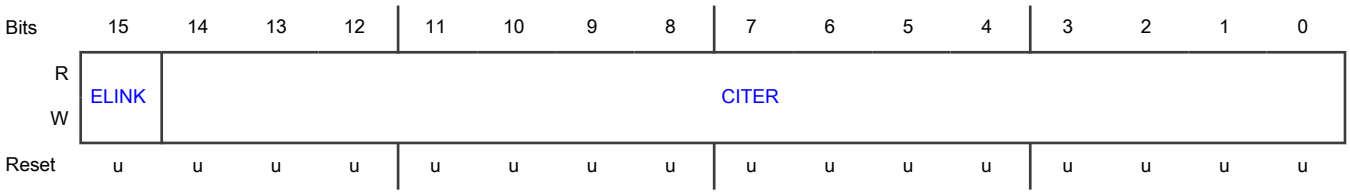
For n = 0 to 15:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 0, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel to 1. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

23.6.4.17 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD15_CITER_ELINKYES)

Offset

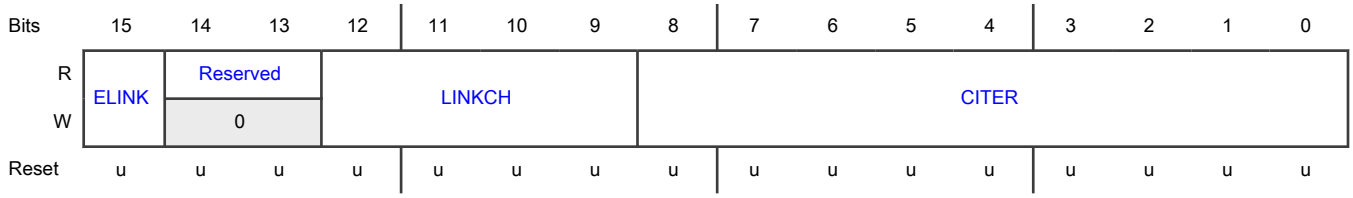
For n = 0 to 15:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 1, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. When enabled, an internal mechanism sets the TCDn_CSR[START] field of the specified channel (LINKCH) upon minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-13 —	Reserved
12-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted the eDMA engine initiates a channel service request to the channel defined by this field by writing that channel's TCDn_CSR[START] field to 1.
8-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

23.6.4.18 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD15_DLAST_SGA)

Offset

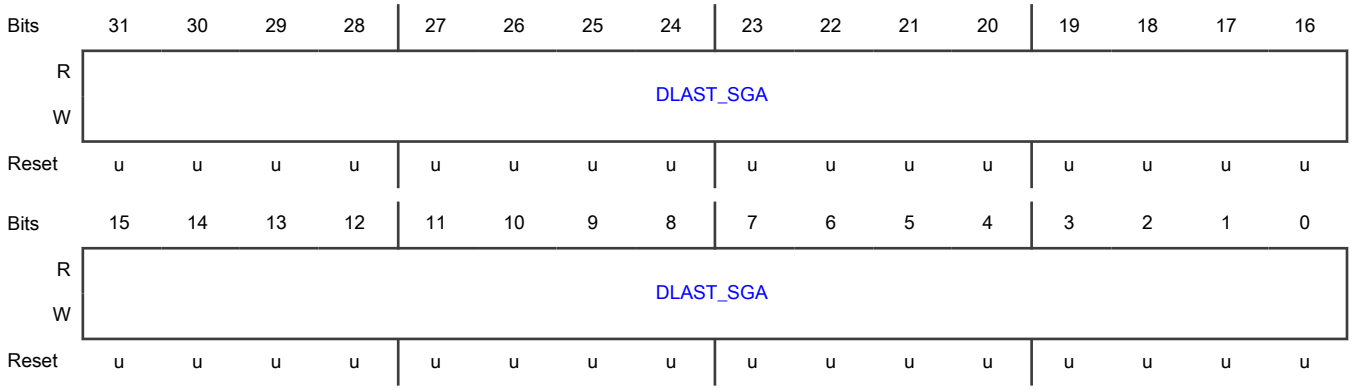
For n = 0 to 15:

Register	Offset
TCDn_DLAST_SGA	38h + (n × 1000h)

Function

This register contains the value added to the destination address when the major loop is complete. When the Scatter/Gather option is enabled, this field provides a pointer to memory for fetching a transfer control descriptor to reprogram the channel.

Diagram



Fields

Field	Function
31-0 DLAST_SGA	Last Destination Address Adjustment / Scatter Gather Address Adjustment of the last destination address or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value is added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo 32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo 32-byte, or else a configuration error is reported.

23.6.4.19 TCD Control and Status (TCD0_CSR - TCD15_CSR)

Offset

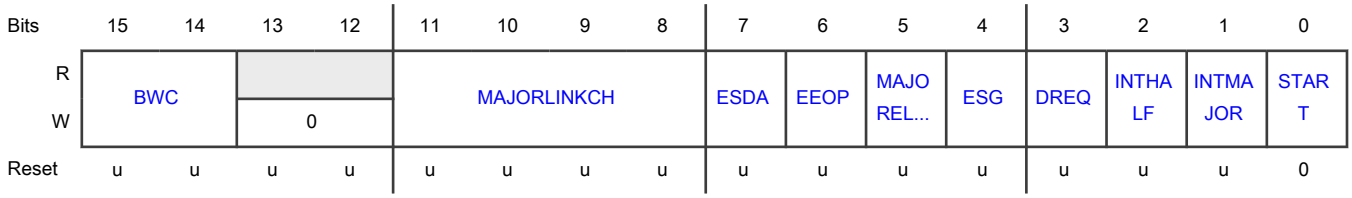
For n = 0 to 15:

Register	Offset
TCDn_CSR	3Ch + (n × 1000h)

Function

This register is used to enable optional features.

Diagram



Fields

Field	Function
15-14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces eDMA to stall after the completion of each read/write access, to control the bus request bandwidth seen by the system bus interconnect. **NOTE** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00b - No eDMA engine stalls 01b - Reserved 10b - eDMA engine stalls for 4 cycles after each R/W 11b - eDMA engine stalls for 8 cycles after each R/W
13-12 —	Reserved
11-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field to 1.
7 ESDA	Enable Store Destination Address As the channel completes the major loop by either the current iteration counter (CITER) decrementing to 0, or by receiving an enabled end-of-packet signal, this field enables writing the destination address (DADDR) to the address stored in the SLAST_SDA field. The value written to system memory is the last DADDR value prior to the DLAST_SGA offset being applied, or overwritten by an enabled scatter/gather operation. When the ESDA bit is 1, SLAST_SDA contains the write pointer instead of the final source address offset. Because this is a pointer and not a final offset, a last source address offset of zero is applied to SADDR instead of the SLAST_SGA value. 0b - Ability to store destination address to system memory disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Ability to store destination address to system memory enabled
6 EEOP	Enable End-Of-Packet Processing When enabled by the EEOP field, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel, and to treat the shutdown as the major-loop-completed event. If the EEOP field is 1, the end-of-packet signal from supported peripherals is accepted. If the EEOP field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA-saved destination address), minus the software-saved initial address (DADDR), reflects the total amount of data transferred. 0b - End-of-packet operation disabled 1b - End-of-packet hardware input signal enabled
5 MAJORELINK	Enable Link When Major Loop Complete As the channel completes the major loop, this flag enables linking to another channel defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses TCDn_DLAST_SGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure, which is loaded as the transfer control descriptor into local memory. **NOTE** To support the dynamic scatter/gather coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Current channel's TCD is normal format 1b - Current channel's TCD specifies scatter/gather format.
3 DREQ	Disable Request If this flag is 1, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches 0. 0b - No operation. Channel's ERQ field not affected 1b - Clear the ERQ field to 0 upon major loop completion, thus disabling hardware service requests. Channel's ERQ field cleared to 0 when major loop complete
2	Enable Interrupt If Major Counter Half-complete

Table continues on the next page...

Table continued from the previous page...

Field	Function
INTHALF	If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use INTHALF; use INTMAJOR instead. 0b - Halfway point interrupt disabled 1b - Halfway point interrupt enabled
1 INTMAJOR	Enable Interrupt If Major count complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count (CITER) reaches 0. 0b - End-of-major loop interrupt disabled 1b - End-of-major loop interrupt enabled
0 START	Channel Start If this flag is 1, the channel is requesting service. The eDMA hardware automatically clears this flag to 0 after the channel begins execution. 0b - Channel not explicitly started 1b - Channel explicitly started via a software-initiated service request

23.6.4.20 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD15_BITER_ELINKNO)

Offset

For n = 0 to 15:

Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is 0, the TCDn_BITER register is defined as follows.

Diagram

Fields

Field	Function
15 ELINK	Enables Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

23.6.4.21 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD15_BITER_ELINKYES)

Offset

For n = 0 to 15:

Register	Offset
TCDn_BITER_ELINKYES	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is set, the TCDn_BITER register is defined as follows.

Diagram

24.1.1 Module instances

This device contains one instance of the WUU module, WUU0.

24.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

24.1.3 WUU sources

The device uses the following inputs as wakeup sources to the WUU module. The WUU_Px inputs are connections to external physical pins. The WUU_MxIF inputs are connections to the internal peripheral interrupt flags from different modules that can operate in low-power modes. The WUU_MxDR inputs are connections to the internal peripheral Asynchronous DMA or module Triggers from different modules that can operate in low-power modes.

NOTE

In addition to the WUU wakeup sources, the device also wakes from low power modes when NMI or RESET pins are enabled and the respective pin is asserted.

24.2 Overview

WUU facilitates in selecting external pins and on-chip modules as interrupt wake-up sources from Power Down/Deep Power Down power modes. You can also configure the external pins to act as interrupt wake-up sources in all power modes. WUU helps pins and modules generate a temporary wake-up from Power Down mode for servicing DMA or trigger events. Digital filtering is also available for the external wake-up pins.

See the chip-specific WUU information section for input sources to WUU.

24.2.1 Block diagram

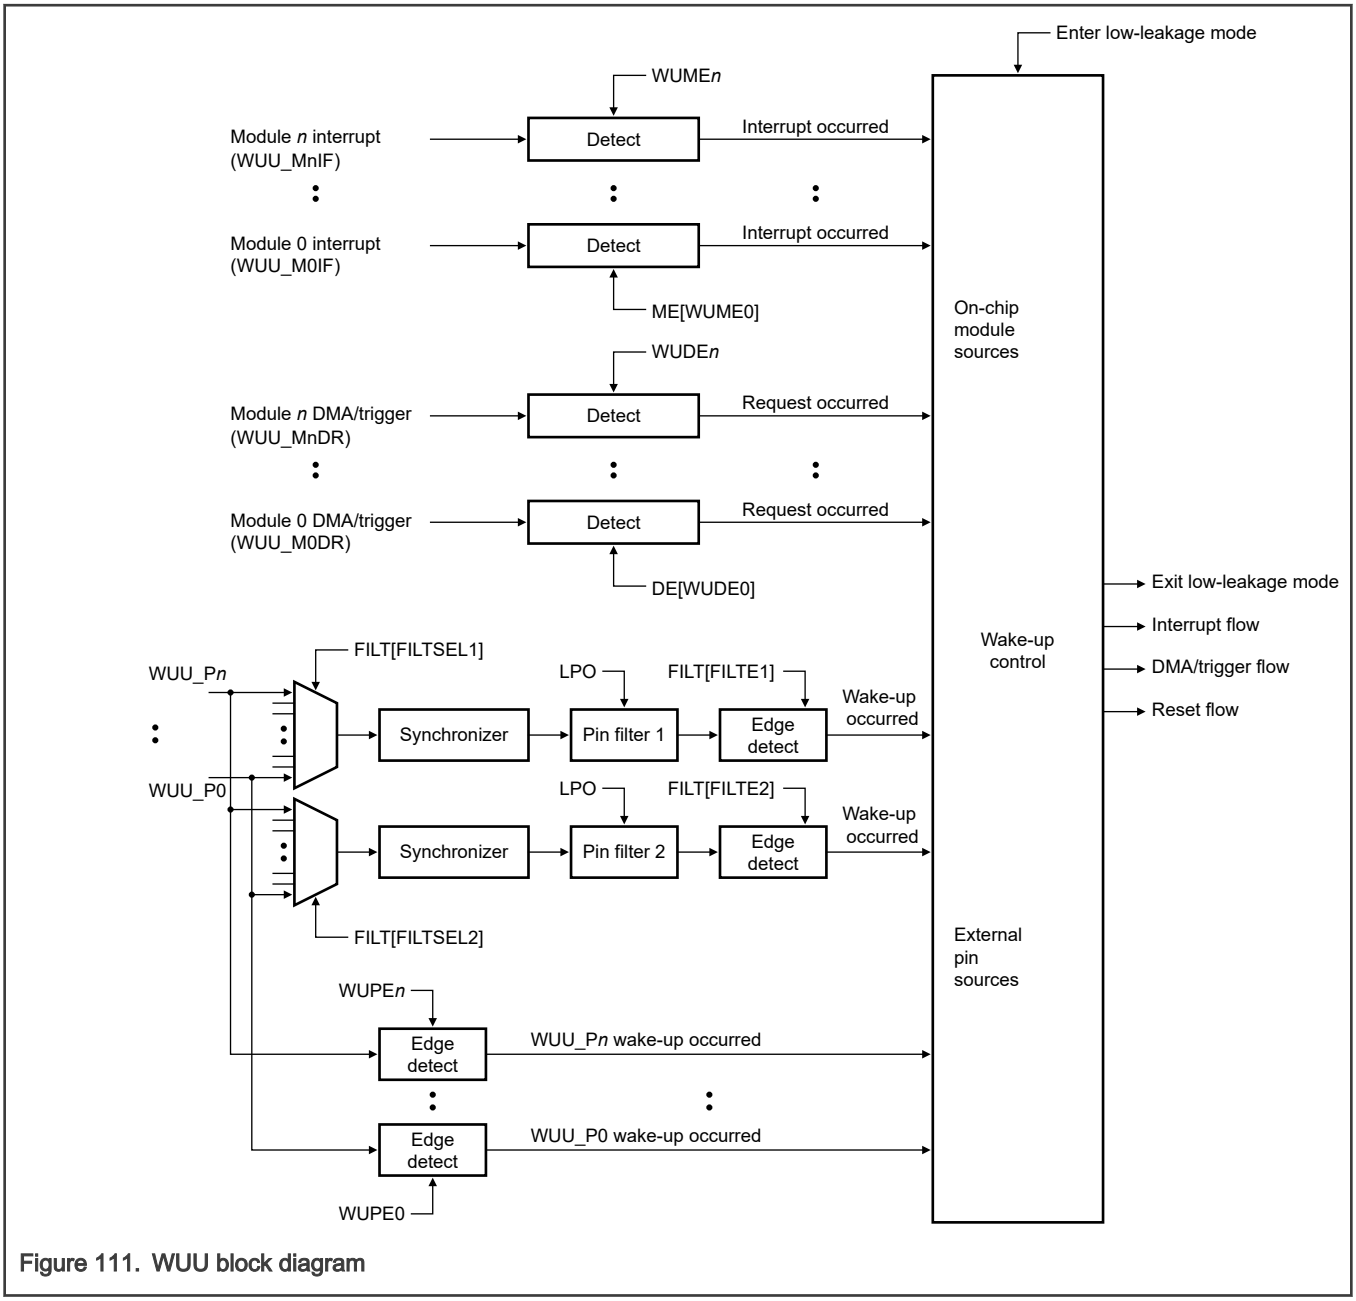

Figure 111. WUU block diagram

24.2.2 Features

- Supports external input pins and on-chip modules with individual enable bits to wake the chip from low-leakage modes.
- Contains input sources that may be external pins or from on-chip modules capable of running in Power Down or Deep Power Down power modes. See the chip-specific WUU information for the wake-up input sources for this chip.
- Supports configuring on-chip modules as DMA or trigger sources for temporary wake-up from Power Down mode.
- Supports configuring external pins as DMA request or trigger sources for temporary wake-up from Power Down mode.
- Provides external input pins programmable for falling-edge, rising-edge, or any edge detection.
- Provides optional digital filters to qualify an external pin detect. Disabling the LPO clock bypasses and disables filters.

- Filters all external input pins; but only 2 filters are available at a given time.
- Enables external input pin and filter detection in all power modes (not limited to Power Down/Deep Power Down power modes).

24.3 Functional description

24.3.1 Operation

WUU allows on-chip modules and external input pins as a source of wake-up from low-leakage modes.

WUU contains pin enables for each external pin and on-chip module. For each external pin, you can disable or select the edge type for the wake-up with the following options:

- Falling edge
- Rising edge
- Either edge

Exit due to a pin event triggers a WUU interrupt after wake-up is complete. When enabling an external pin as a wake-up source, configure the pin as an input pin. You can also configure a pin to generate an interrupt from a Power Down/Deep Power Down mode or a DMA/trigger request for temporary wake-up from Power Down mode. Detection logic for a pin can optionally remain enabled during all power modes using Pin Mode Configuration (PMC).

On the basis of the LPO clock, WUU implements optional 3-cycle glitch filters. Detected external pin must remain asserted until the enabled glitch filter times out. Additional latency of up to two cycles is due to synchronization, which results in a total of up to five cycles of delay before the detect circuit alerts the system to the wake-up event when the filter function is enabled. Two wake-up detect filters are available for selected external pins. Glitch filtering is not provided for the on-chip modules. You can configure a filter to generate an interrupt from Power Down/Deep Power Down mode or a DMA/trigger request for temporary wake-up from Power Down mode. Detection logic for a filter can optionally remain enabled during all power modes using Pin Filter Mode Configuration (FMC).

For on-chip module interrupts, ME[WUME*n*] enables the associated module interrupt as a wake-up source. Exit due to a module interrupt will not trigger a WUU interrupt.

For on-chip module DMA/trigger requests, DE[WUDE*n*] enables the associated module DMA/trigger request as a wake-up source. Exit due to a module DMA/trigger request does not trigger a WUU interrupt.

24.3.2 Modes of operation

WUU becomes functional on entry into a low-leakage power mode. After recovery from Power Down mode, WUU is immediately disabled. After recovery from Deep Power Down mode, WUU continues to detect wake-up events until you have reinitialized the system and deasserted isolation. Detection of external pin/filter events can also optionally remain enabled in all power modes using Pin Mode Configuration (PMC)/Pin Filter Mode Configuration (FMC).

24.3.2.1 Power Down mode

Wake-up events due to either an external pin input (WUU_Px) or an on-chip module interrupt (WUU_MxIF) result in a CPU interrupt flow to begin user code execution. The source of the wake-up determines the subsequent path of code execution:

- Pin events trigger the WUU interrupt service routine.
- Module interrupts trigger that same module's interrupt service routine.

NOTE

The interrupt controller must not mask the WUU interrupt to avoid a scenario where the system does not fully recover from Power Down mode after an external pin event.

Wake-up events due to an on-chip module request (WUU_MxDR) DMA/trigger request result in a temporary exit from Power Down mode to allow the request to be serviced when the CPU clock remains gated. The system reenters Power Down mode after servicing the request.

Wake-up events due to an external pin (WUU_Px) DMA/trigger request result in a temporary exit from Power Down mode to allow the request to be serviced when the CPU clock remains gated. The system reenters Power Down mode after servicing the request.

24.3.2.2 Non–low-leakage modes

WUU is inactive in all non–low-leakage modes, with the exception of external pin/filter detection which can explicitly be kept enabled during all power modes using Pin Mode Configuration (PMC)/Pin Filter Mode Configuration (FMC). WUU chips are accessible in non–low-leakage modes and are available for configuring and reading status when bus transactions are possible.

24.3.3 Clocking

During chip low-power operation, in order to provide the wake-up function for the chip, ensure that clocking is available for WUU by the LPO clock. See the chip-specific WUU information for the chip clock connection details.

24.3.4 Reset

WUU resets after VSYS Warm Reset. This is the global chip reset, but it does not include the reset that asserts due to wake-up from low-power mode.

24.3.5 Interrupts

You can enable on-chip module interrupts as wake-up sources in Module Interrupt Enable (ME).

24.3.6 DMA

You can enable on-chip DMA requests as wake-up sources in Module DMA/Trigger Enable (DE).

With external pin inputs, you can generate a DMA request using either rising edge, falling edge, or both edge detection in Pin DMA/Trigger Configuration 1 (PDC1) and Pin DMA/Trigger Configuration 2 (PDC2).

24.4 External signals

Table 304. External signals

Signal	Description	I/O
WUU_Pn	External pin wake-up inputs; can be enabled to detect a rising edge, a falling edge, or any change.	I
WUU_MnIF	On-chip module interrupt flags	I
WUU_MnDR	On-chip module DMA/trigger requests	I

24.5 Initialization

For an enabled module wake-up input, clear the module's flag before entering Power Down or Deep Power Down mode to avoid an immediate exit from the mode.

Clear the flags associated with external input pins, filtered and unfiltered, prior to entry to Power Down or Deep Power Down mode.

When an external wake-up pin filter is first enabled in Pin Filter (FILT), filter operation begins immediately. After enabling an external pin filter or changing its source pin, wait for at least five LPO clock cycles to allow the filter to initialize before entering Power Down or Deep Power Down mode or before enabling filter detection for all power modes in Pin Filter Mode Configuration (FMC).

NOTE

After recovering from a Deep Power Down mode, you must restore the chip configuration before relaxing any power domain isolation controls. In particular, to avoid any WUU flag from being falsely set, restore the pin configuration for the enabled WUU wake-up pins before removing any voltage isolation between power domains.

24.6 Application information

To enable an external pin as a wake-up source in low-power modes, follow these steps:

1. If the flag is not 0, write 1 to PF[WUF*n*].
2. Configure the PDC*m*[WUPDC*n*] as either an interrupt or DMA request.
3. Configure the PE*m*[WUPE*n*] for rising edge, falling edge, or both edge detection.

When you have configured an external pin to be an active wake-up source in all power modes (PMC[WUPMC*n*] = 1), you must not change the corresponding wake-up pin enable (PE*m*[WUPE*n*]) and wake-up pin configuration (PDC*m*[WUPDC*n*]) settings for that pin. To modify the PE*m*[WUPE*n*] or PDC*m*[WUPDC*n*] settings, follow these steps:

1. Write 0 to PMC[WUPMC*n*] for that pin.
2. Update the corresponding PE*m*[WUPE*n*] or PDC*m*[WUPDC*n*] settings as needed.
3. Write 1 to PMC[WUPMC*n*] for that pin.

24.7 Memory map and register definition

This section includes the WUU module memory map and detailed descriptions of all registers.

24.7.1 WUU register descriptions

NOTE

You can write to WUU registers only in Supervisor mode. A bus error results from write accesses in User mode.

VSYS Warm Reset resets all WUU registers.

24.7.1.1 WUU memory map

WUU0 base address: 4004_6000h

24.7.1.5 Pin Enable 2 (PE2)

Offset

Register	Offset
PE2	Ch

Function

Contains the field to enable and select the edge detect type for the available external wake-up input pins in the range from WUU_P16 to WUU_P31.

NOTE

- Do not modify the value of PE2[WUPE*n*] when its corresponding PMC[WUPMC*n*] = 1.
- VSYS Warm Reset resets this register.

24.7.1.8 Pin Flag (PF)

Offset

Register	Offset
PF	20h

Function

Contains the wake-up flags indicating which wake-up source caused the chip to exit Power Down (if the corresponding PMC[WUPMC*n*] = 1) or Deep Power Down mode. For Power Down mode, this is the source causing the CPU interrupt flow. For Deep Power Down mode, this is the source causing the chip reset flow.

To clear a flag, write a 1 to the corresponding PF[WUF*n*]. If set, the wake-up flag (WUF*n*) remains set even if the associated pin wake-up is disabled in its PE*m*[WUPE*n*] field.

NOTE

VSYS Warm Reset resets this register.

24.7.1.10 Pin DMA/Trigger Configuration 1 (PDC1)

Offset

Register	Offset
PDC1	38h

Function

Configures the available external wake-up input pins in the range from WUU_P0 to WUU_P15 to generate an interrupt, DMA, or a trigger request when detected.

- When configured as an interrupt, the interrupt is asserted when the edge programmed in Pin Enable 1 (PE1) is detected and remains asserted until the corresponding flag is cleared in Pin Flag (PF).
- When configured as a DMA request, the request is asserted when the edge programmed in Pin Enable 1 (PE1) is detected and remains asserted until either the corresponding flag is cleared in Pin Flag (PF) or until the requested DMA transfer is complete.
- When configured as a trigger request, the trigger is asserted when the level programmed in Pin Enable 1 (PE1) is detected and remains asserted when the input pin is asserted. The corresponding flag in Pin Flag (PF) will not be set.

NOTE

- Do not modify the value of PDC*m*[WUPDC*n*] field when its corresponding PMC[WUPMC*n*] = 1.
- VSYS Warm Reset resets this register.

24.7.1.12 Pin Filter DMA/Trigger Configuration (FDC)

Offset

Register	Offset
FDC	48h

Function

Configures the external pin filters to generate an interrupt, DMA, or a trigger request when detected.

- When configured as an interrupt, the interrupt is asserted when the edge programmed in FILT*m*[FILTE*n*] is detected and remains asserted until the corresponding FILTF*n* flag is cleared.
- When configured as a DMA request, the request is asserted when the edge programmed in FILT*m*[FILTE*n*] is detected and remains asserted until either the corresponding FILTF*n* flag is cleared or until the requested DMA transfer is complete.
- When configured as a trigger request, the trigger is asserted when the level programmed in Pin Filter (FILT) is detected and remains asserted when the input pin is asserted. The corresponding FILTF*n* flag will not be set.

NOTE

VSYS Warm Reset resets this register.

Chapter 25
Event Generator (EVTG)

25.1 Chip-specific EVTG information

Table 305. Reference links to related information

Topic	Related module	Reference
Full description	EVTG	EVTG
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing
Input multiplexing	INPUTMUX	See EVTG_TRIGn registers in INPUTMUX

25.1.1 Module instances

This device contains one instance of the EVTG module, EVTG0.

25.2 Overview

EVTG includes two parts:

- Two AND/OR/INVERT (known as the AOI) modules
- One configurable flip-flop

It supports the generation of a configurable number of Event signals. The two AOI combinational expressions share the four associated EVTG inputs: An, Bn, Cn, and Dn. You can configure the flip-flop to make the two expressions act as the Reset port, Set port or D port, CLK port or go through to EVTG output with the flip-flop bypassed.

This module is a slave peripheral module-connecting event input indicators from various chip modules and generates event output signals that you can route to an inter-peripheral crossbar switch or other peripherals. You can access its programming model through the standard IPS (sky blue) slave interface. EVTG is configurable in the integrated AOI functionality and flip-flop variety.

25.2.1 Block diagram

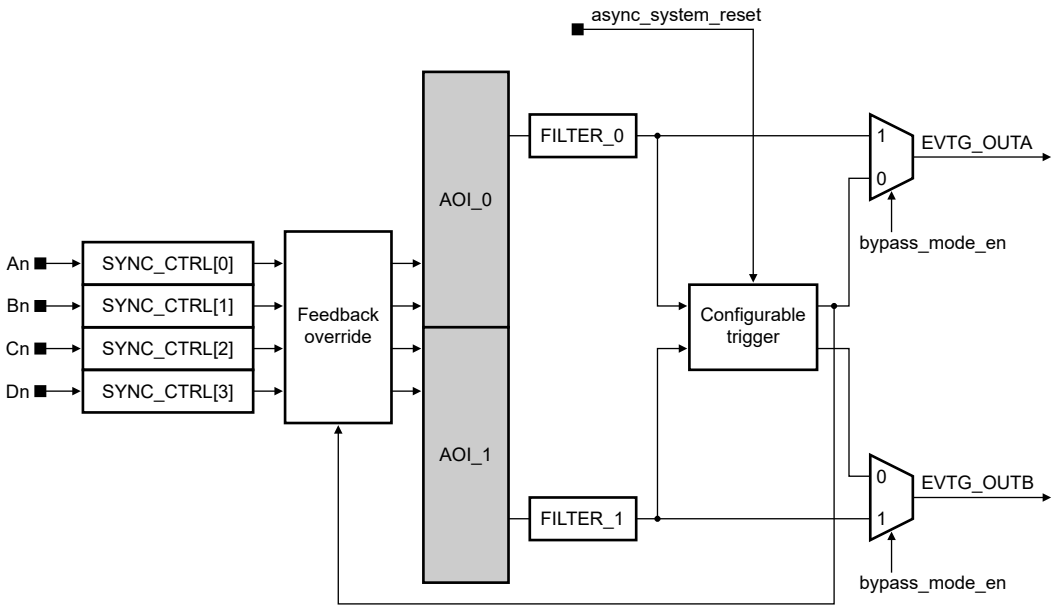

Figure 112. Block diagram

25.2.2 Features

- Includes a highly programmable module for creating combinational boolean events
  - Each EVTG consists of four inputs and two outputs.
  - Each AOI evaluates a combinational boolean expression as the sum of four products, where each product term includes all four selected input sources available as true or complement values.
  - Each EVTG consists of two groups of AOI to generate two combinational expressions.
  - The two outputs can operate as hardware trigger signals or for other purposes.
- Configures one flexible FF as RS, D-FF, T-FF, JK-FF, and Latch
- Includes a programmable filter to remove AOI output glitch
- Specifies that all logics are synchronous in bus clk domain
- Includes a memory-mapped chip connected to the slave peripheral (IPS) bus. Programming model is organized per channel for a simplified software.

25.3 Functional description

The following sections describe functional details of EVTG.

NOTE

n in EVTG*n* denotes the number of EVTG blocks.

25.3.1 Input sync and filter logic description

EVTG supports sync to EVTG inputs and filter function to AOI output.

Both features are disabled by default. To enable input sync function, configure EVTG*n*_CTRL[SYNC_CTRL], or to enable AOI filter function, configure a non-zero value to EVTGn_AOIm_FILT[FITL_PER].

The application scenario for both is different. The input sync feature makes EVTG input sync for two bus clock cycles. Remove the glitch whose width is less than a bus clock period. Because the Filter_Delay is "[(FILT_CNT + 3) x FILT_PER + 2]*(period of bus_clk)", any signal whose width is less than this value is filtered.

NXP recommends enabling just one among both features, and which one depends on the use case.

You can also enable both functions. For some use cases in Bypass mode and RS Trigger mode, both functions have to be disabled. Except for this scenario, NXP recommends enabling at least one input sync and filter.

25.3.2 Flip-flop modes

EVTG inside implements different kinds of flip-flops to generate the desired EVTG output. You can configure the flip-flop as Bypass mode, RS Trigger mode, T-FF mode, D-FF mode, JK-FF mode, and Latch mode.

25.3.2.1 Bypass mode

Bypass mode is selected when you configure EVTG*n*_CTRL[MODE_SEL] as 0h. So Bypass mode is used as a default mode.

In this mode:

- Flip-flop is passed, and directly assigns the two AOI expressions "AOI_0" and "AOI_1" to EVTG outputs (EVTG_OUTA and EVTG_OUTB).
- You can enable or disable input sync logic and filter function.

The following diagram shows the disabled case (input sync and filter are removed from the diagram).

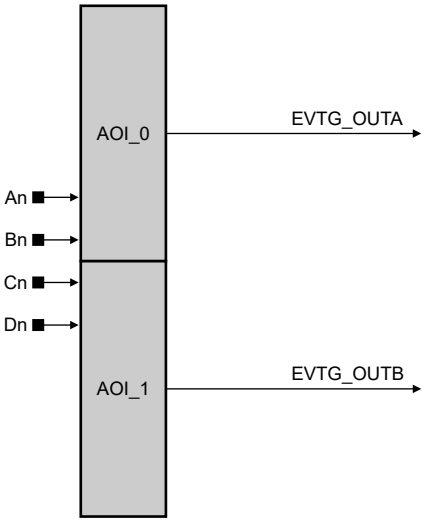

Figure 113. Bypass mode

25.3.2.2 RS Trigger mode

When you configure EVTG*n*_CTRL[MODE_SEL] as 1h, RS Trigger mode is selected.

In this mode the AOI_0 expression is Reset port, and AOI_1 is Set port. Both are active high. When R (Reset) is high, whatever S (Set) is, EVTG_OUTA = 0. When R is low, and S is high, EVTG_OUTA = 1. If both R and S are low, EVTG output is retained (see Figure 114).

EVTG_OUTB is always the complement of EVTG_OUTA.

In this mode, you can enable or disable the input sync logic and filter function. The following diagram shows the disabled case (input sync and filter are removed from the following diagram).

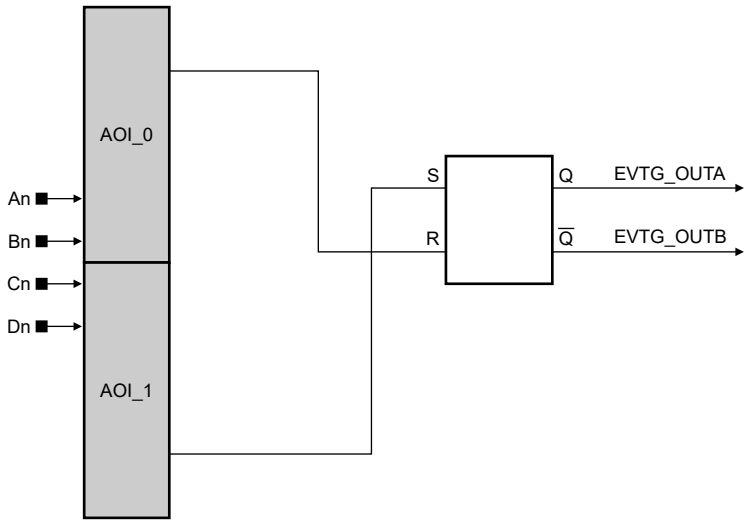

Figure 114. RS Trigger mode

25.3.2.3 T-FF mode

T-FF mode is selected when you configure EVTG*n*_CTRL[MODE_SEL] as 2h.

In this mode, the AOI_0 expression is T port of T-FF, and the AOI_1 is CLK port. When T asserts, the Q port (EVTG_OUTA) turnovers at the rising edge of CLK. When T de-asserts, Q (EVTG_OUTA) is retained (see Figure 115).

EVTG_OUTB is always the complement of EVTG_OUTA.

In this mode, you must enable input sync or filter to remove the possible glitch.

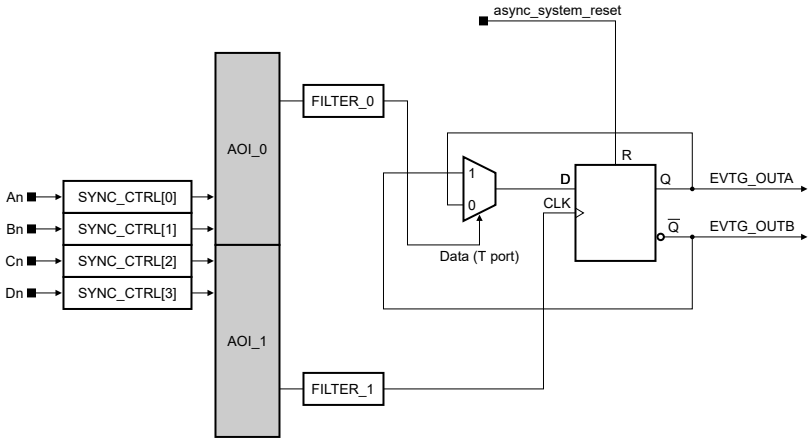

Figure 115. T-FF mode

25.3.2.4 D-FF mode

D-FF mode is selected when you configure EVTG*n*_CTRL[MODE_SEL] as 3h.

In this mode, the AOI_0 expression is the D port of D-FF and the AOI_1 expression is CLK port. At the rising edge of CLK, capture D to Q (EVTG_OUTA) (see Figure 116).

EVTG_OUTB is always the complement of EVTG_OUTA.

In this mode, you must enable input sync or filter to remove the possible glitch.

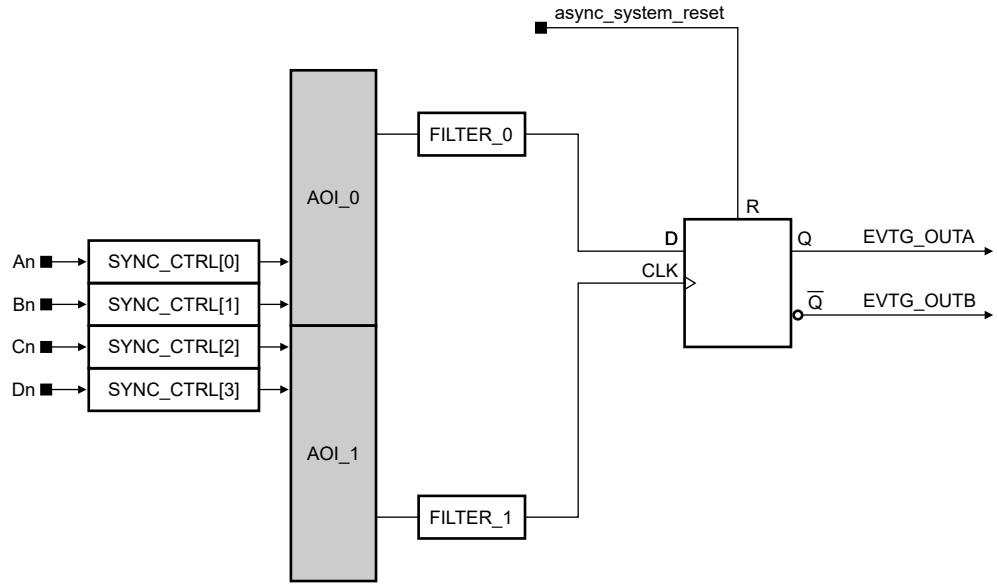

Figure 116. D-FF mode

25.3.2.5 JK-FF mode

In general, JK flip-flop has four input ports: J, K, Q, and CLK (Q is the output of the flip-flop), and the logical expression is "J&~Q | ~K&Q."

JK-FF mode is selected when you configure EVTG*n*_CTRL[MODE_SEL] as 4h.

Here you can implement the logic expression by AOI so that you can reuse the D-FF to implement JK-FF. Consider the following sample EVTG configuration, which Figure 117 also shows:

- An is a J port.
- Cn is a K port.
- Dn is a CLK port.
- Q port is FF feedback and override Bn.

According to the JK logic expression, the AOI_0 expression is "An&~Bn | Bn&~Cn," and the AOI_1 expression is "Dn." So the corresponding register configuration should be:

EVTGn_AOI0_BFT01 = 01101111_11011011;

EVTGn_AOI0_BFT23 = 00000000_00000000;

EVTGn_AOI1_BFT01 = 11111101_00000000;

EVTGn_AOI1_BFT23 = 00000000_00000000;

EVTGn_CTRL = 00001111_01010000; (EVTG*n*_CTRL[FB_OVRD] = 01)

EVTG*n*_CTRL[FB_OVRD] represents, which EVTG input the FF output (EVTG_OUTA) replaces. In this case, Bn is replaced, this is why EVTG*n*_CTRL[FB_OVRD] = 01.

In this mode, you must enable input sync or filter to remove the possible glitch.

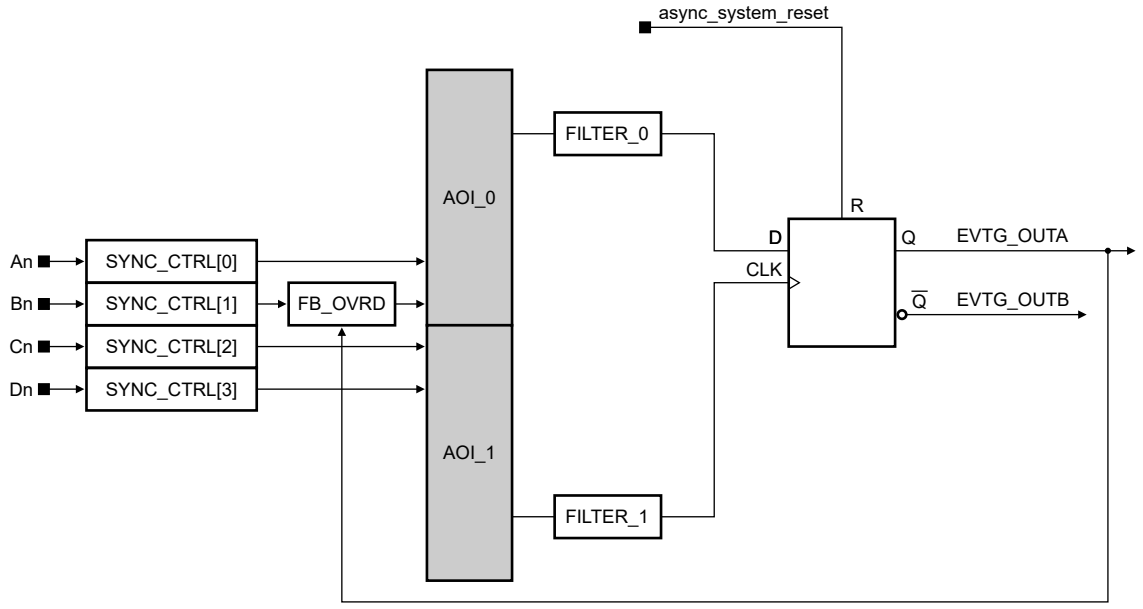

Figure 117. JK-FF mode

25.3.2.6 Latch mode

Latch mode is selected when you configure EVTG*n*_CTRL[MODE_SEL] as 5h.

In this mode, the AOI_0 expression is D port, and AOI_1 is CLK port. Different from D-FF mode, in Latch mode, D port is passed only when CLK is high, and output is retained when CLK is low.

EVTG_OUTB is always the complement of EVTG_OUTA.

In this mode, you must enable input sync or filter to remove the possible glitch.

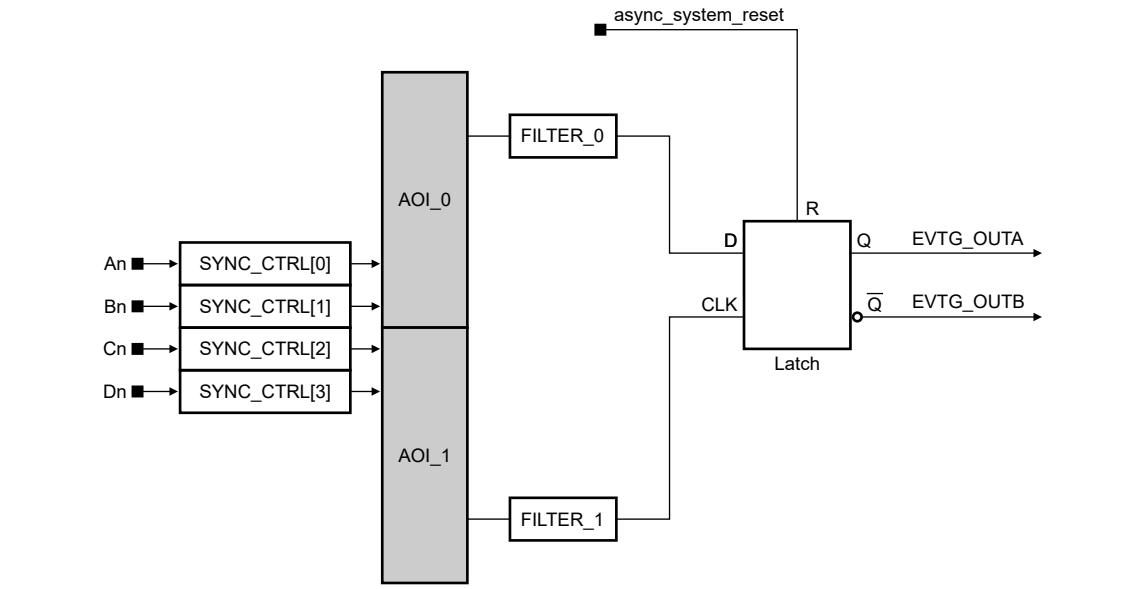

Figure 118. Latch mode

25.3.3 EVTG timing between inputs and outputs

- For Bypass mode and RS Trigger mode with input sync and filter disabled, there is no delay between inputs and outputs.
- For the modes with input sync and filter function enabled, the delay between input and output is:

  Sync_Delay: 2

  Flip-Flop_Delay: 1

  Filter_Delay: (FILT_CNT + 3) x FILT_PER + 2

  Whole_Delay = ((FILT_CNT + 3) x FILT_PER + 2) + 3

  In this case, all signals are synchronous in bus clk.

25.3.4 Clocks

EVTG includes only bus clock.

25.4 External signals

EVTG includes no external I/O signals.

25.5 Application information

This section describes applications that EVTG supports.

25.5.1 Configuration examples for AOI combinational function

This section describes the examples of the programming model configuration for simple boolean expressions.

AOI module provides a universal boolean function generator using a four-term sum of products expression with each product term containing true or complement values of the four selected event inputs (A, B, C, D). Specifically, the EVTG output is defined by the following “4 x 4” boolean expression:

EVTGn_AOIm(m =0,1)

= (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 0

| (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 1

| (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 2

| (0,An,~An,1) & (0,Bn,~Bn,1) & (0,Cn,~Cn,1) & (0,Dn,~Dn,1)// product term 3

You can configure each selected input term in each product term to produce a logical 0 or 1 or pass the true or complement of the selected event input. Each product term uses eight bits of configuration information, two bits for each of the four selected event inputs. The actual boolean expression implemented in each channel is:

EVTGn_AOIm(m=0,1)

= (PT0_AC[0] & A | PT0_AC[1] & ~A)// product term 0

& (PT0_BC[0] & B | PTO_BC[1] & ~B)

& (PT0_CC[0] & C | PTO_CC[1] & ~C)

& (PT0_DC[0] & D | PTO_DC[1] & ~D)

| (PT1_AC[0] & A | PT1_AC[1] & ~A)// product term 1

& (PT1_BC[0] & B | PT1_BC[1] & ~B)

& (PT1_CC[0] & C | PT1_CC[1] & ~C)

& (PT1_DC[0] & D | PT1_DC[1] & ~D)

| (PT2_AC[0] & A | PT2_AC[1] & ~A)// product term 2

& (PT2_BC[0] & B | PT2_BC[1] & ~B)

& (PT2_CC[0] & C | PT2_CC[1] & ~C)

& (PT2_DC[0] & D | PT2_DC[1] & ~D)

| (PT3_AC[0] & A | PT3_AC[1] & ~A)// product term 3

& (PT3_BC[0] & B | PT3_BC[1] & ~B)

& (PT3_CC[0] & C | PT3_CC[1] & ~C)

& (PT3_DC[0] & D | PT3_DC[1] & ~D)

The following table shows the settings of the 32-bit registers for several simple boolean expressions.

Table 306. EVTGn_AOIm_BFT(m=0,1) values for simple boolean expressions

Event output expression	PT0	PT1	PT2	PT3	{EVTGn_AOIm_BFT01, EVTGn_AOIm_BFT23}
A&B	A&B	0	0	0	01011111_00000000_00000000_00000000
A&B&C	A&B&C	0	0	0	01010111_00000000_00000000_00000000
(A&B&C) | D	A&B&C	D	0	0	01010111_11111101_00000000_00000000
A|B|C|D	A	B	C	D	01111111_11011111_11110111_11111101
(A & ~B) | (~A & B)	A & ~B	~A & B	0	0	01101111_10011111_00000000_00000000

These examples show that the resulting logic provides a simple yet powerful boolean function evaluation for defining an AOI output.

25.6 Memory map and register definition

According to the DSC core, EVTG is also word addressed, where a word is 16 bits. Functionality for accesses of other widths is undefined.

1-0 PT3_DC	Product Term 3, D Input Configuration Defines the boolean evaluation associated with the selected input D in product term 3. 00b - Force the D input in this product term to a logical zero 01b - Pass the D input in this product term 10b - Complement the D input in this product term 11b - Force the D input in this product term to a logical one

25.6.1.6 Control and Status (EVTG0_CTRL - EVTG3_CTRL)

Offset

Register	Offset
EVTG0_CTRL	Ah
EVTG1_CTRL	1Ah
EVTG2_CTRL	2Ah
EVTG3_CTRL	3Ah

Function
Contains control and status register for EVTG.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved		FORCE_BYPASS		SYNC_CTRL				FB_OVRD		Reserved	MODE_SEL			0	FF_INIT
W															INIT_EN	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-14 —	Reserved
13-12 FORCE_BYPASS	Force Bypass Control When MODE_SEL is set JK-FF mode, we should not enable FORCE_BYPASS, becasue the FB_OVRD will affect output 0xb - Will not force the bypass 1xb - Whatever MODE_SEL is, will force bypass flip-flop and route the AOI_1(Filter_1) value directly to EVTG_OUTB x0b - Will not force the bypass x1b - Whatever MODE_SEL is, will force bypass flip-flop and route the AOI_0(Filter_0) value directly to EVTG_OUTA
11-8 SYNC_CTRL	Synchronize Control Specifies EVTG inputs synchronous with bus clk. 0xxxb - EVTG input "Dn" will not be synced 1xxxb - EVTG input "Dn" will be synced by two bus clk cycles x0xxb - EVTG input "Cn" will not be synced x1xxb - EVTG input "Cn" will be synced by two bus clk cycles xx0xb - EVTG input "Bn" will not be synced xx1xb - EVTG input "Bn" will be synced by two bus clk cycles xxx0b - EVTG input "An" will not be synced xxx1b - EVTG input "An" will be synced by two bus clk cycles
7-6 FB_OVRD	EVTG Output Feedback Override Control Requires EVTG_OUTA feedback to EVTG input and replaces one of the four inputs, when EVTG*n*_CTRL[MODE_SEL] is configured as JK-FF mode. 00b - Replace An 01b - Replace Bn 10b - Replace Cn

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - Replace Dn
5 —	Reserved
4-2 MODE_SEL	Flip-Flop Mode Selection Selects the flip-flop modes. 000b - Bypass mode 001b - RS Trigger mode 010b - T-FF mode 011b - D-FF mode 100b - JK-FF mode 101b - Latch mode 110b - Reserved 111b - Reserved
1 INIT_EN	Flip-Flop Initial Output Enable Control Forces the value of EVTG*n*_CTRL[FF_INIT] to present on flip-flop positive output. Write a 1 to this field to generate an enable pulse. Read this field returns 0. This field must become 1 after EVTG*n*_CTRL[FF_INIT] = 1. 0b - Write 0 does not generate enable pulse 1b - Write 1 generates enable pulse
0 FF_INIT	Flip flop Initial Value Configuration Configures the positive output of flip-flop either as 0 or 1. FF_INIT does not take effect until you write "1" into EVTG*n*_CTRL[INIT_EN]. This field must become 1 before EVTG*n*_CTRL[INIT_EN] = 1. 0b - 0 1b - 1

25.6.1.7 AOI0 Output Filter (EVTG0_AOI0_FILT - EVTG3_AOI0_FILT)

Offset

Register	Offset
EVTG0_AOI0_FILT	Ch
EVTG1_AOI0_FILT	1Ch

Table continues on the next page...

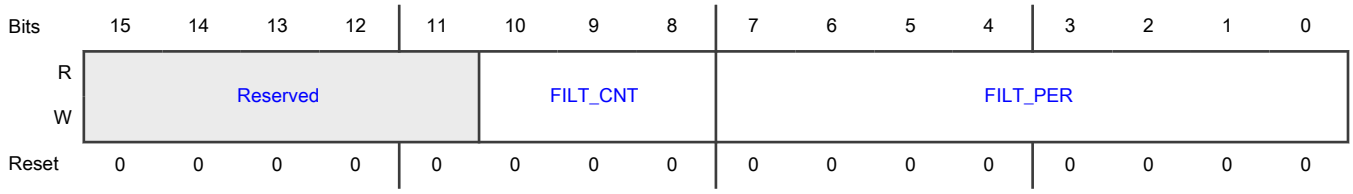
Table continued from the previous page...

Register	Offset
EVTG2_AOI0_FILT	2Ch
EVTG3_AOI0_FILT	3Ch

Function

Contains AOI0 output filter control register.

Diagram



Fields

Field	Function
15-11 —	Reserved
10-8 FILT_CNT	Output Filter Sample Count Represents the number of consecutive samples that must agree before the output filter accepts an input transition. The value of FILT_CNT affects the input latency.
7-0 FILT_PER	Output Filter Sample Period Represents the input signals' sampling period (in IP bus clock cycles). Each input is sampled multiple times at the rate specified by this field. If FILT_PER is 00h (default), then the output filter is bypassed. The value of FILT_PER affects the input latency. When changing values for FILT_PER from one non-zero value to another non-zero value, write zero first to clear the filter.

25.6.1.8 AOI1 Output Filter (EVTG0_AOI1_FILT - EVTG3_AOI1_FILT)

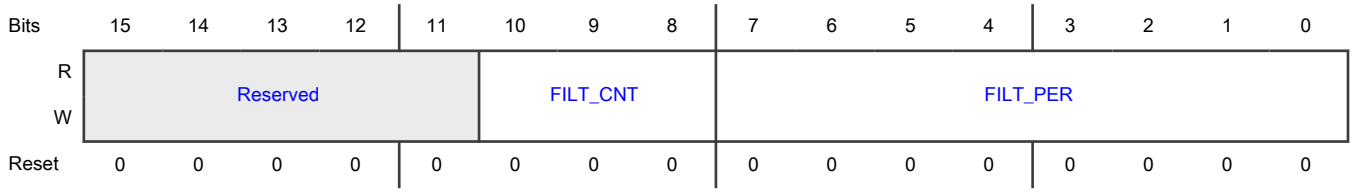
Offset

Register	Offset
EVTG0_AOI1_FILT	Eh
EVTG1_AOI1_FILT	1Eh
EVTG2_AOI1_FILT	2Eh
EVTG3_AOI1_FILT	3Eh

Function

Contains AOI1 output filter control register.

Diagram



Fields

Field	Function
15-11 —	Reserved
10-8 FILT_CNT	Output Filter Sample Count Represents the number of consecutive samples that must agree before the output filter accepts an output transition. The value of FILT_CNT affects the input latency.
7-0 FILT_PER	Output Filter Sample Period Represents the output signals' sampling period (in IP bus clock cycles). Each output is sampled multiple times at the rate which this field specifies. The output filter is bypassed if FILT_PER is 00h (default). The value of FILT_PER affects the output latency. When you change the values of this field from one non-zero to another non-zero value, first write zero to clear the filter.

Chapter 26
Input Multiplexing (INPUTMUX)

26.1 Chip-specific INPUTMUX information

Table 307. Reference links to related information

Topic	Related module	Reference
Full description	INPUTMUX	INPUTMUX
Peripheral memory map		PBRG memory map

Once set up, no clocks are required for the input multiplexer to function. The system clock is needed only to write to or read from the INPUTMUX registers. Once the input multiplexer is configured, disable the clock to the INPUTMUX module in the AHBCLKCTRL register.

26.1.1 Module instances

This device contains one instance of the INPUTMUX module, INPUTMUX0.

26.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

26.2 Overview

The Input Multiplexing module (INPUTMUX) provides signal routing options for internal peripherals. Some peripheral inputs are multiplexed to multiple input sources. The sources can be external pins, interrupts, output signals of other peripherals, or other internal signals.

NOTE

Depending on the package, not all inputs from external pins may be available.

26.2.1 Block Diagram

Figure 119 shows a generic input multiplexer arrangement with n inputs.

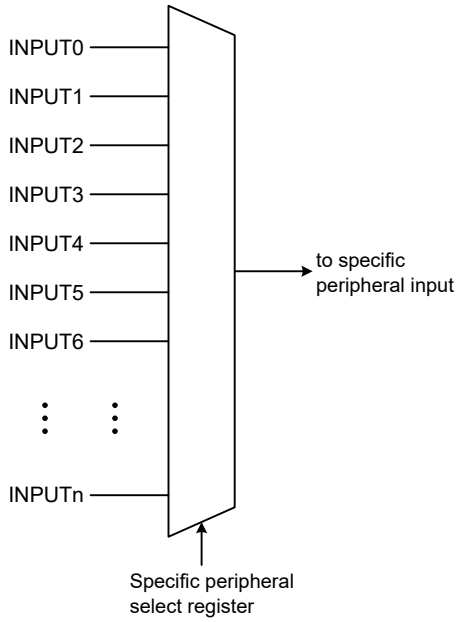


Figure 119. Generic input multiplexing

26.2.2 Features

- Configures the inputs to the SCTIMER.
- Configures the inputs to the asynchronous CTimers.
- Configures the inputs to the Pin Interrupt and Pattern Match (PINT).
- Configures the inputs to CMP, ADC, DAC, QDC, PWM, PWM EXT clock, AOI, TRIG_OUT pins.
- Configures the inputs to the Frequency Measurement (FREQME).

26.3 Functional description

The INPUTMUX implements a number of input multiplexers that select one of many inputs to be routed to a specific input signal for a given peripheral. This is used to allow user configuration of data paths between internal modules and/or external pins on the device. For every module input (output from the INPUTMUX), there is a register that selects the input to use, where the register name and description provide details on the module input controlled by each register. The input signal/pin options for each of the muxes are configurable, and can vary from mux to mux. Refer to the register descriptions for the details on the input signal/pin options used for each INPUTMUX output in Memory map and register definition.

26.4 External signals

The INPUTMUX has no dedicated pins. Multiplexer inputs from external pins work independently of any other function assigned to the pin as long as no analog function is enabled.

26.5 Memory map and register definition

This section includes the INPUTMUX module memory map and detailed descriptions of all registers.

26.5.1 INPUTMUX register descriptions

26.5.1.1 INPUTMUX memory map

26.5.1.2 Inputmux Register for SCT0 Input (SCT0_INMUX0 - SCT0_INMUX7)

Offset

For a = 0 to 7:

Register	Offset
SCT0_INMUXa	0h + (a × 4h)

Function

This register selects one input source for each SCT0 input from 24 external and internal sources. (An exception is SCT0 input SCT0_INMUX7, which is directly connected to SCTASYNCCLK (output of SCT clock divider) PLL clock and not multiplexed with any other signals).The output of SCT0 Input multiplexing register 0 selects the source for SCT0 input 0. The output of SCT0 Input multiplexing register 1 selects the source for SCT0 input 1, and so forth up to SCT0 Input multiplexing register 6, which selects the input for SCT0 input 6.

26.5.1.3 Capture Select Register for CTIMER Inputs (CTIMER0CAP0 - CTIMER2CAP3)

Offset

For a = 0 to 2; b = 0 to 3:

Register	Offset
CTIMERaCAPb	20h + (a × 20h) + (b × 4h)

Function

For each of the 5 standard timers, numbered i = 0 to 4 there are 4 CTIMERiCAPTj, with j = 0 to 3, each allowing selecting between 25 external or internal input sources. The output of TIMER0CAPT0 Input multiplexing register 0 selects the source for TIMER0 capture input 0. The output of TIMER0CAPT1 Input multiplexing register 1 selects the source for TIMER0 capture input 1, and so forth up to TIMER4CAPT3. Input multiplexing register 3, which selects the input for TIMER4 capture input 3.

1. SYS_IRQ combines the CDOG IRQ, WWDT IRQ, MBC secure violation IRQ, Secure AHB Matrix secure violation IRQ, GDET IRQ, ELS S50 error IRQ, PKC error IRQ, and VBAT IRQ using the logical OR operation.

26.5.1.6 Pin Interrupt Select (PINTSEL0 - PINTSEL7)

Offset

For a = 0 to 7:

Register	Offset
PINTSELa	C0h + (a × 4h)

Function

Each of these eight registers selects one pin from among ports 0 and 1 as the source of a pin interrupt or as the input to the pattern match engine. To select a pin for any of the 8 pin interrupts or pattern match engine inputs, write the GPIO port pin number as 0 to 31 for pins P0_0 to P0_31 to the INP bits. Port 1 pins correspond to pin numbers 32 to 63. For example, setting INP to 0x5 in PINTSEL0 selects pin P0_5 for pin interrupt 0. To determine the GPIO port pin number for a given device package, see the pin description table in the data sheet.

26.5.1.9 Capture Select Register for CTIMER Inputs (CTIMER3CAP0 - CTIMER4CAP3)

Offset

For a = 3 to 4; b = 0 to 3:

Register	Offset
CTIMERaCAPb	140h + (a × 20h) + (b × 4h)

Function

For each of the 5 standard timers, numbered i = 0 to 4 there are 4 CTIMERiCAPTj, with j = 0 to 3, each allowing selecting between 25 external or internal input sources. The output of TIMER0CAPT0 Input multiplexing register 0 selects the source for TIMER0 capture input 0. The output of TIMER0CAPT1 Input multiplexing register 1 selects the source for TIMER0 capture input 1, and so forth up to TIMER4CAPT3 Input multiplexing register 3, which selects the input for TIMER4 capture input 3.

26.5.1.40 EXT Trigger Connections (EXT_TRIG0 - EXT_TRIG7)

Offset

For a = 0 to 7:

Register	Offset
EXT_TRIGa	4C0h + (a × 4h)

Function

The EXT_TRIGa regsiters select the source of TRIG_OUTa pins.

26.5.1.78 DMA1 Request Enable1 (DMA1_REQ_ENABLE1_TOG)

Offset

Register	Offset
DMA1_REQ_ENABLE1_TOG	79Ch

Function

Writing a 1 to REQ_EN1 in this register toggles the corresponding bit in DMA1_REQ_ENABLE1.

NOTE

The AHB ID in AHB bus matrix ports table is the Domain ID.

27.1.1 Module instances

This device contains one instance of the Semaphore module, SEMA42_0.

27.2 Overview

SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single - write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

27.2.1 Block diagram

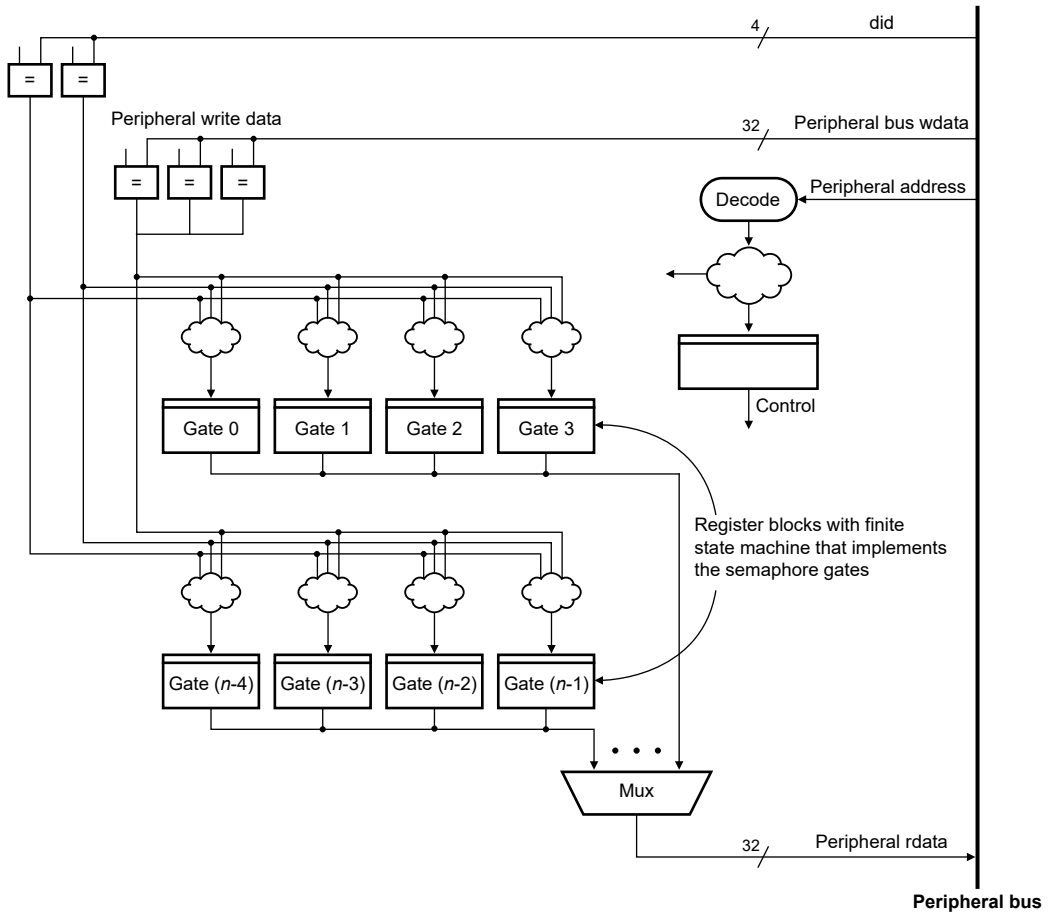

Figure 120. SEMA42 block diagram

27.2.2 Features

SEMA42 implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Support for 16 hardware-enforced gates in a multi-domain configuration that supports up to 15 domains.
- Each hardware gate appears as a 16-state, 4-bit state machine.
- Support for secure reset mechanisms to clear the contents of individual gates, as well as a clear-all capability.
- Memory-mapped slave peripheral that offers programming-model accesses.

27.3 Functional description

The intent of the hardware gate implementation is to specify a protocol where the locking domain must unlock the gate. However, some systems may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset. To support this special gate reset requirement, SEMA42 implements a secure reset mechanism that allows you to initialize a hardware gate (or all the gates) by following a specific dual-write access pattern. The secure-gate reset:

- Uses a technique similar to that required for the servicing of a software watchdog timer
- Requires two consecutive writes with pre-defined data patterns from the same domain

You must do this to force the clearing of the specified gate(s). The required access pattern as follows:

1. A domain performs a 16-bit write to the RSTGT memory location. The most significant byte (RSTGT_W[RSTGDP]) must be E2h. The value of least significant byte is irrelevant for this reference and can be anything.
2. The same domain then performs a second 16-bit write to the RSTGT location. For this write, the upper byte (RSTGT_W[RSTGDP]) is the logical complement of the first data pattern (1Dh) and the lower byte (RSTGT_W[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate or all gates to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, SEMA42 aborts the special gate reset sequence and does not assert an error signal.
3. Reads of the RSTGT location return information on the 2-bit reset state machine (RSTGT_R[RSTGSM]) that implements these functions:
   - The domain performing the reset (RSTGT_R[RSTGMS])
   - The last-cleared gate number(s) (RSTGT_R[RSTGTN])

   Reads of the RSTGT register do not affect the secure-reset finite state machine in any manner.

27.3.1 Multi-core programming: software gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism for system software to control access to shared data structures, shared hardware resources, and so on. The software uses the gating mechanisms to serialize (and synchronize) accesses to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and domains.

Consider the following description of a typical use-case: domain*X* enters a section of code, where shared data values are to be updated. The domain must first acquire a semaphore. Think of this as the locking (or closing) of a software gate. After the gate locks, a properly-architected software system does not allow other processes (or domains) to execute the same code segment or modify the shared data structure protected by the gate. In other words, the system locks out other processes/domains. Many software implementations include a spin-wait loop within the lock function until the gate locks. After domain X obtains the lock, domain X continues execution and updates the data values protected by the particular lock. After domain X completes the updates, it unlocks (or opens) the software gate, allowing other processes/domains access to the updated data values.

A correctly-implemented system solution must follow these important rules:

- A gate variable must protect all writes to shared data values or shared hardware resources.
- After a domain locks a gate, the system must block other processes/domains from accessing the shared data or resources. Software conventions enforce this.
- The domain that locks a particular gate is the only domain that can open (unlock) that gate.

Information in the hardware gate identifying the locking domain can be extremely useful for system-level debugging.

27.3.2 16 Hardware-enforced gates

Gates appear as a 16-entry byte-size array with read and write accesses.

Domains lock gates by writing "domainID_number+1" to the appropriate gate and must read back the gate value to verify that the lock operation succeeded.

After the gate locks, the locking domain unlocks the gate by writing zeroes.

- 16-state implementation

  If gate = 0h, then state = unlocked

  if gate = 1h, then state = locked by domain (master) 0

  if gate = 2h, then state = locked by domain (master) 1

  …

  if gate = Fh, then state = locked by domain (master) 14

SEMA42 uses the logical domain number and the specified data patterns as reference attributes to validate all write operation.

After a gate locks, the locking domain must unlock the gate by writing zeroes.

27.3.3 State machine of the GATE*n* registers

This section describes more about the SEMA42 functional operation and specific details of the state machines of the GATE*n* registers.

As described previously, each of the GATE*n* registers implements a 4-bit, 16-state machine. The following figure shows a simplified diagram of the state transitions for each gate.

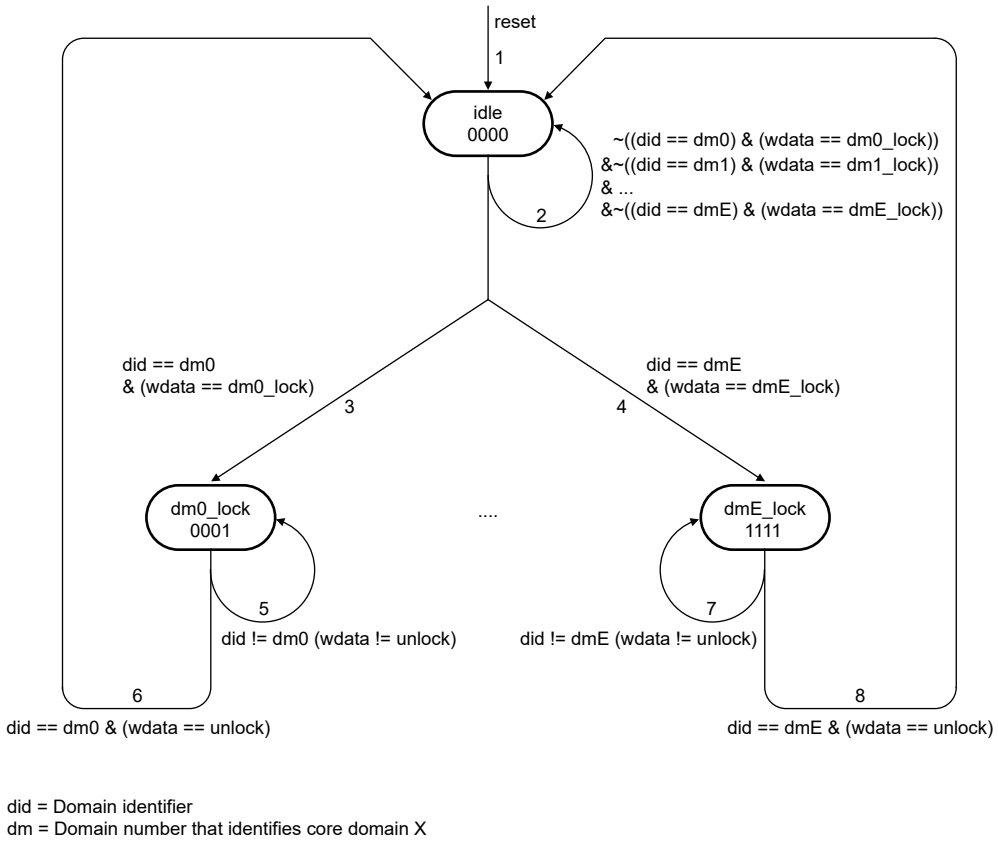

Figure 121. GATE*n* state machine

In the figure above, "dmE" represents domain 14 (E in hexadecimal). The platform passes the domain number to SEMA42.

The following table defines the GATE*n* state transitions.

Table 309. GATE*n* state transitions

Current state	Next state	Transition	Description
–	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding domain occurs, the gate remains in the idle state.
idle	dm0_lock	3	When domain 0h initiates a write of the dm0_lock data value, the gate transitions into the dm0_lock state.

Table continues on the next page...

Table 309. GATE*n* state transitions (continued)

Current state	Next state	Transition	Description
idle	dmE_lock	4	When domain Eh initiates a write of the dmE_lock value, the gate transitions into the dmE_lock state.
dm0_lock	dm0_lock	5	When in this state, the gate remains here if any attempted write is not from domain 0h with the unlock data value.
dm0_lock	idle	6	The gate returns to the idle (unlocked) state after a write from domain 0h with the unlock data value occurs.
dmE_lock	dmE_lock	7	When in this state, the gate remains here if any attempted write is not from domain Eh with the unlock data value.
dmE_lock	idle	8	The gate returns to the idle (unlocked) state after a write from domain Eh with the unlock data value occurs.

SEMA42 uses these gate data values:

- The lock data value is (domain number) + 1.
- The unlock data value is 00h.

27.3.4 Clocking

Type of clock	Description
Module clock (clk)	Functions the module and controls the access to the registers.

27.3.5 Interrupts

This module has no interrupts.

27.4 Memory map/register definition

You can access these registers only in Supervisor mode. User accesses terminate with an error.

27.4.1 SEMA42 register descriptions

27.4.1.1 SEMA42 memory map

SEMA42_0 base address: 400B_1000h

Offset	Register	Width (In bits)	Access	Reset value
0h - Fh	Gate (GATE0 - GATE15) [1]	8	RW	00h
42h	Reset Gate Read (RSTGT_R)	16	R	0000h
42h	Reset Gate Write (RSTGT_W)	16	W	See section

1. In this array, the index and offset values of the registers do not increment in direct alignment. For details, see the register description.

27.4.1.2 Gate (GATE0 - GATE15)

Offset

For n = 0 to 15:

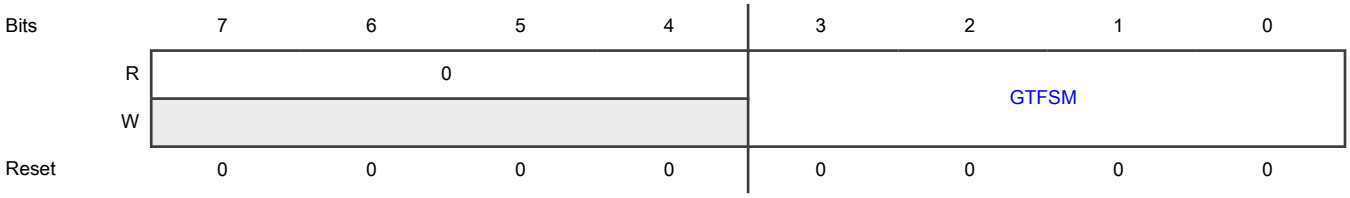
Register	Offset
GATEn	0h + (n + 3 - 2 × (n mod 4))

Function

Implements each semaphore gate in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical domain-identifier number in conjunction with the data patterns to validate all attempted write operations. Only domain masters can modify the gate registers. After a gate locks, only the locking domain must open (unlock) the gate.

You can read multiple gate values in a single access. However, you can update only a single gate at a time, via a write operation. If you attempt to write a byte-wide value that is neither the unlock value (00h) nor the appropriate lock value (domainID_number + 1), SEMA42 considers this as "no operation" and does not change any gate state. Attempts to write multiple gates in a single-aligned access with a size larger than 8 bits (byte) generate an error termination and do not allow any gate state changes.

Diagram



Fields

Field	Function
7-4 —	Reserved
3-0 GTFSM	Gate Finite State Machine Indicates the state of the gate for the last domain that locked the gate. This can be useful during system debug. The hardware gate has a 16-state implementation, defined as: 0000b - The gate is unlocked (free). 0001b - Domain 0 locked the gate. 0010b - Domain 1 locked the gate. 0011b - Domain 2 locked the gate. 0100b - Domain 3 locked the gate.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0101b - Domain 4 locked the gate. 0110b - Domain 5 locked the gate. 0111b - Domain 6 locked the gate. 1000b - Domain 7 locked the gate. 1001b - Domain 8 locked the gate. 1010b - Domain 9 locked the gate. 1011b - Domain 10 locked the gate. 1100b - Domain 11 locked the gate. 1101b - Domain 12 locked the gate. 1110b - Domain 13 locked the gate. 1111b - Domain 14 locked the gate.

27.4.1.3 Reset Gate Read (RSTGT_R)

Offset

Register	Offset
RSTGT_R	42h

Function

Describes the specific hardware gate to be reset and records the logic number of domain. Reset Gate Write (RSTGT_W) also describe the same register showing the fields when you write it.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		RSTGSM		RSTGMS				RSTGTN							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-14 —	Reserved
13-12	Reset Gate Finite State Machine

Table continues on the next page...

Table continued from the previous page...

Field	Function
RSTGSM	Indicates the encoded state machine value when you read the register. RSTGSM = 10b is valid for only a single machine cycle, so a read can never return this value. SEMA42 maintains the reset state machine in a 2-bit, 3-state implementation, defined as follows: 00b - Idle, waiting for the first data pattern write. 01b - Waiting for the second data pattern write 10b - The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. 11b - This state encoding is never used and therefore reserved.
11-8 RSTGMS	Reset Gate Domain Records the logical number of the domain performing the gate reset function. To succeed, this function requires that the same domain initiate the two consecutive writes to this register. SEMA42 updates the field each time a write to this register occurs.
7-0 RSTGTN	Reset Gate Number Specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

27.4.1.4 Reset Gate Write (RSTGT_W)

Offset

Register	Offset
RSTGT_W	42h

Function

Specifies the hardware gate to reset when data patterns are specified.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																
W	RSTGDP								RSTGTN							
Reset [1]	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

1. Reset value is not applicable for writes.

Fields

Field	Function
15-8 RSTGDP	Reset Gate Data Pattern You access this field with the specified data patterns on the two consecutive writes to enable the gate-reset mechanism. For the first write, RSTGDP must be E2h. For the second write, RSTGDP must be 1Dh.
7-0 RSTGTN	Reset Gate Number Specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

27.5 External signals

This module has no external signals.

27.6 Initialization

This module does not require initialization.

Chapter 28
Interrupt Monitor (INTM)

28.1 Chip-specific INTM information

Table 310. Reference links to related information

Topic	Related module	Reference
Full description	INTM	INTM
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

NOTE

INTM only monitors the interrupts that are connected to CPU0.

28.1.1 Module instances

This device contains one instance of the Interrupt Monitor module, INTM0.

28.2 Overview

INTM provides a mechanism to monitor the latency of the responses on interrupt requests to ensure that the processing of these critical interrupts executes within the expected time frame, increasing the reliability of the device.

28.2.1 Block diagram

The following block diagram shows the major registers involved in monitoring the interrupt sources.

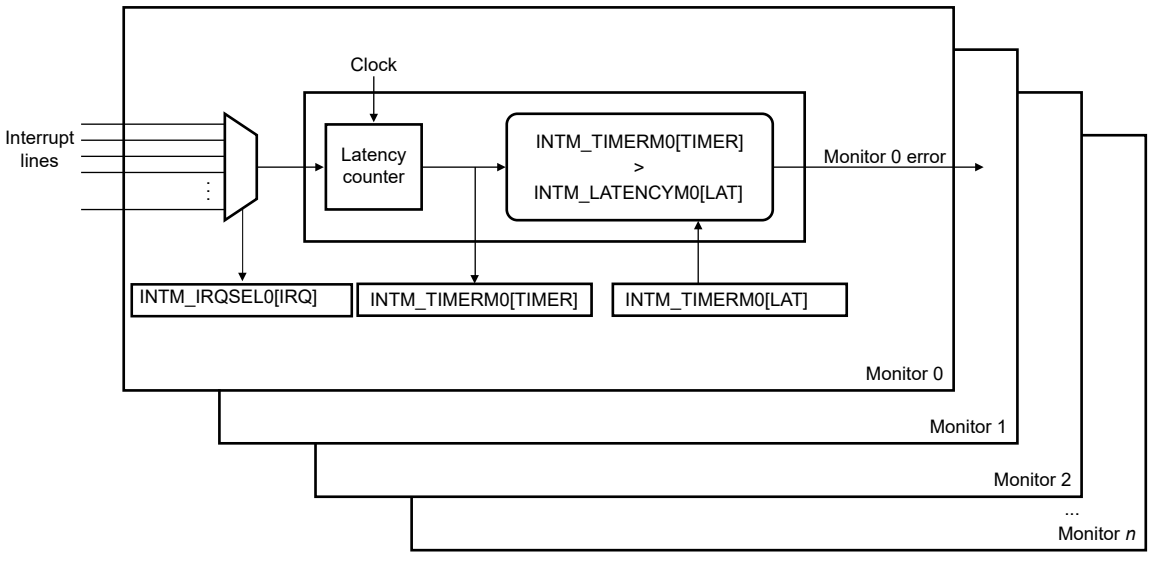


Figure 122. INTM block diagram

28.2.2 Features

INTM supports the following features:

- 4 programmable interrupt monitors
- Programmable interrupt source per monitor
- Programmable 24-bit maximum latency counter per monitor
- Timer expired status bit per monitor
- One interrupt acknowledge for all monitors

28.3 Functional description

Interrupt Request Select for Monitor a (INTM_IRQSEL0 - INTM_IRQSEL3) provides selection of the source, Monitor Mode (INTM_MM) enables the monitor, Interrupt Acknowledge (INTM_IACK) captures the event when the interrupt is acknowledged, Interrupt Latency for Monitor a (INTM_LATENCY0 - INTM_LATENCY3) can be programmed to trigger a monitor error when a threshold value is exceeded, Status for Monitor a (INTM_STATUS0 - INTM_STATUS3) is available to read the monitor error over peripheral bus.

NOTE

INTM supports only level-type interrupts. Hence, the pulse-type interrupts are converted into level-type interrupts for INTM.

28.3.1 Clocking

This module has no clocking considerations.

28.3.2 Interrupts

This module has no interrupts.

28.4 External signals

This module has no external signals.

28.5 Initialization

To monitor a subset of interrupt sources:

1. Program Interrupt Request Select for Monitor a (INTM_IRQSEL0 - INTM_IRQSEL3) with a value corresponding to the interrupt source number to be monitored.
   - You can monitor only defined interrupt sources.
2. Program Interrupt Latency for Monitor a (INTM_LATENCY0 - INTM_LATENCY3) to the maximum expected latency time for each monitored interrupt source.
3. Write 1 to INTM_MM[MM] to monitor the registers.
4. During the interrupt service routine, write the IRQ of the ISR to Interrupt Acknowledge (INTM_IACK).
5. If the maximum expected latency time exceeds the limit defined in Interrupt Latency for Monitor a (INTM_LATENCY0 - INTM_LATENCY3), then an error indication is sent to Fault Collection Control Unit(FCCU). You can also read Status for Monitor a (INTM_STATUS0 - INTM_STATUS3) to see this information.

To clear an error condition, write 0 to the corresponding INTM_TIMERa[TIMER] field for which the interrupt source exceeded the programmed latency value. In case the source is unknown, NXP recommends you to write 0 to all INTM_TIMERa[TIMER] fields.

28.6 INTM register descriptions

INTM allows you to set a maximum timer count for the interrupt latency from interrupt request to interrupt acknowledge. This mechanism monitors the latency of interrupt sources to ensure that these critical interrupts execute within the expected time

frame, increasing the reliability of the chip. The hardware for this function is isolated in its own hierarchy to decrease the risk of fault interference.

An error indication is sent to FCCU if the interrupt processing latency exceeds the programmed threshold of the expected latency. The error indication can be read from INTM_STATUSa[STATUS].

28.6.1 INTM memory map

INTM0 base address: 4005_D000h

R W	Reserved															MM
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-1 —	Reserved
0 MM	Monitor Mode Controls whether the INTM monitors the latency of an interrupt response. 0b - Disable 1b - Enable

28.6.3 Interrupt Acknowledge (INTM_IACK)

Offset

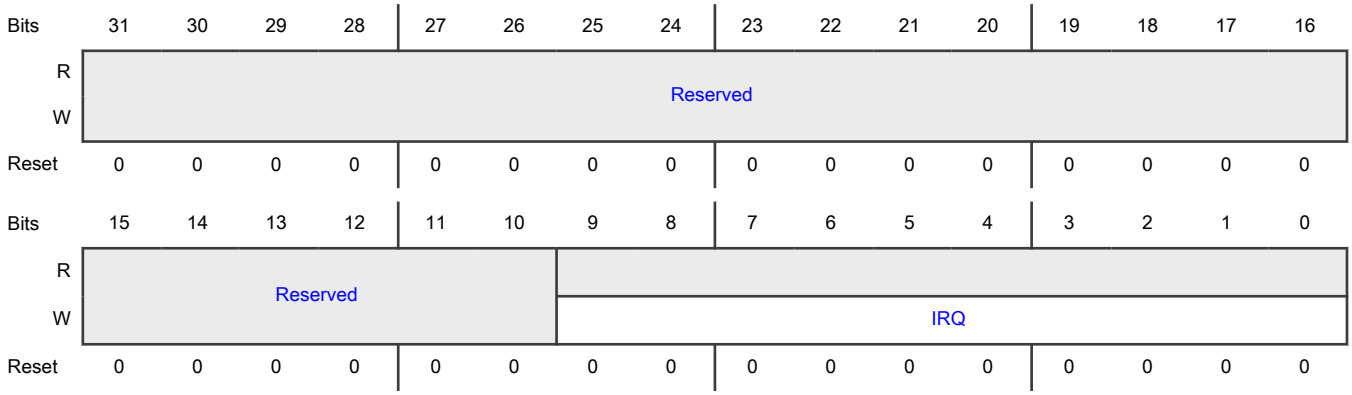
Register	Offset
INTM_IACK	4h

Function

Acknowledges the interrupt processing.

The Interrupt service routine writes to this register after the register acknowledges interrupt processing. This write operation must provide the number of the processed interrupt, which is compared with the interrupt request number in each Interrupt Request Select for Monitor a (INTM_IRQSEL0 - INTM_IRQSEL3) and stops the corresponding Timer for Monitor a (INTM_TIMER0 - INTM_TIMER3) when it found a match.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-0 IRQ	Interrupt Request Specifies the interrupt request number to stop Timer for Monitor a (INTM_TIMER0 - INTM_TIMER3).

28.6.4 Interrupt Request Select for Monitor a (INTM_IRQSEL0 - INTM_IRQSEL3)

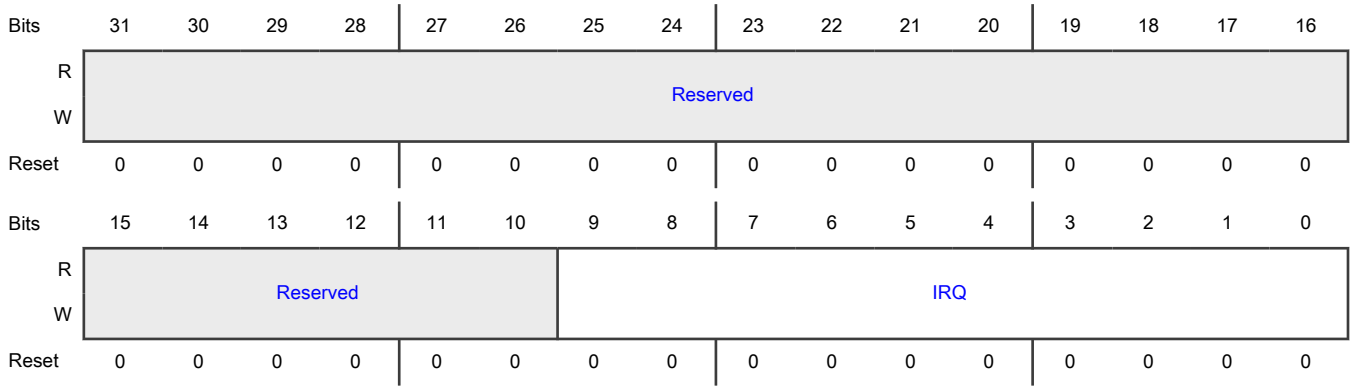
Offset

Register	Offset
INTM_IRQSEL0	8h
INTM_IRQSEL1	18h
INTM_IRQSEL2	28h
INTM_IRQSEL3	38h

Function

Indicates which interrupt request must be monitored or checked.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-0 IRQ	Interrupt Request Selects the interrupt request number to monitor.

28.6.5 Interrupt Latency for Monitor a (INTM_LATENCY0 - INTM_LATENCY3)

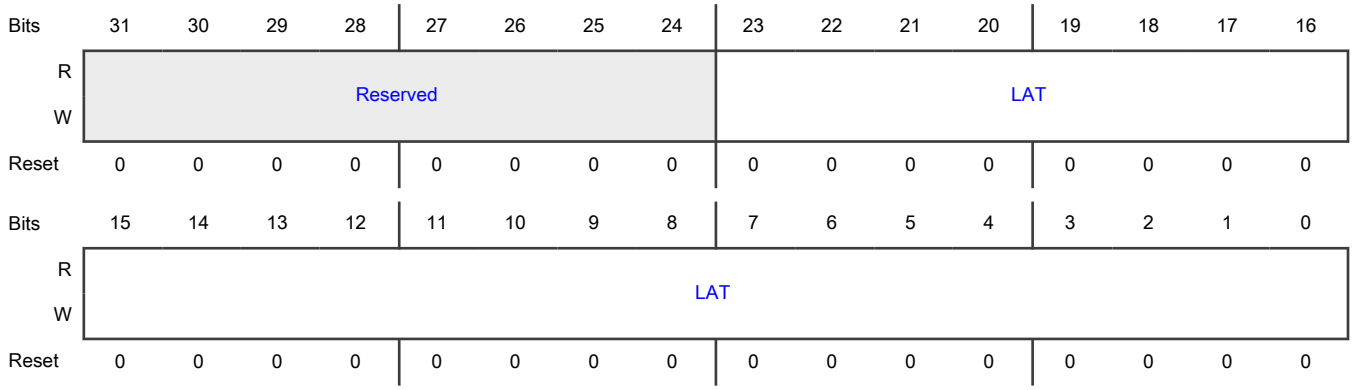
Offset

Register	Offset
INTM_LATENCY0	Ch
INTM_LATENCY1	1Ch
INTM_LATENCY2	2Ch
INTM_LATENCY3	3Ch

Function

Indicates the maximum time before an error signal is asserted for a detected interrupt request to interrupt acknowledge.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 LAT	Latency Specifies the maximum number of INTM clock cycles allowed for the monitored interrupt request. Maximum programmed value must not exceed FF_FFFDh to allow for proper timer error capture.

28.6.6 Timer for Monitor a (INTM_TIMER0 - INTM_TIMER3)

Offset

Register	Offset
INTM_TIMER0	10h
INTM_TIMER1	20h
INTM_TIMER2	30h
INTM_TIMER3	40h

Function

Counts the number of INTM clock cycles for a detected interrupt request to an acknowledged interrupt processing.

Initializes to 1 in following conditions:

- Interrupt Latency for Monitor a (INTM_LATENCY0 - INTM_LATENCY3) is nonzero
- Monitor error is not asserted
- Zero to one transition on the monitored interrupt request

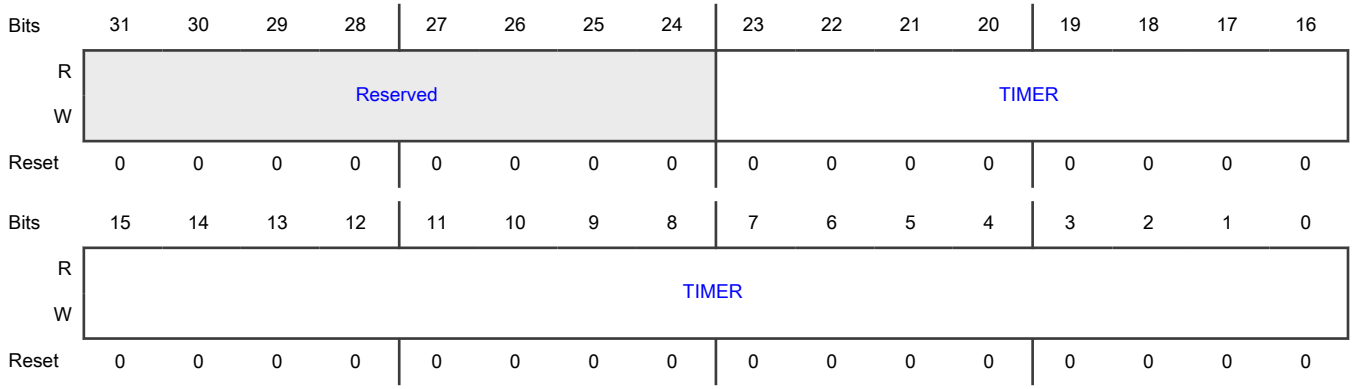
Following are the conditions to enable Timer for Monitor a (INTM_TIMER0 - INTM_TIMER3):

- INTM_MM = 1 and zero-to-one transition on the monitored interrupt source

Following are the conditions to disable Timer for Monitor a (INTM_TIMER0 - INTM_TIMER3):

- Reset
- INTM_MM = 1 and monitor error
- INTM_MM = 1 and monitored interrupt request is not asserted
- Interrupt acknowledge for corresponding interrupt request
- After the timer is enabled, writing 0 to INTM_MM[MM] has no effect.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 TIMER	Timer Counts the number of INTM clock cycles up to 24 bits of resolution.

28.6.7 Status for Monitor a (INTM_STATUS0 - INTM_STATUS3)

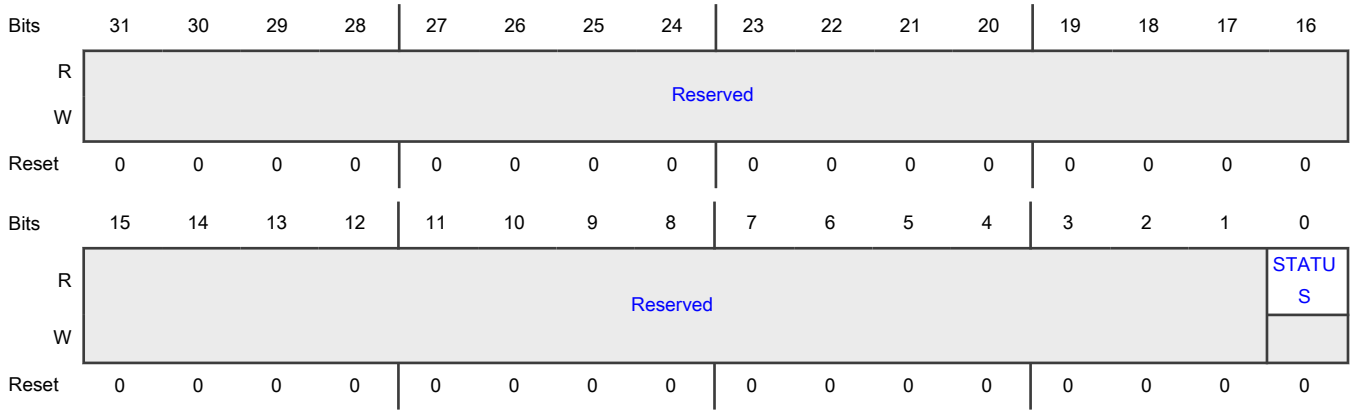
Offset

Register	Offset
INTM_STATUS0	14h
INTM_STATUS1	24h
INTM_STATUS2	34h
INTM_STATUS3	44h

Function

Defines the monitor status. Indicates whether Timer for Monitor a (INTM_TIMER0 - INTM_TIMER3) value has exceeded Interrupt Latency for Monitor a (INTM_LATENCY0 - INTM_LATENCY3) value. You can clear the monitor status by writing 0 to the corresponding INTM_TIMERa[TIMER].

Diagram



Fields

Field	Function
31-1 —	Reserved
0 STATUS	Monitor status Indicates whether Timer for Monitor a (INTM_TIMER0 - INTM_TIMER3) value has exceeded the Interrupt Latency for Monitor a (INTM_LATENCY0 - INTM_LATENCY3) value. 0b - Did not exceed 1b - Exceeded

Chapter 29
Error Injection Module (EIM)

29.1 Chip-specific EIM information

Table 311. Reference links to related information

Topic	Related module	Reference
Full description	EIM	EIM
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

NOTE

EIM is integrated between the memory controller and memory array to enable a controlled way for error injection. Each memory controller has its own EIM channel.

29.1.1 Module instances

This device contains one instance of the Error Injection module, EIM0.

29.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

29.1.3 EIM channel mapping

Table 312. EIM channel mapping

EIM channel #	Target	Data bits of RAM	Check bits of RAM	Word0 number of check bits	Word1 number of data bits

29.1.4 EIM enable

Two enables are supported; GEIEN which enables error injection globally, EICHnEN which enables error injection functionality for a particular channel. This double layer enable provides protection against accidental enabling and reconfiguration of the error injection function of each channel. The EICHDn_WORD0 register is written to inject error in desired check bits, and the EICHDn_WORD1 register is written to inject error in desired data bits.

29.2 Overview

The Error Injection Module (EIM) is mainly used for diagnostic purposes. It provides a method to test the diagnostics (memory ECC, interconnect parity) by error injection in the field. See the chip-specific EIM information to determine which functional safety features are supported by this method.

EIM enables you to inject artificial errors on error-checking mechanisms of a system, such as ECC for RAM read data and parity bits. For each such mechanism that EIM supports on the chip, EIM can inject single-bit and multi-bit inversions on data in the applicable target bus. Injecting faults on memory accesses can be used to exercise the SEC-DED ECC function of the related system.

29.2.1 Features

The EIM includes these features:

- Supports 9 error injection channels. See the chip-specific EIM information for channel assignment details.
- Protection against accidental enable and reconfiguration error injection function via two-stage enable mechanism

29.2.2 Block diagram

The following diagram shows an example of EIM implementation with a 64-bit read data bus and an 8-bit checkbit bus.

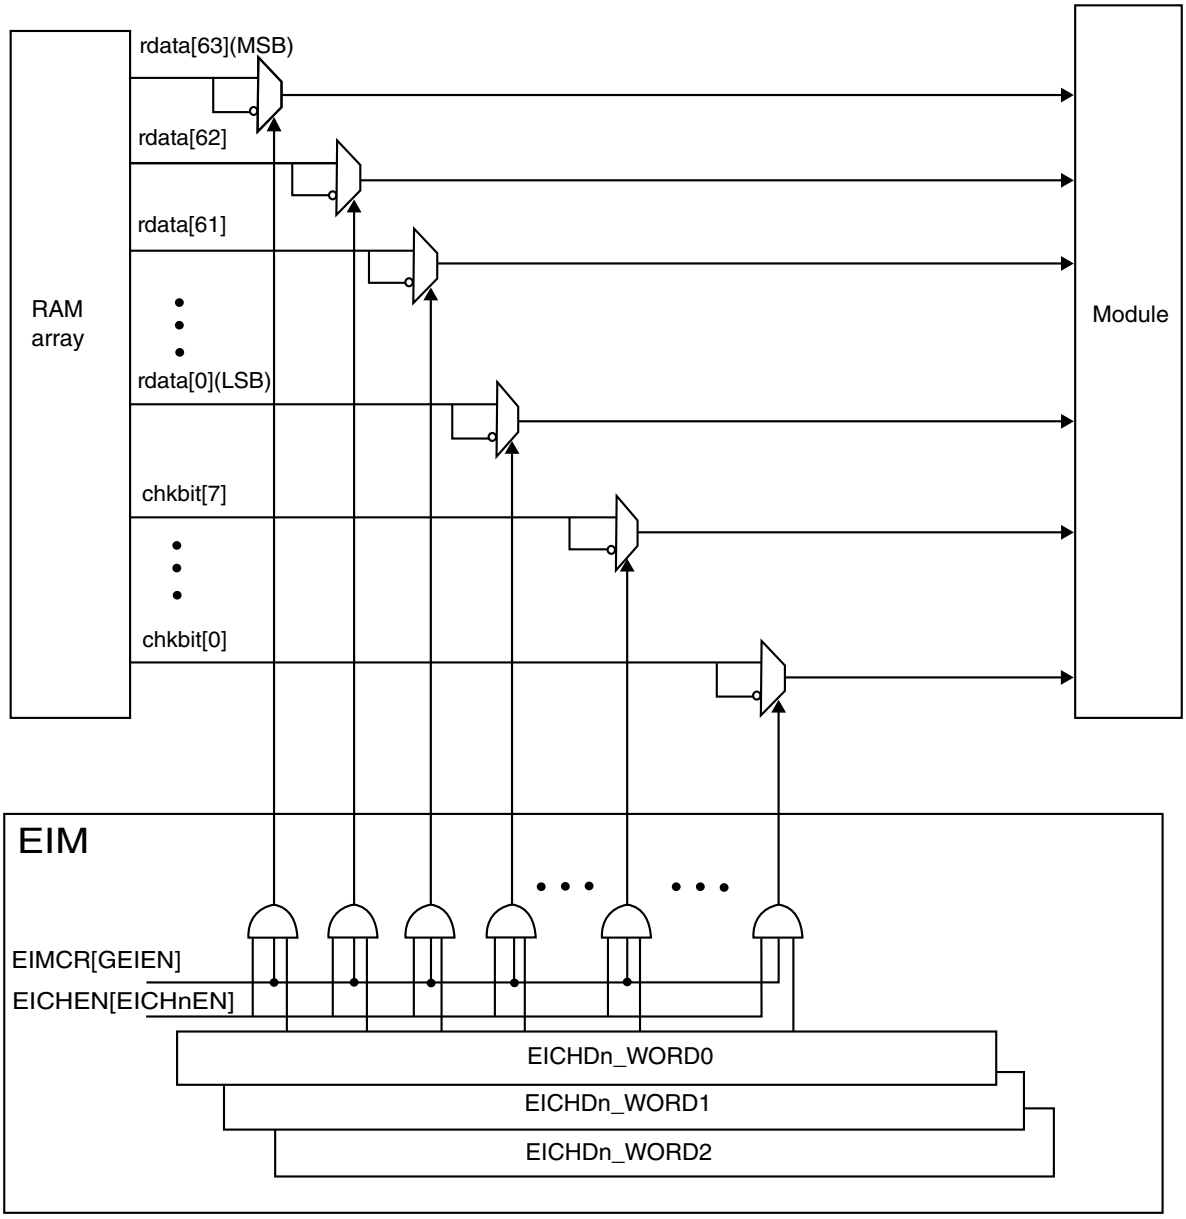

Figure 123. EIM functional block diagram (64-bit read data bus and 8-bit check bit bus)

Several memory elements are implemented within a device, which may not only be the large memory blocks (Flash and SRAM) but also smaller memories like caches, the TCD blocks, and the embedded peripheral memories. Some larger memories may actually be built from multiple memory elements, dependent on their size or function. Each of these memory elements implements its own control logic, the memory controller, that performs the accesses to the actual memory, the memory array. An EIM channel is associated with a memory controller and provides the capability to alter one or multiple signals in the read access path from the corresponding memory array(s). Only memory controllers controlling a safety related memory may be associated with an EIM channel.

29.3 Functional description

The EIM provides protection against accidental enabling and reconfiguration of the error injection function by enforcing a two-stage enablement mechanism. To properly enable the error injection mechanism for a channel:

- Write 1 to the EICHEN[EICH*n*EN] field, where *n* denotes the channel number.
- Write 1 to EIMCR[GEIEN].

NOTE

When the use case for a channel requires writing any EICHD*n*_WORD register, write the EICHD*n*_WORD register before executing the two-stage enablement mechanism. A successful write to any EICHD*n*_WORD register clears the corresponding EICHEN[EICH*n*EN] field.

The EIM supports 9 error injection channels. See the chip-specific EIM information for channel assignment details. Each channel:

- Can be assigned to a single memory array interface by intercepting the assigned memory read data bus and checkbit bus, and injects errors by inverting the value transmitted for selected bits on each bus line.
- Can be assigned to a redundant comparison unit by intercepting the signals being compared, and injecting errors by inverting the value transmitted for selected bits on each bus line.

On a memory read access, the applicable EICHD*n*_WORD registers define which bits of the read data and/or checkbit bus to invert.

Figure 123 depicts the interception and override of a 64-bit read data bus and an 8-bit checkbit data bus for an example memory array.

Error injection scenarios

The EIM supports these cases of error injection:

- To generate a single-bit error, invert only 1 bit of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.
- To generate a multi-bit error, invert only 2 bits of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.

NOTE

An attempt to invert more than 2 bits in one operation might result in undefined behavior.

To enable error injection:

1. Set the EICHD*n*_WORD*m*[CHKBIT_MASK] and EICHD*n*_WORD*m*[B*a*_*b*DATA_MASK] fields for each channel that will be driving an injection.
2. Program the EICHEN register to enable the channels that will be injecting errors.
3. Set the EIMCR[GEIEN] field to globally allow all enabled channels to actively inject errors.

To disable error injection, either disable the EIMCR[GEIEN] field or disable the individual channel enable fields of the EICHEN register.

29.4 Initialization

This module does not require initialization.

29.6 EIM register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode

- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 128-bit (16-byte) structure, composed of four 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1-3 (EICHD*n*_WORD1-3), if present, define the data mask. Word2 and Word3 are present only when required by the total width of the channel's data mask. See Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following table shows the total width of DATA_MASK and the distribution of its bits across the WORD registers.

Table 313. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in		
		WORD1	WORD2	WORD3
0	32	31-0	—	—

29.6.3 Error Injection Channel Enable register (EICHEN)

Offset

Register	Offset
EICHEN	4h

Function

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Fields

Field	Function
31 EICH0EN	Error Injection Channel 0 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 0 1b - Error injection is enabled on Error Injection Channel 0
30 EICH1EN	Error Injection Channel 1 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 1 1b - Error injection is enabled on Error Injection Channel 1
29 EICH2EN	Error Injection Channel 2 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software.

29.6.4 Error Injection Channel Descriptor n, Word0 (EICHD0_WORD0 - EICHD6_WORD0)

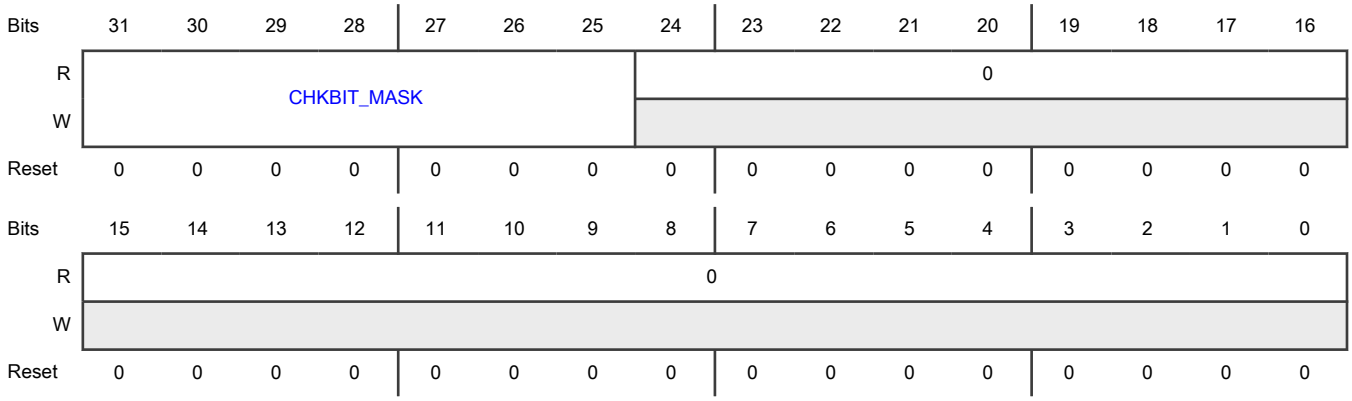
Offset

Register	Offset
EICHD0_WORD0	100h
EICHD1_WORD0	140h
EICHD2_WORD0	180h
EICHD3_WORD0	1C0h
EICHD4_WORD0	200h
EICHD5_WORD0	240h
EICHD6_WORD0	280h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-25 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[6:0] (7 bits wide), CHKBIT_MASK[6] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
24-0 —	Reserved

29.6.5 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD8_WORD1)

Offset

Register	Offset
EICHD0_WORD1	104h
EICHD1_WORD1	144h
EICHD2_WORD1	184h
EICHD3_WORD1	1C4h
EICHD4_WORD1	204h

Table continues on the next page...

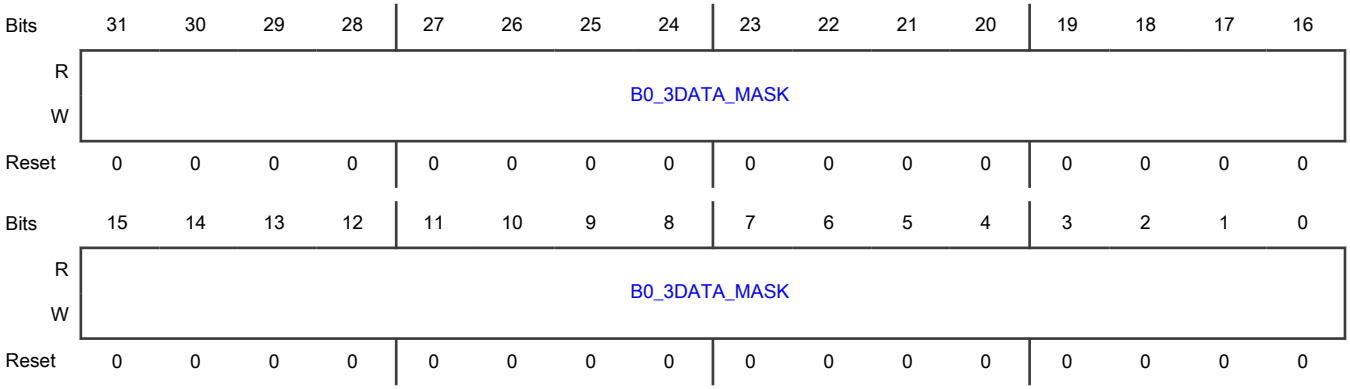
Table continued from the previous page...

Register	Offset
EICHD5_WORD1	244h
EICHD6_WORD1	284h
EICHD7_WORD1	2C4h
EICHD8_WORD1	304h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

29.6.6 Error Injection Channel Descriptor 7, Word0 (EICHD7_WORD0)

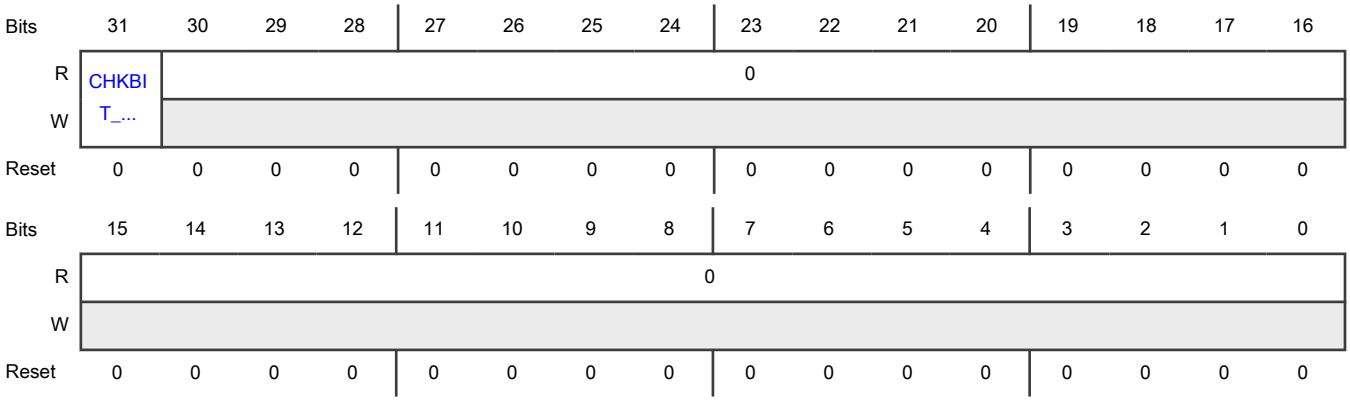
Offset

Register	Offset
EICHD7_WORD0	2C0h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[0:0] (1 bits wide), CHKBIT_MASK[0] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
30-0 —	Reserved

29.6.7 Error Injection Channel Descriptor 8, Word0 (EICHD8_WORD0)

Offset

Register	Offset
EICHD8_WORD0	300h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram

Chapter 30
Error Recording Module (ERM)

30.1 Chip-specific ERM information

Table 314. Reference links to related information

Topic	Related module	Reference
Full description	ERM	ERM
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

30.1.1 Module instances

This device contains one instance of the Error Recording module, ERM0.

30.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

30.1.3 ERM channel mapping

Table 315. ERM channel mapping

Channel no.	Module	Captured status
0	RAMX	Single-bit error, multiple-bit error, error address, syndrome
1	RAMA	Single-bit error, multiple-bit error, error address, syndrome
2	RAMB	Single-bit error, multiple-bit error, error address, syndrome
3	RAMC	Single-bit error, multiple-bit error, error address, syndrome
4	RAMD	Single-bit error, multiple-bit error, error address, syndrome
5	RAME	Single-bit error, multiple-bit error, error address, syndrome
6	RAMF	Single-bit error, multiple-bit error, error address, syndrome
7	LPCAC RAM	Single-bit error, parity error of each word (syndrome)
8	PKC RAM	Single-bit error, parity error of each byte (syndrome)
9	Flash	ECC double bits error

30.1.4 Channels mapped to non-correctable errors

The following channels are mapped to non-correctable errors in ERM and do not change the count value of the number of correctable ECC error events:

- Channel 7
- Channel 8
- Channel 9

30.2 Overview

The Error Reporting Module (ERM) provides information and optional interrupt notification on memory error events associated with ECC and parity. The ERM collects error events on memory accesses for memory arrays, such as flash memory, system RAM, or peripheral RAMs. ERM supports various channels for memory sources where each ERM channel is associated with a different memory module. See the chip-specific ERM information for details about supported memory sources and specific memory channel assignments. If the memory supports ECC, then ERM syndrome and error address information is captured along with the error event. ERM does not capture syndrome or error address for cache memories or memory with parity instead of ECC.

30.2.1 Features

The ERM includes these features:

- Optional interrupt notification on captured error events
- Capturing of address and syndrome information on single-bit correction and non-correctable ECC events
- Support for error event capturing for memory sources, with individual reporting fields and interrupt configuration per memory channel
- Recording the count value of the number of corrected error events

30.2.2 Block diagram

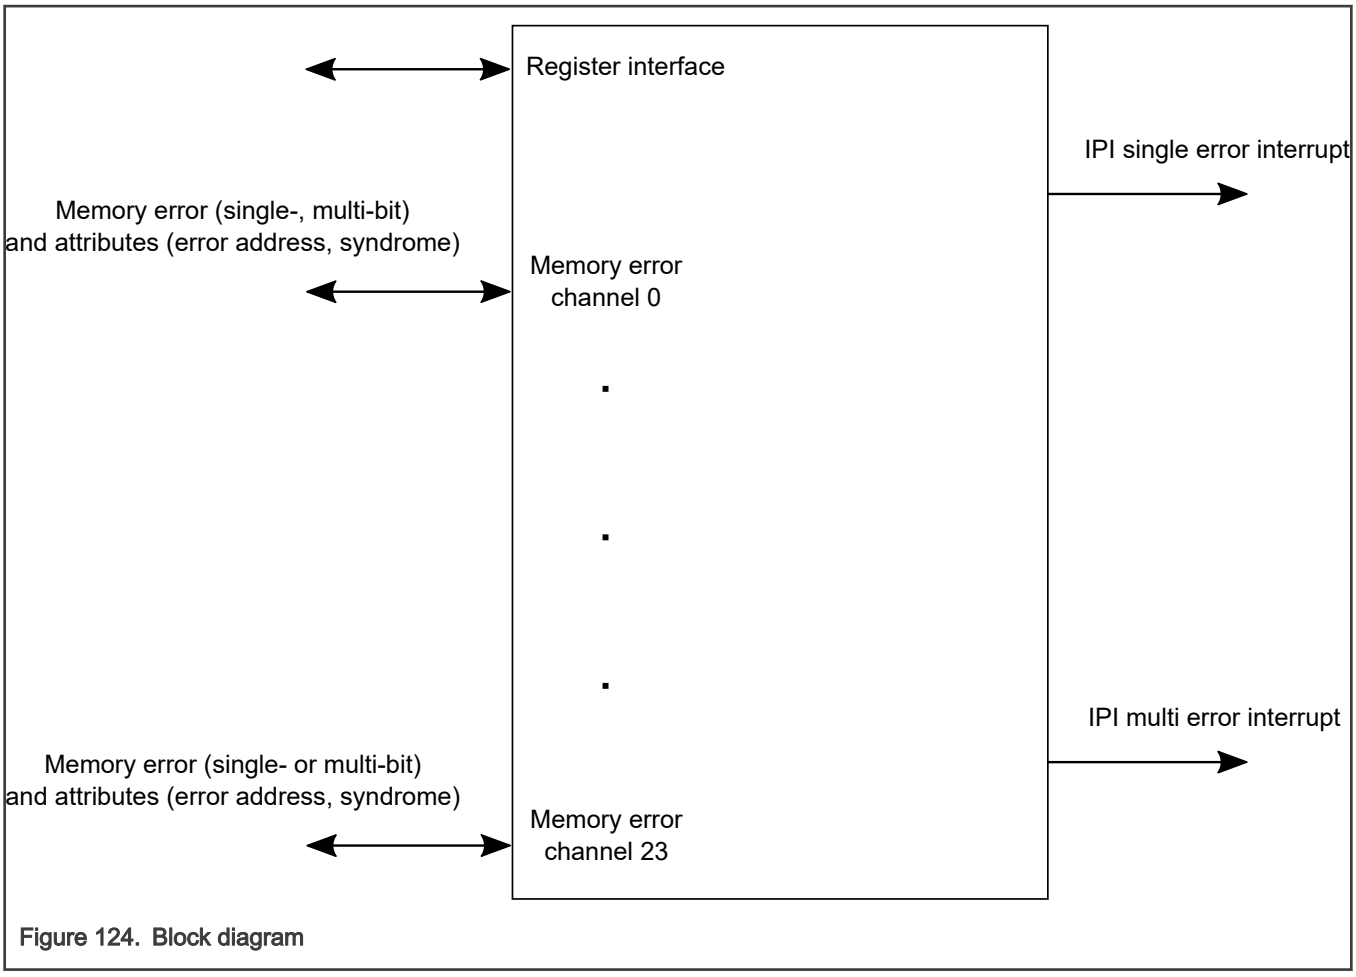

Figure 124. Block diagram

30.3 Functional description

30.3.1 Single-bit correction events

When a single-bit correction event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit SR*x*[SBC*n*] to 1.
- Increments the correctable error count value (until the counter reaches its maximum value): CORR_ERR_CNT*n*[COUNT].
- Records the corresponding access address that initiated the event in the Memory *n* Error Address Register: EAR*n* (if this register is present for the channel).
- Stores the corresponding ECC syndrome in the Memory *n* Error Syndrome Register: SYN*n* (if this register is present for the channel). This register identifies the bit position of the corrected data on single-bit data inversion.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[SBC*n*] to change its value to 0.

To reset the correctable error count value, write all zeros to CORR_ERR_CNT*n*[COUNT].

Optional interrupt notification for single-bit correction events

The ERM provides an option to generate an interrupt notification upon the report of a single-bit correction event. To enable single-bit correction interrupts for a channel:

1. To enable interrupt notification for single-bit correction events on Memory *n*, set CR*x*[ESCIE*n*] to 1.
2. Subsequently, when a single-bit correction event on Memory *n* is detected, the ERM:
   - Records the event and address, and stores the ECC syndrome as usual.
   - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[SBC*n*] to change its value to 0.

30.3.2 Non-correctable error events

When a non-correctable ECC error event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit: SR*x*[NCE*n*] to 1.
- Records the corresponding access address that initiated the event in the Memory *n* Error Address Register: EAR*n* (if this register is present for the channel).
- Stores the corresponding ECC syndrome in the Memory *n* Error Syndrome Register: SYN*n* (if this register is present for the channel).
  - In the event of a non-correctable address bit inversion, SYN*n* identifies the pertinent address bit position.
  - In the event of a non-correctable, multi-bit data inversion, the syndrome value does not provide any additional diagnostic information.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[NCE*n*] to change its value to 0.

Optional interrupt notification for non-correctable error events

The ERM provides an option to generate an interrupt notification upon the report of a non-correctable ECC event. To enable non-correctable error interrupts for a channel:

1. To enable interrupt notifications for non-correctable error events on Memory *n*, set CR*x*[ENCIE*n*] to 1.
2. Subsequently, when a non-correctable error event on Memory *n* is detected, the ERM:
   - Records the event and address and stores the ECC syndrome as usual.
   - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[NCE*n*] to change its value to 0.

NOTE

Parity errors can be mapped to non-correctable errors where error attributes like SYNDROME, ADDRESS are not provided.

30.4 Initialization

For each ERM channel supporting memory with ECC, prepare the corresponding memory array before enabling ERM interrupts about errors for that memory.

1. Initialize the memory to a known value so that the correct corresponding ECC codeword is stored.
2. During the memory's initialization, if the ERM captures information about any ECC error event, clear the corresponding SR*x*[SBC*n*] or SR*x*[NCE*n*] field that stores the record of the event.
3. Program the applicable CR*x*[ESCIE*n*] and CR*x*[ENCIE*n*] fields to enable ERM interrupts as desired.

30.5 ERM register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Based on the design implementation, the following XFR error behavior is evident at the IPS interface.

- Within the ERM memory map, an XFR error is evident at reserved addresses from location 20h to FFh.
- No XFR error is evident at reserved addresses in memory spaces allocated to each channel. For example: For channel 0, for read/write accesses to reserved address 10Ch, the XFR error is 0.
- For accesses to locations beyond the addresses allocated for the final channel, the XFR error is 1.

NOTE

- See the chip-specific ERM information at the beginning of this chapter for details on Memory channel mapping.
- To access the channel registers, corresponding memory channel clock must be enabled.

30.5.6 ERM Memory a Error Address Register (EAR0 - EAR6)

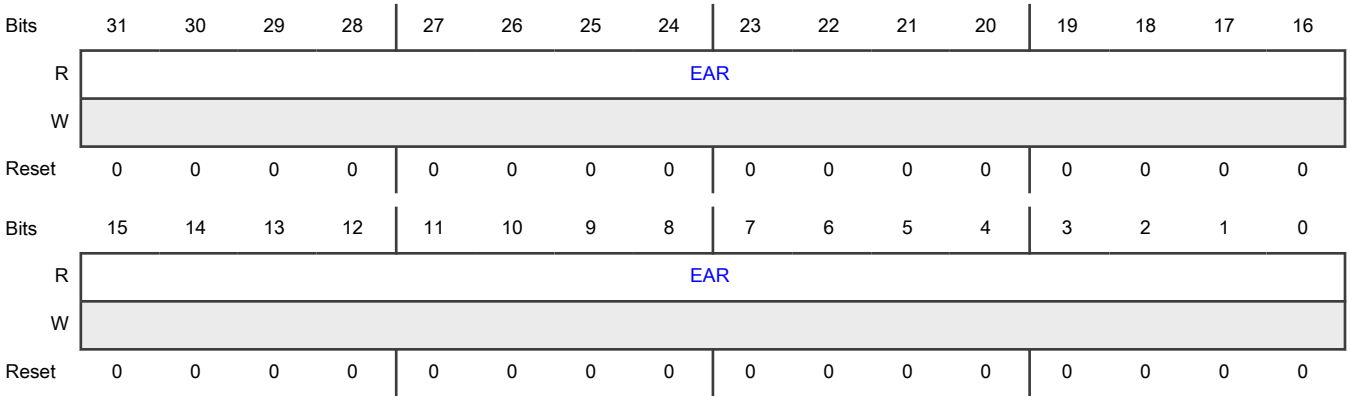
Offset

Register	Offset
EAR0	100h
EAR1	110h
EAR2	120h
EAR3	130h
EAR4	140h
EAR5	150h
EAR6	160h

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory*n*, where*n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

Diagram



Fields

Field	Function
31-0 EAR	EAR Memory*n* Error Address — This field contains the faulting system address of the last recorded ECC event on Memory*n*.

30.5.7 ERM Memory a Syndrome Register (SYN0 - SYN8)

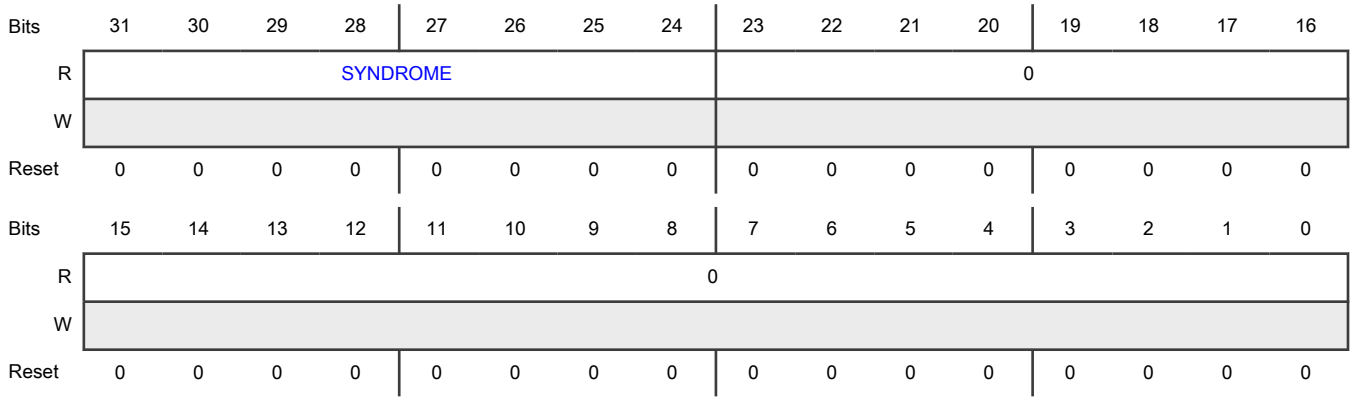
Offset

Register	Offset
SYN0	104h
SYN1	114h
SYN2	124h
SYN3	134h
SYN4	144h
SYN5	154h
SYN6	164h
SYN8	184h

Function

The ERM Memory *n* Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory*n*, where*n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

Diagram



Fields

Field	Function
31-24 SYNDROME	SYNDROME Memory*n* Syndrome — This field contains the ECC syndrome associated with the last recorded ECC event on Memory*n*.
23-0 —	Reserved

30.5.8 ERM Memory a Correctable Error Count Register (CORR_ERR_CNT0 - CORR_ERR_CNT9)

Offset

Register	Offset
CORR_ERR_CNT0	108h
CORR_ERR_CNT1	118h
CORR_ERR_CNT2	128h
CORR_ERR_CNT3	138h
CORR_ERR_CNT4	148h
CORR_ERR_CNT5	158h
CORR_ERR_CNT6	168h
CORR_ERR_CNT7	178h
CORR_ERR_CNT8	188h
CORR_ERR_CNT9	198h

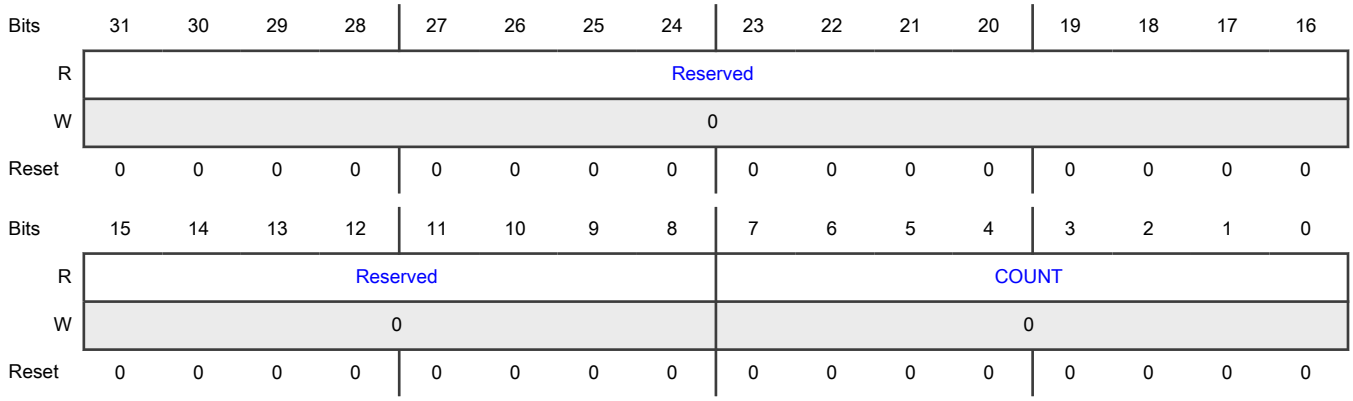
Function

Each 32-bit ERM Memory *n* Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory*n*, where*n* denotes the memory channel.

NOTE

Non-correctable errors are considered a serious fault, so the ERM does not provide any mechanism to count non-correctable errors. Only correctable errors are counted.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT value will stop when it reaches maximum value FFh and will not wrap even if additional errors occur. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing a non-zero value has no effect.

Chapter 31
Programmable Logic Unit (PLU)

31.1 Chip-specific PLU information

Table 316. Reference links to related information

Topic	Related module	Reference
Full description	PLU	PLU
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

31.1.1 Module instances

This device has one instance of PLU module, PLU0.

31.1.2 PLU configuration

PLU is configurable along two parameters: number of LUT elements and number of primary inputs. The chip uses the following configuration:

- 26 LUT elements
- 6 Primary inputs (does not include the clock input, use of which is optional)
- 8 Primary outputs

31.2 Overview

The Programmable Logic Unit (PLU) is used to create both small combinatorial and sequential logic networks including simple state machines. PLU continuously monitors the state of input devices and uses a custom program to control the state of output devices.

31.2.1 Features

PLU includes the following features:

- An array of 26 inter-connectable, 5-input look-up table (LUT) elements, and four flip-flops.
  - Each LUT element has 5 input multiplexer registers and one truth table (look-up table) register.
  - Each LUT input has 35 possible input sources to choose from.
  - All inputs connected directly to the package pins via chip-level I/O multiplexing.
- Eight primary output pins, selected using a multiplexer from among the 26 LUT outputs and the four flip-flops.
  - Up to four of the LUT outputs can be captured in one of the four state flip-flops. They can either be connected to the inputs of other LUTs or be used as primary outputs, or they can be used in both of those functions simultaneously.
- An external clock to drive the four flip-flops if a sequential network is implemented.
- Programmable logic that can drive on-chip inputs or triggers through external pin-to-pin connections.
- A tool suite to facilitate programming of the PLU to implement the logic network.

31.2.2 Block diagram

The following figure shows the PLU block diagram with the following configuration: 26, 5-input LUT elements.

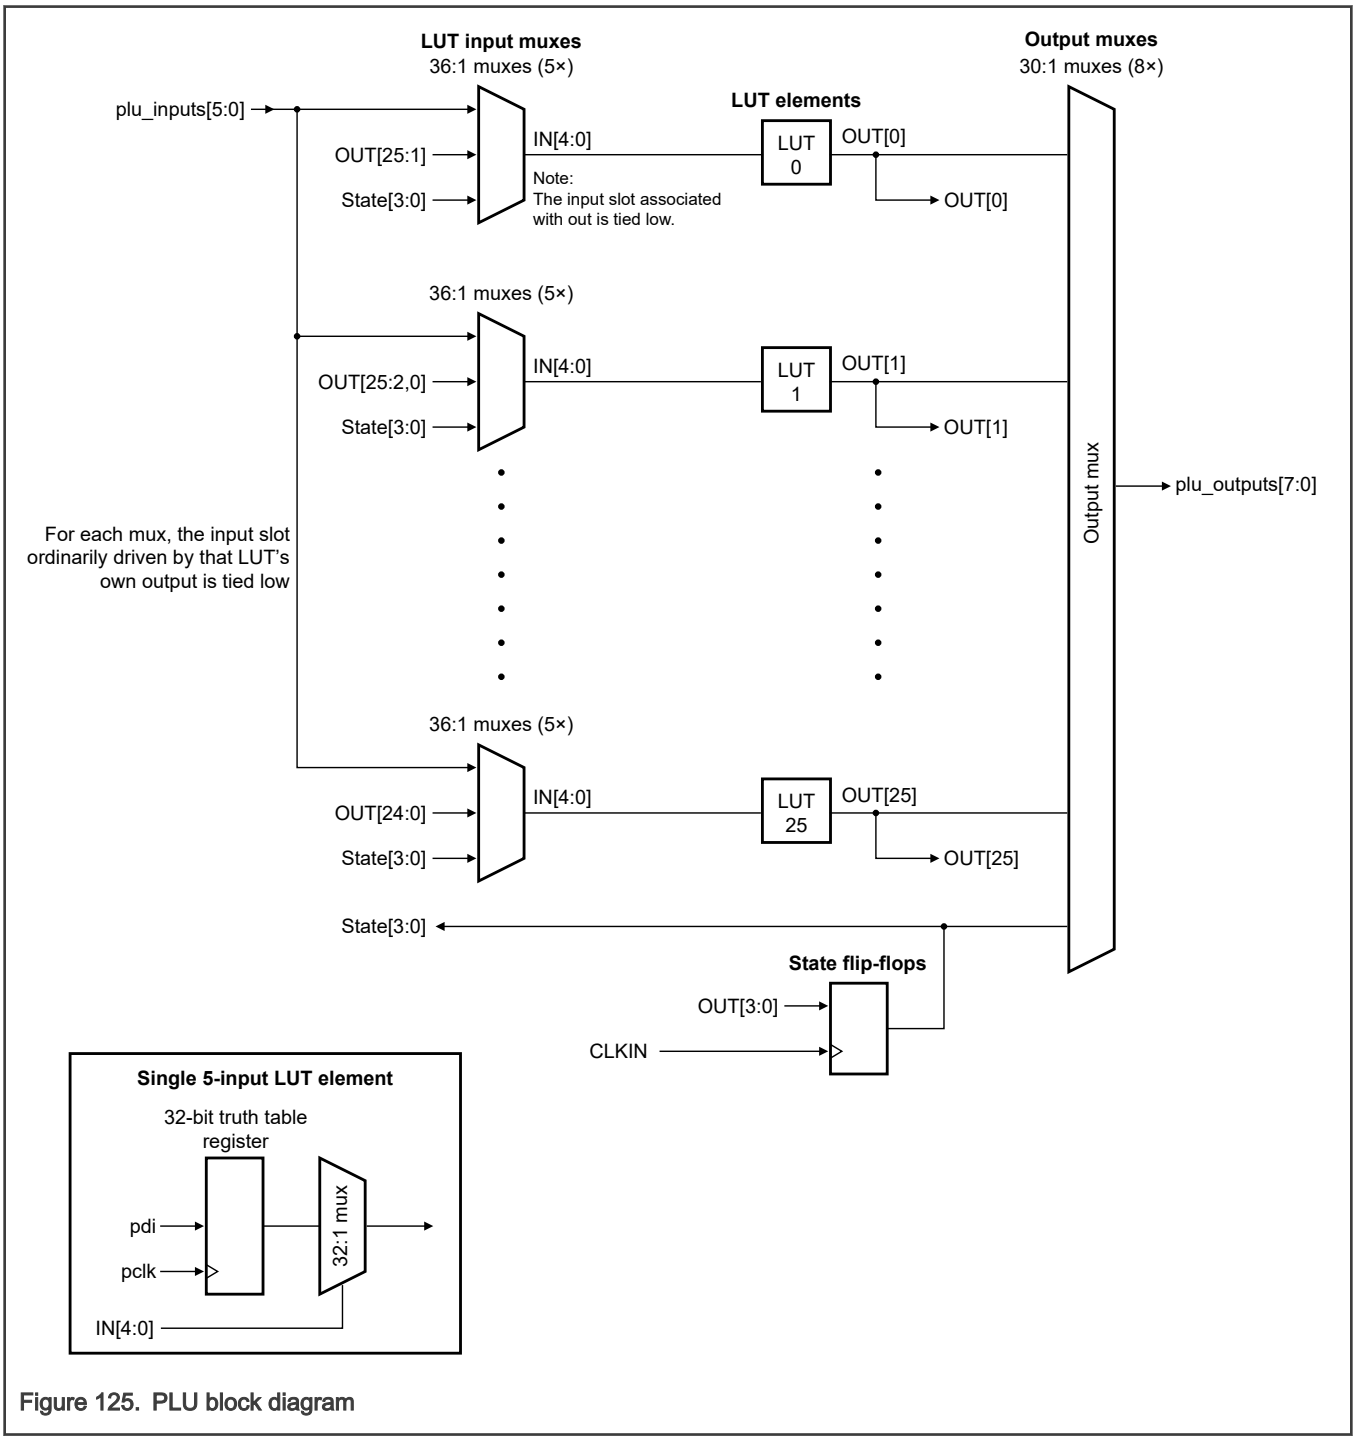


Figure 125. PLU block diagram

31.3 Functional description

PLU is comprised of twenty-six 5-input LUT elements. Each LUT element contains a 32-bit truth table (look-up table) register and a 32:1 multiplexer. During operation, the 5 LUT inputs control the select lines of the multiplexer. This structure allows you to use any logical combination of the 5 LUT inputs.

The 5 inputs to each LUT can be driven from a selection of sources comprised of the primary inputs from pins, the outputs of the other LUTs, and the outputs of the four state flip-flops.

A set of multiplexers associated with each LUT is used to select the 5 inputs to that LUT. These multiplexers are controlled by registers programmed during initialization. Connecting multiple LUT elements together permits construction of complex boolean expressions.

Outputs of up to four of the LUTs can be captured in the four state flip-flops and can be used as primary outputs or connected to the inputs of other LUTs. These four flip-flops, if used by the target logic network, are clocked by the external CLKIN supplied by the user.

The four state flip-flops are automatically cleared to zero by the internal chip reset signal. If a different initial state than all zeros is required for these flip-flops, you must force the primary inputs at startup to a combination that will achieve the required state. That startup combination must be maintained through at least one CLKIN rising-edge.

Generally, the PLU bus clock can be shut off to conserve power after the PLU module is configured. If you need to read the outputs register when PLU is operational, the PLU bus clock must be re-enabled prior to performing the read.

31.3.1 Clocking

The clock that feeds the programmable logic unit can be selected from the following clock inputs:

Global Functional Clock - pclk

- This clock is supposed to be on in normal operations, all of the registers shown in capture 5 are clocked by the internal bus clock.

External Clock - plu_clkin

- This is the external clock from outside the chip which can be used to run the four state flip-flops. Only the four state flip-flops used as part of the target logic network use the externally applied plu_clkin.

Low Reference Clock - hclk

- This clock is used for programmable glitch filter, when no plu_clkin is present, an alternative mechanism for suppressing glitches is provided by means of a programmable, digital glitch filter. hclk is used during deep-sleep mode if required.It will be a low-frequency, low-power clock (For example, a 1 MHz low-power oscillator).

High frequency Clock - hclk_div_2

- This clock performs the same function as hclk, but at a different frequency. hclk_div_2 will be a higher frequency clock (For example,a 12 MHz 16 MHz or 30 MHz FRO) which will be higher-power but provide shorter latency and finer resolution over the filter width.

Medium frequency Clock - hclk_div_4

- This clock performs the same function as hclk or hclk_div_2, but at a different frequency. Should be tied-low and de-spec'd for most chips. Faster or slower clocks 1MHz - 30 MHz not useful.

31.3.2 Programming PLU

Programming PLU to implement a particular logic network requires the following steps:

1. Write to each truth table register to specify the logic functions to be performed by each of the LUT elements.
2. Program the input multiplexer registers to select the five inputs presented to each LUT.
3. Program the output multiplexer register to select the eight primary outputs from the PLU module.

NOTE

Programming of all registers must be performed during initialization. Do not write to the registers during operation.

A tool suite is provided to facilitate the programming of PLU. The tool suite reports the values that must be written to all the registers in order to implement a logic network. See PLU programming tool suite for a complete description of the tool flow.

The I/O multiplexing must be programmed in order to connect the required number of PLU primary inputs and outputs to pins.

31.3.2.1 PLU programming tool suite

The tool suite that is provided facilitates configuring PLU in order to implement the desired logic network. See the tool suite documentation for input information.

The output from the tool suite includes the following:

- Values to be programmed into all LUT*x*_INPUT*x*_MUX registers.
- Values to be programmed into all LUT*x*_TRUTH registers.
- Values to be programmed into all OUTPUT*x*_MUX registers.
- Error response if the described network cannot be implemented—most commonly due to an excessive amount of logic or the use of more than four flip-flops.
- AC Timing parameters for the implemented design.

31.3.3 Interrupts

The raw wake-up or interrupt output generated by PLU is prone to glitching because of the frequent delays within the network of LUTs. If used directly, the raw wake-up or interrupt output is likely to generate false wake-ups and interrupt requests. Two options for eliminating glitches are provided in the following topics.

NOTE

Glitch pulse-widths can reach lengths in excess of tens of nanoseconds.

31.4 External signals

A particular logic network may not require all of the available inputs or outputs. You can specify which inputs and outputs to use and which package pins those inputs and outputs will connect to as part of the overall top-level I/O configuration.

If the logic network uses one or more of the four state flip-flops, an external clock must be applied to the CLKIN input. The package pin used for this function is specified using the chip-level I/O multiplexing. All other PLU inputs must meet specified setup and hold times relative to this clock input. Output timing is also specified relative to this pin.

NOTE

If the logic network is purely combinatorial, there is no need to provide an input clock to CLKIN.

Table 317. External signals

Signal	I/O	Description
plu_inputs[5:0]	Input	Primary inputs. All plu_inputs are available as input sources to all LUT elements.
plu_clkin	Input	Input clock to the four state flip-flops, if used. Not required for purely combinatorial networks. Input/output timing is specified relative to this clock.
plu_outputs[7:0]	Input/Output	Primary outputs. Selectable via multiplexers from among all LUT element outputs and the four state flip-flops.

31.5 Initialization

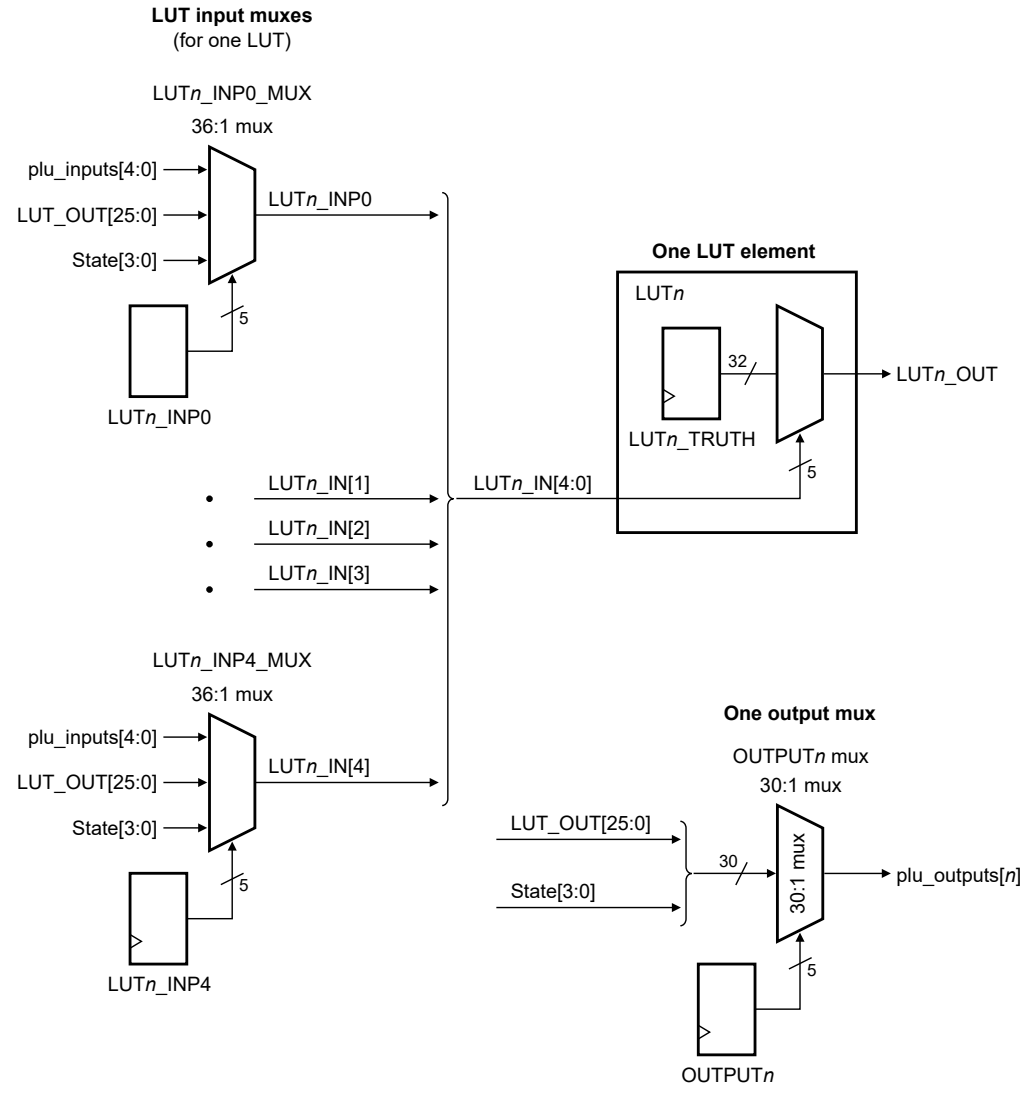
To initialize PLU:

- Enable the clock to the PLU register interface.
- Enable PLU interrupts for waking up from deep-sleep and low-power modes.
- Configure the various truth table registers, input multiplexer registers, output multiplexer register.

31.6 Memory Map and register definition

All of the registers shown are clocked by the internal bus clock. Only the four state flip-flops used as part of the target logic network use the externally applied CLKIN.

All ones in the implemented bits (lsbs) for the LUT*n*_INP*x* and OUTPUT mux registers means none of the input options are selected. In this case, the associated multiplexer output is a fixed logic '0'. These registers must be programmed to a valid value.



Note: For each mux, the input slot driven by the LUT's own output is tied low.

Figure 126. PLU register multiplexing configuration

31.6.1 Programmable Logic Unit (PLU) register descriptions

31.6.1.1 PLU memory map

PLU0 base address: 4003_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h - 330h	Input select register for LUTn (0 to 25), Inputx (5 inputs) (LUT0_INP0_MUX - LUT25_INP4_MUX)	32	RW	See section
800h - 864h	PLU LUT truth table (LUT0_TRUTH - LUT25_TRUTH)	32	RW	0000_0000h
900h	PLU outputs (OUTPUTS)	32	R	0000_0000h
904h	Wakeup interrupt control (WAKEINT_CTRL)	32	RW	0000_0000h
C00h - C1Ch	PLU output multiplexer (OUTPUT0_MUX - OUTPUT7_MUX)	32	RW	0000_001Fh

31.6.1.2 Input select register for LUTn (0 to 25), Inputx (5 inputs) (LUT0_INP0_MUX - LUT25_INP4_MUX)

Offset

For a = 0 to 25; b = 0 to 4:

Register	Offset
LUTa_INPb_MUX	0h + (a × 20h) + (b × 4h)

Function

These registers control the multiplexers to select which input sources to connect to each LUT input.

31.6.1.3 PLU LUT truth table (LUT0_TRUTH - LUT25_TRUTH)

Offset

For a = 0 to 25:

Register	Offset
LUTa_TRUTH	800h + (a × 4h)

Function

Each LUT element contains one 32-bit truth table register which specifies whether the LUT will output a '0' or a '1' for each combination of the LUT inputs. In other words, these registers specify the complex Boolean expression each individual LUT is to perform.

NOTE

The values that must be programmed into each of these registers is provided by the tool suite.

31.6.1.4 PLU outputs (OUTPUTS)

Offset

Register	Offset
OUTPUTS	900h

Function

This register provides the current state of the eight designated PLU outputs. Due to the asynchronous nature of PLU, there is no guarantee that a read of this register will not capture transitional data. It is strongly recommended to read this data multiple times until a consistent result is returned, unless it is known that the PLU inputs will be stable during the read operation.

Fields

Field	Function
31-8 —	Reserved Software should not write ones to reserved bits.
7-0 OUTPUT_STATE	Output state Provides the current state of the eight designated PLU outputs and the four state flip-flop outputs.

31.6.1.5 Wakeup interrupt control (WAKEINT_CTRL)

Offset

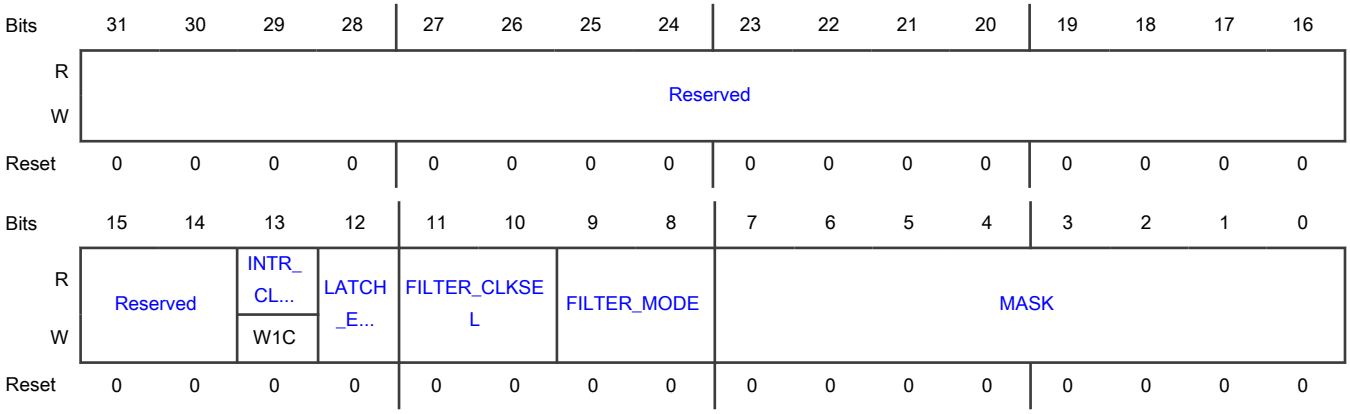
Register	Offset
WAKEINT_CTRL	904h

Function

This register enables PLU outputs to contribute to an asynchronous wake-up or interrupt request. All enabled output signals are logically combined using OR to generate a single wake-up or interrupt request.

A '1' in each bit in this register enables the corresponding PLU output to contribute to wake-up or interrupt generation. All enabled PLU outputs are combined using OR to generate the wake-up or interrupt request. A '0' in any bit of this register blocks the corresponding PLU output from causing a wake-up or interrupt. See Interrupts for more information.

Diagram



Fields

Field	Function
31-14 —	Reserved Software should not write ones to reserved bits.

Table continues on the next page...

Table continued from the previous page...

Field	Function
13 INTR_CLEAR	Write to clear wakeint_latched When using the registered wake-up or interrupt option (LATCH_ENABLE = '1') writing a '1' to this bit will clear the wake-up or interrupt request flag. Writing a '0' to this bit has no effect. There will be a delay of up to 1.5 CLKIN clock cycles before this write-to-clear takes effect, at which point this bit will also be cleared. Software can poll this bit to determine when the wake-up or interrupt request has been removed. **NOTE** It is not necessary for the PLU bus clock to be enabled in order to write-to or read-back this bit. This is not the case for the other bits of this register.
12 LATCH_ENABLE	Latch the interrupt Latch the interrupt and then the interrupt can be cleared with the next bit INTR_CLEAR. Setting this bit specifies use of the registered version of the wake-up or interrupt request instead of the raw or glitch-filtered version. This option can only be used if a CLKIN clock is provided from off-chip. If this bit is set, the wake-up or interrupt request will be set on the rising-edge of CLKIN whenever the raw wake-up or interrupt signal is high. The request must be cleared by software. **NOTE** This mode is not compatible with use of the glitch filter. If this bit is set, the FILTER_MODE field should be set to '00' (Bypass Mode).
11-10 FILTER_CLKSEL	Filter clock select Selects which clock source option to use as the filter clock. See the chip-specific PLU information for the clocking options. 00b - Selects the 1 MHz low-power oscillator as the filter clock. 01b - Selects the 12 MHz FRO as the filter clock. 10b - Reserved 11b - Reserved
9-8 FILTER_MODE	Filter Mode Control input of the PLU, add filtering for glitch. 00b - Bypass mode. Filtering is disabled. The raw wake-up or interrupt will be passed through. 01b - Filter 1 clock period. Any pulse duration shorter than one cycle of the designated filter clock will be filtered out. Pulse widths up to two cycles long may be filtered. 10b - Filter 2 clock period. Any pulse duration shorter than two cycles of the designated filter clock will be filtered out. Pulse widths up to three cycles long may be filtered. 11b - Filter 3 clock period. Any pulse duration shorter than three cycles of the designated filter clock will be filtered out. Pulse widths up to four cycles long may be filtered.
7-0 MASK	Interrupt mask Selects which of the eight PLU outputs contribute to interrupt.

31.6.1.6 PLU output multiplexer (OUTPUT0_MUX - OUTPUT7_MUX)

Offset

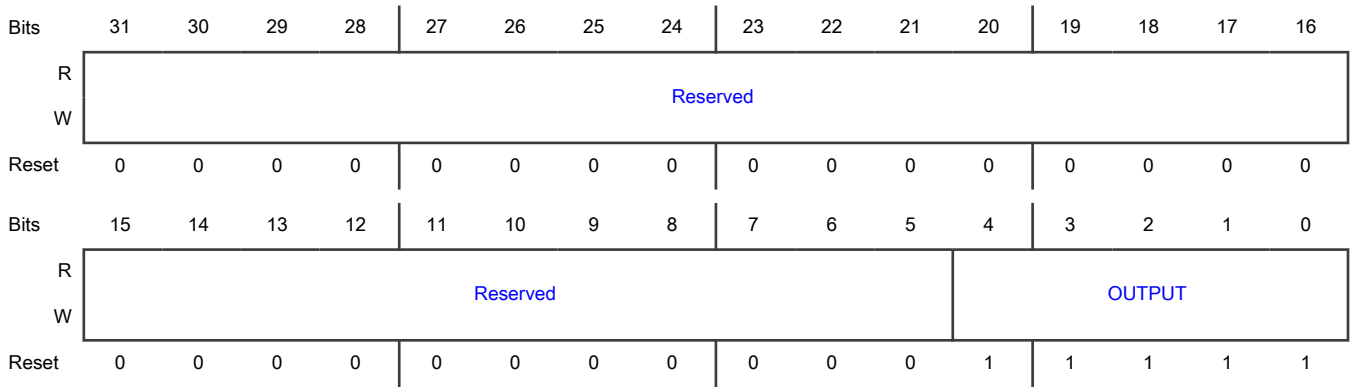
For a = 0 to 7:

Register	Offset
OUTPUTa_MUX	C00h + (a × 4h)

Function

Selects the source to be connected to PLU output *n*. The available choices are all of the individual LUT element outputs and the four state flip-flop outputs.

Diagram



Fields

Field	Function
31-5 —	Reserved Software should not write ones.
4-0 OUTPUT	Selects the source to be connected to PLU output n. For each PLU output the available sources are, in order: 1. The outputs from all of the available LUT elements, beginning with LUT0. 2. The four state flip-flops, beginning with state[0]. 0x0 programmed selects LUT0 as the source of this output. Each higher binary value selects one of the other sources mentioned above. 11111b - Fixed 0 0_0000b - LUT output 0 0_0001b - LUT output 1 0_0010b - LUT output 2 0_0011b - LUT output 3

Chapter 32
Reset

32.1 Overview

The following table shows the reset sources for this chip. Each system reset source has a corresponding field maintained in the system reset status (SRS) register through reset. Use this information to take appropriate action when coming out of a reset.

Table 318. Reset sources

Reset type	Source
Power	• Power-on reset (POR) • Low-voltage detect (LVD) • High-voltage detect (HVD)
External	• External pin reset (RESET_b) • WUU
Internal	• VBAT domain POR • Code watchdog reset • Intrusion and tamper response controller (ITRC) reset • Tamper event reset • WWDT • Software (SW) • SCG • Reset acknowledge timeout (RSTACK) • Low-power acknowledge timeout (LPACK) • Lock up (LOCKUP) • Debug port (DAP) • JTAG

32.2 Power reset sources

Supply voltages must remain in their specified ranges during execution to ensure the predictable operation of the chip. Because this is not possible during power up and power down, the chip implements multiple voltage monitors to detect when the supply is outside an acceptable range. When this occurs, the voltage monitor initiates a reset to halt execution and prevent unexpected behavior.

The voltage monitors detect power-on, low-voltage, and high-voltage events.

32.2.1 Power-on reset (POR)

The POR voltage monitor ensures that the voltage applied to the system is high enough for other analog modules (such as bias circuits and low-voltage monitors) to operate correctly.

When you initially apply voltage to the chip or when the supply voltage drops below the POR falling threshold, the POR monitor triggers the POR condition to the chip.

The POR condition asserts a POR to all power domains. A POR sets the appropriate fields in the CMC registers so that software can determine when a POR occurs. See POR block diagram for more information.

32.2.2 Low-voltage detect (LVD)

The LVD monitors ensure that the voltage supplies to the chip are high enough for the logic and memories to operate correctly. When voltage is applied initially to the chip, the POR voltage monitor holds the LVD monitors in reset until the voltages are high enough. The LVD monitors hold the chip in reset until all monitoring voltages have risen above the respective default LVD low thresholds. The LVD monitors are enabled by default.

When enabled, the LVD monitor triggers a reset when the voltage drops below the V_{LVD} threshold. The voltage threshold that triggers the LVD reset is programmable. The LVD monitor ensures that the chip halts operation and remains in reset when the monitored voltage is outside the desired range.

In active modes, the LVD monitors are enabled by default. They are optionally available in certain low-power modes. See Module operation in low-power modes for more information on the available modes.

The reset sources, which the individual LVD monitors trigger, combine into a single LVD reset. The LVD reset condition initiates a POR in all power domains while only the POR, LVD, and HVD detection logic remain operational. An LVD reset sets the appropriate fields in the CMC registers so that software can determine when an LVD reset occurs.

32.2.3 High-voltage detect (HVD)

The HVD monitors ensure that the voltage supplies to the chip are within the operating range for the logic and memories using those power supplies. The HVD monitors are disabled by default, but when an HVD circuit is enabled, the HVD monitor triggers a reset when the voltage rises above the V_{HVD} threshold. The HVD monitor ensures that the chip halts operation and remains in reset when the monitored voltage is outside the desired range.

The HVD monitors are available in Active and certain low-power modes. See Module operation in low-power modes for more information on the available modes.

The reset sources, which the individual HVD monitors trigger, combine into a single HVD reset. The HVD reset condition initiates a POR in all power domains while only the POR, LVD, and HVD detection logic remain operational. An HVD reset sets the appropriate fields in the CMC registers so that software can determine when an HVD reset occurs.

32.3 External reset sources

The chip supports external resets to reset or awaken the chip from very low-power states. This allows the chip to start at the correct time from a known state.

32.3.1 External pin reset (RESET_b)

The RESET_b pin is a bidirectional, open-drain pin with an internal pullup resistor. The RESET_b pin is functional in two modes:

- During Active and low-power modes, you can assert the RESET_b pin externally to force the chip into a pin-reset condition.
- During reset, RESET_b remains asserted until the chip completes hardware initialization, at which point the RESET_b pin is released. If you assert the RESET_b pin externally, the chip remains in reset until you deassert RESET_b.

The RESET_b signals passed through two digital filters. CMC's reset pin control register configures the RESET_b signals. In Active mode, you can use the CMC reset filter and configure the duration of the filter from 1 to 32 CMC clock cycles. The CMC reset filter clock source is slow_clk. In both Low-Power mode and Active mode, you can enable a low-power reset filter to filter RESET_b signals for the duration of two clock cycles. The clock is sourced from either FRO_16K or OSC_32K. Use RTC.CTRL[CLK_SEL] to select OSC_32K as the lp_osc clock. See Table 319 for more information.

The pin reset condition triggers CMC to assert a warm reset signal to all power domains. A pin reset sets the appropriate fields in the CMC registers so that software can determine when a pin reset occurs.

32.3.2 WUU

WUU provides a number of external pins and on-chip peripherals to wake the chip from Deep Power-down mode. See the WUU chapter for a list of external and internal reset sources connected to WUU.

After wake-up from Deep Power-down mode, the power management logic triggers a wake-up reset in the power domains that were previously powered off. The wake-up reset condition triggers CMC to assert a POR signal to the power domains that were powered down. Wake-up reset does not affect the system voltage domain. A wake-up reset sets the appropriate fields in the CMC registers so that software can determine when a wake-up reset occurs.

32.4 Internal reset sources

When certain erroneous conditions are detected, the chip resets itself internally. The internal reset allows the chip to recover from the erroneous conditions and restart from a known state.

32.4.1 VBAT domain POR

The chip resets when the VBAT domain POR asserts.

32.4.2 Code watchdog reset

The code watchdog timer (CDOG) module detects unexpected changes (faults) in the code execution flow to protect the software integrity. You can configure CDOG to reset or interrupt the processor core when the module detects a fault.

32.4.3 Intrusion and tamper response controller (ITRC) reset

System security violation (SECVIO) events connect to ITRC inputs. You can configure ITRC to generate a reset when any ITRC input is asserted.

32.4.4 Tamper event reset

The Digital Tamper (TDET) module supports active and passive tamper pin function. When a pin tamper event is detected, TDET can generate a reset.

32.4.5 WWDT

One of the WWDT modules generates the WWDT reset.

WWDT receives periodic communication from software, known as servicing or refreshing WWDT, to monitor the operation of the system. If periodic servicing does not occur, the watchdog triggers a WWDT reset condition.

The WWDT reset condition triggers CMC to assert a warm reset signal to all power domains. A WWDT reset sets the appropriate fields in the CMC registers so that software can determine when a WWDT reset occurs.

32.4.6 Software (SW)

During execution, software can initiate a reset to restart the chip from a known state if it detects an erroneous operation.

The SW reset condition, which CPU0 SYSRESETREQ generates, triggers CMC to assert a warm reset signal to all power domains. An SW reset sets the appropriate fields in the CMC registers so that software can determine when an SW reset occurs. See the system reset status register (SRS) in the CMC chapter for more information.

32.4.7 SCG

SCG contains a clock monitor, which detects a loss of the external clock when enabled. A loss of the external clock triggers the SCG reset condition.

The SCG reset condition triggers a warm reset in all power domains. When CMC.SRS[SCG] and CMC.SRS[WARM] status fields are 1, an SCG reset condition has occurred.

See the SCG chapter for more information on enabling the clock monitor.

NOTE

To prevent unexpected reset events, you must disable clock monitors before entering any low-power modes where the external clocks are absent.

32.4.8 Reset acknowledge timeout (RSTACK)

The reset state machine includes a timeout counter. If the reset state machine does not progress within 64 ms, it triggers the timeout counter and the RSTACK reset condition.

The RSTACK reset condition triggers CMC to assert a warm reset signal to all power domains. An RSTACK reset sets the appropriate fields in the CMC registers so that software can determine when an RSTACK reset occurs.

32.4.9 Low-power acknowledge timeout (LPACK)

The low-power entry state machine includes a timeout counter that is triggered if a module does not acknowledge entry into a low-power mode after 64 ms. This triggers the LPACK reset condition.

The LPACK reset condition triggers CMC to assert a warm reset signal to all power domains. An LPACK reset sets the appropriate fields in the CMC registers so that software can determine when an LPACK reset occurs.

32.4.10 Lock up (LOCKUP)

The Cortex-M33 core enters the lockup state as a result of certain illegal operations. This triggers the lockup reset condition.

The lockup reset condition triggers CMC to assert a warm reset signal to all power domains. A lockup reset sets the appropriate fields in the CMC registers so that software can determine when a lockup reset occurs.

32.4.11 Debug port (DAP)

Any debug access port that can initiate a reset request from a connected debugger also triggers the DAP reset condition.

The DAP reset condition triggers CMC to assert a warm reset signal to all power domains. A DAP reset sets the appropriate fields in the CMC registers so that software can determine when a DAP reset occurs.

32.4.12 JTAG

The JTAG reset condition triggers whenever a JTAG instruction places the chip in reset.

The JTAG reset condition triggers CMC to assert a warm reset signal to all power domains. A JTAG reset sets the appropriate fields in the CMC registers so that software can determine when a JTAG reset occurs.

32.5 Reset type

This section describes the different resets that can be generated on this chip and their respective reset sequences. There are two types of reset conditions on this chip:

- POR (see POR)
- Warm reset (see Warm reset)

32.5.1 POR

Each power domain generates a POR to reset the entire chip, including debug and mode control logic. The POR for each power domain can assert as a result of the following events:

- Initial power up of the chip
- LVD or HVD
- Power domain wake-up from Power-Down or Deep Power-Down mode (varies by domain)

A POR does not guarantee the contents of on-chip SRAM. Only a Power Down wake-up guarantees the contents of on-chip SRAM, and only for SRAM that you configure to retain state.

32.5.1.1 POR sequence

The following steps are performed as part of the POR (or LVD or HVD) sequence:

1. RESET_b pin is driven low and internal reset signals assert
2. POR and LVD signals negate, and clocks are enabled in their default configuration
3. Internal reset remains asserted for 32 Cortex-M33 core clock cycles
4. Internal reset to Flash and Fuse controller negates and their initialization sequences commence
5. Initialization sequences for Flash and Fuse complete
6. Internal trim registers are loaded and RESET_b pin is tri-stated
7. Reset state machine waits for RESET_b pin input to pull high or drive high externally
8. Internal reset signals negate
9. Core exits reset and fetches the initial program counter and stack pointer from boot ROM

When the chip wakes up from Deep Power-Down or Power-Down mode, the reset sequence differs slightly from the POR sequence. See Deep power-down (DPD) reset sequence and Warm reset for more information.

32.5.1.2 Deep power-down (DPD) reset sequence

The following steps are performed as part of the deep power down wake-up sequence:

1. Internal reset signals assert
2. Wake-up signal negates and clocks are enabled in their default configuration
3. Internal reset remains asserted for 32 clock cycles
4. Internal reset to Flash and Fuse controller negates and their initialization sequences commence
5. Initialization sequences for Flash and Fuse complete
6. Internal trim registers are loaded
7. Internal reset signals negate
8. Core exits reset and fetches the initial program counter and stack pointer from boot ROM

A DPD reset sequence does not assert RESET_B unless you use the RESET_b pin as the wake-up source. A wake-up from deep power down via the RESET_b pin follows the warm reset sequence.

32.5.2 Warm reset

A warm reset reinitializes the chip to a known state after it runs for a period of time.

A warm reset resets most of the logic in each power domain. Warm resets are divided into the following reset sources:

- Fatal
- Nonfatal

You can configure nonfatal reset sources to generate an interrupt instead of the warm reset. If software can clear the nonfatal reset source (including the status flag) within 64 ms, then the warm reset is averted. Nonfatal resets retain the contents of on-chip SRAM.

You cannot configure fatal reset sources to generate an interrupt and they do not guarantee the contents of on-chip SRAM. See the CMC chapter for which reset sources are fatal resets.

The following steps are performed as part of the warm reset sequence:

1. RESET_b pin drives low and internal reset signals assert
2. Clocks are enabled in their default configuration
3. Internal reset remains asserted for 32 clock cycles
4. Internal reset to Flash and Fuse controller negates and their initialization sequences commence
5. Initialization sequences for Flash and Fuse complete
6. Internal trim registers are loaded and RESET_b pin is tri-stated
7. Reset state machine waits for RESET_b pin input to pull high or drive high externally
8. Internal reset signals negate
9. Core exits reset and fetches the initial program counter and stack pointer from boot ROM

Chapter 33
Clocking

33.1 Configuring the main clock and system clock

The clock source for the registers and memories is derived from the main clock. The main clock can be selected from the sources listed in step 1 below.

The main clock, after optionally being divided by the CPU clock divider, is called the system clock. The system clock provides a clock signal to the core, memories, and peripherals (register interfaces and peripheral clocks).

1. Select the main clock in the SCG RCCR register from these options:
   - 12-MHz free-running oscillator (FRO) output (FRO_12M) from internal oscillator.
   - FRO high-speed output (fro_hf) from internal oscillator. By default, its speed is 48 MHz. fro_hf is default main clock.
   - External oscillator.
   - Output of PLL0.
   - Output of PLL1.
   - RTC 32-kHz oscillator.
   - Output of USB PLL (usb_pll_clk).
2. Select the divider value for the system clock AHBCLKDIV register.
3. Enable the clock for the memories and peripherals used in the application.

NOTE

You must disable the peripheral clock (via AHBCLKCTRLx registers) when performing software reset on peripherals (via PRESETCTRLx registers). After asserting and de-asserting reset, you can enable the respective peripheral clock.

33.2 Clock generation

The system control block facilitates clock generation. Many clocking variations are possible. Figure 127 gives an overview of potential clock options. Table 319 describes signals on the clocking diagram. The maximum clock frequency is 150 MHz.

NOTE

The indicated clock multiplexers shown in Figure 127 are synchronized. For the multiplexer to switch gracefully between the two clocks without glitches, the currently selected clock and the clock to be switched to must be running. Other clock multiplexers are not synchronized. If a glitch-free output is needed, the output divider can be stopped and restarted gracefully during switching.

FRO_12M provides a 1-MHz clock (clk_1m) which is independent of watchdog 0. This clock is accurate within a limited range (±3% of each value) of the temperature, voltage, and silicon processing variations made during assembly after trimming. See the data sheet for specifications. To determine the actual watchdog oscillator output, use the frequency measuring block. See Chip-specific Frequency Measurement information.

The device contains two PLLs (PLL0 and PLL1) that can be configured to use a number of clock inputs and produce an output clock. This output clock can then be used to run most on-chip functions. You can monitor the output of the PLL via the CLKOUT pin.

NOTE

The maximum allowed frequency for the main clock and system clock (to CPU0, AHB bus, sync, and others) is 150 MHz.

Table 319. Clocking diagram signal name descriptions

Name	Description
lp_osc	Low power clock source. It is selected as either FRO_16K or XTAL32K in the RTC register.
system_clk	AHB bus clock. Used by the CPU, AHB bus, APB bus, and others. Derived from main_clk.
slow_clk	Slow clock derived from system_clk divided by 4. slow_clk provides the bus clock for FMU, SPC, CMC, TDET, CMP0, CMP1, VBAT, LPTRM0, LPTRM1, RTC, GPIO5, PORT5, and TSI.
clk_in	Internal clock from the external oscillator. clk_in connects to different modules as three functional clock source options. • Ungated, clk_in goes to ADC0, ADC1, DAC0, DAC1, DAC2, CMP0, CMP1, CMP2, ENET, and FlexIO. • Gated by SYSCON.CLOCK_CTRL[1], clk_in goes to FREQME, USBHS, LPTMR0, and LPTMR1 • Gated by SYSCON.CLOCK_CTRL[5], clk_in goes to MICFIL, EMVSIM0, EMVSIM1, CAN0, CAN1, I3C0, I3C1, SAI0, SAI1, SINC Filter (SINC), TSI, USBFS, SCT, uSDHC, and CLKOUT.
CLKOUT	Clock used for debugging purposes or to drive some external logic (see data sheet for limitations on pin output frequency). Many on-chip clocks can be selected to be output on the CLKOUT function. To use CLKOUT, you must connect it to a pin by selecting it in the PORT block.
fro_12m	12-MHz output from FRO_12M.
clk_1m	1-MHz output of FRO_12M.
fro_hf	Clock output from FRO_144M. SCG_FIRCCFG[RANGE] controls the frequency. This clock can only be used for USB devices and is not reliable for the USB host timing requirements for data signaling rate.
fro_hf_div	fro_hf clock, potentially divided by the FRO_HF divider. Used to save power, when fro_hf is faster than needed.
clk_16k	16-kHz clock output from FRO_16K.
main_clk	Main clock used by the CPU and AHB bus, and potentially many others. The main clock and its source selection are shown in Figure 127.
mclk_in	The MCLK input function, when it is connected to a pin by selecting it in the port control block. There are two MCLK signals: mclk_in_0 connects to SAI0, and mclk_in_1 connects to SAI1.
none	Tied-off source. To save power when the output of the related multiplexer is not used, select this source.
pll_clk_div	Output of PLL0 or PLL1, potentially divided. The output may be divided to save power, or because the frequency of the raw PLL output may be too high to be used directly.
pll0_clk	Output of PLL0. PLL0 and its source selection are shown in Figure 127.
pll1_clk	Output of PLL1. PLL1 and its source selection are shown in Figure 127.
wdt_clk	Clock to the watchdog timer.
XTAL32K	Output of the 32-kHz crystal oscillator.

33.4 Set up PLL0

PLL0 creates a stable output clock at a higher frequency than the input clock. If you need a main clock with a frequency higher than the 12-MHz FRO clock and the 144-MHz FRO clock (fro_hf) is not appropriate, use the PLL to boost the input frequency.

33.5 Set up PLL1

PLL1 creates a stable output clock at a higher frequency than the input clock. If you need a main clock with a frequency higher than the 12-MHz FRO clock and the 144-MHz FRO clock (fro_hf) is not appropriate, use the PLL to boost the input frequency.

34.1.1 Module instances

This device contains one instance of the SCG module, SCG0.

34.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

34.1.3 Crystal oscillator clock sources

In this device, the ROSC is sourced from Crystal Oscillator 32.768 kHz clock in VBAT block, and the SOSC is sourced from System Crystal Oscillator Clock in the SCG block.

34.1.4 SIRCCSR[SIRCSTEN] power domain

SIRCCSR[SIRCSTEN] is enabled when the WAKE domain is in Deep Sleep mode. When the WAKE domain is in Deep Sleep mode, PMCTRLWAKE[LPMODE]=0x1.

34.1.5 Clock name decoder ring

The table below shows translation of clock name sources used in the SCG chapter to the names used throughout the document.

Table 322. Clock name decoder ring

Clock source specified in chapter	Decoded clock name
APLL	PLL0_CLK
SPLL	PLL1_CLK
SOSC	CLK_IN
SIRC	FRO_12M
FIRC	FRO_HF
ROSC	XTAL32K
UPLL	USB_PLL_CLK

34.2 Overview

The System Clock Generator (SCG) provides the main clock and additional peripheral clocks for the MCU. SCG takes clock inputs from a variety of sources and generates the clocks that the MCU requires.

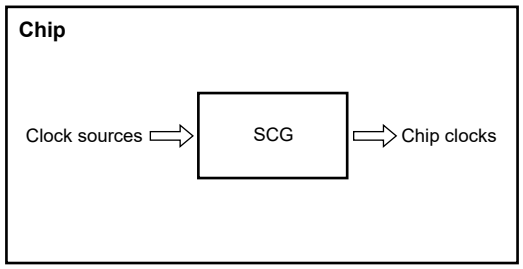

Figure 163. System Clock Generator (SCG) in MCU

34.2.1 Block diagram

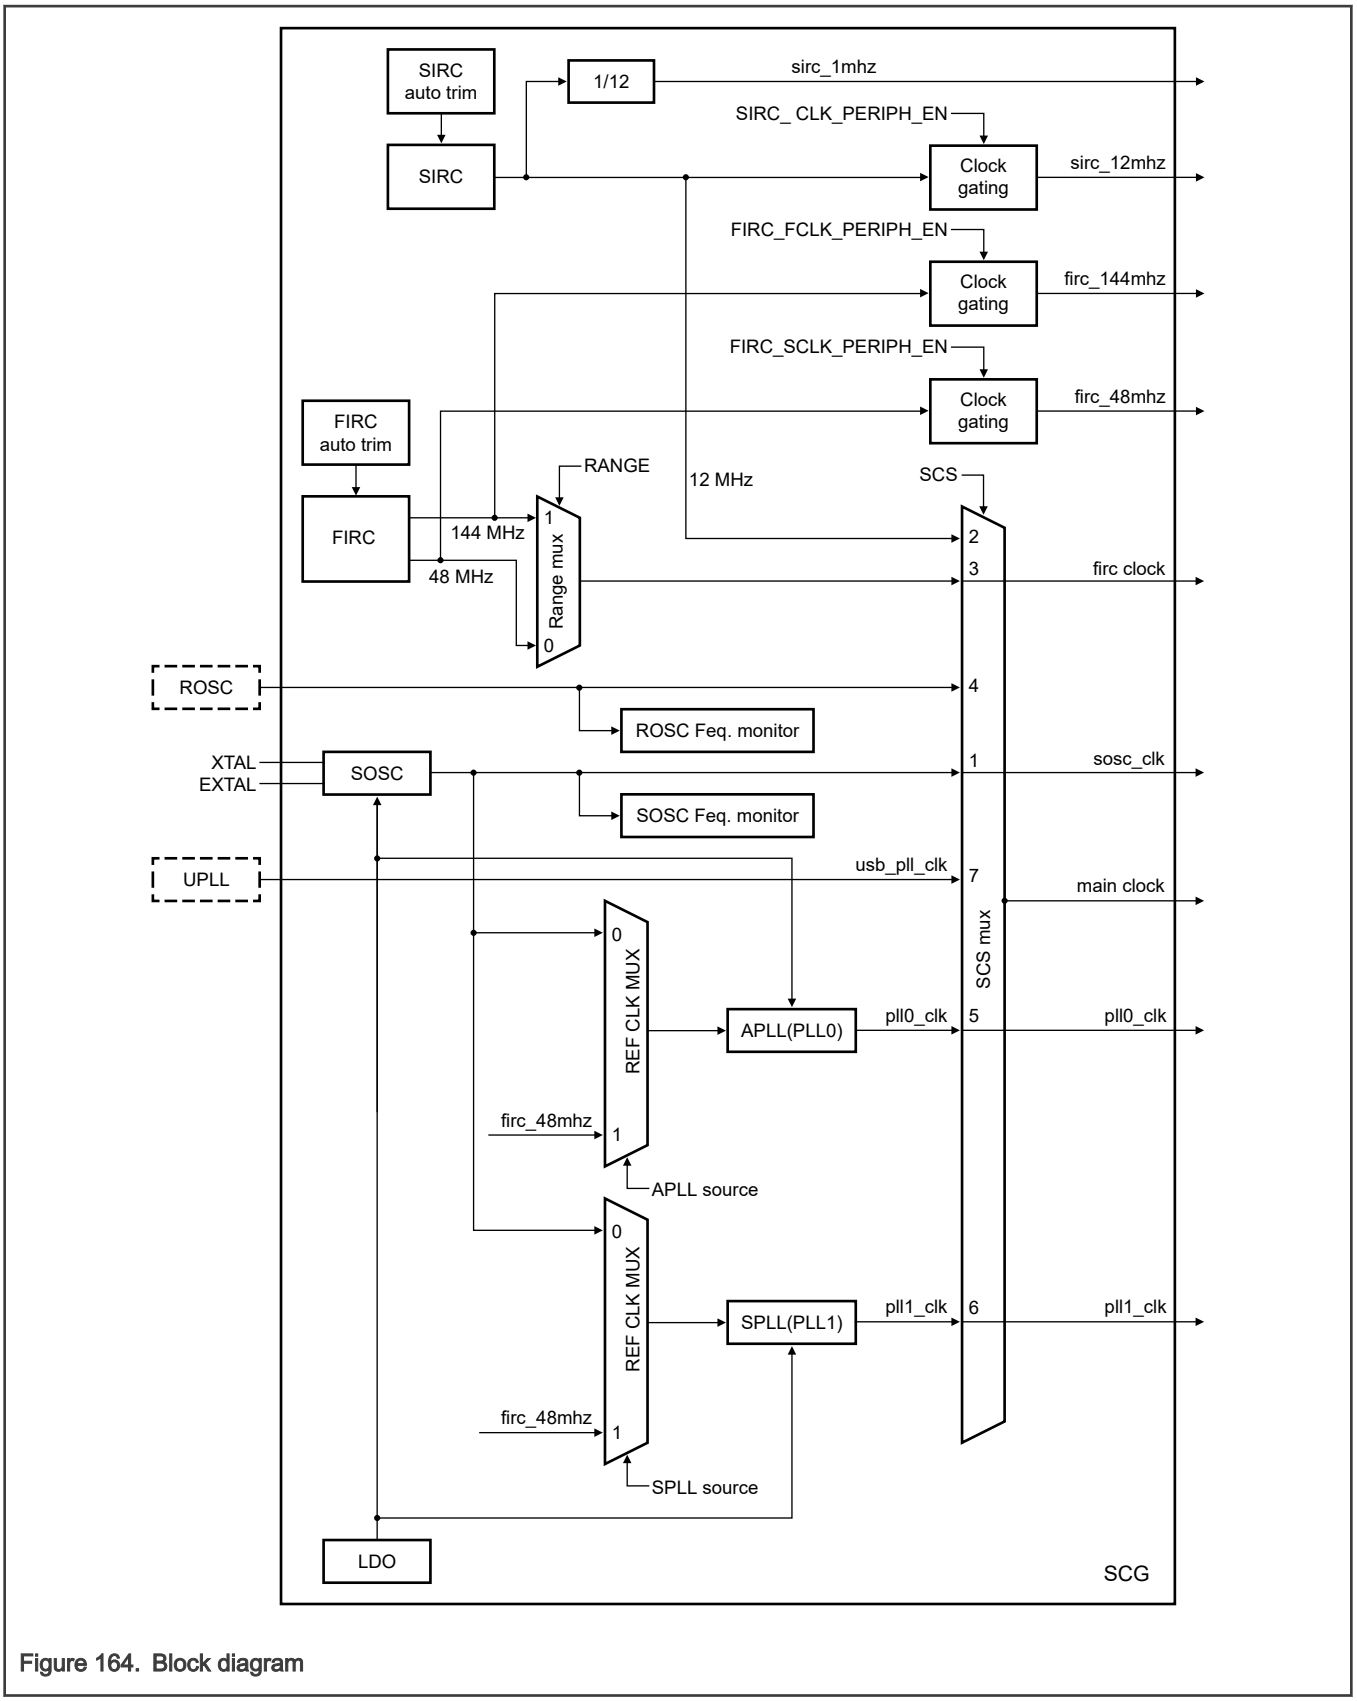

Figure 164. Block diagram

34.2.2 Features

Key features of SCG are:

- Auxiliary phase-locked loop (APLL) clock and system phase-locked loop (SPLL) clock. See PLL features and benefits and Functional features for details.
  - Can be selected as the clock source for system clocks
- Two internal reference clock (IRC) generators with trim capability: FIRC and SIRC
  - FIRC can output 144 MHz or 48 MHz clock by range select and can be used as a source for the APLL and SPLL.
  - SIRC can output 12 MHz clock.
  - Either of the IRC generators can be selected as the clock source for the system clocks.
- System crystal oscillator clock (SOSC)
  - Can be used as a source for the APLL and SPLL.
  - Can be selected as the clock source for system clocks.
- Real-time oscillator clock (ROSC)
  - Can be selected as the clock source for the device. To ascertain which signal the ROSC input maps to, see the chip-specific information.
- Clock monitor with reset and interrupt request capability for SOSC, ROSC, APLL, SPLL, and UPLL clocks
- Low dropout regulator (LDO) used as the supply for the PLL and SOSC
  - Configurable output voltage (1 V to 1.25 V)
  - Wide supply range (1.71 V up to 3.63 V)
  - Wide load current range (up to 8 mA)
  - Low noise, high Power Supply Rejection Ratio (PSRR)
  - Bypass mode

34.3 Functional description

34.3.1 SCG clock mode transitions

The system boots up from the FIRC source. The system clock can be switched between the following clock sources: FIRC, SIRC, SOSC, ROSC, APLL, SPLL, and UPLL.

SCG restricts programming into invalid clock modes, and ignores writes to the System Clock Source (SCS) fields. When a transition between Run modes or a transition from Run mode into Wait mode occurs, SCG switches to the corresponding clock mode as defined in the Run Clock Control Register (RCCR). After the switch is complete, the system switches to the selected Run or Wait mode.

The following table shows the SCG modes of operation.

Table 323. SCG modes of operation

Mode	Description
SOSC	SCG enters SOSC mode when the following occurs: • The device is in Run mode and 0001 is written to RCCR[SCS] • SOSCCSR[SOSCEN] = 1b

Table continues on the next page...

Table 323. SCG modes of operation (continued)

Mode	Description
	• SOSCCSR[SOSCVLD] = 1b In SOSC mode, the system clocks are derived from the external SOSC.
SIRC	SCG enters SIRC mode when the following occurs: • The device is in Run mode and 0010 is written to RCCR[SCS] • SIRCCSR[SIRCVLD] = 1b In SIRC mode, the system clocks are derived from SIRC.
FIRC	FIRC mode is the default clock mode of operation. SCG enters FIRC mode when the following occurs: • The device is in Run mode and 0011 is written to RCCR[SCS] • FIRCCSR[FIRCEN] = 1b • FIRCCSR[FIRCVLD] = 1b In FIRC mode, the system clocks are derived from FIRC. Two frequency range settings are available for FIRC clock, as described in FIRCCFG[RANGE]. Changes to FIRC range settings are ignored when the FIRC clock is enabled.
ROSC	SCG enters ROSC mode when the following occurs: • The device is in Run mode and 0100 is written to RCCR[SCS] • ROSCCSR[ROSCVLD] = 1b • LDOCSR[LDOEN] = 1b and LDOCSR[VOUT_OK] = 1b In ROSC mode, the system clocks are derived from the external ROSC.
APLL	SCG enters APLL mode when the following occurs: • The device is in Run mode and 0101 is written to RCCR[SCS] • APLLCSR[APLLCLKEN] = 1b • APLLCSR[APLLPWREN] = 1b • APLLCSR[APLL_LOCK] = 1b • LDOCSR[LDOEN] = 1b and LDOCSR[VOUT_OK] = 1b In APLL mode, the system clocks are derived from the output of the PLL which is controlled by either the FIRC or SOSC. The selected PLL clock frequency locks to a multiplication factor (as specified by its corresponding MDIV) times the selected PLL reference frequency. The programmable reference divider of the PLL must be configured to produce a valid PLL reference clock. This divide value is defined by the NDIV bits.
SPLL	SCG enters SPLL mode when the following occurs: • The device is in Run mode and 0110 is written to RCCR[SCS] • SPLLCSR[SPLLCLKEN] = 1b • SPLLCSR[SPLLPWREN] = 1b • SPLLCSR[SPLL_LOCK] = 1b

Table continues on the next page...

Table 323. SCG modes of operation (continued)

Mode	Description
	• LDOCSR[LDOEN] = 1b and LDOCSR[VOUT_OK] = 1b In SPLL mode, the system clocks are derived from the output of PLL which is controlled by either the FIRC or SOSC. The selected PLL clock frequency locks to a multiplication factor (as specified by its corresponding MDIV) times the selected PLL reference frequency. The programmable reference divider of the PLL must be configured to produce a valid PLL reference clock. This divide value is defined by the NDIV bits.
UPLL	SCG enters UPLL mode when the following occurs: • The device is in Run mode and 0111 is written to RCCR[SCS] • UPLLCSR[UPLLVLD] = 1b In UPLL mode, the system clocks are derived from the output of UPLL.
Stop	SCG enters Stop mode whenever the CORE domain enters a low power, state retention, or power down state. Power modes are chip-specific. For power mode assignments, see Power Management chapter that describes module operation in low-power modes. All SCG clock signals are static when entering Stop mode, including SCG system clocks (except clocks explicitly configured to continue running and are able to continue running in the target power mode). There are some exceptions. The following clocks can continue to run and stay enabled when all the respective conditions listed below are true. • SIRC is available in Deep Sleep mode when all the following conditions are true: — SIRCCSR[SIRCSTEN] = 1b • FIRC is available in Deep Sleep mode when all the following conditions are true: — FIRCCSR[FIRCEN] = 1b — FIRCCSR[FIRCSTEN] = 1b • SOSC is available in Deep Sleep mode when all the following conditions are true: — SOSCCSR[SOSCEN] = 1b — SOSCCSR[SOSCSTEN] = 1b — LDOCSR[LDOEN] = 1b and LDOCSR[VOUT_OK] = 1b • APLL is available in Deep Sleep mode when all the following conditions are true: — APLLCSR[APLLCLKEN] = 1b — APLLCSR[APLLPWREN] = 1b — APLLCSR[APLLSTEN] = 1b — LDOCSR[LDOEN] = 1b and LDOCSR[VOUT_OK] = 1b • SPLL is available in Deep Sleep mode when all the following conditions are true: — SPLLCSR[SPLLCLKEN] = 1b — SPLLCSR[SPLLPWREN] = 1b — SPLLCSR[SPLLSTEN] = 1b — LDOCSR[LDOEN] = 1b and LDOCSR[VOUT_OK] = 1b

34.3.2 SCG SOSC operation

The following table lists the SOSC configurations and SOSC output clock.

Table 324. SOSC mode operation

SOSCEN	EREFS	SOSC clock
0	0	Off
1	0	EXTAL Pad Clock
1	1	Crystal Oscillator Clock

34.3.3 SCG LOC operation

SCG supports the loss of clock (LOC) monitoring for the external reference clocks, including SOSC and ROSC. To enable the LOC monitor, the CMRE field for each of these clocks must be programmed to 1. To monitor these external reference clocks, the SCG uses an internal 31.25KHz reference clock derived by dividing the SIRC internal clock. You must program the SIRC to be enabled prior to enabling the LOC for either of these external reference clocks.

NOTE

F_{int} = SIRC divided down to 31.25 KHz

When enabled, the LOC monitors generate a system reset or system interrupt request depending on the CMRE field settings (see the CMRE description for each of the clocks for further information). The frequency conditions for the external reference clocks that trigger a LOC event are listed below:

- ROSC loss of external clock minimum frequency
  - When ROSC clock frequency is above (3/5) F_{int}, the chip is never reset and will not generate an interrupt.
  - When ROSC clock frequency is between (2/5) F_{int} and (3/5) F_{int}, the chip might reset or generate an interrupt, depending on the phase dependency between the ROSC clock and the reference clock.
  - When ROSC clock frequency is below (2/5) F_{int}, the chip always resets or generates an interrupt.
- SOSC loss of external clock minimum frequency
  - When SOSC clock frequency is above (16/5) F_{int}, the chip is never reset and will not generate an interrupt.
  - When SOSC clock frequency is between (15/5) F_{int} and (16/5) F_{int}, the chip might reset or generate an interrupt, depending on the phase dependency between the SOSC clock and the reference clock.
  - When SOSC clock frequency is below (15/5) F_{int}, the chip always resets or generates an interrupt.

34.3.4 APLL and SPLL operation

APLL and SPLL have similar functions and registers.

PLL is typically used to create a frequency that is higher than other on-chip clock sources and to operate both the CPU and other on-chip functions. You can also use it to obtain a specific clock that is otherwise not available. For example, a source clock with a frequency of any integer MHz (such as the 12 MHz FIRC) can be divided down to 1 MHz, then multiplied up to any other integer MHz (such as 13, 14, and 15).

PLL can be set up by calling an API supplied by NXP Semiconductors. See APLL and SPLL registers in SCG register descriptions for more information.

NOTE

APLL and SPLL have similar registers. Any references to the register or field names of these registers, without prefix "A" or "S", apply for both registers. For example, PLL_LOCK refers to both APLLCSR[APLL_LOCK] and SPLLCSR[SPLL_LOCK].

34.3.4.1 General description

PLL is a multipurpose phase-locked loop (PLL). It generates a CMOS-compatible clock and can be used in many applications, including as a frequency synthesizer and clock for digital circuits, and analog-to-digital and digital-to-analog converters.

PLL includes several normal modes, spread spectrum mode, fractional mode, and a power-down mode. These are summarized in Table 325 and detailed in the following sections.

Table 325. PLL operating mode summary

Mode	PLLCSR[PLLPWREN]	PLLSSCG1[SS_PD]	PLLCTRL[LIMUPOFF]	PLLSSCG1[SEL_SS_MDIV]	PLLSSCG1[MR[2:0]]	M comes from
Normal	1	1	0	0	0	MDIV[15:0]
Fractional	1	0	1	1	0	SS_MDIV[32:0]
Spread spectrum	1	0	1	x	>0	MDIV[15:0] or SS_MDIV[32:0]
Power-down	0	1	x	x	x	x

34.3.4.2 Abbreviations

Table 326. Abbreviations and notations

Acronym	Description
PLL	Phase-locked loop
PFD	Phase frequency detector
CCO	Current control oscillator
PSR	Power supply rejection
EMI	Electromagnetic interferences
SSCG	Spread spectrum clock generation
clkin	Input clock to the PLL
F_{in}	Frequency of clkin
clkout	Output clock of the PLL
F_{out}	Frequency of clkout, $F_{out} = F_{cco} / (2 * P)$ • $F_{out} = F_{cco} / (2 * P)$ (The divide-by-2 divider in the postdivider is not bypassed.) • $F_{out} = F_{cco} / P$ (Bypass divide-by-2 divider in the postdivider.)
clkref	PLL reference clock. The input clock to the PFD.
F_{ref}	Frequency of clkref, $F_{ref} = F_{in} / N$

Table continues on the next page...

Table 326. Abbreviations and notations (continued)

Acronym	Description
F_{cco}	Frequency of output clock of the CCO, $F_{cco} = M * F_{ref}$
N	Predivider value
M	Feedback divider value
P	Postdivider value
t_{pon}	PLL start-up time

34.3.4.3 PLL block diagram

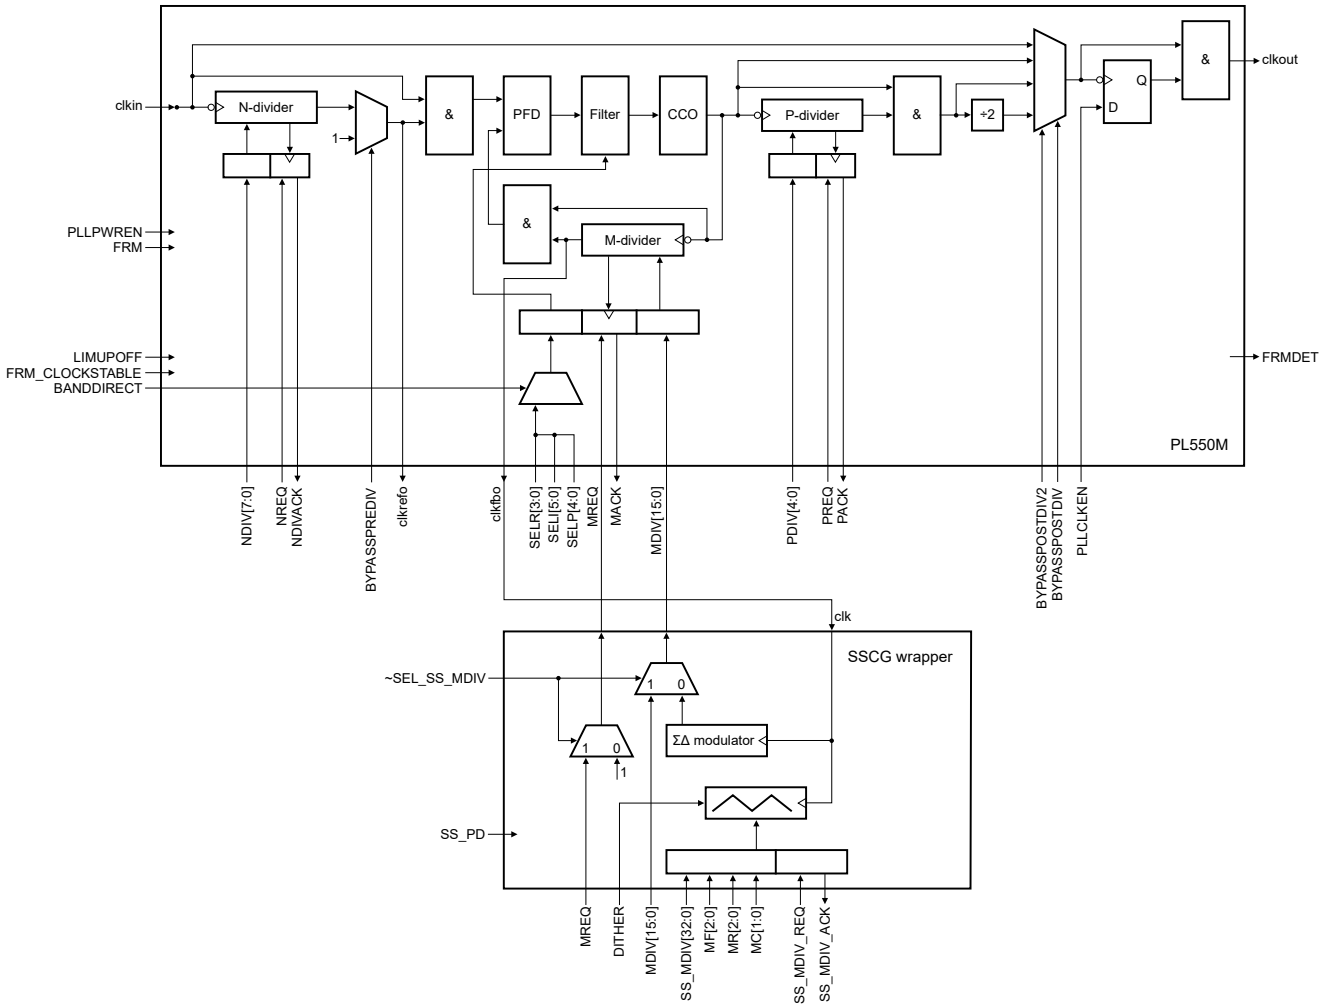

Figure 165. PLL block diagram

34.3.4.4 PLL normal mode

34.3.4.4.1 PLL features and benefits

- Integrated PLL with no external components for clock generation

- Large input range at the phase detector (F_{ref})
- Programmable:
  - Predivider N (N, 1 to 2^8-1)
  - Feedback-divider M (M, 1 to 2^{16}-1)
  - Postdivider P * 2 (P, 1 to 2^5-1)
- Programmable bandwidth (integrating action, proportional action, high frequency pole)
- On-the-fly adjustment of the clock dividers with handshake control
- Positive edge clocking
- Frequency limiter to avoid PLL hang up
- Power down mode
- Support for bypassing the predivider and the postdivider
- Support for bypassing the divide-by-2 in the postdivider
- Support for disabling the output clock
- Free running mode

34.3.4.4.2 PLL functional description

34.3.4.4.2.1 Basic functions

PLL is designed to generate a CMOS compatible clock. PLL can also be used to filter clocks or to make spread spectrum and fractional clocks. The following sections detail these features.

34.3.4.4.2.2 Main blocks

The PLL block diagram is shown in Figure 165. The clock input must be fed to clkin; clkout is the PLL clock output. The analog part of the PLL consists of a phase frequency detector (PFD), a filter, and a current controlled oscillator (CCO). The PFD has two inputs: a reference input from the (divided) external clock and one input from the divided CCO output clock. The PFD compares the phase and frequency of these input signals and generates a control signal if they do not match. This control signal is fed to a filter which drives the CCO.

PLL contains three programmable dividers: predivider (N), feedback-divider (M), and postdivider (P). Every divider contains a bus (XDIV[n:0] in which X is N, M, or P) to load a divider ratio. The dividers also possess the handshake signals, XREQ, and XACK, to select a new divider ratio. See Selecting divider ratios for more information on selecting the divider ratios.

PLL is stable after startup time t_{pon}. There is a hardware timer in the reference clock domain in SCG to count this time. You must configure the LOCK_TIME register to (500 µs/T_{ref} + 300). When the number of reference clocks reaches LOCK_TIME after power on or reconfiguration, the flag PLL_LOCK is set. If the interrupt enable bit PLL_LOCK_IE is set, a PLL_LOCK interrupt is generated.

NOTE

The PLL clock is gated off when PLL_LOCK is low, regardless of the state of the PLLCLKEN field. At start, set PLLPWREN and PLLCLKEN to 1 to enable the PLL. After t_{pon}, the PLL_LOCK is valid and the PLL clock is automatically ungated.

To avoid frequency hang-up, the PLL contains a frequency limiter. This feature is built in to prevent the CCO from running too fast. This can occur if, for example, a wrong feedback-divider (M) ratio is applied to the PLL.

There are additional dividers in the clocking system to bring the PLL output frequency down to what is needed for the CPU and peripherals.

34.3.4.4.3 PLL application information

For more information on the selectable bandwidth, input clocks, and divider ratios of the PLL, see the following sections:

- Selecting bandwidth
- Input clock
- Selecting divider ratios

PLL has eight modes:

- Mode 1: Normal operating mode
- Mode 2: Reserved
- Mode 3: Power down mode (PLLPWREN)
- Mode 4: Reserved
- Mode 5: Free running mode (FRM)
- Mode 6: Reserved
- Mode 7: Reserved
- Mode 8: Enable mode (PLLCLKEN).

34.3.4.4.3.1 Selecting bandwidth

For some applications, such as filtering of the input signal, it can be advantageous to change the bandwidth of the PLL.

In normal applications, you must calculate the bandwidth manually by using the feedback divider M (ranging from 1 to 2^{16}-1), Equation 1, and Equation 2. The PLL is automatically stable in such case. In normal applications, APLLCTRL[BANDDIRECT] and SPLLCTRL[BANDDIRECT] must be 0; in this case, the bandwidth changes as a function of M.

$$A = floor\,(M \div 4) + 1$$

$$SELP = \begin{cases} A & if\ A < 31 \\ 31 & if\ A \geq 31 \end{cases}$$

Equation 1. SELP

$$A = \begin{cases} 1 & if\ M \geq 8000 \\ floor\,(8000 \div M) & if\ 8000 > M \geq 122 \\ 2 \times floor\,(M \div 4) + 3 & if\ 122 > M \geq 1 \end{cases}$$

$$SELI = \begin{cases} A & if\ A < 63 \\ 63 & if\ A \geq 63 \end{cases}$$

Equation 2. SELI

SELR must be 0.

NOTE

In some applications, you may prefer to change the bandwidth directly on the PLL. In such an application, you must write 1 to APLLCTRL[BANDDIRECT] or SPLLCTRL[BANDDIRECT].

34.3.4.4.3.2 Input clock

A good-quality input clock is necessary for good PLL performance. The input clock on clkin, optionally divided by the predivider ratio N, gives the reference frequency F_{ref} for the PLL loop (F_{ref} = F_{in} / N).

Use SOURCE[1:0] to select one of two inputs to the PLL: SOSC and FIRC. The input clock must have an accurate frequency before powering up the PLL. You can confirm a valid clock for SOSC and FIRC by using SOSCCSR[SOSCVLD] and FIRCCSR[FIRCACC], respectively.

For an optimal performance, use a reference frequency within the frequency range 5 MHz - 50 MHz. The total possible reference frequency range is specified in the data sheet.

34.3.4.4.3.3 Selecting divider ratios

The PLL contains three dividers: predivider (N), feedback-divider (M), and postdivider (P). The divider ratios can be selected in different ways.

Start up

For a correct start up, a low to high transition of PLLPWREN is required after the supplies are stable. The divider ratio data XDIV[n:0] (in which X is N, M, or P) must also be stable (see Figure 166) before PLLPWREN is made high.

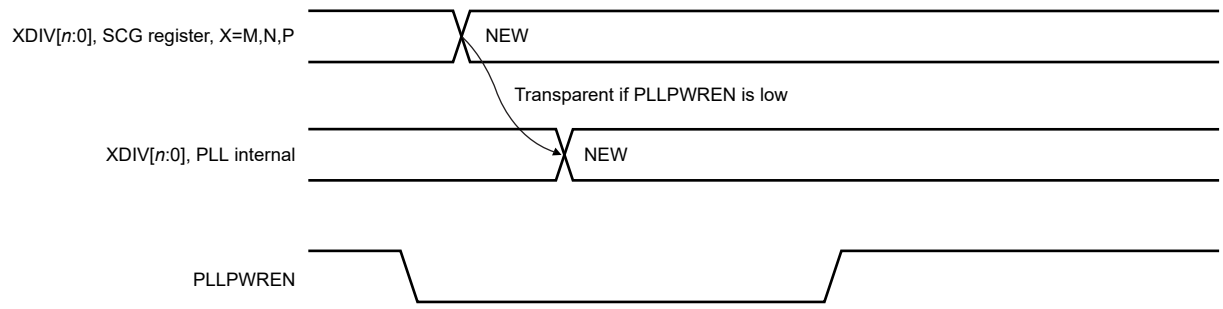

Figure 166. Loading of the divider ratios at power down

Changing divider ratio after starting up

There are two ways to change the divider ratio after the PLL start up: you can reset the PLL or you can read the divider ratio asynchronous.

When changing divider ratios, you must avoid forbidden divider ratio combinations at all times in order to keep the CCO frequency F_{cco} within the specified range. See the product data sheet for the range information. If you need to change more than one divider ratio, it is preferable to use the reset method.

Resetting the PLL

You can select the new divider ratios by making PLLPWREN low. After power down, the new divider ratios at the input buses XDIV[n:0] (in which X is N, M, or P) are loaded into the dividers (Figure 166). You must ensure that the divider ratio data XDIV[n:0] is stable before the PLLPWREN is made high (PLLPWREN=1). This can be done by resetting the PLL (PLLPWREN=0) until the divider ratio data XDIV[n:0] is stable.

Reading the divider ratio asynchronous

You can select the divider ratio of the different dividers (M, N, P) on-the-fly with the help of a handshake protocol (Figure 167). First, a new divider ratio has to be put at the divider input bus (XDIV), and after that a request (XREQ=1) must be given. As soon as the divider gives acknowledgment (XACK=1), the new divider ratio is loaded and the request can be made low (XREQ=0).

For a fractional application, write 1 to SEL_SS_MDIV. Use SS_MDIV_REQ and SS_MDIV[32:0].

NOTE

If the N divider is changed, you should also update the LOCK_TIME according to the new N.

NOTE

Updating divider ratio will clear PLL_LOCK until t_{pon} (defined in LOCK_TIME) is passed. Since PLL_LOCK=0 will gate off the PLL clock before on-the-fly update, you should switch the system to another clock source.

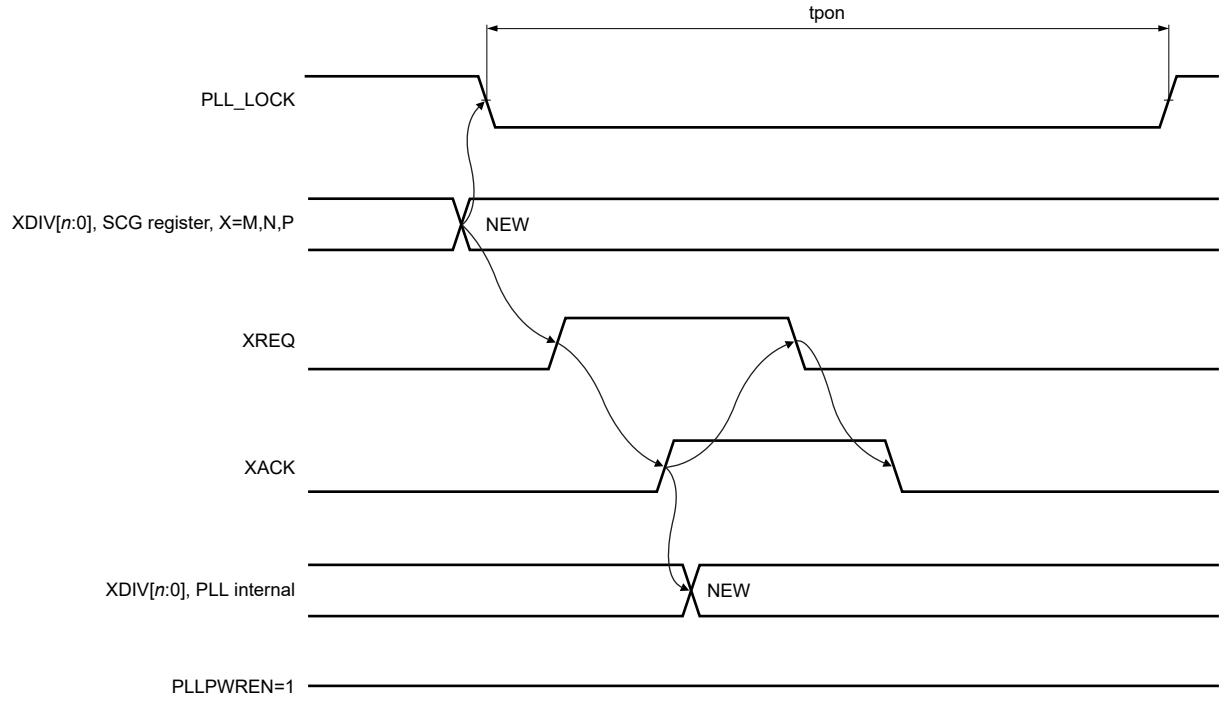

Figure 167. Handshake protocol for asynchronous update divider ratio

34.3.4.4.3.4 Mode 1: Normal operating mode

Typical operation of the PLL includes the following sequence to produce the PLL output:

1. An optional predivider of the PLL input.
2. A frequency multiplication.
3. An optional postdivider.

You can select the predivider and postdivider (see Table 327) to produce:

- Mode 1a: Normal operating mode without postdivider and without predivider
- Mode 1b: Normal operating mode with postdivider and without predivider
- Mode 1c: Normal operating mode without postdivider and with predivider
- Mode 1d: Normal operating mode with postdivider and with predivider

To produce the best phase-noise and jitter performance at the output of the PLL, you must use the highest possible reference clock (clkref) at the PFD. Therefore, NXP recommends modes 1a and 1b, if you can make the right output frequency without a predivider.

By using the postdivider and the divide-by-2 divider, the divider ratio of the PLL clock output (clkout) is even when APLLCTRL[BYPASSPOSTDIV2] or SPLLCTRL[BYPASSPOSTDIV2] is 0. For uneven divider ratios, the divide-by-2 divider can be bypassed when the BYPASSPOSTDIV2 field is 1.

NOTE

If BYPASSPOSTDIV2 is 1, the duty cycle of clkout cannot be 50%.

Table 327. Modes within the normal operating mode

Mode 1	BYPASSPREDIV	BYPASSPOSTDIV
Mode 1a	1	1
Mode 1b	1	0
Mode 1c	0	1
Mode 1d	0	0

Table 328 shows the terms that the equations in this section use.

Table 328. Mode 1*n* equation terms

Term	Description	Allowed values
M	Feedback divider	1 to 2^{16}-1
N	Predivider	1 to 2^{8}-1
P	Postdivider	1 to 2^{5}-1

Mode 1a: Normal operating mode without postdivider and without predivider

Mode 1a bypasses the postdivider and predivider. Equation 3 shows the operating frequency:

$$F_{out} = F_{CCO} = M \times F_{in}$$

Equation 3. Operating frequency in mode 1a

Mode 1b: Normal operating mode with postdivider and without predivider

Mode 1b bypasses the predivider. Equation 4 shows the operating frequency:

$$F_{out} = \frac{F_{cco}}{2 \times P} = \frac{M}{2 \times P} \times F_{in}$$

Equation 4. Operating frequency in mode 1b

Mode 1c: Normal operating mode without postdivider and with predivider

Mode 1c bypasses the postdivider with divide-by-2. Equation 5 shows the operating frequency:

$$F_{out} = F_{cco} = \frac{M}{N} \times F_{in}$$

Equation 5. Operating frequency in mode 1c

Mode 1d: Normal operating mode with postdivider and with predivider

Mode 1d does not bypass either divider. Equation 6 shows the operating frequency:

$$F_{out} = \frac{F_{cco}}{2 \times P} = \frac{M}{N \times 2 \times P} \times F_{in}$$

Equation 6. Operating frequency in mode 1d

34.3.4.4.3.5 Mode 3: Power down mode (PLLPWREN)

If the PLL is not used, or if it is turned off in a running application, power can be saved by putting the PLL in power down mode (PLLPWREN=0). Before this is done, the CPU and any peripherals that are not meant to be stopped must be running from a different clock source.

In power down mode, the oscillator stops and the output clkout will be low.

While in PLL power down mode, the PLL_LOCK will be low to indicate that the PLL is not in lock. When the PLL power down mode is terminated by setting the PLLPWREN field to one, the PLL will resume its normal operation and will make the PLL_LOCK high after the start up time.

34.3.4.4.3.6 Mode 5: Free running mode (FRM)

In normal applications, the output clock of the PLL quickly disappears if the input clock disappears. To avoid the fast disappearance of the clock, you can use free running mode.

In FRM mode, the PLL monitors the input clock clkin. If the input clock disappears for more than six periods, the CCO of the PLL starts running free. The output frequency will be within +1% and -20% for at least 200 µs. After 200 µs of self-clocking, the frequency keeps going down.

NOTE

If the PLL is in free running mode, the FRMDET flag is high.

NOTE

Free running mode only operates for reference frequencies above 100 kHz (F_{in} / N = F_{ref} > 100 kHz). To use the free running mode for 32 kHz <= F_{in} / N = F_{ref} < 100 kHz, write 1 to FRM_CLOCKSTABLE after the PLL output frequency is stable (after startup time t_{pon}).

Free running mode is designed so that if the input clock occurs again, the PLL goes out of free running and locks. Because the output clock has drifted away, overshoot and lock time have to be taken into account. In free running mode (FRM=1), you can choose the same divider settings as set by modes 1, 2, and 3 with logically FRM=1.

NOTE

When FRMDET=1 and the PLL clock monitor is enabled (PLLCM=1), the PLLERR flag is set. When PLL_ERROR=1, switch to another clock and clear the field. PLL_LOCK is not reliable in this case. After t_{pon}, if PLL_ERROR is 0, this means the PLL can be used again.

34.3.4.4.3.7 Mode 8: Enable mode (PLLCLKEN)

In Enable mode, the output clock (clkout) of the PLL is enabled. If PLLCLKEN=0, the output of the PLL is low (clkout=0). Ensure that no spikes occur at the output of the PLL (clkout) by switching into and out of the Enable mode.

Going out of Enable mode can be used for safely switching to other modes, such as power down mode and direct output (BYPASSPOSTDIV). This method ensures that no spikes can occur at the output.

34.3.4.5 PLL spread spectrum and fractional modes

The SSCG wrapper is a ΣΔ modulator for the multi-purpose PLL and makes it a fractional-N PLL.

By controlling the feedback divider of the PLL, the wrapper can also generate a spread spectrum clock. SSCG decreases electromagnetic interferences (EMI).

34.3.4.5.1 Functional features

- Handshake circuit to read the asynchronous SS_MDIV[32:0] at the wrapper
- Twenty-five fractional bits
- Preferred reference frequency F_{ref} > 3 MHz

- Center-spread modulation (default)
- Modulation waveform control
- Modulation waveform dithering
- Power-down mode (SS_PD)
- Triangular-wave modulation frequency:

$$fm = \frac{F_{ref}}{N_{ss}}$$

with N_{ss} ranging from 16 to 512

Equation 7. Triangular-wave modulation frequency

- Frequency-modulation depth:

$$\delta fmod_{pk\text{-}pk} = \frac{F_{ref} \times k_{ss}}{F_{cco}}$$

with k_{ss} ranging from 0 to 4

Equation 8. Frequency-modulation depth

34.3.4.5.2 Functional description

34.3.4.5.2.1 Basic functions

The SSCG WRAPPER is a second order ΣΔ modulator for the multipurpose PLL and makes it a fractional-N PLL. By controlling the feedback divider of the PLL, the wrapper can also generate a spread spectrum clock (Spread Spectrum Clock Generator).

The main block is the ΣΔ modulator which generates the appropriate MDIV[15:0] values from the input word SS_MDIV[32:0] to have at the output (clkout) of the PLL the correct frequency.

34.3.4.5.2.2 Main blocks

The SSCG WRAPPER consist of:

- A handshake circuit to read a new input word on the buses: SS_MDIV[32:0], MR[2:0], MF[2:0], MC[2:0]
- A waveform generator
- A second order ΣΔmodulator
- A multiplexer to bypass the wrapper

The SSCG WRAPPER will generate by default a center spread triangular waveform. It is also possible to generate a down spread triangular waveform which is explained Center spread versus down spread.

34.3.4.5.2.3 Handshake circuit

A new (asynchronous) input word (SS_MDIV[32:0], MF[2:0], MR[2:0], and MC[1:0]) can be read with the help of a handshake protocol (Figure 168).

First the new word must be put on the bus. Then a request (SS_MDIV_REQ=1) must be given. As soon as the acknowledge pin goes high (SS_MDIV_ACK=1), the new input word is loaded and the request can be made low (SS_MDIV_REQ=0).

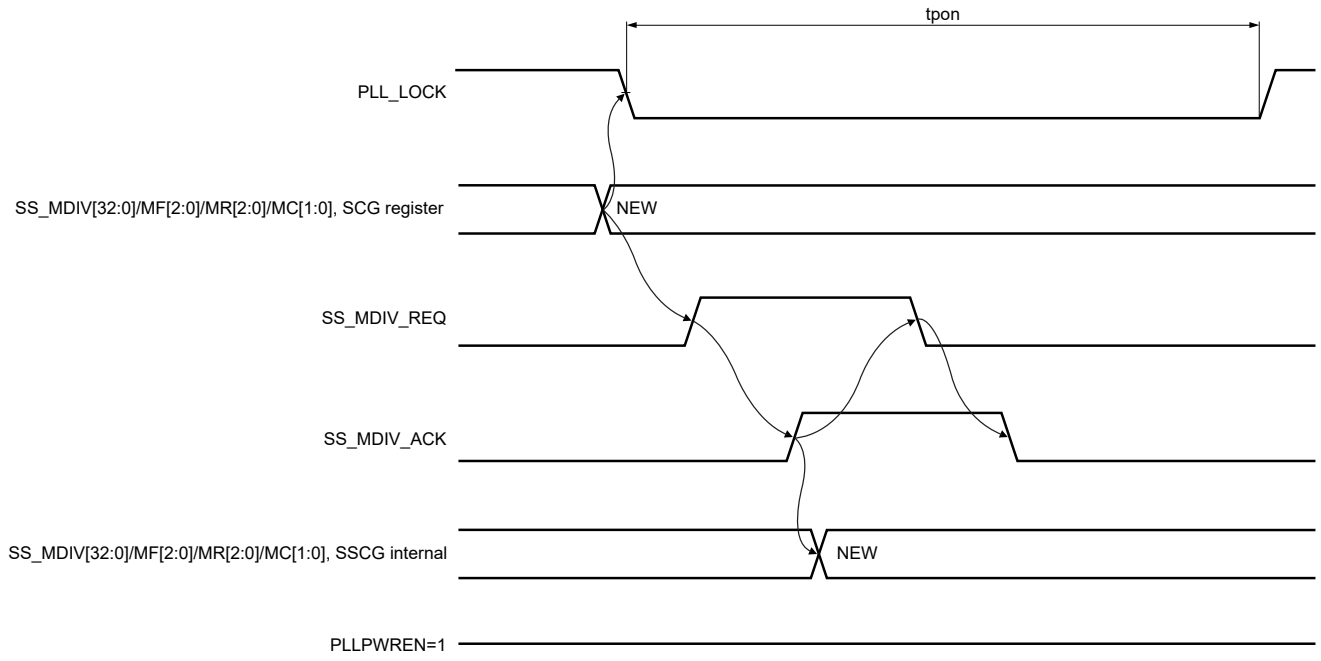

Figure 168. Handshake protocol of the input words SS_MDIV[32:0], MF[2:0], MR[2:0] and MC[1:0]

NOTE

Updating the divider ratio will clear the PLL_LOCK until t_{pon} (defined in LOCK_TIME) is passed. Because PLL_LOCK=0 will gate off the PLL clock, system should be switched to another clock source before on-the-fly updates.

34.3.4.5.2.4 Center spread versus down spread

By default, the wrapper generates a triangular waveform with center spread. This means that the average CCO frequency between MR[2:0] = 0 (no spread spectrum) and MR[2:0] > 0 is the same. see Equation 9.

$$M_{average,\ center\ spread} = M_{average}$$

Equation 9. Divider equivalence

Some applications require a triangular waveform with down spread. For down spread, instead of the average CCO frequency being the same, the maximum frequency must be the same in spread spectrum mode (MR[2:0]>0). For down spread, the average feedback divider ratio must be decreased depending on the modulation depth. See Equation 10 and Equation 11.

$$M_{average,\ down\ spread} = M_{average} - 0.25 \times k_{ss}$$

Equation 10. Average divider, down spread

$$M_{average} = 64.5,\ k_{ss} = 4$$

$$M_{average,center\ spread} = M_{average} = 64.5\ (SS_{MDIV[32:0]} = 0_1000_0001_0000_0000_0000_0000_0000_0000b = 0_8100_0000h)$$

$$M_{average,down\ spread} = M_{average} - 1 = 63.5\ (SS_{MDIV[32:0]} = 0_0111_1111_1000_0000_0000_0000_0000_0000b = 0_7F80_0000h)$$

Equation 11. Average divider example

34.3.4.5.2.5 Triangular wave modulation

You can calculate the clock cycle displacement and spectral tone reduction ΔP for the center spread triangular waveform modulation with a modulation frequency depth δfmodpk-pk and a modulation frequency fm.

Equation 12 shows the theoretical maximum clock-cycle displacement (peak-to-peak).

$$\Delta n_{max;theoretical} = \begin{cases} \frac{N_{ss} \times k_{ss}}{16} & if\ PLLCTRL[BYPASSPOSTDIV] = 1 \\ \frac{N_{ss} \times k_{ss}}{32 \times P_{PLL}} & if\ PLLCTRL[BYPASSPOSTDIV] = 0\ and\ PLLCTRL[PDIV] = 1 \end{cases}$$

Equation 12. Theoretical maximum clock-cycle displacement

In practice the clock cycle displacement could be larger. So, for safety reasons (buffer overflow) use Equation 13:

$$\Delta n_{max;practical} = \begin{cases} \frac{N_{ss} \times k_{ss}}{8} & if\ PLLCTRL[BYPASSPOSTDIV] = 1 \\ \frac{N_{ss} \times k_{ss}}{16 \times P_{PLL}} & if\ PLLCTRL[BYPASSPOSTDIV] = 0\ and\ PLLCTRL[PDIV] = 1 \end{cases}$$

Equation 13. Practical maximum clock-cycle displacement

Equation 14 shows the spectral tone reduction / EMI reduction ΔP at F_{out}.

$$\Delta P \approx \begin{cases} 10 \times \log\left(\frac{N_{ss} \times k_{ss}}{2}\right) & if\ PLLCTRL[BYPASSPOSTDIV] = 1 \\ 10 \times \log\left(\frac{N_{ss} \times k_{ss}}{4}\right) & if\ PLLCTRL[BYPASSPOSTDIV] = 0\ and\ PLLCTRL[PDIV] = 1 \end{cases}$$

Equation 14. ΔP at F_{out}

Table 329 shows the spectral tone reduction and clock cycle displacement for BYPASSPOSTDIV=0 and P_{PLL}=1.

Table 329. Values for different settings, BYPASSPOSTDIV = 0, P_{PLL} = 1

Table values are: ΔP Δn_{max}	MF[2:0]=000 N_{ss} = 512	MF[2:0]=001 N_{ss} ≈ 384	MF[2:0]=010 N_{ss} = 256	MF[2:0]=011 N_{ss} = 128	MF[2:0]=100 N_{ss} = 64	MF[2:0]=101 N_{ss} = 32	MF[2:0]=110 N_{ss} ≈ 24	MF[2:0]=111 N_{ss} = 16
MR[2:0]=000, K_{ss}≈0	0 dB 0	0 dB 0	0 dB 0	0 dB 0	0 dB 0	0 dB 0	0 dB 0	0 dB 0
MR[2:0]=001, K_{ss}≈0.5	21 dB 32	20 dB 24	18 dB 16	15 dB 8	12 dB 4	9 dB 2	8 dB 1.5	6 dB 1

MR[2:0]=111, K_{ss}≈4	30 dB 256	29 dB 192	27 dB 128	24 dB 64	21 dB 32	18 dB 16	17 dB 12	15 dB 8

34.3.4.5.2.6 $M_{divider}$ value, stepsize, and output frequency

Table 330 shows examples of the average feedback-divider ratio $M_{average}$ (which defines) and stepsize.

$$M_{average} = \text{SS_MDIV}[32:25]_{dec} + 2^{-25} \times SS_MDIV[24:0]_{dec} + DITHER \times 2^{-26} = 2^{-25} \times SS_MDIV_{dec} + DITHER \times 2^{-26}$$

Equation 15. Average feedback-divider ratio

If the SSCG WRAPPER is in power down (SS_PD = 1), then the input word SS_MDIV[32:0] is not modulated. Examples of the feedback-divider ratio M and stepsize for SS_PD = 1 can be found in Table 331.

Table 330. Examples of $M_{average}$ and stepsize if SS_PD = 0

SS_MDIV[32:0]	$M_{average}$(DITHER=1)	$M_{average}$(DITHER=0)	Stepsize
0 1000 0000 0000 0000 0000 0000 0000 0000bin = 080000000hex = 64 *2^{25}	64 + 2^{-26}	64	1 ÷ (2^{25}*$M_{average}$) ≈ 0.48ppb
0 1000 0010 0000 0000 0000 0000 0000 0000bin = 082000000hex = 65 *2^{25}	65 + 2^{-26}	65	1 ÷ (2^{25}*$M_{average}$) ≈ 0.46ppb
0 1000 0010 0000 0000 0000 0000 0000 0001bin = 082000001hex = 65 *2^{25}+1	65 + 2^{-25} + 2^{-26}	65 + 2^{-25}	1 ÷ (2^{25}*$M_{average}$) ≈ 0.46ppb
0 1000 0011 0000 0000 0000 0000 0000 0000bin = 083000000hex = 65 * 2^{25}+2^{24}	65 + 2^{-1} + 2^{-26}	65 + 2^{-1}	1 ÷ (2^{25}*$M_{average}$) ≈ 0.46ppb
0 1011 1000 0000 0000 0000 0000 0000 0000bin = 0B8000000hex = 92 *2^{25}	92 + 2^{-26}	92	1 ÷ (2^{25}*$M_{average}$) ≈ 0.33ppb[1]
0 0011 0110 0000 0000 0000 0000 0000 0000bin = 036000000hex = 27 *2^{25}	27 + 2^{-26}	27	1 ÷ (2^{25}*$M_{average}$) ≈ 1.11ppb[2]

1. maximum $M_{average}$, minimum stepsize
2. minimum $M_{average}$, maximum stepsize

Table 331. Examples M and stepsize if SS_PD = 1

SS_MDIV[32:0]	M [1](SS_PD = 1)	stepsize[2](SS_PD = 1)
0 1000 0000 0000 0000 0000 0000 0000 0000bin = 080000000hex = 64 * 2^{25}	64	1 ÷ M ≈ 1.56%
0 1000 0010 0000 0000 0000 0000 0000 0000bin = 082000000hex = 65 *2^{25}	65	1 ÷ M ≈ 1.54%
0 1000 0010 0000 0000 0000 0000 0000 0001bin = 082000001hex = 65 *2^{25} + 1	65	1 ÷ M ≈ 1.54%
0 1000 0011 0000 0000 0000 0000 0000 0000bin = 083000000hex = 65 * 2^{25} + 2^{24}	65	1 ÷ M ≈ 1.54%
0 1011 1000 0000 0000 0000 0000 0000 0000bin = 0B8000000hex = 92 *2^{25}	92	1 ÷ M ≈ 1.09%
0 0011 0110 0000 0000 0000 0000 0000 0000bin = 036000000hex = 27 *2^{25}	27	1 ÷ M ≈ 3.70%

1. M = $SS_MDIV[32:25]_{dec}$
2. stepsize = 1 ÷ M

34.3.4.5.3 Application information

In Figure 165 of the SSCG, WRAPPER and PLL are shown.

The spread spectrum clock can be disabled by setting MR[2:0] to zero. If the fractional part of SS_MDIV[32:0] is set to zero (SS_MDIV[24:0]=0) then the feedback divider ratio will have a constant value (no fractional behavior).

NOTE

If the spread spectrum mode is enabled, choose N to ensure $F_{in}/N > 3$ MHz. The spread spectrum mode cannot be used when F_{in} = 32 kHz.

34.3.4.5.3.1 PLL bandwidth settings

For spread spectrum and fractional application, it is important to set the PLL bandwidth in a preferred setting. The preferred settings for the PLL bandwidth at 3 MHz < F_{ref} < 5 MHz are:

- SELR[3:0]=b0100
- SELI[5:0]=b000100
- SELP[4:0]=b00011

34.3.4.5.3.2 Input clock

For Spread spectrum and fractional application, the preferred reference frequency is F_{ref} > 3 MHz.

34.3.4.6 Procedure for determining PLL settings

In general, the PLL configuration values are as follows:

1. Identify a desired PLL output frequency. This may depend on a specific interface frequency needed or on expected CPU performance requirements, and may be limited by system power availability.
2. Determine which clock source to use as the PLL input. This is based on the required power or accuracy, or by the potential to obtain the desired PLL output frequency.
3. Identify PLL settings to obtain the desired output from the selected input. The F_{cco} frequency must be either the actual desired output frequency, or the desired output frequency times 2 x P, where P is from 1 to 31. The F_{cco} frequency must

also be a multiple of the PLL reference frequency, which is either the PLL input or the PLL input divided by N (where N is from 1 to 255).

4. There are several ways to obtain the same PLL output frequency. PLL power depends on F_{cco} (a lower frequency uses less power) and the divider used. Bypassing the input or output divider, or bypassing both, saves power.
5. Ensure that the selected settings meet all the PLL requirements:
   - F_{in} is in the range of 32 kHz to 150 MHz.
   - F_{cco} is in the range of 275 MHz to 550 MHz.
   - F_{out} is in the range of 4.3 MHz to 2x Max CPU frequency.
   - The predivider is either bypassed, or N is in the range of 1 to 255.
   - The postdivider is either bypassed, or P is in the range of 1 to 31.
   - M is in the range of 1 to 65,535.

NOTE

Also note that the PLL startup time becomes longer as F_{ref} drops. PLL accuracy and jitter is better with higher values of F_{ref}.

34.3.4.7 PLL setup sequence

The sequence of initializing and connecting the PLL is as follows:

1. Enable PLL LDO.
2. Ensure that the PLL output is disconnected from any downstream functions.
3. Select a PLL input clock source. See SOURCE field in APLL Control Register (APLLCTRL) and SPLL Control Register (SPLLCTRL).
4. Set up the PLL dividers and mode settings. See APLL and SPLL registers in Memory map and register definition.
5. Wait for the input clock source to be valid. It is indicated by SOSCCSR[SOSCVLD] for SOSC and FIRCCSR[FIRCACC] for FIRC.
6. Power up PLL and write 1 to PLLPWREN and PLLCLKEN. The PLL clock is gated until PLL_LOCK=1.
7. Wait for the PLL output to stabilize, when PLL_LOCK=1. The start-up time is tpll_lock.
8. If the PLL is used to clock the CPU, you can change the CPU Clock Divider setting for the operation with the PLL, if needed. This must be complete before connecting the PLL.
9. Connect the PLL to whichever downstream function you are using it with. See the chip's Clocking chapter for more information on the clock divider structure.

34.3.5 Clocks

SCG has the following input clocks:

- Bus clock for register access
- External USB PLL (UPLL) and Real-Time oscillator (ROSC) clocks as one of the system clock sources

SCG has the following output clocks:

- Main clock
- System PLL clock (SPLL)
- Auxiliary PLL clock (APLL)
- Fast internal reference clock (FIRC)
  - 144 MHz and 48 MHz

- Slow internal reference clock (SIRC)
  - 12 MHz and 1 MHz, divided from SIRC
- System oscillator clock (SOSC)

34.3.6 Resets

These are the SCG resets:

- The global reset is fed into this module. The entire module is reset by the global reset.
- The clock monitor generates a reset in the following cases:
  - SOSCCSR[SOSCCM] = 1 & SOSCCSR[SOSCCMRE] = 1 & SOSCCSR[SOSCERR] = 1
  - ROSCCSR[ROSCCM] = 1 & ROSCCSR[ROSCCMRE] = 1 & ROSCCSR[ROSCERR] = 1
  - APLLCSR[APLLCM] = 1 & APLLCSR[APLLCMRE] = 1 & APLLCSR[APLLERR] = 1
  - SPLLCSR[SPLLCM] = 1 & SPLLCSR[SPLLCMRE] = 1 & SPLLCSR[SPLLERR] = 1
  - UPLLCSR[UPLLCM] = 1 & UPLLCSR[UPLLCMRE] = 1 & UPLLCSR[UPLLERR] = 1

On the assertion of any reset source, the FIRC 48 MHz clock is enabled or starts up if not already running.

34.3.7 Interrupts

- Clock monitor generates an interrupt when any of the following occurs:
  - SOSCCSR[SOSCCM] = 1 & SOSCCSR[SOSCCMRE] = 0 & SOSCCSR[SOSCERR] = 1
  - ROSCCSR[ROSCCM] = 1 & ROSCCSR[ROSCCMRE] = 0 & ROSCCSR[ROSCERR] = 1
  - APLLCSR[APLLCM] = 1 & APLLCSR[APLLCMRE] = 0 & APLLCSR[APLLERR] = 1
  - SPLLCSR[SPLLCM] = 1 & SPLLCSR[SPLLCMRE] = 0 & SPLLCSR[SPLLERR] = 1
  - UPLLCSR[UPLLCM] = 1 & UPLLCSR[UPLLCMRE] = 0 & UPLLCSR[UPLLERR] = 1
- Interrupt can also be generated when any of the following occurs:
  - SOSC clock source is not valid. SOSCCSR[SOSCVLD_IE] = 1 & SOSCCSR[SOSCVLD] = 1
  - FIRC clock source is not accurate. FIRCCSR[FIRCACC_IE] = 1 & FIRCCSR[FIRCACC] = 1
  - FIRC trimming error detected. FIRCCSR[FIRCERR_IE] = 1 & FIRCCSR[FIRCERR] = 1
  - SIRC trimming error detected. SIRCCSR[SIRCERR_IE] = 1 & SIRCCSR[SIRCERR] = 1
  - APLL is not powered or locked. APLLCSR[APLL_LOCK_IE] = 1 & APLLCSR[APLL_LOCK] = 1
  - SPLL is not powered or locked. SPLLCSR[SPLL_LOCK_IE] = 1 & SPLLCSR[SPLL_LOCK] = 1

34.4 External signals

Table 332. External signal descriptions

Signal	Description	Mode	I/O
XTAL	SOSC Crystal output pin	SOSC	O
EXTAL	SOSC Crystal input pin	SOSC	I
CLKOUT	SCG clock output pin	SCG	O

34.5 Initialization

Out of reset, the following events occur:

- FIRC is default enabled and FIRCCFG[RANGE] is reset to zero. The FIRC 48 MHz clock is selected as the system clock source.
- SIRC is default enabled.
- All other clock sources are disabled.

34.6 Application information

34.6.1 SOSC configuration example

1. Write 1 to LDOCSR[LDOEN] to enable LDO
2. Write 1 to SOSCCFG[EREFS] to select SOSC (internal crystal oscillator) source
3. Write 0 to SOSCCFG[RANGE] to configure SOSC range
4. Write 0 to SOSCCSR[LK] to unlock SOSCCSR
5. Write 1 to SOSCCSR[SOSCCM] to enable SOSC clock monitor
6. Write 1 to SOSCCSR[SOSCSTEN] to enable SOSC in Deep Sleep mode, if needed
7. Write 1 to SOSCCSR[SOSCEN] to enable SOSC
8. Read SOSCCSR[SOSCVLD] until it returns 1, indicating SOSC is valid
9. Read SOSCCSR[SOSCERR] to ensure it returns 0, indicating there is no error
10. Write 1 to RCCR[SCS] to switch main clock to SOSC
11. Read CSR[SCS] until it returns 1, indicating the switch is complete

34.6.2 SIRC configuration example

34.6.2.1 SIRC normal configuration example

1. Write 0 to SIRCCSR[LK] to unlock SIRCCSR
2. Write 1 to SIRCCSR[SIRCSTEN] to enable SIRC in Deep Sleep mode, if needed
3. Write 1 to SIRCCSR[SIRC_CLK_PERIPH_EN] to enable SIRC clock for peripheral use
4. Read SIRCCSR[SIRCVLD] until it returns 1, indicating SIRC is valid
5. Read SIRCCSR[SIRCERR] to ensure it returns 0
6. Write 2 to RCCR[SCS] to switch main clock to SIRC
7. Read CSR[SCS] until it returns 2, indicating the switch is complete

34.6.2.2 SIRC auto trim example

1. Follow steps 1 through 8 in SOSC configuration example
2. Write 2 to SIRCTCFG[TRIMSRC] to select SOSC as auto trim clock source
3. Write 39 to SIRCTCFG[TRIMDIV] to divide SOSC to 1 MHz
4. Write 0 to SIRCCSR[LK] to unlock SIRCCSR
5. Write 1 to SIRCCSR[SIRCTREN] to enable auto trim
6. Write 1 to SIRCCSR[SIRCTRUP] to enable update

7. Read SIRCCSR[SIRCVLD] until it returns 1, indicating SIRC is valid
8. Read SIRCCSR[SIRCERR] to ensure it returns 0
9. Read SIRCCSR]TRIM_LOCK] until it returns 1.

The auto trim process continues until it is disabled. The SIRCSTAT register shows the locked trim values. If there is an unlock after lock, SIRCCSR[SIRCERR] is set.

34.6.3 FIRC configuration example

34.6.3.1 FIRC normal configuration example

1. Write 1 to FIRCCFG[RANGE] to select 144 MHz
2. Write 0 to FIRCCSR[LK] to unlock FIRCCSR
3. Write 1 to FIRCCSR[FIRC_FCLK_PERIPH_EN] to enable FIRC 144 MHz clock for peripheral use, if needed
4. Write 1 to FIRCCSR[FIRC_SCLK_PERIPH_EN] to enable FIRC 48 MHz clock for peripheral use, if needed
5. Write 1 to FIRCCSR[FIRCSTEN] to enable FIRC clock source in Deep Sleep mode, if needed
6. Write 1 to FIRCCSR[FIRCEN] to enable FIRC
7. Read FIRCCSR[FIRCVLD] until it returns 1, indicating FIRC is valid
8. Read FIRCCSR[FIRCERR] to ensure it returns 0
9. Write 3 to RCCR[SCS] to switch main clock to FIRC
10. Read CSR[SCS] until it returns 3, indicating the switch is complete

34.6.3.2 FIRC auto trim example

1. sosc_clk_enable (); // Enable SOSC clock
2. wait_sosc_valid (); // Wait SOSC to be valid
3. Write 2 to FIRCTCFG[TRIMSRC] to select SOSC as auto trim clock source
4. Write 39 to FIRCTCFG[TRIMDIV] to divide SOSC to 1 MHz
5. Write 0 to FIRCCSR[LK] to unlock FIRCCSR
6. Write 1 to FIRCCSR[FIRCTREN] to enable auto trim
7. Write 1 to FIRCCSR[FIRCTRUP] to enable update
8. Read FIRCCSR[FIRCVLD] until it returns 1, indicating FIRC is valid
9. Read FIRCCSR[FIRCERR] to ensure it returns 0
10. Read FIRCCSR[TRIM_LOCK] until it returns 1

The auto trim process continues until it is disabled. The FIRCSTAT register shows the locked trim values. If there is an unlock after lock, FIRCCSR[FIRCERR] is set.

34.6.4 ROSC configuration example

1. Write 0 to ROSCCSR[LK] to unlock ROSCCSR
2. Write 1 to ROSCCSR[ROSCCM] to enable ROSC clock monitor, if needed
3. Read ROSCCSR[ROSCVLD] until it returns 1, indicating ROSC is valid
4. Read ROSCCSR[ROSCERR] to ensure it returns 0, indicating there is no error
5. Write 4 to RCCR[SCS] to switch main clock to ROSC

6. Read CSR[SCS] until it returns 4, indicating the switch is complete

34.6.5 APLL configuration example (SPLL is similar as APLL)

34.6.5.1 APLL outputs 200 MHz clock with normal function

1. Write 1 to LDOCSR[LDOEN] to enable LDO
2. Configure APLL reference clock source: SOSC
    a. Write 1 to SOSCCFG[EREFS] to select SOSC source
    b. Write 2 to SOSCCFG[RANGE] to configure SOSC range
    c. Write 0 to SOSCCSR[LK] to unlock SOSCCSR
    d. Write 1 to SOSCCSR[SOSCCM] to enable SOSC clock monitor
    e. Write 1 to SOSCCSR[SOSCEN] to enable SOSC
    f. Read SOSCCSR[SOSCVLD] returns 1, indicating SOSC is valid
    g. Read SOSCCSR[SOSCERR] to ensure it returns 0, indicating there is no error
3. Configure APLL:

NOTE

clk_out = clk_in/N*M/P (bypass post divider)

    a. Write 0 to APLLCTRL[SOURCE] to select SOSC as clock source
    b. Write 6 to APLLCTRL[SELP]. The value should refer to register SELP
    c. Write 13 to APLLCTRL[SELI]. The value should refer to register SELI
    d. Write 0 to APLLCTRL[SELR]. The value should refer to register SELR
    e. Write 2 to APLLNDIV[NDIV] to configure N divider
    f. Write 2 to APLLPDIV[PDIV] to configure P divider
    g. Write 20 to APLLMDIV[MDIV] to configure M divider
    h. Write 0 to APLLCTRL[BYPASSPREDIV] to use the N divider
    i. Write 0 to APLLCTRL[BYPASSPOSTDIV] to use the P divider
    j. Write 1 to APLLCTRL[BYPASSPOSTDIV2] to bypass P divider_2
    k. Write 1 to APLLCTRL[FRM] to enable free run mode, if needed
    l. Write 0 to APLLCSR[LK] to unlock APLLCSR
    m. Write 1 to APLLCSR[APLLCM] to enable clock monitor
    n. Write 5A5A0001h to the TRIM_LOCK register to unlock the APLLLOCK_CNFG register
    o. Write 10300 to APLLLOCK_CNFG[LOCK_TIME] to configure lock time of APLL stable. 10300 equals 500 µs/50 ns + 300, where 50 ns is the period of clk_ref (clk_in/N).
    p. Write 3 to APLLCSR[APLLCLKEN] and APLLCSR[APLLPWREN] to enable and power on the APLL clock
    q. Either read APLLCSR[APLL_LOCK] until it returns 1, indicating APLL is locked, or enable APLLCSR[APLL_LOCK_IE] to use the interrupt
    r. Read APLLCSR[APLLERR] to ensure it returns 0
4. Write 5 to RCCR[SCS] to switch main clock to APLL
5. Read CSR[SCS] until it returns 5, indicating the switch is complete

34.6.5.2 APLL outputs 150 MHz clock with spread-spectrum function from FIRC 48 MHz reference clock

1. Write 1 to LDOCSR[LDOEN] to enable LDO
2. Configure APLL reference clock source: FIRC 48 MHz
    a. Write 1 to FIRCCSR_FIRC_SCLK_PERIPH_EN] to select 48 MHz
    b. Write 0 to FIRCCSR[LK] to unlock FIRCCSR
    c. Write 1 to FIRCCSR[FIRCEN] to enable FIRC
    d. Read FIRCCSR[FIRCVLD] until it returns 1, indicating FIRC is valid
    e. Read FIRCCSR[FIRCERR] to ensure it returns 0
3. Configure APLL:

NOTE

clk_out = clk_in/N*M/P (bypass post divider)

    a. Write 1 to APLLCTRL[LIMUPOFF] to set to spectrum and fractional applications
    b. Write 1 to APLLCTRL[SOURCE] to select FIRC as clock source
    c. Write 2 to APLLCTRL[SELP]. The value should refer to register SELP.
    d. Write 5 to APLLCTRL[SELI]. The value should refer to register SELI.
    e. Write 0 to APLLCTRL[SELR]. The value should refer to register SELR.
    f. Write 1 to APLLNDIV[NDIV] to configure N divider
    g. Write 2 to APLLPDIV[PDIV] to configure P divider
    h. Write 0C800000h to APLLSSCG0[SS_MDIV_LSB] to configure M divider (M = 6.25)
    i. Write 0 to APLLSSCG1[SS_MDIV_MSB] to configure M divider (M = 6.25)
    j. Write 1 to APLLSSCG1[SEL_SS_MDIV]
    k. Write 0 to APLLSSCG1[DITHER]
    l. Write 2 to APLLSSCG1[MC]
    m. Write 0 to APLLSSCG1[MR]
    n. Write 0 to APLLSSCG1[MF]
    o. Write 0 to APLLCTRL[BYPASSPREDIV] to use the N divider
    p. Write 0 to APLLCTRL[BYPASSPOSTDIV] to use the P divider
    q. Write 1 to APLLCTRL[BYPASSPOSTDIV2] to bypass P divider_2
    r. Write 1 to APLLCTRL[FRM] to enable free run mode, if needed
    s. Write 0 to APLLCSR[LK] to unlock APLLCSR
    t. Write 1 to APLLCSR[APLLCM] to enable clock monitor
    u. Write 5A5A0001h to the TRIM_LOCK register to unlock the APLLLOCK_CNFG register
    v. Write 24300 to APLLLOCK_CNFG[LOCK_TIME] to configure lock time of APLL stable. 24300 equals 500 µs/ 20.8 ns+300, where 20.8 ns is the period of clk_ref (clk_in/N).
    w. Write 0 to APLLSSCG1[SS_PD] to power up SSCG
    x. Write 3 to APLLCSR[APLLCLKEN] and APLLCSR[APLLPWREN] to enable and power on PLL clock
    y. Either read APLLCSR[APLL_LOCK] until it returns 1, indicating APLL is locked, or enable APLLCSR_APLL_LOCK_IE to use the interrupt

z. Read APLLCSR[APLLERR] to ensure it returns 0

4. Write 5 to RCCR[SCS] to switch main clock to APLL
5. Read CSR[SCS until it returns 5, indicating the switch is complete

34.6.6 UPLL configuration example

1. Write 0 to UPLLCSR[LK] to unlock UPLLCSR
2. Write 1 to UPLLCSR[UPLLCM] to enable clock monitor
3. Read UPLLCSR[UPLLVLD] until it returns 1, indicating UPLL is valid
4. Read UPLLCSR[UPLLERR] to ensure it returns 0
5. Write 7 to RCCR[SCS] to switch main clock to UPLL
6. Read CSR[SCS] until it returns 7, indicating the switch is complete
7. Write 1 to UPLLCSR[LK] to lock UPLLCSR

34.7 Memory map and register definition

This section includes information about the memory map and register definitions:

- Accesses on non-implemented registers that are outside the SCG maximum illegal address range generate a transfer error.
- Read accesses on non-implemented registers that are inside the SCG maximum illegal address range do not generate a transfer error.
- Write accesses on non-implemented registers that are inside the SCG maximum illegal address range generate a transfer error.
- Write accesses on read-only registers generate a transfer error.
- Only 32-bit writes are allowed for any writable SCG registers. Writes of 8 or 16 bits result in transfer errors.

34.7.1 SCG register descriptions

34.7.1.1 SCG memory map

SCG0 base address: 4004_4000h

34.7.1.2 Version ID Register (VERID)

Offset

Register	Offset
VERID	0h

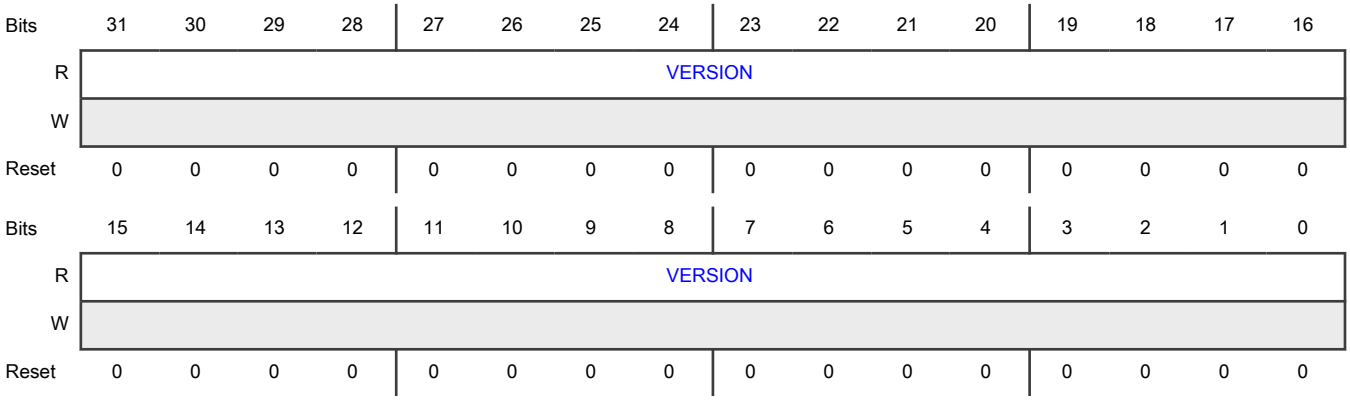
Function

Indicates the version integrated for this instance on the device.

NOTE

Writing to this register results in a transfer error.

Diagram



Fields

Field	Function
31-0 VERSION	SCG Version Number This read-only field returns the SCG module version number.

34.7.1.3 Parameter Register (PARAM)

Offset

Register	Offset
PARAM	4h

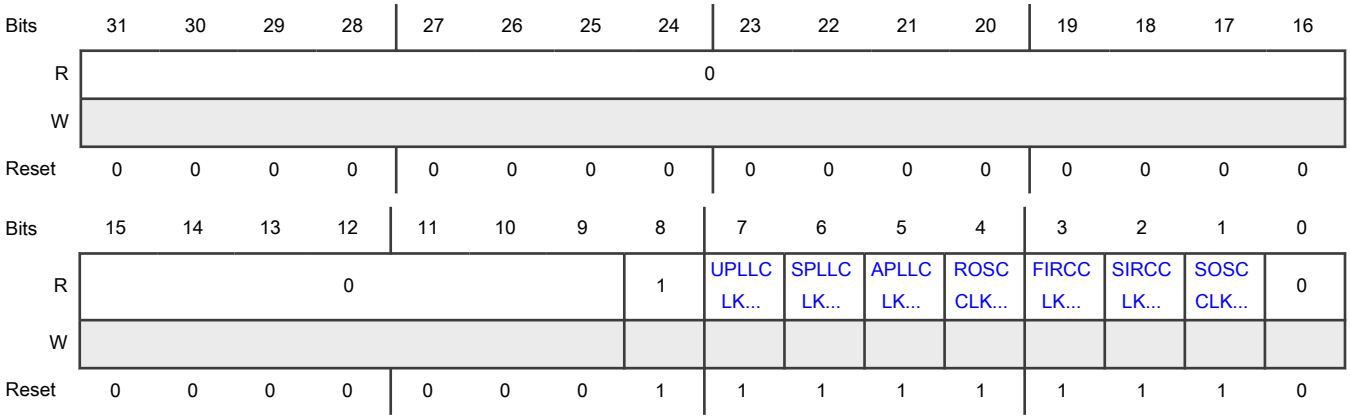
Function

Indicates the feature parameters for this instance on the device.

NOTE

Writing to this register results in a transfer error.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 —	Reserved
7 UPLLCLKPRES	UPLL Clock Present Indicates that the UPLL clock source is present. 0b - UPLL clock source is not present 1b - UPLL clock source is present
6 SPLLCLKPRES	SPLL Clock Present Indicates that the SPLL clock source is present. 0b - SPLL clock source is not present

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - SPLL clock source is present
5 APLLCLKPRES	APLL Clock Present Indicates that the APLL clock source is present. 0b - APLL clock source is not present 1b - APLL clock source is present
4 ROSCCLKPRES	ROSC Clock Present Indicates that the ROSC clock source is present. 0b - ROSC clock source is not present 1b - ROSC clock source is present
3 FIRCCLKPRES	FIRC Clock Present Indicates that the FIRC clock source is present. 0b - FIRC clock source is not present 1b - FIRC clock source is present
2 SIRCCLKPRES	SIRC Clock Present Indicates that the SIRC clock source is present. 0b - SIRC clock source is not present 1b - SIRC clock source is present
1 SOSCCLKPRES	SOSC Clock Present Indicates that the SOSC clock source is present. 0b - SOSC clock source is not present 1b - SOSC clock source is present
0 —	Reserved

34.7.1.4 Trim Lock register (TRIM_LOCK)

Offset

Register	Offset
TRIM_LOCK	8h

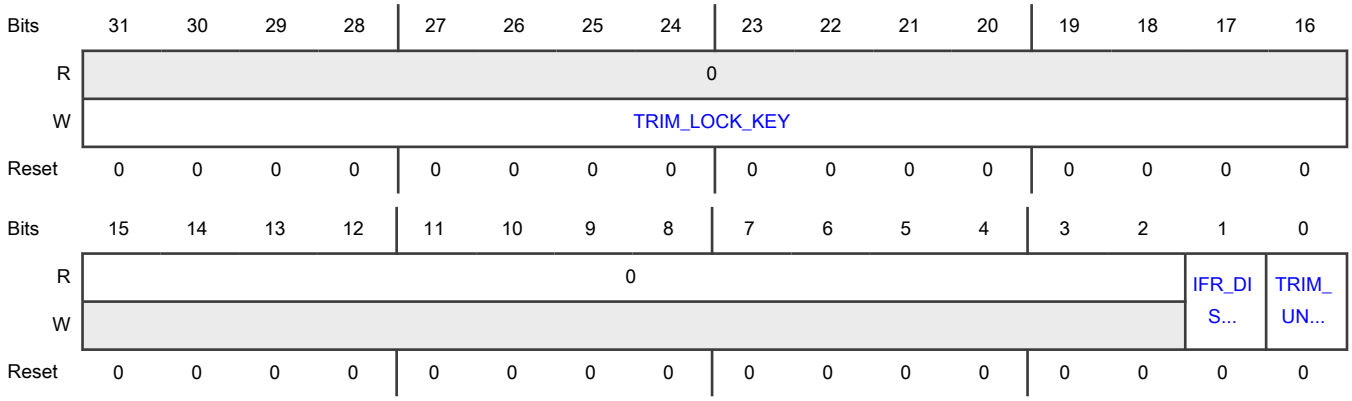
Function

Contains the TRIM_UNLOCK and IFR_DISABLE fields.

NOTE

These fields reset solely on a POR or LVD event.

Diagram



Fields

Field	Function
31-16 TRIM_LOCK_KEY	TRIM_LOCK_KEY Write value that is used to unlock writes to the IFR_DISABLE and TRIM_UNLOCK fields. Write 5A5Ah to allow writes to IFR_DISABLE and TRIM_UNLOCK to take effect. **NOTE** This field is writable but reads always return 0.
15-2 —	Reserved
1 IFR_DISABLE	IFR_DISABLE Locks IFR write access to SCG trim registers. When set, this field prevents SCG trim registers from loading IFR during warm reset. **NOTE** IFR_DISABLE is only writable during write access to TRIM_LOCK when the TRIM_LOCK[31:16] write value equals 16'h5a5a. 0b - IFR write access to SCG trim registers not disabled. The SCG Trim registers are reprogrammed with the IFR values after any system reset. 1b - IFR write access to SCG trim registers during system reset is blocked.
0 TRIM_UNLOCK	TRIM_UNLOCK Locks user write access to SCG Trim and PLL LOCK Configuration registers. **NOTE** TRIM_UNLOCK is only writable during write access to TRIM_LOCK when the TRIM_LOCK[31:16] write value equals 16'h5a5a.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - SCG Trim registers are locked and not writable. 1b - SCG Trim registers are unlocked and writable.

34.7.1.5 Clock Status Register (CSR)

Offset

Register	Offset
CSR	10h

Function

Shows the currently configured clock source that is generating the system clock.

NOTE

Writing to the Clock Status Register (CSR) results in a transfer error.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-28 —	Reserved
27-24 SCS	System Clock Source Returns the currently configured clock source generating the system clock. Reports the configuration set by the RCCR. 0000b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0001b - SOSC 0010b - SIRC 0011b - FIRC 0100b - ROSC 0101b - APLL 0110b - SPLL 0111b - UPLL 1000b-1111b - Reserved
23-0 —	Reserved

34.7.1.6 Run Clock Control Register (RCCR)

Offset

Register	Offset
RCCR	14h

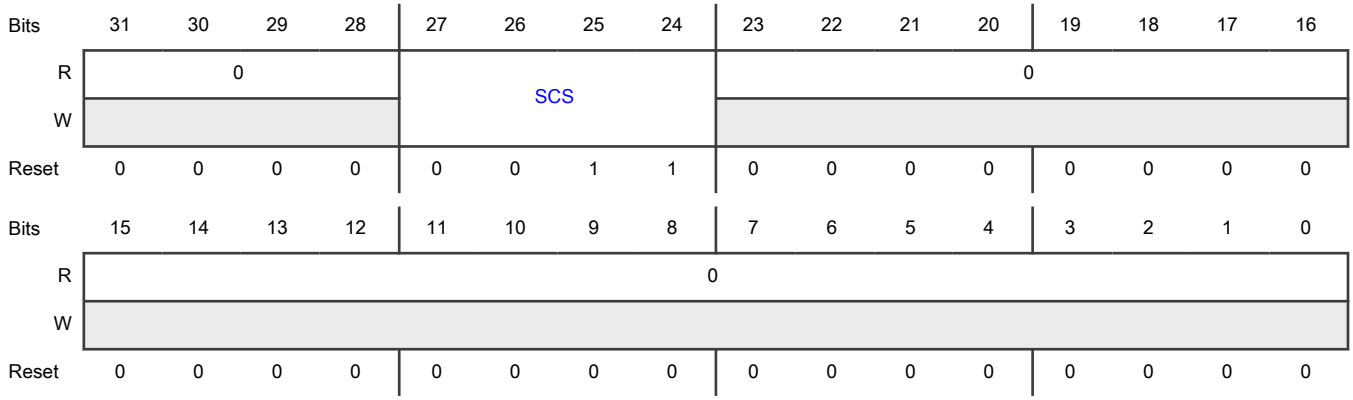
Function

Selects the clock source generating the system clock.

NOTE

Switching to a new system clock source must be done after previous RCCR changes are complete and the Clock Status Register has been updated to match the present RCCR setting.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 SCS	System Clock Source Selects the clock source generating the system clock in Run mode. Attempts to select a clock that is not valid are ignored. In Run mode, the clock source must be enabled and valid before system clocks can switch to a different clock source. **NOTE** You must wait for the previous SCS clock switch to complete before programming SCS to a different value. 0000b - Reserved 0001b - SOSC 0010b - SIRC 0011b - FIRC 0100b - ROSC 0101b - APLL 0110b - SPLL 0111b - UPLL 1000b-1111b - Reserved
23-0 —	Reserved

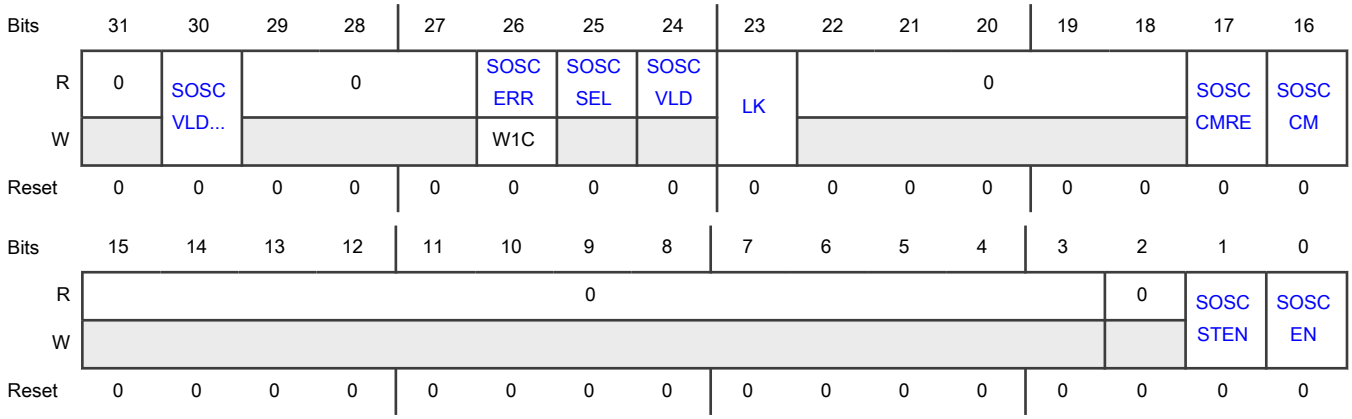
34.7.1.7 SOSC Control Status Register (SOSCCSR)

Offset

Register	Offset
SOSCCSR	100h

Function
Contains control and status fields for the SOSC clock source.

Diagram



Fields

Field	Function
31 —	Reserved
30 SOSCVLD_IE	SOSC Valid Interrupt Enable Generates an interrupt when SOSCVLD is asserted. 0b - SOSCVLD interrupt is not enabled 1b - SOSCVLD interrupt is enabled
29-27 —	Reserved
26 SOSCERR	SOSC Clock Error This flag is reset on Chip POR only. You can also clear this flag by writing 1. 0b - SOSC Clock Monitor is disabled or has not detected an error 1b - SOSC Clock Monitor is enabled and detected an error
25 SOSCSEL	SOSC Selected Indicates if the SOSC clock source is selected as the system clock source. 0b - SOSC is not the system clock source 1b - SOSC is the system clock source
24 SOSCVLD	SOSC Valid Indicates if the SOSC clock source is valid. 0b - SOSC is not enabled or clock is not valid 1b - SOSC is enabled and output clock is valid
23	Lock Register

Table continues on the next page...

Table continued from the previous page...

Field	Function
LK	Locks this register so that it cannot be written to. **NOTE** This field can be cleared or set at any time. 0b - This Control Status Register can be written 1b - This Control Status Register cannot be written
22-18 —	Reserved
17 SOSCCMRE	SOSC Clock Monitor Reset Enable Enables the SOSCERR generate reset. 0b - Clock monitor generates an interrupt when an error is detected 1b - Clock monitor generates a reset when an error is detected
16 SOSCCM	SOSC Clock Monitor Enable Enables the clock monitor when SOSCVLD is set. SOSC clock monitor remains enabled in Deep Sleep mode only if SOSCCM and SOSCSTEN are enabled. If the clock is disabled in Deep Sleep mode, then SOSCCM must be cleared to prevent unexpected SOSC loss of clock. The clock monitor is always disabled in Power Down and Deep Power Down modes. When the clock monitor is disabled in a low power mode, it remains disabled until the clock valid flag is set, following exit from that mode. **NOTE** The reference clock used to monitor the SOSC is the SIRC. This clock must be enabled in order to monitor the SOSC. SIRC is automatically disabled in Power Down and Deep Power Down modes and the SOSC clock monitor is disabled. 0b - SOSC Clock Monitor is disabled 1b - SOSC Clock Monitor is enabled
15-3 —	Reserved
2 —	Reserved
1 SOSCSTEN	SOSC Stop Enable Enables the SOSC clock source in Deep Sleep mode if SOSCEN is set. 0b - SOSC is disabled in Deep Sleep mode 1b - SOSC is enabled in Deep Sleep mode only if SOSCEN is set
0	SOSC Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
SOSCEN	Enables the SOSC clock source. 0b - SOSC is disabled 1b - SOSC is enabled

34.7.1.8 SOSC Configuration Register (SOSCCFG)

Offset

Register	Offset
SOSCCFG	108h

Function

Contains the clock frequency range select and external reference select for the SOSC clock source.

NOTE

You cannot change the SOSCCFG register when the SOSC is enabled. When the SOSC is enabled, writes to this register are ignored and there is no transfer error.

Diagram

5-4 RANGE	SOSC Range Select Selects the frequency range for the system crystal oscillator (OSC). 00b - Frequency range select of 16-20 MHz. 01b - Frequency range select of 20-30 MHz. 10b - Frequency range select of 30-50 MHz. 11b - Frequency range select of 50-66 MHz.
3 —	Reserved
2 EREFS	External Reference Select Selects the source for the external reference clock. This field selects which clock is output from the SOSC into the SCG: either from the crystal oscillator or from an external clock input. 0b - External reference clock selected. LDO can be disabled in this case. 1b - Internal crystal oscillator of OSC selected.
1-0 —	Reserved

34.7.1.9 SIRC Control Status Register (SIRCCSR)

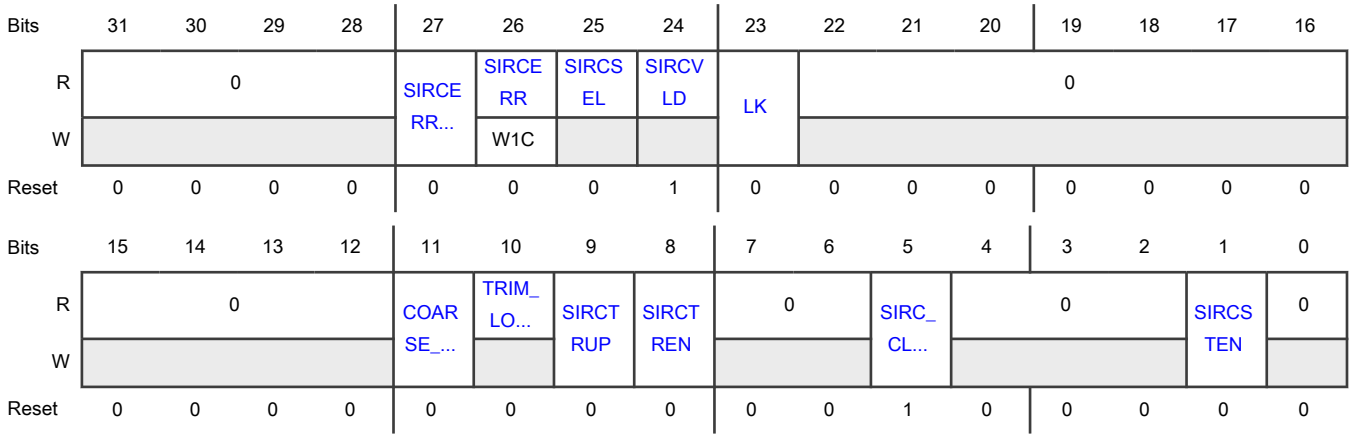
Offset

Register	Offset
SIRCCSR	200h

Function

Contains control and status bits for the SIRC clock source.

Diagram



Fields

Field	Function
31-28 —	Reserved
27 SIRCERR_IE	SIRC Clock Error Interrupt Enable Generates an interrupt when SIRCERR is asserted. 0b - SIRCERR interrupt is not enabled 1b - SIRCERR interrupt is enabled
26 SIRCERR	SIRC Clock Error This flag is reset on chip POR only. You can also clear this flag by writing 1. 0b - Error not detected with the SIRC trimming 1b - Error detected with the SIRC trimming
25 SIRCSEL	SIRC Selected Indicates if the SIRC clock source is selected as the system clock source. 0b - SIRC is not the system clock source 1b - SIRC is the system clock source
24 SIRCVLD	SIRC Valid Indicates if the SIRC clock source is valid. 0b - SIRC is not enabled or clock is not valid 1b - SIRC is enabled and output clock is valid
23 LK	Lock Register This field can be cleared or set at any time. Use this field to prevent runaway code from changing SIRC clock configurations.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Control Status Register can be written 1b - Control Status Register cannot be written
22-12 —	Reserved
11 COARSE_TRIM_BYPASS	Coarse Auto Trim Bypass Use this bit is to bypass the coarse trim step when auto-trimming. 0b - SIRC coarse auto-trim is not bypassed 1b - SIRC coarse auto-trim is bypassed
10 TRIM_LOCK	SIRC TRIM LOCK When SIRCTREN and SIRCTRUP are enabled, the TRIM_LOCK register indicates when auto trimming is complete and output SIRC frequency has locked to target SIRC range. **NOTE** • This field is automatically cleared if SIRCTREN and SIRCTRUP are not set. • TRIM_LOCK is not set when SIRCTCFG[TRIMSRC] = 2'b00, i.e., using full speed USB as the trim source. 0b - SIRC auto trim not locked to target frequency range 1b - SIRC auto trim locked to target frequency range
9 SIRCTRUP	SIRC Trim Update Allows the SIRCSTAT to be updated by auto-trimming hardware. 0b - Disables SIRC trimming updates 1b - Enables SIRC trimming updates
8 SIRCTREN	SIRC 12 MHz Trim Enable (SIRCCFG[RANGE]=1) Enables the auto trim of SIRC 12 MHz by an external clock source. 0b - Disables trimming SIRC to an external clock source 1b - Enables trimming SIRC to an external clock source
7-6 —	Reserved
5 SIRC_CLK_PERIPH_EN	SIRC Clock to Peripherals Enable Enables the SIRC clock for peripheral use. 0b - SIRC clock to peripherals is disabled 1b - SIRC clock to peripherals is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
4-2 —	Reserved
1 SIRCSTEN	SIRC Stop Enable Enables the SIRC clock source in specific power modes. See the chip-specific section for information on what conditions apply when SIRCSTEN is used. 0b - SIRC is disabled in Deep Sleep mode 1b - SIRC is enabled in Deep Sleep mode
0 —	Reserved

34.7.1.10 SIRC Trim Configuration Register (SIRCTCFG)

Offset

Register	Offset
SIRCTCFG	20Ch

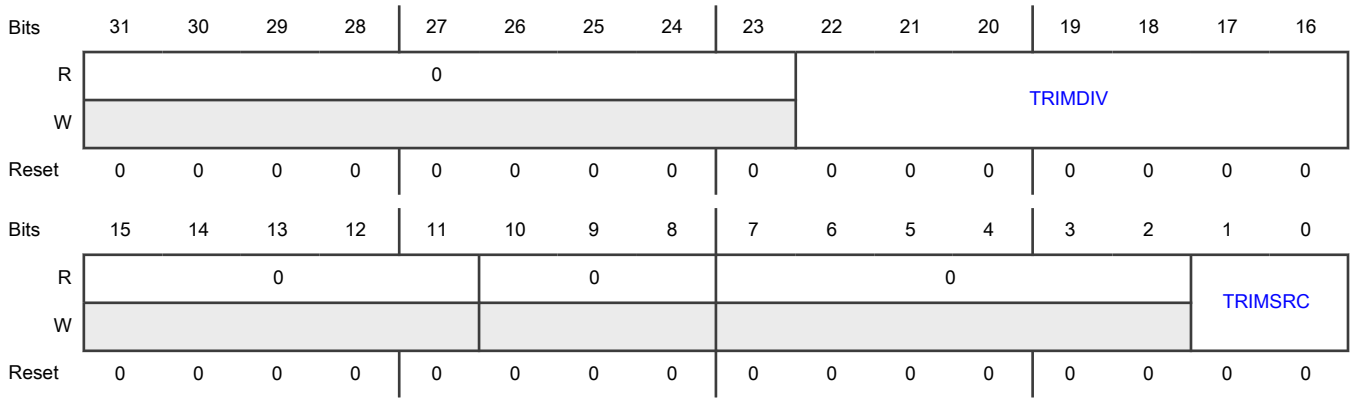
Function

Contains the auto trim clock source select and trim clock divider control for the SIRC clock source.

NOTE

The SIRCTCFG register cannot be changed when SIRC tuning is enabled. When the SIRC tuning is enabled, writes to this register are ignored and there is no transfer error.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 TRIMDIV	SIRC Trim Predivider Divider of SOSC for SIRC trimming. When selecting SOSC as the SIRC trimming source, the TRIMDIV register must be set to correct div ratio to generate 1 MHz output reference trimming clock. **NOTE** TRIMDIV is an N-Divider supporting a div ratio of 1 (TRIMDIV=00h) to a div ratio of 128 (TRIMDIV=7Fh).
15-11 —	Reserved
10-8 —	Reserved
7-2 —	Reserved
1-0 TRIMSRC	Trim Source Configures the external clock source to tune the SIRC. TRIMSRC must be configured before programming SIRCSTAT register for trim update. 00b - Reserved 01b - Reserved 10b - SOSC. This option requires that SOSC be divided using the TRIMDIV field to get a frequency of 1 MHz. 11b - ROSC (32.768 kHz)

34.7.1.11 SIRC Trim Register (SIRCTRIM)

Offset

Register	Offset
SIRCTRIM	210h

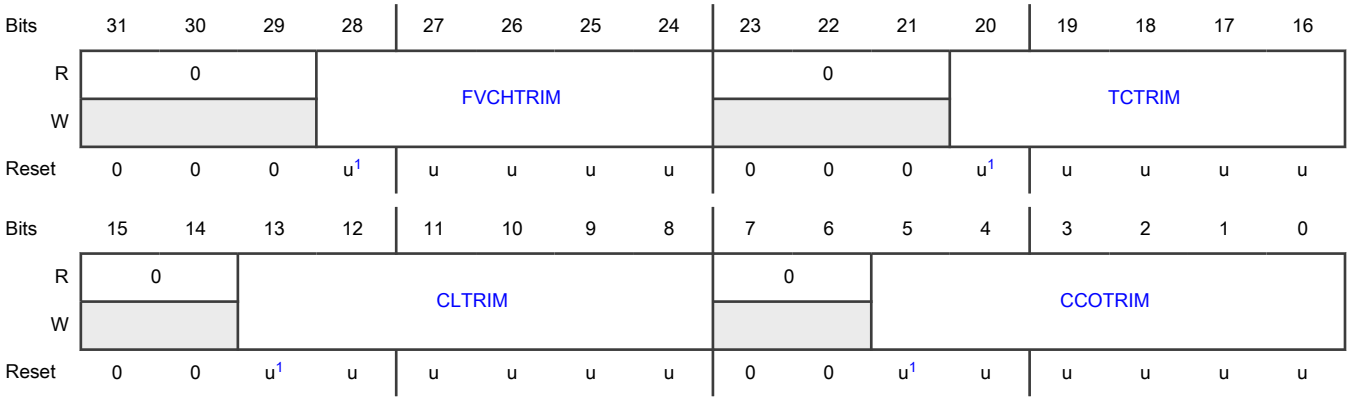
Function

Holds the trim values for the SIRC clock source. This register is loaded from IFR during reset.

NOTE

Writes to this register are protected by the TRIM_LOCK.

Diagram



1. Reset values are loaded out of IFR.

Fields

Field	Function
31-29 —	Reserved
28-24 FVCHTRIM	Calibrates the replica voltage in FSU for CCO to get well frequency at initial period
23-21 —	Reserved
20-16 TCTRIM	Trim Temp Trim bus to calibrate the relationship between freq and temperature.
15-14 —	Reserved
13-8 CLTRIM	CL Trim Trims bus to calibrate the freq of CCO in close loop mode to within approximately ±0.6% of the target 12 MHz frequency.
7-6 —	Reserved
5-0 CCOTRIM	CCO Trim Trims bus to calibrate the freq of CCO in open loop mode to within approximately ±2.5% of the target 12 MHz frequency.

34.7.1.12 SIRC Auto-trimming Status Register (SIRCSTAT)

Offset

Register	Offset
SIRCSTAT	218h

Function

This register is loaded from IFR during reset.

This register is uploaded with the trim values generated by SIRC auto-trimming. SIRC auto-trimming is enabled when SIRCTREN=1 and SIRCTRUP=1. When SIRCTREN=1 and SIRCTRUP=0 (write 10 or 11 to TRIMSRC), writes to this register are allowed and values written to this register are used to trim SIRC clock.

NOTE

You must program TRIMSRC to 10 or 11. Writes to this register are allowed and values written to this register are used to trim the SIRC clock.

5-0	CCO Trim

Table continues on the next page...

Table continued from the previous page...

Field	Function
CCOTRIM	Use CCOTRIM to calibrate the frequency of CCO in open loop mode and to coarsely trim the SIRC clock to within approximately ±2.5% of the target 12 MHz frequency.

34.7.1.13 FIRC Control Status Register (FIRCCSR)

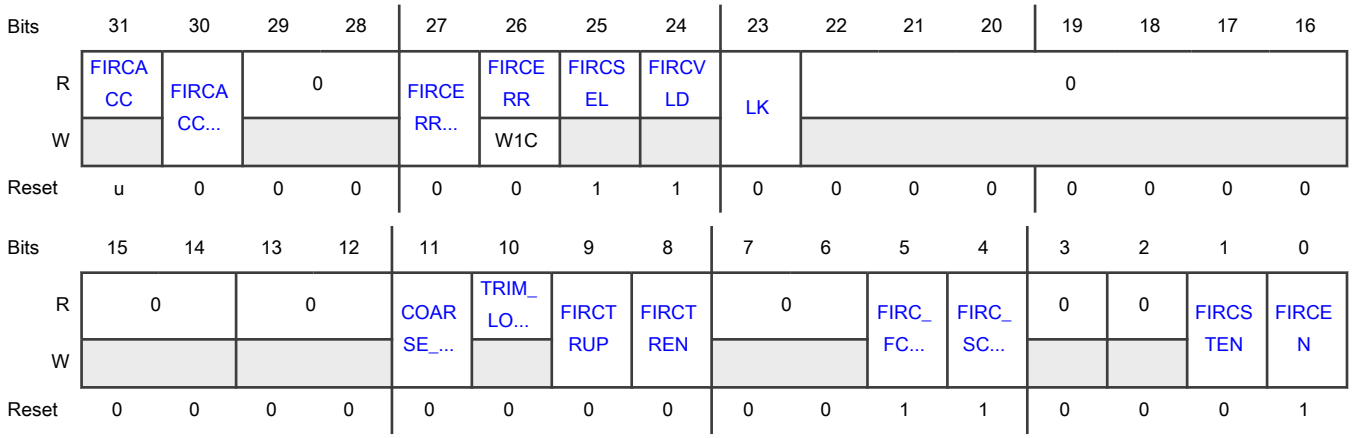
Offset

Register	Offset
FIRCCSR	300h

Function

Contains control and status fields for the FIRC clock source.

Diagram



Fields

Field	Function
31 FIRCACC	FIRC Frequency Accurate Indicates if the FIRC clock source is accurate. 0b - FIRC is not enabled or clock is not accurate. 1b - FIRC is enabled and output clock is accurate. The clock is accurate after 4096 clock cycles of 144 MHz (RANGE=1) or 1365 clock cycles of 48 MHz(RANGE=0) from the FIRC analog.
30 FIRCACC_IE	FIRC Accurate Interrupt Enable Generates an interrupt when FIRCACC is asserted. 0b - FIRCACC interrupt is not enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - FIRCACC interrupt is enabled
29-28 —	Reserved
27 FIRCERR_IE	FIRC Clock Error Interrupt Enable Generates an interrupt when FIRCERR is asserted. 0b - FIRCERR interrupt is not enabled 1b - FIRCERR interrupt is enabled
26 FIRCERR	FIRC Clock Error This flag is reset on Chip POR only. You can also clear this flag by writing 1. 0b - Error not detected with the FIRC trimming 1b - Error detected with the FIRC trimming
25 FIRCSEL	FIRC Selected Indicates if the FIRC clock source is selected as the system clock source. 0b - FIRC is not the system clock source 1b - FIRC is the system clock source
24 FIRCVLD	FIRC Valid status Indicates if the FIRC clock source is valid. 0b - FIRC is not enabled or clock is not valid. 1b - FIRC is enabled and output clock is valid. The clock is valid after there is an output clock from the FIRC analog.
23 LK	Lock Register You can clear or set this field at any time. Use this field to prevent runaway code from changing FIRC clock configurations. 0b - Control Status Register can be written 1b - Control Status Register cannot be written
22-14 —	Reserved
13-12 —	Reserved
11	Coarse Auto Trim Bypass Use this bit is to bypass the coarse trim step when auto-trimming.

Table continues on the next page...

Table continued from the previous page...

Field	Function
COARSE_TRIM_BYPASS	0b - FIRC coarse auto trim is not bypassed 1b - FIRC coarse auto trim is bypassed
10 TRIM_LOCK	FIRC TRIM LOCK When FIRCTREN and FIRCTRUP are enabled, the TRIM_LOCK register indicates when auto trimming is complete and output FIRC frequency has locked to target FIRC range. **NOTE** • This field is automatically cleared if FIRCTREN and FIRCTRUP are not set. • TRIM_LOCK is not set when FIRCTCFG[TRIMSRC] = 2'b00, i.e., using full speed USB as the trim source. 0b - FIRC auto trim not locked to target frequency range 1b - FIRC auto trim locked to target frequency range
9 FIRCTRUP	FIRC Trim Update Allows the FIRCSTAT to be updated by the auto-trimming hardware. 0b - Disables FIRC trimming updates 1b - Enables FIRC trimming updates
8 FIRCTREN	FIRC 144 MHz Trim Enable (FIRCCFG[RANGE]=1) Enables the auto tirm of FIRC 144 MHz by an external clock source. 0b - Disables trimming FIRC to an external clock source 1b - Enables trimming FIRC to an external clock source
7-6 —	Reserved
5 FIRC_FCLK_PERIPH_EN	FIRC 144 MHz Clock to peripherals Enable Enables the FIRC 144 MHz clock for peripheral use. 0b - FIRC 144 MHz to peripherals is disabled 1b - FIRC 144 MHz to peripherals is enabled
4 FIRC_SCLK_PERIPH_EN	FIRC 48 MHz Clock to peripherals Enable Enables the FIRC 48 MHz clock for peripheral use. 0b - FIRC 48 MHz to peripherals is disabled 1b - FIRC 48 MHz to peripherals is enabled
3 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 —	Reserved
1 FIRCSTEN	FIRC Stop Enable Enables the FIRC clock source in Deep Sleep mode if FIRCEN is set. 0b - FIRC is disabled in Deep Sleep mode 1b - FIRC is enabled in Deep Sleep mode
0 FIRCEN	FIRC Enable Enables the FIRC clock source. 0b - FIRC is disabled 1b - FIRC is enabled

34.7.1.14 FIRC Configuration Register (FIRCCFG)

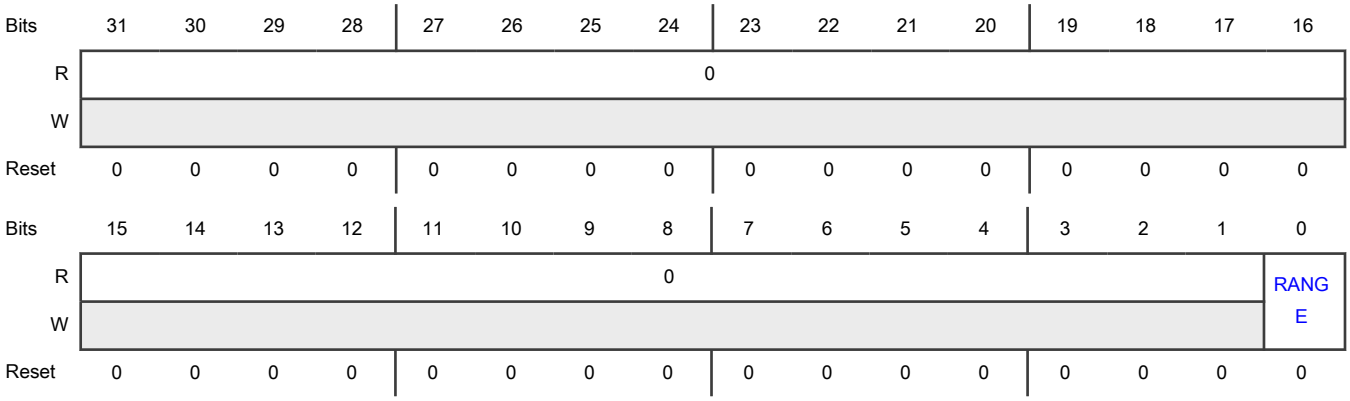
Offset

Register	Offset
FIRCCFG	308h

Function

Controls the clock frequency range select for the FIRC clock source.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 RANGE	Frequency Range Use this field to select the 48 MHz or 144 MHz FIRC clock when used as system clock. **NOTE** This field can be changed while FIRC clock is enabled. 0b - 48 MHz FIRC clock selected 1b - 144 MHz FIRC clock selected

34.7.1.15 FIRC Trim Configuration Register (FIRCTCFG)

Offset

Register	Offset
FIRCTCFG	30Ch

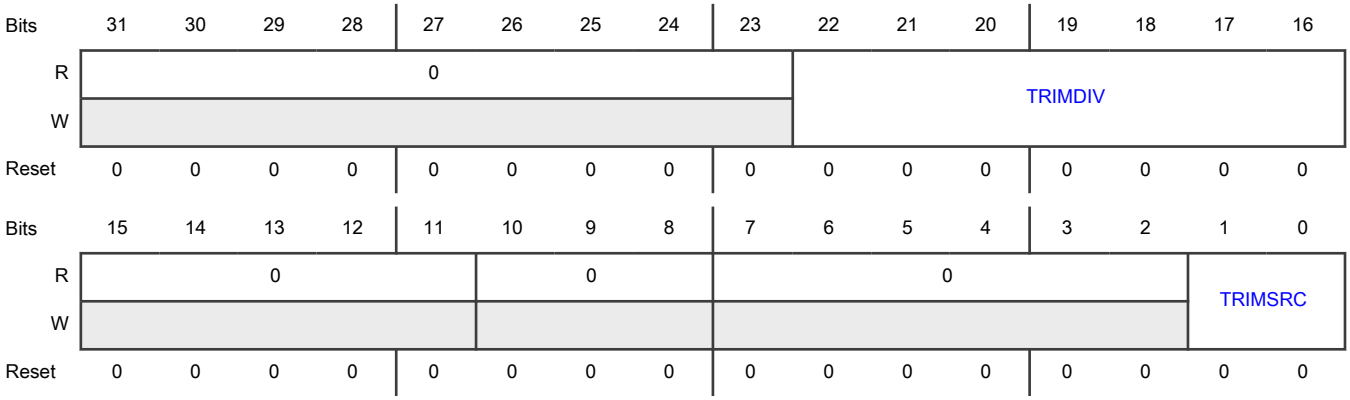
Function

Contains the auto trim clock source select and trim clock divider control for the FIRC clock source.

NOTE

You cannot change this register when FIRC tuning is enabled. When the FIRC tuning is enabled, writes to this register are ignored and there is no transfer error.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 TRIMDIV	FIRC Trim Predivider Divider of SOSC for FIRC trimming. **NOTE** When selecting SOSC as the FIRC trimming source, the TRIMDIV register must be set to correct div ratio to generate 1 MHz output reference trimming clock. **NOTE** TRIMDIV is an N-Divider supporting a div ratio of 1 (TRIMDIV=00h) to a div ratio of 128 (TRIMDIV=7Fh).
15-11 —	Reserved
10-8 —	Reserved
7-2 —	Reserved
1-0 TRIMSRC	Trim Source Configures the external clock source to tune the FIRC. This field must be configured before programming the FIRCSTAT register for trim update. 00b - USB0 Start of Frame (1 kHz). This option does not use TRIMDIV 01b - Reserved 10b - SOSC. This option requires that SOSC be divided using the TRIMDIV field to get a frequency of 1 MHz. 11b - ROSC. 32.768 kHz

34.7.1.16 FIRC Trim Register (FIRCTRIM)

Offset

Register	Offset
FIRCTRIM	310h

Function

The FIRC Trim Register holds the trim values for the FIRC clock source. This register is loaded from IFR during reset. These values are used for trimming the two range (RANGE=0 and RANGE=1) frequencies of FIRC.

NOTE

Writes to this register are protected by TRIM LOCK register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-30 —	Reserved
29-24 TRIMSTART	Trim Start Current DAC adjustment of the replica cco current of start-up circuit.
23-18 —	Reserved
17-16 TRIMTEMP	Trim Temperature Temperature coefficient compensation.
15-14 —	Reserved
13-8 TRIMCOAR	Trim Coarse TRIMCOAR bits are used to coarsely trim the FIRC Clock to within approximately ±3.2% of the target frequency.
7-0 TRIMFINE	Trim Fine Current DAC adjustment of the CCO current. TRIMFINE bits are used to fine trim the FIRC Clock to within approximately ±0.25% of the target frequency.

34.7.1.17 FIRC Auto-trimming Status Register (FIRCSTAT)

Offset

Register	Offset
FIRCSTAT	318h

Function

This register is loaded from IFR during reset.

Trim values are uploaded to this register by FIRC auto-trimming. FIRC auto-trimming is enabled when FIRCTREN=1 and FIRCTRUP=1. When FIRCTREN=1 and FIRCTRUP=0 (write 10 or 11 to TRIMSRC), writes to this register are allowed and values written to this register are used to trim FIRC clock.

Diagram

Fields

Field	Function
31-16 —	Reserved
15-14 —	Reserved
13-8 TRIMCOAR	Trim Coarse Use this field for the current DAC adjustment of the base current and to coarsely trim the FIRC Clock to within approximately ±3.2% of the target 144 MHz frequency.
7-0 TRIMFINE	Trim Fine Use this field for the current DAC adjustment of the CCO current and to trim the FIRC Clock to within approximately ±0.25% of the target 144 MHz frequency.

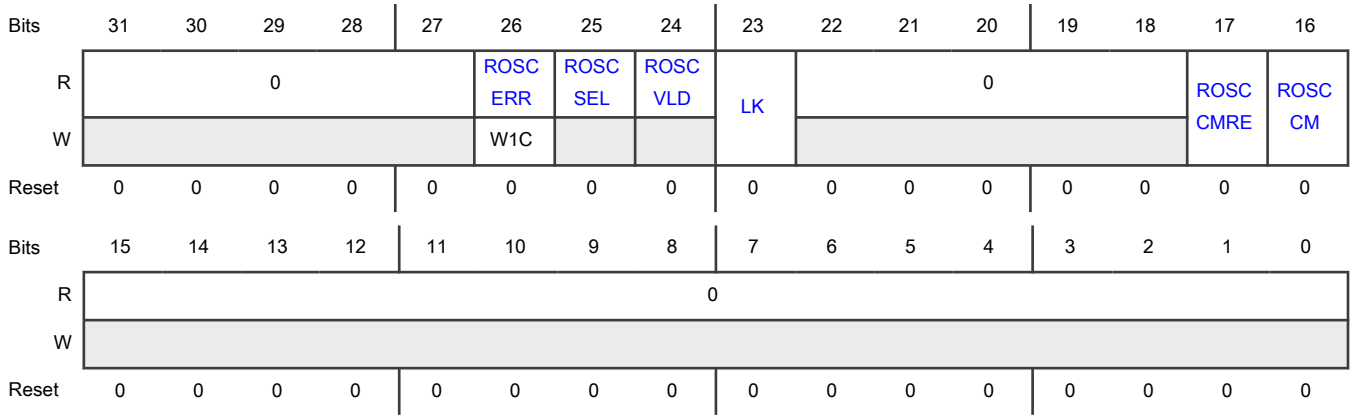
34.7.1.18 ROSC Control Status Register (ROSCCSR)

Offset

Register	Offset
ROSCCSR	400h

Function
Contains control and status bits for the ROSC clock source.

Diagram



Fields

Field	Function
31-27 —	Reserved
26 ROSCERR	ROSC Clock Error This flag is reset on Chip POR only. You can also clear this flag by writing 1. 0b - ROSC Clock Monitor is disabled or has not detected an error 1b - ROSC Clock Monitor is enabled and detected an RTC loss of clock error
25 ROSCSEL	ROSC Selected Indicates if the ROSC clock source is selected as the system clock source. 0b - ROSC is not the system clock source 1b - ROSC is the system clock source
24 ROSCVLD	ROSC Valid Indicates if the ROSC clock source is valid. 0b - ROSC is not enabled or clock is not valid

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - ROSC is enabled and output clock is valid
23 LK	Lock Register Locks this register so that it cannot be written to. **NOTE** This field can be cleared or set at any time. 0b - Control Status Register can be written 1b - Control Status Register cannot be written
22-18 —	Reserved
17 ROSCCMRE	ROSC Clock Monitor Reset Enable Enables the ROSCERR to generate a reset. 0b - Clock monitor generates an interrupt when an error is detected 1b - Clock monitor generates a reset when an error is detected
16 ROSCCM	ROSC Clock Monitor Enables the clock monitor when ROSCVLD is set. When the clock monitor is disabled in a low power mode, it remains disabled until the clock valid flag is set following exit from the low power mode. **NOTE** SIRC is the reference clock used to monitor the ROSC. You must program the SIRC clock to be enabled in order to monitor the ROSC. SIRC is automatically disabled in Power Down and Deep Power Down modes, and the clock monitor of the ROSC is disabled. 0b - ROSC clock monitor is disabled 1b - ROSC clock monitor is enabled
15-0 —	Reserved

34.7.1.19 APLL Control Status Register (APLLCSR)

Offset

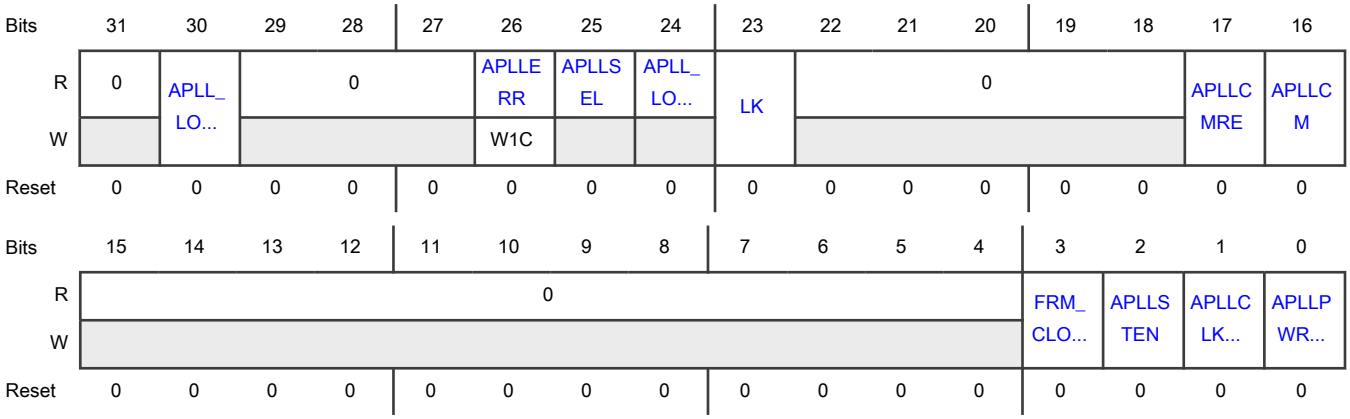
Register	Offset
APLLCSR	500h

Function
Contains control and status fields for the APLL clock source.

NOTE

After the PLL is powered on, do not change the configuration registers except for fields that can be modified on-the-fly.

Diagram



Fields

Field	Function
31 —	Reserved
30 APLL_LOCK_IE	APLL LOCK Interrupt Enable Generates an interrupt when APLL_LOCK is asserted. 0b - APLL_LOCK interrupt is not enabled 1b - APLL_LOCK interrupt is enabled
29-27 —	Reserved
26 APLLERR	APLL Clock Error This flag is reset on-chip POR only. You can also clear this flag by writing 1. **NOTE** This error is only set when FRMDET flag is generated in the free running mode. 0b - APLL Clock Monitor is disabled or has not detected an error 1b - APLL Clock Monitor is enabled and detected an error
25 APLLSEL	APLL Selected Indicates if the APLL clock source is selected as the system clock source. 0b - APLL is not the system clock source 1b - APLL is the system clock source

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 APLL_LOCK	APLL LOCK Indicates when the APLL clock is locked. This flag is set when the number of reference clocks reaches LOCK_TIME after power on. APLL_LOCK clears with any of these conditions: • APLL power down • SOSC error when selected as the reference clock • Writes to APLLCTRL, APLLNDIV, APLLMDIV, APLLSSCG0, or APLLSSCG1 0b - APLL is not powered on or not locked 1b - APLL is locked
23 LK	Lock Register Locks this register so that it cannot be written to. **NOTE** You can clear or set this field at any time. 0b - Control Status Register can be written 1b - Control Status Register cannot be written
22-18 —	Reserved
17 APLLCMRE	APLL Clock Monitor Reset Enable Enables the APLLERR generate reset. **NOTE** This field is only used to monitor whether the FRMDET flag is generated in free running mode. 0b - Clock monitor generates an interrupt when an error is detected 1b - Clock monitor generates a reset when an error is detected
16 APLLCM	APLL Clock Monitor Enables the clock monitor. If the clock source is disabled in a low power mode, then the clock monitor is also disabled in that mode. The clock monitor is always disabled in Power Down and Deep Power Down modes. When the clock monitor is disabled in a low power mode, it remains disabled until the PLL_LOCK is set following exit from the low power mode. **NOTE** This field is only used to monitor whether the FRMDET flag is generated in free running mode. 0b - APLL Clock Monitor is disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - APLL Clock Monitor is enabled
15-4 —	Reserved
3 FRM_CLOCKSTABLE	Free running mode clock stable **NOTE** Use this for free running mode when F_{in} / N = F_{ref} < 100 kHz. Only write 1 to this field after the PLL output frequency is stable. 0b - Free running mode clockstable is disabled 1b - Free running mode clockstable is enabled
2 APLLSTEN	APLL Stop Enable Enables the APLL clock source in Deep Sleep mode if APLLCLKEN and APLLPWREN are set. 0b - APLL is disabled in Deep Sleep mode 1b - APLL is enabled in Deep Sleep mode
1 APLLCLKEN	APLL Clock Enable Enables the APLL clock source. Use this field to enable the analog PLL to send out the clock. You can configure APLLCLKEN and APLLPWREN at the same time because hardware only enables the clock when PLL_LOCK=1. **NOTE** Ensure APLLCLKEN is enabled before using PLL clock. 0b - APLL clock is disabled 1b - APLL clock is enabled
0 APLLPWREN	APLL Power Enable Powers up the APLL clock source. 0b - APLL clock is powered off 1b - APLL clock is powered on

34.7.1.20 APLL Control Register (APLLCTRL)

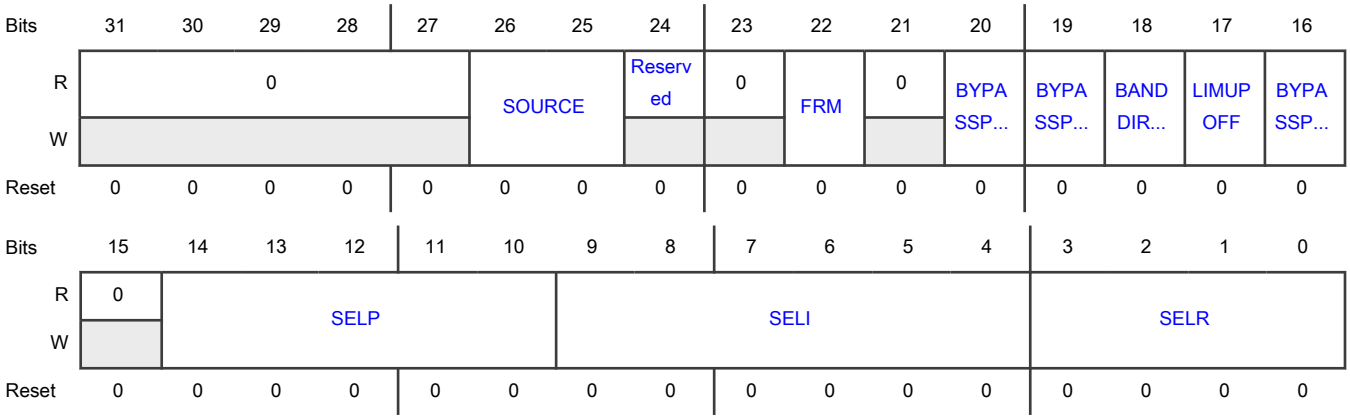
Offset

Register	Offset
APLLCTRL	504h

Function

Contains control fields for the analog PLL.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-25 SOURCE	Clock Source Configures the input clock source (clkin) for the APLL. **NOTE** A good quality input clock is necessary for good PLL performance. The input clock on clkin, optionally divided by the predivider ratio N, gives the reference frequency F_{ref} for the PLL-loop ($F_{ref} = F_{in} / N$). For optimal performance, use a reference frequency within the frequency range 5 MHz to 50 MHz. 00b - SOSC 01b - FIRC 48 MHz clock. FIRC_SCLK_PERIPH_EN must be set to use FIRC 48 MHz clock. 10b - Reserved 11b - No clock
24 —	Reserved
23 —	Reserved
22 FRM	Free Running Mode Enable In FRM mode, PLL monitors the input clock clkin. If the input clock disappears for more than six periods, the CCO of the PLL starts running free. The output frequency is within +1% and -20% for at least 200 µs. After 200 µs of self-clocking, the frequency keeps going down.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If the PLL is in free running mode, FRMDET is high. **NOTE** The free running mode only operates for reference frequencies above 100 kHz (F_{in} / N = F_{ref} > 100 kHz). To use the free running mode for F_{in} / N = F_{ref} < 100 kHz, only make FRM_CLOCKSTABLE = 1 after the PLL output frequency is stable. The free running mode is designed so that if the input clock occurs again, the PLL goes out of free running and is locked. Because the output clock has drifted away, overshoot and lock time have to be taken into account. **NOTE** When FRM=1, and PLL has detected a loss of input clock for more than six periods, the APLLERR flag is set. 0b - Free running mode disabled 1b - Free running mode enabled
21 —	Reserved
20 BYPASSPOSTDIV	Bypass of the postdivider Enables the bypass of the postdivider. **NOTE** Bypass the postdivider also bypasses the divide-by-2 divider in the postdivider. 0b - Use the postdivider. 1b - Bypass of the postdivider
19 BYPASSPREDIV	Bypass of the predivider Enables the bypass of the predivider. 0b - Use the predivider. 1b - Bypass of the predivider.
18 BANDDIRECT	Control of the bandwidth of the PLL. Enables the direct control of the bandwidth. 0b - The bandwidth is changed synchronously with the feedback-divider 1b - Modifies the bandwidth of the PLL directly
17 LIMUPOFF	Up Limiter In spread spectrum and fractional applications, LIMUPOFF must be set to 1. In other applications, LIMUPOFF = 0. 0b - Application set to non-Spectrum and Fractional applications.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Application set to Spectrum and Fractional applications.
16 BYPASSPOSTDIV2	Bypass of Divide-by-2 Divider Bypass of the divide-by-2 divider in the postdivider. 0b - Use the divide-by-2 divider in the postdivider 1b - Bypass of the divide-by-2 divider in the postdivider
15 —	Reserved
14-10 SELP	Bandwidth select P (proportional) value. See related content in Selecting bandwidth and PLL bandwidth settings.
9-4 SELI	Bandwidth select I (integration) value. See related content in Selecting bandwidth and PLL bandwidth settings.
3-0 SELR	Bandwidth select R (resistor) value. See related content in Selecting bandwidth and PLL bandwidth settings.

34.7.1.21 APLL Status Register (APLLSTAT)

Offset

Register	Offset
APLLSTAT	508h

Function

Contains status fields for the analog PLL.

Diagram

31-5 —	Reserved
4 FRMDET	Free running detector (active high) In FRM mode, PLL monitors the input clock clkin. If the input clock disappears for more than six periods, the CCO of the PLL starts running free. The output frequency is within +1% and -20% for at least 200 µs. After 200 µs of self-clocking, the frequency keeps going down. If the PLL is in free running mode, FRMDET is high. 0b - Free running is not detected 1b - Free running is detected
3 PDIVACK	Postdivider(P) ratio change acknowledge. PDIVACK is response to the PREQ that the postdivider (P) ratio change is accepted by the analog PLL. 0b - The postdivider (P) ratio change is not accepted by the analog PLL 1b - The postdivider (P) ratio change is accepted by the analog PLL
2 MDIVACK	Feedback(M) divider ratio change acknowledge. MDIVACK is response to the MREQ that the feedback (M) ratio change is accepted by the analog PLL. 0b - The feedback (M) ratio change is not accepted by the analog PLL 1b - The feedback (M) ratio change is accepted by the analog PLL
1 NDIVACK	Predivider(N) ratio change acknowledge. NDIVACK is response to the NREQ that the predivider (N) ratio change is accepted by the analog PLL. 0b - The predivider (N) ratio change is not accepted by the analog PLL 1b - The predivider (N) ratio change is accepted by the analog PLL
0 —	Reserved

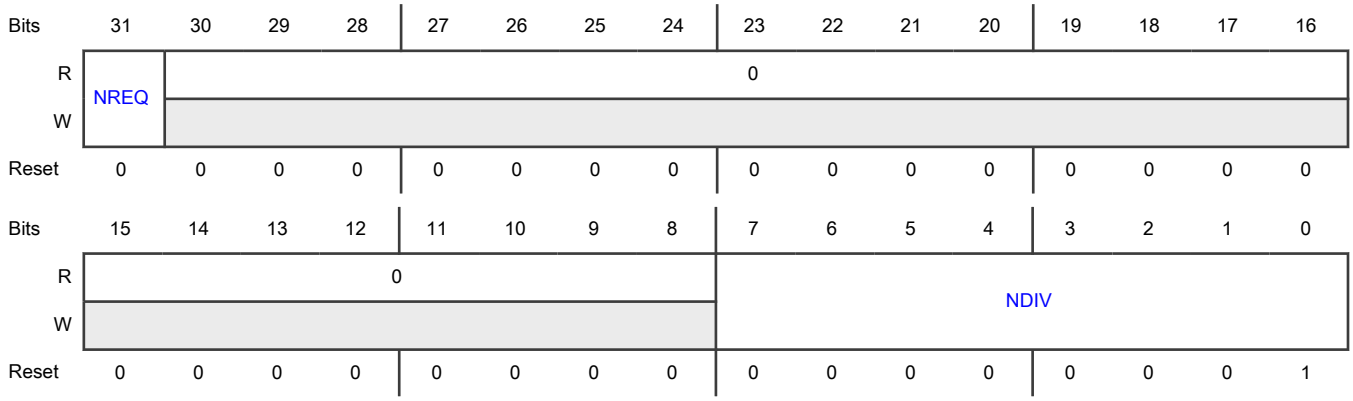
34.7.1.22 APLL N Divider Register (APLLNDIV)

Offset

Register	Offset
APLLNDIV	50Ch

Function
Contains predivider ratio and change request fields for on-the-fly update.

Diagram



Fields

Field	Function
31 NREQ	Predivider ratio change request. Normally, you must program the divider ratio of the different dividers (MDIV, NDIV, PDIV) when PLL is in reset state (APLLPWREN = 0). However, you can also select the divider ratio on-the-fly with the help of a handshake protocol. Normally, you must program the divider ratio for MDIV, NDIV, and PDIV when the PLL is in a reset state (APLLWREN=0). However, you can also select the divider ratio on-the-fly with the help of a handshake protocol: 1. Write to NDIV to select a new divider ratio 2. Write 1 to NREQ to request the ratio change 3. APLLSTAT[NDIVACK] returns 1 to confirm the ratio change is accepted 4. Write 0 to NREQ to end the ratio change request **NOTE** Use the reset method if more than one divider ratio must be changed. **NOTE** During the on-the-fly divider ratio update process, the PLL clock must be switched off from the system clock. APLL_LOCK bit is cleared in this case. Every time F_{ref} changes, a new value LOCK_TIME must be programmed. Before using the PLL clock, you must wait for APLL_LOCK to set again to ensure the PLL is locked. 0b - Predivider ratio change is not requested 1b - Predivider ratio change is requested
30-8 —	Reserved
7-0 NDIV	Predivider divider ratio (N-divider). N-divider supports a divider ratio of 1 (NDIV=01h) to a divider ratio of 255 (NDIV=FFh). **NOTE** Do not write 0 to this field.

34.7.1.23 APLL M Divider Register (APLLMDIV)

Offset

Write 0 to PREQ to end the ratio change request **NOTE** Use the reset method if more than one divider ratio must be changed. **NOTE** During the on-the-fly divider ratio update process, the PLL clock must be switched off from the system clock. APLL_LOCK bit is cleared in this case. Every time F_{ref} changes, a new value LOCK_TIME must be programmed. Before using the PLL clock, you must wait for APLL_LOCK to set again to ensure the PLL is locked. 0b - Postdivider ratio change is not requested 1b - Postdivider ratio change is requested
30-5 —	Reserved
4-0 PDIV	Postdivider divider ratio (P-divider) P-divider supports a divider ratio of PDIV*2, where PDIV is from 1 (PDIV=1h) to 31 (PDIV=1Fh). BYPASSPOSTDIV2 can be set to bypass the divide-by-2 in the postdivider. **NOTE** Do not write 0 to this field.

34.7.1.25 APLL LOCK Configuration Register (APLLLOCK_CNFG)

Offset

Register	Offset
APLLLOCK_CNFG	518h

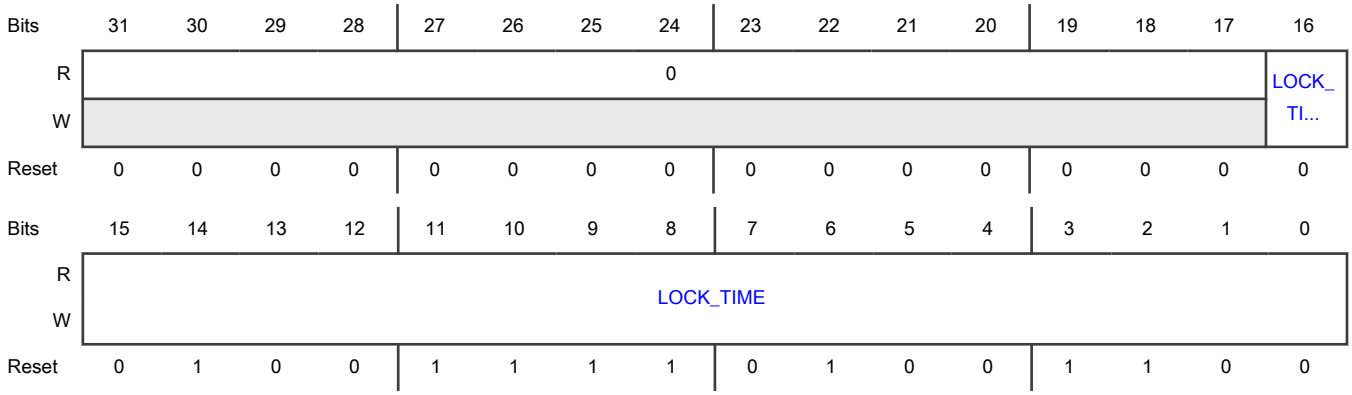
Function

Contains the number of reference clocks to count before APLL is considered locked and valid.

NOTE

Writes to this register are protected by the TRIM_LOCK register register.

Diagram



Fields

Field	Function
31-17 —	Reserved
16-0 LOCK_TIME	Configures the number of reference clocks to count before APLL is considered locked. **NOTE** The lock time programmed in this register must be equal to the PLL 500 µs lock time plus the 300 refclk count startup: LOCK_TIME = 500 µs/T_{ref} + 300, F_{ref} = F_{in}/N (input frequency divided by predivider ratio). **NOTE** Every time F_{ref} changes, you must program a new LOCK_TIME value.

34.7.1.26 APLL SSCG Status Register (APLLSSCGSTAT)

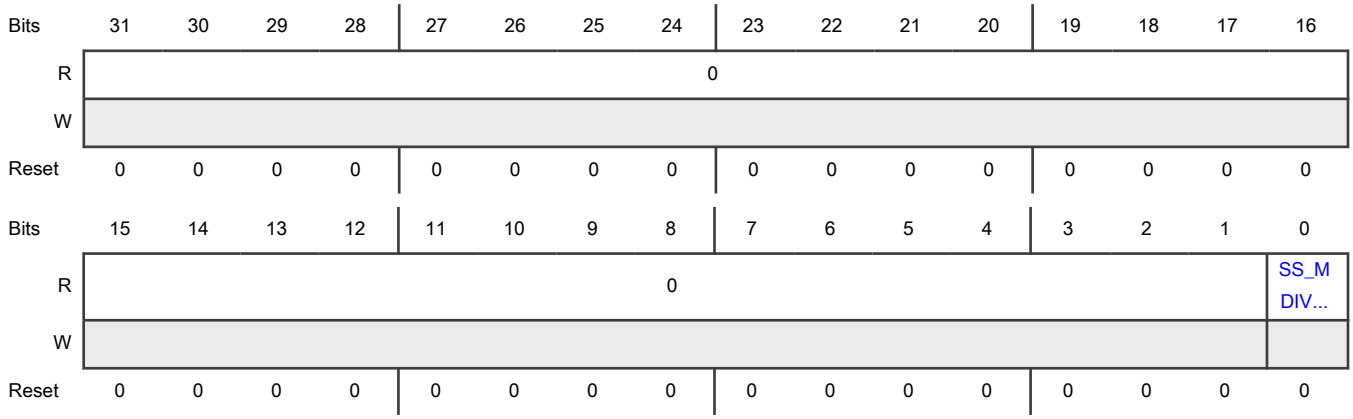
Offset

Register	Offset
APLLSSCGSTAT	520h

Function

Contains status field for the SSCG block.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 SS_MDIV_ACK	SS_MDIV change acknowledge SS_MDIV_ACK responses to the SS_MDIV_REQ. Indicates that the SS_MDIV, MF, MR, and MC change is accepted by the analog PLL. 0b - The SS_MDIV, MF, MR, and MC ratio change is not accepted by the analog PLL 1b - The SS_MDIV, MF, MR, and MC ratio change is accepted by the analog PLL

34.7.1.27 APLL Spread Spectrum Control 0 Register (APLLSSCG0)

Offset

Register	Offset
APLLSSCG0	524h

Function

Contains SS_MDIV.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	SS_MDIV_LSB															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SS_MDIV_LSB	SS_MDIV Represents the average feedback divider ratio $M_{average}$. SS_MDIV[32:25] is the integer part of the feedback divider ratio. SS_MDIV[24:0] is the fractional part of the feedback divider ratio. Average feedback-divider ratio $M_{average}$: $M_{average} = \text{SS_MDIV}[32:25]_{dec} + 2^{-25} \times SS_MDIV[24:0]_{dec} + DITHER \times 2^{-26} = 2^{-25} \times SS_MDIV_{dec} + DITHER \times 2^{-26}$ stepsize = $1/(2^{25} * M_{average})$

34.7.1.28 APLL Spread Spectrum Control 1 Register (APLLSSCG1)

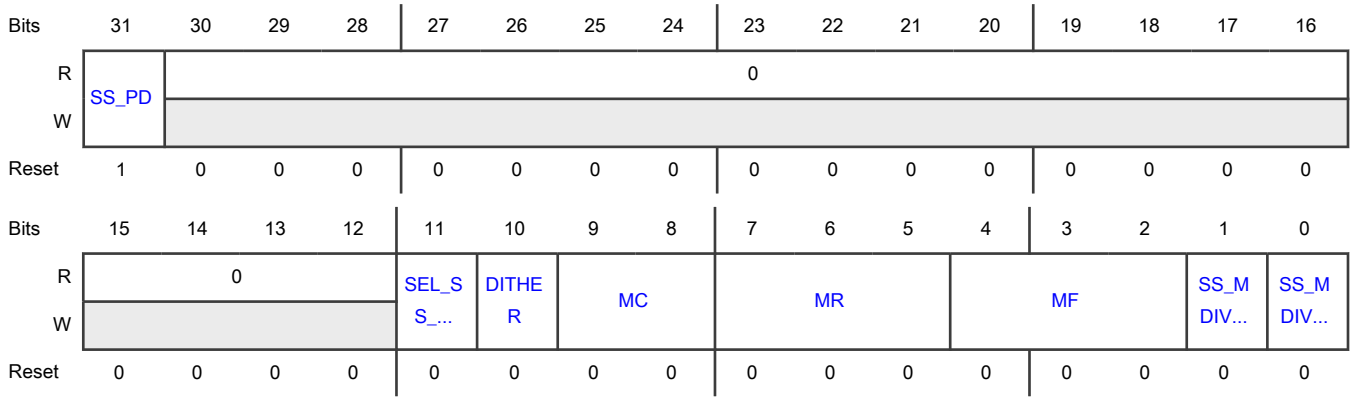
Offset

Register	Offset
APLLSSCG1	528h

Function

Contains SS_MDIV[32] and other control fields for the SSCG.

Diagram



Fields

Field	Function
31 SS_PD	SSCG Power Down Puts SSCG into power down. **NOTE** You must configure DITHER, MC, MF, MR, and SS_MDIV[32:0] before SS_PD is cleared. 0b - SSCG is powered on 1b - SSCG is powered off
30-12 —	Reserved
11 SEL_SS_MDIV	SS_MDIV select. Selects the SS_MDIV value. 0b - Feedback divider ratio is MDIV[15:0] 1b - Feedback divider ratio is SS_MDIV[32:0]
10 DITHER	Dither Enable Enables dithering between two modulation frequencies in a random way. This decreases the probability that the modulated waveform occurs with the same phase on a particular point on the screen. 0b - Dither is not enabled 1b - Dither is enabled
9-8 MC	Modulation Waveform Control Compensation for the low-pass filtering of the PLL in order to get a triangular modulation at the output of the PLL and a flat frequency spectrum. **NOTE** The recommended setting for the modulation waveform control is MC[1:0] = 10.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - MC[1:0] no compensation 11b - MC[1:0] maximum compensation
7-5 MR	Modulation Depth Control Controls the programmable frequency modulation depth according to the following equation. Average feedback-divider ratio: $$fmod_{pk\text{-}pk} = \frac{F_{ref} \times k_{ss}}{F_{sso}} = \frac{k_{ss}}{SS_MDIV[32:25]_{dec}}$$ • MR[2:0] = 000 - k_{SS} = 0 (no spread spectrum) • MR[2:0] = 001 - k_{SS} ≈ 0.5 • MR[2:0] = 010 - k_{SS} ≈ 0.75 • MR[2:0] = 011 - k_{SS} ≈ 1 • MR[2:0] = 100 - k_{SS} ≈ 1.5 • MR[2:0] = 101 - k_{SS} ≈ 2 • MR[2:0] = 110 - k_{SS} ≈ 3 • MR[2:0] = 111 - k_{SS} ≈ 4
4-2 MF	Modulation Frequency Control Controls the programmable modulation frequency. The below modulation frequencies are examples based on a 4 MHz reference frequency (F_{ref}). fm = F_{ref} /N_{SS} • MF[2:0] = 000 - N_{SS} = 512 (fm ≈ 7.8 kHz) • MF[2:0] = 001 - N_{SS} ≈ 384 (fm ≈ 10.4 kHz) • MF[2:0] = 010 - N_{SS} = 256 (fm ≈ 15.6 kHz) • MF[2:0] = 011 - N_{SS} = 128 (fm ≈ 31.3 kHz) • MF[2:0] = 100 - N_{SS} = 64 (fm ≈ 62.5 kHz) • MF[2:0] = 101 - N_{SS} = 32 (fm ≈ 125 kHz) • MF[2:0] = 110 - N_{SS} ≈ 24 (fm ≈ 166.6 kHz) • MF[2:0] = 111 - N_{SS} = 16 (fm ≈ 250 kHz)
1 SS_MDIV_REQ	SS_MDIV[32:0] change request. Change request for SS_MDIV, MF, MR, and MC. Normally, you must program the divider ratio for SS_MDIV, MF, MR, and MC when the PLL is in a reset state (APLLWREN=0). However, you can also select the divider ratio on-the-fly with the help of a handshake protocol: 1. Write to SS_MDIV, MF, MR, and MC to select a new divider ratio

Table continues on the next page...

Table continued from the previous page...

Field	Function
	2. Write 1 to SS_MDIV_REQ to request the ratio change 3. SS_MDIV_ACK returns 1 to confirm the ratio change is accepted 4. Write 0 to SS_MDIV_REQ to end the ratio change request **NOTE** Use the reset method if more than one divider ratio must be changed. **NOTE** During the on-the-fly divider ratio update process, the PLL clock must be switched off from the system clock. APLL_LOCK bit is cleared in this case. Every time F_{ref} changes, a new value LOCK_TIME must be programmed. Before using the PLL clock, you must wait for APLL_LOCK to set again to ensure the PLL is locked. 0b - SS_MDIV change is not requested 1b - SS_MDIV change is requested
0 SS_MDIV_MSB	SS_MDIV[32] See APLLSSCG0[SS_MDIV_LSB].

34.7.1.29 APLL Override Register (APLL_OVRD)

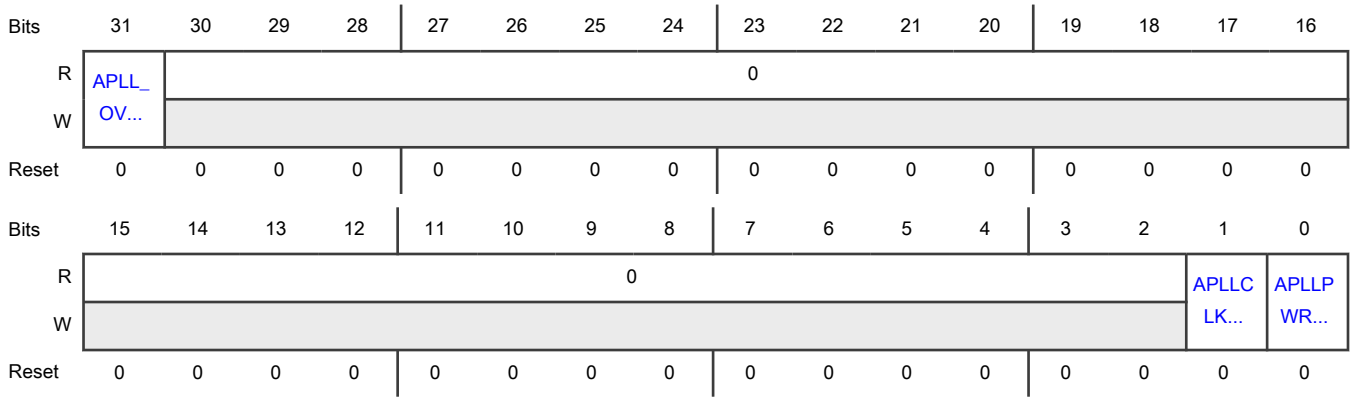
Offset

Register	Offset
APLL_OVRD	5F4h

Function

Contains override fields for the analog PLL.

Diagram



Fields

Field	Function
31 APLL_OVRD_EN	APLL Override Enable Enables the override control for APLL 0b - APLL override is disabled 1b - APLL override is enabled
30-2 —	Reserved
1 APLLCLKEN_OVRD	APLL Clock Enable Override if APLL_OVRD_EN=1 Enables the APLL clock source. 0b - APLL clock is disabled 1b - APLL clock is enabled
0 APLLPWREN_OVRD	APLL Power Enable Override if APLL_OVRD_EN=1 Powers up the APLL clock source. NOTE Write 0 to SS_PD to use the Spread Spectrum function. 0b - APLL clock is powered off 1b - APLL clock is powered on

34.7.1.30 SPLL Control Status Register (SPLLCSR)

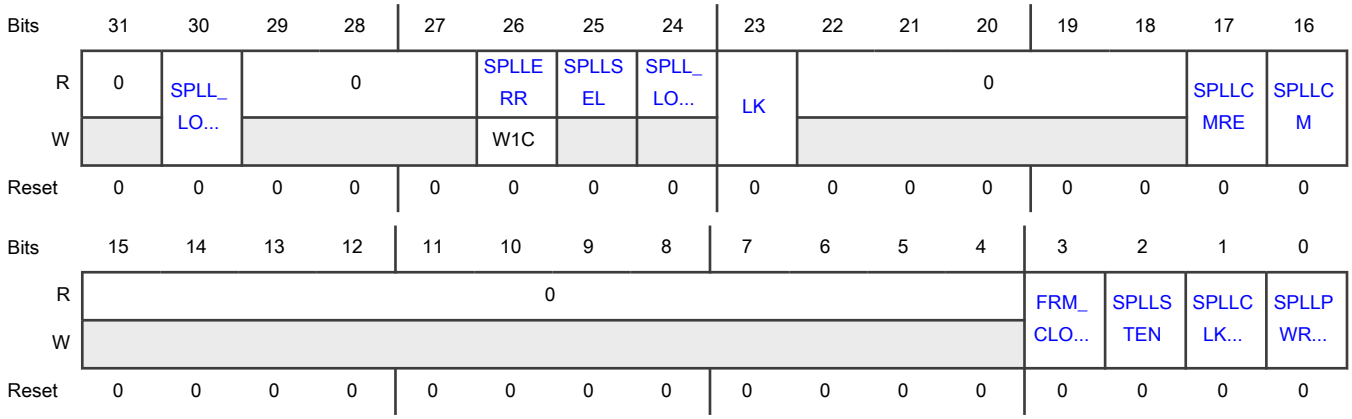
Offset

Register	Offset
SPLLCSR	600h

Function
Contains control and status fields for SPLL clock source.

NOTE
After PLL is powered on, do not change the configuration registers except for fields that can be modified on-the-fly.

Diagram



Fields

Field	Function
31 —	Reserved
30 SPLL_LOCK_IE	SPLL LOCK Interrupt Enable Generates an interrupt when SPLL_LOCK is asserted. 0b - SPLL_LOCK interrupt is not enabled 1b - SPLL_LOCK interrupt is enabled
29-27 —	Reserved
26 SPLLERR	SPLL Clock Error This flag is reset on Chip POR only. You can also clear this flag by writing 1. **NOTE** This field is only set when FRMDET flag is generated in free running mode. 0b - SPLL Clock Monitor is disabled or has not detected an error 1b - SPLL Clock Monitor is enabled and detected an error
25 SPLLSEL	SPLL Selected This flag indicates if the SPLL clock source is selected as the system clock source. 0b - SPLL is not the system clock source 1b - SPLL is the system clock source
24 SPLL_LOCK	SPLL LOCK Indicates when the SPLL clock is locked. This flag is set when the number of reference clocks reaches LOCK_TIME after power on.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	SPLL_LOCK clears with any of these conditions: • SPLL power down • SOSC error when selected as the reference clock • Writes to SPLLCTRL, SPLLNDIV, SPLLMDIV, SPLLSSCG0, or SPLLSSCG1 **NOTE** Use the SPLL_LOCK field to verify that the SPLL is locked after power-on. This field is cleared when you modify the SPLLCTRL, SPLLNDIV, SPLLMDIV, SPLLPDIV, SPLLSSCG0, or SPLLSSCG1 configurations on-the-fly. In this case, you must wait for SPLL_LOCK to set again to ensure PLL is locked before using the PLL clock. **NOTE** To monitor the SPLL clock, use the SPLLCM field to ensure that the SPLL Clock Monitor is enabled. 0b - SPLL is not powered on or not locked 1b - SPLL is locked
23 LK	Lock Register Locks this register so that it cannot be written to. **NOTE** You can clear or set this field at any time. 0b - Control Status Register can be written 1b - Control Status Register cannot be written
22-18 —	Reserved
17 SPLLCMRE	SPLL Clock Monitor Reset Enable Enables the SPLLERR generate reset. **NOTE** This field is only used to monitor whether the FRMDET flag is generated in free running mode. 0b - Clock monitor generates an interrupt when an error is detected 1b - Clock monitor generates a reset when an error is detected
16 SPLLCM	SPLL Clock Monitor Enables the clock monitor. If the clock source is disabled in a low power mode, then the clock monitor is also disabled in that mode. The clock monitor is always disabled in Power Down and Deep Power Down modes. When the clock monitor is disabled in a low power mode, it remains disabled until the PLL_LOCK is set following exit from that mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field is only used to monitor whether the FRMDET flag is generated in free running mode. 0b - SPLL Clock Monitor is disabled 1b - SPLL Clock Monitor is enabled
15-4 —	Reserved
3 FRM_CLOCKSTABLE	Free running mode clock stable **NOTE** Use this field for free running mode when F_{in} / N = F_{ref} < 100 kHz. Only write 1 to this field after the PLL output frequency is stable. 0b - Free running mode clockstable is disabled 1b - Free running mode clockstable is enabled
2 SPLLSTEN	SPLL Stop Enable Enables the SPLL clock source in Deep Sleep mode if SPLLCLKEN and SPLLPWREN are set. 0b - SPLL is disabled in Deep Sleep mode 1b - SPLL is enabled in Deep Sleep mode
1 SPLLCLKEN	SPLL Clock Enable Enables the SPLL clock source. Use this field to enable the analog PLL to send out the clock. You can configure SPLLCLKEN and SPLLPWREN at the same time because hardware only enables the clock when PLL_LOCK=1. **NOTE** Ensure SPLLCLKEN is enabled before using PLL clock. 0b - SPLL clock is disabled 1b - SPLL clock is enabled
0 SPLLPWREN	SPLL Power Enable Powers up the SPLL clock source. **NOTE** Write 0 to SS_PD to use the spread spectrum and fractional functions. 0b - SPLL clock is powered off 1b - SPLL clock is powered on

34.7.1.31 SPLL Control Register (SPLLCTRL)

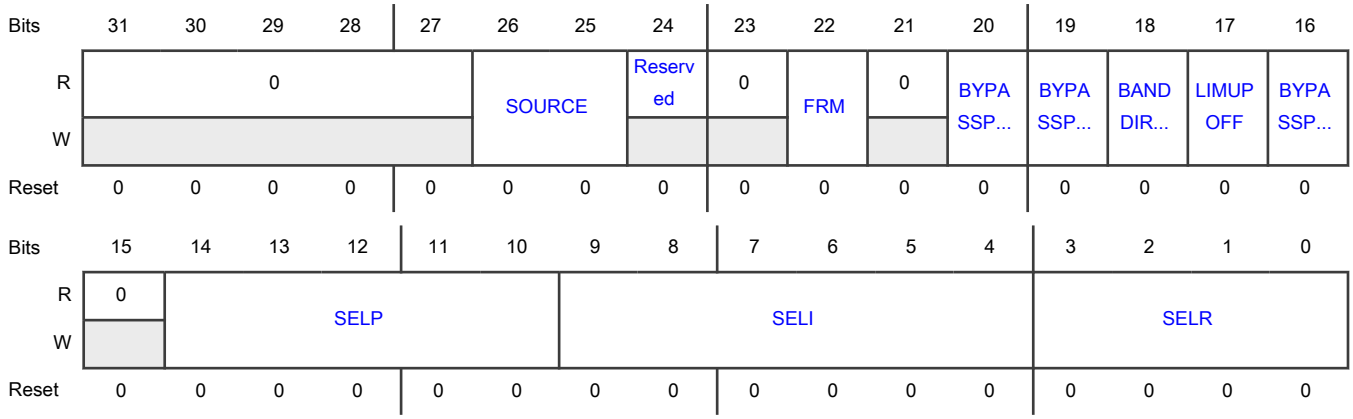
Offset

Register	Offset
SPLLCTRL	604h

Function

Contains control fields for the analog PLL.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-25 SOURCE	Clock Source Configures the input clock source (clkin) for the SPLL. **NOTE** A good-quality input clock is necessary for good PLL performance. The input clock on clkin, optionally divided by the predivider ratio N, gives the reference frequency F_{ref} for the PLL-loop ($F_{ref} = F_{in} / N$). For optimal performance, use a reference frequency within the frequency range 5 MHz to 50 MHz. 00b - SOSC 01b - FIRC 48 MHz clock. FIRC_SCLK_PERIPH_EN must be set to use FIRC 48 MHz clock. 10b - Reserved 11b - No clock
24	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
23 —	Reserved
22 FRM	Free Running Mode Enable In FRM mode, the PLL monitors the input clock clkin. If the input clock disappears for more than six periods, the CCO of the PLL starts running free. The output frequency is within +1% and -20% for at least 200 µs. After 200 µs of self-clocking, the frequency keeps going down. If the PLL is in free running mode, FRMDET is high. **NOTE** The free running mode only operates for reference frequencies above 100 kHz (F_{in} / N = F_{ref} > 100 kHz). To use the free running mode for F_{in} / N = F_{ref} < 100 kHz, only make FRM_CLOCKSTABLE = 1 after the PLL output frequency is stable. The free running mode is designed so that if the input clock occurs again, the PLL goes out of free running and is locked. Because the output clock has drifted away, overshoot and lock time have to be taken into account. **NOTE** When FRM=1, and PLL has detected a loss of input clock for more than six periods, SPLLERR flag is set. 0b - Free running mode disabled 1b - Free running mode enabled
21 —	Reserved
20 BYPASSPOSTDIV	Bypass of the postdivider. Enables the bypass of the postdivider. 0b - Use the postdivider 1b - Bypass of the postdivider
19 BYPASSPREDIV	Bypass of the predivider. Enables the bypass of the predivider. 0b - Use the predivider 1b - Bypass of the predivider
18 BANDDIRECT	Control of the bandwidth of the PLL. Enables the direct control of the bandwidth. 0b - The bandwidth is changed synchronously with the feedback-divider

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Modifies the bandwidth of the PLL directly
17 LIMUPOFF	Up Limiter. In spread spectrum and fractional applications, you must set LIMUPOFF to 1. In other applications, LIMUPOFF = 0. 0b - Application set to non-Spectrum and Fractional applications. 1b - Application set to Spectrum and Fractional applications.
16 BYPASSPOSTDIV2	Bypass of Divide-by-2 Divider Bypass of the divide-by-2 divider in the postdivider. 0b - Use the divide-by-2 divider in the postdivider. 1b - Bypass of the divide-by-2 divider in the postdivider
15 —	Reserved
14-10 SELP	Bandwidth select P (proportional) value. See related content in Selecting bandwidth and PLL bandwidth settings.
9-4 SELI	Bandwidth select I (integration) value. See related content in Selecting bandwidth and PLL bandwidth settings.
3-0 SELR	Bandwidth select R (resistor) value. See related content in Selecting bandwidth and PLL bandwidth settings.

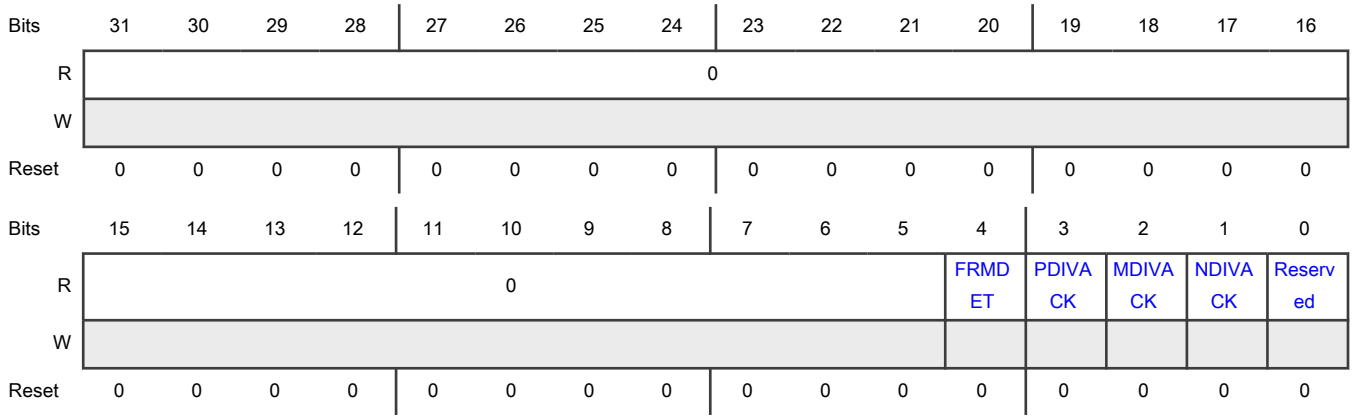
34.7.1.32 SPLL Status Register (SPLLSTAT)

Offset

Register	Offset
SPLLSTAT	608h

Function
Contains status fields for the analog PLL.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 FRMDET	Free running detector (active high) In FRM mode, the PLL monitors the input clock clkin. If the input clock disappears for more than six periods, the CCO of the PLL starts running free. The output frequency is within +1% and -20% for at least 200 µs. After 200 µs of self-clocking, the frequency keeps going down. If the PLL is in free running mode, FRMDET is high. 0b - Free running is not detected 1b - Free running is detected
3 PDIVACK	Postdivider (P) ratio change acknowledge PDIVACK is response to the PREQ that the postdivider (P) ratio change is accepted by the analog PLL. 0b - The postdivider (P) ratio change is not accepted by the analog PLL 1b - The postdivider (P) ratio change is accepted by the analog PLL
2 MDIVACK	Feedback (M) divider ratio change acknowledge Indicates to the MREQ that the feedback (M) ratio change is accepted by the analog PLL. 0b - The feedback (M) ratio change is not accepted by the analog PLL. 1b - The feedback (M) ratio change is accepted by the analog PLL.
1 NDIVACK	Predivider (N) ratio change acknowledge Indicates to the NREQ that the predivider (N) ratio change is accepted by the analog PLL. 0b - The predivider (N) ratio change is not accepted by the analog PLL. 1b - The predivider (N) ratio change is accepted by the analog PLL.
0 —	Reserved

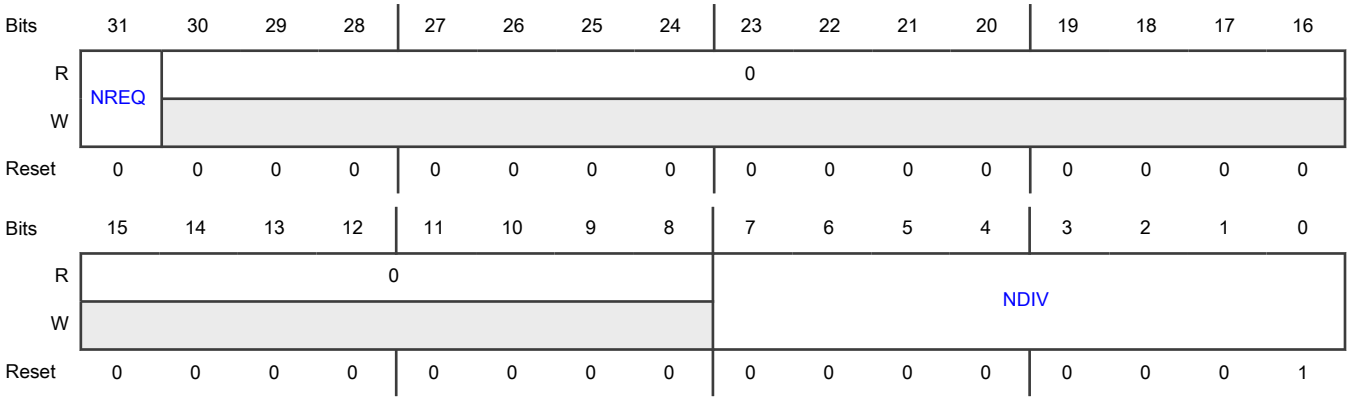
34.7.1.33 SPLL N Divider Register (SPLLNDIV)

Offset

Register	Offset
SPLLNDIV	60Ch

Function
Contains predivider ratio and change request fields for on-the-fly update.

Diagram



Fields

Field	Function
31 NREQ	Predivider ratio change request. Normally, you must program the divider ratio of the different dividers (MDIV, NDIV, PDIV) when PLL is in reset state (SPLLPWREN = 0). However, you can also select the divider ratio on-the-fly with the help of a handshake protocol. Normally, you must program the divider ratio for MDIV, NDIV, and PDIV when the PLL is in a reset state (SPLLWREN=0). However, you can also select the divider ratio on-the-fly with the help of a handshake protocol: 1. Write to NDIV to select a new divider ratio 2. Write 1 to NREQ to request the ratio change 3. SPLLSTAT[NDIVACK] returns 1 to confirm the ratio change is accepted 4. Write 0 to NREQ to end the ratio change request **NOTE** Use the reset method if more than one divider ratio must be changed. **NOTE** During the on-the-fly divider ratio update process, the PLL clock must be switched off from the system clock. SPLL_LOCK bit is cleared in this case. Every time F_{ref} changes, a new value LOCK_TIME must be programmed. Before using the PLL clock, you must wait for SPLL_LOCK to set again to ensure the PLL is locked.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Predivider ratio change is not requested 1b - Predivider ratio change is requested
30-8 —	Reserved
7-0 NDIV	Predivider divider ratio (N-divider). N-divider supports a divider ratio of 1 (NDIV=01h) to a divider ratio of 255 (NDIV=FFh). **NOTE** Do not write 0 to this field.

34.7.1.34 SPLL M Divider Register (SPLLMDIV)

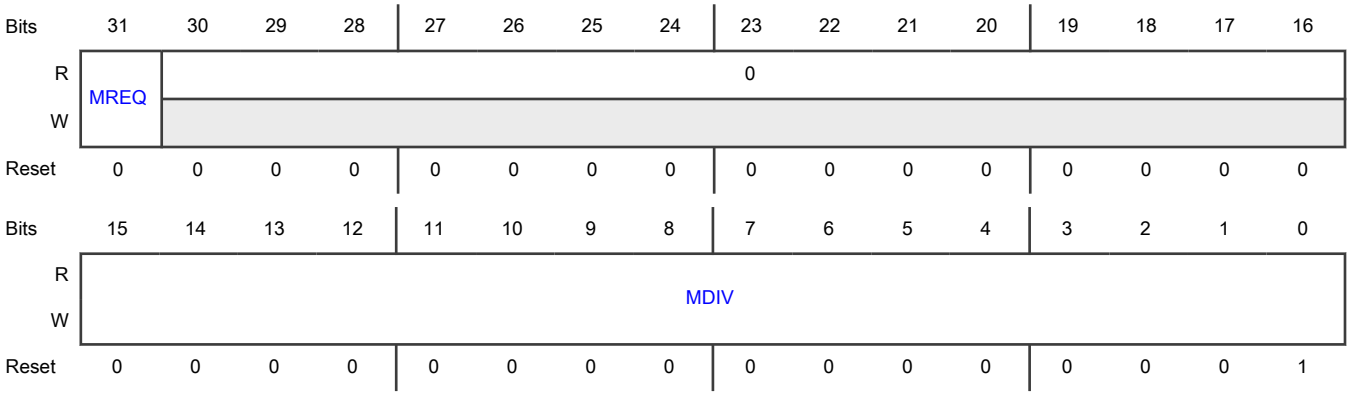
Offset

Register	Offset
SPLLMDIV	610h

Function

Contains feedback divider ratio and change request fields for on-the-fly update.

Diagram



Fields

Field	Function
31 MREQ	Feedback ratio change request.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Normally, you must program the divider ratio for MDIV, NDIV, and PDIV when the PLL is in a reset state (SPLLWREN=0). However, you can also select the divider ratio on-the-fly with the help of a handshake protocol: 1. Write to MDIV to select a new divider ratio 2. Write 1 to MREQ to request the ratio change 3. SPLLSTAT[MDIVACK] returns 1 to confirm the ratio change is accepted 4. Write 0 to MREQ to end the ratio change request **NOTE** Use the reset method if more than one divider ratio must be changed. **NOTE** During the on-the-fly divider ratio update process, the PLL clock must be switched off from the system clock. SPLL_LOCK bit is cleared in this case. Every time F_{ref} changes, a new value LOCK_TIME must be programmed. Before using the PLL clock, you must wait for SPLL_LOCK to set again to ensure the PLL is locked. 0b - Feedback ratio change is not requested 1b - Feedback ratio change is requested
30-16 —	Reserved
15-0 MDIV	Feedback divider divider ratio (M-divider). M-divider supports a divider ratio of 1 (MDIV=0001h) to a divider ratio of 65535 (MDIV=FFFFh). **NOTE** Do not write 0 to this field.

34.7.1.35 SPLL P Divider Register (SPLLPDIV)

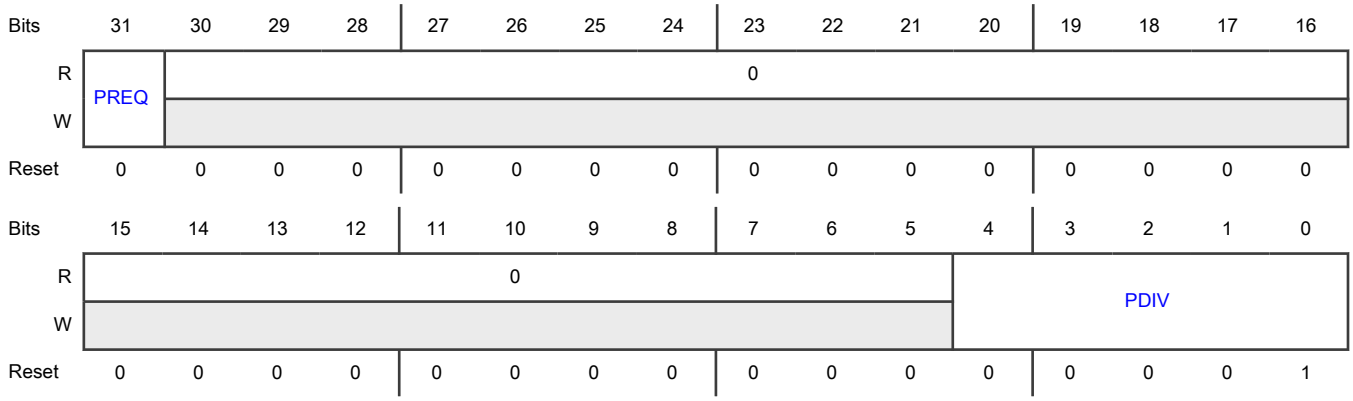
Offset

Register	Offset
SPLLPDIV	614h

Function

Contains postdivider ratio and change request fields for an on-the-fly update.

Diagram



Fields

Field	Function
31 PREQ	Postdivider ratio change request Normally, you must program the divider ratio for MDIV, NDIV, and PDIV when the PLL is in a reset state (SPLLWREN=0). However, you can also select the divider ratio on-the-fly with the help of a handshake protocol: 1. Write to PDIV to select a new divider ratio 2. Write 1 to PREQ to request the ratio change 3. SPLLSTAT[PDIVACK] returns 1 to confirm the ratio change is accepted 4. Write 0 to PREQ to end the ratio change request **NOTE** Use the reset method if more than one divider ratio must be changed. **NOTE** During the on-the-fly divider ratio update process, the PLL clock must be switched off from the system clock. SPLL_LOCK bit is cleared in this case. Every time F_{ref} changes, a new value LOCK_TIME must be programmed. R W	SS_MDIV_LSB															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SS_MDIV_LSB	SS_MDIV[31:0] Represents the average feedback divider ratio $M_{average}$. SS_MDIV[32:25] is the integer part of the feedback divider ratio. SS_MDIV[24:0] is the fractional part of the feedback divider ratio. **NOTE** SS_MDIV[32:0] must not be programmed to value 0 for spread spectrum and fractional function. Average feedback-divider ratio $M_{average}$: $M_{average} = \text{SS_MDIV}[32:25]_{dec} + 2^{-25} \times SS_MDIV[24:0]_{dec} + DITHER \times 2^{-26} = 2^{-25} \times SS_MDIV_{dec} + DITHER \times 2^{-26}$ stepsize = $1/(2^{25} * M_{average})$

34.7.1.39 SPLL Spread Spectrum Control 1 Register (SPLLSSCG1)

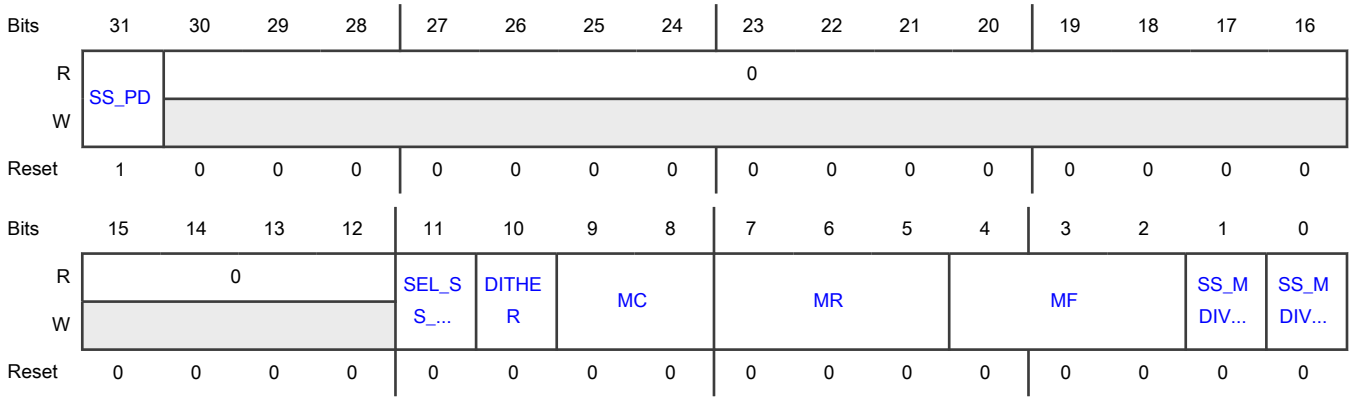
Offset

Register	Offset
SPLLSSCG1	628h

Function

Contains SS_MDIV[32] and other control fields for SSCG.

Diagram



Fields

Field	Function
31 SS_PD	SSCG Power Down Puts SSCG into power down. **NOTE** The configuration of DITHER, MC, MF, MR, and SS_MDIV[32:0] must be written before SS_PD is cleared. 0b - SSCG is powered on 1b - SSCG is powered off
30-12 —	Reserved
11 SEL_SS_MDIV	SS_MDIV select. Selects the SS_MDIV value. 0b - Feedback divider ratio is MDIV[15:0] 1b - Feedback divider ratio is SS_MDIV[32:0]
10 DITHER	Dither Enable Enables dithering between two modulation frequencies in a random way. This decreases the probability of the modulated waveform occurring with the same phase on a particular point on the screen. 0b - Dither is not enabled 1b - Dither is enabled
9-8 MC	Modulation Waveform Control Compensation for the low-pass filtering of the PLL in order to get a triangular modulation at the output of the PLL and a flat frequency spectrum. **NOTE** The recommended setting for the modulation waveform control is MC[1:0] = 10.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - MC[1:0] no compensation 11b - MC[1:0] maximum compensation
7-5 MR	Modulation Depth Control Controls the programmable frequency modulation depth according to the following equation. Average feedback-divider ratio: $$fmod_{pk\text{-}pk} = \frac{F_{ref} \times k_{ss}}{F_{sso}} = \frac{k_{ss}}{SS_MDIV[32:25]_{dec}}$$ • MR[2:0] = 000 - k_{SS} = 0 (no spread spectrum) • MR[2:0] = 001 - k_{SS} ≈ 0.5 • MR[2:0] = 010 - k_{SS} ≈ 0.75 • MR[2:0] = 011 - k_{SS} ≈ 1 • MR[2:0] = 100 - k_{SS} ≈ 1.5 • MR[2:0] = 101 - k_{SS} ≈ 2 • MR[2:0] = 110 - k_{SS} ≈ 3 • MR[2:0] = 111 - k_{SS} ≈ 4
4-2 MF	Modulation Frequency Control Controls the programmable modulation frequency. The below modulation frequencies are examples based on a 4 MHz reference frequency (F_{ref}). fm = F_{ref} /N_{SS} • MF[2:0] = 000 - N_{SS} = 512 (fm ≈ 7.8 kHz) • MF[2:0] = 001 - N_{SS} ≈ 384 (fm ≈ 10.4 kHz) • MF[2:0] = 010 - N_{SS} = 256 (fm ≈ 15.6 kHz) • MF[2:0] = 011 - N_{SS} = 128 (fm ≈ 31.3 kHz) • MF[2:0] = 100 - N_{SS} = 64 (fm ≈ 62.5 kHz) • MF[2:0] = 101 - N_{SS} = 32 (fm ≈ 125 kHz) • MF[2:0] = 110 - N_{SS} ≈ 24 (fm ≈ 166.6 kHz) • MF[2:0] = 111 - N_{SS} = 16 (fm ≈ 250 kHz)
1 SS_MDIV_REQ	SS_MDIV[32:0] change request. Change request for SS_MDIV, MF, MR, and MC. Normally, you must program the divider ratio for SS_MDIV, MF, MR, and MC when the PLL is in a reset state (SPLLWREN=0). However, you can also select the divider ratio on-the-fly with the help of a handshake protocol: 1. Write to SS_MDIV, MF, MR, and MC to select a new divider ratio

Table continues on the next page...

Table continued from the previous page...

Field	Function
	2. Write 1 to SS_MDIV_REQ to request the ratio change 3. SS_MDIV_ACK returns 1 to confirm the ratio change is accepted 4. Write 0 to SS_MDIV_REQ to end the ratio change request **NOTE** Use the reset method if more than one divider ratio must be changed. **NOTE** During the on-the-fly divider ratio update process, the PLL clock must be switched off from the system clock. SPLL_LOCK bit is cleared in this case. Every time F_{ref} changes, a new value LOCK_TIME must be programmed. Before using the PLL clock, you must wait for SPLL_LOCK to set again to ensure the PLL is locked. 0b - SS_MDIV change is not requested 1b - SS_MDIV change is requested
0 SS_MDIV_MSB	SS_MDIV[32] See SS_MDIV_LSB.

34.7.1.40 SPLL Override Register (SPLL_OVRD)

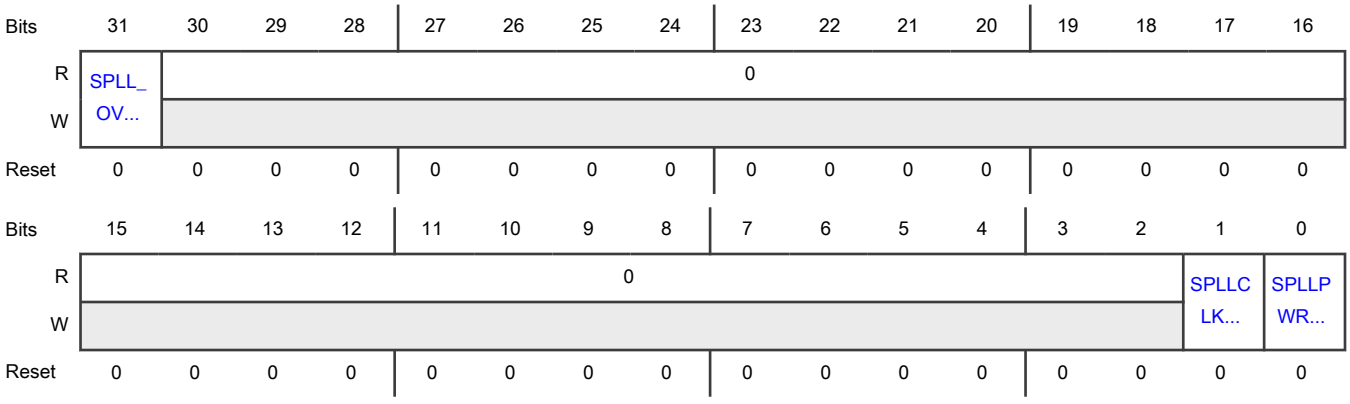
Offset

Register	Offset
SPLL_OVRD	6F4h

Function

Contains override fields for the analog PLL.

Diagram



Fields

Field	Function
31 SPLL_OVRD_EN	SPLL Override Enable Enable the override control for SPLL 0b - SPLL override is disabled 1b - SPLL override is enabled
30-2 —	Reserved
1 SPLLCLKEN_OVRD	SPLL Clock Enable Override if SPLL_OVRD_EN=1 Enable the SPLL clock source. 0b - SPLL clock is disabled 1b - SPLL clock is enabled
0 SPLLPWREN_OVRD	SPLL Power Enable Override if SPLL_OVRD_EN=1 Power up the SPLL clock source. **NOTE** Write 0 to SS_PD to use the Spread Spectrum function. 0b - SPLL clock is powered off 1b - SPLL clock is powered on

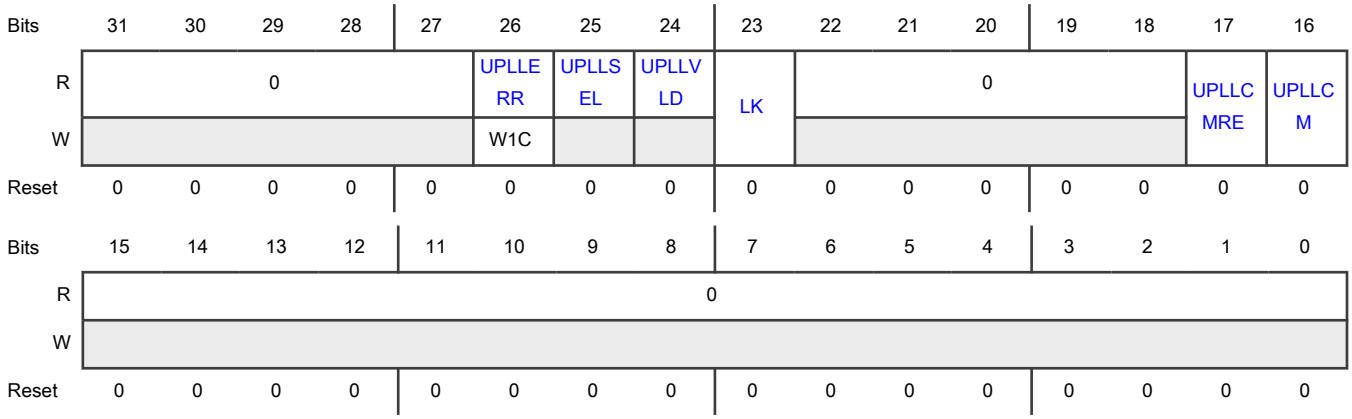
34.7.1.41 UPLL Control Status Register (UPLLCSR)

Offset

Register	Offset
UPLLCSR	700h

Function
Contains control and status bits for UPLL clock source.

Diagram



Fields

Field	Function
31-27 —	Reserved
26 UPLLERR	UPLL Clock Error This flag is reset on Chip POR only. 0b - UPLL Clock Monitor is disabled or has not detected an error 1b - UPLL Clock Monitor is enabled and detected an error
25 UPLLSEL	UPLL Selected Indicates whether the UPLL clock source is selected as the system clock source. 0b - UPLL is not the system clock source 1b - UPLL is the system clock source
24 UPLLVLD	UPLL Valid Indicates when the UPLL clock is valid. 0b - UPLL is not enabled or clock is not valid 1b - UPLL is enabled and output clock is valid
23 LK	Lock Register Locks this register so that it cannot be written to. **NOTE** You can clear or set this field at any time. 0b - Control Status Register can be written 1b - Control Status Register cannot be written
22-18	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
17 UPLLCMRE	UPLL Clock Monitor Reset Enable Enables the UPLLERR generate reset. 0b - Clock monitor generates an interrupt when an error is detected 1b - Clock monitor generates a reset when an error is detected
16 UPLLCM	UPLL Clock Monitor Enables the clock monitor. If the clock source is disabled in a low power mode, then the clock monitor is also disabled in that mode. The clock monitor is always disabled in Power Down and Deep Power Down modes. When the clock monitor is disabled in a low power mode, it remains disabled until the clock valid flag is set following exit from that mode. 0b - UPLL Clock Monitor is disabled 1b - UPLL Clock Monitor is enabled
15-0 —	Reserved

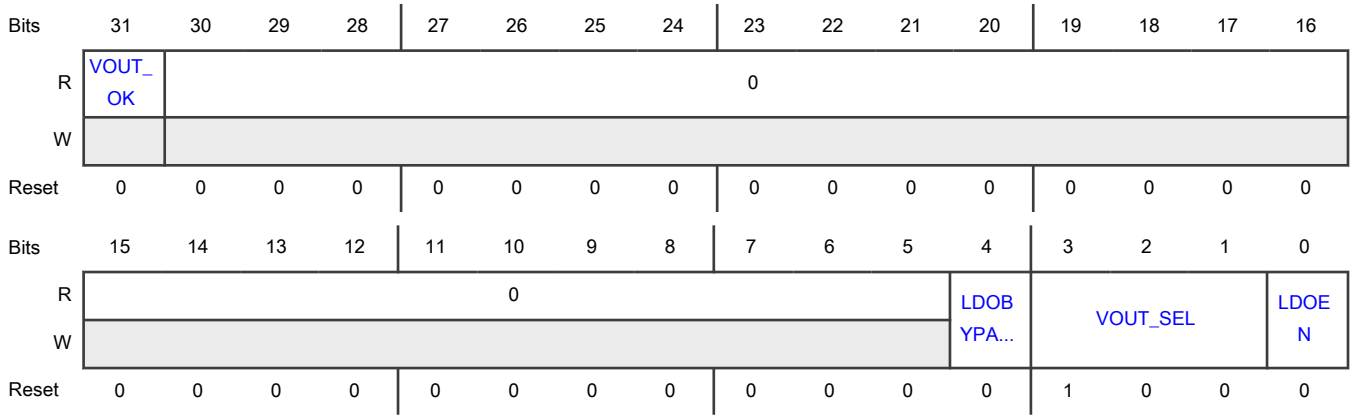
34.7.1.42 LDO Control and Status Register (LDOCSR)

Offset

Register	Offset
LDOCSR	800h

Function
Contains control bits and status bit for the LDO.

Diagram



Fields

Field	Function
31 VOUT_OK	LDO VOUT OK Inform. This flag shows the status of LDO output VOUT. 0b - LDO output VOUT is not OK 1b - LDO output VOUT is OK
30-5 —	Reserved
4 LDOBYPASS	LDO Bypass LDO is bypassed. **NOTE** Writes to this register are protected by the TRIM_LOCK register. 0b - LDO is not bypassed 1b - LDO is bypassed
3-1 VOUT_SEL	LDO output voltage select Sets the LDO output voltage level. **NOTE** Writes to this register are protected by the TRIM_LOCK register. 000b - VOUT = 1V 001b - VOUT = 1V 010b - VOUT = 1V 011b - VOUT = 1.05V 100b - VOUT = 1.1V 101b - VOUT = 1.15V 110b - VOUT = 1.2V 111b - VOUT = 1.25V
0 LDOEN	LDO Enable LDO is enabled. **NOTE** Disable LDO before entering the Power Down mode. 0b - LDO is disabled 1b - LDO is enabled

Chapter 35
Power Management

35.1 Introduction

This chapter describes the power modes that this chip supports. It also describes the power domains and voltage supply options connected to these power domains. For details about changing power modes and configuring those modes, see the CMC chapter.

35.2 Power domains

A power domain is a collection of circuits that can be powered off even when a voltage source is still supplied. This section shows the power domains within the chip and the placement of the modules within these domains.

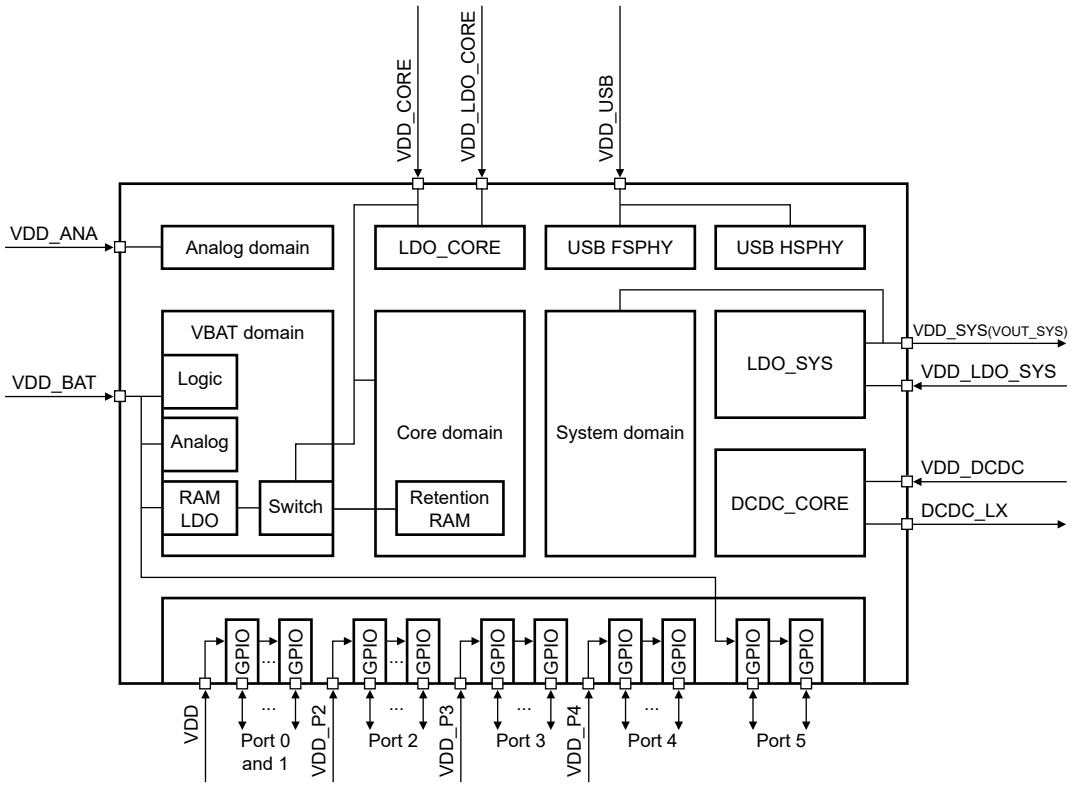


Figure 169. Power domains and voltage supplies

35.3 Power modes

The chip supports these modes:

- Active
- Sleep
- Deep Sleep
- Power Down
- Deep Power Down
- VBAT

Any reset returns the chip to Active mode.

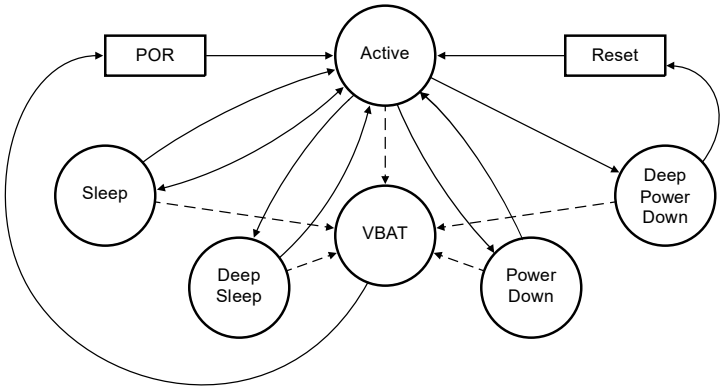

Figure 170. Power modes

35.3.1 Active mode

In Active mode, CPU execution is possible. There are three Active modes, OD (Over Drive), SD (Standard Drive), and MD (Mid Drive). In OD mode, VDD_CORE is 1.2 V; in SD mode, VDD_CORE is 1.1 V; and in MD mode, VDD_CORE is 1.0 V.

To achieve the performance requirements of a given system application while minimizing power consumption, Active mode permits the following power-saving options when possible:

- Configure the voltage level of the CORE subdomains to balance power and performance.
- Gate the clocks to unused modules.

35.3.2 Sleep mode

In Sleep mode, the CPU0 clock is off, and the system clock and bus clock remain on. Most modules can remain operational. To achieve the performance requirements of a given system application while minimizing power consumption, Sleep mode permits the following power-saving options when possible:

- Configure the voltage level of the CORE subdomains to balance power and performance.
- Individually configure SRAM arrays as Active or Deep Sleep via software.
- Gate the clocks to unused modules.

35.3.3 Deep Sleep mode

In Deep Sleep mode, CPU execution is halted. The core clock is gated off.

Deep Sleep mode supports the following behaviors based on different clock configurations:

- CPU clock, system clock, and bus clock are all off.
- Some modules can remain operational with low-power asynchronous clock sources and can serve as wake-up sources.
- System RAM is configured to State Retention mode.
- SRAM is in Deep Sleep mode.

An interrupt or wake-up event triggers waking from Deep Sleep mode.

Deep Sleep mode also supports a partial wake-up, where a wake-up event recovers a bus controller other than the CPU (for example, DMA). The chip automatically reenters Deep Sleep mode after this module finishes its task.

To achieve the performance requirements of a given system application while minimizing power consumption, Deep Sleep mode permits the following power-saving options when possible:

- Configure the voltage level of the CORE subdomains to balance power and performance.
- Gate the clocks to unused modules.

35.3.4 Power Down mode

Power Down mode places most of the chip into a static state. It is the lowest power mode that can retain all registers.

The chip wakes from Power Down mode through the interrupt routine or a wake-up event.

The core clock, system clock, and the bus clock are gated off.

In Power Down mode, the CORE_MAIN and CORE_WAKE subdomains are put into state retention mode.

External signals can wake the chip, via GPIO or VDD_SYS domain peripherals.

To balance different module clock frequencies and power leakage, the voltage level of CORE subdomains can be independently selected from the VDD_CORE voltage or the reduced voltage scaling (IVS) voltage.

Flash memory is powered off. Your software can individually configure SRAM arrays into deep sleep or shutdown.

35.3.5 Deep Power Down mode

The chip wakes from Deep Power Down mode through the Reset routine.

In Deep Power Down mode, the whole CORE domain, including all subdomains, is power-gated.

In Deep Power Down mode, the on-chip regulator for VDD_CORE is powered off. The VDD_SYS on-chip regulator is powered, but modules unrelated to the operation of RTC are clock-gated. To avoid extra leakage, the external power supply to any disabled on-chip regulator must be turned off.

External reset or VDD_SYS domain peripherals can wake the chip.

SRAMA can be retained in Deep Power Down mode.

35.3.6 VBAT mode

VBAT mode permits the lowest power level.

The POR sequence wakes the chip from VBAT mode.

Powering off VDD_SYS and VDD_CORE externally puts the chip into VBAT mode. For example, an external power switch can power off VDD_SYS and the regulator supplying VDD_CORE.

SRAMA can be retained in VBAT mode.

35.4 Module operation in low-power modes

The following tables show the functionality of each module in low-power modes.

Table 334. Overall operation in low-power modes

Module	Active	Sleep	Deep Sleep	Power Down	Deep Power Down	VBAT
CPU	On[1]	Static[2]	Static	Static	Off[3]	Off
CORE_MAIN domain	On	On	LP[4]	Static	Off	Off
CORE_WAKE domain	On	On	LP	LP/Static	Off	Off
System SRAM	On/Static[5]	On/Static	Static	Static/Off[6]	Off	Off
VBAT SRAM RAMA	On/Static	On/Static	Static	Static/Off	Static/Off	Static/Off
Flash	On/LP	On/LP	LP	Off	Off	Off

Table continues on the next page...

Table 334. Overall operation in low-power modes (continued)

Module	Active	Sleep	Deep Sleep	Power Down	Deep Power Down	VBAT
DCDC and LDO_CORE	On/Off	On/Off/LP	On/Off/LP	On/Off/LP	Off	Off
LDO and VDD_SYS	On	On/LP	On/LP	On/LP	On/LP	Off
Wake-up flow	N/A	Interrupt	Interrupt	Interrupt	Reset	Reset
Partial wake-up, no CPU	N/A	N/A	Supported (all sources)	Supported (optional wake domain or VDD_SYS and VBAT sources)	No	No
IVS	Off	Off	On/Off (SRAM only)	On/Off	Off	Off
CKMODE	N/A	0h/1h	Fh	Fh	Fh	N/A
LPMODE	N/A	0h	1h	3h	Fh	N/A

1. On means the module is functional and accessible via memory map. For analog module, it also means the module is enabled.
2. Static means the module is not active in state retention status.
3. Off means the module can be powered off. For analog module, it also means the module can be disabled.
4. LP means the module is in low power state (clock gated, asynchronous operation, etc). For digital module, it can be active with async functional clock.
5. CMC_SRAMDIS register controls configuration of SRAM arrays in Active and Sleep modes.
6. CMC_SRAMRET register controls configuration of SRAM arrays in Power Down mode.

NOTE

You cannot disable the regulator that powers the chip in Power Down mode and in higher-power modes.

35.5 Power supply configurations

35.5.1 Power-efficient supply configuration

Figure 171 shows a power-efficient configuration of the chip power supplies. This configuration uses the on-chip DCDC_CORE switching regulator to power the VDD_CORE supply rail efficiently. For the device package which has VDD_LDO_CORE pin, you should short this VDD_LDO_CORE pin to VDD_CORE pin, and in software you shoud disable LDO_CORE.

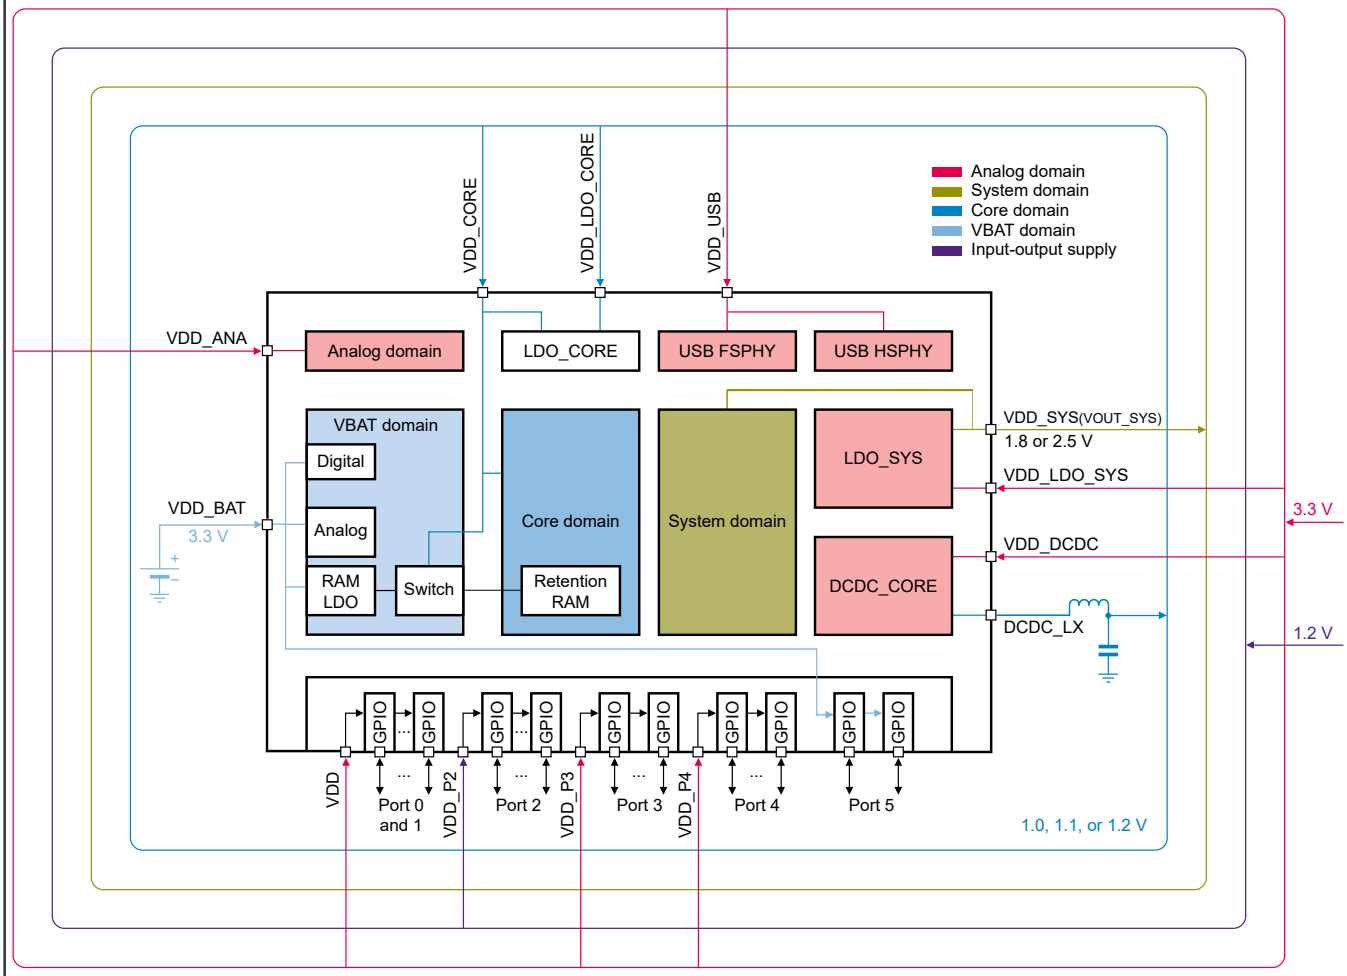

Figure 171. Power-efficient schematic

35.5.2 Low-cost supply configuration

Figure 172 shows a low-cost configuration of the chip power supplies. This configuration uses the on-chip LDO_CORE regulator to save cost and eliminate the passive components for the DCDC_CORE regulator.

For packages where VDD_DCDC has an independent pin, you can connect VDD_DCDC and DCDC_LX to GND with a 10-kΩ resistor to disable DCDC. Your software must disable DCDC.

For packages where VDD_DCDC and VDD_LDO_SYS share a package pin, to disable DCDC, DCDC_LX must be floating, and your software must disable DCDC.

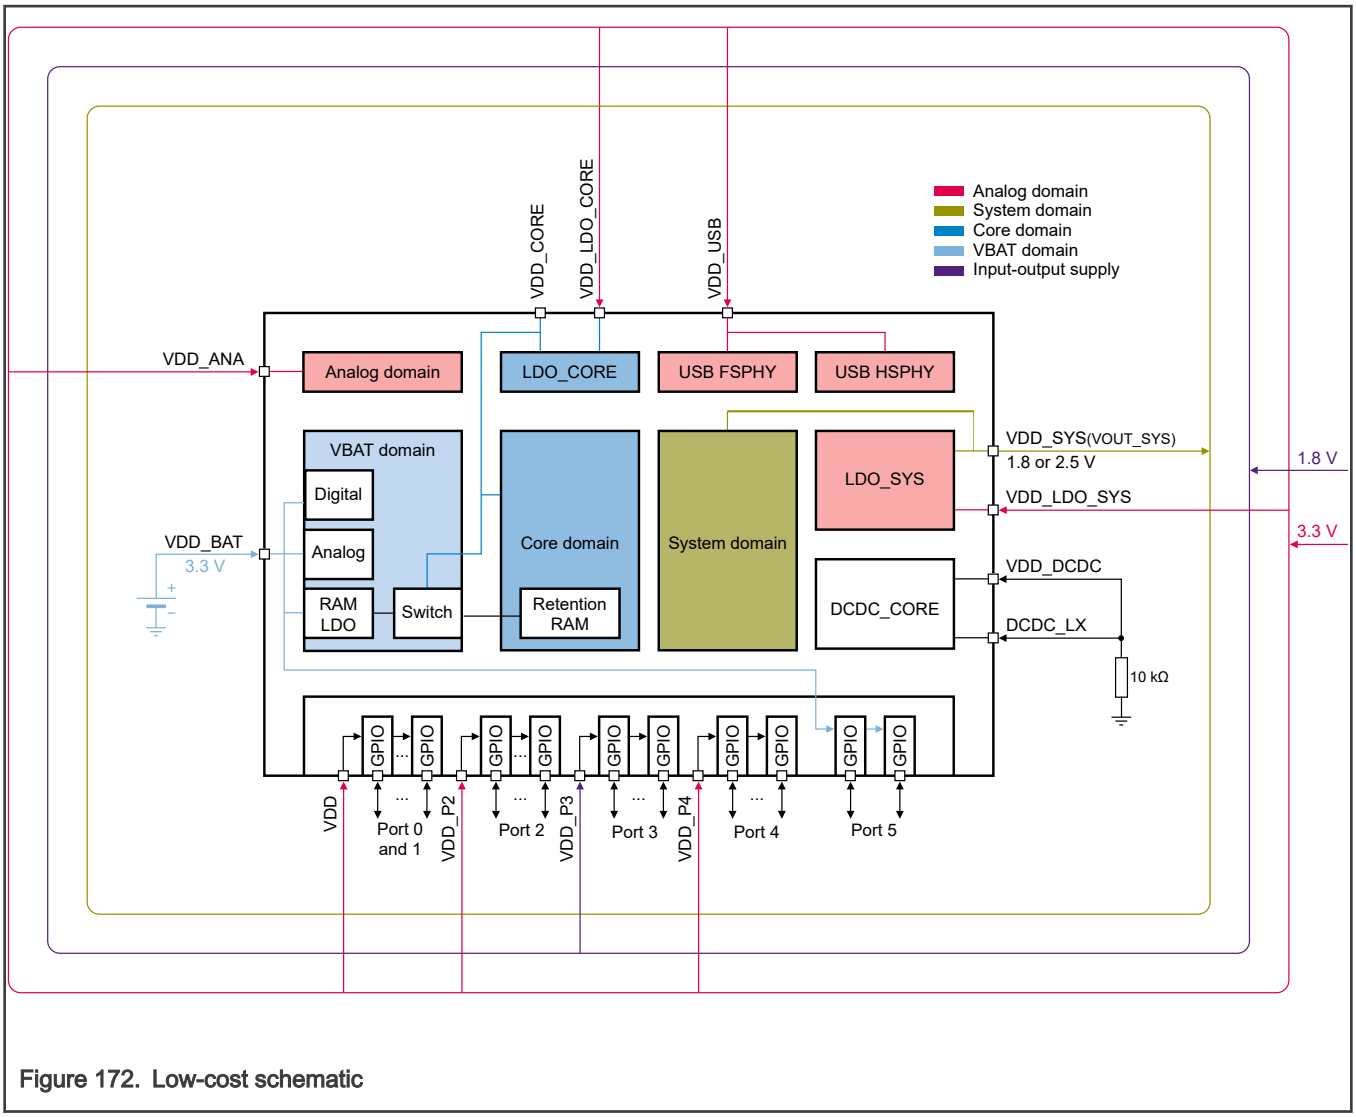

Figure 172. Low-cost schematic

NOTE

See the Hardware Design Guide (UG10092) for more details.

35.6 Power optimization

35.6.1 VDD_CORE voltage scaling

This chip supports VDD_CORE voltage scaling for different performance and power consumption configurations.

This chip supports the following VDD_CORE voltage scaling methods:

- Adjusting VDD_CORE power supply input level directly with Internal Voltage Scaling (IVS) disabled. This method is available for all power modes. To use this method, configure the VDD_CORE voltage level via SPC registers. The high efficiency of the regulators can benefit chip power consumption when DCDC is used as VDD_CORE source. However, the VDD_CORE voltage requires time to reach new levels for charging or discharging the VDD_CORE pin capacitor.
- Using the IVS module. This method applies only to Power Down mode. The VDD_CORE input voltage remains unchanged. The IVS module manipulates the internal supply voltage directly. The voltage reaches the new target value much faster.

Each CORE subdomain can independently enable or disable its own IVS in low-power modes. For example, the CORE_MAIN subdomain can enable its IVS for a lower supply voltage. At the same time, the CORE_WAKE subdomain can continue operating with the higher supply level from VDD_CORE.

35.6.2 SRAM configuration

The SRAM is partitioned, allowing independent configuration of the mode of each SRAM partition.

SRAM power mode	Description
Active	You can access SRAM normally.
Deep Sleep	You cannot access SRAM, but it retains its data.
Shutdown	You cannot access SRAM and it does not retain its data.

Depending on your application requirements, your software can configure an individual SRAM partition into a lower-power mode relative to the overall chip power mode.

When the overall chip power mode is...	You can configure an SRAM partition to operate in this mode...
Active or Sleep	Active
Deep Sleep	Deep Sleep
Power Down	Deep Sleep or Shutdown

NOTE

All SRAM partitions are forced into Shutdown mode after the chip enters Deep Power Down mode, except RAMA. The VBAT domain can power the RAMA partition.

35.6.3 Low-power options for flash memory

The internal flash memory can enter low-power mode when the overall chip is in these modes:

- Active mode under software control (FLASHCR[FLASHDIS])
- Sleep mode, optionally (FLASHCR[FLASHDOZE])
- Deep Sleep mode

NOTE

To avoid unexpected access latencies, take care when configuring the flash module to a low-power mode when the overall chip is in Active mode. The flash module needs time to recover full-speed functionality after entering a low-power mode.

35.6.4 Peripheral clock gating

To conserve power, you can configure the SYSCON module registers to turn off or divide the clocks to modules.

35.6.5 Voltage monitor optimization

Depending on your application requirements, your software can disable individual voltage monitors (LVD, HVD, or both) within the different power domains to save power.

35.6.6 Wake-up time consideration

This chip supports different low-power modes for power consumption level and wake-up time balance.

The wake-up time from Deep Sleep or Power Down mode is the accumulation of:

- VDD_CORE power source recovery time.
- Clock recovery time or flash memory recovery time, whichever is longer.
- Interrupt latency.

The wake-up time from Deep Power Down mode is the boot-up time required after POR releases the chip. This time includes everything in a cold power up, including the boot ROM latency.

These factors can affect the clock recovery time:

- The system clock source status in low-power modes. If the clock remains on in a low-power mode, no recovery time is required.
- The system clock source before entering low-power mode.

The flash memory recovery time depends on the flash memory status in low-power modes.

These factors can affect the VDD_CORE power source recovery time:

- The regulator type used. An on-chip linear regulator starts up faster than an on-chip DCDC.
- The regulator status in low-power modes. If the regulator remains in full-power regulation in low-power modes, no recovery time is required.
- Whether VDD_CORE voltage scaling is enabled before and after entering low-power modes.
- The VDD_CORE voltage scaling method used. Voltage scaling via internal IVS recovers faster.
- If scaling is achieved by adjusting the VDD_CORE voltage directly, the external capacitor on the VDD_CORE pin affects recovery time.

Chapter 36
VBAT

36.1 Chip-specific VBAT information

Table 337. Reference links to related information

Topic	Related module	Reference
Full description	VBAT	VBAT
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

36.1.1 Module instances

This device contains one instance of the VBAT module, VBAT0.

NOTE

VBAT includes some security functionality that is not described here. Refer to the MCX N Security RM for more details.

36.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

36.1.3 WAKEUP_b signal pinout

VBAT_WAKEUP_b is the default signal for P5_2 after a chip reset.

36.1.4 Connections for OSCCLKE[CLKEn] and FROCLKE[CLKEn]

Table 338. Connections for OSCCLKE[CLKEn] and FROCLKE[CLKEn]

VBAT clock enable	Connects to this power domain
CLKE3	CORE_MAIN
CLKE2	CORE_WAKE
CLKE1	VDD_SYS
CLKE0	VDD_BAT

36.1.5 Clearing the CLOCK_DET flag when the CLKMON is disabled

When the CLKMON is disabled, the following register write sequence is needed to clear the STATUSA[CLOCK_DET] register bit:

1. First write 0x5 to the MONTSTA register,
2. Then write 0x0 to MONTSTA.

36.1.6 VBAT power supply

VBAT is supplied from the chip power supply VDD_BAT.

36.1.7 Connections for VBAT interrupt detect signals [IRQn_DET]

Table 339. Connections for [IRQn_DET]

VBAT interrupt detect	Connects to
IRQ3_DET	TDET interrupt
IRQ2_DET	RTC interrupt
IRQ1_DET	GPIO5 interrupt 1
IRQ0_DET	GPIO5 interrupt 0

36.1.8 VBAT LDORAMC[RET] configuration

LDORAMC.RET[3:0] controls retention of RAMA3-RAMA0 in low-power mode in this chip. Each of the four RAMA arrays are 8 KB in size. For example:

- LDORAMC[RET]=0x0 retains all 32 KB of RAMA
- LDORAMC[RET]=0xE retains 8 KB of RAMA0
- LDORAMC[RET]=0xF does not retain any arrays of RAMA

36.2 Overview

VBAT works with the power management system to implement power-saving mechanisms. It provides bandgap timers and a voltage regulator to supply retention SRAM in low-power modes.

VBAT implements the 16 kHz internal clock source.

36.2.1 Block diagram

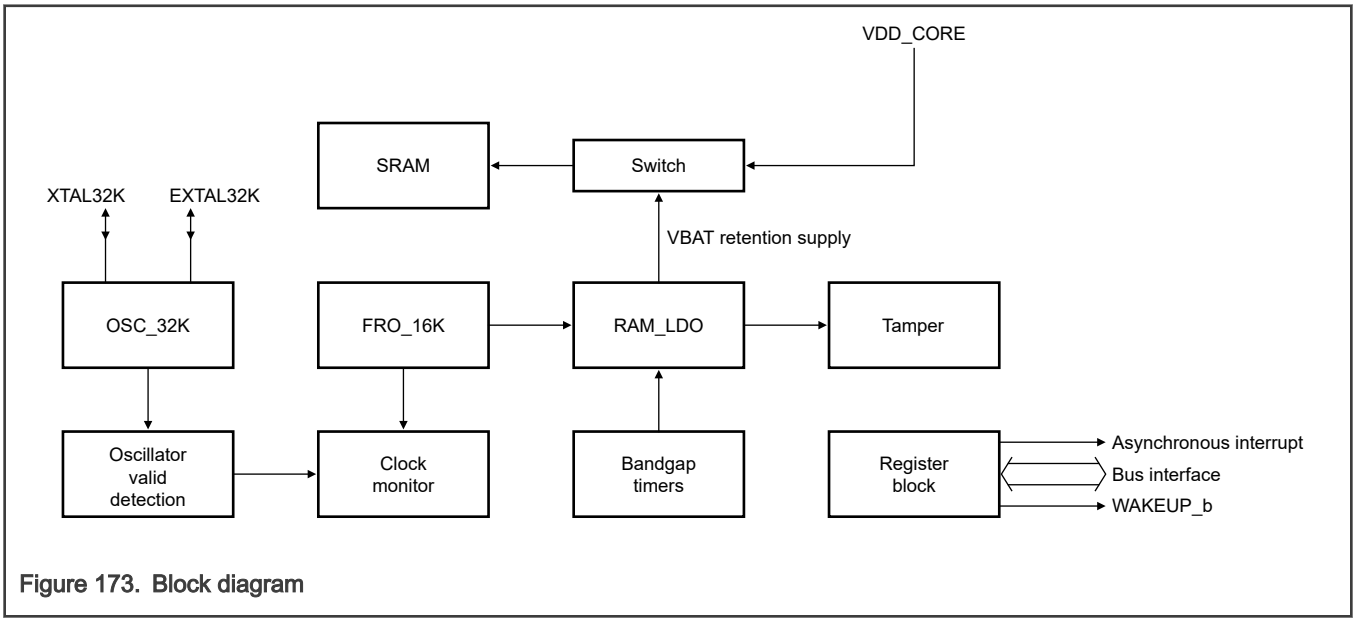

Figure 173. Block diagram

36.2.2 Features

- Includes oscillator for 32.768 kHz crystal (OSC32k)
- Supports internal 16 kHz free-running oscillator (FRO16K)
- Supports backup retention SRAM regulator
- Includes clock monitor (high/low/loss) for the OSC32k clock source
- Supports voltage monitor (high/low) for the VBAT supply
- Monitors temperature (high/low)

36.3 Functional description

The following sections describe the functional details of VBAT.

36.3.1 Operations

This section describes the operations of VBAT.

36.3.1.1 Register protection

The VBAT registers are implemented as separate A and B registers. When configuring an A register, you must write the inverse value to the corresponding B register. The entire B register can be written as the inverse of the A register (for example, LDOCTLB = ~LDOCTLA). The reserved bits in the B register are not writable, and read as 0's. For example, if LDOCTLA = 0x5, LDOCTLB can be written as ~LDOCTLA, and then LDOCTLB will read back as 0x2.

After configuring the A and B registers for a module, it is possible to lock the configuration until the next VBAT POR by configuring the corresponding Lock registers. After the configuration is locked, if any protected A register does not match the inverse of the corresponding B register, then STATUSA[CONFIG_DET] becomes 1. This can trigger an interrupt.

36.3.1.2 FRO 16.384 kHz clock

FRO16K is enabled by default on POR. You can disable it or lock it to prevent any change to the enable field.

36.3.1.3 OSC 32.768 kHz clock

OSC32K is disabled by default on VBAT POR. When enabled, it takes the oscillator start-up time before STATUSA[OSC_RDY] becomes 1, and the clock is output to other modules.

The OSC32k supports 2 modes of operation, a high performance transconductance oscillator mode and a low power switched oscillator mode. A software configurable capacitor bank is supported in normal mode and must be configured when the oscillator is first enabled.

NOTE

For the oscillator characteristics of each mode, refer to the VBAT section of the device datasheet

36.3.1.4 SRAM LDO

SRAM LDO is a retention regulator that retains VBAT retention SRAM in low-power modes, including when VBAT is the only available supply. When IRQENA[LDO_RDY] becomes 1, the chip can enter into a low-power mode where the VBAT supply retains SRAM. Enable the bandgap and LDO before entering a low-power mode where the VBAT supply powers the retention SRAM. Enable Refresh mode for the lowest power consumption.

It takes approximately 8ms for the LDO_RDY flag to set after software enables the bandgap and LDO. When using the SRAM LDO it is recommended to leave it enabled in active modes to avoid this delay before entering a low power mode.

Although SRAM is automatically retained in all low-power modes, you can manually switch SRAM to the VBAT retention supply anytime. Do not access the SRAM when it receives power from the VBAT retention supply. You must manually reverse these steps before accessing the SRAM again.

To manually switch VBAT to power the SRAM:

1. Isolate the SRAM array (write 1 to LDORAMC[ISO]).
2. Switch the supply from VDD_CORE to the VBAT retention LDO (write 1 to LDORAMC[SWI]).

LDORAMC[RETn] can configure how much SRAM is retained in low-power modes. Each bit of the field corresponds to a different SRAM array, and you can configure the number of arrays retained (when SRAM LDO is enabled, retain at least one array).

When SRAM LDO is disabled, LDORAMC[RETn] controls whether the retention of VBAT SRAM happens using VDD_CORE in low-power modes.

In general, using the SRAM LDO to retain the VBAT retention SRAM is a lower power option than using VDD_CORE directly.

NOTE

Enable FRO16K before enabling SRAM LDO or the bandgap.

36.3.1.5 Bandgap timer

Two software-configurable bandgap timers are available when the SRAM LDO bandgap is enabled. These timers share logic with the bandgap timer refresh logic to minimize power, so they use the FRO16K clock source and are only available when the bandgap is enabled. When you change the configured timeout, NXP recommends that you:

1. Disable the timer.
2. Clear the flag.
3. Write the new timeout value.
4. Enable the timeout again.

36.3.1.6 Clock monitor

VBAT has two clock monitors. One uses FRO_16K as its clock source. The other uses OSC_RTC as its clock source. Each monitor checks a divided version of the other clock at the same frequency but divided by 16. The monitor expects a clock edge every 8 cycles, and you can trim the monitor to assert after 10, 12, 14, or 16 cycles with no edge.

NOTE

See the chip's security reference manual for more information on enabling clock monitor and analog tamper features.

36.3.1.7 Analog tamper

You can configure the analog tamper module to generate an interrupt or tamper event using the following detectors:

- VBAT voltage is out of range.
- Temperature is out of range.

NOTE

Enable both the FRO16K and the LDO bandgaps before configuring the analog tamper module.

36.3.2 Low-power modes

VBAT remains functional in all low-power modes.

The VBAT module supports operation in a VBAT only power mode where only the VBAT is powered and the rest of the device is powered off externally. The VBAT_WAKEUP_b output can be used to control an external power switch or to communicate with an

external PMIC.The VBAT_WAKEUP_b output drives low to indicate power supplies to the rest of the device should be powered. This occurs when either WAKECFG[OUT] is low or a status flag as enabled by WAKENA/WAKENB has asserted.When software writes WAKECFG[OUT]=1 and there are no configured status flags asserted, the VBAT_WAKEUP_B output drives high indicating that the rest of the device can be powered off.When a configured status flag asserts when only VBAT is powered, this will cause the VBAT_WAKEUP_b to drive low again and to power up the rest of the device. When WAKEUP_b pin is configured for open drain operation, an external wakeup source can drive this pin low, and the falling edge will assert the WAKEUP_FLAG.

36.3.3 Debug mode

Debug modes do not affect VBAT.

36.3.4 Clocks

VBAT implements the following clock domains:

- Bus interface clock - access the registers
- FRO16 kHz internal clock
- Crystal oscillator 32.768 kHz clock

36.3.5 Reset

Only the POR resets VBAT.

36.3.6 Interrupts

VBAT generates one interrupt combining the following sources:

- VBAT POR
- Wake-up pin assertion
- Bandgap timer 0
- Bandgap timer 1
- Crystal oscillator ready
- Clock monitor frequency error
- VBAT configuration error
- Voltage monitor detect
- Temperature monitor detect

36.4 External signals

Table 340. External signals

Signal	Description	Direction
EXTAL32K	Oscillator input for 32.768 kHz crystal.	Input
XTAL32K	Oscillator output for 32.768 kHz crystal.	Output
WAKEUP_b	Active low wake-up pin, falling edge sets the WAKEUP_FLAG. When WAKEUP_b pin is configured for open drain operation, an external wakeup source can drive this pin low, and the falling edge will assert the WAKEUP_FLAG	Input/Output

36.5 Initialization

To enable and lock the FRO16K:

1. Write 1h to FROCTLA[FRO_EN].
2. Write 0h to FROCTLB[INVERSE].
3. Write 1h to FROLCKA[LOCK].
4. Write 0h FROLCKB[LOCK].
5. Alter FROCLKE[CLKE] to clock gate different FRO16K outputs to different peripherals to reduce power consumption.

To enable and lock the LDO and bandgap:

1. Enable the FRO16K.
2. Write 7h to LDO_RAM Control A (LDOCTLA).
3. Write 0h to LDOCTLB[INVERSE].
4. Wait for STATUSA[LDO_RDY] to become 1.
5. Write 1h to LDOLCKA[LOCK].
6. Write 0h to LDOLCKB[LOCK].

To configure and lock OSC32kHz for normal mode operation:

1. Configure OSCCTLA[EXTAL_CAP_SEL], OSCCTLA[XTAL_CAP_SEL] and OSCCTLA[COARSE_AMP_GAIN] as required based on the external crystal component ESR and CL values, and by the PCB parasitics on the EXTAL32K and XTAL32K pins. Configure 0h to OSCCTLA[MODE_EN], 1h to OSCCTLA[CAP_SEL_EN], and 1h to OSCCTLA[OSC_EN].
2. Write inverse of OSCCTLA to OSCCTLB[INVERSE].
3. Wait for STATUSA[OSC_RDY] to become 1.
4. Write 1h to OSCLCKA[LOCK].
5. Write 0h to OSCLCKB[LOCK].

To configure OSC32kHz for low power mode operation:

1. Write 3h to OSCCFGA[INIT_TRIM].
2. Write inverse of OSCCFGA to OSCCTLB[INVERSE].
3. Configure OSCCTLA[EXTAL_CAP_SEL], OSCCTLA[XTAL_CAP_SEL] and OSCCTLA[COARSE_AMP_GAIN] as required based on the external crystal component ESR and CL values, and by the PCB parasitics on the EXTAL32K and XTAL32K pins. Configure 1h to OSCCTLA[MODE_EN], 1h to OSCCTLA[CAP_SEL_EN], and 1h to OSCCTLA[OSC_EN].
4. Write inverse of OSCCTLA to OSCCTLB[INVERSE].
5. Wait for STATUSA[OSC_RDY] to become 1.
6. Write 0h to OSCCFGA[INIT_TRIM].
7. Write inverse of OSCCFGA to OSCCFGB[INVERSE].
8. Configure 3h to OSCCTLA[MODE_EN], 0h to OSCCTLA[EXTAL_CAP_SEL] and 0h to OSCCTLA[XTAL_CAP_SEL]. Configure OSCCTLA[SUPPLY_DET] as required by application.
9. Write inverse of OSCCTLA to OSCCTLB[INVERSE].
10. Wait for STATUSA[OSC_RDY] to become 1.

36.6 Application information

Configure the VBAT LDO to retain the state of any required SRAM to guard against an unexpected loss of power to the system:

1. Enable the LDO and bandgap.
2. Configure LDORAMC[RETn] to retain the appropriate arrays.

For a software-controlled power down, follow these steps to ensure robust retention of memory before switching off external power:

1. Write 1b to LDORAMC[ISO].
2. Write 1b to LDORAMC[SWI].

You must reverse the above steps to access the SRAM arrays, which the VBAT LDO retains. That is, follow these steps after external power is again switched on:

1. Write 0b to LDORAMC[SWI].
2. Write 0b to LDORAMC[ISO].

36.7 Memory map and register definition

This section includes VBAT memory map and detailed descriptions of all registers.

NOTE

The VBAT registers are reset on VBAT Cold Reset only (VBAT POR).

4 LDO_RDY	LDO Ready Enables the corresponding wake-up in Status A (STATUSA). 0b - Disable 1b - Enable
3 TIMER1_FLAG	Bandgap Timer 2 Enables the corresponding wake-up in Status A (STATUSA). 0b - Disable 1b - Enable
2 TIMER0_FLAG	Bandgap Timer 0 Enables the corresponding wake-up in Status A (STATUSA). 0b - Disable 1b - Enable
1 WAKEUP_FLAG	Wake-up Pin Flag Enables the corresponding wake-up in Status A (STATUSA). 0b - Disable 1b - Enable
0 POR_DET	POR Detect Enables the corresponding wake-up in Status A (STATUSA). 0b - Disable 1b - Enable

36.7.1.8 Wake-up Enable B (WAKENB)

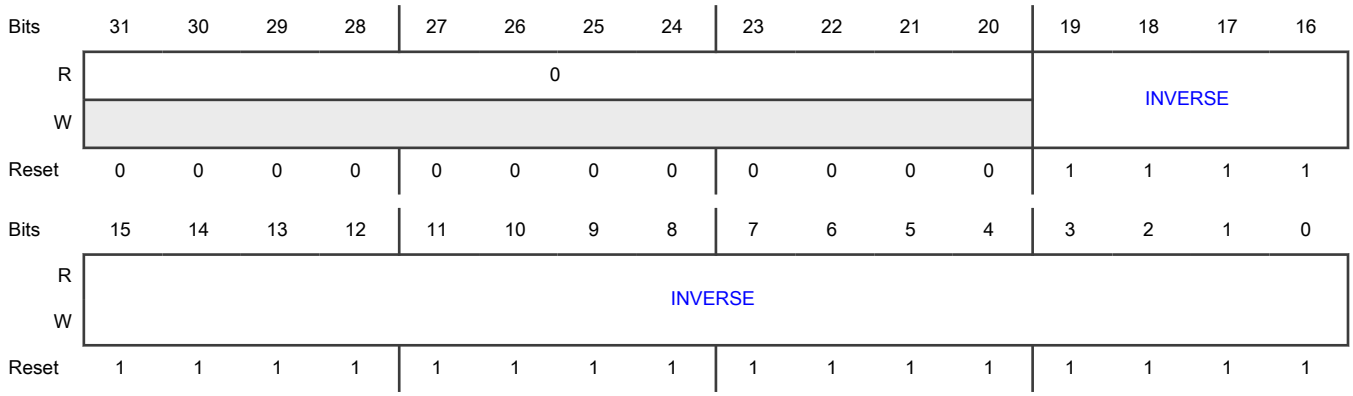
Offset

Register	Offset
WAKENB	24h

Function

Contains the inverted wake-up enables for VBAT. When configuring the wake enables, both enable A and enable B registers need to be programmed to the appropriate values.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-0 INVERSE	Inverse Value Contains the inverted contents of Wake-up Enable A (WAKENA).

36.7.1.9 Wake-up Configuration (WAKECFG)

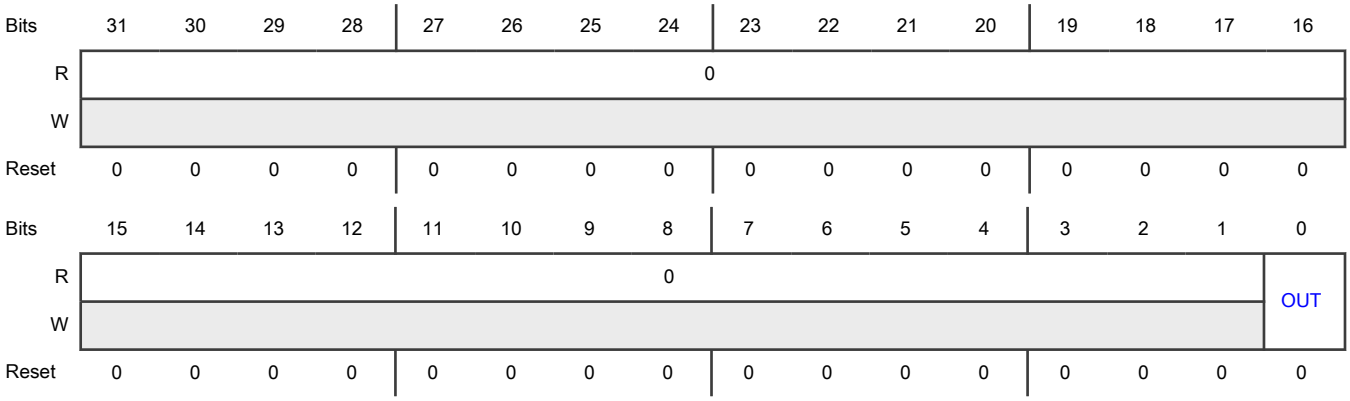
Offset

Register	Offset
WAKECFG	38h

Function

Configures the default state of the WAKEUP_b signal when no enabled wake-up source is asserted.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 OUT	Output Specifies the output state of WAKEUP_b signal. When the value of this field is 1, WAKEUP_b output state is logic one, unless an enabled wakeup source asserts. 0b - Logic zero (asserted) 1b - Logic one

36.7.1.10 Oscillator Control A (OSCCTLA)

Offset

Register	Offset
OSCCTLA	100h

Function

Contains the oscillator control fields. When configuring the oscillator, both control A and control B registers need to be programmed to the appropriate values. Writes to this register are blocked when OSCLCKA[LOCK] is 1.

Some fields in this register uses the following equation to calculate the load capacitance:

$$C_L = \frac{C_{extal} \times C_{xtal}}{C_{extal} + C_{xtal}} + C_{shunt}$$

Equation 16. Equation for load capacitance

where:

- C_{extal} is the selected capacitance on the EXTAL pin.
- C_{xtal} is the selected capacitance on the XTAL pin.
- C_{shunt} is the internal shunt capacitance. You can determine this capacitance value from the chip's data sheet.

11-8 EXTAL_CAP_SEL	Crystal Load Capacitance Selection Selects the internal capacitance for the EXTAL pin from the capacitor bank. Calculate the final load capacitance as shown in Equation 16. The configuration EXTAL_CAP_SEL=0000 and CAP_SEL_EN=1 is required in low power mode and is not supported in other modes 0000b - 0 pF 0001b - 2 pF 0010b - 4 pF 0011b - 6 pF 0100b - 8 pF 0101b - 10 pF 0110b - 12 pF 0111b - 14 pF 1000b - 16 pF 1001b - 18 pF 1010b - 20 pF 1011b - 22 pF 1100b - 24 pF 1101b - 26 pF 1110b - 28 pF 1111b - 30 pF

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 CAP_SEL_EN	Crystal Load Capacitance Selection Enable Enables the internal capacitor banks on the EXTAL and XTAL pins that vary the load capacitance on these pins. You must write 1 to this field and OSCCTLA[OSC_EN] simultaneously. **NOTE** The configuration EXTAL_CAP_SEL=0000 and CAP_SEL_EN=1 is required in low power mode and is not supported in other modes 0b - Disable 1b - Enable
6 —	Reserved
5-4 —	Reserved
3-2 COARSE_AMP_GAIN	Amplifier gain adjustment bits to allow the use of a wide range of external crystal ESR values See the device datasheet for the ranges supported by this device Tunes the internal transconductance (g_m) by increasing the current. 00b - ESR Range 0 01b - ESR Range 1 10b - ESR Range 2 11b - ESR Range 3
1 OSC_BYP_EN	Crystal Oscillator Bypass Enable Bypasses the crystal oscillator. The oscillator outputs the clock, but this clock is the same as the clock provided on EXTAL pin. You must write 1 to both OSCCTLA[OSC_EN] and this field to enable the Bypass mode of the oscillator. To exit Bypass mode, you must write 0 to both OSCCTLA[OSC_EN] and this field. Do not move the oscillator from Bypass mode directly to Normal mode. 0b - Does not bypass 1b - Bypass
0 OSC_EN	Crystal Oscillator Enable Enables the crystal oscillator. The oscillator starts giving the clock output but the clock is not available to the chip until STATUSA[OSC_RDY] is asserted. 0b - Disable 1b - Enable

36.7.1.11 Oscillator Control B (OSCCTLB)

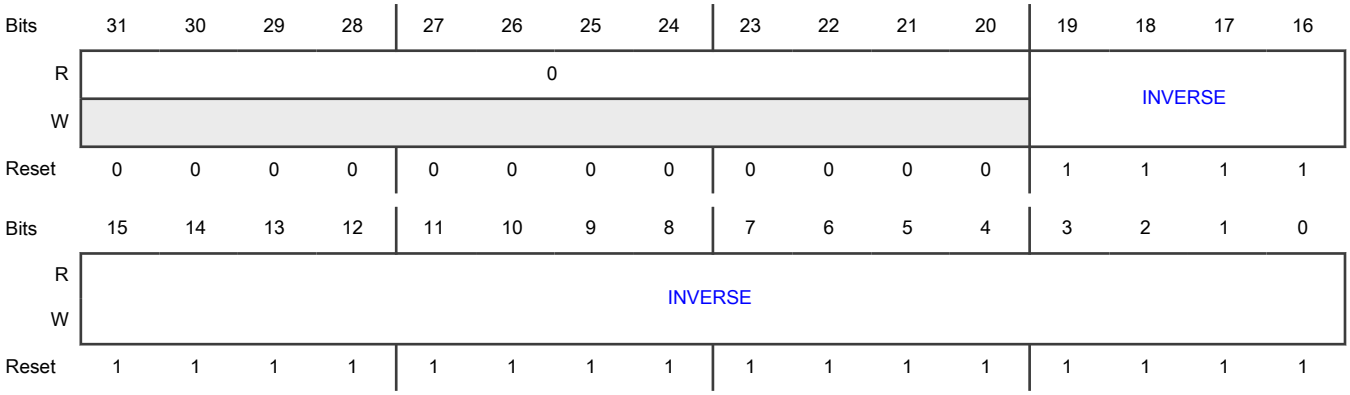
Offset

Register	Offset
OSCCTLB	104h

Function

Contains the inverted oscillator control field. Configure control A and control B registers with the appropriate values when configuring the oscillator. Writes to this register are blocked when OSCLCKB[LOCK] is 1.

Diagram



Fields

Field	Function
31-20 —	Reserved

36.7.1.18 FRO16K Control B (FROCTLB)

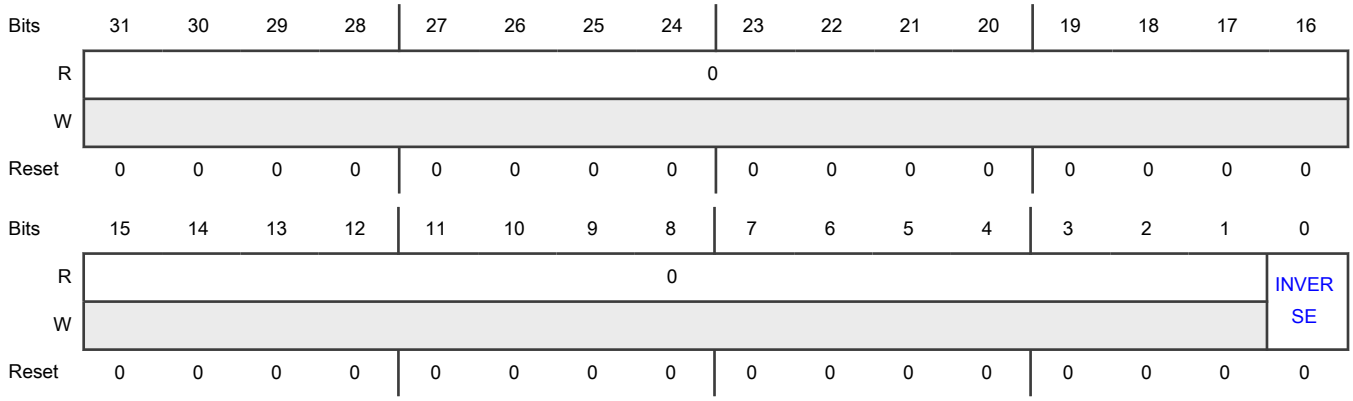
Offset

Register	Offset
FROCTLB	204h

Function

Contains the inverted FRO16K control field. Configure control A and control B registers with the appropriate values when configuring FRO16K. Writes to this register are blocked when FROLCKB[LOCK] is 1.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 INVERSE	Inverse Value Contains the inverted contents of FRO16K Control A (FROCTLA).

36.7.1.19 FRO16K Lock A (FROLCKA)

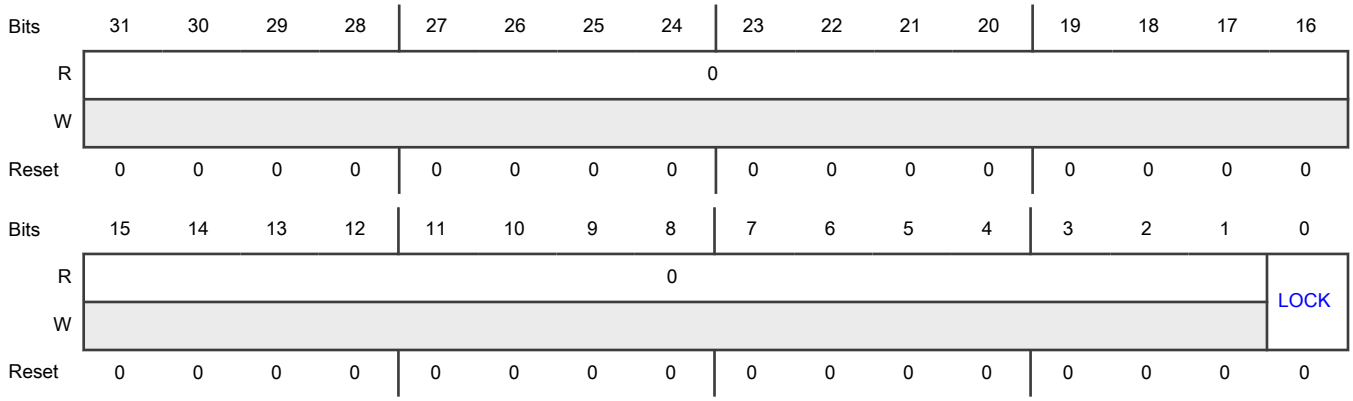
Offset

Register	Offset
FROLCKA	218h

Function

Contains the lock field. When configuring the FRO16K, both lock A and lock B registers need to be programmed to the appropriate values. Writes to this register are blocked when FROLCKA[LOCK] is 1.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 LOCK	Lock Blocks any write to the FRO16K registers when you write 1 to this field. VBAT POR writes 0 to this field. 0b - Do not block 1b - Block

36.7.1.20 FRO16K Lock B (FROLCKB)

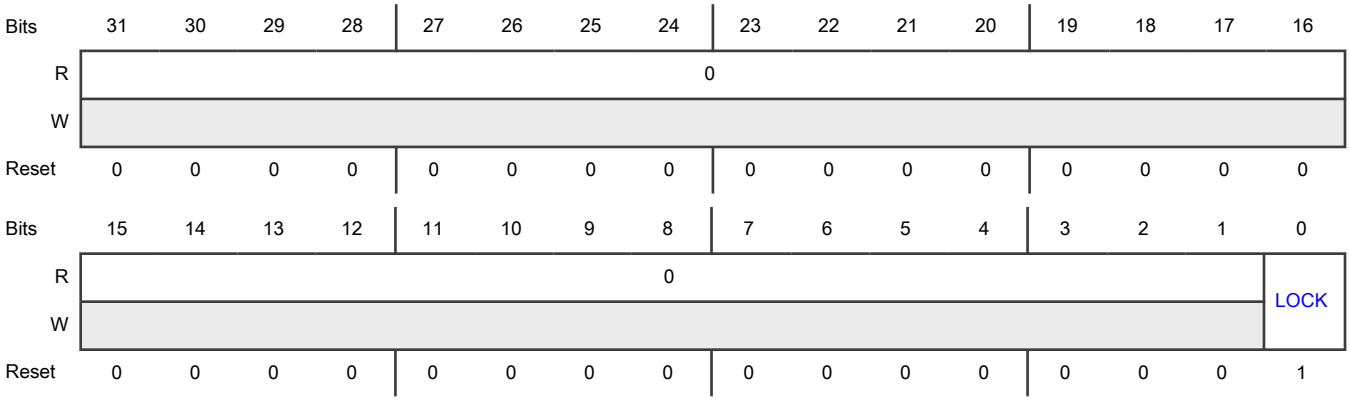
Offset

Register	Offset
FROLCKB	21Ch

Function

Contains the inverted FRO16K lock field. Configure lock A and lock B registers with the appropriate values when configuring FRO16K. Writes to this register are blocked when FROLCKB[LOCK] is 1.

Diagram



Fields

Field	Function
31-1 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 LOCK	Lock Blocks any write to the FRO16K registers and asserts a configuration error when you write 0 to this field. The lock is enabled if any of the FRO16K A registers are not equal to inverted FRO16K B registers. 0b - Block 1b - Do not block

36.7.1.21 FRO16K Clock Enable (FROCLKE)

Offset

Register	Offset
FROCLKE	220h

Function

Contains clock gating register field to gate the FRO16K clock to other modules.

NOTE

FROCLKE cannot be locked (not affected by FRO16K Lock A (FROLCKA)).

Diagram

36.7.1.23 LDO_RAM Control B (LDOCTLB)

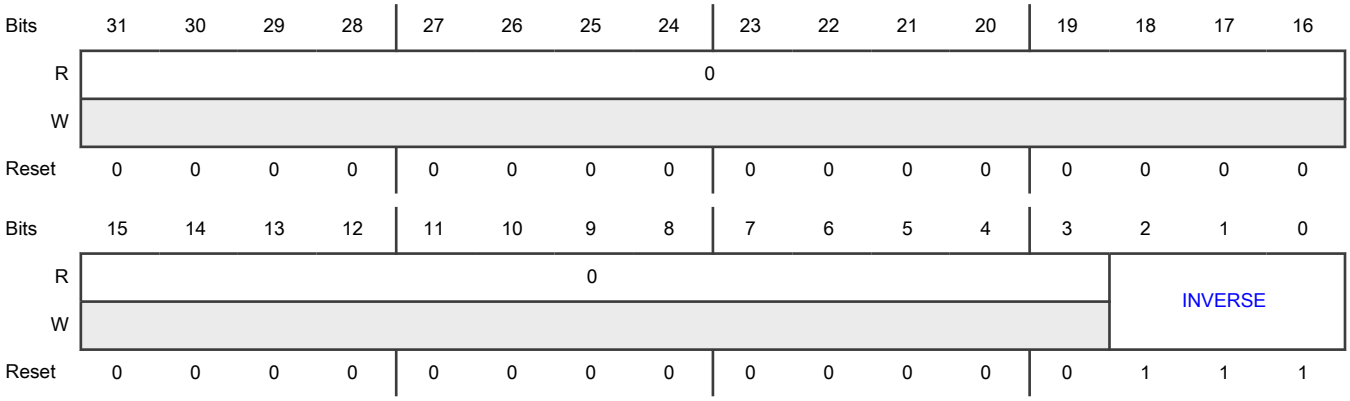
Offset

Register	Offset
LDOCTLB	304h

Function

Contains the inverted LDO_RAM control field. Configure control A and control B registers with the appropriate values when configuring the LDO_RAM. Writes to this register are blocked when LDOLCKB[LOCK] is 1.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 INVERSE	Inverse Value Contains the inverted contents of LDO_RAM Control A (LDOCTLA).

36.7.1.24 LDO_RAM Lock A (LDOLCKA)

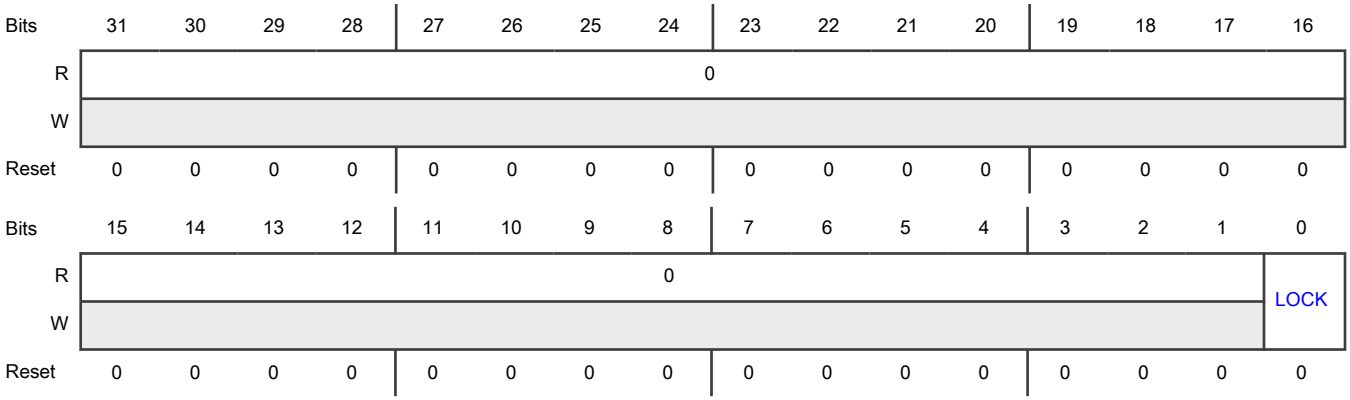
Offset

Register	Offset
LDOLCKA	318h

Function

Contains the lock field. When configuring the LDO_RAM, both lock A and lock B registers need to be programmed to the appropriate values. Writes to this register are blocked when the LDO_RAM lock register is 1.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 LOCK	Lock Blocks any write to the LDO_RAM registers. VBAT POR writes 0 to this field. 0b - Do not block 1b - Block

36.7.1.25 LDO_RAM Lock B (LDOLCKB)

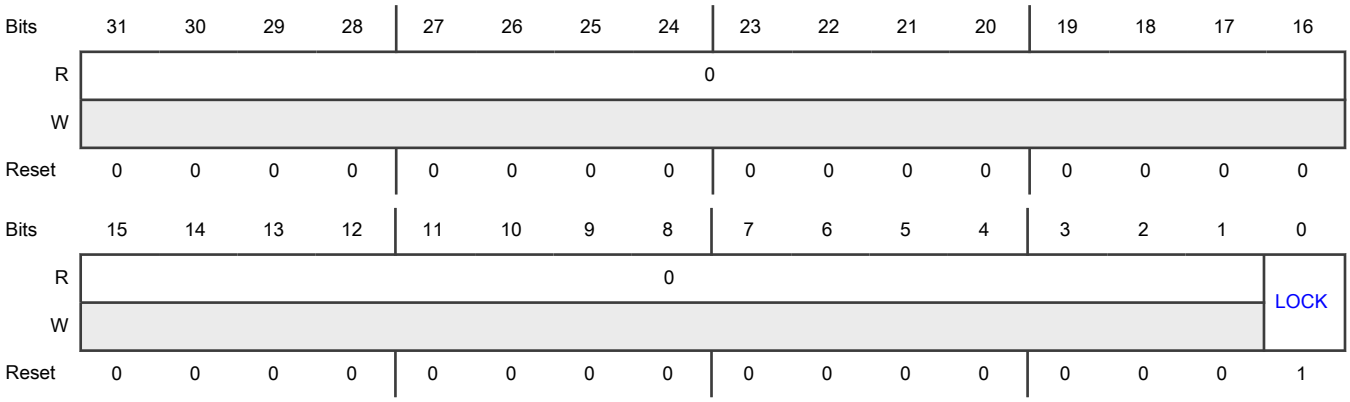
Offset

Register	Offset
LDOLCKB	31Ch

Function

Contains the inverted LDO_RAM lock field. Configure lock A and lock B registers with the appropriate values when configuring the LDO_RAM. Writes to this register are blocked when LDOLCKB[LOCK] is 1.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 LOCK	Lock Blocks any write to the LDO_RAM registers and asserts a configuration error. The lock is enabled if any of the LDO_RAM A registers are not equal to inverted LDO_RAM B registers. 0b - Block 1b - Do not block

36.7.1.26 RAM Control (LDORAMC)

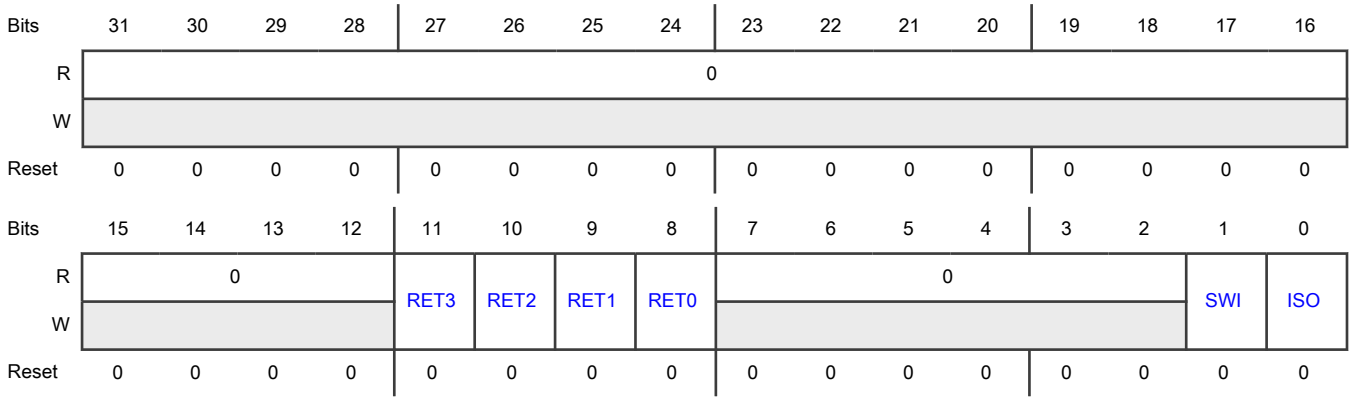
Offset

Register	Offset
LDORAMC	320h

Function

Contains software overrides for the SRAM isolation and backup switch. Always isolate the SRAM array before asserting or negating the switch control.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-8 RETn	Retention Configures retention of each SRAM array in low power modes. See the VBAT chip-specific section for more details on these SRAM arrays. When LDO_RAM is enabled, at least one SRAM array must be retained. When LDO_RAM is disabled, this field specifies whether VDD_CORE continues to provide power to the SRAM array. 0b - Corresponding SRAM array is retained in low-power modes 1b - Corresponding SRAM array is not retained in low-power modes
7-2 —	Reserved
1 SWI	Switch SRAM Specifies how the SRAM array is powered. Change this field when LDORAMC[ISO] = 1. 0b - Supply follows the chip power modes 1b - LDO_RAM powers the array
0 ISO	Isolate SRAM Specifies how the SRAM array is isolated. 0b - State follows the chip power modes 1b - Isolates SRAM and places it in Low-Power Retention mode

36.7.1.27 Bandgap Timer 0 (LDOTIMER0)

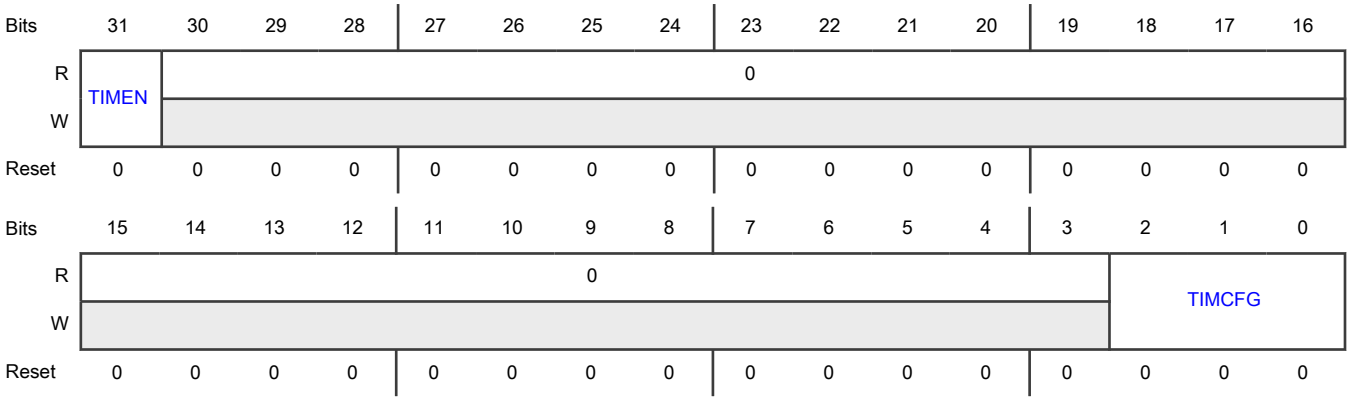
Offset

Register	Offset
LDOTIMER0	330h

Function

Controls one software-configurable timer when the bandgap is enabled and are clocked by FRO16K.

Diagram



Fields

Field	Function
31 TIMEN	Bandgap Timeout Period Enable 0b - Disable 1b - Enable
30-3 —	Reserved
2-0 TIMCFG	Timeout Configuration Configures the bandgap timeout 0 period. Changed when the timer is disabled. 000b - 1 s 001b - 500 ms 010b - 250 ms 011b - 125 ms 100b - 62.5 ms 101b - 31.25 ms 110b - 15.625 ms 111b - 7.8125 ms

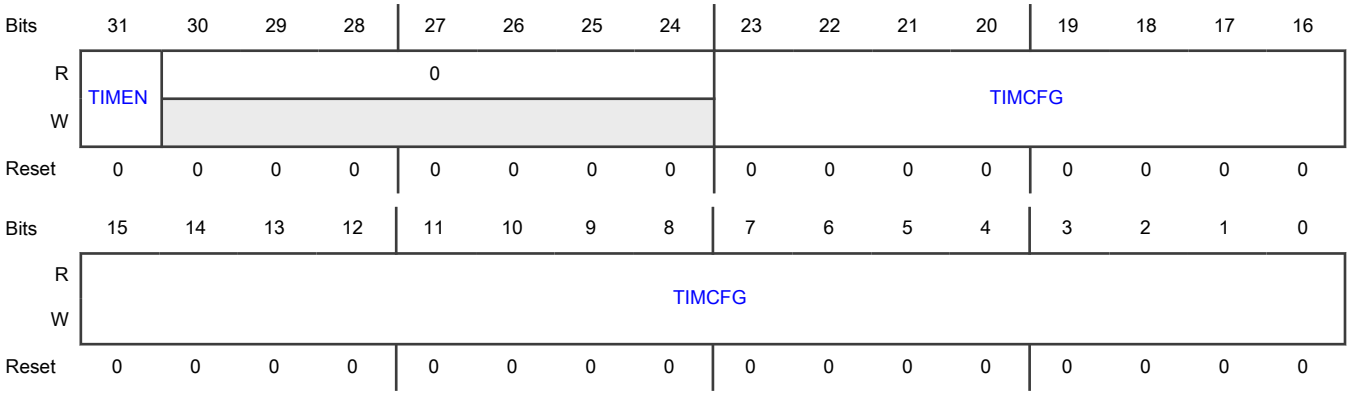
36.7.1.28 Bandgap Timer 1 (LDOTIMER1)

Offset

Register	Offset
LDOTIMER1	338h

Function
Controls the other software-configurable timer when the bandgap is enabled and are clocked by the FRO16K.

Diagram



Fields

Field	Function
31 TIMEN	Bandgap Timeout Period Enable 0b - Disable 1b - Enable
30-24 —	Reserved
23-0 TIMCFG	Timeout Configuration Configures the bandgap timeout 1 period. Configures timeout in number of seconds, ranging from 0 to 65,535 s. You can change this field when the timer is disabled.

36.7.1.29 Wakeup 0 Register A (WAKEUP0A - WAKEUP1A)

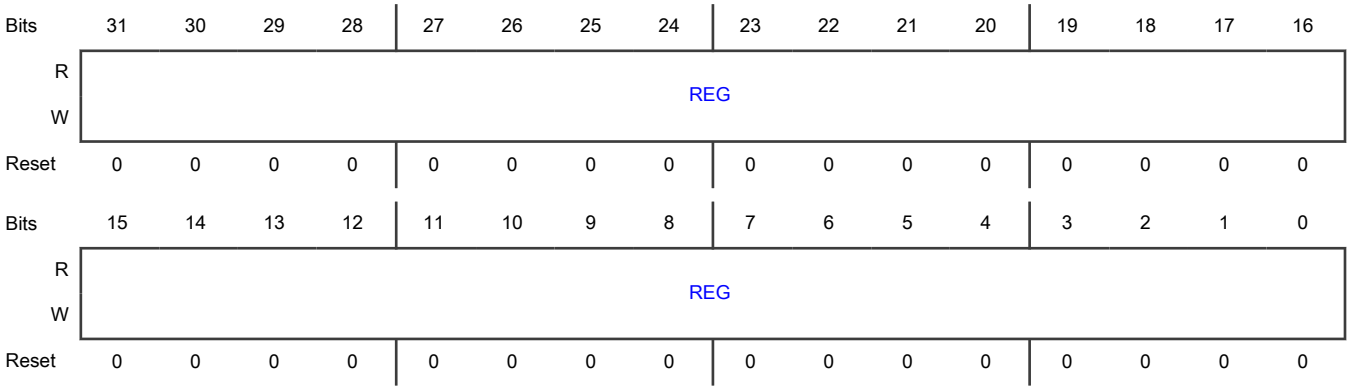
Offset

Register	Offset
WAKEUP0A	700h
WAKEUP1A	708h

Function

Contains software writable bits. Writes to this register are blocked when WAKEUP lock register is set.

Diagram



Fields

Field	Function
31-0 REG	Register Software writable value.

36.7.1.30 Wakeup 0 Register B (WAKEUP0B - WAKEUP1B)

Offset

Register	Offset
WAKEUP0B	704h
WAKEUP1B	70Ch

Function

Contains the inverted Wakeup 0 software writable bits. When configuring the wakeup registers, both wakeup A and wakeup B registers need to be programmed to the appropriate values. Writes to this register are blocked when WAKEUP lock register is set.

LOCK	When clear, blocks writes to the wakeup registers and asserts a configuration error if any of the wakeup A registers are not equal to inverted wakeup B registers. 0b - Lock is enabled 1b - Lock is disabled

Chapter 37
System Power Control (SPC)

37.1 Chip-specific SPC information

Table 341. Reference links to related information

Topic	Related module	Reference
Full description	SPC	SPC
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

NOTE

The device has analog voltage glitch detector (aGDET) and two digital voltage glitch detectors (GDET) which enhance protection against voltage manipulation. The NXP boot ROM configures aGDET and GDET during device initialization to reset the device when voltage manipulation is detected. The aGDET and GDET were validated on silicon across multiple process, voltage, and temperature corners with maximum noise profile generated by activating a large number of possible boot paths. To avoid false triggering due to unforeseen environment or application behavior, NXP recommends disabling aGDET and GDET in early start-up code. aGDET and/or GDET can be used by the application when security-critical operations are taking place, e.g., cryptographic operation using private or symmetric keys (digital signature, encryption, decryption, etc.), or sensitive decision-making process. However, characterization of the system noise profile and interactions with the sensors are required.

37.1.1 Module instances

This device has one instance of the SPC module, SPC0.

37.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

37.1.3 Voltage regulators

This section describes the various on-chip regulators.

Table 342. On-chip regulators

Regulator name	Description
DCDC_CORE	The DCDC_CORE can be used to power the VDD_CORE domain.
LDO_CORE	The LDO_CORE can be used to power VDD_CORE domain.
LDO_SYS	The LDO_SYS can be used to power VDD_SYS domain. It can power the IO ring, other on-chip modules, and external components as well. However, user should take care that the total load current doesn't exceed the maximum capacity.

37.1.4 Registers for power domains

The CMC module controls two power domains on this device. Below are details how SPC registers map to these power domains:

- PD_STATUS0 refers to power domain VDD_CORE_MAIN.
- PD_STATUS1 refers to power domain VDD_CORE_WAKE.

37.1.5 SPC_SC[ISO_CLR]

SPC_SC[ISO_CLR] controls and gives status of the power domain latching. This field maps to each power domain as follows:

- Bit 16 clears the isolation for VDD_CORE_MAIN domain modules, particularly GPIO/PORTs 1 through 4, DAC0/1 and VREF0.
- Bit 17 clears the isolation for VDD_CORE_WAKE domain modules, particularly GPIO/PORT 0.

37.1.6 SOC_CNTRL fields

ACTIVE_CFG1[SOC_CNTRL] field controls which analog modules are enabled and disabled in Active or Sleep modes. LP_CFG1[SOC_CNTRL] field controls which analog modules are enabled and disabled in other low-power modes (like Deep Sleep, PowerDown, or Deep PowerDown). The following table lists the analog modules that these fields control.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W										CMP2_DAC_EN	CMP1_DAC_EN	CMP0_DAC_EN		CMP2_EN	CMP1_EN	CMP0_EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W						OPAMP2_EN	OPAMP1_EN	OPAMP0_EN		DAC2_EN	DAC1_EN	DAC0_EN			USB3v_DET_EN	VREF_EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

37.1.7 Low-power current reference enable

The low-power current reference is used by FRO12M and analog modules CMP0/1/2. You must write 1 to LP_CFG[LP_IREFEN] if you use these analog modules in Deep Power Down mode. For the comparators CMP, you must write 1 to this field when using nano mode in Deep Power Down mode.

37.1.8 SPC output signals bits

The following SPC signals are internal to the MCU and can be trigger sources to other peripherals through the INPUTMUX:

- DCDC_BURST_ACTIVE: Indicates if DCDC is actively bursting or in quiet period. It can trigger the CTimers.
- DCDC_BURST_TRIG_PULSE: Pulses when burst ends and quiet period starts. It can trigger ADC.

37.1.9 HVD and LVD for I/O supply rails

The HVD and LVD circuits for the I/O monitor supply rail VDD for PORT0 and PORT1, and the following fields control these circuits:

- ACTIVE_CFG[IO_HVDE]
- ACTIVE_CFG[IO_LVDE]
- LP_CFG[IO_HVDE]
- LP_CFG[IO_LVDE]
- VD_IO_CFG[HVDIE]
- VD_IO_CFG[LVDIE]

You can read the status of these circuits using VD_STAT[IOVDD_HVDF] and VD_STAT[IOVDD_LVDF].

37.1.10 DCDC drive strength

For the MCU low-power modes, active or sleep mode can use the DCDC in normal or low drive strength using ACTIVE_CFG[DCDC_VDD_DS]. In deep sleep or power down mode, the DCDC can be used in normal, low, or pulse refresh drive strength using LP_CFG[DCDC_VDD_DS]. In deep power down mode, the DCDC is powered down.

NOTE

When the chip is in low-power mode and DCDC is during active mode, the DCDC voltage level must be set the same in ACTIVE_CFG and LP_CFG.

37.1.11 DCDC refresh counter clock

The DCDC pulse refresh counter (PULSE_REFRESH_CNT) is clocked by lp_osc.

37.1.12 Bandgap mode

You must configure the bandgap to be enabled if any of the following modules are enabled in active mode (configure ACTIVE_CFG[BGMODE]) or if they are configured to remain enabled in low power modes (configure LP_CFG[BGMODE]).

- FRO_HF (FRO_144M)
- PLL0 or PLL1 or System Oscillator
- CMP (if enabled in high power or normal power mode)
- Any LVD or HVD or Glitch Detect monitor in SPC
- LDO_CORE (if configured for normal drive strength)
- LDO_SYS (if configured for normal drive strength)
- DCDC (if configured for normal drive strength)

37.1.13 LPWKUP_DELAY register configuration

When a different VDD_CORE level is configured in low power modes (LP_CFG register) compared to active modes (ACTIVE_CFG register), the LPWKUP_DELAY register must be configured to a minimum value, as documented in the following table.

Table 343. LPWKUP_DELAY configuration

Regulator	LP_CFG voltage	ACTIVE_CFG voltage	Minimum delay[1]	Minimum LPWKUP_DELAY
LDO_CORE	1.0 V	1.1 V	17 µs	0x00AA
LDO_CORE	1.0 V	1.1 V	31 µs	0x0136
LDO_CORE	1.1 V	1.2 V	17 µs	0x00AA

Table continues on the next page...

Table 343. LPWKUP_DELAY configuration (continued)

Regulator	LP_CFG voltage	ACTIVE_CFG voltage	Minimum delay[1]	Minimum LPWKUP_DELAY
DCDC	0.7 V	1.0 V	95 µs	0x03BB
DCDC	0.7 V	1.1 V	127 µs	0x04F9
DCDC	0.7 V	1.2 V	159 µs	0x0637
DCDC	1.0 V	1.1 V	39 µs	0x0186
DCDC	1.0 V	1.2 V	78 µs	0x030C
DCDC	1.1 V	1.2 V	39 µs	0x0186

1. Delay numbers are calculated assuming the maximum value of external output capacitor is implemented. The minimum delay can be halved if the maximum external output capacitance is also halved.

When the SPC_LPREQ pin is used during low power modes to control an external switch or external PMIC, the LPWKUP_DELAY register must also be used to compensate for any additional wakeup time required by the external device. In this case, the larger of the two values should be used.

37.2 Overview

SPC contains and controls the following components:

- Two low-drop-out (LDO) voltage regulators (1.1 V LDO_CORE and 1.8 V LDO_SYS)
- One DCDC used for regulating system and core power
- Circuits that monitor and assure correct voltage levels:
  - Power-on reset (POR)
  - Low-voltage detect (LVD)
  - Analog glitch detector
  - High-voltage detect (HVD)

SPC turns these components on and off, and switches them to different power mode levels based on power-mode change requests from each of the chip power domains.

37.2.1 Block diagram

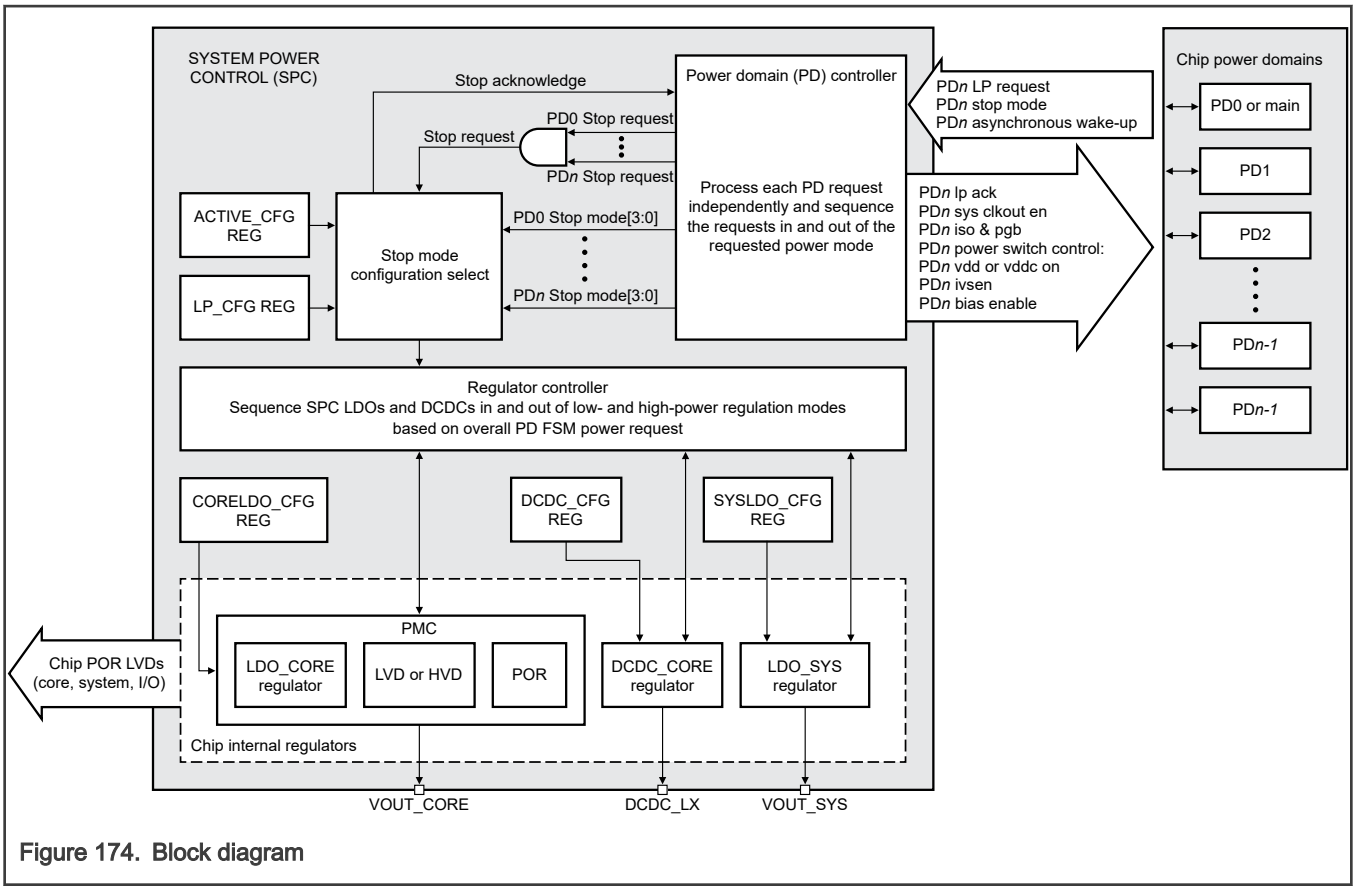

Figure 174. Block diagram

37.2.2 Features

- Selectable core internal voltage regulator (1.1 V LDO_CORE or 1.1 V DCDC)
- Selectable system internal voltage regulator (1.8 V LDO_SYS)
- Active POR providing brown-out detect
- Low-voltage detect
- High-voltage detect
- Core power gate control
- Analog glitch detector

37.3 Functional description

37.3.1 Power mode transitions

Figure 175 shows the power mode state transitions available for each power-down domain. A POR or LVD reset initially returns the power-down domains to ACTIVE state.

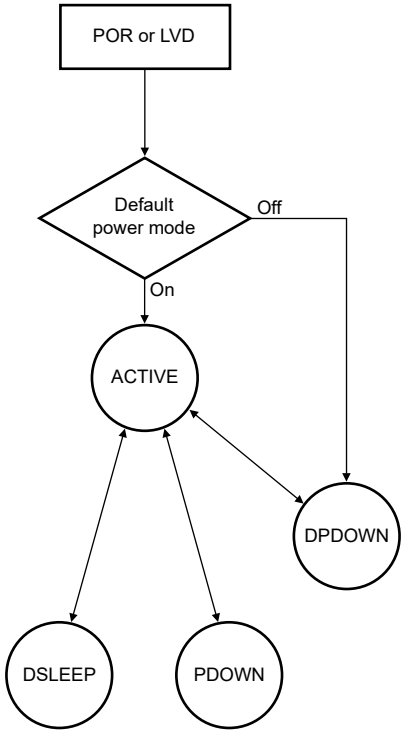

Figure 175. Power mode state diagram

SPC allows each power domain to enter or exit low-power modes independently of the other. You must ensure that any common system resources (for example, clock sources) are always available whenever required for a power-domain current power mode. For example, if a clock source in power domain 0 drives power domain 1, you must ensure that power domain 0 does not enter a low-power mode, because that would disable the clock source.

Figure 176 defines the low-power entry and exit flow for each of the SPC power-down domains.

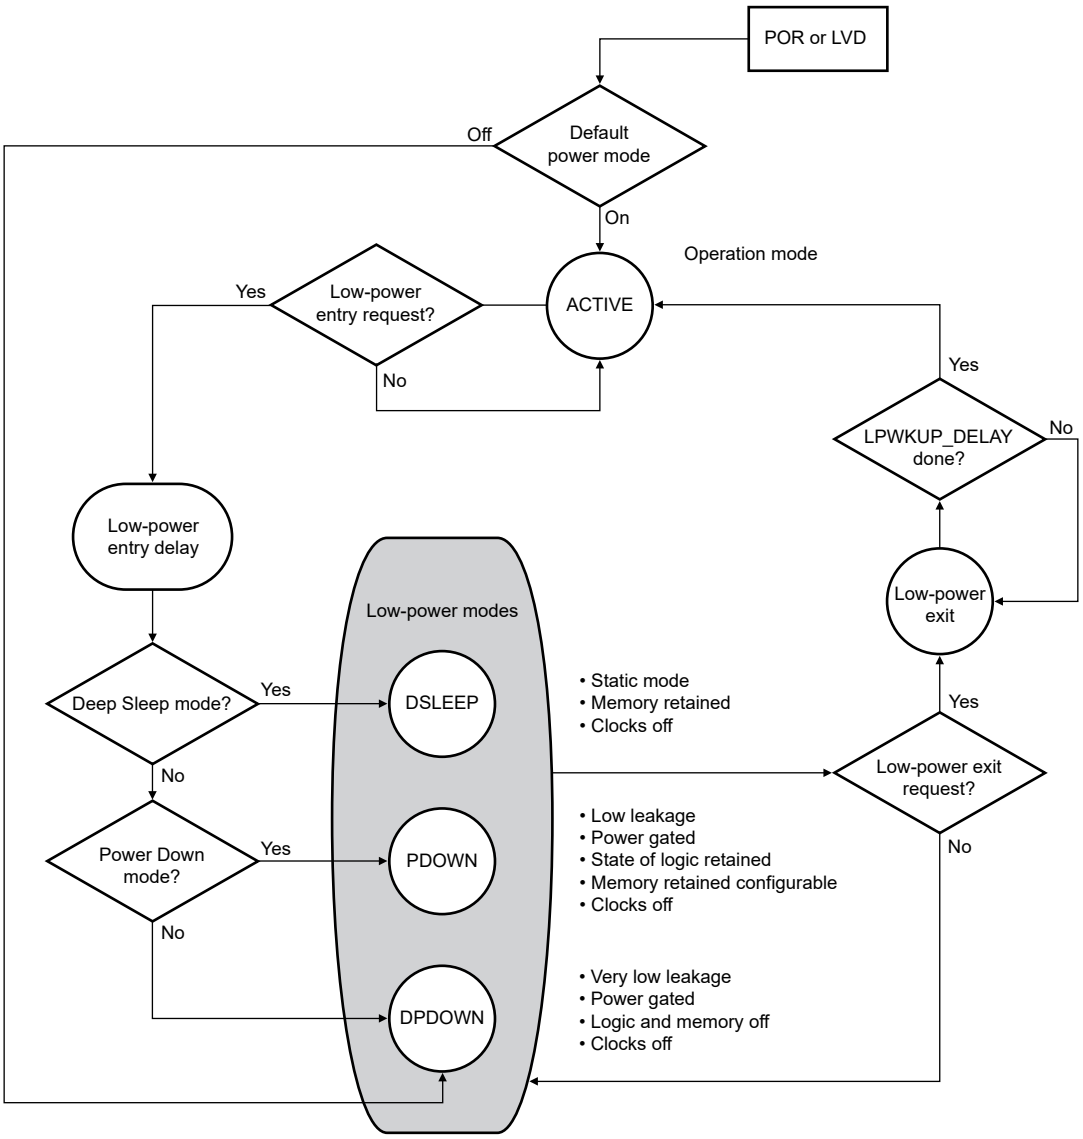

Figure 176. SPC regulator power mode state diagram

NOTE

This section mentions the power modes supported by the module. For the power modes supported on your device, see the chip-specific Power management chapter.

37.3.2 Active mode voltage updates

This section describes voltage and frequency changes in Active mode.

You can alter the operating voltage and frequency during Active mode to optimize power consumption depending on the application's performance requirements.

When increasing voltage and frequency in Active mode, you must perform the following steps:

1. Increase voltage to a new level (ACTIVE_CFG[CORELDO_VDD_LVL] and/or ACTIVE_CFG[DCDC_VDD_LVL]).
2. Wait for voltage change to complete (SC[BUSY] = 0).
3. Configure flash memory to support higher voltage level and frequency (MSF_FCTRL[RWSC]).

4. Configure SRAM to support higher voltage levels (SRAMCTL[VSM]).
5. Request SRAM voltage update (write 1 to SRAMCTL[REQ]).
6. Wait for SRAM voltage change to complete (SRAMCTL[ACK] = 1).
7. Clear request for SRAM voltage change (write 0 to SRAMCTL[REQ]).
8. Increase frequency to a new level (for example, SCG_RCCR).
9. You can continue execution.

When decreasing voltage and frequency in Active mode perform the following steps:

1. Decrease frequency to a new level (for example, SCG_RCCR).
2. Configure flash memory to support lower voltage level and frequency (MSF_FCTRL[RWSC]).
3. Configure SRAM to support lower voltage levels (SRAMCTL[VSM]).
4. Request SRAM voltage update (write 1 to SRAMCTL[REQ]).
5. Wait for SRAM voltage change to complete (SRAMCTL[ACK] = 1).
6. Clear request for SRAM voltage change (write 0 to SRAMCTL[REQ]).
7. Decrease voltage to a new level (ACTIVE_CFG[CORELDO_VDD_LVL] and/or ACTIVE_CFG[DCDC_VDD_LVL]).
8. Wait for voltage change to complete (SC[BUSY] = 0).
9. You can continue execution.

37.3.3 Low-Power Request (LPREQ) pin

The LPREQ pin asserts after low-power entry and negates after low-power wakeup.

The pin is intended to communicate with an external PMIC (for example, to enter low-power mode) or to control external switches (for example, if certain power supply rails are switched off in the low-power mode). The pin can eliminate the latency when communicating with PMIC—for example, through I^2C—for quick power-state transitions. The PMIC can be configured to use the LPREQ pin to switch between two preconfigured power states.

SPC controls the state of the LPREQ pin based on how you configure Low-Power Request Configuration (LPREQ_CFG). You control the LPREQ pin in Active mode. SPC controls the pin when the chip transitions from Active to a low-power mode, and after wake-up from these power modes.

NOTE

If the power supply rails are switched off externally, software must configure the internal isolation of these power domains using the External Voltage Domain Configuration (EVD_CFG) register.

To use the LPREQ pin:

1. Specify the pin polarity (LPREQ_CFG[LPREQPOL]).
2. Enable the pin output (LPREQ_CFG[LPREQOE]).
3. Configure the pin mux for the desired pin using the PORT PCR registers.
4. If the external PMIC or switch needs additional time after wake-up, use Low Power Wake-Up Delay (LPWKUP_DELAY) to extend the wake-up time.

37.3.4 DCDC

DCDC is a hysteretic converter. It is active during a burst period, when it switches the output to charge to a specific voltage. Then DCDC stops switching for a quiet period until the output voltage drops to a lower level, and it does another active burst.

37.3.4.1 DCDC drive strength

DCDC supports multiple drive strength options that you can choose:

- Normal
- Low
- Pulse refresh

The normal and low drive strengths differ in these DCDC characteristics:

- Maximum load current
- Quiescent current
- Transient response

With low drive strength, you can benefit from the lower quiescent current if:

- The load current is below the I_{LOAD} specification in the data sheet.
- Your application can tolerate the slower transient response.

Be careful when choosing low drive strength. If you exceed I_{LOAD} or require faster transient response, you must use normal drive strength. Furthermore, most other DCDC features are only available with normal drive strength.

Pulse-refresh drive strength offers even lower quiescent current in low-power modes, by deactivating DCDC when not active. This strength has an active pulsing period where DCDC charges the output voltage. Then DCDC deactivates for a configurable amount of time. No analog comparator is powered to monitor the DCDC output voltage. Instead, this drive strength is time-based using an SPC timer where DCDC_BURST_CFG[PULSE_REFRESH_CNT] specifies the timer period. Every period, SPC enables DCDC to charge the voltage again. When DCDC is off, no voltage regulation occurs. You must specify DCDC_BURST_CFG[PULSE_REFRESH_CNT] to manage the voltage drop on the DCDC capacitor and avoid a brownout condition.

37.3.4.2 DCDC burst

You can control and monitor the DCDC burst. Synchronizing with the quiet period between bursts can be valuable for noise-sensitive applications—for example, during a high-resolution ADC measurement or a radio transmission.

Before requesting a burst to start, clear the DCDC_BURST_CFG[BURST_ACK] flag. Then, your firmware can request a burst by writing 1 to DCDC_BURST_CFG[BURST_REQ]. SPC sets the DCDC_BURST_CFG[BURST_ACK] flag when the burst has completed and DCDC enters a quiet period.

SPC also provides signals to synchronize the burst activity with other peripherals in the chip. If DCDC_BURST_CFG[EXT_BURST_EN] = 1 before a burst starts, the output DCDC_BURST_TRIG_PULSE signal asserts when a burst completes, and can trigger other actions such as an ADC conversion. Another SPC output signal is DCDC_BURST_ACTIVE, which EXT_BURST_EN does not gate. DCDC_BURST_ACTIVE can also trigger other peripherals such as a timer. You can use this signal to estimate the power that DCDC delivers.

When bursting, you can control the DCDC switching center frequency with the frequency-stabilization feature. DCDC_CFG[FREQ_CNTRL_ON] enables this feature, and when the feature is enabled, DCDC_CFG[FREQ_CNTRL] controls it. The main parameters that control the period between active bursts and quiet period are:

- Load current
- External capacitor
- DCDC hysteresis

NOTE

Writing 1 to DCDC_CFG[FREQ_CNTRL_ON] stabilizes the frequency by limiting DCDC current. See the DCDC I_{LOAD} maximum limit in the data sheet for this mode.

37.3.4.3 DCDC voltage changes

To support power optimization of applications, DCDC can provide multiple output voltages.

Two separate registers, which specify Active mode output and Low-Power mode output, independently control the DCDC output voltage. Whenever an SoC mode change occurs, by using two independent registers, there is no need to reconfigure the output voltage. ACTIVE_CFG[DCDC_VDD_LVL] controls the DCDC output voltage when the SoC mode is Active or in Sleep mode. The DCDC drive strength is normal (ACTIVE_CFG[DCDC_VDD_DS] = 10b). LP_CFG[DCDC_VDD_LVL] controls the DCDC output voltage when the SoC mode is in a Low-Power mode (i.e., not Active or Sleep mode) or the DCDC drive strength is low (ACTIVE_CFG[DCDC_VDD_DS] = 01b) and the SoC is in an Active or Sleep mode.

When Active Power Mode Configuration (ACTIVE_CFG) controls the output, following are the DCDC output options:

- 1.0 V
- 1.1 V
- 1.2 V

Align the output voltage with the desired clock frequencies of the system. When changing the DCDC output voltage level, take care to change the CORE LDO voltage level (ACTIVE_CFG[CORELDO_VDD_LVL]) to the same level (even if you turn off the CORE LDO). ACTIVE_CFG[CORELDO_VDD_LVL] also controls the voltage threshold of the LVD monitoring the VDD_CORE supply. You must adjust it with the DCDC output voltage.

See Active mode voltage updates to change the DCDC output level in Active mode.

When Low-Power Mode Configuration (LP_CFG) controls the output, following are the DCDC output options:

- 0.7 V
- 1.0 V
- 1.1 V
- 1.2 V

When entering SoC power-down mode with IVS disabled, support only the 0.7 V option. You have to configure LPWKUP_DELAY to the correct value. In Deep Sleep mode, you must also align the output voltage with the clock frequencies of any clocks kept alive in the Low-Power mode. If you keep some clock sources active, ensure to leave the bandgap enabled.

When changing the DCDC output voltage level, you must change the CORE LDO voltage level (LP_CFG[CORELDO_VDD_LVL]) to the same level (even when you turn off the CORE LDO). LP_CFG[CORELDO_VDD_LVL] also controls the voltage threshold of the LVD monitoring the VDD_CORE supply. You must adjust it with the DCDC output voltage.

To change the DCDC output level in Low-Power mode, follow this procedure:

1. Configure LP_CFG[DCDC_VDD_LVL] to desired level.
2. Configure LP_CFG[DCDC_VDD_DS] = 0x1.
3. Configure ACTIVE_CFG[DCDC_VDD_LVL] to same level as in configure LP_CFG[DCDC_VDD_LVL].

37.3.5 Clocks

Table 344. Clocks

SPC component:	Clock source
Registers and logic	Slow bus clock
Delay counters	10 MHz internal clock

37.3.6 Reset

37.3.6.1 Reset sources

37.3.6.1.1 Power-on reset (POR)

When you initially apply power to the chip, or the supply voltage is below the POR falling threshold, the POR circuit triggers the POR condition.

The POR condition asserts a cold reset in all power domains. The SRS[POR] and SRS[LVD] status bits are both set after a POR condition.

37.3.6.1.2 Low-voltage detect (LVD)

SPC supports the following LVD circuits:

- Core VDD
- System VDD
- I/O VDD

Each of these circuits is enabled by default and keeps the chip in reset until each of these supply voltages rises above the LVD rising threshold. Enabling any of the LVD circuits triggers an LVD reset condition if the corresponding supply voltage is below the LVD falling threshold.

The LVD reset condition asserts a cold reset in all power domains. The LVD- and HVD-detection logic is the only logic that HVD and LVD resets do not affect. The corresponding status fields in Voltage Detect Status (VD_STAT) become 1 after the corresponding LVD reset condition occurs.

37.3.6.1.3 High-voltage detect (HVD)

SPC supports the following HVD circuits:

- Core VDD
- System VDD
- I/O VDD

Each of these circuits is enabled by default and triggers an HVD reset condition if the corresponding supply voltage is above the HVD threshold.

Any of these reset condition asserts a cold reset in all power domains. The LVD- and HVD-detection logic is the only logic that HVD and LVD resets do not affect. The corresponding status fields in Voltage Detect Status (VD_STAT) become 1 after the corresponding HVD reset condition occurs.

37.3.6.1.4 Glitch detect

This chip guards against short pulses on the core VDD and VSS. This security feature can detect glitches due to a hacking attack and alerts the core to reset the chip or generate a interrupt operation.

After power-on-reset, the core VDD glitch-detect system is enabled. When the system is in Active or Sleep mode, use ACTIVE_CFG[GLITCH_DETECT_DISABLE] to enable or disable the glitch-detect system. When the system is in other Low-Power mode, use LP_CFG[GLITCH_DETECT_DISABLE] to enable or disable the glitch-detect system.

The glitch-detect system uses a 4-bit ripple counter to monitor the quantity of detected glitches. The VDD_CORE_GLITCH_DETECT_SC[GLITCH_DETECT_FLAG] status flags capture the state of each of these counters.

37.3.6.2 Reset sequence

The following steps occur as part of the POR, LVD, or HVD sequence:

1. The RESET_b pin deasserts.
2. The internal reset signals assert.
3. The POR or LVD signals negate.

4. System clocks are enabled.

37.3.7 Interrupts

SPC generates a single interrupt. The trigger for this interrupt comes from:

- Any of the LVD, HVD, or glitch-detect circuits when they are not configured for reset and their corresponding HVDIE or LVDIE register.
- The Interrupt Enable (IE) register (for the glitch-detect case).

37.4 External signals

Signal	Description	Direction
LPREQ	Low-power request pin used to signal external power-management circuits for a change in supply voltage	Output
VOUT_CORE	Output of the LDO_CORE regulator	Output
VOUT_SYS	Output of the LDO_SYS regulator	Output
DCDC_LX	Output of the DCDC_CORE regulator	Output

37.5 Initialization

To initialize SPC with LDO_CORE off, write 0 to CNTRL[CORELDO_EN].

To initialize SPC with LDO_SYS off, write 0 to CNTRL[SYSLDO_EN].

To initialize SPC with DCDC_CORE off, write 0 to CNTRL[DCDC_EN].

Except for the above, SPC does not require any special initialization.

37.6 Application information

To change DCDC level in Low-Power mode:

1. Configure LP_CFG[DCDC_VDD_LVL] to desired level.
2. Configure LP_CFG[DCDC_VDD_DS] = 0x1
3. Configure ACTIVE_CFG[DCDC_VDD_LVL] to same level programmed in Configure LP_CFG[DCDC_VDD_LVL]

To disable Bandgap in Active or Sleep mode:

1. Disable all LVD's and HVD's in ACTIVE_CFG[29:24]= 0x00
2. Disable Glitch Detect, ACTIVE_CFG[GLITCH_DETECT_DISABLE] = 1
3. Configure LDO's and DCDC to Low Drive Strength in ACTIVE_CFG register
4. Configure ACTIVE_CFG[BGMODE] = 0x0

To disable Bandgap in Low-Power mode:

1. Disable all LVD's and HVD's in LP_CFG[29:24]= 0x00
2. Disable Glitch Detect, LP_CFG[GLITCH_DETECT_DISABLE] = 1
3. Configure LDO's and DCDC to Low Drive Strength in LP_CFG register
4. Configure LP_CFG[BGMODE] = 0x0

37.7 SPC register descriptions

Different chip reset types affect the reset of different SPC registers. Each register description provides details. See the Reset chapter for more information about the types of reset on this chip.

You may use only 32-bit writes for any writable SPC registers. 8-bit or 16-bit writes cause a transfer error.

Fields

Field	Function
31 —	Reserved
30-18 —	Reserved
17-16 ISO_CLR	Isolation Clear Flags Indicates whether certain peripherals and I/O pads are in a latched state as a result of having been in PDOWN mode. Each bit of this field is a flag associated with a module on this chip. See the chip-specific SPC information for the module-bit association. For each flag: • A value of 0 means that peripherals and I/O pads are in the normal run state. • A value of 1 means that peripherals and I/O pads can retain their state in their power domain. If a flag in this field is 1, writing 1 to that flag clears the flag and releases the I/O pads and peripherals to their normal run-mode state.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	After recovering from a power-down mode, you must restore the chip configuration before clearing a flag in this field. In particular, you must restore the pin configuration for enabled WUU wake-up to avoid any WUU flag from being falsely set when the associated ISO_CLR flag is cleared. This field resets after a system reset.
15-8 —	Reserved
7-4 SPC_LP_MODE	Power Domain Low-Power Mode Request Indicates the last low-power mode that the power domain requested. 0000b - Sleep mode with system clock running 0001b - DSLEEP with system clock off 0010b - PDOWN with system clock off 0100b - Reserved 1000b - DPDOWN with system clock off
3 —	Reserved
2 —	Reserved
1 SPC_LP_REQ	SPC Power Mode Configuration Status Flag Indicates when all power-down domains requested low-power mode and SPC entered a low-power state. **NOTE** This field behaves differently for register reads and writes. When reading 0b - SPC is in Active or Sleep mode; the ACTIVE_CFG register has control 1b - All power domains requested low-power mode; SPC entered a low-power state; power-mode configuration based on the LP_CFG register When writing 0b - No effect 1b - Clear the flag
0 BUSY	SPC Busy Status Flag Indicates whether SPC is busy. SPC sets this flag:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• When SPC executes any type of power mode transition in Active mode or any of the chip low-power modes. • Due to LP_CFG[CORELDO_VDD_LVL] and LP_CFG[DCDC_VDD_LVL] changes while in Active mode. **NOTE** Wait until this flag is clear before changing power-mode configuration registers. 0b - Not busy 1b - Busy

37.7.4 SPC Regulator Control (CNTRL)

Offset

Register	Offset
CNTRL	14h

Function

Enables the SPC regulators.

You can write to the fields in this register only one time.

The register resets only after a POR, LVD, or HVD event.

37.7.5 Low-Power Request Configuration (LPREQ_CFG)

Offset

Register	Offset
LPREQ_CFG	1Ch

Function

Configures the low-power output request pin.

The register resets only after a POR, LVD, or HVD event.
